Options For Reducing Methane Emissions From Pneumatic Devices In The Natural Gas Industry

Executive Summary

Pneumatic devices powered by pressurized natural gas are used widely in the natural gas industry as liquid level controllers, pressure regulators, and valve controllers. Methane emissions from pneumatic devices, which have been estimated at 51 billion cubic feet (Bcf) per year in the production sector, 14 Bcf per year in the transmission sector and <1 Bcf per year in the processing sector, are one of the largest sources of vented methane emissions from the natural gas industry. Reducing these emissions by replacing high-bleed devices with low-bleed devices, retrofitting high-bleed devices, and improving maintenance practices can be profitable.

Natural Gas STAR Partners have achieved significant savings and methane emission reductions through replacement, retrofit, and maintenance of high-bleed pneumatics. Partners have found that most retrofit investments pay for themselves in little over a year, and replacements in as little as 6 months. To date, Natural Gas STAR Partners have saved 36.4 Bcf by retrofitting or replacing high-bleed with low-bleed pneumatic devices, representing a savings of $254.8 million worth of gas. Individual savings will vary depending on the design, condition and specific operating conditions of the controller.

Technology Background

The natural gas industry uses a variety of control devices to automatically operate valves and control pressure, flow, temperature or liquid levels. Control devices can be powered by electricity or compressed air, when available and economic. In the vast majority of applications, however, the gas industry uses pneumatic devices that employ energy from pressurized natural gas.

Natural gas powered pneumatic devices perform a variety of functions in all three sectors of the natural gas industry. In the production sector, an estimated 400,000 pneumatic devices are used to control and monitor gas and liquid flows and levels in dehydrators and separators, temperature in dehydrator regenerators, and pressure in flash tanks. In the processing sector, about 13,000 gas pneumatic devices are used for compressor and glycol dehydration control in gas gathering/booster stations and isolation valves in processing plants (process control in gas processing plants is predominantly instrument air).

Economic and Environmental Benefits

Method for Reducing Natural Gas Losses	Volume of Natural Gas Savings (Mcf/year)	Value of Natural Gas Savings ($/year)			Implementation Cost ($)	Payback (Months)		
		$3 per Mcf	$5 per Mcf	$7 per Mcf		$3 per Mcf	$5 per Mcf	$7 per Mcf
Replacement								
Change to low-bleed device at end of life.	50 to 200	$150 to $600	$250 to $1,000	$350 to $1,400	$210 to $340[a]	4 to 27	3 to 17	2 to 12
Early-replacement of high-bleed unit.	260	$780	$1,300	$1,820	$1,850	29	17	13
Retrofit	230	$690	$1,150	$1,610 per year	$675	12	7	5
Maintenance	45 to 260	$135 to $780	$225 to $1,300	$315 to $1,820	Negligible to $500	Immediate to 8	Immediate to 5	Immediate to 4

General Assumptions:
[a] Incremental cost of low-bleed over high-bleed equipment.

NMED Exhibit 92 - 0001

Definition of High-Bleed Pneumatic

Any pneumatic device that bleeds in excess of 6 scfh (over 50 Mcf per year) is considered a high-bleed device by the Natural Gas STAR Program.

In the transmission sector, an estimated 85,000 pneumatic devices actuate isolation valves and regulate gas flow and pressure at compressor stations, pipelines, and storage facilities. Non-bleed pneumatic devices are also found on meter runs at distribution company gate stations for regulating flow, pressure, and temperature.

As part of normal operation, pneumatic devices release or bleed natural gas to the atmosphere and, consequently, are a major source of methane emissions from the natural gas industry. The actual bleed rate or emissions level largely depends on the design of the device.

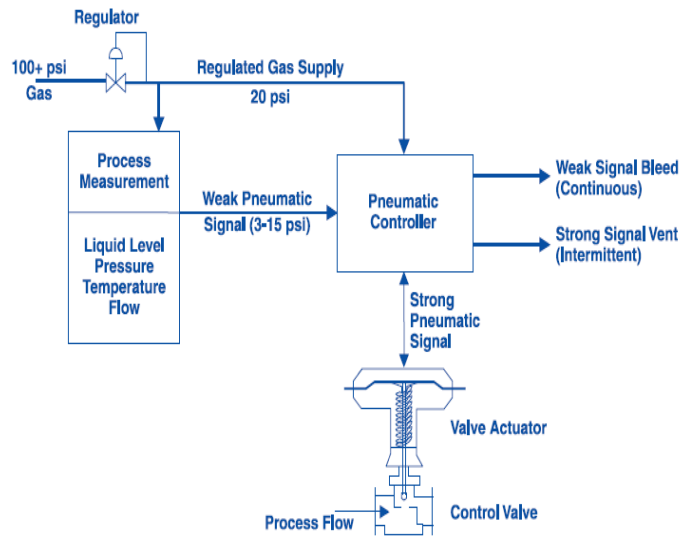

Exhibit 1 shows a schematic of a gas pneumatic control system. Clean, dry, pressurized natural gas is regulated to a constant pressure, usually around 20 psig. This gas supply is used both as a signal and a power supply. A small stream is sent to a device that measures a process condition (liquid level, gas pressure, flow, temperature). This device regulates the pressure of this small gas stream (from 3 to 15 psig) in proportion to the process condition. The stream flows to the pneumatic valve controller, where its variable pressure is used to regulate a valve actuator.

To close the valve pictured in Exhibit 1, 20-psig pneumatic gas is directed to the actuator, pushing the diaphragm down against the spring, which, through the valve stem, pushes the valve plug closed. When gas is vented off the actuator, the spring pushes the valve back open. The weak signal continuously vents (bleeds) to the atmosphere. Electro-pneumatic devices use weak electric current instead of the weak gas stream to signal pneumatic valve actuation.

In general, controllers of similar design usually have similar steady-state bleed rates regardless of brand name. Pneumatic devices come in three basic designs:

- ★ **Continuous** bleed devices are used to modulate flow, liquid level, or pressure and will generally vent gas at a steady rate;
- ★ **Actuating or intermittent** bleed devices perform snap-acting control and release gas only when they stroke a valve open or closed or as they throttle gas flows; and

Exhibit 1: Pneumatic Device Schematic

- ★ **Self-contained** devices release gas into the downstream pipeline, not to the atmosphere.

To reduce emissions from pneumatic devices the following options can be pursued, either alone or in combination:

1. Replacement of high-bleed devices with low-bleed devices having similar performance capabilities.
2. Installation of low-bleed retrofit kits on operating devices.
3. Enhanced maintenance, cleaning and tuning, repairing/replacing leaking gaskets, tubing fittings, and seals.

Field experience shows that up to 80 percent of all high-bleed devices can be replaced with low-bleed equipment or retrofitted. Exhibit 2 lists the generic options applicable for different controller requirements.

In general, the bleed rate will also vary with the pneumatic gas supply pressure, actuation frequency, and age or condition of the equipment. Due to the need for precision, controllers that must operate quickly will bleed more gas than slower operating devices. The condition of a pneumatic device is a stronger indicator of emission potential than age; well-maintained pneumatic devices operate efficiently for many years.

Exhibit 2: Options for Reducing Gas-Bleed Emissions by Controller Type

Action	Pneumatic Types		
	Level Controllers	Pressure Controllers	Positioners/ Transducers
Replacements			
High-bleed with low-bleed	X	X	X (electro-pneumatic)
Retrofits			
Install retrofit kits	X	X	X
Maintenance			
Lower gas supply pressure/replace springs/re-bench	X	X	X
Repair leaks, clean and tune	X	X	X
Change gain setting	X	X	
Remove unnecessary positioners			X

Economic and Environmental Benefits

Reducing methane emissions from high-bleed pneumatic devices through the options presented above will yield significant benefits, including:

- ★ **Financial return from reducing gas-bleed losses.** Using a natural gas price of $7.00 per thousand cubic feet (Mcf), savings from reduced emissions can range from $315 to $1,820 or more per year per device. In many cases, the cost of implementation is recovered in less than a year.

- ★ **Increased operational efficiency.** The retrofit or complete replacement of worn units can provide better system-wide performance and reliability and improve monitoring of parameters such as gas flow, pressure, or liquid level.

- ★ **Lower methane emissions.** Reductions in methane emissions can range from 45 to 260 Mcf per device per year, depending on the device and the specific application.

Decision Process

Operators can determine the gas-bleed reduction option that is best suited to their situation, by following the decision process laid out below. Depending on the types of devices that are being considered, one or more options for reducing pneumatic gas bleed may be appropriate.

Step 1: Locate and describe the high-bleed devices.

Partners should first identify the high-bleed devices that are candidates for replacement, retrofit, or repair. The identification and description process can occur during normal maintenance or during a system-wide or facility-specific pneumatics survey. For each pneumatic device, record the location, function, make and model, condition, age, estimated remaining useful life, and bleed rate characteristics (volume and whether intermittent or continuous).

The pneumatic device's bleed rate can be determined through direct measurement or from data provided by the manufacturer. Direct measurement might include bagging studies at selected instruments, high-volume sampler measurements (see "Directed Inspection and Maintenance at Compressor Stations" Lessons Learned) or the operator's standard leak measurement approach. Operators will find it unnecessary to measure bleed rates at each device. In most cases, sample measurements of a few devices are sufficient. Experience suggests that manufacturers' bleed rates are understated, so measurement data should be used when it can be acquired.

Appendix A lists brand, model, and gas bleed information—as provided by manufacturers—for various pneumatic devices. This is not an exhaustive list, but it covers the most commonly used devices. Where available, actual field data on bleed rates are included.

Step 2: Establish the technical feasibility and costs of alternatives.

Nearly all high-bleed pneumatic devices can be replaced or retrofitted with lower-bleed equipment. Consult your pneumatic device vendor or an instrumentation specialist for availability, specifications and costs of suitable devices. Low-bleed devices can be requested by specifying bleed rates less than 6 standard cubic feet per hour (scfh). It is important to note that not all manufacturers report bleed rates in the same manner, and companies should exercise

Five Steps for Reducing Methane Emissions from Pneumatic Devices:
1. Locate and describe the high-bleed devices;
2. Establish the technical feasibility and costs of alternatives;
3. Estimate the savings;
4. Evaluate the economics; and
5. Develop an implementation plan.

NMED Exhibit 92 - 0003

caution when making purchases of low-bleed devices.

Appendix B lists cost data for many low-bleed pneumatic devices and summarizes the compatibility of retrofit kits with various controllers. This is not an exhaustive list, but it covers the most commonly used devices.

Maintenance of pneumatics is a cost-effective method for reducing emissions. All companies should consider maintenance as an important part of their implementation plan. Cleaning and tuning, in addition to repairing leaking gaskets, tubing fittings, and seals, can save 5 to 10 scfh per device. Tuning to operate over a broader range of proportional band often reduces bleed rates by as much as 10 scfh. Eliminating unnecessary valve positioners can save up to 18 scfh per device.

Some high-bleed devices, however, should not be replaced with low-bleed devices. Control of very large valves that require fast and/or precise response to process changes often require high-bleed controllers. These are found most frequently on large compressor discharge and bypass pressure controllers. EPA recommends contacting vendors for new fast-acting devices with lower bleed rates.

Step 3: Estimate the savings.

Determine the quantity of gas that can be saved with a low-bleed controller, using field measurement of the high-bleed controller and a similar low-bleed device in service. If these actual bleed rates are not available, use bleed specifications provided by manufacturers.

Gas savings can be monetized to annual savings using $7.00 per Mcf and multiplying bleed reduction, typically specified in scfh, by 8,670 hours per year.

Gas Savings = (High-bleed, scfh) — (Low-bleed, scfh)

Annual Gas Savings = Gas Savings (scfh) * 8,760 hrs/yr * 1 Mcf/1000scf * $7.00/Mcf

Step 4: Evaluate the economics.

The cost-effectiveness of replacement, retrofit, or maintenance of high-bleed pneumatic devices can be evaluated using straightforward economic analysis. A cost-benefit analysis for replacement or retrofit is appropriate unless high-bleed characteristics are required for operational reasons.

Exhibit 3 illustrates a cost-benefit analysis for replacement of a high-bleed liquid level controller. Cash flow over a five-year period is analyzed by showing the magnitude and timing of costs (shown in parenthesis) and benefits. In this example, a $513 initial investment buys a level controller that saves 19 scfh of gas. At $7.00 per Mcf, the low-bleed device saves $1,165 per year. Annual maintenance costs for the new and old controllers are shown. The maintenance cost for the older high-bleed controller is shown as a benefit because it is an avoided cost. Net present value (NPV) is equal to the benefits minus the costs accrued over five years and discounted by 10 percent each year. Internal rate of return (IRR) is the discount rate at which the NPV generated by the investment equals zero.

Exhibit 3: Cost-Effectiveness Calculation for Replacement

Type of Costs	Year 0	Year 1	Year 2	Year 3	Year 4	Year 5
Implementation Costs, $ (Capital Costs)[a]	(513)					
Annual Savings, $ (New vs. Old)[b]		1,165	1,165	1,165	1,165	1,165
Maintenance Costs, $ (New Controller)[c]		(34)	(34)	(34)	(34)	(34)
Avoided Maintenance, $ (Replaced Controller)[c]		70	70	70	70	70
Net Benefit	(513)	1,202	1,202	1,202	1,202	1,202
NPV[d] = $4,042 IRR = 234%						

Notes:
[a] Quoted cost of a Fisher 2680 device. Adjusted to 2006 equipment costs. See Appendix B.
[b] Annual savings per device calculated as the change in bleed rate of 19 scfh x 8,760 hrs/hr = 167 Mcf/yr at $7/Mcf.
[c] Maintenance costs are estimated.
[d] Net Present Value (NPV) based on 10% discount rate for 5 years.

Exhibit 4 illustrates the range of savings offered by proven methods for reducing gas bleed emissions. For simplicity, it is assumed that the cost of maintenance of the pneumatic device will be the same before and after the replacement, retrofit, or enhanced maintenance activity.

As seen in Exhibit 4, sometimes more than one option to reduce gas bleed may be appropriate and cost-effective for a given application. For the listed options, please note that the payback period with respect to implementation cost can range from less than one month to two years.

Exhibit 4: Economic Benefits of Reducing Pneumatic Device Emissions

Action	Cost[a] ($)	Bleed Rate Reductions[b] (Mcf/yr/device)	Annual Savings[c] ($/year)	Payback Period (months)	IRR[d] (%)
Replacement					
Level Controllers					
High-bleed to low-bleed	513	166	1,165	6	226
Pressure Controllers					
High-bleed to low-bleed	1,809	228	1,596	14	84

Positioners					
Remove unnecessary	0	158	1,106	Immediate	—-

[a] Implementation costs represent average costs for Fisher brand pneumatic instruments installed.
[b] Bleed rate reduction = change in bleed rate scf/hr x 8,760 hr/yr.
[c] Savings based on $7.00/Mcf cost of gas.
[d] Internal rate of return (IRR) calculated over 5 years.

The case studies in Exhibit 5 on the next page present analyses performed and savings achieved by two Natural Gas STAR Partners who installed retrofit kits at gas production facilities.

Step 5: Develop an implementation plan.

After identifying the pneumatic devices that can be profitably replaced, retrofitted or maintained, devise a systematic plan for implementing the required changes. This can include modifying the current inspection and maintenance schedule and prioritizing replacement or retrofits. It may be most cost-effective to replace all those devices that meet the technical and economic criteria of your analysis at one time to minimize labor costs and disruption of operation.

Where a pneumatic device is at the end of its useful life and is scheduled for replacement, it should be replaced with a low-bleed model instead of a new high-bleed device whenever possible.

When assessing options for replacement of high-bleed pneumatic devices, natural gas price may influence the decision making process. Exhibit 6 shows an economic analysis of early replacement of a high bleed pneumatic device with a lower bleed device at different natural gas prices.

NMED Exhibit 92 - 0005

Exhibit 5: Case Studies on Retrofit To Reduce Gas Leaks at Natural Gas STAR Partner Sites

Study	Implementation Costs ($)	Emissions Reductions (Mcf/yr)	Annual Savings ($/year)	Payback (months)	IRR (%)
Company 1:

Other Technologies

Instrument air, nitrogen gas, electric valve controllers, and mechanical control systems are some of the alternatives to gas powered pneumatics implemented by Partners.

★ **Instrument Air.** These systems substitute compressed, dried air in place of natural gas in pneumatic devices, and thus eliminate methane emissions entirely. Instrument air systems are typically installed at facilities where there is a high concentration of pneumatic control valves and fulltime operator presence (for example, most gas processing plants use instrument air for pneumatic devices). The major costs associated with instrument air systems are capital and energy. Instrument air systems are powered by electric compressors, and require the installation of dehydrators and volume tanks to filter, dry and store the air for instrumentation use. Generally, Partners have found that cost-effective implementation of instrument air systems is limited to field sites with available utility or self-generated electrical power. The Lessons Learned study, "Covert Gas Pneumatic Controls to Instrument Air," provides a detailed description of the technical and economic decision process required to evaluate conversion from gas pneumatic devices to instrument air.

★ **Nitrogen Gas.** Unlike instrument air systems that require capital expenditures and electric power, these systems only require the installation of a cryogenic liquid nitrogen cylinder, that is replaced periodically, and a liquid nitrogen vaporizer. The system uses a pressure regulator to control the expansion of the nitrogen gas (i.e., the gas pressure) as it enters the control system. The primary disadvantage of these systems stems from the cost of liquid nitrogen and the potential safety hazard associated with using cryogenic liquids.

