(a) Rio Costilla, including Comanche, La Cueva, Fernandez, Chuckwagon, Little Costilla, Powderhouse, Holman, Gold, Grassy, LaBelle and Vidal creeks, from their headwaters downstream to the boundary of the United States forest service Valle Vidal special management unit;

(b) Middle Ponil creek, including the waters of Greenwood Canyon, from their headwaters downstream to the boundary of the Elliott S. Barker wildlife management area;

(c) Shuree lakes;

(d) North Ponil creek, including McCrystal and Seally Canyon creeks, from their headwaters downstream to the boundary of the United States forest service Valle Vidal special management unit; and

(e) Leandro creek from its headwaters downstream to the boundary of the United States forest service Valle Vidal special management unit.

(3) the named perennial surface waters of the state, identified in Subparagraph (a) below, located within United States department of agriculture forest service wilderness. Wilderness are those lands designated by the United States congress as wilderness pursuant to the Wilderness Act. Wilderness areas included in this designation are the Aldo Leopold wilderness, Apache Kid wilderness, Blue Range wilderness, Chama River Canyon wilderness, Cruces Basin wilderness, Dome wilderness, Gila wilderness, Latir Peak wilderness, Pecos wilderness, San Pedro Parks wilderness, Wheeler Peak wilderness, and White Mountain wilderness.

(a) The following waters are designated in the Rio Grande basin:

(i) in the Aldo Leopold wilderness: Byers Run, Circle Seven creek, Flower canyon, Holden Prong, Indian canyon, Las Animas creek, Mud Spring canyon, North Fork Palomas creek, North Seco creek, Pretty canyon, Sids Prong, South Animas canyon, Victorio Park canyon, Water canyon;

(ii) in the Apache Kid wilderness Indian creek and Smith canyon;

(iii) in the Chama River Canyon wilderness: Chavez canyon, Ojitos canyon, Rio Chama;

(iv) in the Cruces Basin wilderness: Beaver creek, Cruces creek, Diablo creek, Escondido creek, Lobo creek, Osha creek;

(v) in the Dome wilderness: Capulin creek, Medio creek, Sanchez canyon/creek;

(vi) in the Latir Peak wilderness: Bull creek, Bull Creek lake, Heart lake, Lagunitas Fork, Lake Fork creek, Rito del Medio, Rito Primero, West Latir creek;

(vii) in the Pecos wilderness: Agua Sarca, Hidden lake, Horseshoe lake (Alamitos), Jose Vigil lake, Nambe lake, Nat lake IV, No Fish lake, North Fork Rio Quemado, Rinconada, Rio Capulin, Rio de las Trampas (Trampas creek), Rio de Truchas, Rio Frijoles, Rio Medio, Rio Molino, Rio Nambe, Rio San Leonardo, Rito con Agua, Rito Gallina, Rito Jaroso, Rito Quemado, San Leonardo lake, Santa Fe lake, Santa Fe river, Serpent lake, South Fork Rio Quemado, Trampas lake (East), Trampas lake (West);

(viii) in the San Pedro Parks wilderness: Agua Sarca, Cañon Madera, Cave creek, Cecilia Canyon creek, Clear creek (North SPP), Clear creek (South SPP), Corralitos creek, Dove creek, Jose Miguel creek, La Jara creek, Oso creek, Rio Capulin, Rio de las Vacas, Rio Gallina, Rio Puerco de Chama, Rito

NMED Exhibit 27

Anastacio East, Rito Anastacio West, Rito de las Palomas, Rito de las Perchas, Rito de los Pinos, Rito de los Utes, Rito Leche, Rito Redondo, Rito Resumidero, San Gregorio lake;

(ix) in the Wheeler Peak wilderness: Black Copper canyon, East Fork Red river, Elk lake, Horseshoe lake, Lost lake, Sawmill creek, South Fork lake, South Fork Rio Hondo, Williams lake.

(b) The following waters are designated in the Pecos River basin:

(i) in the Pecos wilderness: Albright creek, Bear creek, Beatty creek, Beaver creek, Carpenter creek, Cascade canyon, Cave creek, El Porvenir creek, Hollinger creek, Holy Ghost creek, Horsethief creek, Jack's creek, Jarosa canyon/creek, Johnson lake, Lake Katherine, Lost Bear lake, Noisy brook, Panchuela creek, Pecos Baldy lake, Pecos river, Rio Mora, Rio Valdez, Rito Azul, Rito de los Chimayosos, Rito de los Esteros, Rito del Oso, Rito del Padre, Rito las Trampas, Rito Maestas, Rito Oscuro, Rito Perro, Rito Sebadilloses, South Fork Bear creek, South Fork Rito Azul, Spirit lake, Stewart lake, Truchas lake (North), Truchas lake (South), Winsor creek;

(ii) in the White Mountain wilderness: Argentina creek, Aspen creek, Bonito creek, Little Bonito creek, Mills canyon/creek, Rodamaker creek, South Fork Rio Bonito, Turkey canyon/creek.

(c) The following waters are designated in the Gila River basin:

(i) in the Aldo Leopold wilderness: Aspen canyon, Black Canyon creek, Bonner canyon, Burnt canyon, Diamond creek, Falls canyon, Fisherman canyon, Running Water canyon, South Diamond creek;

(ii) in the Gila wilderness: Apache creek, Black Canyon creek, Brush canyon, Canyon creek, Chicken Coop canyon, Clear creek, Cooper canyon, Cow creek, Cub creek, Diamond creek, East Fork Gila river, Gila river, Gilita creek, Indian creek, Iron creek, Langstroth canyon, Lilley canyon, Little creek, Little Turkey creek, Lookout canyon, McKenna creek, Middle Fork Gila river, Miller Spring canyon, Mogollon creek, Panther canyon, Prior creek, Rain creek, Raw Meat creek, Rocky canyon, Sacaton creek, Sapillo creek, Sheep Corral canyon, Skeleton canyon, Squaw creek, Sycamore canyon, Trail canyon, Trail creek, Trout creek, Turkey creek, Turkey Feather creek, Turnbo canyon, West Fork Gila river, West Fork Mogollon creek, White creek, Willow creek, Woodrow canyon.

(d) The following waters are designated in the Canadian River basin: in the Pecos wilderness Daily creek, Johns canyon, Middle Fork Lake of Rio de la Casa, Middle Fork Rio de la Casa, North Fork Lake of Rio de la Casa, Rito de Gascon, Rito San Jose, Sapello river, South Fork Rio de la Casa, Sparks creek (Manuelitas creek).

(e) The following waters are designated in the San Francisco River basin:

(i) in the Blue Range wilderness: Pueblo creek;

(ii) in the Gila wilderness: Big Dry creek, Lipsey canyon, Little Dry creek, Little Whitewater creek, South Fork Whitewater creek, Spider creek, Spruce creek, Whitewater creek.

(f) The following waters are designated in the Mimbres Closed basin: in the Aldo Leopold wilderness Corral canyon, Mimbres river, North Fork Mimbres river, South Fork Mimbres river.

(g) The following waters are designated in the Tularosa Closed basin: in the White Mountain wilderness Indian creek, Nogal Arroyo, Three Rivers.

(h) The wetlands designated are identified on the *Maps and List of Wetlands Within United States Forest Service Wilderness Areas Designated as Outstanding National Resource Waters* published at the New Mexico state library and available on the department's website.

(4) The following waters are designated in the headwaters Pecos river watershed:

(a) The Pecos river from Dalton Canyon creek to the Pecos wilderness boundary;

(b) In the Dry Gulch-Pecos river subwatershed, Dalton Canyon creek from the Pecos river upstream to the headwaters, Wild Horse creek from Dalton Canyon creek upstream to the headwaters, Macho Canyon creek from the Pecos river upstream to the headwaters and Sawyer creek from the Pecos river upstream to the headwaters;

(c) In the Indian creek-Pecos river subwatershed, Indian creek from the Pecos river upstream to the headwaters, Holy Ghost creek from the Pecos river upstream to the Pecos wilderness boundary, Doctor creek from Holy Ghost creek upstream to the headwaters, Davis creek from the Pecos river upstream to the headwaters and Willow creek from the Pecos river upstream to the headwaters;

(d) In the Rio Mora subwatershed, Rio Mora from the Pecos river upstream to the Pecos wilderness boundary and Bear creek from the Rio Mora upstream to the Pecos wilderness boundary;

NMED Exhibit 27

(e) In the Rio Mora-Pecos river subwatershed, Carpenter creek from the Pecos river upstream to the Pecos wilderness boundary, Winsor creek from the Pecos river upstream to the Pecos wilderness boundary and Jack's creek from the Pecos river upstream to the Pecos wilderness boundary; and,

(f) In the Panchuela creek subwatershed, Panchuela creek from the Pecos river upstream to the Pecos wilderness boundary;

(g) Unnamed tributaries to waters in Subparagraphs (a) through (f), Paragraph (4) of this Subsection (D) as identified in the *Maps and Lists for Unnamed Tributaries to Perennial Waters and Wetlands in the Headwaters Pecos River Watershed,* published at the New Mexico state library and available on the department's website.

(h) Unnamed wetlands adjacent to waters in Subparagraphs (a) through (f), Paragraph (4) of this Subsection (D) as identified in the *Maps and Lists for Unnamed Tributaries to Perennial Waters and Wetlands in the Headwaters Pecos River Watershed*, published at the New Mexico state library and available on the department's website.

(5) the Rio Grande from directly above the Rio Pueblo de Taos to the New Mexico-Colorado state border.

(6) the Rio Hondo from the Carson National Forest boundary to its headwaters; and Lake Fork creek from the Rio Hondo to its headwaters.

(7) the East Fork Jemez river from San Antonio creek to its headwaters; San Antonio creek from the East Fork Jemez river to its headwaters; and Redondo creek from Sulphur creek to its headwaters.

(8) The following waters located within a national or state park, national or state monument, or national or state wildlife refuge:

(a) in the Valles Caldera national preserve: La Jara creek, Sulphur creek, San Luis creek, Jaramillo creek, and Rito de los Indios;

(b) in the Bandelier national monument: Rito de los Frijoles, Lummis canyon, Alamo canyon, Capulin creek, and Medio creek;

(c) in the Cimarron canyon state park: Cimarron river;

(d) in the Pecos national historical park: Pecos river;

(e) in the Rio Grande del Norte national monument: Rio San Antonio.

(9) The following waters located within a designated wilderness area: in the Columbine – Hondo wilderness areas: Columbine creek, Deer creek, Placer fork, Willow fork, Goose creek, Bear creek, Long canyon, Gavilan canyon, Italianos creek, Yerba creek, Manzanita creek, Gallina creek, Lobo creek, San Cristobal creek, and Lama canyon.

(10) The following wild rivers as designated by the federal Wild and Scenic Rivers Act:

(a) Rio Chama from the US forest service boundary to confluence with the Rio Nutrias;

(b) Red River from the confluence with the Rio Grande to four miles upstream.

(11) The following state special trout waters not already included in Paragraphs 8 through 10 of this Subsection:

(a) in the Edward Sargent wildlife management area: Rio Chamita, Nabor creek, Sixto creek, and Rio Chama;

(b) Rio Chama from Heron Reservoir outlet to Cottonwood flats;

(c) Rio de los Pinos from United States forest service road 87A to private land 2.5 miles upstream, Tanques creek, Canada Tio Grande;

(d) Cabresto creek from United States forest service boundary to headwaters, Frijoles creek, Palociento creek, and West Fork Luna creek;

(e) Rio Cebolla from Seven Springs day use area to its headwaters, Rio Gaudalupe from the confluence with Deer creek upstream to confluence with Stable creek;

(f) Capulin creek from the Dome wilderness boundary to headwaters.

[20.6.4.9 NMAC - Rn, Subsections B, C and D of 20.6.4.8 NMAC, 5/23/2005; A, 5/23/2005; A, 7/17/2005; A, 2/16/2006; A, 12/1/2010; A, 1/14/2011; A, 4/23/2022; A, 9/24/2022; A, 3/15/2025]

20.6.4.10 REVIEW OF STANDARDS; NEED FOR ADDITIONAL STUDIES:

A. Section 303(c)(1) of the federal Clean Water Act requires that the state hold public hearings at least once every three years for the purpose of reviewing water quality standards and proposing, as appropriate, necessary revisions to water quality standards.

NMED Exhibit 27

B. In accordance with 40 CFR 131.10(i), when an existing use, as defined under 20.6.4.7 NMAC, is higher quality water than prescribed by the designated use and supporting evidence demonstrates the presence of that use, the designated use shall be amended accordingly to have criteria no less stringent than the existing use.

C. It is recognized that, in some cases, numeric criteria for a particular designated use may not adequately reflect the local conditions or the aquatic communities adapted to those localized conditions. In these cases, a water quality criterion may be modified to reflect the natural condition of a specific waterbody. The modification of the criterion does not change the designated use; the modification only changes the criterion for that specific waterbody When justified by sufficient data and information, a numeric water quality criterion may be adopted or modified in accordance with Subsections [~~F~~]G [~~of 20.6.4.10~~] and [~~Subsection G~~]H of 20.6.4.10 NMAC, to protect the attainable uses of the waterbody.

D. The removal or amendment of a designated use to a designated use with less stringent criteria can only be done through a use attainability analysis in accordance with 20.6.4.15 NMAC.

E. It is also recognized that contributions of water contaminants by diffuse nonpoint sources of water pollution may make attainment of certain criteria difficult. Revision of these criteria may be necessary as new information is obtained on nonpoint sources and other problems unique to semi-arid regions.

F. Any person may petition the commission to adopt, amend, or repeal any regulation within the jurisdiction of the commission in accordance with 20.1.6.200 NMAC, including ONRW nominations, site-specific criteria, use attainability analyses, temporary standards, and designating classified segments. If the commission grants a rulemaking hearing in response to a petition, the petitioner shall be responsible for the administrative rulemaking costs. The petitioner shall coordinate with the commission administrator and the department on the administrative rulemaking costs and hearing requirements.

[~~F~~]G. Site-specific criteria.

(1) The commission may adopt site-specific numeric criteria applicable to all or part of a surface water of the state based on relevant site-specific conditions such as:

(a) actual species at a site are more or less sensitive than those used in the national criteria data set;

(b) physical or chemical characteristics at a site such as pH or hardness alter the biological availability and/or toxicity of the chemical;

(c) physical, biological or chemical factors alter the bioaccumulation potential of a chemical;

(d) the concentration resulting from natural background exceeds numeric criteria for aquatic life, wildlife habitat or other uses if consistent with Subsection G of 20.6.4.10 NMAC; or

(e) other factors or combination of factors that upon review of the commission may warrant modification of the default criteria, subject to EPA review and approval.

(2) Site-specific criteria must fully protect the designated use to which they apply. In the case of human health-organism only criteria, site-specific criteria must fully protect human health when organisms are consumed from waters containing pollutants.

(3) Any person may submit notice to the department stating their intent to develop site-specific criteria for a surface water of the state. The notice shall include a work plan supporting the development of site-specific criteria for the department's comment.

(4) Site-specific criteria shall be developed in accordance with the work plan, based on one or more of the site-specific conditions in Paragraph (1) of Subsection G of 20.6.4.10 NMAC, derived from a scientifically defensible method and protect the designated uses to which they apply.

(5) The work plan shall identify, at a minimum:

(a) the waterbody to consider and the reasoning for site-specific criteria;

(b) the methodology to be used to derive criteria;

(c) the source and validity of data to be used;

(d) the provisions for consultation with appropriate state and federal agencies;

(e) a description of how stakeholders and potentially affected Indian nations, tribes, or pueblos will be identified and engaged;

(f) a description of the public notice mechanisms to be employed; and

(g) the expected timelines and associated administrative actions to be taken for a rulemaking petition, pending the outcome of criteria development.

(6) Upon completion of site-specific criteria development, the data, findings and conclusions shall be submitted to the department, and public notice shall be provided in accordance with the work plan.

NMED Exhibit 27

[~~(3)~~](7) Any person may petition the commission to adopt site-specific criteria. A petition for the adoption of site-specific criteria shall:

(a) identify the specific waters to which the site-specific criteria would apply;

(b) explain the rationale for proposing the site-specific criteria;

(c) describe the methods used to notify and solicit input from potential stakeholders and from the general public in the affected area, and present and respond to the public input received;

(d) present and justify the derivation of the proposed criteria.

[~~(4)~~](8) A derivation of site-specific criteria shall rely on a scientifically defensible method, such as one of the following:

(a) the recalculation procedure, the water-effect ratio for metals procedure or the resident species procedure as described in the water quality standards handbook (EPA-823-B-94-005a, 2nd edition, August 1994);

(b) the streamlined water-effect ratio procedure for discharges of copper (EPA-822-R-01-005, March 2001);

(c) the biotic ligand model as described in aquatic life ambient freshwater quality criteria - copper (EPA-822-R-07-001, February 2007);

(d) the methodology for deriving ambient water quality criteria for the protection of human health (EPA-822-B-00-004, October 2000) and associated technical support documents; or

(e) a determination of the natural background of the [~~water body~~] waterbody as described in Subsection G of 20.6.4.10 NMAC.

[~~G~~]H. **Site-specific criteria based on natural background.** The commission may adopt site-specific criteria equal to the concentration resulting from natural background where that concentration protects the designated use. The concentration resulting from natural background supports the level of aquatic life and wildlife habitat expected to occur naturally at the site absent any interference by humans. Domestic water supply, primary or secondary contact, or human health-organism only criteria shall not be modified based on natural background. A determination of natural background shall:

(1) consider natural spatial and seasonal to interannual variability as appropriate;

(2) document the presence of natural sources of the pollutant;

(3) document the absence of human sources of the pollutant or quantify the human contribution; and

(4) rely on analytical, statistical or modeling methodologies to quantify the natural background.

[~~H~~]I. **Temporary standards.**

(1) Any person may petition the commission to adopt a temporary standard applicable to all or part of a surface water of the state as provided for in this section and applicable sections in 40 CFR Part 131, Water Quality Standards; specifically, Section 131.14. The commission may adopt a proposed temporary standard if the petitioner demonstrates that:

(a) attainment of the associated designated use may not be feasible in the short term due to one or more of the factors listed in 40 CFR 131.10(g), or due to the implementation of actions necessary to facilitate restoration such as through dam removal or other significant wetland or [~~water body~~] waterbody reconfiguration activities as demonstrated by the petition and supporting work plan requirements in Paragraphs (4) and (5) of Subsection [~~H~~]I of 20.6.4.10 NMAC;

(b) the proposed temporary standard represents the highest degree of protection feasible in the short term, limits the degradation of water quality to the minimum necessary to achieve the original standard by the expiration date of the temporary standard, and adoption will not cause the further impairment or loss of an existing use;

(c) for point sources, existing or proposed discharge control technologies will comply with applicable technology-based limitations and feasible technological controls and other management alternatives, such as a pollution prevention program; and

(d) for restoration activities, nonpoint source or other control technologies shall limit downstream impacts, and if applicable, existing or proposed discharge control technologies shall be in place consistent with Subparagraph (c) of Paragraph (1) of Subsection [~~H~~]I of 20.6.4.10 NMAC.

(2) A temporary standard shall apply to specific designated use(s), pollutant(s), or permittee(s), and to specific [~~water body~~] waterbody segment(s). The adoption of a temporary standard does not exempt dischargers from complying with all other applicable water quality standards or control technologies.

NMED Exhibit 27

(3) Designated use attainment as reported in the federal Clean Water Act, Section 305(b)/303(d) Integrated Report shall be based on the original standard and not on a temporary standard.

(4) A petition for a temporary standard shall:

(a) identify the currently applicable standard(s), the proposed temporary standard for the specific pollutant(s), the permittee(s), and the specific surface [~~water body~~] waterbody segment(s) of the state to which the temporary standard would apply;

(b) include the basis for any factor(s) specific to the applicability of the temporary standard (for example critical flow under Subsection B of 20.6.4.11 NMAC);

(c) demonstrate that the proposed temporary standard meets the requirements in this subsection;

(d) present a work plan with timetable of proposed actions for achieving compliance with the original standard in accordance with Paragraph (5) of Subsection [~~H~~]I of 20.6.4.10 NMAC;

(e) include any other information necessary to support the petition.

(5) As a condition of a petition for a temporary standard, in addition to meeting the requirements in this Subsection, the petitioner shall prepare a work plan in accordance with Paragraph (4) of Subsection [~~H~~]I of 20.6.4.10 NMAC and submit the work plan to the department for review and comment. The work plan shall identify the factor(s) listed in 40 CFR 131.10(g) or Subparagraph (a) of Paragraph (1) of Subsection [~~H~~]I of 20.6.4.10 NMAC affecting attainment of the standard that will be analyzed and the timeline for proposed actions to be taken to achieve the uses attainable over the term of the temporary standard, including baseline water quality, and any investigations, projects, facility modifications, monitoring, or other measures necessary to achieve compliance with the original standard. The work plan shall include provisions for review of progress in accordance with Paragraph (8) of Subsection [~~H~~]I of 20.6.4.10 NMAC, public notice and consultation with appropriate state, tribal, local and federal agencies.

(6) The commission may condition the approval of a temporary standard by requiring additional monitoring, relevant analyses, the completion of specified projects, submittal of information, or any other actions.

(7) Temporary standards may be implemented only after a public hearing before the commission, commission approval and adoption pursuant to Subsection [~~H~~]I of 20.6.4.10 NMAC for all state purposes, and the federal Clean Water Act, Section 303 (c) approval for any federal action.

(8) All temporary standards are subject to a required review during each succeeding review of water quality standards conducted in accordance with Subsection A of 20.6.4.10 NMAC. The petitioner shall provide a written report to the commission documenting the progress of proposed actions, pursuant to a reporting schedule stipulated in the approved temporary standard. The purpose of the review is to determine progress consistent with the original conditions of the petition for the duration of the temporary standard. If the petitioner cannot demonstrate that sufficient progress has been made the commission may revoke approval of the temporary standard or provide additional conditions to the approval of the temporary standard.

(9) The commission may consider a petition to extend a temporary standard. The effective period of a temporary standard shall be extended only if demonstrated to the commission that the factors precluding attainment of the underlying standard still apply, that the petitioner is meeting the conditions required for approval of the temporary standard, and that reasonable progress towards meeting the underlying standard is being achieved.

(10) A temporary standard shall expire no later than the date specified in the approval of the temporary standard. Upon expiration of a temporary standard, the original standard becomes applicable.

(11) Temporary standards shall be identified in 20.6.4.97-899 NMAC as appropriate for the surface water affected.

[~~**(12)** "Temporary standard" means a time-limited designated use and criterion for a specific pollutant(s) or water quality parameter(s) that reflect the highest attainable condition during the term of the temporary standard.~~]

[20.6.4.10 NMAC - Rp 20 NMAC 6.1.1102, 10/12/2000; Rn, 20.6.4.9 NMAC, 5/23/2005; A, 5/23/2005; A, 12/1/2010; A, 3/2/2017; A, 4/23/2022; A, MM/DD/YYYY]

20.6.4.11 APPLICABILITY OF WATER QUALITY STANDARDS:

A. [**RESERVED**]

B. Critical low flow: The critical low flow of a stream at a particular site shall be used in developing point source discharge permit requirements to meet numeric criteria set in 20.6.4.97 through 20.6.4.900 NMAC and Subsection F of 20.6.4.13 NMAC.

NMED Exhibit 27

(1) For human health-organism only criteria, the critical low flow is the harmonic mean flow. For ephemeral waters the calculation shall be based upon the nonzero flow intervals and modified by including a factor to adjust for the proportion of intervals with zero flow. The equations are as follows:

$$\text{Harmonic Mean} = \frac{n}{\sum 1/Q}$$

where n = number of flow values
and Q = flow value

$$\text{Modified Harmonic Mean} = \left[\frac{\sum_{i=1}^{Nt-N0} \frac{1}{Qi}}{Nt - N0}\right]^{-1} x \left[\frac{Nt - N0}{Nt}\right]$$

where Qi = nonzero flow
Nt = total number of flow values
and N_0 = number of zero flow values

(2) For all other narrative and numeric criteria, the critical low flow is the minimum average four consecutive day flow that occurs with a frequency of once in three years (4Q3). The critical low flow may be determined on an annual, a seasonal or a monthly basis, as appropriate, after due consideration of site-specific conditions.

C. Guaranteed minimum flow: The commission may allow the use of a contractually guaranteed minimum streamflow in lieu of a critical low flow determined under Subsection B of this section on a case-by-case basis and upon consultation with the interstate stream commission. Should drought, litigation or any other reason interrupt or interfere with minimum flows under a guaranteed minimum flow contract for a period of at least 30 consecutive days, such permission, at the sole discretion of the commission, may then be revoked. Any minimum flow specified under such revoked permission shall be superseded by a critical low flow determined under Subsection B of this section. A public notice of the request for a guaranteed minimum flow shall be published in a newspaper of general circulation by the department at least 30 days prior to scheduled action by the commission. These water quality standards do not grant to the commission or any other entity the power to create, take away or modify property rights in water.

D. Mixing zones: A limited mixing zone, contiguous to a point source wastewater discharge, may be allowed in any stream receiving such a discharge. Mixing zones serve as regions of initial dilution that allow the application of a dilution factor in calculations of effluent limitations. Effluent limitations shall be developed that will protect the most sensitive existing, designated or attainable use of the receiving water.

E. Mixing zone limitations: Wastewater mixing zones, in which the numeric criteria set under Subsection F of 20.6.4.13 NMAC, 20.6.4.97 through 20.6.4.899 NMAC or 20.6.4.900 NMAC may be exceeded, shall be subject to the following limitations:

(1) Mixing zones are not allowed for discharges to lakes, reservoirs, or playas; these effluents shall meet all applicable criteria set under Subsection F of 20.6.4.13 NMAC, 20.6.4.97 through 20.6.4.899 NMAC and 20.6.4.900 NMAC at the point of discharge.

(2) The acute aquatic life criteria, as set out in Subsection I, Subsection J, and Subsection [~~K~~]L of 20.6.4.900 NMAC, shall be attained at the point of discharge for any discharge to a surface water of the state with a designated aquatic life use.

(3) The general criteria set out in Subsections A, B, C, D, E, G, H and J of 20.6.4.13 NMAC, and the provision set out in Subsection D of 20.6.4.14 NMAC are applicable within mixing zones.

(4) The areal extent and concentration isopleths of a particular mixing zone will depend on site-specific conditions including, but not limited to, wastewater flow, receiving water critical low flow, outfall design, channel characteristics and climatic conditions and, if needed, shall be determined on a case-by-case basis. When the physical boundaries or other characteristics of a particular mixing zone must be known, the methods presented in Section 4.4.5, "Ambient-induced mixing," in "Technical support document for water quality-based toxics control" (March 1991, EPA/505/2-90-001) shall be used.

NMED Exhibit 27

(5) All applicable water quality criteria set under Subsection F of 20.6.4.13 NMAC, 20.6.4.97 through 20.6.4.899 NMAC and 20.6.4.900 NMAC shall be attained at the boundaries of mixing zones. A continuous zone of passage through or around the mixing zone shall be maintained in which the water quality meets all applicable criteria and allows the migration of aquatic life presently common in surface waters of the state with no effect on their populations.

F. Multiple uses: When a surface water of the state has more than a single designated use, the applicable numeric criteria shall be the most stringent of those established for such water.

G. Human health-organism only criteria in Subsection J of 20.6.4.900 NMAC apply to those waters with a designated, existing or attainable aquatic life use. When limited aquatic life is a designated use, the human health-organism only criteria apply only for persistent toxic pollutants, [~~if~~] unless adopted on a segment-specific basis. The human health-organism only criteria for persistent toxic pollutants, as identified in Subsection J of 20.6.4.900 NMAC, also apply to all tributaries of waters with a designated, existing or attainable aquatic life use.

H. Unclassified waters of the state: An unclassified surface water of the state is presumed to support the uses specified in Section 101(a)(2) of the federal Clean Water Act. As such, it is subject to 20.6.4.98 NMAC if nonperennial or subject to 20.6.4.99 NMAC if perennial. The commission may include an ephemeral unclassified surface water of the state under 20.6.4.97 NMAC only if a use attainability analysis demonstrates pursuant to 20.6.4.15 NMAC that attainment of Section 101(a)(2) uses is not feasible.

I. Exceptions: Numeric criteria for temperature, dissolved solids, dissolved oxygen, sediment or turbidity adopted under the Water Quality Act do not apply when changes in temperature, dissolved solids, dissolved oxygen, sediment or turbidity in a surface water of the state are attributable to:

(1) natural causes (discharges from municipal separate storm sewers are not covered by this exception.); or

(2) the reasonable operation of irrigation and flood control facilities that are not subject to federal or state water pollution control permitting; major reconstruction of storage dams or diversion dams except for emergency actions necessary to protect health and safety of the public are not covered by this exception.

[20.6.4.11 NMAC - Rp 20 NMAC 6.1.1103, 10/12/2000; A, 10/11/2002; Rn, 20.6.4.10 NMAC, 5/23/2005; A, 5/23/2005; A, 12/1/2010; A, 4/23/2022; A, MM/DD/YYYY]

20.6.4.12 COMPLIANCE WITH WATER QUALITY STANDARDS: The following provisions apply to determining compliance for enforcement purposes; they do not apply for purposes of determining attainment of uses. The department has developed assessment protocols for the purpose of determining attainment of uses that are available for review from the department's surface water quality bureau.

A. Compliance with acute water quality criteria shall be determined from the analytical results of a single grab sample. Acute criteria shall not be exceeded.

B. Compliance with chronic water quality criteria shall be determined from the arithmetic mean of the analytical results of samples collected using applicable protocols. Chronic criteria shall not be exceeded more than once every three years.

C. Compliance with water quality standards for total ammonia shall be determined by performing the biomonitoring procedures set out in Subsections D and E of 20.6.4.14 NMAC, or by attainment of applicable ammonia criteria set out in Subsections K, L and M of 20.6.4.900 NMAC.

D. Compliance with the human health-organism only criteria shall be determined from the analytical results of representative grab samples, as defined in the water quality management plan. Human health-organism only criteria shall not be exceeded.

E. The commission may establish a numeric water quality criterion at a concentration that is below the minimum quantification level. In such cases, the water quality standard is enforceable at the minimum quantification level.

F. For compliance with [~~hardness-dependent~~]calculated numeric criteria[~~, hardness (as mg $CaCO_3$/L)~~] that depend on water chemistry, all input parameters shall be determined from a sample taken at the same time that the sample for the contaminant is taken. If all input data are not available to calculate criteria, default input values may be used. Default values shall be justified in writing and supported by ecoregional or other watershed data.

G. Compliance schedules: The commission may allow the inclusion of a schedule of compliance in a NPDES permit issued to an existing facility on a case-by-case basis. Such schedule of compliance will be for the purpose of providing a permittee with adequate time to make treatment facility modifications necessary to comply with water quality based permit limitations determined to be necessary to implement new or revised water quality standards or wasteload allocation. Compliance schedules may be included in NPDES permits at the time of

permit renewal or modification and shall be written to require compliance at the earliest practicable time. Compliance schedules shall also specify milestone dates so as to measure progress towards final project completion (e.g., design completion, construction start, construction completion, date of compliance).

H. It is a policy of the commission to allow a temporary standard approved and adopted pursuant to Subsection [~~H~~]I of 20.6.4.10 NMAC to be included in the applicable federal Clean Water Act permit as enforceable limits and conditions. The temporary standard and any schedule of actions may be included at the earliest practicable time, and shall specify milestone dates so as to measure progress towards meeting the original standard. [20.6.4.12 NMAC - Rp 20 NMAC 6.1.1104, 10/12/2000; A, 10/11/2002; Rn, 20.6.4.11 NMAC, 5/23/2005; A, 5/23/2005; A, 12/1/2010; A, 3/2/2017; A, 4/23/2022; A, MM/DD/YYYY]

20.6.4.13 GENERAL CRITERIA: General criteria are established to sustain and protect existing or attainable uses of surface waters of the state. These general criteria apply to all surface waters of the state at all times, unless a specified criterion is provided elsewhere in this part. Surface waters of the state shall be free of any water contaminant in such quantity and of such duration as may with reasonable probability injure human health, animal or plant life or property, or unreasonably interfere with the public welfare or the use of property.

A. Bottom deposits and suspended or settleable solids:

(1) Surface waters of the state shall be free of water contaminants including fine sediment particles (less than two millimeters in diameter), precipitates or organic or inorganic solids from other than natural causes that have settled to form layers on or fill the interstices of the natural or dominant substrate in quantities that damage or impair the normal growth, function or reproduction of aquatic life or significantly alter the physical or chemical properties of the bottom.

(2) Suspended or settleable solids from other than natural causes shall not be present in surface waters of the state in quantities that damage or impair the normal growth, function or reproduction of aquatic life or adversely affect other designated uses.

B. Floating solids, oil and grease: Surface waters of the state shall be free of oils, scum, grease and other floating materials resulting from other than natural causes that would cause the formation of a visible sheen or visible deposits on the bottom or shoreline, or would damage or impair the normal growth, function or reproduction of human, animal, plant or aquatic life.

C. Color: Color-producing materials resulting from other than natural causes shall not create an aesthetically undesirable condition nor shall color impair the use of the water by desirable aquatic life presently common in surface waters of the state.

D. Organoleptic quality:

(1) Flavor of fish: Water contaminants from other than natural causes shall be limited to concentrations that will not impart unpalatable flavor to fish.

(2) Odor and taste of water: Water contaminants from other than natural causes shall be limited to concentrations that will not result in offensive odor or taste arising in a surface water of the state or otherwise interfere with the reasonable use of the water.

E. Plant nutrients: Plant nutrients from other than natural causes shall not be present in concentrations that will produce undesirable aquatic life or result in a dominance of nuisance species in surface waters of the state.

F. Toxic pollutants:

(1) Except as provided in 20.6.4.16 NMAC, surface waters of the state shall be free of toxic pollutants from other than natural causes in amounts, duration, concentrations, or combinations that affect the propagation of fish or that are toxic to humans, livestock or other animals, fish or other aquatic organisms, wildlife using aquatic environments for habitation or aquatic organisms for food, or that will or can reasonably be expected to bioaccumulate in tissues of fish, shellfish and other aquatic organisms to levels that will impair the health of aquatic organisms or wildlife or result in unacceptable tastes, odors or health risks to human consumers of aquatic organisms.

(2) Pursuant to this section, the human health-organism only criteria shall be as set out in 20.6.4.900 NMAC. When a human health-organism only criterion is not listed in 20.6.4.900 NMAC, the following provisions shall be applied in accordance with 20.6.4.11, 20.6.4.12 and 20.6.4.14 NMAC.

(a) The human health-organism only criterion shall be the recommended human health criterion for "consumption of organisms only" published by the U.S. environmental protection agency pursuant to Section 304(a) of the federal Clean Water Act. In determining such criterion for a cancer-causing toxic pollutant, a cancer risk of 10^{-5} (one cancer per 100,000 exposed persons) shall be used.

NMED Exhibit 27

(b) When a numeric criterion for the protection of human health for the consumption of organism only has not been published by the U.S. environmental protection agency, a quantifiable criterion may be derived from data available in the U.S. environmental protection agency's Integrated Risk Information System (IRIS) using the appropriate formula specified in *Methodology for Deriving Ambient Water Quality Criteria for The Protection Of Human Health (2000)*, EPA-822-B-00-004.

(3) Pursuant to this section, the chronic aquatic life criteria shall be as set out in 20.6.4.900 NMAC. When a chronic aquatic life criterion is not listed in 20.6.4.900 NMAC, the following provisions shall be applied in sequential order in accordance with 20.6.4.11, 20.6.4.12 and 20.6.4.14 NMAC.

(a) The chronic aquatic life criterion shall be the "freshwater criterion continuous concentration" published by the U.S. environmental protection agency pursuant to Section 304(a) of the federal Clean Water Act;

(b) If the U.S. environmental protection agency has not published a chronic aquatic life criterion, a geometric mean LC-50 value shall be calculated for the particular species, genus or group that is representative of the form of life to be preserved, using the results of toxicological studies published in scientific journals.

(i) The chronic aquatic life criterion for a toxic pollutant that does not bioaccumulate shall be ten percent of the calculated geometric mean LC-50 value; and

(ii) The chronic aquatic life criterion for a toxic pollutant that does bioaccumulate shall be: the calculated geometric mean LC-50 adjusted by a bioaccumulation factor for the particular species, genus or group representative of the form of life to be preserved, but when such bioaccumulation factor has not been published, the criterion shall be one percent of the calculated geometric mean LC-50 value.

(4) Pursuant to this section, the acute aquatic life criteria shall be as set out in 20.6.4.900 NMAC. When an acute aquatic life criterion is not listed in 20.6.4.900 NMAC, the acute aquatic life criterion shall be the "freshwater criterion maximum concentration" published by the U.S. environmental protection agency pursuant to Section 304(a) of the federal Clean Water Act.

(5) Within 90 days of the issuance of a final NPDES permit containing a numeric criterion selected or calculated pursuant to Paragraph (2), Paragraph (3) or Paragraph (4) of Subsection F of this section, the department shall petition the commission to adopt such criterion into these standards.

G. Radioactivity: The radioactivity of surface waters of the state shall be maintained at the lowest practical level and shall in no case exceed the criteria set forth in the New Mexico Radiation Protection Regulations, 20.3.1 and 20.3.4 NMAC.

H. Pathogens: Surface waters of the state shall be free of pathogens from other than natural causes in sufficient quantity to impair public health or the designated, existing or attainable uses of a surface water of the state.

I. Temperature: Maximum temperatures for surface waters of the state have been specified in 20.6.4.97 through 20.6.4.900 NMAC. However, the introduction of heat by other than natural causes shall not increase the temperature, as measured from above the point of introduction, by more than 2.7°C (5°F) in a stream, or more than 1.7°C (3°F) in a lake or reservoir. In no case will the introduction of heat be permitted when the maximum temperature specified for the reach would thereby be exceeded. These temperature criteria shall not apply to impoundments constructed offstream for the purpose of heat disposal. High water temperatures caused by unusually high ambient air temperatures are not violations of these criteria.

J. Turbidity: Turbidity attributable to other than natural causes shall not reduce light transmission to the point that the normal growth, function or reproduction of aquatic life is impaired or that will cause substantial visible contrast with the natural appearance of the water. Activities or discharges shall not cause turbidity to increase more than 10 NTU over background turbidity when the background turbidity, measured at a point immediately upstream of the activity, is 50 NTU or less, nor to increase more than twenty percent when the background turbidity is more than 50 NTU. However, limited-duration turbidity increases caused by dredging, construction or other similar activities may be allowed provided all practicable turbidity control techniques have been applied and all appropriate permits, certifications and approvals have been obtained.

K. Total dissolved solids (TDS): TDS attributable to other than natural causes shall not damage or impair the normal growth, function or reproduction of animal, plant or aquatic life. TDS shall be measured by either the "calculation method" (sum of constituents) or the filterable residue method. Approved test procedures for these determinations are set forth in 20.6.4.14 NMAC.

L. Dissolved gases: Surface waters of the state shall be free of nitrogen and other dissolved gases at levels above one hundred ten percent saturation when this supersaturation is attributable to municipal, industrial or other discharges.

NMED Exhibit 27

M. Biological integrity: Surface waters of the state shall support and maintain a balanced and integrated community of aquatic organisms with species composition, diversity and functional organization comparable to those of natural or minimally impacted water bodies of a similar type and region.

N. Wetlands: This general criterion applies to wetlands only. Wetlands shall be maintained and protected such that degradation through direct, indirect, or cumulative impacts does not result in the net loss of wetland acreage or biological, chemical, physical, and hydrological functions to the extent that such functions occur, as characterized by state-specific benchmarks. The functions of a wetland that are to be maintained and protected may include:

(1) erosion control through bank and shoreline stabilization;
(2) flood attenuation and flood protection;
(3) sediment and pollutant retention, which prevents or mitigates downstream migration;
(4) groundwater recharge and water storage for future use;
(5) low flow augmentation including baseflow maintenance;
(6) water filtration including removal or storage of nutrients and other contaminants;
(7) propagation or maintenance of aquatic and terrestrial species indigenous to wetlands;
(8) preservation of wildlife habitat including habitat for threatened or endangered species; or
(9) supporting biological diversity.

In addition, wetlands shall support recreation, wildlife habitat, aquatic life and livestock watering uses.

[20.6.4.13 NMAC - Rp 20 NMAC 6.1.1105, 10/12/2000; A, 10/11/2002; Rn, 20.6.4.12 NMAC, 5/23/2005; A, 5/23/2005; A, 12/1/2010; A, 4/23/2022; A, MM/DD/YYYY]

20.6.4.14 SAMPLING AND ANALYSIS:

A. Sampling and analytical techniques shall conform with methods described in the following references unless otherwise specified by the commission pursuant to a petition to amend these standards:

(1) "*Guidelines Establishing Test Procedures For The Analysis Of Pollutants Under The Clean Water Act*," 40 CFR Part 136 or any test procedure approved or accepted by EPA using procedures provided in 40 CFR Parts 136.3(d), 136.4, and 136.5;

(2) *Standard Methods For The Examination Of Water And Wastewater*, latest edition, American public health association;

(3) *Methods For Chemical Analysis Of Water And Waste*, and other methods published by EPA office of research and development or office of water;

(4) *Techniques Of Water Resource Investigations Of The U.S. Geological Survey*;

(5) *Annual Book Of ASTM Standards*: volumes 11.01 and 11.02, water (I) and (II), latest edition, ASTM international;

(6) *Federal Register*, latest methods published for monitoring pursuant to Resource Conservation and Recovery Act regulations;

(7) *National Handbook Of Recommended Methods For Water-Data Acquisition*, latest edition, prepared cooperatively by agencies of the United States government under the sponsorship of the U.S. geological survey; or

(8) *Federal Register*, latest methods published for monitoring pursuant to the Safe Drinking Water Act regulations.

B. Bacteriological Surveys: The monthly geometric mean shall be used in assessing attainment of criteria when a minimum of five samples is collected in a 30-day period.

C. Sampling Procedures:

(1) Streams: Stream monitoring stations below discharges shall be located a sufficient distance downstream to ensure adequate vertical and lateral mixing.

(2) Lakes: Sampling stations in lakes shall be located at least 250 feet from a discharge.

(3) Lakes: Except for the restriction specified in Paragraph (2) of this subsection, lake sampling stations shall be located at any site where the attainment of a water quality criterion is to be assessed.

[~~Water quality measurements taken at intervals in the entire water column at a sampling station shall be averaged for the epilimnion, or in the absence of an epilimnion, for the upper one-third of the water column of the lake to determine attainment of criteria, except that attainment of criteria for toxic pollutants shall be assessed during periods of complete vertical mixing, e.g., during spring or fall turnover, or by taking depth-integrated composite samples of the water column.~~]

D. Acute toxicity of effluent to aquatic life shall be determined using the procedures specified in U.S. environmental protection agency "*Methods for Measuring The Acute Toxicity of Effluents and Receiving Waters To*

Freshwater and Marine Organisms" (5th Ed., 2002, EPA 821-R-02-012), or latest edition thereof if adopted by EPA at 40 CFR Part 136, which is incorporated herein by reference. Acute toxicities of substances shall be determined using at least two species tested in whole effluent and a series of effluent dilutions. Acute toxicity due to discharges shall not occur within the wastewater mixing zone in any surface water of the state with an existing or designated aquatic life use.

E. Chronic toxicity of effluent or ambient surface waters of the state to aquatic life shall be determined using the procedures specified in U.S. environmental protection agency "*Short-Term Methods For Estimating The Chronic Toxicity Of Effluents And Receiving Waters To Freshwater Organisms*" (4th Ed., 2002, EPA 821-R-02-013), or latest edition thereof if adopted by EPA at 40 CFR Part 136, which is incorporated herein by reference. Chronic toxicities of substances shall be determined using at least two species tested in ambient surface water or whole effluent and a series of effluent dilutions. Chronic toxicity due to discharges shall not occur at the critical low flow, or any flow greater than the critical low flow, in any surface water of the state with an existing or designated aquatic life use more than once every three years.

F. Emerging Contaminants Monitoring: The department may require monitoring, analysis and reporting of emerging contaminants as a condition of a federal permit under Section 401 of the federal Clean Water Act.

[20.6.4.14 NMAC - Rp 20 NMAC 6.1.1106, 10/12/2000; Rn, 20.6.4.13 NMAC, 5/23/2005 & A, 5/23/2005; A, 12/1/2010; A 4/23/2022; A, MM/DD/YYYY]

20.6.4.15 USE ATTAINABILITY ANALYSIS:

A. Regulatory requirements for a use attainability analysis. Whenever a use attainability analysis is conducted, it shall be subject to the requirements and limitations set forth in 40 CFR Part 131, Water Quality Standards; specifically, Subsections 131.3(g), 131.10(g), 131.10(h) and 131.10(j) shall be applicable. In accordance with 40 CFR 131.10(i), and 20.6.4.10 NMAC, the amendment of a designated use, based on an existing use with more stringent criteria, does not require a use attainability analysis.

(1) The commission may remove a designated use, that is not an existing use, specified in Section 101(a)(2) of the federal Clean Water Act or adopt subcategories of a use in Section 101(a)(2) of the federal Clean Water Act requiring less stringent criteria only if a use attainability analysis demonstrates that attaining the use is not feasible because of a factor listed in 40 CFR 131.10(g). Uses in Section 101(a)(2) of the federal Clean Water Act, which refer to the protection and propagation of fish, shellfish and wildlife and recreation in and on the water, are also specified in Subsection B of 20.6.4.6 NMAC.

(2) A designated use cannot be removed if it is an existing use unless a use requiring more stringent criteria is designated.

B. Methods for developing a use attainability analysis. A use attainability analysis shall assess the physical, chemical, biological, economic or other factors affecting the attainment of a use. The analysis shall rely on scientifically defensible methods such as the methods described in the latest edition(s) of the following documents:

(1) *Water Quality Standards Handbook*, United States environmental protection agency, office of water, Washington, D.C., for current guidance and case studies for developing and implementing water quality standards;

[~~**(1)**~~]**(2)** *Technical Support Manual: Waterbody Surveys And Assessments For Conducting Use Attainability Analyses*, volume I (November 1983) and volume III (November 1984) [~~or latest editions~~], United States environmental protection agency, office of water, regulations and standards, Washington, D.C., for the evaluation of aquatic life or wildlife uses;

[~~**(2)**~~]**(3)** [~~the department's~~] *Water Quality Management Plan and Continuing Planning Process, Hydrology Protocol*, [~~latest edition, approved by the~~] water quality control commission, Santa Fe, NM, for identifying ephemeral, intermittent, and perennial waters; or

[~~**(3)**~~]**(4)** *Interim Economic Guidance For Water Quality Standards - Workbook*, March 1995, in conjunction with *Clean Water Act Financial Capability Assessment Guidance*, March 2024, United States environmental protection agency, office of water, Washington, D.C. for evaluating economic impacts.

C. Determining the highest attainable use. If the use attainability analysis determines that the designated use is not attainable based on one of the factors in 40 CFR 131.10(g), the use attainability analysis shall demonstrate the support for removing the designated use and then determine the highest attainable use, as defined in 40 CFR 131.3(m), for the protection and propagation of fish, shellfish and wildlife and recreation in and on the water based on methods described in Subsection B of this section.

D. Process to amend a designated use through a use attainability analysis.

NMED Exhibit 27

(1) The process for developing a use attainability analysis and petitioning the commission for removing a designated use and establishing the highest attainable use shall be done in accordance with the State's current *Water Quality Management Plan/Continuing Planning Process*.

(2) If the findings of a use attainability analysis, conducted by the department, in accordance with the department's *Hydrology Protocol* (latest edition) demonstrates that federal Clean Water Act Section 101(a)(2) uses, that are not existing uses, are not feasible in an ephemeral [~~water body~~] waterbody due to the factor in 40 CFR 131.10(g)(2), the department may consider proceeding with the expedited use attainability analysis process in accordance with the State's current *Water Quality Management Plan/Continuing Planning Process*. The following elements must be met for the expedited use attainability analysis process to be authorized and implemented:

(a) The department is the primary investigator of the use attainability analysis;

(b) The use attainability analysis determined, through the application of the *Hydrology Protocol*, that the [~~water~~] waterbody being investigated is ephemeral and has no effluent discharges of sufficient volume that could compensate for the low-flow;

(c) The use attainability analysis determined that the criteria associated with the existing uses of the [~~water~~] waterbody being investigated are not more stringent than those in 20.6.4.97 NMAC;

(d) The designated uses in 20.6.4.97 NMAC have been determined to be the highest attainable uses for the [~~water~~] waterbody being analyzed;

(e) The department posted the use attainability analysis on its water quality standards website and notified its interested parties list of a 30-day public comment period;

(f) The department reviewed and responded to any comments received during the 30-day public comment period; and

(g) The department submitted the use attainability analysis and response to comments to [~~region 6~~] EPA for technical [~~approval~~] review.

(3) If EPA approves the designated use revision(s) under section 303(c) of the Clean Water Act, the water shall be subject to 20.6.4.97 NMAC for federal Clean Water Act purposes. The use attainability analysis, the technical support document, and the applicability of 20.6.4.97 NMAC to the water shall be posted on the department's water quality standards website. The department shall periodically petition the commission to list ephemeral waters under Subsection C of 20.6.4.97 NMAC and to incorporate changes to classified segments as appropriate.

E. Use attainability analysis conducted by an entity other than the department. Any person may submit notice to the department stating their intent to conduct a use attainability analysis.

(1) The [~~proponent~~] notice shall [~~provide such notice along with~~] include a work plan supporting the development of a use attainability analysis [~~to~~] for the department's [~~and region 6 EPA for~~] review and comment.

(2) Upon approval of the work plan by the department, [~~the proponent shall conduct~~] the use attainability analysis shall be conducted in accordance with the applicable portions of Subsections A through D of this Section and [~~implement~~] public [~~noticing~~] notice provided in accordance with the approved work plan.

(3) Work plan elements. The work plan shall identify, at a minimum:

(a) the waterbody of concern and the reasoning for conducting a use attainability analysis;

(b) the source and validity of data to be used to demonstrate whether the current designated use is not attainable;

(c) the factors in 40 CFR 131.10(g) affecting the attainment of that use;

(d) a description of the data being proposed to be used to demonstrate the highest attainable use;

(e) the provisions for consultation with appropriate state and federal agencies;

(f) a description of how stakeholders and potentially affected tribes will be identified and engaged;

(g) a description of the public notice mechanisms to be employed; and

(h) the expected timelines outlining the administrative actions to be taken for a rulemaking petition, pending the outcome of the use attainability analysis.

(4) Upon completion of the use attainability analysis, [~~the proponent shall submit~~] the data, findings and conclusions shall be submitted to the department, and [~~provide~~] public notice of the use attainability analysis provided in accordance with the approved work plan.

NMED Exhibit 27

(5) Pending the conclusions of the use attainability analysis and as described in the approved work plan, the [~~department or the proponent~~] person conducting the use attainability analysis may petition the commission to modify the designated use. [~~The cost of such use attainability analysis shall be the responsibility of the proponent. Subsequent costs associated with the administrative rulemaking process shall be the responsibility of the petitioner.~~]

[20.6.4.15 NMAC - Rp 20 NMAC 6.1.1107, 10/12/2000; Rn, 20.6.4.14 NMAC, 5/23/2005; A, 5/23/2005; A, 7/17/2005; A, 12/1/2010; A, 4/23/2022; A, MM/DD/YYYY]

20.6.4.16 PLANNED USE OF A PISCICIDE: The use of a piscicide registered under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA), 7 U.S.C. Section 136 *et seq*., and under the New Mexico Pesticide Control Act (NMPCA), Section 76-4-1 *et seq*. NMSA 1978 (1973) in a surface water of the state, shall not be a violation of Subsection F of 20.6.4.13 NMAC when such use is covered by a federal national pollutant discharge elimination system (NPDES) permit or has been approved by the commission under procedures provided in this section. The use of a piscicide which is covered by a NPDES permit shall require no further review by the commission and the person whose application is covered by the NPDES permit shall meet the additional notification and monitoring requirements outlined in Subsection G of 20.6.4.16 NMAC. The commission may approve the reasonable use of a piscicide under this section if the proposed use is not covered by a NPDES permit to further a Clean Water Act objective to restore and maintain the physical or biological integrity of surface waters of the state, including restoration of native species.

A. Any person seeking commission approval of the use of a piscicide not covered by a NPDES permit shall file a written petition concurrently with the commission and the surface water bureau of the department. The petition shall contain, at a minimum, the following information:

(1) petitioner's name and address;

(2) identity of the piscicide and the period of time (not to exceed five years) or number of applications for which approval is requested;

(3) documentation of registration under FIFRA and NMPCA and certification that the petitioner intends to use the piscicide according to the label directions, for its intended function;

(4) target and potential non-target species in the treated waters and adjacent riparian area, including threatened or endangered species;

(5) potential environmental consequences to the treated waters and the adjacent riparian area, and protocols for limiting such impacts;

(6) surface water of the state proposed for treatment;

(7) results of pre-treatment survey;

(8) evaluation of available alternatives and justification for selecting piscicide use;

(9) documentation of notice requesting public comment on the proposed use within a 30-day period, including information as described in Paragraphs (1), (2) and (6) of Subsection A of 20.6.4.16 NMAC, provided to:

(a) local political subdivisions;

(b) local water planning entities;

(c) local conservancy and irrigation districts; and

(d) local media outlets, except that the petitioner shall only be required to publish notice in a newspaper of circulation in the locality affected by the proposed use.

(10) copies of public comments received in response to the publication of notice and the petitioner's responses to public comments received;

(11) post-treatment assessment monitoring protocol; and

(12) any other information required by the commission.

B. Within 30 days of receipt of the petition, the department shall review the petition and file a recommendation with the commission to grant, grant with conditions or deny the petition. The recommendation shall include reasons, and a copy shall be sent to the petitioner by certified mail.

C. The commission shall review the petition, the public comments received under Paragraphs (9) and (10) of Subsection A of 20.6.4.16 NMAC, the petitioner's responses to public comments and the department's technical recommendations for the petition. A public hearing shall be held if the commission determines there is substantial public interest. The commission shall notify the petitioner and those commenting on the petition of the decision whether to hold a hearing and the reasons therefore in writing.

D. If the commission determines there is substantial public interest a public hearing shall be held within 90 days of receipt of the department's recommendation in the locality affected by the proposed use in

NMED Exhibit 27

accordance with 20.1.3 NMAC, Adjudicatory Procedures - Water Quality Control Commission. Notice of the hearing shall be given in writing by the petitioner to individuals listed under Subsection A of 20.6.4.16 NMAC as well as to individuals who provided public comment under that subsection at least 30 days prior to the hearing.

E. In a hearing provided for in this section or, if no hearing is held, in a commission meeting, the registration of a piscicide under FIFRA and NMPCA shall provide a rebuttable presumption that the determinations of the EPA Administrator in registering the piscicide, as outlined in 7 U.S.C. Section 136a(c)(5), are valid. For purposes of this Section the rebuttable presumptions regarding the piscicide include:

(1) Its composition is such as to warrant the proposed claims for it;

(2) Its labeling and other material submitted for registration comply with the requirements of FIFRA and NMPCA;

(3) It will perform its intended function without unreasonable adverse effects on the environment; and

(4) When used in accordance with all FIFRA label requirements it will not generally cause unreasonable adverse effects on the environment.

(5) "Unreasonable adverse effects on the environment" has the meaning provided in FIFRA, 7 U.S.C. Section 136(bb): "any unreasonable risk to man or the environment, taking into account the economic, social, and environmental costs and benefits of the use of any pesticide."

F. After a public hearing, or commission meeting if no hearing is held, the commission may grant the petition in whole or in part, may grant the petition subject to conditions, or may deny the petition. In granting any petition in whole or part or subject to conditions, the commission shall require the petitioner to implement post-treatment assessment monitoring and provide notice to the public in the immediate and near downstream vicinity of the application prior to and during the application.

G. Any person whose application is covered by a NPDES permit shall provide written notice to local entities as described in Subsection A of 20.6.4.16 NMAC and implement post-treatment assessment monitoring within the application area as described in Subsection F of 20.6.4.16 NMAC.

[20.6.4.16 NMAC - Rn, Paragraph (6) of Subsection F of 20.6.4.12 NMAC, 5/23/2005; A, 5/23/2005; A, 3/2/2017]

20.6.4.17 - 20.6.4.49 [**RESERVED**]

20.6.4.50 BASINWIDE PROVISIONS - Special provisions arising from interstate compacts, international treaties or court decrees or that otherwise apply to a basin are contained in 20.6.4.51 through 20.6.4.59 NMAC.

[20.6.4.50 NMAC - N, 5/23/2005]

20.6.4.51 [**RESERVED**]

20.6.4.52 PECOS RIVER BASIN - In order to protect existing and designated uses, it is a goal of the state of New Mexico to prevent increases in TDS in the Pecos river above the following benchmark values, which are expressed as flow-weighted, annual average concentrations, at three USGS gaging stations: at Santa Rosa 500 mg/L; near Artesia 2,700 mg/L; and near Malaga 3,600 mg/L. The benchmark values serve to guide state action. They are adopted pursuant to the New Mexico Water Quality Act, not the Clean Water Act.

[20.6.4.52 NMAC - N, 12/1/2010]

20.6.4.53 [**RESERVED**]

20.6.4.54 COLORADO RIVER BASIN - For the tributaries of the Colorado river system, the state of New Mexico will cooperate with the Colorado river basin states and the federal government to support and implement the salinity policy and program outlined in the most current "review, water quality standards for salinity, Colorado river system" or equivalent report by the Colorado river salinity control forum.

A. Numeric criteria expressed as the flow-weighted annual average concentration for salinity are established at three points in the Colorado river basin as follows: below Hoover dam, 723 mg/L; below Parker dam, 747 mg/L; and at Imperial dam, 879 mg/L.

B. As a part of the program, objectives for New Mexico shall include the elimination of discharges of water containing solids in solution as a result of the use of water to control or convey fly ash from coal-fired electric generators, wherever practicable.

[20.6.4.54 NMAC - Rn, Paragraphs (1) through (3) of Subsection K of 20.6.4.12 NMAC, 5/23/2005; A, 5/23/2005]

NMED Exhibit 27

20.6.4.55 - 20.6.4.96 [**RESERVED**]

20.6.4.97 EPHEMERAL WATERS: Ephemeral surface waters of the state as identified below and additional ephemeral waters as identified on the department's water quality standards website pursuant to Paragraph (2) of Subsection D of 20.6.4.15 NMAC are subject to the designated uses and criteria as specified in this section. Ephemeral waters classified in 20.6.4.101-899 NMAC are subject to the designated uses and criteria as specified in those sections.

A. Designated uses: livestock watering, wildlife habitat, limited aquatic life and secondary contact.

B. Criteria: the use-specific criteria in 20.6.4.900 NMAC are applicable to the designated uses.

C. Waters:

(1) the following waters are designated in the Rio Grande basin:

(a) Cunningham gulch from Santa Fe county road 55 upstream 1.4 miles to a point upstream of the Lac minerals mine, identified as Ortiz mine on U.S. geological survey topographic maps;

(b) an unnamed tributary from Arroyo Hondo upstream 0.4 miles to the Village of Oshara water reclamation facility outfall;

(c) an unnamed tributary from San Pedro creek upstream 0.8 miles to the PAA-KO community sewer outfall;

(d) Inditos draw from the crossing of an unnamed road along a power line one-quarter mile west of McKinley county road 19 upstream to New Mexico highway 509;

(e) an unnamed tributary from the diversion channel connecting Blue canyon and Socorro canyon upstream 0.6 miles to the New Mexico firefighters academy treatment facility outfall;

(f) an unnamed tributary from the Albuquerque metropolitan arroyo flood control authority (AMAFCA) Rio Grande south channel upstream of the crossing of New Mexico highway 47 upstream to I-25;

(g) the south fork of Cañon del Piojo from Cañon del Piojo upstream 1.2 miles to an unnamed tributary;

(h) an unnamed tributary from the south fork of Cañon del Piojo upstream 1 mile to the Resurrection mine outfall;

(i) Arroyo del Puerto from San Mateo creek upstream 6.8 miles to the Ambrosia Lake mine entrance road;

(j) an unnamed tributary from San Mateo creek upstream 1.5 miles to the Roca Honda mine facility outfall;

(k) San Isidro arroyo, including unnamed tributaries to San Isidro arroyo, from Arroyo Chico upstream to its headwaters;

(l) Arroyo Tinaja, including unnamed tributaries to Arroyo Tinaja, from San Isidro arroyo upstream to 2 miles northeast of the Cibola national forest boundary;

(m) Mulatto canyon from Arroyo Tinaja upstream to 1 mile northeast of the Cibola national forest boundary; and

(n) Doctor arroyo, including unnamed tributaries to Doctor arroyo, from San Isidro arroyo upstream to its headwaters, and excluding Doctor Spring and Doctor arroyo from the spring to its confluence with the unnamed tributary approximately one-half mile downstream of the spring.

(2) the following waters are designated in the Pecos river basin:

(a) an unnamed tributary from Hart canyon upstream 1 mile to South Union road;

(b) Aqua Chiquita from Rio Peñasco upstream to McEwan canyon; and

(c) Grindstone canyon upstream of Grindstone reservoir.

(3) the following waters are designated in the Canadian river basin:

(a) Bracket canyon upstream of the Vermejo river;

(b) an unnamed tributary from Bracket canyon upstream 2 miles to the Ancho mine; and

(c) Gachupin canyon from the Vermejo river upstream 2.9 miles to an unnamed west tributary near the Ancho mine outfall.

(4) in the San Juan river basin an unnamed tributary of Kim-me-ni-oli wash upstream of the mine outfall.

(5) the following waters are designated in the Little Colorado river basin:

(a) Defiance draw from County Road 1 to upstream of West Defiance Road; and

NMED Exhibit 27

(b) an unnamed tributary of Defiance draw from McKinley county road 1 upstream to New Mexico highway 264.

(6) the following waters are designated in the closed basins:

(a) in the Tularosa river closed basin San Andres canyon downstream of South San Andres canyon; and

(b) in the Mimbres river closed basin San Vicente arroyo from the Mimbres river upstream to Maudes canyon.

[20.6.4.97 NMAC - N, 5/23/2005; A, 12/1/2010; A, 3/2/2017; A, 12/17/2019; A, 4/23/2022]

20.6.4.98 INTERMITTENT WATERS: All non-perennial surface waters of the state, except those ephemeral waters included under section 20.6.4.97 NMAC or classified in 20.6.4.101-899 NMAC.

A. Designated uses: livestock watering, wildlife habitat, marginal warmwater aquatic life and primary contact.

B. Criteria: the use-specific criteria in 20.6.4.900 NMAC are applicable to the designated uses, except that the following site-specific criteria apply: the monthly geometric mean of E. coli bacteria 206 cfu/100 mL or less, single sample 940 cfu/100 mL or less.

[20.6.4.98 NMAC - N, 5/23/2005; A, 12/1/2010; A, 3/2/2017; A, MM/DD/YYYY]

20.6.4.99 PERENNIAL WATERS: All perennial surface waters of the state except those classified in 20.6.4.101-899 NMAC.

A. Designated uses: Warmwater aquatic life, livestock watering, wildlife habitat and primary contact.

B. Criteria: The use-specific criteria in 20.6.4.900 NMAC are applicable to the designated uses, except that the following site-specific criteria apply: the monthly geometric mean of E. coli bacteria 206 cfu/100 mL or less, single sample 940 cfu/100 mL or less.

[20.6.4.99 NMAC - N, 5/23/2005; A, 12/1/2010; A, 3/2/2017; A, MM/DD/YYYY]

20.6.4.100 [**RESERVED**]

20.6.4.101 RIO GRANDE BASIN: The main stem of the Rio Grande from the international boundary with Mexico upstream to one mile downstream of Percha dam.

A. Designated uses: irrigation, marginal warmwater aquatic life, livestock watering, wildlife habitat and primary contact.

B. Criteria:

(1) The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses except that the following segment-specific criterion applies: temperature 34°C (93.2°F) or less.

(2) At mean monthly flows above 350 cfs, the monthly average concentration for: TDS 2,000 mg/L or less, sulfate 500 mg/L or less and chloride 400 mg/L or less.

C. Remarks: sustained flow in the Rio Grande below Caballo reservoir is dependent on release from Caballo reservoir during the irrigation season; at other times of the year, there may be little or no flow.

[20.6.4.101 NMAC - Rp 20 NMAC 6.1.2101, 10/12/2010; A, 12/15/2001; A, 5/23/2005; A, 12/1/2010; A, 3/2/2017]

20.6.4.102 RIO GRANDE BASIN: The main stem of the Rio Grande from one mile downstream of Percha dam upstream to Caballo dam.

A. Designated uses: irrigation, livestock watering, wildlife habitat, primary contact and warmwater aquatic life.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

C. Remarks: sustained flow in the Rio Grande downstream of Caballo reservoir is dependent on release from Caballo reservoir during the irrigation season; at other times of the year, there may be little or no flow.

[20.6.4.102 NMAC - Rp 20 NMAC 6.1.2102, 10/12/2010; A, 5/23/2005; A, 12/1/2010; A, 3/2/2017]

20.6.4.103 RIO GRANDE BASIN: Perennial reaches of tributaries to the Rio Grande in Sierra and Socorro counties not specifically identified under other sections of 20.6.4 NMAC, excluding waters on tribal lands.

NMED Exhibit 27

A. Designated uses: irrigation, livestock watering, wildlife habitat, marginal coldwater aquatic life, secondary contact and warmwater aquatic life.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.103 NMAC - Rp 20 NMAC 6.1.2103, 10/12/2000; A, 5/23/2005; A, 12/1/2010; A, 4/23/2022]

[**NOTE:** This segment was divided effective 4/23/2022. The standards for the main stem of the Rio Grande from the headwaters of Caballo reservoir upstream to Elephant Butte dam, perennial reaches of Palomas creek, perennial reaches of Rio Salado, perennial reaches of Percha creek, perennial reaches of Alamosa creek, Las Animas creek, and perennial reaches of Abo arroyo are under 20.6.4.112 NMAC.]

20.6.4.104 RIO GRANDE BASIN: Caballo and Elephant Butte reservoir.

A. Designated uses: irrigation storage, livestock watering, wildlife habitat, primary contact and warmwater aquatic life.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.104 NMAC - Rp 20 NMAC 6.1.2104, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.105 RIO GRANDE BASIN: The main stem of the Rio Grande from the headwaters of Elephant Butte reservoir upstream to Alameda bridge (Corrales bridge), excluding waters on Isleta pueblo.

A. Designated uses: irrigation, marginal warmwater aquatic life, livestock watering, public water supply, wildlife habitat and primary contact.

B. Criteria:

(1) The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

(2) At mean monthly flows above 100 cfs, the monthly average concentration for: TDS l,500 mg/L or less, sulfate 500 mg/L or less and chloride 250 mg/L or less.

[20.6.4.105 NMAC - Rp 20 NMAC 6.1.2105, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.106 RIO GRANDE BASIN: The main stem of the Rio Grande from Alameda bridge (Corrales bridge) upstream to the Angostura diversion works, excluding waters on Santa Ana pueblo, and intermittent water in the Jemez river below the Jemez pueblo boundary, excluding waters on Santa Ana and Zia pueblos, that enters the main stem of the Rio Grande. Portions of the Rio Grande in this segment are under the joint jurisdiction of the state and Sandia pueblo.

A. Designated uses: irrigation, marginal warmwater aquatic life, livestock watering, wildlife habitat and primary contact; and public water supply on the Rio Grande.

B. Criteria:

(1) The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

(2) At mean monthly flows above 100 cfs, the monthly average concentration for: TDS 1,500 mg/L or less, sulfate 500 mg/L or less and chloride 250 mg/L or less.

[20.6.4.106 NMAC - Rp 20 NMAC 6.1.2105.1, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.107 RIO GRANDE BASIN: The Jemez river from the Jemez pueblo boundary upstream to Soda dam near the town of Jemez Springs and perennial reaches of Vallecito creek.

A. Designated uses: coldwater aquatic life, primary contact, irrigation, livestock watering and wildlife habitat; and public water supply on Vallecito creek.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 25°C (77°F).

[20.6.4.107 NMAC - Rp 20 NMAC 6.1.2105.5, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.108 RIO GRANDE BASIN: Perennial reaches of the Jemez river upstream of Soda dam near the town of Jemez Springs and perennial reaches of tributaries to the Jemez river except those not specifically identified under other sections of 20.6.4 NMAC, and perennial reaches of the Guadalupe river and perennial reaches of tributaries to the Guadalupe river, and Calaveras canyon.

NMED Exhibit 27

A. Designated uses: domestic water supply, fish culture, high quality coldwater aquatic life, irrigation, livestock watering, wildlife habitat and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: specific conductance 400 µS/cm or less (800 µS/cm or less on Sulphur creek); the monthly geometric mean of *E. coli* bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less; and pH within the range of 2.0 to 8.8 on Sulphur creek.

[20.6.4.108 NMAC - Rp 20 NMAC 6.1.2106, 10/12/2000; A, 5/23/2005; A, 12/1/2010; A, 7/10/2012; A, 4/23/2022]

[**NOTE:** The segment covered by this section was divided effective 5/23/2005. The standards for the additional segment are under 20.6.4.124 NMAC. The standards for San Gregorio lake are in 20.6.4.134 NMAC, effective 7/10/2012]

20.6.4.109 RIO GRANDE BASIN: Perennial reaches of Bluewater creek excluding Bluewater lake and waters on tribal lands, Rio Moquino upstream of Laguna pueblo, Seboyeta creek, Rio Paguate upstream of Laguna pueblo, the Rio Puerco upstream of the northern boundary of Cuba, and all other perennial reaches of tributaries to the Rio Puerco, including the Rio San Jose in Cibola county from the USGS gaging station at Correo upstream to Horace springs excluding waters on tribal lands.

A. Designated uses: coldwater aquatic life, domestic water supply, fish culture, irrigation, livestock watering, wildlife habitat and primary contact; and public water supply on La Jara creek.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: phosphorus (unfiltered sample) 0.1 mg/L or less; the monthly geometric mean of *E. coli* bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.109 NMAC - Rp 20 NMAC 6.1.2107, 10/12/2000; A, 5/23/2005; A, 12/1/2010; A, 7/10/2012]

[**NOTE:** The standards for Bluewater lake are in 20.6.4.135 NMAC, effective 7/10/2012]

20.6.4.110 RIO GRANDE BASIN: The main stem of the Rio Grande from Angostura diversion works upstream to Cochiti dam, excluding the reaches on San Felipe, Kewa and Cochiti pueblos.

A. Designated uses: irrigation, livestock watering, wildlife habitat, primary contact, coldwater aquatic life and warmwater aquatic life.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: pH within the range of 6.6 to 9.0 and temperature 25°C (77°F) or less.

[20.6.4.110 NMAC - Rp 20 NMAC 6.1.2108, 10/12/2010; A, 5/23/2005; A, 12/1/2010; A, 3/2/2017]

20.6.4.111 RIO GRANDE BASIN: Perennial reaches of Las Huertas creek from the San Felipe pueblo boundary to the headwaters.

A. Designated uses: high quality coldwater aquatic life, irrigation, livestock watering, wildlife habitat and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 25°C (77°F) or less.

[20.6.4.111 NMAC - Rp 20 NMAC 6.1.2108.5, 10/12/2000; A, 7/25/2001; A, 5/23/2005; A-12/1/2010]

[**NOTE:** The segment covered by this section was divided effective 5/23/2005. The standards for the additional segment are under 20.6.4.125 NMAC.]

20.6.4.112 RIO GRANDE BASIN: The main stem of the Rio Grande from the headwaters of Caballo reservoir upstream to Elephant Butte dam, perennial reaches of Palomas creek, perennial reaches of Rio Salado, perennial reaches of Percha creek, perennial reaches of Alamosa creek, Las Animas creek, and perennial reaches of Abo arroyo.

A. Designated uses: irrigation, livestock watering, wildlife habitat, marginal coldwater aquatic life, primary contact and warmwater aquatic life.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

C. Remarks: flow in this reach of the Rio Grande main stem is dependent upon release from Elephant Butte dam.

[20.6.4.112 NMAC - Rp 20 NMAC 6.1.2109, 10/12/2000; A, 5/23/2005; Repealed, 12/1/2010; A, 4/23/2022]

NMED Exhibit 27

20.6.4.113 RIO GRANDE BASIN: The Santa Fe river and perennial reaches of its tributaries from the Cochiti pueblo boundary upstream to the outfall of the Santa Fe wastewater treatment facility.

A. Designated uses: irrigation, livestock watering, wildlife habitat, primary contact and coolwater aquatic life.

B. Criteria: The use-specific criteria in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 30°C (86°F) or less.

[20.6.4.113 NMAC - Rp 20 NMAC 6.1.2110, 10/12/2000; A, 10/11/2002; A, 5/23/2005; A, 12/1/2010; A, 2/14/2013]

20.6.4.114 RIO GRANDE BASIN: The main stem of the Rio Grande from the Cochiti pueblo boundary upstream to Rio Pueblo de Taos excluding waters on San Ildefonso, Santa Clara and Ohkay Owingeh pueblos, Embudo creek from its mouth on the Rio Grande upstream to the Picuris Pueblo boundary, the Santa Cruz river from the Santa Clara pueblo boundary upstream to the Santa Cruz dam, the Rio Tesuque except waters on the Tesuque and Pojoaque pueblos, and the Pojoaque river from the San Ildefonso pueblo boundary upstream to the Pojoaque pueblo boundary. Some Rio Grande waters in this segment are under the joint jurisdiction of the state and San Ildefonso pueblo.

A. Designated uses: irrigation, livestock watering, wildlife habitat, marginal coldwater aquatic life, primary contact and warmwater aquatic life; and public water supply on the main stem Rio Grande.

B. Criteria:

(1) The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: 6T3 temperature 22°C (71.6°F) and maximum temperature 25°C (78.8°F). In addition, the following criteria based on a 12-month rolling average are applicable to the public water supply use for monitoring and public disclosure purposes only:

Radionuclide	pCi/L
Americium-241	1.9
Cesium-137	6.4
Plutonium-238	1.5
Plutonium-239/240	1.5
Strontium-90	3.5
Tritium	4,000

(2) At mean monthly flows above 100 cfs, the monthly average concentration for: TDS 500 mg/L or less, sulfate 150 mg/L or less and chloride 25 mg/L or less.

[20.6.4.114 NMAC - Rp 20 NMAC 6.1.2111, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.115 RIO GRANDE BASIN: The perennial reaches of Rio Vallecitos, perennial reaches of tributaries to Rio Vallecitos except Hopewell lake, and perennial reaches of Rio del Oso and perennial reaches of El Rito creek above the town of El Rito.

A. Designated uses: domestic water supply, irrigation, high quality coldwater aquatic life, livestock watering, wildlife habitat and primary contact; public water supply on the Rio Vallecitos and El Rito creek.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: specific conductance 300 µS/cm or less; the monthly geometric mean of *E. coli* bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.115 NMAC - Rp 20 NMAC 6.1.2112, 10/12/2000; A, 5/23/2005; A, 12/1/2010; A, 7/10/2012; A, 4/23/2022]

[**NOTE:** The standards for Hopewell lake are in 20.6.4.134 NMAC, effective 7/10/2012]

20.6.4.116 RIO GRANDE BASIN: The Rio Chama from its mouth on the Rio Grande upstream to Abiquiu reservoir, perennial reaches of the Rio Tusas, perennial reaches of the Rio Ojo Caliente, perennial reaches of Abiquiu creek and perennial reaches of El Rito creek downstream of the town of El Rito.

A. Designated uses: irrigation, livestock watering, wildlife habitat, coldwater aquatic life, warmwater aquatic life and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 31°C (87.8°F) or less.

[20.6.4.116 NMAC - Rp 20 NMAC 6.1.2113, 10/12/2010; A, 5/23/2005; A, 12/1/2010; A, 3/2/2017; A, 4/23/2022]

NMED Exhibit 27

20.6.4.117 RIO GRANDE BASIN: Abiquiu reservoir.

A. Designated uses: irrigation storage, livestock watering, wildlife habitat, primary contact, coldwater aquatic life and warmwater aquatic life.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 25°C (77°F) or less.

[20.6.4.117 NMAC - Rp 20 NMAC 6.1.2114, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.118 RIO GRANDE BASIN: The Rio Chama from the headwaters of Abiquiu reservoir upstream to El Vado reservoir and perennial reaches of the Rio Gallina and Rio Puerco de Chama north of state highway 96. Some Rio Chama waters in this segment are under the joint jurisdiction of the state and the Jicarilla Apache tribe.

A. Designated uses: irrigation, livestock watering, wildlife habitat, coldwater aquatic life, warmwater aquatic life and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 26°C (78.8°F) or less.

[20.6.4.118 NMAC - Rp 20 NMAC 6.1.2115, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.119 RIO GRANDE BASIN: All perennial reaches of tributaries to the Rio Chama above Abiquiu dam, except Canjilon lakes a, c, e and f and the Rio Gallina and Rio Puerco de Chama north of state highway 96 and excluding waters on Jicarilla Apache reservation, and the main stem of the Rio Chama from the headwaters of El Vado reservoir upstream to the New Mexico-Colorado line. Some Cañones creek and Rio Chama waters in this segment are under the joint jurisdiction of the state and the Jicarilla Apache tribe.

A. Designated uses: domestic water supply, fish culture, high quality coldwater aquatic life, irrigation, livestock watering, wildlife habitat and primary contact; and public water supply on the Rio Brazos and Rio Chama.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: specific conductance 500 µS/cm or less (1,000 µS or less for Coyote creek); the monthly geometric mean of *E. coli* bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[**NOTE:** The standards for Canjilon lakes a, c, e and f are in 20.6.4.134 NMAC, effective 7/10/2012]

20.6.4.120 RIO GRANDE BASIN: El Vado and Heron reservoirs.

A. Designated uses: irrigation storage, livestock watering, wildlife habitat, public water supply, primary contact and coldwater aquatic life.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.120 NMAC - Rp 20 NMAC 6.1.2117, 10/12/2000; A. 5/23/2005; A, 12/1/2010]

20.6.4.121 RIO GRANDE BASIN: Perennial tributaries to the Rio Grande in Bandelier national monument and their headwaters in Sandoval county and all perennial reaches of tributaries to the Rio Grande in Santa Fe county unless included in other segments and excluding waters on tribal lands.

A. Designated uses: domestic water supply, high quality coldwater aquatic life, irrigation, livestock watering, wildlife habitat and primary contact; and public water supply on Little Tesuque creek, the Rio en Medio, and the Santa Fe river.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: specific conductance 300 µS/cm or less; the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.121 NMAC - Rp 20 NMAC 6.1.2118, 10/12/2000; A. 5/23/2005; A, 12/1/2010; A, 2/14/2013]

[**NOTE:** The segment covered by this section was divided effective 5/23/2005. The standards for the additional segments are under 20.6.4.126, 20.6.4.127 and 20.6.4.128 NMAC.]

20.6.4.122 RIO GRANDE BASIN: The main stem of the Rio Grande from Rio Pueblo de Taos upstream to the New Mexico-Colorado line, the Red river from its mouth on the Rio Grande upstream to the

NMED Exhibit 27

mouth of Placer creek, and the Rio Pueblo de Taos from its mouth on the Rio Grande upstream to the mouth of the Rio Grande del Rancho. Some Rio Grande and Rio Pueblo de Taos waters in this segment are under the joint jurisdiction of the state and Taos pueblo.

A. Designated uses: coldwater aquatic life, fish culture, irrigation, livestock watering, wildlife habitat and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.122 NMAC - Rp 20 NMAC 6.1.2119, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.123 RIO GRANDE BASIN: Perennial reaches of the Red river upstream of the mouth of Placer creek, all perennial reaches of tributaries to the Red river, and all other perennial reaches of tributaries to the Rio Grande in Taos and Rio Arriba counties unless included in other segments and excluding waters on Santa Clara, Ohkay Owingeh, Picuris and Taos pueblos.

A. Designated uses: domestic water supply, high quality coldwater aquatic life, irrigation, livestock watering, wildlife habitat and primary contact; and public water supply on the Rio Pueblo and Rio Fernando de Taos.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: specific conductance 400 µS/cm or less (500 µS/cm or less for the Rio Fernando de Taos); the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less; and phosphorus (unfiltered sample) less than 0.1 mg/L for the Red river.

[20.6.4.123 NMAC - Rp 20 NMAC 6.1.2120, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

[**NOTE:** The segment covered by this section was divided effective 5/23/2005. The standards for the additional segment are under 20.6.4.129 NMAC.]

20.6.4.124 RIO GRANDE BASIN: Perennial reaches of Sulphur creek from its confluence with Redondo creek upstream to its headwaters.

A. Designated uses: limited aquatic life, wildlife habitat, livestock watering and secondary contact.

B. Criteria: the use-specific criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: pH within the range of 2.0 to 9.0, maximum temperature 30ºC (86ºF), and the chronic aquatic life criteria of Subsections I and J of 20.6.4.900 NMAC.

[20.6.4.124 NMAC - N, 5/23/2005; A, 12/1/2010; A, 3/2/2017]

20.6.4.125 RIO GRANDE BASIN: Perennial reaches of San Pedro creek from the San Felipe pueblo boundary to the headwaters.

A. Designated uses: coldwater aquatic life, irrigation, livestock watering, wildlife habitat and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 25°C (77°F) or less.

[20.6.4.125 NMAC - N, 5/23/2005; A, 12/1/2010]

20.6.4.126 RIO GRANDE BASIN: Perennial waters within lands managed by the U.S. department of energy (DOE) within Los Alamos National Laboratory (LANL), including but not limited to: Cañon de Valle from LANL stream gage E256 upstream to Burning Ground spring, Sandia canyon at Sigma canyon upstream to Sandia canyon at Bedrock Road, Pajarito canyon from 0.5 miles below Arroyo de La Delfe upstream to Homestead spring, Arroyo de la Delfe from Pajarito canyon to Kieling spring, Starmers gulch and Starmers spring and Water canyon from Area-A canyon upstream to State Route 501.

A. Designated uses: coldwater aquatic life, livestock watering, wildlife habitat and secondary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.126 NMAC - N, 5/23/2005; A, 12/1/2010; A, 4/23/2022; A, 11/8/2025]

20.6.4.127 RIO GRANDE BASIN: Perennial portions of Los Alamos canyon upstream from Los Alamos reservoir and Los Alamos reservoir.

NMED Exhibit 27

A. Designated uses: coldwater aquatic life, livestock watering, wildlife habitat, irrigation and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.127 NMAC - N, 5/23/2005; A, 12/1/2010]

20.6.4.128 RIO GRANDE BASIN: Ephemeral and intermittent waters within lands managed by U.S. department of energy (DOE) within LANL, including but not limited to: Mortandad canyon, Cañada del Buey, Ancho canyon, Chaquehui canyon, Indio canyon, Fence canyon, Potrillo canyon, and portions of Cañon de Valle, Los Alamos canyon, Sandia canyon, Pajarito canyon and Water canyon not identified in 20.6.4.126 NMAC or 20.6.4.140 NMAC. (Surface waters within lands scheduled for transfer from DOE to tribal, state or local authorities are specifically excluded.)

A. Designated uses: livestock watering, wildlife habitat, limited aquatic life and secondary contact.

B. Criteria: the use-specific criteria in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the acute total ammonia criteria set forth in Subsection L of 20.6.4.900 NMAC (*Oncorhynchus* spp. absent).

[20.6.4.128 NMAC - N, 5/23/2005; A, 12/1/2010; A, 4/23/2022]

[**NOTE:** This section was divided effective 4/23/2022. The standards for some intermittent waters within LANL are in 20.6.4.140 NMAC.]

20.6.4.129 RIO GRANDE BASIN: Perennial reaches of the Rio Hondo.

A. Designated uses: domestic water supply, high quality coldwater aquatic life, irrigation, livestock watering, wildlife habitat and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: specific conductance 400 µS/cm or less and phosphorus (unfiltered sample) less than 0.1 mg/L.

[20.6.4.129 NMAC - N, 5/23/2005; A, 12/1/2010]

20.6.4.130 RIO GRANDE BASIN: The Rio Puerco from the Rio Grande upstream to Arroyo Chijuilla, excluding the reaches on Isleta, Laguna and Cañoncito Navajo pueblos. Some waters in this segment are under the joint jurisdiction of the state and Isleta, Laguna or Cañoncito Navajo pueblos.

A. Designated uses: irrigation, warmwater aquatic life, livestock watering, wildlife habitat and primary contact.

B. Criteria:

(1) The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

(2) At mean monthly flows above 100 cfs, the monthly average concentration for: TDS l,500 mg/L or less, sulfate 500 mg/L or less and chloride 250 mg/L or less.

[20.6.4.130 NMAC - N, 12/1/2010]

20.6.4.131 RIO GRANDE BASIN: The Rio Puerco from the confluence of Arroyo Chijuilla upstream to the northern boundary of Cuba.

A. Designated uses: warmwater aquatic life, irrigation, livestock watering, wildlife habitat and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.131 NMAC - N, 12/1/2010]

20.6.4.132 RIO GRANDE BASIN: Rio Grande (Klauer) spring

A. Designated uses: domestic water supply, wildlife habitat, livestock watering, coldwater aquatic life use and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.132 NMAC - N, 12/1/2010]

NMED Exhibit 27

20.6.4.133 RIO GRANDE BASIN: Bull Creek lake, Cow lake, Elk lake, Goose lake, Heart lake, Hidden lake (Lake Hazel), Horseshoe lake, Horseshoe (Alamitos) lake, Jose Vigil lake, Lost lake, Middle Fork lake, Nambe lake, Nat II lake, Nat IV lake, No Fish lake, Pioneer lake, San Leonardo lake, Santa Fe lake, Serpent lake, South Fork lake, Trampas lakes (east and west) and Williams lake.

A. Designated uses: high quality coldwater aquatic life, irrigation, domestic water supply, primary contact, livestock watering and wildlife habitat.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: specific conductance 300 µS/cm or less; the monthly geometric mean of *E. coli* bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.133 NMAC - N, 7/10/2012]

20.6.4.134 RIO GRANDE BASIN: Cabresto lake, Canjilon lakes a, c, e and f, Fawn lakes (east and west), Hopewell lake and San Gregorio lake.

A. Designated uses: high quality coldwater aquatic life, irrigation, domestic water supply, primary contact, livestock watering and wildlife habitat.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: specific conductance 300 µS/cm or less; the monthly geometric mean of *E. coli* bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.134 NMAC - N, 7/10/2012]

20.6.4.135 RIO GRANDE BASIN: Bluewater lake and Santa Cruz lake.

A. Designated uses: coldwater aquatic life, irrigation, domestic water supply, primary contact, livestock watering and wildlife habitat.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses except that the following segment-specific criteria apply: phosphorus (unfiltered sample) 0.1 mg/L or less; the monthly geometric mean of *E. coli* bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.135 NMAC - N, 7/10/2012; A, MM/DD/YYYY]

20.6.4.136 RIO GRANDE BASIN: The Santa Fe river from the outfall of the Santa Fe wastewater treatment facility to Guadalupe street.

A. Designated uses: limited aquatic life, wildlife habitat, primary contact, livestock watering, and irrigation.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.136 NMAC - N, 2/14/2013]

20.6.4.137 RIO GRANDE BASIN: The Santa Fe river from Guadalupe street to Nichols reservoir.

A. Designated uses: coolwater aquatic life, wildlife habitat, primary contact, livestock watering, and irrigation.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.137 NMAC - N, 2/14/2013]

20.6.4.138 RIO GRANDE BASIN: Nichols and McClure reservoirs.

A. Designated uses: high quality coldwater aquatic life, wildlife habitat, primary contact, public water supply and irrigation.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: specific conductance 300 µS/cm or less; the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.138 NMAC - N, 2/14/2013]

20.6.4.139 RIO GRANDE BASIN: Perennial reaches of Galisteo creek and perennial reaches of its tributaries from Kewa pueblo upstream to 2.2 miles upstream of Lamy.

A. Designated uses: coolwater aquatic life, primary contact, irrigation, livestock watering, domestic water supply and wildlife habitat; and public water supply on Cerrillos reservoir.

NMED Exhibit 27

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.
[20.6.4.139 NMAC - N, 2/14/2013]

20.6.4.140 RIO GRANDE BASIN: Effluent canyon from Mortandad canyon to its headwaters, intermittent portions of S-Site canyon from monitoring well MSC 16-06293 to Martin spring, and intermittent portions of Twomile canyon from its confluence with Pajarito canyon to Upper Twomile canyon. (Surface waters within lands scheduled for transfer from DOE to tribal, state or local authorities are specifically excluded.)

A. Designated uses: livestock watering, wildlife habitat, marginal warmwater aquatic life and secondary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.
[20.6.4.140 NMAC - N, 4/23/2022]

20.6.4.141 RIO GRANDE BASIN: Sandia canyon from Sandia canyon at Bedrock Road upstream to LANL NPDES outfall 001.

A. Designated uses: coolwater aquatic life, livestock watering, wildlife habitat and secondary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following additional segment-specific criterion applies: a 6T3 temperature of 25°C (77°F).
[20.6.4.141 NMAC - N, 11/8/2025]

20.6.4.142 - 20.6.4.200 [RESERVED]

20.6.4.201 PECOS RIVER BASIN: The main stem of the Pecos river from the New Mexico-Texas line upstream to the mouth of the Black river (near Loving).

A. Designated uses: irrigation, livestock watering, wildlife habitat, primary contact and warmwater aquatic life.

B. Criteria:

(l) The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: dissolved boron for irrigation use 2,000 µg/L or less.

(2) At all flows above 50 cfs: TDS 20,000 mg/L or less, sulfate 3,000 mg/L or less and chloride 10,000 mg/L or less.
[20.6.4.201 NMAC - Rp 20 NMAC 6.1.2201, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.202 PECOS RIVER BASIN: The main stem of the Pecos river from the mouth of the Black river upstream to lower Tansil dam, including perennial reaches of the Black river, the Delaware river and Blue spring.

A. Designated uses: industrial water supply, irrigation, livestock watering, wildlife habitat, primary contact and warmwater aquatic life.

B. Criteria:

(l) The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 34°C (93.2°F) or less.

(2) At all flows above 50 cfs: TDS 8,500 mg/L or less, sulfate 2,500 mg/L or less and chloride 3,500 mg/L or less.

C. Remarks: diversion for irrigation frequently limits summer flow in this reach of the main stem Pecos river to that contributed by springs along the watercourse.
[20.6.4.202 NMAC - Rp 20 NMAC 6.1.2202, 10/12/2000; A, 5/23/2005; A, 12/1/2010]
[**NOTE:** The segment covered by this section was divided effective 5/23/2005. The standards for Lower Tansil Lake and Lake Carlsbad are under 20.6.4.218 NMAC.]

NMED Exhibit 27

20.6.4.203 PECOS RIVER BASIN: The main stem of the Pecos river from the headwaters of Lake Carlsbad upstream to Avalon dam.

A. Designated uses: industrial water supply, livestock watering, wildlife habitat, primary contact and warmwater aquatic life.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: temperature 34°C (93.2°F) or less; the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.203 NMAC - Rp 20 NMAC 6.1.2203, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

[**NOTE:** The segment covered by this section was divided effective 5/23/2005. The standards for Lower Tansil Lake and Lake Carlsbad are under 20.6.4.218 and for Avalon Reservoir are under 20.6.4.219 NMAC.]

20.6.4.204 PECOS RIVER BASIN: The main stem of the Pecos river from the headwaters of Avalon reservoir upstream to Brantley dam.

A. Designated uses: irrigation, livestock watering, wildlife habitat, primary contact and warmwater aquatic life.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.204 NMAC - Rp 20 NMAC 6.1.2204, 10/12/2000; A, 5/23/2005; A, 12/1/2010; A, 4/23/2022]

[**NOTE:** The segment covered by this section was divided effective 5/23/2005. The standards for Avalon Reservoir are under 20.6.4.219 NMAC.]

20.6.4.205 PECOS RIVER BASIN: Brantley reservoir.

A. Designated uses: irrigation storage, livestock watering, wildlife habitat, primary contact and warmwater aquatic life.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.205 NMAC - Rp 20 NMAC 6.1.2205, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.206 PECOS RIVER BASIN: Perennial reaches of the Rio Felix[~~ and perennial reaches of tributaries to the Rio Hondo downstream of Bonney canyon, excluding North Spring river~~].

A. Designated uses: irrigation, livestock watering, wildlife habitat, secondary contact and warmwater aquatic life.

B. Criteria:

(1) The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

(2) At all flows above 50 cfs: TDS 14,000 mg/L or less, sulfate 3,000 mg/L or less and chloride 6,000 mg/L or less.

[20.6.4.206 NMAC - Rp 20 NMAC 6.1.2206, 10/12/2010; A, 5/23/2005; A, 12/1/2010; A, 3/2/2017; A, 4/23/2022; A, MM/DD/YYYY]

[**NOTE:** This segment was divided effective 4/23/2022. The standards for the main stem of the Pecos river from the headwaters of Brantley reservoir upstream to Salt creek (near Acme), perennial reaches of the Rio Peñasco downstream from state highway 24 near Dunken, and perennial reaches of the Rio Hondo are under 20.6.4.231 NMAC.]

20.6.4.207 PECOS RIVER BASIN: The main stem of the Pecos river from Salt creek (near Acme) upstream to Sumner dam.

A. Designated uses: irrigation, marginal warmwater aquatic life, livestock watering, wildlife habitat and primary contact.

B. Criteria:

(1) The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

(2) At all flows above 50 cfs: TDS 8,000 mg/L or less, sulfate 2,500 mg/L or less and chloride 4,000 mg/L or less.

[20.6.4.207 NMAC - Rp 20 NMAC 6.1.2207, 10/12/2000; A, 5/23/2005; A, 12/1/2010; A, 4/23/2022]

NMED Exhibit 27

20.6.4.208 PECOS RIVER BASIN: Perennial reaches of the Rio Peñasco above [~~state highway 24 near Dunken~~] Bear Canyon, perennial reaches of tributaries to the Rio Peñasco above [~~state highway 24 near Dunken~~] Bear Canyon, perennial reaches of Cox canyon, perennial reaches of the Rio Bonito downstream from [~~state highway 48 (near Angus)~~] Angus canyon, the Rio Ruidoso downstream of [~~the U.S. highway 70 bridge~~] Palo Verde canyon near Seeping Springs lakes, perennial reaches of the Rio Hondo upstream from Bonney canyon and perennial reaches of Agua Chiquita.

A. Designated uses: fish culture, irrigation, livestock watering, wildlife habitat, coldwater aquatic life and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: temperature 30°C (86°F) or less, and phosphorus (unfiltered sample) less than 0.1 mg/L.

[20.6.4.208 NMAC - Rp 20 NMAC 6.1.2208, 10/12/2000; A, 5/23/2005; A, 12/1/2010; A, 4/23/2022; A, MM/DD/YYYY]

20.6.4.209 PECOS RIVER BASIN: Perennial reaches of Eagle creek upstream of Alto dam to the Mescalero Apache boundary, perennial reaches of the Rio Bonito upstream of [~~state highway 48 (near Angus)~~] Angus canyon excluding Bonito lake, perennial reaches of tributaries to the Rio Bonito upstream of [~~state highway 48 (near Angus)~~] Angus canyon, perennial reaches of the Rio Ruidoso upstream of [~~the U.S. highway 70 bridge~~] Palo Verde canyon near Seeping Springs lakes above and below the Mescalero Apache boundary and perennial reaches of tributaries to the Rio Ruidoso upstream of [~~the U.S. highway 70 bridge~~] Palo Verde canyon near Seeping Springs lakes above and below the Mescalero Apache boundary.

A. Designated uses: domestic water supply, high quality coldwater aquatic life, irrigation, livestock watering, wildlife habitat, public water supply and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: specific conductance 600 µS/cm or less in Eagle creek, 1,100 µS/cm or less in Bonito creek and 1,500 µS/cm or less in the Rio Ruidoso; phosphorus (unfiltered sample) less than 0.1 mg/L; the monthly geometric mean of *E. coli* bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.209 NMAC - Rp 20 NMAC 6.1.2209, 10/12/2000; A, 5/23/2005; A, 12/1/2010; A, 7/10/2012; A, 4/23/2022; A, MM/DD/YYYY]

[**NOTE:** The standards for Bonito lake are in 20.6.4.223 NMAC, effective 7/10/2012]

20.6.4.210 PECOS RIVER BASIN: Sumner reservoir.

A. Designated uses: irrigation storage, livestock watering, wildlife habitat, primary contact and warmwater aquatic life.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.210 NMAC - Rp 20 NMAC 6.1.2210, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.211 PECOS RIVER BASIN: The main stem of the Pecos river from the headwaters of Sumner reservoir upstream to Tecolote creek excluding Santa Rosa reservoir.

A. Designated uses: fish culture, irrigation, marginal warmwater aquatic life, livestock watering, wildlife habitat and primary contact.

B. Criteria:

(1) The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

(2) At all flows above 50 cfs: TDS 3,000 mg/L or less, sulfate 2,000 mg/L or less and chloride 400 mg/L or less.

[20.6.4.211 NMAC - Rp 20 NMAC 6.1.2211, 10/12/2000; A, 5/23/2005; A, 12/1/2010; A, 7/10/2012]

[**NOTE:** The standards for Santa Rosa reservoir are in 20.6.4.225 NMAC, effective 7/10/2012]

20.6.4.212 PECOS RIVER BASIN: Perennial tributaries to the main stem of the Pecos river from the headwaters of Sumner reservoir upstream to Santa Rosa dam.

A. Designated uses: irrigation, coldwater aquatic life, livestock watering, wildlife habitat and primary contact.

NMED Exhibit 27

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 25°C (77°F) or less.
[20.6.4.212 NMAC - Rp 20 NMAC 6.1.2211.1, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.213 PECOS RIVER BASIN: McAllister lake.

A. Designated uses: coldwater aquatic life, secondary contact, livestock watering and wildlife habitat.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 25°C (77°F) or less.
[20.6.4.213 NMAC - Rp 20 NMAC 6.1.2211.3, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.214 PECOS RIVER BASIN: Storrie lake.

A. Designated uses: coldwater aquatic life, warmwater aquatic life, primary contact, livestock watering, wildlife habitat, public water supply and irrigation storage.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.
[20.6.4.214 NMAC - Rp 20 NMAC 6.1.2211.5, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.215 PECOS RIVER BASIN: Perennial reaches of the Gallinas river upstream of the diversion for the Las Vegas municipal reservoir, perennial reaches of tributaries to the Gallinas river upstream of the diversion for the Las Vegas municipal reservoir, perennial reaches of Tecolote creek upstream of Blue creek and all perennial reaches of tributaries to Tecolote creek upstream of Blue creek.

A. Designated uses: domestic water supply, high quality coldwater aquatic life, irrigation, livestock watering, wildlife habitat, industrial water supply and primary contact; and public water supply on the Gallinas river.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: specific conductance 300 µS/cm or less (450 µS/cm or less in Wright Canyon creek); the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.
[20.6.4.215 NMAC - Rp 20 NMAC 6.1.2212, 10/12/2000; A, 5/23/2005; A, 12/1/2010; A, 2/13/2018; A, 4/23/2022]
[**NOTE:** This segment was divided effective 2/13/2018. The standards for Tecolote creek from I-25 to Blue creek are under 20.6.4.230 NMAC.]

20.6.4.216 PECOS RIVER BASIN: The main stem of the Pecos river from Tecolote creek upstream to Cañon de Manzanita.

A. Designated uses: irrigation, livestock watering, wildlife habitat, marginal coldwater aquatic life and primary contact.

B. Criteria:

(1) The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 30°C (86°F) or less.

(2) At all flows above 10 cfs: TDS 250 mg/L or less, sulfate 25 mg/L or less and chloride 5 mg/L or less.
[20.6.4.216 NMAC - Rp 20 NMAC 6.1.2213, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.217 PECOS RIVER BASIN: Perennial reaches of Cow creek and all perennial reaches of its tributaries and the main stem of the Pecos river from Cañon de Manzanita upstream to its headwaters, including perennial reaches of all tributaries thereto except lakes identified in 20.6.4.222 NMAC.

A. Designated uses: domestic water supply, fish culture, high quality coldwater aquatic life, irrigation, livestock watering, wildlife habitat and primary contact; and public water supply on the main stem of the Pecos river.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: specific conductance 300 µS/cm or less; the monthly geometric mean of *E. coli* bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.
[20.6.4.217 NMAC - Rp 20 NMAC 6.1.2214, 10/12/2000; A, 5/23/2005; A, 12/1/2010; A, 7/10/2012]
[**NOTE:** The segment covered by this section was divided effective 5/23/2005. The standards for the additional segments are under 20.6.4.220 and 20.6.4.221 NMAC.]

NMED Exhibit 27

20.6.4.218 PECOS RIVER BASIN: Lower Tansil lake and Lake Carlsbad.

A. Designated uses: industrial water supply, livestock watering, wildlife habitat, primary contact and warmwater aquatic life.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 34°C (93.2°F) or less.

[20.6.4.218 NMAC - N, 5/23/2005; A, 12/1/2010]

20.6.4.219 PECOS RIVER BASIN: Avalon reservoir.

A. Designated uses: irrigation storage, livestock watering, wildlife habitat, [~~secondary~~] primary contact and warmwater aquatic life.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.219 NMAC - N, 5/23/2005; A, 12/1/2010; A, MM/DD/YYYY]

20.6.4.220 PECOS RIVER BASIN: Perennial reaches of the Gallinas river and perennial reaches of tributaries to the Gallinas river from its mouth upstream to the diversion for the Las Vegas municipal reservoir, except Pecos Arroyo.

A. Designated uses: irrigation, livestock watering, wildlife habitat, marginal coldwater aquatic life and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 30°C (86°F) or less.

[20.6.4.220 NMAC - N, 5/23/2005; A, 12/1/2010; A, 4/23/2022]

20.6.4.221 PECOS RIVER BASIN: Pecos Arroyo.

A. Designated uses: livestock watering, wildlife habitat, warmwater aquatic life and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of E. coli bacteria 206 cfu/100 mL, single sample 940 cfu/100 mL.

[20.6.4.221 NMAC - N, 5/23/2005; A, 12/1/2010]

20.6.4.222 PECOS RIVER BASIN: Johnson lake, Katherine lake, Lost Bear lake, Pecos Baldy lake, Spirit lake, Stewart lake and Truchas lakes (north and south).

A. Designated uses: high quality coldwater aquatic life, irrigation, domestic water supply, primary contact, livestock watering and wildlife habitat.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: specific conductance 300 µS/cm or less; the monthly geometric mean of *E. coli* bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.222 NMAC - N, 7/10/2012]

20.6.4.223 PECOS RIVER BASIN: Bonito lake.

A. Designated uses: high quality coldwater aquatic life, irrigation, domestic water supply, primary contact, livestock watering, wildlife habitat and public water supply.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses except that the following segment-specific criteria apply: specific conductance 1100 µS/cm or less; phosphorus (unfiltered sample) less than 0.1 mg/L; the monthly geometric mean of *E. coli* bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.223 NMAC - N, 7/10/2012]

20.6.4.224 PECOS RIVER BASIN: Monastery lake.

A. Designated uses: coolwater aquatic life, primary contact, livestock watering and wildlife habitat.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of *E. coli* bacteria 206 cfu/100 mL or less, single sample 940 cfu/100 mL or less.

[20.6.4.224 NMAC - N, 7/10/2012]

NMED Exhibit 27

20.6.4.225 PECOS RIVER BASIN: Santa Rosa reservoir.

A. Designated uses: coolwater aquatic life, irrigation, primary contact, livestock watering and wildlife habitat.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.225 NMAC - N, 7/10/2012]

20.6.4.226 PECOS RIVER BASIN: Perch lake.

A. Designated uses: coolwater aquatic life, primary contact, livestock watering and wildlife habitat.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses except that the following segment-specific criteria apply: the monthly geometric mean of *E. coli* bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.226 NMAC - N, 7/10/2012]

20.6.4.227 PECOS RIVER BASIN: Lea lake.

A. Designated uses: warmwater aquatic life, primary contact and wildlife habitat.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses except that the following segment-specific criteria apply: the monthly geometric mean of *E. coli* bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.227 NMAC - N, 7/10/2012]

20.6.4.228 PECOS RIVER BASIN: Cottonwood lake and Devil's Inkwell.

A. Designated uses: coolwater aquatic life, primary contact and wildlife habitat.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of *E. coli* bacteria 206 cfu/100 mL or less, single sample 940 cfu/100 mL or less.

[20.6.4.228 NMAC - N, 7/10/2012]

20.6.4.229 PECOS RIVER BASIN: Mirror lake.

A. Designated uses: warmwater aquatic life, primary contact and wildlife habitat.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of *E. coli* bacteria 206 cfu/100 mL or less, single sample 940 cfu/100 mL or less.

[20.6.4.229 NMAC - N, 7/10/2012]

20.6.4.230 PECOS RIVER BASIN: Perennial reaches of Tecolote creek from I-25 to Blue creek.

A. Designated uses: domestic water supply, coolwater aquatic life, irrigation, livestock watering, wildlife habitat, and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.230 NMAC - N, 2/13/2018]

20.6.4.231 PECOS RIVER BASIN: The main stem of the Pecos river from the headwaters of Brantley reservoir upstream to Salt creek (near Acme), perennial reaches of the Rio Peñasco downstream from [~~state highway 24 near Dunken~~]Bear Canyon, [~~perennial reaches of North Spring river and~~]perennial reaches of the Rio Hondo and perennial reaches of its tributaries downstream of Bonney canyon.

A. Designated uses: irrigation, livestock watering, wildlife habitat, primary contact and warmwater aquatic life.

B. Criteria:

(1) The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

(2) At all flows above 50 cfs: TDS 14,000 mg/L or less, sulfate 3,000 mg/L or less and chloride 6,000 mg/L or less.

[20.6.4.231 NMAC - N, 4/23/2022; A, MM/DD/YYYY]

NMED Exhibit 27

20.6.4.232 - 20.6.4.300 [RESERVED]

20.6.4.301 CANADIAN RIVER BASIN: The main stem of the Canadian river from the New Mexico-Texas line upstream to Ute dam, and any flow that enters the main stem from Revuelto creek.

A. Designated uses: irrigation, marginal warmwater aquatic life, livestock watering, wildlife habitat and primary contact.

B. Criteria:

(1) The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

(2) TDS 6,500 mg/L or less at flows above 25 cfs.

[20.6.4.301 NMAC - Rp 20 NMAC 6.1.2301, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.302 CANADIAN RIVER BASIN: Ute reservoir.

A. Designated uses: livestock watering, wildlife habitat, public water supply, industrial water supply, primary contact and warmwater aquatic life.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.302 NMAC - Rp 20 NMAC 6.1.2302, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.303 CANADIAN RIVER BASIN: The main stem of the Canadian river from the headwaters of Ute reservoir upstream to Conchas dam, the perennial reaches of Pajarito and Ute creeks and their perennial tributaries.

A. Designated uses: irrigation, marginal warmwater aquatic life, livestock watering, wildlife habitat and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.303 NMAC - Rp 20 NMAC 6.1.2303, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.304 CANADIAN RIVER BASIN: Conchas reservoir.

A. Designated uses: irrigation storage, livestock watering, wildlife habitat, public water supply, primary contact and warmwater aquatic life.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.304 NMAC - Rp 20 NMAC 6.1.2304, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.305 CANADIAN RIVER BASIN: The main stem of the Canadian river from the headwaters of Conchas reservoir upstream to the New Mexico-Colorado line, perennial reaches of the Conchas river, the Mora river downstream from the USGS gaging station near Shoemaker, the Vermejo river downstream from Rail canyon and perennial reaches of Raton, Chicorica (except Lake Maloya and Lake Alice) and Uña de Gato creeks.

A. Designated uses: irrigation, marginal warmwater aquatic life, livestock watering, wildlife habitat and primary contact.

B. Criteria:

(1) The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

(2) TDS 3,500 mg/L or less at flows above 10 cfs.

[20.6.4.305 NMAC - Rp 20 NMAC 6.1.2305, 10/12/2000; A, 5/23/2005; A, 12/1/2010; A, 3/2/2017]

[**NOTE:** This segment was divided effective 12/1/2010. The standards for Lake Alice and Lake Maloya are under 20.6.4.311 and 20.6.4.312 NMAC, respectively.]

20.6.4.306 CANADIAN RIVER BASIN: The Cimarron river downstream from state highway 21 in Cimarron to the Canadian river and all perennial reaches of tributaries to the Cimarron river downstream from state highway 21 in Cimarron.

NMED Exhibit 27

A. Designated uses: irrigation, warmwater aquatic life, livestock watering, wildlife habitat and primary contact; and public water supply on Cimarroncito creek.

B. Criteria:

(1) The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

(2) TDS 3,500 mg/L or less at flows above 10 cfs.

[20.6.4.306 NMAC - Rp 20 NMAC 6.1.2305.1, 10/12/2000; A, 7/19/2001; A, 5/23/2005; A, 12/1/2010]

20.6.4.307 CANADIAN RIVER BASIN: Perennial reaches of the Mora river from the USGS gaging station near Shoemaker upstream to [~~the state highway 434 bridge in Mora~~]Rio la Casa, all perennial reaches of tributaries to the Mora river downstream from the USGS gaging station at La Cueva in San Miguel and Mora counties except [~~lakes~~]waters identified in 20.6.4.309 NMAC or 20.6.4.313 NMAC, perennial reaches of Ocate creek downstream of Ocate, perennial reaches of tributaries to Ocate creek downstream of Ocate, and perennial reaches of Rayado creek downstream of Miami lake diversion in Colfax county.

A. Designated uses: marginal coldwater aquatic life, warmwater aquatic life, primary contact, irrigation, livestock watering and wildlife habitat.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.307 NMAC - Rp 20 NMAC 6.1.2305.3, 10/12/2000; A, 5/23/2005; A, 12/1/2010; A, 7/10/2012; A, 4/23/2022; A, MM/DD/YYYY]

20.6.4.308 CANADIAN RIVER BASIN: Charette lakes.

A. Designated uses: coldwater aquatic life, warmwater aquatic life, [~~secondary~~]primary contact, livestock watering and wildlife habitat.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.308 NMAC - Rp 20 NMAC 6.1.2305.5, 10/12/2000; A, 5/23/2005; A, 12/1/2010; A, MM/DD/YYYY]

20.6.4.309 CANADIAN RIVER BASIN: The Mora river and perennial reaches of its tributaries upstream from [~~the state highway 434 bridge in Mora~~] Rio la Casa except lakes identified in 20.6.4.313 NMAC, all perennial reaches of tributaries to the Mora river upstream from the USGS gaging station at La Cueva, perennial reaches of Coyote creek upstream of Amola ridge, and perennial reaches of tributaries to Coyote creek upstream to Amola ridge, the Cimarron river above state highway 21 in Cimarron, perennial reaches of tributaries to the Cimarron river above state highway 21 in Cimarron except Eagle Nest lake, all perennial reaches of tributaries to the Cimarron river north and northwest of highway 64 except north and south Shuree ponds, perennial reaches of Rayado creek above Miami lake diversion, perennial reaches of tributaries to Rayado creek above Miami lake diversion, Ocate creek and perennial reaches of its tributaries upstream of Ocate, perennial reaches of the Vermejo river upstream from Rail canyon and all other perennial reaches of tributaries to the Canadian river northwest and north of U.S. highway 64 in Colfax county unless included in other segments.

A. Designated uses: domestic water supply, irrigation, high quality coldwater aquatic life, livestock watering, wildlife habitat, and primary contact; and public water supply on the Cimarron river upstream from Cimarron, on perennial reaches of Rayado creek and on perennial reaches of tributaries to Rayado creek.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: specific conductance 500 µS/cm or less; the monthly geometric mean of *E. coli* bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

20.6.4.310 CANADIAN RIVER BASIN: Perennial reaches of Corrumpa creek.

A. Designated uses: livestock watering, wildlife habitat, irrigation, primary contact and coldwater aquatic life.

B. Criteria:

NMED Exhibit 27

(1) The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: temperature 25°C (77°F) or less; the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

(2) TDS 1,200 mg/L or less, sulfate 600 mg/L or less, chloride 40 mg/L or less.

[20.6.4.310 NMAC - N, 5/23/2005; A, 12/1/2010]

20.6.4.311 CANADIAN RIVER BASIN: Lake Alice.

A. Designated uses: marginal coldwater aquatic life, irrigation, livestock watering, wildlife habitat, primary contact and public water supply.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.311 NMAC - N, 12/1/2010; A, 4/23/2022]

20.6.4.312 CANADIAN RIVER BASIN: Lake Maloya.

A. Designated uses: coldwater aquatic life, irrigation, livestock watering, wildlife habitat, primary contact and public water supply.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.312 NMAC - N, 12/1/2010; A, 4/23/2022]

20.6.4.313 CANADIAN RIVER BASIN: Encantada lake, Maestas lake, Middle Fork lake of Rio de la Casa, North Fork lake of Rio de la Casa and Pacheco lake.

A. Designated uses: high quality coldwater aquatic life, irrigation, domestic water supply, primary contact, livestock watering and wildlife habitat.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: specific conductance 300 µS/cm or less; the monthly geometric mean of *E. coli* bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.313 NMAC - N, 7/10/2012]

20.6.4.314 CANADIAN RIVER BASIN: Shuree ponds (north and south).

A. Designated uses: high quality coldwater aquatic life, irrigation, domestic water supply, primary contact, livestock watering and wildlife habitat.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses except that the following segment-specific criteria apply: specific conductance 500 µS/cm or less; the monthly geometric mean of *E. coli* bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.314 NMAC - N, 7/10/2012]

20.6.4.315 CANADIAN RIVER BASIN: Eagle Nest lake.

A. Designated uses: high quality coldwater aquatic life, irrigation, domestic water supply, primary contact, livestock watering, wildlife habitat and public water supply.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses except that the following segment-specific criteria apply: specific conductance 500 µS/cm or less; the monthly geometric mean of *E. coli* bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.315 NMAC - N, 7/10/2012]

20.6.4.316 CANADIAN RIVER BASIN: Clayton lake.

A. Designated uses: coolwater aquatic life, primary contact, livestock watering and wildlife habitat.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of *E. coli* bacteria 206 cfu/100 mL or less, single sample 940 cfu/100 mL or less.

[20.6.4.316 NMAC - N, 7/10/2012]

20.6.4.317 CANADIAN RIVER BASIN: Springer lake.

A. Designated uses: coolwater aquatic life, irrigation, primary contact, livestock watering, wildlife habitat, and public water supply.

NMED Exhibit 27

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.317 NMAC - N, 7/10/2012; A, 3/2/2017]

20.6.4.318 CANADIAN RIVER BASIN: Doggett creek.

A. Designated uses: Warm water aquatic life, livestock watering, wildlife habitat and primary contact.

B. Criteria: The use-specific criteria in 20.6.4.900 NMAC are applicable to the designated uses, except that the following site-specific criteria apply: the monthly geometric mean of E. coli bacteria 206 cfu/100 mL or less, single sample 940 cfu/100 mL or less.

C. Discharger-specific temporary standard:

(1) Discharger: City of Raton wastewater treatment plant

(2) NPDES permit number: NM0020273, Outfall 001

(3) Receiving waterbody: Doggett creek, 20.6.4.318 NMAC

(4) Discharge latitude/longitude: 36° 52' 13.91" N / 104° 25' 39.18" W

(5) Pollutant(s): nutrients; total nitrogen and total phosphorus

(6) Factor of issuance: substantial and widespread economic and social impacts (40 CFR 131.10(g)(6))

(7) Highest attainable condition: interim effluent condition of 8.0 mg/L total nitrogen and 1.6 mg/L total phosphorus as 30-day averages. The highest attainable condition shall be either the highest attainable condition identified at the time of the adoption, or any higher attainable condition later identified during any reevaluation, whichever is more stringent (40 CFR 131.14(b)(1)(iii)).

(8) Effective date of temporary standard: [~~This temporary standard becomes~~]effective for Clean Water Act purposes on [~~the date of EPA approval~~]July 24,2020.

(9) Expiration date of temporary standard: no later than 20 years from the effective date.

(10) Reevaluation period: at each succeeding review of water quality standards and at least once every five years from the effective date of the temporary standard (Paragraph (8) of Subsection [~~H~~]I of 20.6.4.10 NMAC, 40 CFR 131.14(b)(1)(v)). If the discharger cannot demonstrate that sufficient progress has been made the commission may revoke approval of the temporary standard or provide additional conditions to the approval of the temporary standard. If the reevaluation is not completed at the frequency specified or the Department does not submit the reevaluation to EPA within 30 days of completion, the underlying designated use and criterion will be the applicable water quality standard for Clean Water Act purposes until the Department completes and submits the reevaluation to EPA. Public input on the reevaluation will be invited during NPDES permit renewals or triennial reviews, as applicable, in accordance with the State's most current approved water quality management plan and continuing planning process.

(11) Timeline for proposed actions. Tasks and target completion dates are listed in the most recent, WQCC-approved version of the New Mexico Environment Department, Surface Water Quality Bureau's "Nutrient Temporary Standards for City of Raton Wastewater Treatment Plant, NPDES No. NM0020273 to Doggett Creek."

[20.6.4.318 NMAC - N, 05/22/2020; A, 04/23/2022; A, MM/DD/YYYY]

20.6.4.319 - 20.6.4.400 [RESERVED]

20.6.4.401 SAN JUAN RIVER BASIN: The main stem of the San Juan river from the Navajo Nation boundary at the Hogback upstream to its confluence with the Animas river. Some waters in this segment are under the joint jurisdiction of the state and the Navajo Nation.

A. Designated uses: public water supply, industrial water supply, irrigation, livestock watering, wildlife habitat, primary contact, marginal coldwater aquatic life and warmwater aquatic life.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 32.2°C (90°F) or less.

[20.6.4.401 NMAC - Rp 20 NMAC 6.1.2401, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

[**NOTE:** The segment covered by this section was divided effective 5/23/2005. The standards for the additional segment are under 20.6.4.408 NMAC.]

20.6.4.402 SAN JUAN RIVER BASIN: La Plata river from its confluence with the San Juan river upstream to the New Mexico-Colorado line.

NMED Exhibit 27

A. Designated uses: irrigation, marginal warmwater aquatic life, marginal coldwater aquatic life, livestock watering, wildlife habitat and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 32.2°C (90°F) or less.

[20.6.4.402 NMAC - Rp 20 NMAC 6.1.2402, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.403 SAN JUAN RIVER BASIN: The Animas river from its confluence with the San Juan river upstream to Estes arroyo.

A. Designated uses: Public water supply, industrial water supply, irrigation, livestock watering, wildlife habitat, coolwater aquatic life, and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses[~~, except that the following segment-specific criterion applies: temperature 29°C (84.2°F) or less~~].

[20.6.4.403 NMAC - Rp 20 NMAC 6.1.2403, 10/12/2010; A, 5/23/2005; A, 12/1/2010; A, 3/2/2017; A, MM/DD/YYYY]

20.6.4.404 SAN JUAN RIVER BASIN: The Animas river from Estes arroyo upstream to the Southern Ute Indian tribal boundary.

A. Designated uses: Coolwater aquatic life, irrigation, livestock watering, wildlife habitat, public water supply, industrial water supply and primary contact.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: phosphorus (unfiltered sample) 0.l mg/L or less.

[20.6.4.404 NMAC - Rp 20 NMAC 6.1.2404, 10/12/2010; A, 5/23/2005; A, 12/1/2010; A, 3/2/2017]

20.6.4.405 SAN JUAN RIVER BASIN: The main stem of the San Juan river from Cañon Largo upstream to the Navajo dam.

A. Designated uses: high quality coldwater aquatic life, irrigation, livestock watering, wildlife habitat, public water supply, industrial water supply and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: specific conductance 400 µS/cm or less; the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.405 NMAC - Rp 20 NMAC 6.1.2405, 10/12/2000; A, 5/23/2005; A, 12/1/2010; A, 4/23/2022]

20.6.4.406 SAN JUAN RIVER BASIN: Navajo reservoir in New Mexico.

A. Designated uses: coldwater aquatic life, warmwater aquatic life, irrigation storage, livestock watering, wildlife habitat, public water supply, industrial water supply and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: phosphorus (unfiltered sample) 0.1 mg/L or less; the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.406 NMAC - Rp 20 NMAC 6.1.2406, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.407 SAN JUAN RIVER BASIN: Perennial reaches of the Navajo river from the Jicarilla Apache reservation boundary to the Colorado border and perennial reaches of Los Pinos river in New Mexico.

A. Designated uses: coldwater aquatic life, irrigation, livestock watering, public water supply, wildlife habitat and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: phosphorus (unfiltered sample) 0.1 mg/L or less; the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.407 NMAC - Rp 20 NMAC 6.1.2407, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.408 SAN JUAN RIVER BASIN: The main stem of the San Juan river from its confluence with the Animas river upstream to its confluence with Cañon Largo.

NMED Exhibit 27

A. Designated uses: public water supply, industrial water supply, irrigation, livestock watering, wildlife habitat, primary contact, marginal coldwater aquatic life and warmwater aquatic life.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 32.2°C (90°F) or less.

[20.6.4.408 NMAC - N, 5/23/2005; A, 12/1/2010; A, 4/23/2022]

20.6.4.409 SAN JUAN RIVER BASIN: Lake Farmington.

A. Designated uses: public water supply, wildlife habitat, livestock watering, primary contact, coldwater aquatic life and warmwater aquatic life.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 25°C (77°F) or less.

[20.6.4.409 NMAC - N, 12/1/2010]

20.6.4.410 SAN JUAN RIVER BASIN: Jackson lake.

A. Designated uses: coolwater aquatic life, irrigation, primary contact, livestock watering and wildlife habitat.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of *E. coli* bacteria 206 cfu/100 mL or less, single sample 940 cfu/100 mL or less.

[20.6.4.410 NMAC - N, 7/10/2012]

20.6.4.411 - 20.6.4.450: [**RESERVED**]

20.6.4.451 LITTLE COLORADO RIVER BASIN: The Rio Nutria upstream of the Zuni pueblo boundary, Tampico draw, Agua Remora, Tampico springs.

A. Designated uses: coolwater aquatic life, livestock watering, wildlife habitat and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.451 NMAC - N, 12/1/2010]

20.6.4.452 LITTLE COLORADO RIVER BASIN: Ramah lake.

A. Designated uses: coldwater aquatic life, warmwater aquatic life, irrigation, livestock watering, wildlife habitat and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 25°C (77°F) or less.

[20.6.4.452 NMAC - N, 12/1/2010]

20.6.4.453 LITTLE COLORADO RIVER BASIN: Quemado lake.

A. Designated uses: coolwater aquatic life, primary contact, livestock watering and wildlife habitat.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.453 NMAC - N, 7/10/2012]

20.6.4.454 - 20.6.4.500 [**RESERVED**]

20.6.4.501 GILA RIVER BASIN: The main stem of the Gila river from the New Mexico-Arizona line upstream to Redrock canyon and perennial reaches of streams in Hidalgo county.

A. Designated uses: irrigation, marginal warmwater aquatic life, livestock watering, wildlife habitat and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.501 NMAC - Rp 20 NMAC 6.1.2501, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.502 GILA RIVER BASIN: The main stem of the Gila river from Redrock canyon upstream to the confluence of the West Fork Gila river and East Fork Gila river and perennial reaches of tributaries to the Gila river downstream of Mogollon creek.

NMED Exhibit 27

A. Designated uses: industrial water supply, irrigation, livestock watering, wildlife habitat, marginal coldwater aquatic life, and primary contact[~~ and warmwater aquatic life~~].

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 28°C (82.4°F) or less.

[20.6.4.502 NMAC - Rp 20 NMAC 6.1.2502, 10/12/2010; A, 5/23/2005; A, 12/1/2010; A, 3/2/2017; A. MM/DD/YYYY]

20.6.4.503 GILA RIVER BASIN: All perennial tributaries to the Gila river upstream of and including Mogollon creek.

A. Designated uses: domestic water supply, high quality coldwater aquatic life, irrigation, livestock watering, wildlife habitat and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: specific conductance of 400 µS/cm or less for all perennial tributaries except West Fork Gila and tributaries thereto, specific conductance of 300 µS/cm or less; temperature [~~32.2~~]29°C ([~~90~~]84°F) or less in the east fork of the Gila river and Sapillo creek downstream of Lake Roberts; the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.503 NMAC - Rp 20 NMAC 6.1.2503, 10/12/2010; A, 5/23/2005; A, 12/1/2010; A, 3/2/2017; A, MM/DD/YYYY]

20.6.4.504 GILA RIVER BASIN: Wall lake, Lake Roberts and Snow lake.

A. Designated uses: coldwater aquatic life, irrigation, livestock watering, wildlife habitat and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: specific conductance 300 µS/cm or less.

[20.6.4.504 NMAC - Rp 20 NMAC 6.1.2504, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

[**NOTE:** The segment covered by this section was divided effective 5/23/2005. The standards for the additional segment are under 20.6.4.806 NMAC.]

20.6.4.505 GILA RIVER BASIN: Bill Evans lake.

A. Designated uses: coolwater aquatic life, primary contact, livestock watering and wildlife habitat.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.505 NMAC - N, 7/10/2012]

20.6.4.506 - 20.6.4.600 [RESERVED]

20.6.4.601 SAN FRANCISCO RIVER BASIN: The main stem of the San Francisco river from the New Mexico-Arizona line upstream to [~~state highway 12 at Reserve~~]the confluence with Largo canyon, and perennial reaches of Mule creek.

A. Designated uses: irrigation, [~~marginal warmwater and~~]marginal coldwater aquatic life, livestock watering, wildlife habitat and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.601 NMAC - Rp 20 NMAC 6.1.2601, 10/12/2000; A, 5/23/2005; A, 12/1/2010; A, MM/DD/YYYY]

20.6.4.602 SAN FRANCISCO RIVER BASIN: The main stem of the San Francisco river from [~~state highway 12 at Reserve~~]the confluence with Largo canyon upstream to the New Mexico-Arizona line.

A. Designated uses: coldwater aquatic life, irrigation, livestock watering, wildlife habitat and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: temperature 25°C (77°F) or less.

20.6.4.803 CLOSED BASINS: Perennial reaches of the Mimbres river downstream of the confluence with Allie canyon and all perennial reaches of tributaries thereto.

A. Designated uses: Coolwater aquatic life, irrigation, livestock watering, wildlife habitat and primary contact.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less and temperature of 30°C (86°F) or less.

[20.6.4.803 NMAC - Rp 20 NMAC 6.1.2803, 10/12/2010; A, 5/23/2005; A, 12/1/2010; A, 3/2/2017]

20.6.4.804 CLOSED BASINS: Perennial reaches of the Mimbres river upstream of the confluence with Allie canyon to Cooney canyon, and all perennial reaches of East Fork Mimbres (McKnight canyon) downstream of the fish barrier, and all perennial reaches thereto.

A. Designated uses: Irrigation, domestic water supply, coldwater aquatic life, livestock watering, wildlife habitat and primary contact.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.804 NMAC - Rp 20 NMAC 6.1.2804, 10/12/2010; A, 5/23/2005; A, 12/1/2010; A, 2/28/2018; A, 3/2/2017]

[**NOTE:** The segment covered by this section was divided effective 3/2/2017. The standards for the additional segment are covered under 20.6.4.807 NMAC.]

20.6.4.805 CLOSED BASINS: Perennial reaches of the Sacramento river (Sacramento-Salt Flat closed basin) and all perennial tributaries thereto.

A. Designated uses: domestic water supply, livestock watering, wildlife habitat, marginal coldwater aquatic life and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

[20.6.4.805 NMAC - Rp 20 NMAC 6.1.2805, 10/12/2000; A, 5/23/2005; A, 12/1/2010]

20.6.4.806 CLOSED BASINS: Bear canyon reservoir.

A. Designated uses: coldwater aquatic life, irrigation, livestock watering, wildlife habitat and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criterion applies: specific conductance 300 µS/cm or less.

[20.6.4.806 NMAC - N, 5/23/2005; A, 12/1/2010]

20.6.4.807 CLOSED BASINS: Perennial reaches of the Mimbres river upstream of Cooney canyon and all perennial reaches thereto, including perennial reaches of East Fork Mimbres river (McKnight canyon) upstream of the fish barrier.

A. Designated uses: Irrigation, domestic water supply, high quality coldwater aquatic life, livestock watering, wildlife habitat and primary contact.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: specific conductance 300 µS/cm or less; the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.807 NMAC - N, 3/2/2017]

20.6.4.808 CLOSED BASINS: Perennial and intermittent watercourses within Smelter Tailing Soils Investigation Unit lands at the Chino mines company, excluding those ephemeral waters listed in 20.6.4.809 NMAC and including, but not limited to the mainstem of Lampbright draw, beginning at the confluence of Lampbright Draw with Rustler canyon, all tributaries that originate west of Lampbright draw to the intersection of Lampbright draw with U.S. 180, and all tributaries of Whitewater creek that originate east of Whitewater creek from the confluence of Whitewater creek with Bayard canyon downstream to the intersection of Whitewater creek with U.S. 180.

NMED Exhibit 27

A. Designated uses: Warmwater aquatic life, livestock watering, wildlife habitat and primary contact.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the acute and chronic aquatic life criteria for copper set forth in Subsection I of 20.6.4.900 NMAC shall be determined by multiplying that criteria by the water effect ratio ("WER") adjustment expressed by the following equation:

$$WER = \frac{[10^{0.588+(0.703 \times \log DOC)+(0.395 \times \log Alkalinity)}] \times (\frac{100}{Hardness})^{0.9422}}{19.31}$$

For purposes of this section, dissolved organic carbon (DOC) is expressed in units of milligrams carbon per liter or mg C/L; alkalinity is expressed in units of mg/L as $CaCO_3$, and hardness is expressed in units of mg/L as $CaCO_3$. In waters that contain alkalinity concentrations greater than 250 mg/L, a value of 250 mg/L shall be used in the equation. In waters that contain DOC concentrations greater than 16 mg C/L, a value of 16 mg C/L shall be used in the equation. In waters that contain hardness concentrations greater than 400 mg/L, a value of 400 mg/L shall be used in the equation. The alkalinity, hardness and DOC concentrations used to calculate the WER value are those measured in the subject water sample.

[20.6.4.808 NMAC - N, 3/2/2017]

20.6.4.809 CLOSED BASINS: Ephemeral watercourses within smelter tailing soils investigation unit lands at the Chino mines company, limited to Chino mines property subwatershed drainage A and tributaries thereof, Chino mines property subwatershed drainage B and tributaries thereof (excluding the northwest tributary containing Ash spring and the Chiricahua leopard frog critical habitat transect); Chino mines property subwatershed drainage C and tributaries thereof (excluding reaches containing Bolton spring, the Chiricahua leopard frog critical habitat transect and all reaches in subwatershed C that are upstream of the Chiricahua leopard frog critical habitat); subwatershed drainage D and tributaries thereof (drainages D-1, D-2 and D-3, excluding the southeast tributary in drainage D1 that contains Brown spring) and subwatershed drainage E and all tributaries thereof (drainages E-1, E-2 and E-3).

A. Designated uses: Limited aquatic life, livestock watering, wildlife habitat and secondary contact.

B. Criteria: The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the acute aquatic life criteria for copper set forth in Subsection I of 20.6.4.900 NMAC shall be determined by multiplying that criteria by the water effect ratio ("WER") adjustment expressed by the following equation:

$$WER = \frac{[10^{0.588+(0.703 \times \log DOC)+(0.395 \times \log Alkalinity)}] \times (\frac{100}{Hardness})^{0.9422}}{19.31}$$

For purposes of this section, dissolved organic carbon (DOC) is expressed in units of milligrams carbon per liter or mg C/L; alkalinity is expressed in units of mg/L as $CaCO_3$, and hardness is expressed in units of mg/L as $CaCO_3$. In waters that contain alkalinity concentrations greater than 250 mg/L, a value of 250 mg/L shall be used in the equation. In waters that contain DOC concentrations greater than 16 mg C/L, a value of 16 mg C/L shall be used in the equation. In waters that contain hardness concentrations greater than 400 mg/L, a value of 400 mg/L shall be used in the equation. The alkalinity, hardness and DOC concentrations used to calculate the WER value are those measured in the subject water sample.

[20.6.4.809 NMAC - N, 3/2/2017]

20.6.4.810 CLOSED BASINS: Perennial reaches of Dog Canyon creek.

A. Designated uses: coolwater aquatic life, irrigation, livestock watering, wildlife habitat, public water supply, and primary contact.

B. Criteria: the use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses, except that the following segment-specific criteria apply: the monthly geometric mean of E. coli bacteria 126 cfu/100 mL or less, single sample 235 cfu/100 mL or less.

[20.6.4.810 NMAC - N, 2/13/2018]

20.6.4.811 - 20.6.4.899 [**RESERVED**]

20.6.4.900 CRITERIA APPLICABLE TO EXISTING, DESIGNATED OR ATTAINABLE USES UNLESS OTHERWISE SPECIFIED IN 20.6.4.97 THROUGH 20.6.4.899 NMAC:

NMED Exhibit 27

A. Fish culture and water supply: Fish culture, public water supply and industrial water supply are designated uses in particular classified waters of the state where these uses are actually being realized. However, no numeric criteria apply uniquely to these uses. Water quality adequate for these uses is ensured by the general criteria and numeric criteria for bacterial quality, pH and temperature.

B. Domestic water supply: Surface waters of the state designated for use as domestic water supplies shall not contain substances in concentrations that create a lifetime cancer risk of more than one cancer per 100,000 exposed persons. Those criteria listed under domestic water supply in Subsection J of this section apply to this use.

C. Irrigation and irrigation storage: the following numeric criteria and those criteria listed under irrigation in Subsection J of this section apply to this use:

(1)	dissolved selenium	0.13 mg/L
(2)	dissolved selenium in presence of >500 mg/L SO_4	0.25 mg/L.

D. Primary contact: The following criteria apply to this use:

(1) [~~The monthly geometric mean of~~] E. coli bacteria (monthly geometric mean) [~~of~~] 126 cfu/100 mL or MPN/100 ml[~~,~~].

(2) [~~a single sample of~~]E. coli bacteria (single sample) [~~of~~] 410 cfu/100 mL or MPN/100 mL[~~,~~].

(3) [~~a single sample of~~]total microcystins[~~of~~] 8 µg/L[~~with no more than three exceedances within a 12-month period and~~].

(4) [~~a single sample of~~]cylindrospermopsin[~~of~~] 15 µg/L[~~with no more than three exceedances within a 12-month period, and~~].

(5) pH [~~within the range of~~] 6.6 to 9.0[~~apply to this use. The results for E. coli may be reported as either colony forming units (CFU) or the most probable number (MPN) depending on the analytical method used.~~]

E. Secondary contact: The following criteria apply to this use:

(1) [~~The monthly geometric mean of~~]E. coli bacteria (monthly geometric mean)[~~of~~] 548 cfu/100 mL or MPN/100 mL[~~and~~].

(2) [~~single sample of~~]E. coli bacteria (single sample) 2507 cfu/100 mL or MPN/100 mL[~~apply to this use. The results for E. coli may be reported as either colony forming units (CFU) or the most probable number (MPN), depending on the analytical method used~~].

F. Livestock watering: the criteria listed in Subsection J of this section for livestock watering apply to this use.

G. Wildlife habitat: Wildlife habitat shall be free from any substances at concentrations that are toxic to or will adversely affect plants and animals that use these environments for feeding, drinking, habitat or propagation; can bioaccumulate; or might impair the community of animals in a watershed or the ecological integrity of surface waters of the state. The numeric criteria listed in Subsection J for wildlife habitat apply to this use.

H. Aquatic life: Surface waters of the state with a designated, existing or attainable use of aquatic life shall be free from any substances at concentrations that can impair the community of plants and animals in or the ecological integrity of surface waters of the state. Except as provided in Paragraph (7) of this subsection, the acute and chronic aquatic life criteria set out in Subsections I, J, K and L of this section and the human health-organism only criteria set out in Subsection J of this section are applicable to all aquatic life use subcategories. In addition, the specific criteria for aquatic life subcategories in the following paragraphs apply to surface waters classified under the respective designations.

(1) High quality coldwater: Where a single segment-specific temperature criterion is indicated in 20.6.4.101-899 NMAC, it is the maximum temperature and no 4T3 temperature applies.

(a)	dissolved oxygen	6.0 mg/L or more.
(b)	4T3 temperature	20°C (68°F)[~~,~~].
(c)	maximum temperature	23°C (73°F)[~~,~~].
(d)	pH [~~within the range of~~]	6.6 to 8.8. [~~and~~]
(e)	specific conductance [~~a segment-specific limit between~~]	300 µS/cm and 1,500 µS/cm. This specific conductance criterion is a segment-specific range depending on the natural background in the particular surface water of the state [~~(the intent of this criterion is~~] intended to prevent excessive increases in dissolved solids which would result in changes in community structure[~~)~~]. [~~Where a single segment-specific temperature criterion is indicated in 20.6.4.101-899 NMAC, it is the maximum temperature and no 4T3 temperature applies.~~]

NMED Exhibit 27

(2) Coldwater: Where a single segment-specific temperature criterion is indicated in 20.6.4.101-899 NMAC, it is the maximum temperature and no 6T3 temperature applies.

(a) dissolved oxygen 6.0 mg/L or more[~~,~~].

(b) 6T3 temperature 20°C (68°F)[~~,~~].

(c) maximum temperature 24°C (75°F) [~~and~~].

(d) pH [~~within the range of~~] 6.6 to 8.8.

[~~Where a single segment-specific temperature criterion is indicated in 20.6.4.101-899 NMAC, it is the maximum temperature and no 6T3 temperature applies.~~]

(3) Marginal coldwater: Where a single segment-specific temperature criterion is indicated in 20.6.4.101-899 NMAC, it is the maximum temperature and no 6T3 temperature applies.

(a) dissolved oxygen 6 mg/L or more[~~,~~].

(b) 6T3 temperature 25°C (77°F)[~~,~~].

(c) maximum temperature 29°C (84°F) [~~and~~].

(d) pH [~~within the range from~~] 6.6 to 9.0. [~~Where a single segment-specific temperature criterion is indicated in 20.6.4.101-899 NMAC, it is the maximum temperature and no 6T3 temperature applies.~~]

(4) Coolwater: Where a segment-specific temperature criterion is indicated in 20.6.4.101-899 NMAC, it is the maximum temperature.

(a) dissolved oxygen 5.0 mg/L or more[~~,~~].

(b) maximum temperature 29°C (84°F) [~~and~~].

(c) pH [~~within the range of~~] 6.6 to 9.0.

(5) Warmwater: Where a segment-specific temperature criterion is indicated in 20.6.4.101-899 NMAC, it is the maximum temperature.

(a) dissolved oxygen 5 mg/L or more[~~,~~].

(b) maximum temperature 32.2°C (90°F) [~~and~~].

(c) pH [~~within the range of~~] 6.6 to 9.0.

[~~Where a segment-specific temperature criterion is indicated in 20.6.4.101-899 NMAC, it is the maximum temperature.~~]

(6) Marginal warmwater: Where a segment-specific temperature criterion is indicated in 20.6.4.101-899 NMAC, it is the maximum temperature.

(a) dissolved oxygen 5 mg/L or more[~~,~~].

(b) pH [~~within the range of~~] 6.6 to 9.0 [~~and~~].

(c) maximum temperature[~~s~~] [~~that~~] may [~~routinely~~] exceed 32.2°C (90°F). [~~Where a segment-specific temperature criterion is indicated in 20.6.4.101-899 NMAC, it is the maximum temperature.~~]

(7) Limited aquatic life: pH within the range of 6.0 to 9.0. The acute aquatic life criteria of Subsections I and J of this section apply to this subcategory. Chronic aquatic life criteria do not apply unless adopted on a segment-specific basis. Human health-organism only criteria apply only for persistent toxic pollutants unless adopted on a segment-specific basis.

I. Hardness-dependent acute and chronic aquatic life criteria for metals are calculated using the following equations, excluding aquatic life criteria for copper (Cu) for the Pajarito plateau surface waters in the Rio Grande basin as described in Paragraph (4) of Subsection I of 20.6.4.900 NMAC. The criteria are expressed as a function of hardness (as mg $CaCO_3$/L). With the exception of aluminum, the equations are valid only for hardness concentrations of 0-400 mg/L. For hardness concentrations above 400 mg/L, the criteria for 400 mg/L apply. For aluminum the equations are valid only for hardness concentrations of 0-220 mg/L. For hardness concentrations above 220 mg/L, the aluminum criteria for 220 mg/L apply. Calculated criteria must adhere to the treatment of significant figures and rounding identified in *Standard Methods For The Examination Of Water And Wastewater*, latest edition, American public health association.

(1) Acute aquatic life criteria for metals: The equation to calculate acute criteria in µg/L is $\exp(m_A[\ln(\text{hardness})] + b_A)(CF)$. Except for aluminum, the criteria are based on analysis of dissolved metal. For aluminum, the criteria are based on analysis of total recoverable aluminum in a sample that has a pH between 6.5 and 9.0 and is filtered to minimize mineral phases as specified by the department. The equation parameters are as follows:

Metal	m_A	b_A	Conversion factor (CF)
Aluminum (Al)	1.3695	1.8308	
Cadmium (Cd)	0.9789	-3.866	1.136672-[(ln hardness)(0.041838)]

NMED Exhibit 27

Chromium (Cr) III	0.8190	3.7256	0.316
Copper (Cu)	0.9422	-1.700	0.960
Lead (Pb)	1.273	-1.460	1.46203-[(ln hardness)(0.145712)]
Manganese (Mn)	0.3331	6.4676	
Nickel (Ni)	0.8460	2.255	0.998
Silver (Ag)	1.72	-6.59	0.85
Zinc (Zn)	0.9094	0.9095	0.978

(2) Chronic aquatic life criteria for metals: The equation to calculate chronic criteria in µg/L is $\exp(m_C[\ln(\text{hardness})] + b_C)(CF)$. Except for aluminum, the criteria are based on analysis of dissolved metal. For aluminum, the criteria are based on analysis of total recoverable aluminum in a sample that has a pH between 6.5 and 9.0 and is filtered to minimize mineral phases as specified by the department. The equation parameters are as follows:

Metal	**m_C**	**b_C**	**Conversion factor (CF)**
Aluminum (Al)	1.3695	0.9161	
Cadmium (Cd)	0.7977	-3.909	1.101672-[(ln hardness)(0.041838)]
Chromium (Cr) III	0.8190	0.6848	0.860
Copper (Cu)	0.8545	-1.702	0.960
Lead (Pb)	1.273	-4.705	1.46203-[(ln hardness)(0.145712)]
Manganese (Mn)	0.3331	5.8743	
Nickel (Ni)	0.8460	0.0584	0.997
Zinc (Zn)	0.9094	0.6235	0.986

(3) Selected values of calculated acute and chronic criteria (µg/L).

(4) Copper criteria for Pajarito plateau surface waters: Pajarito plateau surface waters extend from Guaje canyon in the north to the Rito de los Frijoles watershed in the south, from their headwaters to their confluence with the Rio Grande and all tributaries and streams thereto. The equations used to calculate copper criteria, for purposes of this Part, use dissolved organic carbon (DOC) in units of milligrams carbon per liter (mg C/L); and hardness in units of mg/L as $CaCO_3$. In waters that contain DOC concentrations greater than 29.7 mg/L, a value of 29.7 mg/L shall be used in the following equations. In waters that contain hardness concentrations greater than 207 mg/L, a value of 207 mg/L shall be used in the following equations.

(a) Acute aquatic life criteria: The equation to calculate acute criteria in µg/L is $\exp(-22.914+1.017\times\ln(DOC)+0.045\times\ln(hardness)+5.176\times pH-0.261\times pH^2)$.

(b) Chronic aquatic life criteria: The equation to calculate chronic criteria in µg/L is $\exp(-23.391+1.017\times\ln(DOC)+0.045\times\ln(hardness)+5.176\times pH-0.261\times pH^2)$.

J. Use-specific numeric criteria.

(1) Table of numeric criteria: The following table sets forth the numeric criteria in µg/L, unless otherwise indicated, applicable to existing, designated and attainable uses. For metals, criteria represent the total sample fraction unless otherwise specified in the table. Additional criteria that are not compatible with this table are found in Subsections A through I and K through M of 20.6.4.900 NMAC.

(2) Notes applicable to the table of numeric criteria in Paragraph (1) of this subsection.

(a) Where the letter "a" is indicated in a cell, the criterion is based on receiving water characteristics and can be referenced in Subsection I of 20.6.4.900 NMAC.

(b) Where the letter "b" is indicated in a cell, the criterion can be referenced in Subsection C of 20.6.4.900 NMAC.

(c) [~~Criteria are in µg/L unless otherwise indicated.~~] Selenium water column criteria include 30-day mean dissolved selenium concentrations for lentic systems, including lakes and impoundments, and lotic systems, including rivers and streams.

(d) In addition to the definitions for units provided in Subsection A of 20.6.4.7 NMAC, [~~Abbreviations~~] abbreviations in the table are as follows: CAS - chemical abstracts service [~~(see definition for "CAS number" in 20.6.4.7 NMAC)~~]; DWS - domestic water supply; Irr/Irr storage- irrigation and irrigation storage; LW - livestock watering; WH - wildlife habitat; HH-OO - human health-organism only; C – criteria based on cancer-causing endpoint; P - persistent toxic pollutant.

(e) The criteria are based on analysis of an unfiltered sample unless otherwise indicated. The acute and chronic aquatic life criteria for aluminum are based on analysis of total recoverable aluminum in a sample that is filtered to minimize mineral phases as specified by the department.

(f) The criteria listed under human health-organism only (HH-OO) are intended to protect human health when aquatic organisms are consumed from waters containing pollutants. These criteria do not protect the aquatic life itself; rather, they protect the health of humans who ingest fish or other aquatic organisms.

(g) The dioxin criteria apply to the sum of the dioxin toxicity equivalents expressed as 2,3,7,8-TCDD dioxin.

(h) The criteria for polychlorinated biphenyls (PCBs) apply to the sum of all congeners, to the sum of all homologs or to the sum of all aroclors.

(i) The acute and chronic aquatic life criteria for dissolved aluminum only apply when the concurrent pH is less than 6.5 or greater than 9.0 S.U. If the concurrent pH is between 6.5 and 9.0 S.U. then the hardness-dependent total recoverable aluminum criteria in Paragraphs (1) and (2) of Subsection I of 20.6.4.900 NMAC apply.

K. The criteria for total ammonia consider sensitive freshwater mussel species in the family Unionidae, freshwater non-pulmonate snails, and *Oncorhynchus* spp. (a genus of fish in the family Salmonidae), hence further protecting the aquatic community. The total ammonia criteria magnitude is measured as Total Ammonia Nitrogen (TAN) mg/L. TAN is the sum of NH_4^+ and NH_3. TAN mg/L magnitude is derived as a function of pH and temperature (EPA 2013).

L. The acute aquatic life criteria for TAN (mg/L) was derived by the EPA (2013) as the one-hour average concentration of TAN mg/L that shall not be exceeded more than once every three years on average. The EPA acute criterion magnitude was derived using the following equation:

Acute TAN Criterion Magnitude for 1-hour average=

NMED Exhibit 27

$$\text{MIN}\left(\left(\frac{0.275}{1+10^{7.204-pH}}+\frac{39}{1+10^{pH-7.204}}\right),\left(0.7249\text{x}\left(\frac{0.0114}{1+10^{7.204-pH}}+\frac{1.6181}{1+10^{pH-7.204}}\right)\text{x}\left(23.12\times10^{0.036(20-T)}\right)\right)\right)$$

*T (*temperature C) and *pH* are defined as the paired values associated with the TAN sample.

(1) Temperature and pH-dependent values of the acute TAN criterion magnitude -when *Oncorhynchus* spp. absent.

M. The chronic aquatic life criteria for TAN (mg/L) was derived by the EPA (2013) as a thirty-day rolling average concentration of TAN mg/L that shall not be exceeded more than once every three years on average. In addition, the highest four-day average within the 30-day averaging period should not be more than 2.5 times the CCC (e.g., 2.5 x 1.9 mg TAN/L at pH 7 and 20°C, or 4.8 mg TAN/L) more than once in three years on average. The EPA chronic criterion magnitude was derived using the following equation:

Chronic TAN Criterion Magnitude for 30-day average=

$$0.8876 \times \left(\frac{0.0278}{1+10^{7.688-pH}} + \frac{1.1994}{1+10^{pH-7.688}}\right) \times \left(2.126 \times 10^{0.028\times(20-MAX(T,7))}\right)$$

*T (*temperature °C) and *pH* are defined as the paired values associated with the TAN sample.

Temperature and pH-Dependent Values of the Chronic TAN Criterion Magnitude.

STATE OF NEW MEXICO
WATER QUALITY CONTROL COMMISSION

IN THE MATTER OF:

PETITION FOR REGULATORY CHANGE TO
ADOPT AMENDMENTS TO 20.6.4 NMAC –
Standards For Interstate and Intrastate Surface Waters **WQCC 25-75 (R)**

DIRECT TECHNICAL TESTIMONY OF LYNETTE GUEVARA

I. INTRODUCTION

My name is Lynette Guevara and I present this written testimony (**NMED Exhibit 28)** on behalf of the New Mexico Environment Department (NMED or Department) Surface Water Quality Bureau (SWQB or Bureau) concerning the SWQB's proposed amendments to the State of New Mexico's Standards for Interstate and Intrastate Surface Waters (Standards), codified as Title 20, Chapter 6, Part 4 of the New Mexico Administrative Code (20.6.4 NMAC). My testimony outlines the reason behind the following proposed changes:

- amend and update language in 20.6.4.8 NMAC regarding best management practices and maintain a list of ONRWs with documented impairment;
- amend language in 20.6.4.12 NMAC to acknowledge that New Mexico's water quality standards at 20.6.4.900(I) NMAC contain numeric criteria calculations that are dependent on more than concurrent hardness as input values;
- strike language in the Sampling and Analysis section at 20.6.4.14(C) NMAC;
- amend 20.6.4.135 NMAC to include Santa Cruz Lake;
- amend 20.6.4.208, 20.6.4.209, 20.6.4.231, 20.6.4.307, 20.6.4.309, and 20.6.4.403 NMAC to describe the water quality segment breaks by hydrologic feature rather than road crossing and remove unnecessary language; and

- amend 20.6.4.206, 20.6.4.219, 20.6.4.231, and 20.6.4.309 NMAC to change the recreational use designation from secondary contact to primary contact for specified classified waters.

II. QUALIFICATIONS

Since October 2022, I have been the Program Manager for the Monitoring, Assessment, and Standards Section (MASS) for the SWQB, providing grant, project, and program management to three team supervisors with three to five technical staff each. The Monitoring Team's core responsibility is the collection and data management of ambient surface water quality data for all streams, rivers, lakes, and reservoirs around the state on a rotational, watershed schedule. The Standards and Outreach Team's core responsibility is the development and maintenance of New Mexico's water quality standards (WQS) at 20.6.4 NMAC, outreach activities, and data quality assurance procedures. The TMDL and Assessment Team's core responsible is the development and maintenance of SWQB's assessment methodologies (used to determine whether the state's waterbodies are attaining water quality standards and supporting designated uses based on available data), the Clean Water Act (CWA) § 303(d)/§ 305(b) Integrated Report, and the development of total maximum daily load (TMDL) planning documents for each waterbody not meeting standards. The data, assessment, reporting, and planning products created and managed by MASS provide vital information to SWQB's permitting and watershed restoration sections.

