ACRONYMS

AACO	Army Aviation Centre Oakey
AA-QS	annual average quality standards
ADONA	trade name for 4,8-dioxa-3H-perfluorononanoate
AERMOD	American Meteorological Society/EPA Regulatory Model
AFCEC	Air Force Civil Engineering Center
AFFF	aqueous film-forming foam
ALT	alanine aminotransferase
AmPr-FHxSA	N-dimethyl ammonio propyl perfluorohexane sulfonamide
amu	atomic mass unit
ANSES	French National Agency for Food Safety, Environment and Labor
ANSI	American National Standards Institute
AOF	adsorbable organic fluorine
APC	air pollution control
APFN	ammonium perfluorononanoate
APFO	ammonium perfluorooctanoate
ARAR	applicable or relevant and appropriate requirement
AM	arithmetic mean
ANPRM	Advance Notice of Proposed Rulemaking
ARP	advanced reduction processes
ATSDR	Agency for Toxic Substances and Disease Registry
AWI	Air-water interface
AWQC	ambient water quality criteria

BAF	bioaccumulation factor
BARC	bottom antireflective coatings
BAT	best available technology economically achievable
BBMD	Bayesian benchmark dose
BCF	bioconcentration factor
BERA	baseline ecological risk assessment
bgs	below ground surface
BMD	benchmark dose
BMF	biomagnification factor
BMP	best management practices
BOHP	$Bi_3O(OH)(PO_4)_2$
BSAF	biota-sediment accumulation factor
BuFASA	*N*-butyl perfluoroalkane sulfonamide
BuFASE	*N*-butyl perfluoroalkane sulfonamido ethanols
BuFASAA	*N*-butyl perfluoroalkane sulfonamido acetic acid
BV	bed volume
BW	body weight
C	carbon
C8	historical name for PFOA
C&D	construction and demolition
CAA	Clean Air Act
CAC	colloidal activated carbon
CalEPA	California Environmental Protection Agency

CAP	chemical action plan, or corrective action plan
CAPEX	capital expenses
CAS	Chemical Abstracts Service

N-EtFBSE	N-Ethylperfluorobutanesulfonamidoethanol
N-EtFHxSE	N-Ethylperfluorohexanesulfonamidoethanol
N-EtFOSA	N-ethyl perfluorooctane sulfonamide
N-EtFOSE	N-Ethylperfluorohexanesulfonamidethanol
N-MeFBSE	N-Methylperfluorobutanesulfonamidoethanol
N-MeFHxSE	N-Methylperfluorohexanesulfonamidoethanol
N-MeFOSE	N-Methylperfluorooctanesulfonamidoethanol
NF	nanofiltration
NFPA	National Fire Protection Association
NGWA	National Groundwater Association
NHANES	National Health and Nutrition Examination Survey
NHDES	New Hampshire Department of Environmental Services
NJ DEP	New Jersey Department of Environmental Protection
NJDWQI	New Jersey Drinking Water Quality Institute
NMeFOSAA	N-Methylperfluorooctane sulfonamidoacetic acid
NOAEL	no observed adverse effect level
NOEC	no observed effect concentration
NOM	natural organic matter
NOx	nitrogen oxides
NPCA	Norwegian Pollution Control Agency
NPDES	National Pollutant Discharge Elimination System

NPDWRs	National Primary Drinking Water Regulations
NPL	National Priorities List
NSF	National Sanitation Foundation
NTP	National Toxicology Program
NWQC	national water quality criteria
NYDEC	New York State Department of Environmental Conservation
O&M	operation and maintenance
OAT	organic anion transporter protein
OC	organic carbon
OCPSF	organic chemicals, plastics and synthetic fibers
OECD	Organisation for Economic Co-operation and Development
OEHHA	Office of Environmental Health Hazard Assessment (California)
OH	hydroxide ion, or hydroxyl group (**Helmenstine 2018**)
OPEX	operating expenses
ORD	Office of Research and Development (USEPA)
OSB	oriented strand board
OU	operable unit
PAB	permeable absorptive barrier
PA DEP	Pennsylvania Department of Environmental Protection
PAC	powdered activated carbon
PAF	perfluoroalkanoyl fluorides
PAH	polycyclic aromatic hydrocarbon
PAPs	polyfluorinated phosphate esters

PASF	perfluoroalkane sulfonyl fluoride
PBSF	perfluorobutane sulfonyl fluoride
PBT	persistent, bioaccumulative, and toxic
PCA	principal components analysis
PCBs	polychlorinated biphenyls
PCE	perchloroethylene, tetrachloroethene
PE	performance evaluation
PFA	perfluoroalkoxy polymer
PFAA	perfluoroalkyl acid
PFAI	perfluoroalkyl iodides
PFAS	per- and polyfluoroalkyl substances
PFBA	perfluorobutanoate, perfluorobutanoic acid, perfluorobutyrate, perfluorobutyric acid
PFBE	perfluorobutyl ethylene
PFBS	perfluorobutane sulfonate, perfluorobutane sulfonic acid
PFC	perfluorocarbon (C_nF_{2n+1}, for example, perfluorooctane) *Do not use this acronym for any other description including perfluorinated compound or perfluorochemical.*
PFCA	perfluoroalkyl carboxylate, perfluoroalkyl carboxylic acid
PFDA	perfluorodecanoate, perfluorodecanoic acid
PFDoA, or PFDoDA	perfluorododecanoate, perfluorododecanoic acid
PFDoS, or PFDoDS	perfluorododecane sulfonate, perfluorododecane sulfonic acid
PFDS	perfluorodecane sulfonate, perfluorodecane sulfonic acid
PFECA	per- or polyfluoroalkyl ether carboxylic acid
PFEI	perfluoroethyl iodide (aka fluorotelomer iodide)

PFESA	per- or poly- fluoroalkyl ether sulfonic acid
PFEtA	perfluoroethanoate, perfluoroethanoic acid
PFEtS	perfluoroethane sulfonic acid
PFHpA	perfluoroheptanoate, perfluoroheptanoic acid
PFHpS	perfluoroheptane sulfonate, perfluoroheptane sulfonic acid
PFHxA	perfluorohexanoate, perfluorohexanoic acid
PFHxS	perfluorohexane sulfonate, perfluorohexane sulfonic acid
PFIB	perfluoroisobutylene
PFMOAA	perfluoro-2-methoxyacetic acid
PFNA	perfluorononanoate, perfluorononanoic acid
PFNS	perfluorononane sulfonate, perfluorononane sulfonic acid
PFO3OA	perfluoro(3,5,7-trioxaoctanoic) acid
PFOA	perfluorooctanoate, perfluorooctanoic acid, perfluorooctane carboxylate
PFOS	perfluorooctane sulfonate, perfluorooctane sulfonic acid
PFOSA, or FOSA	perfluorooctane sulfonamide
PFPA	perfluorophosphonic acid
PFPE	perfluoropolyether
PFPeA	perfluoropentanoate, perfluoropentanoic acid
PFPeS	perfluoropentane sulfonate, perfluoropentane sulfonic acid
PFPiA	perfluorophosphinic acid
PFPrA	perflurorpropanoate, perfluoropropanoic acid
PFPrS/strong>	perfluoropropane sulfonic acid
PFSA	perfluoroalkyl sulfonate, perfluoroalkane sulfonic acid

PFSiA	perfluoroalkyl sulfinic acid
PFTeDA, or PFTA, PFTDA	perfluorotetradecanoic acid
PFTeDS, or PFTS	perfluorotetradecane sulfonate, perfluorotetradecane sulfonic acid
PFTrDA, or PFTriA	perfluorotridecanoic acid
PFTrDS, or PFTriS	perfluorotridecane sulfonate, perfluorotridecane sulfonic acid
PFUnA, or PFUnDA	perfluoroundecanoate, perfluoroundecanoic acid
PFUnS, or PFUnDS	perfluoroundecane sulfonate, perfluoroundecane sulfonic acid
PVF	polyvinyl fluoride
pg/m^3	picogram per cubic meter
pH	negative log of hydrogen ion concentration (measure of acidity)
PHxSF	perfluorohexane sulfonyl fluoride
PICs	products of incomplete combustion
PIGE	partice-induced gamma-ray emission spectroscopy
PIH	pregnancy-induced hypertension
PILI	polymer with ionic liquid coated iron
PNEC	predicted no-effect concentration
POD	porewater observation device
POE	point of exposure
POET	point of entry treatment
polyDADMAC	Polydiallyldimethylammonium chloride
POP	persistent organic pollutant
POPRC-14	14th meeting of the POPs Review Committee
POSF	perfluorooctane sulfonyl fluoride

POU	point of use
PPAR-α	peroxisome proliferator-activated receptor-α
ppb	parts per billion
PPE	personal protective equipment
ppm	parts per million
ppt	parts per trillion
PPRTV	Provisional Peer-Reviewed Toxicity Values

PSD	passive sampling device
PTFE	polytetrafluoroethylene
PUF	polyurethane foam
PVDF	polyvinylidene fluoride
PWS	public water system
QA	quality assurance
QAPP	quality assurance project plan
QC	quality control
QL	quantitation limit
QPD	qualified products database
QPL	Qualified Product Listing
QSAR	quantitative structure-activity relationship
QSM	Quality Systems Manual
qTOF/MS	quadrupole time of flight-mass spectrometry
RAO	remedial action objective

RCRA	Resource Conservation and Recovery Act
REACH	European Chemicals Regulation
RfD	reference dose
RI/FS	Remedial Investigation/Feasibility Study
RIVM	Netherlands National Institue for Public Health and the Environment
RL	reporting limit
RML	removal management level
RO	reverse osmosis
RPD	relative percent difference
RPF	relative potency factor
RSC	relative source contribution
RSL	regional screening level (Note: In many commercial venues RSL means "restricted substances list.")
RSSCT	rapid small-scale column testing
SAP	Sampling and Analysis Plan
SCWO	supercritical water oxidation
s.d. or SD	standard deviation
SDS	Safety Data Sheet
SDWA	Safe Drinking Water Act
SERDP	Strategic Environmental Research and Development Program
SIP	sorbent-impregnated polyurethane foam
SL	screening level
SMART	specific, measurable, attainable, relevant, and timely (goal)
SMAV	species mean acute value

SML	surface micro layer
SMZ	surface-modified zeolites
SNUR	Significant New Use Rule
SPE	solid-phase extraction
SPFO	sodium perfluorooctanoate
SPLP	Synthetic Precipitation Leaching Procedure
SSD	species sensitivity distribution
STAR	Spill Tactics for Alaska Responders
TANA	Technical Assistance Needs Assessments
TARC	top-layer antireflective coatings
TBC	to-be-considered values
TBEL	technology-based effluent limits
TCE	trichloroethene
TCEQ	Texas Commission for Environmental Quality
TCLP	Toxicity Characteristic Leaching Procedure
TDS	total dissolved solids
TEQ	toxic equivalency quotient
TFA	trifluoroacetic acid
TFE	tetrafluoroethylene
TFMS	trifluoromethanesulfonic acid
TFSI	1,1,1-trifluoro-N-(trifluoromethyl)sulfonylmethanesulfonamide
TMDL	total maximum daily loads
TMF	trophic magnification factor

TO	Toxic Organic (method)
TOC	total organic carbon
TOF	time-of-flight
TOP	total oxidizable precursor
TRRP	Texas Risk Reduction Program
TRV	toxicity reference value
TSH	Thyroid-stimulating hormones
TSCA	Toxic Substances Control Act
TTDs	target organ toxicity doses
UCMR	Unregulated Contaminant Monitoring Rule
UF	ultrafiltration
mg/kg	micrograms per kilogram
UL	Underwriters Laboratories
U.S.C.	United States Code
USDOD	United States Department of Defense
USDW	Underground sources of drinking water
USEPA	United States Environmental Protection Agency
USGS	United States Geological Survey
VDEC	Vermont Department of Environmental Conservation
VDH	Vermont Department of Health
VOC	volatile organic compound
WQBEL	water quality-based effluent limits
WV	wildlife value

ww	wet weight
WWTP	wastewater treatment plant
ZVI	zero-valent iron

GLOSSARY

A

Adsorption
The mechanism whereby ions or compounds within a liquid or gas adhere to a solid surface upon contact. The term also refers to a method of treating wastes in which activated carbon is used to remove organic compounds from wastewater.

Anion
A negatively charged ion.

Arithmetic mean
The sum of a collection of numbers divided by the number of numbers in the collection, commonly referred to as the "average".

B

Biochar
A carbon-rich, porous solid synthesized by heating biomass, such as wood or manure, in a low-oxygen environment (pyrolysis).

Biomaterials
Materials derived from plants or animals created for use as sorption materials.

C

Cation
A positively charged ion.

Coagulation
The process of destabilizing a colloid or suspension that unbalances the forces that separate the particles, often by neutralizing the charges on the particles and allowing the particles to clump or settle.

E

Electro precipitation/electrocoagulation
The use of an electrical current to enhance the coagulation and precipitation of ionic compounds. The electrical current may attract the compounds to an anode or cathode, or create coagulating ions from a sacrificial anode, or both.

Empty Bed Contact Time (EBCT)
A measure of the time during which water to be treated is in contact with the treatment medium in a contact vessel, assuming that all liquid passes through the vessel at the same velocity. EBCT is equal to the volume of the empty bed divided by the flow rate (**Sacramento State University 2019**).

F

Flocculation
A process in which the suspended particles of a destabilized colloid or suspension form groups or

clumps (known as a “floc”). Coagulation and flocculation work together to separate solids and liquids containing colloids and suspensions.

Fluorotelomer substance
A polyfluoroalkyl substance produced by the telomerization process.

G

Geometric mean
The central tendency or typical value of a set of numbers, derived by multiplying the numbers in a set then finding the nth root of the product, where “n” is the number of values in the set.

H

Head
The part of a molecule that is a charged functional group attached at one end of the carbon chain tail.

I

Incineration
Thermal destruction process typically characterized by oxidation at temperatures in excess of 1,000°C.

Isomers
Chemicals with the same chemical formula, but different molecular structures.

M

Membrane fouling
Loss of production capacity of a membrane due to accumulation of compounds or biogrowth on the membrane.

Micelles
Particles in which long hydrocarbon tails, repelled by the water molecules and attracted to each other, make up the interior, whereas the negatively charged heads coat the surface and interact with the surrounding water molecules and positive ions (**Ege 1999**).

Mineralization/decomposition/destruction
The breakdown of a chemical compound into its constituent elements and carbon dioxide and water.

Moiety
A specific group of atoms within a molecule that is responsible for characteristic chemical reactions of that molecule (**Helmenstine 2019**).

O

Organoclays
A naturally occurring clay mineral that is organically modified to incorporate cations and enhance the sorption capability.

P

Perfluorinated chemical
Subset of PFAS. Have carbon chain atoms that are totally fluorinated. Examples are perfluorooctanoate (PFOA) and perfluorooctane sulfonate (PFOS) (Buck et al. 2011).

Perfluoroalkyl substance
Fully fluorinated alkane (carbon chain) molecule. They have a chain (tail) of two or more carbons atoms with a charged functional group (head) attached at one end.

Permeate
The water treated by a membrane filtration technology, which has passed through the membrane, and from which PFAS have been removed. The contaminants not passing the membrane accumulate in the filtrate, which also does not pass through the membrane.

Polyfluorinated chemical
Subset of PFAS. Have at least one carbon chain atom that is not totally fluorinated (Buck et al. 2011).

Polyfluoroalkyl substance
The molecule has a nonfluorine atom (typically hydrogen or oxygen) attached to at least one, but not all, carbon atoms, while at least two or more of the remaining carbon atoms in the carbon chain tail are fully fluorinated.

Polymer
Large molecules formed by combining many identical smaller molecules.

R

Reactivation
A specific, high-temperature process for restoring GAC's adsorptive capacity by thermal removal and oxidation of adsorbed matter.

Redox
Chemical reduction-oxidation processes and conditions that can result in the alteration of a chemical compound.

Regeneration
The act of restoring some or all of the sorption capacity of a sorptive media (such as activated carbon or ion exchange) by removing the adsorbed matter.

S

Sorption
Removal of a compound from solution by solid phase constituents. This term is often used when the mechanism of removal (adsorption, absorption, or precipitation) is unknown. (**Thompson and Goyne 2012**).

Stabilization
A process to reduce mobility of compounds in the environment through physical or chemical means.

Surfactant
A surface-active agent that lowers the surface tension of a liquid.

T

Tail
The part of a molecule that is a chain of two or more carbon atoms.

Thermal desorption
Thermal treatment process intended to remove the contaminants from a solid medium (such as soil, sediment, carbon) and drive them into the vapor phase.

Z

Zwitterion
An ionic compound containing both positively and negatively charged groups with a net charge of zero.

PFAS Data Tables

In many of the sections of the PFAS Guidance Document the team has developed tables that provide additional data and information to support the topics in the sections. These tables can be found in the link below, along with identity of the section with which the table is associated.

https://pfas-1.itrcweb.org/external-data-tables/

PFAS Fact Sheets

This online page includes links for the ITRC PFAS fact sheets, each last updated at various dates. The fact sheets are available as PDF files. The references and acronyms used in these Fact Sheets are maintained in the PFAS-1 Guidance Document.

https://pfas-1.itrcweb.org/fact-sheets/

PFAS Training Resources

Because the state of knowledge and regulatory approaches for PFAS continue to evolve rapidly, ITRC's goal is to periodically review and update the PFAS resources.

1. Introduction

Daniel B. Stephens & Associates, Inc. (DBS&A) has prepared this report for the New Mexico Environment Department (NMED) to present the results of ecological research on per- and polyfluoroalkyl substances (PFAS) contamination at Holloman Lake. To better understand the scope of potential and existing environmental contamination associated with PFAS around the state, NMED has worked with state and federal partners to conduct sampling for PFAS in sediment, surface water, and groundwater around the state. In 2021, with funding from NMED and in partnership with the University of New Mexico (UNM) Museum of Southwestern Biology (MSB), DBS&A began an ecological study on PFAS contamination at Holloman Lake, a wastewater lake located in a publicly accessible area of Holloman Air Force Base (AFB) in Otero County. Very high PFAS concentrations were documented in waterfowl tissue samples, prompting concern about duck hunting and human consumption of contaminated meat (Witt et al., 2024). Very high PFAS concentrations were also found in the tissues of small mammals both along the lake shoreline and in the uplands (Witt et al., 2024).

In early 2024, DBS&A and MSB proposed to expand the scope of the ecological study to conduct the following activities: (1) collect and analyze duck tissue samples from other New Mexico wetlands and, as needed, compare their PFAS contamination profiles with those from Holloman Lake, (2) analyze oryx (or gemsbok, *Oryx gazella*) tissue samples from White Sands Missile Range and other locations to investigate risks associated with hunting of large game species in the vicinity of Holloman Lake, (3) conduct post-mortem examinations of at least 10 euthanized animals from Holloman Lake with microscopic analysis of multiple organs including kidneys and liver, (4) analyze a small number of tissue samples obtained from carcasses of carnivores killed by vehicle traffic along U.S. Highway 70 (US 70) near Holloman Lake, and (5) document PFAS contamination levels at increasing distances from the shoreline, along transects extending in the direction of prevailing winds. The primary goals of the proposed research were to help determine risks to human communities outside of the immediate footprint of PFAS contamination at Holloman Lake and Holloman AFB, begin assessing ecological toxicity, and better understand what physical, chemical, biological, and historical factors contribute to some of the highest contamination levels in wildlife documented worldwide (Witt et al., 2024). The scope of this research does not include any assessment of the size, shape, and directionality of the PFAS groundwater plume, which remains to be investigated due to the continued lack of access for drilling exploratory wells (DBS&A, 2022).

2. Site Description

Established in 1942, Holloman AFB occupies approximately 50,763 acres of federally owned land in Otero County, New Mexico. It is located 6 miles southwest of the central business district of Alamogordo, southeast of and contiguous to the much larger (2.2 million-acre) White Sands Missile Range. US 70, which runs southwest-northeast across New Mexico, borders the south end of Holloman AFB (Figure 1).

Holloman Lake and so-called "Stinky" Playa immediately to the south are remnant alkali playa lakes that were modified in the 1960s through the construction of a non-engineered dam that now separates them (Photographs 1 and 2). The dam was intended to store domestic stormwater and effluent from a chain of wetlands and the Holloman AFB wastewater treatment plant (WWTP), all located upstream of Holloman Lake and forming a wastewater catchment system for the base. Around 2010, additional development at Holloman Lake involved opening the area to the public for camping, nature trails, and bird watching opportunities.

Photograph 1. View to the northwest from the dam at the southern end of Holloman Lake.

Photograph 2. View to the south from the dam at the southern end of Holloman Lake. The presence of water in "Stinky" Playa is indicative of seepage under the dam.

Today, Holloman Lake is an Audubon-designated Important Bird Area sustaining thousands of birds for at least part of the year. A total of 252 bird species have been recorded at Holloman Lake, 113 of which are aquatic species and 41 of which are game species that can be legally hunted (Witt et al., 2024). Through 2023, hunting was still permitted at Holloman Lake at designated times of the year. However, in light of mounting PFAS contamination evidence, Holloman AFB altered its stance on permissible recreational activities in 2024. It no longer authorizes hunting at the lake, though other public uses of the area, such as camping, continue. Cattle and oryx are also a common occurrence in the freshwater wetland at the northern end of the lake.

Holloman Lake currently receives a continuous flow of treated effluent at the north outfall (Figure 1). Before the current WWTP was built in 1996, wastewater was funneled through a series of storage/evaporation lagoons that discharged into the east outfall canal then into the lake. Today, the east outfall canal only carries stormwater; it is lined by vegetation dominated by the non-native, invasive saltcedar (*Tamarix* sp.). Salinity is high in Holloman Lake due to the abundance of calcium sulfate deposits in the area. At the north end of the lake, however, freshwater conditions prevail, sustaining the existence of a wetland with lush vegetation including southern cattail (*Typha domiguensis*), marsh fleabane (*Pluchea odorata*), saltcedar, and desert saltgrass (*Distichlis spicata*). A complete ecosystem exists at Holloman Lake and on the

surrounding uplands, from algae and diatoms to primary and secondary consumers to apex predators, including the peregrine falcon (*Falco peregrinus*), which preys on local waterfowl.

3. Background

PFAS are a large family (perhaps more than 8,000 [Buck et al., 2021]) of manmade organofluorine compounds that were developed in the early 1940s. Certain PFAS, such as perfluorooctanoic acid (PFOA) and perfluorooctane sulfonic acid (PFOS), are mobile, persistent, and bioaccumulative, and are not known to degrade in the environment. The chemical structure of PFAS gives them unique and valuable properties, including the ability to reduce friction and make products more resistant to soil, stain, grease, water, fire, and temperature. These chemical properties make them useful components in a wide array of industrial and commercial applications, such as textiles and leather products, metal plating, the photographic industry, photolithography, semiconductors, paper and packaging, non-stick cookware, food packaging, waterproof clothing, fabric stain protectors, lubricants, and pesticides. Some PFAS are also used as high-performance surfactants in products where an even flow is essential, such as paints, coatings, cleaning products, and fire-fighting foams, such as aqueous film-forming foam (AFFF), for use on liquid (hydrocarbon) fuel fires (U.S. EPA, 2009 and 2021).

PFAS are characterized by linear or branched carbon-fluorine chains connected to a functional group and can vary in length from 4 to 14 molecules. The number of carbon atoms, and therefore the length of the chain comprising a particular PFAS, affects its toxicity and persistence and behavior in humans, wildlife, and the environment. Perfluorosulfonic acids (PFSAs) with six or more carbons (e.g., PFOS) and perfluorinated carboxylic acids (PFCAs) with seven or more carbon atoms (e.g., PFOA) are considered long-chain substances (Buck et al., 2011; U.S. EPA, 2021; ATSDR, 2021). In general, as chain length increases, the bioaccumulation potential of PFAS appears to increase.

PFAS are extremely persistent in environmental mediums because the highly stable carbon-fluorine structure of PFAS can only be broken down at very high temperature. Larger PFAS compounds may transform in the environment to so-called "terminal" PFAS compounds, which are typically less than, or equal to, eight carbon-chain molecules such as PFOA and PFOS, and are resistant to environmental degradation processes such as biodegradation, atmospheric photo-oxidation, direct photolysis, and hydrolysis (ITRC, 2021). Dissipation is by advection, dispersion, and sorption to particulate matter. PFOS has low volatility in ionized form but can

adsorb under limited hydrogeochemical conditions to positively charged sediment particles and be deposited on the ground and into surface water bodies. Because of its persistence, it can be transported long distances in air or water (U.S. EPA, 2016).

Of particular concern at the Holloman site is the use of AFFF to extinguish fires involving highly flammable liquids. AFFF creates a vapor-sealing film on a hydrocarbon fuel surface, cooling the liquid fuel, depriving the fuel of oxygen, and providing protection against reignition by preventing evaporation (Leeson et al., 2021). In 1970, the U.S. Air Force (USAF) began purchasing and using PFAS-containing AFFF for extinguishing petroleum fires and during firefighting training activities (AFIMSC, 2017). By mid-2018, the USAF had transitioned to a new AFFF formula, Phos-Check 3 Percent, which is PFOS-free and contains only trace amounts of PFOA (AFCEC, 2018), although it is possible that stockpiles of old AFFF were used after that time. The USAF restricts use of AFFF to emergency responses and treats all releases as hazardous spills. AFFF contained in aircraft hangar fire protection systems was scheduled to be replaced by the end of 2018 (AFCEC, 2018).

The results of sampling for PFAS conducted by various parties in the Holloman-Alamogordo area indicate that releases of PFAS have occurred from several sources at Holloman AFB, including the AFFF source areas identified by the USAF, as well as Petroleum, Oils, and Lubricants (POL) site 2, and from as yet undetermined sources at the Alamogordo PFAS site in southwest Alamogordo. Additional investigations are required to determine the extent of PFAS contamination in both areas. In 2022, the NMED Ground Water Quality Bureau (GWQB) Superfund Oversight section was planning an additional investigation at the Alamogordo PFAS site, but the schedule for this work had not been determined (DBS&A, 2022).

PFAS concentrations documented at Holloman Lakes from 2021-2023 reached thousands and tens of thousands of nanograms per gram, wet weight (ng/g ww) in liver samples, or near world-records (Witt et al., 2024). The inclusion of historical specimens in the Witt et al. (2024) study showed that contamination of the local wildlife spanned a period of at least three decades. High contamination levels in waterfowl in particular raised concern about the possible ingestion of contaminated meat by local hunters, the apparent reason that Holloman AFB made the decision to no longer allow hunting at Holloman Lake in 2024. However, movement of waterfowl from Holloman Lake to other wetlands around the state still carries a risk for hunters elsewhere. A similar risk exists for large game hunters, as a herd of oryx was often observed at Holloman Lake (Witt et al., 2024). This species should be considered susceptible to PFAS ingestion in the vicinity of the lake.

Recent studies have reported ecological toxicity in Eurasian otters (*Lutra lutra*) (O'Rourke et al., 2024a), Macquarie River turtles (*Emydura macquarii macquarii)* (Beale et al., 2024), and tree swallows (*Tachycineta bicolor)* (Custer et al., 2012 and 2014) at lower or much lower concentrations than those observed at Holloman Lake. In tree swallows, for example, negative associations have been reported between hatching success and PFOS concentrations as low as 150 ng/g ww in eggs (Custer et al., 2012), with Custer et al. (2014) also finding a 20 percent decrease in hatching success at PFOS concentrations of 283 ng/g. In Australia, liver concentrations of PFSAs and PFCAs averaged 3.0 and 0.1 ng/g, respectively, in Macquarie River turtles (Beale et al., 2024). This level of contamination was high enough to produce significant metabolic disruptions in turtles, specifically related to amino acid and lipid metabolism, energy production, and oxidative stress responses. Although no gross or histopathological phenotypical abnormalities could be directly linked to PFAS exposure, proteomic analysis identified several biomarkers of early disease progression (Beale et al., 2024). Gravid females from contaminated sites also showed altered egg composition, particularly in magnesium to calcium ratios, while the biochemical profiles of egg albumin and yolk also exhibited significant differences in metabolites and lipids between contaminated and control sites, suggesting potential impacts on embryo development. Hatchling deformities (e.g., abnormal intergular scale shapes and marginal scale counts) were found to be more pronounced and occur at a higher incidence at the contaminated site. Of particular concern, a lack of juvenile recruitment into the breeding population was observed at the contaminated site, suggesting potential long-term population declines in Macquarie River turtles in Australia. In northern England, linear PFOS (L-PFOS) was detected at a median concentration of 1,740 ng/g ww in river otters (O'Rourke et al., 2024b), or a level of contamination approaching that typically observed at Holloman Lake (Witt et al., 2024). Laboratory studies have suggested associations between exposure to PFSAs and PFCAs and immunotoxicity in animals (Fenton et al., 2020), and in England and Wales, O'Rourke et al. (2024a) found enlarged adrenal glands and unilateral cryptorchidism (linked to environmental pollution) in four otters, three of which showed some of the highest PFOS contamination levels during the study.

4. Methodology

Research conducted in 2024 aimed at (1) studying the fate and transport of PFAS at Holloman Lake to better understand why the local wildlife is contaminated at such high levels, (2) documenting ecological toxicity using a combination of necropsies and reproductive

monitoring, and (3) assessing risks to hunters from the ingestion of contaminated waterfowl and/or oryx meat.

4.1 Ecosystem-Wide Contamination Profiles

4.1.1 Sampling

Collection efforts at Holloman Lake in 2024 resulted in obtaining or preparing 109 surface water, soil, and biological samples for PFAS screening. All collection occurred only in publicly accessible areas around the lake, primarily along the lake shoreline including the freshwater wetland to the north, and in the uplands to the east and northeast (Figure 1). Biological samples included muscle, liver, and bone tissue from birds, mammals, and reptiles, in addition to eggshells and plant, algae, invertebrate, and fish tissue. The shed skin of a western diamondback rattlesnake (*Crotalus atrox*) was also sampled for PFAS screening.

Four surface water samples were collected in the lake at the north and east outfalls and along the south and west shorelines. Soil samples were collected along the east shoreline and at 100-meter intervals along two 900-meter sampling transects extending to the northeast, in the direction of prevailing winds (Figure 1). Sampling of upland plants and invertebrates also occurred every 300 meters along the two transects. Soil, plant, invertebrate, fish, mammal, and/or bird samples were obtained both from the wetland and the main body of the lake, for a comparison of PFAS levels.

Birds were collected by licensed hunters using netting or shotguns with nontoxic shot, operating under federal and state scientific collecting permits and, for game species, in compliance with federal and state hunting regulations. Small mammals were trapped overnight using both live-capture Sherman traps and Museum Special (MS) snap and Victor rat traps, following standard protocols for museum collection and under state scientific collecting permits. Field research protocols were approved by the UNM Institutional Animal Care and Use Committee (Protocols 21-201225-MC and 19-200908-MC).

A coyote (*Canis latrans*) and a western coachwhip (*Masticophis flagellum*) killed by road traffic along US 70 near the turnoff to Holloman Lake were also collected and incorporated into the study.

4.1.2 PFAS Screening

All PFAS screening was conducted by Eurofins Environment Testing Northern California, LLC (Eurofins), where tissue extraction requires 1 gram (g) of homogenized material, weighed out to three significant figures. Tissues were spiked with isotopically labeled extracted internal standards (EISs), and then solvated with 0.4 percent potassium hydroxide (KOH) in methanol and sonicated for 1 hour. Samples were separated by centrifuge at 4,700 relative centrifugal force (RCF) followed by decanting the supernate to a new vessel prior to a second 0.4 percent KOH/methanol solvation. This solution was shaken briefly and sonicated and separated as above. Supernates were combined and the sample was diluted to 125 milliliters (mL) with deionized water and neutralized with glacial acetic acid to pH of 6 to 8. This extract was then passed over a conditioned WAX/graphite carbon black (GCB) solid phase extraction (SPE) (500 milligrams [mg], 50 mg, 6 mL). Cartridges were washed with small volumes of methanol in water prior to drying and then eluted with 0.3 percent ammonium hydroxide in methanol. Samples were not concentrated after SPE, but rather spiked with standards and brought to 10 mL of 80:20 methanol:water prior to analysis.

One method blank (MB) and two laboratory control sample (LCS)/LCS duplicate (LCS/LCSDs) containing 2 percent bovine serum albumin (BSA) for blood batches and 0.02 g corn oil for tissue batches were included with each field sample at a rate of 5 percent (1 MB, LCS/LCSD per 20 samples). The LCS/LCSDs were also spiked with known concentrations of native PFAS. These QC samples are standard practice among U.S. Environmental Protection Agency (EPA) methods and serve as both positive (LCS/LCSD) and negative (MB) controls, as they follow all field samples throughout extraction and analysis.

The analytical configuration consisted of an Exion LC system with two pumps and a SCIEX 5500 mass spectrometer for tissue analyses. Pump-A contained 20 millimole per liter (20mM) ammonium acetate and pump-B delivered 0.5 percent ammonium hydroxide (NH_4OH) in methanol. Pump-A was used to load 20 microliters (µL) of sample extract onto an analytical column (Gemini 3 um C18 50X2 mm) heated to 45°C, where compounds of interest were separated before introduction into the instrument source. The electrospray source was operated in negative polarity, and data were acquired in multiple reaction monitoring (MRM) mode with a minimum of 10 scans per peak. Prior to analysis, optimal voltages for both ionization and collision induced disassociation were determined by direct infusion. Analysis time for this process resulted in an approximate 9-minute cycle time.

4.2 Necropsies

A total of 24 animals (13 small mammals and 11 birds) (Table 1) were collected from Holloman Lake in 2024 and euthanized prior to undergoing necropsies and microscopic analyses of all their organs at the New Mexico Department of Agriculture Veterinary Diagnostic Services (VDS). PFAS screening of their livers and/or muscles was also conducted.

All gross necropsies and microscopic examinations of organ tissues were conducted by VDS pathologists Drs. John Ragsdale and Teresa Garcia. Necropsy reports included organ weights, together with findings of abnormalities listed by organ.

4.3 Bird Nest Monitoring

Nest searches were conducted weekly or biweekly from May through July 2024 along the accessible shoreline of Holloman Lake and in the uplands. Nests were geo-referenced and monitored to determine reproductive outcome to the extent possible.

4.4 Statewide Waterfowl Hunting Risk Assessment

A total of 47 avian tissue samples were sent to Eurofins for establishing a contamination profile specific to Holloman Lake and for PFAS pre-screening of waterfowl from wetlands around New Mexico. Of the 47 samples, 19 were from individual birds collected from 2021 to 2023 at Holloman Lake. The remaining 28 samples were from waterfowl collected at other wetlands around New Mexico. The majority of samples were pooled (or composite) samples that each consisted of several birds belonging to the same feeding guild (dabbling ducks, diving ducks, grazers) and, in most cases, from the same region of New Mexico, while also covering one of several time periods since the 1990s. The 47 samples were prepared from waterfowl livers, hearts, and muscles cryogenically preserved in liquid nitrogen and archived at the MSB. A limitation of the non-Holloman sample PFAS screening was that most of the waterfowl specimens archived at MSB are from northwestern New Mexico.

MSB also prepared and widely distributed a flyer to enlist the assistance of hunters from around New Mexico, asking for donations of (1) frozen carcasses that had been breasted out or (2) at least 4 grams of fresh-frozen liver and one frozen wing from each duck, in separate sealed bags, labeled with date and locality. Volunteer participants were asked to fill out an online form with their contact information for follow-up instructions on how to participate. This critical additional effort started just prior to the expiration of DBS&A's contract with NMED.

4.5 Oryx Hunting Risk Assessment

DBS&A and MSB could not enlist the participation of White Sands Missile Range for acquiring oryx samples from harvested animals. However, owners of the Walker Ranch (adjacent to Holloman Lake and home to a large oryx herd) were contacted, as were Major Wildlife Studios (a Las Cruces area taxidermist that processes many oryx monthly), and a Las Cruces meat processor that deals with hunter-collected oryx. These entities expressed early support for this project, and were projected to be the means of future sample collection.

5. Results and Discussion

5.1 PFAS Fate and Transport

Previous investigations of soil and groundwater indicate that the most significant PFAS source areas at Holloman AFB are the firefighting training area northeast of the main base and the evaporation pond used to test firefighting equipment in the West Area of the main base (DBS&A, 2022). PFAS released to soil at these locations (and potentially other source areas not yet investigated) likely migrated vertically through the vadose zone and impacted groundwater in the basin fill aquifer at and downgradient of the areas (DBS&A, 2022). The USAF investigation of the base-wide sewer system indicated that the sewer was probably leaking, and sampling confirmed that wastewater contained PFAS, making this another source of PFAS contamination in groundwater (DBS&A, 2022). Wastewater was also discharged directly to the now defunct unlined sewage lagoons and eventually to Lake Holloman before the WWTP was constructed in 1996 (DBS&A, 2022). After 1996, treated wastewater (containing PFAS) was discharged to Lagoon G, eventually reaching Lake Holloman (DBS&A, 2022). During a part of this time, treated effluent from the WWTP was used to water the Holloman AFB golf course (DBS&A, 2022). The initial assessment conducted by the USAF in 2017 identified impacts to soil, surface water, and groundwater. The USAF had not determined the extent of PFAS contamination at the base, but impacts reported at Lake Holloman likely extended off-site beyond the lake (DBS&A, 2022).

Ongoing analyses of data collected in 2024 show that surface water and soil contamination may reflect contamination by three (instead of just two) different generations of AFFFs. Sorption of PFAS from surface water to soils was primarily influenced by the length of the fluorinated chain, as expected based on published studies elsewhere (e.g., Fabregat-Palau et al., 2024). Due likely to a combination of factors (e.g., evaporation, a dilution effect from the input of less contaminated effluent at the north outfall), plants and animals collected in the wetland

appeared to be much less contaminated than biotas using the main body of the lake and its shoreline. Particularly low levels of PFAS contamination were detected in the western mosquitofish (*Gambusia affinis*) and the variegated meadowhawk (*Sympetrum corruptum*), both collected from the wetland. PFOS concentrations measured in two composite mosquitofish samples averaged 77 ng/g, while PFOS was detected in the meadowhawk, a dragonfly, at a concentration of only 1.1 ng/g.

PFAS concentrations in soil decreased rapidly to background levels at a distance of 200 meters from the shoreline along both transects but increased again at some of the most distant sampling locations. The rebound in PFAS concentrations was particularly notable at the end of the southern transect (NE4), 900 meters from the shoreline. At that sampling location, soils were found to have a PFOS concentration of 710 ng/g, greater than the concentration found at the edge of the lake along the same transect. Historical aerial and LANDSAT imagery revealed the explanation for this finding. The end of NE4 was shown to correspond to a ghost wetland, where dense vegetation (indicated by a normalized difference vegetation index [NDVI] value of 0.19) existed in 1996, but conditions have now reverted to desert uplands (Photograph 3).

Photograph 3. View to the east from the end of Transect NE-4, 900 meters northeast of the shoreline. A few iodine bushes and saltcedars are all that remain from a past contaminated wetland that has now almost completely reverted to desert vegetation.

Historical imagery further showed the past existence of an overflow spillway and ditch connecting the wastewater storage lagoons to the wetland. Further analysis of the transect

sampling data is forthcoming, but air transport of contaminated dust was ruled out as a mechanism responsible for the contamination of wildlife in the uplands. Instead, historical wastewater transport and possibly groundwater discharge may be more important. LANDSAT imagery of the study area with the ghost wetland is shown in Figure 2.

5.2 Contamination Profiles

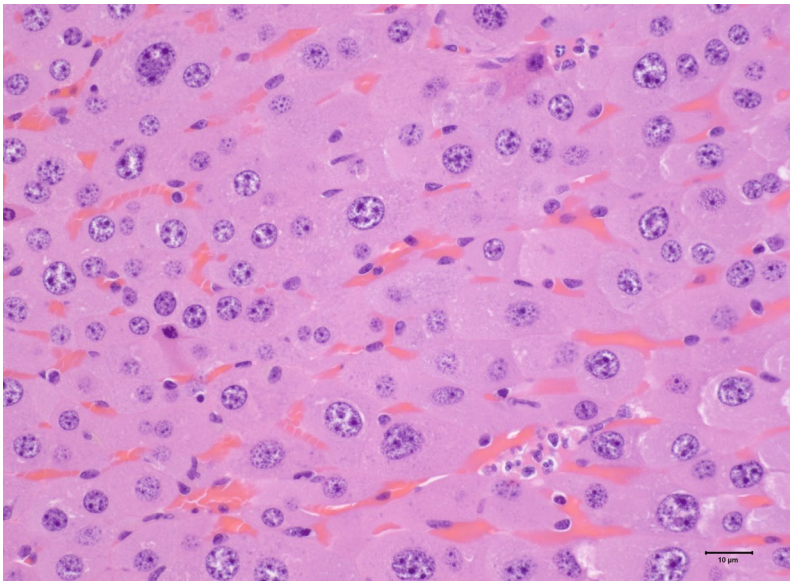
Two degradation products of 6:2 FTS, the short carbon-chain perfluorocarboxylic acids PFHxA (six carbons) and PFPeA (five carbons), were the dominant PFAS in surface water in the lake. In contrast, PFOS was the main PFAS found in sediments along the shoreline. PFOS was the most abundant PFAS found in nearly all biological samples (except in some plants in the freshwater wetland and the uplands). Examples of contamination profiles are shown in Figures 3 through 8.

Among plants, there was a striking difference in the contamination profiles of saltcedar, fourwing saltbush (*Atriplex canescens*), and iodine bush (*Allenrolfea occidentalis*) along the main body of the lake (with PFOS dominant and overall PFAS concentrations much higher) versus southern cattail and fleabane in the wetland or saltbush in the uplands. A possible explanation is that saltcedar, saltbush, and iodine bush growing along the shore of the lake might reach the water table, whereas the other plants do not. As wetland plants, cattail and marsh fleabane in particular are both characterized by shallow, subsurface rhizomes as their root system (Chen et al., 2024; Nature Collective, 2025).

5.3 Bioaccumulation

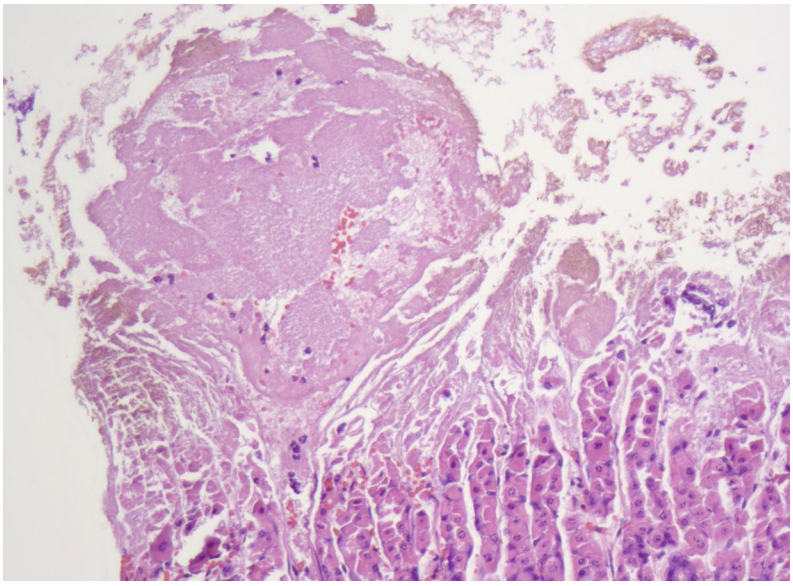
High PFAS levels were detected in nearly all the biological samples from Holloman Lake analyzed in 2024, confirming contamination of the entire ecosystem from algae and terrestrial plants to macroinvertebrates, mammals, birds, and reptiles (Appendix A). PFOS was the most abundant PFAS congener in all animal tissue samples. The highest PFOS concentrations recorded to date are listed in Table 2.

PFAS contamination of wildlife was detected south and southeast of Holloman Lake. Two salvaged specimens found along US 70, a coyote and a western coachwhip—both killed by vehicle traffic—exhibited PFOS tissue concentrations of 640 ng/g ww (muscle) and 6,800 ng/g ww (liver), respectively.



5.4 PFAS Ecological Toxicity

5.4.1 Necropsies



Results of the necropsies are summarized in Table 3. Complete results are provided in Appendix B.

All of the animals necropsied for this study were found to have PFOS concentrations greater than 1,000 ng/g in their livers or muscles. Normal tissues in several migratory birds present at Holloman Lake for only part of the year, two red-winged blackbirds (*Agelaius phoeniceus*) and two common yellowthroats (*Geothlypis trichas*), showed that acute, time-limited exposure does not necessarily lead to observable lesions at the organ or tissue level. The same was true with some of the rodents, all of which are year-round residents at Holloman Lake but also short-lived animals.

Possible abnormalities related to PFAS exposure included liver microgranulomas, spleen and adrenal hyperplasia, and gastric ulcers (Photographs 4 and 5), though these possible signs of toxicity can only be firmly established by also including a control group in future research activities. Possible diffuse cortical hypertrophy of the adrenal gland was discovered in particular in one deer mouse (*Peromyscus maniculatus*) with a PFOS concentration of 290 ng/g in its muscle tissues. Enlarged cells, the presence of anisocytosis (differing cell size), anisokaryosis (differing nuclear size), and multinucleated cells were most consistent with the diagnosis of diffuse cortical hypertrophy (Brändli-Baiocco et al., 2018). However, these same changes are not described in the context of cortical hypertrophy in guidelines from the International Harmonization of Nomenclature and Diagnostic Criteria for Lesions in Rats and Mice. Diffuse adrenocortical hypertrophy is typically caused by increased adrenocorticotropic hormone (ACTH) production—either due to stress or disease, or exogenously administered ACTH (Brändli-Baiocco et al., 2018). Although pollutants that inhibit steroid synthesis can cause cortical hypertrophy of the adrenal gland, they typically also cause increased vacuolation, not observed in the deer mouse that was necropsied.

Photograph 4. Possible diffuse adrenocortical hypertrophy in a deer mouse (*Peromyscus maniculatus*) from Holloman Lake. Anisocytosis, anisokaryosis, and multinucleation can all be observed in the adrenal cortex of this rodent.

Photograph 5. Multiple punctate gastric erosions/ulcers in a Merriam's kangaroo rat. The ulcers resulted in blood loss into the gastrointestinal tract. The underlying cause could not be determined, as there was no evidence of inflammation, infectious organisms, neoplasia, or parasites. Starvation and/or stress could not be ruled out.