★ **Electric Valve Controllers.** Due to advances in technology, the use of electronic control instrumentation is increasing. These systems use small electrical motors to operate valves and therefore do not bleed natural gas into the atmosphere. While they are reliant on a constant

Nelson Price Indexes

In order to account for inflation in equipment and operating & maintenance costs, Nelson-Farrar Quarterly Cost Indexes (available in the first issue of each quarter in the *Oil and Gas Journal*) are used to update costs in the Lessons Learned documents.

The "Refinery Operation Index" is used to revise operating costs while the "Machinery: Oilfield Itemized Refining Cost Index" is used to update equipment costs.

To use these indexes in the future, simply look up the most current Nelson-Farrar index number, divide by the February 2006 Nelson-Farrar index number, and, finally multiply by the appropriate costs in the Lessons Learned.

Methane Content of Natural Gas

The average methane content of natural gas varies by natural gas industry sector. The Natural Gas STAR Program assumes the following methane content of natural gas when estimating methane savings for Partner Reported Opportunities.

Production	79 %
Processing	87 %
Transmission and Distribution	94 %

supply of electricity, and have high associated operating costs, they have the advantage of not requiring the utilization of natural gas or a compressor to operate.

★ **Mechanical Control Systems.** These devices have been widely used in the natural gas and petroleum industry. They operate using a combination of springs, levers, flow channels and hand wheels. While they are simple in design and require no natural gas or power supply to operate, their application is limited due to the need for the control valve to be in close proximity to the process measurement. Also, these systems are unable to handle large flow fluctuations and lack the sensitivity of pneumatic systems.

Each of these options has specific advantages and disadvantages. Where Natural Gas STAR Partners do install these systems as replacements to gas powered pneumatic devices, they should report the resulting emissions reductions and recognize the savings.

One Partner's Experience

Union Pacific Resources replaced 70 high-bleed pneumatic devices with low-bleed pneumatic devices and retrofitted 330 high-bleed pneumatic devices. As a result, this Partner has estimated a total reduction of methane emissions of 49,600 Mcf per year. Assuming a gas price of $7 per Mcf, the savings corresponds to $347,200. The costs of replacing and retrofitting all the devices, including materials and labor, is $166,300 at 2006 costs, resulting in a payback period of less than one year.

One Partner's Experience

Marathon Oil Company surveyed 158 pneumatic control devices at 50 production sites using the Hi-Flow Sampler to measure emissions. Half of these controllers were identified as non-bleed devices (e.g., weighted dump valves, spring operated regulators, enclosed capillary temperature controllers, non-bleed pressure switches). High-bleed devices accounted for 35 of 67 level controllers, 5 of 76 pressure controllers, and 1 of 15 temperature controllers. Measured gas emissions were 583 scfh total; 86 percent of emissions came from level controllers, with leaks up to 48 scfh, and averaging 7.6 scfh. Marathon concluded that "control devices with higher emissions can be identified qualitatively by sound prior to leak measurement, making it unnecessary to quantitatively measure methane emissions using technologically advanced equipment."

Lessons Learned

Natural Gas STAR Partners offer the following Lessons Learned:

★ Hear it; feel it; replace it. Where emissions can be heard or felt, this is a sign that emissions are significant enough to warrant corrective action.

★ Control valve cycle frequency is another indicator of excessive emissions. When devices cycle more than once per minute, they can be replaced or retrofitted profitably.

★ Manufacturer bleed rate specifications are not necessarily what users will experience. Actual bleed rates will generally exceed manufacturer's specifications because of operating conditions different from manufacturer's assumptions, installation settings and maintenance.

★ Combine equipment retrofits or replacements with improved maintenance activities. Do not overlook simple solutions such as replacing tubes and fittings or rearranging controllers.

★ The smaller orifices in low-bleed devices and retrofit kits can be subject to clogging from debris in corroded pipes. Therefore, pneumatic supply gas piping and tubing should be flushed out before retrofitting with

NMED Exhibit 92 - 0007

smaller orifice devices, and gas filters should be well maintained.

- ★ When replacing pneumatic control systems powered by pressurized natural gas with instrument air or other systems, do not forget to account for the savings from the resulting methane emission reductions.

- ★ Include methane emission reductions from pneumatics in annual reports submitted as part of the Natural Gas STAR Program.

Appendix A

The following chart contains manufacturer-reported bleed rates. Actual bleed rates have been included whenever possible. Discrepancies occur due to a variety of reasons, including:

- ★ Maintenance.
- ★ Operating conditions.
- ★ Manufacturer vs. operating assumptions.

It is important to note that manufacturer information has not been verified by any third party and there may be large differences between manufacturer-reported bleed rates and those found during operations. Until a full set of information is available, companies should be careful to compare bleed rates in standard units (CFH) when comparing manufacturers and models. During this study we found that manufacturers reported information in a wide range of different units and operating assumptions.

Gas Bleed Rate for Various Pneumatic Devices

Controller Model	Type	Consumption Rate (CFH)	
		Manufacturer Data	Field Data (where available)
High-Bleed Pneumatic Devices			
**Fisher 4100 Series	Pressure controller (large orifice)	35	
**Fisher 2500 Series	Liquid-level controllers (P.B. in mid range)	10-34	44-72
*Invalco AE-155	Liquid-level controller		44-63

1 Introduction

This report was developed in response to a December 2017 rulemaking, in which the Colorado Air Quality Control Commission (AQCC) established a pneumatic controller (PC) 'Find and Fix' program for oil and gas well production facilities and natural gas compressor stations located in the ozone non-attainment area (NAA). The AQCC recognized that continuous bleed and intermittent pneumatic controllers are designed to have emissions but these emissions can be excessive when the controllers are not operating properly. The AQCC adopted the Find and Fix program to reduce excess emissions from such natural gas-driven pneumatic controllers.

As part of the Statement of Basis and Purpose (SBAP), and at the request of industry and other stakeholders, the AQCC adopted a "reassessment" provision for the Find and Fix program. The reassessment was to follow an Air Pollution Control Division (Division) led study of pneumatic controller emission reduction options, including the rate, type, application, and causes of pneumatic controllers found operating improperly; inspection and repair techniques and costs; available preventative maintenance methods; appropriateness of the definitions of enhanced response, intermittent pneumatic controller, no-bleed pneumatic controller, self-contained pneumatic controller, and pneumatic controller; and other related information. The AQCC also directed that more information on "good engineering and maintenance practices" should be gathered during the pneumatic controller study and implementation of the Find and Fix program to inform the reassessment. As part of the reassessment, industry agreed to participate in a study focused on the Denver-Julesburg (DJ) Basin that would collect data on the types of PCs in service, those PCs determined to be operating improperly, what caused the PCs to not operate properly, and the repairs taken to return the PCs to proper operation across a representative cross section of well production facilities and natural gas compressor stations in the NAA.

The AQCC directed the creation of a Pneumatic Controller Task Force (PCTF) comprised of representatives of the Division, operators and industry trade groups, local governments, and conservation groups. The PCTF was to brief the AQCC annually and make recommendations in this report, and each participant was to have the opportunity to contribute to the briefings and report. The AQCC also recognized that the pneumatic controller study and inspection program might inform the strategies for cost-effective hydrocarbon emission reductions for pneumatic controllers, including zero emission pneumatic controllers, under consideration by the Statewide Hydrocarbon Emission Reduction (SHER) team. The AQCC also established the SHER team through the SBAP for the December 2017 rulemaking.

The PCTF convened for the first time on January 25, 2018. The group held bi-weekly meetings for several months to develop and design the study. Field inspections of production facilities selected for the study started on May 1, 2018. Afterwards, meetings were held bi-monthly to check on the progress of field inspections and updates on data management until the data was submitted to the Division in December 2018. The group met in January 2019 to discuss initial data analysis, finalize the project plan, and revisit goals. The PCTF briefed the AQCC on February 21, 2019 on its progress. Throughout the spring of 2019, industry PCTF members developed and responded to questionnaires to document and assess the effectiveness and costs of inspection techniques as well as to understand opportunities for expanded use of no-bleed PCs. The PCTF and the SHER team held a joint meeting on June 11, 2019, to hear presentations on Canadian regulation of pneumatic controllers.

NMED Exhibit 93

In April 2019, the legislature adopted Senate Bill 19-181, which directs the AQCC to "review its rules for oil and natural gas well production facilities and compressor stations and specifically consider adopting more stringent provisions, including . . . a requirement to reduce emissions from pneumatic devices. The AQCC shall consider requiring oil and gas operators, under appropriate circumstances, to use pneumatic devices that do not vent natural gas." The PCTF was effectively put on hold in the summer of 2019 to allow its members to focus on regulatory proposals to be addressed during the December 2019 SB 19-181 Rulemaking. In that rulemaking, the AQCC adopted the SHER team's proposal to (1) expand the Find and Fix program statewide, (2) include language in the SBAP directing continued work to evaluate the use of zero-bleed pneumatic devices, and (3) provide for a compliance assistance approach for operators outside the nonattainment area while those operators get up to speed on the Find and Fix program. In the SBAP, the AQCC directed the SHER team and PCTF to continue their work on the mandates established in 2017, and to bring back to the AQCC in 2020 their recommendations on the use of zero-bleed pneumatic devices.

Members of the PCTF were requested in April 2020 to review and complete this report.

1.1 2017 AQCC Reg 7 Oil and Gas CTG Rulemaking and Pneumatic Inspection Program

Below is a summary from the Statement of Basis and Purpose prepared for the 2017 AQCC Regulation 7 rulemaking that explains the actions taken by the AQCC for the 2017 rulemaking and the direction given to the Division to convene a PCTF.

1.1.1 Background

On May 4, 2016, the U.S. Environmental Protection Agency ("EPA") published a final rule that determined that Colorado's Marginal ozone NAA failed to attain the 2008 8-hour Ozone National Ambient Air Quality Standard ("NAAQS"). EPA, therefore, reclassified the Denver Metro North Front Range ("DMNFR") area to Moderate and required attainment of the NAAQS no later than July 20, 2018, based on 2015-2017 ozone data.

As a result of the reclassification, on May 31, 2017, Colorado submitted to EPA revisions to its State Implementation Plan ("SIP") to address the Clean Air Act's ("CAA") Moderate NAA requirements, as set forth in CAA § 182(b) and the final SIP Requirements Rule for the 2008 Ozone NAAQS (*See* 80 Fed. Reg. 12264 (March 6, 2015)). As a Moderate NAA, Colorado revised its SIP to include Reasonably Available Control Technology ("RACT") requirements for each category of volatile organic compound ("VOC") sources covered by a Control Technique Guidelines ("CTG") for which Colorado has sources in the DMNFR that EPA finalized prior to a NAA's attainment date. EPA finalized the CTG for the Oil and Natural Gas Industry ("Oil and Gas CTG") on October 27, 2016, with a state SIP submittal deadline of October 27, 2018. Given this timing, the November 2016, SIP revisions did not include RACT for the oil and natural gas source category and Colorado needed to further revise its SIP.

The Oil and Gas CTG recommends controls that are presumptively approvable as RACT and provide guidance to states in developing RACT for their specific sources. In many cases, Colorado had similar, or more stringent, regulations comparable to the recommendations in the Oil and Gas CTG, though many of these provisions were not currently in Colorado's Ozone SIP. Therefore, on November 16, 2017, the AQCC adopted RACT for the oil and gas sources covered by the Oil and Gas CTG (CTG as of October 27, 2016) into the Ozone SIP. In order to make additional progress towards attainment of the NAAQS, the AQCC also adopted State Only revisions to require owners or operators of oil and gas well production facilities and

compressor stations with natural gas-driven PCs in the DMNFR area to inspect and maintain these PCs.

1.1.2 PC Find and Fix program

The AQCC adopted an inspection and enhanced response (*e.g.*, maintenance) program for natural gas-driven PCs. While the Oil and Gas CTG notes the value of PC inspection and maintenance, the Oil and Gas CTG does not specify PC inspection and maintenance as presumptive RACT. The AQCC therefore created a new program that requires that natural gas-driven PCs at well production facilities and natural gas compressor stations in the DMNFR be inspected periodically to determine whether the PC is operating properly. The program requires that owners or operators inspect PCs for proper operation as part of routine LDAR regulatory programs at well production facilities annually, semi-annually, quarterly, or monthly, depending on the well production facility VOC emissions, and at natural gas compressor stations quarterly or monthly, depending on the natural gas compressor station fugitive emissions.

This PC inspection and enhanced response process was intended to be a multi-step process. First, the owner or operator must inspect all natural gas-driven PC using an approved instrument monitoring method (AIMM) to screen for detectable emissions. This first step allows owners or operators to narrow potential response efforts to only those PCs with detected emissions. Second, the owner or operator must determine whether the PCs with detected emissions are operating properly. Use of an AIMM is not required during this second step; the AQCC did not lay out a process for how owners or operators are to determine if their PCs are operating properly. During this second step, if an owner or operator determines that the PC is operating properly, no further action is necessary. Third, where an owner or operator determines the PC is not operating properly, the owner or operator must take actions to return an improperly operating PC to proper operation. Fourth, general recordkeeping and reporting requirements apply broadly to the number of facilities inspected and number of inspections. More detailed recordkeeping and reporting is required for those PCs that the owner or operator determined not to be operating properly. Similar to the LDAR records, owners or operators must keep records of the date the PC was returned to proper operation and a description of the types of actions taken.

1.1.3 Reassessment Provision

The reassessment provision is explained as follows in the SBAP for the 2017 Reg 7 CTG rulemaking.

The AQCC adopted a "reassessment" provision for this inspection and enhanced response program following a Division led study of PC emission reduction options, including the rate, type, application, and causes of PCs found operating improperly; inspection and repair techniques and costs; available preventative maintenance methods; appropriateness of the definitions of enhanced response, intermittent pneumatic controller, no-bleed pneumatic controller, self-contained pneumatic controller, and pneumatic controller; and other related information. The AQCC also recognized that owners and operators may have limited information on "good engineering and maintenance practices" for PCs and intended that more information on these practices are gathered during the pneumatic study and implementation to inform the reassessment of the inspection and enhanced response program. The data collection effort will include data from a representative cross-section of well production facilities and natural gas compressor stations in the DMNFR. In accordance with industry's proposal, a task force was directed to convene by January 30, 2018, consisting of

representatives from industry, the Division, local governments, environmental groups, and other interested parties. Data collection was scheduled to commence no later than by May 1, 2018. The task force *will* brief the AQCC annually and make any recommendations on its findings in a report (this document) to the AQCC due May 1, 2020. The AQCC *intends* that the Division, industry, local government, and environmental group task force participants each have the opportunity to contribute to the final report and provide one representative to speak during the briefings to the AQCC. The AQCC intended that this information be used to reassess the natural gas-driven PC requirements of Regulation Number 7 that will remain in effect until rescinded, superseded, or revised.

1.1.4 2019 Rulemaking Directives

Below is an excerpt from the Statement of Basis and Purpose prepared for the 2019 AQCC Regulation 7 rulemaking that explains the actions taken by the AQCC for the 2019 rulemaking and the direction given to the PCTF and SHER Team:

> "Pneumatic Controllers (Part D, Section III.)
>
> SB 19-181 also directed the Commission to consider a requirement to reduce emissions from pneumatic devices. In the 2017 emissions inventory for the Moderate area ozone nonattainment SIP, pneumatic devices were identified as the second largest oil and gas area source (after tanks). In 2017, the Commission convened the Statewide Hydrocarbon Emission Reduction (SHER) team, to consider measures – both regulatory and voluntary – to reduce hydrocarbon emissions from the oil and gas sector. The Commission, at the same time, also established the Pneumatic Controller Task Force (PCTF), with a mission to collect and review data about pneumatic controllers and identify ways to reduce emissions from that equipment. After almost two years of work, the SHER team developed an early recommendation concerning pneumatic controllers, which the Commission has now adopted.
>
> The SHER team supported a three-prong approach. First, the expansion of the pneumatic controller inspection and enhanced response program state-wide. Second, the SHER team recommended including language in this Statement of Basis and Purpose, directing the continued work to evaluate the use of zero-bleed pneumatic devices. Third, the SHER team supported a compliance assistance approach for operators outside the nonattainment area, while those operators get up to speed on the pneumatic controller inspection and enhanced response program that has been implemented in the nonattainment area since 2018.
>
> The Commission approves of this approach and commends both the SHER team and PCTF for their work since 2017, building the knowledge that informed provisions of this rulemaking. The Commission has therefore expanded the pneumatic controller inspection and enhanced response program state-wide. At the same time, the Commission recognizes that there is much to learn about the inspection and maintenance of natural gas-driven pneumatic controllers outside the nonattainment area, which highlights the need for enforcement discretion. The Commission intends that for operations outside the nonattainment area, the determination of whether a pneumatic controller is operating properly will be made by the owner or operator, with minimal oversight by the Division for the first year of implementation.

> The Commission further directs the SHER team and PCTF to continue their work on the mandates established in 2017, and to bring back to the Commission in 2020 their recommendations on the use of zero-bleed pneumatic devices. Specifically, the Commission continues to direct the PCTF to make recommendations on its findings in a report to the Commission in May 2020. However, the Commission revises its directive to the SHER team to present recommendations by no later than January 2020, to by no later than July 2020. This revised timeline will provide additional time for the SHER team to make any additional recommendations on cost-effective hydrocarbon emission reduction strategies evaluated by the SHER team. The Commission anticipates that the SHER team will also evaluate continuous methane emission monitoring and engage in discussions to determine actual leak rate percentages of components at oil and gas facilities for use in future rulemakings."