I began work with the Department at SWQB in August 2001 as the CWA §303(d)/§305(b) Assessment Coordinator, a role I held for 19 years among other duties including TMDL writing, database design and oversite, and project management. I have had various supervisory and technical roles related to water quality monitoring, assessment, reporting, and standards revisions

during my 25 years with the Department, all focused on water quality. I have collaborated with the U.S. Environmental Protection Agency (EPA) and their contractors as well as surrounding state colleagues numerous times to develop improved surface water assessment methodologies and data reporting tools.

From 1997-2001, I designed, implemented, and supervised water quantity and quality monitoring as well as watershed restoration projects for the Navajo Nation Water Management Branch and Navajo Nation Environmental Protection Agency. I have a Bachelor of Business Administration degree from Gonzaga University and a Master of Science degree in Watershed Science from Colorado State University. I have contributed to several publications as detailed in my updated resume (**NMED Exhibit 29)**.

III. AMENDMENTS ASSOCIATED WITH ONRW IMPLEMENTATION PLAN AND REPORTING

The Department is proposing to amend and update language in 20.6.4.8 NMAC regarding the first occurrence of "best management practices" (BMPs) and use "BMPs" thereafter for consistency and efficiency. In new subsection 20.6.4.8(B)(17) NMAC, the Department proposes to add language to clarify that the Department maintains and publishes a list of Outstanding National Resource Waters (ONRWs) with documented impairments through our Integrated List (Appendix A of the State of New Mexico CWA § 303(d)/§ 305(b) Integrated Report, which is available on the Bureau's website[1] **(NMED Exhibit 30).** All assessment units (AUs, map lines or polygons that represent a single lake or reservoir, length of a stream reach or river, or surface waters within a delineated area such as a sub-watershed) designated as ONRWs are noted as such

[1] https://www.env.nm.gov/surface-water-quality/303d-305b/

in the associated "AU Comment" field including the related ONRW bundle and year established. For example, the Integrated List AU entry for "McCrystal Creek (North Ponil to headwaters)" includes an "AU Comment" that states "ONRW (Valle Vidal, 2006)." Along with many other GIS layers relevant to surface water quality including layers that delineate assessed and impaired waters, SWQB created and maintains a GIS layer of all ONRWs approved by the Water Quality Control Commission (WQCC) by short title and year established on the publicly available Surface Water Quality OpenEnviroMap[2].

In addition, in cooperation with stakeholders, the Department collaborated to create and maintain a Memorandum of Understanding (MOU) with the U.S. Forest Service Southwestern Region[3] (**NMED Exhibit 31).** The MOU serves to increase communication, coordination, and notification of activities with the potential to impact water quality in ONRWs by the Forest Service to the Department. For example, **NMED Exhibit 32** is an example of the recent notification the Forest Service sent SWQB to keep us aware of response activities for the McCauley Springs Fire with potential impacts to ONRWs in the area. The SWQB has also initiated efforts to increase volunteer monitoring of surface water quality with an initial focus on ONRWs through modifying existing grant funding and associated work plans to fund outreach coordination activities and recently met with New Mexico Wild to discuss how we can collaborate with and support each other's volunteer monitoring efforts, starting with a goal of increased ONRW monitoring during the upcoming 2027 SWQB Upper Rio Grande ambient water quality survey.

[3] https://www.env.nm.gov/surface-water-quality/watershed-protection-section/

IV. AMENDMENTS ASSOCIATED WITH COMPLIANCE WITH WATER QUALITY STANDARDS DEPENDENT ON RECEIVING WATER CHARACTERISTICS

The Department proposes to amend language in 20.6.4.12(F) NMAC to clarify that New Mexico's water quality standards at 20.6.4.900(I) NMAC contain numeric criteria calculations that are dependent on more than concurrent hardness as input values to consider receiving water characteristics. For example, copper criteria for Pajarito Plateau surface waters at 20.6.4.900(I)(4) NMAC are dependent on hardness, dissolved organic carbon, and pH. The Department further clarifies that if concurrently collected receiving water data (preferred) are not available, default values that are justified in writing and supported by ecoregional or other watershed data may be acceptable to acknowledge that concurrent collection of or access to several additional input parameters is not always possible or practical due to potential field equipment failure, increased laboratory analysis costs, or other sampling constraints. EPA defines "ecoregions" as delineated areas where the type, quality, and quantity of environmental resources are generally similar **NMED Exhibit 33)**. EPA identifies and categorizes ecoregions into four hierarchical levels by analyzing the patterns and composition of biotic and abiotic characteristics that affect or reflect differences in ecosystem quality and integrity. These characteristics include geology, landforms, soils, vegetation, climate, land use, wildlife, and hydrology. EPA prepared guidance on the data analysis approaches EPA used to develop recommendations for default values for water quality parameters used in the copper biotic ligand model when input data are lacking (**NMED Exhibit 34).**

V. AMENDMENTS ASSOCIATED WITH SAMPLING AND ANALYSIS

The Department proposes to strike the last sentence of 20.6.4.14(C)(3) NMAC that dictates precisely how and when lentic water quality samples shall be collected. The current wording is confusing and has resulted in differing interpretations over the years. For example, it is unclear to some attempting to interpret the phrase "Water quality measurements…" if it is referring specifically to basic field parameters such as temperature, pH, dissolved oxygen, and specific conductance as collected by a sonde or if it was intended to cover all collected samples. In addition, the exception for "attainment of criteria for toxic pollutants" does not make sense in the case of cyanotoxin sampling intended to determine if there is a suspected harmful algal bloom forming because these toxins are related to recreational uses and activities so should therefore be sampled at shallow recreational lake stations near the shore and dock areas where primary contact is most likely versus at depth in the middle of the lake.

The Department believes it is a better and more standard practice to provide this level of sampling specifics in relevant Standard Operating Procedures (SOPs) that can be reviewed and updated periodically with the latest limnological monitoring knowledge. Specifically, detailed procedural sampling information should and does reside in SWQB's SOP 12.1 - Lake Sampling[4] (**NMED Exhibit 35**), which is reviewed and updated a minimum of every two years by the SWQB monitoring staff with lake sampling, fisheries, and quality assurance technical expertise. Documenting sampling procedure details such as these in the SOPs provides the Department flexibility to ensure SWQB's lake monitoring techniques are aligned with the current lake monitoring state of knowledge and best practices such as those proposed and maintained by EPA's

[4] https://www.env.nm.gov/surface-water-quality/sop/

National Lakes Assessment (NLA) (**NMED Exhibit 36**) and aligned with professional limnology and the North American Lake Management Society (NALMS) framework. Being able to directly align and standardize New Mexico's sampling and analysis protocols with EPA, NALMS, and surrounding states allows SWQB to collate regional data into larger datasets that we can then use to statistically analyze and use as model inputs to improve data analysis and assessment methodologies.

V. AMENDMENTS ASSOCIATED WITH CLASSIFIED WATER SEGMENT DESCRIPTIONS AND USES

A. Amend 20.6.4.135 NMAC to include Santa Cruz Lake

The Department proposes to amend lake-specific segment 20.6.4.135 NMAC with a designated coldwater aquatic life use (CWAL) to include Santa Cruz Lake based on similarities to Bluewater Lake, physical location, fisheries data and management, and available temperature and modeling data; available air-water temperature and other modeling performed during SWQB's development of the 2024 WQCC and EPA approved temperature TMDL; and elevation and ecoregion data.

Santa Cruz Lake is a reservoir located in north-central New Mexico in the Sangre de Cristo foothills at an elevation of 6,286 feet. The Santa Cruz Irrigation District owns the concrete gravity dam completed in 1929 to create Santa Cruz Lake for the purposes of irrigation and recreation. The New Mexico Office of the State Engineer is the regulatory authority. Water released from Santa Cruz Lake is primarily used for irrigation, and lake levels can drop significantly during times of high irrigation need. The reservoir has a surface area of approximately 100 acres, with an estimated normal storage of approximately 3,000 acre-feet. Santa Cruz Lake is fed by the Rio Medio and the Rio Frijoles, which converge just upstream of the lake to form the Santa Cruz River.

The reservoir is the primary focus of the Santa Cruz Recreational Area, managed and maintained by the Bureau of Land Management (BLM), providing hiking, fishing, camping, paddling, and boating opportunities for the public **(NMED Exhibit 37)**.

The New Mexico Department of Wildlife (NMDOW) stocks Santa Cruz Lake with triploid (sterile, non-reproducing) rainbow trout to maintain a put-and-take fishery, defined as where waters are stocked with catchable trout to be immediately harvested by anglers especially where angler demand significantly exceeds natural production. The NMDOW also acknowledges a wild population of brown trout, with a note that irrigation withdrawals causing dramatic drops in lake levels through the summer can limit wild trout potential (**NMED Exhibit 38**). Although "no swimming" signs are posted at Santa Cruz Lake as a safety precaution due to the dam design and excessive amounts of fishhooks and other foot hazards in the sediment, it does occur and there is also incidental full immersion when falling off paddleboards and other watercraft.

In 2011, the Department petitioned the WQCC for a rulemaking to consider amendments to the WQS for 62 lakes that were classified with streams[5]. As a result, the WQCC and EPA approved the creation of 19 lake-specific water quality standard segments in 20.6.4 NMAC **(NMED Exhibit 39)**. Both the Department and the WQCC promoted and supported this action to recognize that lakes and streams are different and warrant specific recognition of this fact in 20.6.4 NMAC. This reality is supported by the need to classifying waters into water quality "segments" that are assigned the same designated uses and criteria through the following definition of "segment" at 20.6.4.7(S)(2) NMAC:

> a classified water of the state described in 20.6.4.101 through 20.6.4.899 NMAC. The water within a segment should have the same uses, similar hydrologic characteristics

[5] https://www.env.nm.gov/surface-water-quality/lakes-amendment/

or flow regimes, and natural physical, chemical and biological characteristics and exhibit similar reactions to external stresses, such as the discharge of pollutants.

Some segment descriptions are unclearly written and can be interpreted to include both lakes and stream or river reaches leading to confusion during assessment and permitting processes, and do not adhere to the intention of the definition of "segment." Lakes and streams have very different hydrologic characteristics and residence times that affect physical characteristics such as bottom sediments, temperature, and dissolved oxygen, as well as nutrient cycling. This in turn impacts resident biological communities that respond to these differing characteristics. Recreational patterns and levels also generally vary between streams and lakes. Classifying lakes into lake-specific segments separately from streams allows for the correct identification of existing and designated uses and application of appropriate criteria to protect those uses.

The WQCC approved 20.6.4.135 NMAC during this action to provide clear, concise water quality protection for Bluewater Lake within Bluewater Lake State Park. This 610-acre reservoir is at an elevation of 7,375 feet and is located within Bluewater Lake State Park in northwestern New Mexico. Bluewater Lake was created for irrigation purposes and shares many characteristics with Santa Cruz Lake. In addition, they are both popular water bodies for picnicking, fishing, boating, paddleboarding, and nearby camping. Similar to Santa Cruz Lake, NMDOW stocks Bluewater Lake with triploid (sterile, non-reproducing) rainbow trout to maintain a put-and-take fishery.

Unlike most other lakes and reservoirs in New Mexico, Santa Cruz Lake is not currently identified under a lake-specific water quality standard segment. This has made it unclear what WQS segment Santa Cruz Lake falls under because it is not currently explicitly noted in any lake-specific or other classified segment like other lakes. Given the active put-and-take rainbow trout

fishery and noted wild brown trout population, assigning Santa Cruz Lake to the default perennial waters segment under 20.6.4.99 NMAC with warmwater aquatic life, higher default primary contact *E. coli* criteria, and no irrigation use would be under protective of current swimmable and fishable goals, and irrigation and recreation purposes. Therefore, the Department proposes to amend section 20.6.4.135 NMAC to include Santa Cruz Lake. The table below provides a comparison of designated uses in the segments noted above:

Designated Uses	**Default Perennial 20.6.4.99**	**Proposed 20.6.4.135**
Coldwater aquatic life		X
Warmwater aquatic life	X	
Domestic water supply		X
Irrigation		X
Primary contact	X	X
Livestock watering	X	X
Wildlife habitat	X	X

Available water quality data confirms that the segment-specific *E. coli* sample 235 cfu/100 mL or less can be achieved (**NMED Exhibit 40**). Irrigation is clearly an applicable and ongoing use because the dam was built to create the reservoir to provide irrigation. The Department does not have sufficient information to either confirm or refute domestic water supply as an existing use.

Existing fisheries and modeled lake temperatures at Santa Cruz Lake are consistent with the definition of coldwater aquatic life use descriptions and associated 6T3 and maximum temperature criteria of 20°C (68°F) and 24°C (75°F), respectively. The Department prepared a temperature TMDL for Santa Cruz Lake in 2024. During TMDL development, ecosystem parameters were used to model predicted typical water temperature. Model results indicated that

Santa Cruz Lake summer water levels typically peaked between 24°C and 25°C from 1995 – 2021 (**NMED Exhibit 41**).

The existing lake-specific segment in the Rio Grande Basin that best describes Santa Cruz Lake is 20.6.4.135 NMAC given the lake elevation and latitude, fisheries data and management, available temperature data, and modeling results. Adding Santa Cruz Lake to the existing lake-specific segment 20.6.4.135 NMAC provides regulatory clarity and appropriately protects existing and attainable uses of this important water resource.

B. Amendments to 20.6.4.208, 20.6.4.209, 20.6.4.231, 20.6.4.307, and 20.6.4.309 NMAC to describe segment breaks by hydrologic features rather than road crossings

The Department proposes to amend several water quality segment breaks in 20.6.4 NMAC to describe the segment breaks by hydrologic features rather than by road crossings. Water quality segment breaks at roads have no hydrologic, ecological, or environmental significance, and are an artifact of human activities. In addition, SWQB believes WQS breaks at highway crossings in 20.6.4 NMAC may simply be an artifact of historic water quality sampling stations established several decades ago at road crossings, particularly in locations surrounded by private land where the bridge right of way was the only available water quality sampling access point.

The Department proposed to amend the Rio Penasco segment description break at "state highway 24 near Dunken" to "Bear Canyon *(sic)*" in 20.6.4.208 and 20.6.4.231 NMAC. During direct testimony development, the Department recognized a typographical error and changes its proposal to amend the segment description break at "state highway 24 near Dunken" to "Big Cherry Canyon" (**NMED Exhibit 42**) in 20.6.4.208 and 20.6.4.231 NMAC as noted in green:

> **20.6.4.208 PECOS RIVER BASIN: Perennial reaches of the Rio Peñasco above [~~state highway 24 near Dunken~~] Big Cherry Canyon, perennial reaches of tributaries to the Rio Peñasco above [~~state highway 24 near Dunken~~] Big Cherry Canyon, perennial reaches of Cox canyon, perennial reaches of**

the Rio Bonito downstream from [~~state highway 48 (near Angus)~~] Angus canyon, the Rio Ruidoso downstream of [~~the U.S. highway 70 bridge~~] Palo Verde canyon near Seeping Springs lakes, perennial reaches of the Rio Hondo upstream from Bonney canyon and perennial reaches of Agua Chiquita.

…

20.6.4.231 PECOS RIVER BASIN: The main stem of the Pecos river from the headwaters of Brantley reservoir upstream to Salt creek (near Acme), perennial reaches of the Rio Peñasco downstream from [~~state highway 24 near Dunken~~] Big Cherry Canyon, [~~perennial reaches of North Spring river and~~]perennial reaches of the Rio Hondo and perennial reaches of its tributaries downstream of Bonney canyon.

This proposed action moves the segment break approximately 4.05 miles downstream. The revised segment break moves the break to the outlet of the same U.S. Geological Survey (USGS) 12-digit Hydrologic Unit Code (HUC) watershed (Copeland Canyon-Rio Penasco); and is in the same EPA Level IV Ecoregion (26q – Southern New Mexico Dissected Plains), and land use type (private). There are no point source discharge permits impacted by this proposed change.

The Department proposes to amend the Rio Bonito segment description break at "state highway 48 (near Angus)" to "Angus Canyon" in 20.6.4.208 and 20.6.4.209 NMAC (**NMED Exhibit 43**). The revised segment break moves the break approximately 0.05 miles downstream; and is in the same USGS 12-digit HUC watershed (Middle Rio Bonito), EPA Level IV Ecoregion (23e – Conifer Woodlands and Savannas), and land use type (private). There are no point source discharge permits impacted by this proposed change. The Department also proposes to amend the Rio Ruidoso segment description break at "the U.S. highway 70 bridge" to "Palo Verde Canyon" in 20.6.4.208 and 20.6.4.209 NMAC (**NMED Exhibit 44**). The revised segment break moves the break moves the break approximately 0.58 miles upstream; and is in the same USGS 12-digit HUC watershed (Middle Rio Ruidoso), EPA Level IV Ecoregion (23b – Madrean Lower Montane Woodlands), and land use type (private). NPDES permit NM0029165 is in the area but not impacted by this proposed change because it remains under 20.6.4.208 NMAC. The proposed

amendment to delete "perennial reaches of North Spring river" and replace with "perennial reaches of its tributaries" is explained below in Section C.

In sections 20.6.4.307 and 20.6.4.309 NMAC, the Department proposes to amend the Mora River segment description break at "the state highway 434 bridge in Mora" to "Rio la Casa" (**NMED Exhibit 45)**. This proposed action moves the segment break approximately 1.72 miles upstream to the confluence with tributary Rio La Casa at the USGS 12-digit HUC watershed outlet. The EPA Level IV Ecoregion will change because stretch of river contains the break from ecoregion 21c (Crystalline Mid-Elevation Forests) and 21f (Sedimentary Mid-Elevation Forests). The land use type remains the same (private). The NPDES permit NM0031097 (Mora High School permit for dewatering their football field that naturally floods occasionally) immediately upstream of the highway crossing would be impacted by this proposed change because it would now fall under 20.6.4.307 NMAC with a less stringent aquatic life use. SWQB would re-assess and open any related TMDLs as needed to revise any relevant permit waste load allocations to provide the information for the 7/31/2028 permit renewal.

The Department also proposes to expand the exceptions list of waters identified in 20.6.4.307 NMAC by striking the word "lakes" and adding "…20.6.4.309 NMAC or…" while concurrently revising the reference to Coyote Creek in 20.6.4.309 NMAC to "perennial reaches of Coyote creek upstream of Amola ridge and perennial reaches of tributaries to Coyote creek upstream to Amola ridge" (**NMED Exhibit 46)**. The whole of Coyote Creek is covered by both 20.6.4.307 and 20.6.4.309 NMAC as currently written. Amola Ridge is a prominent geologic formation where Coyote Creek transitions from the high plains to a thin band of foothills as reflected in the EPA Level III Ecoregion change from category 21 (Southern Rockies) to 26 (Southwest Tablelands) and specifically acknowledged by a narrow band of EPA Level IV

Ecoregion 21d where the Department proposes the segment break. As such, Coyote Creek from the Mora River to Amola Ridge is in the corresponding Xeric sedimentation class until Amola Ridge where it transitions into first the Foothills sedimentation class and then further upstream into the Mountain sedimentation class based on EPA Level III and IV ecoregions as documented in the Sedimentation assessment methodologies (**NMED Exhibit 47**). For these reasons, Amola Ridge is the appropriate geological and topographic segment break point between 20.6.4.307 and 20.6.4.309 NMAC on Coyote Creek to discern which stream reaches of Coyote Creek are covered by these two WQS segments. Adding this break point provides clarity to permitting and CWA §303(d)/§305(b) assessment processes.

C. Amendments to 20.6.4.206, 20.6.4.219, 20.6.4.231, 20.6.4.308, associated with Recreational Use Analysis

Per CFR 131.20(a), states shall re-examine any waterbody segment with water quality standards that do not include the uses specified in section 101(a)(2) of the CWA (i.e., fishable/swimmable uses) every three years to determine if any new information has become available. If this information indicates that the uses specified in 101(a)(2) of the CWA are attainable, the state shall revise its standards accordingly.

Based on the findings in the Department's *Recreational Use Analysis for Classified Waters 20.6.4.101-20.6.4.899 NMAC* (**NMED Exhibit 48**), the Department proposes to amend language in segments 20.6.4.206 and 20.6.4.231 NMAC, as well as 20.6.4.219 and 20.6.4.308 NMAC.

The Department proposes to strike from 20.6.4.206 NMAC's segment description "and perennial reaches of tributaries to the Rio Hondo downstream of Bonney canyon, excluding North Spring river" and concurrently add "perennial reaches of its tributaries" to the Rio Hondo downstream of Bonney canyon to 20.6.4.231 NMAC (**NMED Exhibit 49**). Berrendo Creek and

North Spring River are the only two perennial tributaries to the Rio Hondo downstream of Bonney Canyon. The Department reviewed available 2021-2022 *E. coli* and pH data and determined a recreational use change from Secondary Contact to Primary Contact is warranted because all available pH data were within 6.6 to 9, and 5 of 6 *E. coli* measurements were below 410 cfu/100 mL. Therefore, the Department proposed concurrent changes to both 20.6.4.206 and 20.6.4.231 NMAC to reflect the assignment of Primary Contact to both Berrendo Creek and North Spring River. No *E. coli* and pH data were available for perennial reaches of the Rio Felix to determine if a change from secondary to primary contact was warranted; therefore, Secondary Contact remains the recreational designated use for the revised 20.6.4.206 NMAC. In addition, while preparing direct testimony and exhibits, the Department noticed a reference to "state highway 24 near Dunken" in the "NOTE" portion of 20.6.4.206 NMAC. To be consistent with the proposed segment break change to "Big Cherry Canyon" for the reason stated in Paragraph B earlier in my testimony, the Department proposes to make the below change in this 20.6.4.206 NMAC "NOTE" section for consistency along with adding "and perennial reaches of its tributaries downstream of Bonney canyon" as shown in green below:

20.6.4.206 PECOS RIVER BASIN: Perennial reaches of the Rio Felix[~~ and perennial reaches of tributaries to the Rio Hondo downstream of Bonney canyon, excluding North Spring river~~].

A. Designated uses: irrigation, livestock watering, wildlife habitat, secondary contact and warmwater aquatic life.

B. Criteria:

(1) The use-specific numeric criteria set forth in 20.6.4.900 NMAC are applicable to the designated uses.

(2) At all flows above 50 cfs: TDS 14,000 mg/L or less, sulfate 3,000 mg/L or less and chloride 6,000 mg/L or less.

[20.6.4.206 NMAC - Rp 20 NMAC 6.1.2206, 10/12/2010; A, 5/23/2005; A, 12/1/2010; A, 3/2/2017; A, 4/23/2022; A, MM/DD/YYYY]

[**NOTE:** This segment was divided effective 4/23/2022. The standards for the main stem of the Pecos river from the headwaters of Brantley reservoir upstream to Salt creek (near Acme), perennial reaches of the Rio Peñasco downstream from [~~state highway 24 near Dunken~~]Big Cherry Canyon, and perennial reaches of the Rio Hondo and perennial reaches of its tributaries downstream of Bonney canyon are under 20.6.4.231 NMAC.]

The Department proposes to amend 20.6.4.219 NMAC (Avalon Reservoir) to change the recreational use from Secondary Contact to Primary Contact. Recreation at Avalon Reservoir is managed by the Carlsbad Irrigation District under agreement with the Bureau of Reclamation. The recreation area is open year-round. Management at nearby Brantley Lake reports that Avalon Reservoir has "… a lot of public use including paddle boarding and kayaking, as well as high traffic for fishing and swimming." The Department reviewed available 2025-2026 *E. coli* and pH data and determined a recreational use change from Secondary Contact to Primary Contact is warranted because all available pH data were within 6.6 to 9, and 8 of 8 *E. coli* measurements were below 410 cfu/100 mL.

The Department proposed to amend 20.6.4.308 NMAC (Charette Lakes) to change the recreational use from Secondary Contact to Primary Contact Lake. NMDOW manages these lakes as part of the Charette Lakes Wildlife Area. There is public access with regular recreation. The Department reviewed available Lower Charette Lake 2025-2026 *E. coli* and pH data and determined a recreational use change from Secondary Contact to Primary Contact is warranted because all available pH data were within 6.6 to 9, and 6 of 6 *E. coli* measurements were below 410 cfu/100 mL. There are no data available for Upper Charette Lake, which has more wetland, and marsh-like characteristics. Therefore, the Department proposes to keep secondary contact as a designated use for Section 308, but recommends adding primary contact for Lower Charette Lake based on the data as follows (noted in green):

20.6.4.308 CANADIAN RIVER BASIN: Charette lakes.
Designated uses: coldwater aquatic life, warmwater aquatic life, secondary contact, livestock watering, [~~and~~] wildlife habitat; and primary contact on Lower Charette lake.

D. Remove unnecessary language in 20.6.4.403 NMAC

The Department proposes to amend segment 20.6.4.403(B) NMAC to remove "except that the following segment-specific criterion applies: temperature 29°C (84.2°F) or less." This is the exact same value as the default temperature criterion at 20.6.4.900(H)(4) for coolwater aquatic life, which is the designated use for this segment, so it is redundant and unnecessary.

VI. CONCLUSION

The Department recommends that the Commission adopt the proposed amendments to the Standards filed with the Department's First Amended Petition (**NMED Exhibit 27**) and based upon the testimony of the SWQB's witnesses.

This concludes my direct testimony.

LYNETTE STEVENS GUEVARA

1190 S. St. Francis Dr.
Santa Fe, NM 87505 505.629-8811 lynette.guevara@env.nm.gov

Summary of Qualifications:

Thirty+ years of experience in natural resources protection and management with emphasis on water quality monitoring, assessment, restoration, and reuse. Major strengths include project management and collaboration, data management and interpretation, technical report preparation and editing, and developing tools and techniques to increase efficiency.

Professional Experience:

11/22 – present New Mexico Environment Dept. Surface Water Quality Bureau, Santa Fe, NM

Monitoring, Assessment, and Standards Section Program Manager

- Manage a group of fourteen technical staff including mentoring three team supervisors to:
  - Monitor, assess, and report on surface water quality conditions around New Mexico
  - Develop, revise, and maintain New Mexico's surface water quality standards
  - Develop, maintain, and promote total maximum daily load (TMDL) planning documents to address water quality impairments
  - Provide related assistance and support to other Bureau sections and stakeholders as needed
- Participate in grant writing, budget tracking, funding allocations, hiring, and performance reviews
- Review, update, and develop protocols to standardize tasks including sample collection, data assessment, and report writing
- Prepare and implement EPA grants applications and revisions, associated workplans, and budgets designed to achieve Department and Bureau goals
- Participate on various EPA and state counterpart workgroups and technical teams regarding water quality policy, implementation, guidance, and strategies to achieve related goals and deliverables
- Maintain and promote improvements of water quality data storage and retrieval in the Bureau's water quality database, and prepare scheduled uploads of data to EPA's national database
- Initiate, allocate funding, and manage contracts related to the development of NMED's Harmful Algal Blooms Advisory Program
- Work with the Bureau's web authors to create, update, and maintain webpages, resources, and links associated with Section activities.

11/20- 10/22 New Mexico Environment Dept. Ground Water Quality Bureau, Santa Fe, NM

Pollution Prevention Section Reuse Team Leader

- Serve as in-house expert for above-ground use of reclaimed domestic wastewater and aquifer recovery and storage permits to encourage successful implementation of water reuse projects
- Maintain individual groundwater discharge permit case load, provide review and comment on all permits with reuse components, and contribute to the oversight of all discharge permits managed by the Section
- Research and propose IT modernization tools to provide e-Permitting and e-Reporting tools to increase efficiency, compliance, and transparency
- Manage CWA 319 grant including workplans, budgeting, and reporting
- Hire, supervise, and manage a team of three water resource professionals

08/01 – 11/20 New Mexico Environment Dept. Surface Water Quality Bureau, Santa Fe, NM

State on New Mexico Clean Water Act §303(d)/ §305(b) Assessment Coordinator (2001-2020)
Project management duties performed to create the biennial Clean Water Act §303(d)/§305(b) Integrated Report and List to Congress:

- Collated and assessed chemical, physical, and biological data to determine surface water quality impairments based on current surface water quality standards
- Developed and applied assessment protocols used to determine water quality attainment
- Developed automated assessment procedures in R statistical programming language
- Collaborated with NMED IT and EPA Office of Water to merge and improve NMED inhouse and national water quality monitoring and assessment databases
- Presented to the NM Water Quality Control Commission (WQCC) and EPA Region 6 for approval
- Prepared and presented testimony to the NM WQCC regarding Outstanding National Resource Waters nominations in the Valle Vidal and to defend impairment determinations
- Participated in various EPA and state counterpart workgroups and national conferences regarding Clean Water Act policy, procedures, and deliverables
- Collaborated with the USDA National Sedimentation Lab to develop sedimentation assessment protocols for the San Juan River basin
- Collaborated with the EPA Office of Research and Development and EPA Region 6 to develop sedimentation and nutrient assessment protocols and monitoring techniques

Monitoring and Assessment Section Program Manager (2004-2006)

- Manage a group of twelve technical staff including three team supervisors to:
    - Monitor, assess, and report on surface water quality conditions around New Mexico
    - Develop, maintain, and promote total maximum daily load (TMDL) planning documents to address water quality impairments
    - Provide related assistance and support to other Bureau sections and stakeholders as needed
- Participate in grant writing, budget tracking, funding allocations, hiring, and performance reviews
- Review, update, and develop protocols to standardize tasks including sample collection, data assessment, and report writing
- Prepare and implement EPA grants applications and revisions, associated workplans, and budgets designed to achieve Department and Bureau goals
- Participate on various EPA and state counterpart workgroups and technical teams regarding water quality policy, implementation, guidance, and strategies to achieve related goals and deliverables
- Maintain and promote improvements of water quality data storage and retrieval in the Bureau's water quality database, and prepare scheduled uploads of data to EPA's national database

Monitoring and Assessment Section TMDL, GIS and Database Team Leader (2001-2003)

- Supervised and managed three technical staff to develop total maximum daily load (TMDL) water quality planning documents, GIS tools, and water quality databases for the Section
- Prepared and completed performance evaluations, developed team timelines and specific tasks needed to accomplish goals, and participated in the evolution of the Monitoring and Assessment Section
- Developed, public noticed, and presented TMDL water quality planning documents to stakeholders and the NM WQCC to address identified water quality impairments

05/97 – 08/01 Navajo Nation, Window Rock, AZ

Hydrologist II, Navajo Nation EPA Water Quality Program (02/99 -08/01)

- Project management, including the proposal and implementation of watershed restoration projects; designing monitoring networks; preparing outreach materials, presentations, and technical reports; and coordinating activities with federal tribal and federal land management partners

- Developed bioassessment monitoring program, associated quality assurance project plans, and provided training to staff and students
- Coordinated surface water quality sampling, interpreted data, and prepared summary reports

Hydrologist II/Supervisor, Navajo Nation Water Management Branch (05/97 -02/99)

- Supervised and managed stream gage and watershed restoration staff, including hiring, training, evaluations, budgeting, and ensuring deliverables were met
- Project management of watershed restoration projects with tribal and federal land management partners, including the development of RFPs, contracts, workplans, work schedules, permits, project budgets, and monitoring networks
- Maintained nine active continuous stream gages - coordinated with USGS, ordered needed equipment, surveyed benchmarks, measured stream flow, developed rating curves, and assisted with water monitoring design of irrigation canals

10/93 - 09/96 National Park Service Water Resources Division, Ft. Collins, CO

Assistant Contaminants Specialist

- Performed literary and electronic searches of aquatic contaminants research and regulations for inclusion into an electronic contaminants database on a wide variety of water quality, ecotoxicological, risk assessment, and statistical topics; technical editing; report writing; and project lead on petroleum contaminants
- Generated technical response to parks on special projects relating to specific park contaminants issues, rehabilitation, and land use management
- Designed and implemented study using benthic macroinvertebrates as indicators of water quality at Bandelier National Monument, NM (Colorado State University thesis project)

1991-1993 Environmental Information Systems Analyst, Genwest Systems, Inc., Edmonds, WA

- Designed and developed information management databases and graphics for NOAA's Hazardous Materials Response and Assessment Division (HMRAD)
- Updated emergency response chemical database and design of CERCLA site tracking database
- On-site marine spill response with NOAA HMRAD and US Coast Guard, including installation of computer command center, preparation of situation maps, and integration of data collected from all agencies for media and response team briefing packets
- Assisted in preparation of company proposal to acquire base NOAA funding

Education:

Bachelor of Business Administration (Marketing), Gonzaga University, Spokane, WA
Post-baccalaureate coursework at University of Washington and Shoreline CC, Seattle, WA
Master of Science (Watershed Science), Colorado State University, Fort Collins, CO

Computer Skills:

MS Office, Oracle database design team, SSTEMP modeling, RStudio programming, ArcGIS, website maintenance

NMED Exhibit 30

Executive Summary

Purpose of the 2026-2028 CWA §303(d)/§305(b) Integrated Report

The protection of water quality in New Mexico is vitally important to the health and well-being of all New Mexicans and the aquatic life and wildlife that inhabit its waters. New Mexico uses a variety of mechanisms, including state, federal, and local programs, to protect and restore the quality of its ground and surface waters. The Clean Water Act (CWA) and New Mexico Water Quality Act (WQA) provide the basic underpinnings of surface water protection with the water quality standards codified in the State of New Mexico Standards for Interstate and Intrastate Surface Waters [20.6.4 NMAC]. Water quality standards are comprised of designated uses for surface waters of the state, associated water quality criteria necessary to protect these uses, and an antidegradation policy. Designated uses in New Mexico include aquatic life, fish culture, primary and secondary contact (including cultural, religious or ceremonial purposes), public water supply, industrial water supply, domestic water supply, irrigation, livestock watering, and wildlife habitat. The New Mexico Environment Department (NMED) Surface Water Quality Bureau (SWQB) coordinates with local, state, and federal agencies and organizations to monitor, assess, protect, and restore surface water quality throughout New Mexico and fulfill the requirements set forth in the law.

The SWQB begins the process of addressing impairments by identifying and reporting impaired waterbodies (i.e., waterbodies not attaining their designated uses). SWQB has designed this report, the State of New Mexico CWA §303(d)/§305(b) Integrated Report (IR), to fulfill this need as well as to satisfy the statutory requirements of sections 303(d), 305(b), and 314 of the CWA. The IR includes information on surface water quality and water pollution control programs in New Mexico and describes the relative condition of water quality in New Mexico to the United States Environmental Protection Agency (EPA), United States Congress, and stakeholders. SWQB prepares the IR with input from several other NMED bureaus and programs, and the New Mexico Water Quality Control Commission (NMWQCC) approves the Integrated List (Appendix A), otherwise known as the list of impaired waters. Once approved, the Integrated List incorporated by reference into the New Mexico Water Quality Management Plan and Continuing Planning Process (WQMP/CPP, NMWQCC 2020).

Specific Focus of the 2026-2028 CWA §303(d)/§305(b) Integrated Report

The SWQB surveyed the Sacramento Mountains and Chama River in 2023 and 2024, therefore these watersheds are the primary focus of revised or retained assessment conclusions this listing cycle. Additional focus areas based on submitted or acquired datasets include various reaches statewide based on EPA and USGS data downloaded from the Water Quality Portal, SWQB Effectiveness monitoring data, the San Juan River Basin based on data collected by the multijurisdictional monitoring program, Upper Rio Grande and various stream reaches in and around Taos and Red River sampled by watershed monitoring groups as well as Chevron Questa Mine data from Red River submitted by Ground Water Quality Bureau, streams on the Pajarito Plateau using data collected in association with Los Alamos National Laboratory Data and submitted by N3B, and data collected in the Mimbres river drainage by Silver City Watershed Keepers. Assessment conclusions based on data from previous rotational surveys and previously submitted outside data in non-focus areas are typically carried over to the next list until more current data are available to assess, unless, for example, a water quality standard change necessitates a re-assessment. For this assessment cycle, the top causes of impairment remained the same; temperature, *E. coli,* and nutrients/eutrophication are the three most common causes of river and stream water quality impairment in New Mexico. Mercury and PCBs

NMED Exhibit 30

in fish tissue, temperature, and nutrients/eutrophication are the most common causes of water quality impairment in lakes and reservoirs.

During development of the IR, SWQB further evaluates impaired waterbodies to determine if changes to the standard may be appropriate, whether more data collection is necessary to confirm the impairment, or whether a total maximum daily load (TMDL) or alternative water quality improvement plan should be scheduled for development. TMDLs and other planning documents provide information on the probable source(s) of the water quality impairment which is used to determine the best approach to improve water quality. SWQB combines field observations, available geographic information system (GIS) layers and land use imagery, and both stakeholder and staff watershed knowledge to develop draft Probable Source lists, which are finalized in TMDL documents and summarized in the IR. Most surface water quality impairments identified in New Mexico are due to nonpoint sources of water pollution. Agricultural practices (including rangeland grazing), road/bridge runoff, on-site liquid waste treatment systems (septic), streambank modifications and/or destabilization, waterfowl and wildlife, drought related impacts, loss of riparian habitat and rural development are the leading probable sources of impairment in New Mexico's rivers and streams where TMDLs or alternative planning documents have been prepared. The most common probable sources of impairment in lakes and reservoirs where TMDLs or alternative planning documents have been prepared are rangeland grazing, wildlife, recreational pollution sources, road/bridge runoff, site clearance due to new development or infill, on-site treatment systems, rural development, silviculture harvesting, and waterfowl.

The EPA recommends and the SWQB has prepared the 2026-2028 IR consistent with previous guidance memorandums, including EPA's significant 2006 IR Guidance supplemented by subsequent memorandums typically released by EPA for each listing cycle (EPA 2017a, 2021, 2023, 2025). Following the streamlining of the EPA submittal process in 2015 and the subsequent implementation and improvement of the EPA's Assessment and Total Maximum Daily Load Tracking and Implementation System (ATTAINS), SWQB organized and updated the post-2018 Integrated Reports to better describe New Mexico's current water quality framework, focus on required IR elements not reported electronically via ATTAINS, and provide hyperlinks to additional information regarding specific programs or restoration activities.

NMED Exhibit 30

I. Water Quality Identification and Control in New Mexico

A. Pollution Identification and Reporting

The New Mexico Legislature adopted the Water Quality Act (WQA) in 1967 and the New Mexico Pollutant Discharge Elimination System (NMPDES) Act in 2025 [NMSA 1978, §§ 74-6C-1 to 74-6C-11] to protect water quality in New Mexico. Since then, the Legislature has revised the WQA [NMSA 1978, §§ 74-6-1 to -17] numerous times to improve the management and protection of New Mexico's water resources. The WQA created the New Mexico Water Quality Control Commission (NMWQCC), and several of the revisions expanded the duties and powers of the NMWQCC. The NMWQCC is the State water pollution control agency for all purposes of the federal Clean Water Act (CWA) and may take all necessary actions under the WQA to secure the benefits of the WQA [NMSA 1978, § 74-6-3(E)].

Monitoring Team staff sample the Rio Gallina in the Chama River Watershed in August 2024

These duties include adoption of water quality standards and the adoption of regulations to prevent or abate water pollution in the State or in any specific geographic area or watershed of the State or for any class of waters. The WQA defines water as "all water, including water situated wholly or partly within or bordering upon the State, whether surface or subsurface, public or private, except private waters that do not combine with other surface or subsurface water." [NMSA 1978, § 74-6-2(E)]. The NMWQCC assigns responsibilities for water quality management activities to constituent agencies, primarily the New Mexico Environment Department (NMED). [NMSA 1978, § 74-6-4(G)].

The *State of New Mexico CWA §303(d)/§305(b) Integrated Report* (Integrated Report or IR) is designed to satisfy the statutory requirements of sections 303(d), 305(b), and 314 of the CWA. The IR provides information on water quality and water pollution control programs in New Mexico to the EPA and the United States Congress, as well as to the public. The SWQB prepares the IR with input from several other NMED bureaus and programs and presents the final draft 303(d)/305(b) Integrated List portion of the IR (Appendix A) to the NMWQCC for approval. The primary focus of the IR is surface water quality, although groundwater is also briefly discussed according to reporting requirements.

The SWQB has prepared the 2026-2028 IR consistent with EPA "Integrated Reporting Guidance under CWA sections 303(d), 305(b) and 314" memorandums, including the most recent 2025 guidance document. The most important component of the IR for surface water pollution identification is the CWA §303(d)/§305(b) Integrated List, provided as Appendix A. This list details the extent to which surface water quality goals (i.e., designated uses) documented in New Mexico's water quality standards (20.6.4 NMAC) are being met. Designated uses are the desirable, attainable, and existing uses of a surface water segment as specified in 20.6.4.97 through 20.6.4.899 NMAC. These surface water segments are further broken down into one or

more “assessment units” (e.g., stream reaches or waterbodies) for IR categorization and reporting purposes. In accordance with current EPA integrated listing guidance, New Mexico determines and assigns Fully Supporting, Not Supporting, and Not Assessed to each individual designated use to determine an IR category for every reported assessment unit (AU) on the Integrated List. New Mexico’s IR categories are defined in Table 1. A designated use assignment of “Not Assessed” means that a determination of Fully Supporting or Not Supporting could not be made based on available data and information. An AU is considered “impaired” when one or more pollutants prevent a waterbody from meeting its designated use(s). These pollutants are identified as “cause(s)” on the Integrated List.

Waterbodies classified as IR Category 5 (i.e., 5A, 5B, 5C, 5-R) officially constitute the *CWA §303(d) List of Impaired Waters,* however New Mexico and the EPA recognize that waterbodies assigned IR Category 4 are also still impaired (Figure 1). In this case, a Total Maximum Daily Load (TMDL) planning document is either already in place (IR Category 4A), not required because the impairment is not caused by a “pollutant” (IR Category 4C), or other pollution control requirements are in place and expected to result in attainment of the water quality standard within a reasonable amount of time (IR Category 4B).

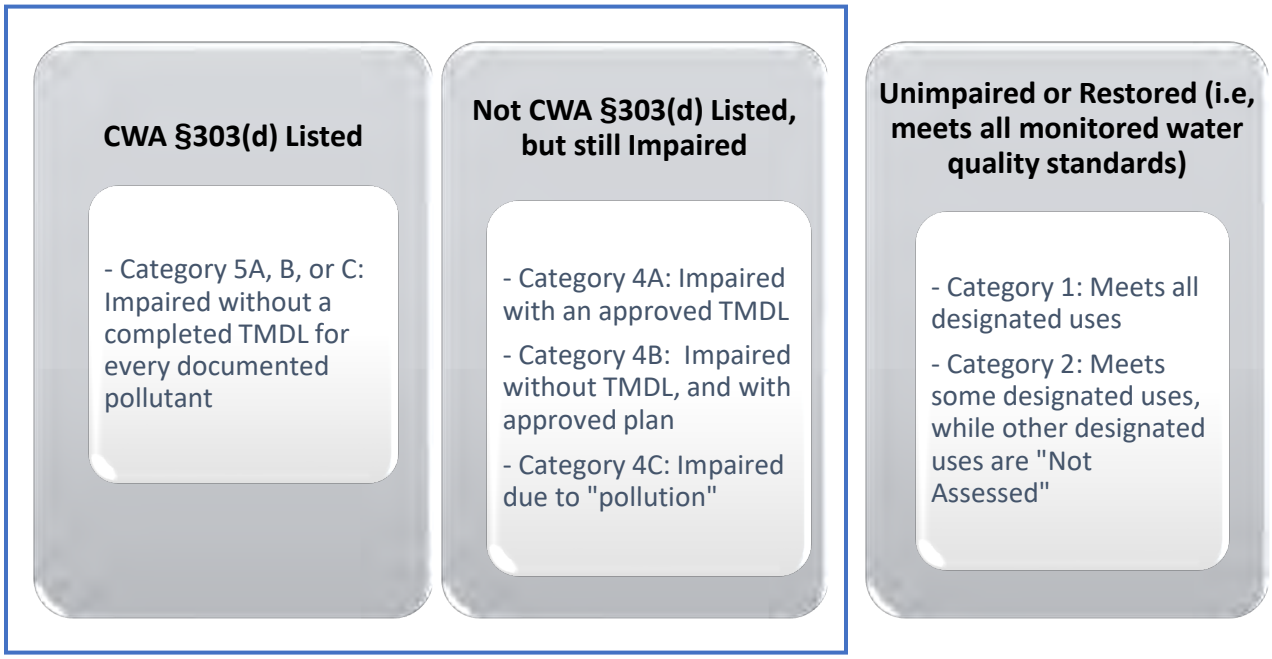

Figure 1. Relationship between CWA section 303(d), Impairments, and IR Categories

For additional information on the Clean Water Act §303(d) Listing of Impaired Waters, visit:
https://www.epa.gov/tmdl/program-overview-303d-listing-impaired-waters

NMED Exhibit 30

Table 1. New Mexico's Integrated Report Categories

Category	Description
1	All designated uses are supported.
2	Available data and/or information indicate that some designated or existing uses are supported based on numeric and narrative parameters that were tested.
2A	Attaining with prior action still in place. The waterbody or parameter is no longer impaired but a previously developed action (e.g., Approved TMDL, Advance Restoration Approach, etc.) exists.
3A	There are insufficient available data and/or information to make a support determination (no data available).
3B	There are insufficient available data and/or information to make a support determination. No data points exceed an applicable water quality criterion.
3C	There are insufficient available data and/or information to make a support determination. Data point(s) exceed an applicable water quality criterion.
4A	Available data and/or information indicate that at least one designated or existing use is not being supported, and a TMDL has already been established.
4B	Available data and/or information indicate that at least one designated or existing use is not being supported, but a TMDL is not needed because other pollution control requirements are reasonably expected to result in attainment of the water quality standard in the near future.
4C	Available data and/or information indicate that at least one designated or existing use is not being supported, but a TMDL is not needed because impairment is not caused by a pollutant.
5A	Available data and/or information indicate that at least one designated or existing use is not being supported and necessary TMDLs are underway or scheduled.
5B	Available data and/or information indicate that at least one designated or existing use is not being supported. A review of the water quality standard is required to verify the appropriate designated or existing use and/or criterion.
5C	Available data and/or information indicate that at least one designated or existing use is not being supported but additional data are necessary to verify the listing before TMDLs are scheduled.
5-R	Formerly 5-ALT. Available data and/or information indicate that at least one designated or existing use is not being supported and an advance restoration approach is in progress or under development.

NMED Exhibit 30

B. New Mexico's Surface Water Synopsis

New Mexico is characterized by high mountains, expansive plains and plateaus, river gorges, and broad valleys. Land surface elevations in New Mexico vary from just under 3,000 feet above sea level at the Texas border in the southeastern portion of the state to just over 13,000 feet in the northern mountains. New Mexico is the fifth largest of the fifty states, with a total area of 121,607 square miles. Of this, approximately 34% is federal land, 12% is State land, 11% is Native American land, and 43% is privately owned (USBLM 2019). New Mexico is one of the driest states in the U.S., with statewide average annual precipitation around 13–14 inches. Annual totals vary widely from less than about seven inches in desert valleys to more than 20 inches in the mountains[1]. Statewide, the annual average precipitation is much less than evaporation from open water surfaces (USBOR 1976). In fact, 96.6% of our rain and snowfall returns to the atmosphere[2]. About half the annual precipitation is received during the summer period within brief but intense summer storms, commonly referred to as the "monsoon season." Much of the winter precipitation falls as snow in the high mountains and as snow or rain at lower elevations. Like much of the western U.S., New Mexico continues to experience long-term drought.

Surface water basins include upper portions of several of the region's principal drainage systems: the San Juan River, Little Colorado River and Gila River watersheds contribute to the Lower Colorado River Basin; the Canadian River and Dry Cimarron River watersheds contribute to the Arkansas-White-Red River Basin; and the Rio Grande and Pecos River watersheds contribute to the Rio Grande basin (Figure 2). Other waters of the State in New Mexico include streams that are in topographically closed basins and drain internally (20.6.4 NMAC).

Rio Chama and Rio Gallina confluence, August 2024

The New Mexico Office of the State Engineer (NMOSE) is charged with administering the state's water resources with respect to quantity. The State Engineer has authority over the supervision, measurement, appropriation, and distribution of all surface and groundwater in New Mexico, including streams and rivers that cross state boundaries. [NMSA 1978, § 72-2-9]. The related New Mexico Interstate Stream Commission (NMISC) has broad powers to investigate, protect, conserve, and develop New Mexico's waters including both interstate and intrastate stream systems. The NMISC's authority under state law includes negotiating with other states to settle interstate stream controversies. [NMSA 1978, § 72-14-3]. New Mexico is a party to eight interstate stream basins. To ensure basin compliance, NMISC staff analyze, review, and implement projects in New Mexico and analyze streamflow, reservoir, and other data on the stream systems. The NMISC is also authorized by statute to investigate and develop the water supplies of the state and institute legal proceedings in the name of the state for planning, conservation, protection and development of public waters. [NMSA 1978, §

[1] https://nm.water.usgs.gov/drought/newmexicosummary.html
[2] https://mainstreamnm.org/data-and-reports/#prev

72-14-3]. New Mexico has sixteen water planning regions, each with its own water plan. New Mexico's State Water Plan was revised in 2023, and the 50-year Water Action Plan was published in 2024 (NMOSE/NMISC 2023, 2024). The regional and state water plans are vital tools intended to guide water management to best meet all the state's water user's needs – now and into the future.

For additional information on New Mexico's Office of the State Engineer or Interstate Stream Commission, visit: http://www.ose.state.nm.us/

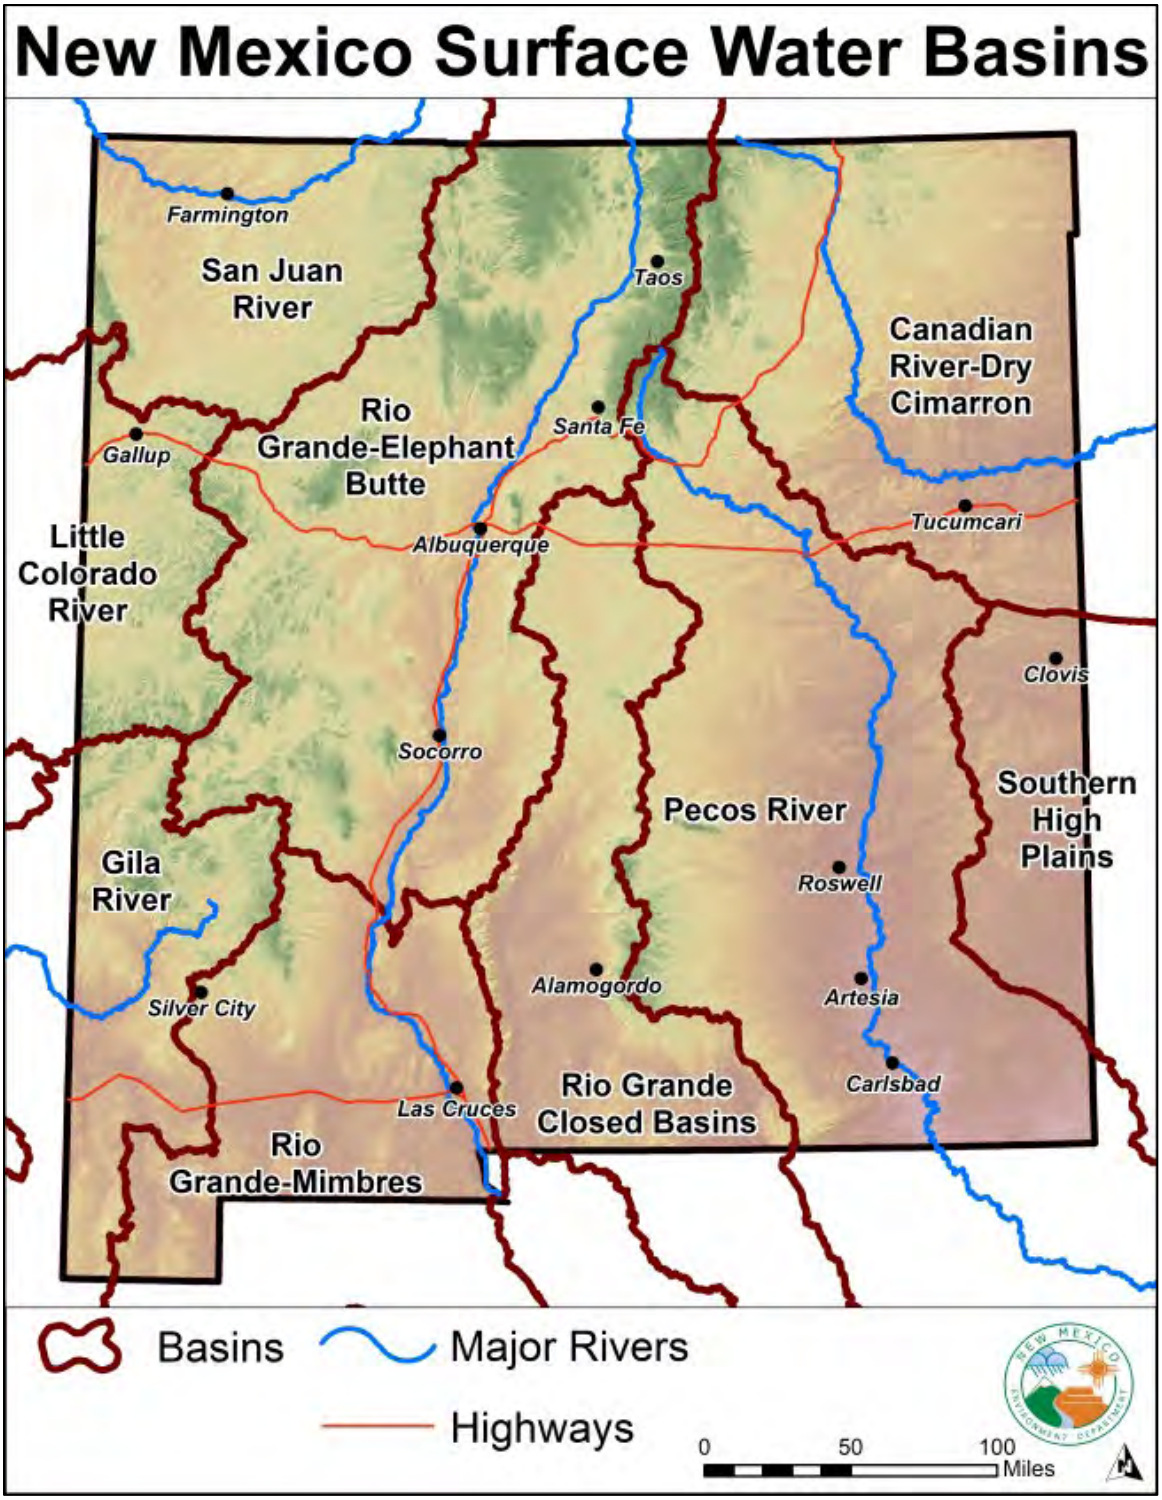

Figure 2. New Mexico Surface Water Basins

Topic	Value
State population[1]	2,130,256
State Surface Area[2]	121,602 mi^2
Total miles of perennial non-tribal rivers / streams[3]	6,592 miles
Total miles of non-perennial non-tribal river / streams[4]	193,191 miles
Number of significant public lakes/reservoirs[4]	173
Acres of significant public lakes/reservoirs[5]	85,369 acres
Acres of freshwater wetlands[6]	519,781 acres

[1] United States Census Bureau July 1, 2024, estimate.

[2] Calculated using the most recent US Census state boundary in RGIS and a NAD83 UTM 13 projection.

[3] Includes both public and private non-tribal stream miles under established Assessment Units in NM's Integrated List (Appendix A) with a Water Type of "STREAM, PERENNIAL" or "RIVER." Note that the perennial rivers/streams layer in NHD+ does not include anything that is "artificial path" or "channelized" (e.g. portions of the lower Rio Grande or Lower Pecos).

[4] Derived by NMED SWQB staff based on flowlines lengths and waterbody areas in the USGS National Hydrography Dataset (NHD) Plus High Resolution (USGS 2026). Flowline segments assigned FCode 46003 (intermittent) and 46007 (ephemeral) in NHD+ HR were clipped to the NM minus tribal lands boundary, which was created using the tribal lands layer from the most recent Census (2020; last updated 2025-09-23). Ephemeral and intermittent waters in this category were then tallied to determine total non-perennial mileage. Once the NHD+ HR layer was clipped to the NM minus tribal lands boundary, the NHD+ HR 46003 and 46007 streams/rivers were projected using NAD83 UTM 13 to calculate the length of each segment in miles. The change from the 2024-2026 IR is due to the updated NHD+ HR layer that includes more detailed flowlines than previous versions and shifting state water boundaries. Total miles of non-perennial non-tribal river/streams may shift due to different projections and/or changing tribal boundaries over time.

[5] Includes significant publicly-owned, or publicly recreated, natural lakes, playa lakes, and reservoirs under established Assessment Units in NM's Integrated List (Appendix A) in NHD+ high resolution (2018).

[5] Compiled from Mapping and Classification of Wetlands in New Mexico (GSS Final Reports on file at SWQB Wetlands Program). Excludes streams and rivers, lakes and riparian wetlands already associated with the metrics above.

Table 2. Summary of New Mexico's Surface Water Resources

NMED Exhibit 30

Table 2 provides a summary of New Mexico's water resources. Prior to the 2020-2022 IR, Assessed Waters geographic information system (GIS) layers depicted AUs[3] were based on the National Hydrography Dataset (NHD) Medium Resolution surface drainage network and waterbodies, however this was updated with the 2020-2022 IR and all IR Assessed Waters GIS information since then has been based on NHD Plus High-Resolution data.

C. New Mexico's Surface Water Quality Framework

Under the authority of the WQA and the CWA, the SWQB developed and the NMWQCC adopted the basic framework for water quality management in New Mexico as described in the *State of New Mexico Statewide Water Quality Management Plan/Continuing Planning Process* (WQMP/CPP) (NMWQCC 2020). The SWQB uses this integrated planning and management strategy to protect or attain the desired uses and levels of surface water quality within a waterbody. The iterative process implemented to identify water quality problems, develop solutions to address them, and assess the effectiveness of the implemented solutions is shown in Figure 3. Problem identification begins with establishing water quality standards and follows with collecting data to assess and identify impaired waters. Problem solving involves the development of TMDLs and other planning documents which help guide National Pollutant Discharge Elimination System (NPDES) permit limits, CWA section 319 restoration projects, and alternative restoration plans to help a waterbody achieve water quality standards. Progress is then measured, and water quality goals and approaches are updated accordingly. The sections below provide greater details on each component and associated programs and approaches.

For additional information on New Mexico's WQMP/CPP, visit:
https://www.env.nm.gov/surface-water-quality/wqmp-cpp/

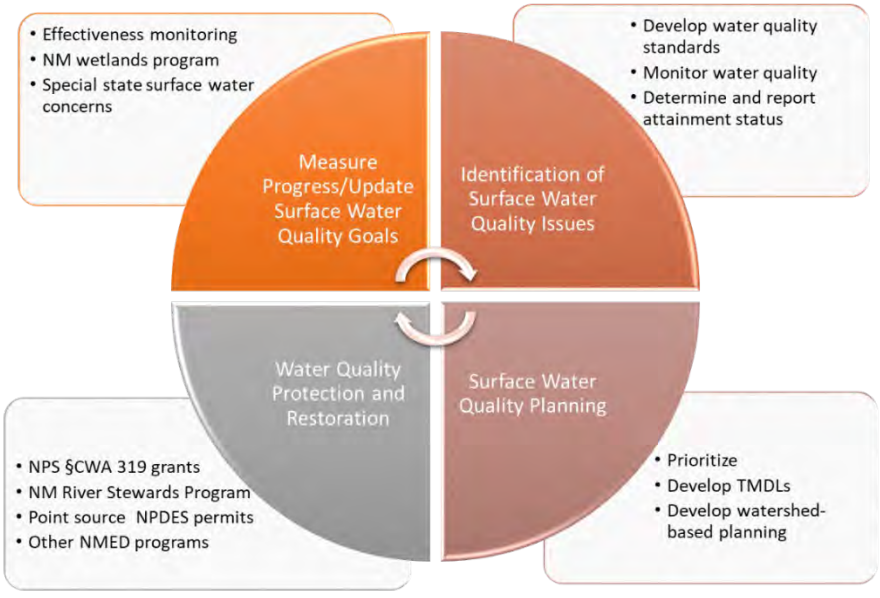

Figure 3. General Framework for Identifying and Restoring New Mexico's Surface Waters

II. Identification of Surface Water Quality Issues

A. Develop Water Quality Standards

SWQB staff sampling turbid waters in the Rio Chama, July 2024

The first step to identify surface water quality issues is to set surface water quality goals through the development and maintenance of New Mexico's *Standards for Interstate and Intrastate Surface Waters* codified at 20.6.4 NMAC. The SWQB's Standards and Outreach Team maintains and refines New Mexico's surface Water Quality Standards (WQS) in 20.6.4 NMAC, proposing changes for approval by the NMWQCC as appropriate. The WQS define the water quality goals for a waterbody by designating uses, assigning criteria to protect those uses, and establishing provisions to apply and implement the WQS. New Mexico continually evaluates the WQS using applicable guidance documents, data, public input, and other sources of information to identify sections that may need to be changed or provisions to be added.

Section 303(c)(1) of the CWA, federal regulations at 40 C.F.R. § 131.20, and state rules at 20.6.4.10 NMAC require NMED to hold a public hearing at least once every three years from the EPA's most recent approval to review WQS, and amend existing or adopt new WQS, as applicable. This process is known as the "triennial review" and is also governed by the WQA, which provides authority for the adoption of WQS by the NMWQCC.

The last Triennial Review public hearing was held before the NMWQCC in July 2021. The WQCC deliberated the proposed rule amendments and adopted the amended WQS in 20.6.4 NMAC (effective September 22, 2022). SWQB subsequently submitted the amended WQS to EPA for review and approval. EPA partially approved the standards to be effective for CWA purposes on January 20, 2023.

The SWQB initiated the 2026 triennial review in 2025. The SWQB published draft amendments to the WQS based on EPA's review and communications regarding previous Triennial Reviews, EPA's recommended CWA section 304(a) criteria, data review for waters lacking Section 101(a)(2) designated uses, and internal programmatic needs, including previous Integrated Lists. The SWQB conducted a 60-day public comment period and held a public meeting where the SWQB solicited input on New Mexico's WQS from tribes, EPA, other state and federal agencies, watershed/river conservation groups, municipalities, water districts, industrial/trade groups, private organizations, and citizens.

After considering comments, the SWQB petitioned the NMWQCC for a hearing for the 2026 Triennial Review. The NMWQCC granted the request and scheduled the hearing for September 28 – October 1, 2026. The SWQB will provide public notice, education, and participation opportunities such as public meetings or

NMED Exhibit 30

webinars, individual meetings, or office hours as part of stakeholder outreach for the triennial review and associated rulemaking process.

The process and requirements for adopting, amending, or revising New Mexico's WQS are codified at 20.1.6 NMAC, *Rulemaking Procedures - Water Quality Control Commission*. Once the stakeholder engagement process is complete, the SWQB will petition the NMWQCC for a rulemaking hearing. If granted a hearing, the SWQB will provide a formal public comment period for proposed changes to the standards. Notice of the public hearing will be provided in accordance with the State Rules Act (NMSA 1978, § 14-4-5.2) and 20.1.6 NMAC. Anyone may provide public comment to the SWQB or to the NMWQCC through the end of the hearing. Additionally, interested parties may also submit and provide written and oral technical testimony for the administrative record. After the hearing is complete and the administrative record is closed, the NMWQCC will deliberate on the matter after which a Statement of Reasons will be issued if they choose to adopt proposed changes. The Department will then begin the process for filing the adopted standards with the State Records Center for inclusion in the NMAC and submit that version to EPA for their review and approval process.

The NMWQCC may adopt new or amended WQS outside of the Triennial Review process, including designating waters as Outstanding National Resource Waters (ONRWs), changing the designated use(s) of a waterbody through a Use Attainability Analysis (UAA), or adopting Site-Specific Criteria (SSC). Additionally, anyone can petition the NMWQCC for a rulemaking hearing and follow the process outlined above to adopt proposed standards. Prior to petitioning the commission, the WQS and federal regulations outline additional administrative and technical requirements. These requirements include workplans containing scientifically defensible methods for developing WQS, and public involvement plans to provide public participation opportunities throughout the process and ensure early engagement with stakeholders, including the SWQB if the petitioner is an outside agency or entity.

Since the previous listing cycle, the NMWQCC has held four hearings to adopt new and amended WQS. In 2024, the NMWQCC designated over 240 stream miles as ONRWs, the highest level of protection under the Antidegradation Policy and Implementation Plan at 20.6.4.8 NMAC. Pursuant to 20.6.4.9(B) and (C) NMAC, a surface water of the state may be designated and classified as an ONRW where the Commission determines it will benefit the state of New Mexico and it meets at least one of the eligibility criteria listed in 20.6.4.9(B)(1)-(3) NMAC. SWQB staff worked with interested third parties to identify and nominate waters eligible for ONRW designation under 20.6.4.9(B)(1) NMAC. An informal public comment period and public meeting were held before petitioning the commission for a hearing, with over 700 people, organizations, and state agencies providing comments in support of the nominations. The rulemaking hearing was held on December 10, 2024, with the NMWQCC deliberating and approving the designation of the nominated waters as ONRWs at the conclusion of the hearing. EPA approved the 2024 ONRW designations with an effective date of April 10, 2025, for federal CWA implementation purposes.

Newport News Nuclear BWXT-Los Alamos; Triad National Security, LLC; and the U.S. Department of Energy, Office of Environmental Management, Los Alamos Field Office, as the operators and contractors for the Los Alamos National Laboratory (LANL), petitioned the NMWQCC to amend WQS to adopt site-specific criteria applicable to the Pajarito Plateau under 20.6.4.900.I.(4) NMAC. The Petitioners developed acute and chronic Copper Site-Specific Water Quality Criteria (Cu SSWQC) based on a multiple linear regression analysis of 531 sampling events and output from EPA's copper biotic ligand model. Additionally, they engaged with stakeholders before requesting and being granted a hearing. The hearing was held on January 14, 2025, with the WQCC deliberating and voting to adopt the proposed amendments at the conclusion of the hearing. EPA approved the Cu SSWQC with an effective date for federal purposes of August 14, 2025.

NMED Exhibit 30

Additionally, the operators and contractors for LANL conducted a UAA and determined that naturally occurring thermal conditions prevented the attainment of the coldwater aquatic life use (ALU) in upper Sandia Canyon (see 2018-2020 303(d)/305(b) Integrated Report). As a result, they petitioned the NMWQCC to split Sandia Canyon into an upper segment at 20.6.4.141 NMAC and lower segment at 20.6.4.126 NMAC. The designated use and criteria for lower Sandia Canyon remained as coldwater ALU[4]under 20.6.4.126 NMAC, while upper Sandia Canyon was changed to coolwater ALU[5] with an additional segment specific 6T3 temperature[6] criteria of 25°C. The Petitioners held early engagement opportunities prior to the hearing that was conducted on May 13, 2025, with no public opposition to the proposed amendment. The WQCC deliberated and approved the amendments at the end of the hearing, with an effective date for state implementation purposes of November 8, 2025. The WQS amendment was submitted to EPA on January 19. 2026 and is currently under review.

National Technology & Engineering Solutions of Sandia, LLC (NTESS), on behalf of the United States Department of Energy, National Nuclear Security Administration, Sandia Field Office, as management and operating contractor for Sandia National Laboratories, conducted a UAA to determine if Tijeras Arroyo, from the Rio Grande to Four Hills Bridge, exhibits characteristics of an ephemeral (20.6.4.97 NMAC), instead of intermittent water body (20.6.4.98 NMAC). The UAA documented the chemical, biological, and physical conditions following the SWQB's Hydrology Protocol. NTESS concluded that the reach was ephemeral and petitioned the NMQCC for a hearing to amend the standards at 20.6.4.97 NMAC. As with other NMWQCC hearings, early engagement and public participation opportunities were provided throughout the process. The hearing was held on December 9, 2025, with the WQCC deliberating and voting to adopt the proposed amendments at the conclusion of the hearing. The rule was published in the NM Register on February 24, 2026 and became effective for state implementation purposes on March 14, 2026. The WQS amendment was submitted to EPA after March 14, 2026 and is currently under review.

B. Monitor Water Quality

The second step to identify surface water quality issues is to collect water quality data and information through organized, quality-controlled monitoring. The purpose of the SWQB's Monitoring Program is to ensure relevant water quality data for New Mexico's surface waters are collected with the most robust scientific methods in a way that is transparent to water quality agencies and the public. The Monitoring Program serves all surface water quality monitoring needs to the extent possible given available resources, NMED priorities, and strategic goals. The waterbody types currently monitored by the program are streams, rivers, lakes, and reservoirs.

Clear goals and objectives are required to implement an effective monitoring program. To meet federal and state requirements and expectations, the SWQB has developed a monitoring strategy per EPA Guidance (EPA 2003b, NMED/SWQB 2016). The strategy provides a detailed description of the SWQB's monitoring objectives and designs, as well as approaches to data quality assurance and management. Key topics are briefly discussed below.

---

[4] Coldwater aquatic life criteria include dissolved oxygen = 6.0 mg/L, maximum temperature = 24°C; 6T3 = 20°C, and a pH of 6.6 – 8.8.

[5] Coolwater aquatic life criteria include dissolved oxygen = 5.0 mg/L, maximum temperature = 29°C, and a pH of 6.6 – 9.0.

[6] 6T3 means the temperature not to be exceeded for six or more consecutive hours in a 24-hour period on more than three consecutive days.

1. Monitoring design

Monitoring staff develop and implement field sampling plans to ensure all necessary chemical, biological, and physical data needed to determine attainment of New Mexico's water quality standards are collected during the survey. The SWQB strives to implement ambient sampling using a rotational watershed monitoring approach. Monitoring occurs during the non-winter months generally from March through November over one to two years, resulting in approximately one-fifth of the states primarily perennial waters being monitored every one to two years. Monitoring focuses primarily on physical, chemical, and biological conditions in perennial waters; and includes sampling for most pollutants that have numeric or narrative water quality criteria in New Mexico.

SWQB staff conducting flow measurements in Rio Ojo Caliente, July 2024

To achieve the goals of New Mexico's surface water quality framework, the SWQB rotational surveys utilize a targeted monitoring design to address data needs identified for assessment, TMDLs, potential standards revisions, and point source monitoring. The SWQB selects monitoring sites that are intended to be representative of the AU based on the data needs for an AU and site accessibility. Each AU is typically represented by one monitoring station which receives four to eight site visits during the survey. Through public outreach, inter-agency coordination, and a scoring system which considers a variety of factors, the SWQB prioritizes AUs. High-ranking priority waters receive the greatest amount of monitoring, whereas lower ranking waters receive less based on available staff and financial resources at the time. The current rotational monitoring schedule is shown in Figure 4.

For survey years 2023-2024, the SWQB conducted a two-year survey of the Rio Chama and the Sacramento Mountains basins. Data and information gathered during this survey are the focus of the 2026-2028 IR attainment determinations in the 303(d)/305(b) Integrated List (Appendix A).

NMED Exhibit 30

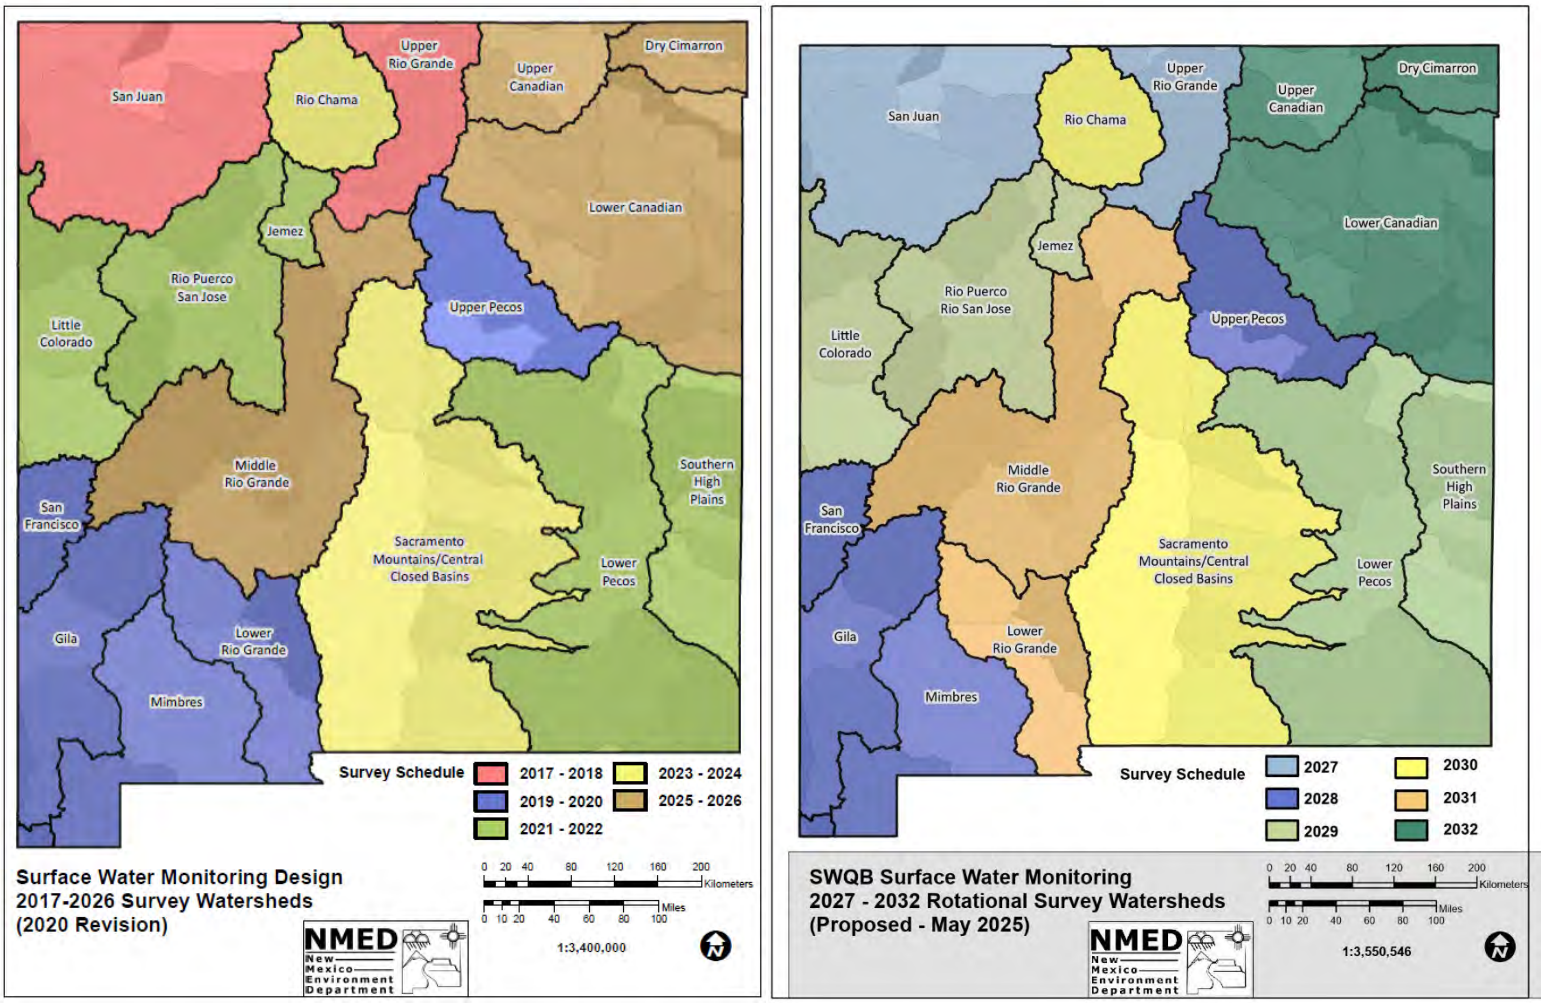

Figure 4. New Mexico's Surface Water Quality Monitoring Schedule (NMED/SWQB – current vs. proposed May 2025 (preliminary draft, under revision))

To review New Mexico's 10-Year Monitoring Strategy, visit:
https://www.env.nm.gov/surface-water-quality/protocols-and-planning/.

CWA section 314 requires an assessment of "…significant publicly-owned lakes." New Mexico has 173 significant publicly-owned lakes, reservoirs, and playas identified on the Integrated List (Appendix A). Lake monitoring is incorporated into the rotational survey design. The SWQB determined the list of significant publicly-owned lakes, reservoirs, and playas using the following criteria:

- Lakes, reservoirs or playas over 10 acres because of their many varied uses including public recreation areas;
- Lakes, reservoirs, or playas smaller than 10 acres with cultural, recreational, or ecological significance; or
- Lakes, reservoirs or playas specifically included in 20.6.4.101-20.6.4.899 NMAC.

2. Probabilistic monitoring (2024-2026)

The EPA requires states to incorporate probabilistic sampling designs into their monitoring programs. Probabilistic studies enable states to generate statistically-based conclusions regarding selected water quality concerns. Accordingly, the SWQB is incorporating the 2025-2026 Rio Grande Probabilistic Monitoring Survey into its monitoring program. In New Mexico, SWQB has defined "Large Rivers" as systems that cannot be monitored effectively with methods developed for wadeable streams and generally have drainage areas greater than 2,300 square miles. The Rio Grande in New Mexico falls under the large river definition. While methods for monitoring and assessing wadeable perennial streams are well established, methods for large rivers are less advanced. The probabilistic survey is focused on providing data for the development and refinement of nutrient monitoring and assessment methods for the Upper and Middle Rio Grande.

Planning for the 2025-2026 probabilistic survey began in 2024. Fifty sites were randomly selected from a sampling frame of the Rio Grande from the Colorado border to above Elephant Butte Reservoir. SWQB developed the sampling frame using the USGS National Hydrography Dataset-High Resolution (NHDHR) validated with SWQB Assessed Streams information. Staff at the EPA National Health and Environmental Effects Research Laboratory in Corvallis, OR, conducted random site generation. Three hundred and fifty sites from the sampling frame were randomly selected with the first fifty sites serving as the sample population and the remaining 300 sites as alternates.

Year 1 of the survey focused primarily on randomly selected sites located within the Upper Rio Grande. At each sampling location, SWQB staff collected water chemistry and biological nutrient stressor and response indicators. Sites that did not meet the sampling frame parameters (i.e., reservoirs) or were inaccessible (unsafe or landowner access denied) were excluded through office and field reconnaissance. Excluded sites were replaced by alternate sites in successive order. Completion of the Rio Grande Probabilistic Survey is planned for 2026, at which point SWQB will work with partners to develop numeric translators of New Mexico's narrative nutrient criteria for the Upper and Middle Rio Grande.

SWQB staff collect periphyton samples from the Upper Rio Grande near Pilar, NM

3. *Quality assurance*

The SWQB is committed to maintaining a quality assurance program that ensures confidence in the environmental data produced by its various water quality programs. The SWQB implements water quality management programs in accordance with the current EPA-approved version of NMED's Quality Management Plan[7] (QMP), which documents the quality system for planning, implementing, documenting, and assessing the effectiveness of activities supporting water quality management programs.

All data collected by the SWQB for water quality attainment determinations are collected and analyzed following established standard operating procedures[8] (SOPs). In addition, all data are handled in accordance with the most current version of the EPA-approved Quality Assurance Project Plan[9] (QAPP). The QAPP describes the quality assurance procedures, quality control specifications, and other technical activities that must be implemented to ensure that the results of the project or tasks to be performed will meet project specifications. By establishing a quality system, New Mexico ensures that water quality management decisions are based on a systematic process and on data of known and acceptable quality. This also ensures that the public funds expended in these efforts are soundly invested. For the SWQB to utilize data collected by outside agencies or stakeholder groups, a review of quality assurance procedures for submitted data is conducted to ensure that submitted data are of equal or greater quality to those collected by the SWQB under the QAPP.

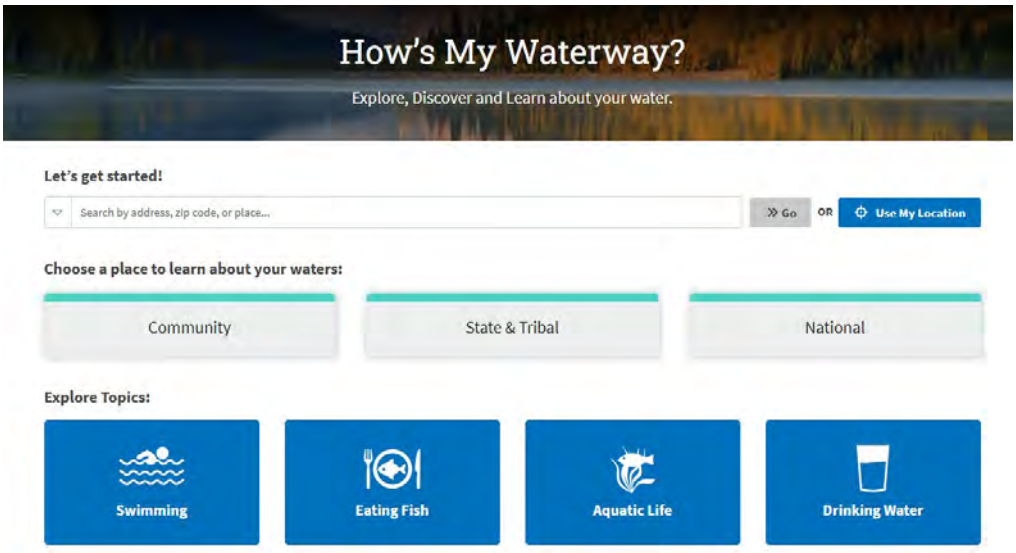
To review New Mexico's QMP, QAPP, and various SOPs, visit:
https://www.env.nm.gov/surface-water-quality/protocols-and-planning/

4. *Data management and survey reporting*

The SWQB's in-house Surface Water Quality Information Database (SQUID) is an integral tool for coordinated storing, assessing, and reporting of water quality data and conclusions between the SWQB programs, to EPA, and to New Mexico's stakeholders. This Oracle© database, developed and maintained by NMED's Office of Information Technology, allows for required electronic reporting of monitoring data to the EPA's water quality exchange (WQX) database and WQS attainment conclusions to the EPA's Assessment and Total Maximum Daily Load Tracking and Implementation System (ATTAINS) database[10]. SQUID also contains many survey planning and tracking tools and reports. SQUID has been updated to be compatible with the EPA's ATTAINS database per EPA guidance (EPA 2023). ATTAINS is a primary data source for How's My Waterway[11], which was designed to provide the public with information about the condition of their local waters based on data that states, federal, tribal, local agencies and others have provided to the EPA.

Following the completion of each rotational watershed survey, the SWQB monitoring staff prepare water quality survey reports. These sampling summary

[7] https://www.env.nm.gov/surface-water-quality/protocols-and-planning/
[8] https://www.env.nm.gov/surface-water-quality/sop/
[9] https://www.env.nm.gov/surface-water-quality/protocols-and-planning/
[10] https://www.epa.gov/waterdata/attains
[11] https://www.epa.gov/waterdata/hows-my-waterway



reports are an update to the associated field sampling plan, detailing the monitoring goals that were accomplished during the survey as well as any deviations from the planned monitoring.

To access SWQB's field sampling plans and survey reports, visit:
https://www.env.nm.gov/surface-water-quality/water-quality-monitoring/

5. Data upload to the EPA ATTAINS database and How's My Waterway?

How's My Waterway is a user-friendly, public-facing tool created by EPA to help people explore the condition of their local waters using data submitted by state, federal, tribal, and local agencies. For New Mexico, this information is drawn directly from the NMED Surface Water Quality Bureau's Integrated Reporting (IR) process for Clean Water Act Sections 303(d) and 305(b). Each IR cycle, SWQB evaluates available water quality data, determines designated use attainment, identifies impairments, and submits these assessment decisions to EPA through the ATTAINS database. Once EPA finalizes the state's Production ATTAINS dataset, those assessment results are published in How's My Waterway. In this way, How's My Waterway turns the technical outputs of the Integrated Reporting process into an accessible, map-based view of local water conditions and ongoing protection and restoration efforts.

Users can explore their watershed through an interactive map interface that displays water quality conditions at community, state, and national scales. The tool provides information on swimming safety, fish consumption, aquatic life, and drinking water, along with details on restoration and protection efforts, identified issues, and monitoring locations. Users can also view information on permitted dischargers, including facilities with discharge violations, and access summaries of restoration plans and projects occurring in their watershed. These features allow the public to see not only current water quality status but also the regulatory and restoration activities happening in their watersheds.

To explore your watershed on How's My Waterway? Visit:
https://mywaterway.epa.gov/

C. Determine and Report Attainment Status

The third step in identifying surface water quality issues is to compare collated water quality data to current water quality standards using consistent, documented processes. New Mexico's listing methodology is described in the Comprehensive Assessment and Listing Methodology[12] (CALM). This document explains how the SWQB evaluates surface water quality data and other information to determine whether surface water quality standards are being met as documented in Appendix A. The listing methodologies described in the CALM are reviewed each odd-numbered year (i.e., 2025) to ensure the methods are clearly defined and consistent with applicable water quality standards, and to incorporate relevant new EPA guidance.

Outside sources of data are solicited and acquired via a public notice process prior to developing the draft IR and associated Integrated List (Appendix A). Simultaneously, the revised CALM is public noticed to solicit input into New Mexico's listing methodologies. In general, all readily available data less than five years old that have been reviewed and accepted for consistency with the SWQB's data collection activities and quality assurance procedures are used to determine whether the applicable water quality standards are attained. Data older than five years old are given a lower priority in assessment than newer data, particularly if newer data indicate a change in water quality or the older data fails to meet data quality requirements. Provisional data is not used to make designated use support determinations.

To review New Mexico's listing methodologies (CALM), visit:
https://www.env.nm.gov/surface-water-quality/calm/

Common surface water quality data sources collated to determine use impairment in New Mexico include, but are not limited to, the following:

- SWQB chemical/physical, biological, habitat, or bacteriological data collected during rotational watershed surveys;
- Chemical/physical, biological, habitat, or bacteriological data from SWQB studies or projects collected by SWQB staff or their cooperators;
- SWQB Effectiveness Monitoring data;
- USGS chemical/physical, biological, habitat, or bacteriological data;
- Statewide datasets downloaded from the Water Quality Portal[13];
- Los Alamos area environmental data publicly available for download from *Intellus New Mexico*[14]; and
- Citizen or volunteer monitoring data.

For additional information regarding the SWQB's data submittal process, visit:
https://www.env.nm.gov/surface-water-quality/data-submittals/

[12] https://www.env.nm.gov/surface-water-quality/calm/
[13] https://www.waterqualitydata.us/
[14] http://www.intellusnmdata.com/

NMED Exhibit 30

The Rio Chama and Sacramento Mountain watersheds were surveyed by the SWQB in 2023-2024 and hence are the primary focus of revised or retained assessment conclusions in the Integrated List for this 2026-2028 cycle. Other datasets that were either submitted or acquired this cycle and assessed as reported include:

- 2022-2024 data for various stream reaches in and around Taos and Red River collected by Sentinels-Rio de Taos and submitted by Amigos Bravos.
- 2022-2025 San Juan River Basin Multijurisdictional monitoring program data stored in SQUID
- 2022-2025 SWQB Effectiveness monitoring data downloaded from SQUID
- 2022-2025 EPA and USGS data from various locations throughout New Mexico downloaded from the Water Quality Portal[15],
- Chevron Questa Mine data from Red River submitted by Ground Water Quality Bureau,
- 2021-2025 Los Alamos National Laboratory Data submitted by N3B, and
- Silver City Watershed Keepers data (submitted)

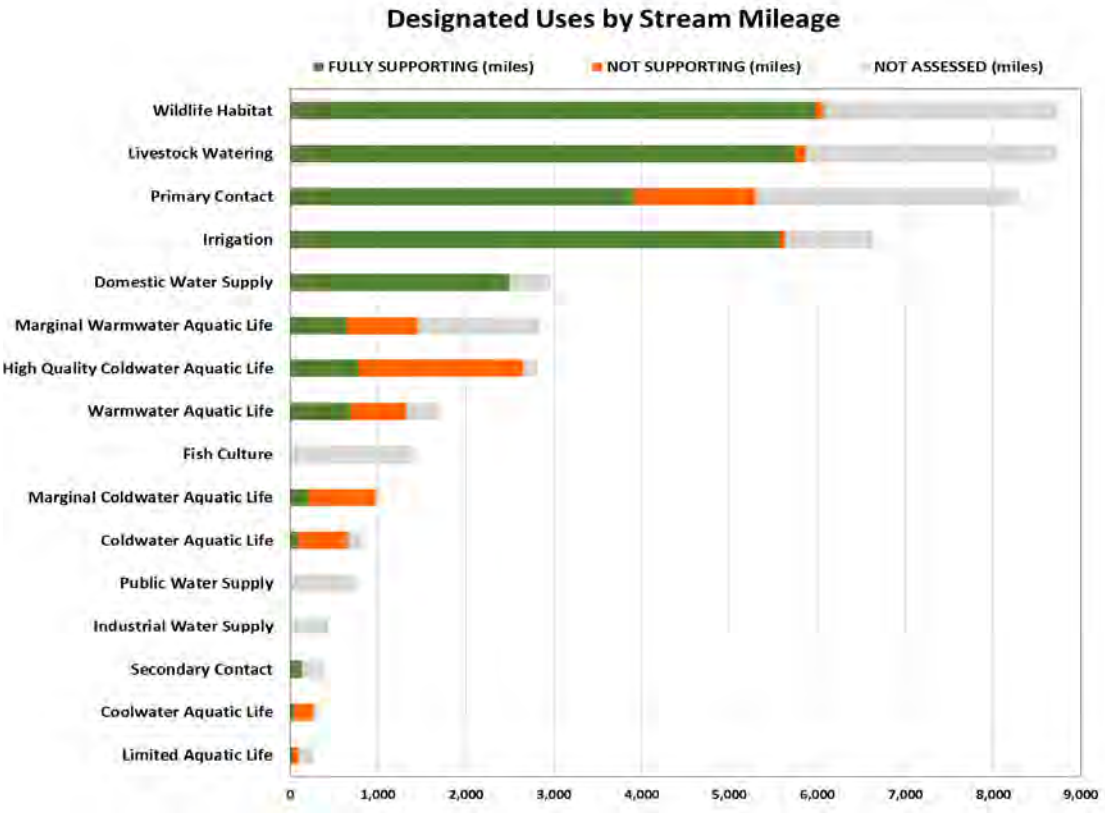
The assessment conclusions in non-focus areas based on data from previous rotational surveys and previously submitted outside data are typically carried over to the next list until more current data are available to assess unless, for example, a water quality standard change or a significant listing methodology change necessitates a re-assessment.

New Mexico maintains assessment information in SQUID and uploads this information to ATTAINS per EPA guidance (EPA 2025). Use of SQUID allows SWQB to automatically generate the entire Integrated List (Appendix A), the associated assessment rationale, the official CWA §303(d) List of Impaired Waters, as well as a variety of summary reports. The SWQB maintains an extensive web site that provides access to the current and several past CWA §303(d)/§305(b) reports and supporting information.

To access the current and past CWA §303(d)/§305(b) reports and supporting information, visit:
https://www.env.nm.gov/surface-water-quality/303d-305b/

The assessment rationale document maintained by the SWQB is a historical record of impaired surface waters (i.e., Category 5 waters) provided to reviewers and users of the list – including the EPA – to help track listing and de-listing information used in the development of New Mexico's Integrated List. The EPA does not require this specific document and does not take action to approve or disapprove its contents. The assessment rationale was originally created as a separate word processing document. All AUs do not have detailed assessment rationale entries because prior to the 2018-2020 IR the assessment rationale generally did not contain entries on AUs that have not been assessed or have never been found to be impaired. The assessment rationale is now a database field in SQUID, making it easier to provide assessment notes by IR cycle on all AUs being assessed. Assessment rationale entries by IR cycle, starting with the 2018-2020 IR, are also uploaded to the EPA's ATTAINS database.

All AUs are assigned IR categories as described in New Mexico's CALM[16]. Assessment units noted with IR Category 5A, 5B, 5C or 5-R on the Integrated List in Appendix A comprise New Mexico's official CWA §303(d) List of Impaired Waters. A listing of Category 5-only waters is included in the beginning of Appendix A. To



[15] https://www.waterqualitydata.us/
[16] https://www.env.nm.gov/surface-water-quality/calm/

NMED Exhibit 30

see details on a specific AU, refer to the AU entry on the full Integrated List in Appendix A and associated assessment rationale entry. Starting with the 2018-2020 IR, each AU entry on the Integrated List now also contains a "PARAMETER IR CATEGORY." This useful field provides additional planning information regarding each cause of impairment or AU-cause pair. For example, a parameter IR category of 5B lets the user know that a review of the applicable water quality standard is needed prior to scheduling TMDL development. New Mexico has several temperature listings that fall under the 5B parameter IR category.

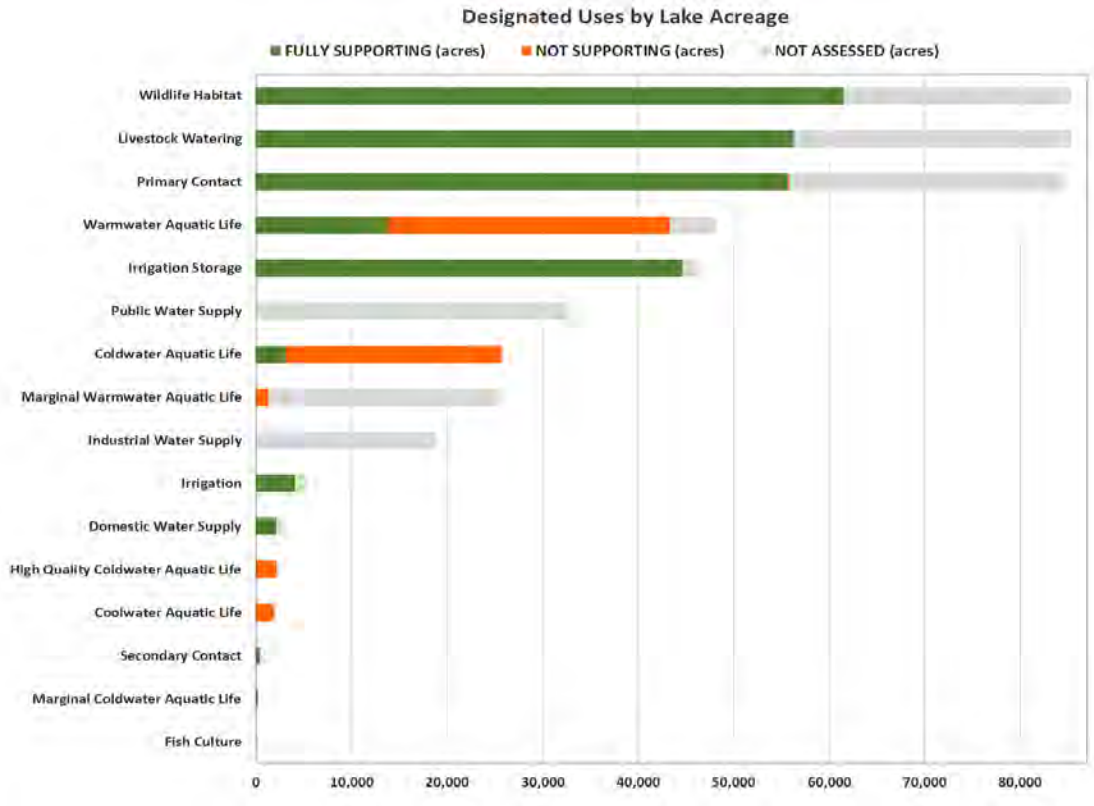
New Mexico's Integrated List also includes an estimated year in the "TMDL DATE" field for all parameter IR category 5A AU-cause pairs. The estimated year is generally based on the SWQB's rotational monitoring schedule, prioritization strategy in the SWQB's long-term vision document (NMED/SWQB 2015), and severity of the impairment. The "TMDL DATE", as well as the projected "MONITORING SCHEDULE" year, is ultimately dependent upon personnel and financial resources which can change on an annual basis. If a TMDL has already been developed for the noted cause of impairment, the EPA TMDL approval date (MM/DD/YYYY) is reported in the TMDL date field.

A summary of the attainment status by river/stream mileage, lake acreage and subwatershed (currently only AUs for Upper Pecos, Rio Chama, and Sacramentos watershed areas) for each designated use, as found in New Mexico's WQS (20.6.4 NMAC), is presented in Figures 5, 6, and 7, respectively. For more information on subwatershed AU development see section 3 below. A full summary with associated mileage and acreage is available in Appendix B. In New Mexico, the CWA goal of "fishable" is reported under the various aquatic life uses while the "swimmable" goal is reported under primary and secondary contact uses.

NOTE: All Fish Culture, Public Water Supply, and Industrial Water Supply designated uses are defaulted to "Not Assessed" because no numeric criteria apply uniquely to these uses per 20.6.4.900.A NMAC.

Figure 5. New Mexico's Designated Use Attainment Status by River/Stream Mileage

NMED Exhibit 30



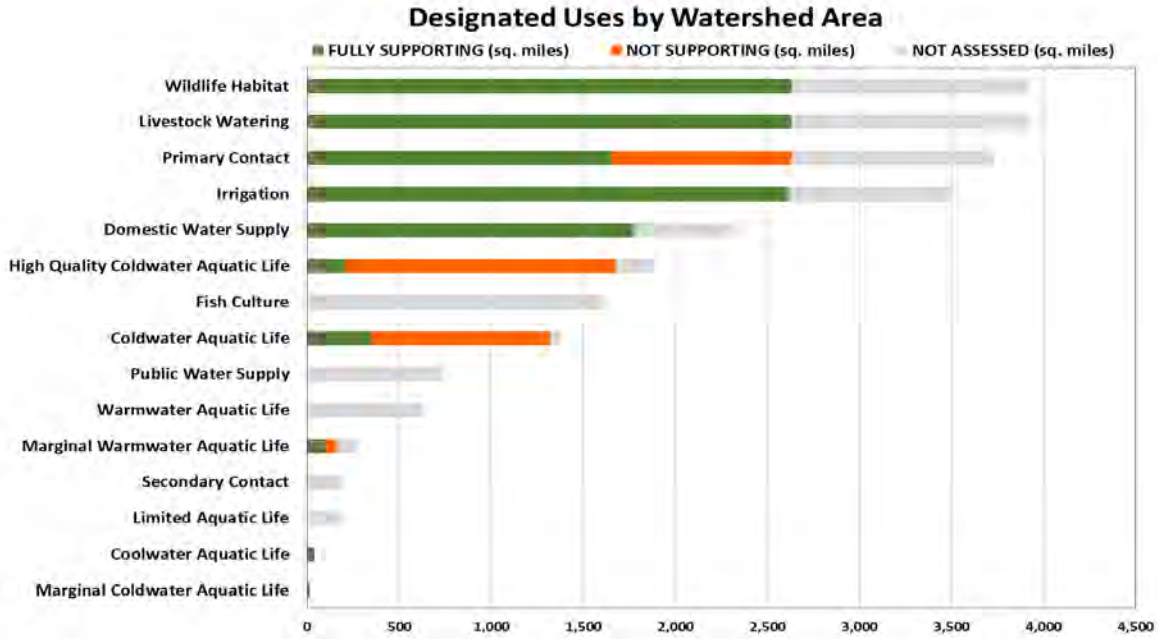


Figure 6. New Mexico's Designated Use Attainment Status by Lake/Reservoir Acreage

NOTE: All Fish Culture, Public Water Supply, and Industrial Water Supply designated uses are defaulted to "Not Assessed" because no numeric criteria apply uniquely to these uses per 20.6.4.900.A NMAC.

Figure 7. New Mexico's Designated Use Attainment Status by Watershed Area

The causes of impairments are summarized by major waterbody type (rivers/streams, lakes/reservoirs and subwatersheds) in the following section.

1. River and Stream Assessment Results

New Mexico's surface waters are assigned to one of the IR categories defined in Table 1 and summarized in Table 3. Individual IR categories for every AU are provided in the Integrated List (Appendix A).

Table 3. Integrated Report Categories for New Mexico's Rivers and Streams

IR Category	Total Size (miles)	Number of River/Stream Assessment Units
1	942	83
2	796	77
3A	1,931	154
3B	4	1
3C	28	4
4A	1,508	105
4C	235	16
5A	1,432	93
5B	840	65
5C	906	88
5-R	6	1
TOTAL	**8,629**	**687**

The largest grouping of assessed lotic (i.e., flowing) waters are IR Category 5. These AUs, along with the Category 5 lake/reservoir waterbodies, comprise New Mexico's official CWA §303(d) List of Impaired Surface Waters. A list of Category 5-only waters was generated from SQUID and is included in the beginning of Appendix A.

IR Category 4A represents stream reaches where SWQB has developed TMDL planning documents for all documented causes of impairment in a particular AU.

These AUs are technically still impaired (see Figure 1) even though the EPA does not officially consider them to be part of the Clean Water Act §303(d) List. Several of these stream reaches also have TMDLs for more than one parameter.

AUs are listed in IR Category 1 and 2 if there are sufficient data and information meeting the requirements of the CALM that can be evaluated to support a determination that some or all uses are attained based on numeric and narrative water quality criteria.

AUs are listed in IR Category 3 when sufficient data to support an attainment determination for any designated use are not available according to the requirements of the assessment and listing methodology[17]. Reasons include access, monitoring and/or analytical logistics (such as the need for automated sampling equipment), and staff and financial resource constraints. The SWQB prioritizes IR Category 3 AUs during rotational survey planning.

The leading impairment causes for New Mexico's rivers and streams are presented in Figure 8. The SQUID-generated summary report of all Cause and Source statistics is provided in Appendix B. Standard EPA impairment cause categories included in SQUID were used to label the graphic. See Appendix B for subcategory information.

Excessive temperature, *E. coli*, and nutrients/eutrophication are identified as the top three causes of impairment of designated uses in New Mexico's streams and rivers based on current WQS (20.6.4

[17] https://www.env.nm.gov/surface-water-quality/calm/

NMED Exhibit 30

NMAC), available data, and applicable listing methodologies. Dissolved oxygen (DO) and nutrient/eutrophication impairments may be redundant in some cases, as DO impairment is often a response resulting from excessive nutrients.

E. coli sampling during watershed surveys has been a SWQB priority since the 2006 listing cycle, using a mobile *E. coli* sampling unit that resolved a chronic issue with meeting the short holding time. Implementation of this sampling method continues to result in the identification of additional contact use impairments due to exceedance of the *E. coli* criteria each listing cycle.

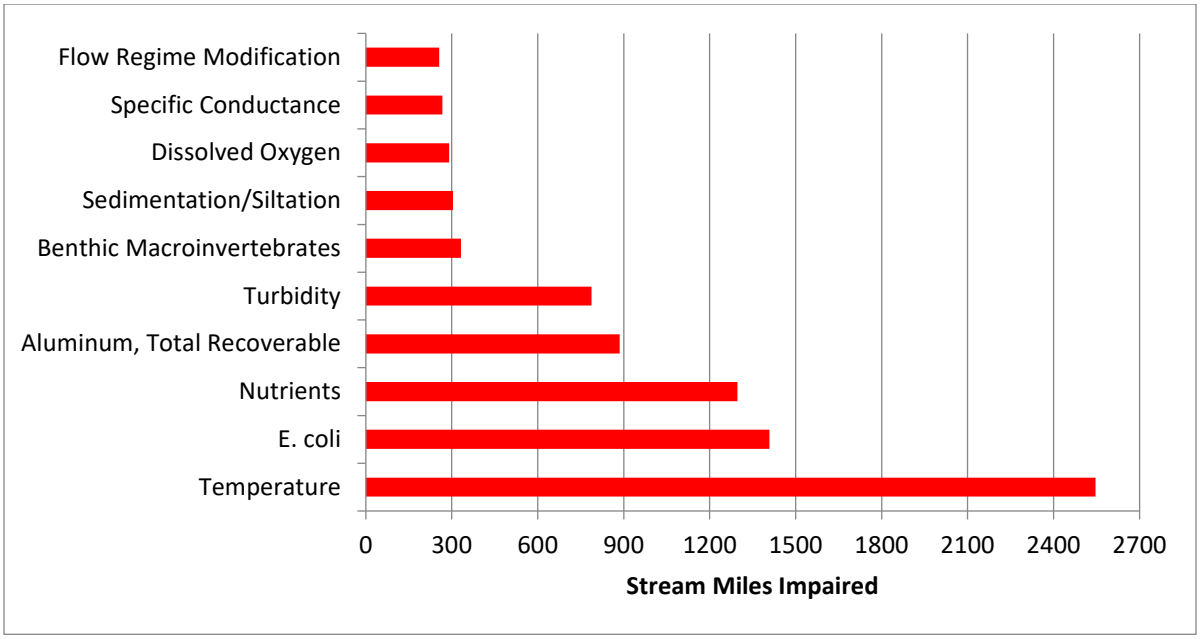

Figure 8. Top Causes of Surface Water Impairment for Rivers and Streams (2026)

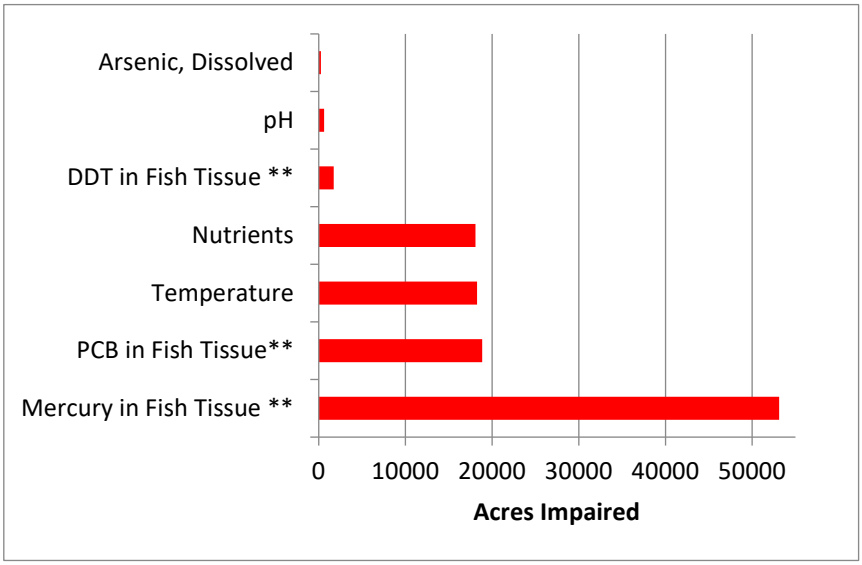
2. Lake and Reservoir Assessment Results

One major challenge regarding both lake monitoring and lake TMDL development has been the loss of specific CWA section 314 funds to address this need. In the past, states received this funding specifically targeted for lake monitoring. States must now carve out their own funding for lake monitoring from core CWA section 106 funds. New revenue sources must be identified to increase lake and reservoir monitoring to support future TMDL development and provide water quality information to the public who utilize these lakes and reservoirs, allowing more scientifically rigorous data and information to be collected could confirm the current cause and source impairment information in New Mexico's lakes and reservoirs.

Table 4 shows the number of New Mexico's lakes and reservoirs assigned to each IR category as defined in Table 1. Individual IR categories are presented for every AU on the Integrated List in Appendix A.

By acreage, the majority of assessed lentic (i.e., not flowing) AUs in New Mexico fall under Category 5. Over 90% of these acres are freshwater reservoirs as opposed to natural lakes. New Mexico has very few natural lakes compared to the number of in-line and off-line reservoirs. These AUs, along with the IR Category 5 river/stream AUs, comprise New Mexico's official CWA §303(d) List of Impaired Surface Waters. A list of Category 5-only waters was generated from SQUID and is included in Appendix A.



NMED Exhibit 30

AUs are listed in IR Category 3 when current data are not available to support an attainment determination. Reasons for this generally include access issues, monitoring and/or analytical logistics, and staff and financial resource constraints. Many of these lakes that are "Not Assessed" are very small in size, such as high elevation natural lakes. These lakes are logistically difficult to sample because they require long, steep hikes. The SWQB sampled a representative subset of these lakes during 2007 as part of a nutrient criteria development grant. Also included in this category are a large portion of the 20,000+ acres of playa lakes that were part of a SWQB special study in the late 1980s and early 1990s when the EPA provided specific CWA section 314 monitoring funding. Attainment status for playas or lakes where adequate resources have not been available to re-monitor in more recent years were changed to "Not Assessed" during the 2008 listing cycle because these data were over 15 years old. Playas or lakes where data from only one sampling event were previously used to make Full Support determinations were changed to "Not Assessed" during the 2014 listing cycle because this is insufficient data to make attainment determinations under current assessment protocols[18].

A summary of the impairment causes for New Mexico's lakes and reservoirs is presented in Figure 9. The SQUID-generated report that was used to generate the below figure is included in Appendix B. Standard EPA cause categories included in SQUID were used to label the graphic. See Appendix B for specific acreage and subcategory information.

Table 4. Integrated Report Categories for New Mexico's Lakes and Reservoirs

Category	Total Size (acres)	Number of Assessment Units
1	323	9
2	8,584	19
3A	21,320	99
4A	2,032	4
5A	15,088	20
5B	282	4
5C	37,740	18
TOTAL	**85,369**	**173**

NOTES: **Based on current fish consumption advisories and 0.3 mg/kg methylmercury in fish tissue criterion.

Figure 9. Top Causes of Surface Water Impairment for Lakes and Reservoirs (2026)

Mercury in fish tissue, PCBs in fish tissue, and temperature are the top three causes of impairment of designated uses in New Mexico's lakes and reservoirs based on

[18] https://www.env.nm.gov/surface-water-quality/calm/

current WQS, available data, and current listing methodologies[19]. Nutrients are becoming an increasingly common impairment in lakes and reservoirs, and nutrients/eutrophication is now nearly tied with temperature for the 3rd most common cause of impairment. The EPA considers fish or shellfish consumption advisories and supporting fish tissue data to be existing and readily available data that demonstrate non-attainment of CWA goals stating that waters should be "fishable" [CWA §101(a), EPA 2005]. New Mexico currently has fish consumption advisories based on mercury, dichlorodiphenyltrichloroethane (DDT), and PCB levels in fish tissue (NMED, *et al*. 2021). All waterbodies listed in the advisory are listed as impaired except waterbodies where available mercury in fish tissue data is below the New Mexico water quality criterion of 0.3 mg/kg methylmercury in fish tissue.

3. Subwatershed Assessment Results

Table 5. Integrated Report Categories for New Mexico's Subwatershed-based AUs

Category	Total Size (square miles)	Number of Assessment Units
1	351	7
2	361	10
3A	711	14
4A	46	1
5A	2,411	34
5C	41	3
TOTAL	**3,921**	**69**

New Mexico's surface waters are assigned to one of the IR categories defined in Table 1 and summarized in Table 5, with AU specific categories provided in the Integrated List (Appendix A). This reporting cycle includes the pilot use of subwatershed-based Assessment Units (AUs), which represent a shift from traditional linear AU delineations to watershed-scale polygons that better capture the full range of activities influencing surface water quality. This approach, used as the sole method or in combination with linear AUs in several other states, aligns with EPA's ATTAINS reporting requirements and established national methodologies. Each subwatershed AU is assessed as a single unit using data from the station located lowest in the watershed (at or near the pour point), ensuring that monitoring results reflect cumulative upstream conditions. Linear AUs associated with these new polygons will be retired in the next assessment cycle, and several of the newly delineated units include Outstanding National Resource Waters (ONRWs) as of 2023.

These results highlight the dominant stressors affecting watershed-scale conditions and provide a more integrated understanding of surface water quality across New Mexico's surface water systems.

The leading impairment causes for New Mexico's subwatersheds are presented in Figure 10. The SQUID-generated summary report of all Cause and Source statistics is provided in Appendix B. Standard EPA impairment cause categories included in SQUID were used to label the graphic. See Appendix B for subcategory information.
Excessive temperature, *E. coli*, and total recoverable aluminum are identified as the top three causes of impairment of designated uses in New Mexico's subwatershed AUs based on current WQS (20.6.4 NMAC), available data, and applicable listing methodologies.

[19] https://www.env.nm.gov/surface-water-quality/calm/

NMED Exhibit 30

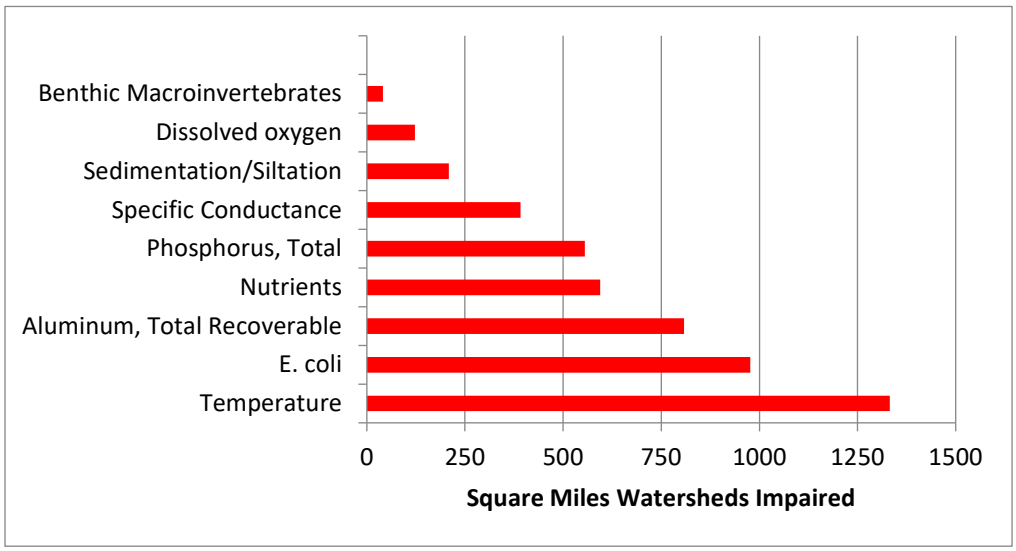


Figure 10. Top Causes of Surface Water Impairment for Subwatershed AUs (2026)

III. Surface Water Quality Planning

A. Prioritize Impairments and Concerns

After water quality impairments and issues are identified, New Mexico engages in water quality planning to address the concern. The first surface water quality planning step is to prioritize impairment listings for subsequent TMDL development or alternative plans to implement restoration strategies with a more holistic approach. The SWQB continues to be involved in national conversations with the EPA and the Association of Clean Water Administrators (ACWA) regarding the Long-Term Vision for the CWA section 303(d) Program (Vision)[20]. The goals of the Vision are prioritization of watershed or waters for restoration and protection; assessment of priority waters; protection of unimpaired waters; alternative approaches to restoration and protection; engagement with the stakeholders; and integration with other CWA programs. As a result of the Vision and goals, the TMDL program in New Mexico is focusing on state water quality priorities, while continuing to evaluate TMDL alternatives and protection of waterbodies that are not impaired. This document, referred to as a Prioritization Framework, summarizes the prioritization of monitoring and TMDL

A herd of wild horses observe monitoring in Alto Reservoir, May 2024

[20] https://www.epa.gov/tmdl/Vision

activities in New Mexico. The first Prioritization Framework was provided to EPA Region 6 staff for review in January 2015. The list of TMDL priorities through 2022 were determined using the process outlined in the Prioritization Framework and were provided to EPA Region 6 in July 2015. 100% of the TMDL priorities outlined in the 2015 Prioritization Framework were completed and submitted to EPA by September 30, 2022.

The Federal fiscal year (FFY) 2022-2032 Long-term Vision Prioritization document (Vision 2.0) was due to EPA by April 1, 2024. This new Vision document includes a list of TMDL program priorities through Federal FY 2032. For the period between the 2015 Vision document and the new Vision document, EPA requested that states provide their federal FY 2023-2024 TMDL priorities as a "bridge metric" in the 2022-2024 Integrated Report. The FFY 2025-26 metrics listed in Appendix B of the 2022-2032 Vision 2.0 document are due to EPA by September 30, 2026, and the FFY 2027-2028 are due to EPA by September 30, 2028.

To review the SWQB's prioritization framework, visit:
https://www.env.nm.gov/surface-water-quality/tmdl/

B. Develop Total Maximum Daily Loads

Santa Cruz Lake, part of the 2024 Canadian and Upper Rio Grande Basin Lakes TMDL

CWA section 303(d)(1) requires that states develop a list of waters within the State that are not supporting their designated uses established in the WQS and to establish a TMDL for each pollutant for those "impaired waters." A TMDL is defined as the "calculation of the maximum amount of a pollutant allowed to enter a waterbody so that the waterbody will meet and continue to meet water quality standards for that pollutant. A TMDL determines a pollutant reduction target and allocates load reductions necessary to the source(s) of the pollutant."[21]

To accomplish this requirement, New Mexico develops a TMDL planning document – a comprehensive plan for a given pollutant and waterbody starting from the relevant WQS, discussing existing water quality data and developing a plan to ensure that WQS are achieved and maintained for that waterbody. At the core of a TMDL is the allocation of pollutant loads to existing and reasonably foreseeable increases from point sources and nonpoint sources in the watershed. As such, TMDLs are an integral part of New Mexico's WQMP/CPP and incorporated by reference (NMWQCC 2020). TMDLs also inform the EPA in developing effluent limits for NPDES permits and help guide the SWQB in prioritizing watershed protection and restoration projects funded under the CWA section 319 and other programs.

[21] https://www.epa.gov/tmdl/overview-total-maximum-daily-loads-tmdls

NMED Exhibit 30

Since the previous listing cycle, the SWQB received EPA approval of the Canadian and Upper Rio Grande Basin Lakes TMDL (6 AU-pollutant pairs) and Gila/Mimbres/San Francisco and Lower Rio Grande Basin TMDL (12 AU-pollutant pairs) in August 2024. The SWQB received EPA approval of the Upper Rio Grande TMDL (36 AU-pollutant pairs) in February 2025.

TMDLs include a list of "probable sources" in the contributing watershed. These are defined as activities that may contribute pollutants or stressors to a waterbody. The probable source list included with any cause of impairment includes all activities occurring or likely to occur in the watershed that have the potential to contribute to the identified impairment. It is not intended to single out any landowner or single land management activity, and has therefore been labeled "probable," and generally includes several possible items. Probable sources listed for any waterbody have not been proven to be a source or the only sources of the identified impairment. The list is based on qualitative field observations made by field staff for AUs sampled during rotational watershed surveys and watershed restoration projects. This is combined with knowledge of known land management activities that have the potential to contribute to the identified impairment. The SWQB updated its standard operating procedure for probable source determination in 2020[22]. Specifically, probable source observations are first recorded during rotational watershed surveys by SWQB staff. Information gathered from the surveys is used to generate a draft Probable Source list in consequent draft TMDL planning documents and shared with SWQB staff familiar with the waterbodies of concern based on their work with permits, watershed-based planning projects, or monitoring in the watershed for review and comment.

Free-range cattle graze near a streambed in the Rio Chama watershed

These draft Probable Source lists are finalized with watershed group/stakeholder input received during any one of the following: pre-survey public meeting, TMDL public meeting, watershed-based planning activities, and various public comment periods. The SWQB continues to maintain probable sources documented in approved TMDLs in SQUID to provide a summary discussion of the primary sources of impairment in New Mexico. This fulfills the CWA section 305(b)(1)(E) requirement to provide "a description of the nature and extent of nonpoint sources of pollutants."

A summary of the top impairment sources as documented in approved TMDLs for New Mexico's rivers and streams is presented in Figure 11. The SQUID-generated report that was used to generate the below figure is included in Appendix

[22] https://www.env.nm.gov/surface-water-quality/sop/

NMED Exhibit 30

B. Standard EPA source categories included in SQUID were used to label the graphic. See Appendix B for specific values and subcategory information. In most instances, more than a single probable source contributes to water quality impairment. The total mileage values reported are summations of AU mileages for all AU-impairment pairs assigned to each probable source. The top sources for lakes are source(s) unknown, rangeland grazing, wildlife other than waterfowl, recreational pollution sources, road/bridge runoff, site clearance (new development or infill), on-site treatment systems (septic), rural (residental areas), silviculture harvesting, and waterfowl.

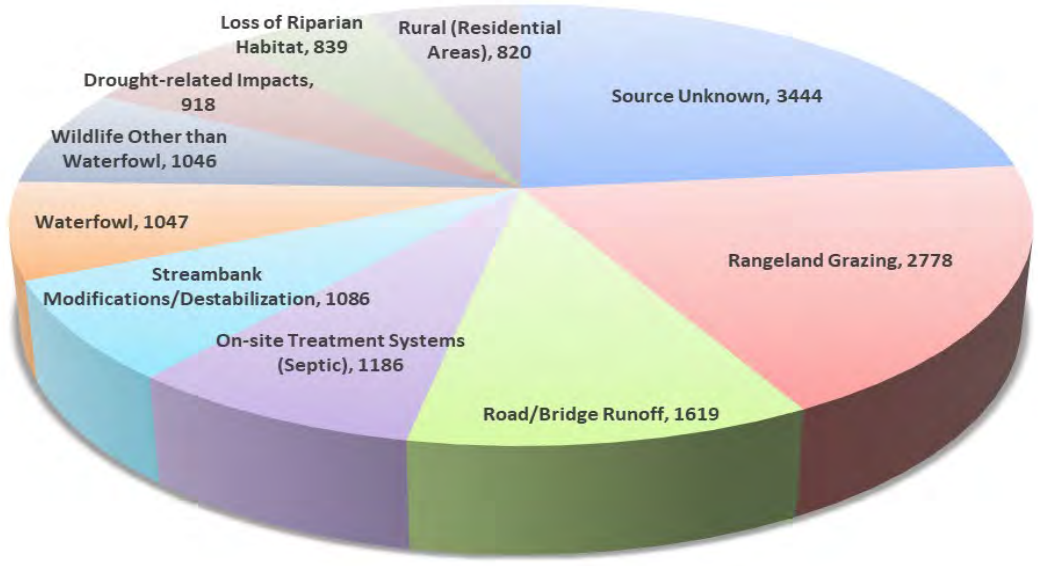

Figure 11. Top Probable Sources of Surface Water Impairment in Rivers/Streams as reported in approved TMDLs (total AU-impairment pair mileage shown)

As seen in the summary graphic, the majority of water quality impairments identified in New Mexico's streams and rivers continues to be due to nonpoint sources (NPS) of water pollution. NPS pollution can be directly related to land use practices on a broad geographic scale and is generally caused by rainfall or snowmelt moving over and through the ground. As the runoff moves, it picks up natural and human-caused pollutants, which are deposited into rivers/streams, lake/reservoirs, wetlands, and groundwater.

For more information on SWQB's TMDL program and to access individual approved TMDL planning documents, visit: https://www.env.nm.gov/surface-water-quality/tmdl/

NMED Exhibit 30

C. Develop Watershed-Based Plans

Freshwater emergent wetland of Wolf Creek, New Mexico. Credit: Hermit's Peak Watershed Alliance, from the Wolf Creek Update to the Watershed Based Plan for the Mora River - Upper Canadian Plateau

New Mexico's NPS Management Program is designed as a cooperative effort among federal and state agencies and watershed stakeholders and is administered by NMED's SWQB Watershed Protection Section (WPS). The EPA-approved 2024 NPS Management Program Plan guides the program with the overarching goal "to implement an adaptive watershed-based restoration and protection program with the substantive involvement of stakeholders, for all watersheds within New Mexico, to meet and maintain water quality standards and designated uses of surface water, and to protect ground water resources."[23] The plan's objectives include watershed-based planning, restoring and protecting ground and surface water quality, education, and interagency cooperation activities to meet the program goal. The NPS Management Program encourages development of WBPs or alternative-WBPs, as appropriate and as described in the EPA's *Nonpoint Source Program and Grants Guidelines for States and Territories* (EPA 2024) and further underscores the development of WBPs by prioritizing watershed restoration projects in areas that have EPA-approved WBPs.

In addition to development of TMDLs, the SWQB works with stakeholders to develop nine-element watershed-based plans (WBPs) to identify on-the-ground implementation projects and best management practices (Table 6) to address water quality impairments and improve surface water quality. In areas where stakeholder interest is high but TMDLs or WBPs have not yet been developed, SWQB works with active stakeholders to encourage planning including development of alternative WBPs to address short-term water quality impairments such as those originating from post-fire runoff or developing Advanced Restoration Plans to complete TMDLs and WBPs in tandem. WBPs are used by local watershed groups and other interested stakeholders to build on the TMDL process with more detailed characterization of pollutant sources, management measures, information and education programs, and monitoring. This approach facilitates coordinated watershed restoration efforts, the development of effective watershed associations, engaged stakeholders, and the implementation of effective best management practices (BMPs) to reduce NPS pollution.

[23] https://www.env.nm.gov/surface-water-quality/nps-plan/

NMED Exhibit 30

Table 6. Common BMPs Implemented Throughout New Mexico to address Nonpoint Source Pollution

NPS Pollution Category	Examples of Best Management Practices (BMPs) utilized in New Mexico
Agriculture	• Residue Management (contour strip cropping, stubble munching, conservation tillage) • Improved irrigation practices (low output sprinklers, vegetation control) • Nutrient Management (split fertilizer applications, nutrient balancing, crop rotation)
Construction	• Sediment Control Structures (silt fences, hay bales, sediment retention ponds) • Heavy equipment cleaning and spill kits • Conduct construction activities during no-flow or low-flow conditions
Fire Suppression/Fuels Management	• Forest thinning / fuels reduction • Post wildfire watershed rehabilitation
Grazing	• Alternate watering sources (trick tanks, upland dirt tanks, and upland wells) • Planned/rotational grazing • Cattle guards to control access • Fencing (pasture cross fencing, creation of additional pastures for improved stock rotation methods, and riparian exclosure fencing)
Loss of Riparian Habitat	• Habitat restoration and rehabilitation - Removal of non-native plant species - Planting native vegetation • Grazing exclosure(s) or planned grazing
Recreational Activities	• Revegetation of impacted areas • Trail maintenance/reconstruction • Provide and maintain waste and sanitation facilities • Limit off-road vehicle use • Restrict vehicular access to riparian areas • Recreational area closure or relocation • Education/Outreach
Resource Extraction	• Sediment Control Structures (silt fences, hay bales, sediment retention ponds) • Stabilizing, relocating, and channeling runoff around mine and mill tailings
Septic Systems	• Identify and replace malfunctioning systems • Outreach to encourage preventative maintenance • Connect to centralized wastewater treatment system
Streambank Modification/ Hydromodification	• Streambank Stabilization via: - Revetment (e.g. vanes, j-hooks) - Grade control (e.g. cross vanes) - Grazing exclosures or rotation - Terracing / revegetation of slopes - Installing vortex weirs - Replacing undersized culverts - Brush control
Urban Stormwater	• Education/Outreach activities • Develop stormwater management plan • Propose new ordinance and/or development codes • Propose new construction standards • Install swales, French drains, detention ponds • Collect and treat runoff

NMED Exhibit 30

IV. Water Quality Protection and Restoration

A. CWA Section 319 Watershed Restoration Grants

One-rock dam built in the Gallinas River during Phase IV of the CWA section 319 project. Photo credit: Hermit's Peak Watershed Alliance (2025)

SWQB provides funding to protect and restore water quality in New Mexico via CWA section 319 for both on-the-ground implementation and planning projects, the state-funded River Stewardship Program (see below), and the newly launched Watershed Protection Assistance Program (see below). Planning projects include the development of a Watershed-Based Plan (WBP), Wetlands Action Plan (WAP), or an alternative-WBP depending on the identified needs of the watershed(s). On-the-ground implementation projects utilize Best Management Practices (BMPs) to reduce NPS pollutants from entering ground and surface waters to improve water quality. CWA section 319 funding for implementation projects is also available to protect water quality soon after a wildfire occurs and for demonstration projects in watersheds that do not already have a WBP, WAP, or alternative-WBP already in place. CWA section 319 grants may include education and outreach activities and are designed to encourage partnerships to address nonpoint source pollution in New Mexico's watersheds.

Since 1998, the NPS Management Program has implemented over 100 watershed restoration projects. New Mexico's current and recently completed CWA section 319 watershed restoration implementation projects can be found on the SWQB Watershed Protection webpage[24]. In addition, CWA section 319(h)(11) requires New Mexico to report to EPA Region 6 annually the progress in meeting milestones in the NPS Management Program plan, reductions in NPS pollutant loading, and improvements in streams that do not meet water quality standards. The SWQB maintains a website providing NPS Annual Reports from calendar year 2000 to present.

Information on projects completed in specific years can be found in the SWQB's *NPS Management Program Annual Reports* at:
https://www.env.nm.gov/surface-water-quality/nps-annual-reports/

[24] See: https://www.env.nm.gov/surface-water-quality/watershed-protection-section/. Direct link for the current list: https://www.env.nm.gov/surface-water-quality/wp-content/uploads/sites/18/2025/02/NMED-319-and-River-Stewardship-Program-Projects-February-2025.pdf

NMED Exhibit 30

B. New Mexico's River Stewardship Program

A key part of the NPS Management Program is the state-funded River Stewardship Program (RSP). The goal of the RSP is to fund projects that enhance the health of rivers by addressing the root causes of poor water quality and stream habitat. The RSP builds on collaboration and restoration techniques developed and implemented during successful CWA section 319 and state funded implementation projects around the state.

Pecos River at Cowles. RSP project on the Pecos River near Cowles, New Mexico with rock and structures creating pool habitat on the Pecos River

Specific RSP objectives include:

- Restoring or maintaining hydrology of streams and rivers to better handle overbank flows and thus reduce flooding downstream;
- Enhancing economic benefits of healthy river systems such as improved opportunities to hunt, fish, float or view wildlife; and
- Providing state matching funds required for federal CWA grants.

RSP projects, like CWA section 319 projects described above, are selected through a competitive, statewide application or Request for Proposals process. RSP projects are distributed statewide. Eligible applicants include municipalities, counties, soil and water conservation districts, irrigation districts, for-profit organizations, non-profit organizations, and Indian Nations, Pueblos and Tribes. Evaluation criteria favor projects that improve water quality, enhance fish and wildlife habitat, support local economies, and reduce downstream flood hazards.

Although RSP projects are not required to implement watershed-based plans, each RSP project proposal is evaluated for its alignment with local, state, tribal or federal planning documents, and watershed-based plans often provide a strong basis in planning for proposals to be competitive. New Mexico's current and recently completed RSP and CWA section 319 projects are displayed in Figure 12.

NMED Exhibit 30

C. Watershed Protection Assistance Program

In 2025, the SWQB created the Watershed Protection Assistance Program (WPAP) to provide small funding opportunities of $75,000 or less to improve surface water quality and river habitat. The program is supplemental to RSP and provides funding to support small projects, planning activities, ongoing projects, or monitoring activities.

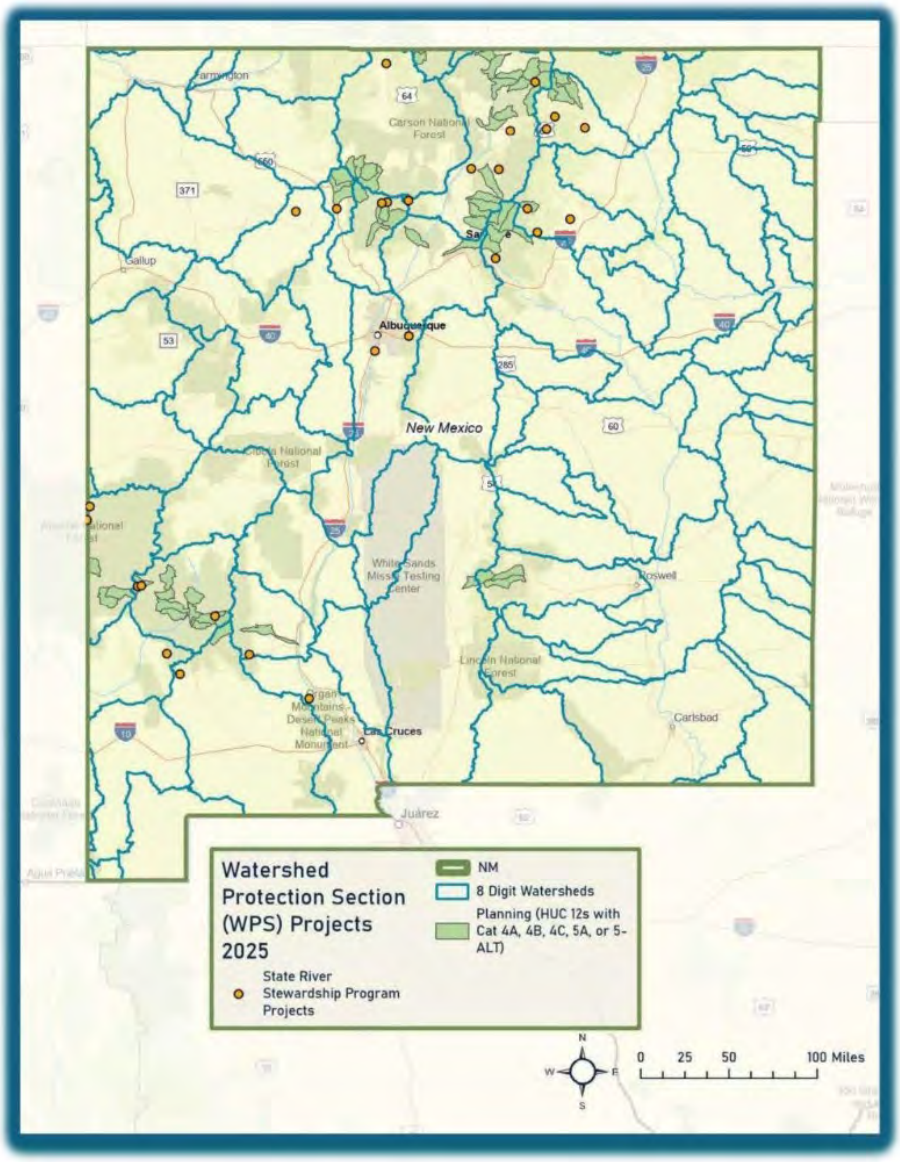

Figure 12. Active CWA Section 319 and River Stewardship Program (RSP) restoration and planning projects, 2025

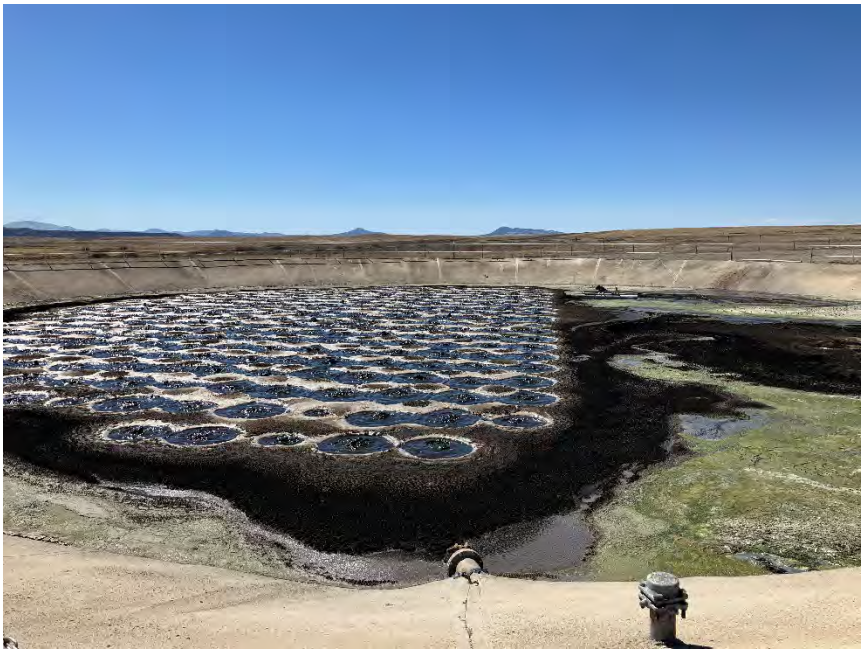
Current and recent Section 319 and River Stewardship Program projects lists are available at: https://www.env.nm.gov/surface-water-quality/wp-content/uploads/sites/18/2024/02/RS8103_NMED-319-and-River-Stewardship-Program-Projects.pdf

D. Point Source Regulation and Other State Certifications

Point source pollution results from discharge of contaminants through discrete conveyances such as pipes, ditches, conduits, or wells. In New Mexico, the EPA under CWA section 402 administers the discharge of pollutants through the National Pollutant Discharge Elimination System (NPDES) program. State certification of federal permits[25] is required under CWA section 401 and ensures that the permits are compatible with state laws, protect the state's water quality standards, and implement the state's WQMP/CPP (NMWQCC 2020). In New Mexico, the NMED is the CWA section 401 authority for certifications (excluding Nation, Tribe or Pueblo receiving waters). The primary goal of the SWQB Point Source Regulation Section (PSRS) is to protect public health and the environment by assuring that regulated point source discharges to surface waters comply with appropriate state and federal statutes and regulations, including applicable New Mexico water quality standards and applicable waste load allocations developed through the TMDL process.

Bloomfield WWTP Outfall observed by SWQB PSRS staff (January 2025)



Gallinas River at Las Vegas WWTP (January 2025)

PSRS fulfilled this responsibility, certifying 14 NPDES individual permits and 1 general permit in state FY 2024, and 21 individual permits in state FY 2025. State FY 2024 certifications included details on the data submittals related to the new per- and polyfluorinated substances (PFAS) monitoring requirements. State FY 2025 certifications included one condition for new dissolved boron effluent limits and one condition for nutrient (total nitrogen and total phosphorus) and dissolved oxygen monitoring. State FY 2025 certifications included a request for seven permittees to develop public communication plans to notify the downstream users of facility overflows, upsets, and bypass events; three permittees to notify downstream Nations, Tribes, and Pueblos of facility overflows, upsets, and bypass events; and three permittees to notify the downstream State of Texas of facility overflows, upsets, and bypass events. PSRS issued one general permit comment set and two downstream user comments in state FY 2024, and one

[25] A list of EPA-issued NPDES permits in New Mexico can be found at: https://www.epa.gov/npdes-permits/new-mexico-npdes-permits.

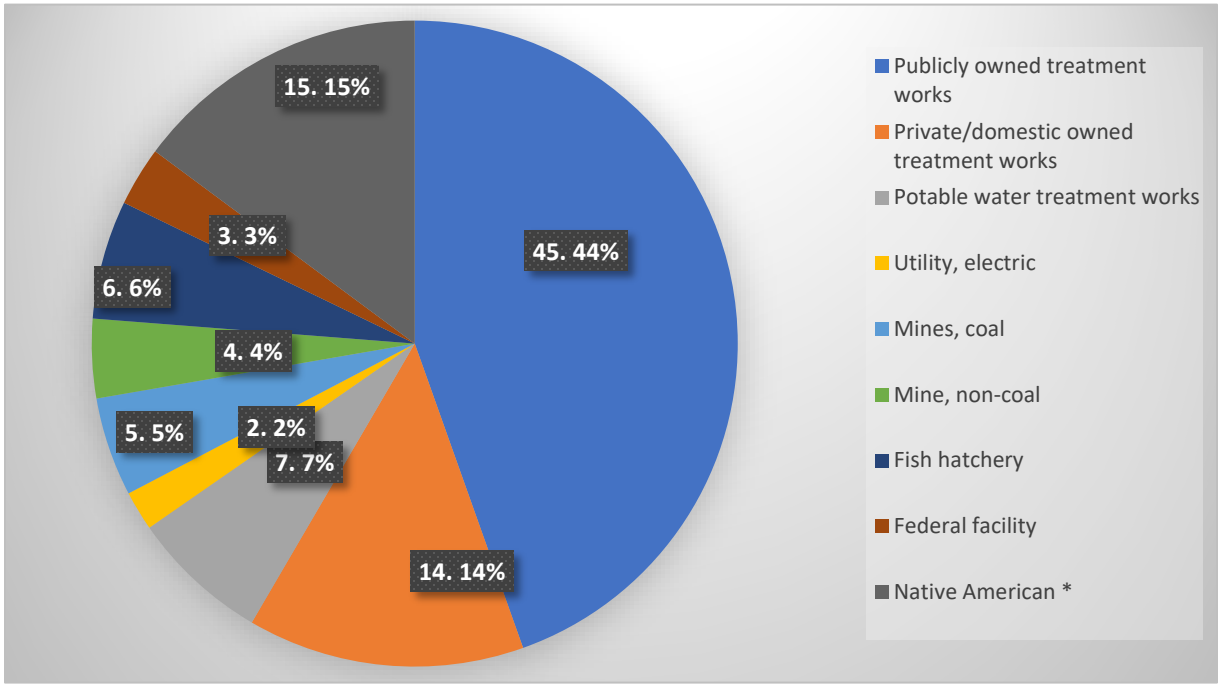
NMED Exhibit 30

general permit comment set in FY2025. In state FY 2024 PSRS completed one antidegradation analysis and related revisions for a new direct discharge to a water of the U.S. In state FY 2025 PSRS completed seven antidegradation analyses for new or increased direct discharges to waters of the U.S.

Raton WWTP Sludge Aeration Basin (March 2026)

PSRS employees are credentialed by the EPA to conduct compliance inspections on behalf of the EPA. PSRS serves as a local point of contact to provide information to operators and other agencies regarding the federal regulatory program and to offer compliance assistance to individual facilities. Inspections help to ensure compliance with applicable effluent limitations and permit conditions and are carried out in accordance with the EPA NPDES Compliance Inspection Manual (EPA 2017b) using current EPA-approved forms, checklists, and computer applications. PSRS and EPA use the data and information collected to evaluate compliance and to support state or federal enforcement and permitting activities. PSRS conducted ten NPDES individual permits compliance inspections in state FY 2024, and twelve NPDES individual permit compliance inspections in state FY 2025.

The EPA executed 74 NPDES enforcement actions in state FY 2024, and 41 enforcement actions in state FY 2025. State enforcement of NPDES permitted discharges has not occurred. State enforcement would be based in large part upon meeting the applicability requirement of 20.6.2.2100 NMAC, which applies to any discharger who is given written notice of a NPDES permit violation from the EPA and who has not corrected the violation. The regulatory applicability clause is designed to prevent dual regulation by state and federal government, while still allowing the State to act in cases where the federal program has been unable to gain compliance within a prescribed time. Furthermore, the NMED has the authority under 20.6.2.1220 NMAC to issue compliance orders, including penalties, for a discharge that exceeds any water quality standard in state regulations, or is not complying with a condition or provision of an approved or modified discharge plan or permit. In state FY 2024, New Mexico issued an administrative compliance order to the City of Santa Fe for *E. coli* and nutrient (total nitrogen and total phosphorus) exceedances of the water quality standards in 20.6.4 NMAC. The state may also enforce provisions of 20.6.2.2201 NMAC prohibiting disposal of refuse in a watercourse.



In addition to conducting individual permit inspections, PSRS also conducts both construction site and industrial facility stormwater inspections in accordance with the provisions of the Construction General Permit or the Multi Sector General Permit. The PSRS conducts outreach to construction site and industrial facility owners and operators to inform them of requirements under the CWA. PSRS conducted ten NPDES construction and industrial facility stormwater inspections in state FY 2024, and ten NPDES construction and industrial facility stormwater inspections in state FY 2025.

NMED Exhibit 30

PSRS also assists with implementation of the Phase I and II Municipal Separate Storm Sewer Systems (MS4) (i.e., urban stormwater) permitting program in New Mexico. PSRS anticipates working with EPA Region 6 on the reissuance of the statewide MS4 permit, to combine the administratively continued 2007 small MS4 permit NMR040000 and the administratively continued 2014 Middle Rio Grande Watershed-Based MS4 permit NMR04A000, in 2026.[26]

PSRS also assists with implementation of the Pesticide General Permit (PGP) and the Concentrated Animal Feeding Operations (CAFO) General Permit, and Hydrostatic Test General Permit. PSRS is working with EPA on the reissuance of the PGP, planned for October 2026. PSRS anticipates working with EPA Region 6 in 2026 on reissuance of the administratively continued 2016 CAFO General Permit for New Mexico. PSRS will continue to provide assistance in conducting audits of these programs as needed.

Figure 13 illustrates the distribution of individual NPDES permitted facilities by type and percentages. Because of the large percentage of wastewater treatment plants in the state, these facilities continue to cause adverse effects on water quality in local areas, in part due to poor operation and maintenance, the lack of certified operators, or limited funding to implement technological improvements and/or upgrades to treatment facilities.

NOTE: * SWQB does not certify permits for Tribal receiving waters. Only downstream-user comments are provided to EPA for Tribal receiving waters and Tribal permits.

Figure 13. Distribution of Individual NPDES permits in New Mexico, as of March 2026 (101 permits total)

[26] See https://www3.epa.gov/npdes/pubs/fact2-1.pdf and https://www.epa.gov/npdes/stormwater-discharges-municipal-sources for additional details on Phase I and II MS4s.

The U.S. Army Corps of Engineers (USACE) administers Section 10 of the Rivers and Harbors Appropriation Act and CWA section 404. The USACE Regulatory Division issues permits (Standard Individual Permits, Regional Permits, Regional General Permits, and Nationwide Permits [NWPs]), which authorize certain activities to discharge dredged or fill material into a water of the U.S. Under CWA section 401, States and Tribes are provided the opportunity to certify CWA section 404 permits to ensure that the federal permit will comply with Surface Water Quality Standards (2.4.6 NMAC) and applicable state law. NMED typically certifies CWA section 404 permits with conditions that include BMPs for protecting water quality from adverse environmental impacts. During Federal fiscal year 2024 (October 1, 2023, to September 30, 2024), WPS staff reviewed 57 projects covered by NWPs, seven projects covered by Regional General Permits (RGPs), and one project requiring an Individual Permit. In Federal fiscal year 2025 (October 1, 2024, to September 30, 2025), WPS staff reviewed 54 projects covered by NWPs, four projects covered by RGPs, and one project covered by an Individual Permit.

https://nmed.commentinput.com/comment/landingPage?lang=EN

E. Other NMED Water Pollution Control Programs

CWA section 303(d) and section 305(b) are primarily implemented by the SWQB. However, because surface water quality is utilized and affected in diverse ways by different activities and needs, the NMED has other bureaus and programs that also address water pollution control in New Mexico under the WQA. A few are highlighted below.

1. Drinking Water Bureau

a) Source Water Protection Program

Systems utilizing surface water sources for drinking water require more sampling of treated water than systems using a groundwater source due to the potential for rapid changes in source water quality. While the quality of the source water does not impact the required quality of the produced drinking water, the quality of the source water will influence treatment considerations and associated costs to comply with all maximum contaminant levels. Just over 60 public drinking water systems use, or purchase water obtained from either surface water or groundwater under the direct influence of surface water. When chlorine is used as part of drinking water treatment, disinfection byproducts can form when organic carbon reacts with the chlorine. Typically, systems can adjust treatment and operations as an effort to return to compliance relative quickly; however, additional infrastructure is sometimes required to remove organic carbon. A system is required to notify the public whenever violations of the SDWA occur.

For additional information on DWB's Source Water Protection Program, visit:
https://www.env.nm.gov/drinking_water/source-water-protection/

City of Santa Fe's Nichols Reservoir (filled (top) and under construction (bottom)). Nichols Reservoir, located within the Santa Fe Municipal Watershed, plays a critical role in supplying drinking water to households and businesses in and around Santa Fe.

In addition to providing oversight to systems, DWB's Source Water Protection Program (SWPP) works with systems to identify potential or actual sources of contamination that might have adverse effects on the source waters and to develop a plan to protect those drinking water sources. The Program assists systems with conducting assessments of potential sources of contamination for their surface water sources. The identified sources of contamination are evaluated based on the number and chemical properties of the associated contaminants, their likelihood of release, their proximity to the surface water source, and chemical monitoring history. Over the past two years the SWPP has been updating and refining the methodology for source water assessments and plans. This includes hydrological analyses of contributing watersheds to delineate source water assessment areas, a new risk assessment for contaminant sources, and a combined and iterative source water assessment and protection plan approach.

In 2021, DWB assisted with the completion of source water assessments and protection plans for the City of Santa Fe for both their groundwater and surface water sources. In 2025, the SWPP resumed assistance to the Village of Ruidoso for an updated source water protection plan that was paused due to wildfires in 2022 and 2024. Ruidoso uses both groundwater and surface water sources that will benefit from this effort.

NMED Exhibit 30

Once the Ruidoso project is complete, 86% of New Mexico's population that relies on streams or reservoirs for drinking water sources will be served by public water systems with active source water plans.

For additional information on NMED's Drinking Water Bureau, visit:
https://www.env.nm.gov/drinking_water/

b) Utility Operator Certification Program

The Utility Operator Certification Program (UOCP) administers the certification program for water and wastewater operators at all public water and wastewater utilities in New Mexico. This includes development, scheduling, and administration of certification examinations; processing applications for certification and renewal; evaluating and tracking all continuing education courses for certified operators; tracking compliance with operator certification requirements; and working with the New Mexico Water Quality Control Commission and the Utility Operator Certification Advisory Board. NMED administers the UOCP pursuant to the New Mexico Utility Operators Certification Act (NMSA 1978, §§ 61-33-1 to -10) and the utility operator certification regulations within the New Mexico Administrative Code (20.7.4 NMAC).

The UOCP ensures that the roughly 2,486 active operators of drinking water systems and wastewater treatment systems in New Mexico are appropriately trained and qualified. The Program tracks required continuing education credit hours (10 hours/year/operator) and certification renewals (renewal required every three years for each certification). UOCP also provides training for operators and coordinates with other assistance providers in the state for additional free training.

UOCP updates:

- In 2020, the UOCP received an EPA Environmental Justice Cooperative Agreement grant in partnership with San Juan College, the Navajo Tribal Utility Authority, and the Ute Mountain Ute Tribe to develop a water utility recruitment, training, and placement program. The project was completed in 2024. Project deliverables included formation of an advisory committee, as well as development and implementaiton of a training curriculum.
- In 2022, the UOCP partnered with the New Mexico Department of Work Force Solutions (DWS) and Water Professionals International (WPI), formerly know as the Association of Boards of Certifications (ABC),to provide operator certification examination through computer-based testing. As a result of switching from paper-booklet exams to computer-based testing (CBT), the UOCP has seen a steady increase in demand for examinations due to the flexibility and ease of access introduced by the partnership with WPI and DWS. In addition, passing rates have greatly improved, from roughly 25% to 40%. The UOCP will continue to identify and implement innovative ways to improve and streamline the UOCP program.
- In 2024, the UOCP successfully completed transition to a data management system within a web-based platform called Certemy. The data management system is custom-tailored to the UOCP water operator certification application work flow process. The system supports that data management needs of both the UOCP and the water operators. The UOCP continued to work closely with Certemy on finetune adjustment of UOCP data management system.
- In 2024, the UOCP experienced significant staff turnover and extensive recruitment efforts were initiated. In 2025, three new UOCP employees have successfully kept the UOCP services running

through the efficiencies made possibly by CBT and the new data management system. Recruitment efforts continue for expanding the UOCP team.

- In October 2025, the UOCP developed a two-year plan to modernize New Mexico utility operator certification. The plan includes development of need-to-know guidebooks, piloting comprehensive operator trianing courses, and rulemaking to revise the utility operator certificaiton rules.