A Merriam's kangaroo rat (*Dipodomys merriami*) with one of the highest PFOS concentrations recorded at Holloman Lake (94,000 ng/g ww in liver) showed a dry hypodermis during the postmortem gross examination. It appeared dehydrated, and the stomach, small intestine, and large intestine were filled with dark red to black digested blood. Histopathology showed multifocal necrosis of the glandular epithelium of the mucosa of the stomach that varied in thickness. The foci of necrosis were filled with necrotic debris, fibrin, hemorrhage, and hemoglobin-breakdown pigments. The submucosa associated with the mucosal epithelial necrosis was edematous. The adjacent gastric glandular epithelium was degenerate with hemorrhage in the associated lamina propria. No obvious underlying cause for the ulcers could be determined.

As indicated by O'Rourke et al. (2024a), it may be challenging to establish a definite link between PFAS exposure and disease in field studies due to many confounding variables with possible impacts on animal health and survival. An association between immune system health and environmentally relevant concentrations of PFCAs and PFSAs has been reported, with PFOA and PFOS concentrations significantly higher in sea otters (*Enhydra lutris*) that died of infectious disease compared to non-diseased animals (Kannan et al., 2006). Many of the animals necropsied had endoparasites, but so do wild rodents and birds in general (e.g., Mohammadi et al., 2022; Parsa et al. 2023).

5.4.2 Monitoring of Breeding Success

Since 2021, a total of 11 bird species have been documented breeding at Holloman Lake. These species consist of the Swainson's hawk (*Buteo swainsoni*), American avocet (*Recurvirostra americana*), black-necked stilt (*Himantopus mexicanus*), killdeer (*Charadrius vociferus*), snowy plover (*Charadrius nivosus*), white-winged dove (*Zenaida asiatica*), Say's phoebe (*Sayornis saya*), western kingbird (*Tyrannus verticalis*), northern mockingbird (*Mimus polyglottos*), red-winged blackbird, and common yellowthroat.

Nest searches were conducted from May through July 2024. A total of 10 shorebird nests were found and monitored for the rest of the breeding season. More nests likely occurred in shoreline areas with restricted access. All four of the monitored black-necked stilt nests failed, as did the two American avocet nests. A snowy plover nest succeeded, with three juveniles observed together with an adult. Two killdeer juveniles were observed at two different locations, though at least one of the monitored nests failed. At the other killdeer nest, two eggs never hatched, while another disappeared and a hatchling was found dead next to the nest, with

no evidence of predation (Photograph 6). In the uplands, a Swainson's hawk nest produced one fledgling from an observed brood of two nestlings.

Photograph 6. Killdeer hatchling found dead within 1 meter of its nest in June 2024.

The dead killdeer hatchling could not be necropsied, but one tissue sample was found to have a PFOS concentration of 48,000 ng/g, the highest PFAS concentration recorded in any bird during this study. The predicted no-effect concentration (PNEC) and toxicity reference value (TRV) derived by Newsted et al. (2005) for PFOS in egg yolk (based on acute and chronic laboratory exposure in northern bobwhite quail [*Colinus virginianus*] and mallard [*Anas platyrhynchos*]) are 1000 and 1700 ng/g, respectively.

A Say's phoebe (*Sayornis saya*) nest with two eggs was discovered on June 3, 2024 on a shelf in an abandoned shed at the northern end of Holloman Lake. As the eggs had not hatched more than two months later, they were collected on July 16, 2024 and one of them was analyzed for PFAS. PFOS eggshell concentration was found to be 1,500 ng/g, more than 5 times greater than the value associated with a 20 percent decrease in hatching success in a population of tree swallows in Minnesota and Wisconsin (Custer et al., 2014).

5.5 Statewide Waterfowl Hunting Risk Assessment

The 47 waterfowl tissue samples used for the preliminary statewide waterfowl hunting risk assessment are listed in Table 4, together with information on species and tissue type composition, collecting location, and PFOS concentration. Of the 47 samples, 19 represented single individual birds from Holloman Lake. These 19 birds exhibited a distinctive contamination profile based on the specific proportions of PFAS analytes detected in their tissues (Figure 9). As

with other wildlife from Holloman Lake, PFOS concentrations were highest by at least an order of magnitude, followed by PFHxS concentrations. PFOA concentrations typically averaged another order of magnitude lower than PFHxS concentrations, while PFHpS could also be abundant in tissue samples at more variable concentrations.

PFOS concentrations above 100 ng/g were found in 25 (89 percent) of the 28 non-Holloman samples (Table 4). In nearly half of the 28 samples, PFOS concentrations exceeded 500 ng/g—even reaching 1,000 ng/g in two instances—indicating high (or very high) contamination in at least some waterfowl that were represented in those samples (Table 4). None of the composite non-Holloman samples had PFOS concentrations below 100 ng/g. Results indicated waterfowl PFAS contamination in waterfowl in northwestern New Mexico and southeastern New Mexico in particular, though the contamination profiles appeared to differ from those found at Holloman Lake, with PFHxS concentrations low and long-chain PFCAs relatively more abundant (Figure 9). A red-breasted merganser (*Mergus serrator*) collected south of Rincon along the Rio Grande was also found to have a mean heart, liver, and muscle PFOS concentration of 750 ng/g, but PFHxS concentration was lower than perfluorodecanoic acid (PFDA) and PFOA concentrations.

PFAS screening of the 28 non-Holloman waterfowl samples should be viewed as an initial step to help guide a more robust, statewide waterfowl hunting risk assessment. More samples are being prepared to expand this effort.

5.6 Large Game Risk Assessment

To assess PFAS levels in mammalian game species potentially using Holloman Lake as a water/food resource, MSB has begun obtaining oryx samples for PFAS testing. Populations in and around the Holloman Lake area will be included, in addition to more distant populations from the Armendaris Ranch and Jornada Basin for an indication of background contamination levels. At the time of this report, MSB projected the collection and testing of approximately 30 to 50 oryx in 2025.

With assistance from individual licensed hunters, two oryx liver and muscle samples have already been tested from the following two animals:

- Specimen MSB:Mamm:341801: New Mexico, Otero County, Culp Canyon
- Specimen MSB:Mamm:348125: New Mexico, Otero County, White Sands Missile Range, Hunt Unit 19, Rhodes Canyon

Five more oryx specimens donated to MSB are available for PFAS testing:

- Specimen MSB:Mamm:196600: New Mexico
- Uncataloged specimen: New Mexico, Otero County, White Sands Missile Range, Hunt Unit 19, Rhodes Canyon
- Uncataloged specimen: Obtained from Major Wildlife Studio, Las Cruces, New Mexico
- Uncataloged specimen: New Mexico, Doña Ana County, San Andres Mountains
- Uncataloged specimen: New Mexico, Otero County. 23.5 km SE Orogrande

6. Conclusions and Recommendations

Extraordinary levels of PFAS contamination have been found in wildlife at Holloman Lake. Two Merriam's kangaroo rats collected in 2024 exhibited liver PFOS concentrations of 120,000 ng/g and 110,000 ng/g, respectively. Based on published studies, these concentrations are the highest reported in any wild animals to date, other than a wood mouse (*Apodemus sylvaticus*) liver sample near a fluorochemical plant in Belgium (Hoff et al., 2004). One saltcedar composite tissue sample from Holloman Lake was also found to have a PFOS concentration of 30,000 ng/g, an apparent world record for plants. Results from the ecological research conducted in 2024 are highly suggestive of ecological toxicity at Holloman Lake, while movements of waterfowl and large mammals indicate a likely risk associated with hunting and the consumption of contaminated game meat outside the immediate area around Holloman Lake. In the case of waterfowl, preliminary results of PFAS screening from other wetlands around New Mexico (but primarily in the northwestern part of the state) show surprisingly high contamination levels that should be further investigated. Some of the funding for this research was saved for testing of more samples with help from hunters recruited for this effort, particularly in areas of New Mexico poorly represented in the specimen collection at MSB.

High levels of contamination were found in bird eggs and in a hatchling found dead next to its nest. Because PFAS research on laboratory animals has shown impairment of both reproduction and development (Witt et al., 2024), the very high rate of nesting failure in shorebirds at Holloman Lake also needs to be investigated in relation to PFAS contamination levels, with monitoring of breeding success at Bitter Lake National Wildlife Refuge for a comparison. Necropsies of highly contaminated rodents from Holloman Lake revealed liver abnormalities such as aggregates of enlarged hepatocytes, in addition to spleen hyperplasia and gastric ulcers.

A definite link to PFAS exposure cannot be established without also including a control group from a nearby, non-contaminated site.

Specific recommendations include the following:

- Expand testing of waterfowl and oryx samples to better characterize the risk to hunters outside the immediate footprint of contamination at Holloman Lake/Holloman AFB.
- Conduct additional necropsies of rodents from Holloman Lake but also a nearby, uncontaminated site (control group) to statistically assess the significance of abnormalities detected during this study.
- Continue research on ecological toxicity at Holloman Lake and include the use of metabolic markers to identify early disease progression in short-lived species.
- Investigate the use of non-lethal tissue sampling methods to study and monitor wildlife at Holloman Lake.
- Monitor shorebird breeding success and implement a sampling protocol to determine hatching success in relation to egg PFAS concentrations, with monitoring of a control group of shorebirds at Bitter Lake National Wildlife Refuge.
- Investigate potential PFAS contamination of beef cattle raised in the Alamogordo and Holloman AFB area.
- Investigate bioaccumulation and community-wide transmission of PFAS using carnivores such as coyotes, badgers, and rattlesnakes
- Initiate a statewide monitoring program with surveys and PFAS monitoring for large game animals and other potential sentinel species.
- Continue to build partnerships with other organizations to expand monitoring and assess toxicity to wildlife and humans.

House mouse	*Mus musculus*	NK 310959	13,000	Liver	Holloman Lake	5/6/2022
		NK 310922	13,000	Liver	Holloman Lake	5/5/2022
Green-winged teal	*Anas crecca*	NK 283635	12,000	Liver	Holloman Lake	1/30/2022
House mouse	*Mus musculus*	NK 310883	12,000	Liver	Holloman Lake	3/4/2022
Red-winged blackbird	*Agelaius phoeniceus*	NK284445	12,000	Liver	Holloman Lake	7/11/2024
House mouse	*Mus musculus*	NK 310882	11,000	Liver	Holloman Lake	3/4/2022
Green-winged teal	*Anas crecca*	NK 283675	11,000	Liver	Holloman Lake	1/8/2022
House mouse	*Mus musculus*	NK 311886	10,000	Liver	Holloman Lake	5/5/2022
Northern pintail	*Anas acuta*	NK 283604	10,000	Liver	Holloman Lake	12/10/2021
Red-winged blackbird	*Agelaius phoeniceus*	NK284446	10,000	Liver	Holloman Lake	7/11/2024

[a] Unless otherwise indicated, all specimens from Holloman Lake were collected at the lake surface, along the shoreline, or at the mouth of the east intake.

[b] Salvaged specimen (hatchling found dead near its nest).

[c] Collected in the uplands near the southern end of the lake.

ng/g ww = Nanograms per gram, wet weight

Table 3. Gross Necropsy and Histopathology Results
Page 1 of 3

Common Name	Scientific Name	NK Number	Findings
Merriam's kangaroo rat	*Dipodomys merriami*	NK 311130	**Occasional, small aggregates of enlarged hepatocytes ("altered foci"), not unusual—at least in *Mus musculus*—and can increase with age and exposure to some carcinogens.**
House mouse	*Mus musculus*	NK 311135	No overt significant findings during gross necropsy and microscopic exam. In the small intestine, the lamina propria contains numerous lymphoid cells, but these are uniformly distributed; the number of lymphoid cells is judged to be within normal limits. The villus tips of the intestine are autolyzed, which makes interpretation difficult.
White-footed mouse	*Peromyscys leucopus*	NK311134	Mild, chronic, interstitial pneumonia. Mild to moderate, granulomatous hepatitis with intralesional trematodes (flatworms). **Lymphofollicular hyperplasia of the spleen, with the prominent germinal centers in the white pulp suggesting antigenic stimulation and marked erythropoiesis in the red pulp consistent with response to anemia**. Cestode within a lymph node adjacent to the pancreas. Occasional intracytoplasmic protozoal cysts (sarcocysts) in the tongue and in skeletal muscle surrounding bones.
White-footed mouse	*Peromyscus leucopus*	NK 311139	Extent and pattern of liver vacuolation within normal limits. Mild changes in the white and red pulp of the spleen likely within normal limits. Adrenal glands subjectively enlarged on gross necropsy but likely within normal limits and with no evidence of pathologic processes on microscopic exam (though anisocytosis, anisokaryosis, and multinucleated cells all noted).
Deer mouse	*Peromyscus maniculatus*	NK 311138	Frequent protozoal cysts (sarcocysts) within skeletal muscle fibers surrounding bones; occasional sarcocysts within the cytoplasm of skeletal muscle fibers in the wall of the esophagus and in the tongue. Liver vacuolation within normal limits for a post-prandial mouse; lymphoid cells surrounding a few bile ducts and a single small focus of necrosis in the liver considered incidental findings.

Notes are provided at the end of the table.

Table 3. Gross Necropsy and Histopathology Results
Page 2 of 3

Common Name	Scientific Name	NK Number	Findings
Merriam's kangaroo rat	*Dipodomys merriami*	NK 311147	**Multiple punctate gastric erosions/ulcers**. The foci of necrosis are filled with necrotic debris, fibrin, hemorrhage, and hemoglobin-breakdown pigments. The submucosa associated with the mucosal epithelial necrosis is edematous. The adjacent gastric glandular epithelium is degenerate with hemorrhage in the associated lamina propria. No evidence of inflammation, infectious organisms, neoplasia, or parasites that could have caused the gastric ulcer. Rare microgranulomas in the liver (i.e., rare random and multifocal small infiltrates of small numbers of macrophages and lesser numbers of lymphocytes in the liver that are occasionally associated with apoptotic hepatocytes) considered incidental findings
Merriam's kangaroo rat	*Dipodomys merriami*	NK 311148	Endoparasitism: Small numbers of adult cestodes (tapeworms) in the lumen of the small intestine. Rare microgranulomas in the liver are considered incidental findings.
Merriam's kangaroo rat	*Dipodomys merriami*	NK 311149	**Gastric ulcer** with focally extensive necrosis of the lumenal aspect of the glandular epithelium of the mucosa of the stomach. The focus of necrosis is filled with necrotic debris, fibrin, hemorrhage, and hemoglobin-breakdown pigments. The submucosa associated with the mucosal epithelial necrosis is edematous. The adjacent gastric glandular epithelium is degenerate with hemorrhage in the associated lamina propria. No evidence of inflammation, infectious organisms, neoplasia, or stomach parasites that could have caused the gastric ulcer. Endoparasitism: The lumen of the small intestine contains small numbers of adult nematodes. Rare microgranulomas in the liver are considered an incidental finding.
Merriam's kangaroo rat	*Dipodomys merriami*	NK 311150	No significant lesions. Rare microgranulomas in the liver are considered an incidental finding
Deer mouse	*Peromyscus maniculatus*	NK 311151	No significant lesions. Rare microgranulomas in the liver are considered an incidental finding.
Merriam's kangaroo rat	*Dipodomys merriami*	NK 311152	Endoparasitism: Small numbers of sarcocysts in the skeletal muscle. Rare microgranulomas in the liver are considered an incidental finding.

Notes are provided at the end of the table.

Table 3. Gross Necropsy and Histopathology Results
Page 3 of 3

Common Name	Scientific Name	NK Number	Findings
Chihuahuan desert pocket mouse	*Chaetodipus eremicus*	NK 311153	No significant lesions.
Merriam's kangaroo rat	*Dipodomys merriami*	NK 311154	Endoparasitism: Small numbers of nematodes in the small intestine. Rare microgranulomas in the liver are considered an incidental finding.
Red-winged blackbird	*Agelaius phoeniceus**	NK 284441	Normal tissue.
Killdeer	*Charadrius vociferus*	NK 284442	Endoparasitism: Lumen of the proventriculus contains two small degenerate helminths.
American avocet	*Recurvirostra americana*	NK 284443	Endoparasitism in the small intestine and ventriculus. Inflammation in the mesentery, fat adjacent to the spleen, and liver likely in response to the endoparasitism; moderate to severe lymphocytic orchitis.
Red-winged blackbird	*Agelaius phoeniceus*	NK 284444	Normal tissue.
Red-winged blackbird	*Agelaius phoeniceus*	NK 284445	Normal tissue.
Red-winged blackbird	*Agelaius phoeniceus*	NK 284446	Very mild inflammation in the portal areas of the liver.
Western kingbird	*Tyrannus verticalis*	NK 284447	Airsac nematode, nematodes in the small intestine (endoparasitism), and flukes within the portal vein (avian schistosomiasis). **Mild lymphohistiocytic interstitial nephritis**, possibly the result of parasite migration through a kidney.
Western kingbird	*Tyrannus verticalis*	NK 284448	Endoparasitism (adult tapeworm in the small intestine); testicular atrophy possibly related to seasonal cycle of testicular activity/inactivity.
Common yellowthroat	*Geothlypis trichas*	NK 284449	Normal tissue.
Common yellowthroat	*Geothlypis trichas*	NK 284450	Normal tissue.
Common yellowthroat	*Geothlypis trichas*	NK 284451	*Sarcocystis* species protozoal cysts in the skeletal muscle (sarcocystosis, rice breast disease). Small focus of nonsuppurative encephalitis likely associated with prior trauma to the area.

Bold indicates the most notable findings.

Job Notes

This report may not be reproduced except in full, and with written approval from the laboratory. The results relate only to the samples tested. For questions please contact the Project Manager at the e-mail address or telephone number listed on this page.

The test results in this report relate only to the samples as received by the laboratory and will meet all requirements of the methodology, with any exceptions noted. This report shall not be reproduced except in full, without the express written approval of the laboratory. All questions should be directed to the Eurofins Environment Testing Northern California, LLC Project Manager.

Qualifiers

LCMS

Qualifier	Qualifier Description
*5+	Isotope dilution analyte is outside acceptance limits, high biased.
E	Result exceeded calibration range.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

NMED Exhibits 65

Job Narrative
320-113143-1

Receipt
The samples were received on 6/18/2024 9:20 AM. Unless otherwise noted below, the samples arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was -33.8º C.

Receipt Exceptions
Samples were not received with a Chain-of-Custody Form, but the lab received a "Specimen Invoice" that does list the sample IDs under the Description section. The collection date and time were not listed. Client provide the collection date as May 16, 2024 in email received on June 18, 2024. The samples were logged in using a default time of 00:00.

LCMS
Method B/L/T PFAS: The concentration of one or more analytes associated with the following samples exceeded the instrument calibration range. These analytes have been qualified; however, the peak(s) did not saturate the instrument detector. Historical data indicate that for the isotope dilution method, dilution and re-analysis will not produce significantly different results from those reported above the calibration range. NK311130-Dipodomys merriami-muscle (320-113143-1), NK311134-Peromyscus leucopus-muscle (320-113143-2), NK311135-Mus musculus-muscle (320-113143-3), NK311138-Peromyscus maniculatus-muscle (320-113143-4) and NK311139-Peromyscus leucopus-muscle (320-113143-5)

Method B/L/T PFAS: Isotope Dilution Analyte (IDA) recovery is above the method recommended limit for the following samples. Quantitation by isotope dilution generally precludes any adverse effect on data quality due to elevated IDA recoveries. NK311130-Dipodomys merriami-muscle (320-113143-1), NK311134-Peromyscus leucopus-muscle (320-113143-2), NK311135-Mus musculus-muscle (320-113143-3), NK311138-Peromyscus maniculatus-muscle (320-113143-4), NK311139-Peromyscus leucopus-muscle (320-113143-5), (MB 320-773440/1-A), (LCS 320-773440/2-A) and (LCSD 320-773440/3-A)

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Organic Prep
Method SHAKE: A matrix spike/matrix spike duplicate (MS/MSD) was not performed with preparation batch 320-773440.

Method SHAKE: Elevated reporting limits (RL) are provided for the following samples due to limited mass available for extraction: NK311134-Peromyscus leucopus-muscle (320-113143-2), NK311135-Mus musculus-muscle (320-113143-3), NK311138-Peromyscus maniculatus-muscle (320-113143-4) and NK311139-Peromyscus leucopus-muscle (320-113143-5).

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Detection Summary

Client: University of New Mexico

LOAN 2024.069.Mamm

SPECIMEN INVOICE
Museum of Southwestern Biology
Division of Mammals
University of New Mexico
17 Jun 2024

320 113143 Chain of Custody

This loan document acknowledges the loan of specimens to:

Attn: Linda C. Laver
Eurofins Environment Testing Northern California
880 Riverside Parkway
West Sacramento, CA 95605

Approved by:

Joseph A. Cook

Loan Type: consumable

Nature of Material: Five muscle samples from Holloman air force base rodents for PFAS analysis.

Remarks:

Description: NK311130 - Dipodomys merriami-muscle; NK311134 - Peromyscus leucopus-muscle; NK311135 - Mus musculus-muscle; NK311138-Peromyscus maniculatus-muscle; NK311139-Peromyscus leucopus-muscle.

Instructions:

Upon receipt, sign and return one copy to:

Jonathan L. Dunnum, Senior Collection Manager
Division of Mammals
Museum of Southwestern Biology
CERIA, Rm #83
1 University of New Mexico
Albuquerque, NM 87131
MSC 03 2020 **Email:** jldunnum@unm.edu

Signature of recipient, date:

06/18/24
0920

Received By

-33.8°C

LOAN REQUIREMENTS: RECIPIENT ACKNOWLEDGES THE FOLLOWING TERMS:

Material loaned from the MSB should be properly acknowledged by MSB catalog number (MSB:Mamm.XXXX) in subsequent publications, reports, presentations, GenBank, IsoBank, MorphoSource or other data submissions - see Loan Instructions. PDFs of publications should be provided to the MSB. By signing this form, you agree to use these materials only for the study outlined in your original proposal. You must obtain written permission for any use outside of the scope of your original proposal. Transfer of MSB material to a third party is not allowed. Non-consumable specimens on loan should be returned to the MSB within 6 months using the same packing container and materials, shipping method, and insurance value unless other arrangements are made with the MSB Mammal Curator. Thank you for your cooperation.

Qualifiers

LCMS

Qualifier	Qualifier Description
*5+	Isotope dilution analyte is outside acceptance limits, high biased.
B	Compound was found in the blank and sample.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Job ID: 320-113430-1 — Eurofins Sacramento

Job Narrative
320-113430-1

Comments
The following samples were canceled by the client on July 2, 2024 due to insufficient volume submitted for analysis: H2O West (320-113430-17), H2O -So (320-113430-18), H2O North Inlet (320-113430-19) and H2O East Inlet (320-113430-20).

The following samples were canceled by the client on July 10, 2024 due to limited sample mass submitted for analysis: Soil NE2-1 (320-113430-1), Soil NE2-2 (320-113430-2), Soil NE2-3 (320-113430-3), Soil NE2-4 (320-113430-4), Soil4-1 (320-113430-5), Soil4-2 (320-113430-6), Soil4-3 (320-113430-7) and Soil4-4 (320-113430-8).

Receipt
The samples were received on 6/27/2024 9:30 AM. Unless otherwise noted below, the samples arrived in good condition, and where required, properly preserved. The temperature of the cooler at receipt was 19.8º C.

Receipt Exceptions
Samples were received at the laboratory outside the required temperature criteria. Client was aware these were shipped without any cooling agent and approved the lab to perform the analyses.

The Chain-of-Custody (COC) was incomplete as received and does not list the requested analyses. Based on communications with the client, the samples were logged in for PFAS (17 Analyte List by 537 Mod).

LCMS
Method B/L/T PFAS: Isotope Dilution Analyte (IDA) recoveries are above the method recommended limit for the following samples. Quantitation by isotope dilution generally precludes any adverse effect on data quality due to elevated IDA recoveries. Saltbush 2-1 (320-113430-9), Saltbush 2-2 (320-113430-10), Saltbush 2-3 (320-113430-11), Saltbush 2-4 (320-113430-12), Saltbush 4-1 (320-113430-13), Saltbush 4-2 (320-113430-14), Saltbush 4-3 (320-113430-15), Saltbush 4-4 (320-113430-16), Algae So (320-113430-21), (MB 320-779766/1-A), (LCS 320-779766/2-A), (LCSD 320-779766/3-A)

Method B/L/T PFAS: Some results for the following sample were reported from the analysis of a diluted extract due to matrix interference and high concentration of target analyte(s) in the undiluted extract. The dilution factor was applied to the labeled internal standard area counts and these area counts were within acceptance limits. Saltbush 4-1 (320-113430-13)

Method B/L/T PFAS: Some results for the following sample were reported from the analysis of a diluted extract due to high concentration of target analyte(s) in the analysis of the undiluted extract. The dilution factor was applied to the labeled internal standard area counts and these area counts were outside acceptance limits. The internal standard is not used to quantitate target analyte concentrations; therefore, the data have been reported. Algae So (320-113430-21)

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Organic Prep
Method SHAKE: Insufficient sample was available to perform a matrix spike/matrix spike duplicate (MS/MSD) associated with preparation batch 320-779760 and 320-779766.

Method SHAKE: The following samples ranged in color from yellow to green after extraction. Saltbush 2-1 (320-113430-9), Saltbush 2-2 (320-113430-10), Saltbush 2-3 (320-113430-11), Saltbush 2-4 (320-113430-12), Saltbush 4-1 (320-113430-13), Saltbush 4-2 (320-113430-14), Saltbush 4-3 (320-113430-15), Saltbush 4-4 (320-113430-16) and Algae So (320-113430-21)

Method SHAKE: Elevated reporting limits are provided for the following samples due to insufficient sample (< 1 gram) provided for preparation. Saltbush 2-1 (320-113430-9), Saltbush 2-2 (320-113430-10), Saltbush 2-3 (320-113430-11), Saltbush 2-4 (320-113430-12), Saltbush 4-1 (320-113430-13), Saltbush 4-2 (320-113430-14), Saltbush 4-3 (320-113430-15) and Saltbush 4-4 (320-113430-16)

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Job Notes

This report may not be reproduced except in full, and with written approval from the laboratory. The results relate only to the samples tested. For questions please contact the Project Manager at the e-mail address or telephone number listed on this page.

The test results in this report relate only to the samples as received by the laboratory and will meet all requirements of the methodology, with any exceptions noted. This report shall not be reproduced except in full, without the express written approval of the laboratory. All questions should be directed to the Eurofins Environment Testing Northern California, LLC Project Manager.

Qualifiers

LCMS

Qualifier	Qualifier Description
*5+	Isotope dilution analyte is outside acceptance limits, high biased.
F1	MS and/or MSD recovery exceeds control limits.
I	Value is EMPC (estimated maximum possible concentration).
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

NMED Exhibits 65

Job ID: 320-113899-1 — Eurofins Sacramento

Job Narrative
320-113899-1

Receipt
The samples were received on 7/18/2024 9:20 AM. Unless otherwise noted below, the samples arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was 2.3º C.

Receipt Exceptions
The Chain-of-Custody (COC) was incomplete as received and does not list the requested analyses. Based on communications with the client, the samples were logged in for PFAS (17 Analyte List by 537 Mod).

LCMS
Method B/L/T PFAS: Isotope Dilution Analyte (IDA) recovery is above the method recommended limit for the following sample. Quantitation by isotope dilution generally precludes any adverse effect on data quality due to elevated IDA recoveries. Hol-East H2O (320-113899-2)

Method B/L/T PFAS: Results for the following samples were reported from the analysis of a diluted extract due to matrix sample of the target analyte in the analysis of the undiluted extract. The dilution factor was applied to the labeled internal standard area counts and these area counts were within acceptance limits. Hol-East H2O (320-113899-2), Hol-South H2O (320-113899-3), Hol-West H2O (320-113899-4), Hol NE4-0=1 Soils (320-113899-5), Hol NE4-900=4 Soils (320-113899-8) and Hol NE2-0=1 Soils (320-113899-9)

Method B/L/T PFAS: The "I" qualifier means the transition mass ratio for the indicated analyte was outside the established ratio limits. The qualitative identification of the analyte has some degree of uncertainty. However, analyst judgment was used to positively identify the analyte. Hol-South H2O (320-113899-3). and Hol NE2-900=4 Soils (320-113899-12)

Method B/L/T PFAS: The matrix spike / matrix spike duplicate (MS/MSD) for preparation batch 320-785917 has recoveries outside control limits for some analytes. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample (LCS) recovery is within acceptance limits.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Organic Prep
Method 3535: Insufficient sample volume was available to perform a matrix spike/matrix spike duplicate/sample duplicate (MS/MSD/DUP) associated with preparation batch 320-781606.

Method 3535: The following samples were yellow in color following extraction. Hol-East H2O (320-113899-2), Hol-South H2O (320-113899-3) and Hol-West H2O (320-113899-4)

Method 3535: Due to the matrix, the following samples were prepared at a reduced volume from the standard operating procedure. The reporting limits (RLs) have been adjusted proportionately [2X]. Hol-East H2O (320-113899-2), Hol-South H2O (320-113899-3) and Hol-West H2O (320-113899-4)

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Detection Summary

Client: University of New Mexico

Job Notes

This report may not be reproduced except in full, and with written approval from the laboratory. The results relate only to the samples tested. For questions please contact the Project Manager at the e-mail address or telephone number listed on this page.

The test results in this report relate only to the samples as received by the laboratory and will meet all requirements of the methodology, with any exceptions noted. This report shall not be reproduced except in full, without the express written approval of the laboratory. All questions should be directed to the Eurofins Environment Testing Northern California, LLC Project Manager.

Job ID: 320-113896-1

Qualifiers

LCMS

Qualifier	Qualifier Description
*5+	Isotope dilution analyte is outside acceptance limits, high biased.
B	Compound was found in the blank and sample.
E	Result exceeded calibration range.
I	Value is EMPC (estimated maximum possible concentration).
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Job ID: 320-113896-1 — Eurofins Sacramento

Job Narrative
320-113896-1

Receipt
The samples were received on 7/18/2024 9:20 AM. Unless otherwise noted below, the samples arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was -36.9º C.

Receipt Exceptions
The Chain-of-Custody (COC) was incomplete as received and was not signed at the time samples were relinquished to the lab and does not list the requested analyses. Based on communications with the client, the samples were logged in for PFAS by 537 Mod.

The container label for each sample did not include a collection date or time. Samples were logged in and according to COC. Sample VDS 0 TEST (320-113896-23) was an empty vial intended to be tested as a blank. The COC does not list a collection date or time and this sample was logged in as 7/17/2024 @ 00:00. The COC does not list a collection time for sample NK284444 V24-20096 liner (320-113896-24) and was logged in as 00:00.

LCMS
Method B/L/T PFAS: Isotope Dilution Analyte (IDA) recoveries are above the method recommended limit for multiple samples due to matrix interferences common to tissue matrices. Quantitation by isotope dilution generally precludes any adverse effect on data quality due to elevated IDA recoveries.

Method B/L/T PFAS: The "I" qualifier means the transition mass ratio for the indicated analyte was outside the established ratio limits. The qualitative identification of the analyte has some degree of uncertainty. However, analyst judgment was used to positively identify the analyte. NK311145 femur (320-113896-6), ArtNE2 01 (320-113896-15) and NK284447 (320-113896-30)

Method B/L/T PFAS: The concentration of one or more analytes associated with the following samples exceeded the instrument calibration range in the diluted analysis. These analytes have been qualified (E); however, the peak(s) did not saturate the instrument detector. Historical data indicate that for the isotope dilution method, further dilution and re-analysis will not produce significantly different results from those reported above the calibration range. NK311145 liver (320-113896-5), NK311146 liver (320-113896-7), NK284439 (320-113896-35) and NK284442 V24-20096 liver (320-113896-37)

Method B/L/T PFAS: Results for multiple samples were reported from the analysis of a diluted extract due to high concentration of the target analyte and/or matrix interference in the analysis of the undiluted extract. The dilution factor was applied to the labeled internal standard area counts and these area counts were within acceptance limits.

Method B/L/T PFAS: Results for the following samples were reported from the analysis of a diluted extract due to high concentration of the target analyte in the analysis of the undiluted extract. The dilution factor was applied to the labeled internal standard area counts and these area counts were outside acceptance limits. The internal standard is not used to quantitate target analyte concentrations, therefore the data have been reported. NK311133 liver (320-113896-11), NK284442 (320-113896-25) and NK284444 (320-113896-27)

Method B/L/T PFAS: Internal standard (ISTD) response for the following sample was outside control limits in the undiluted extract. The sample was re-analyzed at a dilution and the ISTD was within control limits. The ISTD is not used to quantitate target analytes; therefore, the data has been reported. NK284442 V24-20096 liver (320-113896-37)

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Organic Prep
Method SHAKE: A matrix spike/matrix spike duplicate (MS/MSD) was not prepared for preparation batches 320-785621 and 320-320-788729.

Method SHAKE: Elevated reporting limits are provided for the following samples due to insufficient sample available for extraction: NK311142 liver (320-113896-3), NK311143 liver (320-113896-4), NK311145 femur (320-113896-6), NK311146 femur (320-113896-8), NK311129 liver (320-113896-9), NK311131 liver (320-113896-10), NK311133 liver (320-113896-11), Velvet ant NE2 03 (320-113896-14), ArtNE2 01 (320-113896-15), ArtNE2 02 (320-113896-16), ArtNE2 04 (320-113896-18), ArtNE4 01 (320-113896-19), ArtNE4 02 (320-113896-20), ArtNE4 03 (320-113896-21), ArtNE4 04 (320-113896-22), NK284449 (320-113896-32), NK284450 (320-113896-33) and NK284444 V24-20103 liver (320-113896-39).

Method SHAKE: The following samples were discolored following extraction: NK311140 liver (320-113896-1), NK311141 liver (320-113896-2), NK311145 liver (320-113896-5), NK311146 liver (320-113896-7), NK311131 liver (320-113896-10), NK311133 liver (320-113896-11), NK319511 muscle (320-113896-12), NK319092 liver (320-113896-13), ArtNE2 03 (320-113896-17) and NK284439 (320-113896-35).

Job ID: 320-113896-1 (Continued)

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Job Notes

This report may not be reproduced except in full, and with written approval from the laboratory. The results relate only to the samples tested. For questions please contact the Project Manager at the e-mail address or telephone number listed on this page.

The test results in this report relate only to the samples as received by the laboratory and will meet all requirements of the methodology, with any exceptions noted. This report shall not be reproduced except in full, without the express written approval of the laboratory. All questions should be directed to the Eurofins Environment Testing Northern California, LLC Project Manager.

Qualifiers

LCMS

Qualifier	Qualifier Description
*5-	Isotope dilution analyte is outside acceptance limits, low biased.
*5+	Isotope dilution analyte is outside acceptance limits, high biased.
E	Result exceeded calibration range.
H	Sample was prepped or analyzed beyond the specified holding time. This does not meet regulatory requirements.
H3	Sample was received and analyzed past holding time. This does not meet regulatory requirements.
I	Value is EMPC (estimated maximum possible concentration).
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

General Chemistry

Qualifier	Qualifier Description
H	Sample was prepped or analyzed beyond the specified holding time. This does not meet regulatory requirements.
H3	Sample was received and analyzed past holding time. This does not meet regulatory requirements.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
☼	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Job ID: 320-117195-1 Eurofins Sacramento

Job Narrative
320-117195-1

Receipt
The samples were received on 11/21/2024 9:40 AM. Unless otherwise noted below, the samples arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was -23.7º C.

Receipt Exceptions
Client emailed a Chain-of-Custody (COC) that was requested to be used for logging in the samples which had some revisions from the original COC shipped with the samples, Because the original COC was not signed at the time samples were relinquished, it was not included in this report.

Collection times were not provided. Samples were logged in with a default time of 00:00.

LCMS
Method B/L/T PFAS: Isotope Dilution Analyte (IDA) recovery is above the method recommended limit in most samples. Quantitation by isotope dilution generally precludes any adverse effect on data quality due to elevated IDA recoveries.

Method B/L/T PFAS: The Isotope Dilution Analyte (IDA) recovery associated with the following samples is below the method recommended limit: Cattail N wet 2 / MSB:DGR:3155_2 (320-117195-20) and Marsh fleabane / MSB:DGR:3153 (320-117195-22). Generally, data quality is not considered affected if the IDA signal-to-noise ratio is greater than 10:1, which is achieved for all IDA in the samples.

Method B/L/T PFAS: The "I" qualifier means the transition mass ratio for the indicated analyte was outside the established ratio limits. The qualitative identification of the analyte has some degree of uncertainty.

Method B/L/T PFAS: The concentration of one or more analytes associated with the following samples exceeded the instrument calibration range. These analytes have been qualified; however, the peak(s) did not saturate the instrument detector. Historical data indicate that for the isotope dilution method, dilution and re-analysis will not produce significantly different results from those reported above the calibration range. NK 10442 L / MSB:Mamm:89195 (320-117195-9), NK 180975 L / MSB:Mamm:1268357 (320-117195-13) and Gambusia Wet 1 / MSB:DGR:3154_1 (320-117195-16)

Method B/L/T PFAS: Some results for the following samples were reported from the analysis of a diluted extract due to high concentration of the target analyte in the analysis of the undiluted extract: holloman wetland / MSB:DGR:3158 (320-117195-23) and holloman S. Playa / MSB:DGR:3157 (320-117195-24) The dilution factor was applied to the labeled internal standard area counts and these area counts were within acceptance limits.

Method B/L/T PFAS: The internal standard recovery of 13C2 PFOA was outside control limits in sample Cattail N wet 2 / MSB:DGR:3155_2 (320-117195-20). The internal standard is not used to quantitate any target analytes, therefore, the data have been reported.

Method B/L/T PFAS: One or more continuing calibration verification (CCV) aliquots associated with analytical batch 320-820819 recovered above the uppercontrol limit for 8:2 FTS. The samples associated with these CCVs were non-detect (ND) for the affected analyte; therefore, the data have been reported.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

General Chemistry
Method D2216-92: The reference method does not list a specific holding time for the percent moisture analysis; therefore, the laboratory defaults to an in-house holding time of 14 days. The analysis for the following soil samples was performed outside this time period. holloman wetland / MSB:DGR:3158 (320-117195-23) and holloman S. Playa / MSB:DGR:3157 (320-117195-24)

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Organic Prep
Method SHAKE: Several samples were received after the preparation holding time had expired and are qualified accordingly.

Method SHAKE: Elevated reporting limits are provided for the following samples due to limited sample mass provided for extraction: NK 32079 L / MSB:Mamm:75616 (320-117195-2), NK 32043 L / MSB:Mamm:75617 (320-117195-3), NK 32074 L / MSB:Mamm:75618
(320-117195-4), NK 32071 L / MSB:Mamm:75619 (320-117195-5), NK 32039 L / MSB:Mamm:75620 (320-117195-6) and NK 40788 L / MSB:Mamm:89351 (320-117195-11), Dragonfly wetland / MSB:DGR:3159 (320-117195-18), Cattail N wet /

Job ID: 320-117195-1 (Continued) Eurofins Sacramento

MSB:DGR:3155_1 (320-117195-19), Cattail N wet 2 / MSB:DGR:3155_2 (320-117195-20), and saltceder NE4-4 / MSB:DGR:3156 (320-117195-21).

Method SHAKE: The following samples were discolored following extraction: saltceder NE4-4 / MSB:DGR:3156 (320-117195-21), Marsh fleabane / MSB:DGR:3153 (320-117195-22) and holloman wetland / MSB:DGR:3158 (320-117195-23)

Method SHAKE: Insufficient sample volume was available to perform a matrix spike/matrix spike duplicate (MS/MSD) associated with preparation batches 320-818866, 320-818987, 320-819252

Method SHAKE: The following samples were received after the preparation holding time had expired: NK 19893 L / MSB:Mamm:61848 (320-117195-1), NK 32079 L / MSB:Mamm:75616 (320-117195-2), NK 32043 L / MSB:Mamm:75617 (320-117195-3), NK 32074 L / MSB:Mamm:75618 (320-117195-4), NK 32071 L / MSB:Mamm:75619 (320-117195-5), NK 32039 L / MSB:Mamm:75620 (320-117195-6), NK 10447 L / MSB:Mamm:87701 (320-117195-7), NK 10444 L / MSB:Mamm:87702 (320-117195-8), NK 10442 L / MSB:Mamm:89195 (320-117195-9), NK 10446 L / MSB:Mamm:89187 (320-117195-10), NK 40788 L / MSB:Mamm:89351 (320-117195-11), NK 154469 M / MSB:Mamm:198472 (320-117195-12), NK 180975 L / MSB:Mamm:1268357 (320-117195-13), NK 303127 L / MSB:Mamm:326548 (320-117195-14) and NK 310003 L / MSB:Mamm:339709 (320-117195-15).

Method SHAKE: Insufficient sample volume was available to perform a matrix spike/matrix spike duplicate (MS/MSD) associated with preparation batches 320-818866, 320-818987, 320-819252

Method SHAKE: Elevated reporting limits are provided for the following sample due to limited sample provided for extraction: NK 32079 L / MSB:Mamm:75616 (320-117195-2), NK 32043 L / MSB:Mamm:75617 (320-117195-3), NK 32074 L / MSB:Mamm:75618 (320-117195-4), NK 32071 L / MSB:Mamm:75619 (320-117195-5), NK 32039 L / MSB:Mamm:75620 (320-117195-6) and NK 40788 L / MSB:Mamm:89351 (320-117195-11), Dragonfly wetland / MSB:DGR:3159 (320-117195-18), Cattail N wet / MSB:DGR:3155_1 (320-117195-19), Cattail N wet 2 / MSB:DGR:3155_2 (320-117195-20), and saltceder NE4-4 / MSB:DGR:3156 (320-117195-21).

Method SHAKE: The following samples were discolored following extraction: saltceder NE4-4 / MSB:DGR:3156 (320-117195-21), Marsh fleabane / MSB:DGR:3153 (320-117195-22) and holloman wetland / MSB:DGR:3158 (320-117195-23)

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Detection Summary

Job Notes

This report may not be reproduced except in full, and with written approval from the laboratory. The results relate only to the samples tested. For questions please contact the Project Manager at the e-mail address or telephone number listed on this page.

The test results in this report relate only to the samples as received by the laboratory and will meet all requirements of the methodology, with any exceptions noted. This report shall not be reproduced except in full, without the express written approval of the laboratory. All questions should be directed to the Eurofins Environment Testing Northern California, LLC Project Manager.

Client: University of New Mexico
Project/Site: UNM_PFAS in Tissue, Holloman

Job ID: 320-117199-1

Qualifiers

LCMS

Qualifier	Qualifier Description
*5+	Isotope dilution analyte is outside acceptance limits, high biased.
E	Result exceeded calibration range.
I	Value is EMPC (estimated maximum possible concentration).
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
☼	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Job ID: 320-117199-1 — Eurofins Sacramento

Job Narrative
320-117199-1

Receipt
The samples were received on 11/20/2024 9:40 AM. Unless otherwise noted below, the samples arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was -23.7º C.

Receipt Exceptions
Client emailed a Chain-of-Custody (COC) that was requested to be used for logging in the samples which had some revisions from the original COC shipped with the samples, Because the original COC was not signed at the time samples were relinquished, it was not included in this report.

Collection times were not provided. Samples were logged in with a default time of 00:00.

LCMS
Method B/L/T PFAS: Isotope Dilution Analyte (IDA) recovery is above the method recommended limit for some samples. Quantitation by isotope dilution generally precludes any adverse effect on data quality due to elevated IDA recoveries.

Method B/L/T PFAS: The "I" qualifier means the transition mass ratio for the indicated analyte was outside the established ratio limits. The qualitative identification of the analyte has some degree of uncertainty.

Method B/L/T PFAS: The concentration of one or more analytes associated with the following samples exceeded the instrument calibration range: NK 311147 liver (320-117199-1), NK 311147 (320-117199-2), NK 311147 bone (320-117199-3), NK 311148 liver (320-117199-4), NK 311148 (320-117199-5), NK 311148 bone (320-117199-6), NK 311149 liver (320-117199-7), NK 311149 (320-117199-8), NK 311149 bone (320-117199-9), NK 311150 liver (320-117199-10), NK 311150 (320-117199-11), NK 311152 liver (320-117199-13), NK 311153 (320-117199-15) and NK 311154 liver (320-117199-16) These analytes have been qualified; however, the peak(s) did not saturate the instrument detector. Historical data indicate that for the isotope dilution method, dilution and re-analysis will not produce significantly different results from those reported above the calibration range

Method B/L/T PFAS: Some results for the following samples were reported from the analysis of a diluted extract due to high concentration of the target analyte in the analysis of the undiluted extract. The dilution factor was applied to the labeled internal standard area counts and these area counts were within acceptance limits. NK 311147 liver (320-117199-1), NK 311148 liver (320-117199-4), NK 311149 liver (320-117199-7), NK 311150 liver (320-117199-10), NK 311150 (320-117199-11), NK 311151 (320-117199-12), NK 311152 liver (320-117199-13), NK 311154 liver (320-117199-16) and NK 311154 (320-117199-17)

Method B/L/T PFAS: Some results for the following sample were reported from the analysis of a diluted extract due to high concentration of the target analyte in the analysis of the undiluted extract. The dilution factor was applied to the labeled internal standard area counts and these area counts were outside acceptance limits. The internal standard is not used to quantitate any target analytes; therefore, the data have been reported. NK 311152 (320-117199-14)

Method B/L/T PFAS: The internal standard recovery of 13C2 PFOA was outside control limits in samples NK 311149 liver (320-117199-7) and NK 311150 liver (320-117199-10). Re-analysis confirms the out of control recovery. The internal standard is not used to quantitate any target analytes, therefore, the data have been reported NK 311149 liver (320-117199-7) and NK 311150 liver (320-117199-10)

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Organic Prep
Method SHAKE: Insufficient sample volume was available to perform a matrix spike/matrix spike duplicate (MS/MSD) associated with preparation batch 320-818987.

Method SHAKE: Elevated reporting limits are provided for the following sample due to limited sample provided for extraction: NK 311147 liver (320-117199-1), NK 311147 bone (320-117199-3), NK 311148 liver (320-117199-4), NK 311148 bone (320-117199-6), NK 311149 liver (320-117199-7), NK 311149 bone (320-117199-9), NK 311150 liver (320-117199-10), NK 311152 liver (320-117199-13), NK 311153 (320-117199-15) and NK 311154 liver (320-117199-16).

Method SHAKE: The following samples were discolored following extraction: NK 311147 liver (320-117199-1), NK 311148 liver (320-117199-4) and NK 311150 (320-117199-11).

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Job Notes

This report may not be reproduced except in full, and with written approval from the laboratory. The results relate only to the samples tested. For questions please contact the Project Manager at the e-mail address or telephone number listed on this page.

