to exceed 1.0 mg/kg. Although it is not known what percent of the mercury in the fish was methylmercury, it is also not known whether uptake from food would increase the concentration in the fish in natural situations. Species such as rainbow trout, coho salmon, and especially the bluegill, might suffer chronic effects and accumulate high residues of mercury about the same as the fathead minnow.

With regard to long-term exposure to methylmercury, McKim et al. (1976) found that brook trout can exceed the FDA action level without suffering statistically significant adverse effects on survival, growth, or reproduction. Thus for methylmercury the Final Residue Value would be substantially lower than the Final Chronic Value.

Basing a freshwater criterion on the Final Residue Value of 0.012 ug/L derived from the bioconcentration factor of 81,700 for methylmercury with the fathead minnow (Olson et al. 1975) essentially assumes that all discharged mercury is methylmercury. On the other hand, there is the possibility that in field situations uptake from food might add to the uptake from water. Similar considerations apply to the derivation of the saltwater criterion of 0.025 ug/L using the BCF of 40,000 obtained for methylmercury with the Eastern oyster (Kopfler, 1974). Because the Final Residue Values for methylmercury are substantially below the Final Chronic Values for mercury(II), it is probably not too important that many fishes, including the rainbow trout, coho salmon, bluegill, and haddock might not be adequately protected by the freshwater and saltwater Final Chronic Values for mercury(II).

In contrast to all the complexities of deriving numerical criteria for mercury, monitoring for unacceptable environmental effects should be relatively straightforward. The most sensitive adverse effect will probably be exceedence of the FDA action level. Therefore, existing discharges should be acceptable if the concentration of methylmercury in the edible portion of exposed consumed species does not exceed the FDA action level.

The procedures described in the Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses indicate that, except possibly where a locally important species is very sensitive, freshwater aquatic organisms and their uses should not be affected unacceptably if the 4-day average concentration of mercury does not exceed 0.012 ug/L more than once every 3 years on the average and if the 1-hour average concentration does not exceed 2.4 ug/L more than once every 3 years on the average. If the 4-day average concentration exceeds 0.012 ug/L more than once in a 3-year period, the edible portion of consumed species should be analyzed to determine whether the concentration of methylmercury exceeds the FDA action level.

The procedures described in the Guidelines indicate that, except possibly where a localy important species is very sensitive, saltwater aquatic organisms and their uses should not be affected unacceptably if the 4-day average concentration of mercury does not exceed 0.025 ug/L more than once every 3 years on the average and if the 1-hour average concentration does not exceed 2.1 ug/L more than once every 3 years on the average. If the 4-day average concentration exceeds 0.025 ug/L more than once

in a 3-year period, the edible protion of consumed species should be analyzed to determine whether the concentration of mathylmercury exceeds the FDA action level.

EPA believes that a measurement such as "acid-soluble" would provide a more scientifically correct basis upon which to establish criteria for metals. The criteria were developed on this basis. However, at this time, no EPA approved-methods for such a measurement are available to implement the criteria through the regulatory programs of the Agency and the States. The Agency is considering development and approval of methods for a measurement such as acid-soluble. Until available, however, EPA recommends applying the criteria using the total recoverable method. This has two impacts: (1) certain species of some metals cannot be analyzed directly because the total recoverable method does not distinguish between individual oxidation states, and (2) these criteria may be overly protective when based on the total recoverable method.

The recommended exceedence frequency of 3 years is the Agency's best scientific judgment of the average amount of time it will take an unstressed system to recover from a pollution event in which exposure to mercury exceeds the criterion. A stressed system, for example, one in which several outfalls occur in a limited area, would be expected to require more time for recovery. The resilience of ecosystems and their ability to recover differ greatly, however, and site-specific criteria may be established if adequate justification is provided.

The use of criteria in designing waste treatment facilities requires the selection of an appropriate wasteload allocation model. Dynamic models are preferred for the application of these criteria. Limited data or other factors may make their use impractical, in which case one should rely on a steady-state model. The Agency recommends the interim use of 1Q5 or 1Q10 for Criterion Maximum Concentration design flow and 7Q5 or 7Q10 for the Criterion Continuous Concentration design flow in steady-state models for unstressed and stressed systems respectively. These matters are discussed in more detail in the Technical Support Document for Water Quality-Based Toxics Control (U.S EPA, 1985).

HUMAN HEALTH CRITERIA

For the protection of human health from the toxic properties of mercury ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 144 ng/L.

For the protection of human health from the toxic properties of mercury ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 146 ng/L.

NOTE: These values include the consumption of freshwater, estuarine, and marine species.

SEE APPENDIX A FOR METHODOLOGY

METHOXYCHLOR

CRITERIA:

100 ug/L for domestic water supply (health);

0.03 ug/L for freshwater and marine aquatic life.

RATIONALE:

The highest level of methoxychlor found to have minimal or no long-term effects in man is 2.0 mg/kg of body weight/day (Lehman, 1965). Where adequate human data are available for corroboration of the animal results, the total "safe" drinking water intake level is assumed to be 1/100 of the no-effect or minimal effect level reported for the most sensitive animal tested, in this case, man.

Applying the available data and based upon the assumptions that 20 percent of the total intake of methoxychlor is from drinking water, and that the average person weighs 70 kg and consumes 2 liters of water per day, the formula for calculating a criterion is 2.0 mg/kg x 0.2 x 70 kg x 1/100 x 1/2 = 0.14 mg/L. A criterion level for domestic water supply of 100 ug/L is recommended.

Few data are available on acute and chronic effects of methoxychlor on freshwater fish. Merna and Eisele (1973) observed reduced hatchability of fathead minnow (Pimephales promelas) embryos at 0.125 ug/L and lack of spawning at 2.0 ug/L. Yellow perch, Perca flavescens, exposed to 0.6 ug/L for 8 months exhibited reduced growth. The 96-hour LC50 concentration was 7.5 and 22 ug/L for the fathead minnow and yellow perch, respectively. Korn and Earnest (1974) obtained a 96-hour LC50

of 3.3 ug/L with juvenile stripped bass, Morone saxatilis, exposed to methoxychlor in a flowing-water bioassay.

Sanders (1972) determined a 96-hour LC50 value of 0.5 ug/L for the crayfish, Orconectes nais. Merna and Eisele (1973) obtained a 96-hour LC50 value of 0.61 ug/L for the scud, Gammarus pseudolimnaeus and 96-hour LC50's ranging from 1.59 to 7.05 ug/L for the crayfish, Orconectes nais, and three aquatic insect larvae. In 28-day exposures, reduction in emergence of mayflies, Stenonema sp., and in pupation of caddisflies, Cheumatospsyche sp., were observed at 0.5 and 0.25 ug/L concentrations, respectively. They also found methoxychlor to be degraded in a few weeks or less in natural waters.

Eisele (1974) conducted a study in which a section of a natural stream was dosed at 0.2 ug/L methoxychlor for 1 year. The near extinction of one species of scud, Hyallella azteca, and reductions in populations of other sensitive species, as well as biomass, were observed. Residue accumulation of up to 1,000 times the level in the stream was observed in first-year crayfish, Orconectes nais. Metcalf et al. (1971) traced the rapid conversion of methoxychlor to water soluble compounds and elimination from the tissues of snails, mosquito larvae and mosquitofish. Thus, methoxychlor appears to be considerably less bioaccumlative in aquatic organisms than some of the other chlorinated pesticides.

Methoxyhlor has a very low accumulation rate in birds and mammals (Stickel, 1973), and relatively low avian (Heath et al. 1972) and mammalian (Hodge et al. 1950) toxicities. No administrative guidelines for acceptable levels in edible fish

tissues have been established by the U.S. Food and Drug Administration.

The above data indicate that 0.1 ug/L methoxychlor would be just below chronic effect level for the fathead minnow and one-fifth the acute toxicity level in a crayfish species. Therefore, a criterion level of 0.03 ug/L is recommended. This criterion should protect fish as sensitive as striped bass and is 10 times lower than the level causing effects on some invertebrate populations in a 1-year dosing of a natural stream.

Bahner and Nimmo (1974) found the 96-hour LC50 of methoxychlor for the pink shrimp, Penaeus duorarum, to be 3.5 ug/L and the 30-day LC50 to be 1.3 ug/L. Using an application factor of 0.01 with the pink shrimp's acute toxicity of 3.5 ug/L, the recommended criterion for the marine environment is 0.03 ug/L.

Butler (1971) found accumulation factors of 470 and 1,500 for the molluscs, Mercenaria mercenaria and Mya arenaria, respectively, when exposed to 1 ug/L methoxychlor for 5 days. Using the 1,500 accumulation factor as a basis, a water concentration of 0.2 ug/L would be required to meet the U.S. Food and Drug Administration's guideline for methoxychlor in meat products. Thus, the recommended marine criterion of 0.03 ug/L is an order of magnitude lower than this concentration.

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

MIREX

CRITERION:

0.001 ug/L for freshwater and marine aquatic life.

RATIONALE:

Mirex is used to control the imported fire ant Solenopsis saevissima richteri in the southeastern United States. Its use is essentially limited to the control of this insect and it is always presented in bait. In the most common formulation, technical grade mirex is dissolved in soybean oil and sprayed on corncob grits. The bait produced in this manner consists of 0.3 percent mirex, 14.7 percent soybean oil and 85 percent corncob grits. The mirex bait often is applied at a rate of 1.4 kg/ha, equivalent to 4.2 grams of toxicant per hectare.

Relatively few studies have been made of the effects of mirex on freshwater invertebrates of these, only Ludke et al. (1971) report chemical analyses of mirex in the water. Their study reported effects on two crayfish species exposed to mirex by three techniques. First, field-collected crayfish were exposed to several sublethal concentrations of technical grade mirex solutions for various periods of time; second, crayfish were exposed to mirex leached from bait (0.3 percent active ingredient); and third, the crayfish were fed mirex bait.

Procambarus blandingi juveniles were exposed to 1 or 5 ug/L for 6 to 144 hours, transferred to clean water and observed for 10 days. After 5 days in clean water, 95 percent of the animals exposed to 1 ug/L for 144 hours were dead. Exposure to 5 ug/L for 6, 24, and 58 hours resulted in 26, 50, and 98 percent mortality 10 days after transfer to clean water. Crayfish,

Procambarus hayi, were exposed to 0.1 and 0.5 ug/L for 48 hours. Four days after transfer to clean water, 65 percent of the animals exposed to 0.1 ug/L were dead. At the 0.5 ug/L concentration, 71 percent of the animals were dead after 4 days in clean water. Tissue residue accumulations (wet weight basis) ranged from 940- to 27,210-fold above water concentrations. In leached bait experiments, 10 bait particles were placed in 2 liters of water but isolated from 20 juvenile crayfish. Thirty percent of the crayfish were dead in 4 days and 95 percent were dead in 7 days. Water analysis indicated mirex concentrations of 0.86 ug/L. In feeding experiments, 108 crayfish each were fed one bait particle. Mortality was noticed on the first day after feeding, and by the sixth day 77 percent were dead. In another experiment, all crayfish were dead 4 days after having been fed 2 bait particles each. From this report it is obvious that mirex is extremely toxic to these species of crayfish. Mortality and accumulation increase with time of exposure to the insecticide. Concentrations as low as 0.1 ug/L or the ingestion of one particle resulted in death.

Research to determine effects of mirex on fish has been concentrated on species which have economic and sport fishery importance. Hyde et al. (1974) applied mirex bait (0.3 percent mirex) at the standard rate (1.4 kg/ha) in four ponds containing channel catfish, Ictalurus punctatus. Three applications were made over an 8-month period with the first application 8 days after fingerling (average weight 18.4 g) catfish were placed in the ponds. Fish were collected at each subsequent application

(approximately 4-month intervals). Two and one half months after the final application, the ponds were drained, all fish were measured and weighed, and the percent survival was calculated. Mirex residues in the fish at termination of the experiment ranged from 0.015 ug/g (ppm) in the fillet to 0.255 ug/g in the fat.

In another study, Van Valin et al. (1968) exposed bluegills, Lepomis macrochirus, and the goldfish, Carassius auratus, to mirex by feeding a mirex-treated diet (1, 3, and 5 mg mirex per kg body weight) or by treating holding ponds with mirex bait (1.3, 100, and 1000 ug/L computed water concentration). They reported no mortality or tissue pathology for the bluegills; however, after 56 days of exposure, gill breakdown in goldfish was found in the 100 and 1000 ug/L contact exposure ponds, and kidney breakdown was occurring in the 1000 ug/L ponds. Mortality in the feeding experiments was not related to the level of exposure, although growth of the bluegills fed 5 ug/L mirex was reduced.

In laboratory and field test systems, reported concentrations of mirex usually are between 0.5 and 1.0 ug/L (Van Valin et al. 1968: Ludke et al. 1971). Although mirex seldom is found above 1 ug/L in the aquatic environment, several field studies have shown that the insecticide is accumulated through the food chain. Borthwick et al. (1973) reported the accumulation of mirex in South Carolina estuaries. Their data revealed that mirex was transported from treated land and marsh to the estuary animals and that accumulation, especially in predators, occurred. In the test area, water samples consistently were less than 0.01 ug/L.

Residues in fish varied from non-detectable to 0.8 ug/g with 15 percent of the samples containing residues. The amount of mirex and the percent of samples containing mirex increased at higher trophic levels. Fifty-four percent of the raccoons sampled contained mirex residues up to 4.4 ug/g and 78 percent of the birds contained residues up to 17 ug/g. Nagvi and de la Cruz (1973) reported average residues for molluscs (0.15 ug/g), fish (0.26 ug/g), insects (0.29 ug/g), crustaceans (0.44 ug/g) and annelids (0.63 ug/g). They also reported that mirex was found in areas not treated with mirex which suggests movement of the pesticide in the environment. Wolfe and Norment (1973) sampled an area for one year following an aerial application of mirex bait (2.1 g mirex/ha). Crayfish residues ranged from 0.04 to 0.16 ug/g. Fish residues were about 2 to 20 times greater than the controls and averaged from 0.01 to 0.76 ug/g. Kaiser (1974), reported the presence of mirex in fish from the Bay of Quinte, Lake Ontario, Canada. Concentrations range from 0.02 ug/g in the gonads of the northern long nose gar, Lepistosteus osseus, to 0.05 ug/g in the post-anal fin of the northern pike, Esox lucius. Mirex has never been registered for use in Canada.

Mirex does not appear to be greatly toxic to birds, with LC50's for the young of four species ranging from 547 to greater than 1667 ug/g (Heath et al. 1972). Long-term dietary dosages caused no adverse effect at 3 ug/g with mallards and 13 ug/g with pheasants (Heath and Spann, 1973). However, it has been reported (Stickel et al. 1973) that the persistence of mirex in bird tissue exceeds that of all organochlorine compounds tested except

for DDE. Delayed mortality occurred among birds subjected to doses above expected environmental concentration.

A summary examination of the data available at this time shows a mosaic of effects. Crayfish and channel catfish survival is affected by mirex in the water or by ingestion of the bait particles. Bioaccumulation is well established for a wide variety of organisms but the effect of this bioaccumulation on the aquatic ecosystem is unknown. There is evidence that mirex is very persistent in bird tissue. Considering the extreme toxicity and potential for bioaccumulation, every effort should be made to keep mirex bait particles out of water containing aquatic organisms and water concentrations should not exceed 0.001 ug/L mirex. This value is based upon an application factor of 0.01 applied to the lowest levels at which effects on crayfish have been observed.

Data upon which to base a marine criterion involve several estuarine and marine crustaceans. A concentration of 0.1 ug/L technical grade mirex in flowing seawater was lethal to juvenile pink shrimp, Penaeus durorarum, in a 3-week exposure (Lowe et al. 1971). In static tests with larval stages (megalopal) of the mud crab, Rhithropanopeus harrisii, reduced survival was observed in 0.1-ug/L mirex (Bookhout et al. 1972). In three of four 28-day seasonal flow-through experiments, Tagatz et al. (1975) found reduced survival of Callinectes sapidus, Penaeus durorarum, and grass shrimp, Palaemonetes pugio, at levels of 0.12 ug/L in summer, 0.06 ug/L in fall and 0.09 ug/L in winter.

Since two reports, Lowe et al. (1971) and Bookhout et al. (1972), stated that effects of mirex on estuarine and marine

crustaceans were observed only after considerable time had elapsed, it seems reasonable that length of exposure is an important consideration for this chemical. This may not be the case in fresh water since the crayfish were affected within 48 hours. Therefore, a 3- to 4-week exposure might be considered "acute" and by applying an application factor of 0.01 to a reasonable average of toxic-effect levels as summarized above, a recommended marine criterion of 0.001 ug/L results.

SEE APPENDIX C FOR METHODOLOGY

NAPHTHALENE

CRITERIA:

Aquatic Life

The available data for naphthalene indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 2,300 and 620 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

The available data for naphthalene indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 2,350 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of naphthalene to sensitive saltwater aquatic life.

Human Health

Using the present guidelines, a satisfactory criterion cannot be derived at this time because of insufficient available data for naphthalene.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

NICKEL

CRITERIA:

Aquatic Life

For total recoverable nickel the criterion (in ug/L) to protect freshwater aquatic life as derived using the Guidelines is the numerical value given by $e^{(0.76[\ln(\text{hardness})]+1.06)}$ as a 24-hour average, and the concentration (in ug/L) should not exceed the numerical value given by $e^{(0.76[\ln(\text{hardness})]+4.02)}$ at any time. For example, at hardnesses of 50, 100, and 200 mg/L as $CaCO_3$ the criteria are 56, 96, and 160 ug/L, respectively, as 24-hour averages, and the concentrations should not exceed 1,100, 1,800, and 3,100 ug/L, respectively, at any time.

For total recoverable nickel the criterion to protect saltwater aquatic life as derived using the Guidelines is 7.1 ug/L as a 24-hour average, and the concentration should not exceed 140 ug/L at any time.

Human Health

For the protection of human health from the toxic properties of nickel ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 13.4 ug/L.

For the protection of human health from the toxic properties of nickel ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 100. ug/L.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

NITRATES/NITRITES

CRITERION:

10 mg/L nitrate nitrogen (N) for domestic water supply (health).

INTRODUCTION:

Two gases (molecular nitrogen and nitrous oxide) and five forms of nongaseous, combined nitrogen (amino and amide groups, ammonium, nitrite, and nitrate) are important in the nitrogen cycle. The amino and amide groups are found in soil organic matter and as constituents of plant and animal protein. The ammonium ion either is released from proteinaceous organic matter and urea, or is synthesized in industrial processes involving atmospheric nitrogen fixation. The nitrite ion is formed from the nitrate or the ammonium ions by certain microorganisms found in soil, water, sewage, and the digestive tract. The nitrate ion is formed by the complete oxidation of ammonium ions by soil or water microorganisms; nitrite is an intermediate product of this nitrification process. In oxygenated natural water systems nitrite is rapidly oxidized to nitrate. Growing plants assimilate nitrate or ammonium ions and convert them to protein. A process known as denitrification takes place when nitrate-containing soils become anaerobic and the conversion to nitrite, molecular nitrogen, or nitrous oxide occurs. Ammonium ions may also be produced in some circumstances.

Among the major point sources of nitrogen entry into water bodies are municipal and industrial wastewaters, septic tanks, and feed lot discharges. Diffuse sources of nitrogen include farm-site fertilizer and animal wastes, lawn fertilizer, leachate

from waste disposal in dumps or sanitary landfills, atmospheric fallout, nitric oxide and nitrite discharges from automobile exhausts and other combustion processes, and losses from natural sources such as mineralization of soil organic matter (NAS, 1972). Water reuse systems in some fish hatcheries employ a nitrification process for ammonia reduction; this may result in exposure of the hatchery fish to elevated levels of nitrite (Russo et al. 1974).

RATIONALE:

In quantities normally found in food or feed, nitrates become toxic only under conditions in which they are, or may be, reduced to nitrites. Otherwise, at "reasonable" concentration nitrates are rapidly excreted in the urine. High intake of nitrates constitutes a hazard primarily to warmblooded animals under conditions that are favorable to reduction to nitrite. Under certain circumstances, nitrate can be reduced to nitrite in the gastrointestinal tract which then reaches the bloodstream and reacts directly with hemoglobin to produce methemoglobin, consequently impairing transport.

The reaction of nitrite with hemoglobin can be hazardous in infants under 3 months of age. Serious and occasionally fatal poisonings in infants have occurred following ingestion of untreated well waters shown to contain nitrate at concentrations greater than 10 mg/L nitrate nitrogen (N) (NAS, 1974). High nitrate concentrations frequently are found in shallow farm and rural community wells, often as the result of inadequate protection from barnyard drainage or from septic tanks (USPHS,

1961; Stewart et al. 1967). Increased concentrations of nitrates also have been found in streams from farm tile drainage in areas of intense fertilization and farm crop production (Harmeson et al. 1971). Approximately 2,000 cases of infant methemoglobinemia have been reported in Europe and North America since 1945; 7 to 8 percent of the affected infants died (Walton, 1951; Sattelmacher, 1962). Many infants have drunk water in which the nitrate nitrogen content was greater than 10 mg/L without developing methemoglobinemia. Many public water supplies in the United States contain levels that routinely exceed this amount, but only one U.S. case of infant methemoglobinemia associated with a public water supply has ever been reported (Virgil et al. 1965). The differences in susceptibility to methemoglobinemia are not yet understood but appear to be related to a combination of factors including nitrate concentration, enteric bacteria, and the lower acidity characteristic of the digestive systems of baby mammals. Methemoglobinemia systems and other toxic effects were observed when high nitrate well waters containing pathogenic bacteria were fed to laboratory mammals (Wolff et al. 1972). Conventional water treatment has no significant effect on nitrate removal from water (NAS, 1974).

Because of the potential risk of methemoglobinemia to bottle-fed infants, and in view of the absence of substantiated physiological effects at nitrate concentrations below 10 mg/L nitrate nitrogen, this level is the criterion for domestic water supplies. Waters with nitrite nitrogen concentrations over 1

mg/L should not be used for infant feeding. Waters with a significant nitrite concentration usually would be heavily polluted and probably bacteriologically unacceptable.

Westin (1974) determined that the respective 96-hour and 7-day LC50 values for chinook salmon, Oncorhynchus tshawytscha, were 1,310 and 1,080 mg/L nitrate nitrogen in fresh water and 990 and 900 mg/L nitrate nitrogen in 15 o/oo saline water. For fingerling rainbow trout, Salmo gairdneri, the respective 96-hour and 7-day LC50 values were 1,360 and 1,060 mg/L nitrate nitrogen in fresh water, and 1,050 and 900 mg/L nitrate nitrogen in 15 o/oo saline water. Trama (1954) reported that the 96-hour LC50 for bluegills, Lepomis macrochirus, at 20°C was 2,000 mg/L nitrate nitrogen (sodium nitrate) and 420 mg/L nitrate nitrogen (potassium nitrate). Knepp and Arkin (1973) observed that largemouth bass, Micropterus salmoides, and channel catfish, Ictalurus punctatus, could be maintained at concentrations up to 400 mg/L nitrate (90 mg/L nitrate nitrogen) without significant effect upon their growth and feeding activities.

The 96-hour and 7-day LC50 values for chinook salmon, Oncorhynchus tshawytscha, were found to be 0.9 and 0.7 mg/L nitrite nitrogen in fresh water (Westin, 1974). Smith and Williams (1974) tested the effects of nitrite nitrogen and observed that yearling rainbow trout, Salmo gairdneri, suffered a 55 percent mortality after 24 hours at 0.55 mg/L; fingerling rainbow trout suffered a 50 percent mortality after 24 hours of exposure at 1.6 mg/L; and chinook salmon, Oncorhynchus tshawytscha, suffered a 40 percent mortality within 24 hours at

0.5 mg/L. There were no mortalities among rainbow trout exposed to 0.15 mg/L nitrite nitrogen for 48 hours. These data indicate that salmonids are more sensitive to nitrite toxicity than are other fish species, e.g., minnows, Phoxinus laevis, that suffered a 50 percent mortality within 1.5 hours of exposure to 2,030 mg/L nitrite nitrogen, but required 14 days of exposure for mortality to occur at 10 mg/L (Klingler, 1957), and carp, Cyprinus carpio, when raised in a water reuse system, tolerated up to 1.8 mg/L nitrite nitrogen (Saeki, 1965).

Gillette, et al. (1952) observed that the critical range for creek chub, Semotilus atromaculatus, was 80 to 400 mg/L nitrite nitrogen. Wallen et al. (1957) reported a 24-hour LC50 of 1.6 mg/L nitrite nitrogen, and 48- and 96-hour LC50 values of 1.5 mg/L nitrite nitrogen for mosquitofish, Gambusia affinis. McCoy (1972) tested the nitrite susceptibility of 13 fish species and found that logperch, Percina caprodes, were the most sensitive species tested (mortality at 5 mg/L nitrite nitrogen in less than 3 hours of exposure) whereas carp, Cyprinus carpio, and black bullheads, Ictalurus melas, survived 40 mg/L nitrite nitrogen for a 48-hour exposure period; the common white sucker, Catostomus commersoni, and the quillback, Carpiodes cyprinus, survived 100 mg/L for 48 and 36 hours, respectively.

Russo et al. (1974) performed flow-through nitrite bioassays in hard water (hardness = 199 mg/L $CaCO_3$; alkalinity = 176 mg/L $CaCO_3$; pH = 7.9) on rainbow trout, Salmo gairdneri, of four different sizes, and obtained 96-hour LC50 values ranging from 0.19 to 0.39 mg/L nitrite nitrogen. Duplicate bioassays on 12-gram rainbow trout were continued long enough for their toxicity

curves to level off, and asymptotic LC50 concentrations of 0.14 and 0.15 mg/L were reached in 8 days; on day 19, additional mortalities occurred. For 2-gram rainbow trout, the minimum tested level of nitrite nitrogen at which no mortalities were observed after 10 days was 0.14 mg/L; for the 235-gram trout, the minimum level with no mortality after 10 days was 0.06 mg/L.

It is concluded that (1) levels of nitrate nitrogen at or below 90 mg/L would have no adverse effects on warmwater fish (Knepp and Arkin, 1973); (2) nitrite nitrogen at or below 5 mg/L should be protective of most warmwater fish (McCoy, 1972); and (3) nitrite nitrogen at or below 0.06 mg/L should be protective of salmonid fishes (Russo et al. 1974; Russo and Thurston, 1975). These levels either are not known to occur or would be unlikely to occur in natural surface waters.

Recognizing that concentrations of nitrate or nitrite that would exhibit toxic effects on warm- or coldwater fish could rarely occur in nature, restrictive criteria are not recommended.

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

NITROBENZENE

CRITERIA:

Aquatic Life

The available data for nitrobenzene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 27,000 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No definitive data are available concerning the chronic toxicity of nitrobenzene to sensitive freshwater aquatic life.

The available data for nitrobenzene indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 6,680 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No definitive data are available concerning the chronic toxicity of nitrobenzene to sensitive saltwater aquatic life.

Human Health

For comparison purposes, two approaches were used to derive criterion levels for nitrobenzene. Based on available toxicity data, to protect public health the derived level is 19.8 mg/L. Using available organoleptic data, to control undesirable taste and odor qualities of ambient water the estimated level is 30 ug/L. It should be recognized that organoleptic data have limitations as a basis for establishing a water quality criterion, and have no demonstrated relationship to potential adverse human health effects.

SEE APPENDIX B FOR METHODOLOGY

NOTE: The U.S. EPA is currently developing Acceptable Daily Intake (ADI) or Verified Reference Dose (RfD) values for Agency-wide use for this chemical. The new value should

be substituted when it becomes available. The January, 1986, draft Verified Reference Dose document cites an RfD of .0005 mg/kg/day for nitrobenzene.

NITROPHENOLS

CRITERIA:

Aquatic Life

The available data for nitrophenols indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 230 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of nitrophenols to sensitive freshwater aquatic life but toxicity to one species of algae occurs at concentrations as low as 150 ug/L.

The available data for nitrophenols indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 4,850 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of nitrophenols to sensitive saltwater aquatic life.

Human Health

Because of insufficient available data for mono- and trinitrophenols, satisfactory criteria cannot be derived at this time, using the present guidelines.

For the protection of human health from the toxic properties of dinitrophenols and 2,4-dinitro-o-cresol ingested through water and contaminated aquatic organisms, the ambient water criteria are determined to be 70 ug/L and 13.4 ug/L, respectively.

For the protection of human health from the toxic properties of dinitrophenols and 2,4-dinitro-o-cresol ingested through contaminated aquatic organisms alone, the ambient water criteria

are determined to be 14.3 mg/L and 765 ug/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

NITROSAMINES

CRITERIA:

Aquatic Life

The available data for nitrosamines indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 5,850 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of nitrosamines to sensitive freshwater aquatic life.

The available data for nitrosamines indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 3,300,000 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of nitrosamines to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to N-nitrosodiethylamine and all other nitrosamines except those listed below, through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the non threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 8.0 ng/L, 0.8 ng/L, and 0.08 ng/L, respectively. If these estimates are made for

consumption of aquatic organisms only, excluding consumption of water, the levels are 12,400 ng/L, 1,240 ng/L, and 124 ng/L, respectively.

For the maximum protection of human health from the potential carcinoqenic effects of exposure to N-nitrosodimethylamine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10-6, and 10^{-7} The corresponding recommended criteria are 14 ng/L, 1.4 ng/L, and 0.14 ng/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 160,000 ng/L, 16,000 ng/L, and 1,600 ng/L, respectively.

For the maximum protection of human health from the potential carcinogenic effects of exposure to N-nitrosodibutylamine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10-6, and 10^{-7}. The corresponding recommended criteria are 64 ng/L, 6.4 ng/L, and 0.64 ng/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 5,868 ng/L, 587

ng/L, and 58.7 ng/L, respectively.

For the maximum protection of human health from the potential carcinogenic effects of exposure to N-nitrosopyrrolidine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 160 ng/L, 16 ng/L, and 1.6 ng/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 919,000 ng/L, 91,900 ng/L, and 9,190 ng/L, respectively.

For the maximum protection of human health from the potential carcinogenic effects of exposure to N-nitrosodiphenylamine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 49,000 ng/L, 4,900 ng/L, and 490 ng/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 161,000 ng/L, 16,100 ng/L, and 1,610 ng/L, respectively.

SEE APPENDIX B FOR METHODOLOGY

OIL AND GREASE

CRITERIA:

For domestic water supply: Virtually free from oil and grease, particularly from the tastes and odors that emanate from petroleum products.

For aquatic life:

(1) 0.01 of the lowest continuous flow 96-hour LC50 to several important freshwater and marine species, each having a demonstrated high susceptibility to oils and petrochemicals.

(2) Levels of oils or petrochemicals in the sediment which cause deleterious effects to the biota should not be allowed.

(3) Surface waters shall be virtually free from floating nonpetroleum oils of vegetable or animal origin, as well as petroleum-derived oils.

INTRODUCTION:

It has been estimated that between 5 and 10 million metric tons of oil enter the marine environment annually (Blumer, 1970). A major difficulty encountered in the setting of criteria for oil and grease is that these are not definitive chemical categories, but include thousands of organic compounds with varying physical, chemical, and toxicological properties. They may be volatile or nonvolatile, soluble or insoluble, persistent or easily degraded.

RATIONALE:

Field and laboratory evidence have demonstrated both acute lethal toxicity and long-term sublethal toxicity of oils to aquatic organisms. Events such as the Tampico Maru wreck of 1957 in Baja, California, (Diaz-Piferrer, 1962), and the No. 2 fuel oil spill in West Falmouth, Massachusetts, in 1969

(Hampson and Sanders, 1969), both of which caused immediate death to a wide variety of organisms, are illustrative of the lethal toxicity that may be attributed to oil pollution. Similarly, a gasoline spill in South Dakota in November 1969 (Bugbee and Walter, 1973) was reported to have caused immediate death to the majority of freshwater invertebrates and 2,500 fish, 30 percent of which were native species of trout. Because of the wide range of compounds included in the category of oil, it is impossible to establish meaningful 96-hour LC50 values for oil and grease without specifying the product involved. However, as the data in Table 6 show, the most susceptible category of organisms, the marine larvae, appear to be intolerant of petroleum pollutants, particularly the water soluble compounds, at concentrations as low as 0.1 mg/L.

The long-term sublethal effects of oil pollution refer to interferences with cellular and physiological processes such as feeding and reproduction and do not lead to immediate death of the organism. Disruption of such behavior apparently can result from petroleum product concentrations as low as 10 to 100 ug/L (see Table 7).

Table 7 summarizes some of the sublethal toxicities for various petroleum pollutants and aquatic species. In addition to sublethal effects reported at the 10 to 100 ug/L level, it has been shown that petroleum products can harm aquatic life at concentrations as low as 1 ug/L (Jacobson and Boylan, 1973).

Bioaccumulation of petroleum products presents two especially important public health problems: (1) the tainting of edible,

aquatic species, and (2) the possibility of edible marine organisms incorporating the high boiling, carcinogenic polycyclic aromatics in their tissues. Nelson-Smith (1971) reported that 0.01 mg/L of crude oil caused tainting in oysters. Moore et al. (1973) reported that concentrations as low as 1 to 10 ug/L could lead to tainting within very short periods of time. It has been shown that chemicals responsible for cancer in animals and man (such as 3,4-benzopyrene) occur in crude oil (Blumer, 1970). It also has been shown that marine organisms are capable of incorporating potentially carcinogenic compounds into their body fat where the compounds remain unchanged (Blumer, 1970).

Oil pollutants may also be incorporated into sediments. There is evidence that once this occurs in the sediments below the aerobic surface layer, petroleum oil can remain unchanged and toxic for long periods, since its rate of bacterial degradation is slow. For example, Blumer (1970) reported that No. 2 fuel oil incorporated into the sediments after the West Falmouth spill persisted for over a year, and even began spreading in the form of oil-laden sediments to more distant areas that had remained unpolluted immediately after the spill. The persistence of unweathered oil within the sediment could have a long-term effect on the structure of the benthic community or cause the demise of specific sensitive important species. Moore et al. (1973) reported concentrations of 5 mg/L for the carcinogen 3, 4-benzopyrene in marine sediments.

Mironov (1967) reported that 0.01 mg/L oil produced deformed and inactive flatfish larvae. Mironov (1970) also reported inhibition or delay of cellular division in algae by oil

concentrations of 10^{-4} to 10^{-1} mg/L. Jacobson and Boylan (1973) reported a reduction in the chemotactic perception of food by the snail, Nassarius obsoletus, at kerosene concentrations of 0.001 to 0.004 mg/L. Bellen et al. (1972) reported decreased survival and fecundity in worms at concentrations of 0.01 to 10 mg/L of detergent.

Because of the great variability in the toxic properties of oil, it is difficult to establish a numerical criterion which would be applicable to all types of oil. Thus, an application factor of 0.01 of the 96-hour LC50 as determined by using continuous flow with a sensitive resident species should be employed for individual petrochemical components.

There is a paucity of toxicological data on the ingestion of the components of refinery wastewaters by humans or by test animals. It is apparent that any tolerable health concentrations for petroleum-derived substances far exceed the limits of taste and odor. Since petroleum derivatives become organoleptically objectionable at concentrations far below the human chronic toxicity, it appears that hazards to humans will not arise from drinking oil-polluted waters (Johns Hopkins Univ., 1956; Mckee and Wolf, 1963). Oils of animal or vegetable origin generally are nontoxic to humans and aquatic life.

In view of the problem of petroleum oil incorporation in sediments, its persistence and chronic toxic potential, and the present lack of sufficient toxicity data to support specific criteria, concentrations of oils in sediments should not approach levels that cause deleterious effects to important species or the

bottom community as a whole.

Petroleum and nonpetroleum oils share some similar physical and chemical properties. Because they share common properties, they may cause similar harmful effects in the aquatic environment by forming a sheen, film, or discoloration on the surface of the water. Like petroleum oils, nonpetroleum oils may occur at four levels of the aquatic environment: (a) floating on the surface, (b) emulsified in the water column, (c) solubilized, and (d) settled on the bottom as a sludge. Analogous to the grease balls from vegetable oil and animal fats are the tar balls of petroleum origin which have been found in the marine environment or washed ashore on beaches.

Oils of any kind can cause (a) drowning of waterfowl because of loss of buoyancy, exposure because of loss of insulating capacity of feathers, and starvation and vulnerability to predators because of lack of mobility; (b) lethal effects on fish by coating epithelial surfaces of gills, thus preventing respiration; (c) potential fishkills resulting from biochemical oxygen demand; (d) asphyxiation of benthic life forms when floating masses become engaged with surface debris and settle on the bottom; and (e) adverse aesthetic effects of fouled shorelines and beaches. These and other effects have been documented in the U.S. Department of Health, Education and Welfare report on Oil Spills Affecting the Minnesota and Mississippi Rivers and the 1975 Proceedings of the Joint Conference on Prevention and Control of Oil Spills.

Oils of animal or vegetable origin generally are chemically nontoxic to humans or aquatic life; however, floating sheens of

such oils result in deleterious environmental effects described in this criterion. Thus, it is recommended that surface waters shall be virtually free from floating nonpetroleum oils of vegetable or animal origin. This same recommendation applies to floating oils of petroleum origin since they too may produce similar effects.

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

DISSOLVED OXYGEN

NATIONAL CRITERIA:

The national criteria for ambient dissolved oxygen concentrations for the protection of freshwater aquatic life are presented in Table 1. The criteria are derived from the production impairment estimates which are based primarily upon growth data and information on temperature, disease, and pollutant stresses. The average dissolved oxygen concentrations selected are values 0.5 mg/L above the slight production impairment values and represent values between no production impairment and slight production impairment. Each criterion may thus be viewed as an estimate of the threshold concentration below which detrimental effects are expected.

Criteria for coldwater fish are intended to apply to waters containing a population of one or more species in the family Salmonidae (Bailey et al., 1970) or to waters containing other coldwater or coolwater fish deemed by the user to be closer to salmonids in sensitivity than to most warmwater species. Although the acute lethal limit for salmonids is at or below 3 mg/L, the coldwater minimum has been established at 4 mg/L because a significant proportion of the insect species common to salmonid habitats are less tolerant of acute exposures to low dissolved oxygen than are salmonids. Some coolwater species may require more protection than that afforded by the other life stage criteria for warmwater fish and it may be desirable to protect sensitive coolwater species with the coldwater criteria. Many states have more stringent dissolved oxygen standards for cooler waters, waters that contain either

salmonids, nonsalmonid coolwater fish, or the sensitive centrachid, the smallmouth bass The warmwater criteria are necessary to protect early life stages of warmwater fish as sensitive as as channel catfish and to protect other life stages of fish as sensitive as largemouth bass. Criteria for early life stages are intended to apply only where and when these stages occur. These criteria represent dissolved oxygen concentrations which EPA believes provide a reasonable and adequate degree of protection for freshwater aquatic life.

The criteria do not represent assured no-effect levels. However, because the criteria represent worst case conditions (i.e. for wasteload allocation and waste treatment plant design), conditions will be better than the criteria nearly all of the time at most sites. In situations where criteria conditions are just maintained for considerable periods the proposed criteria represent some risk of production impairment. This impairment would depend on innumerable other factors. If slight production impairment or a small but undefinable risk of moderate impairment is unacceptable, than one should use the "no production impairment" values given in the document as means and the "slight production impairment" values as minima. The table which presents these concentrations is reproduced here as table 2.

The criteria do represent dissolved oxygen concentrations believed to protect the more sensitive populations of organisms against potentially damaging production impairment. The dissolved oxygen concentrations in the criteria are intended to be protective at typically high seasonal environmental temperatures for the appropriate taxonomic and life stage classi-

Table 1. Water quality criteria for ambient dissolved oxygen concentration.

	Coldwater Criteria		Warmwater Criteria	
	Early Life Stages[1,2]	Other Life Stages	Early Life Stages[2]	Other Life Stages
30 Day Mean	NA[3]	6.5	NA	5.5
7 Day Mean	9.5 (6.5)	NA	6.0	NA
7 Day Mean Minimum	NA	5.0	NA	4.0
1 Day Minimum [4,5]	8.0 (5.0)	4.0	5.0	3.0

1 These are water column concentrations recommended to achieve the required intergravel dissolved oxygen concentrations shown in parentheses. The 3 mg/L differential is discussed in the criteria document. For species that have early life stages exposed directly to the water column, the figures in parentheses apply.

2 Includes all embryonic and larval stages and all juvenile forms to 30-days following hatching.

3 NA (not applicable).

4 For highly manipulatable discharges, further restrictions apply (see page 37)

5 All minima should be considered as instantaneous concentrations to be achieved at all times.

fications, temperatures which are often higher than those used in the research from which the criteria were generated, especially for other than early life stages.

Where natural conditions alone create dissolved oxygen concentrations less than 110 percent of the applicable criteria means or minima or both, the minimum acceptable concentration is

90 percent of the natural concentration. These values are similar to those presented graphically by Doudoroff and Shumway (1970) and those calculated from Water Quality Criteria 1972 (NAS/NAE, 1973). Absolutely no anthropogenic dissolved oxygen depression in the potentially lethal area below the 1-day minima should be allowed unless special care is taken to ascertain the tolerance of resident species to low dissolved oxygen.

If daily cycles of dissolved oxygen are essentially sinusoidal, a reasonable daily average is calculated from the day's high and low dissolved oxygen values. A time-weighted average may be required if the dissolved oxygen cycles are decidedly non-sinusoidal. Determining the magnitude of daily dissolved oxygen cycles requires at least two appropriately timed measurements daily, and characterizing the shape of the cycle requires several more appropriately spaced measurements.

Once a series of daily mean dissolved oxygen concentrations are calculated, an average of these daily means can be calculated (Table 3). For embryonic, larval, and early life stages, the averaging period should not exceed 7 days. This short time is needed to adequately protect these often short duration, most sensitive life stages. Other life stages can probably be adequately protected by 30-day averages. Regardless of the averaging period, the average should be considered a moving average rather than a calendar-week or calendar-month average.

Table 2. Dissolved Oxygen Concentrations (mg/L) Versus Quantitative Level of Effect.

1. Salmonid Waters

a. Embryo and Larval Stages

No Production Impairment	= 11* (8)
Slight Production Impairment	= 9* (6)
Moderate Production Impairment	= 8* (5)
Severe Production Impairment	= 7* (4)
Limit to Avoid Acute Mortality	= 6* (3)

(* Note: These are water column concentrations recommended to achieve the required intergravel dissolved oxygen concentrations shown in parentheses. The 3 mg/L difference is discussed in the criteria document.)

b. Other Life Stages

No Production Impairment	= 8
light Production Impairment	= 6
Moderate Production Impairment	= 5
Severe Production Impairment	= 4
Limit to Avoid Acute Mortality	= 3

2. Nonsalmonid Waters

a. Early Life Stages

No Production Impairment	= 6.5
Slight Production Impairment	= 5.5
Moderate Production Impairment	= 5
Severe Production Impairment	= 4.5
Limit to Avoid Acute Mortality	= 4

b. Other Life Stages

No Production Impairment	= 6
Slight Production Impairment	= 5
Moderate Production Impairment	= 4
Severe Production Impairment	= 3.5
Limit to Avoid Acute Mortality	= 3

3. Invertebrates

No Production Impairment	= 8
Some Production Impairment	= 5
Acute Mortality Limit	= 4

Table 3. Sample calculations for determining daily means and 7-day mean dissolved oxygen concentrations (30-day averages are calculated in a similar fashion using 30 days data).

Dissolved Oxygen (mg/L)

Day	Daily Max.	Daily Min.	Daily Mean
1	9.0	7.0	8.0
2	10.0	7.0	8.5
3	11.0	8.0	9.5[b]
4	12.0[a]	8.0	9.5
5	10.0	8.0	9.0
6	11.0	9 0	10.0
7	12.0[a]	10.0	10.5[c]
		57.0	65.0
1-day Minimum		7.0	
7-day Mean Minimum		8.1	
7-day Mean			9.3

a Above air saturation concentration (assumed to be 11.0 mg/L for this example).

b (11.0 + 8.0)2.

c (11 0 +10.0)2.

The criteria have been established on the basis that the maximum dissolved oxygen value actually used in calculating any daily mean should not exceed the air saturation value. This consideration is based primarily on analysis of studies of cycling dissolved oxygen and the growth of largemouth bass (Stewart et al., 1967), which indicated that high dissolved oxygen levels (> 6 mg/L) had no beneficial effect on growth.

During periodic cycles of dissolved oxygen concentrations, minima lower than acceptable constant exposure levels are tolerable so long as:

1. the average concentration attained meets or exceeds the criterion;

2. the average dissolved oxygen concentration is calculated as recommended in Table 3; and

3. the minima are not unduly stressful and clearly are not lethal.

A daily minimum has been included to make certain that no acute mortality of sensitive species occurs as a result of lack of oxygen. Because repeated exposure to dissolved oxygen concentrations at or near the acute lethal threshold will be stressful and because stress can indirectly produce mortality or other adverse effects (e.g., through disease), the criteria are designed to prevent significant episodes of continuous or regularly recurring exposures to dissolved oxygen concentrations at or near the lethal threshold. This protection has been achieved by setting the daily minimum for early life stages at the subacute lethality threshold, by the use of a 7-day averaging period for early life stages, by stipulating a 7-day mean minimum value for other life stages, and by recommending additional limits for manipulatable discharges.

The previous EPA criterion for dissolved oxygen published in Quality Criteria for Water (USEPA, 1976) was a minimum of 5 mg/L (usually applied as a 7Q10) which is similar to the current criterion minimum except for other life stages of warmwater fish which now allows a 7-day mean minimum of 4 mg/L. The new criteria are similar to those contained in the 1968 "Green Book" of the Federal Water Pollution Control Federation (FWPCA, 1968).

A. The Criteria and Monitoring and Design Conditions

The acceptable mean concentrations should be attained most of the time, but some deviation below these values would probably not cause significant harm. Deviations below the mean will probably be serially correlated and hence apt to occur on consecutive days. The significance of deviations below the mean will depend on whether they occur continuously or in daily cycles, the former being more adverse than the latter. Current knowledge regarding such deviations is limited primarily to laboratory growth experiments and by extrapolation to other activity-related phenomena.

Under conditions where large daily cycles of dissolved oxygen occur, it is possible to meet the criteria mean values and consistently violate the mean minimum criteria. Under these conditions the mean minimum criteria will clearly be the limiting regulation unless alternatives such as nutrient control can dampen the daily cycles.

The significance of conditions which fail to meet the recommended dissolved oxygen criteria depend largely upon five factors: (1) the duration of the event; (2) the magnitude of the dissolved oxygen depression; (3) the frequency of recurrence; (4) the proportional area of the site failing to meet the criteria, and (5) the biological significance of the site where the event occurs. Evaluation of an event's significance must be largely case- and site-specific. Common sense would dictate that the magnitude of the depression would be the single most important factor in general, especially if the acute value is violated. A

logical extension of these considerations is that the event must be considered in the context of the level of resolution of the monitoring or modeling effort. Evaluating the extent, duration, and magnitude of an event must be a function of the spatial and temporal frequency of the data. Thus, a single deviation below the criterion takes on considerably less significance where continuous monitoring occurs than where sampling is comprised of once-a-week grab samples. This is so because based on continuous monitoring the event is provably small, but with the much less frequent sampling the event is not provably small and can be considerably worse than indicated by the sample. The frequency of recurrence is of considerable interest to those modeling dissolved oxygen concentrations because the return period, or period between recurrences, is a primary modeling consideration contingent upon probabilities of receiving water volumes, waste loads, temperatures, etc. It should be apparent that return period cannot be isolated from the other four factors discussed above. Ultimately, the question of return period may be decided on a site-specific basis taking into account the other factors (duration, magnitude, areal extent, and biological significance) mentioned above. Future studies of temporal patterns of dissolved oxygen concentrations, both within and between years, must be conducted to provide a better basis for selection of the appropriate return period.

In conducting wasteload allocation and treatment plant design computations, the choice of temperature in the models will be important. Probably the best option would be to use temperatures consistent with those expected in the receiving water over the

critical dissolved oxygen period for the biota.

B. The Criteria and Manipulatable Discharges

If daily minimum DOs are perfectly serially correlated, i.e, if the annual lowest daily minimum dissolved oxygen concentration is adjacent in time to the next lower daily minimum dissolved oxygen concentration and one of these two minima is adjacent to the third lowest daily minimum dissolved oxygen concentration, etc., then in order to meet the 7-day mean minimum criterion it is unlikely that there will be more than three or four consecutive daily minimum values below the acceptable 7-day mean minimum. Unless the dissolved oxygen pattern is extremely erratic, it is also unlikely that the lowest dissolved oxygen concentration will be appreciably below the acceptable 7-day mean minimum or that daily minimum values below the 7-day mean minimum will occur in more than one or two weeks each year. For some discharges, the distribution of dissolved oxygen concentrations can be manipulated to varying degrees. Applying the daily minimum to manipulatable discharges would allow repeated weekly cycles of minimum acutely acceptable dissolved oxygen values, a condition of unacceptable stress and possible adverse biological effect. For this reason, the application of the one day minimum criterion to manipulatable discharges must limit either the frequency of occurrence of values below the acceptable 7-day mean minimum or must impose further limits on the extent of excursions below the 7-day mean minimum. For such controlled discharges, it is recommended that the occurrence of daily minima below the acceptable 7-day mean

minimum be limited to 3 weeks per year or that the acceptable one-day minimum be increased to 4.5 mg/L for coldwater fish and 3.5 mg/L for warmwater fish. Such decisions could be site-specific based upon the extent of control and serial correlation.

NMED Exhibit 68

PARATHION

CRITERION:

0.04 ug/L for freshwater and marine aquatic life.

RATIONALE:

Acute static LC50 values of the organophosphorus pesticide, parathion, for freshwater fish have ranged generally from about 50 ug/L for more sensiitive species such as bluegills, Lepomis macrochirus, to about 2.5 mg/L for the more resistant species such as minnows (U.S. Environ. Prot. Agency, 1975). In flowing water exposures, Spacie (1975) obtained 96-hour LC50 values of 0.5 mg/L, 1.6 mg/L, and 1.76 mg/L for bluegills, Lepomis macrochirus, fathead minnows, Pimephales promelas, and brook trout, Salvelinus fontinalis, respectively. Korn and Earnest (1974) found a 96-hour LC50 of 18 ug/L for juvenile freshwater and estuarine striped bass, Morone saxatilis, in a flowing water system.

Few chronic exposure data are available for aquatic organisms. Brown bullheads, Ictalurus nebulosus, exposed to 30 ug/L parathion for 30 days exhibited tremors; at 60 ug/L they convulsed and were found to have developed a deformed vertebral column (Mount and Boyle, 1969). In a 23-month exposure of bluegills, Spacie (1975) observed deformities (scoliosis and a characteristic protrusion in the throat region) at 0.34 ug/L, but not at 0.16 ug/L. Tremors, convulsions, hypersensitivity, and hemorrhages also were evident at higher concentrations.

Reproductive impairment and deformities were observed in fathead minnows exposed to 4.0 ug/L for 8 1/2 months.

Development of brook trout, S. fontinalis embryos exposed to 32 ug/L was abnormal and mortalities associated with premature hatching were observed. Embryos at 10 ug/L appeared normal. No adverse effects on juveniles and adults was evident during 9 months' exposure to 7 ug/L.

Inhibition of cholinesterase enzymes is the well-established mode of physiological action of parathion and other organic phosphorus pesticides (Weiss, 1958). The degree of inhibition of brain acetylcholinesterase (AChE) activity has been the most frequently used measure of effect of these pesticides. Various studies (Weiss, 1958, 1959, 1961; Murphy et al., 1968; Gibson et al. 1969) have shown the degree of inhibition to be dependent upon toxicant concentration, length of exposure, and species sensitivity. The results of these studies have also indicated that death results from AChE inhibition ranging from 25 to 90 percent of normal. Weiss (1959) also showed that susceptibility depended upon the extent of recovery of AChE activity following prior exposure and that the recovery period for fish exposed to parathion was relatively long. In bluegills, AChE activity was only 50 percent recovered 30 days after exposure to 1 mg/L for 6 to 7 hours (Weiss, 1961).

Some of the other physiological effects observed to result from exposure of fish to parathion have been inhibition of spermatogenesis in guppies, Poecilia reticulata, at 10 ug/L (Billard and deKinkelin, 1970), alternation of oxygen consumption rate in bluegills, Lepomis macrochirus, at 100 ug/L (Dowden, 1966), and liver enlargement associated with increased pesticide-hydrolizing capability in mosquitofish, Gambusia

affinis (Ludke, 1970).

Parathion has been found acutely toxic to aquatic invertebrates at under 1 ug/L e.g., a 50-hour LC50 of 0.8 ug/L for Daphnia magna; 48-hour LC50 of 0.6 ug/L for Daphnia pulex; 48-hour LC50 of 0.37 for Simocephalus serrulatus (a daphnid) (Sanders and Cope, 1966); a 5-day LC50 of 0.93 ug/L for the larval stonefly, Acroneuria pacifica (Jensen and Gaufin, 1964); and a 96-hour LC50 of 0.43 ug/L for the larval caddisfly Hydropsyche californica (Gaufin et al. 1965). Mulla and Khasawinah (1969) obtained a 24-hour LC50 of 0.5 ug/L for 4th instar larvae of the midge Tanypus grodhausi. Spacie (1975) obtained 96-hour LC50's in flow-through bioassays of 0.62 ug/L for Daphnia magna, 0.40 ug/L for the scud, Gammarus fasciatus, and 31.0 ug/L for 4th instar of Chironomous tentans, a midge. Other invertebrates have been found acutely sensitive to parathion in concentrations of from 1 to 30 ug/L in water (U.S. Environ. Prot. Agency, 1975).

Few longer exposures have been conducted. Jensen and Gaufin (1964) obtained 30-day LC50's for Pteronarcys californica and Acroneuria pacifica of 2.2 and 0.44 ug/L, respectively. Spacie (1975) found the 3-week LC50 for Daphnia magna to be 0.14 ug/L. Statistically significant reproductive impairment occurred at concentrations above 0.08 ug/L. A 43-day LC50 of 0.07 ug/L was reported for Gammarus fasciatus and a concentration of 0.04 ug/L produced significantly greater mortality than among controls.

Limited information is available on persistence of parathion in water. Eichelberger and Lichtenberg (1971) determined the

half-life in river water (pH 7.3 - 8.0) to be 1 week. Using AChE inhibitory capacity as the indicator, Weiss and Gakstatter (1964) found the half-life of parathion or its active breakdown products to be 40, 35, and 20 days in "natural" waters having a pH of 5.1. 7.0, and 8.4, respectively. The possibility of breakdown resulting in compounds more toxic than parathion was suggested by Burke and Ferguson (1969) who determined that the toxicity of this pesticide to mosquitofish, Gambusia affinis, was greater in static than in flowing water test systems. Sanders (1972), in 96-hour bioassays with the scud, Gammarus fasciatus, and glass shrimp, Palaemonetes kadiakensis, also observed greater toxicity under static than in flow-through conditions.

Tissue accumulations of parathion by exposed aquatic organisms are not great and do not appear to be very persistent. Mount and Boyle (1969) observed concentrations in the blood of bullhead, Ictalurus melas, up to about 50 times water concentrations. Spacie (1975) found muscle concentrations in chronically exposed brook trout, S. fontinalis, to be several hundred times water concentrations; bluegills, Lepomis macrochirus, had about 25 times water concentrations in their bodies. Leland (1968) demonstrated a biological half-life of parathion in rainbow trout, Salmo gairdneri, exposed and then placed in fresh water to be only 30 to 40 hours. It is not expected that parathion residues in aquatic organisms exposed to the recommended criterion concentrations will be a hazard to consumer organisms.

Weiss and Gakstatter (1964) have shown that 15-day continuous exposure to parathion (1.0 ug/L) can produce progressively greater (i.e., cumulative) brain AChE inhibition in a fish species. After substantial inhibition by parathion exposure, it takes several weeks for brain AChE of exposed fishes to return to normal even though exposure is discontinued (Weiss, 1959, 1961). Inhibition of brain AChE of fishes by 46 percent or more has been associated with harmful effects in exposures to organophosphate pesticides for one life cycle (Eaton, 1970) and for short periods (Carter, 1971; Coppage and Duke, 1971; Coppage, 1972; Coppage and Matthews, 1974; Post and Leasure, 1974; Coppage et al. 1975). It has been shown that a concentration of 10 ug parathion/L of flowing seawater kills 40 to 60 percent of the marine fishes Lagodon rhomboides (pinfish) and Leostomus xanthurus (spot) in 24 hours and causes about 87 to 92 percent brain AChE inhibition (Coppage and Matthews, 1974.) Similar inhibition of AChE and mortality were caused in sheepshead minnows, Cyprinodon variegatus, in 2, 24, 48, and 72 hours at concentrations of 5,000, 2,000, 100, and 10 ug/L, respectively in static tests (Coppage, 1972). These data indicate that reductions of brain AChE activity of marine fishes by 70 to 80 percent or more in short-term exposures to parathion may be associated with some deaths.

Other estimates of parathion toxicity to marine organisms follow. The 48-hour EC50 for parathion to Penaeus duorarum was found to be 0.2 ug/L (Lowe et al. 1970). Lahav and Sarig (1969) reported the 96-hour LC50 for mullet, Mugil cephalus to be 125 ug/L. The shell growth of the oyster, Crassostrea virginica, was found by Lowe et al. (1970) to be decreased by 22 percent after 96 hours in 1.0 mg/L.

An application factor of 0.1 is applied to the 96-hour LC50 data for invertebrates which range upward from 0.4 ug/L. A criteria of 0.04 ug/L is recommended for marine and freshwater aquatic life.

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

PENTACHLOROPHENOL

CRITERIA:

Aquatic Life

The available data for pentachlorophenol indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 55 and 3.2 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

The available data for pentachlorophenol indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations as low as 53 and 34 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

For comparison purposes, two approaches were used to derive criterion levels for pentachlorophenol. Based on available toxicity data, to protect public health the derived level is 1.01 mg/L. Using available organoleptic data, to control undesirable taste and odor qualities of ambient water the estimated level is 30 ug/L. It should be recognized that organoleptic data have limitations as a basis for establishing a water quality criterion, and have no demonstrated relationship to potential adverse human health effects.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

pH

CRITERIA:

Range	
5 - 9	Domestic water supplies (welfare)
6.5 - 9.0	Freshwater aquatic life
6.5 - 8.5	Marine aquatic life (but not more than 0.2 units outside of normallyoccurring range.)

INTRODUCTION:

"pH" is a measure of the hydrogen ion activity in a water sample. It is mathematically related to hydrogen ion activity according to the expression: pH = -log 10 (H^+), where (H^+) is the hydrogen ion activity.

The pH of natural waters is a measure of acid-base equilibrium achieved by the various dissolved compounds, salts, and gases. The principal system regulating pH in natural waters is the carbonate system which is composed of carbon dioxide (CO_2), carbonic acid, (H_2CO_3), bicarbonate ion (HCO_3) and carbonate ions (CO_3). The interactions and kinetics of this system have been described by Stumm and Morgan (1970).

pH is an important factor in the chemical and biological systems of natural waters. The degree of dissociation of weak acids or bases is affected by changes in pH. This effect is important because the toxicity of many compounds is affected by the degree of dissociation. One such example is hydrogen cyanide (HCN). Cyanide toxicity to fish increases as the pH is lowered because the chemical equlibrium is shifted toward an increased concentration of HCN. Similar results have been shown for hydrogen sulfide (H_2S) (Jones, 1964).

The solubility of metal compounds contained in bottom sediments or as suspended material also is affected by pH. For example, laboratory equilibrium studies under anaerobic conditions indicated that pH was an important parameter involved in releasing manganese from bottom sediments (Delfino and Lee, 1971).

The pH of a water does not indicate ability to neutralize additions of acids or bases without appreciable change. This characteristic, termed "buffering capacity," is controlled by the amounts of alkalinity and acidity present.

RATIONALE:

Knowledge of pH in the raw water used for public water supplies is important because without adjustment to a suitable level, such waters may be corrosive and adversely affect treatment processes including coagulation and chlorination.

Coagulation for removal of colloidal color by use of aluminum or iron salts generally has an optimum pH range of 5.0 to 6.5 (Sawyer, 1960). Such optima are predicated upon the availability of sufficient alkalinity to complete the chemical reactions.

The effect of pH on chlorine in water principally is on the equilibrium between hypochlorous acid (HOCl) and the hypochlorite ion (OCl^-) according to the reaction:

$$HOCl = H^+ + OCl^-$$

Butterfield (1984) has shown that chlorine disinfection is more effective at values less than pH 7. Another study (Reid and Carlson, 1974) has indicated, however, that in natural waters no significant difference in the kill rate for Escherichia coli was

observed between pH 6 and pH 8.

Corrosion of plant equipment and piping in the distribution system can lead to expensive replacement as well as the introduction of metal ions such as copper, lead, zinc, and cadmium. Langelier (1936) developed a method to calculate and control water corrosive activity that employs calcium carbonate saturation theory and predicts whether the water would tend to dissolve or deposit calcium carbonate. By maintaining the pH at the proper level, the distribution system can be provided with a protective calcium carbonate lining which prevents metal pipe corrosion. Generally, this level is above pH 7 and frequently approaches pH 8.3, the point of maximum bicarbonate/carbonate buffering.

Since pH is relatively easily adjusted prior to and during water treatment, a rather wide range is acceptable for waters serving as a source of public water supply. A range of pH from 5.0 to 9.0 would provide a water treatable by typical (coagulation, sedimentation, filtration, and chlorination) treatment plant processes. As the range is extended, the cost of neutralizing chemicals increases.

A review of the effects of pH on fresh water fish has been published by the European Inland Fisheries Advisory Commission (1969). The commission concluded:

> There is no definite pH range within which a fishery is unharmed and outside which it is damaged, but rather, there is a gradual deterioration as the pH values are further removed from the normal range. The pH range which is not directly lethal to fish is 5 - 9; however, the toxicity of several common pollutants is markedly affected by pH changes within this range, and increasing acidity or alkalinity may make these poisons more toxic. Also, an acid discharge may liberate sufficient CO_2 from bicarbonate in the water either

to be directly toxic, or to cause the pH range 5 - 6 to become lethal.

Mount (1973) performed bioassays on the fathead minnow, Pimephales promelas, for a 13-month, one generation time period to determine chronic pH effects. Tests were run at pH levels of 4.5, 5.2.

pH Range	Effect on Fish*
5.0 - 6.0	Unlikely to be harmful to any species unless either the concentration of free CO_2 is greater than 20 ppm, or the water contains iron salts which are precipitated as ferric hydroxide, the toxicity of which is not known.
6.0 - 6.5	Unlikely to be harmful to fish unless free carbon dioxide is present in excess of 100 ppm.
6.5 - 9.0	Harmless to fish, although the toxicity of other poisons may be affected by changes within this range.

EIFAC, 1969

5.9, 6.6, and a control of 7.5. At the two lowest pH values (4.5 and 5.2) behavior was abnormal and the fish were deformed. At pH values less than 6.6, egg production and hatchability were reduced when compared with the control. It was concluded that a pH of 6.6 was marginal for vital life functions.

Bell (1971) performed bioassays with nymphs of caddisflies (two species) stoneflies (four species), dragonflies (two species), and mayflies (one species). All are important fish food organisms. The 30-day TL50 values ranged from 2.45 to 5.38 with the caddisflies being the most tolerant and the mayflies being the least tolerant. The pH values at which 50 percent of the organisms emerged ranged from 4.0 to 6.6 with increasing percentage emergence occurring with the increasing pH values.

Based on present evidence, a pH range of 6.5 to 9.0 appears to provide adequate protection for the life of freshwater fish and bottom dwelling invertebrates fish food organisms. Outside of this range, fish suffer adverse physiological effects increasing in severity as the degree of deviation increases until lethal levels are reached.

Conversely, rapid increases in pH can cause increased NH_3 concentrations that are also toxic. Ammonia has been shown to be 10 times as toxic at pH 8.0 as at pH 7.0 (EIFAC, 1969).

The chemistry of marine waters differs from that of fresh water because of the large concentration of salts present. In addition to alkalinity based on the carbonate system, there is also alkalinity from other weak acid salts such as borate. Because of the buffering system present in seawater, the

naturally occurring variability of pH is less than in fresh water. Some marine communities are more sensitive to pH change than others (NAS, 1974). Normal pH values in seawater are 8.0 to 8.2 at the surface, decreasing to 7.7 to 7.8 with increasing depth (Capurro, 1970). The NAS Committee's review (NAS, 1974) indicated that plankton and benthic invertebrates are probably more sensitive than fish to changes in pH and that mature forms and larvae of oysters are adversely affected at the extremes of the pH range of 6.5 to 9.0. However, in the shallow, biologically active waters in tropical or subtropical areas, large diurnal pH changes occur naturally because of photosynthesis. pH values may range from 9.5 in the daytime to 7.3 in the early morning before dawn. Apparently, these communities are adapted to such variations or intolerant species are able to avoid extremes by moving out of the area.

For open ocean waters where the depth is substantially greater than the euphotic zone, the pH should not be changed more than 0.2 units outside of the naturally occurring variation or in any case outside the range of 6.5 to 8.5. For shallow, highly productive coastal and estuarine areas where naturally occurring variations approach the lethal limits for some species, changes in pH should be avoided, but in any case not exceed the limits established for fresh water, i.e., pH of 6.5 to 9.0. As with freshwater criteria, rapid pH fluctuations that are caused by waste discharges should be avoided. Additional support for these limits is provided by Zirino and Yamamoto (1972). These investigators developed a model which illustrates the effects of variable pH on copper, zinc, cadmium, and lead; small changes in

pH cause large shifts in these metallic complexes. Such changes may affect toxicity of these metals.

For the industrial classifications considered, the NAS report (NAS, 1974) tabulated the range of pH values used by industry for various process and cooling purposes. In general, process waters used varied from pH 3.0 to 11.7, while cooling waters used varied from 5.0 to 8.9. Desirable pH values are undoubtedly closer to neutral to avoid corrosion and other deleterious chemical reactions. Waters with pH values outside these ranges are considered unusable for industrial purposes.

The pH of water applied for irrigation purposes is not normally a critical parameter. Compared with the large buffering capacity of the soil matrix, the pH of applied water is rapidly changed to approximately that of the soil. The greatest danger in acid soils is that metallic ions such as iron, manganese, or aluminum may be dissolved in concentrations which are subsequently directly toxic to plants. Under alkaline conditions, the danger to plants is the toxicity of sodium carbonates and bicarbonates either directly or indirectly (NAS, 1974).

To avoid undesirable effects in irrigation waters, the pH should not exceed a range of 4.5 to 9.0.

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

PHENOL

CRITERIA:

Aquatic Life

The available data for phenol indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 10,200 and 2,560 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

The available data for phenol indicate that toxicity to saltwater aquatic life occurs at concentrations as low as 5,800 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of phenol to sensitive saltwater aquatic life.

Human Health

For comparison purposes, two approaches were used to derive criterion levels for phenol. Based on available toxicity data, to protect public health the derived level is 3.5 mg/L.

Using available organoleptic data, to control undesirable taste and odor qualities of ambient water the estimated level is 0.3 mg/L. It should be recognized that organoleptic data have limitations as a basis for establishing a water quality criterion, and have no demonstrated relationship to potential adverse human health effects.

NOTE: The U.S. EPA is currently developing Acceptable Daily Intake (ADI) or Verified Reference Dose (RfD) values for Agency-wide use for this chemical. The new value should be substituted when it becomes available. The January, 1986, draft Verified Reference Dose document cites an RfD of 0.1 mg/kg/day for phenol.

SEE APPENDIX B FOR METHODOLOGY

PHOSPHORUS

CRITERION::

0.10 ug/L yellow (elemental) phosphorus for marine or estuarine water.

INTRODUCTION:

Phosphorus in the elemental form is particularly toxic and is subject to bioaccumulation in much the same way as mercury. Phosphorus as phosphate is one of the major nutrients required for plant nutrition and is essential for life. In excess of a critical concentration, phosphates stimulate plant growths. During the past 30 years, a formidable case has developed for the belief that increasing standing crops of aquatic plants, which often interfere with water uses and are nuisances to man, frequently are caused by increasing supplies of phosphorus. Such phenomena are associated with a condition of accelerated eutrophication or aging of waters. Generally, it is recognized that phosphorus is not the sole cause of eutrophication but there is substantiating evidence that frequently it is the key element of all of the elements required by freshwater plants, and generally, it is present in the least amount relative to need. Therefore, an increase in phosphorus allows use of other already present nutrients for plant growth. Further, of all of the elements required for plant growth in the water environment, phosphorus is the most easily controlled by man.

Large deposits of phosphate rock are found near the western shore of Central Florida, as well as in a number of other States. Deposits in Florida are found in the form of pebbles which vary

in size from fine sand to about the size of a human foot. These pebbles are embedded in a matrix of clay and sand. The phosphate rock beds lie within a few feet of the surface and mining is accomplished by using hydraulic water jets and a washing operation that separates the phosphates from waste materials. The process is similar to that of strip-mining. Florida, Idaho, Montana, North Carolina, South Carolina, Tennessee, Utah, Virginia, and Wyoming share phosphate mining activities.

Phosphates enter waterways from several different sources. The human body excretes about one pound per year of phosphorus expressed as "P". The use of phosphate detergents and other domestic phosphates increases the per capita contribution to about 3.5 pounds per year of phosphorus as P. Some industries, such as potato processing, have wastewaters high in phosphates. Crop, forest, idle, and urban land contribute varying amounts of phosphorus-diffused sources in drainage to watercourses. This drainage may be surface runoff of rainfall, effluent from tile lines, or return flow from irrigation. Cattle feedlots, concentrations of domestic duck or wild duck populations, tree leaves, and fallout from the atmosphere all are contributing sources.

Evidence indicates that: (1) high phosphorus concentrations are associated with accelerated eutrophication of waters, when other growth-promoting factors are present; (2) aquatic plant problems develop in reservoirs and other standing waters at phosphorus values lower than those critical in flowing streams; (3) reservoirs and lakes collect phosphates from influent streams

and store a portion of them within consolidated sediments, thus serving as a phosphate sink; and (4) phosphorus concentrations critical to noxious plant growth vary and nuisance growths may result from a particular concentration of phosphate in one geographical area but not in another. The amount or percentage of inflowing nutrients that may be retained by a lake or reservoir is variable and will depend upon: (1) the nutrient loading to the lake or resevoir; (2) the volume of the euphotic zone; (3) the extent of biological activities; (4) the detention time within a lake basin or the time available for biological activities; and (5) the level of discharge from the lake or of the penstock from the reservoir.

Once nutrients are combined within the aquatic ecosystem, their removal is tedious and expensive. Phosphates are used by algae and higher aquatic plants and may be stored in excess of use within the plant cell. With decomposition of the plant cell, some phosphorus may be released immediately through bacterial action for recycling within the biotic community, while the remainder may be deposited with sediments. Much of the material that combines with the consolidated sediments within the lake bottom is bound permanently and will not be recycled into the system.

RATIONALE:

Elemental Phosphorus

Isom (1960) reported an LC50 of 0.105 mg/L at 48 hours and 0.025 mg/L at 160 hours for bluegill sunfish, Lepomis macrochirus, exposed to yellow phosphorus in distilled water at

26 °C and pH 7. The 125-and 195-hour LC50's of yellow phosphorus to Atlantic cod, Gadus morhua, and Atlantic salmon, Salmo salar, smolts in continuous-exposure experiments were 1.89 and 0.79 ug/L, respectively (Fletcher and Hoyle, 1972). No evidence of an incipient lethal level was observed since the lowest concentration of P_4 tested was 0.79 ug/L. Salmon that were exposed to elemental phosphorus concentrations of 40 ug/L or less developed a distinct external red color and showed signs of extensive hemolysis. The predominant features of P_4 poisoning in salmon were external redness, hemolysis, and reduced hematocrits.

Following the opening of an elemental phosphorus production plant in Long Harbour, Placentia Bay, Newfoundland, divers observed dead fish upon the bottom throughout the Harbour (Peer, 1972). Mortalities were confined to a water depth of less than 18 meters. There was visual evidence of selective mortality among benthos. Live mussels were found within 300 meters of the effluent pipe, while all scallops within this area were dead.

Fish will concentrate elemental phosphorus from water containing as little as 1 ug/L (Idler, 1969). In one set of experiments, a cod swimming in water containing 1 ug/L elemental phosphorus for 18 hours concentrated phosphorus to 50 ug/kg in muscle, 150 ug/kg in fatty tissue, and 25,000 ug/kg in the liver (Idler, 1969; Jangaard, 1970). The experimental findings showed that phosphorus is quite stable in the fish tissues.

The criterion of 0.10 ug/L elemental phosphorus for marine or estuarine waters is .1 of demonstrated lethal levels to important marine organisms and of levels that have been found to result in significant bioaccumulation.

Phosphate Phosphorus

Although a total phosphorus criterion to control nuisance aquatic growths is not presented, it is believed that the following rationale to support such a criterion, which currently is evolving, should be considered.

Total phosphate phosphorus concentrations in excess of 100 ug/L P may interfere with coagulation in water treatment plants. When such concentrations exceed 25 ug/L at the time of the spring turnover on a volume-weighted basis in lakes or reservoirs, they may occasionally stimulate excessive or nuisance growths of algae and other aquatic plants. Algal growths inpart undesirable tastes and odors to water, interfere with water treatment, become aesthetically unpleasant, and alter the chemistry of the water supply. They contribute to the phenomenon of cultural eutrophication.

To prevent the development of biological nuisances and to control accelerated or cultural eutrophication, total phosphates as phosphorus (P) should not exceed 50 ug/L in any stream at the point where it enters any lake or reservoir, nor 25 ug/L within the lake or reservoir. A desired goal for the prevention of plant nuisances in streams or other flowing waters not discharging directly to lakes or impoundments is 100 ug/L total P (Mackenthun, 1973). Most relatively uncontaminated lake districts are known to have surface waters that contain from 10 to 30 ug/L total phosphorus as P (Hutchinson, 1957).

The majority of the Nation's eutrophication problems are associated with lakes or reservoirs and currently there are more

data to support the establishment of a limiting phosphorus level in those waters than in streams or rivers that do not directly impact such water. There are natural conditions, also, that would dictate the consideration of either a more or less stringent phosphorus level. Eutrophication problems may occur in waters where the phosphorus concentration is less than that indicated above and, obviously, such waters would need more stringent nutrient limits. Likewise, there are those waters within the Nation where phosphorus is not now a limiting nutrient and where the need for phosphorus limits is substantially diminished. Such conditions are described in the last paragraph of this rationale.

There are two basic needs in establishing a phosphorus criterion for flowing waters: one is to control the development of plant nuisances within the flowing water and, in turn, to control and prevent animal pests that may become associated with such plants; the other is to protect the downstream receiving waterway, regardless of its proximity in linear distance. It is evident that a portion of that phosphorus that enters a stream or other flowing waterway eventually will reach a receiving lake or estuary either as a component of the fluid mass, as bed load sediments that are carried downstream, or as floating organic materials that may drift just above the stream's bed or float on its water's surface. Superimposed on the loading from the inflowing waterway, a lake or estuary may receive additional phosphorus as fallout from the air shed or as a direct introduction from shoreline areas.

Another method to control the inflow of nutrients, particularly phosphates, into a lake is that of prescribing an annual loading to the receiving water. Vollenweider (1973) suggests total phosphorus (P) loadings in grams per square meter of surface area per year that will be a critical level for eutrophic conditions within the receiving waterway for a particular water volume where the mean depth of the lake in meters is divided by the hydraulic detention time in years. Vollenweider's data suggest a range of loading values that should result in oligotrophic lake water quality.

Mean Depth/Hydraulic Detention Time	Oligotrophic or Permissible Loading	Eutrophic or Critical Loading
(meters/year)	(grams/meter^2/year)	(grams/meter^2/year)
0.5	0.07	0.14
1.0	0.10	0.20
2.5	0.16	0.32
5.0	0.22	0.45
7.5	0.27	0.55
10.0	0.32	0.63
25.0	0.50	1.00
50.0	0.71	1.41
75.0	0.87	1.73
100.0	1.00	2.00

There may be waterways wherein higher concentrations or loadings of total phosphorus do not produce eutrophy, as well as those waterways wherein lower concentrations or loadings of total

phosphorus may be associated with populations of nuisance organisms. Waters now containing less than the specified amounts of phosphorus should not be degraded by the introduction of additional phosphates.

It should be recognized that a number of specific exceptions can occur to reduce the threat of phosphorus as a contributor to lake eutrophy: 1. Naturally occurring phenomena may limit the development of plant nuisances. 2. Technological or cost-effective limitations may help control introduced pollutants. 3. Waters may be highly laden with natural silts or colors which reduce the penetration of sunlight needed for plant photosynthesis. 4. Some waters morphometric features of steep banks, great depth, and substantial flows contribute to a history of no plant problems. 5. Waters may be managed primarily for waterfowl or other wildlife. 7. In some waters nutrient other than phosphorus is limiting to plant growth; the level and nature of such limiting nutrient would not be expected to increase to an extent that would influence eutrophication. 6. In some waters phosphorus control cannot be sufficiently effective under present technology to make phosphorus the limiting nutrient.

No national criterion is presented for phosphate phosphorus for the control of eutrophication.

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

PHTHALATE ESTERS

CRITERIA:

Aquatic Life

The available data for phthalate esters indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 940 and 3 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

The available data for phthalate esters indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 2,944 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of phthalate esters to sensitive saltwater aquatic life but toxicity to one species of algae occurs at concentrations as low as 3.4 ug/L.

Human Health

For the protection of human health from the toxic properties of dimethyl phthalate ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 313 mg/L.

For the protection of human health from the toxic properties of dimethyl phthalate ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 2.9 g/l.

For the protection of human health from the toxic properties of diethyl phthalate ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 350 mg/L.

For the protection of human health from the toxic properties of diethyl phthalate ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 1.8 g/l.

For the protection of human health from the toxic properties of dibutyl phthalate ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 34 mg/L.

For the protection of human health from the toxic properties of dibutyl phthalate ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 154 mg/L.

For the protection of human health from the toxic properties of di-2-ethylhexyl phthalate ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 15 mg/L.

For the protection of human health from the toxic properties of di-2-ethylhexyl phthalate ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 50 mg/L.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

POLYCHLORINATED BIPHENYLS

CRITERIA:

Aquatic Life

For polychlorinated biphenyls the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.014 ug/L as a 24-hour average. The concentration of 0.014 ug/L is probably too high because it is based on bioconcentration factors measured in laboratory studies, but field studies apparently produce factors at least 10 times higher for fishes. The available data indicate that acute toxicity to freshwater aquatic life probably will occur only at concentrations above 2.0 ug/L and that the 24-hour average should provide adequate protection against acute toxicity.

For polychlorinated biphenyls the criterion to protect saltwater aquatic life as derived using the Guidelines is 0.030 ug/L as a 24-hour average. The concentration of 0.030 ug/L is probably too high because it is based on bioconcentration factors measured in laboratory studies, but field studies apparently produce factors at least 10 times higher for fishes. The available data indicate that acute toxicity to saltwater aquatic life probably will only occur at concentrations above 10 ug/L and that the 24-hour average criterion should provide adequate protection against acute toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to polychlorinated biphenyls through ingestion of contaminated water and contaminated aquatic

organisms, the ambient water concentration should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 0.79 ng/L, 0.079 ng/L, and 0.0079 ng/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 0.79 ng/L, 0.079 ng/L, and 0.0079 ng/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

POLYNUCLEAR AROMATIC HYDROCARBONS

CRITERIA:

Aquatic Life

The limited freshwater data base available for polynuclear aromatic hydrocarbons, mostly from short-term bioconcentration studies with two compounds, does not permit a statement concerning acute or chronic toxicity.

The available data for polynuclear aromatic hydrocarbons indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 300 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of polynuclear aromatic hydrocarbons to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to polynuclear aromatic hydrocarbons through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 28.0 ng/L, 2.8 ng/L, and 0.28 ng/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 311.0 ng/L,

31.1 ng/L, and 3.11 ng/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

SELENIUM

CRITERIA:

Aquatic Life

For total recoverable inorganic selenite the criterion to protect freshwater aquatic life as derived using the Guidelines is 35 ug/L as a 24-hour average, and the concentration should not exceed 260 ug/L at any time.

For total recoverable inorganic selenite the criterion to protect saltwater aquatic life as derived using the Guidelines is 54 ug/L as a 24-hour average, and the concentration should not exceed 410 ug/L at any time.

The available data for inorganic selenate indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 760 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of inorganic selenate to sensitive freshwater aquatic life.

No data are available concerning the toxicity of inorganic selenate to saltwater aquatic life.

Human Health

The ambient water quality criterion for selenium is recommended to be identical to the existing water standard which is 10 ug/L. Analysis of the toxic effects data resulted in a calculated level which is protective of human health against the ingestion of contaminated water and contaminated aquatic organisms. The calculated value is comparable to the present

standard. For this reason a selective criterion based on exposure solely from consumption of 6.5 grams of aquatic organisms was not derived.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

SILVER

CRITERIA:

Aquatic Life

For freshwater aquatic life the concentration (in ug/L) of total recoverable silver should not exceed the numerical value given by $^{e}(1.72[\ln(\text{hardness})]-6.52)$ at any time. For example, at hardnesses of 50, 100, and 200 mg/L as $CaCO^3$, the concentration of total recoverable silver should not exceed 1.2, 4.1, and 13 ug/L, respectively, at any time. The available data indicate that chronic toxicity to freshwater aquatic life may occur at concentrations as low as 0.12 ug/L.

For saltwater aquatic life the concentration of total recoverable silver should not exceed 2.3 ug/L at any time. No data are available concerning the chronic toxicity of silver to sensitive saltwater aquatic life.

Human Health

The ambient water quality criterion for silver is recommended to be identical to the existing water standard, which is 50 ug/L. Analysis of the toxic effects data resulted in a calculated level which is protective of human health against the ingestion of contaminated water and contaminated aquatic organisms. The calculated value is comparable to the present standard. For this reason a selective criterion based on exposure solely from consumption of 6.5 grams of aquatic organisms was not derived.

SEE APPENDIX B FOR METHODOLOGY

SOLIDS (DISSOLVED) AND SALINITY

CRITERION:

250 mg/L for chlorides and sulfates
in domestic water supplies (welfare).

INTRODUCTION:

Dissolved solids and total dissolved solids are terms generally associated with freshwater systems and consist of inorganic salts, small amounts of organic matter, and dissolved materials (Sawyer, 1960). The equivalent terminology in Standard Methods is filtrable residue (Standard Methods, 1971). Salinity is an oceanographic term, and although not precisely equivalent to the total dissolved salt content it is related to it (Capurro, 1970). For most purposes, the terms total dissolved salt content and salinity are equivalent. The principal inorganic anions dissolved in water include the carbonates, chlorides, sulfates, and nitrates (principally in ground waters); the principal cations are sodium, potassium, calcium, and magnesium.

RATIONALE:

Excess dissolved solids are objectionable in drinking water because of possible physiological effects, unpalatable mineral tastes, and higher costs because of corrosion or the necessity for additional treatment.

The physiological effects directly related to dissolved solids include laxative effects principally from sodium sulfate and magnesium sulfate and the adverse effect of sodium on certain patients afflicted with cardiac disease and women with toxemia associated with pregnancy. One study was made using data

collected from wells in North Dakota. Results from a questionnaire showed that with wells in which sulfates ranged from 1,000 to 1,500 mg/L, 62 percent of the respondents indicated laxative effects associated with consumption of the water. However, nearly one-quarter of the respondents to the questionnaire reported difficulties when concentrations ranged from 200 to 500 mg/L (Moore, 1952). To protect transients to an area, a sulfate level of 250 mg/L should afford reasonable protection from laxative effects.

As indicated, sodium frequently is the principal component of dissolved solids. Persons on restricted sodium diets may have an intake restricted from 500 to 1,000 mg/day (Nat. Res. Coun., 1954). That portion ingested in water must be compensated by reduced levels in food ingested so that the total does not exceed the allowable intake. Using certain assumptions of water intake (e.g., 2 liters of water consumed per day) and sodium content of food, it has been calculated that for very restricted sodium diets, 20 mg/L in water would be the maximum, while for moderately restricted diets, 270 mg/L would be maximum. Specific sodium levels for entire water supplies have not been recommended but various restricted sodium intakes are recommended because: (1) the general population is not adversely affected by sodium, but various restricted sodium intakes are recommended by physicians for a significant portion of the population, and (2) 270 mg/L of sodium is representative of mineralized waters that may be aesthetically unacceptable, but many domestic water supplies exceed this level. Treatment for removal of sodium in

water supplies is costly (NAS, 1974).

A study based on consumer surveys in 29 California water systems was made to measure the taste threshold of dissolved salts in water (Bruvold et al., 1969). Systems were selected to eliminate possible interferences from other taste-causing substances than dissolved salts. The study revealed that consumers rated waters with 319 to 397 mg/L dissolved solids as "excellent" while those with 1,283 to 1,333 mg/L dissolved solids were "unacceptable" depending on the rating system used. A "good" rating was registered for dissolved solids less than 658 to 755 mg/L. The 1962 PHS Drinking Water Standards recommended a maximum dissolved solids concentration of 500 mg/L unless more suitable supplies were unavailable.

Specific constituents included in the dissolved solids in water may cause mineral tastes at lower concentrations than other constituents. Chloride ions have frequently been cited as having a low taste threshold in water. Data from Ricter and MacLean (1939) on a taste panel of 53 adults indicated that 61 mg/L NaCl was the median level for detecting a difference from distilled water. At a median concentration of 395 mg/L chloride a salty taste was distinguishable, although the range was from 120 to 1,215 mg/L. Lockhart, et al. 1955) evaluated the effect of chlorides on water used for brewing coffee indicated threshold concentrations for chloride ranging from 210 mg/L to 310 mg/L depending on the associated cation. These data indicate that a level of 250 mg/L chlorides is a reasonable maximum level to protect consumers of drinking water.

The causation of corrosion and encrustation of metallic surfaces by water containing dissolved solids is well known. In water distribution systems corrosion is controlled by insulating dissimilar metal connections by nonmetallic materials, using pH control and corrosion inhibitors, or some form of galvanic or impressed electrical current systems (Lehmann, 1964). In household systems water piping, wastewater piping, water heaters, faucets, toilet flushing mechanisms, garbage grinders and both clothes and dishwashing machines incure damage.

By using water with 1,750 mg/L dissolved solids as compared with 250 mg/L, service life was reduced from 70 percent for toilet flushing mechanisms to 30 percent for washing equipment. Such increased corrosion was calculated in 1968 to cost the consumer an additional $0.50 per 1,000 gallons used.

All species of fish and other aquatic life must tolerate a range of dissolved solids concentrations in order to survive under natural conditions. Based on studies in Saskatchewan it has been indicated that several common freshwater species survived 10,000 mg/L dissolved solids, that whitefish and pike-perch survived 15,000 mg/L, but only the stickleback survived 20,000 mg/L dissolved solids. It was concluded that lakes with dissolved solids in excess of 15,000 mg/L were unsuitable for most freshwater fishes (Rawson and Moore, 1944). The 1968 NTAC Report also recommended maintaining osmotic pressure levels of less than that caused by a 15,000 mg/L solution of sodium chloride.

Marine fishes also exhibit variance in ability to tolerate salinity changes. However, fishkills in Laguna Madre off the Texas coast have occurred with salinities in the range of 75 to 100 o/oo. Such concentrated seawater is caused by evaporation and lack of exchange with the Gulf of Mexico (Rounsafell and Everhart, 1953).

Estuarine species of fish are tolerant of salinity changes ranging from fresh to brackish to seawater. Anadromous species likewise are tolerant although evidence indicates that the young cannot tolerate the change until the normal time of migration (Rounsefell and Everhart, 1953). Other aquatic species are more dependent on salinity for protection from predators or require certain minimal salinities for successful hatching of eggs. The oyster drill cannot tolerate salinities less than 12.5 o/oo. Therefore, estuarine segments containing salinities below about 12.5 o/oo produce most of the seed oysters for planting (Rounsefell and Everhart, 1953). Based on similar examples, the 1968 NTAC Report recommended that to protect fish and other marine animals no changes in hydrography or stream flow should be allowed that permanently change isohaline patterns in the estuary by more than 10 percent from natural variation.

Many of the recommended game bird levels for dissolved solids concentrations in drinking water have been extrapolated from data collected on domestic species such as chickens. However, young ducklings were reported poisoned in Suisan Marsh by salt when maximum summer salinities varied from 0.55 to 1.74 o/oo with means as high as 1.26 o/oo (Griffith, 1963).

Indirect effects of excess dissolved solids are primarily the elimination of desirable food plants and other habitat-forming plants. Rapid salinity changes cause plasmolysis of tender leaves and stems because of changes in osmotic pressure. The 1968 NTAC Report recommended the following limits in salinity variation from natural to protect wildlife habitats:

Natural Salinity (o/oo)	Variation Permitted (o/oo)
0 to 3.5	1
3.5 to 13.5	2
13.5 to 35	4

Agricultural uses of water are also limited by excessive dissolved solids concentrations. Studies have indicated that chickens, swine, cattle, and sheep can survive on saline waters up to 15,000 mg/L of salts of sodium and calcium combined with bicarbonates, chlorides, and sulfates but only 10,000 mg/L of corresponding salts of potassium and magnesium. The approximate limit for highly alkaline waters containing sodium and calcium carbonates is 5,000 mg/L (NTAC, 1968).

Irrigation use of water depends not only upon the osmotic effect of dissolved solids, but also on the ratio of the various cations present. In arid and semiarid areas general classification of salinity hazards has been prepared (NTAC, 1968) (see Table 9).

Table 9.-Dissolved Solids Hazard for Irrigation Water (mg/L).

water from which no detrimental effects will usually be noticed----------	500

water which can have detrimental effects on sensitive crops----------	500-1,000
water that may have adverse effects on many crops and requires careful management Practices----------	1,000-2,000
water that can be used for tolerant plants on permeable soils with careful management practices----------	2,000-5,000

The amount of sodium and the percentage of sodium in relation to other cations are often important. In addition to contributing to osmotic pressure, sodium is toxic to certain plants, especially fruits, and frequently causes problems in soil structure, infiltration, and permeability rates (Agriculture Handbook #60, 1954). A high percentage of exchangeable sodium in soils containing clays that swell when wet can cause a soil condition adverse to water movement and plant growth. The exchangeable-sodium percentage (ESP)* is an index of the sodium status of soils. An ESP of 10 to 15 percent is considered excessive if a high percentage of swelling clay minerals is present (Agricultural Handbook #60, 1954).

For sensitive fruits, the tolerance for sodium for irrigation water is for a sodium adsorption ratio (SAR)** of about 4, whereas for general crops and forages a range of 8 to 18 is generally considered usable (NTAC, 1968). It is emphasized that application of these factors must be interpreted in relation to specific soil conditions existing in a given locale and therefore frequently requires field investigation.

Industrial requirements regarding the dissolved solids content of raw waters is quite variable. Table 10 indicates

Table 10.-Total Dissolved Solids Concentrations of Surface Waters That Have Been Used as Sources for Industrial Water Supplies

Industry/Use	Maximum Concentration (mg/L)
Textile	150
Pulp and Paper	1,080
Chemical	2,500
Petroleum	3,500
Primary Metals	1,500
Boiler Make-up	35,000

maximum values accepted by various industries for process requirements (NAS, 1974). Since water of almost any dissolved solids concentration can be de-ionized to meet the most stringent requirements, the economics of such treatment are the limiting factor for industry.

$$*ESP = \frac{100\ [a + b(SAR)]}{1\ \ [a + b(SAR)]}$$

where: a = intercept respresenting experimental error (ranges from -0.06 to 0.01)
b = slope of regression line (ranges from 0.014 to 0.016)

$$**SAR = \text{sodium adsorption ratio} = \frac{Na}{[0.5(Ca + Mg)]^{0.5}}$$

SAR is expressed as milliequivalents

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

SOLIDS (SUSPENDED, SETTLEABLE) AND TURBIDITY

CRITERIA

Freshwater fish and other aquatic life:

Settleable and suspended solids should not reduce the depth of the compensation point for photosynthetic activity by more than 10 percent from the seasonally established norm for aquatic life.

INTRODUCTION:

The term "suspended and settleable solids" is descriptive of the organic and inorganic particulate matter in water. The equivalent terminology used for solids in Standard Methods (APHA, 1971) is total suspended matter for suspended solids, settleable matter for settleable solids, volatile suspended matter for volatile solids and fixed suspended matter for fixed suspended solids. The term "solids" is used in this discussion because of its more common use in the water pollution control literature.

RATIONALE:

Suspended solids and turbidity are important parameters in both municipal and industrial water supply practices. Finished drinking waters have a maximum limit of 1 turbidity unit where the water enters the distribution system. This limit is based on health considerations as it relates to effective chlorine disinfection. Suspended matter provides areas where microorganisms do not come into contact with the chlorine disinfectant (NAS,1974). The ability of common water treatment processes (i.e., coagulation, sedimentation, filtration, and chlorination) to remove suspended matter to achieve acceptable final turbidities is a function of the composition of the material as well as its concentration. Because of the variability

of such removal efficiency, it is not possible to delineate a general raw water criterion for these uses.

Turbid water interferes with recreational use and aesthetic enjoyment of water. Turbid waters can be dangerous for swimming, especially if diving facilities are provided, because ofthe possibility of unseen submerged hazards and the difficulty in locating swimmers in danger of drowning (NAS, 1974). The less turbid the water the more desirable it becomes for swimming and other water contact sports. Other recreational pursuits such as boating and fishing will be adequately protected by suspended solids criteria developed for protection of fish and other aquatic life.

Fish and other aquatic life requirements concerning suspended solids can be divided into those whose effect occurs in the water column and those whose effect occurs following sedimentation to the bottom of the water body. Noted effects are similar for both fresh and marine waters.

The effects of suspended solids on fish have been reviewed by the European Inland Fisheries Advisory Commission (EIFAC, 1965). This review in 1965 identified four effects on the fish and fish food populations, namely:

(1) by acting directly on the fish swimming in water in which solids are suspended, and either killing them or reducing their growth rate, resistance to disease, etc.;

(2) by preventing the successful development of fish eggs and larvae;

(3) by modifying natural movements and migrations of fish;

(4) by reducing the abundance of food available to the fish;...

Settleable materials which blanket the bottom of water bodies damage the invertebrate populations, block gravel spawning beds, and if organic, remove dissolved oxygen from overlying waters (ElFAC, 1965; Edberg and Hofsten, 1973). In a study downstream from the discharge of a rock quarry where inert suspended solids were increased to 80 mg/L, the density of macroinvertebrates decreased by 60 percent while in areas of sediment accumulation benthic invertebrate populations also decreased by 60 percent regardless of the suspended solid concantrations (Gammon, 1970). Similar effects have been reported downstream from an area which was intensively logged. Major increases in stream suspended solids (25 ppm turbidity upstream versus 390 ppm downstream) caused smothering of bottom invertebrates, reducing organism density to only 7.3 per square foot versus 25.5 per square foot upstraam (Tebo, 1955).

When settleable solids block gravel spawning beds which contain eggs, high mortalities result although there is evidence that some species of salmonids will not spawn in such areas (EIFAC, 1965).

It has been postulated that silt attached to the eggs prevents sufficient exchange of oxygen and carbon dioxide between the egg and the overlying water. The important variables are particle size, stream velocity, and degree of turbulence (EIFAC, 1965).

Deposition of organic materials to the bottom sediments can cause imbalances in stream biota by increasing bottom animal density principally worm populations, and diversity is reduced as pollution-sensitive forms disappear (Mackenthun, 1973). Algae likewise flourish in such nutrient-rich areas although forms may become less desirable (Tarzwell and Gaufin, 1953).

Plankton and inorganic suspended materials reduce light penetration into the water body, reducing the depth of thephotic zone. This reduces primary production and decreases fish food. The NAS commitee in 1974 recommended that the depth of light penetration not be reduced by more than 10 percent (NAS, 1974). Additionally, the near surface waters are heated because of the greater heat absorbency of the particulate material which tends to stabilize the water column and prevents vertical mixing (NAS, 1974). Such mixing reductions decrease the dispersion of dissolved oxygen and nutrients to lower portions of the water body.

One partially offsetting benefit of suspended inorganic material in water is the sorption of organic materials such as pesticides. Following this sorption process subsequent sedimentation may remove these materials from the water column into the sediments (NAS, 1974).

Identifiable effects of suspended solids on irrigation use of water include the formation of crusts on top of the soil which inhibits water infiltration and plant emergence, and impedes soil aeration; the formation of films on plant leaves which blocks sunlight and impedes photosynthesis and which may reduce the

marketability of some leafy crops like lettuce, and finally the adverse effect on irrigation reservoir capacity, delivery canals, and other distribution equipment (NAS, 1974).

The criterion for freshwater fish and other aquatic lifeare essentially that proposed by the National Academy of Sciences and the Great Lakes Water Quality Board.

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

SULFIDE - HYDROGEN SULFIDE

CRITERION:

2 ug/L undissociated H_2S for fish and other aquatic life, fresh and marine water.

INTRODUCTION:

Hydrogen sulfide is a soluble, highly poisonous, gaseous compound having the characteristic odor of rotten eggs. It is detectable in air by humans at a dilution of 0.002 ppm. It will dissolve in water at 4,000 mg/L at 20° C and one atmosphere of pressure. Hydrogen sulfide biologically is an active compound that is found primarily as an anaerobic degradation product of both organic sulfur compounds and inorganic sulfates. Sulfides are constituents of many industrial wastes such as those from tanneries, paper mills, chemical plants, and gas works. The anaerobic decomposition of sewage, sludge beds, algae, and other naturally deposited organic material is a major source of hydrogen sulfide.

When soluble sulfides are added to water they react with hydrogen ions to form HS or H_2S, the proportion of each depending on the pH. The toxicity of sulfides derives primarily from H_2S rather than from the hydrosulfide (HS^-) or sulfide ($S^{=}$) ions. When hydrogen sulfide dissolves in water it dissociates according to the reactions:

$$H_2S \quad HS_- + H_+ \quad \text{and} \quad HS_- \quad S_= + H_+$$

At pH 9 about 99 percent of the sulfide is in the form of HS_-, at pH 7 the sulfide is equally divided between HS_- and H_2S; and at pH 5 about 99 percent of the sulfide is present as H_2S (NAS

1974). The fact that H_2S is oxidized in well-aerated water by natural biological systems to sulfates or is biologically oxidized to elemental sulfur has caused investigators to minimize the toxic effects of H_2S on fish and other aquatic life.

RATIONALE:

The degree of hazard exhibited by sulfide to aquatic animal life is dependent on the temperature, pH, and dissolved oxygen. At lower pH values a greater proportion is in the form of the toxic undissociated H_2S. In winter when the pH is neutral or below or when dissolved oxygen levels are low but not lethal to fish, the hazard from sulfides is exacerbated. Fish exhibit a strong avoidance reaction to sulfide. Based on data from experiments with the stickleback, Jones (1964) hypothesized that if fish encounter a lethal concentration of sulfide there is a reasonable chance they will be repelled by it before they are harmed. This, of course, assumes that an escape route is open.

Many past data on the toxicity of hydrogen sulfide to fish and other aquatic life have been based on extremely short exposure periods. Consequently, these early data have indicated that concentrations between 0.3 and 0.4 mg/L permit fish to survive (Van Horn 1958, Boon and Follis 1967, Theede et al., 1969). Recent long-term data, both in field situations and under controlled laboratory conditions, demonstrate hydrogen sulfide toxicity at lower concentrations.

Colby and Smith (1967) found that concentrations as high as 0.7 mg/L have been found within 20 mm of the bottom of sludge beds, and the levels of 0.1 to 0.02 mg/L were common within the

first 20 mm of water above this layer. Walleye (Stizostedion vitreum) eggs held in trays in this zone did not hatch. Adelman and Smith (1970) reported that the hatchability of northern pike (Esox lucius) eggs was substantially reduced at 25 ug/L H_2S; at 47 ug/L mortality was almost complete. Northern pike fry had 96-hour LC50 values that varied from 17 to 32 ug/L at normal oxygen levels of 6.0 mg/L. The highest concentration of hydrogen sulfide that had no observable effect on eggs and fry was 14 and 4 ug/L, respectively. Smith and Oseid (1972), working on eggs, fry and juveniles of walleyes and white suckers (Catostomus commersoni) and Smith (1971), Safe levels in working on walleyes and fathead minnows, Pimephales promelas, were found to vary from 2.9 ug/L to 12 ug/L with eggs being the least sensitive and juveniles being the most sensitive in short-term tests. In 96-hour bioassays, fathead minnows and goldfish, Carassius auratus, varied greatly in tolerance to hydrogen sulfide with changes in temperature. They were more tolerant at low temperatures (6 to 10_o C). Holland, et al. (1960) reported that 1.0 mg/L sulfide caused 100 percent mortality in 72 hours with Pacific salmon.

On the basis of chronic tests evaluating growth and survival, the safe H_2S level for bluegill (Lepomis macrochirus) juveniles and adults was 2 ug/L. Egg deposition in bluegills was reduced after 46 days in 1.4 ug/L H_2S (Smith and Oseid, 1974). White sucker eggs were hatched at 15 ug/L, but juveniles showed growth reductions at 1 ug/L. Safe level for fathead minnows were between 2 and 3 ug/L. Studies showed that safe levels for Gammarus Pseudolimnaeus and Hexagenia limbata were 2 and 15 ug/L, respectively (Oseid and Smith, 1974a, 1974b). Some species

typical of normally stressed habitats, Asellus spp., were much more resistant (Oseid and Smith, 1974c).

Sulfide criteria for domestic or livestock use have not been established because the unpleasant odor and taste would preclude such use at hazardous concentrations.

It is recognized that the hazard from hydrogen sulfide to aquatic life is often localized and transient. Available data indicate that water containing concentrations of 2.0 ug/L undissociated H_2S would not be hazardous to most fish and other aquatic wildlife, but concentrations in excess of 2.0 ug/L would constitute a long-term hazard.

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

TAINTING SUBSTANCES

CRITERION:

Materials should not be present in concentrations that individually or in combination produce undesirable flavors which are detectable by organoleptic tests performed on the edible portions of aquatic organisms.

RATIONALE:

Fish or shellfish with abnormal flavors, colors, tastes or odors are either not marketable or will result in consumer complaints and possible rejection of the food source even though subsequent lots of organisms may be acceptable. Poor product quality can and has seriously affected or eliminated the commercial fishing industry in some areas. Recreational fishing also can be affected adversely by off-flavored fish. For the majority of sport fishermen, the consumption of their catch is part of their recreation and off-flavored catches can result in diversion of the sportsmen to other water bodies. This can have serious economic impact on the established recreation industries such as tackle and bait sales and boat and cottage rental.

Water Quality Criteria, 1972 (NAS, 1974) lists a number of wastewaters and chemical compounds that have been found to lower the palatability of fish flesh. Implicated wastewaters included those from 2,4-D manufacturing plants, kraft and neutral sulfite pulping processes, municipal wastewater treatment plants, oily wastes, refinery wastes, phenolic wastes, and wastes from slaughterhouses. The list of implicated chemical compounds is long: it includes cresol and phenol compounds, kerosene, naphthol, styrene, toluene, and exhaust outboard motor fuel. As little as 0.1 ug/L o-chlorophenol was reported to cause tainting

of fish flesh.

Shumway and Palensky 1973) determined estimated threshold concentrations for 22 organic compounds. The values ranged from 0.4 ug/L (2,4-dichlorophenol) to 95,000 ug/L (formaldehyde). An additional 12 compounds were tested, 7 of which were not found to impair flavor at or near lethal levels.

Thomas (1973) reviewed the literature review on tainting substances revealed serious problems that have occurred. Detailed studies and methodology used to evaluate the palatability of fishes in the Ohio River as affected by various waste discharges showed that the susceptibility of fishes to the accumulation of tainting substances is variable and dependent upon the species, length of exposure, and the pollutant. As little as 5 ug/L of gasoline can impart off-flavors to fish (Boyle, 1967).

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

TEMPERATURE

CRITERIA:

Freshwater Aquatic Life

For any time of year, there are two upper limiting temperatures for a location (based on the important sensitive species found there at that time):

1. One limit consists of a maximum temperature for short exposures that is time dependent and is given by the species-specific equation:

$$\text{Temperature}_{(C_o)} = (1/b)(\log_{10}[\text{time}_{(\text{min})}] - a) - 2_o\,C$$

where: $\log_{10}$ = logarithm to base 10 (common logarithm)

a = intercept on the "y" or logarithmic axis of the line fitted to experimental data and which is available for some species from Appendix II-C, National Academy of Sciences 1974 document.

b = slope of the line fitted to experimental data and available for some species from Appendix II-C, of the National Academy of Sciences document.

and

2. The second value is a limit on the weekly average temperature that:

a. In the cooler months (mid-October to mid-April in the north and December to February in the south) will protect against mortality of importr to mid-April in the north and December to February in the south) will protect against mortality of important species if the elevated plume temperature is suddenly dropped to the ambient temperature, with the limit being the

acclimation temperature minus 2Pto C when the lower lethal threshold temperature equals the ambient water temperature (in some regions this limitation may also be applicable in summer).

or

b. In the warmer months (April through October in the north and March through November in the south) is determined by adding to the physiological optimum temperature (usually for growth) a factor calculated as one-third of the difference between the ultimate upper incipient lethal temperature and the optimum temperature for the most sensitive important species (and appropriate life state) that normally is found at that location and time.

or

c. During reproductive seasons (generally April through June and September through October in the north and March through May and October through November in the south) the limit is that temperature that meets site-specific requirements for successful migration, spawning, egg incubation, fry rearing, and other reproductive functions of important species. These local requirements should supersede all other requirements when they are applicable.

or

d. There is a site-specific limit that is found necessary to preserve normal species diversity or prevent appearance of nuisance organisms.

Marine Aquatic Life

In order to assure protection of the characteristic indigenous marine community of a water body segment from adverse thermal effects:

a. the maximum acceptable increase in the weekly average temperature resulting from artificial sources is 1^{o} C (1.8 F) during all seasonsofthe year, providing the summer maxima are not exceeded; and

b. daily temperature cycles characteristic of the water body segment should not be altered in either amplitude or frequency.

Summer thermal maxima, which define the upper thermal limits for the communities of the discharge area, should be established on a site-specific basis. Existing studies suggest the following regional limits:

	Short-term Maximum	Maximum True Daily Mean*
Sub tropical regions (south of Cape Canaveral and Tampa Bay, Florida, and Hawaii	32.2° C (90° F)	29.4° C (85° F)
Cape Hatteras, N.C., to Cape Canaveral, Fla.	32.2° C (90° F)	29.4° C (85° F)
Long Island (south shore) to Cape Hatteras, N.C.	30.6° C (87° F)	27.8° C (82° F)

(* True Daily Mean = average of 24 hourly temperature readings.)

Baseline thermal conditions should be measured at a site where there is no unnatural thermal addition from any source, which is in reasonable proximity to the thermal discharge (within 5 miles) and which has similar hydrography to that of the receiving waters at the discharge.

INTRODUCTION:

The uses of water by man in and out of its natural situs in the environment are affected by its temperature. Offstream domestic uses and instream recreation are both partially temperature dependent. Likewise, the life associated with the aquatic environment in any location has its species composition and activity regulated by water temperature. Since essentially all of these organisms are so-called "cold blooded" or poikilotherms, the temperature of the water regulates their metabolism and ability to survive and reproduce effectively. Industrial uses for process water and for coolingare likewise regulated by the water's temperature. Temperature, therefore, is an important physical parameter which to some extent regulates many of the beneficial uses of water. The Federal Water Pollution Control Administration in 1967 called temperature a

catalyst, a depressant, an activator, a restrictor, a stimulator, a controller, a killer, one of the most important and most influential water quality characteristics to life in water."

RATIONALE:

The suitability of water for total body immersion is greatly affected by temperature. In temperate climates, dangers from exposure to low temperatures is more prevalent than exposure to elevated water temperatures. Depending on the amount of activity by the swimmer, comfortable temperatures range from 20° C to 30° C. Short durations of lower and higher temperatures can be tolerated by most individuals. For example, for a 30-minute period, temperatures of 10° C or 35° C can be tolerated without harm by most individuals (NAS, 1974).

Temperature also affects the self-purification phenomenon in water bodies and therefore the aesthetic and sanitary qualities that exist. Increased temperatures accelerate the biodegradation of organic material both in the overlying water and in bottom deposits which makes increased demands on the dissolved oxygen resources of a given system. The typical situation is exacerbated by the fact that oxygen becomes less soluble as water temperature increases. Thus, greater demands are exerted on an increasingly scarce resource which may lead to total oxygen depletion and obnoxious septic conditions. These effects have been described by Phelps (1944), Carp (1963), and Velz (1970).

Indicator enteric bacteria, and presumably enteric pathogens, are likewise affected by temperature. It has been shown that both total and fecal coliform bacteria die away more rapidly in the environment with increasing temperatures (Ballentine and

Kittrell, 1968).

Temperature effects have been shown for water treatment processes. Lower temperatures reduce the effectiveness of coagulation with alum and subsequent rapid sand filtration. In one study, difficulty was especially pronounced below 5° C (Hannah, et al., 1967). Decreased temperature also decreases the effectiveness of chlorination. Based on studies relating chlorine dosage to temperature, and with a 30-minute contact time, dosages required for equivalent disinfective effect increased by as much as a factor of 3 when temperatures were decreased from 20° C to 10° C (Reid and Carlson, 1974). Increased temperature may increase the odor of water because of the increased volatility of odor-causing compounds (Bumson, 1938). Odor problems associated with plankton may also be aggravated.

The effects of temperature on aquatic organisms have been the subject of comprehensive literature reviews (Brett, 1956; Fry, 1967; FWPCA, 1967; Kine, 1970) and annual literature reviews published by the Water Pollution Control Federation (Coutant, 1968, 1969, 1970, 1971; Coutant and Goodyear, 1972; Coutant and Pfuderer, 1973, 1974). Only highlights from the thermal effects on aquatic life are presented here.

Temperature changes in water bodies can alter the existing aquatic community. The dominance of various phytoplankton groups in specific temperature ranges has been shown. For example, from 20° C to 25° C, diatoms predominated; green algae predominated from 30° C; to 35° C and blue-greens predominated above 35° C

(Cairns, 1956). Likewise, changes from a coldwater fishery to a warm-water fishery can occur because temperature may be directly lethal to adults or fry cause a reduction of activity or limit reproduction (Brett, 1960).

Upper and lower limits for temperature have been established for many aquatic organisms. Considerably more data exist for upper as opposed to lower limits. Tabulations of lethal temperatures for fish and other organisms are available (Jones, 1964: FWPCA, 1967 NAS, 1974). Factors such as diet, activity, age, general health, osmotic stress, and even weather contribute to the lethality of temperature. The aquatic species, thermal accumulation state and exposure time are considered the critical factors (Parker and Krenkel, 1969).

The effects of sublethal temperatures on metabolism, respiration, behavior, distribution and migration, feeding rate, growth, and reproduction have been summarized by De Sylva (1969). Another study has illustrated that inside the tolerance zone there is encompassed a more restrictive temperature range in which normal activity and growth occur and yet an even more restrictive zone inside that in which normal reproduction will occur (Brett, 1960).

De Sylva (1969) has summarized available data on the combined effects of increased temperature and toxic materials on fish indicate that toxicity generally increases with increased temperature and that organisms subjected to stress from toxic materials are less tolerant of temperature extremes.

The tolerance of organisms to extremes of temperature is a function of their genetic ability to adapt to thermal changes

within their characteristic temperature range, the acclimation temperature prior to exposure, and the time of exposure to the elevated temperature (Coutant, 1972). The upper incipient lethal temperature or the highest temperature that 50 percent of a sample of organisms can survive is determined on the organism at the highest sustainable acclimation temperature. The lowest temperature that 50 percent of the warm acclimated organisms can survive in is the ultimate lower incipient lethal temperature. True acclimation to changing temperatures requires several days (Brett, 1941). The lower end of the temperature accommodation range for aquatic life is 0^{o} C in fresh water and somewhat less for saline waters. However, organisms acclimated to relatively warm water, when subjected to reduced temperatures that under other conditions of acclimation would not be detrimental, may suffer a significant mortality caused by thermal shock (Coutant, 1972).

Through the natural changes in climatic conditions, the temperatures of water bodies fluctuate daily, as well as seasonally. These changes do not eliminate indigenous aquatic populations, but affect the existing community structure and the geographic distribution of species. Such temperature changes are necessary to induce the reproductive cycles of aquatic organisms and to regulate other life factors (Mount, 1969).

Artificially induced changes such as the return of cooling water or the release of cool hypolimnetic waters from impoundments may alter indigenous aquatic ecosystems (Coutant, 1972). Entrained organisms may be damaged by temperature

increases across cooling water condensers if the increase is sufficiently great or the exposure period sufficiently long. Impingement upon condenser screens, chlorination for slime control, or other physical insults damage aquatic life (Raney, 1969: Patrick, 1969 (b)). However, Patrick (1969(a)) has shown that algae passing through condensers are not injured if the temperature of the outflowing water does not exceed 345° C.

In open waters elevated temperatures may affect periphyton, benthic invertebrates, and fish, in addition to causing shifts in algal dominance. Trembley (1960) studies of the Delaware River downstream from a power plant concluded that the periphyton population was considerably altered by the discharge.

The number and distribution of bottom organisms decrease as water temperatures increase. The upper tolerance limit for a balanced benthic population structure is approximately 32° C. A large number of these invertebrate species are able to tolerate higher temperatures than those required for reproduction (FWPCA, 1967).

In order to define criteria for fresh waters, Coutant (1972) cited the following was cited as currently definable requirements:

1. Maximum sustained temperatures that are consistent with maintaining desirable levels of productivity,

2. maximum levels of metabolic acclimation to warm temperatures that will permit return to ambient winter temperatures should artificial sources of heat cease,

3. Time-dependent temperature limitations for survival of brief exposures to temperature extremes, both upper and lower,

4. Restricted temperature ranges for various states of reproduction, including (for fish) gametogenesis, spawning migration, release of gametes, development of the embryo, commencement of independent feeding (and other activities) by juveniles, and temperatures required for metamorphosis, emergence, or other activities of lower forms,

5. Thermal limits for diverse species compositions of aquatic communities, particularly where reduction in diversity creates nuisance growths of certain organisms, or where important food sources (food chains) are altered,

6. Thermal requirements of downstream aquatic life (in rivers) where upstream diminution of a coldwater resource will adversely affect downstream temperature requirements.

The major portion of such information that is available, however, is for freshwater fish species rather than lower forms of marine aquatic life.

The temperature-time duration for short-term exposures such that 50 percent of a given population will survive an extreme temperature frequently is expressed mathematically by fitting experimental data with a staright line on a semi-logarithmic plot with time on the logarithmic scale and temperature on the linear scale (see fig. 1). In equation form this 50 percent mortality relationship is:

$$\log^{10} (\text{time}^{(\text{minutes})}) = a + b\,(\text{Temperature } (^{\circ}\text{C}))$$

where: $\log^{10}$ = logarithm to base 10 (common logarithm)

a = intercept on the "y" or logarithmic axis of the line fitted to experimental data and which is available for some species from Appendix II-C, of the National Academy of Sciences document.

b = slope of the line fitted to experimental data and which is available for some species from Appendix II-C, of the National Academy of Sciences document.

To provide a safety factor so that none or only a few organisms will perish, it has been found experimentally that a

criterion of 2° C below maximum temperature is usually sufficient (Black, 1953). To provide safety for all the organisms, the temperature causing a median mortality for 50 percent of the population would be calculated and reduced by 2° C in the case of an elevated temperature. Available scientific information includes upper and lower incipient lethal temperatures, coefficients "a" and "b" for the thermal resistance equation, and information of size, life stage, and geographic source of the particular test species (Appendix II-C, NAS, 1974).

Maximum temperatures for an extensive exposure (e.g., more than 1 week) must be divided into those for warmer periods and winter. Other than for reproduction, the most temperature-sensitive life function appears to be growth (Coutant, 1972). Coutant (1972) has suggested that a satisfactory estimate of a limiting maximum weekly mean temperature may be an average of the optimum temperature for growth and the temperature for zero net growth.

Because of the difficulty in determining the temperature of zero net growth, essentially the same temperature can be derived by adding to the optimum essentially to temperature (for growth or other physiological functions) a factor calculated as one-third of the difference between the ultimate upper incipient lethal temperature and the optimum temperature (NAS, 1974). In equation form:

Maximum weekly average = temperature	optimum + 1/3	(ultimate upper optimum) (incipient lethal - temperature) (temperature)

Since temperature tolerance varies with various states of development of a particular species, the criterion for a

particular location would be calculated for the most important life form likely to be present during a particular month. One caveat in using the maximum weekly mean temperature is that the limit for short-term exposure must not be exceeded. Example calculations for predicting the summer maximum temperatures for short-term survival and for extensive exposure for various fish species are presented in Table 11. These calculations use the above equations and data from EPA's Environmental Research Laboratory in Duluth.

The winter maximum temperature must not exceed the ambient water temperature by more than the amount of change a specimen acclimated to the plume temperature can tolerate. Such a change could occur by a cessation of the source of heat or by the specimen being driven from an area by addition of biocides or other factors. However, there are inadequate data to estimate a safety factor for the "no stress" level from cold shocks (NAS, 1974). Figure 2 was developed from available data in the literature (ERL-Duluth, 1976) and can be used for estimating allowable winter temperature increases.

Coutant (1972) has reviewed the effects of temperature on aquatic life reproduction and development. Reproductive events are noted as perhaps the most thermally restricted of all life phases assuming other factors are at or near optimum levels. Natural short-term temperature fluctuations appear to cause reduced reproduction of fish and invertebrates.

TABLE 11.-Example Calculated Values for Maximum Weekly Average Temperatures for Growth and Short-Term Maxima for Survival for Juveniles and Adults During the Summer (Centigrade and Fahrenheit).

Species	Growth[a]		Maxima[b]	
Atlantic salmon	20	(68)	23	(73)
Bigmouth buffalo				
Black crappie	27	(81)		
Bluegill	32	(90)	35	(95)
Brook trout	19	(66)	24	(75)
Carp				
Channel catfish	32	(90)	35	(95)
Coho salmon	18	(64)	24	(75)
Emerald shiner	30	(86)		
Freshwater drum				
Lake herring (Cisco)	17	(63)	25	(77)
Largemouth bass	32	(90)	34	(93)
Northern pike	28	(82)	30	(86)
Rainbow trout	19	(66)	24	(75)
Sauger	25	(77)		
Smallmouth bass	29	(84)		
Smallmouth buffalo				
Sockeye salmon	18	(64)	22	(72)
Striped bass				
Threadfin shad				
White bass				
White crappie	28	(82)		
White sucker	28	(82)		
Yellow perch	29	(84)		

a - Calculated according to the equation (using optimum temperature for growth)

maximum weekly average temperature for growth = optimum temperature + 1/3 (ultimate incipient lethal temperature-optimum temperature.

b - Based on temperature (^{o}C) = $1/b\ (\log^{10} time_{(min.)} - a)$ 2^{o} C, acclimation at the maximum weekly average temperature for summer growth, and data in Appendix II-C of Water Quality Criteria, published by National Academy of Sciences.

c - Based on data for larvae (ERL-Duluth, 1976).

There are indadequate data available quantitating the most temperature-sensitive life stages among various aquatic species. Uniform elevation of temperature a few degrees but still within the spawning range may lead to advanced spawning for spring spawning species and delays for fall spawners. Such changes may not be detrimental unless asynchrony occurs between newly hatched juveniles and their normal food source. Such asynchrony may be most pronounced among anadromous species or other migrants who pass from the warmed area to a normally chilled, unproductive area. Reported temperature data on maximum temperatures for spawning and embryo survival have been summarized in Table 12 (from ERL-Duluth 1976).

Although the limiting effects of thermal addition to estuarine and marine waters are not as conspicuous in the fall, winter, and spring as during the summer season of maximum heat stress, nonetheless crucial thermal limitations do exist. Hence, it is important that the thermal additions to the receiving waters be minimized during all seasons of the year. Size of harvestable stocks of commercial fish and shellfish, particularly near geographic limits of the fishery, appear to be markedly influenced by slight changes in the long-term temperature regime (Dow, 1973).

Jefferies and Johnson (1974) studied the relationship between temperature and annual variation in 7-year catch data for winter flounder, Pseudopleuronectes americanus, in Narragansett Bay, Rhode Island, revealed that a 78 percent decrease in annual catch correlated closely with a 0.5°C increase in the average

temperature over the 30-month period between spawning and recruitment into the fishery. Sissenwine's 1974 model predicts a 68 percent reduction of recruitment in yellowtail flounder, Limanda ferruginea, with a 1°C long-term elevation in southern New England waters.

TABLE 12.

Summary of Reported Values for Maximum Weekly Average Temperature for Spawning and Short-Term Maxima for Embryo Survival During the Spawning Season (Centigrade and Fahrenheit)

Species	Spawning[a]		Embryo Survival[b]	
Atlantic Salmon	5	(41)	7	(45)
Bigmouth Buffalo	17	(63)	27	(81)c
Black Crappie				
Bluegill	25	(77)	34	(93)
Brook Trout	9	(48)	13	(55)
Carp	21	(70)	33	(91)
Channel Catfish	27	(81)	29	(84)
Coho Salmon	10	(50)	13	(55)
Emerald Shiner	24	(75)	28	(82)c
Freshwater Drum	21	(70)	26	(79)
Lake Herring (Cisco)	3	(37)	8	(46)
Largemouth Bass	21	(70)	27	(81)
Northern Pike	11	(52)	19	(66)
Rainbow Trout	9	(48)	13	(55)
Sauger	10	(50)	21	(70)
Smallmouth Bass	17	(63)		
Smallmouth Buffalo	17	(63)	21	(70)
Sockeye Salmon	10	(50)	13	(55)
Striped Bass	18	(64)	24	(75)
Threadfin Shad	18	(64)	34	(93)
White Bass	17	(63)	26	(79)
White Crappie	18	(64)	23	(73)
White Sucker	10	(50)	20	(68)
Yellow Perch	12	(54)	20	(68)

a - the optimum or mean of the range of spawning temperatures reported for the species (ERL-Duluth, 1976).

b - the upper temperature for successful incubation and hatching reported for the species (ERL-Duluth, 1976).

c - upper temperature for spawning.

Community balance can be influenced strongly by such temperature-dependent factors as rates of reproduction, recruitment, and growth of each component population. A few degrees elevation in average monthly temperature can appreciably alter a community through changes in interspecies relationships. A 50 percent reduction in the softshell clam fishery in Maine by the green crab, Carcinus maenus, illustrates how an increase in winter temperatures can establish new predator-prey relationships. Over a period of 4 years, there was a natural amelioration of temperature and the monthly mean for the coldest month of each year did not fall below 2°C. This apparently precluded appreciable ice formation and winter cold kill of the green crab and permitted a major expansion of its population, with increased predation of the softshell clam resulting (Glude, 1954; Welch, 1968).

Temperature is a primary factor controlling reproduction and can influence many events of the reproductive cycle from gametogenesis to spawning. Among marine invertebrates, initiation of reproduction (gametogenesis) is often triggered during late winter by attainment of a minimum environmental threshold temperature. In some species, availability of adequate food is also a requisite (Pearse, 1970; Sastry, 1975: deVlaming, 1971). Elevated temperature can limit gametogenesis by preventing accumulation of nutrients in the gonads. This problem could be acute during the winter if food availability and feeding activity is reduced. Most marine organisms spawn during the spring and summer; gametogenesis is usually initiated during the

previous fall. It should also be noted that some species spawn only during the fall (herrinhg),while others during the winter and very early spring. At the higher latitudes, winter breeders include such estuarine community dominants as acorn barnacles, Balanus balanus and B. balanoides, the edible blue mussel Mytilus edulis, sea urchin, Strongylocentrotus drobachiensis, sculpin, and the winter flounder, Pseudopleuronectes americanus. The two boreal barnacles require temperatures below 10°C before egg production will be initiated (Crisp, 1957). It is clear that adaptations for reproduction exist which are dependent on temperature conditions close to the natural cycle.

Juvenile and adult fish usually thermoregulate behaviorally by moving to water having temperatures closest to their thermal preference. This provides a thermal environment which approximates the optimal temperature for many physiological functions, including growth (Neill and Magnuson. 1974). As a consequence, fishes usually are attracted to heated water during the fall, winter, and spring. Avoidance will occur as warmer temperature exceeds the preferendum by 1 to 3°C (Coutant, 1975). This response precludes problems of heat stress for juvenile and adult fishes during the summer, but several potential problems exist during the other seasons. The possibility of cold shock and death of plume-entrained fish resulting from winter plant shutdown is well recognized. Also, increased incidence of disease and a deterioration of physiological condition has been observed among plume-entrained fishes, perhaps because of insufficient food (Massengill, 1973). A weight loss of approximately 10 percent for each 1° C rise in water temperature

has been observed in fish when food is absent. (Phillips et al., 1960) There may also be indirect adverse effects on the indigenous community because of increased predation pressure if thermal addition leads to a concentration of fish which are dependent on this community for their food.

Fish migration is often linked to natural environmental temperature cycles. In early spring, fish employ temperature as their environmental cue to migrate northward (e.g., menhaden, bluefish) or to move inshore (winter flounder). Likewise, water temperature strongly influences timing of spawning runs ofanadromous fish into rivers (Leggett and Whitney, 1972). In the autumn, a number of juvenile marine fishes and shrimp are dependent on a drop in temperature to trigger their migration from estuarine nursery grounds for oceanic dispersal or southward migration (Lund and Maltezos, 1970; Talbot, 1966).

Thermal discharges should not alter diurnal and tidal temperature variations normally experienced by marine communities. Laboratory studies show thermal tolerance to be enhanced when animals are maintained under a diurnally fluctuating temperature regime rather than at a constant temperature (Costlow and Bookhout, 1971; Furch, 1972; Hoss, et al.,). A daily cyclic regime can be protective additionally as it reduces duration of exposure to extreme temperatures (Pearce, 1969; Gonzalez, 1972).

Summer thermal maxima should be established to protect the various marine communities within each biogeographic region. During the summer, naturally elevated temperatures may be of

sufficent magnitude to cause death or emigration (Glynn, 1968; Vaughn, 1961). This more commonly occurs in tropical and warm temperate zone waters, but has been reported for enclosed bays and shallow waters in other regions as well (Nichols, 1918). Summer heat stress also can contribute to increased incidence of disease or parasitism (Sinderman, 1965); reduce or block sexual maturation (Thorhaug, et al., 1971: deVlaming, 1972); inhibit or block embryonic cleavage of larval development (Calabrese, 1969); reduce feeding and growth of juveniles and adults (Olla and Studholme, 1971); result in increased predation (Gonzalez, 1972); and reduce productivity of macroalgae and seagrasses (South and Hill, 1970; Zieman, 1970). The general ceilings set forth here are derived from studies delineating limiting temperatures for the more thermally sensitive species or communities of a biogeographic region.

Thermal effects data are presently insufficient to set general temperature limits for all coastal biogeographic regions. The data enumerated in the Appendix, plus any additional data subsequently generated, should be used to develop thermal limits which specifically consider communities relevant to given water bodies.

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

CRITERIA:

Aquatic Life

Not enough data are available concerning the effects of 2,3,7,8-TCDD on aquatic life and its uses to allow derivation of national criteria. The available information indicates that acute values for some freshwater animal species are >1.0 ug/L; some chronic values are <0.01 ug/L; and the chronic value for rainbow trout is <0.001 ug/L. Because exposures of some species of fishes to 0.01 ug/L for <6 days resulted in substantial mortality several weeks later, derivation of aquatic life criteria for 2,3,7,8-TCDD may require special consideration. Predicted bioconcentration factors (BCFs) for 2,3,7,8-TCDD range from 3,000 to 900,000, but the available measured BCFs range from 390 to 13,000. If the BCF is 5,000, concentrations >0.00001 ug/L should result in concentrations in edible freshwater and saltwater fish and shellfish that exceed levels identified in a U.S. FDA health advisory. If the BCF is >5,000 or if uptake in a field situation is greater than that in laboratory tests, the value of 0.00001 ug/L will be too high.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of 2,3,7,8-TCDD exposure through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero. This criterion is

based on the nonthreshold assumption for 2,3,7,8-TCDD. However, zero may not be an attainable level at this time. Therefore, the levels that may result in an increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 1.3×10^{-7}, 1.3×10^{-8} and 1.3×10^{-9} ug/L, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 1.4×10^{-7}, 1.4×10^{-8} and 1.4×10^{-9} ug/L, respectively. If these estimates are made for comsumption of water only, the levels are 2.2×10^{-6}, 2.2×10^{-7} and 2.2×10^{-8} ug/L, respectively.

(49 F.R. 5831, February 15, 1984)
SEE APPENDIX B FOR METHODOLOGY

TETRACHLOROETHYLENE

CRITERIA:

Aquatic Life

The available data for tetrachloroethylene indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 5,280 and 840 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

The available data for tetrachloroethylene indicate that acute and chronic toxicity to saltwater aquatic life occurs at concentrations as low as 10,200 and 450 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to tetrachloroethylene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 8.0 ug/L, 0.80 ug/L, and 0.08 ug/L, respectively. If these estimates are made for

consumption of aquatic organisms only, excluding consumption of water, the levels are 88.5 ug/L, 8.85 ug/L, and 0.88 ug/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

THALLIUM

CRITERIA:

Aquatic Life

The available data for thallium indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 1,400 and 40 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested. Toxicity to one species of fish occurs at concentrations as low as 20 ug/L after 2,600 hours of exposure.

The available data for thallium indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 2,130 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of thallium to sensitive saltwater aquatic life.

Human Health

For the protection of human health from the toxic properties of thallium ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 13 ug/L.

For the protection of human health from the toxic properties of thallium ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 48 ug/L.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

TOLUENE

CRITERIA:

Aquatic Life

The available data for toluene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 17,500 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of toluene to sensitive freshwater aquatic life.

The available data for toluene indicate that acute and chronic toxicity to saltwater aquatic life occurs at concentrations as low as 6,300 and 5,000 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

For the protection of human health from the toxic properties of toluene ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 14.3 mg/L.

For the protection of human health from the toxic properties of toluene ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 424 mg/L.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

NOTE: The U.S. EPA is currently developing Acceptable Daily Intake (ADI) or Verified Reference Dose (RfD) values for Agency-wide use for this chemical. The new value should be substituted when it becomes available. The January, 1986, draft Verified Reference Dose document cites an RfD of 0.3 mg/kg/day for toluene.

TOXAPHENE

CRITERIA:

Aquatic Life

For toxaphene the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.013 ug/L as a 24-hour average, and the concentration should not exceed 1.6 ug/L at any time.

For saltwater aquatic life the concentration of toxaphene should not exceed 0.070 ug/L at any time. No data are available concerning the chronic toxicity of toxaphene to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to toxaphene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero, based on the non threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 7.1 ng/L, 0.71 ng/L, and 0.07 ng/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 7.3 ng/L, 0.73 ng/L, and 0.07 ng/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

TRICHLOROETHYLENE

CRITERIA:

Aquatic Life

The available data for trichloroethylene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 45,000 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of trichloroethylene to sensitive freshwater aquatic life but the behavior of one species is adversely affected at concentrations as low as 21,900 ug/L.

The available data for trichloroethylene indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 2,000 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of trichloroethylene to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to trichloroethylene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 27 ug/L, 2.7 ug/L, and 0.27 ug/L, respectively. If these estimates are made for

consumption of aquatic organisms only, excluding consumption of water, the levels are 807 ug/L, 80.7 ug/L, and 8.07 ug/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

VINYL CHLORIDE

CRITERIA:

Aquatic Life

No freshwater organisms have been tested with vinyl chloride and no statement can be made concerning acute or chronic toxicity.

No saltwater organisms have been tested with vinyl chloride and no statement can be made concerning acute or chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to vinyl chloride through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 20 ug/L, 2.0 ug/L, and 0.2 ug/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 5,246 ug/L, 525 ug/L, and 52.5 ug/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

ZINC

CRITERIA:

Aquatic Life

For total recoverable zinc the criterion to protect freshwater aquatic life as derived using the Guidelines is 47 ug/L as a 24-hour average and the concentration (in ug/L) should not exceed the numerical value given by $e^{(0.83[\ln(\text{hardness})]+1.95)}$ at any time. For example, at hardnesses of 50, 100, and 200 mg/L as $CaCO_3$ the concentration of total recoverable zinc should not exceed 180, 320, and 570 ug/L at any time.

For total recoverable zinc the criterion to protect saltwater aquatic life as derived using the Guidelines is 58 ug/L as a 24-hour average and the concentration should not exceed 170 ug/L at any time.

Human Health

Sufficient data are not available for zinc to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, to control undesirable taste and odor quality of ambient water the estimated level is 5 mg/L. It should be recognized that organoleptic data have limitations as a basis for establishing a water quality criteria, and have no demonstrated relationship to potential adverse human health effects.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

APPENDIX A

DERIVATION OF THE 1985 CRITERION

Derivation of numerical national water quality criteria for the protection of aquatic organisms and their uses is a complex process that uses information from many areas of aquatic toxicology. After a decision is made that a national criterion is needed for a particular material, all available information concerning toxicity to, and bioaccumulation by, aquatic organisms is collected, reviewed for acceptability, and sorted. If enough acceptable data on acute toxicity to aquatic animals are available, they are used to estimate the highest 1-hour average concentration that should not result in unacceptable effects on aquatic organisms and their uses. If justified, this concentration is made a function of a water quality characteristic such as pH, salinity, or hardness. Similarly, data on the chronic toxicity of the material to aquatic animals are used to estimate the highest 4-day average concentration that should not cause unacceptable toxicity during a long-term exposure. If appropriate, this concentration is also related to a water quality characteristic.

Data on toxicity to aquatic plants are examined to determine whether plants are likely to be unacceptably affected by concentrations that should not cause unacceptable effects on animals. Data on bioaccumulation by aquatic organisms are used to determine if residues might subject edible species to restrictions by the U.S. Food and Drug Administration or if such residues might harm some wildlife consumers of aquatic life. All other available data are examined for adverse effects that might

be biologically important.

If a thorough review of the pertinent information indicates that enough acceptable data are available, numerical national water quality criteria are derived for fresh water or saltwater or both to protect aquatic organisms and their uses from unacceptable effects due to exposures to high concentrations for short periods of time, lower concentrations for longer periods of time, and combinations of the two.

I. Collection of Data

A. Collect all available data on the material concerning (a) toxicity to, and bioaccumulation by, aquatic animals and plants, (b) FDA action levels [12], and (c) chronic feeding studies and long-term field studies with wildlife species that regularly consume aquatic organisms.

B. All data that are used should be available in typed, dated, and signed hard copy (publication, manuscript, letter, memorandum, etc.) with enough supporting information to indicate that acceptable test procedures were used and that the results are probably reliable. In some cases it may be appropriate to obtain additional written information from the investigator, if possible. Information that is confidential or privileged or otherwise not available for distribution should not be used.

C. Questionable data, whether published or

unpublished, should not be used. For example, data should usually be rejected if they are from tests that did not contain a control treatment, tests in which too many organisms in the control treatment died or showed signs of stress or disease, and tests in which distilled or deionized water was used as the dilution water without addition of appropriate salts.

D. Data on technical grade materials may be used if appropriate, but data on formulated mixtures and emulsifiable concentrates of the material of concern should not be used.

E. For some highly volatile, hydrolyzable, or degradable materials it is probably appropriate to use only results of flow-through tests in which the concentrations of test material in the test solutions were measured often enough using acceptable analytical methods.

F. Data should be rejected if they were obtained using:

1. Brine shrimp, because they usually occur naturally only in water with salinity greater than 35 g/kg.
2. Species that do not have reproducing wild populations in North America (See Appendix 1).
3. Organisms that were previously exposed to substantial concentrations of the test material or other contaminants.

G. Questionable data, data on formulated mixtures and emulsifiable concentrates, and data obtained with nonresident species or previously exposed organisms may be used to provide auxiliary information but should not be used in the derivation of criteria.

II. Required Data

A. Certain data should be available to help ensure that each of the four major kinds of possible adverse effects receives adequate consideration. Results of acute and chronic toxicity tests with representative species of aquatic animals are necessary so that data available for tested species can be considered a useful indication of the sensitivities of appropriate untested species. Fewer data concerning toxicity to aquatic plants are required because procedures for conducting tests with plants and interpreting the results of such tests are not as well developed. Data concerning bioaccumulation by aquatic organisms are required only if relevant data are available concerning the significance of residues in aquatic organisms.

B. To derive a criterion for freshwater aquatic organisms and their uses, the following should be available:

1. Results of acceptable acute tests (see Section

IV) with at least one species of freshwater animal in at least eight different families such that all of the following are included:

a. the family Salmonidae in the class Osteichthyes

b. a second family in the class Osteichthyes, preferably a commercially or recreationally important warmwater species (e.g., bluegill, channel catfish, etc.)

c. a third family in the phylum Chordata (may be in the class Osteichthyes or may be an amphibian, etc.)

d. a planktonic crustacean (e.g., cladoceran, copepod, etc.)

e. a benthic crustacean (e.g., ostracod, isopod, amphipod, crayfish, etc.)

f. an insect (e.g., mayfly, dragonfly, damselfly, stonefly, caddisfly, mosquito, midge, etc.)

g. a family in a phylum other than Arthropoda or Chordata (e.g., Rotifera, Annelida, Mollusca, etc.)

h. a family in any order of insect or any phylum not already represented.

2. Acute-chronic ratios (see Section VI) with species of aquatic animals in at least three different families provided that of the three species:

a. at least one is a fish

b. at least one is an invertebrate

c. at least one is an acutely sensitive freshwater species (the other two may be saltwater species).

3. Results of at least one acceptable test with a freshwater alga or vascular plant (see Section VIII). If plants are among the aquatic organisms that are most sensitive to the material, results of a test with a plant in another phylum (division) should also be available.

4. At least one acceptable bioconcentration factor determined with an appropriate freshwater species, if a maximum permissible tissue concentration is available (see Section IX).

C. To derive a criterion for saltwater aquatic organisms and their uses, the following should be available:

1. Results of acceptable acute tests (see Section IV) with at least one species of saltwater animal in at least eight different families such that all of the following are included:

a. two families in the phylum Chordata

b. a family in a phylum other than Arthropoda or Chordata

c. either the Mysidae or Penaeidae family

d. three other families not in the phylum Chordata (may include Mysidae or Penaeidae, whichever was not used above)

e. any other family.

2. Acute-chronic ratios (see section VI) with species of aquatic animals in at least three different families provided that of the three species:

a. at least one is a fish

b. at least one is an invertebrate

c. at least one is an acutely sensitive saltwater species (the other one may be a freshwater species).

3. Results of at least one acceptable test with a saltwater alga or vascular plant (see Section VIII. If plants are among the aquatic organisms most sensitive to the material, results of a test with a plant in another phylum (division) should also be available.

4. At least one acceptable bioconcentration factor determined with an appropriate saltwater species, if a maximum permissible tissue concentration is available (see Section IX).

D. If all the required data are available, a numerical criterion can usually be derived, except in special cases. For example, derivation of a criterion

might not be possible if the available acute-chronic ratios vary by more than a factor of 10 with no apparent pattern. Also, if a criterion is to be related to a water quality characteristic T (see Sections V and VII), more data will be necessary.

Similarly, if all required data are not available, a numerical criterion should not be derived except in special cases. For example, even if not enough acute and chronic data are available, it might be possible to derive a criterion if the available data clearly indicate that the Final Residue Value should be much lower than either the Final Chronic Value or the Final Plant Value.

E. Confidence in a criterion usually increases as the amount of available pertinent data increases. Thus, additional data are usually desirable.

III. Final Acute Value

A. Appropriate measures of the acute (short-term) toxicity of the material to a variety of species of aquatic animals are used to calculate the Final Acute Value. The Final Acute Value is an estimate of the concentration of the material corresponding to a cumulative probability of 0.05 in the acute toxicity values for the genera with which acceptable acute tests have been conducted on the material. However, in some cases, if the Species

Mean Acute Value of a commercially or recreationally important species is lower than the calculated Final Acute Value, then that Species Mean Acute Value replaces the calculated Final Acute Value in order to provide protection for that important species.

B. Acute toxicity tests should have been conducted using acceptable procedures [13].

C. Except for tests with saltwater annelids and mysids, results of acute tests during which the test organisms were fed should not be used, unless data indicate that the food did not affect the toxicity of the test material.

D. Results of acute tests conducted in unusual dilution water, e.g., dilution water in which total organic carbon or particulate matter exceeded 5 mg/L, should not be used, unless a relationship is developed between acute toxicity and organic carbon or particulate matter or unless data show that organic carbon, particulate matter, etc., do not affect toxicity.

E. Acute values should be based on endpoints which reflect the total severe acute adverse impact of the test material on the organisms used in the test. Therefore, only the following kinds of data on acute toxicity to aquatic animals should be used:

1. Tests with daphnids and other cladocerans should be started with organisms less than 24 hours old and tests with midges should be stressed with second- or third-instar larvae. The result should be the 48-hr EC50 based on percentage of organisms immobilized plus percentage of organisms killed. If such an EC50 is not available from a test, the 48-hr LC50 should be used in place of the desired 48-hr EC50. An EC50 or LC50 of longer than 48 hours can be used as long as the animals were not fed and the control animals were acceptable at the end of the test.
2. The result of a test with embryos and larvae of barnacles, bivalve molluscs (clams, mussels, oysters, and scallops), sea urchins, lobsters, crabs, shrimp, and abalones should be the 96-hr EC50 based on the percentage of organisms with incompletely developed shells plus the percentage of organisms killed. If such an EC50 is not available from a test, the lower of the 96-hr EC50 based on the percentage of organisms with incompletely developed shells and the 96-hr LC50 should be used in place of the desired 96-hr EC50. If the duration of the test was between 48 and 96 hours, the EC50 or LC50 at the end of the test should be used.

3. The acute values from tests with all other freshwater and saltwater animal species and older life stages of barnacles, bivalve molluscs, sea urchins, lobsters, crabs, shrimps, and abalones should be the 96-hr EC50 based on the percentage of organisms exhibiting loss of equilibrium plus the percentage of organisms immobilized plus the percentage of organisms killed. If such an EC50 is not available from a test, the 96-hr LC50 should be used in place of the desired 96-hr EC50.

4. Tests with single-celled organisms are not considered acute tests, even if the duration was 96 hours or less.

5. If the tests were conducted properly, acute values reported as "greater than" values and those which are above the solubility of the test material should be used, because rejection of such acute values would unnecessarily lower the Final Acute Value by eliminating acute values for resistant species.

F. If the acute toxicity of the material to aquatic animals apparently has been shown to be related to a water quality characteristic such as hardness or particulate matter for freshwater animals or

salinity or particulate matter for saltwater animals, a Final Acute Equation should be derived based on that water quality characteristic. Go to Section V.

G. If the available data indicate that one or more life stages are at least a factor of 2 more resistant than one or more other life stages of the same species, the data for the more resistant life stages should not be used in the calculation of the Species Mean Acute Value (SMAV) because a species can only be considered protected from acute toxicity if all life stages are protected.

H. The agreement of the data within and between species should be considered. Acute values that appear to be questionable in comparison with other acute and chronic data for the same species and for other species in the same genus probably should not be used in calculation of a Species Mean Acute Value. For example, if the acute values available for a species or genus differ by more than a factor of 10, some or all of the values probably should not be used in calculations.

I. For each species for which at least one acute value is available, the Species Mean Acute Value should be calculated as the geometric mean of the results of all flow-through tests in which the concentrations of test material were measured. For a species for which no such result is available,

the Species Mean Acute Value should be calculated as the geometric mean of all available acute values, i.e., results of flow-through tests in which the concentrations were not measured and results of static and renewal tests based on initial concentrations of test material (nominal concentrations are acceptable for most test materials if measured concentrations are not available).

NOTE: Data reported by original investigators should not be rounded off. Results of all intermediate calculations should be rounded [14] to four significant digits.

NOTE: The geometric mean of N numbers is the N^{th} root of the product of the N numbers. Alternatively, the geometric mean can be calculated by adding the logarithms of the N numbers, dividing the sum by N, and taking the antilog of the quotient. The geometric mean of two numbers is the square root of the product of the two numbers, and the geometric mean of one number is that number. Either natural (base 0) or common (base 10) logarithms can be used to calculate geometric means as long as they are used consistently within each set of data, i.e., the antilog used must match the logarithm used.

NOTE: Geometric means, rather than arithmetic means, are used here because the distributions of sensitivities of individual organisms in toxicity tests on most materials and the distributions of sensitivities of species within a genus are more likely to be lognormal than normal. Similarly, geometric means are used for acute-chronic ratios and bioconcentration factors because quotients are likely to be closer to lognormal than normal distributions. In addition, division of the geometric mean of a set of numerators by the geometric mean of the set of corresponding denominators will result in the geometric mean of the set of corresponding quotients.

J. For each genus for which one or more Species Mean Acute Values are available, the Genus Mean Acute Value should be calculated as the geometric mean of the Species Mean Acute Values available for the genus.

K. Order the Genus Mean Acute Value from high to low.

L. Assign ranks, R, to the Genus Mean Acute Value from "1" for the lowest to "N" for the highest. If two or more Genus Mean Acute Values are identical, arbitrarily assign them successive ranks.

M. Calculate the cumulative probability, P, for each Genus Mean Acute Value as R/(N+1).

N. Select the four Genus Mean Acute Value which have cumulative probabilities closest to 0.05 (if there are less than 59 Genus Mean Acute Value, these will always be the four lowest Genus Mean Acute Values).

O. Using the selected Genus Mean Acute Values and Ps, calculate:

$$S_2 = \frac{E(\ln GMAV)_2 - ((E\ln GMAV))_2/4)}{(P) - ((E\ /\hat{}p))_2/4)}$$

$$L = (E(\ln GMAV) - S(E(/\hat{}p)))/4$$

$$A = S(/\hat{}0.05) + L$$

$$FAV = e^A$$

(See [11] for development of the calculation procedure and Appendix 2 for example calculation and computer program.)

NOTE: Natural logarithms (logarithms to base e, denoted as ln) are used herein merely because they are easier to use on some hand calculators and computers than common (base 10) logarithms. Consistent use of either will produce the same result.

P. If for a commercially or recreationally important species the geometric mean of the acute values from flow-through tests in which the concentrations of test material were measured is lower than the calculated Final Acute Value, then that geometric mean should be used as the Final Acute Value instead of the calculated Final Acute

Value.

Q. Go to Section VI.

IV. Final Acute Equation

A. When enough data are available to show that acute toxicity to two or more species is similarly related to a water quality characteristic, the relationship should be taken into account as described in Sections B-G below or using analysis of covariance [15,16]. The two methods are equivalent and produce identical results. The manual method described below provides an understanding of this application of covariance analysis, but computerized versions of covariance analysis are much more convenient for analyzing large data tests. If two or more factors affect toxicity, multiple regression analysis should be used.

B. For each species for which comparable acute toxicity values are available at two or more different values of the water quality characteristic, perform a least squares regression of the acute toxicity values on the corresponding values of the water quality characteristic to obtain the slope and its 95 percent confidence limits for each species.

NOTE: Because the best documented relationship fitting these data is that between hardness and acute toxicity of metals in fresh water and a log-log

relationship, geometric means and natural logarithms of both toxicity and water quality are used in the rest of this section. For relationships based on other water quality characteristics such as pH, temperature, or salinity, no transformation or a different transformation might fit the data better, and appropriate changes will be necessary throughout this section.

C. Decide whether the data for eachspecies are useful, taking into account the range and number of the tested values of the water quality characteristic and the degree of agreement within and between species. For example, a slope based on six data points might be of limited value if it is based only on data for a very narrow range of values of the water quality characteristic. A slope based on only two data points, however, might be useful if it is consistent with other information and if the two points cover a broad enough range of the water quality characteristic. In addition, acute values that appear to be questionable in comparison with other acute and chronic data available for the same species and for other species in the same genus probably should not be used. For example, if after adjustment for the water quality characteristic, the acute values available for a species or genus

differ by more than a factor of 10, probably some or all of the values should be rejected. If useful slopes are not available for at least one fish and one invertebrate or if the available slopes are too dissimilar or if too few data are available to adequately define the relationship between acute toxicity and the water quality characteristic, return to Section IV.G, using the results of tests conducted under conditions and in waters similar to those commonly used for toxicity tests with the species.

D. Individually for each species calculate the geometric mean of the available acute values and then divide each of the acute values for species by the mean for the species. This normalizes the values so that the geometric mean of the normalized values for each species individually and for any combination of species is 1.0.

E. Similarly normalize the values of the water quality characteristic for each species individually.

F. Individually for each species perform a least squares regression of the normalized acute toxicity values on the corresponding normalized values of the water quality characteristic. The resulting slopes and 95 percent confidence limits will be identical to those obtained in Section B.

Now, however, if the data are actually plotted, the line of best fit for each individual species will go through the point 1,1 in the center of the graph.

G. Treat all the normalized data as if they were all for the same species and perform a least squares regression of all the normalized acute values on the corresponding normalized values of the water quality characteristic to obtain the pooled acute slope, V, and its 95 percent confidence limits. If all the normalized data are actually plotted, the line of best fit will go through the point 1,1 in the center of the graph.

H. For each species calculate the geometric mean, W, of the acute toxicity values and the geometric mean, X, of the values of the water quality characteristic. (These were calculated in steps D and E.)

I. For each species calculate the logarithm, Y, of the Species Mean Acute Value at a selected value, Z, of the water quality characteristic using the equation:

$$Y = \ln W - V(\ln X - \ln Z).$$

J. For each species calculate the SMAV at Z using the equation: $SMAV = e^{Y}$.

NOTE: Alternatively, the Species Mean Acute Values at Z can be obtained by skipping step H using the

equations in steps I and J to adjust each acute value individually to Z, and then calculating the geometric mean of the adjusted values for each species individually. This alternative procedure allows an examination of the range of the adjusted acute values for each species.

K. Obtain the Final Acute Value at Z by using the procedure described in Section IV.J-O.

L. If the Species Mean Acute Value at Z of a commercially or recreationally important species is lower than the calculated Final Acute Value at Z, then that Species Mean Acute Value should be used as the Final Acute Value at Z instead of the calculated Final Acute Value.

M. The Final Acute Equation is written as: Final Acute Value = $e^{(V[\ln(\text{water quality characteristic})] + \ln A - V[\ln Z])}$, where V = pooled acute slope and A = Final Acute Value at Z. Because V, A, and Z are known, the Final Acute Value can be calculated for any selected value of the water quality characteristic.

V. Final Chronic Value

A. Depending on the data that are available concerning chronic toxicity to aquatic animals, the Final Chronic Value might be calculated in the same manner as the Final Acute Value or by dividing the Final Acute Value by the Final Acute-

Chronic Ratio. In some cases it may not be possible to calculate a Final Chronic Value.

NOTE: As the name implies, the acute-chronic ratio is a way of relating acute and chronic toxicities. The acute-chronic ratio is basically the inverse of the application factor, but this new name is better because it is more descriptive and should help prevent confusion between "application factors" and "safety factors." Acute-chronic ratios and application factors are ways of relating the acute and chronic toxicities of a material to aquatic organisms. Safety factors are used to provide an extra margin of safety beyond the known or estimated sensitivities of aquatic organisms. Another advantage of the acute-chronic ratio is that it will usually be greater than 1; this should avoid the confusion as to whether a large application factor is one that is close to unity or one that has a denominator that is much greater than the numerator.

B. Chronic values should be based on results of flow-through (except renewal is acceptable for daphnids) chronic tests in which the concentrations of test material in the test solutions were properly measured at appropriate times during the test.

C. Results of chronic tests in which survival,

growth, or reproduction in the control treatment was unacceptably low should not be used. The limits of acceptability will depend on the species.

D. Results of chronic tests conducted in unusual dilution water, e.g., dilution water in which total organic carbon or particulate matter exceeded 5 mg/L, should not be used, unless a relationship is developed between chronic toxicity and organic carbon or particulate matter or unless data show that organic carbon, particulate matter, etc., do not affect toxicity.

E. Chronic values should be based on endpoints and lengths of exposure appropriate to the species. Therefore, only results of the following kinds of chronic toxicity tests should be used:

1. Life-cycle toxicity tests consisting of exposures of each of two or more groups of individuals of a species to a different concentration of the test material throughout a life cycle. To ensure that all life stages and life processes are exposed, tests with fish should begin with embryos or newly hatched young less than 48 hours old, continue through maturation and reproduction, and should end not less than 24 days (90 days for salmonids) after the hatching of the next generation. Tests with daphnids should begin

with young less than 24 hours old and last for not less than 21 days. Tests with mysids should begin with young less than 24 hours old and continue until 7 days past the median time of first brood release in the controls. For fish, data should be obtained and analyzed on survival and growth of adults and young, maturation of males and females, eggs spawned per female, embryo viability (salmonids only), and hatchability. For daphnids, data should be obtained and analyzed on survival and young per female. For mysids, data should be obtained and analyzed on survival, growth, and young per female.

2. Partial life-cycle toxicity tests consisting of exposures of each of two or more groups of individuals of a species of fish to a concentration of the test material through most portions of a life cycle. Partial life-cycle tests are allowed with fish species that require more than a year to reach sexual maturity, so that all major life stages can be exposed to the test material in less than 15 months. Exposure to the test material should begin with immature juveniles at least 2 months prior to active gonad development, continue through maturation and reproduction,

and end not less than 24 days (90 days for salmonids) after the hatching of the next generation. Data should be obtained and analyzed on survival and growth of adults and young, maturation of males and females, eggs spawned per female, embryo viability (salmonids only), and hatchability.

3. Early life-stage toxicity tests consisting of 28- to 32-day (60 days post hatch for salmonids) exposures of the early life stages of a species of fish from shortly after fertilization through embryonic, larval, and early juvenile development. Data should be obtained and analyzed on survival and growth.

NOTE: Results of an early life-stage test are used as predictions of results of life-cycle and partial life-cycle tests with the same species. Therefore, when results of a life-cycle or partial life-cycle test are available, results of an early life-stage test with the same species should not be used. Also, results of early life-stage tests in which the incidence of mortalities or abnormalities increased substantially near the end of the test should not be used because results of such tests are possibly not good predictions of the results of comparable life-cycle or partial life-cycle tests.

F. A chronic value may be obtained by calculating the geometric mean of the lower and upper chronic limits from a chronic test or by analyzing chronic data using regression analysis. A lower chronic limit is the highest tested concentration (a) in an acceptable chronic test, (b) which did not cause an unacceptable amount of adverse effect on any of the specified biological measurements, and (c) below which no tested concentration caused an unacceptable effect. An upper chronic limit is the lowest tested concentration (a) in an acceptable chronic test, (b) which did cause an unacceptable amount of adverse effect on one or more of the specified biological measurements, and (c) above which all tested concentrations also caused such an effect.

NOTE: Because various authors have used a variety of terms and definitions to interpret and report results of chronic tests, reported results should be reviewed carefully. The amount of effect that is considered unacceptable is often based on a statistical hypothesis test, but might also be defined in terms of a specified percent reduction from the controls. A small percent reduction (e.g., 3 percent) might be considered acceptable even if it is statistically significantly different from the control, whereas a large

percent reduction (e.g., 30 percent) might be considered unacceptable even if it is not statistically significant.

G. If the chronic toxicity of the material to aquatic animals apparently has been shown to be related to a water quality characteristic such as hardness or particulate matter for freshwater animals or salinity or particulate matter for saltwater animals, a Final Chronic Equation should be derived based on that water quality characteristic. Go to Section VII.

H. If chronic values are available for species in eight families as described in Sections III.B.1 or III.C.1, a Species Mean Chronic Value (SMCV) should be calculated for each species for which at least one chronic value is available by calculating the geometric mean of all chronic values available for the species, and appropriate Genus Mean Chronic Values should be calculated. The Final Chronic Value should then be obtained using the procedure described in Section IV.J-0. Then go to Section VI.M.

I. For each chronic value for which at least one corresponding appropriate acute value is available, calculate an acute-chronic ratio, using for the numerator the geometric mean of the results of all acceptable flow-through (except static is acceptable for daphnids) acute tests in

the same dilution water and in which the concentrations were measured. For fish, the acute test(s) should have been conducted with juveniles. The acute test(s) should have been part of the same study as the chronic test. If acute tests were not conducted as part of the same study, acute tests conducted in the same laboratory and dilution water, but in a different study, may be used. If no such acute tests are available, results of acute tests conducted in the same dilution water in a different laboratory may be used. If no such acute tests are available, an acute-chronic ratio should not be calculated.

J. For each species, calculate the species mean acute-chronic ratio as the geometric mean of all acute-chronic ratios available for that species.

K. For some materials the acute-chronic ratio seems to be the same for all species, but for other materials the ratio seems to increase or decrease as the Species Mean Acute Value (SMAV) increases. Thus the Final Acute-Chronic Ratio can be obtained in four ways, depending on the data available:

1. If the Species Mean Acute-Chronic ratio seems to increase or decrease as the Species Mean Acute Value increases, the Final Acute-Chronic Ratio should be calculated as the geometric mean of the acute-chronic ratios for species

whose Species Mean Acute Values are close to the Final Acute Value.

2. If no major trend is apparent and the acute-chronic ratios for a number of species are within a factor of 10, the Final Acute-Chronic Ratio should be calculated as the geometric mean of all the Species Mean Acute-Chronic Ratios available for both freshwater and saltwater species.

3. For acute tests conducted on metals and possibly other substances with embryos and larvae of barnacles, bivalve molluscs, sea urchins, lobsters, crabs, shrimp, and abalones (see Section IV.E.2), it is probably appropriate to assume that the acute-chronic ratio is 2. Chronic tests are very difficult to conduct with most such species, but it is likely that the sensitivities of embryos and larvae would determine the results of life-cycle tests. Thus, if the lowest available Species Mean Acute Values were determined with embryos and larvae of such species, the Final Acute-Chronic Ratio should probably be assumed to be 2, so that the Final Chronic Value is equal to the Criterion Maximum Concentration (see Section XI.B)

4. If the most appropriate Species Mean Acute-Chronic Ratios are less than 2.0, and especially if they are less than 1.0, acclimation has probably occurred during the chronic test. Because continuous exposure and acclimation cannot be assured to provide adequate protection in field situations, the Final Acute-Chronic Ratio should be assumed to be 2, so that the Final Chronic Value is equal to the Criterion Maximum Concentration (see Section XI.B).

   If the available Species Mean Acute-Chronic Ratios do not fit one of these cases, a Final Acute-Chronic Ratio probably cannot be obtained, and a Final Chronic Value probably cannot be calculated.

L. Calculate the Final Chronic Value by dividing the Final Acute Value by the Final Acute-Chronic Ratio. If there was a Final Acute Equation rather than a Final Acute Value, see also Section VII.A.

M. If the Species Mean Chronic Value of a commercially or recreationally important species is lower than the calculated Final Chronic Value, then that Species Mean Chronic Value should be used as the Final Chronic Value instead of the calculated Final Chronic Value.

N. Go to Section VIII.

VI. Final Chronic Equation

A. A Final Chronic Equation can be derived in two ways. The procedure described here in Section A will result in the chronic slope being the same as the acute slope. The procedure described in Sections B-N usually will result in the chronic slope being different from the acute slope.

1. If acute-chronic ratios are available for enough species at enough values of the water quality characteristic to indicate that the acute-chronic ratio is probably the same for all species and is probably independent of the water quality characteristic, calculate the Final Acute-Chronic Ratio as the geometric mean of the available Species Mean Acute-Chronic Ratios.
2. Calculate the Final Chronic Value at the selected value Z of the water quality characteristic by dividing the Final Acute Value at Z (see Section V.M) by the Final Acute-Chronic Ratio.
3. Use V = pooled acute slope (see section V.M) as L = pooled chronic slope.
4. Go to Section VII.M.

B. When enough data are available to show that chronic toxicity to at least one species is related to a water quality characteristic, the

relationship should be taken into account as described in Sections B-G or using analysis of covariance [15,16]. The two methods are equivalent and produce identical results. The manual method described below provides an understanding of this application of covariance analysis, but computerized versions of covariance analysis are much more convenient for analyzing large data sets. If two or more factors affect toxicity, multiple regression analysis should be used.

For each species for which comparable chronic toxicity values are available at two or more different values of the water quality characteristic, perform a least squares regression of the chronic toxicity values on the corresponding values of the water quality characteristic to obtain the slope and its 95 percent confidence limits for each species.

NOTE: Because the best documented relationship fitting these data is that between hardness and acute toxicity of metals in freshwater and a log-log relationship, geometric means and natural logarithms of both toxicity and water quality are used in the rest of this section. For relationships based on other water quality characteristics such as pH, temperature, or

salinity, no transformation or a different transformation might fit the data better, and appropriate changes will be necessary throughout this section. It is probably preferable, but not necessary, to use the same transformation that was used with the acute values in Section V.

D. Decide whether the data for each species are useful, taking into account the range and number of the tested values of the water quality characteristic and the degree of agreement within and between species. For example, a slope based on six data points might be of limited value if it is based only on data for a very narrow range of values of the water quality characteristic. A slope based on only two data points, however, might be useful if it is consistent with other information and if the two points cover a broad enough range of the water quality characteristic. In addition, chronic values that appear to be questionable in comparison with other acute and chronic data available for the same species and for other species in the same genus probably should not be used. For example, if after adjustment for the water quality characteristic, the chronic values available for a species or genus differ by more than a factor of 10, probably some or all of the values should be rejected. If

a useful chronic slope is not available for at least one species or if the available slopes are too dissimilar or if too few data are available to adequately define the relationship between chronic toxicity and the water quality characteristic, it might be appropriate to assume that the chronic slope is the same as the acute slope, which is equivalent to assuming that the acute-chronic ratio is independent of the water quality characteristic. Alternatively, return to Section VI.H, using the results of tests conducted under conditions and in waters similar to those commonly used for toxicity tests with the species.

E. Individually for each species calculate the geometric mean of the available chronic values and then divide each chronic value for a species by the mean for the species. This normalizes the chronic values so that the geometric mean of the normalized values for each species individually and for any combination of species is 1.0.

F. Similarly normalize the values of the water quality characteristic for each species individually.

G. Individually for each species perform a least squares regression of the normalized chronic toxicity values on the corresponding normalized values of the water quality characteristic. The resulting slopes and the 95 percent confidence

limits will be identical to those obtained in Section B. Now, however, if the data are actually plotted, the line of best fit for each individual species will go through the point 1,1 in the center of the graph.

H. Treat all the normalized data as if they were all for the same species and perform a least squares regression of all the normalized chronic values on the corresponding normalized values of the water quality characteristic to obtain the pooled chronic slope, L, and its 95 percent confidence limits. If all the normalized data are actually plotted, the line of best fit will go through the point 1,1 in the center of the graph.

I. For each species calculate the geometric mean, M, of the toxicity values and the geometric mean, P, of the values of the water quality characteristic. (These were calculated in steps E and F.)

J. For each species calculate the logarithm, Q, of the Species Mean Chronic Value at a selected value, Z, of the water quality characteristic using the equation: $Q = \ln M - L(\ln P - \ln Z)$.

NOTE: Although it is not necessary, it will usually be best to use the same value of the water quality characteristic here as was used in section V.I.

K. For each species calculate a Species Mean Chronic Value at Z using the equation: $SMCV = e^{Q}$.

NOTE: Alternatively, the Species Mean Chronic Values at Z can be obtained by skipping step J, using the equations in steps J and K to adjust each acute value individually to Z, and then calculating the geometric means of the adjusted values for each species individually. This alternative procedure allows an examination of the range of the adjusted chronic values for each species.

L. Obtain the Final Chronic Value at Z by using the procedure described in Section IV.J-O.

M. If the Species Mean Chronic Value at Z of a commercially or recreationally important species is lower than the calculated Final Chronic Value at Z, then that Species Mean Chronic Value should be used as the Final Chronic Value at Z instead of the calculated Final Chronic Value.

N. The Final Chronic Equation is written as: Final Chronic Value = $e^{(L[\ln(\text{water quality characteristic})] + \ln S - L[\ln Z])}$, where L = pooled chronic slope and S = Final Chronic Value at Z. Because L, S and Z are known, the Final Chronic Value can be calculated for any selected value of the water quality characteristic.

VII. Final Plant Value

A. Appropriate measures of the toxicity of the material to aquatic plants are used to compare the relative sensitivities of aquatic plants and animals. Although procedures for conducting and interpreting the results of toxicity tests with plants are not well developed, results of tests with plants usually indicate that criteria which adequately protect aquatic animals and their uses will probably also protect aquatic plants and their uses.

B. A plant value is the result of a 96-hr test conducted with an alga or a chronic test conducted with an aquatic vascular plant.

NOTE: A test of the toxicity of a metal to a plant usually should not be used if the medium contained an excessive amount of a complexing agent, such as EDTA, that might affect the toxicity of the metal. Concentrations of EDTA above about 200 ug/L should probably be considered excessive.

C. The Final Plant Value should be obtained by selecting the lowest result from a test with an important aquatic plant species in which the concentrations of test material were measured and the endpoint was biologically important.

VIII. Final Residue Value

A. The Final Residue Value is intended to (a) prevent concentrations in commercially or recreationally important aquatic species from affecting marketability because of exceedence of applicable FDA action levels and (b) protect wildlife, including fishes and birds, that consume aquatic organisms from demonstrated unacceptable effects. The Final Residue Value is the lowest of the residue values that are obtained by dividing maximum permissible tissue concentrations by appropriate bioconcentration or bioaccumulation factors. A maximum permissible tissue concentration is either (a) an FDA action level [12] for fish oil or for the edible portion of fish or shellfish, or (b) a maximum acceptable dietary intake based on observations on survival, growth, or reproduction in a chronic wildlife feeding study or a long-term wildlife field study. If no maximum permissible tissue concentration is available, go to Section X because no Final Residue Value can be derived.

B. Bioconcentration Factors (BCFs) and bioaccumulation factors (BAFs) are quotients of the concentration of a material in one or more tissues of an aquatic organism divided by the average concentration in the solution in which the organism had been living. A BCF is intended to account only for net uptake directly from water, and thus almost has to be measured in a laboratory test. Some uptake during the bioconcentration test might not be directly from water if the food sorbs some of the test material before it is eaten by the test organisms. A BAF is intended to account for net uptake from both food and water in a real-world situation. A BAF almost has to be measured in a field situation in which predators accumulate the material directly from water and by consuming prey that itself could have accumulated the material from both food and water. The BCF and BAF are probably similar for a material with a low BCF, but the BAF is probably higher than the BCF for materials with high BCFs. Although BCFs are not too difficult to determine, very few BAFs have been measured acceptably because it is necessary to make enough measurements of the concentration of the material in water to show that it was reasonably constant for a long enough period of time over the range of territory inhabited by the

organisms. Because so few acceptable BAFs are available, only BCFs will be discussed further. However, if an acceptable BAF is available for a material, it should be used instead of any available BCFs.

C. If a maximum permissible tissue concentration is available for a substance (e.g., parent material, parent material plus metabolites, etc.), the tissue concentration used in the calculation of the BCF should be for the same substance. Otherwise the tissue concentration used in the calculation of the BCF should be that of the material and its metabolites which are structurally similar and are not much more soluble in water than the parent material.

D. 1. A BCF should be used only if the test was flow-through, the BCF was calculated based on measured concentrations of the test material in tissue and in the test solution, and the exposure continued at least until either apparent steady-state or 28 days was reached. Steady-state is reached when the BCF does not change significantly over a period of time, such a 2 days or 16 percent of the length of the exposure, whichever is longer. The BCF used from a test should be the highest of (a) the apparent steady-state BCF, if apparent steady-state was reached, (b) the highest BCF

obtained, if apparent steady-state was not reached, and (c) the projected steady-state BCF, if calculated.

2. Whenever a BCF is determined for a lipophilic material, the percent lipids should also be determined in the tissue(s) for which the BCF was calculated.

3. A BCF obtained from an exposure that adversely affected the test organisms may be used only if it is similar to a BCF obtained with unaffected organisms of the same species at lower concentrations that did not cause adverse effects.

4. Because maximum permissible tissue concentrations are almost never based on dry weights, a BCF calculated using dry tissue weights must be converted to a wet tissue weight basis. If no conversion factor is reported with the BCF, multiply the dry weight BCF by 0.1 for plankton and by 0.2 for individual species of fishes and invertebrates [17].

5. If more than one acceptable BCF is available for a species, the geometric mean of the available values should be used, except that if the BCFs are from different lengths of exposure and the BCF increases with length of

exposure, the BCF for the longest exposure should be used.

E. If enough pertinent data exist, several residue values can be calculated by dividing maximum permissible tissue concentrations by appropriate BCFs:

1. For each available maximum acceptable dietary intake derived from a chronic feeding study or a long-term field study with wildlife, including birds and aquatic organisms, the appropriate BCF is based on the whole body of aquatic species which constitute or represent a major portion of the diet of the tested wildlife species.

2. For an FDA action level for fish or shellfish, the appropriate BCF is the highest geometric mean species BCF for the edible portion (muscle for decapods, muscle with or without skin for fishes, adductor muscle for scallops, and total soft tissue for other bivalve molluscs) of a consumed species. The highest species BCF is used because FDA action levels are applied on a species-by-species basis.

F. For lipophilic materials, it might be possible to calculate additional residue values. Because the steady-state BCF for a lipophilic material seems to be proportional to percent lipids from one tissue to another and from one species to another

[18-20], extrapolations can be made from tested tissues or species to untested tissues or species on the basis of percent lipids.

1. For each BCF for which the percent lipids is known for the same tissue for which the BCF was measured, normalize the BCF to a 1 percent lipid basis by dividing the BCF by the percent lipids. This adjustment to a 1 percent lipid basis is intended to make all the measured BCFs for a material comparable regardless of the species or tissue with which the BCF was measured.

2. Calculate the geometric mean normalized BCF. Data for both saltwater and freshwater species should be used to determine the mean normalized BCF, unless the data show that the normalized BCFs are probably not similar.

3. Calculate all possible residue values by dividing the available maximum permissible tissue concentrations by the mean normalized BCF and by the percent lipids values appropriate to the maximum permissible tissue concentrations, i.e.,

$$\text{Residue value} = \frac{(\text{maximum permissible tissue concentration})}{(\text{mean normalized BCF})(\text{appropriate percent lipids})}$$

tissue concentration) Residue value = (mean normalized BCF) (appropriate percent lipids)

a. For an FDA action level for fish oil, the

appropriate percent lipids value is 100.

b. For an FDA action level for fish, the appropriate percent lipids value is 11 for freshwater criteria and 10 for saltwater criteria because FDA action levels are applied on a species-by-species basis to commonly consumed species. The highest lipid contents in the edible portions of important consumed species are about 11 percent for both the freshwater chinook salmon and lake trout and about 10 percent for the saltwater Atlantic herring [21].

c. For a maximum acceptable dietary intake derived from a chronic feeding study or a long-term field study with wildlife, the appropriate percent lipids is that of an aquatic species or group of aquatic species which constitute a major portion of the diet of the wildlife species.

G. The Final Residue Value is obtained by selecting the lowest of the available residue values.

NOTE: In some cases the Final Residue Value will not be low enough. For example, a residue value calculated from an FDA action level will probably result in an average concentration in the edible portion of a fatty species that is at the action level. Some individual organisms, and possibly some species, will have residue concentrations higher than the mean value but no mechanism has been devised to provide appropriate additional protection. Also, some chronic feeding studies and long-term field studies with wildlife identify concentrations that cause adverse effects but do not identify concentrations which do not cause adverse effects; again, no mechanism has been devised to provide appropriate additional protection. These are some of the species and uses that are not protected at all times in all places.

X. Other Data

Pertinent information that could not be used in earlier sections might be available concerning adverse effects on aquatic organisms and their uses. The most important of these are data on cumulative and delayed toxicity, flavor impairment, reduction in survival, growth, or reproduction, or any other adverse effect that has been shown to be biologically important. Especially important are data for species for which no

other data are available. Data from behavioral, biochemical, physiological, microcosm, and field studies might also be available. Data might be available from tests conducted in unusual dilution water (see IV.D and VI.D), from chronic tests in which the concentrations were not measured (see VI.B), from tests with previously exposed organisms (see II.F), and from tests on formulated mixtures or emulsifiable concentrates (see II.D). Such data might affect a criterion if the data were obtained with an important species, the test concentrations were measured, and the endpoint was biologically important.

XI. Criterion

A. A criterion consists of two concentrations: the Criterion Maximum Concentration and the Criterion Continuous Concentration.

B. The Criterion Maximum Concentration (CMC) is equal to one-half the Final Acute Value.

C. The Criterion Continuous Concentration (CCC) is equal to the lowest of the Final Chronic Value, the Final Plant Value, and the Final Residue Value, unless other data (see Section X) show that a lower value should be used. If toxicity is related to a water quality characteristic, the Criterion Continuous Concentration is obtained from the Final Chronic Equation, the Final Plant Value, and the Final Residue Value by selecting

the one, or the combination, that results in the lowest concentrations in the usual range of the water quality characteristic, unless other data (see Section X) show that a lower value should be used.

D. Round [14] both the Criterion Maximum Concentration and the Criterion Continuous Concentration to two significant digits.

E. The criterion is stated as:

The procedures described in the Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses indicate that, except possibly where a locally important species is very sensitive, (1) aquatic organisms and their uses should not be affected unacceptably if the 4-day average concentration of (2) does not exceed (3) ug/L more than once every 3 years on the average and if the 1-hour average concentration does not exceed (4) ug/L more than once every 3 years on the average.

where (1) = insert "freshwater" or "saltwater"

(2) = insert name of material

(3) = insert the Criterion Continuous Concentration

(4) = insert the Criterion Maximum Concentration.

XII. Final Review

A. The derivation of the criterion should be carefully reviewed by rechecking each step of the Guidelines. Items that should be especially checked are:

1. If unpublished data are used, are they well documented?
2. Are all required data available?
3. Is the range of acute values for any species greater than a factor of 10?
4. Is the range of Species Mean Acute Values for any genus greater than a factor of 10?
5. Is there more than a factor of 10 difference between the four lowest Genus Mean Acute Values?
6. Are any of the four lowest Genus Mean Acute Values questionable?
7. Is the Final Acute Value reasonable in comparison with the Species Mean Acute Values and Genus Mean Acute Values?
8. For any commercially or recreationally important species, is the geometric mean of the acute values from flow-through tests in which the concentrations of test material were measured lower than the Final Acute Value?
9. Are any of the chronic values questionable?

10. Are chronic values available for acutely sensitive species?

11. Is the range of acute-chronic ratios greater than a factor of 10?

12. Is the Final Chronic Value reasonable in comparison with the available acute and chronic data?

13. Is the measured or predicted chronic value for any commercially or recreationally important species below the Final Chronic Value?

14. Are any of the other data important?

15. Do any data look like they might be outliers?

16. Are there any deviations from the Guidelines? Are they acceptable?

B. On the basis of all available pertinent laboratory and field information, determine if the criterion is consistent with sound scientific evidence. If it is not, another criterion, either higher or lower, should be derived using appropriate modifications of these Guidelines.

APPENDIX B

SUMMARY OF THE 1980 AQUATIC LIFE GUIDELINES

The Guidelines for Deriving Water Quality Criteria for the Protection of Aquatic Life and its Uses were developed to describe an objective, internally consistent, and appropriate way of ensuring that water quality criteria for aquatic life would provide, on the average, a reasonable amount of protection. The resulting criteria are not intended to provide 100 percent protection of all species and all uses of aquatic life all of the time, but they are intended to protect most species in a balanced, healthy aquatic community.

Minimum data requirements are identified in four areas: acute toxicity to animals (eight data points), chronic toxicity to animals (three data points), toxicity to plants, and residues. Data on acute toxicity are needed for a variety of fish and invertebrate species and are used to derive a Final Acute Value. By taking into account the number and relative sensitivities of the tested species, the Final Acute Value is designed to protect most, but not necessarily all, of the tested and untested species.

Data on chronic toxicity to animals can be used to derive a Final Chronic Value by two different means. If chronic values are available for a specified number and array of species, a Final Chronic Value can be calculated directly. If not, an acute-chronic ratio is derived and then used with the Final Acute Value to obtain the Final Chronic Value.

The Final Plant Value is obtained by selecting the lowest plant toxicity value based on measured concentrations.

The Final Residue Value is intended to protect wildlife which consume aquatic organisms and the marketability of aquatic organisms. Protection of the marketability of aquatic organisms is, in actuality, protection of a use of that water body (commercial fishery). Two kinds of data are necessary to calculate the Final Residue Value: a bioconcentration factor (BCF) and a maximum permissible tissue concentration, which can be an FDA action level or can be the result of a chronic wildlife feeding study. For lipid-soluble pollutants, the BCF is normalized for percent lipids and then the Final Residue Value is calculated by dividing the maximum permissible tissue concentration by the normalized BCF and by an appropriate percent lipid value. BCFs are normalized for percent lipids since the BCF measured for any individual aquatic species is generally proportional to the percent lipids in that species.

If sufficient data are available to demonstrate that one or more of the final values should be related to a water quality characteristic, such as salinity, hardness, or suspended solids, the final value(s) are expressed as a function of that characteristic.

After the four final values (Final Acute Value, Final Chronic Value, Final Plant Value, and Final Residue Value) have been obtained, the criterion is established with the Final Acute Value becoming the maximum value and the lowest of the other three values becoming the 24-hour average value. All of the data used to calculate the four final values and any additional pertinent information are then reviewed to determine if the criterion is reasonable. If sound scientific evidence indicates that the

criterion should be raised or lowered, appropriate changes are made as necessary.

The November 28, 1980, Guidelines have been revised from the earlier published versions (43 FR 21506, May 18, 1978; 43 FR 29028, July 5, 1978; 44 FR 15926, March 15, 1979). Details have been added in many places and the concept of a minimum data base has been incorporated. In addition, three adjustment factors and the species sensitivity factor have been deleted. These modifications were the result of the Agency's analysis of public comments and comments received from the Science Advisory Board on earlier versions of the Guidelines. These comments and the Resultant modifications are addressed fully in Appendix D to this notice.

Criteria for the Protection of Human Health

Interpretation of the Human Health Criteria

The human health criteria issued today are summarized in Appendix A of this Federal Register notice. Criteria for the protection of human health are based on their carcinogenic, toxic, or organoleptic (taste and odor) properties. The meanings and practical uses of the criteria values are distinctly different depending on the properties on which they are based.

The objective of the health assessment portions of the criteria documents is to estimate ambient water concentrations which, in the case of noncarcinogens, prevent adverse health effects in humans, and in the case of suspect or proven carcinogens, represent various levels of incremental cancer risk.

Health assessments typically contain discussions of four elements: exposure, pharmacokinetics, toxic effects, and criterion formulation.

The exposure section summarizes information on exposure routes: ingestion directly from water, indirectly from consumption of aquatic organisms found in ambient water, other dietary sources, inhalation, and dermal contact. Exposure assumptions are used to derive human health criteria. Most criteria are based solely on exposure from consumption of water containing a specified concentration of a toxic pollutant and through consumption of aquatic organisms which are assumed to have bioconcentrated pollutants from the water in which they live. Other multimedia routes of exposure such as air, nonaquatic diet, or dermal are not factored into the criterion formulation for the vast majority of pollutants because of lack of data. The criteria are calculated using the combined aquatic exposure pathway and also using the aquatic organism ingestion exposure route alone. In criteria reflecting both the water consumption and aquatic organism ingestion routes of exposure, the relative exposure contribution varies with the propensity of a pollutant to bioconcentrate, with the consumption of aquatic organisms becoming more important as the bioconcentration factor (BCF) increases. As additional information on total exposure is assembled for pollutants for which criteria reflect only the two specified aquatic exposure routes, adjustments in water concentration values may be made. The demonstration of significantly different exposure patterns will become an element

of a process to adapt/modify human health-based criteria to local conditions, somewhat analogous to the aquatic life criteria modification process discussed previously. It is anticipated that States at their discretion will be able to set appropriate human health criteria based on this process.

Specific health-based criteria are developed only if a weight of evidence supports the occurrence of the toxic effect and if dose/response data exist from which criteria can be estimated. The pharmacokinteics section reviews data on absorption, distribution, metabolism, and excretion to assess the biochemical fate of the compounds in the human and animal system. The toxic effects section reviews data on acute, subacute, and chronic toxicity, synergistic and antagonistic effects, and specific information on mutagenicity, teratogenicity, and carcinogenicity. From this review, the toxic effect to be protected against is identified taking into account the quality, quantity, and weight of evidence characteristic of the data. The criterion formulation section reviews the highlights of the text and specifies a rationale for criterion development and the mathematical derivation of the criterion number.

Within the limitations of time and resources, current published information of significance was incorporated into the human health assessments. Review articles nad reports were used for data evaluation and synthesis. Scientific judgment was exercised in reviewing and evaluating the data in each criteria document and in identifying the adverse effects for which protective criteria were published.

Criteria for suspect or proven carcinogens are presented as concentrations in water associated with a range of incremental cancer risks to man. Criteria for noncarcinogens represent levels at which exposure to a single chemical is not anticipated to produce adverse effects in man. In a few cases, organoleptic (taste and odor) data form the basis for the criterion. While this type of criterion does not represent a value which directly affects human health, it is presented as an estimate of the level of a pollutant that will not produce unpleasant taste or odor either directly from water consumption or indirectly by consumption of aquatic organisms found in ambient waters. A criterion developed in this manner is judged to be as useful as other types of criteria in protecting designated water uses. In addition, where data are available, toxicity-based criteria are also presented for pollutants with derived organoleptic criteria. The choice of criteria used in water quality standards for these pollutants will depend upon the designated use to be protected. In the case of a multiple use water body, the criterion protecting the most sensitive use will be applied. Finally, for several pollutants no criteria are recommended because insufficient information is available for quantitative criterion formulation.

Risk Extrapolation

Because methods do not exist to establish the presence of a threshold for carcinogenic effects, EPA's policy is that there is no scientific basis for estimating "safe" levels for carcinogens. The criteria for carcinogens, therefore, state that the

recommended concentration for maximum protection of human health is zero. In addition, the Agency has presented a range of concentrations corresponding to incremental cancer risks of 10_{-7} to 10_{-5} (one additional case of cancer in populations ranging from 10 million to 100,000, respectively). Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on a "acceptable" risk level.

Summary of the Human Health Guidelines

The health assessments and corresponding criteria were derived based on Guidelines and Methodology Used in the Preparation of Health Effect Assessment Chapters of the Consent Decree Water Criteria Documents (the Guidelines) developed by EPA'S Office of Research and Development. The estimation of health risk associated with human exposure to environmental pollutants requires predicting the effect of low doses for up to a lifetime in duration. A combination of epidemiological and animal dose/response data is considered the preferred basis for quantitative criterion derivation.

No-effect (noncarcinogen) or specified risk (carcinogen) concentrations were estimated by extrapolation from animal toxicity or human epidemiology studies using the following basic exposure assumptions: a 70-kilogram male person (Report of the Task Group on Reference Man, International Commission for Radiation Protection, November 23, 1957) as the exposed individual; the average daily consumption of freshwater and

estuarine fish and shellfish products equal to 6.5 grams/day; and the average ingestion of 2 liters/day of water (Drinking Water and Health, National Academy of Sciences, National Research Council, 1977). Criteria based on these assumptions are estimated to be protective of an adult male who experiences average exposure conditions.

Two basic methods were used to formulate health criteria, depending on whether the prominent adverse effect was cancer or other toxic manifestations. The following sections detail these methods.