Table 7. Number of Exams Taken per Year

Year	Total Exams Taken	Tests taken as of January
2026	_	30
2025	818	29
2024	710	81

Certified utility operators are required to acquire the appropriate number of training credits to renew a certification. The chart below indicates there are currently 3,389 active certifications and 888 of those certified utility operators hold multiple certifications. During the reporting period, 636 certifications became inactive due to not being renewed.

Table 8. Number of Certifications

Current status	
Inactive Utility Operator Certifications	636
Active Utility Operator Certifications	3,389
Multiple Certifications	888

2. Ground Water Quality Bureau

New Mexico's groundwater resources are of vital importance in sustaining life and must be preserved and protected for both present and future generations. Fifty five percent (54%) of New Mexicans depend solely on groundwater for drinking water. As of 2020 the Office of the State Engineer reported surface water shortages in all areas of the state with many areas shorted more than 60%. Communities must now augment their water supplies with groundwater pumping to mitigate the surface water shortages. Public systems with water derived from groundwater sources serve ninety two percent of New Mexicans (over 1,939,687 people). Just over fourteen percent (14.4%) of the State's population depend on private wells for drinking water (NMOSE 2020). Nearly half of the total water annually withdrawn for all uses in New Mexico, including agriculture and industry, is groundwater, the only practicable source of water in many areas of the State. Overall, the quality of these waters is assumed to be good, although there are significant pollution problems known to affect certain areas of New Mexico. New Mexico lacks a comprehensive, statewide, ambient groundwater quality monitoring program.

New Mexico relies on several programs to protect and maintain groundwater quality. The primary statute dealing with groundwater quality management is the WQA, which authorizes the NMWQCC to adopt

groundwater quality protection regulations and standards (20.6.2 NMAC). Key features of the WQA and the NMWQCC regulations relating to groundwater include:

- A requirement for dischargers to obtain a groundwater discharge permit to prevent groundwater contamination from discharges that have the potential to impact groundwater quality, including discharges to underground injection control wells;
- Requirements for reporting and addressing spills and releases;
- Development of groundwater quality standards;
- Requirements to abate groundwater pollution; and
- Provisions for civil and criminal penalties for violation of the regulations and standards.

The role of the NMED Ground Water Quality Bureau (GWQB) is to protect the environmental quality of New Mexico's groundwater resources; and to identify, investigate, and oversee clean-up contaminated sites which pose risks to human health and the environment. Specifically, the GWQB:

- Issues and oversees groundwater pollution prevention (i.e., discharge) permits;
- Implements, along with the SWQB, the NMED's responsibilities under the New Mexico Mining Act to ensure that environmental issues are addressed and standards are met;
- Oversees groundwater investigation and remediation activities;
- Identifies, investigates and remediates inactive hazardous waste sites through implementation of the federal Superfund program;
- Oversees agreements between the state and responsible parties; and
- Implements the Voluntary Remediation Program.

Clovis Water Fair (August 2025)

The GWQB strives to increase industry and public understanding and awareness of the importance of safe groundwater supplies in sustaining the quality of life in New Mexico for this and future generations, and the importance of protecting groundwater quality through pollution prevention initiatives. The GWQB also offers free water quality screening for domestic wells at water fairs routinely held around New Mexico through NMED's CWA section 319 grant funding.

Groundwater quality monitoring is typically required at permitted facilities to determine baseline groundwater quality, serve as a sentinel detection method, and as part of remediation efforts to determine whether remediation efforts are effective. While household septic tanks or unauthorized cesspools are the predominant source of nonpoint source contamination of groundwater in New Mexico, other diffuse sources may also cause groundwater quality degradation. These sources can include minerals from evapotranspiration, land disturbance by

Observation of Groundwater Well Drilling

mineral exploration, urban runoff, or application of agricultural chemicals. Point source categories include publicly and privately-owned sewage treatment plants with discharges of over 5,000 gallons per day, dairy operations, mines, food processing operations, industrial discharges, landfills, leaking above and underground storage tanks, petroleum processing and storage, and accidental spills or leaks.

Programs established under the New Mexico Oil and Gas Act, Hazardous Waste Act, Ground Water Protection Act, Solid Waste Act, Emergency Management Act, Voluntary Remediation Act, and Environmental Improvement Act also contain provisions designed to protect groundwater quality and implement the groundwater regulations and water quality standards directly or by reference. For example, the Voluntary Remediation Program provides state oversight of assessment and cleanup efforts of contaminated sites that are not involved in regulatory or enforcement actions. Upon completion of the process a Certificate of Completion is issued documenting that property conditions meet applicable standards. Lenders and prospective purchasers are provided with liability protection, thus allowing these properties to transact, or be redeveloped more easily. In addition, the State cooperates with local and federal governments on various programs relevant to groundwater pollution control.

Programs established under the New Mexico Oil and Gas Act, Hazardous Waste Act, Ground Water Protection Act, Solid Waste Act, Emergency Management Act, Voluntary Remediation Act, and Environmental Improvement Act also contain provisions designed to protect groundwater quality and implement the groundwater regulations and water quality standards directly or by reference. For example, the Voluntary Remediation Program provides state oversight of assessment and cleanup efforts of contaminated sites that are not involved in regulatory or enforcement actions. Upon completion of the process a Certificate of Completion is issued documenting that property conditions meet applicable standards. Lenders and prospective purchasers are provided with liability protection, thus allowing these properties to transact, or be redeveloped more easily. In addition, the State cooperates with local and federal governments on various programs relevant to groundwater pollution control.

For more information on NMED's Ground Water Quality Bureau (including updates to the petition to amend groundwater regulations), visit: https://www.env.nm.gov/gwqb/

3. Compliance and Enforcement Division

Compliance is a core value of the New Mexico Environment Department. Assuring compliance with state licenses, permits and rules and enforcing against violations when they occur is critical to protecting the public and their environment. Further, enforcing state licenses, permits, and rules ensures a level playing field because facilities that fail to comply with such requirements may incur an economic advantage over competitors. Compliance with state-issued licenses, permits and rules is not optional – it's required.

On July 1, 2025, the Compliance and Enforcement Division (CED) of NMED was created and is responsible for offering compliance assistance, promptly enforcing against entities when violations occur, and resolving violations of federal and state regulatory programs. The Water Protection Compliance and Enforcement Bureau (WPCEB) within CED has the enforcement authority over New Mexico's Water Quality Act and corresponding WQCC regulations as it relates to ground and surface water quality. WPCEB is also responsible for the compliance and enforcement of New Mexico's Drinking Water Regulations (20.7.10 NMAC) and the federal Safe Drinking Water Act (SDWA). Furthermore, once NMED has EPA approval for the NMPDES program and NMED begins issuing permits, WPCEB will include enforcement activities stemming from noncompliance with NMED issued permits.

a) Public Water System Supervision Group or Program - Compliance

NMED's WPCEB is responsible for regulating public water systems who are responsible (obligated to provide/charged with providing) for providing a safe and sustainable supply of drinking water to their consumers. NMEDs mission is to preserve, protect, and improve New Mexico's drinking water quality for present and future generations, by implementing the requirements of New Mexico's Drinking Water Regulations (20.7.10 NMAC) and the federal Safe Drinking Water Act (SDWA), which establish the standards for drinking water throughout the State. These regulations and standards are set to limit the presence or concentration of harmful contaminants such as pesticides, volatile organics, and radiochemical, chemical, and bacteriological contaminants in drinking water. The SDWA originally focused on treatment as the means of providing safe drinking water at the tap. The 1996 SDWA amendments greatly enhanced existing law by recognizing source water protection, operator training, funding for water system improvements, and public information as important components of safe drinking water. NMED has adopted the SDWA amendments, to ensure the quality of drinking water in New Mexico is protected from source to tap.

Regulated public drinking water systems must monitor the quality of water served to consumers for regulated contaminants; and ensure compliance with New Mexico's Drinking Water Regulations and the SDWA. The water samples are analyzed for contaminants according to an established schedule, to ensure water quality meets the standard of federal and state requirements. Regulatory oversight to New Mexico's public drinking water systems, is accomplished through the review of data and documents, the completion of regularly scheduled onsite facility inspections, the development of compliance guidance, and issuance of notices of violation when water systems do not meet compliance standards. Enforcement action may be taken to return the system to compliance if a water system does not make progress toward achieving compliance. WPCEB may issue an Administrative Compliance Order to compel the water system to achieve compliance. These actions typically include providing technical, managerial, or financial assistance to help improve the overall capacity of a system and encouraging systems to regionalize and combine resources when possible.

V. Measure Progress/ Update Surface Water Quality Goals

The fourth phase of New Mexico's implementation of the CWA framework for surface waters is to continually grow and improve water quality identification and control techniques through measuring progress towards and updating surface water quality goals. Identification goals are reviewed and updated through activities such as the triennial review of water quality standards; the biennial revisions and improvements to the IR listing methodologies, especially related to developing numeric thresholds for narrative water quality criteria; and development of tools to identify, measure condition, and restore additional waterbody types such as wetlands. Progress towards meeting these goals is continually evaluated through rotational surface water quality monitoring, wetlands mapping, site inspections, consideration of special needs and concerns that hamper the ability to identify and address water quality impairments, and effectiveness monitoring of restoration implementation activities. Two specific SWQB programs that focus on these areas are highlighted below, along with special water quality issues and concerns in New Mexico.

A. Effectiveness Monitoring Program

An important goal of the NPS Management Program is to monitor the effects of NPS pollution control projects on water quality. These projects are primarily stream restoration measures funded under CWA section 319, but also include projects funded through the RSP and the Wetlands Program. Effectiveness monitoring has focused primarily on projects addressing stream temperature impairments in mountain streams in northern and central New Mexico. Temperature monitoring is ongoing on the following streams: Comanche Creek, Holman Creek, Rito Peñas Negras, Rio de las Vacas, Willow Creek, Jaramillo Creek, and San Antonio Creek.

Stream temperature monitoring provides data for statistical analysis using the before/after upstream/downstream study design, in which the relationship between the upstream and downstream stations is tested for a significant difference before and after restoration. Initial results from the data analysis indicate that peak summer temperatures in many streams have improved but still exceed the associated aquatic life water quality criteria in some streams.

A common restoration technique for temperature impairments is to exclude cattle and elk grazing by building fence exclosures (i.e., structures intended to exclude animals from these areas to remove grazing impacts) and planting native vegetation to bring back the riparian cover. Although this technique is expected to be effective, there is a significant lag time between planting and sufficient vegetation growth to effectively shade the stream. Data collection and analysis is extended for several years to account for this lag time. These projects are expected to have beneficial effects which will continue to increase as riparian vegetation continues to grow and provide shade to the adjacent stream.

Rock armor to protect the road crossing at San Antonio creek above VC02 (stream temperature monitoring location)

NMED Exhibit 30

Watershed-scale change to attain water quality standards is usually a long-term effort. Economic changes, societal values, climate cycles, and climate change may exert as much influence on water quality as isolated projects or shifts in land management practices. NMED's Effectiveness Monitoring Program seeks to recognize water quality standards attainment attributable to projects or intentional land management improvements. A key NPS Management Program milestone is for NMED to submit one or more nominations per year to the EPA for recognition as an NPS Success Story. New Mexico's recognized NPS Success Stories are listed in Table 9.

Table 9. New Mexico NPS success stories

Waterbody	Year
Rio de las Vacas (Rio Cebolla to Clear Creek)	2025
Rito de los Indios (San Antonio Creek to headwaters)	2025
Redondo Creek (Sulphur Creek to headwaters)	2024
Cold Springs Creek (Hot Springs Creek to headwaters)	2022
San Antonio Creek (Valles Caldera boundary to headwaters)	2021
Jaramillo Creek (East Fork Jemez to headwaters)	2018
Bluewater Creek (Perennial portions Bluewater Reservoir to headwaters)	2017
Polvadera Creek (Cañones Creek to headwaters)	2015
Willow Creek (Pecos River to headwaters)	2014
Sitting Bull Creek (Last Chance Canyon to Sitting Bull Springs)	2014
Comanche Creek (Costilla Creek to headwaters)	2013
Santa Fe River (Paseo del Cañon to Santa Fe WWTP)	2011
Rio Cebolla (Rio de las Vacas to Fenton Lake)	2010

For more information on New Mexico restoration success stories, visit:
https://www.epa.gov/nps/success-stories-about-restoring-and-protecting-water-bodies-impaired-nonpoint-source-pollution

B. New Mexico's Wetlands Program

Wetlands are important features of the natural landscape because they function as filters that trap excess sediment, nutrient runoff and other pollutants, thereby improving water quality in adjacent streams and waterbodies. Wetlands mitigate extreme weather events common to New Mexico (and becoming more common due to climate change), such as drought and flashfloods by allowing water to slow down and infiltrate, thus augmenting groundwater storage and aquifer recharge, and attenuating the power and intensity of flashfloods. Wetlands support vegetation that provides a moist green fire break in the event of wildfires. They serve as the headwater sources of perennial streams including some of our State's outstanding streams and fisheries. Wildlife benefit greatly from wetlands, which support greater diversity of terrestrial and aquatic species.

Among the modern threats to New Mexico's wetlands are groundwater pumping that lowers already shallow water tables, invasive exotic plants and animals that are outcompeting natural species, and erosion and channelization of flow that drain wetlands. This latter threat has severely impacted many of New Mexico's wetlands by limiting, and in many cases eliminating, the water-land relationship that would

NMED Exhibit 30

normally have allowed the establishment of wetland vegetation and ecosystems. The results include the loss of natural flood attenuation, nutrient cycling, habitat connectivity, particulate retention, carbon sequestration, dynamic and long-term surface water storage, moderation of groundwater flow or discharge, and maintenance of vertebrate and invertebrate communities and habitat structure.

Lordsburg Playa in 2021. Photo credit: Esha Chiocchio

The SWQB's Wetlands Program administers CWA section 104(b)(3) Wetland Program Development grants. The overall goal of the Wetlands Program is to protect, restore and increase self-sustaining and naturally functioning wetlands and riparian areas. The Wetlands Program has the following long-term objectives, as specified in the 2021 Wetlands Program Plan[27]:

1. Promote wetland protection and restoration as a goal of established watershed groups and partnerships.
2. Increase wetland area (no net loss) as well as restore wetland functions and ecological services and develop a system for tracking gains and losses by wetland type.
3. Assist communities, agencies, tribes, stakeholders, local governments and others with wetlands technical information, project design and planning, training and other guidance.
4. Develop protection, adaptation, and mitigation strategies for wetland resources threatened by the effects of a drying climate in the west, including drying of wetlands in the landscape, loss of mountain snowpack, increased large-scale catastrophic fires and subsequent flooding, scour and sediment delivery.
5. Develop and refine narrative water quality standards for wetlands and for specific wetland types and use these standards to promote more effective Clean Water Act Section 401 Certification.
6. Develop a toolbox of successful restoration techniques that are specific to wetland types and ecoregions.

[27] https://www.env.nm.gov/surface-water-quality/wp-content/uploads/sites/18/2022/01/2021-New-Mexico-Wetlands-Program-Plan.pdf

The Wetlands Program emphasizes the role of wetlands in preventing and reducing water quality issues and providing habitat and life requirements for aquatic and wildlife, including protected species. The following activities support the long-term objectives and goals of the Wetlands Program and include:

- Completing the inventory of wetlands resources through landscape level mapping and classification
- Determining the ecological condition of wetlands in New Mexico through the development and implementation of wetlands rapid assessment methods
- Implementing innovative wetland restoration demonstration projects and sharing the outcomes in Technical Guides or other publications
- Engaging watershed groups, communities, and other citizens groups in the development of Wetlands Action Plans
- Promoting maintenance of instream flow to support streamside and floodplain wetlands and provide other water quality benefits
- Promoting agricultural water use management and supporting wetlands as filtration systems for agricultural runoff
- Promoting land management techniques to restore wetland-supporting beaver habitat
- Increasing wetland acreage in New Mexico through the restoration and protection of wetland corridors
- Ensuring adequate protection of all wetlands at the state level including closed basin and isolated wetlands
- Participating in wetland and riparian education and outreach for schools and interest groups
- Providing a statewide forum for sharing information about wetlands by hosting Wetlands Roundtables meetings

Rainbow over a wetland in the Costilla/Valle Vidal area

For more information on New Mexico Wetlands Program, visit:
https://www.env.nm.gov/surface-water-quality/wetlands/

C. Special State Surface Water Concerns and Recommendations

Agencies and other stakeholders that implement New Mexico's water management programs work continuously to protect surface water quality. However, there are still many challenges in meeting the objectives of the CWA and the WQA. Below are significant surface water quality issues in New Mexico.

Climate Change

A dry Rio Gallina streambed above the Rio Chama, December 2025

New Mexico acknowledges the impact of climate change on the state's water resources because the science shows that these changes will lead to further problems and uncertainties. Droughts are increasing in both frequency and severity in many regions of the world, including the southwestern U.S., due to climate change. In general, droughts and the immediate recovery period have substantial water quality effects on the waterbody and its watershed. For example, decreases in stream flow typically increase pollutant concentrations due to less dilution. Other water quality impacts associated with climate change and drought include higher water temperatures, enhanced algal production, toxic algal blooms, and lower dissolved oxygen levels. As temperature and precipitation patterns undergo extreme cycles, more frequent and more powerful storms will increase pollutant runoff from the watershed, physically modify and erode riparian habitat, and disrupt biological communities that depend on these habitats. In addition, shifting temperature and precipitation patterns affect vegetation composition and density and increase the propensity for wildfire. Climate change will add additional stress to New Mexico's water resources and make attainment of water quality standards more difficult to achieve.

As surface waters become stressed by climate change, drought, wildfires, overuse, and groundwater mining, many perennial and intermittent streams and springs will experience reductions in flow. Currently, many perennial "rivers" and "tributaries" in New Mexico contain non-perennial sections. As a result of climate change, the overall length of "perennial" waters may diminish and the need for clean water will strain these systems even further.

To address some of these concerns, in 2019 Governor Lujan Grisham signed Executive Order 2019-003 on Addressing Climate Change and Energy Waste Prevention, which created an Interagency Climate Change Task Force and directed State agencies to integrate climate change mitigation and adaptation practices into their programs, policies, and operations. In January 2024, Governor Lujan Grisham announced the 50-Year Water Action Plan, which describes how the state can prepare for and mitigate the impacts from climate change and secure a clean and sustainable water supply for present and future generations. The IR ties in directly with various initiatives for resource management in the State of New Mexico, including executive order 2019-003 and the 50-Year Water Action Plan. Water quality challenges identified in this report are important to address as improved watershed health is New Mexico's most effective tool in increasing waterbody and watershed resilience to climate change.

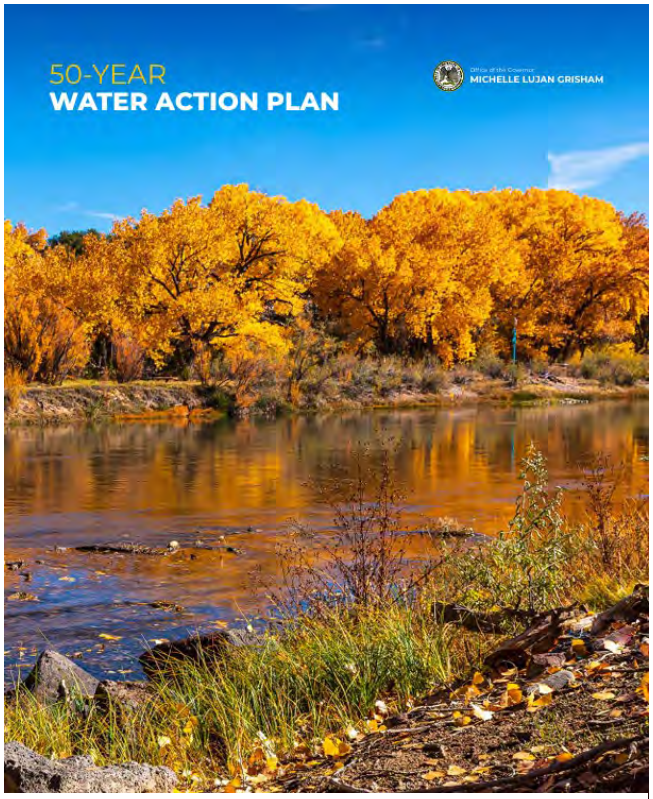
NMED Exhibit 30

Stormwater Management

Controlling stormwater runoff and its impact is a serious issue facing communities across New Mexico. Urban and highway stormwater runoff is rainfall or snowmelt that runs off the ground or impervious surfaces such as buildings, roads, and parking lots, and drains into natural or man-made drainage systems. In most cases, it drains directly into streams, rivers, lakes, or wetlands without receiving any treatment to remove pollutants. Because of this, stormwater is a leading cause of water pollution.

Rio Grande at Pena Blanca, NM

Changes in land use have a major effect on both the quantity and quality of stormwater runoff. Urbanization, if not properly planned and managed, can dramatically alter the natural hydrology of an area because it increases impervious cover, decreases the amount of rainwater that can naturally infiltrate into the soil, and consequently increases the volume and rate of stormwater runoff. Stormwater runoff also typically contains elevated concentrations of a variety of emerging contaminants (e.g., PFAS, microplastics, pharmaceuticals, etc.) as well as pollutants that exceed water quality standards (e.g., copper, lead, and zinc; polyaromatic hydrocarbons [PAHs] and pesticides; oil and grease; nutrients [nitrogen and phosphorus]; sediment; and E. coli bacteria). Untreated stormwater entering our waterways can kill aquatic life and result in the contamination of fish tissue and drinking water supplies; prohibit or limit swimming, fishing or boating; and present dangers to public health and safety. Municipal separate storm sewer systems (MS4s) in urbanized areas transport polluted stormwater runoff to local and then downstream waterbodies. To prevent harmful pollutants from being washed or dumped into designated MS4 areas or watersheds, certain operators are required to obtain National Pollutant Discharge Elimination System (NPDES) MS4 permit coverage and develop stormwater management programs (SWMPs). The SWMP describes the stormwater control practices that will be implemented consistent with permit requirements to minimize the discharge of pollutants from the urbanized area. Furthermore, effective water quality protection requires the “treatment” of stormwater utilizing various preventive and control measures (e.g., best management practices, low impact development, structural controls) to reduce the impact of impervious surfaces and minimize increases in stormwater runoff.



Although MS4 designated areas or watersheds are generally based on population, EPA may also designate certain small MS4 areas when discharges are contributing to violations of applicable water quality standards based on their residual designation authority. One such example in New Mexico is EPA’s November 2023 determination that stormwater discharges in Los Alamos County contribute to water quality standards violations and require Clean Water Act permit coverage. NMED provided support to EPA for the special designation and confirmed that both NMED and LANL studies verify elevated levels of metals and PCBs in urban stormwater from the area. In this determination, EPA identified Los Alamos County, LANL, and NMDOT as entities required to obtain coverage under the sMS4 permit. This important designation is a major step towards eliminating or reducing the transport of sediment-laden stormwater, along with various water contaminants, to one of New Mexico’s most important rivers -- the Rio Grande.

One of the eleven priorities in the 50-Year Water Action Plan focuses on building modern stormwater infrastructure to prevent surface water pollution and address emerging contaminants. By 2045, a long-term goal of the Plan is to have major stormwater management and flood prevention projects, including those that utilize green infrastructure practices, completed or substantially underway in all cities, towns, and villages in New Mexico. If realized, this investment to control and mitigate stormwater would limit pollution, protect water quality, increase groundwater recharge, create opportunities for water reuse, and decrease the risks of loss of life and property destruction from flooding.

Waters of the U.S., Sackett v. EPA, and NM's State Permitting – NPDES Primacy Goals

"Waters of the United States" (WOTUS) is a term used to establish the scope of federal jurisdiction under the CWA and is important for implementing Clean Water Act programs within states. The CWA does not define WOTUS but provides discretion for EPA and the U.S. Department of the Army (U.S. Army Corps of Engineers) (the "Agencies") to define "waters of the United States" in regulations. The Agencies promulgated regulations in 1979 to define WOTUS and the scope of federal regulation, and have since amended their WOTUS regulations in 2015, 2020, 2023, and 2025.

In November 2025, the Agencies published a proposed updated WOTUS rule that codifies and aligns with the U.S. Supreme Court's decision in *Sackett v. EPA*. The *Sackett* decision and proposed WOTUS rule significantly reduce national Clean Water Act safeguards, which now only include protections for traditionally navigable waters (TNWs), impoundments and tributaries of TNWs that are relatively permanent, standing, or continuously flowing bodies of water, and wetlands with a "continuous surface connection" to these protected waters. The proposed rule defines "relatively permanent" as water existing year-round or at least during the wet season. In addition, the proposed rule excludes interstate waters as a standalone category of protected waters.

New Mexico 50-Year Water Action Plan

Rivers, streams, lakes, wetlands, and other surface waters sustain the state's culture, economy, and natural ecosystems. Currently, New Mexico relies on the Agencies to regulate discharges of pollutants into waters within our borders. However, the 50-Year Water Action Plan[28] identifies the need to protect surface water by controlling pollution through a discharge permitting program. Specifically, Action C2 of the 50-Year Water Action Plan prioritizes the development and implementation of, "...a State surface water discharge permitting program to protect watersheds and reduce the amount of pollution entering New Mexico's rivers, lakes, streams and wetlands." New Mexico is one of only three states that does not issue and enforce their own

[28] www.nm.gov/wp-content/uploads/2024/01/New-Mexico-50-Year-WaterAction-Plan.pdf

NPDES permits. Given the many water challenges facing our state, it is time to put regulatory control over surface water discharges at the state level and take ownership of this important water quality program to ensure clean water for drinking, recreational, agricultural, cultural, and other uses.

Leading up to the 2025 Regular Legislative Session, SWQB organized a Surface Water Advisory Panel (SWAP), a diverse group of stakeholders that may be affected by the new permitting program. The SWAP was convened in the Fall of 2024 and over the course of six meetings provided feedback, comments, and concerns to the SWQB regarding potential legislation and rules pertaining to a state-led permitting program. Key discussion areas were regulatory scope and program clarity, public engagement and communication, program funding, and sector-specific operational considerations. A summary of the SWAP meetings and key points made can be found in the SWAP Executive Summary, available on the SWQB SWAP webpage at: https://www.env.nm.gov/surface-water-quality/swap/.

The first piece to establishing a state-run permitting program is legislation to give NMED the authority to develop and implement a program. Senate Bill 21 (SB21), passed during the 2025 Regular Session and signed into law on April 8, 2025, does two critical things to protect water quality. First, it empowers New Mexico to regulate discharges of pollutants from point sources and dredge and fill activities into "surface waters of the state" (SWOTS) that are no longer protected by the Clean Water Act. And second, it provides authority for the State to take over the federal National Pollutant Discharge Elimination System (NPDES) permitting program from EPA. As a result of SB21, NMED is currently building a surface water quality permitting program to protect SWOTS but has not yet implemented the program.

NMED Surface Water Quality Bureau Chief Shelly Lemon and Representative Kristina Ortez present SB 21 & 22 during the 2025 legislative session.

NMED is also pursuing authorization from EPA to administer and enforce the NPDES program to protect WOTUS within our borders. The final version of SB21 can be viewed here: https://www.nmlegis.gov/Legislation/Legislation?Chamber=S&LegType=B&LegNo=21&year=25.

The second piece to establishing a state-run permitting program is rules to implement SB21. NMED solicited comments and feedback on draft rules from the SWAP, tribal environmental directors, various stakeholder groups, and the public. NMED incorporated the comments and feedback received, as appropriate, into proposed surface water permitting rules for both the NMPDES Program and State Permitting Program. The NMPDES regulations are included in 20.6.5 NMAC and serve as the foundation for NMED's application to EPA for NPDES delegation to allow the state to regulate and enforce discharges into WOTUS. Meanwhile, the State Permitting Program regulations are amendments to existing regulations in 20.6.2 NMAC and are the framework for the state-led permitting program for discharges into SWOTS, including discharges of dredged and fill material. The U.S. Army Corps of Engineers will continue to regulate discharges of dredged and fill material into WOTUS under the authority of the Clean Water Act. The draft rules are available at: https://www.env.nm.gov/surface-water-quality/amendments-to-20-6-2-nmac-and-proposed-new-rule-20-6-5-nmac-review/.

For more information on New Mexico State Permitting Program development, including NPDES authorization ("primacy"), **visit:** https://www.env.nm.gov/surface-water-quality/spp/

Wildfires

New Mexico has experienced a growing number of wildfires with increasing size and severity. Wildfires can produce significant watershed changes that may impact water quality, fish and other aquatic organisms, drinking water supplies and wastewater treatment systems. The primary water quality concerns after a wildfire are: (1) the introduction of sediment and debris into the surface waters; (2) the increase of nitrate and other plant nutrients from burned vegetation; (3) the introduction of radionuclides and heavy metals from ash, soils, and geologic sources; and (4) the introduction of fire-retardant chemicals into waterbodies. The magnitude of these effects is largely dependent on the size, intensity, and severity of the fire, and on the condition (e.g., healthy or poor) of the watershed at the time of burning.

Post-wildfire flooding, Carrizo Creek, July 2024

Carrizo Creek flooding, July 2024

A watershed may take decades to completely recover from the effects of wildfire, during which time the waters may exceed WQS for one or more pollutants. Assessing the water quality of an area after a wildfire can be challenging as it may be difficult to determine the cause of any impairments and the time at which fire-caused conditions are no longer influencing the watershed. Whether natural or human-caused, with the increasing frequency and magnitude of wildfires in response to drought and climate change, a standard approach for monitoring, assessing, and listing wildfire affected areas needs to be developed.

In 2024, the South Fork and Salt Fires devasted Sacramento Mountains watersheds, burning over 25,000 acres of forested headwaters and destroying roughly 1,400 structures in the Village of Ruidoso. The severity of the South Fork and Salt Fires led to major evacuations and a federal disaster declaration to assist with response to burned areas and catastrophic post-fire flooding occurring in the Village of Ruidoso during the summers of 2024 and 2025. Many of the watersheds impacted by the fire were intensively monitored in the 2021-2022 SWQB rotational survey, including probabilistic surveys. There are several impairments for nutrients, total phosphorus, temperature, turbidity, and *E. coli* within the fire perimeter, including the following assessment units (AUs): Rio Ruidoso (Carrizo Creek to Mescalero Apache boundary), Grindstone Canyon Reservoir, and Carrizo Creek (Rio Ruidoso to Mescalero Apache boundary). After these fires, and to improve outreach for surface water quality issues in southeast New Mexico, SWQB hired a new staff

NMED Exhibit 30

member in 2025 located in NMED's Ruidoso Field Office to help focus on post-fire recovery efforts. Fortunately, the Village of Ruidoso had just started the process of developing a watershed-based plan for the area before the 2024 fires. The scope of the watershed-based plan has grown from three to five subwatersheds (130600080103 Upper Rio Ruidoso, 130600080101 Carrizo Creek, 130600080106 Middle Rio Ruidoso, 130600080102 Cherokee Bill Canyon, and 130600080105 Devils Canyon) to address the post-fire landscape and improvement of surface water quality impairments.

For more information on Wildfire Impacts on Surface Water Quality in New Mexico, visit:
https://www.env.nm.gov/surface-water-quality/wildfire-impacts-on-surface-water-quality/

Nutrient Reduction Strategy

The EPA, through its National Water Program Guidance, continues to place a high priority on states addressing nutrient pollution and identifying nutrient-impaired waters through adoption of numeric water quality criteria for nitrogen and phosphorous in our nation's waters, although the EPA has allowed appropriate flexibility to states to make incremental improvements to address excess nutrients through other measures (Fox 2022). As documented in the New Mexico Nutrient Reduction Strategy (NMED/SWQB 2014), New Mexico is currently not pursuing adoption of numeric nutrient criteria. Instead, New Mexico is pursuing continued refinement of numeric thresholds for our narrative criteria and associated listing methodologies. Specific accomplishments this listing cycle include:

NMED staff conducting nutrient data collection in the Rio Grande, July 2025

- In collaboration with EPA, initiated and completed a Nutrient Scientific Technical Exchange Partnership and Support (N-STEPS) project to refine numeric nutrient threshold values in New Mexico's listing methodology for lakes and reservoirs;
- Continued protection of water-quality limited segments in accordance with both state (20.6.4.8 NMAC) and federal (40 C.F.R. § 131.12) antidegradation policies and implementation procedures to ensure that Tier 1 waters (i.e., waters identified as "impaired") are not further degraded and that NPDES nutrient effluent limitations, at a minimum, protect existing instream uses;
- Continued improvements to nutrient TMDLs that recognize the nutrient threshold concentrations necessary to protect designated aquatic life uses while developing approaches to implement waste load allocations and load reductions that are achievable; and
- Completed a project with EPA to create a preliminary draft update of the New Mexico Nutrient Reduction Strategy, scheduled for SWQB completion in calendar year 2026.

Harmful Algal Blooms

Harmful Algal Bloom at Quemado Lake, October 2025

As part of the 2020 Triennial Review, SWQB proposed and the WQCC and EPA approved the following addition to 20.6.4.900.D NMAC:

". . . a single sample of total microcystins of 8 µg/L with no more than three exceedances within a 12-month period and a single sample of cylindrospermopsin of 15 µg/L with no more than three exceedances within a 12-month period. . ."

Harmful Algal Bloom at Quemado Lake, October 2025

SWQB then updated SOP 12.1, "Lake Sampling", for microcystin sample collection that is accessible on the SWQB website Standard Operating Procedures and added methodologies for microcystin and cylindrospermopsin as well as cyanobacteria assessment protocols to the Comprehensive Assessment and Listing Methodology. SWQB has started collecting microcystin data as part of the lake monitoring program. In the effort to disseminate information to the public, SWQB created and maintains a new webpage for Harmful Algal Blooms that includes a frequently asked questions (FAQs) section, tips on identifying blooms, and an outlet for the public to report suspected blooms. The website also provides an interagency collaboration tool to disseminate information including links to the most current early warning satellite-based tools, recommended monitoring and response strategies, and information regarding human health through our NMDOH and NMED DWB partners. SWQB also initiated and is leading a related interagency working group on addressing harmful algal blooms in New Mexico. The harmful algal blooms working group will help SWQB communicate with water and land use managers to streamline the process of identifying and addressing emerging environmental and public health concerns as blooms establish in New Mexico's lakes. Since the science of harmful algal blooms is rapidly evolving, SWQB will continue working to implement the most current and effective strategies in addressing them.

VI. Financial Resource Analysis

A. Resources Applied to Surface Water Quality Management

Protecting and preserving water quality to ensure adequate, safe, and reliable water resources for the long term is a top priority for the NMED. The quality of the state's water resources has an impact on every resident and is linked to the economic vitality and quality of life New Mexicans cherish.

Like most states, New Mexico is faced with the challenge of addressing an array of complex surface water quality issues with limited financial resources. As the complexity of environmental needs continues to increase, there is an expectation that the SWQB will continue to meet and exceed the mandates of state and federal legislative and regulatory requirements. This pressure makes it essential that New Mexico evaluate information regarding the fiscal implications and potential benefits of its water quality programs. However, and as referenced throughout this report, there are also local, state, and even private resources that directly or indirectly affect the state's water quality. Table 10 summarizes the amount of funds the SWQB expended in State fiscal year (FY) 2025 to implement a comprehensive water quality management program. Match dollars, provided locally as cash or in-kind support for nonpoint source and wetland projects, are not included in this table.

Table 10. State Fiscal Year 2025 Expenditures for New Mexico's Surface Water Quality Management Implemented Through NMED SWQB

Surface Water Quality Management Program	Federal	State	Total
Monitoring & Assessment (Includes Monitoring, Assessment, TMDL, and Fish Consumption Advisory Programs)	$ 759,511	$ 873,348[1]	$ 1,632,859
Point Source Regulation	$ 342,711	$ 635,162[1]	$ 977,873
State Permitting Program	--	$ 1,661,809	$1,661,809
Nonpoint Source Management	$ 1,167,611	$ 628,431	$ 1,796,042
Wetlands Program	$ 401,885	$ 367,762	$ 769,647
Water Quality Standards (includes planning and reporting activities)	$ 171,356	$ 317,581[1]	$ 488,937
River Stewardship Program (RSP)	--	$ 5,618,314	$ 5,618,314
WIIN Act Gold King Mine Activities: San Juan-Animas Watershed	$ 163,763	--	$ 163,763
Total	**$ 3,006,836[2]**	**$ 10,102,408[3]**	**$ 13,109,244**

NOTES: The above numbers are based on NMED State FY 2025 actual expenditures.

1 = funding includes State Level of Effort Match for the CWA § 106 Grant ($220,100).

2 = This amount has remained relatively stagnant for more than a decade, averaging $3,488,851 Federal investment in New Mexico's surface water quality programs since fiscal year 2011. Federal support continues to decrease when accounting for inflation.

3 = The substantial change in Total State funds expended ($10,102,408 compared to the 14-year average of $1,931,022) is primarily due to increased State support and investment for the SWQB River Stewardship Program and State Permitting Program, and implementation of the Land of Enchantment Legacy Fund.

NMED Exhibit 30

B. Capital Investments in Municipal Facilities

Chapelle MDWCA RIP 00044 Construction of New Waterline.

The estimated annual costs for operating and maintaining various sizes of wastewater treatment facilities in New Mexico is summarized in Table 11. Most of these operation and maintenance costs are funded through fees included in monthly water/sewer rates. Many entities do not include replacement cost in their rate structure; therefore, New Mexico is encouraging communities to utilize the Asset Management approach to rate setting. Asset Management helps wastewater treatment systems prepare for both anticipated and unexpected problems by evaluating the system's current physical, financial, and managerial situation. It requires entities to make fundamental decisions about the water system's purpose, structure, and functions. For more information refer to *Asset Management: A Handbook for Small Water Systems* (EPA 2003a).

Table 11. Estimated Annual Operation and Maintenance Costs for Wastewater Treatment Facilities in New Mexico

Wastewater Treatment Plant Facility Size	Estimated Annual Operation and Maintenance Costs
Small WWTP < 1 MGD	$300,000 per year
Medium WWTP 1-4 MGD	$780,000 per year
Large WWTP > 5 MGD	$1,500,000 per year

Source: Utility Operator Certification Program; MGD = million gallons per day

The NMED Construction Programs Bureau (CPB) administers the Clean Water State Revolving Fund (CWSRF), the Rural Infrastructure Revolving Loan Program (RIP), and the Special Appropriations Capital Outlay Program (SAP). The CWSRF provides funding for a variety of wastewater projects including nonpoint source and solid waste projects; the RIP provides funding for water, wastewater, and solid waste projects; and the SAP oversees legislatively assigned water, wastewater, and environmentally related projects. Technical assistance and oversight are provided for all projects to ensure environmentally sound, high-quality projects free of waste, fraud, and abuse. Table 12 summarizes the programs administered by the CBP, and shows the amounts disbursed in state FY 2024 and FY 2025.

Table 12. Summary of Improvement and Construction Costs for New Mexico Water, Wastewater, and Solid Waste Facilities

Program	Description	Funds Disbursed in FY 2024	Funds Disbursed in FY 2025
State Appropriations Program	State Legislature capital outlay appropriated for the construction of community water supply, wastewater facility, and solid waste facility projects.	$ 58,741,195	$ 38,476,741
Clean Water State Revolving Fund (CWSRF) Program	Revolving loan fund to provide a source of low-cost financing for a wide range of wastewater or storm drainage projects that protect surface and groundwater quality and public health. Funds may also be used for nonpoint source water pollution control projects, such as solid waste projects and septic tank installations	$ 23,705,717	$ 26,676,073
Rural Infrastructure Program	Revolving loan fund to provide financial assistance to local authorities for the planning, design, and construction or modification of water supply, wastewater, and solid waste facilities.	$ 1,979,066	$ 2,585,946
	Water-Related Projects TOTAL	**$ 84,425,978**	**$ 67,738,760**

City of Roswell Flood Emergency Sewer Line Repairs CWSRF 150 ($1.04 million)

City of Anthony South Anthony Arroyo Flood Control Project: CWSRF 067 ($676,115), OSG 001 ($323,520), and OSG 003 ($576,001)

Benefits of these expenditures can be seen directly and indirectly throughout communities in New Mexico. The state's water quality programs, including expenditures for pollutant-reducing infrastructure, result in prevention of water quality degradation from point and NPS sources of pollution, protection of aquatic life and habitat in receiving streams, reduction of pollutant loads that could have financial and public health

NMED Exhibit 30

impacts in areas where surface water is a source of drinking water, increased public awareness regarding the need for water quality protection, and sustainable resource management practices.

The NMED DWB and New Mexico Finance Authority (NMFA) administer the Drinking Water State Revolving Loan Fund (DWSRLF), which provides low-cost loans to eligible public drinking water systems. Representative projects include repair and replacement of failing distribution lines, water treatment upgrades to maintain compliance with the SDWA, and the construction and rehabilitation of wells to ensure an adequate water supply.

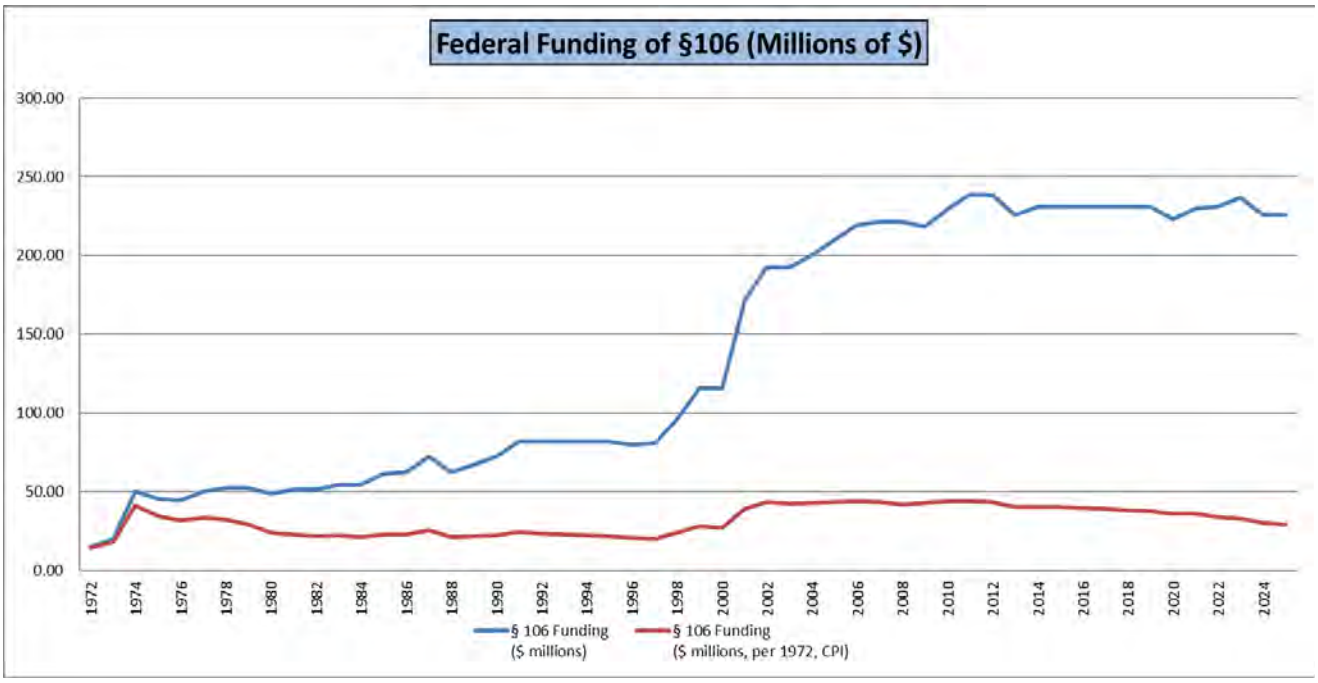
C. Investing in Water Quality Management Programs

Protecting the nation's water from pollution and contaminants relies on cooperation between EPA, states, and tribes; however, over the past two decades state and federal funding for water quality programs has not been sustainable to a point where some basic services may no longer be supported (see tables and figure below). Counter to this fact, a 2021 Gallup poll[29] found that, "of six environmental problems facing the U.S., Americans remain most worried about those that affect water quality. Majorities express 'a great deal' of worry about the pollution of both drinking water (56%) and rivers, lakes and reservoirs (53%)." Similarly, in the State of New Mexico, a bipartisan team conducted a phone poll among 506 likely 2022 voters to evaluate support for a General Obligation Bond for land and water conservation.[30] The survey showed a large and diverse majority supported a general obligation bond in support of land and water conservation, reflecting voters' commitment to the land, water, and heritage of this state. In an open-ended question, voters were asked to state in their own words why they would support the bond. In response, 44 percent volunteered "protect water," which was by far the leading response. In addition, 87 percent noted "conserving and protecting sources of drinking water" as very important and 81 percent noted "protecting water quality in local streams and rivers" as very important. In fact, the top six responses included activities related to surface water quality management programs! Clearly, water quality protection is on the minds and in the hearts of New Mexicans.

State water quality programs play an integral role in building water infrastructure including providing technical assistance to small, rural, disadvantaged, and underserved communities; marketing investments in green infrastructure; processing loan and grant applications; prioritizing projects to meet the greatest need; conducting environmental reviews; performing engineering analyses; certifying and funding projects; monitoring compliance; and providing fiscal accountability. Core Water Quality Protection program components include: water quality standards development and implementation; monitoring and assessment of surface water quality; point source regulation, NPDES permit certification, and compliance inspections; spill response and enforcement; TMDL and watershed-based planning; nonpoint source pollution control, dredge and fill permit certification; watershed restoration, education and outreach; wetlands mapping and condition assessment; water infrastructure and grants management; and groundwater protection.

The Clean Water Act (CWA) section (§) 106 Water Pollution Control Grant Program gives states the flexibility to conduct essential pollution prevention, inspection, monitoring, permitting, and compliance activities as EPA's co-regulator. The CWA § 319 Non-Point Source Pollution Control Program buttresses the quality of our

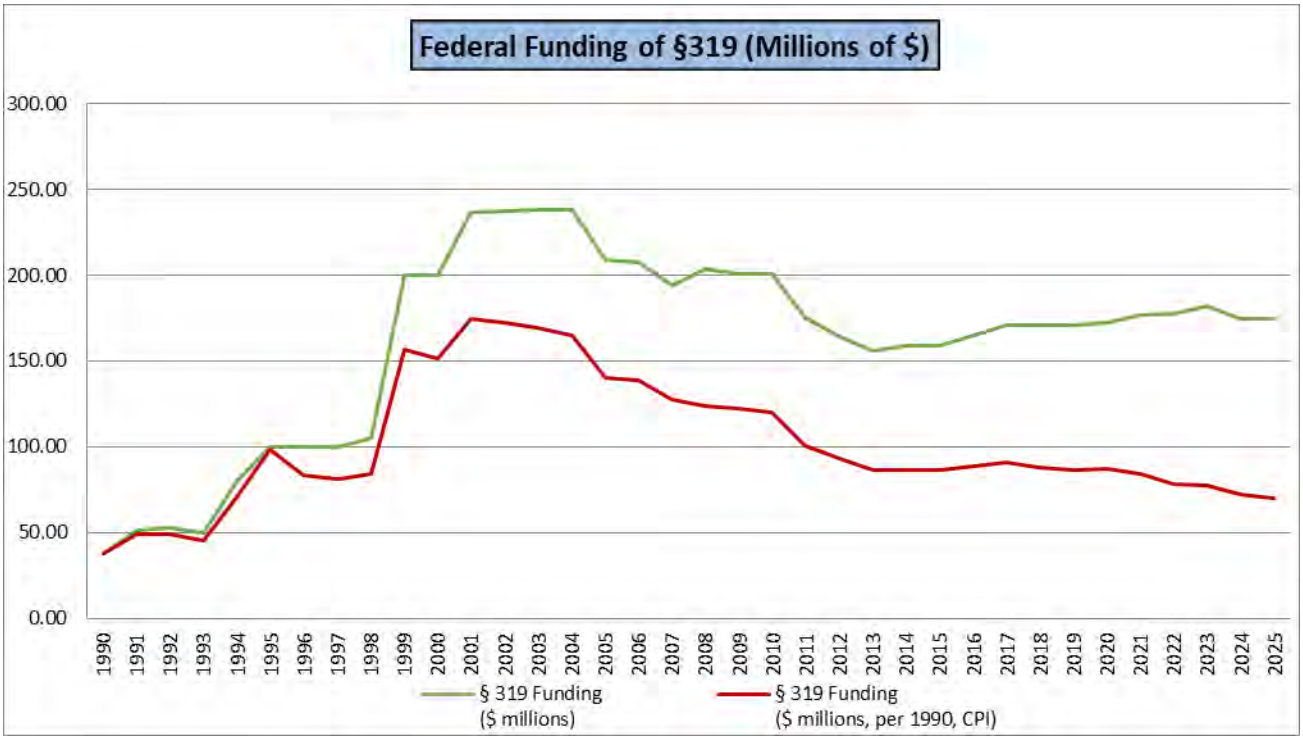
[29] Water Pollution Remains Top Environmental Concern in U.S.



[30] Telephone survey conducted October 19-25, 2021. This survey carries a margin of error of +/- 4.38 percent at a 95 percent confidence interval.

national waterbodies in the face of ever-increasing and evolving non-point source contributions to pollutant loadings. Wetlands Program Development grants assist states, tribes, and local governments in building programs to protect, manage and restore wetlands, and support projects relating to the prevention, reduction, and elimination of water pollution. Table 13 provides a break-down of the Federal fiscal year appropriations for National Water Program federal grants (dollars in millions) over the past several years.

Table 13. Funding Levels for Federal Categorical Grant Programs Nationally (Dollars in Millions)



National Program	FFY 2020 P.L. 116-94 (H.R. 1865)	FFY 2021 Omnibus P.L. 116-260	FFY 2022 (H.R. 2471)	FFY 2023 Omnibus P.L.	FFY 2024 (H.R. 4366)	FFY 2025 (H.R. 8998; S. 4802; Continuing Resolution)
Pollution Control (CWA §106)	$223.29	$230	$231	$237	$225.7	$225.7
Nonpoint Source (CWA §319)	$172.35	$177	$178	$182	$174.5	$174.5
Wetlands Program Development	$14.18	$14.19	$48	$14	$14	$14
TOTALS	**$409.82**	**$421.19**	**$457.00**	**$433.00**	**$414.20**	**$414.20**

Figures 14 and 15 demonstrate that although some federal funding did increase in the 1990s, funding levels adjusted for inflation have generally declined starting around 2002.

NOTE: CPI = consumer price index (to adjust for inflation)

Figure 14. Federal CWA Section 106 Funding Over Time

NOTE: CPI = consumer price index (to adjust for inflation)

Figure 15. Federal CWA Section 319 Funding Over Time

Funding challenges remain a perennial challenge and can exist on the state level as well. Any cuts or sweeps of state funding result in placing more burden on federal grants to fill those gaps, but federal assistance grants do not increase to meet these demands. Table 14 provides a break-down of State of New Mexico expenditures for surface water quality programs by funding source and fiscal year.

Table 14. Expenditures for Surface Water Quality Protection Programs in NM (Dollars in Millions)

State Fiscal Year	Federal Grant Expenditures	State Expenditures	Total Expenditures
2011	$3,537,500	$2,091,900	$5,629,400
2013	$3,808,761	$1,967,221	$5,775,981
2015	$3,226,845	$1,147,312	$4,374,157
2017	$3,086,395	$2,001,255	$5,087,650
2020	$3,661,537	$1,113,509	$4,775,046
2021	$3,773,760	$1,637,655	$5,411,414
2023	$3,809,176	$3,558,300[1]	$7,371,476
AVERAGE (2011-2023)	**$3,557,711**	**$1,931,022[2]**	**$5,488,732**
2025	$3,006,836	$10,102,408[3]	$13,109,244

1 The change in FY 2023 state expenditures compared to prior years is due to increased financial support for river restoration through the SWQB River Stewardship Program and ONRT restoration projects.
2 State expenditures for FY 2025 were not included in the average calculation.

3 The dramatic change in FY 2025 state expenditures compared to prior years is due to increased legislative appropriations for the SWQB River Stewardship Program and the State Permitting Program development, and implementation of the Land of Enchantment Legacy Fund.

With over 61% of assessed surface waters in New Mexico listed as impaired because they fail to meet water quality standards coupled with increasing demands for clean water and stressors related to climate change, there is an abundant need for surface water quality program investments in our state. Moreover, if water quality overall is poorer because water quality management programs are limited due to funding restrictions, then treatment of the water to achieve beneficial uses (such as safe drinking water, livestock watering, irrigation, wildlife habitat, and recreation) will cost more.

Sustainable and recurring funding to protect New Mexico's surface water resources is essential to meet New Mexico's hydrologic complexity and ensure that New Mexico has the programmatic capacity to meet increasing demands for clean water. Not only do increases in state and federal investment help reverse declines in water quality, but they also create jobs, stimulate economic growth, support tourism, provide recreational opportunities, benefit private-sector development, and improve public health with a clean environment.

Blue skies over Heron Reservoir in the Chama watershed

NMED Exhibit 30

VII. Public Participation and Agency Coordination

A. CWA §303(d)/§305(b) Integrated Report Public Participation

All individuals living and working in the New Mexico affect water quality and are affected by water quality. Public awareness and involvement are therefore crucial to the successful implementation of water quality programs. New Mexico's water quality programs promote a multi-stakeholder, consensus-based public participation process. By actively pursuing and considering public input and involvement, New Mexico can more effectively effect changes in behavior and actively improve decision-making concerning water quality with greater public acceptance and support for those decisions.

There are several opportunities for public and other stakeholder participation in the development of the IR, from data collection through impairment determination and reporting. The public participation requirements of specific water quality programs are specified in 40 C.F.R. § 25.4 and described in the WQMP/CPP (NMWQCC 2020). At a minimum, the public participation process for New Mexico's water quality programs consists of the following:

- Providing the public with the information and assistance necessary for meaningful involvement;
- Providing a central location for reports, studies, plans, and other documents;
- Maintaining a list of affected or interested parties and stakeholders; and
- Notifying stakeholders in a timely fashion prior to consideration of major decisions (generally at least 30 days).

What is a Stakeholder?
For the purposes of this report, a stakeholder is defined as any organization, governmental entity, or individual that has a vested interest in or may be impacted by a state directed approach to environmental regulation, pollution prevention, or energy conservation.

Prior to development of the draft Integrated List for each listing cycle, the public has an opportunity to provide comments to the listing methodology (i.e., CALM) through a public participation process that includes a minimum 30-day public comment period with public notification as defined in the WQMP/CPP (NMWQCC 2020). The SWQB typically announces the "call for outside data" at the same time. The CALM used to develop the draft 2026-2028 Integrated List (Appendix A) was released for public comment in this manner. A draft of this listing methodology was opened for a 30-day public comment period from June 16, 2025 – July 18, 2025. Comments received were reviewed, considered, and incorporated as deemed appropriate.

The public participation associated with the development of the Integrated List (Appendix A) included notifying stakeholders of a 45-day public comment period December 8, 2025 – January 22, 2026. Public notices were posted to NMED's website and sent through the GovDelivery e-mail delivery service. The SWQB responded in writing to each comment received in Appendix C of the IR. These responses were forwarded to all commenters prior to the March 10th, 2026 NMWQCC meeting, at which the Integrated List was presented and approved.

NMED Exhibit 30

B. Coordination with state and federal government agencies

Successful surface water quality management and protection is dependent on cooperative interaction between the federal, state, local, and tribal levels of government, and between the public and private sectors. The NPS Management Program relies on established resource protection programs, federal and state NPS pollution prevention programs, and activities of other land management and resource protection agencies to address NPS pollution. In addition to NMED, numerous other New Mexico and federal agencies conduct activities that utilize, protect, and restore surface water quality, including but not limited to:

- Office of the State Engineer (NMOSE);
- Interstate Stream Commission (NMISC);
- Office of Natural Resources Trustee (ONRT);
- Department of Wildlife (NMDW);
- Department of Agriculture (NMDA);
- Energy, Minerals, and Natural Resources Department (EMNRD);
- Department of Health (NMDOH);
- Outdoor Recreation Division (NMORD);
- Department of Homeland Security and Emergency Management (NMDHSEM);
- Federal Emergency Management Agency (FEMA);
- U.S. Army Corps of Engineers (USACE);
- U.S. Bureau of Land Management (USBLM);
- U.S. Bureau of Reclamation (USBOR);
- U.S. Forest Service (USFS);
- Natural Resources Conservation Service (NRCS); and
- Soil and Water Conservation Districts (SWCDs).

2025 Trout Fire burn scar at head of Allie Canyon, Gila National Forest, July 2025.

These and other agencies work with stakeholders during development and implementation of water quality management activities. Coordination is crucial and focuses on informing and including stakeholders on water quality management related activities, seeking input, soliciting data and information, and working collaboratively to implement solutions to water quality problems and concerns. For example, regular coordination between the USFS and the SWQB continues to be an integral part of the NPS Management Program and has facilitated cooperation on many successful NPS pollution reduction projects. As previously mentioned in the state certification section (Chapter IV, section C), the NPS Management Program also coordinates with the USACE to implement the State's CWA section 401 certification responsibilities for CWA section 404 permits.

NMED Exhibit 30

Trout Fire revegetation response two months post-aerial seeding, Gila National Forest, September 2025.

In 2025, the NMED SWQB worked with closely with the U.S. Forest Service Gila National Forest, New Mexico Department of Wildlife, and Freeport McMoRan to support post-fire watershed recovery from impacts of the Trout Fire. This multi-agency, cross-jurisdictional collaboration resulted in a quick response to provide aerial seeding for severely burned areas of the Trout Fire prior to monsoon season to help substantially mitigate downstream impacts to water quality and riparian and aquatic habitat.

Additionally, numerous stakeholder focus groups have been developed for specific issues and meet on a regular basis to coordinate efforts. The NMED participates in many of these groups to address a variety of water quality issues. Examples of such groups include the New Mexico Municipal League Environmental Quality Association, the New Mexico Forest and Watershed Health Coordinating Group, and individual watershed groups' regular meetings.

C. Fish Consumption Advisory Program

Fish consumption advisory sampling in collaboration with New Mexico Department of Wildlife on Bluewater Lake, May 2022

Fish are a lean, low-calorie source of protein, and can be an important part of a balanced diet. However, some fish may contain contaminants that, when consumed in certain quantities, could pose health risks. When contaminant levels may be unsafe, consumption advisories recommend that people limit or avoid eating certain species of fish caught in certain places. NMDOH, NMDoW, and the SWQB work together to implement New Mexico's Fish Consumption Advisory Program. The EPA considers fish or shellfish consumption advisories and supporting fish tissue data to be existing and readily available data that demonstrate non-attainment of CWA goals stating that waters should be "fishable" [CWA §101(a), EPA 2005]. The basis for fish consumption impairments each listing cycle is the most recent, available fish consumption advisories at the time the IR drafted, except in cases where there is a consumption advisory due to mercury, but available fish tissue data indicate New Mexico's methylmercury criterion of 0.3 mg/kg in fish tissue is not exceeded[31].

[31] https://www.env.nm.gov/surface-water-quality/calm/

The Program's monitoring strategy involves screening a select number of sites for chemical contamination where sport, subsistence, or commercial fishing is conducted. Site selection is prioritized based on SWQB and NMDOW sampling resources, and targets areas where it is known that many fish are harvested or where there are known or suspected contamination issues. This screening helps identify those waters where fish tissue contamination may pose unacceptable health risks to human consumers. Fish consumption advisories relay fish tissue contamination information to the public. These advisories are only guidelines and do not constitute legal restrictions that prevent people from eating contaminated fish from New Mexico lakes and streams. Fish consumption advisories pertain to consumption of fish only. There are no known contaminant-related health risks associated with activities such as camping, swimming, boating, or handling fish in areas where there are fish consumption advisories. Currently, advisories have been issued for mercury, DDT and PCBs in fish tissue at several reservoirs, lakes and rivers (NMED, et al. 2025).

New Mexico fish consumption advisories are available online at: https://www.env.nm.gov/surface-water-quality/fish-consumption-advisories/

D. Additional SWQB Outreach Efforts

The SWQB supports or implements several outreach activities throughout the year, including but not limited to:

- Publishing the *Clearing the Waters* newsletter[32];
- Developing and maintaining the extensive SWQB web site[33];
- Coordinating and/or participating in both on-the-ground restoration workshops and technical forums for sharing implementation techniques and research;
- Participating in education opportunities, such as Science, Technology, Engineering, and Math (STEM) events, for local schools and statewide events to promote water quality education;
- Soliciting stakeholder input of important guiding SWQB documents, such as revisions to the Nonpoint Source Management Plan[34]; and
- Presenting on a variety of surface water quality issues and programs at various state and national workshops and meetings.

McCrystal Creek restoration project, a collaboration between the Carson National Forest, Trout Unlimited, Cimarron Watershed Alliance and the Philmont Scout Ranch (2025)

INTEGRATED LIST OF ASSESSED SURFACE WATERS

PREFACE

I. Format and Organization of Integrated List and Assessment Rationale

In 2013, the New Mexico Environment Department (NMED) merged the Surface Water Quality Bureau's (SWQB) in-house water quality database with NMED's *Assessment Database* to create the *Surface water QUality Information Database* (SQUID) so both data and assessment conclusions could be housed in one database. The SWQB took this opportunity to also re-design and streamline the *CWA §303(d)/§305(b) Integrated Report: Appendix A List of Assessed Waters* (Integrated List) format for ease of review, to incorporate additional information, and to reduce the total number of pages. The associated Assessment Rationale (previously called the *Record of Decision* or ROD) that houses additional details on any water body or Assessment Unit (AU) that is currently or has ever been documented as "impaired" is also now housed in SQUID. If there was no action on a specific impaired AU during a particular listing cycle, there may be no entry for that cycle.

The Rio Chama and Sacramento Mountain watersheds were surveyed by the SWQB in 2023-2024 and hence are the primary focus of revised or retained assessment conclusions in the Integrated List for this 2026-2028 cycle. Other datasets that were either submitted or acquired this cycle and assessed as reported include:

- 2022-2024 data for various stream reaches in and around Taos and Red River collected by Sentinels-Rio de Taos and submitted by Amigos Bravos.
- 2022-2025 San Juan River Basin Multijurisdictional monitoring program data stored in SQUID
- 2022-2025 SWQB Effectiveness monitoring data downloaded from SQUID
- 2022-2025 EPA and USGS data from various locations throughout New Mexico downloaded from the Water Quality Portal[1],
- Chevron Questa Mine data from Red River submitted by Ground Water Quality Bureau,
- 2020-2025 Los Alamos National Laboratory Data submitted by N3B, and
- Silver City Watershed Keepers data (submitted)

The assessment conclusions in non-focus areas based on data from previous rotational surveys and previously submitted outside data are typically carried over to the next list until more current data are available to assess unless, for example, a water quality standard change or a significant listing methodology change necessitates a re-assessment.

All AUs are assigned IR categories as described in New Mexico's Comprehensive Assessment and Listing

[1] https://www.waterqualitydata.us/

NMED Exhibit 30

Methodology (CALM)[2]. AUs noted with IR Category 5A, 5B, or 5C on the Integrated List in Appendix A comprise New Mexico's official CWA §303(d) List of Impaired Waters. A listing of Category 5-only waters is included in the beginning of Appendix A. To see details on a specific AU, refer to the particular AU entry on the full Integrated List in Appendix A and associated assessment rationale entry.

Starting with the 2018-2020 IR, each AU entry on the Integrated List also contains a "PARAMETER IR CATEGORY." This useful field provides additional planning information regarding each particular cause of impairment or AU cause pair. For example, a parameter IR category of 5B lets the user know that a review of the applicable water quality standard is needed prior to scheduling TMDL development. New Mexico has several temperature listings that fall under the 5B parameter IR category.

New Mexico's Integrated List also includes an estimated year in the "TMDL DATE" field for all parameter IR category 5A AU cause pairs. The estimated year is generally based on the SWQB's rotational monitoring schedule, prioritization strategy in the SWQB's long-term vision document (NMED/SWQB 2015), and severity of the impairment. The "TMDL DATE", as well as the projected "MONITORING SCHEDULE" year, is ultimately dependent upon personnel and financial resources which can change on an annual basis. If a TMDL has already been developed for the noted cause of impairment, the EPA TMDL approval date (MM/DD/YYYY) is reported in the TMDL date field.

II. Useful Definitions

INTEGRATED LIST FIELD HEADINGS AND CODES --

ASSESSED	This field generally notes the last Integrated Reporting Cycle when data for this particular watershed were assessed and reported.
Assessment Unit (AU)	Descriptive name of a specific waterbody (stream reach or lake). Limited to 60 characters.
ATTAINMENT	The use attainment status for the associated USE (Fully Supporting, Not Supporting, Not Assessed)
ASSESSED	This field generally notes the last Integrated Report Cycle when data for this particular watershed were assessed and reported.
AU ID	An internal database code that is unique to an assessment unit, and is not intended to provide any specific information to the reader of the list.
CAUSE(S)	Parameters and/or constituents that are causing non-attainment of the associated USE
DO	The amount of dissolved oxygen in the water; usually reported in mg/L.

[2] https://www.env.nm.gov/surface-water-quality/calm/

E. coli	Abbreviation of *Escherichia coli*. These bacteria found in the environment, foods, and intestines of people and animals.
FIRST LISTED	This field generally notes the first Integrated Reporting Cycle when the associated impairment was noted.
FS	Full Support or Fully Supporting
HUC	8-digit Hydrologic Unit Codes (HUC) that identify various watersheds. The US Geologic Survey defines these codes and associated watershed names.
IR	Integrated Report
IR Category (AU)	Overall water quality standards attainment category for each assessment unit as determined by combining individual designated use support decisions. The unique IR categories for New Mexico are described as follows as follows:
IR Category (Parameter)	Water quality standards attainment category for each listed cause of impairment. The unique IR categories for New Mexico are described as follows as follows:
IR Category 1	Attaining the water quality standards for all designated and existing uses. AUs are listed in this category if there are data and information that meet all requirements of the assessment and listing methodology and support a determination that the water quality criteria are attained.
IR Category 2	Attaining some of the designated or existing uses based on numeric and narrative parameters that were tested, and no reliable monitored data is available to determine if the remaining uses are attained or threatened. AUs are listed in this category if there are data and information that meet requirements of the assessment and listing methodology to support a determination that some, but not all, uses are attained based on numeric and narrative water quality criteria that were tested. Attainment status of the remaining uses is unknown because there is no reliable monitored data with which to make a determination.
IR Category 3/3A	Insufficient of no reliable monitored data and/or information to determine if any designated or existing use is attained. No data available -- AUs are listed in this subcategory when there are no available data to assess. These are considered high priority for follow up monitoring.
IR Category 3/3B	Insufficient monitored data and/or information to determine if any designated or existing use is attained. Limited data (n = 1 to 3) available, no exceedances -- AUs are listed in this subcategory when there are no exceedances of any applicable criteria in the limited data set. Their

NMED Exhibit 30

	priority for follow up monitoring depends on the parameter and concentration (for example, measurements near the criteria would increase the priority for additional sampling).
IR Category 3/3C	Insufficient monitored data and/or information to determine if any designated or existing use is attained. Limited data (n = 1 to 3) available, exceedance(s) -- AUs are listed in this subcategory when there are exceedances of one or more applicable criteria in the limited data set. These are considered high priority for follow up monitoring.
IR Category 4A	Impaired for one or more designated uses but does not require development of a TMDL because TMDL has been completed. AUs are listed in this subcategory once all TMDL(s) have been developed and approved by USEPA that, when implemented, are expected to result in full attainment of the standard. Where more than one pollutant is associated with the impairment of an AU, the AU remains in IR Category 5A (see below) until all TMDLs for each pollutant have been completed and approved by USEPA.
IR Category 4B	Impaired for one or more designated uses but does not require development of a TMDL because other pollution control requirements are reasonably expected to result in attainment of the water quality standard in the near future. Consistent with the regulation under 40 CFR 130.7(b)(i), (ii), and (iii), AUs are listed in this subcategory where other pollution control requirements required by local, state, or federal authority are stringent enough to implement any water quality standard (WQS) applicable to such waters.
IR Category 4C	Impaired for one or more designated uses but does not require development of a TMDL because impairment is not caused by a pollutant. AUs are listed in this subcategory if a pollutant does not cause the impairment. For example, USEPA considers flow alteration to be “pollution” vs. a “pollutant.”
IR Category 5/5A	Impaired for one or more designated or existing uses and a TMDL is underway or scheduled. AUs are listed in this category if the AU is impaired for one or more designated uses by a pollutant. Where more than one pollutant is associated with the impairment of a single AU, the AU remains in IR Category 5A until TMDLs for all pollutants have been completed and approved by USEPA.
IR Category 5/5B	Impaired for one or more designated or existing uses and a review of the water quality standard will be conducted. AUs are listed in this category when it is possible that water quality standards are not being met because one or more current designated use is inappropriate. After a review of the water quality standard is conducted, a Use Attainability Analysis (UAA) will be developed and submitted to USEPA for consideration, or the AU will be moved to IR Category 5A and a TMDL will

NMED Exhibit 30

	be scheduled.
IR Category 5/5C	Impaired for one or more designated or existing uses and Additional data will be collected before a TMDL is scheduled. AUs are listed in this category if there is not enough data to determine the pollutant of concern or there is not adequate data to develop a TMDL. For example, AUs with biological impairment will be listed in this category until further research can determine the particular pollutant(s) of concern. When the pollutant(s) are determined, the AU will be moved to IR Category 5A and a TMDL will be scheduled. If it is determined that the current designated uses are inappropriate, it will be moved to IR Category 5B and a UAA will be developed. If it is determined that "pollution" is causing the impairment (vs. a "pollutant"), the AU will be moved to IR Category 4C.
IR Category 5-R (previous 5-ALT)	Advance restoration approach is in progress or under development. EPA created this optional subcategory as an organizing tool to clearly articulate which impaired waterbodies have or will have alternative approaches to attain WQS (EPA 2015). The advance restoration approach needs to clearly demonstrate how the WQS will be achieved. The description of the advance restoration approach and the waters to which it applies will be included during public review of the draft Integrated Report, so that the public has an opportunity to view the proposed advance restoration approaches. Additional details on what must be included in the description are found in EPA's listing guidance (EPA 2015).
LOCATION DESCRIPTION	The name of the 8-digit Hydrologic Unit Code (HUC) watershed of the assessment unit as defined by the United States Geologic Survey.
MONITORING SCHEDULE	These proposed dates are primarily based on SWQB's most recent rotational watershed monitoring schedule. This date, as well as the "TMDL DATE" date, is ultimately dependent upon personnel, financial, and laboratory resources which change on an annual basis.
NS	Non-Support or Not Supporting
PCBs	Polychlorinated biphenyls; highly-persistent compounds that are fat soluble and accumulate in the food chain
PROBABLE SOURCE(S)	This field contains either 1) "Source Unknown" if no TMDLs have yet been developed, or 2) the Probable Sources noted in associated TMDLs that may be contributing to the noted impairment(s).
SC	specific conductance
SIZE	Streams and/or rivers = Miles, Lakes and/or playas = Acres, per EPA's current reporting requirement

NMED Exhibit 30

TMDL	Total Maximum Daily Load
TMDL DATE	This field contains either 1) future estimated ("est.") TMDL development year primarily based on SWQB's rotational monitoring schedule, prioritization schedule, date since last intensively surveyed, upcoming permit renewals, etc.; 2) the EPA TMDL approval date (MM/DD/YYYY) if a TMDL has already been developed and approved; or 3) nothing if the water quality standard is under review (IR Category 5B) or additional data are needed (IR Category 5C). This date, as well as the "Monitoring Schedule" date, is ultimately dependent upon personnel and financial resources which change on an annual basis.
TR	total recoverable
USE	Any designated uses specified in the State of New Mexico Standards for Interstate and Intrastate Surface Waters (20.6.4 NMAC) that apply to the given assessment unit and/or any documented existing uses that apply to the given assessment unit. Uses that exist but are not officially designated in the NMAC are also listed here with a note in "Assessment Unit Comments."
WATER TYPE	This field contains the EPA-defined water type that most accurately describes the "normal" hydrologic character of the assessment unit to the best of SWQB's knowledge given available flow data, GIS layers, and Hydrology Protocol survey results (where available).
WQS REF	Applicable Water Quality Standard segment as described in the most recent State of New Mexico Standards for Interstate and Intrastate Surface Waters (20.6.4 NMAC) that applies to the given assessment unit.

NMED Exhibit 30

III. Abbreviations in Assessment Unit Names

The size of the assessment unit name is limited to 60 characters by the database. Therefore, the following abbreviations were used when necessary:

abv	=	above
AZ	=	Arizona
blw	=	below
bnd	=	boundary
BNSF	=	Burlington Northern – Santa Fe
Campgrd	=	Campground
Ck	=	Creek
Cny	=	Canyon
CO	=	Colorado
CR	=	County Road
confl	=	confluence
Div	=	Diversion
E	=	East
Fk	=	Fork
FS	=	Forest Service (usually road)
hdwtrs	=	headwaters
HWY	=	Highway
I	=	Interstate highway
Irr	=	irrigation
LANL	=	Los Alamos National Laboratory
M	=	Middle
mi	=	mile
N	=	North
NM	=	New Mexico
nr	=	near
NWR	=	National Wildlife Refuge
OK	=	Oklahoma
prt	=	Portion (i.e., reaches)
R	=	River or Rio
rd	=	road
RR	=	railroad
Rsvr	=	Reservoir
S	=	South
SFNF	=	Santa Fe National Forest
Spr	=	Spring
SR	=	state road
trib	=	tributary
TX	=	Texas
VCNP	=	Valles Caldera National Preserve
xing	=	crossing
USFS	=	United States Forest Service
W	=	West
WWTP	=	waste water treatment plant

NMED Exhibit 30

(Table of Contents of Category 5 waters on the following Integrated §303(d)/§305(b) List)

HUC: 11040001 - Cimarron Headwaters

- Dry Cimarron River (Oak Creek to headwaters)

HUC: 11080001 - Canadian Headwaters

- Canadian River (Chicorica Creek to CO border)
- Maxwell Lake 13
- Stubblefield Lake
- VanBremmer Creek (HWY 64 to headwaters)
- Vermejo River (Rail Canyon to York Canyon)
- York Canyon (Vermejo R to Left Fork York Canyon)

HUC: 11080002 - Cimarron

- Cimarron River (Canadian River to Ponil Creek)
- Cimarron River (State hwy 21 in Cimarron to Turkey Creek)
- Cimarron River (Turkey Creek to Eagle Nest Lake)
- Greenwood Creek (Middle Ponil Creek to headwaters)
- North Ponil Creek (Seally Canyon to headwaters)
- Ponil Creek (Cimarron River to HWY 64)
- Ponil Creek (HWY 64 to confl of North and South Ponil)
- Rayado Creek (Cimarron River to Miami Lake Diversion)
- Saladon Creek (Cieneguilla Creek to headwaters
- Springer Lake

HUC: 11080003 - Upper Canadian

- Charette Lake (Lower)
- Charette Lake (Upper)
- Wheaton Creek (Manuelas Creek to headwaters)

HUC: 11080004 - Mora

- Coyote Creek (Black Lake to headwaters)
- Rito Cebolla (Mora River to Rito Morphy)
- Sapello River (Mora River to Arroyo Jara)

HUC: 11080005 - Conchas

- Conchas Reservoir

HUC: 11080006 - Upper Canadian-Ute Reservoir

- Canadian River (TX border to Ute Reservoir)
- Ute Reservoir

HUC: 11080008 - Revuelto

- Revuelto Creek (Canadian River to headwaters)

HUC: 11100101 - Upper Beaver

- Clayton Lake

HUC: 13010005 - Conejos

- Beaver Creek (Rio de los Pinos to headwaters)
- Canada Tio Grande (Rio San Antonio to headwaters)
- Rio Nutritas (Rio San Antonio to headwaters)
- Rio San Antonio (CO border to Montoya Canyon)
- Rio San Antonio (Montoya Canyon to headwaters)
- Rio de los Pinos (New Mexico reaches)

HUC: 13020101 - Upper Rio Grande

- Acid Canyon (Pueblo Canyon to headwaters)
- Arroyo del Palacio (Rio Grande to headwaters)
- Bitter Creek (Red River to headwaters)
- Cabresto Creek (Red River to headwaters)
- Cabresto Lake
- Canada Agua (Arroyo La Mina to headwaters)
- Comanche Creek (Costilla Creek to headwaters)
- Costilla Creek (CO border to Diversion abv Costilla)
- Costilla Creek (Comanche Creek to Costilla Dam)
- DP Canyon (100m dwnstm grade ctrl to 400m upstm grade ctrl)
- DP Canyon (400m upstream of grade control to upper LANL bnd)
- DP Canyon (Los Alamos Canyon to 100m dwnstm of grade ctrl)
- Embudo Creek (Canada de Ojo Sarco to Picuris Pueblo bnd)
- Embudo Creek (Rio Grande to Canada de Ojo Sarco)
- Goose Lake
- Graduation Canyon (Pueblo Canyon to headwaters)
- Holman Creek (Comanche Creek to headwaters)
- Los Alamos Canyon (DP Canyon to upper LANL bnd)
- Los Alamos Canyon (NM-4 to DP Canyon)
- Pioneer Creek (Red River to headwaters)
- Pojoaque River (San Ildefonso bnd to Pojoaque bnd)
- Pueblo Canyon (Acid Canyon to headwaters)
- Pueblo Canyon (Los Alamos Canyon to Los Alamos WWTP)

- Pueblo Canyon (Los Alamos WWTP to Acid Canyon)
- Red River (Placer Creek to East Fork Red River)
- Rio Fernando de Taos (R Pueblo d Taos to USFS bnd at canyon)
- Rio Fernando de Taos (Tienditas Creek to headwaters)
- Rio Grande (Embudo Creek to Rio Pueblo de Taos)
- Rio Grande (Ohkay Owingeh bnd to Embudo Creek)
- Rio Grande (Rio Pueblo de Taos to Red River)
- Rio Grande (Santa Clara Pueblo bnd to Ohkay Owingeh bnd)
- Rio Grande del Rancho (R Pueblo de Taos to Rito de la Olla)
- Rio Pueblo (Picuris Pueblo bnd to headwaters)
- Rio Pueblo de Taos (R Grande del Rancho to Taos Pueblo bnd)
- Rio Pueblo de Taos (Rio Grande to Arroyo del Alamo)
- Santa Cruz River (Santa Clara Pueblo bnd to Santa Cruz Dam)
- South Fork Acid Canyon (Acid Canyon to headwaters)
- Vidal Creek (Comanche Creek to headwaters)
- Walnut Canyon (Pueblo Canyon to headwaters)

HUC: 13020102 - Rio Chama

- Abiquiu Creek subwatershed
- Abiquiu Reservoir
- Arroyo Seco subwatershed
- Arroyo del Toro (Rio Chama to headwaters)
- Canada de Horno (Rio Chama to headwaters)
- Canjilon Ck (Perennial portions Abiquiu Rsrv to headwaters)
- Canones Creek (Abiquiu Rsvr to Chihuahuenos Ck)
- Canones Creek (Rio Chama to Jicarilla Apache bnd)
- Canones Creek subwatershed
- Chihuahuenos Creek (Canones Creek to headwaters)
- Daggett Canyon-Canones Creek subwatershed
- El Rito Creek (Perennial reaches HWY 554 to headwaters)
- El Rito Creek (Perennial reaches Rio Chama to HWY 554)
- Heron Reservoir
- Hopewell Lake
- Laguna del Campo
- Lower El Rito subwatershed
- Lower Rio Gallina subwatershed
- Lower Rio Nutrias subwatershed
- Lower Rio Puerco de Chama subwatershed
- Lower Rio Vallecitos subwatershed

- Lower Rio del Oso subwatershed
- Middle Rio Vallecitos subwatershed
- Polvadera Creek subwatershed
- Rio Brazos subwatershed
- Rio Chama (Abiquiu Creek to Abiquiu Dam)
- Rio Chama (Abiquiu Reservoir to El Vado Reservoir)
- Rio Chama (El Vado Reservoir to Rito de Tierra Amarilla)
- Rio Chama (Little Willow Creek to CO border)
- Rio Chama (Ohkay Owingeh to Abiquiu Creek)
- Rio Ojo Caliente (Arroyo El Rito to Rio Vallecitos)
- Rio Puerco de Chama (Abiquiu Reservoir to HWY 96)
- Rio Tusas subwatershed
- Rio del Oso (Rio Chama to La Canada del Almagre)
- Rito Encino (Rio Puerco de Chama to headwaters)
- Rito de Tierra Amarilla (HWY 64 to headwaters)
- Rito de Tierra Amarilla (Rio Chama to HWY 64)
- Rito de Tierra Amarilla subwatershed
- Upper El Rito subwatershed
- Upper Rio Chama subwatershed
- Upper Rio Gallina subwatershed
- Upper Rio Nutrias subwatershed
- Upper Rio Ojo Caliente subwatershed
- Upper Rio Vallecitos subwatershed

HUC: 13020201 - Rio Grande-Santa Fe

- Ancho Canyon (Above Ancho Springs to North Fork Ancho)
- Ancho Canyon (North Fork to headwaters)
- Ancho Canyon (Rio Grande to Ancho Springs)
- Arroyo de la Delfe (Above Kieling Spring to headwaters)
- Arroyo de la Delfe (Pajarito Canyon to Kieling Spring)
- Canada del Buey (within LANL)
- Canon de Valle (LANL gage E256 to Burning Ground Spr)
- Canon de Valle (below LANL gage E256)
- Canon de Valle (upper LANL bnd to headwaters)
- Chaquehui Canyon (within LANL)
- Mortandad Canyon (within LANL)
- North Fork Ancho Canyon (Ancho Canyon to headwaters)
- Pajarito Canyon (0.5 mi ds of and to Arroyo de la Delfe)
- Pajarito Canyon (Above Homestead Spring to LANL boundary)

- Pajarito Canyon (Lower LANL bnd to Twomile Canyon)
- Pajarito Canyon (Starmers Gulch to Homestead Spring)
- Pajarito Canyon (Twomile Cyn to 0.5 mi ds of A. de La Delfe)
- Pajarito Canyon (upper LANL bnd to headwaters)
- Potrillo Canyon (above Water Canyon)
- Rio Grande (Cochiti Reservoir to San Ildefonso bnd)
- Rio Grande (non-pueblo Angostura Div to Cochiti Rsrv)
- Rito de los Frijoles (Rio Grande to headwaters)
- Sandia Canyon (Bedrock Road to NPDES outfall 001)
- Sandia Canyon (Sigma Canyon to Bedrock Road)
- Sandia Canyon (within LANL below Sigma Canyon)
- Santa Fe River (Cienega Creek to Santa Fe WWTP)
- Santa Fe River (Cochiti Pueblo bnd to Cienega Creek)
- Santa Fe River (Guadalupe St to Nichols Rsvr)
- Santa Fe River (Nichols Reservoir to headwaters)
- Santa Fe River (Santa Fe WWTP to Guadalupe St)
- Ten Site Canyon (Mortandad Canyon to headwaters)
- Three Mile Canyon (Pajarito Canyon to headwaters)
- Twomile Canyon (Pajarito to Upper Twomile canyon)
- Twomile Canyon (Upper Twomile canyon to headwaters)
- Water Canyon (upper LANL bnd to headwaters)
- Water Canyon (within LANL below Area-A Cyn)

HUC: 13020202 - Jemez

- American Creek (Rio de las Palomas to headwaters)
- Calaveras Creek (Rio Cebolla to headwaters)
- Clear Creek (Rio de las Vacas to San Gregorio Lake)
- Clear Creek (San Gregorio Lake to headwaters)
- East Fork Jemez (San Antonio Creek to VCNP bnd)
- East Fork Jemez (VCNP to headwaters)
- Fenton Lake
- Jaramillo Creek (East Fork Jemez to headwaters)
- Jemez River (Jemez Pueblo bnd to Rio Guadalupe)
- Jemez River (Soda Dam nr Jemez Springs to East Fork)
- La Jara Creek (East Fork Jemez to headwaters)
- Redondo Creek (Sulphur Creek to headwaters)
- Rio Cebolla (Fenton Lake to headwaters)
- Rio Cebolla (Rio de las Vacas to Fenton Lake)
- Rio de las Vacas (Clear Creek to headwaters)

- Rito Penas Negras (Rio de las Vacas to headwaters)
- Rito de las Palomas (Rio de las Vacas to headwaters)
- Rito de los Indios (San Antonio Creek to headwaters)
- San Antonio Creek (East Fork Jemez to VCNP bnd)
- San Antonio Creek (VCNP bnd to headwaters)
- San Gregorio Lake
- Sulphur Creek (Redondo Creek to headwaters)
- Sulphur Creek (San Antonio Creek to Redondo Creek)
- Vallecito Ck (Perennial Prt Div abv Ponderosa to headwaters)

HUC: 13020203 - Rio Grande-Albuquerque

- Rio Grande (Arroyo de las Canas to Rio Puerco)
- Rio Grande (Isleta Pueblo boundary to Tijeras Arroyo)
- Rio Grande (Rio Puerco to Isleta Pueblo bnd)
- Rio Grande (San Marcial at USGS gage to Arroyo de las Canas)
- Rio Grande (Tijeras Arroyo to Alameda Bridge)
- Rio Grande (non-pueblo Alameda Bridge to HWY 550 Bridge)

HUC: 13020204 - Rio Puerco

- Nacimiento Ck (Perennial prt HWY 126 to Clear Creek)
- Rio Puerco (Arroyo Chijuilla to northern bnd Cuba)
- Rio Puerco (Perennial prt northern bnd Cuba to headwaters)
- Rio Puerco (non-pueblo Arroyo Chico to Arroyo Chijuilla)
- Rio Puerco (non-pueblo Rio Grande to Arroyo Chico)

HUC: 13020207 - Rio San Jose

- Arroyo del Valle (Laguna Pueblo bnd to headwaters)
- Bluewater Lake
- Rio Paguate (Laguna Pueblo bnd to headwaters)

HUC: 13020209 - Rio Salado

- Rio Salado (Rio Grande to Alamo Navajo bnd)

HUC: 13020211 - Elephant Butte Reservoir

- Elephant Butte Reservoir
- Rio Grande (Elephant Butte Rsvr to San Marcial at USGS)

HUC: 13030101 - Caballo

- Caballo Reservoir
- Las Animas Ck (perennial prt Animas Gulch to headwaters)

- Rio Grande (Caballo Reservoir to Elephant Butte Reservoir)

HUC: 13030202 - Mimbres

- Bear Canyon Reservoir
- Gallinas Creek (Little Gallinas Creek to headwaters)
- Mimbres R (Perennial reaches Allie Canyon to Cooney Cny)
- Pinos Altos Creek (San Vicente Creek to headwaters)
- San Vicente Creek (Perennial prt Maudes Cny to Silva Creek)

HUC: 13050003 - Tularosa Valley

- Dog Canyon Creek (perennial portions)
- Fresnal Canyon (La Luz Creek to Salado Canyon)
- Fresnal Canyon subwatershed
- Karr Canyon (Fresnal Canyon to headwaters)
- Lake Holloman
- Nogal Creek (Tularosa Creek to Mescalero Apache bnd)
- Three Rivers subwatershed
- Upper Rio Tularosa subwatershed

HUC: 13050004 - Salt Basin

- Sacramento R (Perennial prt Scott Able Canyon to headwaters)

HUC: 13060001 - Pecos Headwaters

- Carpenter Creek subwatershed
- Cow Creek (Bull Creek to headwaters)
- Cow Creek (Pecos River to Bull Creek)
- El Porvenir Creek (Gallinas River to SFNF bnd)
- El Porvenir Creek (SFNF bnd to Hollinger Canyon)
- Elk Creek (Cow Creek to headwater)
- Gallinas River (Aguilar Creek to USGS Gage 08382000)
- Gallinas River (Las Vegas Diversion to USFS bnd)
- Gallinas River (Pecos Arroyo to Las Vegas Diversion)
- Gallinas River (Pecos River to Aguilar Creek)
- Gallinas River (USFS bnd to headwaters)
- Gallinas River (USGS Gage 08382000 to Pecos Arroyo)
- Glorieta Ck (Perennial prt Pecos R to Glorieta Camps WWTP)
- Holy Ghost and Doctor Creek subwatershed
- Indian Creek subwatershed
- McAllister Lake

- Panchuela Creek subwatershed
- Pecos River (Alamitos Canyon to Jack's Creek)
- Pecos River (Canon de Manzanita to Alamitos Canyon)
- Pecos River (Cow Creek to Canon de Manzanita)
- Pecos River (Jack's Creek to headwaters)
- Pecos River (Santa Rosa Reservoir to Tecolote Creek)
- Pecos River (Sumner Reservoir to Santa Rosa Reservoir)
- Pecos River (Tecolote Creek to Villanueva State Park)
- Pecos River (Villanueva State Park to Cow Creek)
- Santa Rosa Reservoir
- Storrie Lake
- Sumner Reservoir
- Tecolote Creek (I-25 to Blue Creek)
- Tres Lagunas (Northeast)
- Willow Creek subwatershed

HUC: 13060003 - Upper Pecos

- Pecos River (Salt Creek to Crockett Draw)

HUC: 13060007 - Upper Pecos-Long Arroyo

- Figure Eight Lake
- Lake Van
- Pecos River (Eagle Creek to Rio Felix)
- Pecos River (Rio Felix to Rio Hondo)
- Pecos River (Rio Penasco to Eagle Creek)

HUC: 13060008 - Rio Hondo

- Alto Lake
- Berrendo Creek (Rio Hondo to Middle Berrendo Creek)
- Carrizo subwatershed
- Grindstone Canyon Reservoir
- Lower Bonito subwatershed
- Lower Eagle Creek subwatershed
- Lower Rio Ruidoso subwatershed
- Middle Rio Ruidoso subwatershed
- North Spring River (Rio Hondo to headwaters)
- Rio Bonito (Perennial prt NM 48 near Angus to headwaters)
- Rio Hondo subwatershed
- S. Fork Eagle Creek (Eagle Creek to Mescalero Apache bnd)

- Upper Bonito subwatershed
- Upper Rio Ruidoso subwatershed

HUC: 13060010 - Rio Penasco

- Agua Chiquita (perennial portions McEwan Cny to headwaters)

HUC: 13060011 - Upper Pecos-Black

- Black River (Perennial prt Pecos River to Blue Spring)
- Brantley Reservoir
- Lower Tansil Lake/Lake Carlsbad (Carlsbad Municipal Lake)
- Pecos River (Avalon Reservoir to Brantley Reservoir)
- Pecos River (Black River to Six Mile Dam)
- Pecos River (Six Mile Dam to Lower Tansil Lake)
- Pecos River (TX border to Black River)
- Six Mile Dam Lake

HUC: 13070002 - Delaware

- Delaware River (Pecos River to TX border)

HUC: 13070007 - Landreth-Monument Draws

- Jal Lake

HUC: 14080101 - Upper San Juan

- Gallegos Canyon (San Juan River to Navajo bnd)
- Los Pinos River (Navajo Reservoir to CO border)
- Navajo Reservoir
- Navajo River (Jicarilla Apache Nation to CO border)
- San Juan River (Animas River to Canon Largo)
- San Juan River (NM reach upstream of Navajo Reservoir)

HUC: 14080104 - Animas

- Animas River (Estes Arroyo to So. Ute Indian Tribe bnd)
- Animas River (San Juan River to Estes Arroyo)
- Lake Farmington (Beeline Reservoir)

HUC: 14080105 - Middle San Juan

- La Plata R (McDermott Arroyo to So. Ute Indian Tribe bnd)
- La Plata River (San Juan River to McDermott Arroyo)
- San Juan River (Navajo bnd at Hogback to Animas River)
- Shumway Arroyo (San Juan River to Ute Mtn Ute bnd)

- Stevens Arroyo (Perennial prts San Juan R to headwaters)

AU Comment: TMDL (Canadian and URG Lakes) for plant nutrients EPA approved August 2024. Samples collected by the New Mexico Environment Department (NMED) in late 2025 showed the presence of harmful algae and toxins, and a HABs Health Watch was issued for this lake.
Harmful algae blooms, or HABs, occur when certain types of algae grow excessively in water, posing potential health risks to people and animals. HABs can appear blue, bright green, brown or red and may resemble scum or floating grass clippings on the water's surface. These blooms can produce toxins that are harmful to humans and animals. For more information visit: https://www.env.nm.gov/surface-water-quality/habs/

WWAL	Not Supporting	Mercury - Fish Consumption Advisory	2004		5/5C
WH	Fully Supporting				

AU Comment: Fish Consumption Advisory listings are based on NM's current fish consumption advisories for this water body. Per USEPA guidance, these advisories demonstrate non-attainment of CWA goals stating that all waters should be "fishable." Therefore, the impaired designated use is the associated aquatic life even though human consumption of the fish is the actual concern.

AU Comment: TMDL (Canadian and URG Lakes) for plant nutrients EPA approved August 2024.
Samples collected by the New Mexico Environment Department (NMED) in late 2025 showed the presence of harmful algae and toxins, and a HABs Warning Advisory was issued for this lake.
Harmful algae blooms, or HABs, occur when certain types of algae grow excessively in water, posing potential health risks to people and animals. HABs can appear blue, bright green, brown or red and may resemble scum or floating grass clippings on the water's surface. These blooms can produce toxins that are harmful to humans and animals. For more information visit: https://www.env.nm.gov/surface-water-quality/habs/

WH	Fully Supporting				

AU Comment: Fish Consumption Advisory listings are based on NM's current fish consumption advisories for this water body. Per USEPA guidance, these advisories demonstrate non-attainment of CWA goals stating that all waters should be "fishable". Therefore, the impaired designated use is the associated aquatic life even though human consumption of the fish is the actual concern.

AU Comment: Fish Consumption Advisory listings are based on NM's current fish consumption advisories for this water body. Per USEPA guidance, these advisories demonstrate non-attainment of CWA goals stating that all waters should be "fishable." Therefore, the impaired designated use is the associated aquatic life even though human consumption of the fish is the actual concern.
Samples collected by the New Mexico Environment Department (NMED) in late 2025 showed the presence of harmful algae and toxins, and a HABs Health Watch was issued for this lake.
Harmful algae blooms, or HABs, occur when certain types of algae grow excessively in water, posing potential health risks to people and animals. HABs can appear blue, bright green, brown or red and may resemble scum or floating grass clippings on the water's surface. These blooms can produce toxins that are harmful to humans and animals. For more information visit: https://www.env.nm.gov/surface-water-quality/habs/

MWWAL	Not Supporting	Temperature	2018		5/5B
PC	Fully Supporting				
WH	Fully Supporting				

AU Comment: Often dry except for irrigation return flows and stormwater runoff. Application of the SWQB Hydrology Protocol (survey date 7/1/09) indicate this assessment unit is intermittent - see https://www.env.nm.gov/surface-water-quality/hp/ for additional details on the protocol). A TMDL was prepared for boron (2011). There is an inconsistency between the marginal warmwater ALU description in 20.6.4.7.M(2) and the associated temperature criterion in 20.6.4.900.H(6) NMAC that needs review.

		Nutrients	2018	2023 (est.)	5/5A
LW	Fully Supporting				
PC	Fully Supporting				
WH	Fully Supporting				

AU Comment: Fish Consumption Advisory listings are based on NM's current fish consumption advisories for this water body. Per USEPA guidance, these advisories demonstrate non-attainment of CWA goals stating that all waters should be "fishable". Therefore, the impaired designated use is the associated aquatic life even though human consumption of the fish is the actual concern.
Samples collected by the New Mexico Environment Department (NMED) in late 2025 showed the presence of harmful algae and toxins, and a HABs Warning Advisory was issued for this lake.
Harmful algae blooms, or HABs, occur when certain types of algae grow excessively in water, posing potential health risks to people and animals. HABs can appear blue, bright green, brown or red and may resemble scum or floating grass clippings on the water's surface. These blooms can produce toxins that are harmful to humans and animals. For more information visit: https://www.env.nm.gov/surface-water-quality/habs/

AU Comment: Although the next survey date is noted as 2017, SWQB does not plan monitoring of these watersheds in the next ten years. However, ongoing water quality data will continue to be collected on the Pajarito Plateau by LANL and NMED DOE-OB. Application of the SWQB Hydrology Protocol (survey date 7/22/08) indicate this assessment unit is ephemeral (Hydrology Protocol score of 8.25 with 93.3% days with no flow at LANL gage E089 - see https://www.env.nm.gov/surface-water-quality/hp/ for additional details on the protocol). The process detailed in 20.6.4.15 NMAC Subsection C must be completed in order to a waterbody under 20.6.4.97 NMAC. Until such time, this waterbody will remain under 20.6.4.98 NMAC.

AU Comment: TMDL (Upper Rio Grande) for Specific Conductance EPA approved February 2025.
The SWQB Watershed Protection Section completed a special study of E. coli levels with associated flow observations in the upper 3 miles of Rio Fernando de Taos and the Apache Canyon tributary to assess potential impacts from livestock grazing in 2006. The study demonstrated instances when grazing on the Flechado Allotment probably increased E. coli levels in Apache Canyon and this portion of Rio Fernando de Taos in 2006. The USFS Carson National Forest in cooperation with SWQB collected E. coli data in 2007 (combined with 2006 data and assessed for 2008 cycle). NMEDs Hydrology Protocol (https://www.env.nm.gov/surface-water-quality/hp/) was performed at this AU on 5/23/11. According to the protocol and supporting information, this AU falls under the perennial definition in 20.6.4.7 NMAC.

AU Comment: TMDL for turbidity (2005). TMDL (Upper Rio Grande) for temperature EPA approved February 2025.
Fish Tissue Advisory listings are based on NM's current fish consumption advisories for this water body. Per USEPA guidance, these advisories demonstrate non-attainment of CWA goals stating that all waters should be "fishable". Therefore, the impaired designated use is the associated aquatic life even though human consumption of the fish is the actual concern. 2022 TMDL pending WQCC approval

AU Comment: TMDL (Canadian and URG Lakes) for Plant Nutrients, Temperature, Total Aluminum EPA approved August 2024. Samples collected by the New Mexico Environment Department (NMED) in late 2025 showed the presence of harmful algae and toxins, and a HABs Health Watch was issued for this lake. Harmful algae blooms, or HABs, occur when certain types of algae grow excessively in water, posing potential health risks to people and animals. HABs can appear blue, bright green, brown or red and may resemble scum or floating grass clippings on the water's surface. These blooms can produce toxins that are harmful to humans and animals. For more information visit: https://www.env.nm.gov/surface-water-quality/habs/

AU Comment: This was a new assessment unit created in 2025. The AU has been created using a subwatershed-based approach, which means that the AU is visualized as a polygon showing the watershed instead of a singular linear waterway. This subwatershed-based approach is a pilot of this type of AU in New Mexico, but has been used as the sole approach or in combination with linear AU's in other states throughout the U.S. Creating a single assessment conclusion for the watershed unit as a whole aligns with EPA's ATTAINS reporting requirements, and is also consistent with established methodologies in other states. Subwatershed AU's will be assessed in a similar manner as linear AUs, by using the station lowest in the AU (at or near the pourpoint) to capture activities within the AU as a whole. The linear AU associated with the new subwatershed AU's will be retired next assessment cycle.

AU Comment: Fish Consumption Advisory listings are based on NM's current fish consumption advisories for this water body. Per USEPA guidance, these advisories demonstrate non-attainment of CWA goals stating that all waters should be "fishable". Therefore, the impaired designated use is the associated aquatic life even though human consumption of the fish is the actual concern.

AU Comment: Fish Consumption Advisory listings are based on NM's current fish consumption advisories for this water body. Per USEPA guidance, these advisories demonstrate non-attainment of CWA goals stating that all waters should be "fishable." Therefore, the impaired designated use is the associated aquatic life even though human consumption of the fish is the actual concern.

AU Comment: Samples collected by the New Mexico Environment Department (NMED) in late 2025 showed the presence of harmful algae and toxins, and a HABs Health Watch was issued for this lake.
Harmful algae blooms, or HABs, occur when certain types of algae grow excessively in water, posing potential health risks to people and animals. HABs can appear blue, bright green, brown or red and may resemble scum or floating grass clippings on the water's surface. These blooms can produce toxins that are harmful to humans and animals. For more information visit: https://www.env.nm.gov/surface-water-quality/habs/

AU Comment: This was a new assessment unit created in 2025. The AU has been created using a subwatershed-based approach, which means that the AU is visualized as a polygon showing the watershed instead of a singular linear waterway. This subwatershed-based approach is a pilot of this type of AU in New Mexico, but has been used as the sole approach or in combination with linear AU's in other states throughout the U.S. Creating a single assessment conclusion for the watershed unit as a whole aligns with EPA's ATTAINS reporting requirements, and is also consistent with established methodologies in other states. Subwatershed AU's will be assessed in a similar manner as linear AUs, by using the station lowest in the AU (at or near the pourpoint) to capture activities within the AU as a whole. The linear AU associated with the new subwatershed AU's will be retired next assessment cycle.

AU Comment: This was a new assessment unit created in 2025. The AU has been created using a subwatershed-based approach, which means that the AU is visualized as a polygon showing the watershed instead of a singular linear waterway. This subwatershed-based approach is a pilot of this type of AU in New Mexico, but has been used as the sole approach or in combination with linear AU's in other states throughout the U.S. Creating a single assessment conclusion for the watershed unit as a whole aligns with EPA's ATTAINS reporting requirements, and is also consistent with established methodologies in other states. Subwatershed AU's will be assessed in a similar manner as linear AUs, by using the station lowest in the AU (at or near the pourpoint) to capture activities within the AU as a whole. The linear AU associated with the new subwatershed AU's will be retired next assessment cycle.

AU Comment: This was a new assessment unit created in 2025. The AU has been created using a subwatershed-based approach, which means that the AU is visualized as a polygon showing the watershed instead of a singular linear waterway. This subwatershed-based approach is a pilot of this type of AU in New Mexico, but has been used as the sole approach or in combination with linear AU's in other states throughout the U.S. Creating a single assessment conclusion for the watershed unit as a whole aligns with EPA's ATTAINS reporting requirements, and is also consistent with established methodologies in other states. Subwatershed AU's will be assessed in a similar manner as linear AUs, by using the station lowest in the AU (at or near the pourpoint) to capture activities within the AU as a whole. The linear AU associated with the new subwatershed AU's will be retired next assessment cycle.

AU Comment: This was a new assessment unit created in 2025. The AU has been created using a subwatershed-based approach, which means that the AU is visualized as a polygon showing the watershed instead of a singular linear waterway. This subwatershed-based approach is a pilot of this type of AU in New Mexico, but has been used as the sole approach or in combination with linear AU's in other states throughout the U.S. Creating a single assessment conclusion for the watershed unit as a whole aligns with EPA's ATTAINS reporting requirements, and is also consistent with established methodologies in other states. Subwatershed AU's will be assessed in a similar manner as linear AUs, by using the station lowest in the AU (at or near the pourpoint) to capture activities within the AU as a whole. The linear AU associated with the new subwatershed AU's will be retired next assessment cycle.

AU Comment: Metals listings based on exceedances of acute criteria. During the 2022 cycle this AU was split from NM-128.A_06 as a result of Hydrology Protocol surveys that documented a perennial reach downstream of Arroyo de la Delfe. Hydrology Protocol survey results indicate this AU is perennial.

WWAL	Not Supporting	Mercury - Fish Consumption Advisory	2020		5/5C
WH	Fully Supporting				

AU Comment: Some of the impairment listings are based solely on stormwater data. Procedures are in place, under the purview of the Buckman Direct Diversion Board, that are intended to not allow public water supply withdrawal from the Buckman Diversion during significant storm events. Fish Tissue Advisory listings are based on NM's current fish consumption advisories for this water body. Per USEPA guidance, these advisories demonstrate non-attainment of CWA goals stating that all waters should be "fishable". Therefore, the impaired designated use is the associated aquatic life even though human consumption of the fish is the actual concern.

Rio Grande (non-pueblo Angostura Div to Cochiti Rsrv)			AU IR CATEGORY	LOCATION DESCRIPTION

AU Comment: TMDL for E. coli. Fish Consumption Advisory listings are based on NM's current fish consumption advisories for this water body. Per USEPA guidance, these advisories demonstrate non-attainment of CWA goals stating that all waters should be "fishable." Therefore, the impaired designated use is the associated aquatic life even though human consumption of the fish is the actual concern.

WWAL	Not Supporting	Mercury - Fish Consumption Advisory	2004		5/5C
		PCBS - Fish Consumption Advisory	2010		5/5C
WH	Fully Supporting				

AU Comment: Fish Consumption Advisory listings are based on NM's current fish consumption advisories for this water body. Per USEPA guidance, these advisories demonstrate non-attainment of CWA goals stating that all waters should be "fishable." Therefore, the impaired designated use is the associated aquatic life even though human consumption of the fish is the actual concern. The actual size of this AU at any given time depends on fluctuating surface area and reservoir volume.

PC	Fully Supporting				
WH	Fully Supporting				

AU Comment: Fish Consumption Advisory listings are based on NM's current fish consumption advisories for this water body. Per USEPA guidance, these advisories demonstrate non-attainment of CWA goals stating that all waters should be "fishable." Therefore, the impaired designated use is the associated aquatic life even though human consumption of the fish is the actual concern.

Cameron Creek (San Vicente Arroyo to headwaters)			AU IR CATEGORY	LOCATION DESCRIPTION

WH	Fully Supporting				

AU Comment: This was a new assessment unit created in 2025. The AU has been created using a subwatershed-based approach, which means that the AU is visualized as a polygon showing the watershed instead of a singular linear waterway. This subwatershed-based approach is a pilot of this type of AU in New Mexico, but has been used as the sole approach or in combination with linear AU's in other states throughout the U.S. Creating a single assessment conclusion for the watershed unit as a whole aligns with EPA's ATTAINS reporting requirements, and is also consistent with established methodologies in other states. Subwatershed AU's will be assessed in a similar manner as linear AUs, by using the station lowest in the AU (at or near the pourpoint) to capture activities within the AU as a whole. The linear AU associated with the new subwatershed AU's will be retired next assessment cycle.

WH	Fully Supporting				

AU Comment: Lake is actually an impounded playa. Although the reservoir is associated with Holloman Air Force Base, the public does have access. The New Mexico Department of Health is warning people not to swim in or drink from Lake Holloman in southern New Mexico as of May 10, 2019. the lake already is off limits to swimming but state officials reiterated their warning saying people should wash their hands if they get water or foam from the lake on them. They also warned pet owners to avoid letting their animals drink or come into contact with the water or foam. This lake has very high salinity, and is thus not suitable for livestock watering or supporting a viable fishery. Limited aquatic life might be a more realistic use based on salinity.

AU Comment: This was a new assessment unit created in 2025. The AU has been created using a subwatershed-based approach, which means that the AU is visualized as a polygon showing the watershed instead of a singular linear waterway. This subwatershed-based approach is a pilot of this type of AU in New Mexico, but has been used as the sole approach or in combination with linear AU's in other states throughout the U.S. Creating a single assessment conclusion for the watershed unit as a whole aligns with EPA's ATTAINS reporting requirements, and is also consistent with established methodologies in other states. Subwatershed AU's will be assessed in a similar manner as linear AUs, by using the station lowest in the AU (at or near the pourpoint) to capture activities within the AU as a whole. The linear AU associated with the new subwatershed AU's will be retired next assessment cycle.

AU Comment: Tres Lagunas NE is one of three small on-line impoundments on a perennial tributary to the Pecos River origionally constructed by the railroad for flood control and eventual irrigation storage. In the years since the construction, the lake has filled with sediment, now averaging one meter in depth. As a result, WQS segment 20.6.4.212 is likely not appropriate for this waterbody.

AU Comment: This was a new assessment unit created in 2025. The AU has been created using a subwatershed-based approach, which means that the AU is visualized as a polygon showing the watershed instead of a singular linear waterway. This subwatershed-based approach is a pilot of this type of AU in New Mexico, but has been used as the sole approach or in combination with linear AU's in other states throughout the U.S. Creating a single assessment conclusion for the watershed unit as a whole aligns with EPA's ATTAINS reporting requirements, and is also consistent with established methodologies in other states. Subwatershed AU's will be assessed in a similar manner as linear AUs, by using the station lowest in the AU (at or near the pourpoint) to capture activities within the AU as a whole. The linear AU associated with the new subwatershed AU's will be retired next assessment cycle.

AU Comment: This AU may be ephemeral. The process detailed in 20.6.4.15 NMAC Subsection C must be completed in order to classify a waterbody under 20.6.4.97 NMAC. Until such time, this AU remains classified under Intermittent Waters - 20.6.4.98 NMAC. This AU has been absorbed into the new subwatershed-based AU "Lower Eagle Creek subwatershed" . Refer to AU ID W_NM-801-05.B from this cycle onwards.

AU Comment: This was a new assessment unit created in 2025. The AU has been created using a subwatershed-based approach, which means that the AU is visualized as a polygon showing the watershed instead of a singular linear waterway. This subwatershed-based approach is a pilot of this type of AU in New Mexico, but has been used as the sole approach or in combination with linear AU's in other states throughout the U.S. Creating a single assessment conclusion for the watershed unit as a whole aligns with EPA's ATTAINS reporting requirements, and is also consistent with established methodologies in other states. Subwatershed AU's will be assessed in a similar manner as linear AUs, by using the station lowest in the AU (at or near the pourpoint) to capture activities within the AU as a whole. The linear AU associated with the new subwatershed AU's will be retired next assessment cycle.

AU Comment: This was a new assessment unit created in 2025. The AU has been created using a subwatershed-based approach, which means that the AU is visualized as a polygon showing the watershed instead of a singular linear waterway. This subwatershed-based approach is a pilot of this type of AU in New Mexico, but has been used as the sole approach or in combination with linear AU's in other states throughout the U.S. Creating a single assessment conclusion for the watershed unit as a whole aligns with EPA's ATTAINS reporting requirements, and is also consistent with established methodologies in other states. Subwatershed AU's will be assessed in a similar manner as linear AUs, by using the station lowest in the AU (at or near the pourpoint) to capture activities within the AU as a whole. The linear AU associated with the new subwatershed AU's will be retired next assessment cycle.

AU Comment: Fish Consumption Advisory listings are based on NM's current fish consumption advisories for this water body. Per USEPA guidance, these advisories demonstrate non-attainment of CWA goals stating that all waters should be "fishable." Therefore, the impaired designated use is the associated aquatic life even though human consumption of the fish is the actual concern.

AU Comment: Samples collected by the New Mexico Environment Department (NMED) in late 2025 showed the presence of harmful algae and toxins, and a HABs Warning Advisory was issued for this lake.
Harmful algae blooms, or HABs, occur when certain types of algae grow excessively in water, posing potential health risks to people and animals. HABs can appear blue, bright green, brown or red and may resemble scum or floating grass clippings on the water's surface. These blooms can produce toxins that are harmful to humans and animals. For more information visit: https://www.env.nm.gov/surface-water-quality/habs/

AU Comment: Application of the SWQB Hydrology Protocol on 5/19/2009 indicate this assessment unit is intermittent (Hydrology Protocol score of 10.5), while survey data from 10/12/11 indicate ephemeral at the station above the falls (score of 0.0). This AU may be ephemeral. The process detailed in 20.6.4.15 NMAC Subsection C must be completed in order to classify a waterbody under 20.6.4.97 NMAC. Until such time, this AU remains classified under Intermittent Waters - 20.6.4.98 NMAC.

AU Comment: Samples collected by the New Mexico Environment Department (NMED) in late 2025 showed the presence of harmful algae and toxins, and a HABs Health Watch was issued for this lake.
Harmful algae blooms, or HABs, occur when certain types of algae grow excessively in water, posing potential health risks to people and animals. HABs can appear blue, bright green, brown or red and may resemble scum or floating grass clippings on the water's surface. These blooms can produce toxins that are harmful to humans and animals. For more information visit: https://www.env.nm.gov/surface-water-quality/habs/

AU Comment: Land management agencies have posted contact recreation warnings due to toxic blue green algae in the past. SWQB does not have water quality standards or assessment procedures related to blue green algae at this time. Fish Consumption Advisory listings are based on NM's current fish consumption advisories for this water body. Per USEPA guidance, these advisories demonstrate non-attainment of CWA goals stating that all waters should be "fishable". Therefore, the impaired designated use is the associated aquatic life even though human consumption of the fish is the actual concern.

PLEASE NOTE:

Original letters and emails were converted to Microsoft Word when possible. When not possible (i.e. due to unreadable PDFs), screenshots of each comment were inserted into the Word document followed by the response. Submitted comments were converted to Calibri font with standard page margins for ease of collation. All original comment letters/emails are on file at the NMED-SWQB office in Santa Fe, NM and are available electronically.

SUMMARY OF CHANGES TO THE DRAFT 2026-2028 INTEGRATED LIST DUE TO SOLICITED PUBLIC COMMENTS AND/OR DUE TO ADDITIONAL STAFF REVIEW DURING THE COMMENT PERIOD:

New Mexico Environment Department ("NMED") solicited public comments on the draft 2026-2028 Integrated List during a 45-day period (December 8, 2025, through January 22, 2026) and made the following changes during and after the public comment period:

1. *Tijeras Arroyo (Rio Grande to Four Hills Bridge) (NM-9000.A_070) – On 12/9/25 the WQCC approved the Tijeras Arroyo UAA. As a result of the amendment, Tijeras Arroyo (Rio Grande to Four Hills Bridge) has been placed in 20.6.4.97 NMAC.*
2. *Added an Assessment Rationale note to Navajo Reservoir (NM-2406_00) that recent (2025 buoy) LTD data provide documentation that a temperature impairment persists.*
3. *For assessment unit (AU) NM-2112.A_20 (El Rito Creek, perennial reaches from HWY 554 to the headwaters), there were 0 exceedances out of 4 samples for the E. coli criterion at the historic monitoring station. As a result, the E. coli impairment has been removed from this soon-to-be-retired AU. The new watershed-based AU that now includes this station continues to show attainment of the E. coli criterion based on the most recent dataset (2023–2024). However, it remains impaired for temperature (IR Category 5A) due to 4T3 and Tmax exceedances recorded on the 2023 thermograph. Assessment Rationale comments were added to clarify the distinction between the historic AU and the current watershed-based AU.*
4. *DP Canyon (100m downstream of grade control to 400m upstream of grade control) (NM-128.A_24) – reformatted data submitted during the July 2025 call for data was re-assessed, 0/5 exceedances of the new site-specific copper criteria described in Paragraph (4) of Subsection I of 20.6.4.900 NMAC, therefore copper (dissolved) impairment removed.*
5. *Pueblo Canyon (Acid Canyon to headwaters) (NM-9000.A_043) – reformatted data submitted during the July 2025 call for data was re-assessed, 0/5 exceedances of the new site-specific copper criteria described in Paragraph (4) of Subsection I of 20.6.4.900 NMAC, therefore copper (dissolved) impairment removed.*
6. *Assessment Rationale comments were added to the other Pajarito Plateau AUs (NM-97.A_002, NM-128.A_36, NM-97.A_029, NM-128.A_15) that were re-assessed using the new site-specific copper criteria in Paragraph (4) of Subsection I of 20.6.4.900 NMAC, noting that these reassessments did not result in any changes.*

RE: 2026-2028 of New Mexico Clean Water Act Integrated List of Assessed Surface Waters Draft

Surface Water Quality Bureau,

New Mexico Farm and Livestock Bureau (NMF&LB) appreciates the opportunity to provide comments on the 2026-2028 State of New Mexico Clean Water Act Integrated List of Assessed Surface Waters Draft.

New Mexico Farm and Livestock Bureau works to ensure the support of federal regulation of the Clean Water Act within the state for the beneficial use of stakeholders and the impact of imposed regulations. NMF&LB recognizes the continuing efforts to provide the state with clean water and supports the EPA's commitment to following the guidelines put in place by the Clean Water Act and their efforts in assessing and protecting water quality standards for the surface waters within our state.

Water, being a valuable asset for our farmers and ranchers, we ask that the Surface Water Quality Bureau and New Mexico Environment Department consider and create systems in which our rural agriculturalists are able to continue production uninterrupted when waters are classified as impaired. NMF&LB recognizes and supports actions that are used to ensure the future of agriculture for generations to come, any regulatory burden that removes farmer and rancher access to vital inputs such as water, does not ensure the future of agriculture in our rural communities.

As the Surface Water Quality Bureau and New Mexico Environmental Department continues to assess the integrated list of Surface Waters and impaired waters within the state of New Mexico, we respectfully request that you consider having accurate and appropriate representation in the agricultural and rural areas of expertise when deciding on impaired surface waters to be added to the integrated list and how that can affect our agricultural stakeholders in irrigation and livestock management.

Once again, NMF&LB appreciates the opportunity to participate in providing public comment on regulation that will have an impact on the capabilities of farmers and ranchers such as the 2026-2028 State of New Mexico Clean Water Act Integrated List of assessed Surface Waters Draft. NMF&LB looks forward to further engaging in this process and appreciates your consideration of our members' viewpoints.

New Mexico Farm and Livestock Bureau is New Mexico's largest agricultural organization, representing members involved in all aspects of agriculture from dairy and livestock to fruits and vegetables. Our mission is to promote and protect agriculture in the great State of New Mexico. We are charged with the important task of representing our members' interests when it comes to impending regulations and programs.

***NMED RESPONSE**:*

Thank you for your comments on the 2026–2028 State of New Mexico Clean Water Act Integrated List of Assessed Surface Waters Draft. The Surface Water Quality Bureau (SWQB) appreciates the New Mexico Farm and Livestock Bureau's engagement and your commitment to both clean water and the long-term viability of agriculture in New Mexico. We recognize the essential role water plays in sustaining agricultural production and remain committed to implementing the Clean Water Act in a transparent and collaborative manner that supports farmers and ranchers while ensuring scientifically based water quality assessments.

Public participation is a core requirement of the Clean Water Act and is strongly supported by the U.S. Environmental Protection Agency. Consistent with these expectations, the Comprehensive Assessment and Listing Methodology (CALM) was open for an extended public comment period from June 16 through July 18, 2025, and the draft Integrated List was open for an extended public comment period from December 8, 2025 through January 22, 2026, during which specific listing decisions could be reevaluated given supporting data. While NMED did not receive additional comments to reconsider individual impairments during the comment period, we remain committed to ensuring agricultural voices are included in future stages of water quality planning. EPA emphasizes that residents, landowners, and agricultural producers often have unique knowledge of watershed conditions, and this local insight can meaningfully improve both listing decisions and the development of water quality restoration strategies. SWQB values the perspectives of agricultural stakeholders and welcomes continued participation from rural communities. The Water Quality Control Commission, whose membership includes the Director of the New Mexico Department of Agriculture, will consider the final List following a presentation by SWQB staff at the regular monthly meeting on March 10, 2026.

The Integrated List is a Clean Water Act deliverable and a key document used by multiple NMED programs, including permitting and watershed planning, to guide water quality improvement efforts. Impairment decisions are considered by SWQB's Point Source Regulation Section during regulatory and permitting processes. The List is also used by SWQB's Watershed Protection Section to inform watershed-based planning and restoration projects.

Stakeholders also have opportunities for public engagement during the development of Total Maximum Daily Loads (TMDLs), which guide future regulatory and restoration efforts. Public participation is a required and essential component of the TMDL process, including reviewing draft TMDLs, providing data, and offering local context. Completion of a TMDL can lead to additional monitoring, planning, and on the ground restoration projects to address watershed conditions contributing to impairments. Thank you again for your engagement and for representing the interests of New Mexico's agricultural producers. SWQB looks forward to continued dialogue with the New Mexico Farm and Livestock Bureau as we advance the Integrated Report, TMDL development, and future water quality initiatives. We encourage interested organizations to subscribe to GovDelivery alerts and check the NMED events calendar for upcoming engagement opportunities.

Gila Resources Information Project
305A N. Cooper St.
Silver City, NM 88061
grip@gilaresources.info, silvercitywatershedkeepers@gmail.com
22 January 2024

Surface Water Quality Board
New Mexico Environment Department

Public comment on the **2026-2028 Clean Water Act 303(d)/305(b) Integrated List of Assessed Surface Waters**

To whom it may concern,

I am writing this letter as a representative of the Gila Resources Information Project (GRIP), a 503(c) non-profit organization in Silver City, NM that has been promoting healthy communities by protecting our local environment since 1988. GRIP, along with its watershed monitoring and education program, the Silver City Watershed Keepers, has worked to protect and restore watershed functioning and monitor local water quality in and around the Town of Silver City. GRIP has received multiple River Stewardship grants to restore stream and riparian habitat along San Vicente Creek and conducts quarterly water quality monitoring within this watershed.

We are submitting public comments on the 2026-2028 Clean Water Act 303(d)/305(b) Integrated List of Assessed Surface Waters in order to better understand how waterway impairments are classified and how Outstanding National Resource Waters are being protected. *Our goal is to understand how we can best monitor water quality and submit high-quality data to the New Mexico Environment Department for waterways in the Town of Silver City and in the surrounding Grant County and Gila bioregion.*

How are waterways classified as impaired?
Within the Integrated List of Assessed Surface Waters, reaches may be designated as impaired in terms of physical, biological, and chemical factors.

Within Grant County, some surface waters are listed as being impaired. Specifically, the Gila River and Bear Creek are listed as being temperature-impaired and San Vicente Creek (Perennial prt Maudes Cny to Silva Creek), the waterway that flows through downtown Silver City and that is center of our Big Ditch Park and urban trail system, has been listed as being impaired for nutrients and *E. coli*. While the 2025 Comprehensive and Listing Methodology (CALM) discusses the thresholds and number of tests needed to classify a waterway as impaired, it does not specify which specific products or testing methods are acceptable for use.

- We would like to know what metrics were used to designate these waters as impaired? If other water monitoring entities were testing San Vicente Creek, for example, can we access those reports that were cited as part of this designation process?

***NMED RESPONSE**:*

Thank you for your comment and for your interest in understanding how waterways are assessed and how high-quality data can be submitted for consideration in the Integrated List of Impaired Waters. The metrics used to determine whether a waterbody is impaired are outlined in the Comprehensive Assessment and Listing Methodology (CALM), which describes the physical, chemical, and biological criteria applied during assessment.

San Vicente Creek (Perennial portion from Maudes Canyon to Silva Creek) has been listed as impaired for nutrients since 2012. The Assessment Rationale document notes that data collected during the 2019-2020 Gila/Mimbres/San Francisco survey supported a retained nutrient impairment (TN median threshold exceedance). Recent data submitted by the Silver City Watershed Keepers indicated six out of eight exceedances of the dissolved oxygen (DO) criterion. Because low DO is a common response to excess nutrient loading, these results were used as support for the persistent nutrient impairment, and the listing category was updated from IR Category 5C to 5A. In addition, two out of eight samples exceeded the E. coli criterion, which resulted in E. coli being added as a new impairment. The data used for these determinations were submitted by the Silver City Watershed Keepers and by your organization during the call for outside data on 7/16/2025 and 9/8/2025. If you would like to discuss the specific decision-making process in more detail, we would be happy to schedule a meeting.

Regarding acceptable testing methods, Appendix A of the CALM describes the data quality levels required for assessment, including the types of sampling methods, laboratory procedures, and documentation needed for data to be considered "Level 3," which is the level required for use in impairment determinations. SWQB accepts data from external monitoring entities when it meets these quality requirements. A data determination letter was prepared for Silver City Watershed Keepers data explaining the data quality level determination and rationale. If other organizations have collected data on San Vicente Creek or other Grant County waters, those datasets would be included in the administrative record if they met CALM criteria and were submitted during the data solicitation period. You may request access to any such records through NMED, and we can assist you in identifying what was submitted and used.

We appreciate your engagement and your interest in participating in a rigorous, science-based data collection process. Public involvement and high-quality local monitoring are essential components of maintaining accurate assessments of New Mexico's surface waters, and we welcome continued collaboration.

- If a standard or limit was crossed (i.e. phosphorus Total Maximum Daily Load above 1 ppm), what was that limit and was the observed value in our waters? It would be informative to know if waters barely crossed a threshold or were 10x the threshold.

***NMED RESPONSE**:*

Thank you for your comment and for your interest in understanding how nutrient standards are applied when determining impairments. Appendix C of the Comprehensive Assessment and Listing Methodology (CALM) describes how nutrient thresholds, specifically total nitrogen (TN) and total phosphorus (TP), are derived. These thresholds are not single statewide values; instead, they vary based on site-specific factors such as the ecoregion, geology, and natural background conditions of the watershed. This approach ensures that the criteria used to assess a waterbody are appropriate for its natural setting. While some surface waters in the New Mexico Water Quality Standards (20.6.4 NMAC) have segment-specific TP criteria adopted directly into the water quality standards, those numeric criteria apply only to the specific segments where they are designated. For all other wadeable perennial streams without segment-specific nutrient criteria, the nutrient thresholds in CALM Appendix C are used for assessment purposes. This framework ensures that nutrient assessments rely on the most appropriate criteria for each

waterbody, whether those criteria are formally adopted in the standards or derived through the CALM process.

When a waterbody is listed as impaired for nutrients, the associated Total Maximum Daily Load (TMDL) includes a percent reduction table that summarizes the magnitude of exceedances observed in the data. This table provides information on how far the measured values were above the applicable threshold, which can help illustrate whether exceedances were slight or substantially higher than the criterion.

For example, San Vicente Creek (Perennial, Maudes Canyon to Silva Creek) was assessed during SWQB's 2019-2020 rotational survey of the Gila/Mimbres/San Francisco watersheds. Four total nitrogen (TN) samples were collected (0.92, 1.645, 2.342, and 2.451 mg/L), resulting in a site-median TN concentration of 1.9935 mg/L. This median exceeds the applicable "moderate" site-class TN threshold of 0.42 mg/L. Because the median TN concentration remains above the threshold, the existing nutrient impairment for this assessment unit was retained.

If you are interested in the specific values observed in another particular waterbody, we would be happy to walk through the dataset with you. Waterbody-specific data used in the assessment are available upon request, and our staff can help explain how those values compared to the applicable thresholds.

Thank you again for your engagement and for your interest in understanding the technical basis for impairment decisions.

- How often should waters be re-tested to determine their impairment level? We are unsure whether to test for nutrient limitations every quarter, once annually, or at a different frequency

***NMED RESPONSE**:*

Thank you for your interest in collecting high quality data to support water quality assessments. For nutrient monitoring, sampling once per quarter is generally appropriate, which typically results in 6–8 samples per year depending on flow conditions. This frequency provides enough temporal coverage to evaluate whether nutrient criteria are being met (and calculate a median value) while ensuring that samples are spaced far enough apart to represent independent conditions.

A complete nutrient assessment relies on evaluating total nitrogen (TN), total phosphorus (TP), and daily delta dissolved oxygen (DO) together, because each plays a different role in understanding whether excess nutrients are causing ecological harm. TN and TP serve as causal indicators, while delta DO is the response indicator that reveals whether those elevated nutrients are driving biological effects such as excessive algal growth and associated swings in oxygen levels. Since delta DO reflects the actual ecological response, a waterbody cannot be listed as impaired for nutrients without it. TN, TP, and grab DO data still provide valuable supporting information and can signal emerging trends, but they cannot independently confirm impairment. Because of this, in addition to collecting enough TN and TP samples to calculate a reliable site median, long-term DO monitoring (ideally at least seven days of continuous data during the growing season) is recommended to support sound nutrient-impairment decision-making and ensure assessments are based on both cause and response. SWQB's Standard Operating Procedures (SOPs) provide detailed guidance on how to collect high-quality water quality data, including recommended sampling methods, appropriate temporal spacing, and proper use of field and laboratory equipment. These procedures help ensure that data collected for assessments are scientifically defensible, comparable across years and watersheds, and suitable for determining attainment of water quality standards. SWQB's SOPs are publicly available here: https://www.env.nm.gov/surface-water-quality/sop/.

Sampling frequency and data quality expectations are described in both the Surface Water Quality Bureau's Quality Assurance Project Plan (QAPP) and the Comprehensive Assessment and Listing Methodology (CALM). The CALM specifies that a minimum of n = 4 samples is required to assess nutrients (total phosphorus or total nitrogen). SWQB may collect duplicate or replicate samples during special investigations, but we do not routinely collect them for standard chemical monitoring. This is because laboratory quality assurance procedures already address analytical precision, and replicate field samples do not distinguish environmental variability from sampling or analytical error in a way that improves assessment decisions.

The CALM also explains how temporal independence is applied during assessments. For Clean Water Act §303(d)/§305(b) purposes, grab samples collected within a seven-day period are considered duplicates unless they represent distinct hydrologic events. In these cases, the maximum (or minimum, depending on the criterion) value is used to ensure that any exceedance is captured. For certain parameters, such as turbidity, at least four samples must be collected at least 21 days apart within the same calendar year to be considered assessable. Samples captured within 21 days are considered replicates, and the most conservative value is used for assessment.

If you are planning a monitoring program and would like guidance on designing a sampling schedule that meets CALM and QAPP requirements, we would be happy to discuss your goals and help ensure your data can be used in future assessments. Please reach out to the SWQB QA officer Emily Miller (Emily.Miller@env.nm.gov). You may also find it helpful to review the field sampling plans available on our monitoring webpage, which provide useful examples of how SWQB structures its own monitoring efforts: https://www.env.nm.gov/surface-water-quality/water-quality-monitoring/. Thank you again for your engagement and commitment to rigorous water quality monitoring.

- Which tests or products are acceptable to use? In the past, we have used LaMotte Nitrate-Nitrogen test kits, CHEMetrics Nitrate kits, and H2Ok water testing kits to quantify nitrogen levels. We know that we could also submit water samples to various private and state labs. These kits and lab tests range in purchase price and toxicity of test reagents, so of course we would like to collect the highest quality data while minimizing costs and potential environmental or personal exposure to toxic chemicals.

***NMED RESPONSE**:*

Thank you for your interest in collecting high quality data while also considering cost and safety. The Surface Water Quality Bureau's Quality Assurance Project Plan (QAPP), Standard Operating Procedure (SOP) 8.2, and Appendix A of the Comprehensive Assessment and Listing Methodology (CALM) provide guidance on which analytical methods are acceptable for use in Clean Water Act assessments.

In general, any method used for nitrogen, phosphorus, or other chemical parameters must be sufficiently sensitive, meaning the method's detection limit must fall below the applicable water quality standard or the assessment threshold described in the CALM. This ensures that the data can reliably detect exceedances when they occur. Many field test kits, such as LaMotte, CHEMetrics, or H2Ok, can be useful for screening or educational purposes, but they often do not meet the sensitivity, precision, or documentation requirements needed for Level 3 data, which is the level required for impairment determinations.

For data to be used in the Integrated Report, methods must meet or be equivalent to the QAPP's requirements for accuracy, precision, calibration, and quality assurance. This typically means using laboratory-based analytical methods (e.g., EPA-approved methods) or field instruments that have been properly calibrated and documented. Submitting samples to a certified laboratory is often the most reliable way to ensure that data meet these requirements, though we understand that cost is an important consideration.

If you are planning a monitoring program and would like help identifying methods, laboratories or kits that meet CALM and QAPP requirements, or help determining when a field kit may be appropriate versus when laboratory analysis is needed, we would be happy to discuss your goals and provide guidance. Please reach out to the SWQB QA officer Emily Miller (Emily.Miller@env.nm.gov). Thank you again for your commitment to collecting high quality water quality data.

- While the CALM protocols specify how many above-threshold readings are required to classify (or de-classify) a waterway as impaired, we don't believe follow-up testing procedures or frequency are recommended. If we, for example, observe high nitrate values in San Vicente Creek, should we take a follow-up sample within a certain time frame or submit a follow-up sample to a designated lab to confirm the test value? A recommendation would be helpful, especially if local water monitoring organizations want to help test and classify more remote or understudied surface waters.

***NMED RESPONSE**:*

Thank you for your interest in collecting high-quality data; please see the earlier response regarding nutrient sampling frequency, assessment requirements, and recommended monitoring approaches. If you would like assistance designing a monitoring schedule that meets CALM and QAPP requirements, you may contact the SWQB QA Officer, Emily Miller (Emily.Miller@env.nm.gov), and additional examples are available on our monitoring webpage: https://www.env.nm.gov/surface-water-quality/water-quality-monitoring/.

What is the status of Outstanding National Resource Waters?

The Clean Water Act allows for the designation of our state's highest quality and most important waterways as Outstanding National Resource Waters (ONRWs). In Grant County, many reaches are designated as ONRW - USFS Wilderness Streams, marking their importance to our citizens and also their protected status. The Clean Water Act and New Mexico's anti-degradation policies state that ONRWs should receive enhanced protection from degradation in perpetuity.

We would like to know what efforts have been made, by the NM Environment Department or the U.S. Forest Service, to monitor for disturbance or changes to the chemical, physical or biological integrity of the ONRWs in the Gila Bioregion. We, and other environmental monitoring organizations, could contribute to future surveys if we knew the type and frequency of surveys desired on ONRWs.

- What tests or surveys have been conducted since these waters were designated as ONRWs? Have they been surveyed using the full suite of CALM protocols? For example, are ONRWs surveyed once for chemical impairments or are biological, physical, and chemical surveys being conducted once annually?

- What monitoring is planned or desired in the next 5 years? To avoid redundant surveys, it would be useful to share a proposed survey schedule of ONRWs that will be conducted by the state as well as sharing a call for watershed monitoring organizations to conduct more surveys. This would allow us and similar organizations to apply for funding and permits/permissions in time to support ONRW monitoring.

***NMED RESPONSE**:*

Thank you for your comment and for your continued interest in the protection and monitoring of Outstanding National Resource Waters (ONRWs) in the Gila region.

NMED works with the U.S. Forest Service (USFS) under an established Memorandum of Understanding (MOU) for the management of Forest Service waters, including ONRWs. While NMED conducts water quality assessments and antidegradation review, the USFS remains the designated management agency for ONRWs on national forest lands. Under the MOU, the two agencies coordinate on ONRW protection protocols, evaluate potential degradation, and, when impairments are confirmed, work jointly with stakeholders to identify causes and appropriate actions. When resources allow, NMED and the USFS may increase sampling frequency in affected ONRWs.

Regarding past monitoring, NMED last surveyed the Gila/San Francisco/Mimbres watershed in 2019–2020 as part of the statewide rotational monitoring program, with previous surveys in 2014 and 2007. These surveys included chemical, physical, and limited biological monitoring using the most current quality assurance plans, SOPs, and CALM assessment methods available at the time. Chemical sampling is conducted multiple times within a survey period to meet minimum data requirements.

For future monitoring, please see NMED's most recently published Integrated Report for the monitoring schedule planned through 2030, including Figure 4: New Mexico's Surface Water Quality Monitoring Schedule (NMED/SWQB 2016, 2020 revision). We are tentatively planning to sample the Gila in 2028. Some sites within the planned survey watersheds may fall within ONRWs; however, all ONRWs may not be specifically targeted for sampling within the rotational monitoring framework due to resource and access limitations.

NMED welcomes and encourages watershed organizations to conduct additional monitoring on ONRWs, as there is a significant need for focused watershed-level data collection across many areas of the state. Collaboration from external organizations can help fill important data gaps. NMED now offers the Watershed Protection Assistance Program (WPAP) that provides up to $75,000 via one-time grants to do projects, such as water quality monitoring or effectiveness monitoring, which might be of interest to understanding the status of ONRWs in the Gila and inform restoration project development.

NMED's monitoring team conducts an informational public meeting and notifies the public on proposed field sampling plans, including watersheds and specific water quality stations, beginning in the winter prior to each survey year (typically February). We encourage interested organizations to subscribe to GovDelivery alerts and check the NMED events calendar for upcoming engagement and funding opportunities.

Organizations interested in more in-depth ONRW monitoring on USFS-managed lands may also wish to coordinate directly with the U.S. Forest Service to explore collaborative study opportunities.

Thank you for considering these comments and taking the time to address our questions.

Sincerely,

Alesia Hallmark

Program Coordinator, Silver City Watershed Keepers
Gila Resources Information Project

***NMED RESPONSE**: Thank you for your questions and comments. Please reach out if you would like to discuss any of these issues in more depth.*

COMMENT SET 3 – Pueblo of Santa Ana

Submitted on 1/22/26 via email

PUEBLO OF SANTA ANA
2 DOVE ROAD
SANTA ANA, NM 87004

January 22, 2026
Attn: Mrs. Meredith Zeigler
Harold Runnels Building
1190 St. Francis Dr.
Suite N45050
Santa Fe, NM 87505

Re: Public Comment for the State of New Mexico Clean Water Act (CWA) §303(d)/§305(b) Integrated List of Assessed Surface Waters

Dear Mrs. Zeigler

The Pueblo of Santa Ana (the Pueblo) respectfully submits its public comment for the State of New Mexico Clean Water Act (CWA) §303(d)/§305(b) Integrated List of Assessed Surface Waters. The Rio Grande and the Rio Jemez remain as an important and critical component of the way of life for people of Santa Ana Pueblo, as it has for countless centuries. The integrity of both river systems is a critical piece for a healthy river and here at the Pueblo we strive to support the health of both rivers by implementing sampling and monitoring to best support the regulations of the Pueblo of Santa Ana's Water Quality Standards.
We would like to highlight some of our concerns from the integrated list of the assessed surface waters in NM.

- HUC 1320202: Jemez River (Jemez Pueblo to Zia Pueblo)
  - Boron
  - Arsenic
  - E.coli
- HUC 13020201: Rio Grande (Cochiti to Angostura)
  - PCBs
- HUC 13020102: Abiquiu Reservoir
  - Mercury
  - PCBs
- HUC 13020203: Rio Grande (Angostura to 550 Bridge)
  - E.coli

We respectfully request if the NMED could implement more monitoring and sampling in the following areas mentioned. The Pueblo is open and willing to work with NMED to help support this effort. It is in the best interests of both parties to preserve our respective histories, cultures, and traditions to ensure the continued integrity of the Rio Grande and Rio Jemez.

Sincerely,

Tammy Montoya, Department of Natural Resources-
Water Resources Division Manager

***NMED RESPONSE**:*

Thank you for your comment and for the Pueblo of Santa Ana's continued commitment to protecting the Rio Grande and Rio Jemez. NMED deeply values the Pueblo's long-standing relationship with these waters and appreciates your partnership in supporting their health and integrity.

Regarding the specific assessment units identified:

• HUC 1320202 – Jemez River (Jemez Pueblo to Zia Pueblo): This reach was sampled during NMED's 2021–2022 rotational watershed survey. A Total Maximum Daily Load (TMDL) addressing the identified impairments is scheduled for public comment by mid-2026.

• HUC 13020201 – Rio Grande (Cochiti to Angostura): This segment was sampled in 2025 and will be again in 2026 as part of the Middle Rio Grande watershed survey. PCB samples were collected twice during the previous season and twice again during the current season to support assessment of the impairment.

• HUC 13020102 – Abiquiu Reservoir: The mercury and PCB impairments for this reservoir originate from fish tissue data and associated consumption advisories, rather than detections in the water column. Fish tissue was most recently collected in 2024. Results indicated a reduction in recommended meals per month for mercury in brown trout and walleye, with no change to the existing PCB advisory. Mercury and PCB advisories were originally issued in 2000 and 2006, respectively, with a combined advisory noted in 2009.

• HUC 13020203 – Rio Grande (Angostura to 550 Bridge): This reach is currently being sampled (2025-2026) as part of the ongoing watershed survey. Four E. coli samples (n=4) will be collected at two monitoring stations (30RGrand517.3 and 50RGrand508.0) during this survey cycle. The locations of these stations can be viewed on SWQB's interactive map viewer: https://gis.web.env.nm.gov/oem/?map=swqb.

The Assessment Rationale, or Record of Decision (ROD), provides a concise history of each waterbody's assessment decisions, documenting how impairments, data, and criteria have evolved over time. The most recent Assessment Rationale can be accessed here, under "2026-2028 Supporting Documents and Websites": https://www.env.nm.gov/surface-water-quality/303d-305b/.

NMED welcomes the Pueblo's collaboration on ongoing and future monitoring efforts. Your participation in the current watershed survey and in future survey cycles would be greatly appreciated. Continued coordination between NMED and the Pueblo strengthens our shared goal of protecting the cultural, ecological, and historical significance of the Rio Grande and Rio Jemez. Please reach out to the Monitoring, Assessment and Standards (MASS) Program Manager Lynette Guevara (Lynette.Guevara@env.nm.gov) and the Monitoring Team Supervisor Miguel Montoya (Miguel.Montoya@env.nm.gov).

Thank you again for your thoughtful comments and for your ongoing partnership in safeguarding these vital waters.

COMMENT SET 4 –Newport News Nuclear BWXT-Los Alamos, LLC (N3B)/U.S. Department of Energy (DOE) Environmental Management Los Alamos Field Office's (EM-LA's)

The following dataset was submitted on 1/23/26 after the closure of the public comment period on 1/22/26.

As a courtesy to the submitter, the comment and NMED response have been provided below.

Subject: Submittal of Comments in Response to the New Mexico Environment Department Surface Water Quality Bureau's Public Comment Period on the Draft 2026-2028 §303(d)/30S(b) Integrated Report

Dear Ms. Zeigler and Ms. Miller:

Enclosed please find the Newport News Nuclear BWXT-Los Alamos, LLC (N3B)/U.S. Department of Energy (DOE) Environmental Management Los Alamos Field Office's (EM-LA's) "Comments in Response to the New Mexico Environment Department Surface Water Quality Bureau's Public Comment Period on the Draft 2026-2028 §303(d)/305(b) Integrated Report." These comments are being provided to the New Mexico Environment Department Surface Water Quality Bureau based on the recent amendment to New Mexico Administrative Code to include the site-specific water quality criteria for copper on the Pajarito Plateau.

If you have questions, please contact Joel Hebdon at (505) 649-3346 (joel.hebdon@em-la.doe.gov) or Brian Harcek at (505) 692-4261 (brian.harcek@em.doe.gov).

Sincerely,

Lawrence Rodriguez

Comments in Response to the New Mexico Environment Department Surface Water Quality Bureau's Public Comment Period on the Draft 2026–2028 §303(d)/305(b) Integrated Report

During the New Mexico Environment Department Surface Water Quality Bureau's (NMED-SWQB's) Comprehensive Assessment and Listing Methodology (CALM) data call and public comment period in June and July of 2025, Newport News Nuclear BWXT-Los Alamos, LLC (N3B) and the U.S. Department of Energy (DOE) Environmental Management Los Alamos Field Office (EM-LA) submitted data to support the review of 10 assessment units (AUs) on the Pajarito Plateau to remove the copper impairments that are no longer applicable based on the approved and New Mexico Administrative Code– (NMAC-) incorporated site-specific water quality criteria (SSWQC) for copper on the Pajarito Plateau. The SSWQC for copper on the Pajarito Plateau was approved by the New Mexico Water Quality Control Commission on January 14, 2025, and published in the NMAC on May 22, 2025; https://www.env.nm.gov/surface-water-quality/wp-content/uploads/sites/18/2025/04/20.006.0004-NMAC-22May25.pdf. See Appendix A for the full comments and data submitted to NMED-SWQB on July 17, 2025.

N3B and EM-LA have reviewed NMED-SWQB's Public Comment Draft 2026–2028 §303(d)/ 305(b) Integrated Report (Draft Integrated Report) released on December 9, 2025. In that draft document, N3B/EM-LA noted that of the 10 AUs N3B/EM-LA submitted for review, NMED-SWQB has proposed the delisting of 4 AUs but has provided no explanations as to the status of the other six AUs. See Table 1.1 below for a summary of each AU.

N3B/EM-LA is requesting that NMED-SWQB review the six AUs that have no changes noted in the Draft Integrated Report and provide reasoning for why the copper impairment has not been proposed for removal from these six AUs. The data and rationale for delisting of these six AUs was submitted to NMED-SWQB during the CALM data call, included for reference as Appendix A.

If NMED-SWQB is using the criterion of an AU requiring at least 4 samples with no exceedances within the last 5 years, 2 additional AUs meet this criterion for copper delisting. DP Canyon (100 m downstream of grade control to 400 m upstream of grade control) and Pueblo Canyon (Acid Canyon to headwaters) have 10 samples and 5 samples, respectively, within the past 5 years with no exceedances. The other 4 AUs (Acid Canyon [Pueblo Canyon to headwaters], Arroyo de la Delfe [Pajarito Canyon to Kieling Spring], South Fork Acid Canyon [Acid Canyon to headwaters], and Twomile Canyon [Pajarito to Upper Twomile Canyon]) have limited data available from within the last 5 years, but the samples that have been taken either have never shown any exceedances (Arroyo de la Delfe, South Fork Acid Canyon, and Twomile Canyon) or have shown no exceedances since 2009 (Acid Canyon). N3B/EM-LA is requesting that these 6 AUs be reevaluated for removal of the copper impairment. The data for these AUs were submitted in the CALM data call and are included as Appendix A to this comment for reference.

Table 1.1
Assessment Units Eligible for Copper Delisting Under Revised Site-Specific Water Quality Criteria for the Pajarito Plateau and NMED-SWQB's Draft 2026–2028 Assessment Listing

Assessment Unit Name and ID	Gaging Station Name and Number within Assessment Unit	Data Date Range	Number of Copper Samples	Number of Exceedances in the last 5 Years	Rationale for Delisting Copper	2026–2028 Draft Assessment Listing Status
Acid Canyon (Pueblo Canyon to headwaters) (NM-97.A_002)	Acid above Pueblo (E056)	2008–2022	21	0	No acute exceedances in 21 samples collected from 2008–2022, 1 chronic exceedance in 2009, which is greater than 5 years old	No change and no rationale to support the lack of a change
Arroyo de la Delfe (Pajarito Canyon to Kieling Spring) (NM-128.A_36)	La Delfe above Pajarito (E242.5)	2015–2024	6	0	No acute/chronic exceedances in 6 samples collected from 2015–2024	No change and no rationale to support the lack of a change
DP Canyon (100m dwnstm grade ctrl to 400m upstm grade ctrl) (NM-128.A_24)	DP below grade ctrl structure (E039.1)	2013–2025	44	0	No acute/chronic exceedances in 44 samples collected from 2013–2025	No change and no rationale to support the lack of a change
DP Canyon (400m upstream of grade control to upper LANL bnd) (NM-128.A_14)	DP above TA-21 (E038)	2013–2025	36	0	No acute/chronic exceedances in 36 samples collected from 2013–2025	Copper impairment delisted for this AU
Mortandad Canyon (within LANL) (NM-9000.A_042)	Mortandad above Ten Site (E201)	2013–2022	7	0	No acute/chronic exceedances in 7 samples collected from 2013–2022	Copper impairment delisted for this AU
	Mortandad below Effluent Canon (E200)	2005–2024	32	0	No acute exceedances in 32 samples collected from 2005–2024; 3 chronic exceedances occurred in 2006, 2008, and 2018, which are greater than 5 years old	
Pajarito Canyon (Lower LANL bnd to Twomile Canyon) (NM-128.A_08)	Pajarito above SR-4 (E250)	2013–2021	5	0	No acute/chronic exceedances in 5 samples collected from 2013–2021	Copper impairment delisted for this AU
	Pajarito above Threemile (E245.5)	2013–2024	23	0	No acute/chronic exceedances in 23 samples collected from 2013–2024	
Pueblo Canyon (Acid Canyon to headwaters) (NM-9000.A_043)	Pueblo above Acid (E055)	2009–2025	15	0	No acute/chronic exceedances in 15 samples collected from 2009–2025	No change and no rationale to support the lack of a change.
Sandia Canyon (within LANL below Sigma Canyon) (NM-128.A_11)	Sandia above Firing Range (E124)	2014–2023	10	0	No acute/chronic exceedances in 10 samples collected from 2014–2023	Copper impairment delisted for this AU
	Sandia above SR-4 (E125)	2013–2024	3	0	No acute/chronic exceedances in 3 samples collected from 2013–2024	
South Fork Acid Canyon (Acid Canyon to headwaters) (NM-97.A_029)	South Fork of Acid Canyon (E055.5)	2013–2018	9	0	No acute/chronic exceedances in 9 samples collected from 2013–2018	No change and no rationale to support the lack of a change
Twomile Canyon (Pajarito to Upper Twomile Canyon) (NM-128.A_15)	Twomile above Pajarito (E244)	2014–2025	9	0	No acute/chronic exceedances in 9 samples collected from 2014–2025	No change and no rationale to support the lack of a change

***NMED RESPONSE**:*

These public comments were received outside of the public comment period, however, as a courtesy, SWQB reviewed the comments and re-assessed the data submitted during the 2025 call for outside data. Please see the "Summary of Changes to the Draft 2026-2028 Integrated List Due to Solicited Public Comments and/or Due to Additional Staff Review During the Comment Period" #4 through 6 at the beginning of this document, and the 2026-2028 Integrated List and associated Assessment Rationale at https://www.env.nm.gov/surface-water-quality/303d-305b/ for more details.

Cooperator Agreement No. 23-667-2090-27688

MEMORANDUM OF UNDERSTANDING
Between The
NEW MEXICO ENVIRONMENT DEPARTMENT
And The
USDA, FOREST SERVICE
SOUTHWESTERN REGION

This MEMORANDUM OF UNDERSTANDING (MOU) is hereby made and entered into by and between the New Mexico Environment Department hereinafter referred to as "Environment Department," and the United States Department of Agriculture (USDA), Forest Service, Southwestern Region, hereinafter referred to as the "Forest Service."

Background: The New Mexico Water Quality Protection Agreement is a decades-old MOU between the Environment Department and U.S. Forest Service that was last signed in June 2017. The Environment Department is responsible for overseeing water infrastructure systems and water quality issues throughout New Mexico. The Environment Department closely coordinates with U.S. Forest Service on many programs that focus on protecting the quality of New Mexico's waters and assuring safe and effective infrastructure for delivering clean water to communities throughout the state, which is documented in this MOU.

Title: Water Quality Protection in New Mexico

I. PURPOSE: The purpose of this MOU is to document the cooperation between the parties to have a common objective of improving and protecting the quality of New Mexico's waters by implementing progressive watershed-based restoration protection programs to meet applicable water quality standards in accordance with the following provisions.

II. STATEMENT OF MUTUAL BENEFIT AND INTERESTS:

Whereas:

The New Mexico Water Quality Act, NMSA 1978, §§ 74-6-1 to -17, creates the New Mexico Water Quality Control Commission (Commission) and identifies the Commission as the State water pollution control agency for all purposes of the Clean Water Act in New Mexico;

The Commission has designated the Environment Department as the State's lead agency to implement Sections 208 and 319 of the Clean Water Act;

NMED Exhibit 31

DocuSign Envelope ID: BEB4B1B8-E84B-4418-A8CE-DB69FF67C46E

The Commission has authorized the Environment Department to enter into agreements with federal agencies for the purpose of water quality management, while retaining enforcement authority to ensure compliance with 20.6.4 NMAC;

The Forest Service is authorized and directed by acts of Congress, including but not limited to the Organic Act of June 4, 1897, as amended (16 U.S.C. § 551) and the Multiple-Use Sustained Yield Act of June 12, 1960 (16 U.S.C. §§ 528-31), and by regulations issued by the Secretary of Agriculture to administer and protect the lands and resources of National Forest System (NFS) lands and to cooperate with other agencies;

The Forest Service, under Section 313 of the Clean Water Act, 33 U.S.C. §1323, is directed to meet federal, state, interstate, and local substantive and procedural requirements respecting control and abatement of water pollution in the same manner and to the same extent as a non-governmental entity; and

The Commission has designated the Forest Service as the management agency for implementation of the New Mexico Nonpoint Source Management Program on NFS lands.