The test results in this report relate only to the samples as received by the laboratory and will meet all requirements of the methodology, with any exceptions noted. This report shall not be reproduced except in full, without the express written approval of the laboratory. All questions should be directed to the Eurofins Environment Testing Northern California, LLC Project Manager.

Project/Site: UNM_Soil & Snake Skin, Holloman

Qualifiers

LCMS

Qualifier	Qualifier Description
*5+	Isotope dilution analyte is outside acceptance limits, high biased.
4	MS, MSD: The analyte present in the original sample is greater than 4 times the matrix spike concentration; therefore, control limits are not applicable.
E	Result exceeded calibration range.
F1	MS and/or MSD recovery exceeds control limits.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
☼	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Job ID: 320-117252-1 — Eurofins Sacramento

Job Narrative
320-117252-1

Comments
This report contains data for samples requested for PFAS. Data for samples requested for TOC are included in the report for Job 320-117252-2.

Receipt
The samples were received on 11/21/2024 9:25 AM. Unless otherwise noted below, the samples arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was 2.3º C.

Receipt Exceptions
Collection times were not provided. Samples were logged in with a default time of 00:00.

LCMS
Method B/L/T PFAS: Isotope Dilution Analyte (IDA) recovery is above the method recommended limit for some samples. Quantitation by isotope dilution generally precludes any adverse effect on data quality due to elevated IDA recoveries.

Method B/L/T PFAS: The concentration of one or more analytes associated with the following samples exceeded the instrument calibration range: NE-2-200- m (320-117252-5), NE-4-200- m (320-117252-6), (320-117252-A-6-B MS) and (320-117252-A-6-CMSD). These analytes have been qualified; however, the peak(s) did not saturate the instrument detector. Historical data indicate that for the isotope dilution method, dilution and re-analysis will not produce significantly different results from those reported above the calibration range.

Method B/L/T PFAS: Some results for sample C atrox skin (320-117252-7) were reported from the analysis of a diluted extract due to high concentration of the target analyte in the analysis of the undiluted extract. The dilution factor was applied to the labeled internal standard area counts and these area counts were within acceptance limits.

Method B/L/T PFAS: The matrix spike / matrix spike duplicate (MS/MSD) recoveries for preparation batch 320-817586 were outside control limits for one or more analytes. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample (LCS) recovery is within acceptance limits .Due to the high concentration of L-Perfluorohexanesulfonic acid and L-Perfluorooctanesulfonic acid, the MS/MSD could not be evaluated for accuracy and precision for these analytes.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

General Chemistry
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Organic Prep
Method SHAKE: The following samples were discolored following extraction: NE-2-100- m (320-117252-3), NE-4-100- m (320-117252-4), NE-4-200- m (320-117252-6), (320-117252-6 MS) and (320-117252-6 MSD).

Method SHAKE: Insufficient sample volume was available to perform a matrix spike/matrix spike duplicate (MS/MSD) associated with preparation batch 320-819252.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Note: Since laboratory accreditations are subject to change, Eurofins Environment Testing Northern California, LLC places the ownership of method, analyte & accreditation compliance upon our subcontract laboratories. This sample shipment is forwarded under chain-of-custody. If the laboratory does not currently maintain accreditation in the State of Origin listed above for analysis/tests/matrix being analyzed, the samples must be shipped back to the Eurofins Environment Testing Northern California, LLC laboratory or other instructions will be provided. Any changes to accreditation status should be brought to Eurofins Environment Testing Northern California, LLC attention immediately. If all requested accreditations are current to date, return the signed Chain of Custody attesting to said compliance to Eurofins Environment Testing Northern California, LLC.

Job Notes

This report may not be reproduced except in full, and with written approval from the laboratory. The results relate only to the samples tested. For questions please contact the Project Manager at the e-mail address or telephone number listed on this page.

The test results in this report relate only to the samples as received by the laboratory and will meet all requirements of the methodology, with any exceptions noted. This report shall not be reproduced except in full, without the express written approval of the laboratory. All questions should be directed to the Eurofins Environment Testing Northern California, LLC Project Manager.

Project/Site: Holloman Lake PFAS Research

Qualifiers

LCMS

Qualifier	Qualifier Description
*5+	Isotope dilution analyte is outside acceptance limits, high biased.
B	Compound was found in the blank and sample.
E	Result exceeded calibration range.
H	Sample was prepped or analyzed beyond the specified holding time. This does not meet regulatory requirements.
H3	Sample was received and analyzed past holding time. This does not meet regulatory requirements.
I	Value is EMPC (estimated maximum possible concentration).
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
☼	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Job ID: 320-115443-1 — Eurofins Sacramento

Job Narrative
320-115443-1

Receipt
The samples were received on 9/17/2024 9:40 AM. Unless otherwise noted below, the samples arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was -34.2º C.

Receipt Exceptions
The Chain-of-Custody (COC) was incomplete as received and was not signed at the time samples were relinquished to the lab and does not list the requested analyses. Based on communications with the client, the samples were logged in for PFAS by 537 Mod.

The COC and container label for each sample did not include a collection time. Samples were logged with a default time as 00:00.

LCMS
Method B/L/T PFAS: Isotope Dilution Analyte (IDA) recovery is above the method recommended limit for the following samples. Quantitation by isotope dilution generally precludes any adverse effect on data quality due to elevated IDA recoveries. NK284441 liver (320-115443-1), NK284445 liver (320-115443-2), NK284446 liver (320-115443-3), NK284447 liver (320-115443-4), NK284448 liver (320-115443-5), NK284449 liver (320-115443-6), NK284450 liver (320-115443-7), NK284451 liver (320-115443-8), NK284458 liver (320-115443-9), African Rue East Intake (320-115443-11), Saltcedar East Intake (320-115443-12), Saltcedar NE 4-1 (320-115443-13), pickleweed NE 4-1 (320-115443-14), MSBHerp109299 muscle (320-115443-15), MSBHerp109299 liver (320-115443-16), NK319555 muscle (320-115443-17), NK319556 muscle (320-115443-18), NK319556 liver (320-115443-19), MSB89187 femur (320-115443-20), MSB89196 femur (320-115443-23), MSB87701 femur (320-115443-24), MSB87702 femur (320-115443-25), MSB89195 femur (320-115443-26), (MB 320-802924/1-A), (LCS 320-802924/2-A), (LCSD 320-802924/3-A), (MB 320-803280/1-A), (LCS 320-803280/2-A) and (LCSD 320-803280/3-A)

Method B/L/T PFAS: The "I" qualifier means the transition mass ratio for the indicated analyte was outside the established ratio limits. The qualitative identification of the analyte has some degree of uncertainty. However, analyst judgment was used to positively identify the analyte. NK284447 liver (320-115443-4).

Method B/L/T PFAS: Results for the following samples were reported from the analysis of a diluted extract due to high concentration of the target analyte in the analysis of the undiluted extract. The dilution factor was applied to the labeled internal standard area counts and these area counts were within acceptance limits. NK284441 liver (320-115443-1), NK284445 liver (320-115443-2), NK284446 liver (320-115443-3), NK284448 liver (320-115443-5), NK284449 liver (320-115443-6), NK284450 liver (320-115443-7), NK284451 liver (320-115443-8), NK284463 eggshell + contents (320-115443-10), Saltcedar East Intake (320-115443-12), Saltcedar NE 4-1 (320-115443-13), pickleweed NE 4-1 (320-115443-14), MSBHerp109299 muscle (320-115443-15), MSBHerp109299 liver (320-115443-16) and NK319555 muscle (320-115443-17)

Method B/L/T PFAS: The concentration of L-Perfluorooctanesulfonic acid associated with the following sample exceeded the instrument calibration range. The analyte has been qualified (E); however, the peaks did not saturate the instrument detector. The concentration was over calibration range at the laboratory's maximum possible dilution; therefore, no further corrective action was performed and the data have been reported. NK284463 eggshell + contents (320-115443-10)

Method B/L/T PFAS: The method blank for preparation batch 320-802924 had detections of some analytes above the method detection limit (J), but less than the reporting limit (RL); therefore, re-extraction of the associated samples was not performed.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Organic Prep
Method SHAKE: Several samples were received with less than 1 g of material and were processed at reduced mass. The reporting limits (RLs) have been elevated proportionately.

Method SHAKE: The following sample extract contained particulates which clogged the solid phase clean-up column: NK284463 eggshell + contents (320-115443-10).

Method SHAKE: The following samples were discolored following extraction. NK284441 liver (320-115443-1), NK284445 liver (320-115443-2), NK284446 liver (320-115443-3), NK284448 liver (320-115443-5), NK284458 liver (320-115443-9), NK284463 eggshell + contents (320-115443-10), African Rue East Intake (320-115443-11), Saltcedar East Intake (320-115443-12) and Saltcedar NE 4-1 (320-115443-13), pickleweed NE 4-1 (320-115443-14), MSBHerp109299 liver (320-115443-16), NK319555 muscle (320-115443-17), NK319556 liver (320-115443-19), MSB87701 femur (320-115443-24) and MSB87702 femur (320-115443-25).

Job ID: 320-115443-1 (Continued)

Method SHAKE: The following samples were received after the laboratory's default holding time from sample collection to sample preparation had expired: MSB89187 femur (320-115443-20), MSB92667 femur (320-115443-21), MSB61848 femur (320-115443-22), MSB89196 femur (320-115443-23), MSB87701 femur (320-115443-24), MSB87702 femur (320-115443-25), MSB89195 femur (320-115443-26) and MSB61849 femur (320-115443-27)

Method SHAKE: Insufficient sample volume was available to perform a matrix spike/matrix spike duplicate/sample duplicate (MS/MSD/DUP) associated with preparation batches 320-802924 and 320-803280.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Detection Summary

Client: University of New Mexico
Project/Site: Holloman Lake PFAS Research

Job ID: 320-115443-1

Client Sample ID: NK284441 liver — Lab Sample ID: 320-115443-1

Client: University of New Mexico
Project/Site: Holloman Lake PFAS Research

Job ID: 320-115443-1

Client Sample ID: MSB61849 femur

Lab Sample ID: 320-115443-27

No Detections.

This Detection Summary does not include radiochemical test results.

Client: University of New Mexico
Project/Site: Holloman Lake PFAS Research

Job ID: 320-115443-1

Client Sample ID: NK284441 liver
Date Collected: 07/11/24 00:00
Date Received: 09/17/24 09:40

Lab Sample ID: 320-115443-1
Matrix: Tissue

Method: EPA B/L/T PFAS - Branched, Linear and Total PFAS

Analyte	Result	Qualifier	RL	MDL	Unit	D	Prepared	Analyzed	Dil Fac

Job Notes

This report may not be reproduced except in full, and with written approval from the laboratory. The results relate only to the samples tested. For questions please contact the Project Manager at the e-mail address or telephone number listed on this page.

The test results in this report relate only to the samples as received by the laboratory and will meet all requirements of the methodology, with any exceptions noted. This report shall not be reproduced except in full, without the express written approval of the laboratory. All questions should be directed to the Eurofins Environment Testing Northern California, LLC Project Manager.

Project/Site: UNM_PFAS in Tissue, Holloman

Qualifiers

LCMS

Qualifier	Qualifier Description
*1	LCS/LCSD RPD exceeds control limits.
*5-	Isotope dilution analyte is outside acceptance limits, low biased.
*5+	Isotope dilution analyte is outside acceptance limits, high biased.
E	Result exceeded calibration range.
I	Value is EMPC (estimated maximum possible concentration).
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
☼	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Job Narrative
320-117508-1

Receipt
The samples were received on 12/5/2024 9:35 AM. Unless otherwise noted below, the samples arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was -12.3º C.

Receipt Exceptions
Collection times were not provided. Samples were logged in with a default time of 00:00.

The sample ID listed on the container label for the following sample did not match the information listed on the Chain-of-Custody (COC). The ID on the container was "NK283664" but the COC has "NK283644". The rest of the ID did match. The sample was logged in based on the COC. NK283644, S. clypeata, Liver, MSB1011744, P48 (320-117508-45)

LCMS
Method B/L/T PFAS: Isotope Dilution Analyte (IDA) recovery is above the method recommended limit for all samples. Quantitation by isotope dilution generally precludes any adverse effect on data quality due to elevated IDA recoveries.

Method B/L/T PFAS: Isotope Dilution Analyte (IDA) recovery associated with the following sample is below the method recommended limit: NK35935, MSB39605, P17 (320-117508-16). Generally, data quality is not considered affected if the signal-to-noise ratio is greater than 10:1, which is achieved for all IDA in the sample(s).

Method B/L/T PFAS: The "I" qualifier means the transition mass ratio for the indicated analyte was outside the established ratio limits. The qualitative identification of the analyte has some degree of uncertainty.

Method B/L/T PFAS: Internal standard (ISTD) response for sample NK35811, MSB30651, P8 (320-117508-8) in analytical batch 320-821391 was outside acceptance criteria. The internal standard is not used to quantitate any target analytes, therefore, the data have been reported

Method B/L/T PFAS: The concentration of one or more analytes associated with multiple samples exceeded the instrument calibration range. These analytes have been qualified (E); however, the peak(s) did not saturate the instrument detector. Historical data indicate that for the isotope dilution method, dilution and re-analysis will not produce significantly different results from those reported above the calibration range.

Method B/L/T PFAS: Some results for multiple samples were reported from the analysis of a diluted extract due to high concentration of the target analyte in the analysis of the undiluted extract. The dilution factor was applied to the labeled internal standard area counts and these area counts were within acceptance limits.

Method B/L/T PFAS: One or more continuing calibration verification (CCV) aliquots associated with analytical batches 320-820819 and 320-821645 recovered above the upper control limit for 8:2 FTS. The client samples associated with these CCVs were non-detect for the affected analyte; therefore, the data have been reported.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Organic Prep
Method SHAKE: Insufficient sample volume was available to perform a matrix spike/matrix spike duplicate (MS/MSD) associated with preparation batches 320-820080, 320-820824 and 320-820977.

Method SHAKE: Elevated reporting limits are provided for the following samples due to limited sample provided for extraction: Pool 25, Duck PFAS, P25 (320-117508-23), NK282630, MSB50169, P26 (320-117508-24), NK276851, MSB46239, P28 (320-117508-25), NK276660, MSB45963, P30 (320-117508-27), NK282696, MSB50223, P31 (320-117508-28) and NK283629, S. calypteata, Liver, MSB1011446, P44 (320-117508-41).

Method SHAKE: The following samples were discolored prior to and/or following extraction: NK14474, MSB18488, Pool1, P1 (320-117508-1), NK9098, Liver, P2 (320-117508-2), NK2445, Liver, AFP7B, P3 (320-117508-3), NK2444, Liver, AFP7A, P4 (320-117508-4), NK35660, MSB29117, P5 (320-117508-5), NK35661, MSB29140, P6 (320-117508-6), NK35655, MSB29134, P7 (320-117508-7), NK35811, MSB30651, P8 (320-117508-8), NK35643, MSB29100, P9 (320-117508-9), NK170946, P10 (320-117508-10), NK165232, MSB26431, P12 (320-117508-12), NK100328, Liver, AEPIR, P11 (320-117508-11), NK35676, MSB29118, P14 (320-117508-13), NK35678, MSB29131, P15 (320-117508-14), NK35669, MSB29093, P16 (320-117508-15), NK35935, MSB39605, P17 (320-117508-16), NK35958, MSB40165, P18 (320-117508-17), NK35816, MSB30670, P19 (320-117508-18), NK35804, MSB30716, P20 (320-117508-19), NK35876, MSB39746, P22 (320-117508-20), NK35910, MSB39349, P23(320-117508-21), NK282630, MSB50169, P26 (320-117508-24), NK282547, MSB49842, P29 (320-117508-26),

Job ID: 320-117508-1 (Continued)

Geologic Associates, Inc.
6020 Academy Road NE, Sui
ALBUQUERQUE, NM 87109

Received: 07/11/24
Reported: 08/13/24
Final Report

NECROPSY

The carcass presented for postmortem examination was an adult, 76 grams, male, *Charadrius vociferus* (killdeer) identified as "NK284442". The bird was in good body condition with minimal postmortem decomposition. The liver mass was 2.02 grams. The combined kidney mass was 0.75 grams. The testicles were 0.06 centimeters x 0.04 centimeters. There were no significant lesions in the trachea, esophagus, lungs, airsacs, heart, liver, spleen, proventriculus, ventriculus, small intestine, large intestine, pancreas, testicles, kidneys, skeletal muscle, or brain.

HISTOPATHOLOGY

There are rare perivascular infiltrates of small numbers of lymphocytes and plasma cells in the lung.

There are small numbers of perivascular infiltrates of small numbers of lymphocytes, plasma cells, and macrophages in the portal areas of the liver.

The lumen of the proventriculus contains two small degenerate helminths.

There are no significant microscopic lesions in the trachea, esophagus, thyroid tissue, heart, skeletal muscle, spleen, kidneys, ventriculus, small intestine, large intestine, pancreas, adrenal glands, testicles, or brain.

FINAL COMMENTS

The changes in the organs (mild perivascular inflammation in the lung and liver and endoparasitism in the proventriculus) are background lesions and likely of no clinical significance. There is no evidence of an infectious disease, neoplasia, or toxicosis.

Reported: 08/13/24
Final Report

NECROPSY

The carcass presented for postmortem examination was an adult, 322 grams, male, *Recurvirostra americana* (American avocet) identified as "NK284443". The bird was in good body condition with minimal postmortem decomposition. The bird had been gunshot. The liver mass was 9.12 grams. The combined kidney mass was 2.9 grams. The testicles were 0.07 centimeters x 0.03 centimeters. The lumen of the small intestine contained at least one adult cestode (tapeworm). There were no significant lesions in the trachea, esophagus, lungs, airsacs, heart, liver, spleen, proventriculus, ventriculus, large intestine, pancreas, testicles, kidneys, skeletal muscle, or brain.

HISTOPATHOLOGY

The portal areas of the liver contain small numbers of lymphocytes and plasma cells.

The myofibers of the heart contain moderate amounts of perinuclear golden-brown pigment consistent with lipofuscin in the cytoplasm. There are rare perivascular infiltrates of small numbers of lymphocytes in the myocardium.

There are small numbers of myofibers in the skeletal muscle that contain small amounts of perimembrane golden-brown pigment consistent with lipofuscin in the cytoplasm. There are rare perivascular infiltrates of small numbers of lymphocytes.

The interstitium of the testicles contain infiltrates of moderate numbers of lymphocytes with lesser numbers of plasma cells and macrophages. The lymphocytes often extend into the seminiferous tubules where there is degeneration and necrosis of the spermatogenic epithelium and Sertoli cells and almost a complete absence of spermatozoa production.

The lumen of the small intestine contains an adult cestode (tapeworm). The lamina propria of the mucosal epithelium of the large intestine contains numerous lymphocytes, eosinophils, and lesser numbers of plasma cells. The mesentery contains perivascular infiltrates of moderate numbers of lymphocytes and plasma cells.

There are perivascular infiltrates of moderate numbers of lymphocytes and plasma cells on the serosa of the proventriculus.

There are perivascular infiltrates of moderate numbers of lymphocytes and plasma cells in the fat adjacent to the spleen.

The mucosal epithelium and submucosa of the ventriculus contain multiple eosinophilic granulomas characterized by a brightly eosinophilic center of necrotic debris surrounded by macrophages, multinucleated giant cells, eosinophils and small numbers of lymphocytes. One eosinophilic granuloma contains a degenerate nematode. There are large numbers of eosinophils in the lamina propria of the ventriculus. There are rare tangential segments of larval rhabditiform nematodes in the mucosal epithelium of the ventriculus one of which is associated with a large brightly eosinophilic focus of necrosis. The koilin layer contains small numbers of degenerate nematodes.

There are no significant microscopic lesions in the lung, trachea, esophagus, thymus, spleen, kidneys, large intestine, pancreas, adrenal glands, or brain.

FINAL COMMENTS

Most of the lesions in this bird are inflammatory lesions associated with endoparasitism in the small intestine and ventriculus. The inflammation in the mesentery, fat adjacent to the spleen, and in the liver are likely in response to endoparasitism. The bird has lipofuscin in the heart and skeletal muscle. Lipofuscin is considered a "wear-and-tear" pigment that accumulates as an animal ages. It is most commonly seen microscopically in older animals.

The bird also has moderate to severe lymphocytic orchitis (inflammation of the testicles) the cause of which could not be determined. There is degeneration and necrosis of the spermatogenic epithelium and Sertoli cells with almost complete absence of spermatozoa production associated with the orchitis. The orchitis is likely a sporadic event that only occurred in this bird.

Final Report

NECROPSY

The carcass presented for postmortem examination was an adult, 37 grams, female, *Agelaius phoeniceus* (red-winged blackbird) identified as "NK284441". The bird was in good body condition with minimal postmortem decomposition. The liver mass was 1.33 grams. The combined kidney mass was 0.41 grams. The ovary was 0.06 centimeters x 0.04 centimeters with the largest ovum having a diameter of 0.015 centimeters. There were no significant lesions in the trachea, esophagus, lungs, airsacs, heart, liver, spleen, proventriculus, ventriculus, small intestine, large intestine, pancreas, testicles, kidneys, skeletal muscle, or brain.

HISTOPATHOLOGY

There are no significant microscopic lesions in the lung, trachea, esophagus, thyroid tissue, heart, liver, spleen, proventriculus, ventriculus, small intestine, large intestine, pancreas, ovary, oviduct, kidney, adrenal glands, skeletal muscle, or brain.

FINAL COMMENTS

There was no evidence of infectious disease, neoplasia, parasitism, or toxicosis.

NECROPSY

The carcass presented for postmortem examination was an adult, 38 grams, female, *Agelaius phoeniceus* (red-winged blackbird) identified as "NK284445". The bird was in good body condition with minimal postmortem decomposition. The liver mass was 1.16 grams. The combined kidney mass was 0.51 grams. The ovary was 0.12 centimeters x 0.04 centimeters with largest ovum having a diameter of 0.015 centimeters. There were no significant lesions in the trachea, esophagus, lungs, airsacs, heart, liver, spleen, proventriculus, ventriculus, small intestine, large intestine, pancreas, testicles, kidneys, skeletal muscle, or brain.

HISTOPATHOLOGY

There are no significant microscopic lesions in the lung, trachea, esophagus, heart, liver, spleen, kidneys, adrenal glands, proventriculus, ventriculus, small intestine, large intestine, pancreas, ovary, oviduct, skeletal muscle, or brain.

FINAL COMMENTS

There is no evidence of an infectious disease, neoplasia, parasitism, or toxicosis.

ALBUQUERQUE, NM 87109

Received: 07/11/24
Reported: 08/13/24
Final Report

NECROPSY

The carcass presented for postmortem examination was an adult, 31 grams, female, *Tyrannus verticalis* (western kingbird) identified as "NK284447". The bird was in good body condition with minimal postmortem decomposition. The liver mass was 0.92 grams. The combined kidney mass was 0.45 grams. The ovary was 0.08 centimeters x 0.04 centimeters with the largest ovum having a diameter of 0.05 centimeters. There was an approximately 5 cm long thin white nematode in the right abdominal airsac. There were no significant lesions in the trachea, esophagus, lungs, heart, liver, spleen, proventriculus, ventriculus, small intestine, large intestine, pancreas, testicles, kidneys, skeletal muscle, or brain.

HISTOPATHOLOGY

The portal vein adjacent to the liver contains paired adult (female and male) flukes. The flukes are surrounded by fibrin and macrophages. There are small numbers or portal areas in the liver that contain flukes eggs surrounded by variable numbers of macrophages mixed with lesser numbers of lymphocytes and eosinophils. There are also small numbers of filamentous bacteria surrounded by and within the cytoplasm of macrophages in one portal area.

The lumen of the small intestine contained a cross-section of a single small nematode.

The kidneys contain small numbers of interstitial infiltrates of macrophages and lymphocytes that widely separate the tubules.

There are no significant microscopic lesions in the trachea, esophagus, lungs, heart, spleen, ovary, oviduct, proventriculus, ventriculus, large intestine, pancreas, skeletal muscle, or brain.

FINAL COMMENTS

The bird had an airsac nematode, nematodes in the small intestine (endoparasitism), and flukes within the portal vein (avian schistosomiasis). The mild lymphohistiocytic interstitial nephritis could have been the result of parasite migration through a kidney. There was no evidence of an infectious disease, neoplasia, or toxicosis.

CASE DIAGNOSIS

NEPHRITIS - INTERSTITIAL
PARASITISM - HELMINTH

Geologic Associates, Inc.
6020 Academy Road NE, Sui
ALBUQUERQUE, NM 87109

Received: 07/11/24
Reported: 08/13/24
Final Report

NECROPSY

The carcass presented for postmortem examination was an adult, 10 grams, male, *Geothlypis trichas* (common yellowthroat) identified as "NK284451". The bird was in good body condition with minimal postmortem decomposition. The liver mass was 0.27 grams. The combined kidney mass was 0.08 grams. The testicles were 0.09 centimeters x 0.06 centimeters. The pectoral muscles contained numerous approximately 0.4 cm x 0.1 cm white oblong foci with smaller numbers of similar foci in skeletal muscle throughout the body. There were no significant lesions in the trachea, esophagus, lungs, airsacs, heart, liver, spleen, proventriculus, ventriculus, small intestine, large intestine, pancreas, testicles, kidneys, or brain.

HISTOPATHOLOGY

The skeletal muscle contains multiple large ovoid protozoal cysts that measure up to 5,116 um x 1,387 um within an individual myofiber. The cysts contained numerous approximately 10 um long bradyzoites.

The dorsal aspect of a cerebral hemisphere has a small focus of perivascular to diffuse infiltrates of small numbers of microglia, lymphocytes, and rare hemosiderin-laden macrophages.

There are no significant microscopic lesions in the trachea, esophagus, lung, heart, liver, proventriculus, ventriculus, small intestine, large intestine, pancreas, kidneys, adrenal gland, or testicles.

FINAL COMMENTS

The bird had embedded *Sarcocystis* species protozoal cysts in the skeletal muscle (sarcocystosis, rice breast disease). It also had a small focus of nonsuppurative encephalitis that was likely associated with prior trauma to the area. The hemosiderin within macrophages in the focus indicates previous hemorrhage in the area. There were no other lesions to indicate an infectious disease, neoplasia, or toxicosis.

CASE DIAGNOSIS

SARCOCYSTIS
ENCEPHALITIS - NONSUPPURATIVE
PARASITISM - PROTOZOAN

Reported: 08/13/24
Final Report

NECROPSY

The carcass presented for postmortem examination was an adult, 34 grams, male, *Tyrannus verticalis* (western kingbird) identified as "NK284448". The bird was in good body condition with minimal postmortem decomposition. The liver mass was 1.09 grams. The combined kidney mass was 0.50 grams. The testicles were 0.06 centimeters x 0.03 centimeters. There were no significant lesions in the trachea, esophagus, lungs, airsacs, heart, liver, spleen, proventriculus, ventriculus, small intestine, large intestine, pancreas, testicles, kidneys, skeletal muscle, or brain.

HISTOPATHOLOGY

The seminiferous tubules in the right and left testicles are shrunken and separated by a relative increased amount of interstitium. The seminiferous tubules are lined by a thin layer of mostly Sertoli cells with a few spermatogenic epithelial cells. There is no spermatozoa production in the seminiferous tubules or spermatozoa in the epididymis.

The lumen of the small intestine contains an adult cestode (tapeworm).

There are no significant microscopic lesions in the trachea, esophagus, lungs, heart, liver, spleen, kidneys, proventriculus, ventriculus, large intestine, pancreas, skeletal muscle, or brain.

FINAL COMMENTS

The bird had testicular atrophy that was most likely due to seasonal atrophy/testicular inactivity. However, comparison of the testicles of other adult male western kingbirds in mid-July would be necessary to confirm that suspicion. The bird also had an adult tapeworm in the small intestine. There was no evidence of an infectious disease, neoplasia, or toxicosis.

NECROPSY

The carcass presented for postmortem examination was an adult, 37 grams, female, *Agelaius phoeniceus* (red-winged blackbird) identified as "NK284446". The bird was in good body condition with minimal postmortem decomposition. The liver mass was 1.30 grams. The combined kidney mass was 0.44 grams. The ovary was 0.06 centimeters x 0.04 centimeters with the largest ovum have a diameter of 0.015 centimeters. There were no significant lesions in the trachea, esophagus, lungs, airsacs, heart, liver, spleen, proventriculus, ventriculus, small intestine, large intestine, pancreas, testicles, kidneys, skeletal muscle, or brain.

HISTOPATHOLOGY

The liver contains a few portal areas that contain infiltrates of small numbers lymphocytes, macrophages and plasma cells.

There are no significant microscopic lesions in the trachea, esophagus, lungs, heart, spleen, kidneys, adrenal glands, ovary, oviduct, proventriculus, ventriculus, small intestine, large intestine, pancreas, skeletal muscle, or brain.

FINAL COMMENTS

The bird had very mild inflammation in the portal areas of the liver. This is common in many species, including domestic species, and is not clinically significant. There is no evidence of infectious disease, parasitism, neoplasia, or toxicosis.

Final Report

CASE HISTORY

Specimen collected at Holloman Lake in Otero County, New Mexico. High exposure to PFAS very likely based on recent published research. Goal of necropsy is to document pathology related to PFAS at the organ and tissue levels. Specimens should be returned to UNM MSB and 1g of muscle tissue needed for PFAS screening.

NECROPSY

This is the body of a 44 g, adult, male, *Dipodomys merriami* , with minimal autolysis (necropsy performed within hours of death). The liver weighs 1.5 g, and the kidneys both weigh 0.5 g. All organs are within normal limits grossly.

HISTOPATHOLOGY

1. and 2. Brain: Multiple levels of brain are examined. There are no significant findings.
3. Heart: There are no significant findings.
Trachea: There are no significant findings.
Esophagus: There are no significant findings.
Thyroid: There are no significant findings.
4. Trachea: There are no significant findings
Esophagus: There are no significant findings
Lung: There is diffuse vascular congestion. There are multifocal to coalescing areas of mild to moderate acute hemorrhage within alveolar spaces.
5. Liver: There is diffuse vascular congestion. There is mild intracytoplasmic vacuolation of hepatocytes; vacuoles are clear and indistinct (normal for post-prandial mouse).
6. Kidney: There is diffuse vascular congestion.
Liver: There are no new findings.
7. Pancreas: There are no significant findings.
Spleen: There are no significant findings
Favor urinary bladder: Portions of the mucosa appear sloughed (post-mortem change).
Adrenal gland- There are no significant findings.
Fat: There are no significant findings.
8. Stomach: There are no significant findings.
Small intestine: There are no significant findings.
Pancreas: There are no significant findings.
Large intestine: There are no significant findings.
9. Testicle: There are no significant findings.
Eye: There are no significant findings.
Skin: There are no significant findings.
Pancreas: There are no significant findings.
Small intestine: There are no significant findings.
10. Bone marrow (femur, ribs), bone, and surrounding skeletal muscle: There are no significant findings.

FINAL COMMENTS

****Please see addendum below ****

There were no significant findings in this animal on gross necropsy or microscopic exam. The acute hemorrhage in the lungs is interpreted as agonal or perimortem trauma. *Francisella tularensis* and *Yersinia pestis* were not cultured from this animal. PFAS analysis is pending.

Note: For thoroughness, I am seeking the opinions of other pathologists on the liver and adrenals in this case. When completed, the results will be included in an addendum.

ADDENDA COMMENTS

Addendum 06/20/24: The slides with liver and adrenals were shared with Dr. Donna Kusewitt for a formal consult. Dr. John Ragsdale also consulted on the liver, informally. I have copied Dr. Kusewitt's complete assessment below, including her interpretations. Note:

Some of the slides also had other organs, and she commented on them, as well.

In summary, Dr. Kusewitt notes the presence of occasional, small aggregates of enlarged hepatocytes. She notes that these are called "altered foci", and are not unusual -at least in *Mus musculus* – and can increase with age and exposure to some carcinogens. She thinks the liver vacuolation is within normal limits for a non-fasted mouse. Dr. Ragsdale thought that, while the liver vacuolation could be within normal limits for a post-prandial mouse, and he wouldn't call it a toxic hepatopathy, he can't rule out the vacuolation isn't due to a xenobiotic.

Overall, while the "altered foci" described above may just be a non-specific, age related change, and we cannot attribute them to PFAS with the informatino we have, this may be a change worth exploring in future animals.

PFAS analysis is pending for this animal.

Dr. Kusewitt's assessment:

Case Number: V24 15155 (Slides 5 and 7)
Animal Number: NK 311130
Species: *Dipodomys merriami*
Sex: Male

Organ: Liver
Post mortem condition: Good
Observations: Hepatic lobules are not as well-defined as in some other rodent species. There is moderate, diffuse vacuolation of hepatocytes; vacuoles are ragged. This vacuolar change is interpreted as glycogen accumulation. There is mild variation in the size of hepatocyte nuclei and small numbers of binucleate hepatocytes are present. At a few sites on the surface of the liver there are small poorly defined aggregates of enlarged hepatocytes. There is a single small focus of lymphocytes adjacent to a central vein. There is no evidence of neoplasia or infectious disease.

Organ: Pancreas
Post mortem condition: Good
Observations: Acini and islets are easily identified. There is no evidence of neoplasia or inflammation.

Organ: Spleen

Post mortem condition: Good
Observations: The spleen is somewhat contracted, as evidence by pleating of the organ capsule. Multiple lymphoid follicles are present; active germinal centers are not seen. In the centers of many follicles there are small aggregates of amorphous eosinophilic material interpreted as amyloid. Little evidence of extramedullary hematopoiesis is seen. There is no evidence of neoplasia or inflammation.

Organ: Urinary bladder
Post mortem condition: Moderate autolysis
Observations: The bladder is distended. No calculi are seen within the bladder and there is no evidence of neoplasia or inflammation.

Organ: Adrenals
Post mortem condition: Good
Observations: The adrenal surfaces are smooth. All layers of the cortices are present and symmetrical. The medullae are unexceptional. A muscular artery and ganglion adjacent to one adrenal are normal in appearance. There is no evidence of neoplasia or inflammation.

Interpretation: Liver vacuolation is within normal limits for an animal that is not fasting. Variation in the size of liver nuclei and the presence of binucleate hepatocytes are typical of rodents. The presence of lymphocytes adjacent to a blood vessel is considered an incidental finding. Foci of enlarged hepatocytes are called "altered foci" and are not an unusual finding at least in Mus musculus, and increase in number with age and with exposure to some carcinogens.

The low level of extramedullary hematopoiesis in the red pulp of the spleen indicates that the animal was not anemic. The absence of prominent germinal follicles in the white pulp suggests the absence of any marked antigenic stimulus. Amyloid within the spleen is not an unusual finding in the spleens of some species.

Pancreas, urinary bladder, and adrenals show no evidence of pathologic processes.

CASE HISTORY

Specimen collected at Holloman Lake in Otero County, New Mexico. High exposure to PFAS very likely based on recent published research. Goal of necropsy is to document pathology related to PFAS at the organ and tissue levels. Specimens should be returned to UNM MSB and 1g of muscle tissue needed for PFAS screening.

NECROPSY

This is the body of a 19 g, adult, male, *Peromyscus leucopus* . The liver weighs between 1 g and 1.5 g. The kidneys both weigh less than 0.5 g. There are no significant gross findings.

HISTOPATHOLOGY

1. Brain: There are no significant findings.
2. Tongue: In the skeletal muscle, there is a foreign material (plant matter) surrounded by a focal aggregate of macrophages, polymorphonuclear cells, with occasional multinucleated cells, lymphocytes, and plasma cells. There are occasional intracytoplasmic protozoal cysts (sarcocysts), with no associated inflammation.
Esophagus: In the submucosa, there is foreign material (plant matter) surrounded by a focal aggregate of macrophages, polymorphonuclear cells, with occasional multinucleated cells.
Thyroid: There are no significant findings.
Trachea: There is hemorrhage in the lumen, with no lesions in the mucosa or surrounding tissue (agonal or from the lungs).
Fat: There are no significant findings.
Heart: There are no significant findings.
Lungs: There is diffuse congestion and variable atelectasis.
Salivary gland: There are no significant findings.
3. Lungs: There are changes as described above. In addition, there are occasional areas of mild hemorrhage in the alveolar spaces. There are occasional interstitial aggregates of macrophages, polymorphonuclear cells, lymphocytes and plasma cells.
Heart: There are no significant findings.
Esophagus: There are no significant findings.
4. Liver: There is diffuse vascular congestion. There are occasional granulomas within the parenchyma, and one has an intralesional fluke. There are occasional pigment granulomas.
5. Kidney: There are rare aggregates of lymphocytes in the renal pelvis.
Liver : There are no new findings.
6. Pancreas: There are no significant findings.
Liver: There are no new findings.
Adrenal gland: There are no significant findings.
Spleen: Lymphoid follicles in the white pulp are expanded, and occasionally coalesce. There are mixed small mature lymphocytes, lymphoblasts, and macrophages, in these areas.
Bone marrow: There are no significant findings.
7. Stomach: There are no significant findings.
Pancreas: There are no significant findings.
Lymphoid tissue: Adjacent to the pancreas, is lymphoid tissue with germinal centers and sheets of plasma cells, lymphocytes, and macrophages.
Small intestine: There is moderate to severe autolysis of the mucosa. There are no overt significant findings.
8. Skin: There are occasional sarcocysts within underlying skeletal muscle.
Eye: There are no significant findings.
9. Testicle: There are no significant findings.
Urinary bladder: There are no significant findings.
10. Bone marrow, bone, and surrounding skeletal muscle: There are occasional sarcocysts within the skeletal muscle. There are no other significant findings.

FINAL COMMENTS

****Please note addendum below****

There are multiple inflammatory changes in this mouse, attributable to either foreign material (tongue and esophagus), parasites (liver), or other causes (lung). The inflammation in the lung is chronic and mild, and although the exact cause was not seen

histologically, I suspect it may be parasitic, or potentially environmental irritation (eg inorganic dust), but the exact cause is unknown. The mild hemorrhage is interpreted as agonal or perimortem trauma. The cause of the lymphoid hyperplasia in the spleen is not clear, but is likely due to chronic antigenic stimulus.

Regarding PFAS – While the exact cause of the inflammation in the lungs and hyperplasia in the spleen is not clear, I lean towards them not being related to PFAS. The changes documented in the peer-reviewed literature in the spleen are of atrophy, not hypertrophy of lymphoid cells.

Francisella tularensis and *Yersinia pestis* were not cultured from this animal. PFAS analysis is pending.

Note: For thoroughness, I am seeking the opinions of other pathologists in this case. When completed, the results will be included in an addendum.

Guo, H. (2021) Perfluorooctanoic acid (PFOA) exposure induces splenic atrophy via overactivation of macrophages in male mice, Journal of Hazardous Materials, Volume 407, 2021

Diagnoses

Tongue: Focal granulomatous glossitis with intralesional foreign material (plant material)
Liver: Mild to moderate, granulomatous hepatitis with intralesional trematodes
Spleen: Lymphofollicular hyperplasia
Lung: 1) Mild, chronic, interstitial pneumonia; 2) Mild acute hemorrhage (perimortem change)

Esophagus: Focal granulomatous esophagitis with intralesional foregin material (plant material)

ADDENDA COMMENTS

Addendum 06/20/24: The slides with liver and adrenals were shared with Dr. Donna Kusewitt for a formal consult. Dr. John Ragsdale also assessed a few of the slides, informally. I have copied Dr. Kusewitt's complete assessment below, including her interpretations. Note: Some of the slides also had other organs, and she commented on them, as well.

I note that in the cuts of tissue present on her slides, the liver flukes were not present – I saw them in the original slides, and Dr. Ragsdale agreed with this interpretation. Thus, the inflammation in the liver is interpreted as secondary to these parasites. He also noted a cestode within a lymph node adjacent to the pancreas.

PFAS analysis is pending for this animal.

Dr. Kusewitt's assessment:
Case Number: V24-15156 (Slides 4 and 6)
Animal Number: NK311134
Species: *Peromyscus leucopus*
Sex: Male

Organ: Liver
Post mortem condition: Good
Observations: Hepatic lobules are clearly defined. Most hepatocytes contain few vacuoles, although around some central veins there are small numbers of hepatocytes with clear vacuoles in the cytoplasm. These vacuoles are interpreted as fat droplets. Many hepatocytes throughout the hepatic lobules contain small amounts of finely granular brown pigment interpreted as bile. There is moderate variation in the size of hepatocyte nuclei and small numbers of binucleate hepatocytes are present. The hepatic parenchyma contains two granulomas of moderate size. Each granuloma is characterized by a central aggregate of macrophages, some of which have multiple nuclei, surrounded by a rim of lymphoid cells. No microorganisms are evident within granulomas. In one granuloma, many macrophages contain bile pigment. Small aggregates of lymphoid cells lie adjacent to a few bile ducts and one blood vessel. There is no evidence of neoplasia.

Organ: Spleen
Post mortem condition: Good
Observations: The spleen contains multiple lymphoid follicles, many of which have prominent germinal centers. The red pulp contains numerous cells of the erythropoietic series. There is no evidence of neoplasia.

Organ: Pancreas
Post mortem condition: Mild autolysis
Observations: Acini and islets are readily distinguished. There is no evidence of inflammation or neoplasia.

Organ: Adrenal
Post mortem condition: Good
Observations: The adrenal surface is smooth. All layers of the cortex are present and symmetrical. The medulla is unexceptional. There is no evidence of neoplasia or inflammation.

Organ: Bone marrow
Post mortem condition: Good

Observations: A small sample of bone marrow is present. The marrow is highly cellular and contains cells of all hematopoietic series. There is no evidence of neoplasia.

Interpretation: Liver vacuolation in rodents is highly variable, depending on the feeding status. In the present case, the extent and pattern of vacuolation are within normal limits. Variation in the size of liver nuclei and the presence of binucleate hepatocytes are typical of rodents. The liver granulomas do not appear to be associated with an infectious organism; their etiology is unclear. The cause of the bile droplet accumulation within hepatocytes is not apparent. The presence of lymphocytes adjacent to a few bile ducts and a blood vessel is considered an incidental finding.

The presence of prominent germinal centers in splenic white pulp suggests antigenic stimulation. Marked erythropoiesis in the splenic red pulp is consistent with response to anemia.

Pancreas, adrenal, and bone marrow show no evidence of pathologic processes.

CASE HISTORY

Specimen collected at Holloman Lake in Otero County, New Mexico. High exposure to PFAS very likely based on recent published research. Goal of necropsy is to document pathology related to PFAS at the organ and tissue levels. Specimens should be returned to UNM MSB and 1g of muscle tissue needed for PFAS screening.

NECROPSY

This is the body of a 27.5 g, male, adult, *Peromyscus maniculatus*, with minimal autolysis (necropsied within hours of death). The liver weighs 1.5 g, and an enhanced reticular pattern is seen diffusely. The kidneys both weigh less than 0.5 g. The adrenal glands are symmetrical, but appear subjectively enlarged. The stomach is distended by ingested food.

HISTOPATHOLOGY

1. and 2. Brain: Multiple sections of brain are examined. There are no significant findings.
3. Esophagus: There are occasional intracytoplasmic protozoal cysts (sarcocysts) within skeletal muscle fibers in the wall of the esophagus, with no associated inflammation.
Trachea: There are no significant findings.
Thyroid: There are no significant findings.
Brain: There are no significant findings.
Brown fat: There are no significant findings.
Peripheral nerve: There are no significant findings.
4. Heart: There are no significant findings.
Lung: There are multifocal to coalescing areas of mild to moderate hemorrhage within alveolar spaces, occasionally disrupting alveolar septa; this affects approximately 15% of the pulmonary parenchyma in examined sections.
Trachea: There are no significant findings.
Esophagus: There are no significant findings.
5. and 6. Liver: There is diffuse vascular congestion.
7. Adrenal gland: There is diffuse hypertrophy of adrenocortical cells, with severe anisocytosis and anisokaryosis of adrenal cortical cells (zona fasciculata, potentially reticularis), and occasional multinucleation.
Kidney: There are no significant findings.
Spleen: There are no significant findings.
Pancreas: There are no significant findings.
8. Testicles: There are no significant findings.
Eye: There are no significant findings.
Skin: There are no significant findings.
9. Small intestine: Some sections have moderate to severe autolysis of the mucosa. There are no overt significant findings.
Large intestine: There are no overt significant findings.
Stomach: There are no significant findings.
Pancreas: There are no significant findings.
10. Bone marrow, bone, and surrounding skeletal muscle (femur and ribs): There are no significant findings

FINAL COMMENTS

****Please see addendum****

The findings with the most potential for significance in this case are in the adrenal gland, however, the exact significance of the findings is unclear. The adrenal glands were subjectively enlarged on gross necropsy, and, on microscopic exam, in the adrenal cortex, there were changes most consistent with hypertrophy (enlarged cells), with anisocytosis (differing cell size), anisokaryosis (differing nuclear size), and there were multinucleated cells. The portion of the cortex involved is the zona fasciculata, and potentially the zona reticularis (the zona reticularis is not delineated in mice on routine histology). The zona fasciculata secretes glucocorticoids – hormones involved in the stress response.

I shared this case with Dr. John Ragsdale. As far as we are aware, these changes are not normal findings in the mouse adrenal gland. However, I note that most of what is documented in the adrenal gland is from laboratory or captive mice. I am hestitant to say that these changes are definitively abnormal in a wild *Peromyscus maniculatus* without more information (eg could this be some kind of seasonal change?) I have ordered an article via interlibrary loan that details the adrenal gland in a wild mouse of the same

genus (*Peromyscus leucopus* - Costa 1968) – results will be released in an addendum.

Again, the exact diagnosis and significance of these change are not clear, but, using guidelines from the International Harmonization of Nomenclature and Diagnostic Criteria for Lesions in Rats and Mice, the changes are most consistent with diffuse cortical hypertrophy of the adrenal gland (Brändli-Baiocco et al. 2018). I note that the anisocytosis, anisokaryosis, and multinucleation seen in this case are not described in the context of hypertrophy in these guidelines. Diffuse adrenocortical hypertrophy is typically caused by increased ACTH – either due to stress or disease, or exogenously administered ACTH (Brändli-Baiocco et al. 2018). This guide notes that xenobiotics that inhibit steroid synthesis can cause hypertrophy, but typically they also cause increased vacuolation – I do not see overtly increased vacuolation in this case. Again, I am not sure if this is a normal change for a wild mouse of this genus and species, and hopefully the abovementioned paper will provide additional information.