Carcinogens

Extrapolation of cancer responses from high to low doses and subsequent risk estimation from animal data are performed using a linearized multi-stage model. This procedure is flexible enough to fit all monotonically-increasing dose response data, since it incorporates several adjustable parameters. The multi-stage model is a linear nonthreshold model as was the "one-hit" model originally used in the proposed criteria documents. The linear nonthreshold concept has been endorsed by the four agencies in the Interagency Regulatory Liaison Group and is less likely to underestimate risk at the low doses typical of environmental exposure than other models that could be used. Because of the uncertainties associated with dose response, animal-to-human extrapolation, and other unknown factors; because of the use of average consumptions; and because of the serious public health consequences that could result if risks were underestimated, EPA believes that it is prudent to use conservative methods to

estimate risk in the water quality criteria program. The linearized multistage model is more systematic and invokes fewer arbitrary assumptions than the "one-hit" procedure previously used.

It should be noted that extrapolation models provide estimates of risk since a variety of assumptions are built into any model. Models using widely different assumptions may produce estimates ranging over several orders of magnitude. Since there is at present no way to demonstrate the scientific validity of any model, the use of risk extrapolation models is a subject of debate in the scientific community. However, risk extrapolation is generally recognized as the only tool available at this time for estimating the magnitude of health hazards associated with nonthreshold toxicants and has been endorsed by numerous Federal agencies and scientific organizations, including EPA's Carcinogen Assessment Group, the National Academy of Sciences, and the Interagency Regulatory Liaison Group, as a useful means of assessing the risks of exposure to various carcinogenic pollutants.

Noncarcinogens

Health criteria based on toxic effects of pollutants other than carcinogenicity are estimates of concentrations which are not expected to produce adverse effects in humans. They are based upon Acceptable Daily Intake (ADI) levels and are generally derived using no-observed-adverse-effect-level data from animal studies although human data are used wherever available. The ADI is calculated using safety factors to account for uncertainties

inherent in extrapolation from animal to man. In accordance with the National Research Council recommendations (Drinking Water and Health, National Academy of Sciences, National Research Council, 1977), safety factors of 10, 100, or 1,000 are used, depending on the quality and quantity of data. In some instances extrapolations are made from inhalation studies or limits to approximate a human response from ingestion using the Stokinger-Woodward model (Journal of American Water Works Association, 1958). Calculations of criteria from ADIs are made using the standard exposure assumptions (2 liters of water, 6.5 grams of edible aquatic products, and an average body weight of 70 kg).

APPENDIX C

THE PHILOSOPHY OF THE 1976 WATER QUALITY CRITERIA

Water quality criteria specify concentrations of water constituents which, if not exceeded, are expected to support an organic ecosystem suitable for the higher uses of water. Such criteria are derived from scientific facts obtained from experimental or *in situ* observations that depict organic responses to a defined stimulus or material under identifiable or regulated environmental conditions for a specified time period.

Water quality criteria are not intended to offer the same degree of strategy for survival and propagation at all times to all organisms within a given ecosystem. They are intended not only to protect essential and significant life in water and the direct users of water, but also to protect life that is dependent on life in water for its existence, or that may consume intentionally or unintentionally any edible portion of such life.

The criteria levels for domestic water supply incorporate available data for human health protection. Such values are different from the criteria levels necessary for protection of aquatic life. The Agency's interim primary drinking water regulations (40 Federal Register 59566 December 24, 1975), as required by the Safe Drinking Water Act (42 U.S.C. 300f, et seq.), incorporate applicable domestic water supply criteria. Where pollutants are identified in both the quality criteria for domestic water supply and the Drinking Water Standards, the concentration levels are identical. Water treatment may not significantly affect the removal of certain pollutants.

What is essential and significant life in water? Do Daphnia or stonefly nymphs qualify as such life? Why does 1/100th of a concentration that is lethal to 50 percent of the test organisms (LC50) constitute a criterion in some instances, whereas 1/2 or 1/10th of some effect levels constitutes a criterion in other instances? These are questions that often are asked of those who undertake the task of criteria formulation.

The universe of organisms composing life in water is great in both kinds and numbers. As in the human population, physiological variability exists among individuals of the same species in response to a given stimulus. A much greater response variation exists among species of aquatic organisms. Thus, aquatic organisms do not exhibit the same degree of harm, individually or by species, from a given concentration of a toxicant or potential toxicant within the environment. In establishing a level or concentration of a quality constituent as a criterion it is necessary to ensure a reasonable degree of safety for those more sensitive species that are important to the functioning of the aquatic ecosystem even though data on the response of such species to the quality constituent under consideration may not be available. The aquatic food web is an intricate relationship of predator and prey organisms. A water constituent that may in some way destroy or eliminate an important segment of that food web would, in all likelihood, destroy or seriously impair other organisms associated with it.

Although experimentation relating to the effects of particular substances under controlled conditions began in the

early 1900's, the effects of any substance on more than a few of the vast number of aquatic organisms have not been investigated. Certain test animals have been selected by investigators for intensive investigation because of their importance to man, their availability to the researcher, and their physiological responses to the laboratory environment. As general indicators of organism responses such test organisms are representative of the expected results for other associated organisms. In this context Daphnia or stoneflies or other associated organisms indicate the general levels of toxicity to be expected among untested species. In addition, test organisms are themselves vital links within the food web that results in the fish population in a particular waterway.

The ideal data base for criteria development would consist of information on a large percentage of aquatic species and would show the community response to a range of concentrations for a tested constituent during a long time period. This information is not available but investigators are beginning to derive such information for a few water constituents. Where only 96-hour bioassay data are available, judgmental prudence dictates that a substantial safety factor be employed to protect all life stages of the test organism in waters of varying quality, as well as associated organisms within the aquatic environment that have not been tested and that may be more sensitive to the test constituent. Application factors have been used to provide the degree of protection required. Safe levels for certain chlorinated hydrocarbons and certain heavy metals were estimated by applying an 0.01 application factor to the 96-hour LC50 value

for sensitive aquatic organisms. Flow-through bioassays have been conducted for some test indicator organisms over a substantial period of their life history. In a few other cases, information is available for the organism's natural life or for more than one generation of the species. Such data may indicate a minimal effect level, as well as a no-effect level.

The word "criterion" should not be used interchangeably with or as a synonym for the word "standard." The word "criterion" represents a constituent concentration or level associated with a degree of environmental effect upon which scientific judgment may be based. As it is currently associated with the water environment it has come to mean a designated concentration of a constituent that, when not exceeded, will protect an organism, an organism community, or a prescribed water use or quality with an adequate degree of safety. A criterion, in some cases, may be a narrative statement instead of a constituent concentration. On the other hand, a standard connotes a legal entity for a particular reach of waterway or for an effluent. A water quality standard may use a water quality criterion as a basis for regulation or enforcement, but the standard may differ from a criterion because of prevailing local natural conditions, such as naturally occurring organic acids, or because of the importance of a particular waterway, economic considerations, or the degree of safety to a particular ecosystem that may be desired.

Toxicity to aquatic life generally is expressed in terms of acute (short term) or chronic (long-term) effects. Acute toxicity refers to effects occurring in a short time period:

often death is the end point. Acute toxicity can be expressed as the lethal concentration for a stated percentage of organisms tested, or the reciprocal, which is the tolerance limit of a percentage of surviving organisms. Acute toxicity for aquatic organisms generally has been expressed for 24 to 96-hour exposures.

Chronic toxicity refers to effects through an extended time period. Chronic toxicity may be expressed in terms of an observation period equal to the lifetime of an organism or to the time span of more than one generation. Some chronic effects may be reversible, but most are not.

Chronic effects often occur in the species population rather than in the individual. If eggs fail to develop or the sperm does not remain viable, the species would be eliminated from an ecosystem because of reproductive failure. Physiological stress may make a species less competitive with others and may result in a gradual population decline or absence from an area. The elimination of a microcrustacean that serves as a vital food during the larval period of a fish's life could result ultimately in the elimination of the fish from an area. The phenomenon of bioaccumulation of certain materials may result in chronic toxicity to the ultimate consumer in a food chain. Thus, fish may mobilize lethal toxicants from their fatty tissues during periods of physiological stress. Egg shells of predatory birds may be weakened to a point of destruction in the nest. Bird chick embryos may have increased mortality rates. There may be a hazard to the health of man if aquatic organisms with toxic residues are consumed.

The fact that living systems, i.e., individuals, populations, species, and ecosystems, can take up, accumulate, and bioconcentrate manmade and natural toxicants is well documented. In aquatic systems biota are exposed directly to pollutant toxicants through submersion in a relatively efficient solvent (water) and are exposed indirectly through food webs and other biological, chemical, and physical interactions. Initial toxicant levels, if not immediately toxic and damaging, may accumulate in the biota or sediment over time and increase to levels that are lethal or sublethally damaging to aquatic organisms or to consumers of these organisms. Water quality criteria reflect a knowledge of the capacity for environmental accumulation, persistence, and effects of specific toxicants in specific aquatic systems.

Ions of toxic materials frequently cause adverse effects because they pass through the semipermeable membranes of an organism. Molecular diffusion through membranes may occur for some compounds such as pesticides, polychlorinated biphenyls, and other toxicants. Some materials may not pass through membranes in their natural or waste-discharged state, but in water they may be converted to states that have increased ability to affect organisms. For example, certain microorganisms can methylate mercury, thus producing a material that more readily enters physiological systems. Some materials may have multiple effects: for example, an iron salt may not be toxic; an iron floc or gel may be an irritant or clog fish gills to effect asphyxiation; iron at low concentrations can be a trace nutrient

but at high concentrations it can be a toxicant. Materials also can affect organisms if their metabolic byproducts cannot be excreted. Unless otherwise stated, criteria are based on the total concentration of the substance because an ecosystem can produce chemical, physical, and biological changes that may be detrimental to organisms living in or using the water.

In prescribing water quality criteria, certain fundamental principles dominate the reasoning process. In establishing a level or concentration as a criterion for a given constituent it was assumed that other factors within the aquatic environment are acceptable to maintain the integrity of the water. Interrelationships and interactions among organisms and their environment, as well as the interrelationships of sediments and the constituents they contain to the water above, are recognized as fact.

Antagonistic and synergistic reactions among many quality constituents in water also are recognized as fact. The precise definition of such reactions and their relative effects on particular segments of aquatic life have not been identified with scientific precision. Historically much of the data to support criteria development was of an ambient concentration-organism response nature. Recently, data are becoming available on long-term chronic effects on particular species. Studies now determine carcinogenic, teratogenic, and other insidious effects of toxic materials.

Some unpolluted waters in the Nation may exceed designated criteria for particular constituents. There is variability in the natural quality of water and certain organisms become adapted

to that quality, which may be considered extreme in other areas. Likewise, it is recognized that a single criterion cannot identify minimal quality for the protection of the integrity of water for every aquatic ecosystem in the Nation. To provide an adequate degree of safety to protect against long-term effects may result in a criterion that cannot be detected with present analytical tools. In some cases, a mass balance calculation can provide a means of assurance that the integrity of the waterway is not being degraded.

Water quality criteria do not have direct regulatory impact, but they form the basis for judgment in several Environmental Protection Agency programs that are derived from water quality considerations. For example, water quality standards developed by the States under section 303 of the Act and approved by EPA are to be based on the water quality criteria, appropriately modified to take account of local conditions. The local conditions to be considered include actual and projected uses of the water, natural background levels of particular constituents, the presence or absence of sensitive important species, characteristics of the local biological community, temperature and weather, flow characteristics, and synergistic or antagonistic effects of combinations of pollutants.

Similarly, by providing a judgment on desirable levels of ambient water quality, water quality criteria are the starting point in deriving toxic pollutant effluent standards pursuant to section 307(a) of the Act. Other EPA programs that use water quality criteria involve drinking water standards, the ocean

dumping program, designation of hazardous substances, dredge spoil criteria development, removal of in-place toxic materials, thermal pollution, and pesticide registration.

To provide the water resource protection for which they are designed, quality criteria should apply to virtually all of the Nation's navigable waters with modifications for local conditions as needed. To violate quality criteria for any substantial length of time or in any substantial portion of a waterway may result in an adverse affect on aquatic life and perhaps a hazard to man or other consumers of aquatic life.

Quality criteria have been designed to provide long-term protection. Thus, they may provide a basis for effluent standards, but it is not intended that criteria values become effluent standards. It is recognized that certain substances may be applied to the aquatic environment with the concurrence of a governmental agency for the precise purpose of controlling or managing a portion of the aquatic ecosystem; aquatic herbicides and piscicides are examples of such substances. For such occurrences, criteria obviously do not apply. It is recognized further that pesticides applied according to official label instructions to agricultural and forest lands may be washed to a receiving waterway by a torrential rainstorm. Under such conditions it is believed that such diffuse source inflows should receive consideration similar to that of a discrete effluent discharge and that in such instances the criteria should be applied to the principal portion of the waterway rather than to that peripheral portion receiving the diffuse inflow.

The format for presenting water quality criteria includes a concise statement of the dominant criterion or criteria for a particular constituent followed by a narrative introduction, a rationale that includes justification for the designated criterion or criteria, and a listing of the references cited within the rationale. An effort has been made to restrict supporting data to those which either have been published or are in press awaiting publication. A particular constituent may have more than one criterion to ensure more than one water use or condition, i.e., hard or soft water where applicable, suitability as a drinking water supply source, protection of human health when edible portions of selected biota are consumed, provision for recreational bathing or waterskiing, and permitting an appropriate factor of safety to ensure protection for essential warm-or coldwater associated biota.

Criteria are presented for those substances that may occur in water where data indicate the potential for harm to aquatic life, or to water users, or to the consumers of the water or aquatic life. Presented criteria do not represent an all-inclusive list of constituent contaminants. Omissions from criteria should not be construed to mean that an omitted quality constituent is either unimportant or non-hazardous.

The pH of surface waters is important to aquatic life because pH affects the ability of fish and other aquatic organisms to regulate basic life-sustaining processes, primarily the exchanges of respiratory gasses and salts with the water in which they live. Failure to adequately regulate these processes can result in numerous sub-lethal effects (e.g., diminished growth rates) and even mortality in cases when ambient pH exceeds the range physiologically tolerated by aquatic organisms.

DIRECT EFFECTS OF pH ON AQUATIC LIFE

The effects of pH on fish and other freshwater aquatic life have been reviewed in detail (e.g., Doudoroff and Katz 1950; McKee and Wolf 1963; EIFAC 1969; Katz 1969; NAS 1972; AFS 1979; Alabaster and Lloyd 1980). The pH of water affects the normal physiological functions of aquatic organisms, including the exchange of ions with the water and respiration. Such important physiological processes operate normally in most aquatic biota under a relatively wide pH range (e.g., 6-9 pH units). There is no definitive pH range within which all freshwater aquatic life is unharmed and outside which adverse impacts occur. Rather, there is a gradual "deterioration" in acceptability as pH values become further removed from the normal range (EIFAC 1969; AFS 1979; Alabaster and Lloyd 1980). The acceptable range of pH to aquatic life, particularly fish, depends on numerous other factors, including prior pH acclimatization, water temperature, dissolved oxygen concentration, and the concentrations and ratios of various cations and anions (McKee and Wolf 1963).

Alabaster and Lloyd (1980) identified the pH range that is not directly lethal to freshwater fish as 5.0-9.0. With few exceptions, pH values between 6.5 and 9.0 are satisfactory, on a long-term basis, for fish and other freshwater aquatic life. The pH of most inland fresh waters containing fish ranges from about 6 to 9 (Ellis 1937), with most waters, particularly those with healthy, diverse, and productive fish and macroinvertebrates communities having a pH between approximately 6.5 and 8.5 units (Ellis 1937; McKee and Wolf 1963; NTAC1968; NAS 1972). In establishing water quality criteria for pH, ORVWSC (1955) stated that, although fish had been found at pH values from 4-10, the safe range was 5-9 and for maximum productivity the pH should be maintained between 6.5 and 8.5. Some aquatic organisms (e.g., certain species of algae) have been found to live at pH 2 and lower, and others at pH 10 and higher (NAS 1972). However, there are few such organisms, and their extreme tolerances are not reflective of the pH tolerated by the majority of organisms occurring in a given aquatic ecosystem.

Limiting pH Values			
Minimum	*Maximum*	*Remarks*	*References*
3.3	10.7	Trout survived without adverse effects	1467
3.6	---	Tench survived two weeks but carp died	1302
3.6	10.5	96-hour TL_m range for bluegill sunfish	2934
3.8	10.0	Fish eggs could be hatched, but abnormal young were produced of extreme pH's	1468
4.0	10.0	The most resistant fish can tolerate such extreme pH values indefinitely after acclimatization	1460
4.0	10.1	Limits for the most resistant species	361
4.0	10.4	Limits for bluegill sunfish with HCl and NaOH	3606
4.1	8.5	Range tolerated by speckled trout in nature	1467
4.1	9.5	Range tolerated by trout	862
4.3	---	Carp died in 5 days	1303
4.4	8.7	Toxic limits for trout	3609
4.5	8–9	Trout eggs and larvae develop normally	1636
4.6	9.5	Toxic limits for perch	3609
4.6	---	Tench died in two days	2977
4.8	---	Lower limit for trout	1304
4.8	---	Illness and early death for carp	2977
4.8	9.2	Toxic limits for fish	1305
5.0	---	Toxic limit for sticklebacks	2941
5.0	9.0	Tolerable range for most fish	361, 2409, 3609
---	8.7	Upper limit for good fishing water	717
5.4	---	Lower limit for carp and tench	1306
---	9.2	Upper limit for trout and perch	2977
5.5	---	Lower limit for general fish protection	1307
5.4	11.4	Fish avoided waters beyond these limits	1046
6.0	11.0	Fish did not avoid waters in this range	1046
6.0	7.2	Optimum range for fish eggs	1468
6.5	8.4	Range tolerated by most freshwater fish	1466
For other aquatic organisms, ranges were reported as follows:			
1.0	---	Mosquito larvae destroyed at this value	1308
2.5	---	Tolerated by *Chlamydomonas, Fragilaria, Asterionella, Aphanizomenon*	2168
3.3	4.7	Mosquito larvae thrived in this range	1309
4.0	---	Toxic for *Paramecium, Volvox, Asplanchna*	2977
7.5	8.4	Good range for plankton production	1021
---	8.5	Algae are destroyed above this value

A Summary of Some Effects of pH on Freshwater Fish and Other Aquatic Organisms

pH	Known effects
11.5–12.0....	Some caddis flies (Trichoptera) survive but emergence reduced.
11.0–11.5....	Rapidly lethal to all species of fish.
10.5–11.0....	Rapidly lethal to salmonids. The upper limit is lethal to carp (Cyprinus carpio), goldfish (Carassius auratus), and pike. Lethal to some stoneflies (Plecoptera) and dragonflies (Odonata). Caddis fly emergence reduced.
10.0–10.5....	Withstood by salmonids for short periods but eventually lethal. Exceeds tolerance of bluegills (Lepomis macrochirus) and probably goldfish. Some typical stoneflies and mayflies (Ephemera) survive with reduced emergence.
9.5–10.0....	Lethal to salmonids over a prolonged period of time and no viable fishery for coldwater species. Reduces populations of warmwater fish and may be harmful to development stages. Causes reduced emergence of some stoneflies.
9.0–9.5.....	Likely to be harmful to salmonids and perch (Perca) if present for a considerable length of time and no viable fishery for coldwater species. Reduced populations of warmwater fish. Carp avoid these levels.
8.5–9.0.....	Approaches tolerance limit of some salmonids, whitefish (Coregonus), catfish (Ictaluridae), and perch. Avoided by goldfish. No apparent effects on invertebrates.
8.0–8.5.....	Motility of carp sperm reduced. Partial mortality of burbot (Lota lota) eggs.
7.0–8.0....	Full fish production. No known harmful effects on adult or immature fish, but 7.0 is near low limit for Gammarus reproduction and perhaps for some other crustaceans.
6.5–7.0.....	Not lethal to fish unless heavy metals or cyanides that are more toxic at low pH are present. Generally full fish production, but for fathead minnow (Pimephales promelas), frequency of spawning and number of eggs are somewhat reduced. Invertebrates except crustaceans relatively normal, including common occurrence of mollusks. Microorganisms, algae, and higher plants essentially normal.
6.0–6.5.....	Unlikely to be toxic to fish unless free carbon dioxide is present in excess of 100 ppm. Good aquatic populations with varied species can exist with some exceptions. Reproduction of Gammarus and Daphnia prevented, perhaps other crustaceans. Aquatic plants and microorganisms relatively normal except fungi frequent.
5.5–6.0.....	Eastern brook trout (Salvelinus fontinalis) survive at over pH 5.5. Rainbow trout (Salmo gairdneri) do not occur. In natural situations, small populations of relatively few species of fish can be found. Growth rate of carp reduced. Spawning of fathead minnow significantly reduced. Mollusks rare.
5.0–5.5.....	Very restricted fish populations but not lethal to any fish species unless CO_2 is high (over 25 ppm), or water contains iron salts. May be lethal to eggs and larvae of sensitive fish species. Prevents spawning of fathead minnow. Benthic invertebrates moderately diverse, with certain black flies (Simuliidae), mayflies (Ephemerella), stoneflies, and midges (Chironomidae) present in numbers. Lethal to other invertebrates such as the mayfly. Bacterial species diversity decreased; yeasts and sulfur and iron bacteria (Thiobacillus-Ferrobacillus) common. Algae reasonably diverse and higher plants will grow.
4.5–5.0.....	No viable fishery can be maintained. Likely to be lethal to eggs and fry of salmonids. A salmonid population could not reproduce. Harmful, but not necessarily lethal to carp. Adult brown trout (Salmo trutta) can survive in peat waters. Benthic fauna restricted, mayflies reduced. Lethal to several typical stoneflies. Inhibits emergence of certain caddis fly, stonefly, and midge larvae. Diatoms are dominant algae.
4.0–4.5.....	Fish populations limited; only a few species survive. Perch, some coarse fish, and pike can acclimate to this pH, but only pike reproduce. Lethal to fathead minnow. Some caddis flies and dragonflies found in such habitats; certain midges dominant. Flora restricted.
3.5–4.0.....	Lethal to salmonids and bluegills. Limit of tolerance of pumkinseed (Lepomis gibbosus), perch, pike, and some coarse fish. All flora and fauna severely restricted in number of species. Cattail (Typha) is only common higher plant.
3.0–3.5.....	Unlikely that any fish can survive for more than a few hours. A few kinds of invertebrates such as certain midges and alderflies, and a few species of algae may be found at this pH range and lower

Source: USEPA (1973). Table incorporates information presented by Alabaster and Lloyd (1980).

In response to the acid rain problems occurring in the eastern United States and Canada, the physiological effects of acid stress on fish and other aquatic life have been well documented (e.g., see Alabaster and Lloyd 1980; AFS 1982). A number of researchers have proposed that the toxic action of hydrogen ions on fish under acidic conditions involves production of mucus on the gill epithelium, which interferes with the exchange of respiratory gasses and ions across the gill; precipitation of proteins within the epithelial cells; and/or acidosis of the blood (also affecting oxygen uptake) (Ellis 1937; Westfall 1945; Leivestad, in AFS 1982; Boyd 1990). Hence, respiratory distress and osmotic imbalance are the primary physiological symptoms of acid stress in fish. Less research has been conducted on the effects of acid stress on macroinvertebrates. However, those species that exchange respiratory gasses and regulate ions through their gills (e.g., mayflies and stoneflies) and/or species affected by blood acid-base balance may experience effects similar to fish.

Below a pH of 5.0, mortality occurs in some life stages of certain fish species, although some fishes can be acclimated to pH levels below 4.0. Certain species of macroinvertebrates can tolerate very low pH values. Lackey (1938) found Gammarus spp. in two streams with pH values of 2.2 and 3.2, mosquito larvae in a stream at pH 2.4, and caddis fly larvae (Trichoptera) at pH 2.4. Nevertheless, the primary productivity of freshwater aquatic ecosystems is reduced considerably below pH 5.0, which, in turn, reduces the food supply for higher organisms. Hence, fish that remain present would likely experience reduced numbers and/or growth rates (Alabaster and Lloyd 1980).

The physiological effects on aquatic life induced by high pH (>9) have been studied less than those at low pH. This is likely because high pH waters are less common (Doudoroff and Katz 1950; Alabaster and Lloyd 1980). Several researchers concluded that the toxic mode of action of hydroxyl ions (i.e., high pH values) is hypertrophy of mucus cells at the base of the gill filaments and destruction of gill and skin epithelium, with effects on the eye lens and cornea (Alabaster and Lloyd 1980; Boyd 1990).

Studies have shown that pH values of between 9 and 10 can result in partial mortality for bluegill sunfish (Lepomis macrochirus), rainbow trout (Oncorhynchus mykiss), brown trout (Salmo trutta), salmon, and perch. The majority of freshwater fishes and macroinvertebrates experience harmful effects (lethal or sublethal) at one or more life stages at pH values above 10 (Weibe 1931; AFS 1979; Alabaster and Lloyd 1980). Where high pH is caused by aquatic plant photosynthesis, high water temperatures and supersaturation of dissolved gasses may also occur and may contribute to physiological effects experienced by aquatic organisms, making it difficult to correlate mortality with laboratory data on pH alone. Based on their review of the literature,

Alabaster and Lloyd (1980) stated that chronic exposure to pH values above 10 was harmful to all species studied, while salmonids and some other species were harmed at pH values above 9.

The USEPA has concluded that a pH range of 6.5 to 9.0 provides adequate protection for the life of freshwater fish and bottom-dwelling macroinvertebrates. Outside this range, fish suffer adverse physiological effects that increase in severity as the degree of deviation increases until lethal levels are reached (USEPA 1976, 1986).

EFFECTS OF DIURNAL FLUCTUATIONS AND RAPID PH CHANGES ON AQUATIC LIFE

The pH of lakes and streams often changes during the day in response to photosynthetic activity. In ponds having poorly buffered (low alkalinity) waters, the pH may fall to approximately 7 in the early morning and increase to 9 or more in the afternoon (Boyd 1990). Good fish production usually can be maintained in spite of these daily fluctuations. In most lakes and ponds, diurnal pH fluctuations during the summer, when photosynthetic activity peaks, are generally less than 2 pH units, while in streams are generally less (e.g., 0.5-1.0 units). Unless diurnal fluctuations result in ambient pH falling below 6 or being elevated above 9, they generally have no adverse impact on aquatic life. This is supported by the study findings discussed below.

Although it was once believed that fish could not tolerate sudden pH changes, studies conducted by Brown and Jewell (1926) and Wiebe (1931) showed that certain fish species could tolerate such rapid changes, within the normal pH range. Brown and Jewell (1926) observed catfish and perch living in a bog lake having a pH of 4.4-6.4, and also in a nearby glacial lake having a pH of 8.2-8.7. These researchers demonstrated that the fish from both lakes survived transfer from one lake to another.

Wiebe (1931) reported that sunfish (Lepomis spp.) and goldfish (Carassius auratus) survived rapid changes from pH 7.2 to 9.6 (2.4 units); largemouth bass (Micropterus salmoides) from pH 6.1 to 9.6 (3.5 units); and smallmouth bass (Micropterus dolomieui) from pH 6.6 to 9.3 (2.7 units). Witschi and Ziebell (1979) transferred rainbow trout from water of pH 7.2 to waters of pH 8.5, 9.0, 9.5, and 10.0. Survival after 48 hours was 100% for fish transferred to pH 7.2 and 8.5, 88% for those transferred to pH 9.0, 68% for pH 9.5, with complete mortality occurring for fish transferred to pH 10.0. This study clearly demonstrated that rainbow trout could handle rapid pH changes of 1.3 units (from 7.2 to 8.5) without experiencing acute mortality. The acute mortality that occurred when transferred to pH 9.0, 9.5, and 10.0 water was more likely due to being transferred to a pH outside the acceptable range for the species than due to the pH change itself (Modin, pers. comm., 1998). If no acute mortality occurs, no chronic effects would be expected because of physiological acclimation to the new pH, which occurs within a short period of time (i.e., hours to days).

This work demonstrated that the fish species studied tolerated rapid pH changes of 1.3 to 3.5 units when these changes occurred within the physiological-tolerance pH range. When the pH changed to a value that approached the species' normal upper tolerance level (i.e., 9.0) or exceeded their upper tolerance limit (9.5 and 10.0), mortality occurred (Witschi and Ziebell 1979). Based on findings from these studies and personal communications with CDFG fish pathologists (Modin, pers. comm., 1998), it is concluded that neither acute mortality nor chronic sub-lethal effects would be expected in fish experiencing rapid pH changes when all pH levels to which fish are exposed remain within the range of 6.5 to 8.5. Conversely, these studies suggest that small pH changes (e.g., 1 unit) could have adverse impacts when the resulting pH value falls outside the physiologically acceptable range for a given species. For example, rainbow trout acclimated to pH 9.0, which is at or near the species' upper limit, would be expected to experience high mortality if transferred to pH 10.0 and, in fact, would be expected to experience mortality if transferred to pH 9.5 – a change of just 0.5 units (Witschi and Ziebell 1979; Modin, pers. comm., 1998).

The ability of fish to rapidly acclimate to waters having substantially different pH values is further demonstrated by hatchery stocking programs and the freshwater tropical fish (aquarium) industry, where it is common to move fish from one water body or aquarium to another that differ by at least 0.5 pH units, and often by more than 1.0 pH unit. However, it should be noted that this "stocking" of fish typically involves waters with pH values in the range of 6.5 to 8.5 units so that the fish are transferred to waters with pH values well within the range that is physiologically acceptable to them. Available data regarding pH values tolerated by macroinvertebrates suggest that, like fish, they can rapidly adapt to changes in ambient pH levels within their natural pH range (Alabaster and Lloyd 1980; Boyd 1990).

A technical review of the effects of rapid pH changes on benthic macroinvertebrates revealed evidence indicating that macroinvertebrates rapidly exposed to pH changes of one unit or more, when pH is maintained within the 6.5 to 8.5 range, would not experience mortality, or other long-term adverse effects. Information supporting this finding is discussed further below.

The available scientific literature on the effects of rapid pH reductions on benthic macroinvertebrates provides evidence to suggest that rapid pH reductions of one unit or more, when pH is maintained between 6.5 and 8.5, would not cause chronic, adverse effect on individual macroinvertebrates or their populations. A thorough review of the scientific literature was conducted to identify studies that investigated the effects of rapid pH changes on macroinvertebrates, when pH was maintained between 6.5 and 8.5. No such studies were found. The fact that no studies of this nature could be found in the literature further supports the contention that rapid pH changes within the 6.5 to 8.5 range are not problematic to benthic

macroinvertebrates. Based on the commonality of their experimental approaches, the acidification studies that are available in the scientific literature suggest that significant adverse effects to individual macroinvertebrates and their communities would not be expected to occur upon experiencing a rapid pH reduction unless the ending pH is below 6.0. Several studies that investigated the effects of stream acidification on benthic macroinvertebrate communities, where ending pH was below 6.0, shed additional light on how a pH gradient within a point source discharge mixing zone would affect benthic macroinvertebrates drifting through the zone; hence, findings from these studies are briefly summarized below.

Bernard et al. (1990) acidified experimental reaches of a British Columbia stream from pH 7.0 to 5.9 within 30 minutes to assess the effect of mild acidification on short-term invertebrate drift. They reported that small Ephemeroptera showed no initial response to pH reductions from 7.0 to 5.9, but that their drift increased after about 6 hours. Increased drift was observed for Chironomid and Trichoptera within an hour of reaching pH 5.9. Harpactacoid copepods, Hydrcarina, simulid Diptera, Plecoptera, and large Ephemeroptera did not respond. Lack of a drift response induced by rapid pH reduction in certain taxa demonstrates that the organisms were not adversely affected enough to move, and consequently, would not be affected enough to experience mortality. Kratz et al. (1994) reported that Simuliids (black flies) did not respond to rapid depressions of 1 pH unit below ambient, with an ending pH of below 6.0. Also, Hall et al. (1987) reported no effect on daytime drift rates in acidic Norris Brook, where pH was reduced from 6.4 to 5.2-5.5. Bernard et al. (1990) surmised that the rapid, large increases in drift exhibited by chironomids were avoidance behavior. Sensitive organisms may escape by drift to more suitable conditions downstream. Bernard (1985) (cited in Bernard et al. 1990) supported this hypothesis by showing that rapidly responding mayflies collected in a stream rapidly acidified to pH 5.7 had greater than 95% survival when subsequently held in circumneutral water for 24 hours. Kratz et al. (1994) concurred with these findings, suggesting that mild pH reductions (i.e., those with an ending pH near 6.0 or above) would likely elicit increased drift in some species due to behavioral responses rather than from causing pH-related mortality, whereas mortality-induced drift would increase as ending pH decreases, and reached lethal levels (e.g., 5.5 or lower).

To determine the direct effects of water chemistry on invertebrates sensitive to pH reductions, Rosemond et al. (1992) transplanted three mayfly species (i.e., *Drunella conestee (*Family Ephemerellidae) and *Stenonema* sp. and *Epeorus pleuralis* (Family Heptageniidae)) from a stream having pH of 6.6-6.8 to: 1) the stream from which they were collected (i.e., back into pH 6.6-6.8), and 2) a stream of pH 5.0 (a rapid pH change of 1.6-1.8 units). In the first *in situ* transplant experiment, there was no significant difference in mortality among the individuals of *Drunella conestee* transplanted into the two sites through 9 days post transplant. Mortality rates were 32% for organisms transplanted back into the same pH, and 28% for those transplanted into

pH 5.0. In the second *in situ* experiment, using *Stenonema* sp., and *Epeorus pleuralis*, both species transplanted into the pH 5.0 stream experienced significantly higher mortality that those transplanted back into the original stream. In addition, the ultimate mortality experienced by these two species transplanted into the pH 5.0 stream differed significantly. These researchers concluded that the different sensitivities of the three species was due to differences in sensitivities to ending pH and acquired body burdens of aluminum, rather than to the initially-experienced rapid change in pH. This was supported by the fact that it took 2-6 days for mortality rates to differ between transplant groups for the same species. An inability to tolerate the initial pH shock (an acute phenomenon) would be expected to become apparent within a matter of hours rather than days. This is of particular relevance because macroinvertebrates drifting through a mixing zone would typically pass through the zone in a matter of minutes to hours.

Bell and Nebeker (1969) investigated the tolerance of aquatic insects to low pH. In this study, caddisfly, stonefly, dragonfly, and mayfly nymphs were exposed to a range of pH levels for 96 hours (4 days) to determine the pH levels at which 50% of the test organisms died (96-hr TL_{50}). Field-collected nymphs were acclimated to the laboratory for one week at pH 7.8. However, no gradual acclimation to test pH levels was reported. In fact the methods stated: "*If the test pH deviated by more than 0.25 pH units from the desired pH, the test was terminated*." Hence, test organisms were taken directly from their laboratory acclimation tank (pH 7.8), and placed directly into test tanks maintained at pH 1.0-7.0. The 96-hr TL_{50} values reported for the 10 species tested (from the families identified above) ranged from a low of 1.5 (the caddisfly *Brachycentrus americanus*) to a high of 4.65 (the mayfly *Ephemerella subvaria*) pH units. All 10 species tested showed 100% survival at pH 6.0, a 1.8 unit change from their acclimated pH of 7.8. The mayfly *Ephemerella subvaria* began to experience some mortality at test pH levels below 6.0. However, the caddisfly *Hydropsyche betteni*, stonefly *Acroneuria lycorias*, dragonfly *Boyeria vinosa*, and mayfly *Stenonema rubrum* all showed 100% survival at test pH levels as low as 5.5. Hence, these species showed no mortality when transferred from the acclimation tank at pH 7.8 to test tanks at pH 5.5, thereby experiencing a rapid pH change of 2.3 pH units. The caddisfly *Brachycentrus americanus* showed 100% survival to pH levels of 4.5, thereby experiencing a rapid pH change of 3.3 pH units.

In a follow-up study, Bell (1970) performed similar experiments with the same species of benthic macroinvertebrates, but extended the test period from 96 hours to 30 days. Findings were similar to the 96-hr study, except that the 30-day TL_{50}s were somewhat higher (i.e., higher pH levels) than those reported for the 96-exposure. These studies' findings concur with those of the studies discussed above, indicating that the ending pH is more important in determining mortality than the magnitude and rate of initial pH change.

These studies showed that rapid pH reductions of up to 1.6 pH units, with an ending pH below 6.0, did not cause elevated mortality in mayflies, a taxa of benthic macroinvertebrates shown through numerous studies (e.g., Kratz et al. 1994; Feldman and Connor 1992; Rosemond et al. 1992) to be the most sensitive taxa to pH reductions. Mortality was not shown to occur in sensitive mayfly species, or other macroinvertebrate taxa, when the ending pH was maintained at or above 6.5, as would always occur under compliance with the proposed pH objective.

Personal communications with several macroinvertebrate experts provide evidence in support of the conclusions pertaining to rapid pH changes stated above. S. Cooper (U.C. Santa Barbra, pers. comm., 1999), R. Haro (U.W. LaCrosse, pers. comm., 1999), and J. Harrington (CDFG, pers. comm., 1999) all concurred that the lack of studies in the scientific literature addressing pH changes within the 6.5 to 8.5 range suggest that rapid changes within this range are unlikely to adversely affect macroinvertebrates. Moreover, none of these experts were aware of any studies reported in the literature that document mortality to macroinvertebrates resulting from rapid pH changes with in the 6.5 to 8.5 range.

When asked to give their professional opinion regarding potential effects of rapid pH changes on benthic macroinvertebrates within the context of what can occur across the mixing zone associated with a municipal effluent discharge, the following statements were made.

A pH change from 8.5 to 7.0 would not be expected to have a lethal effect, but could have a sublethal (e.g., behavioral) effect. Nevertheless, sublethal effects would be expected to cease when the macroinvertebrates acclimated to the new pH. One would not expect to see lethal effects until the ending pH fell outside the normal pH range, perhaps 5.5 or 5.0 pH units (Cooper, pers. comm., 1999). S. Cooper is considered to be the leading expert on the West Coast regarding the effects of acid pulses on stream benthic macroinvertebrates.

As long as pH remained within the 6.5 to 8.5 range (referred to as circumneutral), there generally would not be any substantial adverse effects to macroinvertebrates drifting downstream into the effluent-dominated portion of the creek, where pH could be 1-2 units lower. Short-term sublethal (e.g., behavioral) effects could occur in some species (Haro, pers. comm., 1999).

In discussions with Jim Harrington of CDFG, regarding ranges of pH acceptable to aquatic life, he stated the following, *"The pH range of 6.5 to 8.5 is accepted to represent safe levels, and this is probably why there is not much literature on its effects to the aquatic system. When I write biological significance reports on pH-related spill events, I would conclude that there would be no deleterious effects within this range."* (Harrington, pers. comm., 1999).

The USEPA's past and current national pH criteria for the protection of aquatic life provide evidence to suggest that rapid pH changes, when pH is maintained within the 6.5 to 8.5 range, would not cause adverse impacts to benthic macroinvertebrates or their communities. Based on the language used by the NAS in its 1972 criteria referring to pH changes above or below the "…natural seasonal", it is clear that the 0.5 unit of change allowed under the "nearly maximum level of protection" was defined to limit the ambient pH range, not the magnitude of rapid change within this range. In fact, no quantitative criterion was assigned to limit rapid pH changes within the preferred pH range of 6.5 to 8.5. Similarly, the USEPA's current pH criterion for the protection of freshwater aquatic life (USEPA 1986, 1999a) simply defines an acceptable ambient pH range (i.e., 6.5-9.0), but does not quantitatively limit the magnitude of rapid change that organisms can be exposed to within this range (e.g., during movement through mixing zones associated with point-source discharges). Because the magnitude of rapid change to which freshwater aquatic life are exposed, within acceptable ambient pH ranges, has never been regulated as part of any national pH criterion, it can be reasonably concluded that all available scientific data on this issue indicate that the effects of rapid pH changes are insignificant when pH is maintained within the acceptable ambient range (e.g., 6.5-8.5).

Based on the above discussion, the proposed pH amendment is strongly supported by the current science regarding pH requirements of freshwater aquatic life and would be consistent with, but somewhat more restrictive than, USEPA's current national recommended criteria for the protection of freshwater aquatic life.

National Pollutant Discharge Elimination System (NPDES) Permit Writers' Manual

This guidance was developed by staff within the U.S. Environmental Protection Agency's (EPA's) Office of Wastewater Management and addresses development of wastewater discharge permits under the National Pollutant Discharge Elimination System (NPDES). NPDES permit development is governed by existing requirements of the Clean Water Act (CWA) and the EPA NPDES implementing regulations. CWA provisions and regulations contain legally binding requirements. This document does not substitute for those provisions or regulations. Recommendations in this guidance are not binding; the permitting authority may consider other approaches consistent with the CWA and EPA regulations. When EPA makes a permitting decision, it will make each decision on a case-by-case basis and will be guided by the applicable requirements of the CWA and implementing regulations, taking into account comments and information presented at that time by interested persons regarding the appropriateness of applying these recommendations to the situation. This guidance incorporates, and does not modify, existing EPA policy and guidance on developing NPDES permits. EPA may change this guidance in the future.

Introduction to the Manual

This manual reviews the statutory and regulatory framework of the National Pollutant Discharge Elimination System (NPDES) program and examines technical considerations for developing NPDES permits for wastewater discharges. The manual is designed, primarily, for new permit writers becoming acquainted with the NPDES program and the process of permit writing, but can also serve as a reference for experienced permit writers or anyone interested in learning about the legal and technical aspects of developing NPDES permits. This manual replaces the *1996 U.S. EPA NPDES Permit Writers' Manual*[1] <www.epa.gov/npdes/pubs/owm0243.pdf>, which updated the *1993 Training Manual for NPDES Permit Writers*[2] <www.epa.gov/npdes/pubs/owm0339.pdf>.

To assist the reader, acronyms and abbreviations are defined for the first use in each chapter and in Appendix A of the manual. Endnotes are provided at the end of each chapter.

Purpose of this Manual

The purpose of this *NPDES Permit Writers' Manual* (manual) is to provide a general reference for permitting authorities that outlines and explains the core elements of the NPDES permit program. The core elements form the foundation of the NPDES program on which guidance for specific areas of the program (e.g., stormwater, concentrated animal feeding operations) can be built. While the guidance for these core program areas will be applicable in many cases, the U.S. Environmental Protection Agency (EPA) recognizes that each EPA Regional Office or authorized state, territory, or tribe (hereafter *state*) will tailor specific aspects of its NPDES permitting procedures to address state and local laws and site-specific concerns and conditions.

The specific objectives and functions of this manual are as follows:

- Provide an overview of the scope and the statutory and regulatory framework of the NPDES program.
- Describe the essential components of a permit and provide an overview of the permitting process.
- Describe the different types of effluent limitations and the legal and technical considerations involved in developing effluent limitations.
- Describe the legal and technical considerations involved in developing other permit conditions including
  - Monitoring and reporting requirements.
  - Special conditions.
  - Standard conditions.
- Describe other permitting considerations including
  - Variances.
  - Anti-backsliding.
  - Other applicable statutes.

- Explain the administrative process for issuing, modifying, revoking and terminating NPDES permits.

This manual is not intended to be a standalone reference document. Rather, it establishes the framework for NPDES permit development and should be supplemented, where necessary, by additional EPA and state regulations, policy, and detailed guidance applicable to specific types of dischargers and circumstances. To that end, this manual identifies and references relevant regulations, policy, and other guidance documents throughout the text.

Publications Referenced

This manual provides links to publications available online that supplement the information in the manual. All documents available electronically were accessed and available as of the date of this manual's publication. Some documents are not available in an electronic format. In those instances, readers should check the following sources to determine the availability of and to obtain printed copies of the documents:

- Office of Water Resource Center (OWRC) <www.epa.gov/safewater/resource/>
  OWRC is a contractor-operated facility providing document delivery, information/referral, and reference services to public users and EPA staff interested in Office of Water Program information
  phone: 202-566-1729 or 800-832-7828, fax: 202-566-1736, e-mail: <center.water-resource@epa.gov>.
- EPA Library Services and Repositories <www.epa.gov/natlibra/libraries.htm>
  EPA's library services and repositories provide access to information about the environment and related scientific, technical, management, and policy information. Library services <www.epa.gov/natlibra/library_services.html> are delivered through the National Library Network <www.epa.gov/natlibra/index.html>.
- National Service Center for Environmental Publications (NSCEP) <www.epa.gov/ncepihom/>
  NSCEP, formerly NCEPI, maintains and distributes EPA publications in hardcopy, CD ROM and other multimedia formats. The publication inventory includes more than 7,000 titles
  phone: 513-489-8190 or 800-490-9198, fax: 513-489-8695, e-mail: ncepimal@one.net.
- National Technical Information Service (NTIS) <www.ntis.gov/>
  NTIS is the largest central resource for government-funded scientific, technical, engineering, and business related information covering more than 350 subject areas from more than 200 federal agencies
  phone: 703-605-6050 or 888-584-8332, fax: 703-605-6900, e-mail: customerservice@ntis.gov.

Legislative and Regulatory Citations

There are a number of different conventions used to cite legislation and regulations. In this manual, the following conventions have been used:

- When citing the *United States Code*, the abbreviation U.S.C. is used. The abbreviation is preceded by the Title of the U.S.C. and then followed by the section number.
  Example: 16 U.S.C. 1531 *et seq*. and 33 U.S.C. §§ 1251-1387.

NMED Exhibit 70

- When citing the Clean Water Act, the abbreviation CWA is used. The abbreviation is followed by the word *section* and then the section number.
  Example: CWA section 402 and CWA section 402(o).
- When citing the *Code of Federal Regulations* (CFR), the convention depends on the location of the reference. For first references, the abbreviation CFR is preceded by the title number of the CFR and followed either by the word *Part* (if it is a part—a whole number) or the number of the subsection (if it is a subpart/subsection). For subsequent references, the title and CFR are omitted and just the word *Part* or the section symbol (§) is used.
  Example: First citation: 40 CFR Part 136 or 40 CFR 122.44
  Subsequent citations: Part 136 or § 122.44.

Almost all the regulatory citations in this manual are for Title 40 of the CFR (with the exception of the other federal laws referenced in section 11.1 of this manual). Any other Titles are explicitly referenced and in the format for the first regulatory citation (e.g., 50 CFR Part 402).

Electronic NPDES Information

Websites and electronically stored publications and data are available to help permit writers draft NPDES permits. Tools have been created to assist permit writers with specific aspects of permit development and are discussed in their respective sections. The electronic tools listed below apply to all aspects of permit development and serve as valuable references for the permit writer.

NPDES Website and Resources

The Water Permits Division (WPD) within the EPA Office of Water (OW), Office of Wastewater Management, has developed a comprehensive NPDES Website <www.epa.gov/npdes> with technical and regulatory information about the NPDES permit program, information on related programs and initiatives, and documents published by WPD. Where applicable, this manual references the NPDES Website and provides links to relevant documents on that site. This manual also references other EPA and non-EPA websites that contain information that might be helpful to NPDES permit writers. Note, however, that EPA is not responsible for information provided on websites outside the EPA Website <www.epa.gov>.

WPD also has prepared several websites and other resources to help permit writers draft permits. This manual references those websites and resources in the appropriate section of this manual.

Electronic Permitting Tools

Many EPA Regions and authorized states have developed tools to help them manage the permit issuance process. Electronic permitting tools range from spreadsheets and word processing applications to sophisticated Web-based systems that enable permitting authorities to manage their entire environmental program. For example, some states have built systems that enable dischargers to electronically sign and submit discharge reports; create, track, and store permit documents; and manage enforcement, compliance, and inspections related to permits. As technologies continue to evolve, many permitting authorities are likely to begin using more information technology applications to manage the process of permitting.

NMED Exhibit 70

ICIS-NPDES

Together with OW, the Office of Enforcement and Compliance Assurance (OECA) is responsible for oversight of implementation of the NPDES program. OW is responsible for the NPDES implementing regulations and oversight of permit issuance by states and EPA Regions. OECA, along with its regional, state, tribal and local counterparts, is responsible for tracking and maintaining enforcement and compliance activities, monitoring and enforcement and compliance status of the regulated community, and reviewing and evaluating program performance. OECA also maintains national data systems to support program management and oversight of the NPDES program.

The Permit Compliance System (PCS), one of two national NPDES electronic databases, supports the management and oversight of the NPDES program. Since the last modernization of PCS in 1985, the NPDES program has evolved significantly to include additional program requirements, such as the NPDES program for stormwater and implementation of the Combined Sewer Overflow Control Policy. Because of limitations to PCS, OECA is working to phase out this system and move to a more modern data management system described below.

The Integrated Compliance Information System for NPDES permits (ICIS-NPDES) <https://icis.epa.gov/icis>, the successor to PCS, provides an updated system that enables national program management and oversight activities such as

- Permit tracking and management.
- Compliance monitoring.
- NPDES program management.
- Enforcement actions.

ICIS-NPDES is a Web-based system with an electronic database capable of handling the large amount of data generated by and about the NPDES program. Section 11.5.1.1 of this manual provides more information on ICIS-NPDES as it relates to NPDES permit compliance.

Hyperlinks in this Document

Where a website provides supplementary information or is referenced in this manual, the actual site or higher level site address appears in the symbols < > so that readers will have a reference to the address even in a printed version of this document. In the electronic version of the manual, the text in carats is also the hyperlink to the referenced website. Care has been taken to provide the correct Web addresses and hyperlinks; however, these references can change or become outdated after this manual's publication.

NMED Exhibit 70

CHAPTER 1. Development of the Clean Water Act and the NPDES Program

This chapter presents an overview of the history of water pollution control in the United States and the evolution and accomplishments of the National Pollutant Discharge Elimination System (NPDES) Program.

1.1 History of Water Pollution Control in the United States

Major water pollution control legislation in the United States dates back to the end of the 19th century. Exhibit 1-1 presents a summary of key legislative and executive actions in the history of clean water program development in the United States.

Exhibit 1-1 Important milestones of clean water program development

1899 Rivers and Harbors Act
1948 Federal Water Pollution Control Act (FWPCA)
1965 Water Quality Act
1970 Executive Order–U.S. Environmental Protection Agency (EPA) established
1970 Refuse Act Permit Program (RAPP)
1972 FWPCA Amendments
1977 Clean Water Act (CWA)
1987 Water Quality Act (WQA)

The first major water pollution control statute was the **1899 Rivers and Harbors Act**, which established permit requirements to prevent unauthorized obstruction or alteration of any navigable water of the United States. That act focused on navigation rather than water quality.

The **1948 Federal Water Pollution Control Act (FWPCA)** initiated the federal government's involvement in water pollution control for public health protection. The act allotted funds to state and local governments for water pollution control and emphasized the states' role in controlling and protecting water resources with few federal limitations or guidelines. The act, however, did charge the U.S. Surgeon General with developing comprehensive programs to eliminate or reduce the pollution of interstate waters.

Over the next two decades, Congress became increasingly interested in the problem of water quality degradation. From 1956 through 1966, it enacted four major laws to strengthen the federal role in water pollution control, including the FWPCA Amendments of 1956 and the FWPCA Amendments of 1961. Those statutes focused primarily on providing funding to municipalities to construct wastewater treatment plants.

Just a few years later, Congress further strengthened federal water pollution control laws by enacting the **1965 Water Quality Act**. This law created the Federal Water Pollution Control Administration and

NMED Exhibit 70

represented a major regulatory advancement in water pollution control by requiring states to develop water quality standards for interstate waters by 1967. The Water Quality Act also called for states to quantify the amount of pollutants that each discharger could release without exceeding the water quality standards (i.e., pollutant loadings). Despite escalating public concern and increased public spending, only about half of the states developed water quality standards by 1971. Furthermore, enforcement of the federal statute was minimal because the regulatory agencies had to demonstrate a direct link between a discharge and a health or water quality problem, and the scientific data to make such demonstrations were often lacking. Finally, there were no criminal or civil penalties for violations of statutory requirements.

Growing concern about the environment prompted President Nixon to form the **U.S. Environmental Protection Agency (EPA**) in 1970 to enforce environmental compliance and consolidate federal pollution control activities. That year, the President also created the **Refuse Act Permit Program (RAPP)** through Executive Order 11574 and under the authority of section 13 of the 1899 Rivers and Harbors Act (a section also known as the Refuse Act). This new permitting program was focused on controlling industrial water pollution. EPA and the U.S. Army Corps of Engineers (Corps) would prepare the program requirements and the Corps would administer the program. EPA was tasked with developing *guidelines on effluent quality* for 22 different categories of sources. A discharger would apply for a permit, and the Corps would ask EPA if the proposed effluent levels were consonant with state water quality standards and with the newly developed guidelines on effluent quality. States would be asked to examine permit applications and advise EPA whether existing or proposed treatment processes would ensure that established water quality standards would be met. EPA would review the state's response for interstate waters and instruct the Corps whether to issue the permit. However, the U.S. District Court for the District of Columbia struck down RAPP (*Kalur v. Resor*, Civ. Action No. 1331-71 [D.D.C. Dec. 21, 1971]) because the program would allow the issuance of permits to discharge refuse to non-navigable tributaries of navigable waterways, which the Court said exceeded the authority given in the Act, and because the regulations implementing the program did not require compliance with certain procedural requirements of the National Environmental Policy Act.

Because of the perceived need for a discharge permit program, and to rectify the problems encountered in earlier water pollution control legislation, Congress enacted the **FWPCA Amendments of 1972**. This legislation, which was passed over a Presidential veto in November 1972, provided a comprehensive re-codification and revision of past federal water pollution control law. The 1972 amendments marked a distinct change in the philosophy of water pollution control in the United States and marked the beginning of the present water programs, including the NPDES permit program. Under those amendments, the federal government assumed a major role in directing and defining water pollution control programs. In establishing the basis for clean water programs, Congress sought a balance between economics (considering both the costs and benefits of cleanup) and ecology (setting deadlines and ambitious requirements for reducing discharges and restoring water quality).

The FWPCA Amendments of 1972 established a series of goals in section 101. Perhaps the most notable goal was that the discharge of pollutants into navigable waters be eliminated by 1985. Although that goal remains unmet, it underlies the CWA approach to establishing the technology standards that are implemented through technology-based effluent limitations (TBELs) in NPDES permits. The FWPCA Amendments of 1972 also set an interim goal of achieving, "water quality [that] provides for the protection and propagation of fish, shellfish, and wildlife and provides for recreation in and on the water" by July 1, 1983. That goal is commonly referred to as the *fishable, swimmable* goal of the act and is one

NMED Exhibit 70

of the factors that states must consider in the development of their water quality standards. The water quality standards are implemented in NPDES permits through water quality-based effluent limitations (WQBELs). By prohibiting the discharge of a pollutant or pollutants from a point source to waters of the United States—except as in compliance with the statute, the FWPCA Amendments of 1972 also established the important principle that the discharge of pollutants to navigable waters is not a right.

Since 1972, the FWPCA has been further amended on several occasions, including the **1977 Clean Water Act** (CWA), which is now the name for the statute, and the **1987 Water Quality Act** (WQA). Both of these statutes are discussed further in section 1.2 below with regard to their impact on the evolution of the NPDES program. Exhibit B-1, Index to Sections of the CWA, in Appendix B of this document matches the key sections of the CWA to their appropriate reference in the *United States Code* (U.S.C.). This information is at U.S.C., Title 33 (Navigation and Navigable Waters), Chapter 26 (Water Pollution Prevention and Control), 1251-1387 (33 U.S.C. §§ 1251-1387) <www.epa.gov/lawsregs/laws/cwa.html>.

1.2 Evolution of the NPDES Program

Section 402 of Title IV of the FWPCA, Permits and Licenses, created today's system for permitting wastewater discharges, known as the NPDES program. Under the requirements of the program, a point source may be authorized to discharge pollutants into waters of the United States by obtaining a permit. Section 1.3 below discusses this basic statutory framework in detail. A permit provides two types of control: technology-based limitations (based on the technological and economic ability of dischargers in the same category to control the discharge of pollutants in wastewater) and water quality-based limitations (to protect the quality of the specific waterbody receiving the discharge).

The FWPCA Amendments of 1972 established several important requirements and deadlines. Municipal facilities were required to meet secondary treatment standards by July 1, 1977. Industrial facilities were required to meet two levels of technology standards: *Best Practicable Control Technology Currently Available* (BPT) and *Best Available Technology Economically Achievable* (BAT), which would bring them further toward the goal of eliminating the discharge of all pollutants. [CWA section 301 (b)(2)(A)]. Compliance deadlines for BPT and BAT were established as of July 1, 1977, and July 1, 1983, respectively.

In addition to BPT and BAT requirements for industrial categories, the 1972 FWPCA Amendments established *new source performance standards* (NSPS) or best available demonstrated control technology including where practicable a standard permitting no discharge of pollutants [CWA section 306(a)]. The Legislative History indicates that Congress believed that technologies would be more affordable for new dischargers who could plan control technologies at the design phase. The standards represent state-of-the-art control technologies for new sources because the permittees have the opportunity to install the most efficient production processes and the latest in treatment technologies during construction. NSPS are effective on the date the facility begins operation, and the facility must demonstrate compliance within 90 days of start-up.

EPA tried to set national, uniform effluent limitations guidelines and standards (effluent guidelines) as a basis for technology-based limitations; however, most effluent guidelines were not in place when the first set of permits was issued between 1973 and 1976. About 75 percent of the first round permits were issued

NMED Exhibit 70

under a section of the act that allows a permit writer to use his or her best professional judgment to establish case-by-case limitations. Using that approach, a single permit writer developed effluent limitations for a specific facility using his or her knowledge of the industry and the specific discharge, rather than using a set of national standards and limitations developed by EPA for the entire industry.

This first round of permitting focused on *conventional pollutants*, which generally are found in sanitary waste from households, businesses, and industries. CWA section 304(a)(4) and Title 40 of the *Code of Federal Regulations* (CFR) 401.16 designate the conventional pollutants with oil and grease added to § 401.16 in 1979. The following are formally designated as conventional pollutants:

- Five-day Biochemical Oxygen Demand (BOD_5).
- Total Suspended Solids (TSS).
- pH.
- Fecal Coliform.
- Oil and Grease.

The 1972 FWPCA Amendments, however, also required that EPA publish a list of toxic pollutants within 90 days and propose effluent standards for those pollutants 6 months later. EPA was not able to meet those requirements because of the lack of information on treatability. The Natural Resources Defense Council (NRDC) sued EPA, resulting in a court supervised *consent decree* (*NRDC et al. v. Train, 8 E.R.C. 2120*, DDC 1976) that identified the following:

- Toxic (priority) pollutants to be controlled.
- Primary industries for technology-based control.
- Methods for regulating toxic discharges through the authorities of the FWPCA Amendments.

The provisions of the consent decree were incorporated into the framework of the 1977 FWPCA Amendments, formally known as the CWA. This statute shifted the emphasis of the NPDES program from controlling conventional pollutants to controlling toxic pollutant discharges. CWA section 307(a)(1) required EPA to publish a list of toxic pollutants or combination of pollutants. Those pollutants often are called the priority pollutants and are listed in § 401.15. The terms *toxic pollutant* and *priority pollutant* are used interchangeably throughout this document.

CWA section 307(a) originally identified 65 toxic pollutants and classes of pollutants for 21 major categories of industries (known as *primary industries*). That list was later further defined as the current list of 126 toxic pollutants. The priority pollutants are listed in Appendix C of this document and in Appendix A of Part 423. Note that the list goes up to 129; however, there are only 126 priority pollutants because 017, 049, and 050 were deleted.

The 1977 CWA adjusted technology standards to reflect the shift toward control of toxics, clarified and expanded the concept of BAT controls, created a new level of control for conventional pollutants, and made changes to strengthen the industrial pretreatment program. The 1977 law created a new pollutant category, nonconventional pollutants, that included pollutants (such as chlorine and ammonia) not specifically categorized as conventional or toxic. The CWA clarified that BAT covers both toxic and nonconventional pollutants, extended the compliance deadline for BAT for toxic pollutants to July 1, 1984, established a three-year deadline for compliance with BAT for newly listed toxics, and gave industries until as late as July 1, 1987 to meet BAT requirements for nonconventional pollutants. In addition, conventional pollutants, controlled by BPT and BAT in the first round of permitting, were now

NMED Exhibit 70

subject to a new level of control termed *Best Conventional Pollutant Control Technology* (BCT). The CWA established a compliance deadline for BCT of July 1, 1984. BCT was not an additional performance standard, but replaced BAT for the control of conventional pollutants. Finally, among other changes, the 1977 CWA authorized EPA to approve local pretreatment programs and required authorized states to modify their programs to provide for local pretreatment program oversight.

The 1977 CWA recognized that the technology-based limitations were not able to prevent the discharge of toxic substances in toxic amounts in all waterways. To complement its work on technology-based limitations, EPA initiated a national policy in February 1984 to control toxics using a water quality approach. On February 4, 1987, Congress amended the CWA with the 1987 WQA that outlined a strategy to accomplish the goal of meeting state water quality standards. The 1987 WQA required all states to identify waters that were not expected to meet water quality standards after technology-based controls on point source were imposed. Each state then had to prepare individual control strategies to reduce toxics from point and nonpoint sources to meet the water quality standards. Among other measures, those plans were expected to address control of pollutants beyond technology-based levels.

The 1987 WQA further extended the compliance deadline for BAT- and BCT-based effluent limitations, this time to a new deadline of March 31, 1989. The 1987 WQA also established new schedules for issuing NPDES permits to industrial and municipal stormwater dischargers. In addition to meeting water quality-based standards, industrial stormwater discharges must meet the equivalent of BAT and BCT effluent quality standards. *Municipal separate storm sewer systems* (MS4s) were required to have controls to reduce pollutant discharges to the *maximum extent practicable* (MEP), including management practices, control techniques and system design and engineering methods, and such other provisions as the Administrator deems appropriate for the control of such pollutants [CWA section 402(p)(3)(B)]. The 1987 WQA also required EPA to identify toxics in sewage sludge and establish numeric limitations to control such toxics. A statutory *anti-backsliding* requirement in the WQA specified the circumstances under which an existing permit can be modified or reissued with less stringent effluent limitations, standards, or conditions than those already imposed.

Since 1987, there have been minor revisions to the CWA (e.g., Combined Sewer Overflow program requirements). However, the basic structure of the NPDES program remains unchanged from the framework established in the 1972 FWPCA Amendments.

1.3 NPDES Statutory Framework

As noted in section 1.2 above, under the NPDES program any point source that discharges or proposes to discharge pollutants into waters of the United States is required to obtain an NPDES permit. Understanding how each of these terms (i.e., permit, pollutant, waters of the United States, and point source) is defined is the key to defining the scope of the NPDES program.

1.3.1 Permit

A permit is a license, issued by the government to a person or persons granting permission to do something that would otherwise be illegal without the permit. An NPDES permit typically is a license for a facility to discharge a specified amount of a pollutant into a receiving water under certain conditions; however, NPDES permits can also authorize facilities to process, incinerate, landfill, or beneficially use

NMED Exhibit 70

biosolids (sewage sludge). A discharger does not have a right to receive a permit, and permits may be revoked for cause such as noncompliance with the conditions of the permit.

1.3.2 Pollutant

The term *pollutant* is defined in CWA section 502(6) and § 122.2. The statute defines pollutant very broadly and includes any type of industrial, municipal, or agricultural waste (including heat) discharged into water. For regulatory purposes, pollutants are grouped into three categories under the NPDES program: conventional, toxic, and nonconventional.

- **Conventional** pollutants are those defined in CWA section 304(a)(4) and § 401.16 (BOD_5, TSS, fecal coliform, pH, and oil and grease).
- **Toxic (priority)** pollutants are those defined in CWA section 307(a)(1) (and listed in § 401.15 and Appendix A of Part 423) and include 126 metals and manmade organic compounds (see Exhibit C-1 in Appendix C of this document).
- **Nonconventional** pollutants are those that do not fall under either of the above categories (conventional or toxic pollutants) and include parameters such as chlorine, ammonia, nitrogen, phosphorus, chemical oxygen demand (COD), and whole effluent toxicity (WET).

Sewage from vessels and, under certain conditions, water, gas, or other material injected into wells to facilitate production of oil or gas or water derived in association with oil and gas production and disposed of in a well are specifically excluded from the definition of pollutant under the NPDES program.

1.3.3 Waters of the United States

The CWA regulates discharges to *navigable waters*. CWA section 502(7) defines navigable waters as "waters of the United States, including the territorial seas." NPDES regulations define *waters of the United States* to mean,

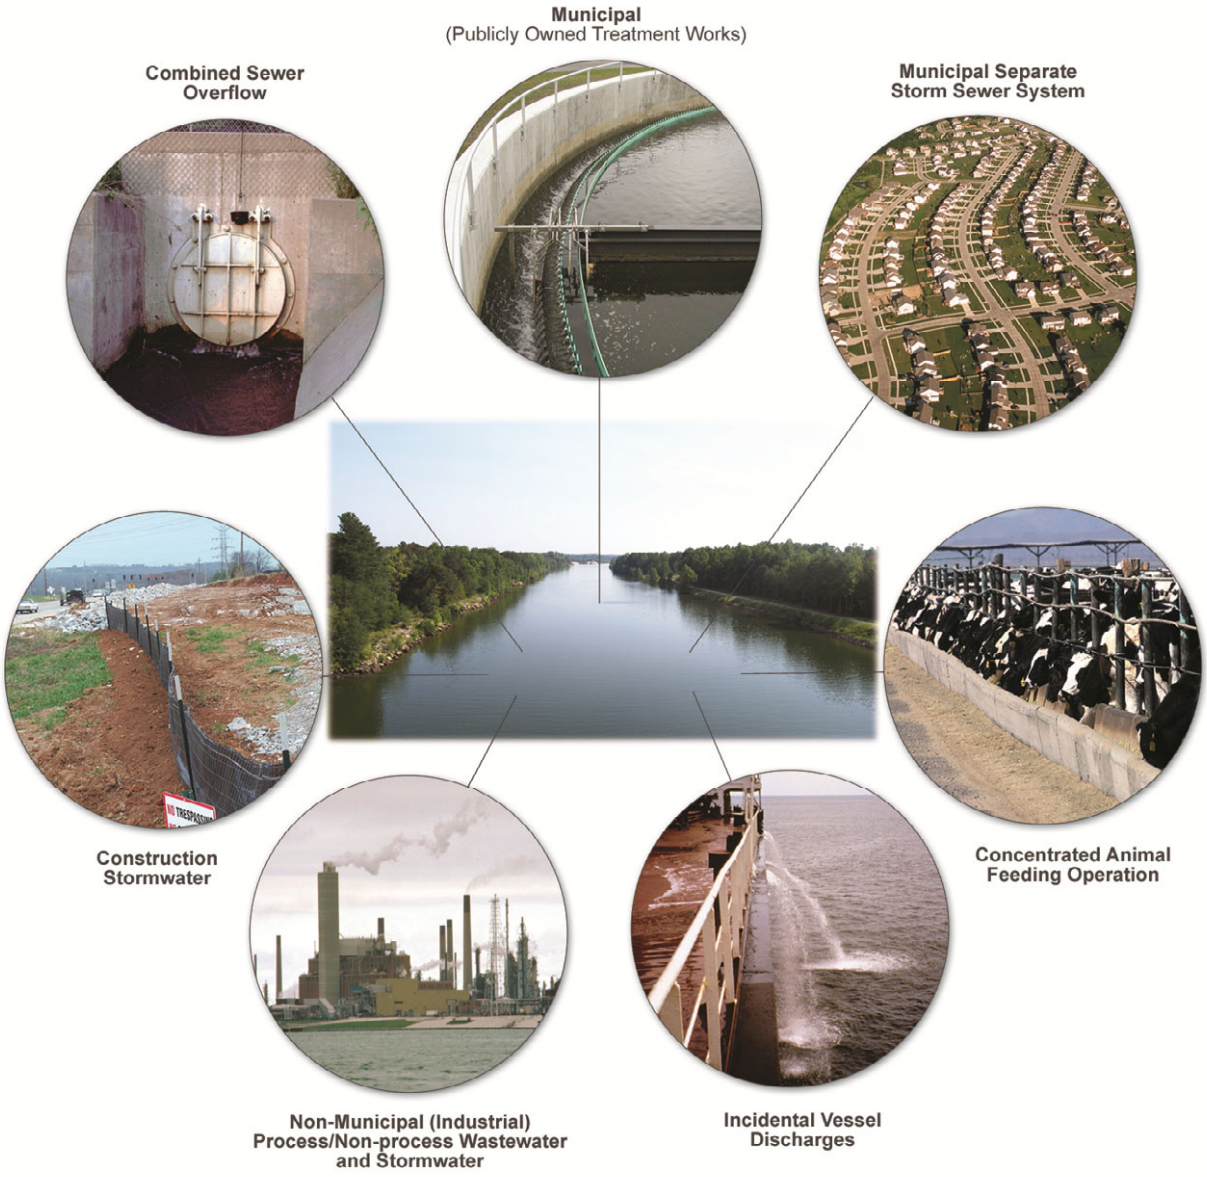
- Waters that are currently used, were used in the past, or may be susceptible to use in interstate or foreign commerce, including waters subject to the ebb and flow of the tide.
- Interstate waters including interstate *wetlands*.
- Other waters that could affect interstate or foreign commerce.
- Impoundments of waters of the United States.
- Tributaries of the above categories of waters.
- Territorial seas.
- Wetlands adjacent to other waters (except wetlands themselves) in the above categories.

Wetlands are further defined in § 122.2. In addition, the definition of waters of the United States contains exclusions for waste treatment systems (other than certain cooling ponds) designed to meet the requirements of the CWA and also for *prior converted croplands*, which is mostly relevant to the CWA section 404 permitting program administered by the Corps.

NMED Exhibit 70

Waters of the United States covers a broad range of surface waters. The CWA does not give EPA the authority to regulate ground water quality through NPDES permits. If a discharge of pollutants to ground water reaches waters of the United States, however, it could be a discharge to the surface water (albeit indirectly via a direct hydrological connection, i.e., the ground water) that needs an NPDES permit.

The scope of waters of the United States has been the subject of several U.S. Supreme Court cases (the most recent as of the time of publication of this manual being a decision from 2006 in the combined Rapanos/Carabell wetland cases) and numerous lower court cases. The court cases often have been difficult to interpret, resulting in much litigation and an evolving understanding of the exact scope of waters subject to CWA jurisdiction. Also, permit writers should keep in mind that discharges through non-jurisdictional features that reach waters of the United States may need a permit even if the discharge is not directly to a jurisdictional waterbody. EPA Regional wetlands staff have significant expertise in jurisdictional issues related to the scope of waters of the United States. Some Regions have interoffice teams to address jurisdictional issues that come up in the different CWA programs. In addition, guidance on waters of the United States is on EPA's Office of Wetlands, Oceans, and Watersheds Website <www.epa.gov/wetlands/guidance/CWAwaters.html>.



1.3.4 Point Source

Pollutants can enter water via a variety of pathways including agricultural, domestic and industrial sources. For regulatory purposes, these sources generally are categorized as either point sources or nonpoint sources. The term *point source* is defined in CWA section 502(14) and § 122.2 to include any discernible, confined, and discrete conveyance from which pollutants are or may be discharged. Point source discharges include discharges from publicly owned treatment works (POTWs), industrial process wastewater discharges, runoff conveyed through a storm sewer system, and discharges from concentrated animal feeding operations (CAFOs), among others (see Exhibit 1-2). Return flows from irrigated agriculture and agricultural stormwater runoff specifically are excluded from the definition of a point source.

Pollutant contributions to waters of the United States may come from both direct and indirect discharges. Direct discharge (which is synonymous with *discharge of a pollutant*) is defined by the NPDES regulations at § 122.2 to include any addition of any pollutant or combination of pollutants to a water of the United States from any point source. An *indirect discharger* is defined as, "a nondomestic discharger introducing pollutants to a POTW." Under the national program, NPDES permits are issued only to direct dischargers. The National Pretreatment Program controls industrial and commercial indirect dischargers (for more on pretreatment, see section 2.3.1.2 of this manual).

NMED Exhibit 70

Exhibit 1-2 Common point source discharges of pollutants to waters of the United States

NMED Exhibit 70

CHAPTER 2. Regulatory Framework and Program Areas of the NPDES Program

This chapter discusses the regulatory framework of the National Pollutant Discharge Elimination System (NPDES) program, identifies the types of activities regulated under the NPDES program, describes the roles and responsibilities of federal and state governments, and presents the program areas that address the various types of regulated activities.

2.1 Regulatory Framework of the NPDES Program

Chapter 1 discussed how Congress, in Clean Water Act (CWA) section 402, required the U.S. Environmental Protection Agency (EPA) to develop and implement the NPDES permit program. While Congress' intent was established in the CWA, EPA was required to develop specific regulations to carry out the congressional mandate. The regulations developed by EPA to implement and administer the NPDES program primarily are in Title 40 of the *Code of Federal Regulations* (CFR) Part 122 <www.epa.gov/lawsregs/search/40cfr.html>.

The CFR is an annual codification of the general and permanent rules published in the *Federal Register* (FR) by the executive departments and agencies of the federal government. The CFR is divided into 50 titles that represent broad areas subject to federal regulation. Title 40 covers protection of the environment. The FR is a legal publication that contains federal agency regulations; proposed rules and notices; and executive orders, proclamations and other presidential documents. The National Archives and Records Administration, an independent federal agency responsible for managing all federal records, publishes the FR and CFR. The text of all final regulations is found in the CFR. The background and implementation information related to these regulations, however, are found in the preamble to the regulations contained in the FR. This information is important to permit writers because it explains the legal, technical, and scientific bases on which regulatory decisions are made.

Exhibit 2-1 lists regulations in 40 CFR that are related to the NPDES program, and Exhibit 2-2 is an outline of the federal NPDES regulations from Part 122. The regulations at § 123.25 should be referenced for information applicable to state NPDES programs. Exhibit B-2 in Appendix B of this document is an Index to NPDES Regulations that provides regulatory citations by topic area.

NMED Exhibit 70

Exhibit 2-1 Regulations related to the NPDES program

Regulation (40 CFR)	Subject
Part 121	State certification
Part 122	The federal NPDES permit program
Part 123	State program requirements
Part 124	Procedures for decision making
Part 125	Technology standards
Part 129	Toxic pollutant effluent standards
Part 130	Water quality planning and management
Part 131	Water quality standards
Part 133	Secondary treatment regulations
Part 135	Citizen suits
Part 136	Analytical procedures
Part 257	State sludge disposal regulations
Part 401	General provisions for effluent limitations guidelines and standards (effluent guidelines)
Part 403	General pretreatment regulations
Parts 405-471	Effluent guidelines
Part 501	State sewage sludge management program requirements
Part 503	Standards for use or disposal of sewage sludge

2.2 Federal and State Responsibilities

This section discusses the relationship between federal and state governments in the administration of the NPDES program and the process by which a state can become *authorized*.

2.2.1 State NPDES Program Authority

EPA may authorize qualified state, territorial, or tribal government agencies to implement all or parts of the NPDES program. States, territories, or tribes (hereafter *states*) are authorized through a process defined by the CWA section 402(b) and NPDES regulations Part 123. A state wanting to be authorized to administer the NPDES program submits to EPA a letter from the governor requesting review and approval of its program submission, a Memorandum of Agreement (MOA), a Program Description, a Statement of Legal Authority (also known as an *Attorney General's Statement* or *AG Statement*), and the underlying state laws and regulations. EPA determines whether the package is complete within 30 days of receipt. Within 90 days of receipt, EPA renders a decision to approve or disapprove the program. The time for review can be extended by agreement. The process of authorization includes a public review and comment period, and a public hearing.

States may apply for the authority to issue one or more of the following five types of NPDES authorization:

- NPDES Base Program for individual municipal and industrial facilities.
- General Permit Program.
- Pretreatment Program.
- Federal Facilities Program.
- Biosolids (Sewage Sludge) Program.

NMED Exhibit 70

Exhibit 2-2 Federal NPDES regulations (40 CFR Part 122)

Subpart A–Definitions and General Program Requirements

§ 122.1 Purpose and scope
§ 122.2 Definitions
§ 122.3 Exclusions
§ 122.4 Prohibitions
§ 122.5 Effect of a permit
§ 122.6 Continuation of expiring permits
§ 122.7 Confidentiality of information

Subpart B–Permit Application and Special NPDES Program Requirements

§ 122.21 Applications
§ 122.22 Signatories to permit applications and reports
§ 122.23 Concentrated animal feeding operations
§ 122.24 Concentrated aquatic animal production
§ 122.25 Aquaculture projects
§ 122.26 Stormwater discharges
§ 122.27 Silviculture activities
§ 122.28 General permits
§ 122.29 New sources and new dischargers
§ 122.30-122.37 MS4s

Subpart C–Permit Conditions

§ 122.41 Standard conditions applicable to all permits
§ 122.42 Standard conditions applicable to specified categories of permits
§ 122.43 Establishing permit conditions
§ 122.44 Establishing limitations, standards, and other permit conditions

(a) Technology basis
(b) Other basis (not WQ)
(c) Reopeners
(d) Water quality basis
(e) Toxic (priority) pollutants
(f) Notification levels
(g) 24 Hour reporting
(h) Duration of permits
(i) Monitoring
(j) Pretreatment program
(k) Best management practices (BMPs)
(l) Anti-backsliding
(m) Privately owned treatment works
(n) Grants
(o) Sewage sludge
(p) Coast Guard
(q) Navigation
(r) Great Lakes
(s) Qualifying programs

§ 122.45 Calculating limitations

(a) Outfalls and discharge points
(b) Production basis
(c) Metals
(d) Continuous discharges
(e) Non-continuous discharges
(f) Mass limitations
(g) Pollutants in intake water
(h) Internal waste streams
(i) Discharge into wells, into publicly owned treatment works or by land application

§ 122.46 Duration of permits
§ 122.47 Schedules of compliance
§ 122.48 Requirements for recording and reporting of monitoring results
§ 122.49 Consideration under federal law
§ 122.50 Disposal into wells, into publicly owned treatment works or by land application

Subpart D–Transfer, Modification, Revocation and Reissuance, and Termination of Permit

§ 122.61 Transfer of permits
§ 122.62 Modification or revocation and reissuance of permits
§ 122.63 Minor modifications of permits
§ 122.64 Termination of permits

NMED Exhibit 70

A state can receive authorization for one or more of the NPDES program components. For example, a state might receive authorization for the NPDES Base Program, General Permit Program, and Pretreatment Program, but not the Federal Facilities Program or Biosolids Program. In such a case, EPA continues to issue permits to federal facilities (e.g., facilities on military installations, federal lands) for discharges originating within the state and continues to implement the Biosolids Program. (Section 2.2.2 below provides additional discussion of Biosolids Program implementation.)

If EPA approves a program, the state assumes permitting authority in lieu of EPA. All new permit applications would then be submitted to the state agency for NPDES permit issuance. Certain permits issued before authorization might continue under EPA administration as set forth in the MOA. Even after a state receives NPDES authorization, EPA continues to issue NPDES permits on tribal lands within the boundaries of the state (if the tribe is not administering its own approved NPDES program). Following authorization, EPA also continues its national program management responsibilities by ensuring that state programs meet applicable federal requirements. If EPA disapproves the program, EPA remains the permitting authority for that state.

The State Program Status Website <www.epa.gov/npdes/authorization> provides the current authorization status for the states.

2.2.2 Roles and Responsibilities of the Federal and State Authorities

Until a state program is authorized, EPA is the permitting authority that issues all permits, conducts all compliance and monitoring activities, and enforces all program requirements.

As noted above, if a state has only partial authority, EPA will implement the other program activities. For example, where a state has an approved NPDES program but has not received EPA approval of its state sewage sludge management program, the EPA Region is responsible for including conditions to implement the Part 503 Standards for the Use or Disposal of Sewage Sludge in permits issued to treatment works treating domestic sewage (TWTDS) in that state. EPA could issue a separate permit with the applicable sewage sludge standards and requirements, or collaborate with the state on joint issuance of NPDES permits containing the Part 503 sewage sludge standards. The same process also applies where a state has not received approval of its pretreatment program or federal facilities program. One exception to that process is where an NPDES-authorized state is not approved to implement the general permit program. In such cases, EPA may not issue a general permit in that state as clarified in the memorandum *EPA's Authority to Issue NPDES General Permits in Approved NPDES States*[1] <www.epa.gov/npdes/pubs/owm0444.pdf>.

Once a state is authorized to issue permits, EPA generally is precluded from issuing permits in the state; however, EPA must be provided with an opportunity to review certain permits and may formally object to elements that conflict with federal requirements. If the permitting agency does not satisfactorily address the points of objection, EPA will issue the permit directly. Once a permit is issued through a government agency, it is enforceable by the approved state and federal agencies (including EPA) with legal authority to implement and enforce the permit. Private citizens may also bring a civil action in federal court against an alleged violator or against the EPA Administrator for alleged failure to enforce NPDES permit requirements. Exhibit 2-3 presents a summary of federal and state roles before and after program authorization.

NMED Exhibit 70

Exhibit 2-3 Summary of federal and state/territorial/tribal roles in the NPDES permitting program

Before state/territorial/tribal program approval:

- EPA issues permits
- EPA conducts compliance and monitoring activities
- EPA enforces
- State/territory/tribe reviews permits and grants CWA section 401 certification

After state/territorial/tribal program approval:

- State/territory/tribe issues permits
- State/territory/tribe conducts compliance and monitoring activities
- State/territory/tribe enforces
- EPA provides administrative, technical and legal support
- EPA ensures state program meets federal requirements
- EPA offers NPDES program training
- EPA oversees grants to states (e.g., CWA section 106)
- EPA reviews permits and, as necessary, comments or objects
- EPA oversees and, as necessary, assumes enforcement of permits

2.3 NPDES Program Areas

NPDES permittees can be broadly classified as municipal (publicly owned treatment works [POTWs] and related discharges) and non-municipal facilities. Federal facilities fall into the broader category of non-municipal facilities. Within those broad categories, there might also be specific types of activities that are subject to unique programmatic requirements in the NPDES regulations. Exhibit 2-4 provides an overview of the different activities related to municipal and non-municipal sources; identifies the NPDES program areas that address these activities; and identifies the applicable regulations for each NPDES program area.

2.3.1 NPDES Program Areas Applicable to Municipal Sources

The NPDES regulations establish technology-based effluent requirements applicable to discharges from POTWs. In addition to effluent requirements, the NPDES regulations establish other programmatic requirements applicable to other POTW activities (e.g., sewage sludge disposal and management, stormwater discharges from the treatment plant site) or activities that may be conducted by a municipality (e.g., municipal separate storm sewer systems, combined sewer overflows). A description of those programs and how they relate to NPDES permits is provided in the following sections.

2.3.1.1 Publicly Owned Treatment Works (POTWs)

The federal regulations at § 403.3 define a POTW as a treatment works (as defined in CWA section 212) that is owned by a state or municipality [as defined in CWA section 502(4)]. The definition includes any devices and systems used in the storage, treatment, recycling, and reclamation of municipal sewage or industrial wastes of a liquid nature. It also includes sewers, pipes, and other conveyances only if they convey wastewater to a POTW. Finally, the term also means the municipality that has the jurisdiction over the indirect discharges to and the discharges from the treatment works. Federally owned treatment works, privately owned treatment works, and other treatment plants not owned by a state or municipality are not considered POTWs.

NMED Exhibit 70

Exhibit 2-4 NPDES program areas and applicable regulations

Source	Program areas	Applicable regulations (40 CFR)
Municipal	Municipal (POTWs) effluent discharges	Part 122 Part 125 Part 133
	Indirect non-municipal discharges (Pretreatment)	Part 122 Part 403 Parts 405-471
	Biosolids (sewage sludge) use and disposal	Part 122 Part 257 Part 501 Part 503
	Combined sewer overflow (CSO) discharges	Part 122 Part 125
	Sanitary sewer overflow (SSO) discharges	Part 122
	Municipal separate storm sewer systems (MS4s) discharges	Part 122 Part 125
Non-municipal (Industrial)	Process wastewater discharges	Part 122 Part 125 Parts 405-471
	Non-process wastewater discharges	Part 122 Part 125
	Stormwater discharges associated with industrial activity	Part 122 Part 125
	Stormwater discharges from construction activities*	Part 122 Part 125
	Cooling water intake structures (CWIS)	Part 122 Part 125 Part 401
	Concentrated animal feeding operations (CAFOs)	Part 122 Part 123 Part 125 Part 412
	Concentrated aquatic animal production (CAAP) facilities	Part 122 Part 125 Part 451
	Vessel Discharges	Part 122

* Though stormwater discharges from construction activity resulting in disturbance of 5 or more acres of total land area technically are considered, "stormwater discharges associated with industrial activity" as defined by §122.26(b)(14)(x), these discharges are commonly referred to as stormwater discharges from *large* construction activities.

POTWs receive, primarily, domestic sewage from residential and commercial customers. Larger POTWs also typically receive and treat wastewater from industrial facilities (indirect dischargers) connected to the collection system. The types of pollutants treated by a POTW always include conventional pollutants and may include nonconventional and toxic pollutants, depending on the characteristics of the sources discharging to the POTW. The treatment provided by a POTW typically produces a treated effluent and a biosolids (sewage sludge) residual.

2.3.1.2 The National Pretreatment Program

The National Pretreatment Program <www.epa.gov/npdes/pretreatment> regulates the introduction of nondomestic (i.e., industrial and commercial) wastewater to POTWs. Because such discharges are treated by the POTW before release to a water of the United States, they are termed *indirect discharges*. The

NMED Exhibit 70

pretreatment program prohibits industrial and commercial indirect dischargers from discharging pollutants to a POTW that will pass through the POTW to receiving waters or interfering with POTW treatment processes or contaminating sewage sludge. The federal program also requires certain indirect dischargers to meet technology-based requirements developed specifically for such POTW users that are similar to those for direct dischargers.

EPA's pretreatment regulations require certain POTWs to develop a pretreatment program, the requirements of which are generally included as conditions of a POTW's NPDES permit. The federal regulations specifying which POTWs must have pretreatment programs, and the authorities and procedures that must be developed by the POTW before program approval, are in Part 403. The requirement to develop and implement a local pretreatment program typically is included as a special condition in the POTW's NPDES permit. Section 9.2.1 of this manual includes a discussion on incorporating pretreatment special conditions into permits.

2.3.1.3 Biosolids (Sewage Sludge)

In 1987 Congress amended CWA section 405 to establish a comprehensive sewage sludge program <www.epa.gov/OW-OWM.html/mtb/biosolids/index.htm>. The program regulates the use and disposal of sewage sludge by POTWs and by other TWTDS. TWTDS include facilities that generate sewage sludge, provide commercial treatment of sewage sludge, manufacture a product derived from sewage sludge, or provide disposal of sewage sludge. CWA section 405 required EPA to develop technical standards that establish sewage sludge management practices and acceptable levels of toxic pollutants in sewage sludge. The terms *biosolids*, *sewage sludge*, and *municipal sludge* are used interchangeably throughout this document.

Regulations for state sewage sludge program approval are at Part 123 or Part 501 (depending on whether the state wishes to administer the sewage sludge program under its NPDES program or under another program, e.g., a solid waste program). The technical standards governing sewage sludge use and disposal are in Part 503. TWTDS not otherwise subject to the NPDES permit requirements under CWA section 402 must apply for and receive a permit addressing standards for use and disposal of sewage sludge in Part 503. Details of this rule are described in *A Plain English Guide to the EPA Part 503 Biosolids Rule*[2] <www.epa.gov/owm/mtb/biosolids/503pe/>. Where applicable, sewage sludge management requirements may be included as a special condition in permits issued to POTWs. Section 9.2.2 of this manual includes a discussion on incorporating special conditions that address sewage sludge requirements.

2.3.1.4 Combined Sewer Overflows (CSOs)

An additional concern for some older POTWs may be combined *sewer systems* (CSS), which are wastewater collection systems owned by a state or municipality [as defined by CWA section 502(4)] that convey sanitary wastewater (domestic, commercial and industrial wastewaters) and stormwater through a single-pipe system to a POTW [as defined by § 403.3(q)]. EPA estimates that CSSs serve about 40 million people in 772 communities nationwide <www.epa.gov/npdes/cso/csodem>. During dry weather, CSSs collect and convey domestic, commercial, and industrial wastewater to a POTW; however, during periods of rainfall, snowmelt, and other forms of precipitation, the systems can become overloaded. When that overloading occurs, the CSS can overflow at designed relief points and discharge a combination of untreated sanitary wastewater and stormwater directly to a surface waterbody.

NMED Exhibit 70

A combined sewer overflow (CSO) <www.epa.gov/npdes/cso> is the discharge from a CSS at a point before the POTW. CSOs can be a major source of water pollution in communities served by CSSs. CSOs often contain high levels of suspended solids (SS), pathogenic microorganisms, toxic pollutants, floatables, nutrients, oxygen-demanding organic compounds, oil and grease, and other pollutants, causing water quality standards to be exceeded.

To address CSOs, EPA issued the National CSO Control Strategy (54 FR 37370, September 8, 1989). While implementation of the 1989 strategy has resulted in progress toward controlling CSOs, significant public health and water quality risks remain. To expedite compliance with the CWA, and to elaborate on the 1989 strategy, EPA, after collaboration with other CSO stakeholders (communities with CSSs, state water quality authorities, and environmental groups), published the CSO Control Policy <www.epa.gov/npdes/cso/controlpolicy> (59 FR 18688, April 19, 1994). The 1994 CSO policy represents a comprehensive national strategy to ensure that municipalities, permitting authorities, water quality standards authorities, and the public engage in a comprehensive and coordinated planning effort to achieve cost-effective CSO controls that ultimately meet appropriate health and environmental objectives. The Wet Weather Water Quality Act of 2000 stipulates that NDPES permits, enforcement orders, or decrees must conform to the 1994 CSO Policy [CWA section 402(q)].

Before issuing a permit with conditions that address CSOs, permit writers should consult the CSO Control Policy and associated guidance. Section 9.2.3 of this manual includes a discussion on incorporating appropriate CSO permit conditions.

2.3.1.5 Sanitary Sewer Overflows (SSOs)

Properly designed, operated, and maintained sanitary sewer systems are meant to collect and transport all the sewage that flows into them to a POTW; however, occasional, unintentional spills of raw sewage from municipal sanitary sewers occur in almost every system. Such types of releases are called sanitary sewer overflows (SSOs) <www.epa.gov/npdes/sso>.

SSOs have a variety of causes including severe weather, improper system operation and maintenance, and vandalism. EPA estimates that over 40.000 SSO events occur per year in the United States (excluding basement backups). Overflows of untreated wastewater can present risks of human exposure when released to certain areas, such as streets, private property, basements, and receiving waters used for drinking water, fishing and shellfishing, or contact recreation. A description of the extent of human health and environmental impacts caused by releases of untreated sewage, along with other information, is provided in the *Report to Congress on the Impacts and Control of CSOs and SSOs*[3] <www.epa.gov/npdes/csossoreport2004>. That 2004 report shows that NPDES permit requirements establishing clear reporting, record keeping, third party notification of overflows from municipal sewage collection systems, and clear requirements to properly operate and maintain the collection system, are critical to effective program implementation.

EPA has developed a draft fact sheet <www.epa.gov/npdes/pubs/sso_fact_sheet_model_permit_cond.pdf> and draft model permit conditions <www.epa.gov/npdes/pubs/sso_model_permit_conditions.pdf> that explain how NPDES permitting authorities can better address SSOs and sanitary sewer collection systems. Section 9.2.4 of this manual discusses incorporation of conditions to address SSOs in NPDES permits.

NMED Exhibit 70

2.3.1.6 Municipal Separate Storm Sewer Systems (MS4s)

Stormwater from major metropolitan areas is a significant source of pollutants discharged to waters of the United States. While rainfall and snow are natural events, the nature of stormwater discharges and their impact on receiving waters are greatly affected by human activities and land use. Stormwater from lands modified by human activities, such as metropolitan areas and urban streets, can affect surface water resources by modifying natural flow patterns or by elevating pollution concentrations and loadings.

To address such concerns, the 1987 amendments to the CWA added section 402(p), a provision that directed EPA to establish phased NPDES requirements for stormwater discharges. Phase I of the stormwater program addresses permits for discharges from medium and large MS4s serving a population of 100,000 or more, as well as certain categories of industrial activity, including construction activity disturbing greater than 5 acres. Phase II expanded the stormwater program to include small MS4s and construction activity disturbing between 1–5 acres.

The MS4 stormwater application regulations (Phase I) established requirements for a two-part permit application that allowed large and medium local governments to help define priority pollutant sources in the municipality and to develop and implement appropriate controls for such discharges to MS4s (55 FR 47990, November 16, 1990). Part II of the application requires municipal applicants to propose municipal stormwater management programs to control pollutants to the *maximum extent practicable* (MEP) and to effectively prohibit non-stormwater discharges to the municipal system. Medium and large MS4 operators are required to submit comprehensive permit applications and are issued individual permits.

Phase II of the stormwater program extended the NPDES permitting program to small MS4s in urbanized areas (64 FR 68722, December 8, 1999). The Phase II MS4 regulations require small MS4s to develop a program to address six *minimum control measures* that include BMPs and measurable goals for each BMP. Permit writers have the option of permitting regulated small MS4 operators using an individual permit, a general permit, or a modification of an existing Phase I MS4's individual permit (although the vast majority of small MS4s have been covered under general permits).

Municipal stormwater management programs combine source controls and management practices that address targeted sources in the boundaries of the municipal system. For example, a municipality that expects significant new development may focus more on proposing requirements for new development and construction. On the other hand, a municipality that does not expect significant new development could focus more on municipal activities that affect stormwater quality such as: maintenance of leaking sanitary sewers, road de-icing and maintenance, operation of municipal landfills, flood control efforts, and control of industrial contributions of stormwater.

MEP is not precisely defined so as to allow maximum flexibility in MS4 permitting to optimize reductions in stormwater pollutants on a location-by-location basis (64 FR 68754, December 8, 1999). Therefore, permit writers must rely on application requirements specified in the regulations and the applicant's proposed management program when developing appropriate permit conditions. The stormwater Phase II rule was challenged in the courts, with the U.S. Court of Appeals for the Ninth Circuit generally upholding the Phase II rule but remanding three issues back to EPA. EPA issued guidance on April 16, 2004 for how new general permits should address the remanded issues of public availability of notices of intent (NOIs), opportunity for public hearings, and permitting authority reviews of NOIs titled *Implementing the Partial Remand of the Stormwater Phase II Regulations Regarding*

NMED Exhibit 70

Notices of Intent & NPDES General Permitting for Phase II MS4s[4] <www.epa.gov/npdes/pubs/hanlonphase2apr14signed.pdf>.

In addition to information on the Stormwater Discharges From Municipal Separate Storm Sewer Systems (MS4s) Website <www.epa.gov/npdes/stormwater/municipal>, EPA has developed the following guidance documents and memoranda to help permit writers and permittees implement the municipal stormwater program:

- *Guidance Manual for the Preparation of Part 2 of the NPDES Permit Applications for Discharge from Municipal Separate Storm Sewer Systems*[5] <www.epa.gov/npdes/pubs/owm0246.pdf>.
- *Interim Permitting Approach for Water Quality-Based Effluent Limitations in Stormwater Permits*[6] <www.epa.gov/npdes/pubs/swpol.pdf>.
- *Establishing Total Maximum Daily Load (TMDL) Wasteload Allocations (WLAs) for Storm Water Sources and NPDES Permit Requirements Based on Those WLAs*[7] <www.epa.gov/npdes/pubs/final-wwtmdl.pdf>.
- *MS4 Program Evaluation Guidance*[8] <www.epa.gov/npdes/pubs/ms4guide_withappendixa.pdf>.
- *MS4 Permit Improvement Guide*[9] <www.epa.gov/npdes/pubs/ms4permit_improvement_guide.pdf>.

The application requirements for stormwater discharges from MS4s serving a population greater than 100,000 and for stormwater discharges from small MS4s are discussed in sections 4.3.10 and 4.3.11 of this manual.

2.3.2 NPDES Program Areas Applicable to Non-Municipal Sources

Non-municipal sources include industrial and commercial facilities, industrial stormwater (including large construction activities), and discharges from small construction activity, concentrated animal feeding operations (CAFOs) and concentrated aquatic animal production (CAAP) facilities. Unlike municipal sources, the types of raw materials, production processes, treatment technologies used and pollutants discharged at industrial facilities vary widely and are dependent on the type of industry and specific facility characteristics. The operations, however, generally are carried out within a more clearly defined area; thus, the collection systems are less complex than POTW collection systems. In addition, unlike biosolids at POTWs, the NPDES program does not regulate residuals (sludge) generated by non-municipal facilities.

Non-municipal facilities can have discharges of stormwater that might be contaminated through contact with manufacturing activities or raw material and product storage, or they can have non-process wastewater discharges such as non-contact cooling water. In addition, some non-municipal facilities take in cooling water. Those discharges and intakes may be regulated under an NPDES permit in addition to any process wastewater.

2.3.2.1 Process Wastewater

Industrial and commercial facilities often use water in the manufacture and processing of products. The regulations at § 122.2 define process wastewater as, "[a]ny water which, during manufacturing or processing, comes into direct contact with, or results from the production or use of any raw material, intermediate product, finished product, byproduct, or waste product."

NMED Exhibit 70

Process wastewater can contain pollutants at levels that could affect the quality of receiving waters. The NPDES permit program establishes specific requirements for discharges of process wastewater from industrial and commercial sources. If a facility discharges directly to surface water, it would require an individual or general NPDES permit. An industrial or commercial facility also may discharge wastewater to a municipal sewer system, which would be covered under the NPDES pretreatment program. Many types of industrial facilities, whether they discharge directly to surface water or to a municipal sewer system, are covered by effluent guidelines and standards (see section 5.2 of this manual). The stormwater that runs off the property of an industrial or commercial facility or from a construction site might require an NPDES permit under the industrial stormwater program (see section 2.3.2.3 below).

2.3.2.2 Non-Process Wastewater

Industrial and commercial facilities often use water for purposes other than processing products, such as using non-contact cooling water for heat exchange, and may discharge wastewater from sources such as sanitary or cafeteria wastes. Like process wastewater, non-process wastewater is regulated under the NPDES program. Non-process wastewater might also be important to the permit writer when drafting monitoring conditions for facilities where the non-process wastewater dilutes the concentration of pollutants of concern in process wastewater. The permit writer must ensure that specified monitoring locations ensure accurate measurement for compliance with all effluent limitations.

2.3.2.3 Stormwater Associated with Industrial Activity

To minimize the impact of stormwater discharges from industrial facilities, the NPDES program includes an industrial stormwater permitting component. Operators of industrial facilities included in 1 of the 11 categories of stormwater discharges associated with industrial activity that discharge or propose to discharge stormwater to an MS4 or directly to waters of the United States require authorization under an NPDES industrial stormwater permit. EPA published permit regulations and permit application requirements for stormwater discharges associated with industrial activity in 55 FR 48063, November 16, 1990.

Permit Regulations for Stormwater Associated with Industrial Activity

The regulations define stormwater discharges associated with industrial activity as discharges from any conveyance used for collecting and conveying stormwater and that is directly related to manufacturing, processing, or raw materials storage areas at an industrial plant. The regulations at § 122.26(b)(14)(i - xi) identify the following 11 industrial categories required to apply for NPDES permits for stormwater discharges:

- Facilities subject to stormwater effluent guidelines, new source performance standards, or toxic pollutant effluent standards under Parts 400-471 (Subchapter N).
- Certain heavy manufacturing facilities (lumber, paper, chemicals, petroleum refining, leather tanning, stone, clay, glass, concrete, ship construction).
- Active and inactive mining operations and oil and gas operations with contaminated stormwater.
- Hazardous waste treatment, storage, or disposal facilities, including Resource Conservation and Recovery Act (RCRA) Subtitle C facilities.
- Landfills, land application sites, open dumps, and RCRA Subtitle D facilities.

NMED Exhibit 70

- Recycling facilities, including metal scrap yards, battery reclaimers, salvage yards, and automotive junkyards.
- Steam electric power generating facilities, including coal-handling sites.
- Transportation facilities that have vehicle maintenance shops, equipment cleaning operations, or airport deicing operations.
- Major POTW sludge handling facilities, including on-site application of sewage sludge.
- Construction activities that disturb five acres or more (see subsection below).
- Light industrial manufacturing facilities.

Operators of industrial facilities that are federally, state- or municipally owned or operated that meet the above descriptions must also submit applications.

EPA issued a final rule for Phase II of the stormwater program in 64 FR 68722, December 8, 1999. That rule clarified that stormwater discharges from industrial facilities that have *no exposure* of industrial activities or materials to stormwater may be conditionally excluded from the stormwater permitting program. To qualify for the no exposure exclusion, the industrial operator must complete a no exposure certification form and submit this to EPA once every 5 years. For more information, see the Conditional No Exposure Exclusion Website <www.epa.gov/npdes/stormwater/noexposure>.

Generally, EPA- or state-issued general permits regulate stormwater discharges from industrial, construction and Phase II municipal sources, while Phase I municipal sources usually are issued individual permits. In some cases, stormwater conditions may be incorporated into a comprehensive individual NPDES permit for a facility or a stormwater-specific individual NPDES permit. Incorporating permit conditions to address stormwater discharges associated with industrial and construction activities into an individual facility permit is discussed in the subsections below. For more information regarding the scope of the NPDES stormwater program, see the NPDES Stormwater Program Website <www.epa.gov/npdes/stormwater>.

Permit Conditions for Stormwater Discharges Associated with Industrial Activity

All stormwater discharges associated with industrial activity that discharge stormwater through a separate MS4 or discharge directly to waters of the United States are required to obtain an NPDES permit. Because of the large number of facilities requiring permits, EPA and most NPDES-authorized states choose to issue general permits to regulate stormwater discharges. The Phase I rule in 1990 established the concept of a permitting exemption for industrial facilities with little or no likelihood of discharging contaminated stormwater; however, this exemption was not well-defined or required to be submitted to the NPDES permitting authority. The Phase II rule in December 1999 clarified and expanded the no exposure certification requirement to require industrial facilities with no exposure of industrial processes to stormwater to submit a written certification notifying EPA or the authorized state that the facility wishes to be excluded from the NPDES program.

Each industrial facility covered under an EPA-issued stormwater general permit must meet the numeric and non-numeric effluent limitations established in the general permit. Industrial facilities can meet those effluent limitations by implementing control measures, including BMPs, that control the discharge of stormwater associated with industrial activity.

NMED Exhibit 70

The EPA- and state-issued stormwater general permits generally require the facility to develop and implement a site-specific *stormwater pollution prevention plan* (SWPPP). The SWPPP describes the control measures, whether structural or nonstructural, which are used for controlling stormwater discharges from the industrial facility. The special conditions component of EPA's stormwater general permits identifies the requirements that must be documented in the SWPPP, including the following:

- A description of potential pollutant sources at the facility, including the following:
  - A map of the facility indicating the drainage areas of the site and the industrial activities that occur in each drainage area.
  - An inventory of materials that could be exposed to stormwater.
  - A description of the likely sources of pollutants from the site and a prediction of the pollutants likely to be present in the stormwater.
  - The history of spills and leaks of toxic and hazardous materials over the past 3 years.
- The measures and controls that will be implemented to prevent or minimize pollution of stormwater, including the following:
  - Good housekeeping or upkeep of industrial areas exposed to stormwater.
  - Preventive maintenance of stormwater controls and other facility equipment.
  - Spill prevention and response procedures.
  - Testing of outfalls to ensure that there are no illicit discharges.
  - Employee training on pollution prevention measure and controls, and record keeping.

A permit writer's best sources of information for developing appropriate special conditions for stormwater control measures are other stormwater general permits. Using existing general permits as the basis for special conditions is encouraged because doing so will reduce duplication of effort. A listing of individual and general permits (stormwater and non-stormwater) issued by EPA and authorized states is on the View NPDES Individual and General Permits Website <www.epa.gov/npdes/permitsearch>. In addition to the Stormwater Discharge From Industrial Facilities Website <www.epa.gov/npdes/stormwater/indust>, EPA published *Developing Your Stormwater Pollution Prevention Plan: A Guide for Industrial Operators*[10] <www.epa.gov/npdes/pubs/industrial_swppp_guide.pdf> to help permit writers identify components of SWPPPs and BMPs and to help permittees develop their own plans. Section 4.3.8 of this manual discusses Form 2F and individual permit requirements for stormwater discharges associated with industrial activity.

Permit Conditions for Stormwater Discharges associated with Construction Activities

EPA and most NPDES-authorized states have issued NPDES general stormwater permits for discharges associated with construction activity that are separate from the industrial stormwater general permits. The Phase I stormwater regulations require permit coverage for all construction activity that results in the disturbance of five acres or greater of the total land area. This includes disturbance of less than five acres of total land area that is part of larger common plan of development or sale if the larger common plan will ultimately disturb five acres of more. The Phase II stormwater regulations require permit coverage for all construction activity that result in land disturbance of equal to or greater than one acre and less than five acres. This includes the disturbance of less than one acre of total land area that is part of a larger common plan of development or sale if the larger common plan will ultimately disturb equal to or greater than one and less than five acres. Since March 2003, most construction activity disturbing one to five acres has been required to comply with the conditions of the relevant NPDES permit (typically under the relevant construction general permit for stormwater discharges), though states have the option of not requiring the submittal of NOIs for stormwater discharges associated with small construction activity.

NMED Exhibit 70

EPA and NPDES-authorized state permitting authorities may include permit conditions that incorporate qualifying state or local erosion and sediment control program requirements by reference. A qualifying state or local erosion and sediment control program is one that includes the requirements at § 122.44(s). Once EPA or an NPDES authorized state identifies and incorporates a qualifying local program in their NPDES construction general permit, operators can follow the erosion and sediment control requirements of the qualifying local program. By incorporating the qualifying local program by reference the permitting authority can avoid duplicative or conflicting erosion and sediment control requirements between the local program requirements and the NPDES general permit control requirements addressing stormwater discharges associated with construction activity. Operators that are engaged in construction activity within a qualifying program must still submit an NOI under the appropriate construction general permit and comply with all other permit conditions.

The permit requirements in a construction general permit may be similar to those in an industrial general permit, including the development of a SWPPP. In addition to the Stormwater Discharges from Construction Activities Website <www.epa.gov/npdes/stormwater/construction>, EPA also developed the Stormwater Pollution Prevention Plans for Construction Activities Website <www.epa.gov/npdes/swpppguide>. Section 4.3.9 of this manual discusses individual permit requirements for stormwater discharges associated with construction activity.

2.3.2.4 Cooling Water Intake Structures

CWA section 316(b) provides that any standard established pursuant to CWA sections 301 or 306 and applicable to a point source will require that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact. This CWA provision is unique because it addresses the *intake* of water, in contrast to other provisions that regulate the discharge of pollutants into waters of the United States. EPA has established national performance standards under CWA section 316(b) designed to reduce the impingement and entrainment of fish and other aquatic organisms as they are drawn into a facility's cooling water intake structure(s). Impingement occurs when organisms are trapped against cooling water intake structures by the force of water being drawn through the intake structure. Entrainment occurs when organisms are drawn through a cooling water intake structure into a cooling system, through the heat exchanger, and then pumped back out into the waterbody. For more information, see section 4.3.12 of this manual.

In April 1976, EPA published regulations at Part 402 to address cooling water intake structures. Fifty-eight electric utility companies challenged the final rule. The U.S. Court of Appeals for the Fourth Circuit remanded the rule in 1977, and in 1979, EPA withdrew Part 402. Beginning in 1977, NPDES permit authorities made decisions implementing CWA section 316(b) on a case-by-case basis using best professional judgment (BPJ) (§§ 125.90(b) and 401.14).

In the 1990s, EPA began developing CWA section 316(b) regulations establishing national standards. EPA divided the rulemaking into three phases:

- Phase I addressed new facilities and was completed in December 2001 (Part 125, Subpart I).
- Phase II addressed existing electric generating plants that use at least 50 million gallons per day (mgd) of cooling water was completed in July 2004 (Part 125, Subpart J).

NMED Exhibit 70

- Phase III addressed other existing facilities, including small existing electric generating plants that use less than 50 mgd of cooling water, manufacturers, and new offshore and coastal oil and gas extraction facilities.

The Phase III regulations, finalized in June 2006, establish national standards only for new offshore and coastal oil and gas extraction facilities (Part 125, Subpart N). EPA decided that other Phase III industrial facilities withdrawing water for cooling purposes would not be covered by national standards but would continue to be subject to CWA section 316(b) requirements set by the NPDES Permitting Director on a case-by-case, BPJ basis (§§ 125.90(b) and 401.14).

All three regulations were subject to judicial challenges. While the Phase I rule was largely upheld, the court reviewing the Phase II regulation rejected a number of its provisions. Under remands from the reviewing courts, EPA is reevaluating the Phase II regulation and the decision in the Phase III regulation not to establish national standards for existing Phase III facilities. In the interim, as noted above, NPDES permits must include CWA section 316(b) conditions developed on a case-by-case basis. For the most current information on regulatory requirements, see the Cooling Water Intake Structure Program Website <www.epa.gov/waterscience/316b/>, and for additional Cooling Water Intake Structures regulatory requirements, see section 4.3.12 of this manual.

2.3.2.5 Concentrated Animal Feeding Operations (CAFOs)

Animal feeding operations (AFOs) are agricultural facilities where animals are kept and raised in confined situations. AFOs typically maintain animals, feed, and manure and have production operations in a limited land area. Manure and wastewater from AFOs have the potential to contribute pollutants such as nitrogen and phosphorus, organic matter, sediments, pathogens, heavy metals, hormones, antibiotics, and ammonia to the environment. An AFO is a lot or facility (other than an aquatic animal production facility) where the following conditions are met:

- Animals have been, are, or will be stabled or confined and fed or maintained for a total of 45 days or more in any 12-month period.
- Crops, vegetation, forage growth, or post-harvest residues are not sustained in the normal growing season over any portion of the lot or facility.

AFOs that meet the regulatory definition of a CAFO, or that are designated as CAFOs by the permitting authority, and that discharge or propose to discharge are required to be permitted under the NPDES permitting program.

An animal operation must meet the definition of an AFO [§ 122.23(b)(1)] before it can be considered a CAFO. To be defined as a CAFO, an AFO must meet the regulatory definition [§§ 122.23(b)(4) or 122.23(b)(6)] of a large or medium CAFO or must be designated by the permitting authority [§ 122.23(c)]. Only CAFOs that discharge or propose to discharge are subject to NPDES permitting requirements.

CAFOs are subject to requirements that limit discharges from the production area and requirements applicable to land application areas under the control of the CAFO operator. Large CAFOs are subject to a no discharge requirement for production areas, whereas other CAFOs are subject to BPJ requirements for their production areas. One of the principal substantive pollution control conditions in any CAFO

NMED Exhibit 70

permit is the requirement to implement the terms of the nutrient management plan (NMP) incorporated into the permit when permit authorization is granted. For more information, see the Animal Feeding Operations Website <www.epa.gov/npdes/cafo>. In addition, section 4.3.4 of this manual discusses application requirements for CAFOs.

2.3.2.6 Concentrated Aquatic Animal Production (CAAP) Facilities

CAAP facilities also are regulated under the NPDES program. In 2004 EPA promulgated new effluent guidelines that address CAAP facilities. The effluent guidelines apply to CAAP facilities (flow-through, recirculating, and net pen) that directly discharge wastewater and have annual production equal to or greater than 100,000 pounds of aquatic animals. The rule requires a BMP plan and implementation of measures, including recordkeeping and reporting requirements, to minimize discharges of solids, to prevent spills of drugs, feed, and chemicals that could result in discharges to waters of the United States, and to ensure proper maintenance of the facility. A facility that does not meet the effluent guideline threshold might still need an NPDES permit if it meets the CAAP facilities thresholds established in the NPDES regulations at § 122.24(b) or if it is designated as a CAAP facility under the designation authority in § 122.24(c). For more information, see the Aquatic Animal Production Industry Effluent Guidelines Website <www.epa.gov/guide/aquaculture/>.

2.3.2.7 Vessel Discharges

On March 30, 2005, the U.S. District Court for the Northern District of California (in *Northwest Environmental Advocates et al. v. EPA*) ruled that the EPA regulation excluding discharges incidental to the normal operation of a vessel from NPDES permitting exceeded the Agency's authority under the CWA. On September 18, 2006, the Court issued an order revoking this regulation [40 CFR 122.3(a)] as of September 30, 2008. EPA appealed the District Court's decision, and on July 23, 2008, the Ninth Circuit upheld the decision, leaving the September 30, 2008, *vacatur* date in effect. In response to the Court order, EPA developed two proposed permits to regulate discharges from vessels. The district court ultimately extended the date of *vacatur* to February 6, 2009.

In July 2008, Congress amended the CWA (P.L. No. 110-288) to add a new section 402(r), which excludes discharges incidental to the normal operation of a recreational vessel from NPDES permitting. Instead, it directs EPA to regulate those discharges under a newly created CWA section 312(o). As a result of the law, EPA did not finalize the previously proposed Recreational Vessel General Permit and is instead undertaking rulemaking to develop BMPs for these vessels under the authority of CWA section 312(o).

In July 2010 P.L. 111-215 (Senate Bill S. 3372) was signed into law. This law amends P.L. 110-299 (Senate Bill S. 3298), which generally imposes a moratorium during which time neither EPA nor states may require NPDES permits for discharges incidental to the normal operation of commercial fishing vessels and other non-recreational vessels less than 79 feet. As a result, of P.L. 110-299, the Vessel General Permit (VGP) does not cover vessels less than 79 feet, or commercial fishing vessels, unless they have ballast water discharges. P.L. 111-215 extended the expiration date of the moratorium from July 31, 2010, to December 18, 2013.

NMED Exhibit 70

As a result of the court ruling, EPA issued the VGP on December 18, 2008. The 2008 VGP regulates discharges incidental to the normal operation of vessels operating in a capacity as a means of transportation. The VGP includes the following:

- general effluent limits applicable to all discharges.
- general effluent limits applicable to 26 specific discharge streams.
- narrative water-quality based effluent limits.
- inspection, monitoring, recordkeeping, and reporting requirements.
- additional requirements applicable to certain vessel types.

EPA estimates that approximately 61,000 domestically flagged commercial vessels and approximately 8,000 foreign flagged vessels could be affected by this permit.

Because this area of the NPDES permit program is relatively new and continues to evolve, for the most current information, see EPA's Vessel Discharges Website <www.epa.gov/npdes/vessels>.

2.4 Major/Minor Facility Designation

In addition to categorizing facilities as municipal and non-municipal, EPA has also developed criteria to determine which of the sources should be considered *major facilities*. The distinction was made initially to assist EPA and states in setting priorities for permit issuance and reissuance. The regulations at § 122.2 define major facility as, "any NPDES *facility or activity* classified as such by the Regional Administrator, or in the case of *approved state programs*, the Regional Administrator in conjunction with the [s]tate Director." All facilities that are not designated as *majors* are considered *minor* facilities.

Through policy, including the memoranda *Procedures for Revising the Major Permit List*[11] <www.epa.gov/npdes/pubs/owm0364.pdf> and *Delegation of Updates to Major/Minor Lists*[12] <www.epa.gov/npdes/pubs/owm0142.pdf>, EPA has established working definitions for POTW and non-municipal major facilities. For POTWs, major facilities are those that have a design flow of one million gallons per day or greater or serve a population of 10,000 or more or cause significant water quality impacts. Non-POTW discharges are classified as major facilities on the basis of the number of points accumulated using the NPDES Permit Rating Work Sheet <www.epa.gov/npdes/pubs/owm0116.pdf>. The worksheet evaluates the significance of a facility using several criteria, including toxic pollutant potential, flow volume, and water quality factors such as impairment of the receiving water or proximity of the discharge to coastal waters.

2.5 Growth and Change in the NPDES Program

The basic structure of the NPDES program has remained the same since the 1972 Federal Water Pollution Control Act amendments, but as EPA develops new regulations, policies, and guidance or modifies existing program requirements and guidance, the existing program is refined and new aspects of the program can emerge. To stay informed about the most recent program developments, permit writers should visit EPA's NPDES Program Website <www.epa.gov/npdes/> frequently.

NMED Exhibit 70

CHAPTER 3. Overview of the NPDES Permitting Process

This chapter presents an overview of the different types of National Pollutant Discharge Elimination System (NPDES) permits, the major permit components, and the permit development and issuance process. The permit process is illustrated by flow charts. The tasks identified within the flow charts are described in detail in subsequent chapters.

3.1 Types of Permits

The two basic types of NPDES permits are individual and general permits. These permit types share the same components but are used under different circumstances and involve different permit issuance processes.

3.1.1 Individual Permits

An individual permit is a permit specifically tailored to an individual facility. Upon receiving the appropriate application form(s), the permitting authority develops a permit for that facility on the basis of information from the permit application and other sources (e.g., previous permit requirements, discharge monitoring reports, technology and water quality standards, total maximum daily loads, ambient water quality data, special studies). The permitting authority then issues the permit to the facility for a specific period not to exceed 5 years, with a requirement to reapply before the expiration date.

3.1.2 General Permits

A permitting authority develops and issues a general permit to cover multiple facilities in a specific category of discharges or of sludge use or disposal practices. General permits can be a cost-effective option for agencies because of the large number of facilities that can be covered under a single permit. According to Title 40 of the *Code of Federal Regulations* (CFR) 122.28(a)(2), general permits may be written to cover stormwater point sources or other categories of point sources having the following common elements:

- Sources that involve the same or substantially similar types of operations.
- Sources that discharge the same types of wastes or engage in the same types of sludge use or disposal.
- Sources that require the same effluent limitations or operating conditions, or standards for sewage sludge use or disposal.
- Sources that require the same monitoring where tiered conditions may be used for minor differences within a class (e.g., size or seasonal activity).
- Sources that are more appropriately regulated by a general permit.

The regulations at § 122.28(a)(1) provide for general permits to cover dischargers within an area corresponding to specific geographic or political boundaries such as the following:

- Designated planning area.
- Sewer district.
- City, county, or state boundary.

NMED Exhibit 70

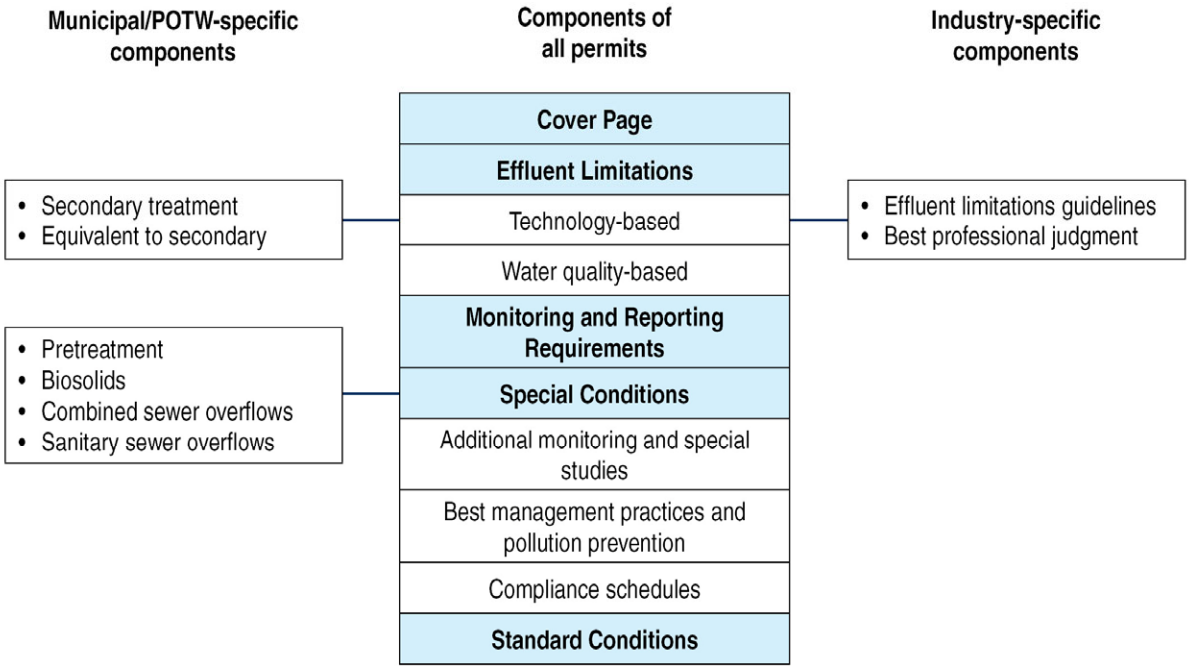
- State highway system.
- Standard metropolitan statistical area.
- Urbanized area.

The regulation also allows a general permit to cover any other appropriate division or combination of such boundaries. For example, EPA has issued general permits that cover multiple states, territories, and tribes where EPA is the permitting authority.

Where a large number of similar facilities require permits, a general permit allows the permitting authority to allocate resources in a more efficient manner and to provide more timely permit coverage than issuing an individual permit to each facility. In addition, using a general permit ensures consistent permit conditions for comparable facilities.

3.2 Major Components of a Permit

All NPDES permits consist, at a minimum, of five sections:



- **Cover Page:** Contains the name and location of the permittee, a statement authorizing the discharge, and a listing of the specific locations for which a discharge is authorized.
- **Effluent Limitations:** The primary mechanism for controlling discharges of pollutants to receiving waters. A permit writer spends the majority of his or her time, when drafting a permit, deriving appropriate effluent limitations on the basis of applicable technology and water quality standards.
- **Monitoring and Reporting Requirements:** Used to characterize wastestreams and receiving waters, evaluate wastewater treatment efficiency, and determine compliance with permit conditions.
- **Special Conditions:** Conditions developed to supplement numeric effluent limitations. Examples include additional monitoring activities, special studies, best management practices (BMPs), and compliance schedules.
- **Standard Conditions:** Pre-established conditions that apply to all NPDES permits and delineate the legal, administrative, and procedural requirements of the NPDES permit.

In addition to the components of the permit, a fact sheet or statement of basis explaining the rationale for permit conditions makes up part of the documentation that supports a draft permit. Section 11.2 of this manual includes additional discussion of permit documentation and the required elements of a fact sheet or statement of basis.

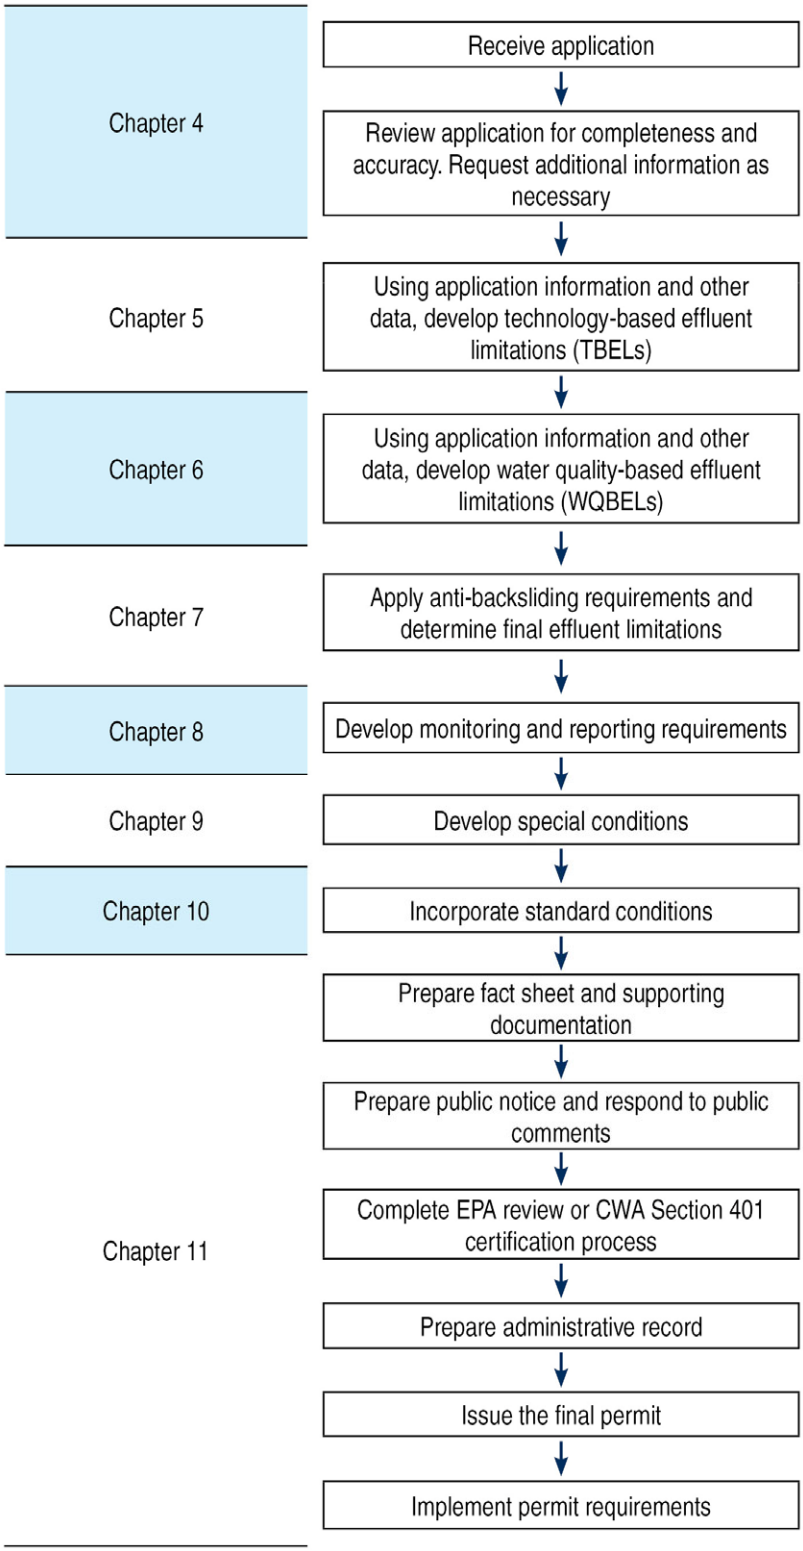
Although the major sections of a permit listed above are part of all permits, the contents of some sections vary depending on the nature of the discharge (e.g., municipal effluent, industrial process wastewater, stormwater, vessel discharges) and whether the permit is issued to an individual facility or to multiple dischargers (i.e., a general permit). Exhibit 3-1 shows the components of a permit and highlights some distinctions between the contents of NPDES permits for municipal (i.e., POTW) and industrial facilities. Permit writers should note that it is common for different permitting authorities to use different names for each section of a permit.

NMED Exhibit 70

Exhibit 3-1 Permit components

3.3 Overview of the Development and Issuance Process for NPDES Individual Permits

While the limitations and conditions in NPDES individual permits are unique to each permittee, the process used to develop the limitations and conditions and issue each permit generally follows a common set of steps. Exhibit 3-2 illustrates the major steps to develop and issue NPDES individual permits and also serves as an index for the subsequent chapters of this manual by identifying which chapter presents more detailed information on each step.



For individual permits, the permitting process generally begins when a facility operator submits an application. After receiving the application and making a decision to proceed with the permit, the permit writer reviews the application for completeness and accuracy. When the permit writer determines that the application is complete and has any additional information needed to draft the permit, the permit writer develops the draft permit and the justification for the permit conditions (i.e., the fact sheet or statement of basis).

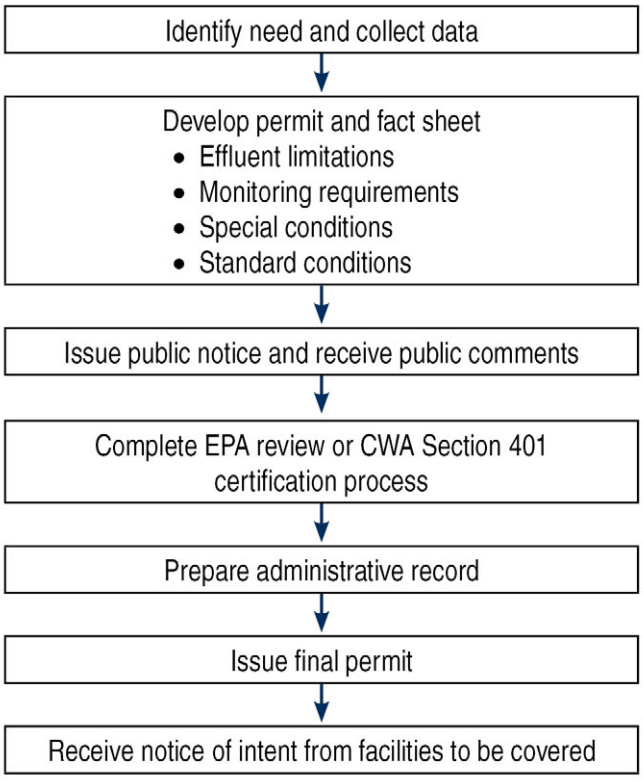
The first major step in the permit development process is deriving technology-based effluent limitations (TBELs). Following that step, the permit writer derives effluent limitations that are protective of state water quality standards (i.e., water quality-based effluent limitations [WQBELs]) as needed. The permit writer then compares the TBELs with the WQBELs and, after conducting an anti-backsliding analysis if necessary, applies the final limitations in the NPDES permit. The permit writer must document the decision-making process for deriving limitations in the permit fact sheet. It is quite possible that a permit will have limitations that are technology-based for some parameters and water quality-based for others. For example, a permit could contain effluent limitations for total suspended solids (TSS) based on national effluent limitations guidelines and standards (effluent guidelines) (technology-based), limitations for ammonia based on preventing toxicity to aquatic life (water quality-based), and limitations for 5-day

NMED Exhibit 70

biochemical oxygen demand (BOD_5) that have different bases, such as an average monthly limitation based on effluent guidelines and a maximum daily limitation based on water quality standards.

Exhibit 3-2 Major steps to develop and issue NPDES individual permits

NMED Exhibit 70



After effluent limitation development, the permit writer develops appropriate monitoring and reporting requirements and facility-specific special conditions. The permit writer then adds standard conditions, which are the same for all permits.

The next step is to provide an opportunity for public participation in the permit process and EPA review of the permit or, in the case of an EPA-issued permit, certification under CWA section 401 by the state with jurisdiction over the receiving water that the permit will comply with its water quality standards. The permitting authority issues a public notice announcing the draft permit and inviting interested parties to submit comments. If there is significant public interest, the permitting authority can hold a public hearing. Taking into consideration the public comments, the permitting authority then produces a final permit, with careful attention to documenting the process and decisions for the administrative record, and issues the final permit to the facility. The permitting authority might decide to make significant changes to the draft permit according to public comment and then provide another opportunity for public review and comment on the revised permit. Section 11.3 of this manual discusses items to address before final permit issuance in more detail.

3.4 Overview of the Development and Issuance Process for NPDES General Permits

The process for developing and issuing NPDES general permits is similar to the process for individual permits; however, there are some differences in the sequence of events. Exhibit 3-3 illustrates the major steps to develop and issue NPDES general permits.

Exhibit 3-3 Major steps to develop and issue NPDES general permits

NMED Exhibit 70

For general permits, the permitting authority first identifies the need for a general permit and collects data that demonstrate that a group or category of dischargers has similarities that warrant a general permit. In deciding whether to develop a general permit, permitting authorities consider whether

- A large number of facilities will be covered.
- The facilities have similar production processes or activities.
- The facilities generate similar pollutants.
- Whether uniform WQBELs (where necessary) will appropriately implement water quality standards.

The remaining steps of the permit process are the same as for individual permits. The permitting authority develops a draft permit that includes effluent limitations, monitoring conditions, special conditions, and standard conditions. The permitting authority then issues a public notice and addresses public comments, completes the EPA review or CWA section 401 certification process, develops the administrative record, and issues the final permit. The final permit will also establish the requirements for the specific information that must be submitted by a facility that wishes to be covered under the general permit.

After the final general permit has been issued, facilities that wish to be covered under the general permit typically submit a Notice of Intent (NOI) to the permitting authority. After receiving the NOI, the permitting authority can request additional information describing the facility, notify the facility that it is covered by the general permit, or require the facility to apply for an individual permit.

The following chapters in this manual describe steps in the permitting process in detail. In general, the chapters focus on the steps necessary to develop and issue an individual permit, but much of the technical discussion applies equally to general permit development.

NMED Exhibit 70

CHAPTER 4. NPDES Permit Application Process

This chapter describes the National Pollutant Discharge Elimination System (NPDES) permit application process, including the permit writer's role in reviewing the application and evaluating background information about the applicant. Through this process the permit writer gains an understanding of the circumstances of the discharge and the characteristics of the proposed effluent, which is necessary to develop appropriate permit limitations and conditions.

4.1 Who Applies for an NPDES Permit?

The NPDES regulations at Title 40 of the *Code of Federal Regulations* (CFR) 122.21(a) require that any person, except persons covered by general permits under § 122.28, who discharges pollutants or proposes to discharge pollutants to waters of the United States must apply for a permit. Further, § 122.21(e) prohibits the permitting authority from issuing an individual permit until and unless a prospective discharger provided a complete application. This regulation is broadly inclusive and ties back to the Clean Water Act (CWA) section 301(a) provision that, except as in compliance with the act, "…the discharge of any pollutant by any person shall be unlawful."

In most instances, the permit applicant will be the owner (e.g., corporate officer) of the facility. However, the regulations at § 122.21(b) require that when a facility or activity is owned by one person but is operated by another person, it is the operator's duty to obtain a permit. The regulations also require the application to be signed and certified by a high-ranking official of the business or activity. The signatory and certification requirements are at § 122.22.

Permits (and applications) are required for most discharges or proposed discharges to waters of the United States; however, NPDES permits are not required for some activities as specified under the *Exclusions* provision in § 122.3. Exceptions include the following:

- Discharge of dredged or fill materials into waters of the United States which are regulated under CWA section 404.
- The introduction of sewage, industrial wastes or other pollutants into publicly owned treatment works (POTWs) by indirect dischargers.
- Any discharge in compliance with the instructions of an On-Scene Coordinator pursuant to Part 300 (The National Oil and Hazardous Substances Pollution Contingency Plan) or 33 CFR 153.10(e) (Pollution by Oil and Hazardous Substances).
- Any introduction of pollutants from nonpoint source agricultural and silvicultural activities, including stormwater runoff from orchards, cultivated crops, pastures, range lands, and forest lands, but not discharges from concentrated animal feeding operations as defined in § 122.23, discharges from concentrated aquatic animal production facilities as defined in § 122.24, discharges to aquaculture projects as defined in § 122.25, and discharges from silvicultural point sources as defined in § 122.27.
- Return flows from irrigated agriculture.

NMED Exhibit 70

- Discharges into a privately owned treatment works, except as the Director may otherwise require under § 122.44(m).

While those types of discharges have been excluded from permitting requirements under the NPDES program, they might be subject to controls under other federal or state regulatory programs.

As of the date of this manual's publication, the exclusion for certain discharges incidental to the normal operation of a vessel is still in the CFR. Similarly, discharges from the application of pesticides consistent with all relevant requirements under the Federal Insecticide, Fungicide and Rodenticide Act (FIFRA) (i.e., those relevant to protecting water quality) are excluded from NPDES permit coverage in the following two circumstances: (1) the application of pesticides directly to waters of the United States to control pests, and (2) the application of pesticides to control pests that are present over waters of the United States, including near such waters, where a portion of the pesticides will unavoidably be deposited to waters of the United States to target the pests effectively. However, because of court decisions, the exclusions for vessels and pesticides are vacated as of February 6, 2009, and April 9, 2011, respectively. The effect of the *vacaturs* on the exclusions in § 122.3 is presented in Exhibit 4-1.

Exhibit 4-1 Effect of court decisions on § 122.3

Exclusion	Issue
Vessel Discharges (www.epa.gov/npdes/vessels)	The Court's ruling does not affect vessel discharge exemptions from permitting that are specifically provided for in the CWA itself. For example, § 502(6)(A) excludes from the act's definition of *pollutant* sewage from vessels (including graywater in the case of commercial vessels operating on the Great Lakes) and discharges incidental to the normal operation of a vessel of the Armed Forces within the meaning of CWA section 312. As another example, the CWA section 502(12)(B) provides that discharges from vessels (i.e., discharges other than those when the vessel is operating in a capacity other than as a means of transportation) do not constitute the, "discharge of a pollutant" when such discharges occur beyond the limit of the 3-mile territorial sea. Because both *a pollutant* and a *discharge of a pollutant* are prerequisites to the requirement to obtain an NPDES permit, those two statutory provisions have the effect of exempting the vessel discharges they address from the requirement to obtain an NPDES permit. In addition, in July 2008, Congress amended the CWA to add a new section 402(r) to the act, which excludes discharges incidental to the normal operation of a recreational vessel from NPDES permitting. For more information, see section 2.3.2.7 of this manual.
Pesticides (www.epa.gov/npdes/aquaticpesticides)	On January 7, 2009, the 6th Circuit Court vacated the final rule in *The National Cotton Council of America et al. v. United States Environmental Protection Agency*. The court held that while an NPDES permit is not required for chemical pesticide applications that leave no residuals, an NPDES permit is required for discharges (1) from chemical pesticide applications to or over, including near water, where there is a residual, or excess pesticide, in the water following the application, and (2) from all biological pesticide applications regardless of whether a residual is left. On June 8, 2009, the court granted a request from the U.S. Department of Justice for a 2-year stay of its decision, until April 9, 2011, to provide time for EPA and the states to develop and issue NPDES general permits for the discharge of pollutants from the application of pesticides. Before April 9, 2011, permits are not required for discharges from these applications when applied in accordance with the product's FIFRA label. Certain related activities continue to be exempt from permitting under the CWA (i.e., irrigation return flow and agricultural stormwater runoff).

NMED Exhibit 70

4.2 Application Deadlines

The regulations at § 122.21(c) and (d) specify the time to apply for NPDES permits. Exhibit 4-2 summarizes the application deadline requirements for dischargers to be covered by an NPDES permit.

Exhibit 4-2 When to apply for an NPDES permit

Type of permit	Type of discharge	Schedule*
Individual	New	At least 180 days before the date on which the discharge is to commence
	Existing	At least 180 days before expiration date of existing permit
	Construction Stormwater	At least 90 days before the date on which construction is to commence
General	New	Specified in general permit
	Existing	X number of days following issuance of permit (specified in the general permit)

* Authorized states may use more stringent deadlines.

Anyone proposing a new discharge must apply to the permitting authority no later than 180 days before the expected commencement of the discharge if applying for an individual permit. Any person with an currently effective individual permit must submit an application to the permitting authority at least 180 days before the expiration of its existing individual permit unless permission for a later date has been granted in accordance with § 122.21(d). For general permits, the deadline for new dischargers to apply is specified in the general permit. A general permit also may specify a number of days after the general permit's issuance that operators of existing facilities are given to apply for coverage. Authorized states may have different schedules for permit applications, but their schedules may be no less stringent than the federal deadlines. The State Director or the Regional Administrator may allow an individual application to be submitted at dates later than those specified in the regulations, but not later than the expiration date of the existing permit.

Note that, according to § 122.6, the conditions of an expired NPDES permit remain in effect until the new permit is issued, as long as the discharger submitted a complete application in accordance with the timeframes prescribed in the regulations (or in accordance with state law, in the case of state-administered NPDES programs). If state law does not allow expired permits to remain in effect until a permit is reissued, or if the permit application is not on time and complete, the facility may be considered to be discharging without a permit from the time the permit expired until the effective date of the new permit.

4.3 Application Forms and Requirements for Individual Permits

When a facility needs an individual NPDES permit, it must submit a permit application. Application forms and requirements are specific to the type of facility and discharge. NPDES permit application requirements are in Part 122, Subpart B and identified on forms developed by the U.S. Environmental Protection Agency (EPA). Authorized states are not required to use the EPA application forms; however, any alternative form used by an authorized state must include the federal requirements at a minimum.

Exhibit 4-3 provides an overview of the types of dischargers required to submit NPDES application forms, identifies the forms that must be submitted, and references the corresponding NPDES regulatory citation. In some cases, a facility might need to file more than one application form. For example, an

NMED Exhibit 70

existing industrial facility (i.e., renewal) discharging stormwater combined with process and non-process wastewater might need to submit Form 1, Form 2C, and Form 2F. Section 2.3 of this manual discusses the NPDES program areas that have application requirements presented below.

Exhibit 4-3 EPA application requirements for NPDES individual permits

Type of facility or program area	Status	Forms	Regulatory citations and additional application requirements (40 CFR)
Municipal facilities • POTWs with design flows greater than or equal to 0.1 million gallons per day (mgd)	New and existing	**Form 2A**, Parts A, B and C; Parts D, E, F, or G as applicable	• § 122.21(a)(2)(i)(B) • § 122.21(j)
• POTWs with design flows less than 0.1 mgd	New and existing	**Form 2A**, Parts A and C; Parts D, E, F, or G as applicable	• § 122.21(a)(2)(i)(B) • § 122.21(j)
TWTDS (sewage sludge)	New and existing	**Form 2S**	• § 122.21(a)(2)(i)(H) • § 122.21(q)
Concentrated animal production facilities • Concentrated animal feeding operations • Concentrated aquatic animal production facilities	New and existing	**Form 1** and **Form 2B**	• § 122.21(a)(2)(i)(A) and (C) • § 122.21(f) and (i)
Industrial facilities • Manufacturing facilities • Commercial facilities • Mining activities • Silvicultural activities	Existing	**Form 1** and **Form 2C**	• § 122.21(a)(2)(i)(A) and (D) • § 122.21(f) and (g)
	New (process wastewater)	**Form 1** and **Form 2D**	• § 122.21(a)(2)(i)(A) and (E) • § 122.21(f) and (k)
	New and existing (non-process wastewater)	**Form 1** and **Form 2E**	• § 122.21(a)(2)(i)(A) and (F) • § 122.21(f) and (h)
Stormwater discharges associated with industrial activities (except stormwater discharges associated with construction activity)	New and existing	**Form 1** and **Form 2F**	• § 122.21(a)(2)(i)(A) and (G) • § 122.21(f) • § 122.26(c)
Stormwater discharges associated with construction activity	New and existing	**Form 1**	• § 122.21(a)(2)(i)(A) • § 122.21(f) • § 122.26(c)(1)(ii)
Stormwater discharges from MS4s serving a population greater than 100,000	New and existing	None	• § 122.26(d)
Stormwater discharges from small MS4s	New and existing	None	• § 122.33 • § 122.21(f)
Cooling water intake structures	New and existing	None	• § 122.21(r)

NMED Exhibit 70

4.3.1 Form 1: General Information

All facilities applying for an individual NPDES permit, with the exception of POTWs, treatment works treating domestic sewage (TWTDS), and municipal separate storm sewer systems (MS4s) applying for a municipal stormwater permit, must submit Form 1 <www.epa.gov/npdes/pubs/form_1.pdf>. The type of general facility information required by Form 1 is specified in §§ 122.21(a)(2)(i)(A) and 122.21(f) and includes the following:

- Name, mailing address, facility contact, and facility location.
- Standard industrial classification (SIC) code and a brief description of the nature of the business.
- Topographic map showing the location of the existing or proposed intake and discharge structures.

4.3.2 Form 2A: New and Existing POTWs

All new and existing POTWs must submit Form 2A <www.epa.gov/npdes/pubs/final2a.pdf>. EPA issued a final rule amending permit application requirements and application forms for POTWs and other TWTDS (64 FR 42433, August 4, 1999). The rule consolidated POTW application requirements, expanded toxic monitoring requirements for POTWs, and revised the forms used to submit permit applications. POTWs must also submit the form for permit renewals. Form 2A replaces Standard Form A and Short Form A.

POTWs with design influent flows equal to or greater than 100,000 gallons per day (gpd) (0.1 mgd) must submit Parts A, B, and C of Form 2A. POTWs with design flows of less than 100,000 gpd must submit Parts A and C of Form 2A. Parts A, B and C are referred to as Basic Application Information:

- Part A of Form 2A contains basic application information for all applicants:
  - Facility and applicant information.
  - Collection system type, areas served, and total population served.
  - Discharges and other disposal methods.
  - If the treatment works discharges effluent to waters of the United States, a description of outfalls, receiving waters, and treatment and effluent testing information.
- Part B of Form 2A collects additional information for applicants with a design flow greater than or equal to 0.1 mgd, including inflow and infiltration estimates, a topographic map, process flow diagram, and effluent testing data for additional parameters.
- Part C is a certification that all applicants must complete.

Form 2A also includes Supplemental Application Information (Parts D–G). POTWs complete these additional forms, as applicable, depending on the characteristics of the municipal discharge:

- Part D requests expanded effluent testing data for metals, volatile organic compounds, acid-extractable compounds, and base-neutral compounds. A POTW that discharges effluent to waters of the United States and meets one or more of the following criteria must complete Part D:
  - Has a design flow rate greater than or equal to 1 mgd.
  - Is required to have a pretreatment program (or has one in place).
  - Is otherwise required by the permitting authority to provide the information.

NMED Exhibit 70

- A POTW that meets one or more of the following criteria must complete Part E (Toxicity Testing Data):
  - Has a design flow greater than or equal to 1 mgd.
  - Is required to have a pretreatment program (or has one in place).
  - Is otherwise required by the permitting authority to submit results of toxicity testing.
- A POTW that accepts process wastewater from any significant industrial users (SIUs) or receives Resource Conservation and Recovery Act (RCRA) or Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) or other remedial wastes must complete Part F. SIUs are defined as:
  - All industrial users subject to Categorical Pretreatment Standards under § 403.6 and 40 CFR Chapter I, Subchapter N.
  - Any other industrial user for which any of the following is true
    - Discharges an average of 25,000 gpd or more of process wastewater to the POTW (excluding sanitary, non-contact cooling, and boiler blowdown wastewater).
    - Contributes a process wastestream that makes up 5 percent or more of the average dry-weather hydraulic or organic capacity of the treatment plant.
    - Is designated an SIU by the control authority on the basis that it has a reasonable potential for adversely affecting the POTWs operation or for violating any pretreatment standard or requirement.
  - The control authority can determine that an industrial user subject to categorical pretreatment standards is a nonsignificant categorical industrial user, rather than an SIU, on a finding that it never discharges more than 100 gpd of total categorical wastewater and if:
    - Before that finding, the industrial user has consistently complied with all applicable categorical pretreatment standards and requirements.
    - The industrial user annually submits a certification statement required in § 403.12(q) and any information necessary to support the certification statement.
    - The industrial user never discharges any untreated concentrated wastewater.
  - If an industrial user meets one of the other criteria for determining that it is an SIU (i.e., discharges an average of 25,000 gpd of process wastewater), but the control authority finds that it has no reasonable potential for adversely affecting the POTW's operation or for violating any pretreatment standards or requirement, the control authority can determine that the industrial user is not an SIU.
- A POTW that has a combined sewer system must complete Part G. Information that must be provided in the section includes a system map and diagram, and descriptions of outfalls, combined sewer overflow (CSO) events, receiving waters, and operations.

4.3.3 Form 2S: New and Existing TWTDS

New TWTDS and TWTDS with effective NPDES permits must submit a new or renewal permit application, respectively, using new Form 2S <www.epa.gov/npdes/pubs/final2s.pdf>. Part 1 of Form 2S is to be completed by *sludge-only* facilities; that is, facilities that do not have, and are not applying for, an NPDES permit for a direct discharge to surface water. Part 1 collects background information on the facility, including identification information, quantities of sewage sludge handled, pollutant concentrations, treatment methods, and use and disposal information.

NMED Exhibit 70

Part 2 is used by facilities that already have or are applying for an NPDES permit. It includes five sections:

- All applicants using Part 2 must complete the general information collected by **section A**.
- Applicants who either generate sewage sludge or derive a material from sewage sludge must complete **section B**.
- Applicants who either apply sewage sludge to the land or generate sewage sludge that is applied to the land by others (unless the sludge from the facility meets certain exemption criteria) must complete **section C**.
- Applicants who own or operate a surface disposal site must complete **section D**.
- Applicants who own or operate a sewage sludge incinerator must complete **section E**.

4.3.4 Form 2B: New and Existing Concentrated Animal Feeding Operations (CAFOs) and Concentrated Aquatic Animal Production (CAAP) Facilities

In addition to Form 1, owners of new and existing CAFOs (defined in § 122.23) and CAAP facilities (defined in § 122.24) must submit Form 2B <www.epa.gov/ne/npdes/2010RevisedCafoFedRegstrForm2b.pdf>. Form 2B was significantly modified as part of the final CAFO Rules (68 FR 7176, February 12, 2003, and 73 FR 70418, November 20, 2008). The type of information required by Form 2B consists of the following:

- For CAFOs
  - The name of the owner or operator.
  - The facility location and mailing addresses.
  - Latitude and longitude of the production area.
  - A topographic map of the geographic area in which the CAFO is located.
  - Specific information about the number and type of animals.
  - The type of containment and total capacity for storage (tons/gallons).
  - The total number of acres under control of the applicant available for land application.
  - Estimated amounts of manure, litter, and process wastewater generated and amounts transferred to other persons per year.
  - A nutrient management plan (NMP) that satisfies the requirements of § 122.42(e).
- For CAAP facilities
  - The maximum daily and average monthly flow from each outfall.
  - The number of ponds, raceways, and similar structures.
  - The name of the receiving water and the source of intake water.
  - For each species of aquatic animals, the total yearly and maximum harvestable weight.
  - The calendar month of maximum feeding and the total mass of food fed during that month.

Note that recent revisions to the NPDES regulations require that a CAFO seeking coverage under a permit submit its NMP with its application for an individual permit or notice of intent (NOI) to be authorized under a general permit. Permitting authorities are required to review the plan and provide the public with an opportunity for meaningful public review and comment. Permitting authorities also are required to incorporate terms of the NMP as NPDES permit conditions. For more information on the revisions to the CAFO regulations, see the Animal Feeding Operations Website <www.epa.gov/npdes/cafo>.

NMED Exhibit 70

Sections 2.3.2.5 and 2.3.2.6 of this manual provide additional information on CAFOs and CAAP facilities, respectively.

4.3.5 Form 2C: Existing Manufacturing, Commercial, Mining, and Silvicultural Discharges

In addition to Form 1, operators of existing (i.e., currently permitted) manufacturing, commercial, mining, and silvicultural discharges must submit Form 2C <www.epa.gov/npdes/pubs/3510-2C.pdf>. The type of information required in Form 2C includes:

- Outfall locations.
- A line drawing of the water flow through the facility.
- Flow characteristics, sources of pollution, treatment technologies.
- Production information (if applicable).
- Improvements (if applicable).
- Intake and effluent characteristics for conventional, nonconventional and toxic (priority) pollutants.
- Potential discharges not covered by analysis.
- Biological testing data.
- Contract laboratory information.
- Certification and signature.

Quantitative effluent data requirements for existing industrial dischargers vary depending on the industrial category of the facility, the facility's discharge characteristics and the types of pollutants expected to be present in the discharge.

4.3.6 Form 2D: New Manufacturing, Commercial, Mining, and Silvicultural Discharges of Process Wastewater

In addition to Form 1, operators of new manufacturing, commercial, mining, and silvicultural discharges of process wastewater must submit Form 2D <www.epa.gov/npdes/pubs/3510-2D.pdf>. *New* dischargers are those that have not previously obtained permits for a discharge and have not commenced operation. The type of information required in Form 2D includes the following:

- Expected outfall locations.
- Date of expected commencement of discharge.
- Expected flow characteristics.
- Sources of pollutants.
- Treatment technologies.
- Production information (if applicable).
- Expected intake and effluent characteristics.

4.3.7 Form 2E: Manufacturing, Commercial, Mining, and Silvicultural Facilities that Discharge Only Non-Process Wastewater

In addition to Form 1, operators applying for an individual NPDES permit for manufacturing, commercial, mining, and silvicultural facilities that are not regulated by effluent limitations guidelines and standards (effluent guidelines) or new source performance standard, and that discharge only

NMED Exhibit 70

non-process wastewaters, must submit Form 2E <www.epa.gov/npdes/pubs/3510-2E.pdf>. *Non-process wastewater* includes sanitary wastes, restaurant or cafeteria wastes, and non-contact cooling water, but it does not include stormwater. Stormwater is specifically excluded from the definition of non-process wastewater. Form 2E also may not be used for discharges by educational, medical, or commercial chemical laboratories or by POTWs. The type of information required in Form 2E includes the following:

- Outfall locations.
- Type of waste discharged.
- Effluent characteristics, including quantitative data for selected parameters.
- Flow characteristics.
- Treatment technologies.

4.3.8 Form 2F: Stormwater Discharges Associated with Industrial Activities

In addition to Form 1, operators applying for an individual NPDES permit for discharges composed entirely of stormwater associated with industrial activity must submit Form 2F <www.epa.gov/npdes/pubs/3510-2F.pdf>. Applicants whose discharge is composed of stormwater and non-stormwater must also submit Form 2C, 2D, or 2E as appropriate. The type of information required in Form 2F includes the following:

- A topographic map and estimates of impervious surface area.
- Descriptions of material management practices and control measures.
- A certification that outfalls have been evaluated for non-stormwater discharges.
- Descriptions of past leaks and spills.
- Analytical data from each outfall for several specified parameters.

EPA developed the *Guidance Manual For the Preparation of NPDES Permit Applications For Stormwater Discharges Associated With Industrial Activity*[1] <www.epa.gov/npdes/pubs/owm0241.pdf> to assist operators of facilities that discharge stormwater associated with industrial activity in complying with the requirements for applying for an NPDES permit.

4.3.9 Stormwater Discharges Associated with Construction Activity

Most stormwater discharges associated with construction activities that result in the disturbance of one acre or more are covered under a general permit issued by EPA or the authorized state. In cases that a general permit does not cover the discharge or the discharger decides that an individual permit is necessary for stormwater discharges associated with construction activity, the discharger is required to submit Form 1, along with a narrative description of the following:

- The location (including a map) and the nature of the construction activity.
- The total area of the site and the area of the site that is expected to undergo excavation during the life of the permit.
- Proposed measures, including best management practices (BMPs), to control pollutants in stormwater discharges during construction, including a brief description of applicable state and local erosion and sediment control requirements.

NMED Exhibit 70

- Proposed measures to control pollutants in stormwater discharges that will occur after construction operations have been completed, including a brief description of applicable state or local erosion and sediment control requirements.
- An estimate of the runoff coefficient of the site and the increase in impervious area after the construction addressed in the permit application is completed, the nature of fill material and existing data describing the soil or the quality of the discharge.
- The name of the receiving water.

4.3.10 Stormwater Discharges from MS4s Serving a Population Greater than 100,000

The stormwater application regulations (55 FR 47990, November 16, 1990) require operators of large or medium MS4s to submit two-part applications. Part 1 application information was required to be submitted by large MS4s (serving a population greater than 250,000) by November 18, 1991, and by medium MS4s (serving a population greater than 100,000 but less than or equal to 250,000) by May 18, 1992. Part 2 application information was required to be submitted by large MS4s by November 16, 1992, and by medium MS4s by May 17, 1993. Those applications could be submitted on a system- or jurisdiction-wide basis. Key requirements of each part of the application include [and are further addressed in § 122.26(d)] the following:

- Part 1
  - General information (e.g., name, address).
  - Existing legal authorities to control discharges to the storm sewer system and any additional authority that might be required.
  - Source identification information (e.g., storm sewer outfalls, land use information).
  - Discharge characterization, including monthly precipitation estimates, average number of storm events, and results from dry-weather flow screening.
  - Characterization plan, including identification of 5 to 10 representative outfalls for stormwater sampling.
  - Description of existing stormwater management practices.
  - Descriptions of existing budget and resources available to complete Part 2 of the application and implement the stormwater program.
- Part 2
  - Demonstration of adequate legal authority.
  - Identification of any major storm sewer outfalls not included in Part 1 of the application.
  - Discharge characterization data from three representative storm events.
  - Proposed stormwater management program.
  - Assessment of controls, including expected reductions in pollutant loadings.
  - Fiscal analysis, including necessary capital and operation and maintenance expenditures for each year of the permit.

Under the NPDES regulations, permittees are required to reapply for a new NPDES permit before the expiration of their existing permit; however, in the case of stormwater permits for MS4s, Part 1 and Part 2 application requirements described above were intended only for the initial issuance of an MS4 permit and specific requirements for reapplication have not been defined in the regulations. On May 17, 1996, EPA issued a policy that sets forth a streamlined approach for reapplication requirements for operators of

NMED Exhibit 70

MS4s (61 FR 41698, August 9, 1996) that allows municipalities to use recommended changes submitted in their fourth year annual report required under § 122.42(c)(2), as the principal component of their reapplication package. It also encourages changes to monitoring programs to make them appropriate and useful to stormwater management decisions. With the policy, EPA seeks to improve municipal stormwater management efforts by allowing municipalities to target their resources for the greatest environmental benefit.

4.3.11 Stormwater Discharges from Small MS4s

The application requirements for small MS4s are addressed in § 122.33. Most states have issued general permits for small MS4s; however, regulated small MS4s may seek authorization to discharge under an individual permit. The application requirements are different depending on whether the MS4 will implement a program under § 122.34 (i.e., a program that follows EPA's six minimum control measures) or a program that varies from § 122.34. EPA anticipates that most MS4s will follow the § 122.34 requirements.

Regulated small MS4s seeking an individual permit and wishing to implement a program under § 122.34 (the six minimum control measures) must submit an application to their NPDES permitting authority that includes the following:

- The information required under §§ 122.21(f) and 122.34(d).
- An estimate of square mileage served by the small MS4.
- Any additional information that the NPDES permitting authority requests.

A storm sewer map that satisfies the requirement of § 122.34(b)(3)(i) will also satisfy the map requirement in § 122.21(f)(7).

Regulated small MS4s seeking an individual permit and wishing to implement a program that is different from the program under § 122.34 must comply with the permit application requirements of § 122.26(d) (for additional information, see section 4.3.10 above). Under § 122.33, the regulated small MS4 is required to submit both parts of the application requirements in §§ 122.26(d)(1) and (2) by March 10, 2003. Small MS4s are not required to submit the information required by §§ 122.26(d)(1)(ii) and (d)(2) regarding their legal authority, unless they intend for the permit writer to take such information into account when developing their other permit conditions. Regulated small MS4s may jointly apply with another regulated entity consistent with the same requirements.

Additionally, another regulated entity may seek a modification of an existing MS4 permit to include a regulated small MS4 as a co-permittee. In such a case, the regulated small MS4 must apply consistent with § 122.26 rather than § 122.34. Application requirements of §§ 122.26(d)(1)(iii) and (iv) and (d)(2)(iii) do not apply and compliance with §§ 122.26(d)(1)(v) and (d)(2)(iv) can be met by referring to the other MS4's stormwater management program.

4.3.12 Cooling Water Intake Structures

Phase I of the CWA section 316(b) rule was finalized on December 18, 2001, in 66 FR 65256. The Phase I Rule (Part 125, Subpart I) implements CWA section 316(b) for most new facilities. The rule applies to new facilities that use cooling water intake structures to withdraw water from waters of the United States and that have or require an NPDES permit. This rule includes new facilities that have a design intake flow of greater than 2 mgd and that use at least 25 percent of water withdrawn for cooling purposes. For other

NMED Exhibit 70

new facilities that have or require an NPDES permit but do not meet the 2-mgd intake flow threshold or use less than 25 percent of their water for cooling water purposes, the permit authority must implement CWA section 316(b) on a case-by-case basis, using best professional judgment (BPJ) (§§ 125.90(b) and 401.14).

Phase II of the CWA section 316(b) rule was finalized on July 9, 2004, in 69 FR 41576. In 2007 EPA suspended the rule following remand of a number of its provisions by the U.S. Court of Appeals for the Second Circuit. CWA section 316(b) requirements for such facilities must be developed on a case-by-case basis.

Phase III of the CWA section 316(b) rule was finalized on June 16, 2006, in 71 FR 35006. The Phase III rule (Part 125, Subpart N) implements CWA section 316(b) for new offshore oil and gas extraction facilities that use cooling water intake structures to withdraw water from waters of the United States and that have or require an NPDES permit. The rule includes facilities with a design intake flow of greater than 2 mgd and that use at least 25 percent of water withdrawn for cooling purposes.

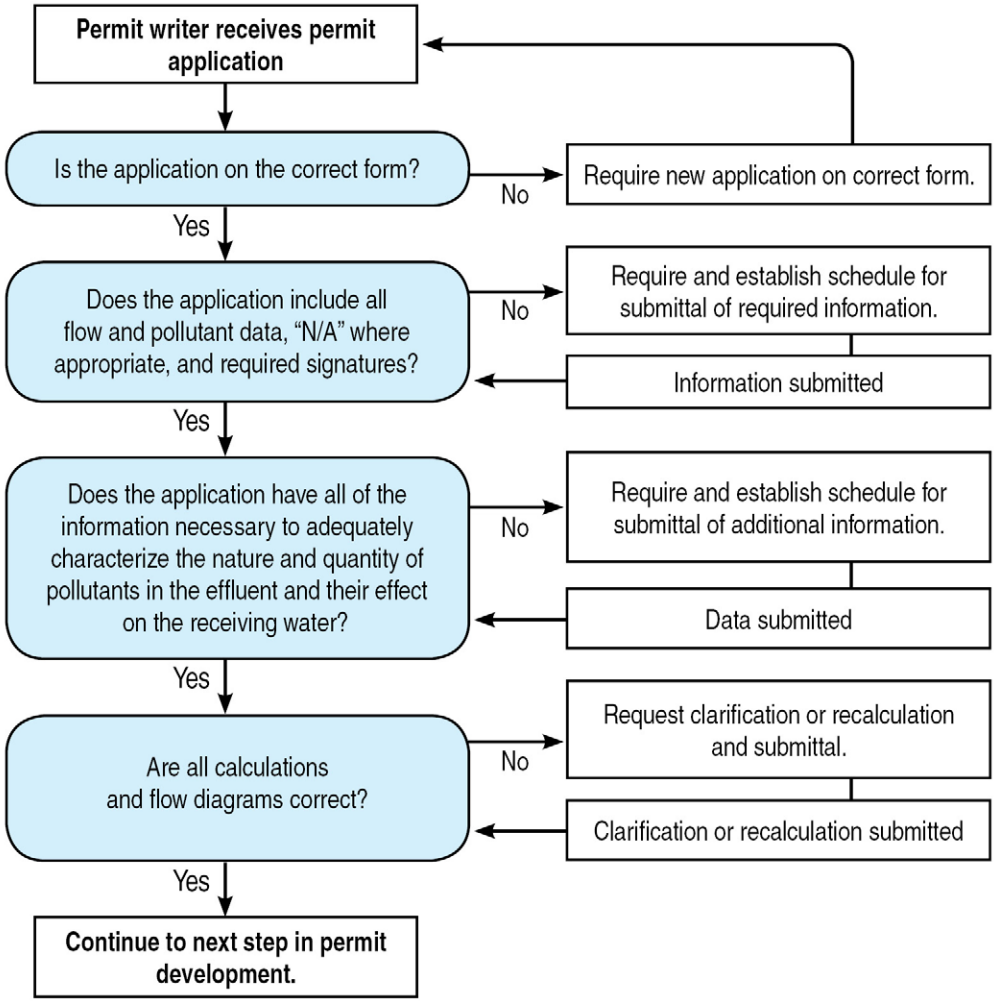
EPA has not established national standards for existing Phase III facilities and is reevaluating its decisions in both Phase II and Phase III because of court remands. In the interim, for Phase III facilities not regulated under national categorical standards, the permitting authority must implement CWA section 316(b) on a case-by-case basis, using BPJ (§§ 125.90(b) and 401.14). For the most current information on regulatory requirements, see the Cooling Water Intake Structure Program Website <www.epa.gov/waterscience/316b/>.

4.4 Requirements for NPDES General Permits

As previously discussed in section 3.1.2 of this manual, general permits (§ 122.28) are permits developed for a specific category of dischargers within a specified geographic or political boundary. Using a general permit could simplify the permitting process for both EPA and the discharger. Owners/operators may seek coverage under a general permit only if one has been issued that is applicable to the type of facility for which coverage is sought and the permit covers the facility's activities. In addition, the permitting authority may determine that a general permit is not appropriate for a facility seeking coverage under the general permit and can require the facility to apply for an individual permit. Furthermore, a facility that otherwise qualifies for a general permit may opt to apply for an individual permit.

In most cases, a facility or activity seeking coverage under a general permit must seek coverage by submitting an NOI. The information that must be provided by the facility or activity in the NOI is specified in the general permit and must include, at a minimum, the following:

- Legal name and address of the owner or operator.
- Name and address of the facility.
- Type of facility or discharges.
- The receiving stream(s).



EPA has developed the Electronic NOI (eNOI) for construction sites and industrial facilities that need to apply for coverage under EPA's Construction General Permit (CGP) or Multi-Sector General Permit (MSGP), respectively. EPA's Electronic Stormwater Notice of Intent (eNOI) Website <www.epa.gov/npdes/stormwater/enoi> presents additional information about eNOI.

NMED Exhibit 70

4.5 Application Review

The contents of individual NPDES permits are based, in part, on the information included in the application. Thus, the application must be complete and accurate before a permit writer can properly develop a permit. Exhibit 4-4 depicts the general process for reviewing a permit application, based on a chart provided in the *Washington Department of Ecology's Permit Writers' Manual*[2].

Exhibit 4-4 Permit application review process

After the initial application review, the permit writer may request that an applicant submit other information needed to decide whether to issue a permit and for permit development. The requested information could include the following:

- Additional information, quantitative data, or recalculated data.
- Submission of a new form (if an inappropriate form was used).
- Resubmission of the application (if incomplete or outdated information was initially submitted).

In some situations, a considerable amount of correspondence might be required before the permit writer obtains all the information that he or she believes is necessary to draft the permit.

NMED Exhibit 70

4.5.1 The Complete Application

The regulations at § 122.21(e) state that the Director, "[must] not issue a permit before receiving a complete application..." At a minimum, the application form must have all applicable spaces filled in. Instructions for the application form state that all items must be completed and that applicants use the statement *not applicable* (N/A) to indicate that the item had been considered. Blanks on a form can occur for a number of reasons, such as the following:

- The response was inadvertently omitted.
- The applicant had difficulty determining the correct response and rather than provide misleading or incorrect information, left the space blank.
- The applicant was unwilling to provide the response.

A permit writer must obtain a response to the blank items by contacting the facility in writing or, in some cases, by telephone. Only minor changes should be handled by telephone and even minor items should be documented in writing in the permit file. Under no circumstances should a permit writer edit or modify the application, which is a legal document that has been signed and certified by the applicant. The original application, any subsequent clarifications, and any supplemental information provided by the applicant should be clearly identified in the file. The information will become part of the administrative record (§ 124.9) for the permit (see section 11.2.1 of this manual), which is critical if any legal challenges regarding permit decisions arise. If the changes or corrections to any application are extensive, the permit writer may require the permit applicant to submit a new application.

The permit writer may also require supplementary information, such as more detailed production information or maintenance and operating data for a treatment system, to process the permit. According to § 122.21(e), an application is considered complete when the permitting authority is satisfied that all required information has been submitted. Supplementary information also can be obtained later when the permit writer is actually drafting the permit. The applicant may submit additional information voluntarily or be required to do so under CWA section 308 or under a similar provision of state law.

4.5.2 Common Omissions in Applications

This section identifies some of the most common omissions and errors found in NPDES permit applications and provides examples of ways to identify missing information and verify the accuracy of certain data.

One of the most commonly omitted items from NPDES permit applications is a topographic map of the area around the discharge, which is required as an attachment to Form 1, Form 2A, and Form 2S. Other industry- or municipality-specific information is also often omitted. For example, industrial applicants sometimes fail to submit a line drawing of the water flow through the facility required by Part II-A of Form 2C. The line drawing is important for ensuring that the location and description of the outfalls and the description of processes (Parts I and II-B of Form 2C) provided by the applicant are accurate.

Sometimes applicants do not properly submit the effluent data necessary to characterize the facility. Below are some required data elements that are commonly omitted from permit applications:

- Valid whole effluent toxicity (WET) testing data, required from POTWs with design flows greater than 1 mgd or those with a pretreatment program. This requirement may be satisfied if the

NMED Exhibit 70

expiring permit contains a requirement for effluent characterization of WET. The permit writer should note the use of this option on the fact sheet.

- Biosolids (sewage sludge) monitoring data; a description of biosolids use and disposal procedures; annual biosolids production volumes; and information on the suitability of the site and a description of the site management for land application sites from POTWs and other TWTDS. A land application plan is required for any sites not identified in the application.
- Expected toxics and other pollutants. Non-municipal dischargers categorized as *primary industries* have some mandatory testing requirements for toxic pollutants (see § 122.21, Appendix D, Table I and Table II and also listed in Application Form 2C).
- Production rates and flow data from industrial facilities that are subject to production- or flow-based effluent guidelines. Applicants must use units of measure corresponding to applicable effluent guidelines to allow calculation of effluent limitations.
- Appropriate sample types for all required pollutants and parameters being analyzed (Part 136) (see sections 8.1.4 and 8.3 of this manual for more information). For example, only grab samples or continuous monitoring may be used for pH, total residual chlorine, and temperature, and only grab samples may be used for total phenols and volatile organics.

Exhibit 4-5 presents three examples of the types of questions that the permit writer should consider to determine whether an application is complete.

Exhibit 4-5 Considerations for an application to be complete

Example 1:

A plastics processor submits Form 1 and Form 2C but fails to indicate *testing required* for any gas chromatograph/mass spectrometer (GC/MS) fractions in section V.C. of Form 2C and does not provide any data for these pollutants.

Question:
Did the applicant provide all the required data for the toxic organic pollutants in Form 2C?

Answer:
No. The plastics processor is required to indicate *testing required* (in the check box) and provide data from at least one sample for each pollutant in the volatile GC/MS fraction (Table 2C-2 in the application form instructions and § 122.21(g)(7)(v)(A) of the NPDES regulations).

Example 2:

A soap and detergent manufacturing facility in the liquid detergents subcategory submits Form 1 and Form 2C but marks thallium and beryllium as *believed absent* in section V.C. of Form 2C and did not provide any data for these pollutants.

Question:
Is it appropriate for this applicant to mark *believed absent* in this section of Form 2C?

Answer:
No. Although an applicant that manufactures liquid detergents is not expected to discharge thallium and beryllium, page 2C-3 of the application form instructions and § 122.21(g)(7)(v)(B) require testing for all listed metals by all applicants in a primary industry category, such as soap and detergent manufacturers. The indication of *believed absent* is incorrect. The applicant should have indicated *testing required* and provided the results of at least one sample per pollutant. Occasionally, unexpected contaminants could be present in a wastestream.

NMED Exhibit 70

Exhibit 4-5 Considerations for an application to be complete (continued)

Example 3:
An integrated slaughterhouse and meat processing facility submits Form 1 and Form 2C and indicates that zinc is *believed absent* from its wastewater.

Question:
Is *believed absent* a proper indication for zinc for this wastewater?

Answer:
Possibly. After consulting the effluent guidelines development documents for the Meat and Poultry Products Point Source Category, the permit writer determines that metals, including zinc, are often used as feed additives and in sanitation products and might be present in the effluent, even though there are no effluent limitations specified for zinc in the applicable effluent guideline. The permit writer should contact the applicant and clarify whether zinc would be expected to be present in the discharge.

The comprehensive testing requirements that apply to the various categories of industry are designed to determine whether any contaminants (some expected, some unexpected) are present in significant quantities and to determine levels of pollutants that are known to be present. Exhibit 4-6 presents an example of how a permit writer makes the determination of pollutant data required in the application.

Exhibit 4-6 Example of required testing during application review

Consider the plastics processor and the liquid detergents manufacturer mentioned above, and answer the following questions:

Question:
What pollutant data are needed to characterize the industries above?
- For which toxic organic pollutants are they required to test?
- For which heavy metals are they required to test?
- Which metals would you expect to find in their wastewaters regardless of whether testing is required?

Answer:
The application form in Table 2C-2 and § 122.21(g)(7)(ii)(A) of the NPDES regulations require testing of the volatile GC/MS fraction by the plastics processor and the volatile, acid, and base/neutral fractions by the liquid detergent manufacturer. Page 2C-3 of the application instructions and § 122.21(g)(7)(ii)(B) require testing of all the metals listed in item V, Part C1 of the application form as well as cyanide and total phenols by both of these primary industry facilities. For information on which, if any, metals might be expected in wastewater discharged by these applicants, see the effluent guidelines development documents.

4.5.3 The Accurate Application

All information submitted on a permit application must be accurate. Although it might be difficult to detect certain inaccuracies, a number of common mistakes can be readily detected. When mistakes are detected, they must be corrected. Generally, any correction or edit to the application should be obtained from the applicant in writing and will become a part of the administrative record for the permit.

In most cases, errors in the application will be inadvertent because of the length and complexity of the form. Note, however, that the application certification statement indicates, "…that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations." If the permit writer believes that falsification has occurred, he or she should refer the findings to the agency's enforcement staff.

NMED Exhibit 70

Some of the most common mistakes on permit applications include failing to provide the correct long-term average and daily maximum values, reporting quantified values below known detection limits, and using misplaced decimal points or incorrect concentration units. Exhibit 4-7 presents three examples of the types of questions that the permit writer should consider while reviewing the permit application for accuracy. Additional guidance from EPA might be available to assist permit writers in reviewing applications for some of these common errors. For example, an August 23, 2007, memorandum *Analytical Methods for Mercury in National Pollutant Discharge Elimination System (NPDES) Permits*[3] <www.epa.gov/npdes/pubs/mercurymemo_analyticalmethods.pdf> describes when a method for mercury is sufficiently sensitive for purposes of permit applications and monitoring under a permit. In the memorandum, EPA strongly recommends that a permitting authority determine that a permit application that lacks effluent data analyzed with a sufficiently sensitive EPA-approved method (such as Method 1631E) is incomplete unless and until the facility supplements the original application with data analyzed with such a method.

4.6 Facility Information Review

In addition to the submitted application form, the permit writer should assemble other information that could be used to develop permit limitations and conditions.

4.6.1 Permit File Review

Before developing the draft permit and fact sheet, the permit writer should assemble and review any additional background information on the facility. If the permit writer is reissuing an existing permit, much of the information should be available in the permit file. Such information would typically include

- The current permit.
- The fact sheet or statement of basis for the current permit.
- Discharge monitoring reports (DMRs).
- Compliance inspection reports.
- Engineering reports.
- Correspondence or information on changes in plant conditions, problems, and compliance issues.

Much of this information, particularly DMR data, is stored in automated data tracking systems such as

- Permit Compliance System (PCS) or state databases.
- Integrated Compliance Information System (ICIS)-NPDES <https://icis.epa.gov>.
- Online Tracking Information System (OTIS) <www.epa.gov/idea/otis/>.
- Envirofacts Warehouse <www.epa.gov/enviro/>.

The permit writer can check with other permit writers who have permitted similar types of facilities to see if there are any special considerations related to the type of facility to be permitted. A permit writer might also wish to discuss compliance issues, changes, or history of complaints with compliance personnel who conducted previous inspections of the facility or with permit writers for other media (e.g., air, solid waste). Examples of some other sources of information that the permit writer could use for permit development include the following:

- Receiving water quality data from databases such as the EPA STOrage and RETrieval database (STORET) <www.epa.gov/STORET/>.

NMED Exhibit 70

Exhibit 4-7 Considerations for an application to be accurate

Example 1:

An industrial applicant provides a daily maximum effluent flow value of 50,000 gpd in its permit application Form 2C. However, a review of historical water usage records and an old permit application indicate estimated wastewater flows ranged from 100,000 to 150,000 gpd. The applicant had not instituted any water use reduction measures, significantly changed its process operations, or decreased its number of employees.

Question:
Are reported values consistent with historical information?

Answer:
No. An inspection of the facility revealed two separate water meters (one for sanitary and one for process water); the applicant had overlooked the sanitary meter. Further, the process water meter was found to be defective. Subsequent flow monitoring of the actual total wastestream recorded a flow of 125,000 gpd. A new water meter was installed, and concurrent wastestream flow monitoring and water meter readings resulted in the following water balances:

- **Water In** (based on both water meter readings):
  148,000 gpd (131,000 gpd process line and 17,000 gpd sanitary line).
- **Water Out** (based on effluent flow monitoring):
  125,000 gpd total treated effluent discharged to the receiving water.
  Evaporative and consumption losses were estimated at 23,000 gpd (15% of total water usage).

The permit writer should require the applicant to submit a signed and certified letter with the revised flow estimates and a new water balance diagram or submit a revised application.

Example 2:

An applicant reported its maximum daily flow as 1.2 mgd, the maximum daily suspended solids concentration as 23 milligrams per liter (mg/L), and the maximum daily mass discharge as 690 pounds per day (lbs/day).

Question:
Do the concentration, mass, and flow values correspond?

Discussion:
No. Even in the unlikely event that the maximum daily flow and the maximum daily concentration occurred on the same day, the mass discharged would be well below the reported value of 690 lbs/day. Using the calculation below, the mass discharge that corresponds to the solids concentration (23 mg/L) and flow (1.2 mgd) would be 230 lbs/day:

$$23 \text{ mg/L} \times 1.2 \text{ mgd} \times \underbrace{8.34 \text{ (lbs)(L)/(mg)(millions of gallons)}}_{\text{(conversion factor)}} = 230 \text{ lbs/day}$$

Because the applicant reported a maximum mass discharge of 690 lbs/day, a significant discrepancy is indicated. The permit writer should contact the applicant to resolve the discrepancy. The applicant should submit a signed and certified letter clarifying the correct maximum daily mass discharge of suspended solids or submit a revised application.

Example 3:

The results submitted in the application for total cyanide are all reported as < 1,000 micrograms per liter (µg/L). When asked, the applicant indicated that total cyanide was analyzed using EPA Method 335.3 (Color, Auto).

Question:
Do concentration values correspond with published method detection limits for the method used?

Answer:
No. EPA Method 335.3 for total cyanide has a published method detection limit (MDL) of 5 µg/L. The applicant should be able to quantify results for total cyanide at values well below 1,000 µg/L using this method. The applicant has most likely used Standard Method 4500-CN (titrimetric) for total cyanide, rather than the testing procedure indicated. If total cyanide is expected to be present in the discharge and would be of concern at effluent concentrations below 1,000 µg/L, the permit writer should require the applicant to retest for total cyanide using the more sensitive method and to submit the results in a signed, certified letter.

NMED Exhibit 70

- Supporting documentation collected by EPA for effluent guidelines and categorical pretreatment standards for a variety of industrial categories.
- Reference textbooks and technical documents that provide information about manufacturing processes and wastestreams for specific industry categories, which are available from libraries such as
  - National Technical Information Service (NTIS) <www.ntis.gov>.
  - EPA libraries <www.epa.gov/natlibra/libraries.htm>.
  - Office of Water Resource Center (OWRC) <www.epa.gov/safewater/resource/>.
  - National Service Center for Environmental Publications (NSCEP) <www.epa.gov/ncepihom/>.
- Related environmental permits that could provide site-specific background information about the types of pollutants and wastestreams at a facility, including, for example
  - RCRA permits, which regulate the management of hazardous waste by owners and operators of treatment, storage, and disposal facilities.
  - Clean Air Act permits, which regulate the discharge of atmospheric pollutants.
- EPA's *Treatability Manual*[4], which is a five-volume guidance manual that provides detailed descriptions of industrial processes, potential pollutants from each process, appropriate treatment technologies, and cost estimating procedures.
- The Toxic Release Inventory (TRI) <www.epa.gov/tri/>, which is accessible on EPA's mainframe and through a public online service. The TRI contains information on more than 300 listed toxic chemicals released by specific facilities, including chemical identification, quantity of chemicals released to various environmental media, off-site waste transfer, and waste treatment and minimization information.

If the permit writer must address special conditions in a permit for a municipal discharger to develop or implement a pretreatment program or to address discharges other than the wastewater treatment plant discharge, he or she should obtain the information needed to develop these special conditions. For example, the permit writer might need information on pretreatment program implementation, combined sewer overflows (CSOs), sanitary sewer overflows (SSOs), sewage sludge use or disposal, or stormwater discharges relevant to the facility. Such information is in

- Annual pretreatment reports, pretreatment compliance inspections and audits.
- CSO reports.
- Bypass notifications or SSO reports.
- Stormwater discharge applications or NOIs for a general permit.

4.6.2 Facility Site Visits

Facility site visits are an invaluable way to update information on manufacturing processes; obtain information about the facility's operations, equipment or management; and verify application information. A site visit also acquaints the permit writer with the people who will be operating under the permit and participating in the permit development process.

Site visits can also allow the permit writer to gain a better understanding of more complex facilities. Site visits are especially warranted if significant pollution control or treatment improvements will be required, if there have been frequent problems in complying with the existing permit, if there are known problems

NMED Exhibit 70

with spills or leaks or with contaminated surface runoff, or if there are other unique on-site activities that could affect the characteristics of the discharge from the facility.

The site visit should include a detailed review of production processes to evaluate the types of toxic or hazardous substances that might be present in raw materials, products, and by-products. The permit writer should review the water uses, the resulting wastewater streams, and any in-process pollution controls. This review is needed to assist in selecting toxic and other pollutants to be limited and in evaluating possible in-process control improvements.

In addition, the site visit should include a review of the performance and operation and maintenance practices of wastewater treatment facilities. The review is useful in evaluating the adequacy of existing treatment performance and assessing the feasibility of improvements in performance. The permit writer should examine effluent monitoring points, sampling methods, and analytical techniques to identify any needed changes to monitoring requirements and to evaluate the quality of DMR data.

Raw material and product storage and loading areas, sludge storage and disposal areas, hazardous waste management facilities, including on-site disposal areas, and all process areas should be observed to determine the need for controls on surface runoff and specific BMPs. Information from other environmental programs (e.g., CERCLA or RCRA) might be important in this regard.

While on-site, the permit writer should note any housekeeping problems or the need for spill prevention actions, which are not usually detectable from permit applications. If allowed, photographs of problem areas should be taken for future use during permit preparation. If necessary, the permit writer should meet with management to ask questions or clarify information provided on the permit application. If any inaccuracies in the application were found because of the site visit, that is the time for the permit writer to request corrected information.

The time required to conduct a site visit will vary according to the complexity of the facility. For facilities with only a few basic processes, one main waste treatment system, limited in-process controls, few surface runoff outfalls, and limited on-site management of sludge or hazardous wastes, an adequate site visit can most likely be completed in one day. Visits to complex, larger plants with several treatment systems, numerous outfalls, and extensive ancillary activities may require several days.

Time spent on site visits often results in time savings during permit preparation. However, time and travel resources might not be adequate to allow visits to all facilities to be permitted. In such cases, the permit writer might be able to obtain much of the desired information from facility compliance inspections and should try to coordinate the timing of compliance inspections with the timing of permit development.

Aerial photographs may provide much of the needed information on the potential for contamination of surface runoff and on ancillary activities without a site visit or inspection. In addition, comparing aerial photographs with site and process diagrams provided with the application can provide the permit writer with a complete visual description of the facility. Aerial photographs are available from a variety of sources, including the U.S. Geological Survey Earth Resources Observation and Science Center <eros.usgs.gov/#/Find_Data>; TerraServer <www.terraserver.com>; Google Earth <earth.google.com>; and other private contractors.

NMED Exhibit 70

4.7 Confidential Information

In accordance with Part 2, information submitted to EPA pursuant to the NPDES permitting regulations under Part 122 may be claimed as confidential; however, EPA has determined that the following information will not be held confidential (§ 122.7):

- Name and address of the applicant.
- Permit applications and information submitted with applications.
- Permits.
- Effluent data.

Information that may be claimed as confidential includes material related to manufacturing processes unique to the applicant, or information that might adversely affect the competitive position of the applicant if released to the public. Under such circumstances, the permit writer will be required to treat the information as confidential in accordance with the requirements in Part 2. Any claims of confidentiality must be made at the time of submission or the information will not be considered confidential.