Therefore, it is mutually advantageous, and in the public interest, for the parties to coordinate their efforts to:

A. Respond to the water quality objectives defined by Congress in the federal Water Pollution Control Act (Clean Water Act), as amended. The objective of the Clean Water Act is to restore and maintain the chemical, physical, and biological integrity of the nation's waters;

B. Fulfill the goals and policies of the State of New Mexico as defined in the New Mexico Nonpoint Source Pollution Management Program developed pursuant to Section 319, 33 U.S.C. § 1329, of the Clean Water Act, and as defined in New Mexico's Standards for Interstate and Intrastate Waters (20.6.4 NMAC);

C. Identify the responsibilities and activities to be performed by each agency in carrying out the New Mexico Water Quality Management Plan (WQMP) developed pursuant to section 208, 33 U.S.C, § 1288, of the Clean Water Act and Nonpoint Source Management Program as related to activities on NFS lands, as that term is defined by 16 U.S.C. § 1609(a); and

D. To foster a collaborative effort in implementing watershed approaches to restore those watersheds not meeting clean water, natural resource, and public health goals and to sustain healthy conditions in other watersheds.

NMED Exhibit 31

DocuSign Envelope ID: BEB4B1B8-E84B-4418-A8CE-DB69FF67C46E

In consideration of the above premises, the parties agree as follows:

III. THE ENVIRONMENT DEPARTMENT SHALL:

A. Recommend that the Commission continue its designation of the Forest Service as the Designated Management Agency for implementation of the New Mexico Nonpoint Source Pollution Management Program on NFS lands;

B. Share timely drafts of Environment Department proposed water quality laws, regulations, standards, and policies to the Forest Service for review and comment during their development;

C. Participate in the Forest Service Land Resource Management Plan (LRMP) implementation process in a manner consistent with the Environment Department's regulatory responsibility and authority, in order to make recommendations on necessary LRMPs and implementing projects, activities, or Best Management Practices (BMPs);

D. Review water quality standards when the Forest Service and/or the Surface Water Quality Bureau monitoring indicates that criteria or designated uses may not be appropriate;

E. Coordinate with the Forest Service in all phases of Total Maximum Daily Load (TMDL) development on NFS lands in ensuring that the Forest Service has the timely opportunity to-share input on monitoring site locations and TMDL plans to restore impaired waters;

F. Share information to the Forest Service regarding the Clean Water Act Section 319(h), 33 U.S.C. § 1329(h), grant process;

G. In addition to the other provisions of this MOU, when an Outstanding National Resource Water (ONRW) located on NFS lands could be affected by Forest Service resource management decisions or determined to be impaired through the Environment Department's assessment process, the Surface Water Quality Bureau shall:

    1. Respond to the Forest Service regarding whether a proposed authorization of a use of NFS lands will comply with all requirements of the State's Antidegradation Policy and Implementation Procedures;

    2. Where a Clean Water Act Section 401 certification is required for a proposed authorization of a use on NFS lands, make determinations about compliance with the State's Antidegradation Policy and Implementation Procedures through the Section 401 certification process;

NMED Exhibit 31

DocuSign Envelope ID: BEB4B1B8-E84B-4418-A8CE-DB69FF67C46E

3. Coordinate with the Forest Service to develop shared protocols for implementing ONRW protections, including strategies to prevent future degradation in ONRW streams and wetlands;

4. Inform the Forest Service of potential ONRW degradation as soon as practicable after the Surface Water Quality Bureau determines potential degradation (including but not limited to potential new ONRW impairments identified through assessment of verified and validated data during the development of the Clean Water Act Section 303(d)/305(b) Integrated Report);

5. If potential degradation of an ONRW has been determined, collaborate with Forest Service to review available verified and validated water quality and other data to determine whether degradation has occurred, and in cases where degradation is confirmed, conduct a joint meeting with the Forest Service and interested parties and stakeholders, including the original petitioners of the ONRW, to identify potential sources of degradation and identify action steps to address and/or remedy the degradation; and

6. In cases where degradation of an ONRW has been confirmed, coordinate with the Forest Service to increase water quality sampling efforts and frequency, if resources are sufficient to do so. The goal is to collect additional data to be able to assess water quality standards attainment every two-year Clean Water Act 303(d) listing cycle until the ONRW attains its designated uses and meets standards.

H. Recognize past projects and management actions that have, and may continue to, improve watershed conditions on NFS lands;

I. Offer timely guidance and assistance regarding the Clean Water Act Section 401 water quality certification process for Forest Service conducted projects and activities subject to Clean Water Act Section 404 requirements; and

J. Coordinate with the Forest Service for appropriate authorization for activities on NFS lands as deemed necessary by the Forest Service.

IV. THE FOREST SERVICE SHALL:

A. Serve as the Designated Management Agency within the context of the WQMP for all NFS lands within the State;

B. Recognize New Mexico identified designated uses of water and nonpoint source management program objectives;

C. Ensure all LRMPs, where water quality is an issue, meet requirements of the New Mexico water quality standards (20.6.4 NMAC), WQMP and the

NMED Exhibit 31

DocuSign Envelope ID: BEB4B1B8-E84B-4418-A8CE-DB69FF67C46E

Nonpoint Source Management Program developed pursuant to federal regulations, the Clean Water Act, and the State Continuing Planning Process;

D. Identify program elements needed to support State programs and projects adopted pursuant to Sections 208 and 319 of the Clean Water Act and incorporate them into the Forest Service program planning (including under the National Environmental Policy Act) and budgeting system;

E. The Forest Service can notify the NMED using their email address env.review@env.nm.gov and to other staff and bureaus upon request, for Forest Service projects and actions in New Mexico made available for public review through the National Environmental Policy Act (NEPA).

F. In addition to other provisions of this MOU, when an ONRW located on NFS lands could be affected by Forest Service resource management decisions or determined to be impaired through the Environment Department's assessment process, the Forest Service shall:

1. Serve as the oversight agency for ONRWs located on NFS lands and implement all elements applicable to oversight agencies of the State's Antidegradation Policy for ONRWs (Paragraphs 3 and 4 of Subsection A of 20.6.4.8 NMAC);

2. The Forest Service may inquire with the Surface Water Quality Bureau and a response in writing regarding whether a proposed action will comply with all applicable antidegradation requirements;

3. Coordinate with the Surface Water Quality Bureau to develop shared protocols for implementing ONRW protections, including strategies to prevent future degradation in ONRW streams and wetlands;

4. Notify the Surface Water Quality Bureau, as soon as practicable after the Forest Service detects or determines potential degradation of an ONRW;

5. If potential degradation of an ONRW has been determined, collaborate with the Surface Water Quality Bureau to review available verified and validated water quality and other data to determine whether degradation has occurred, and in cases where degradation is confirmed conduct a joint meeting with the Bureau and interested parties and stakeholders, including the original petitioners of the ONRW, to identify potential sources of degradation and identify action steps to address and/or remedy the degradation;

6. In cases where degradation of an ONRW has been confirmed, collaborate the Surface Water Quality Bureau to increase water quality sampling efforts and frequency in order to submit verified and validated water quality data to the Surface Water Quality Bureau for assessment. The goal

NMED Exhibit 31

DocuSign Envelope ID: BEB4B1B8-E84B-4418-A8CE-DB69FF67C46E

is for the Bureau to be able to assess water quality standards attainment every two-year Clean Water Act 303(d) assessment cycle until the ONRW attains is designated uses and meets standards; and

7. Consider whether a proposed action will impact water quality in an ONRW when conducting analyses under the National Environmental Policy Act (NEPA).

G. Best Management Practices:

1. Ensure that all work schedules and plans for implementation of projects that have potential to impact water quality contain site-specific BMPs, developed through the LRMP implementation process;

2. Consider technical, economic, and institutional feasibility and potential water quality impacts from the proposed activity in the selection of BMPs, but in no case shall economic and institutional feasibility be used as a basis to allow violations of water quality standards (20.6.4 NMAC); and

3. Comply with BMPs on selected activities to ensure they are implemented and are effective and adjust as necessary.

H. Ensure that all new and renewed authorizations for use of NFS lands contain provisions for compliance with all federal, state, and local water pollution control and abatement statutes, regulations, standards, and ordinances, including compliance with Clean Water Act Section 401, 33 U.S.C. § 1341, as enforceable conditions to those authorizations;

I. Consult with the Surface Water Quality Bureau in situations where the Forest Service does not administer the entire watershed and the parties have mutually determined there will be a significant water quality impact due to an activity within the watershed, that the impact will preclude attainment of water quality standards on or off NFS lands, and that the water does not currently meet water quality standards;

J. Share the Surface Water Quality Bureau appropriate and timely opportunity to participate in project and activity plans, beginning with the scoping phase, that have the potential to impact watershed condition, riparian areas, or water quality, including projects requiring Clean Water Act Section 401, U.S.C. §1341 certification;

K. Share with the Surface Water Quality Bureau, to the same extent as required of non-governmental entities, with an annual general assessment of water quality accomplishments, monitoring results, problems, and priorities, including activities that meet the goals and objectives of TMDL plans to restore impaired waters;

NMED Exhibit 31

DocuSign Envelope ID: BEB4B1B8-E84B-4418-A8CE-DB69FF67C46E

L. Share with the Surface Water Quality Bureau water quality and watershed assessment data collected on NFS lands, including GIS data;

M. Forest Service wills strive to increase internal education and training to increase employee awareness of, and sensitivity to, the importance of maintaining and improving water quality and the requirements of State and federal water quality regulations and standards;

N. Collaborate in the TMDL development process, including providing input to the Surface Water Quality Bureau on monitoring locations and implementation plans;

O. Share Clean Water Act Section 404, 33 U.S.C. § 1344, applications or pre-construction notifications for Forest Service conducted activities to the Surface Water Quality Bureau in a timely manner for Clean Water Act Section 401, 33 U.S.C. § 1344, water quality certification review;

V. IT IS MUTUALLY UNDERSTOOD AND AGREED BY AND BETWEEN THE PARTIES THAT:

A. They will work together in setting priorities for planning watershed actions and in developing watershed-based plans and watershed restoration action plans for watersheds not meeting clean water or natural resource goals;

B. Coordinate efforts on preventative or mitigative land management practices, generally referred to as BMPs, to improve or protect the quality of waters on or downstream of NFS lands;

C. Coordinate efforts on identifying existing or potential nonpoint source water pollution problems on NFS lands, including ONRWs;

D. Coordinate efforts to assess or monitor water quality or watershed conditions on NFS lands using consistent scientific approaches when applicable;

E. Share data, data analysis, and watershed assessment results to improve future planning and management activities on NFS lands;

F. Use such water quality information for validating existing water quality criteria and designated uses and, when appropriate, develop the data into proposed standards revisions for consideration by the Commission during regularly scheduled water quality standards reviews;

G. Share training opportunities;

NMED Exhibit 31

DocuSign Envelope ID: BEB4B1B8-E84B-4418-A8CE-DB69FF67C46E

H. Collaborate and support not otherwise available to the other party, to the extent the supplying party's program priorities, budget, and availability of expertise allow;

I. Meet, no less than annually, to maintain coordination and communication, report on water quality management progress and problems, and review proceedings under this MOU, and:

J. Work together to evaluate complaints regarding potential water quality standards violations to assure that sources of potential violations are addressed.

K. PRINCIPAL CONTACTS. Individuals listed below are authorized to act in their respective areas for matters related to this agreement.

Principal Cooperator Contacts:

Cooperator Program Contact	Cooperator Administrative Contact
Abraham Franklin, Program Manager Watershed Protection Section Surface Water Quality Bureau New Mexico Environment Dept. P.O. Box 5469 Santa Fe, NM 87502 Telephone: (505) 946-8952 Email: wpsprogram.manager@state.nm.us	Christina Keyes, Chief Financial Officer Administrative Services Division New Mexico Environment Department P.O. Box 5469 Santa Fe, NM 87502 Telephone: 505-795-2173 Email: christina.keyes@env.nm.gov

Principal Forest Service Contacts:

Forest Service Program Manager Contact	Forest Service Administrative Contact
Kerry Jones NMED Liaison 11 Forest Lane Santa Fe, NM 87508 Telephone: (505) 438-5673 Email: kerry.jones@usda.gov	Lisa Street 333 Broadway Blvd SE Albuquerque, NM 87102 Telephone: 303-579-5992 Email: lisa.street@usda.gov

L. NOTICES. Any communications affecting the operations covered by this agreement given by the Forest Service or the Environmental Department is sufficient only if in writing and delivered in person, mailed, or transmitted electronically by e-mail or fax, as follows:

To the Forest Service Program Manager, at the address specified in the MOU.

To the Environmental Department at the Environmental Department's address shown in the MOU or such other address designated within the MOU.

NMED Exhibit 31

DocuSign Envelope ID: BEB4B1B8-E84B-4418-A8CE-DB69FF67C46E

Notices are effective when delivered in accordance with this provision, or on the effective date of the notice, whichever is later.

M. PARTICIPATION IN SIMILAR ACTIVITIES. This MOU in no way restricts the Forest Service or the Environmental Department from participating in similar activities with other public or private agencies, organizations, and individuals.

N. ENDORSEMENT. Any of the Environmental Department's contributions made under this MOU do not by direct reference or implication convey Forest Service endorsement of the Environmental Department's products or activities.

O. NONBINDING AGREEMENT. This MOU creates no right, benefit, or trust responsibility, substantive or procedural, enforceable by law or equity. The parties shall manage their respective resources and activities in a separate, coordinated and mutually beneficial manner to meet the purpose(s) of this MOU. Nothing in this MOU authorizes any of the parties to obligate or transfer anything of value.

Specific, prospective projects or activities that involve the transfer of funds, services, property, to a party requires the execution of separate agreements and are contingent upon numerous factors, including, as applicable, but not limited to: agency availability of appropriated funds and other resources; cooperator availability of funds and other resources; agency and cooperator administrative and legal requirements (including agency authorization by statute); etc. This MOU neither provides, nor meets these criteria. If the parties elect to enter into an obligation agreement that involves the transfer of funds, services, property, and/or anything of value to a party, then the applicable criteria must be met. Additionally, under a prospective agreement, each party operates under its own laws, regulations, and/or policies, and any Forest Service obligation is subject to the availability of appropriated funds and other resources. The negotiation, execution, and administration of these prospective agreements must comply with all applicable law.

Nothing in this MOU is intended to alter, limit, or expand the agencies' statutory and regulatory authority.

P. USE OF FOREST SERVICE INSIGNIA. In order for the Environmental Department to use the Forest Service insignia on any published media, such as a Web page, printed publication, or audiovisual production, permission must be granted from the Forest Service's Office of Communications. A written request must be submitted and approval granted in writing by the Office of Communications (Washington Office) prior to use of the insignia.

NMED Exhibit 31

DocuSign Envelope ID: BEB4B1B8-E84B-4418-A8CE-DB69FF67C46E

Q. MEMBERS OF U.S. CONGRESS. Pursuant to 41 U.S.C. 22, no U.S. member of, or U.S. delegate to, Congress shall be admitted to any share or part of this agreement, or benefits that may arise therefrom, either directly or indirectly.

R. FREEDOM OF INFORMATION ACT (FOIA). Public access to MOU or agreement records must not be limited, except when such records must be kept confidential and would have been exempted from disclosure pursuant to Freedom of Information regulations (5 U.S.C. 552).

S. TEXT MESSAGING WHILE DRIVING. In accordance with Executive Order (EO) 13513, "Federal Leadership on Reducing Text Messaging While Driving," any and all text messaging by Federal employees is banned: a) while driving a Government owned vehicle (GOV) or driving a privately owned vehicle (POV) while on official Government business; or b) using any electronic equipment supplied by the Government when driving any vehicle at any time. All cooperators, their employees, volunteers, and contractors are encouraged to adopt and enforce policies that ban text messaging when driving company owned, leased or rented vehicles, POVs or GOVs when driving while on official Government business or when performing any work for or on behalf of the Government.

T. PUBLIC NOTICES. It is the Forest Service's policy to inform the public as fully as possible of its programs and activities. The Environmental Department is encouraged to give public notice of the receipt of this agreement and, from time to time, to announce progress and accomplishments. Press releases or other public notices should include a statement substantially as follows:

"Water Resources Program of the Forest Service, Department of Agriculture, Southwestern Region."

The Environmental Department may call on the Forest Service's Office of Communication for advice regarding public notices. The Environmental Department is requested to provide copies of notices or announcements to the Forest Service Program Manager and to The Forest Service's Office of Communications as far in advance of release as possible.

U. FOREST SERVICE ACKNOWLEDGED IN PUBLICATIONS, AUDIOVISUALS AND ELECTRONIC MEDIA. The Environmental Department shall acknowledge Forest Service support in any publications, audiovisuals, and electronic media developed as a result of this MOU.

V. NONDISCRIMINATION STATEMENT – PRINTED, ELECTRONIC, OR AUDIOVISUAL MATERIAL. The Environmental Department shall include the following statement, in full, in any printed, audiovisual material, or electronic media for public distribution developed or printed with any Federal funding.

NMED Exhibit 31

DocuSign Envelope ID: BEB4B1B8-E84B-4418-A8CE-DB69FF67C46E

In accordance with Federal law and U.S. Department of Agriculture policy, this institution is prohibited from discriminating on the basis of race, color, national origin, sex, age, or disability. (Not all prohibited bases apply to all programs.)

To file a complaint of discrimination, write USDA, Director, Office of Civil Rights, Room 326-W, Whitten Building, 1400 Independence Avenue, SW, Washington, DC 20250-9410 or call (202) 720-5964 (voice and TDD). USDA is an equal opportunity provider and employer.

If the material is too small to permit the full statement to be included, the material must, at minimum, include the following statement, in print size no smaller than the text:

"This institution is an equal opportunity provider."

W. TERMINATION. Any of the parties, in writing, may terminate this MOU in whole, or in part, at any time before the date of expiration.

X. DEBARMENT AND SUSPENSION. The Environmental Department shall immediately inform the Forest Service if they or any of their principals are presently excluded, debarred, or suspended from entering into covered transactions with the federal government according to the terms of 2 CFR Part 180. Additionally, should the Environmental Department or any of their principals receive a transmittal letter or other official Federal notice of debarment or suspension, then they shall notify the Forest Service without undue delay. This applies whether the exclusion, debarment, or suspension is voluntary or involuntary.

Y. MODIFICATIONS. Modifications within the scope of this MOU must be made by mutual consent of the parties, by the issuance of a written modification signed and dated by all properly authorized, signatory officials, prior to any changes being performed. Requests for modification should be made, in writing, at least 30 days prior to implementation of the requested change.

Z. COMMENCEMENT/EXPIRATION DATE. This MOU is executed as of the date of the last signature and is effective through five years for the date of last signature at which time it will expire.

AA. AUTHORIZED REPRESENTATIVES. By signature below, each party certifies that the individuals listed in this document as representatives of the individual parties are authorized to act in their respective areas for matters related to this MOU.

NMED Exhibit 31

DocuSign Envelope ID: BEB4B1B8-E84B-4418-A8CE-DB69FF67C46E

In witness whereof, the parties hereto have executed this MOU as of the last date written below.

Burden Statement

According to the Paperwork Reduction Act of 1995, an agency may not conduct or sponsor, and a person is not required to respond to a collection of information unless it displays a valid OMB control number. The valid OMB control number for this information collection is 0596-0217. The time required to complete this information collection is estimated to average 3 hours per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information.

The U.S. Department of Agriculture (USDA) prohibits discrimination in all its programs and activities on the basis of race, color, national origin, age, disability, and where applicable, sex, marital status, familial status, parental status, religion, sexual orientation, genetic information, political beliefs, reprisal, or because all or part of an individual's income is derived from any public assistance. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (Braille, large print, audiotape, etc.) should contact USDA's TARGET Center at 202-720-2600 (voice and TDD).

To file a complaint of discrimination, write USDA, Director, Office of Civil Rights, 1400 Independence Avenue, SW, Washington, DC 20250-9410 or call toll free (866) 632-9992 (voice). TDD users can contact USDA through local relay or the Federal relay at (800) 877-8339 (TDD) or (866) 377-8642 (relay voice). USDA is an equal opportunity provider and employer.

NMED Exhibit 31

Notification of Emergency Action with the potential to impact Outstanding National Resource Waters on New Mexico National Forests

(To be completed within 7 days of initiating an emergency action that could impact water quality in an ONRW.)

Forest/Ranger District: Santa Fe National Forest, Jemez Ranger District	**Date: 6/26/2026**

Forest contact: *Kevin Carns, kevin.carns@usda.gov*

General Action: *(For wildfires, be sure to include the name and wildfire number, in addition to the suppression actions that may occur.)*
McCauley Springs Fire (NMSNF-312) located at 35.827, -106.626 is adjacent to the East Fork Jemez River (San Antonio Creek to Headwaters) ONRW and the San Antonio Creek (East Fork Jemez River to Headwaters), Redondo Creek (Sulphur Creek to Headwaters) ONRWs are located within the planning area. Additionally, Alamo Canyon, Capulin Creek, La Jara Creek, and San Luis Creek Special Designation Streams are located within the planning area. Full suppression strategy is planned that utilizes tactics to minimize disturbance to soil and water resources. Aerial application of fire retardant has been used and continued use is expected.

ONRWs that could be impacted: East Fork Jemez River (San Antonio Creek to Headwaters), San Antonio Creek (East Fork Jemez River to Headwaters), and Redondo Creek.

HUC 10 - Upper Jemez River 1302020202

	Water Name
Non-Wilderness	East Fork Jemez River (San Antonio Creek to Headwaters)
Non-Wilderness	San Antonio Creek (East Fork Jemez River to Headwaters)
Non-Wilderness	Redondo Creek (Sulphur Creek to Headwaters)

See attached map.

Describe suppression activities that could take place that could impact water quality:

Actions related to emergency fire suppression that are in the vicinity of an ONRW include: water and fire retardant drops and mixed (handline and/or dozer) fire line construction.

Describe what BMPS will be used to address water quality impacts from the suppression activities indicated:

Incident objectives include:

Protect water quality in Watersheds, Water systems, Eligible and Designated Wild and Scenic Rivers, ONRW Streams, Riparian Zones, Springs and Seeps by limiting fire intensities, uncharacteristic fire effects, suppression activities and sedimentation that would negatively affect:

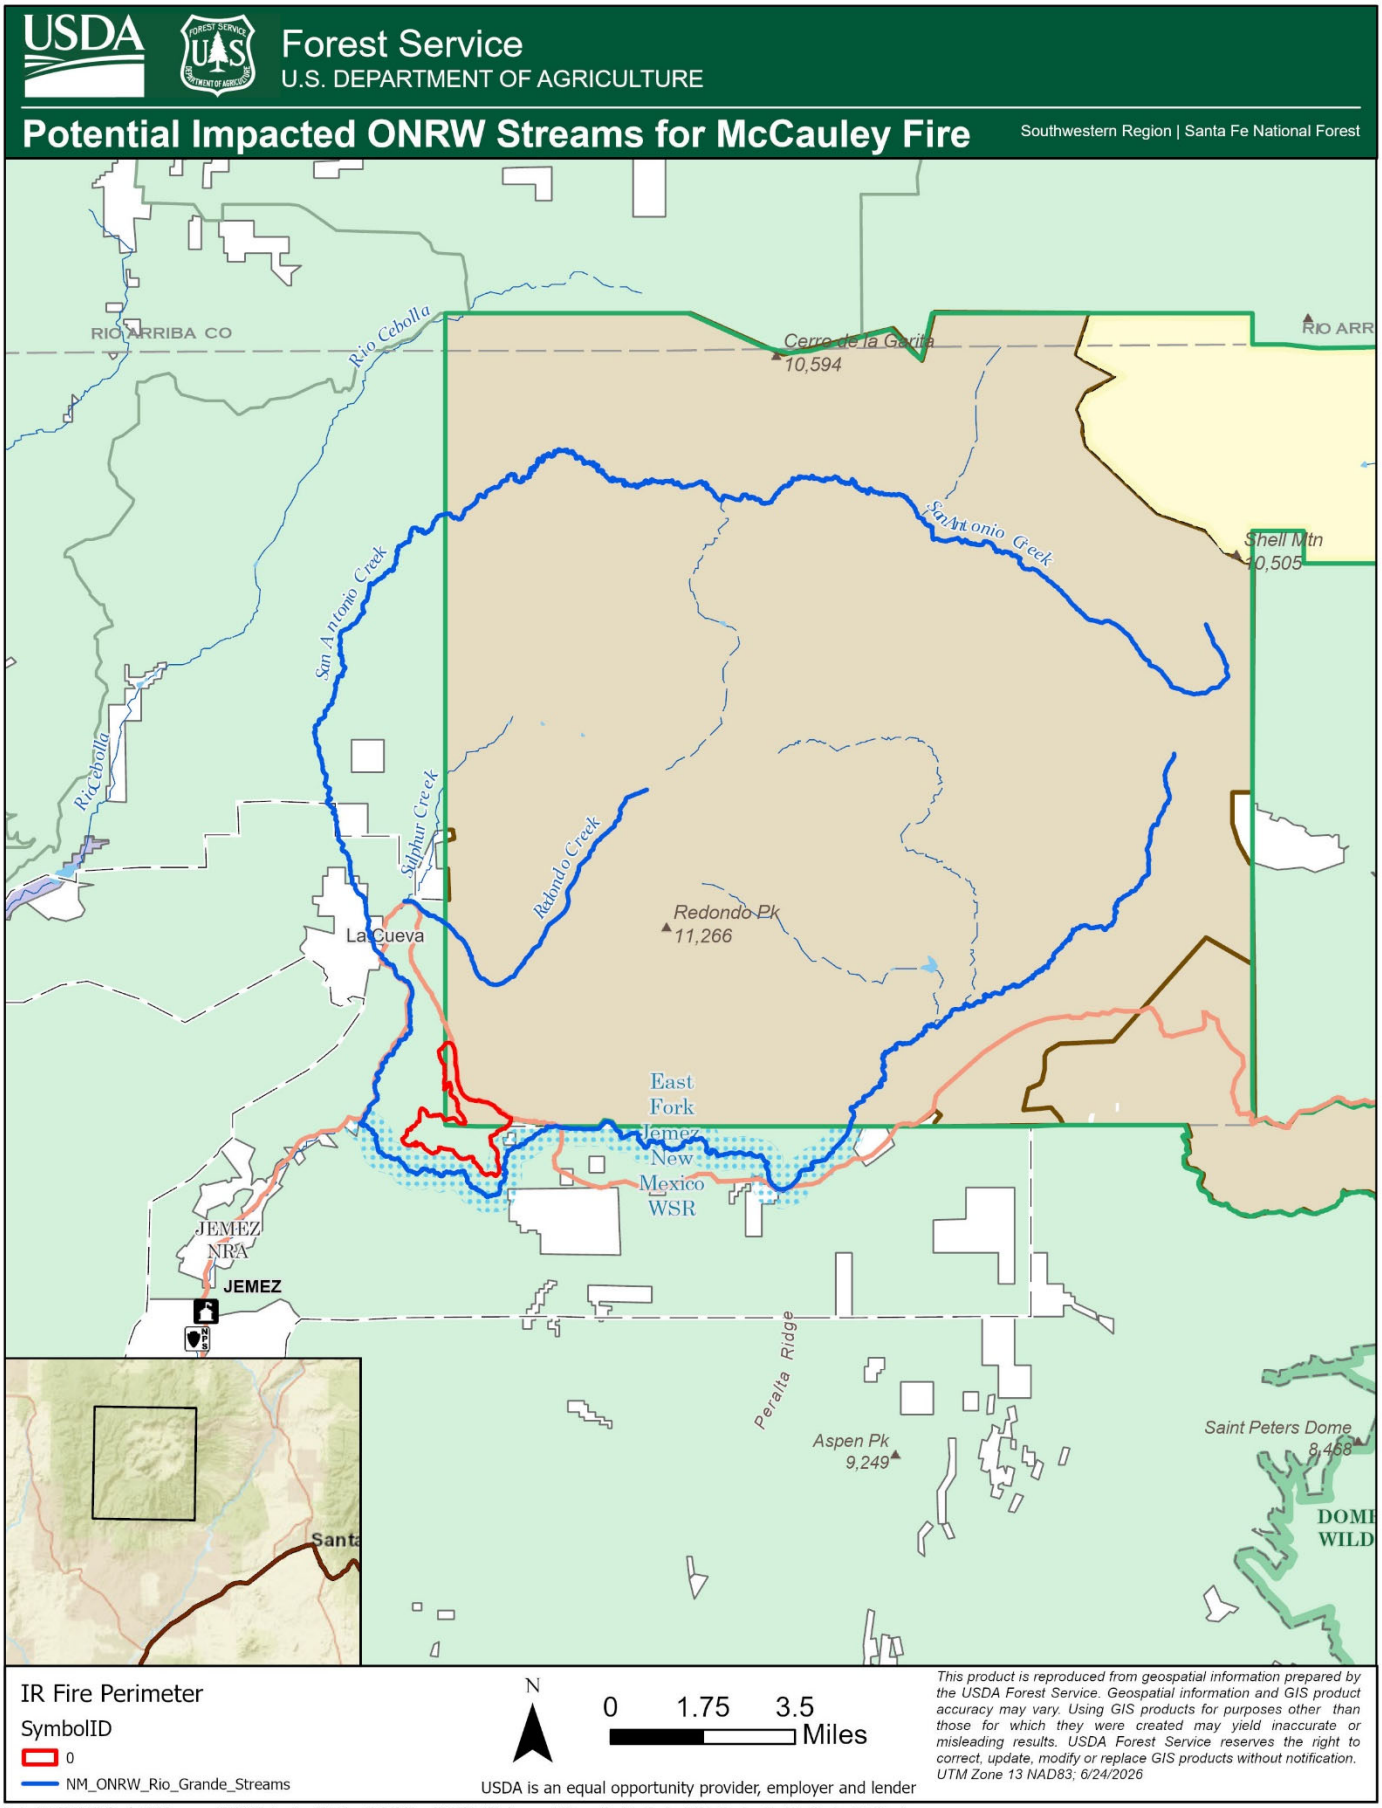
- *Ecosystem function*
- *Water quality*
- *Downstream water users, water systems and acequias*

Aerially delivered fire retardant should not be applied to any mapped terrestrial or aquatic avoidance areas to prevent the potential of impacts to federally listed threatened or endangered species and on mountain peaks within Valles Caldera. The only exception to using aerially applied fire retardant in avoidance areas is for the protection of human life or public safety. The Incident Commander is the decision maker.

Consult with READs to avoid damage to historic cultural sites, traditional use areas, water resources, T&E Habitat, range infrastructure and trail systems.

Consult with READs prior to any using heavy equipment such as dozers on federal lands. REAF/ARCF must be assigned to equipment.

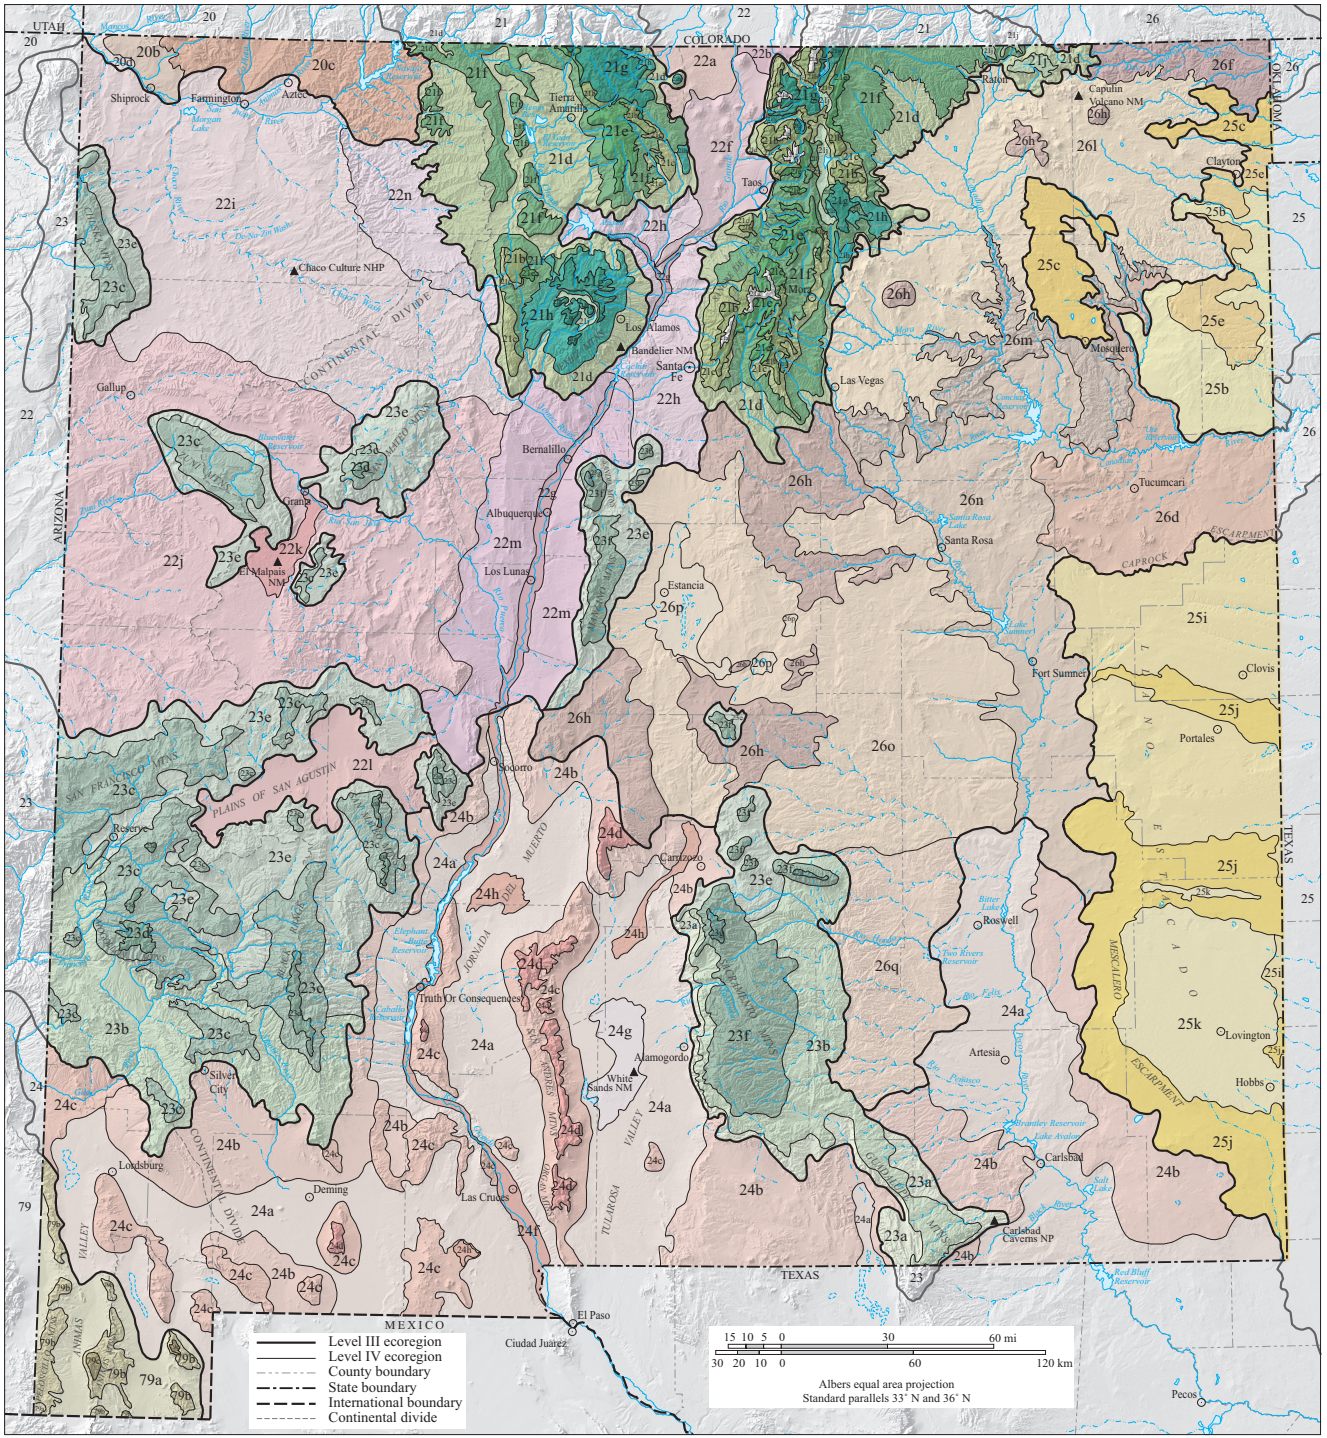
Maximize the use of existing roads, trails, fire lines, dozer lines to reduce impacts to previously undisturbed areas.



Consult with READs on wildfire suppression rehabilitation/repair standards to repair infrastructure, protect biological and cultural resources, stabilize areas affected within the burn perimeter, and protect identified potential values at risk.

Describe any monitoring requirements that will be conducted to assess impacts to ONRWs and evaluate BMPS:

Fire will continue to be monitored by fire and Forest resources including resource advisors (READs). Retardant drops will continue to be tracked to confirm avoidance zones.



Expected completion date of Forest Service actions that could impact ONRWs:

The McCauley Springs Fire currently has no expected completion date for Forest Service actions that could impact ONRWs.

March 2016

Draft Technical Support Document: Recommended Estimates for Missing Water Quality Parameters for Application in EPA's Biotic Ligand Model

Disclaimer Page

This technical support document (herein referred to as the "Missing Parameters TSD") summarizes data analysis approaches EPA used to develop recommendations for default values for water quality parameters used in the copper BLM when data are lacking. When published in final form, this document will provide information to states, tribes, and the regulated community interested in using the Biotic Ligand Model to protect aquatic life from toxic effects of copper. Under the CWA, states and tribes are to establish water quality criteria to protect designated uses. State and tribal decision makers retain the discretion to adopt approaches on a case-by-case basis when appropriate. This document does not substitute for the CWA or EPA's regulations; nor is it a regulation itself. Thus, it cannot impose legally binding requirements on EPA, states, tribes, or the regulated community, and might not apply to a particular situation based upon the specific circumstances. EPA may change this document in the future. This document has been approved for publication by the Office of Science and Technology, Office of Water, U.S. Environmental Protection Agency.

Mention of trade names or commercial products does not constitute endorsement or recommendation for use. This document can be downloaded from:
http://water.epa.gov/scitech/swguidance/standards/criteria/aqlife/copper/2007_index.cfm

BLM	Biotic Ligand Model
BOD	Biochemical Oxygen Demand
CCC	Criterion Continuous Concentration
CMC	Criterion Maximum Concentration
CWA	Clean Water Act
df	Degrees of Freedom
DOC	Dissolved Organic Carbon
Ecoregion	Areas in which ecosystems and the type, quality, and quantity of environmental resources are generally similar. In this document is represented by EPA Level III Ecoregions
EMAP	Environmental Monitoring and Assessment Program
EPA	United States Environmental Protection Agency
FSC	Fixed Site Criteria
GI	Geochemical Ions; ion parameters for the Biotic Ligand Model (Ca, Mg, Cl, Na, K, SO_4, alkalinity)
GIS	Geographic Information System
GLEC	Great Lakes Environmental Center
HUC	Hydrologic Unit Code (a two to eight digit code that identifies each hydrologic unit)
IQR	Interquartile range
IWQC	Instantaneous Water Quality Criteria
LCL	Lower Confidence Limit
LDC	Legacy Data Center (EPA historical STORET database, recently renamed)
LR	Linear Regression
mg/L	Milligrams per liter
NHD	National Hydrography Dataset
NHD-Plus	National Hydrography Dataset Plus
NOCD	National Organic Carbon Database (combined organic carbon data from two databases: USGS WATSTORE and EPA STORET)
NRC	National Research Council
NRSA	National River and Stream Assessment
NWIS	National Waters Information System
PCS	Permit Compliance System
RPDs	Relative Percent Differences
PCA	Principal Components Analysis
pH	Negative logarithm of the hydrogen ion concentration (in moles per liter); scale range from 0 to 14
POC	Particulate Organic Carbon
POTWs	Publicly Owned Treatment Works
RMSE	Root Mean Square Error

Acronym/Abbreviation	Definition
RSS	Residual Sum of Squares
SPLOM	Scatter Plot Matrices
SO	Strahler Stream Order
STORET	EPA STOrage and RETrieval Data Warehouse (recently renamed Legacy Data Center, LDC)
TDS	Total Dissolved Solids
TSD	Technical support document
TSS	Total Suspended Solids
TOC	Total Organic Carbon
UCL	Upper Confidence Limit
U.S.	United States
USGS	United States Geological Survey
WATSTORE	USGS National WATer Data STOrage and REtrieval System (predecessor of NWIS)
WSA	Wadeable Stream Assessment
WQC	Water Quality Criteria
µS/cm	Microsiemens per centimeter
µg/L	Micrograms per liter

Executive Summary

The United States (U.S.) Environmental Protection Agency (EPA) developed revised freshwater aquatic life criteria for copper using the Biotic Ligand Model (BLM) in 2007. The 2007 Freshwater Copper BLM predicts acute copper toxicity based on site-specific water quality parameters, and calculates aquatic life criteria based on the predicted copper toxicity. The current freshwater copper BLM requires 10 input parameters to calculate copper criteria: temperature, pH, dissolved organic carbon (DOC), alkalinity, calcium, magnesium, sodium, potassium, sulfate, and chloride, the last seven of which are also referred to as geochemical ions (GI). Previously available hardness-based copper criteria incorporated consideration only of the effects of hardness on bioavailability, while the BLM incorporates consideration of all of the water chemistry parameters that have a major influence on metal bioavailability. This allows the BLM-based criteria to be customized to the particular water body under consideration. However, given the broad geographical range over which the BLM is likely to be applied, and the limited availability of data for input parameters in many areas, a practical method to estimate missing water quality parameters was needed to successfully run the BLM. This technical support document (herein referred to as the "Missing Parameters TSD") summarizes data analysis approaches EPA used to develop recommendations for default values for water quality parameters used in the Freshwater Copper BLM when data are lacking. These default values could also be used to fill in missing water quality input parameters in the application of other metal BLM models as well, when data are lacking. EPA used three approaches to develop these default value recommendations:

- Conducted geostatistics and conductivity analyses to predict GI parameters
- Applied stream order to refine prediction of GI parameters
- Mined the National Organic Carbon Database (NOCD) to estimate DOC

In brief, EPA found that an approach that used correlation (with conductivity and discharge as explanatory variables), combined with geostatistical techniques (kriging), and a consideration of stream order produced the best estimates for BLM GI parameters. Tables 8, 9, and 10 present estimated inputs for each GI and water hardness in each ecoregion categorized by stream order for low, medium, and high order streams, respectively. Recommended GI values are based on the 10^{th} percentile of ecoregional Level III values for the appropriate stream order (size) and are expected to yield appropriately protective criteria values when applied in the BLM model. In Table 20 of Section 4, EPA provides estimates for DOC by ecoregion based on an analysis of a compilation of national organic carbon databases. The 10^{th} percentile of ecoregional Level III values are recommended for DOC. There was insufficient data to refine the DOC estimates by stream order. EPA recommends measurement of pH and temperature directly to use as an input in the BLM. Temperature is a commonly measured parameter, and should be easily obtainable for use in the BLM. The following paragraphs summarize the contents of each section in this report.

Section 1 provides an introduction to this study, including background on the BLM. In developing the approaches outlined in this study, EPA relied upon several previous studies that attempted to estimate values for BLM input water quality parameters; these studies are outlined briefly in Section 1 and are described in detail in Appendices A through D. This earlier work demonstrates that protective water

NMED Exhibit 34

quality criteria (WQC) for copper generally corresponded to a low percentile of the distribution of instantaneous water quality criteria (IWQC) predicted by the BLM.

Section 2 provides a discussion of the approach taken by EPA to estimate BLM GI parameter values using geostatistics, which are a suite of statistical methodologies that use spatial coordinates to formulate models used in estimation and prediction. Section 2 also describes how EPA supplemented the geostatistical approach with conductivity as an explanatory variable, because conductivity data are abundant and correlate well to the BLM GI parameters.

Section 3 provides an analysis and discussion of the EPA approach to estimation of BLM GI parameters incorporating stream order as a variable, with a goal of providing BLM users with tables of recommended GI parameter estimates based upon both ecoregion and stream order. For each Level III ecoregion, we recalculated the 10^{th} percentiles of the distributions of all daily water quality parameters measured at all NWIS stations taking into account stream orders or ranges (groups) of stream orders within each ecoregion. Values of the BLM GI parameters generally increased with stream order. Based upon this trend, we grouped the estimates for each parameter by stream order: 1 through 3 (headwater streams), 4 through 6 (mid-reaches), and 7 through 9 (rivers).

Section 4 discusses the estimation of DOC based on the NOCD and two other databases. The NOCD was compiled from a number of sources, including EPA's Storage and Retrieval Data Warehouse (STORET) and the United States Geological Survey's National Water Data Storage and Retrieval System (WATSTORE) (the predecessor of the National Waters Information System (NWIS)). The two other databases, the Wadeable Stream Assessment (WSA) and the National River and Stream Assessment (NRSA), were used to supplement and update the DOC analysis. Section 4 summarizes the data sources, analysis, and uncertainty associated with ecoregional statistics for the NOCD and outlines how tests for bias in the data influence selection of 10^{th} percentile DOC concentrations from either the NOCD or the WSA or NRSA databases. The importance of field sampling for DOC is highlighted in Section 4 because of limitations of the NOCD and the importance of DOC in criteria calculation.

Section 5 provides a summary of the three approaches used to develop EPA's recommendations. Taken together, the approaches presented in this TSD describe EPA's recommendations for default input parameters in the BLM to derive protective freshwater aquatic life criteria when data are lacking. However, it should be noted that site-specific data are always preferable for developing criteria based on the BLM and should be used when possible. Users of the BLM are encouraged to sample their water body of interest, and to analyze the samples for the constituent (parameter) concentrations as a basis for determining BLM inputs where possible.

1 INTRODUCTION

1.1 Background and Objective

The United States (U.S.) Environmental Protection Agency (EPA) has a congressional mandate to develop and publish criteria for water quality that reflects the effects of pollutants on aquatic life and human health under 304(a)(1) of the Clean Water Act (CWA). The CWA was intended to protect the chemical, physical, and biological integrity of the Nation's waters. Section 304(a)(1) of the CWA, 33 U.S.C. § 1314(a)(1), directs the Administrator of EPA to publish water quality criteria that accurately reflect the latest scientific knowledge on the kind and extent of all identifiable effects on health and welfare that might be expected from the presence of pollutants in any body of water, including ground water. Under this authority, EPA developed revised aquatic life criteria for copper that are based on the Biotic Ligand Model (BLM) in 2007. The BLM predicts metal toxicity based on site-specific water quality parameters, and derives acute and chronic criteria from the predicted toxicity. Derivation of water quality criteria using the BLM requires 10 input parameters (temperature, pH, dissolved organic carbon (DOC), alkalinity, calcium, magnesium, sodium, potassium, sulfate, and chloride). Data regarding these parameters may not be available for many receiving waters. Given that the BLM is likely to be applied over a broad geographical range, and that limited data are available for many areas, a practical method to estimate missing water quality parameters was needed to facilitate full use of the BLM in water quality standards across the U.S. This technical support document (herein referred to as the "Missing Parameters TSD") summarizes data analysis approaches EPA used to develop recommendations for default values for water quality parameters that may be used in the BLM when data are lacking. The section of the CWA related to the development of the information presented in this technical support document is CWA Section 304(a)(2). CWA Section 304(a)(2) generally requires EPA to develop and publish information on the factors necessary to restore and maintain the chemical, physical, and biological integrity of navigable waters. Section 304(a)(2) also allows EPA to provide information on the conditions necessary for the protection and propagation of shellfish, fish, and wildlife in receiving waters and for allowing recreational activities in and on the water.

The objective of this report is to summarize recommendations that BLM users can apply to estimate values for missing input water quality parameters.

1.2 Input Data and the BLM

The BLM calculates metal toxicity to aquatic organisms as a function of the concentrations of certain chemical constituents of water, including, for example, ions that can complex with metals and limit biological availability, and ions that compete with metals for binding sites at the ion exchange tissues of aquatic organisms (e.g., at the fish gill). The BLM predicts the metal criteria concentrations, such as copper in freshwater, which will vary according to changes in the associated water quality parameters.

An appropriately protective acute and chronic copper (or other metals) criteria must reflect the variability of water quality parameters at the site. In previous analyses, EPA found that protective water quality criteria for copper generally correspond to approximately the 2.5th percentile of the

NMED Exhibit 34

distribution of instantaneous water quality criteria (IWQC) predicted by the BLM[1] (USEPA, 2002). Thus, predictions made for a site using the corresponding low percentile of the water quality parameter distributions are appropriately protective. Copper BLM predictions are most sensitive to the following five important parameters: DOC, pH, and calcium, magnesium, and sodium concentrations (taken together). Estimates are most sensitive to DOC, and vary in direct proportion to a change in value (i.e., they are 100% sensitive to DOC). Estimates are 50% sensitive to a change in pH, and 20% sensitive to the combined concentrations of calcium, magnesium, and sodium.

1.3 Previous Studies

EPA has conducted previous studies to develop tools to estimate BLM water quality parameters for sites where there may be few (or no) water quality data available. Brief summaries of these previous studies are provided below, and more detailed descriptions are provided in Appendices A through D.

1.3.1 An Examination of Spatial Trends in Surface Water Chemistry in the Continental United States: Implications for the Use of Default Values as Inputs to the BLM for Prediction of Acute Metal Toxicity to Aquatic Organisms (Carlton, 2006)

A large database of surface water chemistry monitoring data was examined to look for spatial trends in five chemical constituents that are key inputs to a model for predicting metal toxicity to aquatic organisms: pH, dissolved organic carbon, alkalinity, calcium, and sodium. Continuous prediction maps of concentrations were generated using various kriging techniques to interpolate between site-median values measured at several thousand separate locations throughout the continental U.S. Continuous concentration surfaces were then averaged over 8-digit Hydrologic Unit (HUC) polygons to produce block-averaged mean estimates of site-median concentrations. Pairwise comparisons indicated distinct trends between various HUC-averaged predicted constituents. The same analyses performed on data from 772 locations where all five constituents had been measured revealed similar relationships between monitored constituents. Principal components analyses (PCA) performed on these data sets showed that 80 to 90 percent of the variance in both cases could be explained by a single component with loadings on three of the five constituents. The use of kriging to produce appropriate quantile maps for block-averaging is suggested as a possible approach for developing regional values to use as default model inputs, when site-specific monitoring data are lacking. Refer to Appendix A for more information.

1.3.2 Approaches for Estimating Missing BLM Input Parameters: Correlation Approaches to Estimate BLM Input Parameters Using Conductivity and Discharge as Explanatory Variables (USEPA, 2007)

In this 2007 report, EPA developed regression models to project BLM water quality parameters from conductivity data. EPA assessed supplementing the geostatistical approach with classical estimation methods, such as regression and correlation by assessing the degree of correlation between conductivity and each of the BLM water quality parameters using National Water Information System

[1] This was the median for 17 sites; the range was 1 to 36%.

NMED Exhibit 34

(NWIS) data from three states (Colorado, Utah, and Wyoming). These states were selected because of the large spatial and temporal variability observed.

EPA concluded that conductivity is significantly correlated with BLM water quality parameters between sites, especially for the low-end distribution statistics of interest for parameter estimation. Since conductivity data are abundant and correlate well with BLM water quality parameters, EPA determined it is reasonable to incorporate conductivity in spatial projections of BLM parameters. Correlation coefficients were lower for pH and DOC than for the geochemical ions (GIs) and alkalinity, but were also significant. Refer to Appendix B for more information.

1.3.3 Copper Biotic Ligand Model (BLM) Software and Supporting Documents Preparation: Development of Tools to Estimate BLM Parameters (USEPA, 2008)

In order to predict parameters based on geographic location, this 2008 report investigated how to project BLM water quality parameters for a given site based on other site data using geostatistical methods. There are a number of ways in which the conductivity regressions can be used to project BLM water quality inputs. The regressions allow estimates of the BLM water quality inputs from either: (1) a limited number of conductivity measurements, or (2) a low-end conductivity value estimated by geostatistical methods.

The first approach, projecting BLM water quality inputs from conductivity measurements, was demonstrated for a limited number of test sites. Regression models were developed to project 10^{th} percentiles of BLM water quality input parameters from the 10^{th} percentile of measured conductivity distributions at sites in Colorado, Utah, and Wyoming. The 10^{th} percentile is the value below which 10 percent of the observations may be found. The regression models were tested using data and copper BLM predictions for four sites, and produced highly consistent results. The regression models for pH and DOC, the most sensitive of the BLM water quality parameters, were not sufficiently accurate to make reliable BLM parameter predictions. However, regression models for the GI parameters (calcium, magnesium, sodium, potassium, chloride, sulfate, and alkalinity) were reasonably accurate, as judged by comparing model predictions made using projected values of the these BLM input parameters to model predictions made using measured input data. No estimate for site-specific pH was superior to the observed weak conductivity regression. To improve upon this estimate, it was necessary to use actual site-specific pH data. For DOC, the Level III ecoregion (referred to herein as simply “ecoregion”) and water body type-specific DOC concentration percentiles tabulated by EPA for the National Bioaccumulation Factors Technical Support Document (USEPA, 2003) appear to be far better estimates of lower-percentile DOC concentrations than the estimates made using the conductivity regression.

EPA also provided a proof of concept for the second approach, which was to see whether combining the kriged conductivities with the conductivity-hardness regression would project the 10^{th} percentiles of hardness better than direct kriging of the hardness data. EPA found that both approaches produce estimates of hardness that correlate significantly with the measured data (correlation coefficient $r=0.80$ for direct kriging of hardness; $r=0.95$ for conductivity kriging + regression). However, the kriging + regression approach fits the hardness data substantially better than direct kriging. Refer to Appendix C for more information.

1.3.4 Approaches for Estimating Missing BLM Input Parameters: Projections of Total Organic Carbon as a Function of Biochemical Oxygen Demand (USEPA, 2006a)

DOC concentrations downstream of an effluent discharge are necessary inputs for the BLM to predict toxicity associated with a wastewater discharge. Effluent DOC is monitored by very few publicly-owned treatment works (POTWs) according to data retrieved from EPA's Permit Compliance System (PCS). Biochemical oxygen demand (BOD) is monitored by most POTWs. EPA developed regressions to project total organic carbon (TOC) concentrations from BOD values using effluent samples at all POTWs reporting data for both parameters in EPA's PCS. EPA concluded that this regression gives reasonable estimates of TOC in POTWs effluents and are likely the best available estimates of effluent TOC to determine DOC concentrations for the BLM. Refer to Appendix D for more information.

1.4 Approaches to Estimate Water Quality Parameters for the BLM

Building upon the studies described above, this report uses three approaches to develop default estimates for parameters needed for the BLM when empirical data are lacking. The three approaches are listed below and are detailed in the following sections:

- Section 2: Using Geostatistics and Conductivity to Predict GI Parameters
- Section 3: Using Stream Order to Refine Prediction of GI Parameters
- Section 4: Using the National Organic Carbon Database to estimate DOC

EPA recommends that temperature and pH be measured directly in the field.

NMED Exhibit 34

2 USING GEOSTATISTICS AND CONDUCTIVITY TO PREDICT GI PARAMETERS

The following section describes studies that demonstrate how geostatistical techniques, coupled with conductivity correlations, can be used to predict BLM input parameters for GIs when site-specific data are unavailable. In a previous study (USEPA, 2008) EPA demonstrated that combining kriging with regressions to estimate inputs based on conductivity improves the accuracy of GI estimates. In this section EPA has expanded on this approach and developed national estimates at the Level III ecoregion in the continental U.S.

The current freshwater copper BLM requires 10 input parameters that reflect water chemistry in order to calculate copper criteria: temperature, pH, DOC, alkalinity, calcium, magnesium, sodium, potassium, sulfate, and chloride, the last seven of which are GIs. The concentrations of GIs vary in surface waters due to dissolution, weathering, ground water-surface water interactions, and other geologic processes in the watershed, in addition to dilution by snowmelt and precipitation. Consequently, the concentrations of GI parameters tend to vary according to the regional geology. For example, alkalinity has noticeable geographic trends. Areas dominated by carbonate rocks, such as limestone as in the prairie states, tend toward high alkalinity. Areas dominated by igneous rocks, such as granite, such as parts of the northeast, tend toward low hardness and alkalinity.

In this section we expand on the EPA 2008 proof of concept (in Appendix C) using geostatistics to develop default missing GI parameter values based on geography. Geostatistics are statistical methodologies that use spatial coordinates to help formulate models used in estimation and prediction (ESRI, 2003). Geostatistical techniques are attractive because they explain parameter variation arising from spatial correlations, which are not used in conventional statistics. We have supplemented the geostatistical approach by adding conductivity as an additional explanatory variable. Conductivity is one of the most widely monitored water quality indicators in the U.S. Because conductivity data are abundant and correlate well to the BLM GI parameters, we incorporated conductivity in spatial projections of BLM parameters. Based on the proof of concept described above (and in Appendix C), we expected that this approach, which can be implemented by co-kriging (i.e., an interpolation technique that allows for better estimates by the incorporation of well-sampled, correlated secondary data) in geostatistical software, would allow more robust spatial projections of BLM water quality parameters.

2.1 Data Source and Processing

Water quality data for conductivity and BLM GI water quality parameters were retrieved from the United States Geological Survey (USGS) National Water Information System (NWIS). NWIS contains data from millions of sampling events at tens of thousands of individual sampling locations (stations) in the continental U.S. (Figure 1). Not all water quality parameters of relevance to the BLM were monitored at each location. The numbers of sampling events at individual locations also range widely, with a mean of 15, and a mode of one (i.e., most sites were only sampled once). Examination of the spatial distribution of numbers of sampling events per site reveals that the Midwestern and Western states tended to be sampled most intensively (Carleton, 2006). Because environmental sampling data tend to be lognormally distributed, disparities in numbers of samples may tend to produce higher mean and median values at locations that have been sampled more frequently. As spatial distributions of representative (e.g., median) concentrations are examined, it should be kept in mind that apparent

NMED Exhibit 34

geographic trends in concentration may be in part simply the result of uneven sampling intensity (Carleton, 2006).

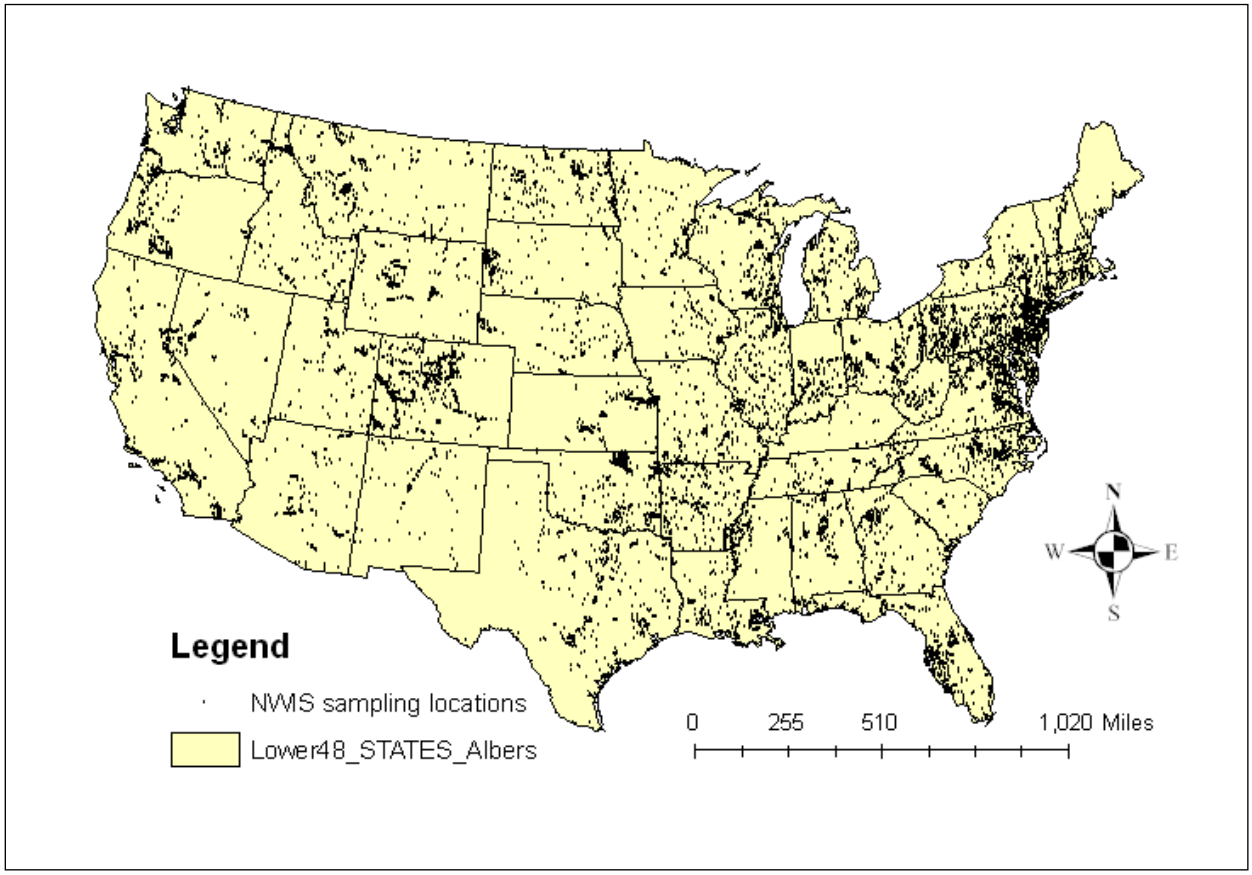

Figure 1. NWIS sample collection locations in the continental U.S. (Carleton, 2006)

We focused our efforts on data collected from rivers and streams between 1984 and 2009. Data collected prior to 1984 were excluded because a number of the analytical methods used by USGS prior to that date have been replaced by methods with improved precision and lower detection limits. Furthermore, only sites with 40 or more samples were included in the analysis. With support from USGS staff, we obtained a complete download of national water quality data from NWIS, which totaled 4,714,165 measurements from 959,946 samples, collected at 5,901 sites. These data included measurements for BLM water quality input parameters required to calculate copper criteria using the BLM: pH, DOC, alkalinity, calcium, magnesium, sodium, potassium, sulfate, and chloride. Data were also collected on filtered (dissolved) copper, and the spatial coordinates (latitude and longitude) of each sampling station were also retrieved. No data were collected on temperature. Only the GI data were included in the geostatistical analysis. A summary of the water quality data retrieved from NWIS is provided in Table 1.

Table 1. Summary of water quality data retrieved from NWIS			
BLM Water Quality Parameter	**NWIS Parameter Code**	**Parameter Description**	**Number of Observations**
Conductivity[1]	00094	Specific conductance, water, unfiltered, field, microsiemens per centimeter at 25 degrees Celsius	553,700
	00095	Specific conductance, water, unfiltered, laboratory, microsiemens per centimeter at 25 degrees Celsius	799
pH	00400	pH, water, unfiltered, field, standard units	352,336
	00403	pH, water, unfiltered, laboratory, standard units	151,161
Dissolver Organic Carbon	00681	Organic carbon, water, filtered, laboratory, milligrams per liter	30,008
Alkalinity	00410	Acid neutralizing capacity, water, unfiltered, fixed endpoint (pH 4.5) titration, field, milligrams per liter as calcium carbonate	35,232
	00417	Acid neutralizing capacity, water, unfiltered, fixed endpoint (pH 4.5) titration, laboratory, milligrams per liter as calcium carbonate	15,264
	00419	Acid neutralizing capacity, water, unfiltered, incremental titration, field, milligrams per liter as calcium carbonate	10,198
	00418	Alkalinity, water, filtered, fixed endpoint (pH 4.5) titration, field, milligrams per liter as calcium carbonate	2,686
Calcium	00915	Calcium, water, filtered, laboratory, milligrams per liter	146,608
Magnesium	00925	Magnesium, water, filtered, laboratory, milligrams per liter	145,938
Sodium	00930	Sodium, water, filtered, laboratory, milligrams per liter	136,310
Potassium	00935	Potassium, water, filtered, laboratory, milligrams per liter	132,659
Sulfate	00945	Sulfate, water, filtered, laboratory, milligrams per liter	147,824
Chloride	00940	Chloride, water, filtered, laboratory, milligrams per liter	146,601

[1] Conductivity is not a BLM parameter, but was used as an explanatory variable for the other water quality parameters.

The data were screened using established quality assurance procedures. All data were checked to confirm that they contained numerical values without null (missing) records and remark codes were

identified and reviewed. Minimum and maximum values for each parameter were confirmed to be within expected ranges and frequency distributions were plotted and examined for each of the parameters to identify outliers. We also confirmed that the spatial coordinate data placed each sampling location within the continental U.S. Additional data processing included the following steps:

- For the data at each station, the observations for each variable were averaged on a daily basis. This was done to reduce the influence of high frequency sampling at a few stations.
- Data were edited by censoring parameter(s) with fewer than 10 to 20 daily values at a station. The 10^{th} percentile for that parameter at that station was censored to improve the reliability of the lower-tail (i.e., 10^{th}) percentile statistics.
- Tenth (rank order/nonparametric) percentiles of the distributions of all water quality parameters measured at each station were calculated.

It should be emphasized that all of the statistical and geostatistical analyses and predictions presented in this report are based on the 10^{th} percentiles of the concentration distribution measured for each parameter at every station. The estimates of water quality parameter values for "missing" data are therefore also 10^{th} percentile concentrations. We selected the 10^{th} percentile of the site parameter distributions as a statistic that is a practical compromise between a lower-bound concentration and a percentile that can be reliably determined from small sample sizes. Initial testing with the BLM suggested that protective water quality criteria (WQC) for copper generally corresponded to approximately the 2.5^{th} percentile of the distribution of instantaneous water quality criteria (IWQC) predicted by the BLM. Thus, BLM predictions made for a site using the corresponding low percentiles of the water quality parameter distributions should (logically) also be a conservative approximation of a protective criterion. As a more reliably determined statistic, the 10^{th} percentile of water quality parameters will also derive reasonably protective criteria, especially for small sample sizes where there may be greater uncertainty at lower percentile estimates. The 10^{th} percentile estimates presented in this document were initially developed to implement the copper BLM published by EPA in 2007 and will apply to other metals as well.

2.2 Geostatistical Analysis of National Data for Geochemical Ions

The ESRI ArcGIS Geostatistical Analyst tool was used to create statistically valid two-dimensional surface models for conductivity and for each of the BLM GI parameters. Using the 10^{th} percentile daily average concentrations at each sampling location from the NWIS data, Geostatistical Analyst was used to create predictions for unmeasured locations throughout the continental U.S. For each parameter, the surface models were fit by minimizing the statistical error of the predicted surface. Surface fitting involved three steps: exploratory spatial data analysis, structural analysis (modeling the semivariogram to analyze surface properties of data from nearby locations), and surface prediction and assessment of the results. The semivariogram represents autocorrelation of measured data points spatially.

Modeling of the semivariogram was based on cross-validation, which calculates error statistics that serve as diagnostics to indicate whether the model is reasonable for map production. Cross-validation was used to select the models that provided the most accurate predictions. The following criteria were used to evaluate goodness of fit for the semivariogram model:

- Mean Standardized Error: close to 0;
- Root Mean Square Error (RMSE): as small as possible;

NMED Exhibit 34

- Root-Mean-Square Standardized Error: close to 1; and,
- RMSE close to Average Standard Error ASE).

The difference between the prediction and the measured data value is the prediction error. For a model that provides accurate predictions, the mean prediction error should be close to 0 if the predictions are unbiased. The root-mean-square standardized prediction error should be close to 1 if the standard errors are accurate, and RMSE should be small if the predictions are close to the measured values (ESRI, 2003).

A tabulation of the geostatistical model selected for each water quality parameter, the number of data points interpolated, and the resulting error statistics are presented in Table 2. We used the optimal parameters for a spherical semivariogram as calculated by the Geostatistical Analyst. No transformations were applied to the data. Anisotropy (directional influence on the semivariogram) was not incorporated in the semivariogram models.

Table 2. Model selection and cross validation statistics for geostatistical fitting of 10th percentiles of BLM GI parameters

Parameter	Geostatistical model	Number of samples	Mean standardized error	Root mean square error	RMS standardized error	Average standard error
Conductivity	Universal kriging	4833	-0.01038	1361	1.081	1259
Alkalinity	Universal cokriging with conductivity	1372	-0.001115	36.62	1.09	33.23
Calcium	Universal cokriging with conductivity	2590	0.0001694	26.81	1.186	22.02
Magnesium	Universal cokriging with conductivity	2578	-0.002258	15.92	1.16	13.58
Sodium	Universal cokriging with conductivity	2439	-0.002929	156.3	1.583	95.78
Potassium	Universal cokriging with conductivity	2379	-0.001184	3.488	1.429	2.381
Sulfate	Universal cokriging with conductivity	2650	-0.0000225	114.5	1.29	87.04
Chloride	Universal cokriging with conductivity	2792	0.001653	375.2	1.51	247

2.2.1 Kriging of Conductivity Data

Universal kriging with a constant trend was used to map the surface of 10th percentile conductivity values. Kriging weights the surrounding measured values to derive a prediction for each location. The weights are based on the distances between the measured points and the prediction location, as well as the overall spatial arrangement among the measured points. The kriged prediction surface of 10th percentiles of conductivity is mapped in Figure 2. As the kriging results show, conductivities are highest in the south-central and southwestern regions, as well as along the Gulf and southern Atlantic coasts. Regions of lower conductivity are found in a number of parts of the country.

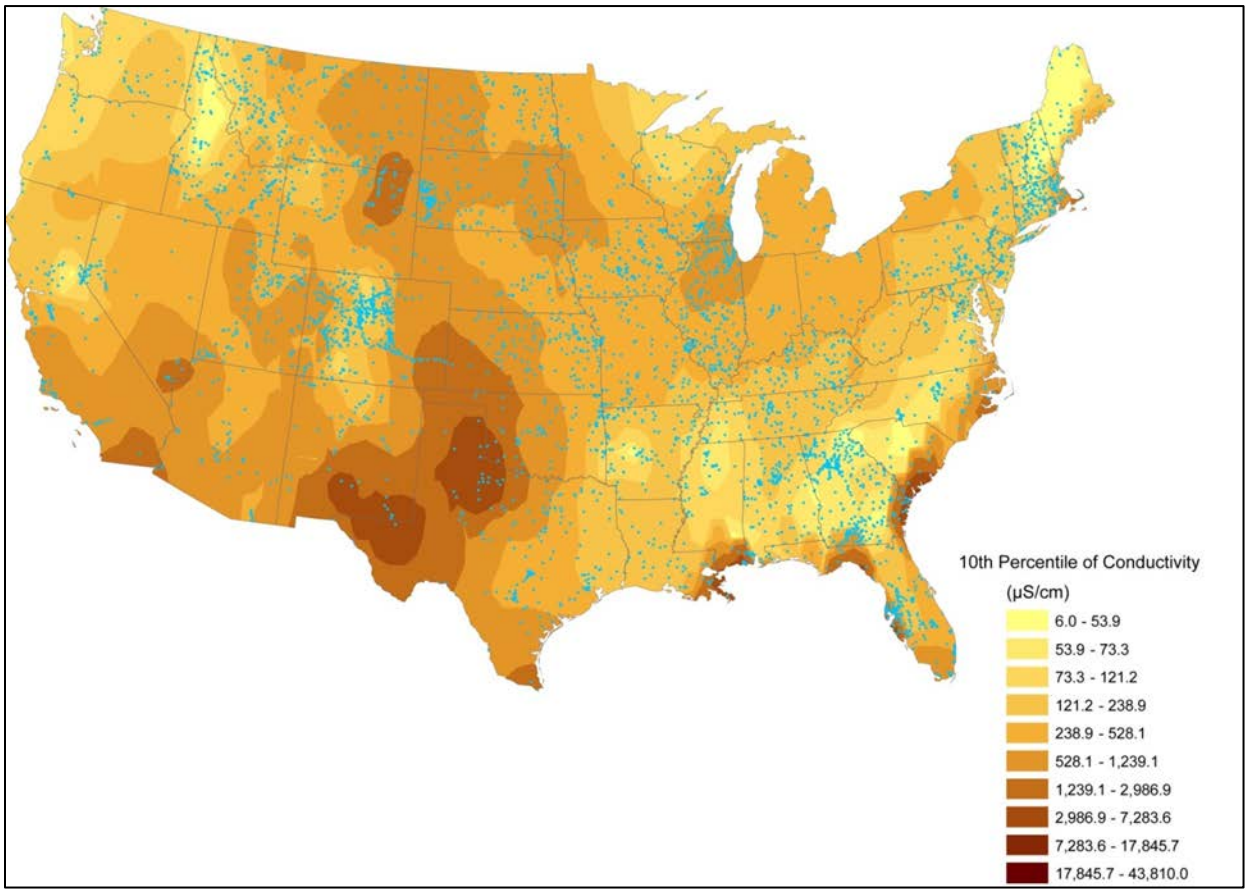

Figure 2. Kriged prediction surface for 10th percentile of conductivity in the continental U.S. (sample locations in blue)

2.2.2 Co-kriging of GI Data

Co-kriging was used to improve surface predictions of the BLM GI parameters by taking into account secondary variables, in this case conductivity. As demonstrated above, conductivity is significantly correlated to all of the BLM GIs. Universal co-kriging with conductivity, assuming a constant trend, was used to map the surface of 10th percentile BLM GIs concentrations. For each of these parameters, co-kriging produced cross-validation errors that were superior in terms of the goodness-of-fit criteria to errors produced by universal kriging. Prediction surfaces for calcium and alkalinity are mapped in Figures 3 and 4. The spatial distribution of calcium (Figure 3) shares a number of similarities with the mapping of conductivity (Figure 2). The co-kriged alkalinity surface (Figure 4) is rather different, with high alkalinity values reflecting geographic features (such as the carbonate geology of the prairie states) and low alkalinity values that reflect the granitic geology of the northeast. Prediction surfaces for the other BLM GI's are generally similar to those for conductivity and calcium.

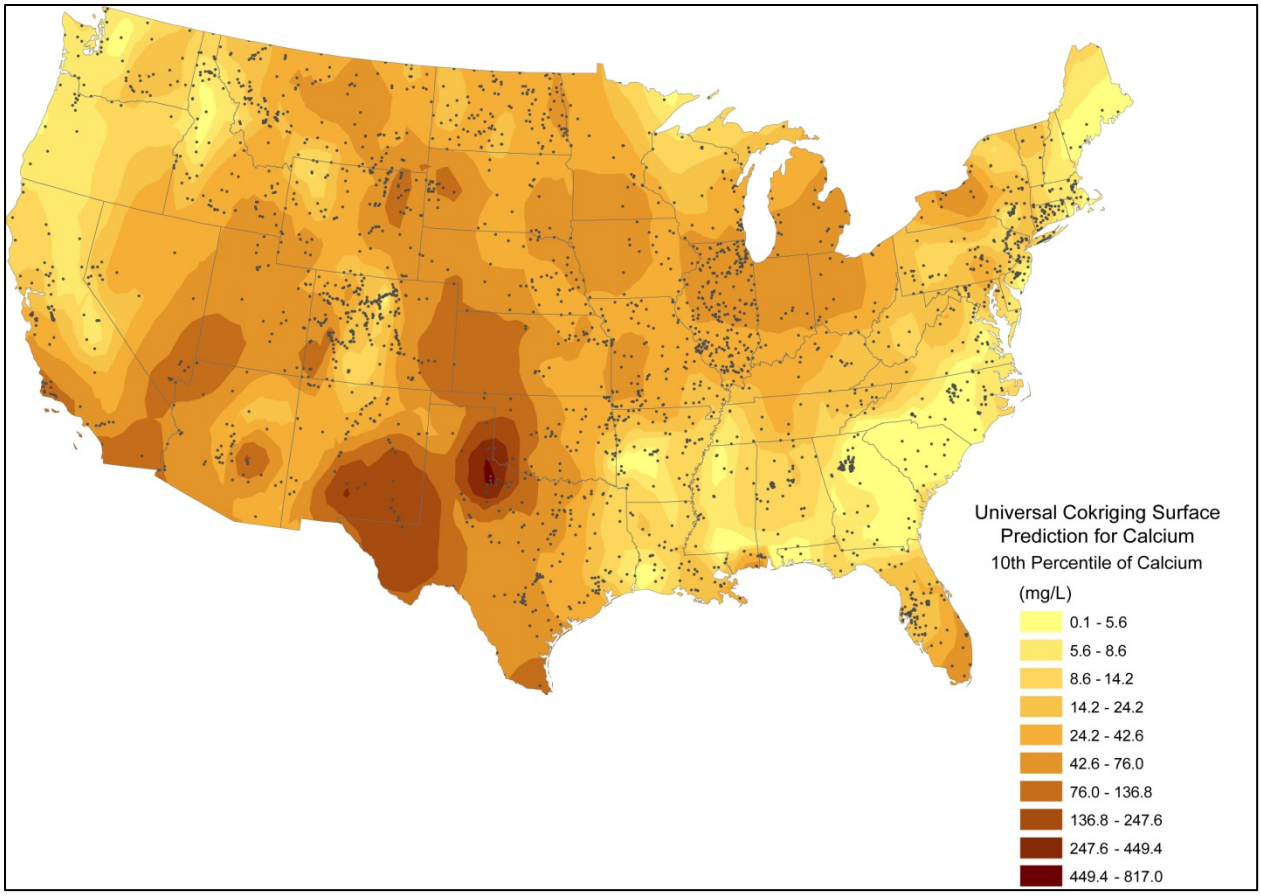

Figure 3. Co-kriged prediction surface for 10th percentile of calcium in the continental U.S.

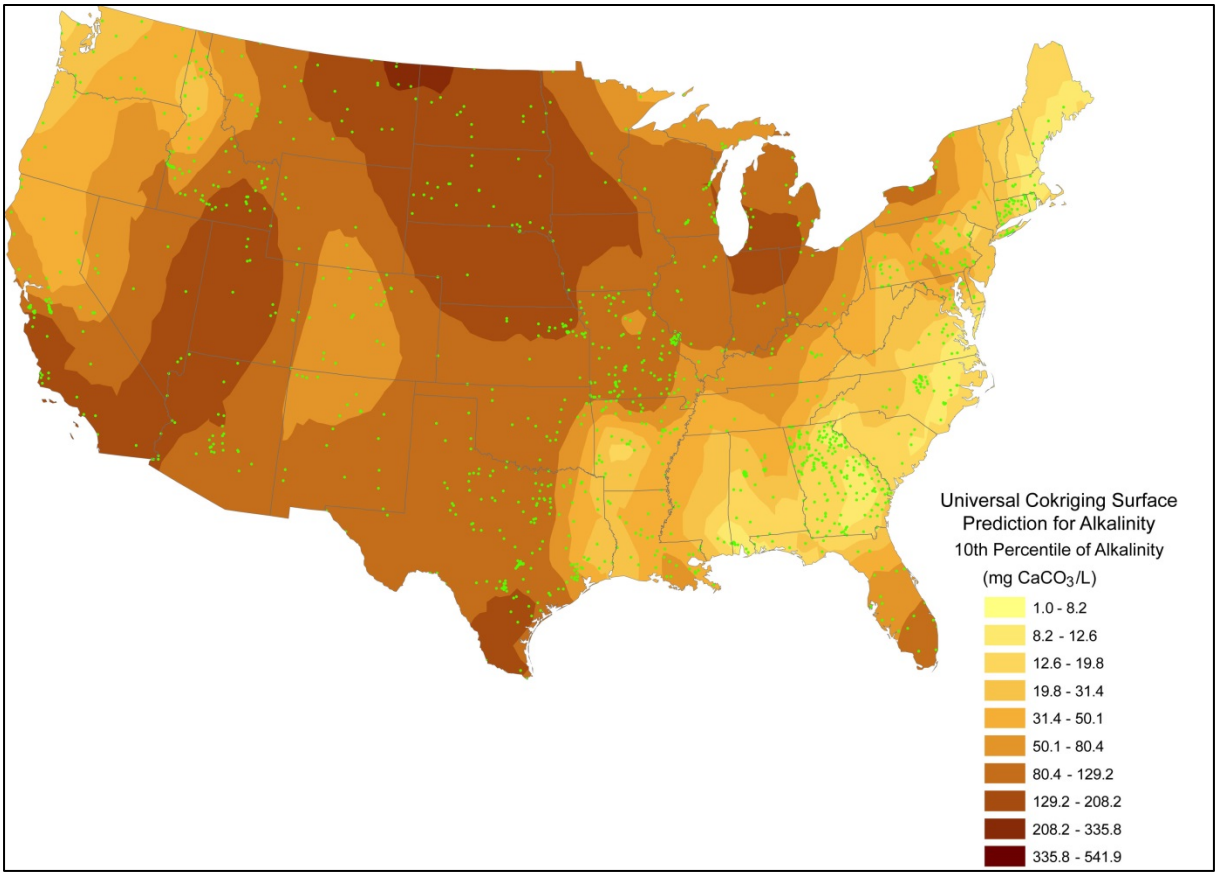

Figure 4. Co-kriged prediction surface for 10th percentile of alkalinity in the continental U.S.

2.2.3 Projection of Geostatistical Predictions onto Level III Ecoregions

Although maps of the geostatistical predictions are informative, a tabulation of the results is preferable for the purpose of providing guidance to BLM users. We chose to spatially average the geostatistical predictions of BLM water quality parameters according to the Level III ecoregions of the continental U.S. (Table 3), as these ecoregions provide a sound basis for spatial averaging of the water quality predictions. Ecoregions are designed to serve as a spatial framework for environmental resource management and denote areas within which ecosystems (and the type, quality, and quantity of environmental resources) are generally similar. They typically provide a logical and useful spatial (geographical) framework for organizing the results of environmental measurements (Omernik and Griffith, 2014). Ecoregions can be distinguished by landscape-level characteristics that cause ecosystem components to reflect different patterns in different regions (Omernik, 1987). "Level III Ecoregions of the Continental U.S." map layer shows ecoregion delineation based on common patterns of geology, physiography, vegetation, climate, soils, land use, wildlife, water quality, and hydrology. The map layer in Figure 5 was compiled by EPA (USEPA, 2013a) (http://www.epa.gov/wed/pages/ecoregions/level_iii_iv.htm).

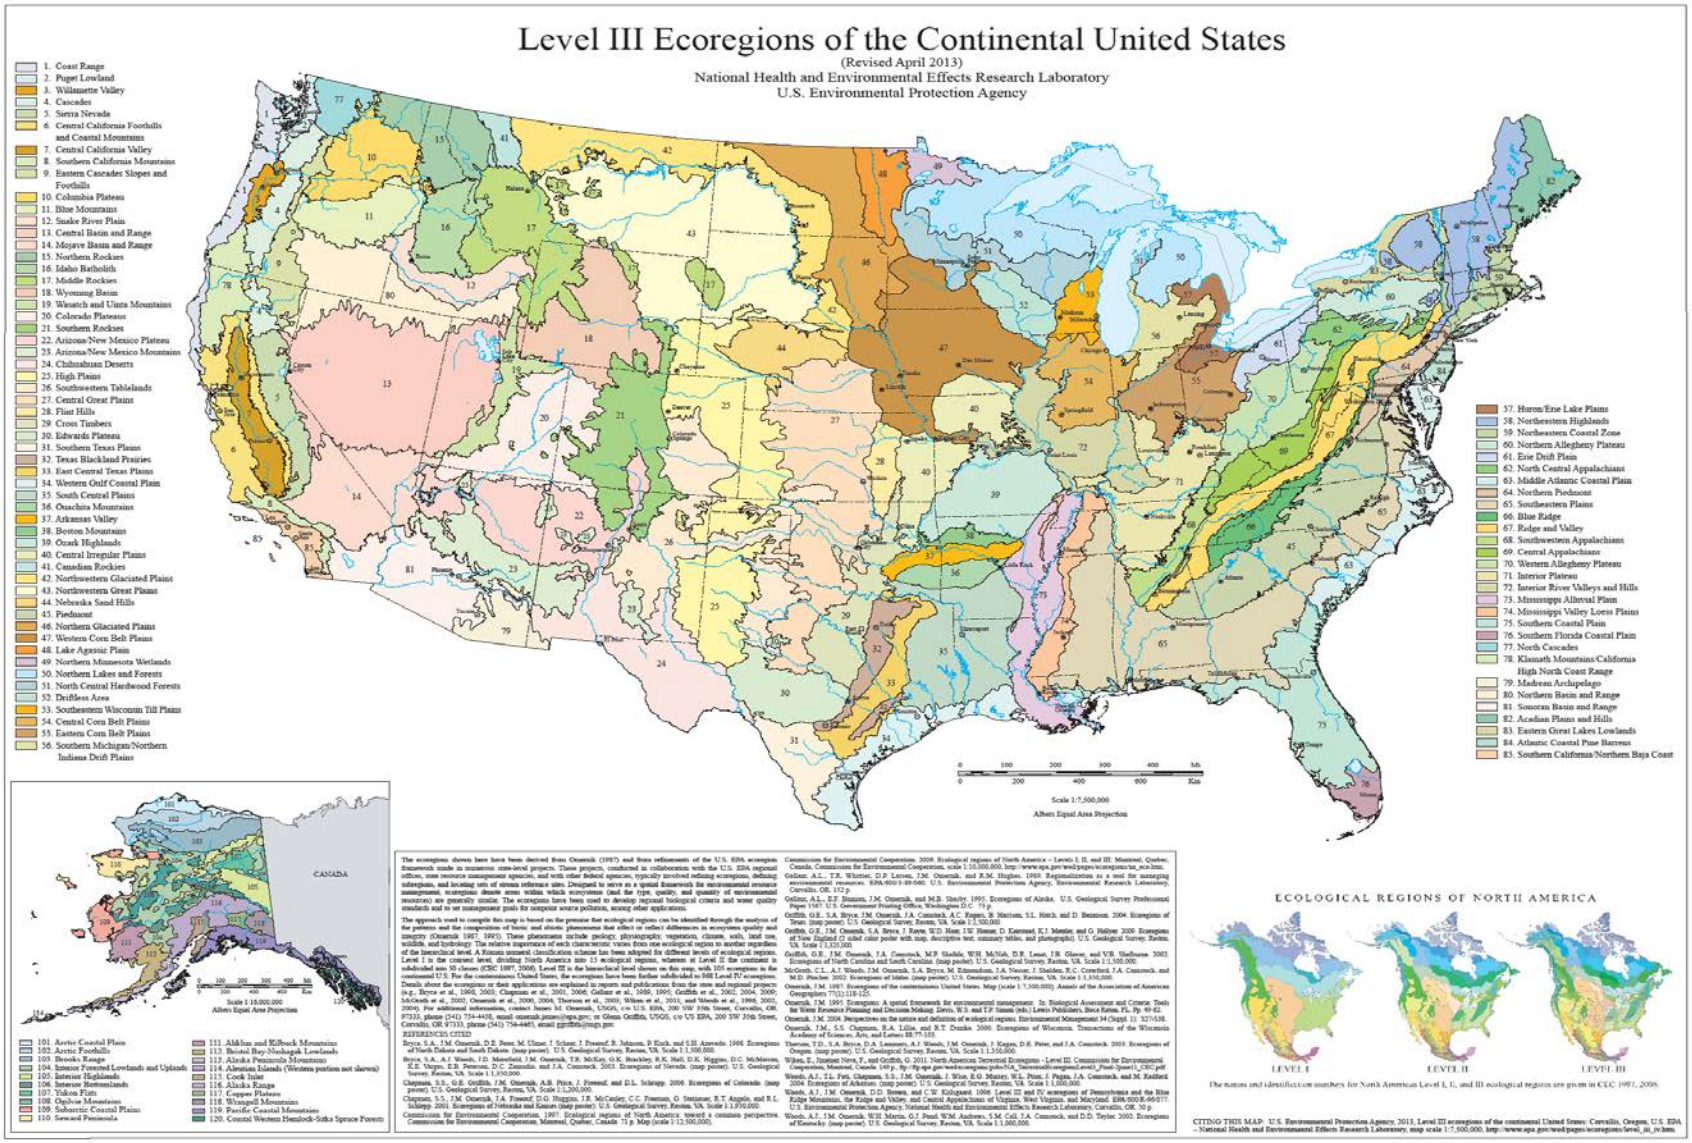

Figure 5. Map of Level III ecoregions in the U.S.

(Image taken from ftp://ftp.epa.gov/wed/ecoregions/us/Eco_Level_III_US.pdf)

Using the differences in land and water interactions, regional variations in attainable water quality, distinct biogeographical patterns (MacArthur, 1972), and similarities and differences in ecosystems to delineate ecoregions makes the application of ecoregions in environmental analyses a powerful tool with which to organize environmental information. The approach can take into account regional factors related to attainable water quality, and thus can be used to designate lakes for protection and to establish lake-restoration goals that are appropriate for each ecoregion (National Research Council (NRC), 1992). The NRC of the National Academy of Sciences has similarly endorsed the use of the concept in restoring and managing streams, rivers, and wetlands (NRC, 1992).

The theory of ecoregion delineation states that natural water quality characteristics of lakes and streams within a single ecoregion will be more similar than the characteristics between ecoregions (Perry and Vanderklein, 1996). Water quality characteristics exist in a landscape framework; neither normal nor impacted conditions of water resources can be separated from controlling influences of the surrounding landscape. The ecoregion concept has been applied and tested rather extensively in streams, rivers, and lakes. Testing and validation has been conducted in many diverse areas of the U.S., including several streams in Arkansas, Colorado, Kansas, Minnesota, Ohio, and Oregon, and in lakes of Michigan, Minnesota, Ohio, and Wisconsin (NRC, 1992).

Carleton (2006) used HUCs instead of ecoregions as the basis for averaging geostatistical results. HUCs are spatial delineations used for river basin management. Although a river basin may offer a logical framework for water supply management, for water quality management river basins are less applicable. The assumption that basins share similar properties is not always borne out, because river basins are often linked only by the water that flows through them. As Carleton (2006) noted, the use of HUCs for spatial averaging of surface water concentrations presents other conceptual difficulties. Only about 45% of HUCs are actual watersheds (Omernik, 2003); the rest receive drainage from additional upgradient areas. Concentrations measured in flowing waters reflect the soil, vegetation, and land use properties of the aggregate upstream drainage areas rather than of the sampling locations themselves (Smith et al., 1997).

2.2.3.1 Averaging Methods

To average the geostatistical predictions, a uniform grid was laid over the predicted surfaces and the predictions were sampled at the grid points falling within the polygons representing each ecoregion. The grid spacing was sized so that at least 30 points were sampled within each ecoregion. Unbiased log means were then calculated from the sampled concentration predictions in each ecoregion. The logarithmic transformation was applied because this normalized the concentration distributions in almost all of the ecoregions.

2.2.3.2 Tabulations of Ecoregional Estimated BLM Water Quality Parameters

The average predicted 10^{th} percentile concentrations for conductivity and the GI parameters for each of the Level III ecoregions in the continental U.S. are presented in Table 4. For each of these parameters, there is considerable variation between the ecoregional averages nationally. Chloride concentrations exhibit the greatest variation, with ecoregional 10^{th} percentile averages that range from 0.7 to 573 milligrams per liter (mg/L). Alkalinity was the least variable, but the ecoregional 10^{th} percentile average concentrations still ranged from 12 to 163 mg/L.

Table 4. Predicted 10th percentile concentrations for conductivity (µS/cm), BLM GI water quality parameters (mg/L) and hardness in each Level III ecoregion in the continental U.S.										
		Unbiased log mean of 10th percentile concentrations

2.2.3.3 Confirmation of Results

To confirm the results of the geostatistical predictions, a number of comparisons were made between the ecoregional average predictions and averages based directly on the data. For each GI parameter, we compared the ecoregional average predictions against the corresponding averages calculated from the data for each ecoregion.

Scatter plot matrices provide a visual presentation of the correlations between different parameters. Scatter plot matrices were developed for the ecoregional averages of conductivity and GI parameters. Figure 6 is the scatter plot matrix for ecoregional averages based on the data, and Figure 7 is the scatter plot matrix for ecoregional averages based on the geostatistical predictions. Comparison of

these figures shows that the predicted averages capture the same trends in terms of distributions and parameter correlations as those that are found for the ecoregional data. The similarities in the distributions and correlation structures between the ecoregional averages in Figures 6 and 7 demonstrate that the geostatistical ecoregion predictions are reasonable.

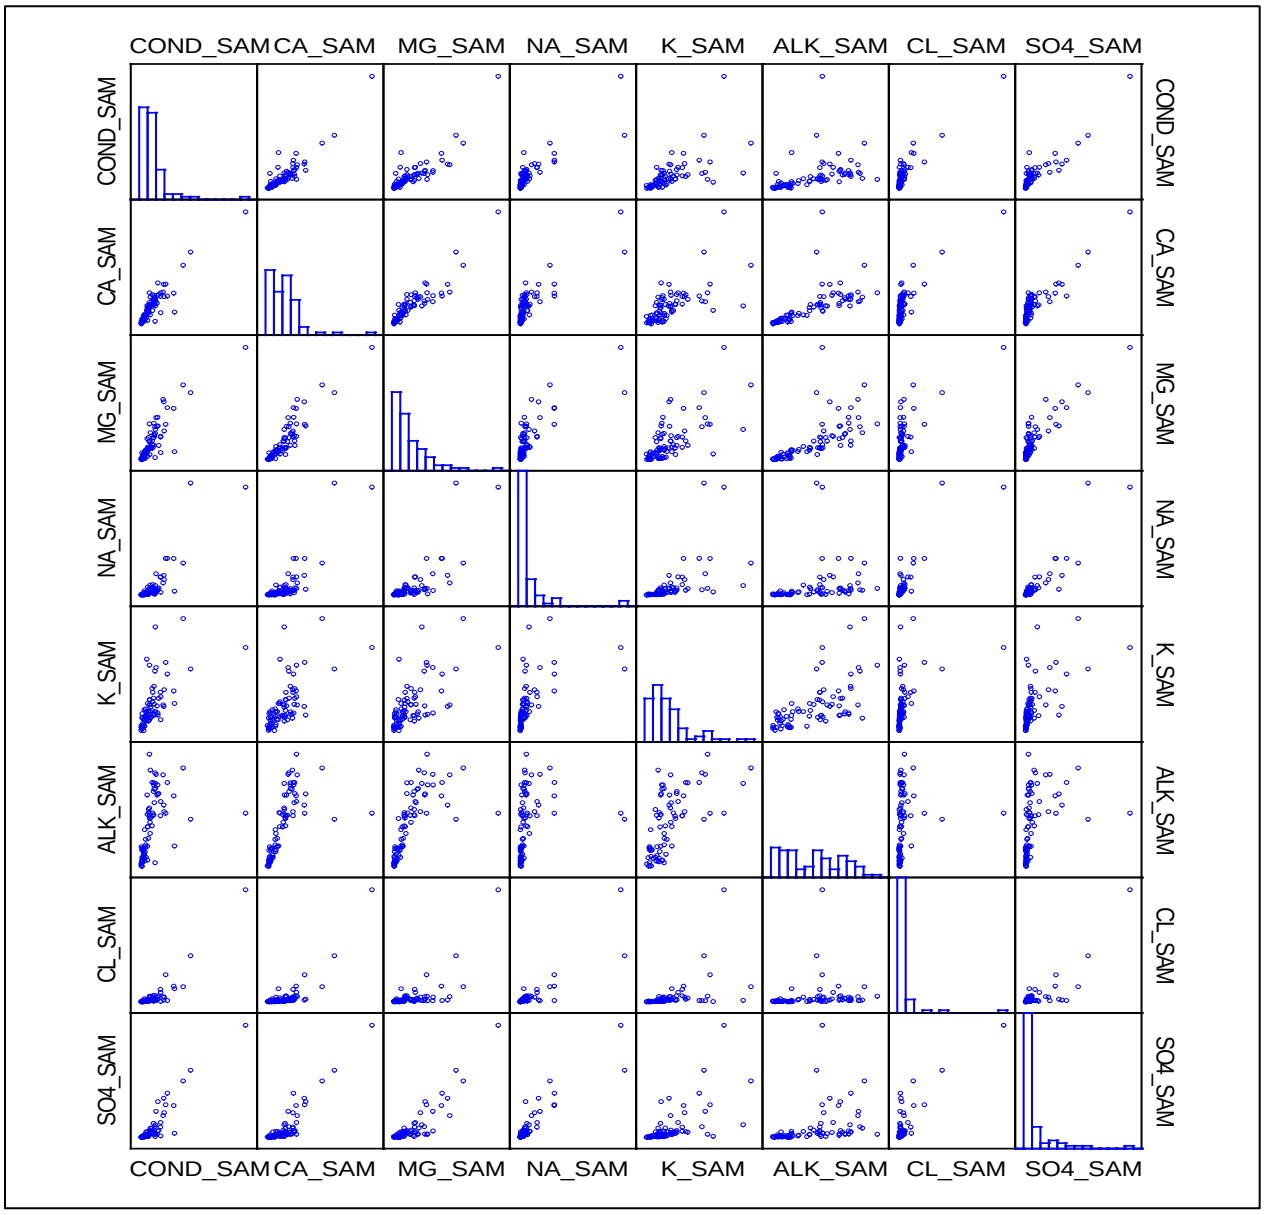

Figure 6. Scatter plot matrix of ecoregional average 10th percentiles of data for conductivity (COND_SAM) and GI parameters (calcium=CA_SAM, magnesium=MG_SAM, sodium=NA_SAM, potassium=K_SAM, alkalinity=ALK_SAM, chloride=CL_SAM, sulfate=SO4_SAM)

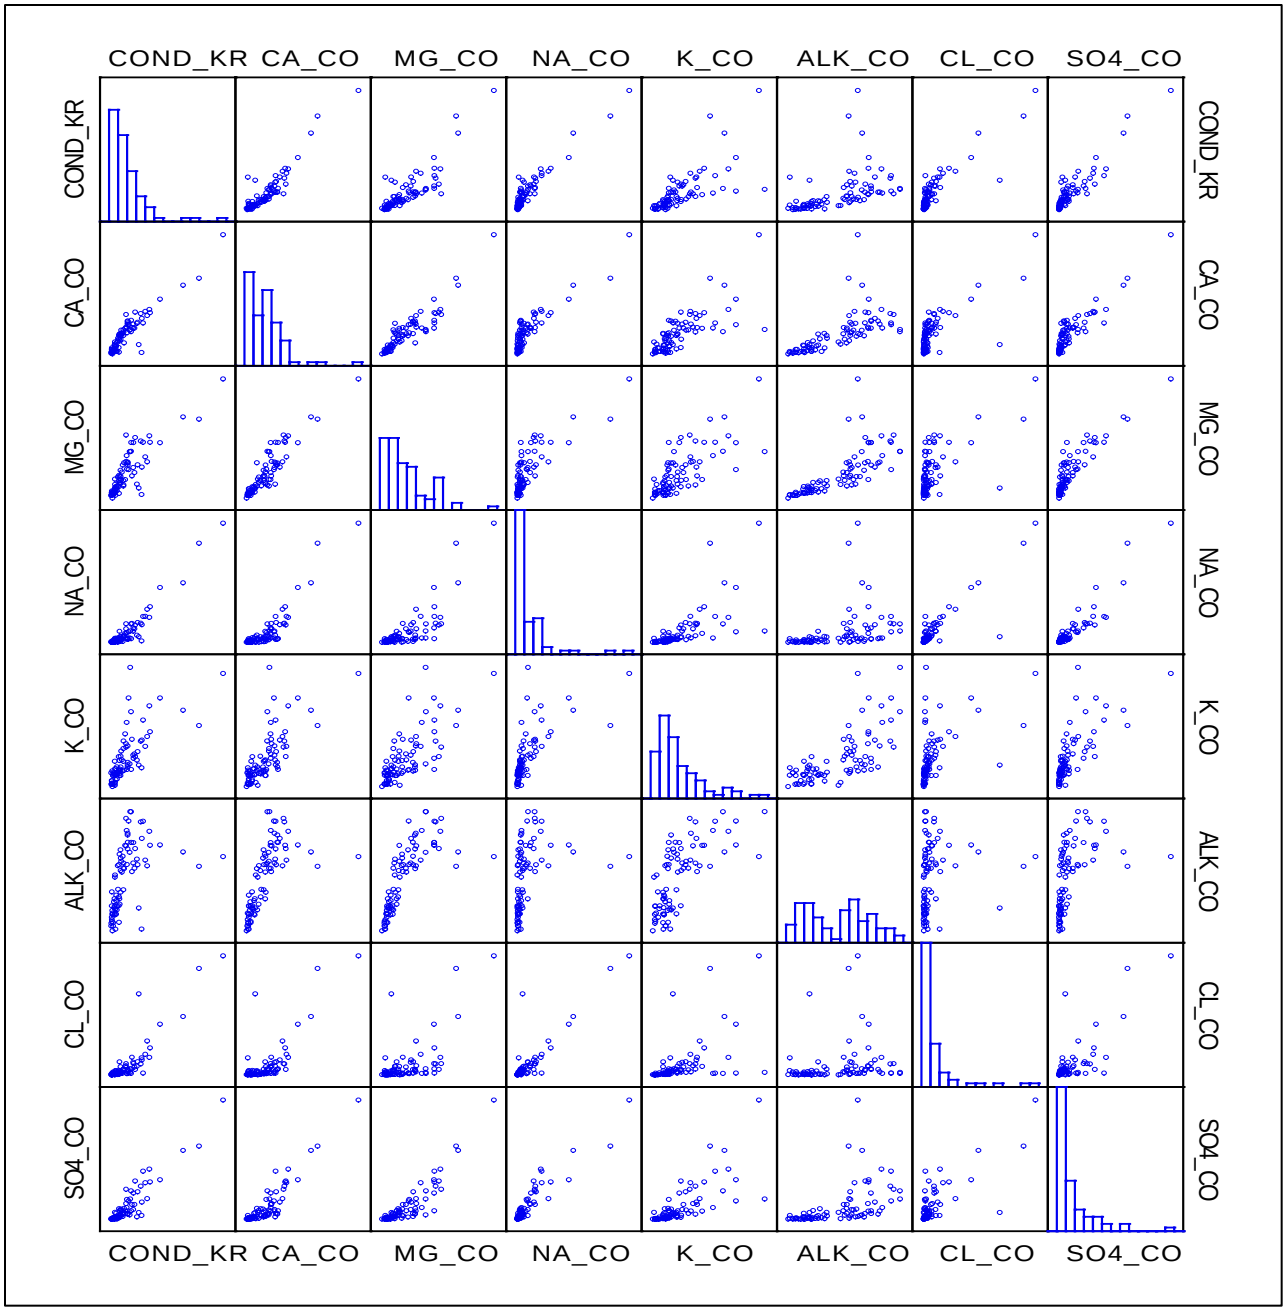

Figure 7. Scatter plot matrix of ecoregional average 10th percentiles of geostatistical predictions of conductivity (COND_KR) and BLM GI parameters (calcium=CA_CO, magnesium=MG_SCO, sodium=NA_CO, potassium=K_CO, alkalinity=ALK_CO, chloride=CL_CO, sulfate=SO4_CO)

In addition to scatter plots, correlation coefficient matrices between the parameters in each of the two data sets were generated. The Spearman (rank order) correlation coefficients for data-based ecoregional averages are presented in Table 5; correlation coefficients for ecoregional average geostatistical predictions are presented in Table 6. Although not identical, the correlation coefficients are similar between the two datasets, again demonstrating that the geostatistical predictions are reasonable.

Table 5. Spearman rank correlation matrix for unbiased log means of 10th percentile concentrations measured in Level III ecoregions								
	Conductivity	Calcium	Magnesium	Sodium	Potassium	Alkalinity	Chloride	Sulfate
Conductivity	1							
Calcium	0.895	1						
Magnesium	0.877	0.927	1					
Sodium	0.865	0.819	0.813	1				
Potassium	0.823	0.758	0.73	0.859	1			
Alkalinity	0.769	0.881	0.898	0.698	0.679	1		
Chloride	0.815	0.774	0.702	0.855	0.788	0.595	1	
Sulfate	0.894	0.864	0.85	0.883	0.786	0.725	0.744	1

Table 6. Spearman rank correlation matrix for unbiased log means of 10th percentile predicted (kriged/cokriged) concentrations in Level III ecoregions								
	Conductivity	Calcium	Magnesium	Sodium	Potassium	Alkalinity	Chloride	Sulfate
Conductivity	1							
Calcium	0.872	1						
Magnesium	0.843	0.924	1					
Sodium	0.87	0.82	0.778	1				
Potassium	0.842	0.803	0.753	0.836	1			
Alkalinity	0.747	0.868	0.901	0.672	0.745	1		
Chloride	0.829	0.715	0.592	0.826	0.725	0.461	1	
Sulfate	0.889	0.873	0.875	0.893	0.831	0.751	0.715	1

As a final test of the accuracy of the geostatistical predictions, we regressed the ecoregional averages based on the geostatistical predictions against the ecoregional averages based on the data. Scatter plots and fitted regression lines are shown for each of the parameters: conductivity (Figure 8), alkalinity (Figure 9), calcium (Figure 10), magnesium (Figure 11), sodium (Figure 12), potassium (Figure 13), sulfate (Figure 14), and chloride (Figure 15). Statistics for the linear regressions are provided in Table 7. For each of the parameters, the predicted and data-based ecoregional averages are significantly correlated. In each case, the linear regression coefficient is nearly 1.0, with a highly significant P value. As with the previous comparisons, the linear regression results demonstrate that the accuracy of the geostatistical predictions is high.

Chloride	0.839	1.039	<0.001	-7.271	0.386

2.2.3.4 Conclusions for Selection of Water Quality Parameters

In this section we used geostatistics to estimate an intermediate step in generating missing GI parameter values based on geography. We supplemented the geostatistical approach by adding conductivity as an additional explanatory variable to generate a more robust spatial estimate of the GI water quality inputs for the BLM because conductivity is one of the most widely monitored water quality indicators in the U.S. and correlates well with GIs. In section 3, these estimates are further refined by stream order. We present here the average predicted 10^{th} percentile concentrations for the BLM GI water quality parameters, as presented in Table 4 by ecoregions. Because they are based on the 10^{th} percentiles of the daily average data from each USGS monitoring station, they are expected to yield copper criteria that are reasonably protective of aquatic life when applied as missing data for parameters in the BLM model. These data could also be used to fill in missing water chemistry parameters in the application of other metal BLM models. The most appropriate parameter selection however would include consideration of stream order in GIs estimates. Section 3 presents further refinements of estimates of the GI parameters by stream order and EPA's recommendations for default GI parameters for the BLM when data are lacking.

As with any estimate or prediction, it is appropriate to seek alternative estimates for the purpose of comparison or confirmation. If conductivity data are available for the site, either site-specific measurement data or data of opportunity from a database such as the NWIS, the regressions in EPA (2008; Appendix C) can be used to make independent estimates of the missing BLM water quality parameters. If the regression projections differ from the geostatistical average predictions, the lower (more conservative) estimate is recommended for application to ensure protection of aquatic life. As always, users of the BLM should be also encouraged to sample the water body of interest and to analyze for the constituent (parameter) concentrations as a basis for determining reliable BLM inputs.

2.2.3.5 Guidance Regarding Selection of Water Quality Parameters: pH and DOC

Although the geostatistical and regression-based approaches can be used to reliably estimate GI parameters used as BLM inputs, the same approaches do not produce accurate site-specific estimates for the two most important BLM inputs: pH and DOC. The BLM is less sensitive to the GI parameters than to pH and DOC predicting site-specific criteria for copper. Since our analysis indicates that there is little or no trend in relationships between conductivity and pH, and direct kriging produced similarly ambiguous predictions, site-specific data for pH must be used for BLM application at a site.

For DOC, analysis of NWIS data indicated a weak relationship with conductivity, so the regression approach is not appropriate for this parameter. In 2008, EPA recommended use of the ecoregional DOC concentration percentiles tabulated by EPA for the *Development of National Bioaccumulation Factors Technical Support Document* (USEPA, 2003) because they appeared to offer reasonable estimates of lower percentile DOC concentrations, and were based on substantially more DOC data than were available in the NWIS. In Section 4 of this report we further tested these ecoregional DOC concentrations for use in the BLM where site-specific data are not available.

NMED Exhibit 34

3 USING STREAM ORDER TO REFINE PREDICTION OF GI PARAMETERS

The following section discusses how stream order was used to address anthropogenic impacts. The goal is to provide BLM users with tables of appropriately protective estimates of GI parameters, building on the ecoregional work described in Section 2.

Estimations of values for the GI parameters (alkalinity, calcium, magnesium, sodium, potassium, sulfate, and chloride) tend to vary regionally. As demonstrated in Section 2, the spatial variation of these factors is generally known or at least predictable, and therefore spatial or geographic analysis of data can be used to estimate GI input parameter values. However, these values also vary due to anthropogenic impact. In the case of conductivity and GI parameters, a positive correlation between ion concentrations and measures of human activity, such as population density, urban and agricultural land use, road density, point and nonpoint pollutant sources, among other activities, is expected and may confound the pattern of geographic variability both within and between ecoregions.

One way to account for surface water quality variability within ecoregions is to distinguish water bodies according to the Strahler stream order (SO). The SO is used to define stream size based on a hierarchy of tributaries (Strahler, 1952; 1957) and may range from 1st order (a stream with no tributaries) to 12th order (the Amazon, at its mouth). First through 3rd order streams are called headwater streams (source waters of a stream). Over 80% of Earth's waterways are headwater streams (Strahler, 1957). A stream that is 7th order or larger constitutes a river. For example, the Ohio River is 8th order and the Mississippi River is 10th order. According to the River Continuum Concept, changes in water quality are commonly observed between the upper, middle, and lower reaches of a stream (FISRWG, 1998; Ward, 1992; USEPA, 2015).

In this section we consider variability in GIs by determining the SO of each surface water sampling location in the USGS NWIS[2] database, and explore methods of incorporating SO variation in the parameter estimates. Tables are provided in this section showing tabulations of parameter estimates based upon both ecoregion and SO to maximize the accuracy of estimated input parameters.

3.1 Determining SO of NWIS Surface Water Sampling Locations

GIS was used to determine the SO of each NWIS surface water sampling location. Flowlines and catchments with SO were obtained from the NHD-Plus V2 geospatial hydrologic framework (McKay et al., 2012).[3] The point locations corresponding to the latitude-longitude coordinates of the NWIS sampling stations were snapped to the NHD-Plus flowlines using ArcGIS. A spatial join was then performed between these shapefiles and the NHD-Plus flowlines to link stream order to the sampling locations. Some of the NHD-Plus flowlines did not have SO data associated with the record. When a sampling location occurred on a flowline that didn't have a SO, the SO from the catchment was used. When the catchment also did not have a SO, the SO of the nearest stream was applied. SO was added as an attribute to the information for each station in the database.

NMED Exhibit 34

3.2 Estimating BLM Parameters for Ecoregions and SO

Estimated (10th percentile) BLM water quality parameters were presented in Section 2 for 84 Level III ecoregions of the continental U.S. In the work presented here, the parameter estimates were recalculated for individual SOs or ranges (groups) of SOs within each ecoregion.

3.3 Results

The distribution of NWIS sampling locations by SO is presented in Figure 16. The largest proportion of sampled locations (78%) was found to be in SO 1 through 4.

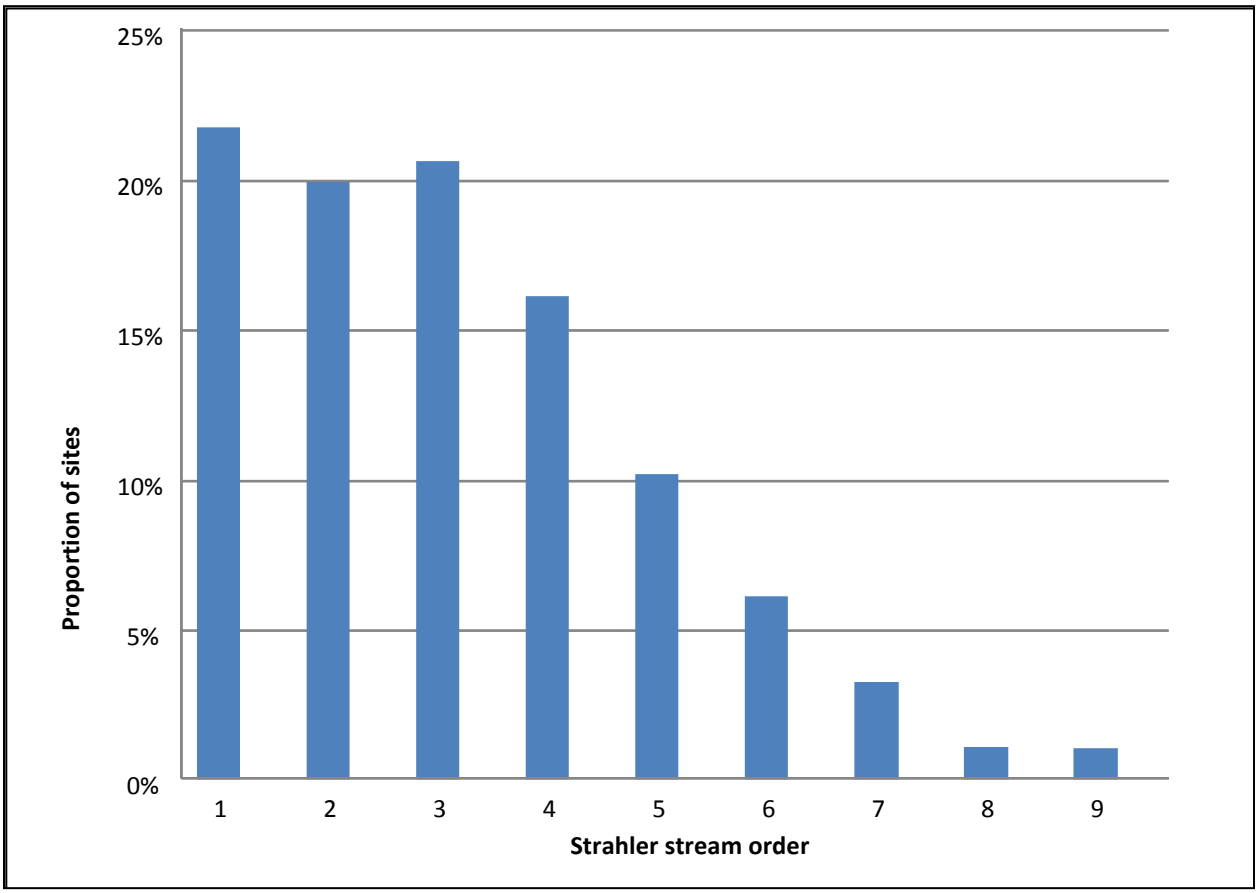

Figure 16. Distribution of NWIS surface water sampling locations by SO

3.3.1 Dependence of Ecoregional Parameter Estimates on SO

Box plots were constructed to examine how the GIs estimates varied with SO. Box plots of conductivity (Figure 17), alkalinity (Figure 18), calcium (Figure 19), magnesium (Figure 20), sodium (Figure 21), potassium (Figure 22), sulfate (Figure 23) and chloride (Figure 24) all show a general increase in the magnitude of the estimate with SO. This trend was most apparent and consistent when comparing medium stream orders (SO 4-6) to higher stream orders (SO ≥7). In addition, the upper quartile parameter estimates were generally higher in SOs 4 through 6 than in lower order streams (SO ≤3). Based upon these trends, we grouped the estimates for each parameter by SO: 1 through 3 (headwater

streams), 4 through 6 (mid-reaches) and 7 through 9 (rivers). There were no data for rivers with SO>9. Grouping simplified the presentation of results and improved the robustness of the parameter estimates, without losing significance of the SO trends. Parameter estimates for these three SO groups are included in the box plots in Figures 18 through 24, labeled as "13," "46," and "79." The classes depicted as 13, 46, and 79 reflect groupings according to SO (i.e., 1 through 3, 4 through 6, and 7 through 9).

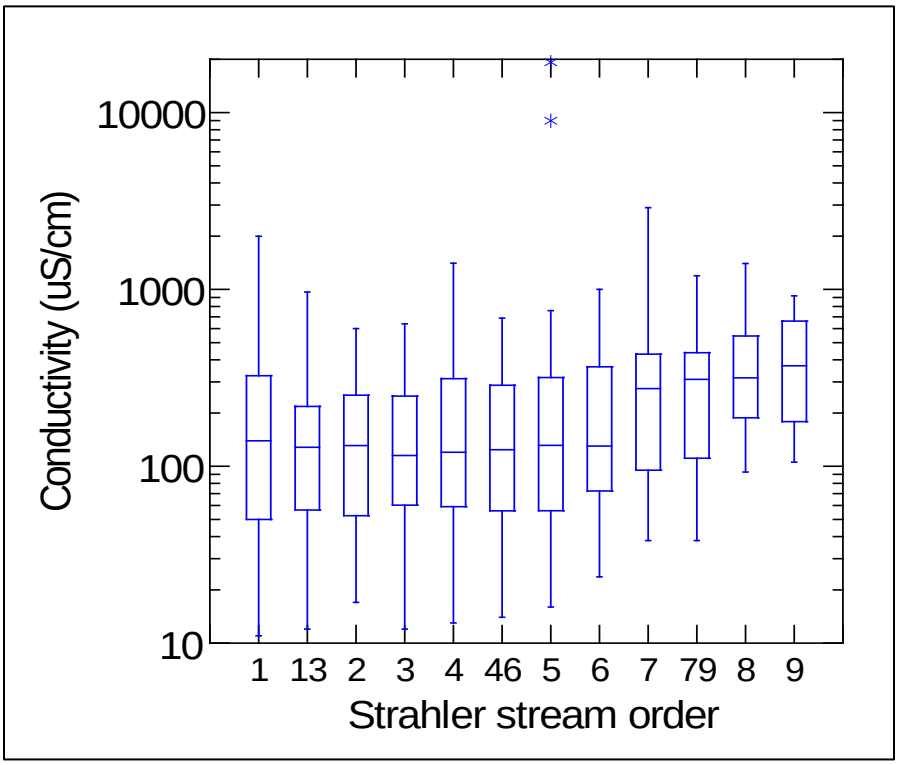

Figure 17. Box plot of estimated ecoregional conductivities as a function of SO

Note: Classifications depicted as 13, 46, and 79 reflect groupings according to stream order (i.e., 1 through 3, 4 through 6, and 7 through 9) as described in the text. For box plots, the bottom and top of each "box" displays the 25th and 75th percentile concentrations defined as the interquartile range (IQR) (i.e., the box contains 50% of the data values), respectively. The median is displayed as the horizontal line within the box. The "whiskers" show the relative distribution of data points outside of the IQR and represent 1.5 times the IQR. Data not included between the whiskers are plotted as outliers with a star/asterisk.

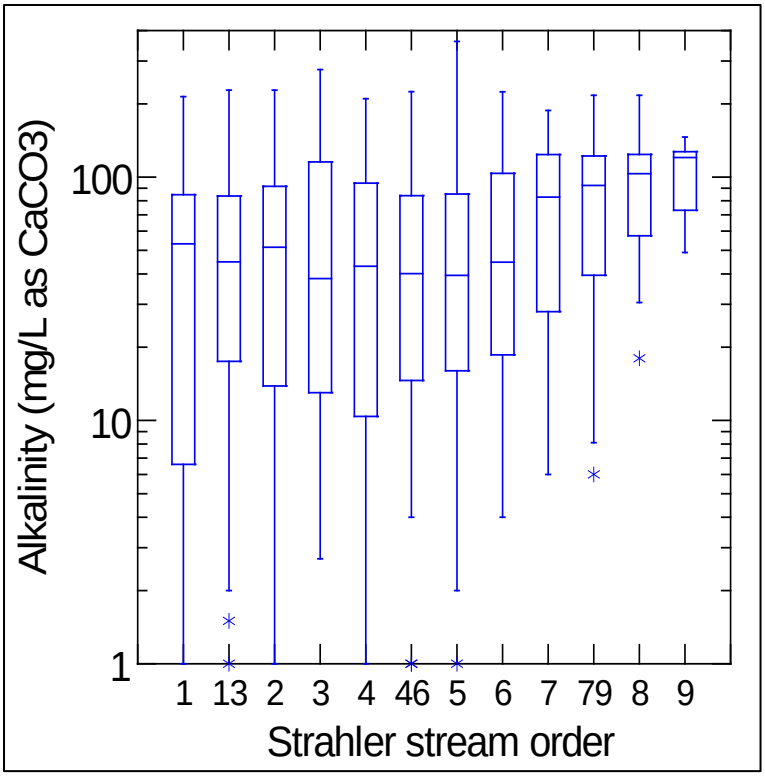

Figure 18. Box plot of estimated ecoregional alkalinity concentrations as a function of SO

(Refer to note in Figure 17.)

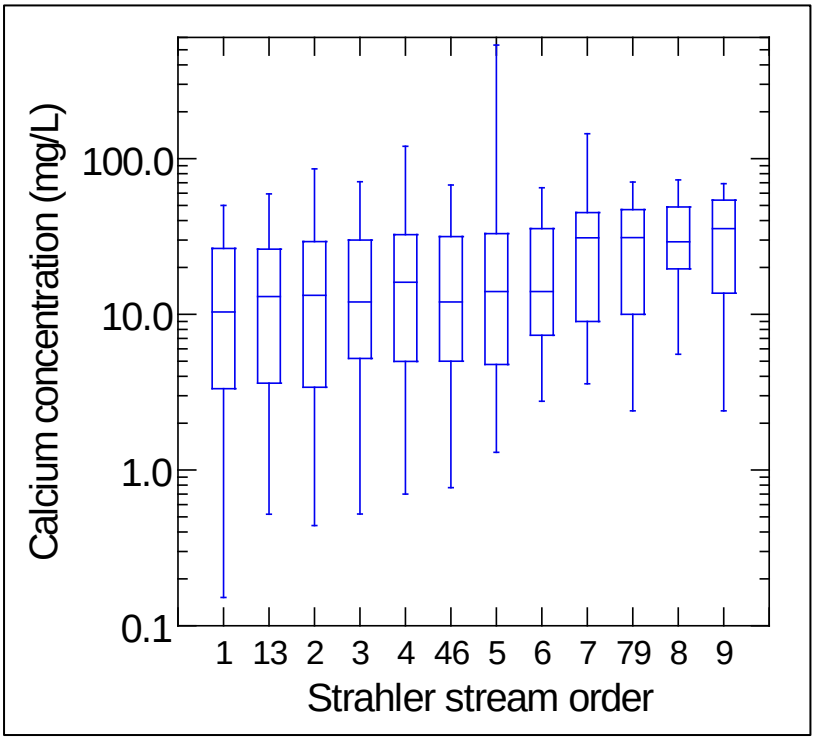

Figure 19. Box plot of estimated ecoregional calcium concentrations as a function of SO

(Refer to note in Figure 17.)

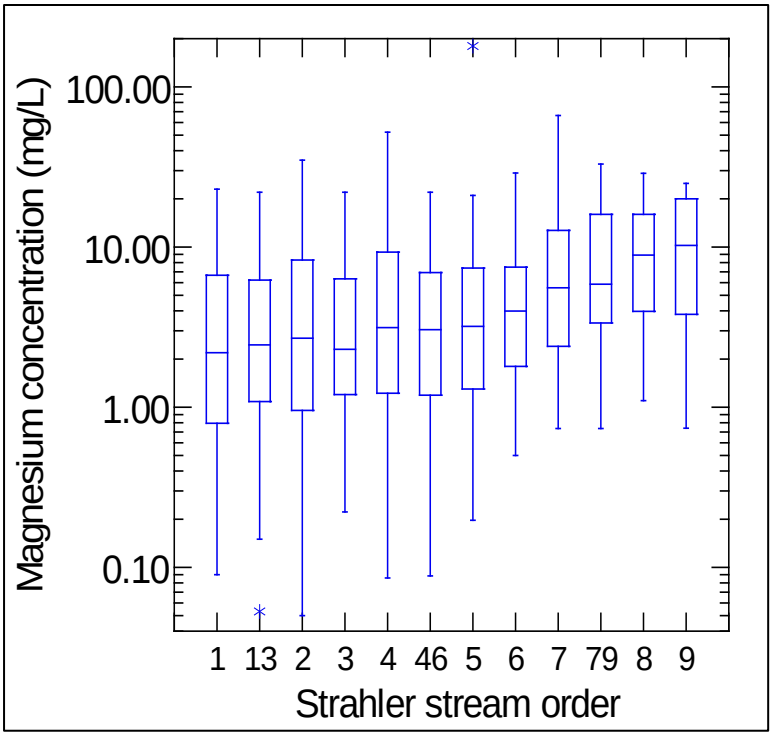

Figure 20. Box plot of estimated ecoregional magnesium concentrations as a function of SO

(Refer to note in Figure 17.)

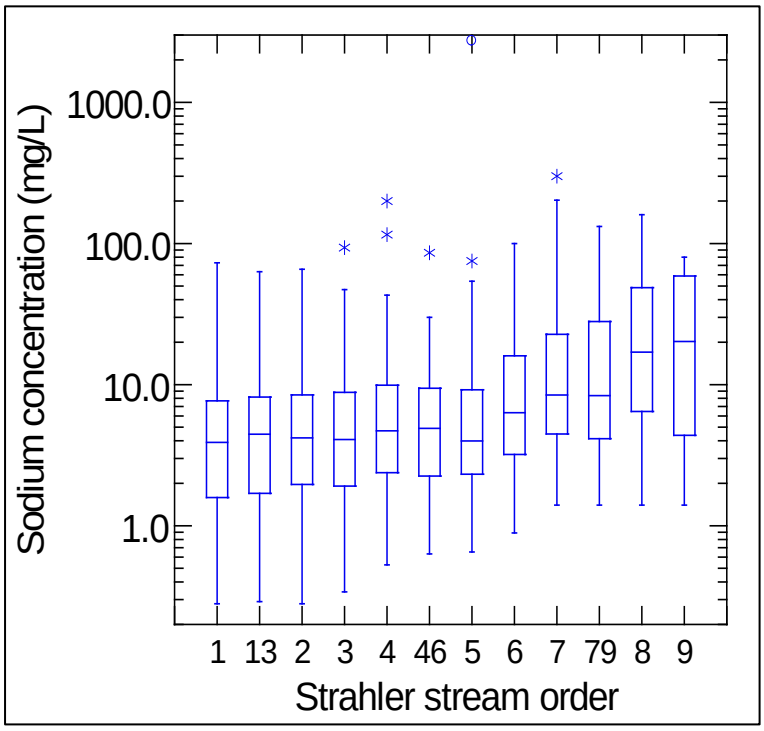

Figure 21. Box plot of estimated ecoregional sodium concentrations as a function of SO

(Refer to note in Figure 17.)

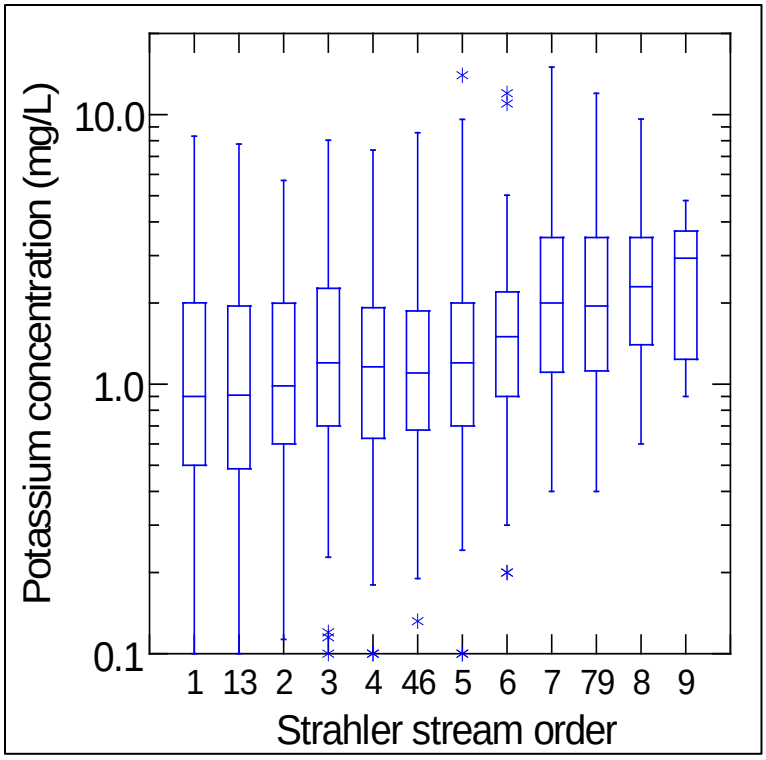

Figure 22. Box plot of estimated ecoregional potassium concentrations as a function of SO

(Refer to note in Figure 17.)

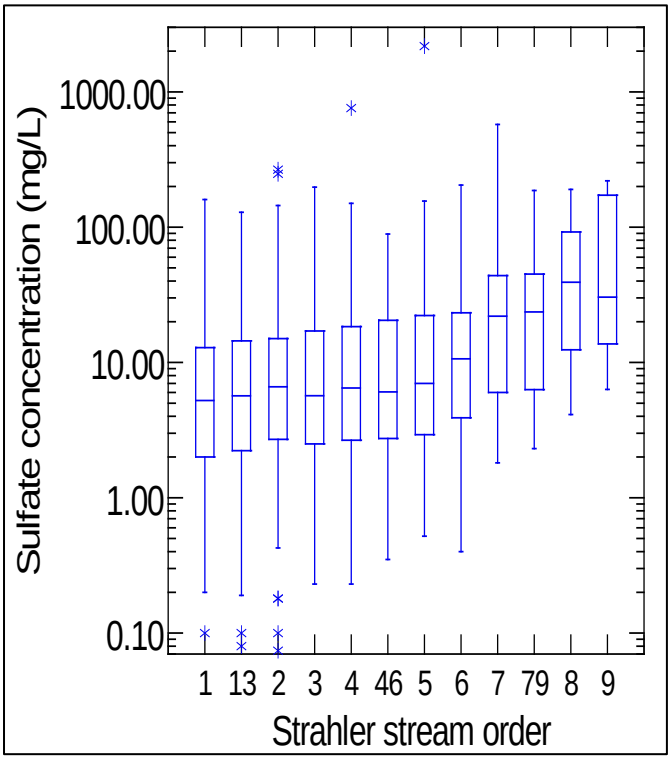

Figure 23. Box plot of estimated ecoregional sulfate concentrations as a function of SO

(Refer to note in Figure 17.)

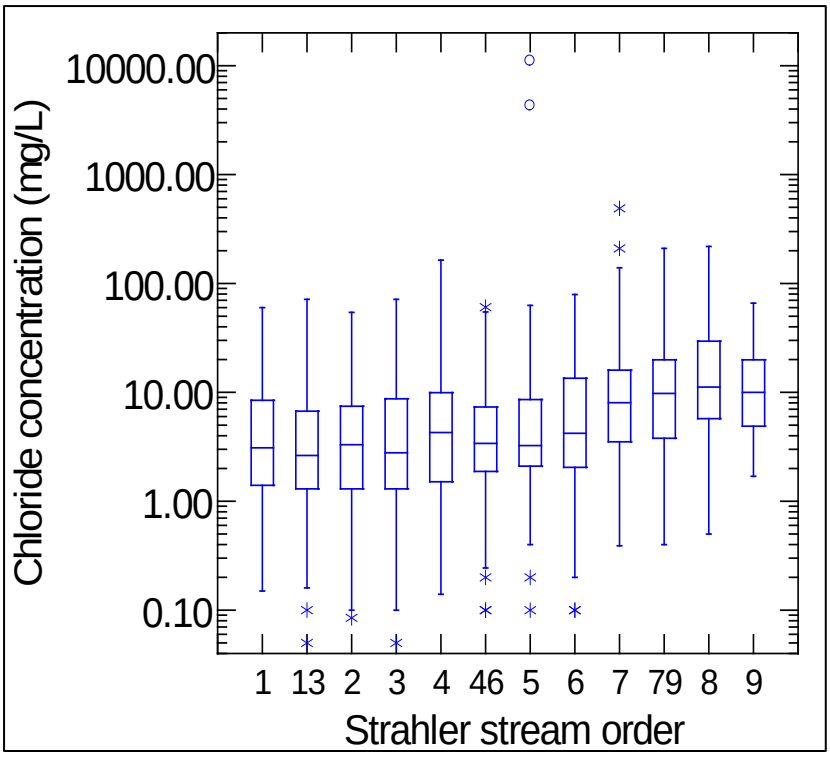

Figure 24. Box plot of estimated ecoregional chloride concentrations as a function of SO

(Refer to note in Figure 17.)

The range of values across SOs overlap greatly due to the inclusion of data across ecoregions. Tenth percentile estimates of conductivity increase with SO group in 58% of ecoregions when comparing low to medium SO groups, and 84% of ecoregions when comparing medium to high SO groups. The same trend was evident for the GIs. For example, 10th percentiles of calcium increased with SO group in 68% of ecoregions for low versus medium SO and 83% of ecoregions for medium versus high SO. In general, parameter estimates (10th percentiles of conductivity and ion concentrations) increased with SO, and the increase was most apparent and consistent for higher SOs (SO ≥7).

3.3.2 SO-Based Parameter Estimates

Tenth percentile parameter estimates for conductivity, GIs and hardness are grouped by SO and Level III ecoregions in Tables 8 through10. Tenth percentile parameter estimates for SOs 1 through 3 are presented in Table 8, for SOs 4 through 6 are presented in Table 9, and SOs 7 through 9 are presented in Table 10. The tables include the sample size for instances in which parameter estimates are highly uncertain due to limited data, i.e., cases where sample size is <10. Water quality data were limited in four ecoregions (11, 16, 49, and 78) for SO group 1 through 3, in Ecoregion 76 for SO group 4 through 6, and in 28 ecoregions for SO group 7 through 9. With the exception of the specific ecoregions and SO classes where data are limited, the parameter estimates in Tables 8 through 10 are recommended as improved default values for use in the BLM when data are not available for a location in a specific Level III ecoregion and SO group.

Table 8. Recommended 10th percentile conductivity, GIs, and hardness estimates for SO Group 1 through 3 (number of stations shown in parentheses if n<10)

84									

At the level of individual ecoregions, the trends in parameter estimates as a function of SO group often reflect the assessment presented in the previous section. In the majority of ecoregions, most of the parameter estimates increase with SO group, as illustrated in Figure 25 for Ecoregion 46, the Northern Glaciated Plains. However, other trends were observed as well. In Ecoregion 83 (Eastern Great Lakes Lowland), conductivity and cation concentrations were approximately equal in the low and high SO groups and lower in the medium SO group, as shown in Figure 26. Figure 27 illustrates the trends in Ecoregion 54, the Central Corn Belt Plains. In this ecoregion (and several others), most of the parameter estimates decreased with SO group. The explanation for different trends within ecoregions, which may reflect different causes, is beyond the scope of this effort.

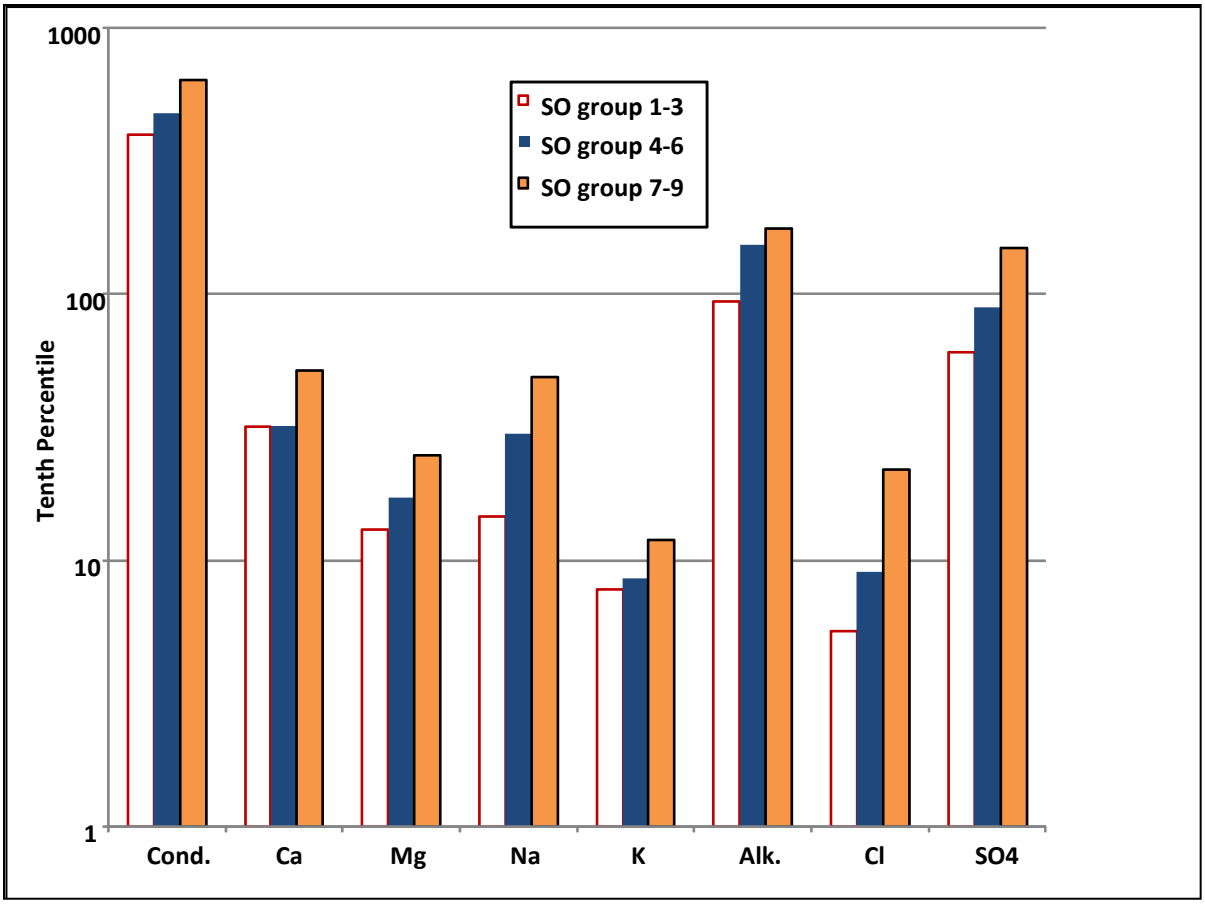

Figure 25. BLM parameter estimates (10th percentile values) for each SO group in Ecoregion 46 (Northern Glaciated Plains)

Key: Stream order: 1-3 are headwater streams, 4-6 are mid-reaches, and 7-9 are rivers.

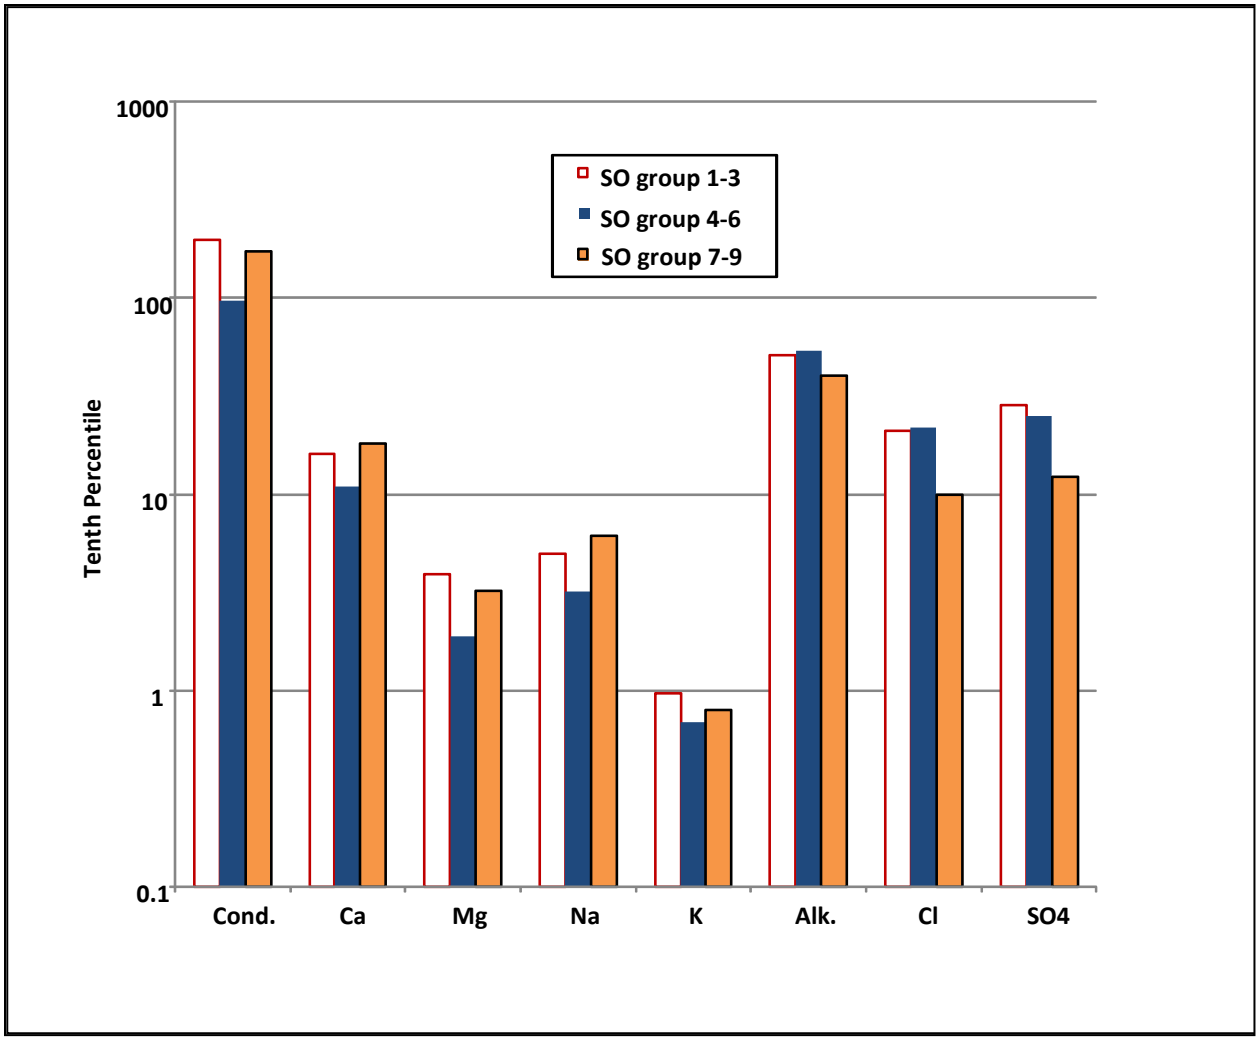

Figure 26. BLM parameter estimates for each SO group in Ecoregion 83 (Eastern Great Lakes Lowland)

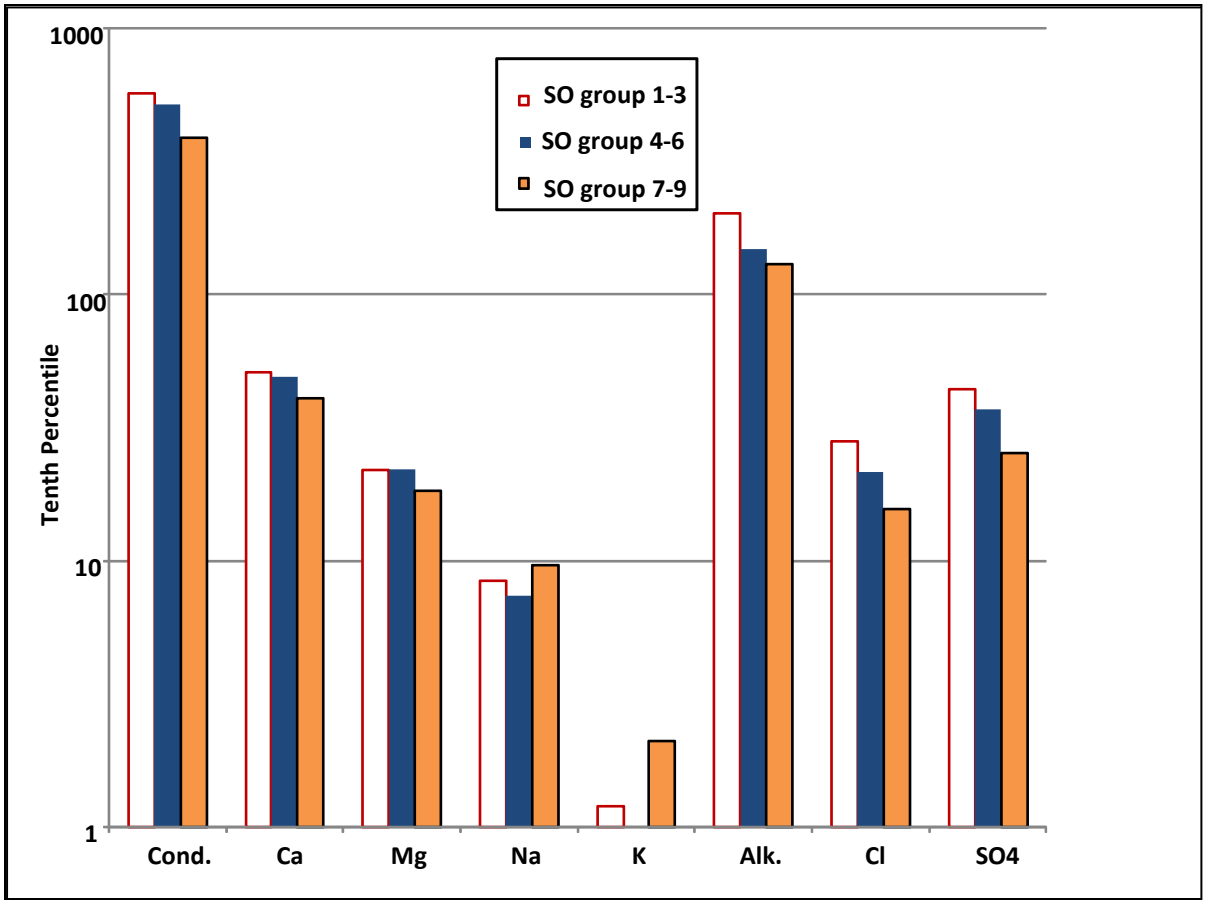

Figure 27. BLM parameter estimates for each SO group in Ecoregion 54 (Central Corn Belt Plains)

3.3.3 Comparison of Parameter Estimates to Results of Probability-Based Surface Water Sampling

There have been relatively few efforts to estimate GI concentrations in surface water at the national scale. Carleton (2006) developed a prototype geostatistical approach to estimate BLM parameters averaged over 8-digit HUC polygons. Carleton examined data from the NWIS and noted several limitations of this dataset in terms of uneven spatial sampling intensity. Carleton's prototype did not incorporate SO in the analysis, nor did it generate BLM parameter estimates.

Griffith (2014) compiled data from probability-based surface water quality sampling surveys conducted by EPA between 1985 and 2009, mostly from wadeable streams (SO group 1 through 4). These surveys included the National Acid Precipitation Assessment Program surveys, EMAP and regional EMAP surveys, WSA, and NRSA. The probability-based sample designs ensured that the results of these surveys represented the character of streams across the continental U.S. The water quality parameters included the same GIs as discussed above, and the results were presented on the same Level III ecoregion-specific basis.

We compared current results to those of Griffith (2014) because the lack of a probability-based sample design is a potential source of bias in the NWIS dataset. Parameter estimates based on the NWIS data for SO group 1 through 3 were compared to the corresponding estimates calculated by Griffith (2014). While Griffith did not tabulate 10th percentiles, he did tabulate first quartile (i.e., 25th percentile)

statistics for each ecoregion in supplemental material published with his article. Accordingly, we calculated 25th percentiles of the ecoregional NWIS data in SO class 1 through 3 (in addition to the 10th percentiles) to facilitate this comparison. The 25th percentiles from the two datasets are compared for conductivity in Figure 28 and calcium in Figure 29. The scatter plots reveal significant log-linear relationships between 25th percentiles for the two datasets; the coefficient of determination (R^2) was 0.668 for conductivity and 0.551 for calcium. For conductivity, the 25th percentiles differed by more than a factor of 2 in 17% of the Level III ecoregions; for calcium, 26% of the ecoregional results differed by more than a factor of 2.

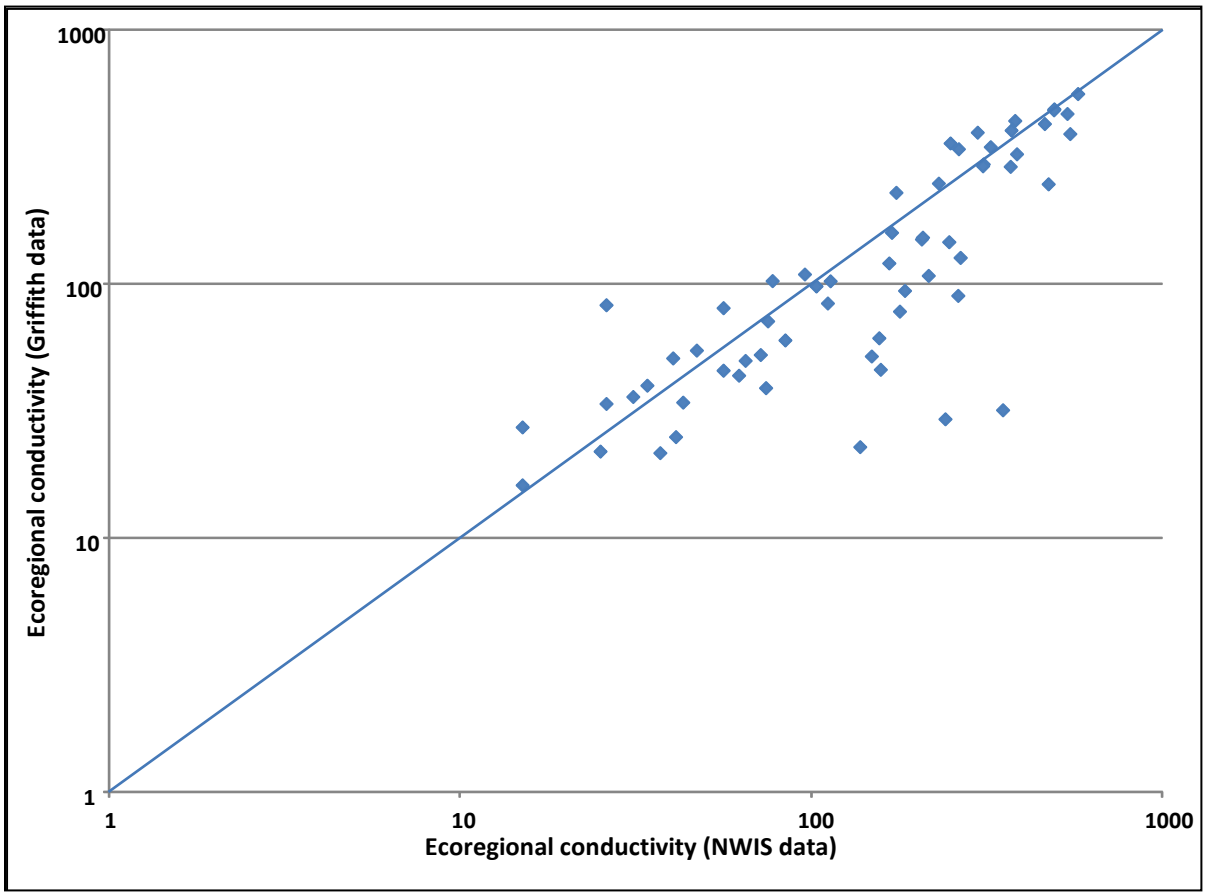

Figure 28. Scatter plot of ecoregional 25th percentile conductivity for NWIS Data (SO Class 1-3) versus ecoregional 25th percentile conductivity for Griffith data (mostly SO 1-4)

Solid diagonal line represents 1:1 agreement.