Regarding potential links to PFAS - Without controlled studies detailing similar changes in mice, it is difficult to assign underlying cause to this change in the adrenal cortex. While I cannot say it is due to PFAS, at this time, I cannot rule out that it is due to PFAS. A brief literature review finds that various PFAS have been found to affect the production of glucocorticoids (Ying Y, et al. 2024; Pereiro, N et al. 2014; Pötzl B, et al 2024), and while some describe the general thickening of the zona fasciculata, I did not find any studies detailing the microscopic changes seen here. Note: I have one of these articles on ILL regarding morphologic changes, but I do not expect the changes to be similar to those seen here based on the abstract. I would also want to make sure muscle sampled from this animal had elevated PFAS (elevated PFAS are expected based on environmental levels).

If you are interested, I think it would be helpful to submit the slide with the adrenal gland to a veterinary pathologist with specialization in toxicology pathology and mice– please let me know if you are interested in doing so.

Other findings:

The liver change seen grossly (enhanced reticular pattern) was microscopically found to be diffuse congestion of vessels. This is a non-specific finding that is likely incidental, and likely occurred as the animal was dying. There were no changes in the heart to suggest it was due to heart failure, or other changes in the liver suggestive of hepatic pathology.

There was hemorrhage in the lung – both John and I agree this is likely an agonal change or due to trauma at the time of death. We did not see evidence of pneumonia or other lung pathology.

Francisella tularensis and *Yersenia pestis* were not cultured from this mouse.

I could not find an average and standard deviation for organ values for wild *Peromyscus maniculatus*, however, there is a paper with organ masses for captive *Peromyscus maniculatus*, with average values and standard error – see below.

Please contact me with any questions or concerns.

Diagnoses
Adrenal gland: Severe, adrenocortical hypertrophy with anisocytosis, anisokaryosis, and multinucleated cells
Lungs: Multifocal to coalescing, moderate, pulmonary hemorrhage

ADDENDA COMMENTS

Addendum 06/20/24: The slides with liver and adrenals were shared with Dr. Donna Kusewitt for a formal consult. Dr. John Ragsdale also assessed a few of the slides, informally. I have copied Dr. Kusewitt's complete assessment below, including her interpretations. Note: Some of the slides also had other organs, and she commented on them, as well.

Dr. Kusewitt thinks the adrenal is within normal limits, and in a personal communication told me the adrenals and male sex organs of *Peromyscus* can vary among populations, depending on living conditions, and time of year. Further, the changes in the paper referenced above note descriptions of changes in wild Peromyscus adrenals similar to the ones seen here. Thus, ultimately, it is most likely the changes in the adrenal are within normal variations for this genus.

PFAS analysis is pending for this animal.

Dr. Kusewitt's assessment:

Case Number: V24 15157 (slides 5 and 7)
Animal Number: NK 311139
Species: *Peromyscus maniculatus*
Sex: Male

Organ: Liver
Post mortem condition: Mild autolysis
Observations: Hepatic lobules are discernible. There is very slight diffuse ragged vacuolation of hepatocyte cytoplasm interpreted as glycogen accumulation. In some centrilobular areas, hepatocytes contain clear-edged vacuoles interpreted as fat droplets. There is mild variation in the size of hepatocyte nuclei and small numbers of binucleate hepatocytes are present. Multiple portal triads contain lymphoid cells; lymphoid cells are generally few in number. There is no evidence of neoplasia.

Organ: Spleen
Post mortem condition: Good
Observations: The spleen contains multiple lymphoid follicles, some of which contain evident germinal centers. There is moderate extramedullary hematopoiesis in the red pulp; most hematopoietic cells are of the erythroid lineage. There is no evidence of neoplasia disease.

Organ: Kidney
Post mortem condition: Moderate autolysis
Observations: Glomeruli are small and uniform in size and cellularity. Tubular lumina do not contain casts or proteinaceous fluid. No aggregates of inflammatory cells or interstitial fibrosis is seen. There is no evidence of neoplasia or infectious disease.

Organ: Adrenals
Post mortem condition: Good
Observations: The surfaces of the adrenals are smooth. Multiple layers of cells are seen in the cortex, but layers are not as well-defined as in some other animals examined, and there is more variation in nuclear size than in the adrenal of some other animals. The medulla is present in only one adrenal and it is unexceptional in appearance. There is no evidence of neoplasia or infectious disease.

Interpretation: Liver vacuolation in rodents is highly variable, depending on the feeding status. In the present case, the extent and pattern of vacuolation is within normal limits. Variation in the size of liver nuclei and the presence of binucleate hepatocytes are typical of rodents. The presence of lymphoid cells in multiple portal triads suggests a mild triaditis, likely an incidental lesion.

Changes in the white and red pulp of the spleen are mild and likely to be within normal limits.

There is no evidence of pathologic processes in kidneys or adrenals.

Reported: 06/20/24
Final Report

CASE HISTORY

Specimen collected at Holloman Lake in Otero County, New Mexico. High exposure to PFAS very likely based on recent published research. Goal of necropsy is to document pathology related to PFAS at the organ and tissue levels. Specimens should be returned to UNM MSB and 1g of muscle tissue needed for PFAS screening.

NECROPSY

This is the body of a 13 g, adult, male *Mus musculus*, with minimal autolysis (necropsy within hours of death). The liver weighs between 0.5 g and 1.0 g. The kidneys are greater than 0 g but less than 0.5 g. Organs are within normal limits grossly.

HISTOPATHOLOGY

1. Brain: There are no significant findings.
Salivary gland: There are no significant findings.
Bone marrow: There are no significant findings.
2. Thyroid and parathyroid: There are no significant findings.
Trachea: There are no significant findings.
Esophagus: There are no significant findings.
Heart: There are no significant findings.
Lungs: There is diffuse vascular congestion, with variable atelectasis.
3. Liver: There is diffuse vascular congestion. Occasionally, there is mild intracytoplasmic vacuolation in hepatocytes (within normal limits for post-prandial mouse).
4. Pancreas: There are no significant findings.
Kidney: There are no significant findings.
Lymph node: There are no significant findings.
5. Testicle: There are no significant findings.
Fat: There are no significant findings.
Adrenal gland: There are no significant findings.
6. Small intestine: There is moderate to severe autolysis of the mucosa. There is increased mitotic activity/turnover in the crypts, but there are no increased chronic inflammatory cells at the base of the lamina propria.
7. Brain: There are no significant findings.
8. Bone marrow, bone, and surrounding skeletal muscle: There are no significant findings.

FINAL COMMENTS

****Please see addendum below****

There were no overt significant findings from this animal's gross necropsy and microscopic exam. There were some changes in the small intestine consistent with increased cell turnover, which can suggest enteritis. The villus tips of the intestine in this cause are autolyzed, which makes interpretation a bit difficult (this unfortunately can happen even with necropsy within hours of death, given the number of bacteria in the GI tract). While this may be an enteritis, I do not see changes suggestive of Inflammatory bowel disease (IBD), which has been described in rats treated with PFOS.

While I am not convinced there are any significant changes in the small intestine we can attribute to PFAS, because IBD like lesions have been found in relation to PFAS in rats, I will consult with another pathologist, with results released in an addendum when this is completed, to see if they would consider this an IBD like lesion. I note that, even if other pathologists disagree and think there is an IBD like enteritis, there are so many possible causes of enteritis in a wild animal that it would be difficult to attribute it to PFAS in this case.

Francisella tularensis and *Yersinia pestis* were not cultured from this animal. PFAS analysis is pending.

Liang H, Yang M, Zeng C, Wu W, Zhao L, Wang Y. Perfluorooctane sulfonate exerts inflammatory bowel disease-like intestinal injury in rats. PeerJ. 2021

ADDENDA COMMENTS

Addendum 06/20/24: The slides with liver, adrenals, and intestine were shared with Dr. Donna Kusewitt for a formal consult. Note: Some of the slides also had other organs, and she commented on them, as well. Dr. Kusewitt does not interpret an overt enteritis in

these slides, and liver and adrenals are within normal limits.

PFAS analysis is pending for this animal.

Dr. Kusewitt's assessment:

Case Number: V24 15158 (slides 3,5, and 6)
Animal Number: NK311135
Species: *Mus musculus*
Sex: Male

Organ: Liver
Post mortem condition: Mild autolysis
Observations: Hepatic lobules are discernible. There is very slight diffuse ragged vacuolation of hepatocyte cytoplasm interpreted as glycogen accumulation. In some centrilobular areas, hepatocytes contain clear-edged vacuoles interpreted as fat droplets. There is mild variation in the size of hepatocyte nuclei and small numbers of binucleate hepatocytes are present. A few portal triads contain small numbers of lymphoid cells. A few small, irregular foci of hemorrhage are seen; these are interpreted as artefactual. There is no evidence of neoplasia or infectious disease.

Organs: Testes
Post mortem condition: Good
Observations: Active spermatogenesis is evident in seminiferous tubules. There is no evidence of neoplasia or infectious disease.

Organ: Epididymis
Post mortem condition: Mild autolysis
Observations: Tubules are packed with mature sperm. There is no evidence of neoplasia or infectious disease.

Organ: Adrenal
Post mortem condition: Good
Observations: The adrenal surface is smooth. All layers of the cortex are present and symmetrical. The medulla is unexceptional. There is no evidence of neoplasia or inflammation.

Organ: Stomach
Post mortem condition: Moderate autolysis
Observations: Both glandular and non-glandular portions of the stomach are present. Mucosa in both areas of the stomach is entirely normal in appearance. Food is present in the stomach lumen. There is no evidence of neoplasia or inflammation.

Organ: Small intestine
Post mortem condition: Marked autolysis
Observations: Marked autolysis makes examination of the small intestine somewhat challenging. No shortening or fusion of villi is seen. There is no evidence of ulceration. The lamina propria contains numerous lymphoid cells, but these are uniformly distributed; the number of lymphoid cells is judged to be within normal limits. There is no evidence of neoplasia or inflammation.

Organ: Large intestine and cecum
Post mortem condition: Variable autolysis
Observations: The cecum is too autolytic to evaluate. Better preserved areas of the large intestine are unexceptional. There is no evidence of neoplasia or inflammation.

Interpretation: Liver vacuolation is within normal limits for an animal that is not fasting. Variation in the size of liver nuclei and the presence of binucleate hepatocytes are typical of rodents. The presence of lymphocytes adjacent to a few bile ducts is considered an incidental finding.

There is marked spermatogenesis in the testes, and the epididymis examined contains numerous mature sperm. This is compatible with active breeding.

No abnormalities are observed in the stomach or intestine, but post mortem autolysis may mask minor pathologic changes.

No abnormalities are seen in the adrenal.

CASE HISTORY

Specimen collected at Holloman Lake in Otero County, New Mexico. High exposure to PFAS very likely based on recent published research. Goal of necropsy is to document pathology related to PFAS at the organ and tissue levels. Specimens should be returned to UNM MSB and 1g of muscle tissue needed for PFAS screening.

NECROPSY

This is the body of a 25.5 g, adult, female, *Peromyscus leucopus*, with minimal autolysis (necropsy performed within hours of death). The liver weighs 1.5 g. Each kidney weighs more than 0 g but less than 0.5 grams. All organs are grossly within normal limits.

HISTOPATHOLOGY

1. Brain: There are no significant findings.
2. Heart: There are no significant findings.
Esophagus: There are no significant findings
Lung: There is diffuse vascular congestion, with variable atelectasis. There is very mild hemorrhage within alveolar spaces.
Trachea: There are no significant findings
Fat: There are no significant findings
3. Esophagus: There are occasional protozoal cysts (sarcocysts) within the cytoplasm of skeletal muscle fibers in the wall of the esophagus, with no associated inflammatory response.
Tongue: There are occasional sarcocysts within skeletal muscle fibers, with no associated inflammatory response.
Liver: There is mild, intracytoplasmic, indistinct, clear vacuolation of hepatocytes, diffusely (within normal limits for a postprandial mouse).
4. Kidneys: There are no significant findings
Spleen: There are no significant findings
5. Liver: There are changes as described above. In addition, there are occasional pigment granulomas.
6. Uterus: There are no significant findings.
Ovaries: There are no significant findings.
7. Eye: There are no significant findings.
Skin: There are no significant findings
8. Stomach: There are no significant findings
Pancreas: There are no significant findings
Small intestine: There are no significant findings
Large intestine: There are no significant findings
9. Bone marrow, bone, and surrounding skeletal muscle: There are frequent sarcocysts within skeletal muscle fibers. There are no significant findings in the bone marrow or bone.

FINAL COMMENTS

****Please see addendum below****

There were no significant findings from this animals necropsy and microscopic exam. *Francisella tularensis* and *Yersinia pestis* were not cultured from this animal. PFAS analysis is pending. I am consulting with another pathologist on a few organs, and, when completed, results will be released in an addendum.

ADDENDA COMMENTS

Addendum 06/20/24: The slide with liver was shared with Dr. Donna Kusewitt for a formal consult. Dr. John Ragsdale also assessed the liver, informally. I have copied Dr. Kusewitt's complete assessment below, including her interpretations. Note: The slide also had other organs, and she commented on them, as well.

Dr. Kusewitt interpreted the liver as being within normal limits for a non-fasted rodent. Similar to the liver for V24-15155, Dr. Ragsdale thought that, while the liver vacuolation could be within normal limits for a post-prandial mouse, and he wouldn't call it a toxic hepatopathy, he can't rule out the vacuolation isn't due to a xenobiotic.

PFAS analysis is pending for this animal.

Dr. Kusewitt's assessment:

Case Number: V24 15159
Animal Number: NK311138
Species: *Peromyscus leucopus*
Sex: Female

Organ: Liver
Post mortem condition: Mild autolysis
Observations: Hepatic lobules are discernible. There is moderate diffuse ragged vacuolation of hepatocyte cytoplasm interpreted as glycogen accumulation. There is mild variation in the size of hepatocyte nuclei and small numbers of binucleate hepatocytes are present. A few portal triads contain small numbers of lymphoid cells. There is a single small focus of parenchymal necrosis. There is no evidence of neoplasia or infectious disease.

Organ: Gall bladder
Post mortem condition: Moderate autolysis
Observations: No abnormalities are seen.

Interpretation: Liver vacuolation in rodents is highly variable, depending on the feeding status. In the present case, the extent and pattern of vacuolation is within normal limits. Variation in the size of liver nuclei and the presence of binucleate hepatocytes are typical of rodents. Lymphoid cells surrounding a few bile ducts and a single small focus of necrosis in the liver are considered incidental findings.

Final Report

NECROPSY

The carcass presented for postmortem examination was an adult, 39.06 grams, female, Merriam's kangaroo rat. The kangaroo rat was identified as "AQ 001" and "NK311147". The rat was in good body condition with minimal postmortem decomposition. The subcutis and organs were dry and tacky suggesting dehydration. The stomach, small intestine, and large intestine were filled with dark red to black digested blood. The liver mass 1.27 grams. The combined mass of the right and left kidneys was 0.54 grams. There were no other significant lesions.

HISTOPATHOLOGY

There is multifocal necrosis of the glandular epithelium of the mucosa of the stomach that varies in thickness. The foci of necrosis are filled with necrotic debris, fibrin, hemorrhage, and hemoglobin-breakdown pigments. The submucosa associated with the mucosal epithelial necrosis is edematous. The adjacent gastric glandular epithelium is degenerate with hemorrhage in the associated lamina propria.

There are rare random and multifocal small infiltrates of small numbers of macrophages and lesser numbers of lymphocytes in the liver that are occasionally associated with apoptotic hepatocytes.

There are no significant microscopic lesions in the tongue, larynx, esophagus, trachea, salivary gland, lymph nodes, lung, heart, spleen, kidneys, adrenal glands, small intestine, large intestine, pancreas, uterus, urinary bladder, skeletal muscle, or brain.

FINAL COMMENTS

The rat had multiple punctate gastric erosions/ulcers that resulted in blood loss into the gastrointestinal tract. The cause of the gastric ulcers could not be determined because there was no evidence of inflammation, infectious organisms, neoplasia, or parasites that could have caused the gastric ulcer. The relationship between the gastric ulcers and PFAS concentrations is not known.

There were rare microgranulomas in the liver of this rat. Microgranulomas are common in the livers of laboratory mice and rats in both control and study populations. The cause of the microgranulomas is not known, and they are typically considered to be nonspecific background changes. The significance of hepatic microgranulomas in wild rats is not known.

NECROPSY

The carcass presented for postmortem examination was an adult, 41.61 grams, male, Merriam's kangaroo rat. The kangaroo rat was identified as "AQ 002" and "NK311148". The rat was in good body condition with minimal postmortem decomposition. The liver mass was 1.64 grams. The mass of the combined right and left kidneys was 0.58 grams. There were significant lesions in the thoracic viscera, abdominal viscera, skeletal muscle, or brain.

HISTOPATHOLOGY

There are rare random and multifocal small infiltrates of small numbers of macrophages and lesser numbers of lymphocytes in the liver that are occasionally associated with apoptotic hepatocytes.

The lumen of the small intestine contains small numbers of adult cestodes (tapeworms).

There are no significant microscopic lesions in the tongue, larynx, esophagus, thyroid gland, lymph nodes, lung, heart, spleen, kidneys, stomach, large intestine, pancreas, testicles, accessory sex glands, urinary bladder, skeletal muscle, or brain.

FINAL COMMENTS

The rat was mildly parasitized by tapeworms in the small intestine.

There were rare microgranulomas in the liver of this rat. Microgranulomas are common in the livers of laboratory mice and rats in both control and study populations. The cause of the microgranulomas is not known, and they are typically considered to be nonspecific background changes. The significance of hepatic microgranulomas in wild rats is not known.

Reported: 12/14/24
Final Report

NECROPSY

The carcass presented for postmortem examination was an adult, 39.64 grams, male, Merriam's kangaroo rat. The kangaroo rat was identified as "AQ 003" and "NK311149". The rat was in good body condition with minimal postmortem decomposition. The liver mass 1.28 grams. The combined mass of the right and left kidneys was 0.47 grams. There were no significant lesions in the thoracic viscera, abdominal viscera, skeletal muscle, or brain.

HISTOPATHOLOGY

There is focally extensive necrosis of the lumenal aspect of the glandular epithelium of the mucosa of the stomach. The focus of necrosis is filled with necrotic debris, fibrin, hemorrhage, and hemoglobin-breakdown pigments. The submucosa associated with the mucosal epithelial necrosis is edematous. The adjacent gastric glandular epithelium is degenerate with hemorrhage in the associated lamina propria.

There are rare random and multifocal small infiltrates of small numbers of macrophages and lesser numbers of lymphocytes in the liver that are occasionally associated with apoptotic hepatocytes.

The lumen of the small intestine contains small numbers of adult nematodes.

There are no significant microscopic lesions in the tongue, larynx, esophagus, trachea, thyroid gland, lung, heart, spleen, kidneys, large intestine, pancreas, testicles, accessory sex glands, urinary bladder, skeletal muscle, or brain.

FINAL COMMENTS

The rat had a punctate gastric erosion/ulcer that resulted in small amounts of blood loss into the stomach. The cause of the gastric ulcer could not be determined because there was no evidence of inflammation, infectious organisms, neoplasia, or stomach parasites that could have caused the gastric ulcer. The relationship between the gastric ulcer and PFAS concentrations is not known.

The rat was parasitized by small numbers of adult nematodes in the small intestine.

There were rare microgranulomas in the liver of this rat. Microgranulomas are common in the livers of laboratory mice and rats in both control and study populations. The cause of the microgranulomas is not known, and they are typically considered to be nonspecific background changes. The significance of hepatic microgranulomas in wild rats is not known.

NECROPSY

The carcass presented for postmortem examination was an adult, 31.34 grams, male, Merriam's kangaroo rat. The kangaroo rat was identified as "AQ 004" and "NK311150". The rat was in good body condition with minimal postmortem decomposition. The liver mass 1.10 grams. The combined mass of the right and left kidneys was 0.47 grams. There were no significant lesions in the thoracic viscera, abdominal viscera, skeletal muscle, or brain.

HISTOPATHOLOGY

There are rare random and multifocal small infiltrates of small numbers of macrophages and lesser numbers of lymphocytes in the liver that are occasionally associated with apoptotic hepatocytes.

There are no significant microscopic lesions in the tongue, larynx, esophagus, trachea, lymph nodes, lung, heart, spleen, kidneys, adrenal glands, stomach, small intestine, large intestine, pancreas, testicles, accessory sex glands, urinary bladder, skeletal muscle, or brain.

FINAL COMMENTS

Reported: 12/14/24
Final Report

NECROPSY

The carcass presented for postmortem examination was an adult, 37.16 grams, female, Merriam's kangaroo rat. The kangaroo rat was identified as "AQ 006" and "NK311152". The rat was in good body condition with minimal postmortem decomposition. The liver mass 1.37 grams. The combined mass of the right and left kidneys was 0.58 grams. There were no significant lesions in the thoracic viscera, abdominal viscera, skeletal muscle, or brain.

HISTOPATHOLOGY

There are rare random and multifocal small infiltrates of small numbers of macrophages and lesser numbers of lymphocytes in the liver that are occasionally associated with apoptotic hepatocytes.

There are small numbers of myofibers in the skeletal muscle that contain variably sized protozoal cysts. The cysts are filled with numerous estimated 5 - 7 micron diameter crescent-shaped bradyzoites.

There are no significant microscopic lesions in the tongue, larynx, thyroid gland, trachea, esophagus, lungs, heart, spleen, kidneys, adrenal glands, stomach, small intestine, large intestine, pancreas, lymph nodes, urinary bladder, or brain.

FINAL COMMENTS

The rat had small numbers of sarcocysts in the skeletal muscle. Sarcocysts are the intermediate stage of *Sarcocystis* species. When a predator eats an animal with sarcocysts, the protozoa will mature within the predator to complete their life cycle.

There were rare microgranulomas in the liver of this rat. Microgranulomas are common in the livers of laboratory mice and rats in both control and study populations. The cause of the microgranulomas is not known, and they are typically considered to be nonspecific background changes. The significance of hepatic microgranulomas in wild rats is not known.

NECROPSY

The carcass presented for postmortem examination was an adult, 11.39 grams, female, Chihuahuan pocket mouse. The pocket mouse was identified as "AQ 007" and "NK311153". The mouse was in good body condition with minimal postmortem decomposition. The liver mass 0.46 grams. The combined mass of the right and left kidneys was 0.20 grams. There were no significant lesions in the thoracic viscera, abdominal viscera, skeletal muscle, or brain.

HISTOPATHOLOGY

There are no significant microscopic lesions in the tongue, larynx, trachea, esophagus, thyroid gland, lungs, heart, liver, spleen, kidneys, adrenal glands, stomach, small intestine, large intestine, pancreas, uterus, skeletal muscle, brain, and a single cross section of the spinal cord.

FINAL COMMENTS

There are no significant lesion in the pocket mouse. There is no evidence of infectious disease, parasitism, neoplasia, or toxicosis.

National Primary Drinking Water Regulations

The National Primary Drinking Water Regulations (NPDWR) (National Primary Drinking Water Regulations)are legally enforceable primary standards and treatment techniques that apply to public water systems. Primary standards and treatment techniques protect public health by limiting the levels of contaminants in drinking water.

- Microorganisms
- Disinfectants
- Disinfection Byproducts
- Inorganic Chemicals
- Organic Chemicals, except for PFAS
  - Selected Per- and poly-fluoroalkyl substances (PFAS)
- Radionuclides

Microorganisms

- **Surface Water Treatment Rules** <https://epa.gov/dwreginfo/surface-water-treatment-rules>
- **Ground Water Rule** <https://epa.gov/dwreginfo/ground-water-rule>
- **Revised Total Coliform Rule And Total Coliform Rule** <https://epa.gov/dwreginfo/revised-total-coliform-rule-and-total-coliform-rule>

Contaminant	MCLG (Maximum Contaminant Level Goal)[1]	MCL (Maximum Contaminant Level) or TT (Treatment Technique)[1]	Potential Health Effects from Long-Term Exposure Above the MCL (Maximum Contaminant Level) (unless specified as short-term)	Sources of Contaminant in Drinking Water
Cryptosporidium	zero	TT (Treatment Technique)[3]	Gastrointestinal illness (such as diarrhea, vomiting, and cramps)	Human and animal fecal waste
Giardia lamblia	zero	TT (Treatment Technique)[3]	Gastrointestinal illness (such as diarrhea, vomiting, and cramps)	Human and animal fecal waste
Heterotrophic plate count (HPC (Heterotrophic plate count))	n/a	TT (Treatment Technique)[3]	HPC (Heterotrophic plate count) has no health effects; it is an analytic method used to measure the variety of bacteria that are common in water. The lower the concentration of bacteria in drinking water, the better maintained the water system is.	HPC (Heterotrophic plate count) measures a range of bacteria that are naturally present in the environment
Legionella <https://epa.gov/ground-water-and-drinking-water/legionella>	zero	TT (Treatment Technique)[3]	Legionnaire's Disease, a type of pneumonia	Found naturally in water; multiplies in heating systems

Contaminant	MCLG (Maximum Contaminant Level Goal)[1]	MCL (Maximum Contaminant Level) or TT (Treatment Technique)[1]	Potential Health Effects from Long-Term Exposure Above the MCL (Maximum Contaminant Level) (unless specified as short-term)	Sources of Contaminant in Drinking Water
Total Coliforms (including fecal coliform and *E. Coli*) • Quick reference guide • Rule Summary <https://epa.gov/dwreginfo/revised-total-coliform-rule-and-total-coliform-rule>	zero	5.0%[4]	Not a health threat in itself; it is used to indicate whether other potentially harmful bacteria may be present[5]	Coliforms are naturally present in the environment; as well as feces; fecal coliforms and *E. coli* only come from human and animal fecal waste.
Turbidity	n/a	TT (Treatment Technique)[3]	Turbidity is a measure of the cloudiness of water. It is used to indicate water quality and filtration effectiveness (such as whether disease-causing organisms are present). Higher turbidity levels are often associated with higher levels of disease-causing microorganisms such as viruses, parasites and some bacteria. These organisms can cause symptoms such as nausea, cramps, diarrhea, and associated headaches.	Soil runoff
Viruses (enteric)	zero	TT (Treatment Technique)[3]	Gastrointestinal illness (such as diarrhea, vomiting, and cramps)	Human and animal fecal waste

Disinfection Byproducts

Inorganic Chemicals

- **Chemical Contaminant Rules Summary** <https://epa.gov/dwreginfo/chemical-contaminant-rules>

Contaminant	MCLG (Maximum Contaminant Level Goal)[1] (mg/L (Milligram per Liter))[2]	MCL (Maximum Contaminant Level) or TT (Treatment Technique)[1] (mg/L (Milligrams per Liter))[2]	Potential Health Effects from Long-Term Exposure Above the MCL (Maximum Contaminant Level) (unless specified as short-term)	Sources of Contaminant in Drinking Water
Antimony	0.006	0.006	Increase in blood cholesterol; decrease in blood sugar	Discharge from petroleum refineries; fire retardants; ceramics; electronics; solder
Arsenic • Quick reference guide • Consumer fact sheet	0	0.010 as of 01/23/06	Skin damage or problems with circulatory systems, and may have increased risk of getting cancer	Erosion of natural deposits; runoff from orchards, runoff from glass and electronics production wastes
Asbestos (fiber > 10 micrometers)	7 million fibers per liter (MFL (Million Fibers per Liter))	7 MFL (Million Fibers per Liter)	Increased risk of developing benign intestinal polyps	Decay of asbestos cement in water mains; erosion of natural deposits
Barium	2	2	Increase in blood pressure	Discharge of drilling wastes; discharge from metal refineries; erosion of natural deposits
Beryllium	0.004	0.004	Intestinal lesions	Discharge from metal refineries and coal-burning factories; discharge from electrical, aerospace, and defense industries
Cadmium	0.005	0.005	Kidney damage	Corrosion of galvanized pipes; erosion of natural deposits; discharge from metal refineries; runoff from waste batteries and paints
Chromium (total) <https://epa.gov/dwstandardsregulations/chromium-drinking-water>	0.1	0.1	Allergic dermatitis	Discharge from steel and pulp mills; erosion of natural deposits

Contaminant	MCLG (Maximum Contaminant Level Goal)[1] (mg/L (Milligram per Liter))[2]	MCL (Maximum Contaminant Level) or TT (Treatment Technique)[1] (mg/L (Milligrams per Liter))[2]	Potential Health Effects from Long-Term Exposure Above the MCL (Maximum Contaminant Level) (unless specified as short-term)	Sources of Contaminant in Drinking Water
Copper	1.3	TT (Treatment Technique)[7]; Action Level=1.3	Short term exposure: Gastrointestinal distress Long term exposure: Liver or kidney damage People with Wilson's Disease should consult their personal doctor if the amount of copper in their water exceeds the action level	Corrosion of household plumbing systems; erosion of natural deposits
Cyanide (as free cyanide)	0.2	0.2	Nerve damage or thyroid problems	Discharge from steel/metal factories; discharge from plastic and fertilizer factories
Fluoride	4.0	4.0	Bone disease (pain and tenderness of the bones); Children may get mottled teeth	Water additive which promotes strong teeth; erosion of natural deposits; discharge from fertilizer and aluminum factories
Lead <https://epa.gov/node/133825/> • Quick reference guide • Rule information <https://epa.gov/node/120819/>	zero	TT (Treatment Technique)[7]; Action Level=0.010	Infants and children: Delays in physical or mental development; children could show slight deficits in attention span and learning abilities Adults: Kidney problems; high blood pressure	Corrosion of household plumbing systems; erosion of natural deposits
Mercury (inorganic)	0.002	0.002	Kidney damage	Erosion of natural deposits; discharge from refineries and factories; runoff from landfills and croplands
Nitrate (measured as Nitrogen)	10	10	Infants below the age of six months who drink water containing nitrate in excess of the MCL could become seriously ill and, if untreated, may die. Symptoms include shortness of breath and blue-baby syndrome.	Runoff from fertilizer use; leaking from septic tanks, sewage; erosion of natural deposits

Contaminant	MCLG (Maximum Contaminant Level Goal)[1] (mg/L (Milligram per Liter))[2]	MCL (Maximum Contaminant Level) or TT (Treatment Technique)[1] (mg/L (Milligrams per Liter))[2]	Potential Health Effects from Long-Term Exposure Above the MCL (Maximum Contaminant Level) (unless specified as short-term)	Sources of Contaminant in Drinking Water
Nitrite (measured as Nitrogen)	1	1	Infants below the age of six months who drink water containing nitrite in excess of the MCL could become seriously ill and, if untreated, may die. Symptoms include shortness of breath and blue-baby syndrome.	Runoff from fertilizer use; leaking from septic tanks, sewage; erosion of natural deposits
Selenium	0.05	0.05	Hair or fingernail loss; numbness in fingers or toes; circulatory problems	Discharge from petroleum refineries; erosion of natural deposits; discharge from mines
Thallium	0.0005	0.002	Hair loss; changes in blood; kidney, intestine, or liver problems	Leaching from ore-processing sites; discharge from electronics, glass, and drug factories

Organic Chemicals, except for PFAS

- **Chemical Contaminant Rules Summary** <https://epa.gov/dwreginfo/chemical-contaminant-rules>

Contaminant	MCLG (Maximum Contaminant Level Goal)[1] (mg/L (Milligrams per Liter))[2]	MCL (Maximum Contaminant Level) or TT (Treatment Technique)[1] (mg/L (Milligrams per Liter))[2]	Potential Health Effects from Long-Term Exposure Above the MCL (Maximum Contaminant Level) (unless specified as short-term)	Sources of Contaminant in Drinking Water
Acrylamide	zero	TT (Treatment Technique)[8]	Nervous system or blood problems; increased risk of cancer	Added to water during sewage/wastewater treatment
Alachlor	zero	0.002	Eye, liver, kidney or spleen problems; anemia; increased risk of cancer	Runoff from herbicide used on row crops
Atrazine	0.003	0.003	Cardiovascular system or reproductive problems	Runoff from herbicide used on row crops
Benzene	zero	0.005	Anemia; decrease in blood platelets; increased risk of cancer	Discharge from factories; leaching from gas storage tanks and landfills

Contaminant	MCLG (Maximum Contaminant Level Goal)[1] (mg/L (Milligrams per Liter))[2]	MCL (Maximum Contaminant Level) or TT (Treatment Technique)[1] (mg/L (Milligrams per Liter))[2]	Potential Health Effects from Long-Term Exposure Above the MCL (Maximum Contaminant Level) (unless specified as short-term)	Sources of Contaminant in Drinking Water
Benzo(a)pyrene (PAHs)	zero	0.0002	Reproductive difficulties; increased risk of cancer	Leaching from linings of water storage tanks and distribution lines
Carbofuran	0.04	0.04	Problems with blood, nervous system, or reproductive system	Leaching of soil fumigant used on rice and alfalfa
Carbon tetrachloride	zero	0.005	Liver problems; increased risk of cancer	Discharge from chemical plants and other industrial activities
Chlordane	zero	0.002	Liver or nervous system problems; increased risk of cancer	Residue of banned termiticide
Chlorobenzene	0.1	0.1	Liver or kidney problems	Discharge from chemical and agricultural chemical factories
2,4-D	0.07	0.07	Kidney, liver, or adrenal gland problems	Runoff from herbicide used on row crops
Dalapon	0.2	0.2	Minor kidney changes	Runoff from herbicide used on rights of way
1,2-Dibromo-3-chloropropane (DBCP (1,2-Dibromo-3-chloropropane))	zero	0.0002	Reproductive difficulties; increased risk of cancer	Runoff/leaching from soil fumigant used on soybeans, cotton, pineapples, and orchards
o-Dichlorobenzene	0.6	0.6	Liver, kidney, or circulatory system problems	Discharge from industrial chemical factories
p-Dichlorobenzene	0.075	0.075	Anemia; liver, kidney or spleen damage; changes in blood	Discharge from industrial chemical factories
1,2-Dichloroethane	zero	0.005	Increased risk of cancer	Discharge from industrial chemical factories
1,1-Dichloroethylene	0.007	0.007	Liver problems	Discharge from industrial chemical factories
cis-1,2-Dichloroethylene	0.07	0.07	Liver problems	Discharge from industrial chemical factories

Contaminant	MCLG (Maximum Contaminant Level Goal)[1] (mg/L (Milligrams per Liter))[2]	MCL (Maximum Contaminant Level) or TT (Treatment Technique)[1] (mg/L (Milligrams per Liter))[2]	Potential Health Effects from Long-Term Exposure Above the MCL (Maximum Contaminant Level) (unless specified as short-term)	Sources of Contaminant in Drinking Water

Uranium	zero	30 ug/L (microgram per liter) as of 12/08/03	Increased risk of cancer, kidney toxicity	Erosion of natural deposits

Notes

[1]Definitions:

- Maximum Contaminant Level Goal (MCLG (Maximum Contaminant Level Goal)) - The level of a contaminant in drinking water below which there is no known or expected risk to health. MCLGs allow for a margin of safety and are non-enforceable public health goals.
- Maximum Contaminant Level (MCL (Maximum Contaminant Level)) - The highest level of a contaminant that is allowed in drinking water. MCLs are set as close to MCLGs as feasible using the best available treatment technology and taking cost into consideration. MCLs are enforceable standards.
- Maximum Residual Disinfectant Level Goal (MRDLG (Maximum Residual Disinfectant Level Goal)) - The level of a drinking water disinfectant below which there is no known or expected risk to health. MRDLGs (Maximum Residual Disinfectant Level Goal) do not reflect the benefits of the use of disinfectants to control microbial contaminants.
- Treatment Technique (TT (Treatment Technique)) - A required process intended to reduce the level of a contaminant in drinking water.
- Maximum Residual Disinfectant Level (MRDL (Maximum Residual Disinfectant Level)) - The highest level of a disinfectant allowed in drinking water. There is convincing evidence that addition of a disinfectant is necessary for control of microbial contaminants.

[2] Units are in milligrams per liter (mg/L (Milligrams per Liter)) unless otherwise noted. Milligrams per liter are equivalent to parts per million (PPM (Parts per Million)).

[3] EPA's surface water treatment rules require systems using surface water or ground water under the direct influence of surface water to

a. Disinfect their water, and
b. Filter their water, or
c. Meet criteria for avoiding filtration so that the following contaminants are controlled at the following levels:

- *Cryptosporidium*: Unfiltered systems are required to include *Cryptosporidium* in their existing watershed control provisions
- *Giardia lamblia*: 99.9% removal/inactivation.
- Viruses: 99.99% removal/inactivation.
- *Legionella*: No limit, but EPA believes that if *Giardia* and viruses are removed/inactivated, according to the treatment techniques in the Surface Water Treatment Rule, *Legionella* will also be controlled.
- Turbidity: For systems that use conventional or direct filtration, at no time can turbidity (cloudiness of water) go higher than 1 Nephelometric Turbidity Unit (NTU) (Nephelometric Turbidity Unit), and samples for turbidity must be less than or equal to 0.3 NTUs (Nephelometric Turbidity Units) in at least 95 percent of the samples in any month. Systems that use filtration other than the conventional or direct filtration must follow state limits, which must include turbidity at no time exceeding 5 NTUs (Nephelometric Turbidity Units).
- Heterotrophic Plate Count (HPC) (Heterotrophic Plate Count): No more than 500 bacterial colonies per milliliter.
- Long Term 1 Enhanced Surface Water Treatment: Surface water systems or groundwater under the direct influence (GWUDI (Groundwater Under The Direct Influence)) systems serving fewer than 10,000 people must comply with the applicable Long Term 1 Enhanced Surface Water Treatment Rule provisions (such as turbidity standards, individual filter monitoring, *Cryptosporidium* removal requirements, updated watershed control requirements for unfiltered systems).

- Long Term 2 Enhanced Surface Water Treatment Rule: This rule applies to all surface water systems or ground water systems under the direct influence of surface water. The rule targets additional *Cryptosporidium* treatment requirements for higher risk systems and includes provisions to reduce risks from uncovered finished water storage facilities and to ensure that the systems maintain microbial protection as they take steps to reduce the formation of disinfection byproducts.
- Filter Backwash Recycling: This rule requires systems that recycle to return specific recycle flows through all processes of the system's existing conventional or direct filtration system or at an alternate location approved by the state.

[4] No more than 5.0% samples total coliform-positive (TC-positive (Total Coliform-positive)) in a month. (For water systems that collect fewer than 40 routine samples per month, no more than one sample can be total coliform-positive per month.) Every sample that has total coliform must be analyzed for either fecal coliforms or *E. coli* if two consecutive TC-positive (Total Coliform-positive) samples, and one is also positive for *E.coli* fecal coliforms, system has an acute MCL (Maximum Contaminant Level) violation.

[5] Fecal coliform and *E. coli* are bacteria whose presence indicates that the water may be contaminated with human or animal wastes. Disease-causing microbes (pathogens) in these wastes can cause diarrhea, cramps, nausea, headaches, or other symptoms. These pathogens may pose a special health risk for infants, young children, and people with severely compromised immune systems.

[6] Although there is no collective MCLG (Maximum Contaminant Level Goal) for this contaminant group, there are individual MCLGs (Maximum Contaminant Level Goals) for some of the individual contaminants:

- Trihalomethanes: bromodichloromethane (zero); bromoform (zero); dibromochloromethane (0.06 mg/L (Milligrams per Liter)): chloroform (0.07 mg/L (Milligrams per Liter).
- Haloacetic acids: dichloroacetic acid (zero); trichloroacetic acid (0.02 mg/L (Milligrams per Liter)); monochloroacetic acid (0.07mg/L (Milligrams per Liter)). Bromoacetic acid and dibromoacetic acid are regulated with this group but have no MCLGs.

[7] Lead and copper are regulated by a treatment technique that requires systems to control the corrosiveness of their water. If more than 10% of tap water samples exceed the action level, water systems must take additional steps. For copper, the action level is 1.3 mg/L (Milligrams per Liter), and for lead is 0.010 mg/L (Milligrams per Liter).

[8] Each water system must certify, in writing, to the state (using third-party or manufacturer's certification) that when acrylamide and epichlorohydrin are used to treat water, the combination (or product) of dose and monomer level does not exceed the levels specified, as follows:

- Acrylamide = 0.05% dosed at 1 mg/L (Milligrams per Liter) (or equivalent)
- Epichlorohydrin = 0.01% dosed at 20 mg/L (Milligrams per Liter) (or equivalent)

[9] Health Based Water Concentration (HBWC) - To calculate the Hazard Index, a ratio is developed for each PFAS by dividing the measured level of the PFAS in drinking water by the level below which adverse health effects are not likely to occur (i.e., the Health Based Water Concentration).

pH

Overview | When to List | Ways to Measure | Conceptual Diagrams | Literature Reviews | References

Overview

- Low pH
  - Checklist of Sources, Site Evidence and Biological Effects
- High pH
  - Checklist of Sources, Site Evidence and Biological Effects

pH is an expression of hydrogen ion concentration in water. Specifically, pH is the negative logarithm of hydrogen ion (H^+) concentration (mol/L) in an aqueous solution:

$pH = -\log_{10}(H^+)$

The term is used to indicate basicity or acidity of a solution on a scale of 0 to 14, with pH 7 being neutral. As the concentration of H^+ ions in solution increases, acidity increases and pH gets lower, below 7 (see Figure 1). When pH is above 7, the solution is basic.

Because pH is a logarithmic function, one unit change in pH (e.g., 7 to 6) indicates a 10x change in H^+ concentration in that solution. However, what is actually measured is hydrogen ion activity, not concentration.

Note that although basic solutions are alkaline, “basicity” and “alkalinity” are not exactly the same thing. Basicity refers to the ratio of hydrogen and hydroxyl (OH^-) ions in solution, and is directly related to pH. Alkalinity is related to the acid-neutralizing capacity (ANC) of a solution. In aquatic ecosystems, processes that increase dissolved carbon dioxide or dissolved organic carbon (DOC) decrease pH but have no effect on ANC.

pH affects most chemical and biological processes in water. It is one of the most important environmental factors limiting species distributions in aquatic habitats. Different species flourish within different ranges of pH, with the optima for most aquatic organisms falling between pH 6.5-8. U.S. EPA water quality criteria for pH in freshwater suggest a range of 6.5 to 9.

Fluctuating pH or sustained pH outside this range physiologically stresses many species and can result in decreased reproduction, decreased growth, disease or death. This can ultimately lead to reduced biological diversity in streams.

Even small changes in pH can shift community composition in streams. This is because pH alters the chemical state of many pollutants (e.g., copper, ammonia), changing their solubility, transport and bioavailability. This can increase exposure to and toxicity of metals and nutrients to aquatic plants and animals.

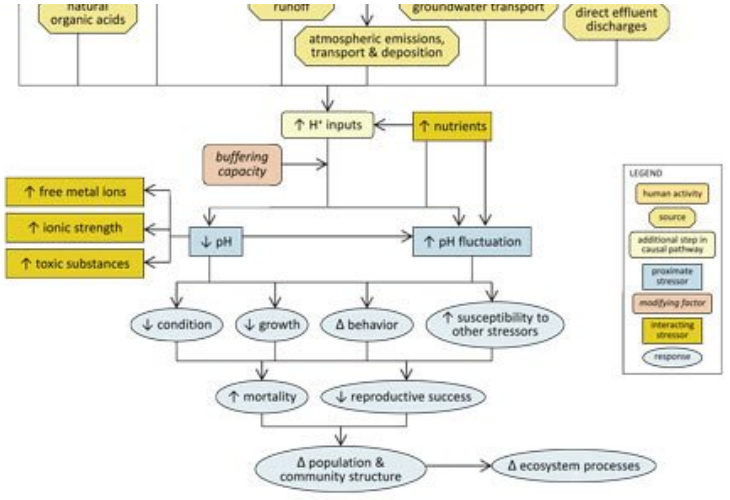
---

Low pH

For a waterbody to be considered to have low pH, pH generally needs to be below 6 or 6.5, depending on the system. Low pH is addressed in this module as a proximate cause of effects on aquatic biota. It should be listed as a candidate cause when potential human sources and activities, site observations or observed biological effects support portions of the source-to-impairment pathways (see Figure 2).

This diagram and some of the other information also may be useful in Step 3: Evaluate Data from the Case.

Checklist of Sources, Site Evidence and Biological Effects



The checklist below will help you determine whether to include low pH among your candidate causes. The list is intended to guide you in collecting evidence to support, weaken or eliminate low pH as a candidate cause. For more information on specific entries, go to the When to List tab.

Consider listing low pH as a candidate cause when the following sources and activities, site evidence and biological effects are present:

Sources and Activities

- Mine wastes
- Historic mine sites
- Acid-generating rocks/soils
- Power plants and other sources of acidic gases
- Coal pile runoff
- Industrial effluents

<https://epa.gov/sites/default/files/2015-12/lowphcd_sim_500.jpg>

Simple conceptual model diagram for **LOW pH**

Figure 2. A simple conceptual diagram illustrating causal pathways, from sources to impairments, related to **low pH**. Click on the diagram to

- Landfill leachate
- Confined animal feeding operations, dairy runoff
- Instream oxidation or reduction processes
- Recent draining of naturally inundated wetlands or floodplains

view a larger version.

Site Evidence

- Low site pH data
- Acidic precipitation
- Geology or soil type (e.g., serpentine geology, soils)
- Mine drainage/overflows (current or historic)
- “Yellow-boy” (iron precipitates on rocks)
- Black or brown (tea colored) water
- Filamentous algae

Biological Effects

- Damage to gill epithelium
- Mucus on gills
- Decreased growth
- Reproductive failure
- Respiratory inhibition
- Ionoregulatory impacts
- Reduced number of species and individuals
- Mortality
- Replacement of acid-sensitive species with acid-tolerant species

Consider contributing, modifying and related factors when listing low pH as a candidate cause:

- **Metals**: Common interactions to consider with low pH involve metals (e.g., aluminum, copper, zinc). Acid rain mobilizes and leaches metals (e.g., aluminum) into groundwater and streams, resulting in higher dissolved metal concentrations combined with low pH. Metals such as aluminum become increasingly bioavailable with decreasing pH (<6.0) due to increases in the free ionic form. This results in greater toxic effects at low pH than at neutral or high pH (Howells et al. 1983, Playle et al. 1989). The direct cause of biological effects may be pH (with metals contributing), metals (with pH contributing), or both pH and metals combined (i.e., neither acting alone would have caused observed effects).
- **Ionic strength**: To a large extent, pH controls both the chemical form and solubility of ionic chemicals.

- **Unspecified toxic chemicals**: The toxicity of compounds (e.g., phenols, cyanides) may increase with decreasing pH. For example, six phenols were more toxic to the guppy *Poecilia reticulata* at pH 5 or 6 than at pH 7 or 8 (Saarikoski 1981). Also, hydrogen cyanide (HCN) predominates at low and middle pH values and is about twice as toxic as CN^-, which is found in appreciable amounts above pH 8.5 (Rand 1995).
- **Ammonia**: Concentration and toxicity of NH_3 increases as pH increases, although less NH_3 is required to produce toxic effects at lower pH (IPCS 1986, Wurts 2003).