2 Pneumatic Controllers

This section provides some basic information regarding PCs, with a focus on the PCs studied recently in Colorado.

2.1 What is a PC, what does it do?

PCs are found widely on oil and natural gas production facilities in Colorado. PCs are used to automate and regulate process control variables such as temperature, pressure, liquid level, and to maintain critical safety fail-safe functions. PCs operate by sensing a condition and then sending a signal to a valve actuator that in turn controls a valve that controls the process parameter in question. For instance, a liquid level controller will sense liquid levels in a separator and send a signal (in the form of natural gas pressure) to a valve actuator on a dump valve which in turn opens the dump valve and lowers the liquid level in the separator. It is important to note that the PC, the valve actuator, and the valve are all different components of the control system. It is not uncommon for the PC to be located several feet away from the valve actuator and the valve it is controlling. Finally, it is important to realize that the valve being controlled by the PC is a component that is already subject to the LDAR provisions of Regulation Number 7. Similarly, there are many connectors associated with PCs and valve actuators - each of which is also a component subject to the LDAR provisions. As such, it is important to distinguish emissions from leaking components that are routinely found and repaired in an LDAR program, from emissions caused by an improperly operating PC.

2.2 Types of PCs

As part of their normal function, PCs emit natural gas when they actuate, either intermittently or continuously. Continuous and intermittent PCs are the two broad categorizations of PCs that were the focus of the 2018 PCTF field study. The categorization refers to how the PC is expected to emit under normal operation. A continuous PC is designed to emit at a steady rate, commonly referred to as a bleed rate. The bleed rate may change during actuation. Contrastingly, an intermittent PC is only expected to emit above a de minimis level during actuations and hence they do not have a bleed rate per se. Some intermittent PCs actuate very frequently and some only rarely. For instance, a liquid-level

controller on a new high producing well may actuate many times within an hour. There may be significant emissions associated with this normal, intended operation.[1]

There are also non-emitting controllers, often referred to as "no-bleed," "zero-bleed" or "zero-emitting"[2] PCs. These devices do not emit natural gas to the atmosphere during any phase of normal operation. Many of these devices are inherently non-emitting because they are driven by electricity or pressurized air, rather than pressurized natural gas. Since the intent of this field study was to examine emissions associated with natural gas-driven PCs, non-emitting PCs were not included in the scope of the 2018 PCTF field study.

Contained within the continuous PC category are high-bleed and low-bleed PCs. High-bleed PCs are designed to emit over 6 standard cubic feet per hour (scf/hr) of gas between actuations. Low-bleed devices emit less than 6 scf/hr. As of 2020, the Division believes that there are no high-bleed devices in use within the State of Colorado and all continuous-bleed PCs reported during this study were low-bleed.

2.3 Improper operation

Numerous studies have identified that a small number of improperly operating PCs are typically responsible for the majority of emissions from the PC population[3,4,5]. This information is what originally prompted the AQCC to adopt a PC find and fix program. The PCTF took a similar approach with the field study by focusing on "proper" vs "improper" operation.

2.3.1 Causes

Improper operation could be caused by any number of issues affecting a PC. These causes range from small amounts of debris keeping the controller from reseating properly to broken internal parts or defects in the housing for the PC. The causes specifically identified in the field study included: abnormal operation parameters, corrosion, debris, diaphragm failure, seal failure, spring failure, and wet supply gas.

2.3.2 Effects and Indicators

Operator personnel utilize AIMM (typically an OGI camera) to detect emissions from production facilities during LDAR inspections. Identification of a PC that is not operating properly requires additional knowledge regarding the types of PCs and their emission characteristics during normal operation in order to distinguish improper operation with an OGI camera.

Common tell-tale signs of PC improper operation include: loss of or improper control of the process parameter the PC is supposed to control; continuous emissions from an intermittent PC; excess emissions, as compared to normal operation, as identified via audio, visual, and olfactory (AVO) inspections or AIMM, from a controller; or obvious signs of significant staining

or corrosion. A subset of improperly operating PCs may also be able to be identified by field personnel using their AVO senses; however, all inspections in this study used AIMM and did not solely rely on AVO observations.

3 PC Task Force

3.1 PCTF Goals

The PCTF members established the following goals for the PC study:

- Identify and collect natural gas-actuated PC data from a representative subset of well production facilities and compressor stations in the NAA
    - Set parameters of "improper operation" for each type of PC
    - Develop, document, and assess the effectiveness and costs of inspection techniques
    - Document malfunction rates and causes for types, makes, and models of PCs in different types of service
    - Document the effectiveness and costs of repair techniques and preventative maintenance
    - Estimate the number of PCs typically associated with a separator or other grouping of equipment

- Gather information regarding "good engineering and maintenance" practices

- Evaluate the appropriateness of the definitions in Regulation No. 7 for enhanced response, intermittent pneumatic controller, no-bleed pneumatic controller, self-contained pneumatic controller, and pneumatic controller

- Gather information about the current applications, cost, effectiveness, current applications and opportunities for expanded use for no-bleed and self-contained PCs

- Produce timely annual presentations and a report to the AQCC

3.2 Implementation Plan

The PCTF formed three distinct groups to address different elements of designing the field study: a main core group and two subgroups. One subgroup selected representative facilities and the second subgroup developed a field data form. Members of the PCTF provided several technical presentations to grow the shared knowledge base during the study development phase.

Once the field inspection campaign commenced on May 1, 2018, bimonthly meetings were held to check on the progress of field inspection and subsequent data management until the compiled and blinded data was submitted to the Division in December 2018. The two subgroups disbanded once 2018 sampling began while the main core group continued to meet.

4 PC Field Study

4.1 Participating Stakeholders

The field study was designed with the help of all PCTF stakeholders. These stakeholders include: the Division, the American Petroleum Institute (API), the Colorado Oil and Gas

Association (COGA), nine upstream oil and gas well production operators, one midstream operator, the Clean Air Task Force (CATF), Earthjustice (EJ), the Environmental Defense Fund (EDF), Boulder County Public Health (BCPH), Denver Public Health and Environment (DDPHE), Colorado Communities for Climate Action (CC4CA), and the Regional Air Quality Council (RAQC).

The field study was implemented and conducted with the participation of nine upstream oil and gas well production facility operators in the DJ Basin. The study also surveyed PCs at the only two known natural gas compressor stations within the DJ Basin that operate natural gas-actuated PCs.

4.2 Study Design

4.2.1 PC Inspection Method Utilized

All PC inspections conducted at the facilities selected for this field study utilized an OGI camera to monitor and identify improperly operating PCs. Some operators also noted whether an improperly operating PC could have been identified using only AVO methods (e.g. visible staining or corrosion or audible hissing when not actuating).

4.2.2 Field Data Form Development

A subgroup was formed to develop the field data forms (Attachment A) that would be used by operators during PC inspections of the selected facilities to collect consistent metadata across operators and facilities. These forms were based on forms utilized by the Stovern et al (2020) study and amended to reflect the different data collection goals of the PCTF inspection process. The final data forms include general, inventory, inspection, and repair information. The data form options include PC type (including manufacturer and model), function, application, depressurization method, and type of service. The forms determine "improper operation" causes, including description(s). The forms note primary causes of improper operation such as debris, corrosion, equipment failures, broken or missing parts, or abnormal operational parameters; there is also an option for other causes.

Industry representatives provided extensive instructions (Attachment B) for field staff that detailed each item on the form step-by-step. The final data forms were available in paper and electronic form. Operators that utilized paper forms tabulated the data into the electronic form once the paper forms were returned to office staff. All data was submitted to the Division in electronic form.

4.2.3 Facility Selection

The PCTF extensively examined appropriate cross-sectional data for well production facilities and natural gas compressor stations. For well production facilities, the Division initially estimated about 7,000 well production facilities in the NAA counties. The group discussed how to appropriately divide the facilities into cohorts in order to identify which facilities should be sampled for the study. The factors discussed included type of drilling (horizontal vs. vertical), operation size based on production levels, facility age, and separator types. Ultimately, the subgroup decided that production level (barrels/day) was most appropriate and representative of the other variables being considered.

Industry then provided "snapshot" daily average production data from December 2017 for each of the nine participating operators to the Division on February 21, 2018, with subsequent updates based on stakeholder meeting discussions. This snapshot dataset for the nine participating operators represented approximately 80% of all well production facilities located

in the NAA. The original dataset was grouped by level of production (barrels/day), and a 50 percent "Plug and Abandon" (P&A) rate for wells in the 0 - 10 bbls production level cohort was assumed, as these wells were largely older vertical wells likely to be shut-in or scheduled for P&A. This P&A rate assumption is based on multiple factors including, but not limited to, line pressure, economic considerations, lease agreement issues, and land use matters.

Industry updated the dataset on March 21, 2018, with more accurate information from the two largest participating operators, which decreased the P&A rate and provided a conservatively low estimate of the number of PCs to be surveyed at each well production facility, based on its level of production. This analysis was conducted to demonstrate that the study would sample a sufficient number of selected facilities in each production cohort, to provide an adequate data set for the study.

After further meetings and discussion, the PCTF decided on the following cross-sectional sample of well production facilities to be subject to PC inspections starting May 1, 2018, shown in Table 1:

Table 1: Preliminary DMNFR Ozone NAA Well Production Facility Dataset (2018 Sampling Estimate)

Production Buckets	Estimated number of controllers per facility	Total No. of Facilities	Proposed Sample %	Proposed No. of Sample Facilities	Estimated # of controllers
>250 bbls/day	50	104	13	14	700
10-250 bbls/day	20	553	7	39	780
0-10 bbls/day	5	2,509	5	125	625
TOTAL		**3,166**		**178**	**2,105**

The actual sampling that took place resulted in one extra facility inadvertently being surveyed by one of the operators. Additionally, because operator PC count estimates were intentionally conservative, a significantly higher number of controllers were actually surveyed during the study. The actual final 2018 well sampling facility and PC numbers inspected are shown below in Table 2.

Table 2: Final DMNFR Ozone NAA Well Production Facility Dataset (May - October 2018)

Production Buckets	Average number of controllers per facility	Total No. of Facilities	Proposed Sample %	Proposed No. of Sample Facilities	Final # of controllers
>250 bbls/day	98	104	13	14	1,378
10-250 bbls/day	34	553	7	39	1,319
0-10 bbls/day	9	2,509	5	126	1,141
TOTAL		**3,166**		**179**	**3,838**

For natural gas compressor stations, the Division initially requested industry feedback on potential data for inclusion in the May 2018 sampling. After further stakeholder discussion, the Division conducted an independent analysis using its databases to determine the number of active natural gas compressor stations in the NAA and gathered industry feedback by facility. The final analysis showed 58 active natural gas compressor stations operated by eight companies. The Division received feedback on 86% of the stations (50 stations) by June 2018 (four out of eight operators). Of these, 48 stations are currently operating or under construction to operate on instrument air, or have been depressurized and are not included in the field inspections. Two natural gas compressor stations were confirmed to use natural gas-driven PCs and were included in the study. These two natural gas compressor stations were sampled in the summer of 2018. Nine compressor stations are operated by non-participating operators and are of an unknown status at the time of the study. It is likely that at least some of these natural gas compressor stations are operated on instrument air since 4% (two out of 50) of the participating stations use natural gas-driven PCs; however, this is assumed and not verified.

4.3 Field Campaign Summary

The PCTF field study began in May 2018 and data collection was finished by October 2018. On August 1, 2018, and September 11, 2018, Patrick Murphy (formerly of Boulder County) and Jeramy Murray (APCD) attended field surveys at four Noble Energy and two PDC Energy facilities to observe how industry field staff were implementing the study design.

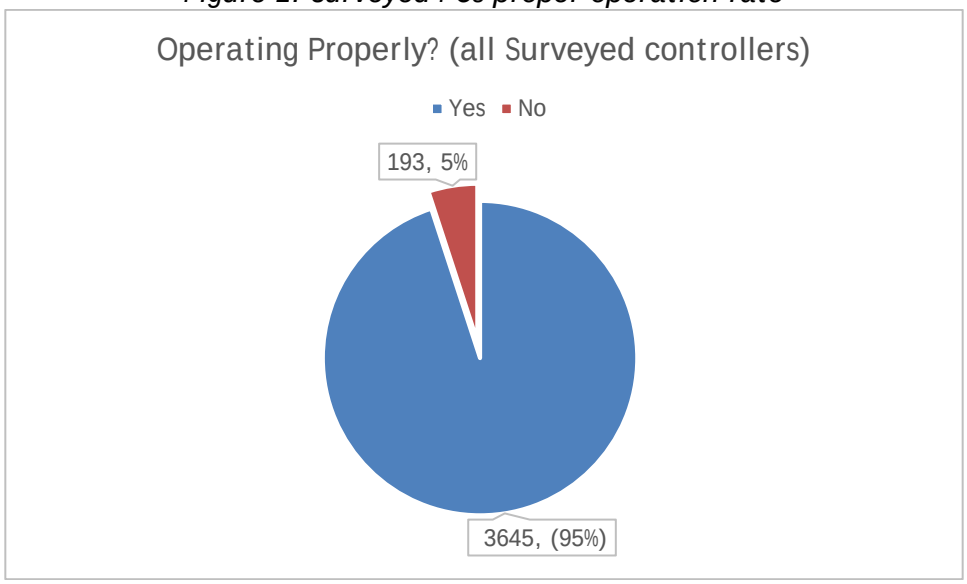
4.3.1 Field Data Compilation

Spirit Environmental (Spirit) was retained by COGA to assist with implementation of the PCTF study plan, including facility selection, field data form development, and data validation and compilation. Once the representative cross-section criteria was developed, Spirit generated a randomly selected list of facilities to be inspected by participating operators. If a facility was not available for inspection, Spirit randomly chose a replacement facility that met the original criteria for that operator. Reasons for assigning a designating a site as unavailable included: depressurized, shut-in, P&A, divested sites, sites operating with instrument air, sites with landowner access restrictions, or incorrectly categorized sites.

4.3.2 Completeness and Consistency Review

All data collected by operators was compiled and blinded by Spirit Environmental before electronic submission to the Division. The data also went through a completeness and consistency check performed by Spirit, where operators were consulted to complete missing

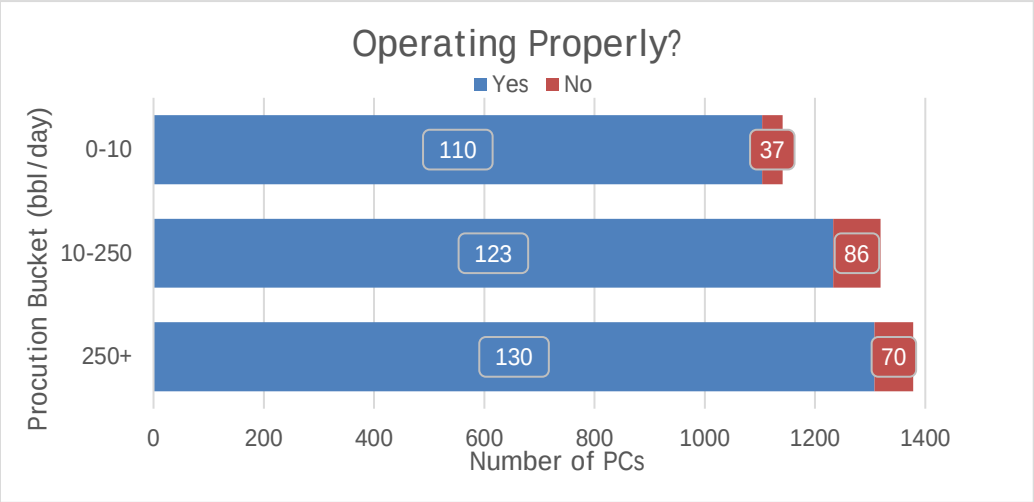
data fields and to better account for information provided, thereby improving field data reporting consistency between operators. For transparency, industry provided the compiled field data in both uncorrected and corrected spreadsheets that were made available to all stakeholders in the PCTF.



4.4 PCTF Study Data

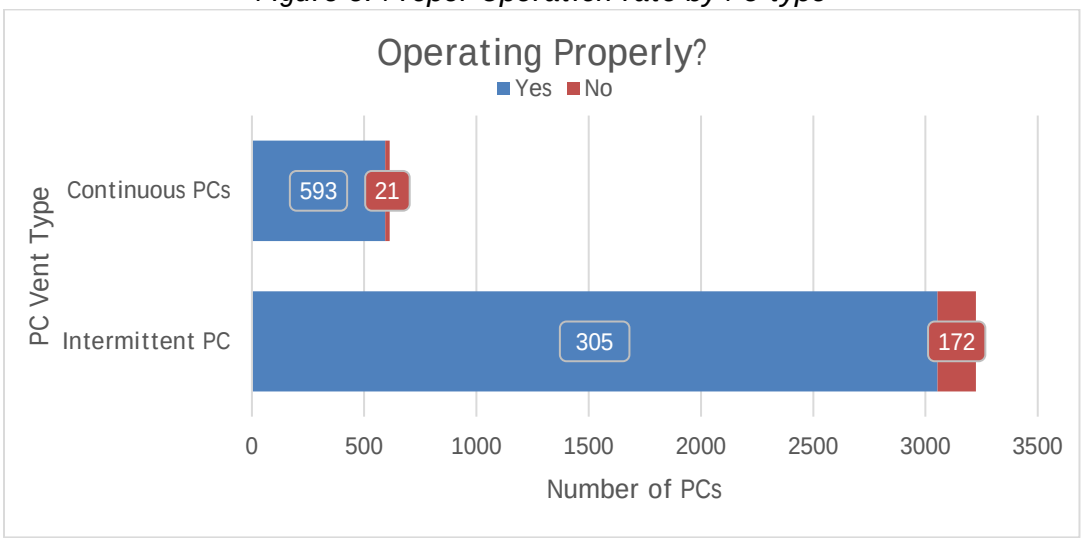
The following sections contain summaries of key data collected during the PCTF field study. A full spreadsheet with all data collected in the program is available to stakeholders for analysis through the Division.