CHAPTER 5. Technology-Based Effluent Limitations

One of the major strategies of the Clean Water Act (CWA) in making "reasonable further progress toward the national goal of eliminating the discharge of all pollutants" is to require effluent limitations based on the capabilities of the technologies available to control those discharges. Technology-based effluent limitations (TBELs) aim to prevent pollution by requiring a minimum level of effluent quality that is attainable using demonstrated technologies for reducing discharges of pollutants or pollution into the waters of the United States. TBELs are developed independently of the potential impact of a discharge on the receiving water, which is addressed through water quality standards and water quality-based effluent limitations (WQBELs). The NPDES regulations at Title 40 of the *Code of Federal Regulations* (CFR) 125.3(a) require NPDES permit writers to develop technology-based treatment requirements, consistent with CWA section 301(b), that represent the minimum level of control that must be imposed in a permit. The regulation also indicates that permit writers must include in permits additional or more stringent effluent limitations and conditions, including those necessary to protect water quality. As described in Chapter 7 of this manual, the permit writer might also need to apply anti-backsliding requirements to determine the final effluent limitations for the NPDES permit.

This chapter discusses development of TBELs for publicly owned treatment works (POTWs) and industrial (non-POTW) dischargers. Chapter 6 discusses development of WQBELs. Exhibit 5-1 illustrates the relationship between TBELs and WQBELs in an NPDES permit and the determination of final effluent limitations.

Exhibit 5-1 Developing effluent limitations

NMED Exhibit 70

5.1 Technology-based Effluent Limitations for POTWs

The largest category of dischargers requiring individual NPDES permits is POTWs. The federal regulations at § 403.3(q) define a POTW as a treatment works (as defined in CWA section 212) that is owned by a state or municipality [as defined in CWA section 502(4)]. Under § 403.3(q), that definition includes "any devices and systems used in the storage, treatment, recycling and reclamation of municipal sewage or industrial wastes of a liquid nature." The definition also includes "sewers, pipes, and other conveyances only if they convey wastewater to a POTW Treatment Plant," as defined in § 403.3(r). Under § 403.3(q), the term POTW "also means the municipality as defined in section 502(4) of the Act, which has jurisdiction over the Indirect Discharges to and the discharges from such a treatment works."

CWA section 304(d) required the U.S. Environmental Protection Agency (EPA) to publish information on the degree of effluent reduction attainable through the application of secondary treatment. Under CWA section 301(b)(1)(B), in general, POTWs in existence on July 1, 1977, were required to meet discharge limitations based on secondary treatment (or any more stringent limitations established under state law, including those necessary to meet state water quality standards). On the basis of those statutory provisions, EPA developed secondary treatment regulations, which are specified in Part 133. Later amendments to CWA section 304(d) called for EPA to develop alternative standards for certain types of POTWs. Those standards are referred to as "equivalent to secondary treatment" standards.

5.1.1 Secondary and Equivalent to Secondary Treatment Standards

Several regulations implement the statutory requirements for developing standards and discharge limitations based on secondary treatment. EPA has promulgated regulations in Part 133 establishing secondary treatment standards, equivalent to secondary treatment standards, and a number of special considerations applied on a case-by-case basis. In addition, § 122.44(a)(1) requires that NPDES permits include applicable technology-based limitations and standards, while regulations at § 125.3(a)(1) state that TBELs for POTWs must be based on secondary treatment standards (which includes the "equivalent to secondary treatment standards") specified in Part 133.

5.1.1.1 Secondary Treatment Standards

In Part 133, EPA published secondary treatment standards based on an evaluation of performance data for POTWs practicing a combination of physical and biological treatment to remove biodegradable organics and suspended solids. The regulation applies to all POTWs and identifies the technology-based performance standards achievable based on secondary treatment for 5-day biochemical oxygen demand (BOD_5), total suspended solids (TSS), and pH. Exhibit 5-2 summarizes the standards.

Exhibit 5-2 Secondary treatment standards

Parameter	30-day average	7-day average
BOD_5	30 mg/L (or 25 mg/L $CBOD_5$)	45 mg/L (or 40 mg/L $CBOD_5$)
TSS	30 mg/L	45 mg/L
BOD_5 and TSS removal (concentration)	not less than 85%	--
pH	within the limits of 6.0–9.0*	

* unless the POTW demonstrates that: (1) inorganic chemicals are not added to the waste stream as part of the treatment process; and (2) contributions from industrial sources do not cause the pH of the effluent to be less than 6.0 or greater than 9.0

mg/L = milligrams per liter

NMED Exhibit 70

The regulation also includes an alternate set of standards that apply to certain facilities employing waste stabilization ponds or trickling filters as the principal process. Those standards are called equivalent to secondary treatment standards.

5.1.1.2 Equivalent to Secondary Treatment

Some biological treatment technologies, such as trickling filters or waste stabilization ponds, are capable of achieving significant reductions in BOD_5 and TSS but might not consistently achieve the secondary treatment standards for these parameters. Congress recognized that unless alternate limitations were set for facilities with trickling filters or waste stabilization ponds, which often are in small communities, such facilities could be required to construct costly new treatment systems to meet the secondary treatment standards even though their existing treatment technologies could achieve significant biological treatment. To prevent requiring upgrades where facilities were achieving their original design performance levels, Congress included provisions in the 1981 amendments to the Clean Water Act Construction Grants program (*Public Law 97-117, Section 23*) that required EPA to make allowances for alternative biological treatment technologies, such as a trickling filters or waste stabilization ponds. In response to that requirement, in 1984, EPA promulgated regulations at § 133.105 that include alternative standards that apply to facilities using "equivalent to secondary treatment." A facility must meet the criteria in § 133.101(g) to qualify for application of those alternative standards.

Equivalent to Secondary Standards

The equivalent to secondary treatment standards, as specified in § 133.105, are shown in Exhibit 5-3.

Exhibit 5-3 Equivalent to secondary treatment standards

Parameter	30-day average	7-day average
BOD_5	not to exceed 45 mg/L (or not to exceed 40 mg/L $CBOD_5$)	not to exceed 65 mg/L (or not to exceed 60 mg/L $CBOD_5$)
TSS	not to exceed 45 mg/L	not to exceed 65 mg/L
BOD_5 and TSS removal (concentration)	not less than 65%	--
pH	within the limits of 6.0–9.0*	

* unless the POTW demonstrates that: (1) inorganic chemicals are not added to the waste stream as part of the treatment process; and (2) contributions from industrial sources do not cause the pH of the effluent to be less than 6.0 or greater than 9.0

Criteria to Qualify for Equivalent to Secondary Standards

To be eligible for discharge limitations based on equivalent to secondary standards, a POTW must meet all three of the following criteria:

Criterion #1—Consistently Exceeds Secondary Treatment Standards: The first criterion that must be satisfied to qualify for the equivalent to secondary standards is demonstrating that the BOD_5 and TSS effluent concentrations consistently achievable through proper operation and maintenance of the treatment works exceed the secondary treatment standards set forth in §§ 133.102(a) and (b). The regulations at § 133.101(f) define "effluent concentrations consistently achievable through proper operation and maintenance" as

NMED Exhibit 70

- (f)(1): For a given pollutant parameter, the 95th percentile value for the 30-day average effluent quality achieved by a treatment works in a period of at least 2 years, excluding values attributable to upsets, bypasses, operational errors, or other unusual conditions.
- (f)(2): A 7-day average value equal to 1.5 times the value derived under paragraph (f)(1).

Some facilities might meet this criterion only for the BOD_5 limitations or only for the TSS limitations. EPA believes that it is acceptable for the permit writer to adjust the limitations for only one parameter (BOD_5 or TSS) if the effluent concentration of only one of the parameters is demonstrated to consistently exceed the secondary treatment standards.

Criterion #2—Principal Treatment Process: The second criterion that a facility must meet to be eligible for equivalent to secondary standards is that its principal treatment process must be a trickling filter or waste stabilization pond (i.e., the largest percentage of BOD and TSS removal is from a trickling filter or waste stabilization pond system).

Criterion #3—Provides Significant Biological Treatment: The third criterion for applying equivalent to secondary standards is that the treatment works provides significant biological treatment of municipal wastewater. The regulations at § 133.101(k) define *significant biological treatment* as using an aerobic or anaerobic biological treatment process in a treatment works to consistently achieve a 30-day average of at least 65 percent removal of BOD_5.

A permit writer should consider each facility on a case-by-case basis to determine whether it meets those three criteria. To apply the criteria, the permit writer should assemble enough influent, effluent, and flow data from the facility to adequately characterize the facility's performance or require the discharger to provide an appropriate analysis. If the facility has made substantial changes in its operations or treatment processes during the current permit term, the permit writer, using his or her best professional judgment (BPJ), may elect to use data for a period that is representative of the discharge at the time the permit is being drafted. Facilities that do not meet all three criteria do not qualify as equivalent to secondary treatment facilities. For such facilities, the secondary treatment standards apply. EPA noted in its December 1985 *Draft Guidance for NPDES Permits and Compliance Personnel—Secondary Treatment Redefinition*[1] that a treatment works operating beyond its design hydraulic or organic loading limit is not eligible for application of equivalent to secondary standards. If overloading or structural failure is causing poor performance, the solution to the problem is construction, not effluent limitations adjustment.

5.1.2 Adjustments to Equivalent to Secondary Standards

In addition to providing secondary treatment standards and equivalent to secondary treatment standards, the federal regulations allow states to make adjustments to the standards and to apply those adjusted standards on a case-by-case basis.

5.1.2.1 Adjusted TSS Requirements for Waste Stabilization Ponds

In accordance with regulations adopted by EPA in 1977 and revised in 1984, states can adjust the maximum allowable TSS concentration for waste stabilization ponds upward from those specified in the equivalent to secondary treatment standards to conform to TSS concentrations achievable with waste stabilization ponds. The regulation, found at § 133.103(c), defines "SS concentrations achievable with waste stabilization ponds" as the effluent concentration achieved 90 percent of the time within a state or

NMED Exhibit 70

appropriate contiguous geographical area by waste stabilization ponds that are achieving the levels of effluent quality for BOD_5 specified in § 133.105(a)(1) (45 milligrams per liter [mg/L] as a 30-day average). To qualify for an adjustment up to as high as the maximum concentration allowed, a facility must use a waste stabilization pond as its principal process for secondary treatment and its operations and maintenance data must indicate that it cannot achieve the equivalent to secondary standards. EPA has published approved alternate TSS requirements in 49 *Federal Register* (FR) 37005, September 20, 1984. Exhibit 5-4 is a summary from the FR notice of the adjusted TSS requirements for each state.

Exhibit 5-4 State-specific adjusted TSS requirements*

Location	Alternate TSS limitation (30-day average) (mg/L)	Location	Alternate TSS limitation (30-day average) (mg/L)
Alabama	90	Nebraska	80
Alaska	70	North Carolina	90
Arizona	90	North Dakota

NMED Exhibit 70

5.1.2.2 Alternative State Requirements (ASRs)

To further address the potential variations in facility performance arising from geographic, weather, or seasonal conditions in different states, the revised secondary treatment regulations (adopted in 1984) also included provisions in § 133.105(d) for ASRs. The ASR provisions give states flexibility to modify the maximum allowable concentrations of both BOD_5 and TSS for trickling filter facilities and for BOD_5 for waste stabilization pond facilities. ASRs are set at levels consistently achievable through proper operation and maintenance [§ 133.101(f)] by the median facility in a representative sample of facilities within a state or appropriate continuous geographical area that meet the definition of facilities eligible for treatment equivalent to secondary treatment. Qualifying facilities are eligible to receive limitations up to the concentrations specified by the ASRs.

5.1.3 Applying Secondary Treatment Standards, Equivalent to Secondary Treatment Standards, and Adjusted Standards

Determining whether secondary treatment standards or equivalent to secondary standards apply to a POTW and determining the specific discharge limitations for the facility based on either set of standards and any other special considerations that might apply can be a complex process. Permit writers should remember that compliance with limitations must be measurable and percent removal limitations require influent monitoring (for more on establishing monitoring conditions, see section 8.1 of this manual). This section presents a step-by-step procedure to establishing technology-based effluent limitations for POTWs as shown in Exhibit 5-5.

Exhibit 5-5 Steps to establish technology-based discharge limitations for POTWs

Step 1.	Determine whether secondary treatment standards or equivalent to secondary treatment standards or adjusted standards apply
Step 2.	Calculate effluent limitations based on secondary treatment standards or
Step 3.	Calculate effluent limitations based on equivalent to secondary standards or
Step 4.	Calculate effluent limitations based on adjusted standards
Step 5.	Apply special considerations for further adjustments
Step 6.	Document the application of secondary or equivalent to secondary treatment standards or adjusted standards and all special considerations in the fact sheet

5.1.3.1 Step 1: Determine Whether Secondary Treatment Standards or Equivalent to Secondary Treatment Standards or Adjusted Standards Apply

The first step for permit writers to develop TBELs for municipal dischargers is to determine whether secondary treatment standards (discussed in section 5.1.1 above), equivalent to secondary standards (discussed in section 5.1.1.2 above), or some adjustments to the equivalent to secondary standards (discussed in section 5.1.2 above) apply to the POTW.

An important consideration for permitting authorities is how to treat new POTW discharges that use a waste stabilization pond or trickling filter, or a combination of the two. New facilities or new discharges from trickling filters or waste stabilization ponds often are capable of achieving secondary treatment standards. In the preamble to the secondary treatment regulation (49 FR 37002, September 20, 1984) and in § 133.105(f)(2), EPA noted that when developing permits for new trickling filter and waste

NMED Exhibit 70

stabilization pond facilities, permitting authorities should consider the ultimate design capability of the treatment process, geographical and weather conditions, and the performance capabilities of recently constructed facilities in similar situations.

After determining whether secondary treatment standards or equivalent to secondary treatment standards apply to a facility or a discharge, the permit writer applies the appropriate standards to develop effluent limitations. Section 5.1.3.2 below (Step 2) details development of effluent limitations for facilities or discharges where secondary treatment standards apply; section 5.1.3.3 below (Step 3) details development of limitations for facilities that qualify for equivalent to secondary standards; and section 5.1.3.4 below (Step 4) details development of limitations for facilities where adjusted standards apply. It is possible that a facility with multiple biological treatment processes could have limitations based on a combination of the standards (see section 5.1.3.5 below [Step 5]); therefore, those sections are presented as separate steps.

5.1.3.2 Step 2: Calculate Effluent Limitations Based on Secondary Treatment Standards

If the facility being permitted is subject to the secondary treatment standards, the permit writer should complete Step 2. Otherwise, he or she should move to Step 3 in section 5.1.3.3 below.

Applying the secondary treatment standards in NPDES permits is straightforward. Where secondary treatment standards apply, the permit should include effluent limitations in the permit as presented in Exhibit 5-6 below, consistent with the secondary treatment standards and the regulatory requirements in § 122.45(d)(2).

Exhibit 5-6 Effluent limitations calculated from secondary treatment standards

Parameter	Average monthly limitation	Average weekly limitation
BOD_5	30 mg/L (or 25 mg/L $CBOD_5$)	45 mg/L (or 40 mg/L $CBOD_5$)
TSS	30 mg/L	45 mg/L
BOD_5 and TSS removal (concentration)	not less than 85%	N/A
pH	Within the range of 6.0–9.0 standard units at all times (or expressed as instantaneous minimum and maximum limitations)*	

* unless the POTW demonstrates that: (1) inorganic chemicals are not added to the waste stream as part of the treatment process; and (2) contributions from industrial sources do not cause the pH of the effluent to be less than 6.0 or greater than 9.0

Certain provisions in the EPA regulations warrant some clarification.

First, the secondary treatment standards are stated as 30-day and 7-day averages, whereas § 122.45(d)(2) requires that effluent limitations for POTWs be expressed, unless impracticable, as average monthly and average weekly limitations. The NPDES regulations in § 122.2 define average monthly and average weekly limitations on a calendar period basis. Therefore, EPA recommends that permit writers apply the 30-day and 7-day average secondary treatment standards directly as average monthly (calendar month) and average weekly (calendar week) discharge limitations.

Second, § 122.45(f)(1) requires that all permit limitations, standards, or prohibitions be expressed in terms of mass except in any of the following cases:

- For pH, temperature, radiation or other pollutants that cannot appropriately be expressed by mass limitations.

NMED Exhibit 70

- When applicable standards and limitations are expressed in terms of other units of measure.
- If in establishing permit limitations on a case-by-case basis under § 125.3, limitations expressed in terms of mass are infeasible because the mass of the pollutant discharged cannot be related to a measure of operation, and permit conditions ensure that dilution will not be used as a substitute for treatment.

The first condition applies to pH requirements established by secondary treatment standards. In addition, because the 30-day and 7-day average requirements for BOD_5 and TSS, including percent removal, are expressed in terms of concentration, the second condition applies to the standards. Thus, mass-based discharge limitations are not specifically required to implement secondary treatment standards; however, permit writers can choose to include mass-based limitations in a permit. In general, regulations at § 122.45(b)(1) require using the design flow rate of the POTW to calculate limitations. To calculate a mass-based limitation for a POTW (in pounds per day [lbs/day]) a permit writer would use the equation and follow the example calculations in Exhibit 5-7.

Exhibit 5-7 POTW mass based limitation calculation equation and example calculations

POTW design flow in million gallons per day (mgd)	x	**Concentration-based limitation** in milligrams per liter (mg/L)	x	**Conversion factor** 8.34 with units of (lbs)(L) / (mg)(millions of gallons)

A POTW with a design flow of 2.0 mgd would have mass-based limitations calculated from secondary treatment standards as follows:

Mass-based limitation*	=	**POTW design flow** x **Concentration-based limitation** x **Conversion factor**		
BOD_5				
Average monthly	=	2.0 mgd x 30 mg/L x 8.34 (lbs)(L) / (mg)(millions of gallons)	=	**500 lbs/day**
Average weekly	=	2.0 mgd x 45 mg/L x 8.34 (lbs)(L) / (mg)(millions of gallons)	=	**750 lbs/day**
TSS				
Average monthly	=	2.0 mgd x 30mg/L x 8.34 (lbs)(L) / (mg)(millions of gallons)	=	**500 lbs/day**
Average weekly	=	2.0 mgd x 45mg/L x 8.34 (lbs)(L) / (mg)(millions of gallons)	=	**750 lbs/day**

* calculated to 2 significant figures

5.1.3.3 Step 3: Calculate Effluent Limitations Based on Equivalent to Secondary Standards

If a facility being permitted is subject to the equivalent to secondary standards without any further adjustments by the state (e.g., ASRs), the permit writer should complete Step 3. Otherwise, he or she should move to Step 4 in section 5.1.3.4 below.

For facilities that qualify for equivalent to secondary standards, effluent limitations must meet the requirements specified in § 133.105 and summarized above in Exhibit 5-3 (not accounting for any further approved adjustments). It is important to note that the equivalent to secondary standards specify the maximum allowable discharge concentration of BOD_5 and TSS and a minimum percent removal requirement for qualified facilities. The regulations at § 133.105(f) require a permitting authority to include more stringent limitations when it determines that the 30-day average and 7-day average BOD_5 and TSS concentrations are achievable through proper operation and maintenance of the treatment works

NMED Exhibit 70

(based on an analysis of the past performance for an existing facility or considering the design capability of the treatment process and geographical and weather conditions for a new facility) would enable the treatment works to achieve more stringent limitations than the least stringent effluent quality allowed by the equivalent to secondary standards. As noted above, the regulations at § 133.101(f) define, "effluent concentrations consistently achievable through proper operation and maintenance" as the 95th percentile value for the 30-day average effluent quality achieved by a treatment works in a period of at least 2 years, excluding values attributable to upsets, bypasses, operational errors, or other unusual conditions. The 7-day average value is set equal to 1.5 times the 30-day average value.

If an existing facility does not have sufficient data to establish past performance, the permit writer could include the limitations from the previous permit in the new permit and require monitoring to generate the necessary data. In addition, the permit writer could choose to include a provision allowing the permitting authority to reopen and, if necessary, modify the permit after reviewing the additional data collected by the discharger.

As with limitations based on secondary treatment standards (shown in Exhibit 5-6 above), limitations based on equivalent to secondary standards are expressed as average monthly (calendar month) and average weekly (calendar week) limitations. Mass-based limitations can be calculated using the procedures outlined above.

5.1.3.4 Step 4: Calculate Effluent Limitations Based on Adjusted Standards

If a facility being permitted is subject to the adjusted standards as described in section 5.1.2 above, the permit writer should complete Step 4. Otherwise, he or she should move to section 5.1.3.5 below (Step 5).

As discussed in sections 5.1.2.1 and 5.1.2.2 above, the federal regulations at § 133.103(c) allow states to adjust the maximum allowable discharge concentration of TSS for waste stabilization ponds upward from what would otherwise be required by the equivalent to secondary standards, and the regulations at § 133.105(d) give states flexibility to adopt ASRs that modify equivalent to secondary requirements for both BOD_5 and TSS for trickling filter facilities and BOD_5 requirements for waste stabilization pond facilities. Where one or more of the adjusted standards apply, average monthly limitation(s) generally should be set at the lower of the following:

- The 30-day average concentration of the pollutant that could be achievable through proper operation and maintenance of the treatment works.
- The maximum concentration of the pollutant that would be allowed under the adjusted standard.

Permit writers should note, however, that if the state has developed an adjusted TSS standard for waste stabilization ponds consistent with § 133.103(c), the regulations would allow uniform application of that standard to POTWs where waste stabilization ponds are the principal process used for secondary treatment and operation and maintenance data indicate that the equivalent to secondary treatment standards for TSS cannot be achieved.

The average weekly limitation can be set equal to 1.5 times the average monthly limitation and mass-based limitations may be calculated using the procedures outlined above.

NMED Exhibit 70

5.1.3.5 Step 5: Apply Special Considerations for Further Adjustments

Part 133 allows a permit writer to make further adjustments when calculating effluent limitations derived from secondary treatment standards or equivalent to secondary standards based on several special considerations. The permit writer should determine whether any of the special considerations outlined in this section apply and, as appropriate, make any further adjustments to the concentration limitations or percent removal requirements. The calculated limitations, after making such adjustments, are the final technology-based effluent limitations for the POTW.

Substitution of $CBOD_5$ for BOD_5

Wastewater contains carbonaceous oxygen demanding substances and nitrogenous oxygen demanding substances. A $CBOD_5$ test measures the 5-day carbonaceous biochemical oxygen demand while the BOD_5 test measures the both carbonaceous biochemical oxygen demand and nitrogenous biochemical oxygen demand. During nitrification, nitrifying bacteria use a large amount of oxygen to consume nitrogenous oxygen demanding substances (unoxidized nitrogen and ammonia-nitrogen) and convert these to oxidized nitrate. For wastewaters with significant nitrogen content, basing permit limitations on $CBOD_5$ instead of BOD_5 eliminates the impact of nitrification on discharge limitations and compliance determinations. EPA recognizes that the $CBOD_5$ test can provide accurate information on treatment plant performance in many cases and, in Part 133, allows permit writers to use $CBOD_5$ limitations in place of BOD_5 limitations to minimize false indications of poor facility performance as a result of nitrogenous oxygen demand.

EPA has established $CBOD_5$ standards for cases where secondary treatment standards or equivalent to secondary treatment standards are applied:

- **Secondary Treatment:** The $CBOD_5$ secondary treatment performance standards specified by the regulations are as follows:
  - 25 mg/L as a 30-day average.
  - 40 mg/L as a 7-day average.
- The EPA-approved test procedures in Part 136 include a $CBOD_5$ (nitrogen inhibited) test procedure. Subject to any state-specific requirements, a permit writer can specify these $CBOD_5$ limitations along with $CBOD_5$ monitoring requirements in any POTW permit requiring performance based on secondary treatment standards [§ 133.102(a)(4)].
- **Equivalent to Secondary Treatment:** The $CBOD_5$ equivalent to secondary treatment performance standards specified by the regulations are as follows:
  - No greater than 40 mg/L as a 30-day average.
  - No greater than 60 mg/L as a 7-day average.
- Where data are available to establish $CBOD_5$ limitations, and subject to any state-specific requirements, a permit writer may substitute $CBOD_5$ for BOD_5 and specify $CBOD_5$ limitations and monitoring requirements when applying equivalent to secondary standards.

Substitution of COD or TOC for BOD_5

Chemical oxygen demand (COD) and total organic carbon (TOC) laboratory tests can provide an accurate measure of the organic content of wastewater in a shorter time frame than a BOD_5 test (i.e., several hours versus five days). The regulations at § 133.104(b) allow a permit writer to set limitations for COD or TOC instead of BOD_5 if a long-term BOD_5:COD or BOD_5:TOC correlation has been demonstrated.

NMED Exhibit 70

Adjustments for Industrial Contributions

Under § 133.103(b), treatment works receiving wastes from industrial categories with effluent limitations guidelines and standards (effluent guidelines) requirements or new source performance standards for BOD_5 or TSS, which are less stringent than the secondary treatment standards or, if applicable, the equivalent to secondary treatment standards in Part 133, can qualify to have their 30-day BOD_5 or TSS limitations adjusted upward provided that the following are true:

- The adjusted 30-day limitations are not greater than the limitations in effluent guidelines or new source performance standards, as applicable, for the industrial category.
- The flow or loading of BOD_5 or TSS introduced by the industrial category exceeds 10 percent of the design flow or loading to the POTW.

When making this adjustment, the Part 133 values for BOD_5 and TSS should be adjusted proportionately. Accordingly, a permit writer should make the adjustment using a flow-weighted or loading-weighted average of the two concentration limitations (i.e., the limitations developed from effluent guidelines for the industrial facility and the secondary or equivalent to secondary limitations).

Adjustments to Percent Removal Requirements

The 85 percent removal requirement (for a 30-day average) in secondary treatment standards was originally established to achieve two basic objectives:

- To encourage municipalities to remove high quantities of infiltration and inflow (I/I) from their sanitary sewer systems.
- To prevent intentional dilution of influent wastewater.

In facilities with dilute influent that is not attributable to high quantities of I/I or intentional dilution, the percent removal requirement could result in forcing *advanced treatment* rather than the intended secondary treatment. Advanced treatment generally refers to treatment processes following secondary treatment (e.g., filtration, chemical addition, or two-stage biological treatment). Advanced treatment can achieve significantly greater pollutant removals than secondary treatment processes but at a higher cost.

The regulations at §§ 133.103(a), (d) and (e) provide that, under certain circumstances, permit writers may set less stringent limitations for BOD_5 and TSS percent removal. The specific circumstances and the potential adjustments to the percent removal requirement are as follows:

- **Treatment works that receive less concentrated wastes from combined sewer systems** are eligible to have less stringent monthly percent removal limitations during wet-weather events [§ 133.103 (a)] and, under certain conditions, less stringent percent removal requirements or a mass loading limitation instead of a percent removal requirement during dry weather [§ 133.103 (e)]. The permit writer must determine on a case-by-case basis whether any attainable percentage removal level can be defined during wet weather and, if so, what the level should be. To qualify for a less stringent percent removal requirement or substitution of a mass limitation during dry weather, the discharger must satisfactorily demonstrate the following:

  1. The facility is consistently meeting, or will consistently meet, its permit effluent concentration limitations, but cannot meet its percent removal limitations because of less concentrated influent. A permitting authority should consider establishing criteria for

NMED Exhibit 70

documenting what constitutes consistently meeting concentration limitations and what constitutes being unable to meet percent removal limitations because of less concentrated influent.

2. To meet the percent removal requirements, the facility would have to achieve significantly more stringent effluent concentrations than would otherwise be required by the concentration-based standards. Each permitting authority also should consider establishing criteria for demonstrating that this condition is met (e.g., because of dilute influent, X percent of the time a discharger would be forced to meet concentration requirements that are X percent more stringent than the concentration limitations otherwise applicable to satisfy the percent removal requirements).

3. The less concentrated influent wastewater does not result from either excessive infiltration or clear water industrial discharges during dry weather periods. The determination of whether the less concentrated wastewater results from excessive infiltration is discussed in regulations at § 35.2005(b)(28). This regulation defines nonexcessive infiltration as the quantity of flow that is less than 120 gallons per capita per day (domestic base flow and infiltration) or the quantity of infiltration that cannot be economically and effectively eliminated from a sewer system as determined in a cost-effectiveness analysis. The regulations at § 133.103(e) include the additional criterion that either 40 gallons per capita per day or 1,500 gallons per inch diameter per mile of sewer may be used as the threshold value for that portion of dry-weather base flow attributed to infiltration. If the less concentrated influent wastewater is the result of clear water industrial discharges, then the treatment works must control such discharges pursuant to Part 403.

- **Treatment works that receive less concentrated wastes from separate sewer systems** can qualify to have less stringent percent removal requirement or receive a mass loading limitation instead of the percent removal requirement provided the treatment plant demonstrates all of the following [§ 133.103(d)]:

  1. The facility is consistently meeting or will consistently meet its permit effluent concentration limitations but cannot meet its percent removal limitations because of less concentrated influent wastewater. For additional detail on this criterion, see discussion above for combined sewers during dry weather.

  2. To meet the percent removal requirements, the facility would have to achieve significantly more stringent limitations than would otherwise be required by the concentration-based standards. For additional detail on this criterion, see the discussion above for combined sewers during dry weather.

  3. The less concentrated influent wastewater does not result from excessive infiltration and inflow (I/I). The regulation indicates that the determination of whether the less concentrated wastewater is the result of excessive I/I will use the definition of excessive I/I at § 35.2005(b)(16), plus the additional criterion that flow is nonexcessive if the total flow to the POTW (i.e., wastewater plus inflow plus infiltration) is less than 275 gallons per capita per day. The regulation at § 35.2005(b)(16) defines excessive I/I as the quantities of I/I that can be economically eliminated from a sewer system as determined in a cost-effectiveness analysis that compares the costs for correcting the I/I conditions to the total costs for

NMED Exhibit 70

transportation and treatment of the I/I. This regulation also refers to definitions of nonexcessive I/I in §§ 35.2005(b)(28) and 35.2005(b)(29).

Secondary Treatment Variance for Ocean Discharge—CWA Section 301(h) Variance

CWA section 301(h) provides for variances from secondary treatment standards for POTWs that discharge into ocean waters if the modified requirements do not interfere with attainment or maintenance of water quality. Permit writers should note that the deadline to apply for a CWA section 301(h) variance (December 29, 1982) has passed, thus no new facilities may apply for this variance.

Eligible POTW applicants meeting the set of environmentally stringent criteria in CWA section 301(h) receive a modified NPDES permit waiving the secondary treatment requirements for the conventional pollutants of BOD_5, TSS, and pH. EPA issued regulations, developed the *Amended Section 301(h) Technical Support Document*[2], and prepared a website titled Amendments to Regulations Issued, the Clean Water Act Section 301 (h) Program <www.epa.gov/owow/oceans/discharges/301h.html>. EPA has promulgated specific regulations pertaining to CWA section 301(h) that are provided in Part 125, Subpart G.

All CWA section 301(h) variance modified permits must contain the following specific permit conditions:

- Effluent limitations and mass loadings that will assure compliance with Part 125, Subpart G.
- Requirements for pretreatment program development, a nonindustrial toxics control program, and control of combined sewer overflows.
- Monitoring program requirements that include biomonitoring, water quality, and effluent monitoring.
- Reporting requirements that include the results of the monitoring programs.

No new or substantially increased discharges from the point source of the affected pollutant can be released above that volume of discharge specified in the permit.

5.1.3.6 Step 6: Document the Application of Secondary or Equivalent to Secondary Treatment Standards and all Adjustments and Considerations in the Fact Sheet

Permit writers need to document their application of secondary or equivalent to secondary treatment standards in the NPDES permit fact sheet for municipal facilities. The permit writer should clearly identify the data and information used to determine whether secondary treatment standards or equivalent to secondary treatment standards or adjusted standards apply and how that information was used to derive effluent limitations for the permit. The permit writer should also note all adjustments and special considerations in the fact sheet. The information in the fact sheet should provide the NPDES permit applicant and the public a transparent, reproducible, and defensible description of how the NPDES permit properly incorporates secondary treatment standards.

5.2 Technology-Based Effluent Limitations for Industrial (Non-POTW) Dischargers

EPA is required to promulgate technology-based limitations and standards that reflect pollutant reductions that can be achieved by categories, or subcategories, of industrial point sources using specific

NMED Exhibit 70

technologies (including process changes) that EPA identifies as meeting the statutorily prescribed level of control under the authority of CWA sections 301, 304, 306, 307, 308, 402, and 501 (33 *United States Code* [U.S.C.] 1311, 1314, 1316, 1318, 1342, and 1361). Those national industrial wastewater controls are called effluent limitations guidelines and standards (effluent guidelines). Unlike other CWA tools, such as water quality standards, effluent guidelines are national in scope and establish performance standards for all facilities within an industrial category or subcategory.

For point sources that introduce pollutants directly into the waters of the United States (direct dischargers), the effluent guidelines promulgated by EPA are implemented through NPDES permits as authorized in CWA sections 301(a), 301(b), and 402. For sources that discharge to POTWs (indirect dischargers), EPA promulgates pretreatment standards that apply directly to those sources and are enforced by POTWs and state and federal authorities as authorized in CWA sections 307(b) and (c).

When developing TBELs for industrial (non-POTW) facilities, the permit writer must consider all applicable technology standards and requirements for all pollutants discharged. Without applicable effluent guidelines for the discharge or pollutant, permit writers must identify any needed TBELs on a case-by-case basis, in accordance with the statutory factors specified in CWA sections 301(b)(2) and 304(b). The site-specific TBELs reflect the BPJ of the permit writer, taking into account the same statutory factors EPA would use in promulgating a national effluent guideline regulation, but they are applied to the circumstances relating to the applicant. The permit writer also should identify whether state laws or regulations govern TBELs and might require more stringent performance standards than those required by federal regulations. In some cases, a single permit could have TBELs based on effluent guidelines, BPJ, and state law, as well as WQBELs based on water quality standards.

Sections 5.2.1 and 5.2.2 below provide an overview of effluent guidelines and development of TBELs in NPDES permits using the effluent guidelines. Section 5.2.3 below discusses the development of TBELs in the absence of effluent guidelines (i.e., case-by-case limitations developed using BPJ).

5.2.1 Effluent Guidelines

Congress saw the creation of a single national pollution control requirement for each industrial category, based on the best technology the industry could afford, as a way to reduce the potential creation of *pollution havens* and to attain a high-level water quality in the nation's waters. Consequently, EPA's goal in establishing effluent guidelines is to ensure that industrial facilities with similar characteristics will meet similar effluent limitations representing the best pollution control technologies or pollution prevention practices regardless of their location or the nature of the receiving water into which the discharge is made. In establishing the effluent guidelines, EPA must consider the industry-wide economic achievability of implementing the technology and the incremental costs in relation to the pollutant-reduction benefits.

Effluent guidelines can include numeric and narrative limitations, including best management practices (BMPs), to control the discharge of pollutants from categories of point sources. The limitations are based on data characterizing the performance of technologies available and, in some cases, from modifying process equipment or the use of raw materials. Although the regulations do not require the use of any particular treatment technology, they do require facilities to achieve effluent limitations that reflect the proper operation of the *model* technologies selected as the basis for the effluent guidelines and from which the performance data were obtained to generate the limitations. Therefore, each facility has the

NMED Exhibit 70

discretion to select any technology design and process changes necessary to meet the performance-based discharge limitations and standards specified by the effluent guidelines.

As of the date of this manual's publication, EPA has issued effluent guidelines for 56 industrial categories, which apply to between 35,000 and 45,000 facilities that discharge directly to waters of the United States and another 12,000 facilities that discharge into POTWs. The regulations prevent the discharge of more than 1.2 billion pounds of toxic (priority) and nonconventional pollutants each year. EPA's Effluent Guidelines Program Website <www.epa.gov/guide/> provides information on existing effluent guidelines, current effluent guidelines rulemaking, and the effluent guidelines planning process.

5.2.1.1 Statutory Foundation for Effluent Guidelines

The CWA directs EPA to promulgate effluent guidelines reflecting pollutant reductions that can be achieved by existing facilities in categories or subcategories of industrial point sources using specific control technologies. In addition, EPA is required to develop effluent guidelines for new sources. Those levels of control are summarized below and in Exhibit 5-8.

Exhibit 5-8 Summary of CWA technology levels of control

Type of sites regulated	BPT	BCT	BAT	NSPS	PSES	PSNS
Existing Direct Dischargers	X	X	X			
New Direct Dischargers				X		
Existing Indirect Dischargers					X	
New Indirect Dischargers						X
Pollutants regulated	**BPT**	**BCT**	**BAT**	**NSPS**	**PSES**	**PSNS**
Conventional Pollutants	X	X		X		
Nonconventional Pollutants	X		X	X	X	X
Toxic (Priority) Pollutants	X		X	X	X	X

Best Practicable Control Technology Currently Available (BPT)

BPT is the first level of technology-based effluent controls for direct dischargers and it applies to all types of pollutants (conventional, nonconventional, and toxic). The Federal Water Pollution Control Act (FWPCA) amendments of 1972 require that when EPA establishes BPT standards, it must consider the industry-wide cost of implementing the technology in relation to the pollutant-reduction benefits. EPA also must consider the age of the equipment and facilities, the processes employed, process changes, engineering aspects of the control technologies, non-water quality environmental impacts (including energy requirements), and such other factors as the EPA Administrator deems appropriate [CWA section 304(b)(1)(B)]. Traditionally, EPA establishes BPT effluent limitations on the basis of the average of the best performance of well-operated facilities in each industrial category or subcategory. Where existing performance is uniformly inadequate, BPT may reflect higher levels of control than currently in place in an industrial category if the Agency determines that the technology can be practically applied. See CWA sections 301(b)(1)(A) and 304(b)(1)(B).

NMED Exhibit 70

Best Conventional Pollutant Control Technology (BCT)

The 1977 CWA requires EPA to identify effluent reduction levels for conventional pollutants associated with BCT for direct discharges from existing industrial point sources. As with BPT, when establishing BCT the Agency considers the age of the equipment and facilities, the processes employed, process changes, engineering aspects of the control technologies, non-water quality environmental impacts (including energy requirements), and such other factors as the EPA Administrator deems appropriate [CWA section 304(b)(4)(B)]. In addition, EPA also considers a two-part *cost reasonableness* test, as required by CWA section 304(b)(4)(B), which includes (1) consideration of the reasonableness of the relationship between the costs of attaining a reduction in effluent and the effluent reduction benefits derived and (2) a comparison of the cost and level of reduction of such pollutants from the discharge from POTWs to the cost and level of reduction of such pollutants from a class or category of industrial sources. EPA explained its methodology for developing BCT limitations in detail in 51 FR 24974, July 9, 1986 <www.epa.gov/npdes/pubs/fr_bct_1986.pdf>. See CWA sections 301(b)(2)(E) and 304(b)(4).

Best Available Technology Economically Achievable (BAT)

For the direct discharge of toxic and non-conventional pollutants, EPA promulgates effluent guidelines based on BAT. The FWPCA amendments of 1972 require EPA to consider the cost of achieving effluent reductions when defining BAT; however, they do not specifically require EPA to balance the cost of implementation against the pollution reduction benefit. The technology selected for BAT must be economically achievable [CWA section 301(b)(2)(A)]. EPA generally defines BAT on the basis of the performance associated with the best control and treatment measures that facilities in an industrial category are capable of achieving. Like BPT and BCT, other factors EPA must consider in assessing BAT include the age of equipment and facilities involved, the process employed, process changes, non-water quality environmental impacts, including energy requirements, and other such factors as the EPA Administrator deems appropriate [CWA section 304(b)(2)(B)]. The Agency retains considerable discretion in assigning the weight accorded to these factors. BAT limitations may be based on effluent reductions attainable through changes in a facility's processes and operations. Where existing performance is uniformly inadequate, BAT may reflect a higher level of performance than is currently being achieved within a subcategory on the basis of technology transferred from a different subcategory or category. BAT may be based on process changes or internal controls, even when those technologies are not common industry practice. See CWA sections 301(b)(2)(A), (C), (D) and (F) and 304(b)(2).

New Source Performance Standards (NSPS)

NSPS reflect effluent reductions that are achievable by direct dischargers based on the best available demonstrated control technology. New sources have the opportunity to install the best and most efficient production processes and wastewater treatment technologies at the time of construction. As a result, NSPS should represent the most stringent controls attainable through the application of the best available demonstrated control technology for all pollutants (i.e., conventional, nonconventional, and toxic pollutants). In establishing NSPS, EPA is directed to take into consideration the cost of achieving the effluent reduction and any non-water quality environmental impacts and energy requirements. See CWA section 306.

NMED Exhibit 70

Pretreatment Standards for Existing Sources (PSES)

PSES are designed to prevent the discharge of pollutants that pass through, interfere with, or are otherwise incompatible with the operation of POTWs, including incompatibility with the POTW's chosen biosolids (sewage sludge) disposal methods. The categorical pretreatment standards for existing indirect dischargers are technology-based and are analogous to BAT. The general pretreatment regulations, which set forth the framework for the implementation of national pretreatment standards, are at Part 403. See CWA section 307(b).

Pretreatment Standards for New Sources (PSNS)

Like PSES, PSNS are designed to prevent the discharges of pollutants that pass through, interfere with, or are otherwise incompatible with the operation of POTWs. PSNS are to be issued at the same time as NSPS. New indirect dischargers have the opportunity to incorporate into their facilities the best available demonstrated technologies at the time of construction. The Agency considers the same factors in promulgating PSNS as it considers in promulgating NSPS. See CWA section 307(c).

EPA typically does not establish pretreatment standards for conventional pollutants (e.g., BOD_5, TSS, oil and grease) because POTWs are designed to treat such pollutants, but EPA has exercised its authority to establish categorical pretreatment standards for conventional pollutants as surrogates for toxic or nonconventional pollutants or to prevent interference. For example, EPA established categorical pretreatment standards for new and existing sources with a one-day maximum concentration of 100 mg/L oil and grease in the Petroleum Refining Point Source Category in Part 419 based on "the necessity to minimize [the] possibility of slug loadings of oil and grease being discharged to POTWs."[3]

The final statutory deadline for meeting BPT requirements was July 1, 1977, and the final statutory deadline for meeting BCT and BAT requirements was March 31, 1989. When applying applicable effluent guidelines, permit writers should note that they do not have the authority to extend the statutory deadlines in an NPDES permit; thus, all applicable technology-based requirements (i.e., effluent guidelines and case-by-case limitations based on BPJ) must be applied in NPDES permits without the benefit of a compliance schedule. In addition, though NSPS do not have specific dates as compliance deadlines, they are effective on the date the new source begins discharging. The facility must demonstrate compliance with NSPS within 90 days of discharge [see § 122.29(d)]. For more information on determining whether a discharge is subject to NSPS, see Appendix D of this manual. For additional information on the statutory and regulatory history of the NPDES program, see section 1.2 of this manual.

5.2.1.2 EPA's Development of Effluent Guidelines

EPA establishes national effluent guidelines for a specific industrial sector by regulation after considering an in-depth engineering and economic analysis of the industrial sector. EPA's Industrial Regulations Website <www.epa.gov/guide/industry.html> provides development documents for some specific industry categories (e.g., Iron and Steel Manufacturing and Metal Products and Machinery). Those documents contain additional information on how EPA develops effluent guidelines.

For each industrial sector, EPA assesses the performance and availability of the best pollution control technologies and pollution prevention practices that are available for an industrial category or subcategory. The effluent guidelines are promulgated for various industrial categories in 40 CFR, Chapter I, Subchapter N - Effluent Guidelines and Standards - Parts 400-471 <www.epa.gov/lawsregs/search/40cfr.html>.

NMED Exhibit 70

In promulgating effluent guidelines, EPA may divide an industrial point source category into groupings of subcategories to provide a method for addressing variations between products, raw materials, processes, and other factors that result in distinctly different characteristics. Regulation of an industrial category using subcategories allows each subcategory to have a uniform set of requirements that take into account technological achievability and economic impacts unique to that subcategory. Grouping similar facilities into subcategories increases the likelihood that the regulations are practicable and diminishes the need to address variations between facilities within a category through a variance process. For more on variances, see section 5.2.2.7 below. EPA considers a number of different subcategorization factors during an effluent guidelines rulemaking, including the following:

- Manufacturing products and processes.
- Raw materials.
- Wastewater characteristics.
- Facility size.
- Geographical location.
- Age of facility and equipment.
- Wastewater treatability.

For each possible treatment technology option for an industry, EPA conducts an analysis of industry-wide incremental compliance costs, pollutant loadings and removals, and related non-water quality effects. The Agency also performs an economic analysis to assess the financial impact on the industry of implementing each option. That entire process involves data collection, rigorous data review, engineering analysis, and public comment. EPA selects a technology to serve as the *model* technology for pollutant removal for each required level of control (i.e., BPT, BCT, BAT, NSPS, PSES, and PSNS). Limitations and other requirements in the effluent guidelines for each level of control are based on application of the model technology to the category or subcategory of facilities.

Effluent guidelines are not always established for every pollutant present in a point source discharge. In many instances, EPA promulgates effluent guidelines for an *indicator* pollutant. Industrial facilities that comply with the effluent guidelines for the indicator pollutant will also control other pollutants (e.g., pollutants with a similar chemical structure). For example, EPA may choose to regulate only one of several metals present in the effluent from an industrial category, and compliance with the effluent guidelines will ensure that similar metals present in the discharge are adequately controlled. Additionally, for each industry sector EPA typically considers whether a pollutant is present in the process wastewater at treatable concentrations and whether the model technology for effluent guidelines effectively treats the pollutant. For example, see Figure 6-1 Pollutant of Concern Methodology <www.epa.gov/guide/cwt/final/develop/ch6.pdf> on page 6-4 of the *Centralized Waste Treatment category Technical Development Document*.

The CWA requires EPA to annually review existing effluent guidelines for both direct and indirect dischargers. CWA section 304(m) also requires EPA to publish an effluent guidelines program plan every 2 years. As part of the development of the biennial plan, the public is provided an opportunity to comment on a *preliminary* plan before it is finalized. The preliminary plan is published in odd-numbered years, and the final plan is published in even-numbered years. EPA encourages permit writers to participate in the effluent guidelines planning process and comment on the preliminary effluent guidelines program plans presented on the Effluent Guidelines Biennial Plan Website <www.epa.gov/guide/304m/index.html>.

NMED Exhibit 70

5.2.1.3 Types of Limitations in Effluent Guidelines

Although the requirements in effluent guidelines generally are numeric limitations on the mass or concentration of a pollutant that can be discharged directly into waters of the United States, CWA section 502(11) defines *effluent limitation* broadly. This section describes several types of possible expressions for the limitations found in effluent guidelines. The permit writer should note that the limitations in effluent guidelines might need to be translated into an appropriate form to be included as effluent limitations in an NPDES permit. That process is discussed further in section 5.2.2 below.

Mass- or Concentration-based Numeric Limitations

Limitations in effluent guidelines generally are expressed as numeric values, which are upper bounds of the amount of pollutant that may be discharged. For most pollutants, these limitations are mass-based or concentration-based values. They are, in effect, measures of how well the production, wastewater treatment, and pollution prevention processes must be operated. In the course of developing effluent guidelines regulations, EPA uses data on a number of different pollutants from facilities with the selected model technologies to determine the appropriate numeric limitations. The limitations generally consist of upper bounds (maximum values) established for both the daily discharge and for the average monthly discharge.

In developing numeric limitations in effluent guidelines, EPA first determines an average performance level (the *long-term average*) that a facility with well-designed and operated model technologies reflecting the appropriate level of control is capable of achieving. That long-term average is calculated from data taken from facilities using the model technologies that were selected as a basis for the limitations. EPA expects that all facilities subject to the limitations will design and operate their treatment systems to achieve the long-term average performance level consistently because facilities with well-designed and operated model technologies have demonstrated that it can be done. The technical development document for the effluent guidelines usually identifies the long-term average for the model technologies; however, they generally are not part of the limitations in the effluent guidelines or TBELs in the permit. The limitations generally are expressed as *maximum daily* and *average monthly limitations* (see definitions in Exhibit A-2 in Appendix A of this document) that include an allowance for variability around the long-term average.

EPA acknowledges that process and treatment systems have inherent variability and, therefore, incorporates an allowance for this variation into the limitations specified in the effluent guidelines. That allowance is based on statistical analysis of the data from facilities using the model technologies. The limitations included in effluent guidelines incorporate all components of variability including shipping, sampling, storage, and analytical variability. By accounting for those reasonable excursions above the long-term average, the limitations in effluent guidelines generally are well above the actual long-term averages. If a facility operates its treatment system to meet the long-term average, EPA expects the facility will be able to meet the limitations specified in the effluent guidelines based on that long-term average.

EPA has different objectives in establishing maximum daily and average monthly limitations in effluent guidelines. In establishing maximum daily limitations, EPA's objective is to restrict the discharges on a daily basis at a level that is achievable for a facility that targets its treatment at the long-term average. In establishing average monthly limitations, EPA's objective is to provide an additional restriction to help

NMED Exhibit 70

ensure that facilities target their average discharges in a manner that will achieve the long-term average. The average monthly limitation requires continuous dischargers to provide ongoing control on a monthly basis that complements controls imposed by the maximum daily limitation. To meet the average monthly limitation, a facility must counterbalance a value near the maximum daily limitation with one or more values well below the maximum daily limitation. To achieve compliance, the values must result in an average monthly value at or below the average monthly limitation. As explained below, EPA uses a smaller percentile basis for the average monthly limitation than the maximum daily limitation to encourage facilities to target their systems to a value closer to the long-term average.

EPA generally uses statistical procedures to determine the values of the limitations specified in the effluent guidelines. Those procedures involve fitting effluent data to distributions and using estimated upper percentiles of the distributions. EPA defines the maximum daily limitation as an estimate of the 99th percentile of the distribution of the daily measurements. The average monthly limitation is an estimate of the 95th percentile of the distribution of the monthly averages of the daily measurements. EPA bases its limitations on percentiles chosen with the intention that they be high enough above the long-term average to accommodate reasonably anticipated variability within control of the facility. In conjunction with the statistical methods, EPA performs an engineering review to verify that the limitations are reasonable on the basis of the design and expected operation of the control technologies and the facility process conditions. Such limitations are translated into effluent limitations in a facility's NPDES permit. Facilities must comply with the effluent limitations in their permits at all times. EPA has prevailed in several judicial challenges to its selection of percentiles and on other issues related to limitations specified in effluent guidelines. [See, for example, *Chemical Manufacturers Association v. U.S. Environmental Protection Agency*, 870 F.2d 177, 230 (5th Cir. 1989) and *National Wildlife Federation, et al v. Environmental Protection Agency*, 286 F.3d 554 (D.C. Cir. 2002)]

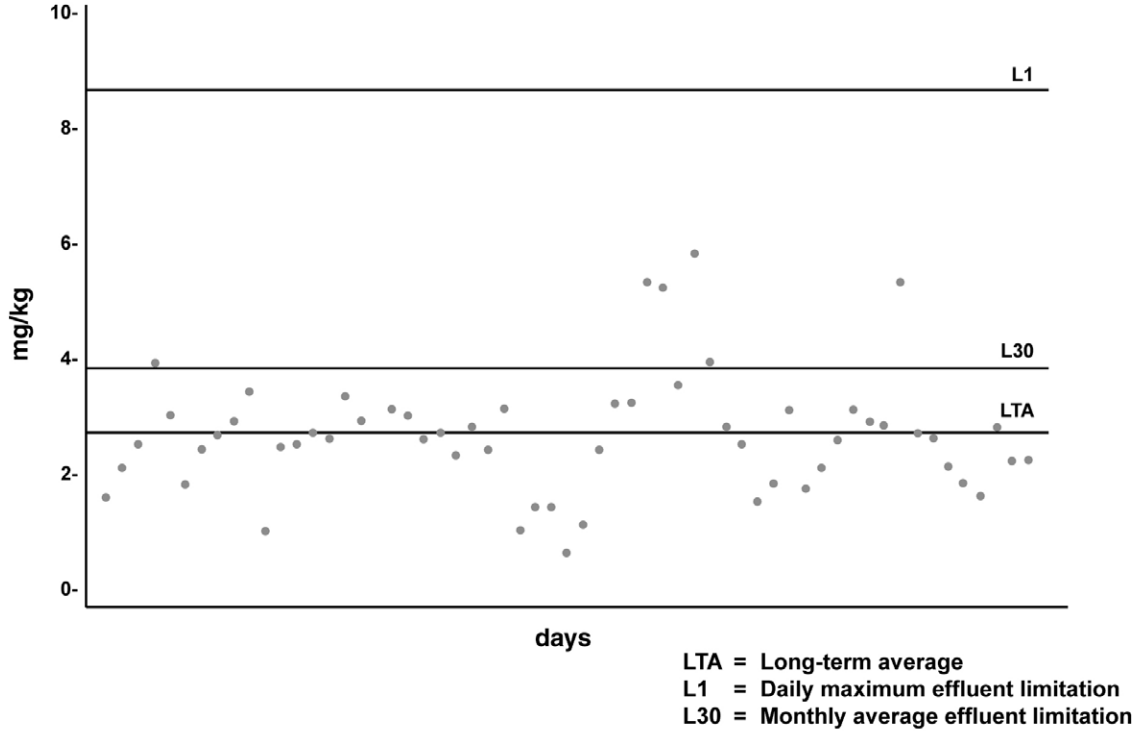

Exhibit 5-9 depicts an example of TSS data for a facility that is operating around a required long-term average level for TSS. The dots represent daily measurements, and the reference lines show the values for the long-term average (LTA), the maximum daily limitation (L1), and the average monthly limitation (L30). The facility has demonstrated compliance with both the maximum daily and average monthly limitations. Daily measurements include values both above and below the long-term average; however, all the data values are below the maximum daily limitation. Some individual daily values exceed the average monthly limitation; however, within each month, the average of the daily values is less than the average monthly limitation.

EPA generally exercises four basic alternatives in setting mass- or concentration-based numeric limitations specified in effluent guidelines:

- Mass-based, production-normalized limitations (e.g., the pollutant discharge is not to exceed 1 pound per 1,000 pounds of production).
- Mass-based, flow-normalized limitations (e.g., the pollutant discharge is not to exceed the mass determined by multiplying the process wastewater flow subject to the effluent guideline by the concentration requirement in the guideline).
- Concentration-based limitations (e.g., the pollutant discharge is not to exceed 1 mg of pollutant per liter of wastewater).
- Limitations requiring *zero discharge* of specific pollutants or all pollutants.

NMED Exhibit 70

Exhibit 5-9 Visual example of TSS LTA, maximum daily limitation and average monthly limitation

Except where a limitation requiring *zero discharge* of pollutants is applicable, EPA generally prefers setting production-normalized, mass-based limitations specified in effluent guidelines, where feasible, because production normalized limitations can reflect some expectation that the facility will conserve water and can reduce any potential for substituting dilution for treatment. EPA generally establishes concentration-based effluent guidelines when production and achievable wastewater flow cannot be correlated nationally. For example, in the Metal Finishing point source Category (Part 433), the Agency considered but decided against expressing the effluent guidelines as production-normalized mass-based effluent guidelines, "With the wide range of operations, product quality requirements, existing process configurations, and difficulties in measuring production, no consistent production normalizing relationship could be found. Concentration-based limits, however, can be consistently attained throughout the industry." [See 47 FR 38465, 31 August 1982.]

Numeric Limitations Established at Minimum Levels

Using percentile estimates to set limitations in effluent guidelines is not a requirement under the CWA. In some cases, the model technology for treating a pollutant might be capable of removing that pollutant to levels that cannot be reliably measured with existing analytical methods. EPA sometimes sets a requirement in the effluent guidelines that the concentration of a pollutant in the discharge must be below a *minimum level* or ML. The ML is the lowest level at which the entire analytical system must give a recognizable signal and an acceptable calibration point for the pollutant being analyzed. Where a limitation in the effluent guidelines is set at *less than the ML*, the value of the ML is specified in the effluent guidelines regulation on the basis of the analytical methods that EPA used to chemically analyze wastewaters in developing the regulation. For example, in the Pulp, Paper, and Paperboard point source

NMED Exhibit 70

category (Part 430) the Daily Maximum BAT effluent guideline for the Tetrachlorodibenzofuran (TCDF) congener of dioxin is expressed as <*ML* for papergrade sulfite (Subpart E) mills, which means "less than the minimum level specified in part 430.01(i)" (i.e., 10 picograms/liter for TCDF). If, in the future, analytical methods become more sensitive with lower MLs, EPA would determine whether the technologies for reducing the amount of the pollutant in the discharge are capable of achieving more stringent limitations and, thus, whether it would be appropriate to modify the requirements of the effluent guideline.

EPA has not established average monthly limitations in effluent guidelines when the maximum daily limitation is an ML limitation. The purpose of an average monthly limitation is to require continuous dischargers to provide better control, on a monthly basis, than required by the maximum daily limitation. However, for these pollutants, the data were determined by analytical methods that could not measure below the ML specified in the regulations. Thus, even if a permitting authority requires monitoring for the pollutants more frequently than once a month, average monthly limitations would still be expressed as *less than the ML* or < *ML*.

Other Expressions for Numeric Limitations

EPA also promulgates effluent guidelines for pollutants that cannot be expressed in terms of mass or concentration (e.g., pH, temperature, radiation) or are better expressed through other means (e.g., unitless ratios). For example, pH is generally expressed as an acceptable range (e.g., 6.0–9.0 standard pH units).

Nonnumeric Effluent Limitations

In some cases, EPA includes nonnumeric or narrative effluent limitations rather than, or in addition to, numeric limitations in effluent guidelines. Nonnumeric effluent limitations might include specific BMPs or requirements to minimize or eliminate discharges. CWA sections 304(e), 308(a), 402(a), and 501(a) authorize the Administrator to prescribe BMPs as part of effluent guidelines and as part of an NPDES permit. CWA section 304(e) authorizes EPA to include supplemental BMPs in effluent guidelines for toxic or hazardous pollutants for the purpose of controlling "plant site runoff, spillage or leaks, sludge or waste disposal, and drainage from raw material storage." Several effluent guidelines include BMPs as requirements. Some effluent guidelines, such as the Concentrated Aquatic Animal Production point source category (Part 451), include the BMPs requirement exclusively. Section 9.1.2 of this manual further discusses BMPs.

CWA section 402(a)(1) and (2) and the NPDES regulations at § 122.44(k) also authorize BMPs in NPDES permits to control or abate the discharge of pollutants when numeric effluent limitations are infeasible, or when the practices are reasonably necessary to achieve effluent limitations and standards or to carry out the purposes and intent of the CWA.

Once EPA establishes effluent guidelines, the permit writer is responsible for translating the limitations and other requirements of the effluent guidelines into TBELs and other conditions appropriate for inclusion in an NPDES permit. Section 5.2.2 below discusses a step-by-step approach for applying effluent guidelines through NPDES permits.

NMED Exhibit 70

5.2.2 Applying Effluent Guidelines through NPDES Permits

Permit writers need to have a detailed knowledge of the industrial facility applying for a new or reissued NPDES permit to identify applicable effluent guidelines and know how to use them to derive TBELs. This section provides a step-by-step procedure for applying effluent guidelines to direct discharges through NPDES permits as shown in Exhibit 5-10.

Exhibit 5-10 Steps for applying effluent guidelines to direct discharges

Step 1.	Learn about the industrial discharger
Step 2.	Identify the applicable effluent guidelines category(ies)
Step 3.	Identify the applicable effluent guidelines subcategory(ies)
Step 4.	Determine whether existing or new source standards apply
Step 5.	Calculate TBELs from the effluent guidelines
Step 6.	Account for overlapping or multiple effluent guidelines requirements
Step 7.	Apply additional regulatory considerations in calculating TBELs
Step 8.	Apply additional effluent guidelines requirements
Step 9.	Document the application of effluent guidelines in the fact sheet

5.2.2.1 Step 1: Learn About the Industrial Discharger

To write a defensible permit, the permit writer should have a solid understanding of the facility's operations. The permit writer should gather sufficient information to identify applicable effluent guidelines and derive TBELs. Facility-specific information the permit writer is likely to need includes the following:

- Industrial processes and raw materials.
- Products and services.
- Amount of manufacturing production or servicing.
- Number of production and non-production days.
- Current pollution prevention practices and wastewater treatment technology(ies).
- Discharge location of the wastewater pollutants and potential compliance sampling points.
- The source and characteristics of the wastewaters (including flow) and pollutants that are being discharged or have the potential to be discharged from the facility.

Sources of information include the facility's permit application, the current permit and fact sheet (if the facility is permitted), discharge monitoring reports, site visits, site inspections (such as compliance evaluation inspections for an existing permit), and other information submitted by the facility. The permit writer also should identify any information that would assist in determining whether the facility or part of the facility is considered a new source (e.g., age of facility and equipment).

5.2.2.2 Step 2: Identify the Applicable Effluent Guidelines Category(ies)

As noted above, EPA's effluent guidelines are at 40 CFR, Chapter I, Subchapter N - Effluent Guidelines and Standards, Parts 400–471 <www.epa.gov/lawsregs/search/40cfr.html>. A summary of promulgated effluent guidelines is presented on EPA's Industrial Regulations Website <www.epa.gov/guide/industry.html> and in Exhibit 5-11 below.

NMED Exhibit 70

Exhibit 5-11 Table of existing point source categories (June 2010)

Industry category (listed alphabetically)	40 CFR Part	Industry category (listed alphabetically)	40 CFR Part
Aluminum Forming	467	Meat and Poultry Products	432
Asbestos Manufacturing	427	Metal Finishing	433
Battery Manufacturing	461	Metal Molding and Casting	464
Canned and Preserved Fruits and Vegetable Processing	407	Metal Products and Machinery	438
Canned and Preserved Seafood Processing	408	Mineral Mining and Processing	436
Carbon Black Manufacturing	458	Nonferrous Metals Forming and Metal Powders	471
Cement Manufacturing	411	Nonferrous Metals Manufacturing	421
Centralized Waste Treatment	437	Oil and Gas Extraction	435
Coal Mining	434	Ore Mining and Dressing	440
Coil Coating	465	Organic Chemicals, Plastics, and Synthetic Fibers	414
Concentrated Animal Feeding Operations (CAFOs)	412	Paint Formulating	446
Concentrated Aquatic Animal Production	451	Paving and Roofing Materials (Tars and Asphalt)	443
Copper Forming	468	Pesticide Chemicals	455
Dairy Products Processing	405	Petroleum Refining	419
Electrical and Electronic Components	469	Pharmaceutical Manufacturing	439
Electroplating*	413	Phosphate Manufacturing	422
Explosives Manufacturing	457	Photographic	459
Ferroalloy Manufacturing	424	Plastic Molding and Forming	463
Fertilizer Manufacturing	418	Porcelain Enameling	466
Glass Manufacturing	426	Pulp, Paper, and Paperboard	430
Grain Mills	406	Rubber Manufacturing	428
Gum and Wood Chemicals	454	Soaps and Detergents Manufacturing	417
Hospitals	460	Steam Electric Power Generating	423
Ink Formulating	447	Sugar Processing	409
Inorganic Chemicals	415	Textile Mills	410
Iron and Steel Manufacturing	420	Timber Products Processing	429
Landfills	445	Transportation Equipment Cleaning	442
Leather Tanning and Finishing	425	Waste Combustors	444

* This category contains only categorical pretreatment standards (no effluent guidelines for direct dischargers).

The following sources of information might be helpful in identifying applicable effluent guidelines for a facility:

- **CFR titles and applicability section of the effluent guidelines**. This is first place to look for information for identifying applicable effluent guidelines. Each effluent guidelines regulation includes an applicability section for the category or each subcategory of the industry. The applicability section gives a general description of the types of facilities regulated by the effluent guidelines. The applicability sections often define certain industrial operations or other criteria (e.g., production or process wastewater flow thresholds) that identify whether a facility is regulated by the effluent guidelines.

NMED Exhibit 70

- **North American Industry Classification System (NAICS) and Standard Industrial Classification (SIC)**. The current NAICS <www.census.gov/epcd/www/naics.html> and former SIC codes <www.census.gov/epcd/www/naicstab.htm> could be helpful to determine the appropriate industrial category(ies) for a facility. NAICS and SIC codes were developed and are maintained by the federal government as a way to classify establishments by type of activity for comparing economic and other types of facility-specific data. Although SIC codes provide a helpful starting point for categorizing a facility, permit writers should be cautious of relying exclusively on SIC codes for determining the appropriate industrial category. SIC codes were not developed using EPA's industrial classification scheme, or vice versa, and, therefore, the codes might not always correspond exactly with the categorization process. In addition, more than one SIC code might apply to a single facility. Item V-II of NPDES Application Form l requires that the applicant provide the SIC code for the activity covered by the permit application. In some instances, the SIC code will identify both the industrial category and the subcategory of a facility. Sometimes the SIC code might identify the appropriate industrial category but not the subcategory. Exhibit 5-12 presents two examples of how a permit writer might identify the applicable effluent guidelines using the facilities SIC codes.

Exhibit 5-12 Examples of identifying applicable effluent guidelines using SIC codes

Example 1

A facility that performs the primary smelting and refining of copper reports SIC code 3331 in its NPDES permit application. By scanning the list of industrial point source categories, the permit writer can determine that the facility is regulated by effluent guidelines in the Nonferrous Metals Manufacturing point source category (Part 421). In this case, the SIC code also indicates that the facility is likely regulated by effluent guidelines in the Primary Copper Smelting Subcategory.

Example 2

A facility that manufactures ethyl acrylate and 2-ethylhexyl acrylate (acrylic acid esters) reports the SIC code 2869 (Industrial Organic Chemicals, Not Elsewhere Classified) in its NPDES permit application. By scanning the list of industrial point source categories, the permit writer can determine that facility is likely regulated by effluent guidelines in the Organic Chemicals, Plastics, and Synthetic Fibers (OCPSF) category (Part 414).

- **EPA's Development Documents and Compliance Guides**. EPA produces a number of documents that will aid permit writers in identifying applicable effluent guidelines and incorporating them into NPDES permits. In particular, development documents summarize the data and information EPA used to develop the effluent guidelines. Such documents are extremely useful in identifying the applicability of the effluent guidelines and how to incorporate the effluent guidelines into NPDES permits. EPA may also publish a compliance guide for permit writers and industry. EPA's Effluent Guidelines Website <www.epa.gov/guide/> provides available documents for specific industrial categories.

- **FR Notices**. The preamble text to the FR notices containing the proposed and final effluent guidelines rulemakings also provide additional insight into applicability of the effluent guidelines. EPA's Effluent Guidelines Website <www.epa.gov/guide/> provides FR notices for specific industrial categories. For example, the preambles to recently promulgated effluent guidelines typically list the SIC and NAICS codes for the potentially regulated facilities. Each Part in the CFR identifies the relevant FR notices. For example, § 419.11 (i.e., specialized definitions for

NMED Exhibit 70

Subpart [subcategory] A for the Petroleum Refining point source category) identifies 47 FR 46446, October 18, 1982, as amended at 50 FR 28522, July 12, 1985, as its source.

- **EPA Industry Experts**. EPA has a number of subject matter experts <www.epa.gov/guide/contacts.html> at its headquarters office in Washington, D.C. that are available to answer questions on specific effluent guidelines. EPA's NPDES Contacts in Regional Offices <www.epa.gov/npdes/regionalcontacts> also offer assistance in sorting through the different effluent guidelines and NPDES regulations.

- **EPA's Effluent Guidelines Planning Support Documents.** EPA's Effluent Guidelines Biennial Plan Website <http://water.epa.gov/lawsregs/lawsguidance/cwa/304m/> provides technical support documents and other information supporting EPA's biennial effluent guidelines program plans.

- **EPA's Sector Notebooks.** EPA's Sector Notebooks <www.epa.gov/compliance/resources/publications/assistance/sectors/notebooks/index.html> describe specific U.S. industries and governments and provide a holistic approach by integrating processes, applicable regulations, and other relevant environment information.

- **Other Sources**. Other sources of information include resources identified below in Exhibit 5-23, BPJ Permitting Tools. Permit and fact sheet and information from similar facilities might aid in identifying applicable effluent guidelines. However, the permit writer should not assume that a similar facility was correctly categorized in its permit and should examine the rationale for how the other permit writer identified any applicable effluent guidelines before relying on another permit to identify the applicable category.

Permit writers should be aware that effluent guidelines from two or more industrial point source categories might apply to a single facility. Step 6 below, provides additional information on overlapping or multiple effluent guidelines requirements.

5.2.2.3 Step 3: Identify the Applicable Effluent Guidelines Subcategory(ies)

In promulgating effluent guidelines, EPA may divide an industrial point source category into groupings called *subcategories* to provide a method for addressing variations between products, raw materials, processes, and other factors that result in distinctly different effluent characteristics or treatment options. Some effluent guidelines categories cover a variety of industrial sectors (e.g., the Nonferrous Metals Manufacturing point source category has 31 subcategories). It is important for the permit writer to correctly identify the applicable subcategory to derive TBELs.

The process of identifying the applicable effluent guidelines requires close review and comparison of information obtained from Step 1 and Step 2 above. Just as effluent guidelines from two or more industrial categories can apply to a single facility, it also is true that requirements from two or more subcategories could apply to a single facility.

Exhibit 5-13 presents two examples of how a permit writer can identify the subcategory containing the applicable effluent guidelines using information from the NPDES permit application.

NMED Exhibit 70

Exhibit 5-13 Examples of identifying the subcategory with the applicable effluent guidelines

Example 1

A permit writer has identified the facility from Example 2 in Exhibit 5-12 above as potentially regulated by the effluent guidelines in the OCPSF point source category (Part 414) <www.epa.gov/guide/ocpsf/>. The permit writer can determine from a further review of the industrial categorization discussion in the *OCPSF Development Document* and the guidance document that the facility is likely subject to effluent guidelines in Subpart G (Bulk Organic Chemicals). Specifically, the applicability criteria section in Subpart G (§ 414.70) states, "The provisions of this subpart are applicable to the process wastewater discharges resulting from the manufacture of the following: SIC 2865 and 2869 bulk organic chemicals and bulk organic chemical groups." Further, acrylic acid esters are listed in § 414.70 as an OCPSF product group.

Example 2

A large poultry slaughterhouse annually produces 200 million pounds of whole, halved, quarter or smaller meat cuts and reports SIC Code 2015 in its NPDES permit application. The permit writer reviewed the list of effluent guidelines and identified that the facility is likely regulated by effluent guidelines in the Meat and Poultry Products point source category (Part 432) <www.epa.gov/guide/mpp/>. The permit writer reviewed the preamble to the final effluent guidelines rule and the rule's development document. In that effluent guidelines regulation, EPA used NAICS codes to assist in applicability decisions. See 69 FR 54475, September 8, 2004. The permit writer used the U.S. Census Bureau's SIC to NAICS crosswalk website <www.census.gov/epcd/www/naicstab.htm> to identify the NAICS code (311615). Using the NAICS code, the permit writer can narrow the list of potentially applicable subcategories to the Poultry First Processing (Subpart K) or the Poultry Further Processing (Subpart L) subcategories. After reviewing the applicability criteria of both subcategories, the permit writer determined that only the effluent guidelines in Subpart K are likely applicable because the facility performs slaughtering operations, which are not regulated by Subpart L. Finally, the permit writer also needed to compare the average annual production of the facility (200 million pounds) with the production threshold in the effluent guidelines (100 million pounds per year). Because the facility produces more than the production threshold, the effluent guidelines in Subpart K are applicable to this facility. See §§ 432.112 and 432.113. In this example the permit writer would use the effluent guidelines for ammonia (as N), BOD_5, fecal coliform, oil and grease (as HEM), TSS, and total nitrogen to derive effluent limitations as detailed in section 5.2.2.5 below.

5.2.2.4 Step 4: Determine whether Existing or New Source Standards Apply

Section 5.2.1.1 above defines the different control technologies that apply to direct dischargers: BPT, BCT, BAT, and NSPS. The first three apply to existing direct dischargers, and the fourth to new sources. To determine whether existing source standards (i.e., BPT, BCT, and BAT) or NSPS apply to the facility, the permit writer must determine whether the facility or any part of the facility is a new source. A new source is defined in § 122.2 as a building, structure, facility, or installation that discharges pollutants or could discharge pollutants and for which construction began after promulgation of the applicable effluent guidelines or after proposal of the applicable effluent guidelines, but only if the effluent guidelines are promulgated within 120 days. Thus, the discharger's entire facility could be subject to new source standards (e.g., a brand new facility). Permit writers should note that the new source date for indirect dischargers is the date on which the pretreatment standard for new sources is proposed. See §403.3(m)(1).

Additional criteria for determining whether a discharge is a new source are defined in § 122.29(b) to cover situations where a facility is adding a new building or process line that results in a discharge to the waters of the United States. Such an addition would result in a new source if any of the following is true for the source:

- Is constructed at a site at which no other source is located.
- Totally replaces the process causing the discharge from an existing source.
- Has processes that are substantially independent of an existing source at the same site.

NMED Exhibit 70

Furthermore, some effluent guidelines, such as the effluent guidelines for the Pulp, Paper, and Paperboard Point Source Category in Part 430, include additional criteria for making new source determinations. See § 430.01(j).

Appendix D of this manual provides the applicable new source dates used in making new source determinations by effluent guideline category as provided in Appendix B of the EPA memorandum *New Source Dates for Direct and Indirect Dischargers*[4] <www.epa.gov/npdes/pubs/newsource_dates.pdf> sent by the directors of the Water Permits Division and the Engineering and Analysis Division to the Regional Water Division Directors. Permit writers can use Appendix D of this manual to find the date for determining whether a facility or part of a facility is subject to NSPS.

Where a new source is the result of a new installation of process equipment at an existing facility, part of the facility might be subject to existing source standards and other parts of the facility subject to new source standards. Permit writers should identify whether the facility has installed any process equipment after the last issuance of the NPDES permit and apply the criteria from § 122.29(b) on a case-by-case basis to new construction or new processes, while applying existing source requirements to the existing portions of the facility. Sometimes it can be difficult to distinguish between a new source and a modification or alteration of an existing source, especially when modifications have occurred slowly over time. The permit writer should consult the effluent guidelines regulation to determine if it defines more specifically what constitutes a new source.

It is important to remember that after the effective date of a new source standard, the CWA stipulates that it is unlawful for any owner or operator to operate such a source in violation of those standards. See 33 U.S.C. 1316(e) and 1317(d). EPA's regulations specify that a new source "[must] install and have in operating condition, and [must] *start up* all pollution control equipment" required to meet applicable standards before beginning to discharge. The regulations also indicate that the owner or operator of a new source must meet all applicable standards within "the shortest feasible time (not to exceed 90 days)." See § 122.29(d)(4).

In addition to the requirement to meet NSPS upon beginning to discharge, an EPA-issued NPDES permit for a new source is a federal action subject to the requirements of the National Environmental Policy Act (NEPA), 33 U.S.C. 1371(c)(1). For more information on NEPA and the NPDES program, see section 11.1.2 of this manual.

For existing facilities and existing sources (where NSPS do not apply), existing source standards (i.e., BPT, BCT, BAT) apply. The permit writer would use the more stringent technology level of control for each pollutant. For example, the BPT level of control in the Veneer Subcategory of the Timber Products Processing category (Part 429, Subpart B) allows a discharge of process wastewater and identifies effluent guidelines for BOD_5 and pH, while the BAT level of control bans the direct discharge of process wastewater. Consequently, the NPDES permit for a facility regulated by the Veneer Subcategory must use the more stringent BAT requirements and prohibit the direct discharge of process wastewater. The effluent guidelines for the Renderers subcategory of the Meat and Poultry Products point source category (Subpart J, Part 432) provide another example. In those effluent guidelines, the BCT requirements for BOD_5, oil and grease, and TSS are more stringent than the corresponding BPT requirements. Accordingly, the permit writer would use the more stringent BCT requirements, rather than the BPT requirements, to derive numeric permit limitations for an existing renderer.

NMED Exhibit 70

5.2.2.5 Step 5: Calculate TBELs from the Effluent Guidelines

Once a permit writer has identified the effluent guidelines that apply to a facility, he or she then uses those effluent guidelines to calculate applicable TBELs.

EPA's regulations at § 122.45(f)(1) stipulate that all pollutants limited in permits must have limitations, standards or prohibitions expressed in terms of mass except under any of the following conditions:

- For pH, temperature, radiation, or other pollutants that cannot appropriately be expressed by mass limitations.
- When applicable standards or limitations are expressed in terms of other units of measure.
- If in establishing technology-based permit limitations on a case-by-case basis, limitations based on mass are infeasible because the mass or pollutant cannot be related to a measure of production (e.g., discharges of TSS from certain mining operations). The permit conditions must ensure that dilution will not be used as a substitute for treatment.

Thus, the type of limitation (i.e., mass, concentration, or other units) calculated for a specific pollutant at a facility will depend on the type of pollutant and the way limitations are expressed in the applicable effluent guideline. Generally, effluent guidelines include both maximum daily and monthly average limitations for most pollutants. Though the effluent guidelines use different terms for monthly effluent limitations (e.g., monthly average, maximum for monthly average, average of daily values for 30 consecutive days), the requirements are expressed in NPDES permits as average monthly limitations as defined in § 122.2.

As stated in Steps 1 and 2 above, the permit writer would use many sources of information to calculate TBELs. From those sources, the permit writer should identify the source and characteristics of the wastewaters (including flow) and pollutants being discharged, or that have the potential to be discharged, and whether and how those pollutants are regulated by effluent guidelines. In particular, the permit writer should identify the following:

- The appropriate permit compliance point(s) (which might be specified in the effluent guidelines).
- Wastewaters subject to the applicable effluent guidelines and whether they are commingled with other wastewaters not regulated by effluent guidelines (e.g., sanitary wastewaters before the permit compliance point).
- Reasonable measure of the facility's actual long-term daily production and average number of production days per year regulated by effluent guidelines (necessary for derived effluent limitations from production-normalized effluent guidelines).
- Average daily facility flows at the compliance point(s) regulated by effluent guidelines.
- Average daily facility flows at the compliance point(s) not regulated by effluent guidelines.

That information is used in conjunction with the effluent guidelines for TBEL calculations as discussed below.

NMED Exhibit 70

Calculating Mass-based TBELs from Production-Normalized Effluent Guidelines

Most effluent guidelines requirements are mass-based and expressed in terms of allowable pollutant discharge per unit of production or some other measure of production (i.e., production normalized). Permit writers incorporate such production-normalized effluent guidelines into NPDES permits as mass-based TBELs by using a reasonable measure of the permittee's actual long-term daily production. The objective in determining the production for a facility is to develop a single estimate of the long-term average daily production that can reasonably be expected to prevail during the next term of the permit (i.e., not the design production rate). Permit writers may establish such a production rate using the past 3 to 5 years of facility data. For example, the permit writer might wish to use the average daily production rate calculated using the highest annual production from the previous 3 to 5 years. Whatever value is selected, the permit writer should ensure that the production rate used in deriving mass-based effluent limitations is representative of the actual production likely to prevail during the next term of the permit.

The examples in Exhibit 5-14 illustrate the application of production-based effluent guidelines using the approach where annual production data are available. In Example 1 in Exhibit 5-14, the highest annual production rate during the past 5 years was used as the estimate of production. If historical trends, market forces, company plans to decrease production, or plant designs and capital expenditures for an increase in production indicated that a different level of production would prevail during the permit term, the permit writer could consider a different basis for estimating production or establish tiered discharge limitations, as discussed in section 5.2.2.7 below.

Calculating Mass-based TBELs from Flow-Normalized Effluent Guidelines

In some cases, permit writers are directed to calculate mass-based TBELs from flow-normalized effluent guidelines that are expressed as concentrations. For example, the Organic Chemicals, Plastics, and Synthetic Fibers (OCPSF) effluent guidelines <www.epa.gov/waterscience/guide/ocpsf/> in Part 414 state that facilities "must achieve discharges not exceeding the quantity (mass) determined by multiplying the process wastewater flow subject to [the effluent guideline] times the concentration listed in the [effluent guideline]…" The *Development Document for Effluent Limitations Guidelines and Standards for the Organic Chemicals, Plastics and Synthetic Fibers Point Source Category*[5] <www.epa.gov/waterscience/guide/ocpsf/#guidance> directs the permit writer to "use a reasonable estimate of process wastewater discharges and the concentration limitations [in the effluent guideline] to develop mass limitations for the NPDES permit." Thus, the process for calculating the TBELs is similar to the process used with production-normalized effluent guidelines, but rather than using a reasonable measure of the actual daily production, the permit writer would use a reasonable measure of the actual daily flow rate as the basis for calculating the TBELs.

As with estimating production to calculate TBELs, the objective in determining a flow estimate for a facility is to develop a single estimate of the actual daily flow rate (in terms of volume of process wastewater per day), which can reasonably be expected to prevail during the next term of the permit (i.e., not the design flow rate). Permit writers can establish that flow rate using the past 3 to 5 years of facility data in a manner similar to the method used to determine production. For example, the permit writer might wish to use the highest average daily flow rate from the average daily flows calculated for each of the past 3 to 5 years. The value selected should be representative of the actual flow likely to prevail during the next term of the permit.

NMED Exhibit 70

Exhibit 5-14 Example of calculating mass-based effluent limitation from production-normalized effluent guidelines[6]

Example 1

Facility A has produced 331,000 tons, 301,500 tons, 321,500 tons, 330,000 tons, and 331,500 tons of product per year for the previous 5 years operating 255 days per year.

Question:
What would be a reasonable measure of production for permitting purposes?

Answer:
Using the highest year of production (331,500 tons per year) might be an appropriate and reasonable measure of production, if this figure is representative of the actual production expected to occur over the next term of the permit. Permit writers also should check to see if the maximum yearly value is within a certain percentage (e.g., 20 percent–see section 5.2.2.7 below) of the average value. In evaluating gross production figures, the number of production days should be considered. If the number of production days per year is not comparable, the permit writer would need to convert the numbers to production per day before comparing them. In this example, all the yearly production figures were based on 255 days per year of production, so they may be compared directly. The 331,500 tons per year figure is the maximum for the past 5 years, which is only 2.6 percent above the average annual production of 323,100 tons. Therefore, 331,500 tons is a reasonable measure of the annual production for the facility.

Example 2

For the same facility in Example 1 above with an annual production of 331,500 tons, the production-normalized effluent guidelines for zinc are 0.1 lbs/1,000 lbs as monthly average and 0.15 lbs/1,000 lbs as daily maximum.

Question:
What are the resulting zinc technology-based effluent limitations for the NPDES permit?

Answer:
The annual production would be converted to an average daily production rate to apply the effluent guidelines. To convert from the annual production rate to an average daily rate, divide the annual production rate by the number of production days per year. To determine the number of production days, subtract the total number of normally scheduled non-production days from the total days in a year. Because Company A normally has 255 production days per year, the annual production rate of 331,500 tons per year would yield an average production daily rate of 1,300 tons per day.

Monthly average discharge limitation for zinc*:

1,300 tons/day	x	2,000 lbs/ton	x	0.10 lbs/1,000 lbs	=	**260 lbs/day**

Daily maximum discharge limitation for zinc*:

1,300 tons/day	x	2,000 lbs/ton	x	0.15 lbs/1,000 lbs	=	**390 lbs/day**

* calculated to 2 significant figures

Calculating TBELs from Concentration-based Effluent Guidelines

Permit writers might want to develop mass-based limitations for facilities with concentration-based effluent guidelines (e.g., for a facility does not have adequate water conservation practices). Mass-based permit effluent limitations encourage water conservation (e.g., minimize the potential for diluting process wastewaters by non-process wastewater, more efficient use of water) and pollution prevention (e.g., reduce waste loads to wastewater treatment facilities by physically collecting solid materials before using water to clean equipment and facilities). Additionally, for facilities with on-site wastewater treatment systems, the combination of water-reduction technologies and practices and well-operated wastewater treatment will reduce the volume and mass of discharged wastewater pollution (i.e., after treatment). Another benefit of mass-based permit effluent limitations is that they provide the permittee with more flexibility. Permittees may elect to control their wastewater discharges through more efficient wastewater control technologies and pollution-prevention practices that result in lower pollutant concentrations in the

NMED Exhibit 70

discharged wastewater, or more efficient water conservation practices that result in less wastewater volume discharged from industrial operations), or both.

"EPA strongly supports water conservation and encourages all sectors, including municipal, industrial, and agricultural, to achieve efficient water use. EPA does not intend for its regulations to present a barrier to efficient water use in any industrial sector." See final 2006 Effluent Guidelines Program Plan in 71 FR 76655, December 21, 2006.

When calculating mass-based effluent limitations, the permit writer should use a conversion factor and document in the fact sheet the conversion factors used to calculate the permit limitations (e.g., concentration [mg/L] × flow [mgd] × 8.34 [conversion factor] = permit limitation [lbs/day]).

Additionally, guidance for implementing concentration-based limitations in effluent guidelines may direct permit writers to develop mass-based TBELs. For example, the *Permit Guidance Document Transportation Equipment Cleaning Point Source Category (40 CFR 442)*[7] industry states:

> The effluent limitations guidelines and standards for the TEC industry are concentration-based and adhere to the *building block* concept. Each regulated wastestream in an outfall is typically assigned a mass-based discharge allowance based on a calculation of its applicable concentration-based limitation and annual average flow. The sum of the allowances is the total mass discharge allowance for the outfall. In other words, the applicable permit limitations for facilities in more than one subcategory is the sum of the mass loadings based upon production in each subcategory and the respective subcategory effluent limitations guidelines. Mass-based limitations for unregulated or dilution wastewater streams at direct discharging facilities are established using [BPJ].

Where a permit writer cannot determine a reasonable measure of actual flow for a regulated discharge, concentration-based TBELs may be determined by directly applying the concentration-based limitations in effluent guidelines to the regulated flow and accounting for non-regulated flows at the point of compliance for the TBELs.

Supplementing Mass-based TBELs with Concentration Limitations

Even where effluent guidelines require permit writers to calculate mass-based TBELs, a permit writer may determine that it is beneficial to include concentration-based limitations to supplement the mass-based limitations. Where effluent limitations are expressed in terms of mass, a provision at § 122.45(f)(2) allows the permit writer, at his or her discretion, to express limitations in additional units (e.g., concentration units). Where limitations are expressed in more than one unit, the permittee must comply with both. The permit writer may determine that expressing limitations in terms of both concentration and mass encourages the proper operation of a treatment facility at all times.

Supplementing mass-based limitations with concentration-based limitations may be especially appropriate where the requirements in the effluent guidelines are flow-normalized (i.e., the effluent guidelines includes a concentration requirement but directs the permit writer to calculate a mass-based TBEL using the concentration requirement and the wastewater flow). The permit writer may determine that if the permit includes only mass-based limitations derived from the concentration-based limitations in the effluent guidelines, a permittee could increase its effluent pollutant concentrations above the applicable concentration requirements during low flow periods (i.e., reduce the efficiency of the wastewater

NMED Exhibit 70

treatment) and still meet its mass-based permit limitations. Supplementing the mass-based TBELs with concentration limitations would discourage the reduction in treatment efficiency during low-flow periods and require proper operation of treatment units at all times.

Incorporating Narrative Requirements from Effluent Guidelines

The permit writer should also ensure that any applicable narrative effluent guidelines controls or requirements are included in the permit. For example, the effluent guidelines for Concentrated Aquatic Animal Production facilities (Part 451) consist of narrative requirements implemented through BMPs. Another example, related to monitoring and compliance rather than effluent limitations, is found in the Metal Finishing effluent guidelines. The effluent guidelines allow a facility to make a statement regarding total toxic organics (TTO) in lieu of monitoring for toxic organics. Exhibit 5-15 provides an example narrative requirement representing BPT performance standards for Concentrated Aquatic Animal Production facilities, Subpart A (flow through and recirculating systems) § 455.11(a).

Exhibit 5-15 Example narrative requirement from the Concentrated Aquatic Animal Production effluent guideline—Subpart A [§ 455.11(a)]

Except as provided in [§§] 125.30 through 125.32, any existing point source subject to this subpart must meet the following requirements, expressed as practices (or any modification to these requirements as determined by the permitting authority based on its exercise of its best professional judgment) representing the application of BPT:

(a) Solids control. The permittee must:

(1) Employ efficient feed management and feeding strategies that limit feed input to the minimum amount reasonably necessary to achieve production goals and sustain targeted rates of aquatic animal growth in order to minimize potential discharges of uneaten feed and waste products to waters of the [United States]

(2) In order to minimize the discharge of accumulated solids from settling ponds and basins and production systems, identify and implement procedures for routine cleaning of rearing units and off-line settling basins, and procedures to minimize any discharge of accumulated solids during the inventorying, grading and harvesting aquatic animals in the production system.

(3) Remove and dispose of aquatic animal mortalities properly on a regular basis to prevent discharge to waters of the [United States], except in cases where the permitting authority authorizes such discharge in order to benefit the aquatic environment.

5.2.2.6 Step 6: Account for Overlapping or Multiple Effluent Guidelines Requirements

There are instances when one facility includes both new and existing sources, produces multiple products or services, or includes production or services belonging to more than one category or subcategory. In such cases, the permit writer must examine the applicable effluent guidelines closely to ensure that (1) one guideline does not supersede another; and (2) the effluent guidelines are properly applied.

Superseding Effluent Guidelines

EPA tries to minimize the overlap of different effluent guidelines by providing exclusions in the applicability sections. The effluent guidelines in the Metal Finishing point source category (Part 433) are an example of where EPA has tried to minimize the overlap of multiple effluent guidelines for certain wastewater discharges. Exhibit 5-16 presents the applicability section in Part 433 [§ 433.10(b)], which specifically excludes certain wastewaters from the Metal Finishing effluent guidelines. Another example

NMED Exhibit 70

is the preamble to the OCPSF effluent guidelines. The preamble identifies numerous circumstances where the OCPSF regulations are superseded by effluent guidelines for other industrial categories. Exhibit 5-17 presents excerpts from the preamble (52 FR 42523, November 5, 1987) to illustrate the point.

Exhibit 5-16 Exclusion of wastewaters in metal finishing effluent guidelines

In some cases, effluent limitations and standards for the following industrial categories might be effective and applicable to wastewater discharges from the metal finishing operations listed above [in paragraph (a)]. In such cases these Part 433 limitations shall not apply and the following regulations shall apply: [emphasis added]

- Nonferrous metal smelting and refining (40 CFR part 421)
- Coil coating (40 CFR Part 465)
- Porcelain enameling (40 CFR Part 466)
- Battery manufacturing (40 CFR Part 461)
- Iron and steel (40 CFR Part 420)
- Metal casting foundries (40 CFR Part 464)
- Aluminum forming (40 CFR Part 467)
- Copper forming (40 CFR Part 468)
- Plastic molding and forming (40 CFR Part 463)
- Nonferrous forming (40 CFR Part 471)
- Electrical and electronic components (40 CFR Part 469)

Exhibit 5-17 Excerpts from preamble to OCPSF effluent guidelines regarding applicability of effluent guidelines

- For the purposes of this regulation, OCPSF process wastewater discharges are defined as discharges from all establishments or portions of establishments that manufacture products or product groups listed in the applicability sections of this regulation, and are included within the following U.S. Department of Commerce Bureau of the Census Standard Industrial Classification (SIC) major groups:
  - SIC 2865: Cyclic Crudes and Intermediates, Dyes, and Organic Pigments.
  - SIC 2869: Industrial Organic Chemicals, not Elsewhere Classified.
  - SIC 2821: Plastic Materials, Synthetic Resins, and Nonvulcanizable Elastomers.
  - SIC 2823: Cellulosic Man-Made Fibers.
  - SIC 2824: Synthetic Organic Fibers, Except Cellulosic.

  The OCPSF regulation does not apply to process wastewater discharges from the manufacture of organic chemical compounds solely by extraction from plant and animal raw materials or by fermentation processes.
- The OCPSF regulation does not apply to discharges from OCPSF product/process operations [that] are covered by the provisions of other categorical industry effluent limitations guidelines and standards if the wastewater is treated in combination with the non-OCPSF industrial category regulated wastewater. (Different processes manufacture some products or product groups and some processes with slight operation condition variations give different products. EPA uses the term *product/process* to mean different variations of the same basic process to manufacture different products as well as to manufacture the same product using different processes.)
- The process wastewater discharges by petroleum refineries and pharmaceutical manufacturers from production of organic chemical products specifically covered by 40 CFR Part 419 Subparts C and E and Part 439 Subpart C, respectively, that are treated in combination with other petroleum refinery or pharmaceutical manufacturing wastewater, respectively, are not subject to the OCPSF regulation no matter what SIC code they use to report their products.
- Today's OCPSF category regulation applies to plastics molding and forming processes when plastic resin manufacturers mold or form crude intermediate plastic material for shipment off-site. The regulation also applies to the extrusion of fibers. Plastics molding and forming processes, other than those described above are regulated by the Plastics Molding and Forming effluent guidelines and standards (40 CFR Part 463).

NMED Exhibit 70

Exhibit 5-17 Excerpts from preamble to OCPSF effluent guidelines regarding applicability of effluent guidelines (continued)

- Public comments requested guidance relating to the coverage of OCPSF research and development facilities, standalone OCPSF research and development, pilot plant, technical service, and laboratory bench scale-operations are not covered by the OCSPF regulation. However, wastewater from such operations conducted in conjunction with and related to existing OCPSF manufacturing operations at OCPSF facilities is covered by the OCPSF regulation because these operations would most likely generate wastewater with characteristics similar to the commercial manufacturing facility. Research and development, pilot plant technical service, and laboratory operations [that] are unrelated to existing OCPSF plant operations, even though conducted on-site, are not covered by the OCPSF regulation because they may generate wastewater with characteristic dissimilar to that from the commercial OCPSF manufacturing facility.
- Finally, as described in the following paragraphs, this regulation does not cover certain production that has historically been reported to the Bureau of Census under a non-OCPSF SIC subgroup heading, even if such production could be reported under one of the five SIC code groups covered by today's regulation.

Multiple Effluent Guidelines Requirements

NPDES permit writers often find that a facility employs multiple processes each with its own effluent guidelines requirement. In addition, sometimes effluent guidelines from multiple categories and subcategories apply to wastewaters for a single facility. When a facility is subject to effluent guidelines for two or more processes in a subcategory or to effluent guidelines from two or more categories or subcategories, the permit writer must apply each of the applicable effluent guidelines to derive TBELs. In applying multiple effluent guidelines, the permit writer should use measures of actual production or flow that are reasonable with respect to operation of multiple processes at the same time. For example, if maximum production for one process can occur only when there is reduced production for a second process, it might not be reasonable to assume maximum production levels for both processes at the same time when applying the effluent guidelines. If all wastewaters regulated by effluent guidelines are treated separately but are combined before the discharge, the permit writer may establish internal outfalls and separately apply the effluent guidelines at the respective internal outfall as discussed in § 122.45(h) and in Step 7 below.

More commonly, wastewater streams regulated by effluent guidelines are combined during or before treatment. In such a case, the permit writer combines the allowable pollutant loadings from each set of requirements or from each set of effluent guidelines to arrive at a single TBEL for the facility using a *building block* approach. The building block approach as applied to a facility with multiple processes in the Primary Tungsten subcategory of the Primary Nonferrous Metals Manufacturing point source category (Part 421, Subpart J) is presented in Exhibit 5-18. The same principles illustrated in the exhibit would apply to a facility with processes subject to requirements from multiple subcategories or categories that are combined before or during treatment.

NMED Exhibit 70

Exhibit 5-18 Building block approach for applying effluent guidelines

A facility is subject to Part 421, Subpart J (Primary Tungsten). The facility uses a tungstic acid rinse, an acid leach wet air pollution control system, and an alkali leach wash in its manufacturing process.

The Maximum daily production rate for the facility is:
4.7 million pounds per day of Tungstic Acid (as W)
3.5 million pounds per day of Sodium Tungstate (as W)

Question:
What is the technology-based effluent limit for lead at the facility?

Answer:
BPT calculation for lead (§ 421.102):

a) **Tungstic acid rinse:**
(4.7 million lbs/day) × (17.230 lbs/million lbs) = 80.981 lbs/day

b) **Acid leach wet air pollution control:**
(4.7 million lbs/day) × (15.040 lbs/million lbs) = 70.688 lbs/day

c) **Alkali leach wash:**
(3.5 million lbs/day) × (0.000 lbs/million lbs) = 0.000 lbs/day

d) **Total allowable discharge** = 80.981 + 70.688 + 0.000 = 151.669 = **152 lbs/day**

BAT calculation for lead (§ 421.103):

a) **Tungstic acid rinse:**
(4.7 million lbs/day) × (11.490 lbs/million lbs) = 54.003 lbs/day

b) **Acid leach wet air pollution control:**
(4.7 million lbs/day) × (1.003 lbs/million lbs) = 4.7141 lbs/day

c) **Alkali leach wash:**
(3.5 million lbs/day) × (0.000 lbs/million lbs) = 0.000 lbs/day

d) **Total allowable discharge** = 54.003 + 4.7141 + 0.000 = 58.7171 = **59 lbs/day***

The technology-based maximum daily limitation for lead at the facility is the BAT limitation of **59 lbs/day**. That value is compared with the water quality-based effluent limitation for lead, to ensure that all applicable standards are implemented through the final effluent limitations.

* calculated to 2 significant figures

The building block approach is applied in other circumstances as well, such as

- **Mixture of mass-based and concentration-based requirements:** The limitations in effluent guidelines for some pollutants are mass-based, production-normalized limitations in some subparts and concentration-based limitations in other subparts. When all the wastewater streams go to the same treatment system, the permit writer would need to convert the concentration-based limitations to mass-based limitations so they could be combined with the mass-based, production-normalized limitations and applied to the combined wastewater streams.
- **Mixture of different concentration-based requirements:** Some facilities could have multiple operations that are each subject to different concentration-based requirements for the same pollutant but with wastewater streams that combine before treatment. In such a case, the permit writer can establish a flow-weighted concentration-based limitation as the TBEL for the combined wastewater streams or convert the concentration-based requirements to equivalent mass-based requirements using flow data and then combine the mass-based requirements into a single limitation for the combined wastewater streams.

NMED Exhibit 70

- **Mixture of regulated and unregulated wastewater streams:** In some cases, wastewater streams containing a pollutant regulated by the applicable effluent guidelines requirements can combine with other wastewater streams that do not have effluent guidelines requirements that regulate the pollutant. In such a case, the permit writer could use BPJ to establish a TBEL for the unregulated wastewater stream(s) (see section 5.2.3 below) and, as appropriate, calculate a final TBEL for the combined wastewater streams. For example, if one of the wastewater streams contributing to an industrial facility's discharge is sanitary wastewater, the permit writer might use BPJ to apply the treatment standards for domestic wastewater and calculate BOD_5 limitations for that wastewater stream. The secondary treatment standards, discussed in section 5.1 above, could be used to calculate mass-based limits for the sanitary wastewater using the concentration-based requirements and an estimate of flow rate that is expected to represent the flow rate during the proposed permit term. A final TBEL for BOD_5 could be calculated for the combined sanitary and process wastewater streams by combining the two mass limitations using the building block approach.
- **Mixture of wastewater streams containing a pollutant with wastewater streams not containing the pollutant:** If a wastewater stream that does not contain a pollutant is combined with another wastewater stream that contains the pollutant (and has applicable requirements in the effluent guidelines or requirements determined by the permit writer using BPJ), the permit writer must ensure that the non-regulated waste stream does not dilute the regulated waste stream to the point where the pollutant is not analytically detectable. If that occurs, the permit writer will most likely need to establish internal outfalls, as allowed under § 122.45(h) and in Step 7 below.

For examples of addressing combined wastewater streams, see section 15.3.3 on page 15-10 of EPA's *Technical Development Document for the Final Effluent Limitations Guidelines and Standards for the Meat and Poultry Products Point Source Category (40 CFR 432)*[8] <www.epa.gov/waterscience/guide/mpp/final/tdd15.pdf>.

Facilities with Both New and Existing Sources

Finally, as noted above, if effluent guidelines are applicable to an existing facility, and that facility adds a new production line, which becomes a *new source*, the permit writer should calculate TBELs for the subsequent permit using BPT, BCT, and BAT standards for the existing production line and NSPS for the new production line, as discussed in section 5.2.2.4 above.

5.2.2.7 Step 7: Apply Additional Regulatory Considerations in Calculating TBELs

The permit writer must consider several additional requirements when deriving TBELs from effluent guidelines. Those additional requirements consist of evaluating or accounting for the following:

- Expected significant increases or decreases in production during the permit term for tiered discharger limitations.
- Internal outfalls.
- Requests for a variance from effluent guidelines.

The following sections provide an overview of those topics.

NMED Exhibit 70

Tiered Discharge Limitations

If production rates are expected to change significantly during the life of the permit, the permit writer can include tiered (alternate) TBELs as allowed by § 122.45(b)(2)(ii)(A)(i). Tiered TBELs would apply to mass-based effluent limitations and would become effective when production or flow (or some other measure of production) exceeded a threshold value, such as during seasonal production variations. Generally, up to a 20 percent fluctuation in production is considered to be within the range of normal variability, while changes in production higher than 20 percent could warrant consideration of tiered limitations. Exhibit 5-19 illustrates application of tiered limitations.

Exhibit 5-19 Example of tiered discharge limitations

Plant B produced approximately 40 tons per day of product during spring and summer months (i.e., March through August) and 280 tons per day during fall and winter months during the previous 5 years. Production during the fall and winter months is significantly higher than during the off-season, and the discharger has made a plausible argument that production is expected to continue at that level. The effluent guidelines requirements for Pollutant Z are 0.08 lbs/1,000 lbs for the average monthly limitation and 0.14 lbs/1,000 lbs for the maximum daily limitation.

Question:
What are appropriate tiered effluent limitations for Plant B?

Answer:
The first tier or lower limitations would be based on a production rate of 40 tons per day. The limitations would apply between March and August.

Monthly average limitation:
40 tons/day × 2,000 lbs/ton x 0.08 lbs/1,000 lbs = **6.4 lbs/day***

Daily maximum limitation:
40 tons/day × 2,000 lbs/ton x 0.14 lbs/1,000 lbs = 11.2 lbs/day = **11 lbs/day***

The second tier or higher limitations would be based on a production rate of 280 tons per day. Those limitations would apply between September and February.

Monthly average limitation:
280 tons/day × 2,000 lbs/ton x 0.08 lbs/1,000 lbs = 44.8 lbs/day = **45 lbs/day***

Daily maximum limitation
280 tons/day × 2,000 lbs/ton x 0.14 lbs/1,000 lbs = 78.4 lbs/day = **78 lbs/day***

* calculated to 2 significant figures

Permit writers should include tiered limitations in a permit only after careful consideration of production data and only when a substantial increase or decrease in production is likely to occur. In the example above, the lower limitations would be in effect when production was at low levels (March through August). During periods of significantly higher production (September through February), the higher limitations would be in effect. In addition, a tiered or alternate set of limitations might be appropriate in the case of special processes or product lines that operate during certain times only.

Permit writers could base thresholds for tiered limitations on an expected increase in production during the term of the permit that will continue through the duration of the permit term. For example, if a facility plans to add a process line and significantly expand production in year 3 of the permit term, the permit could specify a higher tier of limitations that go into effect when the facility reports reaching a production level specified in the permit.

NMED Exhibit 70

Permit writers must detail in the permit the thresholds and time frames when each tier applies, measures of production, and special reporting requirements. Special reporting requirements include provisions such as the following:

- The facility notifying the permitting authority a specified number of business days before the month it expects to be operating at a higher level of production and the duration this level of production is expected to continue.
- The facility reporting, in the discharge monitoring report, the level of production and the limitation and standards applicable to that level.

A detailed discussion of the rationale and requirements for any tiered limitations should be provided in the fact sheet for the permit.

Internal Outfalls

The NPDES regulations at § 122.45(h) give NPDES permit writers the authority to identify internal outfalls when effluent limitations at the final outfall are impractical or infeasible. These internal compliance points might be necessary to ensure proper treatment of persistent, bioaccumulative, and toxic pollutants that are discharged in concentrations below analytic detection levels at the final effluent outfall or other pollutants that may be diluted by flows (e.g., cooling water) not containing the pollutant. Some effluent guidelines may *require* the use of internal outfalls unless the effluent limitations are adjusted based on the dilution ratio of the process wastewater to the wastewater flow at the compliance point. Examples of effluent guidelines with required internal compliance points include the Metal Finishing effluent guidelines (Part 433) and the Pulp, Paper, and Paperboard effluent guidelines (Part 430). Accordingly, the permit writer should identify any internal outfall monitoring that might be required by the applicable effluent guidelines and include monitoring requirements in the final permit.

Effluent Guidelines Variances

The CWA and federal regulations provide limited mechanisms for variances from requirements in effluent guidelines. An NPDES permit applicant must meet very specific data and variance application deadline requirements before a variance may be granted. A variance provides a unique exception to a particular requirement, and the permit writer should not expect to routinely receive variance requests. Nevertheless, the permit writer should be aware of the major types of variances and the basic requirements for each, because the permit writer will most likely be the person to conduct the initial reviews of such requests before submitting them for review to the State Director (if applicable) or to EPA.

Variance applications are submitted by the NPDES permit applicant and must be submitted before the close of the public comment period of the permit, except for Fundamentally Different Factors (FDF) variance requests, which must be requested by the NPDES permit applicant within 180 days of the effluent guidelines publication. The permit writer should consult § 124.62 for the specific procedures for decisions regarding various types of variances. Exhibit 5-20 lists the available variances from effluent guidelines.

NMED Exhibit 70

Exhibit 5-20 Variances from effluent guidelines

Legislation (CWA section)	Type	Regulation (40 CFR)	Approval authority	Application deadline
301(g)	Nonconventional Pollutant	Part 125, Subpart F (Reserved)	EPA Region HQ delegated authority	During permit comment period
301(n)	Fundamentally Different Factors (FDF)	Part 125, Subpart D	EPA Region HQ delegated authority	180 days from the date the limitation or standard is published in the FR
—	Net Intake or Net/Gross	§ 122.45(g)	NPDES state or EPA Region in absence of approved state NPDES program	During permit comment period

The following paragraphs further discuss the variances listed in Exhibit 5-20 and the factors that are considered in a technical review of a variance request.

Nonconventional Pollutant—CWA Section 301(g) Variance

CWA section 301(g) and the regulations at § 122.21(m)(2) provide for a variance from new or revised BAT effluent guidelines for certain nonconventional pollutants because of local environmental factors, so long as the discharger demonstrates that it is meeting BPT and that the discharge does not prevent attainment of water quality standards and would not result in additional requirements on other point or nonpoint sources. The pollutants for which a facility may request a CWA section 301(g) variance are ammonia, chlorine, color, iron, and phenols (as measured by the colorimetric 4-aminoantipyrine [4AAP] method). The CWA also provides a process to petition to include additional pollutants on this list. Industries with facilities that have applied for CWA section 301(g) variances include Iron and Steel Manufacturing (Part 420), Steam Electric Power Generating (Part 423), Inorganic Chemicals Manufacturing (Part 415), Nonferrous Metals Manufacturing (Part 421), Aluminum Forming (Part 467), and Pesticides Chemicals (Part 455) facilities.

In addition to meeting the application deadline, the discharger must file a variance application that meets the following requirements:

- The proposed modified requirements must result in compliance with BPT and water quality standards of the receiving stream.
- No additional treatment will be required of other point or nonpoint source dischargers as a result of the variance approval.
- The modified requirements will not interfere with attainment or maintenance of water quality to protect public water supplies, or with protection and propagation of a balanced population of shellfish, fish, and wildfowl, and will allow recreational activities in and on the water.
- The modified requirements will not result in quantities of pollutants that can reasonably be anticipated to pose an unacceptable risk to human health or the environment, cause acute or chronic toxicity, or promote synergistic properties.

NMED Exhibit 70

The permit writer should review the request to ensure that it complies with each of the requirements for this type of variance. This variance request can involve a great deal of water quality assessment, including aquatic toxicity, mixing zone and dilution model analysis, and possible site-specific criterion development. In addition, it might be necessary to assess many complex human health effects, including carcinogenicity, teratogenicity, mutagenicity, bioaccumulation, and synergistic propensities. Permit writers may use EPA's *Draft Technical Guidance Manual for the Regulations Promulgated Pursuant to Section 301(g) of the Clean Water Act of 1977 40 CFR Part 125 (Subpart F)* <www.epa.gov/npdes/pubs/owm0008.pdf> to assess a completed variance request.

Fundamentally Different Factors—FDF Variance

Alternative effluent limitations or standards different from the otherwise applicable requirements in effluent guidelines may be authorized by EPA if an individual facility is fundamentally different with respect to factors considered in establishing the limitations or standards otherwise applicable to that facility's industrial category. Such a modification is known as a *fundamentally different factors* (FDF) variance.

Facilities must submit all FDF variance applications to the appropriate Director, as defined at § 122.2, no later than 180 days from the date the limitations or standards are published in the FR [see CWA section 301(n)(2) and § 122.21(m)(1)(i)(B)(2)]. An FDF variance is not available to a new source subject to NSPS.

EPA regulations at Part 125, Subpart D, authorizing the EPA Regional Administrators to establish alternative limitations and standards, further detail the substantive criteria used to evaluate FDF variance requests for direct dischargers. The regulations at § 125.31(d) identify six factors that may be considered in determining if a facility is fundamentally different:

- Nature or quality of pollutants contained in the raw process wastewater.
- Volume of the process wastewater and effluent discharged.
- Non-water quality environmental impact of control and treatment of the raw wasteload.
- Energy requirements of the application of control and treatment technology.
- Age, size, land availability, and configurations of discharger's equipment or facilities as well as processes employed, process changes, and engineering aspects of the application of control technology.
- Cost of compliance with required control technology.

The Agency must determine whether, on the basis of one or more of those six factors, the facility in question is fundamentally different from the facilities and factors considered by EPA in developing the nationally applicable effluent guidelines. The regulation also lists four other factors that may not provide a basis for an FDF variance:

- Infeasibility of installation within the time allowed by the CWA.
- Assertion that the national limitations cannot be achieved with the appropriate waste treatment facilities installed (if the assertion is not based on one or more of the six FDF factors above).
- A discharger's ability to pay for the required water treatment.

NMED Exhibit 70

- The impact of a discharge on local receiving water quality.

In addition, under § 125.31(b)(3), a request for limitations less stringent than the national limitation may be approved only if compliance with the national limitations would result in either of the following:

- Removal cost wholly out of proportion to the removal cost considered during development of the national limitations.
- Non-water quality environmental impact (including energy requirements) fundamentally more adverse than the impact considered during development of the national limitations.

The conditions for approval of a request to modify applicable pretreatment standards and factors considered are the same as those for direct dischargers.

The legislative history of CWA section 301(n) underscores the necessity for the FDF variance applicant to establish eligibility for the variance. EPA's regulations at § 125.32(b)(1) are explicit in imposing that burden on the applicant. The applicant must show that the factors relating to the discharge controlled by the applicant's permit, which are claimed to be fundamentally different are, in fact, fundamentally different from those factors considered by the EPA in establishing the applicable effluent guidelines. The pretreatment regulations incorporate a similar requirement at § 403.13(h)(9).

Intake Allowance or Net/Gross Variance

Some facilities might be unable to comply with effluent guidelines because of pollutants in their intake water. Under certain circumstances, the NPDES regulations allow credit for pollutants in intake water. Specifically, permit writers are authorized to grant net credits for the quantity of pollutants in the intake water where (1) the applicable effluent guidelines specify that the guidelines are to be applied on a net basis; or (2) the pollution control technology would, if properly installed and operated, meet applicable effluent guidelines without the pollutants in the intake waters. The following requirements are included in § 122.45(g) for establishing net limitations:

- Credit for conventional pollutants, such as BOD_5 or TSS, are only authorized where the constituents resulting in the effluent BOD_5 and the TSS are similar between the intake water and the discharge.
- Credit is authorized only up to the extent necessary to meet the applicable limitation or standard, with a maximum value equal to the influent concentration.
- Intake water must be taken from the same body of water into which the discharge is made.
- Net credits do not apply to the discharge of raw water clarifier sludge generated during the treatment of intake water.

Permit writers must include influent monitoring in the permit when this type of variance is granted.

Thermal Discharge—CWA Section 316(a) Variance

CWA section 316(a) and the regulations at § 122.21(m)(6) provide for variances from thermal effluent limitations in NPDES permits. EPA has only promulgated thermal limitations in effluent guidelines for two industrial sectors: Beet Sugar Processing Subcategory of the Sugar Processing Point Source Category (Part 409 Subpart A) and the Cement Manufacturing Point Source Category (Part 411, Subparts A and B).

NMED Exhibit 70

Most thermal limitations are based on water quality standards, so most thermal variances actually are not true *technology-based* variances. Dischargers must apply for a thermal discharge variance with its permit application if the thermal effluent limitation is based on an effluent guideline or during the permit comment period if the thermal effluent limitation is based on a WQBEL.

Regulations for submitting and reviewing thermal discharge variance requests are promulgated at Part 125, Subpart H. The approval authority for a thermal discharge variance request is the state permitting authority or the EPA Region if there is no approved state NPDES program. Less stringent alternative thermal effluent limitations may be included in permits if the discharger properly demonstrates that such effluent limitations are more stringent than necessary to assure the protection and propagation of a balanced, indigenous community of shellfish, fish and wildlife in and on the body of water into which the discharge is made, taking into account the cumulative impact of its thermal discharge together with all other significant impacts on the species affected. Once a variance is granted, the discharger must still reapply for the variance each permit term. The majority of thermal variance requests are from power plants seeking relief from water-quality based effluent limitations.

Ambient Water Temperature Considerations

Evaluation of requests for variances under CWA section 316(a) requires consideration of the change to the ambient water temperature because of an effluent discharge. The studies provided by applicants to support their requests frequently include historical thermal data for the receiving water. Permitting authorities should be aware that the effects of global weather patterns could alter the thermal profile of some receiving waters making the historical record of thermal conditions less representative of future conditions. Where appropriate, water quality models should take these potential changes into account.

5.2.2.8 Step 8: Apply Additional Requirements in Effluent Guidelines

The effluent guidelines could provide additional requirements for permit writers to consider when applying them in NPDES permits.

Industrial Stormwater

Industrial stormwater is sometimes regulated by effluent guidelines. In particular, effluent guidelines often regulate stormwater for industrial activities that are unsheltered (e.g., mining, outdoor processing, outside storage of product materials). Examples of contaminated stormwater regulated by effluent guidelines include the Concentrated Animal Feeding Operations (Part 412), Fertilizer Manufacturing (Part 418), Petroleum Refining (Part 419), Iron and Steel Manufacturing (Part 420), Pulp, Paper, and Paperboard (Part 430), Metal Products and Machinery (Part 438), and Ore Mining and Dressing (Part 440) point source categories. The permit writer should identify any specific stormwater controls that may be required by the applicable effluent guidelines accordingly.

Stormwater not regulated by effluent guidelines that is commingled with process wastewater will require the adjustment of the effluent limitations as discussed in Step 6 above. Section 2.3.2.3 of this manual provides additional information about stormwater discharges associated with industrial activities.

NMED Exhibit 70

Identify the Analytical Methods for Measuring Compliance with TBELs

The permit writer should ensure that the permit specifies the use of the correct analytical methods for demonstrating compliance with TBELs derived from effluent guidelines. The effluent guidelines often require specific analytical methods. For example, the *General Definitions* section of the Meat and Poultry Products effluent guidelines [§ 432.2(l)] states, "The approved methods of analysis for the following six parameters [Ammonia (as N), BOD_5, Oil and Grease (O&G), O&G as hexane extractable material (HEM), Total Nitrogen, TSS] are found in Table 1B in [§] 136.3. The nitrate/nitrite part of total nitrogen may also be measured by EPA Method 300.0 (incorporated by reference, see § 432.5)." Section 8.3 of this manual provides additional information on analytical methods in the NPDES permitting process.

Documentation and Recordkeeping Requirements

Specific documentation and recordkeeping requirements (e.g., solvent management plans, BMP plans, alternative monitoring requirements) may be included in the applicable effluent guidelines. The permit writer should ensure that the documentation and recordkeeping requirements are included in the NPDES permit. For example, to use the alternative monitoring compliance method for controlling toxic organics in the Metal Finishing effluent guidelines, the NPDES permit applicant must not only make a certification statement (see Exhibit 5-15), but must also "submit a solvent management plan that specifies to the satisfaction of the permitting authority (or, in the case of indirect dischargers, the control authority) the toxic organic compounds used; the method of disposal used instead of dumping, such as reclamation, contract hauling, or incineration; and procedures for ensuring that toxic organics do not routinely spill or leak into the wastewater" as required by § 433.12(b). Other examples of such documentation and recordkeeping requirements include the BMP Plans used in the Oil and Gas Extraction (Part 435) and the Concentrated Aquatic Animal Production effluent guidelines (Part 451), the pollution prevention alternative in the Pesticide Chemicals effluent guidelines (Part 455), and alternative monitoring requirements (e.g., certification in lieu of monitoring for chloroform, in the Pulp, Paper, and Paperboard effluent guidelines (Part 430).

5.2.2.9 Step 9: Document the Application of Effluent Guidelines in the Fact Sheet

Permit writers need to document their application of effluent guidelines in the NPDES permit fact sheet. The permit writer should clearly identify the data and information used to determine the applicable effluent guidelines and how that information was used to derive effluent limitations for the permit. The information in the fact sheet should provide the NPDES permit applicant and the public a transparent, reproducible, and defensible description of how the NPDES permit properly incorporates effluent guidelines.

Similarly, permit writer should also document the rationale for concluding that there are no applicable effluent guidelines for a discharge or pollutant. In such cases, TBELs may be determined by the permit writer on a case-by-case basis as discussed in section 5.2.3 below.

5.2.3 Case-by-Case TBELs for Industrial Dischargers

As previously stated, § 125.3(a) indicates that technology-based treatment requirements under CWA section 301(b) represent the minimum level of control that must be imposed in an NPDES permit.

NMED Exhibit 70

Where EPA-promulgated effluent guidelines are not applicable to a non-POTW discharge, such requirements are established on a case-by-case basis using BPJ.

5.2.3.1 Legal Authority to Establish Case-by-Case TBELs

Case-by-case TBELs are developed pursuant to CWA section 402(a)(1), which authorizes the EPA Administrator to issue a permit that will meet either all applicable requirements developed under the authority of other sections of the CWA (e.g., technology-based treatment standards, water quality standards, ocean discharge criteria) or, before taking the necessary implementing actions related to those requirements, "such conditions as the Administrator determines are necessary to carry out the provisions of this Act." The regulation at § 125.3(c)(2) specifically cites this section of the CWA, stating that technology-based treatment requirements may be imposed in a permit "on a case-by-case basis under section 402(a)(1) of the Act, to the extent that EPA-promulgated effluent limitations are inapplicable." Further, § 125.3(c)(3) indicates that "where promulgated effluent limitations guidelines only apply to certain aspects of the discharger's operation, or to certain pollutants, other aspects or activities are subject to regulation on a case-by-case basis to carry out the provisions of the Act." When establishing case-by-case effluent limitations using BPJ, the permit writer should cite in the fact sheet or statement of basis both the approach used to develop the limitations, which is discussed further below, and how the limitations carry out the intent and requirements of the CWA and the NPDES regulations.

5.2.3.2 Identifying the Need for Case-by-Case TBELs

As noted above, case-by-case TBELs are established in situations where EPA promulgated effluent guidelines are inapplicable. That includes situations such as the following:

- When EPA has not yet promulgated effluent guidelines for the point source category to which a facility belongs (e.g., a facility that produced distilled and blended liquors [SIC code 2085] and is part of the miscellaneous foods and beverages category, which does not now have any applicable effluent guidelines).
- When effluent guidelines are available for the industry category, but no effluent guidelines are available for the facility subcategory (e.g., discharges from coalbed methane wells are not now regulated by effluent guidelines; however, EPA considers the coalbed methane industrial sector as a potential new subcategory of the existing Oil and Gas Extraction point source category [Part 435] because of the similar industrial operations performed [i.e., drilling for natural gas extraction]).
- When effluent guidelines are available for the industry category but are not applicable to the NPDES permit applicant (e.g., facilities that do not perform the industrial operation triggering applicability of the effluent guidelines or do not meet the production or wastewater flow cutoff applicability thresholds of the effluent guidelines). For example, assume that the poultry slaughterhouse in Example 2 of Exhibit 5-13 above produces 50 million pounds of whole, halved, quarter or smaller meat cuts annually. In that case, any TBELs for the facility would be case-by-case limitations developed using BPJ because the facility is below the annual production threshold of 100 million pounds listed in the effluent guideline (Part 432, Subpart K).
- When effluent guidelines are available for the industry category, but no effluent guidelines requirements are available for the pollutant of concern (e.g., a facility is regulated by the effluent guidelines for Pesticide Chemicals [Part 455] but discharges a pesticide that is not regulated by

NMED Exhibit 70

these effluent guidelines). The permit writer should make sure that the pollutant of concern is not already controlled by the effluent guidelines and was not considered by EPA when the Agency developed the effluent guidelines.

Generally, case-by-case limitations are appropriate when at least one of the conditions listed above applies and the pollutant is present, or expected to be present, in the discharge in amounts that can be treated or otherwise removed (e.g., implementation of pollution prevention measures). The resources listed in sections 5.2.2.2 above and 5.2.3.4 below will help the permit writer in making such determinations. For example, EPA's effluent guidelines planning support documents on EPA's Effluent Guidelines Biennial Plan Website <http://water.epa.gov/lawsregs/lawsguidance/cwa/304m/> identify facilities and industrial sectors that currently are not regulated by effluent guidelines.

5.2.3.3 Factors Considered When Developing Case-by-Case TBELs

The NPDES regulations at § 125.3(c)(2) require that permit writers developing case-by-case effluent limitations consider the following:

- The appropriate technology for the category class of point sources of which the applicant is a member, based on all available information.
- Any unique factors relating to the applicant.

The regulations also require that, in setting case-by-case limitations, the permit writer consider several specific factors established in § 125.3(d) to select a model treatment technology and derive effluent limitations on the basis of that treatment technology. That process and the factors considered by the permit writer are the same factors required to be considered by EPA in developing effluent guidelines and, therefore, are often referred to as the CWA section 304(b) factors. The factors are summarized below in Exhibit 5-21. The permit writer evaluates case-by-case limitations based on BPT, BCT, and BAT and uses the more stringent technology level of control for each pollutant of concern.

Exhibit 5-21 Summary of factors considered when developing case-by-case TBELs

For BPT requirements (all pollutants)
- The age of equipment and facilities involved*
- The process(es) employed*
- The engineering aspects of the application of various types of control techniques*
- Process changes*
- Non-water quality environmental impact including energy requirements*
- The total cost of application of technology in relation to the effluent reduction benefits to be achieved from such application

For BCT requirements (conventional pollutants)
- All items in the BPT requirements indicated by an asterisk (*) above
- The reasonableness of the relationship between the costs of attaining a reduction in effluent and the derived effluent reduction benefits
- The comparison of the cost and level of reduction of such pollutants from the discharge of POTWs to the cost and level of reduction of such pollutants from a class or category of industrial sources

For BAT requirements (toxic and non-conventional pollutants)
- All items in the BPT requirements indicated by an asterisk (*) above
- The cost of achieving such effluent reduction

NMED Exhibit 70

The CWA also gives the permit writer the authority to consider process changes to evaluate case-by-case limitations. As previously stated, technology-based controls in NPDES permits are performance-based measures. EPA incorporates technology-based controls in NPDES permits that correspond to the application of an identified technology (including process changes) but does not require dischargers to install the identified technology. Therefore, EPA leaves to each facility the discretion to select the technology design or process changes necessary to meet the TBELs specified in the NPDES permit.

The permit writer might need to establish a monitoring-only requirement in the current NPDES permit to identify pollutants of concern and potential case-by-case limitations for the subsequent NPDES permit renewal.

5.2.3.4 Resources for Developing Case-by-Case TBELs

There are numerous resources for identifying candidates for model technologies or process changes and developing case-by-case TBELs using BPJ. Exhibit 5-22 lists some example references that permit writers can use to derive such limitations.

5.2.3.5 Statistical Considerations When Establishing Case-by-Case TBELs

The quality of the effluent from a treatment facility will normally vary over time. If, for example, BOD_5 data for a typical treatment plant were plotted against time, one would observe day-to-day variations of effluent concentrations. Some of that behavior can be described by constructing a frequency-concentration plot. From the plot, one could observe that for most of the time, BOD_5 concentrations are near some average value. Any treatment system can be described using the mean concentration of the parameter of interest (i.e., the long-term average) and the variance (or coefficient of variation) and by assuming a particular statistical distribution (usually lognormal).

When developing a case-by-case limitation, permit writers can use an approach consistent with the statistical approach EPA has used to develop effluent guidelines. Specifically, the maximum daily limitation could be calculated by multiplying the long-term average achievable by implementation of the model technology or process change by a daily variability factor determined from the statistical properties of a lognormal distribution. The average monthly limitation can be calculated similarly except that the variability factor corresponds to the distribution of monthly averages instead of daily concentration measurements. The daily variability factor is a statistical factor defined as the ratio of the estimated 99th percentile of a distribution of daily values divided by the mean of the distribution. Similarly, the monthly variability factor is typically defined as the estimated 95th percentile of the distribution of monthly averages divided by the mean of the distribution of monthly averages.

A modified delta-lognormal distribution could be fit to concentration data and variability factors computed for the facility distribution. The modified delta-lognormal distribution models the data as a mixture of measured values and observations recorded as values less than the detectable level. This distribution often is selected because the data for many analytes consist of such a mixture of measured values and results below the detectable level. The modified delta-lognormal distribution assumes that all non-detected results have a value equal to the detection limitations and that the detected values follow a lognormal distribution.

NMED Exhibit 70

Exhibit 5-22 Tools for developing case-by-case TBELs using BPJ

Permit file information
- Current and previous NPDES application forms.
- Previous NPDES permit and fact sheet.
- Discharge monitoring reports.
- Compliance inspection reports.

Information from existing facilities and permits
- NPDES Individual and General Permits for other NPDES permits issued to facilities in the same region or state, or that include case-by-case limitations for the same pollutants.
- Toxicity reduction evaluations for selected industries.
- Other media permit files (e.g., Resource Conservation and Recovery Act [RCRA] permit applications and Spill Prevention Countermeasure and Control [SPCC] plans.
- ICIS-NPDES <https://icis.epa.gov/icis> data.
- Literature (e.g., technical journals and books).

Effluent guidelines development and planning information
- Industry experts within EPA headquarters, EPA Regions, and states <www.epa.gov/guide/contacts.html>.
- Development Documents, CWA section 308 questionnaires, screening and verification data, proposed and final regulations, contractor's reports, and project officer contacts <www.epa.gov/guide>.
- EPA's Technical Support Documents <http://water.epa.gov/lawsregs/lawsguidance/cwa/304m/> and records supporting EPA's biennial effluent guidelines program plans also provide additional useful information. In particular, such resources provide a sample of the current limitation and latest developments in industrial pollutant prevention, water conservation, and wastewater treatment. The Technical Support Documents also identify industrial sectors not currently regulated by effluent guidelines.

Statistical guidance

- *Storm Water Management for Industrial Activities: Developing Pollution Prevention Plans and BMPs*[11] <www.epa.gov/npdes/pubs/contents_indguide.pdf>.
- National Menu of Stormwater Best Management Practices <www.epa.gov/npdes/stormwater/menuofbmps>.

For more details on EPA's use of statistical methods for developing effluent guidelines, refer to *Development Document for Final Effluent Limitations Guidelines and Standards for the Iron and Steel Manufacturing Point Source Category* <www.epa.gov/guide/ironsteel/reg/tdd.htm>.

5.2.3.6 Documenting Case-by-Case TBELs in the Permit Fact Sheet

Permit writers will need to document the development of case-by-case limitations in the NPDES permit fact sheet. The permit writer should clearly identify the data and information used in developing these effluent limitations and how that information was used. The permit writer also should document the rationale for concluding that there are no applicable effluent guidelines for the industrial wastewater or pollutant discharge. The information in the fact sheet should provide the NPDES permit applicant and the public a transparent, reproducible, and defensible description of how the BPJ limitations comply with the CWA and EPA regulations.

NMED Exhibit 70

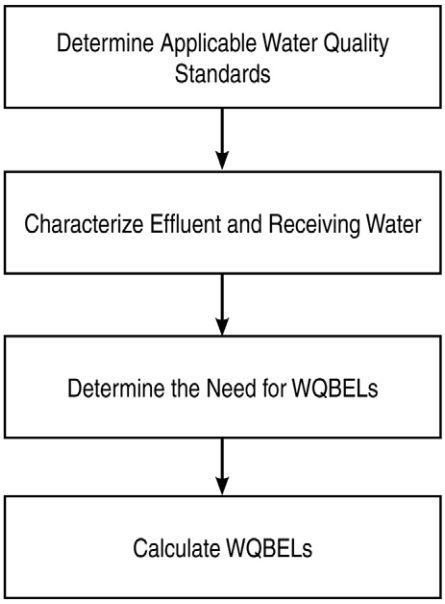
CHAPTER 6. Water Quality-Based Effluent Limitations

When drafting a National Pollutant Discharge Elimination System (NPDES) permit, a permit writer must consider the impact of the proposed discharge on the quality of the receiving water. Water quality goals for a waterbody are defined by state water quality standards. By analyzing the effect of a discharge on the receiving water, a permit writer could find that technology-based effluent limitations (TBELs) alone will not achieve the applicable water quality standards. In such cases, the Clean Water Act (CWA) and its implementing regulations require development of water quality-based effluent limitations (WQBELs). WQBELs help meet the CWA objective of restoring and maintaining the chemical, physical, and biological integrity of the nation's waters and the goal of water quality that provides for the protection and propagation of fish, shellfish, and wildlife and recreation in and on the water (*fishable/swimmable*).

WQBELs are designed to protect water quality by ensuring that water quality standards are met in the receiving water. On the basis of the requirements of Title 40 of the *Code of Federal Regulations* (CFR) 125.3(a), additional or more stringent effluent limitations and conditions, such as WQBELs, are imposed when TBELs are not sufficient to protect water quality. Exhibit 6-1 illustrates the relationship between TBELs and WQBELs in an NPDES permit, as well as the determination of final effluent limitations.

Exhibit 6-1 Developing effluent limitations



CWA section 301(b)(1)(C) requires that permits include any effluent limitations necessary to meet water quality standards. As illustrated above, to satisfy that requirement, permit writers implement a process to determine when existing effluent limitations (e.g., TBELs) and existing effluent quality are not sufficient to comply with water quality standards and to, where necessary, develop WQBELs. Exhibit 6-2 illustrates the four basic parts of the *standards-to-permits* process used to assess the need for and develop WQBELs.

NMED Exhibit 70

After completing that process, the permit writer determines the final effluent limitations, includes any compliance schedules and interim effluent limitations, as appropriate, and documents all his or her decisions and calculations.

Exhibit 6-2 Standards-to-permits process

This chapter provides basic information on the standards-to-permits process. For more detailed information on water quality standards and water quality-based permitting, and some of the specific topics discussed in this chapter, refer to the NPDES Website <www.epa.gov/npdes> and Water Quality Standards Website <www.epa.gov/waterscience/standards>.

6.1 Determine Applicable Water Quality Standards

CWA section 303(c) and Part 131 establish the framework for water quality standards. The CWA and implementing regulations require states to develop and, from time to time, revise water quality standards applicable to waters of the United States, or segments of such waterbodies, that are in the jurisdiction of the state. States must review their water quality standards at least once every 3 years and revise them as appropriate. Wherever attainable, water quality standards should protect water quality that provides for the protection and propagation of fish, shellfish and wildlife, and recreation in and on the water (i.e., the CWA section 101(a)(2) *fishable/swimmable* goal). In establishing standards, states must consider the use and value of their waters for public water supplies, propagation of fish and wildlife, recreation, agriculture and industrial purposes, and navigation. The U.S. Environmental Protection Agency (EPA) has provided information regarding procedures for developing water quality standards in the Water Quality Standards Regulation at Part 131 and EPA's *Water Quality Standards Handbook: Second Edition*[1] <www.epa.gov/waterscience/library/wqstandards/handbook.pdf.> (hereafter *WQS Handbook*). Under CWA section 510, states may develop water quality standards that are more stringent than those required by the CWA.

NMED Exhibit 70

EPA Regions review and approve or disapprove new and revised water quality standards adopted by states. The purpose of EPA's review is to ensure that the new and revised water quality standards meet the requirements of the CWA and the Water Quality Standards Regulation. Water quality standards adopted and submitted to EPA after May 30, 2000, must be approved by EPA before they may be used to implement the CWA (e.g., used in NPDES permitting). If an EPA Region disapproves a submitted new or revised state water quality standard, and the state does not adopt the necessary changes within 90 days of notification of the disapproval, EPA must promptly propose and promulgate a replacement standard [see § 131.22(a)].

When writing an NPDES permit, the permit writer must identify and use the state water quality standards in effect for CWA purposes. EPA maintains a compilation of current state water quality standards on the Water Quality Standards: State, Tribal, & Territorial Standards Website <www.epa.gov/waterscience/standards/wqslibrary/>. In addition, EPA's Water Quality Standards: Laws and Regulations Website <www.epa.gov/waterscience/standards/rules/> provides federally promulgated standards applicable to specific states. The remainder of this section provides permit writers with a general overview of water quality standards and how they are implemented in NPDES permits.

6.1.1 Components of Water Quality Standards

Water quality standards comprise three parts:

- Designated uses.
- Numeric and/or narrative water quality criteria.
- Antidegradation policy.

Each of those three components, along with general policies that also may be included in state water quality standards, is described below.

6.1.1.1 Designated Uses (§ 131.10)

The first part of a state's water quality standards is a classification system for waterbodies based on the expected uses of those waterbodies. The uses in this system are called *designated uses*. The regulations at § 131.10(a) describe various uses of waters that are considered desirable and that must be considered when establishing water quality standards. Those uses include public water supplies, propagation of fish, shellfish, and wildlife, recreation in and on the water, agricultural, industrial, and other purposes including navigation. The regulations allow states to designate more specific uses (e.g., cold water aquatic life) [see § 131.10(c)] or uses not specifically mentioned in the CWA, with the exception of waste transport and assimilation, which are not acceptable designated uses [see § 131.10(a)]. States must also consider and ensure the attainment and maintenance of the water quality standards of downstream waters when establishing designated uses [see § 131.10(b)].

The regulations in § 131.10(j) effectively establish a *rebuttable presumption* that the uses in CWA section 101(a)(2) (fishable/swimmable) are attainable. If a state fails to designate a given waterbody for such uses, or wishes to remove such uses, it must provide appropriate documentation demonstrating why such uses are not attainable. This analysis is commonly called a *Use Attainability Analysis* (UAA) (see § 131.3(g) and section 6.1.2.1 below).

NMED Exhibit 70

6.1.1.2 Water Quality Criteria (§ 131.11)

The second part of a state's water quality standards is the set of water quality criteria sufficient to support the designated uses of each waterbody. EPA's Water Quality Standards Regulation at § 131.11(a) requires states to adopt water quality criteria using sound scientific rationale and to include sufficient parameters or constituents to protect the designated use. If a waterbody has multiple use designations, the criteria must support the most sensitive use. The regulation at § 131.11(b) allows states to adopt both numeric and narrative water quality criteria. Numeric water quality criteria are developed for specific parameters to protect aquatic life and human health and, in some cases, wildlife from the deleterious effects of pollutants. States establish narrative criteria where numeric criteria cannot be established, or to supplement numeric criteria. Criteria newly adopted or revised on or after May 30, 2000, do not become effective for purposes of the CWA until approved by EPA [see § 131.21(c)].

CWA section 304(a) directs EPA to develop, publish, and, from time to time, revise criteria for water quality accurately reflecting the latest scientific knowledge on the following:

- The kind and extent of all identifiable effects on health and welfare, including effects on aquatic life and recreational uses, that may be expected from the presence of pollutants in any body of water.
- The concentration and dispersal of pollutants or their byproducts through biological, physical, and chemical processes.
- The effects of pollutants on biological community diversity, productivity, and stability.

EPA's recommended criteria developed under CWA section 304(a) assist states in developing their water quality standards. EPA's numeric criteria are ambient levels of individual pollutants or parameters or they describe conditions of a waterbody that, if met, generally will protect the CWA section 101(a)(2) fishable and swimmable uses. EPA's recommended criteria developed under CWA section 304(a) do not reflect consideration of economic impacts or the technological feasibility of meeting the chemical concentrations in ambient water. EPA provides a table of the nationally recommended CWA section 304(a) criteria on the National Recommended Water Quality Criteria Website <www.epa.gov/waterscience/criteria/wqctable/>. The regulation at § 131.11(b)(1) indicates that, in establishing numeric criteria, states may (1) adopt EPA's recommended criteria published under CWA section 304(a), (2) adopt those criteria modified to reflect site-specific conditions, or (3) adopt criteria based on other scientifically defensible methods.

CWA section 303(c)(2)(B) specifically requires states to adopt numeric criteria for CWA section 307(a) toxic (priority) pollutants for which EPA has published recommended criteria if the discharge or presence of the pollutant can reasonably be expected to interfere with designated uses. Furthermore, § 131.11(a)(2) requires states to review water quality data and information on discharges to identify specific water bodies where toxic pollutants might be adversely affecting water quality or attainment of designated uses or where levels of toxic pollutants would warrant concern and to adopt criteria for such toxic pollutants applicable to the waterbody that are sufficient to protect the designated use. As discussed in section 1.2 and presented in Exhibit C-1 in Appendix C of this manual, the CWA section 307(a) list contains 65 compounds and families of compounds, which EPA has interpreted to include 126 toxic (priority) pollutants.

NMED Exhibit 70

Numeric Criteria—Aquatic Life

Numeric criteria for the protection of aquatic life are designed to protect aquatic organisms, including both plants and animals. EPA's aquatic life criteria address both short-term (acute) and long-term (chronic) effects on both freshwater and saltwater species. Each of those criteria generally consists of three components:

- **Magnitude:** The level of pollutant (or pollutant parameter), usually expressed as a concentration, that is allowable.
- **Duration:** The period (averaging period) over which the in-stream concentration is averaged for comparison with criteria concentrations.
- **Frequency:** How often criteria may be exceeded.

Are criteria and effluent limitations expressed in the same terms?

Generally, criteria and effluent limitations are not expressed in the same terms. As discussed above, criteria are generally expressed as a magnitude, duration and frequency. Effluent limitations in NPDES permits are generally expressed as a magnitude (e.g., milligrams per liter, micrograms per liter) and an averaging period (e.g., maximum daily, average weekly, average monthly). A permit writer should be aware of the procedures used by his or her permitting authority to appropriately reflect the magnitude, duration, and frequency components of aquatic life criteria when determining the need for and calculating effluent limitations for NPDES permits. Typically, the components of the criteria are addressed in water quality models through the use of statistically derived receiving water and effluent flow values that ensure that criteria are met under *critical conditions* (see section 6.2 below).

Exhibit 6-3 is an example of freshwater aquatic life criteria for cadmium from the National Recommended Water Quality Criteria Website <www.epa.gov/waterscience/criteria/wqctable/> and at 66 FR 18935, April 12, 2001, Notice of Availability of 2001 Update: Aquatic Life Criteria Document for Cadmium <www.epa.gov/EPA-WATER/2001/April/Day-12/w9056.htm>.

Exhibit 6-3 Aquatic life criteria example: Cadmium (dissolved)

Except possibly where a locally important species is unusually sensitive, freshwater aquatic organisms and their uses should not be affected unacceptably if

Chronic criterion:
The 4-day average concentration (in micrograms per liter [µg/L]) does not exceed the numerical value given by $e^{(0.7409[\ln(\text{hardness})]-4.719)}$ (1.101672 – [(ln hardness)(0.041838)]) more than once every 3 years on average.

Acute criterion:
The 24-hour average concentration (in µg/L) does not exceed the numerical value given by $e^{(1.0166[\ln(\text{hardness})]-3.924)}$ (1.136672 – [(ln hardness)(0.041838)]) more than once every 3 years on average.

It is apparent that the acute and chronic aquatic life criteria for cadmium are not simply single numbers. Rather, they are expressed as a magnitude, a duration (4-day average or 24-hour average), and a frequency (not more than once every 3 years). Furthermore, the magnitude is expressed by a formula that is hardness-dependent, as is the case for most criteria for metals.

NMED Exhibit 70

The magnitude of other aquatic life criteria can vary according to other conditions in the water or even based on the presence or absence of certain aquatic life. For example, EPA's 1999 recommended ammonia criteria vary according to pH, temperature, the presence or absence of salmonid species, and the presence or absence of early life stages of fish. A permit writer must be aware of the applicable criteria and any state regulations, policies, and procedures for interpreting numeric criteria and for implementing the criteria in NPDES permits. The durations of aquatic life criteria vary as well. For example, EPA's criteria recommendations for ammonia include a 30-day average chronic criterion. Also, many acute criteria for toxic pollutants are expressed as a 1-hour average. The frequency component of most aquatic life criteria specifies that they should be exceeded no more than once every three years.

Some states have adopted numeric criteria for nutrients as part of their water quality standards. EPA has developed nutrient criteria recommendations that are numeric values for both causative (phosphorus and nitrogen) and response (chlorophyll *a* and turbidity) variables associated with the prevention and assessment of eutrophic conditions. EPA's recommended nutrient criteria are different from most of its other recommended criteria, such as the criteria for cadmium and ammonia. First, EPA's recommended nutrient criteria are *ecoregional* rather than nationally applicable criteria, and they can be refined and localized using nutrient criteria technical guidance manuals. Second, the recommended nutrient criteria represent conditions of surface waters that have minimal impacts caused by human activities rather than values derived from laboratory toxicity testing. Third, the recommended nutrient criteria are do not include specific duration or frequency components; however, the ecoregional nutrient criteria documents indicate that states may adopt seasonal or annual averaging periods for nutrient criteria instead of the 1-hour, 24-hour, or 4-day average durations typical of aquatic life criteria for toxic pollutants. The ecoregional nutrient criteria documents, technical guidance manuals, and other information on EPA's nutrient criteria recommendations, are available on the Water Quality Criteria for Nitrogen and Phosphorus Pollution Website <www.epa.gov/waterscience/criteria/nutrient/>.

Water quality standards also typically include aquatic life criteria for parameters such as temperature and pH that are not chemical constituents. Criteria for pH generally are expressed as an acceptable pH range in the waterbody. Temperature criteria might be expressed as both *absolute temperature values* (e.g., temperature may not exceed 18 degrees Celsius [°C]) and restrictions on causing *changes in temperature* in the waterbody (e.g., discharges may not warm receiving waters by more than 0.5 °C).

In addition to criteria for individual pollutants or pollutant parameters, many states include in their water quality standards criteria for dissolved oxygen. Often, criteria for dissolved oxygen are addressed by modeling and limiting discharges of oxygen-demanding pollutants such as biochemical oxygen demand (BOD), chemical oxygen demand (COD), and nutrients (phosphorus and nitrogen).

Finally, states could also include in their water quality standards numeric criteria to address the effect of mixtures of pollutants. For example, whole effluent toxicity (WET) criteria protect the waterbody from the aggregate and synergistic toxic effects of a mixture of pollutants. WET is discussed in detail later in this chapter.

Numeric Criteria—Human Health

Human health criteria for toxic pollutants are designed to protect people from exposure resulting from consumption of fish or other aquatic organisms (e.g., mussels, crayfish) or from consumption of both water and aquatic organisms. These criteria express the highest concentrations of a pollutant that are not

NMED Exhibit 70

expected to pose significant long-term risk to human health. Exhibit 6-4 is an example of human health criteria for dichlorobromomethane.

Exhibit 6-4 Human health criteria example: Dichlorobromomethane

For the protection of human health from the potential carcinogenic effects of dichlorobromomethane through ingestion of water and contaminated aquatic organisms, the ambient water criterion is determined to be 0.55 µg/L.
For the protection of human health from the potential carcinogenic effects of dichlorobromomethane through ingestion contaminated aquatic organisms alone, the ambient water criterion is determined to be 17 µg/L.
These values were calculated based on a national default freshwater/estuarine fish consumption rate of 17.5 grams per day.

Other criteria for protection of human health (e.g., bacteria criteria) consider a shorter-term exposure through uses of the waterbody such as contact recreation. EPA's current bacteria criteria recommendations use enterococci and *Escherichia coli* bacteria as indicators and include two components: a geometric mean value and a single sample maximum value. EPA has developed information on implementing those criteria in water quality standards on the Microbial (Pathogen) Water Quality Criteria Website <www.epa.gov/waterscience/criteria/humanhealth/microbial/>.

Other Numeric Criteria

In addition to aquatic life and human health criteria, some state water quality standards include other forms of numeric criteria, such as wildlife, sediment, and biocriteria.

Wildlife criteria are derived to establish ambient concentrations of chemicals that, if not exceeded, will protect mammals and birds from adverse impacts resulting from exposure to those chemicals through consumption of aquatic organisms and water. EPA established four numeric criteria to protect wildlife in the Great Lakes system in its *Final Water Quality Guidance for the Great Lakes System* <www.epa.gov/EPA-WATER/1995/March/Day-23/pr-82.html> (60 FR 15387, March 23, 1995).

In a healthy aquatic community, sediments provide a habitat for many living organisms. Controlling the concentration of pollutants in the sediment helps to protect bottom-dwelling species and prevents harmful toxins from moving up the food chain and accumulating in the tissue of animals at progressively higher levels. For more information on this topic, see EPA's Suspended and Bedded Sediments Website <www.epa.gov/waterscience/criteria/sediment/>.

The presence, condition and numbers of types of fish, insects, algae, plants, and other organisms are data that, together, provide direct, accurate information about the health of specific bodies of water. Biological criteria (biocriteria) are narrative or numeric expressions that describe the reference biological integrity (structure and function) of aquatic communities inhabiting waters of a given designated aquatic life use. Biocriteria are based on the numbers and kinds of organisms present and are regulatory-based biological measurements. They are used as a way of describing the qualities that must be present to support a desired condition in a waterbody, and they serve as the standard against which biological assessment results are compared. EPA's Biocriteria: Uses of Data in NPDES Permits Website <www.epa.gov/waterscience/biocriteria/watershed/npdes.html> provides more information on the use of bioassessment information.

NMED Exhibit 70

Narrative Criteria

All states have adopted narrative water quality criteria to supplement numeric criteria. Narrative criteria are statements that describe the desired water quality goal for a waterbody. Narrative criteria, for example, might require that discharges be "free from toxics in toxic amounts" or be "free of objectionable color, odor, taste, and turbidity." Narrative criteria can be the basis for limiting specific pollutants for which the state does not have numeric criteria [§ 122.44(d)(1)(vi)] or they can be used as the basis for limiting toxicity using WET requirements where the toxicity has not yet been traced to a specific pollutant or pollutants [§ 122.44(d)(1)(v)]. For toxic pollutants, EPA's Water Quality Standards Regulation at § 131.11(a)(2) requires states to develop implementation procedures for toxics narrative criteria that address how the state intends to regulate point source discharges of toxic pollutants to water quality limited segments.

6.1.1.3 Antidegradation Policy (§ 131.12)

The third part of a state's water quality standards is its antidegradation policy. Each state is required to adopt an antidegradation policy consistent with EPA's antidegradation regulations at § 131.12. A state's antidegradation policy specifies the framework to be used in making decisions about proposed activities that will result in changes in water quality. Antidegradation policies can play a critical role in helping states protect the public resource of water whose quality is better than established criteria levels and ensure that decisions to allow reductions in water quality are made in a public manner and serve the public good. Along with developing an antidegradation policy, each state must identify the method it will use to implement the policy. It is important for permit writers to be familiar with their state's antidegradation policy and how that policy is to be implemented in NPDES permits.

A state's antidegradation policy provides three levels of protection from degradation of existing water quality:

- **Tier 1:** This tier requires that existing uses, and the level of water quality necessary to protect the existing uses, be maintained and protected.
- **Tier 2:** Where the quality of waters exceeds levels necessary to support propagation of fish, shellfish, and wildlife and recreation in and on the water (sometimes referred to as *high-quality waters*), Tier 2 requires that this level of water quality be maintained and protected unless the state finds, after full satisfaction of the intergovernmental coordination and public participation provisions of the state's continuing planning process, that allowing lower water quality is necessary to accommodate important economic or social development in the area where the waters are located. In allowing any such degradation or lower water quality, the state must assure water quality adequate to protect existing uses fully and must assure that there will be achieved the highest statutory and regulatory requirements for all new and existing point sources and all cost-effective and reasonable best management practices for nonpoint source control.
- **Tier 3:** This tier requires that the water quality of *outstanding national resources waters* (ONRWs) be maintained and protected.

States take a variety of approaches to implementing antidegradation policies. Some states designate their waters as Tier 1, Tier 2 (high-quality water) or Tier 3 waters in their antidegradation implementation methods, while others designate a waterbody as a Tier 2 or high-quality water only when activities that would degrade water quality are proposed. In some cases, states may have classified the waterbody as

NMED Exhibit 70

receiving a tier of protection for all pollutant-related parameters, whereas in other cases, tiers of protection have been determined on a parameter-by-parameter basis.

6.1.1.4 General Policies (§ 131.13)

In addition to the three required components of water quality standards, states may, at their discretion, include in their standards policies that generally affect how the standards are applied or implemented. Examples of such policies include mixing zone policies, critical low flows at which criteria must be achieved, and the availability of variances. Some general policies are discussed in more detail later in this chapter. As with the other components of water quality standards, general policies are subject to EPA review and approval if they are deemed to be new or revised water quality standards (i.e., if they constitute a change to designated use(s), water quality criteria, antidegradation requirements, or any combination).

Additional and more detailed information on water quality standards is available in the WQS Handbook.

6.1.2 Water Quality Standards Modifications

Permit writers should be aware of several types of modifications to water quality standards that could permanently or temporarily change the standards and, thus, change the fundamental basis of WQBELs. Those modifications, described below, are as follows:

- Designated use reclassification.
- Site-specific water quality criteria modification.
- Water quality standard variance.

6.1.2.1 Designated Use Reclassification

Once a use has been designated for a particular waterbody or segment, that use may not be removed from the water quality standards except under specific conditions. To remove a designated use, the state demonstrates that attaining that use is not feasible because of any one of the six factors listed in § 131.10(g). The regulations at § 131.10(j) specifically require a state to conduct a UAA if the designated uses for a waterbody do not include the uses in CWA section 101(a)(2) (i.e., fishable/swimmable uses); if the state wishes to remove designated uses included in CWA section 101(a)(2) from its water quality standards; or if the state wishes to adopt subcategories of CWA section 101(a)(2) uses with less stringent criteria. The WQS Handbook discusses UAAs and removing designated uses in detail. Reclassifying a waterbody's designated uses, as supported by a UAA, is a permanent change to both the designated use(s) and the water quality criteria associated with that (those) use(s).

States may conduct a UAA and remove a designated use but not if it is an existing use. Existing uses are defined in § 131.3 as those uses actually attained in the waterbody on or after November 28, 1975 (the date of EPA's initial water quality standards regulation at 40 *Federal Register* 55334, November 28, 1975). At a minimum, uses are deemed attainable if they can be achieved by the implementing effluent limits required under CWA sections 301(b) and 306 and by implementing cost effective and reasonable best management practices (BMPs) for nonpoint source control. EPA's Water Quality Standards: UAA Website <www.epa.gov/waterscience/standards/uses/uaa/index.htm> provides additional information and some example UAAs.

NMED Exhibit 70

6.1.2.2 Site-Specific Water Quality Criteria Modification

As noted above, CWA sections 303(a)–(c) require states to adopt water quality criteria sufficient to protect applicable designated uses. In some cases, a state might find that the criteria it has adopted to protect a waterbody or segment of a waterbody do not adequately account for site-specific conditions. In such cases, states have the option of modifying water quality criteria on a site-specific basis. Setting site-specific criteria might be appropriate where, for example, a state has adopted EPA's CWA section 304(a) criteria recommendations and finds that physical or chemical properties of the water at a site affect the bioavailability or toxicity of a chemical, or the types of local aquatic organisms differ significantly from those actually tested in developing the EPA-recommended criteria. Site-specific criteria modifications change water quality criteria permanently while continuing to support the current designated uses.

Development of site-specific criteria for aquatic life is discussed in section 3.7 of the WQS Handbook for cases when (1) there might be relevant differences in the toxicity of the chemical in the water at the site and laboratory dilution water (Water-Effect Ratio Procedure) and (2). the species at the site are more or less sensitive than those used in developing the natural criteria (Species Recalculation Procedure). EPA's Office of Science and Technology (OST) has developed the Interim Guidance on Determination and Use of Water-Effect Ratios for Metals <www.epa.gov/waterscience/standards/handbook/handbookappxL.pdf> in Appendix L of the WQS Handbook and the *Streamlined Water-Effect Ratio Procedure for Discharges of Copper*[2] <www.epa.gov/waterscience/criteria/copper/copper.pdf>. In addition, pages 90-97 of Appendix L provide guidance for using the Species Recalculation Procedure. States may also consider establishing aquatic life criteria based on *natural background* conditions. Further information can be found in the memo *Establishing Site Specific Aquatic Life Criteria Equal to Natural Background*[3] <www.epa.gov/waterscience/library/wqcriteria/naturalback.pdf>.

6.1.2.3 Water Quality Standard Variance

Water quality standard variances are changes to water quality standards and have similar substantive and procedural requirements as what are required to remove a designated use. Unlike use removal, variances are time-limited and do not permanently remove the current designated use of a waterbody. Variances are usually discharger- and pollutant-specific, though some states have adopted *general variances*. Where a state has adopted a general variance, the analyses necessary for the variance have been completed on a watershed-wide or statewide basis and, therefore, the process of obtaining a variance is simplified for individual dischargers in that watershed or state.

A variance might be appropriate where the state believes that the existing standards are ultimately attainable and that, by retaining the existing standards rather than changing them, the state would ensure that further progress is made in improving the water quality toward attaining the designated uses while the variance is in effect. State-adopted variances have been approved by EPA where, among other things, the state's standards allow variances and the state demonstrates that meeting the applicable criteria is not feasible on the basis of one or more of the factors outlined in § 131.10(g). A variance typically is granted for a specified period and must be reevaluated at least once every 3 years as reasonable progress is made toward meeting the standards [see section 5.3 of the WQS Handbook and § 131.20(a)].

Modifications of water quality standards could affect effluent limitations in permits in several ways. Specifically, the modifications can change the fundamental basis for WQBELs, potentially affecting an assessment of the need for WQBELs and possibly resulting in either more or less stringent WQBELs than

NMED Exhibit 70

would otherwise be required. It is the permit writer's responsibility to ensure that any EPA-approved modification of water quality standards is properly reflected in an affected NPDES permit.

6.1.3 Water Quality Standards Implementation

As previously noted, CWA section 301(b)(1)(C) requires NPDES permits to establish effluent limitations as necessary to meet water quality standards. Effluent limitations and other conditions in NPDES permits may be based on a parameter-specific approach or a WET testing approach to implementing water quality standards. A third approach to implementing water quality standards, using biocriteria or bioassessment, is not directly accomplished through NPDES permit effluent limitations but can lead to effluent limitations for specific parameters or for WET. Each of those approaches to implementing water quality standards is discussed briefly below.

What procedures should permit writers use to implement water quality standards?

The terminology used and procedures described in this manual when discussing both assessing the need for and calculating WQBELs are based on the procedures in EPA's *Technical Support Document for Water Quality-Based Toxics Control*[4] <www.epa.gov/npdes/pubs/owm0264.pdf> (hereafter *TSD*). Those procedures were developed specifically to address toxic pollutants but have been appropriately used to address a number of conventional and nonconventional pollutants as well. Permit writers should be aware that most permitting authorities have developed their own terminology and procedures for water quality-based permitting, often derived from, but with variations on, EPA's guidance. For example, EPA itself promulgated *Final Water Quality Guidance for the Great Lakes System* (60 FR 15387, March 23, 1995) with minimum water quality criteria, antidegradation policies, and implementation procedures, including permitting procedures based on the TSD. Under the CWA, Illinois, Indiana, Michigan, Minnesota, New York, Ohio, Pennsylvania, and Wisconsin were required to adopt procedures for the Great Lakes system that are consistent with that guidance. Permit writers should always consult the applicable permitting regulations, policy, and guidance for the approved water quality-based permitting procedures in their state.

6.1.3.1 Parameter-Specific Approach

The parameter-specific approach uses parameter-specific criteria for protection of aquatic life, human health, wildlife, and sediments, as well as any other parameter-specific criteria adopted into a state's water quality standards. The criteria are the basis for analyzing an effluent, deciding which parameters need controls, and deriving effluent limitations that will control those parameters to the extent necessary to achieve water quality standards in the receiving water. Parameter-specific WQBELs in NPDES permits involve a site-specific evaluation of the discharge (or proposed discharge) and its potential effect on the receiving water or an evaluation of the effects of multiple sources of a pollutant on the receiving water (e.g., through a total maximum daily load [TMDL] analysis). The parameter-specific approach allows for controlling individual parameters, (e.g., copper, BOD, total phosphorus) before a water quality impact has occurred or for helping return water quality to a level that will meet designated uses.

6.1.3.2 Whole Effluent Toxicity (WET) Approach

WET requirements in NPDES permits protect aquatic life from the aggregate toxic effect of a mixture of pollutants in the effluent. WET tests measure the degree of response of exposed aquatic test organisms to an effluent. The WET approach is useful for complex effluents where it might be infeasible to identify

NMED Exhibit 70

and regulate all toxic pollutants in the effluent or where parameter-specific effluent limitations are set, but the combined effects of multiple pollutants are suspected to be problematic. The WET approach allows a permit writer to implement numeric criteria for toxicity included in a state's water quality standards or to be protective of a narrative "no toxics in toxic amounts" criterion. Like the parameter-specific approach, the WET approach allows permitting authorities to control toxicity in effluents before toxic impacts occur or may be used to help return water quality to a level that will meet designated uses.

6.1.3.3 Bioassessment Approach

The biocriteria approach is used to assess the overall biological integrity of an aquatic community. As discussed in section 6.1.1.2 above, biocriteria are numeric values or narrative statements that describe the biological integrity of aquatic communities inhabiting waters of a given designated aquatic life use. When incorporated into state water quality standards, biocriteria and aquatic life use designations serve as direct endpoints for determining aquatic life use attainment. Once biocriteria are developed, the biological condition of a waterbody can be measured through a biological assessment, or bioassessment.

A bioassessment is an evaluation of the biological condition of a waterbody using biological surveys and other direct measurements of resident biota in surface waters. A biological survey, or biosurvey, consists of collecting, processing, and analyzing representative portions of a resident aquatic community to determine the community structure and function. The results of biosurveys can be compared to the reference waterbody to determine if the biocriteria for the designated use of the waterbody are being met. EPA issued guidance on this approach in *Biological Criteria: National Program Guidance for Surface Waters*[5] <www.epa.gov/bioindicators/html/biolcont.html>. As previously discussed, biocriteria generally are not directly implemented through NPDES permits but could be used in assessing whether a waterbody is attaining water quality standards. Nonattainment of biocriteria could lead to parameter-specific effluent limitations where the permitting authority is able to identify specific pollutant(s) and source(s) contributing to that nonattainment (see EPA's Biocriteria: Uses of Data – Identify Stressors to a Waterbody Website <www.epa.gov/waterscience/biocriteria/uses/stressors.html>) or could lead to WET limitations where the permitting authority identifies sources of toxicity to aquatic life. EPA's Biocriteria: Uses of Data - NPDES <www.epa.gov/waterscience/biocriteria/watershed/npdes.html> provides examples on the use of bioassessment information in the NPDES permitting process.

Sections 6.2–6.4 below discuss, in detail, implementing water quality standards using the parameter-specific approach to assess the need for and develop effluent limitations in NPDES permits. Section 6.5 below provides additional detail on WET requirements in NPDES permits.

6.2 Characterize the Effluent and the Receiving Water

After identifying the most current, approved, water quality standards that apply to a waterbody, a permit writer should characterize both the effluent discharged by the facility being permitted and the receiving water for that discharge. The permit writer uses the information from those characterizations to determine whether WQBELs are required (section 6.3 below) and, if so, to calculate WQBELs (section 6.4 below). Characterizing the effluent and receiving water can be divided into five steps as shown in Exhibit 6-5 and discussed in detail below.

NMED Exhibit 70

Exhibit 6-5 Steps for characterizing the effluent and receiving water

Step 1.	Identify pollutants of concern in the effluent
Step 2.	Determine whether water quality standards provide for consideration of a dilution allowance or mixing zone
Step 3.	Select an approach to model effluent and receiving water interactions
Step 4.	Identify effluent and receiving water critical conditions
Step 5.	Establish an appropriate dilution allowance or mixing zone

6.2.1 Step 1: Identify Pollutants of Concern in the Effluent

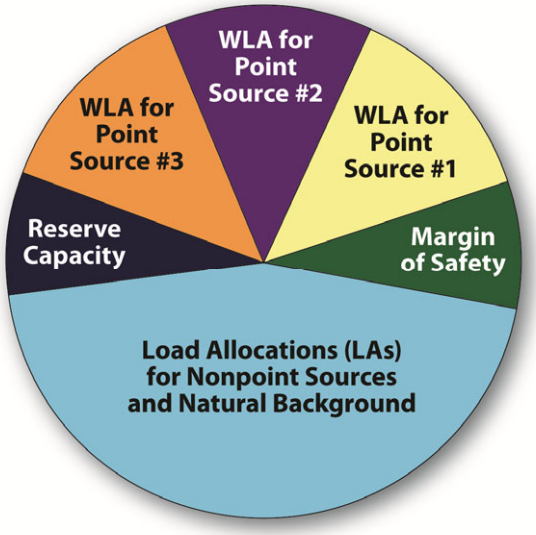
There are several sources of information for and methods of identifying pollutants of concern for WQBEL development. For some pollutants of concern, the permit writer might not need to conduct any further analysis and could, after characterizing the effluent and receiving water, proceed directly to developing WQBELs (section 6.4 below). For other pollutants of concern, the permit writer uses the information from the effluent and receiving water characterization to assess the need for WQBELs (section 6.3 below). The following subsections identify five categories of pollutants of concern for WQBEL development.

6.2.1.1 Pollutants with Applicable TBELs

One category of pollutants of concern includes those pollutants for which the permit writer has developed TBELs based on national or state technology standards or on a case-by-case basis using best professional judgment. By developing TBELs for a pollutant, the permit writer has already determined that there will be some type of final limitations for that pollutant in the permit and must then determine whether more stringent limitations than the applicable TBELs are needed to prevent an excursion above water quality standards in the receiving water (see Exhibit 6-1 above). A permit writer can determine whether the TBELs are sufficiently protective by either proceeding to calculate WQBELs as described in section 6.4 below and comparing them to the TBELs or by assuming that the maximum daily TBEL calculated is the maximum discharge concentration in the water quality assessments described in section 6.3 below.

6.2.1.2 Pollutants with a Wasteload Allocation from a TMDL

Pollutants of concern include those pollutants for which a *wasteload allocation* (WLA) has been assigned to the discharge through a TMDL. Under CWA section 303(d), states are required to develop lists of impaired waters. Impaired waters are those that do not meet the water quality standards set for them, even after point sources of pollution have installed the minimum required levels of pollution control technology. The law requires that those jurisdictions establish priority rankings for waters on their CWA section 303(d) list and develop TMDLs for those waters.



What is a WLA?

The term WLA refers to the portion of a receiving water's loading capacity that is allocated to one of its existing or future point sources of pollution [see § 130.2(h)]. The WLA could be allocated through an EPA-approved TMDL, an EPA or state watershed loading analysis, or a facility-specific water quality modeling analysis.

NMED Exhibit 70

A TMDL is a calculation of the maximum amount of a single pollutant that a waterbody can receive and still meet water quality standards and an allocation of that amount to the pollutant's sources. The portions of the TMDL assigned to point sources are WLAs, and the portions assigned to nonpoint sources and background concentrations of the pollutant are called *load allocations* (LAs). The calculation must include a margin of safety to ensure that the waterbody can be used for the purposes designated in the water quality standards, to provide for the uncertainty in predicting how well pollutant reduction will result in meeting water quality standards, and to account for seasonal variations. A TMDL might also include a reserve capacity to accommodate expanded or new discharges in the future. Exhibit 6-6 depicts the parts of a TMDL.

Exhibit 6-6 Parts of a TMDL

TMDL = ΣWLA + ΣLA + Margin of Safety + Reserve Capacity

The NPDES regulations at § 122.44(d)(1)(vii)(B) require that NPDES permits include effluent limitations developed consistent with the assumptions and requirements of any WLA that has been assigned to the discharge as part of an approved TMDL. Thus, any pollutant for which a WLA has been assigned to the permitted facility through a TMDL is a pollutant of concern.

Permit writers might also choose to consider any pollutant associated with an impairment of the receiving water a pollutant of concern, regardless of whether an approved TMDL has been developed for that pollutant, a WLA has been assigned to the permitted facility, or the permitted facility has demonstrated that the pollutant is present in its effluent. Permitting authorities might consider monitoring requirements to collect additional data related to the presence or absence of the impairing pollutant in a specific discharge to provide information for further analyses.

6.2.1.3 Pollutants Identified as Needing WQBELs in the Previous Permit

Another category of pollutants of concern includes those pollutants that were identified as needing WQBELs in the discharger's previous permit. Permit writers must determine whether the conditions leading to a decision to include WQBELs for the pollutant in the previous permit continue to apply. Where those conditions no longer apply, the permit writer would need to complete an anti-backsliding

NMED Exhibit 70

analysis to determine whether to remove the WQBELs from the reissued permit. Chapter 7 of this manual provides additional information on anti-backsliding requirements of the CWA and NPDES regulations. In addition, the permit writer might need to conduct an antidegradation analysis if the revised limitation would allow degradation of the quality of the receiving water.

6.2.1.4 Pollutants Identified as Present in the Effluent through Monitoring

Pollutants of concern also include any pollutants identified as present in the effluent through effluent monitoring. Effluent monitoring data are reported in the discharger's NPDES permit application, discharge monitoring reports and special studies. In addition, the permitting authority might collect data itself through compliance inspection monitoring or other special study. Permit writers can match information on which pollutants are present in the effluent to the applicable water quality standards to identify parameters that are candidates for WQBELs.

6.2.1.5 Pollutants Otherwise Expected to be Present in the Discharge

A final category of pollutants of concern includes those pollutants that are not in one of the other categories but are otherwise expected to be present in the discharge. There might be pollutants for which neither the discharger nor the permitting authority have monitoring data but, because of the raw materials stored or used, products or by-products of the facility operation, or available data and information on similar facilities, the permit writer has a strong basis for expecting that the pollutant could be present in the discharge. Because there are no analytical data to verify the concentrations of these pollutants in the effluent, the permit writer must either postpone a quantitative analysis of the need for WQBELs and generate, or require the discharger to generate, effluent monitoring data, or base a determination of the need for WQBELs on other information, such as the effluent characteristics of a similar discharge. A discussion on determining the need for WQBELs without effluent monitoring data is provided in section 6.3.3 below.

6.2.2 Step 2: Determine Whether Water Quality Standards Provide for Consideration of a Dilution Allowance or Mixing Zone

Many state water quality standards have general provisions allowing some consideration of mixing of effluent and receiving water when determining the need for and calculating WQBELs. Depending on the state's water quality standards and implementation policy, such a mixing consideration could be expressed in the form of a *dilution allowance* or *regulatory mixing zone*. A dilution allowance typically is expressed as the flow of a river or stream, or a portion thereof. A regulatory mixing zone generally is expressed as a limited area or volume of water in any type of waterbody where initial dilution of a discharge takes place and within which the water quality standards allow certain water quality criteria to be exceeded. Section 6.2.5 below discusses dilution allowances and mixing zones in greater detail.

State water quality standards or implementation policies might indicate specific locations or conditions (e.g., breeding grounds for aquatic species or bathing beaches) or water quality criteria (e.g., pathogens, pH, bioaccumulative pollutants, or narrative criteria) for which consideration of a dilution allowance or mixing zone is not allowed or is otherwise considered inappropriate.

NMED Exhibit 70

6.2.3 Step 3: Select an Approach to Model Effluent and Receiving Water Interactions

Where consideration of a dilution allowance or mixing zone is not permitted by the water quality standards or is not appropriate, the relevant water quality criterion must be attained at the point of discharge. In such cases, there is no need for a water quality model to characterize the interaction between the effluent and receiving water. In this situation effluent limitations are based on attaining water quality criteria at the "end of the pipe."

Where a dilution allowance or mixing zone is permitted, however, characterizing the interaction between the effluent and receiving water generally requires using a water quality model. In the majority of situations, and in all of the examples provided in this manual, permit writers will use a steady-state water quality model to assess the impact of a discharge on its receiving water. Steady-state means that the model projects the impact of the effluent on the receiving water under a single or *steady* set of design conditions. Because the model is run under a single set of conditions, those conditions generally are set at *critical conditions* for protection of receiving water quality as discussed in section 6.2.4 below. The permit writer would determine the amount of the dilution allowance or the size of the mixing zone that is available under these critical conditions as provided in section 6.2.5 below.

6.2.4 Step 4: Identify Effluent and Receiving Water Critical Conditions

Where steady-state models are used for water quality-based permitting, an important part of characterizing the effluent and receiving water is identifying the critical conditions needed as inputs to the water quality model. Permit writers should discuss selection of critical conditions with water quality modelers or other water quality specialists. Identifying the right critical conditions is important for appropriately applying a water quality model to assess the need for WQBELs and to calculate WQBELs. Some key effluent and receiving water critical conditions are summarized below.

What if I am not a water quality modeler?

Permit writers are not always water quality modelers, nor do they necessarily need to be experts in this field. Many permitting authorities have a team of water quality specialists who model point source discharges to provide data required for permit writers to assess the need for and develop WQBELs. In some cases, this team might even calculate WQBELs directly for the permit writers, who then only need to compare them to TBELs and determine the final effluent limitations for the NPDES permit. Permit writers should, at a minimum, familiarize themselves with water quality modeling concepts presented in this manual, particularly the identification of critical conditions input to a steady-state water quality model, and should consult water quality modelers or other water quality specialists as needed in the process of NPDES permit development.

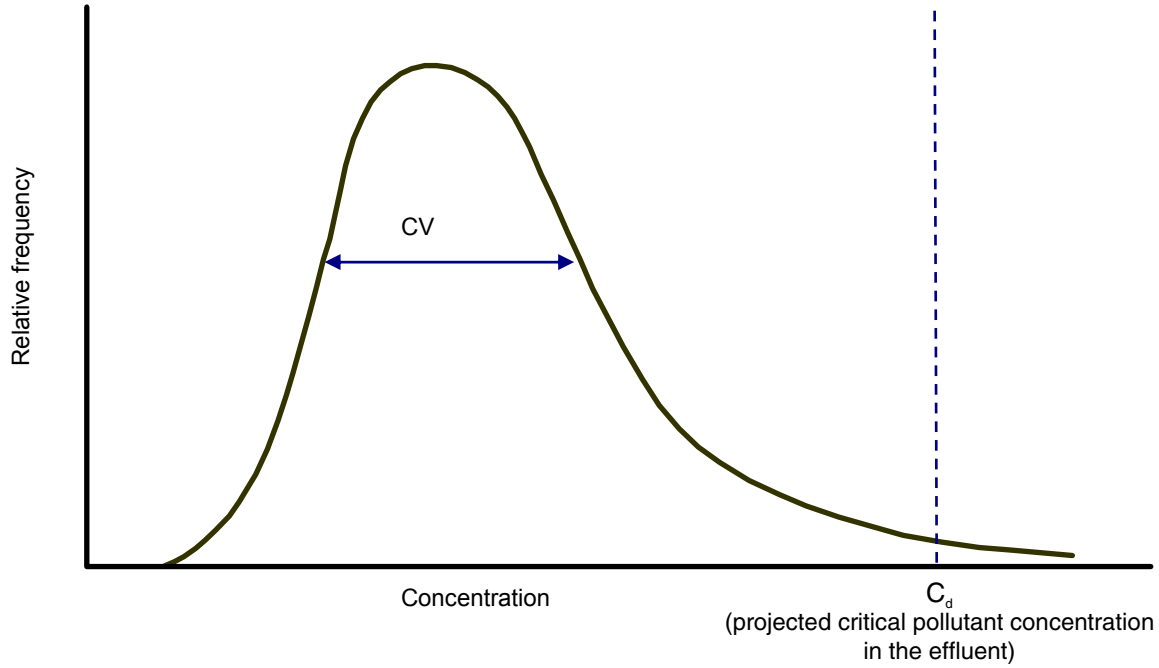
6.2.4.1 Effluent Critical Conditions

In most any steady-state water quality model there will be at least two basic critical conditions related to the effluent: flow and pollutant concentration.

NMED Exhibit 70

Effluent Flow

Effluent flow (designated Q_d in the water quality modeling equations used in this manual) is a critical design condition used when modeling the impact of an effluent discharge on its receiving water. A permit writer should be able to obtain effluent flow data from discharge monitoring reports or a permit application. Permitting authority policy or procedures might specify which flow measurement to use as the critical effluent flow value(s) in various water quality-based permitting calculations (e.g., the maximum daily flow reported on the permit application, the maximum of the monthly average flows from discharge monitoring reports for the past three years, the facility design flow). Permit writers should follow existing policy or procedures for determining critical effluent flow or, if the permitting authority does not specify how to determine this value, look at past permitting practices and strive for consistency.



Effluent Pollutant Concentration

Permit writers can determine the critical effluent concentration of the pollutant of concern (designated C_d) by gathering effluent data representative of the discharge. To establish the critical effluent pollutant concentration from the available data, EPA has recommended considering a concentration that represents something close to the maximum concentration of the pollutant that would be expected over time. In most cases, permit writers have a limited effluent data set and, therefore, would not have a high degree of certainty that the limited data would actually include the maximum potential effluent concentration of the pollutant of concern. In addition, the NPDES regulations at § 122.44(d)(1)(ii) require that permit writers consider the variability of the pollutant in the effluent when determining the need for WQBELs. To address those concerns, EPA developed guidance for permit writers on how to characterize effluent concentrations of certain types of pollutants using a limited data set and accounting for variability. This guidance is detailed in EPA's TSD.

By studying effluent data for numerous facilities, EPA determined that daily pollutant measurements of many pollutants follow a *lognormal distribution*. The TSD procedures allow permit writers to project a critical effluent concentration (e.g., the 99th or 95th percentile of a lognormal distribution of effluent concentrations) from a limited data set using statistical procedures based on the characteristics of the lognormal distribution. These procedures use the number of available effluent data points for the measured concentration of the pollutant and the coefficient of variation (or CV) of the data set, which is a measure of the variability of data around the average, to predict the critical pollutant concentration in the effluent. Exhibit 6-7 provides an example of a lognormal distribution of effluent pollutant concentrations and projection of a critical effluent pollutant concentration (C_d). For additional details regarding EPA's guidance, see Chapter 3 of the TSD. Many permitting authorities have developed procedures for estimating a critical effluent pollutant concentration that are based on or derived from those procedures. For pollutants with effluent concentrations that *do not* follow a lognormal distribution, permit writers would rely on alternative procedures developed by their permitting authority for determining the critical effluent pollutant concentration.

NMED Exhibit 70

Exhibit 6-7 Example of lognormal distribution of effluent pollutant concentrations and projection of critical concentration (C_d)

6.2.4.2 Receiving Water Critical Conditions

As with the effluent, flow (for rivers and streams) and pollutant concentration are receiving water critical conditions used in steady-state water quality models. In addition, depending on the waterbody and pollutant of concern, there could be additional receiving water characteristics that permit writers need to consider in a water quality model.

Receiving Water Upstream Flow

For rivers and streams, an important critical condition is the stream flow upstream of the discharge (designated Q_s). That critical condition generally is specified in the applicable water quality standards and reflects the duration and frequency components of the water quality criterion that is being addressed. For most pollutants and criteria, the critical flow in rivers and streams is some measure of the low flow of that river or stream; however, the critical condition could be different (for example, a high flow, where wet weather sources are a major problem). If a discharge is controlled so that it does not cause water quality criteria to be exceeded in the receiving water at the critical flow condition, the discharge controls should be protective and ensure that water quality criteria, and thus designated uses, are attained under all receiving water flow conditions.

Examples of typical critical hydrologically based low flows found in water quality standards include the 7Q10 (7-day average, once in 10 years) low flow for chronic aquatic life criteria, the 1Q10 low flow for acute aquatic life criteria, and the harmonic mean flow for human health criteria for toxic organic pollutants. The permit writer might examine stream flow data from the state or the U.S. Geological

NMED Exhibit 70

Survey to determine the critical flow at a point upstream of the discharge. The permit writer might also account for any additional sources of flow or diversions between the point where a critical low flow has been calculated and the point of discharge. EPA also has developed a biologically based flow method that directly uses the durations and frequencies specified in the water quality criteria.

Receiving Water Flow Considerations

As noted in this section, the receiving water upstream flow is an important factor in modeling the interaction between the effluent discharge and a river or stream. In most instances, state water quality standards or implementation policies establish the critical low flows that should be used in modeling this interaction. The most common source of upstream flow data for water quality modelers is historical flow gage data available through the U.S. Geological Survey. Modelers should be aware that the effects of global weather patterns could alter historical flow patterns in rivers and streams, making these historical flow records less accurate in predicting current and future critical flows. Where appropriate, water quality modelers should consider alternate approaches to establishing critical low flow conditions that account for these changes.

Receiving Water Background Pollutant Concentration

In addition to determining the critical effluent concentration of the pollutant of concern, the permit writer also should determine the critical background concentration of the pollutant of concern in the receiving water before the discharge (designated C_s) to ensure that any pollutant limitations derived are protective of the designated uses. Permitting authority policies or procedures often address how to determine that critical background concentration value for the pollutant. For example, using ambient data or working with the discharger to obtain reliable ambient data, the permit writer might use the maximum measured background pollutant concentration or, perhaps, an average of measured concentrations as the critical condition. Ambient data will provide the most reliable characterization of receiving water background pollutant concentration. EPA encourages permitting authorities to collect and use actual ambient data, where possible. Where data are not available, however, the state might have other procedures, such as establishing that without valid and representative ambient data, no dilution or mixing will be allowed (i.e., criteria end-of-pipe), or using a percentage of an applicable water quality criterion or a detection, quantitation, or other reporting level. The permit writer should consult the permitting authority's policies and procedures or, if there are no policies or procedures available, look at past permitting practices and maintain consistency with those practices when determining the critical receiving water background concentrations.

Other Receiving Water Characteristics

For waterbodies other than free-flowing rivers and streams, there might be critical environmental conditions that apply rather than flow (e.g., tidal flux, temperature). In addition, depending on the pollutant of concern, the effects of biological activity and reaction chemistry might be important in assessing the impact of a discharge on the receiving water. In such situations, additional critical receiving water conditions that might be used in a steady-state water quality model include conditions such as pH, temperature, hardness, or reaction rates, and the presence or absence of certain fish species or life stages of aquatic organisms, to name a few.

NMED Exhibit 70

Sections 6.3 and 6.4 below provide further discussion of how critical conditions are applied in a water quality model to determine the need for and calculate WQBELs.

6.2.5 Step 5: Establish an Appropriate Dilution Allowance or Mixing Zone

Following verification of whether the applicable water quality standards allow any consideration of effluent and receiving water mixing and, for a steady-state modeling approach, the critical conditions that apply to the effluent and receiving water, permit writers can determine how the effluent and the receiving water mix under critical conditions. Based on this determination, permit writers can then establish the maximum dilution allowance or mixing zone allowed by the water quality standards for each pollutant of concern.

6.2.5.1 Type of Mixing Under Critical Conditions

On the basis of requirements in the water quality standards, the dilution allowance or mixing zone used in water quality models and calculations are likely to vary depending on whether there is rapid and complete mixing or incomplete mixing of the effluent and receiving water under critical conditions. Thus, the permit writer needs to understand something about *how* the effluent and receiving water mix under critical conditions.

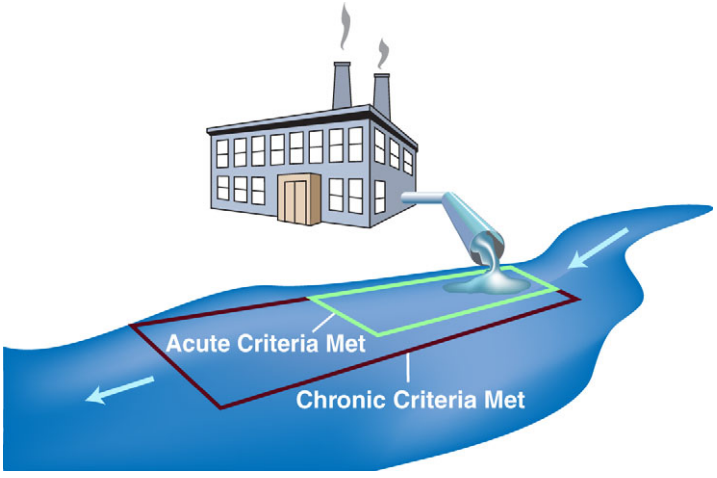
Rapid and complete mixing is mixing that occurs when the lateral variation in the concentration of a pollutant in the direct vicinity of the outfall is small. The applicable water quality standards might specify certain conditions under which a permit writer could *assume* that rapid and complete mixing is occurring, such as the presence of a diffuser. Some standards may also allow a *demonstration* of rapid and complete mixing in cases where the conditions for simply assuming rapid and complete mixing are not met. For example, the applicable water quality standards might specify a distance downstream of a discharge point by which the pollutant concentration across the stream width must vary by less than a certain percentage to assume that there is rapid and complete mixing.

If the permit writer cannot assume rapid and complete mixing and there has been no demonstration of rapid and complete mixing, the permit writer should assume that there is incomplete mixing. Under incomplete mix conditions, mixing occurs more slowly and higher concentrations of pollutants are present in-stream near the discharge as compared to rapid and complete mixing. Thus, an assumption of incomplete mixing is more conservative than an assumption of rapid and complete mixing. For waterbodies other than rivers and streams (e.g., lakes, bays, and the open ocean) the permit writer usually would assume incomplete mixing.

6.2.5.2 Maximum Dilution Allowance or Mixing Zone Size

Once a permit writer determines whether the applicable water quality standards allow consideration of some ambient dilution or mixing and determines the type of mixing taking place (rapid and complete mixing versus incomplete mixing), he or she would again consult the water quality standards to determine the maximum size of the dilution allowance or mixing zone that may be considered in water quality modeling calculations.

NMED Exhibit 70



Dilution Allowances in Rapid and Complete Mix Situations

The maximum permissible dilution allowance for rivers and streams under conditions of rapid and complete mixing should be indicated in the water quality standards or standards implementation policy. For example, some water quality standards allow a permit writer to use up to 100 percent of the critical low flow of a river or stream as a dilution allowance in water quality models and calculations when there is rapid and complete mixing. In some cases, water quality standards implement a factor of safety by permitting only a percentage of the critical low flow to be used as a dilution allowance, even when there is rapid and complete mixing under critical conditions. Water quality standards might incorporate such a factor of safety to account for any uncertainty related to other conditions in the waterbody or to ensure that some assimilative capacity is retained downstream of the discharge being permitted. Recall as well that for some pollutants (e.g., pathogens in waters designated for primary contact recreation, bioaccumulative pollutants), the water quality standards or implementing procedures might not authorize any dilution allowance, even where the effluent and receiving water mix rapidly and completely.

Dilution Allowances and Regulatory Mixing Zones in Incomplete Mix Situations

In an incomplete mixing situation, the water quality standards or implementation policies might allow some consideration of ambient dilution. Rather than permitting as much as 100 percent of the critical low flow as a dilution allowance, however, they will likely specify either a limited dilution allowance (such as a percentage of the critical low flow) or the maximum size of a regulatory mixing zone. A regulatory *mixing zone* is a limited area or volume of water where initial dilution of a discharge takes place and within which the water quality standards allow certain water quality criteria to be exceeded. While the criteria may be exceeded within the mixing zone, the use and size of the mixing zone must be limited such that the waterbody as a whole will not be impaired and such that all designated uses are maintained as discussed in section 6.2.5.3 below. Exhibit 6-8 is a diagram illustrating the concept of a regulatory mixing zone. The mixing zone often is a simple geometric shape inside of which a water quality criterion may be exceeded. The geometric shape does not characterize how mixing actually occurs. Actual mixing is described using field studies and a water quality model.