High pH

A waterbody is considered to have a high pH if pH exceeds 9 for prolonged periods or with high frequency. High pH is less common than low pH as a candidate cause, because anthropogenic sources are acidic more often than basic.

High pH is addressed in this module as a proximate cause of effects on aquatic biota. It should be listed as a candidate cause when potential human sources and activities, site observations or observed biological effects support portions of the source-to-impairment pathways (Figure 3). This conceptual diagram and some of the other information also may be useful in Step 3: Evaluate Data from the Case.

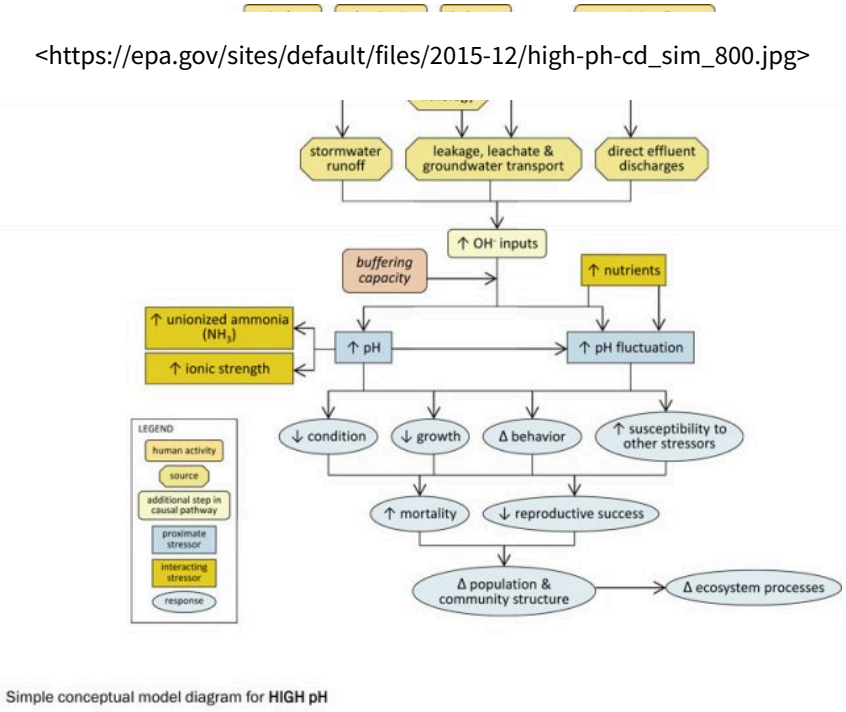
Checklist of Sources, Site Evidence and Biological Effects

The checklist below will help you determine whether to include high pH among your candidate causes. The list is intended to guide you in collecting evidence to support, weaken or eliminate high pH as a candidate cause. For more information on specific entries, go to the When to List tab.

Consider listing high pH as a candidate cause when the following sources and activities, site evidence, and biological effects are present:

Sources and Activities

- Industrial discharges
- Alkaline geology and soils
- Asphalt production or disposal
- Agricultural lime
- Oil and gas brines
- Industrial landfills
- Cement manufacturing
- Soap manufacturing
- Limestone gravel roads



Site Evidence

- Abundant macrophytes, filamentous algae or algal mats
- High site pH data
- Mineral deposits
- Low nighttime or early morning dissolved oxygen concentration
- (e.g., <40% saturation)

Biological Effects

- Decreased reproduction
- Reduced biodiversity
- Decreased growth
- Damage to skin, gills, olfactory organs, eyes

<https://epa.gov/sites/default/files/2015-12/high-ph-cd_sim_800.jpg>

Simple conceptual model diagram for **HIGH pH**

Figure 3. A simple conceptual diagram illustrating causal pathways, from sources to impairments, related to **high pH**. Click on the diagram to view a larger version.

Consider contributing, modifying and related factors when high pH is selected as a candidate cause:

- **Dissolved oxygen**
- **Ionic strength**: To a large extent, pH controls both the chemical form and the solubility of ionic chemicals.
- **Ammonia**: Concentration and toxicity of NH_3 increases as pH increases, although less NH_3 is required to produce toxic effects at lower pH (IPCS 1986, Wurts 2003).

When to List

Low pH	High pH

Low pH

- Sources and Activities that Suggest Listing Low pH as a Candidate Cause
- Site Evidence that Suggests Listing Low pH as a Candidate Cause
- Biological Effects that Suggest Listing Low pH as a Candidate Cause
- Site Evidence that Supports Excluding Low pH as a Candidate Cause

Sources and Activities that Suggest Including Low pH as a Candidate Cause

Mine wastes/historic mine sites: Coal mining is a well known source of low pH, particularly where sulfur-bearing rock is present. Drainage from other mines and mine wastes can also be very acidic.

Acid generating rocks/soils: Interactions between rocks or soils and water (i.e., weathering) can generate acid. For example, andesite soils of the Great Basin region are derived from weathered volcanic rock and are strongly acidic.

Sources of acidic gasses: Acidic deposition is the transfer of acidic compounds via rain, snow, and dry deposition. This process acidifies waters. Sulfur and nitrogen oxides are emitted into the atmosphere from power plants, industrial sources (e.g., pulp mills), and internal combustion engines (where they are transformed into H_2SO_4 and HNO_3) (see Figure 4). When deposited into freshwater systems, these gasses increase SO_4^{2-}, NO_3^-, and H^+, which can decrease pH.

Figure 4. Gases emitted into the air contribute to acidic deposition.
Photo courtesy of The National Acid Precipitation Assessment Program (NAPAP)

Streams and lakes with relatively low buffering capacity or low flow (e.g., intermittent and first order streams) are particularly susceptible to low pH from acidic deposition. Acidic deposition has occurred in the northeastern United States. Numerous cities and industrial plants in the Midwest and New England emit pollutants to air, which are then transported and deposited in the northeastern U.S. Acid deposition stored in snow and ice at high elevations or in cold climates can be a pulsed source of low pH water to streams during spring melting.

Point and nonpoint discharges: Industrial effluents (e.g., from metal plating and other processes requiring acid) can be discharged at a low pH if not properly treated. Nonpoint sources such as confined animal feeding operations (CAFOs), dairies and concentrated poultry farms can generate acidic runoff from manure if not controlled adequately. Coal pile runoff, runoff from urban areas, and leachate from improperly functioning septic systems and landfills can be acidic as well.

Instream oxidation or reduction processes: Inputs of ammonium can contribute to acidification, because the nitrification of NH_4^+ produces H^+.

Recent draining of naturally inundated wetlands or floodplains: Under natural conditions, sulfur in permanently saturated soils is reduced. When those soils are drained and exposed to air, sulfuric acid can be generated and released to streams.

Site Evidence that Suggests Including Low pH as a Candidate Cause

pH changes are generally not directly observable in the field, and observers usually must measure pH to detect a change. Thus, site observations indicative of low pH are typically indirect and largely restricted to

observing one or more acid-producing sources (above).

Low pH may be indicated by the presence of metal precipitates on stream substrate. Common metal precipitates observed in streams under acidic conditions include iron, manganese, and aluminum which have a yellow (or orange or red), black, or white color, respectively (see Figure 5). Metal precipitates, notably iron, can result in a thick floc that smothers biota and degrades habitat quality to the point that many fauna are extirpated.

Black or brown (tea colored) water, common in southeastern U.S. swamps and bayous (e.g., Okefenokee Swamp, GA) are typically acidic due to humic and other natural organic acids derived from peat and dissolved vegetative material.

Figure 5. Example of acid mine drainage.
Photo courtesy of Peters Creek Watershed

Some filamentous algae are tolerant of low pH and may dominate acidified lakes and streams without heavy precipitates (Niyogi et al. 1999). They include the filamentous green algae *Klebsormidium*, *Microspora*, *Mougeotia*, *Ulotrix* and *Stigeoclonium* (Stevens et al. 2001).

Biological Effects that Suggest Including Low pH as a Candidate Cause

Low pH has both lethal and sublethal effects on organisms. For many stream species, prolonged periods of pH <5 are likely to be lethal, resulting in significant changes in species composition and diversity. At pHs between about 5 and 6.5, sublethal effects on many stream species result in reduced fecundity, growth and population size. Acid water also damages the skin and gills of fish, amphibians and invertebrates. Skin damage increases fish susceptibility to fungal infections, which may lead to diseases such as epizootic ulcerative syndrome. Gill and skin damage and associated mucus production reduce the ability of fish to take in oxygen or regulate salt and water intake.

Meyer and Barclay's (1990) fish kill manual states that acids (as well as heavy metals and trinitrophenols) can cause “white film on gills, skin, and mouth.” Meyer and Barclay (1990) also state that hyperexcitability and attempts by fish to swim onto shore may be observed. These effects are symptomatic of low pH, but they are not specific enough to be considered diagnostic.

The presence of stream species that are either especially sensitive to or especially tolerant of low pH may suggest whether to include low pH as a candidate cause. The generalizations about acid tolerance and pH effects thresholds presented in this section are imprecise because responses are heavily dependent on co-occurring toxic and nutrient ions (Baker et al. 1990). However, they can be helpful. For example, if the impairment is characterized by the loss of brook trout, the cause is more likely to be a stressor to which that species is sensitive (e.g., high temperature, low DO) than low pH.

Certain aquatic or semiaquatic plants are indicative of low pH conditions. These include certain spike rushes, water lilies and many insectivorous marsh plants (e.g., venus fly traps, pitcher plants and sundews).

Macroinvertebrate diversity, particularly for the commonly monitored EPT (Ephemeroptera, Plecoptera and Trichoptera) taxa, generally declines with declining pH. Of the EPT taxa, Ephemeroptera (mayflies) are generally most sensitive and Plecoptera (stoneflies) are generally most tolerant. Particularly sensitive species are found in the mayfly genera *Heptagenia* (Heptageniidae), *Ephemerella* (Ephemerellidae) and *Paraleptophlebia* (Leptophlebiidae) and the stonefly families Leuctridae and Perlidae.

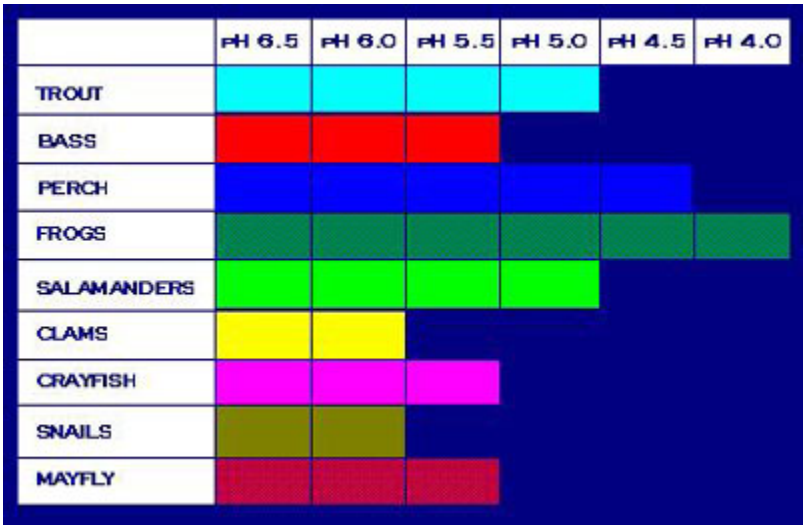


Figure 6. This table illustrates pH values that can be tolerated by different species.

These taxa are generally absent from streams with low pH. A few chironomids, including *Apsectrotanypus trifascipennis* and *Rheocricotopus fuscipes*, also are sensitive to acid and were only found in streams with pH >6 (Orendt, 1999). Invertebrates that require calcium carbonate for shell or cuticle development (e.g., clams, mussels, snails and amphipods) also are intolerant of low pH (<5) because acidic water dissolves calcium carbonate.

Other stream invertebrates are relatively tolerant of low pH (see Figure 6). These include Megaloptera (e.g., *Corydalus*) and craneflies (e.g., *Tipula*). Certain Chironomidae (midge) genera are also tolerant of low pH (e.g., some Orthocladiinae such as *Corynoneura*) and their dominance may indicate low pH (Orendt 1999). Also, northern pike (*Esox lucius*) can survive at pH 4-4.5 (Mackie 2001).

Low pH can cause reproductive failure and local extinction of fish populations due to low egg fertilization rates and failure of normal egg development (see Figure 7). In general, minnows (small members of the family Cyprinidae) are the first to disappear from acidifying streams. Blacknose dace may disappear at pH below 6.1 and common shiners experience embryo mortality below pH 6.0 (U.S. EPA 2008). Eggs of several fish species (e.g., striped bass, lake trout, fathead minnow) will not develop properly at pH less than approximately 5.5 (Howells et al. 1983, Baker et al. 1990). For most North American species, juvenile and adult fish are generally more tolerant of moderately low pH (5-6.5) (Baker et al. 1990). Brook trout is a relatively acid-tolerant species, not disappearing until pH is near 5 (U.S. EPA 2008).

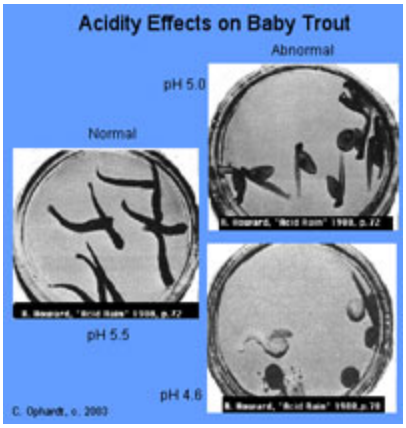

Figure 7. Examples of biological effects on reproduction. Courtesy of C. Ophardt

Low pH can have secondary effects on primary and secondary consumers due to pH stress on lower trophic levels. Low pH also can impede many ecosystem processes that depend on proper biological enzyme function (e.g., photosynthesis and decomposition). The sequence of direct and indirect effects of acidification is summarized in Table 1.

Table 1. General Summary of Biological Changes Anticipated with Surface Water Acidification, Expressed as a Decrease in Surface Water pH

pH Decrease	General Biological Effects
6.5 to 6.0	Small decreases in plankton and benthic invertebrate species richness resulting from loss of a few highly acid-sensitive species, but no measurable change in total community abundance or production.
	Some adverse effects (decreased reproductive success) may occur for highly acid-sensitive fish species (e.g., fathead minnow, striped bass).
6.0 to 5.5	Loss of sensitive species of minnows and dace (e.g., fathead minnow and blacknose dace); in some waters, decreased reproductive success of lake trout and walleye, which are important sport fish species in some areas.
	Visual accumulation of filamentous green algae in near-shore zone of many lakes and in some streams.
	Distinct decrease in species richness and change in species composition of plankton and benthic invertebrate communities, although little if any change in total community abundance or production.
	Loss of some common invertebrate species from zooplankton and benthic communities, including many species of snails, clams, mayflies, amphipods, and some crayfish.

pH Decrease	General Biological Effects
5.5 to 5.0	Loss of several important sport fish species, including lake trout, walleye, rainbow trout and smallmouth bass, as well as additional nongame species such as creek chub.
	Further increase in the extent and abundance of filamentous green algae in lake near-shore areas and streams.
	Continued shift in species composition and decline in species richness of plankton, periphyton and benthic invertebrate communities; decreases in total abundance and biomass of benthic invertebrates and zooplankton may occur in some waters.
	Loss of several additional invertebrate species common in surface waters, including all snails, most species of clams and many species of mayflies, stoneflies and other benthic invertebrates.
	Inhibition of nitrification.
5.0 to 4.5	Loss of most fish species, including most important sport fish species (e.g., brook trout and Atlantic salmon). A few fish species are able to survive and reproduce in water below pH 4.5 (e.g., central mudminnow, yellow perch).
	Measurable decline in whole-system rates of organic matter decomposition, potentially resulting in decreased rates of nutrient cycling.
	Substantial decrease in number plankton and benthic invertebrate species and further decline in plankton and periphyton species richness; measurable decrease in total community biomass of plankton and benthic invertebrates of most waters.
	Loss of additional plankton and benthic invertebrate species, including all clams and many insects and crustaceans.
	Reproductive failure of some acid-sensitive species of amphibians (e.g., spotted salamanders, Jefferson salamanders, leopard frogs).
From Baker et al. (1990).	

Site Evidence that Supports Excluding Low pH as a Candidate Cause

Low pH is buffered by minerals, such as calcium carbonate. If the stream is well buffered, or flows through soils and rocks high in alkaline minerals (e.g., limestone or dolomite), it is less likely that low pH is an appropriate candidate cause. The presence of acid-intolerant species such as ephemerellid mayflies, leuctrid

or perlid stoneflies or an abundance of clams or snails would also be evidence supporting exclusion of low pH as a candidate cause.

However, criteria or other benchmarks alone should not be used to exclude low pH as a cause. Different species have different pH requirements, different sites have different naturally occurring levels of pH, and other agents may enhance the effects of pH.

High pH

- Sources and Activities that Suggest Listing High pH as a Candidate Cause
- Site Evidence that Suggests Listing High pH as a Candidate Cause
- Biological Effects that Suggest Listing High pH as a Candidate Cause
- Site Evidence that Supports Excluding High pH as a Candidate Cause

Sources and Activities that Suggest Including High pH as a Candidate Cause

High pH can be caused by discharges from industries that use lime, lye or sodium hydroxide (NaOH); from agricultural runoff of fertilizers high in lime; or from industrial landfill leachates that contain solvents or lye. In particular, cement, asphalt and soap manufacturing may be sources of high pH due to the use of lime or lye. Runoff from limestone gravel roads also may increase pH.

In rare cases, high pH can be caused by natural conditions and mineralogy (e.g., weathering of chalk rock high in carbonates or olivine basalts). However, even in these cases, it is rare for stream pH to exceed 9.5. Leaching of naturally alkaline rocks and soils is exacerbated by physical disturbances such as tilling, mining and construction. An additional cause of elevated pH is high photosynthetic activity, which removes carbon dioxide from water and raises pH.

Site Evidence that Suggests Including High pH as a Candidate Cause

pH changes are not directly observable in typical field settings, and observers usually must measure pH to detect a change. However, high photosynthetic activity as evidenced by algal blooms or mats, or high macrophyte density, can cause pH to increase above tolerable levels (pH > 9), at least during daylight hours (Figure 8 and Figure 9). Certain species of *Microcystis* and *Coccochloris* algae grow optimally at pH 10 and do not grow below pH 8. *Cladophora glomerata* is only found in streams with pH greater than 8, whereas species such as *Oedogonium kurtzi* (green alga) and *Phaeospaera perforate* (yellow-green alga) are found in streams with pH less than 7 (Mackie 2001). High pH also may be indicated by certain mineral deposits in the stream, notably metal (e.g., nickel and cadmium) hydroxide precipitates that are insoluble above pH 9.

Biological Effects that Suggest Including High pH as a Candidate Cause

Figure 8. Stream with abundant aquatic plants and algae, which are sources of high pH.

As with low pH, effects of high pH usually are not specific enough to be considered symptomatic. Short-term exposures of fish to high pH (~9.5) are rarely lethal to most fish species. However, prolonged exposure to pH between 9.5 and 10 can damage outer surfaces such as gills, eyes, and skin. Cypriniformes (e.g., minnows) often are less sensitive to high pH than Perciformes (e.g., perch). High pH also can affect the sensory epithelium of the fish olfactory system, making it difficult for fish to detect food, sex hormones or pheromones, alarm substances from conspecifics or toxic chemicals.

Figure 9. Excessive *Cladophora* algal growth in a canal.

In addition to direct effects of high pH, an important indirect effect to consider is its interaction with ammonia. As pH increases, unionized ammonia (NH_3), which is more toxic to aquatic life than the ionized form (NH_4^+), becomes the dominant form. At pH > 9, the fraction of unionized ammonia is > 100 times the fraction at pH = 7 (> 90% of the total ammonia). This could result in ammonia toxicity if sufficient ammonia is present (e.g., >5 mg/L total ammonia at 25° C). Because ammonia toxicity can occur over relatively short exposure durations (hours to days depending on concentration), even short-term high pH events can contribute to biological effects. Therefore, when considering high pH as a candidate cause, bear in mind that it might be contributing to ammonia toxicity.

Site Evidence that Supports Excluding High pH as a Candidate Cause

There are no site observations that specifically provide evidence of the absence of high pH. We strongly caution against using benchmarks of effects (e.g., water quality criteria) as evidence for excluding high pH from your initial list of candidate causes. Different species have different pH requirements, different sites have different naturally occurring levels of pH, and other agents may enhance the effects of pH.

Ways to Measure

pH meter: A typical pH meter consists of a measuring probe connected to an electronic meter that measures and displays the pH reading. Because the meter measures hydrogen ion activity rather than concentration, it is affected by temperature and by other ions in solution. The influence of temperature on pH is usually automatically adjusted for by the meter.

Color comparator: Color comparators involve adding an indicator reagent to the sample that colors the sample water. Color intensity is proportional to pH of the sample. This color is then matched against a standard color chart to determine pH.

Conceptual Diagrams

- Detailed Conceptual Model Diagram (High pH)

About Conceptual Diagrams

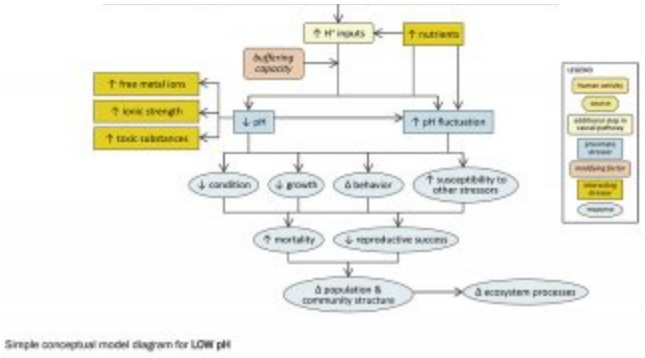
Conceptual diagrams are used to describe hypothesized relationships among sources, stressors and biotic responses within aquatic systems.

- More about Conceptual Diagrams <https://epa.gov/caddis/about-conceptual-diagrams>

Simple Conceptual Model Diagram (Low pH)

pH is a measure of hydrogen ion concentration in an aqueous solution. pH decreases as hydrogen ion concentration increases, and these acidic conditions can adversely affect aquatic biota.

Certain human activities can result in increased hydrogen ion inputs into aquatic systems, including sources associated with agriculture (e.g., animal feedlots), urbanization (e.g., vehicles), industry (e.g., coal-fired power plants) and mining (e.g., acid mine drainage). Natural sources of hydrogen ions include acid-generating geologies and lithologies subjected to weathering and natural organic acids (e.g., humic acids).



Hydrogen ions from these sources can be introduced into aquatic systems via four main transport pathways (or transport-defined sources) (see Figure 10): stormwater runoff, leakage or leachate into groundwater sources and subsequent transport, atmospheric emissions and deposition and direct effluent discharges. Each pathway can contribute to increased hydrogen ion inputs into surface waters.

Whether hydrogen ion inputs to aquatic systems lead to decreases in pH depends upon buffering capacity, or the system's ability to neutralize those inputs. Nutrient concentrations also play a significant role in pH dynamics, because nitrification and respiration both produce hydrogen ions. Decreases in pH can in turn affect other stressors, such as by increasing free metal ions, increasing bioavailability and toxicity of toxic substances, and increasing ionic strength.

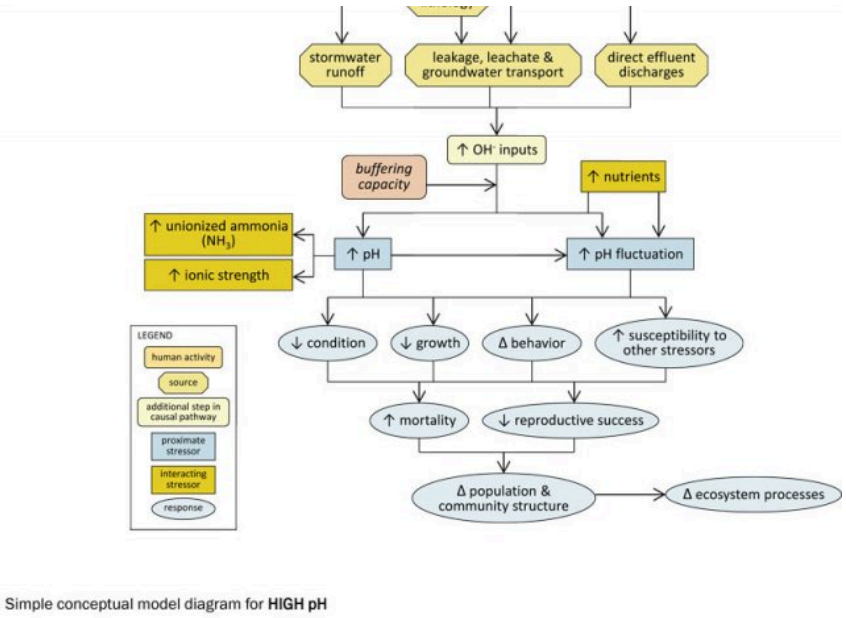
Simple conceptual model diagram for **LOW pH**

Figure 10. Example of a simple conceptual model diagram for **Low pH**. Click on the diagram to view a larger version.

Decreases in pH and associated increases in pH fluctuation can contribute to decreased condition, decreased growth, altered behavior and increased susceptibility to other stressors in affected biota.



Ultimately, these effects may result in increased mortality, decreased reproductive success and changes in population and community structure and ecosystem function. For example, taxa sensitive to low pH (e.g., certain mayfly and stonefly taxa) may decrease, while more tolerant taxa such as tipulids (crane flies), megalopterans (alderflies, dobsonflies, fishflies and hellgrammites) and spike rushes may increase. Sensitive life stages (e.g., eggs in fish) also may decline.

Simple Conceptual Model Diagram (High pH)

High pH levels occur when hydroxide ion concentrations are high and hydrogen ions are scarce. Although acidic conditions more commonly result from human activities, alkaline conditions also can occur and adversely affect aquatic biota.

Certain human activities and associated sources can result in increased pH in aquatic systems (see Figure 11). These include stormwater runoff from sources associated with agriculture (e.g., lime-rich fertilizers) and urbanization (e.g., asphalt roads) and effluents and leachate from sources associated with industry (e.g., soap manufacturing plants) and mining (e.g., oil and gas brine mining wastes). Atmospheric emissions and deposition generally do not contribute to high pH conditions, a marked difference from low pH conditions.

<https://epa.gov/sites/default/files/2015-12/high-ph-cd_sim_800.jpg>

Simple conceptual model diagram for **HIGH pH**

Figure 3. A simple conceptual diagram illustrating causal pathways, from sources to impairments, related to **high pH**. Click on the diagram to view a larger version.

There also are natural sources which can result in high pH conditions, such as naturally alkaline geologies and lithologies and high levels of photosynthesis. Because photosynthesis produces hydroxide ions, elevated nutrient concentrations may contribute to pH increases.

High pH levels can affect other stressors, most notably by increasing the proportion of ammonia in its unionized, toxic form. Increases in pH and pH fluctuation may contribute to decreased condition, decreased growth, altered behavior and increased susceptibility to other stressors in affected biota.

Ultimately, these effects may result in increased mortality, decreased reproductive success and changes in population and community structure and ecosystem function. For example, taxa sensitive to high pH (e.g., perciform fishes) may decrease, while more tolerant taxa (e.g., cypriniform fishes, *Cladophora*) may increase. These changes may result in reduced taxa richness or diversity.

Detailed Conceptual Model Diagram (Low pH)

pH is a measure of hydrogen ion concentration in an aqueous solution. pH decreases as hydrogen ion concentration increases, and these acidic conditions can adversely affect aquatic biota.

This conceptual diagram (see Figure 12) illustrates linkages between low pH and associated pH fluctuations (middle of diagram), the human activities and sources that can contribute to low pH (top of diagram) and the biological responses that can result (bottom of diagram). In some cases, additional steps leading from sources to stressors, modes of action leading from stressors to responses and other modifying factors also are shown. This narrative generally follows the diagram top to bottom, left to right.

<https://epa.gov/sites/default/files/2015-12/lowphcd_det_1500.jpg>

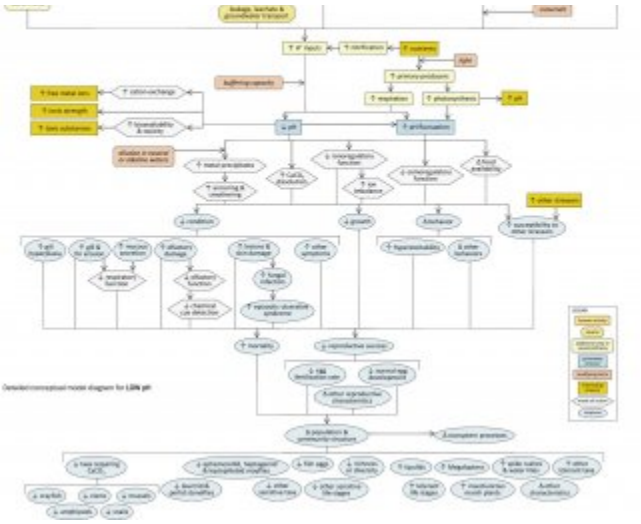


Figure 12. Example of a detailed conceptual model diagram for **Low pH**. Click on the diagram to view a larger version.

Linking Sources to Stressors

Certain human activities and land uses can result in increased input of hydrogen ions into aquatic systems. Land drainage can reduce soil saturation and lead to sulfur oxidation and the release of sulfuric acid. Other sources of hydrogen ions include acid mine drainage and other mining wastes from active and historical mines; natural, acid-generating geologies and lithologies subjected to weathering; natural organic acids (e.g., humic acids); animal wastes from CAFOs, dairies and aquaculture facilities; coal piles and landfills associated with residential, municipal, commercial and industrial facilities; and emissions and effluents from coal-fired power plants, metal plating plants and other industrial facilities.

Hydrogen ions from these sources can be introduced into aquatic systems via four main transport pathways (or transport-defined sources): stormwater runoff, leakage or leachate into groundwater sources and subsequent transport, atmospheric emissions and deposition or direct effluent discharges. Each of these transport-defined sources can contribute to increased hydrogen ion inputs into surface waters. When atmospheric deposition of hydrogen ions occurs in the form of snowfall, snowmelt can result in pulsed delivery of hydrogen ions to surface waters.

Whether hydrogen ion inputs to aquatic systems lead to decreases in pH depends upon buffering capacity, or the ability of the system to neutralize those inputs. Streams with high bicarbonate concentrations are highly buffered, and may not become acidic even with significant hydrogen ion inputs. Once buffering capacity is exceeded, however, pH will decrease.

Instream oxidation-reduction processes also may influence pH. For example, nitrification and respiration both produce hydrogen ions, so nutrient concentrations may play a significant role in pH dynamics. Decreases in pH also can affect other stressors, such as by increasing free metal ions, increasing the bioavailability and toxicity of toxic substances, and increasing ionic strength (see the Metals, Ionic Strength, and Unspecified Toxic Substances modules for more information on these pathways).

Linking Stressors to Biological Responses

Decreases in pH and associated increases in pH fluctuation can adversely affect aquatic organisms via many potential modes of action. Low pH can lead to dissolution of calcium carbonate shells, ultimately leading to decreases in taxa with calcium carbonate shells (e.g., mussels and snails).

When low pH solutions (e.g., acid mine drainage) are neutralized upon entering higher pH streams, metals in those solutions can precipitate and smother or armor stream bottoms. Low pH also can compromise ionoregulatory and osmoregulatory function, or lead to changes in food availability.

These different modes of action all may contribute to decreased condition, decreased growth, altered behavior and increased susceptibility to other stressors in affected biota. Possible decreases in condition include gill hyperplasia, gill and fin erosion, lesions and skin damage (increasing susceptibility to fungal infections) and increased mucous secretion. Possible changes in behavior include hyperexcitability.

Ultimately, these effects may result in increased mortality and decreased reproductive success, particularly in terms of impaired egg fertilization and development. This can lead to changes in population and community structure and ecosystem function. Taxa sensitive to low pH (e.g., certain mayfly and stonefly taxa) may decrease, while more tolerant taxa (e.g., tipulids, megalopterans, spike rushes) may increase. Sensitive life stages (e.g., eggs in fish) also may decline. These changes in community structure may in turn affect ecosystem functions such as leaf decomposition.

Detailed Conceptual Model Diagram (High pH)

High pH levels occur when hydroxide ion concentrations are high and hydrogen ions are scarce. Although acidic conditions more commonly result from human activities, alkaline conditions also can occur and adversely affect aquatic biota.

This conceptual diagram (see Figure 13) illustrates linkages between high pH and associated pH fluctuations (middle of diagram), the human activities and sources that can contribute to high pH (top of diagram) and the biological responses that can result (bottom of diagram). In some cases, additional steps leading from sources to stressors, modes of action leading from stressors to responses and other modifying factors also are shown. This narrative generally follows the diagram top to bottom, left to right.

Linking Sources to Stressors

Certain human activities and land uses can result in increased input of hydroxide ions into aquatic systems, leading to increases in pH. These sources include: runoff of lime-rich fertilizers applied to agricultural cropfields, golf courses and lawns; runoff from limestone gravel roads, asphalt roads and other asphalt waste; and effluents and leachate from oil and gas brine mining wastes or from industries that use lime, lye or sodium hydroxide (e.g., asphalt and cement manufacturing plants, soap manufacturing plants).

Atmospheric emissions and deposition are not significant transport sources for hydroxide ions and thus generally do not contribute to high pH conditions, a marked difference from low pH conditions. There also are natural sources which can result in high pH conditions, such as naturally alkaline geologies and lithologies and high levels of photosynthesis.

<https://epa.gov/sites/default/files/2015-12/high-ph-cd_det_1200.jpg>

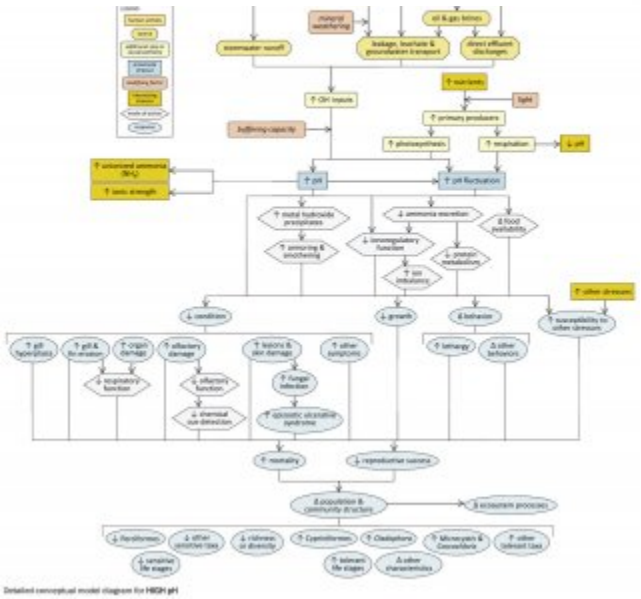

Figure 13. Example of a detailed conceptual model diagram for **High pH**. Click on the diagram to view a larger version.

Because photosynthesis produces hydroxide ions, elevated nutrient concentrations may contribute to pH increases. High pH levels also can affect other stressors, most notably by increasing the proportion of ammonia in its unionized, toxic form (see the ammonia and ionic strength modules for more information on these pathways).

Linking Stressors to Biological Response

Increases in pH and associated increases in pH fluctuation can adversely affect aquatic organisms via many potential modes of action. For example, metal hydroxides can form and precipitate, smothering or armoring stream bottoms. Ammonia excretion may be impaired, adversely affecting ionoregulatory function and protein metabolism. Indirect effects such as changes in food availability also may occur.

These different modes of action all may contribute to decreased condition, decreased growth, altered behavior and increased susceptibility to other stressors in affected biota. Possible decreases in condition include gill hyperplasia, gill and fin erosion, lesions and skin damage (increasing susceptibility to fungal infections) and increased olfactory damage; possible changes in behavior include lethargy.

Ultimately, these effects may result in increased mortality, decreased reproductive success and changes in population and community structure and ecosystem function. Taxa sensitive to high pH (e.g., perciform fishes) may decrease, while more tolerant taxa (e.g., cypriniform fishes, *Cladophora*) may increase. These changes may result in reduced taxa richness or diversity.

Literature Reviews

This section presents an annotated bibliography of references providing information on stressor-response relationships for pH, as well as general background information. This is not meant to be a comprehensive bibliography of references dealing with pH. Rather, it is meant to highlight a few references that may be especially useful.

- Baker JP, Bernard DP, Christensen SW, Sale MJ (1990) Biological effects of changes in surface water acid-base chemistry. National Acid Precipitation Assessment Program, Washington DC. NAPAP Report 13.

This report describes the effects of acidification on biological communities. The described effects include, but are not limited to, changes in taxonomic composition, biomass and density. Mechanisms of effect are also described. The report includes methods for regional assessments of fish community effects and some regional analyses.

- Driscoll CT, Lawrence GB, Bulger AJ, Butler TJ, Cronan SC, Eagar C, Lambert KF, Likens GE, Stoddard JL, Weathers KC (2001) Acidic deposition in the northeastern United States: sources and inputs, ecosystem effects, and management strategies. BioScience 51(3):180-198.

This article provides an excellent general review of effects of acidic deposition on soil, forest vegetation, surface waters and terrestrial and aquatic ecosystems.

- Hamelink JL, Landrum PF, Bergman HL, Benson WH (Eds.) (1994) Bioavailability: Physical, Chemical, and Biological Interactions. Lewis Publishers, Boca Raton FL.

This book discusses factors affecting bioavailability of different pollutant classes (e.g., metals, nonpolar organics). The section *Effects of Redox Processes on Acid-Producing Potential and Metal Mobility in Sediments* has particularly relevant pH information. This book is more technical than the other reviewed literature. A good discussion of buffering factors includes a list the major processes that consume H^+.

- Howells GG, Brown DJA, Sadler K (1983) Effects of acidity, calcium and aluminum on fish survival and productivity: a review. Journal of the Science of Food and Agriculture 34(6):559-570.

This article reviews studies of the effects of calcium and aluminum at low pH on survival. It also presents a section on modeling water quality effects on fish populations in an attempt to relate laboratory and field data.

- Mackie GL (2001) Applied Aquatic Ecosystem Concepts. Kendall/Hunt Publishing, Dubuque IA.

This textbook contains a section about acid precipitation that discusses the pH scale, geochemical influences, biological effects to several aquatic organisms, other atmospheric pollutants and mitigating lake acidification.

- Morris R, Taylor EW, Brown DJA, Brown JA (Eds.) (1989) Acid Toxicity and Aquatic Animals. Cambridge University Press, Cambridge UK.

This collection of papers describes a variety of biotic responses and modes of action in response to acid. The introduction *The Causes and Consequences of Surface Water Acidification* discusses acid precipitation and its effects at length. The rest of the book provides more specific and in-depth information regarding acid toxicity in aquatic systems.

- Orendt C (1999) Chironomids as bioindicators in acidified streams: a contribution to the acidity tolerance of chironomid species with a classification in sensitivity classes. International Review of Hydrobiology 84:439-449.

This study discusses the acid tolerance of chironomids based on their occurrence in a certain pH range.Twenty-five species are classified according to their acid sensitivity.

- Rand GM (Ed.) (1995) Fundamentals of Aquatic Toxicology: Effects, Environmental Fate, and Risk Assessment (2nd edition). Taylor and Francis, Washington DC.

Appendix C, *Factors that Modify Toxicity*, includes a section on hydrogen ion concentration. It contains information on how both low and high pH can modify pollutant toxicity.

- Robertson-Bryan, Inc. (2004) Technical Memorandum: pH Requirements of Freshwater Aquatic Life. California's Central Valley Water Quality Control Board.

This document is a review of many studies on pH requirements and effects on freshwater aquatic life. It reviews both fish and macroinvertebrates with respect to high and low pH.

- Scullion J, Edwards RW (1980) The effects of coal industry pollutants on the macroinvertebrate fauna of a small river in the South Wales coalfield. Freshwater Biology 10:141-162.

This paper is a case study that investigated the effects of coal industry pollutants on the macroinvertebrate fauna of a small river in a South Wales coalfield. It discusses the pH fluctuations due to drainage water from coal stockpiles and seasonal flows. The paper contains water quality data, arithmetic mean density of several species and a range of numbers of species and densities in relation to distance from the source. It contains a good discussion of low pH effects on specific species.

- U.S. EPA (2008) Integrated Science Assessment for Oxides of Nitrogen and Sulfur: Ecological Criteria. U.S. Environmental Protection Agency, Washington DC. EPA/600/R-08/082F.

This assessment reviews field and laboratory studies of the effects of acidification in aquatic and terrestrial ecosystems. Section B.6 contains 24 pages of tables summarizing effects by species and ecosystem.

QUALITY CRITERIA for WATER 1986

NMED Exhibit 68

TO INTERESTED PARTIES

Section 304(a)(1) of the Clean Water Act (33 U.S.C. 1314(a)(1) requires the Environmental Protection Agency (EPA) to publish and periodically update ambient water quality criteria. These criteria are to accurately reflect the latest scientific knowledge (a) on the kind and extent of all identifiable effects on health and welfare including, but not limited to, plankton, fish shellfish, wildlife, plant life, shorelines, beaches, aesthetics, and recreation which may be expected from the presence of pollutants in any body of water including ground water; (b) on the concentration and dispersal of pollutants, or their byproducts, through biological, physical, and chemical processes; and (c) on the effects of pollutants on biological community diversity, productivity, and stability, including information on the factors affecting rates of eutrophication and organic and inorganic sedimentation for varying types of receiving waters. These criteria are not rules and they do not have regulatory impact. Rather, these criteria present scientific data and guidance of the environmental effects of pollutants which can be useful to derive regulatory requirements based on considerations of water quality impacts. When additional data has become available, these summaries have been updated to reflect the latest Agency recommendations on acceptable limits for aquatic life and human health protection.

Periodically EPA and its predecessor agencies has issued ambient water quality criteria, beginning in 1968 with the "Green Book" followed by the 1973 publication of the "Blue Book" (Water Quality Criteria 1972). In 1976, the "Red Book" (Quality

For sale by the Superintendent of Documents, U.S. Government Printing Office
Washington, D.C. 20402

NMED Exhibit 68

Criteria for Water) was published. On November 28, 1980 (45 FR 79318), and February 15, 1984 (49 FR 5831), EPA announced through Federal Register notices, the publication of 65 individual ambient water quality criteria documents for pollutants listed as toxic under section 307(a)(1) of the Clean Water Act. On July 29, 1985 (50 FR 30784), EPA published additional water quality criteria documents.

The development and publication of ambient water quality criteria has been pursued over the past 10 years and is an ongoing process. EPA expects to publish about 10 final criteria documents each year. Some of these will update and revise existing criteria recommendations and others will be issued for the first time.

In a continuing effort to provide those who use EPA's water quality and human health criteria with up-to-date criteria values and associated information, this document Quality Criteria for Water 1986 was assembled. This document includes summaries of all the contaminants for which EPA has developed criteria recommendations (Appendix A-C). The appropriate appendix is identified at the end of each summary. A more detailed description of these procedures can be found in the appropriate Appendix. Copies of this document can be obtained by contacting the U.S. Government Printing Office at:

U.S. Government Printing Office
Superintendent of Documents
N. Capitol and H Street N.W.
Washington, D.C. 20401

A fee is charged for this document.

Copies of the complete background ambient water quality

criteria documents containing all the data used to develop the criteria recommendations summarized herein and the "Red Book", including complete bibliographies are available only from:

National Technical Information Service
5285 Port Royal Road
Springfield, VA 22161

Telephone: (703) 487-4650

The NTIS order numbers for the criteria documents can be found in the Index. A fee is charged for copies of these documents.

As new criteria are developed and existing criteria revised, updated criteria summaries will be made available once a year to those who purchase this document through the U.S. Government Printing Office. You will automatically be placed on the mailing list to receive annual updates. The cost for receiving annual updates is included in the purchase price of the document.

Quality Criteria for Water, 1986 is designed to be easily updated to reflect EPA's continuing work to present the latest scientific information and practices. Our planned schedule for future criteria development in the next few years is attached for your information.

The Agency is currently developing Acceptable Daily Intake (ADI) or Verified Reference Dose (RfD) values on a number of chemicals for Agency-wide use. Based upon this new analysis the values have changed significantly for 5 chemicals from those used in the original human health criteria calculation done in 1980. The chemicals affected are as follows:

Chemical	1980 WQC	Draft RfD
1. Cyanide	200 ug/L	.02 mg/kg/day
2. Ethylbenzene	1.4 mg/L	.01 mg/kg/day
3. Nitrobenzene	19.8 mg/L	.0005 mg/kg/day
4. Phenol	3.5 mg/L	0.1 mg/kg/day
5. Toluene	14.3 mg/L	0.3 mg/kg/day

FOR FURTHER INFORMATION CONTACT:

Dr. Frank Gostomski at the above address or by phoning (202) 245-3030.

It is EPA's goal to continue to develop and make available ambient water quality criteria reflecting the latest scientific practices and information. In this way we can continue to improve and protect the quality of the Nation's waters.

James M. Conlon

James M Conlon

Acting Director,
Office of Water Regulations
and Standards

DRAFT CRITERIA DOCUMENTS TO BE PROPOSED

LATE FY 86/EARLY FY 87

Diethyhexylphthalate
1,2,4, Trichlorobenzene
Silver
Phenanthrene
2,4,5, Trichlorophenol
Organotins
Tributyltin
Selenium (no saltwater criteria)
Hexachlorobenzene
Antimony III
Acrolein (no saltwater criteria)

LATE FY 87/EARLY 88

Thallium (no saltwater criteria)
Tetrachloroethylene (no saltwater criteria)
Phenol
Toluene
Chloroform (no saltwater criteria)
Analine
Acrylontrile
Hexachlorocyclopentadiene (no saltwater criteria)
Dimethylphenol
Hexachlorobutadiene (no saltwater criteria)

- Both lists will incorporate aquatic and human health values.

- All above are toxic pollutants except for organotins and analine which are non-conventionals.

CRITERIA:

Aquatic Life

The available data for acenaphthene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 1,700 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of acenaphthene to sensitive freshwater aquatic animals but toxicity to freshwater algae occur at concentrations as low as 520 ug/L.

The available data for acenaphthene indicate that acute and chronic toxicity to saltwater aquatic life occurs at concentrations as low as 970 and 710 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested. Toxicity to algae occurs at concentrations as low as 500 ug/L.

Human Health

Sufficient data are not available for acenaphthene to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, to control undesirable taste and odor quality of ambient water the estimated level is 0.02 mg/L. It should be recognized that organoleptic data, have limitations as a basis for establishing water quality criteria, and have no demonstrated relationship to potential adverse human health effects.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

ACROLEIN

CRITERIA:

Aquatic Life

The available data for acrolein indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 68 and 21 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

The available data for acrolein indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 55 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of acrolein to sensitive saltwater aquatic life.

