1 INTRODUCTION

Parsons Transportation Group, Inc. (Parsons) conducted a Stage 1 Uranium Mine Site Assessment at the Lost Mine, located in northern McKinley County, New Mexico, and included the portion of the Section 34 Mine located on the same property, due to its close proximity and similar historical development. The remainder of the Section 34 Mine is on tribal land and was not investigated. The location of Lost Mine and Section 34 Mine are shown in Figure 1. Stage 1 Site Assessment Field work was completed November 17 – 21, 2025 according to the Stage 1 Uranium Mine Site Assessment Work Plan (Parsons, November 2025) with the purpose of establishing a baseline understanding of site conditions by identifying and documenting mine features, evaluating potential physical and radiological hazards, reviewing historical mining and reclamation records, and assessing access routes and property ownership boundaries. The information collected during this assessment will guide subsequent investigation phases and support future remedial planning efforts, if needed, in coordination with the New Mexico Environment Department (NMED) and the New Mexico Energy, Minerals, and Natural Resources Department (EMNRD).

Parsons served as the primary contractor for the Stage 1 Assessment, with Tidewater, Inc. (Tidewater) providing subcontractor support for radiological surveys and data interpretation. The investigation followed guidance consistent with NMED's Abandoned Uranium Mines (AUM) program (ASTM E1527) and incorporated radiological survey methodologies in accordance with Multi-Agency Radiation Survey and Site Investigation Manual (MARSSIM) principles. Together, these efforts provide a defensible foundation for planning Stage 2 Investigation activities.

1.1 Stage 1 Goals and Objectives

A Stage 1 Assessment at Lost Mine was conducted to establish a clear baseline understanding of site conditions, ownership, and historical context. The work focused on documenting physical characteristics of the site, evaluating potential hazards, and reviewing access and ownership information. In addition, the investigation included a review of historical mining records and reclamation efforts to place the site within its broader regional and regulatory context. Together, these objectives will provide NMED and EMNRD with the information needed to determine next steps for investigation and potential remediation. Goals and objectives of this effort included:

Stage 1 Goals:

- Establish baseline physical and radiological conditions at Lost Mine.
- Identify and document mine features, disturbances, and potential Technologically Enhanced Naturally Occurring Radioactive Material (TENORM) areas.
- Characterize site access, ownership, and historical land use.
- Provide foundational information to support future investigation phases.
- Support Stage 2 planning with defensible field data and observations.

Stage 1 Objectives:

- Conduct systematic visual reconnaissance to map mine-related features.
- Perform low-density gamma walkover surveys to locate radiological anomalies.
- Use portable X-ray fluorescence (XRF) to screen disturbed soils and mine materials for metals associated with uranium mineralization.
- Identify potential contaminant pathways, including drainages and downslope depositional areas.
- Integrate visual, gamma, and XRF data into GIS for feature mapping and Stage 2 planning.

2 BACKGROUND

2.1 Location and Access

Lost Mine (the Site), with EPA and NMED tracking number NM0151 is an abandoned uranium mine located in McKinley County, New Mexico, at approximately latitude 35.402645° N and longitude -107.975066° W. Section 34 Mine (NM0152) is located approximately 1000 feet to the west along the same escarpment at latitude 35.402355° N and longitude -107.982981° W. Figure 1 shows the location of Lost Mine and Section 34 Mine. The Site lies within a rugged portion of the Zuni Uplift, a geologic feature characterized by high-elevation mesas, steeply incised sandstone cliffs, and narrow canyons. Vegetation within the area consists primarily of piñon-juniper woodlands, mixed desert shrubs, and grassland benches typical of the semi-arid southwestern plateau environment.

Land ownership at Lost Mine is designated as private, although access to the Site is obtained via an unpaved road network crossing a combination of private and federal lands. The Navajo Nation maintains adjacent land holdings in proximity to the Site. The majority of the Section 34 Mine claim is located on Navajo Nation land; however, a portion (approx. 25%) of the claim boundary is on private property. The Lost Mine claim boundary is approximately 8 acres, located on the northern mesa escarpment in Rincon Canyon. The portion of Section 34 Mine residing on private property is approximately 2 acres. The Site is accessed from State Highway 19, north of Prewitt, New Mexico, by traveling east on Hoodoo Hills Road for approximately 4 miles, followed by an additional 4 miles south on a two-track road to reach the mine (Figure 1). A rural residential population of roughly 439 residents is estimated to live within the 5-mile radius surrounding the Site. A nearby groundwater well (well reference number B-01821-POD1), located on the plateau above the mine approximately 1000 feet north, indicates water level is 420 feet bgs (New Mexico Office of the State Engineer, 2025).

2.2 Mining History

Lost Mine and Section 34 Mine were developed for uranium extraction in the 1950s, during the peak of mid-20th century uranium exploration in northwestern New Mexico. Historical records indicate that the mines were small-scale operation, likely part of a cluster of similar claims developed along the mesa escarpments in this region. The uranium-bearing ore occurs primarily within Jurassic-age sedimentary formations, notably the Todilto Limestone, which is a thinly bedded limestone and dolomite unit known for localized uranium mineralization. Several other historic uranium mines are located nearby.

Both Lost Mine and Section 34 Mine were mined using strip mining (or rim strip) techniques. This process involves the removal of surface layers to access near-surface uranium deposits and is commonly used when mineral deposits are spread out in horizontal layers. The process creates waste piles of overburden or low-grade ore material (i.e., waste rock) adjacent to the mined area, and often resulted in environmental disruption including habitat destruction, soil erosion, and water contamination.

No known cleanup, reclamation, or remediation activities have been documented at the Site to date.

2.3 Previous Investigations

A site survey conducted by the New Mexico Bureau of Mines and Mineral Resources (Anderson, 1980) documented visible mine features. At Lost Mine, a bench cut and associated waste piles were identified. At Section 34 Mine, a bench cut, waste pile, and a small adit were identified, however these features are primarily located on Navajo Nation land holdings.

Additionally, in 2009, Weston Solutions performed a Site Screening Assessment under the U.S. Environmental Protection Agency's Abandoned Uranium Mines program, observing no evidence of reclamation or recent mining

disturbance at either mine location (Weston 2009a, 2009b). Gamma radiation surveys conducted during those assessments identified multiple areas exhibiting radiation levels elevated above background, indicating the potential presence of residual mine-related contamination. Recently, (September 2025), NMED conducted a Site visit and identified several areas of interest, including the bench cuts, waste piles, access roads, and areas of potential reclamation activities to be investigated at the Site.

The current investigation builds upon these prior findings to further assess the extent of radiological impacts, physical hazards, and site access conditions at Lost Mine and the surrounding area.

2.4 Record Search Results

Parsons researched and reviewed existing and readily available property documentation available for Lost Mine and used this information to inform the project approach. Findings are summarized here and are provided in Appendix A.

A title search for Lost Mine (also known historically as the Section 35 Strip and Berryhill–Elkins) indicates that the surface estate is privately owned by the Lynn Elkins Family Limited Partnership, LLP (as of May 9, 2000), while the mineral estate is privately held by Uranium Energy Corporation (as of 2007). Historic ownership records list members of the Elkins and Berryhill families as prior surface and mineral owners. The site is subject to ingress/egress rights associated with the mineral estate but has no known encumbrances, liens, or other restrictions relevant to the assessment. Lost Mine is not part of any federal, state, tribal, or voluntary cleanup program. The mine workings, located at approximately 35.40264° N, –107.97506° W, consist of surface rim cuts approximately 100 feet by 400 feet situated roughly 70 feet below the mesa top, with documented uranium production occurring in 1954. Additional historic ownership details may exist but were not identified through available public records.