Exhibit 6-8 Regulatory mixing zones for aquatic life criteria

NMED Exhibit 70

Note that Exhibit 6-8 above illustrates two different mixing zones, one for an acute aquatic life criterion and one for a chronic aquatic life criterion. The water quality standards could specify different maximum mixing zones sizes for different pollutants, different types of criteria, and different waterbody types. Exhibit 6-9 provides examples of different maximum mixing zone sizes and dilution allowances.

Exhibit 6-9 Examples of maximum mixing zone sizes or dilution allowances under incomplete mixing conditions by waterbody type*

For rivers and streams:
- Mixing zones cannot be larger than 1/4 of the stream width and 1/4 mile downstream
- Mixing must be less than 1/2 stream width with a longitudinal limit of 5 times the stream width
- Dilution cannot be greater than 1/3 of the critical low flow

For lakes and the ocean:
- Mixing zones for lakes cannot be larger than 5% of the lake surface
- A maximum of 4:1 dilution is available for lake discharges
- A maximum of 10:1 dilution is available for ocean discharges
- The maximum size mixing zone for the ocean is a 100-foot radius from the point of discharge

* Examples were adapted from state standards and procedures and do not reflect EPA guidance or recommendations.

Permit writers should always check the applicable water quality standards to see if mixing zones are permitted and determine the maximum mixing zone size for the waterbody type, pollutant of concern, and specific criterion being considered.

6.2.5.3 Restrictions on Dilution Allowance or Mixing Zone Size

In addition to specifying the maximum dilution allowance or mixing zone size allowed under both rapid and complete mixing conditions and incomplete mixing conditions, the water quality standards or implementation policies generally include constraints that could further limit the available dilution allowance or mixing zone size to something less than the absolute maximum allowed. For example, one restriction on the size of the acute mixing zone could be that it must be small enough to ensure that the potential time of exposure of aquatic organisms to a pollutant concentration above the acute criterion is very short, and organisms passing through that acute mixing zone will not die from exposure to the pollutant. Such a restriction might lead the permitting authority to give a discharger an acute mixing zone for a specific pollutant that is smaller than the maximum size allowed by the water quality standards or to not allow any acute mixing zone at all. Other possible restrictions on dilution and mixing zone size include preventing impairment of the integrity of the waterbody as a whole and preventing significant risks to human health. For example, a permitting authority might restrict the size of a mixing zone for a human health criterion to prevent the mixing zone from overlapping a drinking water intake.

6.3 Determine the Need for WQBELs

After determining the applicable water quality standards and characterizing the effluent and receiving water, a permit writer determines whether WQBELs are needed. This section provides an overview of that process.

NMED Exhibit 70

6.3.1 Defining Reasonable Potential

EPA regulations at § 122.44(d)(1)(i) state, "Limitations must control all pollutants or pollutant parameters (either conventional, nonconventional, or toxic pollutants) which the Director determines are or may be discharged at a level that will *cause*, have the *reasonable potential to cause*, or *contribute* to an excursion above any [s]tate water quality standard, including [s]tate narrative criteria for water quality." [emphasis added] Because of that regulation, EPA and many authorized NPDES states refer to the process that a permit writer uses to determine whether a WQBEL is required in an NPDES permit as a *reasonable potential analysis*. Wording the requirements of the regulation another way, a reasonable potential analysis is used to determine whether a discharge, alone or in combination with other sources of pollutants to a waterbody and under a set of conditions arrived at by making a series of reasonable assumptions, could lead to an excursion above an applicable water quality standard. The regulation also specifies that the reasonable potential determination must apply not only to numeric criteria, but also to narrative criteria (e.g., *no toxics in toxic amounts*, *presence of pollutants or pollutant parameters in amounts that would result in nuisance algal blooms*). A permit writer can conduct a reasonable potential analysis using effluent and receiving water data and modeling techniques, as described above, or using a non-quantitative approach. Both approaches are discussed below.

6.3.2 Conducting a Reasonable Potential Analysis Using Data

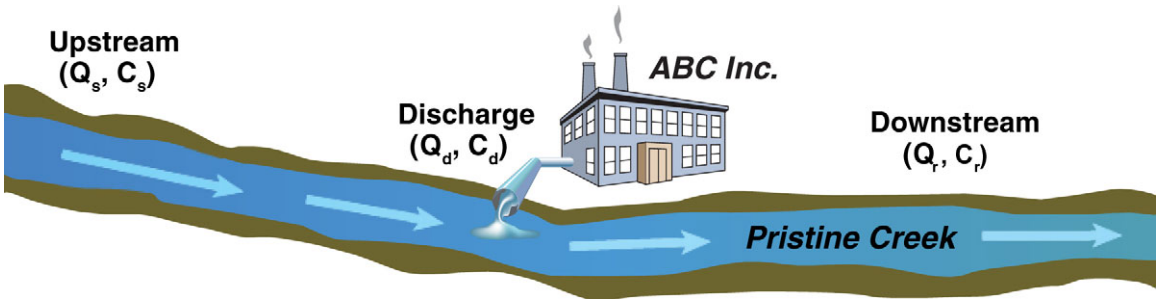
When determining the need for a WQBEL, a permit writer should use any available effluent and receiving water data as well as other information pertaining to the discharge and receiving water (e.g., type of industry, existing TBELs, compliance history, stream surveys), as the basis for a decision. The permit writer might already have data available from previous monitoring or he or she could decide to work with the permittee to generate data before permit issuance or as a condition of the new permit. EPA recommends that monitoring data be generated before effluent limitation development whenever possible. Monitoring should begin far enough in advance of permit development to allow sufficient time to conduct chemical analyses. Where data are generated as a condition of the permit (for example for a new permittee), it might be appropriate for the permit writer to include a reopener condition in the permit to allow the incorporation of a WQBEL if the monitoring data indicate that a WQBEL is required.

A reasonable potential analysis conducted with available data can be divided into four steps as shown in Exhibit 6-10 and discussed in detail below.

Exhibit 6-10 Steps of a reasonable potential analysis with available data

Step 1.	Determine the appropriate water quality model
Step 2.	Determine the expected receiving water concentration under critical conditions
Step 3.	Answer the question, "Is there reasonable potential?"
Step 4.	Document the reasonable potential determination in the fact sheet

6.3.2.1 Step 1: Determine the Appropriate Water Quality Model



Steady-state or dynamic water quality modeling techniques can be used in NPDES permitting. As discussed in section 6.2.3 above, the examples in this manual consider only steady-state modeling techniques, which consider the impact of a discharge on the receiving water modeled under a single set of critical conditions.

NMED Exhibit 70

The specific steady-state model used will depend on the pollutant or parameter of concern and whether there is rapid and complete mixing or incomplete mixing of the effluent and the receiving water under critical conditions. For example, to model dissolved oxygen in a river, the permit writer might choose the Streeter-Phelps equation. For modeling heavy metals in an incomplete mix situation, the permit writer might choose the CORMIX model. For pollutants such as BOD, nutrients, or non-conservative parameters, the effects of biological activity and reaction chemistry should be modeled, in addition to the effects of dilution, to assess possible impacts on the receiving water. This manual focuses only on dilution of a pollutant discharged to the receiving water and does not address modeling biological activity or reaction chemistry in receiving waters. For additional information, permit writers should discuss modeling that accounts for biological activity or reaction chemistry with water quality modelers or other water quality specialists as needed and consult EPA's Water Quality Models and Tools Website <www.epa.gov/waterscience/models/>.

For many pollutants such as most toxic (priority) pollutants, conservative pollutants, and pollutants that can be treated as conservative pollutants when near-field effects are of concern, if there is rapid and complete mixing in a river or stream, the permit writer could use a simple mass-balance equation to model the effluent and receiving water. The simple mass-balance equation as applied to a hypothetical facility, ABC, Inc., discharging Pollutant Z to a free-flowing stream called Pristine Creek is presented in Exhibit 6-11 below.

Exhibit 6-11 Simple mass-balance equation

Mass = **Flow** (Q) in million gallons per day (mgd) or cubic feet per second (cfs) X **Pollutant concentration** (C) in milligrams per liter (mg/L)

$$Q_sC_s + Q_dC_d = Q_rC_r$$

where

Q_s	=	stream flow in mgd or cfs above point of discharge
C_s	=	background in-stream pollutant concentration in mg/L
Q_d	=	effluent flow in mgd or cfs
C_d	=	effluent pollutant concentration in mg/L
Q_r	=	resultant in-stream flow, after discharge in mgd or cfs
C_r	=	resultant in-stream pollutant concentration in mg/L (after complete mixing occurs)

NMED Exhibit 70

6.3.2.2 Step 2: Determine the Expected Receiving Water Concentration under Critical Conditions

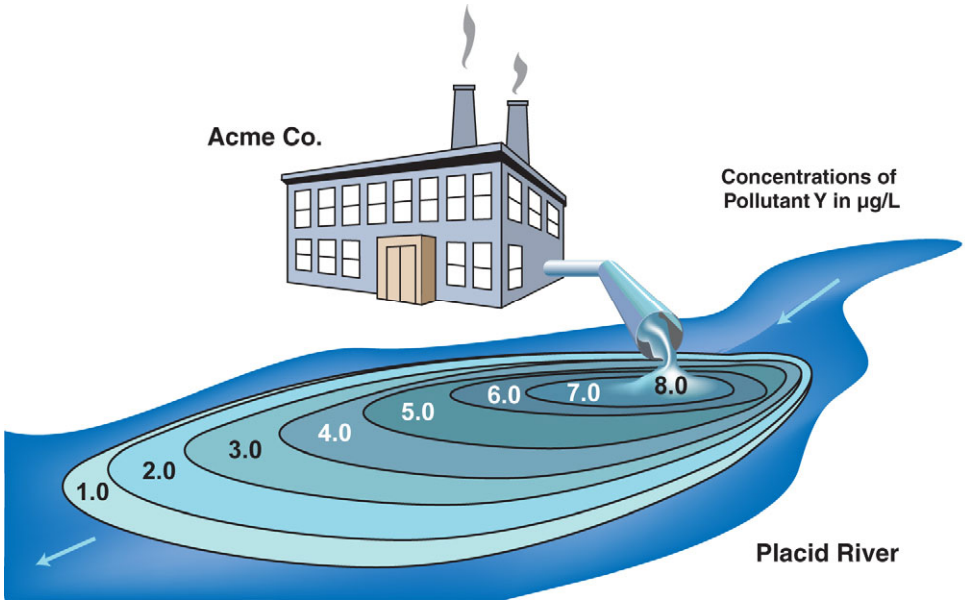
When using a steady-state model, the permit writer, or water quality modeler, determines the impact of the effluent discharge on the receiving water under critical conditions. This step examines how this steady-state analysis is conducted in situations where there is incomplete mixing and then provides a detailed discussion of this analysis for situations where there is rapid and complete mixing.

How are *critical conditions* defined?

When using a steady-state water quality model, permit writers generally input values that reflect critical conditions. State permitting procedures should guide permit writers in this task. When characterizing the effluent and receiving water for water quality-based permitting, the permit writer should follow the permitting authority's policies and procedures for selecting the critical conditions to use in a steady-state model. The discussion in section 6.2.4 above provides a discussion of how those values might be selected.

Permit writers generally would input into a steady-state model for a reasonable potential analysis the critical conditions identified in the effluent and receiving water characterization discussed in section 6.2.4 above. Recall that critical conditions include the following:

- Effluent critical conditions
  - Flow.
  - Pollutant concentration.
- Receiving water critical conditions
  - Flow (for rivers and streams).
  - Pollutant concentration.
  - Other receiving water characteristics such as tidal flux, temperature, pH, or hardness (depending on the waterbody and pollutant of concern)



As discussed in section 6.2.4.1 above, EPA and other permitting authorities have developed guidance for determining those critical conditions. Permit writers should rely on their permit authority's policies and procedures or past practices to determine values for all other critical conditions.

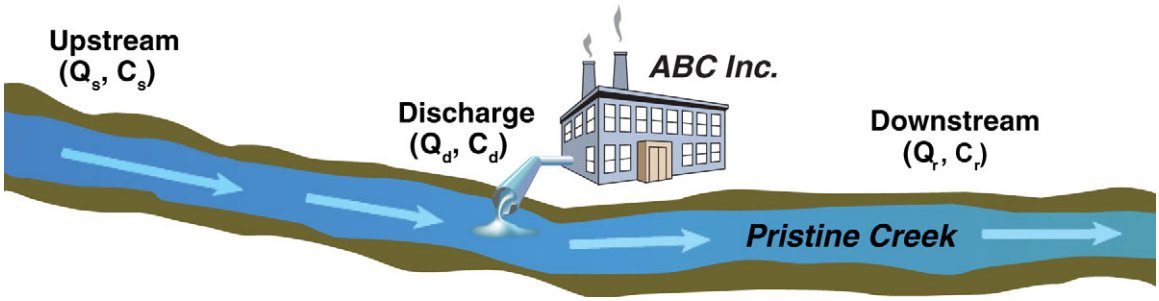
Expected Receiving Water Concentration in an Incomplete Mixing Situation

Exhibit 6-12 illustrates a situation where there is incomplete mixing of a discharge from a hypothetical facility, Acme Co., with the receiving water, the Placid River. The concentration of the pollutant of concern discharged by Acme Co. (Pollutant Y) is highest nearest the point of discharge and gradually decreases until the pollutant is completely mixed with the receiving water. To determine expected receiving water concentrations resulting from the Acme Co.'s discharge of Pollutant Y to the Placid River, the permit writer, or water quality modeler, would use the appropriate incomplete mixing model, calibrated to actual observations from field studies or dye studies, to simulate mixing under critical conditions. In Step 3 below, the concentrations of the pollutant of concern in the receiving water, as predicted by the water quality model, will be overlaid by a regulatory mixing zone established by the applicable water quality standard to determine whether WQBELs are needed.

NMED Exhibit 70

Exhibit 6-12 Example of receiving water concentrations in an incomplete mixing situation determined using an incomplete mixing water quality model

Expected Receiving Water Concentration in Rapid and Complete Mixing Situation



For many pollutants, if there is rapid and complete mixing in a river or stream, the permit writer could use the simple mass-balance equation presented in Exhibit 6-11 above to determine the expected receiving water concentration of the pollutant of concern under critical conditions. As noted previously, the simple mass-balance equation is a very basic steady-state model that can be used for most toxic pollutants, conservative pollutants, and other pollutants for which near-field effects are the primary concern. In Exhibit 6-13, that equation is applied to ABC Inc.'s, discharge of Pollutant Z (a conservative pollutant) to Pristine Creek under conditions of rapid and complete mixing. The mass-balance equation is rearranged to show how it would be used in a reasonable potential analysis.

To use the simple mass-balance equation to predict receiving water impacts for a reasonable potential analysis, the permit writer needs to input one value for each variable and solve the equation for C_r, the downstream concentration of the pollutant. Because this model, like other steady-state models, uses a single value for each variable, the permit writer should be sure that the values selected reflect critical conditions for the discharge and the receiving water. In Exhibit 6-14, those critical conditions have been identified and the equation has been solved for C_r.

It is important for permit writers to remember that, in some situations, the selected steady-state model could be more complex than the simple mass-balance equation shown. For example, there could be other pollutant sources along the stream segment; the pollutant might not be conservative (e.g., BOD); or the parameter to be modeled might be affected by multiple pollutants (e.g., dissolved oxygen affected by BOD and nutrients). For illustrative purposes, this example focuses on a situation where using a simple mass-balance equation is sufficient (i.e., rapid and complete mixing of a conservative pollutant in a river or stream under steady-state conditions).

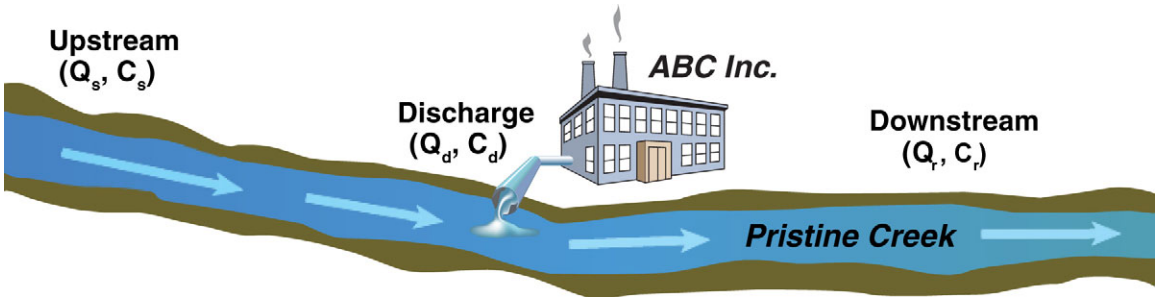
NMED Exhibit 70

Exhibit 6-13 Mass-balance equation for reasonable potential analysis for conservative pollutant under conditions of rapid and complete mixing

The mass-balance equation can be used to determine whether the discharge from ABC Inc., would cause, have the reasonable potential to cause, or contribute to an excursion above the water quality standards applicable to Pristine Creek. The equation is used to predict the concentration of Pollutant Z, a conservative pollutant, in Pristine Creek under critical conditions. The predicted concentration can be compared to the applicable water quality criteria for Pollutant Z. Assume the discharge mixes rapidly and completely with Pristine Creek.

Mass	=	**Flow** (Q) in million gallons per day (mgd) or cubic feet per second (cfs)	X	**Pollutant concentration** (C) in milligrams per liter (mg/L)

$$Q_sC_s + Q_dC_d = Q_rC_r$$



where

Q_s	=	critical stream flow in mgd or cfs above point of discharge
C_s	=	critical background in-stream pollutant concentration in mg/L
Q_d	=	critical effluent flow in mgd or cfs
C_d	=	critical effluent pollutant concentration in mg/L
Q_r	=	resultant in-stream flow, after discharge in mgd or cfs ($Q_r = Q_s + Q_d$)
C_r	=	resultant in-stream pollutant concentration in mg/L (after complete mixing occurs)

Rearrange the equation to determine the concentration of Pollutant Z in the waterbody downstream of a discharge under critical conditions:

$$C_r = \frac{(Q_d)(C_d) + (Q_s)(C_s)}{Q_r}$$

Exhibit 6-14 Example of applying mass-balance equation to conduct reasonable potential analysis for conservative pollutant under conditions of rapid and complete mixing

Mass-Balance Equation: $Q_sC_s + Q_dC_d = Q_rC_r$

Dividing both sides of the mass-balance equation by Q_r gives the following:

$$C_r = \frac{(Q_d)(C_d) + (Q_s)(C_s)}{Q_r}$$

where C_r is the receiving water concentration downstream of the discharge

The following values are known for ABC Inc. and Pristine Creek:

Q_s = critical upstream flow (water quality standards allow a dilution allowance of up to 100% of 1Q10 low flow for rapid and complete mixing)	= 1.20 cfs
C_s = critical upstream concentration of Pollutant Z in Pristine Creek	= 0.75 mg/L
Q_d = critical discharge flow	= 0.55 cfs
C_d = statistically projected critical discharge concentration of Pollutant Z	= 2.20 mg/L
Q_r = downstream flow = Q_d + Q_s	= 0.55 + 1.20 = 1.75 cfs
Acute aquatic life water quality criterion for Pollutant Z in Pristine Creek	= 1.0 mg/L

Find the projected downstream concentration (C_r) by inserting the given values into the equation as follows:

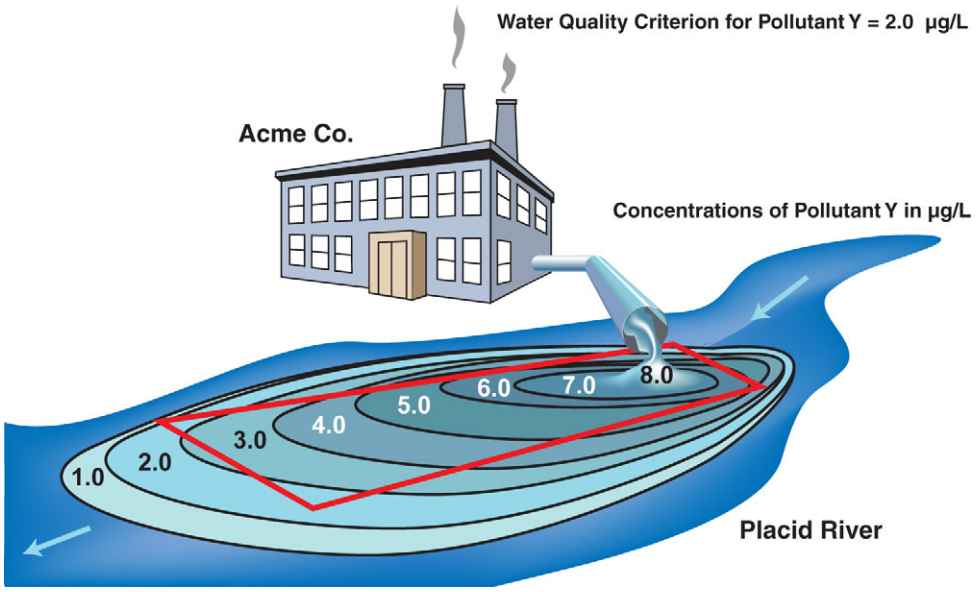
$$C_r = \frac{(0.55\,\text{cfs})(2.20\,\text{mg/L}) + (1.20\,\text{cfs})(0.75\,\text{mg/L})}{(1.75\,\text{cfs})}$$

C_r = 1.2 mg/L of Pollutant Z*

* calculated to 2 significant figures

6.3.2.3 Step 3: Answer the Question, Is There Reasonable Potential?

The next step in the reasonable potential analysis is to consider the results of water quality modeling to answer the question, *Is there reasonable potential?*



- For most pollutants, if the receiving water pollutant concentration projected by a steady-state model (e.g., a simple mass-balance equation or a more complex model) exceeds the applicable water quality criterion, there is *reasonable potential*, and the permit writer must calculate WQBELs. (Note that for dissolved oxygen, reasonable potential would occur if the water quality model indicates that the projected effluent concentration of the oxygen-demanding pollutants would result in depletion of dissolved oxygen below acceptable values in the receiving water).
- If the projected concentration is equal to or less than the applicable criterion, there is no reasonable potential and, thus far, there is no demonstrated need to calculate WQBELs.

NMED Exhibit 70

Reasonable Potential Determination in an Incomplete Mixing Situation

To determine whether there is reasonable potential in an incomplete mixing situation, the permit writer would compare the projected concentration of the pollutant of concern at the edge of the regulatory mixing zone or after accounting for the available dilution allowance, with the applicable water quality criterion. Exhibit 6-15 illustrates the reasonable potential determination for Acme Co. in a situation where the regulatory mixing zone is described by a geometric shape. In the example, the water quality criterion for Pollutant Y being considered is 2.0 micrograms per liter (µg/L). The illustration shows that at many points along the edge of the regulatory mixing zone specified by the water quality standards, which is represented by the rectangle, the concentration of Pollutant Y exceeds 2.0 µg/L. Therefore, there is reasonable potential, and the permit writer must calculate WQBELs for Pollutant Y for Acme Co.

Exhibit 6-15 Reasonable potential determination in an incomplete mixing situation

Reasonable Potential Determination in a Rapid and Complete Mixing Situation

In the rapid and complete mixing example for ABC, Inc., shown in Exhibit 6-14 above, a projected downstream concentration (C_r) of 1.2 mg/L of Pollutant Z was calculated. The permit writer would compare the calculated concentration to the acute aquatic life water quality criterion of 1.0 mg/L for Pollutant Z in Pristine Creek presented in Exhibit 6-14. Because 1.2 mg/L > 1.0 mg/L, the projected downstream concentration exceeds the water quality criterion; therefore, there is a reasonable potential for the water quality criterion to be exceeded, and the permit writer must calculate WQBELs for Pollutant Z.

A permit writer should repeat the reasonable potential analysis for all applicable criteria for the pollutant of concern and must remember that the critical conditions could differ depending on the criterion being evaluated. For example, the critical stream flow used when considering the acute aquatic life criterion might be the 1Q10 low flow, whereas the critical stream flow used when considering the chronic aquatic life criterion might be the 7Q10 low flow. If calculations demonstrate that the discharge of a pollutant of concern would cause, have the reasonable potential to cause, or contribute to an excursion of *any one* of the applicable criteria for that pollutant, the permit writer must develop WQBELs for that pollutant.

NMED Exhibit 70

In addition, it is important for permit writers to remember that they must repeat the reasonable potential analysis for each pollutant of concern and calculate WQBELs where there is reasonable potential. For each pollutant for which there is no reasonable potential, the permit writer should consider whether there are any existing WQBELs in the previous permit and whether they should be retained. The permit writer would complete an anti-backsliding analysis (see Chapter 7 of this manual) to determine whether it is possible to remove any existing WQBELs from the reissued permit.

6.3.2.4 Step 4: Document the Reasonable Potential Determination in the Fact Sheet

As a final step, permit writers need to document the details of the reasonable potential analysis in the NPDES permit fact sheet. The permit writer should clearly identify the information and procedures used to determine the need for WQBELs. The goal of that documentation is to provide the NPDES permit applicant and the public a transparent, reproducible, and defensible description of how each pollutant was evaluated, including the basis (i.e., reasonable potential analysis) for including or not including a WQBEL for any pollutant of concern.

6.3.3 Conducting a Reasonable Potential Analysis without Data

State implementation procedures might allow, or even require, a permit writer to determine reasonable potential through a qualitative assessment process without using available facility-specific effluent monitoring data or when such data are not available. For example, as noted in section 6.2.1.2 above, where there is a pollutant with a WLA from a TMDL, a permit writer must develop WQBELs or other permit requirements consistent with the assumptions of the TMDL. Even without a TMDL, a permitting authority could, at its own discretion, determine that WQBELs are needed for any pollutant associated with impairment of a waterbody. A permitting authority might also determine that WQBELs are required for specific pollutants for all facilities that exhibit certain operational or discharge characteristics (e.g., WQBELs for pathogens in all permits for POTWs discharging to contact recreational waters).

Types of information that the permit writer might find useful in a qualitative approach to determining reasonable potential include the following:

- Effluent variability information such as history of compliance problems and toxic impacts.
- Point and nonpoint source controls such as existing treatment technology, the type of industry, POTW treatment system, or BMPs in place.
- Species sensitivity data including in-stream data, adopted water quality criteria, or designated uses.
- Dilution information such as critical receiving water flows or mixing zones.

The permit writer should always provide justification for the decision to require WQBELs in the permit fact sheet or statement of basis and *must* do so where required by federal and state regulations. A thorough rationale is particularly important when the decision to include WQBELs is not based on an analysis of effluent data for the pollutant of concern.

After evaluating all available information characterizing the nature of the discharge without effluent monitoring data for the pollutant of concern, if the permit writer is not able to decide whether the discharge causes, has the reasonable potential to cause, or contributes to an excursion above a water

NMED Exhibit 70

quality criterion, he or she may determine that effluent monitoring should be required to gather additional data. The permit writer might work with the permittee to obtain data before permit issuance, if sufficient time exists, or could require the monitoring as a condition of the newly issued or reissued permit. The permit writer might also include a clause in the permit that would allow the permitting authority to reopen the permit and impose an effluent limitation if the required monitoring establishes that there is reasonable potential that the discharge will cause or contribute to an excursion above a water quality criterion.

6.4 Calculate Parameter-specific WQBELs

If a permit writer has determined that a pollutant or pollutant parameter is discharged at a level that will cause, have reasonable potential to cause, or contribute to an excursion above any state water quality standard, the permit writer must develop WQBELs for that pollutant parameter. This manual presents the approach recommended by EPA's TSD for calculating WQBELs for toxic (priority) pollutants. Many permitting authorities apply those or similar procedures to calculate WQBELs for toxic pollutants and for a number of conventional or nonconventional pollutants with effluent concentrations that tend to follow a lognormal distribution. Permit writers should consult permitting authority policies and procedures to determine the methodology specific to their authorized NPDES permitting program, including the approach for pollutants with effluent concentrations that do not follow a lognormal distribution.

6.4.1 Calculating Parameter-specific WQBELs from Aquatic Life Criteria

The TSD process for calculating WQBELs from aquatic life criteria follows five steps as shown in Exhibit 6-16 and discussed in detail below.

Exhibit 6-16 Calculating parameter-specific WQBELs from aquatic life criteria

Step 1.	Determine acute and chronic WLAs
Step 2.	Calculate long-term average (LTA) concentrations for each WLA
Step 3.	Select the lowest LTA as the performance basis for the permitted discharger
Step 4.	Calculate an average monthly limitation (AML) and a maximum daily limitation (MDL)
Step 5.	Document the calculation of WQBELs in the fact sheet.

6.4.1.1 Step 1: Determine Acute and Chronic WLAs

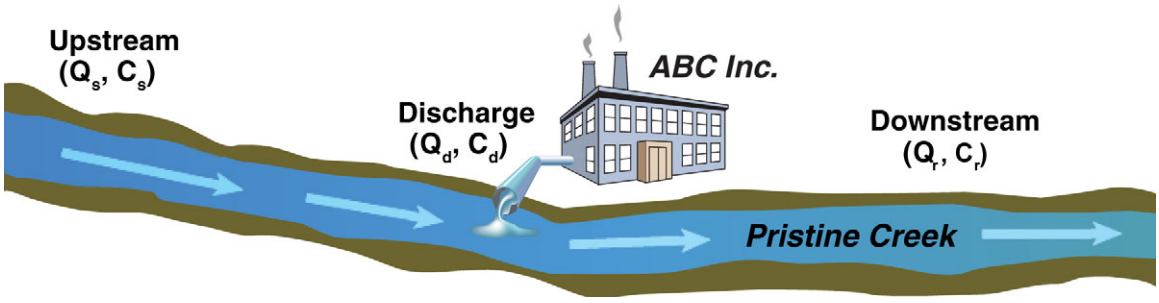
Before calculating a WQBEL, the permit writer will first need to determine the appropriate WLAs for the point source discharge based on both the acute and chronic criteria. A WLA may be determined from a TMDL or calculated for an individual point source directly. Where an EPA-approved TMDL has been developed for a particular pollutant, the WLA for a specific point source discharger is the portion of that TMDL that is allocated to that point source, as discussed in section 6.2.1.2 above. Where no TMDL is available, a water quality model generally is used to calculate a WLA for the specific point source discharger. The WLA is the loading or concentration of pollutant that the specific point source may discharge while still allowing the water quality criterion to be attained downstream of that discharge. Of course, the WLA calculation should take into account any reserve capacity, safety factor, and contributions from other point and nonpoint sources as might be required by the applicable water quality standards regulations or implementation policies.

NMED Exhibit 70

When a WLA is not given as part of a TMDL or where a separate WLA is needed to address the near-field effects of a discharge on water quality criteria, permit writers will, in many situations, use a steady-state water quality model to determine the appropriate WLA for a discharge. As discussed in section 6.3 above, steady-state models generally are run under a single set of critical conditions for protection of receiving water quality. If a permit writer uses a steady-state model with a specific set of critical conditions to assess reasonable potential, he or she generally may use the same model and critical conditions to calculate a WLA for the same discharge and pollutant of concern.

As with the reasonable potential assessment, the type of steady-state model used to determine a WLA depends on the type of mixing that occurs in the receiving water and the type of pollutant or parameter being modeled. As discussed in section 6.3.2 above, permit writers can use the mass-balance equation as a simple steady-state model for many pollutants, such as most toxic (priority) pollutants or any pollutant that can be treated as a conservative pollutant when considering near-field effects, if there is rapid and complete mixing in the receiving water. For pollutants or discharge situations that do not have those characteristics (e.g., non-conservative pollutants, concern about effects on a downstream waterbody), a water quality model other than the mass-balance equation would likely be more appropriate.

The mass-balance equation is presented again in Exhibit 6-17. In the exhibit, the equation is rearranged to show how it would be used to calculate a WLA for a conservative pollutant discharged to a river or stream under conditions of rapid and complete mixing.



6.4.1.2 Step 2: Calculate LTA Concentrations for Each WLA

The requirements of a WLA generally must be interpreted in some way to be expressed as an effluent limitation. The goal of the permit writer is to derive effluent limitations that are enforceable, adequately account for effluent variability, consider available receiving water dilution, protect against acute and chronic impacts, account for compliance monitoring sampling frequency, and assure attainment of the WLA and water quality standards. In developing WQBELs, the permit writer develops limitations that require a facility to perform in such a way that the concentration of the pollutant of concern in the effluent discharged is nearly always below the WLA.

To accomplish that goal, EPA has developed a statistical permit limitation derivation procedure to translate WLAs into effluent limitations *for pollutants with effluent concentration measurements that tend to follow a lognormal distribution*. EPA believes that this procedure, discussed in Chapter 5 of the TSD, results in defensible, enforceable, and protective WQBELs for such pollutants. In addition, a number of states have adopted procedures based on, but not identical to, EPA's guidance that also provide defensible, enforceable, and protective WQBELs. Permit writers should always use the procedures adopted by their permitting authority. In addition, permit writers should recognize that alternative procedures would be used to calculate effluent limitations for pollutants with effluent concentrations that cannot generally be described using a lognormal distribution.

NMED Exhibit 70

Exhibit 6-17 Example of applying mass-balance equation to calculate WLAs for conservative pollutant under conditions of rapid and complete mixing

Mass Balance Equation: $Q_sC_s + Q_dC_d = Q_rC_r$

where

Q_s	=	background stream flow in mgd or cfs above point of discharge
C_s	=	background in-stream pollutant concentration in mg/L
Q_d	=	effluent flow in mgd or cfs
C_d	=	effluent pollutant concentration in mg/L **= WLA**
Q_r	=	resultant in-stream flow, after discharge in mgd or cfs
C_r	=	resultant in-stream pollutant concentration in mg/L (after complete mixing occurs)

Rearrange the equation to determine the WLA (C_d) for ABC Inc., necessary to achieve the acute water quality criterion for Pollutant Z in Pristine Creek (C_r) downstream of the discharge:

$$C_d = \frac{Q_rC_r - Q_sC_s}{Q_d}$$

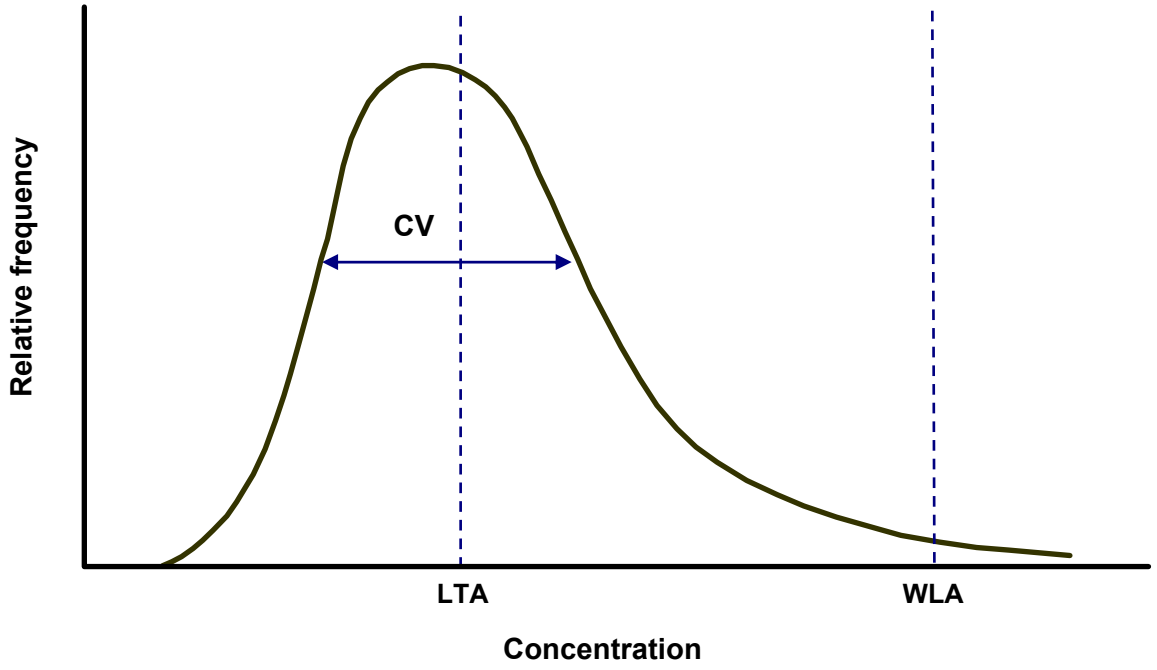
The following values are known for ABC Inc., and Pristine Creek:

Q_s = critical upstream flow (water quality standards allow a dilution allowance of up to 100% of 1Q10 low flow for rapid and complete mixing)	= 1.20 cfs
C_s = upstream concentration of Pollutant Z in Pristine Creek	= 0.75 mg/L
Q_d =discharge flow	= 0.55 cfs
Q_r = downstream flow = $Q_d + Q_s$	= 0.55 + 1.20 = 1.75 cfs
C_r = acute water quality criterion for Pollutant Z in Pristine Creek	= 1.0 mg/L

Determine the WLA for ABC Inc., by inserting the given values into the equation as follows:

$$\text{WLA for ABC Inc.} = C_d = \frac{(1.75\ \text{cfs})(1.0\ \text{mg/L}) - (1.20\ \text{cfs})(0.75\ \text{mg/L})}{(0.55\ \text{cfs})}$$

C_d = 1.5 mg/L of Pollutant Z*



* calculated to 2 significant figures

For those pollutants with effluent concentrations that do follow a lognormal distribution, the distribution can be described by determining a long-term average (or LTA) that ensures that the effluent pollutant concentration remains nearly always below the WLA and by the CV, a measure of the variability of data around the LTA. Exhibit 6-18 illustrates a lognormal distribution with the LTA, CV, and WLA highlighted.

When applying aquatic life criteria, a permit writer generally establishes a WLA based on the acute aquatic life criterion and a WLA based on the chronic aquatic life criterion. Thus, the permit writer determines two LTAs—one that would ensure that an effluent concentration is nearly always below the acute WLA and one that would ensure that an effluent concentration nearly always below the chronic WLA. Each LTA, acute and chronic, would represent a different performance expectation for the discharger.

NMED Exhibit 70

Exhibit 6-18 Example of lognormal distribution of effluent pollutant concentrations and calculation of LTA

6.4.1.3 Step 3: Select the Lowest LTA as the Performance Basis for the Permitted Discharger

EPA recommends that WQBELs be based on a single performance expectation for a facility; therefore, once a permit writer has calculated LTA values for each WLA, he or she would select only one of those LTAs to define the required performance of the facility and serve as the basis for WQBELs. Because WQBELs must assure attainment of all applicable water quality criteria, the permit writer would select the lowest LTA as the basis for calculating effluent limitations. Selecting the lowest LTA would ensure that the facility's effluent pollutant concentration remains below all the calculated WLAs nearly all the time. Further, because WLAs are calculated using critical receiving water conditions, the limiting LTA would also ensure that water quality criteria are fully protected under nearly all conditions.

6.4.1.4 Step 4: Calculate an Average Monthly Limitation (AML) and a Maximum Daily Limitation (MDL)

The NPDES regulations at § 122.45(d) require that all effluent limitations be expressed, unless impracticable, as both AMLs and MDLs for all discharges other than POTWs and as both AMLs and average weekly limitations (AWLs) for POTWs. The AML is the highest allowable value for the average of daily discharges over a calendar month. The MDL is the highest allowable daily discharge measured during a calendar day or 24-hour period representing a calendar day. The AWL is the highest allowable value for the average of daily discharges over a calendar week. For pollutants with limitations expressed in units of mass, the daily discharge is the total mass discharged over the day. For limitations expressed in other units, the daily discharge is the average measurement of the pollutant over the period of a day.

NMED Exhibit 70

In the TSD, EPA recommends establishing an MDL, rather than an AWL, for discharges of toxic pollutants from POTWs. That approach is appropriate for at least two reasons. First, the basis for the AWL for POTWs is the secondary treatment requirements discussed in section 5.1.1.1 of this manual and is not related to the need for assuring attainment of water quality standards. Second, an AWL, which could be the average of up to seven daily discharges, could average out peak toxic concentrations and, therefore, the discharge's potential for causing acute toxic effects might be missed. An MDL would be more likely to identify potential acutely toxic impacts.

Chapter 5 of the TSD includes statistical tools for calculating MDLs and AMLs from the LTA value selected in Step 3 above. Again, note that those procedures apply to *pollutants with effluent concentration measurements that tend to follow a lognormal distribution*. EPA has not developed guidance on procedures for calculating effluent limitations for pollutants with effluent concentrations that generally cannot be described using a lognormal distribution. For such pollutants, permit writers should use other procedures as recommended by their permitting authority in its policies, procedures, or guidance.

Whether using the TSD procedures or other procedures for calculating WQBELs, the objective is to establish limitations calculated to require treatment plant performance levels that, after considering acceptable effluent variability, would have a very low statistical probability of exceeding the WLA and, therefore, would comply with the applicable water quality standards under most foreseeable conditions.

6.4.1.5 Step 5: Document Calculation of WQBELs in the Fact Sheet

Permit writers should document in the NPDES permit fact sheet the process used to develop WQBELs. The permit writer should clearly identify the data and information used to determine the applicable water quality standards and how that information, or any applicable TMDL, was used to derive WQBELs and explain how the state's antidegradation policy was applied as part of the process. The information in the fact sheet should provide the NPDES permit applicant and the public a transparent, reproducible, and defensible description of how the permit writer properly derived WQBELs for the NPDES permit.

6.4.2 Calculating Chemical-specific WQBELs based on Human Health Criteria for Toxic Pollutants

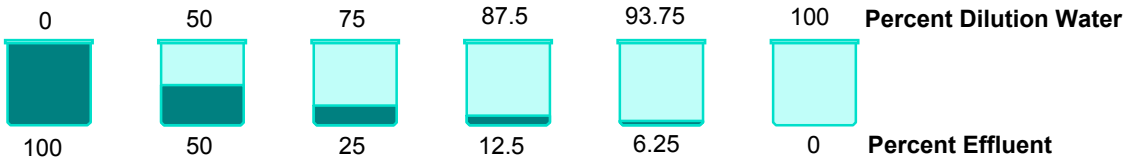
Developing WQBELs for toxic pollutants affecting human health is somewhat different from calculating WQBELs for other pollutants because (1) the exposure period of concern is generally longer (e.g., often a lifetime exposure) and (2) usually the average exposure, rather than the maximum exposure, is of concern. EPA's recommended approach for setting WQBELs for toxic pollutants for human health protection is to set the AML equal to the WLA calculated from the human health toxic pollutant criterion and calculate the MDL from the AML. Section 5.4.4 of the TSD describes statistical procedures used for such calculations for pollutants with effluent concentrations that follow a lognormal distribution. Once again, for pollutants with effluent concentrations that do not follow a lognormal distribution, permit writers should use other procedures as specified by their permitting authority.

If the permit writer calculates chemical-specific WQBELs from human health criteria, he or she should compare the limitations to any other calculated WQBELs (e.g., WQBELs based on aquatic life criteria) and TBELs and apply antidegradation and anti-backsliding requirements to determine the final limitations that meet all technology and water quality standards. As discussed above, that process should be documented in the fact sheet for the NPDES permit.

NMED Exhibit 70

6.5 Calculate Reasonable Potential and WQBELs for WET

WET tests measure the degree of response of exposed aquatic test organisms to an effluent mixed in some proportion with control water (e.g., laboratory water or a non-toxic receiving water sample). WET testing is used as a second approach, in addition to the chemical-specific approach, to implementing water quality standards in NPDES permits. This section provides a brief introduction to WET testing and WET limitations.



Test of Significant Toxicity (TST)

At the time of the writing of this guidance manual, EPA had recently published a new statistical approach that assesses the whole effluent toxicity (WET) measurement of wastewater effects on specific test organisms' ability to survive, grow, and reproduce. This new approach is called the Test of Significant Toxicity (TST) and is a statistical method that uses hypothesis testing techniques based on research and peer-reviewed publications. The hypothesis test under the TST approach examines whether an effluent, at the critical concentration (e.g., in-stream waste concentration [IWC]), and the control within a WET test differ by an unacceptable amount (the amount that would have a measured detrimental effect on the ability of aquatic organisms to thrive and survive). The TST implementation document and the TST technical document are available at the NPDES WET Website <www.epa.gov/npdes/wet>.

6.5.1 Types of WET Tests

In many WET tests, the effluent and control water are mixed in varying proportions to create a dilution series. Exhibit 6-19 is an example of a typical dilution series used in WET testing.

Exhibit 6-19 Example of typical dilution series

There are two types of WET tests: acute and chronic. An acute toxicity test usually is conducted over a short time, generally 96 hours or less, and the endpoint measured is mortality. The endpoint for an acute test is often expressed as an LC_{50} (i.e., the percent of effluent that is lethal to 50 percent of the exposed test organisms). A chronic toxicity test is usually conducted during a critical life phase of the organism and the endpoints measured are mortality and sub-lethal effects, such as changes in reproduction and growth. A chronic test can occur over a matter of hours or days, depending on the species tested and test endpoint. The endpoint of a chronic toxicity test often is expressed in one of the following ways:

- No observed effect concentration (NOEC), the highest concentration of effluent (i.e., highest percent effluent) at which no adverse effects are observed on the aquatic test organisms.
- Lowest observed effect concentration (LOEC), the lowest concentration of effluent that causes observable adverse effects in exposed test organisms.

NMED Exhibit 70

- Inhibition concentration (IC), a point estimate of the effluent concentration that would cause a given percent reduction in a biological measurement of the test organisms.
- Effect concentration (EC), a point estimate of the effluent concentration that would cause an observable adverse effect in a given percentage of test organisms.

For additional information on WET monitoring and WET test methods, see section 8.2.4 of this manual.

6.5.2 Expressing WET Limitations or Test Results

There are two options for expressing WET limitations or test results. First, WET limitations or test results can be expressed directly in terms of the WET test endpoints discussed above (e.g., LC_{50}, NOEC, and IC_{25}). Alternatively, the limitations or test results can be expressed in terms of *toxic units* (TUs). A TU is the inverse of the sample fraction, calculated as 100 divided by the percent effluent. Exhibit 6-20 presents example TUs for expressing acute and chronic test results.

Exhibit 6-20 Example of toxic units

If an **acute test** result is a LC_{50} of 60 percent, that result can be expressed as

$$\frac{100}{60} = 1.7 \text{ acute toxic units} = 1.7 \text{ TU}_a$$

If a **chronic test** result is an IC_{25} of 40 percent effluent, that result can be expressed as

$$\frac{100}{40} = 2.5 \text{ chronic toxic units} = 2.5 \text{ TU}_c$$

It is important to distinguish acute TUs (TU_a) from chronic TUs (TU_c). The difference between TU_a and TU_c can be likened to the difference between miles and kilometers. Both miles and kilometers are used to measure distance, but a distance of 1.0 mile is not the same as a distance of 1.0 kilometer. Likewise, both TU_a and TU_c are expressions of the toxicity of an effluent, but 1.0 TU_a is not the same as 1.0 TU_c. It is possible, however, to determine the relationship between the acute toxicity of an effluent and the chronic toxicity of that same effluent, just as it is possible to determine the relationship between miles and kilometers (i.e., through a conversion factor). Unlike the conversion between miles and kilometers that remains constant, the conversion factor between acute and chronic toxic units varies from effluent to effluent.

For an effluent, the permit writer could develop a conversion factor that would allow conversion of TU_a into equivalent TU_c or vice versa. This conversion factor is known as an acute-to-chronic ratio (ACR) for that effluent. The ACR for an effluent may be calculated where there are at least 10 sets of paired acute and chronic WET test data available. The ACR is determined by calculating the mean of the individual ACRs for each pair of acute and chronic WET tests. Where there are not sufficient data to calculate an ACR for an effluent (i.e., less than 10 paired sets of acute and chronic WET test data), EPA recommends a default value of ACR = 10. Exhibit 6-21 presents examples showing how the ACR converts TU_a into TU_c, how to calculate an ACR from existing data, and how, once an ACR is calculated, a permit writer could estimate the chronic toxicity of an effluent sample from its measured acute toxicity or vice versa.

NMED Exhibit 70

Exhibit 6-21 Using the ACR

The ACR is expressed

$$ACR = \frac{\text{Acute Endpoint}}{\text{Chronic Endpoint}} = \frac{LC_{50}}{IC_{25}}$$

A TU is the inverse of the sample fraction. Therefore, by definition

$$TU_a = \frac{100}{LC_{50}} \qquad TU_c == \frac{100}{IC_{25}}$$

Consequently, toxicity as percent sample, may be expressed

$$LC_{50} = \frac{100}{TU_a} \qquad IC_{25} = \frac{100}{TU_c}$$

Substituting into the original equation gives

$$ACR = \frac{LC_{50}}{IC_{25}} = \frac{\frac{100}{TU_a}}{\frac{100}{TU_c}} = \frac{TU_c}{TU_a}$$

Example 1
Given: LC_{50} = 28%, IC_{25} = 10%

$$ACR = \frac{LC_{50}}{IC_{25}} = \frac{28\%}{10\%} = 2.8$$

Example 2
Given: TU_a = 3.6, TU_c = 10.0

$$ACR = \frac{TU_c}{TU_a} = \frac{10.0}{3.6} = 2.8$$

Example 3
Given: Toxicity data for a facility's effluent for *C. dubia*. as presented in the table to the right.

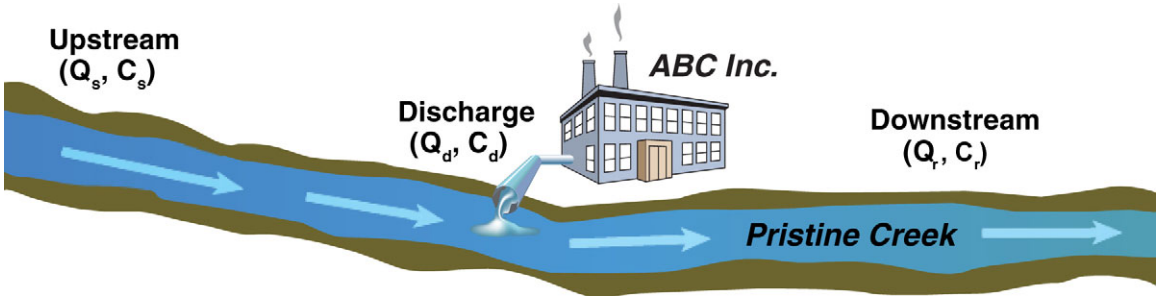
The ACR in the third column is calculated using the following equation:

$$ACR = \frac{LC_{50}}{IC_{25}}$$

LC_{50} (% effluent)	IC_{25} (% effluent)	ACR
62	10	6.2
18	10	1.8
68	25	2.7
61	10	6.1
63	25	2.5
70	25	2.8
17	5	3.4
35	10	3.5
35	10	3.5
35	25	1.4
47	10	4.7
Mean		**3.5**

Example 4
Given: TU_a = 1.8, ACR = 3.5

$$ACR = \frac{TU_c}{TU_a} \qquad TU_c = ACR \times TU_a$$



$$\text{Estimated } TU_c = ACR \times TU_a = 3.5 \frac{TU_c}{TU_a} \times 1.8\ TU_a = 6.3\ TU_c$$

6.5.3 Determining the Need for WET Limitations

If a state has numeric criteria for WET, a permit writer could use the results of WET tests to project acute or chronic toxicity in the receiving water after accounting for the applicable dilution allowance or mixing zone made available in the water quality standards. The permit writer would compare the projected toxicity of the receiving water to the applicable water quality criterion for WET. If the projected toxicity exceeds the applicable numeric water quality criterion for WET, the discharge would cause, have the reasonable potential to cause, or contribute to an excursion above the applicable water quality standards, and the permit writer must develop a WQBEL for WET [see § 122.44(d)(1)(iv)]. In that way, numeric criteria for WET can be treated similarly to chemical-specific criteria. Exhibit 6-22 provides an example of how the mass-balance equation is used to conduct a reasonable potential analysis for WET.

NMED Exhibit 70

Exhibit 6-22 Example of mass-balance equation for a WET reasonable potential analysis

The mass-balance equation can be used to determine whether the discharge from ABC Inc. would cause, have the reasonable potential to cause, or contribute to toxicity in Pristine Creek that exceeds the numeric water quality criteria for acute or chronic toxicity. Assume the discharge mixes rapidly and completely with Pristine Creek.

Mass-Balance Equation: $Q_sC_s + Q_dC_d = Q_rC_r$

Dividing both sides of the mass-balance equation by Q_r gives the following:

$$C_r = \frac{(Q_d)(C_d) + (Q_s)(C_s)}{Q_r}$$

The following values are known for ABC Inc. and Pristine Creek:

Q_s = Critical upstream flow (1Q10 for acute protection)	= 23.6 cfs
(7Q10 for chronic protection)	= 70.9 cfs
C_s = Upstream toxicity in Pristine Creek (acute)	= 0 TU_a
(chronic)	= 0 TU_c
Q_d = Discharge flow	= 7.06 cfs
C_d = Discharge toxicity (acute)	= 2.50 TU_a
(chronic)	= 8.00 TU_c
Q_r = Downstream flow	= Q_d + Q_s
Acute Water Quality Criterion in Pristine Creek	= 0.3 TU_a
Chronic Water Quality Criterion in Pristine Creek	= 1.0 TU_c

Find the downstream concentration (C_r) by inserting the given values into the equation as follows:

For acute toxicity:

$$C_r = \frac{(7.06\ \text{cfs})(2.5\ TU_a) + (23.6\ \text{cfs})(0\ TU_a)}{7.06\ \text{cfs} + 23.6\ \text{cfs}} = 0.58\ TU_a$$

The downstream concentration (C_r) exceeds the water quality criterion for acute toxicity of 0.3 TU_a.

For chronic toxicity:

$$C_r = \frac{(7.06\ \text{cfs})(8.00\ TU_c) + (70.9\ \text{cfs})(0\ TU_c)}{7.06\ \text{cfs} + 70.9\ \text{cfs}} = 0.72\ TU_c$$

The downstream concentration (C_r) does not exceed the water quality criterion for chronic toxicity of 1.0 TU_c.

In Exhibit 6-22 above, the downstream concentration under critical conditions for the acute water quality criterion (C_r = 0.58 TU_a) exceeds the water quality criterion for acute toxicity (0.3 TU_a); therefore there is reasonable potential and WET limitations are required. WET limitations would be calculated in much the same way as limitations on specific chemicals. The limitations would be calculated to ensure that WET criteria are not exceeded after any available dilution or at the edge of the applicable mixing zone.

NMED Exhibit 70

Where state water quality standards do not include numeric criteria for WET, a permit writer could evaluate the need for WQBELs for WET on the basis of narrative criteria; specifically, a narrative criterion stating that waterbodies must be free from *toxics in toxic amounts*. To make it easier for a permit writer to readily establish WET limitations in this situation, the permitting authority should have a policy for implementing the narrative criterion. Following the permitting authority's policy, if the permit writer determines that a discharge causes, has the reasonable potential to cause, or contributes to an in-stream excursion above a narrative criterion, the regulations at § 122.44(d)(1)(v) require that the permit include WQBELs for WET unless the permit writer demonstrates that parameter-specific limitations for the effluent are sufficient to attain and maintain applicable numeric and narrative water quality criteria. In other words, the permit must include WET limitations unless the permit writer is able to determine the specific pollutants that are the source of toxicity and include parameter-specific limitations for those pollutants that assure, and will continue to assure, attainment of water quality standards. If there are no criteria in the state water quality standards for the specific parameters causing the toxicity, the permit writer can establish WQBELs using one of three approaches outlined in § 122.44(d)(1)(vi):

- Use EPA's national recommended criteria.
- Calculate a numeric criterion that will attain and maintain the applicable narrative criterion.
- Control the pollutant using an indicator parameter for the pollutant of concern.

A permit also could include a requirement to conduct a toxicity identification evaluation and toxicity reduction evaluation (TIE/TRE) as a special condition in an NPDES permit. (Chapter 9 of this manual presents more information on special conditions.) A TIE/TRE is a site-specific study designed to systematically investigate and identify the causes of effluent toxicity problems, isolate the sources of that toxicity, identify and implement appropriate toxicity control options, and confirm the effectiveness of those control options and the reduction in toxicity. The permit writer might require a TIE/TRE when WET limitations are exceeded or, if there are no WET limitations in the permit, where WET testing demonstrates an unacceptable level of effluent toxicity. Because WET testing indicates the degree of toxicity of an effluent, but does not specifically identify the cause of that toxicity or ways to reduce toxicity, a TIE/TRE is necessary to achieve compliance with effluent limitations or other effluent toxicity requirements in NPDES permits. If a TIE/TRE is not required through the special conditions section of the permit, it could be required via a CWA section 308 letter, a CWA section 309 administrative order, or a consent decree.

6.6 Antidegradation Review

Early in the permit development process, a permit writer should check the state's antidegradation policy and implementation methods to determine what tier(s) of protection, if any, the state has assigned to the proposed receiving water for the parameter(s) of concern. The regulations concerning antidegradation and each of the tiers are described above in section 6.1.1.3. The tier of antidegradation protection is important for determining the required process for developing the water quality-based permit limits and conditions. In some cases, where a waterbody is classified as Tier 3 for antidegradation purposes, the permit writer might find that it is not possible to issue a permit for the proposed activity.

If the state has not specified the tier, the permit writer will need to evaluate, in accordance with the state's implementation procedures, whether the receiving waterbody is of high water quality for the parameters of concern, and thus will require Tier 2 protection. After identifying the tier(s) of protection for the

NMED Exhibit 70

proposed receiving waterbody and parameter(s) of concern, the permit writer should consult the state's antidegradation implementation procedures relevant to the tier(s).

The following sections provide methods permit writers should consider for implementing, through the WQBEL development process, the three levels of protection typically found in a state's antidegradation policy. Implementation of the state's antidegradation policy could have a significant effect on the calculation of WQBELs.

6.6.1 Tier 1 Implementation

All waterbodies receive at least Tier 1 protection. Tier 1 protection means that the permit writer must include limits in the permit sufficient to maintain and protect water quality necessary to protect existing uses. In practice, for a Tier 1 receiving waterbody, the permit writer typically calculates the WQBELs on the basis of the applicable criteria because the state's designated uses and criteria to protect those uses must be sufficient to protect the existing uses. If a Tier 1 waterbody is impaired for a parameter that would be present in the proposed discharge, the permit writer should identify and consult any relevant TMDLs to determine what quantity of pollutant (if any) is appropriate.

6.6.2 Tier 2 Implementation

For new or increased discharges that could potentially lower water quality in high-quality waters, Tier 2 protection provides the state with a framework for making decisions regarding the degree to which it will protect and maintain the high water quality. A new or expanded discharge permit application typically triggers a Tier 2 antidegradation review. Depending on the outcome of the review, the permit could be written to maintain the existing high water quality or could be written to allow some degradation.

Each state's antidegradation policy or implementation procedures should describe the Tier 2 antidegradation review process. Though the process varies among states, EPA's antidegradation regulation at § 131.12 outlines the common elements of the process. To permit a new or increased discharge that would lower water quality, the state is required to make a finding on the basis of the following:

- The state must find that allowing lower water quality is necessary for important social or economic development in the area in which the waters are located.
  - The state would perform an alternatives analysis to evaluate whether the proposed discharge is actually *necessary* (i.e., whether there are less degrading feasible alternatives) and that might include consideration of a wide range of alternatives (e.g. non-discharging options, relocation of discharge, alternative processes, and innovative treatments).
  - The state should provide a justification of important social or economic development (or both) that would occur as a result of permitting the proposed discharge.
- The state's finding must be made after full satisfaction of its own intergovernmental coordination and public participation provisions.
- The state must assure that the highest statutory and regulatory requirements for all new and existing point sources will be achieved.
- The state must assure that all cost-effective and reasonable BMPs for nonpoint source control will be achieved.

NMED Exhibit 70

- The state must assure that water quality will still protect existing uses.

If, after fulfilling the above conditions of the Tier 2 antidegradation review process, the state makes a determination to allow a new or increased discharge that would lower water quality, the permit writer may include such limitations in the NPDES permit for that discharge provided the limitations meet all other applicable technology and water quality standards.

6.6.3 Tier 3 Implementation

States identify their own ONRWs for Tier 3 protection, which requires that the water quality be maintained and protected. This is the most stringent level of protection. ONRWs often include waters in national or state parks, wildlife refuges, and waters of exceptional recreational or ecological significance. Waterbodies can be given Tier 3 protection regardless of their existing level of water quality. Some states implement Tier 3 by prohibiting any new or increased discharges to ONRWs or their tributaries that would result in lower water quality, with the exception of some limited activities such as those that would result in temporary changes in water quality ultimately resulting in restoration. Some states allow increased discharges as long as they are offset by equivalent or greater reductions elsewhere in the waterbody.

In addition to Tiers 1, 2, and 3, some states have a class of waters considered outstanding to the state and for which the state might have specific antidegradation requirements. Such waterbodies are sometimes referred to as *Tier 2 ½* waters because implementation of the antidegradation policy for them affords a greater degree of protection than Tier 2 but more flexibility than Tier 3.

Chapter 4 of EPA's WQS Handbook and the *Water Quality Standards Regulation Advance Notice of Proposed Rulemaking* (64 FR 36742, July 7, 1998) include additional information on implementing antidegradation policies. The permit writer should clearly explain the antidegradation analysis and how it affects calculation of WQBELs in the fact sheet or statement of basis for the permit.

NMED Exhibit 70

CHAPTER 7. Final Effluent Limitations and Anti-backsliding

As illustrated in Exhibit 7.1, after calculating applicable technology-based effluent limitations (TBELs) and water quality-based effluent limitations (WQBELs), the permit writer must determine the final effluent limitations that will be included in the National Pollutant Discharge Elimination System (NPDES) permit for each pollutant or pollutant parameter. For reissued permits, that determination must also include an assessment of whether the revised effluent limitations are consistent with the Clean Water Act (CWA) requirements and NPDES regulations related to anti-backsliding.

Exhibit 7-1 Developing effluent limitations

7.1 Determining Final Effluent Limitations

When determining the final effluent limitations, the permit writer must ensure that all applicable statutory and regulatory requirements, including technology and water quality standards, are fully implemented.

- The permit writer determines the calculated limitations (TBELs, WQBELs, or some combination of the calculated limitations) that will ensure that all applicable CWA standards are met.
- As noted above, for reissued permits, if any of the limitations are less stringent than limitations on the same pollutant in the previous NPDES permit, the permit writer then conducts an anti-backsliding analysis and, if necessary, revises the limitations accordingly. A detailed discussion of the anti-backsliding provisions of the CWA and the NPDES regulations is included below in Section 7.2.

NMED Exhibit 70

In addition, the permit writer should clearly explain in the fact sheet for the permit how the final limitations in the permit were determined and how those limitations meet both technology and water quality standards (including antidegradation) and, where appropriate, how an anti-backsliding analysis was applied to the final effluent limitations.

7.2 Applying Anti-backsliding Requirements

As noted in Section 7.1, after selecting the calculated effluent limitations for a pollutant that ensure that all CWA standards are met, the permit writer applies anti-backsliding requirements, as necessary, to determine the final effluent limitations. In general, the term anti-backsliding refers to statutory and regulatory provisions that prohibit the renewal, reissuance, or modification of an existing NPDES permit that contains effluent limitations, permit conditions, or standards less stringent than those established in the previous permit. There are, however, exceptions to the prohibition, and determining the applicability and circumstances of the exceptions requires familiarity with both the statutory and regulatory provisions that address anti-backsliding.

7.2.1 Anti-backsliding Statutory Provisions

Clean Water Act (CWA) section 402(o) expressly prohibits backsliding from certain existing effluent limitations. CWA section 402(o) consists of three main parts: (1) a prohibition on specific forms of backsliding, (2) exceptions to the prohibition, and (3) a *safety clause* that provides an absolute limitation on backsliding.

7.2.1.1 Statutory Prohibition Against Backsliding

First, CWA section 402(o)(1) prohibits the relaxation of effluent limitations for two situations:

- To revise an existing TBEL that was developed on a case-by-case basis using best professional judgment (BPJ) to reflect subsequently promulgated effluent limitations guidelines and standards (effluent guidelines) that would result in a less stringent effluent limitation.
- Relaxation of an effluent limitation that is based on state standards, such as water quality standards or treatment standards, unless the change is consistent with CWA section 303(d)(4). Section 303(d)(4) may be applied independently of section 402(o).

The prohibition against relaxation of effluent limitations is subject to the exceptions in CWA section 402(o)(2) and, for limitations based on state standards, the provisions of CWA section 303(d)(4). Those exceptions are outlined further in the following sections.

7.2.1.2 Exceptions for Case-by-Case TBELs

CWA section 402(o)(2) outlines specific exceptions to the general prohibition against revising an existing TBEL that was developed on a case-by-case basis using BPJ to reflect subsequently promulgated, less stringent effluent guidelines in a renewed, reissued, or modified permit. CWA section 402(o)(2) provides that relaxed limitations may be allowed where

- There have been material and substantial alternations or additions to the permitted facility that justify the relaxation.

NMED Exhibit 70

- New information (other than revised regulations, guidance, or test methods) is available that was not available at the time of permit issuance and that would have justified a less stringent effluent limitation. If the effluent limitation was based on water quality standards, any changes must result in a decrease in pollutants discharged.
- Technical mistakes or mistaken interpretations of the law were made in issuing the permit under CWA section 402(a)(1)(b).
- Good cause exists because of events beyond the permittee's control (e.g., natural disasters) and for which there is no reasonably available remedy.
- The permit has been modified under CWA sections 301(c), 301(g), 301(h), 310(i), 301(k), 301(n), or 316(a).
- The permittee has installed and properly operated and maintained required treatment facilities but still has been unable to meet the effluent limitations (relaxation may be allowed only to the treatment levels actually achieved).

7.2.1.3 Exceptions for Limitations Based on State Standards

EPA has consistently interpreted CWA section 402(o)(1) to allow relaxation of WQBELs and effluent limitations based on state standards if the relaxation is consistent with the provisions of CWA section 303(d)(4) or if one of the exceptions in CWA section 402(o)(2) is met. The two provisions constitute independent exceptions to the prohibition against relaxation of effluent limitations. If either is met, relaxation is permissible.

CWA section 303(d)(4) has two parts: paragraph (A), which applies to *nonattainment waters*, and paragraph (B), which applies to *attainment waters*.

- **Nonattainment water:** CWA section 303(d)(4)(A) allows the establishment of a less stringent effluent limitation when the receiving water has been identified as not meeting applicable water quality standards (i.e., a *nonattainment water*) if the permittee meets two conditions. First, the existing effluent limitation must have been based on a total maximum daily load (TMDL) or other wasteload allocation (WLA) established under CWA section 303. Second, relaxation of the effluent limitation is only allowed if attainment of water quality standards will be ensured or the designated use not being attained is removed in accordance with the water quality standards regulations. This subsection does not provide an exception for establishing less stringent limitations where the original limitation was based on state permitting standards (e.g., state treatment standards) and was not based on a TMDL or WLA.
- **Attainment water:** CWA section 303(d)(4)(B) applies to waters where the water quality equals or exceeds levels necessary to protect the designated use, or to otherwise meet applicable water quality standards (i.e., an *attainment water*). Under CWA section 303(d)(4)(B), a limitation based on a TMDL, WLA, other water quality standard, or any other permitting standard may only be relaxed where the action is consistent with state's antidegradation policy.

Although the statute also identifies six exceptions in section 402(o)(2) where effluent limitations otherwise subject to the prohibition in section 402(o)(1) may be relaxed, the exceptions for technical mistakes or mistaken interpretations and permit modification, which are described above, would not apply to WQBELs.

NMED Exhibit 70

7.2.1.4 Exception Safety Clause

CWA section 402(o)(3) is a *safety clause* that provides an absolute limitation on backsliding. This section of the CWA prohibits the relaxation of effluent limitations in all cases if the revised effluent limitation would result in a violation of applicable effluent guidelines or water quality standards, including antidegradation requirements. Thus, even if one or more of the backsliding exceptions outlined in the statute is applicable and met, CWA section 402(o)(3) acts as a floor and restricts the extent to which effluent limitations may be relaxed. The requirement affirms existing provisions of the CWA that require effluent limitations, standards, and conditions to ensure compliance with applicable technology and water quality standards.

7.2.2 Anti-backsliding Regulatory Provisions

Anti-backsliding regulations are found at Title 40 of the *Code of Federal Regulations* (CFR) 122.44(l). The regulations do not specifically address backsliding where a permittee seeks relaxation of an effluent limitation that is based on a state treatment standard or water quality standard [i.e., based on CWA section 301(b)(1)(C), 303(d) or 303(e)]. They do, however, address all other forms of backsliding.

First, the regulations at § 122.44(l)(1) restrict the relaxation of *final effluent limitations* and the relaxation of *standards or conditions* contained in existing permits. Thus, this regulation, in effect, addresses all types of backsliding not addressed in the CWA provisions (e.g., backsliding from limitations derived from effluent guidelines, from new source performance standards, from existing case-by-case limitations to new case-by-case limitations, and from conditions such as monitoring requirements that are not effluent limitations). Under the regulation, a permittee must meet one of the causes for modification under § 122.62 for the reissued permit to allow relaxation of such limitations, standards, or conditions.

Second, the regulations at § 122.44(l)(2)(i) directly reflect the specific prohibition imposed by CWA section 402(o) on backsliding where a permittee seeks to revise an existing case-by-case TBEL developed using BPJ to reflect a subsequently promulgated effluent guideline that is less stringent than the case-by-case requirement. The regulations include the same exceptions to this prohibition that are in CWA section 402(o)(2) and the same *safety clause* in CWA section 402(o)(3).

Thus, if the permit condition being considered for relaxation is either a case-by-case effluent limitation developed using BPJ or is any other limitation, standard, or condition other than an effluent limitation based on a state standard, the permit writer can apply the requirements in § 122.44(l). For effluent limitations based on state standards, the permit writer should apply the provisions of CWA sections 402(o) and 303(d)(4) directly. Exhibit 7-2 illustrates the process of applying the statutory and regulatory provisions addressing anti-backsliding.

NMED Exhibit 70

Exhibit 7-2 Application of anti-backsliding requirements

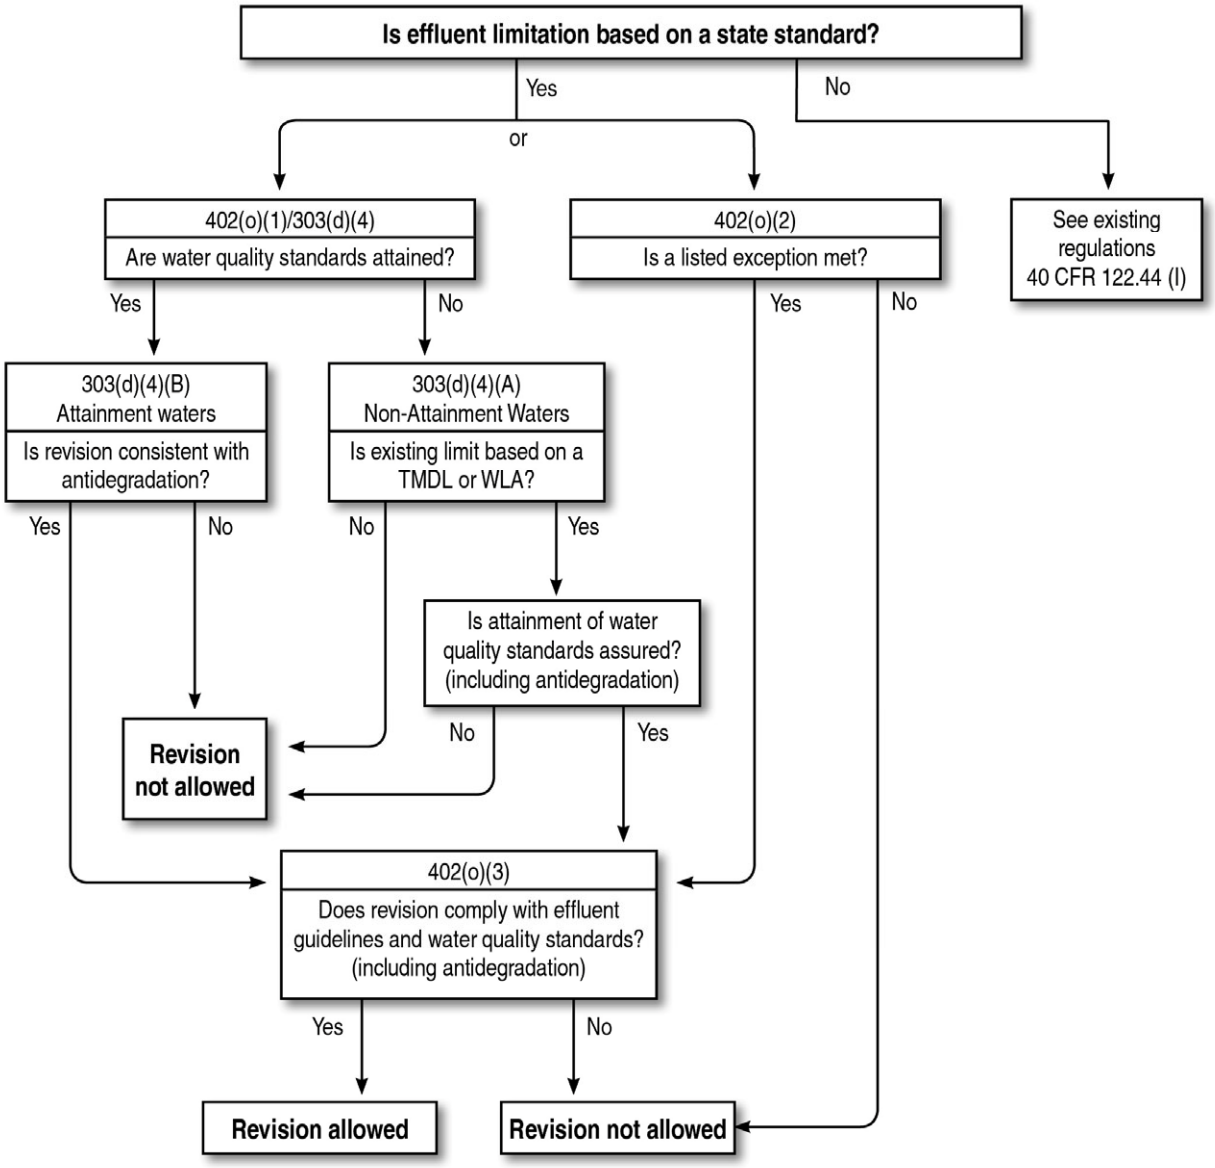

Exhibit 7-3 presents some examples of situations when backsliding might be a factor in effluent limitation development.

NMED Exhibit 70

Exhibit 7-3 Backsliding examples

Example 1

- A publicly owned treatment works (POTW) seeks to relax its WQBEL for Pollutant X
- The current effluent limitation for Pollutant X is based on a TMDL and WLA for the POTW developed in accordance with § 130.7.
- The POTW is in compliance with its existing effluent limitation, and the applicable water quality standards for Pollutant X are attained.
- The POTW has developed new models with new river flow information. The models indicate that the water quality standards for Pollutant X would be maintained with a relaxed permit limitation.

Question:
May the effluent limitation for Pollutant X be relaxed?

Answer:
Possibly. Under the interpretation discussed above, WQBELs may be relaxed where one of the exceptions in CWA sections 402(o)(1) or (2) are met. In this case, although the new information from the models might meet the exception requirements criteria under CWA section 402(o)(2)(B)(i), CWA section 402(o)(2) will not justify the request unless the state reduces the pollutant loadings from other point sources or nonpoint sources of pollution. That is because, as discussed in Section 7.1 above, CWA section 402(o)(2) restricts the use of new information to cases where there is a decrease in the amount of pollutants being discharged.

The CWA section 402(o)(1) exceptions, on the other hand, might justify the request. In this case, the reference to CWA section 303(d)(4)(B) in CWA section 402(o)(1) is the relevant exception. CWA section 303(d)(4)(B) provides that, for receiving waters that meet water quality standards, permit limitations based on a TMDL or other WLA or other permit standard may be relaxed if the state's antidegradation policy requirements are met.

Example 2

- The state has established a technology-based treatment standard for fecal coliform pursuant to CWA section 301(b)(1)(C).
- The state later relaxes the standard in a revised regulation.
- A POTW, which has been in violation of its effluent limitation for fecal coliform based on the old standard, requests a revision of the limitation to reflect the new standard.
- Water quality standards for fecal coliform are not being attained.
- There was no TMDL or WLA developed. The basis of the effluent limitation was a state technology-based treatment standard.

Question:
May the fecal coliform effluent limitation be relaxed?

Answer:
No. Under CWA section 402(o)(1), the applicable provision is CWA section 303(d)(4)(A). This subsection does not authorize backsliding in this case (i.e., nonattainment waters) because it applies only to permit limitations based on a TMDL or other WLA. Here, the limitation in question is based on a state technology-based treatment standard.

Furthermore, if the permit sought to apply the exceptions in CWA section 402(o)(2), the new information provision would not allow the revision. For purposes of this section of the CWA, new information does not include *revised regulations*.

NMED Exhibit 70

Exhibit 7-3 Backsliding examples (continued)

Example 3

- The state has a narrative water quality criterion of *no toxics in toxic amounts*.
- On the basis of WET testing data or other information, the state found that the discharge would cause, have the reasonable potential to cause, or contribute to an excursion of the water quality standards in the receiving water—specifically the narrative water quality criterion.
- The permitting authority imposed a WET limitation under § 122.44(d)(1)(v).
- The permittee determines that Pollutant Z is the cause of WET measured in its discharge.
- The permittee can demonstrate through sufficient data (including WET testing data) that an effluent limitation for Pollutant Z will assure compliance with the narrative water quality criterion as well as the state's numeric criteria for Pollutant Z, as required by § 122.44(d)(1)(v).

Question:
May the state modify the permit to delete the WET limitation and to add the effluent limitation for Pollutant Z?

Answer:
Possibly. CWA section 303(d)(4) might justify the action. The applicable provision is CWA section 303(d)(4)(B) because the narrative water quality criterion is currently attained. The permittee is complying with the existing WET limitation to attain and maintain the criterion. Under CWA section 303(d)(4)(B), the existing effluent limitation may be relaxed as long as antidegradation requirements are met and the relaxed limitation will not cause a violation of any effluent guidelines or water quality standards applicable to the discharge. In this case, it appears likely that a relaxation would be permissible because the permittee can demonstrate that the new limitation for Pollutant Z will assure compliance with both the narrative and numeric water quality criteria; however, the permit writer might consider continuing WET monitoring to identify other potential sources of toxicity in the future.

Example 4

- An industrial permittee seeks to revise its WQBEL of 60 mg/L for total suspended solids (TSS) to 100 mg/L, which is its actual discharge level.
- The current effluent limitation is based on a WLA from a TMDL developed in accordance with § 130.7.
- The water quality standards are not being attained. The ambient concentration of TSS exceeds the applicable water quality criteria.
- An effluent limitation of 100 mg/L is consistent with applicable effluent guidelines.
- New modeling information shows that the water quality standards will be attained with an effluent limitation of 75 mg/L TSS.

Question:
May the effluent limitation for TSS be revised from 60 mg/L to 100 mg/L?

Answer:
No; however, the effluent limitation could be relaxed to 75 mg/L under either CWA sections 402(o)(1) or (2) exceptions.

The water quality standards are not being attained because of TSS. Therefore, under CWA section 402(o)(1), the applicable exception is CWA section 303(d)(4)(A). In this case, the permitting authority may allow backsliding to 75 mg/L because the existing effluent limitation is based on a WLA from a TMDL, and the data show that attainment of the water quality standards is assured with an effluent limitation of 75 mg/L (but not with a limitation of 100 mg/L).

NMED Exhibit 70

CHAPTER 8. Monitoring and Reporting Conditions

This chapter describes the monitoring and reporting conditions that a permit writer establishes in a National Pollutant Discharge Elimination System (NPDES) permit. The monitoring and reporting conditions require the permittee to conduct routine or episodic self-monitoring of permitted discharges and internal operations (where applicable) and report the analytical results to the permitting authority with the information necessary to evaluate discharge characteristics and compliance status. Periodic monitoring and reporting establish an ongoing record of the permittee's compliance status and, where violations are detected, create a basis for any necessary enforcement actions.

The monitoring and reporting conditions section of an NPDES permit generally includes specific requirements for the following items:

- Monitoring locations.
- Monitoring frequencies.
- Sample collection methods.
- Analytical methods.
- Reporting and recordkeeping requirements.

The following sections provide an overview of the considerations involved in determining appropriate monitoring, reporting, and recordkeeping requirements, and how to properly incorporate the appropriate requirements in an NPDES permit.

8.1 Establishing Monitoring Conditions

The NPDES regulations require facilities discharging pollutants to waters of the United States to periodically evaluate compliance with the effluent limitations established in their permits and provide the results to the permitting authority. A permit writer should consider several factors when determining the specific requirements to be included in the NPDES permit. Inappropriate or incomplete monitoring requirements can lead to inaccurate compliance determinations. Factors that could affect sampling location, sampling method, and sampling frequency include the following:

- Applicability of effluent limitations guidelines and standards (effluent guidelines).
- Wastestream and process variability.
- Access to sample locations.
- Pollutants discharged.
- Effluent limitations.
- Discharge frequencies (e.g., continuous versus intermittent).
- Effect of flow or pollutant load or both on the receiving water.
- Characteristics of the pollutants discharged.
- Permittee's compliance history.

NMED Exhibit 70

8.1.1 Purposes of Monitoring

Monitoring is performed to determine compliance with effluent limitations established in NPDES permits, establish a basis for enforcement actions, assess treatment efficiency, characterize effluents and characterize receiving water.

Regulations requiring the establishment of monitoring and reporting conditions in NPDES permits are at Title 40 of the *Code of Federal Regulations* (CFR) 122.44(i) and 122.48. Regulations at § 122.44(i) require permittees to monitor pollutant mass (or other applicable unit of measure) and effluent volume and to provide other measurements (as appropriate) using the test methods established at Part 136. That subpart also establishes that NPDES permits (with certain specific exceptions as discussed in section 8.1.3 below) must require permittees to monitor for all limited pollutants and report data at least once per year.

Regulations at § 122.48 stipulate that all permits must specify requirements concerning the proper use, maintenance, and installation of monitoring equipment or methods (including biological monitoring methods when appropriate). NPDES permits must also specify the monitoring type, intervals, and frequency sufficient to yield data that are representative of the activity. The following sections focus on developing permit monitoring conditions that properly address these regulatory requirements.

8.1.2 Monitoring Location

The permit writer should specify the appropriate monitoring location in an NPDES permit to ensure compliance with the permit limitations and provide the necessary data to determine the effects of an effluent on the receiving water. The NPDES regulations do not prescribe exact monitoring locations; rather, the permit writer is responsible for determining the most appropriate monitoring location(s) and indicating the location(s) in the permit. Ultimately, the permittee is responsible for providing a safe and accessible sampling point that is representative of the discharge [§ 122.41(j)(1)].

The permit writer should consider the following questions when selecting a monitoring location:

- Is the monitoring location on the facility's property?
- Is the monitoring location accessible to the permittee and the permitting authority?
- Will the results be representative of the targeted wastestream?
- Is monitoring at internal points needed?

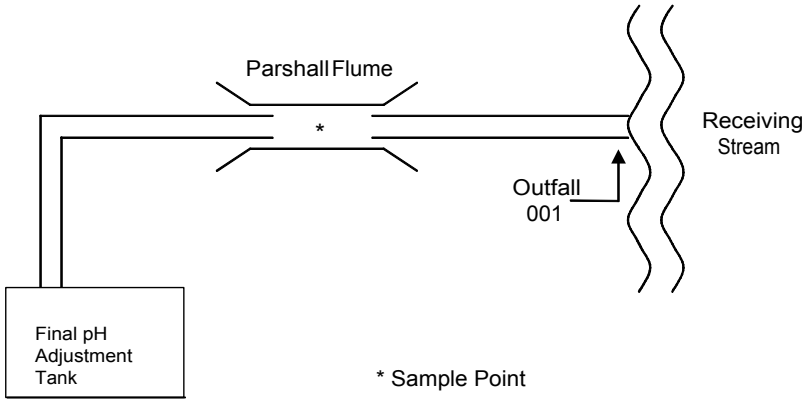
Permit writers should establish monitoring locations where the wastewater is well mixed, such as near a Parshall flume or at a location in a sewer with hydraulic turbulence. Weirs tend to enhance the settling of solids immediately upstream and the accumulation of floating oil or grease immediately downstream. Such locations should be avoided for sampling.

The permit writer can specify monitoring locations with either a narrative description or a diagram of the permittee's facility. Exhibit 8-1 provides examples of how to specify monitoring locations in a permit either by narrative or by diagram.

NMED Exhibit 70

Exhibit 8-1 Examples of specifying monitoring locations in permits

Narrative



A. Monitoring Locations

1. Discharge from the Chemistry-Fine Arts Building must be sampled at the Parshall flume before the discharge point for Outfall 001.
2. Discharge from the Physics Building must be sampled at the Parshall flume before the discharge point for Outfall 002.
3. Discharge from the Research Lab No. 1 must be sampled at the Parshall flume before the discharge point for Outfall 003.

Diagram

A. Monitoring Locations

Outfall	Description
001	Discharge Pipe: Discharge of wastewater generated by all regulated metal finishing processes at the facility. Samples must be collected at the point indicated on the diagram below.

The monitoring location will vary depending on the type of monitoring required. The following sections discuss monitoring location considerations for each monitoring type.

8.1.2.1 Influent and source water monitoring locations

Influent monitoring is monitoring of a wastestream before that wastestream receives treatment. The permit writer should require influent monitoring when a characterization of the influent is needed to determine compliance with a permit condition, such as the 5-day biochemical oxygen demand (BOD_5) and total suspended solids (TSS) percent removal limitations required by the secondary treatment standards for publicly owned treatment works (POTWs).

Source water monitoring is the monitoring of source water before use as process water (e.g., river water used as contact cooling water). The permit writer should require source water monitoring if intake credits are established as specified in § 122.45(g).

Influent and source water monitoring locations should ensure a representative sample of raw intake water before any processes or treatment that could alter the properties of the intake water.

NMED Exhibit 70

8.1.2.2 Internal monitoring locations

Internal monitoring is the monitoring of wastestreams at a location within the facility before discharge to waters of the United States. The NPDES regulations at § 122.45(h) allow internal monitoring points to be established when needed to determine compliance with a standard and in cases where setting an external monitoring location is not feasible. The permit writer may require internal monitoring to determine compliance with technology-based effluent limitations (TBELs) for a wastestream before commingling with other process or non-process wastestreams. Internal monitoring is generally not appropriate for determining compliance with water quality-based effluent limitations (WQBELs) unless final effluent monitoring is impractical (e.g., the final discharge point is submerged or inaccessible).

Examples of reasons for requiring designation of internal monitoring locations include the following:

- **Ensuring compliance with effluent guidelines (at non-POTW facilities):** When non-process wastewaters dilute process wastewaters subject to effluent guidelines, monitoring the combined discharge might not accurately allow determination of whether the facility is complying with the effluent guidelines. Under such circumstances, the permit writer might consider requiring monitoring for compliance with TBELs before the process wastewater is combined with non-process wastewater.
- **Ensuring compliance with secondary treatment standards (for POTWs only):** Some POTWs include treatment processes that do not address pollutants regulated by secondary treatment standards and that could interfere with the ability to accurately monitor for compliance with secondary treatment standards. Under such circumstances, the permit writer could consider requiring monitoring for compliance with limitations derived from secondary treatment standards before such processes. For example, the permit could require effluent monitoring for compliance with limitations derived from secondary treatment standards after secondary clarification but before disinfection.
- **Allowing detection of a pollutant:** Instances could arise where the combination of process and non-process wastewaters result in dilution of a pollutant of concern such that it would not be detectable using approved analytical methods. Internal monitoring would enable characterization of the pollutant before dilution with other wastewaters.

Where the permit writer determines that internal monitoring is necessary, § 122.45(h)(2) states that limitations on internal wastestreams may be imposed only where the permit fact sheet sets forth the exceptional circumstances requiring application of limitations at those locations.

8.1.2.3 Effluent monitoring locations

Effluent monitoring is monitoring of the final effluent after all treatment processes. The permit writer should require effluent monitoring to determine compliance with final effluent limitations established in the permit. Effluent monitoring also can be used to provide data to assess the possible impact of the discharge on the receiving water.

Effluent monitoring locations should provide a representative sample of the effluent being discharged into the receiving water. Effluent monitoring locations should be established after all industrial uses and treatment processes. Most importantly, the point where a final effluent limitation applies and the point

NMED Exhibit 70

where monitoring is required must be the same. A logical effluent monitoring point is just before discharge to the receiving water. This is particularly true for ensuring compliance with WQBELs.

8.1.3 Monitoring Frequency

The permit writer should establish monitoring frequencies sufficient to characterize the effluent quality and to detect events of noncompliance, considering the need for data and, as appropriate, the potential cost to the permittee. Monitoring frequency should be determined on a case-by-case basis, and decisions for setting monitoring frequency should be described in the fact sheet. Some states have their own monitoring guidelines that can help a permit writer determine an appropriate monitoring frequency.

To establish a monitoring frequency, the permit writer should consider the variability of the concentration of various parameters by reviewing effluent data for the facility (e.g., from discharge monitoring reports [DMRs]) or, without actual data, information from similar dischargers. A highly variable discharge should require more frequent monitoring than a discharge that is relatively consistent over time (particularly in terms of flow and pollutant concentration). Other factors that should be considered when establishing appropriate monitoring frequencies include the following:

- **Design capacity of the treatment facility.** The monitoring frequency might need to be increased at facilities where the treatment facility is nearing design capacity. For example, at equivalent average flow rates, a large lagoon system that is not susceptible to bypasses would require less frequent monitoring than an overloaded treatment facility that experiences fluctuating flow rates from infiltration or large batch discharges from an industrial user system. The lagoon should have a relatively low variability compared to the facility receiving batch discharges.
- **Treatment method used.** The monitoring frequency will be similar for similar treatment processes. The type of wastewater treatment used by the facility might affect the frequency of effluent monitoring. An industrial facility employing biological treatment would have a similar monitoring frequency as a secondary treatment plant with the same units used for wastewater treatment. If the treatment method is appropriate and achieving high pollutant removals on a consistent basis, monitoring could be less frequent than for a plant with little or insufficient treatment.
- **Compliance history.** The monitoring frequency might need to be adjusted to reflect the compliance history of the facility. A facility with problems achieving compliance generally should be required to perform more frequent monitoring to characterize the source or cause of the problems or to detect noncompliance.
- **Cost of monitoring relative to permittee's capabilities.** The monitoring frequency should not be excessive and should be what is necessary to provide sufficient information about the discharge.
- **Location of the discharge.** The monitoring frequency could be increased if the discharge is to sensitive waters or is near a public water supply.
- **Nature of the pollutants.** To accurately characterize the discharge, the monitoring frequency might be increased for wastewaters with highly toxic pollutants or where the nature of the pollutants varies.

NMED Exhibit 70

- **Frequency of the discharge.** The monitoring frequency for a wastewater discharged in batches infrequently should differ from that for a continuous discharge of highly concentrated wastewater or a wastewater containing a pollutant that is found infrequently and at very low concentrations. The production schedule of the facility (e.g., seasonal, daily), the plant washdown schedule, and other similar factors should be considered.
- **Number of monthly samples used in developing effluent limitations.** When establishing monitoring frequency, the permit writer should consider the number of monthly samples used in developing average monthly WQBELs. If the discharger monitors less frequently than the monthly monitoring frequency assumed when developing applicable effluent guidelines or in calculating a WQBEL, it could be more difficult for the discharger to comply with its average monthly effluent limitations. For example, if an average monthly limitation is established assuming a monitoring frequency of four times per month (i.e., the limit is the expected average of four samples taken during a month), a discharger taking only one sample per month would statistically have a greater chance of exceeding its average monthly limit than if it sampled at least four times per month.
- **Tiered limitations.** The monitoring frequency requirements should correspond to the applicable tiers in cases where the permit writer has included tiered limitations. If a facility has seasonal discharge limitations, it might be appropriate to increase the monitoring frequency during the higher production season, and reduce the frequency during the off-season.
- **Other Considerations.** To ensure representative monitoring, permit conditions could be included to require monitoring on the same day, week, or month for parameters that might be correlated in some way. For example, coordinating the monitoring requirements for parameters such as pathogens and chlorine or metals and pH can provide information for both compliance assessment and determination of treatment efficacy.

A permit writer could also establish a tiered monitoring schedule that reduces or increases the monitoring frequency during a permit cycle. Tiered monitoring might be appropriate for discharges where the initial sampling shows compliance with effluent limitations, justifying a reduction in monitoring frequency over time. Conversely, if problems are found during the initial sampling, more frequent sampling and more comprehensive monitoring can be applied. This step-wise approach could lead to lower monitoring costs for permittees while still providing the data needed to demonstrate compliance with effluent limitations.

In 1996 EPA issued *Interim Guidance for Performance-Based Reductions of NPDES Permit Monitoring Frequencies* <www.epa.gov/npdes/pubs/perf-red.pdf>. Under the guidance, NPDES reporting and monitoring requirements may be reduced on the basis of a demonstration of excellent historical performance. Facilities can demonstrate that historical performance by meeting a set of compliance and enforcement criteria and by demonstrating their ability to consistently discharge pollutants below the levels necessary to meet their existing NPDES permit limitations. Reductions are determined parameter-by-parameter, on the basis of the existing monitoring frequency and the percentage below the limitation at which the parameter is being discharged. The reductions are incorporated when the permit is reissued. To remain eligible for the reductions, permittees are expected to maintain the parameter performance levels and good compliance on which the reductions were based.

NMED Exhibit 70

8.1.4 Sample Collection

The permit writer must specify the sample collection method for all parameters required to be monitored in the permit. The permit writer should determine the sample collection method on the basis of the characteristics of each specific discharge. Certain sample collection and storage requirements are identified as part of the analytical methods specified in Part 136. (Section 8.3 below presents more on analytical methods.) The two most frequently used sampling methods are grab and composite. For more detailed information on sample collection methods, permit writers should refer to Chapter 5 (Sampling) of the NPDES Compliance Inspection Manual[1] <www.epa.gov/compliance/resources/publications/monitoring/cwa/inspections/npdesinspect/npdesmanual.html>.

8.1.4.1 Grab Samples

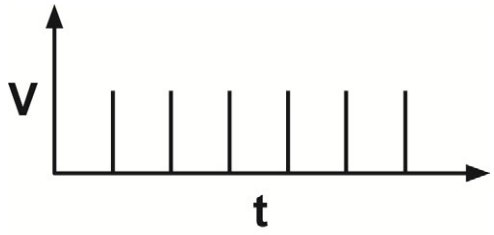
Grab samples are individual samples collected over a period not exceeding 15 minutes and that are representative of conditions at the time the sample is collected. Grab samples are appropriate when the flow and characteristics of the wastestream being sampled are relatively constant. The sample volume depends on the type and number of analyses to be performed. A grab sample is appropriate when a sample is needed to

- Monitor an effluent that does not discharge on a continuous basis.
- Provide information about instantaneous concentrations of pollutants at a specific time.
- Allow collection of a variable sample volume.
- Corroborate composite samples.
- Monitor parameters not amenable to compositing (e.g., temperature).

Grab samples can also be used to determine the spatial variability of a parameter or information on variability over a short period. They also are useful for monitoring intermittent wastewater flows from well-mixed batch process tanks.

8.1.4.2 Composite Samples

Composite samples are collected over time, either by continuous sampling or by mixing discrete samples, and represent the average characteristics of the wastestream during the sample period. Composite samples might provide a more representative measure of the discharge of pollutants over a given period than grab samples, and are used when any of the following is true:



- A measure of the average pollutant concentration during the compositing period is needed.
- A measure of mass loadings per unit of time is needed.
- Wastewater characteristics are highly variable.

Composite samples can be discrete samples (see discussion of sequential sampling in section 8.1.4.3 below) or a single combined sample and are collected either manually or with automatic samplers. There are two general types of composite sampling: time-proportional and flow-proportional. The permit writer should clearly express which type is required in the permit.

Time-proportional composite sample: This method collects a fixed volume (V) of discrete sample aliquots in one container at constant time intervals (t) as shown in Exhibit 8-2.

NMED Exhibit 70

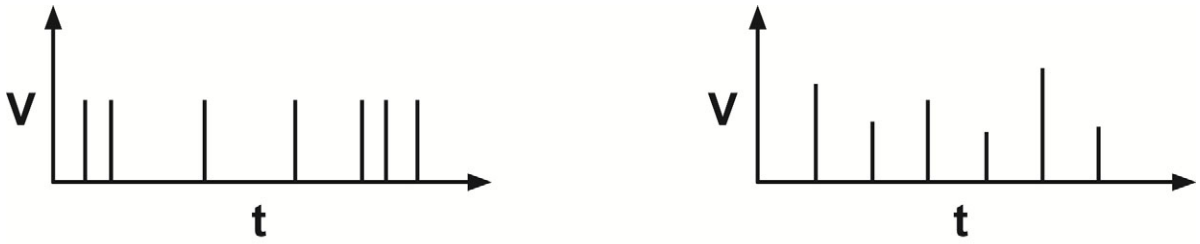


Exhibit 8-2 Visual interpretation of time-proportional composite monitoring

Time-proportional composite monitoring is appropriate when the flow of the sampled stream is constant (flow rate does not vary more than ±10 percent of the average flow rate) or when flow-monitoring equipment is not available. Automatically timed composited samples are usually preferred over manually collected composites. Composite samples collected by hand are appropriate for infrequent analyses and screening or if the subsamples have a fixed volume at equal time intervals.

Flow-proportional composite sample: There are two methods used for this type of sample: constant-volume when the interval time varies between samples, or constant-time when the interval volume collected varies between samples as shown in Exhibit 8-3.

Exhibit 8-3 Visual interpretation of flow-proportional composite monitoring

The constant-volume, flow-proportional, composite monitoring method collects a constant sample volume at varying time intervals proportional to stream flow (e.g., 200 milliliters sample collected for every 5,000 gallons of flow). The constant-time, flow-proportional, composite monitoring method collects the sample by adjusting the volume of each aliquot as the flow varies, while maintaining a constant time interval between the aliquots.

Flow-proportional composite sampling is usually preferred over time-proportional composite sampling when the effluent flow volume varies appreciably over time. If there is no flow-measuring device, effluent samples can be manually composited using the influent flow measurement without any correction for time lag. The error in the influent and effluent flow measurement is insignificant except in those cases where large volumes of water are impounded, as in equalization basins.

If a sampling protocol is not specified in the regulations, the permit writer should establish the duration of the compositing period and frequency of aliquot collection. The permit writer should also establish the time frame within which the sample is to be collected and the number of individual aliquots in the composite.

NMED Exhibit 70

There are instances where composite samples are inappropriate. For example, the permit application regulations at § 122.21(g)(7) indicate that grab samples must be used for sampling several parameters that may change during the time it takes to composite the sample. Composite samples can be used for whole effluent toxicity (WET) testing; however, if there is concern that there are toxicity spikes or that the toxicant is a parameter for which composite sampling is not appropriate, grab samples for WET testing could be specified in the permit.

8.1.4.3 Sequential and Continuous Monitoring

Sequential monitoring refers to collecting discrete samples in individual containers in regular succession, such as timed intervals or discharge increments. Sequential grab samples provide a characteristic of the wastestream over a given time. Automatic sequential monitoring may be done with a special type of automatic sampling device that collects relatively small amounts of a sampled wastestream with the interval between sampling proportioned based on either time or effluent flow. Unlike a combined composite sampler, the sequential sampling device automatically retrieves a sample and holds it in a bottle separate from other automatically retrieved samples. Many individual samples can be stored separately in the unit rather than combining aliquots in a common bottle.

Continuous monitoring is another option for a limited number of parameters such as flow, total organic carbon (TOC), temperature, pH, conductivity, residual chlorine, fluoride, and dissolved oxygen. When establishing continuous monitoring requirements, the permit writer should be aware that the NPDES regulations concerning pH limitations allow for a period of excursion when the effluent is being continuously monitored (§ 401.17). The reliability, accuracy, and cost of continuous monitoring vary with the parameter monitored. The permit writer should consider the environmental significance of the variation of any of these parameters in the effluent and the cost of continuous monitoring before establishing continuous monitoring requirements in the permit.

8.2 Additional Monitoring Requirements and WET Testing

A variety of discharges other than traditional POTW or industrial wastewater discharges, including biosolids (sewage sludge), combined sewer and sanitary sewer overflows, and stormwater, are regulated under the NPDES permit program. In addition, many permits include requirements for WET testing. As discussed in this section, a permit writer should account for such unique discharges and testing requirements in establishing monitoring requirements.

8.2.1 Biosolids (Sewage Sludge)

The purpose of monitoring sewage sludge is to ensure safe use or disposal of the sludge. Sewage sludge regulations specified in Part 503 require monitoring of sewage sludge that is applied to land, placed on a surface disposal site, or incinerated. The frequency of monitoring is based on the annual amount of sewage sludge that is used or disposed of by those methods. POTWs that provide the sewage sludge to another party for further treatment (such as composting) must provide that party with the information necessary to comply with regulations at Part 503. Sewage sludge disposed of in a municipal solid waste landfill unit must meet the criteria for municipal solid waste landfills in the regulations at Part 258.

NMED Exhibit 70

Exhibit 8-4 shows the minimum monitoring requirements established in Part 503 for sewage sludge before use and disposal. More frequent monitoring for any of the required or recommended parameters is appropriate when the POTW has any of the following:

- A highly variable influent load of toxics or organic solids.
- A significant industrial load.
- A history of process upsets due to toxics, or of adverse environmental impacts due to sludge use or disposal activities.

Exhibit 8-4 Minimum requirements for sewage sludge monitoring, based on method of sludge use or disposal

Method	Monitoring requirements	Frequency	Citation (40 CFR)
Land application	• Sludge weight and percent total solids • Metals: As, Cd, Cu, Pb, Hg, Mo, Ni, Se, and Zn • Pathogen Density • Vector Attraction Reduction	Based on dry weight of sludge in metric tons per year: • > zero but < 290: annually • = or > 290 but < 1,500: quarterly • = or > 1,500 but < 15,000: bimonthly • = or > 15,000: monthly	§ 503.16
Co-disposal in municipal solid waste landfill	• Sludge weight and percent total solids • Passes Paint-Filter Liquid Test • Suitability of sludge used as cover • Characterize in accordance with hazardous waste rules	Monitoring requirements or frequency not specified by Part 503. Determined by local health authority or landfill owner/operator.	Part 258
Surface disposal: lined sites with leachate collection and unlined sites	• Sludge weight and percent total solids • Metals: As, Cr, Ni (Unlined sites only) • Pathogen Density • Vector Attraction Reduction	Based on dry weight of sludge in metric tons per year: • > zero but < 290: annually • = or > 290 but < 1,500: quarterly • = or > 1,500 but < 15,000: bimonthly • = or > 15,000: monthly	§ 503.26
	• Methane gas	• Continuously	
Incineration	• Sludge weight and percent total solids • Metals: As, Cd, Cr, Pb, and Ni	Based on dry weight of sludge in metric tons per year: • > zero but < 290: annually • = or > 290 but < 1,500: quarterly • = or > 1,500 but < 15,000: bimonthly • = or > 15,000: monthly	§ 503.46
	• Be and Hg (National Emissions Standards)	• As required by permitting authority (local air authority)	
	• THC or O_2, moisture, combustion temperatures	• Continuously	
	• Air pollution control device operating parameters	• As required by permitting authority	

Notes:
Monitoring frequencies required by Part 503 may be reduced after 2 years of monitoring, but in no case may be less than once per year.
A successful land application program could necessitate sampling for other constituents of concern (such as nitrogen) in determining appropriate agronomic rates. The permit writer will determine additional monitoring requirements.

NMED Exhibit 70

The sampling and analysis methods specified in § 503.8 and Part 136 should be followed for monitoring the required parameters. Without any specific methods in Part 503, guidance on appropriate methods is in the following documents:

- *Part 503 Implementation Guidance*[2] <www.epa.gov/npdes/pubs/owm0237.pdf>.
- *POTW Sludge Sampling and Analysis Guidance Document*[3] <www.epa.gov/npdes/pubs/owm012.pdf>.
- *Control of Pathogens and Vector Attraction in Sewage Sludge*[4] <www.epa.gov/ORD/NRMRL/pubs/625r92013/625r92013.htm>.

8.2.2 Combined Sewer Overflows (CSOs) and Sanitary Sewer Overflows (SSOs)

EPA's Combined Sewer Overflow (CSO) Control Policy (59 FR 18688, April 19, 1994) requires monitoring to characterize the combined sewer system, assist in developing a Long-Term Control Plan (LTCP), and show compliance with permit requirements. The permit writer should ensure the following:

- Monitoring is done to develop an initial system characterization as part of the nine minimum controls to reduce CSOs and their effect on receiving water quality. Such monitoring includes analyzing existing data on precipitation events, on the combined sewer system and CSOs, on water quality, and conducting field inspections.
- As part of the LTCP, a permittee is required to develop a more complete characterization of the sewer system through monitoring and modeling.
- To show compliance with the permit requirements and ultimately the attainment of water quality standards, the permittee is required to conduct a post-construction compliance monitoring program. Specific monitoring requirements of the post-construction compliance monitoring program will be unique to each permittee's LTCP and should be established as specific monitoring conditions in the individual NPDES permit.

These monitoring conditions should require monitoring of certain key parameters during a representative number of CSOs from a representative number of wet-weather events along with ambient water quality monitoring to ascertain attainment of water quality standards. EPA has prepared a guidance manual on monitoring entitled *Combined Sewer Overflows: Guidance for Monitoring and Modeling*[5] <www.epa.gov/npdes/pubs/sewer.pdf>.

A facility's permit might also contain monitoring requirements for sanitary sewer overflows (SSOs). SSO monitoring requirements would be developed on a case-by-case basis.

8.2.3 Stormwater Monitoring Considerations

Stormwater monitoring requirements vary according to the type of permit regulating the stormwater discharge and the activity. Municipal separate storm sewer systems (MS4s) serving more than 100,000 people (and some serving less than 100,000) are typically issued individual NPDES permits with monitoring requirements that are specific to the MS4. Smaller MS4s regulated under the stormwater Phase II rule are typically not required to conduct water quality monitoring as a condition in their NPDES general permit, though evaluation of measurable goals may include monitoring. EPA's multi-sector general permit (MSGP) for stormwater discharges from industrial facilities includes analytical monitoring requirements based on the type of industrial activity. Finally, operators of construction activity regulated under the

NMED Exhibit 70

construction general permit are typically not required to conduct water quality monitoring; however, some states and EPA Regions do require monitoring if the construction activity will discharge to a water impaired by sediment.

Specific monitoring conditions for the federal general stormwater permits are detailed in the most recent Construction General Permit or MSGP issued by EPA (available on the EPA Stormwater Program Website <www.epa.gov/npdes/stormwater>). Additional documents on stormwater monitoring are:

- *Urban Stormwater BMP Performance: A Guidance Manual for Meeting the National Stormwater BMP Database Requirements*[6] <www.epa.gov/npdes/pubs/montcomplete.pdf>.
- *Guidance Manual for the Monitoring and Reporting Requirements of the NPDES Stormwater Multi-Sector General Permit (MSGP)*[7] <www.epa.gov/npdes/pubs/dmr-fin.pdf>.

8.2.4 WET Monitoring

The use of WET testing to evaluate the toxicity in a receiving stream is discussed in section 6.4 of this manual and on the NPDES WET Website <www.epa.gov/npdes/wet>. The WET (or biomonitoring) test procedures were promulgated in § 136.3 (60 FR 53529, October 16, 1995). EPA revised the WET methods in 67 FR 69951, November 19, 2002. WET monitoring conditions included in permits should specify the particular biomonitoring test to be used, the test species, required test endpoints, and quality assurance/quality control procedures.

To support permitting agencies in implementing WET methods, EPA has revised and published manuals for toxicity test protocols:

- *Methods for Measuring the Acute Toxicity of Effluents and Receiving Waters to Freshwater and Marine Organisms*. 5th ed.[8] <www.epa.gov/waterscience/WET/disk2/atx.pdf>.
- *Short-Term Methods for Estimating the Chronic Toxicity of Effluents and Receiving Waters to Freshwater Organisms*. 4th ed.[9] <www.epa.gov/waterscience/WET/disk3/ctf.pdf>.
- *Short-Term Methods for Estimating the Chronic Toxicity of Effluents and Receiving Waters to Marine and Estuarine Organisms*. 3rd ed.[10] <www.epa.gov/waterscience/WET/disk1/ctm.pdf>.
- *NPDES Compliance Monitoring Inspector Training: Biomonitoring*[11] (No Link).

WET testing samples could be composite or grab samples. Twenty-four hour composite samples are suggested except when any of the following are true:

- The effluent is expected to be more toxic at a certain time of day.
- Toxicity may be diluted during compositing.
- The size of the sample needed exceeds the composite sampler volume.

WET tests are relatively expensive compared to single parameter tests. Therefore, a permit writer should carefully consider the appropriate frequency for WET testing. A discharge with highly variable flow or observed toxicity should have more frequent monitoring than a discharge that is relatively consistent over time. As with other parameters, factors that a permit writer should consider when establishing appropriate WET monitoring frequencies include the following:

- Type of treatment process.

NMED Exhibit 70

- Environmental significance and nature of the toxicity.
- Past compliance record or history.
- Cost of monitoring relative to financial capabilities.
- Number of monthly samples used in developing the permit limitation.
- The frequency of intermittent discharges.

Samples should be evenly spaced throughout the year so that seasonal variability can be ascertained.

8.3 Analytical Methods

The permit writer must specify the analytical methods to be used for monitoring. EPA's Office of Science and Technology's Clean Water Act Analytical Methods Website <www.epa.gov/waterscience/methods/> contains information about analytical methods.

The standard conditions of the permit [§§ 122.41(j)(4) and 122.44(i)] require that, when available, permittees use test procedures specified in Part 136 <www.epa.gov/waterscience/methods/basic.htm>. The analytical methods contained in Part 136 are established for conventional, toxic (priority), and some nonconventional pollutants. Without analytical methods for a parameter, the permit writer should specify the analytical method to be used. There are also procedures to apply for approval of alternative test methods in accordance with § 136.4.

While Part 136 identifies the analytical methods approved for use in the NPDES program, additional methods information is available through the National Environmental Methods Index (NEMI) <www.nemi.gov/>. NEMI is a Web-based, searchable clearinghouse of methods supported by the U.S. Geological Survey and EPA's Office of Water. NEMI contains summaries of more than 1,100 methods and describes them by their performance characteristics and their regulatory status, relative cost, detection level, detection level type, accuracy, precision, spiking level, instrumentation, lab equipment, and the *greenness* of analytic methods. Permit writers might find that information useful in comparing the features of Part 136 methods that will be used for assessing compliance with the calculated effluent limitations.

When establishing effluent limitations for a specific parameter (based on technology or water quality regulatory requirements), it is possible for the value of the calculated limit to fall below the method detection limit (MDL) and the minimum level (ML) established by the approved analytical method(s). Regardless of whether current analytical methods are available to detect and quantify the parameter at the concentration of the calculated limitation, the limitation must be included in the permit as calculated.

In some instances, there might be two or more approved Part 136 analytical methods available for the analysis of a parameter. In such cases, the permit should determine whether there is a need to select one of the approved methods and to include a requirement in the permit mandating the use of only the selected method. That approach might be necessary where an effluent limit is established at a level that is quantifiable by one approved method but is below the ML of another approved method.

Such a situation often occurs where a permit contains a WQBEL for mercury. To clarify the EPA's position with respect to effluent monitoring for mercury, EPA developed a memo *Analytical Methods for Mercury in National Pollutant Discharge Elimination System (NPDES) Permits*[12] <www.epa.gov/npdes/pubs/mercurymemo_analyticalmethods.pdf>.

NMED Exhibit 70

***Sufficiently Sensitive* Methods**

At the time of the writing of this manual, EPA had proposed regulations at §§ 122.21(e), 122.44(i), and Part 136, to require the use of sufficiently sensitive methods for analyses conducted for NPDES permit applications and for compliance monitoring (75 FR 35712, June 23, 2010). To ensure that appropriate analytical methods are required and performed, see the most current version of these federal regulations and applicable state analytical method regulations and policy.

8.4 Reporting Monitoring Results

The NPDES regulations require the permittee to maintain records and periodically report on monitoring activities. The regulations at § 122.41(l)(4)(i) require that monitoring results must be reported on a DMR <www.epa.gov/npdes/pubs/dmr.pdf>. Data reported include both data required by the permit and any additional data the permittee has collected consistent with permit requirements. All facilities must submit reports (on discharges and sludge use or disposal) at least annually, as required by § 122.44(i)(2). POTWs with pretreatment programs must submit a pretreatment report at least annually as required by § 403.12(i). However, the NPDES regulation states that monitoring frequency and reporting should be dependent on the nature and effect of the discharge or sludge use or disposal. Thus, the permit writer can require reporting more frequent than annually.

8.5 Recordkeeping Requirements

Generally, the permit writer is required by § 122.41(j) to include in the permit the requirement to retain records for at least three years, subject to extension by the State Director. Recordkeeping requirements for sewage sludge [§ 122.41(j)] and the CAFO program [§ 122.42(e)(2)] require records be kept five years or longer if required by the State Director. The permit writer should designate in the permit where records should be kept.

Monitoring records must include the following:

- Date, place, time of sampling.
- Name of sampler.
- Date of analysis.
- Name of analyst.
- Analytical methods used.
- Analytical results.

According to § 122.41(j), monitoring records must be representative of the discharge. Monitoring records, which must be retained, include continuous strip chart recordings, calibration data, copies of all reports for the permit, and copies of all data used to compile reports and applications.

Sewage sludge regulations under §§ 503.17, 503.27, and 503.47 establish recordkeeping requirements that vary depending on the use and disposal method for the sewage sludge. The same recordkeeping requirements should be applied to other sludge monitoring parameters not regulated by the Part 503 rule.

NMED Exhibit 70

CHAPTER 9. Special Conditions

Special conditions in National Pollutant Discharge Elimination System (NPDES) permits supplement numeric effluent limitations and require the permittee to undertake activities designed to reduce the overall quantity of pollutants being discharged to waters of the United States, to reduce the potential for discharges of pollutants, or to collect information that could be used in determining future permit requirements.

There are many different reasons to incorporate special conditions into a permit including:

- To address unique situations, such as facilities discharging pollutants for which data are absent or limited, making development of technology- or water quality-based effluent limitations (TBELs or WQBELs) more difficult or impossible.
- To incorporate preventive requirements, such as requirements to install process control alarms, containment structures, good housekeeping practices, and the like.
- To address foreseeable changes to discharges, such as planned changes to process, products, or raw materials that could affect discharge characteristics.
- To incorporate compliance schedules to provide the time necessary to comply with permit conditions.
- To incorporate other NPDES programmatic requirements (e.g., pretreatment, sewage sludge).
- To impose additional monitoring requirements that provide the permit writer with data to evaluate the need for changes in permit limitations.
- To increase or decrease monitoring requirements, depending on monitoring results or changes in processes or products.
- To impose requirements for special studies such as ambient stream surveys, toxicity identification evaluations (TIEs) and toxicity reduction evaluations (TREs), bioaccumulation studies, sediment studies, mixing or mixing zone studies, pollutant reduction evaluations, or other such information-gathering studies.

Section 9.1 below addresses several types of special conditions that apply to both municipal and non-municipal facilities. Section 9.2 addresses special conditions unique to municipal facilities.

9.1 Special Conditions Potentially Applicable to Any Type of Discharger

This section discusses several types of special conditions that could be included in any NPDES permit (i.e., municipal or non-municipal). Those special conditions can be thought of as the *ABCs* of special conditions and include the following:

- **A**dditional monitoring and special studies.
- **B**est management practices (BMPs).
- **C**ompliance schedules.

NMED Exhibit 70

A summary of the use of those special conditions follows.

9.1.1 Additional Monitoring and Special Studies

Additional monitoring requirements, beyond those required under the effluent limitations section of the permit, and special studies are useful for collecting data that were not available to the permit writer for consideration during permit development. Additional monitoring requirements and special studies generally are used to supplement numeric effluent limitations or support future permit development activities. Examples of the types of special studies that could be required in an NPDES permit include the following:

- **Treatability studies:** Might be required in a permit when insufficient treatability information for a pollutant or pollutants would hinder a permit writer from developing defensible TBELs. Treatability studies can also be required when the permit writer suspects that a facility might not be able to comply with an effluent limitation.
- **Toxicity identification evaluation/toxicity reduction evaluation (TIE/TRE):** Could be required in a permit when wastewater discharges are found to be toxic using whole effluent toxicity (WET) tests. The purpose of those evaluations is to identify and control the sources of toxicity in an effluent. Further guidance related to U.S. Environmental Protection Agency (EPA) recommended TIE/TRE procedures and requirements is found in the following guidance manuals:
  - *Toxicity Reduction Evaluation Guidance for Municipal Wastewater Treatment Plants*[1] <www.epa.gov/npdes/pubs/tre.pdf>.
  - *Clarifications Regarding Toxicity Reduction and Identification Evaluations in the National Pollutant Discharge Elimination System Program*[2] <www.epa.gov/npdes/pubs/owmfinaltretie.pdf>.
  - *Generalized Methodology for Conducting Industrial Toxicity Reduction Evaluations*[3] (No link—see the endnote for ordering instructions).
  - *Methods for Aquatic Toxicity Identification Evaluations: Phase I Toxicity Characterization Procedures*. 2nd ed[4] <www.epa.gov/npdes/pubs/owm0330.pdf>.
  - *Toxicity Identification Evaluation: Characterization of Chronically Toxic Effluents, Phase I*[5] <www.epa.gov/npdes/pubs/owm0255.pdf>.
  - *Methods for Aquatic Toxicity Identification Evaluations: Phase II Toxicity Identification Procedures for Samples Exhibiting Acute and Chronic Toxicity*[6] <www.epa.gov/npdes/pubs/owm0343.pdf>.
  - *Methods for Aquatic Toxicity Identification Evaluations: Phase III Confirmation Procedures for Samples Exhibiting Acute and Chronic Toxicity*[7] <www.epa.gov/npdes/pubs/owm0341.pdf>.
- **Mixing or mixing zone studies:** Might be required in a permit to assist in determining how effluent and receiving water mix and in establishing a regulatory mixing zone that can be applied when developing WQBELs.
- **Sediment monitoring:** Could be included in a permit if a permit writer suspects that pollutants contained in wastewater discharges accumulate in the sediments of the receiving water.
- **Bioaccumulation studies:** Might be required in a permit to determine whether pollutants contained in wastewater discharges bioaccumulate in aquatic organisms (e.g., fish, invertebrates). Such studies could be required when water quality criteria are expressed in terms of fish tissue levels. Additional guidance related to evaluating the bioaccumulation potential of a pollutant can

NMED Exhibit 70

be found in the *EPA Great Lakes Water Quality Initiative Technical Support Document for the Procedure to Determine Bioaccumulation Factors*[8] (No link—see the endnote for ordering instructions).

When establishing additional monitoring or special studies, permit writers must ensure that any requirements related to the study (e.g., special sampling or analytical procedures) are specified in the appropriate permit condition. In addition, permit writers should establish a reasonable schedule for completion and submission of the study or monitoring program. If the anticipated timeline is longer than one year, an interim progress report during the study is advisable.

9.1.2 Best Management Practices (BMPs)

In general, BMPs are actions or procedures to prevent or reduce the discharge of pollution to waters of the United States. Title 40 of the *Code of Federal Regulations* (CFR) section 122.2 includes the following in the definition of BMPs:

- Schedules of activities.
- Prohibitions of practices.
- Maintenance procedures.
- Treatment requirements.
- Operating procedures and practices to control
  - Plant site runoff.
  - Spillage or leaks.
  - Sludge or waste disposal.
  - Drainage from raw material storage areas.

9.1.2.1 When to Use BMPs

Clean Water Act (CWA) section 304(e) authorizes EPA to require BMPs as part of effluent limitations guidelines and standards (effluent guidelines) to control plant site runoff, spillage or leaks, sludge or waste disposal, and drainage from raw material storage that it determines are associated with or ancillary to the industrial manufacturing or treatment process and can contribute significant amounts of pollutants to navigable waters. Where effluent guidelines require specific control measures, including BMPs or development of a BMP plan, permit writers must include such requirements in permits. In addition, CWA section 402(p)(3)(B)(iii) states that permits for discharges from municipal storm sewers must require controls, including management practices, to reduce the discharge of pollutants. Finally, CWA sections 402(a)(1) and (2) give the permitting authority the ability to include BMPs in permits on a case-by-case basis to carry out the provisions of the CWA.

The NPDES regulations at § 122.44(k) track the statutory provisions cited above. This section of the regulations provides that permits must contain BMPs (when applicable) to control or abate the discharge of pollutants when any of the following are true:

- They are authorized under CWA section 304(e).
- They are authorized under CWA section 402(p) for the control of stormwater discharges.
- Numeric effluent limitations are infeasible.
- The practices are necessary to achieve effluent limitations and standards or carry out the purpose and intent of the CWA.

NMED Exhibit 70

Circumstances under which numeric effluent limitations might be infeasible include the following:

- Regulating a pollutant for which limited treatability or aquatic impact data are available to allow development of numeric TBELs or WQBELs.
- Regulating discharges when the types of pollutants vary greatly over time.

In addition, a permit writer should consider using BMPs under any of the following circumstances:

- When chemical analyses are inappropriate or impossible.
- When there is a history of leaks and spills or when housekeeping is sloppy.
- When a complex facility lacks data for a pollutant or pollutants.

9.1.2.2 BMPs in NPDES Permits

Permit writers include BMP requirements in permits using two approaches: (1) site-, process-, or pollutant-specific BMPs, or (2) a requirement to develop a BMP plan. Site-, process-, or pollutant-specific BMPs might be appropriate in the case of an individual permit where a permit writer has the opportunity to review the circumstances at the facility. On the other hand, it might not be appropriate to include site-, process-, or pollutant-specific BMPs as conditions in a general permit, a permit for a particularly complex facility, or a permit for a facility with operations not familiar to the permit writer. Instead, complicated facilities and discharges covered under a general permit could be required to develop a BMP plan that requires the permittee to determine appropriate BMPs on the basis of circumstances at its facility.

Specific BMPs

Specific BMPs are designed to address conditions particular to a type of facility or to a specific site, process, or pollutant. Specific BMPs might be used in a permit when

- They are needed to address ancillary activities that could result in the discharge of pollutants to waters of the United States.
- Numeric effluent limitations for a specific process are otherwise infeasible and BMPs serve as effluent limitations for that process.
- They are required to supplement and ensure compliance with effluent limitations in the permit.

To select a specific BMP, the permit writer could

- Review the industry profiles or the specific facility to determine the applicable and appropriate management practices.
- Evaluate whether the BMP would help to achieve effluent limitations or other environmental objectives for that facility.
- Use information from other permits, pollution prevention sources, and EPA guidance documents to identify applicable and appropriate BMPs.

Specific BMPs frequently are required for certain types of dischargers such as concentrated animal feeding operations (CAFOs), combined sewer overflows (CSOs), and stormwater discharges.

NMED Exhibit 70

BMP Plans

The *Guidance Manual for Developing Best Management Practices*[9] <www.epa.gov/npdes/pubs/owm0274.pdf> describes the activities and materials at an industrial or municipal facility that are best addressed by BMPs. The manual also describes how BMPs work and gives examples of types of BMPs.

If a permit writer requires a BMP plan, it is the facility's responsibility to develop, implement, and evaluate the success or shortfalls of its own plan. Often, a BMP committee (i.e., a group of individuals within the plant organization) is responsible for developing the BMP plan and assisting the plant management in implementing and updating the BMP plan.

EPA has identified several recommended components of effective BMP plans and detailed each component in the *Guidance Manual for Developing Best Management Practices*. The minimum suggested components of a general BMP plan are presented below:

- General Provisions
  - Name and location of facility.
  - Statement of BMP policy and objective.
  - Review by plant manager.
- Specific Provisions
  - BMP committee.
  - Risk identification and assessment.
  - Reporting of BMP incidents.
  - Materials compatibility.
  - Good housekeeping.
  - Preventive maintenance.
  - Inspections and records.
  - Security.
  - Employee training.

BMP plans used to supplement effluent limitations or to describe how the discharger plans to meet effluent limitations can be submitted to the regulatory agency or be kept on-site and made available to the permitting authority upon request. A general schedule for BMP plan development can be included in the permit (e.g., complete and submit the plan within six months of permit issuance and begin implementing the plan within nine months of permit issuance).

Exhibit 9-1 presents example permit text for a requirement to develop and implement a BMP plan and should be adapted as necessary to reflect conditions at the individual facility.

NMED Exhibit 70

Exhibit 9-1 Example BMP plan requirement

The following is example text for requiring development and implementation of a BMP plan through an NPDES permit. The text should be crafted and changed as necessary to meet the individual facility's needs and the permitting authority's goals. The bracketed text should be updated to be specific to the permit.

1. Implementation.

[IF A BMP PLAN DOES NOT EXIST:]

The permittee, must develop and implement a best management practices (BMP) plan that achieves the objectives and the specific requirements listed below. A copy of the plan must be submitted to the U.S. Environmental Protection Agency (EPA) **[AND/OR STATE AGENCY]** within six months of the effective date of this permit. The plan must be implemented as soon as possible but no later than nine months from the effective date of the permit. The permittee must update and amend the plan as needed.

[IF A BMP PLAN ALREADY EXISTS:]

The permittee must during the term of this permit operate the facility in accordance with the BMP plan **[CITE EXISTING PLAN]** and in accordance with subsequent amendments to the plan. The permittee must amend the plan to incorporate practices to achieve the objectives and specific requirements listed below, and a copy of the amended plan must be submitted to the U.S. Environmental Protection Agency (EPA) **[AND/OR STATE AGENCY]** within three months of the effective date of this permit. The amended plan must be implemented as soon as possible but not later than six months from the effective date of the permit.

2. Purpose

Through implementation of the BMP plan the permittee must prevent or minimize the generation and the potential for the release of pollutants from the facility to the waters of the United States through normal operations and ancillary activities.

3. Objectives

The permittee must develop and amend the BMP plan consistent with the following objectives for the control of pollutants.

a. The number and quantity of pollutants and the toxicity of effluent generated, discharged, or potentially discharged at the facility must be minimized by the permittee to the extent feasible by managing each influent waste stream in the most appropriate manner.
b. Under the BMP plan, and any Standard Operating Procedures (SOPs) included in the plan, the permittee must ensure proper operation and maintenance of the treatment facility as required by § 122.41(e).
c. The permittee must establish specific objectives for the control of pollutants by conducting the following evaluations.
    1. Each facility component or system must be examined for its waste minimization opportunities and its potential for causing a release of significant amounts of pollutants to waters of the United States because of equipment failure, improper operation, and natural phenomena such as rain or snowfall, etc. The examination must include all normal operations and ancillary activities including material storage areas, plant site runoff, in-plant transfer, process and material handling areas, loading or unloading operations, spillage or leaks, sludge and waste disposal, or drainage from raw material storage. **[NOTE THAT ONLY THE APPLICABLE AREAS SHOULD BE INCLUDED IN THE PREVIOUS LIST.]**
    2. Where experience indicates a reasonable potential for equipment failure (e.g., a tank overflow or leakage), natural condition (e.g., precipitation), or other circumstances that may result in significant amounts of pollutants reaching surface waters, the program should include a prediction of the direction, rate of flow and total quantity of pollutants that could be discharged from the facility as a result of each condition or circumstance.

4. Requirements

The BMP Plan must be consistent with the objectives in the Objectives section above and the general guidance contained in the publication entitled *Guidance Manual for Developing Best Management Practices (BMPs)*, EPA 833-B-93-004, <www.epa.gov/npdes/pubs/owm0274.pdf> or any subsequent revisions to the guidance document. The BMP plan must

a. Be documented in narrative form, must include any necessary plot plans, drawings or maps, and must be developed in accordance with good engineering practices. The BMP plan must be organized and written with the following structure:
    1. Name and location of the facility.
    2. Statement of BMP policy.
    3. Structure, functions, and procedures of the BMP Committee.
    4. Specific management practices and standard operating procedures to achieve the above objectives, including the following:

NMED Exhibit 70

Exhibit 9-1 Example BMP plan requirement (continued)

a. Modification of equipment, facilities, technology, processes, and procedures.
b. Reformulation or redesign of products.
c. Substitution of materials.
d. Improvement in management, inventory control, materials handling or general operational phases of the facility.

5. Risk identification and assessment.
6. Reporting of BMP incidents.
7. Materials compatibility.
8. Good housekeeping.
9. Preventative maintenance.
10. Inspections and records.
11. Security.
12. Employee training.

b. Include the following provisions concerning BMP plan review:
   1. Review by plant engineering staff and the plant manager.
   2. Review and endorsement by the permittee's BMP Committee.
   3. A statement that the above reviews have been completed and that the BMP plan fulfills the requirements set forth in this permit. The statement must include the dated signatures of each BMP Committee member as certification of the reviews.

c. Establish specific BMPs to meet the objectives identified in the Objectives section above, addressing each component or system capable of generating or causing a release of significant amounts of pollutants, and identifying specific preventive or remedial measures to be implemented.

d. Establish specific BMPs or other measures that ensure that the following specific requirements are met:
   1. Ensure proper management of solid and hazardous waste in accordance with regulations promulgated under the Resource Conservation and Recovery Act (RCRA). Management practices required under RCRA regulations must be referenced in the BMP plan.
   2. Reflect requirements for Spill Prevention, Control, and Countermeasure (SPCC) plans under Clean Water Act (CWA) section 311 and 40 CFR Part 112 and may incorporate any part of such plans into the BMP plan by reference.
   3. Reflect requirements for stormwater control under CWA section 402(p) and the regulations at 40 CFR 122.26 and 122.44, and otherwise eliminate to the extent practicable, contamination of stormwater runoff.

   etc.

[NOTE: SECTION d. ABOVE COULD BE TAILORED TO EACH FACILITY BY THE PERMIT WRITER AND MAY INCLUDE PROCESSES OR AREAS OF THE FACILITY WITH HOUSEKEEPING PROBLEMS, NONCOMPLIANCE, SPILLS/LEAKS, OR OTHER PROBLEMS THAT COULD BE REMEDIED THROUGH A BMP. IF THERE IS A KNOWN SOLUTION TO THE PROBLEM (E.G., MORE FREQUENT INSPECTIONS, PREVENTIVE MAINTENANCE, ETC.), THIS REMEDY COULD ALSO BE INCLUDED AS A PART OF THE BMP PLAN REQUIREMENTS. TO GATHER IDEAS FOR SUCH REQUIREMENTS, THE PERMIT WRITER MAY WANT TO CONTACT THE PERMITTEE, COMPLIANCE PERSONNEL, FACILITY INSPECTORS, OPERATIONS OFFICE PERSONNEL, AND STATE AGENCY COUNTERPARTS. THE PERMIT WRITER MIGHT ALSO WANT TO CHECK REQUIREMENTS IN OTHER PERMITS AND BMP PLANS FOR SIMILAR FACILITIES.]

5. Documentation

The permittee must maintain a copy of the BMP plan at the facility and must make the plan available to EPA **[AND/OR STATE AGENCY]** upon request. All offices of the permittee, which are required to maintain a copy of the NPDES permit, must also maintain a copy of the BMP plan.

6. BMP Plan Modification

The permittee must amend the BMP plan whenever there is a change in the facility, or in the operation of the facility, that materially increases the generation of pollutants or their release or potential release to the receiving waters. The permittee must also amend the plan, as appropriate, when plant operations covered by the BMP plan change. Any such changes to the BMP plan must be consistent with the objectives and specific requirements listed above. All changes in the BMP plan must be reported to EPA **[AND/OR STATE AGENCY]** in writing.

7. Modification for Ineffectiveness

If at any time the BMP plan proves to be ineffective in achieving the general objective of preventing and minimizing the generation of pollutants and their release and potential release to the receiving waters and/or the specific requirements above, the permit and/or the BMP plan must be subject to modification to incorporate revised BMP requirements.

NMED Exhibit 70

9.1.2.3 Pollution Prevention in BMPs

BMPs are, by their nature, pollution prevention practices. Traditionally, BMPs have focused on good housekeeping measures and good management techniques that attempt to avoid contact between pollutants and water as a result of leaks, spills, and improper waste disposal. However, on the basis of the authority granted under the regulations, BMPs may include a range of pollution prevention options, including production modifications, operational changes, materials substitution, and materials and water conservation.

When developing BMPs, permit writers should be familiar with the fundamental principles of pollution prevention:

- Pollution should be prevented or reduced at the source, whenever feasible (*Reduce*).
- Pollution that cannot be prevented should be reused or recycled in an environmentally safe manner, whenever feasible (*Reuse-Recycle*).
- Pollution that cannot be prevented or recycled should be treated in an environmentally safe manner, whenever feasible (*Treat*).
- Disposal or other release into the environment should be employed only as a last resort and should be conducted in an environmentally safe manner (*Dispose of*).

When writing an NPDES permit, a permit writer who has familiarity with a certain type of processes might identify pollution prevention practices that are not used at a facility and that would help that facility achieve its pollution prevention goals. Where the pollution prevention practices are necessary to carry out the purposes and intent of the CWA, the permit writer may develop BMPs to implement those practices.

9.1.3 Compliance Schedules

The NPDES regulations at § 122.47 allow permit writers to establish schedules of compliance to give permittees additional time to achieve compliance with the CWA and applicable regulations. Schedules developed under this provision must require compliance by the permittee *as soon as possible*, but may not extend the date for final compliance beyond compliance dates established by the CWA. Thus, compliance schedules in permits are not appropriate for every type of permit requirement. Specifically, a permit writer may not establish a compliance schedule in a permit for TBELs because the statutory deadlines for meeting technology standards (i.e., secondary treatment standards and effluent guidelines) have passed. This restriction applies to both existing and new dischargers. Permit writers should note, however, that § 122.29(d)(4) allows a new source or new discharger up to 90 days to *start-up* its pollution control equipment and achieve compliance with its permit conditions (i.e., provides for up to a 90-day period to achieve compliance).

Examples of requirements for which a compliance schedule in an NPDES permit might be appropriate include:

- Pretreatment program development.
- Sludge use and disposal program development and implementation.
- BMP plan development and implementation.
- Effluent limitations derived from new or revised water quality standards.

NMED Exhibit 70

An EPA Administrator's decision specifically addresses compliance schedules for effluent limitations derived from new or revised water quality standards. In the decision *In the Matter of Star-Kist Caribe, Inc*., documented in the memorandum *Order Denying Modification Request With Respect to the Administrator's 1990 Decision in Star-Kist Caribe, Inc. (NPDES Appeal No. 88-5)*[10] <www.epa.gov/npdes/pubs/owm0121.pdf>, the EPA Administrator interpreted CWA section 301(b)(1)(C) to mean that 1) after July 1, 1977, permits may not contain compliance schedules for effluent limitations based on water quality standards adopted before July 1, 1977, and 2) compliance schedules are allowed for effluent limitations based on standards adopted after that date *only* if the state has clearly indicated in its water quality standards or implementing regulations that it intends to allow them.

In May 2007, the Director of EPA's Office of Wastewater Management issued a memorandum to EPA Region 9 that clarified the requirements of § 122.47 as they relate to WQBELs [see *Compliance Schedules for Water Quality-Based Effluent Limitations in NPDES Permits*[11] <www.epa.gov/npdes/pubs/memo_complianceschedules_may07.pdf>. Permit writers should consider the principles outlined in this memo when assessing whether a compliance schedule for achieving a WQBEL is consistent with the CWA and its implementing regulations and when documenting the basis for a compliance schedule in a permit. Considerations outlined in the memo include the following:

- Demonstrate that the permittee cannot immediately comply with the new effluent limitation on the effective date of the permit.
- Include an enforceable *final* effluent limitation and a date for achievement in the permit.
- Justify and document the *appropriateness* of the compliance schedule; factors relevant to a determination that a compliance schedule is appropriate include how much time the discharger had to meet the WQBEL under prior permit(s), whether there is any need for modifications to treatment facilities, operations, or other measures and, if so, how long it would take to implement such modifications.
- Justify and demonstrate that compliance with the final WQBEL is required *as soon as possible*; factors relevant to a determination that a compliance is required as soon as possible include the steps needed to modify or install treatment facilities, operations, or other measures and the time those steps would take.
- Include an enforceable sequence of events leading to compliance with interim milestones for schedules longer than one year.
- Recognize that a schedule solely to provide time to develop a total maximum daily load (TMDL) or to conduct a use attainability analysis (UAA) is not appropriate.

Many of the principles outlined in the memo could be more generally applied to compliance schedules for requirements other than WQBELs.

9.2 Special Conditions for Municipal Facilities

This section explains several common special conditions that are applicable only to municipal facilities. These conditions reflect requirements for publicly owned treatment works (POTWs) to implement and enforce local pretreatment programs for their industrial users; biosolids (sewage sludge) disposal requirements; CSO requirements; SSO requirements; and municipal separate storm sewer system (MS4) requirements.

NMED Exhibit 70

9.2.1 The National Pretreatment Program

CWA section 402(b)(8) requires that certain POTWs receiving pollutants from significant industrial sources (subject to CWA section 307(b) standards) establish a pretreatment program to ensure compliance with these standards. The implementing regulations at § 403.8(a) state that:

> Any POTW (or combination of POTWs operated by the same authority) with a total design flow greater than 5 million gallons per day (mgd) and receiving from industrial users pollutants which pass through or interfere with the operation of the POTW or are otherwise subject to pretreatment standards will be required to establish a POTW pretreatment program unless the NPDES state exercises its option to assume local responsibilities as provided in § 403.10(e).

As specified in § 403.8(a), the Regional Administrator or Director of an authorized state may require a POTW with a design flow of 5 mgd or less to develop a POTW pretreatment program. Program development could be determined to be necessary to prevent interference with or pass through of the POTW based on the nature, or volume, of the industrial influent, a history of treatment process upsets and violations of POTW effluent limitation(s), and contamination of municipal sludge.

Since 1978, approximately 1,500 POTWs have been required to develop and implement pretreatment programs through special conditions of NPDES permits. The pretreatment program was developed to control industrial discharges to POTWs and to meet the following objectives:

- To prevent pass through of pollutants.
- To prevent interference with POTW processes, including interference with the use or disposal of municipal sludge.
- To improve opportunities to recycle and reclaim municipal and industrial wastewater and sludges.

The pretreatment program also helps ensure POTW personnel health and safety.

As authorized by the pretreatment regulations at §§ 403.8(c), 403.8(d) and 403.8(e) and the NPDES regulations at § 122.44(j)(2), the requirements to develop and implement a POTW pretreatment program are included as enforceable conditions in the POTW's NPDES permit. NPDES permits drive the development and implementation of pretreatment programs by requiring the following:

- Adequate legal authority.
- Maintenance of an industrial user inventory.
- Development and implementation of local limits.
- Control mechanisms issued to significant industrial users (SIUs).
- Compliance monitoring activities.
- Swift and effective enforcement.
- Data management and recordkeeping.
- Reporting to the approval authority (EPA or state).
- Public participation.

NMED Exhibit 70

Through the NPDES permit, the POTW is required to develop and implement a pretreatment program. The POTW is required to submit an approvable program that meets the requirements in § 403.9(b). A more detailed description of these required program elements is in § 403.8(f). The POTW must have the legal authority enabling it to do the following:

- Deny or condition new or increased contributions of pollutants, or changes in nature of pollutants, to the POTW by industrial users.
- Require compliance with applicable pretreatment standards and requirements by industrial users.
- Control through a permit, order, or similar means the contribution to the POTW by each industrial user to ensure compliance with applicable pretreatment standards and requirements. These control mechanisms must have certain conditions as laid out in § 403.8(f)(1)(iii) and be enforceable.
- Require the development of compliance schedules where necessary by each industrial user for the installation of technology required to meet applicable pretreatment standards and requirements, and submission of all notices and self-monitoring reports to assess and ensure compliance.
- Carry out all inspection, surveillance, and monitoring procedures necessary to determine compliance with applicable pretreatment standards and requirements independent of information submitted by the industrial user (including the authority to enter the premises of the industrial user).
- Obtain remedies for noncompliance (e.g., injunctive relief, penalties).
- Comply with confidentiality requirements.

Further, at a minimum, the POTW must have procedures to do the following:

- Identify and locate all possible industrial users that might be subject to the POTW pretreatment program.
- Identify the character and volume of pollutants contributed to the POTW by the industrial users.
- Notify industrial users of applicable pretreatment standards and applicable requirements under CWA sections 204(b) and 405 and RCRA Subtitles C and D.
- Receive and analyze self-monitoring reports.
- Conduct sampling, inspections and other surveillance activities to determine compliance with applicable pretreatment standards and requirements independent of information supplied by the industrial user.
- Investigate instances of noncompliance.
- Comply with public participation requirements, including annual public notice of industrial users determined to be in significant noncompliance during the previous 12-month period.

Also, as part of the POTW pretreatment program, POTWs must have adequate resources and funding to implement the program, evaluate the need for and, as necessary, develop local limits and develop an enforcement response plan.

NMED Exhibit 70

The NPDES permit should include the conditions specified in § 403.9, including that the POTW be required to submit the program documentation, detailing the authority and procedures to be implemented, along with other information about the program. The permit will allow the POTW up to one year, from the time when written notification from the approval authority determined the need for a pretreatment program, to develop and submit a program for approval as stated in § 403.8(b). Once the permitting authority reviews and approves the program, the requirement to implement the approved program is then incorporated into the permit.

The permit writer generally incorporates the requirement to develop a pretreatment program at the time of permit reissuance. The requirement, however, may also be incorporated through a modification of the permit if there is *cause*, as defined in detail in § 403.8(e), to make such a modification. The permit writer must follow procedures outlined by § 122.62 related to modifications when including the requirement to develop a pretreatment program in an NPDES permit

During the life of the permit, it might be necessary for the POTW to modify its approved pretreatment program (changes to local limits, changes to the ordinance, and such). The changes can be brought about by the POTW's desire to change the way the program operates, or they can be the result of changes that are necessary to address deficiencies in the program found during inspections or audits done by the permitting authority. Whatever the reason for the modification, the permitting authority must review and approve any modification to the approved program that is considered substantial, as required by § 403.18. All substantial program modifications to the POTW's approved pretreatment program require minor modifications to the NPDES permit and are subject to the procedural requirements in §§ 122.63(g) and 403.18. In addition, incorporating the requirement for a previously approved pretreatment program for the purpose of making the implementation of the program an enforceable part of the permit is also considered a minor modification to the NPDES permit.

The majority of POTWs that need pretreatment program requirements in their permits currently have them in place. In addition, an NPDES state or an EPA region will often designate a pretreatment coordinator to serve as the pretreatment expert to review the annual report from the POTW and recommend any action to be taken. The state or EPA regional pretreatment coordinator is a key resource on pretreatment issues, particularly at the time of NPDES permit reissuance. EPA regions and approved states have developed standard pretreatment development or implementation conditions (with minor modifications made to tailor the conditions to the specific discharger) that are placed in all applicable NPDES permits in that region or state. The permit writer can usually obtain examples of these NPDES pretreatment conditions from the EPA or state pretreatment coordinators. The permit writer might need to update or modify pretreatment implementation language or initiate corrective action related to the pretreatment program.

EPA has developed the Pretreatment Program Website <www.epa.gov/npdes/pretreatment> and prepared a number of guidance manuals for POTWs on how to implement their local pretreatment programs that are accessible through this website. In addition, EPA prepared the *Introduction to the National Pretreatment Program*[12] <www.epa.gov/npdes/pubs/final99.pdf> as a reference for anyone interested in understanding the basics of pretreatment program requirements and to provide a roadmap to additional and more detailed guidance materials for those trying to implement specific elements of the pretreatment program.

NMED Exhibit 70

Pretreatment program information and monitoring data obtained through the POTW's pretreatment program are useful to the permit writer in identifying possible modifications to the pretreatment program's local limits or procedures, or the need for water quality-based controls. The permit writer should obtain such data with the aid of the pretreatment coordinator. Permits must include conditions requiring a POTW to provide a written technical evaluation of the need to revise local limits under § 403.5(c)(1) following permit issuance or reissuance [§ 122.44(j)(2)(ii)]. In addition, POTWs with a design flow greater than or equal to one mgd and with an approved pretreatment program or required to develop a pretreatment program must sample and analyze their effluent for priority (toxic) pollutants listed in Part 122, Appendix J, Table 2 as part of the permit application process [see § 122.21(j)(4)(iv)]. Those data and information also are useful for determining the need for WQBELs.

9.2.2 Biosolids (Sewage Sludge)

CWA section 405(d) requires that EPA regulate the use and disposal of sewage sludge to protect public health and the environment from any reasonably anticipated adverse effects of these practices. In the CWA, Congress directed EPA to develop technical standards for municipal sludge use and disposal options and enacted strict deadlines for compliance with these standards. Within one year of promulgation of the standards, compliance was required unless construction of new pollution control facilities was necessary, in which case compliance was required within two years.

EPA promulgated Part 503, Standards for the Use or Disposal of Sewage Sludge in 58 *Federal Register* (FR) 9248, February 19, 1993, with amendments in 59 FR 9095, February 19, 1994 and 60 FR 54764, October 25, 1995. These regulations address four sludge use and disposal practices: land application, surface disposal, incineration, and disposal in a municipal solid waste landfill. The standards for each end use and disposal method consist of general requirements, numeric effluent limitations, operational standards, and management practices, as well as monitoring, recordkeeping, and reporting requirements. Unlike technology standards, which are based on the ability of treatment technologies to reduce the level of pollutants, EPA's sewage sludge standards are based on health and environmental risks. Part 503 imposes requirements on four groups:

- Persons who prepare sewage sludge or material derived from sewage sludge.
- Land appliers of sewage sludge.
- Owners/operators of sewage sludge surface disposal sites.
- Owners/operators of sewage sludge incinerators.

Details of that rule are described in *A Plain English Guide to the EPA Part 503 Biosolids Rule*[13] <www.epa.gov/owm/mtb/biosolids/503pe/>.

The risk assessment for the Part 503 rule that governs the land application of biosolids took nearly 10 years to complete and had extensive rigorous review and comment. The risk assessment evaluated and established limitations for a number of pollutants. These limitations are in chapter 4 of *A Guide to the Biosolids Risk Assessments for the EPA Part 503 Rule*[14] <www.epa.gov/owm/mtb/biosolids/503rule/>.

The regulation is largely self-implementing, and anyone who engages in activities covered by the regulation must comply with the appropriate requirements on or before the compliance deadlines. A person who violates Part 503 requirements is subject to administrative, civil, and criminal enforcement actions.

NMED Exhibit 70

CWA section 405(f) requires the inclusion of sewage sludge use or disposal requirements in any NPDES permit issued to a Treatment Works Treating Domestic Sewage (TWTDS) and authorizes the issuance of sewage sludge-only permits to non-discharging TWTDS. In response, EPA promulgated revisions to the NPDES permit regulations at Parts 122 and 124 in 54 FR 18716, May 2, 1989, to address inclusion of sewage sludge use and disposal standards in NPDES permits and NPDES permit issuance to treatment works that do not have an effluent discharge to waters of the United States, but are involved in sewage sludge use or disposal as preparers, appliers, or owners/operators. TWTDS includes all sewage sludge generators and facilities, such as blenders, that change the quality of sewage sludge.

EPA recognizes that implementation of Part 503 requirements is a source of confusion for permit writers and permittees who might already have NPDES permits with special conditions addressing sewage sludge requirements. EPA has provided several guidance documents to help clarify NPDES permitting expectations, and explain the requirements of Part 503:

- *Part 503 Implementation Guidance*[15] <www.epa.gov/npdes/pubs/owm0237.pdf>.
- *Land Application of Sewage Sludge—A Guide for Land Appliers on the Requirements of the Federal Standards for the Use or Disposal of Sewage Sludge Management in 40 CFR Part 503*[16] <www.epa.gov/npdes/pubs/sludge.pdf>.
- *Surface Disposal of Sewage Sludge—A Guide for Owners/Operators of Surface Disposal Facilities on the Monitoring, Recordkeeping, and Reporting Requirements of the Federal Standards for the Use or Disposal of Sewage Sludge in 40 CFR Part 503*[17] <No Link–see the endnote for ordering instructions>.
- *Preparing Sewage Sludge for Land Application or Surface Disposal—A Guide for Preparers of Sewage Sludge on the Monitoring, Record Keeping, and Reporting Requirements of the Federal Standards for the Use or Disposal of Sewage Sludge in 40 CFR Part 503*[18] <No Link–see the endnote for ordering instructions>.
- *Domestic Septage Regulatory Guidance, A Guide to the EPA 503 Rule*[19] <www.epa.gov/npdes/pubs/owm0026.pdf>.
- *Control of Pathogens and Vector Attraction in Sewage Sludge*[20] <www.epa.gov/nrmrl/pubs/625r92013/625R92013.pdf>.

The permit writer should refer to the *Part 503 Implementation Guidance* and EPA Region and state guidelines or policies for instructions on how to implement the applicable Part 503 standards into the permit. The permit writer will need to determine the type of sewage sludge use or disposal practice(s) used by the discharger and apply the appropriate Part 503 standards. In general, conditions will need to be established to address the following:

- Pollutant concentrations or loading rates.
- Operational standards (such as pathogen and vector attraction reduction requirements for land application and surface disposal and total hydrocarbons (THC) concentrations for incinerators).
- Management practices (e.g., siting restrictions, design requirements, operating practices).
- Monitoring requirements (e.g., pollutants to be monitored, sampling locations, frequency, and sample collection and analytical methods).

NMED Exhibit 70

- Recordkeeping requirements.
- Reporting requirements (e.g., contents of reports and frequency or due dates for submission of reports).
- General requirements (e.g., specific notification requirements before land application, submission of closure and post closure plan for surface disposal sites).

In addition to any specific applicable Part 503 standards, three boilerplate conditions must be written in the NPDES permit where applicable. These consist of the following:

- Text requiring the POTW/TWTDS to comply with all existing requirements for sewage sludge use and disposal, including the Part 503 standards [see § 122.44(b)(2)].
- A reopener clause, which authorizes reopening a permit to include technical standards if the technical standards are more stringent or more comprehensive than the conditions in the permit [see § 122.44(c)].
- A notification provision requiring the permittee to give notice to the permitting authority when a significant change in the sewage sludge use or disposal practice occurs (or is planned) [see standard conditions in § 122.41(l)(1)(iii)].

If permit conditions based on existing regulations are insufficient to protect public health and the environment from adverse effects that could occur from toxic pollutants in sewage sludge, permit conditions should be developed on a case-by-case basis using best professional judgment (BPJ) to fulfill the statutory requirement. The *Part 503 Implementation Guidance* contains information to assist permit writers in developing effluent limitations and management practice requirements on a case-by-case basis to protect public health and the environment from adverse effects that could occur from toxic pollutants in sewage sludge. For more information on biosolids, see section 2.3.1.3 of this manual and the Biosolids Website <www.epa.gov/owm/mtb/biosolids/index.htm>

9.2.3 Combined Sewer Overflows (CSOs)

Combined sewer systems were designed and built in the 19th and early 20th centuries to collect sanitary and industrial wastewater and stormwater runoff. During dry weather, combined sewers carry sanitary wastes and industrial wastewater to a treatment plant. In periods of heavy rainfall, however, stormwater is combined with untreated wastewater, which can overflow and discharge directly to a waterbody without being treated. These overflows are called combined sewer overflows (CSOs).

EPA published a CSO Control Policy in 59 FR 18688, April 19, 1994. That policy represents a comprehensive national strategy to ensure that municipalities, permitting authorities, water quality standards authorities, and the public engage in a comprehensive and coordinated planning effort to achieve cost-effective CSO controls that ultimately meet appropriate health and environmental objectives.

The CSO Control Policy includes expectations for NPDES permitting authorities. In general, EPA envisioned a phased permit approach, including initial requirements to implement Nine Minimum CSO Controls (NMC) and develop a Long-Term CSO Control Plan (LTCP), followed by requirements to implement the controls in the approved LTCP. The Wet Weather Water Quality Act of 2000 amended the CWA to add section 402(q), which required that CSO permits be issued in conformance with the CSO Control Policy.

NMED Exhibit 70

CSOs are point source discharges subject to both the technology-based requirements of the CWA and applicable state water quality standards. Under the CWA, CSOs must comply with Best Available Technology Economically Achievable (BAT) for nonconventional and toxic pollutants and Best Conventional Technology (BCT) for conventional pollutants. However, there are no promulgated BAT or BCT limitations in effluent guidelines for CSOs. As a result, permit writers must use BPJ in developing technology-based permit requirements for controlling CSOs. Permit conditions also must achieve compliance with applicable water quality standards.

The 1994 CSO Control Policy contains the recommended approach for developing and issuing NPDES permits to control CSOs. In addition, EPA has developed the following CSO guidance documents to help permit writers and permittees implement the CSO Control Policy:

- *Combined Sewer Overflows–Guidance for Long-Term Control Plan*[21] <www.epa.gov/npdes/pubs/owm0272.pdf>.
- *Combined Sewer Overflows–Guidance for Nine Minimum Controls*[22] <www.epa.gov/npdes/pubs/owm0030.pdf>.
- *Combined Sewer Overflows–Guidance for Screening and Ranking*[23] <www.epa.gov/npdes/cso>.
- *Combined Sewer Overflows–Guidance for Monitoring and Modeling*[24] <www.epa.gov/npdes/pubs/sewer.pdf>.
- *Combined Sewer Overflows–Guidance for Financial Capability Assessment and Schedule Development*[25] <www.epa.gov/npdes/pubs/csofc.pdf>.
- *Combined Sewer Overflows–Guidance for Funding Options*[26] <www.epa.gov/npdes/pubs/owm0249.pdf>.
- *Combined Sewer Overflows–Guidance for Permit Writers*[27] <www.epa.gov/npdes/cso>.
- *Combined Sewer Overflows–Guidance: Coordinating Combined Sewer Overflow Long-Term Planning with Water Quality Standards Reviews*[28] <www.epa.gov/npdes/pubs/wqs_guide_final.pdf>.

Combined Sewer Overflows–Guidance for Permit Writers[24] contains guidance and example permit language that permit writers can use. Controlling CSOs typically requires substantial long-term planning, construction, financing and continuous reassessment; therefore, the implementation of CSO controls will probably occur over several permit cycles. The guidance explains a phased permitting approach to CSOs. Exhibit 9-2 depicts this phased permitting approach and the types of permit conditions that should be developed for each phase.

NMED Exhibit 70

Exhibit 9-2 Categories of CSO permitting conditions

NPDES permit	Phase I	Phase II	Post phase II
A. Technology-based	• NMC, at a minimum	• NMC, at a minimum	• NMC, at a minimum
B. Water Quality-based	• Narrative	• Narrative + performance-based standards	• Narrative + performance-based standards + numeric WQBELs (as appropriate)
C. Monitoring	• Characterization, monitoring, and modeling of CSS	• Monitoring to evaluate water quality impacts • Monitoring to determine effectiveness of CSO controls	• Post-construction compliance monitoring
D. Reporting	• Documentation of NMC implementation • Interim LTCP deliverables	• Implementation of CSO controls (both NMC and long-term controls)	• Report results of post-construction compliance monitoring
E. Special conditions	• Prohibition of dry weather overflows (DWO) • Development of LTCP	• Prohibition of DWO • Implementation of LTCP • Reopener clause for water quality standards violations • Sensitive area reassessment	• Prohibition of DWO • Reopener clause for water quality standards violations

Depending on the permittee's situation, a permit may contain both Phase I and Phase II elements. Phase I permits require demonstration of implementation of the NMC, shown in Exhibit 9-3.

Exhibit 9-3 Nine minimum CSO controls

1. Proper operation and regular maintenance programs for the sewer system and the CSOs
2. Maximum use of the collection system for storage
3. Review and modification of pretreatment requirements to ensure that CSO impacts are minimized
4. Maximization of flow to the POTW for treatment
5. Prohibition of CSOs during dry weather
6. Control of solid and floatable materials in CSOs
7. Establishment of pollution prevention programs
8. Public notification to ensure that the public receives adequate notification of CSO occurrences and CSO impacts
9. Monitoring to effectively characterize CSO impacts and the efficacy of CSO controls

In the Phase I permit issued/modified to reflect the CSO Control Policy, the NPDES authority should at least require permittees to

- Immediately implement BAT/BCT, which at a minimum includes the NMC, as determined on a BPJ basis by the permitting authority.
- Develop and submit a report documenting the implementation of the NMC within 2 years of permit issuance/modification.

NMED Exhibit 70

- Comply with applicable water quality standards, no later than the date allowed under the state's water quality standards expressed in the form of a narrative limitation.
- Develop and submit, consistent with the CSO Control Policy and based on a schedule in an appropriate enforceable mechanism, an LTCP, as soon as practicable, but generally within 2 years after the effective date of the permit issuance/modification. Permitting authorities may establish a longer timetable for completion of the long-term CSO control plan on a case-by-case basis to account for site-specific factors that could influence the complexity of the planning process. Exhibit 9-4 shows the minimum elements of the LTCP.

Exhibit 9-4 Elements of the long-term CSO control plan

1. Characterization, monitoring, and modeling of the combined sewer system
2. Public participation
3. Consideration of sensitive areas
4. Evaluation of alternatives
5. Cost/performance considerations
6. Operational plan
7. Maximizing treatment at the existing POTW treatment plant
8. Implementation schedule
9. Post-construction compliance monitoring program

Phase II permits require the implementation of an LTCP. The Phase II permit should contain the following:

- Requirements to implement the technology-based controls including the NMC determined on a BPJ basis.
- Narrative requirements that ensure that the selected CSO controls are implemented, operated and maintained as described in the LTCP.
- Water quality-based effluent limits under §§ 122.44(d)(1) and 122.44(k), requiring, at a minimum, compliance with, no later than the date allowed under the state's water quality standards, the numeric performance standards for the selected CSO controls, based on average design conditions specifying at least one of the following:
  - A maximum number of overflow events per year for specified design conditions consistent with II.C.4.a.i of the CSO Control Policy.
  - A minimum percentage capture of combined sewage by volume for treatment under specified design conditions consistent with II.C.4.a.ii of the CSO Control Policy.
  - A minimum removal of the mass of pollutants discharged for specified design conditions consistent with II.C.4.a.iii of CSO Control Policy.
  - Performance standards and requirements that are consistent with II.C.4.b of the CSO Control Policy.
- A requirement to implement, with an established schedule, the approved post-construction water quality assessment program including requirements to monitor and collect sufficient information to demonstrate compliance with water quality standards and protection of designated uses as well as to determine the effectiveness of CSO controls.

NMED Exhibit 70

- A requirement to reassess overflows to sensitive areas in those cases where elimination or relocation of the overflow is not physically possible and economically achievable.
- Conditions establishing requirements for maximizing the treatment of wet-weather flows at the POTW, as appropriate, consistent with section II.C.7. of the CSO Policy.
- A reopener clause authorizing the NPDES authority to reopen and modify the permit upon determination that the CSO controls fail to meet water quality standards or protect designated uses.

Reviewing the permittee's LTCP and consultations with other staff involved in the CSO control process and the permittee are important steps in the process of determining the appropriate Phase II permit conditions. Water quality-based controls in Phase II generally are expressed as narrative requirements and performance standards for the combined sewer system. Finally, post Phase II permit conditions would address continued implementation of the NMC, long-term CSO controls, and post-construction compliance monitoring. There may also be numeric WQBELs when there are sufficient data to support their development.

LTCP implementation schedules were expected to include project milestones and a financing plan for design and construction of necessary controls as soon as practicable. The CSO Control Policy expected permitting authorities to undertake the following:

- Review and revise, as appropriate, state CSO permitting strategies developed in response to the National CSO Control Strategy.
- Develop and issue permits requiring CSO communities to immediately implement the NMC and document their implementation and develop and implement an LTCP.
- Promote coordination among the CSO community, the water quality standards authority, and the general public through LTCP development and implementation.
- Evaluate water pollution control needs on a watershed basis and coordinate CSO control with the control of other point and nonpoint sources of pollution.
- Recognize that it might be difficult for some small communities to meet all the formal elements of LTCP development, and that compliance with the NMC and a reduced scope LTCP might be sufficient.
- Consider sensitive areas, use impairment, and a CSO community's financial capability in the review and approval of implementation schedules.

Communities must develop and implement LTCPs to meet water quality standards, including the designated uses and criteria to protect those uses for waterbodies that receive CSO discharges. The CSO Control Policy recognized that substantial coordination and agreement among the permitting authority, the water quality standards authority, the public, and the CSO community would be required to accomplish this objective. The CSO Control Policy also recognized that the development of the LTCP should be coordinated with the review and appropriate revision of water quality standards and their implementation procedures.

In developing permit requirements to meet technology-based requirements and applicable state water quality standards, the permit writer, in conjunction with staff involved in water quality standards and the

NMED Exhibit 70

permittee, should identify the appropriate site-specific considerations that will determine the CSO conditions to be established in the permit. EPA believes that the following information will be particularly relevant in developing the appropriate conditions:

- CSO Discharge
  - Flow, frequency, and duration of the CSO discharge.
  - Available effluent characterization data on the CSO discharge.
  - Available information and data on the impacts of the CSO discharge(s) (e.g., CWA section 305(b) reports, ambient survey data, fish kills, CWA section 303(d) lists of impaired waters).
  - Compliance history of the CSO owner, including performance and reliability of any existing CSO controls.
  - Current NPDES permit and NPDES permit application.
  - Facility planning information from the permittee that addresses CSOs.
- Technologies
  - Performance data (either from the manufacturer or from other applications) for various CSO technologies that may be employed, including equipment efficiency and reliability.
  - Cost information associated with the installation, operation and maintenance of CSO technologies.
  - Reference materials on various types of CSO.

For more information on CSOs, see section 2.3.1.4 of this manual and the Combined Sewer Overflows Website <www.epa.gov/npdes/cso>.

9.2.4 Sanitary Sewer Overflows (SSOs)

EPA's *Report to Congress on the Impacts and Control of CSOs and SSOs*[29] <www.epa.gov/npdes/csossoreport2004> shows that NPDES permit requirements establishing clear reporting, recordkeeping and third party notification of overflows from municipal sewage collection systems, as well as clear requirements to properly operate and maintain the collection system, are critical to effective program implementation. NPDES authorities should be improving NPDES permit requirements for SSOs and sanitary sewer collection systems, which could lead to improved performance of municipal sanitary sewer collection systems and improved public notice for SSO events.

The NPDES regulations provide standard conditions that are to be in NPDES permits for POTWs as discussed in Chapter 10 of this manual. Standard conditions in a permit for a POTW apply to portions of the collection system for which the permittee has ownership or has operational control. When reissued, permits for POTW discharges should clarify how key standard permit conditions apply to SSOs and sanitary sewer collection systems. On August 20, 2007, EPA circulated a draft fact sheet, NPDES Permit Requirements for Municipal Sanitary Sewer Collection Systems and SSOs <www.epa.gov/npdes/pubs/sso_fact_sheet_model_permit_cond.pdf>, which explains the ways NPDES permitting authorities should be improving implementation of NPDES permit requirements to address SSOs and sanitary sewer collection systems.

NMED Exhibit 70

The draft fact sheet indicates that clarifications should address the particular application of standard permit conditions to SSOs and municipal sanitary sewer collection systems as discussed below.

- **Immediate reporting.** Permits should clarify that the permittee is required to notify the NPDES authority of an overflow that could endanger health or the environment from portions of the collection system over which the permittee has ownership or operational control as soon as practicable but within 24 hours of the time the permittee becomes aware of the overflow. [See § 122.41(l)(6)].
- **Written reports**. Permits should clarify that the permittee is required to provide the NPDES authority a written report within 5 days of the time it became aware of any overflow that is subject to the immediate reporting provision. [See § 122.41(l)(6)(i).] In addition, permits should clarify that any overflow that is not immediately reported as indicated above, should be reported in the discharge monitoring report. [See § 122.41(l)(7)].
- **Third party notice.** Permits should establish a process for requiring the permittee or the NPDES authority to notify specified third parties of overflows that could endanger health because of a likelihood of human exposure; or unanticipated bypass and upset that exceeds any effluent limitation in the permit or that could endanger health because of a likelihood of human exposure. Permits should clarify that the permittee is required to develop, in consultation with appropriate authorities at the local, county, or state level (or any combination), a plan that describes how, under various overflow (and unanticipated bypass and upset) scenarios, the public, and other entities, would be notified of overflows that may endanger health. The plan should identify all overflows that would be reported, to whom they should be reported, the specific information that would be reported, a description of lines of communication, and the identities of responsible officials. [See § 122.41(l)(6)].
- **Recordkeeping**. Permits should clarify that the permittee is required to keep records of overflows. Clarified permit language for recordkeeping should require the permittee to retain the reports submitted to the NPDES authority and other appropriate reports that could include work orders associated with investigation of system problems related to an overflow, that describes the steps taken or planned to reduce, eliminate, and prevent reoccurrence of the overflow. [See § 122.41(j)].
- **Capacity, management, operation and maintenance programs.** Permits should clarify requirements for proper operation and maintenance of the collection system. [See §§ 122.41(d) and 122.41(e)]. This may include requiring the development and implementation of capacity, management, operation and maintenance (CMOM) programs. EPA's Region 4 has developed materials and guidance that can help a municipality with its CMOM program on the Management, Operation and Maintenance (MOM) Programs Project Website <www.epa.gov/region4/water/wpeb/momproject/>. The CMOM program may use a process for self-assessment and information management techniques for ongoing program improvement and may develop and implement emergency response procedures to overflows. In addition, the CMOM permit condition may specify appropriate documentation requirements, including the following:
  - CMOM program summary. Permittees may be required to develop a written summary of their CMOM programs, which would be available to the NPDES authority and public on request. The program summary would give an overview of the management program and summarize major implementation activities.

NMED Exhibit 70

- Program audit report. Permittees may be required to conduct comprehensive audits of their programs during the permit cycle, and submit a copy of the audit report to the NPDES authority with the application for permit renewal. EPA's Sanitary Sewer Overflow Toolbox Website <www.epa.gov/npdes/sso/ssotoolbox> provides information on CMOM.
- System evaluation and capacity assurance plan. Capacity assurance refers to a process to identify, characterize and address hydraulic deficiencies in a sanitary sewer collection system. The permit may require the permittee to implement a program to assess the current capacity of the collection system and treatment facilities that they own or over which they have operational control to ensure that discharges from unauthorized locations do not occur. Where peak flow conditions contribute to an SSO discharge or to noncompliance at a treatment plant, the permittee may be required to prepare and implement a system evaluation and capacity assurance plan. In some instances, the permittee may already be under an enforceable obligation and schedule, in which case this permit provision would be redundant and, thus, unnecessary.

Section 2.3.1.5 of this manual and EPA's Sanitary Sewer Overflows Website <www.epa.gov/npdes/sso> provide more information on SSOs.

NMED Exhibit 70

CHAPTER 10. Standard Conditions of NPDES Permits

This chapter describes standard conditions, sometimes called *boilerplate* conditions, that must be incorporated in National Pollutant Discharge Elimination System (NPDES) permits. Standard conditions, specified in Title 40 of the *Code of Federal Regulations* (CFR) 122.41 and 122.42, play an important supporting role to effluent limitations, monitoring and reporting requirements, and special conditions because they delineate various legal, administrative, and procedural requirements of the permit. Standard conditions cover various topics, including definitions, testing procedures, records retention, notification requirements, penalties for noncompliance, and other permittee responsibilities. The conditions provided in § 122.41 apply to all types and categories of NPDES permits and must be included in all permits (see § 123.25 for applicability to state NPDES permits). The conditions provided in § 122.42 apply only to certain categories of NPDES facilities. Any permit issued to a facility in one of the categories listed in § 122.42 must contain the additional conditions, as applicable.

The use of standard conditions helps ensure uniformity and consistency of all NPDES permits issued by authorized states or the U.S. Environmental Protection Agency (EPA) Regional Offices. Permit writers need to be aware of the contents of the standard conditions because it might be necessary to explain portions of the conditions to a discharger. The permit writer should keep abreast of any changes in EPA's standard conditions set out in §§ 122.41 and 122.42. According to § 122.41, standard conditions may be incorporated into a permit either expressly (verbatim from the regulations) or by reference to the regulations. It generally is preferable for permit writers to attach the standard conditions expressly because permittees might not have easy access to the regulations. Some states have developed an attachment for NPDES permits that includes the federal standard conditions.

10.1 Types of Standard Conditions

A brief summary of the § 122.41 standard conditions that must be included in all types of NPDES permits follows:

- **Duty to Comply** § 122.41(a): The permittee must comply with all conditions of the permit. Noncompliance is a violation of the Clean Water Act (CWA) and is grounds for enforcement action, changes to or termination of the permit, or denial of a permit renewal application.
- **Duty to Reapply** § 122.41(b): A permittee wishing to continue permitted activities after the permit expiration date must reapply for and obtain a new permit.
- **Need to Halt or Reduce Activity not a Defense** § 122.41(c): The permittee may not use as a defense in an enforcement action the reasoning that halting or reducing the permitted activity is the only way to maintain compliance.
- **Duty to Mitigate** § 122.41(d): The permittee is required to take all reasonable steps to prevent any discharge or sludge use or disposal in violation of the permit that has a reasonable likelihood of adversely affecting human health or the environment.
- **Proper Operation and Maintenance** § 122.41(e): The permittee must properly operate and maintain all equipment and treatment systems used for compliance with the terms of the permit.

NMED Exhibit 70

The permittee must provide appropriate laboratory controls and quality assurance procedures. Operation of backup systems is required only when needed to ensure compliance.

- **Permit Actions** § 122.41(f): The permit may be modified, revoked and reissued, or terminated for cause. A request by the permittee for a permit modification, revocation or reissuance, termination, or a notification of planned changes or anticipated noncompliance does not suspend the permittee's obligation to comply with all permit conditions.
- **Property Rights** § 122.41(g): The permit does not convey any property rights of any sort, or any exclusive privilege.
- **Duty to Provide Information** § 122.41(h): The permittee must furnish, within a reasonable time, any information needed to determine compliance with the permit or to determine whether there is cause to modify, revoke and reissue, or terminate the permit. The permittee also must furnish, on request, copies of records that must be kept as required by the permit.
- **Inspection and Entry** § 122.41(i): The permittee must, upon presentation of valid credentials by the Director or his or her representative, allow entry into the premises where the regulated activity or records are present. The Director must have access to and be able to make copies of any required records; inspect facilities, practices, operations, and equipment; and sample or monitor at reasonable times.
- **Monitoring and Records** § 122.41(j): Samples must be representative of the monitored activity. The permittee must retain records for 3 years (5 years for sewage sludge activities) subject to extension by the Director. Monitoring records must identify the sampling dates and personnel, the sample location and time, and the analytical techniques used and corresponding results. Wastewater and sludge measurements must be conducted in accordance with Parts 136 or 503 or other specified procedures. Falsification of results is a violation under the CWA.
- **Signatory Requirement** § 122.41(k): The permittee must sign and certify applications, reports, or information submitted to the Director in accordance with the requirements in § 122.22. Knowingly making false statements, representations, or certifications is punishable by fines or imprisonment.
- **Planned Changes** § 122.41(l)(1): Notice must be given to the Director as soon as possible of planned physical alterations or additions to the facility (or both) that could meet the criteria for determining whether the facility is a new source under § 122.29(b); result in changes in the nature or quantity of pollutants discharged; or significantly change sludge use or disposal practices.
- **Anticipated Noncompliance** § 122.41(l)(2): The permittee must give advance notice of any planned changes that could result in noncompliance.
- **Permit Transfers** § 122.41(l)(3): The permit is not transferable except after written notice to the Director. The Director may require modification or revocation and reissuance, as necessary.
- **Monitoring Reports** § 122.41(l)(4): Monitoring results must be reported at the frequency specified in the permit and be reported on a discharge monitoring report (DMR) or forms provided or specified by the Director for reporting results of monitoring sludge use or disposal practices. Monitoring for any pollutant that occurs more frequently than is required by the permit and uses approved test procedures or test procedures specified in the permit must also be reported. Calculations requiring averaging must use an arithmetic mean unless otherwise specified in the permit.

NMED Exhibit 70

- **Compliance Schedules** § 122.41(l)(5): Reports of compliance or noncompliance or any progress report must be submitted no later than 14 days following the interim or final compliance date specified in a compliance schedule.
- **Twenty-Four Hour Reporting** § 122.41(l)(6): The permittee must orally report any noncompliance that might endanger human health or the environment within 24 hours after becoming aware of the circumstances. Within 5 days of becoming aware of the circumstances, the permittee must provide a written submission including a description of the noncompliance and its cause; the period of noncompliance, including exact dates and times; the anticipated time the noncompliance is expected to continue (if not already corrected); and steps taken to reduce, eliminate, or prevent reoccurrence unless the Director waives the requirement. In addition, 24-hour reporting is required for an unanticipated bypass exceeding effluent limits; an upset exceeding effluent limits; and a violation of a maximum daily effluent limitation for pollutants listed in the permit for 24-hour reporting.
- **Other Noncompliance** § 122.41(l)(7): The permittee must report all instances of noncompliance not reported under other specific reporting requirements at the time monitoring reports are submitted.
- **Other Information** § 122.41(l)(8): If the permittee becomes aware that it failed to submit any relevant facts in its application, or submitted incorrect information in its application or other reports, it must promptly submit such facts or information.
- **Bypass** § 122.41(m): The intentional diversion of wastestreams from any portion of a treatment facility. Bypass is prohibited unless the bypass does not cause the effluent to exceed limits and is for essential maintenance to assure efficient operation (no notice or 24-hour reporting is required in such a case). All other bypasses are prohibited, and the Director of the NPDES program may take enforcement action against a permittee for a bypass, unless the bypass was unavoidable to prevent loss of life, personal injury, or severe property damage, there was no feasible alternative, and the proper notification was submitted.
- **Upset** § 122.41(n): An upset (i.e., an exceptional incident in which there is unintentional and temporary noncompliance with technology-based effluent limits because of factors beyond the permittee's control) can be used as an affirmative defense in actions brought against the permittee for noncompliance. An upset does not include noncompliance to the extent caused by operational error, improperly designed or inadequate treatment facilities, lack of preventative maintenance, or careless or improper operation. The permittee (who has the burden of proof to demonstrate that an upset has occurred) must have operational logs or other evidence that shows
  - When the upset occurred and its causes.
  - The facility was being operated properly.
  - Proper notification was made.
  - Remedial measures were taken.

10.2 Other Standard Conditions

In addition to standard conditions specified in § 122.41 that are applicable to all permittees, § 122.42 includes additional conditions applicable to certain categories of NPDES permits. Below are summaries of these additional standard conditions applicable to various types of NPDES permits.

NMED Exhibit 70

Non-Municipal (Industrial) Permits: Additional standard conditions applicable to non-municipal permits are found in § 122.42(a) and specify that the permittee must notify the Director as soon as it knows or has reason to believe that the discharge has or will exceed certain notification levels specified in §§ 122.42(a)(1) and (2). In addition, § 122.44(f) allows the Director to establish alternate notification levels upon petition by the permittee or by his or her own initiative.

Publicly Owned Treatment Work (POTW) Permits: Additional standard conditions applicable to POTWs are found in § 122.42(b). The standard conditions specify that the permittee must provide adequate notice to the Director of the new introduction of certain pollutants into the POTW from an indirect discharger and of substantial changes in the volume or character of pollutants introduced into the POTW. That notice must include information on the quality and quantity of effluent introduced to the POTW and information on the impact to the quality and quantity of the POTW's effluent.

Municipal Separate Storm Sewer Systems: Additional standard conditions applicable to large, medium or EPA-designated municipal separate storm sewer systems are in § 122.42(c). Those standard conditions require that the permittee submit an annual report addressing the status, and changes to, the stormwater management program, water quality data and other information specified in §§ 122.42(c)(1)-(6).

Individual Stormwater Permits: Initial permits for discharges composed entirely of stormwater and permitted under § 122.26(e)(7) must require compliance no later than 3 years after permit issuance.

Concentrated Animal Feeding Operations (CAFO) Permits: The regulations at § 122.42(e) specify conditions that must be included in all permits for CAFOs.

NMED Exhibit 70

CHAPTER 11. NPDES Permit Administration

Previous discussions in this manual focused on the process of developing National Pollutant Discharge Elimination System (NPDES) permit conditions and effluent limitations. This chapter describes the administrative process associated with the issuance of an NPDES permit including a discussion of the other federal laws that might affect the development or issuance of NPDES permits.

11.1 Other Federal Laws Applicable to NPDES Permits

This section addresses other federal laws, besides the Clean Water Act (CWA), that permit writers should consider when drafting an NPDES permit. The requirements imposed under these statutes only apply to federal actions (i.e., U.S. Environmental Protection Agency [EPA] issuance of permits). Permits issued by states authorized to administer the NPDES program are not subject to the requirements of these statutes. However, many states may have enacted state legislation that is modeled on federal law and, therefore, it is prudent to review state law in these areas before preparing an NPDES permit.

The following sections briefly discuss the other federal laws and contain links to other websites for more information. Because these laws are implemented by other federal agencies, many of the links provided below are to websites outside EPA, and EPA is not responsible for the information provided on those websites. The NPDES regulations at Title 40 of the *Code of Federal Regulations* (CFR) 122.49 also include a discussion of how some of the laws relate to the federal NPDES program. Exhibit 11-1 presents the other federal laws that are applicable to NPDES permits and includes the legislative citations from the *United States Code* (U.S.C.) and the implementing regulations in the CFR.

Exhibit 11-1 Other federal laws applicable to NPDES permits

Federal law	Year	Federal agency	Legislative citations	Implementing regulations
Endangered Species Act (ESA)	1973	FWS, NMFS	16 U.S.C. 1531 et seq.	50 CFR Part 402
National Environmental Policy Act (NEPA)	1969	CEQ	42 U.S.C. 4321 et seq.	40 CFR Part 6
National Historic Preservation Act (NHPA)	1992	ACHP	16 U.S.C. 470 et seq.	36 CFR Part 800
Coastal Zone Management Act (CZMA)	1972	NOAA	16 U.S.C. 1451 et seq.	15 CFR Part 930
Wild and Scenic Rivers Act	1968	Various	16 U.S.C. 1271 et seq.	36 CFR Part 297
Fish and Wildlife Coordination Act (FWCA)	1934	FWS	16 U.S.C. 661 et seq.	--
Essential Fish Habitat Provisions (EFH)	1996	NOAA	16 U.S.C. 1855(b)(2)	50 CFR Part 600

11.1.1 Endangered Species Act

This section discusses procedures intended to protect endangered species that apply only to permits issued by EPA. The 1973 Endangered Species Act (ESA) <www.fws.gov/endangered/esa-library/pdf/ESAall.pdf>, 16 U.S.C. 1531 *et seq.*, was enacted to protect and conserve endangered and threatened species and critical habitat. The Fish and Wildlife Service (FWS) <www.fws.gov/endangered/> of the Department of the Interior and the National Marine Fisheries Service (NMFS) <www.nmfs.noaa.gov/pr/> of the National

NMED Exhibit 70

Oceanic and Atmospheric Administration (NOAA) within the Department of Commerce (collectively *the Services*) share primary responsibility for administration of the ESA.

ESA section 7 requires that federal agencies consult with the Services to ensure that any action authorized, funded, or carried out by the agencies that could affect a listed species or critical habitat and to ensure that their actions are not likely to jeopardize the continued existence of any endangered species or threatened species, or result in the destruction or adverse modification of critical habitat of such species. The ESA section 7 regulations are in 50 CFR Part 402. FWS/NMFS published the ESA Section 7 Consultation Handbook <www.fws.gov/endangered/esa-library/pdf/TOC-GLOS.PDF> to address the major consultation processes pursuant to ESA section 7.

Consultation may be either informal or formal. An informal consultation determines if an action is or is not likely to adversely affect the species. A formal consultation is required if the findings from the informal consultation show that there is a likelihood for adverse impacts and evaluates whether the proposed action is likely to jeopardize the continued existence of the species. It is EPA's responsibility to ensure that consultation occurs; however, a nonfederal representative (i.e., the discharger) may be designated for the informal consultation.

On February 22, 2001, EPA entered into a National Memorandum of Agreement (*National MOA*) <www.epa.gov/fedrgstr/EPA-SPECIES/2001/February/Day-22/e2170.pdf> with the Services that outlines the process for consulting on federally issued NPDES permits. In addition, because consultation is not required for state-issued permits, the National MOA includes a process for coordinating with the Services on state-issued permits. EPA permit writers should review the ESA consultation regulations and the ESA section 7 Consultation Handbook, and coordinate with the Region's ESA coordinator (if such a position has been established in a Region) and the Service office(s) nearest to the site.

11.1.2 National Environmental Policy Act

This section discusses environmental review procedures that apply only when EPA issues permits to *new sources* (dischargers subject to New Source Performance Standards). The 1969 National Environmental Policy Act (NEPA) <www.epa.gov/compliance/basics/nepa.html>, 42 U.S.C. 4321 *et seq*., requires that agencies perform environmental impact reviews and prepare an *Environmental Impact Statement* (EIS) for major federal actions significantly affecting the quality of the human environment [see section 102(2)(C)]. The President's Council on Environmental Quality (CEQ) <www.whitehouse.gov/ceq/> coordinates federal environmental efforts to comply with NEPA.

Within EPA, the Office of Federal Activities under the Office of Enforcement and Compliance Assurance (OECA) is responsible for EPA's implementation of NEPA <www.epa.gov/compliance/nepa/>. EPA's NEPA regulations are at 40 CFR Part 6. With respect to NPDES permits, CWA section 511 establishes that only EPA-issued permits to new sources are subject to NEPA's environmental review procedures before permit issuance. States may have their own state law versions of NEPA. Federal permit writers should coordinate efforts with the Office of Federal Activities and document all NEPA activities in the permit file and fact sheet.

NMED Exhibit 70

11.1.3 National Historic Preservation Act Amendments

Section 106 of the 1992 National Historic Preservation Act (NHPA) <www.achp.gov/nhpa.html>, 16 U.S.C. 470 *et seq.*, as amended, and implementing regulations 36 CFR Part 800 require the Regional Administrator, before issuing a license (permit), to identify the area of potential effect of a permitted discharge and, if historic or cultural resources within that area would be adversely affected by the discharge, to adopt measures when feasible to mitigate potential adverse effects of the licensed activity and properties listed or eligible for listing in the National Register of Historic Places.

The Act's requirements are to be implemented in cooperation with State Historic Preservation Officers <www.achp.gov/shpo.html>, and upon notice to, and when appropriate, in consultation with the Advisory Council on Historic Preservation <www.achp.gov/>, which provides national oversight for the NHPA. A decision by the D.C. Circuit in 2003 concluded that NHPA consultation is not required for state-issued permits (*National Mining Ass'n v. Fowler*, 324 F.3d 752 (D.C. Cir. 2003) <caselaw.findlaw.com/us-dc-circuit/1169695.html>).

Federal permit writers should evaluate potential effects of NHPA and submit written documentation of the evaluation to the State Historic Preservation Office and to the permit file.