Human Health

For the protection of human health from the toxic properties of acrolein ingested through contaminated aquatic organisms, the ambient water criterion is determined to be 320 ug/L.

For the protection of human health from the toxic properties of acrolein ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 780 ug/L.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

ACRYLONITRILE

CRITERIA:

Aquatic Life

The available data for acrylonitrile indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 7,550 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No definitive data are available concerning the chronic toxicity of acrylonitrile to sensitive freshwater aquatic life but mortality occurs at concentrations as low as 2,600 ug/L with a fish species exposed for 30 days.

Only one saltwater species has been tested with acrylonitrile and no statement can be made concerning acute or chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects resulting from exposure to acrylonitrile through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 0.58 ug/L, 0.058 ug/L, and 0.006 ug/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption

of water, the levels are 6.5 ug/L, 0.65 ug/L, and 0.065 ug/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

AESTHETIC QUALITIES

CRITERIA:

All waters free from substances attributable to wastewater or other discharges that:

(1) settle to form objectionable deposits;

(2) float as debris, scum, oil, or other matter to form nuisances;

(3) produce objectionable color, odor, taste, or turbidity;

(4) injure or are toxic or produce adverse physiological responses in humans, animals or plants; and,

(5) produce undesirable or nuisance aquatic life.

RATIONALE:

Aesthetic qualities of water address the general principles laid down in common law. They embody the beauty and quality of water and their concepts may vary within the minds of individuals encountering the waterway. A rationale for these qualities cannot be developed with quantifying definitions; however, decisions concerning such quality factors can portray the best in the public interest.

Aesthetic qualities provide the general rules to protect water against environmental insults: they provide minimal freedom requirements from pollution; they are essential properties to protect the Nation's waterways.

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

ALKALINITY

CRITERION:

20 mg/L or more as $CaCO_3$ freshwater aquatic life except where natural concentrations are less.

INTRODUCTION:

Alkalinity is the sum total of components in the water that tend to elevate the pH of the water above a value of about 4.5. It is measured by titration with standardized acid to a pH value of about 4.5 and it is expressed commonly as milligrams per liter of calcium carbonate. Alkalinity, therefore, is a measure of the buffering capacity of the water, and since pH has a direct effect on organisms as well as an indirect effect on the toxicity of certain other pollutants in the water, the buffering capacity is important to water quality. Examples of commonly occurring materials in natural waters that increase the alkalinity are carbonates, bicarbonates, phosphates and hydroxides.

RATIONALE:

The alkalinity of water used for municipal water supplies is important because it affects the amounts of chemicals that need to be added to accomplish calculation, softening and control of corrosion in distribution systems. The alkalinity of water assists in the neutralization of excess acid produced during the addition of such materials as aluminum sulfate during chemical coagulation. Waters having sufficient alkalinity do not have to be supplemented with artificially added materials to increase the alkalinity. Alkalinity resulting from naturally occurring

materials such as carbonate and bicarbonate is not considered a health hazard in drinking water supplies, per se, and naturally occurring maximum levels up to approximately 400 mg/L as calcium carbonate are not considered a problem to human health (NAS, 1974).

Alkalinity is important for fish and other aquatic life in freshwater systems because it buffers pH changes that occur naturally as a result of photosynthetic activity of the chlorophyll-bearing vegetation. Components of alkalinity such as carbonate and biocarbonate will complex some toxic heavy metals and reduce their toxicity markedly. For these reasons, the National Technical Advisory Committee (NATC, 1968) recommended a minimum alkalinity of 20 mg/L and the subsequent NAS Report (1974) recommended that natural alkalinity not be reduced by more than 25 percent but did not place an absolute minimal value for it. The use of the 25 present reduction avoids the problem of establishing standards on waters where natural alkalinity is at or below 20 mg/L. For such waters, alkalinity should not be further reduced.

The NAS Report recommends that adequate amounts of alkalinity be maintained to buffer the pH within tolerable limits for marine waters. It has been noted as a correlation that productive waterfowl habitats are above 25 mg/L with higher alkalinities resulting in better waterfowl habitats (NATC, 1968).

Excessive alkalinity can cause problems for swimmers by altering the pH of the lacrimal fluid around the eye, causing irritation.

For industrial water supplies, high alkalinity can be damaging to industries involved in food production, especially those in which acidity accounts for flavor and stability, such as the carbonated beverages. In other instances, alkalinity is desirable because water with a high alkalinity is much less corrosive.

A brief summary of maximum alkalinities accepted as a source of raw water by industry is included in Table 1. The concentrations listed in the table are for water prior to treatment and thus are only desirable ranges and not critical ranges for industrial use.

The effect of alkalinity in water used for irrigation may be important in some instances because it may indirectly increase the relative proportion of sodium in soil water. As an example, when bicarbonate concentrations are high, calcium and magnesium ions that are in solution precipitate as carbonates in the soil water as the water becomes more concentrated through evaporation and transpiration. As the calcium and magnesium ions decrease in concentration, the percentage of sodium increases and results in soil and plant damage. Alkalinity may also lead to chlorosis in plants because it causes the iron to precipitate as a hydroxide (NAS, 1974). Hydroxyl ions react with available iron in the soil

TABLE I*

water and make the iron unavailable to plants. Such deficiencies induce chlorosis and further plant damage. Usually alkalinity must exceed 6 mg/L before such effects are noticed, however.

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

*ALDRIN-DIELDRIN

CRITERIA:

Aquatic Life

Dieldrin

For dieldrin the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.0019 ug/L as a 24-hour average, and the concentration should not exceed 2.5 ug/L at any time.

For dieldrin the criterion to protect saltwater aquatic life as derived using the Guidelines is 0.0019 ug/L as a 24-hour average, and the concentration should not exceed 0.71 ug/L at any time.

Aldrin

For freshwater aquatic life the concentration of aldrin should not exceed 3.0 ug/L at any time. No data are available concerning the chronic toxicity of aldrin to sensitive freshwater aquatic life.

For saltwater aquatic life the concentration of aldrin should not exceed 1.3 ug/L at any time. No data are available concerning the chronic toxicity of aldrin to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to aldrin through ingestion of contaminated water and contaminated aquatic organisms, the

*Indicates suspended, canceled or restricted by U.S. EPA Office of Pesticides and Toxic Substances

ambient water concentration should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6} and 10^{-7} The corresponding recommended criteria are 0.74 ng/L, 0.074 ng/L, and 0.0074 ng/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 0.79 ng/L, 0.079 ng/L, and 0.0079 ng/L, respectively.

For the maximum protection of human health from the potential carcinogenic effects of exposure to dieldrin through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6} and 10^{-7}. The corresponding recommended criteria are 0.71 ng/L, 0.071 ng/L, and 0.0071 ng/L, respectively. If these above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 0.76 ng/L, 0.076 ng/L, and 0.0076 ng/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

AMMONIA

SUMMARY:

All concentrations used herein are expressed as un-ionized ammonia (NH_3), because NH_3, not the ammonium ion (NH_4^+) has been demonstrated to be the principal toxic form of ammonia. The data used in deriving criteria are predominantly from flow through tests in which ammonia concentrations were measured. Ammonia was reported to be acutely toxic to freshwater organisms at concentrations (uncorrected for pH) ranging from 0.53 to 22.8 mg/L NH_3 for 19 invertebrate species representing 14 families and 16 genera and from 0.083 to 4.60 mg/L NH_3 for 29 fish species from 9 families and 18 genera. Among fish species, reported 96-hour LC50 ranged from 0.083 to 1.09 mg/L for salmonids and from 0.14 to 4.60 mg/L NH_3 for nonsalmonids. Reported data from chronic tests on ammonia with two freshwater invertebrate species, both daphnids, showed effects at concentrations (uncorrected for pH) ranging from 0.304 to 1.2 mg/L NH_3, and with nine freshwater fish species, from five families and seven genera, ranging from 0.0017 to 0.612 mg/L NH_3.

Concentrations of ammonia acutely toxic to fishes may cause loss of equilibrium, hyperexcitability, increased breathing, cardiac output and oxygen uptake, and, in extreme cases, convulsions, coma, and death. At lower concentrations ammonia has many effects on fishes, including a reduction in hatching success, reduction in growth rate and morphological development, and pathologic changes in tissues of gills, livers, and kidneys.

Several factors have been shown to modify acute NH_3 toxicity in fresh water. Some factors alter the concentration of un-ionized ammonia in the water by affecting the aqueous ammonia equilibrium, and some factors affect the toxicity of un-ionized ammonia itself, either ameliorating or exacerbating the effects of ammonia. Factors that have been shown to affect ammonia toxicity include dissolved oxygen concentration, temperature, pH, previous acclimation to ammonia, fluctuating or intermittent exposures, carbon dioxide concentration, salinity, and the presence of other toxicants.

The most well-studied of these is pH; the acute toxicity of NH_3 has been shown to increase as pH decreases. Sufficient data exist from toxicity tests conducted at different pH values to formulate a mathematical expression to describe pH-dependent acute NH_3 toxicity. The very limited amount of data regarding effects of pH on chronic NH_3 toxicity also indicates increasing NH_3 toxicity with decreasing pH, but the data are insufficient to derive a broadly applicable toxicity/pH relationship. Data on temperature effects on acute NH_3 toxicity are limited and somewhat variable, but indications are that NH_3 toxicity to fish is greater as temperature decreases. There is no information available regarding temperature effects on chronic NH_3 toxicity.

Examination of pH and temperature-corrected acute NH_3 toxicity values among species and genera of freshwater organisms showed that invertebrates are generally more tolerant than fishes, a notable exception being the fingernail clam. There is no clear trend among groups of fish; the several most sensitive

tested species and genera include representatives from diverse families (Salmonidae, Cyprinidae, Percidae, and Centrarchidae). Available chronic toxicity data for freshwater organisms also indicate invertebrates (cladocerans, one insect species) to be more tolerant than fishes, again with the exception of the fingernail clam. When corrected for the presumed effects of temperature and pH, there is also no clear trend among groups of fish for chronic toxicity values, the most sensitive species including representatives from five families (Salmonidae, Cyprinidae, Ictaluridae, Centrarchidae, and Catostomidae) and having chronic values ranging by not much more than a factor or two. The range of acute-chronic ratios for 10 species from 6 families was 3 to 43, and acute-chronic ratios were higher for the species having chronic tolerance below the median. Available data indicate that differences in sensitivities between warm and coldwater families of aquatic organisms are inadequate to warrant discrimination in the national ammonia criterion between bodies of water with "warm" and "coldwater" fishes; rather, effects of organism sensitivities on the criterion are most appropriately handled by site-specific criteria derivation procedures.

Data for concentrations of NH_3 toxic to freshwater phytoplankton and vascular plants, although limited, indicate that freshwater plant species are appreciably more tolerant to NH_3 than are invertebrates or fishes. The ammonia criterion appropriate for the protection of aquatic animals will therefore in all likelihood be sufficiently protective of plant life.

Available acute and chronic data for ammonia with saltwater organisms are very limited, and insufficient to derive a saltwater criterion. A few saltwater invertebrate species have been tested, and the prawn Macrobrachium rosenbergii was the most sensitive. The few saltwater fishes tested suggest greater sensitivity than freshwater fishes. Acute toxicity of NH_3 appears to be greater at low pH values, similar to findings in freshwater. Data for saltwater plant species are limited to diatoms, which appear to be more sensitive than the saltwater invertebrates for which data are available.

More quantitative information needs to be published on the toxicity of ammonia to aquatic life. Several key research needs must be addressed to provide a more complete assessment of ammonia toxicity. These are: (1) acute tests with additional saltwater fish species and saltwater invertebrate species; (2) life-cycle and early life-stage tests with representative freshwater and saltwater organisms from different families, with particular attention to trends of acute-chronic ratios; (3) fluctuating and intermittent exposure tests with a variety of species and exposure patterns; (4) more complete tests of the individual and combined effects of pH and temperature, especially for chronic toxicity; (5) more histopathological and histochemical research with fishes, which would provide a rapid means of identifying and quantifying sublethal ammonia effects; and (6) studies on effects of dissolved and suspended solids on acute and chronic toxicity.

NATIONAL CRITERIA:

The procedures described in the Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses indicate that, except possibly where a locally important species is very sensitive, freshwater aquatic organisms and their uses should not be affected unacceptably if:

(1) the 1-hour* average concentration of un-ionized ammonia (in mg/L NH_3) does not exceed, more often than once every 3 years on the average, the numerical value given by 0.52/FT/FPH/2,

where:

$$FT = 10^{0.03(20-TCAP)}; \quad TCAP \leq T \leq 30$$

$$10^{0.03(20-T)}; \quad 0 \leq T \leq TCAP$$

$$FPH = 1 \quad ; \quad 8 < pH < 9$$

$$\frac{1+10^{7.4-pH}}{1.25} \quad ; \quad 6.5 \leq pH \leq 7.7$$

TCAP = 20 C; Salmonids or other sensitive coldwater species present

= 25 C; Salmonids and other sensitive coldwater species absent

(*An averaging period of 1 hour may not be appropriate if excursions of concentrations to greater than 1.5 times the average occur during the hour; in such cases, a shorter averaging period may be needed.)

(2) the 4-day average concentration of un-ionized ammonia (in mg/L NH_3) does not exceed, more often than once every 3 years on the average, the average* numerical value given by 0.80/FT/FPH/RATIO, where FT and FPH are as above and:

$$\text{RATIO} = 16 \qquad ; \ 7.7 \leq \text{pH} \leq 9$$

$$= 24 \ \frac{10^{7.7-\text{pH}}}{1+10^{7.4\text{pH}}} \qquad ; 6.5 \leq \text{pH} \leq 7.7$$

TCAP = 15 C; Salmonids or other sensitive coldwater species present

= 20 C; Salmonids and other sensitive coldwater species absent

(*Because these formulas are nonlinear in pH and temperature, the criterion should be the average of separate evaluations of the formulas reflective of the fluctuations of flow, pH, and temperature within the averaging period; it is not appropriate in general to simply apply the formula to average pH, temperature, and flow.)

The extremes for temperature (0, 30) and pH (6.5, 9) given in the above formulas are absolute. It is not permissible with current data to conduct any extrapolations beyond these limits. In particular, there is reason to believe that appropriate criteria at pH > 9 will be lower than the plateau between pH 8 and 9 given above.

Criteria concentrations for the pH range 6.5 to 9.0 and the temperature range 0 C to 30 C are provided in the following tables. Total ammonia concentrations equivalent to each un-ionized ammonia concentration are also provided in these tables. There are limited data on the effect of temperature on chronic toxicity. EPA will be conducting additional research on the effects of temperature on ammonia toxicity in order to fill perceived data gaps. Because of this uncertainty, additional site-specific information should be developed before these

criteria are used in wasteload allocation modeling. For example, the chronic criteria tabulated for sites lacking salmonids are less certain at temperatures much below 20 C than those tabulated at temperatures near 20 C. Where the treatment levels needed to meet these criteria below 20 C may be substantial, use of site-specific criteria is strongly suggested. Development of such criteria should be based upon site-specific toxicity tests.

Data available for saltwater species are insufficient to derive a criterion for saltwater.

The recommended exceedence frequency of 3 years is the Agency's best scientific judgment of the average amount of time it will take an unstressed system to recover from a pollution event in which exposure to ammonia exceeds the criterion. A stressed system, for example, one in which several outfalls occur in a limited area, would be expected to require more time for recovery. The resilience of ecosystems and their ability to recover differ greatly, however, and site-specific criteria may be established if adequate justification is provided.

The use of criteria in designing waste treatment facilities requires the selection of an appropriate wasteload allocation model. Dynamic models are preferred for the application of these criteria. Limited data or other factors may make their use impractical, in which case one should rely on a steady-state model. The Agency recommends the interim use of 1Q5 or 1Q10 for Criterion Maximum Concentration design flow and 7Q5 or 7Q10 for the Criterion Continuous Concentration design flow in steady-state models for unstressed and stressed systems respectively.

* To convert these values to mg/liter N, multiply by 0.822.

The Agency acknowledges that the Criterion Continuous Concentration stream flow averaging period used for steady-state wasteload allocation modeling may be as long as 30 days in situations involving POTWs designed to remove ammonia where limited variability of effluent pollutant concentration and resultant concentrations in receiving waters can be demonstrated. In cases where low variability can be demonstrated, longer averaging periods for the ammonia Criterion Continuous Concentration (e.g., 30-day averaging periods) would be acceptable because the magnitude and duration of exceedences above the Criterion Continuous Concentration would be sufficiently limited. These matters are discussed in more detail in the Technical Support Document for Water Quality-Based Toxics Control (U.S. EPA, 1985a).

SEE APPENDIX A FOR METHODOLOGY

ANTIMONY

CRITERIA:

Aquatic Life

The available data for antimony indicate that acute and chronic toxicity to freshwater aquatic life occur at concentrations as low as 9,000 and 1,600 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested. Toxicity to algae occurs at concentrations as low as 610 ug/L.

No saltwater organisms have been adequately tested with antimony, and no statement can be made concerning acute or chronic toxicity.

Human Health

For the protection of human health from the toxic properties of antimony ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 146 ug/L.

For the protection of human health from the toxic properties of antimony ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 45 mg/L.

SEE APPENDIX B FOR METHODOLOGY

ARSENIC

AQUATIC LIFE SUMMARY:

The chemistry of arsenic in water is complex and the form present in solution is dependent on such environmental conditions as Eh, pH, organic content, suspended solids, and sediment. The relative toxicities of the various forms of arsenic apparently vary from species to species. For inorganic arsenic(III) acute values for 16 freshwater animal species ranged from 812 ug/L for a cladoceran to 97,000 ug/L for a midge, but the three acute-chronic ratios only ranged from 4.660 to 4.862. The five acute values for inorganic arsenic(V) covered about the same range, but the single acute-chronic ratio was 28.71. The six acute values for MSMA ranged from 3,243 to 1,403,000 ug/L. The freshwater residue data indicated that arsenic is not bioconcentrated to a high degree but that lower forms of aquatic life may accumulate higher arsenic residues than fish. The low bioconcentration factor and short half-life of arsenic in fish tissue suggest that residues should not be a problem to predators of aquatic life.

The available data indicate that freshwater plants differ a great deal as to their sensitivity to arsenic(III) and arsenic(V). In comparable tests, the alga, Selenastrum capricornutum, was 45 times more sensitive to arsenic(V) than to arsenic(III), although other data present conflicting information on the sensitivity of this alga to arsenic(V). Many plant values for inorganic arsenic(III) were in the same range as the available chronic values for freshwater animals; several

plant values for arsenic(V) were lower than the one available chronic value.

The other toxicological data revealed a wide range of toxicity based on tests with a variety of freshwater species and endpoints. Tests with early life stages appeared to be the most sensitive indicator of arsenic toxicity. Values obtained from this type of test with inorganic arsenic(III) were lower than chronic values contained in Table 2. For example, an effect concentration of 40 ug/L was obtained in a test on inorganic arsenic(III) with embryos and larvae of a toad.

Twelve species of saltwater animals have acute values for inorganic arsenic(III) from 232 to 16,030 ug/L and the single acute-chronic ratio is 1.945. The only values available for inorganic arsenic(V) are for two invertebrate and are between 2,000 and 3,000 ug/L. Arsenic(III) and arsenic(V) are equally toxic to various species of saltwater algae, but the sensitivities of the species range from 19 ug/L to more than 1,000 ug/L. In a test with an oyster, a BCF of 350 was obtained for inorganic arsenic(III).

NATIONAL CRITERIA:

The procedures described in the Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses indicate that, except possibly where a locally important species is very sensitive, freshwater aquatic organisms and their uses should not be affected unacceptably if the 4-day average concentration of arsenic(III) does not exceed 190 ug/L more than once every 3 years on the

average and if the 1-hour average concentration does not exceed 360 ug/L more than once every 3 years on the average.

The procedures described in the Guidelines indicate that, except possibly where a locally important species is very sensitive, saltwater aquatic organisms and their uses should not be affected unacceptably if the 4-day average concentration of arsenic(III) does not exceed 36 ug/L more than once every 3 years on the average and if the 1-hour average concentration does not exceed 69 ug/L more than once every 3 years on the average. This criterion might be too high wherever Skeletonema cosrarum or Thalassiosira aestivalis are ecologically important.

Not enough data are available to allow derivation of numerical national water quality criteria for freshwater aquatic life for inorganic arsenic(V) or any organic arsenic compound. Inorganic arsenic(V) is acutely toxic to freshwater aquatic animals at concentrations as low as 850 ug/L and an acute-chronic ratio of 28 was obtained with the fathead minnow. Arsenic(V) affected freshwater aquatic plants at concentrations as low as 48 ug/L. Monosodium methanearsenace (MSMA) is acutely toxic to aquatic animals at concentrations as low as 1,900 ug/L, but no data are available concerning chronic toxicity to animals or toxicity to plants.

Very few data are available concerning the toxicity of any form of arsenic other than inorganic arsenic(III) to saltwater aquatic life. The available data do show that inorganic arsenic(V) is acutely toxic to saltwater animals at concentrations as low as 2,319 ug/L and affected some saltwater

plants at 13 to 56 ug/L. No data are available concerning the chronic toxicity of any form of arsenic other than inorganic arsenic(III) to saltwater aquatic life.

EPA believes that a measurement such as "acid-soluble" would provide a more scientifically correct basis upon which to establish criteria for metals. The criteria were developed on this basis. However, at this time, no EPA approved methods for such a measurement are available to implement the criteria through the regulatory programs of the Agency and the States. The Agency is considering development and approval of methods for a measurement such as acid-soluble. Until available, however, EPA recommends applying the criteria using the total recoverable method. This has two impacts: (1) certain species of some metals cannot be analyzed directly because the total recoverable method does not distinguish between individual oxidation states, and (2) these criteria may be overly protective when based on the total recoverable method.

The recommended exceedence frequency of 3 years is the Agency's best scientific judgment of the average amount of time it will take an unstressed system to recover from a pollution event in which exposure to arsenic(III) exceeds the criterion. a stressed system, for example, one in which several outfalls occur in a limited area, would be expected to require more time for recovery. The resilience of ecosystems and their ability to recover differ greatly, however, and site-specific criteria may be established if adequate justification is provided.

The use of criteria in designing waste treatment facilities requires the selection of an appropriate wasteload allocation

model. Dynamic models are preferred for the application of these criteria. Limited data or other factors may make their use impractical, in which case one should rely on a steady-state model. The Agency recommends the interim use of 1Q5 or 1Q10 for Criterion Maximum Concentration design flow and 7Q5 or 7Q10 for the Criterion Continuous Concentration design flow in steady-state models for unstressed and stressed systems respectively. These matters are discussed in more detail in the Technical Support Document for Water Quality-Based Toxics Control (U.S. EPA, 1985).

HUMAN HEALTH CRITERIA:

For the maximum protection of human health from the potential carcinogenic effects due to exposure of arsenic through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-6}, and 10^{-7}. The corresponding criteria are 22 ng/L, 2.2 ng/L, and .22 ng/L, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 175 ng/L, 17.5 ng/L, and 1.75 ng/L, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purpoes and does not represent an Agency judgment on an "acceptable" risk level.

(45 F.R. 79318 Nov. 28,1980) (50 F.R. 30784, July 29, 1985)
SEE APPENDIX A FOR METHODOLOGY

ASBESTOS

CRITERIA:

Aquatic Life

No freshwater organisms have been tested with any asbestiform mineral and no statement can be made concerning acute or chronic toxicity

No saltwater organisms have been tested with any asbestiform mineral and no statement can be made concerning acute or chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to asbestos through ingestion of water and contaminated aquatic organisms, the ambient water concentration should be zero. The estimated levels which would result in increased lifetime cancer risks of 10^{-5}, 10^{-6}, and 10^{-7} are 300,000 fibers/L, 30,000 fibers/L, and 3,000 fibers/L, respectively. Estimates for consumption of aquatic organisms only, excluding the consumption of water cannot be made.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

BACTERIA

CRITERIA

Freshwater Bathing

Based on a statistically sufficient number of samples (generally not less than 5 samples equally spaced over a 30-day period), the geometric mean of the indicated bacterial densities should not exceed one or the other of the following:(1)

E. coli	126 per 100 ml; or
enterococci	33 per 100 ml;

no sample should exceed a one sided confidence limit (C.L.) calculated using the following as guidance:

designated bathing beach	75% C.L.
moderate use for bathing	82% C.L.
light use for bathing	90% C.L.
infrequent use for bathing	95% C.L.

based on a site-specific log standard deviation, or if site data are insufficient to establish a log standard deviation, then using 0.4 as the log standard deviation for both indicators.

Marine Water Bathing

Based on a statistically sufficient number of samples (generally not less than 5 samples equally spaced over a 30-day period), the geometric mean of the enterococci densities should not exceed 35 per 100 ml; no sample should exceed a one sided confidence limit using the following as guidance:

designated bathing beach	75% C.L.
moderate use for bathing	82% C.L.
light use for bathing	90% C.L.
infrequent use for bathing	95% C.L.

based on a site-specific log standard deviation, or if site data are insufficient to establish a log standard deviation, then using 0.7 as the log standard deviation.

Note (1) - Only one indicator should be used. The Regulatory agency should select the appropriate indicator for its conditions.

Shellfish Harvesting Waters

The median fecal coliform bacterial concentration should not exceed 14 MPN per 100 ml with not more than 10 percent of samples exceeding 43 MPN per 100 ml for the taking of shellfish.

RATIONALE

Bathing Waters

A recreational water quality criterion can be defined as a "quantifiable relationship between the density of an indicator in the water and the potential human health risks involved in the water's recreational use." From such a definition, a criterion can be adopted which establishes upper limits for densities of indicator bacteria in waters that are associated with acceptable health risks for swimmers.

The Environmental Protection Agency, in 1972, initiated a series of studies at marine and fresh water bathing beaches which were designed to determine if swimming in sewage-contaminated marine and fresh water carries a health risk for bathers; and, if so, to what type of illness. Additionally, the Agency wanted to determine which bacterial indicator is best correlated to swimming-associated health effects and if the relationship is strong enough to provide a criterion. (1)

The quantitative relationships between the rates of swimming-associated health effects and bacterial indicator densities were determined using regression analysis. Linear relationships were estimated from data grouped on the basis of summers or trials with similar indicator densities. The data for each summer were analyzed by pairing the geometric mean indicator density for a summer bathing season at each beach with the corresponding swimming-associated gastrointestinal illness rate for the same summer. The swimming-associated illness rate was determined by subtracting the gastrointestinal illness rate in nonswimmers from that for swimmers. Ihese two variables from multiple beach sites were used to calculate a regression coefficient, y-intercept and 95% confidence intervals for the paired data. In the marine studies the total number of points for use in regression analysis was increased by collecting trial days with similar indicator densities from each study location and placing them into groups. The swimming-associated illness rate was determined as before, by subtracting the nonswimmer illness rate of all the individuals included in the grouped trial days from the swimmer illness rate during these safe grouped trial days. The grouping by trial days with similar indicator densities approach was not possible with the freshwater data because the variation of bacterial indicator densities in freshwater samples was not larqe enouqh to allow such an adjustment to be made. For the saltwater studies the results of the regression analyses of illness rates against indicator density data was very similar using the "by summer" or "by grouped trial days" approaches.

The methods used to enumerate the bacterial indicator densities which showed the best relationship to swimming-associated gastroenteritis rates were specifically developed for the recreational water quality studies.

These membrane filter methods have successfully undergone precision and bias testing by the EPA Environmental Monitoring and Support Laboratory. (2)

Several monitoring situations to assess bacterial quality are encountered by regulatory agencies. The situation needing the most rigorous monitoring is the designated swimming beach. Such areas are frequently lifeguard protected, provide parking and other public access and are heavily used by the public. Public beaches of this type were used by EPA in developing the relationship described in this document.

Other recreational activities may involve bodies of water which are regulated by individual State water quality standards. These recreational resources may be natural wading ponds used by children or waters where incidential full body contact occurs because of water skiing or other similar activities.

EPA's evaluation of the bacteriological data indicated that using the fecal coliform indicator group at the maximum geometric mean of 200 per 100 ml, recommended in Quality Criteria for Water would cause an estimated 8 illness per 1,000 swimmers at fresh water beaches and 19 illness per 1,000 swimmers at marine beaches. These relationships are only approximate and are based on applying ratios of the geometric means of the various indicators from the EPA studies to the 200 per 100 ml fecal

coliform criterion. However, these are EPA's best estimates of the accepted illness rates for areas which apply the EPA fecal coliform criterion.

The E. coli and enterococci criteria presented in Table 1 were developed using these currently accepted illness rates. The equations developed by Dufour[3] and Cabelli[4] were used to calculate the geometric mean indicator densities corresponding to the accepted gastrointestinal illness rates. These densities are for steady state dry weather conditions. The beach is in noncompliance with the criteria if the geometric mean of several bacterial density samples exceeds the value listed in Table 1.

Noncompliance is also signaled by an unacceptably high value for any single bacterial sample. The maximum acceptable bacterial density for a single sample is set higher than that for the geometric mean, in order to avoid necessary beach closings based on single samples. In deciding whether a beach should be left open, it is the long term geometric mean bacterial density that is of interest. Because of day-to-day fluctuations around this mean, a decision based on a single sample (or even several samples) may be erroneous, i.e., the sample may exceed the recommended mean criteria even though the long-term geometric mean is protective, or may fall below the maximum even if this mean is in the nonprotective range.

To set the single sample maximum, it is necessary to specify the desired chance that the beach will be left open when the protection is adequate. This chance, or confidence level, was based on Agency judgment. For the simple decision rule considered here, a smaller confidence level corresponds to a more

stringent (i.e. lower) single sample maximum. Conversely, a greater confidence level corresponds to less stringent (i.e. higher) maximum values. This technique reduces the chances of single samples inappropriately indicating violations of the recommended criteria.

By using a control chart analogy [5] and the actual log standard deviations from the EPA studies, single sample maximum densities for various confidence levels were calculated. EPA then assigned qualitative use intensities to those confidence levels. A low confidence level (75%) was assigned to designated beach areas because a high degree of caution should be used to evaluate water quality for heavily used areas. Less intensively used areas would allow less restrictive single sample limits. Thus, 95% confidence might be appropriate for swimmable water in remote areas. Table 1 summarizes the results of these calculations. These single sample maximum levels should be recalculated for individual areas if significant differences in log standard deviations occur.

The levels displayed in Table 1 depend not only on the assumed standard deviation of log densities, but also on the chosen level of acceptable risk. While this level was based on the historically accepted risk, it is still arbitrary insofar as the historical risk was itself arbitrary.

Currently EPA is not recommending a change in the stringency of its bacterial criteria for recreational waters. Such a change does not appear warranted until more information based on greater experience with the new indicators can be accrued. EPA and the

State Agencies can then evaluate the impacts of change in terms of beach closures and other restricted uses.

Shellfish Harvesting Waters

The microbiological criterion for shellfish water quality has been accepted by international agreement to be 70 total coliforms per 100 ml, using a median MPN, with no more than 10 percent of the values exceeding 230 total coliforms. No evidence of disease outbreak from consumption of raw shellfish which were grown in waters meeting this bacteriological criterion has been demonstrated. This standard has proven to be a practical limit when supported by sanitary surveys of the growing waters, acceptable quality in shellfish meats, and good epidemiological evidence. However, evidence from field investigations suggests that not all total coliform occurrences can be associated with fecal pollution. Thus, attention has been directed toward the adoption of the fecal coliform test to measure more accurately the occurrence and magnitude of fecal pollution in shellfish-growing waters.

A series of studies was initiated by the National Shellfish Sanitation Program and data relating the occurrence of total coliforms to numbers of fecal coliforms were compiled. The data show that a 70 coliform MPN per 100 ml at the 50th percentile was equivalent to a fecal coliform MPN of 14 per 100 ml. The data, therefore, indicate that a median value for a fecal coliform standard is 15 and the 90th percentile should not exceed 43 for a 5-tube, 3-dilution method.

EPA is currently (1986) co-sponsoring, with the National

Oceanic and Atmospheric Administration, research into the application of the enterococci and E. coli indicators for assessing the quality of shellfish harvesting waters. The Food and Drug Administration is also reviewing the results of these studies. A change to the new indicators may be forthcoming if the studies show a correlation between gastrointestinal disease and the consumption of raw shellfish from waters with defined densities of the new indicators. However, these studies have not sufficiently progressed to justify any change at this time. Thus, evaluation of the microbiological suitability of waters for recreational taking of shellfish should be based upon the fecal coliform bacterial levels. (6)

CRITERIA FOR INDICATOR FOR BACTERIOLOGICAL DENSITIES

	Acceptable Swimming Associated Gastro-enteritis Rate per 1000 swimmers	Steady State Geometric Mean Indicator Density	Single Sample Maximum Allowable Density (4), (5)			
			Designated Beach Area (upper 75% C.L.)	Moderate Full Body Contact Recreation (upper 82% C.L.)	Lightly Used Full Body Contact Recreation (upper 90% C.L.)	Infrequently Used Full Body Contact Recreation (upper 95% C.L.)
Freshwater						
enterococci	8	33(1)	61	89	108	151
E. coli	8	126(2)	235	298	406	576
Marine Water						
enterococci	19	35(3)	104	124	276	500

Notes:

(1) Calculated to nearest whole number using equation:

$$\text{(mean enterococci density)} = \text{antilog}_{10} \frac{\text{illness rate/1000 people} + 6.28}{9.40}$$

(2) Calculated to nearest whole number using equation:

$$\text{(mean } \textit{E. coli} \text{ density)} = \text{antilog}_{10} \frac{\text{illness rate/1000 people} + 11.74}{9.40}$$

(3) Calculated to nearest whole number using equation:

$$\text{(mean enterococci density)} = \text{antilog}_{10} \frac{\text{illness rate/1000 people} - 0.20}{12.17}$$

(4) Single sample limit = antilog_{10} (Log_{10} indicator geometric mean density/100 ml) + Factor determined from areas under the Normal probability curve for the assumed level of probability x ($\log_{10}$ stand. deviation)

The appropriate factors for the indicated one sided confidence levels are:

75% C.L. - .675
82% C.L. - .935
90% C.L. - 1.28
95% C.L. - 1.65

(5) Based on the observed log standard deviations during the EPA studies: 0.4 for freshwater *E. coli* and enterococci; and 0.7 for marine water enterococci. Each jurisdiction should establish its own standard deviation for its conditions which would then vary the single sample limit.

BARIUM

CRITERION:

1 mg/L for domestic water supply (health).

INTRODUCTION:

Barium is a yellowish-white metal of the alkaline earth group. It occurs in nature chiefly as barite, $BaSO_4$ and witherite, $BaCO_3$, both of which are highly insoluble salts. The metal is stable in dry air, but readily oxidized by humid air or water.

Many of the salts of barium are soluble in both water and acid, and soluble barium salts are reported to be poisonous (Lange, 1965; NAS, 1974). However, barium ions generally are thought to be rapidly precipitated or removed from solution by absorption and sedimentation (McKee and Wolf, 1963 NAS, 1974).

While barium is a malleable, ductile metal, its major commercial value is in its compounds. Barium compounds are used in a variety of industrial applications including the metallurgic, paint, glass and electronics industries, as well as for medicinal purposes.

RATIONALE:

Concentrations of barium drinking water supplies generally range from less than 0.6 ug/L to approximately 10 ug/L with upper limits in a few midwestern and western States ranging from 100 to 3,000 ug/L (PHS, 1962/1963; Katz, 1970; Little, 1971). Barium enters the body primarily through air and water, since appreciable amounts are not contained in foods (NAS, 1974).

The fatal dose of barium for man is reported to be 550 to 600 mg. Ingestion of soluble barium compounds may also result in effects on the gastrointestinal tract, causing vomiting and diarrhea, and on the central nervous system, causing violent tonic and clonic spasms followed in some cases by paralysis (Browning, 1961; Patty, 1962, cited in Preliminary Air Pollution Survey of Barium and Its Compounds, 1969). Barium salts are considered to be muscle stimulants, especially for the heart muscle (Sollman, 1957). By constricting blood vessels, barium may cause an increase in blood pressure. On the other hand, it is not likely that barium accumulates in the bone, muscle, kidney or other tissues because it is readily excreted (Browning, 1961; McKee and Wolf, 1963).

Stokinger and Woodward (1958) developed a safe concentration for barium in drinking water based on the limiting values for industrial atmospheres, an estimate of the amount absorbed into the blood stream, and daily consumption of 2 liters of water. From other factors they arrived at a limiting concentration of 2 mg/L for a healthy adult human population, to which a safety factor was applied to allow for any possible accumulation in the body. Since barium is not removed by conventional water treatment processes and because of the toxic effect on the heart and blood vessels, a limit of 1 mg/L is recommended for barium in domestic water supplies.

Experimental data indicate that the soluble barium concentration in fresh and marine water generally would have to exceed 50 mg/L before toxicity to aquatic life would be expected. In most natural waters, there is sufficient sulfate or carbonate

to precipitate the barium present in the water as a virtually insoluble, non-toxic compound. Recognizing that the physical and chemical properties of barium generally will preclude the existence of the toxic soluble form under usual marine and fresh water conditions, a restrictive criterion for aquatic life appears unwarranted.

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

BENZENE

CRITERIA:

Aquatic Life

The available data for benzene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 5,300 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of benzene to sensitive freshwater aquatic life.

The available data for benzene indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 5,100 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No definitive data are available concerning the chronic toxicity of benzene to sensitive saltwater aquatic life, but adverse effects occur at concentrations as low as 700 ug/L with a fish species exposed for 168 days.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to benzene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the non threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 6.6 ug/L, 0.66 ug/L, and

0.066 ug/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 400 ug/L, 40.0 ug/L, and 4.0 ug/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

BENZIDINE

CRITERIA:

Aquatic Life

The available data for benzidine indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 2,500 ug/L and would occur at lower concentrations among species that are more sensitive than those tested No data are available concerning the chronic toxicity of benzidine to sensitive freshwater aquatic life.

No saltwater organisms have been tested with benzidine and no statement can be made concerning acute and chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to benzidine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 1.2 ng/L, 0.12 ng/L, and 0.01 ng/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 5.3 ng/L, 0.53 ng/L, and 0.05 ng/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

BERYLLIUM

CRITERIA:

Aquatic Life

The available data for beryllium indicate that acute and chronic toxicity to freshwater aquatic life occur at concentrations as low as 130 and 5.3 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested. Hardness has a substantial effect on acute toxicity.

The limited saltwater data base available for beryllium does not permit any statement concerning acute or chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to beryllium through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero, based on the non threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 68 ng/L, 6.8 ng/L, and 0.68 ng/L, respectively. If these estimates are made for

consumption of aquatic organisms only, excluding consumption of water, the levels are 1170 ng/L, 117.0 ng/L, and 11.71 ng/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

BORON

CRITERION:

750 ug/L for long-term irrigation on sensitive crops.

INTRODUCTION:

Boron is not found in its elemental form in nature: it is usually found as a sodium or calcium borate salt. Boron salts are used in fire retardants, the production of glass, leather tanning and finishing industries, cosmetics, photographic materials, metallurgy and for high energy rocket fuels. Elemental boron also can be used in nuclear reactors for neutron absorption. Borates are used as "burnable" poisons.

RATIONALE:

Boron is an essential element for growth of plants but there is no evidence that it is required by animals. The maximum concentration found in 1,546 samples of river and lake waters from various parts of the United States was 5.0 mg/L; the mean value was 0.1 mg/L (Kopp and Kroner, 1967). Ground waters could contain substantially higher concentrations at certain places. The concentration in seawater is reported as 4.5 mg/L in the form of borate (NAS, 1974). Naturally occurring concentrations of boron should have no effects on aquatic life.

The minimum lethal dose for minnows exposed to boric acid at 20 ^{o}C for 6 hours was reported to be 18,000 to 19,000 mg/L in distilled water and 19,000 to 19,500 mg/L in hard water (Le Clerc and Devlaminck, 1955: Le Clerc, 1960).

In the dairy cow, 16 to 20 g/day of boric acid for 40 days

produced no ill effects (McKee and Wolf, 1963).

Sensitive crops have shown toxic effects at 1000 ug/L or less of boron (Richards, 1954). Bradford (1966), in a review of boron deficiencies and toxicities, stated that when the boron concentration in irrigation waters was greater than 0.75 ug/L, some sensitive plants such as citrus began to show injury. Biggar and Fireman (1960) showed that with neutral and alkaline soils of high absorption capacities, water containing 2 ug/L boron might be used for some time without injury to sensitive plants. The criterion of 750 ug/L is thought to protect sensitive crops during long-term irrigation.

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

CADMIUM

AQUATIC LIFE SUMMARY:

Freshwater acute values for cadmium are available for species in 44 genera and range from 1.0 ug/L for rainbow trout to 28,000 ug/L for a mayfly. The antagonistic effect of hardness on acute toxicity has been demonstrated with five species. Chronic tests have been conducted on cadmium with 12 freshwater fish species and 4 invertebrate species with chronic values ranging from 0.15 ug/L for Daphnia magna to 156 ug/L for the Atlantic salmon. Acute-chronic ratios are available for eight species and range from 0.9021 for the chinook salmon to 433.8 for the flagfish.

Freshwater aquatic plants are affected by cadmium at concentrations ranging from 2 to 7,400 ug/L. These values are in the same range as the acute toxicity values for fish and invertebrate species, and are considerably above the chronic values. Bioconcentration factors (BCFs) for cadmium in fresh water range from 164 to 4,190 for invertebrates and from 3 to 2,213 for fishes.

Saltwater acute values for cadmium and five species of fishes range from 577 ug/L for larval Atlantic silverside to 114,000 ug/L for juvenile mummichog. Acute values for 30 species of invertebrates range from 15.5 ug/L for a mysid to 135,000 ug/L for an oligochaete worm. The acute toxicity of cadmium generally increases as salinity decreases. The effect of temperature seems to be species-specific. Two life-cycle tests with Mysidopsis bahia under different test conditions resulted in similar chronic values of 8.2 and 7.1 ug/L, but the acute-chronic ratios were 1.9 and 15, respectively. The acute values appear to

reflect effects of salinity and temperature, whereas the few available chronic values apparently do not. A life-cycle test with Mysidopsis bigelowi also resulted in a chronic value of 7.1 ug/L and an acute-chronic ratio of 15. Studies with microalgae and macroalgae revealed effects at 22.8 to 860 ug/L.

BCFs determined with a variety of saltwater invertebrates ranged from 5 to 3,160. BCFs for bivalve molluscs were above 1,000 in long exposures, with no indication that steady-state had been reached. Cadmium mortality is cumulative for exposure periods beyond 4 days. Chronic cadmium exposure resulted in significant effects on the growth of bay scallops at 78 ug/L and on reproduction of a copepod at 44 ug/L.

NATIONAL CRITERIA:

The procedures described in the Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses indicate that, except possibly where a locally important species is very sensitive, freshwater aquatic organisms and their uses should not be affected unacceptably if the 4-day average concentration (in ug/L) of cadmium does not exceed the numerical value given by $e^{(0.7852[\ln(\text{hardness})]-3.490)}$ more than once every 3 years on the average and if the one-hour average concentration (in ug/L) does not exceed the numerical value given by $e^{(1.128[\ln(\text{hardness})]-3.828)}$ more than once every 3 years on the average. For example, at hardnesses of 50, 100, and 200 mg/L as $CaCO_3$ the 4-day average concentrations of cadmium are 0.66, 1.1, and 2.0 ug/L, respectively, and the 1-hour average concentrations are

1.8, 3.9 and 8.6 ug/L. If brook trout, brown trout, and striped bass are as sensitive as some data indicate, they might not be protected by this criterion.

The procedures described in the Guidelines indicate that, except possibly where a locally important species is very sensitive, saltwater aquatic organisms and their uses should not be affected unacceptably if the 4-day average concentration of cadmium does not exceed 9.3 ug/L more than once every 3 years on the average and if the 1-hour average concentration does not exceed 43 ug/L more than once every 3 years on the average. The little information that is available concerning the sensitivity of the American lobster to cadmium indicates that this important species might not be protected by this criterion. In addition, data suggest that the acute toxicity of cadmium is salinity dependent; therefore, the 1-hour average concentration might be underprotective at low salinities and overprotective at high salinities.

EPA believes that a measurement such as "acid-soluble" would provide a more scientifically correct basis upon which to establish criteria for metals. The criteria were developed on this basis. However, at this time, no EPA-approved methods for such a measurement are available to implement the criteria through the regulatory programs of the Agency and the States. The Agency is considering development and approval of methods for a measurement such as acid-soluble. Until available, however, EPA recommends applying the criteria using the total recoverable method. This has two impacts: (1) certain species of some metals

cannot be analyzed directly because the total recoverable method does not distinguish between individual oxidation states, and (2) these criteria may be overly protective when based on the total recoverable method.

The recommended exceedence frequency of 3 years is the Agency's best scientific judgment of the average amount of time it will take an unstressed system to recover from a pollution event in which exposure to cadmium exceeds the criterion. A stressed system, for example, one in which several outfalls occur in a limited area, would be expected to require more time for recovery. The resilience of ecosystems and their ability to recover differ greatly, however, and site-specific criteria may be established if adequate justification is provided.

The use of criteria in designing waste treatment facilities requires the selection of an appropriate wasteload allocation model. Dynamic models are preferred for the application of these criteria. Limited data or other factors may make their use impractical, in which case one should rely on a steady-state model. The Agency recommends the interim use of 1Q5 or 1Q10 for Criterion Maximum Concentration design flow and 7Q5 or 7Q10 for the Criterion Continuous Concentration design flow in steady-state models for unstressed and stressed systems, respectively. These matters are discussed in more detail in the Technical Support Document for Water Quality-Based Toxics Control (U.S. EPA, 1985).

HUMAN HEALTH CRITERIA:

The ambient water quality criterion for cadmium is recommended to be identical to the existing drinking water

standard which is 10 ug/L. Analysis of the toxic effects data resulted in a calculated level which is protective of human health against the ingestion of contaminated water and contaminated aquatic organisms. The calculated value is comparable to the present standard. For this reason a selective criterion based on exposure solely from consumption of 6.5 grams of aquatic organisms was not derived.

(45 F.R. 79318 Nov. 28,1980) (50 F.R. 30784, July 29, 1985)
SEE APPENDIX A FOR METHODOLOGY

CARBON TETRACHLORIDE

CRITERIA:

Aquatic Life

The available data for carbon tetrachloride indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 35,200 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of carbon tetrachloride to sensitive freshwater aquatic life.