4.4.1 Oil and Gas Production Facility Data



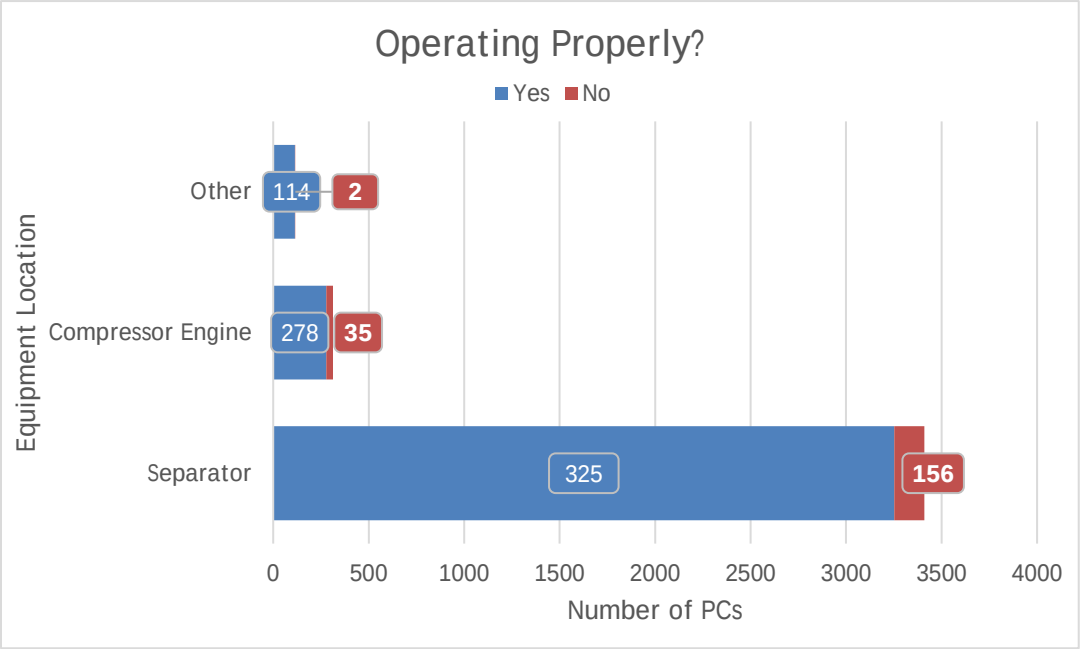
The study resulted in data points based on inspections for over 3800 PCs in the DJ Basin. Of the PCs observed, approximately 5% were observed to be improperly operating.

Figure 1. Surveyed PCs proper operation rate



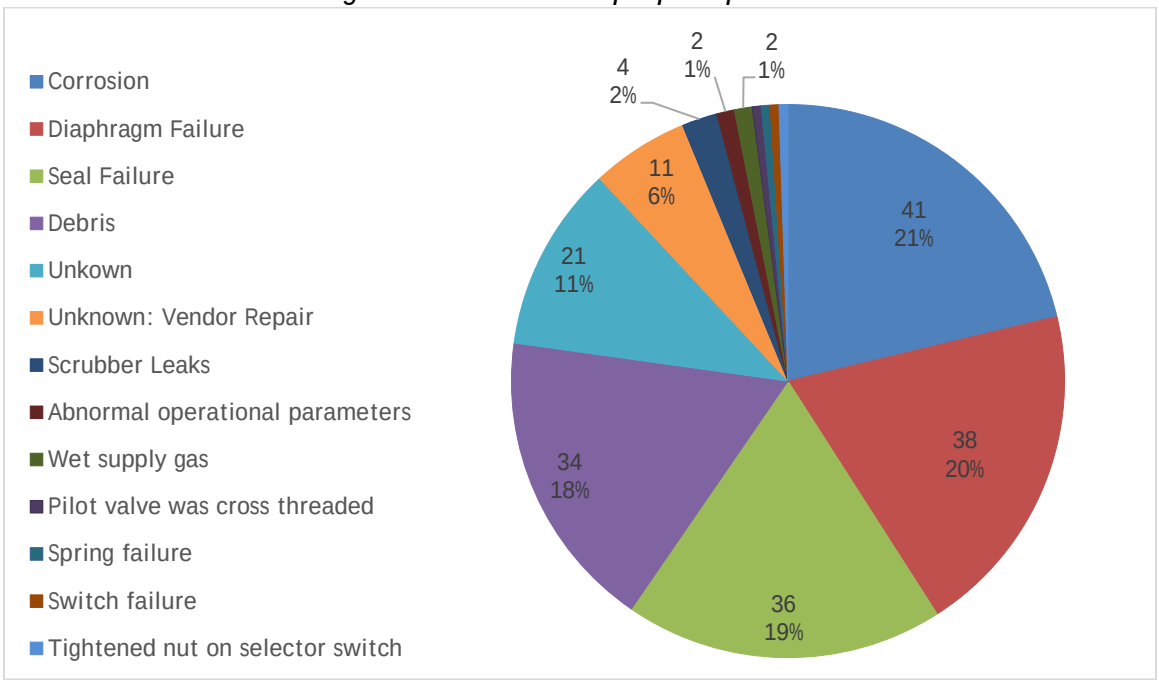
This data was also broken down by the three predetermined inventory production buckets. In the 0-10 bbl/day production bucket, 3.2% of all PCs were improperly operating. In the 10-250 and 250+ bbl/day buckets, 6.5 and 5.1% of PCS respectively were found to be improperly operating.

Figure 2. Proper Operation rate by inventory production bucket



Breaking down the data by PC type (continuous vs. Intermittent) is also a useful way to look at the data. Continuous PCs were found to have an improper operation rate of 3.5% and intermittent controllers had a rate of 5.6%.

Figure 3. Proper Operation rate by PC type

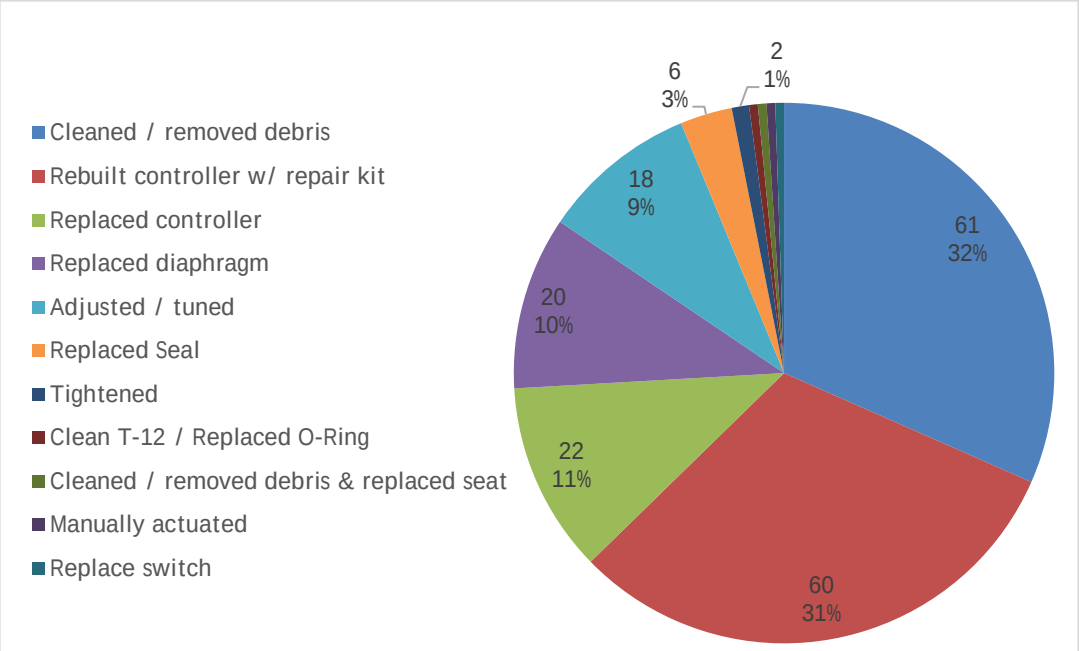


Operators tracked the facility equipment associated with each PC in the study. The majority of PCs are in-service on separation vessels. About 5% of PCs on separators were found to be improperly operating. The second most common PC equipment location was on the compressor engines. PCs on compressor engines had a relatively high improper rate of 12.3%. PCs found on all other equipment had a 2% improper operation rate.

Figure 4. Proper Operation rate by equipment location

The study revealed that there were a myriad of reasons that a PC might operate in an improper manner. The four largest causes were attributed to corrosion, diaphragm failure, seal failure, and debris blocking the internal mechanism from reseating.

Figure 5. Causes of improper operation



Operators made attempts to return all PCs to proper operation at the time of inspection if possible. Fifty (26%) of the 193 improperly operating PCs were repaired immediately. Ninety-

two PCs that needed repair were done on the same day of the inspection. 101 of the repairs were made at least a day later, with an average lag time of 4 days later.

Some repairs required a shut down or replacement of the PC. Those types of repairs take longer to complete and may have to be scheduled for repair soon thereafter or during the next planned shutdown of the facility. The majority of repairs were simply cleaning the PC and/or removing debris. Another common repair was to rebuild the PC with spare parts provided in a manufacturer repair kit.

Figure 6. PC repair actions

4.4.2 Midstream Data

As discussed previously, only two natural gas compressor stations of the 50 operated by participating companies use natural gas-driven PCs and were surveyed by the participating operator. All other natural gas compressor stations in the NAA owned by these participating operators utilized air-driven controllers and so therefore were not part of this study. The inspections of the two subject natural gas compressor stations occurred over two days in late August and early September. A total of 23 PCs were inspected. Four (4) models of PCs were documented. None of the surveyed PCs were found to be operating improperly. The PCs were used to monitor and control liquid levels and pressure.

4.5 PCTF Study Findings and Conclusions

The key findings and conclusions from the PCTF study are summarized below in narrative form. Additional findings are provided in the industry surveys of PC inspection costs and effectiveness, and use of no-bleed PCs, provided in Section 5.

4.5.1 Key Findings

PC Survey

- The most common manufacturers of PCs surveyed for this study were Kimray (43%), Wellmark (36%), and Fisher (15%).

- The most common models of PCs surveyed for this study were Wellmark 7400 Snaptrol (32%), Kimray T-12 (21%), Fisher 4660 (14%), Kimray 230 SGT (7%), Murphy LS200N (3%), and Norriseal 1001A (2%).
- Intermittent PCs comprise 84% and low bleed, continuous PCs comprise 16% of the 3838 PCs surveyed for this study.
- For equipment location, the PCs surveyed were found as follows:
    - 89% on separators
    - 8% on compressor engines
    - 1.4% on liquid knockouts
    - <1% on various equipment

PC Improper Operation

- The rate of PC improper operation varied:
    - by facility production:
        - Ranging from 5.1% for greater than 250 bbl/day, to 6.5% for 10-250 bbl/day, and 3.2% for 0-10 bbl/day.
    - by controller type:
        - 4.3% for pilot PCs and 8.0% for integrated PCs.
    - by controller vent type:
        - 5.3% for intermittent PCs and 3.4% for continuous PCs.
    - by controller enclosure:
        - 3.1% for enclosed PCs and 7.9% for non-enclosed PCs
    - by equipment location:
        - 4.9% for separators, 11% for compressor engines, 0% for liquid knockouts, and varying percentages for those few PCs that serviced various types of equipment.
- Overall, the observed rate of improper operation for all surveyed PCs was 5%.
- Actuations of PCs were observed only for 33% of the PCs surveyed.
- PC emissions were observed at the following locations and frequencies:
    - Vent port – 79%
    - Body – 20%
    - Vent port and body – 1%
- The following frequencies of common indicators of PC improper operations were reported.
    - 86% - Continuous bleed from vent port of intermittent PC
    - 11% - More venting than normal from continuous PC based on inspector's judgement
    - 1% - Continuous bleed from vent port of intermittent PC and PC was making unusual sound

Causes of PC Improper Operation

- The following frequencies of common causes of PC improper operations were reported:
    - Corrosion – 21%
    - Diaphragm failure - 20%
    - Seal failure – 19%
    - Debris – 18%
    - Other: Unknown - - 11%
    - Other: Vendor repair – 6%

- Other: Scrubber leaks – 2%
- Abnormal operations parameters – 1%
- Other: Wet supply gas – 1%
- Various - <1%

PC Repairs

- The following frequencies of common types of repairs of PCs that were not operating properly were reported:
  - Cleaned/removed debris – 32%
  - Rebuilt PC – 31%
  - Replaced PC – 11%
  - Replaced diaphragm – 10%
  - Adjusted/tuned PC – 9%
  - Replaced seal – 3%
  - Tightened – 1%
  - Various - <1%
- Double block and bleed was performed for 36% of the PC repairs.
- Equipment shutdown was performed for 37% of the PC repairs. Shutdown of a well was performed for 24% of the repairs.
- The time to make a PC repair varied by the type of repair, yet the average time for all types of repairs was less than 30 minutes.

4.5.2 Conclusions

This PCTF study represents the largest sample set of PC inspections in the nation to date, with 3838 PCs surveyed during the facility inspections conducted during the spring and summer of 2018. The 5% rate of improper PC operation found in the 3838 PCs inspected for this study based on emissions observed using an OGI camera demonstrates that typically (~95% of the time) PCs sampled in this study were found to be operating properly.

This study also demonstrated that an OGI camera can identify improperly operating natural gas-driven PCs. Detection of improper operation of an intermittent PC is largely determined by the observation of continuous emissions between actuations. Given that 84% of the PCs surveyed consist of intermittent PCs, the use of an IR camera is particularly effective in identifying excess emissions from intermittent PCs. Discerning improper operation of a low bleed continuous PC is less straightforward and is subject to the experience and judgement of the inspector in discerning excess emissions from improper operation.

Additionally, where an existing LDAR program exists for fugitive leaks, adding the inspection of natural gas-driven PCs to the inspections adds minimal incremental inspection costs. Repairs of improperly operating PCs are readily made by cleaning the PC of corrosion and debris, replacing broken parts and adjusting/tuning the PC and the supply gas pressure.

4.6 Separate EPA/CDPHE Study on PCs in Denver-Julesburg Basin

4.6.1 Overview

Over a similar time period as the PCTF inspection study, EPA and CDPHE conducted a parallel study on natural-gas actuated PC emissions in the DJ Basin. The results of this parallel study were published in early 2020 in the Journal of the Air and Waste Management Association in a

paper by Stovern et al. entitled "Understanding oil and gas pneumatic controllers in the Denver-Julesburg basin using optical gas imaging."

Briefly, the Stovern et al. paper focused on a smaller sample size of PCs (500 controllers servicing 102 wells at 31 facilities operated by seven different companies) and included counts and observations of intermittent and continuous low bleed PCs. The PCs were inspected with OGI, and the emission rate from a small subset of the inspected PCs was quantified using high-volume sampling. Although measurements required to quantify actuation volumes were outside the scope of this study, the OGI camera survey provided limited information on the frequency of occurrence for actuations. This study was performed in the spring 2018 over a period of 10 field days.

4.6.2 Study Design

Stovern et al identify two objectives for this study: 1) gather information on the types and uses of PCs employed by randomly selecting facilities representative of the overall basin and 2) investigate the use of an expeditious and less invasive PC emissions survey approach based on optical gas imaging (OGI) camera that could help inform PC operational and maintenance states.

An important aspect of the PC survey was to confirm that the exhaust port of the PC was visible during the OGI inspection so that any continuous emission through the PC pilot could be assessed. A FLIR GF320 camera was utilized to monitor emission profiles of PC for this study, which has a normal or "auto" imaging mode and a high sensitivity mode (HSM), where onboard differential image processing can enhance an operator's ability to identify lower emission rates approaching 0.5 scf/hr natural gas or even lower under ideal conditions. Comparisons between the auto and high sensitivity mode imaging were made in monitoring PC emissions to explore their differences in detection capability as a rough indicator of emission level. An extended OGI observation time of 60 sec for each PC was used to enhance detection capability, to look for anomalous temporal emission profiles indicative of potential malfunctions, and to document short time duration PC actuation events as activity data where possible. If an actuation event or unusual temporal profile was observed, the observation time was increased to 120 seconds to bound actuation frequency and further diagnose potential malfunction issues.

The well production facilities ranged in production and complexity from small facilities with minimal equipment (such as one wellhead, one separator, and one or two tanks) to larger facilities with multiple wellheads, separators including second and third stage separation vessels, complex tank batteries with vapor capture systems, multiple control devices, gas lift compressor engines, and vapor recovery units. Of the 31 well production facilities selected, the wells were 50.0% vertical, 33.3% horizontal and 16.7% directional. This distribution is consistent with the overall well type distribution for the 24,220 actively producing wells in the basin of 42.1% vertical, 38.9% horizontal, and 19% directional.