11.1.4 Coastal Zone Management Act

The 1972 Coastal Zone Management Act (CZMA) <www.coastalmanagement.noaa.gov/czm/czm_act.html>, 16 U.S.C. 1451 *et seq.*, was enacted to manage the nation's coastal zone and is implemented through a state-federal partnership. Section 307 of the CZMA (16 U.S.C. 1456 and 15 CFR Part 930) prohibits the issuance of federal NPDES permits for activities affecting land or water use in coastal zones unless the permit applicant certifies that the proposed activity complies with the state Coastal Zone Management Program and the relevant state either concurs with the applicant's certification or the state's concurrence is conclusively presumed as a result of the state's failure to concur or non-concur. *Coastal States*, according to the CZMA, include those states and territories adjacent to the Atlantic, Pacific, or Arctic oceans; the Gulf of Mexico; or one or more of the Great Lakes. Any of those states that have completed the development of its management program is required, as a condition of receipt of federal grant money under the CZMA, to adopt coastal management plans, which designate boundaries, identify areas of particular concern, and establish inventories of permitted uses and enforcement policies. Beach access, emergency planning, and erosion control also must be addressed in such plans.

The Office of Ocean and Coastal Resource Management <www.coastalmanagement.noaa.gov/>, which is part of NOAA within the Department of Commerce, oversees the CZMA. The CZMA implementing regulations are at 15 CFR Part 930. EPA and other federal agencies must coordinate their activities on coastal lands with state CZMA plans. Federal permit writers should document all activities relating to CZMA in the permit file.

11.1.5 Wild and Scenic Rivers Act

The 1968 Wild and Scenic Rivers Act (WSRA) <www.rivers.gov/publications/wsr-act.pdf>, 16 U.S.C. 1271 *et seq.*, established a National Wild and Scenic Rivers System (System) and prescribed the process by which additional rivers may be added to this System. Rivers may be added by act of Congress [WSRA section 2(a)(i)] or by the Secretary of the Interior at the initiative of a state governor [WSRA section 2(a)(ii)]. Under WSRA section 7(a), EPA is prohibited from assisting, by license or otherwise, in the construction

NMED Exhibit 70

of any water resources project that would have a direct and adverse effect on the values for which a national wild and scenic river was established. The WSRA regulations are codified at 36 CFR Part 297.

Federal permit writers should verify whether the receiving water is part of the System and document all activities related to the Act in the permit file and fact sheet. For detailed explanation of WSRA section 7, refer to Wild and Scenic Rivers Act: Section 7 <www.rivers.gov/publications/section-7.pdf>, a technical report of the Interagency Wild and Scenic Rivers Coordinating Council. Permit writers may also refer to Water Quantity and Quality as Related to the Management of Wild and Scenic Rivers <www.rivers.gov/publications/water.pdf>, a technical report of the Interagency Wild and Scenic Rivers Coordinating Council.

11.1.6 Fish and Wildlife Coordination Act

The 1934 Fish and Wildlife Coordination Act (FWCA) <www.fws.gov/habitatconservation/fwca.html>, 16 U.S.C. 661 *et seq.*, requires mitigation for the loss of wildlife habitat due to the construction of federal water resources projects. The FWCA requires designers of federal dams, reservoirs, and irrigation works to include the costs and benefits to fish and wildlife when determining the benefit/cost ratio of a project and requires that EPA and other federal agencies consult with state and federal wildlife and fisheries agencies to minimize the impacts of the activity on fish and wildlife. The FWCA specifically calls for ongoing studies by the U.S. Department of the Interior on the effects of domestic sewage and industrial wastes on fish and wildlife (16 U.S.C. 665).

No implementing regulations directly related to the FWCA and NPDES permits exist. However, the FWCA describes actions taken or compelled by the affected federal agencies. The Water Resources Development under the Fish and Wildlife Coordination Act manual <www.fws.gov/habitatconservation/fwca.pdf> provides the FWS guidance on implementing the FWCA. Federal permit writers should note any FWCA consultation activities in the permit file.

11.1.7 Essential Fish Habitat Provisions

The 1996 Essential Fish Habitat (EFH) provisions of the Magnuson-Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act or MSA) promote the protection of essential fish habitat in any federal action authorized, funded, or undertaken, or proposed to be authorized, funded, or undertaken, by such agency that might adversely affect such habitat identified under the MSA [16 U.S.C. 1855(b)(2)]. The MSA requires that federal agencies, such as EPA, consult with the NMFS for any EPA-issued permits that might adversely affect essential fish habitat identified under the MSA. The regulations applicable to federal agencies' coordination and consultation under the MSA are codified at 50 CFR 600.905 through 600.930, and other EFH information can be found on the NMFS EFH Website <www.habitat.noaa.gov/protection/efh/index.html>. Federal permit writers should note any EFH determinations and consultation activities in the permit file.

11.2 Documentation for Development of the Draft Permit

EPA regulations at 40 CFR 124.2 define a draft permit as a document that indicates the Director's tentative decision to issue or deny, modify, revoke and reissue, terminate, or reissue a permit. After the permit is issued, the fact sheet and supporting documentation (administrative record) are the primary support for defending the permit in the administrative appeals process. Documenting the permit requires

NMED Exhibit 70

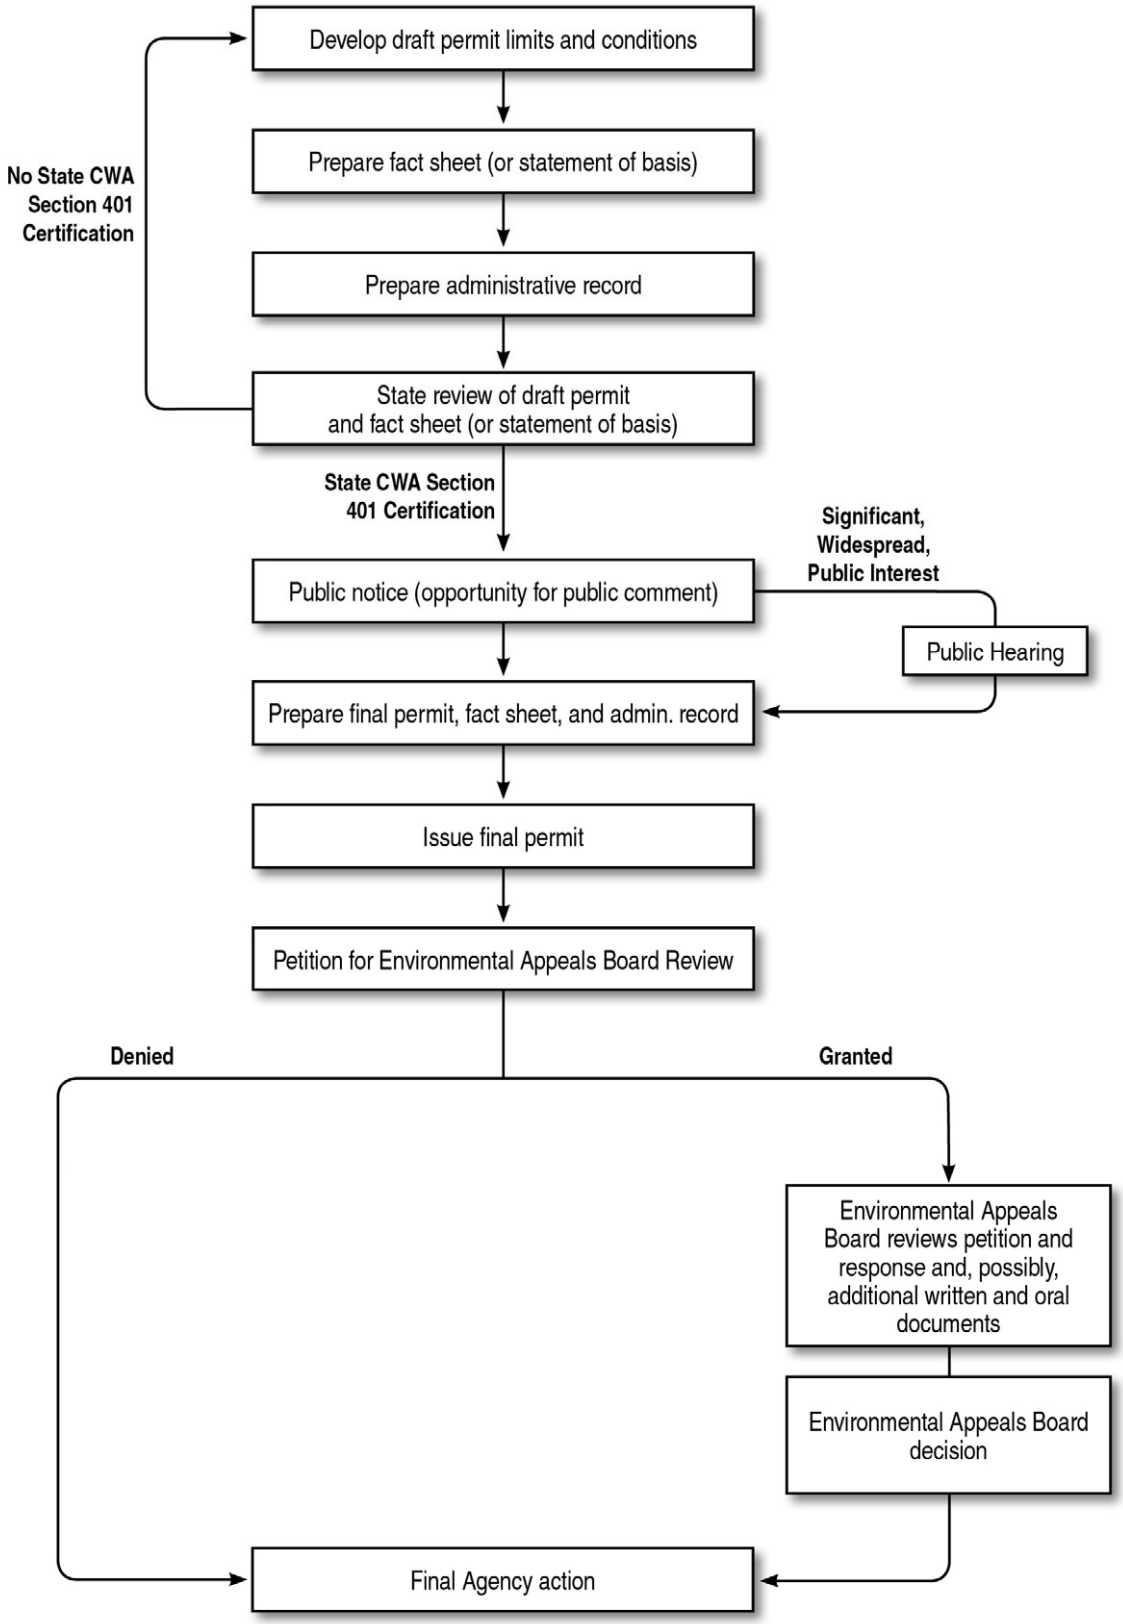
the permit writer to be organized and logical throughout the permit development process. Some of the content of the fact sheet and administrative record is specified by federal and state regulation, and the remainder is dictated by good project management. Permit writers should recognize the importance of

- Developing a thorough permit in a logical fashion.
- Meeting legal requirements for preparation of an administrative record, fact sheet, and statement of basis.
- Substantiating permit decisions and providing a sound basis for the derivation of permit terms, conditions, and limitations if challenges are made.
- Establishing a permanent record of the basis of the permit for use in future permit actions.

Exhibit 11-2 presents reasons for good documentation in the permit file and fact sheet.

Exhibit 11-2 Reasons for good documentation

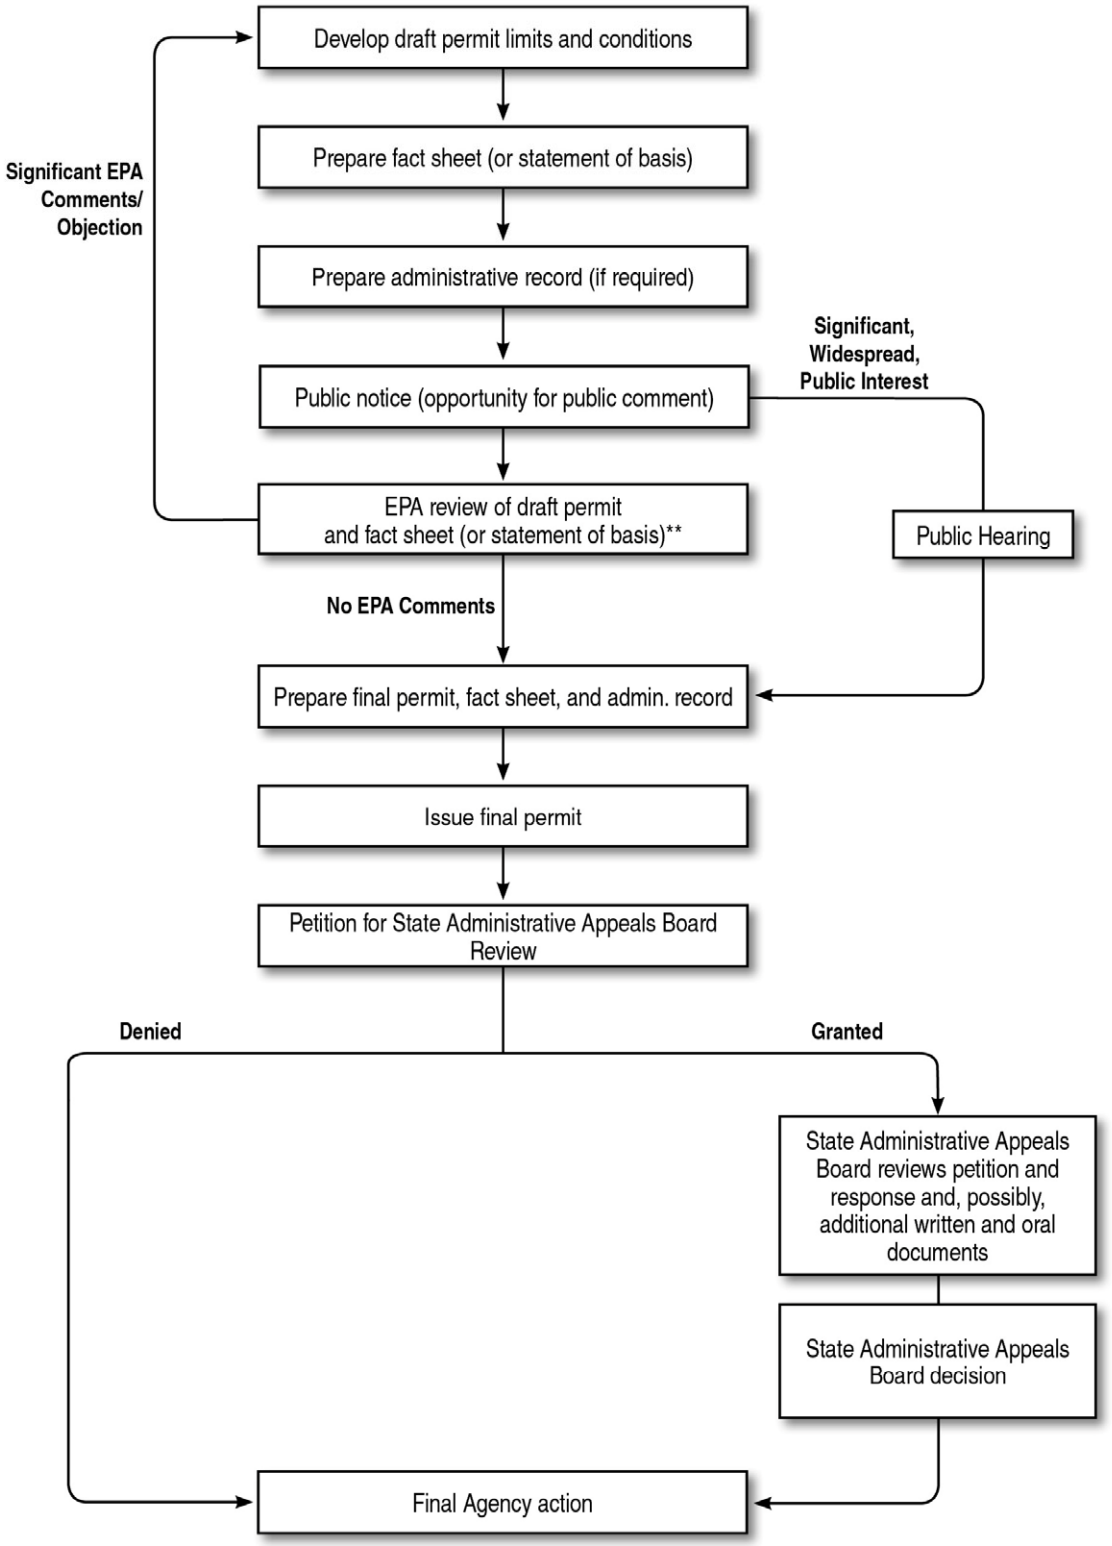
- Streamlines the permit reissuance/ compliance monitoring process
- Establishes a permanent record of the basis for the permit
- Explains the legal and technical basis of the permit
- Provides a sound basis for future modifications and permits
- Requires the permit writer to be organized and logical throughout permit development process



Exhibits 11-3 and 11-4 provide flow diagrams of the NPDES permit administrative process. In general, the administrative process includes the following:

- Documenting all permit decisions.
- Coordinating EPA and state review of the draft (or proposed) permit.
- Providing public notice, conducting hearings (if appropriate), and responding to public comments.
- Defending the permit and modifying it (if necessary) after issuance.

Note that Exhibit 11-3 provides the general framework for the administrative process where EPA is the NPDES permitting authority and Exhibit 11-4 provides a typical framework for the administrative process where a state is the permitting authority. State requirements need not be identical to federal regulatory requirements, provided they are at least as stringent. Some authorized states have slightly different processes for developing and issuing NPDES permits. The same holds true for the appeal process. This manual presents EPA's procedure; state procedures for NPDES permit hearings and appeals vary according to state law.



NMED Exhibit 70

Exhibit 11-3 Administrative process for EPA-issued NPDES permits

NMED Exhibit 70

Exhibit 11-4 Typical administrative process for state-issued NPDES permits*

* State statutes and regulations govern the specific steps of the state administrative process, which may differ from the process outlined in this exhibit.
** Under State/EPA MOA, EPA may review draft or proposed permit.

11.2.1 Administrative Record

The administrative record should be considered the foundation that supports the NPDES permit. If EPA issues the permit, the contents of the administrative record are prescribed by regulation, with § 124.9 identifying the required content of the administrative record for a draft permit and § 124.18 describing the requirements for final permits. Regardless of whether a state or EPA issues the permit, all supporting materials must be made available to the public at any time and may be examined during the public comment period and any subsequent public hearing. The importance of maintaining the permit records in a neat, orderly, complete, and retrievable form cannot be over emphasized. The record allows personnel from the permitting agency to reconstruct the justification for a given permit and defend the permit during any legal proceedings regarding the permit.

The administrative record for a draft permit consists, at a minimum, of the specific documents shown in Exhibit 11-5. Materials that are readily available in the permit issuing office or published material that is generally available do not need to be physically included with the record as long as they are specifically referred to in the fact sheet or statement of basis. If EPA issues a draft permit for a new source, the administrative record should include any EISs or *Environmental Assessments* (EAs) performed in accordance with § 122.29(c).

Exhibit 11-5 Elements of the administrative records for a draft permit

- Permit application and supporting data
- Draft permit
- Statement of basis or fact sheet
- All items cited in the statement of basis or fact sheet, including calculations used to derive the permit limitations
- Meeting reports
- Correspondence with the applicant and regulatory personnel
- All other items in the supporting file
- For new sources, any EA, draft/final EIS, or other such background information, such as a Finding of No Significant Impact (only applies if EPA issues the permit)

The administrative record should include all meeting reports and correspondence with the applicant and other regulatory agency personnel, trip reports, and records of telephone conversations. All correspondence, notes, and calculations should be dated and indicate the name of the writer and all other persons involved. Because correspondence is subject to public scrutiny, references or comments that do not serve an objective purpose should be avoided. Finally, the presentation of calculations and documentation of decisions should be organized in such a way that they can be reconstructed and the logic supporting the calculation or decisions can easily be found.

11.2.2 Fact Sheets and Statements of Basis

A fact sheet is a document that briefly sets forth the principal facts and the significant factual, legal, methodological, and policy questions considered in preparing the draft permit. When the permit is in the draft stage, the fact sheet and supporting documentation serve to explain the rationale and assumptions used in deriving the limitations to the discharger, the public, and other interested parties.

NMED Exhibit 70

The NPDES regulations at § 124.8(a) stipulate that every EPA and state-issued permit must be accompanied by a fact sheet if the permit

- Involves a major facility or activity.
- Incorporates a variance or requires an explanation under § 124.56(b) (toxic pollutants, internal waste stream, and indicator pollutants and for privately owned waste treatment facilities).
- Is an NPDES general permit.
- Is subject to widespread public interest.
- Is a Class I sludge management facility.
- Includes a sewage sludge land application plan.

A well-documented rationale for all permit decisions reduces the work necessary to reissue a permit by eliminating conjecture concerning the development of those permit conditions that are being carried forward to the next permit. That is also true if a modification is initiated during the life of the permit. The required contents of a fact sheet, as specified in §§ 124.8 and 124.56, are listed in Exhibit 11-6.

Exhibit 11-6 Required elements of a fact sheet

Required element	Regulatory citation (40 CFR)
General facility information • Description of the facility or activity • Sketches or a detailed description of the discharge location • Type and quantity of waste/pollutants discharged	 § 124.8 § 124.56 § 124.8
Summary rationale of permit conditions • Summary of the basis for the draft permit conditions • References to the applicable statutory or regulatory provisions • References to the administrative record	§ 124.8
Detailed rationale of permit conditions • Explanation and calculation of effluent limitations and conditions • Specific explanations of – Toxic pollutant limitations – Limitations on internal wastestreams – Limitations on indicator pollutants – Case-by-case requirements – Decisions to regulate non-publicly owned treatment works (POTWs) under a separate permit • For EPA-issued permits, the requirements of any state certification • For permits with a sewage sludge land application plan, a description of how all required elements of the land application plan are addressed in the permit • Reasons why any requested variances do not appear justified, if applicable	 § 124.56 § 124.8
Administrative Requirements • A description of the procedures for reaching a final decision on the draft permit, including – Public comment period beginning and ending dates – Procedures for requesting a hearing – Other procedures for public participation • Name and telephone number of the person to contact for additional information	 § 124.8

NMED Exhibit 70

The fact sheet should include detailed discussions of the development of permit limitations for each pollutant, including the following:

- Calculations and assumptions related to production and flow.
- Type of limitations (i.e., limitations based on secondary treatment standards, effluent limitations guidelines and standards (effluent guidelines), case-by-case determinations, or water quality standards).
- Whether the effluent guidelines used were Best Practicable Control Technology Currently Available (BPT), Best Available Technology Economically Achievable (BAT), Best Conventional Pollutant Control Technology (BCT), or New Source Performance Standards (NSPS).
- The water quality standards or criteria used.
- Whether any parameters were used as indicators for other pollutants.
- Citations to appropriate wasteload allocation or total maximum daily load studies, guidance documents, other references.

Often, decisions to include certain requirements lead to a decision to exclude other requirements. It is just as important to keep a thorough record of items that were not included in the draft permit as it is to keep a record of included items. Such records might include the following:

- Why were secondary treatment standards, case-by-case determinations, or effluent guidelines used as the basis for final effluent limitations rather than water quality standards (i.e., demonstrate that the limitations checked to see that water quality standards would be attained)?
- Why was biomonitoring not included?
- Why were pollutants that were reported as present in the permit application not specifically limited in the permit?
- Why is a previously limited pollutant no longer limited in the draft permit?

Finally, the fact sheet should address the logistics of the permit issuance process, including the beginning and ending dates of the public comment period, procedures for requesting a hearing, and other means of public involvement in the final decision.

A statement of basis, as described in § 124.7, is required for EPA-issued permits that are not required to have a fact sheet. A statement of basis describes the derivation of the effluent limitations and the reasons for special conditions. However, a prudent permit writer will develop the detailed rationale required in a fact sheet for any permit that includes complex calculations or special conditions (e.g., case-by-case effluent limitations based on best professional judgment [BPJ]) even if a fact sheet is not required by regulation.

11.3 Items to Address before Issuing a Final Permit

This section describes the public participation activities that must be conducted in the permit issuance process. These include providing public notices, collecting and responding to public comments, and holding public hearings as necessary.

NMED Exhibit 70

11.3.1 Public Notice

The public notice is the vehicle for informing all interested parties and members of the general public of the contents of a draft NPDES permit or other significant actions with respect to an NPDES permit or permit application. The basic intent of this requirement is to ensure that all interested parties have an opportunity to comment on significant actions of the permitting agency with respect to NPDES permits. The exact scope, required contents, and methods for effecting public notices are found in § 124.10. The NPDES permit-related actions for which public notice is required are shown in Exhibit 11-7.

Exhibit 11-7 Actions for which public notice is required

- Tentative denial of an NPDES permit application (not necessarily applicable to state programs)
- Preparation of a draft NPDES permit, including a proposal to terminate a permit
- Scheduling of a public hearing
- An appeal has been granted by the Environmental Appeals Board
- Major permit modifications (after permit issuance)
- New Source determinations (EPA only)

The permit writer should be particularly concerned with the first three items in Exhibit 11-7. It is important to note that no public notice is required when a request for a permit modification, revocation, reissuance, or termination is denied.

Public notice of NPDES permit-related activities should be provided using the following methods:

- For major permits, publication of a notice in daily or weekly newspaper within the area affected by the facility or activity.
- For general permits issued by EPA, publication in the FR.
- For all permits, direct mailing to various interested parties. This mailing list should include the following:
  - The applicant.
  - Any interested parties on the mailing list.
  - Any other agency that has issued or is required to issue a Resource Conservation and Recovery Act (RCRA), Underground Injection Control (UIC), Prevention of Significant Deterioration (PSD) (or other permit under the Clean Air Act), NPDES, CWA section 404, sludge management, or ocean dumping permit under the Marine Research Protection and Sanctuaries Act for the same facility or activity.
  - Federal and state agencies with jurisdiction over fish, shellfish, and wildlife resources and over coastal zone management plans, the Advisory Council on Historic Preservation, State Historic Preservation Officers, including any affected states and tribes.
  - State agencies conducting area-wide and continuing planning under CWA sections 208(b)(2), 208(b)(4) or 303(e) and the FWS, NMFS, and the U.S. Army Corps of Engineers.
  - Users identified in the permit application of a privately owned treatment work.
  - Persons on any mailing lists developed by including those who request inclusion in writing and persons solicited for *area lists* from participants in past permit proceedings in the area.
  - Any local government having jurisdiction over the locality of the facility.

NMED Exhibit 70

A public notice must contain the information shown in Exhibit 11-8.

Exhibit 11-8 Contents of the public notice

- Name and address of the office processing the permit action
- Name and address of the permittee or applicant and, if different, of the facility or activity regulated by the permit
- A brief description of the business conducted at the facility or activity described in the permit
- Name, address, and telephone number of a contact from whom interested persons can obtain additional information
- A brief description of the comment procedures required, the time and place of any hearing to be held including procedures to request a hearing
- For EPA-issued permits, the location and availability of the administrative record and the times at which the record will be open for public inspection and a statement that all data submitted by the applicant is available as part of the administrative record
- A description of the location of each existing or proposed discharge point and the name of the receiving water and the sludge use and disposal practice(s) and the location of each sludge treatment works treating domestic sewage and use or disposal sites known at the time of permit application
- Requirements applicable to a thermal variance under CWA section 316(a)
- Requirements applicable to cooling water intake structures under CWA section 316(b)
- Any additional information considered necessary

The regulatory agency preparing the permit must provide public notice of the draft permit (including a notice of intent to deny a permit application), and it must provide at least 30 days for public comment. The draft permit is usually submitted for public notice after it has undergone internal review by the regulatory agency that is issuing the permit. State-issued permits typically undergo public notice after EPA has reviewed and commented on the draft permit. In the special case of those EPA-issued permits that require an EIS, public notice is not given until after a draft EIS is issued.

11.3.2 Public Comments

Public notice of a draft permit might elicit comments from concerned individuals or agencies. Frequently, such comments are simply requests for additional information. However, some comments are of a substantive nature and suggest modifications to the draft permit or indicate that the draft permit is inappropriate for various reasons. In such cases, commenters must submit all reasonable arguments and factual material in support of their positions and comments by the close of the public comment period, and the permitting authority must consider those comments in making final decisions. If the approach is technically correct and clearly stated in the fact sheet, it will be difficult for commenters to find fault with the permit. Commenters can always suggest alternatives, however. In addition, an interested party may also request a public hearing.

To the extent possible, it is desirable to respond to all public comments as quickly as possible. In some cases, it might be possible to diffuse a potentially controversial situation by providing further explanation of permit terms and conditions. Additionally, permit writers should also consider notifying commenters that their comments have been received and are being considered.

The permitting agency must respond to all significant comments, in accordance with § 124.17, at the time a final permit decision is reached (in the case of EPA-issued permits) or at the same time a final permit is

NMED Exhibit 70

actually issued (in the case of state-issued permits). The response should incorporate the following elements:

- Changes in any of the provisions of the draft permit and the reasons for the changes.
- Description and response to all significant comments on the draft permit or the permit application raised during the public comment period or during any hearing.

If any information is submitted during the public comment period raises substantial new questions about the draft permit, one of the following actions can occur:

- A new draft permit with a revised fact sheet or statement of basis is prepared.
- A revised statement of basis, a fact sheet, or revised fact sheet is prepared, and the comment period is reopened.
- The comment period is reopened but is limited to new findings only.

If any of those actions is taken, a new public notice, as described earlier, must be given.

For EPA-issued permits, any documents cited in the response to comments must be included in the administrative record. If new points are raised or new material is supplied during the public comment period, EPA may document its response to these new materials by adding new materials to the administrative record.

11.3.3 Public Hearings

Any interested party may request a public hearing. The request should be in writing and should state the nature of the issues proposed to be raised during the hearing. However, a request for a hearing does not automatically necessitate that a hearing be held. A public hearing should be held when there is a significant amount of interest expressed during the public comment period or when it is necessary to clarify the issues involved in the permit decision.

Thus, the decision of whether to hold a public hearing is actually a judgment call. Such decisions are usually made by someone other than the permit writer. However, the permit writer will be responsible for ensuring that all the factual information in support of the draft permit is well documented.

Public notice of a public hearing must be given at least 30 days before the public meeting. Public notice of the hearing may be given at the same time as public notice of the draft permit, and the two notices may be combined. The public notice of the hearing should contain the following information:

- Brief description of the nature and purpose of the hearing, including the applicable rules and procedures.
- Reference to the dates of any other public notices relating to the permit.
- Date, time, and place of the hearing.

Scheduling a hearing automatically extends the comment period until at least the close of the hearing [§ 124.12(c)] and the public comment period may be extended by request during the hearing. Anyone may submit written or oral comments concerning the draft permit at the hearing. A presiding officer is responsible for scheduling the hearing and maintaining orderly conduct, including setting reasonable time

NMED Exhibit 70

limitations for oral statements. Note that a transcript or recording of the hearing must be available to interested persons.

11.3.4 Reserved

11.3.5 EPA and State/Tribal Roles in Reviewing Draft Permits

The CWA and the NPDES regulations include review roles for EPA and for states, tribes, and territories (states) depending on whether EPA or a state is issuing an NPDES permit.

11.3.5.1 State-issued Permits

Each authorized state administering an NPDES program must transmit to the EPA Region copies of permit applications received and copies of draft or proposed permits [§ 123.43(a)]. The state and the EPA Region execute a Memorandum of Agreement (MOA) under § 123.24 that addresses administration and enforcement of the state's regulatory program. The MOA may specify that EPA will review draft permits rather than proposed permits [§ 123.44(j)] and specify the classes or categories of permit applications and draft or proposed permits that the state will send to the EPA Region for review, comment, and, where applicable, objection. In addition, the MOA specifies classes or categories of permits for which EPA will waive its right to review the draft or proposed permit. EPA cannot waive its right to review classes or categories of permits for the following:

- Discharges into the territorial seas.
- Discharges that could affect waters of a state other than the one in which the discharge originates.
- Discharges proposed to be regulated by general permits.
- Discharges from a POTW with a daily average discharge exceeding 1 million gallons per day.
- Discharges of uncontaminated cooling water with a daily average discharge exceeding 500 million gallons per day.
- Discharges from any major discharger or from any NPDES primary industry category.
- Discharges from other sources with a daily average discharge exceeding 500,000 gallons per day (however, EPA may waive review for non-process wastewater).

The MOA provides a period up to 90 days from receipt of a permit during which the EPA Region can make general comments on, objections to, or recommendations with respect to the permit. If the EPA

NMED Exhibit 70

Region objects to a permit, within 90 days of receiving the permit it must transmit to the state a statement of the reasons for the objection and the actions that the state must take to eliminate the objection [§ 123.44(a)-(b)]. Specific causes for objection are outlined in the regulations at § 123.44(c). Any interested party can request a public hearing on an objection by the EPA Region. After such a hearing, the Region can affirm the objection, modify the terms of the objection, or withdraw the objection and notify the state of that decision. If the EPA Region does not withdraw the objection, the state then has 30 days to resubmit a permit revised to meet the objection. If the state does not do so, exclusive authority to issue the permit passes to the EPA Region. If no public hearing on the objection is held, the time frame for the state to resubmit a revised permit is 90 days from receipt of the objection.

11.3.5.2 EPA-issued Permits

Permits issued by EPA require an opportunity for state review and certification under CWA section 401. The state in which a discharge originates or will originate is provided the opportunity to review an application or a draft permit and certify that the discharge will comply with the applicable water quality standards. This process also has the benefits of ensuring that state initiatives or policies are addressed in EPA-issued NPDES permits and promoting consistency between state-issued and EPA-issued permits where not all permits within the state are issued by the same agency.

Regulations at §§ 124.53 (State Certification) and 124.54 (Special provisions for state certification and concurrence on applications for CWA section 301(h) variances) describe procedures an EPA permit writer should follow to obtain state certification. Under CWA section 401(a)(1), EPA may not issue a permit until a certification is granted or waived. If EPA is preparing the draft permit, state certification can be accomplished by allowing states to review and certify the application before draft permit preparation. Under § 124.53, if EPA has not received a state certification by the time the draft permit is prepared, EPA must send the state a copy of the draft permit along with a notice requesting state certification.

If the state does not respond within a specified reasonable time, which cannot exceed 60 days, it is deemed to have waived its right to certify. If the state chooses to certify the draft permit, it may include any conditions more stringent than those in the draft permit necessary to ensure compliance with the applicable provisions of the CWA or state law, and must cite the CWA or state law references that support the changes. In addition, the state is required to include a statement of the extent to which each condition of the draft permit can be made less stringent without violating the requirements of state law, including water quality standards. Failure to provide this statement for any condition waives the right to certify or object to any less stringent condition that might be established during the EPA permit issuance process. When a permit applicant requests a CWA section 301(h) variance (§ 124.54), the state certification process is very similar to the process described above. For more on CWA section 301(h) variances, see section 5.1.3.5 of this manual.

11.3.6 Schedule for Final Permit Issuance

The final permit may be issued after the close of the public notice period and after state certification has been received (for permits issued by EPA). The public notice period consists of the following:

- A 30-day period that gives notice of intent to issue or deny the permit.
- A 30-day period advertising a public hearing (if applicable).
- Any extensions or reopening of the comment period.

NMED Exhibit 70

Final EPA permit decisions are effective immediately upon issuance unless comment were received on the draft permit, in which case, the effective date of the permit is 30 days after issuance (or a later date if specified in the permit). In addition, permit decisions will not be immediately effective if review is requested on the permit under § 124.19. As discussed earlier, any comments that are received must be answered at the time of final permit issuance (in the case of NPDES states or tribes) or after a final decision is reached (in the case of EPA). The administrative record for the final permit consists of the items in Exhibit 11-9.

Exhibit 11-9 Elements of the administrative records for a final permit

- All elements for the draft permit administrative record (see Exhibit 11-5)
- All comments received during the comment period
- The tape or transcript of any public hearing
- Any materials submitted at a hearing
- Responses to comments
- For NPDES new source permits, the draft or final EIS
- The final permit

11.4 Administrative Actions after Final Permit Issuance

Once the final permit has been issued, the issuing authority should enter the permit limitations and any special conditions into the Integrated Compliance Information System for the NPDES program (ICIS-NPDES) (for more on ICIS-NPDES, see the introduction to this manual and section 11.5.1.1 below). Entering permit information into ICIS-NPDES will ensure that the facility's performance will be tracked and the permitting agency will be alerted to the need for corrective action if violations of permit limitations, terms, or conditions occur.

After final permit issuance, interested parties have opportunities to change the permit through permit appeals, major/minor permit modifications, termination and revocation, or transfer. Those administrative procedures are described below.

11.4.1 Permit Appeals

Throughout the process of developing a permit and during the public notice period, the permit writer should carefully consider all legitimate concerns of the applicant/permittee and any other interested party. Nevertheless, there will inevitably be situations in which a permit is issued in spite of the objections of the permittee or a third party. In such instances, the permittee or interested party can choose to legally contest or appeal the NPDES permit, as provided in § 124.19. Permit appeals are the process by which any person that filed comments on the draft permit may contest the final limitations and conditions in a permit.

Appeals of EPA-issued permits consist of petitioning the Environmental Appeals Board (EAB) for review. Such review must be requested within 30 days of issuance of the final permit, and challenges must be limited to issues raised during the draft permit's public comment or hearing processes, although persons not participating in these processes may seek review of changes in the permit from draft to final permit. During the appeals process, only those conditions of an existing permit that are being contested

NMED Exhibit 70

are stayed. Within a reasonable time following the filing of the petition for review, the EAB must grant or deny the petition. Only individual permits may be appealed to the EAB; general permits may be challenged in court or an individual permit may be sought and appealed.

Many states have similar administrative appeal procedures designed to resolve challenges to the conditions of a permit. For the sake of convenience, such procedures, which could be known by different names (e.g., evidentiary hearing, administrative appeal), are hereafter *permit appeals*. Permit writers will, from time to time, be involved in permit appeals and will need to address the types of issues discussed below.

Aside from preparing the administrative record and notices, the permit writer might not be involved in the procedural matters relating to permit appeals. All requests for permit appeals are coordinated through the office of the EPA Regional Counsel or the appropriate state legal counsel. The permit writer's first involvement with the appeals process will likely come as a result of designation of the appeals staff, and his or her role will be limited to that of a technical advisor to legal counsel and, where a state uses an evidentiary hearing procedure, possibly a witness.

11.4.1.1 Deposition and Testimony

In a state hearing procedure, a permit writer might be required to give a deposition during which the appellant attorney conducts the questioning that would otherwise occur in the hearing. The deposition is transcribed and presented as evidence. The appellant attorney may ask some of the same questions at the hearing.

To prepare for a deposition and testimony, the permit writer should first consult with his or her general counsel to become familiar with laws, regulations, and policies that could affect the permit. The permit writer should also be thoroughly familiar with the technical basis for the permit conditions. For example, if final effluent limitations are based on water quality standards, the permit writer should thoroughly study the applicable water quality standards, water quality models, and procedures used to develop the effluent limitations and be prepared to defend all assumptions and decisions made in the effluent limitation calculations. For case-by-case limitations based on BPJ, the permit writer should carefully review all applicable data and procedures used to calculate the effluent limitations and should be sure that the information on which case-by-case limitations are based is unimpeachable, the limitations were derived from the data in a logical manner in accordance with established procedures, and the limitations are technically sound and meet applicable standards for economic reasonableness.

A permit appeal before the EAB relies on the information presented in the petitions and briefs, and possibly includes oral argument, but typically does not use depositions and direct testimony.

11.4.1.2 The Permit Writer's Role in the Appeals Process

As technical advisor to legal counsel, the permit writer's most important function is to develop support for contested permit conditions. A permit writer should not attempt to support technically indefensible conditions. Contested permit conditions that are not technically defensible and are not based on any legal requirement should be brought to counsel's attention, with advice that EPA or the state withdraw those conditions.

NMED Exhibit 70

The second most important advisory function of the permit writer is assisting counsel in identifying weaknesses in the appellant's arguments. That process could include developing questions for cross-examination of opposing witnesses in a state permit appeal that involves a hearing. Questions should be restricted to the subject material covered by the witness' direct testimony and should be designed to elicit an affirmative or negative response, rather than an essay-type response.

Finally, the permit writer should remember that when a person petitions for EAB review or requests a hearing for a state-issued permit, the permit writer should refrain from any discussion about the case without first consulting with legal counsel.

In the role of technical advisor or witness, the permit writer should do the following:

- Cultivate credibility.
- Never imply or admit weakness in his or her area of expertise.
- Never attempt to testify about subjects outside his or her area of expertise.
- Always maintain good communication with counsel.

The EAB generally will attempt to resolve permit appeals in the initial stage of granting review. If that is not possible, the EAB conducts formal review of the contested conditions and publishes a written opinion (an Environmental Administrative Decision). The result of an EAB or state permit appeal might be relief from certain permit conditions, validation or strengthening of contested permit conditions, or a combination of these two outcomes. Under certain circumstances, decisions of the EAB can be appealed in federal court. Authorized state's permit appeal procedures typically provide for further appeal of administrative decisions regarding contested permit conditions in state court when all administrative steps have been fulfilled.

11.4.2 Modification or Revocation and Reissuance of Permits

In most cases, a permit will not need to be modified (or revoked and reissued) during the term of the permit if the facility can fully comply with permit conditions. However, under certain circumstances, it might be necessary to modify the permit before its expiration date. A permit modification could be triggered in several ways. For example, a representative of the regulatory agency might inspect the facility and identify a need for the modification (i.e., the improper classification of an industry), or information submitted by the permittee might suggest the need for a change. Of course, any interested person may make a request for a permit modification.

Modifications differ from revocations and reissuance. In a permit modification, only the conditions subject to change are reconsidered while all other permit conditions remain in effect. Conversely, the entire permit could be reconsidered when it is revoked and reissued.

Except where the permittee requests or agrees, permit modifications are limited to specific *causes* identified in §§ 122.62(a) and 122.62(b) and summarized in Exhibit 11-10. Most NPDES permit modifications require EPA or the state to conduct the public notice and participation activities of Part 124, similar to the issuance or reissuance of the permit; however, only those specific conditions being modified are open to review and comment. The permitting authority may revoke and reissue a permit during its term for the causes identified in § 122.62(b) (i.e., the final two bulleted items in Exhibit 11-10).

NMED Exhibit 70

Exhibit 11-10 Causes for permit modification

- **Alterations**: When there are material and substantial alterations or changes to the permitted facility or activity occur that justify new conditions that are different from the existing permit.
- **New information**: When information is received that was not available at the time of permit issuance.
- **New regulations**: Under limited circumstances, when standards or regulations on which the permit was based have been changed by the modification, withdrawal or promulgation of amended standards or regulations or by judicial decision.
- **Compliance schedules**: To modify the compliance schedule when good cause exists, such as an act of God, strike, or flood.
- **Variance requests**: When requests for variances or fundamentally different factors are filed within the specified time but not granted until after permit issuance.
- **Toxics**: To insert CWA section 307(a) toxic effluent standard or prohibition.
- **Reopener**: Conditions in the permit that require it to be reopened under certain circumstances.
- **Net limits**: Upon request of a permittee who qualifies for effluent limitations on a net basis under § 122.45(g) or when a permittee is no longer eligible for net limitations, as provided in § 122.45(g)(1)(ii).
- **Pretreatment**: As necessary under § 403.8 (e) to put a compliance schedule in place for the development of a pretreatment program or to change the schedule for program development.
- **Failure to notify**: Upon failure of an approved state to notify another state whose waters may be affected by a discharge from the approved state.
- **Non-limited pollutants**: When the level of any pollutant that is not limited in the permit exceeds the level that can be achieved by the technology-based treatment requirements appropriate to the permit.
- **Notification levels**: To establish notification levels for toxic pollutants as provided in §122.44(f).
- **Compliance schedules for innovative or alternative facilities**: To modify the compliance schedule in light of the additional time that might be required to construct such a facility.
- **Small municipal separate storm sewer system (MS4) minimum control measures**: For a small MS4 to include required minimum control measures when the permit does not include such measure(s) based on the determination that another entity was responsible for implementation and the other entity fails to fulfill its responsibility to implement such measure(s).
- **Technical mistakes**: To correct technical mistakes or mistaken interpretations of law made in developing the permit conditions.
- **Failed BPJ compliance**: When BPJ technology is installed and properly operated and maintained but the permittee is unable to meet its limitations, the limitations may be reduced to reflect actual removal; however, they may not be less than the limitations in the effluent guidelines. If BPJ operation and maintenance costs are extremely disproportionate to the costs considered in a subsequent effluent guideline, the permittee may be allowed to backslide to the limitations in the effluent guideline.
- **Land application plans**: When required by a permit condition to incorporate a land application plan for beneficial reuse of sewage sludge, to revise an existing land application plan, or to add a land application plan.
- **Cause exists for termination**: Cause exists under § 122.64, and the Director determines that modification is appropriate.
- **Notification of proposed transfer**: Director may modify the permit upon receipt of ownership transfer notification.

NMED Exhibit 70

There are certain minor modifications that, upon consent of the permittee, may be processed by the permitting authority without following the procedures for public notice in Part 124. Minor modifications are generally non-substantive changes (e.g., typographical errors) and are exempt from the administrative procedures; that is, a draft permit and public review are not required. The specific permit changes that can be processed as minor modifications, described in § 122.63, are to

- Correct typographical errors.
- Incorporate more frequent monitoring or reporting.
- Revise an interim compliance date in the schedule of compliance, provided the new date is not more than 120 days after the date specified in the permit and does not interfere with attainment of the final compliance date requirement.
- Allow for a change of ownership, provided no other change is necessary (see section 11.4.4 below).
- Change the construction schedule for a new source discharger.
- Delete a point source outfall when that outfall is terminated and does not result in discharge of pollutants from other outfalls except in accordance with permit limits.
- Incorporate an approved local pretreatment program.

11.4.3 Permit Termination

Situations could arise during the life of the permit that are causes for termination of the permit. Such circumstances, described in § 122.64(a), include the following:

- Noncompliance by the permittee with any condition of the permit.
- Misrepresentation or omission of relevant facts by the permittee.
- Determination that the permitted activity endangers human health or the environment, and can be regulated to acceptable levels only by permit modification or termination.
- A change in any condition that requires either a temporary or permanent reduction or elimination of a discharge (e.g., plant closure).

Terminations are used to retract a permittee's privileges to discharge during the permit term. A notice of intent to terminate a permit is a type of draft permit that follows the same procedures as any draft permit prepared under § 124.6. Administrative procedures, such as public notice, must be followed in permit termination proceedings. If a facility with a terminated permit wishes to obtain permit coverage, it would have to submit an application and apply for a new permit.

The regulations at § 122.64(b) do provide one exception to the more formal permit termination process described above. Where the entire discharge is permanently terminated by elimination of the flow or by connection to a POTW (but not by land application or disposal into a well) the permit can be terminated by notice to the permittee, and the Part 124 administrative process is not required. However, if the permittee objects to such an expedited termination, the Permitting Authority must then proceed in accordance with the administrative procedures described above.

NMED Exhibit 70

11.4.4 Permit Transfer

Regulatory agencies occasionally receive notification of a change in ownership of a facility covered by an NPDES permit. Such changes require that a permit be transferred by one of two provisions:

- **Transfer by modification or revocation**: The transfer may be made during the process of a major or minor permit modification. It may also be addressed by revoking and subsequently reissuing the permit.
- **Automatic transfer**: A permit may automatically be transferred to a new permittee if three conditions are met:
  - The current permittee notifies the Director 30 days in advance of the transfer date.
  - The notice includes a written agreement between the old and new owner that contains the specific date for transfer of permit responsibility, coverage, and liability between them.
  - The Director of the regulatory agency does not notify the old permittee and the proposed new permittee that the subject permit will be modified or revoked and reissued.

11.5 Permit Compliance and Enforcement

EPA's OECA is responsible for nationally managing EPA's compliance and enforcement programs for all media including the CWA and NPDES. EPA uses a mix of tools including compliance assistance, incentives, and monitoring and enforcement. EPA and state environmental agencies authorized to administer the NPDES program seek to achieve and maintain a high level of compliance with environmental laws and regulations. Enforcement provides a powerful incentive for NPDES permittees to comply, and the way in which an NPDES permit is written directly affects its enforceability. Each permit must be written clearly and unambiguously so that compliance can be tracked effectively and the permit can be enforced if violations occur.

The permit writer could become actively involved with the compliance monitoring and enforcement of the terms and conditions of the NPDES permits that he or she has written. The extent of the permit writer's involvement will usually depend on the organizational structure of the regulatory agency. Larger, centrally organized agencies typically have separate personnel responsible for enforcing the terms of NPDES permits. In other organizations, the individual who writes the permit will also be responsible for such enforcement activities as discharge monitoring report (DMR) tracking, facility inspections, and enforcement recommendations. If a civil judicial enforcement action occurs, the permit writer might be called on to testify regarding the specific requirements of the permit or its basis.

Regardless of a regulatory agency's organizational structure, the permit writer should have an appreciation for the various aspects of a meaningful NPDES compliance enforcement program. The following sections address compliance monitoring reviews and inspections and data in the national ICIS-NPDES (formerly the Permit Compliance System or PCS) database, which provides the basis for evaluating compliance. This section concludes with a brief description of the enforcement actions available to facilitate permit compliance. For more information about CWA enforcement, see OECA's Clean Water Act Enforcement Website <www.epa.gov/compliance/civil/cwa/index.html>.

NMED Exhibit 70

11.5.1 Compliance Monitoring

Compliance monitoring is a broad term that includes all activities that federal or state regulatory agencies take to ascertain a permittee's compliance with the conditions specified in an NPDES permit. Compliance monitoring data collected as part of the NPDES program are used to evaluate compliance and support enforcement actions. The process includes receiving, reviewing, and entering data into the ICIS-NPDES database, conducting on-site inspections, identifying violators, and determining an appropriate response.

A primary function of the compliance monitoring program is to verify compliance with permit conditions, including effluent limitations and compliance schedules. Compliance verification is achieved through

- **Compliance review**: A review of all written reports and other material relating to the status of a permittee's compliance.
- **Compliance inspections**: Field-related regulatory activities (i.e., facility inspections, effluent sampling) to determine compliance.

11.5.1.1 Compliance Review

Compliance and enforcement personnel use two primary sources of information to carry out compliance reviews:

- Permit/compliance files.
- The ICIS-NPDES database.

Permit/compliance files include the permit, application, fact sheet, compliance schedule reports, compliance inspection reports, DMRs, enforcement actions, and correspondence (e.g., summaries of telephone calls, copies of warning letters). Compliance personnel periodically review that information and use it to determine if enforcement is necessary and, if so, what level of enforcement is appropriate.

The ICIS-NPDES database <https://icis.epa.gov/icis> is the national database for tracking compliance with NPDES requirements and is discussed further in this manual's introduction. Information in ICIS-NPDES includes facility and discharge characteristics, self-monitoring data, compliance schedules, permit conditions, inspections, and enforcement actions. Permittees are required to submit effluent monitoring data, and compliance and status information, via Compliance Schedule Reports and DMRs. EPA Regions and NPDES states enter such information into ICIS-NPDES and evaluate permittees on compliance with NPDES permit requirements. Inspection and enforcement information is collected and entered by Regions or authorized states or both. Quarterly, EPA reviews the ICIS-NPDES system data and generates a *quarterly noncompliance report* (QNCR) for all major facilities following the requirements of § 123.45.

ICIS-NPDES supports compliance and enforcement actions and assists EPA staff in evaluation and oversight of the NPDES program. The database also promotes national consistency and uniformity in permit and compliance evaluations. NPDES permits must be written so that compliance can be tracked using ICIS-NPDES. Situations might arise in which permit limitations and monitoring conditions are not initially compatible with ICIS-NPDES entry and tracking. In such cases, the permit writer should alert the state or EPA Regional staff responsible for entering ICIS-NPDES codes and work with them to resolve any coding issues. To assist ICIS-NPDES coders in accurately interpreting and entering the permit into ICIS-NPDES and to assist enforcement personnel in reviewing permittee's self-monitoring data and

NMED Exhibit 70

reports in a timely manner, permit writers should follow the compliance inspection procedures discussed in the next section.

11.5.1.2 Compliance Inspections

Compliance inspections refer to all field-related regulatory activities conducted to determine permit compliance. Such field activities can include compliance evaluation inspections (non-sampling), sampling inspections, other specialized inspections, and remote sensing. Certain inspections, such as diagnostic inspections and performance audit inspections, aid the regulatory agency in evaluating the facility's problems in addition to providing information to support enforcement action. Biomonitoring inspections are specifically targeted at facilities with effluent suspected or identified as causing toxicity problems that threaten the ecological balance of the receiving waters.

Compliance inspections are undertaken to fulfill one or more of the following purposes:

- Establish a regulatory presence to deter noncompliance.
- Ensure that permit requirements are being met or determine if permit conditions are adequate.
- Check the completeness and accuracy of a permittee's performance and compliance records.
- Assess the adequacy of the permittee's self-monitoring and reporting program including on-site laboratory functions.
- Determine the progress or completion of corrective action.
- Obtain independent compliance data on a facility's discharge.
- Evaluate the permittee's operation and maintenance activities.
- Observe the status of construction required by the permit.

11.5.2 Quarterly Noncompliance Reports

EPA Regional offices and NPDES states are required by the regulations at § 123.45 to report quarterly on major facilities that are not in compliance with the terms and conditions of their permit or enforcement order (i.e., that meet the criteria for *reportable noncompliance* [RNC] for effluent limitation, schedules, and reporting violations).

The regulations in § 123.45 establish requirements for listing facility violations and resulting regulatory enforcement action on QNCRs. The regulation establishes reporting requirements for violations that meet specific, quantifiable reporting criteria, as well as for violations that are more difficult to quantify but are of sufficient concern to be considered reportable. The regulation also specifies the format that the reports must follow and the schedule for their submission.

Only major facilities that meet RNC criteria must be reported on the QNCR. RNC consists of several general types of violations as established in § 123.45:

- Effluent limitations
  - Monthly average effluent limitations (see below for more).
  - Other effluent limitations with water quality or health impacts.

NMED Exhibit 70

- Schedule: Violations of compliance schedule milestones by 90 days or more.
- Reporting: Reports late by 30 days or more.

A violation of any monthly average limitation should be evaluated for magnitude by comparing the measured amount in the DMR to the product of the monthly average limitation times the Technical Review Criteria (TRC) for that pollutant or parameter. The TRC is 1.4 for Group I (conventional) pollutants and 1.2 for Group II (generally toxic) pollutants. Appendix A to Part 123 contains a list of pollutants in each Group. RNC includes violations of a given Group I or Group II pollutant or parameter that equals or exceeds the product of the TRC times the monthly average limitation for any 2 or more months during a 6-month reporting period. RNC also includes violations of a Group I or Group II parameter by any amount (not necessarily TRC times the limitation or greater) for 4 months during the 6-month reporting period.

A subset of instances of RNC that appear on the QNCR could be noted as *significant noncompliance* (SNC). This distinction is used solely for management accountability purposes as a means of tracking trends in compliance and evaluating the relative timeliness of enforcement response toward priority violations.

The definition of SNC is not regulatory and can change as the NPDES program evolves to encompass new enforcement priorities. For example, in September 1995, EPA revised the definition of SNC to include violations of non-monthly average permit limitations by major facilities. Many permits for NPDES major facilities lacked required monthly average limitations and, thus, were not evaluated for SNC violations and follow-up formal enforcement action. The new definition became effective as of October 1, 1996. EPA's SNC policy is described in the memorandum Revision of NPDES Significant Noncompliance (SNC) Criteria to Address Violations of Non-Monthly Average Limits[1] <www.epa.gov/compliance/resources/policies/civil/cwa/revisedsncmemo.pdf>.

Generally, the designation of SNC indicates a violation is of sufficient magnitude or duration or both to be considered among EPA's priorities for regulatory review or response. The categories of SNC are

- Effluent limitations: The effluent limitation SNC criteria are the same as for QNCR discussed above.
- Schedule: The schedule SNC criteria are the same as for QNCR discussed above.
- Reporting: The reporting SNC criteria are the same as for QNCR discussed above.
- Order requirements: Violation of requirements in administrative or judicial orders.

The instance of SNC is considered resolved when the SNC criteria are no longer met during the review period, or when the permittee formerly in SNC exhibits compliance for all 3 months of the most recent 3-month reporting period. A permittee with SNC violations under a compliance schedule that is meeting its deadlines for corrective actions is in *resolved pending* status.

Any major permittee that is listed on the QNCR for two consecutive 3-month reporting periods for the same instance of SNC (e.g., same outfall point, same parameter, same category of violation) is expected to return to compliance or to be addressed with an appropriate enforcement action before the reporting deadline for the second QNCR. If the facility is in SNC after the second QNCR, and no enforcement

NMED Exhibit 70

action has been taken, the facility is placed on the Watch List. The Watch List is a management tool that identifies and tracks facilities with serious violations and no apparent formal enforcement response.

11.5.3 Enforcement

EPA's NPDES compliance and enforcement principles and recommendations are described in the NPDES Enforcement Management System (EMS)[2] <www.epa.gov/compliance/resources/policies/civil/cwa/emscwa-jensen-rpt.pdf>. By choosing an appropriate enforcement response to CWA violations, EPA tries to achieve several goals:

- Correction of the violation as soon as possible.
- Deterrence of future violations by the same permittee or other permittees.
- Equal treatment of the regulated community through use of a uniform approach to selecting enforcement responses (i.e., similar violations are treated similarly).
- Assessment of an appropriate penalty.
- Protection of human health and the environment.

Once a facility has been identified as having potential CWA violations, EPA or the NPDES state reviews the facility's compliance history. The review includes an assessment of the magnitude, frequency, and duration of violations. The permitting authority identifies significant violations and makes a determination of the appropriate enforcement response. CWA section 309 authorizes the Agency to bring civil or criminal action against facilities that discharge pollutants without a permit or discharge in violation of NPDES permit conditions and judicial penalties up to $32,500 per day per violation.

EPA Regions and authorized states have specific procedures for reviewing self-monitoring and inspection data and for deciding what type of enforcement action is warranted. EPA recommends an escalating response to continuing noncompliance. The range of enforcement responses includes the following:

- Informal action (e.g., *notice of violation* [NOV]).
- Formal action.
- Administrative compliance order.
- Administrative order with or without an administrative penalty order (up to $157,500).
- Civil judicial action that imposes injunctive relief seeking compliance or penalty or both.
- Criminal prosecution.

Considerations when making determinations on the level of the enforcement response include the following:

- The duration of the violation.
- The severity of the violation.
- The degree of economic benefit obtained through the violation.
- Compliance history and previous enforcement actions taken against the violator.
- The degree of culpability.
- The deterrent effect of the response on similarly situated permittees.

Equally important considerations may include fairness and equity, national consistency, and the integrity of the NPDES program.

NMED Exhibit 70

Citizens can participate in the enforcement process in a number of ways. Under the Freedom of Information Act, citizens have the right to request certain facility-specific compliance information from EPA's ICIS-NPDES database. In addition, under NPDES regulations, interested citizens can intervene in any federal civil judicial action to enjoin any threatened or continuing violation of program requirements or permit conditions, and to recover civil penalties in court. Citizens also have the opportunity to review and comment on any proposed consent decree to resolve a state or federal civil judicial enforcement action.

CWA section 505 allows any citizen to begin a civil judicial enforcement action on his or her own behalf. In certain circumstances, citizens may not begin suit if EPA or the state is diligently prosecuting a civil or criminal judicial action or an administrative action to obtain a penalty under CWA section 309(g) or a comparable provision of state law. Citizens must also give EPA, the state, and the alleged violator 60 days' notice of the alleged violation before beginning a citizen suit.

Appendix A. Acronyms, Abbreviations and Glossary

This appendix contains two tables for permit writers to more easily navigate through the acronyms and the terms that are mentioned throughout this manual. The first table, *Acronyms and Abbreviations*, provides the full text of the acronyms and abbreviations used throughout and indicates whether they are defined in the *Glossary* (the second table), which provides definitions of terms used in the Clean Water Act and NPDES permit program. It provides a reference to the source of the definitions, where available.

A.1 Acronyms and Abbreviations

Exhibit A-1 presents the abbreviations used in the *NPDES Permit Writers' Manual*.

Exhibit A-1 Acronyms and abbreviations

Acronym or abbreviation	Full phrase	Glossary
1Q10	1-day, 10-year Low Flow	
7Q10	7-day, 10-year Low Flow	
4AAP	4-Aminoantipyrine (used for detecting phenolic compounds colorimetrically)	
ACHP	Advisory Council on Historic Preservation	
ACR	Acute-to-Chronic Ratio	
AFO	Animal Feeding Operation	x
AML	Average Monthly Limitation	x
ASR	Alternative State Requirement	
AWL	Average Weekly Limitation	x
BA	Biological Assessment	
BAT	Best Available Technology Economically Achievable	x
BCT	Best Conventional Pollutant Control Technology	x
BE	Biological Evaluation	
BMP	Best Management Practice	x
BOD	Biochemical Oxygen Demand	x
BOD_5	5-day Biochemical Oxygen Demand	
BPJ	Best Professional Judgment	x
BPT	Best Practicable Control Technology Currently Available	x
CAAP	Concentrated Aquatic Animal Production	
CAFO	Concentrated Animal Feeding Operation	x
CBOD	Carbonaceous Biochemical Oxygen Demand	x
$CBOD_5$	5-day Carbonaceous Biochemical Oxygen Demand	
CEQ	Council on Environmental Quality	
CERCLA	Comprehensive Environmental Response, Compensation and Liabilities Act	
CFR	*Code of Federal Regulations*	x
cfs	Cubic Feet per Second	
CGP	Construction General Permit	
CMOM	Capacity, Management, Operation and Maintenance	

NMED Exhibit 70

Exhibit A-1 Acronyms and abbreviations (continued)

Acronym or abbreviation	Full phrase	Glossary
COD	Chemical Oxygen Demand	x
CSO	Combined Sewer Overflow	x
CSS	Combined Sewer System	x
CV	Coefficient of Variation	
CWA	Clean Water Act	x
CWIS	Cooling Water Intake Structure	
CZMA	Coastal Zone Management Act	
DMR	Discharge Monitoring Report	x
DWO	Dry Weather Overflow	
EA	Environmental Assessment	
EAB	Environmental Appeals Board	
EC	Effect Concentration	
EFH	Essential Fish Habitat	
EIS	Environmental Impact Statement	
ELG	Effluent Limitations Guidelines or Effluent Guidelines	x

WSRA	Wild and Scenic Rivers Act	

A.2 Glossary

Exhibit A-2 includes definitions of terms used in the *NPDES Permit Writers' Manual*. For terms that have a definition in the federal regulations, that definition is included with an appropriate citation. The citations also indicate where this guidance manual has paraphrased or modified the regulatory definitions for consistency with the format of the glossary. For terms that do not have a regulatory definition, but that are defined in another published EPA document, the citation to the relevant EPA document is provided.

Note that the definitions provided in the Glossary do not constitute EPA's official use of terms and phrases for regulatory purposes, and nothing in this document should be construed to alter or supplant any

NMED Exhibit 70

other federal document. Official terminology is in the laws and related regulations as published in such sources as the Congressional Record, *Federal Register*, and elsewhere.

Exhibit A-2 Glossary

Term	Definition	Citation
401(a) Certification	A requirement of CWA section 401(a) that all federally issued permits be certified by the state in which the discharge occurs. The state certifies that the proposed permit will comply with state water quality standards and other state requirements.	1996 U.S. EPA NPDES Permit Writers' Manual (1996 PWM) <www.epa.gov/npdes/pubs/owm0243.pdf>
Acute Effect	The effect of a stimulus severe enough to rapidly induce an effect; in aquatic toxicity tests, an effect generally observed in 96 hours or less is typically considered acute. When referring to aquatic toxicology or human health, an acute effect is not always measured in terms of lethality.	1996 PWM
Animal Feeding Operation (AFO)	Lot or facility (other than an aquatic animal production facility) where the following conditions are met: • Animals (other than aquatic animals) have been, are, or will be stabled or confined and fed or maintained for a total of 45 days or more in any 12-month period. • Crops, vegetation, forage growth, or post-harvest residues are not sustained in the normal growing season over any portion of the lot or facility.	§ 122.23(b)(1)
Anti-backsliding	In general, a statutory provision that prohibits the renewal, reissuance, or modification of an existing NPDES permit that contains effluent limitations, permit conditions, or standards that are less stringent than those established in the previous permit. For more information on anti-backsliding, see Chapter 7 of this manual.	CWA section 402(o)
Antidegradation	A policy developed and adopted as part of a state's water quality standards that ensures protection of existing uses and maintains the existing level of water quality where that water quality exceeds levels necessary to protect fish and wildlife propagation and recreation on and in the water. This policy also includes special protection of water designated as Outstanding National Resource Waters.	Adapted from 1996 PWM
Authorized Program or Authorized State	A state, territorial, tribal, or interstate NPDES program that has been approved or authorized by EPA under Part 123.	1996 PWM
Average Monthly Discharge Limitation	The highest allowable average of daily discharges over a calendar month, calculated as the sum of all daily discharges measured during that month divided by the number of daily discharges measured during that month.	§ 122.2
Average Weekly Discharge Limitation	The highest allowable average of daily discharges over a calendar week, calculated as the sum of all daily discharges measured during a calendar week divided by the number of daily discharges measured during that week.	§ 122.2
Best Available Technology Economically Achievable (BAT)	Technology standard established by the CWA as the most appropriate means available on a national basis for controlling the direct discharge of toxic and nonconventional pollutants to navigable waters. BAT limitations in effluent guidelines, in general, represent the best existing performance of treatment technologies that are economically achievable within an industrial point source category or subcategory.	Adapted from 1996 PWM

NMED Exhibit 70

Exhibit A-2 Glossary (continued)

Term	Definition	Citation
Best Conventional Pollutant Control Technology (BCT)	Technology-based standard for the discharge from existing industrial point sources of conventional pollutants including BOD, TSS, fecal coliform, pH, oil and grease. The BCT is established in light of a two-part cost reasonableness test, which compares the cost for an industry to reduce its pollutant discharge with the cost to a POTW for similar levels of reduction of a pollutant loading. The second test examines the cost-effectiveness of additional industrial treatment beyond BPT. EPA must find limits which are reasonable under both tests before establishing them as BCT.	1996 PWM
Best Management Practice (BMP)	Schedules of activities, prohibitions of practices, maintenance procedures, and other management practices to prevent or reduce the pollution of *waters of the United States*. BMPs also include treatment requirements, operating procedures, and practices to control plant site runoff, spillage or leaks, sludge or waste disposal, or drainage from raw material storage.	§ 122.2
Best Practicable Control Technology Currently Available (BPT)	The first level of technology standards established by the CWA to control pollutants discharged to waters of the U.S. BPT limitations in effluent guidelines are generally based on the average of the best existing performance by plants within an industrial category or subcategory.	Adapted from 1996 PWM
Best Professional Judgment (BPJ)	The method used by permit writers to develop technology-based NPDES permit conditions on a case-by-case basis using all reasonably available and relevant data.	1996 PWM
Bioassay	A test used to evaluate the relative potency of a chemical or a mixture of chemicals by comparing its effect on a living organism with the effect of a standard preparation on the same type of organism.	1996 PWM
Biochemical Oxygen Demand (BOD)	A measurement of the amount of oxygen used by the decomposition of organic material, over a specified time (usually 5 days) in a wastewater sample; it is used as a measurement of the readily decomposable organic content of a wastewater.	1996 PWM
Biosolids	See *Sewage Sludge*.	--
Bypass	The intentional diversion of waste streams from any portion of a treatment facility. This definition applies to both direct and indirect discharges.	§ 122.41(m)(1)(i) and § 403.17
Carbonaceous Biochemical Oxygen Demand (CBOD)	The biochemical oxygen demand of carbonaceous sources. This differs from BOD in that BOD measures both nitrogenous and carbonaceous sources, whereas CBOD excludes nitrogenous sources (e.g., nitrifying bacteria) from determination through the addition of a nitrification inhibitor.	--
Categorical Industrial User (CIU)	An industrial user subject to national categorical pretreatment standards.	1996 PWM
Categorical Pretreatment Standards	National pretreatment standards , expressed as Pretreatment Standards for Existing Sources (PSES) or Pretreatment Standards for New Sources (PSNS), specifying quantities or concentrations of pollutants or pollutant properties that may be discharged to a POTW by existing or new industrial users in specific industrial subcategories established as separate regulations under the appropriate subpart of 40 CFR chapter I, subchapter N.	Adapted from § 403.6

NMED Exhibit 70

Exhibit A-2 Glossary (continued)

Term	Definition	Citation
Chemical Oxygen Demand (COD)	A measure of the oxygen-consuming capacity of inorganic and organic matter present in wastewater. COD is expressed as the amount of oxygen consumed in mg/L. Results do not necessarily correlate to the biochemical oxygen demand (BOD) because the chemical oxidant can react with substances that bacteria do not stabilize.	Adapted from 1996 PWM
Chronic Effect	The effect of a stimulus that lingers or continues for a relatively long period, often one-tenth of the life span or more. The measurement of a chronic effect can be reduced growth, reduced reproduction, and such, in addition to lethality.	1996 PWM
Clean Water Act (CWA)	The Clean Water Act is a statute passed by the U.S. Congress to control water pollution. It was formerly referred to as the Federal Water Pollution Control Act of 1972 or Federal Water Pollution Control Act Amendments of 1972 (Public Law 92-500), 33 U.S.C. 1251 *et seq.*, as amended by: Public Law 96-483; Public Law 97-117; Public Laws 95-217, 97-117, 97-440, and 100-04.	1996 PWM
Code of Federal Regulations (CFR)	A codification of the final rules published daily in the *Federal Register*. Title 40 of the CFR contains regulations for the protection of the environment.	1996 PWM
Combined Sewer Overflow (CSO)	A discharge of untreated wastewater from a combined sewer system at a point before the headworks of a publicly owned treatment works. CSOs generally occur during wet weather (rainfall or snowmelt). During periods of wet weather, these systems become overloaded, bypass treatment works, and discharge directly to receiving waters at designed overflow points.	1996 PWM
Combined Sewer System (CSS)	A wastewater collection system that conveys sanitary wastewaters (domestic, commercial and industrial wastewaters) and stormwater through a single pipe to a publicly owned treatment works for treatment before discharge to surface waters.	1996 PWM
Compliance Schedule (or Schedule of Compliance)	A schedule of remedial measures included in a permit, including an enforceable sequence of interim requirements (for example, actions, operations, or milestone events) leading to compliance with the CWA and regulations.	§ 122.2
Composite Sample	Sample composed of two or more discrete aliquots (samples). The aggregate sample will reflect the average water quality of the compositing or sample period.	--
Conventional Pollutants	Pollutants typical of municipal sewage, and for which publicly owned treatment works typically are designed to remove; defined by Federal Regulation (§ 401.16) as BOD, TSS, fecal coliform bacteria, oil and grease, and pH.	1996 PWM
Daily Discharge	The *discharge of a pollutant* measured during a calendar day or any 24-hour period that reasonably represents the calendar day for purposes of sampling. For pollutants with limitations expressed in units of mass, the daily discharge is calculated as the total mass of the pollutant discharged over the day. For pollutants with limitations expressed in other units of measurement, the daily discharge is calculated as the average measurement of the pollutant over the day.	§ 122.2

Exhibit A-2 Glossary (continued)

Term	Definition	Citation
Designated Uses	Those uses specified in water quality standards for each waterbody or segment whether they are being attained (§ 131.3). Examples of designated uses include cold and warm water fisheries, public water supply, and irrigation.	Adapted from EPA. Terms of Environment: Glossary, Abbreviations, Acronyms. <www.epa.gov/OCEPAterms/dterms.html>
Development Document	A report prepared during development of an effluent guideline by EPA that provides the data and methodology used to develop effluent guidelines and categorical pretreatment standards for an industrial category.	Adapted from 1996 PWM
Director	The Regional Administrator or the State Director, as the context requires, or an authorized representative. When there is no *approved state program*, and there is an EPA-administered program, *Director* means the Regional Administrator. When there is an approved state program, Director normally means the State Director. In some circumstances, however, EPA retains the authority to take certain actions even when there is an approved state program. (For example, when EPA has issued an NPDES permit before the approval of a state program, EPA may retain jurisdiction over that permit after program approval, see § 123.1.) In such cases, Director means the Regional Administrator and not the State Director.	§ 122.2
Discharge Monitoring Report (DMR)	The EPA uniform national form, including any subsequent additions, revisions, or modifications for the reporting of self-monitoring results by permittees. DMRs must be used by *approved states* as well as by EPA. EPA will supply DMRs to any approved state upon request. The EPA national forms may be modified to substitute the state agency name, address, logo, and other similar information, as appropriate, in place of EPA's.	§ 122.2
Draft Permit	A document prepared under § 124.6 indicating the Director's tentative decision to issue, deny, modify, revoke and reissue, terminate, or reissue a *permit.* A notice of intent to terminate a permit, and a notice of intent to deny a permit, as discussed in § 124.5, are types of *draft permits*. A denial of a request for modification, revocation and reissuance, or termination, as discussed in § 124.5, is not a draft permit. A *proposed permit* is not a draft permit.	§ 122.2
Effluent Limitation	Any restriction imposed by the Director on quantities, discharge rates, and concentrations of *pollutants* which are *discharged* from *point sources* into waters of the United States, the waters of the *contiguous zone*, or the ocean.	§ 122.2
Effluent Limitations Guidelines (Effluent Guidelines or ELG)	A regulation published by the Administrator under CWA section 304(b) to adopt or revise *effluent limitations*.	§ 122.2
Existing Uses	Those uses actually attained in the waterbody on or after November 28, 1975, whether they are included in the water quality standards.	§ 131.3

NMED Exhibit 70

Exhibit A-2 Glossary (continued)

Term	Definition	Citation
Fact Sheet	A document that must be prepared for all draft individual permits for NPDES major dischargers, NPDES general permits, NPDES permits that contain variances, NPDES permits that contain sewage sludge land application plans and several other classes of dischargers. The document summarizes the principal facts and the significant factual, legal, methodological and policy questions considered in preparing the draft permit and explains how the public may comment (§§ 124.8 and 124.56). Where a fact sheet is not required, a statement of basis must be prepared (§ 124.7).	1996 PWM
Fundamentally Different Factors (FDF)	Those components of a petitioner's facility that are determined to be so unlike those components considered by EPA during the effluent guidelines and pretreatment standards rulemaking that the facility is worthy of a variance from the effluent guidelines or categorical pretreatment standards that would otherwise apply.	Adapted from 1996 PWM
General Permit	An NPDES permit issued under § 122.28 that authorizes a category of discharges under the CWA within a geographical area. A general permit is not specifically tailored for an individual discharger.	1996 PWM
Grab Sample	A sample taken from a wastestream on a one-time basis without consideration of the flow rate of the wastestream and without consideration of time.	Adapted from 1996 PWM
Hazardous Substance	Any substance—as designated under Part 116 pursuant to CWA section 311—that presents an imminent and substantial danger to the public health or welfare, including fish, shellfish, wildlife, shorelines, and beaches, upon discharge to navigable waters of the United States.	Adapted from § 122.2 and CWA section 311(b)(2)(A)
Indirect Discharger	A nondomestic discharger introducing *pollutants* to a publicly owned treatment works.	40 CFR 122.2
Instantaneous Maximum Limit	The maximum allowable concentration or other measure of a pollutant determined from the analysis of any discrete or composite sample collected, independent of the flow rate and the duration of the sampling event.	1996 PWM
Instantaneous Minimum Limit	The minimum allowable concentration or other measure of a pollutant determined from the analysis of any discrete or composite sample collected, independent of the flow rate and the duration of the sampling event.	--
Load Allocation	The portion of a receiving water's loading capacity that is attributed either to one of its existing or future nonpoint sources of pollution or to natural background sources. Load allocations are best estimates of the loading, which may range from reasonably accurate estimates to gross allotments, depending on the availability of data and appropriate techniques for predicting the loading. Wherever possible, natural and nonpoint source loads should be distinguished.	§ 130.2
Local Limits	Where specific prohibitions or limits on pollutants or pollutant parameters are developed by a POTW in accordance with § 403.4(c), such limits must be deemed Pretreatment Standards for the purposes of CWA section 307(d).	Adapted from § 403.4(d)

Exhibit A-2 Glossary (continued)

Term	Definition	Citation
Major Facility	Any NPDES facility or activity classified as such by the Regional Administrator, or in the case of approved state programs, the Regional Administrator in conjunction with the State Director (§ 122.2). Major municipal dischargers include all facilities with design flows of greater than one million gallons per day and facilities with EPA/state approved industrial pretreatment programs. Major industrial facilities are determined based on specific ratings criteria developed by EPA or are classified as such by EPA in conjunction with the state.	1996 PWM
Method Detection Limit (MDL)	The minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero and is determined from analysis of a sample in a given matrix containing the analyte.	§ 136 - Appendix B
Maximum Daily Effluent Limitation (MDL)	The highest allowable daily discharge of a pollutant. (Chapter 6)	--
Million Gallons per Day (or mgd)	A unit of flow commonly used for wastewater discharges. One million gallon per day is equivalent to 1.547 cubic feet per second.	1996 PWM
Minimum Level (ML)	The level at which the entire analytical system must give a recognizable signal and acceptable calibration point. It is equivalent to the concentration of the lowest calibration standard, assuming that all method-specified sample weights, volumes, and cleanup procedures have been employed.	§ 136 - Appendix A
Mixing Zone	An area where an effluent discharge undergoes initial dilution and is extended to cover the secondary mixing in the ambient waterbody. A mixing zone is an allocated impact zone where water quality criteria can be exceeded as long as acutely toxic conditions are prevented.	Technical Support Document for Water Quality-based Toxics Control <www.epa.gov/npdes/pubs/owm0264.pdf>
Municipal Separate Storm Sewer System (MS4)	A conveyance or system of conveyances (including roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, man-made channels, or storm drains): a. Owned or operated by a state, city, town, borough, county, parish, district, association, or other public body (created by or pursuant to state law) having jurisdiction over disposal of sewage, industrial wastes, stormwater, or other wastes, including special districts under state law such as a sewer district, flood control district or drainage district, or similar entity, or an Indian tribe or an authorized Indian tribal organization, or a designated and approved management agency under CWA section 208 that discharges to waters of the United States. b. Designed or used for collecting or conveying stormwater. c. [That] is not a combined sewer. d. [That] is not part of a Publicly Owned Treatment Works (POTW) as defined at § 122.2.	§ 122.26(b)(8)
Municipal Sludge	See *Sewage Sludge*.	--

NMED Exhibit 70

Exhibit A-2 Glossary (continued)

Term	Definition	Citation
National Pollutant Discharge Elimination System (NPDES)	The national program for issuing, modifying, revoking and reissuing, terminating, monitoring and enforcing permits, and imposing and enforcing pretreatment requirements, under CWA sections 307, 318, 402, and 405. The term includes *approved program*. NPDES permits regulate discharges of pollutants from point sources to waters of the United States. Such discharges are illegal unless authorized by an NPDES permit.	Adapted from § 122.2
National Pretreatment Standard or Pretreatment Standard	Any regulation promulgated by EPA in accordance with CWA sections 307(b) and 307(c) that applies to a specific category of industrial users and provides limitations on the introduction of pollutants into publicly owned treatment works. The term includes the prohibited discharge standards under § 403.5.	Adapted from § 403.3(l)
New Discharger	Any building, structure, facility, or installation: a. From which there is or may be a discharge of pollutants. b. That did not begin the discharge of pollutants at that site before August 13, 1979. c. That is not a new source. d. That has never received a finally effective NPDES permit for discharges at that site. This definition includes an *indirect discharger* that begins discharging into waters of the United States after August 13, 1979. It also includes any existing mobile point source (other than an offshore or coastal oil and gas exploratory drilling rig or a coastal oil and gas developmental drilling rig) such as a seafood processing rig, seafood processing vessel, or aggregate plant, that begins discharging at a *site* for which it does not have a permit; and any offshore or coastal mobile oil and gas exploratory drilling rig or coastal mobile oil and gas developmental drilling rig that commences the discharge of pollutants after August 13, 1979, at a site under EPA's permitting jurisdiction for which it is not covered by an individual or general permit and which is in an area determined by the Regional Administrator in the issuance of a final permit to be an area or biological concern. In determining whether an area is an area of biological concern, the Regional Administrator must consider the factors specified in §§ 125.122(a)(1) - 125.122(a)(10). An offshore or coastal mobile exploratory drilling rig or coastal mobile developmental drilling rig will be considered a *new discharger* only for the duration of its discharge in an area of biological concern.	Adapted from § 122.2

Exhibit A-2 Glossary (continued)

Term	Definition	Citation
New Source	Any building, structure, facility, or installation from which there is or could be a discharge of pollutants, the construction of which commenced: a. After promulgation of standards of performance under CWA section 306, which are applicable to such source; or b. After proposal of standards of performance in accordance with CWA section 306, which are applicable to such source but only if the standards are promulgated in accordance with CWA section 306 within 120 days of their proposal. Additional Criteria: Except as otherwise provided in an applicable new source performance standard, a source is a *new source* if it meets the definition in § 122.2; and i. It is constructed at a site at which no other source is located; or ii. It totally replaces the process or production equipment that causes the discharge of pollutants at an existing source; or iii. Its processes are substantially independent of an existing source at the same site. In determining whether these processes are substantially independent, the Director shall consider such factors as the extent to which the new facility is integrated with the existing plant; and the extent to which the new facility is engaged in the same general type of activity as the existing source.	Adapted from § 122.2 and § 122.29(b)(1)
New Source Performance Standards (NSPS)	Technology standards for facilities that qualify as new sources under § 122.2 and § 122.29. Standards consider that the new source facility has an opportunity to design operations to more effectively control pollutant discharges.	1996 PWM
Nonconventional Pollutants	All pollutants that are not included in the list of conventional or toxic pollutants in Part 401. Includes pollutants such as chemical oxygen demand (COD), total organic carbon (TOC), nitrogen, and phosphorus.	1996 PWM
Nonpoint Source	Diffuse pollution sources (i.e., without a single point of origin or not introduced into a receiving stream from a specific outlet). The pollutants are generally carried off the land by stormwater. Atmospheric deposition and hydromodification are also sources of nonpoint source pollution.	--
North American Industrial Classification System (NAICS)	The North American Industry Classification System (NAICS) is the standard used by federal statistical agencies in classifying business establishments for the purpose of collecting, analyzing, and publishing statistical data related to the U.S. business economy.	Retrieved from <www.census.gov/epcd/www/naics.html>
Nutrients	Chemical elements and compounds found in the environment that plants and animals need to grow and survive. Nutrients include compounds of nitrogen (nitrate, nitrite, ammonia, organic nitrogen) and phosphorus (orthophosphate and others), both natural and man-made.	--
Permitting Authority	The agency authorized to issue and enforce specific requirements of the NPDES permit program. The permitting authority may be EPA, or a state, territorial, or tribal agency that has been authorized under CWA section 402(b) to administer the NPDES program within its jurisdiction.	--

NMED Exhibit 70

Exhibit A-2 Glossary (continued)

Term	Definition	Citation
pH	A measure of the hydrogen ion concentration of water or wastewater; expressed as the negative log of the hydrogen ion concentration in mg/L. A pH of 7 is neutral. A pH less than 7 is acidic, and a pH greater than 7 is basic.	1996 PWM
Point Source	Any discernible, confined, and discrete conveyance, including any pipe, ditch, channel, tunnel, conduit, well, discrete fixture, container, rolling stock, concentrated animal feeding operation, landfill leachate collection system, vessel or other floating craft from which pollutants are or may be discharged. The term does not include return flows from irrigated agriculture or agricultural stormwater runoff.	Adapted from § 122.2
Pollutant	Dredged spoil, solid waste, incinerator residue, filter backwash, sewage, garbage, sewage sludge, munitions, chemical wastes, biological materials, radioactive materials (except those regulated under the Atomic Energy Act of 1954, as amended [42 U.S.C. 2011 *et seq.*)], heat, wrecked or discarded equipment, rock, sand, cellar dirt and industrial, municipal, and agricultural waste discharged into water. It does not mean a. Sewage from vessels. b. Water, gas, or other material that is injected into a well to facilitate production of oil or gas, or water derived in association with oil and gas production and disposed of in a well, if the well used either to facilitate production or for disposal purposes is approved by authority of the state in which the well is located, and if the state determines that the injection or disposal will not result in the degradation of ground or surface water resources.	§ 122.2
Pollutant, Conservative	Pollutants that do not readily degrade in the environment and that are mitigated primarily by dilution after entering receiving waters (e.g., metals, total suspended solids).	Adapted from 1996 PWM
Pollutant, Non-Conservative	Pollutants that are mitigated by natural biodegradation or other environmental decay or removal processes in the receiving water after mixing and dilution have occurred (e.g., biochemical oxygen demand, pH, volatile organic compounds).	Adapted from 1996 PWM
Pretreatment	The reduction of the amount of pollutants, the elimination of pollutants, or the alteration of the nature of pollutant properties in wastewater prior to or in lieu of discharging or otherwise introducing such pollutants into a POTW.	§ 403.3(s)
Primary Industry Category	Any industry category listed in the NRDC settlement agreement (*Natural Resources Defense Council et al. v. Train,* 8 E.R.C. 2120 [D.D.C. 1976], modified 12 E.R.C. 1833 [D.D.C. 1979]); also listed in Appendix A of Part 122.	§ 122.2
Primary Treatment	The practice of removing some portion of the suspended solids and organic matter in wastewater through sedimentation. Common usage of this term also includes preliminary treatment to remove wastewater constituents that may cause maintenance or operational problems in the system (i.e., grit removal, screening for rags and debris, oil and grease removal, etc.).	1996 PWM
Priority Pollutants	Those pollutants considered to be of principal importance for control under the CWA based on the NRDC Consent Decree (*NRDC et al. v. Train,* 8 E.R.C. 2120 [D.D.C. 1976], modified 12 E.R.C. 1833 [D.D.C. 1979]); a list of the pollutants is provided as Appendix A to 40 CFR Part 423.	1996 PWM

NMED Exhibit 70

Exhibit A-2 Glossary (continued)

Term	Definition	Citation
Process Wastewater	Any water [that], during manufacturing or processing, comes into direct contact with, or results from the production or use of any raw material, intermediate product, finished product, by-product, or waste product.	§ 122.2
Production-Based Standard	A discharge standard expressed in terms of pollutant mass allowed per unit of product manufactured or some other measure of production.	1996 PWM
Proposed Permit	A state NPDES *permit* prepared after the close of the public comment period (and when applicable, any public hearing and administrative appeals) [that] is sent to EPA for review before final issuance by the state. A *proposed permit* is not a *draft permit*.	§ 122.2
Publicly Owned Treatment Works (POTW)	A treatment works as defined by CWA section 212, which is owned by a state or municipality [as defined by CWA section 502(4)]. This definition includes any devices and systems used in the storage, treatment, recycling, and reclamation of municipal sewage or industrial wastes of a liquid nature. It also includes sewers, pipes, and other conveyances only if they convey wastewater to a POTW. The term also means the municipality as defined in CWA section 502(4), which has jurisdiction over the indirect discharges to and the discharges from such a treatment works.	§ 403.3(q)
Sanitary Sewer	A pipe or conduit (sewer) intended to carry wastewater or water-borne wastes from homes, businesses, and industries to the POTW.	1996 PWM
Sanitary Sewer Overflows (SSO)	Untreated or partially treated sewage overflows from a sanitary sewer collection system.	1996 PWM
Secondary Industry Category	Any industry category, which is not a *primary industry category*.	§ 122.2
Secondary Treatment	Technology-based requirements for direct discharging POTWs. Standard is based on the expected performance of a combination of physical and biological processes typical for the treatment of pollutants in municipal sewage. Standards are expressed as a minimum level of effluent quality in terms of: BOD_5, total suspended solids (TSS), and pH (except as provided by treatment equivalent to secondary treatment and other special considerations).	Adapted from 1996 PWM
Section 304(a) Criteria	Developed by EPA under authority of CWA section 304(a) based on the latest scientific information on the relationship that the effect of a constituent concentration has on particular aquatic species and/or human health. This information is issued periodically to the states as guidance for use in developing criteria.	§ 131.3(c)
Self-Monitoring	Sampling and analyses performed by a facility to determine compliance with effluent limitations or other regulatory requirements.	1996 PWM

NMED Exhibit 70

Exhibit A-2 Glossary (continued)

Term	Definition	Citation
Sewage Sludge	Any solid, semi-solid, or liquid residue removed during the treatment of municipal waste water or domestic sewage. Sewage sludge includes solids removed during primary, secondary, or advanced wastewater treatment, scum, septage, portable toilet pumpings, type III marine sanitation device pumpings (33 CFR Part 159), and sewage sludge products. Sewage sludge does not include ash generated during the firing of sewage sludge in a sewage sludge incinerator or grit and screenings generated during preliminary treatment of domestic sewage in a treatment works.	Adapted from § 122.2 and Part 503
Significant Industrial User (SIU)	An indirect discharger that is the focus of control efforts under the National Pretreatment Program. SIUs include [with exceptions provided under § 403.3(v)]: i. All Industrial Users subject to Categorical Pretreatment Standards under § 403.6 and Chapter 1, Subchapter N. ii. Any other Industrial User that: discharges an average of 25,000 gallons per day or more of process wastewater to the POTW (excluding sanitary, noncontact cooling and boiler blowdown wastewater); contributes a process wastestream that makes up 5 percent or more of the average dry weather hydraulic or organic capacity of the POTW; or is designated as such by the Control Authority on the basis that the Industrial User has a reasonable potential for adversely affecting the POTW's operation or for violating any Pretreatment Standard or requirement [in accordance with § 403.8(f)(6)].	Adapted from § 403.3(v)
Spill Prevention Control and Countermeasure Plan (SPCC)	A plan prepared by a facility to minimize the likelihood of a spill and to expedite control and cleanup activities if a spill occurs. Such plans are required for certain facilities under the Oil Pollution Prevention Regulations at 40 CFR Part 112.	Adapted from 1996 PWM
Standard Industrial Classification (SIC) Code	A code number system used to identify various types of industries. A particular industry may have more than one SIC code if it conducts several types of commercial or manufacturing activities onsite. An online version of the 1987 SIC Manual <www.osha.gov/pls/imis/sic_manual.html> is available courtesy of the Occupational Safety & Health Administration (OSHA).	Adapted from 1996 PWM
Statement of Basis	A document prepared for every draft NPDES permit for which a fact sheet is not required. A statement of basis briefly describes how permit conditions were derived and the reasons the conditions are necessary for the permit.	1996 PWM
STORET	EPA's computerized STOrage and RETrieval water quality data base that includes physical, chemical, and biological data measured in waterbodies throughout the United States.	1996 PWM
Storm Water (or Stormwater)	Stormwater runoff, snow melt runoff, and surface runoff and drainage.	§ 122.26(b)(13)
Technology-Based Effluent Limitation (TBEL)	An effluent limit for a pollutant that is based on the capability of a treatment method to reduce the pollutant to a certain concentration or mass loading level. TBELs for POTWs are derived from the secondary treatment regulations in Part 133 or state treatment standards. TBELs for non-POTWs are derived from effluent guidelines, state treatment standards, or by the permit writer on a case-by-case basis using best professional judgment.	Adapted from 1996 PWM

NMED Exhibit 70

Exhibit A-2 Glossary (continued)

Term	Definition	Citation
Tiered Permit Limits	Permit limits that apply to the discharge only when a certain threshold (e.g., production level), specific circumstance (e.g., batch discharge), or time frame (e.g., after 6 months, during the months of May through October) triggers their use.	Adapted from 1996 PWM
Total Maximum Daily Load (TMDL)	The sum of the individual wasteload allocations (WLAs) for point sources and load allocations (LAs) for nonpoint sources and natural background. If a receiving water has only one point source discharger, the TMDL is the sum of that point source WLA plus the LAs for any nonpoint sources of pollution and natural background sources, tributaries, or adjacent segments. TMDLs can be expressed in terms of either mass per time, toxicity, or other appropriate measure. If best management practices (BMPs) or other nonpoint source pollution controls make more stringent load allocations practicable, then wasteload allocations can be made less stringent. Thus, the TMDL process provides for nonpoint source control tradeoffs.	40 CFR § 130.2(i)
Total Suspended Solids (TSS)	A measure of the filterable solids present in a sample, as determined by the method specified in Part 136.	1996 PWM
Toxic Pollutant	Any pollutant listed as toxic under CWA section 307(a)(1) or, in the case of *sludge use or disposal practices*, any pollutant identified in regulations implementing CWA section 405(d).	§ 122.2
Toxicity Reduction Evaluation (TRE)	A site-specific study conducted in a step-wise process designed to identify the causative agent(s) of effluent toxicity, isolate the sources of toxicity, evaluate the effectiveness of toxicity control options, and then confirm the reduction in effluent toxicity.	1996 PWM
Toxicity Test	A procedure to determine the toxicity of a chemical or an effluent using living organisms. A toxicity test measures the degree of effect on exposed test organisms of a specific chemical or effluent.	1996 PWM
Trading (or Water Quality Trading)	An innovative approach to achieve water quality goals more efficiently. Trading is based on the fact that sources in a watershed can face very different costs to control the same pollutant. Trading programs allow facilities facing higher pollution control costs to meet their regulatory obligations by purchasing environmentally equivalent (or superior) pollution reductions from another source at lower cost, thus achieving the same water quality improvement at lower overall cost.	Water Quality Trading Fact Sheet: <www.epa.gov/owow/watershed/trading/handbook/factsheet.html>
Treatability Manual	Five-set library of EPA guidance manuals that contain information related to the treatability of many pollutants. The manual may be used in developing effluent limitations for facilities and pollutants, which, at the time of permit issuance, are not subject to industry-specific effluent guidelines. The five volumes that comprise this series consist of Vol. I – Treatability Data (EPA-600/8-80-042a); Vol. II – Industrial Descriptions (EPA-600/8-80-042b); Vol. III – Technologies (EPA-600/8-80-042c); Vol. IV – Cost Estimating (EPA-600/8-80-042d); and Vol. V – Summary (EPA-600/8-80-042e).	1996 PWM
Treatment Works Treating Domestic Sewage (TWTDS)	A POTW or any other sewage sludge or waste water treatment devices or systems, regardless of ownership (including federal facilities), used in the storage, treatment, recycling, and reclamation of municipal or domestic sewage, including land dedicated for the disposal of sewage sludge. This definition does not include septic tanks or similar devices. For purposes of this definition, *domestic sewage* includes waste and waste water from humans or household operations that are discharged to or otherwise enter a treatment works.	Adapted from § 122.2

NMED Exhibit 70

Exhibit A-2 Glossary (continued)

Term	Definition	Citation
Upset	An exceptional incident in which there is unintentional and temporary noncompliance with technology-based permit effluent limitations because of factors beyond the reasonable control of the permittee. An upset does not include noncompliance to the extent caused by operational error, improperly designed treatment facilities, inadequate treatment facilities, lack of preventive maintenance, or careless or improper operation.	§ 122.41(n)
Use Attainability Analysis	A structured scientific assessment of the factors affecting the attainment of the use that [can] include physical, chemical, biological, and economic factors as described in § 131.10(g).	§ 131.3
Variance	Any mechanism or provision under CWA sections 301 or 316 or under 40 CFR Part 125, or in the applicable *effluent limitations guidelines*, which allows modification to or waiver of the generally applicable effluent limitation requirements or time deadlines of the CWA. This includes provisions, [that] allow the establishment of alternative limitations based on fundamentally different factors or on CWA sections 301(c), 301(g), 301(h), 301(i), or 316(a).	§ 122.2
Wasteload Allocation (WLA)	The portion of a receiving water's loading capacity that is allocated to one of its existing or future point sources of pollution.	Adapted from § 130.2(h)
Water Quality Criteria	Elements of state water quality standards, expressed as constituent concentrations, levels, or narrative statements, representing a quality of water that supports a particular use. When criteria are met, water quality will generally protect the designated use.	§ 131.3(b)
Water Quality Limited Segment	Any segment where it is known that water quality does not meet applicable water quality standards, and/or is not expected to meet applicable water quality standards, even after the application of the technology-based effluent limitations required by CWA sections 301(b) and 306.	§ 131.3
Water Quality Standards (WQS)	Provisions of state or federal law that consist of a designated use or uses for the waters of the United States and water quality criteria for such waters based on such uses. Water quality standards are to protect the public health or welfare, enhance the quality of water, and serve the purposes of the CWA.	Adapted from §131.3
Water Quality-Based Effluent Limitation (WQBEL)	An effluent limitation determined by selecting the most stringent of the effluent limits calculated using all applicable water quality criteria (e.g., aquatic life, human health, wildlife, translation of narrative criteria) for a specific point source to a specific receiving water.	Adapted from 1996 PWM

Exhibit A-2 Glossary (continued)

Term	Definition	Citation
Waters of the United States	Means a. All waters [that] are currently used, were used in the past, or [could] be susceptible to use in interstate or foreign commerce, including all waters [that] are subject to the ebb and flow of the tide. b. All interstate waters, including interstate *wetlands*. c. All other waters such as intrastate lakes, rivers, streams (including intermittent streams), mudflats, sandflats, *wetlands*, sloughs, prairie potholes, wet meadows, playa lakes, or natural ponds the use, degradation, or destruction of which would affect or could affect interstate or foreign commerce including any such waters 1. [That] are or could be used by interstate or foreign travelers for recreational or other purposes. 2. From which fish or shellfish are or could be taken and sold in interstate or foreign commerce or 3. [That] are used or could be used for industrial purposes by industries in interstate commerce. d. All impoundments of waters otherwise defined as waters of the United States under this definition. e. Tributaries of waters identified in paragraphs (a) through (d) of this definition. f. The territorial sea and g. Wetlands adjacent to waters (other than waters that are themselves wetlands) identified in paragraphs (a) through (f) of this definition. [see additional notes in § 122.2]	§ 122.2
Whole Effluent Toxicity (WET)	The aggregate toxic effect of an effluent measured directly by a toxicity test.	§ 122.2

Appendix B. Index to the CWA and NPDES Regulations

This appendix provides two tables to help permit writers navigate Clean Water Act (CWA) legislation and National Pollutant Discharge Elimination System (NPDES) regulations. The first table provides key sections of the CWA and the second table provides an index to NPDES regulations.

B.1 Index to Sections of the CWA

Title 33 of the *United States Code* (U.S.C.) includes the statutes and amendments to the CWA. Exhibit B-1 matches key sections of the CWA to the appropriate reference in the U.S.C. This latest version, dated December 20, 2004, was provided by the New England Interstate Water Pollution Control Commission.

Exhibit B-1 Index to sections of the CWA

33 U.S.C. section	Section title	CWA section
	Subchapter I Research and Related Programs	
1251	Congressional declaration of goals and policy	**101**

064	Pentachlorophenol	127	Thallium
065	Phenol	128	Zinc
066	Bis(2-ethylhexyl) phthalate	129	2,3,7,8-tetrachloro-dibenzo-p-dioxin (TCDD)

NMED Exhibit 70

Appendix D. New Source Dates by Effluent Guideline Category

This appendix provides the applicable new source dates used in making new source determinations by effluent guideline category as provided in Appendix B of the U.S. Environmental Protection Agency (EPA) memorandum *New Source Dates for Direct and Indirect Dischargers*[1] <www.epa.gov/npdes/pubs/newsource_dates.pdf> sent by the directors of EPA's Water Permits Division and the Engineering and Analysis Division to the Regional Water Division Directors on September 28, 2006. Section 5.2.2.4 of this manual discusses the determination of whether existing or new source standards apply.

EPA has promulgated regulations under the Clean Water Act (CWA) that establish effluent limitations guidelines for existing sources, standards of performance for new sources and pretreatment standards for new and existing sources. EPA has codified these regulations at Title 40 of the *Code of Federal Regulations* (CFR) Subchapter N. As discussed in section 5.2.1 of this manual, EPA has published effluent guidelines for 56 major industrial categories (over 450 subcategories) since the passage of the 1972 CWA. Those regulations limit the discharge of pollutants to surface waters by point source dischargers (*direct dischargers*). The regulations also limit the introduction of pollutants into publicly owned treatment works (POTWs) by industrial users (*indirect dischargers*). The CWA and EPA regulations define when a source is a *new source*. A discharger is defined as a new source in CWA sections 306(a)(2) and 307(c) and §§ 122.2 (for direct dischargers) and 403.3(m) (for indirect dischargers). In general, a facility is a new source if it begins construction after either the date of promulgation of new source performance standards applicable to the direct dischargers or the date of publication of a proposed new source performance standard applicable to an indirect discharger.

Exhibit D-1 lists new source dates for direct or indirect dischargers based on regulatory definitions. In some cases, effluent guidelines in 40 CFR Chapter I, Subchapter N, specify New Source Dates, and these dates are reported in the table below. If dates are not specified in the rule language, EPA based the date on the regulatory definitions of new source, which are cited above. EPA's General Pretreatment Regulations provide that an indirect source is a new source if construction of the source began after the publication of proposed pretreatment standards for new sources if the proposed standard is later finalized [§ 403.3(m)]. For direct dischargers, § 122.2 states that the New Source date is the proposal date if the standard is finalized within 120 days after its proposal; otherwise, the New Source date is the *promulgation date*. EPA's regulations establish the time and date of EPA's actions for purposes of determining when the action is subject to judicial review. The regulations, in the case of the CWA, define the date of an EPA promulgation action as two weeks after the rule appears in the *Federal Register* (see § 23.2). Before February 1985, the date on which the final rule was published was considered the promulgation date.

This document is not a regulation itself, nor does it substitute for any requirements under the CWA or EPA's regulations. Thus, it does not impose legally binding requirements on EPA, states or the regulated community. While EPA has made every effort to ensure the accuracy of this table, dischargers' obligations are determined, in the case of direct dischargers, by the terms of their NPDES permit and the CWA and EPA's regulations, and, in the case of indirect dischargers, by permits or equivalent control

NMED Exhibit 70

mechanisms issued to POTW industrial users and the CWA and EPA regulations. Nothing in this document changes any statutory or regulatory requirement. If the discussion in this memorandum conflicts with any permit or regulation, this document would not be controlling.

[1] Boornazian, Linda and Mary Smith. 2006. *New Source Dates for Direct and Indirect Dischargers*. U.S. Environmental Protection Agency, Office of Water Memorandum. September 28, 2006. <www.epa.gov/npdes/pubs/newsource_dates.pdf>.

[2] The rule was finalized within 120 days of its October 30, 1973, proposal (38 FR 22606).

[3] The New Source date is specified in 40 CFR 434.11(j)(1).

[4] The New Source date is specified in 40 CFR 434.11(j)(1).

[5] New Source date derived from the 10-year protection period [see 40 CFR 412.35(d) and 412.43(d)].

[6] Direct dischargers formerly regulated under Part 413 are now regulated under Part 433 (metal finishing).

[7] Pretreatment categorical standards in Part 413 currently apply only to job shop electroplaters and independent printed circuit board manufacturers that were in existence before the New Source date for Part 433 (metal finishing). Job shop electroplaters and independent printed circuit board manufacturers that are "New Sources" must comply with PSNS in Part 433. Except for these "existing" job shop electroplaters and independent printed circuit board manufacturers, all other operations formerly subject to Part 413 are now subject to Part 433.

[8] The rule was finalized within 120 days of its October 7, 1974, proposal.

[9] Section 41 8.46 (the PSNS under Subpart D) was suspended until further notice, at 40 FR 26275, June 23, 1975, effective July 20, 1975.

[10] The rule was finalized within 120 days of its December 4, 1973, proposal (38 FR 33438).

Endnotes for this chapter continued on the next page.

NMED Exhibit 70

[11] Date specified in 40 CFR 420.14(a)(2), 420.16(a)(2), 420.24(b), and 420.26(a)(2).

[12] See previous footnote.

[13] The 2004 Amendment did not revise NSPSs for small meat products facilities in Subparts A-I, so the 2004 New Source date does not affect these facilities.

[14] See previous footnote.

[15] Date specified in 40 CFR 438.15.

[16] See promulgated standards at 40 CFR 58 FR 12505 and 66 FR 6850 for complete information on the applicability of New Source standards.

[17] New Source date derived from the 10-year protection period [see 40 CFR 439.15(c), 439.35(c), and 439.45(b)].

[18] Date specified in 40 CFR 430.25(b) and 430.55(b). Refer to these sections for additional information regarding the applicability of NSPSs.

[19] NSPS promulgated were not removed via the 1982 regulation; therefore wastewaters generated by Part 423-applicable sources that were New Sources under the 1974 regulations are subject to the 1974 NSPS. The New Source date for the 1974 regulations was 10/8/1974.

[20] The rule was finalized within 120 days of its December 7, 1973, proposal (38 FR 33846).

PBT - Persistent Bioaccumulative Toxic Chemicals

Substance List Details

Type	Ad Hoc
Number of Entries	72
Description	EPA has finalized enhanced reporting requirements that focus on toxic chemicals which persist and bioaccumulate in the environment. These are known as persistent bioaccumulative toxic (PBT) chemicals. EPA is increasing the utility of the Toxic Release Inventory (TRI) to the public by adding PBT chemicals to the TRI list and by lowering the reporting thresholds for some of these chemicals. Toxic chemicals that persist and bioaccumulate are of particular concern because they remain in the environment for significant periods of time and concentrate in the organisms exposed to them. These PBT chemicals have the potential to cause serious human health and environmental effects resulting from low levels of release and exposure that would not be reported under the thresholds that apply to other toxic chemicals under Section 313.

NMED Exhibit 71

ENVIRONMENTAL PROTECTION AGENCY

40 CFR Part 372

[OPPTS–400132C; FRL–6389–11]

RIN 2070–AD09

Persistent Bioaccumulative Toxic (PBT) Chemicals; Lowering of Reporting Thresholds for Certain PBT Chemicals; Addition of Certain PBT Chemicals; Community Right-to-Know Toxic Chemical Reporting

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: EPA is lowering the reporting thresholds for certain persistent bioaccumulative toxic (PBT) chemicals that are subject to reporting under section 313 of the Emergency Planning and Community Right-to-Know Act of 1986 (EPCRA) and section 6607 of the Pollution Prevention Act of 1990 (PPA). EPA is also adding a category of dioxin and dioxin-like compounds to the EPCRA section 313 list of toxic chemicals and establishing a 0.1 gram reporting threshold for the category. In addition, EPA is adding certain other PBT chemicals to the EPCRA section 313 list of toxic chemicals and establishing lower reporting thresholds for these chemicals. EPA is removing the fume or dust qualifier from vanadium and adding all forms of vanadium with the exception of vanadium when contained in alloys. EPA is also adding vanadium compounds to the EPCRA section 313 list of toxic chemicals. However, EPA is not lowering the reporting thresholds for either vanadium or vanadium compounds. EPA is taking these actions pursuant to its authority under EPCRA section 313(f)(2) to revise reporting thresholds and pursuant to its authority to add chemicals and chemical categories that meet the EPCRA section 313(d)(2) toxicity criteria. The additions of these chemicals are based on their carcinogenicity or other chronic human health effects and/or their significant adverse effects on the environment. Today's actions also include modifications to certain reporting exemptions and requirements for those toxic chemicals that are subject to the lower reporting thresholds. This document also announces the effective date of § 372.27 of the Code of Federal Regulations, which contained information collection requirements and which was originally published in the **Federal Register** on November 30, 1994.

DATES: 40 CFR 372.27 became effective on March 17, 1995, when the Office of Management and Budget approved its information collection requirements. This rule shall take effect on December 31, 1999. For purposes of EPCRA section 313(d)(4), the chemical additions shall be considered made as of November 30, 1999, and shall apply for the reporting year beginning January 1, 2000.

FOR FURTHER INFORMATION CONTACT: For technical information on this final rule contact: Daniel R. Bushman, Petitions Coordinator, Environmental Protection Agency, Mail Code 7408, 401 M St., SW., Washington, DC 20460; telephone number 202–260–3882, e-mail address: bushman.daniel@epa.gov. For general information on EPCRA section 313, contact the Emergency Planning and Community Right-to-Know Hotline, Environmental Protection Agency, Mail Code 5101, 401 M St., SW., Washington, DC 20460, Toll free: 1–800–535–0202, in Virginia and Alaska: 703–412–9877 or Toll free TDD: 1–800–553–7672.

SUPPLEMENTARY INFORMATION:

I. General Information

A. Does this Action Apply to Me?

You may be affected by this action if you manufacture, process, or otherwise use aldrin, chlordane, dioxin and certain dioxin-like compounds, heptachlor, hexachlorobenzene, isodrin, mercury, mercury compounds, methoxychlor, octachlorostyrene, pendimethalin, pentachlorobenzene, polychlorinated biphenyls, certain polycyclic aromatic compounds, tetrabromobisphenol A, toxaphene, trifluralin, and vanadium (except alloys) or vanadium compounds. See Table 1 in Unit V.C. for a more detailed listing. Potentially affected categories and entities may include, but are not limited to:

Category	Examples of Potentially Affected Entities
Industry	SIC major group codes 10 (except 1011, 1081, and 1094), 12 (except 1241), or 20 through 39; industry codes 4911 (limited to facilities that combust coal and/or oil for the purpose of generating power for distribution in commerce); 4931 (limited to facilities that combust coal and/or oil for the purpose of generating power for distribution in commerce); or 4939 (limited to facilities that combust coal and/or oil for the purpose of generating power for distribution in commerce); or 4953 (limited to facilities regulated under the Resource Conservation and Recovery Act, subtitle C, 42 U.S.C. section 6921 *et seq.*), or 5169, or 5171, or 7389 (limited to facilities primarily engaged in solvent recovery services on a contract or fee basis)
Federal Government	Federal facilities

This table is not intended to be exhaustive, but rather provides a guide for readers regarding entities likely to be affected by this action. Other types of entities not listed in the table could also be affected. To determine whether your facility would be affected by this action, you should carefully examine the applicability criteria in part 372, subpart B of Title 40 of the Code of Federal Regulations. If you have questions regarding the applicability of this action to a particular entity, consult the person listed in the ''FOR FURTHER INFORMATION CONTACT'' section.

B. How Can I Get Additional Information or Copies of this Document or Other Support Documents?

1. *Electronically*. You may obtain electronic copies of this document from the EPA Internet Home Page at http://www.epa.gov/. On the Home Page select ''Laws and Regulations'' and then look up the entry for this document under the ''**Federal Register**--Environmental Documents.'' You can also go directly to the ''**Federal Register**'' listings at http://www.epa.gov/fedrgstr/.

2. *In person*. The Agency has established an official record for this action under docket control number OPPTS–400132. The official record consists of the documents specifically referenced in this action, any public comments received during an applicable comment period, and any other information related to this action, including any information claimed as confidential business information (CBI). This official record includes the

documents that are physically located in the docket, as well as the documents that are referenced in those documents. The public version of the official record does not include any information claimed as CBI. The public version of the official record, which includes printed, paper versions of any electronic comments submitted during an applicable comment period, is available for inspection in the TSCA Nonconfidential Information Center, North East Mall Rm. B–607, Waterside Mall, 401 M St., SW., Washington, DC. The Center is open from noon to 4 p.m., Monday through Friday, excluding legal holidays. The telephone number for the Center is (202) 260–7099.

II. Statutory Authority

EPA is finalizing these actions under sections 313(d)(1) and (2), 313(f)(2), 313(g), 313(h), and 328 of EPCRA, 42 U.S.C. 11023(d)(1)-(2), 11023(f)(2), 11023(g), 11023(h) and 11048; PPA section 6607, 42 U.S.C. 13106.

Section 313 of EPCRA requires certain facilities manufacturing, processing, or otherwise using a listed toxic chemical in amounts above reporting threshold levels, to report certain facility specific information about such chemicals, including the annual quantity entering each environmental medium. These reports must be filed by July 1 of each year for the previous calendar year. Such facilities also must report pollution prevention and recycling data for these chemicals, pursuant to section 6607 of PPA.

A. What is the Authority for the Addition of Chemicals?

Section 313 established an initial list of toxic chemicals comprised of more than 300 chemicals and 20 chemical categories. Section 313(d) authorizes EPA to add or delete chemicals from the list, and sets forth criteria for these actions. EPA has added and deleted chemicals from the original statutory list on the basis of the criteria in subparagraph (A), (B) and/or (C) of subsection (d)(2) of EPCRA section 313. Under section 313(e)(1), any person may petition EPA to add chemicals to, or delete chemicals from, the list on the grounds that it does or does not meet the criteria at 313(d)(2)(A) or (B). Pursuant to EPCRA section 313(e)(1), EPA must respond to petitions within 180 days, either by initiating a rulemaking or by publishing an explanation of why the petition is denied. EPCRA section 313(d)(2) states that a chemical may be added to the list if any of the three listing criteria set forth there are met. Therefore, in order to add a chemical, EPA must find that at least one criterion is met, but does not need to examine whether all other criteria are also met. EPA has published a statement elaborating its interpretation of the section 313(d)(2) and (3) criteria for adding and deleting chemicals from the section 313 list (at 59 FR 61432, November 30, 1994) (FRL–4922–2).

B. What is the Authority for the Lowering of Reporting Thresholds?

EPA is finalizing these actions pursuant to its authority under EPCRA section 313(f)(2) to revise reporting thresholds. EPCRA section 313 establishes default reporting thresholds, which are set forth in section 313(f)(1). Section 313(f)(2), however, provides that EPA:

> may establish a threshold amount for a toxic chemical different from the amount established by paragraph (1). Such revised threshold shall obtain reporting on a substantial majority of total releases of the chemical at all facilities subject to the requirements of this section. The amounts established by EPA may, at the Administrator's discretion, be based on classes of chemicals or categories of facilities.

This provision provides EPA with broad, but not unlimited, authority to establish thresholds for particular chemicals, classes of chemicals, or categories of facilities, and commits to EPA's discretion the determination that a different threshold is warranted. Congress also committed the determination of the levels at which to establish any alternate thresholds to EPA's discretion, requiring only that any ''revised threshold shall obtain reporting on a substantial majority of total releases of the chemical at all facilities subject to the requirements'' of section 313. 42 U.S.C. 11023(f)(2).

For purposes of determining what constitutes a ''substantial majority of total releases,'' EPA interprets the language in section 313(f)(2), ''facilities subject to the requirements of [section 313],'' to refer to those facilities that fall within the category of facilities described by sections 313(a) and (b), i.e., the facilities currently reporting. Subsection (a) lays out the general requirement that ''the owner or operator of facilities subject to the requirements of this section shall'' file a report under EPCRA section 313. Subsection (b) then defines the facilities subject to the requirements of this section:

> [t]he requirements of this section shall apply to owners and operators of facilities that have 10 or more full-time employees and that are in Standard Industrial Classification Codes 20-39, . . . and that manufactured, processed, or otherwise used a toxic chemical listed under subsection (c) of this section in excess of the quantity of that toxic chemical established under subsection (f) of this section during the calendar year for which a toxic chemical release form is required under this section.

Thus, in revising the reporting thresholds, EPA must ensure that, under the new thresholds, a substantial majority of releases currently being reported will continue to be reported. No further prerequisites for exercising this authority appears in the statute.

C. What is the Authority for Modifications to Other EPCRA Section 313 Reporting Requirements?

Today's actions also include modifications to certain reporting exemptions and requirements for those toxic chemicals that are subject to the lower reporting thresholds. Congress granted EPA rulemaking authority to allow the Agency to fully implement the statute. EPCRA section 328 provides that the ''Administrator may prescribe such regulations as may be necessary to carry out this chapter'' (28 U.S.C. 11048).

III. Background Information

A. What is the General Background for this Action?

Under EPCRA section 313, Congress set the initial parameters of the Toxic Release Inventory, but also gave EPA clear authority to modify reporting in various ways, including authority to change the toxic chemicals subject to reporting, the facilities required to report, and the threshold quantities that trigger reporting. By providing this authority, Congress recognized that the TRI program would need to evolve to meet the needs of a better informed public and to refine existing information. EPA has, therefore, undertaken a number of actions to expand and enhance TRI. These actions include expanding the number of reportable toxic chemicals by adding 286 toxic chemicals and chemical categories to the EPCRA section 313 list in 1994. Further, a new category of facilities was added to EPCRA section 313 on August 3, 1993, through Executive Order 12856, which requires Federal facilities meeting threshold requirements to file annual EPCRA section 313 reports. In addition, in 1997 EPA expanded the number of private sector facilities that are required to report under EPCRA section 313 by adding seven new industrial groups to the list of covered facilities. At the same time, EPA has sought to reduce the burden of EPCRA section 313 reporting by actions such as delisting chemicals it has determined do not meet the statutory listing criteria and establishing

NMED Exhibit 72

an alternate reporting threshold of 1 million pounds for facilities with 500 pounds or less of production-related releases and other wastes. Facilities meeting the requirements of this alternate threshold may file a certification statement (Form A) instead of reporting on the standard EPCRA section 313 form, the Form R.

In today's actions, EPA is finalizing enhanced reporting requirements that focus on a unique group of toxic chemicals. These toxic chemicals which persist and bioaccumulate in the environment are commonly referred to as persistent bioaccumulative toxic chemicals or PBT chemicals. To date, with the exception of the alternate threshold certification on Form A, EPA has not altered the statutory reporting threshold for any listed chemicals. However, as the TRI program has evolved over time and as communities identify areas of special concern, thresholds and other aspects of the EPCRA section 313 reporting requirements may need to be modified to assure the collection and dissemination of relevant, topical information and data. Towards that end, EPA is increasing the utility of TRI to the public by adding a number of chemicals to the section 313 list of toxic chemicals that persist and bioaccumulate in the environment and by lowering the reporting thresholds for a number of toxic chemicals that have these properties. Toxic chemicals that persist and bioaccumulate are of particular concern because they remain in the environment for significant periods of time and concentrate in the organisms exposed to them. EPA believes that the public understands that these PBT chemicals have the potential to cause serious human health and environmental effects resulting from low levels of release and exposure (Refs. 75 and 76). Lowering the reporting thresholds for PBT chemicals will ensure that the public has important information on the quantities of these chemicals released or otherwise managed as waste, that would not be reported under the 10,000 and 25,000 pound/year thresholds that apply to other toxic chemicals.

B. What Outreach Has EPA Conducted?

EPA has engaged in a comprehensive outreach effort. This outreach served to inform interested parties, including industry groups affected by the rule, state regulatory officials, environmental organizations, labor unions, community groups, and the general public of EPA's intention to add certain PBT chemicals to the list of toxic chemicals under EPCRA section 313 and lower the applicable reporting thresholds for a subset of PBT chemicals. For all interested parties, EPA held three public meetings (in Chicago, IL (February 23, 1999); San Francisco, CA (March 5, 1999); and Washington, DC (February 16, 1999)) during the comment period for the proposal. Participants included a range of industry representatives, trade associations (representing both small and large businesses), law firms representing industry groups, environmental groups, the general public, plus other groups and organizations. For state and tribal governments, EPA attended the regularly-held public meetings of the Forum on State and Tribal Toxics Action (FOSTTA) to discuss the PBT proposal. EPA also received substantial public comment on this proposal, to which EPA is responding in this Final Rule and the Response to Comments document (Ref. 69). In response to the strong interest by the public, and to allow more individuals and groups to submit their comments, EPA extended the public comment period to April 7, 1999 (at 64 FR 9957, March 1, 1999) (FRL–6066–1). Additional information regarding EPA's outreach may be found in supporting documents included in the public version of the official record.

IV. Summary of Proposal

A. What Chemicals Did EPA Propose to Add to the EPCRA Section 313 List of Toxic Chemicals?

In an initial screening of PBT chemicals that appear on the list of chemicals of concern in the various chemical initiatives, EPA identified seven chemicals and one category of chemicals that persist and bioaccumulate in the environment but that were not on the list of EPCRA section 313 toxic chemicals. Although identification of these chemicals for initial consideration prior to this rulemaking was based on their status as PBT chemicals, their proposed addition in this rulemaking was based solely on the determination that they meet the EPCRA section 313(d)(2) listing criteria. All of the chemicals proposed for addition were found to be reasonably anticipated to cause serious or irreversible chronic human health effects at relatively low doses or ecotoxicity at relatively low concentrations, and thus are considered to have moderately high to high chronic toxicity or high ecotoxicity. The chemicals and chemicals categories EPA proposed to add to the list of EPCRA section 313 toxic chemicals include: Dioxin and dioxin-like compounds category, benzo(g,h,i)perylene, benzo(j,k)fluorene (fluoranthene), 3-methylcholanthrene, octachlorostyrene, pentachlorobenzene, tetrabromobisphenol A (TBBPA), vanadium (except alloys) and vanadium compounds.

B. What Persistence and Bioaccumulation Issues Did EPA Consider?

As noted above, for purposes of the proposed rule, EPA conducted its first, limited review of chemicals for their persistence and bioaccumulation properties under EPCRA section 313. EPA first established criteria to be used under section 313 for determining if a chemical persists or bioaccumulates in the environment. These criteria were then applied to determine whether the chemicals included in the review have the potential to persist and bioaccumulate in the environment. The initial group of chemicals reviewed were the result of EPA's screening assessment of two lists of persistent and bioaccumulative chemicals: (1) The Great Lakes Binational Level 1 list (Ref. 24); and (2) chemicals that received high scores for persistence and bioaccumulation in the initial version of the Waste Minimization Prioritization Tool (WMPT) developed by EPA's Office of Solid Waste (Ref. 74). Finally, included in this initial review were the chemicals included in the dioxin and dioxin-like compounds category that EPA had proposed for addition to the section 313 list in 1997 (at 62 FR 24887, May 7, 1997) (FRL–5590–1).

1. *Persistence*. A chemical's persistence refers to the length of time the chemical can exist in the environment before being destroyed (i.e., transformed) by natural processes. The proposal discussed those aspects of persistence that are important to consider in determining a chemical's persistence in the environment and set forth the criteria that EPA used for determining whether a chemical is persistent for purposes of reporting under EPCRA section 313. Numerous organizations and internationally negotiated agreements have set numerical criteria for environmental persistence, many of which have been developed through consensus processes (Ref. 68). Of those reviewed, the criteria for persistence in water, soil, and sediment tend to cluster around two half-lifes, 1 to 2 months and 6 months while the persistence criterion for air was either a half-life of 2 or 5 days. A half-life of 6 months for water, soil, and sediment and half-lifes of either 2 or 5 days for air were chosen by the international organizations as criteria for chemicals that are being banned or

NMED Exhibit 72

severely restricted. However, EPCRA section 313 is an information collection and dissemination program. EPA believes that persistence criteria consistent with the criteria applied to chemicals that are of global or regional (e.g., Europe and the Great Lakes) concern and that are targeted for ban, restriction, or phase-out are inappropriate for such a program. Chemicals that meet the persistence criteria used in the international agreements are the extremely persistent chemicals. Applying these strict criteria to EPCRA section 313 would result in a very narrow list of chemicals that would focus on only extremely persistent chemicals. This is inconsistent with one of the fundamental tenets of right-to-know which is to provide the public with information on toxic chemicals that have the potential to cause adverse effects in their community. Further, persistence criteria of half-lifes of 6 months and 5 days have not been used to establish whether a chemical is a PBT chemical but rather whether a chemical should have restrictions on its uses. The Agency stated in the proposal its belief that half-life criteria of 2 months for water, sediment, and soil and 2 days for air will include a better representative sample of chemicals that persist in the environment. Therefore, EPA used a half-life criterion of 2 months for water, sediment, and soil and a half-life of 2 days for air for the purposes of determining under EPCRA section 313 whether a toxic chemical is persistent in the environment. Under these criteria, if a toxic chemical meets any one of the media-specific criteria, it is considered to be persistent.

2. *Bioaccumulation*. Bioaccumulation is a general term that is used to describe the process by which organisms may accumulate chemical substances in their bodies. The term refers to both uptake of chemicals from water (bioconcentration) and from ingested food and sediment residues. The discussions and data on bioaccumulation in the proposed rule dealt strictly with aquatic organisms because most of the bioaccumulation data are from aquatic studies. The proposal also discussed, in detail, those aspects of determining bioaccumulation that are important to consider in assessing whether a particular chemical will bioaccumulate in the environment.

A chemical's potential to bioaccumulate can be quantified by measuring or predicting a chemical's bioaccumulation factor (BAF) or a chemical's bioconcentration factor (BCF). Sources of BAF and BCF data for the chemicals included in the proposed rule included a mixture of both predicted and measured BAF and BCF values. The record for the proposed rule includes a document that explains the origin of the BAF or BCF value selected for each PBT chemical (Ref. 71). Most data were retrieved from the U.S. EPA's AQUIRE data base (Ref. 58) and the Japanese Chemicals Inspection and Testing Institute (CITI) data base (Ref. 18a).

As with persistence, a number of organizations and internationally negotiated agreements have set numerical criteria for bioaccumulation, many of which have been developed through a consensus processes. Of those reviewed, the criteria used for bioaccumulation was a BAF/BCF numerical value of either 5,000 or 1,000 or, in some cases, 500. The bioaccumulation criteria chosen by the international organizations as criteria for chemicals that are being banned or severely restricted was 5,000. However, for the same reasons discussed in Unit IV.B.1., EPA stated that the criteria used by the international organizations would not be appropriate for purposes of EPCRA section 313. Therefore, EPA used a BAF/BCF numerical criterion of 1,000 for determining if a chemical is bioaccumulative for purposes of EPCRA section 313.

3. *Persistence and bioaccumulation data*. In the proposal, EPA presented the bioaccumulation and persistence data for the PBT chemicals being considered. More detailed discussions of the sources of these data are provided in the support documents (Refs. 7 and 71). When considering the bioaccumulation and persistence potential of chemical categories, EPA reviewed the individual bioaccumulation and persistence data for the category members and determined in which tier the entire chemical category should be placed. For chemicals that had half-life ranges that bracketed the persistence tiers, EPA considered the types of studies supporting the half-life ranges and determined the most appropriate tier for each chemical.

C. How Did EPA Propose to Address Dioxin and Dioxin-Like Compounds?

In response to a petition from Communities For A Better Environment, EPA issued a proposed rule (at 62 FR 24887) to add a category of dioxin and dioxin-like compounds to the EPCRA section 313 list of toxic chemicals. As part of that action, EPA proposed to move 11 co-planar polychlorinated biphenyls (PCBs) from their listing under Chemicals Abstract Service Registry (CAS) Number 1336–36–3 to the dioxin and dioxin-like compounds category. However, since PCBs persist and bioaccumulate, EPA stated its belief in the proposed rule that PCBs should be subject to lower reporting thresholds. Thus EPA believed there was no need to move the 11 co-planar PCBs to the proposed dioxin and dioxin-like compounds category. Therefore, EPA withdrew its original proposal to modify the listing for PCBs and instead proposed to lower the reporting thresholds for the current PCB listing which covers all PCBs (at 64 FR 710). Because of this change, the proposed dioxin and dioxin-like compounds category included only the 7 polychlorinated dibenzo-*p*-dioxins and the 10 polychlorinated dibenzofurans identified in the proposed rule. In order to focus reporting on those facilities that actually add to the environmental loading of the dioxin and dioxin-like compounds and to reduce reporting burden, EPA proposed to add the activity qualifier ''manufacture only'' to the category. This qualifier would have limited reporting to those dioxin and dioxin-like compounds that are manufactured at the facility, including those coincidentally manufactured.

D. What Proposed Changes to Reporting Requirements for PBT Chemicals Did EPA Consider?

1. *Changes to reporting thresholds*. In evaluating potential lower reporting thresholds for PBT chemicals, EPA considered not only their persistence and bioaccumulation and the purposes of EPCRA section 313, but also the potential burden that might be imposed on the regulated community. Because all PBT chemicals persist and bioaccumulate in the environment, they have the potential to pose greater exposure to humans and the environment over a longer period of time (Refs. 75 and 76). The nature of PBT chemicals indicates that small quantities of such chemicals are of concern, which provides strong support for setting lower reporting thresholds than the current section 313 thresholds of 10,000 and 25,000 pounds. For determining the levels at which reporting thresholds should be set for these chemicals, EPA adopted a two-tiered approach. EPA made a distinction between persistent bioaccumulative toxic chemicals and highly persistent, highly bioaccumulative toxic chemicals by proposing to set lower reporting thresholds based on two levels of persistence and bioaccumulation potential. EPA proposed to set a manufacture, process and otherwise use threshold of 100 pounds for PBT chemicals and a threshold of 10 pounds for that subset of PBT chemicals that are highly persistent and highly

NMED Exhibit 72

bioaccumulative toxic chemicals. One exception to this is the reporting threshold for the dioxin and dioxin-like compounds category, see the discussion in Unit IV.D.2.

In determining the appropriate reporting thresholds to propose for PBT chemicals, EPA started with the premise that low or very low reporting thresholds may be appropriate for these chemicals based on their persistence and bioaccumulation potentials only. EPA then considered the burden that would be imposed by lower reporting thresholds and the distribution of reporting across covered facilities. Considering the factors described above, in addition to the purposes of EPCRA section 313, EPA proposed to lower the manufacture, process, and otherwise use thresholds to 100 pounds for PBT chemicals and to 10 pounds for that subset of PBT chemicals that are highly persistent and highly bioaccumulative. EPA presented the proposed section 313 reporting thresholds for each of the PBT chemicals considered. For purposes of section 313 reporting, threshold determinations for chemical categories are based on the total of all toxic chemicals in the category (see 40 CFR 372.25(d)).

2. *Special reporting threshold for dioxin and dioxin-like compounds.* The category of dioxin and dioxin-like compounds are highly persistent and highly bioaccumulative toxic chemicals. However, this category of chemicals poses unique problems with regard to setting section 313 reporting thresholds because these chemicals are generally produced in extremely small amounts compared to other section 313 chemicals. In response to EPA's original proposal to add dioxin and dioxin-like compounds, EPA received numerous comments suggesting that the reporting threshold for this category be set at zero. EPA stated its belief that rather than setting a zero reporting threshold it would be better to set a very low threshold that provides facilities with a clear indicator of when they are required to report. EPA proposed a manufacture threshold of 0.1 gram for the category. EPA expressed its intent to develop reporting guidance for industries that may fall within this reporting category. In addition to the proposed lower reporting threshold for the dioxin and dioxin-like compounds category, EPA requested comment on an alternative way of reporting release and other waste management data for this category. This alternative included reporting release and other waste management data for the dioxin and dioxin-like compounds category in terms of grams of toxicity equivalents (TEQs).

E. What Other Reporting Issues Did EPA Consider for PBT Chemicals?

1. *De minimis exemption.* In 1988, EPA promulgated the *de minimis* exemption because: (1) The Agency believed that facilities newly covered by EPCRA section 313 would have limited access to information regarding low concentrations of toxic chemicals in mixtures that are imported, processed, otherwise used or manufactured as impurities; (2) the Agency did not believe that these low concentrations would result in quantities that would significantly contribute to threshold determinations and release calculations at the facility (53 FR 4509, February 16, 1988); and (3) the exemption was consistent with information collected by the Occupational Safety and Health Administration's (OSHA) Hazard Communication Standard (HCS). However, given that: (1) Covered facilities currently have several sources of information available to them regarding the concentration of PBT chemicals in mixtures; (2) even minimal releases of persistent bioaccumulative chemicals may result in significant adverse effects and can reasonably be expected to significantly contribute to exceeding the proposed lower thresholds; and (3) the concentration levels chosen, in part, to be consistent with the OSHA HCS are inappropriately high for PBT chemicals, EPA's original rationale for the *de minimis* exemption does not apply to PBT chemicals. EPA therefore proposed to eliminate the *de minimis* exemption for PBT chemicals. EPA did not propose, however, to modify the applicability of the *de minimis* exemption to the supplier notification requirements (40 CFR 372.45(d)(1)) because the Agency believed there was sufficient information available.

2. *Use of the alternative threshold and Form A.* EPA stated its belief that use of the existing alternate threshold and reportable quantity for Form A would be inconsistent with the intent of expanded PBT chemical reporting. The general information provided in the Form A on the quantities of the chemical that the facility manages as waste is insufficient for conducting analyses on PBT chemicals and would be virtually useless for communities interested in assessing risk from releases and other waste management of PBT chemicals. EPA, therefore, proposed excluding all PBT chemicals from the alternate threshold of 1 million pounds.

3. *Proposed changes to the use of range reporting.* EPA stated its belief that use of ranges could misrepresent data accuracy for PBT chemicals because the low or the high end range numbers may not really be that close to the estimated value, even taking into account its inherent error (i.e., errors in measurements and developing estimates). EPA believed this uncertainty would severely limit the applicability of release information where the majority of releases, particularly for PBT chemicals, are expected to be within the amounts eligible for range reporting. Given EPA's belief that the large uncertainty that would be part of these data would severely limit their utility, EPA proposed to eliminate range reporting for PBT chemicals.

4. *Proposed changes to the use of the half-pound rule and whole numbers.* EPA currently allows facilities to report whole numbers and to round releases of 0.5 pound or less to zero. EPA explained its concern that the combination of requiring the reporting of whole numbers and allowing rounding to zero would result in a significant number of facilities reporting their releases of some PBT chemicals as zero. EPA, therefore, proposed that all releases or other waste management quantities greater than 1/10 of a pound of PBT chemicals (except dioxins) be reported, provided that the appropriate activity threshold has been exceeded. For the category of dioxin and dioxin-like compounds, which have a proposed reporting threshold of 0.1 gram, EPA proposed that facilities report all releases and other waste management activities greater than 100 micrograms (ug) (i.e., 0.0001 gram).

5. *Proposed changes to other EPCRA section 313 reporting requirements.* The alkyl lead compounds tetraethyl lead (CAS No. 78–00–2) and tetramethyl lead (CAS No. 75–74–1) are currently reportable under the EPCRA section 313 category listing for lead compounds. However, these two chemicals specifically appear on the Binational Level 1 list of chemicals that have been identified for virtual elimination from the Great Lakes and thus are of special concern. EPA, therefore, proposed that separate reports be filed for these two members of the lead compounds category, which would allow better tracking of these specific lead compounds. In addition, EPA proposed to list ''vanadium'' and ''vanadium compounds'' and delete the EPCRA section 313 listing for ''vanadium (fume or dust).'' Since vanadium without the fume or dust qualifier would be a new section 313 listing, EPA did not propose to include additional reporting on alloys containing vanadium. In the proposal, EPA deferred making a final decision on

NMED Exhibit 72

vanadium contained in alloys until the Agency could complete a scientific review of issues pertinent to some alloys. EPA proposed to include the qualifier ''except when contained in an alloy'' in the vanadium listing. EPA also requested comment on the adequacy of existing studies for determining the bioaccumulation potential of cobalt and cobalt compounds.

V. Summary of the Final Rule

A. Which Chemicals is EPA Adding to the List of Toxic Chemicals Under EPCRA Section 313?

In this action, EPA is adding seven chemicals and two chemical compound categories to the list of toxic chemicals subject to reporting under EPCRA section 313. These chemicals include: benzo(g,h,i)perylene, benzo(j,k)fluorene (fluoranthene), 3-methylcholanthrene, octochlorostyrene, pentachlorobenzene, TBBPA, vanadium (except when in an alloy), vanadium compounds, and a category consisting of 17 specified dioxin and dioxin-like compounds. EPA has determined that each of these chemicals and chemical compound categories meets the listing criteria under EPCRA section 313(d)(2). Two of these chemicals, 3-methylchloanthrene and benzo(j,k)fluorene (fluoranthene), are being added as members of the polycyclic aromatic compounds (PACs) category. Vanadium, with the qualifier ''fume or dust,'' has been on the list of toxic chemicals since the program's inception in 1987. In today's action, however, the Agency is removing the ''fume or dust'' qualifier from the vanadium listing. However, EPA is not including reporting on vanadium when contained in alloys. EPA is finalizing the proposed qualifier ''except when contained in an alloy'' to the vanadium listing. Therefore all elemental vanadium, unless it is in an alloy, is now reportable under EPCRA section 313. In addition to modifying the qualifier, EPA is also adding a new vanadium compounds category. Thus, all chemical compounds that contain vanadium are reportable under this listing. Further, EPA is finalizing its proposal (62 FR 24887) to add dioxins and 16 dioxin-like compounds. However, the Agency is modifying the qualifier that it originally included with this listing. In the PBT proposed rule, EPA proposed to add the dioxin and dioxin-like compounds category with the qualifier ''manufacturing only.'' However, based on comments the Agency received, EPA is changing this qualifier to include: Manufacturing; and the processing or otherwise use of dioxin and dioxin-like compounds if the dioxin and dioxin-like compounds are present as contaminants in a chemical and if they were created during the manufacturing of that chemical.

B. Which Chemicals is EPA Including as PBT Chemicals Under EPCRA Section 313?

EPA has made the final determination that 18 of the chemicals and chemical categories proposed meet the EPCRA section 313 criteria for persistence and bioaccumulation. Thus EPA is lowering the reporting threshold for all of these toxic chemicals. These chemicals and their final thresholds are listed in Table 1 below:

Table 1.—Reporting Thresholds for EPCRA Section 313 Listed PBT Chemicals

Chemical Name or Chemical Category Name	CASRN	Section 313 Reporting Threshold (in pounds unless noted otherwise)
Aldrin	309-00-2	100
Benzo(g,h,i)perylene	191-24-2	10
Chlordane	57-74-9	10
Dioxin and dioxin-like compounds category (manufacturing; and the processing or otherwise use of dioxin and dioxin-like compounds if the dioxin and dioxin-like compounds are present as contaminants in a chemical and if they were created during the manufacturing of that chemical)	NA	0.1 grams
Heptachlor	76-44-8	10
Hexachlorobenzene	118-74-1	10
Isodrin	465-73-6	10
Methoxychlor	72-43-5	100
Octachlorostyrene	29082-74-4	10
Pendimethalin	40487-42-1	100
Pentachlorobenzene	608-93-5	10
Polycyclic aromatic compounds category	NA	100
Polychlorinated biphenyl (PCBs)	1336-36-3	10
Tetrabromobisphenol A	79-94-7	100
Toxaphene	8001-35-2	10
Trifluralin	1582-09-8	100
Mercury	7439-97-6	10

Table 1.—Reporting Thresholds for EPCRA Section 313 Listed PBT Chemicals—Continued

Chemical Name or Chemical Category Name	CASRN	Section 313 Reporting Threshold (in pounds unless noted otherwise)
Mercury compounds	NA	10

EPA is deferring its decision for two chemicals and one chemical category. Specifically, EPA is deferring a determination on dicofol while the Agency continues to review the available persistence data. EPA is also deferring its decision on cobalt and cobalt compounds because it needs to further investigate the bioaccumulative potential of these chemicals.

C. What Thresholds Has EPA Established for PBT chemicals?

EPA is finalizing the thresholds it proposed for PBT chemicals in the January 5, 1999 (64 FR 688) **Federal Register**. Specifically, EPA is finalizing two thresholds based on the chemicals' potential to persist and bioaccumulate in the environment. The two levels include setting section 313 manufacture, process, and otherwise use thresholds at 100 pounds for PBT chemicals and at 10 pounds for that subset of PBT chemicals that are highly persistent and highly bioaccumulative. One exception is the dioxin and dioxin-like compounds category. The dioxin and dioxin-like compounds category threshold determination required special consideration because these highly persistent and highly bioaccumulative compounds are manufactured in extremely small amounts compared to other section 313 chemicals. In order to capture release and other waste management data, EPA is setting the threshold for the dioxin and dioxin-like compound category at 0.1 gram.

D. What Exemptions and Other Reporting Issues is EPA Addressing?

EPA is eliminating the *de minimis* exemption for the PBT chemicals included in today's final rule. However, this action will not affect the applicability of the *de minimis* exemption to the supplier notification requirements (40 CFR 372.45(d)(1)). During the inter-agency review process, it was suggested that EPA consider constructing an exemption for facilities in SIC code 5171, i.e., Petroleum Bulk Plants and Terminals. Specifically, it was suggested that EPA exempt the processing of PBT chemicals in petroleum products. Before EPA can consider this exemption, EPA must determine that these facilities process and release and otherwise manage as waste very small aggregate quantities of PBT chemicals. The Agency is soliciting comments and information on this suggestion, particularly any information that could provide a factual basis for such an exemption. Please send your comments to the person listed in the ''FOR FURTHER INFORMATION CONTACT'' section within the next 60 days. EPA will evaluate this suggestion, and provide a response within approximately 180 days.

In today's action, EPA is also excluding all PBT chemicals from eligibility for the alternate threshold of 1 million pounds and eliminating for PBT chemicals range reporting for on-site releases and transfers off-site for further waste management. This will not affect the applicability of the range reporting of the maximum amount on-site as required by EPCRA section 313(g). EPA is addressing the alkyl lead compounds, tetraethyl lead (CAS No. 78–00–2), and tetramethyl lead (CAS No. 75–74–1), in a separate rulemaking for lead and lead compounds (64 FR 42222, August 3, 1999) (FRL–6081–4). Therefore, EPA is not finalizing any action with respect to these two lead compounds in today's action.

EPA proposed to require reporting of all releases and other waste management quantities greater than 1/10 of a pound of PBT chemicals (except dioxin), provided that the accuracy in the underlying data on which the estimate is based supports this level of precision. Also, EPA stated that releases and other waste management quantities would continue to be reported to two significant digits. In addition, EPA stated that for quantities of 10 pounds or greater, only whole numbers would be required to be reported. For the category of dioxin and dioxin-like compounds, which have a proposed reporting threshold of 0.1 gram, EPA proposed that facilities report all releases and other waste management activities greater than 100 µg (i.e., 0.0001 gram). After reviewing all the comments on this issue, EPA is providing additional guidance on the level of precision at which facilities should report their releases and other waste management quantities of PBT chemicals. Facilities should still report releases and other waste management quantities greater than 0.1 pound (except dioxins) provided the accuracy and the underlying data on which the estimate is based supports this level of precision. Rather than reporting in whole numbers and to two significant digits, if a facility's release or other waste management estimates support reporting an amount that is more precise than whole numbers and two significant digits, then the facility should report that more precise amount. The Agency believes that, particularly for PBT chemicals, facilities may be able to calculate their estimates of releases and other waste management quantities to 1/10 of a pound and believes that such guidance is consistent with the reporting requirements of sections 313(g) and (h).

E. What is the Relationship Between This Rule and the Clean Air Act Mercury Information Collection Request?

Throughout calendar year 1999, EPA has been using authority under section 114 of the Clean Air Act to require all coal-fired power plants over 25 mega watts to submit to EPA the results of analyses of the mercury content of their coal. A representative sample of these plants, stratified by type of plant and type of coal burned, have been required to perform stack testing to determine the amount (and species) of mercury emitted. The stack testing will allow EPA to develop a set of emissions factors that can be applied to the mercury in coal analysis to generate mercury emissions estimates for each coal-fired plant. EPA does not intend to continue to require plants to submit either the coal analysis or the stack testing beyond the current requirement. Therefore for the purpose of reporting mercury releases to the TRI, EPA expects coal-fired power plants that do not have monitoring or stack test data for the reporting year to use the emissions factors that EPA will develop and make available to the public in the summer of 2000.

NMED Exhibit 72

VI. Summary of Public Comments and EPA Responses

A. What Comments Did EPA Receive on its Statutory Authority to Add Chemicals and Lower the Reporting Threshold and What is EPA's Response?

Several commenters assert that EPCRA section 313(f)(2) only grants EPA the authority to raise the statutory thresholds, but not to lower them. They agree that the substantial majority test is met ''as a matter of logical necessity'' when EPA lowers the reporting threshold, and argue that this makes the ''substantial majority'' test essentially meaningless when thresholds are lowered. They argue that this demonstrates that Congress did not intend for EPA to lower reporting thresholds, only to raise them.

These commenters also rely on the language of other provisions of EPCRA section 313 to support their argument that Congress did not grant EPA authority to lower thresholds. They rely on the fact that section 313(f)(2) does not provide that EPA can ''raise or lower'' thresholds, unlike section 313(d), under which EPA can ''add or delete'' chemicals from the list, and section 313(b), under which EPA can ''add or delete'' industry sectors. In addition, the commenters argue that section 313(f)(2) is analogous to section 313(l), where, despite the use of the otherwise neutral term ''modify,'' Congress clearly meant for EPA only to make the reporting requirements less frequent (i.e., less stringent). Based on these provisions, they also argue that, where Congress intended EPA to have the authority to both expand and restrict reporting, the statute explicitly provides the authority, but where Congress only intended to authorize EPA to reduce the reporting burden, it provided a neutral term, and then restricted it. The commenters argue that in section 313(f)(2), Congress qualified EPA's authority with a substantial majority restriction that only makes sense if EPA raises the thresholds.

EPA disagrees with the commenters' interpretations. Section 313(f)(2) clearly authorizes EPA to lower thresholds, as well as to raise them. The plain language of this provision provides that ''the Administrator may establish a threshold different from the amount established by paragraph (1).'' It clearly does not state that the Administrator may only establish a higher threshold than the amount established by paragraph (1), which appears to be the commenters' interpretation. Moreover, in the House debate on the conference report, Representative Edgar, one of EPCRA's sponsors, noted:

> The EPA is authorized to revise these thresholds, but only if such revised thresholds obtain reporting on a substantial majority of total releases, *especially if such revised thresholds raise the statutory levels*,. . . (A Legislative History of the Superfund Amendments and Reauthorization Act of 1986, Committee Print, vol. 6, 5315) (emphasis added).

The clear implication of this statement is that Congress intended EPA to have the authority to lower, as well as to raise, the statutory thresholds.

The commenters' interpretation that EPA lacks the authority to lower the thresholds conflicts with Congressional intent in other ways. During debate on the Conference Report, Representative Edgar noted that ''This act is intended to provide a *comprehensive view of toxic chemical exposure* and, hopefully, provide a basis for more sensible and effective local, State, and national policies.'' *Legislative History* at 5316. See, also, *Legislative History* at 5313 and 5338. And yet without the authority to lower the thresholds, EPA cannot ensure that this objective is achieved. For example, Congress included PCBs on the original list of EPCRA section 313 chemicals, thereby indicating an intent to provide the public with a ''comprehensive view of exposure'' to PCBs; but under the original reporting requirements, EPA only received 6 reports. Under no interpretation can six reports be characterized as obtaining ''a comprehensive view of toxic chemical exposure.'' *Legislative History* at 5315.

EPA also disagrees with the comment that the Agency's interpretation has rendered this provision meaningless. This argument is based on a logical fallacy; a standard need not constrain agency action to the same degree in all circumstances to be meaningful. Congress may impose a standard that constrains actions to varying degrees in different circumstances. In this case, the Congressional debate on this provision indicates that Congress was most concerned with the loss of publicly available information that may result from raising the thresholds. See, e.g., *Legislative History* at 5315-16. It is therefore reasonable to assume that Congress chose to impose a standard that presented a greater constraint on the Agency's ability to raise thresholds, and therefore created a ceiling beyond which the Agency was not authorized to modify thresholds.

Further, notwithstanding the fact that under EPA's interpretation of section 313(f)(2), the Agency can meet the statutory standard without the need for quantitative support when it lowers the threshold, EPA does not believe that Congress has granted it unfettered discretion to establish a different threshold. As discussed at length in Unit VI.E., Congress provided significant guidance in other provisions of the statute and the legislative history, to guide the Agency's exercise of discretion under this provision. Moreover, as noted above, the substantial majority requirement establishes a ceiling beyond which the Agency is not authorized to modify thresholds.

EPA also disagrees with the commenters' interpretation of other provisions of EPCRA section 313. In general, Congress established the basic framework of right-to-know reporting in EPCRA section 313, and selectively granted EPA carefully qualified authority to adjust individual parameters as appropriate. For example, EPA is authorized to modify the chemicals on the EPCRA section 313 list, the SIC codes and facilities covered by section 313, the reporting frequency, and the reporting thresholds, but each grant of authority is constrained to varying degrees by the standards contained in each respective provision. As the commenters have correctly noted, where Congress intended to restrict the Agency's authority to modify the original requirements, it did so explicitly. For example section 313(l) specifically limits EPA's authority to modify the reporting frequency: ''. . .but the Administrator may not modify the frequency to be any more often than annually.'' Similarly Congress included no provision authorizing any amendments to the generally applicable employee threshold. It is therefore reasonable to assume that had Congress intended to only permit EPA to raise the thresholds, they would have included such an explicit restriction in the provision. Moreover, as noted earlier in this unit, the little legislative history that exists on this provision indicates that Congress intended EPA to have the discretion to both raise and lower the reporting thresholds. Further, EPA disagrees with the commenters' interpretation that Congress relied on different statutory construction to indicate its decision not to grant the Agency authority to decrease reporting thresholds, rather than relying on an explicit restriction in the plain language of the statute. EPA is aware of no indication of such Congressional intent in the legislative history, nor have the commenters cited to any. More to the point, the commenters' interpretation is clearly refuted by the inclusion in section 313(l) of an explicit restriction, demonstrating that where Congress

NMED Exhibit 72

intended to restrict EPA's authority, it did so explicitly.

One commenter argues that EPA lacks authority to lower the thresholds based on a comparison of the language in EPCRA sections 311 and 312 authorizing EPA to revise the section 311 and section 312 thresholds, with the language of section 313(f)(2). The commenter states that Congress could have used this same broad and simple language in section 313, and argues that because it did not, but instead chose to impose the ''substantial majority'' requirement, this demonstrates that Congress did not intend EPA to have the authority to lower the thresholds. Instead, the commenter argues, Congress was concerned with reporting burden when it crafted section 313, and so declined to grant EPA authority to lower the thresholds.

EPA disagrees. There is no significant difference between the language in sections 311, 312, and 313 that supports the commenter's interpretation. Unlike section 313, Congress did not establish thresholds in sections 311 and 312, but granted the Administrator broad discretion to determine whether a threshold was even appropriate; at what level to establish the threshold; and to modify it as appropriate. The language with which Congress conferred this authority provides that ''the Administrator may establish threshold quantities. . . .'' This is almost identical to the language of section 313(f)(2), which simply provides that ''the Administrator may establish a threshold amount for a toxic chemical different from the amount established by paragraph (1).'' The commenter's argument turns wholly on the inclusion of the ''substantial majority'' requirement, and as explained above, EPA does not believe that this standard either precludes EPA from lowering thresholds or demonstrates Congressional intent to do so.

Several commenters challenged EPA's finding that its alternate thresholds would capture a substantial majority of total releases, contending that the Agency had impermissibly relied on an increase in the number of reports submitted. The commenters assert that EPA is required to estimate releases at these facilities and determine, on a percentage basis, whether a ''substantial majority'' of all releases of each chemical, from all facilities subject to EPCRA section 313, will be captured. One commenter noted that, even if lowering the threshold for an EPCRA section 313 chemical results in an increase in the number of reports on the chemical, this does not necessarily mean that the additional reports will capture a substantial majority of the total releases from all facilities subject to EPCRA section 313 reporting. In order for the lower threshold to meet the statutory test, the threshold must result in capturing at least two thirds of all releases of the chemical at covered facilities. The commenter contended that the number of reports is irrelevant to the percentage of releases captured by the reports. If a certain chemical were present at only one facility in the country subject to EPCRA section 313, the submission of one report on the chemical accounting for at least 66% of the releases from that facility would satisfy the ''substantial majority'' test. By contrast, if a lower threshold generated 1,000 new reports on a EPCRA section 313 chemical, the ''substantial majority'' test would not be met if those reports did not account for at least 66% of the total releases from all facilities subject to EPCRA section 313. This may be the case, for example, if a large percentage of releases of the EPCRA section 313 chemical occurred at facilities otherwise subject to EPCRA section 313 that do not meet the threshold for that particular chemical that triggers the obligation to report the releases.

EPA disagrees with the commenter's interpretation. As noted in the proposed rule, EPA interprets the language in 313(f)(2), ''facilities subject to the requirements of [section 313],'' to refer to those facilities that fall within the category of facilities described by sections 313(a) and (b). Subsection (a) lays out the general requirement that ''the owner or operator of facilities subject to the requirements of this section'' file an EPCRA section 313 report. Subsection (b) then further defines the facilities subject to the requirements of this section:

> [t]he requirements of this section shall apply to owners and operators of facilities that have 10 or more full-time employees and that are in Standard Industrial Classification Codes 20-39, . . . and that manufactured, processed, or otherwise used a toxic chemical listed under subsection (c) of this section in excess of the quantity of that toxic chemical established under subsection (f) of this section during the calendar year for which a toxic chemical release form is required under this section.

Thus, to be subject to the requirements, a facility must meet all three of the requirements laid out in subsection (b). This means that the class of facilities subject to reporting under section 313 will vary according to the individual chemical. Moreover, facilities that have not exceeded a threshold for a particular chemical are not ''subject to the requirements'' of EPCRA section 313 for that chemical.

To determine whether a particular threshold, either higher or lower, for an individual chemical meets the substantial majority test, one would compare the total national aggregate of releases of the chemical by covered facilities at the existing thresholds with the estimated total national aggregate of releases at the proposed alternate threshold, and determine whether a substantial majority of releases reported under the original thresholds would be reported. Logically, the universe of facilities subject to the requirements under a lower threshold will always be either equivalent to, or greater, than the universe of facilities that are subject to the requirements under the existing thresholds. Moreover, because facilities subject to the requirements of section 313 must report ''the annual quantity of the toxic chemical entering each environmental medium,'' EPA can meet the substantial majority standard when lowering the thresholds, without the need for quantitative support; i.e., facilities that report, must report their releases and other waste management quantities. In this instance, the number of reports serves as an adequate surrogate for releases because essentially all releases (and other waste management quantities) will be reported by facilities subject to the requirements of this section.

In other words, facilities ''subject to the requirements of this section'' are those that must file EPCRA section 313 reports. Thus, the baseline against which the ''substantial majority of total releases'' is measured is the category of facilities that currently submit reports. Consequently, if quantitative support for its finding were necessary, EPA would be justified in relying on the number of reports to make its finding.

By contrast, although it is not clear exactly how the commenters interpret the phrase ''facilities subject to the requirements of this section,'' it is clear that they do so without reference to all of the requirements in subsections (a) and (b). And essentially, any interpretation that ignores any portion of subsection (b), results in an interpretation of EPCRA section 313(f)(2) as ''facilities *otherwise* or *potentially* subject to the requirements of this section.'' This is inconsistent with the plain language of section 313(f)(2). The commenters can only support their argument that EPA has not met the ''substantial majority'' test by assuming that all facilities, irrespective of whether they are in a covered SIC code or they exceed the existing thresholds, are subject to EPCRA section

NMED Exhibit 72

313, and that EPA must ensure that it captures a substantial majority of releases from the universe of those facilities. If this were correct, the addition of certain SIC codes could be a prerequisite to lowering thresholds for certain chemicals. Such a requirement is not currently included in section 313. The commenters have provided no support in either the statute or legislative history for these interpretations. Nor have the commenters provided any support for the interpretation that ''substantial majority'' equates to a particular percentage, such as 66%.

Finally, EPA notes, as it noted in the proposed rule, that, for several reasons, it does not believe that it has the necessary information to develop even reasonably accurate estimates of the potential releases that would be reported at an average facility at each of the identified options for a lowered threshold. Specifically, EPA believes that: (1) Sufficient information is not currently available for these chemicals, and (2) there is insufficient information on the numerous processes employed by all the sectors involved to calculate a comprehensive release estimate for each sector. While there are some data available, comprehensive data are not available for all sectors and chemicals. EPA further notes that none of the commenters provided either any information or methodology to address this issue, notwithstanding EPA's specific request.

Two commenters rely on excerpts from the debate on the Conference Report with respect to section 313(f)(2) to argue that EPA is only authorized to revise the thresholds if EPA presents a convincing analysis that revisions to the threshold will capture a substantial majority of the releases while also ensuring that it is not placing undue burdens on facilities which contribute little to such releases. The commenters argue that EPA has not satisfied the substantial majority requirement, and to do so, must conduct a more thorough assessment of the burden imposed on industry focused on the volume of releases that will be captured, not the number of reports. Another commenter compares the legislative history of sections 311 and 312 with 313, and concludes that Congress clearly intended EPA to factor burden into section 313 threshold questions.

EPA disagrees. Ultimately, EPA must comply with the statutory language, and section 313(f)(2) does not impose any requirement on the Agency to rely on the type of analyses described by the commenter. In addition, the commenters' reliance on the statements made during the Conference Report debate are misplaced. The commenter only quotes part of Representative Edgar's statement; the full quotation indicates only that EPA must present a convincing case, ''based on verifiable, historical data'' that the statutory thresholds warrant revision. As discussed below in Unit VI.E., EPA believes it has presented a convincing case that the thresholds should be lowered for PBT chemicals. The commenter also failed to include the portion of Representative Edgar's statement explaining that a convincing case was particularly necessary if the effect of the modification was to raise the thresholds. See, *Legislative History* at 5315.

Nonetheless, as discussed in greater detail in Unit VI.E., EPA considered the burden that lower thresholds would impose on industry in selecting the PBT thresholds. EPA believes that the levels it has adopted will capture significantly more information about PBT chemicals than current thresholds, but will not be unduly burdensome on industry. In addition, as discussed in the Response to Comments document (Ref. 69), EPA believes that the number of reports filed is a more accurate measure of burden than the volume of releases.

A commenter alleges that EPA's interpretation of section 313(f)(2) contradicts its prior statements regarding threshold changes. The commenterstates that EPA was clear in the original EPCRA section 313 rulemaking that the statute requires a substantial majority finding supported by actual data. For example, in the June 1987 proposed rule, EPA stated: ''The Agency is interested in data that would support the necessary finding that a modified threshold would still generate reporting on a substantial majority of total releases, as the statute requires.'' And in the February 16, 1988 final rule promulgating EPCRA section 313 requirements, EPA stated

> . . .the first few years' data should be evaluated to determine whether modifications of the threshold would meet the statutory test of obtaining reporting on a substantial majority of the releases (i.e., pounds released per year) of each chemical from subject facilities. EPA may consider changing the reporting thresholds based on several years of data collection.

The commenter also notes that in neither the proposed nor final rule establishing EPCRA section 313 requirements did EPA specifically assert that it had the authority to lower thresholds.

EPA disagrees that its statements in this rulemaking contradict its prior statements in the 1988 rulemaking. As a preliminary matter, EPA has never denied that the requirement that a revised threshold obtain reporting on a substantial majority of total releases applies to any action lowering the reporting thresholds. Specifically, EPA's discussion in the 1987 proposed rule was in the context of a response to proposals from the Small Business Administration (SBA) that the Agency raise the thresholds to capture only larger facilities. EPA's statements in the 1988 final rule also need to be evaluated with SBA's proposals in mind. Moreover, while it is true that the discussion to which the commenter cited did not distinguish between lowering and raising the thresholds (it was intended as a response to comments on both sides of the issue), EPA notes that the majority of the comment summary focuses on requests to raise the thresholds. Finally, while it is true that EPA did not specifically assert its authority to lower the thresholds in either rule, neither did EPA deny that EPCRA section 313(f)(2) grants it this authority. However, it is worth noting that in the final rule, EPA responded to comments from environmental and public interest groups requesting that the Agency lower the thresholds, and that EPA never stated or implied that it lacked the authority to lower thresholds.

One commenter states that EPA's authority to lower reporting thresholds is not limitless. The commenter argues that a decision to lower the thresholds must be tied to the overall purpose of the Act, namely, to inform the public of potential health risks posed by the presence of toxic chemicals released to the environment in their communities. A regulatory decision to capture more reports under EPCRA section 313 must be based on the need to inform the public of health risks associated with the releases captured in those reports. Otherwise, the usefulness of the TRI data base begins to diminish. EPA needs to demonstrate that the releases of the PBTs at such small amounts pose a meaningful risk to the public health. Another commenter asserts that EPA is relying on the purposes of EPCRA to support its interpretation of section 313(f), and argues that, although section 313(h) does describe intended uses for TRI data, section 313(h) itself does not describe the purposes or intention of section 313. The commenter instead relies on several provisions of section 313 and argues that the purpose and intention of Congress to make information available to the public was balanced by concerns about the potential burden of the TRI program. The commenter also states that the uses

NMED Exhibit 72

Congress anticipated for TRI data do not outweigh the balance that Congress intended between generating information and minimizing burden, and do not grant EPA blanket authority to expand the reporting requirements.

EPA agrees with the commenter that its authority to lower reporting thresholds is not limitless, and that its decision to lower the thresholds must be tied to EPCRA's overall purposes. However, EPA believes that Congress granted the Agency broad, but not unfettered, discretion to determine when it is appropriate to lower thresholds, and to determine the specific thresholds that are appropriate. As discussed in greater detail in Unit VI.E., EPA believes that its decision to lower the thresholds, and the thresholds it has chosen, reflect these principles.

However, EPA generally disagrees with the remainder of the commenter's conclusions. As discussed in more detail in Unit VI.F., EPA is not required to base its decisions under EPCRA section 313 on the need to inform the public of health risks associated with reported releases and other waste management quantities. And as discussed elsewhere in this preamble and the Response to Comments document (Ref. 69), EPA believes that the information that will be reported as a result of this rulemaking will provide useful information to the public.

In large measure, the issues raised in the second comment closely relate to the specific thresholds and EPA's rationale for choosing them, and this issue is discussed in more detail in Unit VI.E. However, to the extent it relates to EPA's interpretation of section 313(f)(2), some response is also provided here.

As a preliminary matter, while it is true that EPCRA section 313 does not explicitly identify the purposes of the section, the Conference Report makes clear that subsection (h) of section 313:

> Describes the intended uses of the toxic chemical release forms required to be submitted by this section and expresses the purposes of this section. The information collected under this section is intended to inform the general public and the communities surrounding covered facilities about releases of toxic chemicals, to assist in research, to aid in development of regulations, guidelines, and standards, and for other similar purposes. (Conference Report at 299).

Contrary to the commenter's assertion, the Agency never indicated that it was relying on section 313(h) to expand its authority under section 313(f)(2). Rather, EPA noted that it was relying on the purposes of section 313 as an additional source of Congressional direction to guide the Agency's exercise of discretion under this provision. EPA relied on section 313(h), in part, because the Agency believes that its implementation of EPCRA generally should be guided by EPCRA section 313's purposes. In addition, section 313(h) shares certain elements with the Congressional guidance on section 313(f)(2) in the legislative history. As discussed in greater detail in Unit VI.E., EPA has distilled those common elements, and relied on them to guide its discretion in establishing the specific thresholds under section 313(f)(2).

EPA also disagrees with the commenter's assertion that the purpose of EPCRA is to achieve a balance between the public's right to information about their potential exposures to toxic chemicals and the reporting burden imposed on industry. EPCRA section 313(f)(2) does not require EPA to consider burden in establishing revised thresholds. Although EPA has included the reporting burdens imposed on industry as one consideration in determining the appropriate thresholds, the Agency is also mindful that the authors of EPCRA, while sensitive to the burdens EPCRA section 313 reporting placed on industry, never intended this consideration to outweigh the public's need for access to information concerning release and waste management, and thus their potential exposure to toxic chemicals. See, e.g., *Legislative History* at 5315–16 and 5338–39. And with respect to the assertion that the general purposes of section 313 are to balance the public's right-to-know about toxic chemical releases and other waste management in their communities against the reporting burdens EPCRA section 313 imposes, EPA notes that reporting burden is not included anywhere in section 313(h). Nor does the strong policy directive underlying EPA's overall implementation of EPCRA section 313 support such an interpretation. Representative Edgar, one of the bill's primary architects noted:

> The heart of the Federal Right-to-Know Program is its reporting requirements, which are intended to provide a comprehensive picture of the community's and the Nation's exposure to toxic chemicals. As the Environmental Protection Agency, the States, and localities implement this program, they should be guided by several general principles.
>
> First, Congress recognizes a compelling need for more information about the Nation's exposure to toxic chemicals. Until now, the success of such regulatory programs such as the Clean Air Act, the Resource Conservation and Recovery Act, and the Clean Water Act has been impossible to measure because no broad-based national information has been compiled to indicate increases or decreases in the amounts of toxic pollutants entering our environment. As a result, the reporting provision in this legislation should be construed expansively to require the collection of the most information permitted under the statutory language. Any discretion to limit the amount of information reported should be exercised only for compelling reasons. . . . *Legislative History* at 5313.

Significantly, Representative Edgar did not include reporting burden as one of the general principles that should guide the Agency's implementation of EPCRA section 313. Rather, he stated:

> This is a new Federal initiative, and I recognize the desire of some of my colleagues to move ahead cautiously to ensure that burdens imposed on industry are not excessive. Frankly, my concerns rest with the families that live in the shadows of these chemical and manufacturing plants. I have put myself in their shoes and have fought for a program that looks after their needs. This legislation gets us well on the path to the full disclosure they deserve. *Id* at 5316.

Nonetheless, EPA has considered the legislative history on section 313(f)(2), including the excerpts cited by the commenter, and determined it would be reasonable to include some consideration of the reporting burdens in selecting its revised thresholds. The degree to which EPA included burden in its selection of the thresholds established in this rulemaking is discussed at length in Unit VI.E. and the Response to Comments document (Ref. 69).

EPA agrees that section 313(h) does not grant EPA unfettered discretion to expand EPCRA's reporting requirements; as noted in a previous response, Congress established the basic parameters of the EPCRA section 313 reporting requirements, and selectively granted EPA carefully qualified authority to modify certain of them. In this action, for example, EPA is only affecting the activity thresholds, but Congress established other limitations that govern whether a facility is subject to reporting. For example, facilities with fewer than 10 employees are not subject to reporting under subsection 313(b)(1).

B. What Comments Did EPA Receive on Persistence Criteria, Bioaccumulation Criteria, and Toxicity Criteria, and What Are EPA's Responses?

1. *Comments on EPA's general approach.* Several commenters contend that only chemicals which are globally recognized as persistent bioaccumulative toxic chemicals should form the foundation of the EPCRA section 313 PBT chemical list and criteria. The application of the criteria in this manner is consistent with several existing international agreements and

NMED Exhibit 72

programs, such as the Great Lakes Binational Strategy, the North American Commission on Environmental Cooperation (NACEC), the United Nations Economic Commission for Europe's (UNECE) agreement to address persistent organic pollutants (POPs), and the United Nations Environmental Programme (UNEP). These programs have prompted widely accepted numerical values for persistence and bioaccumulation and defined parameters for assessing toxicity. These criteria have also been adopted with U.S. support and leadership and the commenters contend that it is not clear why EPA is now taking a vastly different approach to identifying PBT criteria in the proposed rule. The commenters suggest that EPA conform the criteria for PBT chemicals on EPCRA section 313 with the criteria and chemicals that are part of the programs being implemented by the NACEC, UNECE, and UNEP. By doing so, EPA would harmonize the U.S. program with similar international programs that focus on a narrow set of PBT chemicals.

EPA believes that it would be inappropriate to merely adopt the criteria and list of chemicals managed under the international programs cited because the purposes of the TRI program are different than the purposes of the cited international programs. The TRI was established by Congress under EPCRA section 313 in response to public demand for information on toxic chemicals being released in their communities. The TRI program is national in scope, but a significant part of its overriding goal is to provide information on releases to local communities so that they can determine if the releases result in potential risks. The entire concept of TRI, and indeed other, similar Pollutant Release and Transfer Registries (PRTRs) since established in several nations, is founded on the belief that the public has the right to know about chemical use, release, and other waste management in the areas in which they live, as well as the hazards associated with these chemicals. This emphasis is fundamentally different from the global focus of the UNEP negotiation and its concept of residual risk. It is EPA's position that the domestic, community-based purposes of EPCRA section 313 have important implications with regard to the criteria used to identify toxic chemicals as persistent and/or bioaccumulative, as well as the methods and models used to evaluate persistence and/or bioaccumulation.

EPCRA section 313 charges EPA with collecting and disseminating information on releases, among other waste management data, so that communities can estimate local exposure and local risks. One intent of EPCRA section 313 is to provide information to the public so that they can take an active role in determining what risks resulting from toxic chemical releases in their community are acceptable. This basic local empowerment is a cornerstone of the right-to-know program.

EPCRA section 313(h) states that:

> The release forms required under this section are intended to provide information to the Federal, State, and local governments and the public, including citizens of communities surrounding covered facilities. The release form shall be available, consistent with section 11044(a) of this title, to inform persons about releases of toxic chemicals to the environment; to assist governmental agencies, researchers, and other persons in the conduct of research and data gathering; to aid in the development of appropriate regulations, guidelines, and standards; and for other similar purposes.

EPCRA section 313 establishes an information collection and dissemination program. EPA interprets EPCRA section 313(g)(2) to require facilities to use readily available information to prepare each chemical-specific EPCRA section 313 report. The statute does not require that the facility conduct additional monitoring or emissions measurements to determine these quantities. A facility must only use readily available data or reasonable estimation methods in preparing the quantitative information it reports.

The purpose of EPCRA section 313 is not to ban the manufacture or use of a chemical, to restrict releases of the chemical, or to dictate how it should be used or released. As a result, the burden and control EPCRA section 313 imposes is significantly less than that imposed by a statute that controls the manufacture, use, and/or release of a chemical. The focus of EPCRA section 313 is not equivalent to the focus of a statute or international agreements in which chemicals are to be banned, phased-out, or restricted.

In contrast, the international agreements cited by the commenters are intended to ban, restrict, or phase-out the manufacture, use and/or release of a limited set of persistent organic pollutants and certain heavy metals that are highly persistent and highly bioaccumulative. Descriptions of the purposes of the Protocol on Persistent Organic Pollutants (POPs); Convention on Long-Range Transboundary Air Pollution (LRTAP), UNECE, UNEP on POPs, North American Commission for Environmental Cooperation's Sound Management of Chemicals (NACEC SMOC), as well as the International Council of Chemical Associations' (ICCA) position on POPs are presented below. The following quotes clearly illustrate that the intent of the international agreements is to narrowly focus on that subset of toxic chemicals which are of regional (e.g., North America and Europe) or global concern.

UNECE LRTAP

> The ultimate objective is to eliminate any discharges, emissions and losses of POPs. The Protocol bans the production and use of some products outright (aldrin, chlordane, chlordecone, dieldrin, endrin, hexabromobiphenyl, mirex and toxaphene). Others are scheduled for elimination at a later stage (DDT, heptachlor, hexachlorobenzene, PCBs). Finally, the Protocol severely restricts the use of DDT, HCH (including lindane) and PCBs. The Protocol includes provisions for dealing with the wastes of products that will be banned. (The 1998 Aarhus Protocol on Persistent Organic Pollutants (POPs); Convention on Long-Range Transboundary Air Pollution, United Nations Economic Commission for Europe (UNECE) at http://www.unece.org/env/lrtap) (Ref. 54)

UNEP

> International action to protect health and the environment through measures which will reduce and/or eliminate emissions and discharges of persistent organic pollutants, including the development of an international legally binding instrument. (Governing Council Decisions 20/24, 1999; United Nations Environmental Programme at http://irptc.unep.ch/pops/newlayout/negotiations.htm) (Ref. 57)

NACEC SMOC

> NACEC SMOC has developed action plans for PCBs, DDT, chlordane, and mercury. The action plans include 1) for PCBs ''work toward the virtual elimination of PCBs in the environment, which the task force is interpreting as no measurable release to the environment'', 2) for DDT ''gradual reduction of DDT use for malaria control'' and ''additional reductions,'' 3) for chlordane ''phase-out of chlordane use'', and 4) for mercury ''reduce sources of anthropogenic mercury pollution.'' The longer-term goal of the plan is to reduce the presence of mercury in the environment to achieve naturally occurring levels.'' (North American Cooperation for the Sound Management of Chemicals (June 1998); North American Commission for Environmental Cooperation at http://www.cec.org/english/profile/coop/Pollute—f.cfm?format=1) (Ref. 40)

ICCA

> *ICCA Position*: ICCA member associations have demonstrated their commitment to sound chemicals management, and to the goal of reducing the potential human health and environmental risks that may be associated with POPs. Many POPs are already subject to considerable voluntary risk management by chemical companies, and the uses of most substances identified as POPs has been discontinued or extremely limited

NMED Exhibit 72

by chemical companies within the countries represented by ICCA member associations. (International Council of Chemical Associations (ICCA) Briefing Note on Persistent Organic Pollutants (POPs) (April 21, 1998) at http://www.icca-chem.org/issues.htm) (Ref. 26)

In addition, as directed under EPCRA section 313(h), EPA makes the TRI data available to various groups, including international organizations, that, in turn, use the information to decide whether to ban, restrict, or phase-out chemicals.

For the same reasons, EPA also disagrees that only substances globally recognized as POPs should provide the basis of persistence criteria for this rulemaking. POPs are organic chemicals whose characteristics of persistence in the environment, accumulation in biological organisms and toxicity make them priority pollutants that cause significant environmental risks to humans and ecosystems. The substances or substance categories being considered for implementation of global controls through the UNEP negotiations (UNEP/GC.18/32, 1995: aldrin, chlordane, DDT, dieldrin, endrin, heptachlor, mirex, toxaphene, hexachlorobenzene, PCBs, polychlorinated dibenzo-*p*-dioxins and furans) (Refs. 44 and 45) were selected largely because they or their degradation products pose risks that may occur far from their sites of initial entry into the environment. The UNEP action is the global counterpart to similar, regional negotiations, most notably the UNECE Convention on Long-Range Transboundary Air Pollution (LRTAP) (Ref. 54); the North American Free Trade Agreement (NAFTA) CEC Initiative on the Sound Management of Chemicals (Ref. 39); and the bilateral US/Canada agreement to control discharge or release of POPs in the Great Lakes basin (Ref. 23). A central theme of the UNEP action, consistent with its global scope, is the notion of residual risk, meaning specifically that to be subject to the negotiations, it is not sufficient for a substance to pose risks within a nation or regionally, rather it must pose risks to populations and nations distant from release sites.

2. *Comments on EPA's individual criteria.* The same commenters state that EPA should use the international criteria being applied by UNEP, UNECE LRTAP, NACEC SMOC, for persistence, bioaccumulation, and toxicity. Some of these commenters also include the criteria developed by CMA (CMA, PTB Policy Implementation Guidance: Product Risk Management Guidance for PTBs (February 1996)). One commenter includes the criteria developed by the ICCA for POPs. Another commenter states that there is no reason to adopt criteria that are significantly more stringent than those used in other programs. One commenter states that EPA should consider the degree of toxicity and focus on the most toxic chemicals. Some commenters state that EPA should couple the persistence and bioaccumulation criteria to each other. They believe that these criteria should not be considered independently. The numerical criteria presented by some of the commenters are provided below:

Table 2.—Numerical Persistence and Bioaccumulation Criteria Suggested by Commenters

	CMA PTB Policy	NACEC SMOC	UNECE (LRTAP) POPs	UNEP POPs/CEG FRAMEWORK	Environment Canada Toxic Substances Management Policy (June 1995)	ICCA
Persistence	Half-life = 6 months in water or 1 year in soil	Half-life > = 2 days air; 6 months water/soil; or 1 year sediment	Half-life> 2 months water or 6 months soils/sediment; or otherwise sufficiently persistent to be of concern	Half-life > [2 or 6] months soil/sediment; or other evidence that substance is sufficiently persistent to be of concern	Half-life > = 2 days air; 6 months water/soil; 1 year sediment	Half-life = 6 months water, 1 year soil sediments, or 5 days air
Bioaccumulation	BAF/BCF > = 5,000 or estimation techniques	BAF/BCF >= 5,000 or Log K_{ow} > = 5	BAF/BCF > 5,000 or Log K_{ow} > 5 or factors such as high toxicity	BCF/BAF > 5,000 or Log K_{ow}> [4 or 5]; evidence that substance with significantly lower BCF/BAF is of concern, e.g., due to high toxicity/ecotoxicity; or monitoring data in biota indicating sufficient bioaccumulation to be of concern	Half-life > 2 months water or 6 months soils/sediment (or otherwise sufficiently persistent to be of concern)	BCF > 5,000 or log Log K_{ow} > 5 and <7.5, MW<700 and substance is not metabolized

Table 2.—Numerical Persistence and Bioaccumulation Criteria Suggested by Commenters—Continued

	CMA PTB Policy	NACEC SMOC	UNECE (LRTAP) POPs	UNEP POPs/CEG FRAMEWORK	Environment Canada Toxic Substances Management Policy (June 1995)	ICCA
Toxicity	Professional judgment in evaluation of aquatic toxicity, wildlife toxicity, oral/dermal/inhalation toxicity (mammals and birds), reproductive toxicity, neurological toxicity; carcinogenicity, mutagenicity, and/or teratogenicity	Acute and chronic (including toxicity of breakdown products, if appropriate)	Potential to affect human health and/or the environment adversely	Evidence that (chronic) toxicity or ecotoxicity data indicate a potential for damage to human health or the environment caused by the substance resulting or anticipated from long-range transport	CEPA - toxic	Expert judgment that acute aquatic lethality, subchronic and chronic aquatic toxicity, acute wildlife toxicity, oral/dermal/inhalation toxicity in mammals and birds, carcinogenicity, mutagenicity, teratogenicity, reproductive toxicity, neurological toxicity, and immune system effects must be demonstrated or expected to occur at the concentrations observed in the environment

EPA is establishing criteria in this rulemaking for the TRI program for persistence and bioaccumulation. EPCRA section 313(d)(2) already provides toxicity criteria for the TRI program. While EPA chose in this rulemaking to focus on chemicals that are toxic and persistent and bioaccumulative, EPA did not state that the persistence criterion could only be applied in conjunction with the bioaccumulation criterion and vice versa. EPA has not tied the criteria together because there is no scientific rationale to define persistence criteria in terms of both bioaccumulation and persistence and to define bioaccumulation both in terms of persistence and bioaccumulation. As illustrated by the descriptions of persistence and bioaccumulation provided in the proposed rule, persistence and bioaccumulation are separate chemical and/or biological processes. They are not by definition dependent upon the other.

A chemical's persistence refers to the length of time the chemical can exist in the environment before being destroyed. (at 64 FR 698)

and

Bioaccumulation is a general term that is used to describe the process by which organisms may accumulate chemical substances in their bodies. (at 64 FR 703)

A chemical is not considered to be persistent if it is only bioaccumulative. For example, a chemical may be extremely persistent and yet not bioaccumulate appreciably. For example, metals cannot be destroyed in the environment and thus are extremely persistent. Some metals bioaccumulate appreciably while others do not. However, the degree to which a metal can bioaccumulate does not affect the metal's persistence in the environment. The connection suggested by the commenters is not scientifically justified. Thus, EPA does not believe that persistence criteria can be applied only in conjunction with the bioaccumulation criteria. EPA reiterates that in this rulemaking the Agency chose to focus on those toxic chemicals that meet both the persistence and bioaccumulation criteria proposed for EPCRA section 313. In the future, the Agency may focus on toxic chemicals that are either persistent or bioaccumulative.

A discussion of the individual criteria is presented in the remainder of this unit.

a. *Persistence*. EPA proposed persistence criteria for the TRI program of half-lifes of 2 months in water, soil, and sediment and 2 days in air. As discussed in Unit VI.B.1., EPA disagrees that it must choose persistence criteria for EPCRA section 313, an information collection and dissemination program, consistent with the international criteria being applied to chemicals that are of global or regional (e.g., Europe and the Great Lakes) concern and that are being targeted for ban, restriction, or phase-out. Chemicals that meet the persistence criteria used in the international agreements are extremely persistent chemicals. Applying these criteria to EPCRA section 313 would result in a very narrow list of chemicals that would focus on only extremely persistent chemicals. This is inconsistent with both the purposes of EPCRA section 313 and with EPA's technical judgment. There is no ''bright line'' that separates what is persistent from what is not persistent. The degree of persistence is a continuum. Chemicals with a half-life of 2 to 6 months are not non-persistent. They are less than chemicals with a half-life of greater than 6 months. The degree of persistence that should be used as criteria is not an absolute scientific determination. Rather it is a combination of science and policy. As discussed in the proposed rule and the remainder of this section, organizations have generally used as persistence criteria half-lifes of 2 months and/or 6 months for water, soil, and sediment.

The determination of which set of numerical criteria to apply will depend on the final intent: for example, providing communities with information on persistent chemicals that can build up in their environment versus banning the manufacture and use and eliminating releases of a chemical that has global impacts. For EPCRA section 313, which provides information on toxic chemicals to communities, researchers, and governments, the criteria should be in keeping with both science and the intent of the statute.

Long-range transport (LRT) and residual risk are relevant domestically, since chemical substances may be transported regionally and transcontinentally, resulting in exposures at sites distant from releases but still within U.S. borders. Nevertheless, as a general rule, the closer the sources and receptor are, the more likely it is that released material will reach that receptor. The 12 UNEP POPs or their degradation products all meet or exceed the half-life criterion of 6 months for soil, water, or sediment, often by large margins (Refs. 44 and 45), and the 6 months criterion thus acts to isolate these substances for international attention aimed at limiting LRT. But a shorter half-life criterion is necessary to protect communities from bioaccumulative toxicants derived from sources closer to home, since, all other things being equal, a pollutant reaches nearby populations in less time than distant ones.

An article by Wania and Mackay (Ref. 81) is often cited in discussions of ''global distillation'' of relatively mobile POPs such as hexachlorobenzene and lindane, which tend to have inverted concentration profiles such that concentrations increase with distance from the source (i.e., from temperate to polar regions) rather than the reverse. What may be less obvious is that the converse is also true; namely, that less volatile substances show no significant latitudinal dependence; that low-mobility POPs such as mirex and the more highly chlorinated PCBs tend to undergo *rapid deposition and retention* close to their sources; and that all but high or relatively high mobility chemicals are expected to show ''normal'' concentration profiles, such that concentrations decline with distance from warmer sources to colder remote regions (Ref. 81). A recent study of organochlorine contaminants in sea otters illustrates this point. Although the levels of total DDTs observed were not considered toxicologically significant, Bacon *et al.* (Ref. 8) found the highest levels in California sea otters (ca. 850 micrograms per kilogram (µg/kg)) but much lower levels in Aleutian otters (40 µg/kg) and southeast Alaska otters (1 µg/kg), and attributed the higher levels in the California otters to extensive DDT use and production in this region from the 1950s to the 1970s. Even UNEP's Criteria Expert Group (CEG), which is charged with developing criteria and procedures for addition of substances beyond the original 12 POPs, has highlighted the importance of ''near-field'' exposures:

> In warmer climates exposures may occur closer to the source; e.g., occupational exposure during use, or local exposure caused by runoff from use or leaking from stockpiles. Food, such as fish, may be a major route of intake also in warmer climates [in contrast to Arctic and sub-Arctic regions] and POPs may accumulate in the food chain and reach high levels in predatory species in these conditions. (UNEP/POPS/INC/CEG/1/2: 1998) (Ref. 56)

An additional factor that argues for adopting the more protective persistence criterion is the need for communities with vulnerable populations to have access to data on release and other waste management quantities. Examples of such populations include toddlers who play in contaminated soil, local farmers who consume their own produce, and subsistence as well as sport fishers, who often consume large quantities of what they catch. The relative importance of any of these pathways depends on the properties of the substance, rates and media of release and other factors, but ingestion of bioaccumulating substances may occur by all of these routes. The Organization for Economic Cooperation and Development (OECD) guidance on the assessment of indirect human exposure to chemical toxicants is consistent with EPA policy, and states that in the case of local, site-specific emissions, one or more of these subgroups may be particularly endangered (Ref. 53).