The available data for carbon tetrachloride indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 50,000 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of carbontetrachloride to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to carbon tetrachloride through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 4.0 ug/L, 0.40ug/L, and 0.04 ug/L, respectively. If these estimates are made for

consumption of aquatic organisms only, excluding consumption of water, the levels are 69.4 ug/L, 6.94 ug/L, and 0.69 ug/L respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

CHLORDANE

CRITERIA:

Aquatic Life

For chlordane the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.0043 ug/L as a 24-hour average, and the concentration should not exceed 2.4 ug/L at any time.

For chlordane the criterion to protect saltwater aquatic life as derived using the Guidelines is 0.0040 ug/L as a 24-hour average, and the concentration should not exceed 0.09 ug/L at any time.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to chlordane through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 4.6 ng/L, 0.46 ng/L, and 0.046 ng/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 4.8 ng/L, 0.48 ng/L, and 0.048 ng/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

2-CHLOROPHENOL

CRITERIA:

Aquatic Life

The available data for 2-chlorophenol indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 4,380 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No definitive data are available concerning the chronic toxicity of 2-chlorophenol to sensitive freshwater aquatic life, but flavor impairment occurs in one species of fish at concentrations as low as 2,000 ug/L.

No saltwater organisms have been tested with 2-chlorophenol and therefore, no statement can be made concerning acute or chronic toxicity.

Human Health

Sufficient data are not available for 2-chlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, to control undesirable taste and odor qualities of ambient water the estimated level is 0.1 ug/L. It should be recognized that organoleptic data have limitations as a basis for establishing a water quality criterion, and have no demonstrated relationship to potential adverse human health effects.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

CHLORINATED BENZENES

CRITERIA

Aquatic Life

The available data for chlorinated benzenes indicate that acute toxicity to fresh water aquatic life at concentrations as low as 250 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of the more toxic of the chlorinated benzenes to sensitive freshwater aquatic life but toxicity occurs at concentrations as low as 50 ug/L for a fish species exposed for 7.5 days.

The available data for chlorinated benzenes indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations as low as 160 and 129 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

For comparison purposes, two approaches were used to derive criterion levels for monochlorobenzene. Based on available toxicity data, for the protection of public health, the derived level is 488 ug/L. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 20 ug/L. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

Trichlorobenzenes

Due to the insufficiency in the available information for the trichlorobenzenes, a criterion cannot be derived at this time using the present guidelines.

1,2,4,5-Tetrachlorobenzene

For the protection of human health from the toxic properties of 1,2,4,5-tetrachlorobenzene ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 38 ug/L.

For the protection of human health from the toxic properties of 1,2,4,5-tetrachlorobenzene ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 48 ug/L.

Pentachlorobenzene

For the protection of human health from the toxic properties of pentachlorobenzene ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 74 ug/L.

For the protection of human health from the toxic properties of pentachlorobenzene ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 85 ug/L.

Hexachlorobenzene

For the maximum protection of human health from the potential carcinogenic effects due to exposure of hexachlorobenzene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero

level may not be attainable at the present time. Therefor, the levels which may result in incramental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 7.2 ng/L, 0.72 ng/L, and 0.072 ng/L, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 7.4 ng/L, 0.74 ng/L and 0.074. ng/L respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

CHLORINATED ETHANES

CRITERIA:

Aquatic Life

The available freshwater data for chlorinated ethanes indicate that toxicity increases greatly with increasing chlorination, and that acute toxicity occurs at concentrations as low as 118,000 ug/L for 1,2-dichloroethane, 18,000 ug/L for two trichloroethanes, 9,320 ug/L for two tetrachloroethanes, 7,240 ug/L for pentachloroethane, and 980 ug/L for hexachloroethane. Chronic toxicity occurs at concentrations as low as 20,000 ug/L for 1,2-dichloroethane, 9,400 ug/L for 1,1,2-trichloroethane, 2,400 ug/L for 1,1,2,2-tetrachloroethane, 1,100 ug/L for pentachloroethane, and 540 ug/L for hexachloroethane. Acute and chronic toxicity would occur at lower concentrations among species that are more sensitive than those tested.

The available saltwater data for chlorinated ethanes indicate that toxicity increases greatly with increasing chlorination and that acute toxicity to fish and invertebrate species occurs at concentrations as low as 113,000 ug/L for 1,2-dichloroethane, 31,200 ug/L for 1,1,1-trichloroethane, 9,020 ug/L for 1,1,2,2-tetrachloroethane, 390 ug/L for pentachloroethane, and 940 ug/L for hexachloroethane. Chronic toxicity occurs at concentrations as low as 281 ug/L for pentachloroethane. Acute and chronic toxicity would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to 1,2-dichloroethane through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 9.4 ug/L, 0.94 ug/L, and 0.094 ug/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 2,430 ug/L, 243 ug/L, and 24.3 ug/L, respectively.

For the maximum protection of human health from the potential carcinogenic effects of exposure to 1,1,2-trichloroethane through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 6.0 ug/L, 0.6 ug/L, and 0.06 ug/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 418 ug/L, 41.8 ug/L, and 4.18 ug/L, respectively.

For the maximum protection of human health from the potential carcinogenic effects of exposure to 1,1,2,2-tetrachloroethane through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 1.7 ug/L, 0.17 ug/L, and 0.017 ug/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 107 ug/L, 10.7 ug/L, and 1.07 ug/L, respectively.

For the maximum protection of human health from the potential carcinogenic effects of exposure to hexachloroethane through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 19 ug/L, 1.9 ug/L, and 0.19 ug/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 87.4 ug/L, 8.74 ug/L, and 0.87 ug/L, respectively.

For the protection of human health from the toxic properties of 1,1,1-trichloroethane ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 18.4 mg/L.

For the protection of human health from the toxic properties of 1,1,1-trichloroethane ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 1.03 ug/1.

Because of insufficient available data for monochloroethane, 1,1-dichloroethane, 1,1,1,2-tetrachloroethane, and pentachloroethane, satisfactory criteria cannot be derived at this time, using the present guidelines.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

CHLORINATED NAPHTHALENES

CRITERIA:

Aquatic Life

The available data for chlorinated naphthalenes indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 1,600 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of chlorinated naphthalenes to sensitive freshwater aquatic life.

The available data for chlorinated naphthalenes indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 7.5 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of chlorinated naphthalenes to sensitive saltwater aquatic life.

Human Health

Using the present guidelines, a satisfactory criterion cannot be derived at this time because of insufficient available data for chlorinated naphthalenes.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

CHLORINE

SUMMARY:

Thirty-three freshwater species in 28 genera have been exposed to TRC and the acute values range from 28 ug/L for Daphnia magna to 710 ug/L for the threespine stickleback. Fish and invertebrate species had similar ranges of sensitivity. Freshwater chronic tests have been conducted with two invertebrate and one fish species and the chronic values for these three species ranged from less than 3.4 to 26 ug/L, with acute-chronic ratios from 3.7 to greater than 78.

The acute sensitivities of 24 species of saltwater animals in 21 genera have been determined for CPO, and the LC50 range from 26 ug/L for the eastern oyster to 1,418 ug/L for a mixture of two shore crab species. This range is very similar to that observed with freshwater species, and fish and invertebrate species had similar sensitivities. Only one chronic test has been conducted with a saltwater species, Menidia peninsulae, and in this test the acute chronic ratio was 1.162.

The available data indicate that aquatic plants are more resistant to chlorine than fish and invertebrate species.

NATIONAL CRITERIA:

The procedures described in the Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses indicate that, except possibly where a locally important species is very sensitive, freshwater aquatic organisms and their uses should not be affected

unacceptably if the 4-day average concentration of total residual chlorine does not exceed 11 ug/L more than once every 3 years on the average and if the 1-hour average concentration does not exceed 19 ug/L more than once every 3 years on the average.

The procedures described in the Guidelines indicate that, except possibly where a locally important species is very sensitive, saltwater aquatic organisms and their uses should not be affected unacceptably if the 4-day average concentration of chlorine-produced oxidants does not exceed 7.5 ug/L more than once every 3 years on the average and if the one-hour average concentration does not exceed 13 ug/L more than once every 3 years on the average.

The recommended exceedence frequency of 3 years is the Agency's best scientific judgment of the average amount of time it will take an unstressed system to recover from a pollution event in which exposure to chlorine exceeds the criterion. A stressed system, for example, one in which several outfalls occur in a limited area, would be expected to require more time for recovery. The resilience of ecosystems and their ability to recover differ greatly, however, and site-specific criteria may be established if adequate justification is provided.

The use of criteria in designing waste treatment facilities requires the selection of an appropriate wasteload allocation model. Dynamic models are preferred for the application of these criteria. Limited data or other factors may make their use impractical, in which case one should rely on a steady-state model. The Agency recommends the interim use of 1Q5 or 1Q10 for Criterion Maximum Concentration design flow and 7Q5 or 7Q10 for

the Criterion Continuous Concentration design flow in steady-state models for unstressed and stressed systems, respectively. These matters are discussed in more detail in the Technical Support Document for Water Quality-Based Toxics Control (U.S. EPA, 1985).

(50 F.R. 30784, July 29, 1985)
SEE APPENDIX A FOR METHODOLOGY

CHLORINATED PHENOLS

CRITERIA:

Aquatic Life

The available freshwater data for chlorinated phenols indicate that toxicity generally increases with increasing chlorination, and that acute toxicity occurs at concentrations as low as 30 ug/L for 4-chloro-3-methylphenol to greater than 500,000 ug/L for other compounds. Chronic toxicity occurs at concentrations as low as 970 ug/L for 2,4,6-trichlorophenol. Acute and chronic toxicity would occur at lower concentrations among species that are more sensitive than those tested.

The available saltwater data for chlorinated phenols indicate that toxicity generally increases with increasing chlorination and that acute toxicity occurs at concentrations as low as 440 ug/L for 2,3,5,6-tetrachlorophenol and 29,700 ug/L for 4-chlorophenol. Acute toxicity would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of chlorinated phenols to sensitive saltwater aquatic life.

Human Health

Sufficient data are not available for 3-chlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, to control undesirable taste and odor qualities of ambient water, the estimated level is 0.1 ug/L. It should be recognized that organoleptic data have limitations as a basis for establishing a water quality criterion, and have no demonstrated

relationship to potential adverse human health effects.

Sufficient data are not available for 4-chlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, to control undesirable taste and odor qualities of ambient water the estimated level is 0.1 ug/L. It should be recognized that organoleptic data have limitations as a basis for establishing a water quality criterion, and have no demonstrated relationship to potential adverse human health effects.

Sufficient data are not available for 2,3-dichlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, to control undesirable taste and odor qualities of ambient water the estimated level is 0.04 ug/L. It should be recognized that organoleptic data have limitations as a basis for establishing a water quality criterion, and have no demonstrated relationship to potential adverse human health effects.

Sufficient data are not available for 2,5-dichlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, to control undesirable taste and odor qualities of ambient water the estimated level is 0.5 ug/L. It should be recognized that organoleptic data have limitations as a basis for establishing a water quality criterion, and have no demonstrated relationship to potential adverse human health effects.

Sufficient data are not available for 2,6-dichlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, to control

undesirable taste and odor qualities of ambient water the estimated level is 0.2 ug/L. It should be recognized that organoleptic data have limitations as a basis for establishing a water quality criterion, and have no demonstrated relationship to potential adverse human health effects.

Sufficient data are not available for 3,4-dichlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, to control undesirable taste and odor qualities of ambient water the estimated level is 0.3 ug/L. It should be recognized that organoleptic data have limitations as a basis for establishing a water quality criterion, and have no demonstrated relationship to potential adverse human health effects.

For comparison purposes, two approaches were used to derive criterion levels for 2,4,5-trichlorophenol. Based on available toxicity data, to protect public health the derived level is 2.6 mg/L. Using available organoleptic data, to control undesirable taste and odor quality of ambient water the estimated level is 1.0 ug/L. It should be recognized that organoleptic data have limitations as a basis for establishing a water quality criterion, and have no demonstrated relationship to potential adverse human health effects.

For the maximum protection of human health from the potential carcinogenic effects of exposure to 2,4,6-trichlorophenol through the ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero, based on the nonthreshold assumption for this

chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 12 ug/L, 1.2 ug/L, and 0.12 ug/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 36 ug/L, 3.6 ug/L, and 0.36 ug/L, respectively. Using available organoleptic data, to control undesirable taste and odor qualities of ambient water the estimated level is 2 ug/L. It should be recognized that organoleptic data have limitations as a basis for establishing. a water quality criterion, and have no demonstrated relationship to potential adverse human health effects.

Sufficient data are not available for 2,3,4,6-tetrachlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, to control undesirable taste and odor qualities of ambient water the estimated level is 1.0 ug/L. It should be recognized that organoleptic data have limitations as a basis for establishing a water quality criterion, and have demonstrated relationship to potential adverse human health effects.

Sufficient data are not available for 2-methyl-4-chlorophenol to derive a criterion level which would protect against any potential toxicity of this compound. Using available organoleptic data, to control undesirable taste and odor qualities of ambient water the estimated level is 1,800 ug/L. It

should be recognized that organoleptic data have limitations as a basis for establishing a water quality criterion and have no demonstrated relationship to potential adverse human health effects.

Sufficient data are not available for 3-methyl-4-chlorophenol to derive a criterion level which would protect against any potential toxicity of this compound. Using available organoleptic data, to control undesirable taste and odor qualities of ambient water the estimated level is 3,000 ug/L. It should be recognized that organoleptic data have limitations as a basis for establishing a water quality criterion, and have no demonstrated relationship to potential adverse human health effects.

Sufficient data are not available for 3-methyl-6-chlorophenol to derive a criterion level which would protect against any potential toxicity of this compound. Using available organoleptic data, to control undesirable taste and odor qualities of ambient water the estimated level is 20 ug/L. It should be recognized that organoleptic data have limitations as a basis for establishing a water quality criterion, and have no demonstrated relationship to potential adverse human health effects.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

CHLOROALKYL ETHERS

CRITERIA:

Aquatic Life

The available data for chloroalkyl ethers indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 238,000 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No definitive data are available concerning the chronic toxicity of chloroalkyl ethers to sensitive freshwater aquatic life.

No saltwater organism has been tested with any chloroalkyl ether and therefore, no statement can be made concerning acute or chronic toxicity.

Human Health

For the protection of human health from the toxic properties of bis(2-chloroisopropyl) ether ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 34.7 ug/L.

For the protection of human health from the toxic properties of bis(2-chloroisopropyl) ether ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 4.36 mg/L.

For the maximum protection of human health from the potential carcinogenic effects of exposure to bis(chloromethyl) ether through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the nonthreshold assumption for this chemical. However, zero

level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 37.6×10^{-6} ug/L, 3.76×10^{-6} ug/L, and 0.376×10^{-6} ug/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 18.4×10^{-3} ug/L, 1.84×10^{-3} ug/L, and 0.184×10^{-3} ug/L, respectively.

For the maximum protection of human health from the potential carcinogenic effects of exposure to bis(2-chloroethyl) ether through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 0.30 ug/L, 0.030 ug/L, and 0.003 ug/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 13.6 ug/L, 1.36 ug/L, and 0.136 ug/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

CHLOROFORM

CRITERIA:

Aquatic Life

The available data for chloroform indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 28,900 ug/L, and would occur at lower concentrations among species that are more sensitive than the three tested species Twenty-seven-day LC50 values indicate that chronic toxicity occurs at concentrations as low as 1,240 ug/L, and could occur at lower concentrations among species or other life stages that are more sensitive than the earliest life cycle stages of the rainbow trout. The data base for saltwater species is limited to one test and therefore, no statement can be made concerning acute or chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to chloroform through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 1.90 ug/L, 0.19 ug/L, and 0.019 ug/L, respectively. If these

estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 157 ug/L, 15.7 ug/L, and 1.57 ug/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

CHLOROPHENOXY HERBICIDES
2,4-D; 2,4,5-TP

CRITERIA:

2,4-D 100 ug/L for domestic water supply (health)

2,4,5-TP 10 ug/L for domestic water supply (health)

RATIONALE:

Two widely used herbicides are 2,4-D (2, 4-dichlorophenoxyacetic acid) and 2,4,5-TP (silvex) [2-(2,4, 5-trichlorophenoxy) propionic acid. Each of these compounds is formulated in a variety of salts and esters that may have a marked difference in herbicidal properties, but all are hydrolyzed rapidly to the corresponding acid in the body.

The subacute oral toxicity of chlorophenoxy herbicides has been investigated in a number of species of experimental animals (Palmer and Radeleff, 1964; Lehman, 1965). The dog was found to be sensitive and often displayed mild injury in response to doses of 10 mg/kg/day for 90 days, and serious effects from a dose of 20 mg/kg/day for 90 days. Lehman (1965) reported that the no-effect level of 2,4-D is 0.5 mg/kg/day in the rat, and 8.0 mg/kg/day in the dog.

Data are available on the toxicity of 2,4-D to man. A daily dosage of 500 mg (about 7 mg/kg) produced no apparent ill effects in a volunteer over a 21-day period (Kraus, 1946). When 2,4-D was investigated as a possible treatment for disseminated coccidioidomycosis, the patient had no side effects from 18 intravenous doses during 33 days; each of the last 12 doses in

the series was 800 mg (about 15 mg/kg) or more, the last being 2000 mg (about 37 mg/kg) (Seabury, 1963). A 19th and final dose of 3600 mg (67 mg/kg) produced mild symptoms.

The long-term no-effects levels (mg/kg/day) are listed for the rat and the dog. Those values are adjusted by a factor of 1/500 for 2,4-D and 2,4,5-TP. The safe levels are then readjusted to reflect total allowable intake per person. Since little 2,4-D or 2,4,5-TP is expected to occur in foods, 20 percent of the safe exposure level can reasonably be allocated to water without jeopardizing the health of the consumer.

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

CHROMIUM (VI)

AQUATIC LIFE SUMMARY:

Acute toxicity values for chromium(VI) are available for freshwater animal species in 27 genera and range from 23.07 ug/L for a cladoceran to 1,870,000 ug/L for a stonefly. These species include a wide variety of animals that perform a wide spectrum of ecological functions. All five tested species of daphnids are especially sensitive. The few data that are available indicate that the acute toxicity of chromium(VI) decreases as hardness and pH increase.

The chronic value for both rainbow trout and brook trout is 264.6 ug/L, which is much lower than the chronic value of 1,987 ug/L for the fathead minnow. The acute-chronic ratios for these three fishes range from 18.55 to 260.8. In all three chronic tests a temporary reduction in growth occurred at low concentrations. Six chronic tests with five species of daphnids gave chronic values that range from <2.5 to 40 ug/L and the acute-chronic ratios range from 1.130 to >9.680. Except for the fathead minnow, all the chronic tests were conducted in soft water. Green algae are quite sensitive to chromium(VI). The bioconcentration factor obtained with rainbow trout is less than 3. Growth of chinook salmon was reduced at a measured concentration of 16 ug/L.

The acute toxicity of chromium (VI) to 23 saltwater vertebrate and invertebrate species ranges from 2,000 ug/L for a polychaete worm and a mysid to 105,000 ug/L for the mud snail. The chronic values for a polychaete range from <13 to 36.74 ug/L, whereas

that for a mysid is 132 ug/L. The acute-chronic ratios range from 15.38 to >238.5. Toxicity to macroalgae was reported at 1,000 and 5,000 ug/L. Bioconcentration factors for chromium(VI) range from 125 to 236 for bivalve molluscs and polychaetes.

CHROMIUM (III)

Acute values for chromium(III) are available for 20 freshwater animal species in 18 genera ranging from 2,221 ug/L for a mayfly to 71,060 ug/L for caddisfly. Hardness has a significant influence on toxicity, with chromium(III) being more toxic in soft water.

A life-cycle test with Daphnia magna in soft water gave a chronic value of 66 ug/L. In a comparable test in hard water the lowest test concentration of 44 ug/L inhibited reproduction of Daphnia magna, but this effect may have resulted from ingested precipitated chromium. In a life-cycle test with the fathead minnow in hard water the chronic value was 1,025 ug/L. Toxicity data are available for only two freshwater plant species. A concentration of 9,900 ug/L inhibited growth of roots of Eurasian watermilfoil. A freshwater green alga was affected by a concentration of 397 ug/L in soft water. No bioconcentration factor has been measured for chromium(III) with freshwater organisms.

Only two acute values are available for chromium (III) in saltwater 10,300 ug/L for the eastern oyster and 31,500 ug/L for the mummichog. In a chronic test effects were not observed on a polychaete worm at 50,400 ug/L at pH = 7.9, but acute lethality occurred when pH = 4.5. Bioconcentration factors for saltwater

organisms and chromium(III) range from 86 to 153, similar to the bioconcentration factors for chromium(VI) and saltwater species.

NATIONAL CRITERIA:

CHROMIUM(VI)

The procedures described in the Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses indicate that, except possibly where a locally important species is very sensitive, freshwater aquatic organisms and their uses should not be affected unacceptably if the 4-day average concentration of chromium(VI) does not exceed 11 ug/L more than once every 3 years on the average and if the 1-hour average concentration does not exceed 16 ug/L more than once every 3 years on the average.

The procedures described in the Guidelines indicate that, except possibly where a locally important species is very sensitive, saltwater aquatic organisms, and their uses should not be affected unacceptably if the 4-day average concentration of chromium(VI) does not exceed 50 ug/L more than once every 3 years on the average and if the 1-hour average concentration does not exceed 1,100 ug/L more than once every 3 years on the average. Data suggest that the acute toxicity of chromium (VI) is salinity dependent; therefore, the 1-hour average concentration might be underprotective at low salinities.

CHROMIUM(III)

The procedures described in the Guidelines indicate that, except possibly where a locally important species is very sensitive, freshwater aquatic organisms and their uses should not

be affected unacceptably if the 4-day average concentration (in ug/L) of chromium(III) does not exceed the numerical value given by $e^{(0.8190[\ln(\text{hardness})]+1.561)}$ more than once every 3 years on the average and if the 1-hour average concentration (in ug/L) does not exceed the numerical value given by $e^{(0.8190[\ln(\text{hardness})]+3.688)}$ more than once every 3 years on the average. For example, at hardnesses of 50, 100, and 200 mg/L as $CaCO_3$ the 4-day average concentrations of chromium(III) are 120, 210, and 370 ug/L, respectively, and the 1-hour average concentrations are 980, 1,700, and 3,100 ug/L.

No saltwater criterion can be derived for chromium(III), but 10,300 ug/L is the EC50 for eastern oyster embryos, whereas 50,400 ug/L did not affect a polychaete worm in a life-cycle test.

EPA believes that a measurement such as "acid-soluble" would provide a more scientifically correct basis upon which to establish criteria for minerals. The criteria were developed on this basis. However, at this time, no EPA-approved methods for such a measurement are available to implement the criteria through the regulatory programs of the Agency and the States. The Agency is considering development and approval of methods for a measurement such as acid-soluble. Until available, however, EPA recommends applying the criteria using the total recoverable method. This has two impacts: (1) certain species of some metals cannot be analyzed directly because the total recoverable method does not distinguish between individual

oxidation states, and (2) these criteria may be overly protective when based on the total recoverable method.

The recommended exceedence frequency of 3 years is the Agency's best scientific judgment of the average amount of time it will take an unstressed system to recover from a pollution event in which exposure to chromium exceeds the criterion. A stressed system, for example, one in which several outfalls occur in a limited area, would be expected or require more time for recovery. The resilience of ecosystems and their ability to recover differ greatly, however, and site-specific criteria may be established if adequate justification is provided.

The use of criteria in designing waste treatment facilities requires the selection of an appropriate wasteload allocation model. Dynamic models are preferred for the application of these criteria. Limited data or other factors may make their use impractical, in which case one should rely on a steady-state model. The Agency recommends the interim use of 1Q5 or 1Q10 for Criterion Maximum Concentration design flow and 7Q5 or 7Q10 or the Criterion Continuous Concentration design flow in steady-state models for unstressed and stressed systems, respectively. These matters are discussed in more detail in the Technical Support Document for water Quality-Based Toxics Control (U.S. EPA, 1985).

HUMAN HEALTH CRITERIA:

For the protection of human health from the toxic properties of Chromium III ingested through water and contaminated aquatic

organisms, the ambient water criterion is determined to be 170 mg/L.

For the protection of human health from the toxic properties of Chromium III ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 3433 mg/L.

The ambient water quality criterion for total Chromium VI is recommended to be identical to the existing drinking water standard which is 50 ug/L. Analysis of the toxic effects data resulted in a calculated level which is protective of human health against the ingestion of contaminated water and contaminated aquatic organisms. The calculated value is comparable to the present standard. For this reason a selective criterion based on exposure solely from consumption of 6.5 grams of aquatic organisms was not derived.

(45 F.R. 79318 Nov. 28,1980) (50 F.R. 30784, July 29, 1985)
SEE APPENDIX A FOR METHODOLOGY

COLOR

CRITERIA:

Waters shall be virtually free from substances producing objectionable color for aesthetic purposes;

the source of supply should not exceed 75 color units on the platinum-cobalt scale for domestic water supplies; and

increased color (in combination with turbidity) should not reduce the depth of the compensation point for photosynthetic activity by more than 10 percent from the seasonally established norm for aquatic life.

INTRODUCTION:

Color in water principally results from degradation processes in the natural environment. Although colloidal forms of iron and manganese occasionally are the cause of color in water, the most common causes are complex organic compounds originating from the decomposition of naturally occurring organic matter (AWWA, 1971). Sources of organic material include human materials from the soil such as tannins, human acid and humates; decaying plankton; and other decaying aquatic plants. Industrial discharges may contribute similar compounds: for example, those from the pulp and paper and tanning industries. Other industrial discharges may contain brightly colored substances such as those from certain processes in textile and chemical industries.

Surface waters may appear colored because of suspended matter which comprises turbidity. Such color is referred to as apparent color and is differentiated from true color caused by colloidal human materials (Sawyer, 1960). Natural color is reported in

color "units" which generally are determined by use of the platinum-cobalt method (Standard Methods, 1971).

There is no general agreement as to the chemical composition of natural color, and in fact the composition may vary chemically from place to place (AWWA, 1971). Black and Christman (1963a) characterized color-causing colloids examined as aromatic, polyhydroxy, methoxy carboxylic acids. Shapiro (1964) characterized color-causing constituents as being dialyzable and composed of aliphatic, polyhydroxyl carboxylic acids with molecular weights varying from less than 200 to approximately 400. The colloidal fraction of color exists in the 3.5 to 10 mu diameter range (Black and Christman, 1963b). These same authors summarized other characteristics of color observed in laboratory studies of natural waters: color is caused by light scattering and fluorescence rather than absorption of light energy, and pH affects both particle size of the color-causing colloids and the intensity of color itself.

RATIONALE:

Color in water is an important constituent in terms of aesthetic considerations. To be aesthetically pleasing, water should be virtually free from substances introduced by man's activities which produce objectionable color. "Objectionable color" is defined to be a significant increase over natural background levels. Non-natural colors such as dyes should not be perceptible by the human eye as such colors are especially objectionable to those who receive pleasure by viewing water in its natural state. Because of the extreme variations in the

natural background amount of color, it is meaningless to attempt numerical limits. The aesthetic attributes of water depend on one's appreciation of the water setting.

The effects of color on public water supplies also are principally aesthetic. The 1962 Drinking Water Standards (PHS, 1962) recommended that color in finished waters should not exceed 15 units on the platinum-cobalt scale. Water consistently can be treated using standard coagulation, sedimentation and filtration processes to reduce color to substantially less than 15 color units when the source water does not exceed 75 color units AWWA, 1971; NAS, 1974).

The effects of color in water on aquatic life principally are to reduce light penetration and thereby generally reduce photosynthesis by phytoplankton and to restrict the zone for aquatic vascular plant growth.

The light supply necessary to support plant life is dependent on both intensity and effective wave lengths (Welch, 1952). In general, the rate of photosynthesis increases with the intensity of the incident light. Photosynthetic rates are most affected in the red region and least affected in the blue-violet region of incident light (Welch, 1952). It has been found that in colored waters the red spectrum is not a region of high absorption so that the effective penetration, and therefore the intensity for photosynthesis, is not as restricted as are other wave lengths. It should be emphasized that transmission of all parts of the spectrum is affected by color, but the greatest effect is on the standard or blue end of the spectrum (Birge and Juday, 1930). In

TABLE 2.

Maximum color of surface waters that have been used as sources for industrial water supplies.

Industry or Industrial Use	Color units
Boiler make up	1,200
Cooling water	1,200
Pulp and paper	360
Chemical and allied products	500
Petroleum	25

highly colored waters (45 to 132 color units) Birge and Juday (1930) measured the light transmission as a percentage of the incident level and found very little blue, 50 percent or less yellow, and 100 to 120 percent red.

The light intensity required for some aquatic vascular plants to photosynthetically balance the oxygen used in respiration may be 5 percent of full sunlight during maximum summer illumination periods (NTAC, 1968). As much as 10 percent of the incident light may be required for plankton to likewise photosynthetically produce sufficient oxygen to balance their respiration requirements (NTAC, 1968). The depth at which such a compensation point is reached, calledthe compensation depth, delineates the zone of effective photosynthetic oxygen production. To maintain satisfactory biological conditions, this depth cannot be substantially reduced.

Industrial requirements as related to water color have been standardized (NAS, 1974). Table 2 lists the maximum value used as a source of water for various industries and industrial uses. Through treatment, such waters can be made to meet almost any industrial requirement.

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

*COPPER

AQUATIC LIFE SUMMARY:

Acute toxicity data are available for species in 41 genera of freshwater animals. At a hardness of 50 mg/L the genera range in sensitivity from 16.74 ug/L for Ptychocheilus to 10,240 ug/L for Acroneuria. Data for eight species indicate that acute toxicity decreases as hardness increases. Additional data for several species indicate that toxicity also decreases with increases in alkalinity and total organic carbon.

Chronic values are available for 15 freshwater species and range from 3.873 ug/L for brook trout to 60.36 ug/L for northern pike. Fish and invertebrate species seem to be about equally sensitive to the chronic toxicity of copper.

Toxicity tests have been conducted on copper with a wide range of freshwater plants and the sensitivities are similar to those of animals. Complexing effects of the test media and a lack of good analytical data make interpretation and application of these results difficult. Protection of animal species, however, appears to offer adequate protection of plants. Copper does not appear to bioconcentrate very much in the edible portion of freshwater aquatic species.

The acute sensitivities of saltwater animals to copper range from 5.8 ug/L for the blue mussel to 600 ug/L for the green crab. A chronic life-cycle test has been conducted with a mysid, and adverse effects were observed at 77 ug/L but not at 38 ug/L, which resulted in an acute-chronic ratio of 3.346. Several

*Indicates suspended, canceled or restricted by U.S.EPA Office of Pesticides and Toxic Substances

saltwater algal species have been tested, and effects were observed between 5 and 100 ug/L. Oysters can bioaccumulate copper up to 28,200 times, and become bluish-green, apparently without significant mortality. In long-term exposures, the bay scallop was killed at 5 ug/L.

NATIONAL CRITERIA:

The procedures described in the Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Uses indicate that, except possibly where a locally important species is very sensitive, freshwater aquatic organisms and their uses should not be affected unacceptably if the 4-day average concentration (in ug/L) of copper does not exceed the numerical value given by $e^{(0.8545[\ln(\text{hardness})]-1.465)}$ more than once every 3 years on the average and if the 1-hour average concentration (in ug/L) does not exceed the numerical value given by $e^{(0.9422[\ln(\text{hardness})]-1.464)}$ more than once every 3 years on the average. For example, at hardnesses of 50, 100, and 200 mg/L as $CaCO_3$ the 4-day average concentrations of copper are 6.5, 12, and 21 ug/L, respectively, and the 1-hour average concentrations are 9.2, 18, and 34 ug/L.

The procedures described in the Guidelines indicate that, except possibly where a locally important species is very sensitive, saltwater aquatic organisms and their uses should not be affected unacceptably if the 1-hour average concentration of copper does not exceed 2.9 ug/L more than once every 3 years on the average.

EPA believes that a measurement such as "acid-soluble" would

provide a more scientifically correct basis upon which to establish criteria for metals. The criteria were developed on this basis. However, at this time, no EPA approved methods for such a measurement are available to implement the criteria through the regulatory programs of the Agency and the States. The Agency is considering development and approval of methods for a measurement such as acid-soluble. Until available, however, EPA recommends applying the criteria using the total recoverable method. This has two impacts: (1) certain species of some metals cannot be analyzed directly because the total recoverable method does not distinguish between individual oxidation states, and (2) these criteria may be overly protective when based on the total recoverable method.

The recommended exceedence frequency of 3 years is the Agency's best scientific judgment of the average amount of time it will take an unstressed system to recover from a pollution event in which exposure to copper exceeds the criterion. A stressed system, for example, one in which several outfalls occur in a limited area, would be expected to require more time for recovery. The resilience of ecosystems and their ability to recover differ greatly, however, and site-specific criteria may be established if adequate justification is provided.

The use of criteria in developing waste treatment facilities requires the selection of an appropriate wasteload allocation model. Dynamic models are preferred for the application of these criteria. Limited data or other factors may make their use impractical, in which case one should rely on a steady-state model. The Agency recommends the interim use of 1Q5 or 1Q10 for

Criterion Maximum Concentration design flow and 7Q5 or 7Q10 for the Criterion Continuous Concentration (CCC) design flow in steady-state models for unstressed and stressed systems respectively. These matters are discussed in more detail in the Technical Support Document for Water Quality-Based Toxics Control (U.S. EPA, 1985).

HUMAN HEALTH CRITERIA:

Sufficient data is not available for copper to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 1 mg/L. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

(45 F.R. 79318 Nov. 28,1980) (50 F.R. 30784, July 29, 1985)
SEE APPENDIX A FOR METHODOLOGY

CYANIDE

AQUATIC LIFE SUMMARY:

Data on the acute toxicity of free cyanide (the sum of cyanide present as HCN and CN-, expressed as CN) are available for a wide variety of freshwater species that are involved in diverse community functions. The acute sensitivities ranged from 44.73 ug/L to 2,490 ug/L, but all of the species with acute sensitivities above 400 ug/L were invertebrates. A long-term survival, and a partial and life-cycle test with fish gave chronic values of 13.57, 7.849, and 16.39 ug/L, respectively. Chronic values for two freshwater invertebrate species were 18.33 and 34.06 ug/L. Freshwater plants were affected at cyanide concentrations ranging from 30 ug/L to 26,000 ug/L.

The acute toxicity of free cyanide to saltwater species ranged from 4.893 ug/L to >10,000 ug/L and invertebrates were both the most and least sensitive species. Long-term survival in an early life-stage test with the sheepshead minnow gave a chronic value of 36.12 ug/L. Long-term survival in a mysid life-cycle test resulted in a chronic value of 69.71 ug/L. Tests with the red macroalga, Champia parvula, showed cyanide toxicity at 11 to 25 ug/L, but other species were affected at concentrations up to 3,000 ug/L.

NATIONAL CRITERIA:

The procedures described in the Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses indicate that, except possibly where a locally important species is very sensitive, freshwater aquatic organisms and their uses should not be affected

unacceptably if the 4-day average concentration of cyanide does not exceed 5.2 ug/L more than once every 3 years on the average and if the 1-hour average concentration does not exceed 22 ug/L more than once every 3 years on the average.

The procedures described in the Guidelines indicate that, except possibly where a locally important species is very sensitive, saltwater aquatic organisms and their uses should not be affected unacceptably if the 1-hour average concentration of cyanide does not exceed 1.0 ug/L more than once every 3 years on the average.

EPA believes that a measurement such as "acid soluble" would provide a more scientifically correct basis upon which to establish criteria for cyanide. The criteria were developed on this basis. However, at this time, no EPA-approved methods for such a measurement are available to implement the criteria through the regulatory programs of the Agency and the States.

The Agency is considering development and approval of methods for a measurement such as acid soluble. Until available, however, EPA recommends applying the criteria using the total recoverable method. These criteria may be overly protective when based on the total recoverable method.

The recommended exceedence frequency of 3 years is the Agency's best scientific judgment of the average amount of time it will take an unstressed system to recover from a pollution event in which exposure to cyanide exceeds the criterion. A stressed system, for example, one in which several outfalls occur in a limited area, would be expected to require more time for recovery. The resilience of ecosystems and their ability to

recover differ greatly, however, and site-specific criteria may be established if adequate justification is provided.

The use of criteria in designing waste treatment facilities requires the selection of an appropriate wasteload allocation model. Dynamic models are preferred for the application of these criteria. Limited data or other factors may make their use impractical, in which case one should rely on a steady-state model. The Agency recommends the interim use of 1Q5 or 1Q10 for Criterion Maximum Concentration design flow and 7Q5 or 7Q10 for the Criterion Continuous Concentration design flow in steady-state models for unstressed and stressed systems respectively. These matters are discussed in more detail in the Technical Support Document for Water Quality-Based Toxics Control (U.S. EPA, 1985).

HUMAN HEALTH CRITERIA

The ambient water quality criterion for cyanide is recommended to be identical to the existing drinking water standard which is 200 ug/L. Analysis of the toxic effects data resulted in a calculated level which is protective of human health against the ingestion of contaminated water and contaminated aquatic organisms. The calculated value is comparable to the present standard. For this reason a selective criterion based on exposure solely from consumption of 6.5 grams of aquatic organisms was not derived.

NOTE: The U.S. EPA is currently developing Acceptable Daily Intake (ADI) or Verified Reference Dose (RfD) values for Agency-wide use for this chemical. The new value should be substituted when it becomes available. The January, 1986, draft Verified Reference Dose document cites an RfD of .02 mg/kg/day for free cyanide.

DDT AND METABOLITES

CRITERIA:

Aquatic Life

DDT

For DDT and its metabolites the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.0010 ug/L as a 24-hour average and the concentration should not exceed 1.1 ug/L at any time.

For DDT and its metabolites the criterion to protect saltwater aquatic life as derived using the Guidelines is 0.0010 ug/L as a 24-hour average and the concentration should not exceed 0.13 ug/L at any time.

TDE

The available data for TDE indicate that acute toxicity to freswater aquatic life occurs at concentrations as low as 0.6 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of TDE to sensitive freshwater aquatic life.

The available data for TDE indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 3.6 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of TDE to sensitive saltwater aquatic life.

DDE

The available data for DDE indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as

1,050 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of DDE to sensitive freshwater aquatic life.

The available data for DDE indicate that acute toxicity to saltwater aquatic life occurs in concentrations as low as 14 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of DDE to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to DDT through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6} and 10^{-7}. The corresponding recommended criteria are 0.24 ng/L, 0.024 ng/L, and 0.0024 ng/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 0.24 ng/L, 0.024 ng/L, and 0.0024 ng/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

DEMETON

CRITERION:

0.1 ug/L for freshwater and marine aquatic life

RATIONALE:

Static LC50 bioassays yielded toxicity values for the organophosphorus pesticide demeton for carp, goldfish, fathead minnow, channel catfish, guppy, rainbow, trout and bluegill, ranging from 70 ug/L to 15,000 ug/L (Henderson and Pickering, 1958; Ludemann and Neumann, 1982; Macek and McAllister, 1970; McCann and Jasper, 1972; Pickering et al. 1962). Results of these tests demonstrate an apparent sharp division in species sensitivity, with bluegill (Lepomis macrochirus), rainbow trout (Salmo gairdneri) and guppy, (Poecilia reticulata), being susceptible to lower concentrations while the remaining species were comparatively resistant. In the 96-hour exposures toxicity did not increase significantly with time, indicating that concentrations close to nominal may not have been maintained for more than a few hours. Bluegills with a 24-hour LC50 of 70 ug/L were the most sensitive fish (McCann and Jasper, 1972).

When fish were exposed to acutely toxic levels of demeton for 12 hours by Weiss (1959, 1961) the maximum inhibition of brain acetiylcholinesterase (AChE) was not reached. The lowest levels of AChE occurred after 24 to 48 hours. It was demonstrated that maximum inhibition could last as long as two weeks after exposure, and subsequent recovery to levels approaching normal took many more weeks. Weiss (1958) reported a significant increase in mortality of fathead minnows exposed for a second

time to the organophosphate, Sarin, before the fish had recovered normal brain AChE levels. The resistance of fully recovered fish was equal to that of previously unexposed controls. Weiss and Gakstatter (1964a) reported no significant inhibition of brain AChE in bluegills, goldfish and shiners (Notemigonus crysoleucas), following 15-day exposures to demeton at continuously replenished, nominal concentrations of 1 ug/L.

Acute toxicity values reported for invertebrates range from 10 to 100,000 ug/L (Ludemann and Neumann, 1962; Sanders, 1972). In general, molluscs and tubifex worms were very resistant while the smaller crustaceans and insect larvae were susceptible. Ludemann and Neumann (1962) reported that Chironomus plumosus larvae were the most sensitive species they tested. A 24-hour exposure at 10 ug/L produced undefined effects while 100 percent were killed at 1000 ug/L. Calculated LC50 data for invertebrates apparently are limited to a single, nominal concentration static exposure of Gammarus fasciatus (Sanders, 1972). These 24- and 96-hour LC50 values are reported as 500 and 27 ug/L, indicating a time-related effect not observed in the bioassays with fishes. As only a few of the sensitive species have been tested and great variance in response can result with different test methods, caution must be exercised in estimating the sub-acute concentration for aquatic fauna in general. It appears that no study has been made of possible residual effects other than AChE inhibition, which might result from short exposures to subacute concentrations of organophosphates.

There are few data on the toxicity of demeton to marine organisms. Butler (1964) reported a 48-hour EC50 of 63 ug/L for

the pink shrimp, Peneaus duorarum, and a 24-hour LC50 of 550 ug/L for the spot, Leiostomus xanthurus.

Chronic demeton toxicity data for freshwater organism are not currently available. Since no data are available at this time to indicate long-term no-effect levels for aquatic organisms, a criterion must be derived based partly on the fact that all organophosphates inhibit the production of the AChE enzyme. Demeton is unique, however, in that the persistence of its AChE-inhibiting ability is greater than that of 10 other common organophosphates, even though its acute toxicity is apparently less. The effective "half-life" of AChE inhibition for demeton is greater than one year (Weiss and Gakstatter, 1964b). Because such inhibition may be additive with repeated exposures and may be compounded by any of the organophosphates, it is recommended that a criterion for demeton be based primarily on its enzyme-inhibiting potential. A criterion of 0.1 ug/L demeton for freshwater and marine aquatic life is recommended since it will not be expected to significantly inhibit AChE over a prolonged period of time. In addition, the criteria recommendation is in close agreement with the criteria for the other organophosphates.

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

DICHLOROBENZENES

CRITERIA:

Aquatic Life

The available data for dichlorobenzenes indicate that acute and chronic toxicity to freshwater aquatic life occur at concentrations as low as 1,120 and 763 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

The available data for dichlorobenzenes indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 1,970 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of dichlorobenzenes to sensitive saltwater aquatic life.

Human Health

For the protection of human health from the toxic properties of dichlorobenzene ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 400 ug/L.

For the protection of human health from the toxic properties of dichlorobenzenes ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 2.6 mg/L.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

DICHLOROBENZIDINE

CRITERIA:

Aquatic Life

The data base available for dichlorobenzidines and freshwater organisms is limited to one test on bioconcentration of 3,3-dichlorobenzidine, and therefore, no statement can be made concerning acute or chronic toxicity.

No saltwater organisms have been tested with any dichlorobenzidine, and therefore, no statement can be made concerning acute or chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to dichlorobenzidine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 0.103 ug/L, 0.010 ug/L, and 0.001 ug/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 0.204 ug/L, 0.020 ug/L, and 0.002 ug/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

DICHLOROETHYLENES

CRITERIA:

Aquatic Life

The available data for dichloroethylenes indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 11,600 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No definitive data are available concerning the chronic toxicity of dichloroethylenes to sensitive freshwater aquatic life.

The available data for dichloroethylenes indicate that acute and chronic toxicity to saltwater aquatic life occurs at concentrations as low as 224,000 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of dichloroethylenes to sensitive saltwater aquatic life.

Human Health

1,1-Dichloroethylene

For the maximum protection of human health from the potential carcinogenic effects of exposure to 1,1 dichloroethylene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the non threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 0.33 ug/L, 0.033 ug/L, and 0.003 ug/L, respectively. If

these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 18.5 ug/L, 1.85 ug/L, and 0.185 ug/L, respectively.

1,2-Dichloroethylene

Using the present guidelines, a satisfactory criterion cannot be derived at this time because of insufficient available data for 1,2-dichloroethylene.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

2,4-DICHLOROPHENOL

CRITERIA:

Aquatic Life

The available data for 2,4-dichlorophenol indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 2,020 and 365 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested. Mortality to early life stages of one species of fish occurs at concentrations as low as 70 ug/L.

Only one test has been conducted with saltwater organisms and 2,4-dichlorophenol and therefore, no statement can be made concerning acute or chronic toxicity.

Human Health

For comparison purposes, two approaches were used to derive criterion levels for 2,4-dichlorophenol. Based on available toxicity data, to protect public health the derived level is 3.09 mg/L. Using available organoleptic data, to control undesirable taste and odor qualities of ambient water the estimated level is 0.3 ug/L. It should be recognized that organoleptic data have limitations as a basis for establishing a water quality criterion, and have no demonstrated relationship to potential adverse human health effects.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

DICHLOROPROPANES/DICHLOROPROPENES

CRITERIA:

Aquatic Life

The available data for dichloropropanes indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 23,000 and 5,700 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

The available data for dichloropropene indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 6,060 and 244 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

The available data for dichloropropane indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations as low as 10,300 and 3,040 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

The available data for dichloropropene indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 790 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of dichloropropene to sensitive saltwater aquatic life.

Human Health

Using the present guidelines, a satisfactory criterion cannot be derived at this time because of insufficient available data for dichloropropanes.

For the protection of human health from the toxic properties of dichloropropenes ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 87 ug/L.

For the protection of human health from the toxic properties of dichloropropenes ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 14.1 mg/L.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

2,4-DIMETHYLPHENOL

CRITERIA

Aquatic Life

The available data for 2,4-dimethylphenol indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 2,120 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of dimethylphenol to sensitive freshwater aquatic life.

No saltwater organisms have been tested with 2,4-dimethyl-phenol and therefore, no statement can be made concerning acute or chronic toxicity.