Information gathered for each pneumatic system (PS)/PC included: process working status (in use or shut-in), PS/PC identification (make/model), motive gas type, PC configuration and operational mode, process function (control, safety, or both), process equipment application (separator, combustor, compressor, etc.), and sensed process variables (e.g. temperature, pressure, and liquid level). PC-specific information such as model configuration variables, retrofit status, installation date, actuator components, and supply line pressures were also documented to the extent possible.

4.6.3 Findings

Stovern et al. (2020) reported the following findings for the EPA/CDPHE PC study:

Survey of PCs at Facilities

- A total of 615 process control pneumatic systems (PSs) were found at the 31 facilities with 59 of these being of the electronic variety that does not use gas-emitting PC pilots.
- Of the 556 PSs with gas-emitting PC pilots, 38 of these were instrument air-driven. Natural gas was found to be the exclusive motive gas type at 30 of the 31 facilities surveyed. One facility used instrument air on 38 out of 52 PCs with the natural gas models at that facility primarily serving back pressure regulation functions. Operations of instrument air-driven PCs were not further studied by Stovern et al.
- Of the 518 natural gas-driven PCs, 18 (3.5%) of these comprised a "no-vent" design where the natural gas emitted from the pilot is fully captured. These integrated pilot-actuator PCs have the potential to emit natural gas only by diaphragm or connector leaks that would be classified as equipment leaks and therefore were not further studied by Stovern et al.
- A total of 500 natural gas emitting PCs were found at 31 facilities servicing 102 wells (average of 4.9 PCs/well).
- A total of 453 of the 500 natural gas-driven PCs were found to be in service (i.e. not shut-in or depressurized); this number represents the primary count of the PCs assessed for proper operation. Of this total, 377 (83%) of the PCs were intermittent and 76 (17%) were continuous.
- A total of 447 PCs were monitored with an OGI camera for emissions as six intermittent PCs were not surveyed due to wind speeds exceeding the 9 m/s method limit.

PCs with Maintenance Issues

- Of the 371 intermittent PCs monitored, 42 (11.3%) were observed with continuous emissions and 22 were observed with actuations (5.9%). This 11.3% represent intermittent PCs experiencing some level of maintenance issue. The severity of the maintenance issues is unknown without emission rate measurement. The authors note that due to the fact that some controllers were observed in the less sensitive "auto" mode of the OGI camera (see below), the true level of maintenance issues among the intermittent PCs they surveyed was probably higher. They estimate that the true frequency of maintenance issues in this population was 11.6 to 13.6%.
- Of the 76 continuous PCs, 28 (37%) were found to have continuous emissions. Yet, it is unknown what portion of these emitting continuous PCs reflect a potential maintenance issue, since they may have been operating as designed. As described below, at least one continuous PC had measured emissions above the State regulatory standard (6 scf/hr).
- It was critical to determine the design type of the PC (intermittent or continuous) during the on-site survey because the type assignment played a role in the assessment of potential maintenance issue conditions.

PC Emission Measurements

- Emission measurements were conducted on 18 total PCs (14 intermittent PCs and 4 continuous PCs) with continuous emissions detected during the OGI camera survey. In general, the measurements were conducted on PCs that appeared to have the most significant gas signature.
- 36.8% of continuous low-bleed PCs (28 controllers) had continuous emissions that were observable with the OGI camera. Emissions were measured from four of these continuous PCs with a high-flow sampler. Measured emission rates ranged from 0.7 to 9.9 scf/hr with an average ER of 4.2 scf/hr. Three of the continuous PCs exhibited emission rates above 1.39 scf/hr; one was considered to be malfunctioning as it was emitting in excess of the 6 scf/hr State regulatory limit. Two of the measured continuous PCs had measured emissions above 1.39 scf/hr and below 6 scf/hr.
- Snapshot measurements were conducted on 14 intermittent PCs that were observed using an OGI camera to have continuous emissions (not including actuations). Three of the measurements were near or below the estimated method detection limit of the technique at (0.1 scf/hr). Observed emissions rates ranged from 0.1 up to 31.3 scf/hr (mean = 2.8 scf/hr).
- In two cases, the intermittent PCs were cycling between actuations with the OGI camera video showing steadily increasing emissions prior to actuating, followed by a sharp drop in emissions below the OGI detection threshold. These significantly variable (heavy ramping and temporally sustained) emissions were categorized as maintenance issues for these snap-acting intermittent PCs.
- The highest measured intermittent PC emission rate (31.3 scf/hr) was caused by a process issue. This PC managed back pressure on the low-pressure side of a high-low pressure separator. A suspected process control issue was identified where a bleeding valve upstream of the low-pressure vessel caused the PC to continuously actuate because the low-pressure vessel was continually exceeding the pressure set point of the PC. In this situation, the intermittent PC itself was not malfunctioning.

Auto vs. High Sensitivity Mode

- The initial protocol for the OGI camera included evaluating only auto imaging mode (the less-sensitive mode for the OGI camera used in the study) at 85 PCs that serviced 26 wells at 9 facilities. Later, both high sensitivity mode (HSM) imaging and auto mode (HSM/auto) were used for most of the PC assessments (N= 362 PCs, 22 facilities, and 76 wells).
- The continuous PC emission detection rates for the auto-only versus the HSM/auto subgroups differed significantly. For the auto-only mode subgroup, 1 of 16 continuous PC (6.3%) and 1 of the 69 intermittent PCs (1.4%) exhibited continuous emissions. For the HSM/auto subgroup, 27 of 60 continuous PCs (45%) and 41 of 302 intermittent PCs (13.6%) exhibited continuous emissions.
- OGI camera imaging modes were observed to have a significant effect on emission detectability with HSM mode detection rates being approximately 2 times higher compared to auto mode.

Actuations

- A total of 33 actuation events (AEs) were observed from 22 different PCs in the 447 monitored for this study. Based on observed emissions, only a few percent of intermittent PCs in this basin appear to have actuation frequencies greater than 1/min, with many PCs (e.g. safety category) very infrequently actuating.
- AEs were observed at only 9 of 31 facilities with the top two highest oil producing facilities accounting for 54.5% (12 of 22) of the PCs with actuations. The highest producing facilities had five separate intermittent PCs exhibiting AEs with a total of 13 observed, whereas the second-highest producing facilities had 7 PCs and 8 total AEs. There were a total of six PCs surveyed that had multiple actuations observed during the OGI survey (extended up to 2 min). Three of those PCs were located at the highest producing facility, and one PC with multiple actuations was located at the second, fifth, and sixteenth highest producers.
- The OGI camera survey indicates an expected relationship between normalized oil production and observed actuations. At a high producing facility, the same PC and process will require more actuations than at a lower producing facility. However, PCs with a maintenance issue do not show the same correlation with facility production.
- Estimated actuation volumes ranged from 0.005 to 0.185 scf per actuation event, which indicates that potential emissions from continuous emissions due to a maintenance issue may often be the dominant factor in overall emission rates for infrequently actuating PC populations. At lower producing facilities, the continuous emission component of emissions for intermittent PCs with maintenance issues becomes a more significant factor affecting average PC emissions rates for lower producing facilities.

4.6.4 Conclusions

- Although the findings of this study are representative of the DJ Basin, they are not intended to be representative of PC operating characteristics at a national level and therefore should be used with caution at that scale.
- The observed PCs per well are reasonably consistent with the 2018 data from EPA's Greenhouse Gas Reporting program for the Denver Basin with an average of 3.1 PCs per well and are significantly higher than the national average of 1.6 PCs per well (U.S. EPA 2019c).
- 83% of the PCs surveyed for this study were intermittent PCs, which is consistent with the 91% reported by Allen et al. (2014) for PCs in the Rocky Mountain region.
- The use of an OG camera to profile PC emissions was found to be a helpful approach to inform PC maintenance issues.
- Observing continuous emissions from a PC with an OGI camera on a snap-acting intermittent PC is indicative of emissions beyond the designed shut-off rate and is indicative of a maintenance issue.
- The identification of actuation events for continuous PCs and throttling process control applications was more challenging than those for intermittent PCs in snap acting applications.
- For a low bleed CPC, continuous emissions observed with an OGI camera was not informative to detect a potential maintenance issue unless in the OGI operator's judgment the emission appeared abnormally large compared to typical operation.
- 11.3% of intermittent PCs surveyed were directly observed with OGI to have continuous emissions. Due to an issue with the use of the OGI camera at some sites, this figure probably represents an underestimate of the frequency of continuous

emissions from these controllers. Stovern et al. estimate that the true frequency of continuous emissions in this population was 11.6% to 13.6%. These observations may reflect maintenance issues since these emissions were likely above the designed seepage rate of these intermittent PCs.

- As opposed to intermittent PCs, it is unknown what portion of continuous PCs were experiencing a potential maintenance issue, without measurement. One of the four continuous PCs measured was classified as malfunctioning with a measured emission rate of 9.9 scf/hr, above the 6.0 scf/hr State regulatory limit.
- The type of imaging mode (i.e. auto vs high sensitivity) utilized during the OGI camera survey was observed to significantly affect the detection rate of continuous emissions. The detection rate of continuous emissions using high sensitivity mode was 1.6 and 2.1 times higher than when using auto-mode imaging for intermittent PCs and continuous PCs, respectively. The difference between observation capabilities in high sensitivity vs. auto modes could be used in an inspection approach to approximately separate the PC populations (e.g. minor maintenance issues and significant malfunctions), so that repairs can be prioritized to minimize unnecessary emissions.
- PC actuations from process control-based PCs correlate with facility production. Facilities with lower production will have lower actuation emissions rates among its PC population and continuous emissions from PCs with maintenance issues will therefore be the controlling factor for the average operational PC emission rate. For higher producing facilities that cause PCs to actuate much more frequently, actuations will be a significant contributor to the overall average operational PC emission rate

4.7 Comparison of PCTF Study and EPA/CDPHE Study Findings and Conclusions

The following statements offer key comparisons between the findings and conclusions for the PCTF Study and EPA/CDPHE Study.

4.7.1 Findings

- Both field inspections of PCs were conducted in the DJ Basin during the spring/summer of 2018.
- Both studies focused on identifying improper operation (aka maintenance issues) of PCs using an OGI camera by trained and experienced personnel during facility inspections.
- Facility selection for each of these studies was done randomly for the operators participating in each study.
- Both studies found that the majority of natural gas-driven PCs observed consisted of intermittent PCs (PCTF – 84% vs EPA – 83%)
- The EPA/CDPHE study estimated that 11-14% of the intermittent PCs inspected were not operating properly, while the PCTF study found 5.3% of intermittent PCs were not operating properly.
- The EPA/CDPHE study found that using a camera in high sensitivity mode was more effective in finding smaller emissions from intermittent PCs.
- The EPA/CDPHE study did not evaluate whether continuous PCs were operating properly based on emissions observed with an OGI camera. The PCTF study found 3.4% of continuous PCs were not operating properly. Emissions measurements were performed by EPA/CDPHE on four continuous PCs, finding one of these PCs to have emissions in excess of the 6 scf/hr regulatory limit.
- The EPA/CDPHE study measured 14 intermittent PCs that were observed using an OGI camera to have continuous emissions. Observed emissions rates ranged from 0.1 up to

31.3 scf/hr. The elevated reading of 31.3 scf/hr was attributed to a process issue and not PC improper operation.

A significant contrast between the PCTF study and the EPA/CDPHE study is related to how integrated pilot-actuator devices were classified. Simpson (2014)[6] defines an *integral* PC as a PC that is built into an end device (i.e. valve) and does not require an external source of gas, nor does it release actuation gas to the atmosphere. Rather, it releases actuation gas into the process downstream. Similarly, Simpson defines a *local* controller is also defined as one built into the end device, but it exhausts gas to the atmosphere to move the process valve toward closed. In contrast, remote pilot controllers are PCs that are not integrated into the end device.

Note that "integral" controllers, as defined by Simpson, would be considered "Self-contained PCs" under Regulation 7. Additionally, note that Stovern et al. refer to both integral and local PCs as "integrated" PCs, and they use the term "no-vent" for PCs that Simpson defines as "integral" – those that release gas into a process downstream. The discussion below uses Simpson's terminology.

- The EPA/CDPHE study did not include integral devices in their assessment of PCs. EPA stated in its report that integral PCs have the potential to emit natural gas only by diaphragm or connector leaks and that any such leakage should be classified as an LDAR component leak, rather than as a PC that is operating improperly.
- For the PCTF study, integral devices were classified as a type of PC. 59 (8%) of the 740 integral PCs surveyed were determined to be not operating properly, compared to 134 (4.3%) of the 3,098 pilot PCs surveyed. Presumably, these devices were leaking from the diaphragm or connector, as described above.
- Since the PCTF study included integral controllers, while the EPA/CDPHE study did not, and integral controllers were operating improperly at a relatively *high* rate in the PCTF study, this suggests that the inclusion of integral controllers in the PCTF study skewed the improper operation rate slightly higher.
- Regardless if classified as a PC or not, integral controllers are included as a component in a LDAR program for equipment leaks and will therefore be assessed for leakage and repaired as needed to ensure proper operation.

4.7.2 Conclusions

- The Stovern et al. study found that using the high sensitivity mode of the OGI camera resulted in a nearly 2 times higher emission detectability compared to the auto mode. This might explain why Stovern et al found more than twice the percentage of intermittent PCs that were not operating properly compared to the PCTF study (11-14% vs 5%).
- The Stovern et al. study used a set observation time of 60-120 seconds for every PC/PS. The PCTF study did not have this requirement and if the OGI camera operator did not detect emissions within a few seconds, they would move on with the inspection. These varying approaches were utilized because each study had a different objective. The PCTF study set out, in part, to determine the effectiveness of the find and fix program, so inspection protocols were adapted to current industry practices.

[6] Simpson (2014), *Pneumatic Controllers in Upstream Oil and Gas*. https://pubs.spe.org/en/ogf/ogf-article-detail/?art=238.

The longer observation time used by Stovern et al. may also be a contributing factor to the discrepancy between the proper operation rates.

- Both studies concluded that using an OGI camera to profile PC emissions was an effective method to inform possible improper operation of intermittent PCs. However, the use of this method for identifying improper operation of continuous PCs is more challenging, except when the emissions appear to be abnormally large compared to normal operation.

5 Industry Surveys

In order to achieve the goals established by the PCTF for reassessment of the Find and Fix program, additional information needed to be gathered on the effectiveness and costs related to inspection of PCs under the find and fix program and to better understand the use of self-contained and no bleed PCs. A series of questions were developed and incorporated into survey questionnaires that operators were requested to complete. A total of three surveys were developed:

1. The effectiveness and costs of PC inspection techniques
2. The effectiveness and costs of PC repairs
3. The use of self-contained and no bleed PCs.

The surveys were completed in confidence, and then blinded and compiled by API and COGA to address industry anti-trust concerns before being shared with the PCTF in presentations that summarized the survey responses. The first two surveys were to be completed by the nine operators participating in the PCTF study within the ozone NAA. The third survey was distributed to COGA and API members with oil and gas production operations in the state. As described below, the second survey was developed but not completed.

5.1 Effectiveness and Costs of Inspection Techniques (NAA only)

Highlights from the results of survey questions provided to the nine operators participating in the PCTF study on the effectiveness and costs of PC inspection techniques are provided in the following bullets.

- The majority of operators use a combination of employees and contractors to conduct PC inspections. Some operators use employees only.
- The majority of operators use the same party for both LDAR and PC inspections.
- Operators typically conduct LDAR and PC inspections during the same facility visit.
- Operators generally replied that it can be helpful to know in advance whether the PC is an intermittent or low bleed in order to understand if emissions are expected between actuations (low bleed) or not (intermittent).
- Operators also indicated that understanding the process the PC is controlling is beneficial in making a determination whether a PC is operating properly or not.
- For intermittent PCs, operators typically look for continuous emissions between actuations. For continuous bleed PCs, operators typically look for emissions that appear abnormal for that type and application of controller.
- Operators found using OGI camera inspections along with AVO indicators was effective, although OGI cameras are more effective at finding smaller leaks. Soapy water may be used to further pinpoint a leak location.

NMED Exhibit 93

- AVO indicators such as the presence of liquids at or around/below the vent and whether dependent processes are operating properly can be useful to determine whether a PC is operating properly or not.
- Safety limitations in the use of OGI cameras are largely driven by whether the OGI camera is intrinsically safe or not. An intrinsically safe camera does not pose a potential ignition source and can be used in Class 1 Division 2 areas as defined by OSHA in CFR 1926.449. OGI cameras that are not intrinsically safe may require a hot work permit to be allowed on site at a facility or the camera operator may have to maintain a minimum safe distance from the equipment being observed.
- Responses on the average time to inspect a PC varied depending on the experience of the inspector and included various caveats including weather conditions. The inspection time varies and is dependent on the type of PC and if emissions are observed. If no emissions are observed, then only a few to several seconds is generally sufficient to determine that the controller is operating properly. If emissions are observed, then the time to make this determination is dependent on whether the controller is actuating or not, the type of controller, and the characteristics of emissions observed. It could take up to several minutes to make this determination.
- The costs to conduct PC inspections are variable and likely highly dependent on the size and makeup of facilities of operators and internal programs and processes. Some operators indicated that the incremental equipment costs are not significant since this equipment is required for LDAR inspections. Other operators estimated that incremental annual equipment costs for PC inspections represent a small percent of LDAR related equipment costs. Ultimately, incremental annual equipment costs for PC inspections are dependent on the number of PC inspections performed.