From a scientific perspective there is no one best persistence criterion. However, it is simply not accurate to state that there is no precedent or basis for using a persistence criterion of 2 months. As outlined in the proposed rule (64 FR 701), similar values have been proposed by several authorities, including the Ontario, Canada Ministry of Environment and Energy (MOEE) for its Candidate Substances List for Bans or Phaseouts (Ref. 36); the Canadian initiative for Accelerated Reduction/Elimination of Toxics (ARET) (Refs. 1 and 2); the International Joint Commission's (IJC) Great Lakes Water Quality Agreement (GLWQA) (Ref. 27); and the UNECE's LRTAP Convention, which did adopt 2 months as the persistence criterion of record for water (Ref. 54). In each of these programs the focus was on persistent, bioaccumulative and toxic substances, and it is noteworthy that all are national or regional, not global, in scope. Thus, a trend exists in which authorities with domestic or regional mandates to take action to reduce risks from indirect exposure to PBT chemicals have recommended half-life criteria substantially lower than 6 months.

EPA's Office of Water maintains a Listing of Fish and Wildlife Advisories (LFWA) for the U.S. and territories, which listed 2,299 advisories in 1997 (Ref. 29). U.S. states and territories and Native American tribes have primary responsibility for issuing advisories for the general population, which include recommendations to limit or avoid consumption of certain fish and wildlife from specific water bodies. The overwhelming majority of the advisories are for well recognized PBT chemicals (chlordane, mercury, PCBs, etc.), but many less familiar substances are also represented. The number and content of advisories in LFWA clearly indicate that toxicologically significant levels of chemical contaminants, specifically PBT chemicals, are often found in fish and wildlife that are caught noncommercially and consumed by the U.S. population. It is generally impossible to determine the exact source(s) of exposure for the species and locations included in any given advisory, but it seems highly unlikely that the majority of listed contaminants in U.S. waters could be derived from non-U.S. (i.e., geographically distant) sources. The LFWA thus lends further support to the contention that concern for exposure to PBT chemicals is not limited to situations where the exposure results primarily from LRT. It should be noted that the fact that no advisories have been issued for a particular chemical does not mean that it does not persist. Not all species of aquatic organisms are tested nor are all water bodies, in addition, each state determines what it will use as the level of concern for issuing an advisory.

A series of Toxic Substances Control Act (TSCA) section 5 Premanufacture Notifications (PMNs) submitted to EPA in 1990 also illustrates that exposure to PBT chemicals is not limited to LRT (Refs. 37 and 38), and also demonstrates: (i) Why EPA believes that the persistence criterion for bioaccumulating substances in soil, water, or sediment should be set substantially lower than 6 months; and (ii) that for purposes of EPCRA section 313, concern for potential exposures to persistent and bioaccumulative toxics

NMED Exhibit 72

must extend beyond the UNEP's 12 widely acknowledged POPs. The substances in question were alkylated diphenyls for use as solvents, and for which EPA expected discharge to receiving streams and rivers. The submitter supplied data on use and disposal, aquatic toxicity, and biodegradability. The submitted environmental fate data and EPA estimates of biodegradability based on structural analogs suggested that half-lifes in water would be well below 6 months, but not necessarily lower than 2 months. As a result of concerns expressed by EPA, use was limited to sites where resulting water concentrations could be limited to 1 microgram per liter (µg/L) or less; concomitantly, the submitter was also informed of EPA's belief that a potential for *long-term risk* existed, but that EPA could not quantify this risk since assessments typically evaluated releases over only 1 year. In 1998, results of monitoring were announced by the State EPA and revealed that the alkylated biphenyls had been found in fish fillets and sediment samples from the receiving stream.

One commenter contends that the persistence criteria of half-lifes of 2 months for water, soil, and sediment and 2 days for air may not be sufficiently protective (i.e., the criteria may be too high).

EPA disagrees with the comment. EPA believes that it should adopt criteria that focus on toxic chemicals that will build up in the environment, while at the same time not limiting the list of persistent toxic chemicals to only those that are of global concern. As discussed earlier in this section, EPA believes that 2 months is a reasonable half-life criterion given the purposes of EPCRA section 313. EPA believes that application of lower criteria would include so many substances as to be impractical. Further, given the uncertainties that often exist regarding physical properties and environmental behavior of chemicals, caution is especially appropriate for substances with shorter half-lifes, since they are (all other things being equal) less likely to build up in the environment than more persistent substances. EPA believes that the adoption of criteria of half-lifes of 2 months in water, soil, and sediment and a half-life of 2 days in air allows EPA to balance the need to provide communities and other data users with information on toxic chemicals that persist in their environment without being overly inclusive or restrictive.

One commenter contends that a half-life criterion for air of 2 days should be considered sufficient in and of itself for designating substances as persistent.

EPA agrees with the comment. EPA made the following statements in the proposed rule regarding the 2–day air half-life criterion and its use in the determination as to whether a chemical was a PBT under EPCRA section 313:

> For the purposes of determining whether a toxic chemical is persistent in the environment under section 313, EPA used a half-life criterion of 2 months for water/sediment and soil and a half-life of 2 days for air. Given the above discussions, EPA believes that, for purposes of reporting under section 313, these values are appropriate for determining whether a toxic chemical is persistent in the environment and will persist long enough in the environment to bioaccumulate or be transported to remote locations. Under these criteria, if a toxic chemical meets any one of the media specific criteria, then it is considered to be persistent. Thus if a toxic chemical's half-life in water or sediment or soil is equal to or greater than 2 months or greater than 2 days for air then the toxic chemical is considered to be persistent for purposes of section 313. Note that when considering persistence in connection with the potential for a toxic chemical to bioaccumulate, meeting the air half-life criteria alone would not be sufficient, since a chemical's potential to bioaccumulate is usually dependent on it being persistent in either water, sediment, or soil. In determining whether the chemicals in this proposal were persistent, EPA did not rely solely on the persistence in air. (at 64 FR 702)

It is clear from the discussion above that EPA agrees with the commenter that when considering persistence alone an air half-life of 2 days would be considered sufficient to classify a chemical as persistent under EPCRA section 313. However, for the reasons explained above, if a chemical only meets the 2–day air half-life persistence criteria, EPA does not believe that would be sufficient for classifying a chemical as a PBT under EPCRA section 313.

Some commenters contend that EPA's two-tiered approach to the persistence criteria is confusing.

EPA notes that it proposed only one set of persistence criteria for EPCRA section 313, half-lifes of 2 months or greater in water, soil, and sediment and 2 days in air. The Agency did not propose to use half-lifes of 6 months or greater in water, soil, and sediment and 2 days in air as a second set of persistence criteria for EPCRA section 313. However, for purposes of setting reporting thresholds in this rulemaking, the Agency did choose to focus on the subset of PBT chemicals that have half-lifes of 6 months or greater in water, soil, or sediment (and BCF/BAFs greater than 5,000) by proposing a 10 pound reporting threshold.

For the reasons given above, EPA reaffirms its intention to use a half-life of 2 months as the criterion for persistence in water, soil, and sediment and a half-life of 2 days as the criterion for air when characterizing a chemical as persistent for purposes of EPCRA section 313.

b. *Bioaccumulation*. EPA proposed as bioaccumulation criteria for the TRI program bioaccumulation/bioconcentration factors of 1,000. As discussed in Unit VI.B.1., EPA disagrees that it must choose for EPCRA section 313, bioaccumulation criteria consistent with the international criteria. Applying these strict criteria to EPCRA section 313 would result in a very narrow list of chemicals that would focus on only extremely bioaccumulative chemicals. This is inconsistent with the purposes of EPCRA section 313 and with EPA's technical judgment. There is no ''bright line'' that separates what is bioaccumulative from what is not bioaccumulative. The degree of bioaccumulation is a continuum. Chemicals with BCFs or BAFs of 1,000 to 5,000 are not non-bioaccumulative. They are less bioaccumulative than chemicals with BCFs or BAFs greater than 5,000. The degree of bioaccumulation that should be used as a criterion is not an absolute scientific determination. Rather it is a combination of science and policy. As discussed in the proposed rule and below, organizations have generally used as bioaccumulation criteria BAFs/BCFs of 1,000 and 5,000. The determination of which numerical criterion to apply will depend on the final intent: for example, providing communities with information on bioaccumulative chemicals that can accumulate in organisms versus banning the manufacture and use and eliminating releases of a chemical that has global impacts. For EPCRA section 313 which provides information on toxic chemicals to communities, researchers, and governments, the criteria should be in keeping with both the Agency's scientific judgment and the intent of the statute.

From a scientific perspective there is no one bioaccumulation criterion. However, it is simply not accurate to state that there is no precedent or basis for using a bioaccumulation criterion of 1,000. As noted in the proposed rule, for a number of years EPA scientists and programs have used a BCF of 1,000 or more to indicate a high level of concern for bioaccumulation. In addition, this value has been used in some Canadian projects, many dealing with the Great

NMED Exhibit 72

Lakes basin. Also, Germany proposed a BAF/BCF criterion of 1,000 during negotiation of the LRTAP Protocol. Support for a BAF criterion of 1,000 also comes from the Final Water Quality Guidance for the Great Lakes System (FWQGGLS) (60 FR 15366, March 23, 1995) (FRL–5173–7). In this document, EPA stated that bioaccumulation of persistent pollutants is a serious environmental threat to the Great Lakes Basin Ecosystem and that chemicals identified as bioaccumulative chemicals of concern (BCCs) (i.e., with BAF values greater than 1,000) would receive increased attention and more stringent controls. The final guidance designated as BCCs those chemicals with human health BAFs greater than 1,000 that were derived from certain field-measured BAFs. One commenter believed that the BAF criteria used in the FWQGGLS did not provide support for the use of a BAF of 1,000 since a more strenuous methodology taking more factors into account was used. However, EPA believes that this does provide support for the criteria established for the purposes of EPCRA section 313 because, although the underlying technical assessments may be more stringent, the bioaccumulation level of concern is still a BAF of 1,000. Also, as noted by some commenters, EPA has proposed to use a BCF/BAF of 1,000 to trigger testing under TSCA section 5(e) (63 FR 53417). Specifically, for chemicals subject to TSCA section 5 that have a BAF of 1,000 or greater and that meet certain toxicity and persistence criteria (similar to the EPCRA section 313 persistence criteria) testing would be ''triggered'' by specific production limits. While the manufacturer of the chemical would be allowed to commercialize the substance, certain controls could be stipulated, including specific limits on exposures, releases, or uses. EPA notes that in the same **Federal Register** document, the Agency has proposed that chemicals that have a bioaccumulation factor of 5,000 and that meet certain toxicity and persistence criteria (e.g., half-life of 6 months or greater in soil) be placed in a ''Ban Pending Testing,'' bin. Chemicals meeting these criteria could be subject to more stringent control up to a ban on commercial production.

Not only is there precedent for the use a BCF/BAF of 1,000, but EPA believes that the purposes of the statute argue for the use of the more expansive criterion. Data on PBT chemicals are the type of information that will be of particular use to specific communities such as those that consist of subsistence fishers. Subsistence fishers (as well as sports fishers) are more highly exposed to PBT chemicals than the general population. Subsistence fishers consume large quantities of what they catch. In addition, children are affected by lower doses of certain PBTs than are adults. Children of both subsistence fishers and sport fishers will consume larger quantities of lake food and seafood than children in other communities. As discussed in Unit VI.B.2., EPA's Office of Water maintains a Listing of Fish and Wildlife Advisories (LFWA) for the U.S. and its territories, which listed 2,299 advisories in 1997 (Ref. 29). The overwhelming majority of the advisories are for well-recognized PBT chemicals (chlordane, mercury, PCBs, etc.), but many less familiar substances are also represented. The number and content of advisories in LFWA clearly indicate that toxicologically significant levels of chemical contaminants, specifically PBTs, are often found in fish and wildlife that are caught noncommercially and consumed by the U.S. population. It should be noted that the fact that no advisories have been issued for a particular chemical does not mean that the chemical does not bioaccumulate. Not all species of aquatic organisms are tested nor are all water bodies. In addition, each state determines what it will use as the level of concern for issuing an advisory. EPA believes that it would be inconsistent with the intent of EPCRA section 313 to limit the information on bioaccumulative toxic chemicals to only information for the most bioaccumulative.

One commenter contends that EPA did not provide scientific justification for its choice of the bioaccumulation criterion of a BCF/BAF of 1,000. The commenter states the EPA's discussion of the origin of the 1,000 BCF/BAF value at a 1976 meeting sponsored by the American Society of Testing and Materials, and its reaffirmation in 1995 in a research article by two of the original authors, the use of the value by scientists in EPA's Office of Research and Development's Duluth Laboratories, by EPA's Office of Pollution Prevention and Toxics in the review of chemicals under TSCA sections 4 and 5, by EPA's Office of Water in the Final Water Quality Guidance for the Great Lakes System, and the use by other authorities, such as the German government, to identify chemicals of high concern for bioaccumulation do not provide a technical basis for choosing a value of 1,000 as a criterion for bioaccumulation. The commenter contends that a criterion of 5,000 is scientifically supportable because chemicals with a BCF/BAF of 5,000 have a high potential to biomagnify.

As discussed above, there is no scientifically ''best'' bioaccumulation criterion. The degree of bioaccumulation is a continuum. A chemical does not bioaccumulate only if it has a BCF that is 5,000 or greater. A chemical that has a BCF of 1,000 will bioaccumulate, specifically the chemical will be present in an organism at a concentration that is 1,000 times greater than its concentration in the surrounding aqueous environment. Rather the choice of a value along the bioaccumulation spectrum is based to a large degree on how the criterion is to be used, e.g., to track chemicals entering a particular environment, or to restrict the use of chemicals, etc. As such the choice of a bioaccumulation criterion is a combination of science and policy.

The commenter did not provide support for the contention that 5,000 was scientifically the ''best'' bioaccumulation criterion. Specifically, the commenter did not indicate why as a scientific matter a BCF of 5,000 was preferable to a BCF of, for example 4,000 or a BCF of 15,500. While the commenter did note that chemicals that have a BCF of 5,000 tend to have a high potential to biomagnify, the commenter did not indicate in what way this factored into his determination that a BCF of 5,000 is the scientifically ''best'' bioaccumulation criterion. In addition, EPA does not agree that a BAF or BCF of 5,000 indicates that a chemical will be more likely to biomagnify since biomagnification is a much more complex process. Biomagnification is not a separate process from bioaccumulation or bioconcentration, but is instead a specific example or subset of both. Biomagnification has been defined as: The result of the processes of bioconcentration and bioaccumulation by which tissue concentrations of bioaccumulated chemicals increase as the chemical passes up through two or more trophic levels (Ref. 43). The difference between bioaccumulation and biomagnification is that for a chemical to biomagnify its level of bioaccumulation must increase as it moves up the food chain. The whole concept of biomagnification can be viewed as controversial (Ref. 9) and biomagnification has been studied for only a few chemicals. Most importantly, biomagnification is not required in order to have a concern for chemicals that bioaccumulate. This is because bioaccumulation in even one species can have a serious impact on that species or any other species that feeds on it. For example, if a chemical only bioaccumulates in fish then the fish will

NMED Exhibit 72

be exposed to higher concentrations of the chemical as will anything that eats the fish. Therefore, EPA believes that there is no reason to establish biomagnification as a criterion for PBT chemicals since bioaccumulation is of more than sufficient concern in and of itself.

None of the other commenters who believe that the bioaccumulation criterion of 1,000 is too expansive suggested that EPA adopt another value, other than the 5,000 value used in international agreements, addressed in previous responses in this unit. At most, several commenters took issue with the fact that the EPCRA section 313 bioaccumulation criterion (BCF/BAF of 1,000) is 5 fold less than the international bioaccumulation criterion of a BCF/BAF or 5,000. Given that for each of these programs the focus was on PBT chemicals that are of global concern, EPA believes that as a matter of public policy, it is more appropriate for a reporting program to use a more protective criterion than that used in international agreements that seek to ban or severely restrict the use and/or release of chemicals.

One commenter believes that EPA should not adopt a bioaccumulation criterion (BCF/BAF of 1,000) for EPCRA section 313 that is more stringent than the criterion for a Great Lakes BCCs (a human health BAF of 1,000). EPA notes that BCCs will receive stringent controls which is not the case for toxic chemicals identified as bioaccumulative (and persistent) under EPCRA section 313.

Many commenters supported the proposed bioaccumulation criterion of a BCF/BAF or 1,000. However, one of these commenters believes that 1,000 should be the criterion only if the BCF or BAF is a measured value. If the BCF is an estimated value, then the criterion should be 500.

EPA believes that such a two-tiered approach will add confusion. Further, estimated or predicted BCFs are often based on measured data and equations that have been found to correlate well with measured data. In addition, EPA believes that a BCF of 500 is overly expansive. EPA believes that expanding the criteria to include estimated BCFs of 500 would label so many chemicals as bioaccumulative as to be impractical. EPA believes that the adoption of the criterion of BCF/BAF of 1,000 allows EPA to balance the need to provide communities with information on toxic chemicals that bioaccumulate without being overly inclusive or restrictive.

Some commenters contend that EPA's two-tiered approach to the bioaccumulation criteria is confusing. EPA notes that it proposed only one bioaccumulation criterion for EPCRA section 313, a BCF/BAF of 1,000. The Agency did not propose to use a BCF/BAF of greater 5,000 as a second bioaccumulation criterion for EPCRA section 313. However, for purposes of setting reporting thresholds in this rulemaking, the Agency did choose to focus on the subset of PBT chemicals that have a BCF/BAF greater than 5,000 (and half-lifes greater than 6 months) by proposing an even lower reporting threshold.

For the reasons given above, EPA reaffirms its intention to use a BCF/BAF of 1,000 as the criterion for characterizing a chemical as bioaccumulative under EPCRA section 313.

c. *Toxicity*. A number of commenters contend that EPA should set a separate toxicity criteria for PBT chemicals. EPA disagrees. EPCRA section 313 provides toxicity criteria at section 313(d)(2) to be used in adding a chemical to or deleting a chemical from the EPCRA section 313 list of toxic chemicals. These criteria are:

(A) The chemical is known to cause or can reasonably be anticipated to cause significant adverse acute human health effects at concentration levels that are reasonably likely to exist beyond facility site boundaries as a result of continuous, or frequently recurring, releases.

(B) The chemical is known to cause or can reasonably be anticipated to cause in humans-

(i) cancer or teratogenic effects, or

(ii) serious or irreversible-

(I) reproductive dysfunctions,

(II) neurological disorders,

(III) heritable genetic mutations, or

(IV) other chronic health effects.

(C) The chemical is known to cause or can reasonably be anticipated to cause, because of-

(i) its toxicity,

(ii) its toxicity and persistence in the environment, or

(iii) its toxicity and tendency to bioaccumulate in the environment, a significant adverse effect on the environment of sufficient seriousness, in the judgment of the Administrator, to warrant reporting under this section.

Given that Congress has provided EPA with specific toxicity criteria, and that listed chemicals are statutorily defined as ''toxic chemicals,'' the Agency does not believe that additional ''toxicity'' criteria would be appropriate. One reason is that the Agency is concerned that this would imply that TRI data on the toxic chemicals that meet the statutory toxicity criteria are of less value than TRI data that meet both the statutory toxicity criteria and some additional toxicity criteria that would be developed by EPA. EPA believes that bifurcating the list with an additional, non-statutory toxicity criteria would be inconsistent with the intent of Congress. In addition, it is worth noting that some of the toxicity criteria presented by the commenters are fundamentally consistent with the toxicity criteria outlined in the statute. However, EPA notes that some of the criteria provided by the commenters are risk criteria rather than hazard criteria. For example, see ICCA Briefing Note on POPs (April 21, 1998) (Ref. 26). As discussed at length in the final rule adding 286 chemicals to the EPCRA section 313 list (59 FR 61432), the EPCRA section 313(d)(2)(B) toxicity criteria (chronic toxicity) are hazard criteria, not risk criteria. The EPCRA section 313(d)(2)(C) criteria are primarily hazard based with only a limited exposure component. To impose additional toxicity criteria for purposes of defining a PBT or a PT or BT chemical based on risk rather than hazard would be inconsistent with EPCRA section 313. See, e.g., *Legislative History* at 5186. Risk assessment may be appropriate for use under statutes that control the manufacture, use and/or release of a chemical. However, EPCRA section 313 is an information collection provision that is fundamentally different from other environmental statutes that control or restrict chemical activities. For these reasons, EPA believes that it is inappropriate to add toxicity criteria, beyond the criteria provided by Congress at EPCRA section 313(d)(2).

3. *Persistence and bioaccumulation consideration under EPCRA section 313(d)(2)(C)(ii) and (iii).* The criteria that EPA has laid out in this rule for determining if a chemical is a persistent and/or bioaccumulative chemical are not the same criteria EPA uses when conducting assessments for listing chemicals pursuant to EPCRA section 313(d)(2)(C)(ii) and (iii). These sections of EPCRA allow EPA to consider whether a chemical meets the listing criteria based on ''its toxicity and persistence in the environment'' or ''its toxicity and tendency to bioaccumulate in the environment.'' Including consideration of persistence and/or bioaccumulation modifies the way in which EPA assesses a chemical's toxicity for purposes of listing. EPA interprets the results of the toxicity data in light of a chemical's persistence and/or bioaccumulation, and adjusts its concerns for the chemical's toxicity in accordance with the degree to which a chemical persists or bioaccumulates. For example, standard aquatic toxicity tests provide toxicity results in time frames that range from hours to a few weeks. For aquatic toxicity that results

NMED Exhibit 72

from such short exposure times, a chemical with a persistence half-life of even 2 weeks will result in a greater potential for exposure and therefore increased concern for the concentration at which toxicity is expressed. In this case, EPA would be concerned about the chemical's persistence at levels well below a half-life of 2 months or more. Because EPA's concern under these provisions is with the interrelationship between two chemical properties and how that affects whether the chemical can reasonably be anticipated to cause a significant adverse effect on the environment, EPA believes that it needs to be able to consider a broader range of values. By contrast, the persistence and bioaccumulation criteria established in today's rulemaking serve a different purpose; they are intended to operate independent of a chemical's toxicity, to identify a fixed class of chemicals. EPA has provided this explanation to clarify the different purposes of the persistence and bioaccumulation criteria established in this rule, and the use of persistence and bioaccumulation in assessments pursuant to EPCRA section 313(d)(2)(C)(ii) and (iii).

C. Criteria as they Apply to Metals

Many commenters contend that the persistence criteria proposed by EPA were developed for organic chemicals and cannot be applied to metals, or if applied, are not useful in screening for hazard. The critical parameter in determining risk is bioavailability, not persistence. This has been recognized by international organizations of which EPA is a member, so it is unclear why it is now necessary for EPA to deviate from these policies. Metals are not harmful if they are not in a bioavailable form. Moreover, metals are natural components of the earth's crust and many are accumulated by living organisms because they are essential nutrients. Two of the commenters state that because persistence is defined as ''the failure of a substance to readily biodegrade,'' this concept has no relevance for metals.

EPA disagrees. The scientific literature contains many definitions of persistence which vary in detail, but center on a common theme: persistence is the *ability of a chemical substance to remain in a particular environment in an unchanged form*. This definition makes no mention whatsoever of any specific processes that may impact a substance's environmental fate, such as biodegradation. According to this definition, specific metal compounds may or may not be persistent depending on the form of the metal and environmental conditions, but the elemental metal itself obviously meets the definition, and this was acknowledged in the majority of comments received.

That elemental metals are persistent by definition is widely accepted. While they may take different oxidation states that can be interconverted, the elemental metal itself cannot be destroyed. For example, chromium (VI) may convert to chromium (III). Both are simply different forms of chromium. All elemental metals therefore meet the 2 months half-life criterion automatically. Given this, it is obviously false to assert, as did the majority of commenters on this issue, that EPA's proposed persistence criteria *cannot be applied* to metals. The position of many commenters was that in determining whether a metal or metal compound may actually pose a risk if released to the environment, bioavailability is much more important than the fact that a substance meets the formal ''definition'' of persistence. EPA agrees that bioavailability is important in determining the potential for the metal to be accumulated in organisms, but parent metals do have the potential to become available from metal compounds under common environmental conditions. Availability of the metal ion may be the result of biotic or abiotic processes. There are a number of environmental factors which EPA considers in determining the availability of the metal ion. These include hydrolysis, pH effects on solubility, photolysis, aerobic and anaerobic transformations, and *in vivo* transformations. As outlined in the remainder of this section, it is realistic to expect that, in general, metals when released into the environment can encounter conditions in which they are available at levels sufficient to exert toxicity and bioaccumulate.

EPA also disagrees with the commenters' claims, direct or implied, that metals released to the environment as a result of human activity must be of negligible concern because they:

- Cannot be converted to bioavailable forms; or even if initially bioavailable are rapidly sequestered in such a way that subsequent exposure is impossible; or
- If bioavailable, are naturally wholesome and good because organisms need them to function.

EPA disagrees with this simplistic view. Metals can enter the environment in bioavailable forms or can be converted in the environment into bioavailable forms. As shown below, metals and metal compounds may be available to bioaccumulate under many realistic and common environmental conditions.

The commenters are correct in stating that metals released to the environment from anthropogenic sources are affected by prevailing environmental conditions, meaning broadly the wide variety of physical, chemical and biological processes that act upon them, and these collectively determine the form in which the metal ultimately exists.

According to Klein (Ref. 28), interconversion of inorganic metal compounds can be quite rapid, especially for ionic forms, and as a result the chemical form in which an elemental metal is released may not be the predominant form post-release. Generally, the ionic forms of inorganic metals are the most available. Availability is affected by many factors and its determination is complex. For metals environmental conditions can affect their availability. A detailed scientific discussion of the environmental fate of lead, which is representative of other metals, and that is illustrative of many of the more important environmental variables that affect availability is provided in Refs. 14, 28, 30, 50, 66a, 72, and 84. See also the preamble to EPA's recent proposal to lower the EPCRA section 313 reporting thresholds for lead and lead compounds (64 FR 42222). The same basic chemical properties and environmental variables will affect the degree of availability of a metal in the environment regardless of the specific metal. There is no metal that is unavailable under all conditions.

EPA recognizes that lead and lead compounds are the subject of an EPA proposal under EPCRA section 313 (64 FR 42222). The inclusion of the discussion of the environmental fate of lead and lead compounds does not predetermine EPA's decision on the appropriate thresholds that should be set for lead and lead compounds. That determination will be based on a number of factors, including the bioaccumulation of lead.

Microbial transformations in soil, water, and sediment are often important in determining the overall fate of metals and metal compounds, and therefore the potential for formation of bioavailable forms. Metals known to undergo microbial oxidation/reduction processes include, antimony, arsenic, iron, mercury, selenium, and tellurium (Ref. 11). Arsenic microbiology illustrates the importance of environmental conditions in the interconversion of inorganic forms of arsenic. Microbial populations in activated sludge can oxidize arsenite to arsenate under aerobic conditions, but under anaerobic conditions such as often predominate in sediments, arsenate can be reduced to arsenite and

NMED Exhibit 72

beyond. Both arsenites and arsenates can be available in the environment (Ref. 11). Microorganisms can reduce mercury in the form of mercuric chloride to elemental mercury, and are also capable of producing elemental mercury from organomercurials such as phenylmercuric acetate and methylmercuric chloride. Although the reduction of Hg^{2+} to elemental mercury can be regarded as decreasing availability, the elemental mercury formed is volatile and more likely to enter the global atmospheric circulation.

Mercury is perhaps better known for its potential to be biomethylated by bacteria in the environment (Ref. 11). Mercury has very high stability constants with organic ligands and can form true organometallic compounds (Ref. 6). As indicated by Stumm and Morgan (Ref. 49), metals and metalloids that form stable alkyl compounds are of special concern because they may be volatile; may accumulate in cells; and are toxic to the central nervous system of higher organisms. Methylmercury is highly bioaccumulative and is by far the best studied example of microbial bioalkylation. However, methylation of arsenic is also fairly well-characterized, involves the replacement of substituent oxygen atoms by methyl groups (e.g., arsenate is biomethylated to form dimethylarsine), and is important in the transfer of arsenic from sediment to the atmosphere (Ref. 11). Lead, germanium, selenium, tellurium, tin, and several other metals can also be biomethylated (Ref. 49).

Many of the commenters noted that certain metals are indeed micronutrients (e.g., cobalt, copper, and iron), and are accumulated precisely because they are required for certain cellular functions. It does not follow, however, that any amount of the same metal is acceptable or desirable. Accumulation of essential elements is usually governed by homeostatic mechanisms that control uptake (Ref. 28), but excessive uptake is possible and can be toxic to an organism. For example, selenium which is a micronutrient can cause selenosis at doses as low as 0.023 milligrams per kilogram per day (mg/kg/day). Clinical signs of selenosis include the characteristic ''garlic odor'' of excess selenium excretion in the breath and urine, thickened and brittle nails, hair and nail loss, lowered hemoglobin levels, mottled teeth, skin lesions, and central nervous system (CNS) abnormalities (peripheral anesthesia, acroparesthesia, and pain in the extremities) (Ref. 61). Similarly, copper, which is an essential nutrient, at high doses can cause vascular injury and hemolytic anemia. It should also be noted that copper exhibits high acute and chronic toxicity to aquatic organisms that results in the death of the organism (61 FR 54381, October 18, 1996) (FRL–5396–9), and inhalation of hexavalent chromium is known to cause cancer in humans (Ref. 60), even though chromium in very small oral doses is a micronutrient (Ref. 25). Moreover, the commenters freely cite Allen (Ref. 4), Chapman (Ref. 18) and other authors to the effect that metals are accumulated ''deliberately'' depending on the physiological needs of the organism, but it is clear that this applies only to metals that are essential nutrients. Metals are generally taken into cells by nutrient metal transport systems, and these are not sufficiently specific to completely exclude nonessential metals, some of which may be toxic and/or bioaccumulative. In this situation nutrient metals can be displaced from their binding sites by undesirable, toxic metals, which then gain access to the cell interior with concomitant exclusion of the essential metal (Ref. 49). Toxic metal ions are then free to react with critical enzymes or otherwise disrupt cellular functions if they reach certain levels. Often this toxicity occurs at relatively low doses. For example, inorganic arsenic is a known human carcinogen and causes chronic toxicity at doses as low as 0.014 mg/kg/day (Ref. 59). Lead has no known biological function in humans but is readily absorbed and has been shown to cause various toxic effects. For example, children can suffer permanent damage from lead poisoning, resulting in lowered intelligence, learning disabilities, hearing loss, reduced attention span, and behavioral abnormalities (Ref. 66).

EPA concludes that under many environmental conditions, metals and metal compounds may be available to express toxicity and to bioaccumulate, and that these effects are not necessarily limited to metals that are not essential nutrients. It is appropriate, therefore, to be concerned about the potential adverse effects, and one step in this direction is to more accurately assess emissions from anthropogenic activities. EPCRA section 313 provides that opportunity. Precedent for this concern exists at the international level in the form of a protocol for heavy metals under the UNECE LRTAP, which is currently being negotiated. The draft protocol expresses concern ''. . .that emissions of certain heavy metals are transported across national boundaries and may cause damage to ecosystems. . .and may have harmful effects on human health. . .,'' and specifically advocates assessing and controlling emissions caused by human activities (Ref. 54).

Several commenters raised the issue of EPA participation in various international organizations, claiming that any attempt to apply EPA's proposed persistence and bioaccumulation criteria and/or assessment approach to metals would violate the policies of these organizations, whose positions EPA has previously endorsed. These claims are false because the commenters either misunderstand or misstate the aforementioned policies. The main focus of the commenter's attention is two documents, the OECD's *Harmonized Integrated Hazard Classification System for Human Health and Environmental Effects of Chemical Substances* (Ref. 41), and the North American Agreement on Environmental Cooperation (NAAEC)'s *Process for Identifying Candidate Substances for Regional Action under the Sound Management of Chemicals Initiative* (Ref. 39). A report from a joint Canada/European Union Technical Workshop on metals (Ref. 17) was also cited by commenters and reached similar conclusions.

The OECD document's pronouncements on metals are contained in paragraphs 22 and 23 of that document. Paragraph 22 reads as follows:

> For inorganic compounds and metals, the concept of degradability as applied to organic compounds has limited or no meaning. Rather the substance may be transformed by normal environmental processes to either increase or decrease the bioavailability of the toxic species. Equally, the use of bioaccumulation data should be treated with care. Specific guidance will be [but has not yet been] provided on how these data for such materials may be used in meeting the requirements of the classification criteria. (Ref. 41)

By ''degradability as applied to organic compounds'' OECD means molecular degradation, most often by microbial degradation and/or hydrolysis or other abiotic processes, to progressively simpler organic chemical structures, leading eventually to inorganic substances like carbon dioxide and water. But, note, paragraph 22 does not in any way suggest that metals are not persistent. Moreover, it does not suggest that OECD hazard classification criteria cannot be applied, only that ''care'' (i.e., professional judgment) is required in the interpretation of data relative to the classification criteria. In fact, EPA agrees that bioavailability is important in determining the potential for the metal to be accumulated in organisms.

NMED Exhibit 72

The Agency has analyzed information on the environmental fate of metals, and, as noted above, asserts its professional judgment that the parent metals do have the potential to become available from metal compounds under commonly encountered environmental conditions. Therefore, the Agency's treatment of metals is consistent with the OECD's intent.

The same holds with respect to NAAEC's pronouncements under the SMOC (Ref. 39). The focus of NAAEC/SMOC (Ref. 39) is the development of North American Regional Action Plans (NARAPs) for substances that pose significant risk to human health and the environment in all three member countries (namely, Mexico, Canada, and the United States). To date, NARAPs have been established for DDT/chlordane, PCBs, and mercury (note: a metal). NAAEC/SMOC (Ref. 39) acknowledges the persistence of metals, but highlights the role of expert judgment in assessing potential bioavailability of metals and metal compounds:

> For naturally occurring substances such as metals and minerals, the Task Force understands that the direct application of the persistence and bioaccumulation criteria proves very difficult.....Organometals can behave like other persistent organic pollutants in their metallic form, and as certain compounds, metals tend to be infinitely persistent though not necessarily in a form that is bioavailable, and in some cases, they naturally bioaccumulate for beneficial purposes in organisms (i.e., essential elements). Expert judgment is essential for a meaningful evaluation of these substances.

Further, an earlier section of the document (Ref. 39) states,

> It is understood that expert scientific judgment plays a significant role in acknowledging and addressing the difficulties posed by quantitative criteria for persistence and bioaccumulation, particularly in relation to naturally-occurring substances like metals and minerals where the potential for transformation to complexes or metallic species which are more or less bioavailable, are emerging as important considerations.

It is difficult to read into the preceding any intention to *exclude* metals and metal compounds from consideration, as many commenters imply, and more specifically, to declare that these substances have no potential to pose risk because they are never released in bioavailable forms; cannot be converted to bioavailable forms under any foreseeable circumstances, etc. On the contrary, it is clear from the preceding language as well as the inclusion of mercury among the NARAPs developed to date that any substance judged to be potentially bioavailable and that otherwise meets the SMOC criteria, whether organic or inorganic, should not be excluded as a candidate for action. As outlined above, it is realistic to expect that, in general, released metals can encounter conditions in which they are available at levels sufficient to exert toxicity and bioaccumulate. Therefore, the Agency's treatment of metals is consistent with international policy under NAAEC/SMOC (Ref. 39).

Finally, EPA reminds commenters that a mechanism already exists to address concerns for any metal compound for which the data show that the metal cannot become available. The issue of bioavailability was addressed previously for EPCRA section 313 chemical assessments through EPA's policy and guidance concerning petitions to delist individual members of the metal compound categories listed under EPCRA section 313 (56 FR 23703, May 23, 1991). This policy states that if the metal in a metal compound cannot become available as a result of biotic or abiotic processes, then the metal will not be available to express its toxicity, and by extension, to bioaccumulate. If the intact metal compound is not toxic and the metal is not available from the metal compound, then such a chemical is a potential candidate for delisting. EPA has received fewer than 10 petitions to delete individual metal compounds because the petitioner contended that the metal portion of the metal compound would not be available under environmental conditions or *in vivo*.

D. Multimedia Modeling

One commenter contends that EPA should clarify how and when multimedia models will be used in the evaluation of PBT chemicals. EPA should not use the EQC model or other multimedia models as the sole determinant of potential risk. If exposure and use information is available, a detailed technical evaluation based on these data is preferred over modeling based on hypothetical exposure and loading scenarios.

The purpose of this rulemaking is to lower reporting thresholds for certain EPCRA section 313 substances that are being designated as persistent and bioaccumulative, and to list several additional substances that meet EPCRA section 313 listing criteria and are also persistent and bioaccumulative. Although neither quantitative risk nor exposure assessments have been performed, nor are they required under EPCRA, designation as a PBT does imply the existence of *potential* risk. However, contrary to the comment, EPA has not proposed that multimedia models be used as the sole factor in determining persistence. As clearly stated in the proposed rule, EPA intends to use such modeling ''as an additional factor, in conjunction with reaction half-lifes for individual media, bioaccumulation/bioconcentration factors, etc., in justifying [the] actions proposed.''

In the proposed rule EPA did explain in a general way (at 64 FR 703) how models would be used in PBT evaluation, and stated that results of multimedia modeling may be used to override compartment (medium)-specific degradation half-lifes, but only if all model inputs are judged sufficiently accurate. This leaves unspecified what specific value(s) might be used for overall environmental persistence *criteria* (expressed either as an overall residence time or overall half-life). To date no international scientific or regulatory authority has proposed any such criterion for POPs/PBT chemicals, and the complex relationship between compartment-specific and overall persistence criteria is in fact a major topic of current research.

One commenter raises concerns regarding the modification EPA made to the EQC III model that deleted advective losses and sediment burial.

EPA modified the model to exclude advective losses and sediment burial because if these processes are included the persistence based on destruction will be underestimated. In multimedia modeling, advection can be viewed as the flow into or out of the evaluative environment or ''box.'' These include processes such as downstream flow in surface waters, dispersion downwind in air, and burial in sediments. The model considers these non-destructive processes to result in loss from the evaluative environment in the same way that destruction does. However, these processes simply result in the transport of a chemical to another part of the environment downwind or downstream from where it is released, or its deposition into sediments, but not the destruction of the chemical.

The persistence of a chemical calculated when the model is run considering advective losses include non-destructive transport processes which remove the chemical from the evaluative environment. For example, the environmental persistence of a chemical released to water which does not significantly partition to sediments, degrade, or volatilize will reflect the rate at which the water to which it is released flows out of the evaluative environment. In this example, the

relative rate of non-destructive transport out of the evaluative environment may be more rapid than the processes which result in the destruction of the chemical. Thus, the persistence calculated by the model will be less than if advective transport from the evaluative environment was not considered.

EPA used the model to evaluate persistence based on destruction in a multimedia environment. This is consistent with EPCRA section 313 persistence criteria in that the criteria are based on destruction, not transport of the chemical. The Level III (non-equilibrium partitioning, steady state mass balance) models are preferred for developing qualitative and quantitative predictions of chemical distribution, pathways, and relative concentrations (Ref. 16). Level III models can also be used to assess persistence (Ref. 33). At steady state (level III) conditions the amount of chemical is unchanging with time and the input and output rates for a compartment are equal. The overall residence time of the chemical is the mass of the chemical in the compartment divided by the input or output rates. This represents the average time the chemical will reside in the compartment. Output may be by reactions that result in the destruction of the chemical or by advective flow (non-destructive) usually in air or water. When the model is modified to eliminate advective flow, the persistence of a chemical based on the rates of reactions that result in the destruction of the chemical can be assessed. Webster et al (Ref. 82) used this approach in evaluating the environmental persistence of chemicals using a multimedia fate model and noted that if advective loss is included, the residence time is reduced and can give a misleading impression of a short persistence. It was also noted that these advective losses ''. . .merely relocate the chemical; they do not destroy it.'' EPA also used a modified version of the EQC level III model as a tool to assist on the characterization of the persistence of the chemicals subject to this rule. In this version of the model only irreversible transformation contributes to net loss of a chemical. In other words, the model was modified to represent a ''closed box'' in which the effect of processes that serve only to move the chemical from within the evaluative environment to outside of it, primarily in air and water (advective losses) were nullified. Sediment processes responsible for transport of the chemical from the evaluative environment such as sediment burial were similarly treated. The intent of this modification was to make sure that only processes responsible for the destruction of the chemical were considered in evaluating its persistence in a multimedia environment. EPA supports the use of level III multimedia models modified, as described, for their ability to simultaneously consider reaction rates and partitioning so as to give a reasonable assessment of the persistence of chemicals in the multimedia environment.

However, EPA notes that its reliance on the multimedia modeling was limited. As discussed in the proposed rule (at 64 FR 703) and in Unit VI.B.2., EPA primarily considered media-specific data and made a case-by-case determination about the persistence of each chemical.

E. Thresholds

The issue most frequently raised by commenters was the Agency's choice of thresholds and the factors that EPA considered in lowering the thresholds. Many commenters contended that EPA should not consider burden in choosing thresholds. They believe that EPA should set a threshold of 10 pounds for PBT chemicals and 1 pound for that subset of PBT chemicals that are both highly persistent and highly bioaccumulative. Some commenters believe that EPA should set a threshold of 1 pound for all chemicals that are PBT chemicals. Numerous commenters believe that the threshold for reporting should be zero. Other commenters believe that burden should have been a greater consideration in EPA's choice of reporting thresholds. Many of these commenters believe that EPA should set thresholds based on some percentage of releases that would be reported.

EPA disagrees with these commenters. As explained in the proposal, the Agency considered a number of factors to determine the appropriate thresholds that should be established for these chemicals. EPA relied on the language of EPCRA sections 313(f)(2) and (h), and the legislative history to elicit the following principles to guide its exercise of discretion in lowering the thresholds, and in selecting the specific thresholds for PBT chemicals: (1) The purposes of EPCRA section 313; (2) the ''verifiable, historical data'' that convinces EPA of the need to lower the thresholds; (3) the chemical properties shared by the members of the class of toxic chemicals for which EPA is lowering the thresholds i.e., the degree of persistence and bioaccumulation; and (4) the reporting burden imposed by revised thresholds to the extent that such consideration would not deny the public significant information from a range of covered industry sectors. Further, EPA believes that in the language of EPCRA section 313, and its legislative history, Congress provided direction on the appropriate weight to allocate to each of these considerations in implementing EPCRA section 313(f)(2). These considerations underlay the entire process by which EPA determined the appropriate thresholds. But, as noted below, the Agency's choice of revised thresholds was governed, and ultimately constrained, by EPCRA section 313's overriding purpose, which is to provide government agencies, researchers, and local communities, with a comprehensive picture of toxic chemical releases and potential exposures to humans and ecosystems.

In general, EPA's implementation of EPCRA section 313 is guided by the statutory purposes described by EPCRA section 313(h), which provides:

> The release forms required under this section are intended to provide information to the Federal, State, and local governments and the public, including citizens of communities surrounding covered facilities. The release form shall be available. . .to inform persons about releases of toxic chemicals to the environment; to assist governmental agencies, researchers, and other persons in the conduct of research and data gathering; to aid in the development of appropriate regulations, guidelines, and standards; and for other similar purposes.

In addition to section 313(h), EPA was also guided by several statements on the principles intended to guide EPA's implementation of EPCRA section 313 made by Representative Edgar, one of EPCRA section 313's principal architects, during debate on the Conference Report. See, *Legislative History* at 5313–16. In the course of his statement, Representative Edgar also articulated EPCRA section 313's overriding purpose, which is:

> to provide a *comprehensive view of toxic chemical exposure* and, hopefully, provide a basis for more sensible and effective local, State, and national policies. *Legislative History* at 5316 (emphasis added).

Based on the existing reporting requirements, the Agency believes that there are still significant gaps in the picture the TRI data provides local communities, government agencies, and researchers. One of the most significant of these gaps is a comprehensive picture of the releases and potential exposure of PBT chemicals to humans and the environment. Currently, only a very limited picture of releases and other waste management of PBT chemicals is available from the TRI data, in part, as a result of the current thresholds. For

NMED Exhibit 72

example, under the current reporting thresholds, in 1997, EPA received only 29 reports on mercury and mercury compounds, and 6 reports on PCBs. This does not present a ''comprehensive view of toxic chemical exposure.'' In addition, information on the releases and other waste management of PBT chemicals is particularly significant because these chemicals both persist and bioaccumulate. Individually, each of these attributes has the potential to pose increased exposures to humans and the environment. Toxic chemicals possessing both attributes have the potential to pose *significant* exposures to humans and ecosystems over a longer period of time; even small amounts of PBT chemicals that enter the environment can accumulate to elevated concentrations in the environment and in organisms, and therefore have a greater potential to result in adverse effects on human health and the environment.

As a first step in addressing the significant gap of information on PBT chemical releases and waste management, EPA considered whether to lower the reporting thresholds for PBT chemicals. EPA then looked to section 313(f)(2) for further guidance on how to proceed. Since lowering the thresholds ensures that ''all facilities subject to the requirements of [section 313]'' will continue to report, the requirement in section 313(f)(2) that a revised threshold obtain a ''substantial majority of total releases of each chemical at all facilities subject to the requirements of this section'' can be met without the need for quantitative support. Consequently, EPA looked to other sources of Congressional direction in the statute and legislative history to guide its exercise of discretion in establishing revised thresholds.

Given that there is no guidance on implementing section 313(f)(2) in the Conference Report, EPA looked to the debate on the Conference Report. In this context, Representative Edgar, stated:

> It is also important to clarify the intent of Congress in establishing thresholds for reporting under this section. . . .These thresholds were designed to obtain reporting on both *a substantial majority of the Nation's toxic chemical releases and to obtain reporting from a large number of firms.* These thresholds reflect Congress' judgement that such thresholds appropriately balance the need for information against the burden on facilities required to provide such information. The EPA is authorized to revise these thresholds, but only if such revised thresholds continue to obtain reporting on a substantial majority of total releases. Any determination by the EPA regarding the ability of revised thresholds to obtain reporting on a substantial majority of releases, especially if such revised thresholds raise the statutory levels, *must be based on verifiable, historical data which presents a convincing case that the statutory levels must be revised. Legislative History* at 5313 (emphasis added).

And during the House debate, Representative Swift noted that any revised threshold ''should be *designed to improve the usefulness of the reports.* It must be structured to obtain reporting on a substantial majority of the *total nationwide releases* of the toxic chemical at *all facilities covered by section 313.*'' *Id.* at 5338 (emphasis added).

In determining how to structure its threshold revisions, and particularly how it would improve the usefulness of the reports, EPA also consulted EPCRA's purposes, laid out in subsection (h). In this context, EPA also considered the statements made by Senator Stafford during debate on the Conference Report:

> This section also requires the Administrator to computerize the data reported on the required forms and to make these data public by various means. Successful implementation of this requirement is vital to the basic purpose of the program. *The data should be managed in the computer in such a way as to allow a wide variety of analyses. For example, it should be possible to retrieve data, not only about individual facilities, but also aggregate data organized by type of chemical, type of effect, geographic location, company name, etc. as well as combinations of these parameters. . . . Legislative History* at 5186 (emphasis added).

Based on this Congressional guidance, EPA reached several conclusions. First, ample ''verifiable, historical data'' exists to support EPA's conclusions that PBT chemicals persist for long periods of time in the environment and bioaccumulate in organisms, including humans; that this persistence and bioaccumulation can result in higher exposures to humans and the environment; and that to ''obtain a substantial majority of the Nation's toxic chemical releases,'' lower thresholds for PBT chemicals are warranted. For example, PCBs have been found throughout the Great Lakes in sediments, water, and aquatic organisms. Multimedia analyses indicate that the majority (80–90%) of human exposure to chlorinated organic compounds, such as PCBs comes from the food pathway, a lesser amount (5–10%) from air, and minute amounts (less than 1%) from water. Most of the data available on human exposure to PCBs in the Great Lakes come from the analyses of contaminant levels in drinking water and sport fish. The consumption of contaminated sport fish and wildlife can significantly increase human exposure to the Great Lakes critical pollutants, such as PCBs. The sport fish are exposed to PCBs by consumption of sediments and through water (Ref. 76). See also Refs. 75 and 77.

Further, EPA strongly believes that increased reporting on PBT chemicals will improve the usefulness of the data on these chemicals. There are currently very few reports for some of the PBT chemicals, such as mercury, mercury compounds and PCBs. The currently available data provide a distorted picture of potential exposures to humans and the environment, because at the current thresholds only a fraction of the releases from facilities otherwise subject to EPCRA section 313 are reported. This limited reporting results in a significant underestimation of the releases from the industry sectors covered by EPCRA section 313. As such, the current data are of limited use for evaluating the potential exposures to humans and the environment of toxic chemicals that persist and bioaccumulate. Expanding the picture of releases, and therefore potential exposures, will increase the utility of all the TRI data on these chemicals. See, e.g., Economic Analysis, Chapter 6.4 (Ref. 67).

On these bases, EPA determined that revising the thresholds would be an important first step in closing the information gap on PBT chemicals. The Agency then began the process of determining the appropriate levels at which to establish the revised thresholds. For a number of technical and policy reasons, EPA chose an approach focused on two classes of PBT chemicals: (1) Toxic chemicals that meet the EPCRA section 313 persistence and bioaccumulation criteria discussed in Unit VI.B., i.e., those toxic chemicals that have half-lifes of 2 months or greater in water/sediment or soil and that have bioaccumulation or bioconcentration factors of 1,000 and (2) the subset of PBT chemicals that are highly persistent and highly bioaccumulative, i.e., those toxic chemicals that have half-lifes of 6 months or greater in water/sediment or soil and that have bioaccumulation or bioconcentration factors of 5,000 or greater.

First, for the most persistent and bioaccumulative toxic chemicals any release will lead to elevated concentrations in the environment and in organisms. EPA believes that such highly persistent and highly bioaccumulative toxic chemicals are of international, as well as national concern, because of the extent of their

persistence and bioaccumulation. As discussed elsewhere in this preamble, these facts have been widely recognized; there are a number of international agreements that ban, restrict, or phase out the manufacture, use and/or release of highly persistent and highly bioaccumulative toxic chemicals.

Similarly, toxic chemicals that are persistent and bioaccumulative are of national, regional, and local concern. As discussed elsewhere in this preamble, toxic chemicals that are persistent and bioaccumulative present a significant concern to many local communities due to the proximity of the communities to industrial sources. All other things being equal, a pollutant reaches nearby populations in less time than distant ones. Thus, toxic chemicals that persist and bioaccumulate can pose significant exposures to communities and ecosystems that immediately surround industrial sources as well as those communities that are subject to regional transport.

Given the international support for the extreme limitations on the use and release of toxic chemicals that are highly persistent and highly bioaccumulative, and the significant exposures that persistent and bioaccumulative toxic chemicals can pose to both local communities and broader regions of the United States and North America, EPA believes that it is appropriate to lower the reporting thresholds for *both* (1) Persistent and bioaccumulative toxic chemicals and (2) for highly persistent and highly bioaccumulative toxic chemicals. In addition, EPA believes this information is important to the public, government agencies, and researchers; for example, the information reported by facilities under the lower thresholds will help these groups assess the loading of the PBT chemicals in both local and regional ecosystems, e.g., a small lake or river or a larger ecosystem such as the Great Lakes or the Chesapeake Bay. See also, Economic Analysis at Chapter 6, pages 32–50 for examples of other uses of TRI data (Ref. 67).

Second, EPA considered how the revised thresholds would provide the information on PBT chemicals needed to assist the public to obtain ''a comprehensive view of toxic chemical exposure,'' as well as to assist government agencies, researchers, and other persons to conduct research and to establish appropriate regulations, guidelines and standards, in accordance with the directives laid out in subsection (h). EPA determined that providing greater information on two identifiable classes of chemicals best achieved these ends. It is consistent with the actions of a significant number of the groups that would use this information; for example, as discussed in Unit VI.B., UNEP is in the process of negotiating an international agreement on the class of persistent organic pollutants with half-lifes of 6 months and BCF/BAF values of 5,000. See also Economic Analysis at Chapter 6, pages 46–48 for examples of how TRI data will be used (Ref. 67). Moreover, EPA determined that data on members within the same class are more easily comparable; the members of the classes EPA established in this rulemaking share a qualitatively comparable level of concern based on their potential for increased exposure. The Agency believed that creating two distinct classes of comparable chemicals would significantly enhance the ability of researchers, government agencies, and other similar persons, to use the reports. Establishing distinct classes of comparable chemicals normalizes the subsequent years' data, providing a baseline against which data users can ascertain trends over time. Consequently researchers can more easily distinguish, and therefore track, the releases and other waste management of highly PBT chemicals, to evaluate the efficacy and progress of the policy strategies intended to address the risks of PBT chemicals, such as the Binational Great Lakes Water Quality Initiative. Finally, administrative convenience argued for establishing a limited number of alternate thresholds. As a practical matter, it would be burdensome for both the Agency and the regulated community to track a variety of individual thresholds for separate chemicals. In addition, because this was only the Agency's initial rulemaking to lower thresholds for certain PBT chemicals, EPA intended that the revised thresholds establish a set of categories that would be generally applicable to future designated PBT chemicals. All of these considerations led the Agency to conclude that it should establish two sets of revised thresholds based on two classes of PBT chemicals.

Thus, having concluded it was appropriate to focus the rulemaking on two classes of chemicals, persistent and bioaccumulative toxic chemicals and that subset of PBT chemicals that are highly persistent and highly bioaccumulative, EPA began the process of determining the specific thresholds that would achieve the purposes of subsections (f)(2) and (h). The intrinsic properties of PBT chemicals argue for very low thresholds. The subset of PBT chemicals that are highly persistent and highly bioaccumulative warrant, in the absence of other considerations, a threshold approaching zero. Any release of these toxic chemicals is of global concern because they can persist for long periods of time, can maintain their identity even after undergoing long range transport, and can bioaccumulate to a significant degree. As discussed above, and at length in Unit VI.B., the potential impacts that can result from any release of toxic chemicals that are highly persistent and highly bioaccumulative have been widely recognized. There are a number of international agreements that ban, restrict, or phase out the manufacture, use and/or release of the most persistent and bioaccumulative toxic chemicals.

However, EPA believes that a zero threshold would be impractical. Attempting to require facilities to determine if they manufacture, process, or otherwise use any amount whatsoever of these chemicals would be extremely burdensome and perhaps technically impossible. Without an actual numerical threshold, many facilities might report some amount of these chemicals in a misguided attempt to assure compliance. This could lead to misleading and inaccurate data on the actual sources of these chemicals. EPA believes that rather than setting a zero reporting threshold it would be better to set a very low threshold that provides facilities with a clear indicator of when they are required to report. In general for purposes of EPCRA section 313, 1 pound is the practical equivalent of zero for these chemicals. EPA explained these considerations in the proposed rule (64 FR 712) and has received no information from commenters that convinces the Agency to pursue a different approach.

EPA then considered the relative degree of persistence and bioaccumulation between the two classes of chemicals. EPA wanted to establish two sets of revised thresholds with the same approximate relationship to each other, as the relative exposure potentials of PBT chemicals to that subset of highly persistent and highly bioaccumulative PBT chemicals. Simply stated, chemicals with half-lifes of 6 months or greater and a BAF/BCF of 5,000 or greater have a higher exposure potential than chemicals with half-lifes of 2 months or greater and a BAF/BCF of 1,000 or greater. However, although, as discussed below, EPA could establish a qualitative relationship, the Agency could not reliably quantify the relative exposure potential across the board for all of the members of both classes. Therefore, in attempting to translate the qualitative exposure potential of PBT

NMED Exhibit 72

chemicals to that subset of PBT chemicals that are highly persistent and highly bioaccumulative into a qualitative threshold relationship, EPA considered both the attributes of these chemicals and factors specific to thresholds.

The manufacture, process, and otherwise use thresholds are not equivalent to release thresholds although, in many cases, the quantity manufactured or otherwise used will be very similar to the quantity released. Thus, even if EPA were able to quantify the relative exposure potential of PBT chemicals and that subset of PBT chemicals that are highly persistent and highly bioaccumulative, based on their degrees of persistence and bioaccumulation, and their interrelationship, the Agency would not rely solely on this to select a quantitative threshold relationship between these two classes of chemicals because: (1) The manufacturing, processing, and otherwise use thresholds are not equivalent to release thresholds, and (2) the quantity released, not the quantity manufactured, processed or otherwise used, is a critical factor in determining exposure.

Nonetheless, EPA believes that the relative reporting thresholds should be based to some extent upon the qualitative differential between the potential exposures that may result from releases of PBT chemicals and that subset of PBT chemicals that are highly persistent and highly bioaccumulative.

There is not a direct quantifiable relationship between the potential exposures that can result from equivalent releases of a toxic chemical that persists in the environment with a half-life of 6 months and that has a bioaccumulation factor of 5,000 and releases of a toxic chemical that persists in the environment with a half-life of 2 months and that has a bioaccumulation factor of 1,000. The potential exposure to humans and the environment will depend upon a number of factors, including release patterns, environment variables such as soil type, surface water chemistry, the types and distribution of flora and fauna, and fish consumption patterns. However, EPA did consider the relative differences in the potential exposures between these two classes. For example, after 1 year, there will be more than 15 times as much of a highly persistent chemical that remains in the environment than of a persistent chemical, all other things being equal. Similarly, fish will accumulate more than 5 times as much of the highly bioaccumulative chemical than of the bioaccumulative chemical, all other things being equal. While EPA believes that it can qualitatively describe the relative relationship of highly persistent chemicals to persistent chemicals and the relative relationship of highly bioaccumulative chemicals to bioaccumulative chemicals, the Agency cannot at the present time, define the relative relationship of persistence and bioaccumulation between the two classes of chemicals. This is in large part due to the many variables that must be considered in determining the potential exposures both due to the interaction of these chemical attributes and the large number of environmental factors that must be considered when evaluating persistence and bioaccumulation together.

Although EPA could not develop an exact quantitative threshold relationship between the two classes of chemicals, the Agency did consider the factors discussed above and did rely to some extent on the numerical relationships between the highly persistent and persistent chemicals and the highly bioaccumulative and bioaccumulative chemicals. Therefore, given that: (1) Highly bioaccumulative toxic chemicals will accumulate approximately 5 times greater than bioaccumulative toxic chemicals, (2) highly persistent toxic chemicals will remain in the environment after 1 year, at a level about 15 times greater than persistent toxic chemicals, (3) the fact that the EPCRA section 313 reporting thresholds are not release thresholds but that in some instances the quantities manufactured or otherwise used will be very similar to the quantity released, and (4) toxic chemicals that persist in the environment with half-lifes of 2 months and bioaccumulation factors of 1,000 or greater can be of both local and regional concern, EPA believes that the threshold for PBT chemicals should be a factor of 10 greater than the threshold for that subset of PBT chemicals that are highly persistent and highly bioaccumulative. EPA believes that this ratio balances the uncertainties and factors, including numerical factors, that the Agency considered. Therefore, based on the chemicals' intrinsic characteristics, EPA would establish thresholds of 1 pound for that subset of PBT chemicals that are highly persistent and highly bioaccumulative and 10 pounds for PBT chemicals.

However, the legislative history of section 313(f)(2) indicates that in establishing the original thresholds, Congress recognized the burden imposed on the regulated community. Lowering thresholds necessarily will increase that burden. Therefore, EPA determined it would be reasonable to include some consideration of reporting burden in selecting thresholds for PBT chemicals. But EPA accorded less weight to burden than to the other considerations discussed above. First, neither section 313(f)(2), section 313(h), nor any other provision of EPCRA requires EPA to consider burden. Second, EPA was mindful of the fact that in several places in the legislative history Congress made clear it never intended impacts on reporting facilities to outweigh the public's right-to-know about their potential exposures to toxic chemicals. For example, although Representative Edgar recognized that Congress had considered burden in establishing the statutory thresholds, he did not include reporting burden as one of the general principles that should guide the Agency's implementation of EPCRA section 313 as a whole. Rather, he stated:

> This is a new Federal initiative, and I recognize the desire of some of my colleagues to move ahead cautiously to ensure that burdens imposed on industry are not excessive. Frankly, my concern rest with the families that live in the shadows of these chemical and manufacturing plants. I have put myself in their shoes and have fought for a program that looks after their needs. This legislation gets us well on the path to the full disclosure they deserve. *Legislative History* at 5316. See also, *Legislative History* at 5185–86 (Senate debate on the Conference Report).

As noted in Unit VI.A, one of the major pieces of Congressional guidance on the establishment of alternate thresholds was to obtain a comprehensive picture of ''total nationwide releases of the toxic chemical at all facilities covered by section 313.'' This language, plus other Congressional directives on implementing section 313 generally, such as section 313(h), reflect an interest in obtaining information from a broadly representative range of sources. Consequently, EPA determined that the Agency should consider burden only to the extent that it would not deny the public significant information from a range of covered industry sectors.

Therefore, EPA estimated the number of reports that would be submitted by each industry sector for four groups of thresholds, 1 and 10 pounds, 10 and 100 pounds, 100 and 1,000 pounds, and 1,000 pounds for both classes of chemicals. These options were selected for the following reasons. EPA needed a reasonable but finite number of options to evaluate, and the options described above represent a reasonable picture of the entire range of potential revised thresholds. Data limitations on the manufacturing, processing, and otherwise use of PBT chemicals in the numerous industries, processes, and uses covered by EPCRA section 313

NMED Exhibit 72

constrained EPA's ability to make meaningful and reliable distinctions between threshold options that are less than an order of magnitude apart. For example, while EPA believes it can reliably estimate the difference in the number of reports from a 10 pound reporting threshold and a 100 pound reporting threshold, EPA believes that the data are insufficient to allow it to make a meaningful and reliable distinction in estimates of options that are closer than an order of magnitude such as 35 pounds and 50 pounds. EPA explained its data limitations in the proposal, and commenters provided no information that would allow the Agency to increase the resolution of its analysis. Consequently, for the final rule, EPA analyzed options that were orders of magnitude apart from the two thresholds identified through its technical review: 1 pound for highly persistent and highly bioaccumulative chemicals, and 10 pounds for persistent and bioaccumulative chemicals.

Based on information provided in the economic analysis for this rulemaking, at the technical reporting thresholds EPA would obtain information from a broad range of facilities (Ref. 67a). The analysis showed that at a threshold of 1 pound, the public would obtain information from all industry sectors that are currently subject to EPCRA section 313, and that have been identified as manufacturing, processing, or otherwise using those highly persistent highly bioaccumulative toxic chemicals that are part of this rulemaking (except dioxin and dioxin-like compounds which are discussed below). At a threshold of 10 pounds, the public would obtain information from all industry sectors that are currently subject to EPCRA section 313, and that have been identified as manufacturing, processing, or otherwise using those PBT chemicals that are part of this rulemaking. At the technical reporting thresholds, the estimated costs of the additional reports filed would have totaled $355 million in the first year, and $193 million in subsequent years (Ref. 67). EPA considered these costs, even though it cannot quantify the value of the information obtained or lost at the various thresholds, and cannot quantify the relationship between the reporting costs and the value of the information reported, or lost, at a particular threshold.

At thresholds of 10 pounds for highly persistent and highly bioaccumulative chemicals and 100 pounds for persistent and bioaccumulative chemicals, EPA is still able to obtain a significant amount of information on both classes of PBT chemicals from a wide range of industry sectors and sources. For example, no reporting on TBBPA would be lost from any sources or industry sectors at 100 pounds, and some information on octachlorostyrene would be potentially lost from only one industry sector, pesticide manufacturing facilities. At these thresholds, EPA does, however, lose information significant to local communities; for example, EPA loses considerable reporting on mercury and mercury compounds at 10 pounds, but the loss of information is localized in a limited number of industry sectors, and the public will still obtain some reporting from all of the currently covered industry sectors (Ref. 67a). For this threshold option, EPA estimated the total burden at these thresholds to be $191 million for the first year, and $105 million for subsequent years (Ref. 67).

At thresholds of 100 and 1,000 pounds and higher, EPA's analysis indicated that the public, government agencies, and researchers would lose information on many of the PBT chemicals from certain industry sectors and sources. For example, at a threshold of 100 pounds for toxic chemicals that are highly persistent and highly bioaccumulative, the Agency would not obtain reporting on mercury and mercury compounds generated in boilers in the manufacturing sector or information on octachlorostyrene from the primary metal industries (Ref. 67a). However, at these thresholds, EPA estimated the total first year costs to be $99 million and $55 million in subsequent years (Ref. 67).

These analyses led EPA to several conclusions. First, thresholds of 10 pounds for highly persistent and highly bioaccumulative chemicals and 100 pounds for persistent and bioaccumulative chemicals, achieve a significant reduction in reporting burden. Second, at these thresholds EPA obtains information from a broad distribution of industry sectors. Although EPA also loses information significant to local communities at these thresholds, it maintains the overall distribution of reporting from a broad range of industry sectors nationally. EPA could have attempted to compensate for the community-level loss of information on individual members of the classes of PBT chemicals (i.e., by establishing separate thresholds of 1 pound or 10 pounds for individual chemicals), but only by failing to take reporting burden into account for those individual chemicals. As explained previously, the availability of the data limited EPA's ability to distinguish meaningfully between thresholds separated by less than an order of magnitude. In addition, establishing separate thresholds would sacrifice many of the benefits of receiving information from comparable facilities using comparable chemicals, discussed earlier in this unit. Thus greater information for local communities would be achieved at the expense of the increased utility of the reports for other purposes established under EPCRA section 313(h)--e.g., assisting governmental agencies, researchers, agencies and other persons in the conduct of research and data gathering; and aiding in the development of appropriate regulations, guidelines, and standards. EPA believes that, to be consistent with the overriding policy directive in subsection (h), it must achieve a balance between improving the utility of the reports for all of the groups that rely on TRI data. Finally, as noted earlier in this Unit, administrative convenience argues against the establishment of individual thresholds. Among other issues, it would be burdensome on both EPA and the regulated community to track a variety of separate thresholds. Moreover, EPA intends the revised thresholds established in this rulemaking for the two classes of PBT chemicals to be generally applicable to future members of the two classes; absent a strong technical or policy concern to the contrary, it would ultimately be inconsistent with the purposes of EPCRA section 313 for chemicals that share such common characteristics to have vastly different thresholds.

Therefore, EPA believes its selection of thresholds of 100 pounds for PBT chemicals and 10 pounds for that subset of PBT chemicals that are highly persistent and highly bioaccumulative, balances the purposes of EPCRA section 313 and the Agency's desire to provide a comprehensive picture on releases and potential exposures of PBT chemicals, while factoring in an appropriate degree of the consequent impact on the regulated community.

Dioxin and dioxin-like compounds are highly persistent and highly bioaccumulative toxic chemicals. As discussed above, toxic chemicals that are highly persistent and highly bioaccumulative warrant, in the absence of other considerations, a threshold approaching zero. But, for the reasons discussed previously in this section, EPA does not believe that a zero threshold would be practical. However, because the dioxin and dioxin-like compounds are manufactured in extremely small amounts, EPA needed to select a threshold lower than that for the other highly persistent and highly

NMED Exhibit 72

bioaccumulative chemicals in order to obtain any reporting.

In choosing reporting thresholds for these chemicals, the Agency considered the extent of the information on dioxin and dioxin-like compounds that would be made available to the public, government agencies and researchers. EPA considered whether this level of information would provide them with ''a comprehensive view of toxic chemical exposure,'' given the attributes of dioxin and dioxin-like compounds, and with ''broad-based national information.'' At a threshold of 0.1 gram, the public would obtain information from all industry sectors that are subject to EPCRA section 313 and that have been identified in the *Inventory of Sources of Dioxin in the United States* (Ref. 3). EPA does not believe that a higher threshold, i.e., 1.0 grams, would provide the public with broad-based national information because there would be no information on the manufacture and release and other waste management of certain sectors. For example, at a higher threshold, EPA anticipates that there would be no reporting from hazardous waste incinerators, pulp mills, non high ferrous foundry industries, and secondary lead smelters (Ref. 67a). At thresholds lower than 0.1 gram, there is greater coverage *within* certain industry sectors, with a concomitant significant increase in burden. EPA believes its selection of a threshold of 0.1 gram for dioxin and dioxin-like compounds balances the purposes of EPCRA section 313 and the Agency's desire to provide a comprehensive picture on releases and exposures of dioxin and dioxin-like compounds while factoring in an appropriate degree of the resultant impact on the regulated community.

F. What Comments Did EPA Receive on Exposure and Risk Considerations and What Are EPA's Responses?

One of the most significant issues raised by commenters relates to the Agency's lack of consideration of quantitative risk in modifying the section 313(f) reporting thresholds. Specifically, a number of commenters believe that EPA should use quantitative risk as a criterion in determining whether to lower the reporting thresholds and in choosing a particular reporting threshold for each PBT chemical. The commenters contend that EPA should conduct risk assessments and make a formal determination that at a particular threshold releases of the PBT chemical pose a risk before lowering the reporting threshold. While the majority of commenters who commented on the issue believe that EPA should make a risk determination before modifying the reporting thresholds, the rationale for their conclusions varied. Some commenters state that a risk determination is required by EPCRA because the intent of EPCRA is to provide information to the public of potential risks posed by the presence of toxic chemicals released to the environment in their communities. Some commenters state that in addition to addressing the substantial majority test, EPCRA section 313(f)(2) requires EPA to use the degree of risk that releases will pose to communities as a determinant in choosing new thresholds. Other commenters state that consideration of risk is a required component of any action under EPCRA section 313. In support of this position, one of the commenters cites two D.C. Circuit Court decisions. Other commenters contend that it would be good public policy to choose a threshold based on risks. Some commenters contend that EPA should lower the reporting thresholds only for those chemicals that present the highest risks to the public. One commenter, however, believes that the Agency should not consider the degree of risk in making a determination to lower the reporting thresholds for PBT chemicals because the consideration of risk in past actions taken by EPA under other environmental statutes have not resulted in a decrease of human health or environmental risks due to PBT chemicals. The commenter states that the increasing number of fish advisories and the lingering and, in some cases, increasing levels of PBT chemicals in the environment and in fish, wildlife, and human tissue demonstrates the magnitude of the failure of the ''risk management strategy.''

EPA disagrees with the commenters' assertion that evidence of risk is required prior to lowering the threshold for any EPCRA section 313 chemical. Section 313(f)(2) addresses revisions to the reporting thresholds. It does not require EPA to establish, prior to the lowering of reporting thresholds, that releases at a particular threshold will result in specific quantitative risks. That section expressly provides that the Administrator may establish a threshold amount for a toxic chemical different from the 25,000 pound threshold for manufacturing and processing activities and the 10,000 pound threshold for otherwise use activities. The only prerequisite for revising the reporting threshold for a toxic chemical is that the revised threshold obtain reporting on a substantial majority of total releases of the chemical at all facilities subject to the requirements of EPCRA section 313. As discussed in Units II.B. and VI.A., EPA believes that it has satisfied the requirements of EPCRA section 313(f)(2) without the need for quantitative support.

EPA believes that the commenters attribute a purpose to EPCRA that is inconsistent with that clearly intended by Congress. Specifically, Congress stated in EPCRA section 313(h) that:

> The release forms required under this section are intended to provide information to the Federal, State, and local governments and the public, including citizens of communities surrounding covered facilities. The release form shall be available,. . .to inform persons about releases of toxic chemicals to the environment; to assist government agencies, researchers, and other persons in the conduct of research and data gathering; to aid in the development of appropriate regulations, guidelines, and standards; and for other similar purposes. 42 U.S.C. section 11023(h).

Neither EPCRA section 313(h) nor its legislative history directs EPA to limit the collection of information on releases to those releases that, from the Federal government's perspective, pose significant local human and environmental exposure and human health and environmental risks. See, e.g., *Legislative History* at 5186.

Federal and local perspectives on what may be an acceptable risk are likely to be very different. The roles of local government and the Federal government differ significantly in terms of ensuring environmental quality. In passing EPCRA, Congress determined that it is for the public to take the information reported on the use and releases and other waste management of toxic chemicals, and to determine whether these releases result in potential risks that the community determines warrant further action given other factors, such as economic and environmental conditions, or particularly vulnerable human or ecological populations. Congress did not intend the Federal government to consider these specific local factors prior to determining whether certain information should be made public or prior to determining whether a different threshold should be established for one or more toxic chemicals.

The intent of EPCRA section 313 is to move the determination of what risks are acceptable from EPA to the communities in which the releases occur. This basic local empowerment is a cornerstone of the right-to-know program. EPCRA section 313 establishes an information collection and dissemination program. The burden it imposes is significantly less than the

burden imposed by a statute which controls the manufacture, use, and/or disposal of a chemical. EPCRA section 313 requires that a facility use readily available data, or if such data are not available, reasonable estimates to prepare each chemical-specific report. The statute does not require that the facility conduct monitoring or emissions measurements to determine these quantities. This is in contrast to other environmental statutes that may require a facility to monitor releases, change its manufacturing process, install a specific waste treatment technology, or dispose of wastes in a certain manner. As such, the Agency believes that as a matter of policy the standard that must be met to require information pursuant to EPCRA section 313 is less than that required to regulate a chemical under a statute such as the Clean Air Act. See, e.g., *Legislative History* at 5186.

Further, contrary to assertions by some commenters, EPCRA section 313 does not require the collection of quantitative risk data nor does the statute require that risk data be disseminated to the public. Rather TRI data provide communities with information on releases and other waste management quantities. TRI data cannot, in themselves, provide information on quantitative risks to individual communities. A determination of the potential risk that a chemical release may pose is dependent upon a number of factors, including the toxicity of the chemical, the physical chemical properties of the chemical, the specific media to which the chemical is released, and site-specific information that will determine the estimated exposures. While TRI data are not in themselves measures of risk, they are an important input that local communities can use along with the factors described in this section to determine potential risks to themselves, their children, their communities, and their environment that may result from releases of toxic chemicals.

EPA's decision to lower the reporting threshold for PBT chemicals is rationally related to the EPCRA section 313 goals of informing communities, assisting research and data gathering, and aiding the development of regulations and guidelines. Because PBT chemicals persist in the environment for a significant period of time and bioaccumulate in animal tissues, PBT chemicals have the potential to be pervasive in the environment, in the food chain, and often in humans. In short, for PBT chemicals, releases and other waste management activities for relatively small amounts of PBT chemicals are of concern. Accordingly, pursuant to the intended purposes of EPCRA, even relatively small releases and other waste management activities for PBT chemicals need to be reported in order to inform communities, assist those engaged in research and data gathering, and to aid the development of regulations and guidelines. Lowered reporting thresholds for PBT chemicals are needed to obtain reporting on these relatively small releases and other waste management activities for PBT chemicals. Consequently, EPA believes that including consideration of the quantitative risk in establishing the thresholds would be poor public policy that would be inconsistent with the overall principles of EPCRA.

Finally, the reference by one of the commenters to two D.C. Circuit Court decisions is misplaced. In support of its position that EPA must undertake a risk assessment of any toxic chemical it is considering for lower reporting thresholds, the commenter cites *American Petroleum Institute* v. *Costle*, 665 F.2d 1176, 1187 (D.C. Cir. 1981), *cert. denied*, 455 U.S. 1034 (1982), and *Milwaukee Metropolitan Sewerage District* v. *EPA*, 40 F.3d 392 (D.C. Cir. 1994). Neither case cited by the commenter addresses EPCRA. Nor do these cases establish a generally applicable principle of law that risk assessments are required prior to any government action. In *Milwaukee Metropolitan Sewerage* the court reviewed standards adopted by EPA in a Clean Water Act regulation. In *American Petroleum Institute* the court reviewed the primary and secondary national ambient air quality standards for ozone promulgated by EPA under the Clean Air Act. Both the Clean Air Act and the Clean Water Act have no bearing on EPCRA section 313. Unlike the statutes at issue in the cases cited by the commenter, consideration of risk is not a requirement of section 313(f)(2) for modifying the reporting thresholds for EPCRA section 313 listed chemicals, and, in fact, the consideration of risk is generally not required for any rulemaking under section 313. *Troy Corporation* v. *EPA*, 120 F.3d 277 (D.C. Cir. 1997).

Some commenters further state that in proposing to change EPCRA section 313 reporting thresholds, EPA has not addressed any of the factors the Agency mentioned when it originally promulgated EPCRA section 313 regulations. In the February 16, 1988 final rule, EPA stated:

> EPA may consider a number of factors for threshold modification including exposure factors such as population density, the distance of population from covered facilities, and the types of releases. Threshold modifications could also take into account the relative potency of the chemical or class of chemicals and effects of concern. (53 FR 4508).

In this statement, the commenters contend that EPA correctly mentions factors that relate to risk (i.e., exposure and relative toxicity). The current proposal to change reporting thresholds under EPCRA section 313 fails to address these factors.

As is clearly evident in the quote from the February 16, 1988 final rule, EPA stated that these were things that it ''may consider'' or that could be taken into account. These statements do not require that the possible factors mentioned above be a basis for any change in the reporting thresholds nor do they preclude the consideration of factors such as the persistence and/or bioaccumulation of toxic chemicals in modifying the reporting thresholds. This statement was not a commitment that EPA would consider risk in any decision to modify reporting thresholds. It merely provided examples of things that the Agency may consider.

As explained in previous responses, EPA does not believe that it would be good public policy to consider factors related to quantitative risk with respect to establishing thresholds for PBT chemicals. Given the degree of persistence and bioaccumulation that these toxic chemicals exhibit, EPA believes that the value of this information to the public outweighs the policy considerations presented in favor of considering risk factors in establishing revised thresholds. Any other decision would be inconsistent with the legislative intent underlying EPCRA section 313.

Finally, EPA notes that this decision is consistent with the approach adopted in modifying the thresholds to establish a 1 million pound manufacture, process, or otherwise use threshold for facilities that have 500 pounds or less of production-related waste (59 FR 61488, November 30, 1994) (FRL–4920–5). Any decision to include risk considerations in establishing modified thresholds under section 313(f)(2) would compel the Agency to re-examine the thresholds established for facilities with less than 500 pounds of production-related waste.

Several commenters contend that a chemical's degree of persistence and bioaccumulation are unrelated to the chemical's exposure potential. They disagree that persistence and bioaccumulation are necessarily indicators of exposure or exposure potential. As an example, the commenter states that many of the compounds EPA is targeting are highly lipophilic, non-water soluble

NMED Exhibit 72

compounds, and the greatest potential for bioaccumulative effects is through uptake from the water column. EPA should evaluate how these compounds partition in the environment. Those that are not bioavailable have limited exposure potential, and therefore limited risk. Thus, the commenter believes that EPA must consider exposure in conjunction with persistence and bioaccumulation.

EPA disagrees with the commenters. All other things being equal, the chemical with a higher degree of persistence and bioaccumulation will have a greater exposure potential than the chemical with a lower degree of persistence and bioaccumulation. For example, all other things being equal, a chemical that has a half-life in water of 4 months will have a higher exposure potential to aquatic organisms than a chemical with a half-life in water of 1 month. Fifty percent of the first chemical will remain in the water after 4 months while only 12.5% of the second chemical will remain in the water after 4 months. After 4 months, aquatic organisms will be exposed to 4 times more of the first chemical than the second chemical. Clearly the chemical with the greater persistence has the higher exposure potential.

EPA does not believe that the commenter's example supports their contention that persistence and bioaccumulation are unrelated to exposure potential. As EPA understands the commenter's example, chemicals that have the greatest bioaccumulation potential will not be bioavailable in water because they are highly lipophilic and non-water soluble. Thus, because they are not bioavailable in water, they cannot bioaccumulate in aquatic organisms. A well-studied example that clearly contradicts the commenter's claim is the bioaccumulation of polychorinated biphenyls (PCBs) in the Great Lakes. PCBs have BAFs as high as 141,000,000 (Table 1, at 64 FR 707–8) and very, very low water solubility. PCBs have been found throughout the Great Lakes in sediments, water, and aquatic organisms. Multimedia analyses indicate that the majority (80–90%) of human exposure to chlorinated organic compounds, such as PCBs comes from the food pathway, a lesser amount (5–10%) from air, and minute amounts (less than 1%) from water. Most of the data available on human exposure to toxic substances in the Great Lakes come from the analyses of contaminant levels in drinking water and sport fish. The consumption of contaminated sport fish and wildlife can significantly increase human exposure to the Great Lakes critical pollutants. The sport fish are exposed to PCBs by consumption of sediments and in water, from which they bioaccumulate the PCBs (Ref. 62).

Some commenters contend that EPCRA requires that EPA consider the risks that a chemical may pose when making determinations to add a chemical to the EPCRA section 313 list of toxic chemicals. In support of this position, one commenter cites two D.C. Circuit Court decisions.

As discussed in detail in the final rule adding 286 chemicals to EPCRA section 313 (59 FR 61432), EPA disagrees with commenters that the Agency must include a risk assessment component to EPCRA section 313 determinations. While the Agency believes that there are limited circumstances where it may be appropriate to consider risk in making listing determinations, e.g., acute human health effects, EPA does not believe that the intent of EPCRA, the EPCRA section 313 toxicity criteria, or the legislative history support the contention that risk assessment is a required component of all EPCRA section 313 listing determinations.

The EPCRA section 313 toxicity criteria require that exposure and risk factors be considered only when determining if the toxic chemical should be listed on EPCRA section 313 based on its acute human health effects, but even then in only a very limited manner. The statute mandates that EPA consider whether ''a chemical is known to cause or can reasonably be anticipated to cause significant adverse acute human health effects at concentration levels that are reasonably likely to exist beyond facility site boundaries.'' EPA has, and will continue to look at exposures reasonably likely to exist beyond facility site boundaries when making a listing determination pursuant to EPCRA section 313(d)(2)(A). However, EPA notes that none of the toxic chemicals added in today's action were added pursuant to paragraph (A) of that section.

The statute is silent on the issue of exposure considerations for the section 313(d)(2)(B) and (C) criteria. The language of section 313 does not prohibit EPA from considering exposure factors when making a finding under either section 313(d)(2)(B) or section 313(d)(2)(C). However, the language of sections 313(d)(2)(B) and (C) does not require the type of exposure assessment and/or risk assessment argued by the commenters. EPA believes that it has the discretion under both section 313(d)(2)(B) and section 313(d)(2)(C) to consider, where appropriate, those exposure factors that may call into question the validity of listing of any specific chemical on EPCRA section 313.

EPA believes that its position regarding the limited use of risk in listing decisions is consistent with the purpose and legislative history of EPCRA section 313, as illustrated in the following passage from the Conference report:

> The Administrator, in determining to list a chemical under any of the above criteria, may, but is not required to, conduct new studies or risk assessments or perform site-specific analyses to establish actual ambient concentrations or to document adverse effects at any particular location. (H. Rep. 99-962, 99th Cong., 2nd Sess., p. 295 (October 3, 1986)). See also *Legislative History* at 5186.

This passage indicates that Congress did not intend to require EPA to conduct new studies, such as exposure studies, or to perform risk assessments. Therefore, Congress did not consider these activities to be mandatory components of all section 313 decisions. EPA believes that this statement combined with the plain language of the statutory criteria clearly indicate that Congress intended that the decision of whether and how to consider exposure under EPCRA section 313(d)(2)(B) and (C) should be left to the Agency's discretion. EPA has carefully considered when and how to use exposure to fully implement the right-to-know provisions of EPCRA. The Agency believes that exposure should be considered only in very limited circumstances when adding a chemical to EPCRA section 313(d)(2)(B) or (C). The Agency's interpretation of the section 313(d)(2) and (d)(3) criteria for modifying the section 313 list of toxic chemicals is discussed in the final rule adding 286 chemicals to EPCRA section 313 (at 59 FR 61440–2). And in fact, EPA's interpretation was upheld by the D.C. Circuit in *Troy* v. *EPA*, 120 F.3d 277. The addition of chemicals pursuant to EPCRA section 313(d)(2)(B) and (C) in today's rulemaking is consistent with this interpretation.

The intent of EPCRA section 313 is to move the determination of which risks are acceptable from EPA to the communities in which the releases occur. This basic, local empowerment is a cornerstone of the right-to-know program. EPCRA section 313 establishes an information collection and dissemination program. It provides the public with information that can be used with other site-specific factors to determine if releases into their communities result in risks that the community determines warrant further action given other factors, such as economic and environmental

NMED Exhibit 72

conditions, or particularly vulnerable human or ecological populations.

In addition, the reference by one of the commenters to two D.C. Circuit Court decisions is misplaced. In support of its position that EPA must undertake a risk assessment of any toxic chemical it is considering to add to EPCRA section 313, the commenter cites *American Petroleum Institute* v. *Costle*, 665 F.2d 1176, 1187 (D.C. Cir, 1981), *cert. denied*, 455 U.S. 1034 (1982), and *Milwaukee Metropolitan Sewerage District* v. *EPA*, 40 F.3d 392 (D.C. Cir. 1994). As discussed in a previous response in this unit, neither case cited by the commenter addresses EPCRA. In addition, since both cases were decided prior to *Troy*, by the same court, that decided the specific issue raised by the commenter, nothing in the two earlier cases cited by the commenter can overrule that decision.

G. Which Chemicals is EPA Adding to the List of EPCRA Section 313 Toxic Chemicals?

EPA is adding the following chemicals to the EPCRA section 313 list of toxic chemicals: dioxin and dioxin-like compounds, benzo(g,h,i)perylene, benzo(j,k)fluorene (fluoranthene), 3-methylcholanthrene, octachlorostyrene, pentachlorobenzene, tetrabromobisphenol A, vanadium (except alloys) and vanadium compounds. EPA conducted a hazard assessment on each chemical being added to the EPCRA section 313 list of toxic chemicals today. This assessment was separate and independent from the review conducted to determine each chemical's persistence and bioaccumulation potential, although EPA considered some of the same data in certain of its hazard assessments. EPA finds that each chemical being added today meets the criteria for chronic human toxicity and/or environmental toxicity, as set forth at EPCRA sections 313(d)(2)(B) and (C). A summary discussion of the basis for listing each of these chemicals as well as other related issue are presented in the remainder of this unit. A more extensive discussion of these issues is included in the Response to Comments document (Ref. 69) and supporting documents.

1. *Dioxin and dioxin-like compounds category*. There were a number of comments received on the addition of the dioxin and dioxin-like compounds category and these are addressed in detail in the Response to Comments document (Ref. 69). Most of the comments on the toxicity data that EPA presented in support of the addition of the category concern the dioxin-like compounds since most commenters seemed to agree that 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (dioxin or 2,3,7,8-TCDD) meets the criteria for listing under EPCRA section 313(d)(2)(B). A number of commenters did not believe that there was sufficient information to add any of the dioxin-like compounds while several commenters argue that the data on the octa- and heptachlorodibenzo-*p*-dioxins in particular were not sufficient. Commenters also argue that reliance on established toxicity equivalence factors (TEFs) does not provide sufficient support for determining that the dioxin-like compounds meet the EPCRA section 313(d)(2)(B) criteria.

EPA disagrees with the commenters that contend that there are not sufficient data to add the dioxin-like compounds pursuant to EPCRA section 313(d)(2)(B). 2,3,7,8-TCDD is generally recognized as one of the most studied toxic compounds found in the environment. To require the degree of documentation supporting toxicological classification of 2,3,7,8 -TCDD as a necessary criterion for determining that other dioxin-like compounds exhibit dioxin-like toxicity or for listing under EPCRA section 313 is an arbitrary and unrealistic criteria. As discussed in more detail in the Response to Comments document (Ref. 69), a more scientifically supportable set of criteria for determining if compounds exhibit dioxin-like toxicity was proposed by the World Health Organization European Centre for Environmental Health (WHO-ECEH) and the International Programme on Chemical Safety (IPCS) consultation group. These criteria include: (1) A compound must show a structural relationship to TCDD; (2) a compound must bind to the Ah receptor; (3) a compound must elicit Ah receptor-mediated biochemical and toxic responses; and (4) a compound must be persistent and accumulate in the food chain. Each of the 2,3,7,8 substitute dioxins and furans included in the dioxin TEQ approach meet these criteria (Ref. 3).

The commenters often quoted from the EPA Science Advisory Board (SAB) review of EPA's draft dioxin reassessment, to help support the claim that dioxin-like compounds other than 2,3,7,8-TCDD should not be included in the toxic release inventory. The SAB report is a complex document containing a number of contrasting observations. Care must be taken to accurately capture the SAB's concerns. For example, in their Executive Summary, the SAB concluded that, ''The use of the TEFs as a basis for developing an overall index of public health risk is clearly justified''; they caution, however, ''that practical application depends on the reliability of the TEFs and the availability of representative and reliable data.'' In their summary conclusions, the SAB stated:

> The document (EPA Draft Reassessment) represents a departure from the earlier EPA risk assessment for dioxin, which dealt primarily with 2,3,7,8-TCDD. In addressing a broad range of dioxin-like compounds having the common property of binding to the Ah receptor and producing related responses in cells and whole animals, it creates opportunities for a holistic assessment of the cumulative impacts of these broadly distributed anthropogenic pollutants. Thus, while the environmental concentrations of each compound alone may be too low to produce effects of concern, the combined exposure may be producing effects that warrant concern. The use of the concept of TEFs and the concentrations of the compounds in foods and environmental media to produce an overall index of public health risk is clearly justifiable.

The character and thrust of these statements made by the SAB are significantly different from those selectively chosen by many of the commenters opposing the addition of some or all of the dioxin-like compounds. The apparent contradiction between these broad concluding statements by the SAB and those cited by several commenters is due, in part, to commenters confusing the SAB criticisms of the text of the draft reassessment with statements about the general state of scientific knowledge. The SAB clearly felt that EPA needed to do a more rigorous job of discriminating between the inferences it drew about the toxicity of 2,3,7,8-TCDD, other 2,3,7,8 substitute dioxins and furans, and dioxin-like PCBs. Many of the comments cited were intended to help EPA generate a more rigorous scientific discussion in its final reassessment document rather than to represent substantive conclusions reached by the SAB on the nature of dioxin toxicology. Fully taking these concerns into consideration it was still the SAB's overall judgment, as stated above, that ''the use of the TEFs as a basis for developing an overall index of public health risk is clearly justified.''

Some commenters argue that there are qualitative differences in the toxicity of the different 2,3,7,8-substituted isomers of polychlorinated dioxins (PCDDs) and furans (PCDFs). Specifically, there are structural differences between the more toxic, lower chlorinated isomeric PCDDs and PCDFs and the higher chlorinated cogeners to the extent that the octa- and hepta-PCDDs and PCDFs should not be added to the list of EPCRA section 313

NMED Exhibit 72

toxic chemicals. These arguments are not valid for several reasons. First, there are data from subchronic studies for both octa- and hepta-PCDDS and PCDFs which demonstrate dioxin-like effects (Refs. 19, 21, 79, and 80). The new WHO TEFs are based on these subchronic studies (Ref. 78). While short-term studies indicate limited dioxin-like effects of these chemicals, these contrasting results are readily explained by the structural differences between the octa- and hepta-PCDDS and PCDFs compared to the lower chlorinated PCDDs and PCDFs. The relative potency of the dioxin-like compounds is related to both their ability to bind to the Ah receptor and their pharmacokinetic properties (Ref. 20). The water solubility of PCDDs and PCDFs decrease with increasing chlorine substitution. Hence the octa- and hepta-PCDDS and PCDFs are significantly less soluble in aqueous solutions compared to the lower chlorinated PCDDs and PCDFs. These solubility problems limit the amount of chemical that can be absorbed in high dose acute toxicity studies. The lack of effect observed in the high dose acute studies is consistent with the limited aqueous solubility of these compounds. However, low dose subchronic studies allow the chemicals to be better absorbed and bioaccumulate to concentrations which produce biochemical and toxic effects (Refs. 19, 21, 79, and 80). Once again this is consistent with the evidence of dioxin-like effects of these chemicals observed in the low-dose subchronic studies. Although not legally required to determine that a chemical meets the listing criteria under EPCRA section 313(d)(2)(B), it should be noted that human exposure to octa- and hepta-PCDDs and PCDFs are subchronic low dose exposures, similar to the experimental studies which demonstrate dioxin-like effects of these chemicals (Refs. 19, 21, 79, and 80).

While there are structural differences between the octa- and hepta- PCDDs and PCDFs compared to the lower chlorinated PCDDs and PCDFs, these differences result in quantitative not qualitative differences in the toxicity of these chemicals. The quantitative differences are demonstrated by the lower potency of the octa- and hepta-congeners compared to TCDD. In addition, the TEFs reflect these quantitative differences by assigning lower TEF values to the octa- and hepta-PCDDS and PCDFs. While there is limited evidence that the shape of the dose-response curve for induction of CYP1A1 activity *in vitro* for octachlorodibenzo-*p*-dioxin (OCDD) is different from TCDD, *in vivo* evidence indicates that the dose response for CYP1A1 induction by octachlorodibenzofuran (OCDF) in three tissues is equivalent to TCDD (Ref. 20). However, it should be noted that these are quantitative not qualitative differences.

Commenters also argue that octa- and hepta-PCDDs and PCDFs should not be listed because ''there is a growing consensus in the scientific community that the potential risks posed by dioxins are largely driven by a limited number of dioxin and dioxin-like compounds (tetra-, penta-, and hexa-PCDDs and PCDFs and certain coplanar PCBs).'' It is important to remember that, as discussed in Unit VI.F., EPCRA section 313 is primarily a hazard-based rather than a risk-based statute. The ''growing consensus'' on dioxin toxicity is probably best captured by the revised TEFs recently established by the WHO (Ref. 78). In this review the scientific evidence for ascribing values of relative toxicity to octa- and hepta-PCDDs and PCDFs was specifically reviewed, as evidenced by the lowering of the TEF for OCDD and OCDF by a factor of 10. In the course of the deliberations by the WHO panel of internationally distinguished scientists, there was the opportunity to remove both octa- and hepta-PCDDs and PCDFs from the TEF listings. However, the WHO panel concluded that the best scientific interpretation of the data available was to leave hepta-PCDDs and PCDFs unchanged and reduce but not eliminate OCDD from TEQ calculations. Even with this reduced toxicity, OCDD and OCDF clearly meet the listing criteria of EPCRA section 313(d)(2)(B).

EPA disagrees with the commenters that contend that TEFs are not adequate support for listing chemicals under EPCRA section 313. The development of TEFs has been a rigorous scientific effort involving a number of international panels of scientific experts and has involved the careful review of all relevant scientific literature. EPA believes that the development and review processes used for the generation of the TEFs was sound and represents a reasoned and reliable judgment on the dioxin toxicity of each of the 17 dioxin and dioxin-like compounds. The Response to Comments document (Ref. 69) includes an extensive discussion of the history of the development of dioxin TEFs which demonstrates why EPA believes that the TEFs are well supported scientifically and consequently have been openly adopted by the international scientific and regulatory community. In addition, as EPA has previously explained (59 FR 61432), the Agency believes that EPCRA section 313 allows a chemical category to be added to the list, where EPA identifies the toxic effects of concern for at least one member of the category and then shows why those effects can reasonably be expected to be caused by all other members of the category. Here, individual toxicity data are not available for all members of the category; however, there is sufficient information to conclude based on generally accepted scientific principles, that all of these chemicals are highly toxic based on structural and physical/chemical property similarities to those members of the category for which data are available.

Thus, EPA reaffirms that there is sufficient evidence for adding dioxin and dioxin-like compounds on EPCRA section 313 pursuant to EPCRA section 313(d)(2)(B) based on the available cancer and other serious chronic health effects data for these compounds. Therefore, EPA is finalizing the listing of dioxin and dioxin-like compounds on the EPCRA section 313 list.

a. *Manufacturing only qualifier for dioxins and dioxin-like compound category*. Comments were mixed with regard to EPA's proposal to add a manufacture only qualifier to the dioxin and dioxin-like compounds category. Some commenters agree with EPA's statements in the proposed rule concerning the burden reduction aspects of the qualifier and the fact that as a result, the dioxin reporting would focus on facilities that manufacture dioxin and dioxin-like compounds rather than those that process or otherwise use raw materials containing dioxin and dioxin-like compounds that have accumulated in those raw materials. Some commenters state that the qualifier would avoid duplicative testing and administrative costs among many processing and using industries which do not necessarily discharge dioxins or furans into the environment. Some commenters state that all releases of dioxin and dioxin-like compounds must be reported, not just those resulting from the manufacture of these chemicals. Other commenters note that a significant gap is created by the manufacture only qualifier because it would exclude the processing and otherwise use of chemicals than contain dioxin and dioxin-like compounds as a result of the processes used to manufacture them. Commenters specifically cite pentachlorophenol as an example of a chemical that is contaminated with dioxin and dioxin-like compounds from its manufacturing process. Commenters state that the processing and use of such chemicals

NMED Exhibit 72

result in the release of dioxin and dioxin-like compounds that would go unreported under the manufacture only qualifier. One commenter states that if the qualifier is finalized the commenter would like to see language that requires facilities to report if the background levels of dioxin are modified, concentrated, or somehow added to in the manufacturing process. Another commenter states that if the Agency wants to exempt animal sources of dioxin, such as dioxin contained in meat and other animal products, it should craft the rule to do so and not cut out other significant sources of dioxin in the environment by exempting all facilities that process material containing dioxin.

EPA believes that in order to obtain any reporting on dioxin and dioxin-like compounds a very low threshold is required, which is several orders of magnitude lower than the thresholds for other PBT chemicals. At such a low reporting threshold it is estimated that thousands of reports could potentially be filed by facilities, mainly food processing facilities, due to the amount of dioxins in the raw materials they process. The dioxins found in the meat and dairy products that food processors handle have been previously released, circulated in the environment, and bioaccumulated in animals; thus these are not additional loadings to the environment but loadings that have already occurred and cycled through the environment due to the persistence and bioaccumulative properties of these compounds. The unique combination of very low thresholds, the number of food processors that would be required to file, and the fact that they would be filing because of the bioaccumulation of previously released material, led EPA to add the manufacture only qualifier to the dioxins category. The qualifier was added in response to the unique set of conditions that apply to the reporting of dioxin and dioxin-like compounds. The manufacture only qualifier was added to reduce reporting burden on facilities, mainly in the food processing industry, that results from the unique combination of circumstances related to the reporting for these chemicals and to focus on those activities that add to the loading of dioxins in the environment rather than on activities dealing with previously released and bioaccumulated chemicals.

However, EPA acknowledges that the commenters who noted that the processing and otherwise use of chemicals contaminated with dioxin and dioxin-like compounds as a result of their manufacturing process, are correct that these would be newly created and thus any releases of dioxin and dioxin-like compounds that are due to the processing and otherwise use of such chemicals would be new loadings on the environment. In addition, EPA agrees, and has never stated otherwise, that the processing or use of chemicals contaminated with dioxin and dioxin-like compounds could result in the release of these chemicals to the environment. Given the fact that the manufacture of certain chemicals also results in the manufacture of dioxin and dioxin-like compounds that remain with those chemicals as impurities, EPA believes that releases and other waste management quantities for the dioxin and dioxin-like compounds found as impurities with those chemicals should be reported under the dioxin and dioxin-like compounds category. Thus, EPA's original proposal would have created an exemption that was too broad. Consequently, EPA is modifying the qualifier to read as follows:

> Dioxin and dioxin-like compounds (Manufacturing; and the processing or otherwise use of dioxin and dioxin-like compounds if the dioxin and dioxin-like compounds are present as contaminants in a chemical and if they were created during the manufacturing of that chemical)

EPA believes that narrowing its proposal in this fashion is consistent with EPA's intention to focus on new loadings to the environment for dioxin and dioxin-like compounds.

One commenter states that the activity qualifier for dioxin and dioxin-like compounds is intended to minimize the burden of reporting on naturally-occurring constituents of raw materials and that this qualifier would be consistent with the PBT criteria set forth by Canada's Department of the Environment in their Toxic Substances Management Policy. The commenter states that the Canadian policy requires a chemical to be ''predominantly anthropogenic'' to be considered a PBT chemical. The commenter states that EPA's assumption that these compounds are ubiquitous in raw materials may be incorrect. The commenter further states that these compounds may be formed in combustion processes due to the ubiquitous presence of *precursor* chemicals in coal, such as natural hydrocarbons and chlorine. The commenter argues that it is not reasonable to expect the hydrocarbon nor the chlorine to be removed from the raw material prior to combustion. Thus, the ''incidental manufacture'' of extremely minute amounts of these chemicals may be unavoidable.

EPA disagrees that the sole basis for its qualifier was to minimize the burden of reporting. The qualifier was added in response to the unique set of conditions that apply to the reporting of dioxin and dioxin-like compounds. As noted above, EPA was, and remains, concerned that, because dioxin is ubiquitous in the environment, the reporting be focused on those facilities that actually add to the environmental loading of these chemicals. EPA did not state that dioxin and dioxin-like compounds would be ubiquitous in all raw material and did not intend to imply that all raw materials contain these compounds. EPA stated that these compounds are ubiquitous in the environment and, thus, facilities that process raw materials containing these compounds might have to report because of the very low reporting threshold necessary to obtain reports from any sources, including those facilities that coincidentally manufacture them. In addition, although the qualifier may be consistent with Canada's Toxic Substances Management Policy, EPA has not proposed any requirement that a chemical must be ''predominantly anthropogenic'' to be considered a PBT chemical under EPCRA section 313. The commenter is correct that dioxin and dioxin-like compounds may be manufactured in combustion processes due to the ''ubiquitous presence of precursor chemicals'' and that such ''incidental manufacture'' may be unavoidable. However, the mere presence of the dioxin precursors will not guarantee dioxin production. There are well documented conditions that favor the formation of dioxins during combustion, and in some cases it may be possible to stringently control fuel composition, flow times, temperature, and other conditions in order to substantially reduce or even eliminate the incidental manufacture of dioxins during combustion processes.

b. *Withdrawal of the proposal to include dioxin-like PCBs in the dioxin category*. Several commenters support EPA's decision to withdraw the proposal to modify the current PCB listing and move the 11 co-planar PCBs to the proposed dioxin and dioxin-like compounds category and retain the co-planar PCBs as part of the current PCB listing. Two commenters support EPA's decision to leave co-planar PCBs out of the dioxin and dioxin-like compounds category since the structure, metabolism, gene regulation, and toxicities of PCBs are substantially different from those of 2,3,7,8-tetrachlorodibenzo-*p*-dioxin. One commenter takes exception to the use of the term ''dioxin-like'' as a way of describing PCBs and other chlorinated

NMED Exhibit 72

compounds and agrees that the PCBs should be kept out of the ''dioxin-like'' class. Other commenters also argue that PCBs are more appropriately classified as PCBs, not dioxin-like compounds.

One commenter contends that since these chemicals are no longer allowed to be distributed in commerce, maintaining a separate EPCRA section 313 chemical category for these chemicals will streamline data management. This approach will also enable EPCRA section 313 reporting for this category of chemicals to be more consistent with existing data already collected for the purposes of complying with TSCA. Further the commenter asserts that approach is also consistent with EPA's Reinvention Policy and will enable ''one-stop'' reporting.

Another commenter asserts that it is unclear just how many grams of dioxin-like compounds would be excluded from this reporting since there are conflicting Agency proposals at work: the first is a much lower threshold for dioxins. The second includes only dioxins manufactured on site. Since PCBs are not generally manufactured on site, these 11 dioxin-like compounds would not be reported under the proposal if they were included as dioxins. On the other hand, if all dioxins (manufactured, processed, and otherwise used) are included in the EPCRA section 313 threshold determination, these 11 PCBs could make the difference between a facility's reporting or not reporting dioxins. If the dioxin threshold remains as proposed, then the 11 PCBs should remain with the PCB category. Further the commenter argues that if the threshold is expanded to include sources other than those that manufacture dioxin on-site, then the PCBs should be part of the dioxin-like compounds category. If EPA does not modify the dioxin threshold to include all dioxin uses, the 11 dioxin-like PCBs should remain with the PCB category.

While EPA agrees with the commenters that the co-planar PCBs should remain as part of the current PCB listing, the Agency does not agree with all of the reasons the commenters have presented. As EPA stated in the proposed rule:

> . . .EPA has determined that all PCBs persist and bioaccumulate. Since PCBs persist and bioaccumulate, EPA believes that they should be subject to lower reporting thresholds, and thus there is no need to move the 11 co-planar PCBs to the proposed dioxin and dioxin-like compounds category. Therefore, EPA has decided to withdraw its proposal to modify the current listing for PCBs and instead proposes to lower the reporting thresholds for the current PCB listing which covers all PCBs. EPA believes that, since all PCBs persist and bioaccumulate, it is appropriate to lower the reporting threshold for this class of chemicals and that this proposal is less burdensome than requiring separate reporting on the dioxin-like PCBs as part of the proposed dioxin and dioxin-like compounds category (at 64 FR 710).

EPA did not base its decision on a determination that co-planar PCBs were not ''dioxin-like'' and keeping them under the current PCB listing should not be interpreted as such a determination. Also, since EPA is not expanding the qualifier for the dioxin and dioxin-like compounds category to include all processing and otherwise use activities, the amounts of co-planar PCBs that might be reportable under the category would not be expected to contribute significantly to threshold determinations for the category at most facilities.

Four commenters specifically do not support EPA's decision to withdraw the proposal to modify the current PCB listing. Commenters assert that the aggregation of dioxin-like PCBs together with other PCBs will fail to provide reporting of useful information on dioxin-like PCBs. The commenters either contend that the PCBs should be included in the dioxin-like compounds category or the PCBs and all dioxin-like compounds should be reported separately. One commenter argues that the aggregate reporting of dioxin-like PCBs and other PCBs fails to provide any information on the release of dioxin-like PCBs to meet the research, regulatory, or public information goals of EPA's proposal. This commenter raises several points. The commenter contends that specifically, even if some facilities releasing dioxin-like PCBs reported these releases as a portion of their total PCBs production of 10 pounds annually or greater, information on dioxin-like PCBs releases would still be unobtainable. The commenter asserts that aside from the food chain, where some dioxin-like PCBs tend to concentrate disproportionately, available measurements indicate that these dioxin compounds are only a small portion of the mass of all PCB compounds. The commenter further argues that some of these dioxin compounds such as PCB-126 are far more toxic than other dioxin-like and non dioxin-like PCBs. Thus, the commenter asserts that in addition to all of the problems of dioxin-like chemical aggregate reporting, one would not know what, if any, portion of the total PCBs reported were dioxin-like. The commenter contends that the dioxin-like co-planar PCBs also should be reported individually so that a TEQ for all 28 dioxin and dioxin-like compounds can be calculated. Another commenter argues that based on information about current body burdens of co-planar PCBs, they compose as much or an even greater percentage of one's overall exposure than the 17 dioxin and dioxin-like compounds. This commenter cites an EPA document that stated that: ''[e]stimates of exposure to dioxin-like CDDs and CDFs based on dietary intake are in the range of 1-3 pg TEQ/kg/day. Estimates based on the contribution of dioxin-like PCBs to toxicity equivalents raise the total to 3-6 pg TEQ/kg/day.'' Some commenters contend that reporting the co-planar PCBs differently from the 17 dioxin and dioxin-like compounds would make any assessment of the overall release and potential health impact of these types of compounds difficult. One commenter argues that PCBs are currently contaminating sediments and industrial sites nationally and have ruined fish as a natural resource for human consumption across the nation and that the distinction between dioxin-like PCBs and dioxin-like compounds made under this rule is a distinction without a difference. This commenter urges EPA to include all dioxin-like compounds, including PCBs, in the dioxin-like compounds category and to require strict accounting from all sources which release these compounds and which manufacture them, incidentally or by design.

One commenter contends that the failure to report dioxin-like PCBs as a distinct entity separate from other PBT chemicals may hold back information on a significant portion of the total dioxin-like hazard from releases by facilities that report under EPCRA section 313, even if all dioxin and furan releases were reported. The commenter argues that environmental exposure measurements, such as those from fish in San Francisco Bay and from human tissues nationally, indicate that dioxin-like PCBs contribute a very significant portion of the total toxicity hazard from exposure to all dioxin-like chemicals. The commenter also asserts that PCB releases might in some cases represent an inadequately measured yet significant portion of the ongoing dioxin release hazard. If, for example, PCB-126 comprises even 1/10 of the PCBs release measured from San Francisco Bay Area sources, it would contribute substantially to total dioxin-like toxicity emission from some of these facilities. The commenter contends that the failure to provide release information on dioxin-like PCBs under EPA's proposal

NMED Exhibit 72

may result in failure to inform the public about a significant portion of the total dioxin toxicity that is still released.

EPA agrees that PCBs are toxic chemicals of concern that have caused significant contamination of the environment and that co-planar PCBs may have dioxin-like health effects. However, this does not, in itself, create a requirement that the co-planar PCBs must be moved from their current PCB listing to the dioxin and dioxin-like compounds category. EPA does not believe that the co-planar PCBs must be reported separately from the non co-planar PCBs because they may be more toxic than other PCBs. In general, chemical categories consist of chemicals that vary in their level of toxicity but this variability alone does not mean that release information must be reported separately for each chemical in the category. EPA believes that all PCBs are of concern and that leaving the co-planar PCBs under the current PCB listing will still provide the public with useful and important information. In deciding not to move the co-planar PCBs to the dioxin category, EPA also considered any potential additional burden associated with splitting the reporting for PCBs into two different listings, as well as the fact that facilities are not likely to be able to determine quantities of the specific co-planar PCBs in question. Specifically, EPA considered the lack of readily available estimation techniques for determining quantities of co-planar PCBs, as opposed to other PBT chemicals and the PCB listing as a whole (co-planar PCBs will be included in the estimation of PCBs). EPA determined that since all PCBs are of concern and since the reporting threshold for all of the PCBs under the PCB listing would be lowered substantially, that requiring separate reporting on the co-planar PCBs was not warranted.

One commenter contends that the failure to report dioxin-like PCBs would fail to provide information on that subgroup of dioxin-like compounds for which there is the greatest need for additional information. The commenter argues that EPA's evaluation of the emission of dioxin-like chemicals nationwide shows that there is less information on releases of dioxin-like PCBs than there is for other dioxin compounds. The commenter asserts that similarly, their survey of source information in the San Francisco Bay Area shows that, despite many measurements of dioxin and furan releases, and despite a handful of source measurements confirming PCBs, there are few or no source measurements for dioxin-like PCBs. The commenter argues that the information on releases from facilities is even less available for the dioxin-like PCBs than it is for the other dioxin-like chemicals and that EPA's analysis in the proposed rule fails to consider adequately this extreme need for source release information.

EPA agrees that there is far less information available on co-planar PCBs than for dioxin and other dioxin-like compounds. Much less testing and analysis has been conducted for these chemicals. This would pose an additional problem for reporting on the co-planar PCBs separately from the other PCBs. EPA considered the ability to estimate quantities of specific co-planar PCBs and determined that there is a lack of readily available estimation techniques for co-planar PCBs. In fact, at this time, the Agency would not be able to provide guidance for making a reasonable estimate of quantities of co-planar PCBs that may be manufactured in certain processes. In addition, EPCRA section 313 does not require any additional monitoring beyond that required by other provisions of law so listing the co-planar PCBs separately would not mean that additional source measurements would be developed. Thus, listing under EPCRA section 313 will not require the development of additional monitoring data that could be used to make reasonable estimations of thresholds or releases and other waste management quantities. Given the lack of information available for estimating quantities of co-planar PCBs and the potential additional burden associated with splitting the reporting for PCBs into two different listings, EPA decided to leave the co-planar PCBs under the current PCB listing.

One commenter asserts that the burden on industrial producers of dioxin-like PCBs is not an appropriate reason for excluding dioxin-like PCBs from the dioxin and dioxin-like compounds category because this will not meet EPCRA's right-to-know goal for dioxin-like PCBs. The commenter contends that EPA's cost analysis does not address dioxin-like PCBs specifically and thus, EPA's rationale in Unit VI. of the preamble of the proposed rule (64 FR 688) that ''this proposal is less burdensome than requiring separate reporting on the dioxin-like PCBs'' is not based on any cost analysis in EPA's proposal. The commenter argues further that in any case, aggregate reporting of dioxin-like PCBs with a 10 pound threshold will fail to obtain the required reporting on a substantial majority of dioxin-like PCBs or to provide needed information about dioxin-like PCB releases and therefore, EPA's perceptions regarding reporting burden cannot properly outweigh the public's need for the information which is denied under EPA's new proposal. The commenter refers to the proposal to retain dioxin-like PCBs under the PCB listing as the ''less than 10 pounds exemption.'' The commenter asserts that existing evidence demonstrates that many dioxin producing processes such as waste incinerators, oil-fired boilers, and other processes also produce potentially significant amounts of PCBs which are released to the environment from these facilities. The commenter argues that this evidence suggests that at least some facilities reporting under EPCRA section 313 are likely to be releasing dioxin-like PCBs as a portion of these PCB releases. The commenter contends that the evidence also suggests that most or all releases of dioxin-like PCBs at these facilities may be associated with total annual PCB production of less than 10 pounds per facility and thus, EPA may not meet the requirement that a substantial majority of dioxin-like PCBs be reported under this exemption.

Reporting burden was not the sole or even most important factor in EPA's decision not to move the co-planar PCBs to the dioxin and dioxin-like compounds category. In reaching its final decision, EPA considered the fact that additional information would be collected on all PCBs by lowering the threshold for the PCB listing and that the additional information that would be collected was sufficient for EPCRA section 313 purposes, as well as less burdensome. Even in its proposal EPA did not conclude that reporting burden alone outweighed the public's right-to-know about chemical releases. As stated in other responses to this issue, EPA is also concerned about the ability to estimate quantities of specific co-planar PCBs since there is a lack of readily available estimation techniques for co-planar PCBs. It is correct that EPA did not attempt to quantify the reduction in burden that would result from not including the co-planar PCBs in the dioxin and dioxin-like compounds category. However, EPA believes that it would be inherently less burdensome since facilities would not have to attempt to determine if they can estimate co-planar PCBs separately and filing one form would obviously be easier and less confusing than attempting to track and adjust the amounts that must be applied to two different listings and filing two reports. With regard to the issue of obtaining reporting on a substantial majority of ''dioxin-like PCB'' releases, as stated in EPCRA section 313(f)(2), the

NMED Exhibit 72

determination of whether a revised threshold meets the ''substantial majority'' standard is measured against the ''total releases of the chemical at all facilities subject to the requirements of this section.'' As EPA stated in the proposed rule:

> For purposes of determining what constitutes a ''substantial majority of total releases'', EPA interprets ''facilities subject to the requirements'' of section 313 as the facilities currently reporting, ... (at 64 FR 689).

Currently, facilities required to report on PCBs must report on all PCBs, not just the co-planar PCBs or any other individual PCBs. The current listing includes all PCBs. Consequently EPA does not believe that the requirements of section 313(f)(2) function as an impediment to its decision to withdraw its proposal to include the co-planar PCBs in the dioxin and dioxin-like compounds category. As discussed in Units II.B. and VI.A., EPA believes that it has satisfied the requirements of EPCRA section 313(f)(2), without the need for quantitative support.

c. *Listing dioxin and dioxin-like compounds as a category versus individual listing of each chemical.* Some commenters contend that reporting dioxin and dioxin-like compounds as one category would not provide useful information and asked that the individual compounds be reported. One commenter recommends that reporting on individual chemical species should be required when the information is available. One commenter who supports the individual reporting of all of the dioxin and dioxin-like compounds, states that the amounts of individual dioxin compounds released from facilities is part of the important public information needed to assist research and policy development. The commenter claims that reporting as a category will not provide the public with the information to assess the relative hazards of releases since one dioxin-like compound can have a relative hazard several orders of magnitude less than 2,3,7,8-tetrachlorodibenzo-*p*-dioxin. This commenter also states that different sources often emit a different mix of dioxin compounds and that this information is widely used to trace dioxin contamination to specific root causes. The commenter states that the relative amounts of the many different dioxin-like chemicals in a sample are compared to create a ''profile'' which might match the profile created by emission from a particular source. The commenter did not support the reporting of the category based on toxic equivalents (TEQs) but thought it important for the users of the data to be able to determine TEQs. Some other commenters make the same general argument that individual isomer reporting is needed to facilitate risk characterization including transport and fate of the different isomers.

Some commenters contend that certain dioxin-like compounds such as octachlorodibenzo-*p*-dioxin and octachlorodibenzofuran should not be reported since they are ubiquitous in the environment and are the least toxic under the toxic equivalent factors (TEFs). One commenter states that EPA should require reporting only for the most toxic congeners: the tetra-, penta-, and hexa-congeners and not the hepta- and octa-congeners which are less toxic and less relevant from a risk standpoint. Other commenters state that only 2,3,7,8-tetrachlorodibenzo-*p*-dioxin should be reported. Some commenters contend that reporting for these compounds should not be required at the same reporting threshold as the other dioxin and dioxin-like compounds. Most commenters who would like to exclude certain dioxin-like compounds did not indicate that they wanted individual reporting of the remaining compounds. Some commenters support the reporting of dioxin and dioxin-like compounds as a category, as EPA proposed. One commenter states that if reporting is not limited to just 2,3,7,8-tetrachlorodibenzo-*p*-dioxin, then the commeter supports EPA's proposal to limit the category to only the 7 dioxins and 10 furans listed in the proposed rule.

After consideration of all of the comments on this issue, EPA has decided that the best way to report on dioxin and dioxin-like compounds is to report them as a category. This is consistent with the way EPA has addressed other groups of chemicals that share the same toxic effect and in this case are also generated as complex mixtures. As discussed in Units VI.G.1.d. and e., reporting as a category and based on TEQs would not provide users of the data with information on which compounds contribute the most to the TEQ total. In addition, requiring facilities to report each compound individually would impose an additional burden on the industries that will be required to report. However, EPA agrees that being able to determine the amounts of the individual dioxin and dioxin-like compounds would make the data more useful. Therefore EPA will add a section to the Form R that will require the reporting facility to provide the distribution of dioxin and each dioxin-like compound for the total quantity that the facility is reporting. If a facility has information on the distribution of the dioxin and dioxin-like compounds, the facility must report either the distribution that best represents the distribution of the total quantity of dioxin and dioxin-like compounds released to all media from the facility; or its one best media-specific distribution. This information is only required if it is available from the data used to calculate thresholds, releases, and other waste management quantities, no additional analysis is required. As with all other reporting under EPCRA section 313, this information will only be required if the facility has information that can be used to make a reasonable estimate of the distribution from the available data. With the distribution of congeners reported on each Form R, the user of the data can determine the grams of dioxin and each individual dioxin-like compound that makes up the total quantity reported on the Form R. Under this reporting mechanism, all of the information that the commenters have stated is important to determining the significance of quantities reported under this category will be provided to the public but the reporting facilities will still only have to file one report. Any of the other possible options, such as reporting in terms of TEQs or reporting each individual compound separately, either do not provide all of the information the commenters would like to have, or impose too great an additional reporting burden without providing the public with significant additional information.

d. *Using mass versus TEQs for reporting releases and other waste management quantities.* Most of the commenters on this issue suggest that EPA should require that release and other waste management data for the dioxin and dioxin-like compounds category be reported in terms of TEQs rather than in terms of absolute grams. The following list is a summary of the various reasons provided by the commenters in support of reporting dioxin and dioxin-like compounds in terms of TEQs: (1) All dioxin data reported under other EPA programs as well as other Federal and state regulatory programs are reported in terms of toxicity equivalents; (2) the public is familiar with dioxin data reported in terms of TEQs and reporting in other units would cause confusion and be misleading; (3) TEQs provide more meaningful information than total weights since they take into account the relative toxicities of the various dioxin-

NMED Exhibit 72

like compounds; (4) facilities that report under other regulatory programs are likely to rely upon TEQ data that they already have; (5) use of absolute mass may cause misleading comparisons between grams and grams TEQ; (6) releases reported in absolute mass make it difficult to assess the impacts these compounds may have on the environment due to the differences in their toxicities; and (7) reports based on TEQs would provide far more useful information about potential community risks than reports based on the total mass of compounds in the category since more risk information would be provided.

One commenter argues that EPA's justification for adding the category is based on assumptions about the toxicity of the other dioxin-like compounds relative to dioxin itself and that given these assumptions the reporting of TEQs makes sense. The commenter states that under current TEQ schemes, these dioxin-like compounds are all less toxic than dioxin, as much as 1,000 times less, and that facilities should not simply sum emissions on the Form R for compounds with such drastically different toxicities. One commenter suggests that EPA require the reporting of both grams and TEQs and if not both, then just grams. This commenter asserts that if only grams are reported, the data will be somewhat difficult to interpret without any further information, but if only TEQs are required to be reported, then there are uncertainties about what and how much is discharged.

Another commenter states that if EPA is going to require dioxin reporting as a group and not by specific chemicals, TEQ reporting is an unnecessary complication. The commenter states that the TEFs used to formulate the TEQs are constantly reviewed and changed, which would necessitate EPA review and possible reissuance of new TEFs each year. The commenter argues that this would make previous years' TRI data impossible to compare once the changes were made.

While EPA recognizes that TEQs are a common way of expressing quantities of dioxin-like compounds, EPA does not believe that reporting in these units would be the best or most appropriate way to report for the dioxin and dioxin-like compounds category under EPCRA section 313. Although some commenters believe that TEQ reporting should be used since not all of the dioxin-like compounds are as toxic as dioxin itself, EPA has determined that all of the dioxin-like compounds meet the listing criteria of EPCRA section 313. Since all of these compounds meet the listing criteria, the actual mass of each member of the category should be reported. To do otherwise would deny the public information on the actual quantities of toxic chemicals entering the environment. It would also be inconsistent with all other reporting of EPCRA section 313 toxic chemicals since none of them are reported based on relative toxicities. In addition, this would be inconsistent with EPCRA section 313(g)(1)(C)(iv) which requires that ''the annual quantity of the toxic chemical entering each environmental medium'' be reported.

Some of the commenters state that TEQs should be used because they provide more risk information to the public than just reporting mass. While TEQs do provide information on relative toxicity, EPA does not believe that increasing the amount of risk information is a basis for changing the EPCRA section 313 method for reporting from mass-based to relative toxicity-based. As discussed in Unit VI.F., EPCRA section 313 is not a risk-based program, and reporting is not intended to communicate information about relative risks. Rather it provides local communities with data on release and other waste management quantities on listed toxic chemicals, so that they may use the data in conjunction with information on chemical properties (e.g., persistence and bioaccumulation) and site-specific information to determine if releases present a potential risk. It is also not clear, as some commenters state, that the public is more familiar with dioxin data reported in terms of TEQs or that they will understand TEQs any better than grams.

EPA does not believe that the fact that other programs require reporting in TEQs and that facilities will already have TEQ information is a significant reason to require TEQ reporting under EPCRA section 313. Since the first piece of information that is required to determine TEQs is the grams of dioxin and each dioxin-like compound, these facilities should already have the gram-based information they would need. In addition, as stated above, EPCRA section 313 reporting serves the purposes of EPCRA section 313; other programs, e.g., the CWA, are risk-based command and control programs.

Several commenters also disagree with the concerns that EPA raised in the proposed rule, which were:

> . . .there are three significant disadvantages to reporting in TEQs. First, revisions in TEF factors for individual dioxin-like compounds in future years would require changes to the calculations in the reported release and other waste management quantities, thus making year to year comparisons more difficult, unless the particular dioxin-like compounds are identified. Second, some facilities may not be able to report in TEQs, since, although they may be able to estimate a mass quantity for the category as a whole, they may not have enough information to estimate the relative distribution of all category members. Third, TEQ reporting would be different from all other TRI reporting, which is mass-based, and may cause additional confusion. (at 64 FR 712-713)

Some commenters contend that EPA's first concern is not valid since the EPCRA section 313 reporting requirements have been changed several times in the past in spite of difficulties in comparing future reports to past performance. Two commenters state that this same logic could be applied to the use of AP–42 factors which EPA acknowledges have been revised and refined over the years, and that this also diminishes the value of year-to-year reporting comparisons. One commenter suggests that EPA could minimize any confusion that might be caused by a subsequent change in one or more TEFs by each year specifically publishing or cross referencing the TEFs that must be used for that reporting period.

One commenter contends that EPA's second and third concerns appeared weak in light of the much greater risk information provided by a TEQ approach. Some commenters contend that EPA's third concern is not valid since the reporting requirement being proposed for dioxin and dioxin-like compounds is different whether TEQs are used or not. One commenter states that the third concern is clearly dwarfed by the confusion that would ensue if all dioxin-like compounds were reported as equivalent, when the hazards vary by a factor of 500. One commenter states that reporting dioxin on a TEQ basis will cause more rather than less confusion if the public mistakenly compares data in grams with data presented in grams TEQ. Some commenters agreed with the concerns EPA expressed in the preamble. One commenter states that it agreed with these concerns but that the concern about year-to-year comparisons being more difficult also applies to the reporting of a single mass value for the entire category. The commenter contends that since the amounts of the individual dioxin-like compounds would not be known, if TEFs change, one cannot adjust previously reported values to reflect the changes in TEFs. This commenter suggests that in order to make the information reported of greatest use, the mass of dioxin and each of the dioxin-like compounds should be reported once a TEQ threshold is exceeded.

One commenter argues that while TEQs are a valid and scientifically

NMED Exhibit 72

sound metric for reporting the likely health hazard of a compound, that was not the intended purpose of the EPCRA section 313 reporting requirement. The commenter claims that reporting dioxin and dioxin-like compounds in TEQs will cause confusion, since all other reporting under EPCRA is done in terms of mass and does not take toxicity into account.

EPA believes, as do some of the commenters, that the concerns that were expressed in the proposed rule for reporting dioxin and dioxin-like compounds in terms of TEQs under EPCRA section 313 are valid. EPA disagrees with those commenters who claim that since other changes in reporting have occurred, such as revisions to AP-42 emission factors, there should be no concern for the changes that might occur in TEFs and the resulting TEQs. The fact that certain changes have occurred in reporting requirements or methods of estimation and that those changes may make certain year-to-year comparisons more difficult does not reduce the concern for knowingly selecting reporting units, based on relative toxicity as opposed to emission factors, that have changed in the past and may well change in the future. Also, EPA would be required to choose a particular set of TEFs (i.e., as of 1999) and would need to amend them by rulemaking each time the TEFs were revised. Changes in TEFs and the resulting TEQs would be unlike any of the past changes in EPCRA section 313 reporting since none of these reporting changes were related to the relative toxicity of chemicals that meet the listing criteria of EPCRA section 313. The cross referencing or publishing of the TEFs that must be used for each reporting period would still not allow year-to-year comparisons since without knowing a facility's distribution of each of the category members the TEQ cannot be recalculated. EPA's concerns that some facilities may not be able to report in terms of TEQs are also valid. Although most facilities that will be able to make reasonable estimations for the dioxin and dioxin-like compounds category should be able to report in terms of TEQs, there may be some that can only report in actual mass units and they should not be exempt from reporting. EPA is also still concerned that TEQs would be different than other EPCRA section 313 reporting units, since they are not based on absolute mass, and that this could cause confusion. EPA does not agree with the commenters that state that this does not matter since the reporting for the dioxin and dioxin-like compounds category is going to be different anyway. The only real reporting difference for the dioxin and dioxin-like compounds category is that the reporting units are in grams rather than pounds. To determine the amounts in pounds all that one would have to do is multiply the grams by 0.002204. However, TEQ reporting would be much different since in order to understand the reported value one would need to understand the basis for TEFs, what they are, how they relate to dioxin, and how TEQs are calculated from the individual TEFs. This obviously requires more knowledge on the part of the data user than simply understanding different units of mass and does have the potential to cause some confusion.

One commenter contends that neither total mass nor TEQ reporting provides sufficient information on reduction in potential exposure and risk. The commenter asserts that it is possible that a facility could reduce its dioxin TEQ while releasing a greater mass of dioxin-like compounds, but neither total mass nor TEQ reporting would really provide a good picture of what a facility was doing. The commenter suggests that if EPA wants to provide TEQ information to the public, it should also require facilities to report dioxins by individual chemical, rather than as a group.

Another commenter that favors the reporting of dioxin and dioxin-like compounds as individual chemicals claims that reporting as a category but in TEQs would still fail to reveal the amounts of individual dioxin compounds released. The commenter argues that this alternative would provide no information on individual compounds for use in tracing dioxin source profiles. The commenter contends that reporting in TEQs would provide better information on the relative toxicity hazard based upon today's toxicity information but that information on the relative toxicity of the many dioxin-like chemicals is improving and thus toxicity factors for some of these compounds will change in the future. The commenter claims that in future years the Inventory would have to choose between keeping the old toxicity calculation (and becoming irrelevant in comparison with other research data), or changing the toxicity calculation (and becoming irrelevant for tracking changes in dioxin release rates over time). The commenter contends that the need to aid research and policy development based on current science and the need to track release rates over time are fundamental to the Inventory's purpose and that this alternative must be rejected as just another ill-advised aggregate reporting scheme. The commenter recommends that EPA require the reporting of dioxin and dioxin-like compounds in the way these compounds are measured and analyzed by scientists and government agencies, as individual chemicals, and consider an additional service by EPA to calculate and report dioxin toxicity as TEQ for the year-to-year data using the most recent toxicity information which becomes available.

Several commenters make the point that for dioxin and dioxin-like compounds neither reporting total mass nor reporting in terms of TEQs provides sufficient information on potential exposures and risks, and that neither would allow for the tracing of dioxin source profiles. EPA agrees that neither approach would provide all of the data that the commenters would like to have reported and that being able to determine TEQs would provide additional useful information. A common solution to the TEQ issue that the commenters suggest, was to report dioxin and each individual dioxin-like compound separately rather than as a category. However, EPA believes that this approach would be overly burdensome and unnecessary to get the kind of data that would be the most useful. As discussed in the previous section of this unit, many other commenters requested that dioxin and dioxin-like compounds be reported separately rather than as a category. After consideration of all of the comments on this issue, EPA has determined that the best way to report for the dioxin and dioxin-like compounds category is to report in terms of absolute grams for the entire category. This is consistent with all other reporting under EPCRA section 313 and will provide the most consistent information from year-to-year. However, EPA agrees with most of the commenters that being able to determine TEQs from the reported data and being able to determine which individual chemicals are include in a facilities report would make the data more useful to the public. Therefore, as discussed in the previous section of this unit, EPA will add a section to the Form R that will require the reporting facility to provide the distribution of dioxin and each dioxin-like compound for the total quantity that the facility is reporting. If a facility has information on the distribution of the dioxin and dioxin-like compounds, the facility must report either the distribution that best represents the distribution of the total quantity of dioxin and dioxin-like compounds released to all media from the facility; or its one best media-

NMED Exhibit 72

specific distribution. This information is only required if it is available from the data used to calculate thresholds, releases, and other waste management quantities, no additional analysis is required. As with all other reporting under EPCRA section 313, this information will only be required if the facility has information that can be used to make a reasonable estimate of the distribution from the available data. With the distribution of the individual members of the category reported on each Form R, the user of the data can determine the grams TEQ that correspond to the absolute grams reported and can adjust the grams TEQ as TEF values change over time. Under this reporting mechanism, all of the information that the commenters state is important to determining the significance of quantities reported for this category will be provided to the public on one Form R. This way all parties can express the data in whichever format they believe is best, and since the first thing that must be determined under any reporting method is the mass of each member of the category, there should be little, if any, additional burden associated with including the distribution.

e. *Using TEQs as the basis for reporting thresholds.* All of the commenters on this issue requested that the reporting threshold for the dioxin and dioxin-like compounds be set in terms of TEQs. Most of the commenters indicate that the reasons they support a TEQ-based threshold were the same as the reasons they support reporting release and other waste management quantities in terms of TEQs (see the first paragraph of the preceding section of this unit). Two commenters argue that since EPA proposed to use TEQs for reporting release and other waste management quantities, that not basing the reporting threshold on TEQs would be inconsistent. The commenters contend that a facility may trigger reporting by having emissions that exceed the threshold (in terms of absolute weight) but have no significant reporting quantity (in terms of TEQ equivalent weight) and, therefore, no significant health risk. The commenters recommend the use of a consistent approach where TEQs are used for both threshold determinations and release and other waste management quantities. The commenters state that such an approach would be consistent with the health risk rationale for EPCRA reporting, yet not rely on site-specific risk approaches that may evolve over time. Another commenter had similar concerns suggesting that it would be extremely burdensome and unnecessarily complex to have thresholds based on absolute grams and release and other waste management quantities reported in TEQs and recommends that EPA should use TEQs for both.

One commenter claims that it may ease the reporting burden somewhat to base the EPCRA section 313 reporting threshold on a TEQ basis rather than attempting to develop mass-based estimates. Another commenter contends that in order to determine the sum of the mass of the 17 dioxin and dioxin-like compounds, one already will have determined the mass of each compound individually and that with data reported by compound, a TEQ can easily be calculated. The commenter also suggests that there are short-term screening bioassays for determining the TEQ of a sample that are less expensive, more sensitive, and can be done more rapidly than traditional analytical chemistry methods. The commenter states that rather than facilities trying to guess what their releases may be, in an attempt to avoid spending money on expensive analytical chemistry methods, if the reporting threshold were based on TEQs, a facility can readily and more inexpensively screen its releases. The commenter argues that having a reporting threshold based on TEQ is more representative of potential health risks and recommends that EPA consider using some amount of TEQs as the reporting threshold. Another commenter suggests that one option would be to report releases of each dioxin-like compound if the total, in TEQ, exceeds some chosen threshold.

One commenter that suggests that TEQs should be used for thresholds, notes that reporting dioxin on a mass basis is quite different from reporting on a TEQ basis. The commenter asserts that since some of the dioxin-like compounds have TEFs of 0.001 then the 0.1 gram threshold could require facilities that produce 0.0001 gram TEQ of dioxin to report. The commenter claims that when compared to the estimate that there are 2,973 grams TEQ of U.S. dioxin emissions such amounts are insignificant and meaningless. The commenter maintains that using TEQs instead of the mass of each compound for determining whether an EPCRA reporting threshold for dioxin and dioxin-like compounds is exceeded would not deprive EPA or the public of information regarding meaningful releases of dioxin. The commenter also recommends that whatever units EPA decides to use should be the same for thresholds and for release and other waste management quantities.

One commenter suggests that EPA should require sources to use toxicity factors in calculating the manufacturing threshold for dioxin and dioxin-like compounds to avoid triggering the threshold based solely on non-detection. The commenter states that the 17 dioxin-like compounds to which the 0.1 gram proposed reporting threshold would apply vary in toxicity by a factor of 1,000 but that EPA does not take this variation in toxicity into consideration for the purpose of determining the manufacturing threshold.

EPA did not propose to use TEQs as the units of measurement for the EPCRA section 313 reporting threshold for dioxin and dioxin-like compounds. EPA has the same concerns for using TEQs for EPCRA section 313 thresholds as it does for reporting releases and other waste management quantities in terms of TEQs, and most of the issues raised here have been addressed in the preceding section of this unit. Most importantly, since EPA has determined that each of the dioxin-like compounds meets the listing criteria of EPCRA section 313, the actual mass of each member of the category should be included in threshold determinations. Also, the fact that the TEFs and thus the TEQs can change over time, is even more important for thresholds since TEF changes would in effect change the threshold, because for example, the same mass quantity that would have exceeded the threshold before the change may not exceed the threshold after the change.

As one of the commenters pointed out, using TEQs as the units for the reporting threshold is much different than using actual mass. The commenter showed how a 0.1 gram threshold for a dioxin-like compound with a TEF of 0.001 would be equivalent to a 0.0001 gram TEQ threshold. The opposite of this is that if the 0.1 gram threshold were in units of TEQ, then for dioxin-like compounds with a 0.001 TEF, it would take 100 grams to reach the reporting threshold. Using TEQs as the units for the reporting threshold would thus be equivalent to establishing separate thresholds for each member of the dioxin and dioxin-like compounds category based on their relative toxicity. EPA does not believe that any of the reporting requirements of EPCRA section 313 should be based on relative toxicities since, as discussed in Unit VI.F., EPCRA section 313 is not a risk-based program and reporting is not intended to communicate information about the Federal government's risk determinations for individual chemicals. Rather it provides local communities with data on release and

NMED Exhibit 72

other waste management quantities on listed toxic chemicals, so that they may use the data in conjunction with information on chemical properties (e.g. persistence and bioaccumulation) and site-specific information to determine if releases present a potential risk.

Several commenters express concern about consistency between the units of measurement for the threshold for the dioxin and dioxin-like compounds category and the units of measurement used to report releases and other waste management quantities. While EPA is not adopting the use of TEQ as some commenters requested, EPA is being consistent since absolute gram quantities will be used for both thresholds and the reporting of releases and other waste management quantities.

EPA does not agree with those commenters who state that the information collected under a 0.1 gram threshold would, in some cases, represent such a small portion of the estimated national amount of dioxin TEQs that the data would not be useful. On a facility-by-facility basis, the amounts reported may be a small percentage of the national total, but that does not mean that it will not be useful or meaningful to the public. One of the purposes of EPCRA section 313 is to provide information to communities about releases into their community. A small percentage of national releases may pose potential risks to local communities. Further, even information that shows little or no releases helps communities to understand what risks may be or may not be present in their communities and helps government agencies to target resources. In addition, since not all of the sources of dioxin and dioxin-like compounds will be reporting under EPCRA section 313, the amount reported will be a larger portion of the total amount reported under EPCRA section 313 than it will be on a national basis. The issue of how many sources of dioxin and dioxin-like compounds are captured by EPCRA section 313 are addressed in the Response to Comments document (Ref. 69) for this rulemaking.

EPA does not agree that reporting in terms of TEQs would necessarily be less burdensome. As one commenter states, in order to determine the sum of the mass of the 17 dioxin and dioxin-like compounds, one already will have determined the mass of each compounds individually and that with data reported by compound, a TEQ can easily be calculated. Since the TEQs are calculated from the relative amounts of dioxin and each dioxin-like compound that is present, it is an additional step to present the data in terms of TEQs and therefore it should not be less burdensome.

f. *Reporting guidance for dioxin and dioxin-like compounds.* A number of commenters requested that EPA develop reporting guidance for the dioxin and dioxin-like compounds category.

EPA agrees that guidance should be provided to assist facilities in determining threshold and release quantities for the dioxin and dioxin-like compounds category. As EPA stated in the proposed rule:

> EPA intends to develop reporting guidance for industries that may fall within this reporting category. The guidance developed will be consistent with the methods and procedures that EPA has developed for determining if dioxin and dioxin-like compounds are present in various industrial processes, including Method 23 (Ref. 77) developed for electric utilities. In developing the reporting guidance for the dioxin and dioxin-like compounds category EPA will work with interested parties to provide the best possible guidance for reporting facilities (at 64 FR 712).

EPA will provide a guidance document to assist certain facilities in making thresholds and release determinations for the dioxin and dioxin-like compounds category. The guidance document will be consistent with EPA established methods of measuring or estimating quantities of dioxin and dioxin-like compounds, including Method 23.

2. *Benzo(g,h,i)perylene (CAS No. 191-24-2) (Ref. 70).* EPA proposed to add benzo(g,h,i)perylene to EPCRA section 313 pursuant to EPCRA section 313 (d)(2)(C). One commenter states that EPA should not add benzo(g,h,i)perylene to the EPCRA section 313 list of toxic chemicals because there are insufficient data to support the EPCRA section 313(d)(2)(C) determination. The commenter states that EPA used predicted aquatic toxicity values based on quantitative structure activity relationship (QSAR) analysis but did not provide any toxicity data. The commenter contends that EPA did not provide any evidence to support the statement that aquatic QSAR equations show a high correlation between predicted and measured toxicity values, and did not provide any other information to support use of QSAR for this type of chemical.

EPA disagrees with the commenter's statements. EPA provided the following discussion in the proposed rule:

> Three of the chemicals being proposed for listing (benzo(g,h,i)perylene, 3-methylcholanthene, and octachlorostyrene) have been found to meet the EPCRA section 313(d)(2)(C) criteria for ecotoxicity based on predicted aquatic toxicity values generated from quantitative structure activity relationship (QSAR) equations and other predictive techniques. As previously stated (58 FR 63500, December 1, 1993), EPA believes that, where no or insufficient actual measured aquatic toxicity data exist upon which to base a decision, toxicity predictions generated by QSARs and other predictive techniques may constitute sufficient evidence that a chemical meets the section 313 listing criteria. EPA's authority to use such predictive techniques derives from section 313(d)(2) of the statute, which states that EPA shall base its listing determinations on, inter alia, ''generally accepted scientific principles.'' EPA believes that the aquatic QSAR equations that are in widespread use and show a high correlation between predicted and measured aquatic toxicity values can be considered to be ''generally accepted scientific principles'' and can appropriately form the basis of a listing determination (Ref. 70). (at 64 FR 693)

EPA believes that QSAR data is valid predicted aquatic toxicity data and the fact that no actual toxicity studies were provided does not mean that the available data were insufficient to determine that benzo(g,h,i)perylene met the listing criteria of EPCRA section 313(d)(2)(C). In addition, EPA did provide support for the statement that aquatic QSAR equations are in widespread use and show a high correlation between predicted and measured aquatic toxicity values. The docket for the proposed rule contained a document titled ''SAR/QSAR in the Office of Pollution Prevention and Toxics'' In: Environmental Toxicology and Risk Assessment: 2nd Volume, STP 1216. One of the articles in this reference was titled *Validation of Structure Activity Relationships Used By the USEPA's Office of Pollution Prevention and Toxics for the Environmental Hazard Assessment of Industrial Chemical.* This includes the methods of SAR for the class of neutral organic chemicals which, as discussed in the support document, was used for benzo(g,h,i)perylene since it is a neutral organic chemical. Thus, EPA did provide support for its conclusions about QSAR analysis and for the use of QSAR for benzo(g,h,i)perylene.

This commenter also states that EPA uses an estimated Log K_{ow} in its aquatic toxicity prediction and argues that Log K_{ow} is an inaccurate predictor for many chemicals particularly if it is estimated rather than measured. The commenter contends that EPA's basis for the listing of benzo(g,h,i)perylene is a prediction based upon a prediction, with no actual data and that this is not a sufficient basis for listing under EPCRA section 313 and it does not meet the statutory requirements for listing that a chemical is ''known to cause or can reasonably be

NMED Exhibit 72

anticipated to cause'' a significant adverse effect.

EPA disagrees with the commenter's conclusions. The majority of the SAR calculations in the ECOSAR Class Program are based upon the octanol/water partition coefficient (K_{ow} or Log P) since there is a correlation between Log P and toxicity. Using the measured aquatic toxicity values and estimated Log P values, regression equations can be developed for a class of chemicals. Toxicity values for a chemical within that class may then be calculated by inserting the estimated K_{ow} into the class regression equation and correcting the resultant value for the molecular weight of the compound. The ecological assessment guidelines for predicting the toxicity of chemicals with limited measured aquatic toxicity data have been used for over a decade (Ref. 35). The commenter has not provided the Agency with any concrete information or data indicating that this approach either is not a generally accepted scientific approach or is unreliable, and the Agency finds no reasonable basis to change these techniques at this time. In addition, the commenter did not provide any data to indicate that the predicted Log K_{ow} for benzo(g,h,i)perylene was inaccurate.

This commenter also contends that EPA's failure to consider exposure in this proposed rule is particularly important for benzo(g,h,i)perylene. The commenter argues that given the properties of benzo(g,h,i)perylene, any release into water will result in the vast majority (more than 99%) of the compound being partitioned to sediment or adsorbed onto suspended particulates and organics in the water column and thus the potential for this chemical to be in a toxic form and pose risk in natural systems is low.

EPA disagrees with the commenters' contention that EPA should consider exposure in its determination that benzo(g,h,i)perylene meets the EPCRA section 313(d)(2)(C) listing criteria. As discussed in Unit VI.F., EPA is only required to consider exposure under a limited set of circumstances. In the final chemical expansion rule (59 FR 61432), EPA further explained its policy on the use of exposure considerations under EPCRA section 313(d)(2)(C) and the fact that the Agency does not consider exposure for chemicals that are highly ecotoxic. As EPA explained in the final rule:

> The Agency believes that exposure considerations are not appropriate in making determinations (1) under section 313(d)(2)(B) for chemicals that exhibit moderately high to high human toxicity (These terms, which do not directly correlate to the numerical screening values reflected in the Draft Hazard Assessment Guidelines, are defined in unit II.) based on a hazard assessment, and (2) under section 313(d)(2)(C) for chemicals that are highly ecotoxic or induce well-established adverse environmental effects (at 59 FR 61441).

Although EPA does not believe that it would be appropriate to consider exposure, EPA also disagrees with the commenter's characterization of the fate of benzo(g,h,i) perylene. Environmental fate models show that the chemical will only partition about 60% to the sediment. Also, the Agency cannot rely on the environment to serve as a sink for this chemical. Other environmental conditions such as turbidity, biological activity, or the chemical activity in water could cause redistribution of the chemical into the water column again.

Based upon QSAR equations and other predictive techniques, EPA has concluded that benzo(g,h,i)perylene is toxic. It has the potential to kill fish, daphnia, and algae, among other adverse effects, based on chemical and/or biological interactions. Benzo(g,h,i)perylene can cause these toxic effects at relatively low concentrations. The predicted aquatic toxicity values for benzo(g,h,i)perylene, based upon QSAR analysis using the equation for neutral organics and an estimated Log K_{ow} of 6.7, included calculated values of 0.030 milligrams per liter (mg/L) for the fish 96–hour LC_{50} (i.e., the concentration that is lethal to 50% of test organisms) and 0.0002 mg/L for fish chronic toxicity; 0.012 mg/L for daphnia 48–hour LC_{50} and 0.027 mg/L for the daphnid 16–day chronic LC_{50}; and 0.03 mg/L for the algae 96–hour EC_{50} (i.e., the concentration that is effective in producing a sublethal response in 50% of tests organisms) with an algal chronic toxicity of 0.012 mg/L.

Benzo(g,h,i)perylene can cause its toxic effects at relatively low concentrations, therefore EPA considers it to be highly toxic. Since benzo(g,h,i) perylene is toxic at relatively low concentrations EPA believes that it causes or can reasonably be anticipated to cause a significant adverse effect on the environment. In addition, because of the nature of the potential significant adverse effects, e.g., fish, daphnia, and algae kills, and the impacts such effects can have on ecological communities and ecosystems, EPA has determined that they are of sufficient seriousness to warrant reporting.

EPA reaffirms that there is sufficient evidence for listing benzo(g,h,i)perylene on the EPCRA section 313 list of toxic chemicals pursuant to EPCRA section 313(d)(2)(C)(i) based on the available ecotoxicity information for this chemical. Therefore, EPA is finalizing the addition of benzo(g,h,i)perylene on the EPCRA section 313 list.

3. *Benzo(j,k)fluorene (fluoranthene) (CAS No. 206–44–0) (Ref 70).* EPA proposed to add fluoranthene to EPCRA section 313 pursuant to EPCRA sections 313 (d)(2)(B) and (C). EPA received no comments specific to the carcinogenicity data that EPA presented in the proposed rule in support of the addition of fluoranthene to the EPCRA section 313 list of toxic chemicals. Thus, EPA reaffirms that there is sufficient evidence for adding fluoranthene to this list of EPCRA section 313 toxic chemicals pursuant to EPCRA section 313(d)(2)(B) based on the available carcinogenicity data for this chemical.

One commenter argues that EPA should refrain from listing fluoranthene pending additional assessment of the data. The commenter contends that EPA's reported toxicity values for fluoranthene span a range of about two orders of magnitude and that for such a wide range, it is necessary to evaluate potential exposure to determine which scenarios, and therefore which types of data, are most relevant to this compound following a release. The commenter argues that fluoranthene is a highly lipophilic compound that will bind primarily to sediment and suspended organics, so it is not clear whether the reported toxicity values on which EPA relies for the listing are applicable to this compound in the environment. EPA assumes the commenter was referring to data used to support EPA's proposal to list fluoranthene pursuant to EPCRA section 313(d)(2)(C).

As discussed in Unit VI.F., EPA does not believe that it is appropriate to consider exposure for chemicals that are highly ecotoxic as the data for fluoranthene clearly shows it is. However, even if EPA were to consider exposure, the commenter provided no data to support the assumption that fluoranthene will bind primarily to sediments and suspended organics, and EPA believes that fluoranthene will partition to water as well as sediment. While the ecotoxicity data for fluoranthene does range over about two orders of magnitude that does not, in itself, form a basis for conducting an exposure assessment. There are data that clearly show that fluoranthene is highly ecotoxic. Thus, an exposure assessment is not required. While it does not impact EPA's assessment, EPA notes that of the ecotoxicity values presented in the proposed rule, 9 were within the same order of magnitude, 4

NMED Exhibit 72

were one order of magnitude higher, and 2 were two orders of magnitude higher. Thus, 60% are within the same order of magnitude and 87% are within one order of magnitude. EPA does not believe that this represents a very wide distribution as the commenter implies.

Based on the available toxicity data, EPA has concluded that fluoranthene is toxic. It has the potential to kill mysid shrimp, a variety of freshwater benthic species and various saltwater species and it can also cause other adverse effects on fish and mysids, based on chemical and/or biological interactions. Fluoranthene can cause these toxic effects at relatively low concentrations. Ecotoxicity values for fluoranthene include a calculated 96–hour LC_{50} of 0.04 mg/L for mysid shrimp. Using standard acute toxicity tests, fluoranthene has been tested in 12 freshwater species from 11 genera. For freshwater benthic species, the acute 96–hour LC_{50} calculated values are 0.032 mg/L for an amphipod (*Gammarus minus*), 0.070 mg/L for a hydra (*Hydra americana*), 0.17 mg/L for an annelid (*Lumbriculus variegatus*), and 0.17 mg/L for a snail (*Physella virgata*). For saltwater species, the 96–hour LC_{50} values are 0.051 mg/L for a mysid (*Mysidopsis bahia*), 0.066 mg/L for an amphipod (*Ampelisca abdita*), 0.14 mg/L for a grass shrimp (*Palaemonetes pugio*), and 0.50 mg/L for an annelid (*Neanthes arenaceodentata*). Fathead minnows exposed to fluoranthene at a concentration of 0.0217 mg/L for 28 days in a chronic early life-stage test showed a reduction of 67% in survival and a 50.2% reduction in growth relative to the controls. In a 28–day chronic study, mysids exposed to 0.021 mg/L of fluoranthene showed a 26.7% reduction in survival and a 91.7% reduction in reproduction; at 0.043 mg/L all mysids died. In a 31–day study, mysids showed a reduction of 30% in survival, 12% in growth, and 100% in reproduction relative to controls at a concentration of 0.018 mg/L of fluoranthene.

Fluoranthene can cause its toxic effects at these relatively low concentrations, therefore EPA considers it to be highly toxic. Since fluoranthene is toxic at relatively low concentrations, EPA believes that it causes or can reasonably be anticipated to cause a significant adverse effect on the environment. In addition, because of the nature of the potential significant adverse effects, e.g., kills of mysid shrimp, a variety of freshwater benthic species, and various saltwater species, and the impacts such effects can have on ecological communities and ecosystems, EPA has determined that they are of sufficient seriousness to warrant reporting.

Thus, EPA reaffirms that there is sufficient evidence for adding fluoranthene on the EPCRA section 313 list of toxic chemicals pursuant to EPCRA section 313(d)(2)(C)(i) based on the available ecotoxicity information for this chemical.

Therefore, EPA is finalizing the listing of fluoranthene on the EPCRA section 313 list.

4. *3-Methylcholanthrene (CAS No. 56–49–5) (Ref. 70).* EPA proposed to add 3-methylcholanthrene to EPCRA section 313 pursuant to EPCRA sections 313(d)(2)(B) and (C). EPA received no comments on the carcinogenicity data that EPA presented in the proposed rule in support of the addition of 3-methylcholanthrene to the EPCRA section 313 list of toxic chemicals. Thus, EPA reaffirms that there is sufficient evidence for adding 3-methylcholanthrene to the list of EPCRA section 313 toxic chemicals pursuant to EPCRA section 313(d)(2)(B) based on the available carcinogenicity data for this chemical.

No comments were received concerning the ecotoxicity data that EPA presented for 3-methylcholanthrene in the proposed rule. Based upon quantitative structure activity relationship (QSAR) equations and other predictive techniques, EPA has concluded that 3-methylcholanthrene is toxic. It has the potential to kill fish and daphnia as well as cause other adverse effects on fish, daphnia, and algae based on chemical and/or biological interactions. 3-Methylcholanthrene can cause these toxic effects at relatively low concentrations. The predicted aquatic toxicity values for 3-methylcholanthrene, based on QSAR analysis using the equation for neutral organics and an estimated Log K_{ow} of 7.05, include a calculated fish 96–hour LC_{50} of 0.009 mg/L and a chronic fish toxicity value of 0.003 mg/L, a daphnia 48–hour LC_{50} of 0.005 mg/L and a 16–day chronic LC_{50} of 0.015 mg/L, and an algae 96–hour EC_{50} of 0.0105 mg/L with a calculated chronic toxicity value of 0.014 mg/L.

3-Methylcholanthrene can cause its toxic effects at these relatively low concentrations; therefore, EPA considers it to be highly toxic. Since 3-methylcholanthrene is toxic at relatively low concentrations, EPA believes that it causes or can reasonably be anticipated to cause a significant adverse effect on the environment. In addition, because of the nature of the potential significant adverse effects, e.g., fish and daphnia kills, and the impacts such effects can have on ecological communities and ecosystems, EPA has determined that they are of sufficient seriousness to warrant reporting.

Thus, EPA reaffirms that there is sufficient evidence for listing 3-methylcholanthrene on the EPCRA section 313 list of toxic chemicals pursuant to EPCRA section 313(d)(2)(C)(i) based on the available ecotoxicity information for this chemical.

Therefore, EPA is finalizing the listing of 3-methylcholanthrene on the EPCRA section 313 list.

5. *Octachlorostyrene (CAS No. 29082–74–4) (Ref. 70).* EPA proposed to add octachlorostyrene to EPCRA section 313 pursuant to EPCRA sections 313(d)(2)(B) and (C). One commenter argues that octachlorostyrene (OCS) should not be included in the EPCRA section 313 PBT chemicals list. The commenter contends that OCS was included as a PBT chemical simply because it appears on several lists of persistent and bioaccumulative chemicals and not based on a thorough evaluation of its toxicity. The commenter argues that there is limited toxicity data for OCS and cited two statements that were in EPA's support document for the addition of OCS and the other chemicals being added in this rulemaking. The two statements the commenter cited were:

> The health hazard data which support TRI listing are very limited. Human health data were not located. (Ref. 70 p. 48)

EPA disagrees with the commenters' conclusions. The commenter did not comment on the actual toxicity data that EPA provided as the basis for listing OCS pursuant to EPCRA section 313(d)(2)(B). Rather the commenter takes two statements that were contained in the support document out of context to support their apparent contention that there are insufficient data to list OCS under EPCRA section 313(d)(2)(B). The fact that the commenter has taken these statements out of context is demonstrated by the content of the rest of the paragraph that contained the statements the commenter cited:

> Laboratory studies on rats suggest OCS may have acute and chronic effects on the liver, kidneys, and thyroid. In a long-term study (one year) of rats a LOAEL of 0.31 mg/kg/day was determined based on significant histological effects on these organs. (Ref. 70)

The statements the commenter cited only acknowledged that there was not a vast amount of toxicity data for OCS and specifically, that there were no human studies; they do not support the commenters' conclusion that OCS does not meet listing criteria of EPCRA

NMED Exhibit 72

section 313(d)(2)(B). In addition, these statements were from the summary section of the discussion on OCS, more detailed discussion of the toxicity data for OCS was contained in the other sections on OCS toxicity but the commenter provided no comments on this information.

EPA reaffirms that there is sufficient evidence for adding OCS to the EPCRA section 313 list of toxic chemicals pursuant to EPCRA section 313(d)(2)(B) based on the available hepatic, nephric, and thyroid toxicity data for this chemical.

The same commenter also claims that the toxicity comparisons to hexachlorobenzene are not supported and that no references or rationale are provided to support basing the aquatic toxicity of OCS on that of hexachlorobenzene. As with the human health data, the commenter argues that there are limited environmental toxicity data for OCS and cited some statements that were in EPA's support document. The statements the commenter cited were:

> So far as is known, after a search of former EEB chemical files, the ecological hazard of OCS has never been formally reviewed under TSCA section 4 or in the OPPT Risk Management (RM) process. OCS was briefly reviewed for aquatic toxicity in August 1986, as part of an OTS (now OPPT) chemical scoring project. Thus, available information on OCS is very limited. (Ref. 70, p. 52)

EPA disagrees with the commenter's conclusions. The commenter has not commented on the actual toxicity data but rather states that the data are limited and that hexachlorobenzene is not an appropriate analogue for predicting the aquatic toxicity data for OCS. The statements the commenter cited only acknowledged that there was not a vast amount of toxicity data for OCS, they do not support the commenter's conclusion that OCS does not meet the listing criteria of EPCRA section 313(d)(2)(C). Contrary to the commenter's statement, EPA did provide a reference to the use of hexachlorobenzene as an appropriate analogue for OCS. As EPA stated in the same section of the support document the commenter cited:

> OCS is one of 7 compounds in this chemical class (chlorinated styrenes) with the generic formula $C_8H_{8-x}Cl_x$, where x equals 8 for OCS. This class is analogous to the chlorinated benzenes; for example hexachlorobenzene (HCB), is considered to be an appropriate analogue chemical for OCS (2). (Ref. 70, page 52).

The reference EPA cited is a previous EPA analysis of this class of chemicals that also used hexachlorobenzene as an appropriate analogue for OCS. EPA believes that since OCS and hexachlorobenzene are both highly chlorinated derivatives of benzene they can reasonably be anticipated to have similar toxicities. However, in addition to aquatic toxicity data on hexachlorobenzene, EPA provided the results of a QSAR analysis of OCS, using a measured Log K_{ow} of 7.7, that gave a predicted 14–day LC_{50} value of 6 µg/L for guppies.

Based upon QSAR equations and analogue data, EPA has concluded that OCS is toxic. It has the potential to kill fish and inhibit photosynthesis in algae, among other adverse effects, based on chemical and/or biological interactions. OCS can cause these toxic effects at relatively low concentrations. The predicted aquatic toxicity value for OCS, based upon QSAR analysis using a measured Log K_{ow} of 7.7, is an estimated 14–day LC_{50} of 6 µg/L for guppies. Based on the chemical analogue hexachlorobenzene, OCS can reasonably be anticipated to inhibit photosynthesis in algae at a concentration of 30 µg/L and have a calculated subchronic EC_{50} value of 16 µg/L for daphnids.

OCS can cause its toxic effects at these relatively low concentrations; therefore, EPA considers it to be highly toxic. Since OCS is toxic at relatively low concentrations, EPA believes that it causes or can reasonably be anticipated to cause a significant adverse effect on the environment. In addition, because of the nature of the potential significant adverse effects, e.g., fish kills, and inhibition of photosynthesis in algae and the impacts such effects can have on ecological communities and ecosystems, EPA has determined that they are of sufficient seriousness to warrant reporting.

EPA reaffirms that there is sufficient evidence for listing OCS on the EPCRA section 313 list of toxic chemicals pursuant to EPCRA section 313(d)(2)(C)(i) based on the available ecotoxicity information for this chemical.

Therefore, EPA is finalizing the addition of OCS on the EPCRA section 313 list.

6. *Pentachlorobenzene (CAS No. 609–93–5) (Ref. 70).* EPA proposed to add pentachlorobenzene to EPCRA section 313 pursuant to EPCRA sections 313(d)(2)(B) and (C). No comments were received concerning the human health toxicity data that EPA presented in the proposed rule. Thus, EPA reaffirms that there is sufficient evidence for adding pentachlorobenzene on EPCRA section 313 pursuant to EPCRA section 313(d)(2)(B) based on the available hepatic, nephric, hematological, and developmental toxicity data for this chemical.

No comments were received concerning the ecotoxicity data that EPA presented for pentachlorobenzene in the proposed rule. Based on the available toxicity data, EPA has concluded that pentachlorobenzene is toxic. It has the potential to kill fish and mysid shrimp as well as cause other adverse effects on algae and daphnia, based on chemical and/or biological interactions. Pentachlorobenzene can cause these toxic effects at relatively low concentrations. Aquatic acute toxicity calculated values for pentachlorobenzene include a sheepshead minnow 96–hour LC_{50} of 0.83 mg/L, bluegill sunfish 96–hour LC_{50}s of 0.25 mg/L and 0.3 mg/L, a guppy 96–hour LC_{50} of 0.54 mg/L, and a mysid shrimp 96–hour LC_{50} of 0.16 mg/L. Because pentachlorobenzene can cause these toxic effects at these relatively low concentrations, EPA considers it to be highly toxic. Additional acute toxicity calculated values include algae 96–hour EC_{50}s of 1.98 mg/L and 6.78 mg/L, and daphnia 48–hour EC_{50}s of 1.3 mg/L and 5.28 mg/L. Considering pentachlorobenzene's persistence and bioaccumulation potential pentachlorobenzene is considered highly toxic to aquatic organism at these higher concentrations.

As discussed above, pentachlorobenzene is highly toxic. Because pentachlorobenzene is highly toxic at relatively low concentrations, EPA believes that it causes or can reasonably be anticipated to cause a significant adverse effect on the environment. In addition, because of the nature of the potential significant adverse effects, e.g., fish and mysid shrimp kills as well as other adverse effects on algae and daphnia, and the impacts such effects can have on ecological communities and ecosystems, EPA has determined that they are of sufficient seriousness to warrant reporting.

Thus, EPA reaffirms that there is sufficient evidence for adding pentachlorobenzene on the EPCRA section 313 list of toxic chemicals pursuant to EPCRA section 313(d)(2)(C)(i), (ii), and (iii) based on the available ecotoxicity information for this chemical.

Therefore, EPA is finalizing the listing of pentachlorobenzene on the EPCRA section 313 list.

7. *Tetrabromobisphenol A (CAS No. 79–94–7) (Ref. 70).* EPA proposed to add TBBPA to EPCRA section 313 pursuant to EPCRA sections 313(d)(2)(B) and (C). One commenter claims that the study cited by EPA in support of its

conclusion that TBBPA meets the EPCRA section 313(d)(2)(B) criteria for listing based on developmental toxicity was not a study on TBBPA. The study in question was submitted to EPA by ICI Americas Inc. with a cover letter identifying Saytex 111, the product tested, as being TBBPA. The product was identified as TBBPA by both name and CAS number.

EPA has determined that the product tested was not TBBPA as claimed by the submitter but has been unable to determine why it was misidentified by the submitter. ICI Americas is now Zeneca at the Delaware location that submitted the study. A Zeneca staff member researched the submission and found that the report was originally from Ethyl Corporation and that no other report on TBBPA was submitted to EPA on that date. Without the misidentified developmental study, no adequate toxicology studies or other data were located by EPA that support the addition of TBBPA pursuant to EPCRA section 313(d)(2)(B). Thus, EPA is not adding TBBPA based on concerns for developmental toxicity or any other human health effects.

The same commenter provides comments on the persistence and bioaccumulation of TBBPA and contends that there are insufficient data to conclude that TBBPA meets the listing criteria of EPCRA section 313(d)(2)(C)(ii) and 313(d)(2)(C)(iii). These two sections deal with EPA's authority to add a chemical based on its ''toxicity and persistence in the environment'' and its ''toxicity and tendency to bioaccumulate in the environment'' respectively. However, the commenter does not contend that TBBPA does not meet the listing criteria of EPCRA section 313(d)(2)(C)(i) which addresses EPA's authority to add a chemical based on its ''toxicity'' without consideration of persistence and bioaccumulation. EPA believes that TBBPA is persistent and bioaccumulative as discussed in Unit VI.H. However, EPA did not propose to add TBBPA to the EPCRA section 313 list of toxic chemicals based on its persistence or bioaccumulation data, and neither of these properties were mentioned in the toxicity discussion of TBBPA in the proposed rule. Rather, EPA based its listing decision on the ecotoxicity data alone which indicated that TBBPA was highly toxic even without consideration of persistence or bioaccumulation.

Based the available toxicity data, EPA has concluded that TBBPA is toxic. It has the potential to kill fish, daphnid, and mysid shrimp, among other adverse effects, based on chemical and/or biological interactions. TBBPA can cause these toxic effects at relatively low concentrations. Aquatic acute toxicity calculated values for TBBPA include a fathead minnow 96–hour LC_{50} of 0.54 mg/L, a rainbow trout 96–hour LC_{50} of 0.40 mg/L, a bluegill sunfish 96–hour LC_{50} of 0.51 mg/L, and a daphnid 48–hour LC_{50} of 0.96 mg/L; mysid shrimp 96–hour LC_{50} values ranged from 0.86 to 1.2 mg/L depending on the age of the shrimp. Aquatic chronic toxicity calculated values from a daphnia 21–day study resulted in a Maximum Acceptable Toxicant Concentration (MATC) that was between 0.30 and 0.98 mg/L (geometric mean 0.54 mg/L) based on a significant reduction in reproduction rates; a fathead minnow 35–day study resulted in a MATC that was calculated to be between 0.16 and 0.31 mg/L (geometric mean 0.22 mg/L) based on adverse effects on embryo and larval survival.

TBBPA can cause its toxic effects at these relatively low concentrations; therefore, EPA considers it to be highly toxic. Since TBBPA is toxic at relatively low concentrations, EPA believes that it causes or can reasonably be anticipated to cause a significant adverse effect on the environment. In addition, because of the nature of the potential significant adverse effects, e.g., fish, daphnid, and mysid shrimp kills, and the impacts such effects can have on ecological communities and ecosystems, EPA has determined that they are of sufficient seriousness to warrant reporting.

EPA reaffirms that there is sufficient evidence for listing TBBPA on the EPCRA section 313 list of toxic chemicals pursuant to EPCRA section 313(d)(2)(C)(i) based on the available ecotoxicity information for this chemical. Therefore, EPA is finalizing the addition of TBBPA on the EPCRA section 313 list.

8. *Vanadium and vanadium compounds.* EPA proposed to add vanadium and vanadium compounds to EPCRA section 313 pursuant to EPCRA sections 313(d)(2)(C). One commenter cited the following statement from the proposed rule, ''However, very few toxicity tests have been conducted with invertebrates.'' The commenter argues that, beyond vanadium pentoxide, the Agency appears to have very little toxicity data on vanadium compounds. The commenter contends that the paucity of toxicity data on many different forms of vanadium compounds in the proposal, as well as in the literature, does not appear to support the Agency's belief that ''the evidence is sufficient to list vanadium and vanadium compounds on EPCRA section 313 pursuant to EPCRA section 313(d)(2)(C) based on the available ecotoxicity information on vanadium and vanadium compounds'' (at 64 FR 698).

EPA disagrees with the commenters' conclusions. Although there is limited information on vanadium's toxicity on invertebrates, data that were available for invertebrates shows that vanadium is toxic to these species. Furthermore, EPA's assessment of vanadium's toxicity included algae and vertebrates, and showed that the chemical is highly toxic to aquatic organisms. The data on vanadium are not limited to vanadium pentoxide, the ecological data provided in the proposed rule for vanadium evaluates vanadium toxicity based on data for other vanadium compounds including: sodium metavanadate, sodium orthovanadate, vanadyl sulfate, and ammonium vanadate. In assessing the ecological toxicity of vanadium and vanadium compounds, EPA evaluated the parent metal (vanadium) and determined that it is highly toxic to some aquatic species and anticipated to cause a significant adverse effect on the environment of sufficient seriousness to warrant reporting. Thus, vanadium, the parent metal in vanadium compounds, is the concern, not the other components of each vanadium compound. Many metals are tested in the salt form because these forms are readily soluble in aqueous solutions. The toxicity data for vanadium shows that the metal is highly toxic (aquatic toxicity < 1 mg/L) to the most sensitive species. This evaluation of vanadium's toxicity is acceptable according to traditional guidelines for the assessment of toxic substances as conducted by the Agency for over 2 decades. In addition, when consideration is given to vanadium's persistence it is also considered highly toxic at higher concentrations.

Three commenters contend that since most vanadium compounds are practically insoluble, they consequently have very low bioavailability, and thus it is likely that they could qualify for delisting. The commenters argue that the delisting process is extremely cumbersome, time-consuming and costly. One of these commenters contends that it is inappropriate to list all of vanadium compounds based on aquatic toxicity of the few compounds cited in the proposed rule. The bioavailability of metals such as vanadium was also raised as an issue at the public meetings held for this rulemaking. It was suggested that the parent metal will not be bioavailable from certain metal compounds that may be released into the environment and that therefore the compounds cannot be

NMED Exhibit 72

properly characterized as a PBT chemicals.

EPA disagrees with these comments. First, it should be noted that EPA has not addressed whether vanadium and vanadium compounds can properly be classified as PBT chemicals in this rulemaking. The sole issue, therefore, is whether vanadium and vanadium compounds meet the EPCRA section 313(d)(2)(C) listing criteria. EPA's analysis of the environmental fate of vanadium and vanadium compounds shows that under many environmental conditions vanadium will be available and thus is able to express its toxicity. The commenters have not provided EPA with any data or acceptable scientific studies indicating that vanadium in any particular compound will not become available in the environment. In fact, at least one commenter appears to indicate that these vanadium compounds may merely have low solubility. In these compounds, the parent metal vanadium can become available. While water soluble vanadium compounds would obviously provide vanadium in an immediately bioavailable form, solubility is not the only factor to consider in determining the bioavailability of vanadium from a vanadium compound. In addition to solubility, processes such as: hydrolysis at various pHs; solubilization in the environment at various pHs; photolysis; aerobic transformations (both abiotic and biotic); anaerobic transformation (both abiotic and biotic); and bioavailability when the compounds are ingested (solubilization in and/or absorption from the gastrointestinal tract and solubilization in various organs) need to be considered. In Unit VI.C., EPA discusses in detail the persistence and bioavailability of metals in general.

The issue of bioavailability has been addressed for EPCRA section 313 chemical assessments through EPA's policy and guidance concerning petitions to delist individual members of the metal compound categories on the EPCRA section 313 toxic chemical list (56 FR 23703). This policy states that if the metal in a metal compound cannot become available as a result of biotic or abiotic processes then the metal will not be available to express its toxicity. If the intact metal compound is not toxic and the metal is not available from the metal compound then such a chemical is a potential candidate for delisting.

One commenter argued that the lowest toxicity value cited by EPA for a marine algal species was for *Dunaliella marina* with a 9–day LC_{50} of 0.5 mg/L but that EPA omitted a study which tested the same species and reported no significant adverse effects at a concentration of 50 mg/L.

EPA believes that the study that reported the 9–day LC_{50} of 0.5 parts per million (ppm) on *Dunaliella marina,* is accurate and was acceptably conducted within the guidelines for ecological assessments of hazardous chemicals. This study shows the most sensitive species' response to the chemical. There are differences in the two studies that could explain the range of toxicity between the two. They are: (1) Differences in the exposure times, (2) the species used in the experiments, and (3) the form of vanadium that was exposed to the organisms. The exposure time in the study EPA cited reported a 9–day LC_{50} of 0.5 mg/L. However, the study the commenter cites did not report an LC_{50} duration. Also, the species for the study EPA cited reported the test species to be *Dunaliella marina* (*salina*), but the study the commenter cited only reported the genus name for this organism. Furthermore, the study EPA cited reported the form of vanadium as sodium vanadate, but the study the commenter cites only reported using the vanadium compound without reporting the specific salt form. It is clear that any one of the three factors mentioned, or some combination of these factors, likely accounts for the variation in toxicity between the two studies.

One commenter argues that a study, omitted in EPA's review of vanadium toxicity, on nine algal species showed no significant reduction in productivity (as measured by chlorophyll synthesis) at vanadium concentrations in excess of 10 mg/L. The commenter also contends that the authors of the study also demonstrated that phosphate concentrations were critical in the toxicity of vanadium to algae.

The Agency has not neglected to review the study cited by the commenter. However, EPA interprets the study cited by the commenter as describing the competition uptake between vanadium and phosphorus in an algal medium containing two different kinds of phosphorus concentrations (i.e., phosphorus deficient and phosphorus sufficient). Also, this study was performed only on freshwater algae and one form of vanadium (orthovanadate) which only exists in a pH range of 3 to 6. This study did report a moderately high toxicity value for *Scenedesmus acutus* between 5 and 177 M, which continues to support EPA's findings that vanadium is toxic to algae. Furthermore, EPA is aware that there are studies that were not included in the assessment that showed that the chemical was more toxic than the values reported in EPA's assessment. However, each study was carefully reviewed based on EPA's extensive evaluation process which reviews studies for conformance with generally accepted scientific standards and tests. The studies that were reported in EPA's assessment used generally accepted, validated scientific methods for evaluating aquatic toxicity. The toxicity values that were reported in the ecological assessment of vanadium toxicity were from well-conducted studies.

One commenter argues that it appears from a review of the data that the contention that vanadium is highly toxic to algae has no basis. The commenter contends that with the exception of one study on a single species, *Ceratium hirundinella,* none of the studies on freshwater algae showed significant toxicity at concentrations below 10 mg/L. The commenter states that the lowest level of toxicity reported for a marine species (*Dunaliella marina*) was an LC_{50} of 0.5 mg/L, but that there is conflicting evidence that the threshold of toxicity for this species may be higher than 50 mg/L. The commenter concludes that there appears to be little evidence that vanadium is a highly toxic agent to algae. The commenter also argues that evaluating the toxicity of a compound based on the response of individual algal species can be misleading. The commenter contends that algae never exist within either marine or freshwater environments as monocultures, but rather as dynamic mixed populations. The commenter concludes that unless a compound can be shown to have a broad effect over an entire assemblage or over numerous species of either freshwater or marine species, it is not likely to have a significant effect within the natural environment.

EPA's assessment on algae toxicity shows that vanadium is highly toxic based on the most sensitive species' response to the chemical. There is no conflict in the threshold of toxicity of *Dunaliella marina*. As stated above, there are three factors that most probably account for the differences between the study EPA cited and the study the commenter cites. After careful review of the available data, it is EPA's professional judgment that the study EPA cited provides accurate and valid data.

Algae studies have been included in ecological risk assessments for over 2 decades. Several guidelines on different species have been written to show that these genera are important in the environment and show sensitivity in how chemicals affect the biota. EPA

NMED Exhibit 72

agrees that algae usually do not exist in monocultures in the marine or freshwater environment. However, testing monocultures species is the most accurate method to determine whether a chemical is directly harmful to that species. Therefore, if a compound is highly toxic to a particular species of algae or any species, its effects can be extrapolated to represent other species exposed to that chemical. This evaluation process has been used by the Agency and accepted by OECD for over two decades, and used on thousands of chemicals. Vanadium's toxicity ranges from highly toxic to moderately toxic for algae in EPA's assessment. It is reasonable from the evidence in EPA's assessment of vanadium that the species that is the most sensitive to the chemical can represent the toxicity for all other species based on this narrow range. EPA's final evaluation of any chemical's toxicity is based on the most sensitive species' response.

One commenter contends that the study EPA cited that reported the 144–hour LC_{50} of 0.4 and 0.5 mg/L for vanadyl sulfate ($VOSO_4$) and ammonium metavanadate (NH_4VO_3), respectively, were actually values for $VOSO_4$ and sodium metavanadate ($NaVO_3$) respectively. The commenter contends that the 144–hour LC_{50} for NH_4VO_3 was l.5 mg/L. The commenter also argues that EPA neglected to report from the same study a 144–hour LC_{50} of 1.1 mg/L for vanadate pentoxide (V_2O_5) for this species. The commenter also contends that the findings of 144–hour LC_{50}s of 2.5 to 8.1 mg/L in goldfish (*Carassius auratus*) for the same four vanadium species were also omitted.

The comment concerning the vanadium compounds for the 144–hour LC_{50}s of 0.4 and 0.5 mg/L is correct. EPA inadvertently cited to the incorrect compound in the study. The correct vanadium compounds will be reflected in an update to the support document. However, sodium metavanadate, is still a vanadium compound and the study therefore continues to support EPA's findings that vanadium is highly toxic to fish. The other values of 2.5 and 8.1 mg/L merely provide further support for EPA's finding that the vanadium is moderately toxic to fish. However, considering vanadium's persistence in the environment, EPA believes that it is highly toxic at concentrations between 1 and 10 mg/L. Thus the goldfish values provide further support to EPA's finding that vanadium is highly toxic to some aquatic organisms.

One commenter contends that in assessing the toxicity of vanadium to fish, EPA neglected to review the following studies: (1) Hamilton and Buhl (1997), who reported a 96–hour LC_{50} for the flannelmouth sucker (*Catostomus latipinnis*) of 11.7 mg/L; (2) Taylor et al. (1985), who reported a 96–hour LC_{50} for English sole (*Limanda limanda*) of 26.8 mg/L; (3) Ernst and Garside (1987), who reported a 96–hour LC_{50} for the brook trout (*Salvelinus fontinaliis*) alevins of 24 mg/L and for yearlings of 7–15 mg/L (the authors also reported that the method by which stock solutions are formulated could have a dramatic effect on the toxicity of vanadium through its effects on the polymeric form of the metal in the test study); and (4) Hamilton and Buhl (1990), who reported a 96–hour LC_{50} for chinook salmon (*Oncorhynchus tshawytscha*) fry of 16.5 mg/L.

EPA undertook an exhaustive review of vanadium toxicity. The studies the commenter has listed show that vanadium compounds are moderately toxic to fish, which further support EPA's findings on the toxicity of vanadium. EPA's review of the studies cited in the proposed rule are not contradicted or undermined by the studies provided by the commenter, and continue to support the Agency's conclusion that vanadium and vanadium compounds are highly toxic to some aquatic species.

One commenter states that the background document to support EPA's proposal to list vanadium and vanadium compounds indicates that the proposed listing is based on data for five vanadium compounds: vanadium pentoxide, sodium metavanadate, sodium orthovanadate, vanadyl sulfate, and ammonium vanadate. The commenter contends that EPA may consider listing under EPCRA section 313 for the individual compounds for which the Agency has data, but EPA is not justified in listing a broad ''vanadium and vanadium compounds'' category based on data for only five compounds. The commenter suggests that EPA consider individual listings for these compounds, or a category consisting only of the compounds for which the Agency has data.

EPA disagrees with the commenter's characterization of the Agency's assessment of vanadium and vanadium compounds. In assessing the ecological toxicity of vanadium and vanadium compounds, EPA evaluated the parent metal (vanadium) and determined that it is highly toxic to some aquatic organisms and can reasonably be anticipated to cause a significant adverse effect on the environment of sufficient seriousness to warrant reporting pursuant to EPCRA section 313(d)(2)(C). Thus, vanadium, the parent metal in vanadium compounds, is the concern, not the other components of each compound. Many metals are tested in the salt form because they are readily soluble in aqueous solutions. The toxicity data for vanadium shows that the metal is highly toxic (aquatic toxicity < 1 mg/L) to the most sensitive species. In addition, because vanadium is persistent, EPA considers any toxicity values between 1 and 10 mg/L as indicating high ecotoxicity. This evaluation of vanadium's toxicity is acceptable according to traditional guidelines for the assessment of toxic substances conducted by the Agency for over two decades.

EPA has also provided sufficient basis for the inclusion of all vanadium compounds in the category. As EPA stated in the 1994 chemical expansion final rule:

> The Agency believes it satisfies the statutory criteria to add a category to the list by identifying the toxic effect of concern for at least one member of the category and then showing why that effect may reasonably be expected to be caused by all other members of the category. (at 59 FR 61442) See also, *Troy, supra* at 277.

EPA developed a hazard assessment for vanadium which reviewed the toxicity data for several vanadium compounds. The assessment indicated that the vanadium from these compounds is highly toxic to aquatic organisms. Since it is the vanadium from these compounds that is highly toxic rather than the intact chemical compound, EPA believes that all chemicals that are a source of vanadium meet the EPCRA section 313(d)(2)(C) listing criteria. Thus, EPA has established the toxic effect of concern, the chemical species that causes the effect, and the basis for why it may reasonably be expected that all members of the vanadium compounds category can cause the effects of concern.

Based on the available toxicity data, EPA has concluded that vanadium and vanadium compounds are toxic. They have the potential to kill fish, algae, and invertebrates as well as causing a range of other adverse effects on fish, algae, and invertebrates, based on chemical and/or biological interactions. Vanadium and vanadium compounds can cause these toxic effects at relatively low concentrations. Toxicity data for vanadium and vanadium compounds include for algae, a 9–day LC_{50} of 0.5 mg/L, a 15–day LC_{50} of 0.5 mg/L, inhibition of growth at 0.1 ppm, adverse effects on cell division at 3 ppb, 20 ppb, and 0.5 ppm; and for fish, a 96–hour LC_{50} of 0.62 ppm, and growth and survival depression of larvae at 0.17 ppm. Because vanadium and vanadium

NMED Exhibit 72

compounds can cause these toxic effects at these relatively low concentrations, EPA considers these chemicals to be highly toxic. Additional toxicity values include for algae, 9–day LC_{50}s of 2 and 3 ppm, and a 15–day LC_{50} of 2 mg/L; for invertebrates, a 9–day LC_{50} of 10 ppm; and for fish, 96–hour LC_{50}s of 6.4 ppm, 10 ppm, and 7 mg/L, an LC_{50} of 5.6 mg/L, an 11–day LC_{50} of 1.99 mg/L, 14–day LC_{50}s from 1.95 to 4.34 mg/L, and 7–day LC_{50}s from 1.9 to 6.0 ppm. Considering vanadium's persistence, vanadium and vanadium compounds are considered highly toxic to aquatic organism at these higher concentrations.

As discussed above, vanadium and vanadium compounds are highly toxic. Because vanadium and vanadium compounds are toxic at relatively low concentrations, EPA believes that they cause or can reasonably be anticipated to cause a significant adverse effect on the environment. In addition, because of the nature of the potential significant adverse effects, e.g., fish, algae, and invertebrate kills as well as a range of other adverse effects on fish, algae, and invertebrates, and the impacts such effects can have on ecological communities and ecosystems, EPA has determined that they are of sufficient seriousness to warrant reporting.

Thus, EPA reaffirms that there is sufficient evidence for adding vanadium and vanadium compounds on the EPCRA section 313 list of toxic chemicals pursuant to EPCRA section 313(d)(2)(C)(i) and (ii), based on the available ecotoxicity information for vanadium and vanadium compounds.

Therefore, EPA is finalizing the listing of vanadium and vanadium compounds on the EPCRA section 313 list.

a. *Reporting limitation of alloys.* A number of commenters support EPA's proposed determination to defer the reporting of vanadium when contained in alloys (64 FR 717). Many commenters also suggest that the Agency adopt a reporting limitation for the other metals such as chromium, copper, manganese, and nickel which are commonly found in alloys. The commenters assert that alloys have significantly different bioavailability, bioaccumulation, and toxicity characteristics than other forms of metals, and thus should be treated separately. The commenters argue that alloys are inherently more stable than unalloyed materials, do not enter the environment as readily as unalloyed materials and hence do not interact as greatly with organisms, and should be considered safer from an environmental and human health perspective. The commenters suggested that alloys should be treated separately not only for threshold changes, but also for EPCRA section 313 listings in general and recommend excluding alloys from general EPCRA section 313 listings for metals.

One commenter states in regard to the reporting of metals in alloys that it makes little or no sense to require the reporting of such ''useless'' information, since the information does not serve the purpose of informing the community. The commenter contends that not adding vanadium when contained in alloys would help to achieve EPCRA section 313's underlying purpose, i.e., to provide the public with meaningful information, while at the same time reducing the burden on reporting facilities. Another commenter argues that the proposed alloys exemption correctly recognizes that metals in alloys are not generally available for exposure or for toxic effects. The commenter argues that expansion of the exemption would improve the TRI data base by reporting only releases that may pose risks to human health and the environment, thereby providing the public with more meaningful data.

Two commenters state that the definition of vanadium alloys should include ''fused alloy slag'' in the qualifier as well. The commenters contend that the state of the vanadium in a ferroalloy form is one of intimate chemical combination on the atomic level, not a simple mixture of individual components and it is inherently stable and cannot be dissociated by ordinary means. The commenters argue that likewise, the fused alloy slag formed represents an intimate chemical combination of materials as a result of the smelting operation. The commenters assert that these elemental materials may include various components such as gangue or ore, ash of fuel, refractory lining, or other stable oxides with the ultimate characterization resting upon the chemical stability of the resultant fused alloy bearing slag. Thus, the commenters argue, vanadium contained in either alloy or alloy slag form is fused in a stable compound and therefore, no releases of vanadium into the environment would occur from either substance. The commenters state that the true environmental issue to consider in the formulation of an activity qualifier is the leachability of the material in that state, and since in both of the aforementioned cases the vanadium is in a stable compound, leaching would not be expected. The commenters assert that without allowing an exemption for fused alloy slag, large volumes of steelmaking and ferroalloy slag will unnecessarily fall under this reporting requirement. The commenters request that EPA reconsider its position and expand the definition of alloy to include both vanadium alloys and vanadium alloy slags.