2.5 Geologic Setting

The Lost Mine site is located along the southern flank of the Zuni uplift, a northwest-trending Laramide-age structural dome that forms part of the southern margin of the San Juan Basin in west-central New Mexico. The uplift exposes a broad stratigraphic section ranging from Precambrian crystalline rocks in the core to Paleozoic, Mesozoic, and locally Cenozoic sedimentary units on its flanks. The Zuni uplift and adjacent monoclines have acted both as sediment sources and structural barriers through time, influencing depositional patterns, groundwater flow, and the distribution of mineralization along the margins of the Colorado Plateau (Smith 1959).

Jurassic strata are particularly well exposed along the northern and eastern flanks of the uplift and define a characteristic Entrada–Todilto–Summerville sequence in the “water-deposited” lithofacies belt of west-central New Mexico (USGS 2003). In this area, eolian sandstones of the Entrada Formation are overlain by the carbonate–evaporite succession of the Todilto Formation, which in turn is overlain by mixed marine and sabkha deposits of the Summerville Formation and younger Jurassic units (Lucas et al 2003, Kirkland et al 2021). This stratigraphic position is important because the Todilto represents the only significant carbonate–evaporite interval in an otherwise siliciclastic Jurassic section and is a key host to uranium mineralization in the Grants uranium district and related belts (Berglof 2022, Gabelman 1988).

Regionally, the Middle Jurassic Todilto Formation is widely exposed in northern New Mexico and southwestern Colorado and consists of two primary members: a lower limestone unit (Luciano Mesa Member) and an upper gypsum unit (Tonque Arroyo Member) or their brecciated residues where gypsum has been dissolved (Kirkland et al 2021, Lucas et al 2003). The limestone member is typically on the order of 1.5–6 m thick, composed of laminated to nodular micritic limestone and calcareous mudstone, while the overlying gypsum member may reach thicknesses of 10–30+ m in some parts of west-central New Mexico (Kirkland et al 2003).

Sedimentologic, stratigraphic, and geochemical evidence indicate that the Todilto was deposited in a restricted salina or coastal lagoon that periodically communicated with a larger epeiric sea (Kirkland et al 2003, Ridgley 1979). Varved carbonate laminae in the Luciano Mesa Member, together with evaporite textures in the gypsum member, suggest deposition under fluctuating salinity, relatively low energy conditions, and episodic restriction and evaporation (Kirkland et al 2003). Local intraformational folding and soft-sediment deformation within the limestone have been interpreted as the result of differential loading by overlying eolian sandstones (Summerville–Entrada equivalents) and are spatially associated with several uranium deposits in the Ambrosia Lake–Grants belt (Green 1982).

Within the Zuni uplift region, the Todilto limestone tends to crop out as ledges or benches along the escarpment, with the gypsum forming more recessive slopes or brecciated intervals. The unit's lateral continuity, predictable stratigraphic position above Entrada sandstones, and distinctive carbonate/evaporite lithologies make it a useful marker horizon and a key control on the localization of uranium mineralization where reduced fluids or structural focusing have occurred (Berglof 2022, Green 1982).

Geochemically, the Luciano Mesa limestone member of the Todilto is dominated by micritic calcite with subordinate dolomite, minor detrital siliciclastic material, and locally abundant organic matter and pyrite (Berglof et al 2022, Green 1982). The restricted salina environment, combined with periodic influxes of marine and meteoric waters, produced pore waters enriched in sulfate, chloride, and calcium, with locally reducing microenvironments associated with organic-rich laminae and pyrite-bearing zones. These conditions are favorable for the reduction and precipitation of uranium transported in oxidized form (e.g., U^{6+} in carbonate complexes) from up-gradient aquifers or sandstone reservoirs (Everhard 1951).

Uranium deposits in the Todilto limestone occur primarily as small- to medium-sized, fracture, joint, and fold-controlled bodies localized within intraformational folds, shear zones, and breccias in the Luciano Mesa Member (Berglof 2022, Gabelman 1988, Green 1982). Mineralization typically consists of uraninite and coffinite with associated vanadium-, molybdenum-, and selenium-bearing phases, disseminated within carbonaceous limestone, calcite veins, or along fracture surfaces. Common geochemical associations include elevated U, V, Mo, As, Se, and locally Pb, reflecting both the chemistry of mineralizing fluids and interaction with organic matter and sulfides (Berglof 2022, Gabelman 1988).

Isotopic and geochronologic data indicate that uranium mineralization in the Todilto likely formed relatively soon after deposition of the host limestone, with U–Pb ages for uraninite clustering between ~160 and 138 Ma, broadly consistent with Middle Jurassic timing and predating the main phase of mineralization in overlying sandstone-hosted systems such as the Morrison Formation (Smith et al 2023, Berglof et al 2022). Later structural reactivation along the Zuni uplift and adjacent monoclines may have locally remobilized or reconcentrated uranium within favorable structural traps, but the primary control remains the combination of reactive carbonate host rock, reducing geochemical microenvironments, and focused fluid flow along fractures and folds within the Todilto salina succession (Smith et al 2023, Green 1982, Kelley 1967).

In the Lost Mine area, the Todilto Formation occupies the same stratigraphic position and regional geochemical framework as in the Ambrosia Lake/Grants mining district, and it is reasonable to infer similar controls on mineralization and background geochemical signatures, even where localized structural or hydrologic conditions differ. This regional context is important for interpreting both gamma and XRF data from Stage 1 and for anticipating the distribution and behavior of uranium and associated metals in Stage 2 investigations.

3 SITE ASSESSMENT METHODS

A systematic survey of Lost Mine, a portion of the Section 34 Mine, and the surrounding area was completed to document site features and existing conditions. Figure 2 provides a depiction of the known site features that

guided the field survey. The survey established a detailed record of mine features, radiation levels, land disturbances, and environmental indicators to inform hazard evaluation and future remedial planning.

Parsons and Tidewater mapped the Site using GPS-enabled tools, field photography, and detailed notes to ensure accurate documentation of site conditions and features. A low-density gamma scan was conducted to identify areas of elevated radioactivity and to support feature identification. Particular attention was given to waste rock piles, rim-strip areas, natural drainage pathways, and any structures or disturbed areas.

Tidewater performed the gamma walkover survey in accordance with MARSSIM guidance. Background radiation levels were established during the assessment, and twice the background value was used as the Investigation Level for identifying radiological anomalies. Targeted soil analyses using non-intrusive techniques, including hand augers and handheld XRF screening, were selectively used to further characterize areas of interest. Because of the size of the Site and the large volume of data generated during the survey, evaluation of results and delineation of investigation units requiring further study were conducted electronically during post-survey data analysis.

The investigation area, shown in Figure 3, included the Lost Mine claim boundary and the portion of the Section 34 Mine claim located on private property, along with a buffer zone extending 100 feet beyond the claim boundaries and other identified areas of special interest. The assessment did not extend beyond the property boundary. Due to potential inaccuracies in mapping the boundary between Navajo Allotment land and private property, caution was exercised to ensure that no investigation activities occurred on Navajo land.

This minimum survey area was intended to capture potential impacts immediately adjacent to the mine footprint. In addition, historic haul roads and access roads were evaluated using a survey corridor extending 20 feet on either side of the alignments and a minimum of 1,000 feet in both directions from the claim boundary. Emphasis was placed on rim strip areas and waste rock piles, which represent key features for radiological and physical hazard evaluation.

Features assessed during the survey included access and haul roads, rim-strip areas, waste piles, downgradient ephemeral drainages, and the alluvial area below the waste piles. Several additional areas of interest were documented to provide a comprehensive understanding of the broader Site setting. Two ponding areas were also evaluated as potential accumulation zones for contaminated sediments (shown on Figure 3).