5.2 Effectiveness and Costs of Repairs (NAA only)

Due to the need to focus on regulatory proposals to be considered for the December 2019 AQCC rulemaking, and the willingness of operators to expand the PC "find and fix program" statewide, it was not necessary to complete the planned repair cost survey.

Separately, the PCTF study results indicated that those PCs found to be improperly operating were successfully repaired and the majority of repairs were completed either immediately, the same day of the inspection, or within a few days of the inspection.

Operators seek to repair PCs in order to return them to proper operation since it is in their interest to maintain and optimize production operations. The cost of repairs is considered a normal operation and maintenance cost. The ability to more readily identify PCs that are not operating properly using an OGI camera allows earlier detection of those PCs needing repair that would otherwise eventually fail to control their intended process function and need subsequent repair.

The repair costs range in regard to the extent of the repair. These repairs can range from cleaning the PC of debris or residue that collects over time, replacing worn parts, or replacing the entire controller. Operators stock spare parts, repair kits or extra PCs that are then used to repair or replace the defective PC as a means to promptly make a repair.

The costs of repairs was not considered an impediment to supporting expansion of the PC "find and fix" program from the NAA to statewide during the AQCC December 2019 rulemaking.

5.3 Use of Self-contained and No-Bleed PCs (State-wide survey)

COGA developed and distributed a survey to better understand the use of self-contained and no-bleed PCs. The survey utilized the following definitions in order to establish a common understanding in completing the questions.

- Instrument air-driven PC: Any PC that is uses compressed air as the valve's actuating gas. Known as "no-bleed" under CO Regulation 7.
- Natural gas-driven PC with exhaust routed to process/sales: Any PC that directs gas to a process or sales line instead of to the atmosphere. Known as "self-contained" under CO Regulation 7.
- Natural gas-driven PC with exhaust routed to combustion control: Any PC that directs gas to a combustion control device instead of to the atmosphere.
- Non-pneumatic mechanical controllers: Any controller that uses mechanical force (not a pressurized gas) to trigger actuation.
- Non-pneumatic electric controllers: Any controller that uses an electrical signal (not a pressurized gas) and motor to trigger actuation.

The survey results are summarized below:

- 12 Operator Responses for production facilities
  - 3 Operators in Piceance, 9 in DJ.
    - >5,400 Total Production Facilities: ~4,200 DJ NAA, ~100 DJ AA & ~1,200 Piceance
    - >22,400 total wells: ~15,700 DJ NAA, ~500 DJ AA & ~6,200 Piceance
    - Percentage of facilities where on-site electrical grid power is used:
      - 19% DJ NAA
      - 63% DJ AA
      - 4% Piceance
- Operator Responses for compressor stations
  - 4 Operators in Piceance, 1 in DJ responded.
    - 16 Compressors stations in DJ NAA, 38 in Piceance
    - Percentage of compressor stations where on-site electrical grid power is used:
      - 100% in DJ NAA
      - 76% in Piceance
  - DJ NAA - 1 operator
    - 16 compressor stations
    - All use instrument air-driven PCs (11 new, 5 retrofitted)
  - DJ AA - No compressor station operator responded
  - Piceance Basin - 4 operators responded
    - 38 compressor stations
    - 9 new stations use instrument air-driven PCs
- Summary of Usage
  - The majority of PCs in use in Colorado are conventional natural gas-driven PCs
  - Most of the non-conventional controllers in use in the state are located
    - In the DJ NAA
    - At new facilities receiving production from horizontal wells
  - The most commonly used non-conventional controllers are air-driven PCs
  - Other non-conventional controller technologies usually only replace a fraction of the PCs at a site

- Consideration for Use
  - Safety
    - Instrument air-driven PCs
      - Some operators expressed concern with facilities using both instrument air-driven and natural gas-driven PCs: potential risk of flammable mixtures or explosion
      - One operator noted that fail-safe close valves need to be used so the site/well can shut-in in case of power loss or air compressor malfunction
    - Natural gas-driven PC with exhaust routed to process/sales or to combustion control
      - The required additional piping/plumbing could significantly complicate work areas
      - There are backpressure issues with remote PCs preventing exhaust vapors from reaching process/sales or combustion control
      - Backpressure can also slow actuation and affect operation
    - Non-pneumatic mechanical controllers
      - Some operators indicated mechanical dumps are more prone to failure due to erosion.
      - One operator noted that mechanical dumps may not have emergency shut down ability.
    - Non-pneumatic electric controllers
      - It was noted electrical controllers may not have a fail-safe capability and do not return to a safe position when power is lost, unlike conventional natural gas-driven PCs. Electric fail safe close valves require programming.
      - Electrical classification determines safe location on site.
    - Overall
      - Non-conventional have a positive impact on safety by reducing the quantity of hydrocarbon vapors in the atmosphere at facilities.
  - Costs
    - Instrument air-driven PCs
      - New facilities: incremental capital cost of $70K - $140K (depending on production/number of wells)
        - Additional piping, air compressor, supporting infrastructure, grid power/generator.
        - Use of grid power is critical for most, generators also used by some.
        - Additional maintenance costs required for air compressor and a desiccant air dryer.
        - One operator reported reduced maintenance on instrument air-driven PCs themselves.
        - One operator mentioned a backup instrument gas may be required, increasing costs.
      - Existing facilities: incremental capital cost of $90K - $180K (depending on production/number of wells)

        - Several operators reported that, due to declining production, retrofits are not cost effective and have primarily been done under compliance order.
        - Loss of production for retrofit, in addition to reasons listed above.
        - Additional incremental cost is on top of the initial cost to run instrument gas line.
        - One operator reported the need to hydro vacuum instrument air lines before retrofitting
    - Natural gas-driven PC with exhaust routed to process/sales
        - Significant cost associated with design of a complex vapor capture system.
        - Cost associated with compression to safely and reliably get emissions into process lines.
        - Additional maintenance on vapor control system (VCS) lines.
    - Natural gas-driven PC with exhaust routed to combustion control
        - Cost associated with re-piping equipment. May be do-able for PCs in close proximity to control device, very high cost otherwise.
        - VCS: Additional maintenance on lines and may require updates to the VCS analysis.
        - Some compressor stations are not equipped with ECD: high cost for low reductions.
    - Non-pneumatic mechanical controllers
        - Some mechanical dumps usually have lower upfront cost but higher maintenance cost.
        - For retrofits, cost of new controllers when natural gas-driven controllers are already in use.
    - Non-pneumatic electrical controllers
        - One operator reported an incremental cost of $7K - $10K per well.
        - Controllers have a higher upfront cost and higher maintenance cost.
        - Several operators reported that retrofits are not cost effective.
- Technical
    - Instrument air-driven PC
        - Sufficient grid power availability (true for new and potential retrofits).
        - Very frequent maintenance on air compressors required to ensure reliability.
            - One operator noted liquid collection and freezing may require backup compressors.
        - Considerations for power loss:
            - Some operators do not have back up options and site shuts in.
            - One operator reported using natural gas powered back up air compressors.
            - One operator reported using pressurized air bottles.
    - Natural gas-driven PC with exhaust routed to process/sales

        - Low pressure and low volume gas needing compression to process/sales.
        - Concerns with vapor collection lines such as air intrusion through components, debris and/or condensate build up, freezing, and backpressure concerns.
        - Not all exhaust from natural gas-driven PCs can be captured.
    - Natural gas-driven PCs with exhaust routed to combustion control
        - Low pressure and low volume may make it difficult for gas to reach combustor.
        - One operator mentioned experience indicating back pressure which affects valve actuation and maintaining stable stream to the combustor.
    - Non-pneumatic mechanical controllers
        - Generally can only replace a specific type of PC: dump valves/liquid level.
        - Experience shows that mechanical controllers are not as precise or as reliable as natural gas-driven PCs for process control.
    - Non-pneumatic electric controllers
        - Need for reliable electrical power (e.g. solar with battery and generator/grid as backup).
        - There are no electric replacement options for some natural gas-driven PCs.
        - There are limitations on where those controllers can be located (e.g. not compressors).
        - Electric fail safe close valves requires programming knowledge.
- Land/Leasehold
    - Instrument air-driven PCs
        - Ability to bring grid power may be limited: landowner restrictions, BLM land & FS land with approval requirements, remote/mountainous locations.
        - Pad size needs to be sufficient to accommodate air compressor and additional infrastructure in an area that is safe for electrical equipment.
            - Especially challenging for existing facilities where land has already been reclaimed.
    - Natural gas-driven PC with exhaust routed to process/sales or to combustion control
        - None identified
    - Non-pneumatic mechanical controllers
        - None identified
    - Non-pneumatic electric controllers
        - None identified
- Other
    - Instrument air-driven PCs
        - Pros:
            - Instrument air-driven PCs are a proven technology and usually use same/similar PCs.
            - Instrument air-driven PCs are not subject to the find and fix program.

        - Reg. 7 requires the use of no-bleed (instrument air-driven PCs) at facilities that use grid power.
    - Cons:
        - Grid power availability is utility dependent and can be very complex (permitting and approvals for new lines, proximity to power line does not mean availability).
        - Electric generators, if used, require permitting through APCD and have extra emissions.
        - Retrofits are not cost effective and primarily been done under compliance order.
- Natural gas-driven PC with exhaust routed to process/sales
    - Reliability (operation and maintenance very complex). Other options are more desirable.
    - Required by Reg. 7 once grid power is used on site and if technically and economically feasible.
    - Process/sales gas line occasional downtime may require redundancy.
    - Emissions associated with required additional compression.
- Natural gas-driven PC with exhaust routed to combustion control
    - Not considered as no-bleed or self-contained under Reg. 7 definitions.
    - Reliability is a major concern: other options are more desirable.
- Non-pneumatic mechanical controllers
    - None identified
- Non-pneumatic electric controllers
    - One operator reported less maintenance needed for such controllers.
    - Not a proven technology, cannot cover all functions usually covered by natural gas-driven PCs.
    - Use and maintenance requires staff with knowledge related to electrical systems.

- Survey Takeaways
    - Fail-safe options a concern for non-natural gas-driven technologies
    - Instrument air-driven PCs
        - Electrical grid power use is crucial, upfront cost is high
        - Proven technology, familiar make/model of PCs, less training
        - Safety and cost effectiveness concerns for retrofits
    - Natura gas-driven PCs with exhaust routed to process/sales/control
        - Operationally burdensome, reliability issues
        - Only feasible for a small subset of PCs
    - Mechanical controllers
        - Can only replace very specific functions (dump valves)
        - Cheaper upfront
        - Reliability and precision concerns
    - Electrical controllers
        - Require reliable power
        - Require trained staff
        - Only feasible for a small subset of controllers

According to the industry survey on zero-emitting PCs, the practice of capturing gas and routing emissions from a self-contained PC to emission control devices (ECD) is relatively uncommon and is highly dependent upon the distance between the vent port of the PC and the ECD. The PCTF study identified 50 PCs where PC vented emissions were routed to a nearby ECD. All of these PCs that were routed to an ECD were operating properly. The majority of these 50 PCs serviced a level control for a liquid condensate burner knockout pot which was located within a few feet of the ECD. In most cases, these knockout pots are drained by gravity or manually and are not controlled by a PC.

Routing to a process is relatively uncommon due to pressure differences between the vent port and the process. In general, the gas pressure from the vent port is too low to route to a facility process.

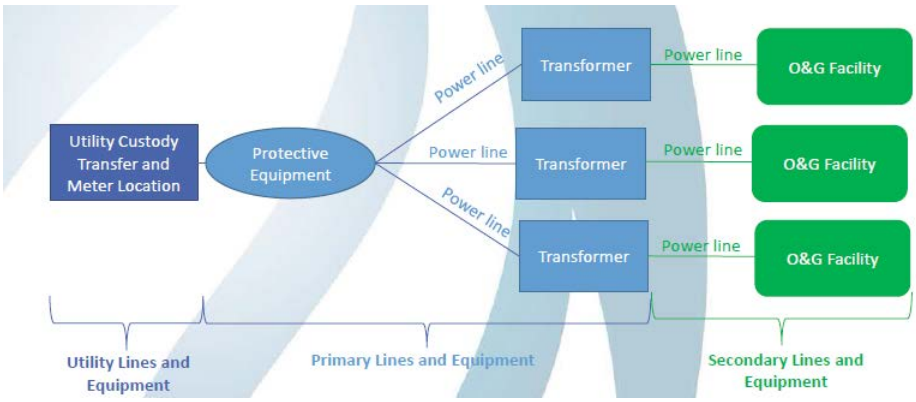
The category of no-bleed PCs can be considered a misnomer as all "pneumatic" controllers bleed or vent as part of their normal operation. The term "no-bleed" usually refers to those PCs that use instrument air as a motive force, rather than natural gas. In order to utilize instrument air, an air compressor, desiccants and filters, and pressure regulators are typically installed. The power to operate the air compressor is either provided using an electrical generator that is fueled by natural gas or diesel, or by a connection to an accessible utility line that provides adequate electrical power to the facility. The use of a natural gas or diesel fuel powered generator may result in a net emissions disbenefit in providing instrument air in lieu of natural gas for operating PCs. However, the net emissions benefit or disbenefit would vary on a case-by-case basis.

(Note that low power air compressors designed driving pneumatics using solar-battery systems for electricity,[7] and hybrid solar-gas powered electric compression systems,[8] are both available on the market in Canada.)

For new development of multi-well pads, operators pursue commitments from electric utilities to provide a connection and adequate power to a planned facility for electrification of equipment including air compressors for instrument air. A number of factors, many of which are beyond the operator's control, dictate whether the utility can provide an accessible connection and adequate power when the facility is being constructed. If the utility is not capable of meeting the requested commitment, then the operator will typically either rely on a natural gas or diesel-fired generator to power an air compressor, or utilize natural gas pressure as a conventional power source for PC operation.

5.4 Electrical Infrastructure for Oil and Gas Development

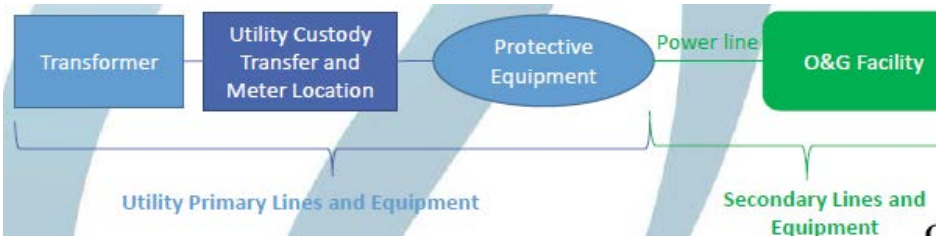
As part of the joint effort with the SHER work group, information was collected from API and COGA operators regarding the availability and planning for the use of electrical power from the grid or the use of natural gas or diesel oil powered generators to provide electrical power at oil and gas production facilities. A presentation was given during the July 12, 2019, SHER meeting which included the following talking points:



- Urban growth and development is an issue and impacts infrastructure availability

[7] See https://lcotechnologies.com/crossfire-compressor.html.
[8] See https://westgentech.com/.

NMED Exhibit 93



- Federal Lands and The National Environmental Policy Act (NEPA)/ The Federal Land Policy and Management Act (FLPMA) processes in remote areas are also obstacles to the use of electrical grid power
- Colorado has public utilities and cooperatives that provide power:
    - Each utility has different power drop timelines (1-3 years)
    - Each utility has different requirements on ownership and installation requirements between primary and secondary power lines and equipment
    - Primary lines are typically higher voltage lines while secondary lines are supplying power to a location (480-120 volts)
- Primary Meter – primary and secondary lines and equipment after custody transfer are installed, owned, operated and maintained by the company. In this case the O&G Facilities owner.

Figure 7. Primary Meter Ownership

- Secondary Meter –Only secondary lines and equipment after custody transfer are owned, operated and maintained by the O&G Facility owner. Everything upstream of custody transfer is installed, owned and operated by the utility.

Figure 8. Secondary Meter Ownership

- Primary Metering
    - The company has the staffing and technical ability to install, own, operate and maintain all the electrical equipment
    - Shorter lead times for power drop because less line and equipment needs to be installed by the utility
    - Higher costs for companies that only have a few O&G facilities in an area that requires power
    - Lower cost for companies with many O&G facilities in an area that requires power
    - Might not be an option because of right-of-way and surface user agreements

- Secondary Metering
    - Longer lead times for power drop to wait for utility to install primary lines and equipment
    - Costs may be higher depending on the location and amount of power needed
    - Some utilities require companies to perform primary metering so this might not be an option
- Challenges include:
    - Slowdowns from utility companies due to increased residential development
    - Changes in schedule from drilling permit issuance delays, operator agreement challenges with local governments, or right-of-way changes
    - Can be limited by proximity and capacity of grid power depending on utility
    - Power plant expansions dependent on air and other permitting
    - Cost may be prohibitive for operators in limited development areas
    - Small operators may not be able to effectively negotiate cost and availability
    - Contractual third party agreements may limit operator access
    - Timing often uncertain and power generation needed as backup

6 Good Engineering and Maintenance Practices

In 2017, the AQCC adopted Regulation 7 Part D, Section III.F.1. (formerly Section XVIII.F.1), requiring operators to operate and maintain PCs consistent with manufacturer's specifications, if available, or utilize good engineering and maintenance practices. The SBAP recognizes the need to more fully develop and document those practices, which include but are not necessarily limited to, ensuring proper operation. Data collected by the PCTF can be used to develop and document good engineering and maintenance practices.