EPA agrees with those commenters that support EPA's belief that it would be inappropriate, at this time, to change the status quo regarding reporting vanadium when contained in an alloy. As EPA stated in the proposed rule, the Agency is reviewing the issue of whether there should be any changes to the reporting requirements for metals contained in alloys.

In the proposed rule, EPA did not state, and did not intend to imply, that EPA considers alloys to be ''safe,'' or as some commenters suggested, that EPA had ''correctly'' recognized that metals in alloys are not generally available for exposure or to express their toxic effects. EPA has not completed its review of the alloys issue and has made no conclusions regarding whether there should or should not be any type of limitation or exemption for any metals contained in alloys. EPA's proposal merely recognized that while this issue was under review, it would not be appropriate to add alloy forms of vanadium.

The commenters contend that alloys have significantly different bioavailability, bioaccumulation, toxicity characteristics than other forms of metals and are inherently more stable than unalloyed materials and do not enter the environment as readily as unalloyed materials. EPA believes that the issue with alloys is primarily bioavailability, i.e., do the metals contained in alloys become available. This issue is the focus of EPA's current review. At this point in time, while EPA is in the process of a scientific review of the issues pertinent to alloys, the Agency is not prepared to make a final determination on whether vanadium in vanadium alloys meet the EPCRA section 313(d)(2) toxicity criteria.

The commenters did not provide any data to support their contention. The Agency does not believe that a metal compound in a slag necessarily will be environmentally unavailable; rather, the Agency's experience with a previous EPCRA section 313(d) review of manganese slags, indicates that at least in some cases the metal will be available (60 FR 44000, August 24, 1995) (FRL–4954–6).

Some commenters suggested that EPA create an alloys reporting limitation for all metals contained in alloys. However, as EPA has stated, the review of whether any kind of exemption or reporting limitation should be granted for certain metals in alloys is still under review and until the Agency has thoroughly reviewed the available data, EPA is not

NMED Exhibit 72

prepared to extend the reporting limitation to any other metals. For example, EPA is not lowering the reporting threshold for cobalt and cobalt compounds, and therefore the Agency is taking no action with respect to a reporting limitation for cobalt when contained in alloys.

One commenter asserts that for reasons of consistency--which helps ensure data quality--with existing EPCRA section 313 metal compound categories, they oppose adding the qualifier ''except when contained in an alloy'' in any new listing for vanadium.

EPA has not completed its review of the alloys issue and has made no conclusions regarding whether there should be any type of general limitation or exemption for any metals contained in alloys. EPA merely recognized that while this issue was under review it would not be appropriate to increase the reporting requirements for those facilities that would otherwise submit reports for vanadium contained in alloys. Therefore, as discussed earlier in this section, EPA has expanded the EPCRA section 313 listing for vanadium by removing the ''fume or dust'' qualifier for vanadium, but has not added the alloy forms of vanadium. Until EPA has the opportunity to fully evaluate the available data, the Agency is not prepared to make a final determination whether vanadium contained in alloys meets the EPCRA section 313(d)(2) listing criteria and should therefore be added. EPA believes that consistency, in this context, does not provide a sufficient basis to require reporting of vanadium contained in alloys.

H. Persistence and Bioaccumulation

The persistence and bioaccumulation data for the PBT chemicals covered by this final rule are listed in Table 3. A discussion of these data follows Table 3.

Table 3.—Persistence and Bioaccumulation Data

Chemical Category/Chemical Name	CASRN	BCF	BAF	Air Half-life	Surface Water Half-life	Soil Half-life
Dioxin/Dioxin-Like Compounds

[1]The reported half-life data for water are suspected to include significant removal from the medium by processes other than degradation (e.g., volatilization).
[2]Values are for Piscivorous Fish.
[3]Since data could not be found for this chemical, the data for the dibenzopyrenes (192–65–4; 189–64–0; 191–30–0), which are structural analogues, was used.
[4]Since data could not be found for this chemical, the data for benzo(a)phenanthrene (218–01–9), a structural analogue was used.
[5]The bioaccumulation potential for the parent metals is assumed to be equivalent to the associated metal compounds since in the environment the parent metals may be converted to a metal compound. Since metals are not destroyed in the environment they persist longer than 6 months.
[6]Lowest value reported for a dichlorinated PCB.
[7]Since no data could be found for this chemical, the data for the structural analogues hexachlorobenzene (118–74–1) and pentachlorobenzene (608–93–5) was used.

1. *Persistence*—a. *Dioxin and dioxin-like compounds*. In the proposal, EPA preliminarily determined that dioxin and dioxin-like compounds have persistence half-life values in soil that ranged from 1.5 years to more than 20 with all but one chemical having a soil half-life of more than 20 years. EPA has reviewed information and all comments received on dioxin and dioxin-like compounds' persistence characteristics. Taking into account this information, as indicated in Table 3, EPA finds that dioxin and dioxin-like compounds persist in the environment with half-lives of 2 months or greater and therefore meet the persistence criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical category can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 7). In addition, dioxin and dioxin-like compounds persist in the environment with a half-life of greater than 6 months making it highly persistent. This, plus other factors, supports EPA's decision to lower the threshold to 0.1 gram.

b. *Aldrin*. In the proposal, EPA preliminarily determined that aldrin has persistence half-life values in soil of 291 days to 9 years and a persistence half-life value in water of 24 days. EPA has reviewed information and all comments received on aldrin's persistence characteristics. Taking into account this information, as indicated in Table 3, EPA finds that aldrin persists in the environment with a half-life of 2 months or greater and therefore meets the persistence criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 7).

c. *Chlordane*. In the proposal, EPA preliminarily determined that chlordane has persistence half-life values in soil of 0.4–8 years and a persistence half-life value in water of 239 days. EPA has reviewed information and all comments received on chlordane's persistence characteristics. Taking into account this information, as indicated in Table 3, EPA finds that chlordane persists in the environment with a half-life of 2 months or greater and therefore meets the persistence criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69)

and/or in EPA's support documents for this rulemaking (Ref. 7). In addition, chlordane persists in the environment with a half-life of greater than 6 months which supports EPA's decision to lower the threshold to 10 pounds.

d. *Heptachlor*. In the proposal, EPA preliminarily determined that heptachlor has persistence half-life values in soil of 8 days to 4 years and a persistence half-life value in water of 23.1–129.4 hours. EPA has reviewed information and all comments received on heptachlor's persistence characteristics. Taking into account this information, as indicated in Table 3, EPA finds that heptachlor persists in the environment with a half-life of 2 months or greater and therefore meets the persistence criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 7). In addition, heptachlor persists in the environment with a half-life of greater than 6 months which supports EPA's decision to lower the threshold to 10 pounds.

e. *Isodrin*. In the proposal, EPA preliminarily determined that isodrin has persistence half-life values in soil of 180 days to 5 years. EPA has reviewed information and all comments received on isodrin's persistence characteristics. Taking into account this information, as indicated in Table 3, EPA finds that isodrin persists in the environment with a half-life of 2 months or greater and therefore meets the persistence criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 7). In addition, isodrin persists in the environment with a half-life of greater than 6 months which supports EPA's decision to lower the threshold to 10 pounds.

f. *Methoxychlor*. In the proposal, EPA preliminarily determined that methoxychlor has persistence half-life values in soil of 81 to 136 days and a persistence half-life value in water of 5 to 15.2 days. EPA has reviewed information and all comments received on methoxychlor's persistence characteristics. Taking into account this information, as indicated in Table 3, EPA finds that methoxychlor persists in the environment with a half-life of 2 months or greater and therefore meets the persistence criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 7).

g. *Pendimethalin*. In the proposal, EPA preliminarily determined that pendimethalin has a persistence half-life value in soil of 54 to 1,300 days. EPA received several significant comments addressing pendimethalin's persistence potential which are addressed below. EPA has reviewed information and all comments received on pendimethalin's persistence characteristics. Taking into account this information, as indicated in Table 3, EPA finds that pendimethalin persists in the environment with a half-life of 2 months or greater and therefore meets the persistence criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 7).

One commenter contends that EPA has miscategorized pendimethalin as a PBT chemical based on limited screening data which conflicts with conclusions reached by EPA in its risk assessment under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA). The commenter believes that the characterization of pendimethalin is inaccurate and will lead to misplaced effort and misplaced focus on listed chemicals, and that there will be no benefit to the public or the environment in lowering the reporting threshold for pendimethalin.

EPA disagrees with the commenter. EPA did not base its determination that pendimethalin meets the EPCRA section 313 persistence criteria, nor that pendimethalin is highly persistent on ''screening'' data. EPA's conclusion that pendimethalin persists with a half-life greater than 6 months is based on a well-conducted study in which pendimethalin degrades in soil with a half-life of 1,322 days. Further, even if these data were discounted, there are numerous data submitted in support of reregistration of pendimethalin under FIFRA that provide strong evidence that pendimethalin meets the EPCRA section 313 persistence criteria, i.e., a half-life greater than 2 months. A more detailed discussion of these data is presented in the following responses. Contrary to the assertion by the commenter, the categorization of pendimethalin as a PBT chemical as described in the proposed rule is not in conflict with the conclusions reached by EPA during the FIFRA assessment. In addition, EPA disagrees that there will be no benefits to the public or the environment from lowering the thresholds for pendimethalin. EPA believes that pendimethalin, like all PBT chemicals, is of special concern because it has the potential to cause adverse effects even when released to the environment in small quantities because it can bioaccumulate in organisms to levels much greater than those present in the environment. EPA believes that lowering the reporting threshold for pendimethalin will provide information to the public that will increase their awareness of low levels of releases to the environment which have the potential to concentrate in organisms and cause adverse effects, which is fully consistent with the purposes of EPCRA section 313.

The commenter states that EPA has ignored bioavailability in designating pendimethalin as a PBT chemical and argues that the true bioaccumulation potential for pendimethalin is greatly overestimated based on the results of the standard laboratory fish bioconcentration study. The commenter asserts that when data on bioavailability, degradation, and depuration are all considered, the ''real world'' bioconcentration potential for pendimethalin is low and, therefore pendimethalin should not be mischaracterized as a PBT chemical.

The bioavailability data the commenter refers to was not specifically identified. Bioavailability of a chemical will vary from environment to environment and soil type to soil type. Caution must be taken, however, not to draw the erroneous conclusion that because a chemical has been shown to have a high affinity to sorb to sediments in aquatic environments that it will not be available for uptake by aquatic organisms. Examples like the PCBs (see Unit VI.F. for a further discussion on this issue) indicate that although some of these compounds have sorption coefficients much greater than pendimethalin, they are still widely found in the tissues of aquatic organisms in contaminated waters. Further, it would be erroneous to state that pendimethalin is not bioavailable because if it were not bioavailable it could not function as an herbicide.

The commenter claims that using EPA's own criteria (half-lifes longer than 2 months in water, sediment, or soil, or a half-life longer than 2 days in air) pendimethalin cannot be classified as persistent. Rather the commenter contends that pendimethalin has ''low'' or ''low to moderate'' persistence.

The commenter is incorrect. The Agency has set persistence criteria of half-lifes for soil, sediment, and water

greater than 2 months and a half-life in air of greater than 2 days. Chemicals meeting these criteria are considered persistent for purposes of EPCRA section 313. There are, in fact, no qualifiers such as ''low,'' ''moderate,'' or ''high'' associated with the persistence criteria. The commenter's characterization of the persistence of pendimethalin as ''low'' or ''low to moderate'' is thus not particularly relevant. It appears, based on the comments, that the commenter defines low to moderate persistence as a half-life of greater than 2 days in air and greater than 2 months in soil, sediment, or water. If this is the case, then the commenter in fact concurs with EPA's assessment of pendimethalin as persistent (half-life greater than 2 months in soil or water and greater than 2 days in air).

If the commenter, instead, meant that pendimethalin has half-lifes of less than 2 months in soil or water, and 2 days in air, EPA notes that the commenter has failed to provide data to support that assertion, and that EPA's review of the data support the Agency's conclusion.

A commenter cites numerous laboratory and field dissipation studies in support of the claim that pendimethalin does not meet the persistence criteria.

EPA disagrees that the degree of persistence of pendimethalin can be characterized by the field dissipation studies cited by the commenter. Field dissipation studies are not equivalent to the studies which measure the half-life for destruction of a chemical in a specific medium (i.e., soil, water, or air). Field dissipation studies are designed to measure the rate or extent of chemical loss from the medium after application of the chemical. The processes by which the chemical is lost may include not only those that result in destruction of the chemical, but those which only transport the chemical from one medium to another such as volatilization. The studies cited by the commenter measure the dissipation of pendimethalin from soil. For a relatively volatile chemical such as pendimethalin, field dissipation studies are of limited use in assessing persistence because an unknown amount of pendimethalin will be transported from soil to air, resulting in a measured loss from that medium, but not destruction. Thus, the field dissipation studies cited by the commenter will underestimate the persistence of pendimethalin in soil.

The commenter cites several laboratory experiments on the degradation of pendimethalin in soil to support the argument that pendimethalin does not meet the persistence criteria. For example, they state that laboratory aerobic soil degradation studies have been conducted in which pendimethalin was applied to soil grab samples and incubated under controlled conditions. Pendimethalin degraded in laboratory soil studies with half-lifes ranging from 31 to 1,322 days. In the *Reregistration Eligibility Decision (RED) for Pendimethalin* (Ref 63) document, EPA explained that 172 days was used instead of 1,322 days because:

> The half-lifes for aerobic soil metabolism ranged from 42-563 days in the literature studies referenced below with a guideline study reporting a half-life of 1,322 days for a total of 27 total observations. Because of the range of half-life values, statistical analyses of the available data were performed. The mean, median, and modal half-lifes are 126, 122, and 122 days, respectively, with a standard deviation of 66 days (n=24). The half-life values of 409, 563, and 1,322 days were not included in the final statistical analyses because they were greater than three standard deviations from the mean. Based on soils and crops that are normally treated with pendimethalin, the reviewer assumed that temperatures would likely range from 20–30 °C and soil moisture contents from 50-75% Field Capacity (FC). The range of observed half-lifes in the above experimental conditions was 72–172 days.

The commenter contends that the 1,322–day half-life value is assumed to be an outlier (Ref. 5), the range was 31 to 172 days. Thus, it is claimed that laboratory studies also indicate that pendimethalin has a low to moderate persistence according to the EPCRA section 313 persistence criteria.

EPA believes that the guideline study that reported a half-life of 1,322 days represents an accurate and representative value for the assessment of the persistence of pendimethalin in the environment. In situations where multiple values for half-lifes are submitted under FIFRA to EPA's Office of Pesticide Program (OPP), statistical analysis may be conducted to determine mean values and standard deviations. The analysis permits the use of a value for exposure assessment modeling that takes into account the variability in data, and allows the exclusion of values more than three standard deviations outside the mean as ''outliers.'' The designation as an outlier does not invalidate the study, and in fact, EPA maintains that even a study designated as an ''outlier,'' if valid, gives useful half-life information.

In their assessment of the persistence of chemicals in soils, OPP focuses on studies using soil types, soil moisture contents, and temperatures consistent with the field application of the chemical in its intended use. In the OPP review of the studies, the reviewer assumed that in the field application of the chemical, temperatures would likely range from 20-30 °C and that soil moisture would range from 50 to 75% field capacity. The consideration of data from studies conducted under these conditions resulted in a half-life range of 72 to 172 days for pendimethalin. It should be noted that even after the elimination of outliers and consideration of studies relevant to normal field application, the entire half-life range is above 2 months, clearly meeting the criteria for persistence in soil, i.e., a half-life of 2 months.

The releases of pendimethalin subject to EPCRA section 313 reporting, in many cases, will not be to agricultural soils under typical application scenarios. EPA, therefore, contends that even though some soil half-life values were not considered by OPP, either because they were derived using studies that did not represent the desired field conditions, or because they were labeled as statistical outliers, the study conditions still represent realistic scenarios for releases reported under EPCRA section 313 and are valid for use in the determination of persistence.

The commenter cites studies conducted using flooded soils to support the argument that pendimethalin does not meet the persistence criteria. The commenter asserts that the studies involved the use of pendimethalin spiked into soil grab samples covered with a shallow layer of water and incubated in the laboratory under controlled conditions. In laboratory flooded soil studies, pendimethalin degradation half-lifes ranged from seven to 104 days with the majority of studies giving half-lifes of less than 2 months. Degradation of pendimethalin was more rapid in flooded soils than in nonflooded soils in most instances. The commenter asserts that these results demonstrate that pendimethalin has a low to moderate persistence in flooded soils according to the EPCRA section 313 persistence criteria.

EPA agrees that the reported degradation half-lifes in laboratory flooded soils studies range from 7 to 104 days. The studies were reviewed for quality and preferred methodologies. Of the studies that are of acceptable quality, EPA chose the highest value (most protective) of the range to determine if the chemical meets the EPCRA section 313 persistence criteria. In this case, the value of 104 days would be used to characterize pendimethalin as persistent in flooded soils. However,

NMED Exhibit 72

there is not a separate persistence criterion for flooded soils, nor are data on flooded soils preferable to other soil data. EPA notes that other soil studies, as discussed above in this section, indicate a half-life of 1,322 days in soils.

The commenter states that while pendimethalin is stable to hydrolysis, it will degrade in natural water and water/sediment systems under laboratory conditions with degradation half-lifes ranging from 4 to 22 days. Photodegradation is also rapid with half-lifes of approximately 3.5 days. The commenter concludes that these results indicate that pendimethalin has a low persistence in both water and its underlying sediment according to the EPCRA section 313 persistence criteria.

Two of the aerobic aquatic degradation studies cited by the commenter were not provided to the Agency or are not publicly available, (i.e., they are internal American Cyanamid studies). It is unclear from the summary provided whether the cited studies measured destruction of pendimethalin or its loss from the medium by non-destructive water to air transport processes. If the latter is the case, the ''dissipation half-lifes'' cited cannot be used to characterize persistence. EPA agrees that if the half-lifes reported for aerobic aquatic degradation represent half-lifes for destruction of the chemical, they do not meet the criteria for persistence in water. However, as noted, the full studies were not available for review and as such, EPA cannot assume that the studies followed destruction of pendimethalin, or that the studies meet the quality criteria outlined in this rule.

The commenter cites a half-life range of 6 to 22 days derived from an anaerobic aquatic degradation study to support the argument that pendimethalin has a low persistence in both water and its underlying sediment according to the EPCRA section 313 persistence criteria. EPA agrees that the persistence half-life values cited by the commenter do not meet the EPCRA section 313 persistence criteria, but points out that additional data submitted in support of the reregistration of pendimethalin indicated that half-lifes in aquatic environments could be longer. OPP used flooded soil degradation studies to assess the persistence of pendimethalin under anaerobic aquatic conditions. Half-lifes in these studies ranged from 6 to 105 days. In its discussion of the potential impact of pendimethalin on water resources, OPP in the RED notes that pendimethalin has an anaerobic aquatic metabolism half-life of 60 days. EPA believes that after review of the available data on its persistence in water pendimethalin meets the EPCRA section 313 persistence criteria.

EPA agrees that rapid aqueous photodegradation under laboratory studies has been reported for pendimethalin. However, the photolysis screening tests used are designed to allow the determination of rates of photolysis at shallow depths in pure water as a function of lattitude and season. EPA believes that the environmental relevence of these tests should be considered in their use to determine persistence, and that the results are most applicable to shallow, clear waters. EPA believes that the application of the results beyond these environments is tenuous due to the attenuation of light by suspended matter and increasing depth in the aquatic environment. EPA believes that pendimethalin's tendency to sorb to soil and sediments may result, under some circumstances, in its deposition in benthic environments beyond the effects of aqueous photolysis. Therefore, EPA does not believe that the half-life for pendimethalin in water should be based on aqueous photolysis.

The commenter claims pendimethalin will not persist in air according to the EPCRA section 313 persistence criteria for air since it has a half-life of less than 2 days. The commenter discusses the estimation of pendimethalin's atmospheric half-life and a study on its photodegradation in air. The commenter cites the results of a calculation according to the method of Atkinson performed to determine the rate constant for reaction of pendimethalin with OH radicals in the gas phase (Ref 42). A tropospheric half-life of 3.4 hours was calculated using the method. The photolysis of pendimethalin was investigated by Bossan, *et al.*, 1995 (Ref. 15), who reported on the photoreactivity of pendimethalin on airborne fly ash and kaolin using simulated sunlight. Approximately 70% of applied pendimethalin degraded within 30 minutes when adsorbed to fly ash but little degradation was observed after 100 minutes when pendimethalin was bound to kaolin.

EPA agrees that pendimethalin does not meet the persistence half-life criteria for air of greater than 2 days, but because it meets the persistence criteria for soil and water, this does not affect EPA's conclusion. As noted in the proposed final rule (at 64 FR 702), a chemical need only meet one of the media-specific criteria to be considered persistent.

The commenter cites EPA's pendimethalin RED document and cites its conclusion in support of the argument that pendimethalin does not meet the persistence criteria. The commenter describes the RED conclusions as follows:

> Pendimethalin dissipates in the environment by binding to soil, microbially-mediated metabolism and volatilization. It is essentially immobile in soil.
>
> Based on laboratory studies and limited field study information, pendimethalin is slightly to moderately persistent in aerobic soil environments. Persistence decreases with increased temperature, increased moisture and decreased soil organic carbon.

EPA disagrees with the commenters' suggestion that the OPP RED for pendimethalin concludes that it does not meet the EPCRA 313 persistence criteria. As stated in an earlier response, ''moderate'' persistence has no relevance in the context of the proposed rule. A chemical is considered persistent if it has half-lifes of 2 days in air or 2 months in soil, sediment, or water, respectively.

The commenter implies that OPP has concluded that pendimethalin does not meet the persistence criteria by selectively citing the OPP RED while failing to acknowledge other information OPP discussed in the document confirming the persistence of pendimethalin. OPP did not make any formal summary conclusions regarding the overall environmental persistence of pendimethalin. The commenter has selectively cited from the RED by taking a few comments out of context while ignoring additional findings which demonstrate that pendimethalin meets the persistence criteria.

The first statement cited by the commenter addresses dissipation in the environment. Two of the three processes (soil binding and volatilization) responsible for dissipation do not result in the destruction of the chemical and cannot be directly related to persistence. Volatilization results in the relocation of the chemical to the atmosphere. Binding to soil does not destroy pendimethalin and under some soil conditions has been shown to increase persistence. While microbial metabolism of pendimethalin can result in its destruction, it has been shown to be a slow process under many environmental conditions.

The commenter cites OPP's qualitative description of the persistence of pendimethalin in aerobic soil environments as slight to moderate. This does not serve as, nor did OPP intend for this statement to represent, a quantitative description of pendimethalin's persistence in soil. OPP does not attempt to relate this characterization to a numeric range of persistence values in the RED, and the

commenter does not provide a rationale for concluding that OPP's language indicates that pendimethalin does not meet the EPCRA section 313 persistence criteria.

The final sentence of the citation points out factors that decrease persistence, but a more detailed reading of the RED on the subject of pendimethalin persistence in aerobic soils reveals that its persistence increases as temperature and soil moisture decrease, and soil organic carbon increase.

The commenter performed a Level III EQC Multimedia Modeling assessment for pendimethalin assuming ''best case, reasonable case, and worst case'' scenarios. The calculated overall environmental persistence was determined for pendimethalin to be 5 days, 58 days, and 142 days under the ''best, reasonable, and worst case'' scenarios, respectively. The results of the multimedia model indicated that pendimethalin will have a persistence in the environment of less than 2 months, assuming a reasonable case scenario. The commenter claims that multimedia modeling results indicate that pendimethalin will not be persistent according to the EPCRA section 313 persistence criteria.

The commenter notes that the values it calculated using the EQC model are much lower than the 30 days and 487 days calculated for EPA (Ref. 51) assuming best case and worst case scenarios. The commenter alleges that EPA assumed that half-lifes in soil, sediment and water were identical, 54 days and 1,322 days, respectively (Ref. 7). The data presented above, however, indicate that these were erroneous assumptions. The half-lifes for pendimethalin dissipation in water, soil, and sediment are not identical, and the 1,322 day half-life is an outlier.

The commenter concludes that pendimethalin will have a low to moderate persistence whether found in the air, water, soil, or sediment compartments of the environment. The commenter asserts that this is supported by field and laboratory degradation studies, multimedia modeling, and EPA's FIFRA registration environmental assessment of pendimethalin. Therefore, pendimethalin should not be classified as persistent for purposes of inclusion on the EPCRA section 313 list of PBT chemicals.

EPA disagrees that pendimethalin will have low persistence in the environment whether laboratory and field studies or multimedia modeling are considered. Multimedia mass balance models offer the most convenient means to estimate overall environmental persistence from information on sources and loadings, chemical properties and transformation processes, and intermedia partitioning. For the chemicals included in the proposed rule, EPA used a modified version of the EQC model (Ref. 33) to estimate overall environmental persistence. Overall persistence estimated in this way is used as an additional factor, in conjunction with reaction half-lifes for individual media, bioaccumulation/bioconcentration factors, in justifying the determination made by EPA in this rule.

The EQC model is based on the fugacity approach first delineated by Mackay (Ref. 31) and subsequently applied to numerous environmental processes (Ref. 32). It uses an ''evaluative environment'' in which environmental parameters such as bulk compartment dimensions and volumes (e.g., total area, volume of soil and sediment, etc.) are standardized, so that overall persistence for chemicals with different properties and rates of transformation may be compared on an equal basis (Ref. 15). EPA used a version of the EQC level III model (Ref. 33) which was modified to focus on net losses by deleting model terms for advective losses (movement out of the evaluative environment of air and water potentially containing a chemical) and sediment burial (Ref. 82). In this version of the model only irreversible transformation contributes to net loss of a chemical.

The overall persistence obtained from this model is calculated as the total amount in the evaluative environment when steady state is achieved, divided by the total loss rate. The results thus obtained are neither an overall environmental half-life nor a compartment (or transformation)-specific half-life; rather they are equivalent to an environmental residence time. When only irreversible transformation contributes to net loss--i.e., under the conditions of this version of the EQC model--overall environmental persistence times can be converted to half-lifes by multiplying the former by ln 2 (i.e., 0.693). The overall half-life calculated in this way is for dissipation in the environment as a whole and cannot be related directly to any individual compartment.

The commenter selected media-specific environmental half-lifes for use as input to the EQC model. The values were characterized as ''best,'' ''reasonable'' and ''worst'' case. No justification was given for this classification. It appeared that the shortest half-lives were categorized as ''best case.'' Based on the information provided by the commenter, it was not always possible to determine whether the half-lifes for soil or water selected by the commenter for use as input to the EQC model were for destruction of chemical, or its dissipation from the medium. As noted previously, dissipation half-lifes do not necessarily represent destruction of the chemical since non-destructive transport processes such as volatilization can be responsible for loss from the medium. Their use in multimedia modeling could potentially underestimate overall environmental persistence. This is particularly important since the modified EQC model predicted that greater than 90% of the pendimethalin would partition to soil at steady state. If a soil half-life based on loss from soil by nondestructive processes was used rather than one based on the destruction of pendimethalin, its persistence would have been underestimated.

In its modeling of the overall environmental persistence of pendimethalin EPA used the highest, lowest and mean values for the ranges of media-specific half-lifes from valid studies as inputs to the modified EQC model, not the highest and lowest as stated by the commenter. These included a half-life for pendimethalin in soil of 1,322 days. EPA determined that the study was properly conducted and chose the half-life value of 1,322 days for soil because it represented the most environmentally protective half-life derived from a valid study. The calculated overall environmental persistence half-lifes were 1 month, 8 months, and 16 months based on the highest, mean, and lowest half-lifes, respectively. For chemicals in this rulemaking, EPA considered the multi-media modeling EQC results in characterizing persistence in the overall environment. EPA only intended to use multimedia modeling results to override the medium-specific persistence data in limited circumstances, e.g., only if all model inputs are judged to be accurate (and, as noted above, the commenter's inputs cannot be determined to be accurate). But even if EPA were to use the EQC model to assess persistence, pendimethalin would be considered persistent because, with the EPA inputs described above, EQC overall environmental persistence half-lifes were calculated to be greater than 6 months using the mean and maximum air, soil, and water half-lifes calculated.

In response to this comment (even though it was unclear whether the commenter was basing its assertion on degradation data or dissipation data), EPA conducted a new EQC assessment for pendimethalin using the same half-

life inputs selected by the commenter. The calculated overall environmental persistence half-life was greater than 2 months using the longest half-lifes provided by the commenter for air, soil, water, and sediment. These results support EPA's assertion that the persistence of pendimethalin in the environment meets the EPCRA section 313 persistence criteria.

The commenter argues that the scientifically-based risk assessments conducted on pendimethalin as a part of the pesticide registration process should not be ignored, and that EPA should review pesticide PBT chemical classifications with EPA registration information to ensure an accurate analysis has been performed.

The commenter notes that EPA has determined through the review of a complete set of studies that this material used at an approximate rate of 1.0 to 2.0 pounds of active ingredient per acre does not present an unreasonable risk to human health or the environment, that low levels of pendimethalin in manufacturing wastewater releases do not pose an unacceptable risk to the environment, and that reported EPCRA section 313 air releases do not pose a significant risk to human health or the environment.

The commenter concludes that based on the weight of evidence it is clear that releases of pendimethalin from manufacturing do not pose a significant threat to human health and the environment and that pendimethalin should not be branded as having a high potential for harm as indicated by the proposed listing as a PBT chemical and lowering of the reporting threshold.

EPA disagrees that the risk assessments cited by the commenter are relevant to the characterization of pendimethalin as a PBT chemical. The characterization of chemicals as PBT chemicals for the purpose of this rule are based on intrinsic physical-chemical properties. Risk is not an intrinsic property of a substance, but rather the result of the combination of intrinsic hazard (toxicity) a substance possesses and the exposure to a target organism under a defined set of circumstances. It is possible for a substance to present a risk under one set of exposure conditions, but not another. In contrast, a substance characterized as a PBT chemical will remain a PBT chemical, regardless of the exposure to it or its levels in the environment. (See Unit VI.C.)

Toxic chemicals that persist and bioaccumulate are of particular concern because they remain in the environment for significant periods of time and concentrate in the organisms exposed to them. Furthermore, these PBT chemicals can have serious human health and environmental effects resulting from low levels of release and exposure.

EPA believes that the substances subject to this rule have been characterized as PBT chemicals using scientifically sound indicators based on the intrinsic properties of the substances. The PBT characterization is independent of the risk the substance may pose under a given set of circumstances. These substances have been characterized as persistent, bioaccumulative and toxic and, therefore, meet the criteria for lowered reporting thresholds.

Further, FIFRA requires the Agency to determine that pesticidal uses of a chemical do not cause ''unreasonable adverse effects on the environment,'' which is defined in FIFRA section 2(bb) as ''any unreasonable risk to man or the environment taking into account the economic, social, and environmental costs and benefits of the use of pesticides'' (7 U.S.C. section 136(bb)). FIFRA is a regulatory statute, and the impacts of regulation can be immediate and direct (e.g., banning of a chemical), and as such EPA examines not only the hazards presented by the chemical, but also the specific exposure scenarios, and weighs the risks against the benefits of the chemical. The ''unreasonable adverse effects'' determination under FIFRA is specific to the intentional use of the chemical as a pesticide and does not address other uses or releases of the chemical that may result from manufacture, processing, or other use. Furthermore, a determination under FIFRA that the use of a chemical will not result in an ''unreasonable adverse effect'' is not a determination that the chemical is not hazardous or persistent or that the use of the chemical is without risk, but merely that the benefits of agricultural use as a pesticide outweigh its risks as an agricultural pesticide or that the pesticide chemical residues on food or feed meet the standards of section 408 of the Federal Food, Drug, and Cosmetic Act. EPCRA section 313 was not enacted to serve the same purpose as FIFRA. Listing on EPCRA section 313 provides communities with some of the information required to determine what risks may result from the manufacture, processing, and use of a chemical, and to allow local communities to determine for themselves whether such risks are acceptable, information not provided under FIFRA.

h. *Toxaphene*. In the proposal, EPA preliminarily determined that toxaphene has persistence half-life values in soil of 1 to 11 years and a persistence half-life value in water of 1 to 5 years. EPA has reviewed information and all comments received on toxaphene's persistence characteristics. Taking into account this information, as indicated in Table 3, EPA finds that toxaphene persists in the environment with a half-life of 2 months or greater and therefore meets the persistence criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking. (Ref. 7). In addition, toxaphene persists in the environment with a half-life of greater than 6 months which supports EPA's decision to lower the threshold to 10 pounds.

i. *Trifluralin*. In the proposal, EPA preliminarily determined that trifluralin has persistence half-life values in soil of 99 to 394 days and a persistence half-life value in water of 5 to 37 days. EPA has reviewed information and all comments received on trifluralin's persistence characteristics. Taking into account this information, as indicated in Table 3, EPA finds that trifluralin persists in the environment with a half-life of 2 months or greater and therefore meets the persistence criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 7).

j. *Polycyclic aromatic compounds*. In the proposal, EPA preliminarily determined that PACs have persistence half-life values in soil that ranged from 20 days to 13 years. All but a few had half-lifes well in excess of 6 months. These chemicals had persistence half-life values in water that ranged from 79 days to 44 years. EPA received one significant comment addressing the persistence potential of PACs, which is discussed below. EPA has reviewed information and all comments received on PACs' persistence characteristics. Taking into account this information, as indicated in Table 3, EPA finds that PACs persist in the environment with half-lives of 2 months or greater and therefore meet the persistence criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical category can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 7).

One commenter contends that EPA has incorrectly ignored biotreatment

NMED Exhibit 72

studies in evaluating persistence for PACs. EPA has also ignored a large body of recent research on sequestration and other phenomena that collectively act to reduce the bioavailability of soil contaminants, such as PACs.

Biotreatment studies include activated sludge or other wastewater treatment studies. As EPA stated in the proposed rule (at 64 FR 700), the reason for excluding such studies is that wastewater treatment in general and activated sludge in particular represent conditions that are far removed from ambient (surface) waters, soils, and sediments. Data on environmental fate and persistence of substances in wastewater and activated sludge normally cannot be extrapolated to the other conditions. The commenter seems most concerned about land biotreatment (bioremediation) studies, but in fact goes well beyond the concept of treatability, appearing to infer that EPA has ignored all biodegradation studies of PACs. However, this is incorrect because all mixed-culture biodegradation studies other than activated sludge tests--i.e., field tests as well as lab studies that used authentic soil, water and/or sediment grab samples--were considered in determining persistence for all of the listed substances.

The commenter also discusses recent research indicating that bioavailability of a substance may decline with time of incubation in soil, and suggests that EPA should include ''reasonable bioavailability factors'' in its determination of persistence. As an example of why this is relevant, there has been a concern that Superfund site remediation actions may be mistargeted if they are based on residues released from the soils by vigorous extraction procedures, since chemical substances in soil may become nonbioavailable yet still be extractable for analytical purposes. Additionally, bioremediation may fail to destroy all of a substance that such analysis shows is present, if some portion is sequestered in a non-bioavailable state. Further, the commenter contends that chemicals (including many PACs) are not bioavailable if the bioavailability is considerably less than 100%. The commenter does further specify a numerical bioavailability criteria.

The commenter over-generalizes from the research findings, using selective citation and quotation from the literature to give the impression that all is now known and any substance released to soil is as good as gone toxicologically speaking. Other reports can be quoted to the effect that the many factors determining bioavailability, sequestration, etc. are far from completely resolved, and deserve much further research. Moreover, sequestration does not necessarily imply non-bioavailability. For example, in a study of PAC sequestration and bioremediation, Tang et al. (Ref. 51a) state that:

> The results of the present study suggest that extensive biodegradation by microorganisms does not necessarily remove all of the fraction of an aged compound that is bioavailable since some uptake by worms occurred even after the laboratory-scale bioremediation. . . .it is also possible that a portion of a compound that is sequestered is available to different degrees to dissimilar organisms. . . .It may be that the mass of material that becomes sequestered should be considered as existing in two forms. One form may be unavailable to all organisms because it is physically remote and thus inaccessible. The second form may be differentially available, and its assimilation, toxicity, and/or biodegradation may depend on the properties of the species and its ability to mobilize the molecules from this non-remote location.
>
> [There is] danger if it is assumed that the disappearance of lethality denotes the absence of bioavailability....The point is reinforced by the case of DDT, which is sequestered in soil (13) and whose lethality to insects totally disappears as a result of such sequestration (5), yet a portion of that insecticide was still assimilated by earthworms introduced into soil that was treated in the field with DDT *more than 40 years before the bioassay was performed*. . . .(emphasis added)

And in a similar paper on DDT and dieldrin, Robertson and Alexander (Ref. 43a) state that:

> The significance of soil properties in controlling sequestration is evident in the early observation that the degree of sequestration of lindane after 22 months was greatest in a muck, intermediate in extent in a loam, and least in a sandy loam (11). Thus, *soil properties must be considered in attempting to predict the bioavailability of persistent compounds*. It is also evident from the data presented herein that the bioavailability of a sequestered toxicant varies with the exposed species. Thus, the declines in toxicity of aged DDT and dieldrin to the three test insects were quite different; whereas the lethality of the sequestered compound to one species had almost disappeared, it still was effective against a second. (emphasis added)

The conclusion is manifest: it is that although chemical substances released to soil may become sequestered over time, it cannot be assumed that this process necessarily leads to nonbioavailability even when the time horizon is years. Site- and species-specific factors, as well as substance properties, are important in determining bioavailability. Therefore, it is appropriate to be concerned about the bioavailability in soil and sediment of PACs and other substances that meet the PBT criteria established for this rulemaking.

Further, there is no scientific reason why a chemical can only be considered bioavailable if its bioavailability approaches 100%. The degree of bioavailability will vary depending upon the environmental conditions. In addition, as noted above the degree of bioavailability will also be species dependent. Therefore, EPA believes that the commenter's approach is overly simplistic.

k. *Benzo(g,h,i)perylene*. In the proposal, EPA preliminarily determined that benzo(g,h,i)perylene has persistence half-life values in soil of 173 days to 1.8 years and persistence half-life values in water of greater than 100 days. EPA has reviewed information and all comments received on benzo(g,h,i)perylene's persistence characteristics. Taking into account this information, as indicated in Table 3, EPA finds that benzo(g,h,i)perylene persists in the environment with a half-life of 2 months or greater and therefore meets the persistence criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking. (Ref. 7). In addition, benzo(g,h,i)perylene persists in the environment with a half-life of greater than 6 months which supports EPA's decision to lower the threshold to 10 pounds.

1. *Mercury and mercury compounds*. Because metals may convert to different oxidation states but can never be destroyed, all metals meet the 6 months half-life criterion automatically. EPA received a few significant comments addressing mercury and mercury compounds' persistence. These are discussed below. EPA has reviewed information and all comments received on mercury and mercury compounds' persistence characteristics. Taking into account this information, as indicated in Table 3, EPA finds that mercury and mercury compounds persist in the environment with half-lives of 2 months or greater and therefore meet the persistence criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical category can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and in EPA's support documents for this rulemaking (Ref. 7). In addition, mercury and mercury compounds persist in the environment with a half-life of greater

NMED Exhibit 72

than 6 months which supports EPA's decision to lower the threshold to 10 pounds.

One commenter asserts that EPA should not classify all forms of mercury as persistent. The commenter agrees that Hg (0) is properly characterized as persistent. However, the commenter contends that EPA is incorrect in characterizing Hg (II) as persistent because it is removed rapidly from the atmosphere via wet and dry deposition.

EPA believes that the commenter confuses residence time with half-life; these terms do not represent equivalent processes. There is a distinction between atmospheric ''half-life,'' which is the amount of time necessary for half of the chemical present to be destroyed in the medium, and atmospheric ''residence time'' which is the length of time a chemical resides in a particular environmental medium. For the purposes of this rule ''half-life'' includes only irreversible chemical transformations resulting in the destruction of chemical whereas ''residence time'' includes factors such as transport of the substance to another medium, for example, wet and dry deposition, sorption, complexation or sequestration; and reversible changes in speciation (i.e., oxidation reduction reactions). EPA agrees that Hg (0) has an average ''residence time'' in the atmosphere of about 1 year and that Hg (II) may be deposited relatively quickly by wet and dry deposition processes, leading to a ''residence time'' of hours to months (Ref. 42a). But the shorter residence times noted for Hg (II) are due to physical transport from the medium, rather than irreversible transformations resulting in the destruction of chemical. Hg (0) released to the atmosphere is rapidly converted to Hg (II) through ozone-mediated oxidation. However, this is not an irreversible reaction, nor does it result in the destruction of the substance since the Hg (II) produced from oxidation of Hg (0) by ozone can be reduced back to Hg (0) by sulfite (Ref. 28a). The persistence of mercury will not be mitigated simply by redox reactions of Hg (0) to and from Hg (II). Whether as Hg (0) or as Hg (II), mercury persists in the environment. Environmental processes may cause it to change oxidation states or to be transported from one environmental medium to another; however, these processes will not destroy it.

EPA agrees that the report cited provides reasonable estimates of the fraction of mercury emissions from each source category that is likely to be in the form of Hg (II) versus the fraction as Hg (0). However, this information is not relevant to the assessment of the persistence of mercury and mercury compounds because persistence considers destruction only.

m. *Polychlorinated biphenyls*. In the proposal, EPA preliminarily determined that polychlorinated biphenyls (PCBs) have persistence half-life values in soil that ranged from 1 to 7 years and persistence half-life values in water that ranged from 56 to 98 days. EPA has reviewed information and all comments received on PCBs' persistence characteristics. Taking into account this information, as indicated in Table 3, EPA finds that PCBs persist in the environment with half-lifes of 2 months or greater and therefore meet the persistence criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical listing can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 7). In addition, all of the PCBs persist in the environment with a half-life of greater than 6 months which supports EPA's decision to lower the threshold to 10 pounds.

n. *Hexachlorobenzene*. In the proposal, EPA preliminarily determined that hexachlorobenzene has persistence half-life values in soil of 3 to 6 years. EPA has reviewed information and all comments received on hexachlorobenzene's persistence characteristics. Taking into account this information, as indicated in Table 3, EPA finds that hexachlorobenzene persists in the environment with a half-life of 2 months or greater and therefore meets the persistence criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and in EPA's support documents for this rulemaking (Ref. 7). In addition, hexachlorobenzene persists in the environment with a half-life of greater than 6 months which supports EPA's decision to lower the threshold to 10 pounds.

o. *Octachlorostyrene*. In the proposal, EPA preliminarily determined that OCS has persistence half-life values in soil of 3 to 6 years. EPA received one significant comment addressing OCS's persistence potential which is discussed below. EPA has reviewed information and all comments received on OCS's persistence characteristics. Taking into account this information, as indicated in Table 3, EPA finds that OCS persists in the environment with a half-life of 2 months or greater and therefore meets the persistence criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 7). In addition, OCS persists in the environment with a half-life of greater than 6 months which supports EPA's decision to lower the threshold to 10 pounds.

One commenter believes that OCS should not be considered to be a PBT chemical. The commenter admits that OCS has the potential to bioaccumulate and may theoretically persist in the environment, but cites falling environmental levels of OCS and the lack of evidence of human and environmental toxicity as justification for why OCS should not be considered to be a persistent, bioaccumulative and toxic chemical. The commenters contend that pentachlorobenzene and hexachlorobenzene are not good analogs for OCS.

EPA disagrees. As discussed in Unit VI.G., EPA believes that OCS meets the EPCRA section 313 toxicity criteria. Further, EPA believes that OCS is highly persistent. No measured half-life data for soil or water that met the standards for data acceptability could be located for octachlorostyrene (CAS No. 29082–74–4). Therefore, EPA used half-lifes for the structural analogs pentachlorobenzene (CAS No. 608–93–5) and hexachlorobenzene (CAS No. 118–74–1) for estimating half-lifes for OCS. EPA believes that pentachlorobenzene and hexachlorobenzene are good analogs for OCS because they, like OCS, are highly chlorinated benzene derivatives, which are structurally very similar. By analogy, OCS is expected to have a half-life in soil of greater than 6 months and greater than 2 days in air (Ref. 7). These half-lifes are sufficient to designate OCS as persistent using the criteria described in the proposed rule. EPA believes that its use of analog data is scientifically supportable because like OCS both analogs are highly chlorinated monocyclic aromatics.

EPA believes that the degree of toxicity as well as the degree of persistence and bioaccumulation are inherent to a chemical. The absolute level of a chemical in the environment does not affect its degree of persistence, bioaccumulation, or whether or not it has been shown to cause adverse effects to aquatic organisms. The absolute level in the environment is a factor of both how much is entering the environment and the persistence of the chemical in the environment. The degree to which a chemical is present in aquatic organisms is not only a measure of the BAF, but also inputs into the environment and

NMED Exhibit 72

persistence. The assertions made by the commenter do not support their contentions concerning the toxicity, persistence, or bioaccumulation of OCS.

p. *Pentachlorobenzene*. In the proposal, EPA preliminarily determined that pentachlorobenzene has persistence half-life values in soil of 194 days to more than 22 years. EPA received no significant comments addressing pentachlorobenzene's persistence potential. EPA has reviewed information and all comments on pentachlorobenzene's persistence characteristics. Taking into account this information, as indicated in Table 3, EPA finds that pentachlorobenzene persists in the environment with a half-life of 2 months or greater and therefore meets the persistence criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 7). In addition, pentachlorobenzene persist in the environment with a half-life of greater than 6 months which supports EPA's decision to lower the threshold to 10 pounds.

q. *Tetrabromobisphenol A*. In the proposal, EPA preliminarily determined that TBBPA has persistence half-life values in soil of 44 to 179 days and persistence half-life values in water of 48 to 84 days. EPA received several significant comments addressing TBBPA's persistence and discusses them below. EPA has reviewed information and all comments received on TBBPA's persistence characteristics. Taking into account this information, as indicated in Table 3, EPA finds that TBBPA persists in the environment with a half-life of 2 months or greater and therefore meets the persistence criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 7).

One commenter states that EPA's determination that TBBPA is persistent in the environment appears to be based upon a model which uses default data, that it is difficult to interpret EPA's methodology for applying its *EQC Model Output for Toxics Release Inventory PBT Rule Chemicals*, and it therefore is not clear how EPA arrived at the conclusion that TBBPA is persistent.

EPA disagrees that it is unclear how the EQC model was used in the assessment of chemical persistence and that EPA used only default data. EPA provided discussion on the conduct of the multimedia modeling in the document titled *EQC Model Output for Toxics Release Inventory PBT Rule Chemicals* (Ref. 33). EPA used chemical-specific input data (i.e., half-lifes in air, soil, water, and sediment and chemical properties) where available in all multimedia modeling runs. No default data were used in lieu of chemical-specific inputs. All chemical-specific inputs for each chemical were listed in this document. Further, EPA explained its use of the modified EQC model not only in the support document identified earlier, but also in the preamble to the proposed rule. In its description of the modeling EPA stated:

> Multimedia mass balance models offer the most convenient means to estimate overall environmental persistence from information on sources and loadings, chemical properties and transformation processes, and intermedia partitioning. For the chemicals included in this proposed rule EPA used the [modified] EQC model. . .to estimate overall environmental persistence. Overall persistence estimated in this way is used as an additional factor, in conjunction with reaction half-lifes for individual media, bioaccumulation/ bioconcentration factors, etc., in justifying actions proposed in this rule.

The EQC model is based on the fugacity approach first delineated by Mackay (Ref. 31) and subsequently applied to numerous environmental processes (Ref. 32). It uses an ''evaluative environment'' in which environmental parameters such as bulk compartment dimensions and volumes (e.g., total area, volume of soil and sediment) are standardized, so that overall persistence for chemicals with different properties and rates of transformation may be compared on an equal basis (Ref. 15). EPA used a version of the EQC level III model (Ref. 33) which was modified to focus on net losses by deleting model terms for advective losses (movement out of the evaluative environment of air and water potentially containing a chemical) and sediment burial (Ref. 82). In this version of the model only irreversible transformation contributes to net loss of a chemical.

The overall persistence obtained from this model is calculated as the total amount in the evaluative environment when steady state is achieved, divided by the total loss rate. The results thus obtained are neither an overall environmental half-life nor a compartment (or transformation)-specific half-life; rather they are equivalent to an environmental residence time. When only irreversible transformation contributes to net loss--i.e., under the conditions of this version of the EQC model--overall environmental persistence times can be converted to half-lifes by multiplying the former by ln 2 (i.e., 0.693). The overall half-life calculated in this way is for dissipation in the environment as a whole and cannot be related directly to any individual compartment.

In the analysis EPA used the highest, lowest and mean values for the ranges of half-lifes for soil, air, and water as inputs to the model. These half-lifes were collected from the literature from scientifically sound studies and were subject to data quality standards. The overall environmental persistence half-life for TBBPA calculated based on the EQC model was greater than 2 months but less than 6 months using the longest half-lifes for air, soil, water, and sediment. These results support EPA's assertion that the persistence of TBBPA in the environment will meet the EPCRA section 313 persistence criteria.

The commenter believes that TBBPA does not meet the persistence criteria for air. To support this contention the commenter refers to a study cited in a World Health Organization (WHO) document (Ref. 83). Specifically the commenter cites photodegradation studies that demonstrated that the half-life of TBBPA absorbed onto silica gel exposed to ultraviolet (UV) radiation was 0.12 day in air. In addition, the commenter contends that studies of the photolysis of TBBPA in the presence of UV light and hydroxyl radicals show that TBBPA was totally degraded within 5 to 6 days with an estimated 33–hour half-life. The commenter did not provide these studies or provide references to the original studies.

Further, the same commenter cites WHO EHC 172 (Ref. 83) for data on photodegradation to support the claim that TBBPA does not meet the persistence criteria for air. A review of the citation provided by the commenter reveals that it is a secondary reference taken from unpublished data from Bayer (Ref. 10). EPA was unable to review the full unpublished study to determine the quality of the data, only the summary found in the WHO document was available. In the WHO summary of the Bayer study TBBPA adsorbed onto silica gel and was exposed to ultraviolet irradiation at the 254 nanometer (nm) wavelength. Eight metabolites were detected and a half-life value of 0.12 days obtained. WHO noted that ''[i]t is difficult to derive environmental conclusions from the results of these experiments.''

EPA believes that the environmental relevance of the test results is doubtful.

While the experiment may demonstrate the potential for TBBPA to undergo photodegradation under laboratory conditions, the experimental conditions, to the extent they could be determined from the short summary provided, were not environmentally relevant.

In order for a molecule to undergo photochemical change it must absorb light. It is well known that only the transitions corresponding to ultraviolet/visible light absorption are inherently energetic enough to lead to chemical reactions. The wavelengths of importance for photochemical transformations is thus ultraviolet/visible light with a wavelength of 110 - 750 nm. When environmental photochemistry at or near the earth's surface is considered, the wavelengths of light of importance are further narrowed because the stratospheric ozone layer effectively prevents UV irradiation of less than 290 nm from reaching the earth's surface. Thus, only the light of the 290-750 nm wavelength absorbed by a molecule can potentially lead to photochemical changes of that molecule in the environment near the earth's surface. EPA believes that because the subject study utilized UV irradiation at the 254 nm wavelength, a wavelength that does not reach the earth's surface due to mitigation by stratospheric ozone, the half-life derived is not relevant and, therefore, cannot be used to determine the persistence of TBBPA in air.

The commenter also refers to studies of the photolysis of TBBPA in the presence of UV light and hydroxyl radicals in which TBBPA was shown to totally degrade within 5 to 6 days with an estimated 33–hour half-life. No additional information or references were provided to enable EPA to evaluate these findings for use in the characterization of the atmospheric half-life TBBPA.

The commenter contends that TBBPA's molecular structure makes it inherently biodegradable. The hydroxyl moiety on the TBBPA molecule can be readily transformed by organisms in the environment. The parent TBBPA molecule is no longer present once this biotransformation takes place. Therefore, based on TBBPA's structure alone, the Agency should consider TBBPA as unlikely to be environmentally persistent.

EPA disagrees with the statement that based on structure alone, the Agency should consider TBBPA as unlikely to be environmentally persistent. While EPA generally believes that measured values from well conducted studies are preferable to structure activity relationships (SAR) as an indicator of persistence, the Agency believes that it is possible to make some general statements about the biodegradability of TBBPA based on its structure.

Current knowledge of structure biodegradability relationships suggests that the presence of multiple bromines on an aromatic molecule adversely effects biodegradation. In fact, when the biodegradability of TBBPA is assessed with EPA structure activity relationship tools for predicting biodegradation from structure (Refs. 46 and 47), the presence of multiple aromatic bromines, a carbon with four single bonds, and the molecular weight of TBBPA are all structural features that reduce biodegradability. Therefore, even if EPA were to base its assessment of the persistence of TBBPA on its molecular structure, the Agency would conclude that it is not readily biodegradable.

The commenter contends that TBBPA will not meet the persistence criteria for water, soil, and sediment because TBBPA will biodegrade in these media. The commenter cites the results of several biodegradation studies as demonstrating that TBBPA is not persistent in these media. The commenter states that even though degradation studies have shown that TBBPA is not ''readily biodegradable'' (i.e., TBBPA is not mineralized to a significant extent by sewage sludge within 28 days) there are studies that indicate it is not persistent. Specifically, in studies submitted to EPA in 1989, TBBPA has been shown to be subject to biodegradation both in soil and sediment under aerobic or anaerobic conditions; TBBPA's estimated half-life derived from these studies is 50 days. In studies submitted by the Brominated Flame Retardants Industry Panel to EPA, TBBPA also was shown to undergo degradation in a sediment/water system with an estimated half-life of 48 to 84 days. (These data were reported under the Agency's TSCA Section 4 test rule.) The commenter argues that these data demonstrate that TBBPA does not meet most widely (and internationally) accepted criteria for persistence in soil or sediments (See Unit VI.B.) Therefore, TBBPA should not be considered to be persistent for purposes of EPCRA Section 313.

The commenter cites additional research conducted on the biodegradation of TBBPA under aerobic and anaerobic conditions in soil (Refs. 47) and asserts that the data indicate that ''TBBPA does not meet the most widely and internationally accepted criteria.'' EPA discusses its assessment of the Springborn soil biodegradation studies elsewhere in the Response to Comments document (Ref. 69). As explained earlier, the international persistence criteria are not relevant to the classification of persistence under the criteria adopted by the Agency, and EPA disagrees that TBBPA should not be considered persistent because it does not meet the ''most widely (and internationally) accepted'' criteria. (See Unit VI.B.)

The commenter makes the argument that TBBPA has been shown to be subject to biodegradation in soil and sediment under aerobic and anaerobic conditions with ''estimated'' half-lifes of 50 days. Although the commenter derived a biodegradation half-life, the method used to do so and the validity of the value could not be determined because no supporting information was provided. EPA questions the validity of the 50–day half-lifes estimated by the commenter on those grounds.

The commenter refers to two soil grab sample studies and a sediment/water microbial system study. These studies investigated the biodegradation of TBBPA in three different soil types in the presence (aerobic) and absence (anaerobic) of oxygen, and the biodegradation of TBBPA in a system containing sediment and river water in the presence of oxygen. In the aerobic soil studies less than 6% ultimate biodegradation (complete biodegradation to CO_2) was observed over the 64–day test period. The major portion of TBBPA remained in the soil. Analysis showed after 64 days 74 to 82% TBBPA remained in a Massachusetts sandy loam soil, 36 to 40% remained in an Arkansas silt loam, and 41 to 43% remained in a California clay loam soil. Over the course of the experiments, TBBPA either remained in soil undegraded, underwent minor structural changes (primary biodegradation), or to a very small extent (<6%), underwent complete biodegradation to CO_2. Individual values for evolved CO_2 in each soil type over time were not reported and biodegradation half-life values were not calculated. If it is assumed in the absence of values for CO_2 evolution at sampling times spaced evenly over the test period reported data, that TBBPA underwent a steady rate of degradation over the duration of the experiments, approximate half-lifes of 44 to 179 days can be estimated (Ref. 7).

Biodegradation half-lifes from the aerobic soil biodegradation experiments can be approximated. The half-life is defined as the amount of time necessary for the destruction of half of the chemical present in the medium. Given that the duration of the soil biodegradation test is 64 days (equivalent to greater than 2 months), a

NMED Exhibit 72

chemical that undergoes less than 50% biodegradation by the end of the test period would have a half-life of greater than 2 months and meet the EPCRA 313 persistence criteria for soil. In one of the soils in which TBBPA was tested (a Massachusetts sandy loam soil) 74 to 82% of the original TBBPA applied remained in the soil unchanged at the end of the 64–day test period. Thus, in this study, TBBPA was shown to have a half-life in soil of greater than 2 months since less than 50% degradation of TBBPA occurred in 64 days.

The biodegradation of TBBPA in the same three soils as above under anaerobic conditions in a 64–day test has also been studied. The results showed that 44 to 57% of the TBBPA applied to soil remained undegraded in the Massachusetts sandy loam soil after a 64–day test period, 53–65% in an Arkansas silt loam soil, and 90% in a California clay loam soil. Less than 50% destruction of the test chemical occurred over a 64–day (> 2 month) test period in all soils tested. Thus, in this study, TBBPA was shown to have a half-life in soil of greater than 2 months since less than 50% degradation of TBBPA occurred in 64 days.

Aerobic sediment water microbial test systems containing natural sediments and river water were used to measure degradation half-lifes for TBBPA in 56–day experiments. Half-lifes calculated for the biodegradation of TBBPA ranged from 48 to 84 days. Researchers found an apparent correlation between half-lifes and TBBPA concentration, and half-lifes and microbial concentrations. Thus, in this study, TBBPA was shown to have a half-life in sediment water systems of greater than 2 months when either the larger value or the mean of the two values is considered.

Further, the commenter claims that abiotic degradation of TBBPA in water also is expected. The calculated half-life of decomposition of TBBPA by UV radiation in water was 10.2 days in spring, 6.6 in summer, 25.9 in autumn, and 80.7 days in winter. Therefore, TBBPA is not expected to be persistent in water. No other information was provided.

The commenter cites WHO EHC 172 (Ref. 83) for data on photodegradation to support the claim that TBBPA does not meet the persistence criteria for water. In its review of the literature to evaluate the persistence of TBBPA, EPA found no information on its photodegradation in water. A review of the citation provided by the commenter reveals that it is a secondary reference taken from an unpublished study from Bayer (Ref. 10). EPA was unable to review the full unpublished study to determine the quality of the data. Only the summary found in the WHO document was available. The Bayer study on photodegradation in water yielded calculated half-lifes ranging from 6.6 days to 80.7 days with the longest half-life calculated during the winter, when solar irradiation is least intense and the shortest half-life occurring in the summer, when the solar irradiation is most intense. The commenter did not include the fact that the effect of cloud cover lengthened the calculated half-life by a factor of 2. Water depth was also found to influence the direct photodegradation of TBBPA. At the surface of a water body, solar irradiation is fairly uniform; however, as depth increases, both the water itself and materials in it can attenuate the transmission of solar energy through the water column. Irradiance has been shown to decrease by greater than 90% for both ultraviolet and visible light at a depth of 5 meters in a eutrophic lake (Ref. 52). EPA disagrees with the commenter's conclusion that TBBPA photodegradation in water will be sufficiently rapid that it will not meet the persistence criteria. Based on the study cited by the commenter which includes an 80–day (> 2 month) half-life for photodegradation of TBBPA in winter, and the mitigating effects of water depth and cloud cover on rates of photodegradation, EPA believes that a half-life of greater than 2 months in water is supported. EPA, therefore asserts that based on these findings, TBBPA meets the EPCRA section 313 persistence criteria of greater than 2 months in soil and water.

2. *Bioaccumulation*—a. *Dioxin and dioxin-like compounds*. In the proposal, EPA preliminarily determined that dioxin and dioxin-like compounds have BCF values that range from 1,259–42,500 with 6 chemicals over 5,000 and 6 chemicals between 3,500 and 5,000. EPA has reviewed information and all comments received on dioxin and dioxin-like compounds' bioaccumulation characteristics. As indicated in Table 3, EPA finds that dioxin and dioxin-like compounds bioaccumulate in the environment with BAF/BCF values greater than 1,000 and therefore meet the bioaccumulation criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical category can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 71). In addition, most of the members of the dioxin and dioxin-like compounds category bioaccumulate in the environment with a value close to, or well above, 5,000, which supports EPA's decision to lower the threshold to 0.1 gram.

b. *Aldrin*. In the proposal, EPA preliminarily determined that aldrin has a BCF value of 3,715. EPA has reviewed information and all comments received on aldrin's bioaccumulation characteristics. Taking into account this information, as indicated in Table 3, EPA finds that aldrin bioaccumulates in the environment with a BAF/BCF value greater than 1,000 and therefore meets the bioaccumulation criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 71).

c. *Chlordane*. In the proposal, EPA preliminarily determined that chlordane has a BCF value of 11,050. EPA has reviewed information and all comments received on chlordane's bioaccumulation characteristics. Taking into account this information, as indicated in Table 3, EPA finds that chlordane bioaccumulates in the environment with a BAF/BCF value greater than 1,000 and therefore meets the bioaccumulation criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 71). In addition, chlordane bioaccumulates in the environment with a BCF value greater than 5,000 which supports EPA's decision to lower the threshold to 10 pounds.

d. *Heptachlor*. In the proposal, EPA preliminarily determined that heptachlor has a BCF value of 19,953. EPA has reviewed information and all comments received on heptachlor's bioaccumulation characteristics. Taking into account this information, as indicated in Table 3, EPA finds that heptachlor bioaccumulates in the environment with a BAF/BCF value greater than 1,000 and therefore meets the bioaccumulation criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and in EPA's support documents for this rulemaking (Ref. 71). In addition, heptachlor bioaccumulates in the environment with a BAF/BCF value greater than 5,000 which supports EPA's decision to lower the threshold to 10 pounds.

NMED Exhibit 72

e. *Isodrin*. In the proposal, EPA preliminarily determined that isodrin has a BCF value of 20,180. EPA has reviewed information and all comments received on isodrin's bioaccumulation characteristics. Taking into account this information, as indicated in Table 3, EPA finds that isodrin bioaccumulates in the environment with a BAF/BCF value greater than1,000 and therefore meets the bioaccumulation criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 71). In addition, isodrin bioaccumulates in the environment with a BAF/BCF value greater than 5,000 which supports EPA's decision to lower the threshold to 10 pounds.

f. *Methoxychlor*. In the proposal, EPA preliminarily determined that methoxychlor has a BCF value of 8,128. EPA has reviewed information and all comments received on methoxychlor's bioaccumulation characteristics. Taking into account this information, as indicated in Table 3, EPA finds that methoxychlor bioaccumulates in the environment with a BAF/BCF value greater than 1,000 and therefore meets the bioaccumulation criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 71).

g. *Pendimethalin*. In the proposal, EPA preliminarily determined that pendimethalin has a BCF value of 1,944. EPA has reviewed information and all comments received on pendimethalin's bioaccumulation characteristics. Taking into account this information, as indicated in Table 3, EPA finds that pendimethalin bioaccumulates in the environment with a BAF/BCF value greater than 1,000 and therefore meets the bioaccumulation criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 71).

h. *Toxaphene*. In the proposal, EPA preliminarily determined that toxaphene has a BCF value of 34,050. EPA has reviewed information and all comments received on toxaphene's bioaccumulation characteristics. Taking into account this information, as indicated in Table 3, EPA finds that toxaphene bioaccumulates in the environment with a BAF/BCF value greater than 1,000 and therefore meets the bioaccumulation criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 71). In addition, toxaphene bioaccumulates in the environment with a BAF/BCF value greater than 5,000 which supports EPA's decision to lower the threshold to 10 pounds.

i. *Trifluralin*. In the proposal, EPA preliminarily determined that trifluralin has a BCF value of 5,674. EPA has reviewed information and all comments received on trifluralin's bioaccumulation characteristics. Taking into account this information, as indicated in Table 3, EPA finds that trifluralin bioaccumulates in the environment with a BAF/BCF value greater than 1,000 and therefore meets the bioaccumulation criterion. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 71).

j. *Polycyclic aromatic compounds*. In the proposal, EPA preliminarily determined that PACs have BCF values that ranged from 800 to 31,440 with 16 of the 21 members of the category having BCF values greater than 5,000. EPA received several comments concerning the PACs category listing and the bioaccumulation data which are addressed below. EPA has reviewed information and all comments received on PACs' bioaccumulation characteristics. Taking into account this information, as indicated in Table 3, EPA finds that PACs bioaccumulate in the environment with BAF/BCF values greater than 1,000 and therefore meet the bioaccumulation criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical category can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 71).

Three of the commenters support the retention of a single PACs category while one commenter believes that splitting the category into two categories would be the most appropriate option. Additional specific comments were as follows. One commenter stated that PACs are typically found as mixtures in incoming natural organic raw materials, such as coal and that it would be difficult to separate information into two reporting categories. Another commenter stated that reporting as one category is also more consistent with the Great Lakes Binational Toxics Strategy Level 2 listing for these chemicals. A commenter stated that the alternate proposal to create two PAC categories would be unnecessarily burdensome for the regulated community since reporting facilities would be required to speciate their PAC releases, and, if chemicals from both categories exceeded reporting thresholds, file two Form R reports, instead of one. One commenter stated that use of a single PACs category will simplify the reporting requirements; thus, it will reduce reporting burden. Several commenters stated that according to the proposed rule, 16 of the 21 members of the category had BCF values greater than 5,000 and that one proposal would regard the entire PACs category to be highly persistent and bioaccumulative, regardless of each individual PAC's actual persistence and bioaccumulative properties. Several commenters stated that they believed that splitting the category into two categories would be the most appropriate course. Another commenter stated that no chemical should be added to the highly persistent/bioaccumulative category when it does not fit the criteria and that in order to gain the most accurate information, two separate categories would be the superior solution. The commenter stated that lowering the reporting threshold for the PACs category to 10 pounds is unjustified considering that, according to EPA data, many of the individual PACs within the category do not meet the PBT criteria.

EPA considered splitting the PACs category into two or three categories or listings, but EPA believes, as do most of the commenters, that the most appropriate option is to retain a single PACs category. The PACs category was created because the members of the category are chemically and structurally very similar, share the same toxicological effect (carcinogenicity), and typically are produced, released, and otherwise managed as waste as complex mixtures rather than individual chemicals. As such it would be more difficult to estimate releases if the category were split into two or three categories based on the currently available bioaccumulation data. These reasons support retaining a single PACs category. EPA agrees with those commenters that stated that the retention of a single PACs category would be the simpler and less burdensome option. EPA also

NMED Exhibit 72

recognizes that, based on currently available information, not all members of the PACs category meet the highly persistence and highly bioaccumulative criteria. Of the 21 chemicals in the PACs category proposed for a lower threshold, 5 have BCF values that nominally do not meet the highly bioaccumulative criteria, while the rest exceed the highly bioaccumulative criteria. Given the structural similarities of the members of this category and the higher bioaccumulation values for 16 of the 21 PACs, the 5 BCF values below 5,000 may underestimate, to some extent, the bioaccumulation potential of these compounds. For purposes of this rulemaking, EPA is classifying the PACs category as persistent and bioaccumulative rather than highly persistent and highly bioaccumulative. Thus, the PACs category will have a reporting threshold of 100 pounds. However, the Agency will continue to assess the bioaccumulation potential of this category and specifically whether the lower bioaccumulation values for 5 members of the category are appropriate.

k. *Benzo(g,h,i)perylene*. In the proposal, EPA preliminarily determined that benzo(g,h,i)perylene has a BCF value of 25,420. EPA has reviewed information and all comments received on benzo(g,h,i)perylene's bioaccumulation characteristics. Taking into account this information, as indicated in Table 3, EPA finds that benzo(g,h,i)perylene bioaccumulates in the environment with a BAF/BCF value greater than 1,000 and therefore meets the bioaccumulation criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 71). In addition, benzo(g,h,i)perylene bioaccumulates in the environment with a BCF value greater than 5,000 which supports EPA's decision to lower the threshold to 10 pounds.

l. *Mercury and mercury compounds*. In the proposal, EPA preliminarily determined that mercury and mercury compounds have BCF values that ranged from 7,000 to 36,000. EPA has reviewed information and all comments received on mercury and mercury compounds' bioaccumulation characteristics. Taking into account this information, as indicated in Table 3, EPA finds that mercury and mercury compounds bioaccumulate in the environment with BAF/BCF values greater than 1,000 and therefore meet the bioaccumulation criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical category can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 71). In addition, mercury and mercury compounds bioaccumulate in the environment with a value above 5,000, which supports EPA's decision to lower the threshold to 10 pounds.

m. *Polychlorinated biphenyls*. In the proposal, EPA preliminarily determined that PCBs have BCF values that ranged from 4,922 to 196,900. All of the PCBs, except one, had BCF values far exceeding 5,000. The one exception, 2,3,3',4,4',5,5' heptachlorobiphenyl, had a BCF value of 4,922. EPA has reviewed information and all comments received on PCBs' bioaccumulation characteristics. Taking into account this information, as indicated in Table 3, EPA finds that PCBs bioaccumulate in the environment with BAF/BCF values greater than 1,000 and therefore meet the bioaccumulation criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical listing can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 71). In addition, with one exception, all of the PCBs listed bioaccumulate in the environment with a value far exceeding 5,000, which supports EPA's decision to lower the threshold to 10 pounds.

n. *Hexachlorobenzene*. In the proposal, EPA preliminarily determined that hexachlorobenzene has a BCF value of 29,600 to 66,000. EPA has reviewed information and all comments received on hexachlorobenzene's bioaccumulation characteristics. Taking into account this information, as indicated in Table 3, EPA finds that hexachlorobenzene bioaccumulates in the environment with a BAF/BCF value greater than 1,000 and therefore meets the bioaccumulation criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 71). In addition, hexachlorobenzene bioaccumulates in the environment with a BAF/BCF value greater than 5,000 which supports EPA's decision to lower the threshold to 10 pounds.

o. *Octochlorostyrene*. In the proposal, EPA preliminarily determined that OCS has a BCF value of 33,113. EPA received one significant comment addressing OCS's bioaccumulation potential which is discussed below. EPA has reviewed this comment and information on OCS's bioaccumulation characteristics. Taking into account this information, as indicated in Table 3, EPA finds that OCS bioaccumulates in the environment with a BAF/BCF value greater than 1,000 and therefore meets the bioaccumulation criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking. (Ref. 71). In addition, OCS bioaccumulates in the environment with a BAF/BCF value greater than 5,000 which supports EPA's decision to lower the threshold to 10 pounds.

One commenter argued that OCS should not be included in the EPCRA section 313 PBT chemicals list. The commenter contends that OCS was included as a PBT chemical simply because it appears on several lists of persistent and bioaccumulative chemicals and not based on a thorough evaluation of its bioaccumulation. The commenter states that OCS has the potential to bioaccumulate, but nonetheless, OCS levels in fish and aquatic species in the Great Lakes continue to decline. The commenter provides a report on the Great Lakes region and argues that OCS should not be considered a PBT chemical since environmental concentration data show OCS levels in the environment are decreasing at a rate of 8% to 30% per year.

EPA disagrees with the commenter's conclusions. The commenter does not dispute the bioaccumulation values EPA presented in the proposed rule. Rather the commenter agrees that OCS has the potential to bioaccumulate but contends that since environmental concentrations are declining in the Great Lakes region OCS should not be considered a PBT chemical. The fact that OCS levels in the Great Lakes region may be declining is not a basis for concluding that OCS is not a PBT chemical or that it cannot bioaccumulate. There are a number of reasons that could explain a decrease in environmental concentrations of OCS but they do not change the fact that OCS has been shown to be highly bioaccumulative. OCS was included as a PBT chemical because it meets the EPCRA section 313 criterion for bioaccumulation laid out in the proposed rule, not simply because it has appeared on several other lists of PBT chemicals.

p. *Pentachlorobenzene*. In the proposal, EPA preliminarily determined

NMED Exhibit 72

that pentachlorobenzene has a BCF value of 8,318. EPA has reviewed information and all comments received on pentachlorobenzene's bioaccumulation characteristics. Taking into account this information, as indicated in Table 3, EPA finds that pentachlorobenzene bioaccumulates in the environment with a BAF/BCF value greater than 1,000 and therefore meets the bioaccumulation criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 71). In addition, pentachlorobenzene bioaccumulates in the environment with a BAF/BCF value greater than 5,000 which supports EPA's decision to lower the threshold to 10 pounds.

q. *Tetrabromobisphenol A*. In the proposal, EPA preliminarily determined that TBBPA was found to have BCF values of 780; 1,200; and 3,200. EPA received one significant comment addressing TBBPA's bioaccumulation which is discussed below. EPA has reviewed the comments and information on TBBPA's bioaccumulation characteristics. Taking into account this information, as indicated in Table 3, EPA finds that TBBPA bioaccumulates in the environment with a BAF/BCF value greater than 1,000 and therefore meets the bioaccumulation criterion established in this rulemaking. A complete discussion of EPA's findings on this chemical can be found in EPA's Response to Comments document for this rulemaking (Ref. 69) and/or in EPA's support documents for this rulemaking (Ref. 71).

One commenter contends that the available data on TBBPA do not support its classification as a PBT chemical. The commenter argues that the oyster BCF value of 780 does not support the proposed criterion of 1,000. The commenter also notes that EPA fails to consider that TBBPA is not retained in the body once dosing stops in a BCF test and that TBBPA is rapidly eliminated. The commenter states that rapid elimination limits any potential for biomagnification. The commenter notes that only the highest chironomid BCF value (3,200) was cited by EPA and not the fact that this is from a range of 650–3,200.

EPA believes that the available data do support classification of TBBPA as a PBT chemical. Measured BCF values of 780, 1,200, and 3,200 were obtained from TSCA section 4 tests with oysters, fish and chironomids, respectively. The measured BCF values of 1,200 and 3,200 for fish and chironomids respectively, clearly satisfy the EPCRA section 313 bioaccumulatioin criterion of 1,000. EPA is aware that TBBPA will be eliminated from the body eventually once exposure to the chemical is halted; however, continuous or intermittent exposures of TBBPA to organisms may result in significant tissue residues depending on the exposure or release scenarios. The issue of biomagnification of TBBPA is not relevant to determining if TBBPA is a PBT chemical. As discussed in Unit VI.B.3., biomagnification is not required in order to have a concern for chemicals that bioaccumulate. The highest chironomid BCF value was listed because it is considered as a worst case indication of bioaccumulation in sediment-dwelling invertebrates.

I. Exemptions and Other Reporting Requirements

1. *De minimis exemption*. Many of the commenters assert that the initial reasons for adopting the *de minimis* exemption are still valid and that this exemption should be maintained for PBT chemicals. Specifically, several commenters contend that the *de minimis* exemption was initially adopted to alleviate undue burden on reporting facilities and that the elimination of this exemption for PBT chemicals will significantly increase the reporting burden for this rulemaking.

EPA disagrees with the commenters' contention that the initial reasons for adopting the *de minimis* exemption are valid for PBT chemicals. As originally explained in the 1988 final rule implementing the reporting provisions of EPCRA section 313, reiterated in the 1997 final rule adding seven new industry sectors, and discussed in the proposal to this final rule, EPA promulgated the *de minimis* exemption for several reasons, of which burden was only one. In addition to burden reduction, EPA promulgated the *de minimis* exemption because: (1) The Agency believed that facilities newly covered by EPCRA section 313 would have limited access to information regarding low concentrations of toxic chemicals in mixtures that are imported, processed, otherwise used or manufactured as impurities; (2) the Agency did not believe that these low concentrations would result in quantities that would significantly contribute to threshold determinations and release calculations at the facility (53 FR 4509); and (3) the exemption was consistent with information collected under the Occupational Safety and Health Administration's (OSHA) Hazard Communication Standard (HCS). If EPA had adopted the exemption only to reduce burden, the exemption would have covered all uses of *de minimis* quantities of the toxic chemical in mixtures. The exemption, however, includes only limited uses of the toxic chemical in mixtures (i.e., importing, processing, otherwise use, and manufacturing impurities) that were roughly tailored to whether EPA expected that facilities were reasonably likely to have information that would allow them to determine thresholds and make release calculations.

The purpose of the PBT rulemaking, however, is different from past rulemakings in that it is intended to capture information on significantly smaller quantities of releases and other waste management associated with these chemicals. Most of the PBT chemicals addressed in this rule have been shown to cause adverse effects at concentrations far less than the *de minimis* levels. For example, dioxins have been shown to cause adverse effects at levels in the parts per trillion. In addition, after 10 years of experience with the program, the Agency believes there are many sources of information in addition to material safety data sheets (MSDSs), readily available to reporters to use in making EPCRA section 313 determinations. Some of these sources of information include EPA guidance documents (e.g., *EPCRA Section 313 Industry Guidance: Electricity Generating Facilities* (EPA 745–B–99–003)) and trade association guidance documents (e.g., National Council of the Paper Industry for Air and Stream Improvement (NCASI) Technical Bulletins and NCASI's *Handbook of Chemical Specific Information for SARA Title III Section 313 Form R Reporting*). In addition, relevant information has become much more accessible to covered facilities over the past 10 years. For example, although the United States Geological Survey's U.S. Coal Quality Database has been in existence since the mid 1970s, only more recently has it been made available on the Internet. (http://energy.er.usgs.gov/products/databases/UScoal/index.htm). Further, the Agency believes that it underestimated how much information covered facilities had available to them in 1988 regarding small concentrations of toxic chemicals in mixtures. Therefore, given that: (1) Covered facilities have several sources of information available to them regarding the concentration of PBT chemicals in mixtures; (2) even minimal releases of persistent bioaccumulative chemicals may result in significant adverse effects and these small

NMED Exhibit 72

quantities can reasonably be expected to significantly contribute to the lower thresholds; and (3) the concentration levels originally chosen, in part, to be consistent with the OSHA HCS are inappropriately high for PBT chemicals, EPA believes that the reasons for the *de minimis* exemption that the Agency held for previous rulemakings do not apply to PBT chemicals.

A few commenters assert that reviewing each MSDS, when a facility may have many MSDSs for mixtures used on-site, to see if it includes trace quantities of PBT chemicals will be very time consuming. They contend that they do not have the manpower to track products on an individual basis looking for trace quantities of PBT chemicals and that these activities will be very burdensome.

EPA disagrees that eliminating the *de minimis* exemption for PBT chemicals will greatly increase burden under EPCRA section 313. Covered facilities are not required to report on toxic chemicals in mixtures and trade name products for which they have no concentration information or such information that is not reasonably known. However, if facilities do have information concerning the concentration of PBT chemicals in mixtures, such as on MSDSs, EPA does not believe it is more burdensome for facilities to identify and evaluate process streams containing relatively small quantities of PBT chemicals than for larger quantities of chemicals. Although some burden is associated with the identification and evaluation of process streams, EPA disagrees that the elimination of the *de minimis* exemption would vastly increase the extent of this required effort. Covered facilities will need to identify and evaluate process streams when considering a PBT chemical in concentrations below the *de minimis* level in the same manner they already do for toxic chemicals found in process streams in concentrations above the *de minimis* level. The additional burden can be attributed to resources spent considering and reporting on information they currently are allowed to disregard. Further, as explained above, EPA adopted the *de minimis* exemption for several reasons, of which burden reduction was only one, and EPA does not believe that these original reasons apply to this PBT rulemaking.

Some commenters assert that it is unrealistic for EPA to assume that industry will report only on what they know without making an effort to fill the data gaps and that enforcement actions could arise from reports based on only what is known to a facility.

EPA disagrees, however, because covered facilities are expected to have reasonable knowledge of the toxic chemicals present at their site and need only document their considerations concerning threshold determinations and release and other waste management calculations. As stated in EPCRA section 313(g)(2):

> [i]n order to provide the information required under this section, the owner or operator of a facility may use readily available data (including monitoring data) collected pursuant to other provisions of law, or, where such data are not readily available, reasonable estimates of the amounts involved. *Nothing in this section requires the monitoring or measurement of the quantities, concentration, or frequency of any toxic chemical released into the environment beyond that monitoring and measurement required under other provisions of law or regulation.* . . . (emphasis added)

Further, as stated previously, covered facilities are not required to report on toxic chemicals in mixtures and trade name products for which they have no concentration information, or for which such information is not readily available. Therefore, it is unlikely that facilities will have additional enforcement concerns.

Several commenters argue that the need to be consistent with the OSHA HCS that EPA cited in the 1988 final rule continues to be relevant with regards to collecting information on very small quantities.

EPA disagrees that the need to be consistent with OSHA to reduce burden is sufficient to justify retaining the *de minimis* exemption for PBT chemicals. EPA is not required to be consistent with the OSHA HCS. In 1988, EPA chose to be consistent with the OSHA HCS as part of its rationale for the exemption, because the Agency expected facilities to be familiar with these levels and thought that covered facilities might only have access to MSDSs for information on the content and percentage composition of toxic chemicals in mixtures. (See 53 FR 4509) However, EPA has never instructed facilities to stop looking if information concerning a toxic chemical is not on an MSDS. Rather, EPA has consistently instructed facilities to use their best readily available data in determining compliance with EPCRA section 313. As EPA explained earlier, given 10 years of experience with the program, the Agency believes that facilities may have other sources of information, in addition to MSDSs, available to them. Therefore, if a facility has better information regarding the concentration of a toxic chemical in a mixture, for example, that the chemical is above the *de minimis* level, the facility should be using that information to comply with EPCRA section 313. Further, EPA is consistent in some respects because under the OSHA HCS, if an employer has reason to believe that a permissible exposure limit for a component may be exceeded under the mixture's normal circumstances of use, the HCS also requires employers to list chemicals that are below the 1.0% and 0.1% thresholds. Therefore, OSHA adopted exceptions to the 1.0% and 0.1% limits under the HCS. Similarly, PBT chemicals are different from other toxic chemicals in that they may pose a more significant concern to the environment in much smaller quantities than other toxic chemicals. Furthermore, as explained in other responses in this unit, EPA believes the remainder of its rationale for the *de minimis* exemption is not applicable to PBT chemicals. For example, contrary to the commenter's statement, the small concentrations subject to the *de minimis* exemption are not necessarily small quantities and may contribute significantly to exceeding the lowered reporting thresholds.

Some commenters argue that the Agency has not justified why the exemption will result in increased health risk to the public or the environment. One commenter specifically argues that given the extremely low levels of these PBT chemicals in coal, the risk to the general public from these releases, which they believe is the original purpose of the legislation, is not apparent. Another commenter asserts that EPA must demonstrate that the removal of the exemption for specific PBT chemicals will have a public health or environmental benefit. Yet another commenter argues that the concentration of toxic chemicals contained in mixtures is irrelevant to public health concerns when the compounds of concern remain chemically bound within benign compounds.

EPA strongly disagrees with those commenters who indicated that EPA must consider risk to the general public when determining whether to eliminate the *de minimis* exemption. A primary purpose of the TRI program is to provide data on the releases (and other waste management activities) of listed toxic chemicals to communities so that they may use these data in conjunction with toxicity information for the chemical and site-specific information to determine if releases present a potential risk. They can also use TRI data in other ways. For example, an individual can use TRI data as a factor

NMED Exhibit 72

in choosing a neighborhood in which to live. The purpose of TRI, however, is not to make a national determination of risk, nor did EPA consider risk in its original adoption of the *de minimis* exemption under EPCRA section 313.

Moreover, as previously explained, EPA originally promulgated the *de minimis* exemption based on several considerations that are inapplicable to PBT chemicals. Where, as here, the rationale and factual bases underlying an exemption no longer exist with respect to a particular class, the Agency believes it cannot justify retaining the exemption for that class. Further, the Agency has received no information from any commenters that contradicts the Agency's factual and legal conclusions, or that would otherwise present a basis for retention of the *de minimis* exemption.

EPA also disagrees with the comment that because there are very low levels of PBT chemicals (e.g., mercury) in coal that the risk to the general public is not apparent. EPA believes that the commenter misunderstands the concept of risk. Because a chemical is in a low concentration in coal does not in itself control the level of risk that can result when coal is combusted. For example, mercury compounds are found in very low concentrations in coal. When coal is combusted, mercury compounds are either converted into mercury chloride or reduced to elemental mercury. Some of the mercury/mercury chloride is released to air and some remains in the bottom ash. The concentration of the mercury/mercury chloride in the air wastestream will not be the same as the concentration originally present in the coal. Once the mercury/mercury chloride is released, it will be carried varying distances before it is deposited. Mercury can be transported over large distances, while mercury chloride may be deposited relatively rapidly by wet and dry deposition processes. The amount of mercury in a community or ecosystem will depend upon sources both local and distant. Once mercury has been deposited, it will bioaccumulate in organisms and will also persist in the environment as a sink for exposure and bioaccumulation. The amount of mercury that a human, animal, or plant will be exposed to is related more closely to exposure pathways and the quantity that is present in an ecosystem rather than the concentration in the coal that is combusted. Thus, EPA believes that the commenter is incorrect.

One commenter asserts that the elimination of the *de minimis* thresholds would not yield meaningful additional information. The commenter argues that the proposed rule vastly overstates the significance of TRI data and therefore incorrectly concludes that the *de minimis* thresholds would ''deprive communities of important information on PBT chemicals'' (at 64 FR 714). Instead, the commenter contends, TRI data only provide a snapshot view of releases from the chemical industry and the few other industry sectors subject to TRI reporting and that many potential release sources are not subject to TRI reporting. The commenter argues that these sources overwhelm the limited additional information that will be reported by eliminating the *de minimis* exemption.

EPA disagrees that the proposed rule vastly overstates the significance of the TRI data. The public, all levels of government, and the regulated community have come to rely on TRI data in improving decision-making, measuring pollution prevention, and understanding the environmental and health consequences of toxic chemical releases and other waste management activities. Although the Toxics Release Inventory does not contain a complete inventory of every release, EPA believes it does provide one of the most comprehensive and accessible sources of release and other waste management information available. EPA also disagrees with the commenter's assertion that the data base only contains information from the chemical industry and a few others. In fact, all 20 manufacturing industry groups as well as an additional 7 other industries including metal and coal mining facilities and hazardous waste management facilities are subject to EPCRA section 313. Further, with the addition of these 7 newly covered industries, EPA expects over 27,500 facilities to submit over 110,000 reports on more than 630 toxic chemicals to the TRI for the 1998 reporting year. Currently no other sources of information can provide releases and information on other waste management quantities and qualitative source reduction data with the scope, level of detail, and chemical coverage as data currently included in TRI.

Further, as EPA has previously explained, PBT chemicals can remain in the environment for a significant amount of time and can bioaccumulate in animal tissues. Even relatively small releases of such chemicals have the potential to accumulate over time and cause significant adverse impacts on human health and the environment. Therefore, EPA believes it is particularly important to gather and disseminate to the public relevant information on even relatively small amounts of releases and other waste management of PBT chemicals. Under the 10,000 and 25,000 pound/year reporting thresholds, a significant amount of the releases and other waste management activities involving PBT chemicals are not being captured and thus the public does not have the information needed to determine if these chemicals are present in their communities at levels that may pose a significant risk.

Several commenters argue that the *de minimis* exemption already does not apply to the manufacture of a toxic chemical unless the toxic chemical is manufactured as an impurity or is imported. Therefore, any incidental manufacturing of a PBT chemical as a by-product would not be eligible for the *de minimis* exemption and would be subject to reporting. Thus, they argue, the elimination of the exemption will provide little additional information and will not provide added value.

The commenters are correct in stating that there are instances where PBT chemicals are manufactured as by-products and would, therefore, not be affected by the elimination of the *de minimis* exemption. However, as EPA explained in the PBT proposal, there are also many instances where a PBT chemical may exist in a mixture or trade name product at a concentration below the 1% or 0.1% *de minimis* limit but where the processing or otherwise use of the PBT chemical in that mixture would otherwise contribute significantly to or in itself exceed the reporting thresholds (at 64 FR 714). For example, mercury can be found at very low concentrations in steel. A resmelting facility could process and release more than 100 pounds of mercury a year from its resmelting activities. However, although this total quantity is greater than the 10 pound proposed threshold for mercury, if the concentration of mercury in the steel is less than the *de minimis* limit, none of the mercury would be reportable if the *de minimis* level is retained for PBT chemicals. Releases and other waste management associated with these exempt activities would be absent from the TRI data base. Because even minimal releases of PBT chemicals may result in elevated concentrations in the environment or in an organism and can have the potential to cause an adverse effect, EPA believes that all releases of these chemicals are of concern and that such information is significant and of value to the public.

a. *Readily available data.* Some commenters assert that the elimination of the *de minimis* exemption will conflict with the condition that reporters obtain data from readily

NMED Exhibit 72

available sources. They argue that because concentrations below 1% (and 0.1% for carcinogens) are not required on MSDSs, reporters will no longer be able to use MSDSs to screen for products containing PBT chemicals below these concentrations. They further contend that AP-42 guidance, Air CHIEF CD-ROM, TANKS, CHEMDAT8 and WATER8 would provide additional assistance in estimating the amount of a PBT coincidentally manufactured in wastestreams or released; however, these tools will not help quantify the amount of chemical in materials which are distributed in commerce or used as feedstock. They assert that there are no other consistent sources of information on whether a product contains a PBT chemical below *de minimis* levels. They also assert that the elimination of the *de minimis* exemption will cause additional burden for the regulated community because covered facilities will struggle with how to comply in the absence of information.

The Agency believes that since reporting first began in 1988, new sources of information have become available to covered facilities to use to determine concentrations of toxic chemicals in mixtures. In addition to the data bases and information sources cited by the commenter, EPA believes there are other sources of data that can and should be used in making threshold determinations and release and other waste management calculations for PBT chemicals. Examples of these sources of information include EPA guidance documents (e.g., *EPCRA Section 313 Industry Guidance: Electricity Generating Facilities* (EPA 745–B–99–003)) and trade association guidance documents (e.g., National Council of the Paper Industry for Air and Stream Improvement (NCASI) Technical Bulletins and NCASI's *Handbook of Chemical Specific Information for SARA Title III Section 313 Form R Reporting*). In addition, relevant information has become much more accessible to covered facilities over the past 10 years. For example, the United States Geological Survey's U.S. Coal Quality Database has been in existence since the mid 1970s, but only more recently has it been made available on the Internet. (http://energy.er.usgs.gov/products/databases/UScoal/index.htm) EPA believes that these tools, in addition to the ones cited by the commenter, will help covered facilities quantify the amount of chemical in materials which are distributed in commerce or used as feedstock and will allow covered facilities to make reasonable calculations to comply with EPCRA section 313. Further, the Agency believes that it underestimated how much information covered facilities had available to them in 1988 regarding small concentrations of toxic chemicals in mixtures. Therefore, EPA believes that facilities have sufficient information to make threshold determinations and release and other waste management calculations for PBT chemicals below *de minimis* concentrations. However, as EPA explained above, if a covered facility has no information, including no reasonable estimates or other reasonably known information, on the concentration of the toxic chemical in the mixture, they need not consider the chemical in that mixture for threshold determinations and release and other waste management calculations (at 53 FR 4511). Therefore if the only source of information on a toxic chemical in a mixture is from an MSDS, and the MSDS does not indicate if the chemical is contained in the mixture, the facility is not required to consider the toxic chemical towards threshold determinations or release and other waste management calculations.

Because some facilities covered under EPCRA section 313 have more extensive information available to them than they did in 1988, or EPA underestimated how much information they had available in 1988, and because these facilities are not required to report if they have no information on the concentration of the toxic chemical, the Agency believes that in these cases retention of the *de minimis* exemption would allow facilities to avoid reporting when information is available to them that would otherwise permit them to report.

Some commenters assert that facilities will have to begin monitoring for trace quantities of chemicals in mixtures if the *de minimis* exemption is eliminated for PBT chemicals. One commenter argues that the only way facilities would be able to estimate the levels of dioxin in combustion products and wastewater treatment ''would be to undertake the costly burden of monitoring what comes off at a series of concentrations and temperatures.'' Another commenter asserts that if the *de minimis* level is eliminated, industry would be subject to increased enforcement action because exhaustive testing may be insufficient to detect the chemicals.

EPA disagrees with the commenters because, as stated previously, EPCRA section 313(g)(2) limits monitoring requirements under EPCRA section 313. Under this section, facilities are not required to perform any additional monitoring or analysis of production, process or use other than that already collected under other requirements. However, if a facility is required to monitor toxic chemicals under another statute, this data must be considered in determining thresholds and release and other waste management calculations under EPCRA section 313. EPCRA section 313(g)(2) requires that facilities use readily available data, or in absence of such data, facilities are required to use reasonable estimates. If no monitoring data are available, the facility should use other readily available information in making threshold determinations and release and other waste management calculations. Further, if the facility believes that it has other, more representative data than its monitoring data, the facility should use that information instead.

As to specifically tracking PBT chemicals in wastewater, the commenter does not specify whether the toxic chemicals discussed in the comment are manufactured as by-products, are processed, or otherwise used. As discussed above, the *de minimis* exemption does not apply to toxic chemicals manufactured as by-products. Therefore, if PBT chemicals are coincidentally manufactured during on-site wastewater treatment, covered facilities would be required to consider those PBT toxic chemicals for threshold determinations and release and other waste management calculations even if the *de minimis* exemption were retained for PBT chemicals. Similarly, PBT chemicals manufactured as a result of burning fuel would not be exempt even if the *de minimis* exemption were retained because manufactured by-products are not eligible for this exemption. PBT chemicals in below *de minimis* concentrations in mixtures that are imported, processed, or otherwise used will be affected by the elimination of the *de minimis* exemption. Covered facilities will need to consider these quantities towards threshold determinations and release and other waste management calculations. These calculations would include the amounts contained in combustion by-products and wastewater treatment units. Additional monitoring of these quantities, however, would not be required under EPCRA section 313. Finally, EPA has limited the dioxin listing with the qualifier ''manufacturing; and the processing or otherwise use of dioxin and dioxin-like compounds if the dioxin and dioxin-like compounds are present as contaminants in a chemical and if they were created

during the manufacturing of that chemical.'' Therefore, not all processing or otherwise use activities of the dioxin and dioxin-like compounds category must be considered towards a facility's threshold determinations.

Some commenters assert that EPA should maintain the *de minimis* exemption for PBT chemicals present as impurities. They argue that information on PBT chemicals present as impurities is not readily available and that obtaining the relevant data, conducting the initial reviews to determine what information is available, and identifying data gaps would impose a huge burden on industry. They argue that even developing estimates with any accuracy entails a significant amount of time. In the instance of impurities, they assert that the absence of data and the difficulty in developing estimates will result in a heavy burden with little information of value being reported. These commenters believe that the elimination of the *de minimis* level is a requirement to provide new data when utilizing the *de minimis* exemption.

EPA disagrees with these commenters. Although there are burdens associated with obtaining relevant data, determining available information and identifying data gaps, EPA disagrees that the elimination of the *de minimis* exemption for PBT chemicals present as impurities would vastly increase the extent of this required effort. From the comment, it is unclear why requiring facilities to identify and evaluate process streams containing small quantities of PBT chemicals as impurities is more burdensome than for larger quantities of these chemicals manufactured, processed, or otherwise used at a covered facility in excess of the activity thresholds. For example, a facility monitors for chemical A at a concentration of greater than 0.001% and monitors for chemical B at a concentration of greater than 1.5%. The monitoring is done for the same wastestream and the same frequency. There is no differential in effort or burden. Currently, the only difference is that facilities can ignore available data when utilizing the *de minimis* exemption.

One commenter asserts that the *de minimis* exemption should be retained for PBT chemicals present at mining facilities. The commenter argues that the burden upon the mining industry is even greater in the context of the low thresholds proposed for PBT chemicals. Further, the commenter asserts that although EPCRA does not require covered facilities to conduct tests concerning the amount of listed chemicals processed, most reporters rely upon their knowledge of their manufacturing processes and raw materials to produce meaningful data for EPCRA section 313 reporting purposes. The commenter contends that this is not true of the mining industry. Due to the volume of materials moved in the extraction process and the heterogeneous nature of the materials mined, process knowledge often is inadequate to produce a meaningful picture of the minute levels of PBT chemicals that may be present in mining operations. The commenter asserts that inadequate process knowledge combined with the enormous expense of constantly testing the processed materials makes the elimination of the *de minimis* exemption for PBT chemicals unworkable as applied to mining operations.

EPA disagrees with the commenter. As the commenter points out, under EPCRA section 313(g)(2), facilities are not required to perform any additional monitoring or analysis of production, process, or use other than that already collected under other statutory or regulatory requirements. Therefore, there should be no added cost due to testing to comply with EPCRA section 313. However, EPA believes that in many cases mining facilities have the information needed to make reasonable estimates regarding small concentrations of PBT chemicals in the ores mined. In addition, as EPA explained in the 1988 final rule, if a covered facility has no information on the concentration of the toxic chemical in the mixture, including no reasonable estimates, the facility need not consider the chemical in that mixture for threshold determinations and release and other waste management calculations. If a mining facility does have information regarding the concentration of a toxic chemical in a mixture or trade name product, the facility must consider all non-exempted sources of the chemical for threshold determinations. If an activity threshold is exceeded for the chemical, the facility must then calculate release and other waste management quantities. Covered mining facilities will need to identify and evaluate process streams when considering a PBT chemical in concentrations below the *de minimis* level just as they already do for toxic chemicals found in process streams in concentrations above the *de minimis* level. Therefore, given that covered facilities: (1) Are not required to perform additional monitoring; (2) are not required to consider concentrations of toxic chemicals for which they have no information; and (3) need only consider readily available data, EPA disagrees that identifying and evaluating mining activities involving mixtures containing less than 1.0% or 0.1% concentrations of PBT chemicals will be more burdensome than for larger quantities of these chemicals manufactured, processed, or otherwise used at a mining facility in excess of the activity thresholds.

b. *Alternate de minimis level.* Several commenters argue that in lieu of eliminating the *de minimis* exemption for PBT chemicals, it would make more sense to change the level for the *de minimis* exemption for these chemicals. Some commenters argue that a more appropriate approach would be to compare the current thresholds and the current *de minimis* levels and use the same ratio to create a new *de minimis* level for the lowered PBT chemical thresholds. Therefore, they argue, the existing level is 1% for a threshold of 10,000 pounds, so an analogous reduction of the *de minimis* level would be 0.01% for the new proposed threshold of 100 pounds and 0.001% for the new proposed threshold of 10 pounds per year and 1 ppb for dioxins. One commenter argues that the current *de minimis* level of 0.1% for known or suspected carcinogens is not appropriate for dioxins. They suggest that EPA lower the *de minimis* exemption for dioxins proportionally to the lower reporting threshold EPA sets in the final rule. They assert that a reporting threshold for dioxins of 0.002 pound TEQ (not the threshold in the PBT proposal nor the one that EPA is finalizing today), is approximately seven orders of magnitude less than the current 10,000 pound threshold. Therefore, they argue, the 0.1% *de minimis* exemption should be lowered proportionally to 1×10^{-8}%. This translates to a concentration of 100 parts per trillion.

EPA disagrees with these commenters. As explained previously, EPA adopted the *de minimis* exemption for several reasons including the desire to be consistent with information mandated by the OSHA HCS. This OSHA standard requires the listing of hazardous chemicals on MSDSs but allows chemical suppliers to omit from the MSDSs hazardous chemicals that are below certain concentrations: Specifically, levels of 0.1% for OSHA carcinogens and 1.0% for other hazardous chemicals. However, the rationale for the OSHA HCS *de minimis* exemption is not relevant to PBT chemicals and therefore, is insufficient by itself to support an alternative *de minimis* exemption for PBT chemicals.

NMED Exhibit 72

As explained in the 1983 final rule, OSHA chose the 1.0% concentration limit based on comments that this level seemed to be sufficiently protective of workers and was considered to be reasonable by a number of commenters (48 FR 53280, at 53290, November 25, 1983). OSHA was also persuaded by comments that in some instances the 1.0% cut-off levels may not be protective enough with respect to certain health hazards and adopted the 0.1% level for carcinogens (at 48 FR 53292). Specifically, PBT chemicals are of concern because they persist and bioaccumulate in the environment. Persistence and bioaccumulation were not considered as a part of the OSHA rulemaking. In addition, as explained in other responses in this unit, EPA's original rationale for this exemption is inapplicable to PBT chemials, and the commenters have provided no alternate rationale to support an exemption based on extrapolating new *de minimis* levels from the proposed thresholds. Therefore, given the different intents between the OSHA HCS and EPCRA section 313, EPA does not believe that creating alternative *de minimis* levels for PBT chemicals based on a ratio between the lowered threshold and the OSHA HCS levels is appropriate.

Several commenters support EPA's elimination of the *de minimis* exemption for PBT chemicals. They assert that retention of the *de minimis* exemption would undermine the changes to the reporting threshold and would allow an unnecessary loophole from reporting. They assert that the rule does not require any additional testing for impurities and that the only additional reporting would be for those facilities that use sufficient quantities of mixtures or trade name products containing PBT chemicals as impurities. One commenter asserts that one of the original reasons for the *de minimis* exemption levels, that it was based on OSHA HCS thresholds of 1.0% for hazardous chemicals in mixtures and 0.1% for carcinogens in mixtures, does not apply to raw materials that are not manufactured chemicals, such as crude oil, coal, and mining inputs.

EPA agrees with these commenters and is eliminating the *de minimis* exemption for PBT chemicals addressed in today's rule. As discussed above, the reasons EPA indicated for originally adopting the *de minimis* exemption are not applicable to PBT chemicals. In addition, EPA has received no compelling arguments from commenters to extend the *de minimis* exemption to PBT chemicals. Because the purpose of today's rulemaking is different from past rulemakings in that it is intended to capture information on significantly smaller quantities of releases and other waste management associated with these chemicals, the *de minimis* exemption could significantly limit the amount of reporting on PBT chemicals. Therefore, given that: (1) Covered facilities have several sources of information available to them regarding the concentration of PBT chemicals in mixtures; (2) even minimal releases of persistent bioaccumulative chemicals may result in significant adverse effects and can reasonably be expected to significantly contribute to the proposed lower thresholds; and (3) the concentration levels chosen, in part, to be consistent with the OSHA HCS are inappropriately high for PBT chemicals, EPA believes that the reasons for the *de minimis* exemption that the Agency held for previous rulemakings do not apply to PBT chemicals. EPA is therefore eliminating the *de minimis* exemption for PBT chemicals.

c. *Supplier notification*. Several commenters were confused by EPA's failure to modify the *de minimis* exemption for PBT chemicals under the supplier notification requirements. As explained in the PBT proposal, the Agency believes that covered facilities have sufficient information available to them on PBT chemicals. The requirement of additional information under the supplier notification requirements would result in redundancies. Commenters that correctly understood EPA's inaction on this topic support the retention of the *de minimis* exemption for purposes of Subpart C Supplier Notification Requirements under 40 CFR 372.45(d)(1). EPA agrees with these commenters and has therefore taken no action on the supplier notification requirements for PBT chemicals.

2. *Other exemptions*. Although the Agency received several comments regarding the existing exemptions, EPA is not modifying any of these exemptions in this rule. Any changes to these exemptions would require additional rulemaking, and any comments submitted to EPA during this rulemaking will be considered as part of EPA's evaluation of these exemptions.

3. *Use of alternate threshold and Form A*. One issue that commenters raise relates to EPA's proposal to exclude all PBT chemicals from the alternate threshold of 1 million pounds for PBT chemicals. Several commenters argue that EPA should retain the alternate threshold of 1 million pounds for PBT chemicals. EPA disagrees. As stated in detail in the proposal, EPA believes that use of the existing alternate threshold and reportable quantity for Form A would be inconsistent with the intent of expanded PBT chemical reporting. The general information provided on the Form A, on the quantities of the chemical that the facility manages as waste is insufficient for conducting meaningful analyses on PBT chemicals.

A commenter states that because PACs in fuel are destroyed during combustion, EPA should retain the alternate threshold or provide a new alternate threshold. First, the commenter did not provide any information to support the contention that PACs in fuel are destroyed during combustion. And, to the contrary, EPA believes that, even if some or all of the PACs in fuel are destroyed during combustion, additional PACs may be created during the combustion process. Consequently, absent any information to support the basis for such an option, or the need for an alternate threshold, EPA does not believe it would be appropriate at this time to provide a new alternate Form A threshold. Although EPA solicited comments on this issue in the proposal, at this time, the Agency believes that it is appropriate to collect and analyze several years worth of data at the lowered thresholds before EPA considers developing a new alternate threshold and reportable quantity appropriate for PBT chemicals.

In addition, the commenter also appears to be raising a broader issue than just the destruction of PACs during combustion. The commenter implies that when a facility estimates its releases to be zero, the facility should be eligible to use the Form A. However, the commenter appears to misunderstand how to calculate the amounts required to determine eligibility for the Form A. Facilities may use the Form A provided that they do not exceed 500 pounds for the total annual reportable amount for a chemical, and that their amounts manufactured or processed or otherwise used do not exceed 1 million pounds. The annual reportable amount is equal to the combined total quantities released at the facility, treated at the facility, recovered at the facility as a result of recycle operations, combusted for the purpose of energy recovery at the facility, and amounts transferred from the facility to off-site locations for the purpose of recycle, energy recovery, treatment, and/or disposal. The commenter only appears to consider their releases as reportable amounts and does not appear to consider quantities generated from their other waste management activities as reportable amounts. This additional waste management information on PBT chemicals is very important to

NMED Exhibit 72

communities because it helps them understand the quantities of EPCRA section 313 chemicals that are being transported through their communities, the destination of these EPCRA section 313 chemicals, as well as the reported waste management activity at the receiving facility. In conclusion, EPA has not proposed to disregard this waste management information in calculating the annual reportable amount, therefore the commenter's approach is not consistent with current reporting under Form A or appropriate as an approach for reporting on PBT chemicals.

The commenter also states that the alternate threshold should be retained in order to ensure that only meaningful amounts of substances are reported under EPCRA section 313. EPA disagrees that retention of the alternate threshold would ensure that only meaningful information is reported under EPCRA section 313. The 500 pound waste eligibility could be interpreted by some data users, as a worst case, to mean that greater than 500 pounds of the chemical has been released into the environment (i.e., 500 pounds of production-related waste as release and some quantity of catastrophic release). Other data users may assume that the facility had no catastrophic releases and all of the toxic chemical in waste was managed in a manner other than as a release, e.g., the toxic chemical in waste was recycled. For PBT chemicals where any release is a concern, an uncertainty level of 500 pounds may result in data that is virtually unusable. As a result, EPA does not agree with the commenter that the alternate threshold will ensure that only meaningful amounts of substances will be reported under EPCRA section 313.

In addition, the commenter argues elimination of the alternate threshold for PBT chemicals will cause reporting burdens to increase while failing to provide for the collection of substantial additional release information. EPA's economic analysis used reporting costs for the Form R to estimate the costs to those facilities that would not be able to use the alternate threshold. The economic analysis also evaluated the benefits of the collection of additional release and other waste management of PBT chemicals (Ref. 67). The commenter does not dispute those estimates. As a result, EPA sees no compelling argument to revise its decision to exclude all PBT chemicals from the alternate threshold of 1 million pounds.

A number of commenters argue that EPA should eliminate the alternate threshold of 1 million pounds for all PBT chemicals on the EPCRA section 313 list. One commenter asserts that in light of the relatively small quantities of concern for PBT chemicals, particularly those with no deliberate commercial manufacture, it makes little sense to retain the Form A. The commenter further states that it believes that a modified Form A would be inappropriate due to the concern over releases of these chemicals at low levels. Another commenter adds that the Form A is clearly inappropriate for chemicals that will now have thresholds significantly lower than the 500 pound waste generation level. The commenter further contends that it is not appropriate for EPA to set a new Form A threshold for PBT chemicals, given the need to collect more information on these substances.

EPA agrees with the commenters that all PBT chemicals should be excluded from the alternate threshold of 1 million pounds. As stated in detail in the proposal, EPA believes that use of the existing alternate threshold and reportable quantity for Form A would be inconsistent with the intent of expanded PBT chemical reporting (at 64 FR 715–716). The general information provided in the Form A on the quantities of the chemical that the facility manages as waste is insufficient for conducting meaningful analyses on PBT chemicals.

EPA also agrees that a new alternate threshold for PBT chemicals would be inappropriate due to the concern over releases and other waste management of these chemicals at low levels. As stated in the proposal, even small quantities of persistent bioaccumulative chemicals may cause elevated concentrations in the environment and organisms that may cause significant adverse effects. Given the persistent and bioaccumulative nature of these chemicals and the need for the public to have information about smaller amounts of these PBT chemicals, EPA believes it would be inappropriate at this time to allow an option that would exclude significant information on some releases and other waste management of these chemicals.

In response to EPA's proposal to exclude all PBT chemicals from the alternate threshold of 1 million pounds, one commenter argues that EPA should consider establishing a new alternate reporting threshold for these chemicals. The commenter states that, at a minimum, an alternate reporting threshold of 10 to 100 pounds would be consistent with the throughput-reporting threshold proposed for all PBT chemicals except dioxins. The commenter further states that the SBA's analysis suggests significant reductions in burden associated with alternate reporting thresholds of 50 pounds for PBT chemicals. The commenter states that, based on an SBA study commissioned of petroleum bulk plants, which it estimates will be the largest group of reporters under this proposal, it finds that most of the reports avoided by this alternate threshold would reflect zero releases.

EPA disagrees with the comment suggesting that a new alternate threshold be established for PBT chemicals. As stated in the proposal, even small quantities of persistent bioaccumulative chemicals may cause elevated concentrations in the environment and organisms that may cause significant adverse effects. Given the persistent and bioaccumulative nature of these chemicals and the need for the public to have information about smaller amounts of these PBT chemicals, EPA believes it would be inappropriate at this time to allow an option that would exclude significant information on some releases and other waste management of these chemicals. The general information provided in the Form A on the quantities of the chemical that the facility manages as waste is insufficient for conducting meaningful analyses on PBT chemicals. Therefore, EPA does not agree that a new alternate threshold for PBT chemicals should be established.

The commenter also suggests that reporting burdens will increase while failing to provide for the collection of substantial additional release information. EPA's economic analysis used reporting costs for the Form R to estimate the costs to those facilities that would not be able to use the alternate threshold. The economic analysis also evaluated the benefits of the collection of additional release and other waste management of PBT chemicals (Ref. 67). The commenter does not dispute those estimates. As a result, EPA sees no compelling argument to revise its decision to exclude all PBT chemicals from the alternate threshold of 1 million pounds.

4. *Data precision issues*—a. *Use of significant digits, half pound and whole numbers*. EPA proposed to require reporting of all releases and other waste management quantities of PBT chemicals (except dioxin) that are greater than 1/10 of a pound, provided that the accuracy in the underlying data on which the estimate is based supports this level of precision. EPA further stated that releases and other waste management quantities would continue to be reported to two significant digits. In addition, EPA stated that for quantities of 10 pounds or greater, only

NMED Exhibit 72

whole numbers would be required to be reported. For the category of dioxin and dioxin-like compounds, which have a proposed reporting threshold of 0.1 gram, EPA proposed that facilities report all releases and other waste management activities greater than 100 µg (i.e., 0.0001 gram).

After reviewing all comments on this issue, EPA is providing the following guidance on the level of precision covered facilities should use to report their releases and other waste management quantities of PBT chemicals. Facilities should continue to report releases and other waste management amounts greater than 1/10 of a pound (except dioxin), at a level of precision supported by the accuracy of the underlying data and the estimation techniques on which the estimate is based.

This approach is consistent with the statutory reporting requirements when estimating reportable amounts. The statute requires facilities to, among other things, report ''[t]he annual quantity of the toxic chemical entering each environmental medium.'' (42 U.S.C. 11023(g)(1)(C)(iv)). To determine this ''annual quantity,'' the statute directs facilities to use readily available data (including monitoring data). When such data are not readily available, the statute directs facilities to use reasonable estimates. (42 U.S.C. 11023(g)(2)). However, while the statute allows for some level of imprecision regarding reportable amounts, it does not create an exemption or exception that would allow facilities to report less precisely than provided for by their data or estimation techniques. Therefore, facilities should report PBT chemicals as precisely as their estimation techniques or readily available data allow. If a facility's release or other management calculations support reporting an amount that is more precise than two significant digits, then the facility should report that more precise amount.

b. *Use of range reporting.* In the preamble to the proposed rule, EPA requested comments on its proposal to eliminate the use of range reporting in Form Rs for PBT chemicals. Commenters disagree with the proposal for a number of reasons outlined below.

Commenters argue that applying different reporting conventions for PBT chemicals would complicate EPCRA section 313 reporting, cause compliance difficulty, and introduce data inconsistencies (i.e., ranges for some chemicals but not for others). Commenters also argue that eliminating the use of range reporting for PBT chemicals has the potential to mislead the public and divert attention from actual risks.

EPA disagrees that the elimination of the use of range reporting for PBT chemicals will cause insurmountable obstacles to EPCRA section 313 reporting and cause compliance difficulties and data inconsistencies. There are already many different industries that report to EPA for 643 chemicals. EPA provides numerous guidance documents and training opportunities to reporting industries. With the finalization of the PBT rule, EPA will provide updated guidance documents, will prepare and provide, in those cases where it is appropriate, chemical-specific guidance documents, and will continue to offer training in order to assist facilities in reporting under EPCRA section 313. EPA also believes that the Agency will be able to adequately explain to the public the different reporting requirements for PBT chemicals so that they are put in context of other TRI data. EPA currently does this for other types of chemicals on the EPCRA section 313 list such as metals and pesticides.

Additionally, EPA believes that the elimination of range reporting is a critical part of this rulemaking, of which the ultimate intent is to provide useful information on PBT chemicals to assist communities in determining if PBT chemicals are present in their communities at levels that may pose an unacceptable risk. This information on PBT chemicals can also be used by government agencies and others to identify problems, set priorities, and take appropriate steps to reduce any potential risks to human health and the environment. Consequently, the information collected about these PBT chemicals will inform the public rather than mislead the public and will actually assist the public in determining the risk of PBT chemicals in their communities.

Commenters also argue that reporting numerical values for PBT chemicals assumes a level of accuracy that generally does not exist in the measurement of releases. In addition, commenters state that estimating numerical values would require the use of material balances, which are difficult to apply and essentially inaccurate for chemicals used in low concentrations. Commenters contend that, especially where reports are estimates, ranges may in fact provide more information than point estimates. Commenters argue that, for these reasons, elimination of range reporting will result in inaccurate estimates. Commenters also state that eliminating the use of range reporting for PBT chemicals would give the false impression of precise data, where uncertainty inherently exists.

As stated in the proposal, EPA believes that the use of ranges could misrepresent data accuracy because the low or the high end range numbers may not really be that close to the estimated value, even taking into account its inherent error (i.e., error in measurements and developing estimates) (at 64 FR 716). The user of the data must make a determination on whether to use the low end of the range, the mid-point, or the upper end. For example, a release of 501 pounds could be misinterpreted as 999 pounds if reported as a range of 500–999. This represents nearly a 100% error. This uncertainty severely limits the applicability of release information where the majority of releases, particularly for PBT chemicals, are expected to be within the amounts eligible for range reporting. The utility of these data would be severely limited given the uncertainty associated with data reported using ranges. Therefore, due to this uncertainty, EPA believes that facilities should report numerical values, not ranges, for PBT chemicals.

In addition, EPA believes that the information available to the typical EPCRA section 313 reporter is generally greater and/or more accessible than it was 10 years ago. Because of this improved information availability, EPA believes that many facilities will be able to accurately estimate releases and off-site transfers for further waste management of PBT chemicals in quantities of less than 1,000 pounds without the use of range codes. Although it may be true that some facilities will be better able to make those estimates than others, EPA does not believe this justifies not collecting the more specific and useful information from those facilities that can provide it.

Further, the Form R and Instructions and annual TRI data release provide information on the methods used to generate information reported and characterize many of the limitations that may apply to the data. This aids the data user in understanding the overall nature of the information available under EPCRA section 313. Facilities are required, for each release or transfer amount, to indicate on the the principal method used to determine the amount of release reported. There are codes which allow the facility to indicate whether the estimate is based on monitoring data, mass balance calculations, published emission factors, or other approaches such as engineering calculations or best engineering judgment. By looking at the

NMED Exhibit 72

information provided through the use of these codes, users of the data can gain an understanding of the degree of accuracy or uncertainty in any particular number reported by a facility. Thus, EPA believes that false impressions will not be communicated to the data user about the accuracy of the information filed.

Finally, EPCRA permits facilities to use reasonable estimates in the absence of readily available data to calculate reportable amounts. Compliance with EPCRA section 313 does not require that additional monitoring or sampling be done. Thus, the statute contemplates some level of imprecision in the data that may be filed, yet, by authorizing reporting based on reasonable estimates, affirms the community right-to-know purposes relative to information based on such reasonable estimates. Reporting releases of low volumes of PBT chemicals based on such reasonable estimates is no different than reporting on other toxic chemicals based on the same kind of information. The TRI data that has been reported since 1987 is a blend of estimates based on monitoring data, mass balance calculations, published emissions factors, and engineering calculations or engineering judgment.

The commenters contend that eliminating the use of range reporting for PBT chemicals would be extremely burdensome to facilities. EPA explained in the proposal that the original intent of providing the range reporting option was primarily as a burden reducing measure focused on small businesses. In past expansion activities, EPA has tried to retain burden reducing options wherever feasible. However, EPA does not expect the elimination of range reporting to significantly affect the unit cost of reporting because many facilities that could use range reporting are not choosing to do so. An analysis of the 1997 data reported under EPCRA section 313 reveals that the number of instances in which a range code was used for reporting quantities in sections 5 and 6 of the Form R was 37,168. These 37,168 instances included 7,605,305 pounds of releases and transfers using the median of the range code reported. However, there were 66,842 instances in which range reporting could have been used (i.e., the amounts reported where below 1,000 pounds), but the reporting facility chose instead to report a number rather than a range. These 66,842 instances included 13,662,758 pounds of releases and transfers. Thus, in 64% of the instances where range reporting could have been used facilities reported a number instead. The fact that in a majority of the instances in which range reporting could have been used facilities opted to report specific numbers would appear to indicate that the elimination of range reporting for PBT chemicals is unlikely to impose any significant additional burden on facilities. Therefore, EPA does not expect the elimination of range reporting to have any significant effect on unit reporting costs.

Commenters also argue that the elimination of the use of range reporting for PBT chemicals could result in an increase in the threat to confidential information and a possible increase in trade secret claims. Commenters maintain that Congress considered the need to protect trade secret information in the discussion of reporting chemical use and presence in ranges for EPCRA section 313:

> The conference substitute provides for reporting categories of use and ranges of chemicals present because the exact use of an identified chemical at a facility or the exact amount present may disclose secret processes. In some circumstances, this information may need to be reported in terms of broad 43 categories of use or amount ranges. . . . (H.R. Report No. 99–962, 298)

However, EPA believes that the conference report language cited by the commenter clearly refers only to the use of range reporting for the data element entitled ''maximum amount of the toxic chemical on-site at any time during the calendar year.'' EPA is not precluding range reporting for maximum amounts on-site. Contrary to the notion expressed by the commenter, Congress did not expressly direct EPA to allow range reporting for the reporting of releases and transfers off-site for further waste management. Additionally, in the statute, Congress provided the only means and mechanism for facilities to protect confidential business information (CBI) through the statute's trade secret provisions. If the commenter believes that any report filed might reveal confidential information as to the identity of the chemical, the commenter may choose to file a CBI claim by following the procedures as outlined in 40 CFR part 350. In addition, the statute is clear that trade secret claims may only be made for the identity of the chemical. Therefore, EPA believes that Congress adequately provided procedures for the protection of CBI and that a possible increase in CBI claims does not outweigh the need for increased information on releases and other waste management of PBT chemicals. See, *Legislative History* at 5185.

Commenters also argue that eliminating the use of range reporting for PBT chemicals will not result in the collection of substantial additional release information. EPA disagrees. The issue of range reporting is closely tied to the lowering of the reporting thresholds for PBT chemicals. As EPA noted in the proposal,

> Since PBT chemicals can remain in the environment for a significant amount of time and can bioaccumulate in animal tissues, even relatively small releases of such chemicals from individual facilities have the potential to accumulate over time to higher levels and cause significant adverse impacts on human health and the environment.

EPA also noted in the proposal that,

> Under current reporting thresholds, a significant amount of the releases and other waste management activities involving PBT chemicals are not being captured and thus the public does not have the information needed to determine if PBT chemicals are present in their communities and at levels that may pose a significant risk.

Therefore, by the lowering of reporting thresholds, EPA will receive important information on the quantities of PBT chemicals being released or otherwise managed as waste. Given the lowering of the reporting thresholds, continued use of ranges could misrepresent data accuracy because the low or the high end range numbers may not really be that close to the estimated value, even taking into account any inherent error (i.e., errors in measurements and developing estimates). The user of the data must make a determination on whether to use the low end of the range, the mid-point, or the upper end. For example, a release of 501 pounds could be misinterpreted as 999 pounds if reported as a range of 500–999. This represents a nearly 100% error. This uncertainty severely limits the applicability of release information where the majority of releases, particularly for PBT chemicals, are expected to be within the amounts eligible for range reporting. Given that the large uncertainty would be part of these data and would severely limit their utility, EPA has concluded that facilities must report numerical values, not ranges, for PBT chemicals.

In addition to the above comments, several commenters recommend the use of multiple ranges rather than total elimination of ranges just for PBT chemicals. One commenter generally agrees with EPA's position that reporting ranges ''B'' (11 to 499 pounds) and ''C'' (500 to 999 pounds), as they currently exist, may be too broad to provide meaningful information for PBT chemicals. Because the proposal does not impose any new obligation to measure or test beyond what is currently required, however, the commenter believes it is still

NMED Exhibit 72

appropriate to retain the ''A'' reporting range of 1 to 10 pounds for PBT chemicals. The commenter contends that the use of a specific number conveys a sense of precision that may not actually exist. The commenter argues that the retention of the ''A'' reporting range in its current form, coupled with the new reporting range of ''greater than zero, but less than 1 pound,'' will provide meaningful and valuable information to the public on PBT chemical transfers or releases.

Another commenter agrees with the purpose underlying the EPA's proposal to prohibit the use of range reporting for PBT chemicals and believes the ranges authorized under the current rules are too broad to be useful for PBT chemicals. However, the commenter believes that EPA should recognize that reporting in ranges is often necessary because uncertainty makes the selection of a single number arbitrary.

Another commenter argues that EPA should retain range reporting for PBT chemicals, even if the ranges are lower than those allowed for non-PBT chemicals. The commenter further contends that they believe that range reporting helps to correct some of the error introduced to EPCRA section 313 reporting through the use of estimates.

EPA disagrees that the Agency should retain the ''A'' reporting range of 1 to 10 pounds for PBT chemicals or that the Agency should retain some form of range reporting for PBT chemicals. As stated in the proposal, EPA believes that the use of ranges could misrepresent data accuracy because the low or the high end range numbers may not really be that close to the estimated value, even taking into account its inherent error (i.e., error in measurements and developing estimates). The user of the data must make a determination on whether to use the low end of the range, the mid-point, or the upper end. For example, a release of 501 pounds could be misinterpreted as 999 pounds if reported as a range of 500–999. This represents a nearly 100% error. Even with a lower range such as 1 to 10 pounds, the uncertainty associated with range reporting could severely limit the applicability of release information for PBT chemicals. Numerical values are particularly important since PBT chemicals can remain in the environment for a significant amount of time and can bioaccumulate in animal tissues. This means that even relatively small releases of such chemicals from individual facilities have the potential to accumulate over time to higher levels and cause adverse impacts on the environment and organisms. The utility of these data would be limited given the uncertainty associated with data reported using ranges. Therefore, due to this uncertainty, EPA is requiring that facilities report numerical values, not ranges, for PBT chemicals.

In addition, EPA believes that the information available to the typical EPCRA section 313 reporter is generally greater and more accessible than it was 10 years ago. Because of this improved information availability, EPA believes that facilities will be able to accurately estimate releases and off-site transfers for further waste management of PBT chemicals in quantities of less than 1,000 pounds without the use of range codes. Although it may be true that some facilities will be better able to make those estimates than others, EPA does not believe this justifies not collecting the more specific and useful information from those facilities that can provide it. Further, in the Form R, facilities are required, for each release or transfer amount, to indicate the principal method used to determine the amount of release reported. There are codes which allow the facility to indicate whether the estimate is based on monitoring data, mass balance calculations, published emission factors, or other approaches such as engineering calculations or best engineering judgment. By looking at the information provided through the use of these codes, users of the data can gain an understanding of the degree of accuracy or uncertainty in any particular number reported by a facility. Thus, EPA does not believe that false impressions will be communicated to the data user about the accuracy of the information filed.

Finally, as noted earlier EPCRA permits facilities to use reasonable estimates in the absence of readily available data to calculate reportable amounts. EPCRA does not require that additional monitoring or sampling be done in order to report. Thus, the statute contemplates some level of imprecision in the data that may be filed, yet, by authorizing reporting based on reasonable estimates, affirms the community right-to-know purposes relative to information based on such reasonable estimates.

A number of commenters agreed with EPA's proposal that range reporting be eliminated for all PBT chemicals on the EPCRA section 313 list. The commenters agreed with EPA's belief that the use of ranges could misrepresent data accuracy and significantly impact the usefulness of the data.

J. Other Issues

1. *Placing reported data into context.* Several commenters make the same general comment that EPCRA section 313 does not capture all sources of PBT chemical releases and therefore will not provide a complete or accurate picture of the releases of these chemicals. Commenters criticize the proposal for not putting the PBT releases from EPCRA section 313 covered facilities into context, in terms of either risk or the amount of PBT releases expected from non-covered facilities or sources. EPA disagrees with the implication by several commenters that simply because EPCRA section 313 may not capture all the sources of releases of PBT chemicals EPA should not attempt to capture more information from the facilities that do report under EPCRA section 313. This comment has been voiced in every major rulemaking under EPCRA section 313 but, as EPA has stated in the past, this is not an argument that EPA believes should restrict any efforts to collect additional data under EPCRA section 313. The mere fact that for some chemicals significant release sources are not captured does not in any way diminish the importance of the information that can be provided by those facilities that are required to report under EPCRA section 313. There is currently no one single reporting requirement that captures all of the releases of PBT chemicals and makes that information available to the public. For those chemicals that do have large release sources not captured under EPCRA section 313, EPA will use all available data to aid its actions and those of other international and national organizations and the public in efforts to address concerns on PBT chemicals. For example, all data will be considered to aid EPA's PBT strategy or other EPA PBT related programs; EPA will not rely solely on the data collected under EPCRA section 313. In addition, if there are significant sources of PBT chemicals that are not reported under EPCRA section 313, EPA will attempt to let the public know that some sources are not captured. In fact, in the most recent TRI data release documents, EPA has been providing information to the pubic on other sources of releases for certain EPCRA section 313 chemicals. In addition, EPA will continue to improve and augment public information materials so that users of the data will have information available to put in context the releases and other waste management of PBT chemicals by industries reporting under EPCRA section 313 versus those industries that do not report under EPCRA section 313.

NMED Exhibit 72

In fact, rather than an argument against lowering the reporting thresholds for PBT chemicals, EPA believes that the argument the commenters are making is one that supports expanding the types of facilities that should be required to report under EPCRA section 313 and not an argument that supports denying the public the right-to-know about PBT chemical releases from EPCRA section 313 covered facilities.

Some commenters stated that since EPA did not use exposure or risk considerations, the data on PBT chemical releases will be misleading to the public by indicating risks where none exist. EPCRA section 313 is not a risk-based reporting system, and, as discussed in Unit VI.F., EPA believes that a risk-based approach to EPCRA section 313 reporting is at odds with the overriding policy of EPCRA section 313, which is to get information about the use, disposition, and management of toxic chemicals into the public domain, enabling the users of this information to evaluate the information and draw their own conclusions about risk. The intent of EPCRA section 313 is to move the determination of which risks are acceptable from EPA to the communities in which the releases occur. This basic, local empowerment is a cornerstone of the right-to-know program. In addition, EPA will continue to improve its annual public data release as well as its outreach and education efforts to assist users in understanding the data. Consequently, EPA disagrees with the commenters that the information reported on releases and other waste management of PBT chemicals will be misleading to the public.

Another commenter states that the quantities of PBT chemicals reported in the TRI will be far smaller than the quantities of other chemicals which pose far less significant health risks. The commenter is concerned that the small quantities could lead members of the public to overlook the data on PBT chemicals. Therefore, the commenter argues that EPA should present PBT data in a way that draws the public's attention to it. The commenter states that it sees a danger that without sufficient education and guidance, the public may either overestimate or underestimate the health risks from PBT chemicals. The commenter believes that EPA should make a commitment to ensuring that the public is given the necessary education and guidance. EPA understands that the quantities of PBT chemicals may be reported in smaller quantities than other chemicals under EPCRA section 313 and that these quantities have the potential to be overlooked. EPA is also sensitive to the issue that data on PBT chemicals must be presented clearly to assist data users in understanding how the information on PBT chemicals is different from that reported on other chemicals under EPCRA section 313. EPA will continue to improve its annual public data release as well as its outreach and education efforts to assist users in understanding the data. Despite the concerns voiced by the commenters, EPA still believes that it is important to collect and disseminate this information so that communities can use the information with other site-specific factors to determine if releases into their communities result in risks that the community determines warrant further action given other factors, such as economic and environmental conditions, or particularly vulnerable human or ecological populations.

Another commenter expresses concern that release numbers for PBT chemical will not be comparable to those for other chemicals with higher reporting thresholds or to releases of the PBT chemical in previous years. The commenter adds that the lower thresholds may mislead the public into thinking that releases are rising or that a new chemical has been introduced at a facility. EPA understands the commenter's concern but does not believe this is a justification for not collecting additional information about PBT chemicals. EPA believes that it will be able to adequately explain to the public the different reporting requirements for PBT chemicals so that they are put in context of other TRI data. EPA will make clear which PBT chemicals were reportable prior to the finalization of this rule and what the reporting threshold was for these chemicals. Finally, EPA will continue to improve its annual public data release as well as its outreach and education efforts to assist users in understanding the data.

2. *Manufacture only qualifier for chemicals other than dioxin.* Many commenters request that EPA add a ''manufacture only'' qualifier to all PBT chemicals, not just the dioxin and dioxin-like compounds category. The commenters assert that the addition of the manufacture only qualifier to all PBT chemicals would greatly reduce the burden of the rule. Some commenters suggest that at a minimum the manufacture only qualifier should apply to polychlorinated biphenyls (PCBs), since EPA's rationale for applying the qualifier to dioxin and dioxin-like compounds is equally applicable to PCBs. One commenter contends that EPA's statement that the manufacture qualifier is appropriate for chemicals that are ''ubiquitous in the environment'' because otherwise many facilities would be required to report simply due to background levels in raw materials applies to PCBs as well. Some commenters suggest that unintentionally manufactured by-products such as hexachlorobenzene and octachlorostyrene should also have the manufacture only qualifier. Some commenters argue that the burden of the rule could be significantly reduced if EPA focused the reporting effort on the manufacturing sector, which should help concentrate EPA's pollution prevention efforts on the sector most likely to be able to make reductions. Some commenters contend that the primary source for PBT chemicals within the EPCRA section 313 reporting sectors is from manufacturing, and these are the sources that should be focused on for tracking PBT chemicals. Some commenters assert that EPA has acknowledged that many chemicals identified as persistent and bioaccumulative are not imported, processed, or otherwise used, but are manufactured as by-products (at 64 FR 715). Some commenters assert that they agree that manufacturing is the primary source for environmental loading of PBT chemicals from EPCRA section 313 facilities, and thus the effort for reporting should be concentrated on the sources where PBT chemicals are generated and data can be gathered. Some commenters argue that concentration on the manufacturing of PBT chemicals provides an efficient focus for meaningful pollution prevention efforts. Some commenters assert that they are concerned that data from importing, processing, or otherwise use of PBT chemicals will be inaccurate and misleading since processors and users may not have the resources to conduct the analyses required to provide accurate estimates. One commenter contends that the fear of enforcement might motivate those importing, processing, or otherwise using PBT chemicals to report ''some amount'' and that such information is likely to be inaccurate, and will not accurately reflect the true level of concern. Some commenters assert that instead of requiring reports from the many sources where effective emissions reductions may not be possible, that the addition of a manufacture only activity qualifier for all PBT chemicals will provide the public with the most accurate information on PBT chemical emissions and the best opportunity to monitor EPCRA section 313-related

NMED Exhibit 72

environmental loading of these chemicals.

EPA believes that in order to obtain any reporting on dioxin and dioxin-like compounds a very low threshold is required, which is several orders of magnitude lower than the thresholds for other PBT chemicals. At such a low reporting threshold it is estimated that thousands of reports could potentially be filed by facilities, mainly food processing facilities, due to the amount of dioxins in the raw materials they process. The dioxins found in the meat and dairy products that food processors handle have been previously released, circulated in the environment, and bioaccumulated in animals, thus these are not additional loadings to the environment but loadings that have already occurred and cycled through the environment due to the persistence and bioaccumulative properties of these compounds. The unique combination of very low thresholds, the number of food processors that would be required to file, and the fact that they would be filing because of the bioaccumulation of previously released material led EPA to propose to add only dioxin and dioxin-like compounds that are manufactured. EPA is finalizing the addition of dioxin with a revised qualifier in response to the unique set of conditions that apply to the reporting of dioxin and dioxin-like compounds. EPA proposed and is finalizing the addition of dioxin with a qualifier to reduce reporting burden on facilities, mainly in the food processing industry, that results from the unique combination of circumstances related to the reporting for these chemicals and to focus on those activities that add to the loading of dioxins in the environment rather than on activities dealing with previously released and bioaccumulated chemicals.

EPA did not conclude and does not believe that the manufacturing activity is the only important source of PBT chemical releases to the environment and believes that other activities such as processing or use can result in significant releases of PBT chemicals, including chemicals released to the environment for the first time. As discussed in Unit VI.G., EPA has modified the dioxin qualifier to reflect this. The unique combination of circumstances that exists for dioxin and dioxin-like compounds does not exists for any of the other PBT chemicals being added by this rule. EPA did not conclude that the manufacture qualifier is generally appropriate for other chemicals that are being added and that are ''ubiquitous in the environment.'' The full statement in the proposal was ''These dioxin and dioxin-like compounds are ubiquitous in the environment and thus under the very low reporting thresholds necessary to get reports from any sources (see discussion in Unit VII.A.2.), facilities that process raw materials would be required to report simply because the raw material contains background levels of these chemicals'' (at 64 FR 710). Clearly EPA made this statement in the context of the ''very low reporting thresholds necessary to get reports [for the dioxin and dioxin-like compounds category] from any sources.'' This statement is consistent with the unique combination of circumstances that exists for dioxin and dioxin-like compounds and was not intended to apply to all PBT chemicals.

Neither did EPA conclude that the manufacturing activity is the activity for which facilities would be most likely to be able to make reductions or that EPA's pollution prevention efforts should focus solely on the manufacturing of PBT chemicals. Commenters provided no basis for such a conclusion and EPA believes that processors and users of PBT chemicals also have the opportunity to make effective emissions reductions by using less of a PBT chemical, by not using materials that contain PBT chemicals as contaminants, etc. In addition, the purposes of reporting under EPCRA section 313 are not limited to the collection of information from sources where effective reductions in release and other waste management quantities are possible. Data collected under EPCRA section 313 can serve a variety of information purposes that do not depend on how easy it is for the source to achieve reduction in releases and other waste management. The commenter statement that EPA has acknowledged that many chemicals identified as persistent and bioaccumulative are not imported, processed, or otherwise used, but are manufactured as by-products, is incorrect. The actual statement was: ''[m]any of the chemicals identified as persistent and bioaccumulative in today's action are not imported, processed, or otherwise used but are manufactured as by-products'' (at 64 FR 715). As the words ''today's action'' clearly demonstrate, this statement was not a broad statement about all PBT chemicals but simply an acknowledgment that many of the PBT chemicals in the proposed rule were by-products. In addition, this statement was made in the context of the discussion on the *de minimis* exemption about how removing the exemption for PBT chemicals would affect the chemicals in the proposed rule; it was not a statement made in connection with the discussion on the manufacture only qualifier. EPA also did not state that manufacturing is the primary source for environmental loading of PBT chemicals from facilities covered under EPCRA section 313. The discussion on the loading of chemicals in the environment from manufacturing was in relation to the reporting of dioxin which, as discussed above, presents a unique combination of circumstances that EPA considered to determine how to focus its listing decision and does not apply to all PBT chemicals. EPA disagrees with the statements that data from facilities that import, process, or otherwise use PBT chemicals will be inaccurate and misleading or that such facilities will report some quantity out of fear of enforcement and that such information is likely to be inaccurate, and will not accurately reflect the true level of concern. EPA believes that facilities that import, process, or otherwise use PBT chemicals will be just as able to report as facilities that manufacture PBT chemicals. It is no more difficult to do calculations regarding small numbers than it is to do calculations on larger numbers, so if a facility that imports, processes, or otherwise uses PBT chemicals has information that allows them to make a reasonable estimation of quantities then they should be just as able to report as any manufacturing facility would be able to report on small quantities manufactured as by-products. If facilities that import, process, or otherwise use PBT chemicals do not have data available that allows them to make a reasonable estimation of quantities then they are not required to report. As for fear of enforcement, EPA can take enforcement actions both for under reporting and over reporting so facilities should not report an amount of a PBT chemical in order to avoid an enforcement action.

EPA does not believe that the unique combination of circumstances that exists for dioxin and dioxin-like compounds exists for any of the other PBT chemicals being added by this rule nor does EPA believe that reduced burden or any of the other reasons suggested by the commenters provide a sufficient reason to focus on manufacturing activity only for the other PBT chemicals in this rule. Therefore, EPA does not believe that it is appropriate to add a manufacture only qualifier to any of the other PBT chemicals in this rule.

3. *Waste management issues.* Some commenters contend that because activities such as recycling, approved

NMED Exhibit 72

waste disposal, and treatment are incorporated into reported volumes, the EPCRA section 313 reported releases will be substantial overestimates of the actual quantities released to the ambient environment. They further argue that although this information may be useful to source reduction efforts, merging of reporting requirements under section 313 of EPCRA and section 6607 of PPA has resulted in information which is misleading to the public's desire to know the actual exposures that are occurring. Another commenter asserts that by requiring electricity generating facilities to report transfers off-site for treatment and disposal of PCBs from transformers, EPA has established a disincentive to properly dispose of PCB transformers and remove them from use because most PCB wastes transferred to off-site facilities are destroyed in regulated units which destroy at least 99.9999% of the PCBs. They are concerned that because the casual reader may conclude additional releases of PCBs to the environment have occurred, companies would have a disincentive to voluntarily remove PCBs.

The commenters are incorrect in stating that EPCRA section 313 release quantities include recycling and treatment amounts. Under EPCRA section 313, if a chemical activity threshold is met for the chemical, covered facilities are required to report the quantity of the toxic chemical entering each environmental medium; this includes ''releases.'' The definition of release pursuant to EPCRA section 329(8) means:

> any spilling, leaking, pumping, pouring, emitting, emptying, discharging, injecting, escaping, leaching, dumping, or disposing into the environment (including the abandonment or discarding of barrels, containers, and other closed receptacles) of any hazardous chemical, extremely hazardous substance, or toxic chemical.

There is no language in this definition, any other provision of EPCRA, or in the regulations promulgated pursuant to EPCRA section 313, that limit this definition to ambient releases to the environment which may result in public exposure. In fact the definition specifically includes disposing of toxic chemicals as well as the abandonment of closed receptacles. In addition, neither the statute nor the regulations limit this definition to on-site releases. Therefore, the statutory definition of release under EPCRA section 313 is significantly broader than the commenter seems to believe.

In addition to release reporting, under section 6607(b)(1) of the PPA, if a covered facility meets the reporting thresholds under EPCRA section 313, the facility is required to report the ''quantity of the chemical entering any wastestream (or otherwise released to the environment). . . .'' This quantity includes amounts of the toxic chemical released, treated, and recycled. However, this quantity does not include:

> [t]he amount of any toxic chemical released into the environment which resulted from a catastrophic event, remedial action, or other one time event, *and is not associated with production processes during the reporting year*. (PPA 6607 (b)(7)) (emphasis added)

Therefore, the quantity of the toxic chemical entering the wastestream as collected under section 6607(b)(1) of the PPA, is the amount of the toxic chemical in production related waste. Covered facilities currently report the amount of the toxic chemical in production related waste as quantities of the toxic chemical released, treated, combusted for energy recovery and recycled. These quantities are collected as separate data elements in section 8 of the Form R. Further, facilities report the ultimate disposition of toxic chemicals in waste such that these quantities (i.e., amounts released, treated, combusted for energy recovery, and recycled) are mutually exclusive. Collectively, then, these quantities are the amount entering the waste stream or the quantity of the toxic chemical in production related waste. For example, a covered facility transfers 1,000,000 pounds of PCBs to an incinerator for treatment. The covered facility knows that 999,999 pounds are destroyed in the incinerator and the remaining 1 pound is disposed in a landfill. The facility reports 999,999 pounds as transferred off-site for treatment and 1 pound as transferred off-site for disposal. These two quantities are reported as separate data elements on the Form R. The quantity reported as disposed off-site is considered released because, as explained previously, disposal is a type of release. The entire quantity (1,000,000 pounds) is the amount of production related waste.

Once collected, EPA presents the TRI data to the public in a number of formats. In its annual data release documents, EPA highlights different aspects of the quantities of toxic chemicals released and otherwise managed as waste. For example, EPA presents total on-site releases and, as subsets, presents the quantities released to air, surface water, underground injection and on-site land releases. (See *1997 Toxics Release Inventory* (EPA 745–R–99–003) Figure 2-3 ''TRI On-site Releases'') EPA also presents the quantity of total releases in the public data release. As discussed earlier, under EPCRA section 313, release quantities are not limited to quantities released to the ambient environment. Therefore, total releases, as presented in the public data release include both on and off-site releases as well as a variety of disposal methods. For example, in Table 2-20A of the 1997 public data release, EPA presents TRI on-site and off-site releases by chemical and type of release (e.g., air emissions, underground injection, etc.) (*1997 Toxics Release Inventory*; EPA 745–R–99–003).

In addition to TRI release data, EPA presents production related waste quantities in the public data release. Because production related waste includes releases, EPA includes release quantities with other waste management quantities. However, in this document, the Agency generally distinguishes quantities of the toxic chemical released from other types of waste management. EPA does not count the quantities of toxic chemicals treated, combusted for energy recovery or recycled as quantities released. (See, for example, 1997 Toxics Release Inventory (EPA 745-R-99-003) Table 2-20A ''TRI On-site and Off-site Releases, by Chemical, 1997'' and Table 2-20B ''TRI Chemicals in Waste, by Chemical, 1997'')

Further, EPA does not believe that the TRI program provides a disincentive for the proper and safe handling of PCBs in transformers managed as waste. As explained earlier, covered facilities are required under EPCRA section 313 and section 6607 of the PPA to report quantities of toxic chemicals released or otherwise managed as waste if they meet a chemical activity threshold. Quantities of toxic chemicals sent off-site for treatment are described as such. These transfers are not included as releases. In addition, EPA disagrees that quantities of PCBs sent off-site for treatment will be misunderstood by the public because these quantities are accurately represented in the TRI data base and in the public data release as a separate type of waste management.

Another commenter asserts that the proposed rule will not encourage waste minimization because facilities will not be able to modify process designs to accomodate such minimization simply on the basis of data generated from guidance documents or reasonable estimates. The commenter asserts that although industry has made substantial minimization gains, the technology is not available to treat or remove chemicals of concern from manufactured products or waste (prior to generation) at such low

NMED Exhibit 72

concentrations and that any future improvements will be enormously expensive due to the low concentrations that would likely be involved.

EPA disagrees with the commenter. In the preamble to the proposed rule, EPA did not assert that covered facilities will begin performing waste minimization activities as a direct result of this rulemaking. Rather, the Agency stated that the PBT chemical rulemaking will provide data on PBT chemicals to EPA, industry, and the public. For example, several EPA offices have ongoing projects and programs that deal with issues concerning PBT chemicals. EPA has established the PBT planning group which is a coordinating body consisting of representatives from various program offices throughout EPA that are dealing with PBT chemicals. This group has developed a strategy to reduce pollution from PBT chemicals through the application of regulatory and nonregulatory authorities, with a strong emphasis on pollution prevention. The availability of that data, in turn, can allow all parties to identify and track releases of PBT chemicals and monitor the progress of the programs designed to reduce the amount of PBT chemicals entering the environment. The data will also allow EPA and others to design prevention strategies that are focused and effective.

In addition, EPA disagrees with the commenter's last assertion concerning the available technology and its costs. Although there are some processes that might not, at present, be amenable to source reduction in terms of PBT chemicals, some processes may be. For example, it may be possible to stringently control fuel composition, flow times, temperature, and other conditions in order to substantially reduce or even eliminate the incidental manufacture of dioxins during combustion processes. Therefore, EPA continues to believe that in some cases, opportunities for pollution prevention will present themselves resulting from information reported under EPCRA section 313 and section 6607 of the PPA.

4. *Modulated reporting thresholds.* The majority of commenters contend that modulating thresholds for reporting so that lower reporting thresholds are used every other year (with current thresholds used in alternate years) would introduce confusion for the regulated community and data users and would not significantly reduce burden. Further it could discourage facilities from establishing common standard procedures for data collection. Modulation will also result in data gaps, undermining data consistency and tracking. Many commenters believe that annual reporting is a fundamental attribute of TRI.

EPA agrees that modulating the reporting thresholds would introduce confusion for both the regulated community and data users. For data users, EPA believes that modulating the reporting thresholds would limit the usefulness of the TRI data because there would be poor data consistency and poorer data quality. For the regulated community, EPA believes that the burden reduction would not be significant and would possibly be offset by the confusion that would be introduced by different thresholds in alternate years.

VII. What Were the Results of EPA's Economic Analysis?

EPA has prepared an economic analysis of the impact of this action, which is contained in a document entitled *Economic Analysis of the Final Rule to Modify Reporting of Persistent Bioaccumulative Toxic Chemicals under EPCRA Section 313* (Ref. 67). This document is available in the public docket for this rulemaking. The analysis assesses the costs, benefits, and associated impacts of the rule, including potential effects on small entities. The major findings of the analysis are briefly summarized here.

A. What is the Need for the Rule?

Federal regulations exist, in part, to address significant market failures. Markets fail to achieve socially efficient outcomes when differences exist between market values and social values. Two causes of market failure are externalities and information asymmetries. In the case of negative externalities, the actions of one economic entity impose costs on parties that are ''external'' to any market transaction. For example, a facility may release toxic chemicals without accounting for the consequences to other parties, such as the surrounding community, and the prices of that facility's goods or services thus will fail to reflect those costs. The market may also fail to efficiently allocate resources in cases where consumers lack information. For example, where information is insufficient regarding toxic releases, individuals' choices regarding where to live and work may not be the same as if they had more complete information. Since firms ordinarily have little or no incentive to provide information on their releases and other waste management activities involving toxic chemicals, the market fails to allocate society's resources in the most efficient manner.

This rule is intended to address the market failures arising from private choices about PBT chemicals that have societal costs, and the market failures created by the limited information available to the public about the release and other waste management activities involving PBT chemicals. Through the collection and distribution of facility-specific data on toxic chemicals, TRI overcomes firms' lack of incentive to provide certain information, and thereby serves to inform the public of releases and other waste management of PBT chemicals. This information enables individuals to make choices that enhance their overall well-being. Choices made by a more informed public, including consumers, corporate lenders, and communities, may lead firms to internalize into their business decisions at least some of the costs to society relating to their releases and other waste management activities involving PBT chemicals. In addition, by helping to identify areas of concern, set priorities and monitor trends, TRI data can also be used to make more informed decisions regarding the design of more efficient regulations and voluntary programs, which also moves society towards an optimal allocation of resources.

If EPA were not to take this action adding certain PBT chemicals to EPCRA section 313 and lowering reporting thresholds, the market failure (and the associated social costs) resulting from the limited information on the release and other waste management of PBT chemicals would continue. EPA believes that today's action will improve the scope of multi-media data on the release and other waste management of PBT chemicals. This, in turn, will provide information to the public, empower communities to play a meaningful role in environmental decision-making, and improve the quality of environmental decision-making by government officials. In addition, this action will serve to generate information that reporting facilities themselves may find useful in such areas as highlighting opportunities to reduce chemical use or release or other waste management and thereby lower costs of production and/or waste management. EPA believes that these are sound rationales for adding chemicals to the EPCRA section 313 list of toxic chemicals and lowering reporting thresholds for PBT chemicals.

B. What Are the Costs Associated With This Rule?

This action will result in the expenditure of resources that, in the absence of the regulation, could be used

NMED Exhibit 72

for other purposes. The cost of the rule is the value of these resources in their best alternative use. Most of the costs of the rule result from requirements on industry. Approximately 11,300 facilities are expected to submit approximately 20,000 additional Form R reports annually. The estimated composition of this reporting, by chemical, is shown in Table 4.

Table 4.—Summary of Chemical Reporting as Estimated for Proposed and Final Rules

Chemical or Chemical Category	Estimated Number of Reports (Annual)	
	Proposed Rule	Final Rule
Alkyl lead (tetraethyl lead and tetramethyl lead)	134	N/A
Benzo(g,h,i)perylene	353	909
Dioxin and dioxin-like compounds category	1,863	1,475
Hexachlorobenzene	778	778
Mercury; mercury compounds category	5,230	5,346
Octachlorostyrene	230	230
Pentachlorobenzene	707	707
Pesticides (aldrin, chlordane, heptachlor, isodrin, methoxychlor, pendimethalin, toxaphene, trifluralin)	264	264
Polycyclic aromatic compounds (PACs) category	4,699	7,166
Polychlorinated biphenyls (PCBs)	2,267	2,310
Tetrabromobisphenol A	150	150
Vanadium; vanadium compounds category	654	655
Total	17,329	19,990

Table 5 displays the industry costs for this action based on the estimated number of facilities affected and the estimated number of additional reports. Aggregate industry costs in the first year for the rule are estimated to be $145 million; in subsequent years they are estimated to be $80 million per year. Industry costs are lower after the first year because facilities will be familiar with the reporting requirements, and many will be able to update or modify information from the previous year's report. EPA is expected to expend $2.0 million in the first year, and $1.6 million in subsequent years as a result of the rule.

Table 5.—Summary of Reporting and Associated Costs as Estimated for Proposed and Final Rules

	Proposed Rule	Final Rule
Number of new facilities	2,600	3,114
Total number of facilities	9,515	11,257
Number of Form Rs submitted	17,329	19,990
First year industry costs	$126 million	$145 million
Subsequent year industry costs	$70 million	$80 million
EPA costs	$1.4 million	$1.6 million

The estimated cost of the final rule differs from the estimated cost of the proposed rule as shown in Table 5. There are six major reasons for this change. First, EPA received new data during the comment period on the concentrations of PACs and benzo(g,h,i)perylene in distillate fuel oil. Since approximately 18,000 manufacturing facilities subject to EPCRA 313 reporting use distillate fuel oil, this change had a significant positive effect on the estimated number of reports for PACs and benzo(g,h,i)perylene as shown in Table 4. Second, the methodology for estimating reporting from facilities in SIC 5171 (Bulk Petroleum Stations and Terminals) was revised to account for the mix of products containing PBT chemicals that are processed at these facilities. This revision also had a positive effect on the estimated number of reports. Third, because facility-level dioxin emission factors for coal- and oil-burning manufacturing facilities have not been developed, the estimated number of reporting facilities was reduced. Fourth, the reporting qualifier for dioxin was changed from

''manufacture only'' to ''manufacturing; and the processing or otherwise use of dioxin and dioxin-like compounds if the dioxin and dioxin-like compounds are present as contaminants in a chemical and if they were created during the manufacturing of that chemical'' in the final rule. This resulted in additional expected reporting from facilities that process or otherwise use chemicals with dioxin impurities. Fifth, the Agency is not lowering EPCRA section 313 reporting thresholds for alkyl leads as part of this rulemaking. Therefore, no additional EPCRA section 313 reporting on alkyl leads is expected at this time. Sixth, the threshold for the PACs category was changed from 10 pounds in the proposed rule to 100 pounds in the final rule.

C. What Are the Benefits of This Rule?

In enacting EPCRA and PPA, Congress recognized the significant benefits of providing the public with information on toxic chemical releases and other waste management practices. EPCRA section 313 has empowered the Federal government, State governments, industry, environmental groups, and the general public to fully participate in an informed dialogue about the environmental impacts of toxic chemicals in the United States. EPCRA section 313's publicly available data base provides quantitative information on toxic chemical releases and other waste management practices. Since the TRI program's inception in 1987, the public, government, and the regulated community have had the ability to understand the magnitude of chemical releases in the United States, and to assess the need to reduce the uses, releases and other waste management of toxic chemicals. TRI enables all interested parties to establish credible baselines, to set realistic goals for environmental progress over time, and to measure progress in meeting these goals over time. The TRI program is a neutral yardstick by which progress can be measured by all stakeholders.

The information reported under EPCRA section 313 increases knowledge of the amount of toxic chemicals released and waste management practices, and thus aids in the evaluation of the potential pathways of exposure, improves scientific understanding of the health and environmental risks of toxic chemicals; allows the public to make informed decisions on where to work and live; enhances the ability of corporate leaders and purchasers to more accurately gauge a facility's potential environmental liabilities; provides reporting facilities with information that can be used to save money as well as reduce emissions; and assists Federal, State, and local authorities in making better decisions on acceptable levels of toxic chemicals in the environment.

There are two types of benefits associated with EPCRA section 313 reporting, those resulting from the actions required by the rule (such as reporting and recordkeeping), and those derived from follow-on activities that are not required by the rule. Benefits of activities required by the rule include the value of improved knowledge about the release and waste management of toxic chemicals, which leads to improvements in understanding, awareness, and decision-making. It is expected that this rule will generate such benefits by providing readily accessible information that otherwise would not be available to the public. The rule will benefit ongoing research efforts to understand the risks posed by PBT chemicals and to evaluate policy strategies that address the risks.

The second type of benefits derive from changes in behavior that may result from the information reported under EPCRA section 313. These changes in behavior, including reductions in releases of and changes in the waste management practices for toxic chemicals may yield health and environmental benefits. These changes in behavior come at some cost, and the net benefits of the follow-on activities are the difference between the benefits of decreased chemical releases and transfers and the costs of the actions needed to achieve the decreases.

Because the state of knowledge about the economics of information is not highly developed, EPA has not attempted to quantify the benefits of adding chemicals to EPCRA section 313 or changing reporting thresholds. Furthermore, because of the inherent uncertainty in the subsequent chain of events, EPA has also not attempted to predict the changes in behavior that result from the information, or the resultant net benefits (i.e., the difference between benefits and costs). EPA does not believe that there are adequate methodologies to make reasonable monetary estimates of either the benefits of the activities required by the rule, or the follow-on activities. The economic analysis of the rule, however, does provide illustrative examples of how the rule will improve the availability of information on PBT chemicals (Ref. 67).

A number of commenters asserted that information on the magnitude of PBT chemical releases that would be reported as a result of this rule is required for EPA and commenters to evaluate the benefit of EPA's proposed alternatives. EPA disagrees with these commenters for the following reasons.

Existing data do not support estimates of releases to multiple environmental media from the full range of facilities that may be affected by the rule because most of the data required for the analysis would only be available after the rule is in place. For most PBT chemicals and industry sectors, up-to-date multi-media release and other waste management estimates for affected facilities do not exist. Even where release estimates are available for an industry sector, most are derived from national activity levels rather than from facility-level information. To the extent that release estimates are available, they tend to cover only a single medium such as air. EPA does not believe that there is sufficient information to make reasonable predictions of the multi-media releases and other waste management information that will be reported as a result of EPCRA section 313 rulemakings.

Some commenters note that EPA has estimated releases of certain PBT chemicals in recent reports such as the Mercury Study Report to Congress (Ref. 65) and the Inventory of Source of Dioxin in the United States (Ref. 73). In fact, EPA reported the results of these reports in its economic analysis for this proposal. These studies do not provide community- or facility-level release estimates. The estimates in these studies are derived using a ''top-down'' methodology in which emission factors are applied to activity levels for entire industries. While having an estimate of multi-media PBT releases for a specific industry sector is a first step, other information would also be required to estimate the releases that would be reported as a result of each proposed alternative. Assuming that multi-media release estimates were available for an entire industry sector, these releases would still have to be divided among individual facilities according to some currently unknown distribution. In addition, there is the complication that EPCRA section 313 reporting thresholds are based on chemical throughput (manufacture, process, or use) rather than chemical release. The relationship between a chemical throughput that triggers the submission of a report, and the releases reported will vary in some currently unknown manner among industries, as well as among facilities within an industry.

Therefore, EPA does not believe that there is sufficient information to make reliable release estimates for this rule, when considering all the affected chemicals and industries. The

NMED Exhibit 72

uncertainties in the estimated values that go into such a calculation make predictions of facility level reporting extremely imprecise. Historical attempts to estimate the releases expected to be reported under EPCRA section 313 would have been imprecise to the point of being misleading, particularly in respect to estimates of releases per report or per facility (which some commenters have suggested that EPA should make). Further information on the feasibility of *ex ante* release estimates is available in the Response to Comments document (Ref. 69).

Aside from the general issue of uncertainty in the estimates of aggregate releases, predictions of releases per facility or per report (or dollars of reporting cost per pound of releases reported) are likely to be misleading due to the biases built into the estimates. The predicted number of reports (and thus costs) is generally an overestimate, since EPA's economic analyses use conservative estimates to avoid underestimating true costs. On the other hand, predictions of releases will tend to underestimate emissions, because while there may be information available on releases of some chemicals from some sectors, such estimates will not include other sources where releases are not identified until more detailed data (such as TRI data) are collected. Combining the two sets of estimates compounds the problem. Since estimated pounds of releases are underestimated and reports are overestimated, pounds per report would be biased significantly downward. Likewise, estimates of dollars of reporting cost per pound of releases (which varies as the inverse of pounds per report) would be biased significantly upward.

EPA notes that there were various reports and studies about air emissions of toxic chemicals prior to EPCRA section 313, but the collection of facility-level data provided significant new information on releases as well as other waste management. EPA cannot predict, at this stage, the quantity of releases and other waste management that will be reported as the result of this action any more accurately than it could have predicted when it proposed the original EPCRA section 313 rule.

Aside from the issue of whether EPA can predict releases and other waste management quantities prior to TRI reporting, EPA notes that pounds of releases (even if known) are not a reasonable proxy for the benefits of the information being provided. This is because the benefits of an informational regulation are not a linear function of the magnitude of the information being reported. EPA disagrees with the implicit assumption by commenters that the benefits of information from different facilities is strictly and systematically related to the quantity reported as being released. Calculations such as the commenters have suggested presume that the benefit to the public of knowing about a release of 20,000 pounds is twice as large as the benefit of knowing about a release of 10,000 pounds; and that the benefit of knowing about a 40,000 pound release is twice the benefit of knowing about a 20,000 pound release and four times the benefit of knowing about a 10,000 pound release. EPA does not believe this characterization to be accurate.

One of the central purposes of TRI data is to inform the public about releases and other waste management of EPCRA section 313 listed toxic chemicals in their community so that the public can form its own conclusions about risks. The amount of releases and waste management quantities that a community may find relevant or useful will vary depending on numerous factors specific to that community, such as the toxicity of the various chemicals, potential exposure to these toxic chemicals, and the number of other facilities in the area that release EPCRA section 313 listed toxic chemicals. Section 313(h) of EPCRA states that the data are ''to inform persons about releases of toxic chemicals to the environment; to assist governmental agencies, researchers, and other persons in the conduct of research and data gathering; to aid in the development of appropriate regulations, guidelines, and standards; and for other similar purposes'' (See Unit VI.E. for a more detailed discussion on the purposes of EPCRA section 313). Pounds of releases reported does not measure how the data perform these functions, and thus is not a measure of benefits.

Finally, EPA notes that commenters on this rule did not provide information on approaches or methodologies for estimating releases and/or throughput, or on estimating releases from throughput data, for the spectrum of industries, chemicals, and facilities covered by the rule. Instead, some commenters submitted data from EPA studies (that EPA had already reviewed in the context of this rule and used as references for the economic analysis of the proposed rule) for very narrow slices of the regulated universe (for example, estimated mercury releases from electric utilities or estimated dioxin releases from the vinyl industry). EPA considered these data and determined that they are not sufficient to predict the releases and/or throughput that will be reported as a result of this rule. Other commenters simply stated that EPA should consider releases without referencing any data. None of the commenters suggested new methodologies or approaches, or provided information from any sources that EPA had not already reviewed and considered. As a result, EPA continues to conclude that while there are data available to estimate national releases for some chemicals for some sectors, comprehensive, reliable data for all sectors and chemicals are unavailable, resulting in an incomplete data set. Furthermore, as stated previously, the quantity of releases reported are not a measure of the benefits of the rule. EPA does not believe that inaccurate or incomplete estimates of releases would aid the decision-making process for the rule. Therefore, EPA has not estimated the releases that would be reported as a result of the rule.

D. What are the Potential Impacts on Small Entities?

In accordance with the Regulatory Flexibility Act (RFA) and the Agency's longstanding policy of always considering whether there may be a potential for adverse impacts on small entities, the Agency has evaluated the potential impacts of this rule on small entities. The Agency's analysis of potentially adverse economic impacts is included in the Economic Analysis for this rule (Ref. 67). The following is a brief overview of EPA's findings.

1. *Overall methodology*. This rule may affect both small businesses and small governments. For the purpose of its analysis for the rule, EPA defined a small business using the small business size standards established by the Small Business Administration (SBA) at 13 CFR part 121. EPA defined small governments using the RFA definition of jurisdictions with a population of less than 50,000. No small organizations are expected to be affected by the rule.

Only those small entities that are expected to submit at least one report are considered to be affected for the purpose of the small entity analysis, although EPA recognizes that other small entities will conduct compliance determinations under lower thresholds. The number of affected entities will be smaller than the number of affected facilities, because many entities operate more than one facility. Impacts were calculated for both the first year of reporting and subsequent years. First year costs are typically higher than continuing costs because firms must familiarize themselves with the requirements. Once firms have become familiar with how the reporting

requirements apply to their operations, costs fall. EPA believes that subsequent year impacts present the best measure to judge the impact on small entities because these continuing costs are more representative of the costs firms face to comply with the rule.

EPA analyzed the potential cost impact of the rule on small businesses and governments for the manufacturing sector and in each of the recently added industry sectors separately in order to obtain the most accurate assessment for each. EPA then aggregated the analyses for the purpose of determining whether it could certify that the rule will not, if promulgated, have a ''significant economic impact on a substantial number of small entities.'' RFA section 605(b) provides an exemption from the requirement to prepare a regulatory flexibility analysis for a rule where an agency makes and supports the certification statement quoted above. EPA believes that the statutory test for certifying a rule and the statutory consequences of not certifying a rule all indicate that certification determinations may be based on an aggregated analysis of the rule's impact on all of the small entities subject to it.

2. *Small businesses*. EPA used annual compliance costs as a percentage of annual company sales to assess the potential impacts on small businesses of this rule. EPA believes that this is a good measure of a firm's ability to afford the costs attributable to a regulatory requirement, because comparing compliance costs to revenues provides a reasonable indication of the magnitude of the regulatory burden relative to a commonly available measure of a company's business volume. Where regulatory costs represent a small fraction of a typical firm's revenue (for example, less than 1%, but not greater than 3%), EPA believes that the financial impacts of the regulation may be considered not significant. As discussed above, EPA also believes that it is appropriate to apply this measure to subsequent year impacts.

Based on its estimates of additional reporting as a result of the rule, the Agency estimates that approximately 6,300 businesses will be affected by the rule, and that approximately 4,400 of these businesses are classified as small based on the applicable SBA size standards. For the first reporting year, EPA estimates that approximately 17 small businesses may bear compliance costs between 1% and 3% of revenues, and that no small businesses will bear costs greater than 3%. In subsequent years, EPA estimates that approximately 5 small businesses may bear compliance costs between 1% and 3% of revenues, and that no small businesses will bear costs greater than 3%. As stated above, EPA believes that subsequent-year impacts are the appropriate measure of small business impacts.

3. *Small governments*. To assess the potential impacts on small governments, EPA used annual compliance costs as a percentage of annual government revenues to measure potential impacts. Similar to the methodology for small businesses, this measure was used because EPA believes it provides a reasonable indication of the magnitude of the regulatory burden relative to a government's ability to pay for the costs, and is based on readily available data.

EPA estimates that 39 municipalities operate 49 publicly owned electric utility facilities. Of these facilities, 44 are expected to file additional reports as a result of this action. Of these affected facilities, 15 are operated by 15 small governments (i.e., those with populations under 50,000). It is estimated that none of these small governments will bear annual costs greater than 1% of annual government revenues.

4. *All small entities*. As discussed above, approximately 5 small businesses are expected to bear annual costs between 1% and 3% of annual revenues after the first year of reporting. None of the affected small governments are estimated to bear annual costs greater than 1% of annual revenues. No small organizations are expected to be affected by the rule. Thus, the total number of small entities with impacts above 1% of revenues does not change when the results are aggregated for all small entities (i.e., small businesses, small governments, and small organizations).

IX. Which Regulatory Assessment Requirements Apply to This Action?

A. What is the Determination under Executive Order 12866

Under Executive Order 12866, entitled *Regulatory Planning and Review* (58 FR 51735, October 4, 1993), this is an economically ''significant regulatory action'' because it is likely to have an annual effect of $100 million or more. This action was submitted to the Office of Management and Budget (OMB) for review, and any substantive comments or changes made during that review have been documented in the public version of the official record.

EPA has prepared an economic analysis of the impact of this action, which is contained in a document entitled *Economic Analysis of the Final Rule to Modify Reporting of Persistent Bioaccumulative Toxic Chemicals under EPCRA Section 313* (Ref. 67). This document is available as a part of the public version of the official record for this action (instructions for accessing this document are contained in Unit I.B.) and is discussed in Unit VII.

B. What is the Determination under the Regulatory Flexibility Act?

Pursuant to section 605(b) of the Regulatory Flexibility Act (RFA) (5 U.S.C. 601 *et seq.*), the EPA Administrator hereby certifies that this final rule will not have a significant economic impact on a substantial number of small entities. The factual basis for this determination is presented in the small entity impact analysis prepared as part of the Economic Analysis for this final rule (Ref. 67), which is also discussed in detail in Unit VII. and contained in the public version of the official record for this rule. The following is a brief summary of the Agency's factual basis for this certification.

For the purpose of analyzing potential impacts on small entities, EPA used the RFA definition of small entities in section 601(6) of the RFA. Under this section, small entities include small governments, small non-profit organizations, and small businesses. No small organizations are expected to be affected by this final rule. EPA defined small governments using the RFA definition of jurisdictions with a population of less than 50,000, and defined a small business using the small business size standards established by the Small Business Administration (SBA), which are generally based on the number of employees or annual sales/revenue a business in a particular industrial sector has.

Based on EPA's economic analysis, approximately 11,300 facilities are expected to submit approximately 20,000 additional Form R reports annually. Of these facilities, approximately 3,100 are expected to file TRI reports for the first time as a result of today's action. EPA estimates that the cost for collecting this information averages $5,079 per Form R in the first reporting year, and $3,557 in subsequent years. EPA estimates that there are 15 small governments that may be affected by the rule (i.e., EPA analysis estimates that these entities may have to file one or more reports under the final rule). EPA estimates that none of these small governments will bear annual costs greater than 1% of annual government revenues. EPA estimates that 5 small businesses of the approximately 4,400 small businesses potentially affected by the rule will experience annual compliance costs between 1% and 3% of annual sales after the first year of reporting. Given the relatively small estimated impacts on small entities, EPA believes that the rule will not have a significant economic impact on a substantial number of small entities. This determination is for the entire population of small entities potentially affected by this rule, since the test for certification is whether the rule as a whole has a significant economic impact on a substantial number of small entities.

Notwithstanding the Agency's certification of this rule under section 605(b) of the RFA, EPA remains committed to minimizing real impacts

on small entities where this does not unacceptably compromise the informational benefits of the rule. Although not required, EPA intends to prepare guidance for reporting on dioxin that will assist facilities in determining their compliance needs and in properly completing the form, which will help ensure that small entities receive assistance to ease their burden of compliance. EPA has prepared such documents for current reporters and has received positive feedback on their utility from the targeted facilities. In addition, the Agency is always interested in any comments regarding the economic impacts that this regulatory action would impose on small entities, particularly suggestions for minimizing that impact. Such comments may be submitted to the Agency at any time, to the address listed in Unit I.B.

Information relating to this determination has been provided to the Chief Counsel for Advocacy of the Small Business Administration, and is included in the public version of the official record for this rulemaking.

C. What is the Determination under the Paperwork Reduction Act?

The information collection requirements contained in this final rule have been submitted to OMB under the Paperwork Reduction Act (PRA), 44 U.S.C. 3501 *et seq*., and in accordance with the procedures at 5 CFR 1320.11. OMB has approved the existing reporting and recordkeeping requirements EPA Toxic Chemical Release Inventory Form R (EPA Form No. 9350-1), supplier notification, and petitions under OMB Control No. 2070–0093 (EPA ICR No. 1363). An Information Collection Request (ICR) document has been prepared by EPA (EPA ICR No. 1363.10) to amend the existing ICR to include the burden associated with the lower reporting thresholds, and a copy may be obtained from Sandy Farmer, Office of Information Collections (OIC); U.S. Environmental Protection Agency (2137), 401 M St., SW., Washington, DC 20460, by calling (202) 260–2740, or electronically by sending an e-mail message to ''farmer.sandy@epa.gov.'' An electronic copy has also been posted with this **Federal Register** document on EPA's Homepage with other information related to this action as described in Unit I.B., and may also be downloaded from the Internet at http://www.epa.gov.icr/.

An Agency may not conduct or sponsor, and a person is not required to respond to a collection of information subject to OMB approval under the PRA unless it displays a currently valid OMB control number. The OMB control numbers for EPA's regulations, after initial publication in the **Federal Register**, are maintained in a list at 40 CFR part 9. The information requirements contained in this final rule are not effective until OMB approves them.

EPCRA section 313 requires owners or operators of certain facilities manufacturing, processing, or otherwise using any of over 600 listed toxic chemicals and chemical categories in excess of the applicable threshold quantities, and meeting certain requirements (i.e., at least 10 Full Time Employees or the equivalent), to report environmental on-site releases and transfers off-site for release and treatment. Under section 6607 of the PPA, facilities must also provide information on the quantities of the toxic chemicals in certain waste streams, and the efforts made to manage those waste quantities. The regulations codifying the EPCRA section 313 reporting requirements appear at 40 CFR part 372. Respondents may designate the specific chemical identity of a substance as a trade secret, pursuant to EPCRA section 322 (42 U.S.C. 11042). Regulations codifying the trade secret provisions can be found at 40 CFR part 350. Under the final rule, all facilities reporting under EPCRA section 313 on PBT chemicals would have to use the Form R (EPA Form No. 9350-1), which is currently approved by OMB.

For Form R, EPA estimates the industry reporting burden for collecting this information (including recordkeeping) to average 74 hours per report in the first year, at an estimated cost of $5,079 per Form R. In subsequent years, the burden is estimated to average 52.1 hours per report, at an estimated cost of $3,557 per Form R. These estimates include the time needed to review instructions; search existing data sources; gather and maintain the data needed; complete and review the collection of information; and transmit or otherwise disclose the information. The actual burden on any specific facility may be different from this estimate depending on the complexity of the facility's operations and the profile of the releases at the facility.

This final rule is estimated to result in reports from 11,300 respondents. Of these, 3,100 facilities are estimated to be reporting under EPCRA section 313 for the first time as a result of the rule, while 8,200 are currently reporting facilities that will be submitting additional reports. These facilities will submit an estimated additional 20,000 Form Rs. This rule therefore results in an estimated total burden of 2.1 million hours in the first year, and 1.2 million hours in subsequent years, at a total estimated industry cost of $145 million in the first year and $80 million in subsequent years. The existing ICR will be amended to include an additional annual burden of 1.5 million hours (annual average burden for the first 3 years of ICR approval).

Under the PRA, ''burden'' means the total time, effort, or financial resources expended by persons to generate, maintain, retain, or disclose or provide information to or for a Federal agency. This includes, where applicable, the time needed to review instructions; develop, acquire, install, and utilize technology and systems for the purposes of collecting, validating, and verifying information, processing and maintaining information, and disclosing and providing information; adjust the existing ways to comply with any previously applicable instructions and requirements; train personnel to be able to respond to a collection of information; search data sources; complete and review the collection of information; and transmit or otherwise disclose the information. EPA's burden estimates for the rule take into account all of the above elements, considering that under section 313, no additional measurement or monitoring may be imposed for purposes of reporting.

D. What are the Determinations under the Unfunded Mandates Reform Act and Executive Orders 12875 and 13084?

Pursuant to Title II of the Unfunded Mandates Reform Act of 1995 (UMRA) (Public Law 104–4), EPA has determined that this action contains a Federal mandate that may result in expenditures of $100 million or more for the private sector in any 1 year, but that it will not result in such expenditures for State, local, and tribal governments, in the aggregate. Accordingly, EPA has prepared a written statement for this rule pursuant to section 202 of UMRA, and that statement is available in the public version of the official record for this rulemaking (Ref. 71a). The costs associated with this action are estimated in the economic analysis prepared for this rule (Ref. 67), which is also included in the public version of the official record and summarized in Unit VII. The following is a brief summary of the UMRA statement for the rule.

This rule is being promulgated pursuant to sections 313(d)(1) and (2), 313(f)(2), 313(g), 313(h), and 328 of EPCRA, 42 U.S.C. 11023(d)(1)–(2), 11023(f)(2), 11023(g), 11023(h) and

11048; PPA section 6607, 42 U.S.C. 13106. The economic analysis contains an analysis of the benefits and costs of this rule, which estimates that the total industry costs of the rule will be $145 million in the first year and $80 million per year thereafter, and concludes that the benefits will be significant but cannot be assigned a dollar value due to the lack of adequate methodologies. EPA believes that the benefits provided by the information to be reported under this rule will significantly outweigh the costs imposed by today's action. The benefits of the information will in turn have positive effects on health, safety, and the natural environment through the behavioral changes that may result from that information.

EPA has not identified any Federal financial resources that are available to cover the costs of this rule. As set forth in the economic analysis, EPA has estimated the future industry compliance costs (after the first year) of this rule to be $80 million annually. Of those entities affected by today's action, EPA has not identified any disproportionate budgetary impact on any particular region, government, or community, or on any segment of the private sector. Based on the economic analysis, EPA has concluded that it is highly unlikely that this rule will have an appreciable effect on the national economy.

EPA has determined that it is not required to develop a small government agency plan as specified by section 203 of UMRA or to conduct prior consultation with State, local, or tribal governments under section 204 of UMRA, because the rule will not significantly or uniquely affect small governments and does not contain a significant Federal intergovernmental mandate.

Finally, EPA believes this rule complies with section 205(a) of UMRA. The objective of this rule is to expand the public benefits of the TRI program by exercising EPA's discretionary authority to add chemicals to the program and to lower reporting thresholds, thereby increasing the amount of information available to the public regarding the use, management, and disposition of PBT chemicals and enabling a more comprehensive view of PBT chemical exposures. In making additional information available through TRI, the Agency increases the utility of TRI data as an effective tool for empowering local communities, the public sector, industry, other agencies, and State and local governments to better evaluate risks to public health and the environment.

As described in Unit IV.D., EPA considered burden in the threshold selection. Existing burden-reducing measures (e.g., the laboratory exemption and the otherwise use exemptions, which include the routine janitorial or facility grounds maintenance exemption, motor vehicle maintenance exemption, structural component exemption, intake air and water exemption and the personal use exemption) will continue to apply to the facilities that file new reports as a result of this rule. EPA also will be assisting small entities subject to the rule, by such means as providing meetings, training, and compliance guides in the future, which also will ease the burdens of compliance. Many steps have been and will be taken to further reduce the burden associated with this rule, and to EPA's knowledge there is no available alternative to the rule that would obtain the equivalent information in a less burdensome manner. For all of these reasons, EPA believes the rule complies with UMRA section 205(a).

In addition, today's rule does not create an unfunded Federal mandate on State, local or tribal governments, nor does it significantly or uniquely affect the communities of Indian tribal governments. Accordingly, the requirements of section 1(a) of Executive Order 12875, entitled *Enhancing the Intergovernmental Partnership* (58 FR 58093, October 28, 1993), and section 3(b) of Executive Order 13084, entitled *Consultation and Coordination with Indian Tribal Governments* (63 FR 27655, May 19, 1998), do not apply to this proposed rule.

E. What are the Determinations under Executive Orders 12898 and 13045?

Pursuant to Executive Order 12898, entitled *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations* (59 FR 7629, February 16, 1994), the Agency must consider environmental justice related issues with regard to the potential impacts of this action on environmental and health conditions in low-income populations and minority populations. Pursuant to Executive Order 13045, entitled *Protection of Children from Environmental Health Risks and Safety Risks* (62 FR 19885, April 23, 1997), if an action is economically significant under Executive Order 12866, the Agency must, to the extent permitted by law and consistent with the Agency's mission, identify and assess the environmental health risks and safety risks that may disproportionately affect children.

By lowering the section 313 reporting thresholds for PBT chemicals, EPA will provide communities across the United States (including low-income populations and minority populations) with access to data that may assist them in lowering exposures and consequently reducing chemical risks for themselves and their children. This information can also be used by government agencies and others to identify potential problems, set priorities, and take appropriate steps to reduce any potential risks to human health and the environment. Therefore, the informational benefits of the rule will have a positive impact on the human health and environmental impacts of minority populations, low-income populations, and children.

F. What are the Determinations under Executive Orders 13132 and 12612?

On August 4, 1999, President Clinton issued a new executive order on federalism, Executive Order 13132, entitled *Federalism* (64 FR 43255, August 10, 1999), which will take effect on November 2, 1999. In the interim, the current Executive Order 12612, entitled *Federalism* (52 FR 41685, October 30, 1987) still applies. This action is expected to have a limited impact on municipal governments which operate electric utilities. EPA estimates that 39 municipalities operate 49 publicly owned electric utility facilities. Of these facilities, 44 are expected to file additional reports as a result of this action. Therefore EPA concludes that this rule will not have a substantial direct effect on States, on the relationship between the national government and the States, or on the distribution of power and responsibilities among the various levels of government, as specified in Executive Order 12612.

G. What are the Determinations under the National Technology Transfer and Advancement Act?

Section 12(d) of the National Technology Transfer and Advancement Act of 1995 (NTTAA) (15 U.S.C. 272 note) directs EPA to use voluntary consensus standards in its regulatory activities unless doing so would be inconsistent with applicable law or impractical. Voluntary consensus standards are technical standards (e.g., materials specifications, test methods, sampling procedures, etc.) that are developed or adopted by voluntary consensus standards bodies. The NTTAA directs EPA to provide Congress, through OMB, explanations when the Agency decides not to use

NMED Exhibit 72

available and applicable voluntary consensus standards.

This action does not involve technical standards, nor did EPA consider the use of any voluntary consensus standards. In general, EPCRA does not prescribe technical standards to be used for threshold determinations or completion of EPCRA section 313 reports. EPCRA section 313(g)(2) states that ''In order to provide the information required under this section, the owner or operator of a facility may use readily available data (including monitoring data) collected pursuant to other provisions of law, or, where such data are not readily available, reasonable estimates of the amounts involved. Nothing in this section requires the monitoring or measurement of the quantities, concentration, or frequency of any toxic chemical released into the environment beyond that monitoring and measurement required under other provisions of law or regulation.''

H. What are the Determinations under the Congressional Review Act?

The Congressional Review Act, 5 U.S.C. 801 *et seq.*, as added by the Small Business Regulatory Enforcement Fairness Act of 1996, generally provides that before a rule may take effect, the agency promulgating the rule must submit a rule report, which includes a copy of the rule, to each House of the Congress and to the Comptroller General of the United States. EPA will submit a report containing this rule and other required information to the U.S. Senate, the U.S. House of Representatives, and the Comptroller General of the United States prior to publication of the rule in the **Federal Register**. A major rule cannot take effect until 60 days after it is published in the **Federal Register**. This action is a ''major rule'' as defined by 5 U.S.C. 804(2). This rule will be effective December 31, 1999.

List of Subjects in 40 CFR Part 372

Environmental protection, Community right-to-know, Hazardous substances, Intergovernmental relations, Reporting and recordkeeping requirements, Superfund.

Dated: October 25, 1999.

Carol M. Browner,

Administrator.

Therefore, 40 CFR part 372 is amended as follows:

PART 372—[AMENDED]

1. The authority citation for part 372 continues to read as follows:

Authority: 42 U.S.C. 11023 and 11048.

§ 372.22 [Amended]

2. In § 372.22(c), remove the phrase ''§ 372.25 or § 372.27.'' and add in its place ''§ 372.25, § 372.27, or § 372.28.''.

§ 372.25 [Amended]

3. Section 372.25 is amended as follows:

i. In the introductory text of § 372.25, remove the first clause ''Except as provided in § 372.27,'' and add in its place ''Except as provided in §§ 372.27 and 372.28,''.

ii. In paragraphs (f), (g), and (h), remove the reference ''§ 372.25'' and add in its place ''§ 372.25, § 372.27, or § 372.28''.

4. In § 372.27, add a new paragraph (e) to read as follows:

§ 372.27 Alternate threshold and certification.

* * * * *

(e) The provisions of this section do not apply to any chemicals listed in § 372.28.

5. Add a new § 372.28 to subpart B to read as follows:

§ 372.28 Lower thresholds for chemicals of special concern.

(a) Notwithstanding § 372.25 or § 372.27, for the toxic chemicals set forth in this section, the threshold amounts for manufacturing (including importing), processing, and otherwise using such toxic chemicals are as set forth in this section.

(1) Chemical listing in alphabetic order.

Chemical name	CAS No.	Reporting threshold
Aldrin	00309–00–2	100
Benzo(g,h,i)perylene	00191–24–2	10
Chlordane	00057–74–9	10
Heptachlor	00076–44–8	10
Hexachlorobenzene	00118–74–1	10
Isodrin	00465–73–6	10
Mercury	07439–97–6	10
Methoxychlor	00072–43–5	100
Octachlorostyrene	29082–74–4	10
Pendimethalin	40487–42–1	100
Pentachlorobenzene	00608–93–5	10
Polychlorinated biphenyl (PCBs)	01336–36–3	10
Tetrabromobisphenol A	00079–94–7	100
Toxaphene	08001–35–2	10
Trifluralin	01582–09–8	100

(2) Chemical categories in alphabetic order.