Some portions of the Site presented terrain and access challenges requiring special consideration. Inaccessible areas were documented, and partially accessible areas were surveyed to the extent practicable without compromising safety or data quality. For areas that could not be safely or effectively surveyed, Parsons may recommend additional clearance, specialized equipment, or drone-assisted surveys in future phases.

3.1 Gamma Survey Methods

A systematic gamma walkover survey was conducted across all accessible portions of the Lost Mine investigation area to measure gross gamma radiation levels in surface soils and materials. The entire area was treated as a single survey unit for the Stage 1 Assessment. Survey traverses were guided by real-time GPS positioning and pre-established waypoints to ensure consistent spacing, minimize data gaps, and maintain uniform coverage. GPS units provided continuous positional feedback, allowing surveyors to correct their path in real time. All gamma and positional data were electronically logged, downloaded daily, and transferred to secure project systems for quality review and GIS integration.

The walkover survey was performed using 2-inch by 2-inch sodium iodide (NaI) scintillation detectors (Ludlum Model 44-10) connected to count-rate meters (Ludlum Model 3000) integrated with sub-meter GPS units and electronic dataloggers. Measurements were recorded at one-second intervals in counts per minute (cpm). The detectors were carried approximately 6 inches above ground surface to maximize sensitivity to near-surface radionuclides within the upper ~6 inches of soil. Surveyors maintained a steady pace of roughly 2 ft/s (0.5 m/s),

adjusting as needed for terrain or vegetation. Vertical or near-vertical features were surveyed by lowering the detector down the face in 1-meter increments while maintaining a 6-inch standoff distance.

Where dense brush, steep slopes, or other obstacles prevented standard transect spacing, the grid was adjusted to maintain coverage without compromising safety or data quality. Beta/gamma detectors (Ludlum Model 44-9 connected to a Model 3 meter) were used to screen personnel and equipment for removable contamination prior to exiting work areas.

All instruments operated under active calibration (within 12 months or manufacturer recommendations). Daily performance checks including background and source checks were completed for each detector/meter pair. Instrument responses were required to fall within ±20% of expected values per NRC license SOP RS-013..

To establish a defensible radiological baseline, two background survey areas were selected using the same methods applied to the main investigation area. However, only one background survey area (Figure 3) was able to be surveyed completely due to terrain restraints. Background areas were chosen based on similarities in soil and geology, absence of historical uranium mining influence, adequate distance from roadways and potential contamination sources, comparable vegetation and land use, and sufficient size (≥100 m^2) to support statistical confidence in natural variability. Background data were evaluated to confirm the absence of anomalous hotspots prior to use in calculating site-specific Investigation Levels.

The results of the background survey indicated that background (average gamma count rate in background area) was approximately 12,000 counts per minute (cpm) (Background average was 11,762.41 cpm, rounded to 12,000 cpm for the purposes of this investigation). Using the project's defined criteria, the Investigation Level (IL) was set at greater than 24,000 cpm, equivalent to two times background. This threshold served as the basis for identifying radiological anomalies during the Stage 1 walkover survey and was used consistently throughout data interpretation. Background gamma measurements were stable and showed no anomalous hotspots, confirming the validity of the selected reference area and supporting its use as the comparative baseline for subsequent stages of the investigation. Handheld XRF measurements were also collected in the background areas to confirm the absence of mine-impacted material and provide a basis for evaluating elevated metal concentrations across the site.

All gamma measurements were georeferenced and integrated into the GIS database for subsequent evaluation by qualified Tidewater health physicists. Field data underwent daily review, and anomalous results prompted resurvey or method adjustments. The established IL served as the threshold for identifying areas of elevated radiation requiring further delineation or targeted soil sampling during later phases of the investigation.

3.2 Handheld XRF Methods

Handheld XRF spectrometry was used during the Stage 1 Assessment as a rapid, non-destructive screening method to characterize the elemental composition of mine-related materials and disturbed soils. The use of XRF supported the identification of metals commonly associated with uranium mineralization and helped distinguish mine waste from natural colluvial or alluvial materials. Although XRF data were considered screening-level, they provided important context for interpreting radiological measurements and will guide the selection of locations requiring analytical sampling during Stage 2 investigations.

A portable handheld XRF analyzer equipped with a mining/mineralization analytical mode was used for field measurements. Prior to daily deployment, the instrument underwent internal system checks, including energy calibration and detector function verification, followed by manufacturer-recommended calibration checks using certified reference materials (OREAS 120) and blank readings to confirm the absence of contamination or carryover. Calibration verification was repeated throughout the day to maintain data consistency under changing field conditions.

XRF measurements were collected in areas where visual observations or gamma survey results suggested the presence of mine-impacted materials. These locations included waste rock piles, rim strip areas/bench cuts, disturbed soils, vertical or altered ground surfaces, and sediment accumulations within colluvial and alluvial drainage and depositional pathways. Measurements were also taken at locations where gamma readings exceeded twice background. When necessary, loose surface debris was removed to ensure consistent instrument contact, and each reading was collected for the manufacturer-recommended count time to maximize analytical precision.

Several subsurface locations within the alluvial plain, along the base of the escarpment below the waste piles, were investigated using a hand auger to determine the depth of alluvial material (Figure 5). For these locations, XRF screening was completed on the interval nearest the bottom of the alluvial material. In this area, the alluvial material extended to between 1 and 2 feet below ground surface (bgs). An additional location on the west side of the ponding area was completed to 3.5 feet bgs, and XRF screening was completed on samples from 0-0.5 feet bgs, 1.5-2.0 feet bgs, and 3.0-3.5 feet bgs.

For each XRF measurement, the field team recorded the GPS location with sub-meter accuracy, the material type and surface condition, and a representative photograph. The instrument reported concentrations of metals associated with uranium mineralization, including uranium, vanadium, molybdenum, selenium, arsenic, iron, manganese, lead, and zinc as well as other elements relevant to the geochemical signature of regional uranium-bearing material (Hall et al 2023, Brookins 1977, Gabelman 1988, Granger et al. 1961). These measurements were used qualitatively and semi-quantitatively to identify mine waste materials, evaluate correlations with gamma anomalies, identify areas potentially affected by TENORM, and prioritize sampling locations for Stage 2 investigations. Because handheld XRF is a screening tool, laboratory confirmation will be required during the next phase to validate concentrations for regulatory comparison or risk assessment. Factors such as soil moisture, mineral heterogeneity, and surface irregularities can influence XRF accuracy; therefore, all XRF results were interpreted in conjunction with visual observations and gamma survey data as part of a multi-line-of-evidence approach.

4 SITE ASSESSMENT RESULTS

The combined use of handheld XRF screening, low-density gamma surveying, and systematic visual reconnaissance provided multiple lines of evidence for identifying mine-impacted materials and evaluating site conditions. These complementary datasets, including radiological, geochemical, and visual observations, form the basis for interpreting surface disturbance patterns, locating areas of elevated radiological activity, and understanding potential pathways for contaminant migration. The following section presents the results of these assessment activities, including documented mine features, mapped areas of disturbance, preliminary radiological findings, and screening-level XRF observations that together inform the site's conceptual model and guide priorities for the Stage 2 investigation.

4.1 Mine Site Access

Access to the Lost Mine site presents several logistical challenges that influenced Stage 1 field activities and will likely affect planning for future investigation and remediation efforts. Figure 4 presents the main access challenges encountered during field exercises and a potential alternative route. The primary access route to the site is in poor condition, with portions of the road exhibiting erosion, deep ruts, and sections washed out during precipitation events (Photos of the access issues are presented in Appendix D). Passage beneath the nearby railroad crossing is constrained by limited vertical clearance (approximately 10 feet high), preventing the use of larger vehicles or equipment. Beyond the railroad underpass, the route transitions to a narrow two-track road (approximately 8-10 feet wide) that requires four-wheel-drive capability and careful navigation due to uneven surfaces, loose material, and steep approaches. These access constraints restrict entry during periods of wet

weather, limit the types of vehicles and equipment that can be safely mobilized, and may increase the time and effort required for routine fieldwork.