Due to the unavailability of documentation from PC manufacturers, there are no widely agreed upon routine or preventive maintenance schedules. Individual operators have developed their own maintenance and operating plans in accordance with industry best practices and Regulation Number 7 requirements. While individual operators may have company-specific protocols for their PC program, all operators are in agreement on some key practices. The use of OGI cameras as the proper inspection tool to identify improperly operating PCs is universally accepted, at this time, by all industry members of the PCTF. However, identification of improper operation from a continuous low-bleed PC may require additional training/experience for the OGI camera operator. The findings above from the survey results on PC inspections also reflect key practices.

There are some barriers to developing prescriptive PC protocols because of the wide variability in how these devices function and the wide variety of designs and specific applications that are employed. More work needs to be done if developing prescriptive maintenance protocols is a goal of the AQCC.

6.1.1 The Environmental Partnership

API established The Environmental Partnership (TEP) in 2017 to "continuously improve the industry's environmental performance by taking action, learning about best practices and technologies, and fostering collaboration in order to responsibly develop our nation's essential natural gas and oil resources." TEP's initial focus is to further reduce the industry's air emissions in continuing to reduce methane, a greenhouse gas, and VOCs, which is one precursor to the formation of ground-level ozone. TEP hosted their first annual conference in

2018 as described in their 2019 Annual Report[9]. The conference focused on PCs and brought together producers, manufacturers, researchers, and regulators to discuss PC technology and how it might be improved.

In addition to periodically checking for proper operation of the controller through AVO and AIMM inspections, operators participating in this study concur with the "Pneumatic Controller Maintenance Work Practices" published by TEP as a wallet card for its members to provide to field personnel responsible for inspecting and maintaining PCs for proper operation of oil and gas production facilities. This wallet card is shown below:

7 Recommendations

The PCTF offers the following recommendations for consideration by the AQCC. Where there was not consensus on specific elements assigned to the PCTF, individual stakeholder positions are presented as such.

7.1 Effectiveness of current program (NAA only)

Pursuant to AQCC Reg 7 CTG rulemaking in November 2017, the PC find and fix program that applied only to the ozone NAA took effect on June 30, 2018, which was during the same summer of the PC field surveys performed for the PCTF study. The PC find and fix program has proven effective as demonstrated in the Division's 2018 LDAR Annual Report[10], which included the results of the PC find and fix program for the NAA, as described below. The AQCC extended the PC find and fix program state-wide effective May 1, 2020, as part of the AQCC SB-181 Reg 7 rulemaking in December 2019.

[9] See https://www.api.org/~/media/Files/Policy/Environment/TEP/The-Environmental-Partnership-Annual-Report-2019.pdf

[10] See https://www.colorado.gov/pacific/cdphe/2018-ldar-annual-reports-regulation-7-section-xii-xvii-and-xviii

The Division's 2018 LDAR Annual Report (pp. 4-6) summarizes the results of PC inspections performed for the PC find and fix program. Although the report does not break out the number of PC inspections using AIMM at well production facilities that were performed in the NAA in 2018, a total of 4,053 PCs were found to need repair and of these 4,015 (99%) were returned to proper operation. For natural gas compressor stations subject to PC inspections using AIMM in the NAA in 2018, a total of 7 PCs were needed to be repaired and 6 (86%) were returned to proper operation. Upon discovery of an improperly operating PC, repairs must begin no later than five working days and the PC must be returned to proper operation no later than 30 working days. A delay in a repair may be attributed to unavailability of parts, the equipment requires a scheduled shutdown to complete the repair, or other good cause. The Division developed a list of standardized enhanced response actions to repair PCs with input from the oil and gas industry to be used for recordkeeping and annual reporting purposes. These include the following options to return a natural gas-driven PC to proper operation:

1. adjusted/tuned;
2. cleaned/removed debris;
3. tightened;
4. heated/insulated;
5. replaced part(s) of controller;
6. rebuilt controller with repair kit;
7. replaced controller; and
8. other.

Below is Figure 2 from the Division's 2018 LDAR Annual Report that shows the distribution of each type of response action, with a total of 4,060 actions reported. The two most common types of response action were to clean/remove debris, and to rebuild the pneumatic controller with a repair kit.

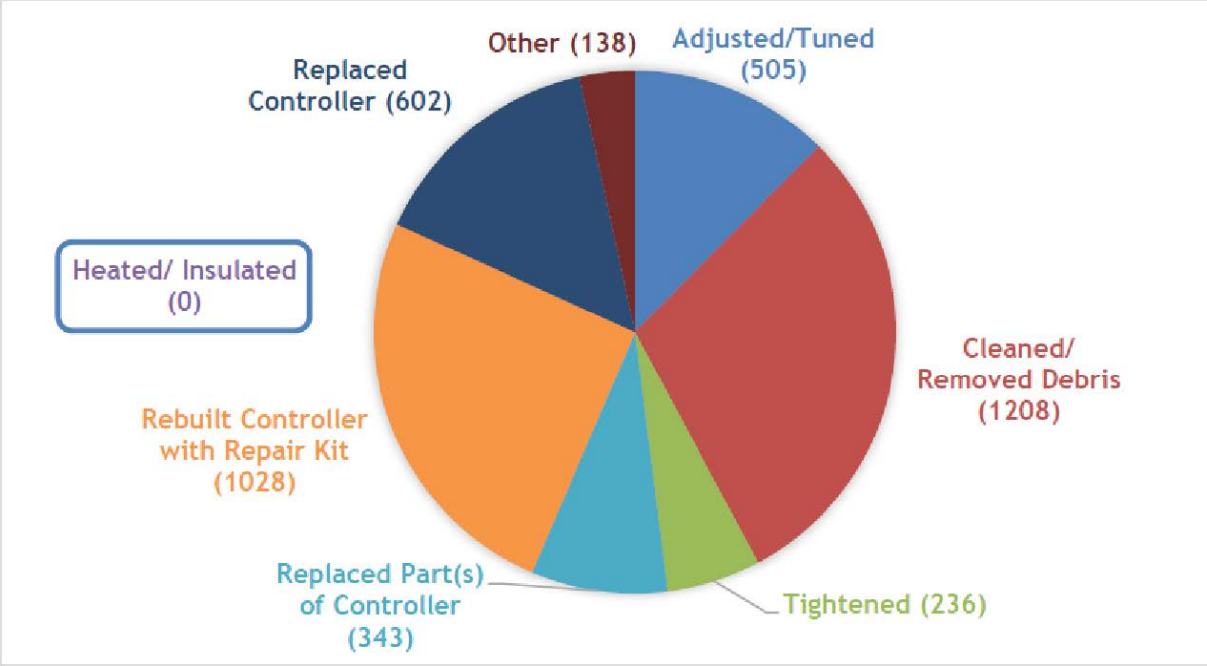


Figure 2: Enhanced response actions taken to return pneumatic controllers to proper operation, by enhanced response action category

Although not specific to natural gas-fired PCs, the Division's 2018 LDAR Annual Report on p.4 indicated that the use of an OGI camera was more effective than AVO observations during facility inspections for emission leaks from components. On page 4, the report states:

"Based on the data reported by owners/operators, more than 90% of leaks were identified through AIMM inspections despite AIMM inspections constituting only 3% of the total number of inspections at WPFs. While AVO inspections are valuable for operations and maintenance purposes, as well as being required by other sections of Regulation No. 7, the data from this year's LDAR annual reporting indicate that AIMM is a more effective monitoring method than AVO for detecting leaks."

Given the results from the 2018 PCTF field inspections, and the 2018 LDAR program and PC find and fix results, the PCTF believes the use of AIMM inspections using an OGI camera is an effective means for identifying both those emissions from PCs that indicate improper operation and from leaky LDAR components.

7.2 Definition Appropriateness

As discussed previously, due to the need to focus on regulatory proposals for consideration during the AQCC December 2019 rulemaking hearing, the PCTF did not complete its evaluation of the appropriateness of the current Reg 7 definitions related to PCs. However, revisions to these definitions will be included in the regulatory proposal specific to the use of no-bleed PCs (aka zero-bleed PCs). Currently, industry is developing a proposal that may be further modified through a future stakeholder and rulemaking process.

Stakeholder meetings will be scheduled and facilitated by the Division staff to review and solicit comments on the no-bleed PC regulatory proposal, which will include the need to make

appropriate revisions to PC-related definitions. As such, for the purposes of completing this report, the PCTF does not recommend making any changes at this time to the definitions for "enhanced response", "intermittent pneumatic controller", "no-bleed pneumatic controller", "self-contained pneumatic controller", or "pneumatic controller". Changes to these definitions will be considered separate from this report in vetting the regulatory proposal with stakeholders.

7.3 No-bleed and Self-contained PCs

As defined by Regulation 7 Part D Section III., a no-bleed PC is "any pneumatic controller that is not using hydrocarbon gas as the valve's actuating gas." Alternative actuating gases include compressor air or nitrogen, but in practice such PCs in Colorado are mainly compressed air, also known as instrument air. Instrument air systems utilize a skid-mounted compressor and often come with a dryer system to remove moisture from the air prior to compression. Once compressed, the air is routed through the same supply gas system that would otherwise contain pressurized natural gas to actuate the PCs.

As defined in Regulation 7 Part D Section III., a self-contained PC is "a pneumatic controller that releases gas to a process or sales line instead of to the atmosphere." Such PCs utilize natural gas as the actuating gas, but have minimal emissions to atmosphere because the vent port of the controller is routed back to a process line. Likewise, although not addressed in the current Regulation 7 rule language, emissions from the vent port of the PC can be routed to a control device in some limited applications. As previously mentioned and further discussed below, the use of self-contained PCs is very limited due to technical infeasibility, safety concerns, and cost.

Additionally, mechanical or electric controllers (non-pneumatic) can be used in some very limited applications as described below. These controllers are neither no-bleed or self-contained as defined by Regulation 7 and because they have no emissions, are not subject to the regulatory requirements. However, the PCTF included these controllers in the operator survey so they are also addressed below.

BCPH, DDPHE, and CC4CA Position:

SB181 directed the AQCC to consider a requirement to reduce emissions from pneumatic devices and in 2019 the AQCC directed the PCTF to develop recommendations on the use of zero-bleed pneumatic devices for rulemaking in 2020. Because the PCTF was unable to reach consensus on a recommendation, we believe the AQCC should direct the Division to continue its research and develop a proposal for the planned December 2020 rulemaking. Specifically, the Division should continue to research and put forth recommendations based on the information provided below by Earthjustice and CATF. No-bleed and self-contained PCs are a proven technology that should be implemented in Colorado. Furthermore, the successful implementation of solar-powered PCs in Canada points to the need for serious consideration of this technology in Colorado.

7.3.1 Current applications

As discussed above in Section 5.3, most of the no-bleed PCs in use in Colorado are in the DJ basin NAA and at newer multi-horizontal well pad facilities producing significant volumes of oil and gas. The PC field study also demonstrates that the majority of compressor stations in the NAA are currently operating or under construction to operate on instrument air.

Industry Position:

No-bleed controllers can generally be utilized on any piece of equipment that utilizes a natural gas actuated PC, but as detailed below, technical feasibility, safety concerns, other regulatory requirements, contractual obligations, and cost can all limit the ability of an owner or operator to utilize no-bleed PCs on some or all pieces of equipment at a facility.

Solar-powered PCs have recently been utilized in Alberta, Canada under specific operating conditions for where they are included in the design for a separator equipment package. However, industry believes that the array of solar batteries and battery storage has not yet been fully demonstrated to be sufficient and reliable for the power demands of well pads with multiple horizontal wells that produce significant volumes of oil and gas. As technology advances and costs decrease, the use of solar panels and battery storage to provide electrical power at large oil and gas production facilities may become feasible.

Industry is currently working on a regulatory proposal regarding the use of no-bleed PCs to be considered for a future AQCC rulemaking. This regulatory proposal will build on the work developed for a no-bleed PC emission mitigation strategy proposed under the SHER stakeholder process.

CATF/EJ Position:

Regulations currently in force in Alberta and British Columbia (BC) will significantly limit the use of venting gas-driven PCs moving forward. In BC, new facilities cannot use venting gas-driven PCs after January 1, 2021. Large compressor stations will require retrofit of all venting gas-driven PCs by January 1, 2022.[11] In Alberta, no new gas-driven venting PCs can be installed after January 1, 2022 (this regulation was very recently tightened – previously operators were to be allowed to use gas-driven venting controllers for up to 10% of new controllers after January 1, 2022).[12] Both provinces also will subject existing PCs, including intermittent PCs, to various emission limits.

Solar-powered PCs have been utilized for a number of years in Alberta where they are included in the design for separator equipment packages from certain manufacturers. Other operators have utilized similar solar-powered systems in custom configurations (for example to provide more electrical power and storage than is available in standard packages). Solar systems are used on both low-production wellsites and modern, high-production tight/shale wells.

This technology has proven reliable in Alberta north of 55°N latitude, where sunlight on a clear winter day is far weaker than in Colorado, snowfall is higher, winter cloud cover is much more common, and winter temperatures are much lower (affecting battery capacity). In short, CATF and EJ believe that there is no reason that this technology cannot succeed in Colorado.

[11] See BC Regulation 282/2010, §52.05.
http://www.bclaws.ca/civix/document/id/regulationbulletin/regulationbulletin/Reg286_2018
[12] See Alberta Energy Regulator (2020), "Directive 060 - Upstream Petroleum Industry Flaring, Incinerating, and Venting," §8.6.1. https://www.aer.ca/documents/directives/Directive060_2020.pdf

As noted above, there are also air compression systems designed for solar-powered sites on the market.

7.3.2 Effectiveness of devices

Industry Position:

Industry believes that the effectiveness of a no-bleed or self-contained PC is highly dependent on the application of the controller. The scope of the PCTF study did not evaluate the effectiveness of no-bleed PCs so no conclusions can be offered in this report. The consideration of the use of no-bleed PCs is being addressed under a SHER work group regulatory proposal as directed by SB 19-181.

CATF/EJ Position:

CAFT and EJ believe that previous work has documented the general applicability and reliability of solar-powered electric controllers;[13] this approach will be one of the key technologies allowing operators in Alberta and BC to comply with the provincial rules mentioned above.

7.3.3 Costs for new and retrofit facilities

Industry Position:

Based on operator survey results, the cost of instrument air systems (no-bleed pneumatic controllers) is highly variable and significantly higher for retrofits versus new installations.
The cost of self-contained PCs was not able to be ascertained through this study. However, industry has estimated that the cost to design the large and intricate vapor recovery system to capture these small emissions is significant and not cost-effective in most cases.

Likewise, industry estimates that the cost of routing controllers to a combustion device is prohibitively expensive unless the controller is located in close proximity to the control device (e.g. on the inlet to the control device itself).

Mechanical controllers, which can only be used for liquid level control in specific applications, were reported to have low capital costs, but higher maintenance costs than PCs based on operator survey results. Electric controllers were reported to cost significantly more, and also have higher maintenance costs, than PCs.

CATF/EJ Position:

The Conservation Groups' pneumatics proposal from the 2017 oil and gas rulemaking (which was also included as a SHER team proposal) was supported by an Economic Impact Assessment (EIA) documenting the cost-effectiveness of using zero-emitting approaches instead of gas-driven venting controllers. All cost calculations included in the Conservation Group's 2017 EIA include full costs for solar-powered electric systems, including: solar panels, batteries, and control panels and electronics; over-

[13] See Carbon Limits (2016), *Zero emission technologies for pneumatic controllers in the USA: Applicability and cost effectiveness.* https://www.catf.us/wp-content/uploads/2019/09/CL2016-ZeroEmitting-Pneumatics-Alts-1Aug2016.pdf

capacity for solar panels and batteries to ensure power will be available during (for example) extended cloudy periods in winter; electric actuators; installation; and maintenance. Operators report lower maintenance costs with electric systems than gas-driven systems when only wet gas is available to operate PCs, due to deleterious effects of wet gas on some PC components.[14]

In the 2017 rulemaking and as part of the SHER team, the Conservation Groups made available spreadsheets listing parameters for calculating cost-effectiveness, such as cost estimates for various components and labor, and engineering design assumptions such as the appropriate oversizing of solar panels and maximum allowable discharge from batteries.

7.3.4 Limitations and Barriers to expanded use

Industry Position:

In addition to cost, industry believes that there are technical, safety, regulatory, and land/leasehold concerns that limit the use of no-bleed and self-contained pneumatic controllers.

In terms of instrument air systems, operators must have sufficient grid or other power to run the instrument air skid and associated equipment. Further, some facilities will not have sufficient area at the facility to install the instrument air skid and associated infrastructure or may have landowner or regulatory restrictions on the grid power right of way or installation of additional equipment at the facility. Additionally, even where some controllers can be converted to instrument air there may be some processes that need to be controlled with natural gas-driven PCs for safety or technical reasons.

The biggest limitations to utilizing self-contained PCs or routing the vent port of the controller to a control device, aside from cost, are related to pressures. If there is not a process that is operating at a relatively low pressure then the pressure released from the vent port will not be sufficient to push the gas into the process line, potentially creating a safety hazard if a safety valve is not able to actuate against the process pressure. Additionally, beyond the cost of the amount of tubing that is required the route emissions from controllers that are located throughout a facility to a process line or control device, the longer that tubing is the more pressure differential (higher than the process or control device backpressure) is required to overcome the backpressure created by the tubing itself.

As mentioned previously, industry claims that mechanical and electric controllers can only be used to control liquid level and can only be used in certain applications (such as liquid level control). Additionally, mechanical controllers have been shown to be less accurate than PCs and electric controllers cannot typically be located on compressors due to vibration and require more technical knowledge to ensure safe application.