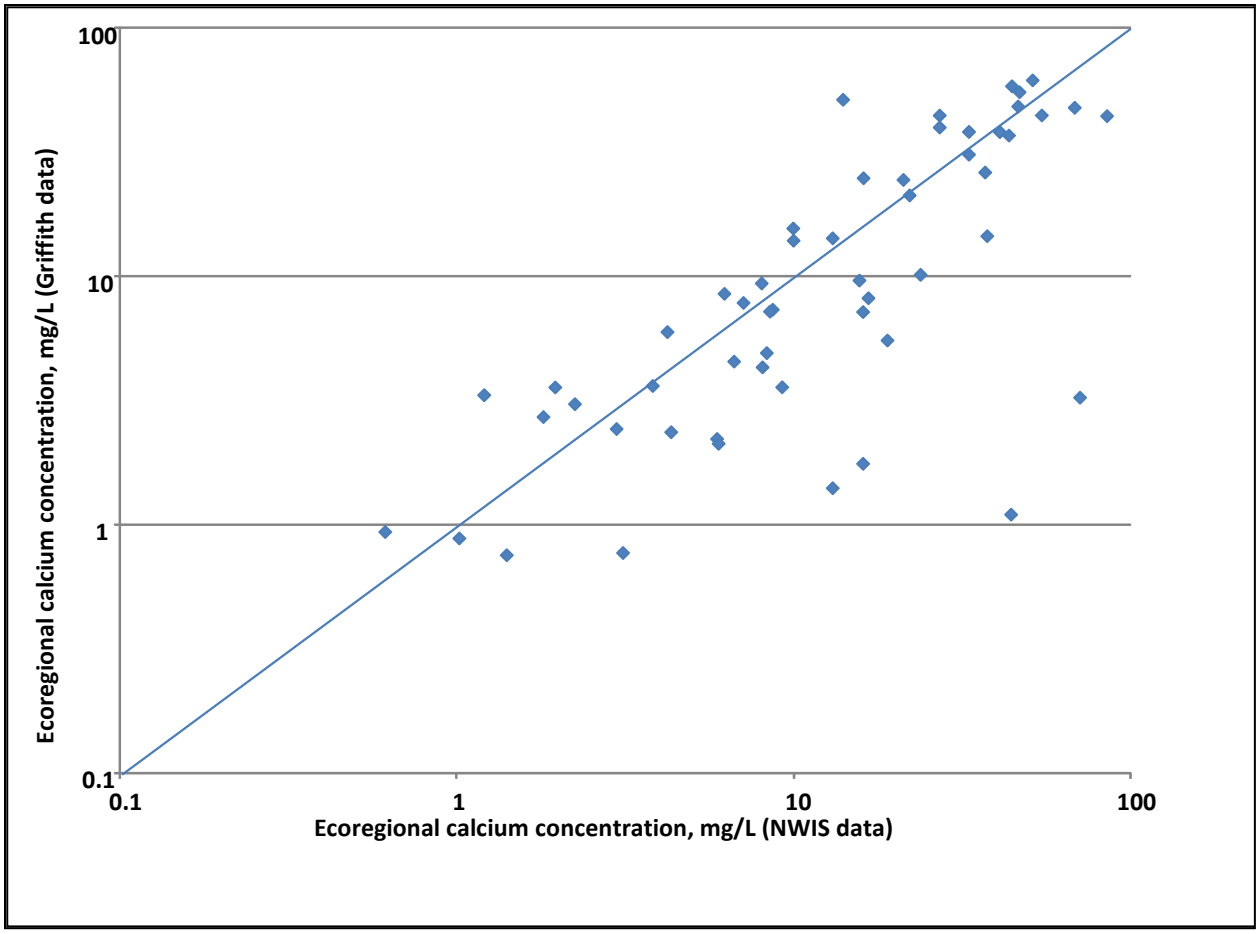

Figure 29. Scatter plot of ecoregional 25th percentile calcium concentration for NWIS data (SO class 1-3) versus ecoregional 25th percentile calcium concentration for Griffith data (mostly SO 1-4)

Solid diagonal line represents 1:1 agreement.

These results suggest reasonable overall consistency between datasets, as well as significant disparity in specific ecoregions. For example, agreement was especially poor in Ecoregions 19 (Wasatch and Uinta Mountains), 37 (Arkansas Valley), 38 (Boston Mountains), 39 (Ozark Highlands), 75 (Southern Coastal Plain), and 78 (Klamath Mountains). NWIS data were examined at the station-specific level to understand why these ecoregional 25th percentiles of conductivity and calcium in the low SO group were so inconsistent with corresponding percentiles presented by Griffith. Table 11 presents salient characteristics of the conductivity data for Ecoregion 19, including the number of stations, samples per station, 25th percentile conductivity, the lowest station-specific 25th percentile conductivity in the NWIS data, and other remarks. In that ecoregion, conductivity data were reported for 62 stations in the NWIS database; the number of observations per station ranged from 1 to 189, with a median of 22 observations per station. In comparison, the EPA data analyzed by Griffith reported conductivity data for 32 stations, with a single observation per station. The 25th percentile conductivity based on NWIS data was 240 versus 22.9 microsiemens per centimeter (µS/cm) based on Griffith's analysis of EPA data. When recalculated for individual stations in Ecoregion 19 low SO group, the 25th percentile conductivities varied widely, from 18.25 to 1590 µS/cm. Griffith reported a median conductivity of 213

µS/cm (nine times larger than the 25th percentile), indicating considerable variability in that data as well.

Table 11. Characteristics of the conductivity data for Ecoregion 19 in the low SO group.		
	NWIS data	Griffith data
Number of stations	62	32
Samples per station	1 – 189	1
Median samples per station	22	1
25th percentile conductivity (µS/cm)	240	22.9
Range of station-specific 25th percentile conductivity (µS/cm)	18.25-1590	
Other remarks	25th percentiles of conductivity reported by Griffith were marginally higher than the *minimum* station-specific 25th percentiles calculated from the NWIS data	Median conductivity = 213 µS/cm (19x the 25th percentile value) indicates high variability

The same information is tabulated for Ecoregions 37, 38, 75, and 78 in Tables 12 through 15. Although the details regarding the data vary in each of these ecoregions, a number of commonalities emerge from these examinations:

- In four ecoregions, the number of NWIS stations in SO group 1 through 3 was small relative to other ecoregions (the median number of ecoregional stations in SO group 1 through 3 was 68).
- In three ecoregions, 10th and 25th percentiles of conductivity and/or calcium decreased with SO group, contrary to the general trend.
- In three ecoregions, 25th percentiles of conductivity reported by Griffith were marginally higher than the minimum station-specific 25th percentiles calculated from the NWIS data for the corresponding ecoregion and low SO group.

Table 12. Characteristics of the conductivity data for Ecoregion 37 in the low SO group.		
	NWIS data	Griffith data
Number of stations	34	45
Samples per station	1 – 129	1
Median samples per station	2	1
25th percentile conductivity (µS/cm)	350	32
Range of station-specific 25th percentile conductivity (µS/cm)	29-846.5	
Other remarks	10th and 25th conductivity percentiles *decrease* with SO group; Small number of NWIS stations; 25th percentiles of conductivity reported by Griffith were marginally higher than the *minimum* station-specific 25th percentiles calculated from the NWIS data	

Table 13. Characteristics of the conductivity data for Ecoregion 38 in the low SO group

Range of station-specific 25th percentile conductivity (µS/cm)	19-326.5	
Other remarks	Small number of NWIS stations; 6 of 15 stations were Ashland Creek (OR) or tributaries	

It is possible that the disparities noted above arise in part from non-representative sampling in the NWIS data. For example, representativeness of NWIS data is questionable in Ecoregion 78 because 40% of the stations were sampled in a single water body. There was also a difference in the way data for repeated sampling at individual stations were processed, due to differences between the NWIS data and data compiled by Griffith. In the NWIS data, water quality was sampled repeatedly at a significant

number of stations, and we included daily averages of all of these measurements in the calculation of 10^{th} percentile estimates. In the probabilistic EPA surveys analyzed by Griffith, individual stations were usually sampled once. In the case of repeated sampling at a station, Griffith used data from only the first sample reported for the station in the statistics he calculated. This difference implies that our estimates of BLM parameters incorporate temporal as well as spatial variability in water quality, while Griffith's results do not. Thus, it would be unrealistic to expect complete agreement between these results. It should also be reiterated that sampling bias in SO is probably not a factor in these disparities because the estimates from the NWIS data were based on measurements from stream orders 1 through 3, which is generally consistent with the data compiled by Griffith (2014).

It is particularly of concern when percentiles based on NWIS data are higher than those calculated based on Griffith data because this suggests the parameter estimates may result in non-conservative BLM predictions of copper, or others metals, criteria. To evaluate this concern, we ran the BLM (version 2.1.2) using the 25^{th} percentile GI estimates of Griffith and those from the current analysis for NWIS SO group 1 through 3 for each ecoregion in which parameters were available. If the 25^{th} percentile of a GI was not available, the value was projected from the 25^{th} percentile of conductivity using regressions based on NWIS data. If the 25^{th} percentile of conductivity was not available (this occurred in 24 ecoregions), no BLM prediction was made. The inputs for pH and DOC were ecoregional values. There were 60 ecoregions where BLM predictions of copper criteria using the 25^{th} percentile GI estimates from NWIS and Griffith could be compared. The criteria estimated in these ecoregions using GI input parameters from the two sources agree very well, as shown in Figure 30. The R^2 was 0.9897, and relative percent differences (RPDs) ranged from -21 to 39% with an average RPD of 3% and a median of 0.1%.

NMED Exhibit 34

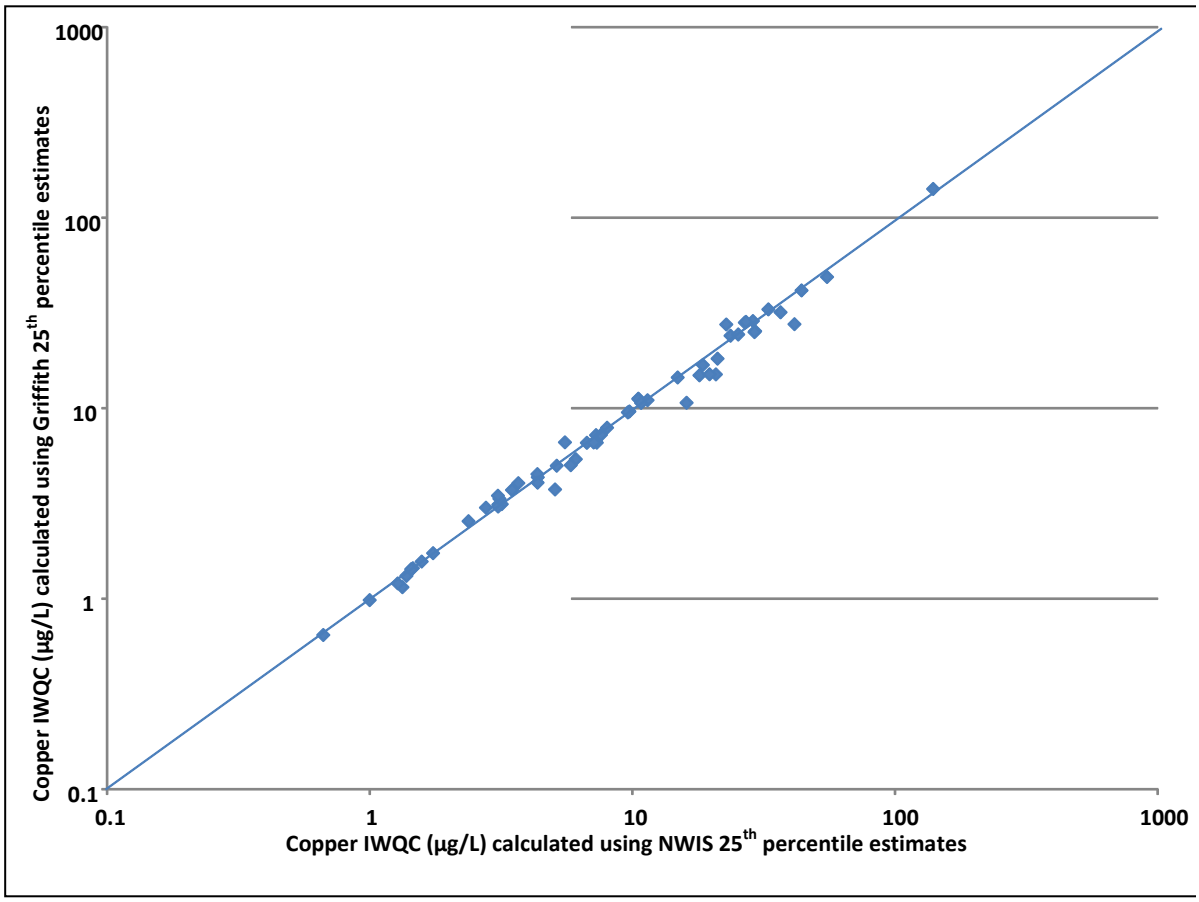

Figure 30. BLM predictions of copper criteria made with GI water quality parameters based on ecoregional 25th percentile from NWIS data (SO class 1-3) versus ecoregional 25th percentile calcium Concentration for Griffith data (mostly SO 1-4).

R^2 = 0.99. Solid diagonal line represents 1:1 agreement

While it is possible that the GI estimates presented here as recommended input values for use in the BLM for copper could be improved, it is not clear that such improvement would result in substantially better predictions of protective copper criteria based on the BLM. This is because BLM predictions for copper are much more sensitive to pH and DOC.

3.4 Summary

In this section we have incorporated SO variation in the GI water quality parameter estimates to refine the default parameters estimates for use in the BLM when data are not available.

EPA found that values of the GI parameter estimates generally increased with SO. This trend was most apparent and consistent for higher order streams (SO≥7). Tenth percentile estimates of conductivity increase with stream order group in 58% of ecoregions (comparing low to medium SO groups) and 84% of ecoregions (comparing medium to high SO groups). The same trend was evident for the GIs that are input parameters to the BLM.

We compared the parameter estimates for SO group 1 through 3 to those calculated by Griffith (2014). This comparison revealed significant log-linear relationships between 25th percentiles for the two datasets; the coefficient of determination (R^2) was 0.668 for conductivity and 0.551 for calcium. For conductivity, the 25th percentiles differed by more than a factor of 2 in 17% of the Level III ecoregions; for calcium, 26% of ecoregional results differed by more than a factor of 2. There is also considerable variability in the relationship between ecoregional statistics based on NWIS versus Griffith's data. Possible causes of these disparities may be due to sampling bias in the NWIS database, limited numbers of samples in some ecoregions, and differences in the degree and treatment of repeated sampling at individual locations.

NWIS percentiles higher than Griffith (2014) suggest that the recommended parameter estimates may result in non-conservative BLM predictions of copper criteria. The BLM was run to predict copper criteria for 60 ecoregions using 25th percentile GI estimates as parameter inputs from NWIS and Griffith's data. The criteria predicted using the two sets of GI parameter inputs agreed favorably. The R^2 was 0.990, and RPDs ranged from -21 to 39% with an average RPD of 3% and a median of 0.1%. These results demonstrated that the recommended default GI parameter estimates are reasonably conservative.

EPA incorporated SO variation in the parameter estimates to refine recommended input values for use in the BLM. EPA found the 10th percentile ecoregion, SO group specific estimates to be reasonably protective inputs and recommends their use where site-specific parameters are not readily available.

4 DOC ESTIMATION USING THE NATIONAL ORGANIC CARBON DATABASE

The following section summarizes our investigation into whether ecoregion and water body-type-specific DOC concentration percentiles tabulated by EPA for the *Development of National Bioaccumulation Factors Technical Support Document* (hereafter referred to as the National Organic Carbon Database (NOCD)) (USEPA, 2003)) offer reasonable estimates of lower-percentile DOC concentrations. A summary of the NOCD's data sources, analysis, and uncertainty associated with ecoregional statistics derived from the NOCD is provided below. This section also discusses how we recalculated ecoregional DOC percentiles for rivers and streams, and then tested for bias in the NOCD. Finally, we compared results based on the NOCD and data from the Wadeable Stream Assessment (WSA) (USEPA, 2006b)) and the National River and Stream Assessment (NRSA) (USEPA, 2013)).

4.1 Description of the NOCD

The NOCD is a compilation of pre-2003 organic carbon data derived from two sources: EPA's Storage and Retrieval Data Warehouse (STORET), recently renamed the STORET Legacy Data Center (LDC), and USGS's National Water Data Storage and Retrieval System (WATSTORE), the predecessor of NWIS. A complete background on the NOCD is available in USEPA 2003.

EPA's LDC database contains water quality monitoring data collected by academia, volunteer groups, and tribes, as well as federal, state, and local agencies. Geographically, the LDC data represent all 50 states and all U.S. territories and jurisdictions, along with portions of Canada and Mexico. The database queried for this investigation is often referred to as the "historical" or "old" STORET database because it contains water quality data dating back to the early part of the 20th century through the end of 1998. Data from 1999 to the present are stored in the "modernized" STORET Data Warehouse.[4] The LDC contains raw biological, chemical, and physical data for both surface water and groundwater. Each sampling result is accompanied by: information on sample collection location (latitude, longitude, state, county, HUC, and a brief site description), date the sample was gathered, the medium sampled, and the name of the organization that sponsored the monitoring.

We retrieved data from LDC and WATSTORE in January 2000. Approximately 800,000 records containing data on particulate organic carbon (POC), dissolved organic carbon (DOC), or total organic carbon (TOC) were obtained for the period beginning in 1970 through the latest year that data were available (1999 for WATSTORE and 1998 for LDC). This initial retrieval was limited to samples taken from ambient surface waters (i.e., samples from wells, springs, effluents, and other non-ambient sources were excluded). Additionally, this retrieval included multiple types of organic carbon measurements to ensure that the data would be sufficiently comprehensive.

WATSTORE was established in 1972 to provide an effective and efficient means for processing and maintaining water data collected through USGS activities and to facilitate release of that data to the public. The WATSTORE database resides on the central computer facilities of the USGS and contains results of approximately two million analyses of both surface and groundwater that provide data on

[4] Refer to http://www.epa.gov/storet/dbtop.html for more information on the STORET Data Warehouse and the LDC.

NMED Exhibit 34

chemical, physical, biological, and radiological characteristics. EPA queried WATSTORE, the Water Quality File, to retrieve DOC data.

After retrieval, the data from LDC and WATSTORE were combined into a single database. The data were then processed and screened to ensure that only the most appropriate data would be retained. This screening process is outlined below:

- Values that were coded in such a way as to suggest uncertainty in the measurement were deleted from the database.
- The database was restricted to the following water body types: estuaries, lakes, reservoirs, and streams (including rivers).
- "Pseudo-ecoregions" were added for the five Great Lakes.
- The time period for the data was restricted to 1980 through 1999.
- Some values for DOC were reported to be below analytical detection levels. In this situation, the value was assumed to be half of the reported detection level. Values with "high" detection levels (i.e., >1.0 mg/L for DOC) were deleted from the database because of the greater uncertainty involved in estimating definitive values of DOC in these situations.
- A small fraction of the DOC and POC concentrations obtained from the LDC database exceeded concentrations considered to represent upper limits of DOC concentrations reported in U.S. water bodies (i.e., 0.2% exceeded 60 mg/L for DOC). These extreme values were based on a review of organic carbon data by Thurman (1985), who reported extreme values of DOC concentrations as high as 50 mg/L in dystrophic lakes and 60 mg/L in tributaries draining wetland systems. Therefore, values for DOC above 60 mg/L were removed from the database.

The NOCD that resulted from processing and screening data retrieved from the LDC and WATSTORE databases has some limitations, which are described below:

- The WATSTORE and LDC databases do not reflect a random sampling of U.S. surface waters. They contain datasets with a diversity of sampling design and thus data may be biased towards locations and water bodies with known water quality impairments.
- These data also reflect spatial bias due to unequal sampling efforts in different areas. For example, about half of the DOC and POC values in the databases were from samples collected in Maryland, New York, Ohio, Florida, and Delaware. Therefore some states are disproportionally represented, even when one considers the relative surface water area likely to be contained within each state.
- WATSTORE and LDC generally contain more data from sampling sites in larger river and stream systems, and areas subjected to proportionately greater human influence compared with random statistical sampling.

4.2 Recalculation of Ecoregional DOC Percentiles for Rivers and Streams

Lower percentile (1^{st}, 5^{th}, 10^{th}, and 25^{th} percentiles) DOC concentrations were calculated from all data for rivers and streams in each Level III ecoregion (Table 16). Nonparametric (i.e., rank) percentiles were calculated following the recommendations of Dierickx (2008) and Hyndman and Fan (1996). We also calculated confidence limits for the percentiles using the method presented in Berthouex and Brown

NMED Exhibit 34

(1994). Upper and lower 95% confidence limits (UCLs and LCLs) were calculated if 20 or more DOC concentrations were available for an ecoregion (Berthouex and Brown, 1994).

Table 16. Lower percentile values of DOC in U.S. streams and rivers by ecoregion, including 95% confidence limits for percentile concentrations if n>20.

As was the case for the BLM GI input parameters, we consider low percentiles of the ecoregional DOC concentration distributions to be reasonably protective inputs to the BLM for sites where DOC measurements are not available.

4.3 Testing for Bias in the NOCD

EPA conducted an evaluation of bias in the NOCD (USEPA, 2003) using data from EPA's Environmental Monitoring and Assessment Program's (EMAP) 1997 to 1998, which sampled mid-Atlantic streams and rivers (USEPA, 2006b). This effort is described below in Section 4.3.1.

We also evaluated the bias in the NOCD using independent data from EPA's Wadeable Streams Assessment (WSA), which included DOC measurements from a statistically based random sample of approximately 2,000 wadeable, perennial 1st through 5th order streams (USEPA, 2006c). In Section 4.3.2, we compare the WSA data to the ecoregion-specific DOC concentration percentiles calculated from the NOCD.

4.3.1 Previous Efforts Using EMAP Data

Ideally, the data used to generate the distribution of national organic carbon concentration values should originate from a random sampling of U.S. surface waters, and should be appropriately stratified and weighted by spatial and temporal factors that would be expected to influence organic carbon concentrations in aquatic ecosystems (e.g., water body type, hydrologic and watershed characteristics, ecoregion, season). However, these data are not available on a national scale. The strength of this analysis is that the data from USGS's WATSTORE and EPA's LDC databases include a large number of

records (e.g., >110,000 DOC values), a representation of DOC values for all 50 states, and reasonably long period over which data were collected (1980 through 1999 for these analyses).

Data generated by EMAP are based on a stratified, random sampling strategy that was specifically designed to minimize the influence of sampling bias on the data and to enable statistically based extrapolations across geographic regions (Herlihy et al., 2000). At the time the NOCD was developed, the EMAP databases containing DOC measurements were limited to smaller geographic scales and specific water body types.

Previously, to address the question of sampling bias and its impact on the representativeness of the NOCD values, EPA made quantitative comparisons that involved contrasting geographically distinct subsets of the WATSTORE/LDC databases with geographically similar subsets of data produced by EMAP. DOC data from EMAP's 1997 to 1998 sampling of mid-Atlantic streams and rivers were compared with similar geographic subsets from the WATSTORE/LDC databases. The mid-Atlantic EMAP database was chosen because sufficient DOC data were available for rivers and streams to make meaningful comparisons at the state and ecoregion levels. Similar comparisons are made for four mid-Atlantic ecoregions (Piedmont, Ridge and Valley, Central Appalachians, Western Allegheny Plateau) which is well represented in the WATSTORE/LDC databases (USEPA, 2003).

Based on both sets of comparisons, it is apparent that the agreement between the WATSTORE/LDC and EMAP data was best at the middle to lower tails of the distributions, and poorest at the higher end of the distributions. At the lower tails of the distributions (e.g., 10^{th}, 25^{th} percentiles) the WATSTORE/LDC DOC data are generally within 30% of the EMAP data (Ecoregion 70 being the only exception). The median DOC values of the WATSTORE/LDC data show a slightly higher bias compared with median values from the EMAP data, but are usually within a factor of 1.5 (Ecoregions 47 and 70 are about a factor of 2 greater). This result is expected, given the greater focus of the WATSTORE/LDC sampling sites on larger river and stream systems, and on areas subjected to proportionately greater human influence compared with the EMAP sampling sites. Since EPA is interested in supporting the generation of BLM values that are protective of aquatic life, the lack of bias noted for the lower tails of the DOC concentration distributions is noteworthy.

4.3.2 Testing for Bias Using Data from the WSA

A more comprehensive evaluation of the effects of sampling bias on the NOCD can now be made using the results of national statistically-designed water quality sampling surveys. We assembled a database of organic carbon data from 1,313 randomly selected sites throughout the continental U.S. collected for the WSA. GIS procedures were used to associate each site with the Level III ecoregion corresponding to its location.

The 1,392 sites sampled for the WSA were identified using a probability-based sample design, a technique in which every element in the population has a known probability of being selected for sampling (USEPA, 2006). This ensured that the results of the WSA reflect the full range of variation among wadeable streams across the U.S. The target population for the WSA was wadeable, perennial streams in the conterminous U.S. (lower 48 states). The WSA used the National Hydrography Dataset (NHD), a comprehensive set of digital spatial data on surface waters (USGS, 2012), to identify the location of wadeable perennial streams. Rules for site selection included weighting to provide balance in the number of stream sites from each of the 1^{st} through 5^{th} SO size classes (Strahler, 1952, 1957),

and controlled spatial distribution to ensure that sample sites were distributed across the U.S.). The basic sampling design drew 50 sampling sites randomly distributed in each of the EPA Regions and WSA ecoregions. The unbiased site selection of the survey design ensures that assessment results represent the condition of the streams throughout the nation.

4.3.2.1 Selection of Statistical Test to Assess Potential Bias in DOC Data

The most appropriate statistical test for determining bias in the NOCD is the comparison of WSA and organic carbon database DOC data within each ecoregion as independent groups of data to determine if one group tends to contain larger values (Helsel and Hirsch, 2002; USGS, 2002). The WSA and organic carbon database DOC data are independent because there is no natural structure in the order of observations across groups. A nonparametric statistical test is most appropriate since no assumptions regarding normality of the data are required. As noted by Helsel and Hirsch (2002), nonparametric tests are, in general, never worse than their parametric counterparts in their ability to detect departures from the null hypothesis, and may be better. These considerations led us to select the rank-sum test, a nonparametric procedure for determining whether data are significantly different between two independent groups. This test is also known as the Wilcoxon Rank-Sum Test or, alternatively, the Mann-Whitney U-Test.

In its most general form, the rank-sum test is a test to determine whether one group tends to produce larger observations than another group. It has as its null hypothesis:

H_0: Prob [x > y] = 0.5

where x are data from one group and y are from another group (the probability of an x value being higher than any given y value is one-half). The test is typically used to determine whether two groups come from the same population (same median and other percentiles), or alternatively whether they differ only in location (central value or median). If both groups of data are from the same population, about half of the time an observation from either group could be expected to be higher than that from the other, so the above null hypothesis applies. If the groups belong to different populations the null hypothesis does not apply.

In practice, the rank-sum test takes several forms, depending upon the size of the smaller sample (*n* observations) and the larger sample (*m* observations). Walpole and Myers (1978; Section 13.2) present the details of four alternative forms of the rank-sum test, depending on the sizes of *n* and *m*. The exact form of the rank-sum test is the only form appropriate for comparing groups of sample sizes of 10 or smaller per group. When both groups have samples sizes greater than 10 (*n*, *m* > 10), the large-sample approximation may be used.

4.3.2.2 Rank-Sum Test Comparing WSA DOC Data to NOCD

Table 17 presents the results of the rank-sum test comparing Level III ecoregional DOC data from the WSA (USEPA, 2006b) and the NOCD. The left-hand columns present statistics (sample size, median, and Mann-Whitney U_x, and U_y) for the ecoregion-specific DOC data from the two datasets. The next six columns to the right present the test statistics for the appropriate form of the rank-sum test. The right-hand column provides a summary interpretation of the test for each ecoregion indicating whether the null hypothesis (H_0: DOC concentrations from both datasets are not different) should be rejected at the 5% level of significance, in favor of the alternative hypothesis (H_1: DOC concentrations are higher in the

NMED Exhibit 34

national organic carbon database). In other words, rejection of the null hypothesis implies that DOC concentrations from the National Organic Carbon Database are biased high in that ecoregion relative to the WSA data.

4.3.3 Results and Implications of Bias Testing

The results of the rank-sum test indicate that DOC concentrations from the NOCD are biased high (i.e., the null hypothesis was not rejected) in 52 of 81 (64%) of Level III ecoregions in which comparable data were available (no comparison was possible in four ecoregions). For those ecoregions where the null hypothesis was not rejected, BLM users can be confident that the lower percentile DOC concentrations listed in Table 16 are representative for that ecoregion.

For ecoregions where the null hypothesis was rejected, the result suggests that the DOC data from the national organic carbon database are from biased samples. Recall discussion of both database in Sections 4.3, 4.3.1, and 4.3.2 that WSA is a random design sampling that ensures unbiased site selection. Whereas the NOCD is more influenced by locations with known water quality impairments and reflect unequal sampling efforts potentially creating a bias. It is likely that the percentile DOC concentrations tabulated for those ecoregions in Table 16 also reflect this bias towards high concentrations. This was confirmed by comparing the probability distributions of DOC concentrations in the ecoregions where n and m were large (n, m > 30).

In large-sample ecoregions where the null hypothesis was rejected by the rank-sum test (Ecoregions 1, 6, 11, 13, 23, 43, and 47), the probability distributions also show that the DOC concentration percentiles are substantially different, with the NOCD showing higher values. An example of such a comparison of DOC probability distribution is shown in Figure 31. On the other hand, in such large-sample ecoregions where the null hypothesis was not rejected (Ecoregions 17, 21, and 77), the probability distributions show that the DOC concentration percentiles are comparable. An example of such a probability distribution is shown in Figure 32. In all cases where it was possible to compare the DOC probability distributions, the results of the rank-sum test were confirmed.

NMED Exhibit 34

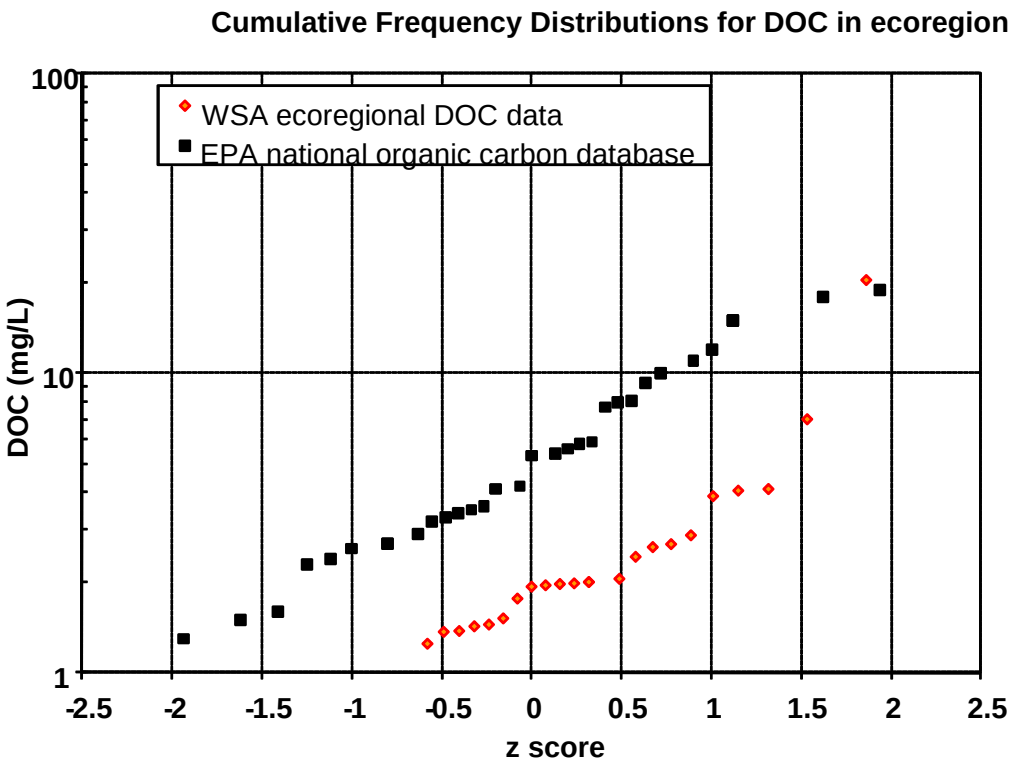

Figure 31. Comparison of probability distributions of DOC concentrations in Ecoregion 23

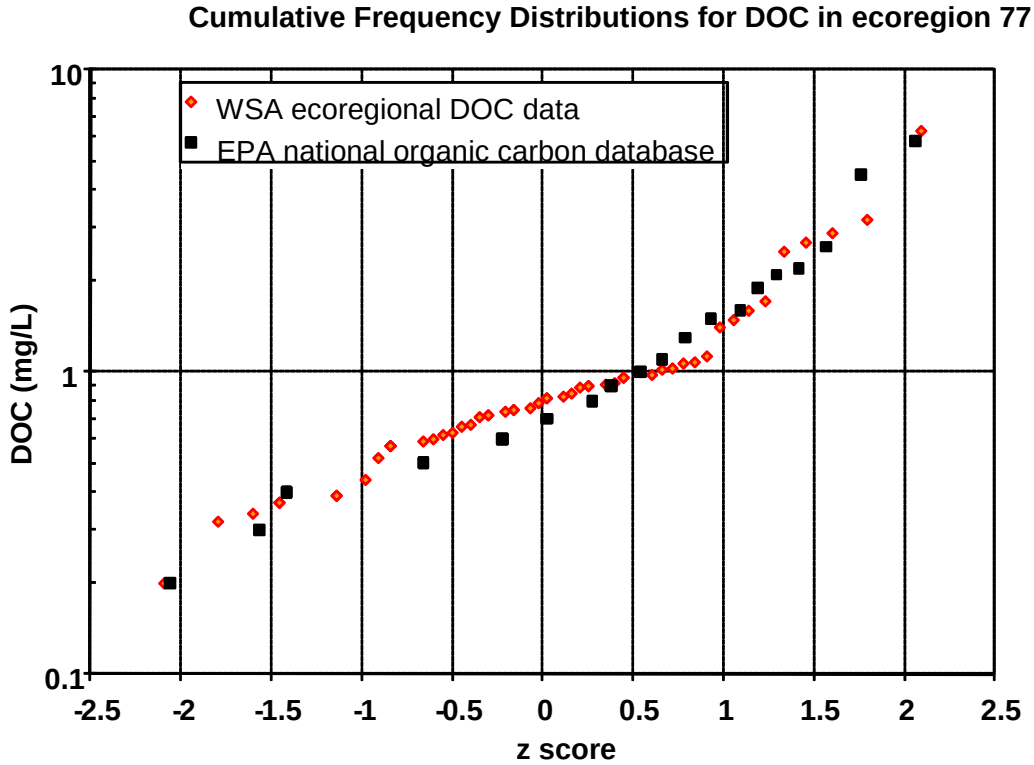

Figure 32. Comparison of probability distributions of DOC concentrations in Ecoregion 77

Because using a DOC concentration that is biased high as input to the BLM may lead to a non-conservative (high) site-specific copper criterion, it would be inappropriate to use the 10th percentile DOC concentrations in Table 16 for ecoregions in which the data from the NOCD come from biased samples.

We have not addressed the issue of whether the streams sampled for the WSA are representative in terms of DOC concentrations for all lotic (flowing) waters. It is possible that larger rivers may have DOC concentrations that are different from streams. For this reason, we recommend that the estimated ecoregional DOC values be compared to data from EPA's NRSA (NRSA, USEPA, 2013b; EPA 841-D-13-001). If necessary, adjustment of the estimated DOC values can be made at that time.

4.4 Comparing NOCD to WSA/NRSA DOC Data

The representativeness of the DOC data in the NOCD was evaluated by statistically comparing the data, at the ecoregional level, with the combined DOC data from two smaller random statistical surveys of rivers and streams. The two smaller surveys were:

(1) the 2004-05 WSA (1,313 sites), and

(2) the 2008-09 NRSA (2,113 sites).

The NRSA was the first nationally consistent survey assessing the ecological condition of the full range of flowing waters in the conterminous U.S. The target population includes the Great Rivers (such as the Mississippi and the Missouri), small perennial streams, and urban and non-urban rivers. Run-of-the-river ponds and pools are included, along with tidally influenced streams and rivers up to the leading edge of dilute sea water.

NRSA sampling locations were selected by random selection. The locations of perennial streams were identified using the EPA-USGS National Hydrography Dataset Plus (NHD-Plus), a comprehensive set of digital spatial data on surface waters at the 1:100,000 scale. Information about stream order was also obtained from the NHD-Plus. The 1,924 sites sampled for the NRSA were identified using a probability-based sample design. Details about the NRSA probabilistic sampling design are described in Section 1.1 of the NRSA: Field Operations Manual (USEPA, 2007; EPA-841-B-07-009). Site selection rules included weighting to provide balance in the number of river and stream sites from each of the size classes. Site selection was also controlled for spatial distribution to make sure sample sites were distributed across the U.S. Among these randomly selected sample sites were 359 of the original 2004 WSA sites. These were revisited as part of the NRSA to examine whether conditions have changed. When sites were selected for sampling, research teams conducted office evaluations and field reconnaissance to determine if the sites were accessible or if a river or stream labeled as perennial in NHD-Plus was, in fact, flowing during the sampling season. If a river or stream was not flowing or was determined to be inaccessible, it was dropped from the sampling effort and replaced with a perennial river or stream from a list of replacement sites within the random design.

The DOC data from these two smaller datasets were combined and described, hereafter, as WSA/NRSA data. GIS was used to determine which sampling sites were in each Level III ecoregion. The statistical test used was the non-parametric Wilcoxon 2-sample test, with a null hypothesis that DOC concentrations in the two different DOC sample datasets were equal. The alternative hypothesis was that DOC concentrations in the NCOD were significantly greater than those in the WSA/NRSA data,

NMED Exhibit 34

indicating positive bias possibly due to over-representation of impacted sites. The test was applied for each of 84 Level III ecoregions at alpha=0.05.

Table 18 below includes the number of data (n) in each ecoregion, and the 10th percentiles of DOC based upon data from the EPA DOC database (NOCD) and the combined WSA/NRSA data. For each ecoregion, the table also provides the result of the Wilcoxon 2-sample test, in terms of whether the null hypothesis (the two samples are equal) should be accepted or rejected. The null hypothesis was rejected in 59 of 83 ecoregions, indicating bias in DOC concentrations higher in the national organic carbon dataset for the majority of ecoregions. In these 59 ecoregions, low-end percentiles based on DOC concentrations in the WSA/NRSA data were selected as reasonably protective estimates of ecoregional DOC concentrations.

Table 18. DOC concentrations (mg/L) in each Level III ecoregion based upon data from the NOCD and the combined WSA/NRSA data: number of data (n); 10th percentiles; and results of the Wilcoxon 2-sample test

In the 24 ecoregions where the null hypothesis was not rejected (i.e., no significant difference in DOC concentrations was found between datasets), the data were combined and the percentiles of the combined dataset were recalculated (Table 19). In these 24 ecoregions, low-end percentiles based on DOC concentrations in the combined data (NOCD and WSA/NRSA) were selected as reasonably protective estimates of ecoregional DOC concentrations.

Recommended DOC estimated values for 83 of the 84 ecoregions are summarized in Table 20. In the remaining ecoregion (76; Southern Florida Coastal Plain), there were insufficient data in either dataset (NOC database or WSA/NRSA) to calculate DOC concentration percentiles.

Table 19. DOC concentrations (mg/L) in 24 ecoregions where no significant difference in DOC concentrations was found between national organic carbon database (NOCD) and the WSA/NRSA datasets: number of data (n); 10th percentiles from combined NOCD & WSA/NRSA data

4.5 Conclusions

EPA tested the 10th percentiles of ecoregional DOC concentrations against data from the Southern Rocky Mountains (Level III Ecoregion 21) as input to the copper BLM. Broad ranges of errors (including some that were larger than an order-of magnitude) were observed in BLM predictions made with the DOC estimates, in comparison to predictions made with actual measured site data. Although the copper criteria values predicted using the parameter estimates for DOC were found to be protective in 90% of the cases, in many of these cases these predictions were overly-protective (e.g., IWQC lower by a factor of 4 to 5). For this reason, BLM users should be cautious when considering lower percentiles of the distribution of DOC as estimates for missing input parameters to the BLM. In general, it is preferable to use site-specific measurements of DOC as BLM input because: (1) copper toxicities (and BLM model predictions) are highly sensitive to DOC concentrations and (2) reasonably protective DOC concentrations can be difficult to estimate at the ecoregional level, when data are limited.

For many ecoregions, the EPA recommended percentiles in Table 20 are based upon a relatively small number of DOC data, which can be a cause for concern in terms of the reliability of these values. For

NMED Exhibit 34

example, in 47 ecoregions the DOC percentiles were calculated from 50 or fewer concentration values, and in seven ecoregions the DOC percentiles were calculated from fewer than 10 values. In the former case (n≤50), the lower 95% confidence limit of the 10^{th} percentile cannot be calculated (Berthouex and Brown, 1994), while in the latter (n<9) the 10^{th} percentile itself is below the lowest concentration value. Because of these and other limitations on the DOC database and the importance of this parameter in criteria calculation, users are encouraged to sample for DOC as a basis for determining BLM input rather than using default parameters where possible.

5 SUMMARY AND RECOMMENDATIONS

The BLM predicts acute copper toxicity based on site-specific water quality parameters, and calculates aquatic life criteria based on the predicted copper toxicity. The BLM requires 10 input parameters to calculate copper criteria: temperature, pH, DOC, alkalinity, calcium, magnesium, sodium, potassium, sulfate, and chloride, the last seven of which are also referred to as GIs. Given the broad geographical range over which the BLM is likely to be applied, and the limited availability of data for input parameters in many areas, a practical method to estimate missing water quality parameters was developed to support the use of the copper BLM for copper aquatic life criteria.

In this report we described three approaches EPA used to estimate default input parameters for GI and DOC for BLM that could be used where site-specific data are not available. EPA's goal was to provide estimates for these missing input parameters that are reasonably protective. EPA used geostatistics to predict ecoregional input parameters from national water quality databases, and developed correlations between GI parameters and conductivity. These estimates were further refined using stream order.

Our analysis of national data indicates that there is no relationship between conductivity and pH, and geostatistical methods were found to produce similarly ambiguous results. Because pH is one of the most important BLM inputs for predicting criteria for copper, we conclude that site-specific data for pH are needed for successful BLM application. Temperature is a commonly measured parameter and should be easy to obtain by users for input in the BLM.

5.1 Recommendations for BLM inputs for geochemical ions where site-specific data are not available

In Section 2 we used geostatistics to estimate missing GI parameter values based on geography. We supplemented the geostatistical approach by adding conductivity as an additional explanatory variable to generate a more robust spatial estimate of the GI water quality inputs for the BLM because conductivity is one of the most widely monitored water quality indicators in the U.S. and correlates well with GIs. We presented average predicted 10^{th} percentile concentrations for the BLM GI water quality parameters Level III ecoregions. We further refined these estimates by considering the effect of stream order (size) in Section 3. We found that values of the GI estimates generally increased with stream order, a trend that was most apparent and consistent for higher order streams. Tables 8, 9, and 10 present best estimates of GI input parameters for the BLM. Estimated inputs are provided for each GI in each ecoregion categorized by stream order for low, medium, and high order streams, respectively. EPA recommends these 10^{th} percentile Level III ecoregion, stream order group-specific values be used in the BLM where site-specific data are not available.

NMED Exhibit 34

5.2 Recommendations for BLM inputs for DOC where site-specific data are not available

In Section 4 we determined that the geostatistical and regression-based approaches used to estimate GI input parameters for the BLM do not produce accurate site-specific estimates for DOC. Because previous analyses indicate that DOC is the most important BLM input for estimating criteria for copper, we further refined our approach in Section 4 based on analyses using the NOCD to estimate lower-percentile DOC concentrations. Based on statistical comparisons to an independent probabilistic dataset, we found that DOC concentrations from the NOCD are reasonably protective estimates of DOC for use as input parameters for the BLM for some ecoregions. For other ecoregions, EPA recommends using estimates based on the WSA dataset. Recommended 10^{th} percentile DOC estimated values for 83 of the 84 ecoregions are summarized in Table 20. In the remaining ecoregion (76; Southern Florida Coastal Plain), there were insufficient data in either dataset (NOC database or WSA/NRSA) to calculate DOC concentration percentiles. Because limitations in the DOC database and the importance of this parameter in criteria calculation, users are encouraged to sample for DOC as a basis for determining BLM input rather than using default parameters wherever possible.

5.3 Recommendations for BLM inputs for pH where site-specific data are not available

In Section 2 we determined that geostatistical and regression-based approaches used to estimate GI input parameters for the BLM did not produce accurate site-specific estimates for pH. Our analysis of national data indicates that there is no relationship between conductivity and pH, and geostatistical methods were found to produce similarly ambiguous results. Because pH is one of the most important BLM inputs for predicting criteria for copper, we conclude that site-specific data for pH are needed for successful BLM application. Temperature along with pH is similarly recommended to acquire site-specific data for BLM application with the advantage of both of these been easy parameters to measure.

5.4 Conclusions

The approaches described in this TSD can be used to provide reasonable default values for input parameters in the BLM to derive protective freshwater aquatic life criteria for copper when data are lacking. These data could also be used to provide reasonable default values to fill in missing water quality input parameters in the application of other metal BLM models as well when data are lacking. Default recommended values for GI parameters are 10^{th} percentile ecoregional, stream-order specific values. Default recommended values for DOC are 10^{th} percentile ecoregional values. Both pH and temperature should be measured values when using the BLM. It should be noted that site-specific data are always preferable for use in the BLM and should be used to develop copper criteria via the BLM when possible. Users of the BLM are encouraged to sample their water body of interest, and to analyze the samples for the constituent (parameter) concentrations as a basis for determining BLM inputs where possible.

Appendix A: An Examination of Spatial Trends in Surface Water Chemistry in the Continental United States: Implications for the Use of Default Values as Inputs to the Biotic Ligand Model for Prediction of Acute Metal Toxicity to Aquatic Organisms

Internal EPA Report (2006)
James N. Carleton
EPA, Office of Water, Office of Science & Technology.

A.1 Abstract

A large database of surface water chemistry monitoring data was examined to look for spatial trends in five chemical constituents that are key inputs to a model for predicting metal toxicity to aquatic organisms. Continuous prediction maps of concentrations were generated using various kriging techniques to interpolate between site-median values measured at several thousand separate locations throughout the continental United States (U.S.). Continuous concentration surfaces were then averaged over 8-digit Hydrologic Unit Code (HUC) polygons to produce block-averaged mean estimates of site-median concentrations. Pairwise comparisons indicated distinct trends between various HUC-averaged predicted constituents. The same analyses performed on data from 772 locations where all five constituents had been measured revealed similar relationships between monitored constituents. Principal components analyses performed on these data sets showed that 80 to 90% of the variance in both cases could be explained by a single component with loadings on three of the five constituents. The use of kriging to produce appropriate quantile maps for block-averaging is suggested as a possible approach for developing regional values to use as default model inputs, when site-specific monitoring data are lacking.

A.2 Background

The U.S. Environmental Protection Agency is planning in the near future to release proposed water quality criteria for copper (*Note: EPA's BLM-based Freshwater Copper Aquatic Life Ambient Water Quality Criteria document was released in 2007, EPA-822-R-07-001*). These criteria are unlike most water quality criteria in that acceptable (safe) concentrations for aquatic life support, rather than being defined as simple numerical values that apply everywhere, will be addressed through the use of a chemical speciation model – the Biotic Ligand Model (BLM) (EPA, 2003). The BLM calculates metal toxicity to aquatic organisms as a function of simultaneous concentrations of additional chemical constituents of water, for example other ions that can either complex with copper and render it biologically unavailable, or compete with copper for binding sites at the point of entry into a vulnerable organism (i.e. at the fish gill). While the BLM has the potential to improve the accuracy of metal ecotoxicity predictions, its use requires input concentrations of nine separate chemical constituents and water temperature. Of these nine chemical constituents (Alkalinity (alk), calcium (Ca), magnesium (Mg), sodium (Na), sulfate (SO42-), potassium (K), chloride (Cl), dissolved organic carbon (DOC), and pH), model-predicted toxicity is most sensitive to five: Ca, alk, pH, Na, and DOC. States or other entities wishing to use the BLM to assess compliance with the proposed criteria in specific waters, or to develop effluent permit limits, will therefore require monitoring information on a suite of chemical

constituents – information that is not always available. One possible way to deal with such missing information is to develop reasonably protective default values for these various model inputs, especially the five to which the BLM is most sensitive. Given that ambient surface water chemistry reflects, among other things, the influences of local soil types and land uses, it may make sense that any such defaults be developed on some kind of regional or local basis.

The exercise described in this report comprises a geospatial examination of a large amount of water chemistry monitoring data collected in recent years by the U.S. Geological Survey, and recorded in their National Water Information System (NWIS) database. The data includes monitoring information from several thousand separate surface water sampling locations throughout the U.S. (Figure A-1). The latitudes and longitudes of each sampling location are part of the data record. The primary objective of this analysis is to look for any obvious spatial trends in typical concentrations of the five most sensitive constituents, and to suggest procedures for making use of these trends to define regional default values for use as inputs to the BLM. For purposes of expediency, the geographic extent of this analysis is limited to the continental U.S.

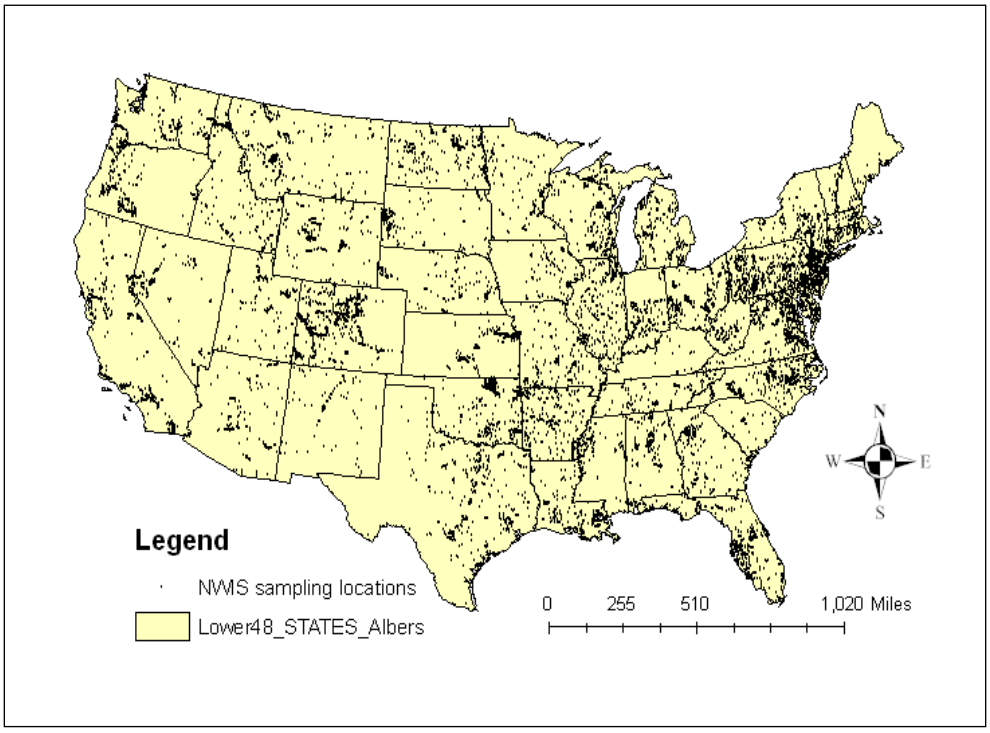

Figure A-1. NWIS sample collection locations in the continental U.S.

A.3 Description of Data

Although NWIS contained data from 207,153 sampling events at 13,824 individual sampling locations in the continental U.S. (Figure A-1), all 10 constituents of relevance to the BLM were not monitored at each location. For the five constituents of interest, the numbers of discrete sampling locations were as follows: alk, 5,900; Ca, 10,940; DOC, 3,726; Na, 10,424; pH, 11,780. Numbers of sampling events at individual locations ranged from 1 to 2,605, with a mean of 15, and a mode of one (i.e. most sites were

only sampled once). Examination of the spatial distribution of numbers of sampling events per site reveals that the most intensive sampling tended to occur in Midwestern and western states (Figure A-2). Because environmental sampling data tend to be lognormally distributed, disparities in numbers of samples may tend to produce higher mean and median values at more-frequently-sampled locations. As spatial distributions of representative (e.g., median) concentrations are examined, it should be kept in mind that apparent geographic trends in concentration may be in part simply the result of uneven sampling intensity.

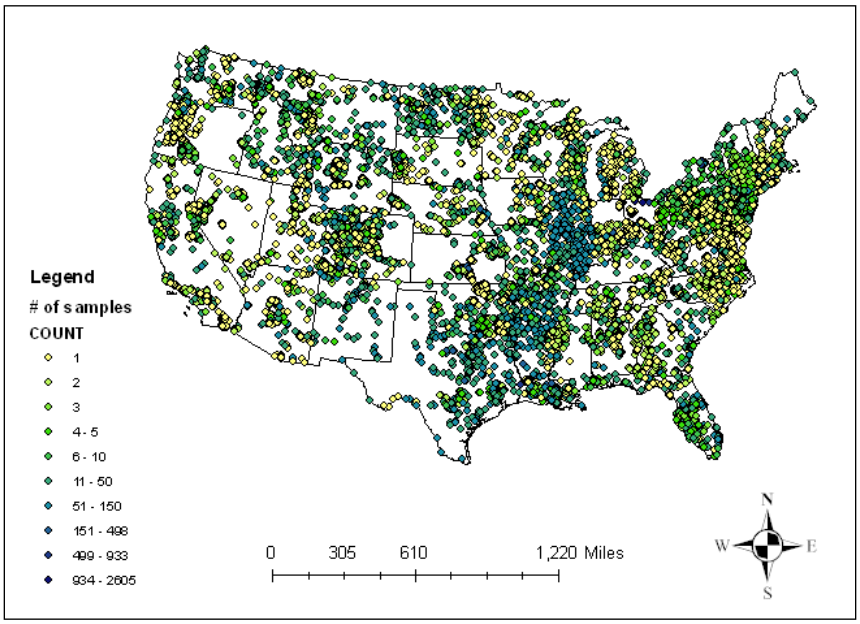

Figure A-2. Intensity of sampling (number of separate sampling dates) at each NWIS site

A.4 Data Analysis

Because environmental data tend to be positively skewed, the median statistic was chosen as providing the best central-tendency representation of each location's concentration. For the purpose of looking for general spatial trends in the five constituents, the first step involved simply mapping the sampling locations as points, color-graded by median concentration. Figure A-3, for example, shows some apparent trends in alkalinity across the country, with lower concentrations along the eastern seaboard, and higher concentrations in parts of the Midwest. Similar kinds of trends at the national scale were also seen with the other constituents.

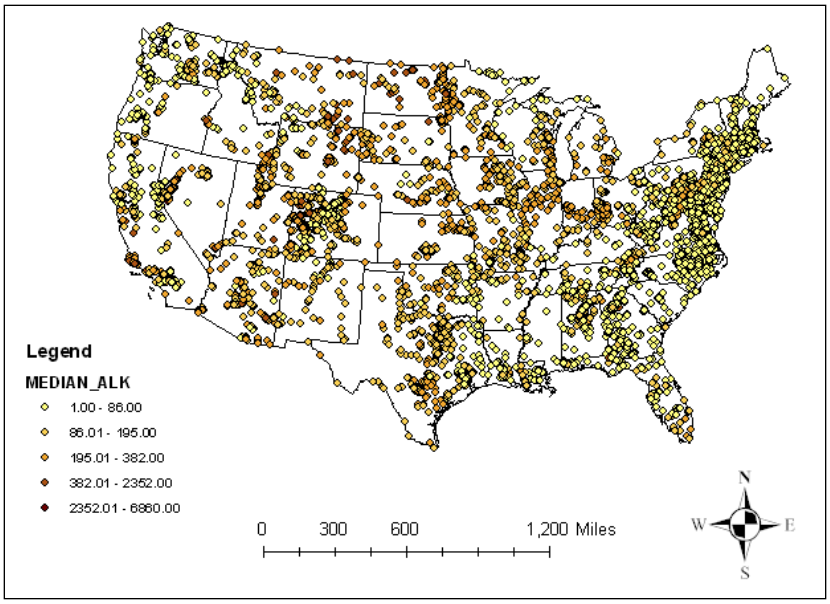

Figure A-3. Median measured alkalinity (mg/L as CaCO3) at NWIS locations

The next step in data visualization involved the calculation of median concentrations averaged over each 8-digit HUC containing sampling locations. These display essentially the same information as the point displays (Figure A-3), but with a degree of smoothing and summarization provided by the spatial averaging process, to make visual interpretation of general trends easier (Figure A-4).

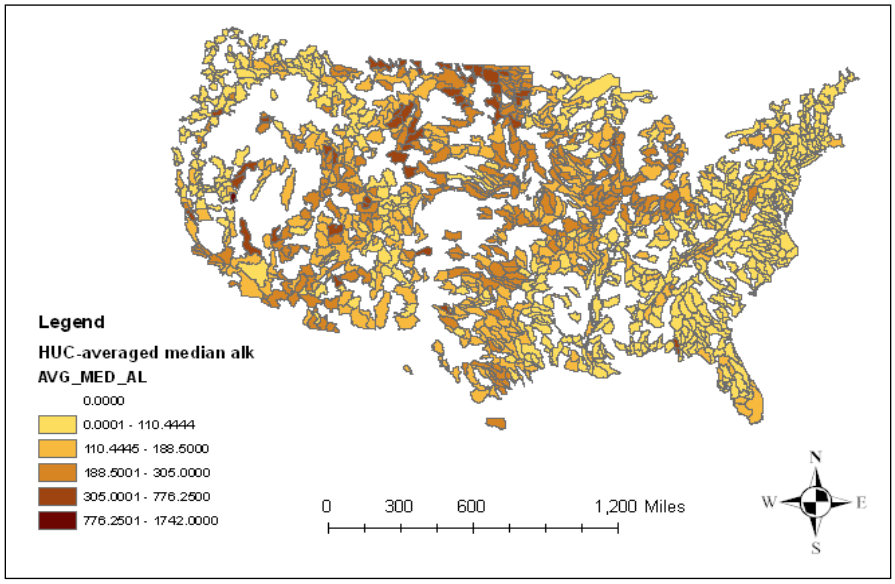

Figure A-4. HUC-averaged mean median observed alkalinity in the continental U.S.

The use of 8-digit HUCs as the areal units over which to calculate representative concentrations for default BLM inputs makes some physical sense: HUCs are areas that are defined by some degree of

interconnection between associated surface water features. HUCs may be either watersheds in their own right or downstream sections of larger watersheds (Omernik, 2003). In either case, all flowing surface water that passes through a HUC eventually (in theory) passes through the same downstream "pour point". One advantage of using HUCs is that they divide the land area into roughly equally sized areas at a level of resolution roughly consistent with gross variations in median concentration (Figure A-3). One problem with using HUCs for spatial aggregation is that not all HUCs contain NWIS sampling locations, as the blank areas in Figure A-4 make clear. The third step in this analysis therefore involved the use of kriging to create continuous surfaces of interpolated concentrations that cover the entire area of interest. Spatial averaging of the results over each HUC was then used to provide estimates of expected concentrations for all HUCs, including those lacking NWIS samples.

For each of the five key constituents, the Geostatistical Analyst extension in ArcGIS was used to explore the data, and to look for sets of kriging model options that provided the best fit to the data. The criteria used to evaluate goodness of fit were as follows:

1. Mean Standardized Error as small as possible
2. RMSE as small as possible
3. Root-Mean-Square Standardized Error close to 1.0
4. RMSE and Average Standard Error close together

Trial and error parameter selection was used to search for a set of model options that best attained each of these four goals simultaneously. For each constituent, 10 to 20 combinations were tried, until a best option for each emerged, as determined by judgment of the author. The results are as follows:

Alk: Universal kriging, log transformation, constant trend, 50% global, 50% local, spherical semivariogram, no anisotropy.

Ca: Ordinary kriging, log transformation, constant trend, 50% global, 50% local, exponential semivariogram, anisotropy.

DOC: Universal kriging, log transformation, constant trend, 50% global, 50% local, hole-effect semivariogram, anisotropy.

Na: Universal kriging, log transformation, constant trend, 50% global, 50% local, hole-effect semivariogram, anisotropy.

pH: Ordinary kriging, no transformation, constant trend, 50% global, 50% local, spherical semivariogram, no anisotropy.

Prediction surface maps were generated for each constituent using the above sets of kriging options. Figure A-5, which displays the results for alkalinity, shows patterns that are generally consistent with those in the data (Figures A-3 and A-4). Figure A-6 shows the predicted alkalinities projected into three dimensions using ArcScene.

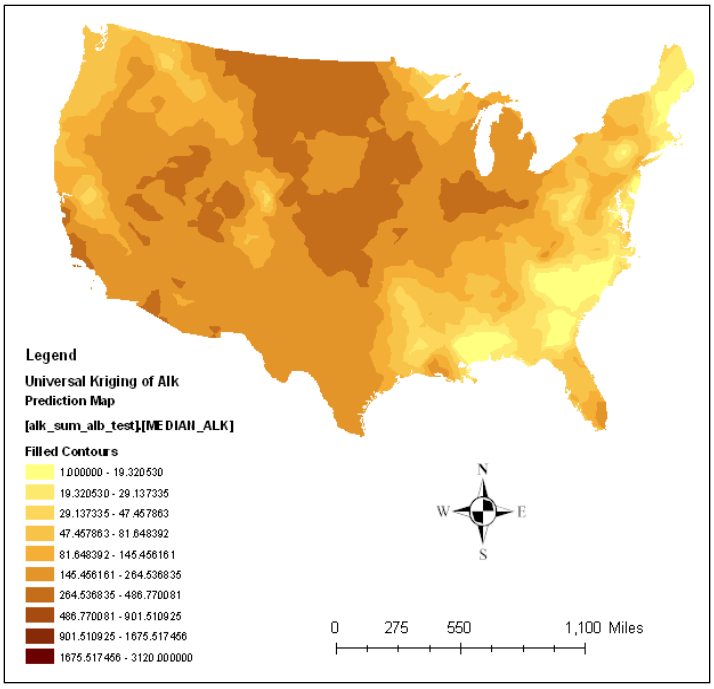

Figure A-5. Kriging prediction map of median alkalinity

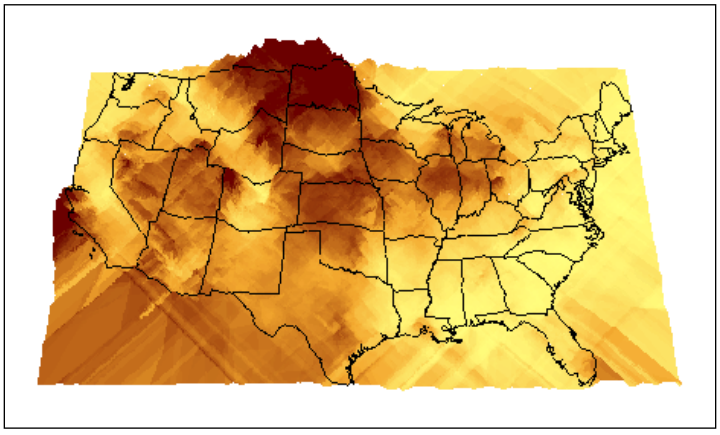

Figure A-6. Kriging map of alkalinity, projected into vertical dimension

This technique demonstrates broad geographic trends most dramatically, for example emphasizing the fact that the highest alkalinities are apparently found in northern North Dakota and Montana. Figure A-7 shows the predicted values averaged over HUC polygons by using the Zonal Statistics function of ArcGIS Spatial Analyst.

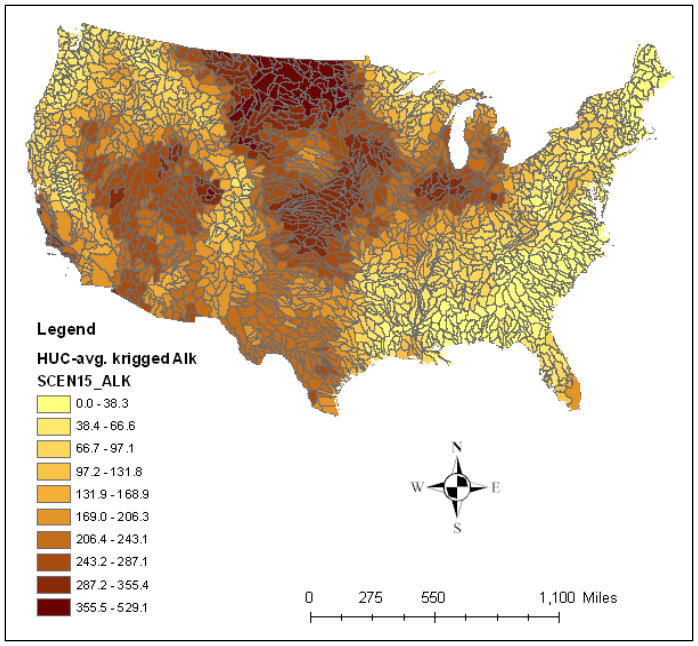

Figure A-7. Kriging-based alkalinity predictions, averaged over 8-digit HUC polygons

For HUCs containing NWIS sampling locations, linear regression plots of predicted versus measured concentrations (Figure A-8) provided a check on the accuracy of the kriging predictions. R-squared values for the five constituents were: 0.537 (alk), 0.238 (Ca), 0.686 (DOC), 0.351 (Na), and 0.139 (pH). In most cases, a handful of outliers appeared to be responsible for smaller-than-expected correlation coefficients.

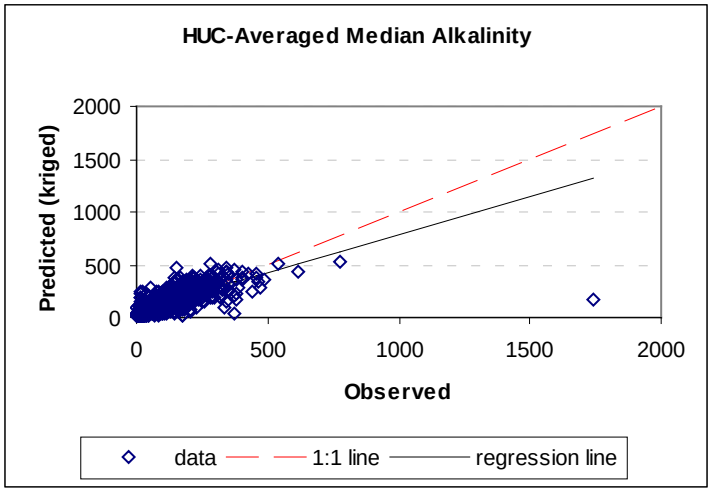

Figure A-8. Kriging-predicted vs. calculated HUC-averaged alkalinity; r^2=0.537

A scatter plot matrix of cross-constituent comparisons revealed some interesting, non-random relationships between HUC-averaged concentrations (Figure A-9). For comparative purposes, a subset of 772 sampling locations was also identified, at which sampling for all five of the constituents had taken place. Coincident concentrations of all constituents allowed a scatter plot matrix of this data (Figure A-10) to also be constructed. Similarities between the kinds of relationships in Figure A-9 and A-10 suggest that the predicted HUC mean median values are reasonable.

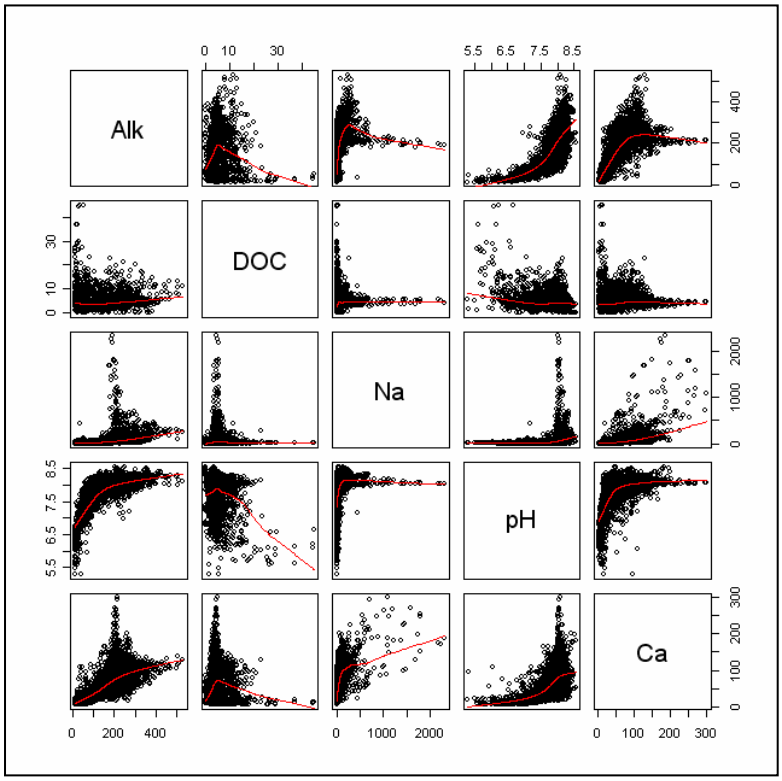

Figure A-9. Scatter plot matrix of median concentration kriged predictions, averaged over 8-digit HUCs regions covering the continental U.S.

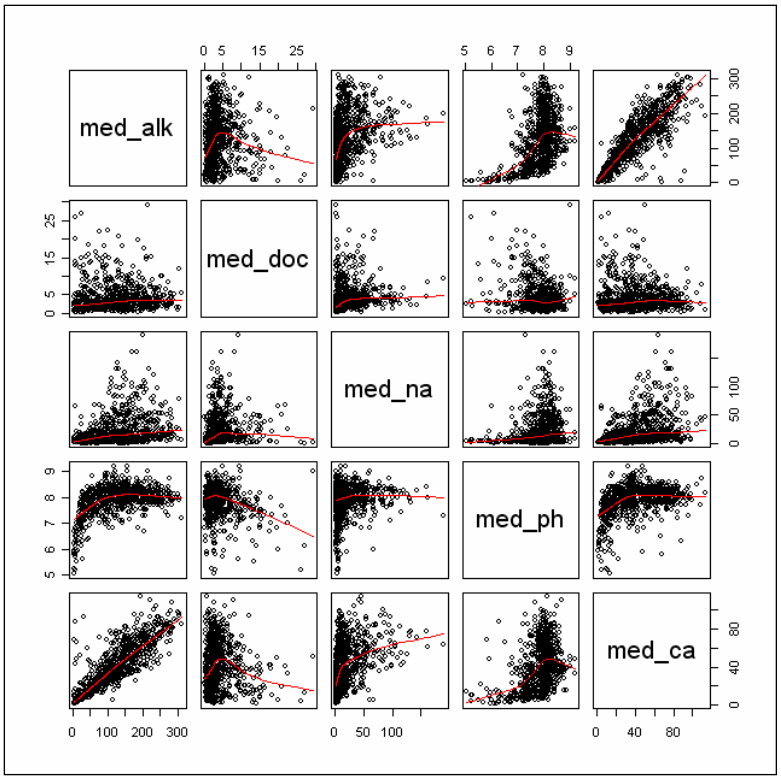

Figure A-10. Scatter plot matrix of median concentrations from 772 monitoring locations in the continental U.S.

In addition to scatter plots, correlation coefficient matrices between constituents in each of the two data sets (HUC-mean kriged median values and site median values for 772 locations) were generated (Table A-1). Although not identical, the coefficients were generally similar between the two datasets, again suggesting that the kriging predictions are reasonable.

Table A-1. Matrices of correlation coefficients between constituent concentrations

2096 HUC-averaged predicted median values					
	Alk	DOC	Na	pH	Ca
Alk	1				
DOC	-0.01456	1			
Na	0.327599	-0.02661	1		
pH	0.761675	-0.27746	0.286512	1	
Ca	0.698379	-0.02585	0.531727	0.58514	1
772 site-median values					
	Alk	DOC	Na	pH	Ca
Alk	1				
DOC	0.019145	1			
Na	0.327028	0.165445	1		
pH	0.453161	-0.24067	0.169238	1	
Ca	0.842484	-0.05097	0.387617	0.374592	1

Principal components analyses (PCA) were also run on both the HUC-averaged predictions and the 772 sets of monitored constituent concentrations to look for linear combinations of variables that might explain most of the observed variation. Figures A-11 and A-12 show the resulting plots of the variance explained by each component, and Table A-2 lists the loadings of the components onto the original variables. The first component comprised 80 and 88% of the variance in the HUC-based and site-based analyses, respectively. As Table A-2 indicates, this component loaded entirely onto alk, Na, and Ca in both cases. For the HUCs, component 1 was primarily loaded on Na, while for the sites, it primarily loaded on alk.

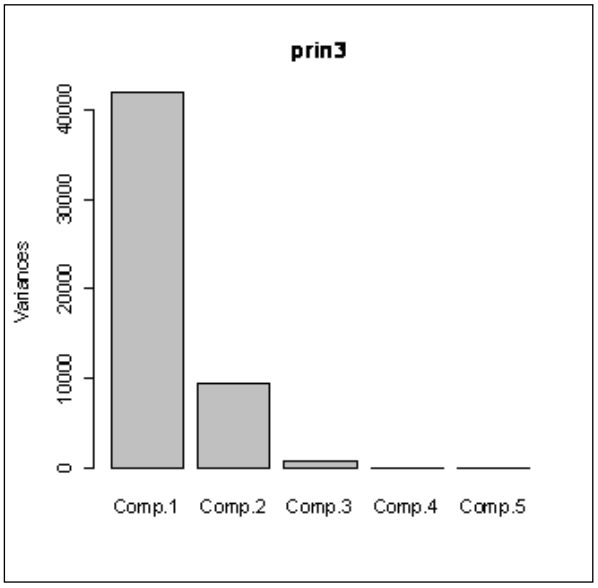

Figure A-11. Variance plot from PCA of HUC-average kriging-predicted concentrations

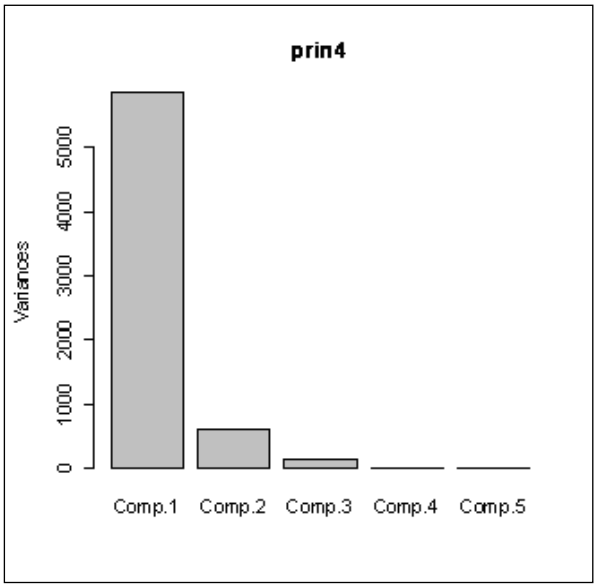

Figure A-12. Variance plot from PCA of site-median measured concentrations

Table A-2. Loadings onto original variables from PCA on HUC-averaged predictions and site-median concentrations

HUCs:					
	Comp.1	Comp.2	Comp.3	Comp.4	Comp.5

Na	0.13	-0.982	0.133		
pH					0.999
Ca	0.277		-0.955		

A.5 Developing Regional Defaults

Besides prediction maps of best-estimate median concentrations, the Geostatistical Analyst can be used, with the same sets of kriging parameters listed previously, to generate quantile surface maps that represent reasonably protective inputs to the BLM than standard kriging predicted values. The five key inputs examined in this paper are all positively associated with BLM-predicted LC50s. Thus, lower values of all of them tend to result in lower (i.e., more protective) site-specific criteria. Lower quantile predictions can be used to produce protective regional default inputs. As an example, Figure A-13 displays the 25th percentile prediction map for alkalinity. When these values are block-averaged over the HUC polygons, the resulting alkalinities are lower than 67% of the site-minimum alkalinities (Figure A-14) measured inside the same areas.

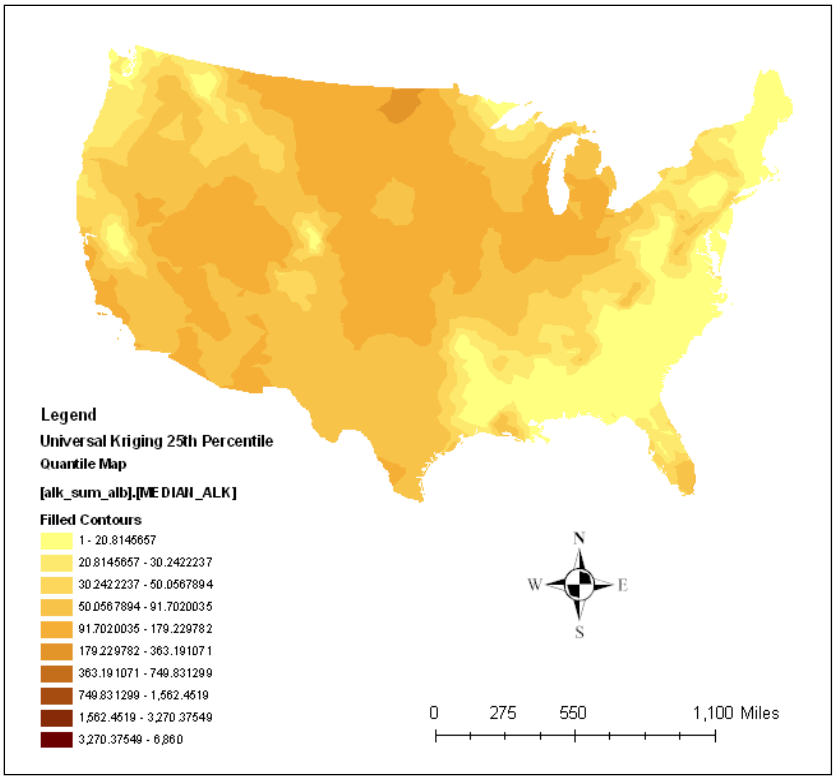

Figure A-13. Kriging 25th percentile map of median alkalinity

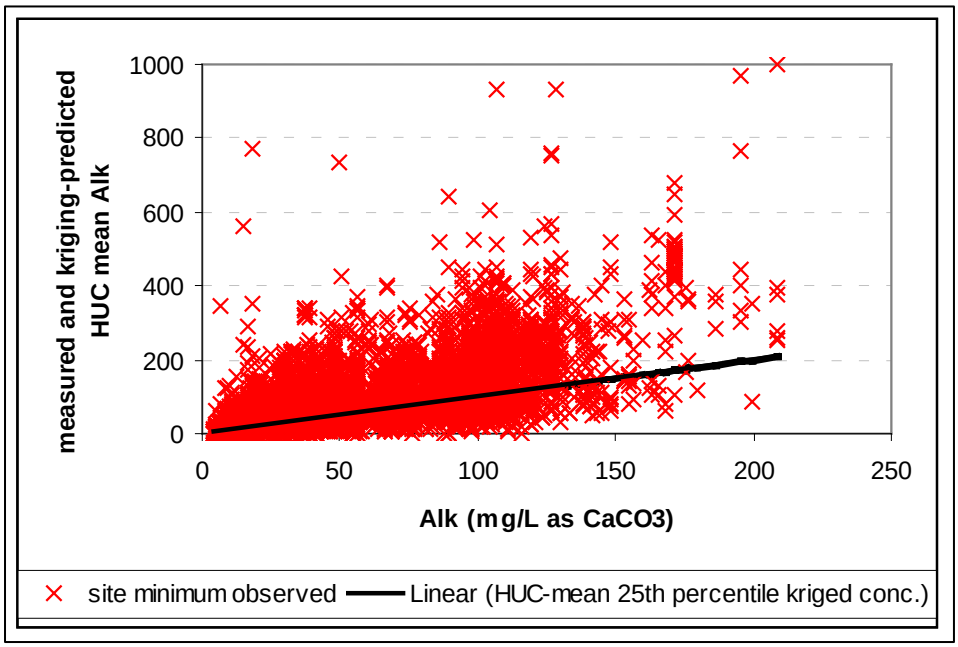

Figure A-14. Comparison of observed site-minimum alkalinities with HUC-mean 25th percentile kriging-predicted values

A.6 Discussion

The use of HUCs for spatial averaging of surface water concentrations is not without conceptual difficulties. First, only about 45% of HUCs are actual watersheds (Omernik, 2003); the rest receive drainage from additional upgradient areas. Concentrations measured in flowing waters reflect the soil, vegetation and land use properties of the aggregate upstream drainage areas, rather than of the sampling locations themselves (Smith et al., 1997). Assignment of measured concentrations to a HUC through block averaging may understate the spatial relevance of the samples for HUCs that are only parts of watersheds. One way to address this concern might be to use, as the aggregation polygons, only samples from watersheds that are entirely contained within single ecoregions (Omernik, 1987). However, this would have the unacceptable consequence of excluding large areas, and perhaps much of the data, from analysis. Another critical problem with this idea is that watershed boundaries for all of the NWIS sampling locations are not readily available, so there is currently no basis for deciding which points should be included or excluded. One advantage provided by the use of HUCs is that they divide the entire land mass of interest in this case into roughly equal sized polygons, at a level of resolution that appears to be roughly compatible with that of observed concentration trends. Block averaging using other sets of similarly sized polygons, such as counties, might serve equally well for empirically capturing broad spatial variability in concentrations. However the resulting concentrations would be less useful because they would lack even the incomplete degree of organization by connected hydrology that HUCs provide.

A.7 Conclusions

Kriging-predicted median concentrations of five water quality constituents, averaged over 8-digit HUCs, showed similar inter-constituent relationships as median concentrations from 772 specific sampling locations. PCA analyses revealed that in both cases, most of the observed variability was related to variations in three of the five constituents: alk, Na, and Ca. Results suggest that block averaging of kriging predictions over irregularly spaced sampling points can provide estimates that preserve much of the interrelationships between different measured entities. The use of suitable low-quantile kriging predictions is suggested as a way to estimate reasonably protective concentrations to serve as regional default inputs to the BLM.

B.1 Introduction

Derivation of water quality criteria for copper and other metals from predictions of bioavailability generated by the Biotic Ligand Model (BLM) introduces a number of issues. For example, obtaining the data needed to apply the BLM may be problematic for many dischargers and receiving waters. The BLM requires 10 input parameters to characterize water quality at a particular site; the most important ones for predicting copper bioavailability and toxicity include pH, dissolved organic carbon (DOC), calcium, magnesium, sodium, alkalinity, and temperature. In stream segments with only small dischargers, or possibly no dischargers at all, the data needed to apply the BLM may not be available. Water quality criteria that rely upon BLM predictions would be greatly facilitated by the development of practical approaches to estimate values for BLM water quality parameters, which could be applied when data for one or more of these parameters are missing at a site.

Given the broad geographical range over which the BLM is likely to be applied, potentially over the entire Nation, and the limited information that is available for many areas, a practical method to estimate missing water quality parameters is needed. The geostatistical methods employed by the U.S. Environmental Protection Agency (EPA) (Carleton, 2006) presented a viable system to estimate missing water quality parameters required by the BLM. The prototype work developed by Carleton applied kriging to predict average concentrations of alkalinity, DOC, sodium, pH and calcium over hydrologic units (8-digit Hydologgic Unit Codes [HUCs]), using the U.S. Geological Service (USGS) National Water Information Service (NWIS) as the source of spatial data. Comparison of measured concentrations with kriging predictions were encouraging for several of the BLM water quality parameters, although the errors and uncertainties associated with these predictions were not fully explored.

The geostatistical approach utilizes knowledge of spatial correlation to project values of a water quality parameter at sites where it has not been measured. The accuracy of these projections depends upon the availability of sufficient and spatially-proximate data for the specific parameter of interest. In addition, the seasonal and annual temporal variation in water quality must also be addressed in order to apply the BLM at a site. Water quality parameters often experience large changes during periods of snowmelt or intense rainfall. In many rivers and streams, the chemical composition and physical properties of water are following trends associated with increased land use in watersheds, water diversion for irrigation, regulation of river flow by dams, and other anthropogenic disturbances.

The acute BLM predicts an *instantaneous* acute copper criterion (i.e., a maximum short-term, non-toxic concentration of copper), which will vary according to changes in the water quality parameters. An appropriately protective copper criterion must therefore reflect the variability of water quality parameters at the site. In previous analyses we found that protective water quality criteria for copper

NMED Exhibit 34

generally corresponded to approximately the 2.5th percentile of the distribution of instantaneous water quality criteria (IWQC) predicted by the BLM.[5] BLM criteria predictions made for a site using the corresponding percentiles (i.e., 2.5%) of the water quality parameter distributions will be a conservative approximation of this protective criterion. The sensitivity of criteria predictions to the most important BLM water quality inputs is proportional (sensitivity to DOC is ~100%[6], [H^+] is ~50%, calcium, magnesium and sodium is ~20%). Relevant site-specific water quality parameters will be values from the lower "tail" of the measured or estimated distributions.

There may be great value in supplementing the geostatistical approach with classical estimation methods, such as regression and correlation. Examination of the NWIS data used to develop the geostatistical approach suggests that two variables, discharge (flow rate) and conductivity, may be useful for estimating BLM input water quality parameters. The USGS maintains the most comprehensive routine water flow and water quality data for streams and rivers in the Nation. Discharge may be a relevant explanatory variable because the USGS measures or estimates flow on a daily basis for a large number of stream and river segments. Among water quality parameters, the data for conductivity are the most complete and cover the longest time period (Wang and Yin, 1997). The literature also indicates that conductivity is one of the most widely monitored water quality indicators in the U.S. In part, this is because conductivity measurements are usually included in automated multiparameter systems for monitoring changes in the quality of surface waters (Allen and Mancy, 1972).

Conductivity is useful as a general measure of stream water quality. Each stream tends to have a relatively constant range of conductivity that, once established, can be used as a baseline for comparison with regular conductivity measurements (USEPA, 1997). Conductivity in streams and rivers is affected primarily by the geology of the area through which the water flows. Streams that run through areas with granite bedrock tend to have lower conductivity because granite is composed of more inert materials that do not ionize (dissolve into ionic components) when washed into the water. On the other hand, streams that run through areas with clay soils tend to have higher conductivity because of the presence of materials that ionize when washed into the water. Ground water inflows can have the same effects depending on the bedrock they flow through.

Conductivity reflects the strength of major ions in water and is a good estimator of total dissolved solids (TDS). Linear relationships between conductivity and TDS have been developed for many USGS monitoring sites. Conductivity is also linearly related to the sum of cations (McCutcheon et al., 1993). In addition, conductivity measurements provide information about the total concentration of ionic species in a water sample (Tyson, 1988). Figure B-1 illustrates how conductivity relates to hardness and anion concentrations in a river that has a rather saline base flow maintained by irrigation drainage and groundwater inflows. The chemical characteristics of the base flow are generally constant but they are subject to seasonal dilution by runoff. Relationships between conductivity and chloride and sulfate concentrations are well defined. A similarly good association with hardness (calcium+magnesium) is

[5] This was the median for 17 sites; the range was 1 to 36%.

[6] 100% sensitivity implies that a model prediction (in this case, the criteria predicted by the BLM) varies in direct proportion to the change in the value of a specified input parameter.

indicated. Lines drawn by eye through the points for chloride and sulfate show slight curvature, but the departure from linearity is insignificant. It seems evident that a record of conductivity at this station could be used to compute the other chemical characteristics of the water with a good level of accuracy for major ions, except at high flow when the relationships would not be as well defined (Hem, 1985).

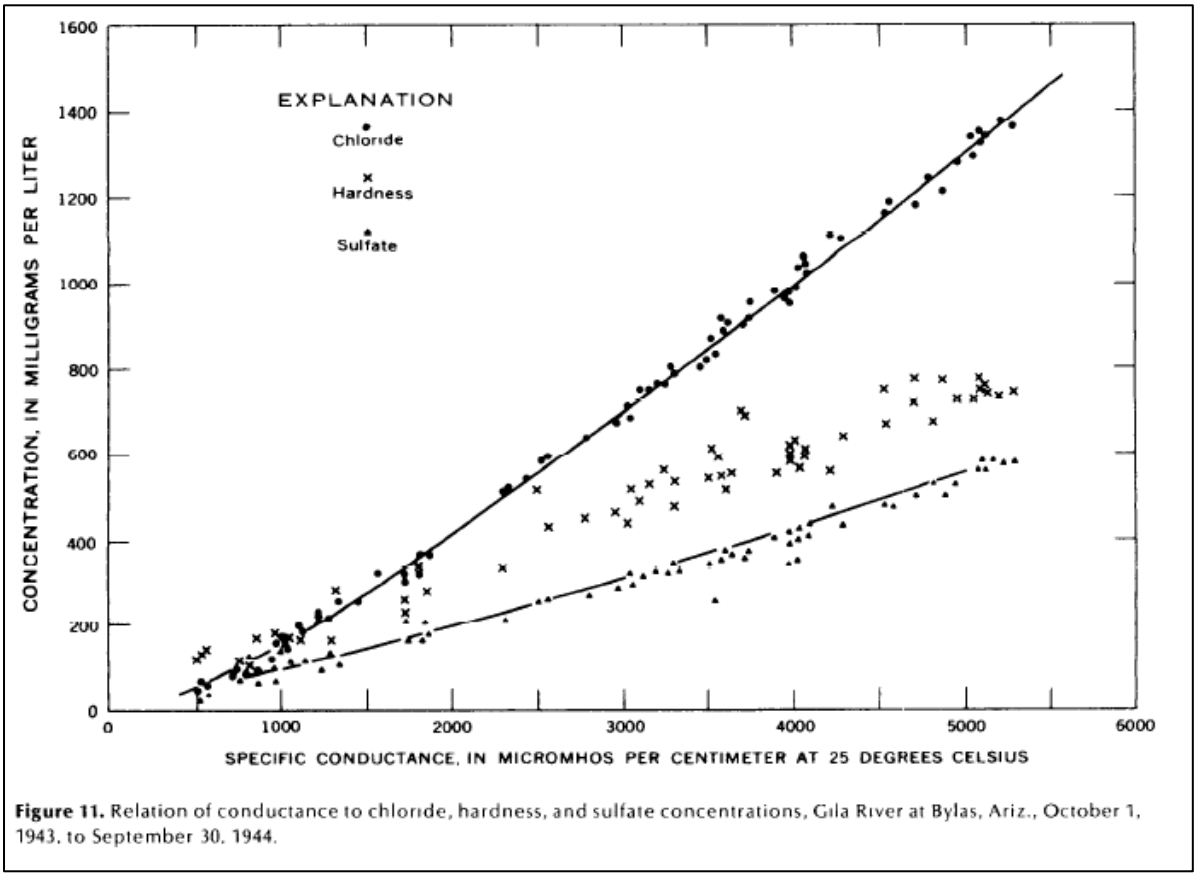

Figure 11. Relation of conductance to chloride, hardness, and sulfate concentrations, Gila River at Bylas, Ariz., October 1, 1943, to September 30, 1944.

Figure B-1. Relation of conductivity to chloride, hardness and sulfate concentrations in the Gila River at Bylas, Arizona

(reprinted from Hem, 1985)

Wang and Yin (1997) established conductivity as a general water quality indicator based on spatial data. The concentration of major base metal cations in water explained the positive correlation between conductivity and hardness. This also explained a rather weak correlation between conductivity and the pH value. Its relationship with other materials, however, most likely resulted from the dilution effect of stream flow. Conductivity was negatively correlated with discharge (ρ=-0.729), and the same was found for most water quality variables that were positively correlated with conductivity. With increasing stream flow, the concentration of the dissolved material decreased, as did the conductivity. Wang and Yin's analysis suggests that conductivity could be used as a general indicator of water quality, which is positively related to dissolved materials and soluble metals. As it is

widely monitored and has relatively long records, conductivity has the potential to be a very useful variable for estimating missing water quality input parameters for the BLM.

We explored this possibility by assessing the degree of correlation between conductivity and each of the BLM water quality parameters. We used NWIS data from three contiguous states in the Western U.S. (Colorado, Utah and Wyoming) for this analysis. These states were selected because of the large spatial and temporal variability observed in BLM water quality parameters, and because they provided us a tractable dataset for analysis.

Discharge was included as one of the parameters in this correlation analysis. However, discharge is most often used to explain water quality variation at a particular site (Hem, 1985). The concentration of dissolved solids in the water of a stream is related to many factors, but it seems obvious that one of the more direct and important factors is the volume of water from rainfall available for dilution and transport of weathering products. Presumably, therefore, the concentrations of dissolved solids should be an inverse function of the rate of discharge of water over all or at least most of the recorded range (Hem, 1985). Regressing water quality parameter measurements against discharge is a common practice in environmental engineering, and many references on this subject are available (McDiffett et al.,1989; Chanat and Hornberger, 2002; Christensen et al., 2005; Godsey and Kirchner, 2005). We should also point out that correlating the variation in water quality parameters to streamflow is also necessary for effluent dilution calculations associated with use of the BLM (for example, the probabilistic dilution framework incorporated in the BLM-Monte software [HydroQual, 2001]).

B.2 Data

Data for discharge, conductivity, and BLM water quality parameters (temperature, pH, DOC, alkalinity calcium, magnesium, sodium, potassium, sulfate, and chloride,) were retrieved from the USGS NWIS web interface (http://nwis.waterdata.usgs.gov/usa/nwis/qwdata). Data were selected for 790 stream and river stations in Colorado, Utah, and Wyoming reporting 100 or more water quality observations. This latter constraint was imposed to eliminate the large number of stations reporting very few (often one) water quality observations. Even when the analysis was restricted to sites with more than 100 water quality observations, there were frequently a marginal number of data for the multiple parameters needed to measure between-parameter correlations. We also restricted the analysis to observations made since 1975 to avoid the possible influence of pre-Clean Water Act discharges on water quality.

Natural logarithms of the discharge data were used in the analysis, because discharge was clearly lognormally distributed at the majority of sites. In cases where a parameter was measured simultaneously by more than one method (field pH versus laboratory pH, for example), the reported results were averaged for analysis. We did not consider other approaches for selecting data based on preference for a particular analytic method (Roberson et al., 1963).

B.3 Results

Table B-1 provides an inventory of the number of observations, and number of sites with data, for several of the parameters in the state of Colorado (these numbers reflect the full NWIS dataset, uncensored for minimum number of observations or date). From this table, it is apparent that a vast amount of conductivity data exists, both in terms of the total number of observations and the number of sites reporting this parameter in comparison to the BLM water quality parameters. For example,

there are almost four times as many observations of conductivity as there are for calcium, and they are measured at more than twice the number of sites. Discharge data is similarly abundant.

Table B-1. Number of observations and sites reported in NWIS for streams and rivers in Colorado

Parameter	Number of Observations	Number of Sites
pH	62,005	3668
alkalinity	8136	839
calcium	45,490	2708
conductivity	168,110	6101
discharge	127,275	3340

To quantify the relationship between conductivity levels and values of water quality parameters required by the BLM, we performed correlation analyses on the NWIS water quality data for the three states. We estimated correlations for several statistics that summarized the distribution of conductivity and water quality values at each station. These included median levels, as well as the first quartile and fifth quantile. The last two statistics represent the lower end of the distribution of parameter values at a site, and are appropriate statistics for calculation of BLM instantaneous criteria. A non-parametric correlation (Spearman's rank correlation) was employed to avoid the problems of unknown data distributions and possibly non-linear relationships. To determine the statistical significance of the rank correlation coefficient (ρ), the significance level (P) was also calculated. The Spearman's rank correlation was also used to examine the relationship between stream discharge and the water quality variables to reveal the effect of dilution.

For the median site concentrations, we found that six BLM water quality parameters, two-thirds of the nine variables examined in this study, had non-zero rank correlation coefficients at the 0.001 significance level (Table B-2). As expected, strong positive correlations between conductivity and salt concentrations were found. For example, the correlation coefficients between conductivity and the concentration of salt cations and anions (sodium, potassium, magnesium, calcium, sulfate and chloride) were all higher than 0.80. However, median site conductivity was not significantly correlated to several other important BLM parameters including pH, DOC, and alkalinity. In terms of the site medians, there appears to be limited correlation between conductivity and the BLM water quality parameters. Furthermore, for the median site concentrations neither conductivity nor any of the BLM water quality parameters were significantly correlated to discharge.

Table B-2. Results of Spearman rank tests for correlation (ρ) between median values of variables at each site.

Probability values (P) are not exact due to the presence of ties in the data

	Conductivity	Discharge
Conductivity		ρ: 0.012 P: 0.892
pH	ρ: 0.175 P: 0.019	ρ: 0.441 P: 0.008
DOC	ρ: 0.866 P: 0.333	ρ: P:
Ca	ρ: 0.867 P: <0.001	ρ: -0.371 P: 0.068
Mg	ρ: 0.882 P: <0.001	ρ: -0.516 P: 0.008
Na	ρ: 0.921 P: <0.001	ρ: 0.139 P: 0.695
K	ρ: 0.846 P: <0.001	ρ: -0.128 P: 0.551
SO_4	ρ: 0.905 P: <0.001	ρ: -0.514 P: 0.010
Alkalinity	ρ: -0.600 P: 0.350	ρ: P:
Cl	ρ: 0.827 P: <0.001	ρ: -0.866 P: 0.333

We then repeated the correlation analysis for the site first quartiles (Table B-3) and fifth quantiles (Table B-4). For both of these low-end distribution statistics, *all* of the BLM water quality parameters were significantly correlated to conductivity, having non-zero rank correlation coefficients at the 0.001 significance level, as listed in Tables B-3 and B-4. The correlation coefficients are lower for pH and DOC than for the salts and alkalinity, but are nevertheless significant. Apparently, the correlation structure between conductivity and the BLM water quality parameters is much stronger at the lower end of the site distributions. Ambiguity in correlations between conductivity and BLM water quality parameters disappears when low-end distribution statistics are analyzed. As was the case for the median site concentrations; neither conductivity nor any of the BLM water quality parameters were correlated with discharge for the low-end distribution statistics.

NMED Exhibit 34

Table B-3. Results of Spearman rank tests for correlation (ρ) between the first quartile of values at each site.

Probability values (P) are not exact due to the presence of ties in the data

	Conductivity	Discharge
Conductivity		ρ: 0.057 P: 0.144
pH	ρ: 0.287 P: <0.001	ρ: 0.070 P: 0.168
DOC	ρ: 0.618 P: <0.001	ρ: -0.149 P: 0.031
Ca	ρ: 0.920 P: <0.001	ρ: -0.060 P: 0.305
Mg	ρ: 0.935 P: <0.001	ρ: -0.107 P: 0.066
Na	ρ: 0.910 P: <0.001	ρ: -0.075 P: 0.129
K	ρ: 0.773 P: <0.001	ρ: -0.109 P: 0.075
SO_4	ρ: 0.941 P: <0.001	ρ: -0.068 P: 0.247
Alkalinity	ρ: 0.829 P: <0.001	ρ: 0.099 P: 0.381
Cl	ρ: 0.752 P: <0.001	ρ: 0.004 P: 0.958

Table B-4. Results of Spearman rank tests for correlation (ρ) between the fifth quantile of values at each site.

Probability values (P) are not exact due to the presence of ties in the data

	Conductivity	Discharge
Conductivity		ρ: 0.056 P: 0.213
pH	ρ: 0.382 P: <0.001	ρ: 0.032 P: 0.579
DOC	ρ: 0.558 P: <0.001	ρ: -0.107 P: 0.134
Ca	ρ: 0.920 P: <0.001	ρ: 0.017 P: 0.791
Mg	ρ: 0.929 P: <0.001	ρ: -0.056 P: 0.383
Na	ρ: 0.845 P: <0.001	ρ: -0.089 P: 0.078

K	ρ: 0.694 P: <0.001	ρ: -0.065 P: 0.353
SO_4	ρ: 0.908 P: <0.001	ρ: 0.017 P: 0.790
Alkalinity	ρ: 0.784 P: <0.001	ρ: 0.184 P: 0.102
Cl	ρ: 0.706 P: <0.001	ρ: 0.034 P: 0.671

To further illustrate these correlations, scatter plot matrices (or SPLOMs) were prepared for the first quartiles (Figure B-2) and fifth quantiles (Figure B-3). SPLOMs show scatter plots for each combination of parameters, arrayed as a matrix, with parameters labeled along the borders of the plot. Histograms for each parameter are plotted on the main diagonal. The correlations between conductivity and each of the BLM water quality parameters are apparent by examining the second row (from the top) of scatter plots in Figures B-2 and B-3. Likewise, the lack of correlation between these parameters and discharge is apparent in the top row of the scatter plots in these same figures.

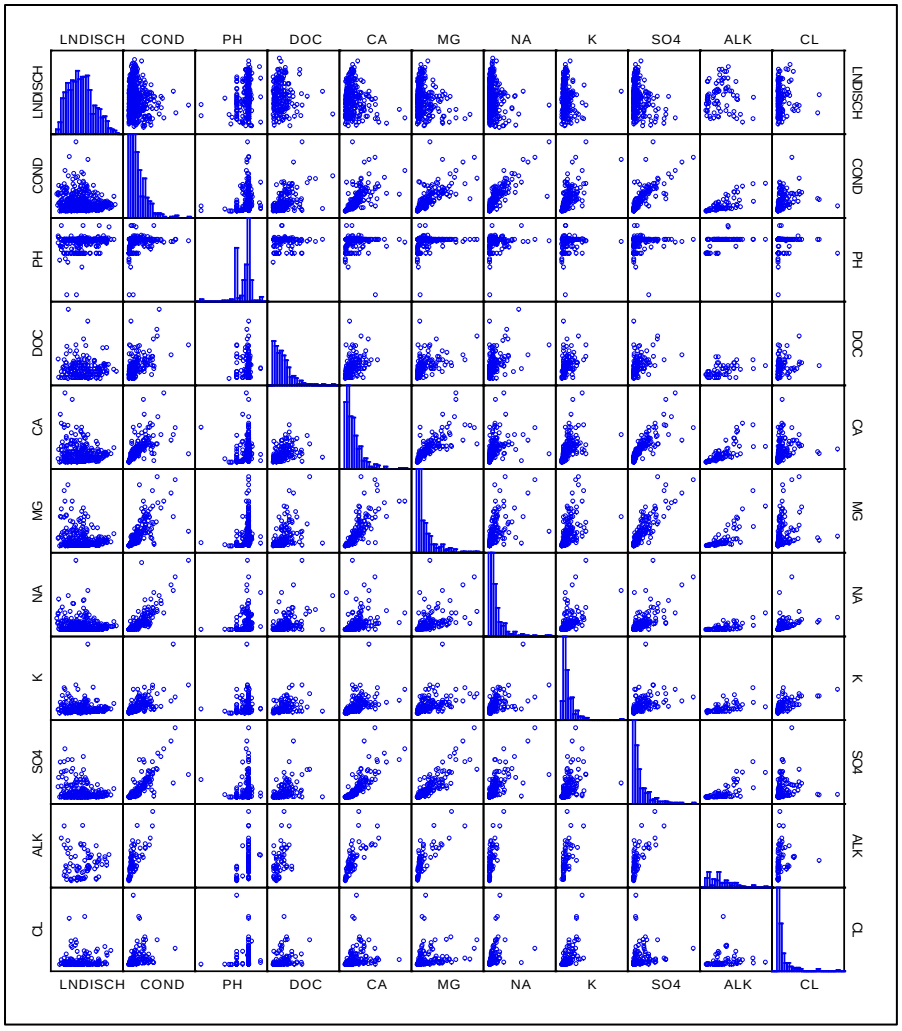

Figure B-2. Scatter plot matrix for first quartile of site-specific data for discharge (LNDISCH), conductivity (COND), and BLM water quality parameters

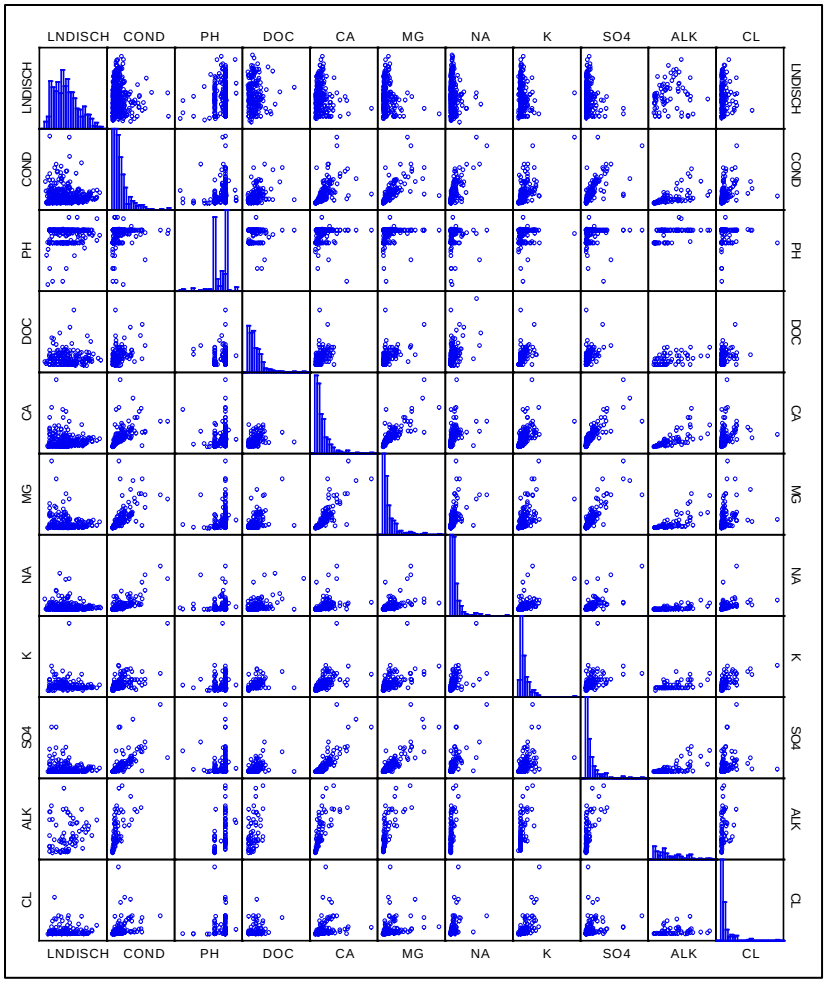

Figure B-3. Scatter plot matrix for fifth quantile of site-specific data for discharge (LNDISCH), conductivity (COND), and BLM water quality parameters

To understand why the correlations between conductivity and the other BLM water quality parameters are so much stronger for the low-end distribution statistics than for the medians, it is necessary to examine the site-specific data itself. Figure B-4 is a SPLOM of the conductivity, discharge, and BLM water quality parameter data for a representative USGS station in Colorado. The histograms for conductivity, salts, and alkalinity are remarkable in that the distribution of each is clearly bimodal (i.e., two separate peaks are evident in the histograms). This was observed for many of the sites in this dataset (not shown). In Figure B-5, the conductivity and discharge data for this site are plotted as a time series, which reveals why the water quality data are bimodal: high values of conductivity (> 5,000 micromhos/cm) occur when streamflow discharge is low, and low values of conductivity (< 2,000 micromhos/cm) occur when the discharge is high. At this station (and many others in this region), streamflow discharge is high in the May-June period coinciding with snowmelt at higher elevations. Feth and others (1964) reported conductivities of melted snow in the Western US ranging from about 2 to 42 picomhos/cm. Thus, the low values of conductivity (as well as concentrations of the salts and alkalinity) are the result of annual dilution from snow melt. At most other times, conductivity and salt and alkalinity concentration values are much higher. Depending upon how the water quality samples

are allocated at a site, the median concentration of these parameters may fall in either mode of the bimodal distribution, resulting in quite different values that appear almost random. Fortunately, the low-end distribution statistics avoid this seeming randomness because they consistently reflect sampling from the lower mode of the concentration distribution.

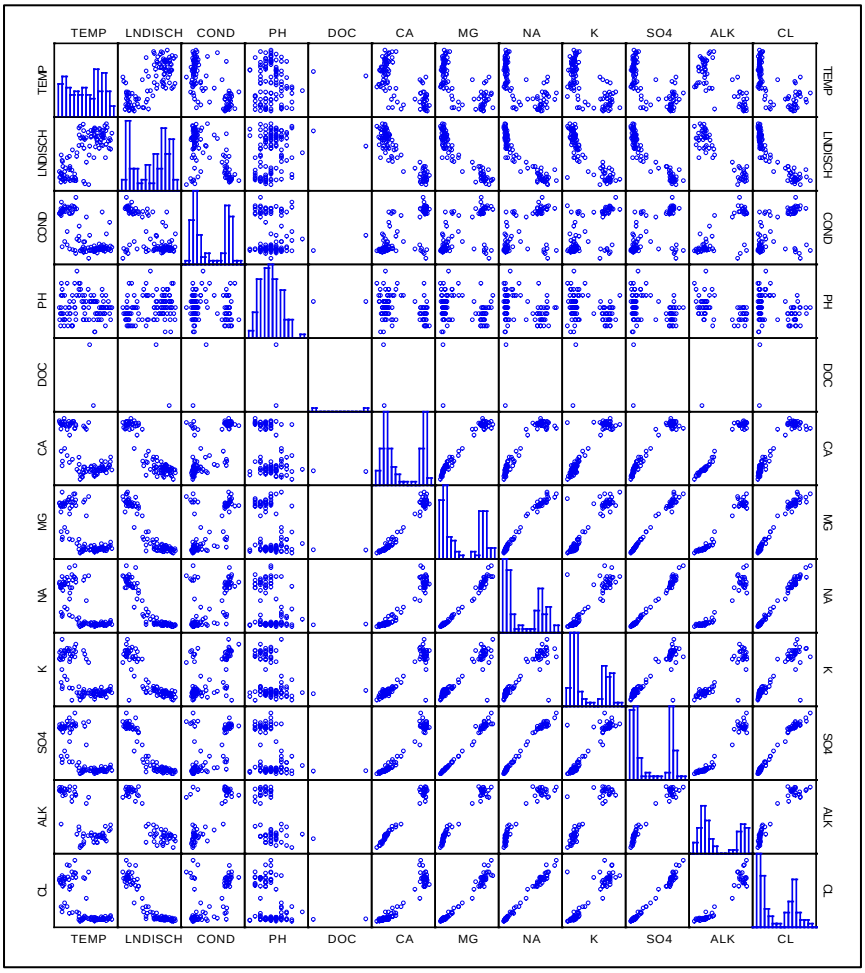

Figure B-4. Scatter plot matrix of BLM water quality parameter data from NWIS Station 384551107591901 (Sunflower Drain at Highway 92, near Read, Delta County, Colorado)

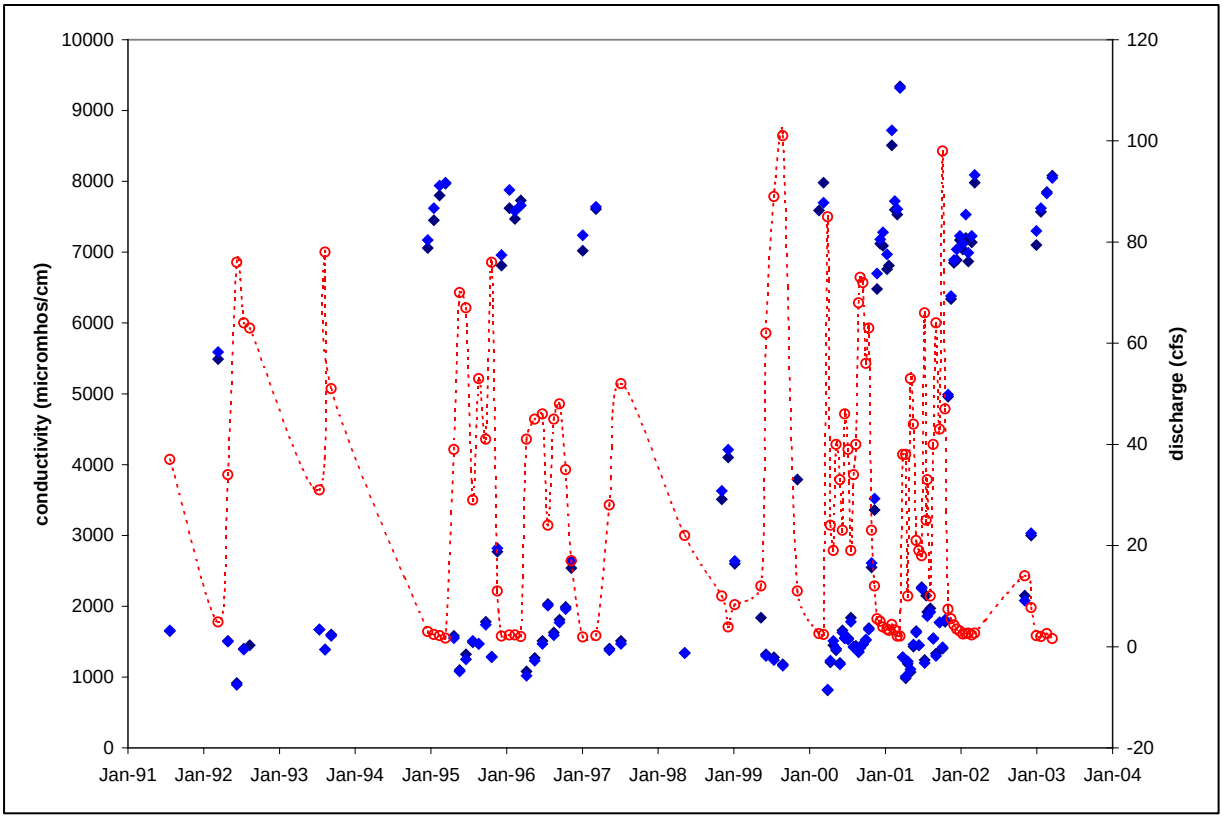

Figure B-5. Time series plot of conductivity (diamond symbols) and discharge (open circles connected by dashed line) at Station 384551107591901 (Sunflower Drain at Highway 92, near Read, Delta County, Colorado)

Figure B-4 also illustrates that, in terms of explaining site-specific variability, discharge is a much better predictive variable for a number of the BLM water quality parameters than conductivity. Each of these parameters (alkalinity calcium, magnesium, sodium, potassium, sulfate, and chloride) is clearly correlated to discharge, but not to conductivity. Discharge correlations are observed at many locations, and are commonly used to project water quality for various applications (Hem, 1985).

B.4 Discussion

Incorporating classical water quality correlation approaches, using conductivity and discharge as explanatory variables, within the geostatistical approach prototyped by EPA, appears promising. Conductivity, but not discharge, is significantly correlated to BLM water quality parameters between sites, especially for the low-end distribution statistics of interest for criteria calculations. Since conductivity data is abundant and it correlates well to BLM water quality parameters, it is reasonable to incorporate conductivity in spatial projections of BLM parameters. This may simplify the geostatistical approach and allow more robust spatial extrapolation of BLM water quality parameters.

Conversely, discharge is correlated to concentrations of a number of BLM parameters (salts and alkalinity) within many sites. Streamflow is a good explanatory variable for a number of the BLM water quality parameters (the salts and alkalinity) because their variabilities largely reflect dilution at high flow rates. Discharge data are also plentiful, so we believe that incorporating classical methods of

correlating concentration to discharge may be a useful means to address within-station variability for BLM water quality parameters.

It should also be recognized that geostatistical and/or correlation approaches appear to most often fail for those water quality parameters which are the most sensitive and important to the BLM, namely DOC and pH. Additional sampling effort will likely be required to address these deficiencies. In the case of pH, it is worth noting that many surface water sampling crews carry electronic multiparameter instruments which measure pH, conductivity, and temperature simultaneously in the field. Therefore, data collection strategies which incorporate these three measurements may be especially effective.

Measurement of DOC is considerably more difficult and expensive. It may be worthwhile to investigate whether ultraviolet (UV) absorption spectroscopy could be used as a surrogate measurement technique for DOC. The organic ligands that bind metals are humic and fulvic compounds (HydroQual, 2005). At least some of these compounds can be measured by UV absorption spectroscopy or related methods (Kalbitz et al., 2000; Wang and Hsieh, 2001), which may be easier and less expensive than DOC analysis.

Appendix C: Development of Tools to Estimate Biotic Ligand Model Parameters

C.1 Introduction

The U.S. Environmental Protection Agency (EPA) explored using regression models that project BLM water quality parameters from conductivity data for sites where there may be few or no data available to characterize water. We demonstrated previously (USEPA, 2007) that conductivity (specific conductance) is significantly correlated to Biotic Ligand Model (BLM) water quality parameters between a large number of monitoring sites in three western states (Colorado, Utah, and Wyoming), especially for the low-end distribution statistics of interest for site-specific fixed water quality criteria calculations. Since conductivity data are also abundant, it is reasonable to incorporate conductivity in spatial projections of BLM parameters.

C.2 Regression Analysis

Water quality data were retrieved from the U.S. Geological Survey (USGS) National Water Information System (NWIS; http://waterdata.usgs.gov/nwis/qw). We focused our efforts on data collected from rivers and streams in the western states of Colorado, Utah, and Wyoming between 1984 and 2005. Data from these three states were selected because conductivity was known to vary substantially, and the legacy of past mining in the region made the contamination of waterbodies by trace metals a possibility. Data collected prior to 1984 was excluded because a number of the analytical methods used by USGS prior to that date have been replaced by methods with improved precision and lower detection limits. Furthermore, only sites with 40 or more samples were included in the analysis. Data were retrieved for all BLM water quality input parameters including pH, dissolved organic carbon (DOC) (or total organic carbon (TOC), if no DOC data were available) and the geochemical ions (GIs). We also retrieved discharge measurements and filtered (dissolved) copper concentration data, although these data were not included in the regression analysis.

In work described in Appendix B, we found that the correlation structure between conductivity and the BLM water quality parameters was much stronger at the lower end of the concentration distributions. For various low-end distribution statistics, all of the BLM water quality parameters were significantly correlated to conductivity, having non-zero rank correlation coefficients at the 0.001 significance level. The correlation coefficients for pH and DOC were lower than for the GIs, but were nevertheless significant. We exploited this feature of the data in our current work. For each site, we estimated the 10^{th} percentile (i.e., the value exceeded by 90% of the data) of conductivities and the 10^{th} percentile of BLM water quality parameter values. We then fit regression models to project 10^{th} percentiles of BLM parameter values as a function of 10^{th} percentiles of conductivities.

We also fit regression models to the full NWIS dataset (data for all rivers and streams sampled in Colorado, Utah, and Wyoming between 1984 and 2005). This was done out of concern that the lower percentile data might be skewed due to sampling bias, censoring, fewer sites, etc. The results of both approaches are presented below.

C.2.1 pH

The following regression model appeared to be optimum for projecting the 10^{th} percentile of pH from the 10^{th} percentile of conductivity at the sites for which appropriate data were available:

$$\ln(pH) = 1.85 + 0.0352 \cdot \ln(EC)$$

NMED Exhibit 34

We did not fit a regression model to the full NWIS dataset, because no trend was evident between conductivity and pH.

C.2.2 DOC

The following regression model appeared to be optimum for projecting the 10th percentile of DOC concentrations from the 10th percentile of conductivity at the sites for which appropriate data were available:

$$\ln(DOC) = 0.671 \cdot \ln(EC) - 1.60$$

As with pH, we did not fit a regression model to the full NWIS dataset, since no trend was evident between conductivity and DOC.

C.2.3 Alkalinity

The following regression model appeared to be optimum for projecting the 10th percentile of alkalinity concentrations from the 10th percentile of conductivity at the sites for which appropriate data were available:

$$\ln(alkalinity) = 1.14 \cdot \ln(EC) - 4.68$$

For the full NWIS dataset, the following regression model was developed to project alkalinity concentrations from conductivity:

$$\ln(alkalinity) = 0.652 \cdot \ln(EC) + 0.530$$

C.2.4 Calcium

The following regression model appeared to be optimum for projecting the 10th percentile of calcium concentrations from the 10th percentile of conductivity at the sites for which appropriate data were available:

$$\ln(Ca) = 1.14 \cdot \ln(EC) - 4.35$$

For the full NWIS dataset, the following regression model was developed to project calcium concentrations from conductivity:

$$\ln(Ca) = 0.866 \cdot \ln(EC) - 1.51$$

C.2.5 Magnesium

The following regression model appeared to be optimum for projecting the 10th percentile of magnesium concentrations from the 10th percentile of conductivity at the sites for which appropriate data were available:

$$\ln(Mg) = 1.27 \cdot \ln(EC) - 4.81$$

For the full NWIS dataset, the following regression model was developed to project magnesium concentrations from conductivity:

$$\ln(Mg) = 0.986 \cdot \ln(EC) - 3.48$$

C.2.6 Sodium

The following regression model appeared to be optimum for projecting the 10th percentile of sodium concentrations from the 10th percentile of conductivity at the sites for which appropriate data were available:

$$\ln(Na) = 0.578 \cdot \ln(EC) - 2.62$$

For the full NWIS dataset, the following regression model was developed to project sodium concentrations from conductivity:

$$\ln(Na) = 1.32 \cdot \ln(EC) - 4.96$$

C.2.7 Potassium

The following regression model appeared to be optimum for projecting the 10th percentile of potassium concentrations from the 10th percentile of conductivity at the sites for which appropriate data were available:

$$\ln(K) = 0.882 \cdot \ln(EC) - 3.29$$

For the full NWIS dataset, the following regression model was developed to project potassium concentrations from conductivity:

$$\ln(K) = 0.647 \cdot \ln(EC) - 3.04$$

C.2.8 Sulfate

The following regression model appeared to be optimum for projecting the 10th percentile of sulfate concentrations from the 10th percentile of conductivity at the sites for which appropriate data were available:

$$\ln(SO_4) = 1.16 \cdot \ln(EC) - 4.85$$

For the full NWIS dataset, the following regression model was developed to project sulfate concentrations from conductivity:

$$\ln(SO_4) = 1.43 \cdot \ln(EC) - 4.47$$

C.2.9 Chloride

For the full NWIS dataset, the following regression model was developed to project chloride concentrations from conductivity:

$$\ln(\text{chloride}) = 1.39 \cdot \ln(EC) - 6.15$$

Unfortunately, there were an insufficient number of sites reporting chloride data for a regression model to be developed for the 10th percentile of chloride.

C.3 Application of Conductivity Regressions

There are a number of ways in which the conductivity regressions could be used to project BLM water quality inputs. However, the most important situation may be when a fixed copper criteria value must be calculated for a site where there may be little data available to characterize water quality. In such cases, the regressions allow some or all of the BLM water quality inputs to be projected from either (1)

NMED Exhibit 34

a limited number of conductivity measurements or (2) a low-end conductivity value estimated by geostatistical or other methods. The first approach, projecting BLM water quality inputs from conductivity measurements, will be demonstrated in this section for a limited number of test sites. The second approach, projecting the BLM water quality inputs based on conductivities estimated by geostatistical methods, is demonstrated in the following section (Section C4).

The regression models presented above for projecting BLM water quality inputs from conductivity were tested using data and BLM predictions from a number of sites. For each site, a fixed copper criteria value was calculated using the Monte Carlo method described in EPA 2002. The BLM version 2.2.3 was used for all BLM calculations. Fixed copper criteria values were determined by the Monte Carlo method, utilizing site-specific data for parameter distributions and variance-covariance structure of all BLM water quality parameter inputs as well as filtered copper concentrations. The test sites (below) were selected on the basis of convenience, number of water quality observations, and geographic location.

The BLM water quality inputs projected from the conductivity regressions are low-end percentiles appropriate for predicting the instantaneous criterion (IC) predicted by the BLM to estimate the fixed site criteria (FSC) value. We suggested this approximation previously, based on the observation that protective FSC for copper generally corresponded to approximately the 2.5^{th} percentile of the distribution of IC predicted by the BLM. BLM estimates made for a site using the corresponding percentiles of the water quality parameter distributions will be a conservative approximation of this protective criteria values. For the present work, we are using this approach to test the 10^{th} percentile water quality parameter values projected from the conductivity regressions.

Previously we noted that filtered copper concentrations were correlated to BLM input water quality parameters at many sites. Furthermore, we found that the degree of correlation between copper concentrations and BLM input parameters appeared to be an important site-specific factor in determining the relationship between the FSC and the IC. Copper concentrations are not required to run the BLM in its toxicity prediction mode, but they are used in the Monte Carlo method to determine the FSC. Because of this, we calculated the FSC both with and without (neglecting) the correlation between copper concentrations and BLM input parameters at each test site.

C.3.1 Naugatuck River, Connecticut

The USGS has sampled the Naugatuck River near Waterville, Connecticut (Station 01208049) since 1967. Ninety-one water samples collected since 1984 provided near-concurrent measurements of all BLM water quality inputs and filtered copper concentrations. The water is low in hardness and alkalinity, slightly acidic (mean pH = 7.32), and fairly low in conductivity (10^{th} percentile = 134 µS/cm at 25º C). Organic carbon concentrations are representative for rivers and streams in this region and nationwide (logmean TOC = 4.02 mg/L), and the filtered copper concentrations are low (logmean filtered copper = 3.62 µg/L). The FSC for copper at this site was calculated to be 11.4 µg/L when the correlation between copper concentrations and BLM parameters was considered, and 7.0 µg/L when this correlation was neglected. Test results at this site are show in Table C-1.

NMED Exhibit 34

Table C-1. Copper Fixed Site Criterion predictions for the Naugatuck River, Connecticut using various calculation methods

Calculation Method	DOC (mg/L)	pH	Geochemical Ions	Copper Fixed Site Criterion (µg/L)
Monte Carlo FSC with [copper] correlated to inputs (r =0.7)	Data	Data	Data	11.4
Monte Carlo FSC with no [copper] correlation	Data	Data	Data	7.0
IC calculated with 10th % of input data	2.8 (10th % of data)	7.1 (10th % of data)	(10th % of data)	6.4
IC calculated with input from 10th % of conductivity and correlations	5.49 (projected from correlations)	7.55 (projected from correlations)	(projected from correlations)	21.5
IC calculated with input from 10th % of conductivity and correlations except DOC	2.7 (10th % from L3 ecoregion)	7.55 (projected from correlations)	(projected from correlations)	10.5
IC calculated with input from 10th % of conductivity and correlations except pH & DOC	2.7 (10th % from L3 ecoregion)	7.1 (10th % of data)	(projected from correlations)	5.7
IC calculated with input from 10th % of conductivity and correlations except pH & DOC	2.8 (10th % of data)	7.1 (10th % of data)	(projected from correlations)	5.9

The BLM was then applied to predict IC for copper, using low-end percentiles of the measured BLM water quality inputs. Using the 10th percentile values of all measured input data, an IC of 6.4 µg/L was predicted. This IC is 43% smaller than the FSC calculated considering the copper correlation, but only 21% smaller than the FSC neglecting this correlation. When the 10th percentiles of all of the BLM water quality inputs were instead projected from conductivity using the regression models, the predicted ICs were 21.7 µg/L (using the regressions based on 10th percentiles of the three-state data) and 21.5 µg/L (using the regressions based on all of the data). These results illustrate two important points. First, the BLM predictions based on water quality inputs all projected from conductivity correlations are quite different from BLM predictions based on site data; this will be further considered below. Secondly, however, the BLM predictions based on projected water quality inputs do not really depend on which correlations are used.

Clearly, this result shows that the regression models are unable to accurately project all BLM water quality inputs at this site. However, this was almost entirely due to inaccuracy in the pH and organic carbon projections. To demonstrate this, we recalculated the IC several times, using better estimates of the organic carbon and/or pH data, but all other BLM water quality inputs projected from conductivity using the regression models. The first recalculation was made using the 10th percentile of DOC from rivers and streams in the Northeastern Coastal Zone, the Level III ecoregion where the

NMED Exhibit 34

Naugatuck River is located.[7] In this case the predicted IC was 10.5 µg/L, a value much closer to the FSCs as well as the IC calculated using the 10th percentile values of all the measured input data. A second recalculation was made using the 10th percentile of the pH data, together with the ecoregional 10th percentile of DOC and all other BLM water quality inputs projected from conductivity using the regression models. Finally, a third recalculation was made in which the 10th percentiles of both pH and DOC data were input, with the remaining BLM water quality inputs projected from conductivity using the regression models. For both of these cases, the ICs were within about 10% of the prediction made using the 10th percentile values of all the measured input data. In summary, if BLM predictions are made for copper IC using measured values of pH and organic carbon, minimal error results from projecting the other BLM water quality inputs using conductivity and the regression models. As will be shown in the following sections, the same result was found for the other test sites.

The correlation between filtered copper concentrations and BLM parameters and output was quite strong at this location (r = 0.70 between filtered copper and IC predictions). As a result, the FSC corresponds to an elevated percentile (40%) of the IC predictions. If this correlation is neglected in the Monte Carlo method, the FSC corresponds to only the 14th percentile of the IC predictions. This suggests that the relationship between FSC and IC (in terms of the percentile of the IC distribution corresponding to the FSC) may be somewhat site-specific. Regardless of this complication, the conductivity regressions appear to project reliable low-end percentile estimates of the BLM water quality inputs other than pH and organic carbon. This was demonstrated by repeating the analysis described above using 5th, 2.5th, and 1st percentile input values and projections, each of which produced comparable results (not shown).

C.3.2 San Joaquin River, California

The USGS has sampled the San Joaquin River near Vernalis, California (Station 1130500) since 1950. Water samples collected since 1984 provided 283 near-concurrent measurements of all BLM water quality inputs and 77 filtered copper concentrations. The water has moderate values of hardness and alkalinity, neutral pH, and moderately high conductivity (10th percentile = 307 µS/cm at 25º C). DOC concentrations are representative for rivers and streams in this region and nationwide (logmean DOC = 5.35 mg/L), and the filtered copper concentrations are low (logmean filtered copper = 1.75 µg/L). The FSC for copper at this site was calculated to be 39.1 µg/L, and the correlation between copper concentrations and BLM parameters was strong (r = 0.624 between filtered copper and IC predictions). This FSC value corresponds to the 46th percentile of the distribution of IC. When the FSC for copper was recalculated assuming no correlation between copper concentrations and BLM parameters, the value decreased to 11.1 µg/L (corresponding to the 4.5th percentile of the IC distribution). Test results at this site are tabulated Table C-2.

[7] Ecoregion and water body-type specific DOC concentration percentiles were tabulated for the *Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health (2000), Technical Support Document Volume 2: Development of National Bioaccumulation Factors* (EPA-822-R-03-030).

NMED Exhibit 34

Table C-2. Copper Fixed Site Criterion predictions for the San Joaquín River, California using various calculation methods

Calculation Method	DOC (mg/L)	pH	Geochemical Ions	Fixed Site Criterion (µg/L)
Monte Carlo FSC with [copper] correlated to inputs (r =0.6)	Data	Data	Data	39.1
Monte Carlo FSC with no [copper] correlation	Data	Data	Data	11.1
IC calculated with 10th % of input data	2.7 (10th % of data)	7.5 (10th % of data)	(10th % of data)	11.9
IC calculated with input from 10th % of conductivity and correlations	9.38 (projected from correlations)	7.77 (projected from correlations)	(projected from correlations)	54.0
IC calculated with input from 10th % of conductivity and correlations except DOC	2.79 (10th % from L3 ecoregion)	7.77 (projected from correlations)	(projected from correlations)	16.0
IC calculated with input from 10th % of conductivity and correlations except pH & DOC	2.79 (10th % from L3 ecoregion)	7.5 (10th % of data)	(projected from correlations)	11.6
IC calculated with input from 10th % of conductivity and correlations except pH & DOC	2.7 (10th % of data)	7.5 (10th % of data)	(projected from correlations)	11.2

The BLM was then applied to predict IC for copper, using low-end percentiles of the BLM water quality inputs. Using the 10th percentile values of all measured input data, an IC of 11.9 µg/L was predicted, which is 70% smaller than the FSC calculated considering the copper concentration correlation but 7% higher than the FSC neglecting this correlation. When the 10th percentiles of all of the BLM water quality inputs were instead projected from conductivity using the regression models, the predicted IC were 50.0 µg/L (using the regressions based on 10th percentiles of the three-state data) and 54.0 µg/L (using the regressions based on all of the data). Again, the BLM predictions based on projected water quality inputs do not really depend on which correlations are used. And, as was the case at the Naugatuck River site, the regression models were unable to accurately project all BLM water quality inputs at this site, although the error is again almost entirely due to inaccuracy in the pH and organic carbon projections. As in the previous case, we demonstrated this by recalculating the IC several times, using better estimates of the organic carbon and/or pH data, but all other BLM water quality inputs projected from conductivity using the regression models. The first recalculation was made using the 10th percentile of DOC from rivers and streams in the Central California Valley, the Level III ecoregion where the San Joaquin River is located. In this case the predicted IC was 16.0 µg/L, a value much closer to the uncorrelated FSCs as well as the IC calculated using the 10th percentile values of all the measured input data. A second recalculation was made using the 10th percentile of the pH data, together with the ecoregional 10th percentile of DOC and all other BLM water quality inputs projected from conductivity using the regression models. Finally, a third recalculation was made in which the 10th percentiles of both pH and DOC data were input, with the remaining BLM water quality inputs projected from conductivity using the regression models. For both of these cases, the ICs were within

NMED Exhibit 34

about 5% of the prediction made using the 10th percentile values of all the measured input data. BLM predictions made for copper IC at this site using measured values of pH and organic carbon, but all other BLM water quality inputs projected using conductivity regressions, were found to be accurate in comparison to model predictions made using all measured input data.

C.3.3 South Platte River, Colorado

The South Platte River has been sampled by the USGS at Denver, Colorado (Station 06714000) since 1972. Water samples collected since 1984 provided 93 near-concurrent measurements of all BLM water quality inputs and 10 filtered copper concentrations. The water is moderately high in hardness and alkalinity, neutral pH, and moderate conductivity (10th percentile = 229 µS/cm at 25° C). Organic carbon concentrations are representative for rivers and streams in this region (logmean DOC = 5.50 mg/L), and the filtered copper concentrations are low (logmean filtered copper = 3.27 µg/L). The FSC for copper at this site was calculated to be 35.4 µg/L. This FSC value corresponds to the 32nd percentile of the distribution of IC. Moderate correlation between copper concentrations and BLM parameters was observed at this site (r = 0.50 between filtered copper and IC predictions). When the FSC for copper was recalculated assuming no correlation between copper concentrations and BLM parameters, the value decreased to 20 µg/L (corresponding to the 4.3rd percentile of the IC distribution). Test results at this site are shown in Table C-3.

Table C-3. Copper Fixed Site Criterion predictions for the South Platte River, Colorado using various calculation methods

Calculation Method	DOC (mg/L)	pH	Geochemical Ions	Copper Fixed Site Criterion (µg/L)
Monte Carlo FSC with [copper] correlated to inputs (r =0.5)	Data	Data	Data	35.4
Monte Carlo FSC with no [copper] correlation	Data	Data	Data	20.0
IC calculated with 10th % of input data	4.1 (10th % of data)	7.5 (10th % of data)	(10th % of data)	17.3
IC calculated with input from 10th % of conductivity and correlations	7.7 (projected from correlations)	7.7 (projected from correlations)	(projected from correlations)	37.5
IC calculated with input from 10th % of conductivity and correlations except DOC	4.5 (10th % from L3 ecoregion)	7.7 (projected from correlations)	(projected from correlations)	21.6
IC calculated with input from 10th % of conductivity and correlations except pH & DOC	4.5 (10th % from L3 ecoregion)	7.5 (10th % of data)	(projected from correlations)	17.3
IC calculated with input from 10th % of conductivity and correlations except pH & DOC	4.1 (10th % of data)	7.5 (10th % of data)	(projected from correlations)	15.9

NMED Exhibit 34

The BLM was applied to predict IC for copper, using low-end percentiles of the BLM water quality inputs. Using the 10th percentile values of all measured input data, an IC of 17.3 µg/L was predicted, which is 51% smaller than the FSC calculated considering the copper concentration correlation but only 14% smaller than the FSC neglecting this correlation. When the 10th percentiles of all of the BLM water quality inputs were instead projected from conductivity using the regression models, the predicted IC was 37.5 µg/L. As was the case at the previous sites, the regression models were again unable to accurately project pH and organic carbon concentrations for input to the BLM. We demonstrated this by recalculating the IC several times, using better estimates of the organic carbon and/or pH data, but all other BLM water quality inputs projected from conductivity using the regression models. The first recalculation was made using the 10th percentile of DOC from rivers and streams in the Western High Plains, the Level III ecoregion where the South Platte River is located. In this case the predicted IC was 21.6 µg/L, a value much closer to the uncorrelated FSCs as well as the IC calculated using the 10th percentile values of all the measured input data. A second recalculation was made using the 10th percentile of the pH data, together with the ecoregional 10th percentile of DOC and all other BLM water quality inputs projected from conductivity using the regression models. Finally, a third recalculation was made in which the 10th percentiles of both pH and DOC data were input, with the remaining BLM water quality inputs projected from conductivity using the regression models. For both of these cases, the ICs were within 10% of the prediction made using the 10th percentile values of all the measured input data. As with the previous cases, the BLM predictions made for copper IC at this site using measured values of pH and organic carbon, but where all other BLM water quality inputs were projected using conductivity regressions, were found to be accurate in comparison to model predictions made using all measured input data.

C.3.4 Halfmoon Creek, Colorado

The USGS has sampled Halfmoon Creek near Malta, Colorado (Station 07083000) since 1959. Seventy-three water samples collected since 1984 provided near-concurrent measurements of all BLM water quality inputs and 18 filtered copper concentrations. The water is very low in hardness and alkalinity, slightly acidic (mean pH = 7.76), and low in conductivity (10th percentile = 50.1 µS/cm at 25° C). Organic carbon concentrations are low (logmean DOC = 0.92 mg/L), as are the filtered copper concentrations (logmean filtered copper = 1.75 µg/L). The FSC for copper at this site was calculated to be 1.56 µg/L, corresponding to the 6th percentile of the distribution of IC. The correlation between copper concentrations and BLM parameters was negligible at this site, so the Monte Carlo FSC were not calculated twice (i.e., with and without the copper correlation) as was done at the other sites. Test results at this site are shown in Table C-4.

NMED Exhibit 34

Table C-4. Copper Fixed Site Criterion predictions for the Halfmoon Creek, Colorado using various calculation methods

Calculation Method	DOC (mg/L)	pH	Geochemical Ions	Copper Fixed Site Criterion (µg/L)
Monte Carlo FSC with [copper] correlated to inputs (r =0.01)	Data	Data	Data	1.56
IC calculated with 10th % of input data	0.6 (10th % of data)	7.2 (10th % of data)	(10th % of data)	1.42
IC calculated with input from 10th % of conductivity and correlations	2.8 (projected from correlations)	7.3 (projected from correlations)	(projected from correlations)	7.43
IC calculated with input from 10th % of conductivity and correlations except DOC	0.6 (10th % from L3 ecoregion)	7.3 (projected from correlations)	(projected from correlations)	1.58
IC calculated with input from 10th % of conductivity and correlations except pH & DOC	0.6 (10th % from L3 ecoregion)	7.2 (10th % of data)	(projected from correlations)	1.39
IC calculated with input from 10th % of conductivity and correlations except pH & DOC	0.6 (10th % of data)	7.2 (10th % of data)	(projected from correlations)	1.39

The BLM was then applied to predict IC for copper, using low-end percentiles of the BLM water quality inputs. Using the 10th percentile values of all measured input data, an IC of 1.42 µg/L was predicted, only 9% smaller than the FSC. When the 10th percentiles of all of the BLM water quality inputs were instead projected from conductivity using the regression models, the predicted IC was 7.43 µg/L. Again, this result clearly shows that the regression models are unable to accurately project all BLM water quality inputs at this site. As in the previous examples, this was almost entirely due to inaccuracy in the pH and organic carbon projections. As in the previous cases, we demonstrated this by recalculating the IC several times, using better estimates of the organic carbon and/or pH data, but all other BLM water quality inputs projected from conductivity using the regression models. The first recalculation was made using the 10th percentile of DOC from rivers and streams in the Southern Rockies, the Level III ecoregion where Halfmoon Creek is located. In this case the predicted IC was 1.58 µg/L, a value within about 10% of the FSC as well as the IC calculated using the 10th percentile values of all the measured input data. A second recalculation was made using the 10th percentile of the pH data, together with the ecoregional 10th percentile of DOC and all other BLM water quality inputs projected from conductivity using the regression models. Finally, a third recalculation was made in which the 10th percentiles of both pH and DOC data were input, with the remaining BLM water quality inputs projected from conductivity using the regression models. For both of these cases, the ICs were within about 2% of the prediction made using the 10th percentile values of all the measured input data. As in the previous examples, if BLM predictions are made for copper IC using measured values of pH and organic carbon, minimal error results from projecting the other BLM water quality inputs using conductivity and the regression models.

NMED Exhibit 34

C.3.5 Summary of Site-Specific Test Results

The results of this work can be summarized as follows:

Regression models were developed to project 10th percentiles of BLM water quality parameters from the 10th percentile of conductivity distributions at sites in Colorado, Utah, and Wyoming. The regression models were tested using data and copper BLM predictions for four sites, and produced highly consistent results. The regression models for pH and DOC, the most sensitive of BLM water quality parameters, were not sufficiently accurate to make reliable BLM predictions. However, regression models for the GI parameters (alkalinity, calcium, magnesium, sodium, potassium, sulfate, and chloride,) were reasonably accurate, as judged by comparison of model predictions made using projected values of the GI BLM input parameters to model predictions made using all measured input data. The regression models used to project GI parameters from conductivity were calculated two different ways; however, the BLM predictions of IC were not sensitive to this difference.

We were unable to find an estimate for site-specific pH that was superior to the (admittedly poor) conductivity regression. To improve upon this estimate it was necessary to use actual site-specific pH data. This appears to be the general case for reliable site-specific BLM application.

For DOC, the ecoregion and water body-type specific DOC concentration percentiles tabulated by EPA for the National Bioaccumulation Factors Technical Support Document appear to be far better estimates of lower-percentile DOC concentrations than the projections made using the conductivity regression. These tabulations are based on an organic carbon database compiled prior to 2003 from a number of sources including EPA's STOrage and RETrieval Data Warehouse (STORET) and the USGS NWIS. The utility of these tabulations could be improved by updating them to incorporate newer information. For example, EPA recently released data from the Wadeable Stream Assessment, which included DOC measurements from a statistically based random sample of ~2,000 streams. Other statistically-based national water quality surveys, including national assessments of lakes and large rivers, will also be providing additional data in future years.

The Monte Carlo method developed to calculate FSC for copper was applied at each of the four sites, both with and without the correlation between filtered copper concentrations and the BLM water quality parameters that were found to be significant at three of the sites. We also approximated the FSC using the 10th percentile of the distribution of IC predicted by the BLM at each site. When copper concentration correlations were considered in the FSC calculations, the 10th percentile of the IC distributions was found to be highly conservative approximations of the FSC, underestimating the FSC by 44 to 70%. This is illustrated in Figure C-1, which also shows the good agreement between IC predicted with the BLM using site-specific data and IC predicted using measured pH and organic carbon but projected values of the GI BLM input parameters. Ecoregion and water body-type specific DOC concentration percentiles ("L3-DOC" in the figure below) were also an improvement over the projections based on conductivity regressions.

NMED Exhibit 34

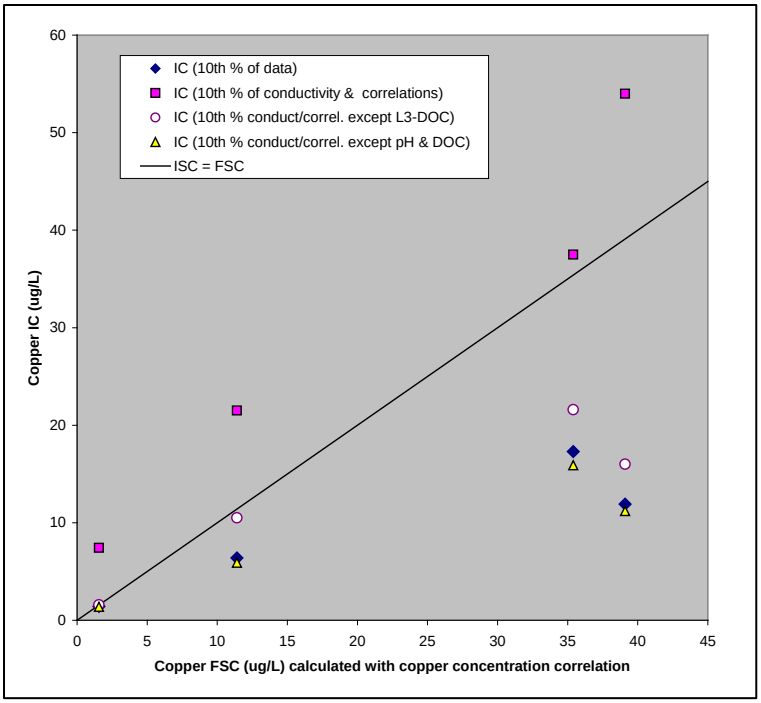

Figure C-1. Instantaneous Criteria (IC) predicted with the BLM using site-specific data and IC predicted using measured pH and organic carbon and projected values of the GI BLM input parameters

When copper concentration correlations were neglected in the FSC calculations, the 10th percentile of the IC distributions did a much better job approximating the FSC. This is shown in Figure C-2. In this case, the 10th percentile of the IC distributions was within 15% of the FSC. This figure also shows the good agreement between IC predicted with data and projected values of the GI BLM input parameters.

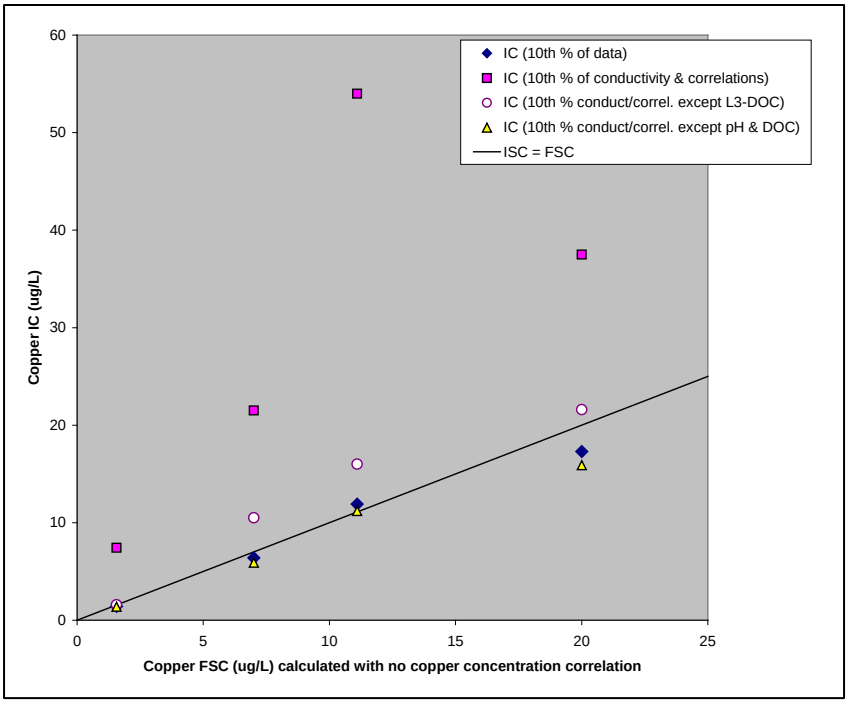

Figure C-2. 10th percentile of the IC distributions using data and projected (predicted) values of the GI BLM parameters

The degree of correlation between filtered copper concentrations and BLM input water quality parameters appears to be an important site-specific factor in determining the relationship between the FSC and the IC. Figure C-3 plots the percentile of the IC corresponding to the FSC for each site as a function of the correlation coefficient between the copper concentrations and the IC, for two cases: (1) FSC calculated by the Monte Carlo method including the observed correlations between concentrations of copper and BLM input water quality parameters, and (2) FSC calculated with no correlation between concentrations of copper and BLM input water quality parameters. In the first case (plotted with dark diamond symbols), the percentile of the IC corresponding to the FSC increases substantially (6th to 46th percentile) as the correlation coefficient between the copper concentrations and the IC increases. If the correlation between concentrations of copper and BLM input water quality parameters is neglected (the second case, plotted in lighter square symbols), the percentile of the IC corresponding to the FSC is considerably lower (4.3rd to 14th percentile). This suggests that correlations between copper concentrations and BLM input parameters should be given careful consideration when calculating FSC.

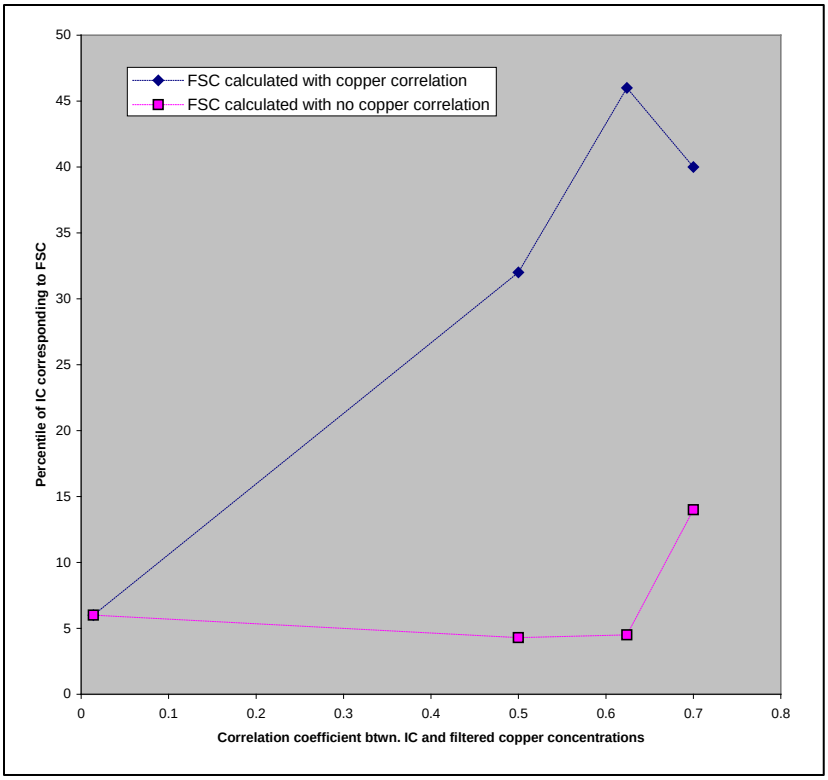

Figure C-3. Percentile of the IC corresponding to the FSC for each site as a function of the correlation coefficient between the copper concentrations and the IC when the FSC is calculated with Copper correlation and when FSC is calculated without Copper correlation

C.4 Combining GI-Conductivity Regressions with Geostatistical Techniques

Geostatistical techniques are attractive because they explain parameter variation arising from spatial correlations, which are otherwise ignored by (and may, in fact, violate the assumptions of) conventional statistics. BLM input water quality parameters (except for pH and DOC) are GIs, the concentrations of which vary in surface water due to dissolution, weathering, ground water-surface water interactions, and other geologic processes in the watershed. Consequently, the concentrations of GI parameters tend to vary according to the regional geology. For example, water hardness has noticeable geographic trends. Areas with limestone geology, such as in the prairie states, tend toward high hardness and alkalinity. Areas of with granite geology, such as parts of the Northeast, tend toward low hardness and alkalinity. The estimation of GI parameter values based on geography thus seems possible. EPA has provided a prototype of a geostatistical approach[8] that demonstrated this potential. That work applied kriging to predict median concentrations of five of the BLM water quality input parameters (pH, DOC, alkalinity, sodium, and calcium) averaged over 8-digit HUCs, using the USGS NWIS as the source of spatial data. Comparison of measured concentrations with kriging predictions were encouraging, especially for DOC and alkalinity. Geostatistical techniques to project BLM GI input

parameters might well be developed from the same nationwide monitoring data used to develop a correlation approach. By the same token, geostatistical techniques based on these data may suffer the same problems experienced when developing the correlation approach. Most significantly, the NWIS data are not randomly distributed in either time or space, and the measurements of the BLM GI parameters are generally uneven (considerable differences in terms of the number of observations for different parameters) and/or inconsistent (i.e., relatively few concurrent measurements of BLM GI parameters).