The access limitations at Lost Mine have direct implications for future remediation activities. Any remedial action involving excavation, waste removal, or transport of materials will require reliable and repeated access for equipment and trucks, which may not be feasible using the existing route without significant improvements. Improvements to access route would require approval from the landowner(s). An alternative access route has been identified but requires Rights of Entry from multiple landowners to assess condition of the roadways. Any improvements to roads will need to include cultural surveys and biological assessment/evaluations of the route prior to construction activities. Restricted access may also limit the size and type of machinery that can be brought to the site, potentially increasing reliance on smaller, less efficient equipment and prolonging construction or cleanup timelines. Additionally, emergency access during remediation could be hindered by current road conditions, presenting safety considerations for field crews. These constraints must be evaluated early in the remedial planning process to determine whether road improvements, alternative access routes, or modified remediation approaches will be required.

During the Stage 1 Assessment, potential alternative access routes were identified to determine whether safer or more reliable entry points exist. One route identified approaches the Lost Mine site from the southwest; however, this road crosses Navajo Nation land prior to reaching the project area. Although not investigated, this route appears to more direct use of this route would require formal coordination with and approval from the Navajo Nation. Access authorization may involve land-use agreements, right-of-entry permissions, or other administrative requirements defined by the Navajo Nation. In addition, livestock frequently grazes along portions of this route, which presents potential safety concerns and may complicate vehicle movement or equipment mobilization during future field or remediation activities.

Other informal paths and ranch roads in the surrounding area remain limited by private landownership, insufficient surface stability, or lack of defined driving corridors. Given these constraints, none of the alternative routes currently offer a fully viable or unencumbered means of accessing the site for remediation-scale operations without significant administrative coordination or roadway improvements. Any improvement to roads may require cultural and biological surveys and right of way permits/negotiations.

4.2 Mine Features Identified

The visual reconnaissance conducted during the Stage 1 Assessment documented multiple site features and surface disturbances associated with historical mining activities (Figure 5). Bench cuts, waste rock piles, and remnants of historic access/haul roads were clearly identifiable across the Site. Several areas of disturbed ground were observed downslope of the mine workings, including colluvial channels and alluvial fan deposits that showed evidence of sediment transport from the source areas (bench cut and waste piles).

Vegetation patterns supported these interpretations: sparse or stressed vegetation commonly occurred in areas of disturbed soils or where mine-derived materials were present, while undisturbed areas exhibited more consistent vegetative cover. The field team also identified cultural artifacts, including scattered pottery sherds, which were documented at undisturbed areas, and avoided during all survey activities.

Two depositional or ponding areas at the base of the drainage system were noted as likely sediment accumulation zones. No areas of prior reclamation were observed. Visual indicators such as the presence of continuous vegetative cover, undisturbed native soil, and numerous pottery sherds observed at the ground surface suggest that reclamation activities have not occurred. No adits, shafts, or other subsurface openings were identified at Lost Mine or at the portion of the Section 34 Mine located on private property, although several steep slopes and loose-soil areas present ongoing physical hazards.

All data collected during the survey were compiled into site maps, a photographic log, and GIS files prepared in formats compatible with NMED's data systems. The low-density gamma walkover survey effectively established

background radiological conditions and revealed multiple areas where gamma readings exceeded the IL of 24,000 cpm (two times background). The full Radiological Summary report from Tidewater is presented in Appendix B. Handheld XRF screening provided complementary geochemical information that further confirmed the presence and distribution of mine-impacted material across the Site. Table 1 presents the XRF sample results for uranium-associated metals, sorted by location. Sample location descriptions are provided in Appendix C-1, and the complete XRF results are compiled in Appendix C-2. Field Logs for sample locations are attached as Appendix C-3, Photos of site locations and soils area presented in Appendix D.

Several distinct mining-related features were documented within the Lost Mine claim boundary and the adjacent portion of Section 34 (Figure 6) and are discussed further below.

4.2.1 Rim Strip Area

The Rim Strip area consists of a linear bench cut (Figure 6) excavation located approximately 70 feet below the mesa top, consistent with historical rim-strip mining practices. These areas contain exposed mineralized rock and residual waste material and show elevated gamma responses and contain mineralized lithologies associated with uranium-bearing units.

Visual Survey Results:

- Bench cuts were clearly identifiable along the escarpment, showing exposed mineralized bedrock, disturbed soils, and sparse vegetation. No evidence of subsurface openings was found.
- No Cultural resources were observed in this area.
- See Appendix D for photos of this area.

Gamma Survey Results:

- Multiple exceedances above the IL were recorded directly along and immediately downslope of the bench cuts, consistent with exposed uranium-bearing material (see Figure 5).

XRF Results:

- Elevated uranium associated metals concentrations were detected in material collected from the bench edges and disturbed soils below, confirming the presence of mine-derived material.

4.2.2 Waste Rock Piles

Multiple piles and dispersed zones of coarse and fine waste materials were observed immediately downslope of the bench cuts. These materials exhibit visual and radiological characteristics consistent with uranium mine waste. Uranium and other metals were elevated in surface scans of these piles.

Visual Survey Results:

- Coarse waste rock and fine waste material were observed in several piles below the bench cuts. Vegetation was sparse, and disturbed soil surfaces were common.
- No Cultural resources were observed in this area.
- See Appendix D for photos of this area.

Gamma Survey Results:

- Strong, consistent gamma exceedances were recorded across waste piles, with peak values located along outer margins where finer material had eroded downslope (see Figure 5).

XRF Results:

- Waste piles showed some of the highest concentrations of uranium-associated metals on site. Elevated readings were spatially consistent with gamma anomalies.

4.2.3 Historic Haul and Access Roads

Several remnants of former haul/access routes were mapped, some of which exhibit erosion, cut-and-fill patterns, and radiological signatures indicative of vehicle traffic through contaminated materials. Elevated metals were also found in surface soils along the access road, particularly in drainages crossing the access road.

Visual Survey Results:

- Segments of historic road alignments were identifiable by compacted soils with a road cut to the north, fairly level (but sloping) ground, and vegetation breaks. Some areas showed minor erosion or sediment accumulation.
- No Cultural resources were observed in this area
- See Appendix D for photos of this area.

Gamma Survey Results:

- Occasional anomalies were observed where roads intersected disturbed or mineralized areas, the Eastern (lower) half of the road remained within background levels. The western (upper) of the road, which approached the bench cut, exhibited gamma counts at or above the IL.

XRF Results:

- Metal concentrations varied, with localized enrichment occurring where roads crossed impacted drainages or eroded waste material. The three sample locations nearest to the bench cut exhibited high metal concentrations.

4.2.4 Impacted Area and Disturbed Ground

Field observations and radiological/geochemical data indicate that mine-impacted materials have migrated away from the primary source areas (Figure 6): See Appendix D for photos of this area.

- **Colluvial Channels:** Narrow downslope pathways that show elevated gamma readings and metal signatures consistent with mine waste. These channels appear to serve as primary transport routes for loose, contaminated material. Evidence of cultural resources (pottery sherds) were observed in this area.
- **Alluvial Fans and Sheetwash Deposits:** Broader depositional areas at the base of the escarpment containing fine-grained sediments that show both elevated gamma signatures and XRF metal enrichment. Evidence of cultural resources (pottery sherds) were observed in this area.
- **Ephemeral Drainage:** The main drainage feature south (down-gradient) of the mine contains accumulated sediments with radiological and geochemical attributes consistent with transported mine-impacted material. Evidence of cultural resources (pottery sherds) were observed in this area.
- **Ponding Zones:** Two localized depressions at the distal end of the drainage system appear to act as sediment sinks and may contain concentrated mine-impacted material.