Human Health

Sufficient data are not available for 2,4-dimethylphenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, to control undesirable taste and odor quality of ambient water the estimated level is 400 ug/L. It should be recognized that organoleptic data have limitations as a basis for establishing a water quality criterion, and have no demonstrated relationship to potential adverse human health effects.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

DINITROTOLUENE

CRITERIA:

Aquatic Life

The available data for dinitrotoluenes indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 330 and 230 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

The available data for dinitrotoluenes indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 590 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of dinitrotoluenes to sensitive saltwater aquatic life but a decrease in algal cell numbers occurs at concentrations as low as 370 ug/L.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to 2,4-dinitrotoluene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6} and 10^{-7}. The corresponding recommended criteria are 1.1 ug/L, 0.11 ug/L, and 0.011 ug/L, respectively. If these estimates are made for consumption of aquatic organ-isms only, excluding consumption

of water, the levels are 91 ug/L, 9.1 ug/L, and 0.91 ug/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

DIPHENYLHYDRAZINE

CRITERIA:

Aquatic Life

The available data for 1,2-diphenylhydrazine indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 270 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of 1,2-diphenylhydrazine to sensitive freshwater aquatic life.

No saltwater organisms have been tested with 1,2-diphenylhydrazine and therefore, no statement can be made concerning acute or chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to diphenylhydrazine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 422 ng/L, 42 ng/L, and 4 ng/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 5.6 ug/L, 0.56 ug/L, and 0.056 ug/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

ENDOSULFAN

CRITERIA:

Aquatic Life

For endosulfan the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.056 ug/L as a 24-hour average and the concentration should not exceed 0.22 ug/L at any time.

For endosulfan the criterion to protect saltwater aquatic life as derived using the Guidelines is 0.0087 ug/L as a 24-hour average and the concentration should not exceed 0.034 ug/L at any time.

Human Health

For the protection of human health from the toxic properties of endosulfan ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 74 ug/L.

For the protection of human health from the toxic properties of endosulfan ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 159 ug/L.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

*ENDRIN

CRITERIA:

Aquatic Life

For endrin the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.0023 ug/L as a 24-hour average, and the concentration should not exceed 0.18 ug/L at any time.

For endrin the criterion to protect saltwater aquatic life as derived using the Guidelines is 0.0023 ug/L as a 24-hour average, and the concentration should not exceed 0.037 ug/L at any time.

Human Health

The ambient water quality criterion for endrin is recommended to be identical to the existing water standard which is 1.0 ug/L. Analysis of the toxic effects data resulted in a calculated level which is protective of human health against the ingestion of contaminated water and contaminated aquatic organisms. The calculated value is comparable to the present standard. For this reason a selective criterion based on exposure solely from consumption of 6.5 g of aquatic organisms was not derived.

*Indicates suspended, canceled or restricted by U.S. EPA Office of Pesticides and Toxic Substances

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

ETHYLBENZENE

CRITERIA:

Aquatic Life

The available data for ethylbenzene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 32,000 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No definitive data are available concerning the chronic toxicity of ethylbenzene to sensitive freshwater aquatic life.

The available data for ethylbenzene indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 430 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of ethylbenzene to sensitive saltwater aquatic life.

Human Health

For the protection of human health from the toxic properties of ethylbenzene ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 1.4 mg/L.

For the protection of human health from the toxic properties of ethylbenzene ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 3.28 mg/L.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

NOTE: The U.S. EPA is currently developing Acceptable Daily Intake (ADI) or Verified Reference Dose (RfD) values for Agency-wide use for this chemical. The new value should be substituted when it becomes available. The January, 1986, draft Verified Reference Dose document cites an RfD of 0.1 mg/kg/day for ethylbenzene.

FLUORANTHENE

CRITERIA:

Aquatic Life

The available data for fluoranthene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 3,980 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of fluoranthene to sensitive freshwater aquatic life.

The available data for fluoranthene indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations as low as 40 and 16 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

For the protection of human health from the toxic properties of fluoranthene ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 42 ug/L.

For the protection of human health from the toxic properties of fluoranthene ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 54 ug/L.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

GASES, TOTAL DISSOLVED

CRITERION:

To protect freshwater and marine aquatic life, the total dissolved gas concentrations in water should not exceed 110 percent of the saturation value for gases at the existing atmospheric and hydrostatic pressures.

RATIONALE:

Fish in water containing excessive dissolved gas pressure or tension are killed when dissolved gases in their circulatory system come out of solution to form bubbles (emboli) which block the flow of blood through the capillary vessels. In aquatic organisms this is commonly referred to as "gas bubble disease". External bubbles (emphysema) also appear in the fins, on the opercula, in the skin and in other body tissues. Aquatic invertebrates are also affected by gas bubble disease, but usually at supersaturation levels higher than those lethal to fish.

The standard method of analyzing for gases in solutions has been the Van Slyke method (Van Slyke et al. 1934); now, gas chromatography also is used for determination of individual and total gases. For determination of total gas pressure, Weiss has developed the saturometer, a device based upon a thin-wall silicone rubber tube that is permeable to gases but impermeable to water. Gases pass from the water through the tube, thus raising the internal gas pressure which is measured by a

manometer or pressure gauge connected to the tube (NAS, 1974). This method alone does not separate the total gas pressure into the separate components, but Winkler oxygen determinations can be run simultaneously, and gas concentrations can be calculated.

Total dissolved gas concentrations must be determined because analysis of individual gases may not determine with certainty that gas supersaturation exists. For example, water could be highly supersaturated with oxygen, but if nitrogen were at less than saturation, the saturation as measured by total gas pressure might not exceed 100 percent. Also, if the water was highly supersaturated with dissolved oxygen, the oxygen alone might be sufficient to create gas pressures or tensions greater than the criterion limits, but one would not know the total gas pressure or tension, or by how much the criterion was exceeded. The rare and inert gases such as argon, neon and helium are not usually involved in causing gas bubble disease as their contribution to total gas pressures is very low. Dissolved nitrogen (N_2), which comprises roughly 80 percent of the earth's atmosphere, is nearly inert biologically and is the most significant cause of gas bubble disease in aquatic animals. Dissolved oxygen, which is extremely bioactive, is consumed by the metabolic processes of the organism and is less important in causing serious gas bubble disease though it may be involved in initiating emboli formation in the blood (Nebeker et al. 1976a).

Percent saturation of water containing a given amount of gas varies with the absolute temperature and with the pressure. Because of the pressure changes, percent saturation with a given

amount of gas changes with depth of the water. Gas supersaturation decreases by 10 percent per meter of increase in water depth because of hydrostatic pressure; a gas that is at 130 percent saturation at the surface would be at 100 percent saturation at 3 meters' depth. Compensation for altitude may be needed because a reduction in atmospheric pressure changes the water/gas equilibria, resulting in changes in solubility of dissolved gases.

There are several ways that total dissolved gas supersaturation can occur:

1. Excessive biological activity--dissolved oxygen concentrations often reach supersaturation because of excessive algal photosynthesis. Renfro (1963) reported gas bubble disease in fishes resulting, in part, from algal blooms. Algal blooms often accompany an increase in water temperature and this higher temperature further contributes to supersaturation.

2. Lindroff (1957) reported that water spillage at hydropower dams caused supersaturation. When excess water is spilled over the face of a dam it entrains air as it plunges to the stilling or plunge pool at the base of the dam. The momentum of the fall carries the water and entrained gases to great depths in the pool; and, under increased hydrostatic pressure, the entrained gases are driven into solution, causing supersaturation of dissolved gases.

3. Gas bubble disease may be induced by discharges from power-generating and other thermal sources (Marcello et al. 1975). Cool, gas-saturated water is heated as it passes through the condenser or heat exchanger. As the temperature of the water

rises, percent saturation increases because of the reduced solubility of gases at higher temperatures. Thus, the discharged water becomes supersaturated with gases and fish or other organisms living in the heated water may exhibit gas bubble disease (DeMont and Miller, 1972: Malouf et al. 1972; Keup, 1975).

In recent years, gas bubble disease has been identified as a major problem affecting valuable stocks of salmon and trout in the Columbia River system (Rulifson and Abel, 1971). The disease is caused by high concentrations of dissolved atmospheric gas which enter the river's water during heavy spilling at hydroelectric dams. A report by Ebel et al. (1975) presents results from field and laboratory studies on the lethal, sublethal and physiological effects of gas on fish, depth distribution of fish in the river (fish can compensate for some high concentrations of gas by moving deeper into the water column), detection and avoidance of gas concentrations by fish, intermittent exposure of fish to gas concentrations, and bioassays of many species of fish exposed to different concentrations of gas. Several conclusions resulting from these studies are:

1. When either juvenile or adult salmonids are confined to shallow water (1 m), substantial mortality occurs at and above 115 percent total dissolved gas saturation.

2. When either juvenile or adult salmonids are free to sound and obtain hydrostatic compensation either in the laboratory or in the field, substantial mortality still occurs when saturation

levels (of total dissolved gases) exceed 120 percent saturation.

3. On the basis of survival estimates made in the Snake River from 1966 to 1975, it is concluded that juvenile fish losses ranging from 40 to 95 percent do occur and a major portion of this mortality can be attributed to fish exposure to supersaturation by atmospheric gases during years of high flow.

4. Juvenile salmonids subjected to sublethal periods of exposure to supersaturation can recover when returned to normally saturated water, but adults do not recover and generally die from direct and indirect effects of the exposure.

5. Some species of salmon and trout can detect and avoid supersaturated water; others may not.

6. Higher survival was observed during periods of intermittent exposure than during continuous exposure.

7. In general, in acute bioassays, salmon and trout were less tolerant than the nonsalmonids.

Dawley and Ebel (1975) found that exposure of juvenile spring chinook salmon, Oncorhynchus tshawytscha, and steelhead trout, Salmo gairdneri, to 120 percent saturation for 1.5 days resulted in over 50 percent mortality; 100 percent mortality occurred in less than 3 days. They also determined that the threshold level where significant mortalities begin occurring is at 115 percent nitrogen saturation (111 percent total gas saturation in this test).

Rucker (1974), using juvenile coho salmon, Oncorhynchus kisutch, determined the effect of individual ratios of oxygen and nitrogen and established that a decrease in lethal effect occurred when the nitrogen content fell below 109 percent

saturation even though total gas saturation remained at 119 percent saturation, indicating the importance of determining the concentration of the individual components (O_2 and N_2) of the atmospheric supersaturation. Nebeker et al. (1976a), using juvenile sockeye salmon, Oncorhynchus nerka, also showed that there was a significant increase in fish mortality when the nitrogen concentration was increased while holding the total percent saturation constant. They also showed that there was no significant difference in fish mortality at different CO_2 concentrations.

Research collected by Bouck et al. (1975) showed that gas supersaturated water at and above 115 percent total gas saturation is acutely lethal to most species of salmonids, with 120 percent saturation and above rapidly lethal to all salmonids tested. Levels as low as 110 percent will produce emphysema in most species. Steelhead trout were most sensitive to gas-supersaturated water followed by sockeye salmon, Oncorhyncnus nerka. Chinook salmon, Oncorhynchus tshawytscha, were intermediate in sensitivity. Coho salmon, Oncorhyncnus kisutch, were significantly the more tolerant of the salmonids though still much more susceptible than non-salmonids like bass or carp.

Dapnnia magna exhibited a sensitivity to supersaturation similar to that of the salmonids (Nebeker et al. 1975), with 115 percent saturation lethal within a few days. Stoneflies exhibited an intermediate sensitivity similar to bass with mortality at 130 percent saturation. Crayfish were very tolerant, with levels near 140 percent total gas saturation resulting in mortality.

No differences are proposed in the criteria for freshwater and marine aquatic life as the data available indicate that there probably is little difference in overall tolerances between marine and freshwater species.

The development of gas bubble disease in menhaden, Brevoortia sp., and their tolerance to gas saturation in laboratory bioassays and in the field (Pilgrim Nuclear Power Station Discharge Canal) are discussed by Clay et al. (1975) and Marcello et al. (1975). At 100 percent and 105 percent nitrogen saturation, no gas bubbles developed externally or in any of the internal organs of menhaden. At 105 percent nitrogen saturation, however, certain behavioral changes became apparent. Fish sloughed off mucus, swam erratically, were more excitable, and became darker in color. Menhaden behavioral changes observed at 110 percent nitrogen saturation were similar to those noted at 105 percent. In addition, at 110 percent gas emboli were found in the intestines, the pyloric caeca, and occasionally the operculum. The behavioral changes described were also observed at 115 percent, and clearly defined subcutaneous emphysema was observed in the fins and occasionally in the eye. At 120 percent and 130 percent nitrogen saturation, menhaden developed within a few hours classic symptoms of gas bubble disease. Externally, emboli were evident in all fins, the operculum and within the oral cavity.

Exophthalmia also occurred and emboli developed in internal organs. The bulbous arteriosis and swim bladder were severely distended, and emboli were found along the length of the gill arterioles, resulting in hemostasis. At water temperatures of 30

°C, menhaden did not survive, regardless of gas saturation level. At water temperatures of 15 , 22 , and 25 °C 100 percent of the menhaden died within 24 hours at 120 percent and 130 percent gas saturation. Fifty percent died after 96 hours at 115 percent (22 °C) Menhaden survival after 96 hours at 110 percent nitrogen saturation ranged from 92 percent at 22° and 25° to 83 percent at 15 °C. Observations on the relationship between the mortality rate of menhaden and gas saturation levels at Pilgrim Station during the April 1975, incident suggest that the fish may tolerate somewhat higher gas saturation levels in nature.

It has been shown by Bouck et al. (1975) and Dawley et al. (1975) that survival of salmon and steelhead smolts in seawater is not affected by prior exposure to gas supersaturation while in fresh water. No significant mortality of juvenile coho and sockeye salmon occurred when they were exposed to sublethal concentrations of supersaturated water and then transferred to seawater (Nebeker et al. 1976b).

SEE APPENDIX C FOR METHODOLOGY

GUTHION

CRITERION:

.01 ug/L for freshwater and marine aquatic life.

RATIONALE:

Ninety-six-hour LC50 values for fish exposed to the organophosphorus pesticide guthion range from 4 to 4270 ug/L (Katz, 1961; Pickering et al. 1962; Lahav and Sarig, 1969; Macek et al. 1969; Macek and McAllister, 1970). The only long-term fish exposure data available are those obtained recently by Adelman and Smith (unpublished data). Decreased spawning (eggs produced per female) was observed in fathead minnows, Pimephales promelas, exposed during a complete life cycle. An estimated "safe" long-term exposure concentration for fathead minnows lies between 0.3 and 0.5 ug/L. Survival of larvae was reduced at approximately 0.7 ug/L.

An investigation of the persistence of guthion in fish revealed that 50 percent of the chemical was lost in less than one week (Meyer, 1965). Analysis of plankton and pond water in the same study indicated a 50 percent loss of guthion in about 48 hours. Flint et al. (1970) determined the half-life of guthion at 30C in pond water and in a phosphate buffer protected from light in the laboratory. The half-life in pond water was 1.2 days whereas that in the laboratory solution was 10 days. The more rapid degradation in pond water was attributed to the effect of sunlight and microorganisms.

Organophosphate pesticides are toxic because they inhibit the

enzyme acetylcholinesterase (AChE) which is essential to nerve impulse conduction and transmission (Holland et al. 1967). Weiss (1958, 1959, 1961) demonstrated that a 40 to 70 percent inhibition of fish brain AChE usually is lethal. Centrarchids generally are considered one of the more sensitive groups of fish to guthion (Pickering et al. 1962; Weiss and Gakstatter, 1964; Meyer, 1965). Weiss and Gakskatter (1964) found that over a 15-day period bluegills, Lepomis macrochirus, exhibited AChE inhibition at 1.0 ug/L guthion but not at 0.1 ug/L. Exposure at 0.05 ug/L for 30 days also failed to produce inhibition below the range of normal variation, but the authors stated that it appeared there was a downward trend in brain enzyme activity and that if exposure was continued a definite reduction might develop. Weiss (1961) found that about 30 days were required for fathead minnow and bluegill brain AChE levels to recover after 8 to 24 hours exposure to 10 ug/L guthion.

Benke and Murphy (1974) showed that repetitive injection of fish with guthion caused cumulative inhibition of brain AChE and mortality. After substantial inhibition by guthion exposure, it takes several weeks for brain AChE of fishes to return to normal even though exposure is discontinued (Weiss, 1959, 1960; Carter, 1971). Inhibition of brain AChE of fishes by 46 percent or more has been associated with harmful effects in exposures to there organophosphate pesticides for a life cycle (Eaton, 1970) and for shorter periods (Carter, 1971; Coppage and Duke, 1971; Coppage, 1972; Coppage and Matthews, 1974; Post and Leasure, 1974; Coppage et al. in press). In static tests, similar inhibition of AChE and mortality were caused in the sheepshead minnow, Cyprinodon

variegatus, in 2, 24, 48 and 72 hours at concentrations of 50, 7, 3.5 and 3 ug/L, respectively (Coppage, 1972). These data indicate that reduction of brain AChE activity of marine fishes by 70 to 80 percent or more in short-term exposures to guthion may be associated with some deaths.

There is no evidence to indicate that guthion would cause adverse effects through the food chain. Tissue residue accumulation for whole fish calculated from the data of Meyer (1965) indicate no more than a twentyfold accumulation. LC50 toxicity values for birds are relatively high and range from 70 to 2,000 mg/kg (Tucker and Crabtree, 1970).

Ninety-six-hour LC50 values for aquatic invertebrates range from 0.10 to 22.0 ug/L (Nebeker and Gaufin, 1964; Gaufin et al. 1965: Jensen and Gaufin, 1966: Sanders and Cope, 1968; Sanders, 1969, 1972). Sanders (1972) exposed the grass shrimp, Paleomonetes kadiakensis, to guthion in a continuous flow bioassay for up to 20 days and found that the 5- and 20-day LC50 values were 1.2 and 0.16 ug/L, respectively. He found that the amphipod, Gammarus fasciatus, was the most sensitive aquatic organism tested, with a 96-hour LC50 of 0.10 ug/L. Jensen and Gaufin (1966), also using a continuous flow system, exposed two species of stonefly naiads in 4- and 30-day studies. They observed 96-hour and 30-day LC50 values for Acroneuria pacifica of 2.0 and 0.24 ug/L, respectively, whereas for Pteronarcys californica the values were 4.6 and 1.3 ug/L, respectively.

Results of other toxicity studies on marine organisms have been reported. The 24-hour LC50 for the white mullet, Mugil

curema, was found to be 5.5 ug/L guthion (Butler, 1963). The 96-hour LC50 for the striped mullet, Mugil cephalus, was determined by Lahav and Sarig (1969) to be 8 ug/L guthion. Portman (1972) reported the 48-hour LC50 for the fish, Pleuronectes limanda, to be 10 to 30 ug/L. The 48-hour LC50 for the European shrimp, Crangon crangon, was found to be 0.33 ug/L guthion (Portman, 1972). Butler (1963) found that the 24-hour EC50 for blue crab, Callinectes sapidus, was 550 ug/L and the 48-hour EC50 for pink shrimp, Penaeus duorarum, was 4.4 ug/L guthion. The 48-hour TLm was estimated to be 620 ug/L for fertilized oyster eggs, Crassostrea virginica, and 860 ug/L for fertilized clam eggs, Mercenaria mercenaria (Davis and Hidu, 1969).

A criterion level of .01 ug/L for guthion is based upon use of an 0.1 application factor applied to the 96-hour LC50 of 0.1 ug/L for Gammarus and a similar value of 0.3 ug/L for the European shrimp.

SEE APPENDIX C FOR METHODOLOGY

HALOETHERS

CRITERIA:

Aquatic Life

The available data for haloethers indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 360 and 122 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

No saltwater organisms have been tested with any haloether and therefore, no statement can be made concerning acute or chronic toxicity.

Human Health

Using the present guidelines, a satisfactory criterion cannot be derived at this time because of insufficient available data for haloethers.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

HALOMETHANES

CRITERIA:

Aquatic Life

The available data for halomethanes indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low a 11,000 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of halomethanes to sensitive freshwater aquatic life.

The available data for halomethanes indicate that acute and chronic toxicity to saltwater aquatic life occurs at concentrations as low as 12,000 and 6,400 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested. A decrease in algal cell numbers occurs at concentrations as low as 11,500 ug/L.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to chloromethane, bromomethane, dichloromethane, bromodichloromethane, tribromomethane, dichlorodifluoromethane, trichlorofluoromethane, or combinations of these chemicals through ingestion of contaminated water and aquatic organisms, the ambient water concentration should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime

are estimated at 10^{-5}, 10^{-6} and 10^{-7}. The corresponding recommended criteria are 1.9 ug/L, 0.19 ug/L, and 0.019 ug/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 157 ug/L, 15.7 ug/L, and 1.57 ug/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

HARDNESS

INTRODUCTION:

Water hardness is caused by the polyvalent metallic ions disolved in water. In fresh water these are primarily calcium and magnesium although other metals such as iron, strontium and manganese contribute to the extent that appreciable concentrations are present. Hardness commonly is reported as an equivalent concentration of calcium carborate ($CaCO_3$).

The concept of hardness comes from water supply practice. It is measured by soap requirements for adequate lather formation and as an indicator of the rate of scale formation in hot water heaters and low pressure boilers. A commonly used classification is given in the following table (Sawyer, 1960).

TABLE 3.

Classification of Water by Hardness Content

Conc. mg/L $CaCO_3$	Description
0 - 75	soft
75 - 150	moderately hard
150 - 300	hard
300 and up	very hard

Natural sources of hardness principally are limestones which are dissolved by percolating rainwater made acid by dissolved carbon dioxide. Industrial and industrially related sources include the inorganic chemical industry and discharges from operating and abandoned mines.

Hardness in fresh water frequently is distinguished in carbonate and non-carbonate fractions. The carbonate fraction is chemically equivalent to the bicarbonates present in water.

Since bicarbonates generally are measured as alkalinity, the carbonate hardness usually is considered equal to the alkalinity.

RATIONALE:

The determination of hardness in raw waters subsequently treated and used for domestic water supplies is useful as a parameter to characterize the total dissolved solids present and for calculating dosages where lime-soda softening is practiced. Because hardness concentrations in water have not been proven health related, the final level achieved principally is a function of economics. Since hardness in water can be removed with treatment by such processes as lime-soda softening and zeolite or ion exchange systems, a criterion for raw waters used for public water supply is not practical.

The effects of hardness on freshwater fish and other aquatic life appear to be related to the ions causing the hardness rather than hardness. Both the NTAC (1968) and NAS (1974) panels have recommended against the use of the term hardness but suggest the inclusion of the concentrations of the specific ions. This procedure should avoid confusion in future studies but is not helpful in evaluating previous studies. For most existing data, it is difficult to determine whether toxicity of various metal ions is reduced because of the formation of metallic hydroxides and carbonates caused by the associated increases in alkalinity, or because of an antagonistic effect of one of the principal cations contributing to hardness, e.g., calcium, or a combination of both effects. Stiff (1971) presented a theory (without proof)

that if cupric ions were the toxic form of copper whereas copper carbonate complexes were relatively non-toxic, then the observed difference in toxicity of copper between hard and soft waters can be explained by the difference in alkalinity rather than hardness. Doudoroff and Katz (1953), in their review of the literature on toxicity, presented data showing that increasing calcium in particular reduced the toxicity of other heavy metals. Under usual conditions in fresh water and assuming that other bivalent metals behave similarly to copper, it is reasonable to assume that both effects occur simultaneously and explain the observed reduction of toxicity of metals in waters containing carbonate hardness. The amount of reduced toxicity related to hardness, as measured by a 40-hour LC50 for rainbow trout, has been estimated to be about four times for copper and zinc when the hardness was increased from 10 to 100 mg/L as $CaCO_3$ (NAS, 1974).

Limits on hardness for industrial uses are quite variable. Table 4 lists maximum values that have been accepted by various industries as a source of raw water (NAS, 1974). Subsequent treatment generally can reduce hardness to tolerable limits although costs of such treatment are an important factor in determining its desirability for a particular water source.

Hardness is not a determination of concern for irrigation use of water. The concentrations of the cations calcium and magnesium, which comprise hardness, are important in determining the exchangeable sodium in a given water. This particular calculation will be discussed under total dissolved solids rather

TABLE 4.

Maximum Hardness Levels Accepted
By Industry as a Raw Water Source*

Industry	Maximum Concentration mg/L as $CaCO_3$
Electric utilities	5,000
Textile	120
Pulp and paper	475
Chemical	1,000
Petroleum	900
Primary metals	1,000

* Requirements for final use within a process may be essentially zero, which requires treatment for concentration reductions.

than hardness.

SEE APPENDIX C FOR METHODOLOGY

HEPTACHLOR

CRITERIA:

Aquatic Life

For heptachlor the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.0038 ug/L as a 24-hour average, and the concentration should not exceed 0.52 ug/L at any time.

For heptachlor the criterion to protect saltwater aquatic life as derived using the Guidelines is 0.0036 ug/L as a 24-hour average, and the concentration should not exceed 0.053 ug/L at any time.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to heptachlor through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero, based on the non threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 2.78 ng/L, 0.28 ng/L, and 0.028 ng/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 2.85 ng/L, 0.29 ng/L, and 0.029 ng/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

HEXACHLOROBUTADIENE

CRITERIA:

Aquatic Life

The available data for hexachlorobutadiene indicate that acute and chronic toxicity to freshwater aquatic life occur at concentrations as low as 90 and 9.3 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

The available data for hexachlorobutadiene indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 32 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of hexachlorobutadiene to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to hexachlorobutadiene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 4.47 ug/L, 0.45 ug/L, and 0.045 ug/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding

consumption of water, the levels are 500 ug/L, 50 ug/L, and 5.0 ug/L, respectively.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

CRITERIA:

Aquatic Life

Lindane

For lindane the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.080 ug/L as a 24-hour average and the concentration should not exceed 2.0 ug/L at any time.

For saltwater aquatic life the concentration of lindane should not exceed 0.16 ug/L at any time. No data are available concerning the chronic toxicity of lindane to sensitive saltwater aquatic life.

BHC

The available data for a mixture of isomers of BHC indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 100 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of a mixture of isomers of BHC to sensitive freshwater aquatic life.

The available data for a mixture of isomers of BHC indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 0.34 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of a mixture of isomers of BHC to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects of exposure to alpha-hexachlorocyclohexane through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 92 ng/L, 9.2 ng/L, and .92 ng/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 310 ng/L, 31.0 ng/L, and 3.10 ng/L, respectively.

For the maximum protection of human health from the potential carcinogenic effects of exposure to beta-hexachlorocyclohexane through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 163 ng/L, 16.3 ng/L, and 1.63 ng/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 547 ng/L, 54.7 ng/L, and 5.47 ng/L, respectively.

For the maximum protection of human health from the potential carcinogenic effects due to exposure of gama-hexachlorocyclohexane through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 186 ng/L, 18.6 ng/L, and 1.86 ng/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 625 ng/L, 62.5 ng/L, and 6.25 ng/L, respectively.

For the maximum protection of human health from the potential carcinogenic effects of exposure to technical-hexachlorocyclohexane through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero, based on the nonthreshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 123 ng/L, 12.3 ng/L, and 1.23 ng/L, respectively. If these estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 414 ng/L, 41.4 ng/L, and 4.14 ng/L, respectively.

Using the present guidelines, satisfactory criteria cannot be derived at this time for delta and epsilon hexachlorocyclohexane because of insufficient available data.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

HEXACHLOROCYCLOPENTADIENE

CRITERIA:

Aquatic Life

The available data for hexachlorocyclopentadiene indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 7.0 and 5.2 ug/L, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

The available data for hexachlorocyclopentadiene indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 7.0 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of hexachlorocyclopentadiene to sensitive saltwater aquatic life.

Human Health

For comparison purposes, two approaches were used to derive criterion levels for hexachlorocyclopentadiene. Based on available toxicity data, to protect public health the derived level is 206 ug/L. Using available organoleptic data, to control undersirable taste and odor quality of ambient water the estimated level is 1 ug/L. It should be recognized that organoleptic data have limitations as a basis for establishing water quality criteria, and have no demonstrated relationship to potential adverse human health effects.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

IRON

CRITERIA:

0.3 mg/L for domestic water supplies (welfare).

1.0 mg/L for freshwater aquatic life.

INTRODUCTION:

Iron is the fourth most abundant, by weight, of the elements that make up the earth's crust. Common in many rocks, it is an important component of many soils, especially the clay soils where usually it is a major constituent. Iron in water may be present in varying quantities dependent upon the geology of the area and other chemical components of the waterway.

Iron is an essential trace element required by both plants and animals. In some waters it may be a limiting factor for the growth of algae and other plants; this is true especially in some marl lakes where it is precipitated by the highly alkaline conditions. It is a vital oxygen transport mechanism in the blood of all vertebrate and some invertebrate animals.

The ferrous, or bivalent (Fe^{++}), and the ferric, or trivalent (Fe^{+++}) irons, are the primary forms of concern in the aquatic environment, although other forms may be in organic and inorganic wastewater streams. The ferrous (Fe^{++}) form can persist in waters void of dissolved oxygen and originates usually from groundwaters or mines when these are pumped or drained. For practical purposes the ferric (Fe^{+++}) form is insoluble. Iron can exist in natural organometallic or humic compounds and colloidal forms. Black or brown swamp waters may contain iron concentrations of several mg/L in the presence or absence of dissolved oxygen, but this iron form has little effect on aquatic

life.

(QUALITY CRITERIA FOR WATER, JULY 1976) PB-263943
SEE APPENDIX C FOR METHODOLOGY

ISOPHORONE

CRITERIA:

Aquatic Life

The available data for isophorone indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 117,000 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of isophorone to sensitive freshwater aquatic life.

The available data for isophorone indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 12,900 ug/L and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of isophorone to sensitive saltwater aquatic life.

Human Health

For the protection of human health from the toxic properties of isophorone ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 5.2 mg/L.

For the protection of human health from the toxic properties of isophorone ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 520 mg/L.

(45 F.R. 79318, November 28, 1980)
SEE APPENDIX B FOR METHODOLOGY

LEAD

AQUATIC LIFE SUMMARY:

The acute toxicity of lead to several species of freshwater animals has been shown to decrease as the hardness of water increases. At a hardness of 50 mg/L the acute sensitivities of 10 species range from 142.5 ug/L for an amphipod to 235,900 ug/L for a midge. Data on the chronic effects of lead on freshwater animals are available for two fish and two invertebrate species. The chronic toxicity of lead also decreases as hardness increases and the lowest and highest available chronic values (12.26 and 128.1 ug/L) are both for a cladoceran, but in soft and hard water, respectively. Acute-chronic ratios are available for three species and range from 18 to 62. Freshwater algae are affected by concentrations of lead above 500 ug/L, based on data for four species. Bioconcentration factors are available for four invertebrate and two fish species and range from 42 to 1,700.

Acute values are available for 13 saltwater animal species and range from 315 ug/L for the mummichog to 27,000 ug/L for the soft shell clam. A chronic toxicity test was conducted with a mysid; unacceptable effects were observed at 37 ug/L but not at 17 ug/L and the acute-chronic ratio for this species is 124.8. A species of macroalgae was affected at 20 ug/L. Available bioconcentration factors range from 17.5 to 2,570.

NATIONAL CRITERIA:

The procedures described in the Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of

Aquatic Organisms and Their Uses indicate that, except possibly where a locally important species is very sensitive, freshwater aquatic organisms and their uses should not be affected unacceptably if the 4-day average concentration (in ug/L) of lead does not exceed the numerical value given by $_{e}$(1.273[ln(hardness)]-4.705) more than once every 3 years on the average and if the 1-hour average concentration (in ug/L) does not exceed the numerical value given by $_{e}$(1.273[ln(hardness)]-1.460) more than once every 3 years on the average. For example, at hardnesses of 50, 100, and 200 mg/L as $CaCO_3$ the 4-day average concentrations of lead are 1.3, 3.2, and 7.7 ug/L, respectively, and the 1-hour average concentrations are 34, 82, and 200 ug/L.

The procedures described in the Guidelines indicate that, except possibly where a locally important species is very sensitive, saltwater aquatic organisms and their uses should not be affected unacceptably if the 4-day average concentration of lead does not exceed 5.6 ug/L more than once every 3 years on the average and if the 1-hour average concentration does not exceed 140 ug/L more than once every three years on the average.

EPA believes that a measurement such as "acid-soluble" would provide a more scientifically correct basis upon which to establish criteria for metals. The criteria were developed on this basis. However, at this time, no EPA-approved methods for such a measurement are available to implement the criteria through the regulatory programs of the Agency and the States. The Agency is considering development and approval of methods for a measurement such as acid-soluble. Until available, however, EPA recommends applying the criteria using the total recoverable.

method. This has two impacts: (1) Certain species of some metals cannot be analyzed directly because the total recoverable method does not distinguish between individual oxidation states, and (2) these criteria may be overly protective when based on the total recoverable method.

The recommended exceedence frequency of 3 years is the Agency's best scientific judgment of the average amount of time it will take an unstressed system to recover from a pollution event in which exposure to lead exceeds the criterion. A stressed system, for example, one in which several outfalls occur in a limited area, would be expected to require more time for recovery. The resilience of ecosystems and their ability to recover differ greatly, however, and site-specific criteria may be established if adequate justification is provided.

The use of criteria in designing waste treatment facilities requires the selection of an appropriate wasteload allocation model. Dynamic models are preferred for the application of these criteria. Limited data or other factors may make their use impractical, in which case one should rely on a steady-state model. The Agency recommends the interim use of 1Q5 or 1Q10 for Criterion Maximum Concentration design flow and 7Q5 or 7Q10 for the Criterion Continuous Concentration design flow in steady-state models for unstressed and stressed systems, respectively. These matters are discussed in more detail in the Technical Support Document for Water Quality-Based Toxics Control (U.S. EPA, 1985).

HUMAN HEALTH CRITERIA:

The ambient water quality criterion for lead is recommended to be identical to the existing drinking water standard which is 50 ug/L. Analysis of the toxic effects data resulted in a calculated level whic is protective to human health against the ingestion of contaminated water and contaminated aquatic organisms. The calculated value is comparable to the present standard. For this reason a selective criterion based on exposure soley from consumption of 6.5 grams of aquatic organisms was not derived.

MALATHION

CRITERION:

0.1 ug/L for freshwater and marine aquatic life.

RATIONALE:

The freshwater fish most sensitive to malathion, an organophosphorus pesticide, appear to be the salmonids and centrarchids. Post and Schroeder (1971) report a 96-hour LC50 between 120 and 265 ug/L for 4 species of salmonids. Macek and McAllister (1970) found a 96-hour LC50 range between 101 and 285 ug/L for 3 species of centrarchids and 3 species of salmonids. Other 96-hour LC50's are: rainbow trout, Salmo gairdneri, 68 ug/L (Cope, 1965); largemouth bass, Micropterus salmoides, 50 ug/L (Pickering et al. 1962); and chinook salmon, Oncorhynchus tshawytscha, 23 ug/L (Katz, 1961). All of the above tests were in static systems. Eaton (1970) determined a 96-hour LC50 for bluegill, Lepomis macrochirus, in a flow-through system at 110 ug/L. Macek and McAllister (1970) reported a similar 96-hour LC50 for the bluegill in a static exposure. Static 96-hour LC50s of 120 and 160 ug/L were reported by Post and Schroeder (1971) for brook trout, Salvelinus fontinalis. Bender (1969) indicated that the acute toxicity to fathead minnows, Pimephales promelas, is slightly greater (about 2.0 times) in a static system than in a flow-through system. The flow-through acute toxicity to fathead minnows reported by Mount and Stephan (1967) approximated the static acute toxicity reported by Henderson and Pickering (1958) and Bender (1969).

Many aquatic invertebrates appear to be more sensitive than fish to malathion. The 96-hour LC50 for Gammarus lacustris was 1.0 ug/L (Sanders, 1969); for Pteronarcella badia, 1.1 ug/L (Sanders and Cope, 1968); and for Gammarus fasciatus, 0.76 ug/L (Sanders, 1972). The 48-hour LC50 for Simocephalus serrulatus was 3.5 ug/L and for Daphnia pulex, 1.8 ug/L (Sanders and Cope, 1966). Daphnia were immobilized in 50 hours in 0.9 ug/L (Anderson, 1960). The 24-hour LC50s for two species of midge larvae were 2.1 ug/L (Mulla and Khasawinah, 1969) and 2.0 ug/L (Karnak and Collins, 1974).

Safe life cycle exposure concentrations for the more sensitive invertebrates are not known. The most sensitive aquatic organisms probably have not yet been tested; safe concentrations for the most sensitive invertebrates exposed through a complete life cycle have not been determined; and effects of low concentrations on invertebrate behavior are unknown.

The stability of malathion in water is dependent on the chemical and biological conditions of the water (Paris et al. 1975). Weiss and Gakstatter (1964) have shown that the half-life of malathion was reduced from about 5 months at pH 6 to 1 to 2 weeks at pH 8. Eichelberger and Lichtenberg (1971) found that only 10 percent remained in the Little Miami River (pH 7.3-8.0) after 2 weeks. Bender (1969) states that one of the malathion breakdown products may be more toxic than the parent compound.

It has been shown that a measured concentration of 575 ug/L malathion in flowing seawater kills 40 to 60 percent of the

marine fish, Lagodon rhomboides, in 3.5 hours and causes about 75 percent brain acetylcholinesterase (AChE) inhibition (Coppage et al. 1975). Similar inhibition of AChE and mortality were caused in pinfish in 24, 48, and 72 hours at measured concentrations of 142, 92 and 58 ug/L, respectively. A concentration of 31 ug/L caused 34 percent AChE inhibition in pinfish but no deaths in 72 hours. Coppage and Matthews (1974) demonstrated that death may be associated with reductions of brain AChE activity of four marine fishes by 70 to 80 percent or more in short-term exposures to malathion. Coppage and Duke (1971) found that moribund mullet, Mugil cephalus, in an estuary sprayed with malathion (3 oz./acre) during a large-scale mosquito control operation had about 98 percent inhibition of brain AChE. This is in agreement with 70 to 80 percent or more inhibition of brain AChE levels at and below which some deaths are likely to occur in short-term exposure. Spot, Leiostomus xanthurus, and Atlantic croaker, Micropogon undulatus, also had substantial inhibition of brain during the spray operation (70 percent or more inhibition).

Toxicity studies have been made on a number of marine animals. Eisler (1970) studied the 96-hour LC50 for several marine fishes at 20 ^{o}C in static, aerated seawater. The 96-hour LC50 values (in ug/L) were: Menidia menidia, 125; Mugil cephalus, 550; Fundulus majalis, 250; Fundulus heteroclitus, 240; Sphaeroides maculatus, 3250; Anguilla rostrata, 82; and Thalassoma bifasciatum, 27. Katz (1961) reported the static 24-hour LC50 for Gasterosteus aculeatus in 25 o/oo saltwater as 76.9 ug/L active ingredient. The 96-hour LC50 for striped bass,

Morone saxatilis, in intermittent flowing seawater has been reported as 14 ug/L (U.S. BSFW, 1970).

Reporting on studies of the toxicity of malathion on marine invertebrates, Eisler (1969) found the 96-hour LC50 (static, 24 o/oo salinity aerated) to be 33 ug/L for sand shrimp, Crangon septemspinosa; 82 ug/L for grass shrimp, Palaemonetes vulgaris; and 83 ug/L for hermit crab, Pagurus longicarpus. Growth of oyster, Crassostrea virginica, was reduced 32 percent by 96-hour exposure to 1 mg/L (Butler, 1963). The 48-hour LC50 for fertilized eggs of oysters was estimated by Davis and Hidu (1969) to be 9.07 mg/L and the 14-day LC50 for larvae, 2.66 mg/L.

Malathion enters the aquatic environment primarily as a result of its application as an insecticide. Because it degrades quite rapidly in most waters, depending on pH, its occurrence is sporadic rather than continuous. Because the toxicity is exerted through inhibition of AChE and because such inhibition may be additive with repeated exposures and may be caused by any of the organophosphorus insecticides, inhibition of AChE by more than 35 percent may be expected to result in damage to aquatic organisms.

An application factor of 0.1 is applied to the 96-hour LC50 data for Gammarus lacustris, G. fasciatis and Daphnia, which are all approximately 1.0 ug/L, yielding a criterion of 0.1 ug/L.

MANGANESE

CRITERIA:

50 ug/L for domestic water supplies (welfare);

100 ug/L for protection of consumers of marine molluscs.

INTRODUCTION:

Manganese does not occur naturally as a metal but is found in various salts and minerals, frequently in association with iron compounds. The principal manganese-containing substances are manganese dioxide (MnO_2), pyrolusite, manganese carbonate (rhodocrosite) and manganese silicate (rhodonite). The oxides are the only important minerals mined. Manganese is not mined in the United States except when manganese is contained in iron ores that are deliberately used to form ferro-manganese alloys.

The primary uses of manganese are in metal alloys, dry cell batteries, micro-nutrient fertilizer additives, organic compounds used in paint driers and as chemical reagents. Permanganates are very strong oxidizing agents of organic materials.

Manganese is a vital micro-nutrient for both plants and animals. When manganese is not present in sufficient quantities, plants exhibit chlorosis (a yellowing of the leaves) or failure of the leaves to develop properly. Inadequate quantities of manganese in domestic animal food results in reduced reproductive capabilities and deformed or poorly maturing young. Livestock feeds usually have sufficient manganese, but beef cattle on a high corn diet may require a supplement.

RATIONALE:

Although inhaled manganese dusts have been reported to be toxic to humans, manganese normally is ingested as a trace nutrient in food. The average human intake is approximately 10 mg/day (Sollman, 1957). Very large doses of ingested manganese can cause some disease and liver damage but these are not known to occur in the United States. Only a few manganese toxicity problems have been found throughout the world and these have occurred under unique circumstances, i.e., a well in Japan near a deposit of buried batteries (McKee and Wolf, 1963).

It is possible to partially sequester manganese with special treatment but manganese is not removed in the conventional treatment of domestic waters (Riddick et al. 1958; Illig, 1960). Consumer complaints arise when manganese exceeds a concentration of 150 ug/L in water supplies (Griffin, 1960). These complaints are concerned primarily with the brownish staining of laundry and objectionable tastes in beverages. It is possible that the presence of low concentrations of iron may intensify the adverse effects of manganese. Manganese at concentrations of about 10 to 20 ug/L is acceptable to most consumers. A criterion for domestic water supplies of 50 ug/L should minimize the objectionable qualities.

McKee and Wolf (1963) summarized data on toxicity of manganese to freshwater aquatic life. Ions of manganese are found rarely at concentrations above 1 mg/L. The tolerance values reported range from 1.5 mg/L to over 1000 mg/L. Thus, manganese is not considered to be a problem in fresh waters. Permanganates have been reported to kill fish in 8 to 18 hours at

concentrations of 2.2 to 4.1 mg/L, but permanganates are not persistent because they rapidly oxidize organic materials and are thereby reduced and rendered nontoxic.

Few data are available on the toxicity of manganese to marine organisms. The ambient concentration of manganese is about 2 ug/L (Fairbridge, 1966). The material is rapidly assimilated and bioconcentrated into nodules that are deposited on the sea floor. The major problem with manganese may be concentration in the edible portions of molluscs, as bioaccumulation factors as high as 12,000 have been reported (NAS, 1974). In order to protect against a possible health hazard to humans by manganese accumulation in shellfish, a criterion of 100 ug/L is recommended for marine water.

Manganese is not known to be a problem in water consumed by livestock. At concentrations of slightly less than 1 mg/L to a few milligrams per liter, manganese nay be toxic to plants from irrigation water applied to soils with pH values lower than 6.0. The problem may be rectified by liming soils to increase the pH. Problems may develop with long-term (20 year) continuous irrigation on other soils with water containing about 10 mg/L of manganese (NAS, 1974). But, as stated above, manganese is rarely found in surface waters at concentrations greater than 1 mg/L. Thus, no specific criterion for manganese in agricultural waters is proposed. In select areas, and where acidophilic crops are cultivated and irrigated, a criterion of 200 ug/L is suggested for consideration.

Most industrial users of water can operate successfully where the criterion proposed for public water supplies is observed. Examples of industrial tolerance of manganese in water are summarized for industries such as dyeing, milk processing, paper, textiles, photography and plastics (McKee and Wolf, 1963). A more restrictive criterion may be needed to protect or ensure product quality.

SEE APPENDIX C FOR METHODOLOGY

*MERCURY

AQUATIC LIFE SUMMARY:

Data are available on the acute toxicity of mercury(II) to 28 genera of freshwater animals. Acute values for invertebrate species range from 2.2 ug/L for Daphnia pulex to 2,000 ug/L for three insects. Acute values for fishes range from 30 ug/L for the guppy to 1,000 ug/L for the Mozambique tilapia. Few data are available for various organomercury compounds and mercurous nitrate, and they all appear to be 4 to 31 times more acutely toxic than mercury(II).

Available chronic data indicate that methylmercury is the most chronically toxic of the tested mercury compounds. Tests on methylmercury with Daphnia magna and brook trout produced chronic values less than 0.07 ug/L. For mercury(II) the chronic value obtained with Daphnia magna was about 1.1 ug/L and the acute-chronic ratio was 4.5. In both a life-cycle test and an early life-stage test on mercuric chloride with the fathead minnow, the chronic value was less than 0.26 ug/L and the acute-chronic ratio was over 600.

Freshwater plants show a wide range of sensitivities to mercury, but the most sensitive plants appear to be less sensitive than the most sensitive freshwater animals to both mercury(II) and methylmercury. A bioconcentration factor of 4,994 is available for mercury(II), but the bioconcentration factors for methylmercury range from 4,000 to 85,000.

*Indicates suspended, canceled or restricted by U.S. EPA Office of Pesticides and Toxic Substances

Data on the acute toxicity of mercuric chloride are available for 29 genera of saltwater animals, including annelids, molluscs, crustaceans, echinoderms, and fishes. Acute values range from 3.5 ug/L for a mysid to 1,678 ug/L for winter flounder. Fishes tend to be more resistant and molluscs and crustaceans tend to be more sensitive to the acute toxic effects of mercury(II). Results of a life-cycle test with the mysid show that mercury(II) at a concentration of 1.6 ug/L significantly affected time of first spawn and productivity; the resulting acute-chronic ratio was 3.1.

Concentrations of mercury that affected growth and photosynthetic activity of one saltwater diatom and six species of brown algae range from 10 to 160 ug/L. Bioconcentration factors of 10,000 and 40,000 have been obtained for mercuric chloride and methylmercury with an oyster.

NATIONAL CRITERIA:

Derivation of a water quality criterion for mercury is more complex than for most metals because of methylation of mercury in sediment, in fish, and in the food chain of fish. Apparently almost all mercury currently being discharged is mercury(II). Thus mercury(II) should be the only important possible cause of acute toxicity and the Criterion Maximum Concentrations can be based on the acute values for mercury(II).

The best available data concerning long-term exposure of fish to mercury(II) indicates that concentrations above 0.23 ug/L caused statistically significant effects on the fathead minnow and caused the concentration of total mercury in the whole body