Category name	Reporting threshold
Dioxin and dioxin-like compounds (Manufacturing; and the processing or otherwise use of dioxin and dioxin-like compounds if the dioxin and dioxin-like compounds are present as contaminants in a chemical and if they were created during the manufacturing of that chemical) (This category includes only those chemicals listed below).	0.1 grams
67562–39–4 1,2,3,4,6,7,8-Heptachlorodibenzofuran	

NMED Exhibit 72

Category name		Reporting threshold
55673–89–7	1,2,3,4,7,8,9-Heptachlorodibenzofuran	
70648–26–9	1,2,3,4,7,8-Hexachlorodibenzofuran	
57117–44–9	1,2,3,6,7,8-Hexachlorodibenzofuran	
72918–21–9	1,2,3,7,8,9-Hexachlorodibenzofuran	
60851–34–5	2,3,4,6,7,8-Hexachlorodibenzofuran	
39227–28–6	1,2,3,4,7,8-Hexachlorodibenzo-*p*-dioxin	
57653–85–7	1,2,3,6,7,8-Hexachlorodibenzo-*p*-dioxin	
19408–74–3	1,2,3,7,8,9-Hexachlorodibenzo-*p*-dioxin	
35822–46–9	1,2,3,4,6,7,8-Heptachlorodibenzo-*p*-dioxin	
39001–02–0	1,2,3,4,6,7,8,9-Octachlorodibenzofuran	
03268–87–9	1,2,3,4,6,7,8,9-Octachlorodibenzo-*p*-dioxin	
57117–41–6	1,2,3,7,8-Pentachlorodibenzofuran	
57117–31–4	2,3,4,7,8-Pentachlorodibenzofuran	
40321–76–4	1,2,3,7,8-Pentachlorodibenzo-*p*-dioxin	
51207–31–9	2,3,7,8-Tetrachlorodibenzofuran	
01746–01–6	2,3,7,8 Tetrachlorodibenzo-*p*-dioxin	
Mercury compounds		10
Polycyclic aromatic compounds (PACs) (This category includes only those chemicals listed below).		100
00056–55–3	Benz(a)anthracene	
00205–99–2	Benzo(b)fluoranthene	
00205–82–3	Benzo(j)fluoranthene	
00207–08–9	Benzo(k)fluoranthene	
00206–44–0	Benzo(j,k)fluorene	
00189–55–9	Benzo(r,s,t)pentaphene	
00218–01–9	Benzo(a)phenanthrene	
00050–32–8	Benzo(a)pyrene	
00226–36–8	Dibenz(a,h)acridine	
00224–42–0	Dibenz(a,j)acridine	
00053–70–3	Dibenzo(a,h)anthracene	
00194–59–2	7H-Dibenzo(c,g)carbazole	
05385–75–1	Dibenzo(a,e)fluoranthene	
00192–65–4	Dibenzo(a,e)pyrene	
00189–64–0	Dibenzo(a,h)pyrene	
00191–30–0	Dibenzo(a,l)pyrene	
00057–97–6	7,12-Dimethylbenz(a)anthracene	
00193–39–5	Indeno[1,2,3-cd]pyrene	
00056–49–5	3-Methylcholanthrene	
03697–24–3	5-Methylchrysene	
05522–43–0	1-Nitropyrene	

(b) The threshold determination provisions under § 372.25(c) through (h) and the exemptions under § 372.38(b) through (h) are applicable to the toxic chemicals listed in paragraph (a) of this section.

§ 372.30 [Amended]

6. Section 372.30 is amended as follows:

i. In paragraph (a), remove the phrase ''in § 372.25 at'' and add in its place ''in § 372.25, § 372.27, or § 372.28 at''.

ii. In paragraphs (b)(1), the introductory text of (b)(3), (b)(3)(i), and (b)(3)(iv), remove the reference ''§ 372.25'' and add in its place ''§ 372.25, § 372.27, or § 372.28''.

§ 372.38 [Amended]

7. Section 372.38 is amended as follows:

i. In paragraph (a), add the following sentence at the end of the paragraph to read as follows: ''This exemption does not apply to toxic chemicals listed in § 372.28, except for purposes of § 372.45(d)(1).''.

ii. In paragraphs (b), (c) introductory text, (d) introductory text, and (f), remove the reference ''§ 372.25'' and add in its place ''§ 372.25, § 372.27, or § 372.28''.

iii. In paragraphs (g) and (h), remove the phrase ''§ 372.25 or § 372.27'' and add in its place ''§ 372.25, § 372.27, or § 372.28''.

8. Section 372.65 is amended as follows:

i. In the table in paragraph (a), revise the entry for ''Vanadium'' and alphabetically add four chemicals.

ii. In the table in paragraph (b), revise the CAS no. entry ''7440–62–2'' and add four chemicals in numerical CAS no. sequence.

iii. In the table in paragraph (c), alphabetically add two categories, ''dioxin and dioxin-like compounds'' and ''vanadium'', and alphabetically add two chemicals, ''benzo(j,k)fluorene'' and ''3-methylcholanthrene'', under the polycyclic aromatic compounds (PACs) category.

The revisions and additions read as follows:

§ 372.65 Chemicals and chemical categories to which the part applies.

* * * * *

9. In § 372.85, revise the introductory text of paragraph (b)(15)(i), add a new paragraph (b)(15)(ii), and revise paragraphs (b)(16)(i)(B) and (b)(16)(ii)(B) to read as follows:

§ 372.85 Toxic chemical release reporting form and instructions.

* * * * *

(b) * * *

(15) * * *

(i) An estimate of total releases in pounds (except for dioxin and dioxin-like compounds, which shall be reported in grams) per year (releases of less than 1,000 pounds per year may be indicated in ranges, except for chemicals set forth in § 372.28) from the facility plus an indication of the basis of estimate for the following:

* * * * *

(ii) Report a distribution of the chemicals included in the dioxin and dioxin-like compounds category. Such distribution shall either represent the distribution of the total quantity of dioxin and dioxin-like compounds released to all media from the facility; or its one best media-specific distribution.

(16) * * *

(i) * * *

(B) An estimate of the amount of the chemical transferred in pounds (except for dioxin and dioxin-like compounds, which shall be reported in grams) per year (transfers of less than 1,000 pounds per year may be indicated as a range, except for chemicals set forth in § 372.28) and an indication of the basis of the estimate.

* * * * *

(ii) * * *

(B) An estimate of the amount of the chemical in waste transferred in pounds (except for dioxin and dioxin-like compounds, which shall be reported in grams) per year (transfers of less than 1,000 pounds may be indicated in ranges, except for chemicals set forth in § 372.28) to each off-site location, and an indication of the basis for the estimate and an indication of the type of treatment or disposal used.

NMED Exhibit 73

INTRODUCTION

The Stockholm Convention on Persistent Organic Pollutants was adopted at a Conference of Plenipotentiaries on 22 May 2001 in Stockholm, Sweden. The Convention entered into force on 17 May 2004.

Since its adoption, the Stockholm Convention has seen the addition of Annex G on arbitration and conciliation procedures for settlement of disputes as well as a number of amendments to its Annexes A, B and C to eliminate and restrict additional persistent organic pollutants.

The version of the Stockholm Convention contained in this booklet does not substitute the original authentic texts of the Convention and amendments thereto as deposited with the Secretary-General in New York. Should you wish to access the authentic texts of the Convention, obtain a certified true copy of the Convention or, more generally, have access to amendments and modifications to the certified true copies, rectifications of authentic texts or any other relevant formalities circulated under the cover of depositary notifications (CNs), you are advised to visit the United Nations Treaty Section online (https://treaties.un.org) or kindly contact the Treaty Section for further assistance.

The Secretariat of the Stockholm Convention, 2025.

NMED Exhibit 73

STOCKHOLM CONVENTION ON PERSISTENT ORGANIC POLLUTANTS

The Parties to this Convention,

Recognizing that persistent organic pollutants possess toxic properties, resist degradation, bioaccumulate and are transported, through air, water and migratory species, across international boundaries and deposited far from their place of release, where they accumulate in terrestrial and aquatic ecosystems,

Aware of the health concerns, especially in developing countries, resulting from local exposure to persistent organic pollutants, in particular impacts upon women and, through them, upon future generations,

Acknowledging that the Arctic ecosystems and indigenous communities are particularly at risk because of the biomagnification of persistent organic pollutants and that contamination of their traditional foods is a public health issue,

Conscious of the need for global action on persistent organic pollutants,

Mindful of decision 19/13 C of 7 February 1997 of the Governing Council of the United Nations Environment Programme to initiate international action to protect human health and the environment through measures which will reduce and/or eliminate emissions and discharges of persistent organic pollutants,

Recalling the pertinent provisions of the relevant international environmental conventions, especially the Rotterdam Convention on the Prior Informed Consent Procedure for Certain Hazardous Chemicals and Pesticides in International Trade, and the Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and their Disposal including the regional agreements developed within the framework of its Article 11,

Recalling also the pertinent provisions of the Rio Declaration on Environment and Development and Agenda 21,

Acknowledging that precaution underlies the concerns of all the Parties and is embedded within this Convention,

Recognizing that this Convention and other international agreements in the field of trade and the environment are mutually supportive,

Reaffirming that States have, in accordance with the Charter of the United Nations and the principles of international law, the sovereign right to exploit their own resources

NMED Exhibit 73

pursuant to their own environmental and developmental policies, and the responsibility to ensure that activities within their jurisdiction or control do not cause damage to the environment of other States or of areas beyond the limits of national jurisdiction,

Taking into account the circumstances and particular requirements of developing countries, in particular the least developed among them, and countries with economies in transition, especially the need to strengthen their national capabilities for the management of chemicals, including through the transfer of technology, the provision of financial and technical assistance and the promotion of cooperation among the Parties,

Taking full account of the Programme of Action for the Sustainable Development of Small Island Developing States, adopted in Barbados on 6 May 1994,

Noting the respective capabilities of developed and developing countries, as well as the common but differentiated responsibilities of States as set forth in Principle 7 of the Rio Declaration on Environment and Development,

Recognizing the important contribution that the private sector and non-governmental organizations can make to achieving the reduction and/or elimination of emissions and discharges of persistent organic pollutants,

Underlining the importance of manufacturers of persistent organic pollutants taking responsibility for reducing adverse effects caused by their products and for providing information to users, Governments and the public on the hazardous properties of those chemicals,

Conscious of the need to take measures to prevent adverse effects caused by persistent organic pollutants at all stages of their life cycle,

Reaffirming Principle 16 of the Rio Declaration on Environment and Development which states that national authorities should endeavour to promote the internalization of environmental costs and the use of economic instruments, taking into account the approach that the polluter should, in principle, bear the cost of pollution, with due regard to the public interest and without distorting international trade and investment,

Encouraging Parties not having regulatory and assessment schemes for pesticides and industrial chemicals to develop such schemes,

Recognizing the importance of developing and using environmentally sound alternative processes and chemicals,

Determined to protect human health and the environment from the harmful impacts of persistent organic pollutants,

NMED Exhibit 73

Have agreed as follows:

ARTICLE 1
Objective

Mindful of the precautionary approach as set forth in Principle 15 of the Rio Declaration on Environment and Development, the objective of this Convention is to protect human health and the environment from persistent organic pollutants.

ARTICLE 2
Definitions

For the purposes of this Convention:

a) "Party" means a State or regional economic integration organization that has consented to be bound by this Convention and for which the Convention is in force;

b) "Regional economic integration organization" means an organization constituted by sovereign States of a given region to which its member States have transferred competence in respect of matters governed by this Convention and which has been duly authorized, in accordance with its internal procedures, to sign, ratify, accept, approve or accede to this Convention;

c) "Parties present and voting" means Parties present and casting an affirmative or negative vote.

ARTICLE 3
Measures to reduce or eliminate releases from intentional production and use

1. Each Party shall:

   a) Prohibit and/or take the legal and administrative measures necessary to eliminate:

      i. Its production and use of the chemicals listed in Annex A subject to the provisions of that Annex; and

      ii. Its import and export of the chemicals listed in Annex A in accordance with the provisions of paragraph 2; and

   b) Restrict its production and use of the chemicals listed in Annex B in accordance with the provisions of that Annex.

NMED Exhibit 73

2. Each Party shall take measures to ensure:

    a) That a chemical listed in Annex A or Annex B is imported only:

        i. For the purpose of environmentally sound disposal as set forth in paragraph 1 (d) of Article 6; or

        ii. For a use or purpose which is permitted for that Party under Annex A or Annex B;

    b) That a chemical listed in Annex A for which any production or use specific exemption is in effect or a chemical listed in Annex B for which any production or use specific exemption or acceptable purpose is in effect, taking into account any relevant provisions in existing international prior informed consent instruments, is exported only:

        i. For the purpose of environmentally sound disposal as set forth in paragraph 1 (d) of Article 6;

        ii. To a Party which is permitted to use that chemical under Annex A or Annex B; or

        iii. To a State not Party to this Convention which has provided an annual certification to the exporting Party. Such certification shall specify the intended use of the chemical and include a statement that, with respect to that chemical, the importing State is committed to:

            a. Protect human health and the environment by taking the necessary measures to minimize or prevent releases;

            b. Comply with the provisions of paragraph 1 of Article 6; and

            c. Comply, where appropriate, with the provisions of paragraph 2 of Part II of Annex B.

The certification shall also include any appropriate supporting documentation, such as legislation, regulatory instruments, or administrative or policy guidelines. The exporting Party shall transmit the certification to the Secretariat within sixty days of receipt.

    c) That a chemical listed in Annex A, for which production and use specific exemptions are no longer in effect for any Party, is not exported from it except for the purpose of environmentally sound disposal as set forth in paragraph 1 (d) of Article 6;

    d) For the purposes of this paragraph, the term "State not Party to this Convention" shall include, with respect to a particular chemical, a State or regional economic integration organization that has not agreed to be bound by the Convention with respect to that chemical.

NMED Exhibit 73

3. Each Party that has one or more regulatory and assessment schemes for new pesticides or new industrial chemicals shall take measures to regulate with the aim of preventing the production and use of new pesticides or new industrial chemicals which, taking into consideration the criteria in paragraph 1 of Annex D, exhibit the characteristics of persistent organic pollutants.

4. Each Party that has one or more regulatory and assessment schemes for pesticides or industrial chemicals shall, where appropriate, take into consideration within these schemes the criteria in paragraph 1 of Annex D when conducting assessments of pesticides or industrial chemicals currently in use.

5. Except as otherwise provided in this Convention, paragraphs 1 and 2 shall not apply to quantities of a chemical to be used for laboratory-scale research or as a reference standard.

6. Any Party that has a specific exemption in accordance with Annex A or a specific exemption or an acceptable purpose in accordance with Annex B shall take appropriate measures to ensure that any production or use under such exemption or purpose is carried out in a manner that prevents or minimizes human exposure and release into the environment. For exempted uses or acceptable purposes that involve intentional release into the environment under conditions of normal use, such release shall be to the minimum extent necessary, taking into account any applicable standards and guidelines.

ARTICLE 4
Register of specific exemptions

1. A Register is hereby established for the purpose of identifying the Parties that have specific exemptions listed in Annex A or Annex B. It shall not identify Parties that make use of the provisions in Annex A or Annex B that may be exercised by all Parties. The Register shall be maintained by the Secretariat and shall be available to the public.

2. The Register shall include:

   a) A list of the types of specific exemptions reproduced from Annex A and Annex B;

   b) A list of the Parties that have a specific exemption listed under Annex A or Annex B; and

   c) A list of the expiry dates for each registered specific exemption.

3. Any State may, on becoming a Party, by means of a notification in writing to the Secretariat, register for one or more types of specific exemptions listed in Annex A or Annex B.

NMED Exhibit 73

4. Unless an earlier date is indicated in the Register by a Party, or an extension is granted pursuant to paragraph 7, all registrations of specific exemptions shall expire five years after the date of entry into force of this Convention with respect to a particular chemical.

5. At its first meeting, the Conference of the Parties shall decide upon its review process for the entries in the Register.

6. Prior to a review of an entry in the Register, the Party concerned shall submit a report to the Secretariat justifying its continuing need for registration of that exemption. The report shall be circulated by the Secretariat to all Parties. The review of a registration shall be carried out on the basis of all available information. Thereupon, the Conference of the Parties may make such recommendations to the Party concerned as it deems appropriate.

7. The Conference of the Parties may, upon request from the Party concerned, decide to extend the expiry date of a specific exemption for a period of up to five years. In making its decision, the Conference of the Parties shall take due account of the special circumstances of the developing country Parties and Parties with economies in transition.

8. A Party may, at any time, withdraw an entry from the Register for a specific exemption upon written notification to the Secretariat. The withdrawal shall take effect on the date specified in the notification.

9. When there are no longer any Parties registered for a particular type of specific exemption, no new registrations may be made with respect to it.

ARTICLE 5
Measures to reduce or eliminate releases from unintentional production

Each Party shall at a minimum take the following measures to reduce the total releases derived from anthropogenic sources of each of the chemicals listed in Annex C, with the goal of their continuing minimization and, where feasible, ultimate elimination:

a) Develop an action plan or, where appropriate, a regional or subregional action plan within two years of the date of entry into force of this Convention for it, and subsequently implement it as part of its implementation plan specified in Article 7, designed to identify, characterize and address the release of the chemicals listed in Annex C and to facilitate implementation of subparagraphs (b) to (e). The action plan shall include the following elements:

   i. An evaluation of current and projected releases, including the development and maintenance of source inventories and release estimates, taking into consideration the source categories identified in Annex C;

NMED Exhibit 73

ii. An evaluation of the efficacy of the laws and policies of the Party relating to the management of such releases;

iii. Strategies to meet the obligations of this paragraph, taking into account the evaluations in (i) and (ii);

iv. Steps to promote education and training with regard to, and awareness of, those strategies;

v. A review every five years of those strategies and of their success in meeting the obligations of this paragraph; such reviews shall be included in reports submitted pursuant to Article 15;

vi. A schedule for implementation of the action plan, including for the strategies and measures identified therein;

b) Promote the application of available, feasible and practical measures that can expeditiously achieve a realistic and meaningful level of release reduction or source elimination;

c) Promote the development and, where it deems appropriate, require the use of substitute or modified materials, products and processes to prevent the formation and release of the chemicals listed in Annex C, taking into consideration the general guidance on prevention and release reduction measures in Annex C and guidelines to be adopted by decision of the Conference of the Parties;

d) Promote and, in accordance with the implementation schedule of its action plan, require the use of best available techniques for new sources within source categories which a Party has identified as warranting such action in its action plan, with a particular initial focus on source categories identified in Part II of Annex C. In any case, the requirement to use best available techniques for new sources in the categories listed in Part II of that Annex shall be phased in as soon as practicable but no later than four years after the entry into force of the Convention for that Party. For the identified categories, Parties shall promote the use of best environmental practices. When applying best available techniques and best environmental practices, Parties should take into consideration the general guidance on prevention and release reduction measures in that Annex and guidelines on best available techniques and best environmental practices to be adopted by decision of the Conference of the Parties;

e) Promote, in accordance with its action plan, the use of best available techniques and best environmental practices:

i. For existing sources, within the source categories listed in Part II of Annex C and within source categories such as those in Part III of that Annex; and

NMED Exhibit 73

ii. For new sources, within source categories such as those listed in Part III of Annex C which a Party has not addressed under subparagraph (d).

When applying best available techniques and best environmental practices, Parties should take into consideration the general guidance on prevention and release reduction measures in Annex C and guidelines on best available techniques and best environmental practices to be adopted by decision of the Conference of the Parties;

f) For the purposes of this paragraph and Annex C:

i. "Best available techniques" means the most effective and advanced stage in the development of activities and their methods of operation which indicate the practical suitability of particular techniques for providing in principle the basis for release limitations designed to prevent and, where that is not practicable, generally to reduce releases of chemicals listed in Part I of Annex C and their impact on the environment as a whole. In this regard:

ii. "Techniques" includes both the technology used and the way in which the installation is designed, built, maintained, operated and decommissioned;

iii. "Available" techniques means those techniques that are accessible to the operator and that are developed on a scale that allows implementation in the relevant industrial sector, under economically and technically viable conditions, taking into consideration the costs and advantages; and

iv. "Best" means most effective in achieving a high general level of protection of the environment as a whole;

v. "Best environmental practices" means the application of the most appropriate combination of environmental control measures and strategies;

vi. "New source" means any source of which the construction or substantial modification is commenced at least one year after the date of:

a) Entry into force of this Convention for the Party concerned; or

b) Entry into force for the Party concerned of an amendment to Annex C where the source becomes subject to the provisions of this Convention only by virtue of that amendment.

g) Release limit values or performance standards may be used by a Party to fulfil its commitments for best available techniques under this paragraph.

NMED Exhibit 73

ARTICLE 6
Measures to reduce or eliminate releases from stockpiles and wastes

1. In order to ensure that stockpiles consisting of or containing chemicals listed either in Annex A or Annex B and wastes, including products and articles upon becoming wastes, consisting of, containing or contaminated with a chemical listed in Annex A, B or C, are managed in a manner protective of human health and the environment, each Party shall:

    a) Develop appropriate strategies for identifying:

        i. Stockpiles consisting of or containing chemicals listed either in Annex A or Annex B; and

        ii. Products and articles in use and wastes consisting of, containing or contaminated with a chemical listed in Annex A, B or C;

    b) Identify, to the extent practicable, stockpiles consisting of or containing chemicals listed either in Annex A or Annex B on the basis of the strategies referred to in subparagraph (a);

    c) Manage stockpiles, as appropriate, in a safe, efficient and environmentally sound manner. Stockpiles of chemicals listed either in Annex A or Annex B, after they are no longer allowed to be used according to any specific exemption specified in Annex A or any specific exemption or acceptable purpose specified in Annex B, except stockpiles which are allowed to be exported according to paragraph 2 of Article 3, shall be deemed to be waste and shall be managed in accordance with subparagraph (d);

    d) Take appropriate measures so that such wastes, including products and articles upon becoming wastes, are:

        i. Handled, collected, transported and stored in an environmentally sound manner;

        ii. Disposed of in such a way that the persistent organic pollutant content is destroyed or irreversibly transformed so that they do not exhibit the characteristics of persistent organic pollutants or otherwise disposed of in an environmentally sound manner when destruction or irreversible transformation does not represent the environmentally preferable option or the persistent organic pollutant content is low, taking into account international rules, standards, and guidelines, including those that may be developed pursuant to paragraph 2, and relevant global and regional regimes governing the management of hazardous wastes;

NMED Exhibit 73

iii. Not permitted to be subjected to disposal operations that may lead to recovery, recycling, reclamation, direct reuse or alternative uses of persistent organic pollutants; and

iv. Not transported across international boundaries without taking into account relevant international rules, standards and guidelines;

e) Endeavour to develop appropriate strategies for identifying sites contaminated by chemicals listed in Annex A, B or C; if remediation of those sites is undertaken it shall be performed in an environmentally sound manner.

2. The Conference of the Parties shall cooperate closely with the appropriate bodies of the Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and their Disposal to, inter alia:

a) Establish levels of destruction and irreversible transformation necessary to ensure that the characteristics of persistent organic pollutants as specified in paragraph 1 of Annex D are not exhibited;

b) Determine what they consider to be the methods that constitute environmentally sound disposal referred to above; and

c) Work to establish, as appropriate, the concentration levels of the chemicals listed in Annexes A, B and C in order to define the low persistent organic pollutant content referred to in paragraph 1 (d) (ii).

ARTICLE 7
Implementation plans

1. Each Party shall:

a) Develop and endeavour to implement a plan for the implementation of its obligations under this Convention;

b) Transmit its implementation plan to the Conference of the Parties within two years of the date on which this Convention enters into force for it; and

c) Review and update, as appropriate, its implementation plan on a periodic basis and in a manner to be specified by a decision of the Conference of the Parties.

2. The Parties shall, where appropriate, cooperate directly or through global, regional and subregional organizations, and consult their national stakeholders, including women's groups and groups involved in the health of children, in order to facilitate the development, implementation and updating of their implementation plans.

3. The Parties shall endeavour to utilize and, where necessary, establish the means to integrate national implementation plans for persistent organic pollutants in their sustainable development strategies where appropriate.

NMED Exhibit 73

ARTICLE 8
Listing of chemicals in Annexes A, B and C

1. A Party may submit a proposal to the Secretariat for listing a chemical in Annexes A, B and/or C. The proposal shall contain the information specified in Annex D. In developing a proposal, a Party may be assisted by other Parties and/or by the Secretariat.

2. The Secretariat shall verify whether the proposal contains the information specified in Annex D. If the Secretariat is satisfied that the proposal contains the information so specified, it shall forward the proposal to the Persistent Organic Pollutants Review Committee.

3. The Committee shall examine the proposal and apply the screening criteria specified in Annex D in a flexible and transparent way, taking all information provided into account in an integrative and balanced manner.

4. If the Committee decides that:

   a) It is satisfied that the screening criteria have been fulfilled, it shall, through the Secretariat, make the proposal and the evaluation of the Committee available to all Parties and observers and invite them to submit the information specified in Annex E; or

   b) It is not satisfied that the screening criteria have been fulfilled, it shall, through the Secretariat, inform all Parties and observers and make the proposal and the evaluation of the Committee available to all Parties and the proposal shall be set aside.

5. Any Party may resubmit a proposal to the Committee that has been set aside by the Committee pursuant to paragraph 4. The resubmission may include any concerns of the Party as well as a justification for additional consideration by the Committee. If, following this procedure, the Committee again sets the proposal aside, the Party may challenge the decision of the Committee and the Conference of the Parties shall consider the matter at its next session. The Conference of the Parties may decide, based on the screening criteria in Annex D and taking into account the evaluation of the Committee and any additional information provided by any Party or observer, that the proposal should proceed.

6. Where the Committee has decided that the screening criteria have been fulfilled, or the Conference of the Parties has decided that the proposal should proceed, the Committee shall further review the proposal, taking into account any relevant additional information received, and shall prepare a draft risk profile in accordance with Annex E. It shall, through the Secretariat, make that draft

NMED Exhibit 73

available to all Parties and observers, collect technical comments from them and, taking those comments into account, complete the risk profile.

7. If, on the basis of the risk profile conducted in accordance with Annex E, the Committee decides:

   a) That the chemical is likely as a result of its long-range environmental transport to lead to significant adverse human health and/or environmental effects such that global action is warranted, the proposal shall proceed. Lack of full scientific certainty shall not prevent the proposal from proceeding. The Committee shall, through the Secretariat, invite information from all Parties and observers relating to the considerations specified in Annex F. It shall then prepare a risk management evaluation that includes an analysis of possible control measures for the chemical in accordance with that Annex; or

   b) That the proposal should not proceed, it shall, through the Secretariat, make the risk profile available to all Parties and observers and set the proposal aside.

8. For any proposal set aside pursuant to paragraph 7 (b), a Party may request the Conference of the Parties to consider instructing the Committee to invite additional information from the proposing Party and other Parties during a period not to exceed one year. After that period and on the basis of any information received, the Committee shall reconsider the proposal pursuant to paragraph 6 with a priority to be decided by the Conference of the Parties. If, following this procedure, the Committee again sets the proposal aside, the Party may challenge the decision of the Committee and the Conference of the Parties shall consider the matter at its next session. The Conference of the Parties may decide, based on the risk profile prepared in accordance with Annex E and taking into account the evaluation of the Committee and any additional information provided by any Party or observer, that the proposal should proceed. If the Conference of the Parties decides that the proposal shall proceed, the Committee shall then prepare the risk management evaluation.

9. The Committee shall, based on the risk profile referred to in paragraph 6 and the risk management evaluation referred to in paragraph 7 (a) or paragraph 8, recommend whether the chemical should be considered by the Conference of the Parties for listing in Annexes A, B and/or C. The Conference of the Parties, taking due account of the recommendations of the Committee, including any scientific uncertainty, shall decide, in a precautionary manner, whether to list the chemical, and specify its related control measures, in Annexes A, B and/or C.

NMED Exhibit 73

ARTICLE 9
Information exchange

1. Each Party shall facilitate or undertake the exchange of information relevant to:

    a) The reduction or elimination of the production, use and release of persistent organic pollutants; and

    b) Alternatives to persistent organic pollutants, including information relating to their risks as well as to their economic and social costs.

2. The Parties shall exchange the information referred to in paragraph 1 directly or through the Secretariat.

3. Each Party shall designate a national focal point for the exchange of such information.

4. The Secretariat shall serve as a clearing-house mechanism for information on persistent organic pollutants, including information provided by Parties, intergovernmental organizations and non-governmental organizations.

5. For the purposes of this Convention, information on health and safety of humans and the environment shall not be regarded as confidential. Parties that exchange other information pursuant to this Convention shall protect any confidential information as mutually agreed.

ARTICLE 10
Public information, awareness and education

1. Each Party shall, within its capabilities, promote and facilitate:

    a) Awareness among its policy and decision makers with regard to persistent organic pollutants;

    b) Provision to the public of all available information on persistent organic pollutants, taking into account paragraph 5 of Article 9;

    c) Development and implementation, especially for women, children and the least educated, of educational and public awareness programmes on persistent organic pollutants, as well as on their health and environmental effects and on their alternatives;

    d) Public participation in addressing persistent organic pollutants and their health and environmental effects and in developing adequate responses, including opportunities for providing input at the national level regarding implementation of this Convention;

NMED Exhibit 73

e) Training of workers, scientists, educators and technical and managerial personnel;

f) Development and exchange of educational and public awareness materials at the national and international levels; and

g) Development and implementation of education and training programmes at the national and international levels.

2. Each Party shall, within its capabilities, ensure that the public has access to the public information referred to in paragraph 1 and that the information is kept up-to-date.

3. Each Party shall, within its capabilities, encourage industry and professional users to promote and facilitate the provision of the information referred to in paragraph 1 at the national level and, as appropriate, subregional, regional and global levels.

4. In providing information on persistent organic pollutants and their alternatives, Parties may use safety data sheets, reports, mass media and other means of communication, and may establish information centres at national and regional levels.

5. Each Party shall give sympathetic consideration to developing mechanisms, such as pollutant release and transfer registers, for the collection and dissemination of information on estimates of the annual quantities of the chemicals listed in Annex A, B or C that are released or disposed of.

ARTICLE 11
Research, development and monitoring

1. The Parties shall, within their capabilities, at the national and international levels, encourage and/or undertake appropriate research, development, monitoring and cooperation pertaining to persistent organic pollutants and, where relevant, to their alternatives and to candidate persistent organic pollutants, including on their:

a) Sources and releases into the environment;

b) Presence, levels and trends in humans and the environment;

c) Environmental transport, fate and transformation;

d) Effects on human health and the environment;

e) Socio-economic and cultural impacts;

f) Release reduction and/or elimination; and

NMED Exhibit 73

g) Harmonized methodologies for making inventories of generating sources and analytical techniques for the measurement of releases.

2. In undertaking action under paragraph 1, the Parties shall, within their capabilities:

   a) Support and further develop, as appropriate, international programmes, networks and organizations aimed at defining, conducting, assessing and financing research, data collection and monitoring, taking into account the need to minimize duplication of effort;

   b) Support national and international efforts to strengthen national scientific and technical research capabilities, particularly in developing countries and countries with economies in transition, and to promote access to, and the exchange of, data and analyses;

   c) Take into account the concerns and needs, particularly in the field of financial and technical resources, of developing countries and countries with economies in transition and cooperate in improving their capability to participate in the efforts referred to in subparagraphs (a) and (b);

   d) Undertake research work geared towards alleviating the effects of persistent organic pollutants on reproductive health;

   e) Make the results of their research, development and monitoring activities referred to in this paragraph accessible to the public on a timely and regular basis; and

   f) Encourage and/or undertake cooperation with regard to storage and maintenance of information generated from research, development and monitoring.

ARTICLE 12
Technical assistance

1. The Parties recognize that rendering of timely and appropriate technical assistance in response to requests from developing country Parties and Parties with economies in transition is essential to the successful implementation of this Convention.

2. The Parties shall cooperate to provide timely and appropriate technical assistance to developing country Parties and Parties with economies in transition, to assist them, taking into account their particular needs, to develop and strengthen their capacity to implement their obligations under this Convention.

3. In this regard, technical assistance to be provided by developed country Parties, and other Parties in accordance with their capabilities, shall include, as

NMED Exhibit 73

appropriate and as mutually agreed, technical assistance for capacity-building relating to implementation of the obligations under this Convention. Further guidance in this regard shall be provided by the Conference of the Parties.

4. The Parties shall establish, as appropriate, arrangements for the purpose of providing technical assistance and promoting the transfer of technology to developing country Parties and Parties with economies in transition relating to the implementation of this Convention. These arrangements shall include regional and subregional centres for capacity-building and transfer of technology to assist developing country Parties and Parties with economies in transition to fulfil their obligations under this Convention. Further guidance in this regard shall be provided by the Conference of the Parties.

5. The Parties shall, in the context of this Article, take full account of the specific needs and special situation of least developed countries and small island developing states in their actions with regard to technical assistance.

ARTICLE 13
Financial resources and mechanisms

1. Each Party undertakes to provide, within its capabilities, financial support and incentives in respect of those national activities that are intended to achieve the objective of this Convention in accordance with its national plans, priorities and programmes.

2. The developed country Parties shall provide new and additional financial resources to enable developing country Parties and Parties with economies in transition to meet the agreed full incremental costs of implementing measures which fulfil their obligations under this Convention as agreed between a recipient Party and an entity participating in the mechanism described in paragraph 6. Other Parties may also on a voluntary basis and in accordance with their capabilities provide such financial resources. Contributions from other sources should also be encouraged. The implementation of these commitments shall take into account the need for adequacy, predictability, the timely flow of funds and the importance of burden sharing among the contributing Parties.

3. Developed country Parties, and other Parties in accordance with their capabilities and in accordance with their national plans, priorities and programmes, may also provide and developing country Parties and Parties with economies in transition avail themselves of financial resources to assist in their implementation of this Convention through other bilateral, regional and multilateral sources or channels.

NMED Exhibit 73

4. The extent to which the developing country Parties will effectively implement their commitments under this Convention will depend on the effective implementation by developed country Parties of their commitments under this Convention relating to financial resources, technical assistance and technology transfer. The fact that sustainable economic and social development and eradication of poverty are the first and overriding priorities of the developing country Parties will be taken fully into account, giving due consideration to the need for the protection of human health and the environment.

5. The Parties shall take full account of the specific needs and special situation of the least developed countries and the small island developing states in their actions with regard to funding.

6. A mechanism for the provision of adequate and sustainable financial resources to developing country Parties and Parties with economies in transition on a grant or concessional basis to assist in their implementation of the Convention is hereby defined. The mechanism shall function under the authority, as appropriate, and guidance of, and be accountable to the Conference of the Parties for the purposes of this Convention. Its operation shall be entrusted to one or more entities, including existing international entities, as may be decided upon by the Conference of the Parties. The mechanism may also include other entities providing multilateral, regional and bilateral financial and technical assistance. Contributions to the mechanism shall be additional to other financial transfers to developing country Parties and Parties with economies in transition as reflected in, and in accordance with, paragraph 2.

7. Pursuant to the objectives of this Convention and paragraph 6, the Conference of the Parties shall at its first meeting adopt appropriate guidance to be provided to the mechanism and shall agree with the entity or entities participating in the financial mechanism upon arrangements to give effect thereto. The guidance shall address, inter alia:

    a) The determination of the policy, strategy and programme priorities, as well as clear and detailed criteria and guidelines regarding eligibility for access to and utilization of financial resources including monitoring and evaluation on a regular basis of such utilization;

    b) The provision by the entity or entities of regular reports to the Conference of the Parties on adequacy and sustainability of funding for activities relevant to the implementation of this Convention;

    c) The promotion of multiple-source funding approaches, mechanisms and arrangements;

NMED Exhibit 73

d) The modalities for the determination in a predictable and identifiable manner of the amount of funding necessary and available for the implementation of this Convention, keeping in mind that the phasing out of persistent organic pollutants might require sustained funding, and the conditions under which that amount shall be periodically reviewed; and

e) The modalities for the provision to interested Parties of assistance with needs assessment, information on available sources of funds and on funding patterns in order to facilitate coordination among them.

8. The Conference of the Parties shall review, not later than its second meeting and thereafter on a regular basis, the effectiveness of the mechanism established under this Article, its ability to address the changing needs of the developing country Parties and Parties with economies in transition, the criteria and guidance referred to in paragraph 7, the level of funding as well as the effectiveness of the performance of the institutional entities entrusted to operate the financial mechanism. It shall, based on such review, take appropriate action, if necessary, to improve the effectiveness of the mechanism, including by means of recommendations and guidance on measures to ensure adequate and sustainable funding to meet the needs of the Parties.

ARTICLE 14
Interim financial arrangements

The institutional structure of the Global Environment Facility, operated in accordance with the Instrument for the Establishment of the Restructured Global Environment Facility, shall, on an interim basis, be the principal entity entrusted with the operations of the financial mechanism referred to in Article 13, for the period between the date of entry into force of this Convention and the first meeting of the Conference of the Parties, or until such time as the Conference of the Parties decides which institutional structure will be designated in accordance with Article 13. The institutional structure of the Global Environment Facility should fulfil this function through operational measures related specifically to persistent organic pollutants taking into account that new arrangements for this area may be needed.

ARTICLE 15
Reporting

1. Each Party shall report to the Conference of the Parties on the measures it has taken to implement the provisions of this Convention and on the effectiveness of such measures in meeting the objectives of the Convention.

NMED Exhibit 73

2. Each Party shall provide to the Secretariat:

   a) Statistical data on its total quantities of production, import and export of each of the chemicals listed in Annex A and Annex B or a reasonable estimate of such data; and

   b) To the extent practicable, a list of the States from which it has imported each such substance and the States to which it has exported each such substance.

3. Such reporting shall be at periodic intervals and in a format to be decided by the Conference of the Parties at its first meeting.

ARTICLE 16
Effectiveness evaluation

1. Commencing four years after the date of entry into force of this Convention, and periodically thereafter at intervals to be decided by the Conference of the Parties, the Conference shall evaluate the effectiveness of this Convention.

2. In order to facilitate such evaluation, the Conference of the Parties shall, at its first meeting, initiate the establishment of arrangements to provide itself with comparable monitoring data on the presence of the chemicals listed in Annexes A, B and C as well as their regional and global environmental transport. These arrangements:

   a) Should be implemented by the Parties on a regional basis when appropriate, in accordance with their technical and financial capabilities, using existing monitoring programmes and mechanisms to the extent possible and promoting harmonization of approaches;

   b) May be supplemented where necessary, taking into account the differences between regions and their capabilities to implement monitoring activities; and

   c) Shall include reports to the Conference of the Parties on the results of the monitoring activities on a regional and global basis at intervals to be specified by the Conference of the Parties.

3. The evaluation described in paragraph 1 shall be conducted on the basis of available scientific, environmental, technical and economic information, including:

   a) Reports and other monitoring information provided pursuant to paragraph 2;

   b) National reports submitted pursuant to Article 15; and

   c) Non-compliance information provided pursuant to the procedures established under Article 17.

NMED Exhibit 73

ARTICLE 17
Non-compliance

The Conference of the Parties shall, as soon as practicable, develop and approve procedures and institutional mechanisms for determining non-compliance with the provisions of this Convention and for the treatment of Parties found to be in non-compliance.

ARTICLE 18
Settlement of disputes

1. Parties shall settle any dispute between them concerning the interpretation or application of this Convention through negotiation or other peaceful means of their own choice.

2. When ratifying, accepting, approving or acceding to the Convention, or at any time thereafter, a Party that is not a regional economic integration organization may declare in a written instrument submitted to the depositary that, with respect to any dispute concerning the interpretation or application of the Convention, it recognizes one or both of the following means of dispute settlement as compulsory in relation to any Party accepting the same obligation:

   a) Arbitration in accordance with procedures to be adopted by the Conference of the Parties in an annex as soon as practicable;

   b) Submission of the dispute to the International Court of Justice.

3. A Party that is a regional economic integration organization may make a declaration with like effect in relation to arbitration in accordance with the procedure referred to in paragraph 2 (a).

4. A declaration made pursuant to paragraph 2 or paragraph 3 shall remain in force until it expires in accordance with its terms or until three months after written notice of its revocation has been deposited with the depositary.

5. The expiry of a declaration, a notice of revocation or a new declaration shall not in any way affect proceedings pending before an arbitral tribunal or the International Court of Justice unless the parties to the dispute otherwise agree.

6. If the parties to a dispute have not accepted the same or any procedure pursuant to paragraph 2, and if they have not been able to settle their dispute within twelve months following notification by one party to another that a dispute exists between them, the dispute shall be submitted to a conciliation commission at the request of any party to the dispute. The conciliation commission shall render a

NMED Exhibit 73

report with recommendations. Additional procedures relating to the conciliation commission shall be included in an annex to be adopted by the Conference of the Parties no later than at its second meeting.

ARTICLE 19
Conference of the Parties

1. A Conference of the Parties is hereby established.

2. The first meeting of the Conference of the Parties shall be convened by the Executive Director of the United Nations Environment Programme no later than one year after the entry into force of this Convention. Thereafter, ordinary meetings of the Conference of the Parties shall be held at regular intervals to be decided by the Conference.

3. Extraordinary meetings of the Conference of the Parties shall be held at such other times as may be deemed necessary by the Conference, or at the written request of any Party provided that it is supported by at least one third of the Parties.

4. The Conference of the Parties shall by consensus agree upon and adopt at its first meeting rules of procedure and financial rules for itself and any subsidiary bodies, as well as financial provisions governing the functioning of the Secretariat.

5. The Conference of the Parties shall keep under continuous review and evaluation the implementation of this Convention. It shall perform the functions assigned to it by the Convention and, to this end, shall:

   a) Establish, further to the requirements of paragraph 6, such subsidiary bodies as it considers necessary for the implementation of the Convention;

   b) Cooperate, where appropriate, with competent international organizations and intergovernmental and non-governmental bodies; and

   c) Regularly review all information made available to the Parties pursuant to Article 15, including consideration of the effectiveness of paragraph 2 (b) (iii) of Article 3;

   d) Consider and undertake any additional action that may be required for the achievement of the objectives of the Convention.

6. The Conference of the Parties shall, at its first meeting, establish a subsidiary body to be called the Persistent Organic Pollutants Review Committee for the purposes of performing the functions assigned to that Committee by this Convention. In this regard:

NMED Exhibit 73

a) The members of the Persistent Organic Pollutants Review Committee shall be appointed by the Conference of the Parties. Membership of the Committee shall consist of government-designated experts in chemical assessment or management. The members of the Committee shall be appointed on the basis of equitable geographical distribution;

b) The Conference of the Parties shall decide on the terms of reference, organization and operation of the Committee; and

c) The Committee shall make every effort to adopt its recommendations by consensus. If all efforts at consensus have been exhausted, and no consensus reached, such recommendation shall as a last resort be adopted by a two-thirds majority vote of the members present and voting.

7. The Conference of the Parties shall, at its third meeting, evaluate the continued need for the procedure contained in paragraph 2 (b) of Article 3, including consideration of its effectiveness.

8. The United Nations, its specialized agencies and the International Atomic Energy Agency, as well as any State not Party to this Convention, may be represented at meetings of the Conference of the Parties as observers. Anybody or agency, whether national or international, governmental or non-governmental, qualified in matters covered by the Convention, and which has informed the Secretariat of its wish to be represented at a meeting of the Conference of the Parties as an observer may be admitted unless at least one third of the Parties present object. The admission and participation of observers shall be subject to the rules of procedure adopted by the Conference of the Parties.

ARTICLE 20
Secretariat

1. A Secretariat is hereby established.

2. The functions of the Secretariat shall be:

a) To make arrangements for meetings of the Conference of the Parties and its subsidiary bodies and to provide them with services as required;

b) To facilitate assistance to the Parties, particularly developing country Parties and Parties with economies in transition, on request, in the implementation of this Convention;

c) To ensure the necessary coordination with the secretariats of other relevant international bodies;

d) To prepare and make available to the Parties periodic reports based on information received pursuant to Article 15 and other available information;

e) To enter, under the overall guidance of the Conference of the Parties, into such administrative and contractual arrangements as may be required for the effective discharge of its functions; and

f) To perform the other secretariat functions specified in this Convention and such other functions as may be determined by the Conference of the Parties.

3. The secretariat functions for this Convention shall be performed by the Executive Director of the United Nations Environment Programme, unless the Conference of the Parties decides, by a three-fourths majority of the Parties present and voting, to entrust the secretariat functions to one or more other international organizations.

ARTICLE 21
Amendments to the Convention

1. Amendments to this Convention may be proposed by any Party.

2. Amendments to this Convention shall be adopted at a meeting of the Conference of the Parties. The text of any proposed amendment shall be communicated to the Parties by the Secretariat at least six months before the meeting at which it is proposed for adoption. The Secretariat shall also communicate proposed amendments to the signatories to this Convention and, for information, to the depositary.

3. The Parties shall make every effort to reach agreement on any proposed amendment to this Convention by consensus. If all efforts at consensus have been exhausted, and no agreement reached, the amendment shall as a last resort be adopted by a three-fourths majority vote of the Parties present and voting.

4. The amendment shall be communicated by the depositary to all Parties for ratification, acceptance or approval.

5. Ratification, acceptance or approval of an amendment shall be notified to the depositary in writing. An amendment adopted in accordance with paragraph 3 shall enter into force for the Parties having accepted it on the ninetieth day after the date of deposit of instruments of ratification, acceptance or approval by at least three-fourths of the Parties. Thereafter, the amendment shall enter into force for any other Party on the ninetieth day after the date on which that Party deposits its instrument of ratification, acceptance or approval of the amendment.

NMED Exhibit 73

ARTICLE 22
Adoption and amendment of annexes

1. Annexes to this Convention shall form an integral part thereof and, unless expressly provided otherwise, a reference to this Convention constitutes at the same time a reference to any annexes thereto.

2. Any additional annexes shall be restricted to procedural, scientific, technical or administrative matters.

3. The following procedure shall apply to the proposal, adoption and entry into force of additional annexes to this Convention:

   a) Additional annexes shall be proposed and adopted according to the procedure laid down in paragraphs 1, 2 and 3 of Article 21;

   b) Any Party that is unable to accept an additional annex shall so notify the depositary, in writing, within one year from the date of communication by the depositary of the adoption of the additional annex. The depositary shall without delay notify all Parties of any such notification received. A Party may at any time withdraw a previous notification of non-acceptance in respect of any additional annex, and the annex shall thereupon enter into force for that Party subject to subparagraph (c); and

   c) On the expiry of one year from the date of the communication by the depositary of the adoption of an additional annex, the annex shall enter into force for all Parties that have not submitted a notification in accordance with the provisions of subparagraph (b).

4. The proposal, adoption and entry into force of amendments to Annex A, B or C shall be subject to the same procedures as for the proposal, adoption and entry into force of additional annexes to this Convention, except that an amendment to Annex A, B or C shall not enter into force with respect to any Party that has made a declaration with respect to amendment to those Annexes in accordance with paragraph 4 of Article 25, in which case any such amendment shall enter into force for such a Party on the ninetieth day after the date of deposit with the depositary of its instrument of ratification, acceptance, approval or accession with respect to such amendment.

5. The following procedure shall apply to the proposal, adoption and entry into force of an amendment to Annex D, E or F:

   a) Amendments shall be proposed according to the procedure in paragraphs 1 and 2 of Article 21;

NMED Exhibit 73

b) The Parties shall take decisions on an amendment to Annex D, E or F by consensus; and

c) A decision to amend Annex D, E or F shall forthwith be communicated to the Parties by the depositary. The amendment shall enter into force for all Parties on a date to be specified in the decision.

6. If an additional annex or an amendment to an annex is related to an amendment to this Convention, the additional annex or amendment shall not enter into force until such time as the amendment to the Convention enters into force.

ARTICLE 23
Right to vote

1. Each Party to this Convention shall have one vote, except as provided for in paragraph 2.

2. A regional economic integration organization, on matters within its competence, shall exercise its right to vote with a number of votes equal to the number of its member States that are Parties to this Convention. Such an organization shall not exercise its right to vote if any of its member States exercises its right to vote, and vice versa.

ARTICLE 24
Signature

This Convention shall be open for signature at Stockholm by all States and regional economic integration organizations on 23 May 2001, and at the United Nations Headquarters in New York from 24 May 2001 to 22 May 2002.

ARTICLE 25
Ratification, acceptance, approval or accession

1. This Convention shall be subject to ratification, acceptance or approval by States and by regional economic integration organizations. It shall be open for accession by States and by regional economic integration organizations from the day after the date on which the Convention is closed for signature. Instruments of ratification, acceptance, approval or accession shall be deposited with the depositary.

2. Any regional economic integration organization that becomes a Party to this Convention without any of its member States being a Party shall be bound by all the obligations under the Convention. In the case of such organizations, one or more of whose member States is a Party to this Convention, the organization

NMED Exhibit 73

and its member States shall decide on their respective responsibilities for the performance of their obligations under the Convention. In such cases, the organization and the member States shall not be entitled to exercise rights under the Convention concurrently.

3. In its instrument of ratification, acceptance, approval or accession, a regional economic integration organization shall declare the extent of its competence in respect of the matters governed by this Convention. Any such organization shall also inform the depositary, who shall in turn inform the Parties, of any relevant modification in the extent of its competence.

4. In its instrument of ratification, acceptance, approval or accession, any Party may declare that, with respect to it, any amendment to Annex A, B or C shall enter into force only upon the deposit of its instrument of ratification, acceptance, approval or accession with respect thereto.

ARTICLE 26
Entry into force

1. This Convention shall enter into force on the ninetieth day after the date of deposit of the fiftieth instrument of ratification, acceptance, approval or accession.

2. For each State or regional economic integration organization that ratifies, accepts or approves this Convention or accedes thereto after the deposit of the fiftieth instrument of ratification, acceptance, approval or accession, the Convention shall enter into force on the ninetieth day after the date of deposit by such State or regional economic integration organization of its instrument of ratification, acceptance, approval or accession.

3. For the purpose of paragraphs 1 and 2, any instrument deposited by a regional economic integration organization shall not be counted as additional to those deposited by member States of that organization.

ARTICLE 27
Reservations

No reservations may be made to this Convention.

ARTICLE 28
Withdrawal

1. At any time after three years from the date on which this Convention has entered into force for a Party, that Party may withdraw from the Convention by giving written notification to the depositary.

NMED Exhibit 73

2. Any such withdrawal shall take effect upon the expiry of one year from the date of receipt by the depositary of the notification of withdrawal, or on such later date as may be specified in the notification of withdrawal.

ARTICLE 29
Depositary

The Secretary-General of the United Nations shall be the depositary of this Convention.

ARTICLE 30
Authentic texts

The original of this Convention, of which the Arabic, Chinese, English, French, Russian and Spanish texts are equally authentic, shall be deposited with the Secretary General of the United Nations.

IN WITNESS WHEREOF the undersigned, being duly authorized to that effect, have signed this Convention.

Done at Stockholm on this twenty-second day of May, two thousand and one.

NMED Exhibit 73

ANNEXES

ANNEX A[1]
ELIMINATION

Part I
Procedure

Chemical	Activity	Specific exemption[2]
Aldrin* CAS No: 309-00-2	Production	None
	Use	Local ectoparasiticide Insecticide
Alpha hexachlorocyclohexane* CAS No: 319-84-6	Production	None
	Use	None
Beta hexachlorocyclohexane* CAS No: 319-85-7	Production	None
	Use	None
Chlordane* CAS No: 57-74-9	Production	As allowed for the Parties listed in the Register
	Use	Local ectoparasiticide Insecticide Termiticide Termiticide in buildings and dams Termiticide in roads Additive in plywood adhesives
Chlordecone* CAS No: 143-50-0	Production	None
	Use	None

[1] *Secretariat note: As amended by decisions SC-4/10 to SC-4/18 of 8 May 2009; SC-5/3 of 29 April 2011; SC-6/13 of 10 May 2013; SC-7/12 to SC-7/14 of 15 May 2015; and SC-8/10 to SC-8/12 of 5 May 2017; and SC-9/4, SC-9/11 and SC-9/12 of 10 May 2019; SC-10/13 of 17 June 2022; SC-11/9, SC-11/10 and SC-11/11 of 12 May 2023; and SC-12/9, SC-12/10, SC-12/12, and SC-12/14 of 9 May 2025.*

[2] *Secretariat note: Please note that, in accordance with paragraph 9 of Article 4 of the Convention, when there are no longer any Parties registered for a particular type of specific exemption no new registrations may be made with respect to such exemptions, which appear in grey text in the table.*

NMED Exhibit 73

Chlorpyrifos* **CAS No. 2921-88-2**	Production	As allowed for the Parties listed in the Register
	Use	• Crop-pest complexes as listed in accordance with the provisions of part XV of this Annex • Control of leaf-cutting ants (*Atta* spp. and *Acromyrmex* spp.) for agricultural use only • Control of locusts for agricultural use only • Control of ticks in cattle • Wood preservation against borers and termites in building foundations
Decabromodiphenyl ether (BDE-209) present in commercial decabromodiphenyl ether (CAS No: 1163-19-5)	Production	As allowed for the Parties listed in the Register
	Use	In accordance with Part IX of this Annex: • Parts for use in vehicles specified in paragraph 2 of Part IX of this Annex • Aircraft for which type approval has been applied for before December 2018 and has been received before December 2022 and spare parts for those aircraft • Textile products that require anti-flammable characteristics, excluding clothing and toys • Additives in plastic housings and parts used for heating home appliances, irons, fans, immersion heaters that contain or are in direct contact with electrical parts or are required to comply with fire retardancy standards, at concentrations lower than 10 per cent by weight of the part • Polyurethane foam for building insulation

NMED Exhibit 73

Dechlorane Plus **CAS No: 13560-89-9** **"Dechlorane Plus" includes its syn-isomer (CAS No: 135821-03-3) and its anti-isomer (CAS No: 135821-74-8)**	Production	None
	Use	In accordance with part XI of this Annex: • Aerospace • Space and defence applications • Medical imaging and radiotherapy devices and installations • Replacement parts for, and repair of, articles in applications in accordance with the provisions of paragraphs 2 and 3 of part XI of this Annex
Dicofol **CAS No: 115-32-2** **CAS No: 10606-46-9**	Production	None
	Use	None
Dieldrin* **CAS No: 60-57-1**	Production	None
	Use	In agricultural operations
Endrin* **CAS No: 72-20-8**	Production	None
	Use	None
Heptachlor* **CAS No: 76-44-8**	Production	None
	Use	Termiticide Termiticide in structures of houses Termiticide (subterranean) Wood treatment In use in underground cable boxes
Hexabromobiphenyl * **CAS No: 36355-01-8**	Production	None
	Use	None
Hexabromocyclododecane	Production	As allowed for the Parties listed in the Register in accordance with the provisions of Part VII of this Annex
	Use	Expanded polystyrene and extruded polystyrene in buildings in accordance with the provisions of Part VII of this Annex

NMED Exhibit 73

Hexabromodiphenyl ether* and heptabromodiphenyl ether*	Production	None
	Use	Articles in accordance with the provisions of Part IV of this Annex
Hexachlorobenzene CAS No: 118-74-1	Production	As allowed for the Parties listed in the Register
	Use	Intermediate Solvent in pesticide Closed system site limited intermediate
Hexachlorobutadiene CAS No: 87-68-3	Production	None
	Use	None
Lindane* CAS No: 58-89-9	Production	None
	Use	Human health pharmaceutical for control of head lice and scabies as second line treatment
Long-chain perfluorocarboxylic acids, their salts and related compounds **"Long-chain perfluorocarboxylic acids, their salts and related compounds" means the following:** **(i) Long-chain perfluorocarboxylic acids or their salts, for the purposes of the Convention, are a homologous series of substances with the molecular formula of $C_nF_{2n+1}COOH$ (where $8 \leq n \leq 20$);**	Production	As allowed for the Parties listed in the Register in accordance with the provisions of Part XIV of this Annex
	Use	In accordance with Part XIV of this Annex: • Semiconductors designed for replacement parts not covered in paragraphs 2 (a) and (b) of Part XIV of this Annex • Semiconductors designed for replacement parts for combustion-engine-powered vessels in accordance with the provisions of paragraph 2 of Part XIV of this Annex • Replacement parts for motor vehicles that have ceased mass production in accordance with the provisions of paragraph 2 of Part XIV of this Annex

NMED Exhibit 73

(ii) Compounds related to long-chain perfluorocarboxylic acids, for the purposes of the Convention, are any substance that is a precursor and may transform to long-chain perfluorocarboxylic acids, where the perfluorinated alkyl moiety has the formula C_nF_{2n+1} (where 8 ≤ n ≤ 20) and is directly bonded to any chemical moiety other than a fluorine, chlorine or bromine atom. **The following compounds are not included as long-chain perfluorocarboxylic acids, their salts and related compounds: perfluorooctanoic acid (PFOA), its salts and PFOA-related compounds as listed in Annex A to the Convention.**		
Medium-chain chlorinated paraffins (MCCPs) **For the purposes of this Convention, substances or mixtures are considered as "Medium-chain chlorinated paraffins (MCCPs)" when they meet the definition in (i), (ii), or both (i) and (ii):**	Production	As allowed for the Parties listed in the Register in accordance with the provisions of Part XIII of this Annex
	Use	In accordance with Part XIII of this Annex: • Flexible polyvinyl chloride (PVC), limited to the following uses:

NMED Exhibit 73

(i) Substances or mixtures that contain linear chloroalkanes with carbon chain lengths in the range $C_{14–17}$ and chlorination levels at or exceeding 45 per cent chlorine by weight; **(ii) Substances or mixtures that contain linear $C_{14–17}$ chloroalkanes of the following molecular formulae:** **$C_{14}H_{(30–y)}Cl_y$ where y ≥ 5; $C_{15}H_{(32–y)}Cl_y$ where y ≥ 5; $C_{16}H_{(34–y)}Cl_y$ where y ≥ 6; $C_{17}H_{(36–y)}Cl_y$ where y ≥ 6.**		◦ Construction sector, including maintenance of buildings and other structures, for uses other than flooring in indoor spaces that are not used for commercial purposes ◦ Wires and cables in the construction sector ◦ Wires and cables in medical devices and in-vitro diagnostic devices ◦ Calendered films in the packaging field, excluding food packaging • Solid woven conveyor belts used in underground coal mines • Flexible elastomeric foam for thermal insulation • Adhesives and sealants, limited to the following uses: ◦ Polysulfide sealant and one-component polyurethane foam used in sealing for doors and windows ◦ Waterproof coatings and anticorrosion coatings ◦ Aerospace and defence applications (e.g., polyurethane adhesives and tamper-proof putty) • Tape used for non-structural bonding in aerospace and defence products • Fatliquoring component in leather, except in children's products • Emergency response pyrotechnic devices

NMED Exhibit 73

		• Paints and coatings for ammunition and ammunition markings • Metalworking fluids, in accordance with the provisions of paragraphs 5 and 6 of Part XIII of this Annex • Polymers and rubbers (including PVC, ethylene propylene diene monomer (EPDM) rubber, chloroprene (CR), nitrile butadiene rubber (NBR) and chlorinated polyethylene (CPE)) used in repair and replacement parts, in accordance with the provisions of paragraph 7 of Part XIII of this Annex • Ammunition pyrotechnic defence devices to achieve specific effects (e.g., sound, smoke, light), in accordance with the provisions of paragraphs 8 and 12 of Part XIII of this Annex • Intumescent coating and paint for space and defence equipment and its packaging to protect against extreme temperature, in accordance with the provisions of paragraphs 9 and 12 of Part XIII of this Annex • Coating and paint for the repair of, and use in replacement parts for, space and defence equipment, in accordance with the provisions of paragraphs 10 and 11 of Part XIII of this Annex

NMED Exhibit 73

Methoxychlor*	Production	None
"Methoxychlor" refers to any possible isomer of dimethoxydiphenyl-trichloroethane or any combination thereof.	Use	None
For example:		
CAS No: 72-43-5;		
CAS No: 30667-99-3;		
CAS No: 76733-77-2;		
CAS No: 255065-25-9;		
CAS No: 255065-26-0;		
CAS No: 59424-81-6;		
CAS No: 1348358-72-4.		
Mirex* **CAS No: 2385-85-5**	Production	As allowed for the Parties listed in the Register
	Use	Termiticide
Pentachlorobenzene* **CAS No: 608-93-5**	Production	None
	Use	None
Pentachlorophenol and its salts and esters	Production	As allowed for the Parties listed in the Register in accordance with the provisions of Part VIII of this Annex
	Use	Pentachlorophenol for utility poles and cross-arms in accordance with the provisions of Part VIII of this Annex
Perfluorohexane sulfonic acid (PFHxS), its salts and PFHxS-related compounds	Production	None
"Perfluorohexane sulfonic acid (PFHxS), its salts and PFHxS-related compounds" means the following:	Use	None

NMED Exhibit 73

(i) Perfluorohexane sulfonic acid (CAS No: 355-46-4, PFHxS), including branched isomers; **(ii) Its salts;** **(iii) Any substance that contains the chemical moiety $C_6F_{13}SO_2$- as one of its structural elements and that potentially degrades to PFHxS.**		
Perfluorooctanoic acid (PFOA), its salts and PFOA-related compounds **"Perfluorooctanoic acid (PFOA), its salts and PFOA-related compounds" means the following:** **(i) Perfluorooctanoic acid (PFOA; CAS No. 335-67-1), including any of its branched isomers;** **(ii) Its salts;** **(iii) PFOA-related compounds which, for the purposes of the Convention, are any substances that degrade to PFOA, including any substances (including salts and polymers) having a linear or branched**	Production	• Fire-fighting foam: None • For other production, as allowed for the Parties listed in the Register in accordance with the provisions of part X of this Annex
	Use	In accordance with the provisions of part X of this Annex: • Photolithography or etch processes in semiconductor manufacturing • Photographic coatings applied to films • Textiles for oil and water repellency for the protection of workers from dangerous liquids that comprise risks to their health and safety • Invasive and implantable medical devices • Fire-fighting foam for liquid fuel vapour suppression and liquid fuel fires (Class B fires) in installed systems, including both mobile and fixed systems, in accordance with paragraph 2 of part X of this Annex

NMED Exhibit 73

perfluoroheptyl group with the moiety (C_7F_{15}) C as one of the structural elements;
The following compounds are not included as PFOA-related compounds:
(iv) C_8F_{17}-X, where X= F, Cl, Br;
(v) Fluoropolymers that are covered by CF_3 $[CF_2]_n$-R', where R'=any group, n>16;
(vi) Perfluoroalkyl carboxylic and phosphonic acids (including their salts, esters, halides and anhydrides) with ≥8 perfluorinated carbons;
(vii) Perfluoroalkane sulfonic acids (including their salts, esters, halides and anhydrides) with ≥9 perfluorinated carbons;
(viii) Perfluorooctane sulfonic acid (PFOS), its salts and perfluorooctane sulfonyl fluoride (PFOSF), as listed in Annex B to the Convention.
		• Use of perfluorooctyl iodide for the production of perfluorooctyl bromide for the purpose of producing pharmaceutical products, in accordance with the provisions of paragraph 3 of part X of this Annex
		• Manufacture of polytetrafluoroethylene (PTFE) and polyvinylidene fluoride (PVDF) for the production of:
		  ◦ High-performance, corrosion-resistant gas filter membranes, water filter membranes and membranes for medical textiles
		  ◦ Industrial waste heat exchanger equipment
		  ◦ Industrial sealants capable of preventing leakage of volatile organic compounds and PM2.5 particulates
		• Manufacture of polyfluoroethylene propylene (FEP) for the production of high-voltage electrical wire and cables for power transmission
		• Manufacture of fluoroelastomers for the production of O-rings, v-belts and plastic accessories for car interiors

NMED Exhibit 73

Polychlorinated Biphenyls (PCB)*	Production	None
	Use	Articles in use in accordance with the provisions of Part II of this Annex
Polychlorinated naphthalenes, including dichlorinated naphthalenes, trichlorinated naphthalenes, tetrachlorinated naphthalenes, pentachlorinated naphthalenes, hexachlorinated naphthalenes, heptachlorinated naphthalenes, octachlorinated naphthalene	Production	Intermediates in production of polyfluorinated naphthalenes, including octafluoronaphthalene
	Use	Production of polyfluorinated naphthalenes, including octafluoronaphthalene
Short-chain chlorinated paraffins (Alkanes, C_{10-13}, chloro)+ : straight-chain chlorinated hydrocarbons with chain lengths ranging from C_{10} to C_{13} and a content of chlorine greater than 48 per cent by weight **For example, the substances with the following CAS numbers may contain short-chain chlorinated paraffins:** **CAS No. 85535-84-8; CAS No. 68920-70-7; CAS No. 71011-12-6; CAS No. 85536-22-7; CAS No. 85681-73-8; CAS No. 108171-26-2.**	Production	As allowed for the Parties listed in the Register
	Use	• Additives in the production of transmission belts in the natural and synthetic rubber industry • Spare parts of rubber conveyor belts in the mining and forestry industries • Leather industry, in particular fatliquoring in leather • Lubricant additives, in particular for engines of automobiles, electric generators and wind power facilities, and for drilling in oil and gas exploration, petroleum refinery to produce diesel oil • Tubes for outdoor decoration bulbs

NMED Exhibit 73

		• Waterproofing and fire-retardant paints • Adhesives • Metal processing • Secondary plasticizers in flexible polyvinyl chloride, except in toys and children's products
Technical endosulfan* (CAS No: 115-29-7) and its related isomers* (CAS No: 959-98-8 and CAS No: 33213-65-9)	Production	As allowed for the Parties listed in the Register
	Use	Crop-pest complexes as listed in accordance with the provisions of part VI of this Annex
Tetrabromodiphenyl ether* and pentabromodiphenyl ether*	Production	None
	Use	Articles in accordance with the provisions of Part V of this Annex
Toxaphene* CAS No: 8001-35-2	Production	None
	Use	None
UV-328 CAS No. 25973-55-1	Production	As allowed for the Parties listed in the Register in accordance with the provisions of part XII of this Annex
	Use	In accordance with part XII of this Annex: • Parts of motor vehicles (covering all land-based vehicles, such as cars, motorcycles, agricultural and construction vehicles and industrial trucks), such as bumper systems, radiator grills, spoilers, car garnish, roof modules, soft/hard tops, trunk lids and rear window wipers • Industrial coating applications for motor vehicles, engineering machines, rail transportation vehicles, and heavy-duty coatings for large steel structures

NMED Exhibit 73

		• Mechanical separators in blood collection tubes • Triacetyl cellulose (TAC) film in polarizers • Photographic paper • Replacement parts for articles in applications in accordance with the provisions of paragraphs 2 and 3 of part XII of this Annex • Water-seal tape for insulation blankets and decking on aircraft; and polyurethane and polyamide adhesives, and polyurethane coatings, for structural, mechanical, interior and electrical assemblies, and emergency, propulsion, environmental control, and flight control systems, on aircraft.

Notes:

(i) Except as otherwise specified in this Convention, quantities of a chemical occurring as unintentional trace contaminants in products and articles shall not be considered to be listed in this Annex;

(ii) This note shall not be considered as a production and use specific exemption for purposes of paragraph 2 of Article 3. Quantities of a chemical occurring as constituents of articles manufactured or already in use before or on the date of entry into force of the relevant obligation with respect to that chemical, shall not be considered as listed in this Annex, provided that a Party has notified the Secretariat that a particular type of article remains in use within that Party. The Secretariat shall make such notifications publicly available;

(iii) This note, which does not apply to a chemical that has an asterisk following its name in the Chemical column in Part I of this Annex, shall not be considered as a production and use specific exemption for purposes of paragraph 2 of Article 3. Given that no significant quantities of the chemical are expected to reach humans and the environment during the production and use of a closed-system site-limited intermediate, a Party, upon notification to the Secretariat, may allow the production and use of quantities of a chemical listed in this Annex as a closed-system site-limited intermediate that is chemically transformed in the manufacture of other chemicals that, taking into consideration the criteria in paragraph 1 of Annex D, do not exhibit the characteristics of persistent organic pollutants. This notification shall include information on total production and use of such chemical or a reasonable estimate of such information and information regarding the nature of the closed-system site-limited process including the amount of any non-transformed and unintentional trace contamination of the persistent organic pollutant-starting material in the final product. This procedure applies except as otherwise specified in this Annex. The Secretariat shall make such notifications available to the Conference of the Parties and to the public. Such production or use shall not be considered a production or use specific exemption. Such production and use shall cease after a ten-year period, unless the Party concerned submits a new notification to the Secretariat, in which case the period will be extended for an additional ten years

NMED Exhibit 73

unless the Conference of the Parties, after a review of the production and use decides otherwise. The notification procedure can be repeated;

(iv) All the specific exemptions in this Annex may be exercised by Parties that have registered exemptions in respect of them in accordance with Article 4 with the exception of the use of polychlorinated biphenyls in articles in use in accordance with the provisions of Part II, and the use of hexabromodiphenyl ether and heptabromodiphenyl ether in accordance with the provisions of Part IV of this Annex, and the use of tetrabromodiphenyl ether and pentabromodiphenyl ether in accordance with the provisions of Part V of this Annex, which may be exercised by all Parties.

(v) Technical endosulfan (CAS No: 115-29-7), its related isomers (CAS No: 959-98-8 and CAS No: 33213-65-9) and endosulfan sulfate (CAS No: 1031-07-8) were assessed and identified as persistent organic pollutants.

(vi) Pentachlorophenol (CAS No: 87-86-5), sodium pentachlorophenate (CAS No: 131-52-2 and 27735-64-4 (as monohydrate)) and pentachlorophenyl laurate (CAS No: 3772-94-9), when considered together with their transformation product pentachloroanisole (CAS No: 1825-21-4), were identified as persistent organic pollutants.

(vii) Note (i) does not apply to quantities of a chemical that has a plus sign ("+") following its name in the "Chemical" column in Part I of this Annex that occurs in mixtures at concentrations greater than or equal to 1 per cent by weight.

Part II
Polychlorinated biphenyls

Each Party shall:

a) With regard to the elimination of the use of polychlorinated biphenyls in equipment (e.g. transformers, capacitors or other receptacles containing liquid stocks) by 2025, subject to review by the Conference of the Parties, take action in accordance with the following priorities:

   i. Make determined efforts to identify, label and remove from use equipment containing greater than 10 per cent polychlorinated biphenyls and volumes greater than 5 litres;

   ii. Make determined efforts to identify, label and remove from use equipment containing greater than 0.05 per cent polychlorinated biphenyls and volumes greater than 5 litres;

   iii. Endeavour to identify and remove from use equipment containing greater than 0.005 percent polychlorinated biphenyls and volumes greater than 0.05 litres;

b) Consistent with the priorities in subparagraph (a), promote the following measures to reduce exposures and risk to control the use of polychlorinated biphenyls:

   i. Use only in intact and non-leaking equipment and only in areas where the risk from environmental release can be minimised and quickly remedied;

NMED Exhibit 73

ii. Not use in equipment in areas associated with the production or processing of food or feed;

iii. When used in populated areas, including schools and hospitals, all reasonable measures to protect from electrical failure which could result in a fire, and regular inspection of equipment for leaks;

c) Notwithstanding paragraph 2 of Article 3, ensure that equipment containing polychlorinated biphenyls, as described in subparagraph (a), shall not be exported or imported except for the purpose of environmentally sound waste management;

d) Except for maintenance and servicing operations, not allow recovery for the purpose of reuse in other equipment of liquids with polychlorinated biphenyls content above 0.005 per cent;

e) Make determined efforts designed to lead to environmentally sound waste management of liquids containing polychlorinated biphenyls and equipment contaminated with polychlorinated biphenyls having a polychlorinated biphenyls content above 0.005 per cent, in accordance with paragraph 1 of Article 6, as soon as possible but no later than 2028, subject to review by the Conference of the Parties;

f) In lieu of note (ii) in Part I of this Annex, endeavour to identify other articles containing more than 0.005 per cent polychlorinated biphenyls (e.g. cable-sheaths, cured caulk and painted objects) and manage them in accordance with paragraph 1 of Article 6;

g) Provide a report every five years on progress in eliminating polychlorinated biphenyls and submit it to the Conference of the Parties pursuant to Article 15;

h) The reports described in subparagraph (g) shall, as appropriate, be considered by the Conference of the Parties in its reviews relating to polychlorinated biphenyls. The Conference of the Parties shall review progress towards elimination of polychlorinated biphenyls at five year intervals or other period, as appropriate, taking into account such reports.

Part III
Definitions

For the purpose of this Annex:

a) "Hexabromodiphenyl ether and heptabromodiphenyl ether" mean 2,2',4,4',5,5'-hexabromodiphenyl ether (BDE-153, CAS No: 68631-49-2), 2,2',4,4',5,6'-hexabromodiphenyl ether (BDE-154, CAS No: 207122-15-4), 2,2',3,3',4,5',6-heptabromodiphenyl ether (BDE-175, CAS No: 446255-22-7),

NMED Exhibit 73

2,2',3,4,4',5',6-heptabromodiphenyl ether (BDE-183, CAS No: 207122-16-5) and other hexa- and heptabromodiphenyl ethers present in commercial octabromodiphenyl ether.

b) "Tetrabromodiphenyl ether and pentabromodiphenyl ether" means 2,2',4,4'-tetrabromodiphenyl ether (BDE-47, CAS No: 5436-43-1) and 2,2',4,4',5-pentabromodiphenyl ether (BDE-99, CAS No: 60348-60-9) and other tetra- and pentabromodiphenyl ethers present in commercial pentabromodiphenyl ether.

c) "Hexabromocyclododecane" means hexabromocyclododecane (CAS No: 25637-99-4), 1, 2, 5, 6, 9, 10-hexabromocyclododecane (CAS No: 3194-55-6) and its main diastereoisomers: alpha-hexabromocyclododecane (CAS No: 134237-50-6); beta-hexabromocyclododecane (CAS No: 134237-51-7); and gamma-hexabromocyclododecane (CAS No: 134237-52-8).

Part IV
Hexabromodiphenyl ether and heptabromodiphenyl ether

1. A Party may allow recycling of articles that contain or may contain hexabromodiphenyl ether and heptabromodiphenyl ether, and the use and final disposal of articles manufactured from recycled materials that contain or may contain hexabromodiphenyl ether and heptabromodiphenyl ether, provided that:

   a) The recycling and final disposal is carried out in an environmentally sound manner and does not lead to recovery of hexabromodiphenyl ether and heptabromodiphenyl ether for the purpose of their reuse;

   b) The Party takes steps to prevent exports of such articles that contain levels/concentrations of hexabromodiphenyl ether and heptabromodiphenyl ether exceeding those permitted for the sale, use, import or manufacture of those articles within the territory of the Party; and

   c) The Party has notified the Secretariat of its intention to make use of this exemption.

2. At its sixth ordinary meeting and at every second ordinary meeting thereafter the Conference of the Parties shall evaluate the progress that Parties have made towards achieving their ultimate objective of elimination of hexabromodiphenyl ether and heptabromodiphenyl ether contained in articles and review the continued need for this specific exemption. This specific exemption shall in any case expire at the latest in 2030.

NMED Exhibit 73

Part V
Tetrabromodiphenyl ether and pentabromodiphenyl ether

1. A Party may allow recycling of articles that contain or may contain tetrabromodiphenyl ether and pentabromodiphenyl ether, and the use and final disposal of articles manufactured from recycled materials that contain or may contain tetrabromodiphenyl ether and pentabromodiphenyl ether, provided that:

    a) The recycling and final disposal is carried out in an environmentally sound manner and does not lead to recovery of tetrabromodiphenyl ether and pentabromodiphenyl ether for the purpose of their reuse;

    b) The Party does not allow this exemption to lead to the export of articles containing levels/concentrations of tetrabromodiphenyl ether and pentabromodiphenyl ether that exceed those permitted to be sold the within the territory of the Party; and

    c) The Party has notified the Secretariat of its intention to make use of this exemption.

2. At its sixth ordinary meeting and at every second ordinary meeting thereafter the Conference of the Parties shall evaluate the progress that Parties have made towards achieving their ultimate objective of elimination of tetrabromodiphenyl ether and pentabromodiphenyl ether contained in articles and review the continued need for this specific exemption. This specific exemption shall in any case expire at the latest in 2030.

NMED Exhibit 73

Part VI
Technical endosulfan and its related isomers (endosulfan)

1. The production and use of endosulfan shall be eliminated except for Parties that have notified the Secretariat of their intention to produce and/or use it in accordance with Article 4 of the Convention. Specific exemptions may be available for the use of endosulfan for the following crop-pest complexes:

Crop	Pest
Apple	Aphids
Arhar, gram	Aphids, caterpillars, pea semilooper, pod borer
Bean, cowpea	Aphids, leaf miner, whiteflies
Chilli, onion, potato	Aphids, jassids
Coffee	Berry borer, stem borers
Cotton	Aphids, cotton bollworm, jassids, leaf rollers, pink bollworm, thrips, whiteflies
Eggplant, okra	Aphids, diamondback moth, jassids, shoot and fruit borer
Groundnut	Aphids
Jute	Bihar hairy caterpillar, yellow mite
Maize	Aphids, pink borer, stem borers
Mango	Fruit flies, hoppers
Mustard	Aphids, gall midges
Rice	Gall midges, rice hispa, stem borers, white jassid
Tea	Aphids, caterpillars, flushworm, mealybugs, scale insects, smaller green leafhopper, tea geometrid, tea mosquito bug, thrips
Tobacco	Aphids, oriental tobacco budworm
Tomato	Aphids, diamondback moth, jassids, leaf miner, shoot and fruit borer, whiteflies
Wheat	Aphids, pink borer, termites

NMED Exhibit 73

Part VII
Hexabromocyclododecane

Each Party that has registered for the exemption pursuant to Article 4 for the production and use of hexabromocyclododecane for expanded polystyrene and extruded polystyrene in buildings shall take necessary measures to ensure that expanded polystyrene and extruded polystyrene containing hexabromocyclododecane can be easily identified by labelling or other means throughout its life cycle.

Part VIII
Pentachlorophenol and its salts and esters

Each Party that has registered for the exemption, pursuant to Article 4 for the production and use of pentachlorophenol for utility poles and cross-arms shall take the necessary measures to ensure that utility poles and cross-arms containing pentachlorophenol can be easily identified by labelling or other means throughout their life cycles. Articles treated with pentachlorophenol should not be reused for purposes other than those exempted.

Part IX
Decabromodiphenyl ether

1. The production and use of decabromodiphenyl ether shall be eliminated except for Parties that have notified the Secretariat of their intention to produce and/or use it in accordance with Article 4.

2. Specific exemptions for parts for use in vehicles may be available for the production and use of commercial decabromodiphenyl ether limited to the following:

    a) Parts for use in legacy vehicles, defined as vehicles that have ceased mass production, and with such parts falling into one or more of the following categories:

        i. Powertrain and under-hood applications such as battery mass wires, battery interconnection wires, mobile air-conditioning (MAC) pipes, powertrains, exhaust manifold bushings, under-hood insulation, wiring and harness under hood (engine wiring, etc.), speed sensors, hoses, fan modules and knock sensors;

NMED Exhibit 73

ii. Fuel system applications such as fuel hoses, fuel tanks and fuel tanks under body;

iii. Pyrotechnical devices and applications affected by pyrotechnical devices such as air bag ignition cables, seat covers/fabrics (only if airbag relevant) and airbags (front and side);

iv. Suspension and interior applications such as trim components, acoustic material and seat belts.

b) Parts in vehicles specified in paragraphs 2 (a) (i)–(iv) above and those falling into one or more of the following categories:

i. Reinforced plastics (instrument panels and interior trim);

ii. Under the hood or dash (terminal/fuse blocks, higher-amperage wires and cable jacketing (spark plug wires));

iii. Electric and electronic equipment (battery cases and battery trays, engine control electrical connectors, components of radio disks, navigation satellite systems, global positioning systems and computer systems);

iv. Fabric such as rear decks, upholstery, headliners, automobile seats, head rests, sun visors, trim panels, carpets.

3. The specific exemptions for parts specified in paragraph 2 (a) above shall expire at the end of the service life of legacy vehicles or in 2036, whichever comes earlier.

4. The specific exemptions for parts specified in paragraph 2 (b) above shall expire at the end of the service life of vehicles or in 2036, whichever comes earlier.

5. The specific exemptions for spare parts for aircraft for which type approval has been applied for before December 2018 and has been received before December 2022 shall expire at the end of the service life of those aircraft.

Part X
Perfluorooctanoic acid (PFOA), its salts and PFOA-related compounds

1. The production and use of perfluorooctanoic acid (PFOA), its salts and PFOA related compounds shall be eliminated except for Parties that have notified the Secretariat of their intention to produce and/or use them in accordance with Article 4 of the Convention.

2. Each Party that has registered for a specific exemption pursuant to Article 4 for the use of PFOA, its salts and PFOA-related compounds for fire-fighting foam shall:

NMED Exhibit 73

a) Notwithstanding paragraph 2 of Article 3, ensure that fire-fighting foam that contains or may contain PFOA, its salts and PFOA-related compounds shall not be exported or imported except for the purpose of environmentally sound disposal as set forth in paragraph 1 (d) of Article 6;

b) Not use fire-fighting foam that contains or may contain PFOA, its salts and PFOA-related compounds for training;

c) Not use fire-fighting foam that contains or may contain PFOA, its salts and PFOA-related compounds for testing unless all releases are contained;

d) By the end of 2022, if it has the capacity to do so, but no later than 2025, restrict uses of fire-fighting foam that contains or may contain PFOA, its salts and PFOA-related compounds to sites where all releases can be contained;

e) Make determined efforts designed to lead to the environmentally sound management of fire-fighting foam stockpiles and wastes that contain or may contain PFOA, its salts and PFOA-related compounds, in accordance with paragraph 1 of Article 6, as soon as possible;

3. With regard to the specific exemption for the use of perfluorooctyl iodide for the production of perfluorooctyl bromide for the purpose of producing pharmaceutical products, at its thirteenth ordinary meeting and at every second ordinary meeting thereafter, the Conference of the Parties shall review the continued need for this specific exemption. This specific exemption shall in any case expire at the latest in 2036.

Part XI
Dechlorane Plus

1. The use of Dechlorane Plus shall be eliminated except for Parties that have notified the Secretariat of their intention to use it in accordance with Article 4.

2. Specific exemptions for the use of Dechlorane Plus for replacement parts for, and repair of, articles shall apply where Dechlorane Plus was originally used in the manufacture of those articles and may be available, limited to the following applications, until the end of the service life of the articles or 2044, whichever comes earlier:

   a) Aerospace (such as aircraft engine fan case rub strip products and void-filling and edge-sealing products, aircraft engine manufacturing repairs, electrical items, structural panels and aircraft cabin interiors);

NMED Exhibit 73

b) Space (such as satellites, probes and other exploration equipment, manned cabins and laboratories, heat-insulating materials for rocket motors and ground support equipment);

c) Defence (such as naval vessels, missiles, launch platforms, ordnance, communication equipment, radar and lidar systems and support equipment);

d) Motor vehicles (covering all land-based vehicles, such as cars, motorcycles, agricultural and construction vehicles and industrial trucks; applications include cables, wire harnesses, connectors and insulation tapes);

e) Stationary industrial machines (such as tower cranes, concrete plants and hydraulic crushers; applications include cables, wire harnesses, connectors and insulation tapes) for use in agriculture, forestry and construction;

f) Marine, garden, forestry and outdoor power equipment;

g) Instruments for analysis, measurements, control, monitoring, testing, production and inspection.

3. Specific exemptions for the use of Dechlorane Plus for replacement parts for, and repair of, articles shall apply where Dechlorane Plus was originally used in the manufacture of those articles and may be available, limited to the following applications, until the end of the service life of those articles, subject to review by the Conference of the Parties no later than 2041:

a) Medical devices (such as ultrasound diagnostic devices, magnetic resonance imaging systems, X-ray imaging systems, flexible endoscopes and radiotherapy devices and installations);

b) In-vitro diagnostic devices (such as immunoassay analysers, haematology analysers, polymerase chain reaction (PCR) testing systems, genetic analysers, clinical chemistry analysers, blood coagulation analysers and urinalysis analysers).

Part XII
UV-328

1. The production and use of UV-328 shall be eliminated except for Parties that have notified the Secretariat of their intention to produce and/or use it in accordance with Article 4.

2. Specific exemptions for the production and use of UV-328 for replacement parts for articles shall apply where UV-328 was originally used in the manufacture of those articles and may be available, limited to the following applications, until the end of the service life of the articles or 2044, whichever comes earlier:

NMED Exhibit 73

a) Motor vehicles (covering all land-based vehicles, such as cars, motorcycles, agricultural and construction vehicles and industrial trucks);

b) Stationary industrial machines (such as tower cranes, concrete plants and hydraulic crushers) for use in agriculture, forestry and construction;

c) Liquid crystal displays in instruments for analysis, measurements, control, monitoring, testing, production and inspection (such as recorders, infrared radiation thermometers, digital storage oscilloscopes and radiographic testing instruments) other than for medical applications.

3. Specific exemptions for the use of UV-328 for replacement parts for articles for the following applications for medical purposes shall apply where UV-328 was originally used in the manufacture of those articles and may be available until the end of the service life of those articles, subject to review by the Conference of the Parties no later than 2041:

a) Liquid crystal displays in medical and in-vitro diagnostic devices (such as ultrasound diagnostic devices, flexible endoscopes, immunoassay analysers, clinical chemistry analysers and blood coagulation analysers);

b) Liquid crystal displays in instruments for analysis, measurements, control, monitoring, testing, production and inspection (such as recorders, infrared radiation thermometers, digital storage oscilloscopes and radiographic testing instruments).

4. Regarding the specific exemption for "water-seal tape for insulation blankets and decking on aircraft; and polyurethane and polyamide adhesives, and polyurethane coatings, for structural, mechanical, interior and electrical assemblies, and emergency, propulsion, environmental control, and flight control systems, on aircraft", it is limited to use only. This exemption shall in any case expire by the end of 2030.

Part XIII
Medium-chain chlorinated paraffins

1. The production and use of medium-chain chlorinated paraffins shall be eliminated except for Parties that have notified the Secretariat of their intention to produce and/or use them in accordance with Article 4.

2. Note (i) of Annex A does not apply when the summed concentration of the following C_{14-17} chloroalkanes ($C_{14}H_{(30-y)}Cl_y$ where $y \geq 5$; $C_{15}H_{(32-y)}Cl_y$ where $y \geq 5$; $C_{16}H_{(34-y)}Cl_y$ where $y \geq 6$; $C_{17}H_{(36-y)}Cl_y$ where $y \geq 6$) in substances or mixtures occurs at a concentrations greater than 3 per cent by weight, subject to review by the

NMED Exhibit 73

Conference of the Parties at its fourteenth ordinary meeting and every second ordinary meeting thereafter, with the aim to reduce this limit over time.

3. Each Party is encouraged to require that manufacturers of chlorinated paraffins within their jurisdiction disclose information, including to others in the supply chain, on the summed concentration of the following linear C_{14-17} chloroalkanes in those chlorinated paraffins:

   a) $\Sigma C_{14}H_{(30-y)}Cl_y$ where $y \geq 5$;

   b) $\Sigma C_{15}H_{(32-y)}Cl_y$ where $y \geq 5$;

   c) $\Sigma C_{16}H_{(34-y)}Cl_y$ where $y \geq 6$;

   d) $\Sigma C_{17}H_{(36-y)}Cl_y$ where $y \geq 6$.

Alternatively, manufacturers of chlorinated paraffins can provide information, including to others in the supply chain, on the concentration of linear C_{14-17} alkanes present in the feedstock used to produce the corresponding chlorinated paraffins.

4. For mixtures containing more than one chlorinated paraffin product, or containing chlorinated paraffin products and other substances, Parties are encouraged to require that the information on the concentrations specified in paragraph 3 above be provided for all chlorinated paraffin products present in the mixture.

5. Specific exemptions for the production and use of medium-chain chlorinated paraffins for metalworking fluids shall apply where they are used in professional or industrial settings with collection systems, and may be available until 2036, limited to use as extreme temperature and pressure additives for metalworking fluids used in "heavy-duty" processes (including deep drawing, broaching and fine blanking, drawing with ironing, precision metalworking (cutting/punching/drilling), tapping, cold drawing, cold rolling (pilgering), stamping, forging, and grinding) for the production and repair of metals and metal alloy components (including steel, titanium, nickel, aluminium, copper, magnesium and beryllium) such as those used in the following applications and sectors:

   a) Aerospace;

   b) Defence;

   c) Motor vehicles covering all land-based vehicles, such as cars, motorcycles, agriculture and construction vehicles, and industrial trucks;

   d) Electrical and electronic equipment (EEE) used in medical devices, in-vitro diagnostics devices, and instruments for measurement, analysis, manufacturing, control, monitoring, testing and inspection;

NMED Exhibit 73

e) Machinery and tools used in agriculture, building/construction, forestry and landscaping;

f) Energy and power generation;

g) Oil and gas extraction;

h) Chemical production and refining;

i) Nuclear power facilities;

j) Low-carbon and renewable energy technologies;

k) Non-EEE medical devices;

6. Each Party that has registered for a specific exemption pursuant to Article 4 for the use of medium-chain chlorinated paraffins for metalworking fluids in professional or industrial settings with collection systems shall take measures to ensure protection of workers from risks associated with these uses.

7. Specific exemptions for the production and use of medium-chain chlorinated paraffins for polymers and rubbers (including PVC, ethylene propylene diene monomer (EPDM) rubber, chloroprene (CR), nitrile butadiene rubber (NBR) and chlorinated polyethylene (CPE)), used in replacement parts for, and repair of, articles shall apply where the substances were originally used in the manufacture of those articles, and may be available, limited to use in the following applications, until the end of service life of the articles or 2041, whichever comes earlier:

   a) Parts for land-based motor vehicles and machinery used in agriculture, construction, forestry, and landscaping (including powertrain and under-hood applications such as powertrains: wiring and under-hood harnesses (engine wiring, etc.); hoses, caps, tubes, filters; fuel system applications such as fuel hoses, fuel tanks, caps and underbodies; suspension and interior applications such as trim components, acoustic material and seat belts; exterior vehicle applications such as foam pads, sealers, gaskets, fasteners and windows; pyrotechnical devices and applications affected by pyrotechnical devices such as airbag ignition cables, seat covers/fabrics (only if airbag-relevant) and airbags);

   b) EEE used for medical devices, in-vitro diagnostics devices, and instruments for measurement, analysis, manufacturing, control, monitoring, testing and inspection;

   c) Aerospace and defence applications.

NMED Exhibit 73

8. Specific exemptions for the production and use of medium-chain chlorinated paraffins for ammunition pyrotechnic defence devices to achieve specific effects (e.g. sound, smoke, light) may be available until 2041.

9. Specific exemptions for the production and use of medium-chain chlorinated paraffins for intumescent coating and paint for space and defence equipment and its packaging to protect against extreme temperature may be available until 2041.

10. Specific exemptions for the production and use of medium-chain chlorinated paraffins in coating and paint for the repair of, and use in replacement parts for, space and defence equipment shall apply where medium-chain chlorinated paraffins were originally used in the manufacture of that equipment and may remain available until the end of service life of that equipment for its repair and maintenance, subject to review by the Conference of the Parties no later than 2041.

11. Each Party that has registered for a specific exemption pursuant to Article 4 for the use of medium-chain chlorinated paraffins in coating and paint for the repair of, and use in replacement parts for, space and defence equipment shall take measures to ensure the protection of workers from risks associated with this use.

12. With regard to the specific exemptions for the production and use of medium chain chlorinated paraffins for the applications referred to in paragraphs 8 and 9, at its fifteenth ordinary meeting and at every second ordinary meeting thereafter, the Conference of the Parties shall review the continued need for these specific exemptions.

Part XIV
Long-chain perfluorocarboxylic acids, their salts and related compounds

1. The production and use of long-chain perfluorocarboxylic acids, their salts and related compounds shall be eliminated except for Parties that have notified the Secretariat of their intention to produce and/or use them in accordance with Article 4.

2. Specific exemptions for the production and use of long-chain perfluorocarboxylic acids, their salts and related compounds, limited to the following applications, may be available until the end of the service life of articles being repaired or until 2041, whichever comes earlier:

NMED Exhibit 73

a) Semiconductors designed for replacement parts for combustion-engine-powered vessels;

b) Replacement parts for motor vehicles that have ceased mass production, covering all land-based vehicles, such as cars, motorcycles, agricultural and construction vehicles, and industrial trucks. Applications include semiconductors, coatings, cables, electronics, engines and under-hood applications, modules, hydraulic system components and relay assemblies.

Part XV
Chlorpyrifos

1. The production and use of chlorpyrifos shall be eliminated except for Parties that have notified the Secretariat of their intention to produce and/or use it in accordance with Article 4 of the Convention.

2. Specific exemptions for chlorpyrifos may be available for agricultural use only for the following crop pest complexes:

Crop	Pest
Barley	Termites
Cabbage	Diamondback moth *(Plutella xylostella)*
Cacao	Cacao-mosquitos *(Helopeltis spp.)*, cacao pod borer *(Conopomorpha cramerella)*
Chickpea	Cutworms
Citrus	Scale insects
Cotton, cotton seed	Aphids, carpophagous caterpillars, cutworms, spider mites, cotton leaf roller *(Syllepte derogata)*, whitefly larvae, whitefly adults
Eggplant	Shoot and fruit borer *(Leucinodes orbonalis)*
Maize	Armyworms *(Spodoptera cosmioides and Spodoptera frugiperda)*, lesser cornstalk borer *(Elasmopalpus lignosellus)*, variegated cutworm *(Peridroma saucia)*, corn earworm *(Helicoverpa armigera)*, sugarcane white grub *(Lepidiota stigma)*, seedling flies *(Atherigona spp.)*, stem borer *(Ostrinia furnacalis)*, green stink bug *(Nezara viridula)*

NMED Exhibit 73

Onion	Root grubs
Peanut	White grubs
Pineapple	Mealybug *(Dysmicoccus brevipes)*, pineapple weevil *(Metamasius dimidiatipennis)*, glasshouse symphylid *(Scutigerella immaculata)*
Rapeseed	Crucifer flea beetle, turnip sawfly, common pollen beetle, turnip gall weevil
Rice	Rice planthoppers, rice stemborers, rice leaf rollers
Sorghum	Armyworms *(Spodoptera cosmioides* and *Spodoptera frugiperda)*, lesser cornstalk borer *(Elasmopalpus lignosellus)*
Soya bean	Armyworm *(Spodoptera litura)*, soybean pod borer *(Etiella zinckenella)*, soybean seed fly *(Ophiomyia phaseoli)*, soybean leaf beetle *(Phaedonia inclusa stall)*, tobacco whitefly *(Bemisia tabaci)*, soybean aphid *(Aphis glycines)*, spiraling whitefly *(Aleurodicus dispersus)*, green stink bug *(Nezara viridula)*, brown stink bug *(Riptortus linearis)*, spider mite *(Tetranychus cinnabarinus)*
Sugar cane	Termites, beetles, sugarcane white grub *(Lepidiota stigma)*, sugarcane top borer *(Triporyza vinella)*, sugarcane stem borer *(Proceras sacchariphagus)*
Teff	Termites
Wheat	Termites, corn bugs, wheat chafers, leaf beetles, aphids, thrips

NMED Exhibit 73

ANNEX B[3]
RESTRICTION

Part I

Chemical	Activity	Acceptable purpose or specific exemption[4]
DDT (1,1,1-trichloro-2,2-bis (4-chlorophenyl)ethane) CAS No: 50-29-3	Production	Acceptable purpose: Disease vector control use in accordance with Part II of this Annex Specific exemption: Intermediate in production of dicofol Intermediate
	Use	Acceptable purpose: Disease vector control in accordance with Part II of this Annex Specific exemption: Production of dicofol Intermediate
Perfluorooctane sulfonic acid (CAS No. 1763-23-1), its salts[a] and perfluorooctane sulfonyl fluoride (CAS No. 307-35-7) **[a] For example: potassium perfluorooctane sulfonate (CAS No. 2795-39-3);**	Production	Acceptable purpose: In accordance with Part III of this Annex, production of other chemicals to be used solely for the use below. Production for uses listed below. Specific exemption: None

[3] *Secretariat note: As amended by decision SC-4/17 of 8 May 2009 and SC-9/4 of 10 May 2019*

[4] *Secretariat note: Please note that, in accordance with paragraph 9 of Article 4 of the Convention, when there are no longer any Parties registered for a particular type of specific exemption no new registrations may be made with respect to such exemptions, which appear in grey text in the table.*

NMED Exhibit 73

lithium perfluorooctane sulfonate (CAS No. 29457-72-5); ammonium perfluorooctane sulfonate (CAS No. 29081-56-9); diethanolammonium perfluorooctane sulfonate (CAS No. 70225-14-8); tetraethylammonium perfluorooctane sulfonate (CAS No. 56773-42-3); didecyldimethylammonium perfluorooctane sulfonate (CAS No. 251099-16-8)	Use	Acceptable purpose: In accordance with Part III of this Annex for the following acceptable purpose, or as an intermediate in the production of chemicals with the following acceptable purpose: • Insect baits with sulfluramid (CAS No. 4151-50-2) as an active ingredient for control of leaf-cutting ants from *Atta* spp. and *Acromyrmex* spp. for agricultural use only Specific exemption: • Metal plating (hard-metal plating) only in closed-loop systems • Fire-fighting foam for liquid fuel vapour suppression and liquid fuel fires (Class B fires) in installed systems, including both mobile and fixed systems, in accordance with paragraph 10 of part III of this Annex

Notes:

(i) Except as otherwise specified in this Convention, quantities of a chemical occurring as unintentional trace contaminants in products and articles shall not be considered to be listed in this Annex;

(ii) This note shall not be considered as a production and use acceptable purpose or specific exemption for purposes of paragraph 2 of Article 3. Quantities of a chemical occurring as constituents of articles manufactured or already in use before or on the date of entry into force of the relevant obligation with respect to that chemical, shall not be considered as listed in this Annex, provided that a Party has notified the Secretariat that a particular type of article remains in use within that Party. The Secretariat shall make such notifications publicly available;

(iii) This note shall not be considered as a production and use specific exemption for purposes of paragraph 2 of Article 3. Given that no significant quantities of the chemical are expected to reach humans and the environment during the production and use of a closed-system site-limited intermediate, a Party, upon notification to the Secretariat, may allow the production and use of quantities of a chemical listed in this Annex as a closed-system site-limited intermediate that is chemically transformed in the manufacture of other chemicals that, taking into consideration the criteria in paragraph 1 of Annex D, do not exhibit the characteristics of persistent organic pollutants. This notification shall include information on total production and use of such chemical or a reasonable estimate of such information and information regarding the nature of the closed-system site-limited process including the amount of any non-transformed and unintentional trace contamination of the persistent organic pollutant-starting material in the final product. This procedure applies except as otherwise specified in this Annex. The Secretariat

NMED Exhibit 73

shall make such notifications available to the Conference of the Parties and to the public. Such production or use shall not be considered a production or use specific exemption. Such production and use shall cease after a ten-year period, unless the Party concerned submits a new notification to the Secretariat, in which case the period will be extended for an additional ten years unless the Conference of the Parties, after a review of the production and use decides otherwise. The notification procedure can be repeated;

(iv) All the specific exemptions in this Annex may be exercised by Parties that have registered in respect of them in accordance with Article 4.

Part II
DDT (1,1,1-trichloro-2,2-bis (4-chlorophenyl)ethane)

1. The production and use of DDT shall be eliminated except for Parties that have notified the Secretariat of their intention to produce and/or use it. A DDT Register is hereby established and shall be available to the public. The Secretariat shall maintain the DDT Register.

2. Each Party that produces and/or uses DDT shall restrict such production and/ or use for disease vector control in accordance with the World Health Organization recommendations and guidelines on the use of DDT and when locally safe, effective and affordable alternatives are not available to the Party in question.

3. In the event that a Party not listed in the DDT Register determines that it requires DDT for disease vector control, it shall notify the Secretariat as soon as possible in order to have its name added forthwith to the DDT Register. It shall at the same time notify the World Health Organization.

4. Every three years, each Party that uses DDT shall provide to the Secretariat and the World Health Organization information on the amount used, the conditions of such use and its relevance to that Party's disease management strategy, in a format to be decided by the Conference of the Parties in consultation with the World Health Organization.

5. With the goal of reducing and ultimately eliminating the use of DDT, the Conference of the Parties shall encourage:

    a) Each Party using DDT to develop and implement an action plan as part of the implementation plan specified in Article 7. That action plan shall include:

        i. Development of regulatory and other mechanisms to ensure that DDT use is restricted to disease vector control;

        ii. Implementation of suitable alternative products, methods and strategies, including resistance management strategies to ensure the continuing effectiveness of these alternatives;

NMED Exhibit 73

iii. Measures to strengthen health care and to reduce the incidence of the disease.

b) The Parties, within their capabilities, to promote research and development of safe alternative chemical and non-chemical products, methods and strategies for Parties using DDT, relevant to the conditions of those countries and with the goal of decreasing the human and economic burden of disease. Factors to be promoted when considering alternatives or combinations of alternatives shall include the human health risks and environmental implications of such alternatives. Viable alternatives to DDT shall pose less risk to human health and the environment, be suitable for disease control based on conditions in the Parties in question and be supported with monitoring data.

6. Commencing at its first meeting, and at least every three years thereafter, the Conference of the Parties shall, in consultation with the World Health Organization, evaluate the continued need for DDT for disease vector control on the basis of available scientific, technical, environmental and economic information, including:

   a) The production and use of DDT and the conditions set out in paragraph 2;

   b) The availability, suitability and implementation of the alternatives to DDT; and

   c) Progress in strengthening the capacity of countries to transfer safely to reliance on such alternatives.

7. A Party may, at any time, withdraw its name from the DDT Registry upon written notification to the Secretariat. The withdrawal shall take effect on the date specified in the notification.

Part III
Perfluorooctane sulfonic acid, its salts, and perfluorooctane sulfonyl fluoride

1. The production and use of perfluorooctane sulfonic acid (PFOS), its salts and perfluorooctane sulfonyl fluoride (PFOSF) shall be eliminated by all Parties except as provided in Part I of this Annex for Parties that have notified the Secretariat of their intention to produce and/or use them for acceptable purposes. A Register of Acceptable Purposes is hereby established and shall be available to the public. The Secretariat shall maintain the Register of Acceptable Purposes. In the event that a Party not listed in the Register determines that it requires the use of PFOS, its salts or PFOSF for the acceptable purposes listed in Part I of this Annex it shall notify the Secretariat as soon as possible in order to have its name added forthwith to the Register.

NMED Exhibit 73

2. Parties that produce and/or use these chemicals shall take into account, as appropriate, guidance such as that given in the relevant parts of the general guidance on best available techniques and best environmental practices given in Part V of Annex C of the Convention.

3. Every four years, each Party that uses and/or produces these chemicals shall report on progress made to eliminate PFOS, its salts and PFOSF and submit information on such progress to the Conference of the Parties pursuant to and in the process of reporting under Article 15 of the Convention.

4. With the goal of reducing and ultimately eliminating the production and/or use of these chemicals, the Conference of the Parties shall encourage:

    a) Each Party using these chemicals to take action to phase out uses when suitable alternatives substances or methods are available;

    b) Each Party using and/or producing these chemicals to develop and implement an action plan as part of the implementation plan specified in Article 7 of the Convention;

    c) The Parties, within their capabilities, to promote research on and development of safe alternative chemical and non-chemical products and processes, methods and strategies for Parties using these chemicals, relevant to the conditions of those Parties. Factors to be promoted when considering alternatives or combinations of alternatives shall include the human health risks and environmental implications of such alternatives.

5. The Conference of the Parties shall evaluate the continued need for these chemicals for the various acceptable purposes and specific exemptions on the basis of available scientific, technical, environmental and economic information, including:

    a) Information provided in the reports described in paragraph 3;

    b) Information on the production and use of these chemicals;

    c) Information on the availability, suitability and implementation of alternatives to these chemicals;

    d) Information on progress in building the capacity of countries to transfer safely to reliance on such alternatives.

6. The evaluation referred to in the preceding paragraph shall take place no later than in 2015 and every four years thereafter, in conjunction with a regular meeting of the Conference of the Parties.

NMED Exhibit 73

7. Due to the complexity of the use and the many sectors of society involved in the use of these chemicals, there might be other uses of these chemicals of which countries are not presently aware. Parties which become aware of other uses are encouraged to inform the Secretariat as soon as possible.

8. A Party may, at any time, withdraw its name from the Register of acceptable purposes upon written notification to the Secretariat. The withdrawal shall take effect on the date specified in the notification.

9. The provisions of note (iii) of Part I of Annex B shall not apply to these chemicals.

10. Each Party that has registered for an exemption pursuant to Article 4 for the use of PFOS, its salts and PFOSF for fire-fighting foam shall:

    a) Notwithstanding paragraph 2 of Article 3, ensure that fire-fighting foam that contains or may contain PFOS, its salts and PFOSF shall not be exported or imported except for the purpose of environmentally sound disposal as set forth in paragraph 1 (d) of Article 6;

    b) Not use fire-fighting foam that contains or may contain PFOS, its salts and PFOSF for training;

    c) Not use fire-fighting foam that contains or may contain PFOS, its salts and PFOSF for testing unless all releases are contained;

    d) By the end of 2022, if it has the capacity to do so, restrict uses of fire-fighting foam that contains or may contain PFOS, its salts and PFOSF to sites where all releases can be contained;

    e) Make determined efforts designed to lead to the environmentally sound management of fire-fighting foam stockpiles and wastes that contain or may contain PFOS, its salts and PFOSF, in accordance with paragraph 1 of Article 6, as soon as possible.

NMED Exhibit 73

ANNEX C[5]
UNINTENTIONAL PRODUCTION

Part I
Persistent organic pollutants subject to the requirements of Article 5

This Annex applies to the following persistent organic pollutants when formed and released unintentionally from anthropogenic sources:

Chemical
Hexachlorobenzene (HCB) (CAS No: 118-74-1)
Hexachlorobutadiene (CAS No: 87-68-3)
Pentachlorobenzene (PeCB) (CAS No: 608-93-5)
Polychlorinated biphenyls (PCB)
Polychlorinated dibenzo-p-dioxins and dibenzofurans (PCDD/PCDF)
Polychlorinated naphthalenes, including dichlorinated naphthalenes, trichlorinated naphthalenes, tetrachlorinated naphthalenes, pentachlorinated naphthalenes, hexachlorinated naphthalenes, heptachlorinated naphthalenes, octachlorinated naphthalene

Part II
Source categories

Hexachlorobenzene, hexachlorobutadiene, pentachlorobenzene, polychlorinated biphenyls, polychlorinated dibenzo-p-dioxins and dibenzofurans, polychlorinated naphthalenes, including dichlorinated naphthalenes, trichlorinated naphthalenes, tetrachlorinated naphthalenes, pentachlorinated naphthalenes, hexachlorinated naphthalenes, heptachlorinated naphthalenes, octachlorinated naphthalene are unintentionally formed and released from thermal processes involving organic matter and chlorine as a result of incomplete combustion or chemical reactions.

The following industrial source categories have the potential for comparatively high formation and release of these chemicals to the environment:

[5] *Secretariat note: As amended by decisions SC-4/16 and SC-4/18 of 8 May 2009; SC-7/14 of 15 May 2015; and SC-8/12 of 5 May 2017.*

NMED Exhibit 73

a) Waste incinerators, including co-incinerators of municipal, hazardous or medical waste or of sewage sludge;
b) Cement kilns firing hazardous waste;
c) Production of pulp using elemental chlorine or chemicals generating elemental chlorine for bleaching;
d) The following thermal processes in the metallurgical industry:
    i. Secondary copper production;
    ii. Sinter plants in the iron and steel industry;
    iii. Secondary aluminium production;
    iv. Secondary zinc production.

Part III
Source categories

Hexachlorobenzene, hexachlorobutadiene, pentachlorobenzene, polychlorinated biphenyls, polychlorinated dibenzo-p-dioxins and dibenzofurans, polychlorinated naphthalenes, including dichlorinated naphthalenes, trichlorinated naphthalenes, tetrachlorinated naphthalenes, pentachlorinated naphthalenes, hexachlorinated naphthalenes, heptachlorinated naphthalenes, octachlorinated naphthalene may also be unintentionally formed and released from the following source categories, including:

a) Open burning of waste, including burning of landfill sites;
b) Thermal processes in the metallurgical industry not mentioned in Part II;
c) Residential combustion sources;
d) Fossil fuel-fired utility and industrial boilers;
e) Firing installations for wood and other biomass fuels;
f) Specific chemical production processes releasing unintentionally formed persistent organic pollutants, especially production of chlorophenols and chloranil;
g) Crematoria;
h) Motor vehicles, particularly those burning leaded gasoline;
i) Destruction of animal carcasses;
j) Textile and leather dyeing (with chloranil) and finishing (with alkaline extraction);
k) Shredder plants for the treatment of end-of-life vehicles;
l) Smouldering of copper cables;
m) Waste oil refineries.

NMED Exhibit 73

Part IV
Definitions

1. For the purposes of this Annex:

    a) "Polychlorinated biphenyls" means aromatic compounds formed in such a manner that the hydrogen atoms on the biphenyl molecule (two benzene rings bonded together by a single carbon-carbon bond) may be replaced by up to ten chlorine atoms; and

    b) "Polychlorinated dibenzo-p-dioxins" and "polychlorinated dibenzofurans" are tricyclic, aromatic compounds formed by two benzene rings connected by two oxygen atoms in polychlorinated dibenzo-p-dioxins and by one oxygen atom and one carbon-carbon bond in polychlorinated dibenzofurans and the hydrogen atoms of which may be replaced by up to eight chlorine atoms.

2. In this Annex, the toxicity of polychlorinated dibenzo-p-dioxins and dibenzofurans is expressed using the concept of toxic equivalency which measures the relative dioxin-like toxic activity of different congeners of polychlorinated dibenzo-p-dioxins and dibenzofurans and coplanar polychlorinated biphenyls in comparison to 2,3,7,8-tetrachlorodibenzo-p-dioxin. The toxic equivalent factor values to be used for the purposes of this Convention shall be consistent with accepted international standards, commencing with the World Health Organization 1998 mammalian toxic equivalent factor values for polychlorinated dibenzo-p-dioxins and dibenzofurans and coplanar polychlorinated biphenyls. Concentrations are expressed in toxic equivalents.

Part V
General guidance on best available techniques and best environmental practices

This Part provides general guidance to Parties on preventing or reducing releases of the chemicals listed in Part I.

A. General prevention measures relating to both best available techniques and best environmental practices

Priority should be given to the consideration of approaches to prevent the formation and release of the chemicals listed in Part I. Useful measures could include:

a) The use of low-waste technology;

b) The use of less hazardous substances;

NMED Exhibit 73

c) The promotion of the recovery and recycling of waste and of substances generated and used in a process;

d) Replacement of feed materials which are persistent organic pollutants or where there is a direct link between the materials and releases of persistent organic pollutants from the source;

e) Good housekeeping and preventive maintenance programmes;

f) Improvements in waste management with the aim of the cessation of open and other uncontrolled burning of wastes, including the burning of landfill sites. When considering proposals to construct new waste disposal facilities, consideration should be given to alternatives such as activities to minimize the generation of municipal and medical waste, including resource recovery, reuse, recycling, waste separation and promoting products that generate less waste. Under this approach, public health concerns should be carefully considered;

g) Minimization of these chemicals as contaminants in products;

h) Avoiding elemental chlorine or chemicals generating elemental chlorine for bleaching.

B. Best available techniques

The concept of best available techniques is not aimed at the prescription of any specific technique or technology, but at taking into account the technical characteristics of the installation concerned, its geographical location and the local environmental conditions. Appropriate control techniques to reduce releases of the chemicals listed in Part I are in general the same. In determining best available techniques, special consideration should be given, generally or in specific cases, to the following factors, bearing in mind the likely costs and benefits of a measure and consideration of precaution and prevention:

a) General considerations:

   i. The nature, effects and mass of the releases concerned: techniques may vary depending on source size;

   ii. The commissioning dates for new or existing installations;

   iii. The time needed to introduce the best available technique;

   iv. The consumption and nature of raw materials used in the process and its energy efficiency;

   v. The need to prevent or reduce to a minimum the overall impact of the releases to the environment and the risks to it;

NMED Exhibit 73

vi. The need to prevent accidents and to minimize their consequences for the environment;

vii. The need to ensure occupational health and safety at workplaces;

viii. Comparable processes, facilities or methods of operation which have been tried with success on an industrial scale;

ix. Technological advances and changes in scientific knowledge and understanding.

b) General release reduction measures: When considering proposals to construct new facilities or significantly modify existing facilities using processes that release chemicals listed in this Annex, priority consideration should be given to alternative processes, techniques or practices that have similar usefulness but which avoid the formation and release of such chemicals. In cases where such facilities will be constructed or significantly modified, in addition to the prevention measures outlined in section A of Part V the following reduction measures could also be considered in determining best available techniques:

i. Use of improved methods for flue-gas cleaning such as thermal or catalytic oxidation, dust precipitation, or adsorption;

ii. Treatment of residuals, wastewater, wastes and sewage sludge by, for example, thermal treatment or rendering them inert or chemical processes that detoxify them;

iii. Process changes that lead to the reduction or elimination of releases, such as moving to closed systems;

iv. Modification of process designs to improve combustion and prevent formation of the chemicals listed in this Annex, through the control of parameters such as incineration temperature or residence time.

C. Best environmental practices

The Conference of the Parties may develop guidance with regard to best environmental practices.

NMED Exhibit 73

ANNEX D
INFORMATION REQUIREMENTS AND SCREENING CRITERIA

1. A Party submitting a proposal to list a chemical in Annexes A, B and/or C shall identify the chemical in the manner described in subparagraph (a) and provide the information on the chemical, and its transformation products where relevant, relating to the screening criteria set out in subparagraphs (b) to (e):

   a) Chemical identity:

      i. Names, including trade name or names, commercial name or names and synonyms, Chemical Abstracts Service (CAS) Registry number, International Union of Pure and Applied Chemistry (IUPAC) name; and

      ii. Structure, including specification of isomers, where applicable, and the structure of the chemical class;

   b) Persistence:

      i. Evidence that the half-life of the chemical in water is greater than two months, or that its half-life in soil is greater than six months, or that its half-life in sediment is greater than six months; or

      ii. Evidence that the chemical is otherwise sufficiently persistent to justify its consideration within the scope of this Convention;

   c) Bio-accumulation:

      i. Evidence that the bio-concentration factor or bio-accumulation factor in aquatic species for the chemical is greater than 5,000 or, in the absence of such data, that the log Kow is greater than 5;

      ii. Evidence that a chemical presents other reasons for concern, such as high bio-accumulation in other species, high toxicity or ecotoxicity; or

      iii. Monitoring data in biota indicating that the bio-accumulation potential of the chemical is sufficient to justify its consideration within the scope of this Convention;

   d) Potential for long-range environmental transport:

      i. Measured levels of the chemical in locations distant from the sources of its release that are of potential concern;

      ii. Monitoring data showing that long-range environmental transport of the chemical, with the potential for transfer to a receiving environment, may have occurred via air, water or migratory species; or

NMED Exhibit 73

iii. Environmental fate properties and/or model results that demonstrate that the chemical has a potential for long-range environmental transport through air, water or migratory species, with the potential for transfer to a receiving environment in locations distant from the sources of its release. For a chemical that migrates significantly through the air, its half-life in air should be greater than two days; and

e) Adverse effects:

i. Evidence of adverse effects to human health or to the environment that justifies consideration of the chemical within the scope of this Convention; or

ii. Toxicity or ecotoxicity data that indicate the potential for damage to human health or to the environment.

2. The proposing Party shall provide a statement of the reasons for concern including, where possible, a comparison of toxicity or ecotoxicity data with detected or predicted levels of a chemical resulting or anticipated from its long-range environmental transport, and a short statement indicating the need for global control.

3. The proposing Party shall, to the extent possible and taking into account its capabilities, provide additional information to support the review of the proposal referred to in paragraph 6 of Article 8. In developing such a proposal, a Party may draw on technical expertise from any source.

NMED Exhibit 73

ANNEX E
INFORMATION REQUIREMENTS FOR THE RISK PROFILE

The purpose of the review is to evaluate whether the chemical is likely, as a result of its long-range environmental transport, to lead to significant adverse human health and/or environmental effects, such that global action is warranted. For this purpose, a risk profile shall be developed that further elaborates on, and evaluates, the information referred to in Annex D and includes, as far as possible, the following types of information:

a) Sources, including as appropriate:

   i. Production data, including quantity and location;

   ii. Uses; and

   iii. Releases, such as discharges, losses and emissions;

b) Hazard assessment for the endpoint or endpoints of concern, including a consideration of toxicological interactions involving multiple chemicals;

c) Environmental fate, including data and information on the chemical and physical properties of a chemical as well as its persistence and how they are linked to its environmental transport, transfer within and between environmental compartments, degradation and transformation to other chemicals. A determination of the bio-concentration factor or bio-accumulation factor, based on measured values, shall be available, except when monitoring data are judged to meet this need;

d) Monitoring data;

e) Exposure in local areas and, in particular, as a result of long-range environmental transport, and including information regarding bio-availability;

f) National and international risk evaluations, assessments or profiles and labelling information and hazard classifications, as available; and

g) Status of the chemical under international conventions.

NMED Exhibit 73

ANNEX F
INFORMATION ON SOCIO-ECONOMIC CONSIDERATIONS

An evaluation should be undertaken regarding possible control measures for chemicals under consideration for inclusion in this Convention, encompassing the full range of options, including management and elimination. For this purpose, relevant information should be provided relating to socio-economic considerations associated with possible control measures to enable a decision to be taken by the Conference of the Parties. Such information should reflect due regard for the differing capabilities and conditions among the Parties and should include consideration of the following indicative list of items:

a) Efficacy and efficiency of possible control measures in meeting risk reduction goals:
    i. Technical feasibility; and
    ii. Costs, including environmental and health costs;
b) Alternatives (products and processes):
    i. Technical feasibility;
    ii. Costs, including environmental and health costs;
    iii. Efficacy;
    iv. Risk;
    v. Availability; and
    vi. Accessibility;
c) Positive and/or negative impacts on society of implementing possible control measures:
    i. Health, including public, environmental and occupational health;
    ii. Agriculture, including aquaculture and forestry;
    iii. Biota (biodiversity);
    iv. Economic aspects;
    v. Movement towards sustainable development; and
    vi. Social costs;
d) Waste and disposal implications (in particular, obsolete stocks of pesticides and clean-up of contaminated sites):
    i. Technical feasibility; and
    ii. Cost;
e) Access to information and public education;
f) Status of control and monitoring capacity; and
g) Any national or regional control actions taken, including information on alternatives, and other relevant risk management information.

NMED Exhibit 73

ANNEX G[6]
ARBITRATION AND CONCILIATION PROCEDURES FOR SETTLEMENT OF DISPUTES

Part I
Arbitration procedure

The arbitration procedure for purposes of paragraph 2 (a) of Article 18 of the Convention shall be as follows:

Article 1

1. A Party may initiate recourse to arbitration in accordance with Article 18 of the Convention by written notification addressed to the other party to the dispute. The notification shall be accompanied by a statement of the claim, together with any supporting documents, and state the subject-matter of arbitration and include, in particular, the articles of the Convention the interpretation or application of which are at issue.

2. The claimant party shall notify the Secretariat that the parties are referring a dispute to arbitration pursuant to Article 18. The notification shall be accompanied by the written notification of the claimant party, the statement of claim and the supporting documents referred to in paragraph 1 above. The Secretariat shall forward the information thus received to all Parties.

Article 2

1. If a dispute is referred to arbitration in accordance with Article 1 above, an arbitral tribunal shall be established. It shall consist of three members.

2. Each of the parties to the dispute shall appoint an arbitrator and the two arbitrators so appointed shall designate by common agreement the third arbitrator, who shall be the President of the tribunal. The President of the tribunal shall not be a national of one of the parties to the dispute, nor have his or her usual place of residence in the territory of one of those parties, nor be employed by any of them, nor have dealt with the case in any other capacity.

3. In disputes between more than two parties, parties in the same interest shall appoint one arbitrator jointly by agreement.

---

[6] *Secretariat note: Annex G was adopted by the first meeting of the Conference of the Parties in its decision SC-1/2 of 6 May 2005*

NMED Exhibit 73

4. Any vacancy shall be filled in the manner prescribed for the initial appointment.

5. If the parties do not agree on the subject-matter of the dispute before the President of the arbitral tribunal is designated, the arbitral tribunal shall determine the subject-matter.

Article 3

1. If one of the parties to the dispute does not appoint an arbitrator within two months of the date on which the respondent party receives the notification of the arbitration, the other party may inform the Secretary-General of the United Nations, who shall make the designation within a further two-month period.

2. If the President of the arbitral tribunal has not been designated within two months of the date of the appointment of the second arbitrator, the Secretary-General of the United Nations shall, at the request of a party, designate the President within a further two-month period.

Article 4

The arbitral tribunal shall render its decisions in accordance with the provisions of the Convention and international law.

Article 5

Unless the parties to the dispute otherwise agree, the arbitral tribunal shall determine its own rules of procedure.

Article 6

The arbitral tribunal may, at the request of one of the parties, indicate essential interim measures of protection.

Article 7

The parties to the dispute shall facilitate the work of the arbitral tribunal and, in particular, using all means at their disposal, shall:

a) Provide it with all relevant documents, information and facilities; and

b) Enable it, when necessary, to call witnesses or experts and receive their evidence.

NMED Exhibit 73

Article 8

The parties and the arbitrators are under an obligation to protect the confidentiality of any information they receive in confidence during the proceedings of the arbitral tribunal.

Article 9

Unless the arbitral tribunal determines otherwise because of the particular circumstances of the case, the costs of the tribunal shall be borne by the parties to the dispute in equal shares. The tribunal shall keep a record of all its costs, and shall furnish a final statement thereof to the parties.

Article 10

A party that has an interest of a legal nature in the subject matter of the dispute which may be affected by the decision in the case may intervene in the proceedings with the consent of the tribunal.

Article 11

The tribunal may hear and determine counterclaims arising directly out of the subject matter of the dispute.

Article 12

Decisions both on procedure and substance of the arbitral tribunal shall be taken by a majority vote of its members.

Article 13

1. If one of the parties to the dispute does not appear before the arbitral tribunal or fails to defend its case, the other party may request the tribunal to continue the proceedings and to make its award. Absence of a party or a failure of a party to defend its case shall not constitute a bar to the proceedings.

2. Before rendering its final decision, the arbitral tribunal must satisfy itself that the claim is well founded in fact and law.

Article 14

The tribunal shall render its final decision within five months of the date on which it is fully constituted unless it finds it necessary to extend the time limit for a period which should not exceed five more months.

NMED Exhibit 73

Article 15

The final decision of the arbitral tribunal shall be confined to the subject matter of the dispute and shall state the reasons on which it is based. It shall contain the names of the members who have participated and the date of the final decision. Any member of the tribunal may attach a separate or dissenting opinion to the final decision.

Article 16

The award shall be binding on the parties to the dispute. The interpretation of the Convention given by the award shall also be binding upon a Party intervening under Article 10 above insofar as it relates to matters in respect of which that Party intervened. The award shall be without appeal unless the parties to the dispute have agreed in advance to an appellate procedure.

Article 17

Any controversy which may arise between those bound by the final decision in accordance with Article 16 above, as regards the interpretation or manner of implementation of that decision, may be submitted by any of them for decision to the arbitral tribunal which rendered it.

Part II
Conciliation procedure

The conciliation procedure for purposes of paragraph 6 of Article 18 of the Convention shall be as follows:

Article 1

1. A request by a party to a dispute to establish a conciliation commission in consequence of paragraph 6 of Article 18 shall be addressed in writing to the Secretariat. The Secretariat shall forthwith inform all Parties to the Convention accordingly.

2. The conciliation commission shall, unless the parties otherwise agree, be composed of three members, one appointed by each party concerned and a President chosen jointly by those members.

Article 2

In disputes between more than two parties, parties in the same interest shall appoint their members of the commission jointly by agreement.

NMED Exhibit 73

Article 3

If any appointments by the parties are not made within two months of the date of receipt by the Secretariat of the written request referred to in Article 1, the Secretary-General of the United Nations shall, upon request by a party, make those appointments within a further two-month period.

Article 4

If the President of the conciliation commission has not been chosen within two months of the second member of the commission being appointed, the Secretary General of the United Nations shall, upon request by a party, designate the President within a further two-month period.

Article 5

1. The conciliation commission shall, unless the parties to the dispute otherwise agree, determine its own rules of procedure.

2. The parties and members of the commission are under an obligation to protect the confidentiality of any information they receive in confidence during the proceedings of the commission.

Article 6

The conciliation commission shall take its decisions by a majority vote of its members.

Article 7

The conciliation commission shall render a report with recommendations for resolution of the dispute within twelve months of being established, which the parties shall consider in good faith.

Article 8

Any disagreement as to whether the conciliation commission has competence to consider a matter referred to it shall be decided by the commission.

Article 9

The costs of the commission shall be borne by the parties to the dispute in shares agreed by them. The commission shall keep the record of all its costs and shall furnish a final statement thereof to the parties.

MR. MAGGIORE: Good afternoon everybody. My name is Pete Maggiore. I'm the Chairman of the Water Quality Control Commission. I've been designated by the Water Quality Control Commission to act as Hearing Officer at this hearing.

It's being held to consider proposed amendments to Section -- as I was saying, thank you -- amendments to Sections 10, 11, 12, 113 and 900 of the New Mexico Water Quality Control Commission's Standards for Interstate and Intrastate Surface Waters, 20 NMAC 6.4.

Timely notice of this hearing was published in the Albuquerque Journal, the Newsline for the Blind, and the New Mexico Register.

The amendments are proposed by the Surface Water Bureau of the Environment Department. The proposed amendments would adopt human health and aquatic life criteria for Environmental Protection Agency priority toxic pollutants.

The Commission may make a decision on the proposed amendments at the conclusion of this hearing, and if the regulations are approved, the regulations will be reformatted for consistency with the New Mexico Administrative Code.

The record in this matter includes the petition to amend the regulations and to request this hearing, the

notice of public hearing and evidence of publications, and several notices of intent to provide technical testimony.

This hearing will be conducted in accordance with the Commission's Guidelines for Regulation Hearings. Pursuant to Section 401 of these guidelines, I will conduct the hearing so as to provide a reasonable opportunity for all persons to be heard without making the hearing unreasonably lengthy or cumbersome.

The Rules of Civil Procedure and the Rules of Evidence do not apply, but I will make whatever orders are necessary to preserve the decorum and to protect the orderly hearing process.

All testimony will be given under oath and all persons giving testimony will be subject to cross-examination by any other person in attendance on the subject matter of their testimony and on matters affecting their credibility. I may limit cross-examination, if necessary, to avoid harassment, intimidation or repetition.

This hearing is being transcribed. Transcription services are provided by Kathy Townsend Court Reporters. Please contact them directly if you wish to purchase a transcript.

We will first proceed by hearing the technical

case. The order of presentation will be as follows: the Surface Water Bureau, as proponents of the amendments, shall present its case first. Those generally supporting the petition will go next, and I have listed there Larry Webb, the New Mexico Municipal Environmental Quality Association, the US Department of Interior, the Fish & Wildlife Service, and the Board of Regents of the University of California. Then we'll proceed with those who are generally opposed to the petition, which include the San Juan Water Commission.

The Commission's secretary received no other notices of intent to present technical testimony, so we will then go to nontechnical testimony, which will be taken in the order in which the attendees signed in. If you have not previously signed in, please do so now regardless of whether you wish to present testimony.

Are there any questions from any of the Commissioners or members of the audience regarding the hearing format?

MS. HUGHES: Mr. Chairman, there are no questions regarding the format. I just bring up a preliminary procedural matter.

Prior to the hearing, you got a letter from the San Juan Water Commission requesting that this hearing be postponed or delayed and held during the regular

NMED Exhibit 74

triennial review. It was your position that you didn't have authority --

MR. MAGGIORE: That's right.

MS. HUGHES: -- on behalf of the Commission to -- after the Commission had decided to hear this matter, that you didn't have authority to postpone or delay the hearing unilaterally.

MR. MAGGIORE: Right.

MS. HUGHES: So I just bring that up as a preliminary procedural matter.

MR. MAGGIORE: I did correspond, I think -- or you corresponded on my behalf -- with the San Juan Water Commission precisely that, that I did not have unilateral authority given to me by the Commission to summarily change or postpone the hearing.

I guess, Commissioners, there was that correspondence, though, and if there is any -- is there any need to discuss that?

Do you have some concerns, ma'am?

MS. MC CALEB: My name is Jolene L. McCaleb. I'm the attorney for the San Juan Water Commission.

What I would like to do at this point in time is -- I'm not certain whether it's correct to call it still a pending motion, given your letter, or whether I need to make a -- I need to move to renew --

MS. HUGHES: I would renew your motion.

Go ahead.

MS. MC CALEB: What I would like to do is I would like to renew the San Juan Water Commission's motion that this hearing be postponed.

The grounds for the motion are twofold: One is based on policy reasons why the subject matter of this hearing should be considered during the next triennial review. Also, we now have some procedural grounds based on concerns about the procedural fairness of this proceeding.

So I would propose that Mr. Kirkpatrick be permitted to present the policy concerns of San Juan Water Commission, and then I can make the legal arguments about the procedure.

MR. MAGGIORE: Any objections, Commissioners? If not, please proceed.

MS. MC CALEB: Thank you.

We'll try asking questions of Mr. Kirkpatrick from up here, if that works, so everyone doesn't need to move.

MR. MAGGIORE: Do we have a witness table?

MS. HUGHES: Let me just ask you, are you making argument? All you're making is argument, or is Mr. Kirkpatrick going to present testimony regarding -- I

mean, your motion is really a procedural motion, it sounds like, or a --

MS. MC CALEB: It's twofold.

MS. HUGHES: Okay.

MS. MC CALEB: The first portion of the motion is that for public policy reasons, it is not appropriate to consider this petition until the triennial review.

MS. HUGHES: Can you argue that? Can't you, as counsel, argue that motion?

MS. MC CALEB: I could argue that, if you would prefer.

MS. HUGHES: I think we would, because I think this is a motion for just -- that the lawyers should argue on that behalf, and then the Commission could make a decision.

MS. MC CALEB: Sure.

MS. HUGHES: Rather than having the witness be sworn in, et cetera, I think you should argue it.

MS. MC CALEB: Since I have people behind me, is it all right if I sit and make my argument?

MR. MAGGIORE: Do you have a microphone that she could use?

MR. PIERCE: We don't have a speaker.

MS. MC CALEB: You know what --

MR. MAGGIORE: Why don't you come down to the

front.

MS. MC CALEB: Thank you. Mr. Hearing Officer, Members of the Commission.

By letter of January 31st, Mr. Kirkpatrick, on behalf of the San Juan Water Commission, sent a letter to the Water Quality Control Commission requesting that this hearing be postponed for various policy reasons.

The primary policy reason is the scope of the Environment Department's proposal. The petition that we are here to discuss today essentially proposes the adoption of 113 new water quality standards.

It is the position of the San Juan Water Commission that such a broad proposal would more appropriately be considered during the next triennial review, so that it could be considered in context with the review of all other water quality issues at that time.

With regard to procedural issues and concerns, the New Mexico Environment Department, in our opinion, has made several substantive changes to its original petition, and, therefore, that requires a renoticing of this hearing.

For example, the Environment Department has submitted a revised petition that creates, for example, a new subset of, quote, persistent toxic pollutants, and

there have been various other changes that we believe are substantive and not just fine-tuning.

In addition, with regard to the fairness of the current procedure, I would like to bring to the Commission's attention that it was not possible to obtain copies of notices of intent that were filed, including the one filed by the Department, until six days after they were actually filed, because the Commission office was closed. We left several phone messages, and I guess because of the transition in the administrative secretary's position, no one was minding the shop, and that worked a disadvantage for my client.

In addition, we have a concern about the procedure under which the Environment Department listed its written technical testimony as an exhibit to potentially be filed in its notice of intent and then ten days later actually filed significant written testimony.

Other parties who actually intended to make an exhibit of written technical testimony provided it with their notice of intent, and I think that that is an unfair procedure for the Environment Department to be able to do that.

In addition, if you have the guidelines in front of you, I'm not sure whether you do, for Commission

hearings, Guideline 303, with regard to the submission of the notice of intent to present technical testimony states that the notice of intent shall either summarize or include a copy of the direct testimony.

It's our position that the Environment Department's notice of intent did neither of those things.

If you will look at the Department's notice of intent with regard to each witness, they indicate the topic that a witness will testify about, but in no way summarize or indicate what that testimony will be, and for the Department to then later file their written direct ten days after everyone else is an unfair procedure.

So for these various policies reasons and procedural reasons, we request that this hearing be postponed.

MR. MAGGIORE: Okay.

Thank you.

MS. MC CALEB: Thank you.

MR. MAGGIORE: Counsel?

MR. AMES: Yes. Thank you, Mr. Chairman, Members of the Commission.

My name is Eric Ames. I'm an attorney in the Office of General Counsel at the New Mexico Environment

Department, and I'm here today on behalf of the Surface Water Quality Bureau.

The Department opposes San Juan's request for a delay in this hearing. There are a number of reasons, in our estimation, why a delay is neither warranted nor prudent.

First, there is no defect in public notice. None has been mentioned here. Second, there would be prejudice to both the Department and the other parties who have prepared and sat and waited for this hearing for the past two days. Third, there is some urgency in having this hearing and proceeding to a decision on the petition. Finally, this is a regular Commission hearing on a proposal to amend these water quality standards. It's subject to the exact same procedural safeguards as any proceeding this Commission holds to amend the water quality standards, including the triennial review.

Before discussing these reasons in more detail, however, I'd like to provide a little context for the motion you just heard.

As Chairman Maggiore and Ms. McCaleb said, there was a letter on January 31st from the Commission -- the San Juan Water Commission requesting a delay. That was the first request for a delay that was made by a letter, as was said.

NMED Exhibit 74

The San Juan Water Commission never sent a copy to the Department -- a copy of that letter to the Department. They never called us before sending the letter to tell us they were going to ask for a delay, and they never called us after the letter to tell us they had asked for a delay. In fact, we only learned about the request for a delay on February 25th when I went down to the hearing clerk's office to obtain copies of the other parties' notices of intent.

More troubling, the letter is essentially an argument on the merits. I thought the whole matter had been resolved, because the Chairman, as he said, sent a letter to the Commission on February 20th telling them that the request for a delay had been denied, and on February 26th, San Juan sent a letter to the Commission Chairman telling him that, in fact, they were withdrawing their request for a delay -- or at least that's how we understood the letter.

So we're a bit surprised to hear the request raised for a second time here.

With that said, we'll wait until our case in chief to argue the merits of the so-called policy reasons for San Juan's request for a delay. At this time I'll explain in a little more detail our reasons for opposing the delay on procedural grounds.

First, as I said, there is no defect in the legitimacy of this hearing. There has been no claim that the public notice was improper or this hearing was improperly scheduled.

Second, the delay would be prejudicial to the Department and to the other parties. A petitioner generally has a right to a prompt hearing on its petition. It shouldn't be strung along for months by repeated requests for a delay.

Finally, the Department and other parties have expended a significant amount of time and resources to prepare for this hearing and to be here today.

The final reason is one which I would not have intended to offer in response to a motion, but since it was raised earlier by Dr. Davis, I will say, again, that Mr. Pierce will not be here after the 21st of March, and Mr. Pierce is an important part of the Department's case in chief, and it would work a severe hardship on the Department if this hearing were not held today or at least before March 21st.

San Juan did not make a proposal for how long a delay they would like. I presume they are asking for more than a week, based on the grounds for stay identified as the basis for their request.

Third, as I said, there is some urgency in

hearing this petition. The Department has filed this petition to address deficiencies in the triennial review identified by the EPA. The EPA has said that it will initiate federal promulgation for numeric criteria for the State of New Mexico unless the Commission acts. It's the Commission's decision whether to act, but we don't even get to that point unless we have a hearing, and we need to move promptly to get this done.

Second, there is a risk that an ongoing federal lawsuit could be amended to include a claim against the EPA, and that would only make the matter -- make matters much worse. It would thrust the state -- well, it would raise the stakes for the state in a matter in which it has already decided to intervene.

Lastly, I'd like to respond to the arguments that were made by Ms. McCaleb. Basically, in my view, San Juan has not made a convincing argument for delay.

First, they've had ample notice and time to prepare for this hearing. This hearing was petitioned when we -- let me rephrase. The petition was filed three-and-a-half months ago. A hearing was scheduled three months ago. The Department met with San Juan to discuss the proposal that's currently before you two months ago.

Since this petition was filed three-and-

one-half months ago, San Juan has made only one request for information. The Department responded promptly to that request, and we've heard nothing since. Nowhere in San Juan's written testimony is there a challenge to any specific criterion that the Department has proposed. They haven't even brought an expert witness to testify in this hearing or to listen to the testimony that's about to be offered.

I would submit that this is not a function of insufficient time to prepare for the hearing, but a function of having no evidence.

As to the argument that this proceeding should be delayed until the next triennial review, I would submit that this is still the triennial review. New Mexico has not completed the triennial review that it began in 1997. This is the last item.

Second, the next triennial review is not due until January of 2003. Under EPA guidance -- EPA -- the way EPA interprets the requirements, the next triennial review must begin three years after the submittal of the prior. This hearing excluded, we interpret that as January of 2000, meaning the next hearing would need to be initiated by January of 2003. Holding off on this hearing that long does raise the stakes with regard to this hearing.

NMED Exhibit 74

If this hearing is delayed, I would suggest there is a significant risk that EPA would act in the interim. There is nothing to be gained with respect to procedural safeguards. This is an identical public notice and procedure as the regular triennial review that was held in '97 and that will be held again in January of 2003. This hearing and the triennial review are conducted under the same Commission guidelines, and they must comply with the same EPA requirements for amending water quality standards.

Further, there is the same opportunity for public participation as the triennial review. The Department, in fact, conducted a wide -- talked to a wide number of people in getting ready for this hearing, consulted with a wide range of people after it initiated its petition.

San Juan, in its written submittal, acknowledges the Department addressed many of its concerns. In some it's hard to see what the Department could have done more or should have done more prior to this hearing.

As for the argument that the Department made additional changes to its petition after November 21st -- November 29th, that, in fact, is true; the Department, on February 1st, revised its petition and sent copies to

everyone who attended any of the meetings, including San Juan, as well as all people on the Commission mailing list and all members of the Commission.

These changes were in direct response to concerns raised at the meetings the Department held in January with a wide range of interest groups, including San Juan.

There is no need to renotice this petition in order for the Commission to proceed. The Water Quality Control Commission guidelines allow a party -- or allow a petitioner, as well as any party -- to submit modifications to the petition with its notice of intent.

The Department decided that it would be in the best interests of everyone if it did it sooner than the notice of intent. Notices of intent weren't due until February 22nd. The Department decided to do it immediately, and, therefore, within days of concluding the meetings, it submitted the revisions to everyone so they could prepare their written testimony and prepare their notices of intent.

I submit the Department did more than it was required to do by the Commission guidelines. It seems strange the Department now would be punished for it.

As to the one item which the Department did change that was addressed in San Juan's motion, the list

regarding persistent toxins, I would suggest that's a red herring.

The Department had already proposed to apply the human health criteria, all of them, to ephemeral waters, and, more appropriately, to tributaries of water with designated or existing attainable fishery use.

In the parlance you'll hear today, we're talking about them as ephemeral waters because they are waters that are not themselves designated as fisheries, but are a tributary to fisheries, so I will call them ephemeral waters.

Our original proposal was to apply the human health criteria to all tributaries, all ephemeral waters. In our proposal we restricted that list, we actually backed off from our broader proposal and limited it to those pollutants which the Department termed are persistent bioaccumulative toxic pollutants.

So to the extent that San Juan didn't have notice that we were going to restrict the list, that's a bit of a red herring, since we'd already said we were going to apply the -- apply the criteria -- all the criteria to these waters.

San Juan's next argument is that the Department violated the Commission guidelines regarding notices of intent. Their argument is essentially the Department did

not submit its written testimony with the notice of intent; and that, secondly, the Department's summary of its testimony in the notice of intent was not sufficient to meet that requirement.

The requirement is to submit a summary; that's it. There is no requirement to submit all your written testimony. San Juan chose to do so; Los Alamos National Laboratory chose to do so. Dr. Hernandez, I believe, did not choose to do so, he submitted an outline. The Department submitted a summary.

The fact that the Department listed its written testimony as an exhibit and then provided it ten days later does not create a violation of the Commission guidelines.

As to the argument that the summary is not sufficient, that is for the Commission to decide. The Department's notice of intent in this case is fundamentally no different than the Department's notices of intent that it filed in the primary contact designation hearing in Las Cruces in October or in the hearing on the changes to the surface water definition that it did, oh, last spring. In fact, I don't think it's much different than the notice of intent the Department filed in the triennial review in 1997.

The Commission has never established a standard

for what constitutes a summary. So there is very little for the Department to do in that context, but the Department believes that what it did provided a broad enough outline to put other parties on notice of the scope of its testimony and that that meets the requirement.

San Juan's final argument is that it was unable to obtain the notices of intent until six days after the filing deadline, and that, therefore, it was prejudiced in its ability to prepare for this hearing. Six days seems like a fairly short time in the scope of the -- of this matter to allege a prejudice, particularly since San Juan had already prepared its full position at the time it filed its notice of intent.

At the time it filed its notice of intent, it was prepared to go to hearing. It had already written down and announced to the public and to this Commission what it was going to say. What was left for it to prepare was to review everyone else's notice of intent.

It had a delay of six days. That's not the Surface Water Quality Bureau's fault, but that said, it's hard to see how a delay of six days can require this entire hearing be rescheduled for some undefined period of time in order to correct it.

In conclusion, the Department sees no need and

NMED Exhibit 74

no good reason for a delay. The hearing is required to give the state a chance to avoid federal imposition of numeric criteria. A delay increases the risk that this will occur.

The hearing was properly noticed and scheduled. There is going to be significant prejudice to the Department, as well as other parties, if a delay is granted.

In this light, the Department urges the Commission to proceed with this hearing today.

Thank you.

MR. MAGGIORE: Thank you, Counselor.

Any other parties wishing to argue this motion?

MS. MC CALEB: If I may, I would like to respond to the Environment Department.

MR. MAGGIORE: Please proceed.

MS. MC CALEB: Thank you.

The first comment I would like to make, before I get into the substance of what Mr. Ames said, is that I believe it is entirely inappropriate, the derogatory remarks he made to this Commission concerning the type of San Juan -- the type of testimony that San Juan Water Commission may be presenting and his interpretation that because we do not have a technical expert here that there are no -- essentially, there is nothing important to hear

from the San Juan Water Commission.

I believe that that was the shadow that was cast over what we are here to do, and I think that was entirely inappropriate on Mr. Ames' part.

With regard to the prejudice issue, and specifically, again, with Mr. Ames' concern that we are not here with an expert witness, that is because of circumstances outside our control and the date that this hearing was scheduled for, and so we have done our best to prepare Mr. Kirkpatrick in place of Mr. Pitts.

However, I would like to point out that in our attempts to get assistance from our technical expert, we were prejudiced in the fact that the Environment Department did not even send us a copy of its notice of intent, and I had to wait to try to get that from the Commission secretary.

Mr. Ames did provide the information to me on February 28th, when I had not been able to get ahold of the Commission secretary, but the Environment Department, even though they had our notice of intent and knew we would be participating, did not voluntarily provide their notice of intent to us.

With regard to Mr. Kirkpatrick's letter to the Commission to postpone this hearing, I have no proof that a copy of the letter was sent to Mr. Davis, because,

unfortunately, Mr. Kirkpatrick's secretary did not include the copy list on her letter; however, she was instructed to send a copy of that letter to Mr. Davis, and it's my belief that it was sent, and we certainly had no intention to not notify the Environment Department of our request to the Commission.

With regard to Mr. Ames' statement that he believes that San Juan Water Commission withdrew its motion based on Mr. Kirkpatrick's February 26th letter, Mr. Maggiore's letter and Mr. Kirkpatrick's letters passed in the mail.

In his letter, Mr. Kirkpatrick essentially said, "We haven't heard from the Water Quality Control Commission, and, therefore, do we need to assume that our motion has been denied?"

So in no way did we withdrew our motion; we just indicated that we hadn't heard anything, because the letters crossed in the mail.

With regard to our motion and when we would request that this hearing be rescheduled, we would request that it be part of the next triennial review, and that is for this Commission to set.

With regard to the severe hardship that would be imposed on the Department, I'd first like to point out that I realize everyone is here today prepared to go to a

hearing, but there is no other procedure available for an interested party to request that a motion -- that a hearing be postponed other than the way we attempted to do it. That's the best way we thought we could do it, first to send a letter to the Commission, after you had scheduled the hearing, requesting a postponement; and then if the Water Quality Control Commission does not consider that at that time, this is our first opportunity to present our motion.

And while we do understand that Mr. Pierce will be retiring, and we will miss him greatly, we mean that wholeheartedly, he's always been very helpful to us, I don't believe that the fact that the Department may be losing an employee is a sufficient reason to fail to postpone a hearing of this magnitude that requires more consideration and should appropriately be heard during the triennial review.

Thank you.

MR. MAGGIORE: Thank you.

Commissioners, any thoughts on the preliminary motion?

I'll entertain a motion.

MR. GLASS: One second before the motion, please.

MR. MAGGIORE: Commissioner Glass.

MR. GLASS: When Mr. Ames testified that the hearing we have scheduled today is really an extension of or a completion of the 1997 triennial review, I guess that brings to me -- brings up for me a question of what constitutes the conclusion of the triennial review.

Is it the final full approval by EPA of the standards, or is it some other measure of conclusion?

In fact, is this a continuation, or can it be classified as that?

MR. AMES: Mr. Glass, my understanding is that the Department's position is that the triennial review that was initiated in '97 will conclude when the Department -- when this Commission has considered all remaining issues left from EPA's record of decision issued in January of 2001. This is the last issue.

MR. GLASS: So it's predicated on Commission consideration of -- not so much EPA approval of the water quality --

MR. AMES: That's correct.

MR. GLASS: Okay.

MR. AMES: If this Commission were to decide to take no action on the Department's petition, or deny the petition, I suppose that would be the end of the triennial review, and from the Department's perspective, the ball would then be in EPA's court to decide how to

respond, but in the record of decision, EPA clearly left open for the Commission the opportunity to address issues which it considered problematic, and among those were the priority contact designation for the lower Rio Grande, a few involving the definition of surface waters, and this big issue of numeric criteria for toxic pollutants.

EPA said it would consider making a finding that the Department's -- or that the state's standards were inadequate, essentially giving us the opportunity to address that concern before EPA did it for us, and it's in that light that the Department has come back with this petition as an effort to close out all remaining open issues which EPA has given us an opportunity to address.

So it's the Department's position that this is the last piece of the 1997 triennial review.

MR. GLASS: In my view, a denial to even consider the petition would not constitute a Commission hearing or consideration of the issue brought up by EPA, just a -- if we were to deny to hear any of the petition today, we would not have considered it, and you've stated that our denial would bring the triennial review to a close, but I don't think that's true.

MR. AMES: Mr. Glass, I think you may have misunderstood me. I meant a denial of the petition after a hearing.

NMED Exhibit 74

MR. GLASS: Oh, okay. So we're considering --

MR. AMES: I think one could also argue that if the Commission refused to even consider the petition, that would be a final action by this Commission that the EPA could look at and say, "Well, the Commission has decided -- the State of New Mexico has decided that it's not going to deal with this issue, so now the ball is now in our court."

So I think we come to the same place, yes.

MR. GLASS: Okay. Thanks.

MR. MAGGIORE: Commissioner Hutchinson.

MR. HUTCHINSON: I just have a question for our legal counsel. Well, I guess Mr. Ames could answer it as well.

It's my understanding that regardless of a triennial review taking place that any person can request a change to the standards or a new standard at any time. So -- is that correct?

MR. AMES: Mr. Hutchinson, I'd be pleased to answer that.

I half expected that issue to be raised in San Juan's motion. It was not.

It is entirely appropriate for this Commission to hold separate hearings on a distinct issue -- on any issue. Anyone can petition this Commission for a change

in the water quality standards, and this Commission would decide whether to have a hearing and would have a hearing and decide on the matter. This is particularly true when there may be some urgency to the matter.

From a different perspective, the Commission might want to consider whether it's really a good idea to postpone hearing issues, particularly issues of some magnitude, until the triennial review, which then makes the triennial review quite an unwieldy and potentially unproductive forum.

Many of us sat through the -- or participated in the eight-and-a-half days that that triennial review required, and it led to a number of problems both for the Commissioners and for the parties themselves in terms of participating and gathering the necessary information to make a decision.

So not only do the guidelines allow -- not only does the act allow the Commission to have hearings when it deems it appropriate, but from a policy perspective, it makes sense for the Commission to have hearing when they -- on issues as they arise.

MR. GLASS: I move that we proceed with the hearing.

MR. JOHNSON: Second.

MR. MAGGIORE: A motion from Commissioner

Glass; a second from John the very end.

MR. MAGGIORE: The very end, Commissioner Johnson.

Any further discussion?

Seeing none, all in favor please signify by saying aye.

(Vote taken.)

MR. MAGGIORE: Motion carries.

We'll proceed.

Thank you, Counselors.

Please proceed with your case in chief.

MR. AMES: Thank you, Mr. Chairman.

As I stated at the beginning, my name is Eric Ames. I'm representing the Department here today.

The Department in this proceeding proposes the adoption of numeric criteria for priority toxic pollutants. There are 23 criteria for the protection of aquatic life, 11 are acute and 10 are chronic and 92 criteria are for the protection of human health based on fish consumption.

These criteria are the values recommended by EPA pursuant to the Clean Water Act, adjusted for the cancer-causing pollutants to reflect the Commission's preferred risk level.

The Department also proposes a procedure for

setting or deriving numeric criteria for the protection of human health in the future. The procedure would allow EPA, which issues NPDES permits in the State of New Mexico, to write and issue these permits for toxic pollutants in effluent discharges where the Commission has not adopted a numeric criteria for a specific priority toxic pollutant.

In addition, the Department proposes a special requirement that it return to the Commission for hearing on any such criterion. In other words, when EPA derives a criterion pursuant to the procedure, the Department will come back to this Commission and ask that it consider and adopt that criterion into the standards themselves.

Finally, the Department proposes to apply these human health criteria to all waters with a designated, existing or attainable fishery use and their tributaries.

With me today to present the Department's proposal are four members of the Surface Water Quality Bureau. The first to my right is Dr. James Davis, chief of the Bureau; to his right, Mr. Saums, manager of the Point Source Regulation Section; next to him is Mr. John Montgomery, who is the water quality standards coordinator for the Department, or will be upon Steve's retirement, I'm not sure of the precise timing of the

transition; and, lastly, Mr. Pierce, who is the manager of the Surveillance and Standards Section, which has traditionally been the section within the Bureau responsible for maintaining and updating the water quality standards.

I'll give you a very brief outline of our testimony.

Dr. Davis will begin by explaining the purpose of the Department's petition and explaining how it responds to EPA's identification of deficiencies in the last triennial review and why it is necessary for this Commission to take action to avert federal promulgation.

He will describe how the Department solicited public input during meetings with groups, and he will explain why the Department modified the petition on February 1st.

Mr. Montgomery will go next. He'll explain the legal and regulatory framework for the requirement to adopt numeric criteria for toxic pollutants. His discussion will include the relevant provisions of the Clean Water Act, including the specific requirement for states to adopt numeric criteria, and EPA's process for developing and updating its recommended criteria upon which the Department relies today.

Mr. Pierce will pick up John's thread. He'll

describe the evolution of the national policy for the control of toxic pollutants in surface waters of the United States, New Mexico's response to that national policy or strategy, and EPA's decision in January of 2001 which started this whole petition rolling.

He will describe the options for adopting numeric criteria to comply with the Clean Water Act and avoid federal promulgation, and he will describe the Department's preferred alternative for doing so.

He will then proceed with a section-by-section analysis of the Department's proposal, beginning with the numeric criteria and their bases on EPA's values. He will explain why numeric criteria should be generally applicable to fishery waters and why certain criteria, specifically those for persistent toxic pollutants, those that are persistent and bioaccumulative, to be more specific, should be applied to tributaries of fishery waters, even when those tributaries do not have water and do not have fish at the point of discharge.

He will describe why other approaches to controlling these kinds of discharges are not effective. He will explain why the Department is proposing the harmonic mean flow, why it is consistent with EPA's policy and practice, and why the Department has agreed to support LANL's -- or Los Alamos National Laboratory's

proposal for a modified harmonic mean flow formula for tributary waters which are ephemeral.

Mr. Saums will be next. He will testify regarding the effect of these criteria and the translation procedure on the development and issuance of NPDES permits in the State of New Mexico, to explain how the Department's proposal promotes consistency in the development of permits, and, in fact, will have a minimal impact on NPDES permittees, at least in the near term, and he will finally explain why the Commission's adoption of the Department's proposal provides the greatest opportunity for state control of numeric criteria within the EPA regulatory framework.

Finally, Dr. Davis will close out. He will testify about the effect of these criteria on the 303(d) program, specifically the impaired listings, and the TMDL program, as well as nonpoint sources.

The Department's testimony is accompanied, as you can tell, by a PowerPoint presentation. Copies of the presentation have been distributed to everyone in the audience, at least as of the beginning of the hearing. If anyone needs a copy, there are some more in the box at the front of this box here. Feel free to come down and get a copy.

The Department has already submitted its full

written testimony. That, too, has been distributed. Therefore, the Department will make every effort to abbreviate its oral testimony using the PowerPoint slides as guideposts.

You may note some changes in the Department's oral testimony from the written testimony. Those changes were made to reflect the testimony of other parties. The Department read and reviewed and discussed everyone else's testimony and decided that in some cases changes were warranted, and we will indicate what those changes are during our oral presentation.

Finally, the Department has submitted 21 exhibits in support of the petition. NMED Exhibits 1 through 20 were filed with the notice of intent. They were supplied on the compact disk for all Commissioners. I assume they were -- that most Commissioners, or all the Commissioners, received it. The CD was also available to anyone who asked, as indicated in the notice of intent, and the CDs were sent to counsel for Los Alamos and San Juan Water Commission.

NMED Exhibit 21, which is the Department's written testimony, was filed on March 4th, about -- what's that? -- about ten days after the notice of intent.

The testimony was sent electronically and by

mail to all Commissioners, as well as to all parties or their counsel.

In addition, there are nine paper copies of the entire set of the Department's exhibits, including the written testimony available here in this box. If anyone needs one, feel free to take one. As you can tell by the volume of the exhibits, we were attempting to save paper and state resources by not simply sending full copies, but as Mr. Olson knows, we made copies available when people needed them.

One point with respect to the CD approach to distributing exhibits and testimony. When this hearing is all over, if you had some problem with this approach, or you'd like it in a different way, or you think the way we did it can be improved, we would welcome some input. This may be the first time that a party to a proceeding for the Commission has tried to do everything -- or a large portion of their proposal electronically, and we'd like to know how it worked for you.

All these exhibits, including the testimony, are already in the record, but I will still move for their introduction at the close of the Department's case in chief.

That concludes my opening statement, and now I ask that the Hearing Officer swear the witnesses.

(Oath administered to James Davis, John Montgomery, Steven Pierce and Glenn Saums.)

JAMES DAVIS

after having been first duly sworn under oath, was questioned and testified as follows:

DIRECT EXAMINATION

BY MR. AMES:

Q. Please state your name for the record.

A. James Davis.

Q. Where do you work, Dr. Davis?

A. I work in Santa Fe, at the New Mexico Environment Department, Surface Water Quality Bureau.

Q. What is your position there?

A. I'm Bureau chief.

Q. How long have you been Bureau chief?

A. A little over four years.

Q. Is your resume accurately reflected in the Department's notice of intent?

A. I believe so, yes.

Q. Then we'll proceed directly to your testimony. What is the purpose of the Department's petition today?

A. The purpose of the Department's petition, as has been alluded to in introductory comments, is to complete the triennial review process that began in 1997,

or was initiated in 1997, and that was heard by this Commission during September of 1998.

This Commission deliberated on the record that resulted from that hearing -- do I need this? I'll simply speak up. I have never -- there was a witness yesterday who indicated that they'd never been accused of having a soft voice, and in this very similar manner, I have never been accused of having a soft voice; however, if there is anyone in the audience that has difficulty hearing me, I would be pleased to use the microphone. I don't believe it's necessary, however.

MS. VIGIL: Excuse me. Some people in the back can't hear. Maybe if you can face your voice that way.

MR. AMES: That seems to indicate the microphone is probably necessary.

MR. DAVIS: Okay.

Hopefully, there will come -- it's worse.

I'll speak up, and if anybody can't hear me, let me know.

This Commission deliberated on the record that was generated during that eight-and-a-half day hearing in September of 1998. Following that deliberation, this Commission issued a decision concerning the items discussed in the triennial review, revised the water quality standards accordingly, and submitted that to the

USEPA in January of 2000.

EPA responded to that submittal on January 23rd of 2001. In their response, they included what's known as a record of decision, or ROD, R-O-D. In that record of decision, they approved most of the revisions to New Mexico's Water Quality Standards, they disapproved some revisions, and they advised that they would consider recommending disapproval of other revisions unless New Mexico took certain actions.

Now, these various documents, I believe, are found in Exhibit NMED 12.

Since that time, since January of 2001, both the Water Quality Control Commission and the New Mexico Environment Department have worked to address those various revisions that were either disapproved or provisionally disapproved by EPA.

Again, as has been alluded to in introductory comments, the Water Quality Control Commission clarified the exemption that applies to five numeric standards, the violation of which may arise from the reasonable operation of irrigation and flood control facilities.

In addition, the Department petitioned the Water Quality Control Commission to revise the definition of surface waters of the state. Also, as many of the Commissioners know, last October, the Commission held a

hearing in Las Cruces to consider more stringent fecal coliform criteria for the lower Rio Grande.

Q. (BY MR. AMES) What does the Department propose today?

A. Specifically, today, the Department is proposing for the Commission's consideration the adoption of numeric criteria for priority toxic pollutants.

As you can see on the slide, these consist primarily of numeric criteria to protect human health, and this addresses the last pending issue for completion of the triennial review process initiated in 1997.

Specifically, the Department proposes 11 acute and 10 chronic numeric criteria for priority toxic pollutants to protect various fishery designated uses. The Department also proposes 92 numeric criteria for priority toxic pollutants to protect human health.

We propose a procedure for selecting or deriving numeric criteria when there are no criteria in the water quality standards, and a method of determining compliance with the human health criteria.

The Department also is proposing to apply these human health criteria to waters with an existing, designated, or attainable fishery use and tributaries for those waters.

Today, the Department will provide to the Water

Quality Control Commission information that is both necessary and sufficient to support a decision to adopt these criteria.

Q. Dr. Davis, what might happen if the Commission does not adopt the criteria?

A. Again, as was heard in introductory remarks, if the Commission does not adopt criteria today -- that are being proposed today, there is a risk that the US Environmental Protection Agency will impose more stringent criteria that would be broadly based on national concerns.

Specifically, EPA stated in their record of decision in January of last year that New Mexico's failure to address these issues could result in a finding that new water quality standards are needed to comply with the federal Clean Water Act, specifically Section 303(c)(4)(B) of the federal Clean Water Act.

Again, I would refer you to Exhibits NMED 1 and 12 in this regard. Specifically, that section of the Clean Water Act requires EPA to promulgate water quality standards whenever it finds that such standards are required to meet the requirements of the federal Clean Water Act.

On the slide in front of you now, you'll see examples where EPA has already taken such action for many

states.

In 1992, EPA promulgated the National Toxics Rule, which imposed priority toxic pollutant criteria on 11 states. I do not have an exhaustive list in front of me, but these included Nevada, Alaska and Florida, the District of Columbia, the territory of Puerto Rico and one recognized Indian reservation, the Colville Indian Reservation. This list is found in NMED Exhibit 2.

Additionally, EPA promulgated what is known as the Great Lakes Initiative in 1995. The Great Lakes Initiative imposed priority toxic pollutant criteria on the several states and Indian tribes which border the Great Lakes.

Most recently, EPA promulgated what is known as the California Toxics Rule in 2000, which imposed priority toxic pollutant criteria on the State of California.

In short, EPA has a well-developed procedure and a successful track record for imposing priority pollutant criteria on states which do not act for themselves.

Q. Does EPA have any other incentive for imposing the priority criteria?

A. Yes.

Again, as was mentioned in introductory

remarks, there is a suit -- a federal lawsuit pending. EPA has been sued over the New Mexico standards.

In December of last year, 2001, two New Mexico environmental groups filed a notice of intent to sue EPA for several alleged failures relating to New Mexico's surface water quality standards. Included in that was EPA's failure to promulgate priority toxic pollutant criteria for the State of New Mexico in the NOI.

The complaint, which was filed last month, does not repeat this particular claim, and it is our presumption that that is because the Commission seems poised to consider and decide this matter.

Q. If the EPA is not sued, what might it do, or what will it do with regard to numeric criteria?

A. As you'll hear in much more detail later in the testimony, EPA will continue to apply numeric criteria equivalent to the National Toxics Rule.

In fact, this has been occurring, and you'll hear much more detail about that later in the testimony.

The additional witnesses from the Department will explain the reasons, but, again, in summary, if New Mexico does not adopt numeric criteria, by default, EPA will impose its own.

Q. It has been argued that the Commission should only adopt limited criteria for toxic pollutants now.

What is the Department's response to that?

A. We believe that it's a very straightforward thing to do it now. If there is any need in the future to revise numeric criteria, we have well-established procedures to allow that before this Commission. There is really no benefit in delaying adoption.

Again, as I stated just a moment ago, EPA already uses criteria at a more stringent level, and it could very easily continue to do that, and there is -- there is no cost -- no additional cost right now in adopting all of these criterion; however, any future effort to do so would incur the costs of another hearing and all of the ancillary activities associated with it.

Q. How do the Department's proposed numeric criteria compare to the criteria EPA is using right now?

A. EPA's criteria are more stringent, at least with respect to the risk factor for cancer-causing pollutants. We believe they are less responsive to New Mexico water quality issues than those proposed by the Department.

The principal difference is the risk level for cancer-causing pollutants. The Department is proposing a risk level of ten to the minus fifth. Interpreting that,

that would be the risk of one additional cancer in 100,000 exposed persons, and this is consistent with this Commission's policy.

EPA, on the other hand, would impose criteria using a risk level of ten to the minus sixth, which would be the risk of one additional cancer in one million exposed persons.

There is a potential, a real potential, that EPA's more stringent criteria could affect NPDES permittees in New Mexico -- NPDES stands for National Pollutant Discharge Elimination System -- including municipalities with treatment works discharging into waters of the US.

In this light, we recommend that the WQCC, the Commission, should carefully consider this issue in adopting numeric criteria for priority toxic pollutants.

Q. The Department will explain in its testimony why it's proposing ten to the minus five as opposed to ten to the minus six as the risk level, correct?

A. That's correct.

Q. Why don't we skip a little bit.

A. Yes.

Q. What has the Department done to solicit public input?

A. We made a fairly substantial effort in this

regard. As the Commission knows, on November 29th of last year, the Department submitted the original petition to the Water Quality Control Commission, and that's found in Exhibit NMED 16.

On December 11th of last year, at the regularly scheduled meeting of the Commission, the Commission considered the petition and granted the public hearing, set it for this meeting.

Following the Commission's decision, the Department published the petition and notice of public hearing on its web page and in the Albuquerque Journal. We gave specific notice to all persons on the Commission's mailing list, and to other persons who had expressed interest or would likely be interested in the matter, and this is found in Exhibits NMED 17 and 18; and then the Bureau initiated a dialogue with several organizations and persons known to be interested in the triennial review and surface water quality standards.

Specifically, we met with a list of entities during the month of January, and that's on the slide in front of you.

On January 11th, we met with the Municipal League, Environmental Quality Association. On January 15th, we met with Los Alamos National Laboratory. That same day, January 15th, we met with the Dairy Producers

of New Mexico. On January 16th, we met with Forest Guardians and Amigos Bravos. On January 18th, we met with the Middle Rio Grande Conservancy District, the Elephant Butte Irrigation District, the Carlsbad Irrigation District, the San Juan Water Commission and representatives from the City of Farmington. On January 31st, we met with the US Fish & Wildlife Service. Exhibit NMED 19 contains the sign-in sheets from these several meetings.

We also attempted to meet with the New Mexico Acequia Commission, the New Mexico Cattle Growers Association, and the New Mexico Department of Agriculture. We were not successful in that. Scheduling difficulties for those various organizations prevented that.

Q. Did these meetings prompt any changes to the Department's proposal?

A. Yes, in fact, they did.

Our purpose in holding these meetings was to engage in dialogue with interested parties and persons, hoping to obtain their insights into this petition. We specifically selected these persons or parties because they had participated in previous hearings before the Water Quality Control Commission, they had demonstrated a continued interest in the Commission's work and in the

protection of the state's waters, and we felt that they were knowledgeable about the petition, about the issues at hand, and were affected by the petition.

Speaking very personally, I am pleased in the outcome of this effort. This required a fair amount of time and commitment on the part of the persons who met with us. We appreciate that.

It's also important to state that information was presented in these meetings that helped to clarify both our objective and intent with respect to the several sections of the petition.

So this was an effort that I believe very strongly benefited the Department, and I would hope also benefited the participants in the meeting -- meetings.

MR. AMES: Okay. We'll now move on to Mr. Montgomery.

JOHN MONTGOMERY

after having been first duly sworn under oath, was questioned and testified as follows:

DIRECT EXAMINATION

BY MR. AMES:

Q. Please state your name for the record.

A. John Montgomery.

Unlike Dr. Davis, I have been accused of having a soft voice. The microphones are gone, so I'll do my

best.

Q. Okay. Mr. Montgomery, where do you work?

A. I work in the Surveillance and Standards Section of the Surface Water Quality Bureau, New Mexico Environment Department.

Q. What is your job there?

A. I'm the surface water quality standards coordinator.

Q. How long have you done that?

A. A little over six months.

Q. What did you do before coming to the Department?

A. For about 14-and-a-half years, I worked for the Wyoming State Engineer's Office. I was in the Groundwater Section for nine years as a geologist. I worked another four-and-a-half years as the hydrographic commissioner on the Upper Green River, basically administering water rights.

I then attended law school. After graduation, I practiced law for about five years. I then took a position as the county planning director in Laramie, Wyoming, until the time I moved down here to take this position.

Q. Is your biography accurately reflected in the notice of intent?

A. I believe it is.

Q. Let's move on to your testimony.

What is the subject of your testimony?

A. I'll be testifying regarding the interrelated provisions of federal and state law and the regulations that combine to form the legal framework of regulating toxic pollutants in the surface water.

First, I'll describe the provisions of the federal Clean Water Act that establish the requirements for states to regulate toxic pollutants in surface water.

Second, I will identify the EPA regulations implementing these requirements.

Finally, I will discuss the provisions of state law that authorize the Commission to adopt the narrative and numeric criteria necessary to comply with the federal Clean Water Act.

Q. Please continue.

A. If it pleases the Commission, I won't read the statutes verbatim, in the interest of time.

First, we start with Section 101 of the Clean Water Act, which states the policy of Congress with regard to toxic pollutants -- that being that it is the national policy that the discharge of toxic pollutants in toxic amounts be prohibited.

Congress then set forth a method by which this goal should be achieved in Section 303(c)(2)(B), which requires states to adopt toxic pollutant criteria to protect designated uses. The state must adopt numeric criteria if they are available; and if not, the state must adopt criteria based on biological monitoring or assessment methods.

Next, Section 307(a)(1) establishes the preliminary list of toxic pollutants and authorizes EPA to revise the list and add to or remove pollutants after consideration of specified factors. EPA has exercised this authority, adding and removing pollutants on a number of occasions. Initially, there was a list of 65 chemicals and families of chemicals that was expanded to a list of 129, and three have been delisted, bringing the current list to 126 toxic pollutants in the National Recommended Water Quality Criteria.

Finally, Section 304(a)(1) requires EPA to develop and publish numeric criteria for the toxic pollutants that are listed in Section 307(a)(1). These values are commonly known as the Section 304(a) criteria for toxic pollutants.

We have some examples on this slide of some of the substances, certainly not a full list of the 92, but perhaps gives an idea of the types of substances that are

involved.

EPA has published numeric criteria for many, but not all, of the priority toxic pollutants. These criteria are compiled in 40 CFR 131.36(b)(1). This is contained in NMED Exhibit 2 and in related EPA documents, such as the National Recommended Water Quality Criteria - Correction of April of 1999, which is available as Exhibit NMED 5.

Most of the criteria were originally published in 1980. Those were a series of documents for demonstration purposes. They look like this. They take up about two-and-a-half to three feet of shelf space.

Okay. Many of these documents are available from the EPA website. There are a number that have not been put onto the site, but a large number of them are. The documents can also be found in most federal repository libraries.

The basis for each criterion, and a full list of references on which the criterion is based, is set forth in these formal criteria documents.

Q. Are these criteria subject to ongoing review by EPA?

A. Yes. The criteria are subject to ongoing review.

Section 304(a)(1) requires EPA to revise its

criteria to accurately reflect the latest scientific knowledge. Accordingly, EPA has, from time to time, updated criteria based on the new information. In addition, EPA derives new criteria for listed pollutants through a routine process.

In my written testimony, there may be a small amount of confusion. I believe I stated in there that EPA would routinely revise their criteria. In fact, it is not something that happens that frequently, but when it does happen, it happens through a routine process.

That process begins with a comprehensive review by EPA of available data and information. EPA then publishes a notice in the Federal Register and on the Internet announcing its intent to evaluate an existing criterion, or to derive a new one, identifying the available data and information and inviting the submission of new data and information relative to criteria development.

After reviewing any responses, EPA develops a draft recommended water quality criterion and publishes notice in the Federal Register and on the Internet announcing the availability of the draft criterion and inviting public comment and scientific review.

Concurrently with the notice, EPA initiates an agency peer review. This review is conducted by a panel

of experts who produce a report of their findings. The peer review process is itself subject to public scrutiny. EPA's peer review practices are published in the Science Policy Council's Peer Review Handbook, which is EPA Document 100-B-98-001, and it may be viewed at the EPA website.

At the conclusion of the public comment and peer review processes, EPA evaluates the public comments and the panel's report and publishes its response in the record. EPA then revises the draft criterion, if necessary, and again publishes notice in the Federal Register and on the Internet announcing the availability of the final water quality criterion. At this point, the EPA's decision is subject to judicial review.

Q. John, how does the EPA reflect to the public how -- that it's actually conducting this ongoing review?

A. If I understand your question correctly, it is through publication, through notice in the Federal Register and on the Internet. Is that --

Q. And is the IRIS a part of this?

A. Oh, okay. Well, yes.

EPA maintains a record of its ongoing review of scientific knowledge relating to water quality criteria by posting new data and information on the Integrated Risk Information System, or IRIS, database. A detailed

description of IRIS is contained in Exhibit NMED 4, Appendix N.

On the screen we have, for demonstration purposes, a slide of the introductory IRIS web page. IRIS is a publicly available electronic database that provides chemical-specific risk information on the relationship between exposure and human health effects.

The next slide shows a drop-down list where you can click on a particular substance of interest. The next slide is a sample of one of the -- at least the beginning of one of the pages. This one happens to be for PCBs. The next screen shows a later portion of one of these that shows where the cancer risk information is published.

EPA originally developed the IRIS to assist federal government agencies in responding to the growing demand for consistent chemical-specific information for risk assessments, standard-setting, and other regulatory activities. Information is posted on IRIS only after a consensus has been reached by an interdisciplinary team of scientists representing EPA's various program offices that information -- after a consensus that the information is credible.

Consequently, the IRIS represents an agency-wide consensus regarding the latest scientific

knowledge about the chemical. The EPA updates this IRIS list on a monthly basis.

In addition to chemical-specific information, the IRIS database also identifies the most significant and recent references on which EPA's risk assessment is based. To be added to the IRIS database, each reference must have been peer reviewed.

Exhibit NMED 6 contains a compilation of references for each of the toxic pollutant numeric criteria adopted by EPA under Section 304(a)(1). The compilation includes references in the original 1980 criterion documents, as well as references considered by EPA in its ongoing review of those criteria. These latter references were obtained from the IRIS database.

Q. Would it be correct to say that the listings of references in Exhibit 6 are the scientific basis for the numeric criteria that EPA has adopted pursuant -- or recommended pursuant to Section 304(a)(1) of the Clean Water Act?

A. Yes.

In my discussions with personnel of EPA and other research I've done, I found that the references listed in the 1980 documents -- well, let me rephrase.

The 1980 documents are the criteria guidance, and the references in there are the references that were

cited by EPA in the development of those documents, and then, as they are revised, as new information is made available, that information appears on the IRIS database and its list of references.

Q. You've compiled all the references, as you said, for all of the pollutants for which the Department is proposing to correct here today, or all the criteria the Department is proposing today; correct?

A. That's correct.

Q. How long is that document?

A. The document, including some chemical synonyms lists, is approximately 750 pages. There are 683 pages of actual references.

Q. Do you know how many references are actually there?

A. I calculated that once. I don't recall the number, but it seems like it's in excess of 10,000 references. Some of those references do duplicate between different substances, so the actual count will be less than that.

Q. How has EPA implemented Section 303(c)(2)(B) of the Clean Water Act?

A. EPA has established and published regulations to implement the statutory requirements in Section 303(c)(2)(B). These regulations are set forth in 40 CFR,

Part 131, Water Quality Standards.

Of particular relevance is Section 131.11(a)(2), which requires the state to adopt criteria for toxic pollutants which may adversely affect water quality or the attainment of the designated water use or which warrant concern.

The criteria must be set at levels sufficient to protect the designated use, and 40 CFR 131.11(a)(1) requires the criteria must be based on sound, scientific rationale.

The EPA regulations also establish the acceptable form of criteria. 40 CFR 131.11(b) states a presumption that numeric criteria will be adopted. However, the states are authorized to adopt narrative criteria when numeric criteria cannot be established or to supplement numeric criteria.

This Commission long ago adopted, and EPA approved, a general narrative criteria for toxic pollutants. More recently, the Commission has adopted numeric criteria for certain chemicals and heavy metals. Steve Pierce will describe the Commission's historical approach to toxic pollutants during his testimony, as well as the basis for the Department's proposal to add numeric criteria and a procedure for selecting and deriving new criteria.

With respect to numeric criteria, Section 131.11(b) authorizes the state to use one of three approaches. First, the state may rely on EPA's published Section 304(a) criteria for priority toxic pollutants. As I previously described, these criteria are developed and published by EPA pursuant to the Clean Water Act and only after scientific peer review process and subject to judicial review.

As Steve Pierce will explain, these criteria, with one exception, are the numeric values which the Department proposes today.

Second, the state may adopt EPA's Section 304(a) criteria for priority toxic pollutants with modifications to reflect site-specific conditions. This approach requires substantial information about a water body, and if applied state-wide, will quickly exhaust the Department's resources. However, it may be possible to use this approach to adjust the numeric criteria, after their adoption by the Commission, to account for surface waters with substantially different physical, chemical, or biological characteristics.

Finally, the state may use other scientifically defensible methods. However, the Department is reluctant to develop its own method for deriving new values for all of the priority toxic pollutants in Sections 307(a)(1)

due to the cost and uncertainty whether EPA would accept those methods.

Q. Mr. Montgomery, does the New Mexico Water Quality Act authorize the Commission to adopt numeric and narrative criteria for priority toxic pollutants?

A. Yes.

The New Mexico Water Quality Act establishes the Commission and its powers and duties regarding the water quality in the State of New Mexico.

First, the New Mexico Water Quality Act designates the Commission as the state water pollution control agency, quote, for all purposes of the federal act, unquote, and directs the Commission to take all action necessary and appropriate to secure the state -- to secure to this state the benefits of the federal Clean Water Act and its programs.

One such benefit is the opportunity, under Section 303(c)(2)(B), for the state to adopt toxic pollutant criteria for itself under its own terms, rather than having the criteria imposed upon it by the federal government.

Second, the New Mexico Water Quality Act expressly authorizes the Commission to adopt water quality standards that shall, at a minimum, protect the public health and welfare, including water quality

criteria to protect designated uses.

The scope of this power is broad enough to authorize numeric and narrative criteria, and, in practice, the Commission has interpreted and applied this power to adopt both types of criteria as necessary to secure to this state the benefits of the federal act.

MR. AMES: Thank you, Mr. Montgomery.

Now, I'll move to Mr. Pierce.

STEVEN PIERCE

after having been first duly sworn under oath, was questioned and testified as follows:

DIRECT EXAMINATION

BY MR. AMES:

Q. Mr. Pierce, please state your name for the record.

A. My name is Steven Pierce.

Q. And, Mr. Pierce, where do you work?

A. I work at the Environment Department, Surface Water Quality Bureau, in the Surveillance and Standards Section.

Q. What do you do there?

A. I'm the program manager of the section.

Q. Is your biography accurately reflected in the notice of intent?

A. It is.

MR. AMES: At this point I'd like to interject a statement. Mr. Pierce is a bit under the weather and is not going to be able to present all of his testimony as planned.

The written testimony had already been previously provided to all the Commissioners, and I hope the Commission has had a chance to look it over, so we're actually going to skip substantial portions of Mr. Pierce's testimony, both to preserve time, move this proceeding to a conclusion, and also to preserve Mr. Pierce's voice for cross -- at least when we get there.

Q. So with your indulgence, Mr. Pierce, we're going to skip through the national -- the discussion about the national experience, which is background information for you all to understand how the United States got to this point, or how we got to the point of 303(c)(2)(B) of the Clean Water Act, which is the driver behind this particular petition. We're going to hit some questions along the way.

In particular, I'd like to ask Mr. Pierce what EPA has done to enforce the requirement for numeric criteria.

A. EPA has taken two steps to accelerate compliance with the requirement to adopt numeric

criteria.

First, while the states take the necessary steps to adopt --

MR. AMES: I think we're actually going to interrupt Mr. Pierce at this point, because I don't know how productive this is going to be for anyone, particularly Mr. Pierce.

I think we'll let Mr. Davis -- Dr. Davis present his testimony, if that's acceptable. It is Mr. Pierce's testimony, he's available for cross on that testimony. I don't believe that there have been, in the section that Dr. Davis is going to do, any changes from the written testimony itself.

With the Hearing Officer's indulgence, could we proceed in that manner?

In the Hearing Officer's absence, can we proceed?

MR. JOHNSON: Proceed.

MR. KEYES: We could take a five-minute break.

MR. AMES: That would be fine. I'd sure appreciate that.

(Recess held.)

MR. MAGGIORE: Let's go ahead and return from our recess.

I apologize for -- I was powdering my nose when

I guess Commissioner Keyes made an executive decision to go on break, which is excellent judgment.

I believe you were going to proceed with the direct testimony from Mr. Pierce?

MR. AMES: Yes, we are --

MR. MAGGIORE: Okay.

MR. AMES: -- Mr. Chairman.

Thank you.

MR. MAGGIORE: Please proceed.

Q. (BY MR. AMES) Mr. Pierce, what has EPA done to enforce the requirement for numeric criteria in the Clean Water Act?

A. EPA has taken two steps to accelerate compliance with the criteria.

First, while the states take the necessary steps to adopt numeric criteria, EPA adopted an interim measure to provide numeric criteria for NPDES permitting. The measure authorizes three alternatives for translating narrative toxic criterion, which is no toxics in toxic amounts, into chemical-specific applicable numeric criteria.

One alternative is to use the EPA's numeric criteria for priority toxic pollutants. Another alternative is to use the state-approved translation procedure.

The second step taken by EPA is to begin federal promulgation of numeric criteria. Rather than rely on permit writers, state and federal, to comply with the interim measure, EPA has imposed numeric criteria through the National Toxics Rule, the California Toxics Rule, and the Great Lakes Initiative.

It's in the context of these federal promulgations that EPA has demanded that New Mexico adopt numeric criteria for itself.

Q. What has New Mexico done to regulate toxic pollutants in surface water?

A. Well, for many years the State of New Mexico has relied on the narrative toxics criteria to satisfy its obligation under the Clean Water Act. In 1991, at the Department's request, the Commission supplemented this narrative criterion with numeric criteria for 13 priority toxic pollutants, but only for the protection of aquatic life.

EPA approved the new criteria, although it cautioned that additional criteria would be required in the future.

In 1992, EPA promulgated the National Toxics Rule. The Department responded by expanding its sampling program to include the entire list of priority toxic pollutants. The Department collected these samples

during all major water quality surveys at each location that was deemed to pose the highest probability of detecting priority toxic pollutants. The Department entered all these results into EPA's STORET water quality database. After considerable data evaluation, the Department determined that two organic priority toxic pollutants were present in state waters -- DDE, a breakdown of DDT, and gamma BHC, also known as lindane.

These priority toxic pollutants were detected in samples collected and analyzed by USGS -- DDE in two tributary drains of the Rio Grande, and lindane in the Santa Fe River. However, the measured concentrations were far below EPA's 304(a) criteria for these pollutants.

Accordingly, the Department determined that no priority toxic pollutants could reasonably be expected to interfere with the designated use of any water covered by the Clean Water Act, and it did not propose that the Commission adopt any numeric criteria for priority toxic pollutants during the 1998 triennial review.

Q. What was EPA's response?

A. On January 23rd, 2001, EPA issued its record of decision on New Mexico's 1998 triennial review. The ROD stated that EPA would consider recommending that the administrator make a finding that New Mexico water

quality standards did not comply with the Clean Water Act because they do not contain human health and aquatic life criteria for all priority toxic pollutants listed pursuant to Section 307(a)(1).

EPA gave two options for avoiding this result: we could adopt aquatic life and human health criteria for the remaining priority pollutants, or we could provide data analysis demonstrating these criteria are not needed because the pollutants are not present in concentrations that threaten aquatic life and human health.

Q. Now, in response to the ROD, the Department sought data from EPA and then they got back some effluent discharge screening data.

In addition to that data, you mentioned the ambient data we had on the tributaries to the Rio Grande and the Santa Fe River.

After the Department reviewed all this information, what position did it take and what position is it taking now regarding EPA's demand for numeric criteria?

A. Well, the Department has pretty well concluded that it might be most prudent to adopt all the remaining priority pollutant criteria. We have no data to prove that the presence of priority toxic pollutants in various effluent discharges and in the ambient waters of Los

Alamos National Laboratory and the Santa Fe River will not interfere with designated uses in affected waters of the United States.

Indeed, the levels of priority toxic pollutants in the ambient waters at Los Alamos National Laboratory indicate a threat to aquatic life and human health downstream in the Rio Grande. Moreover, it must be acknowledged that EPA's interpretation of the Clean Water Act, which it's charged with implementing, may be entitled to substantial deference.

Indeed, having stated its position that the Clean Water Act requires New Mexico to adopt numeric criteria for all priority toxic pollutants, EPA may have a difficult time evading the obligation to promulgate such criteria in the face of state inaction. In this light, the Department recommends that the Commission take the opportunity to adopt the numeric criteria it deems most appropriate and advantageous to the interests of the State of New Mexico.

Q. Assuming the Commission accepts the Department's recommendation, what options does it have?

A. EPA recognizes three options for complying with these requirements. The options are explained in more detail in the Water Quality Standards Handbook, which is

Exhibit NMED 4.

Option one is to adopt numeric criteria for all priority pollutants for which EPA has developed Section 304(a) recommended criteria, which are applicable to all state waters without regard to whether the pollutants are known to be present in those waters.

Most states exercise this option, and use EPA's Section 304(a) recommended criteria, because it achieves comprehensive coverage with scientifically defensible criteria, therefore, avoiding the need to conduct resource-intensive evaluations of numerous waters.

Option two. The state could adopt numeric criteria only for those priority toxic pollutants which are discharged or present in a state water and which could reasonably be expected to interfere with designated uses, and only to the extent necessary to protect those uses.

Functionally, this option requires the development of site-specific criteria. While the option comports with the statutory requirement and only requires criteria in response to a specific problem, in practice this option is difficult to implement. It is time- and resource-intensive to determine if, and which, priority pollutants are interfering with a designated use.

Moreover, the time and resources required to

develop and defend site-specific criterion on a recurring basis pose substantial problems for the Department, for the Commission, and for other interested parties.

In this regard, the option suffers from the same flaws that doomed the pre-1972 approach to water pollution control.