4.2.5 Section 34 Mine Investigation Area

Visual observations and XRF data were collected from the portion of the Section 34 mine that is located on the property. Two areas of interest were identified on the north-west end of the property, which is the easternmost portion of the Section 34 Mine. An access road partially located on Navajo Land Holdings leads to a linear excavation (bench cut) located approximately 20 feet below the canyon rim and a single pile of course and fine waste materials were observed immediately downslope of the bench cut. These materials exhibit visual and

geochemical characteristics consistent with uranium mine waste. Uranium and other metals were elevated in surface scans of these at the bench cut and the waste pile.

Visual Survey Results:

- Bench cut/access roads were clearly identifiable along the escarpment, showing exposed mineralized bedrock, disturbed soils, and sparse vegetation. No evidence of subsurface openings was found.
- Segments of historic road alignments were identifiable by compacted soils and vegetation breaks. Some areas showed minor erosion or sediment accumulation.
- Coarse waste rock and fine waste material were observed in several piles below the bench cuts. Vegetation was sparse, and disturbed soil surfaces were common.
- No cultural resources were observed in this area.
- See Appendix D for photos of this area.

Gamma Survey Results:

- Low-density gamma survey was not completed in this area due to terrain restraints.

XRF Results:

- Bench cut and waste pile material showed concentrations of uranium-associated metal concentrations consistent with mining activity.

4.3 Correlation among Datasets

A strong correlation was observed among the visual evidence of disturbed ground, gamma radiation exceedances, XRF metal signatures, and the geomorphic setting of the Lost Mine site. Areas displaying clear physical disturbance (exposed waste rock, eroded soils, sparse or stressed vegetation, and reworked sediment surfaces) consistently aligned with zones of elevated gamma activity, indicating the presence of radiologically impacted materials at or near the surface. These same areas also exhibited enriched concentrations of uranium-associated metals measured by handheld XRF, reinforcing the interpretation that mine-derived materials originated from the bench cuts and waste piles and were subsequently transported downslope. The geomorphology of the site provides a coherent framework for this pattern: steep slopes and colluvial channels act as conduits for sediment movement away from the source areas, while broader alluvial fans and the ephemeral drainage along the valley floor serve as natural depositional zones where contaminated sediments accumulate. The consistency observed across multiple lines of evidence, including visual assessments, radiological data, geochemical analyses, and geomorphic observations, demonstrates the presence of an integrated and active transport pathway for mine-impacted materials across the site. This finding underscores the need for more detailed characterization in Stage 2. To delineate the extent and magnitude of these impacts, high-resolution gamma surveys and targeted soil and sediment sampling will be required. The resulting data will be critical for assessing potential exposure pathways and guiding future remediation efforts.

5 NEXT STEPS & RECOMMENDATIONS

Findings from the Stage 1 Assessment clearly indicate the presence of mine-impacted (TENORM) materials at Lost Mine and Section 34 Mine, both at the source areas and within multiple downslope depositional environments. To fully delineate the extent, magnitude, and potential migration pathways of these materials, a Stage 2 Investigation will be required. Stage 2 should focus on high-resolution radiological characterization, targeted surface and subsurface soil sampling, and limited surface water/sediment evaluation to develop a detailed understanding of site conditions and support future risk and remedial planning.

5.1 High-Resolution Gamma Surveying

Stage 1 results identified several areas where elevated gamma readings indicate the presence of mine-impacted materials. To refine the spatial boundaries of these impacts and waste volume estimates, Stage 2 investigations should include high-resolution gamma surveys in the following areas:

- Historic mine features, including the rim-strip area, waste piles, and the historic haul/access road.
- Drainages south of the source areas, including narrow colluvial pathways where contaminated material appears to have migrated.
- Alluvial deposits downslope of the ephemeral drainage, including the broader fan and sheetwash zones where fine-grained material has accumulated.
- Portions of the Section 34 Mine located on private property, where Stage 1 reconnaissance identified disturbed ground and geochemical anomalies.
- Additional background areas, to improve confidence in baseline radiological conditions and to refine the Investigation Level during Stage 2 data evaluation.

These surveys will reduce data gaps from Stage 1 and provide the resolution needed to delineate and quantify both source-area contamination and tail-end depositional impacts.

5.2 Sampling of Mine-Impacted Materials

To quantify the depth and volume of mine-impacted material, Stage 2 investigations should include targeted surface and subsurface sampling using hand augers or shallow hand-dug test pits, as appropriate. Sampling should focus on:

- Mine waste piles and access road (waste rock material, rim-strip debris) to determine the lateral and vertical extent of TENORM-impacted material.
- Colluvial and alluvial deposits within the drainages and fan areas where mine-derived sediments have been transported and accumulated.
- Distal depositional zones, including alluvial material below source areas and areas adjacent to the ephemeral drainage and ponding features where finer-grained sediments exhibit radiological or geochemical indicators of mine impacts.

Analytical results will support volume estimates and exposure pathway evaluation and will provide the dataset necessary for potential feasibility or remedial planning in later project phases.

5.3 Surface Water and Sediment Sampling

Stage 1 reconnaissance identified an ephemeral drainage and a ponding area capable of conveying or accumulating mine-impacted sediments during storm events. To evaluate potential environmental transport mechanisms, Stage 2 investigations should include:

- Surface water sampling (as available during storm events or seasonal flow) in the ephemeral channel or ponding areas.
- Sediment sampling within the channel and ponding zone to determine whether mine-impacted material is being mobilized or concentrated in these areas.

These data will support the development of a preliminary Conceptual Site Model (CSM) for contaminant transport and will help assess whether off-property migration is occurring or likely.

5.4 Purpose and Outcome of Stage 2

The Stage 2 Investigation will provide the detailed radiological, geochemical, and subsurface information required to:

- Delineate the horizontal and vertical extent of TENORM-impacted materials.
- Distinguish mine-related contaminants from natural background conditions with greater certainty.
- Quantify the magnitude of impacted materials for future evaluation of removal, containment, or other remedial options.
- Evaluate potential exposure pathways, including sediment transport and human or ecological contact.
- Provide a defensible dataset for NMED and EMNRD to determine next steps

6 CONCLUSION

The Stage 1 Uranium Site Assessment at Lost Mine and the adjacent portion of Section 34 Mine successfully established the baseline physical and radiological conditions necessary to support informed planning for subsequent investigation phases. Through a combination of visual reconnaissance, low-density gamma surveying, handheld XRF screening, historical research, and site access evaluation, the assessment identified multiple mine features and areas where mine-impacted (TENORM) materials are present or have migrated downslope from historical mining activities.

Key findings from Stage 1 assessment include the confirmation of mining related features (waste rock piles, rim-strip disturbances, haul/access road), colluvial and alluvial deposits containing mine-derived materials, and localized areas of elevated gamma activity and metal enrichment consistent with uranium mining residues. The reconnaissance also documented drainage pathways and depositional zones that serve as conduits and accumulation areas for impacted sediment, as well as access limitations and land status considerations that may influence future investigation and remediation activities.

Based on these observations, multiple areas have been designated as priorities for a Stage 2 investigation, including:

- Waste Rock Piles (estimated 2 acres) where the highest gamma readings were observed, requiring high-resolution gamma survey grids and subsurface sampling for estimating vertical and lateral extent of waste material and volume estimation.
- Historic haul/access roads (estimated 0.5 acres), with a focus on areas where gamma readings were above background and areas where alluvial channels cross the historic road.
- Colluvial Slope Deposits below the mine footprint (estimated 6.5 acres, focused on drainages and mobilization pathways) initially identified for radiological delineation and potential excavation feasibility screening.
- Alluvial Plain and Valley Floor Depositional Zones (estimated 7.5 acres) where gamma readings were above the IL and surface and subsurface sediment sampling will evaluate downgradient transport and accumulation of TENORM-bearing material.
- Ephemeral Drainage Network, including the primary drainage and the ponding areas identified for sediment and surface water sampling; and
- A Secondary Background Reference Area (approximately 2 acre), selected to confirm defensible background gamma levels and geochemical baselines.