There may be great value in supplementing the geostatistical approach with classical estimation methods, such as regression and correlation. Examination of the NWIS data suggests that conductivity may be useful for estimating BLM input water quality parameters in conjunction with geostatistics. The literature indicates that conductivity is one of the most widely monitored water quality indicators in the US. Among water quality parameters, the data for conductivity are the most complete and cover the longest time period (Wang and Yin, 1997). In part, this is because conductivity measurements are usually included in automated multiparameter systems for monitoring changes in the quality of surface waters (Allen and Mancy, 1972). A vast amount of conductivity data exists, both in terms of the total number of observations and the number of sites reporting this parameter in comparison to the BLM GI quality parameters. For example, NWIS data for the state of Colorado have almost four times as many observations of conductivity as for calcium, and they are measured at more than twice the number of sites. There are 20 times as many observations of conductivity as for alkalinity, and they are measured at more than seven times the number of sites. Since conductivity data are abundant, and correlate well to the BLM GI parameters (GLEC, 2007), it is reasonable to incorporate conductivity in spatial projections of BLM parameters. This may simplify the geostatistical approach and allow more robust spatial projections of BLM water quality parameters.

Although combining GI-conductivity regressions with geostatistical techniques seems promising for the reasons mentioned above, this approach had never been demonstrated. We conducted a simple test using NWIS conductivity and hardness data from the state of Colorado. We used data from Colorado because many more stations were sampled in comparison to the surrounding states.

The data were processed in a manner similar to the methods used to develop the regressions in Section C.2. For each station, we calculated the 10^{th} percentiles of conductivity and hardness. A regression model was fit to the full dataset (data for all rivers and streams sampled in Colorado between 1984 to 2005). The following regression model was developed to project hardness from conductivity:

$$\ln(\text{hardness}) = 0.984 \cdot \ln(EC) - 0.870$$

We also kriged the 10^{th} percentiles of conductivity and hardness, using latitude and longitude coordinates reported by USGS for each sampling station. Figure C-4 shows the kriged surface of the 10^{th} percentile of conductivity at all stations in Colorado, Utah, and Wyoming. Data are far more abundant in Colorado, as shown by the density of the dots representing the locations of sampling stations. Figure C-5 shows the kriged surface of the 10^{th} percentile of hardness at all stations in Colorado. Kriging was done using the Vertical Mapper program, version 3.1; no attempts were made to optimize the kriging of conductivity or hardness by parameter adjustment.

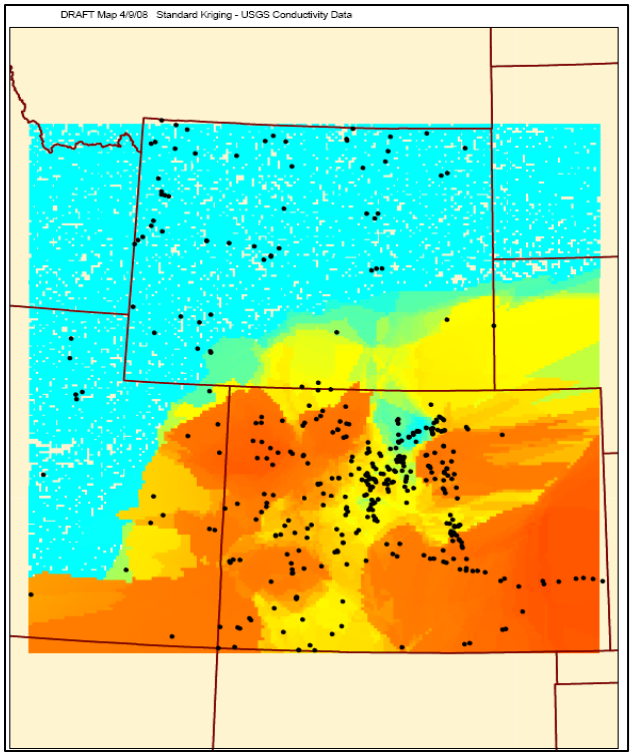

Figure C-4. Kriged surface of the 10th percentile of conductivity at all stations in Colorado, Utah and Wyoming

Dots represent sampling stations; notice that data are far more abundant in Colorado.

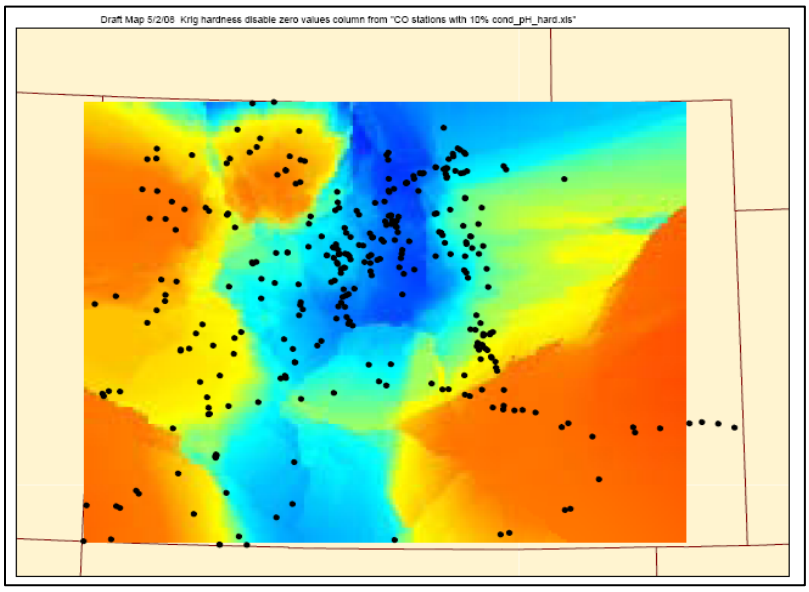

Figure C-5. Kriged surface of the 10th percentile of hardness at all stations in Colorado

Our goal was to see whether combining the kriged conductivities with the conductivity-hardness regression would project the 10th percentiles of hardness better than direct kriging of the hardness

data. For the combined kriging/regression approach, we determined the kriged conductivity values at all of the sampling locations and then projected the 10th percentiles of hardness at these locations using the regression equation. We also determined the directly-kriged 10th percentiles of hardness at all of the sampling locations.

The hardness estimates obtained by each approach were then compared to the 10th percentiles of hardness measured at each station. The results of this comparison are shown graphically in Figure C-6. Both approaches produce estimates of hardness that correlate significantly with the measured data (correlation coefficient r= 0.80 for direct kriging of hardness; r= 0.950 for conductivity kriging + regression projection). However, the kriging+regression approach fits the hardness data substantially better than direct kriging. To quantify this, we calculated the residual sum of squares (RSS), a composite measure of the discrepancy between the data and our alternative hardness estimates. The smaller this discrepancy is, the better the estimation will be. In natural log space, the RSS for the kriging+regression approach is 18.6 (135 degrees of freedom, or df) while the log-space RSS for the direct kriging approach is 73.4 (136 df). Thus, for this test case substantially better estimates of the 10th percentile of hardness were made by the kriging/regression approach compared to direct kriging.

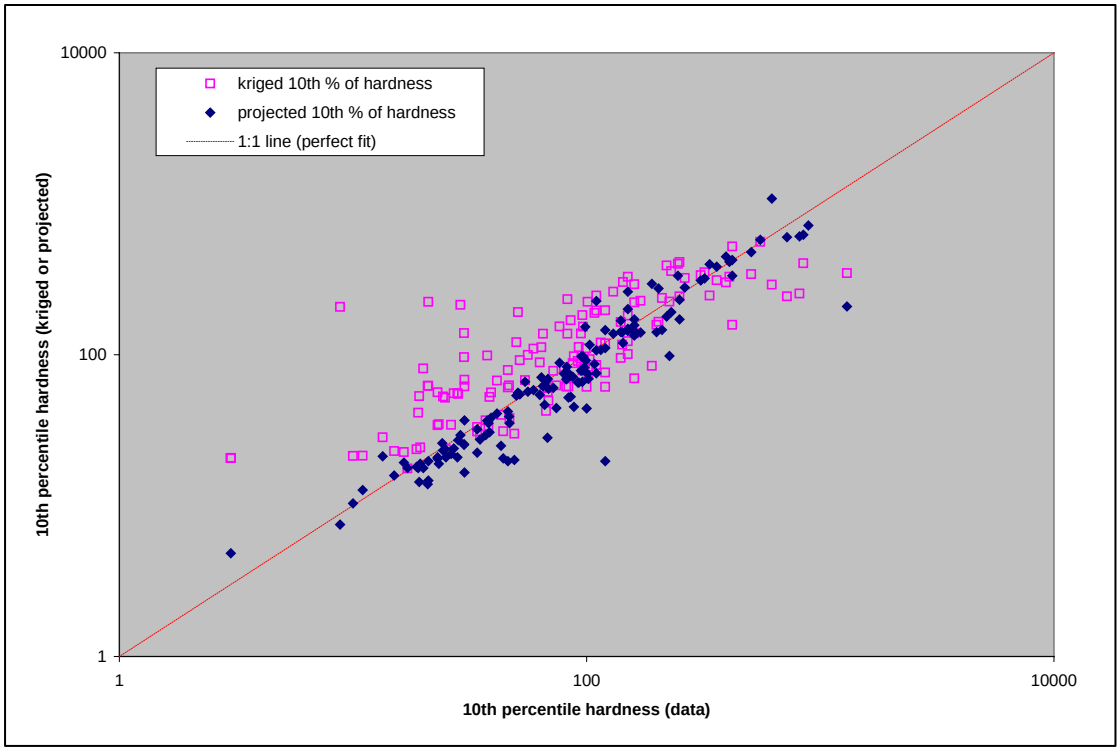

Figure C-6. Comparison of the 10th percentile of hardness at all stations in Colorado with estimates based on (a) direct kriging of hardness data and (b) kriging of conductivity to station locations and projecting conductivity to hardness via regression ("kriging/regression")

As this test demonstrated, combining kriging with regressions to project BLM GI inputs from conductivity appears to improve the accuracy of estimates of parameters used as BLM inputs. Applying the conductivity kriging/regression projection approach on a broader scale should be considered as a

"next step" in developing tools to estimate BLM water quality parameters for sites where there may be few or no data available to characterize water quality. Since direct kriging of most BLM GI parameters has already been done using data from NWIS, it will also be worthwhile to continue comparing the alternative estimates to the observed data in order to obtain the best estimates.

We should also note that although the kriging/regression approach can be used to improve the accuracy of estimates of GI parameters used as BLM inputs, this approach cannot be expected to produce accurate site-specific estimates for the two most important BLM inputs: pH and DOC. As shown in Section C.3, accurate estimates of the GI parameters are less important than pH and DOC in terms of predicting appropriate site-specific IC and FSC. Since our analysis of NWIS data indicates there to be either little no trend between conductivity and pH, and direct kriging produced similarly ambiguous predictions, we must conclude that site-specific data for pH must either be available or be collected for BLM application at a site. This may not be a significant obstacle, since pH data can be cheaply and readily acquired.

Lack of methods to accurately estimate DOC is a bigger problem, since measurements of this parameter are comparatively rare and DOC is a relatively expensive measurement to make. For DOC, analysis of NWIS data again indicates no trend with conductivity, so the kriging/regression approach is not appropriate for this parameter. However, other analyses conducted suggested that DOC could be kriged with some success. And, as was demonstrated for the test sites in Section C.3, the ecoregion and water body-type specific DOC concentration percentiles tabulated by EPA for the National Bioaccumulation Factors Technical Support Document appear to offer reasonable estimates of lower-percentile DOC concentrations. Further development of these approaches for estimating site-specific DOC appears worthwhile, for example by incorporating new data from the Wadeable Stream Assessment and other statistically-based national water quality surveys.

Appendix D: Approaches for Estimating Missing Biotic Ligand Model Input Parameters: Projections of Total Organic Carbon as a Function of Biochemical Oxygen Demand

D.1 Introduction

The 2007 Update of the Ambient Water Quality Criteria for Copper (EPA-822-R-07-001) employs the Biotic Ligand Model (BLM) to estimate bioavailability of this metal in toxicity tests used in Criterion Maximum Concentration derivation, which requires data on the 10 input parameters for the BLM, including dissolved organic carbon (DOC). Data for DOC concentrations, in both effluents and receiving waters, are extremely limited. The BLM is very sensitive to DOC concentrations (HydroQual, 2005), which means that to ensure accurate predictions of copper bioavailability and toxicity reliable data on DOC concentrations in the water are needed. Effluent DOC concentrations, which are necessary for application of the BLM to predict copper toxicity associated with a wastewater discharge, are monitored by very few publicly-owned treatment works (POTWs).

Projections of DOC concentrations from biochemical oxygen demand (BOD) values may be a viable solution for surmounting the lack of data on DOC. Effluent BOD (most typically 5-day BOD) is monitored by most POTWs. We expect a positive correlation between BOD and DOC, because the two parameters are conceptually related. While DOC quantifies the concentration of many organic compounds dissolved in water, BOD is a routine surrogate test for estimating the load of organic carbon into the environment. Ideally, one might expect an almost stoichiometric relationship between organic carbon (i.e., DOC) and the oxygen consumed during its metabolization (i.e., BOD). For instance, Fadini et al. (2004) evaluated the possible replacement of BOD for DOC measurements in a number of different wastewater categories. A statistical relationship between effluent BOD and DOC would provide estimates of DOC concentrations, needed for application of the BLM, from routine BOD monitoring data. The effluent contribution to in-stream DOC could then be estimated, for example, by using a dilution model for a site.

Evidence, from analyses of effluent monitoring data from the New York State Department of Environmental Conservation (NYSDEC) Contaminant Assessment and Reduction Project (CARP), suggests that most of the total organic carbon (TOC) in POTW effluent is in the form of DOC. Therefore, a regression between BOD and TOC could be used as a surrogate for the relationship between BOD and DOC. The advantage of using TOC is the greater availability of data. TOC is reported for a significant number of major POTW dischargers.

D.2 Data

In 2006, monitoring data from all major POTWs reporting TOC and 5-day BOD in the United States were downloaded from the U.S. Environmental Protection Agency (EPA) Permit Compliance System (PCS) web site http://www3.epa.gov/enviro/facts/pcs-icis/search.html. Nine POTWs had 30 or more synchronous records of TOC and BOD, while 23 POTWs had at least 10 synchronous records. These numbers include both monthly average and maximum monthly values.

Review of the data indicated several extremely high (>1,000 milligrams per liter [mg/L]) effluent TOC values for discharger CA0079243. We assumed that they presented errors in the reported unit, and divided them by 1,000 to convert from units of microgram per liter (µg/L) to mg/L. TOC and BOD

NMED Exhibit 34

records were matched by POTW, location (e.g., upstream, downstream, influent or effluent), year and month. Thus, "synchronous" measurements do not necessarily correspond to samples collected on the same day and time. The resulting table had 341 records.

D.3 Results

D.3.1 TOC and BOD at All Monitoring Locations

The first statistical evaluation involved data for all monitoring locations at the eight POTWs reporting 30 or more synchronous records of TOC and BOD. Table D-1 presents the results of least squares regression of the average monthly data: TOC*avg* = *a* + *b* BOD*avg*. A scatter plot of this data is shown in Figure D-1. Table D-2 presents the results of least squares regression of the maximum monthly data: TOC*max* = *a* + *b* BOD*max*. A scatter plot of this data is shown in Figure D-2. Bimodal distributions are observed for TOC and especially BOD in this data set. It should be noted that the BOD concentrations of 200 mg/L or higher were measured in samples of untreated (influent) wastewater; TOC concentrations were also quite high in these samples. Both scatter plots (Figures D-1 and D-2) show a fairly strong correlation between TOC and BOD in the combined data for all POTWs. The linear relationship between TOC and BOD is better defined in the average data (Figure D-1).

Figure D-2. Scatter Plot of Maximum Monthly Data (all Monitoring Locations)

Results of regression analyses revealed large differences in slopes of the linear model TOC = *a* + *b* BOD among locations and POTWs. Slopes for individual regressions ranged from –0.40 to 0.73 for average, and from -0.82 to 0.50 for maximum BOD and TOC values. Coefficients of determination (r^2) for the regressions were low; for most of them $r^2 < 0.2$. Pooling the data from all POTWs and locations increased the r^2 to 0.87 for average and 0.70 for maximum BOD and TOC values.

Diagnosis of regression analyses revealed that variance in both the average and maximum TOC rose with increasing values of biochemical oxygen demand. Such patterns were also evident from a simple inspection of the plots cited above. Homogeneity of variance, though, is a core assumption of ordinary least squares regression, and its violation compromises the quality of results generated by the analysis. The solution was to perform quantile regression analysis because it does not assume that variance of the response is homogeneous along the range of the independent variable. The fitted model for the 50^{th} quantile (median) was:

$$TOC_{avg} = 5.5647 + 0.2088\ BOD_{avg} \quad (243\ df,\ R^1 = 0.77)$$

D.3.2 TOC and BOD at Effluent Monitoring Locations

Although the quantile regression model above provided a reasonable fit of the data at all monitoring locations, we were specifically interested in the relationship between TOC and BOD measured in POTW effluents. Therefore, we conducted a separate statistical analysis of effluent monitoring data from the 17 POTWs with more than one synchronous record of TOC and BOD retrieved from PCS. TOC and BOD records were again matched by POTW, year, and month. The resulting data tabulation had 373 records.

The results of least squares regression of the average monthly effluent data: TOC*avg* = *a* + *b* BOD*avg* are presented in Table D-3. A scatter plot of this data is shown in Figure D-3. Table D-4 presents the results of least squares regression of the effluent maximum monthly data: TOC*max* = *a* + *b* BOD*max*. A scatter plot of this data is shown in Figure D-4.

Figure D-4. Scatter Plot of Maximum Monthly Data (Effluent Monitoring Locations)

Results of the effluent regression analyses revealed large differences in slopes of the linear model TOC = *a* + *b* BOD among POTWs. Slopes for individual regressions ranged from –1.13 to 0.73 for average, and from -0.82 to 1.07 for maximum BOD and TOC values. Coefficients of determination (r^2) for the regressions were low; all $r^2 < 0.55$ and for most of them $r^2 < 0.24$. Low coefficients of determination were also recorded for regressions of TOC on BOD values from all POTWs ($r^2 = 0.245$ and 0.276, for average and maximum values, respectively). Further investigations of the effluent regression analyses were performed, because visual inspection of Figures D-3 and D-4 suggested the presence of outliers in the data.

We examined the fit of the linear model, TOC*avg* = *a* + *b* BOD*avg*, by inspecting its residuals (Figure D-5). Studentized residuals were plotted against projected (fitted) TOC values in the left pane, and against quantiles of the standard normal distribution in the right pane. Four suspiciously-low average TOC points in Figure D-4 are labeled '324', '308', plus the two points adjacent to the latter (left pane). This plot reveals that residuals for high-TOC points '489' and '64' are far larger in magnitude than residuals for the four suspiciously-low points. Residuals for these two points greatly deviate from the normal distribution (right pane). Furthermore, points '335' and '336' have much greater leverage than any other (leverages for '335': 0.164, '336': 0.127). Fitting the linear model without points '489', '64', '335', and '336' results in the following parameter values:

TOC*avg* = 6.0388 + 0.2171 BOD*avg* ($r^2 = 0.185$, 170 df) (Equation 1)

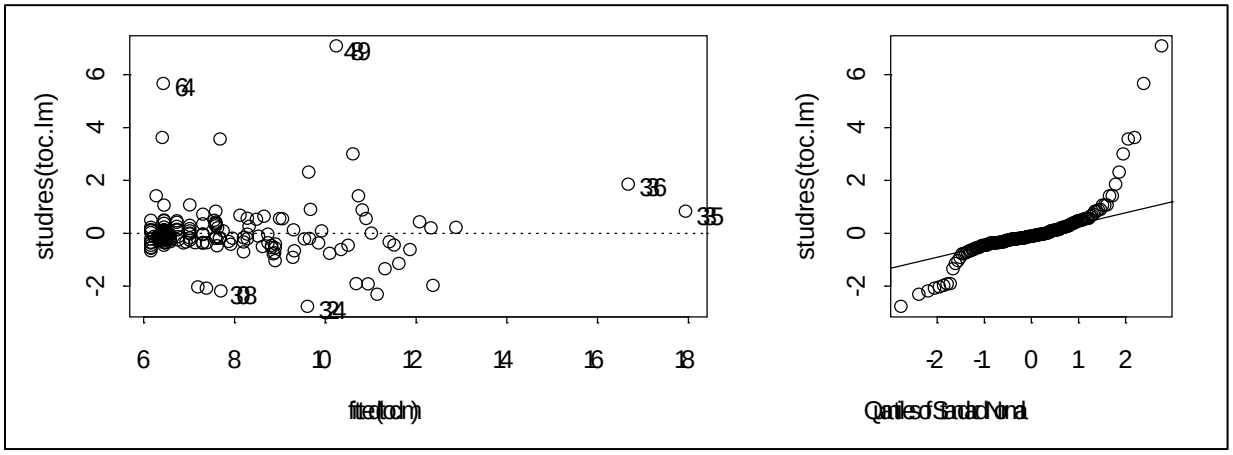

Figure D-5. Residuals of the linear model, TOCavg = a + b BODavg

(Left: plot of Studentized residuals (studres) against projected (fitted) TOC values; Right: plot of studies against quantiles of the standard normal distribution).

It should be noted that this model (Equation 1) projects average TOC concentrations very similar to the regression based upon the uncensored data (i.e., within ± 2 mg/L), for the range of BOD concentrations of interest (less than 30 mg/L).

Diagnosis of the regression analysis, TOC*max* = *a* + *b* BOD*max*, revealed an excessively high residue for the (19, 91) point and very high leverage for the (71, 31) point. The projected regression line without those two points was:

$TOC_{max} = 6.6242 + 0.4095\ BOD_{max}$ ($r^2 = 0.352$, 297 df) (Equation 2)

This model (Equation 2) fits a single slope for all data. Our results, though, revealed large differences in slopes of regression lines among POTWs (Table D-4). We tested the significance of such differences with an *F*-test, which required fitting two additional models, one with the same slope for all POTWs and the other with a distinct slope for each POTW. The *F*-test compares model fits while taking into account the loss in degrees of freedom associated with the computation of multiple slopes. The estimated *F*-value ($F = 4.92$, 13 df) was highly significant ($P < 0.001$), indicating that distinct slopes are necessary to accurately project maximum TOC from maximum BOD values.

D.3.3 TOC and DOC at CARP Effluent Monitoring Locations

Effluent discharge samples were collected from 11 New Jersey POTWs in 2000 and 2001 for the NYSDEC CARP project (www.dec.state.ny.us/website/dow/bwam/CARP). These samples were analyzed for DOC, particulate organic carbon (POC), and total suspended solids (TSS) by the U.S. Geological Survey. TOC was calculated by adding together DOC and POC concentrations. The results are shown in Table D-5. Effluent DOC concentrations are generally much higher than POC because most of the particulate organic matter is removed from wastewater during secondary treatment. A scatter plot of the TOC and DOC data, Figure D-6, shows the strong linear correlation between TOC and DOC that results from the predominance of DOC in effluent. These data are replotted in Figure D-7 for TOC concentrations less than 50 mg/L.

Table D-5. CARP organic carbon and total suspended solids (TSS) monitoring data for New Jersey discharger

Figure D-6. Scatter plot of TOC versus DOC in CARP effluent monitoring data

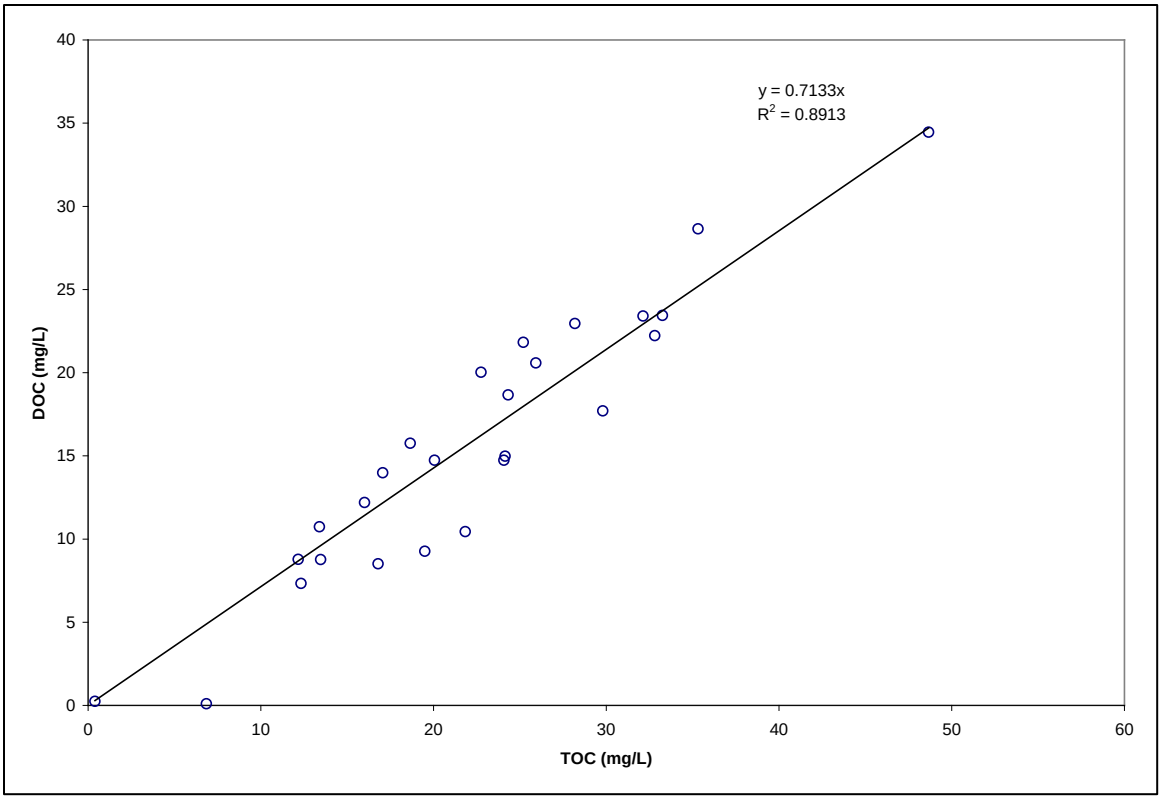

Figure D-7. Scatter plot of TOC versus DOC in CARP effluent monitoring data (TOC <50 mg/L)

Least squares regression of the CARP effluent data (Table D-5) produces the following model:

DOC = 0.9266 TOC (r^2 = 0.9898, 32 df)

This regression was forced through the origin by constraining the intercept to be zero. At the limit of removal efficiency (i.e., as effluent TOC approaches zero), any remaining TOC should be in the form of DOC, as mentioned above. This argument justifies forcing the regression through the origin. If only the data for which TOC falls in the expected range for effluent concentrations (TOC < 50 mg/L) are considered, the regression (again forced though the origin) is:

DOC = 0.7133 TOC (r^2 = 0.8913, 25 df)

For either case, the CARP effluent data show the strong linear relationship between TOC and DOC. Because TOC and DOC are linearly related in POTW effluent, the relationships between BOD and TOC reported above (Sections D.1 and D.2) also apply to DOC.

D.4 Discussion

Initially, we attempted to correlate BOD and TOC concentration measurements using data for all monitoring locations retrieved from PCS for major POTWs. We produced significant linear regression models for both average (Figure D-1) and maximum monthly (Figure D-2) data. Coefficients of determination were 0.87 and 0.70, respectively, for these data when combined for all locations. However, these correlations were substantially influenced by very high (i.e., greater than 50 mg/L) concentrations of BOD and TOC measured in untreated wastewater.

When we repeated the statistical analysis using effluent monitoring data, we found large differences in the slopes of the linear model TOC = *a* + *b* BOD among POTWs. Low coefficients of determination were also recorded for regressions of TOC on BOD values from all POTWs (r^2 = 0.245 and 0.276, for average and maximum values, respectively). In part, this may reflect random errors in the measurements of BOD and TOC, since data quality issues including loss of precision tend to be more frequent and significant at lower concentrations. The greater scatter in the plots of effluent BOD and TOC (Figures D-3 and D-4) may also reflect the limitations of working with the monthly average and maximum data reported by PCS.

Direct inspection of the TOC data in Figures D-3 and D-4 is nevertheless instructive. Aside from some extreme high and low values, the great majority of effluent TOC concentrations are in the range of 5 to 10 mg/L, especially for effluents with BOD concentrations below 10 mg/L. This is true for both average and maximum monthly TOC values. Table D-6 presents summary statistics for average monthly effluent TOC, for all data as well as data categorized according to the following BOD ranges: ≤5 mg/L, 5 to 10 mg/L, 10 to 20 mg/L and > 20 mg/L. As noted in Table D-6, four very low TOC values (≤ 0.5 mg/L) were judged to be anomalies and were therefore censored from the data for these statistics. The same summary statistics are presented for maximum monthly effluent TOC in Table D-7. In this context, the regressions of TOC on BOD values from effluent samples at all POTWs are quite reasonable, despite the low coefficients of determination. For average monthly effluent data, the regression of TOC on BOD is:

$$TOC_{avg} = 5.8740 + 0.2859\ BOD_{avg} \quad (r^2 = 0.245,\ 174\ df)$$

Table D-6. Summary statistics for POTW average monthly effluent TOC concentrations, categorized according to average monthly effluent BOD concentration

TOC_{avg}	BODavg level				
	≤5 mg/L	>5-10 mg/L	>10-20 mg/L	>20 mg/L	All levels
Mean	6.75	8.45	9.83	13.32	7.98
Median	6.17	8.15	8.70	13.25	6.90
Standard Deviation	2.47	2.41	5.26	5.79	3.76
5^{th} quantile	4.90	6.08	4.46	6.53	4.96
95^{th} quantile	10.00	10.58	18.40	21.8	14.52
n	98*	32*	34*	8	172*

*Four suspiciously-low TOC values were censored from the data for these statistics

Table D-7. Summary statistics for POTW maximum monthly effluent TOC concentrations, categorized according to maximum monthly effluent BOD concentration

TOCmax	BODmax level				
	≤5 mg/L	>5-10 mg/L	>10-20 mg/L	>20 mg/L	All levels
Mean	7.95	7.88	14.73	20.57	10.08
Median	7.30	7.85	11.00	20.60	7.90
Standard Deviation	3.28	2.74	15.97	7.75	7.60
5^{th} quantile	5.50	3.00	2.00	11.00	5.4
95^{th} quantile	10.94	12.00	25.55	35.3	23.6
n	164	72	30	35	301

Given the substantial limitations imposed by the data available from PCS, we believe that this regression gives reasonable estimates of TOC in POTW effluents. These are also probably the best available estimates of effluent TOC for dilution calculations to determine DOC concentrations for use in the BLM (for example, the probabilistic dilution framework incorporated in the BLM-Monte software [HydroQual, 2001]). As shown in Section D.3, effluent DOC concentrations can be reliably predicted from TOC values:

$$DOC = 0.7133\ TOC \qquad (r^2 = 0.8913,\ 25\ df)$$

It should be noted that the regressions presented here should not be applied to project water quality in natural receiving waters unimpacted by POTW effluent, because they are based solely on POTW effluent monitoring data. The characteristics of the constituents DOC, TOC, and BOD, as well as the relationships between them, may be quite dissimilar between natural waters and effluents.

Program Manager – Monitoring, Assessment, and Standards Section

Date

1.0 Purpose and Scope

The purpose of this document is to describe the sample collection techniques, preservation requirements, equipment, and quality control activities associated with chemical, physical, and core biological sampling of surface water in lentic environments. The following describes accepted approaches used in the studies of lentic systems of New Mexico. For purposes of this document, the term “lake” shall include natural lakes and ponds, as well as reservoirs, impoundments, and any other human-made lentic waters. Where appropriate this SOP references the chemical sampling techniques used for lotic waters (SWQB SOP 8.2 Chemical Sampling in Lotic Environments) and only discusses where lake sampling differs.

2.0 Responsibilities

The Monitoring, Assessment, and Standards Section (MASS) Program Manager coordinates with the Project Manager(s), Technical Staff, and the QAO as applicable to ensure quality data is collected, verified, and validated to support program commitments. The Program Manager will provide input on the scope and intent of the SOP as it pertains to the program’s goals and objectives.

The Quality Assurance Officer (QAO) is involved in the development and revision of this SOP to ensure the SOP meets the requirements of the SWQB’s Quality Assurance Project Plan. The QAO, the MASS Program Manager, and SWQB subject matter experts (e.g., the MASS Monitoring Team Supervisor and assigned field staff scientists) will determine if any revisions to this SOP are needed at a minimum of every two (2) years in accordance with the most current SOP 1.1 for the Creation and Maintenance of SOPs (https://www.env.nm.gov/surface-water-quality/sop/). Pending the review and approval of the document, the QAO will ensure the SOP is accessible through the SWQB’s website.

The Project Manager (e.g., Monitoring Team Supervisor and assigned field staff scientists) are responsible for organizing and planning data collection activities and ensuring monitoring activities adhere to applicable SOPs and Field Sampling Plans.

Bureau personnel who conduct sampling activities in lentic environments, or who supervise those who do, are responsible for implementing this procedure, using the most up to date field sheets, and are required to sign the SOP acknowledgment statement for Lake Sampling.

3.0 Background and Precautions

3.1 Background

Water quality samples will be collected according to 20.6.4.14.C(3) NMAC which states:

> *"Lake sampling stations shall be located at any site where the attainment of a water quality criterion is to be assessed. Water quality measurements taken at intervals in the entire water column at a sampling station shall be averaged for the epilimnion, or in the absence of an epilimnion, for the upper one-third of the water column of the lake to*

> *determine attainment of criteria, except that attainment of criteria for toxic pollutants shall be assessed during periods of complete vertical mixing, e.g., during spring or fall turnover, or by taking depth-integrated composite samples of the water column.*"

Based on current staff and funding levels, state fiscal year change over financial constraints (July 1), and New Mexico's assessment protocols and related impairments, lake sampling should occur during the growing season, preferably June through September. Assessment details for determining lake impairments can be found in the current Comprehensive Assessment and Listing Methodology (CALM) (NMED/SWQB 2023b or current).

Methods of sample collection, preservation and handling used in this SOP are in accordance, except where otherwise noted, with methods described in the following references:

- "Guidelines establishing test procedures for the analysis of pollutants under the Clean Water Act," 40 CFR Part 136 or any test procedure approved or accepted by EPA using procedures provided in 40 CFR Parts 136.3(d), 136.4 and 136.5;

3.2 Precautions

All water sampling field activities in lentic waters will be conducted in accordance with this SOP. Site conditions or project-specific data collection objectives may necessitate the use of alternative field procedures not included in this SOP. The use of field methods other than those presented in this SOP must be approved by the MASS Program Manager or QAO and alternative methods must be accurately documented on field forms.

Organic samples collected with equipment that is not constructed of glass, fluoropolymer, or stainless steel are inconsistent with sampling methods described in Table II of 40 CFR Part 136.3 (e). However,

previous results from samples collected using non-compliant equipment have not shown detections of organic analytes that would implicate the sampling equipment as a potential source of contamination. Regardless, organic results obtained using non-compliant equipment should be flagged with a SWQB validation code.

3.3 Safety

Use gloves when handling caustic and acidic substances and waters suspected to have high bacterial contamination. Follow lab safety procedures if preparing Lugol's solution. All reagent containers and chemicals must be properly stored, labeled, and properly disposed. Take precautions to minimize exposure to chemicals in the lab and in the field.

Boating Safety

All personnel operating and working aboard watercraft must complete a US Coast Guard boating safety course every three years. Do not operate the watercraft in hazardous weather conditions such as thunderstorms or high winds/rough water. If weather conditions become hazardous while out on water sampling must cease and you must return to boat ramp as safely as possible. Before leaving the boat ramp, check that engine coolant water is discharging and isn't clogged with debris. Failure to do so may lead to engine overheating. All personnel must wear US Coast Guard type lll personal flotation devices (PFD) while on board a watercraft.

Before launching the boat, make sure the drain plug(s) is securely fastened to the drain and that the following safety equipment is present onboard the watercraft:

- Oars
- First aid kit
- Fire extinguisher
- PFDs for all onboard
- Throw rope
- Cell phone or radio
- Whistle

4.0 Definitions

For common definitions and acronyms not defined in this SOP, refer to the most up to date SWQB Quality Management Plan for Environmental Data Operations.

Depth-integrated composite sample or composite sample – Multiple samples collected at different depths and integrated to represent entire water column or specific region of water column.

Epilimnion – The top-most layer in a thermally stratified lake, occurring above the deeper hypolimnion.

Euphotic zone – the depth of water in a lake that is exposed to enough light for photosynthesis to occur estimated at 2.8 times the Secchi depth (French et al. 1982).

Hypolimnion – The dense, bottom layer of water in a thermally-stratified lake. It is the layer that lies below the thermocline.

Grab sample – Water sample collected at the surface of the lake.

Littoral – The shallow or nearshore areas of a body of water.

Oligotrophic – An oligotrophic lake has low nutrient concentrations and low plant growth with abundant oxygen in deeper parts.

Profile measurement – Interval measurements taken with a sonde, which include temperature, DO (concentration and percent saturation), pH, turbidity, salinity, and specific conductivity.

SLD – Department of Health Scientific Laboratory Division.

Thermocline – Zone of the water column where the temperature changes one degree C or more per meter of depth. In a thermally stratified lake, the thermocline is a relatively thin transition between the warmer, shallower layer (epilimnion) and the colder, deeper layer (hypolimnion).

Constituents/Analytes Acronyms:

DO – Dissolved Oxygen

DOC – Dissolved Organic Carbon

TOC- Organic Carbon

HAB – Harmful Algal Bloom

Rads – Radionuclide Sample

TDS – Total Dissolved Solids

TSS – Total Suspended Solids

5.0 Equipment

Required equipment for lakes sampling is detailed in the Lake/Reservoir Sampling Equipment Checklist. Lugol's solution must be prepared in the laboratory prior to the field sampling event as follows:

Lugol's Solution Preparation Steps:

1. Using a Mettler balance or equivalent. Measure 25 g KI and 12.5 g of I_2.
2. Cover the I_2 reagent with tinfoil as it is light sensitive and will evaporate.

3. Combine 225 ml DI water and dry chemicals in a large flask. This must be performed in a fume hood.

4. Add a magnetic stir bar and place on a hotplate equipped with stirring action.

5. Warm slightly while stirring to facilitate dissolution of the dry chemicals. ***Do Not Boil!***

6. In about an hour, once the solution is completely dissolved, pour into an opaque container using a glass funnel.

7. Add 25 ml Glacial Acetic acid to container and cap tightly.

8. Invert several times to mix solution.

9. Label container with date, contents, and pH (usually around 2.4 s.u.)

6.0 Lake Sample Collection (Step-by Step Process Description)

Lake water samples must be collected in accordance with 20.6.4.14.C(3) NMAC and this SOP. For biological data (i.e., phytoplankton, chlorophyll a, zooplankton, E. *coli and* microcystins) refer to Section 6.3-6.8 of this SOP.

Lake sampling stations shall be located at least 250 feet from a point source discharge when data will be used for assessment of water quality standards.

All lake samples which require preservation and filtration will be processed within 15 minutes of sample collection in accordance with 40 CFR 136.3 (e) Table II. However, due to wind, waves, weather and unforeseen events, preservation may not occur within 15 mins of sample collection but as soon as practically possible.

A plastic (acrylic), polyethylene, or fluoropolymer Kemmerer must be used for collecting water chemistry samples for TSS/TDS, anions, nutrients, DOC, metals, phytoplankton, and chlorophyll *a*. Organic samples must be collected using a fluoropolymer (i.e., PTFE, Teflon®) Kemmerer and composited in a glass or fluoropolymer carboy.

6.1 Lake Profile Measurements at Monitoring Location

Prior to beginning lake sampling ensure the Lake and Reservoir Field Sheets are drafted for planned sampling stations (monitoring Location IDs, RIDs, etc.).

The first step is to locate the index site for sampling parameters except E. coli and microcystin (and other harmful algal bloom related parameters) that are generally sampled near shoreline recreational areas (see sections 6.7. and 6.8 of this SOP for more information).

The index sampling site may deviate from the current established lake sampling stations. If this is the case, note in the Comments section of SQUID. The index site is located near the mid-point of the reservoir rather than at the deepest point, which may be near the dam. The index site should be representative of the waterbody. If this would result in an index site that is very shallow or otherwise non-representative of the reservoir as a whole, choose a point near the center of a main basin, where depths and the water column will be more representative of the reservoir.

Next, record wind speed, wind direction, % cloud cover, water color (Forel-Ule Color scale).

At the lake index station, use a calibrated multi-parameter sonde to measure the depth profile for dissolved oxygen (DO) concentration and percent saturation, specific conductance, salinity, temperature, turbidity and pH. Sondes must be calibrated according to SWQB SOP 6.1 Sondes (NMED/SWQB 2024a or current) prior to data collection.

Lake Depth Profile Data Collection Procedure

1. Data are collected beginning at the surface and proceeding at one-meter intervals up to 30 meters (m) depth or the top one third of the lake, whichever is greatest.

2. After 30 meters or the top one third of the lake, collect measurements every five meters.

3. Measurements are taken at the surface to within one meter of the bottom of the lake or to the maximum depth allowed by current equipment (60m).

4. Measurements must be recorded on the Depth Profile section of the Lake and Reservoir Field Sheet prior to finalization of field sheet.

Examination of Lake Depth Profile for Presence of a Thermocline

1. If depth profile measurements are transferable at the time of sample collection the macro enabled field sheet will provide notification of a thermocline. However, this is not always possible due to cell service and space limitations while sampling.

2. If measurements are not transferable at the time of collection results will have to be visually inspected utilizing Steps 3 and 4 of this section.

3. Review temperature results collected in depth profile for greater than one-degree Celsius (C°) change per meter for identifying a thermocline.

4. When determining a thermocline, rapid changes in other parameters, such as pH and DO, also may indicate where stratification is occurring. See Table 1 for example.

> NOTE: One degree or more change in temperature from nonconsecutive measurements is not considered a thermocline. The 1° C change must be observed in successive measurements (e.g., 2 meters to 3 meters).

Table 1. Example of thermocline present between 2 and 3 meters with sharp decline in dissolved oxygen

Determine Euphotic Zone utilizing Secchi Depth Measurements

The NMED SWQB uses 2.8 times the Secchi depth in meters to estimate euphotic zone (French et al. 1982).

Secchi Depth Measurements

1. Measure Secchi depth on the shaded side of the boat with sunglasses removed and record on Lake and Reservoir Field Sheet.

2. Multiply the Secchi depth (meters) by 2.8 or click on “Calc” button on field sheet.

3. Ensure the euphotic zone has been documented on the Lake and Reservoir Field Sheet.

6.2 Collecting Lake Water Samples for Chemical Analysis

During periods of lake stratification (i.e., when **thermocline is present**) TSS/TDS, nutrients, DOC, dissolved metals, total metals, radionuclides and organics are integrated from the top, middle and bottom of the **entire water column** by taking three Kemmerer samples (Figure 1) and compositing in a 5-gallon carboy (glass or fluoropolymer for collecting organics). If any of the Kemmerer samples fall at the same depth as the thermocline, collect from one meter above. For the bottom sample, keep the Kemmerer at least 1 meter away from the bottom to avoid stirring up sediments.

Thermocline Present – Sampling Procedure for TSS/TDS, Anions, Nutrients, DOC, Metals, Radionuclides

1. Begin by reviewing the depth profile for determining sample location, see Figure 1.

2. Next, double rinse the Kemmer (i.e., acrylic, polyethylene, or fluoropolymer) and 5-gallon polyethylene carboy (or polyethylene bucket).

3. Proceed with collecting surface (i.e., top) sample and deposit in carboy.

4. Next, collect sample from the middle of water column and deposit in carboy.

5. Last, collect water sample from the bottom of the water column at least 1 meter from bottom of lake and deposit in carboy.

6. Pour water quality samples off composited sample into their respective containers; 1-liter Cubitainers® or other containers as prescribed per the analysis to be performed.

7. Next, preserve samples as prescribed by applicable method.

Thermocline Present – Sampling Procedure for Organics
Same as above, however a fluoropolymer (i.e., PTFE, Teflon®) Kemmerer must be used and samples must be composited in a glass or fluoropolymer carboy.

Thermocline Present – Sampling Procedure for Chlorophyll a and Phytoplankton
Follow Figure 1 below and Section 6.3 of this SOP for the collection of chlorophyll a and phytoplankton samples. Samples should be taken from the top, middle and bottom of the euphotic zone and composited into a polyethylene carboy (or polyethylene bucket) and then processed according to their respective procedures prescribed in this SOP.

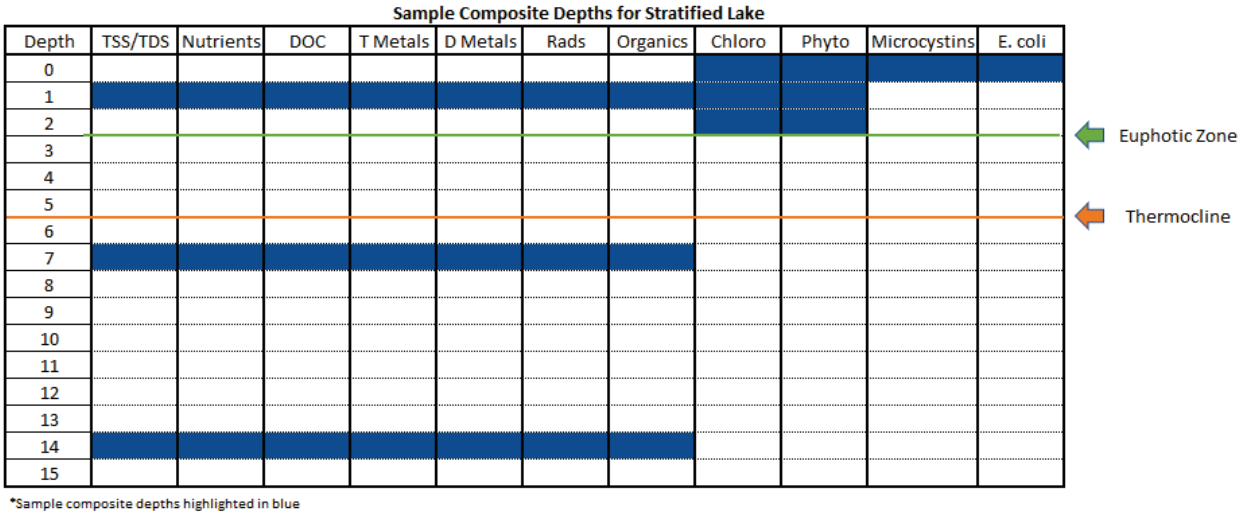

Figure 1. Sample collection methods when a thermocline is present.

Absence of Thermocline (no epilimnion)
When the lake is well mixed (i.e. **thermocline is not present**), all samples except microcystins and *E. coli* are collected from the top, middle, and bottom of the **euphotic zone** (Figure 2), or the upper 1/3 of the water column, whichever is shallowest. If the lake max depth is 3 meters or less, samples must be collected at two meters or less from the surface of lake. If the lake is one and a half meters or less the vertical Kemmerer cannot be used and water samples must be taken from just below the surface.

Thermocline Absent – Sampling Procedure for TSS/TDS, Anions, Nutrients, DOC, Metals, Radionuclides, Chlorophyll a and Phytoplankton

1. Begin by reviewing depth profile for determining sample location within the euphotic zone, see Figure 2

2. Next, double rinse the Kemmer (i.e., acrylic, polyethylene, or fluoropolymer) and 5-gallon polyethylene carboy (or polyethylene bucket).

3. Proceed with collecting lake sample from top of euphotic zone and depositing into carboy.

4. Next, collect lake sample from middle of euphotic zone and deposit in carboy.

5. Last, collect water sample from bottom of euphotic zone (must be at least 1 meter from bottom of lake) and deposit in carboy.

6. Pour water quality samples off composited sample into their respective containers; 1-liter Cubitainers® or other containers as prescribed per the analysis to be performed.

7. Next, preserve samples as prescribed by applicable method.

Thermocline Absent – Sampling Procedure for Organics

Same as above, however a fluoropolymer (i.e., PTFE, Teflon®) Kemmerer must be used and samples must be composited in a glass or fluoropolymer carboy.

Figure 2. Sample collection methods when a thermocline is not present

6.3. Sampling for Phytoplankton and Chlorophyll a

Phytoplankton and chlorophyll a samples are composited from the top, middle, and bottom of the euphotic zone in **both** stratified and mixed lakes (Figures 1 & 2).

1. Begin by determining sample locations within the euphotic zone.

> If the lake max depth is 2 meters or less, samples must be collected at one meter or less from the surface. If the lake is one and a half meters or less in depth, the Kemmerer cannot be and water samples must be taken just below the surface as a grab sample using a Cubitainer®.

2. Composite samples from the appropriate depths with a clean Kemmerer (acrylic, fluoropolymer or glass) and fill a 1-liter Cubitainer® for phytoplankton and 1-gallon Cubitainer® for chlorophyll a. Samples can be poured off from TSS/TDS, anions, nutrients, DOC, metals, and radionuclides composite if the lake is **well mixed (no thermocline).**

6.4 Phytoplankton sample Preservation

1. Preserve sample within 2 hours of collection using approximately 10 milliliters of Lugol's solution until the sample appearance looks like a weak tea color.

2. Store samples in the dark and on ice or under refrigeration (EPA 2012).

3. At the end of the sampling season after all samples are collected (but no longer than one year from earliest sample collection) ship samples to the contracted lab for identification and enumeration.

6.5 Chlorophyll *a* Preservation and Processing

Confirm sample processing methods from selected lab prior to processing. If processing methods differ from below, follow instructions provided by the contract lab.

The 1-gallon Cubitainer® must be stored on ice and out of sunlight and filtered as soon as possible after collection.

Filtering procedure for chlorophyll a processing is described below.

Processing of Chlorophyll a Samples

1. Begin by double rinsing the chlorophyll flask and funnel with DI water.

2. Filter sample water through a Whatman Glass Fiber Grade GF/F or GF/C filter until substantial color development is on the filter medium, indicating adequate chlorophyll pigment is present. Volume of sample filtered must be documented.

> NOTE: If clogging or filtering time is a concern, use the larger retention of the GF/C filter. It has been shown that there is no difference between chlorophyll concentrations collected on Whatman GF/F of GF/C filters (Prepas et al. 1988).

3. Do not exceed a vacuum pressure of 6in. Hg (20kPa) during filtration.

> If filtering must be delayed, hold sample water on ice or at 4°C and protect from exposure to light by using opaque bottles and storing in the dark.

4. Excessively long filtration times (>10 min) and high pressures may damage cells and result in a loss of chlorophyll (EPA 1997).

5. Remove the filter from the filtering apparatus, fold it in half, place it in a petri dish labeled with sample identification and filter volume

6. Then wrap the petri dish with aluminum foil, put in a zip lock bag and place on dry ice.

7. Record the volume of water filtered on the field sheet

8. Upon returning to the SWQB lab, store samples in a freezer until they are shipped to the contract lab.

Samples should be sent to the laboratory for processing as soon as possible after collection; however, samples on filters taken from water having pH 7 or higher can be frozen for up to 28 days before analysis, if necessary. Samples from acidic water (< pH 7) should be processed promptly after filtration to prevent possible chlorophyll degradation from residual acidic water on filter.

6.6 Zooplankton Sample Collection

The objective of zooplankton sample collection is to sample a sufficient volume of water to obtain at least 300 organisms per sample from oligotrophic lakes. Oligotrophic lakes are low in nutrient concentrations, low plant growth and contain abundant oxygen in the deeper parts. This will be verified with the depth profile measurements, visual examination of lake for excessive plant growth and reviewing historical sampling events. Zooplankton sample collection is completed by collecting two vertical samples using fine mesh (50 µm) and coarse mesh (150 µm) Wisconsin style nets with collection bucket attached at the cod end following the Sample Collection Procedure below. Figure 3 provides the equipment and supplies needed for the collection of zooplankton. Figure 4 is an illustration of the zooplankton nets and collection buckets required for sampling.

Type	**Item**	**Quantity per site**
Form	-Lake Field Sheet	1
Collection	-Plankton net fine (50µm) and collection bucket	1
	- Plankton net course (150 µm) and collection bucket	1
	- Calibrated line (30 m, calibrated, marked in .5 m intervals)	1
	- Funnel	1
	- Squirt bottle – de-ionized (DI) water	1
	- Squirt bottle- lake water	1
	- Effervescent sodium bicarbonate (e.g., Alka seltzer) tablets	1
	- Pail (for narcotization and concentration of samples)	1
Storing and Preservation	- HDPE bottle (125ml or 250 ml)	2

	- Ethanol (95%) - Labels for fine and course samples	1 As needed

Figure 3. Equipment and supplies for Zooplankton Sample Collection

National Lakes Assessment 2022

Version 1.2, May 2022

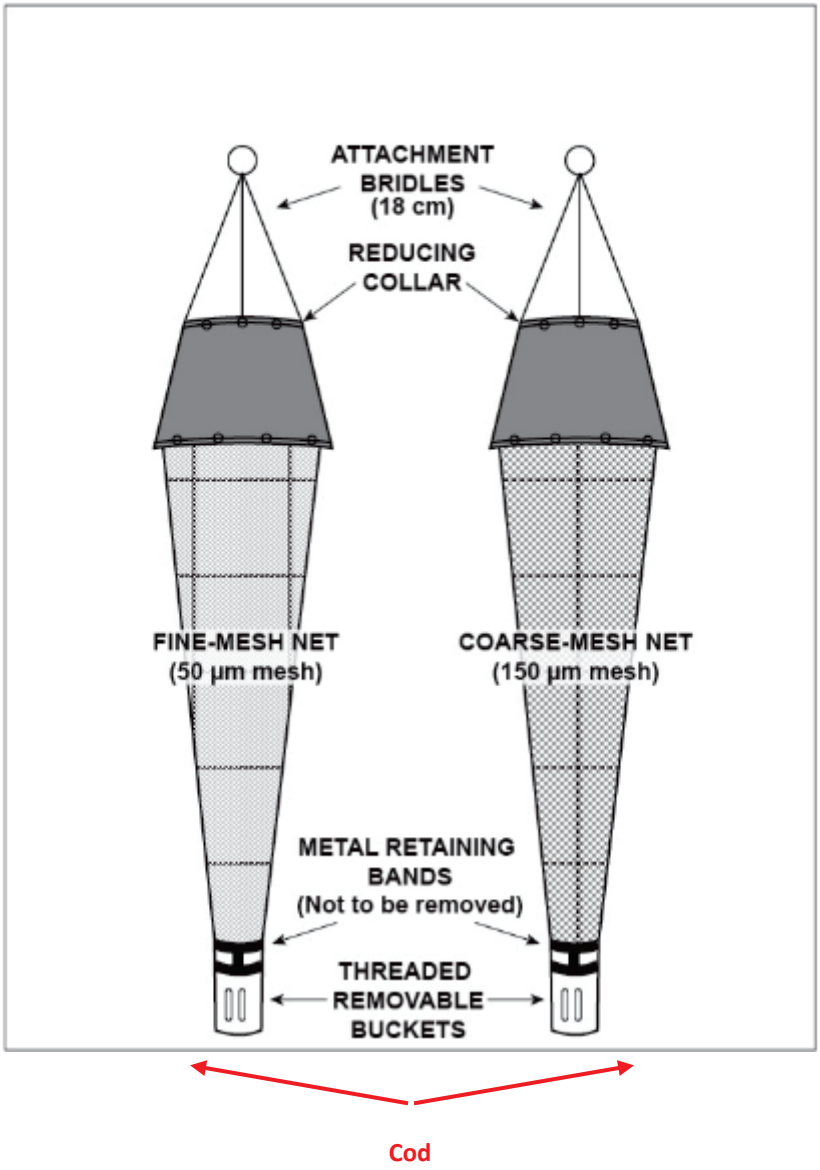

Figure 4. Wisconsin Net and Collection Diagram for Zooplankton

The procedures for collecting and processing zooplankton samples are presented below.

Sample Collection

1. Determine and record the number of tows required to achieve the standard cumulative 5-meter(m) tow on the Lake field sheet.
    a. For lakes deeper than 7 m, you will take a single 5 m tow with each net.
    b. For lakes with a depth less than 7 m, you will determine and record the number of tows that will be required to achieve a standard cumulative 5 m tow for each net (Figure 5). For example, if the lake is 6 m deep, you will take two 2.5 m tows with each net. All lakes less than 7 m deep require at least two tows because the collection bucket should never touch the sediment due to potential fouling.

Depth of lake (m)	Length of Tow	Number of Tows
7 or more	5 m	1
4 to <7	2.5 m	2
2 to <4	1 m	5
less than 2	0.5 m	10

Figure 5. Lengths and numbers of zooplankton tows based on lake depth.

    c. The zooplankton collection methods vary slightly depending on the number of tows required to achieve a standard cumulative 5 m tow.
        i. If the number of tows = 1: follow steps 2 through 13 described below.
        ii. If the number of tows ≥ 2, follow steps 2 through 12 described below. After step 12, pour the contents of the collection bucket into a clean (i.e., DI rinsed) 1- gallon pail. Rinse the collection bucket with DI. While taking care not to tip the zooplankton sample in the pail, repeat steps 2 through 12 for the second tow. Add the contents of the collection bucket from the second tow to the pail. Continue to take zooplankton tows and add samples from the collection bucket into the pail until the target number of tows (2, 5, or 10) is reached. On the last tow, pour the contents of the pail into the collection bucket to filter the excess water. Rinse the bucket with DI water and pour the contents of this rinse into the collection bucket with the zooplankton sample. Once the zooplankton sample has been filtered down to an appropriate volume in the collection bucket, continue on to step 13.

2. Prior to each use, carefully clean and thoroughly rinse the interior of the nets and buckets with DI water.

3. Carefully inspect the nets and buckets for holes or tears.

4. Attach the collection buckets to the “cod” end of the nets and secure. Make sure the correct bucket is attached to the correct net (i.e., the mesh sizes match).

5. Attach the bridled end of the net to a calibrated line with markings every 0.5 m.

6. Carefully and slowly lower the first net in a constant upright position over the side of the boat.

7. Continue lowering the net to the correct depth (remember to account for the length of the bridle). If more than one tow is needed, be sure to take additional tows from different locations around the boat.

8. Retrieve the net by pulling back to the surface at a steady rate (0.3 m/s or 1 ft/s) without stopping.

9. Once at the surface, slowly dip the net up and down in the water without submersing the net mouth to rinse contents into the collection bucket.

10. Complete the rinsing of the net contents by spraying lake water against the outside of the net with a squirt bottle or similar tool (a peristaltic pump may be used at low speed). Be careful not to splash or squirt lake water into the net mouth, or additional organisms may be collected.

11. If additional rinsing is needed on the interior of the net, use a squirt bottle or similar tool with DI water to avoid introducing additional organisms.

12. Once all organisms have been rinsed into the collection bucket, hold the collection bucket in a vertical position, and carefully remove the bucket from the net.

13. Repeat steps 5-12 with the second net on the opposite side (or end) of the boat.

Sample Processing

1. Set the collection buckets in a pail filled half full of lake water, inset two (2) CO_2 (e.g., Alka-Seltzer) tablets outside of the collection buckets. Wait 30 to 60 seconds for the CO2 tablets to dissolve.

2. Ensure that the organisms in the collection buckets are submerged in the water but be careful not to submerge the top of the collection buckets, or sample loss will occur. Wait until zooplankton movement has stopped (usually about one-two minute)

> Note: The CO_2 narcotizes the zooplankton to relax their external structure to facilitate identification

3. Raising and lowering the collection buckets in the pail can help water exchange within the bucket to disperse CO_2 tablets.

4. Check the sample label on the collection buckets to verify which sample has been collected (coarse or fine mesh).

5. Use small volumes of DI water from a squirt bottle to rinse the contents of the mesh net collection bucket into the 125 or 250 mL polyethylene bottle. Rinse the collection bucket with DI water three to four times or until the majority of zooplankton have been removed without allowing the bottle to fill more than half full (~60-70 mL or 120-130 mL of sample and rinse water combined).

6. After the zooplankton have been transferred and the sample bottle is half full of sample and rinsate, fill the bottle to the shoulder with 95% ethanol. Use a funnel, if necessary, when transferring the sample, rinsate or ethanol to the sample bottle.

7. In some cases, the volume of zooplankton collected in the collection bucket may exceed 125-250 mLs. Under this scenario do not try to force the entire sample into a single bottle, or the preservative will not function properly, and the sample may be lost. In such cases, fill the first bottle half full, and then use a second bottle to preserve the additional amount of sample. Complete the label on second bottle. Ensure the Lake field sheet is properly labeled.

8. Seal sample bottles with electrical tape.

9. On the Lake Field Sheet, indicate that the sample is preserved.

10. Verify that all information on the labels and the form is complete and correctly recorded.

11. Repeat steps 2-9 for the second sample collected.

Sample Storage
Zooplankton samples should be stored in a secure location while awaiting delivery to the laboratory for analysis, samples may remain at room temperature. Contact the contract laboratory for transportation requirements. Samples should be analyzed within 1 year of sample collection, if sealed properly as described sample processing.

Storage and Cleaning of Zooplankton Nets
Briefly soak zooplankton nets in a 1% bleach solution and dry after each use. Do not dry in sunlight because the mesh is photosensitive.

6.7 *E. coli* Sampling

Collect *E. coli* samples from the surface of the water at lake sampling location in accordance with the procedures in Bacteriological Sampling SOP 9.1 (NMED/SWQB 2023c or current). Lake sampling stations sampled for E. coli should be conducted at high recreational areas along beaches/shore. Record the GPS coordinates of the monitoring site on the field form if differs from index site.

6.8 Microcystin Samples

Microcystin samples are collected to identify Harmful Algal Blooms (HABs) in areas of a lake where HABs have been observed or are of concern due to heavy recreation (swim beach, boat launch, etc.). Record the GPS coordinates of the monitoring site on the field form if differs from index site. Sampling should be performed from mid-summer to late-fall when HABs are most likely.

1. Begin by collecting surface grab samples using a 1-liter Cubitainer™.
   Note: If long, filamentous algae are present, leave headspace in Cubitainer™ and shake vigorously to ensure sample is homogenized.

2. Immediately store sample on ice away from sunlight.

3. Samples must be maintained at 0-10° C until arrival at lab.

4. If samples are not processed by laboratory within 5 days of collection samples must be maintained at -20 ° C until sent to laboratory for processing.

Maximum hold time for samples is not to exceed 14 days after collection unless stored at -20 ° C, however, most laboratories requires samples to be delivered within 5 days of collection. Be sure to notify the laboratory as soon as possible prior to sampling to ensure they are prepared for sample processing and relay any additional requirements for sample collection and processing.

At sites where E. coli and microcystin samples are collected, record the water color using the Forel-Ule Color scale, collect grab data using a calibrated sonde and a Secchi depth as outlined in this SOP. If samples are taken from the shore/beach a Secchi depth may not be collected. Ensure GPS location is recorded. A nutrient and phytoplankton sample at each microcystin location may also be collected dependent on project objectives.

6.9 Sampling Harmful Algal Blooms (HAB) at Recreational Stations

See SWQB SOP on HABs, under Specialized Monitoring.

6.10 Deployment of Bouy in New Mexico Lakes

The SWQB deploys buoy(s) at priority lakes within New Mexico. Buoy deployment is highly specialized and requires assistance from the SWQB Monitoring Team. Loggers are attached to buoys and are deployed to collect long-term data in lakes. At the time of deployment and retrieval a lake profile is required using a calibrated sonde. All required quality control processes detailed in SWQB SOPS are adhered to so that the data can be used for its intended purpose(s). For more information contact the Monitoring Team Supervisor. Please be sure to take extra caution when deploying buoys from the Jon Boat or rafts due to safety concerns.

7.0 Data and Records Management

All field data and samples collected following the procedures outlined in this SOP are entered in SWQB's water quality database as part of a Lake Sampling Event. A second staff member verifies that the data are entered correctly. Date of entry and verification are noted on the field sheet.

Sampling events and data are stored in the SQUID database. Hard copy forms are stored in the project binder located in the SWQB file storage cabinets. Electronic forms are stored within the project file within the shared server. Per 1.21.2.436 NMAC, water quality records are to be maintained for five years from the close of file.

Enter all field form data into appropriate electronic Lake Field Sheet (form can be found on the SWQB SOP website). Save these forms in the project folder on the SWQB network. Open a blank/new electronic SLD Submittal Auto form and follow the instructions to create submittals. Copy and save the combined data tab into its own Excel file. In the electronic field form, copy the profile tab into its own Excel file and save within the project file.

Uploading field sampling event data into the SQUID database:

- Select the Data Management tab.
- Select Imports.
- Select Sampling Event Data.
- Navigate to the project file and select the file with the combined data and import.

Uploading Depth Profile into the SQUID database:

- In SQUID under the Projects tab locate the project and sampling event you want to add a depth profile to.
- Select “Add Depth Profile” located in the same row as the Lake-Chemical sampling event
- Choose the appropriate .csv or .xlsx file and click “Upload File”

Phytoplankton and Zooplankton Data Upload

Data received from the contracted lab must be formatted properly in new Excel upload sheet in order to be entered into SQUID. Copy and paste lab data received from the contracted lab into the appropriate columns of the upload spread sheet. Follow the format presented in Figure 6. For taxon data you must combine the genus and species columns from the lab spread sheet. The easiest way to do this is to use the Excel formula (=GENUS&” “&SPECIES). For example: (=J2&” “&K2). Copy and re-paste cells values to remove the formula but keep text. In SQUID, under the Data Management Tab, select imports then biological results. Select appropriate file and select “insert” then select “process results”. Make sure both columns match (for “count” row select “number of natural units”). Click process results and ensure there are no import errors. Click “Import Results” to finish upload process.

	A	B	C	D	E	F	G	H	I
1	LAB ID	Sample ID	Water Body	Collection Date	Status	Taxon	Life Stage	Exclude	Number of Natural Units
2	Water Quality Lab	2530652	Snow Lake	9/3/2019	Final	Achnanthidium minutissimum	Adult	N	1
3	Water Quality Lab	2530652	Snow Lake	9/3/2019	Final	Cylotella striata	Adult	N	77
4	Water Quality Lab	2530652	Snow Lake	9/3/2019	Final	Plagioselmis nannoplanctica	Adult	N	35
5	Water Quality Lab	2530652	Snow Lake	9/3/2019	Final	Rhodomonas lacustris	Adult	N	2
6	Water Quality Lab	2530660	Bill Evans Lake	9/4/2019	Final	Cryptomonas erosa	Adult	N	4
7	Water Quality Lab	2530660	Bill Evans Lake	9/4/2019	Final	Plagioselmis nannoplanctica	Adult	N	71
8	Water Quality Lab	2530660	Bill Evans Lake	9/4/2019	Final	Chroococcus microscopicus	Adult	N	9

Figure 6. Proper phytoplankton spreadsheet formatting for data upload

***E. Coli* Data Upload**

See SWQB SOP 9.1 Bacteriological Sampling and Analysis (NMED/SWQB 2023c or current) for upload instructions into SQUID.

Chlorophyll *a* Data Upload

Results from the laboratory are uploaded to SQUID using the *Chlorophyll a Analysis Sheet*.
Uploading data into the SQUID database:

- Select the Data Management tab.
- Select Imports.
- Select Biological Results.
- Navigate to the project file and select the file with the combined data
- Click upload

Water Chemistry, Metals, Organics, Radionuclides and Microcystin data Upload
Data are received electronically from applicable laboratories and are uploaded to SWQB SQUID database. For most analytical analysis of samples, the SWQB uses the Air and Heavy Metals, Organics, Water, and Radiochemistry Sections of SLD Chemistry Bureau. SLD uses a software-based Laboratory Information Management System (LIMS) to issue standardized result reports which include detection limits, quantitation limits, and data qualifiers. For more information on the upload process contact the Monitoring Team Supervisor or the SWQB QAO.

8.0 Quality Control and Quality Assurance

The SWQB controls the quality of lake sampling data by using standardized methods that are documented in this SOP. All personnel who conduct lake sampling must be familiar with these protocols, sign the acknowledgment form associated with this specific SOP and collect data in accordance with the procedures as they are defined in this SOP. In addition to standardized methods, proper training of field personnel represents a critical aspect of meeting the data quality objectives in order to fulfill the goals of the SWQB's QAPP (NMED/SWQB 2024).

QA/QC activities for sampling (bacteriological, water chemistry, metals, organics, radionuclides and microcystin) are the same as described in the Chemical Sampling SOP in Lotic Environments (SOP 8.2) and Bacteriological Sampling (SOP 9.1).

Any SWQB personnel who conduct lake sampling are required to receive training in the field and be supervised by MASS Monitoring Team Supervisor for all aspects of sample collections. Any MASS Monitoring staff who conduct training in the field must have conducted at least 1 field season of lake sampling prior to training of other staff or unsupervised sampling. Once training has occurred and all aspects of lake sampling procedures have been observed as correct, personnel may conduct unsupervised lake sampling for the SWQB with approval from Monitoring Team Supervisor. This process will ensure comparability and accuracy of data used for water quality assessments, refinement of water quality standards and TMDL development.

Assurance of field data collection for lake sampling are done through adherence to the processes outlined in this and other applicable SOPs and oversight of the process by the QAO. If at any time the QAO determines this process is not being adhered to, the QAO has the authority to cease activities specific to this SOP with prior support and approval by the SWQB Bureau Chief and MASS Program Manager, until such a time that the issue can be resolved.

10.0 Revision History

Originally modified from SOP 2007.

Revision 1 – March 2012 –clarified sampling procedures for conditions with a thermocline present (stratified) and when a thermocline is absent (mixed); added guidance on sampling lakes where low DO is a suspected water quality concern

Revision 2 – March 2013 – added information regarding compliant and non-compliant sampling equipment for organic samples to be consistent with SOP 8.2 Chemical Sampling and 40 CFR Part 136; added clarification for sampling in shallow lakes (≤ 3 meters in depth) and use of larger filters for chlorophyll

Revision 3 – March 2014 – revised language and figures to clarify sampling depths during different mixing conditions. Added the use of either a contract lab or in-house analysis.

Revision 4 – August 13, 2020 – revised language and figures to include organics sampling. Clarified sampling depths in compliance with 20.6.4.14(C)(3). Added Lugol's solution formula. Added microcystin sampling. Added process for depth profile data upload into SQUID. Added DOC sampling. Updated sampling location figures. Added sampling at recreational sites. Added phytoplankton and chlorophyll-*a* lab result upload instructions. Added boating safety section. Standard Operating No. changed from 12.0 to 12.1.
Miguel Montoya, QAO; Jonathan Celmer, SME; Kris Barrios, MASS Program Manager

Revision 5 – May 22, 2025 – addition of zooplankton sample collection and processing. Updated *E. coli* sample location. Deleted duplicative language on processes.
Emily Miller, QAO; Lynette Guevara, MASS Program Manager

National Lakes Assessment 2022

Field Operations Manual

Version 1.2, May 2022

NMED Exhibit 36

Version History

Version	Date	Revisions and Comments
0.0	December 2021	Internal EPA version for project QAC review and comments
0.0	February 2022	• Updated introduction to be consistent with other NLA 2022 manuals • Corrected typos, formatting, numbering of tables and figures • Updated field data and tracking form names to be consistent with the NLA App • Updated sample bottle types • Added ESA conservation measures (Section 6.4, Section 10 and Appendix C)
1.0	February 2022	Final approved document • Corrected NLA App entry inconsistencies • Clarified whole fish sample storage and shipping (Section 7.3) • Revised ESA conservation measures (Section 6.4, Section 10 and Appendix C) • Updated base kit list
1.1	March 2022	• Added a project identifier (NLA2022) for bloomWatch reports (Section2.2.4.5) • Clarified DO probe calibration requirements (Section 5.2.2.3) • Added direction to homogenize last integrated sample if the last pull does not fit in container (Section 5.5.3) • Updated Figure 5-4 with attachment bridle length • Corrected shipping timeframe for T-2 samples in Table B-1 • Corrected cross reference errors, formatting and typos
1.2	May 2022	• Corrected atrazine preservation and shipping. Atrazine samples are to be kept chilled until analysis (Section 5.5.3.2, Section 8.4 and Appendix B (T-2 Frozen Batched Samples)) • Added Appendix D: NLA Handpicked Sites: Resampling of the National Eutrophication Study Lakes

NMED Exhibit 36

NOTICE

The intention of the National Lakes Assessment 2022 (NLA 2022) project is to provide a comprehensive "State of the Lakes" assessment for lakes, ponds, and reservoirs across the United States. The complete documentation of overall project management, design, methods, and standards and Quality Assurance/Quality Control (QA/QC) measures is contained in this document and companion documents, including:

National Lakes Assessment 2022: Quality Assurance Project Plan (QAPP) (EPA 841-B-21-009)

National Lakes Assessment 2022: Site Evaluation Guidelines (SEG) (EPA 841-B-16-008)

National Lakes Assessment 2022: Laboratory Operations Manual (LOM) (EPA 841-B-16-010)

These documents together comprise the integrated set of QAPP documents. This document (*Field Operations Manual [FOM]*) contains a brief introduction and procedures to follow at the base location and on-site, including methods for sampling water chemistry (grabs and *in situ*), phytoplankton, zooplankton, *Enterococci*, environmental DNA (eDNA), algal toxins, benthic macroinvertebrates, physical habitat, and contaminants in fish tissue. These methods are based on both the guidelines developed and followed in the Western Environmental Monitoring and Assessment Program (Baker, et. al., 1997), methods employed by several key states that were involved in the planning phase of this project and prior National Lakes Assessments. Methods described in this document are to be used specifically in work relating to the NLA 2022. All Project Cooperators should follow these guidelines. Mention of trade names or commercial products in this document does not constitute endorsement or recommendation for use. Details on specific methods for site evaluation and sample processing can be found in the appropriate companion document.

1.0 BACKGROUND

This manual describes field protocols and daily operations for crews to use in the National Lakes Assessment 2022 (NLA 2022). The NLA 2022 is a statistical assessment of the condition of our nation's lakes, ponds, and reservoirs (subsequently referred to in this manual as "lakes"). The survey is designed to address three key questions about the quality of the nation's lakes:

1. What percent of the nation's lakes are least, moderately, and most disturbed for key indicators of trophic state, ecological health, and human use (recreation)?
2. What is the relative importance of key stressors such as nutrients and pathogens?
3. What changes are occurring in the condition of the nation's lakes?

The surveys are also designed to help expand and enhance state and tribal monitoring programs. Through these surveys, states and tribes have the opportunity to collect data that can be used to supplement their existing monitoring programs or to begin development of new programs.

The NLA 2022 is one of a series of water surveys being conducted by states, tribes, the U.S. Environmental Protection Agency (EPA), and other partners. In addition to lakes, partners will also study coastal waters, wadeable streams, rivers, and wetlands in a revolving sequence. The purpose of these surveys is to generate statistically-valid reports on the condition of our nation's water resources and identify key stressors to these systems.

The NLA 2022 is designed to be completed during the summer growing season before fall lake turnover (June through September[a]). Field crews will collect a variety of measurements and indicators from an "index site" located at the deepest point of the lake up to 50 meters (or near the middle of the lake if the lake is a reservoir), and document conditions of the littoral zone and shoreline from stations around the lake.

1.1 Selection of Sampling Locations

EPA selected sampling locations using a probability-based survey design (Stevens and Olsen, 2004). Sample surveys have been used in a variety of fields (e.g., election polls, monthly labor estimates, and forest inventory analysis) to determine the status of populations or resources of interest using a representative sample of relatively few members or sites. Using this survey design allows data from the subset of sampled lakes to be applied to the larger target population and assessments with known confidence bounds to be made.

With input from the states and other partners, EPA used the following framework to guide the site selection process:

1. The National Hydrography Dataset Plus High Resolution (NHDplusHR) data layer was used to derive a list of lakes for potential inclusion in the NLA 2022.
2. For purposes of this survey, "lakes" refers to natural and man-made freshwater lakes, ponds,

[a] The NLA index period is June through September. Sampling in May could be approved for lakes in areas where stratification is expected earlier in the year. Please coordinate these requests with your Regional EPA Coordinator and the NLA Technical Lead.

and reservoirs greater than one hectare (approximately 2.5 acres) in the conterminous U.S., excluding the Great Lakes.

Mine ponds, retention basins, cooling ponds, and tidally-influenced lakes were excluded from this study. For more information on the site exclusion criteria refer to the National Lakes Assessment 2022: Site Evaluation Guidelines (EPA 841-B-21-008).

3. The sample size was set to include 1,000 lake sampling events.

EPA used an unequal probability design to select 904 lakes and reservoirs greater than 1 hectare (ha) in size (note: in NLA 2007, the lower size limit was 4 ha) in the continental United States. The design includes 2 revisits in each state resulting in the target total of 1,000 site visits. Revisit samples are collected for quality assurance purposes including evaluation of the ability of an indicator to distinguish *among* sites from differences *within* individual sites. Of the 904 lakes, approximately 50% of the lakes are new lakes selected for 2022 and 50% are previously sampled lakes as part of the NLA 2017. The NLA 2017 lakes are referred to as *resample lakes*. Also, of the 904 lakes, approximately 70% of the lakes (i.e., 636 lakes) are designated for whole fish composite sample collection for human health. An "oversample" list of additional lakes was also generated to allow for replacement of non-target or otherwise unsampleable sites. The oversample list will also accommodate any state wishing to conduct a state scale survey.

Lakes selected for the NLA 2022 are distributed among five size class categories and are spatially distributed across the lower 48 states and nine aggregated Omernik Level 3 ecoregions (USEPA, 2013).

Related NLA 2022 documents include the following:

National Lakes Assessment 2022: Quality Assurance Project Plan (EPA 841-B-21-009)

National Lakes Assessment 2022: Site Evaluation Guidelines (EPA 841-B- 21-008)

National Lakes Assessment 2022: Laboratory Operations Manual (EPA 841- 21-010)

These documents are available at: https://www.epa.gov/national-aquatic-resource-surveys/manuals-used-national-aquatic-resource-surveys.

1.2 Selection and Description of Survey Indicators

As part of the indicator selection process, EPA and the NLA 2022 Steering Committee evaluated indicators used in prior NLAs, refined methodologies, and identified new indicators for NLA 2022. The Steering Committee, comprised of state representatives from each of the EPA regions, provided advice and recommendations to the Agency on matters related to the NLA 2022. Key screening and evaluation criteria included indicator applicability on a national scale, the ability of an indicator to reflect various aspects of ecological condition, and cost-effectiveness (e.g., Kurtz et al., 2001). EPA used the Committee's recommendations to refine methods and develop final documents.

The remainder of this section briefly describes the indicators that the NLA 2022 will use to assess trophic status, ecological integrity, human use value, and lake characteristics (Table 1.1). Some indicators provide a basis for evaluating more than one category. For example, an assessment of zooplankton allows for an examination of ecological integrity and trophic status, and to a certain extent, human use.

NMED Exhibit 36

1.2.1 Trophic Status and Water Quality Indicators

Lakes are classified according to their trophic state. “Trophic” means nutrition or growth. A eutrophic (“well-nourished”) lake has high nutrients and high plant growth. An oligotrophic lake has low nutrient concentrations and low plant growth. Mesotrophic lakes fall somewhere in between eutrophic and oligotrophic lakes.

Chlorophyll-a, total phosphorus, and Secchi disk transparency are most often used to estimate biomass and define the trophic state of a particular lake. Other variables are measured in conjunction with the trophic state variables to supplement and enhance understanding of lake processes that affect primary productivity.

1.2.1.1 Chlorophyll-a

Chlorophyll is the pigment that allows plants (including algae) to use sunlight to convert simple molecules into organic compounds via the process of photosynthesis. Of the several kinds of chlorophyll, chlorophyll-*a* is the predominant type found in green plants and algae. Measuring chlorophyll-*a* concentrations in water is a surrogate for actually measuring algae biomass and it is used to estimate trophic status.

1.2.1.2 Secchi Disk Transparency

A Secchi disk is a black and white patterned disk commonly used to measure the clarity of water based on the distance the disk can be seen when it is lowered into the water column. The Secchi disk measurement is used to estimate the euphotic zone depth in the field which is generally defined as two-times the Secchi disk depth.

1.2.1.3 Vertical Profile Measurements

Depth profiles for temperature, pH, and dissolved oxygen (DO) are taken with a calibrated water quality probe meter or multi-parameter probe sonde from the index site in each lake. This information is used to determine the extent of stratification and the availability of the appropriate temperature range and level of DO necessary to support aquatic life.

1.2.1.4 Water Chemistry and Associated Measurements

Water chemistry measurements are used to determine the acidic conditions, trophic state and nutrient enrichment, and water chemistry type.

1.2.1.5 Atrazine Pesticide Screen

Atrazine pesticides are herbicides used to control the growth of weeds. Although applied to the land, these chemicals can enter lakes via transport in water (e.g., runoff, groundwater, etc.) or atmospheric transport. This screen will provide information about the occurrence and concentration of atrazine pesticides in water samples from lakes across the nation.

1.2.2 Biological Indicators

Ecological integrity describes the ecological condition of a lake based on different assemblages of the aquatic community and their physical habitat (PHab). The indicators include zooplankton, benthic macroinvertebrates, and the physical habitat of the shoreline and littoral zones.

NMED Exhibit 36

1.2.2.1 Benthic Macroinvertebrate Assemblage

Benthic macroinvertebrates are bottom-dwelling animals without backbones ("invertebrates") that are large enough to be seen with the naked eye ("macro"). Examples of macroinvertebrates include crayfish, snails, clams, aquatic worms, leeches, and the larval and nymph stages of many insects, including dragonflies, mosquitoes, and mayflies. Populations in the benthic assemblage respond to a wide array of stressors in different ways so that it is often possible to determine the type of stress that has affected a macroinvertebrate assemblage (e.g., Klemm et al., 1990). Because many macroinvertebrates have relatively long life cycles of a year or more and are relatively immobile, the structure and function of the macroinvertebrate assemblage is a response to exposure of present or past conditions. For the NLA, the benthic macroinvertebrate assemblage occupying the littoral zone will be assessed, rather than the profundal assemblage occupying the deeper regions of lakes.

1.2.2.2 Zooplankton Assemblage

Zooplankton are animal microorganisms that consist of crustaceans (e.g., copepods and cladocerans), rotifers ("wheel-animals"), pelagic insect larvae (e.g., phantom midges), and aquatic mites. The zooplankton assemblage constitutes an important element of the food web, where zooplankton transfer energy from algae (primary producers) to larger invertebrate predators and fish. The zooplankton assemblage responds to environmental stressors such as nutrient enrichment and acidification (e.g., Stemberger and Lazorchak 1994, Dodson et al. 2005). The effects of these environmental stressors on zooplankton can be detected through changes in species composition, abundance, and body size distribution.

1.2.3 **Physical Habitat Characterization**

The characterization of shoreline and littoral zone (the nearshore areas of a lake) physical habitat (PHab) conditions serves three purposes. First, habitat information is essential to the interpretation of expected lake ecological condition in the absence of human disturbance (anthropogenic impacts). Second, the habitat evaluation is a reproducible, quantified estimate of habitat condition, serving as a benchmark against which to compare future habitat changes that might result from anthropogenic activities. Third, the specific selections of habitat information collected aid in the diagnosis of probable causes of ecological degradation in lakes.

In addition to information collected in the field by the shoreline and littoral surveys, the physical habitat description of each lake includes many map-derived variables such as lake surface area, shoreline length, and shoreline complexity. Furthermore, an array of information, including watershed topography and land use, supplements the physical habitat information. The shoreline and littoral characterizations concentrate on information best derived "on the ground". As such, these results provide the linkage between large watershed-scale influences and those influences that directly affect aquatic organisms day to day. Together with water chemistry, the habitat measurements and observations describe the variety of physical and chemical conditions that are necessary to support biological diversity and foster long-term ecosystem stability. These characteristics of lakes and their shorelines are the very aspects that are often changed as a result of anthropogenic activities.

NMED Exhibit 36

1.2.4 Human Health and Recreational Use Indicators

Human health indicators address the ability of the lake population to support recreational uses such as swimming, fishing, and boating. The protection of these uses is one of the requirements of the Clean Water Act. The NLA 2022 human health indicators include the extent of cyanobacterial harmful algal bloom (cyanoHAB), algal toxins (microcystins and cylindrospermopsin), fecal indicator (*enterococci*) and fish fillet contaminants.

1.2.4.1 CyanoHAB Visual Observations and Real-time Reporting

Cyanobacteria are microscopic organisms found naturally at low concentrations in freshwater systems. Under optimal conditions (such as high light and calm weather, usually in summer), cyanobacteria occasionally form harmful algal blooms (HABs), or dense aggregation of cells, that float on the surface of the water. At higher concentrations, cyanoHAB events may be so dense that they resemble bright green paint that has been spilled in the water. These blooms potentially affect water quality, human health (e.g., *Microcystis* can produce microcystin, a liver toxin), and natural resources. Decomposition of large blooms can lower the concentration of DO in the water, resulting in hypoxia (low oxygen) or anoxia (no oxygen) which may result in fish kills. Field crews will be submitting real-time reports of a potential cyanoHAB events to the state and tribal organizations that monitor water quality for recreational use support and swimming advisories. These organizations may use this information to determine if follow up monitoring and reporting is needed.

1.2.4.2 Algal toxins (microcystins and cylindrospermopsin)

Microcystins and cylindrospermopsin are two types of toxins produced by cyanobacteria. During a cyanoHABs event, the toxin concentration can rapidly increase and may become elevated before a visible bloom is observed. Elevated cyanotoxin concentrations in surface waters can persist after the bloom fades, so human exposures can occur even after the visible signs of a bloom are gone or have moved downstream. Exposure to elevated-levels of microcystins can potentially lead to liver damage; the kidneys and liver appear to be the primary target organs for cylindrospermopsin toxicity.

1.2.4.3 Fecal indicator (Enterococci)

Enterococci are bacteria whose presence indicates that water may be contaminanted by human or animal wastes. Microbes in these wastes can cause short term effects, such as diarrhea, cramps, nausea, headaches, or other symptoms. They may pose a special health risk for infants, young children, and people with severely compromised immune systems.

1.2.4.4 Fish Fillet Contaminants Indicator

Fish are important integrators of toxic contaminants that are bioavailable in the water column and in sediment. EPA monitors the occurrence of toxic chemicals in fish fillet samples to assess the potential health impacts for people who consume fish. Collecting whole fish composite samples and submitting them to the laboratory for filleting and homogenization during the NLA 2022 provides sufficient tissue for analysis of multiple chemical contaminants of concern (e.g., mercury, polychlorinated biphenyls or PCBs, and per- and polyfluoroalkyl substances or PFAS).

1.2.5 **Other Indicators**

1.2.5.1 Lake Characterizations

Observations and impressions about the lake and its surrounding catchment by field crews will be useful for ecological value assessment, development of associations and stressor indicators, and data verification and validation.

1.2.5.0 Environmental DNA

Two water samples will be collected and analyzed for environemtnal DNA (eDNA). Consistent with NLA 2017, one sample will be collected from the index site. The second sample will be a composite sample from 10 littoral stations. This research measure will be used to explore indicator development for future NLAs.

NMED Exhibit 36

Table 1-1 Summary table of indicators and sampling location.

Indicator Type	Indicator	Specifications/Location in Lake			
		Desktop Evaluation	**Boat Launch**	**Index Site**	**Littoral Site**
Trophic and Chemical Indicators	Vertical profile measurements (DO, Temperature, pH)			X	
	Secchi Disk transparency			X	
	Water chemistry (NH_4, NO_3), major anions and cations, alkalinity (ANC), DOC, TSS, silica, conductivity, nutrients (total and dissolved TN and TP)			Integrated water sample	
	Chlorophyll-*a*			Integrated water sample	
	Atrazine pesticide screen			Integrated water sample	
Biological	Benthic macroinvertebrate assemblage				10 stations
	Zooplankton assemblage (composition, structure, and size distribution)			Vertical tow (2 mesh sizes) through water column	
Physical Habitat	Physical habitat characterization				10-12 stations
Human Health	Fecal indicator (*Enterococci*)		Grab sample; lakes >10,000 ha		Grab sample; last station, lakes < 10,000 ha
	Phytoplankton (cyanobacteria)			Integrated water sample	
	CyanoHAB visual observations		X	X	X
	Algal toxins (microcystins and cylindrospermopsin)			Integrated water sample	
	Fish fillet contaminants		Whole fish composite sample (for fillet analysis) collected lake wide		
Other Indicators	eDNA		1L Grab sample; lakes >10,000 ha	1L Grab sample	10 sample composite; 1L total
	Lake area, basin morphometry, and characteristics of watershed	Using GIS			

2.0 LOGISTICS

2.1 Roles and Contact Information

Effective communication between field crews, EPA coordinators, and NLA 2022 contractor support staff is essential for the survey to proceed with maximum efficiency and to ensure collection of high quality data. This section provides:

- A general description of the roles of key NLA 2022 personnel in providing logistical and technical support to the field crews;
- Flow of communication between Field Crews and these individuals (i.e., *who to call for specific types of questions or support needs*); and
- Contact information.

The **EPA Headquarters (HQ) Project Management Team** consists of the Project Leader, Logistics Leader, and Project QA Lead, along with the EPA Technical Lead for the Fish Fillet Contaminants Indicator. The Team is responsible for overseeing all aspects of the project and ensuring technical and QA requirements are properly carried out. The Team is the final authority on all decisions regarding field sampling, site evaluation, site replacement, and laboratory analysis.

The **EPA Regional Coordinators** are the primary EPA point of contact for Field Crews operating in their Region. Field Crews should direct all technical and logistical questions to their EPA Regional Coordinator, who will work with the EPA HQ Team to resolve the issue. Field Crews should also work with their EPA Regional Coordinator to schedule an **Assistance Visit** to occur within the first two weeks of field sampling. An Assistance Visit is part of the QA component of the NLA 2022 QAPP. To meet the requirements of the QAPP, each Field Crew will allow an EPA employee or contractor to observe that crew sampling for one day. The Assistance Visit is used to confirm the protocols are implemented as intended and to suggest corrective actions, if needed, to the Field Crew's sampling approach.

The **Information Management (IM) Coordinator** provides the Field Crews with packets of forms and labels for each site scheduled to be sampled. Crews will request these packets through a fillable PDF Request form. The IM Team also tracks the transition of each NLA 2022 sample from the field to the laboratory.

The Contract **Field Logistics Coordinator (FLC)** is responsible for tracking the Field Crew's sampling activities and overall progress throughout the field season, ensuring that requests for supplies and equipment are filled, and assisting Field Crews with questions concerning field logistics, equipment, and supplies as they arise during the field season. The FLC will also review submitted status and tracking forms to ensure that the correct samples have been taken and that those samples are being sent to the laboratories in an appropriate timeframe.

NMED Exhibit 36

Table 2-1 Personnel to call for specific types of questions and support needs.

Personnel	Call
EPA Regional Coordinators	First, to ask any questions about NLA, including questions on field protocols Grant questions Schedule Field Assistance Visit
EPA HQ Project Management Team	Ask questions about site access, site evaluation, and site replacement Ask questions about shipping locations and sample handling procedures Ask questions about Field Methods Ask questions about Target Fish species Ask questions about Survey Design Ask questions about QA procedures Ask questions about Laboratory Methods If you can't reach Regional Coordinator, IM Coordinator, or Field Logistics Coordinator If you are unsure who to call
Personnel	**ONLY Call**
Information Management (IM) Coordinator	Order field forms or site kits Submit a status report Notify EPA about change in sampling schedule Ask questions about submitting data packet If EPA Regional Coordinator directs you to them
Contract Logistics Coordinator	Order replacement items for site kits, base kits, or miscellaneous supplies Ask questions about shipping contract, or to order more shipping forms If EPA Coordinator directs you to them If you can't reach an EPA HQ or Regional Coordinator and it is an urgent question

2.2 Key Information and Materials

2.2.1 Site Maps

Geospatial files in the form of geographic information system (GIS) design point and polygon files and state leaflet maps have been provided on the NLA SharePoint sites to assist in the site evaluation process. From these files, crews should generate their own site maps with relevant information displayed. The site maps will be helpful in the planning and preparation for visiting and sampling a

NMED Exhibit 36

particular NLA 2022 site. These maps should become part of your site packet. See more information on the site packet in Section 4.1.

2.2.2 **Forms**

Forms are the key to data collection and tracking for the NLA 2022. For NLA 2022 we have developed electronic forms which will be accessed via the NLA App. Paper forms will only be provided as backups to the App forms.

2.2.2.1 Field Forms

The NLA App is the primary way crews will record measures, observations, and collection information during the course of the field day. Additional information regarding specifics of data entry is contained in Section 3.2.

- **Electronic Field Forms:** This form of data collection will be collected through an Apple iPad which will be provided for all state, tribal, and EPA crews. Each of the field forms are separated into sections for easier data entry. It is important for a field crew to familiarize themselves with the NLA App prior to field sampling. Field crews should note that each individual field form must be submitted by only one device. For example, if there are 5 field forms (A,B,C,D,E) and iPad 1 submits forms A, B, and D, then iPad 2 should not submit those 3 forms or data will be overwritten. In this example, iPad 2 could still submit forms C and E with no issues. While a data or Wi-Fi connection is required to submit the data, no data connection is required for the data collection process.

- **Paper Field Forms:** Extra paper field forms will only be provided to field crews to serve as backup copies in case of problems with electronic field forms. As soon as possible, the completed paper field forms should be transcribed to the NLA App for data submission. The original completed version of the forms must also be scanned, emailed to the EPA Logistic Lead and stored by the field crew for two years.

2.2.2.2 Tracking Form

The **Tracking** form in the App describes the status and location of all samples and specimens collected during the sampling of an NLA site and is transmitted electronically to the IM Team at specified times. When samples are shipped to the lab, a packing slip is included in the shipping container to convey to the lab which samples are included in the shipment. These packing slips (which are pre-printed with the same sample IDs as the individual sample labels) are included in the Label Packet with each Site Kit.

The **Tracking** form is divided into several shipping groups, each labelled with a shipping group number (e.g., T-1, T-2, T-3, etc.). Sample labels, packing slips, and FedEx shipping labels also carry these shipping group numbers to help Field Crews group correct items together for shipping. See APPENDIX B: SHIPPING GUIDELINES for more information.

2.2.3 **Equipment and Supplies**

2.2.3.1 Request Form

Field Crews will submit requests for site kits, whole fish composite sample kits, and other needed supplies via an electronic **Request** form provided by the FLC. This form will be submitted to the NARS IM Coordinator who will ensure that the request reaches the appropriate entity. Crews must submit basic

NMED Exhibit 36

sampling information (i.e., tentative start date and number of sites crews are planning to sample) to the FLC at or before the time of submitting request forms. Crews should submit the **Request** form at least two weeks prior to their desired sampling date. The **Request** form will be in fillable PDF format. Users must enter the required information, save a copy of the form to their computer or device and attach the updated copy to an email to sampletracking@epa.gov. The IM Team will send email notification that the request has been received.

2.2.3.2 Base Kit

The Base Kit is comprised of the subset of durable equipment and supplies needed for NLA 2022 sampling and is provided by EPA through the FLC. Typically one Base Kit is provided to each Field Crew and contains some of the equipment that is used throughout the field season. SeeAPPENDIX A: EQUIPMENT & SUPPLIES for a list of the items provided by EPA in the Base Kit. EPA anticipates that Base Kitequipment will be available for use in future NLA efforts.

2.2.3.3 Site Kit

A Site Kit contains the subset of consumable supplies (i.e., items used up during sampling or requiring replacement after use) provided by EPA through the FLC. The site kit will contain all the sample bottles necessary for sampling a single lake. A new Site Kit should be requested for each site sampled, and crews should consider having at least one additional site kit available as a spare should any supplies be lost See APPENDIX A: EQUIPMENT & SUPPLIES for the consumable items that will be provided by EPA.

2.2.3.4 Whole Fish Composite Sample Kit

A sampling kit for the whole fish composite sample will be provided for all designated fish sampling sites. In the survey design, “FT” in the “Panel_Use” identifies lakes designated for fish sampling. This sampling kit contains consumable supplies provided by EPA. Field crews should request a new whole fish sampling kit for each designated fish site to be sampled. See APPENDIX A: Equipment & Supplies for the consumable items that will be provided by EPA.

2.2.3.5 Field Crew Supplied Items

The field crew will also supply particular items for the field sampling day. These items might include supplies from the NLA 2007, NLA 2012, or NLA 2017, typical field equipment (like a global position system (GPS) receiver or multi-paramter probe), or boat equipment. See APPENDIX A: EQUIPMENT & SUPPLIES for the items that the field crew will need to provide.

2.2.4 **Other Resources**

The complete documentation of overall project management, design, methods and standards, and QA/QC measures is contained in this document and companion documents (listed in NOTICE and described below). The NLA 2022 participants must agree to follow the QAPP, including the protocols and design, and the associated documents – the NLA 2022 FOM, LOM, and SEG.

2.2.4.1 Quick Reference Guide

Field crews will NOT receive a NLA 2022 QRG. All components of the QRG will be contained in the FOM and as “i” buttons in the NLA App. The electronic version of the FOM will be provided on the EPA issued Apple iPads and will be a searchable document. Detailed steps to complete protocols can be found in the FOM. Many of the tables and figures in the FOM will also be included in the App.

NMED Exhibit 36

2.2.4.2 Site Evaluation Guidelines

The NLA 2022 SEG (EPA 841-B-16-001) outlines the process to compile the final list of candidate lakes for sampling. The process includes locating a candidate lake, evaluating the lake to determine if it meets the criteria for inclusion in the target population and is accessible for sampling, and if not, replacing it with an alternate candidate lake.

2.2.4.3 Quality Assurance Project Plan

Large-scale and/or long-term monitoring programs such as those envisioned for national surveys and assessments require a rigorous QA program that can be implemented consistently by all participants throughout the duration of the monitoring period. QA is a required element of all EPA-sponsored studies that involve the collection of environmental data (USEPA 2000a, 2000b). Field crews will be provided a copy of the NLA 2022 QAPP (EPA 841-B-16-003) and the field crew leader is required to sign the QAPP signature page prior to beginning field sampling activities. The QAPP contains more detailed information regarding QA/QC activities and procedures associated with general field operations, sample collection, measurement data collection for specific indicators, and data reporting activities. For more information on the project level QA procedures, refer to the NLA 2022 QAPP.

2.2.4.4 Laboratory Operations Manual

The methods used for the laboratory sample analysis is available in the NLA 2022 Laboratory Operations Manual (LOM) (EPA 841-B-21-010).

2.2.4.5 Realtime cyanoHAB Reports

Field crew leads are to report a cyanoHAB event if a bloom is occuring at the time of sampling. The Apple iPads are preloaded with the bloomWatch application to support realtime reporting of a bloom to the appropriate state, tribal and/or watershed organization authority. Alternatively, field crews are encouraged to download state-specific monitroing and reporting tools that will be in use for the 2022 recreation season. Additional information on state-specific HABs monitoring programs can be found here (https://www.epa.gov/cyanohabs/state-habs-monitoring-programs-and-resources). To submit a report to bloomWatch or a state-specific tool, the field crews should should be prepared with emails for state officals that are to receive these report (i.e., officals that monitor and report on cyanobacterial bloom events). Field crews must select the preferred reporting approach and be familiar with its input needs (e.g., extent, photos, email contacts etc.) prior to initiating field work. All reports submitted via the bloomWatch app should add the project identifier 'NLA2022' in the comment section in the app.

3.0 DAILY FIELD ACTIVITIES SUMMARY

This section presents a general overview of the activities that a field crew conducts during a typical 1-day sampling visit to a lake. The following sections include general guidelines for health and safety, recording data, and using standardized field data forms and sample labels.

3.1 Health and Safety

Collection and analysis of samples can involve risks to personal safety and health, and **the safety of the field crew must always be the primary consideration during sampling**. This section describes general safety considerations, some safety equipment, and safety guidelines for field operations.

This section does not substitute for an official Health and Safety Plan. The crew MUST ALWAYS carefully follow the protocols in their Health and Safety Plan for the NLA field work that was approved by the state, tribe, or other organization with which the field crew is affiliated. The crew should carry a copy of this approved Health and Safety plan in the field.

3.1.1 General Considerations

It is the responsibility of the group safety officer or project leader to ensure that the necessary safety courses are taken by all field personnel and that all safety policies and procedures are followed. Each state, tribe, or other organization must have a specific safety plan for the sampling the NLA sites, including a communications plan that addresses safety and emergency situations. The plan should have a daily check-in procedure for field personnel, and emergency contacts for police, ambulance, fire departments, hospitals, and search and rescue personnel. Important considerations related to field safety are listed below. It is the responsibility of the group safety officer or project leader to ensure that the necessary safety courses are taken by all field personnel and that all safety policies and procedures are followed. Sources of information regarding health and safety considerations and/or safety-related training include the American Red Cross (http://www.redcross.org/m/phssmrd/take-a-class), the National Institute for Occupational Safety and Health (1981) (see the most recent revisions at https://www.cdc.gov/niosh/docs/81-123/, and the U.S. Coast Guard (http://www.uscgboating.org/recreational-boaters/boating-safety-courses.php).

3.1.1.1 Recommended Training

- First aid;
- Cardiopulmonary resuscitation (CPR);
- Vehicle safety (e.g., operation of 4-wheel drive vehicles, trailer towing and maneuvering);
- Boating and water safety;
- Field safety (weather, personal safety, orienteering, site reconnaissance prior to sampling);
- Equipment design, operation, and maintenance; and
- Handling of chemicals and other hazardous materials.

3.1.1.2 Communications

A communications plan to address safety and emergency situations is essential. All field personnel need to be fully aware of all lines of communication. Field personnel should have a daily check-in procedure

NMED Exhibit 36

with their supervisor for safety. An emergency communications plan should include contacts for police, ambulance, fire departments, hospitals, and search and rescue personnel. Below are some items to address:

- Check-in schedule;
- Sampling itinerary (vehicle used & description, time of departure & return, and travel route);
- Contacts for police, ambulance, hospitals, fire departments, and search and rescue personnel;
- Emergency services available near each sampling site and base location; and
- Cell (or satellite) phone number, if possible.

3.1.1.3 Personal Safety

Proper field clothing should be worn to prevent hypothermia, heat exhaustion, sunstroke, drowning, or other dangers. Field personnel should be able to swim, and a personal flotation device (PFD) must be used. Chest waders made of rubberized or neoprene material and suitable footwear must always be worn with a belt to prevent them from filling with water in case of a fall. Below are some personal safety items to address:

- Field clothing and other protective gear including lifejackets for all crew members;
- Medical and personal information (allergies, personal health conditions, and required medications);
- Personal contacts (family, telephone numbers, etc.); and
- Physical exams and immunizations.

Many hazards lie out of sight in the bottoms of lakes, rivers, and streams. Broken glass or sharp pieces of metal embedded in the substrate can cause serious injury if care is not exercised when walking or working with the hands in such environments. Infectious agents and toxic substances that can be absorbed through the skin or inhaled may also be present in the water or sediment. Personnel who may be exposed to water known or suspected to contain human or animal wastes that carry causative agents or pathogens must be immunized against tetanus, hepatitis, typhoid fever, and polio. Biological wastes can also be a threat in the form of viruses, bacteria, rickettsia, fungi, or parasites.

Lakes and surrounding landscapes can be home to dangerous organisms. Field crews should take care to minimize contact with biting insects, bees, poisonous snakes and dangerous animals. Insect repellent and protective clothing will help to limit exposure. At the end of each field day, workers should inspect their bodies for ticks. Any person allergic to bee stings, other insect bites, or plants (i.e., poison ivy, poison oak, poison sumac, etc.) should take proper precautions and have any needed medications on hand. In addition, field crew members should always be aware of their surroundings to protect themselves from dangerous animals, such as alligators, mountain lions, bears, and wolves.

3.1.1.4 Sampling Equipment

Field crew members should be familiar with hazards associated with the use of sampling equipment and establish appropriate safety practices prior to their use. They must ensure that all equipment is in safe working condition.

Because boats are used to access NLA sampling sites, personnel must be trained in operating the type of boat in use incouding appropriate state or other certifications. Personnel must consider and prepare for

NMED Exhibit 36

hazards associated with the operation of motor vehicles, boats, winches, tools, and other incidental equipment. Boat operators should be familiar with U.S. Coast Guard rules and regulations for safe boating contained in a pamphlet, *Federal Requirements for Recreational Boats*, available from a local U.S. Coast Guard Director or Auxiliary or State Boating Official and online (U.S. Coast Guard, https://www.uscgboating.org/images/420.PDF). All boats with motors must have fire extinguishers, boat horns, life jackets or flotation cushions, and flares or communication devices.

3.1.2 Safety Equipment

Appropriate safety apparel such as life jackets, waders, gloves, safety glasses, etc. must be available and used when necessary. First aid kits, fire extinguishers, and blankets must be readily available in the field. Cellular or satellite telephones and/or portable radios should be provided to field crews working in remote areas for use in case of an emergency. Supplies such as anti-bacterial soap and an adequate supply of clean water or ethyl alcohol must be available for cleaning exposed body parts that may have been contaminated by pollutants in the water or sediments.

3.1.2.1 Safety Guidelines for Field Operations

General safety guidelines for field operations are presented below.

Personnel participating in field activities on a regular or infrequent basis should be in sound physical condition and have a physical examination annually or in accordance with Regional, State, or organizational requirements.

All surface waters and sediments should be considered potential health hazards due to potential toxic substances or pathogens. Persons must become familiar with the health hazards associated with using chemical fixing and/or preserving agents. Chemical wastes can be hazardous due to flammability, explosiveness, toxicity, causticity, or chemical reactivity. All chemical wastes must be discarded according to standardized health and hazards procedures (e.g., National Institute for Occupational Safety and Health [1981]; for the most recent revisions see https://www.cdc.gov/niosh/docs/81-123/;.)

During the course of field research activities, field crews may observe violations of environmental regulations, may discover improperly disposed hazardous materials, or may observe or be involved with an accidental spill or release of hazardous materials. In such cases it is important that the proper actions be taken and that field personnel do not expose themselves to something harmful. The following guidelines should be applied:

1. First and foremost, protect the health and safety of all personnel. Take any necessary steps to avoid injury or exposure to hazardous materials. If you have been trained to take action such as cleaning up a minor fuel spill during fueling of a boat, do it. However, you should always err on the side of personal safety.
2. Field personnel should never disturb or retrieve improperly disposed hazardous materials from the field to bring back to a facility for "disposal." To do so may worsen the impact, may incur personal liability or liability for the crew members and their respective organizations, may cause personal injury, or may cause unbudgeted expenditure of time and money for proper treatment and disposal of the material. However, it is important not to ignore environmental incidents. Notify the proper local, state, and/or federal authorities of any incident of this type so that they may take the necessary actions to properly respond to the incident.
3. For most environmental incidents, the following emergency telephone numbers should be

provided to all field crews: State or Tribal department of environmental quality or protection, U.S. Coast Guard, and the EPA regional office. In the event of a major environmental incident, the National Response Center may need to be notified at 1-800-424-8802.

Specific Safety Guidelines are below:

- Two persons must be present during all sample collection activities, and no one should be left alone while in the field.
- Minimize exposure to lake water and sediments as much as possible. Use gloves when necessary, and clean exposed body parts as soon as possible after contact.
- All electrical equipment must bear the approval seal of Underwriters Laboratories (UL) and must be properly grounded to protect against electric shock.
- Use heavy gloves when hands are used to agitate the substrate during collection of benthic macroinvertebrate samples.
- Use appropriate protective equipment (e.g., gloves, safety glasses, specialized garments, etc.) when handling and using hazardous chemicals.
- Persons working in areas where venomous snakes may be encountered must check with the local Drug and Poison Control Center for recommendations on what should be done in case of a bite from a venomous snake.
- Any person allergic to bee stings, other insect bites, or plants (i.e., poison ivy, oak, sumac, etc.) must take proper precautions and have any needed medications handy (e.g., an “Epi-Pen”).
- Protect yourself against the bite of deer or wood ticks because of the potential risk of acquiring pathogens that can cause Rocky Mountain spotted fever, Lyme disease, and other diseases.
- Be familiar with the symptoms of hypothermia and know what to do in case symptoms occur. Hypothermia can kill a person at temperatures much above freezing (up to 10°C or 50°F) if he or she is exposed to wind or becomes wet.
- Be familiar with the symptoms of heat/sun stroke and be prepared to move a suffering individual into cooler surroundings and hydrate immediately.
- Handle and dispose of chemical wastes properly. Do not dispose of any chemicals in the field.

3.1.3 COVID Precautions

Safety is the number one concern for all personnel. In implementing the NLA, crews should follow their agencies’ guidance on maintaining social distance, use of personal protective equipment, travel restrictions, sanitizing equipment, vehicles and boats, and if necessary, hotel rooms. NLA training and assistance visits will be implemented in a manner that considers Covid-19 safety requirements and restrictions.

3.2 Recording Data and Other Information

All samples need to be identified and tracked; and associated information for each sample must be recorded. It is imperative that field and sample information be recorded accurately, consistently, and legibly. The cost of a sampling visit coupled with the short index period severely limits the ability to resample a lake if the initial information recorded was inaccurate. As mentioned in Section 2.2.2, there are two forms for collecting sample data: electronic field forms and backup paper field forms. See below for important information pertaining to data entry for each of these forms.

NMED Exhibit 36

3.2.1 Field Forms

The NLA 2022 field data and tracking forms are formatted in the NLA App so that the data you record can be electronically submitted to the NARS IM database. It is important that field data and sample information are recorded accurately and consistently. General guidelines for recording field measurements are presented in **Table 3-1.** More detailed instructions for filling out specific forms are provided in each protocol chapter of this manual.

Table 3-1 Guidelines for recording field measurements and tracking information.

ACTIVITY	GUIDELINES
Field Measurements	
Data Recording	• Record observations and measurement values only using the official NLA App (provided on EPA owned Apple iPads for all regional, state, and tribal crews). • If you make an error when recording data and changes are required, it is best to enter the new value and resubmit that electronic form. • Use the correct crew ID assigned during field training. • Use the units and formats specified on individual data forms for recording data. • For any sample or data where additional explanation is needed, use the provided comment bubble adjacent to the data
Sample Collection	
Sample Labels and Tags	• Use a writing instrument that leaves clear, dark text to record information (e.g., a No. 2 pencil on paper tags or a water or smear proof fine-point indelible marker on adhesive labels). Use the sample-type appropriate adhesive labels with preprinted Sample ID numbers for each sample. Be sure to fill in any requested information about the sample on the sample label and affix it to the outside of the sample container. Cover completed labels with clear tape. • Place a waterproof paper tag inside each benthic macroinvertebrate collection jar with the required information written with a No. 2 lead pencil.
Sample Collection Information	• Record that each sample has been collected on the appropriate data form. Be sure to cross-check the Sample ID number from labels and tags with the Sample IDs populated in the **Tracking** form .
QA and Tracking	
Before Leaving Site: Review of Data Forms and Comparison of Sample Labels and Data Forms	• Review all data forms for accuracy and completeness. • Review all sample labels for accuracy, completeness, and legibility. • Verify that the information recorded on the sample labels and tags is consistent with all Sample IDs listed on the **Tracking** form in the NLA App.
Before Shipping Samples: Review of Sample Labels and Tracking Form	• Complete all sections in the **Tracking** form required for all samples being shipped. Review the **Tracking** form for consistency and correctness. • Compare labels on samples with the Sample IDs recorded on the **Tracking** form for accuracy and completeness before shipping samples.
Review of Data Forms	• The Field Crew Leader should review the completed forms in the NLA App as soon as is practicable to ensure they are complete and all data forms are consistent and correct

NMED Exhibit 36

ACTIVITY	GUIDELINES
	• Confirm that the forms have been reviewed by selecting the reviewed bubble in the App for each electronic data form. • If any revisions are made, re-submit the updated form(s) as soon as possible to update the IM Database. • After each submission, a data summary email will be sent to the email address which submitted the data. This data summary contains a list of the data forms and their most recent submissions date/time as well as a list of the most critical data points collected at the site. The Field Crew Leader should review this data summary to ensure that the data forms were successfully received and that critical values are present and correct.

3.3 Sampling Scenario

Field methods for the NLA 2022 are designed to be completed in one field day for most lakes. Depending on the time needed for both the sampling and traveling for that day, an additional day may be needed for pre-departure and post-sampling activities (e.g., cleaning equipment, repairing gear, shipping samples, and traveling to the next lake). Remote lakes with lengthy or difficult approaches may require more time to gain access to the lake, and field crews will need to plan accordingly.

A field crew typically will consist of at least two people. Two people are always required in the boat together to execute the sampling activities and to ensure safety. Any additional crew members may either remain on shore to provide logistical support or be deployed in a second boat to assist in data collection. Figure 3-1 and Figure 3-2 present a daily field sampling scenario showing how the workload may be split between crew members. Each field crew should define roles and responsibilities for each crew member to organize field activities efficiently. Minor modifications to the sampling scenario may be made by crews; however, the sequence of sampling events presented in Figure 3-1 cannot be changed and is based on the need to protect some types of samples from potential contamination and to minimize the possibility of holding time exceedance once samples are collected. The following sections further define the sampling sequence and the protocols for sampling activities.

***NOTE**: When sampling large lakes (lakes > 10,000 hectares), field crews may omit the physical habitat, benthic macroinvertebrate, and littoral eDNA sampling efforts altogether.*

NMED Exhibit 36

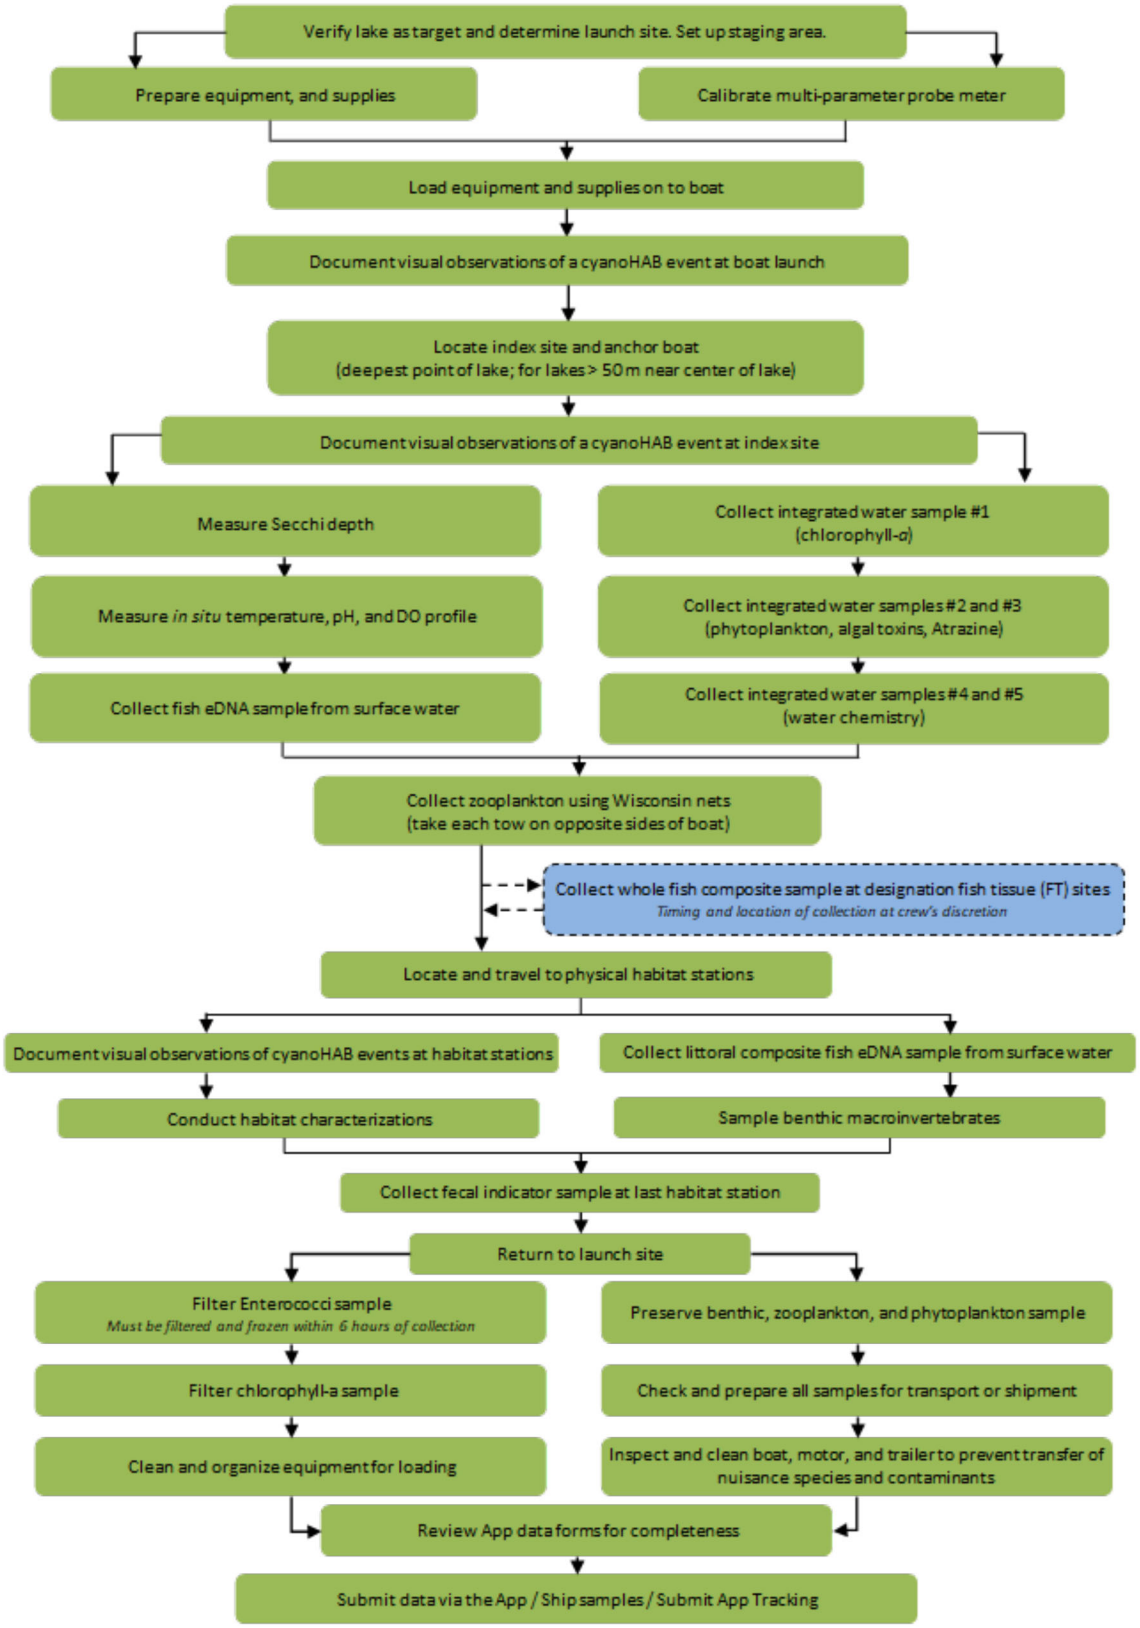

Figure 3-1 Daily operations summary

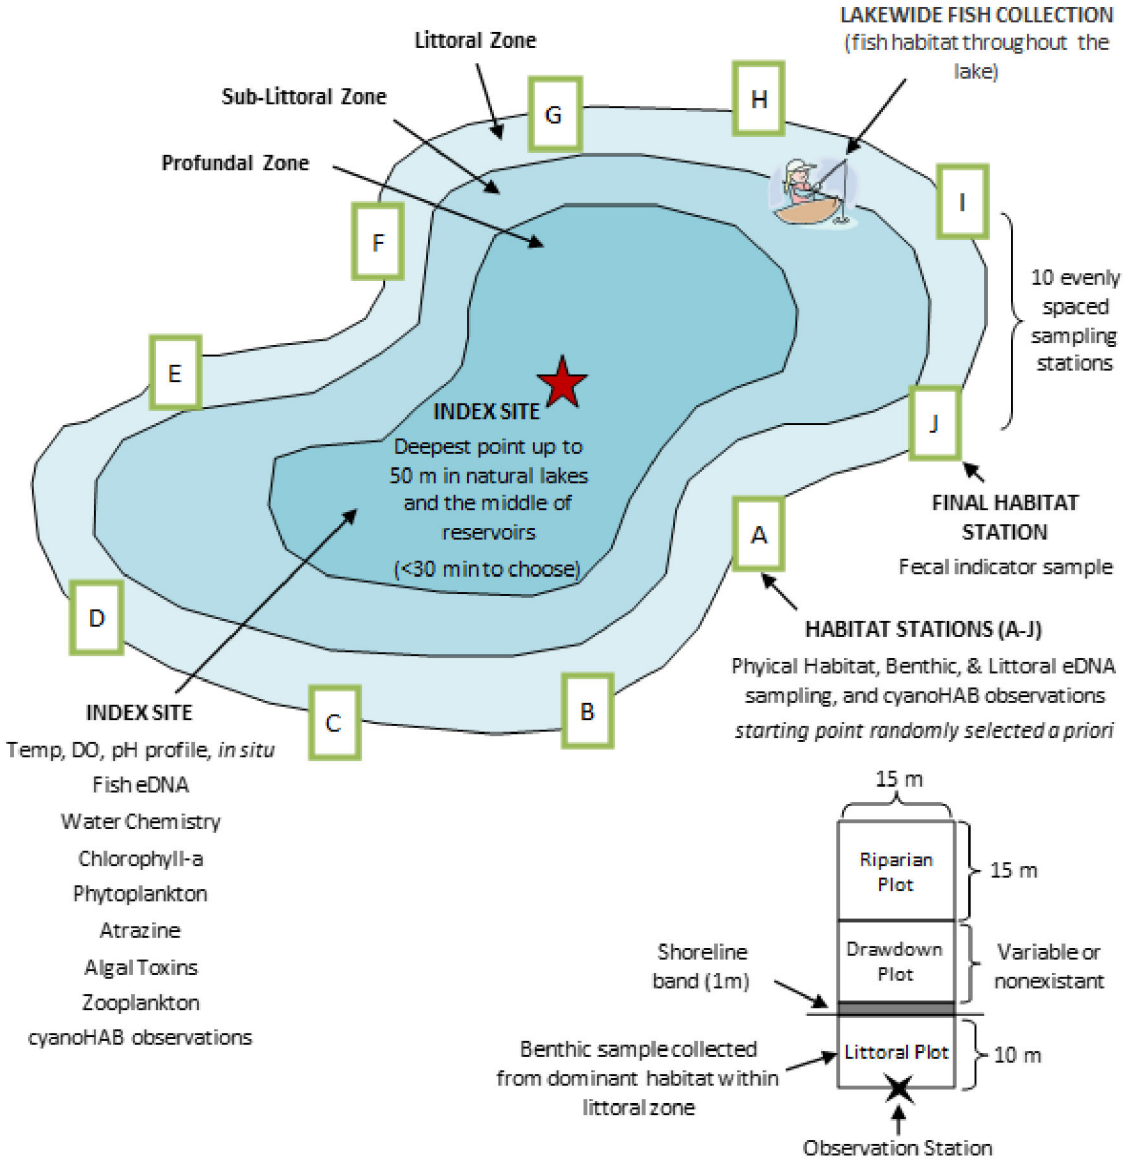

Figure 3-2 Location of sample collection points and physical habitat (PHab) stations.

The field crew arrives at the lake in the early morning to complete the sampling in a single day. The sampling sequence is to:

1. verify lake, calibrate equipment, locate, and travel to the index site;
2. document visual observations of a cyanoHAB event at boat launch and index site;
3. conduct depth profile measurements of DO, temperature, and pH;
4. take Secchi disk transparency depth measurement;
5. collect fish eDNA sample;
6. use the integrated sampler to collect water chemistry, chlorophyll-*a*, atrazine, algal toxin, and phytoplankton samples;
7. collect zooplankton samples;

8. collect fish eDNA sample for composite sample from the littoral plot at the ten PHAb stations (A,B,C,D,E,F,G,H,I,J) prior to initiating physical habitat characterization or benthic sampling;
9. document visual observations of cyanoHABs and conduct physical habitat characterization around the margin of the lake at ten PHab stations (A,B,C,D,E,F,G,H,I,J);
10. collect benthic samples at ten PHAb stations (A,B,C,D,E,F,G,H,I,J) concurrent with physical habitat characterization;
11. collect whole fish composite samples;
12. collect fecal indicator sample at last PHab station (<10,000 ha lakes) or boat launch when exiting lake (>10,000 ha lakes);
13. filter enterococci and chlorophyll-*a* samples;
14. preserve and prepare all samples for shipment;
15. review App field forms ;
16. report sampling event; and
17. ship time-sensitive samples (water chemistry, chlorophyll-*a*, eDNA, and fecal indicator samples).

NMED Exhibit 36

4.0 BASE SITE ACTIVITIES

Field crews are to conduct a number of activities at their base site (i.e., office or laboratory, camping site, or motel). These include tasks that must be completed both before departure to the lake site and after return from the field (Figure 4-1). Close attention to these activities is required to ensure that the field crews know:

- where they are going;
- that access is permissible and possible;
- that equipment and supplies are available and in good working order to complete the sampling effort; and
- that samples are packed and shipped appropriately.

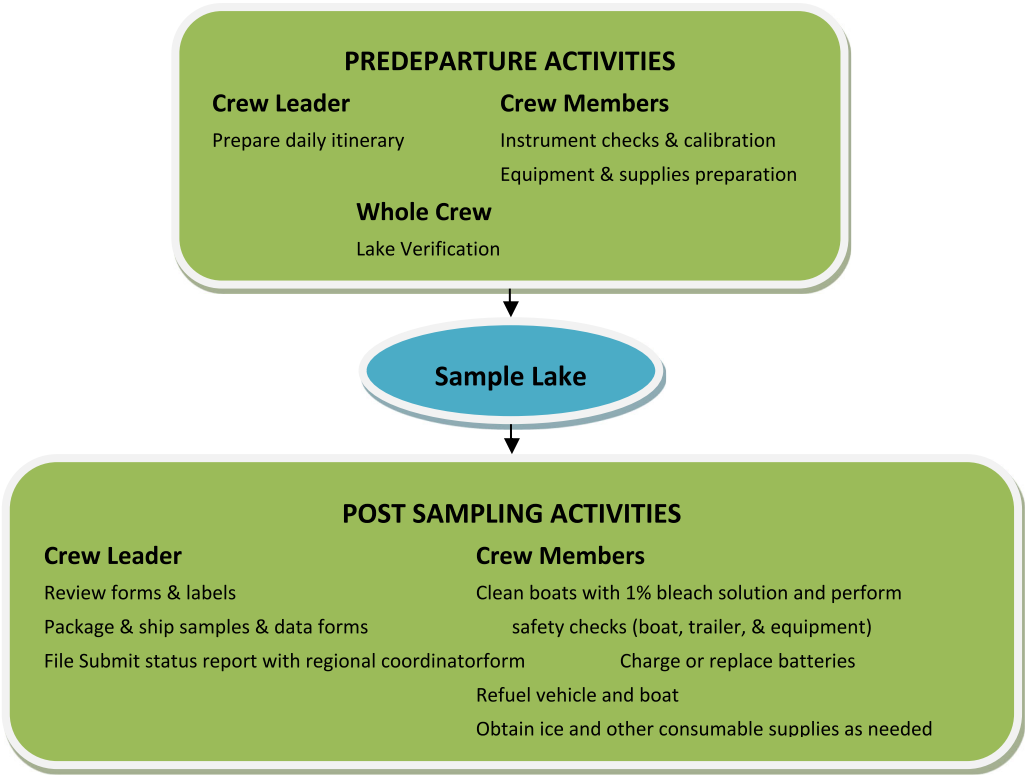

Figure 4-1 Overview of base site activities

4.1 Pre-departure Activities

Pre-departure activities include developing daily itineraries, checking and calibrating instruments, and preparing equipment and supplies. Procedures for these activities, which will take place at your office or laboratory, camping site, or motel, are described in the following sections.

4.1.1 Daily Itineraries and Site Packets

The Field Crew Leader is responsible for developing daily itineraries and a site packet. A site packet contains information key to the planning and preparation for visiting and sampling a particular NLA site.

NMED Exhibit 36

Development of site packets should have been initiated during site evaluation and reconnaissance (See NLA 2022 Site Evaluation Guidelines); however, the field crew may need to gather additional information for the site packet during preparation for the sampling visit. Also, it is the responsibility of the field crew to obtain access permissions and any needed permits as part of developing the site packet.

Prior to a field crew traveling to a NLA site for sampling, the information for the site packet must be gathered and reviewed. Site packet development entails compiling maps, contact information, copies of permission letters, and access instructions. The Field Crew Leader must be sure to lay out the physical habitat (PHab) stations on a site map before the sampling day (see Section 6.2.3). Additional activities include confirming the best access routes, calling the landowners or local contacts, and confirming lodging plans. The site packet may include the following documents:

- **Site maps**: Generated by crew (see Section 2.2.1 Site Maps).
- **Other Maps, Imagery, or GIS Data:** Any other maps, aerial photos, GIS data, or sources of information compiled by Field Crews and/or their partners that could be helpful to sampling the NLA sites.
- **Land Ownership Status, Requirements and Permissions for Access:**
    - Landowner identity and contact information.
    - Results of communication with landowners.
    - Documentation of permission to access private land.
    - Permissions for crossing private lands to reach sites located on public lands.
    - For public land, response of relevant agency to notification that you will be accessing a site, and, if needed, permissions to do so.
- **Permits:** Any permits or documentation required for site access, or for data collection activities or sample/specimen collection.
- **Information for Accessing the Site:**
    - Contact information for landowners.
    - Notes about whether landowner(s) want to be informed when Field Crew is on site.
    - Contact information for individuals who must be available to open gates or allow entry to a site, and the time and location for meeting them.
    - Notes on locked gates, pets, livestock, or other things that could impede access.
    - Notes about active hunting, farming, mining, or other activities on or near the site.
    - Current conditions that could prevent access (e.g., high water, forest fires, road closures, etc.).
- **Site Evaluation Notes:**
    - Site Evaluation notes, annotated aerial photos, sketch map, and completed site evaluation form that can aid with planning for accessing or sampling a site.
- **Driving and Hiking Routes to the Site:**
    - Detailed driving directions may be obtained from the NLA Google Earth files.
    - Results from the Site Evaluation may include driving directions and notations about site access or logistically challenging conditions on the site, which can be useful in relocating the site or helpful in anticipating special circumstances.

NMED Exhibit 36

- **Preliminary Plan for Establishing Physical Habitat Stations:** As part of the base location activities to prepare for field work, review aerial photos and maps of the site and make a plan for laying out the PHab stations. This plan should be included in the site packet.
- **Federally Protected Species (EPA Regional and Contract Crews ONLY):** See Section 10.0.
- Any other site specific information (e.g., road construction and road closings) useful to the Field Crew.

4.1.2 Instrument Checks and Calibration

Test and calibrate instruments prior to sampling. You can calibrate instruments and probes prior to departure for the lake site or at the lake, with the exception of the DO probe. Because of the potential influence of altitude, calibrate the DO probe at the lake site (NOTE: some newer instruments may allow for calibration independent of altitude). Field instruments include a multi-parameter probe unit for measuring temperature, DO, and pH and a GPS receiver. Field crews should have access to backup instruments if any instruments fail the manufacturer performance tests or calibrations.

4.1.2.1 Depth sounding equipment

Crews are responsible for checking the accuracy of their devices against a sounding line at the beginning of the field season to verify that the device is providing accurate depth information.

4.1.2.2 Multi-parameter probe Meter Performance Test

Test and pre-calibrate the multi-parameter probe meter prior to departure from the base site, following either the Standard Operating Procedure (SOP) developed for the instrument or the manufacturer's calibration and maintenance procedures. Field crews should perform a QC check of the pH meter calibration (and conductivity meter calibration, if this optional measurement is taken) at regular intervals designated by the manufacturer. Field crews will be responsible for preparing or purchasing their own QC solution.

4.1.2.3 Global Positioning System Use and Battery Check

A GPS unit is used to locate the launch, index site and each of the physical habitat stations. Therefore, it is imperative that the Field Crew understands how to operate their GPS unit. The Global Positioning System (GPS) uses signals sent from multiple orbiting satellites to a ground-based sensor in order to fix a position on the earth. GPS uses signals sent from multiple orbiting satellites to a ground-based sensor in order to fix a position on the earth. Position accuracy depends on the Position Dilution of Precision (PDOP) which is a measure of the geometry of the satellite spread over the location of the observer. Low PDOP values are typically conveyed to the user as a measure of accuracy or precision and represent more advantageous satellite geometry and therefore less locational error. For NLA, crews should regularly monitor the accuracy reading on their GPS and should record coordinates only after achieving the lowest amount of error possible.

GPS uses many alternative mathematical models to describe the spherical shape of the earth and each is a separate datum. Commonly used datums include NAD27 CONUS, NAD83, and WGS84. Each represents a different interpretation of the shape of the earth. The NARS standard is **NAD83**. Thus, all GPS units should be switched to this standard - prior to completing any field activities. Crews should also confirm that the NAD83 datum is being used when the GPS is turned on prior to data collection. If the GPS is not

NMED Exhibit 36

set for NAD83 and the unit cannot be changed readily, note the datum used on the data forms for later conversion.

GPS devices use a variety of units for position designation based on an imaginary latitude and longitude coordinate grid system laid across the earth (degrees, minutes, seconds, or degrees and decimal minutes, and UTM (a metric system). The NARS standard is **decimal degrees** for reporting all GPS positions.

Refer to the GPS user's manual to provide specific instructions on setting the Datum, coordinate system, and units to NLA standards. Turn on the GPS receiver and check the batteries prior to departure. Replace batteries immediately if a battery warning is displayed.

4.1.2.4 Electronic Data Capture Device Battery Check (Apple iPad)

Charge the Apple iPad each night and check the power prior to departure. External battery packs are often available for these devices if battery life is a concern.

Table 4-1 Instrument checks and calibration

Equipment	Preparation
GPS Unit	Check the batteries prior to departure Ensure map datum is set to NAD83 Ensure locational units are set to decimal degrees • latitude xx.xxxxxx; longitude -xxx.xxxxxx Perform manufacturer checks as necessary to ensure accuracy
Multi-parameter Probe	Calibrate per manufacturer guidelines (DO to be calibrated at lake) Check the batteries prior to departure Perform QC Check as directed by manufacturer and/or laboratory protocols (field crews will supply QC check solution)
Electronic Data Capture Device (Apple iPad)	Check the power prior to departure Ensure NLA Data collection App is installed, up to date, and functioning

4.1.3 Equipment and Supply Preparation

Check your inventory of supplies and equipment prior to departure using the equipment and supplies checklists provided in the Appendix; use of the lists is strongly recommended. Pack meters, probes, and sampling gear in such a way as to minimize physical shock and vibration during transport. If necessary, prepare stock preservation solutions as described in Table 4-2. Follow the regulations of the Occupational Safety and Health Administration (OSHA).

Table 4-2 Stock solutions, uses, and methods for preparation.

Solution	Use	Preparation
Bleach (1%)	Clean nets, other gear, and inside of boat.	Add 40 mL bleach to 4,000 mL distilled water.
Lugol's	Preservative for phytoplankton samples.	Lugol's will be supplied with base kit. If preparation is needed: Dissolve 100 g KI in 1 L of distilled water. Dissolve 50 g iodine (crystalline) in 100 mL glacial acetic acid. Mix these two solutions. Remove any precipitates. Store in the dark.
95% Ethanol	Preservative for benthic invertebrate samples and zooplankton samples.	No preparation needed (use stock solution as is).

NMED Exhibit 36

Refuel vehicle(s) and conduct maintenance activities the night before a sampling trip. Check trailer lights, turn signals, and brake lights before departure. In addition, inspect your vehicles, boats, and trailers every morning before departure. Pay particular attention to the trailer hitch, electrical connections, tie downs, tire pressure, and the overall condition of the boats.

Label and package as many of the sample containers as possible in the site kit prior to departure. Container labels should not be covered with clear tape until all information is completed during sampling at the lake. Store an extra kit of sampling supplies (Cubitainers®, bottles, filters, foil, gloves, forms, pencils, permanent markers, and labels) in the vehicles. Inventory these extra supply kits prior to each lake visit. Be sure to order field sampling site kits well in advance (two week minimum) by submitting the electronic **Request** form.

4.1.4 General Equipment and Supplies for all Activities

Table 4-3 indicates equipment and supplies that will be used for all activities.

Table 4-3 Equipment and supplies – all activities.

Type	Item	Quantity
Forms	NLA App pre-installed on Apple iPad	2
Reference	NLA 2022 Field Operations Manual (FOM) NLA 2022 Quality Assurance Project Plan (QAPP) NLA 2022 Site Evaluation Guidelines (SEG) NLA 2022 Fact Sheets	1 1 1 10
Documentation	Clipboard Pencils (#2, for benthos inner sample tags) Permanent markers (fine tip, for adhesive labels) Labels Field Notebook (optional) Clear tape strips (to cover sample labels)	1 1 1 1 As needed
Collection	Access permission documents/permit (if required)	1

4.2 Lake Verification

4.2.1 Equipment and Supply List

Table 4-4 is the checklist for equipment and supplies required to conduct protocols described in this section. It is similar to, but may be somewhat different from, the checklist that is used at a base site to assure that all equipment and supplies are taken to, and available at, the lake. Field crews should use the checklist presented in this section to ensure that the equipment and supplies are organized and available on the boat in order to conduct protocols correctly and efficiently.

Table 4-4 Equipment and supplies – lake verification.

Type	Item	Quantity
Form	NLA Verification Form	1
Collection	Depth Finder (hand-held or boat mounted sonar) GPS unit (with manual, reference card, extra battery) Anchor (with 75 m line or sufficient to anchor in 50 m depth)	1 1 1-2

NMED Exhibit 36

4.2.2 Lake Verification at the Launch Site

Before sampling activities begin, you must verify that you are at the correct lake and whether it meets the criteria for sampling. Confirming that you are at the correct lake is based on map coordinates, locational data from the GPS when possible, and any other evidence such as signs or conversations with local residents. The Design Name for the site is pre-populated in the App (UNKNOWN if no name), crews should populate the Lake Name if known. Record locational coordinates for the lake on the **Verification** form. If GPS coordinates are obtained, fill in the bubble to indicate GPS and record the latitude, longitude in decimal degrees.

Determine the number of satellites being used by the GPS and select if 3 or fewer satellites or if 4 or more satellites were used. All coordinates will be recorded in the NAD83 datum. Compare the map coordinates pre-populated in the App for the lake with the GPS coordinates you record and verify that you are at the correct lake. [Note: The map coordinates in the App represent the “labeling point” in NHD and may not be near either the index site or the launch site]. Verification that you are at the target lake can be confirmed via other methods (e.g., map, landowner confirmation). If GPS coordinates are not available, do not record any information, but try to obtain the information at a later time during the visit. A GPS location may be taken at any time during a lake visit and recorded by flagging the launch site coordinates and providing a comment.

Record directions to the lake and a description of the launch site on the **Verification** form regardless of whether the site is sampled or not. This information is very important and will be used in the future if the lake is revisited by another sampling crew. Provide information about signs, road numbers, gates, landmarks, and any additional information you feel will be useful to another sampling crew in locating this lake in the future. It is also helpful to describe the distance traveled (miles) between turns. Also describe the launch site. For example: Can the boat be launched with a trailer? Are there fees? Is the launch paved or does it consist of soft sand? What landmarks are at the launch? Due to privacy concerns, do not record landowner contact information (e.g., name, address, phone, email address) on the **Verification** form.

In addition to, or in the absence of, an accurate GPS reading, use as many of the following methods as possible to verify the site:

- Obtain confirmation from a local person familiar with the area.
- Identify confirming roads and signs.
- Compare the lake shape to that shown on a topographic map (United States Geological Survey (USGS) 7.5-minute map or equivalent).
- Determine lake position relative to identifiable topographic features shown on the map.

If the lake shape on the USGS topographic map does not correspond with the actual lake shape from your site map, and you cannot verify the lake by any other means, check "Not Verified" and provide comments on the **Verification** form. At each lake, evaluate whether or not the lake meets the NLA operational definition of a “lake”:

- ≥ one ha in total surface area;
- ≥ 1,000 square meters of open water;
- ≥ one meter in depth;
- Not saline (due to saltwater intrusion or tidal influence); and

NMED Exhibit 36

- Not used for aquaculture, disposal-tailings, mine-tailings, sewage treatment, evaporation, or other unspecified disposal use.

If the lake does not meet this definition, select the "non-target" bubble in the lake sampled section on the **Verification** form and provide an explanation for not sampling the lake. Add any additional explanation as required. (For complete details on the Site Evaluation process, refer to the companion document *Site Evaluation Guidelines* [EPA 841-B-06-003]).

Record the names of each crew member on the **Verification** form. At the launch site, document visual observations of a potential cyanobacterial bloom in the NLA App and photo document the bloom according to the reporting mechanism selected by the field crew (i.e., bloomWatch or state-specific reporting mechanism).

Regardless of whether the lake is sampled or not, the field crew must fill out and submit a **Verification** form for every lake that is visited with the intent to sample.

4.2.3 Locating Index Site

When determining lake origin, i.e., lake vs. reservoir in the field, a body of water that was a stream or river and subsequently dammed to create a lake is considered a reservoir. A lake which has had its level raised because of a dam is an “enhanced” lake and will be considered a natural lake for NLA 2022.

For natural lakes, go to the deepest point in the lake to locate the index site (or middle of the lake for reservoirs). If the deepest point exceeds 50 m in depth, do not establish the index site at this location; instead, choose a point as close to the middle of the lake as you can without exceeding 50 m in depth. The procedure below outlines sonar operation and procedures for finding the index site.

For reservoirs, the index site is located near the mid-point of the reservoir rather than at the deepest point, which may be near the dam. If this would result in an index site that is very shallow or otherwise non-representative of the reservoir as a whole, choose a point near the center of a main basin, where depths and the water column will be more representative of the reservoir.

Once in the general area, use the sonar unit to locate the deepest point (≤ 50 m). When an acceptable site is located, anchor the boat. Lower the anchor slowly to minimize disturbance to the water column and sediment. Determine the coordinates of the index site by GPS (if satellite coverage is available) and record on the **Index Samples** form. In addition, select if 3 or fewer or 4 or more satellites were used. If satellite coverage is not available at that time, try again before leaving the index site. The following is the procedure to be used to locate the index site:

1. Operate sonar unit according to manufacturer's specific operating procedures. If possible, depth readings should be made and recorded in metric units (be sure to specify units on the **Index Samples** form).
2. Use the sonar in the area expected to be the deepest. Spend no more than 30 minutes searching for the deepest point; the maximum depth for the index site is 50 meters.
3. Anchor the boat.
4. Determine the coordinates using GPS. Record GPS coordinates on the **Index Samples** form.

NMED Exhibit 36

4.3 Post Sampling Activities

Upon return to the launch site after sampling, review all labels and completed data forms for accuracy and completeness, and make a final inspection of samples. If information is missing from the forms or labels, the Field Crew Leader gathers and records the missing information. The Field Crew Leader selects the red circle at the top of each data form after review. Other post sampling activities include: sample filtering, inspection and cleaning of sampling equipment, inventory and sample preparation, sample shipment, and communications.

4.3.1 Equipment Cleanup and Check for Invasive Species

You must inspect all equipment, including nets, boat, and trailer, and clean off any plant and animal material. This effort ensures that introductions of invasive species such as Eurasian watermilfoil (*Myriophyllum spicatum*) quagga mussels (*Dreissena rostriformis* bugensis), and zebra mussels (*Dreissena polymorpha*) do not occur between lakes. Prior to leaving a lake, drain all bilge water or live wells in the boat. Inspect, clean, and handpick plant and animal remains from vehicle, boat, motor, and trailer that contact lake water. Inspect and remove any remnants of vegetation or animal life. Before moving to the next lake, if a commercial car wash facility is available, thoroughly clean vehicle, boat, and trailer (hot water pressurized rinse – no soap). Rinse equipment and boat with 1% bleach solution or other approved biological disinfectant to prevent spread of exotics. Procedures are below.

1. Clean for biological contaminants (e.g., Eurasian watermilfoil, zebra mussels, and alewife):
    a. Prior to departing from a lake, drain all bilge water from the boat.
    b. At the lake, inspect motors, boat, and the trailer for evidence of plant fragments, especially in or near the propeller and water intakes. Remove all plant fragments.
    c. At the lake or base site, dry out and inspect nets and buckets and remove any remnant vegetation or animal life. Disinfect gear with 1% bleach solution or other approved biological disinfectant.
    d. If a commercial car wash facility is available, thoroughly clean vehicle and boat (hot water pressurized rinse--no soap).
2. Clean and dry other equipment prior to storage:
    a. Rinse chlorophyll-*a* collection bottle three times with DI water after each use.
    b. Rinse graduated cylinders, integrated sampler, and other sampling devices three times with DI water after each use.
    c. Briefly soak zooplankton nets and fishing nets in a 1% bleach solution or other approved biological disinfectant and dry after each use. Do not dry in sunlight because the mesh is photosensitive.
    d. Rinse coolers with water to clean off any dirt or debris on the outside and inside.
    e. Rinse boots and waders with water to clean off any dirt, debris, or biological contaminants on the outside and inside.
3. Inventory equipment and supply needs and request supplies via the electronic **Request** form (forms or site kits) or from the FLC (other items or urgent requests).
4. Remove multi-parameter probe meter and GPS from carrying cases and set up for pre-departure checks and calibration. If present (i.e., not using optical DO sonde), examine the oxygen membranes for cracks, wrinkles, or bubbles. Replace if necessary.
5. Recharge/replace batteries as necessary.
6. Recheck field forms from the day's sampling activities. Make corrections and completions where possible, and initial each form after review.

NMED Exhibit 36

4.3.2 Shipment of Samples and Forms

You must ship or deliver time-sensitive samples (i.e., all chilled samples) to the appropriate analytical laboratories as soon as possible after collection and no later than the day after collection. These samples will be shipped in two groups for next day delivery. Other frozen and non-chilled samples may be shipped or delivered in batches provided they can be adequately stored. Report all sample shipments to the NARS IM Coordinator (by submitting the **Tracking** form in the NLA App) as soon as possible so that and they can be tracked if they do not arrive when expected.

Field crews are to fill out the pertinent section(s) of the **Tracking** for each sample shipment. In each section of the tracking form, the following information must be recorded:

- Package tracking number
- Date sample(s) were sent
- Sample type code:
  - ENTE – Fecal Indicator (*Enterococci*)
  - BENT – Benthic macroinvertebrates
  - CHEM – Water Chemistry
  - CHLX – Chlorophyll-*a*
  - FDNA – eDNA (index)
  - LDNA - eDNA (littoral)
  - MICZ – Algal toxin (microcystins and cylindrospermopsin)
  - PHYX – Phytoplankton
  - TRIA – Atrazine Pesticide Screen
  - ZOCN – Zooplankton coarse (150-micron mesh)
  - ZOFN – Zooplankton fine (50-micron mesh)
  - FTIS - Human health fish tissue sample
- Sample ID number from preprinted sample label
- Number of containers for each sample
- Any additional shipping comments

See APPENDIX B: SHIPPING GUIDELINES for further information.

4.3.3 Communications

After the Field Crew Leader has reviewed form content at the end of the sampling day, click the SUBMIT menu button and choose the form(s) that you wish to submit. After you have chosen which form to submit, click the green submit button at the bottom of the form list. An email will pop up on your device addressed to NARSFieldData@epa.gov. Copy yourself and any other crew members or managers and click send. To ensure that the email was sent, check the SENT mailbox on your email App and look for the recent email containing the data. If the email is not in the SENT mailbox, it was not sent and you should try again after verifying an internet connection.

NMED Exhibit 36

After each submission, a data summary email will be sent to the email address which submitted the data. This data summary contains a list of the data forms and their most recent submission date/time as well as a list of the most critical data points collected at the site. The Field Crew Leader should review this data summary to ensure that the data forms were successfully received and that critical values are present and correct.

At any point, if it is determined that data needs to be revised or updated, crews should feel free to do so in the App and re-submit any edited data forms using the steps above. Newly revised data will supersede previous data. It is not necessary to re-submit data forms that were unchanged.

Each field crew must submit the **Verification** form in the NLA App after each site visit (whether the site is sampled or not). General communications information, including contact information for the NARS IM Center, is outlined in Section 2.1.

If the field crew documented the potential occurrence of a cyanoHAB event at one or more station in the lake, the Field Crew leader is responsible for reporting the bloom to the appropriate state, tribal and/or watershed organization. See Section 2.2.4.5 for potential reporting mechanisms.

NMED Exhibit 36

5.0 INDEX SITE ACTIVITIES

Field crews will collect several different measurements and indicators at the index site (as described in Table 1-1): cyanoHABs assessment, a temperature, DO, and pH depth profile, secchi transparency, fish eDNA, chlorophyll-*a*, phytoplankton, algal toxins, water chemistry, atrazine, and zooplankton samples. A detailed description of the individual elements is provided below.

5.1 CyanoHABs Visual Assessment

When arriving at the index site, field crew views and documents visual observations of a potential cyanobacterial bloom in the NLA App and photo documents the bloom according to the reporting mechanism selected by the field crew (i.e., bloomWatch or state-specific reporting mechanism).