High-resolution gamma surveys, subsurface sampling, and targeted sediment and surface water evaluations will be required to delineate the horizontal and vertical extent of TENORM-impacted materials, quantify impacted volumes, and refine the conceptual site model. The Stage 2 investigation data will be essential for evaluating exposure pathways, assessing potential risks, and determining whether remedial actions are warranted under NMED and EMNRD programs.

Overall, the Stage 1 Assessment has met its objectives by defining the current condition of the site, identifying priority areas for further evaluation, and establishing the framework for a defensible and systematic Stage 2 Investigation. Continued coordination with NMED and EMNRD will ensure that subsequent phases of work address regulatory expectations and support long-term decision-making for the management of legacy uranium mine impacts at Lost Mine and Section 34 Mine.

Notes:

1 - XRF results are semi-quantitative: concentrations are intended for screening-level evaluation and relative comparison only and are not equivalent to laboratory-derived values

Sample Locations considered to be elevated in uranium-associated metals

2 - Data were collected using a field portable X-ray florescence (XRF) analyzer operated in soil mode in accordance with the manufacture's specifications

3 - Reported concentrations represent in-situ measurements and may be influenced by soil moisture content, grain size, surface heterogeneity, and matrix effects

Results Above Background

4 - Values in *Red Italics* were at or below the error for the specified element during the scan.

APPENDIX A – TITLE SEARCH FINDINGS: LOST MINE

Title Search Findings: Lost Mine		
Aliases: Section 35 Strip, Berryhill-Elkins		
Ownership Details	Current:	Surface Land Status: Private - Elkins, Lynn Family Limited Partnership (as of May 9, 2000)
		Mineral: Private - Uranium Energy Corp. (as of 2007)
	Historic:	Surface: Lynn E. Elkins, Fred V. Elkins, Hattie B Elkins
		Mineral: Annie May Berryhill, Wallace A. Berryhill, Adrian Berryhill
Encumbrances, liens, ROWs, or restrictions:		Subject to ingress/egress for Uranium Energy Corp. mineral rights.
PRP status, if applicable:		Not applicable
Under federal, state, tribal or voluntary cleanup program?:		Not under any dedicated site-specific program.
Coordinates (Lat, Long):		35.40264, -107.97506
Mine Summary & Description:		The workings consist of 100 ft x 400 ft surface rim cuts below 70 ft below the mesa. Initial and final production of uranium from Lost Mine both were indicated as being in 1954.
Additional Information:		Potentially other unnamed / unidentified historic surface and mineral ownership details.

Notes:
ROW = right-of-way
PRP = potentially responsible party
Lat = latitude
Long = longitude
Ft = feet

APPENDIX B – TIDEWATER, INC. LOST MINE STAGE 1 GAMMA SURVEY REPORT

Stage 1 Uranium Mine Site Assessment Work Plan

NMED Lost Mine Stage 1 Gamma Survey Report

Prepared for:

PARSONS

1050 W. Washington Street, Suite 114,
Tempe, AZ 85288

Prepared by:

TIDEWATER INC
ENGINEERS / SCIENTISTS / PROGRAM MANAGERS

1804 Tribute Road, Suite B
Sacramento, CA 95816

December 2025

Introduction and Purpose

Parsons is the prime contractor with Tidewater providing subcontractor support for gamma surveying and radiological characterization. This Gamma Survey Radiation Survey Report summarizes the work performed and the results for the Stage 1 Uranium Site Assessment (Stage 1 Assessment) at Lost Mine (Site), located in northern New Mexico (**Figure 1**). Due to its close proximity, a portion of Section 34 Mine was included in these activities. The objectives were to perform a gamma survey for the purpose of developing the Stage 2 work to be performed. Results of the work will guide subsequent phases of the investigation and potential remedial planning in coordination with the New Mexico Environment Department (NMED) and the New Mexico Energy, Minerals, and Natural Resources Department (EMNRD).

The Stage 1 Assessment was conducted to establish background radiological levels and identify areas requiring further evaluation. Conditions that may influence subsequent investigation activities or remedial actions were also identified. This broad-scale assessment of surface radiological conditions will help focus future, higher-resolution investigations on areas with the greatest potential for elevated radiological impacts. Together, these tasks will provide a comprehensive foundation for understanding current site conditions and prioritizing follow-up investigation activities.

Target Radionuclides

Table 1 provides information on the identified target radionuclides selected for the Site. The target radionuclides were selected based on the radionuclides associated with mining operations. It should be noted that the identified target radionuclides listed in the table below do not include their respective decay progeny.

Table 1. Target Radionuclides for the Site

Radionuclide	Half-Life	Principal Emissions
Radium-226	1.6E03 yr	4.78, 4.60 MeV alpha; 0.186 MeV gamma
Uranium-234	2.5E05 yr	4.72, 4.77 MeV alpha; 0.053 MeV gamma
Uranium-235	7.0E08 yr	4.39, 4.36 MeV alpha; 0.18, 0.14 MeV gamma
Uranium-238	4.5E09 yr	4.19, 4.14 MeV alpha;

Instrumentation

The gamma radiation surveys were performed by qualified radiological control technicians following guidance of Tidewater standard operating procedure (SOP) RSP-022, Gamma Scanning Survey. **Table 2** provides a summary of the instrumentation used for the gamma radiation surveys.

The gamma radiation surveys were conducted using Ludlum Model 44-10 (2-inch x 2-inch NaI) detectors. The detectors are compatible with general purpose survey meters, ratemeters, and scalers for high energy gamma detection of approximately 60 keV to 2 MeV range.

For gamma walkover surveys (GWSs), the NaI detector(s) was coupled with a Ludlum Model 3000 meter. The Ludlum Model 3000 is a general purpose ratemeter and scaler with digital

displays for use with a single detector. The Ludlum Model 3000 meter was connected via Bluetooth to a touch enabled data logger, sub-meter GPS receiver. The system was set to record data at 1-second intervals. Data to be recorded were the sequence number, longitude, latitude, easting, northing, date, timestamp, file name, and count rate. The coordinate system used was State Plane 1983 - New Mexico FIPS 3003 (US Feet).

Table 2. Gamma Radiation Survey Instrumentation

Meter	Serial Number	Detector	Serial Number	Calibration Due Date	Purpose
Ludlum 3000	25039953	Ludlum 44-10	PR373560	09 Jul 26	Gamma Surveys
Ludlum 3000	25039967	Ludlum 44-10	PR355767	09 Jul 26	Gamma Surveys

Investigation Approach

Gamma Walkover Surveys

GWS were performed with a Ludlum 44-10 (2-inch x 2-inch NaI detector) connected to a Ludlum Model 3000 and to a GPS. The detectors were suspended approximately 4-6 inches over the surface being measured. The surveyor moved at a maximum rate of approximately 0.5 meters per second.

Prior to initiation of the survey, the name of the technician performing the survey and the area being surveyed were entered into the data logger. The data logger records the instrument and detector serial number, the date, and the timestamp of data collected.

The site was divided into the areas on the hillside (waste piles/source materials and the colluvial area) and the lower basin (alluvial area). A background area was used to establish background and an action level (twice the mean result of the background area). Background surveys were performed utilizing the same method as those to be used in the investigation areas. Areas of investigation are shown on **Figure 2**. **Appendix A** provides the processed data for the gamma walkover surveys.

Instrument Calibration

Field instruments were calibrated at least annually with National Institute of Standards and Technology (NIST) traceable sources, and to radiation emission types and energies that will provide detection capabilities similar to the nuclides of concern. Copies of instrument calibration certificates were maintained on site.

Functional Checks

Radiological instrumentation was used, operated, and maintained by project Health Physics Technicians (HPT) under the supervision of a Certified Health Physicist. Functional checks were performed daily prior to use in accordance with Tidewater procedure, RS-013.0, "*Routine Operability of Field Instruments*". **Appendix B** provides the calibration certificates for the instruments used for the survey.

Scanning Minimum Detectable Concentration and Minimum Detectable Count Rate

Scan Minimum Detectable Concentration (MDC) is determined based on the guidance described in MARSSIM, Revision 1, Section 6.7.2 – Scanning Sensitivity and

Decommissioning Health Physics, Second Edition, Section 9.3 – Scan MDC.

Scanning is performed to identify areas of elevated activity in the survey unit. The scan MDC depends on many of the same factors that influence the detection of contamination under static conditions: the level of the background radiation levels; the nature (type and energy of emissions) and relative distribution of potential contamination (point versus distributed source and depth of contamination; the intrinsic characteristics of the detector (efficiency, physical probe area, etc.); the desired level of confidence (type I and type II); and the surveyor's skill in recognizing an increase in the audible or display output of an instrument.

If one assumes constant parameters for each of the above variables, except for the specific radionuclide of interest, the scan MDC may be reduced to a function of the radionuclide alone. These calculations are provided in Section 6 of MARSSIM. The scan MDCs are determined based upon site-specific background data, using the equations below. The number of source counts required for a specific time interval utilizing MARSSIM Equation 6-8:

$$s_i = d'\sqrt{b_i}$$

Where:

d' = The performance factor based on required true and false positives rates. First scanning stage, a high rate (95%) of correct detections is required, and a correspondingly rate of false positives (60%) will be tolerated. From MARSSIM Table 6.5, the performance goal value is 1.38.

b_i = The number of background counts in the observation interval

Assuming that the source remains under the detector for 1 second (e.g., i=1) and the background count rate is the site-specific background, the value for bi is then calculated:

bi (counts) = (Background (cpm)) x (i (sec.)) x (1 min/60 sec)

The scan minimum detectable count rate (MDCR) is then calculated using the number of source counts required for a specific time interval is calculated by MARSSIM Equation 6-8:

$$s_i = d'\sqrt{b_i}$$

MARSSIM Equation 6-9:

MDCR (cpm) = (d') x (√bi (counts)) x (60 sec/1min)

The $MDCR_{surveyor}$ is calculated assuming a surveyor efficiency (p) of 0.5 (see MARSSIM page 6-45):

$MDCR_{SURVEYOR}$ (cpm) = MDCR (cpm)/(√p)

Using the above input parameters, the scan MDC necessary to yield the minimum detectable concentration is calculated using MARSSIM Equation 6-10 for structures and surfaces and MARSSIM Equation 6-11 for land areas (soils).

An example of the surface and structures scanning MDC at a 95 percent confidence level is calculated using the following equation, which is a combination of MARSSIM Equations 6-

8, 6-9 and 6-10:

$$MDC_{scan} = \frac{d'\sqrt{b_i}\left(\frac{60}{i}\right)}{\sqrt{p}\cdot\varepsilon_{tot}\cdot\frac{A}{100cm^2}}$$

Where:

d'	=	minimum detectable concentration level in dpm/100 cm^2
b_i	=	background counts during the observation interval
I	=	observation interval
P	=	surveyor efficiency (0.5)
ε_{tot}	=	total detection efficiency for radionuclide emission of interest (includes combination of instrument and surface efficiencies)
A	=	active area of the detector in cm^2

Data Evaluation

Data subsets were evaluated using the Microsoft Excel® data analysis tool and ProUCL Version 5.0 (USEPA, 2013). The data analysis tool was used to generate basic descriptive statistics. The summary tables included mean, median, mode, standard deviation, standard variance, kurtosis, minimum, maximum, and sample population count. **Table 3** provides a summary of the statistics for the gamma surveys.

Table 3. Gamma Radiation Survey Summary Statistics

Survey Area	Mean (cpm)	Median (cpm)	Standard Deviation	Minimum (cpm)	Maximum (cpm)
Background Area	11,762	11,800	860	7,900	14,500
Alluvial Area	17,622	13,500	8,953	7,400	53,000
Source/Colluvial Area	27,112	23,500	12,952	9,000	96,400

ProUCL software was used to provide similar general statistics and generated percentile information for the data subsets. ProUCL was also used to generate histograms, quantile-quantile (Q-Q) plots, and scatter plots for each data subset. Histogram plots are a graphical representation of a data series that condenses the data by taking many data points and grouping them into logical ranges or bins. The histogram will show the projected normal distribution curve of the data sets and indicating the mean and median on this curve. Q-Q plots provide a graphical view of how properties such as location, scale, and skewness are similar or different in the data set against a hypothetical curve. Scatter plots will graph the average, maximum, and minimum values per grid subset along two axes, with the x-axis indicating the result values and the y-axis indicating the grid number. Displaying the data on a scatter plot reveals any correlations present in the data set.

RESULTS

A total of 34,202 data points were collected as part of the Phase 1 Assessment of the Lost Mine Site. For the background area to establish an action level for the assessment, a total of 5,839 data points were collected. An action level (twice the mean of the background) was established at 23,525 cpm. **Figures 3 through 5** show the histogram, posting, and Q-Q plots for the background data set.