5.2 Temperature, DO, and pH profile

5.2.1 Summary of Method

Use a multi-parameter water quality meter (or sonde) to measure temperature, DO, and pH at predefined depth intervals. Measurement intervals for the profile are based on the site depth (see Section 5.2.3). Once the profile is completed, make another DO measurement at the surface and compare it to the initial reading to see if the probe is functioning correctly and holding calibration. If the lake is thermally stratified, note the top and bottom of the metalimnion based on the temperature readings (observed as a change of ≥1 °C per meter of depth).

The meters and probes are delicate; take care to avoid putting the probe into contact with sediments which could foul the probes. An accurate measure of the site depth will help prevent contact between the sediment and the probes.

5.2.2 Equipment and Supplies

Table 5-1 is the checklist for equipment and supplies required to conduct protocols described in this section.

Table 5-1 Equipment and supplies – temperature, pH, and DO profiles.

Type	Item	Quantity
Forms	NLA Profile Calibration NLA Index Profile	1 1
Collection: **Water column depth**	Depth Finder (hand-held or boat mounted sonar) Sounding line (50 m, calibrated, marked in 0.5 m intervals) with clip OR Sounding rod (calibrated) for very shallow lakes	1 1
Collection: **Profile measurements & calibration**	Multi-parameter water quality meter (with temperature, pH, and DO probes) Sounding line or 50-meter tape Sounding weight Squirt bottle (1 L Nalgene) – De-ionized (DI) Squirt bottle (1 L Nalgene) – lake water Calibration cups and standards QC check solution Barometer or elevation chart to use for calibration	1 1 1 1 1

NMED Exhibit 36

5.2.2.1 Multi-parameter Sonde

The multi-parameter sonde must be heavy enough to minimize sway and wobbling as it is lowered and raised in the water column. The instrument must be stabilized prior to taking a reading. Experiment with the sonde prior to sampling and add weight to the cable if needed.

5.2.2.2 Temperature Meter Calibration

Check the accuracy of the sensor against a thermometer (a non-mercury type is recommended) that is traceable to the National Institute of Standards and Technology (NIST) at least once per sampling season. The entire temperature range encountered in the NLA 2022 should be incorporated in the testing procedure and a record of test results kept on file.

5.2.2.3 DO Probe Calibration

Crews are to calibrate the DO probe at the lake prior to each sampling event. The probe calibration is to be completed in the field against an atmospheric standard (ambient air saturated with water, or water saturated with air for optical probes) prior to launching the boat. In addition, manufacturers typically recommend periodic comparisons with a DO chemical analysis procedure (e.g., Winkler titration) to check accuracy and linearity. Small "mini-Winkler" titration kits are suitable for this check and can be taken into the field.

5.2.2.4 pH Meter Calibration

Calibrate the pH electrode daily, prior to each sampling event in accordance with the manufacturer's instructions and your organization's existing SOP. Conduct a QC check with a different standard to verify the calibration and periodically evaluate instrument precision (see Section 2). Ideally, a quality control solution (QCS) should be used that is similar in ionic strength to the lake water samples you will be measuring. Standard buffer solutions used to calibrate electrodes may not be representative of typical lake waters.

5.2.2.5 Conductivity Calibration

A field conductivity measurement is optional for the NLA 2022. If the Field Crew opts to take conductivity measurements, the conductivity meter must be calibrated prior to each sampling event. Calibrate the meter in accordance with the manufacturer's instructions. Ensure that the conductivity meter is temperature corrected to 25 °C.

5.2.3 **Depth Profile Procedure**

Below are the step-by-step procedures for measuring temperature, pH, and DO profiles at the index site.

1. Calibrate Instrument
    a. Check meter and probes and calibrate according to manufacturer's specifications.
    b. Enter calibration information on the **Profile Calibration** form.
2. Record Site Conditions:
    a. Observe site conditions and fill out the "Site Conditions" portion of the **Index Samples** form. Conditions to be reported include:
        i. Precipitation ("None", "Light," or "Heavy")
        ii. Surface conditions ("Flat," "Ripples," "Choppy," or "Whitecaps")
    b. Presence or absence of odor or scum. If present, select "Yes" and describe the odor or scum.

NMED Exhibit 36

3. Determine Site Depth:
    a. Accurately measure the depth using a sounding line with a weight or other means and record on the **Index Samples** form.
    b. Indicate method used.
4. Determine Measurement Intervals:
    a. The number of readings and the depth intervals taken depends on the site depth. Below is a list of rules for determining the intervals:
        i. The profile will always begin with a measurement just below the surface (e.g., approximately 10 cm or the minimum depth required to keep all probes submerged).
        ii. The last (deepest) measurements will always be at 0.5 m above the bottom.
        iii. If the site is < 3.0 m deep, record measurements beginning just below the surface and at 0.5 m intervals, until 0.5 m above the bottom.
        iv. If the depth is between 3.0-20 m (inclusive), record measurements beginning just below the surface and then at 1.0 m intervals until reaching 0.5 m above the bottom.
        v. If the depth exceeds 20 m, record measurements beginning just below the surface, then at 1.0 m intervals until you reach 20 m, then at 2.0 m intervals until 0.5 m above the bottom.
        vi. If the metalimnion is encountered (observed as a change of ≥1 °C per meter of depth), take measurements at least every meter within the metalimnion.
5. Measure Temperature, DO, and pH:
    a. Lower the sonde in the water and measure the vertical profile of temperature, DO and pH at the predetermined depth intervals. Be careful not to let the probe touch the bottom.
    b. Record the intervals and measurements on the **Profile Data** form.
    c. Use the provided comment bubble to provide extra information about any measurements that the crew feels needs further comment or when a measurement cannot be made.
6. Duplicate Surface DO Measurement
    a. When the profile is completed, take another DO measurement at the surface, record it, and compare it to the initial surface DO reading.
    b. Mark ‘Yes’ or ‘No’ on the form if the second DO reading is within 0.5 mg/L of the initial surface reading. This provides information regarding measurement precision and possible calibration drift during the profile.
        i. If measurement is not within 0.5 mg/L, verify your calibration.
        ii. If DO is found to be out of calibration, re-calibrate and re-record DO measurements.
7. Determine the Metalimnion:
    a. If the lake is thermally stratified, note the top and bottom of the metalimnion in the Metalimnion column.
    b. For standardization purposes, the metalimnion has been defined in the protocol as an area where water temperature changes at least 1 degree Celsius per meter.
    c. If you suspect that the metalimnion exists but does not change at the specified rate, estimate the top and bottom of the metalimnion to the best of your ability, use the provided comment bubble to flag the data, and explain.
    d. In deep sites where measurement intervals are 2.0 meters apart, decrease the interval

NMED Exhibit 36

to 1.0 meters while taking measurements within the metalimnion.

5.3 Secchi Disk Transparency

5.3.1 Summary of Method

A Secchi disk is a black and white patterned disk used to measure a lake's clarity (see Figure 5-1). Take the reading on the shady side of the boat, without sunglasses, hat, or other viewing aids. Record the depths where the disk disappears when descending and reappears when retrieving.

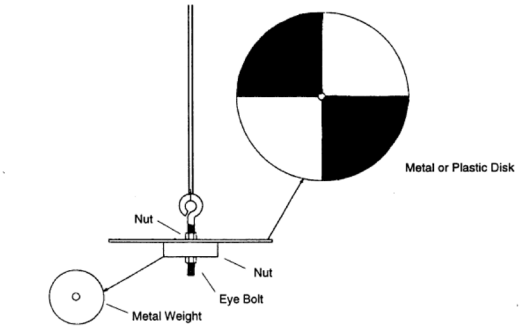

Figure 5-1 Secchi disk diagram (USEPA, 1991).

5.3.2 Equipment and Supplies

Table 5-2 is the checklist for equipment and supplies required to conduct protocols described in this section.

Table 5-2 Equipment and supplies – Secchi disk transparency.

Type	Item	Quantity
Form	NLA Index Samples	1
Collection	Metric tape measure Secchi Disk (20 cm diameter) Sounding line (50 m, calibrated, marked in 0.5 m intervals) with clip	1 1 1

5.3.3 Procedure for Determining Secchi Transparency

Because different people measuring Secchi transparency at the same site may obtain different results (due to differences in vision and interpreting disk disappearance and reappearance), it is recommended that one crew member conduct Secchi disk measurements at all lakes.

If the lake is shallow and the water clear, the Secchi disk might reach the bottom and still be visible. If this is the case, it is important to not stir up the bottom sediments while anchoring the boat. Move the boat away from the anchor before taking the reading. If the disk is visible at the bottom of the lake, indicate this by filling in the "clear to bottom" check box on the **Index Samples** form and record the water depth in both the disappearance and reappearance fields.

States that wish to take additional measurements for comparisons using a view scope are encouraged to do so after completing the Secchi disk measurements are completed following the NLA protocols.

The following procedure is to be followed when collecting NLA Secchi disk measurements:

1. Confirm that the lowering line is firmly attached to the Secchi disk.
2. Remove sunglasses and hat. Also, do not use view scopes or other visual aids. If wearing prescription sunglasses, temporarily replace them with regular clear lens prescription glasses.
3. Lower the Secchi disk over the shaded side of the boat until it disappears.
4. Read the depth indicated on the lowering line. If the disappearance depth is <1.0 meter, determine the depth to the nearest 0.05 meter by marking the line at the nearest depth marker and measuring the remaining length with a tape measure or meter stick. Otherwise, record the disappearance depth to the nearest 0.1 meter. Record the disappearance depth on the **Index Samples** form.
5. Lower the disk a bit farther and then slowly raise the disk until it reappears and record the reappearance depth, using the same level of precision as before.
6. Calculate the euphotic zone depth by multiplying the depth where the Secchi disk reappears by two. Use this calculation to determine the depth at which water samples will be taken with the integrated water sampler:
    - 6.1 If euphotic zone is less than 2 meters, water samples will be collected only within the euphotic zone.
    - 6.2 If euphotic zone is greater than 2 meters, water samples will be taken from the top 2 meters of the water column.
    - 6.3 If the Secchi is clear to the bottom and the lake is less than 2.5 m deep, water samples will be collected 0.5 m from the depth at the index site.
7. Record the depth that will be targeted for the integrated water samples.
8. Note any conditions that might affect the accuracy of the measurement in the comments field.

5.4 eDNA Sample Collection - Index

5.4.1 Summary of Method

Collect water samples for eDNA with a grab sample collected at the water surface from the boat.

5.4.2 Equipment and Supplies

Table 5-3 provides the equipment and supplies needed for field operations to collect fish eDNA samples at the index site.

NMED Exhibit 36

Table 5-3 Equipment and supplies - index eDNA samples.

Type	Item	Quantity
Form	NLA Index Samples	1
Documentation	Label: FDNA - Index Clear tape strips (to cover sample labels)	1 As needed
Collection	Index eDNA bottle (1 L clear, square) Gloves (latex/nitrile, non-powdered)	1 1 pair
Storing and preserving	Wet ice Cooler Plastic electrical tape	As needed 1 As needed

5.4.3 Sampling Procedure

While anchored at the index site, collect a grab sample from the water surface using the 1 liter index eDNA bottle.

1. Make sure all necessary data has been written on the sample label, the label is placed on the outside of the bottle, and the label is completely covered with clear tape.
2. Put on surgical gloves (non-powdered). Do not handle any food, drink, sunscreen, or insect repellant until after the water samples have been collected, or implement measures to reduce contamination by such chemicals, if applied, such as washing, wearing long gloves, etc.
3. Remove the cap from the bottle.
4. Do not rinse the bottle and avoid touching the inside of the bottle or the inside of the cap.
5. Dip the sample container into the surface water (do not fully submerge mouth of bottle). At the surface of the water, angle the mouth of the sample container away from the boat. Collect any surface scums, if present, at the site.
6. Fill the 1 L bottle to the 1000 mL mark, leaving headspace for air. This headspace is important since the sample will be frozen.
7. If the bottle is filled above the 1000 mL mark, discard excess water.
8. Carefully replace the cap. Seal the cap with plastic electrical tape.
9. Immediately after sample is collected, place in a cooler with ice to minimize exposure to light and begin chilling the sample.
10. Upon return to the vehicle or a base location, freeze the sample. The sample will be sent frozen with dry ice.

5.5 Water Sample Collection and Preservation

5.5.1 Summary of Method

Collect water samples using an “integrated sampler”, which is based on a design by the Minnesota Pollution Control Agency (MPCA) (see

Figure 5-2). The device is a PVC tube 6.6 feet (2 meters) long with an inside diameter of 1.24 inches (3.2 centimeters) fitted with a stopper plug on one end and a valve on the other. The device allows collection

NMED Exhibit 36

of water from the upper two meters of the water column (e.g., within the euphotic zone). If the euphotic zone is < 2.0 m deep (as calculated in the Secchi Disk Transparency section of the form), lower the integrated sampler only to the depth of the euphotic zone, and take additional grab samples as necessary to collect the total volume needed for the samples.

5.5.2 Equipment and Supplies

Table 5-4 provides the equipment and supplies needed to collect water samples at the index site.

Table 5-4 Equipment and supplies – water samples.

Type	Item	Quantity
Form	NLA Index Samples	1
Documentation	Labels: water chemistry, algal toxins, phytoplankton, atrazine, and chlorophyll-*a*	1 per sample
	Clear tape strips (to cover sample labels)	As needed
Collection	Integrated sampler device (MPCA design)	1
	Funnel	1
	Gloves (latex/nitrile, non-powdered)	1
Storing & Preservation	Cubitainer® (4L) – water chemistry	1
	HDPE bottle (60 mL, white, wide-mouth) – atrazine	1
	HDPE bottle (500 mL, white, round) – algal toxins (MICZ)	1
	HDPE bottle (1 L, white, narrow-mouth) – phytoplankton	1
	Poly bottle (2 L, brown) – chlorophyll-*a*	1
	Wet ice	As needed
	Lugol's solution (250 mL bottle)	5-10 mL
	Cooler	1
	Plastic electrical tape	As needed

NMED Exhibit 36

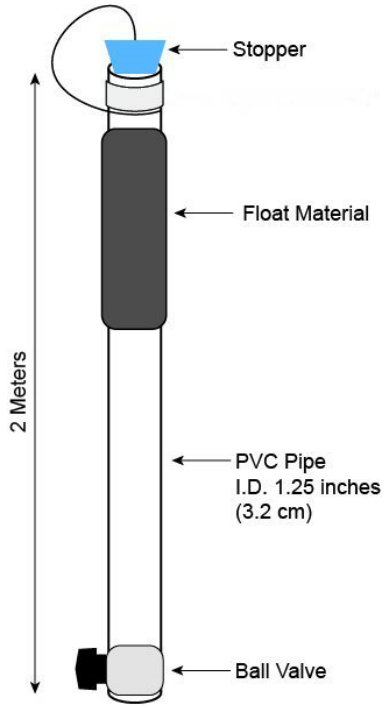

Figure 5-2 Integrated water sampler device (MPCA).

5.5.3 Sampling Procedure

Assuming the euphotic zone is ≥ 2 meters and the depth of the lakes is greater than 2.5 m, collect four integrated water samples (Figure 5-3). Sample #1 is emptied into a 2 L sample bottle for ***chlorophyll-a*** filtering. Sample #2 is to be transferred from the sampler to the 4 L Cubitainer®, mixed thoroughly, and, poured off into one 1 L sample bottle for ***phytoplankton*** processing, one 500 mL bottle for the ***algal toxins*** samples, and one 60 mL bottle for the ***atrazine*** pesticide sample. Samples #3 and #4 are to be transferred from the sampler to the 4 L Cubitainer® for the ***water chemistry*** sample. If the euphotic zone is <2 meters, only collect water from the euphotic zone and increase the number of grab samples accordingly. Additionally, if the secchi is clear to the bottom and the lake is less than 2.5 m deep, water samples will be collected 0.5 m from the depth at the index site.

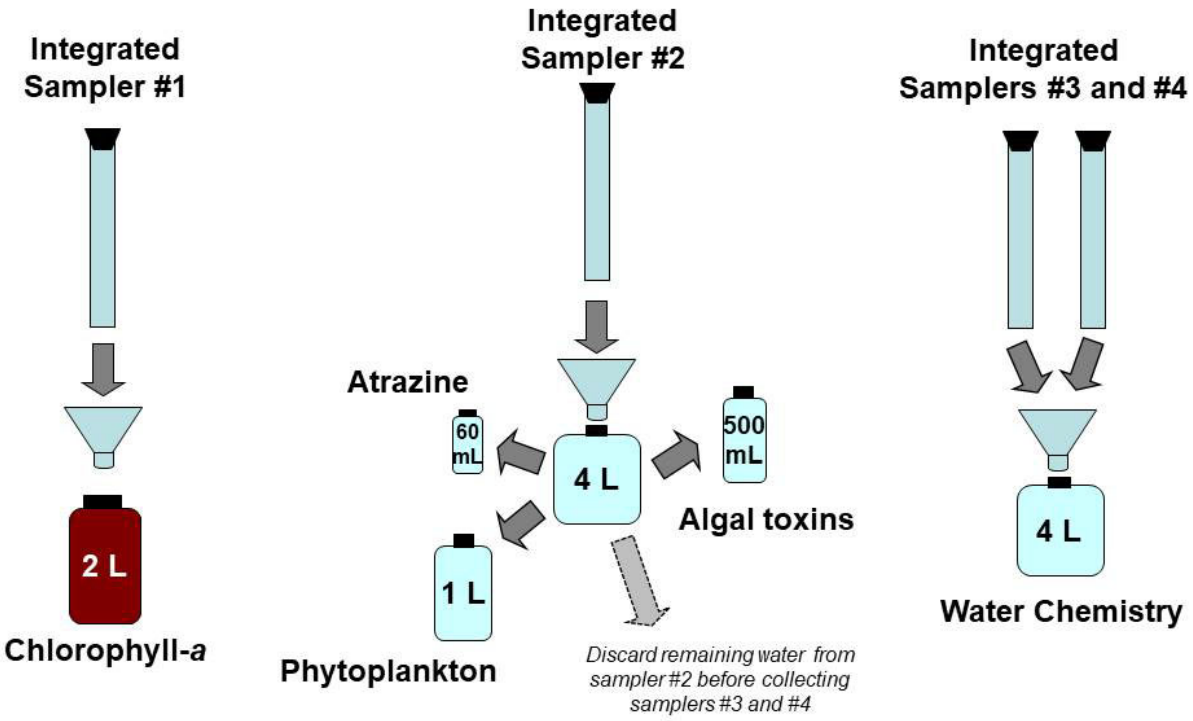

Figure 5-3 Procedure for using the integrated sampler device to collect depth integrated samples.

5.5.3.1 Sample Collection

1. Make sure all necessary data has been written on the sample labels and labels are completely covered with clear tape.
2. Put on surgical gloves (non-powdered). Do not handle any food, drink, sunscreen, or insect repellant until after samples have been collected, or implement measures to reduce contamination by such chemicals, if applied, such as washing, wearing long gloves, etc.
3. Rinse each water sample collection container and lid with surface water three times.
4. Remove the rubber stopper cap and open the valve on the bottom end of the integrated sampler. Rinse by submerging it three times in the lake and draining after each rinse. Complete rinsing on the opposite side of the boat from which you plan to sample. Do not take samples near the motor or other sources of contamination.
5. Slowly lower the sampler into the lake as vertically as possible. For a 2 m sample, stop lowering the device when the upper end is just above the surface. If the euphotic zone is < 2.0 m deep (as calculated in the Secchi Disk Transparency section of the form), the integrated sampler will be lowered only to the depth of the euphotic zone; additional

NMED Exhibit 36

samples will be taken to collect the volume needed for the samples (8 L total). In clear shallow lakes, samples will be collected 0.5 m from the depth at the index site.

6. Cap the upper end with the rubber stopper firmly and slowly raise the sampler.
7. When the bottom of the sampler is near the surface, reach underwater and close the valve on the bottom end.
8. Lift the sampler into the boat, keeping it as vertical as possible. When possible, move the containers to a shaded area of the boat to avoid exposing the sample to direct sunlight when dispensed.
9. Carefully open the valve and dispense the contents of sample #1 (or more, as necessary to fill bottle**) into the 2 L brown bottle. This is the chlorophyll-*a* sample, which will be filtered on shore (see Section 8.2). Place the bottle on ice until filtration can be initiated.

   ***if the last sample pull does not completely fit in the container, homogenize the sample in the integrated tube prior to dispensing*
10. Repeat the collection process in steps 5-8 and dispense the contents of sample #2 (or more, as necessary) into the 4 L Cubitainer® and mix well.
11. Fill the 1 L phytoplankton bottle from the 4 L Cubitainer®, allowing enough headspace to add at least 5 mL of Lugol's preservative.
12. Fill the 500 mL bottle from the 4 L Cubitainer®, leaving headspace so that the bottle doesn't burst when frozen. This is the algal toxin sample. Seal the cap with plastic electrical tape. Place the bottle in the cooler with ice.
13. Fill the 60 mL bottle from the 4 L Cubitainer® to just below the shoulder, leaving headspace so that the bottle does not burst when frozen. This is the atrazine sample. Seal the cap with plastic electrical tape. Place the bottle in the cooler with ice.
14. Discard the residual water in the Cubitainer®.
15. Pour the contents of sample #3 and sample #4 (or more, as necessary) from the integrated sampler into the 4 L Cubitainer®, removing as much air from the Cubitainer® as possible. This is the water chemistry sample. Seal the cap with plastic electrical tape. Place the Cubitainer® in the cooler with ice.

5.5.3.2 Sample Preservation

1. All samples are to be kept in a cooler on wet ice until preservation as needed.
2. For the phytoplankton sample, add 5 mL of Lugol's solution to the 1 L phytoplankton bottle. (Fill the provided plastic transfer pipette up to the bulb with Lugol's three times to get 5 mL). Cap the bottle and invert until well mixed. The sample should resemble the color of weak tea. If needed, add additional Lugol's 2-3 mL at a time up to a maximum of 10 mL. Seal the cap with plastic electrical tape.
3. Upon return to a base location with a freezer or portable freezer, freeze the algal toxin and eDNA samples. These samples will be sent frozen with dry ice.

NMED Exhibit 36

5.6 Zooplankton Collection

5.6.1 Summary of Method

Collect two vertical samples using a fine mesh (50 µm) and coarse mesh (150 µm) Wisconsin nets with collection bucket attached at the cod end. Each net is slowly lowered over the side of the boat into the water. The net is retrieved back to the surface at a slow, steady rate. Lift the net out of the water; rinse it from the outside to free organisms from the side of the net and to concentrate them in the collection bucket. Narcotize the organisms with an effervescent sodium bicarbonate tablet (e.g., Alka-Seltzer® tablet). Transfer the sample from the collection bucket to a 125 mL sample container and preserve each sample with 95% ethanol. You will repeat the procedure with the other net on the opposite side (or end) of the boat. The cumulative tow length for each net is 5 m. In shallow lakes, multiple tows with each net are required to achieve the cumulative tow length. The objective is to sample a sufficient volume of water to obtain at least 300 organisms per sample from all but the most oligotrophic lakes.

5.6.2 Equipment and Supplies

Table 5-5 provides the equipment and supplies needed to collect a zooplankton sample. Figure 5-4 is an illustration of the zooplankton nets and collection buckets.

Table 5-5 Equipment and supplies – zooplankton collection.

Type	Item	Quantity
Form	NLA Index Samples	1
Documentation	Labels: zooplankton course and zooplankton fine	1 per sample
	Clear tape strips (to cover sample labels)	As needed
Collection	Plankton net fine (50 µm) and collection bucket	1
	Plankton net course (150 µm) and collection bucket	1
	Sounding line (50 m, calibrated, marked in 0.5 m intervals) with clip	1
	Funnel	1
	Squirt bottle (1 L Nalgene) – de-ionized (DI)	1
	Squirt bottle (1 L Nalgene) – lake water	1
	Effervescent sodium bicarbonate (Alka seltzer) tablets	1
	Pail (narcotization and concentration chambers)	1
		2
Storing & Preservation	HDPE bottle (125 mL, white, wide-mouth)	2
	Ethanol (95%)	1
	Plastic electrical tape	As needed

NMED Exhibit 36

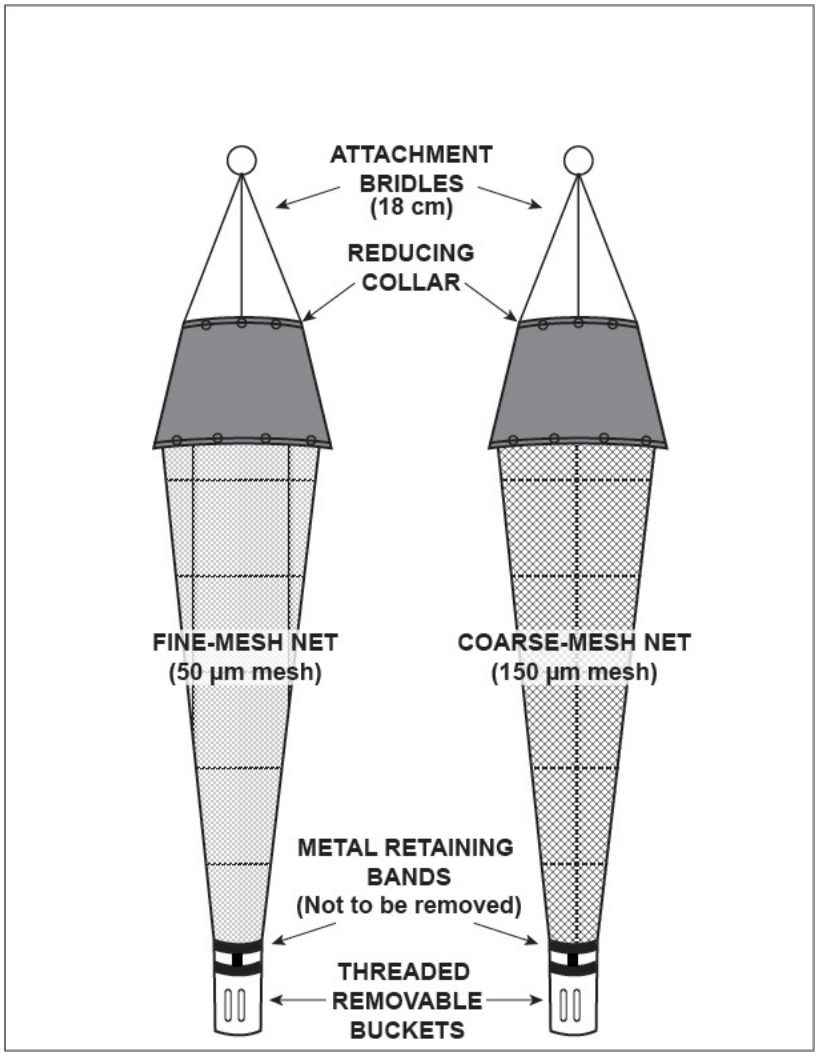

Figure 5-4 Wisconsin net and collection bucket diagram.

5.6.3 Sampling Procedure

The procedures for collecting and processing zooplankton samples are presented below.

5.6.3.1 Sample Collection

1. Determine and record the number of tows required to achieve the standard cumulative 5 m tow on the **Index Samples** form.
    a. For lakes deeper than 7 m, you will take a single 5 m tow with each net.
    b. For lakes with a depth less than 7 m, you will determine and record the number of tows that will be required to achieve a standard cumulative 5 m tow for each net (Table 5-6). For example, if the lake is 6 meters deep, you will take two 2.5 m tows with each net. All lakes less than 7 m deep require at least two tows because the collection bucket should never touch the sediment due to potential fouling.

NMED Exhibit 36

Table 5-6 Lengths and numbers of zooplankton tows based on Index Site depth

Depth of lake (m)	Length of Tow	Number of Tows
7 or more	5 m	1
4 to <7	2.5 m	2
2 to <4	1 m	5
less than 2	0.5 m	10

c. The zooplankton collection methods vary slightly depending on the number of tows required to achieve a standard cumulative 5 m tow.
    i. If the number of tows = 1: follow steps 2 through 13 described below.
    ii. If the number of tows ≥ 2, follow steps 2 through 12 described below. After step 12, pour the contents of the collection bucket into a clean (i.e., DI rinsed) 1-gallon pail. Rinse the collection bucket with DI. While taking care not to tip the zooplankton sample in the pail, repeat steps 2 through 12 for the second tow. Add the contents of the collection bucket from the second tow to the pail. Continue to take zooplankton tows and add samples from the collection bucket into the pail until the target number of tows (2, 5, or 10) is reached. On the last tow, pour the contents of the pail into the collection bucket to filter the excess water. Rinse the bucket with DI water and pour the contents of this rinse into the collection bucket with the zooplankton sample. Once the zooplankton sample has been filtered down to an appropriate volume in the collection bucket, continue on to step 13.

2. Prior to each use, carefully clean and thoroughly rinse the interior of the plankton nets and buckets with DI water.
3. Carefully inspect the nets and buckets for holes or tears.
4. Attach the collection buckets to the “cod” end of the nets and secure. Make sure the correct bucket is attached to the correct net (i.e., the mesh sizes match).
5. Attach the bridled end of the plankton net to a 0.25” calibrated line with markings every 0.5 m (use the same line as was used with the Secchi disk).
6. Carefully and slowly lower the first net in a constant upright position over the side of the boat.
7. Continue lowering the net to the correct depth (remember to account for the length of the bridle). If more than one tow is needed, be sure to take additional tows from different locations around the boat.
8. Retrieve the net by pulling back to the surface at a steady rate (0.3 m or 1 ft/s) without stopping.
9. Once at the surface, slowly dip the net up and down in the water without submersing the net mouth to rinse contents into the collection bucket.
10. Complete the rinsing of the net contents by spraying lake water against the outside of the net with a squirt bottle or similar tool. Be careful not to splash or squirt lake water into the net mouth, or additional organisms may be collected.
11. If additional rinsing is needed on the interior of the net, use a squirt bottle with DI water only to avoid introducing additional organisms.

NMED Exhibit 36

12. Once all organisms have been rinsed into the collection bucket, hold the collection bucket in a vertical position, and carefully remove the bucket from the net.
13. Repeat steps 5-12 with the second net on the opposite side (or end) of the boat.

5.6.3.2 Sample Processing

1. Set the collection buckets in a pail filled half full of lake water to which 2 CO_2 (e.g., Alka-Seltzer) tablets have been added outside of the collection buckets. Wait 30 to 60 seconds for the CO_2 tablets to dissolve before placing the collection buckets into the water. Ensure that the organisms in the collection buckets are submerged in the water, but be careful not to submerge the top of the collection buckets, or sample loss will occur. The CO_2 narcotizes the zooplankton to relax their external structure prior to preservation in 95% ethanol. This facilitates taxonomic identification. Wait until zooplankton movement has stopped (usually about one minute). Raising and lowering the collection buckets in the pail can help water exchange within the bucket.
2. Check the sample label on the bottle to verify which sample has been collected (coarse or fine mesh).
3. Use small volumes of DI water from a squirt bottle to rinse the contents of the mesh net collection bucket into the 125 mL polyethylene bottle. Rinse the collection bucket with DI water three to four times or until the majority of zooplankton have been removed without allowing the bottle to fill more than half full (~60-70 mL of sample and rinse water combined). After the zooplankton have been transferred and the sample bottle is half full with sample and rinsate, fill the bottle to the shoulder with 95% ethanol. Use a funnel, if necessary, when transferring the sample, rinsate or ethanol to the 125 mL sample bottle
4. In some cases, the volume of zooplankton collected in the collection bucket may exceed 125 mL. Under this scenario do not try to force the entire sample into a single bottle, or the preservative will not function properly and the sample may be lost. In such cases, fill the first bottle half full, and then use a second bottle to preserve the additional amount of sample. Use an “extra jar” label (i.e., one with no sample ID pre-printed on it) for identification purposes. Complete the label and print in the sample number assigned to the first container on the label of the second container. On the form, record a “2” in the “No. Jars” field.
5. On the **Index Samples** form, fill in the bubble to indicate that the sample is preserved.
6. Verify that all information on the labels and the form is complete and correctly recorded.
7. Repeat steps 2-6 for the second sample collected.

6.0 LITTORAL AND SHORELINE ACTIVITIES

To better understand near-shore habitats and their condition, travel to 10 evenly spaced physical habitat (PHab) stations around the lake and document conditions and characteristics observed within defined plot areas. The full set of measurements, observations, and sampling described in this chapter includes:

- water sample for eDNA analyses at each of the 10 stations;
- measures or observations of physical habitat cover and structure in the littoral, shoreline, draw-down, and riparian zone plots at the 10 PHab stations;
- visual assessment of a cyanobacterial bloom;
- sampling of benthic macroinvertebrates at each of the 10 stations; and
- water sample for Enterococci at the last station sampled (for lakes 10,000 ha or less) or boat launch (for lakes >10,000 ha).

For lakes with a surface area of greater than 10,000 ha (defined as large lakes), crews are **not** required to travel to the 10 PHab stations to make physical habitat measurements and collect benthic macroinvertebrate samples. The requirement was waived on large lakes because of the increased level of effort required to travel around the shorelines of these large lakes. Nevertheless, we encourage crews to complete the physical habitat characterizations and macroinvertebrate collections on large lakes, just as they are done on smaller lakes, so that large lake physical habitat information can be included in the national assessment.

Note: When large islands are present, more than 10 PHab sites will be identified and assessed for a lake.

6.1 Littoral eDNA Sample Collection

6.1.1 Summary of Method

Collect a grab sample for eDNA at each of the 10 shoreline PHab stations. Grab samples are collected at the water surface from the boat and added to a single 1L littoral composite sample. If more than 10 PHab stations are identified for the lake, littoral eDNA samples will only be collected from the 10 standard PHab stations around the perimeter of the lake. For “large lakes” (greater than 10,000 ha) the entire 1L sample is to be collected from the launch site at the end of the day with the enterococci sample.

NMED Exhibit 36

6.1.2 Equipment and Supplies

Table 6-1 provides the equipment and supplies needed for field operations to collect the littoral eDNA sample.

Table 6-1. Equipment and supplies – fish littoral eDNA samples.

Type	Item	Quantity
Form	NLA Littoral Samples	1
Documentation	Label: LDNA - littoral Clear tape strips (to cover sample labels)	1 As needed
Collection	Littoral eDNA bottle (1 L clear, square) Littoral eDNA collection bottle (125 mL clear, square) Gloves (latex/nitrile, non-powdered)	1 1 1-2 pairs
Storing and preserving	Wet ice Cooler Plastic electrical tape	As needed 1 As needed

6.1.3 Sampling Procedure

When arriving at the PHab station, prior to the collection of PHab and benthic macroinvertebrate sample , collect a 100 mL littoral eDNA sub-sample from an undisturbed area in the littoral plot. Sub-samples from all stations are added to the 1 L littoral eDNA composite bottle.

1. At the first PHab station, make sure all necessary data has been written on the littoral eDNA label, the label is placed on the outside of the 1L littoral eDNA bottle, and the label is completely covered with clear tape. Samples from 10 physical habitat stations will be added to this bottle.
2. Put on surgical gloves (non-powdered). Do not handle any food, drink, sunscreen, or insect repellant until after the water samples have been collected, or implement measures to reduce contamination by such chemicals, if applied, such as washing, wearing long gloves, etc.
3. Identify an area in or near the littoral plot that is about 1 m deep (~waist deep) to collect the sample. Avoid sampling shallower water and water at the shoreline due to potential sediment contamination. If the entire littoral plot is less than 1 m deep, you may collect the sample outside the littoral plot (e.g., as you are approaching the plot from a location that is about 1 m deep).
4. Remove the cap from the 125 mL collection bottle. Avoid touching the inside of the bottle or the inside of the cap.
6. Dip the sample container into the surface water (do not fully submerge mouth of bottle) in an undisturbed area of the lake. At the surface of the water, angle the mouth of the sample container away from the boat or body and fill the collection bottle to the 100 mL mark. Collect any surface scums, if present, at the site. If more than 100 mL is collected, pour off excess.Remove the cap from the 1L composite bottle. Do not rinse this bottle and avoid touching the inside of the bottle or the inside of the cap.

NMED Exhibit 36

7. Add the 100 mL sample to the 1 L composite bottle. Cap both bottles and place both bottles in a cooler with wet ice while transporting to the next station to minimize exposure to light and begin chilling the sample.
8. REPEAT steps 2-6 at the next PHab station, up to a total of ten stations (1L sample total).
9. At the last (10th) PHab station, ensure the sample does not exceed the 1000 mL mark, leaving headspace for air. This headspace is important since the sample will be frozen. If the bottle is filled above the 1000 mL mark, cap the bottle, gently mix 3 times, and discard excess water down to the 1000 mL mark.
10. Carefully replace the cap. Seal the cap with plastic electrical tape.
11. Immediately place the 1L bottle in a cooler with ice and keep the sample chilled throughout the sampling day.
12. Discard the 125 mL collection bottle after collecting all 10 subsamples. A new collection bottle will be sent in each site kit.
13. Upon return to the vehicle or a base location, freeze the sample. The sample will be sent frozen with dry ice.

**At large lakes (lakes over 10,000 hectares) when littoral sampling is not conducted, the entire 1L littoral eDNA sample will be collected at the launch site with the enterococci sample.

6.2 Physical Habitat Characterization

6.2.1 Summary of Method

Prior to the sampling visit, determine the approximate locations of the 10 PHab stations and mark them on a Site Map (see Chapter 3), if applicable. Figure 3-2 shows example placement and distribution of PHab stations around a lake. At each of the 10 PHab stations, you will set up a plot as shown in Figure 6-1 based on visually estimated dimensions. The plot measures 15 m wide and includes: a littoral plot extending 10 m out from the shoreline; a drawdown zone plot extending inland from the shoreline to the normal high-water level; a 1 m shoreline zone band at the shore just above the present water line; and a 15 m wide riparian plot that begins at the normal high water mark and extends 15 m landward. The drawdown zone plot extends a variable distance inland depending on the degree of drawdown and, if the distance from the present shoreline to the normal high water mark is negligible (i.e., <1m), there will be no drawdown zone plot.

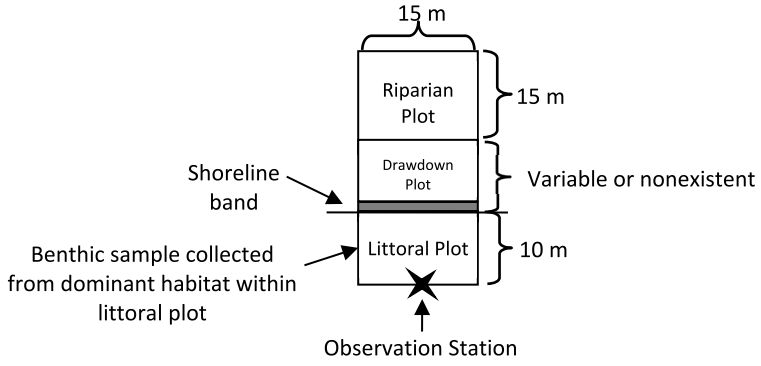

Figure 6-1 Dimensions and layout of a physical habitat station.

NMED Exhibit 36

As described below, you will record observations from each of the zones on the **Physical Habitat** form.

6.2.2 Equipment and Supplies

Table 6-2 lists the equipment and supplies needed to locate the PHab stations and conduct the physical habitat characterization.

Table 6-2 Equipment and supplies – physical habitat assessment.

Type	Item	Quantity
Forms	NLA Verification	1
	NLA Physical Habitat	10-12
Collection	Depth Sounder (hand-held or boat mounted sonar)	1
	Sounding rod (3 m, marked in 0.1 m increments, calibrated, PVC)	1
	GPS unit (with manual, reference card, extra battery)	1
	Rangefinder (for estimating horizontal drawdown)	1 (optional)
	Clinometer (for use as a level to measure vertical drawdown)	1 (optional)
	Surveyors rod (for measuring vertical drawdown)	1 (optional)
	50-meter tape (measurements as needed)	1
	Binoculars (for making observations of distant riparian)	1
	Map wheel or string (for measuring shoreline distances on site map)	1
	Anchor (with 75 m line or sufficient to anchor in 50 m depth)	1
	Buoy (for marking observation point)	1

6.2.3 Locating the Physical Habitat Stations and Defining the Shoreline Boundary

6.2.3.1 Base Site Activities

It is important that you set up PHab stations in the office to minimize bias in site selection and to ensure efficient location of stations once at the lake.

1. Using a lake map, select a random starting point on the lake outline. Any reasonable method may be used select the starting point (e.g., toss a pencil randomly on the map, letting the sharp end point to the nearest shoreline location). This random starting point is your “A” station.
2. It is important that the remaining nine stations be located at equal distances around the lake (see Figure 3-2). These will be your “B” through “J” stations. Field crews can do this manually (by either using a string to trace the perimeter of the lake, which can then be straightened and marked in equal intervals, or by using a map wheel) or electronically (with GIS or other digital mapping tools) to measure the perimeter of the lake and divide by 10.
3. Using a GIS or other digital mapping tool application to locate the coordinates of the 10 stations that can then be entered as GPS waypoints greatly facilitates correctly locating PHab stations by boat in the field, especially on large lakes.
4. Mark the physical habitat stations on a site map, if applicable.

Note: In revisit lakes (see Section 9.1 for more information), crews will re-randomize and relocate the PHab stations. The stations are re-randomized because the revisit data is used to examine variability of the entire lake assessment.

NMED Exhibit 36

6.2.3.2 Littoral and Shoreline Activities

Using the site maps and GPS, proceed by boat around the lake, locate, and stop at each of the 10 PHab stations. Position the boat at a distance of 10 m from shore, anchor if necessary, and make the measurements and semi-quantitative observations specified on the **Physical Habitat** form in the NLA App. Complete a separate **Physical Habitat** form for each station (see tabs A-L at the top of the form).

Make every reasonable attempt to record physical habitat observations and measurements for all 10 PHab stations. Where physical habitat observation and measurements are impossible, record comments as specified in Table 3-1.

6.2.3.3 Shoreline and Station Location Adjustments

Once in the field, you may encounter situations that require you to modify the shoreline and/or station location(s) from the intended locations marked on the site map. If this occurs, make the corrections and adjustments on the **Physical Habitat** form and note the reasons in the comments section of the form. The general guidelines for locating or modifying the location of the littoral and shoreline stations are summarized below.

1. Locate station using maps, aerial photos, or GPS units.
2. Define shore as either the current waterline OR the boundary between open water and the edge of dense vegetation (terrestrial, wetland, or emergent vegetation) or extensive very shallow water (shoreline defined by limit for navigating your boat).
3. If the shoreline observed in the field differs from the mapped shoreline, mark “Station Relocated” and enter a comment on the **Physical Habitat** form stating the apparent reason (e.g., drought, lake drawdown, flooding, dredging, limited boat access, etc.).
4. If a PHab station is inaccessible because of shoreline changes, mark “Station Relocated” at the top of the **Physical Habitat** form, and position one or more new stations at approximately equal intervals.
5. If a station is eliminated, select the check box at the top of the form.
6. If the shoreline observed in the field differs radically from the site map and you are sure you are at the correct lake, you can sketch a map of the lake. Use a string to measure the new outline, divide it into 10 equal parts, and lay out the 10 station locations.

6.2.3.3.1 Islands

Islands may be an additional source of shoreline habitat on a lake and those will be accounted for by adding island physical habitat stations. Island stations are in addition to the 10 stations (A-J). The guidelines for adding island stations follow:

- If the combined shoreline of all islands make up 10-20% of the lake’s total shoreline, add one PHab station (stations will now be labeled A through K)
- If the combined shoreline of all islands make up more than 20% of the lake’s total shoreline, add two PHab stations (stations will now be labeled stations A through L)
- Island stations are designated by marking the “Is it an island?” bubble on the form, by a new station letter (K or L), and by marking the island location and station on a site map.

Island stations, i.e., K and L, should be selected at random (e.g., toss a pencil randomly on a map, letting the sharp end point to the nearest island location, if needed, repeat to identify station L).

NMED Exhibit 36

6.2.3.3.2 Ambiguous Shorelines

The shoreline is defined as the interface between "lake-like" conditions and riparian or wetland conditions. In most cases, the shoreline will be easily identified as the current waterline. In some instances, however, the shoreline might not be obvious. Listed below are some general situations and rules that should be applied to ambiguous shorelines.

- If there has been a significant drop in lake level due to drought, purposeful drawdown, dam repair, or other reasons, shallow areas may be exposed that are usually covered with water. In this case, consider the current waterline as shoreline for the purposes of this survey, not the normal waterline.
- If there are extensive very shallow areas or shoals, consider the shoreline to be the boundary between the shallow area and deeper open water, as defined by ease of access by a small sampling boat.
- If access to the true shoreline is prevented by an area of dense aquatic or terrestrial vegetation, consider the shoreline to be the boundary between the vegetation and deeper open water. Again, define the operational shoreline by ease of access by a small sampling boat. This may result in a riparian zone that can be more of a wetland than an upland vegetation plot.
- If a river or stream enters a lake, the shoreline begins where no flow is visible.
- If there is flooding, try to find the position of the normal high water mark. The normal high water mark may be evident by the extent of flooded trees or other terrestrial vegetation.

6.2.3.3.3 Actual shoreline is different than appears on the map

The goal of the physical habitat survey is to characterize the lakeshore based on observations of conditions at 10 evenly spaced PHab stations around the lake. Adjustments to station locations might be needed if the field crew runs into unusual conditions or problems. Below are some rules concerning modifications to the station location(s).

- If only a small portion of the shoreline differs and it does not affect, or only slightly affects, a PHab site location, sketch the lake shoreline on the site map and reposition the station (if needed).
- If the difference causes a contraction of the shoreline and a PHab station location is lost, sketch the lake shoreline on the site map and make a decision to either: (a) keep the station, relocate it on the revised shoreline map and adjust some or all other stations in order to keep stations evenly spaced around the lake (i.e., keep 10 stations), or (b) eliminate the station altogether (i.e., reduce the number of stations).
- If the Site Map does not in any way match the lake shoreline, draw a new sketch map approximating the shoreline, and re-establish the 10 PHab stations. A quick way to locate 10 evenly-spaced PHab stations is to: (a) lay a piece of string on the lake perimeter, (b) pick up the string, measure it, and mark out 10 equal parts, and (c) lay the string back on the perimeter and use the marks to locate the 10 sites on the map.

6.2.3.3.4 PHab Station is inaccessible

- If a PHab station is inaccessible, you must make a decision to either: (a) relocate the station and adjust some or all other stations so that they are evenly spaced around the lake (i.e., keep 10 stations), or (b) eliminate the station altogether (i.e., reduce the number of

NMED Exhibit 36

stations). The size of the lake will help drive this decision.

- Draw all adjustments to the shoreline based on field observations directly on the Site Map and explain the adjustments in the comments section of the **Physical Habitat** form.

6.2.3.3.5 Identifying Relocated and New Stations on the Form

Use the following notations when recording station location modifications.

- If you relocate a station, note the new location on the Site Map and fill in the bubble corresponding to the original station letter (e.g., "C") on the **Physical Habitat** form. In addition, fill in the "Station Relocated" bubble on the form to indicate that the station has been moved from its originally intended location.
- If a station is lost and cannot be replaced, cross out the original station location on the Site Map, fill in the bubble corresponding to the original station letter, and fill in the "Dropped" bubble on the **Physical Habitat** form.

6.2.4 Establishing the Physical Habitat Plots at each station

Establish a plot for physical habitat characterization at each PHab station by visually estimating the plot dimensions. Most littoral, shore, and near-shore observations and measurements can be made from the boat at the observation point 10 m off-shore (estimated by eye). Limit observations at each station to the area that is within the defined plot dimensions (additional observations of human activities are made adjacent to or behind the defined plots). After setting plot dimensions, you may need to move around within the littoral plot to see or probe the bottom, or even go onto shore to make observations.

6.2.4.1 Physical Habitat Plot Dimensions

You will identify up to four distinct zones within each physical habitat plot (Figure 6-1), where you estimate the zone dimensions by eye or with the aid of a rangefinder.

6.2.4.1.1 Littoral

This within-lake zone is a fixed size that is 15 m wide along the shoreline and extending 10 m offshore into the lake.

6.2.4.1.2 Shoreline

The shoreline band is a fixed 15 m wide strip along the shore from the present water line to 1 m inland. If the horizontal drawdown distance is <1 m, the shoreline band is within the riparian plot; if the horizontal drawdown is ≥1 m, the shoreline band is within the drawdown plot. The shoreline boundary is defined as the approximate interface between "lake-like" conditions and riparian or wetland conditions. In cases where the lake shoreline is not obvious (e.g., where there is evidence of large seasonal change in lake level), define the shoreline as the current waterline. In cases where the lake shoreline is not visible, define the lake shoreline as the approximate boundary between open water and swamp or marsh conditions into which your boat could not easily move.

6.2.4.1.3 Drawdown

Under all circumstances, vertical height and horizontal distance of drawdown or water level fluctuations are measured or estimated. When horizontal drawdown is ≥1 m, establish a drawdown zone plot with a fixed width (15 m) but with a variable extent inland. The inland extent of the drawdown plot is equal to the horizontal extent of drawdown and may differ among the 10 PHab stations, depending on the topography at each station. It is determined by your judgment and measurement of the horizontal

NMED Exhibit 36

drawdown distance from the shore to the normal high water mark at each station.

The vertical height can be visually estimated or measured using a clinometer as a level in combination with a survey rod or metric tape measure. Similarly, the horizontal distance up the bank between the current lake level and the evidence of the normal high water level can be estimated visually, or measured with with a laser range finder, survey rod or metric tape measure when distances are greater than approximately 15m.

The intent of the drawdown assessment is to capture and track changes in the magnitude of lake level fluctuation or progressive decline or drawdown of lake levels relative to the normal high water mark. The normal high water mark is best indicated by the terrestrial vegetation and substrate present. In most regions of the US, summertime lake levels will be below the high water mark, so the NLA assessment may register a small amount of drawdown for most lakes. Negligible drawdown depends, to some extent, on the size of the lake. For NLA, an assessment of the vegetation and potential fish cover in the drawdown plot is not required when horizontal exposure of the littoral bottom is <1m. The vertical and horizontal drawdown must still be measured and recorded in order to establish the range of natural variability in lake level fluctuations. If no drawdown is present at the lake, enter zeros for both the vertical and horizontal drawdown distances.

6.2.4.1.4 Riparian

At stations that have <1 m horizontal distance of lake-level fluctuations or anthropogenic drawdown, there will be no drawdown zone and you will therefore define the riparian plot as a 15 m x 15 m square located at the water's edge, as presented in Figure 6-1, extending 15 m inland. When a drawdown plot is defined (i.e., stations that have ≥1m horizontal drawdown), the riparian zone plot is a 15m x 15m square just inland of the drawdown plot (i.e., a fixed size 15 m wide along the shoreline and extending 15m inland from the normal high-water mark).

6.2.4.2 Physical Habitat Station Layout Procedures

6.2.4.2.1 Normal High Water

1. Using the present shoreline, place the littoral plots lakeward from the current water's edge or the operational shoreline as defined in previous sections.
2. Draw or sight a straight line inland perpendicular to the shoreline. If this line does not intersect with the normal high water mark, move the littoral plot laterally in either direction until the perpendicular line intersects the normal high water mark. Choose to move the plot left or right based on the direction which results in the least distance moved.
3. Establish a 1 m shoreline band at the current water's edge or the operational shoreline.
4. Establish the riparian plot inland from the current water's edge or the operational shoreline identified above. If using an operational shoreline, the riparian plot may include shallow water and/ or impenetrable wetland.
5. The left and right edges of the riparian plot, the shoreline band, and the littoral plot should all align with one another.

6.2.4.2.2 Below Normal High Water (Drawdown)

1. Using the present shoreline, place the littoral plots from the current water's edge or the operational shroreline lakeward as defined in previous sections.

NMED Exhibit 36

2. Draw or sight a straight line inland perpendicular to the shoreline. If this line does not intersect with the normal high water mark, move the littoral plot laterally in either direction until the perpendicular line intersects the normal high water mark. Choose to move the plot left or right based on the direction which results in the least distance moved.
3. Establish a 1 m shoreline band at the current water's edge or the operational shoreline.
4. Establish the riparian plot inland from the normal high water mark identified above.
5. Establish a drawdown plot between the littoral and riparian plots. If the drawdown plot is greater than 1 m, cover estimates will be assessed in this plot.
6. The left and right edges of the riparian plot, the shoreline band, the littoral plot, and the drawdown plot should all align with one another.

6.2.4.2.3 Above Normal High Water (Flooding)

1. Establish the littoral plots lakeward from the normal high water mark, which may be evident by the extent of flooded trees or other terrestrial vegetation, lakeward.
2. Establish the riparian plot inland from the normal high water mark. In flooded situations, the riparian zone might be dry, partly flooded, or completely flooded with lake water.
3. Establish a 1 m shoreline band at the current water's edge. In flooded situations, the shoreline band might be within or inland from the riparian plot.
4. The left and right edges of the riparian plot, shoreline band, and the littoral plot should all align with one another.

6.2.5 **General Observations**

Begin the physical habitat characterization with general observations.

1. Set up your plots within your physical habitat station.
2. Measure and record the lake depth 10 m from the shore at each PHab station (observation point)
3. Note on the **Physical Habitat** form whether there is shoreline flooding (i.e., observed water level presently above the normal high water mark) by checking the box.
    a. If flooding is present, try to find the position of the normal high water mark, which may be evident by the extent of flooded trees or other terrestrial vegetation. Measure the depth at this point; record this as the "depth of flooding." Measure or estimate the distance from this normal high water position landward towards the margin of flooding; this establishes the location of the 1m shoreline band and the horizontal distance of flooding. The riparian plot is located as a 15 x 15 meter square abutting the normal high water mark, regardless of whether it is dry, partly flooded, or completely flooded with lake water.
    b. If the current water level is not above normal high water, enter zeros for height and horizontal distance of flooding.
4. Note on the **Physical Habitat** form whether the horizontal drawdown distance is greater than 1m by checking the box. **Regardless of the amount of drawdown of lake level fluctuation, measure or estimate it by recording the vertical height and the horizontal distance between the present lake level and the normal high water line**. Note that these measurements or estimates may be zeros if the water level is at or above the normal high-water mark, but should

NMED Exhibit 36

never be left blank. If the horizontal drawdown distance is <1m, the drawdown zone cover and human influence estimates are left blank in the form.

5. Record the bank angle description that best reflects the current shoreline that is dominant within your field of vision in the 1 m shoreline band:
    a. Near vertical/undercut (>75 degrees);
    b. steep (>30 to 75 degrees; need hands to climb up);
    c. gradual, (5 to 30 degrees; can walk up); or
    d. flat (< 5 degrees).

    NOTE: Complete this estimate even if there is no drawdown.
6. Record the presence or absence of water surface scums, algal mats, or oil slicks within the littoral zone.

6.2.6 Estimate Substrate Characteristics

You will estimate and assign percentage areal cover for substrate types (e.g. bedrock, boulders, cobble, gravel, sand, silt/clay/muck, woody debris, organic matter, and vegetation) and also for fish habitat cover, aquatic macrophytes, and terrestrial vegetation. The categories are as follows:

- 0 = absent (0% cover)
- 1 = sparse (<10% cover)
- 2 = moderate (10 – 40% cover)
- 3 = heavy (>40 – 75% cover)
- 4 = very heavy (>75% cover)

When estimating cover combinations in the substrate section of the **Physical Habitat** form, combinations consider that the combined cover of the various types of substrate should add up to approximately 100%. Because you are assigning cover percentage categories, look at various combinations of the high and low end of each class. Accordingly, more than one class might be given sparse (1), moderate (2), or heavy (3) ratings. One dominant class with no clear subdominant class might be ranked very heavy (4) with all the remaining classes either sparse (1) or absent (0). Two dominant classes with more than 40 percent cover can both be given a 3.

Estimate the areal cover of bottom substrate types and particle size classes observed within the littoral and the shoreline zones. Cover categories range from absent to very heavy. Record all observations by filling in the appropriate bubbles on the **Physical Habitat** form. In most cases these estimates can be made from the boat or can be made while wading, if preferred. Substrate types not present should be assigned zero cover.

- If the bottom substrate is not visible, you should probe the bottom beneath the boat with the sounding rod (you may have to move closer to shore if you are too deep to use the rod). Soft sediment can be brought to the surface for examination. Hard sediments can be "felt" with the sounding rod. Sandy substrate can be "felt" or "heard" by twisting the sounding rod and detecting grittiness. Estimating cover of various substrate types will typically require multiple probes within the littoral plot. If you have to move into shallow water to use the sounding rod to observe sediment characteristics, use the provided comment bubble to flag the observation and record the depth where you observed the sediment.
- If the bottom is covered with materials other than mineral substrates, choose “Woody Debris”, “Organic (leaf pack, detritus)”, or “Vegetation/Other”.

NMED Exhibit 36

- If the substrate is concealed and remote sampling is not possible, identify that the substrate is “not observed” in a comment bubble associated with each zone.

Record the color of sediment within the littoral plot. Select "None” or “Other" if the sediment does not match one of the color categories options on the **Physical Habitat** form.

Record sediment odor within the littoral zone. For sediment odor, the choices are "H_2S" (sulfurous, rotten egg), "Anoxic" (sewage odor), "Chemical" (strong odor like turpentine, paint, etc.), "Oil", or “Other" (including musty, organic, and fishy odors). If "Other" is indicated, explain the observation in the comment section of the form.

6.2.7 Estimate Aquatic Macrophyte Cover

Note and record whether macrophytes extend lake-ward from the observation point (e.g., further than 10 meters from the shoreline).

Estimate the areal cover of submerged, emergent (i.e., has erect portions above the water surface), floating/floating leafed (either rooted or non-rooted vegetation), and total macrophytes within the littoral zone. Cover categories range from absent to very heavy, as described in 6.2.6. Each of the three types of aquatic macrophyte (submergent, emergent, floating) can have cover ranging from 0 – 100%. They are evaluated independently, so the sum of their separate covers is theoretically 0% to 100% times the number of types. So, in contrast to substrate cover percentages, the combined cover of submergent, floating, and emergent aquatic macrophytes could theoretically add up to 300% due to the overlap of plant types within the water column. The fourth question on the form about aquatic macrophyte cover asks how much areal cover is there if you ignore the types and just estimate how much of the littoral plot has aquatic macrophyte cover of any type, where this value is constrained to 0-100%.

As with substrate, estimating aquatic macrophyte cover may require multiple probes within the littoral plot. Record all observations by filling in the appropriate bubbles on the **Physical Habitat** form. These estimates can be made from the boat or while wading.

- If you cannot see or probe the bottom, move closer to shore, use the provided comment bubble to flag your observation and note your new location and depth in the comments field on the form.

6.2.8 Estimate Fish Habitat Cover

Estimate the areal cover of potential fish habitat observed within the littoral plot and, when present, in the separate drawdown zone plot. Littoral fish habitat cover features are within or partially within the water and conceal fish from aquatic and terrestrial predators such as large fish, otters, kingfishers, and osprey. When evaluating cover of potential fish habitat in the drawdown zone, however, estimate the percentage cover that would be present at normal high water conditions, when these features would be inundated. Cover categories range from absent to very heavy, as specified in Section 6.2.6. Record all observations by filling in the appropriate bubbles on the **Physical Habitat** form. In most cases these estimates can be made from the boat. Estimating fish habitat cover may require multiple probes within the littoral plot. If certain cover types are not present, mark absent (0% cover) as your entry. In contrast to the cover of substrate types, the sum of the various types of fish habitat features can exceed 100%, sometimes summing to several hundred percent. Each type of fish cover can have cover ranging from 0 to 100%. They are evaluated independently, so the sum of their covers is theoretically 0 to 100% times the number of cover types.

NMED Exhibit 36

Estimate and record cover for the following fish habitat types:

- Aquatic macrophytes and Inundated Herbaceous Vegetation: Submerged, floating, or emergent live aquatic or non-woody herbaceous plants
- Woody Debris/Snags: Inundated or partially inundated dead trees, branches, or rootwads with diameter >0.3 m (1 ft)
- Woody brush/woody debris: Inundated dead or living woody vegetation <0.3 m diameter.
- Inundated Live Trees: Inundated portions of trees >0.3 m in diameter
- Overhanging Vegetation: <1 m from the water surface (do not include higher overhanging vegetation, which might provide perches for birds such as kingfishers)
- Ledges or Sharp Drop-offs: Overhanging banks, submerged rock shelves, and steep sloping rock walls
- Boulders: Larger than basketball size
- Human Structures: Docks, barges, houseboats, swimming platforms, tires, car bodies, and habitat enhancement structures (e.g., log rafts)

Note: In the drawdown zone you will estimate the potential fish cover. The potential fish cover estimates are made only if there is a visible drawdown zone extending ≥1 m from the shoreline. For these observations, the question is “What cover would there be if the drawdown zone were inundated – i.e., it were to become part of the littoral zone? “ Then, for example, a bunch of dried aquatic macrophtes would be “Aquatic and Inundated Herbaceous Vegetation”, as would newly-grown terrestrial grasses. Cyprus trees left “high and dry” would qualify as “Inundated Live Trees >0.3m diameter” and overhanging vegetation rooted above the drawdown zone could be “Overhanging Vegetation within 1m of the Surface”.

6.2.9 Estimate the Cover and Type of Riparian and Drawdown Zone Vegetation

Three independent layers of riparian vegetation will be examined, each of which can range in cover from 0 to 100%. The ground layer components must add up to 100% because this layer includes bare ground and water. The mid-layer and upper layer do not include ground or water, so vegetation within these layers do not have to add up to 100%.

The areal cover of different types of vegetation will be estimated in the riparian plot and, when present, in the drawdown zone. Vegetation cover is divided into three layers, which are described below. Remember that individual plants can contribute cover to more than one layer and cumulatively the three layers can potentially add up to 300% cover (up to 100% per layer). Also note that some things other than vegetation are possible entries for the "Ground Cover" layer (e.g., water or barren ground). Within each layer, the summed cover cannot exceed 100%, but, the ground layer covers must add up to 100%. As with the other visual cover estimates, you are assigning cover percentage categories, so the summed cover is estimated by looking at various combinations of the high and low end of each percentage cover class.

6.2.9.1 Canopy Vegetation (greater than 5 m high)

Record the type of vegetation in the canopy as deciduous, coniferous (needle-leafed evergreen), broadleaf evergreen, or mixed, where mixed is defined as a segment where chosen if there is more than one of these types of vegetation that has at least 10% areal coverage. If no canopy exists in the plot, do not mark any of the bubbles.

NMED Exhibit 36

Estimate the areal cover of big (trunk >0.3 m diameter at breast height [dbh]) and small (trunk <0.3 m dbh) trees. Cover categories range from absent to very heavy, as described in Section 6.2.6. Record all observations by filling in the appropriate bubbles on the **Physical Habitat** form.

Total cover in the canopy layer can range anywhere from 0% to 100% depending on conditions present.

6.2.9.2 Understory Vegetation (5m to 0.5m high)

Record the type of vegetation in the understory as deciduous, coniferous, broadleaf evergreen, or mixed, where mixed is defined as above. If no understory exists in the plot, do not mark any of the bubbles.

Estimate the areal cover of all woody vegetation (which includes both the trunks and branches of trees and shrubs, woody stems of perennial plants, etc.) and tall herbs, grasses, and forbs. Cover categories range from absent to very heavy, as specified in Section 6.2.6. Record all observations by filling in the appropriate bubbles on the **Physical Habitat** form. Total cover in the understory layer can range anywhere from 0% to 100% depending on conditions present.

6.2.9.3 Ground Cover (lower than 0.5m high)

Estimate the areal cover of woody vegetation; tall herbs, grasses, and forbs; standing water or inundated vegetation; and barren, bare dirt, or buildings. Areas of exposed rock or bedrock should be considered 'barren'. Cover categories range from absent to very heavy, as specified in Section 6.2.6. Record all observations by filling in the appropriate bubbles on the **Physical Habitat** form.

Ground cover is the only layer in which cover estimates should add up to roughly 100% (as opposed to ranging from 0-100% in the other two layers). Certain ground cover types should be considered mutually exclusive, i.e., if ground layer vegetation overlays barren ground, record the vegetation cover even though there is barren ground beneath it.

6.2.9.4 Considerations for Drawdown conditions

Drawdown Zone vegetation entries are located to the right of Riparian Zone Vegetation on the **Physical Habitat** form. They are filled out only if there is a drawdown zone extending ≥1 m from shore. Unlike the case with potential fish cover, record these vegetation estimates just as you see them --- i.e., do not in this case imagine that the drawdown zone is under water. For example: there must be water on the ground (e.g., puddles) to have an entry for "standing water or inundated vegetation" in the drawdown zone. Large trees rooted above the drawdown zone can contribute cover over the drawdown zone. Dried aquatic macrophyte vegetation cover is entered under "Herbs, Grasses, & Forbs" with comment that it is dried aquatic macrophytes. There may also be a lot of zeros for vegetation in the drawdown zone (especially if the drawdown is fairly recent).

6.2.10 **Record Evidence of Human influence**

You will record any observations of human influences within the littoral, riparian, and, when present, drawdown zone plots. Human influences within the littoral plot will be recorded in different locations on the form depending on whether or not there is a drawdown plot.

- When drawdown or lake level fluctuations are minimal, i.e., <1 m horizontal distance, there is no drawdown zone plot, and the drawdown zone human influence field will be left blank. Human influences in the littoral plot are recorded along with the influences in riparian zone plot and recorded in the riparian zone portion of the form.

NMED Exhibit 36

- When a drawdown zone extending ≥1 m from shore is present, a drawdown plot is defined and human influences within both the drawdown and littoral zone are recorded in the drawdown portion of the **Physical Habitat** form.

Within each zone, observations are recorded as not present (0), present outside and/or adjacent to (P), or contained within (C) the plot area (Figure 6-2). Record all observations by filling in the appropriate bubbles on the **Physical Habitat** form. The proximity "P" zones have a defined width of 15 m as shown in Figure 6-2. If there is no drawdown zone plot, all C and P human disturbances in the littoral plot are recorded on the riparian part of the form along with human influences present in the riparian zone, and the drawdown portion of the human influences section will be left blank. In contast, if there is a drawdown zone, all C and P human disturbances in the littoral plot are recorded in the drawdown part of the form along with human influences present in the drawdown zone.

For each zone and influence, indicate the presence only of the influence 'closest' to the plot itself. Do not mark "P" for a particular influence type if it is already marked "C" in that zone (use the more influential proximity code). Human Disturbances absent (0) and within-plot (C) are straightforward. For 'Present but outside or adjacent to the plots' (P), use these guidelines:

- A disturbance is marked "P" if the disturbance is seen entirely outside of any of the plots, but is adjacent to (i.e., within 15 meters left or right hand side of the entire Littoral-Drawdown-Riparian plot), or behind, the riparian plot within the defined areas.
- A disturbance is also marked "P" if the disturbance is seen behind, but entirely outside of all of the plots but is visible looking on-shore through the three plot zones (littoral, drawdown, and riparian)
- As a result, a single disturbance that is adjacent to both plots would be marked "P" in both the Riparian-Littoral and the Drawdown zones.
- If there is a drawdown plot, the presence of a human influence item WITHIN THE LITTORAL PLOT is recorded as "C" in the DRAWDOWN portion of the form (e.g., consider the littoral and drawdown zones to be a single plot when drawdown is present).
- If there is NO DRAWDOWN PLOT, i.e., the riparian plot abuts the shoreline, then human disturbances in the littoral plot are recorded by entering "C" in the Riparian portion of the form (e.g., consider the littoral and riparian zones to be a single plot when no drawdown is present).

NMED Exhibit 36

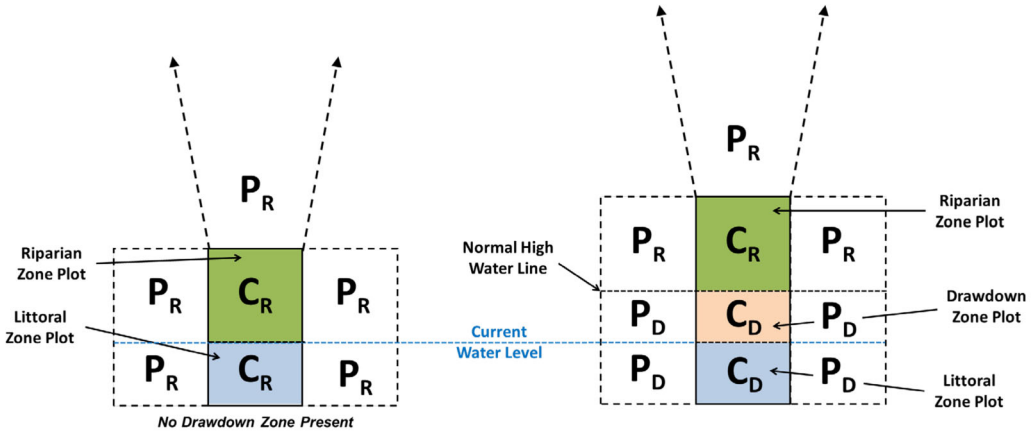

Figure 6-2 Human disturbance and proximity determinations

C_R = Marked on form as contained within riparian plot
P_R = Marked on form as adjacent to riparian plot
C_D = Marked on form as contained within drawdown zone
P_D = Marked on form as adjacent to drawdown zone

6.3 CyanoHABs Visual Assessment

Field crew views and documents visual observations of a potential cyanobacterial bloom in the NLA App and photo documents the bloom according to the reporting mechanism selected by the field crew (i.e., bloomWatch or state-specific reporting mechanism).

6.4 Benthic Macroinvertebrate Sampling

6.4.1 Summary of Method

Benthic macroinvertebrates are collected using a semi-quantitative sampling of multiple habitats in the littoral zone of lakes using a 500 µm mesh D-frame dip net (Figure 6-3). Sample collection is stratified on the following specific habitat types: rocky/cobble/large woody debris; macrophyte beds; fines (including mud, sand, or silt); and leaf packs.

Figure 6-3 D-frame net (500 µm mesh) used for collecting benthic macroinvertebrates.

6.4.2 Equipment and Supplies

Table 6-3 provides the equipment and supplies needed for field operations to collect benthic macroinvertebrates.

Table 6-3 Equipment and supplies – benthic macroinvertebrate collection.

Type	Item	Quantity
Form	NLA Littoral Samples	1
Documentation	Inner and outer labels: Benthic samples	1
	Labels: Benthic extra jar	As needed
	Scissors	1
	Clear tape strips (to cover sample labels)	As needed
Collection	Kick net (500 µm D-shaped, modified) with 4-foot handle	1
	Spare net(s) and/or spare bucket assembly for end of net	As needed
	Bucket (5-gallon capacity, plastic)	1
	Sieve bucket (500 µm)	1
	Watchmakers' forceps	1
	Squirt bottle (1 L Nalgene) – lake water	1
	Spoon (stainless steel)	1
	Funnel	1
	HDPE bottle (1 L, white, wide-mouth)	1 or more
	Ethanol (95%)	2 gal
	Gloves (latex/nitrile, non-powdered, box)	2 pair
Storing and preserving	Cooler	1
	Plastic electrical tape	As needed

6.4.3 Sampling Procedure

6.4.3.1 Site Selection and Sample Collection

The process for selecting the PHab stations is described in Section 6.1. All benthic samples should be collected from the dominant habitat type within the 10 m x 15 m littoral zone component of each of the PHab stations (Figure 3-2). The sampling process is described below. As part of the 2022 survey, new conservation measures for native freshwater mussels were added to the benthic sampling protocol[b].

6.4.3.2 Sample Processing in the Field

Use a 500-mm mesh sieve bucket placed inside a larger bucket full of lake water while sampling to carry the composite sample as you travel around the lake.

6.4.3.2.1 Benthic macroinvertebrate sampling

1. After locating the sample site according to procedures described in the physical habitat section, identify the dominant habitat type within the plot from the classifiers below:

[b] For this protocol, native freshwater mussels only refer to bivalves in the families Unionidae and Margaritiferidae. See Appendix C for examples of freshwater mussels. The conservation measures do not apply to the invasive quagga and zebra mussels, nor do they apply to any other mussel or clam (e.g., native fingernail clams, invasive Asiatic clam).

NMED Exhibit 36

- Rocky/cobble/large woody debris;
- Macrophyte beds;
- Fines (including mud, sand or silt); or
- Leaf pack.

2. Prior to collecting the sample and when the water clarity allows, inspect the targeted substrate for the presence of native freshwater mussels. If native freshwater mussels are present, move to an area within the same habitat type where native mussels are absent and the previously identified mussels will not be exposed to sampling pressures. Check the box in the NLA App that identifies native mussels were observed and the collection location was shifted.
3. Use the D-frame dip net (equipped with 500-µm mesh) to sweep through one linear meter of the dominant habitat type at a single location within the 10 m x 15 m littoral zone sampling area, making sure to disturb the substrate enough to dislodge organisms.
    - When safe to do so, it is preferable that you exit the boat and disturb the substrate (e.g., overturn rocks, logs) using your feet while sweeping the net through the disturbed area.
    - Because a dip-net is being used for sampling, the maximum depth for sampling will be approximately 1 m (the length of the dip-net handle); therefore, in cases in which the depth of the lake quickly drops off, it may be necessary to sample in the nearest several meters to the shore.
4. After completing the 1 m sweep, remove all organisms and debris from the net and place them in a bucket following sample processing procedures described in the following section.
5. Inspect the sample for native freshwater mussels after each sweep. If one or more native mussels were unintentionally collected:
    a. In the bucket, gently rise each mussel with lake water to remove invertebrates that may be on its shell.
    b. Carefully return the native mussel to the same habitat it was sampled from and away from further sampling pressures. They are NOT to be pushed into the substrate but to be placed gently on their side on top of the same substrate type or as instructed by local permit.
    c. Check the box in the NLA App that native freshwater mussels were removed from the sample and returned to the lake.
    d. <u>For EPA contractor and regional crews:</u> when sampling a lake where ESA-listed freshwater mussels have the potential to be present, crews must report the encounter in the **Federal ESA** form in the NLA App.
    e. Never intentionally collect and retain a native freshwater mussel that has the potential to be an ESA-listed species.
6. Proceed to the next sampling station and repeat steps 1-5. The organisms and detritus collected at each station on the lake should be combined in a single bucket to create a single composite sample for the lake. After sampling at all PHab stations is complete, process the composite sample in the bucket according to procedures described in the following section. One to five bottles should be sufficient to hold the composited sample from each lake.

NMED Exhibit 36

- If there is a large amount of debris (rocks, sticks, etc.) accumulating in the composite sample, remove debris between sampling stations, after the debris is inspected, picked, and/or washed to ensure no organisms are lost.
- If your first collection at a sampling station results in too much debris, discard it, move the location within the same habitat station, and take another sample.
- It is recommended that crews carry a sample bottle containing a small amount of ethanol with them to enable them to immediately preserve larger predaceous invertebrates such as hellgrammites and water beetles. Doing so will help reduce the chance that other specimens will be consumed or damaged prior to the end of the field day. Crews should NEVER, however, attempt to 'field-pick' the samples.

6.4.3.2.2 Preparing composite samples for benthic macroinvertebrates

1. Pour the entire contents of the bucket through a sieve (or into a sieve bucket) with 500 µm mesh size. Remove any large objects and wash off any clinging organisms back into the sieve before discarding. Once again review the sample for native freshwater mussels and follow the steps identified above in the sampling process.
2. Using a wash bottle filled with clean lake water, rinse all the organisms from the bucket into the sieve. This is the composite sample for the lake.
3. Estimate the total volume of the sample in the sieve and determine how many jars (1 L jars, each no more than half-full with sample) will be required.
4. Fill in a sample label with the Site ID and date of collection. Attach the completed label to the jar and cover it with a strip of clear tape. Record the sample ID number for the composite sample on the **Littoral Samples** form. For each composite sample, make sure the number on the form matches the number on the label.
5. Wash the contents of the sieve to one side by gently agitating the sieve in the water. Wash the sample into a jar using as little water from the wash bottle as possible. Use a large-bore funnel if necessary. If the jar is too full, pour off some water through the sieve until the jar is not more than half full, or use a second jar if necessary. Carefully examine the sieve for any remaining organisms and use watchmakers' forceps to place them into the sample jar.
6. If additional jars are needed, use a pre-printed benthos extra jar label or, if needed, fill in a blank sample label that does not have a pre-printed ID number on it. Record the ID number from the pre-printed label prepared in Step 4 in the "SAMPLE ID" field of the label. Attach the label to the additional jars and cover them with a strip of clear tape. Record the number of jars required for the sample on the **Littoral Sample**s form. **Make sure the number you record matches the actual number of jars used.** Write "Jar *N* of *X*" on each sample label using a waterproof marker ("*N*" is the individual jar number, and "*X*" is the total number of jars for the sample).
7. Place a waterproof label inside each jar with the following information written with a number 2 lead pencil:
   - Site ID;
   - Site name;
   - Date of collection;
   - Sample type;
   - Collector(s) names or initials; and
   - Sample ID.

NMED Exhibit 36

8. Completely fill the jar with 95% ethanol (no headspace). It is very important that sufficient ethanol be used, or the organisms will not be properly preserved. Existing water in the jar should not dilute the concentration of ethanol below 70%. **NOTE:** Prepared composite samples can be transported back to the vehicle before adding ethanol if necessary. In this case, fill the jar with lake water, which is then drained using the net (or sieve) across the opening to prevent loss of organisms, and replaced with ethanol at the vehicle.
9. Replace the cap on each jar. Slowly tip the jar to a horizontal position, then gently rotate the jar to mix the preservative. Do not invert or shake the jar. After mixing, seal each jar with plastic electrical tape.
10. Store labeled composite samples in a container with absorbent material that is suitable for use with 70% ethanol until transport or shipment to the laboratory.

6.5 Fecal Indicator Sample (Enterococci)

6.5.1 Summary of Method

Field teams are to collect a water sample within or near the littoral zone of the **last PHab station** where the water is about waist deep (1 meter). The water sample should be collected when the crew first arrives at the station (i.e., prior to substrate assessment and collection of the benthic macroinvertebrate sample). For "large lakes" (greater than 10,000 ha) the sample is to be collected from the launch site at the end of the day. **Filters must be frozen within six hours of collection.** Teams are to use a pre-sterilized, 250 ml bottle and collect the sample at about 0.3 meter (12 inches) below the water. Following collection, samples are placed in coolers and maintained on ice prior to filtration of two 50 mL volumes. Again, samples must be filtered and frozen on dry ice within six hours of collection.

6.5.2 Equipment and Supplies

Table 6.4 provides the equipment and supplies needed to collect the fecal indicator sample.

Table 6-4 Equipment and supplies: fecal indicator sample

Type	Item
Form	NLA Littoral Samples
Collection	Nitrile gloves Pre-sterilized, 250 ml sample bottle Sodium thiosulfate tablet Wet ice Cooler

NMED Exhibit 36

6.5.3 Sampling Procedure

The procedure for collecting the fecal indicator sample is presented in Table 6-5.

Table 6-5 Procedure: fecal indicator (enterococci) sample collection

Enterococci Sample
1. **Put on nitrile gloves**.
2. Identify an undisturbed area within or near the littoral zone of the final habitat station where the water is about waist deep (1 meter). For "large lakes" (greater than 10,000 ha) the sample is to be collected from the launch site at the end of the day.
3. Lower the uncapped, inverted 250 ml sample bottle to a **depth of 1 foot (0.3 m) below the water surface,** avoiding surface scum, vegetation, and substrates.
4. Point the mouth of the container away from the body or boat. Right the bottle and raise it through the water column, allowing bottle to fill completely.
5. After removing the container from the water, discard a small portion of the sample to allow for proper mixing before filtering (down to the 250 mL mark on the bottle).
6. **Add the sodium thiosulfate tablet, cap, and gently shake the bottle 25 times**.
Storage
7. Store the sample in a cooler on ice to chill (do not freeze immediately). Chill for at least 15 minutes before filtering.
8. Sample must be filtered and all filters frozen within six hours of collection.

6.5.4 Sample Processing in the Field

You will need to process two separate filters for the *Enterococci* sample. All the filters required for an individual site should be sealed in plastic bags until use to avoid external sources of contamination. Please refer to Section 8.2 for more information regarding prcessing the *Enterococci* samples.

NMED Exhibit 36

7.0 LAKE WIDE FISH SAMPLE COLLECTION

7.1 Summary of Method

Procedures for the whole fish composite sample are described in detail in Section 7.3**.**The objective is to collect one whole fish composite sample from the 636 designated lakes. This subsample is approximately 70% of the survey design (904 lakes total). Sites with "FT" in the design panel (i.e. Panel_Use) identify lakes designated for fish sampling. The two revisit sites in each state are also designated as fish sampling sites. Crews should collect fish during the *first* site visit for a revisit site, to allow for a second opportunity, if fish cannot be collected during the first visit.

The focus is on obtaining predator fish species that:

- are commonly consumed by humans;
- satisfy legal requirements of harvestable size for each lake site (or at least consumable size if no legal harvest requirements exist); and
- are sufficiently abundant within the lake.

Each fish sample will be a **composite of five adult whole fish** of the same species that are similar in size (i.e., the smallest individual in the sample is no less than 75% of the total length of the largest individual). See the last paragraph in 7.1 for clarification about the acceptable number of predator fish in a composite sample.

Collection of the whole fish composite sample is a lakewide activity. It does not need to be associated with the index site or PHab stations. Field crews may target areas in the lake with high quality habitat for the target fish species, except for areas near a lake inlet or adjacent to riverine habitat. Crews are to avoid these areas (a minimum of a 5-meter buffer zone) since they are more likely to contain nonresident fish. Additionally, when sampling run-of- the river reservoirs, crews should focus their sampling efforts in lacustrine habitats and avoid the river-reservoir transtion zone (i.e., do not sample in habitats with flowing water). Crews should make a reasonable effort to collect a whole fish composite sample before determining a fish sample cannot be collected. This may take *up to* three hours, depending on the waterbody.

If a lake designated for fish sampling is determined target and sampleable, but the crew was unable to collect a whole fish composite sample, no site replacement is needed. If a lake designated for fish sampling is dropped (i.e., determined non-target or not accessible), a replacement site is identified following procedures described in the NLA 2022 SEG and a whole fish composite sample must be collected at the replacement site. At revisit sites, this sample is only collected at one of the two site visits; however, crews that are unsuccessful at collecting the whole fish composite sample during visit 1 are expected to attempt the collection of that sample during visit 2. Whole fish composite samples are shipped to the laboratory designated for interim storage of the samples.

This section contains the sampling procedures and target predator fish species for the whole fish composite sample collection. Note that the target fish species list (Table 7-2) includes 12 primary target predator fish species and 10 secondary predator fish species. Field crews must attempt to collect a primary target predator fish species wherever possible. If primary target predator species are not available at a particular site, then the field crew collects a composite of one of the secondary predator fish species. In the event that a crew is unable to collect fish which are on either of the predator species

NMED Exhibit 36

lists, then the on-site biologist can select an appropriate **pelagic predator**. If the field crew has any questions they should contact the NLA Fish Fillet Indicator Trainer or the EPA Technical Lead for the Fish Fillet Contaminants Indicator (Table 2.2).

Field crews are encouraged to collect fish for the composite sample using hook and line or electrofishing. Crews may also seine or use gill nets when this would be an efficient approach to sample the target fish species and when allowed by the sampling permit. Crews are not to use trawling to collect the fish. **Crews may not purchase fish for the whole fish composite sample**.

The whole fish composite sample should consist of five similarly sized (i.e., the total length of the smallest specimen is no less than 75% of the total length of the largest specimen) adult predator fish of the same species. The minimum acceptable length for a fish in any composite sample is 190 mm. **Field crews should make every effort to consistently obtain five fish for the composite sample; however, a sample of fewer than five fish is acceptable. Conversely, for the exceptions where field crews collect five fish that are small, they should collect up to five additional fish (for an overall composite of up to 10 fish)** to provide adequate tissue for analysis. Fish retained as the fish composite sample should remain intact and be submitted as whole specimens.

7.2 Equipment and Supplies

Table 7-1 lists the equipment and supplies necessary for field crews to collect whole fish composite samples. A human health fish sampling kit will be provided to field crews for whole fish sampling sites (separately from site kits) as requested by the crew (see Appendix A). Additional fish collection supplies can be ordered through the **Request** form. A list of frequently asked questions and responses will be provided with the fish sampling supplies to clarify situations that field crews may encounter while collecting whole fish composite samples. Detailed procedures for collecting and processing the whole fish composite samples are presented below.

Table 7-1. Equipment & supplies: whole fish composite sample collection for human health

Type	Item
Form	NLA Whole Fish Sample in NLA App
Collection	scientific collection permit electofisher, hook and line, trap nets (or other device allowed in the sample collection permit) sampling vessel (including boat, motor, trailer, oars, gas, and safety equipment) nitrile gloves* Coast Guard-approved personal floatation devices Global Positioning System (GPS) livewell and/or buckets measuring board (millimeters)
Storing and preserving	aluminum foil (solvent rinsed)* polyethylene tubing (food-grade)* large plastic (composite) bags*

NMED Exhibit 36

	plastic cable ties* human health fish sample coolers* dry ice (for preservation) or wet ice (for temporary transport)
Documentation	human health fish sample labels (individual fish labels and composite bag labels)** fine-tipped indelible markers (for labels) Tyvek label tag with grommet (for composite bag)* clear tape

*Provided by EPA in FTIS kits.

**Provided by EPA in site kits.

7.3 Sampling Procedure

Note: *Do not handle any food, drink, sunscreen, or insect repellant until after the composite sample has been collected, measured, and wrapped (or implement measures to reduce contamination by such chemicals if applied such as washing, wearing long gloves, etc.).*

1. Put on clean nitrile gloves before handling the fish.
2. Rinse potential target species/individuals in ambient water to remove foreign material from the external surface and place them in clean holding containers (e.g., livewells, buckets).
3. For each human health fish composite sample, select five whole fish. Criteria for inclusion in the human health fish composite sample:
    a. All fish are of the same primary target species or secondary fish species (See Table 7-2) ***Note:*** *It is essential that field crews accurately identify the organisms submitted for analysis. Do not submit organisms from different species in a single sample.*
    b. All fish are adult fish; and
    c. All fish are of similar size, so that the smallest individual in a composite is no less than 75% of the total length of the largest individual. The minimum acceptable fish length is 190 mm.
4. Measure each fish selected for the composite from the anterior-most part of the fish to the tip of the longest caudal fin ray (when the lobes of the caudal fin are depressed dorsoventrally) to determine total body length in millimeters.
5. On the **Whole Fish Sample** form in the NLA App:
    - Verify the date of the fish collection on the top of the form. The date in this field will be automatically entered based on the date recorded on the **Verification** form. If you have not filled out the Verification Form or if the date of the fish collection is different, you can edit the date here. Note however that changing the value on this form will not change the value on the Verification Form.
    - Ensure the sample identification number is entered.
    - Check the boxes verifying that all samples are of similar length and the same species.
    - Record species selected for analysis, individual specimen lengths (total length in mm), and any relevant comments. Extra rows are provided in the App in the event that additional specimens are collected to ensure adequate tissue for analysis (refer to Frequently Asked Questions for further clarification).

NMED Exhibit 36

- Make sure the sample ID and specimen numbers recorded in the App match those on the sample labels.

6. Wearing clean nitrile gloves, remove each fish selected for analysis from the clean holding container(s). Dispatch each fish using the most humane method available.
7. Wrap each fish specimen in extra heavy-duty aluminum foil, with the dull side in contact with the fish (foil is solvent rinsed and baked and will be provided by EPA).
8. Prepare a sample label for each sample specimen, ensuring that the label information matches the information recorded on the **Whole Fish Sample** form in the App. **Be sure to record the common name and specimen length on each label.**
9. Cut separate lengths of food grade tubing (provided by EPA) long enough to contain each individual fish, allowing extra length on each end to seal with cable ties. Place each foil-wrapped specimen into the appropriate length of tubing. Seal the ends of each tube with a plastic cable tie. Attach the appropriate sample label to the plastic tubing by wrapping clear tape around the label and then completely around the wrapped fish (so that the clear tape wraps over itself).
10. Double-bag the entire set of specimens in the composite by placing all fish composited from the site inside a large plastic bag (provided by EPA). If additional bags are required for large fish specimens or fish samples, please use plastic bags of similar thickness as those provided by EPA.
11. Fill out a Sample Identification Label for the outer bag, ensuring that the label information matches the information recorded on the **Whole Fish Sample** form in the App. **Be sure to record the common name and specimen length range on the label.**
12. Affix the sample label to a composite bag tag (Tyvek tag) and cover with clear plastic tape. Thread a cable tie through the grommet in the tag and seal the outer bag with the cable tie.

SAMPLE STORAGE AND SHIPPING PREPARATION

1. After the fish sample is packaged, immediately place the fish sample in a cooler of dry ice and use either of the following options: (1) replenish dry ice at least daily until the sample can be properly frozen at ≤-20°C in a laboratory or other interim facility or (2) pack cooler with 50 pounds of block dry ice and ship to Microbac Laboratories (Baltimore, MD) before the end of the day.
   - If a fish sample is held on dry ice in the field, the field crew should replenish the supply of dry ice at least daily until the sample can be properly frozen or shipped.
   - Packaged fish samples may be placed on wet ice in coolers if they will be immediately transported to a nearby laboratory or other interim facility to be frozen before shipment (wet ice should be replenished frequently before it melts).
   - Keep all specimens in a particular fish composite sample in the same cooler for transport. Ship only one fish composite sample in a cooler.
2. Crews have two options for freezing and shipping fish composite samples, depending on site logistics:
   a. Ship the samples via priority overnight delivery service (i.e., Federal Express), packed on dry ice, so that they arrive at Microbac Laboratories (Baltimore, MD) within 24 hours from the time of sample collection. Do NOT ship on Fridays, Saturdays, or the day before federal holidays. Fish samples must be packed on sufficient dry ice (**50 pounds minimum**, with blocks of dry ice layered to ensure direct contact between fish and dry

NMED Exhibit 36

ice) to keep them frozen for up to 48 hours. **Do not use dry ice pellets for shipping the whole fish composite sample.** Remember to record the tracking number on the **Tracking** form in the App before submitting it to NARS IM.

b. Add fish samples to a freezer capable of maintaining temperatures of ≤-20°C within 24 hours of collection, and store the frozen samples until shipment within two weeks of sample collection. If fish samples cannot be stored in a freezer within 24 hours of collection, the field crew should replenish the supply of dry ice in the cooler containing the samples, at least daily, until the samples can be properly frozen or shipped. Frozen fish samples will subsequently be packed on at least 50 pounds of layered blocks of dry ice and shipped to Microbac Laboratories (Baltimore. MD) via priority overnight delivery service. Refer to reminders in option 2a (above) about not shipping on Fridays, Saturdays, or the day before federal holidays and about including sample tracking numbers on App tracking forms.

Table 7-2. Primary and secondary NLA target species for human health fish collection

PRIMARY PREDATOR HUMAN HEALTH FISH TARGET SPECIES		
FAMILY	SCIENTIFIC NAME	COMMON NAME
Centrarchidae	*Micropterus salmoides*	Largemouth Bass
	Micropterus dolomieu	Smallmouth Bass
	Pomoxis nigromaculatus	Black Crappie
	Pomoxis annularis	White Crappie
Percidae	*Sander vitreus*	Walleye
	Perca flavescens	Yellow Perch
Moronidae	*Morone chrysops*	White Bass
Esocidae	*Esox lucius*	Northern Pike
Salmonidae	*Salvelinus namaycush*	Lake Trout
	Salmo trutta	Brown Trout
	Oncorhynchus mykiss	Rainbow Trout
	Salvelinus fontinalis	Brook Trout
SECONDARY PREDATOR HUMAN HEALTH FISH SPECIES		
FAMILY	SCIENTIFIC NAME	COMMON NAME
Centrarchidae	*Lepomis macrochirus*	Bluegill
	Ambloplites rupestris	Rock Bass
	Micropterus punctulatus	Spotted Bass
Percidae	*Sander canadensis*	Sauger
Moronidae	*Morone saxatilis*	Striped Bass
	Morone americana	White Perch
Esocidae	*Esox niger*	Chain Pickerel
Salmonidae	*Oncorhynchus clarkii*	Cutthroat Trout
	Coregonus clupeaformis	Lake Whitefish
	Prosopium williamsoni	Mountain Whitefish

NMED Exhibit 36

8.0 FINAL LAKE ACTIVITIES

Prior to leaving the lake, make a general visual assessment of the lake and its surrounding catchment. This assessment is based on the collective observations of all crew members. The objective of the lake assessment is to record field crew observations of catchment and lake characteristics that are useful for future data interpretation, ecological value assessment, development of associations, and verification of stressor data. While often subjective, these observations and impressions are extremely valuable.

In addition, review all data forms and sample labels for completeness, accuracy, and legibility. Make sure all samples are labeled, sealed, and properly preserved. Activities described in this section are summarized in Figure 8-1.

NMED Exhibit 36

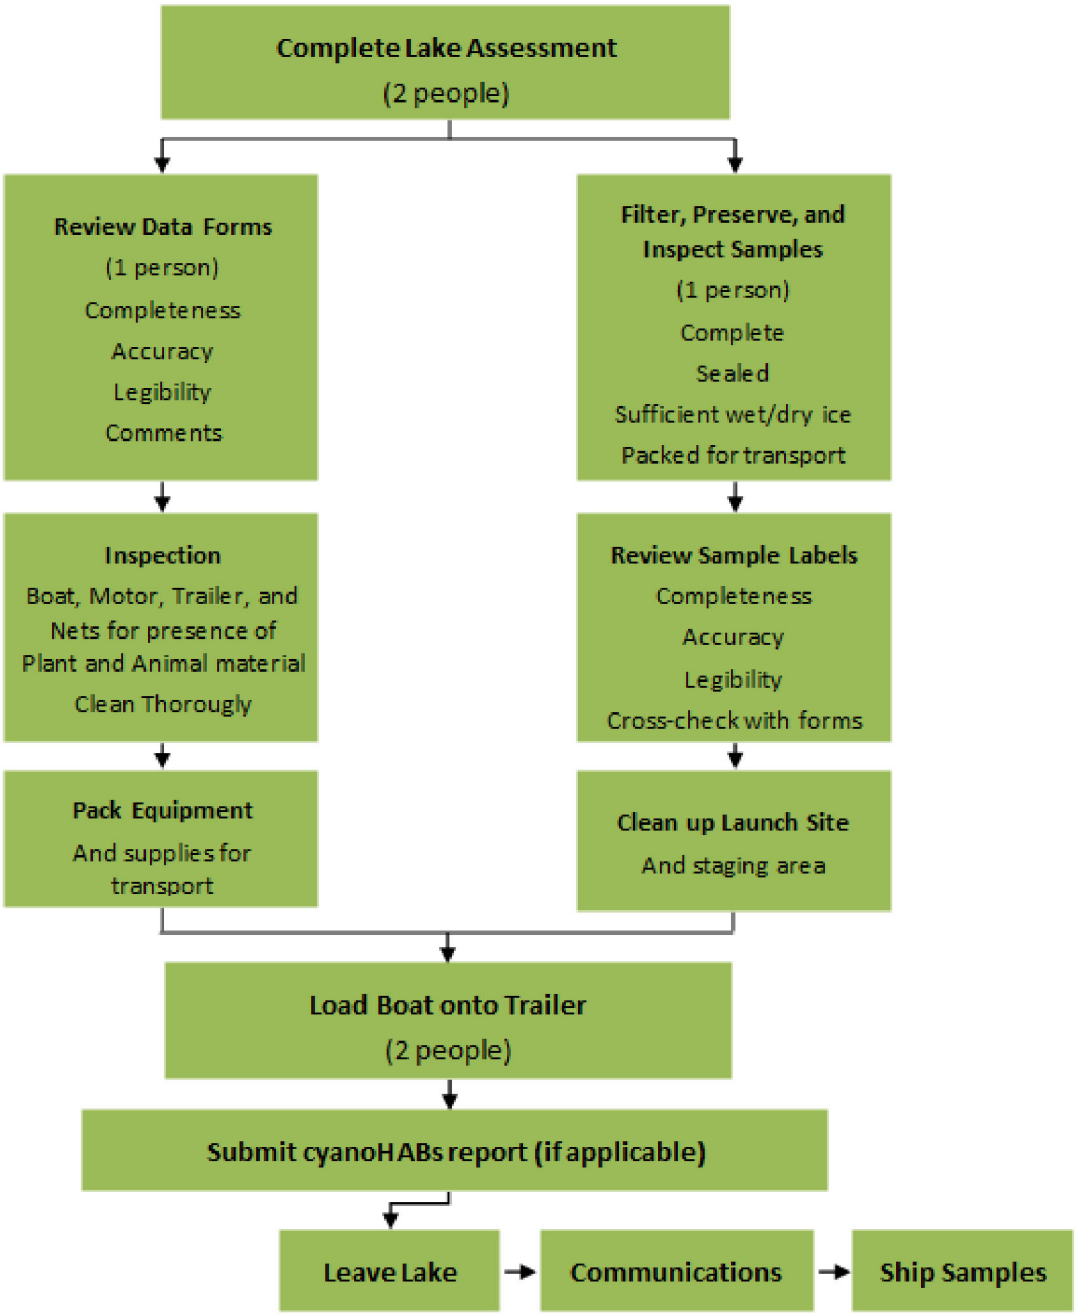

Figure 8-1 Final lake activities summary

8.1 General Lake Assessment

Complete the **Assessment** form at the end of lake sampling, recording all observations from the lake that were noted by all crew members during the course of the visit. This form is designed as a template for recording pertinent field observations. It is by no means comprehensive, and any additional observations should be recorded in the comments section. The form consists of six major sections: 1) Lake/Catchment Site Activities and Disturbances Observed, 2) General Lake Information, 3) Shoreline

Characteristics, 4) Qualitative Macrophyte Survey, 5) Waterbody Character, and 6) Qualitative Assessment of Environmental Values. In 2022, new questions were added to assist the determination of natural and human-made lakes.

8.1.1 Lake/Catchment Site Activities and Disturbances Observed

Record any of the sources of potential stressors listed in Table 8-1 on the **Assessment** form. These potential stressors may have been observed while on the lake, while driving or walking through the lake catchment, or while flying over the lake and catchment. For activities and stressors that you observe, rate their abundance or influence as low (L), moderate (M), or heavy (H) by filling in the correct bubble next to each disturbance listed. Leave the line blank for any disturbance not observed. The distinction between low, moderate, and heavy will be subjective. For example, if there are two to three houses on a lake, fill in the "L" bubble for low next to "Houses." If the lake is ringed with houses, rate it as heavy (H). Similarly, a small patch of clear-cut logging on a hill overlooking the lake would rate a low ranking. Logging activity right on the lake shore, however, would get a heavy disturbance ranking. The section for “Lake Site Activities and Disturbances Observed” includes residential, recreational, agricultural, industrial, and lake management categories.

Table 8-1 Site activities and disturbances observed during final lake assessment.

Observe lake activities or disturbances listed and record as L (low), M (moderate), or H (heavy) intensity on the Assessment form (except as noted below):	
Residences	Presence of any houses and residential buildings around the lake.
Maintained Lawns	Presence of any maintained lawns around the lake.
Construction	Presence of any recent construction in the immediate area around the lake or signs of recent sedimentation events (depositional fans).
Pipes/Drain	Presence of any pipes or drains feeding into or out of the lake. If known, record the type of activity with which the pipe is associated (e.g., storm sewer, plant intake) in the "Comments" section of the form.
Dumping	Any evidence of landfill or dumping around the lake, including garbage pits and informal dumping of large amounts of trash or cars and appliances along roads or lakeshore. This does not include small amounts of litter. If informal dumping areas exist, note that they are informal sites in the "Comments" section of the form.
Roads	Presence of any maintained roads in the immediate area around the lake.
Bridges/Causeways	Presence of any bridges or causeways across or in the immediate vicinity of the lake.
Sewage Treatment	Presence of sewage treatment facility.
Hiking Trails	Presence of formal hiking trails around the lake.
Parks, Campgrounds	Presence of organized public or private parks, campgrounds, beaches or other recreational areas around the lake.
Primitive Parks, Camping	Presence of informal or primitive parks, camping areas, beaches or other recreational areas (e.g., swimming holes) around the lake.
Resorts	Level of resort activity; this could include motels, resorts, golf courses, and stores.
Marinas	Presence of any marinas.
Trash/Litter	Relative abundance of trash or litter around the lake.
Surface Films, Scum or Slicks	Relative abundance of surface films, scum, or slicks on the lake.
Cropland	Presence of cropland.

NMED Exhibit 36

Observe lake activities or disturbances listed and record as L (low), M (moderate), or H (heavy) intensity on the Assessment form (except as noted below):	
Pasture	Presence of pastures.
Livestock Use	Presence of livestock use.
Orchards	Presence of orchards.
Poultry	Presence of poultry operations.
Feedlot	Presence of feedlot or concentrated animal feeding operations.
Water Withdrawal	Any evidence of water withdrawal from the lake.
Industrial Plants	Any industrial activity (e.g., canning, chemical, pulp) around the lake or in the catchment. Describe the type of industry in the "Comments" section of the form.
Mines/Quarries	Any evidence of mining or quarrying activity in the catchment or around the lake.
Oil/Gas Wells	Any evidence of oil or gas wells in the catchment or around the lake.
Power Plants	Presence of any power plants.
Logging	Any evidence of logging or fire removal of trees in the lake area.
Evidence of Fire	Any evidence of forest fires in the lake area.
Odors	Presence of any strong odors.
Commercial	Any commercial activity (e.g., convenient stores, shopping centers, restaurants) around the lake or in the catchment.
Liming	Any evidence of liming activities.
Chemical Treatment	Presence of any chemical treatment facilities.
Angling Pressure	Estimate of the intensity of fishing activity in the lake.
Drinking Water Treatment	Presence of any drinking water treatment facilities.
Macrophyte Control	Any evidence of dredging or other activities to control macrophyte growth; describe these in the "Comments" section of the form.
Water Level Fluctuations	Any evidence of water level fluctuations due to lake management.
Fish Stocking	Any evidence of fish stocking in the lake.
Record any other oddities observed or additional information for any specific activity in the "Comments" section of the form.	

8.1.2 General Lake Information

Observations regarding the general characteristics of the lake are described in Table 8-2. Record these observations on the **Assessment** form. The hydrologic lake type is a very important variable for defining subpopulations for acidic deposition effects. Note if there are any stream outlets from the lake, even if they are not flowing. If no lake outlets are observed, record the lake as a seepage lake. If the lake was created by a manmade dam (not that a dam is present just to raise the water level), record the lake as a reservoir. Otherwise record the lake as a drainage lake. Note any flight hazards that might interfere with either low-altitude fly-overs by aircraft (for future aerial photography or videography) or landing on the lake for sampling purposes (either by float plane or helicopter). When estimating the intensity of motor boat usage, in addition to the actual number of boats observed on the lake during the visit, use other observations such as the presence of boat houses, docks, and idle craft**.** Note your opinion as to the swimmability of the lake in general. Observe any regular change in the lake levels and estimate the typical elevation change.

NMED Exhibit 36

Table 8-2 General lake information observed during final lake assessment.

Record general information about the lake as a whole	
Hydrologic Lake Type	Note if there are any stream outlets from the lake, even if they are not flowing. If no lake outlets are observed, record the lake as a seepage lake. If the lake was created by a manmade dam (not that a dam is present just to raise the water level), record the lake as a reservoir. Otherwise record the lake as a drainage lake.
Outlet Dams	Note the presence of any dams (or other flow control structures) on the lake outlet(s). Differentiate between artificial (man-made) structures and natural structures (beaver dams).
Motor Boat Density	Record your impression of the density of motor boat usage on this lake (high or low). If there is a restriction on the size of motor boat engines, check "Restricted." If motor boats are banned, check "Banned." Consider the day of the week and weather in your assessment as well as the number of boathouses, idle craft. Count jet skis and any other motorized craft, which could stir up the lake, as motor boats.
Swimmability	Record a subjective impression about the aesthetics of swimming in this lake (swimmability) along the range of "good" to "not swimmable."
Lake Level Changes	Examine the lake shoreline for evidence of lake level changes (e.g., bathtub ring). If there are none, check "zero;" otherwise try to estimate the extent of vertical changes in lake level from the present conditions based on other shoreline signs. Estimates should be made to the nearest 0.1 m.

8.1.3 Shoreline Characteristics

Shoreline characteristics of interest during the final lake assessment are described in Table 8-3. Record observations related to this portion of the assessment on the **Assessment** form. To estimate the extent of major vegetation types, limit the assessment to the immediate lake shoreline (i.e., within 20 m of the water). Also estimate the percentage of the immediate shoreline that has been developed or modified by humans.

Table 8-3 Shoreline characteristics observed during final lake assessment.

Record percent of shoreline characteristics (within 20 meters of water):	
Forest	Deciduous, coniferous, or mixed forest, including sapling vegetation.
Grass	Meadows, lawns, or other open vegetation.
Shrub	Shrub vegetation
Wetland	Forested and non-forested wetlands (submerged terrestrial vegetation).
Bare Ground	Non-vegetated areas such as beaches, sandy areas, paved areas, and exposed rock.
Agriculture	Cropland, orchard, feedlot, pastureland, or other horticultural activity.
Shoreline Modifications	Actual shoreline that has been modified by the installation of riprap, revetments, piers, or other human modifications.
Development	Immediate shoreline area developed by human activity; include lawns, houses, stores, malls, marinas, golf courses, or any other human-built land use.

NMED Exhibit 36

8.1.4 Qualitative Macrophyte Survey

Aquatic macrophytes (aquatic plants large enough to be seen without magnification) are important indicators of lake trophic status. The most important indicator for this survey is the percentage of the entire lake area (not just near the shore) covered with macrophytes, as perceived by observers. For both "emergent/floating" and "submergent" coverage, choose one of the four percentage groupings (<5%, 5-25%, 26-75%, >75%) on the **Assessment** form. In some cases, it will be fairly easy to estimate the percentage from observations made at the PHab stations. In other cases, it will be an educated guess, especially if the water is turbid or the lake is deep. After recording the areal percentage of macrophyte coverage, record the typical density of the plants in the observed macrophyte beds as absent, sparse, moderate, or high. Record your estimates on the **Assessment** form.

8.1.5 Waterbody Character

Rate the ***waterbody character*** which is the physical habitat integrity of the waterbody. Waterbody character is largely a function of riparian and littoral habitat structure, volume change, trash, turbidity, slicks, scums, color, and odor. The NLA 2022 attempts to define waterbody character through two attributes: degree of human disturbance and aesthetics. Rate each of these attributes on a scale of 1 to 5. For development, give the lake a "5" if it is pristine, with no signs of any human disturbance. A "1" would indicate that a lake is highly disturbed; for example, the entire lake is ringed with houses, seawalls, docks, etc. For aesthetics (whether the lake is appealing or not) base the decision on any factors about the lake that disturb you (trash, algal growth, weed abundance, overcrowding). Fill in the bubble next to the number that best describes your opinion about how suitable the lake is for recreation and aesthetic enjoyment today:

1. Enjoyment is nearly impossible;
2. Level of enjoyment is substantially reduced;
3. Enjoyment is slightly impaired;
4. There are very minor aesthetic problems; it is otherwise excellent for swimming, boating, and enjoyment; or
5. It is beautiful and could not be any nicer.

8.1.6 Qualitative Assessment of Environmental Values

The primary goal of this study is to assess three major ecological values with respect to lakes: trophic state, ecological integrity, and human health (through use of the lake). Based on your field experience, record your own assessment of these values on the **Assessment** form. Write comments on these values in this section.

1. ***Ecological integrity*** is the ability to support and maintain a balanced, integrated, adaptive community with a biological diversity, composition, and functional organization comparable to natural lakes of the region. Record your overall impression of the "health" of the biota in the lake. Note any possible causes of impairment. The presence of higher order consumers (fish-eating birds and mammals) is an indication of a healthy food web and should be noted here. Similarly, the absence of an organism that you might expect to see is an important observation.
2. ***Trophic state*** is the rate or amount of phytoplankton and macrophytes produced or present in a lake. Give your visual impression of the trophic status as oligotrophic (little or no biomass in the lake water), mesotrophic (intermediate amounts of biomass in the lake water), eutrophic (large

NMED Exhibit 36

amounts of biomass in the lake water), or hypereutrophic (choked lake, with more biomass than water). Give your overall impression of algal abundance and general type (e.g., filamentous). List any observed potential nutrient sources to the lake (e.g., septic tanks and agricultural runoff).

3. ***Recreational value*** is the ability to support recreational uses such as swimming, fishing, and boating. Record your overall impression of the lake as a site for recreation. Note any possible causes of impairment or risk to human health. Note the presence or absence of people using the lake for recreational activities.

Use the comments section on the **Assessment** form to note any other pertinent information about the lake or its catchment. Here the field crew can record any observations that may be useful for future data interpretation, especially data that was not captured during other sampling or data collection activities.

8.1.7 CyanoHAB assessment and report

In the **Assessment** form, field crews document the presence of potential cyanobacterial blooms that were observed in areas of the lake that were not associated with the launch site, index site or physical habitat stations (i.e., not previously reported the NLA App). Crews are to photo document the bloom according to the reporting mechanism selected by the field crew (i.e., bloomWatch or state-specific reporting mechanism).

If the field crew documented the potential occurrence of a cyanoHAB event at one or more station in the lake, the Field Crew leader is responsible for reporting the bloom to the appropriate state, tribal or local organization. See Section 2.2.4.5 for potential reporting mechanisms. A cyanoHAB report will only be submitted when a potential bloom was observed. Reports are not needed to document the lack of a bloom. All reports submitted via the bloomWatch app should add the project identifier ‘NLA2022’ in the comment section in the app.

NMED Exhibit 36

8.2 Filtering: Processing the Fecal Indicator (Enterococci) and Chlorophyll-*a* Samples

8.2.1 Equipment and Supplies: Fecal Indicator

Table 8-4 provides the equipment and supplies needed for field crews to collect the fecal indicator sample.

Table 8-4 Equipment and Supplies: Fecal Indicator (Enterococci) Sample

Type	Item	Quantity
Form	NLA Littoral Samples form	1
For recording measurements	Fine-tipped indelible markers for filling out sample labels	1
	Fecal Indicator sample labels: vial	
	Fecal Indicator sample labels: bag label)	2
	Filter blank label if collecting filter blank	1
For processing samples	Nitrile gloves	1
	Sterile centrifuge tube (50 mL, screw top) in zip top bag	1
	Filtration apparatus with collection flask	1
	Sterile filter holder, Nalgene 145/147	1
	Vacuum pump (electric pump may be used if available)	1
	Sterile phosphate buffered saline (PBS)	1
	Osmotics 47 mm polycarbonate sterile filters	1+
	Sterile disposable forceps	1
	Petri dishes (60 x 15, disposable)	1
	Sterile microcentrifuge tubes containing sterile glass beads	2
	Additional sterile microcentrifuge tube if collecting filter blank	1
	Bubble bag	1
	Zip-top bag	1
	Dry ice	As needed
	Cooler	1

8.2.2 Procedures for Processing the Fecal Indicator (*Enterococci*) Sample

The fecal indicator sample **must be filtered before the chlorophyll-*a*** sample since the filtering apparatus needs to be sterile. The procedures for processing the fecal indicator sample are presented in **Table 8-5**. The sample must be filtered and frozen within six hours of collection.

Table 8-5 Procedure: Processing Fecal Indicator (*Enterococci*) Sample

Filtering for the fecal indicator (Enterococci) Sample
Prior to beginning the filtering process, chill the Enterococci sample and PBS on WET ice for at least 15 minutes and chill the microcentrifuge tubes on DRY ice. 1. Put on nitrile gloves. 2. Set up sample filtration apparatus on flat surface and attach vacuum pump. Set out 50 mL sterile PP tube, sterile 60 mm Petri dish, chilled phosphate buffered saline (PBS), Osmotics 47 mm polycarbonate sterile filter box, and two sterile filter forceps. 3. Chill Filter Extraction tubes with beads on dry ice. 4. Aseptically transfer two polycarbonate filters from filter box to base of opened Petri dish. Close filter box and set aside (this step is to prevent wind from disturbing the remaining filters in the box but is optional in calm/controlled environments). 5. Remove the pre-loaded cellulose nitrate (CN) filter (the filter with grid design on it) from funnel and discard. Be sure to leave the support pad in the filter funnel. 6. Load filtration funnel with sterile polycarbonate filter on support pad (shiny side up). 7. Gently shake sample collection bottle 25 times to mix well. 8. Measure 25 mL of the mixed water sample in the sterile graduated sterile PP tube and pour into filter funnel. 9. Replace cover on filter funnel and pump to generate a vacuum (do not generate more than 7 inches of Hg of vacuum [3.44 psig]). Keep pumping until all liquid is in filtrate collection flask. 10. If the first 25 mL volume passes readily through the filter, measure and add another 25 mL and continue filtration. If it was very difficult to filter the first 25 mL, proceed to step 11. If the filter clogs before completely filtering the first or second 25 mL volume, discard the filter and repeat the filtration using a lesser volume. 11. Pour approx. 10 mL of the chilled phosphate buffered saline (PBS) into the graduated PP tube used for the sample. Cap the tube and shake 5 times. Remove the cap and pour rinsate into filter funnel to rinse filter. 12. Filter the rinsate and repeat with another 10 mL of PBS, ensuring all PBS is filtered through. 13. Remove filter funnel from base without disturbing filter. Using sterile disposable forceps remove the filter (touching only the filter edges) and fold it in half, in quarters, in eighths, and then in sixteenths (filter will be folded four times). 14. Insert filter into chilled filter extraction tube (with beads). Filter should be inserted open end down (pointed side up) into the tube. Replace and tighten the screw cap. 15. Record the volume of sample filtered through the filter on the small yellow label (marked as FILTER 1) and apply the label to the extraction tube (DO NOT cover with clear tape). 16. Record the volume of sample filtered through the filter on the outer bag label and apply the label to the bubble bag (DO NOT cover with clear tape). 17. Insert tube(s) into bubble bag and zip-top bag on dry ice for preservation during transport and shipping.

NMED Exhibit 36

18. Record the volume of water sample filtered through each filter and the volume of buffer rinsate each filter was rinsed with on the **Littoral Samples** form. Record the filtration start time and finish time for the sample as well as the time the filters were frozen.
19. Repeat steps 6 to 15 for the remaining 50 mL sub-sample volume to be filtered. Make every effort to filter the same volume of sample through each of the two filters.

Processing procedure—fecal indicator (*Enterococci*) filter blank

Enterococci filter blanks will be prepared at all revisit sites during the first visit. Prepare the filter blanks **before** filtering the lake sample.

1. Set up sample filtration apparatus using same procedure as used for the lake sample. Chill Filter Extraction tubes with beads on dry ice.
2. Aseptically transfer 1 polycarbonate filter from filter box to base of opened Petri dish. Close filter box and set aside (this step is to prevent wind from disturbing the remaining filters in the box but is optional in calm/controlled environments).
3. Remove the pre-loaded cellulose nitrate (CN) filter (the filter with grid design on it) from funnel and discard. Be sure to leave the support pad in the filter funnel.
4. Load filtration funnel with sterile polycarbonate filter on support pad (shiny side up).
5. Measure 10 mL of the chilled phosphate buffered saline (PBS) in the sterile graduated PP tube and pour into filter funnel.
6. Replace cover on filter funnel and pump to generate a vacuum (do not generate more than 7 inches of Hg of vacuum [3.44 psig]). Keep pumping until all liquid is in filtrate collection flask.
7. Remove filter funnel from base without disturbing filter. Using sterile disposable forceps remove the filter (touching only the filter edges) and fold it in half, in quarters, in eighths, and then in sixteenths (filter will be folded 4 times).
8. Insert filter into chilled filter extraction tube (with beads). Filter should be inserted open end down (pointed side up) into the tube. Replace and tighten the screw cap.
9. Record the volume of PBS filtered through the filter on the small yellow label (marked as BLANK) and apply the label to the extraction tube (DO NOT cover with clear tape). Note that there is a specific label for the blank sample. At sites where a blank is not collected, this label will be discarded.
10. Insert tube(s) into bubble bag and zip-top bag on dry ice for preservation during transport and shipping.
11. Package and submit this sample to the lab with the standard samples.
12. Indicate that you have collected a filter blank by filling in the “Blank Collected” button on the **Littoral Samples** form.

NMED Exhibit 36

8.2.3 Equipment and Supplies: Chlorophyll-*a*

Table 8-6 provides the equipment and supplies needed to process the chlorophyll-*a* sample. Much of this equipment will have been used previously for the filtering of the Enterococci sample.

Table 8-6 Equipment and supplies – chlorophyll-*a* processing.

Type	Item	Quantity
Form	NLA Index Samples	1
Documentation	Labels: Chlorophyll-*a* sample label	1
	Chlorophyll-*a* outer bag label	1
	Clear tape strips (to cover sample labels)	As needed
Processing	Poly bottle (2 L, brown)	1
	Centrifuge tube (50 mL, screw top) in zip top bag	1
	Sterile disposable forceps	1
	Filtration chamber (with filter holder)	1
	Filtration flask (with silicone stopper and adapter)	1
	Filtration pump (hand vacuum)	1
	Graduated cylinder (250 mL)	1
	Squirt bottle (1 L Nalgene) – de-ionized (DI)	1
	Test tube holder	1
	Whatman 0.7 µm GF/F glass fiber filter	1
Storing and preserving	Cooler	1
	Plastic electrical tape	As needed
	Foil squares	1
	Zip top bag	1
	Wet ice	As needed

8.2.4 Procedures for Processing the Chlorophyll-*a* Samples

The procedure for processing the chlorophyll-*a* sample is presented below. Whenever possible, sample processing should be done in subdued light, out of direct sunlight.

1. Place a glass fiber filter in the filter holder apparatus with the grid side down. Do not handle the filter with bare hands; use clean forceps.
2. Gently shake the chlorophyll-*a* sample collection bottle to homogenize the sample, measure and pour 250 mL of water into the filter holder using the graduated cylinder, replace the cap of the filter holder, and pump the sample through the filter. Take care not to exceed 7 inches of Hg (approximately 3.4 psi) in the vacuum gauge on the filtration pump. If 250 mL of lake water will not pass through the filter, discard the filter, rinse the apparatus with DI water, and repeat the procedures using a new filter and 100 mL of lake water. **NOTE: If the water is green or turbid, use a smaller volume to start.**
3. Observe the filter for visible color. If no visible color is present, repeat step 3 until color is visible on the filter or until a maximum of 2,000 mL have been filtered.
4. Once visible color is present and/or 2,000 mL of lake water has been filtered, record the actual sample volume filtered on the **Index Sample**s form and on the sample label. Rinse the graduated cylinder and upper portion of the filtration apparatus thoroughly with DI water to

NMED Exhibit 36

include any remaining cells adhering to the sides and pump through the filter. Monitor the level of water in the lower chamber to ensure that it does not contact the filter or flow into the pump.

5. Disconnect the upper portion of the filter apparatus from the lower portion. Remove the filter from the holder with clean forceps. Avoid touching the colored portion of the filter. Fold the filter in half, with the colored side folded in on itself.
6. Place the folded filter into a 50 mL screw-top centrifuge tube and replace the cap. Tighten the cap as tightly as possible. The cap will seal tightly after an additional ¼ turn past the point at which initial resistance is met. Failure to tighten the lid completely could allow water to infiltrate into the sample and may compromise its integrity. Seal the cap of the centrifuge tube with plastic electrical tape
7. Record the sample volume filtered on a chlorophyll-*a* label and attach it to the centrifuge tube. Ensure that all written information is complete and legible. Cover with a strip of clear tape. Double check that the "total volume of water filtered" on the **Index Samples** form matches the total volume recorded on the sample label.
8. Wrap the tube in aluminum foil and place in a zip top bag. Place the completed outer label on the outside of the bag. Place this bag on ice in a cooler.
9. Remove the filter holder silicone stopper and adapter from the filtration flask. Pour off water from the filtration flask.
10. Discard filter chamber, forceps and filter holder. New sterile items will be used at each site.
11. Retain the filter flask, graduated cylinder, silicone stopper, and adapter. Rinse these items with DI water between sites. After returning to the office or lab: thoroughly rinse the graduated cylinder, the brown sample collection bottle and cap with tap water, complete a final rinse with DI water, and store for next sample event.

8.3 Preservation of Samples

Preserve the samples as specified in the specific protocol sections. Record the preservation information on the index and littoral sample collection forms.

8.4 Preparation of Samples for Shipping

General information regarding the preparation and shipment of samples is available in Section 4.3.2. General steps that apply to samples are the following:

- Purge the Cubitainer® of any air bubbles, seal the cap tightly and wrap plastic electrical tape clockwise around the cap. Place the Cubitainer® in a cooler with wet ice.
- Seal all pertinent caps tightly.
- Wrap plastic electrical tape clockwise around the caps, and then place the bottles in the cooler with wet ice.
- Keep chilled samples (water chemistry and chlorophyll-*a* filter) on wet ice until shipment (daily).
- Keep the atrazine samples chilled on wet ice in the field and then refrigerate until shipment (batched weekly).

NMED Exhibit 36

- Keep the algal toxins, eDNA, and fecal indicator samples chilled on wet ice in the field and FREEZE as soon as practicable. Keep frozen until shipping (batched weekly).

**** The enterococci sample does not get tape around the cap and the sample label is not placed on the sample bottle. This sample will be shipped on dry ice.**

8.5 Data Forms and Sample Inspection

After the **Assessment** form is completed, the Field Crew Leader reviews all of the data forms and sample labels for accuracy, completeness, and legibility. The other crew member inspects all sample containers and package them in preparation for transport, storage, or shipment.

Ensure that all required data forms for the lake have been completed. Confirm that the Site ID, crew ID, and date of visit are correct. On each form, verify that all information has been recorded accurately and comments are used to explain data as needed. After reviewing each form, select the red circle at the top, which will turn green after selection. This is an indication to the crew that the form has been reviewed, but forms can be submitted before final review and amended at a later date if needed.

Ensure that all samples are labeled, all labels are completely filled in, and each label is covered with clear tape. NOTE: Do not tape over the enterococci labels. Make sure that all sample containers are properly sealed.

8.6 Launch Site Cleanup

Load the boat on the trailer and inspect the boat, motor, and trailer for evidence of plant material. Clean the boat, motor, and trailer as completely as possible before leaving the launch site. Inspect all nets for pieces of macrophyte or other organisms and remove as much as possible before packing the nets for transport. Pack all equipment and supplies in the vehicle and trailer for transport; keep them organized as presented in the equipment checklists (APPENDIX A: EQUIPMENT & SUPPLIES). Lastly, be sure to clean up all waste material at the launch site and dispose of or transport it out of the site if a trash can is not available. See Section 4.3 for additional information and follow appropriate state, tribal or other applicable protocols.

NMED Exhibit 36

9.0 FIELD QUALITY CONTROL

Standardized training and data forms provide the foundation to help assure that data quality standards for field sampling are met. These methods for field sampling and data collection are the primary guidelines for all cooperators and field crews. In addition, repeat sampling and field evaluation and assistance visits will address specific aspects of the data quality standards for the NLA 2022.

9.1 Revisit Site

Approximately 10% of the target sites visited (96 lakes) will be revisited during the same field season by the same field crew that initially sampled the lake. If a site selected for repeat sampling is dropped, then the alternate site assigned to replace it should be revisited. The NLA 2022 Site Evaluation Guidelines provides further information regarding the replacement of revisit sites. The primary purpose of this "revisit" set of sites is to provide variance estimates that can be used to evaluate the survey design for its potential to estimate status and detect trends in the target population of lakes. The time period between the initial (Visit 1) and repeat visit (Visit 2) to a lake must be at least two weeks and should be as long as possible.

Visit 2 will include the full set of indicators and associated parameters with two notable exceptions. A fecal indicator blank will be collected at Visit 1 only and human health fish tissue will only be collected at only one of the two site visits. Crews should collect fish during Visit 1 for a revisit site, to allow for a second opportunity if fish cannot be collected during the first visit. If the crew collects fish on Visit 1, they do not need to collect fish on Visit 2. If they are unable to collect fish on Visit 1, the crew should collect fish on Visit 2.

9.2 Field Evaluation and Assistance Visits

No national program of accreditation for field work currently exists. For this reason, a rigorous program of field evaluation and assistance visits has been developed to support the NLA 2022.

9.2.1 General Information

Evaluation and assistance visits will be conducted with each field crew early in the sampling and data collection process, if possible, and corrective actions will be conducted in real time. These visits provide both a quality check for the uniform evaluation of the data collection methods and an opportunity to conduct procedural reviews, as required, minimizing data loss due to improper technique or interpretation of field procedures and guidance. Through uniform training of field crews and review cycles conducted early in the data collection process, sampling variability associated with specific implementation or interpretation of the protocols will be significantly reduced. The assistance visit also provides the field crews with an opportunity to clarify procedures and offer suggestions for future improvements based on their sampling experience preceding the visit. The field evaluations, while performed by a number of different supporting collaborator agencies and participants, will be based on the uniform training, plans, and checklists. This review and assistance task will be conducted for each unique field crew collecting and contributing data under this program; hence no data will be recorded to the project database that was produced by an 'unaudited' process or individual. The field evaluations will be based on the evaluation plan and field evaluation checklist. The checklist will be made available to all parties associated with NLA.

NMED Exhibit 36

One or more designated EPA, state, or contractor staff members who are qualified in the procedures of the NLA 2022 field sampling operations will visit trained state, tribal, contractor, and EPA field sampling crews during sampling operations on site. If membership of a field crew changes, and at least two of the members have not been evaluated previously, the field crew must be evaluated again during sampling operations as soon as possible to ensure that all members of the field crew understand and can perform the procedures.

The purpose of this on-site visit will be to identify and correct deficiencies during field sampling operations. The process will involve the following preparation steps and field day activities .Additionally, conference calls with crews may be held approximately every two weeks to discuss issues and clarifications as they come up throughout the sampling season.

9.2.2 Preparation Activities

1. Each Field Crew Evaluator will schedule an assistance visit with their designated crews in consultation with the QA Officer, Regional NLA Coordinator, and respective Field Sampling Crew Leader. **Evaluators should be prepared to spend additional time in the field if needed (see below).** Ideally, each Field Crew will be evaluated within the first two weeks of beginning sampling operations, so that procedures can be corrected or additional training provided, if needed.
2. Each Field Crew Evaluator will ensure that field crews are aware of their visit plans and all capacity and safety equipment will be provided for the Field Crew Evaluator.
3. Each Field Crew Evaluator will need to bring along the following in Table 9-1.

Table 9-1 Equipment and supplies – field evaluation and assistance visits.

Type	Item	Quantity
Form	Field Evaluation and Assistance Visit Checklist (sent from EPA)	1
Documentation	NLA 2022 Field Operations Manual	1
	NLA 2022 Quality Assurance Project Plan	1
	Clipboard	1
	Pencils (#2, for data forms)/Pen	1
	Field notebook (optional)	1
Gear	Field gear (e.g., protective clothing, sunscreen, insect repellent, hat, water, food, backpack, cell phone)	As needed

9.2.3 Field Day Activities

1. The Field Crew Evaluator will review the Field Evaluation and Assistance Visit Checklist with each crew during the field sampling day and establish and plan and schedule for their evaluation activities for the day.
2. The Field Crew Evaluator will view the performance of a field crew through one complete set of sampling activities as detailed on the checklist.
    - Scheduling might necessitate starting the evaluation midway on the list of tasks at a site, instead of at the beginning. In that case, the Field Crew Evaluator will follow the crew to the next site to complete the evaluation of the first activities on the list.

NMED Exhibit 36

- If the field crew misses or incorrectly performs a procedure, the Field Crew Evaluator will note this on the checklist and *immediately point this out so the mistake can be corrected on the spot*. The role of the Field Crew Evaluator is to provide additional training and guidance so that the procedures are being performed consistently with the FOM, all data are recorded correctly, and paperwork is properly completed at the site.

3. When the sampling operation has been completed, the Field Crew Evaluator will review the results of the evaluation with the field crew before leaving the site (if practicable), noting positive practices and problems (i.e., weaknesses [might affect data quality]; deficiencies [would adversely affect data quality]). The Field Crew Evaluator will ensure that the field crew understands the findings and will be able to perform the procedures properly in the future.
    - The Field Crew Evaluator will review the list and record responses or concerns from the field crew, if any; on the checklist (this may happen throughout the field day).
    - The Field Crew Leader will sign the checklist after this review.

9.2.4 Post Field Day Activities

1. The Field Crew Evaluator will review the checklist that evening and provide a summary of findings, including lessons learned and concerns.
    - If the Field Crew Evaluator finds major deficiencies in the field crew operations (e.g., less than two members, equipment, or performance problems) the Field Crew Evaluator must contact the EPA NLA 2022 Project Lead. The EPA NLA 2022 Project Lead will contact the EPA Technical Lead for the Human Health Fish Fillet Contaminants Indicator in OST and the EPA NARS QA Project Officer to determine the appropriate course of action.
2. The Field Crew Evaluator will retain a copy of the checklist and submit to the NLA logistics lead.
3. The EPA NLA 2022 Project Lead and EPA NARS QA Project Officer or authorized designee will review the returned Field Evaluation and Assistance Visit Checklist, note any issues, and check off the completion of the evaluation for each field crew.

9.2.5 Summary

Table 9-2 summarizes the plan, checklist, and corrective action procedures.

Table 9-2 Summary of field evaluation and assistance visit information.

Field Evaluation Plan	The Field Crew Evaluator: • Arranges the field evaluation visit in consultation with the QA Officer, Regional NLA Coordinator, and respective Field Sampling Crew Leader, ideally within the first two weeks of sampling • Observes the performance of a crew through one complete set of sampling activities • Takes note of errors the field crew makes on the checklist and immediately point these out to correct the mistake • Reviews the results of the evaluation with the field crew before leaving the site, noting positive practices, lessons learned, and any concerns
Field Evaluation Checklist	The Field Crew Evaluator: • Observes all pre-sampling activities and verifies that equipment is properly calibrated and in good working order, and protocols are followed • Checks the sample containers to verify that they are the correct type and size, and checks the labels to be sure they are correctly and completely filled out

NMED Exhibit 36

	• Confirms that the field crew has followed NLA protocols for locating the lake and determining the index site on the lake • Observes the index site sampling, confirming that all protocols are followed • Observes the littoral sampling and habitat characterization, confirming that all protocols are followed • Records responses or concerns, if any, on the Field Evaluation and Assistance Checklist
Corrective Action Procedures	• If the Field Crew Evaluator's findings indicate that the Field Crew is not performing the procedures correctly, safely, or thoroughly, the Evaluator must continue working with this Field Crew until certain of the crew's ability to conduct the sampling properly so that data quality is not adversely affected. • If the Field Crew Evaluator finds major deficiencies in the Field Crew operations the Evaluator must contact the EPA NLA 2022 Project Lead who, in turn, must contact the EPA Technical Lead for the Human Health Fish Fillet Contaminants indicator if any of the major deficiencies relate to this indicator.

NMED Exhibit 36

10.0 EPA Regional and Contracted Crews Only: Endangered Species Act Conservation Measures

A generally applicable element of all NLA sampling is that field crews make every effort not to disrupt nontarget habitats. NLA protocols are specifically designed to sample target lakes, ponds and reservoirs and to avoid non-target habitats (e.g., rivers, marine, riparian, and wetlands). This section identifies conservation and mitigations measures that are to be performed by EPA regional and contracted crews (EPA crews) at all sites where federally listed species under the Endangered Species Act (ESA) are possible, as appropriate. Before sampling or accessing an NLA site, EPA field crews will receive a list of their sites screened for ESA-listed species possible at the sites. Crews will use this information to familiarize themselves with the ESA species and to implement appropriate conservation measures. Any additional ESA documentation used to supplement the EPA provided ESA information, such as contact between the crew and local U.S. Fish and Wildlife Service office ("FWS" or "Service"), will be retained and provided electronically to the NLA ESA lead periodically throughout the field season.

The below mitigations are not an exhaustive list of requirements for EPA crews. Crews are expected to implement any additional conservation measures required by local permit. Crews should also be aware of any relevant and reasonable state conservation measures, these may be completed at the discretion of the crew lead. Field crew leads are expected to be cognizant of the federally listed species, listed species critical habitats, and state species of concern that have the potential to occur at or near a given sampling site, including habitats that will be used to access the sampling site. They are responsible for making their crew members aware of potential occurrences of listed species and their critical habitat. Efforts should be made to minimize risks to listed species and their critical habitats and avoid the take of listed species while implementing the NLA field protocols. For sites without ESA listed species possible, the following mitigations are not required.

10.1 Always Applicable

- Crews refrain from intentionally targeting known ESA species in any way (handling, harassing, feeding etc.).
- If a known or suspected ESA-listed species is accidently encountered while sampling, it will be returned as quickly as possible to the appropriate habitat and away from further sampling pressures.
- Any samples taken as part of the NLA survey protocol will be inspected carefully for the presence of ESA organisms or other resources from listed taxa groups that could be associated with collecting a non-listed species (such as glochidia on fish gills on a collected sample). Any samples collected must be carefully inspected for their presence and, if found, removed prior to sample preservation.
- Crews will wait to allow a listed species to naturally move away from the sampling area (do not herd or harass).
- All encounters with any ESA species are to be recorded in the **Federal ESA** form in the NLA App, which documents the species, number of individuals, the encounter type, and the disposition of the individual after the encounter.

NMED Exhibit 36

10.2 When Entering or Leaving a Site and Shorline Activities

- Be aware of the habitat requirements for each life cycle stage and avoid unnecessary activity within that habitat. Crews are to limit damaging ESA species habitat when accessing or working a site.
    - Whenever available crews will use existing roads, pathways, or trails to the sampling site for activities including transporting equipment and boats. Crews will adhere to a "stay on trail" rule and refrain from roaming from designated pathways. If a trail is not available, crews will attempt to navigate to and from the site on durable surfaces which can tolerate repeated trampling. If no areas can be found that would tolerate repeated trampling without notable impacts, then crews are to walk in a single file line to and from the site whenever possible.
- When walking through or at a site, avoid stepping on vegetation mounds or holes which may contain listed reptiles, nests, or burrowing species. Whenever possible, avoid areas where listed species are congregating.
- Crews will utilize public boat docks whenever possible. Private boat docks can also be used with owner permission.
- Before putting a vessel or sampling equipment in the water, visually investigate the area for ESA species and avoid areas where observed ESA are present.
- Special Consideration: Shoreline, burrowing and sub-surface nesting ESA species possible
    - Piping Plover and other listed birds which utilize ground nesting in sandy areas: in addition to the applicable species-specific mitigations listed in FWS documentations, crews are to avoid traversing across a beach or sandy area if such species may be present. If an area is cordoned off, crews are not to enter a closed area.
    - When walking through or at a site, avoid stepping on vegetation mounds or holes which may contain listed reptiles, nests, or burrowing species (see below for more information).

10.3 Index Site Activities

Listed species that may be encountered are fish, birds, mammals, invertebrates, amphibians, and reptiles.

- Prior to introducing any equipment that disturbs the water column or aquatic habitat, the area should be carefully inspected for the presence of listed species. Avoid collecting or disturbing listed species.

10.4 Littoral Activities

Listed species that may be encountered are fish, freshwater mussels (Unionidae and Margaritiferidae), birds, mammals, invertebrates, amphibians, and reptiles.

- Prior to introducing any equipment that disturbs the water column or aquatic habitat, the area should be carefully inspected for the presence of listed species. Avoid collecting or disturbing listed species.
- Follow all freshwater mussel handling and documentation protocols in Section 6.4.

EPA Regional and Contracted Crews Only: Endangered Species Act Conservation Measures

NMED Exhibit 36

10.5 Lake Wide Activites: Fish Sample Collection

10.5.1 Sites with ESA fish possible

- When identifying a suspected fish ESA-listed species, each individual of the species is to be kept in their own bucket of fresh water. The water in the bucket is to be obtained from the collection site. The species will only be kept in the bucket for the time it takes to quickly and urgently identify that species and to provide recovery time as needed. During identification, each individual may not be continually handled for more than 1-minutes.
- Crews must not perform active electrofishing for longer than 3 hours.
    - If performing fish sampling at sites where Bull Trout (*Salvelinus confluentus*) are possible, no electrofishing is allowed.
- No gillnetting, trawling, or seining are allowed.
- All other allowable fishing methods should not exceed 4 hours.
- Crews will not perform fishing methods before sunrise or after sunset at sites where encounters with ESA-listed species are possible.
- Crews are to return any ESA-listed fish back into the lake (alive) as quickly as feasible. No ESA fish may be kept for collection.

10.5.2 Sites with ESA freshwater mussles possible (indirect impacts to lake habitat-based bivalves' host fishes)

- Crews must not perform active electrofishing for longer than 3 hours.
- No gillnetting, trawling, or seining are allowed.
- All other allowable fishing methods should not exceed 4 hours.
- Any collected target fish must be inspected for glochidia. If glochidia are found, the fish must be returned alive to the site away from further sampling pressures. All fish with glochidia must be reported in the **Federal ESA** form the app.
    - If glochidia on gills are found, crews are to be very aware of the likelihood of mussels present and make sure to properly execute the mussel conservation methods.

APPENDIX A: EQUIPMENT & SUPPLIES

Base Kit

A Base Kit will be provided to the field crews for all sampling sites that they will go to. Some items are sent in the base kit as extra supplies to be used as needed.

Base Kit Item	Quantity	Protocol
Centrifuge tube (50 mL, screw top) - extras	2	Chlorophyll-*a*
Centrifuge tube stand	1	Enterococci, Chlorophyll-*a*
Electrical tape*	2	General
Filter forceps (flat blade) - extras	6	Enterococci, Chlorophyll-*a*
Filters - Millipore 47mm polycarbonate 0.4 µ (Box of 50)	1	Enterococci
Filters - Whatman 0.7 µm GF/F glass fiber (box of 100)	1	Chlorophyll-*a*
Filtration chamber (with filter holder) - extras	5	Enterococci, Chlorophyll-*a*
Filtration chamber adapter	3	Enterococci, Chlorophyll-*a*
Filtration flask (side arm, 500 mL)	1	Enterococci, Chlorophyll-*a*
Filtration pump (hand vacuum)	1	Enterococci, Chlorophyll-*a*
Filtration flask stopper (silicone)	2	Enterococci, Chlorophyll-*a*
Foil squares (package of 25)*	1	Chlorophyll-*a*
Funnel	1	Water samples Zooplankton Benthics
Gloves (latex/nitrile, non-powdered, box of 100)	1	General
Graduated cylinder (250 mL)	1	Chlorophyll-*a*
HDPE bottle (1 L, white, wide-mouth) – extras	6	Benthics
HDPE bottle (125 mL, white, wide-mouth) – extras	6	Zooplankton
Littoral eDNA collection bottle (125 mL, clear, square) - extras	3	Littoral eDNA collection
Integrated water sampler device (MPCA design)†	1	Water Samples
Kick net (500 µm D-shaped, modified) with 4 foot handle†	1	Benthics
Lugol's solution (250 mL bottle)	1	Phytoplankton
Metric tape measure (8 meter)	1	Secchi Physical Habitat
Microcentrifuge tubes (extras)	5	Enterococci
Packing tape (extra rolls)*	2	General
Packing tape (on holder)*	1	General
Pail (narcotizing/concentrating chamber)	2	Zooplankton
Petri dishes (60x15, disposable)	20	Enterococci
Plankton net course (150 µm; 30 cm diameter net with a 20 cm reducing collar)	1	Zooplankton

NMED Exhibit 36

Base Kit Item	Quantity	Protocol
Plankton net fine (50 µm; 30 cm diameter net with a 20 cm reducing collar)	1	Zooplankton
Plankton net carry case for 2 nets	1	Zooplankton
Plastic tranfer pipette for Lugol's	5	Phytoplankton
Poly bottle (2 L, brown)	1	Chlorophyll-*a*
Rubbermaid action packer	1	General
Secchi disk (20 cm diameter) with weight†	1	Secchi
Sieve bucket (500 µm)†	1	Benthics
Small tote with lid	1	General
Sodium Thiosulfate (25 tablets in vial)	1	Enterococci
Sounding line (50 m, marked in 0.5 m intervals) with clip	1	Depth Secchi Zooplankton
Sounding rod (3 m , marked in 0.1 m increments, PVC, 2-section)†	1	Index Site Depth Physical Habitat
Sounding weight with clip	1	Depth
Spoon (stainless steel)	1	Benthics
Squirt bottle (1 L Nalgene) – for de-ionized (DI) water	1	General
Squirt bottle (1 L Nalgene) – for lake water	1	General
Surveyor's tape (50m)†	1	Depth Physical Habitat
Tape strips (3M, pad of 25)*	6	General
Watchmaker's forceps	1	Benthics

*Items may need to be replenished by field crews during field season
† Item supplied if needed

NMED Exhibit 36

Site Kit

A Site Kit will be provided upon request to the field crews for each sampling site. Please submit an electronic **Request** form well in advance of field sampling to request the Site Kits. Each site kit will also include necessary coolers and shipping supplies for all samples collected.

Site Kit Item	Quantity Per Site Kit	Protocol(s)
Centrifuge tube (50 mL, screw top) in bag	1	Chlorophyll-*a*
CO2 (Alka seltzer) tablets (packet of 2)	1	Zooplankton
Cooler liners (1 per cooler)	-	General
Cubitainer® (4L)	1	Water Chemistry
FedEx Express shipping labels (1 per cooler)	-	Sample shipping
Gloves (latex/nitrile, non-powdered)	4 pair	Sample collection
Filtration unit (sterile 250 mL filter funnel, cap, and filter holder)	1	Enterococci Chlorophyll-*a*
Filter forceps (sterile, flat blade)	2	Enterococci Chlorophyll-a
HDPE bottle (1 L, white, narrow mouth)	1	Phytoplankton
HDPE bottle (60 mL, white, wide-mouth)	1	Atrazine
HDPE bottle (125 mL, white, wide-mouth)	2	Zooplankton
HDPE bottle (1 L, white, wide-mouth)	2	Benthics
Littoral eDNA collection bottle (125 mL, clear, square)	1	Littoral eDNA collection
Enterococci bottle (250 mL, sterile, clear, narrow-mouth)	1	Enterococci collection
HDPE bottle (500 mL, white, wide-mouth)	1	Algal Toxins (MICZ)
eDNA bottle (1 L, clear, square, narrow-mouth)	2	eDNA (Index and Littoral)
Phosphate buffered saline (sterile PBS)	1	Enterococci
Microcentrifuge tubes w/glass beads (in bubble & Zip bags)	2	Enterococci

Human Health Fish Sampling Kit

A **human health fish sampling kit** will be provided to the field crews for designated human health fish sampling sites (separately from site kits). Please submit an electronic **Request** form **well in advance** of field sampling. Kits must be requested at least two weeks before sampling is to take place. Prior to sampling, inspect each site kit to ensure all supplies are included. These human health fish sampling kits include:

Human Health Fish Sampling Kit Item	Quantity
Aluminum foil (solvent-rinsed and oven dried)	5 packs
Cable ties	24
Cooler	1
Dry ice Shipping Label	1
FedEx airbill (Pre-addressed)	1
Frequently Asked Questions handout	1
Heavy-duty food grade polyethylene tubing	1 roll
Large plastic composite bag	1
Nitrile gloves	10
NLA 2022 Human Health Fish Fillet Contaminants Site List	1
Tyvek tag	1

Electronic Forms & Labels

Apple iPads Labels will be supplied by the NARS IM Center upon request.

Item	Quantity	Protocol
Apple iPads: Field forms packet (paper backup copies as needed): NLA 2022 Verification NLA 2022 Profile Calibration NLA 2022 Profile Data NLA 2022 Index Samples NLA 2022 Littoral Samples NLA 2022 Physical Habitat NLA 2022 Assessment NLA 2022 Tracking NLA 2022 Whole Fish Sample NLA 2022 Federal ESA	2 1	General General

Field Crew Supplied Equipment

This equipment will need to be supplied by the field crew. Some items are optional.

Field Crew Supplied Item	Quantity	Protocol(s)
Access instructions	1	Site Evaluation
Access permission documents/permit (if required)	1	Site Evaluation
Barometer or elevation chart to use for calibration	1	Calibration
Binoculars	1	Physical Habitat
Bleach (or bleach alternative)	1	General
Buckets (5 gallon capacity, plastic)	2	Benthic Macroinvertebrates
Buoy (for marking observation point)	1	Physical Habitat
Calibration cups and standards (for multi-parameter meter)	1	Calibration
Calibration QC check solution (for multi parameter meter, pH and conductivity)	1	Calibration
Clinometer	1	Physical Habitat
Clipboard	1	General
Depth Finder (hand-held or boat mounted sonar)	1	Index Site Profile Physical Habitat
Electronic data capture devices (tablet/phone/computer) with NARS App and extra battery pack (if needed)	1-2 (optional)	General
Ethanol (95%)		Benthic Macroinvertebrates Zooplankton
Field gear (e.g., protective clothing, sunscreen, insect repellent, hat, water, food, backpack, cell phone)		General
Field notebook - optional	1	General

NMED Exhibit 36

Field Crew Supplied Item	Quantity	Protocol(s)
Field thermometer (not mercury)	1	Calibration
Fishing gear (e.g., electrofishing unit, fishing rods, nets, livewell and/or buckets, measuring board etc.)		Whole Fish Sample
GPS unit (with manual, reference card, extra battery)	1	Lake Verification Index Site Coordinates Physical Habitat
Kick net (500 µm D-shaped) with 4 foot handle (spare)	1	Benthic Macroinvertebrates
Laser rangefinder (for estimating drawdown) - optional	1	Physical Habitat
Map wheel or string (for measuring shoreline distances on site map)	1	Physical Habitat
Multi-parameter water quality meter (with temperature, pH, and DO probes)	1	Index Site Profile
Multi-parameter communication cable (50 m)	1	Index Site Profile
Net(s) and/or bucket assembly for end of net (spares)	1	Zooplankton
NLA 2022 Fact Sheets	20	General
Pen	1	General
Pencils (#2, for data forms)	2	General
Permanent marker (fine tip, for labels)	2	General
Scissors	1	General
Shipping tape	1	Shipping
Surveyors rod - optional	1	Physical Habitat
Water (deionized)		General

Boat Equipment List

This is suggested boat equipment.

Item
Anchor (with 75 m line or sufficient to anchor in 50 m depth)
Boat horn
Boat plug (extra)
Bow/stern lights
Emergency tool kit
Fire extinguisher
First aid kit
Gas Can
Hand bilge pump
Life jackets
Motor
Oars or paddles
Second anchor for windy conditions and littoral sampling (w/ 75m line)
Sonar unit

NMED Exhibit 36

Spare prop shear pin
Type IV PFD (throwable life saving device)

NMED Exhibit 36

APPENDIX B: SHIPPING GUIDELINES

General Shipping Guidelines

Samples will be shipped by the field crews according to the chart below. The Field Crew Leader will complete the appropriate section(s) of the **Tracking** form for the samples and will submit tracking via the NLA App. The Field Crew Leader will place the samples and the packing slip (in a waterproof bag or plastic sleeve) in the shipment cooler, and then the Field Crew Leader will attach the appropriate pre-addressed FedEx label from the site kit or cooler marked for the appropriate lab. The field crew will either drop off the cooler for shipment at a local FedEx location or arrange for a pick up at the hotel or other appropriate facility. If the field crew has chosen a pick up, they must follow up with the facility at which it has been left and/or track the package through FedEx tracking tools to ensure that the shipment cooler has actually been picked up by FedEx. Once the package is in the possession of FedEx, the IM Team and Field Logistics Coordinator (FLC) will track the package to its destination and take steps necessary to ensure timely delivery.

A packing slip must be filled out to accompany each sample shipment. Be very careful to fill in the information correctly and legibly, especially the Site ID. When using a packing slip that was paired with a sample label sheet, the Sample ID numbers will be pre-printed on the packing slips. The packing slip is to be placed in a resealable plastic bag/pouch secured to the inside of the cooler lid. Seal the shipping container with clear packing tape. In the NLA App, fill in the shipping details in the pertinent section(s) of the **Tracking** form and submit the **Tracking** form to the NARS IM Center to indicate that samples will be in transit to the laboratory. The **Tracking** form must be submitted the same day that the samples are shipped.

Before shipping, it is very important to preserve each sample as directed in the sample collection portion of the appropriate chapter in the NLA 2022 FOM. General directions for sample processing, shipping and tracking are found below:

- Preserve the samples as specified for each indicator before shipping.
- Be aware of the holding times for each type of sample.
- Always line the cooler with a heavy duty plastic bag (cooler liner) when shipping preserved samples or when shipping wet ice.
- When shipping frozen batched samples, use the foil-backed dry ice liner and foam pad inside the cooler.
- When shipping with dry ice, it’s best to layer or intermix dry ice and samples to increase the contact between samples and dry ice.
- When shipping samples preserved with ethanol, surround the jars with crumpled newspaper or other absorbent material.

When wet ice is used for shipment:

- Ensure that the ice is fresh before shipment and use adequate amounts of ice to ensure samples will remain cold for up to 48 hours.
- Place samples and all ice inside the cooler liner and seal the cooler liner to avoid leakage of melted ice.

- Secure the cooler with clear packing tape.

When dry ice is used for shipment:

Note: Not all FedEx locations will accept shipments containing dry ice. Dry ice shipments can be shipped from "FedEx staffed" locations, which is how these locations are referred to online. You can also arrange for a pick-up from your lab or hotel. Dry ice shipments usually cannot be shipped from FedEx Office® locations, FedEx Retail locations such as Walgreens/Walmart/OfficeMax, or at FedEx Authorized ShipCenter® locations. These types of locations are differentiated on FedEx.com in the "Find FedEx Locations" feature. Please be sure to call in advance to ensure your location will accept the package for shipment.

- Label the cooler with a Class 9 Dangerous Goods label
    - Place the label on the front side of the cooler, not the top.
    - If it is not already completed, fill out the upper corners of the label with the shipper and recipient information as on the FedEx airbill.
    - Declare the weight (in kg) of the dry ice in the lower right hand corner of the label, ensuring it is the same weight listed on the airbill.
- Ensure that the dry ice is fresh before shipment, and use adequate amounts of dry ice to ensure samples will remain frozen for up to 48 hours.
- Secure the cooler with clear packing tape. Do not completely seal the entire edge of the cooler such that the pressure inside the cooler could build.
- Place the provided FedEx airbill on the top of the cooler or on a handle tag secured to one of the cooler's handles.
    - Ensure the label indicates the amount of dry ice in the package and matches the weight listed on the dry ice label.

Tracking Forms and Shipment Types

Whenever NLA samples are shipped, one or more sections of the **Tracking** form is completed to relay important shipping information to the IM Team, FLC and the destination lab. The **Tracking** form is submitted electronically at the time of shipping and a packing slip is included as a hard copy in the shipping container with the samples.

Each section for the **Tracking** form has been assigned a "T" number to help crews identify the correct section of the form to use when sending samples. This "T" number is located on the top of each tracking form section). Crews will also find reference to the same "T" numbers on the individual sample labels and on the top of the pre-printed FedEx return labels provided in the site kits or with batch coolers. The FedEx return labels are pre-paid and allow crews to ship samples to any of the nationally contracted laboratories. States using their own labs for certain samples will need to arrange for shipping on their own.

When crews order site kits (via the **Request** form), a set of packing slips will accompany each set of labels in the site kit. Sample IDs for the suite of samples collected at a single site will be pre-populated

NMED Exhibit 36

on both the labels and the packing slips. By entering the water chemistry sample ID in the **Tracking** form, the rest of the sample IDs will auto-populate in the **Tracking** form. It is important to keep the labels and packing slips organized so the sample IDs will match when shipping occurs.