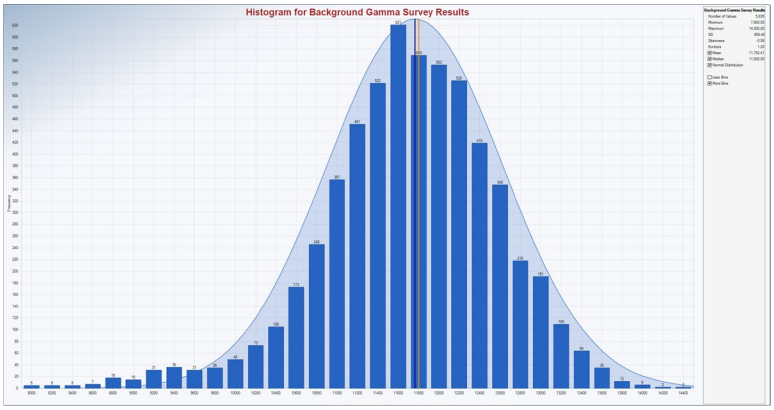

Figure 3. Histogram for Background Gamma Survey Results

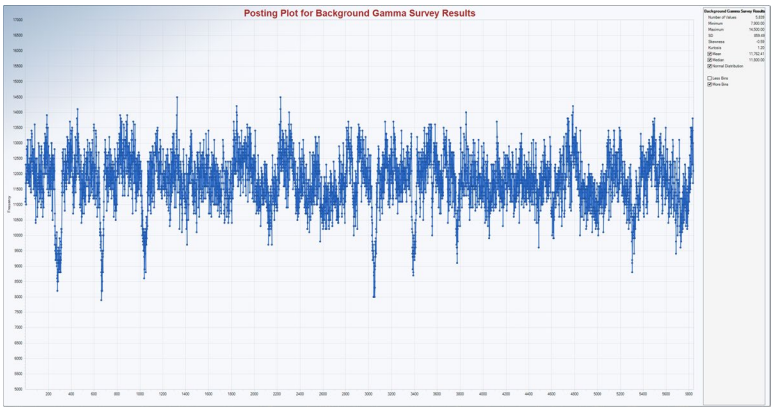

Figure 4. Posting Plot for Background Gamma Survey Results

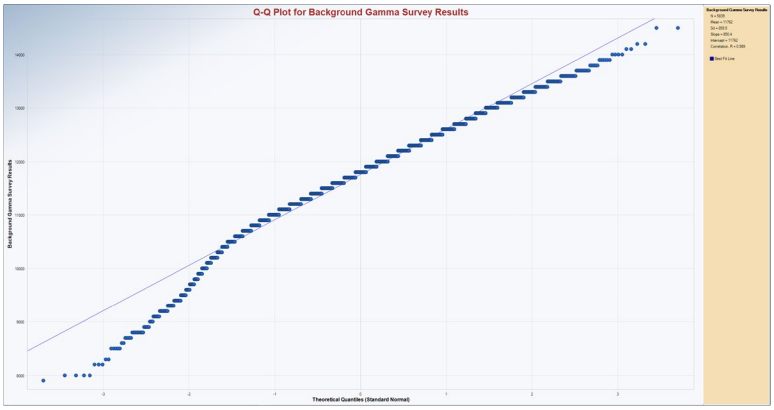

Figure 5. Q-Q Plot for Background Gamma Survey Results

Results of the mining area and colluvial area were mainly focused on the top and bottom of the waste piles. This includes the former haul road along the upper ridge of the waste piles. The maximum result was identified at the top of the slope with a result of 96,400 cpm. Nearly 50% of the data points collected from this area exceeded the action level. **Figures 6 through 8** show the histogram, posting, and Q-Q plots for the mining area/colluvial data set.

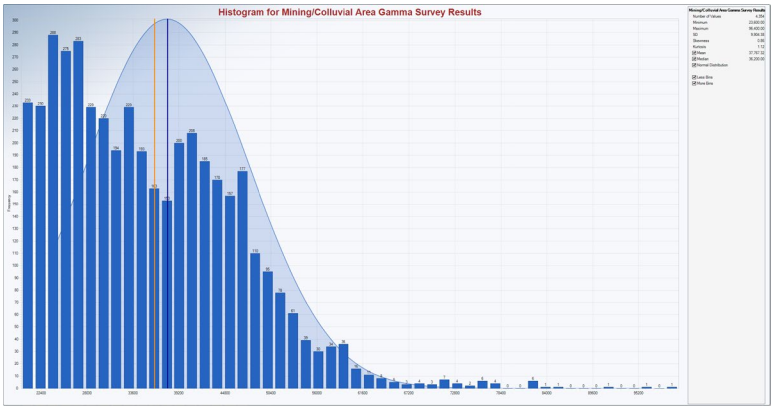

Figure 6. Histogram for Mining/Colluvial Area Gamma Survey Results

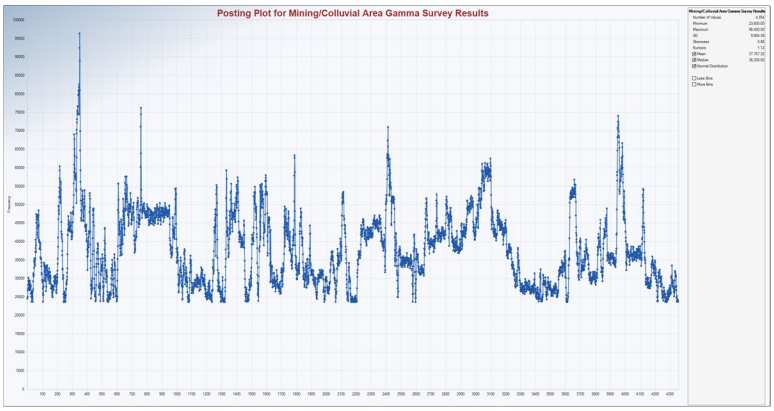

Figure 7. Posting Plot for Mining/Colluvial Area Gamma Survey Results

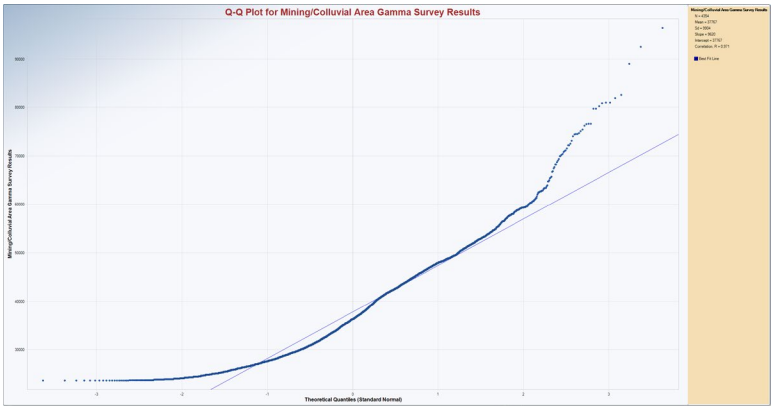

Figure 8. Q-Q Plot for Mining/Colluvial Area Gamma Survey Results

Results of the alluvial area (lower basin) included the areas from the bottom of the slope to the drainage swale (north/south) and main road to areas located west of the water body. The maximum result was identified in the drainage swale where runoff waste materials were visually present with a result of 53,000 cpm. Of 19,626 data points collected from this area, 4,038 data points exceeded the action level. **Figures 9 through 11** show the histogram, posting, and Q-Q plots for the alluvial data set.

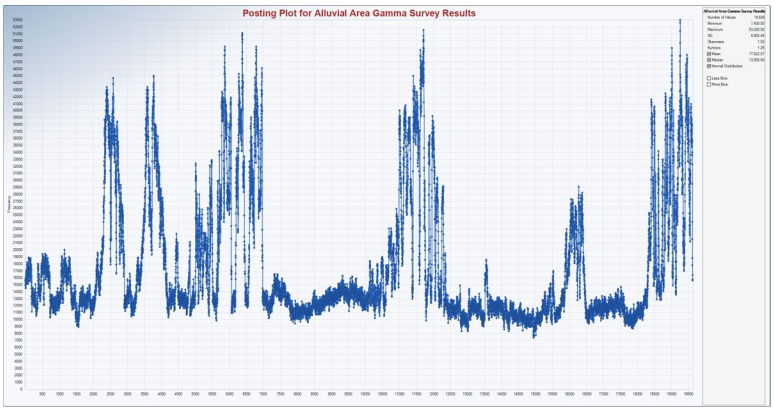

Figure 10. Posting Plot for Alluvial Area Gamma Survey Results

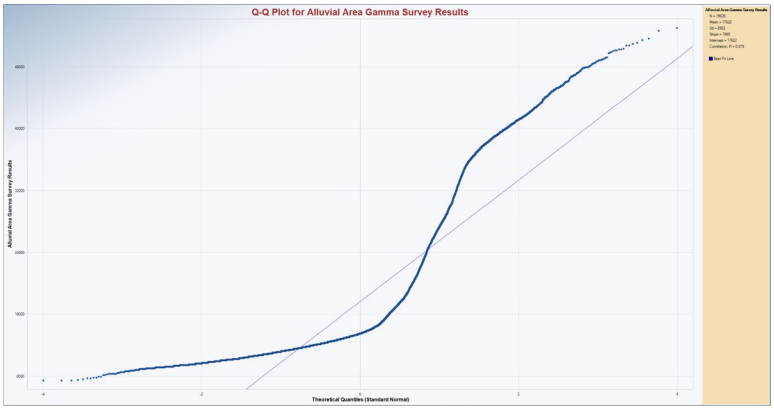

Figure 11. Q-Q Plot for Alluvial Area Gamma Survey Results

Figures 12 through 14 show the results posted on aerial maps of the site. Based on these results, the investigation area for the Lost Mine showed that the waste pile, colluvial area (drainage channels on the hillside), and the alluvial area showed significant impact from the historical mining operations. Additional investigations are required to further delineate the lateral and vertical extents of contamination.