Crews include the pertinent packing(s) slip in the cooler (placed in the plastic sleeve affixed to the inside of the cooler lid) when they send samples to the labs, and they also must submit the completed section of the **Tracking** form that is associated with that sample shipment via the NLA App. If a cooler contains samples from more than one site, then multiple packing slips must be placed in the cooler and the **Tracking** form for each site must be submitted.

When a crew visits a site with the intent to sample, they complete and submit the **Verification** form via the NLA App. It is very important to submit this form as soon as possible after every attempted sampling event to provide key items such as the date of the event, the crew ID, and whether the site wa ssampled. Prompt status reports allow the FLC to closely track sampling progress. More importantly, it enables NARS IM to track samples that were collected at each successfully sampled site versus those that were not, and to immediately track the shipment of the time-sensitive samples after each sampling event. Submitting the **Verification** form is crucial to report the date of a completed sampling event and must be submitted (along with sample tracking information) on the same day that samples are shipped.

Procedure for filling out and submitting tracking via the App

1. After ensuring all of the samples to be shipped are properly preserved and prepared for shipment, access the **Tracking** form in the App.
2. Ensure the correct water chemistry sample ID has been entered at the top of the form. Doing so will populate the sample IDs of all other collected samples. Samples that were not collected will display a blank sample ID field and the not collected bubble will be transferred from the individual sample collection forms. The not collected bubbles are not editable in the **Tracking** form; to change the collection status of a sample, access the pertinent sample collection forms (e.g., Index Samples, Littoral Samples, and/or Whole Fish Sample forms).
3. In the pertinent section of the **Tracking** form , check the box under the 'To Ship' column for each sample being sent in the shipment.
4. Click the 'Enter Shipping Details' button and fill out the resulting popup window with the destination lab, date shipped, tracking number, sender and sender's phone number.
5. Click the 'save shipping info' button to save the details and the **Tracking** form .
6. Once the shipping details have been saved in the App, a date will appear in the shipped column of the **Tracking** form . If the shipping details for a sample need to be edited, click the date in the shipped column to access the saved shipping details. Editing the details in this manner changes ONLY one sample at a time. The only way to enter shipping details for an entire group of samples is during the initial details entry.
    a. If the status of the sample needs to change from shipped to **not** shipped, click the date in the shipped column to access the saved shipping details and delete all the shipping info. Click the "save shipping info" button after deleting all the shipping information.

NMED Exhibit 36

The sample will no longer be marked as shipped and the "to ship" checkbox will reappear.

7. After all pertinent shipping details have been saved, click the SUBMIT menu button and select the button next to 'Tracking' and any other the forms that you wish to submit. Click the green submit button at the bottom of the form list. An email will pop up on your device addressed to NARSFieldData@epa.gov. Copy yourself, any other crew members or managers and click send. To ensure that he email was sent, check the SENT mailbox on your email app and look for the recent email containing the data. If the email is not in the SENT mailbox, it was not sent and you should try again after verifying an internet connection.
8. At any point, if it is determined that data needs to be revised or updated, crews should feel free to do so in the App and re-submit any edited data or tracking forms using the steps above. Newly revised data will automatically take the place of previous data. It is not necessary to re-submit data or tracking forms that were unchanged however.
9. After submission, a data summary will be automatically emailed back to the email address from which the submission was received. The Field Crew Leader or his/her designee should review this data summary for accuracy and make any corrections necessary and re-submit the pertinent form(s).

Shipping Groups:

T-1 – Daily Water Chemistry Samples

- Complete the T-1 section of the **Tracking** form for the samples that are shipped immediately after each sampling event (e.g., same day as sampling or the next day):
  - water chemistry
  - chlorophyll-*a*
- These samples are shipped together in the site kit cooler with a heavy duty liner bag and ample wet ice.
- Samples from two sites may be shipped together in a single cooler if they were collected on the same day.
- Send the **Tracking** form and all data forms from the site to the IM Team via the NLA App.
- Ship all of the samples to the lab in the same cooler with the packing slip that was provided with the label packet. If any sample listed on the packing slip is not being shipped, line out the sample ID to indicate that the sample is not in the cooler. If samples from multiple sites are shipped together, then multiple packing slips must be used.
- Samples need to be shipped on as much fresh wet ice as will fit in the cooler liner. Water chemistry and chlorophyll-*a,* samples should be shipped within 24 hours of collection (i.e., the same day as sampling or the following day).

T-2 – Frozen Batched Samples

- Complete this section of the **Tracking** form when shipping the frozen batched samples:
  - Enterococci (frozen)
  - eDNA (index and littoral; frozen)

- algal toxins (frozen)
- atrazine (chilled)

- These samples are shipped together in a cooler (ordered via the **Request** form) with a two-piece dry ice liner and 20 pounds of dry ice.
- 2-3 site's worth of samples may be shipped together in a single cooler.
- Ship all of the samples to the lab in the same cooler with the packing slip that was provided with the label packet. If any sample listed on the packing slip is not being shipped, line out the sample ID to indicate that the sample is not in the cooler. If samples from multiple sites are shipped together, then multiple packing slips must be used.
- To pack the T2 cooler:
    1. Place the foam pad in the bottom of the T2 cooler and line the cooler with the foil-backed dry ice liner.
    2. Place frozen samples from up to three sites and dry ice (approximately 20 lbs) inside the dry ice liner, intermixing samples and dry ice.
    3. Please the enterococci samples on top of the frozen bottles to prevent damage during shipping.
    4. Place the foil-backed separator pad on top of the frozen samples and dry ice creating a thermal barrier within the cooler.
    5. Place the chilled atrazine samples (up to 3) inside the atrazine sleeve and insert the foam plug into the end of the sleeve.
    6. Place the sleeve ON TOP of the second foam pad inside the dry ice liner (such that the foam pad is used as a separator between the dry ice and the atrazine samples).
    7. Close the "lid" portion of the dry ice liner.
    8. Insert the T2 packing slip(s) into the provided pouch inside the cooler lid.
    9. Close the cooler lid, taping and applying FedEx shipping label as usual.
- Frozen batched samples should be shipped at least every week.
- In cases where a state lab is processing some, but not all of the samples, first select “To Ship” checkboxes for the samples being sent to the national lab and select the appropriate lab in the shipping details popup window. The T-2 packing slip should be placed in the cooler being shipped to the national lab and should only indicate the sample(s) being shipped in that cooler. Line out the sample IDs to indicate which samples are not in the cooler. Select “To Ship” checkboxes for the remaining samples being sent to the state lab and select the appropriate lab in the shipping details popup window.
- Verify the sample IDs for the sample(s) being shipped.
- Submit the **Tracking** form to NARS IM in the NLA App using the steps above.

NMED Exhibit 36

T-3 – Non-Chilled Batched Samples

- Complete this section of the **Tracking** form for shipping batches of non-chilled samples:
  - Benthic macroinvertebrates
  - Zooplankton (course and fine)
  - Phytoplankton
- These samples are shipped together in a cooler (ordered via the **Request** form) with a heavy duty liner bag and no ice.
- The number of samples that will fit in a cooler will depend largely on the number of benthos bottles collected from each site. In most cases, samples from three to six site visits will fit in a cooler together. NEVER split samples from one site into more than one cooler.
- Ship all of the samples to the lab in the same cooler with the packing slip that was provided with the label packet. If samples from multiple sites are shipped together, then multiple packing slips must be used.
- Place 1-liter benthos bottles upright in the lined cooler and use newspaper or cardboard to fill any empty space between benthos bottles to keep them in an upright position during shipping.
- Place bagged zooplankton bottles on top of the upright benthos bottles.
- Non-chilled batched shipped samples should be shipped within two weeks of collection.
- In cases where a state lab is processing some, but not all of the samples, first select “To Ship” checkboxes for the samples being sent to the national lab and select the appropriate lab in the shipping details popup window. The T-3 packing slip should be placed in the cooler being shipped to the national lab and should only indicate the sample(s) being shipped in that cooler. Line out the sample IDs to indicate which samples are not in the cooler. Select “To Ship” checkboxes for the remaining samples being sent to the state lab and select the appropriate lab in the shipping details popup window.
- Verify the sample IDs for the sample(s) being shipped.
- Submit the **Tracking** form to NARS IM in the NLA App using the steps above.

***NOTE**: Federal regulations and FedEx rules allow for ground shipping of certain quantities of flammable liquids WITHOUT the need for special certifications and labeling. Flammable liquids may NOT be shipped via air carrier unless shipper is trained and qualified to do so and specific documentation and labeling requirements are met.*

The Code of Federal Regulations (49 CFR Section 173.150) lists the exceptions which allow shipping of flammable liquids via ground carrier without labeling or special certifications. Ethanol and formalin can be considered to be in either Packaging Group 2 or 3, so we use the more stringent PG 2 as our guideline. The limited quantity exclusion allows ground shipping of PG 2 flammable liquids provided that the individual containers inside the package are not over 1.0 liters each, that the gross weight of the package does not exceed 66 pounds, and that the outer packaging is a sturdy container. Please ensure that your shipment meets these criteria to ensure the legal ground shipment of these samples.

NMED Exhibit 36

1T4 – Whole Fish Composite Sample – *designated sites only*

- Complete this section of the App tracking form for shipping frozen whole fish tissue samples (FTIS).
- Only one fish composite sample may be shipped in a single cooler.
- Ship the sample to the lab in the whole fish tissue kit cooler with the packing slip that was provided with the label packet.
- Samples need to be shipped with a minimum of 50 pounds of dry ice (blocks of dry ice only).
- Human health fish composite samples should be shipped within 1 week of collection.
- Verify the sample ID for the sample being shipped.
- Submit the **Tracking** form to NARS IM in the NLA App using the steps above.

Table B-1. Sample preservation, packaging, and holding times

Sample Group & Lab	Sample Type	Sample Code	Location	Sample Target Volume	Container	Preparation/ Preservation	Shipping Time Frame	Packaging for Shipping
T-1 – Daily Water Chemistry Samples **WRS Laboratory - Corvallis, OR**	Water chemistry (raw, unfiltered site water)	CHEM	Index	4 L	Cubitainer (4 L)	Wet ice in field	Immediate (ship within 24 hours of sampling)	**Water Chemistry Cooler** with wet ice PRIORITY OVERNIGHT
	Chlorophyll-*a*	CHLX	Index Collection	2 L	Poly bottle (2 L, brown)	Wet ice in field		
			Processing	Stain on filter – max 2 L filtration	centrifuge tube (50 mL), in zip-top bag	Wet ice in field (after filtration)		
T2 – Frozen Batched Samples **GLEC – Traverse City, MI**	Fecal indicator (*Enterococci*)	ENTE	Last habitat station *	200 mL	Sterile 250 mL bottle (clear, square)	Dry Ice	Batch up to one week maximum	**Frozen Batched Cooler** with 2-piece dry ice liner and 20 pounds dry ice PRIORITY OVERNIGHT
	eDNA	FDNA	Index	1 L	Clear square bottle (1 L)	Wet ice in field, freeze ASAP		
		LDNA	Littoral Stations (10) *	1 L	Clear square bottle (1 L)	Wet ice in field, freeze ASAP		
	Algal toxins	MICZ	Index	500 mL	HDPE bottle (500 mL, white, wide-mouth)	Wet ice in field, freeze ASAP		
	Atrazine	TRIA	Index	50 mL	HDPE bottle (60 mL, white, wide-mouth)	Wet ice in field, keep chilled Place chilled in provided sleeve		
T3 – Non-Chilled Batched Samples **GLEC – Traverse City, MI**	Phytoplankton	PHYX	Index	1 L	HDPE bottle (1 L, white narrow mouth)	Lugol's added in field Wet ice in field	Batch up to two weeks maximum	**Non-Chilled Batched Cooler** with absorbent material No Ice GROUND
	Zooplankton (coarse – 150 µm) (fine – 50 µm	ZOCN ZOFN	Index	Vertical tow(s) 5-meter total length	HDPE bottle (125 mL, white, wide-mouth)	95% ethanol added in field		
	Benthic invertebrates	BENT	Littoral Stations (10+) *	All organisms in grabs	HDPE bottle (1 L, white, wide-mouth)	95% ethanol added in field (at least 500 mL per bottle)		
T4 - Whole Fish Composite Sample **Microbac Laboratories, Inc. – Baltimore, MD**	Whole fish	FTIS	Lakewide	5-10 whole fish (minimum fish length 190 mm)	Wrapped individually in solvent rinsed foil Sealed in poly tubing Large outer plastic bag	Dry ice in field, hold in freezer	Ship weekly (except on Fridays, Saturdays, or the day before Federal holidays) to FTIS lab. Only ship one sample per cooler.	**Ship in provided FTIS cooler with 50 pounds of DRY ICE** PRIORITY OVERNIGHT

** At large lakes (lakes over 10,000 hectares) littoral sampling is encouraged but not required. If littoral stations are not visited, BENT will NOT be collected; ENTE and LDNA will be collected at the launch site; LDNA will then be a single 1L grab sample*

APPENDIX D: NLA 2022 HANDPICKED SITES: RESAMPLING OF THE NATIONAL EUTROPHICATION STUDY LAKES

Background

In 1972, the US Congress passed the landmark environmental legislation that became known as the Clean Water Act (CWA). The CWA has become a model for countries around the world and is heralded as the gold standard of environmental legislation. This year, 2022, marks the 50th Anniversary of the CWA, which coincides with the 4th iteration of the National Lakes Assessment (NLA). One hallmark of the CWA was inclusion of monitoring and measuring progress as an integral component to restoration and protection efforts. To that effect, the U.S. initiated a survey in 1972 to measure and report on the acceleration of eutrophication in lakes by assessing nutrient pollution known as the National Eutrophication Survey (NES). Importantly, the year 2022 also represents the 50th Anniversary of this landmark national survey.

Today, the NARS program is an EPA, State and Tribal partnership designed to address the need for monitoring the long-term progress toward the water quality objective and goals of the CWA. Through NARS, EPA and our partners are providing information on the condition and trends in coastal waters, lakes, rivers and streams, and wetlands. As a part of the NLA starting in 2007, ~200 of the original ~800 NES lakes were included as a subpopulation in the survey design and resampled. These ~200 lakes were selected using a probability-based design, similar to the broader NLA, which allowed change estimates to be made for the broader population of ~800 NES lakes. This ~200 lake subpopulation was used to report on the changes in trophic condition in the 2007 report.

As part of the celebration of the 50th Anniversary of the CWA, a resurvey of the NES lakes is taking place in conjunction with the NLA 2022. The statistically valid sampling design for NES sampling since the NLA 2007 survey will allow EPA to track environmental progress by assessing the change in condition of the NES lakes in the intervening 50 years (1972, 2007, 2012, 2017, and 2022). In additions to reporting on the condition of the NES lakes, the NES 2022 resampling will combine field data with watershed information to identify the progress we have made, the challenges we still face, and highlight the importance of water quality in our lives.

Field Crews and Coordination

The NES 2022 will rely on many of the key contacts and coordinators for NLA 2022 (See **Table 2-2**). All ten EPA Regions are supporting the NES field work in addition to the NLA field sampling contractors. In some regions, the field crew leads are the same as the regional NLA coordinator (**Table D-1**).

Project and Data Quality Objectives

NES dataset provides a unique opportunity to assess change in lake condition in the intervening 50 years (1972, 2007, 2012, 2017, and 2022). In addition to the analysis of the filed collected data, analyses will include information on the types of management practices implemented at and near the lakes (wastewater treatment, etc.), population changes and other stressors to evaluate water quality changes in lakes with restoration and protection activities.

The NES 2022 resampling study is designed to address the following objectives:

1. How as the trophic condition of the NES lakes changed in the last 50 years (1972, 2007, 2012, 2017, and 2022). Are conditions better or worse?
2. Have stressors within the watersheds changed since the 1970s?
3. What stressors contribute to the current trophic condition of the NES lakes?

NES Indicators

The original NES study included the collection of lake profile data, water chemistry, chlorophyll -a, and secchi. The NES 2022 resurvey will continue to focus on measurements of trophic condition and will include the NLA indicators identified in **Table D-2.**

Table D-2 NLA 2022 NES site water quality indicators.

Indicator Type	Indicator	NES 1970s	NLA/NES 2007	NLA/NES 2022
Trophic and Chemical Indicators	*Vertical profile measurements* (DO, Temperature, pH)	x	x	X
	Secchi disk transparency	x	x	X
	Water chemistry (NH_4, NO_3), major anions and cations, alkalinity (ANC), DOC, TSS, silica, conductivity, nutrients (total and dissolved TN and TP)	x	x	x
	Chlorophyll-*a*	x	x	x
Human Health	CyanoHAB visual observations at index site and boat launch			x

Indicator Type	Indicator	NES 1970s	NLA/NES 2007	NLA/NES 2022
	Algal toxins (microcystins and cylindrospermopsin)			x
	Phytoplankton (cyanobacteria cell count)		x	x
Other Indicators	eDNA			Water chemistry filter only
	Lake area, basin morphometry, and characteristics of watershed	x	x	x

Study Design

In NLA 2007, 210 NES lakes were included in the survey design and resampled. This subpopulation was used to report on the changes in trophic condition in the 2007 report. The NES 2022 design is a random design of the NES 2007 lakes stratified by EPA Region. Due to resource limitation, all 210 lakes cannot be sampled, therefore we identified the target number of lakes in each Region (**Table D-3**). In Regions with 12 or less lakes, all NES lakes will be targeted for sampling. In Regions with greater than 12 sites, 60% of the lakes will be targeted for sampling. Note that 3 lakes will likely be sampled as part of the NLA probabilistic sampling efforts. The selection of target lakes must happen in the order of the site ID; however, sampling may happen in any order.

Table D-3 Target number of hand-picked lakes for sampling by EPA Region.

Row Labels	NES Lakes per Region	Target # of Sites	Lakes in the NLA 2022 Design	Total # of Target Lakes by Region	Regional sites	Contractor Sites
Region_1	5	5-6	1 (likely)	6	5	0
Region_2	6	6		6	6	0
Region_3	9	9		9	10**	0
Region_4	35	24*	1	25	24*	0
Region_5	48	29		29	28**	0
Region_6	32	19		19	5	14
Region_7	10	10		10	10	0
Region_8	38	23		23	9	14
Region_9	13	13		13	8	5
Region_10	12	11	1	12	6	5
Total	206	146	3	152	82	38

* Region 4 will sample the first 3 oversample lakes given there proximity to the target lakes, increasing the total number of lakes sampled by R4 to 24.

**One OH lake in Region 5 will be sampled by R3.

NMED Exhibit 36

Field Methods and Procedures

Field Crew Training

The NES field crew leads and crew members are encouraged to participate in all portions of the NLA 2022 training. In the event crew members are not able to complete the full training program, below is the required list of training material for NES sampling teams:

1. Review the NLA QAPP, SEG and FOM (see Daily Field Activities below for FOM details)
2. Review the following training videos and take the associated quizzes:
    a. Block 1 – Background (all 4 videos)
    b. Block 2 – Launch sites activities and index sampling (videos 2-1 through 2-5; no zooplankton)
    c. Block 5 – Final lake activities (all 3 videos)
3. Participate in a Q&A session
4. Attend a regional in-person training (requirement for field crew leads only)

The NLA also includes Endangered Species Act (ESA) training for federal field crews. Although the NES sampling does not include the NLA biological indicators that are most likely to effect ESA listed species (i.e., benthic macroinvertebrates and fishing), all NES crew leads are to participate in the training in the event listed species are encountered while in the field.

Daily Field Activities

The NES sampling will include the following field activities:

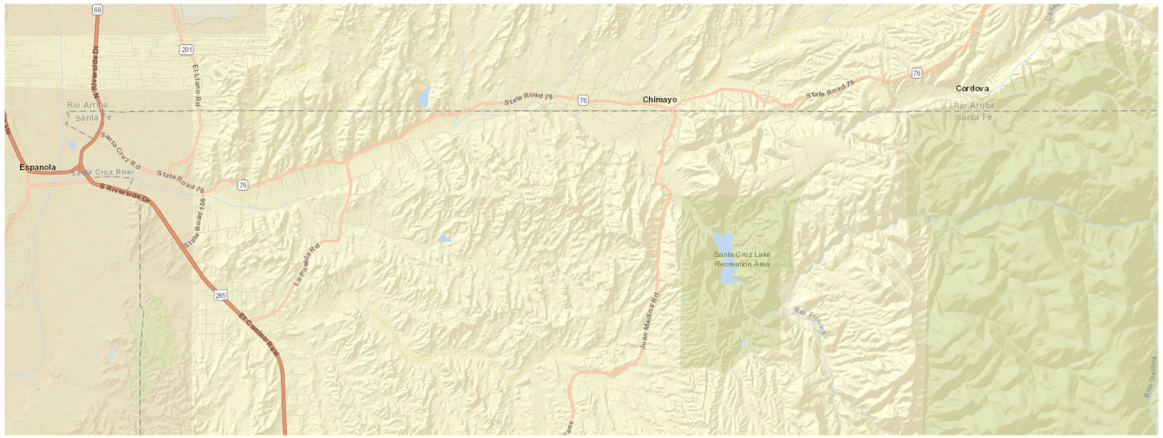
1. All base site activities (see **Section 4.0**).
2. The following index site activities (see **Section 5.0**):
    a. CyanoHABS Visual Assessment
    b. Temperature, DO and pH profile
    c. Secchi Dish Transparency
    d. Water sample collection for chlorophyll-a, phytoplankton, algal toxins and water chemistry
        i. NES sampling <u>will not include</u> the collection of eDNA, atrazine, and zooplankton samples
3. All final lake activities
    a. Filtering only includes the chlorophyll-a sample (see **Sections 8.2.3** and **8.2.4**)

Field Forms and Sample Shipment

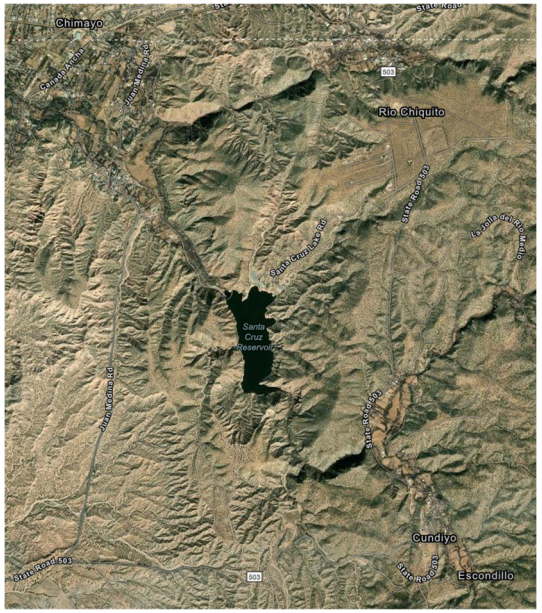
Table D-4 identifies the NLA field forms that will be used for the NES sampling. Many forms will include samples that are not part of NES field work. For the samples that are not collected at NES lakes (i.e., atrazine, all littoral samples, eDNA, zooplankton), the field crew is to identify that no sample was collected in the assoiceated forms. The Physical Habitat form <u>will not</u> be submitted.

NMED Exhibit 36

Table D-4 NES field forms.

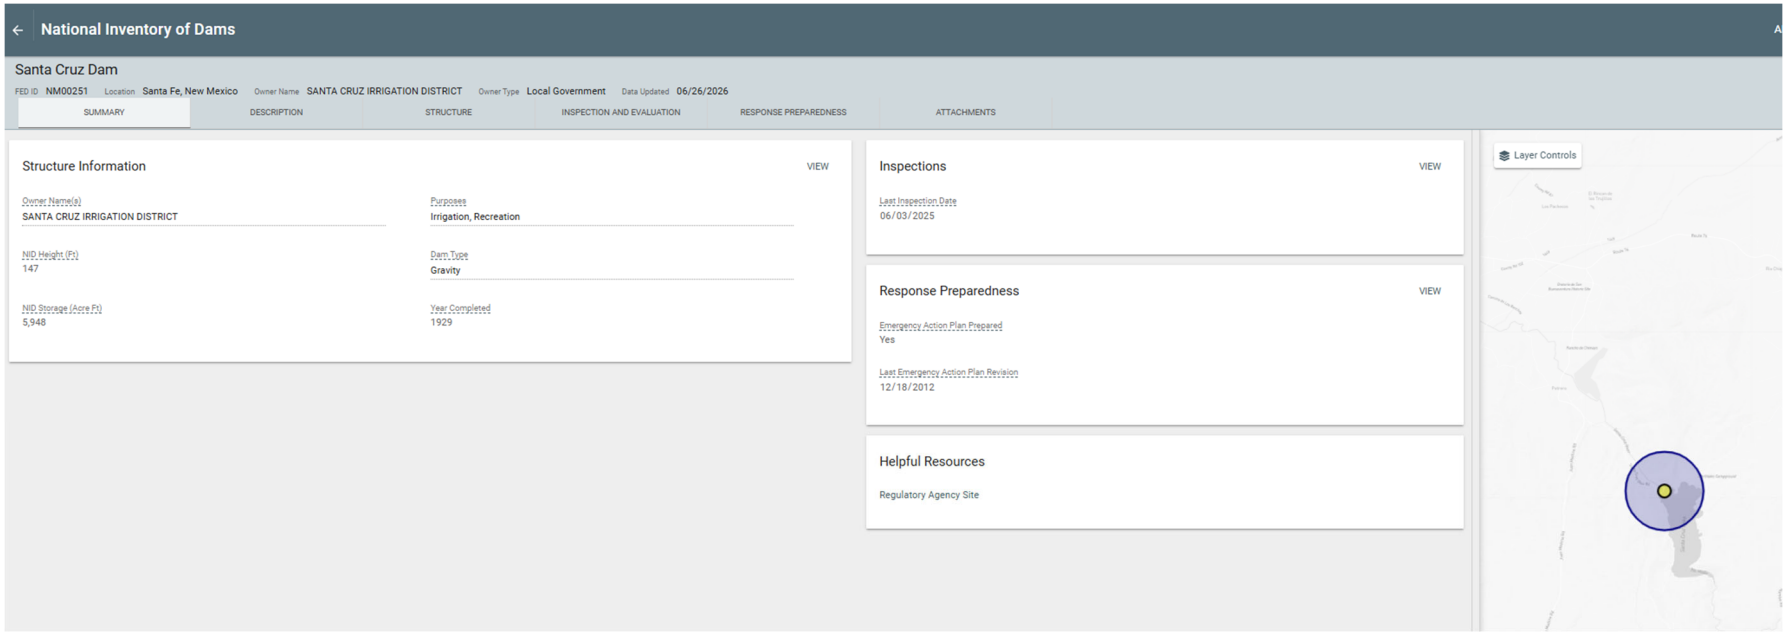


Form	Fill out	Submit?
Verification	Entire form	Yes
Calibration	Entire form	Yes
Index Samples	Entire form; mark FDNA, TRIA, ZOCN, and ZOFN as not collected	Yes
Profile	Entire form	Yes
Littoral Samples	Bottom of form only; mark BENT, LDNA, and ENTE as not collected	Yes
Physical Habitat	None	No
Assessment	Entire form	Yes
Whole Fish Sample	Top of form only; mark 'No'	Yes
Federal ESA	Fill in a pertinent section if an ESA-listed species is encountered	If data are entered
Tracking	T1, T2, and T3 sections when shipping samples from those groups	Yes



Sample shipments will include:

- T-1 (daily water chemistry samples);
- T-2 (frozen batched samples – algal toxins only); and
- T-3 (non-chilled batched samples – phytoplankton only).



See **APPENDIX B: SHIPPING GUIDELINES** for additional details.

New Mexico Department of Game and Fish

Conserving New Mexico's Wildlife for Future Generations

2022 Statewide Fisheries Management Plan

Approved by the New Mexico State Game Commission on June 17, 2022

This plan is supported by

NMED Exhibit 38

Welcome to the Fisheries of New Mexico!

In 2016 the Department published its first comprehensive Statewide Fisheries Management Plan. The intent of the Plan was to provide the public and our partner agencies with a clear roadmap for our plans to manage fisheries across the state. It established population management parameters for a number of sportfish species and laid out a management approach for nearly all of the waters in the state. At the time of its publication, the Department described it as "as summary of the conventional knowledge, vision, and decades of work by the Department and its partners who work to conserve our aquatic resources." As with any plan, the Statewide Fisheries Management Plan requires occasional updates in order to continue to reflect contemporary knowledge and vision for the management of our extraordinarily diverse fisheries. With this update our aim is to highlight accomplishments since 2016, refine species management parameters, identify changes in management approaches to specific waters, describe regulatory and administrative updates, and lay out new ideas for fisheries and their management. We have also added an index of waterbodies to the end of this update that will help readers find information about specific waters within the Plan.

The years since publication of the 2016 Plan have brought plenty of challenges to New Mexico's diverse angling opportunities. Some of these challenges, like drought, are familiar while others are completely novel. The global pandemic that resulted from the spread of Covid-19 touched all aspects of life in New Mexico and fishing was no exception. The Department saw a modest increase in fishing license sales from 2019 to 2020 but with access to popular angling locations undergoing an array of ever-changing closures and many people engaging in outdoor recreation, our anglers perceived substantial changes in use at many of their favorite fishing spots. It is simply too early to tell if the increased engagement in angling is an anomaly or a "new normal" but we are committed to continuing to track both fishing and fish populations to ensure the sustainability of our fisheries.

We hope that our anglers, partners, and the public find this updated plan useful in understanding the Department's evolving approaches to managing our diverse native fish communities and world-class sport fisheries.

NMED Exhibit 38

Glossary of Terms

Adult fish: Fish that have reached a sufficient size and age to be sexually mature.

Aquatic invasive species: Any non-native plant, animal, or pathogen that can harm our economy, environment, human, animal, or plant health.

Angler catch rates: Number of fish caught by anglers over a specified period of time (e.g., one fish per hour).

Angler day: One visit to a waterbody by an angler generally fishing for about four hours.

Angler harvest rates: Number of fish harvested by anglers over a specified period of time (e.g., one fish harvested per angler day).

Augmentation: Stocking fish into an existing population to increase abundance. Synonymous with supplemental stocking.

Basin: An entire river system or an area drained by a river and its tributaries. Synonymous with drainage.

Black bass: A group of popular sportfish in the family Centrarchidae which in New Mexico includes Largemouth, Smallmouth, and Spotted bass.

Catchables: Size category of fish that are at harvestable size. Length categories for catchables include: trout ≥9 inches, Channel Catfish ≥14 inches, and Largemouth Bass ≥14 inches.

Conservation Population (Rio Grande Cutthroat Trout): Those populations with 10 percent or less introgression (hybridization) from non-native trout.

Core Conservation Population (Rio Grande Cutthroat Trout): Those populations with 1 percent or less introgression (hybridization) from nonnative trout.

Cutthroat Trout: Any trout which has orange or red slash marks below the jaw, other than Rio Grande Cutthroat Trout. This includes Snake River Cutthroat Trout and any hybrid cutthroat trout that are less than 90 percent Rio Grande Cutthroat Trout.

Delisting: The removal of a species from the federal Endangered Species Act or the New Mexico Wildlife Conservation Act. Delisting is a result of successful recovery efforts or species extinction.

Downlisting: The reclassification of a species from endangered to threatened under the Endangered Species Act or New Mexico Wildlife Conservation Act. Downlisting is the result of progress towards delisting.

Drainage: An entire river system or an area drained by a river and its tributaries. Synonymous with basin.

Fingerling: Size category of fish in early life stages, also known as juveniles. Length categories for fingerling include: trout 2 to 6 inches, Channel Catfish 2 to 6 inches, and Largemouth Bass 1.5 to 5 inches.

Fry: Size category of fish in the earliest life stages from after hatching to fingerling size. Length categories for fry include: trout ≤2 inches, Channel Catfish ≤2 inches, and Largemouth Bass ≤1.5 inches.

Game or sportfish: Include black bass, catfish, perch, pike, sunfish, temperate bass, tiger muskie, trout, and Walleye as defined by 17-2-3 NMSA 1978.

Green Chile Water: A type of Special Trout Water with a reduced bag limit of two trout per day and tackle restricted to artificial fly and lure with a single barbless hook.

Hybridization: Mating between two individuals of different species resulting in offspring of an intermediate form. In New Mexico, this is most common between native trout and Rainbow Trout.

Low Density Bass Waters: Waters that may maintain a population of bass, however this population is often limited by extreme environmental conditions. Often these populations experience a boom or bust progression driven by environmental conditions.

Native Fish Waters: Waters where the primary management goal is conservation or recovery of native fish species.

Native species: A species living within its historical range and habitat.

Native Trout Conservation Waters: Waters managed to conserve native trout by allowing unlimited harvest of non-native trout to suppress these species and reduce competition while maintaining catch-and-release regulations for native trout.

Proportional Stock Density: A commonly used index to describe a “balanced” population of fish composed of young and adult fish. A measurement of fish population size structure. A high Proportional Stock Density (80 to 100) is a population skewed toward larger individuals. A low Proportional Stock Density (0 to 40) is a population skewed toward smaller individuals.

Protected species: All animals defined as protected wildlife species and game fish under Section 17-2-3 NMSA 1978; all animals listed as endangered or threatened species or subspecies as stated in 19.33.6 NMAC: and all animals listed under Sections 17-2-13, 17-2-14 or 17-2-4.2 NMSA 1978.

Put, Grow, and Take Catfish Waters: Consist of medium size reservoirs stocked with subcatchable Channel Catfish that grow in the waterbody to catchable size. Most Put, Grow, and Take waters have insufficient natural reproduction rates to support existing angler harvest.

Put, Grow, and Take Trout Waters: Waters stocked with subcatchable, fingerling or fry trout with the expectation that the fish will grow to larger sizes within the receiving water.

Put and Take Catfish Waters: Waters stocked with catchable size Channel Catfish to be immediately harvested by anglers especially where angler demand significantly exceeds natural production.

Put and Take Trout Waters: Waters stocked with catchable trout to be immediately harvested by anglers especially where angler demand significantly exceeds natural production.

Quality Trout Waters: Waters managed to provide higher trout densities and five percent of the population is greater than 12 inches or larger.

Recreational Bass Waters: Waters that exhibit conditions for producing fish that reach legal length limits. In most instances these waters maintain self-sustaining populations but may receive supplemental stocking.

Recreational Trout Waters: Waters that contain self-sustaining trout populations of moderate density (> 80/acre) and multiple year classes present.

Recovery populations/waters: Recovery populations and recovery waters are those that contribute toward recovery goals as identified in federal or state species recovery plans.

Red Chile Water: A type of Special Trout Water with catch-and-release and tackle restricted to artificial fly and lure with a single barbless hook.

Red Chile Native Trout Conservation: A type of Special Trout Water with catch-and-release on native trout and unlimited harvest on non-native trout and tackle restricted to artificial fly and lure with a single barbless hook.

Relative weight: An index of fish condition (length to weight relationship) compared to expected weight for a fish at a certain length. For most species, fish with a relative weight 80% or higher are considered in healthy condition.

Self-sustaining population: A population that naturally reproduces at levels sufficient to support long-term population persistence. If a population is self-sustaining, it is generally not stocked.

Special Summer Catfish Waters: Small lakes, ponds, and stream reaches, generally in urban areas, stocked with large, catchable Channel Catfish (approximately 17 inches or greater) multiple times per year (May to September) with reduced harvest limit of two fish per day.

Special Trout Waters: Waters where harvest of trout is prohibited or limited and terminal tackle type may be restricted (e.g., artificial lure or fly only, single barbless hook).

Stocking schedule: A plan that specifies the dates, species of fish, numbers of fish, sizes of fish, and waters to be stocked throughout the state over a calendar year.

Subcatchables or sub-adults: Size category of fish that are smaller than catchable length but larger than fingerlings. Length categories for subcatchables include: trout 6 to 9 inches, Channel Catfish 6 to 14 inches, and Largemouth Bass 5 to 14 inches.

Suppression: Actively removing unwanted fish via angling regulations or mechanical means such as electrofishing or nets.

Trophy Bass Waters: Adopted in 2018, these are waters with a reduced harvest limit of two fish per day. The minimum length limit for Largemouth Bass and Spotted Bass is 14 inches statewide. Trophy Bass Waters provide ideal conditions for producing fish larger than 5 pounds and provide opportunities to catch fish exceeding 8 pounds. These waters are highly productive, have high growth rates, and excellent habitat for all life stages of bass. These waters often produce fish at or near state records.

Triploid: Fish with three sets of chromosomes, unlike fertile fish that have two sets of chromosomes (a diploid fish). A triploid fish is sterile.

Trophy Trout Waters: Waters managed to produce large size trout where five percent of the population or angler catches are 20 inches or larger.

Urban Bass Waters: Bass may occur in these waters or may be stocked as a tool to manage other fish species. While bass in these waters may provide angling opportunities, they are not the focal species and population parameters have not been set for Urban Bass Waters. Retired brood bass are occasionally stocked into Urban Bass Waters to provide additional angling opportunity and/or manage sunfish populations.

Watershed: A land area that channels rainfall and snowmelt to creeks, streams, and rivers, and eventually to outflow points such as reservoirs, bays, and the ocean.

Wild Catfish Waters: Waters consisting of self-sustaining Channel Catfish, Blue Catfish, or Flathead Catfish. Some wild populations receive supplemental stocking of Channel Catfish.

Wild Trout Waters: Waters with self-sustaining trout populations.

Winter Trout Waters: Subset of Put and Take Trout Waters where the Department stocks trout during cooler months when water temperatures are suitable for trout (November through March).

X-mas Chile Water: A type of Special Trout Water with a reduced bag limit of two trout per day and no additional tackle restrictions.

Introduction and Purpose of Plan

Despite our arid landscape, New Mexico is home to dozens of fish species that provide quality and unique angling opportunities. Our state also hosts a high diversity of native fish, some of which are only found within our borders. Ranging from world-class Rainbow Trout angling, to high mountain Rio Grande Cutthroat Trout, to pupfish tolerant of salt levels greater than seawater, our fisheries truly fit New Mexico's landscape. Such diversity also presents ever-growing challenges to fisheries management and conservation. Each year, approximately 249,000 anglers spend nearly 3.8 million days fishing in New Mexico and contribute approximately $266 million to our state's economy. The New Mexico Department of Game and Fish (Department) is a primary steward of these fisheries resources within the state and is charged with managing fish in New Mexico. In close collaboration with local, state, federal, tribal, and non-governmental organizations, the Department actively engages in various management programs and activities at statewide and regional levels to invest in the long-term conservation and management of our fisheries.

Management of fisheries in New Mexico is a complex and challenging venture. Climate change, population growth, resource development, habitat alteration, competing resource interests, cyclical drought, and conflicting management directions all create programmatic challenges at a statewide level. In addition, competing species, hybridization, aquatic invasive species (AIS), illegal fish introductions, and the occurrence of threatened or endangered species present challenges for management of individual waters and at the watershed scale. Faced with these challenges, the Department and its partners must consider dozens of factors when implementing current actions and planning for the future. Demands placed upon our fisheries resources require a clear definition and communication of current and future management expectations for a waterbody to ensure continued angling opportunities, appropriate conservation actions, consistent planning expectations, and pursuit of the Department's mission.

The purpose of this Statewide Fisheries Management Plan is to express the Department's vision for the fishery resources of the State. At the core of this vision is a balance between providing angling opportunity and conserving native fishes. This balance will ensure the economic and cultural vitality of the State by maintaining angling opportunities, recovering or stabilizing state or federally protected species, and preventing the need for new listings under state or federal law. This plan identifies broad management classifications and, in some cases, specific actions for individual waters to clearly define priorities, actions, and possible changes to current management. The Department first adopted this comprehensive fisheries management plan in 2016 as a means to consider nearly all native and non-native fishes in New Mexico. The Department's prior operational plan for aquatic management and non-game management had

lapsed in 1995 and was limited to sportfishing. With approval from the New Mexico State Game Commission in April 2016, this plan began to provide a clearer picture of what to expect in particular waters to secure New Mexico's fishery resources now and into the future.

This document is an update to the 2016 Plan that will reflect contemporary information for waters across the state, report progress made towards priorities and projects identified by the original plan, identify new and ongoing priorities, refine management parameters for sport fisheries which were first adopted in 2016, and provide an index to more easily locate individual waters within the plan.

Scope and Organization of Plan

This plan is intended to identify the priority species for a water, the general management type used to support a species or community, and designate general management direction for all waters within the jurisdiction of the Department. The general management direction also identifies areas which have been or may be considered for expanding sportfishing opportunities or to implement federal or state recovery plans. This plan is not intended to identify a comprehensive list of activities or research needs at the individual water or species scale. The Department has and will continue to develop water or species-specific management or recovery plans to provide fine-scale detail, where warranted, and potentially adopt or coordinate with federal recovery plans. The Department recognizes the myriad threats posed to the state's fisheries by the additive and compounding effects of climate change, drought, wildfire, increasing demand for water, and invasive species. However, this update does not present a detailed threats analysis for these or other factors, instead maintaining a focus on the near-term management approach for virtually every fishery in the state. Regardless, many of the accomplishments and priorities identified in this update are in response to threats. For example, stream habitat improvement projects aim to narrow and deepen channels and restore vegetative cover to streambanks in order to maintain cooler stream temperatures and thereby build resilience to climate change and other factors. Further, many of the species' conservation and recovery plans listed on pages 30 and 31 below specifically contemplate climate change and other threats. This plan does not override previously adopted plans unless otherwise noted.

Several waters within New Mexico, in whole or part, fall within the jurisdiction of Native American tribes, nations, or pueblos. This plan is not intended to set any management direction for those waters under their sole jurisdiction. The Department will, however, work cooperatively to seek common management direction and coordinate joint activities for all waters, especially those which cross jurisdictional boundaries. The Department has successfully

planned and implemented fisheries management actions with multiple tribes, nations, and pueblos in recent years and hopes to continue and expand this coordination into the future.

This plan is divided into two major sections. The first section includes a description of the fisheries management and conservation program within the Department's Fisheries Management Division, angler survey information, and a summary of funding sources. This information provides a background on the organizational structure and funding available for Department activities and contributions in the state. This section also describes the Department's ongoing management efforts for specific taxa or groups of fishes. Objective parameters were first developed in 2016 for some species to demonstrate desired population abundance or angler catch rates for some fisheries, where appropriate. The Department has since identified needs to refine existing and adopt additional parameters based upon contemporary fisheries research projects and data analysis (e.g., Channel Catfish stocking analysis and minimum relative weight for Walleye). The Department will continue to use these parameters to assess the status of particular taxa and guide potential management actions such as stocking or angling regulation changes.

The second section includes delineations of specific waters with focal species identified, a management type associated with each species, as well as brief descriptions of management directions for each water. These directions may include current and future management such as stocking strategies, special regulation potential, restoration needs, among others. In some cases, the management direction is a departure from past management or clarifies past inconsistencies between Department activities. This section is a collection of most recent fisheries data, environmental and social realities, and future possibilities for fisheries in New Mexico. This information was developed through extensive discussions among Department staff, partner agencies, researchers, anglers, and the general public and has continually evolved over the past several decades into its current form. Overall, this section defines the Department's long-range planning and management within a particular water or water segment.

Overview of Department Fisheries Program

Statutory Authority

Enabling legislation for the New Mexico State Game Commission and the Department is found in Chapter 17 of New Mexico Statutes Annotated. This chapter empowers the State Game Commission to set regulations for open or closed seasons, establish bag or possession limits, authorize or prohibit the killing or taking of game fish, and prescribe the manner and method for taking game fish (17-2-1 NMSA 1978 *et seq.*). Protected species are generally limited to sportfish and state or federally listed threatened and endangered species. Specific fishing rules

NMED Exhibit 38

adopted by the State Game Commission include Fisheries (19.31.4 NMAC), Hunting and Fishing – Manner and Method of Taking (19.31.10 NMAC), Commercial Use of Fish (19.31.9 NMAC), and Importation of Live Non-domesticated Animals, Birds, and Fish (19.35.7 NMAC). The Department typically seeks renewal of the Fisheries rule by the State Game Commission on a four-year cycle. The most recent changes were adopted in November 2021 and went into effect on April 1, 2022.

The New Mexico Wildlife Conservation Act (17-2-37 NMSA 1978) empowers the State Game Commission to adopt a list of species of wildlife indigenous to the state that are determined to be threatened or endangered within the state. Once listed as threatened or endangered by the State Game Commission, it is unlawful for any person to possess, transport, export, process, sell or offer for sale any species of listed wildlife. The New Mexico Wildlife Conservation Act (NMWCA) also prescribes a listing or delisting process, a biennial review process to evaluate species status, and drafting of state recovery plans.

Department Fisheries Program

The Fisheries Management Division is divided into a Hatchery Section and a Research and Management Section. Six state hatcheries rear fish to support ongoing fisheries management activities in New Mexico. These hatcheries focus on both warm and coldwater fishes as well as native and non-native sportfish. They largely exist in rural communities and many offer youth angling opportunities on their properties. Four of the six facilities culture Rainbow Trout to support the extensive network of fisheries for that species across the state. Beginning in 2008, the Department switched to rearing only all-female, triploid Rainbow Trout. These fish are sterile and minimize hybridization concerns with native trout. In total, the Department's hatcheries produce nearly 4.0 million Rainbow Trout per year. The Hatchery Section also coordinates acquisitions of fish and fish eggs from external sources, such as private vendors, other states, and federal facilities. These acquisitions support fisheries management programs by providing species traditionally not reared at New Mexico state hatcheries, diversifying genetic integrity of existing populations, and meeting demands that exceed internal production capacity.

The Lisboa Springs State Fish Hatchery near Pecos, NM primarily focuses on rearing of Rainbow Trout for supporting regional put and take fisheries. The facility also occasionally raises Pecos River Strain Rio Grande Cutthroat Trout for stocking into recreational fisheries.

The Seven Springs State Fish Hatchery is located in the Jemez Mountains near Jemez Springs, NM. The hatchery is the Department's facility for spawning, hatching, rearing, and stocking Rio Grande Strain Rio Grande Cutthroat Trout. The hatchery maintains a broodstock for the fish and has also routinely integrated eggs from wild Rio Grande Cutthroat Trout populations into the

brood. The Rio Grande Cutthroat Trout produced at Seven Springs have been integral to species restoration efforts in places like the Rio Costilla. The hatchery also provides Rio Grande Cutthroat Trout for recreational purposes, mostly into put, grow, and take fisheries although some catchable fish are produced. In the near-future the Department intends to develop a Pecos Strain Rio Grande Cutthroat Trout broodstock at the hatchery to support restoration efforts in that basin.

Red River State Fish Hatchery near Questa, NM raises Rainbow Trout for regional put and take and put, grow, and take fisheries. The facility also recently began receiving fingerling Rio Grande Strain Rio Grande Cutthroat Trout from Seven Springs State Fish Hatchery. The intent of this effort is to grow additional Rio Grande Cutthroat Trout to catchable size for increased recreational opportunities for the species.

The Los Ojos State Fish Hatchery near Chama, NM also focuses on producing recreational Rainbow Trout, including put and take and put, grow, and take fisheries. Los Ojos is also the state's sole Kokanee rearing facility. Kokanee eggs are collected and fertilized from Heron Reservoir, and sometime other locations, before being hatched, reared, and stocked into put, grow, and take fisheries. Additionally, since 2018 the hatchery has annually received YY Brook Trout eggs, hatched, reared, and then provided them for research purposes.

Glenwood State Fish Hatchery in Glenwood, NM is currently being renovated to facilitate the propagation of native Gila Trout to support conservation for this unique trout species. Initially, the facility will produce Gila Trout for recreational fisheries. Ultimately, the Department hopes to expand operations in the future to include assisting with recovery stocking efforts for the species.

The Rock Lake State Fish Hatchery in Santa Rosa, NM is the Department's only warmwater facility. The hatchery hosts a broodstock of Largemouth Bass which are spawned and reared on station before being stocked into large and small impoundments across the state. The hatchery also and rears Walleye that are spawned in the wild each year. Walleye eggs are then brought to the facility, hatched, and stocked into reservoirs as fry. In addition to warmwater operations, Rock Lake has coldwater facilities and rears Rainbow Trout for put and take fisheries across the region.

The Research and Management Section is organized into teams of sportfish biologists, native fish biologists, and AIS staff, as well as a fish health specialist and an environmental compliance specialist. The Sportfish Program is charged with managing fisheries that provide recreational angling opportunities for warmwater species such as bass and catfish and coldwater species such as trout and salmon. The Native Fish Program is charged with managing New Mexico's native fisheries and aquatic invertebrates such as Arkansas River Shiner, Rio Grande Cutthroat

Trout, Roundtail Chub, and Texas hornshell (a freshwater mussel). The Sportfish and Native Fish Programs are each currently composed of ten full-time permanent employees. Biologists are typically assigned a watershed or suite of species though coordination among biologists is necessary to consider all aspects of the Department's management efforts.

Current AIS intervention efforts include education and outreach, coordination of intervention efforts, and seasonal watercraft inspection and decontamination. Coordination of AIS intervention at the state and regional levels helps to protect New Mexico fisheries as well as significant water resources infrastructure, and public boating access. The Department, along with state, federal and private partners, work diligently to stop the introduction and spread of AIS. Of particular concern is invasion of our lakes by zebra and quagga mussels. Introduction of these mussels pose a risk to our native aquatic wildlife, water-based recreation including boating and fishing, and surface water delivery systems. For more information on AIS please visit the Department's AIS webpage at www.wildlife.state.nm.us/ais.

Annual fish health testing is completed at all hatcheries to ensure they are free of significant fish pathogens such as whirling disease. Fish health testing for wild fish is completed on select waters when fish or eggs are moved within or among watersheds or to a hatchery facility. Fish health testing for wild salmonids is also completed to document presence or absence of whirling disease. Importation permits and associated fish health certifications are reviewed to ensure fish and eggs imported into New Mexico are free of significant pathogens, comply with New Mexico state regulations, and comply with interagency fish health agreements.

Environmental compliance is required when conducting many activities, including but not limited to rearing fish at hatcheries, fish monitoring and surveys, habitat projects, and stocking fish. The Department is required to comply with all state and federal laws and obtain permits or authorization when necessary. Compliance includes meeting the requirements of the Clean Water Act, Endangered Species Act (ESA), National Historic Preservation Act, and the National Environmental Policy Act.

Nearly all divisional activities are implemented in close coordination with local, state, or federal agencies as well as non-governmental organizations who own land, water or are actively engaged in aquatic conservation efforts in New Mexico. Together, these programs provide a comprehensive management approach for New Mexico's aquatic resources.

Fisheries Management Division Programmatic Priorities

Priorities for the entire Department are identified in the Department's Strategic Plan (NMDGF 2020). Identified Objectives and Strategies specifically relevant to the Fisheries Management Division include:

- That by 2023, the Department develops appropriate population objectives based on sustainable wildlife management practices (Objective 2, pg. 8)
    - Collaborate with sportsmen, land management agencies, landowners and other affected interests to establish broadly supported resource-based management objectives for game animals and game fish (Strategy 2.1)
- Maintain an overall angler satisfaction rate of 80% regarding angler opportunity, fishing experiences, and the Department's management of sport fishing issues through 2023 (Objective 4, pg. 10)
    - Monitor angler issues, interests, and satisfaction and employ findings to inform and evaluate management decisions (Strategy 4.1)
    - Maintain a hatchery system and associated facilities to culture fish and supplement fish populations through stocking in accordance with fisheries management plans (Strategy 4.2)
    - Construct, operate, and maintain a warmwater fish hatchery and associated Watershed Education and Training (WET) Center (Strategy 4.3)
    - Continue to promulgate rules that protect fish stocks from overexploitation and equitably distribute fishing opportunity (Strategy 4.4)
    - Minimize losses of fish populations and hatchery stocks due to diseases (Strategy 4.5)
    - Increase opportunities for anglers to pursue native game fish (Strategy 4.6)
- By 2023 realize a level of public opportunity for recreational hunting and fishing as indicated by 110,000 and 200,000 certified annual licensees, respectively (Objective 5, pg. 11)
    - Identify and implement methods by which hunting and fishing opportunity and participation might be increased (Strategy 5.1)
- Restore up to 70 user-days of public hunting and up to 200 user-days of fishing opportunity for selected diminished game species and furbearers by 2023 (Objective 6, pg. 12)
    - Develop and implement long-range and operational plans for the restoration, management, and use of selected diminished game species and furbearers for which limited sport fishing, hunting, or trapping opportunity may be restored without compromising species conservation (Strategy 6.1)
- That through 2023 hunting and fishing opportunities are maintained through prevention and control of wildlife disease and invasive species (Objective 7, pg. 12)

    - Detect, monitor, manage, and prevent the spread of wildlife diseases and invasive species through coordination with the New Mexico Department of Health, the New Mexico Livestock Board, the New Mexico Department of Agriculture, USDA Animal Plant and Health Inspection Service, USDA Wildlife Services, and USDA Veterinary Services and other appropriate agencies (Strategy 7.1)
- Conserve, enhance, or positively affect an additional 500,000 acres of wildlife habitat statewide by 2023 (Objective 8, pg. 13)
    - Collaborate with federal, state, and local agencies, tribal governments, non-governmental organizations, and private interests that manage significant land and water areas in New Mexico to plan and implement habitat improvement projects consistent with the habitat enhancement prescriptions in the State Wildlife Action Plan (Strategy 8.1)
- By 2023, attain measurable progress toward the restoration of wildlife identified as being at risk of depletion or extinction (Objective 10, pg. 16)
    - Pursuant to the Wildlife Conservation Act (WCA), conduct biennial reviews of all indigenous wildlife currently listed as threatened or endangered by the state, investigate and assess the status of species the Department suspects to be threatened or endangered, and recommend changes to the status if warranted (Strategy 10.1)
    - Develop and implement plans for the management and recovery of state listed threatened or endangered species (Strategy 10.2)
    - Provide public, state, and private entities with guidance for conserving and improving populations of threatened or endangered wildlife (Strategy 10.3)
    - Collaborate with state, federal, and tribal governments in the recovery of federally listed species occurring in, or extirpated from, New Mexico (Strategy 10.4)

In furtherance of the Department's Strategic Plan, the Fisheries Management Division developed a set of divisional priorities to focus management and conservation efforts for division staff and resources:

1. Rearing and Stocking Fish – This priority includes all efforts at the six Department hatcheries to meet developed stocking schedules for Channel Catfish, Gila Trout, Largemouth Bass, Rainbow Trout, Rio Grande Cutthroat Trout, Striped Bass, and tiger muskie. Stocking schedules are routinely modified to reflect changing environmental conditions, altered angler use, changing priority areas, and addition or loss of angler access. This priority specifically addressed Department Strategies 4.2 and 4.3.

2. Evaluation of Hatchery Stocking – This priority includes investigating and altering the use of hatchery produced resources to more efficiently stock waters, maximize angler catch rates, and ensure equitable distribution of fish. Examples of such investigations include Largemouth Bass or Rainbow Trout stocking strategies, appropriate stocking rates for tiger muskie, and put, grow, and take opportunities for Rio Grande Cutthroat Trout. This priority specifically addressed Department Strategies 2.1, 4.1, 4.4, 4.6, 5.1, and 6.1.
3. Species Recovery Efforts – This priority includes development and implementation of various aquatic species recovery efforts to improve or stabilize the status of federal or state protected species. Specifically, priority actions will include augmentation programs, habitat restoration, removal or exclusion of competing or hybridizing species, and restoring habitat connectivity. In addition, significant efforts are directed towards addressing or preventing the further decline of other species that could need state or federal protection in the future. This priority specifically addressed Department Strategies 4.6, 6.1, 10.1, 10.2, 10.3, and 10.4.
4. Aquatic Invasive Species – This priority seeks to galvanize support by state, federal, and non-governmental entities to collaboratively protect the states waters from AIS and prevent the spread or negative effects from previously established fish pathogens. The introduction or spread of species such as zebra mussel or quagga mussel, rock snot, or whirling disease could produce devastating effects on individual fisheries, local or state economies, and/or water resource infrastructure. This priority specifically addresses Department Strategy 4.5 and 7.1.
5. Habitat Restoration – The Department expends significant resources restoring and augmenting riparian habitats for the benefit of fish and wildlife. Future habitat enhancements are anticipated in the Cimarron River, Costilla Creek, Whitewater Creek, Willow Creek (Gila) and lakes in the Carlsbad area. This priority specifically addresses Department Strategy 5.1, 8.3 and 10.4.
6. Statewide Fisheries Management – This priority refers to ongoing efforts to constantly adapt to changes in environmental conditions and provide the best possible angling opportunities to New Mexico anglers. This priority specifically addresses Department Strategies 4.1 and 4.3.

Angler Survey Data

Dating to the 1970s, the Fisheries Management Division has assessed angler days, catch rates, species preference, and/or angler satisfaction via mail, phone, or web-based surveys. From 2000 to 2016, annual phone surveys of resident and non-resident anglers were completed. Since 2017 surveys have been completed via a web-based method. The purpose of these surveys is to assess annual angler satisfaction, seek input on emerging issues, and refine

existing management programs. For example, individualized surveys could be conducted for topics such as bait fishing, Gila Trout angling, or fish importation.

New Mexico anglers consistently prefer to fish for coldwater species such as trout and salmon with approximately 11% preferring solely warmwater species in 2021 (Figure 1). A significant percentage of anglers prefer both warmwater and coldwater species. Of the coldwater species in New Mexico, Rainbow Trout and Brown Trout are consistently preferred over other coldwater species (www.wildlife.state.nm.us/fishing/fisheries-management/). Black bass, catfish, and Walleye are the most preferred species of warmwater fish. Since 1997, an average of 60% of anglers release most of the fish they catch compared to 40% who prefer to harvest most of their catch with an increasing trend of anglers that practice catch-and-release (Figure 2). About half of anglers prefer to pursue stocked fish compared to wild fish (Figure 3). These data are essential to proactively address the desires and preferences of New Mexico anglers within the environmental and sociopolitical context of our state.

In late 2019 and early 2020 the world became aware of the emerging SARS-COV-2 virus and the Covid-19 disease that could occur from its transmission. The resulting global pandemic has affected nearly every aspect of life in New Mexico since 2020, including angling. While most of the information that we have regarding the precise effects of the pandemic on angling is anecdotal, there is little doubt that during the summer and fall of 2020 patterns of use in New Mexico's fisheries differed from normal. The Department's license sales and angler use data yield insight into these changes and suggest how this change may carry forward. Surprisingly, despite the increase in angling pressure observed by Department staff, partners, and the public in locations that remained open to angling, overall license sales increased by only 1% from the 2019-20 to 2020-21 license years and the average number of days each angler fished declined slightly from 2019 levels (Figure 4). The closures of normally popular waters at State Parks, Department-owned properties, municipal waterbodies, and many other locations likely shifted angling pressure to waters that remained open. Changes in patterns of work, school, and child care also likely led to increased angling pressure at dates and times outside of normal. Based on available statewide data, which show a modest increase in licenses sold and little change in overall angler days, we expect that as closures lift and normalcy returns to other aspects of life that angling pressure is also likely to return to pre-pandemic levels. Of course, the future is impossible to predict with certainty and the Department is committed to managing the state's fisheries and their use in a sustainable manner.

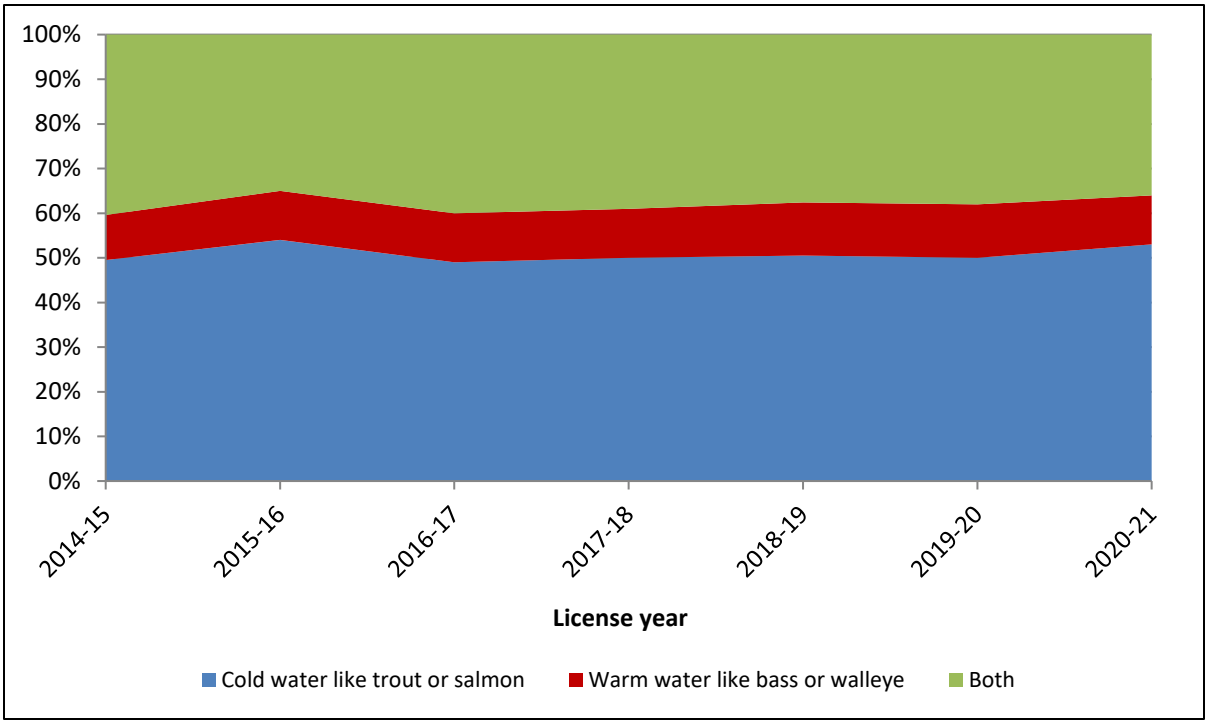

Figure 1. Summary of New Mexico angler preferences for coldwater (e.g., trout and salmon) or warmwater (e.g., bass and catfish) angling in the state. Percentages are derived from annual angler surveys, 2014-15 to 2020-21 license years. Note, 2014-15 to 2015-16 license years data from phone survey and 2016-17 to 2020-21 license years data from web-based survey.

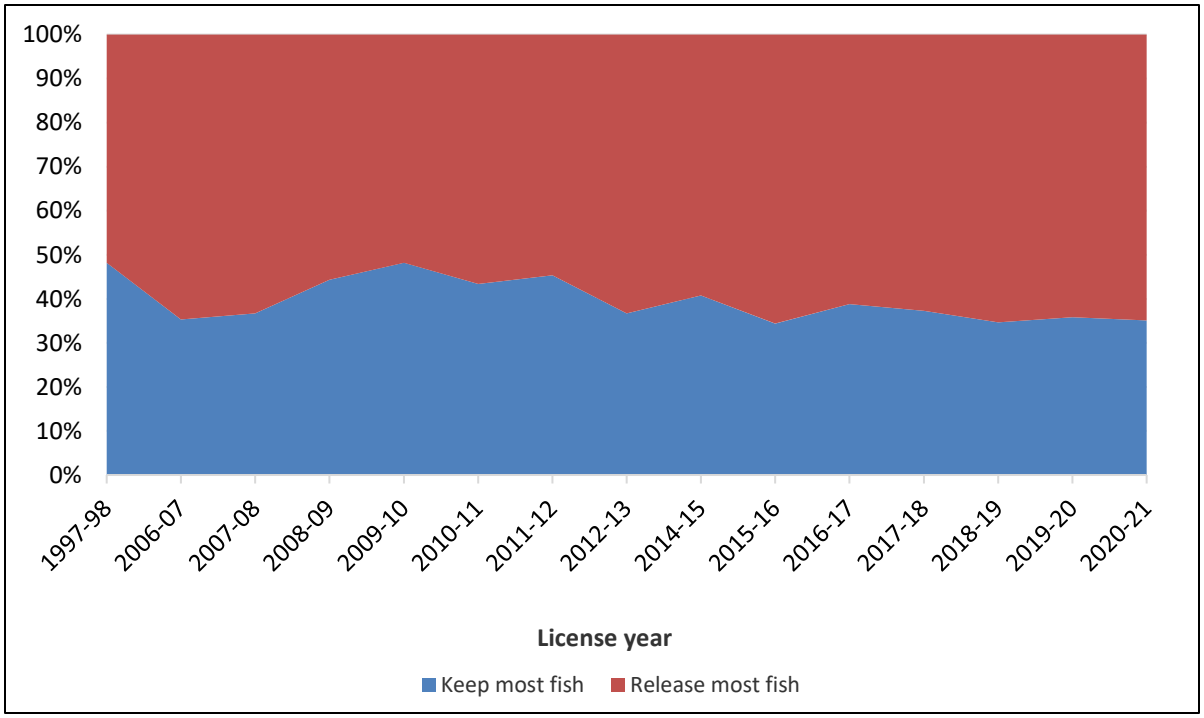

Figure 2. Summary of New Mexico angler preference for harvesting game species derived from annual angler surveys, 1997-98 to 2020-21 license years. Note, 1997-98 to 2015-16 license years data from phone survey and 2016-17 to 2020-21 license years data from web-based survey.

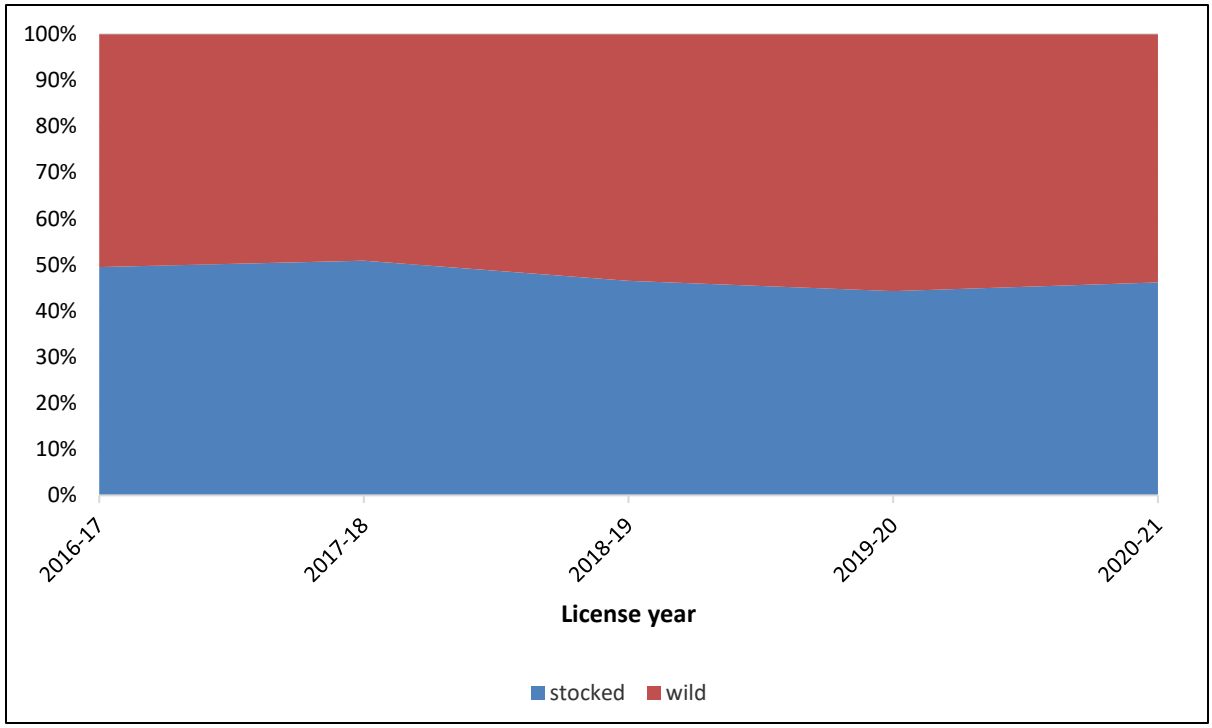

Figure 3. Summary of New Mexico angler preference for fishing in areas they expect to find stocked fish or wild fish 2016-17 to 2020-21 license years.

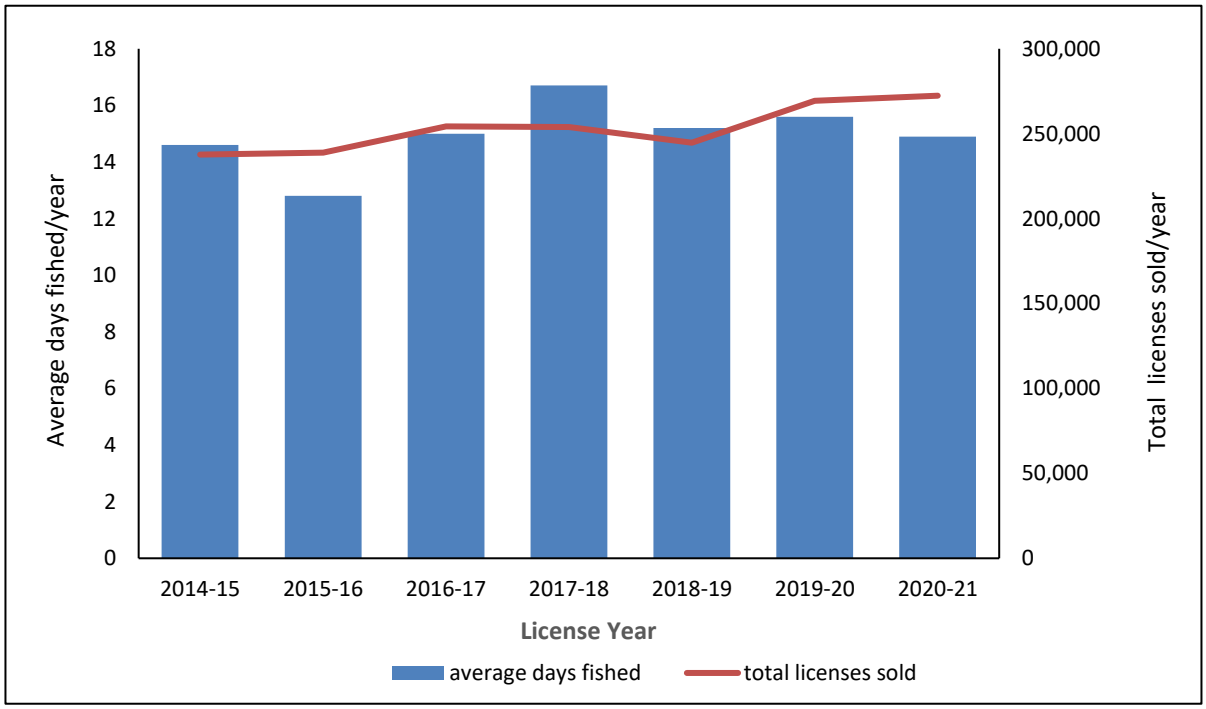

Figure 4. Total number of New Mexico fishing licenses, including combo licenses (e.g., Game Hunting and Fishing), and average days fished by each angler from 2014-15 to 2020-21 license years.

Funding

The Fisheries Management Division receives a portion of the Department's annual budget which is primarily funded by legislative appropriations from the Game Protection Fund. The Game Protection Fund is funded entirely through the sale of hunting and fishing licenses. The Fisheries Management Division leverages expenditures from the Game Protection Fund for reimbursement from various federal grant programs. The primary source of federal funds is the Sportfish Restoration Act program administered by the Wildlife and Sportfish Restoration program of the U.S. Fish and Wildlife Service (FWS). This federal grant program is funded via federal excise taxes on fishing tackle and motorboat fuel. For every dollar of Game Protection Fund spent, the Department is reimbursed $0.75 through the Sportfish Restoration Act program. This program is the primary funding source for the Department's hatchery operations, sportfish research and management, AIS outreach and education, Rio Grande Cutthroat Trout conservation efforts, habitat restoration, and fish health investigations.

Various federal grant programs also provide cost share opportunities for imperiled fish and aquatic invertebrate species. In all cases, the Game Protection Fund provides the base funding until reimbursement is obtained from the federal program. The Department receives an annual allocation of ESA Section 6 funding from the FWS to implement conservation activities for threatened or endangered species with the same reimbursement requirements as the Sportfish Restoration Act program discussed above. The Department also receives an annual allocation of State Wildlife Grant funding from FWS to support conservation programs for Species of Greatest Conservation Need as identified in the Department's State Wildlife Action Plan. The total amount of State Wildlife Grant funds used by the Fisheries Management Division varies annually. The Department supports several ongoing research efforts either through State Wildlife Grant or Section 6 funds. The Department also receives funding through different Bureau of Reclamation (BOR) project mitigation programs such as Central Arizona Project mitigation funds and San Juan River Basin Recovery Implementation Program funds. Species that benefit from these state and federal funding sources include Colorado Pikeminnow, Gila Trout, Loach Minnow, Pecos Pupfish, Rio Grande Chub, Rio Grande Sucker, Socorro isopod, Spikedace, Texas hornshell, and dozens of others throughout the state. The FWS also provides funding for AIS prevention through Sportfish Restoration Grants and other sources.

In Fiscal Year 2021, funding for the Fisheries Management Division was primarily derived from Sportfish Restoration Act and the unreimbursed Department costs (Figure 5). State Wildlife Grants provided 10% and Section 6 and BOR program funding each provided 2% of the Fisheries Management Division's budget. Lastly, 1% of the budget came from various FWS programs for AIS prevention.

In addition to the direct funding discussed here, the Department's many partner agencies, NGO's, and private individuals contribute immeasurably to fish and aquatic habitat in New Mexico through direct expenditures and volunteerism.

In 2021 the State Game Commission updated the Department's Habitat Stamp Program in a manner that will increase funding and dedicate a portion of the program to fish habitat projects. This funding source is not reflected in the Fiscal Year 2021 information included here but it is anticipated to be a substantial source of additional funding for fish habitat projects beginning in Fiscal Year 2022.

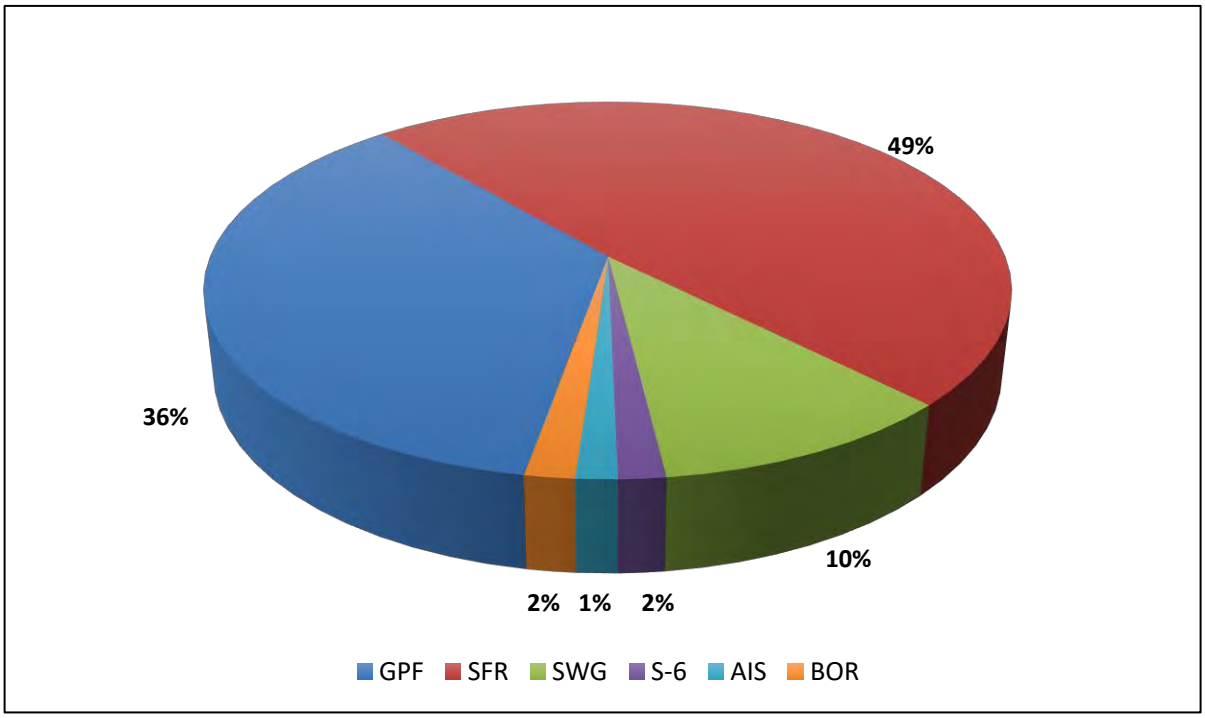

Figure 5. Summary of Fiscal Year 2021 funding sources for the $8.8 million Fisheries Management Division budget. Game Protection Fund (GPF) are unreimbursed state funds. The remaining sources are reimbursed federal funding sources including Sportfish Restoration (SFR), State Wildlife Grants (SWG), Endangered Species Act Section 6 (S-6), Aquatic Invasive Species (AIS) Grants, and Bureau of Reclamation (BOR) Programs.

Specific Information for Fish Species, Taxa, or Communities

The individual characteristics of a particular water in New Mexico along with active management such as stocking or regulation development help determine community composition and available management actions to sustain, suppress, or expand a particular fishery. Below are descriptions of individual species or groups of fish which are popular sportfish species for a water, a focal species for management at a particular water, or the focus of a significant recovery program in which the Department participates. Individual abundance or density indices, growth rates, angler catch rates, and other metrics are identified for some species to provide objective parameters for measuring management success and possible

indicators of challenges within a fishery. Parameters were amended for some species in this plan update to more accurately reflect species potential, refine management goals, and as part of adaptive management (Appendix A). For some sportfish, individual demographic parameters are not available or the species is too rare to effectively monitor. For others, state or federal recovery plans are better suited for identifying such criteria.

Catfish

Three species of catfish provide recreational angling opportunities in New Mexico. Channel Catfish are native to the central United States, south central Canada, portions of the Atlantic Coast of the United States, and have been widely introduced throughout the United States and northern Mexico. In New Mexico, Channel Catfish are native to the Canadian drainage and widely introduced to all other drainages in the state. Blue Catfish are native to the Mississippi, Missouri, and Ohio drainages of the central and southern United States and along the Texas Gulf Coast. In New Mexico, it is considered native to the Rio Grande downstream of Bernalillo County and in the Pecos River downstream of Puerto de Luna. In the Rio Grande drainage, Blue Catfish is currently known to occur in Elephant Butte and Caballo reservoirs. Flathead Catfish are found in the central United States south into eastern Mexico. Flathead Catfish are native to the Rio Grande and Pecos River drainages and were introduced to the Gila River prior to 1950. Flathead Catfish were also introduced into Clayton Lake by the Department in 2017 as a management tool to reduce and control the Black Bullhead population.

The Department has four management classes for catfish in New Mexico. These management classes are primarily focused on Channel Catfish though Blue and Flathead catfish provide quality angling opportunities in select waters. Management classes for catfish in New Mexico are: Wild, Put and Take, Special Summer Catfish Waters, and Put, Grow, and Take waters. The definition of each management type can be found in the Glossary of Terms. Channel Catfish are acquired for stocking from other state and federal agencies or purchased from private producers. Blue and Flathead catfish are not stocked by the Department at this time, but Flathead Catfish have been transplanted to other waters as a management tool.

A long-term analysis of Put, Grow, and Take stocking proved this strategy unsuccessful in providing a Channel Catfish fishery in most waters tested. The Put, Grow, and Take stocking strategy will likely only be used on a limited or experimental basis in the future.

In some waters, Channel Catfish populations are purposefully suppressed to facilitate native species recovery, like in the San Juan River downstream of Shiprock, NM. Current suppression efforts are implemented using mechanical means (e.g., electrofishing) by the San Juan River Basin Recovery Implementation Program.

Management strategies for Put and Take Catfish Waters and Special Summer Catfish Waters are focused on maximizing stocked fish return to the angler and equitable distribution of angling opportunity, predominantly in an urban environment. Alternatively, strategies for Wild Waters are focused on maintaining viable populations through time especially those that are entirely dependent upon natural reproduction. As a result, the objective parameters established for Put and Take and Special Summer Catfish waters relate to angler catch rates compared to population statistics documented during Department monitoring efforts for Wild Waters.

Channel Catfish Parameters:

Put and Take and Special Summer Catfish Waters

- Average harvest rate: 1 fish/angler day during stocking season (late May to early September)

Wild

- Multiple size-classes of adults present exhibiting a balanced population and consistent natural reproduction

Black Bass

Black bass in New Mexico include Largemouth Bass, Smallmouth Bass and Spotted Bass. The native range of Smallmouth Bass includes southern Canada, south to the Tennessee River and Alabama and west to eastern Oklahoma and western Arkansas. In New Mexico, Smallmouth Bass were first stocked into Throttle Reservoir (Colfax County) in 1914 and since that time have been stocked throughout the state. Smallmouth Bass now occur in every major basin in New Mexico including river systems such as the lower Gila River and upper Rio Grande. Two subspecies of Largemouth Bass exist or have been stocked in New Mexico: Northern Largemouth Bass and the Florida Largemouth Bass. Florida Largemouth Bass were stocked into reservoirs within the southern part of the state in the 1980s with limited long-term success in terms of contributing to the fishery. Northern Largemouth Bass are native to New Mexico's Pecos Drainage and possibly the Rio Grande Drainage but have been introduced to all other basins in the state. Spotted Bass were stocked into Cochiti Lake and Lake Sumner in the 1980s and currently exist in Bataan Lake, Brantley Lake, Lake Carlsbad, and Lake Sumner. Largemouth Bass are the most popular warmwater species in the state followed consistently by Smallmouth Bass.

Most populations of black bass are self-sustaining in the state though many Largemouth Bass fisheries receive supplemental stockings from Rock Lake State Fish Hatchery. Local conditions of a particular water, however, can limit or inhibit consistent reproduction. For example, sudden reservoir level decreases that negatively affect nests built in shallow areas can reduce or

eliminate fish spawning and recruitment. Stocking rates and schedules have been developed for multiple Largemouth Bass waters. A consistent brood population of Largemouth Bass is raised at Rock Lake State Fish Hatchery to meet stocking needs. Smallmouth and Spotted bass are not routinely stocked by the Department at this time.

Statewide regulations vary for black bass among species and management direction. Harvest in most waters is limited to five fish per day. Trophy Bass Waters were adopted in 2018 and feature a reduced harvest limit of two fish per day. The minimum length limit for Largemouth Bass and Spotted Bass is 14 inches statewide. The statewide minimum length limit for Smallmouth Bass is 12 inches with the exception of 14 inches at Conchas and Ute lakes. The purpose of this regulation is to protect fish from harvest until reaching a more desirable length. Effective April 1, 2022, the minimum length limit for Smallmouth Bass was removed on the Rio Grande near Pilar, NM to reduce population densities and competition to address potential stunting.

The Department has four black bass management types: Trophy, Recreational, Low Density, and Urban. The definition of each fish type can be found in the Glossary of Terms. These management types were developed to help set or maintain realistic expectations for black bass populations in the state. Once set, the Department may seek to manipulate physical, biological, or social variables to attain the desired outcomes via habitat improvement, forage or other species management, or harvest regulations. Each parameter is used as an indicator for different aspects of overall population health. For example, the abundance parameter (Catch Per Unit Effort) is different for Trophy Waters (where overall abundance of larger fish is desired) compared to Recreational Bass Waters (where an abundance of multiple size classes is desired). Alternatively, parameters for recruitment are based upon the survey catch rate of Age-2 bass whereas Catch Per Unit Effort is based upon catch rates of fish greater than a particular length. Proportional Stock Density is a commonly used index to describe a “balanced” population of fish composed of young and adult fish. Low or high Proportional Stock Density indicates a skewing of the population towards small or large fish, respectively. All of these parameters are used to measure different elements of the population. Below are specific descriptions of black bass management types and objective parameters for each management type. All Smallmouth Bass waters are designated as Recreational Bass Waters with no specific parameters developed for stream systems. Several waters contain multiple species of black bass; however, parameters are compared independently for the focal management species designated for a particular water.

Black Bass Parameters:

Trophy Bass Waters (Largemouth Bass only)

- Catch Per Unit Effort: > 5 fish/hour of electrofishing that are > than 20 inches in length

- Recruitment: > 10 Age-2 bass/hour of electrofishing
- Size Structure: Proportional Stock Density between 50 and 70
- Growth: Mean length of Age-4 bass > 14 inches
- Body Condition: Average relative weight of at least 90

Recreational Bass Waters

- Catch Per Unit Effort: 20 to 40 fish/hour of electrofishing
- Recruitment: > 5 Age-2 bass/hour of electrofishing
- Size Structure: Proportional Stock Density between 40 and 60
- Body Condition: Average relative weight of at least 80

Low Density Bass Waters

- Catch Per Unit Effort: 0 to 20 fish/hour of electrofishing
- Body Condition: Average relative weight of at least 80

Temperate Basses

The temperate basses include Striped Bass, White Bass, and hybrid striped bass. Striped Bass are native to the Atlantic Coast and the eastern part of the Gulf of Mexico (Sublette et al. 1990). Striped Bass have been stocked in Elephant Butte Reservoir intermittently depending on availability. Striped Bass also inhabit Lake Powell, AZ/UT and could potentially swim upstream into the San Juan River. There is no evidence that Striped Bass have successfully reproduced in New Mexico and the population in Elephant Butte Reservoir is maintained by stocking fry or fingerlings obtained from other states or private hatcheries. White Bass are native to the central Mississippi Drainage down to the Gulf of Mexico and a few watersheds in Texas. They were first introduced into New Mexico in 1969 into Willow Lake and can be found in many lakes and reservoirs throughout the state, excluding the Gila Basin. White Bass successfully reproduce in New Mexico reservoirs and are not stocked by the Department.

Management strategies for Striped and White bass are different due to differences in life history and “trophy” fish potential. The Department manages the Striped Bass fishery at Elephant Butte Reservoir to increase the likelihood of fish growing to trophy size. Such a size structure is slightly biased towards a greater proportion of adults in the population compared to juveniles as measured by Proportional Stock Density. Regulations for Striped Bass at Elephant Butte Reservoir are currently set as one fish per day and no length limit. There is no harvest, possession or length limit for any Striped Bass in the San Juan River to support endangered fish recovery efforts in that basin. Because White Bass populations are highly cyclical, current regulations limit harvest to 25 fish per day with no length limit. This management approach is intended to support liberal harvest of White Bass when abundant. Considering the cyclical nature of White Bass, no specific management parameters have been developed.

Hybrid striped bass, an artificial cross between Striped Bass and White Bass, are being considered as a new management species in New Mexico to expand angling opportunity. Hybrid striped bass, also known as wipers, Palmetto bass, or sunshine bass, are a popular recreational species in other states due to their rapid growth potential, adaptability to various water quality parameters, and availability from state and private hatcheries. A pilot project to establish a hybrid striped bass fishery in Caballo Lake has been proposed and is anticipated for implementation in 2022.

Striped Bass Parameters at Elephant Butte Reservoir

- Catch Per Unit Effort: 1 fish/net night
- Size Structure: Proportional Stock Density between 50 and 70
- Body Condition: Average relative weight of at least 85

Walleye

Native to the upper midwestern United States and Canada, Walleye were first introduced into New Mexico in 1959 to expand angling opportunity in the State's reservoirs. Walleye are highly piscivorous (i.e., fish eating) with Gizzard Shad and Yellow Perch as their dominant prey. In New Mexico, natural spawning success is typically low to nonexistent and most populations are dependent upon annual stocking. The Department has conducted Walleye field spawns (i.e., egg collection) from various reservoirs since the 1970's. In the spring, eggs are collected, fertilized, and transported to the Rock Lake State Fish Hatchery for incubation and hatching. When local spawns provide inadequate egg collection, eggs are obtained from other state or federal hatcheries. Walleye are then stocked into reservoirs as fry, typically at a rate of 500 per surface acre. All Walleye populations are currently managed with statewide regulations of five fish per day. Effective April 1, 2022 there is no length limit for Walleye statewide.

Walleye Parameters

- Catch Per Unit Effort: ≥ 4 fish/net night
- Body Condition: Average relative weight of at least 80

Tiger Muskellunge and Northern Pike

Tiger muskellunge or "tiger muskie" are a sterile hybrid between Northern Pike and Muskellunge. Both Northern Pike and Muskellunge are native to the upper midwest and northeast United States. Northern Pike were first introduced into New Mexico in the 1960s and tiger muskie were first introduced in the early 2000s. Several self-sustaining populations of Northern Pike exist in the state and the Department does not stock them. The Department stocked tiger muskie in Bluewater and Quemado reservoirs in the early 2000s to control Goldfish and White Sucker. These are still the only waters the Department manages with this

hybrid species and a popular sport fishery has grown around the opportunity. The Department must continually stock tiger muskie to maintain a population. Challenges with tiger muskie management include maintaining enough tiger muskie to control unwanted fish at low abundances, providing a unique angling experience for tiger muskie, and maintaining or expanding angling for other species including trout.

Statewide regulations for Northern Pike are 10 fish per day with no length limit. No specific population parameters have been developed for Northern Pike. Regulations at Eagle Nest Lake for Northern Pike are mandatory harvest with unlimited take. These regulations are intended to suppress the illegally introduced species at Eagle Nest Lake and minimize potential deleterious effects on the popular trout and salmon fisheries.

Current regulations for tiger muskie are one fish over 40 inches per day at Bluewater and Quemado reservoirs. The Department conducts routine surveys of tiger muskie at each lake to estimate the density of fish (number of fish/surface acre of lake habitat) and evaluate population size structure. Coupled with carefully developed stocking rates, the Department has refined the balance between tiger muskie density, potential harvest, trophy fishing opportunities, and other recreational angling opportunities.

Tiger Muskie Parameters

- Density: 4 fish/surface acre (10-year average of surface area)
- Unwanted Fish Catch Per Unit Effort: <20 fish/hour electrofishing of Goldfish and White Sucker in target waters
- Body Condition: Average relative weight of at least 90 for fish ≥30 inches

Other Warmwater Species

Several additional sportfish species inhabit New Mexico waters which provide alternative yet less popular fisheries. They also provide important forage sources for larger predatory fishes. These species include Black and White crappie, Yellow Perch, and several species within the sunfish family such as Bluegill and Green Sunfish. Active management specifically for these species is not common, and the Department does not typically rear them, although some waters have one or more of these species identified as a focal species. Some urban fishing ponds provide excellent habitat for sunfish species and provide exciting opportunities for young anglers. Sunfish can overpopulate small ponds so, where warranted, Largemouth Bass are occasionally stocked to reduce sunfish density and increase growth rates. Currently, Yellow Perch are managed as self-sustaining populations and by statewide regulation of 30 fish per day with no length limit. The Department occasionally transplants Yellow Perch within the state to establish or supplement prey base and could do this for other species. Sunfish in New Mexico are not actively managed other than by a statewide limit of 20 fish per day with no size limit

and occasional supplemental stocking. Crappie are managed by a statewide regulation of 20 fish per day with no length limit. No specific parameters have been developed for these fish species.

Trout and Salmon

Several salmonid species inhabit New Mexico waters. Trout native to New Mexico include Gila Trout, historically found in coldwater reaches within the Gila River basin, and Rio Grande Cutthroat Trout, historically found in coldwater reaches of the Canadian, Pecos, and Rio Grande River basins. Both species have declined considerably from their historical distribution and Gila Trout are currently listed as "Threatened" under the ESA and the NMWCA.

Introduced species include Brook Trout, Brown Trout, kokanee, Lake Trout, Rainbow Trout, and other subspecies of Cutthroat Trout. Rainbow Trout are native to Pacific slope drainages in North America and were first introduced to New Mexico in 1896. Due primarily to stocking, Rainbow Trout are the most widely distributed and sought-after trout in the state. Brown Trout were transplanted from Europe, while Brook Trout are native to lakes and streams in eastern North America. Other subspecies of Cutthroat Trout which have been stocked in New Mexico include Snake River and Yellowstone cutthroat trout which have hybridized with our native trout and Rainbow Trout. Lake Trout have been introduced to several lakes in New Mexico but currently only inhabit Heron and El Vado reservoirs. Kokanee are inland Sockeye Salmon and have been stocked into several large coldwater reservoirs in the state. The Department conducts annual field spawns for kokanee to maintain these populations. While wild populations of Rainbow Trout exist in the state, the majority of Rainbow Trout angling opportunities are maintained via stocking. The Department currently stocks Rainbow Trout in approximately 150 waters statewide (https://www.wildlife.state.nm.us/fishing/weekly-report/).

The Department employs three management strategies for trout and salmon fisheries. Management strategies include: Put and Take, Put, Grow, and Take, and Wild waters; see the Glossary of Terms for a definition of each fishery type. In some cases, different management strategies may be employed for different species within the same water. Put and Take Trout Waters range from popular mountain streams with high angler use to large reservoirs and urban ponds. In nearly all cases, Put and Take Trout Waters are stocked consistently throughout a stocking season with catchable Rainbow Trout.

In limited cases, surplus catchable Gila Trout and Rio Grande Cutthroat Trout are stocked to increase recreational angling opportunities. A Framework for Management of Gila Trout Angling was approved by both the Department and the FWS which includes waters which will be stocked with Gila Trout for recreational purposes as well as recovery waters which are open

to angling. Different regulations are in place for Put and Take Trout Waters though the daily bag limit is generally 5 fish per day for Rainbow Trout and 2 fish per day for Cutthroat Trout. In some cases, Special Trout Water regulations are in place to equitably distribute angling opportunities and increase the retention time of stocked catchable trout within a waterbody.

Put, Grow, and Take Trout Waters may have limited habitat to support natural reproduction or angler harvest exceeds the number of fish produced via natural reproduction. In other cases, the Department stocks native trout with hopes of increasing the opportunity for anglers to catch a native trout within historical habitats. Waters managed as Put, Grow, and Take Trout Waters range from high mountain lakes, large coldwater reservoirs, to small streams. All kokanee fisheries and some triploid Rainbow Trout, recreational Rio Grande Cutthroat Trout, and recreational Gila Trout are managed as Put, Grow, and Take Waters. Rio Grande Cutthroat Trout that are surplus to restoration needs, discussed below, are stocked with hopes of contributing 5 to 15% of the overall trout abundance in select reaches. Harvest regulations are similar for Put and Take Waters and Put, Grow, and Take Waters. Daily bag limit for kokanee during the non-snagging season is 5 fish per day. During the annual snagging seasons at select waters, the daily bag limit is 12 fish per day. Snagging of kokanee is permitted because these fish will die after reaching spawning condition. In some cases, Special Trout Water regulations are in place to increase growth potential of stocked fish to larger sizes (e.g., San Juan River tailwater).

Wild Trout Waters include populations of trout that are maintained entirely via natural reproduction. Fisheries may be composed of a single species or include several species. Wild Trout Waters include Brook, Brown, Cutthroat, Gila, Lake, and Rainbow trout. The recovery populations of Gila Trout that are open to angling and Conservation Populations of Rio Grande Cutthroat Trout are included in Wild Trout Waters. At this time, five wild populations of Gila Trout are open to angling in New Mexico along with dozens open for Rio Grande Cutthroat Trout. Considering the conservation status of these species, these waters are formally designated as Native Fish Waters and are discussed further below. Specific criteria for both Conservation Populations of Rio Grande Cutthroat Trout and Gila Trout populations which are open to angling are discussed in the relevant conservation and recovery planning documents for each species. Since Wild Trout Waters are entirely supported by natural reproduction, avoiding overfishing via harvest regulations is of significant importance. The wild Lake Trout population in Heron Reservoir is managed to limit harvest and promote a stable population with a limited daily bag limit of 2 fish per day. Most Wild Trout Waters are subject to the statewide daily bag limit of 5 fish per day while others have Special Trout Water regulations.

Special Trout Waters have unique regulations intended to manipulate or protect the population through reduced bag limits and/or restrictions of allowable terminal tackle. In 2018, Special

Trout Water regulations were restructured with a New Mexico chile theme. Red Chile Waters prohibit harvest and limit terminal tackle (e.g., artificial lure or fly only, single barbless hook) and are geared toward producing trophy size trout (e.g., San Juan River tailwater), conserving native trout species, or protecting waters with special angling interest. Green Chile Waters allow daily harvest of two trout while still limiting terminal tackle. Green Chile Waters allow opportunity to harvest fish while still providing a unique experience of a quality fishery. X-mas Chile Waters allow daily harvest of two trout with any legal terminal tackle and are focused on providing quality fisheries without limiting any one angler group. In addition, a subset of Red Chile Waters, known as Native Trout Conservation Waters, were adopted to conserve native trout by allowing unlimited harvest of non-native trout to suppress these species and reduce competition.

Management strategies for Put and Take Trout Waters are focused on maximizing stocked fish return to the angler and spreading angling opportunity throughout an entire season and among anglers. Conversely, Put, Grow, and Take Trout Waters and Wild Trout Waters seek to provide angling opportunity yet ensure populations are maintained through time. As a result, objective parameters for Put and Take Trout Waters are focused on angler harvest rates and stocking rates. These parameters measure how effectively the Department allocates catchable Rainbow Trout and how those fish return to anglers. Objective parameters for Put, Grow, and Take Trout Waters are intended to establish desired population density and growth rates of stocked fish. Considering the diversity of Wild Trout Waters in the state, no single population parameters will fit all populations. In this case, general indicators of desired population status were developed for Wild Trout Waters.

Trout Parameters

Put and Take:

- Angler Harvest Rate: 1 fish/angler day during stocking season
- Stocking Rate: Stock at least 1 fish/angler day

Put, Grow, and Take:

Rainbow Trout

- Catch Per Unit Effort: 10 fish/hour of electrofishing
- Size Structure: 50% of Rainbow Trout surveyed > 10 inches in length

Rio Grande Cutthroat Trout

- Trout Community: > 5% of trout abundance composed of Rio Grande Cutthroat Trout

Kokanee

- Catch Per Unit Effort: 20 fish/net night with pelagic set nets

- Age structure: Equal contribution of Age-3 and Age-4 fish in annual spawning population

Wild:

Recreational Trout Waters

- Size Structure: Multiple year classes of trout including young of year
- Density: > 80 adult trout/acre of habitat

Quality Trout Waters

- Quality Potential: 5% of trout ≥ 12 inches
- Density: ≥ 400 adult trout/acre of habitat

Trophy Trout Waters

- Trophy Potential: 5% of trout ≥ 20 inches
- Angler Catch Rate: ≥ 1 fish/hour
- Density: ≥ 1,250 adult trout/acre of habitat

Native Species

New Mexico waters historically supported at least 66 native fish species. Several species or subspecies have been extirpated though over 50 still exist in the state. Many of these native species have declined from historical levels due to a variety of factors and are protected under the NMWCA or the ESA. Some native species such as Gila Trout and Rio Grande Cutthroat Trout are better known to the public compared to rare endemic fishes such as Loach Minnow or White Sands Pupfish. In some areas, conservation efforts and angling opportunity are complementary. The purpose of Departmental conservation efforts for native fishes is to address or mitigate existing threats to species to preclude the need to list a species under federal or state law, increase the distribution of species to warrant downlisting or removal from listing status, and maintain the ecological roles that many of these species play in our landscape. Improving the status of these taxa also benefit New Mexico anglers by minimizing potential restrictions imposed on sportfish activities where conflicts exist with listed species. The Department allocates significant resources to native fish conservation efforts in every river basin in the state.

Native fish management in New Mexico varies by species, drainage, and available resources to improve species status. They are also part of a fish assemblage that could include native, non-native, and sportfish species. In many cases, some native fish coexist with other species or can thrive in a modified environment. In those cases, native fish are managed in conjunction with typical management activities such as monitoring, regulation of sportfish take, alteration of species stocking or location, or species importation evaluations. In areas with no known direct conflict between sportfish and native fish management, the Department does not specifically

take actions to the detriment of native fish, though species management is typically focused on sportfish. In others, the aquatic environment has been altered to a degree where certain native fish do not persist in any significant manner. Sportfish management can be in direct conflict with native fish or communities due to predation, interbreeding, or competition. How Department management is focused on instances of altered waters and species hinges upon the feasibility of certain management actions to benefit a species or community, competing resource development (e.g., dams and water withdrawals), and existing programs currently addressing a particular species. All of this must be carefully balanced with existing or potential angler use within all watersheds in the state. To facilitate species recovery for some native fishes, sport fisheries have been targeted for suppression or complete removal.

Gila Trout is listed as threatened under the ESA and the NMWCA. The FWS downlisted Gila Trout from endangered to threatened in 2006 and issued a special rule, also known as a "4d" rule. This special rule permits take of Gila Trout when conducted in accordance with applicable state fish and wildlife conservation laws including fishing activities under state laws and regulations, educational and scientific purposes, the enhancement of propagation, and other conservation actions consistent with the ESA. The Department has been engaged in Gila Trout recovery efforts for decades. Downlisting and delisting criteria for Gila Trout are defined in the Gila Trout Recovery Plan (2003) and a revision of this plan is drafted and expected to be finalized in 2022. The Department plans to continue to conduct restoration efforts including piscicide treatments to remove competing or hybridizing non-native trout species, habitat protection via fish migration barriers, and development of angling regulations, in accordance with the recovery plan and future revisions. The Framework for Management of Gila Trout Angling (2015) provides additional guidance for recreational stocking efforts as well as monitoring of streams open to angling.

Warmwater reaches of the Gila River Basin support several endemic and imperiled native species including Loach Minnow, Roundtail Chub, and Spikedace. These species are negatively affected by non-native predators and their distribution has declined significantly from historical levels. While non-native predators are a threat to some Gila River fishes, other activities have altered habitats that negatively affect native fisheries. Active conservation efforts in the Gila River basin for native fish include active suppression of non-native fishes in certain reaches and repatriating rare fishes to historically occupied habitats. Future activities to benefit native species could include angling regulations to encourage removal of non-native predators from priority reaches, non-native fish removal via piscicide treatments, and habitat protection via fish barriers. The Department participates in various recovery activities for fish as described below.

Federal listing of Rio Grande Cutthroat Trout was determined to be not warranted in 2014 and it was removed from the candidate species list under the ESA. In 2019, as a result of ongoing litigation, a Federal Court for the District of Colorado vacated the previous decision and Rio Grande Cutthroat Trout were returned to Candidate status. The Department has been a signatory to the Rangewide Conservation Agreement for Rio Grande Cutthroat Trout since 2002 and a complementary Conservation Strategy since 2013. The purpose of these documents is to memorialize formal commitments by the Department and other federal, state, and tribal cooperators to Rio Grande Cutthroat Trout conservation efforts including desired population numbers within certain watersheds. The Department will continue ongoing restoration efforts that benefit Rio Grande Cutthroat Trout similar to those described for Gila Trout above. This will include mechanical suppression efforts and angling regulations intended to suppress non-native trout in designated reaches. The Department has also included Rio Grande Sucker and Rio Grande Chub into restoration planning efforts to restore the entire native fish community when appropriate.

Warmwater reaches of the San Juan River and tributaries currently support Colorado Pikeminnow, Razorback Sucker, and, to a lesser extent, Roundtail Chub. Both Colorado Pikeminnow and Razorback Sucker are federally protected and their recovery is the primary purpose for the San Juan River Basin Recovery Implementation Program (SJRBRIP) in which the Department participates. Management activities conducted as part of that program include annual monitoring, non-native fish suppression (Channel Catfish removal), and participation in the SJRBRIP Biology Committee meetings. The Department plans to continue participation in these efforts, craft new approaches to recovery, as well as develop other potential conservation efforts that could benefit Roundtail Chub.

Multiple conservation plans, agreements, and state and federal recovery plans also guide Department actions for native fish management and conservation. Many of these plans and agreements summarize threats to each species and include approaches to address those threats. Below is a list of conservation planning documents organized by the primary basin to which they are relevant. Some plans are applicable to multiple drainages. Copies of these plans can be found on the Department website at https://www.wildlife.state.nm.us/fishing/fisheries-management/.

Gila River Basin

- Colorado River Basin Chubs Recovery Plan, 2006 (State)
- Framework for Management of Gila Trout Angling, 2015
- Gila Trout Recovery Plan, 2003 (Federal)
- Loach Minnow Recovery Plan, 1991 (Federal)
- Spikedace Recovery Plan, 1991 (Federal)

Mimbres River Basin

- Chihuahua Chub Recovery Plan, 1986 (Federal)
- Fishes of the Rio Yaqui Recovery Plan, 1995 (Federal)

Rio Grande and Pecos River Basins

- Conservation Agreement for Pecos Pupfish, 2013
- Conservation Agreement for Rio Grande Chub and Rio Grande Sucker, 2018
- Conservation Agreement for Rio Grande Cutthroat Trout in the States of Colorado and New Mexico, 2013
- Pecos Bluntnose Shiner Recovery Plan, 1992 (Federal)
- Pecos Gambusia Recovery Plan, 1983 (Federal)
- Recovery and Conservation Plan for Four Invertebrate Species: Noel's Amphipod, Pecos Assiminea, Koster's Springsnail, and Roswell Springsnail, 2005 (State)
- Recovery Plan for Four Invertebrates of the Pecos River Valley: Noel's Amphipod, Pecos Assiminea, Koster's Springsnail, and Roswell Springsnail, 2019 (Federal)
- Rio Grande Chub Conservation Strategy, 2021
- Rio Grande Cutthroat Trout Conservation Strategy, 2013
- Rio Grande Silvery Minnow Recovery Plan, 2010 (Federal)
- Rio Grande Sucker Conservation Strategy for, 2021
- Texas Hornshell Recovery Plan (State), 2007
- Texas Hornshell Draft Recovery Plan, 2020 (Federal)

San Juan River Basin

- Colorado Pikeminnow Recovery Plan, 2002 (Federal)
- Colorado River Basin Chubs Recovery Plan, 2006 (State)
- Range-wide Conservation Agreement and Strategy for Roundtail Chub, Bluehead Sucker, and Flannelmouth Sucker, 2006
- Razorback Sucker Recovery Plan, 2002 (Federal)

Zuni Basin

- Zuni Bluehead Sucker Recovery Plan, 2004 (State)

Tularosa River Basin

- Cooperative Agreement for Protection and Maintenance of White Sands Pupfish, 2020
- White Sands Pupfish Conservation Plan, 2015 (State)

Major Accomplishments since 2016

Since adoption of the Statewide Fisheries Management Plan in 2016, major accomplishments by the Department and our partners include:

- Gila Trout have been restored to 24 miles of habitat in Whitewater Creek. Removal of nonnative trout was completed in 2019 and stocking of Gila Trout began in 2020 and will continue through at least 2022
- The Glenwood State Fish Hatchery is currently undergoing a major renovation to become the Department's Gila Trout facility. When complete, the facility will house a broodstock to propagate Gila Trout for species recovery and expanded angling opportunities
- In 2021, the Department purchased the property adjacent to the Glenwood State Fish Hatchery including water rights significant to the hatchery's operations. The purchase included portions of Whitewater Creek and the San Francisco River that are occupied habitat for endangered Loach Minnow and Spikedace, thus securing an important refuge for both species
- From 2016 to 2020 the proportion of stocked catchable Rainbow Trout over 10 inches increased from 61% to 73%
- Rio Grande Cutthroat Trout have been restored to 90 miles of stream and Costilla Reservoir. The Department anticipates completing removal of nonnative fishes from the final areas of the project in 2022 and for stocking to begin in 2023
- Five fish migration barriers were constructed since 2016. Barriers were completed in Willow Creek (Gila Drainage), Willow Creek (Pecos Drainage), the BLM Overflow Wetlands on the Pecos River, and Costilla Creek. Each barrier protects a population of Gila Trout, Pecos Pupfish, or Rio Grande Cutthroat Trout and provides benefits for other native fish like Rio Grande Chub and Rio Grande Sucker
- In 2017, the Department transitioned angler surveys to a web-based survey method from traditional methods (e.g., phone and mail). The surveys provide insight on annual angler satisfaction, seek input on current topics, refine existing management programs, and monitor trends in angler use and harvest. Gila Trout were also added to the survey to explore increased angler interest for this species
- Since 2016, the Department has improved fish habitat on seven streams and rivers, totaling 14.5 miles, and one 60-acre lake
- In 2018, warmwater fish production at Rock Lake State Fish Hatchery converted to primarily Largemouth Bass. Since that conversion, the hatchery has refined spawning practices, increased annual stocking by an average of 8700%, and stocked 1,017,697 Largemouth Bass in 25 waters statewide

- The Department expanded youth angling opportunities by opening Rock Lake State Fish Hatchery settling ponds to anglers 11 years old and younger, providing Rainbow Trout and Largemouth Bass to support multiple fishing derbies, and expanded Rio Grande Cutthroat Trout stocking at the Seven Springs Kids Pond. In addition, age-restricted waters were simplified to four basic types and daily harvest limits were aligned with statewide regulations at multiple waters to reduce confusion and increase opportunity
- In 2021, the Department provided two new tools to the state's anglers: Fishing Conditions and Trip Planner that synthesizes fishing report data to help anglers find the best times and places to fish for certain species and a new Fishing Waters Map that is a wealth of information about fishing locations throughout New Mexico. Both can be found at www.wildlife.state.nm.us/fishing/fishing-conditions-trip-planner/
- In July 2017, the State Game Commission amended 19.30.14 NMAC to increase protection of New Mexico's waters from AIS by requiring inspections for out of state watercraft, advanced notice for watercraft 26 feet or larger being transported into the state, and hull plug to be removed during transport. The new rule also implements a watercraft inspection seal program. The amended rule along with the Department's ongoing AIS inspection and decontaminations have thus far succeeded in preventing zebra and quagga mussels from becoming established in the state
- In February 2021, the State Game Commission amended 19.35.7 NMAC to update and clarify importation rules associated with fish health
- The Special Trout Water system was simplified to four basic regulation packages with a New Mexico chile theme. These regulations were tailored to improve angler understanding, facilitate native trout restoration, and maximize biotic potential in these trout fisheries
- The State Game Commission designated three waters as Trophy Bass Waters that included a regulatory change and focused stocking strategy to protect and enhance angling opportunities for trophy sized Largemouth Bass

Identified Priority Projects and Needs for Further Investigation and Research

The 2016 Plan identified a number of programmatic fisheries priorities including evaluation of hatchery stocking, habitat restoration, AIS monitoring and prevention, species recovery efforts, and statewide fisheries management. The 2016 priorities and details regarding progress made toward them can be found in Appendix B. Below are the ongoing and new priorities, in many cases these priorities are direct responses to challenges and threats, like climate change and reduced water availability.

Evaluation of Hatchery Stocking

Trout

- Investigate potential for reducing or eliminating stocking of catchable trout from five waters or reaches which support wild trout and reallocate to higher use systems including lakes and ponds
- Continue to evaluate allocation of catchable and subcatchable trout
- Continue to investigate areas where native trout, surplus to recovery efforts, can be used to increase angling opportunities for native trout including high mountain lakes
- Investigate opportunities for additional native trout production to expand angling opportunities for Gila and Rio Grande Cutthroat trout
- Monitor and adjust kokanee stocking strategies in accordance with varying reservoir levels and differing spawning success

Catfish

- Refine Channel Catfish stocking strategies to best allocate private-sourced catfish

Walleye

- Monitor and adjust Walleye stocking strategies in accordance with varying reservoir levels and differing spawning success

Black Bass

- Establish long-term stocking goals for Largemouth Bass produced at Rock Lake State Fish Hatchery
- Investigate success of stocked Largemouth Bass
- Investigate genetic composition of wild bass in New Mexico's reservoirs to identify potential of diversifying hatchery brood and stocking strategies

Temperate Bass

- Investigate potential of hybrid striped bass as a management species and identify candidate reservoirs for stocking
- Stock hybrid striped bass into Caballo Lake and monitor for success

Habitat Restoration

- Work with partners and volunteers, design and implement instream, riparian, and reservoir habitat restoration efforts on Commission owned Wildlife Management Areas including monitoring and maintenance of existing projects
- Work with partners and volunteers, design and implement instream, riparian, and reservoir habitat restoration efforts on non-Commission owned properties

- Implement fish habitat improvement projects under the Department's 2021 updated Habitat Stamp Program

Aquatic Invasive Species

- Maintain prevention efforts including watercraft inspection stations
- Review and update the 2008 New Mexico Aquatic Invasive Species Management Plan

Fish Health

- Maintain hatchery and wild fish health program to mitigate risk from known fish pathogens
- Provide recommendations for fish health risk assessments, management practices, and hatchery improvements
- Develop and test a Fish Quality and Health Assessment tool for stocked Rainbow Trout that aligns with angler expectation for fish quality and appearance

Environmental Compliance

- Complete a comprehensive, statewide Biological Assessment for ESA Section 7 compliance for all Departmental fish monitoring and surveys in New Mexico
- Maintain all environmental compliance for Fisheries Management Division activities

Species Recovery Efforts

Native Trout Restoration

- Continue Rio Grande Cutthroat Trout restoration in the Costilla Creek watershed as well as identify restoration waters in the Pecos River and Canadian River watersheds
- Continue Gila Trout restoration in the Gila River Basin
- Install, enhance, and maintain fish migration barriers used to protect restored and existing populations of native trout
- Assess and act on opportunities for restoration created by wildfire or other disturbances as they occur, as done in Mineral, Willow, and Whitewater creeks (Gila Basin), and Rito de los Frijoles and Las Animas Creek (Rio Grande Basin)
- Continue investigating use and effects of YY trout to aid in native trout restoration efforts
- Incorporate other native fishes into restoration efforts including warmwater reaches, where possible. Examples include Rio Grande Sucker, Rio Grande Chub, Spikedace, and Loach Minnow.

Rio Grande Basin Warmwater Fishes

- Investigate distribution and genetic status of Rio Grande Chub and Rio Grande Sucker throughout the state
- Implement restoration activities for Rio Grande Chub and Rio Grande Sucker as described each species Conservation Strategies

Gila River Basin Warmwater Fishes

- Identify potential restoration and repatriation opportunities for Spikedace, Loach Minnow, and Roundtail Chub in the Middle Fork Gila River, San Francisco River drainage, and other locations
- Incorporate native trout into restoration efforts to complement coldwater reaches and other sensitive or listed taxa recovery efforts, where possible

San Juan River Basin Fishes

- Investigate opportunities to increase passage for native fish
- Identify potential restoration and repatriation opportunities for Roundtail Chub
- Investigate potential use and effects of YY fish to aid non-native fish suppression efforts

Lower Pecos River Basin Fishes

- Investigate genetic status of Pecos Pupfish populations

Statewide Fisheries Management

- Work to encourage expanded youth angling opportunities
- Investigate regulatory structure to manage potential hybrid striped bass fisheries in Caballo Lake and other waters
- Investigate potential regulatory structure to allow expanded use of set lines including ice fishing tip-ups and jug-lines for catfish
- Update, refine, and improve angler information sources including but not limited to the Fishing Conditions and Trip Planner and Fishing Waters Map
- Investigate angler use and harvest in native trout populations
- Refine an approach for resolving sportfish/native fish conflicts
- Work with NGO's to develop and implement conservation projects with direct volunteer involvement such as habitat improvement for sport and native fish, fish stocking, and nonnative fish control

Watershed Descriptions and Fisheries Management

To initiate the management reach delineations below, the National Hydrography Dataset (NHD) flowline and waterbody files for New Mexico were imported into existing Department geodatabases. Department staff identified management reaches based upon available fish distribution datasets and management activities. Management reaches were based upon individual waters, in some cases, but also grouped into watersheds or sub-watersheds where feasible. Once identified, corresponding features from the NHD datasets were exported into a new dataset. Additional spatial information, including hydrologic unit codes and geographic names information system (GNIS) codes, were appended into the new dataset. Non-spatial information including priority fish species, management type, and management direction for each were then incorporated. Some reservoirs were not included in the NHD and were digitized using the National Agriculture Imagery Program (U.S. Department of Agriculture) aerial photography from 2011 to 2014.

The term "Fish Species" in the tables below refers to individual species that are a management focus for the water identified. The management reaches that are identified for a species or suite of species does not necessarily mean that the entire reach is occupied by those species due to variation in water quality, flow regime, and habitat availability. Some of the mapped reaches could be dry or wet depending upon an individual water year. In many cases, the species identified are not a comprehensive list of species present within the water or could identify a species that does not yet inhabit a water. Activities such as monitoring or restoration will be focused on the focal species identified with potential community benefits for others when possible. Failure to mention a species does not imply that the Department intends to actively remove a species from a water. The maps included are intended for management direction only and do not reflect absolute distribution. Individual species accounts, datasets, and distributions are available from the Department, other state or federal agencies, and the BISON-M database maintained by the Department.

"Management Type" refers to general categories of activities such as stocking strategy, self-sustaining populations, or population suppression. The Native Fish designation includes all activities which could help to monitor, support, or restore the identified species as well as other members of the community.

"Management Direction" includes a brief synopsis of the Department's expected management for a water or species in that water. Stocking rates will generally follow the Department's stocking schedule (www.wildlife.state.nm.us/fishing/weekly-report/) which may be modified over time. Stocking rates that vary by year or water levels are specifically noted in the tables below.

Canadian Watershed and Clovis Area Waters

The Canadian Watershed, in northeast New Mexico, encompasses about one-sixth of the land area of the state or about 10.9 million acres (New Mexico Water Quality Control Commission 2002). Canadian River tributaries flow east and southeast from their origins on the east slopes of the Sangre de Cristo cordillera of northern New Mexico and southern Colorado. As it traverses the Great Plains in a southerly and then easterly direction several perennial tributaries, including the Cimarron, Conchas, Mora, and Vermejo rivers, join the South Canadian River before it exits New Mexico near the town of Logan. The Upper Canadian, Middle Canadian, Upper Beaver, and the Dry Cimarron are the only perennial sub-basins.

Settlement and irrigation withdrawal along high mountain valleys in the Mora River dates to the 1700's. Numerous impoundments and diversions have been built throughout the upper drainage for irrigation and municipal water. Livestock grazing continues to be the primary land use throughout the drainage. Two large dams on the Canadian River, Conchas Dam (constructed 1938) and Ute Dam (constructed 1962), impound reservoirs and modify natural flows as the river approaches the New Mexico-Texas border. These reservoirs provide suitable habitat for sportfish such as Largemouth Bass, Smallmouth Bass, and Walleye.

Historical fisheries management in the Canadian River Watershed has focused primarily on trout management in the headwaters with warmwater species in lower elevation habitats. Popular trout populations open to the general public include the Cimarron River, Eagle Nest Lake, Lake Maloya, and Morphy Lake. Popular warmwater fisheries within the drainage occur in Conchas and Ute lakes. Significant portions of the Canadian Watershed are privately owned which limits general public access to these areas without landowner permission. The Department also leases several waters from landowners to expand angling opportunities either through long-term leases or the Department's Open Gate Program. For example, the Department pays the Interstate Stream Commission $100,000 annually to obtain access to Ute Lake for the general public. Other examples of the Department leasing fishing access include Morphy and Springer lakes.

Several imperiled fish inhabit the New Mexico reaches of the Canadian River watershed. Arkansas River Shiner, federally threatened, inhabits the Canadian River below Ute Dam to the stateline. Peppered Chub, state threatened and currently proposed for federal listing as endangered, also inhabits the Canadian River below Ute Dam to the stateline. The state endangered Southern Redbelly Dace inhabits a small reach of Coyote Creek and is a disjunct population from other populations in the Mississippi River drainage. In addition, state threatened Suckermouth Minnow occur in the Canadian Basin. There is currently limited conflict among non-native sportfish and native fish management. Where some overlap exists, introduced species such as Brown Trout and Southern Redbelly Dace seem to co-exist.

Nevertheless, the Department has identified reaches to monitor and proactively manage the fish communities.

HUC 11080001 Canadian Headwaters, HUC 11080002 Cimarron

Management Direction for HUC 11080001 Canadian Headwaters

Water	Fish Species	Management Type	Management Direction
Canadian River and Tributaries (headwaters downstream to Cimarron River confluence)	Central Stoneroller	Native Fish	Maintain distribution
	Creek Chub	Native Fish	Maintain distribution
Lake Maloya (Sugarite Canyon)	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout
Lake Alice	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout
Vermejo River and Tributaries (headwaters downstream to Canadian River confluence)	Rio Grande Cutthroat Trout	Native Fish	Core Conservation Population of Rio Grande Cutthroat Trout in Ricardo, Leandro, and Little Vermejo drainages. Conservation Population of Rio Grande Cutthroat Trout in the Vermejo River down to approximately Vermejo Park Ranch headquarters. Most of the watershed is privately owned. Leandro Creek portions located on Valle Vidal with Special Trout Water regulation (Red Chile Native Trout Conservation Water)
	Central Stoneroller	Native Fish	Maintain distribution
	Creek Chub	Native Fish	Maintain distribution
	Brook Trout	Suppression	Periodically remove Brook Trout in collaboration with private landowner to maintain the Rio Grande Cutthroat Trout population. Leandro Creek portions located on Vermejo Park Ranch have an ongoing YY Brook Trout stocking study. Unlimited angler harvest
Stubblefield Reservoir	Walleye	Put, Grow, and Take	Stock Walleye at 500 fry/surface acre. Actual stocking varies with reservoir elevation. Prone to drying during drought necessitating supplemental stocking of all species such as Bluegill, Crappie, Green Sunfish, Fathead Minnow, and Yellow Perch
	Channel Catfish	Put and Take	Stock catchable Channel Catfish as available

Management Direction for HUC 11080001 Canadian Headwaters			
Water	**Fish Species**	**Management Type**	**Management Direction**
	Yellow Perch	Wild	Supplement Yellow Perch from other sources as necessary during drought periods
	Largemouth Bass	Wild/ Supplemental stocking	Manage as Low-Density Bass Water and maintain statewide bass regulations. Supplement Largemouth Bass as necessary during drought periods
Maxwell Lake 13	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout during spring and fall. Fishing season is March 1 through October 31. Lake closed during winter for waterfowl resting. Prone to drying during drought necessitating supplemental stocking of all species such as Bluegill, Crappie, Green Sunfish, Fathead Minnow, and Yellow Perch
	Channel Catfish	Put and Take	Stock catchable Channel Catfish as available
	Yellow Perch	Wild	Supplement Yellow Perch from other sources as necessary during drought periods
	Largemouth Bass	Wild/ Supplemental stocking	Manage as Low-Density Bass Water and maintain statewide bass regulations. Supplement Largemouth Bass as necessary during drought periods
	Walleye	Put, Grow, and Take	Stock Walleye at 500 fry/surface acre. Actual stocking varies with reservoir elevation, low priority water
Maxwell Lake 14	Channel Catfish	Put and Take	Stock catchable Channel Catfish as available. Fishing season is March 1 through October 31. Lake closed during winter for waterfowl resting. Prone to drying during drought necessitating supplemental stocking of all species such as Bluegill, Crappie, Green Sunfish, Fathead Minnow, and Yellow Perch
	Yellow Perch	Wild/ Supplemental stocking	Supplement Yellow Perch from other sources as necessary during drought periods
	Largemouth Bass	Wild/ Supplemental stocking	Manage as Low Density Bass Water and maintain statewide bass regulations. Supplement Largemouth Bass as necessary during drought periods
	Walleye	Put, Grow, and Take	Stock Walleye at 500 fry/surface acre. Actual stocking varies with reservoir elevation, low priority water
Laguna Madre	Channel Catfish	Put and Take	Stock catchable Channel Catfish as available. Prone to drying during drought necessitating supplemental stocking of all species such as Bluegill, Crappie, Green Sunfish, Fathead Minnow, and Yellow Perch
	Yellow Perch	Wild	Supplement Yellow Perch from other sources as necessary during drought periods

NMED Exhibit 38

Water	Fish Species	Management Type	Management Direction
	Largemouth Bass	Wild/ Supplemental stocking	Manage as Low Density Bass Water and maintain statewide bass regulations. Supplement Largemouth Bass as necessary during drought periods
	Walleye	Put, Grow, and Take	Stock Walleye at 500 fry/surface acre. Actual stocking varies with reservoir elevation, low priority water

Management Direction for HUC 11080002 Cimarron

Water	Fish Species	Management Type	Management Direction
Cimarron River and Tributaries (Eagle Nest Dam downstream to Cimarron, NM)	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout
	Brown Trout	Wild	Special Trout Water regulation (Red Chile Water), from east end of Tolby Campground downstream 1.4 miles to the first Highway 64 bridge. Manage as a Quality Trout Water within the Special Trout Water reach
Gravel Pit Lakes	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout
Clear Creek	Rio Grande Cutthroat Trout	Native Fish	Core Conservation Population of Rio Grande Cutthroat Trout
Cimarron River and Tributaries (Cimarron, NM downstream to confluence with Canadian River)	Central Stoneroller	Native Fish	Maintain distribution. Significant portions of this area are on private land
	Creek Chub	Native Fish	Maintain distribution
Eagle Nest Lake	Triploid Rainbow Trout	Put, Grow, and Take	Stock subadult and catchable triploid Rainbow Trout. Consistently monitor to document effects of Northern Pike
	Kokanee	Put, Grow, and Take	Stock kokanee fry. Consistently monitor to document effects of Northern Pike
	Yellow Perch	Wild	Yellow Perch source for transplants to other waters
	Northern Pike	Suppression	Unlimited and mandatory harvest on Northern Pike to manage as unwanted species. Illegally introduced into the lake and are negatively affecting trout and salmon fishery
Springer Lake	Channel Catfish	Put and Take	Stock catchable Channel Catfish as available
	Northern Pike	Wild	Maintain regulations to support northern pike fishery

Management Direction for HUC 11080002 Cimarron			
Water	**Fish Species**	**Management Type**	**Management Direction**
	Largemouth Bass	Wild/ Supplemental stocking	Manage as Low Density Bass Water and maintain statewide bass regulations. Supplement Largemouth Bass as necessary during drought periods
Ponil Creek and Tributaries	Trout	Wild	Maintain regulations to support angling for wild trout
	Creek Chub	Native Fish	Maintain distribution
South Ponil Creek	Rio Grande Cutthroat Trout	Native Fish	Core Conservation Population of Rio Grande Cutthroat Trout on Philmont Scout Ranch
McCrystal Creek	Rio Grande Cutthroat Trout	Native Fish	Core Conservation Population of Rio Grande Cutthroat Trout. Special Trout Water regulation (Red Chile Water)
	Creek Chub	Native Fish	Maintain distribution
Rayado Creek	Creek Chub	Native Fish	Maintain distribution
Shuree Ponds	Triploid Rainbow Trout	Put and Take	Stock triploid Rainbow Trout annually. Size at stocking is typically > 15 inches in length. Special Trout Water regulation (Green Chile Water). One pond reserved for anglers 11 years of age or younger
Middle Ponil Creek (Headwaters downstream to Shuree Creek)	Rio Grande Cutthroat Trout	Native Fish	Conservation Population of Rio Grande Cutthroat Trout. Special Trout Water regulation (Red Chile Water). Investigate potential to restore area to support Core Conservation Population
North Ponil Creek	Rio Grande Cutthroat Trout	Native Fish	Core Conservation Population of Rio Grande Cutthroat Trout present from McCrystal Creek downstream to FS Road 1950. Thermal barrier present at Seally Canyon confluence
	Creek Chub	Native Fish	Maintain distribution

NMED Exhibit 38

Pecos Watershed

The Pecos River arises on the southern slope of the Sangre de Cristo Mountain range in San Miguel County, New Mexico, and runs south through Guadalupe, De Baca, Chaves, and Eddy counties before it enters Texas. The Pecos Watershed encompasses 12.3 million acres in New Mexico. Principal New Mexico cities in the watershed include Las Vegas, Santa Rosa, Fort Sumner, Roswell, Artesia, and Carlsbad. Land use in this watershed is mainly rangeland, with some irrigated cropland and pastureland along the Pecos River. Roughly 10% of the industry in the lower Pecos Valley is agriculture based (De Baca, Chavez, and Eddy Counties). Primary crops include small grains, alfalfa, and other hay crops. Oil and gas development occur within the lower Pecos River valley.

Fisheries management in the Pecos Watershed has focused on trout management in the headwaters and warmwater species in the lower reaches and man-made reservoirs. Popular trout fisheries include the Pecos Canyon and Monastery Lake. Populations of Rio Grande Cutthroat Trout occur in Pecos River tributaries providing unique angling opportunities and significantly contributing to the status of this native trout. In 2012, the Department and other federal and state partners committed to restoring Rio Grande Cutthroat Trout to portions of the Pecos Watershed in the Rio Grande Cutthroat Trout Conservation Strategy. Conservation strategies have also been developed for Rio Grande Chub and Rio Grande Sucker and include waters in the Pecos Watershed. Specific waters are identified below where all or part will be restored to fulfill those commitments.

Several moderate to large reservoirs impound the Pecos River beginning with Santa Rosa Lake and ending with Avalon Dam near the New Mexico/Texas state line. Several urban ponds are intensively managed via seasonal stocking of Channel Catfish or Rainbow Trout. Golden algae blooms have negatively affected fisheries in several reservoirs in the lower Pecos since the early 2000s and continue to negatively affect some fisheries as blooms occur.

Several state or federally protected and sensitive fish species occur within the Pecos River. Designated critical habitat for Pecos Bluntnose Shiner includes significant reaches of the Pecos River between Lake Sumner and Brantley Lake. State threatened Pecos Pupfish inhabit multiple locations in the lower Pecos including waters on the Bottomless Lakes Sate Park. Blue Sucker, Gray Redhorse, and Texas hornshell, a native mussel that was recently declared federally endangered, occupy the Black River. Golden algae has also negatively affected native fish within the Pecos River, particularly downstream of Brantley Lake.

HUC 13060001 Pecos Headwaters – Headwaters to Santa Rosa

Management Direction for HUC 13060001 Pecos Headwaters – Headwaters to Santa Rosa Lake

Water	Fish Species	Management Type	Management Direction
Pecos River (above Pecos Falls)	Rio Grande Cutthroat Trout	Native Fish	Conservation Population of Rio Grande Cutthroat Trout. Special Trout Water regulation (Red Chile Water)
Pecos River and Tributaries (headwaters downstream to Cowles)	Brown Trout	Wild	Maintain regulations to support angling for wild trout
	Rio Grande Cutthroat Trout	Native Fish	Significant portions of this drainage to be considered for Rio Grande Cutthroat Trout restoration in the future
Holy Ghost Creek and Tributaries	Brown Trout	Wild	Maintain regulations to support angling for wild trout
	Rio Grande Cutthroat Trout	Native Fish	Significant portions of this drainage to be considered for Rio Grande Cutthroat Trout restoration in the future
	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout at Holy Ghost Campground downstream to Pecos River confluence
Bear Creek (Upstream of Barrier)	Rio Grande Cutthroat Trout	Native Fish	Conservation Population of Rio Grande Cutthroat Trout
Rito los Esteros	Rio Grande Cutthroat Trout	Native Fish	Conservation Population of Rio Grande Cutthroat Trout
Rio Valdez (Above Barrier)	Rio Grande Cutthroat Trout	Native Fish	Core Conservation Population of Rio Grande Cutthroat Trout. Special Trout Water regulation (Red Chile Water) from waterfall barrier 0.8 miles below FS Trail 239 upstream to its headwaters
Rio Mora Headwaters	Rio Grande Cutthroat Trout	Native Fish	Core Conservation Population of Rio Grande Cutthroat Trout
Cave Creek (Above Barrier)	Rio Grande Cutthroat Trout	Native Fish	Conservation Population of Rio Grande Cutthroat Trout
Rito del Padre and Tributaries	Rio Grande Cutthroat Trout	Native Fish	Conservation Population of Rio Grande Cutthroat Trout. Special Trout Water regulation (Red Chile Native Trout Conservation Water) from the fish migration barrier 0.3 miles upstream of confluence with Rito Sebadilloses to its headwaters including Rito de los Chimayosos
	Brown Trout	Suppression	Unlimited angler harvest
Dalton Creek	Rio Grande Cutthroat Trout	Native Fish	Core Conservation Population of Rio Grande Cutthroat Trout

Management Direction for HUC 13060001 Pecos Headwaters – Headwaters to Santa Rosa Lake

Water	Fish Species	Management Type	Management Direction
Macho Creek	Rio Grande Cutthroat Trout	Native Fish	Core Conservation Population of Rio Grande Cutthroat Trout
Jack's Creek	Rio Grande Cutthroat Trout	Native Fish	Core Conservation Population of Rio Grande Cutthroat Trout. Special Trout Water regulation (Red Chile Water) from waterfalls 0.25 miles downstream of Highway 63 crossing to headwaters. Consider barrier improvements to further protect population
Cowles Ponds (Mt. View Ponds)	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout. Upper pond open to anglers 11 years old and younger, 65 years old and older, and individuals with disabilities
Panchuela Creek and Tributaries	Brown Trout	Wild	Maintain regulations to support angling for wild trout
	Brook Trout	Wild	Maintain regulations to support angling for wild trout
	Rio Grande Cutthroat Trout	Native Fish	Conservation Population of Rio Grande Cutthroat Trout present in Cave Creek. Significant portions of this drainage to be considered for Rio Grande Cutthroat Trout restoration
Rio Mora (adjacent to Mora Campground)	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout
Rio Mora and Tributaries (Upstream of Mora Campground)	Trout	Wild	Maintain regulations to support angling for wild trout
	Rio Grande Cutthroat Trout	Native Fish	Significant portions of this drainage to be considered for Rio Grande Cutthroat Trout restoration in the future
Willow Creek	Rio Grande Cutthroat Trout	Native Fish	Active Rio Grande Cutthroat Trout restoration. Anticipated completion 2024
Lake Katherine	Rio Grande Cutthroat Trout	Put, Grow, and Take	Stock periodically with Pecos strain Rio Grande Cutthroat Trout, as available
Johnson Lake	Cutthroat Trout	Wild	Maintain regulations to support angling for wild trout. Lake would be part of Panchuela Creek Rio Grande Cutthroat Trout restoration
Pecos Baldy Lake	Rio Grande Cutthroat Trout	Put, Grow, and Take	Stock periodically with Pecos strain Rio Grande Cutthroat Trout, as available

NMED Exhibit 38

Management Direction for HUC 13060001 Pecos Headwaters – Headwaters to Santa Rosa Lake

Water	Fish Species	Management Type	Management Direction
Stewart Lake	Cutthroat Trout	Wild	Maintain regulations to support angling for wild trout
Truchas Lakes	Rio Grande Cutthroat Trout	Put, Grow, and Take	Stock periodically with Pecos strain Rio Grande Cutthroat Trout, as available
Monastery Lake	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout
Pecos River and Tributaries (Cowles downstream to Village of Pecos)	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout
	Brown Trout	Wild	Special Trout Water regulation (Green Chile Water) in the box canyon 0.5 miles upstream of the confluence with the Mora River to 0.2 miles downstream of the Cowles Bridge. Other species of trout exist in tributaries though the predominant species is Brown Trout. Maintain regulations to support angling for wild trout. Manage habitat improvement reaches within the Pecos Canyon State Park as Quality Trout Waters
Cow Creek and Tributaries	Trout	Wild	Brook, Brown, and Cutthroat trout are present depending upon individual watersheds. Need to investigate fishery status in lower reach of Cow Creek downstream of North San Ysidro
	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout near Cow Creek campground
	Rio Grande Cutthroat Trout	Native Fish	Portions of this drainage to be considered for Rio Grande Cutthroat Trout restoration in the future
Pecos River (Village of Pecos downstream to Interstate 25)	Brown Trout	Wild	Maintain regulations to support angling for wild trout. Collaborate with National Park Service to maintain angler opportunities with the Pecos National Historic Park
	Rio Grande Chub	Native Fish	Maintain distribution
Pecos River (Interstate 25 downstream to Santa Rosa Lake)	Rio Grande Chub	Native Fish	Maintain distribution
	Flathead Chub	Native Fish	Maintain distribution
	Triploid Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout within Villanueva State Park
	Channel Catfish	Put and Take	Special Summer Catfish Water - Stock catchable Channel Catfish within Villanueva State Park

NMED Exhibit 38

Management Direction for HUC 13060001 Pecos Headwaters – Headwaters to Santa Rosa Lake

Water	Fish Species	Management Type	Management Direction
Gallinas Creek (River) and Tributaries (Headwaters downstream to Interstate 25)	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout
	Brown Trout	Wild	Maintain regulations to support angling for wild trout. Limited wild trout potential in lower reaches due to dewatering and increased temperatures
Gallinas River (Downstream of Interstate 25)	N/A	N/A	Limited information is available about the status of this reach
Gallinas Ice Pond	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout
El Porvenir Creek (Headwaters downstream to El Porvenir Campground)	Brown Trout	Wild	Maintain regulations to support angling for wild trout. Limited information on the status of this watershed
El Porvenir Creek (El Porvenir Campground downstream to confluence with Gallinas Creek)	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout
Storrie Lake	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout
	Channel Catfish	Wild	Maintain regulations to support angling for wild Channel Catfish. Stock Channel Catfish as necessary
Harris Lake	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout. Open to anglers 11 years old and younger
	Channel Catfish	Put and Take	Special Summer Catfish Water - Stock catchable Channel Catfish
Tecolote Creek (Headwaters downstream to confluence with Falls Creek)	Trout	Wild	Brook, Brown, and Cutthroat trout are present in different reaches of this watershed. Maintain regulations to support angling for wild trout
Tecolote Creek (Falls Creek confluence downstream to Pecos River)	Rio Grande Chub	Native Fish	Maintain distribution. Limited information is available about the status of this reach. Primarily on private land

NMED Exhibit 38

Management Direction for HUC 13060001 Pecos Headwaters – Headwaters to Santa Rosa Lake

Water	Fish Species	Management Type	Management Direction
El Rito Creek (Santa Rosa)	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout
	Roundnose Minnow	Native Fish	Maintain distribution
Santa Rosa Lake	Channel Catfish	Wild	Reservoir subject to significant water level fluctuations both within and between years. Stock Channel Catfish as necessary
	Walleye	Put, Grow, and Take	Stock Walleye at 500 fry/surface acre. Actual stocking varies with reservoir elevation. Brood source for Walleye
	Largemouth Bass	Wild/ Supplemental stocking	Manage as a Recreational Bass Water. Supplement with Largemouth Bass fry as available
	Smallmouth Bass	Wild	Manage as a Recreational Bass Water
Pecos River (Santa Rosa Lake to Lake Sumner)	N/A	N/A	Limited access, limited use and no native species of concern occur in this reach. Located primarily on private land
Lake Sumner	Channel Catfish	Wild	Reservoir subject to significant water level fluctuations both within and between years. Stock Channel Catfish as necessary
	Walleye	Put, Grow, and Take	Stock Walleye at 250 fry/surface acre. Actual stocking varies with reservoir elevation. Brood source for Walleye
	Spotted Bass	Wild	Manage as a Recreational Bass Water. One of two lakes in NM with Spotted Bass fisheries
	Smallmouth Bass	Wild	Manage as a Recreational Bass Water
Perch Lake	Channel Catfish	Put and Take	Special Summer Catfish Water - Stock catchable Channel Catfish
	Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout
Rock Lake Kid's Pond	Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout. Open to anglers 11 years old and younger
	Largemouth Bass	Put and Take	Stock occasionally with retired brood bass
	Channel Catfish	Put and Take	Investigate potential as Special Summer Catfish water

Management Direction for HUC 13060001 Pecos Headwaters – Headwaters to Santa Rosa Lake			
Water	**Fish Species**	**Management Type**	**Management Direction**
Blue Hole Park Ponds	Channel Catfish	Put and Take	Special Summer Catfish Water - Stock catchable Channel Catfish. Open to anglers 11 years old and younger, 65 years old and older, and individuals with disabilities
	Triploid Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout
Tres Lagunas	N/A	N/A	Often dry. Some interest from the City of Santa Rosa in stocking but no current plans in place

Management Direction for HUC 13060003 Upper Pecos, 13060005 Arroyo del Macho, 13060006 Gallo Arroyo, 13060007 Upper Pecos – Long Arroyo, 13060008 Rio Hondo, 13060010 Rio Peñasco, 13060011 Upper Pecos Black, 13070002 Delaware, 13070007 Landreth-Monument Draws, and 12080003 Monument Seminole Draws

Water	Fish Species	Management Type	Management Direction
Pecos River (Lake Sumner to Fort Sumner)	Triploid Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout in tailwater reach of Sumner Lake
Pecos River (Fort Sumner to Brantley Reservoir)	Pecos Bluntnose Shiner	Native Fish	Designated critical habitat for Pecos Bluntnose Shiner
	Pecos Pupfish	Native Fish	Pecos Pupfish occupy habitats on Bureau of Land Management, Bitter Lake National Wildlife Refuge, and Bottomless Lakes State Park. Implement actions identified in the Pecos Pupfish Conservation Agreement. All Pecos Pupfish downstream of Brantley Reservoir are Sheepshead Minnow/Pecos Pupfish hybrids
	Rio Grande Shiner	Native Fish	Maintain distribution
	Speckled Chub	Native Fish	Maintain distribution
	Flathead Catfish	Wild	Maintain regulations to support Flathead Catfish
Brantley Lake	Channel Catfish	Wild	Catch-and-release regulations removed in 2018 based on reduced contaminants in fish tissues. Department of Health, NM Environment Department, and NM Department of Game and Fish collaborated on new advisories in 2018. Regular golden algae blooms limit fishery potential and not consistently stocked. Subject to significant water level fluctuation
	White Bass	Wild	Catch-and-release regulations removed in 2018 based on reduced contaminants in fish tissues. Department of Health, NM Environment Department, and NM Department of Game and Fish collaborated on new advisories in 2018
	Largemouth Bass	Wild	Manage as a Recreational Bass Water. Stock Largemouth Bass as necessary

Management Direction for HUC 13060003 Upper Pecos, 13060005 Arroyo del Macho, 13060006 Gallo Arroyo, 13060007 Upper Pecos – Long Arroyo, 13060008 Rio Hondo, 13060010 Rio Peñasco, 13060011 Upper Pecos Black, 13070002 Delaware, 13070007 Landreth-Monument Draws, and 12080003 Monument Seminole Draws

Water	Fish Species	Management Type	Management Direction
Pecos River (Brantley Dam downstream to and including Lake Avalon)	N/A	N/A	Historical stronghold for Blue Sucker, Gray Redhorse and Black Bass. Currently limited potential for any fisheries management due to golden algae. Investigate mitigation measures to reduce the effects of golden algae
Lake Carlsbad	Triploid Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout. Subject to periodic golden algae blooms
	Spotted Bass	Wild	Manage as a Recreational Bass Water
	Largemouth Bass	Wild	Manage as a Recreational Bass Water. Initiate habitat improvement project to support fishery. Stock Largemouth Bass as necessary Investigate potential as a Trophy Bass Water
	Channel Catfish	Put and Take	Stock with catchable Channel Catfish as available
Bataan Lake	Triploid Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout. Subject to periodic golden algae blooms. Other sportfish species present but not managed due to limited habitat
	Largemouth Bass	Wild	Manage as a Recreational Bass Water. Initiate habitat improvement project to support fishery. Stock Largemouth Bass as necessary
	Channel Catfish	Put and Take	Special Summer Catfish Water - Stock catchable Channel Catfish
Pecos River (Lower Tansill Dam downstream to State Line including Six Mile and Ten Mile Dam Lakes)	Largemouth Bass	Wild	Manage Six Mile Dam as a Recreational Bass Water and Ten Mile Dam as a Low Density Bass Water. Subject to periodic golden algae blooms
	Gray Redhorse	Native Fish	Maintain distribution
	Channel Catfish	Wild	Maintain regulations to support Channel Catfish fishery. Consumption advisory for Channel Catfish – updated in 2018 to allow some consumption
	Blue Sucker	Native Fish	Investigate potential for repatriation of Blue Sucker

Management Direction for HUC 13060003 Upper Pecos, 13060005 Arroyo del Macho, 13060006 Gallo Arroyo, 13060007 Upper Pecos – Long Arroyo, 13060008 Rio Hondo, 13060010 Rio Peñasco, 13060011 Upper Pecos Black, 13070002 Delaware, 13070007 Landreth-Monument Draws, and 12080003 Monument Seminole Draws

Water	Fish Species	Management Type	Management Direction
Rio Bonito (Headwaters downstream to Bonito Lake)	Rio Grande Cutthroat Trout	Native Fish	Ongoing YY Brook Trout stocking study to investigate possibility for repatriation of Rio Grande Cutthroat Trout.
Bonito Lake	Triploid Rainbow Trout	Put and Take	Severely impacted by Little Bear Fire. Awaiting completion of dam rehabilitation and resolution of access issues. Stock catchable triploid Rainbow Trout
Rio Bonito (Downstream of Bonito Lake to the Rio Hondo confluence)	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout
	Brown Trout	Wild	Limited Brown Trout. Maintain regulations to support wild trout angling. Investigate potential of expanding habitat improvements on lower Rio Bonito
	Rio Grande Chub	Native Fish	Maintain distribution
Copeland Creek	Brook Trout	Wild	Maintain regulations to support wild trout angling
Rio Ruidoso and Tributaries	Brown Trout	Wild	Significant portions of the watershed within the jurisdiction of Mescalero Apache Tribe or on private land. Special Trout Water regulation (X-mas Chile Water) from Mescalero Reservation boundary downstream to Friedenbloom Drive
	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout
	Rio Grande Chub	Native Fish	Maintain distribution
Pine Lodge Creek	Triploid Rainbow Trout	Put and Take	Investigate potential of stocking triploid Rainbow Trout
Grindstone Reservoir	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout
	Channel Catfish	Wild	Maintain regulations to support fishery
	Smallmouth Bass	Wild/ Supplemental stocking	Manage as a Recreational Bass Water

NMED Exhibit 38

Management Direction for HUC 13060003 Upper Pecos, 13060005 Arroyo del Macho, 13060006 Gallo Arroyo, 13060007 Upper Pecos – Long Arroyo, 13060008 Rio Hondo, 13060010 Rio Peñasco, 13060011 Upper Pecos Black, 13070002 Delaware, 13070007 Landreth-Monument Draws, and 12080003 Monument Seminole Draws

Water	Fish Species	Management Type	Management Direction
Eagle Creek	Brook Trout	Wild	Headwaters of the watershed within the jurisdiction of Mescalero Apache Tribe. Maintain regulations to support wild trout angling
Alto Lake	Channel Catfish	Put and Take	Special Summer Catfish Water - Stock catchable Channel Catfish.
	Triploid Rainbow Trout	Put and Take	Stock catchable triploid Rainbow Trout
	Largemouth Bass	Wild/ Supplemental Stocking	Manage as a Recreational Bass Water for Goldfish control. Also continue stocking other species such as Bluegill as necessary to balance bass to sunfish predator/prey ratios
Agua Chiquita	Brook Trout	Wild	Prone to drying. Maintain regulations to support wild trout angling
Rio Peñasco	Brown Trout	Wild	Primarily private property with small section of Forest Service property. Investigate Open Gate properties. Maintain regulations to support wild trout angling
	Triploid Rainbow Trout	Put and Take	Investigate Open Gate opportunities to provide a Rainbow Trout fishery
	Rio Grande Chub	Native Fish	Maintain distribution
	Greenthroat Darter	Native Fish	Maintain distribution
Bosque Redondo Lake	Channel Catfish	Put and Take	Special Summer Catfish Water - Stock catchable Channel Catfish
	Triploid Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout
Bottomless Lakes	Triploid Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout. Maintain prohibition of fishing with baitfish. Triploid Rainbow Trout stocking locations limited to reduce negative interactions with Pecos Pupfish
	Pecos Pupfish	Native Fish	Implement actions identified in the Pecos Pupfish Conservation Agreement

Management Direction for HUC 13060003 Upper Pecos, 13060005 Arroyo del Macho, 13060006 Gallo Arroyo, 13060007 Upper Pecos – Long Arroyo, 13060008 Rio Hondo, 13060010 Rio Peñasco, 13060011 Upper Pecos Black, 13070002 Delaware, 13070007 Landreth-Monument Draws, and 12080003 Monument Seminole Draws

Water	Fish Species	Management Type	Management Direction
Lake Van	Channel Catfish	Put and Take	Special Summer Catfish Water - Stock catchable Channel Catfish
	Triploid Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout
Roswell Kids Pond	Channel Catfish	Put and Take	Special Summer Catfish Water - Stock catchable Channel Catfish. Open to anglers 11 years old and younger
	Triploid Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout
Corona Pond	Channel Catfish	Put and Take	Special Summer Catfish Water - Stock catchable Channel Catfish
	Triploid Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout
Black River	Blue Sucker	Native Fish	Limited public access. Few Blue Sucker collected over the past several years. Investigate the feasibility of replacing road crossings (2) fragmenting population
	Gray Redhorse	Native Fish	Investigate the feasibility of replacing road crossings (2) fragmenting population
	Largemouth Bass	Wild	Maintain angling regulations to support Recreational Bass Water
	Triploid Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout
Pecos River (Avalon Dam to Lake Carlsbad)	N/A	N/A	Often dry, limited angling opportunities
Eunice Lake	Channel Catfish	Put and Take	Special Summer Catfish Water - Stock catchable Channel Catfish
	Triploid Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout
Jal Lake	Channel Catfish	Put and Take	Special Summer Catfish Water - Stock catchable Channel Catfish
	Triploid Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout

Management Direction for HUC 13060003 Upper Pecos, 13060005 Arroyo del Macho, 13060006 Gallo Arroyo, 13060007 Upper Pecos – Long Arroyo, 13060008 Rio Hondo, 13060010 Rio Peñasco, 13060011 Upper Pecos Black, 13070002 Delaware, 13070007 Landreth-Monument Draws, and 12080003 Monument Seminole Draws

Water	Fish Species	Management Type	Management Direction
Delaware River	Gray Redhorse	Native Fish	Repatriation efforts have ceased due to absence of perennial flows in recent years. Investigate feasibility of restoring perennial flows and if successful repatriate Gray Redhorse
Chaparral Park Lake	Channel Catfish	Put and Take	Special Summer Catfish Water - Stock catchable Channel Catfish
	Triploid Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout
	Sunfish	Suppression	Stock and maintain Largemouth Bass to control overpopulated sunfish populations
Green Meadow Lake	Channel Catfish	Put and Take	Special Summer Catfish Water - Stock catchable Channel Catfish
	Triploid Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout
Harry McAdams Park Pond	Triploid Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout. Open to anglers 11 years old and younger, 65 years old and older, and individuals with disabilities

Tularosa Watershed

The Tularosa Basin encompasses approximately 3.2 million acres in south central New Mexico and is a closed basin. There has been limited development in the watershed because much of the Tularosa Basin is federal government property (White Sands Missile Range, Holloman Air Force Base, White Sands National Monument). Due to limited perennial habitats in the Tularosa Watershed, fisheries management activities are limited to monitoring of White Sands Pupfish in coordination with federal agencies and recreational fisheries in the Three Rivers drainage near Alamogordo and Carrizozo Recreation Lake. The mainstem of the Tularosa River is primarily located on private lands and the status of the fisheries on public reaches are unknown.

HUC 13050003 Tularosa Valley

Management Direction for HUC 13050003 Tularosa Valley

Water	Fish Species	Management Type	Management Direction
Carrizozo Recreation Lake	Channel Catfish	Put and Take	Special Summer Catfish Water - Stock catchable Channel Catfish
	Triploid Rainbow Trout	Put and Take	Winter Trout Water - Stock catchable triploid Rainbow Trout
Salt Creek and Malpais Spring	White Sands Pupfish	Native Fish	Implement actions identified in the White Sands Pupfish Conservation Agreement
Three Rivers	Brook Trout	Wild	Maintain regulations to support angling for wild trout