CATF/EJ Position:

[14] See Carbon Limits (2016) at p. 15.

As noted above, air compressors designed for solar-powered sites are on the market, as are packages systems that provide compressed air using hybrid electrical systems utilizing solar and batteries for the majority of the power they consume, with a gas-fired generator available as backup for the solar generation and battery. CATF and EJ believe that previous work has documented the general applicability and reliability of solar-powered electric controllers.[15]

7.3.5 Opportunities for expanded use

Industry Position:

Given the current state of technology, the use of electric and mechanical controllers is limited due to the limitation outlined in the section above. Industry believes that electric and mechanical controllers have very limited applications and cannot be used in the place of all traditional PCs at a facility. While there are extensive barriers that exist for retro-fitting existing facilities with instrument air, opportunity exists to expand the use of instrument air at new larger horizontal facilities that have sufficient grid power. Many of the land use and spacing limitations can be avoided if these systems are included during the planning phase. Additionally, there is a lower cost associated with installing a new system compared to retrofitting a location.

The ability to be able to plan for and allow utilities to commit to providing access to electrical grid power with sufficient power in advance of constructing new oil and gas production facilities represents a significant opportunity to expand the use of no-bleed PCs.

CATF/EJ Position:

CATF and EJ believe that zero-emitting technology can cost-effectively reduce emissions in Colorado at both new and existing sites. The CATF and EJ recommend that the AQCC consider requiring operators to utilize zero emitting pneumatic controllers statewide at all natural gas compressor stations and all well production facilities with four or more wells producing hydrocarbons so long as it is technically feasible to do so. CATF and EJ have previously offered this proposal in the 2017 oil and gas rulemaking and through the SHER team process. CATF and EJ believe that it is supported by the EIA and supporting spreadsheets, as well as the documented use of zero-emitting technology in Canada and the fact that venting PCs are being phased out for new facilities in British Columbia and Alberta.

8 Acknowledgments

The Division would like to thank all of the members of the PCTF for all of their time and hard work over the last two and a half years. The input from all stakeholders was vital to develop and implement what was the largest study of PCs to date. The information contained in this report is the culmination of thousands of hours of effort. The Division would also like to recognize the high level of engagement, collaboration, and resource expenditure from the industry members on the PCTF.

INSTRUCTIONS FOR COMPLETING THE DATA COLLECTION FORM FOR APCD PNEUMATIC CONTROLLER STUDY

MAY 9, 2018

These instructions serve to assist operators participating in the APCD's Pneumatic Controller (PC) Study specific to selected oil and gas facilities in the Front Range/Denver Metro Area Ozone Nonattainment Area (NAA) in the collection of data related to whether PCs in service at these facilities are operating properly.

It is important the persons conducting these inspections understand the focus of this study is limited to assessing the proper operation of PCs that are actuated using pressurized natural gas as a motive force and have the ability to vent to the atmosphere during normal operation. Leaks found to be originating from a component are not considered to represent improper operation of a PC. Instead, these observations should be considered leaks of components subject to a Leak Detection and Repair Program (LDAR).

Operators conducting these inspections of PCs at facilities selected for the purposes of this study will utilize concurrently an Audio, Visual and Olfactory (AVO) method along with an Approved Instrument Monitoring Method (AIMM) for each PC being inspected. Although other potential methods may be used to detect whether a PC is operating properly or not, these methods are not utilized by participating operators with facilities in the NAA and therefore will not be considered in the scope for Phase 1 of this study. Persons conducting these inspections of PCs for this study should strive to identify and document insights that were gained in applying methods in the field to determine whether a PC is properly operating or not. Although this form serves a purpose to document a specific inspection of a PC, the real value will be in being able to accurately describe what was done, observed or evaluated to determine if a PC was operating properly, along with any repairs necessary to a PC that was not operating properly.

General Instructions

- This form is to be used by an operator in conducting an inspection at a facility selected for the PC Study to document whether a PC is properly operating or not. As an option, the inspection data can also be captured using a flat table.
- If an inspector uses the form for data entry, one form is to be completed by the operator for each PC inspected at a facility. If the inspector uses the flat table rather than the form for data entry, one row in the table is to be completed for each PC inspected at a facility.
- PCs are not considered to be in service if the supply gas is depressurized; therefore, these out of service PCs are not to be inventoried or inspected for this study.
- For a PC that is found to be operating properly, the form or table row must be completed through the Inspection Information section.
- For PC that is found to be operating improperly, the entire form or table row must be completed including the Repair Information section. Neither the repair nor the Repair Information section must be completed at the time of the inspection. If the repair is not successfully completed at the time of the inspection, the details of the successful repair must be added to the form or flat table once completed.

NMED Exhibit 93

- The confirmation of successful repair does not need to be completed at the time of the repair. The details of the repair confirmation must be added to the form or flat table once completed.
- The data collection form is provided in an Excel format tied to a flat table that can be used to compile the data for each PC inspected at a facility. Although the use of the electronic version of this form is encouraged, a hard copy of the form can be used in the field if the dropdown options are used appropriately and consistently with those in the electronic form. However, this will require that the data in the hard copy of the form be re-entered into the Excel form or flat table so that the data can be compiled for subsequent reporting.

Specific Instructions

- The specific instructions herein address the completion of individual subject fields in the data collection form or flat table.
- An asterisk symbol (*) next to the data field indicates that a dropdown menu of options exists for this specific field. To open the dropdown menu, click on the data field until the down arrow symbol is highlighted to the right of the data field and then click on this symbol. Select by clicking the option that correctly describes the characteristic specific to the PC inspected. Only one option can be selected for each data field with a dropdown menu.
- The "Other" option for a specific data field is to be used when none of the options in the dropdown menu applies to the PC. When none of the specific dropdown options apply, select the "other" option from the dropdown menu and enter as text the information in the separate "Other" data field.
- Use the additional notes data field provided in each section of the form to add free form text describing noteworthy information relevant to the inventory, inspection, or repair sections.

General Information Section

Inspector – Enter the first and last name of the person performing the inspection of the PC.

Pad/Battery/Facility/Location – Enter the operator's designated name of the facility.

Facility ID – Enter the blinded ID designated by Spirit Env. for the facility being inspected. Each operator will be provided a list of facilities randomly selected for inspection by Spirit Env. and each facility selected will have a Blinded ID.

Date – Enter the date when the inspection of the PC was conducted using the numerical month/day/year format (xx/xx/xxxx).

Time – Enter the approximate time that the inspection of the PC started in a numerical format (xx:xx) with an AM or PM designation.

Ambient Temperature - Enter the approximate temperature at the time that the inspection started in Fahrenheit degrees.

Wind Speed - Enter the approximate wind speed at the time that the inspection started in miles per hour.

Inventory Information Section

Manufacturer* – Select the manufacturer of the PC if known. The dropdown options represent PC manufacturers that are believed to be common in the DJ Basin, yet may not cover all makes. If not listed, select "Other" as a dropdown option and enter the full manufacturer name using text in the separate "Other" data field. If the manufacturer is unknown or not certain, take a photograph of the PC and later attempt to confirm the manufacturer of the PC using available information.

Family – This data field is to be completed, as applicable, if the manufacturer of the PC uses a family classification to describe its line of PCs. If no family classification exists, leave this data field blank.

Model* – Select the model of the PC if known. The dropdown options represent PC models that are believed to be common in the DJ Basin, yet may not cover all models. If not listed, select "Other" as a dropdown option and enter the model as text in the separate "Other" data field. If the model is unknown or not certain, take a photograph of the PC and later attempt to confirm the model of the PC using available information. Please be careful in selecting the correct model as some model designations may vary slightly in their labeling.

Sensed Variable* – This data field describes the process variable that the PC is controlling. Dropdown options include pressure, temperature, position, differential pressure, and level. If the process variable is not listed, select "Other" as a dropdown option and describe the variable using text in the separate "Other" data field.

Type* – This data field distinguishes the type of PC being inspected in terms of its configuration. Only three options exist: integrated, pilot or other. An integrated PC refers to a PC that has both the sensing and actuating components contained in one housing. A pilot PC describes a PC that senses a signal and remotely actuates a device that is not contained in the same housing. If the type is not listed, select "Other" as a dropdown option and describe the type by entering text in the separate "Other" data field.

Supply Pressure & Source

- This data field records the pressure of the natural gas being applied as a motive force to the PC being inspected. If a pressure gauge exists on the supply line to the PC being inspected, record the pressure reading of the gauge. If no pressure gauge is present, then enter "None" in this data field. Do not enter "zero" or "0" instead of "None" as this suggests that there is zero pressure, or the gauge is broken.
- The data field for "Source" refers to where the source of the natural gas as a motive force originates from and the dropdown options include wellhead, separator, pipeline quality or "Other". To confirm the source of the gas, the supply tubing to the PC being inspected may have to be followed to its point of origin. If the source of the natural gas is not listed, select "Other" as a dropdown option and describe the source using text in the separate "Other" data field.

Primary Function* – This data field describes the primary function that the PC being inspected. Only two options apply to this data field: process control or safety. An "Other" option is not

available. The safety option should be selected where the PC is used to isolate a pressure source or cease operation of a process.

Vent Type* – This data field describes how the PC being inspected vents during an actuation cycle. Three dropdown options are available: a continuous high bleed (> 6scf/hr); a continuous low bleed (< 6 scf/hr); and an intermittent bleed. An "Other" option is not available. To determine the correct vent type, the operators should research the vent type classified by the manufacturer for the model of the PC being inspected. Measurement of the actual vent rate is not required for this study.

Vent Control Type* – This data field describes whether the vent from the PC being inspected is captured and routed. Three dropdown options are available: vented to atmosphere; captured and routed to sales or process; or captured and routed to a flare/combustor header. An "Other" option is not available. To determine the correct option, the operator may need to follow the vent tubing to the point where it connects to piping and determine whether the piping connects to a process or sales line, or a flare/combustion device.

Equipment Location* – This data field describes the equipment associated with the PC being inspected in terms of its purpose to control the equipment's operation. Available dropdown options include: wellhead, separator, heater, combustor, compressor engine, generator, dehydrator (dehydration unit), and other. If the type of equipment is not listed, select "Other" as a dropdown option and enter the type of equipment using text in the separate "Other" data field.

Service Type* – This data field describes the service of the PC being inspected in terms of how the process variable is controlled. The dropdown options are: on/off, throttling, or unknown. An "Other" option is not available. If the inspector is unsure of whether a PC is on/off or throttling, the inspector should select unknown.

Name/Description – This data field provides a more specific description of the piece of equipment so that the PC being inspected can be identified and located, especially at facilities where there is more than one of the same equipment type (i.e. heater treater 4, water dump). No dropdown menu is available.

Is PC Enclosed? – This data field provides a yes or no answer to whether the PC is located within some type of enclosure that shields the PC from the elements such as a hinged case, a cabinet, or building. Answer "No" if no enclosure exists around the PC being inspected.

Enclosure Type (If Not Exposed to Elements) – This data field is to be completed only if the PC is enclosed as indicated by a "Yes" response to the previous data field. Three dropdown options exist for a "Yes" response: inside separator cabinet, inside compressor enclosure, or inside other enclosure? An "Other" option is not available.

Additional Notes – This data field is a text box that allows additional information to be provided that are worth noting to describe conditions specific to the facility, equipment or PC being inspected.

Inspection Information Section

Operating Properly – This data field identifies whether the PC being inspected is operating properly. Two dropdown options exist: Yes or No. An "Other" option is not available. If the "Yes" option is selected because the PC is found to be operating properly, ~~then~~ then do not complete the Detection Method data field below ~~must be completed~~. If the "No" option is selected because the PC is found to not be operating properly, then ~~do not~~ complete the Detection Method data field below.

Actuation Observed – This data field identifies whether the PC being inspected was observed to actuate during the inspection. Three dropdown options exist: Yes, No or Unknown. An "Other" option is not available.

Detection Method – This data field identifies the method used to detect whether a PC is not operating properly ~~or not~~. This data field must be completed only if the "No~~Yes~~" option is selected for the "Operating Properly" data field above. Three dropdown options exist: Audio-Visual-Olfactory (AVO) Only, Approved Instrument Monitoring Method (AIMM) Only, and AVO/AIMM. An "Other" option is not available.

- AVO refers to hearing, seeing or smelling something that indicates a PC is not operating properly. Indicators associated with hearing may include hissing or clicking. Detection of a hydrocarbon odor near a PC may not be telltale yet could still indicate a process is not being controlled properly due to an improper operation of a PC. AVO to be selected as a dropdown option when this method was able to independently determine that a PC was not operating properly.
- AIMM refers to methods approved for use by APCD under Reg 7 such as an optical gas imaging (OGI) camera. For the purposes of this PC study for the NAA, an OGI camera will be the only AIMM used. AIMM is to be selected as a dropdown option when this method was able to identify that a PC was not operating properly and AVO was not able to independently make this determination.
- AVO/AIMM is to be selected as a dropdown option when both methods in concert were required to detect that a PC was not operating properly.

Emissions Location – This data field identifies where emissions are detected from a PC being inspected that is not operating properly. Three dropdown options exist: Vent Port, Body or "Other". If the emission location is other than the Vent Port of Body, then select "Other" as a dropdown option and enter a description using text in the separate "Other" data field. Emissions from supply tubing connections or other components do not represent improper operation of a PC.

Indication of Proper Operation – This data field describes what indicator(s) were found that led to a determination that the PC being inspected was not operating properly. Two data fields with dropdown menus with options are provided including an "Other" option. If the indicator is not listed in the dropdown menu, then select "Other" as a dropdown option and enter a description using text in the separate "Other" data field. If there are more than two indicators, use the Other field to enter text describe any additional indicators.

Additional Notes – This data field is a text box that allows additional information worth noting specific to the PC being inspected. These notes can be used to provide further insight into what was done, observed or evaluated during the inspection to determine whether the PC was operating properly or not.

Repair Information Section

Primary Cause of Improper Operation – This data field identifies the primary cause of improper operation of the PC being inspected. Ten dropdown options are provided including an "Other" option. Select the option that is believed to be the primary cause. If the primary cause is not listed in the dropdown menu, then select "Other" as an option and enter a description using text in the separate "Other" data field.

Repair Date - Enter the date when the repair of the PC that was found to be operating improperly was successfully completed using the numerical month/day/year format (xx/xx/xxxx).

PC Repair Method – This data field identifies the method(s) applied to repair the PC that was inspected and found to be operating improperly. Eleven dropdown options are provided including an "Other" option. Select the option that best represents the repair method necessary to return the PC to proper operation. If the repair method applied is not listed in the dropdown menu, then select "Other" as an option and enter a description using text in the separate "Other" data field.

Did the Repair Require a double block and bleed? Shutdown and purge equipment to atmosphere? Shutdown of the well? - These data fields describe whether any of the listed actions were necessary to make the repair of the PC that was found to be operating improperly. A Yes or No response is needed for each of the three actions listed. An "Other" option is not available.

PC Repair Confirmation Method – This data field identifies the method used to confirm that the PC repair was successful to restore the PC to proper operation. Five dropdown options exist: AIMM, AVO, Soapy Water, Method 21, and Physical Inspection. Select the method used to confirm a successful repair. An "Other" option is not available.

Repair Time Onsite – This data field documents the amount of time needed once onsite to complete the successful repair of a PC found to be operating improperly. Enter the amount of time in hours using 15-minute increments (i.e. 0.25, 0.5, 0.75, 1.0, 1.25, 1.50, etc.). Repair Travel Time (if required) – This data field documents the travel time needed to visit the facility to make a necessary repair of a PC found to be improperly operating. This travel time information is only required if a separate trip is needed to make the repair separate from the trip made to conduct the inspection for this study. Enter the amount of time in hours using 15-minute increments (i.e. 0.25, 0.5, 0.75, 1.0, 1.25, 1.50, etc.)

Re-Inspection Date – Enter the date when re-inspection of a PC that was subject to repair was completed to confirm its proper operation using the numerical month/day/year format (xx/xx/xxxx).

PC Repair Re-Inspection Method – This data field identifies the method used to re-inspect a PC that was subject to repair. Three dropdown options are provided – AIMM, AVO or soapy water. Select the method used to confirm the successful repair. An "Other" option is not available.

Additional Notes - This data field is a text box that allows additional information worth noting specific to the PC being repaired and re-inspected. These notes can be used to provide further insight into what was done, observed or evaluated to successfully complete the repair and confirm the repair during the re-inspection to demonstrate that the PC was returned to proper operation.

PLEASE CHECK THAT THE FORM IS COMPLETE AFTER EACH INSPECTION AND IF A REPAIR IS REQUIRED.

RIN 2060–AS37

Greenhouse Gas Reporting Rule: 2015 Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: The Environmental Protection Agency (EPA) is finalizing revisions and confidentiality determinations for the petroleum and natural gas systems source category of the Greenhouse Gas Reporting Rule. These revisions include the addition of calculation methods and reporting requirements for greenhouse gas (GHG) emissions from gathering and boosting facilities, completions and workovers of oil wells with hydraulic fracturing, and blowdowns of natural gas transmission pipelines between compressor stations. The revisions also include the addition of well identification reporting requirements to improve the EPA's ability to verify reported data and enhance transparency. This action also finalizes confidentiality determinations for new data elements contained in these amendments.

DATES: This final rule is effective on January 1, 2016.

ADDRESSES: The EPA has established a docket for this action under Docket ID No. EPA–HQ–OAR–2014–0831. All documents in the docket are listed on the *http://www.regulations.gov* Web site. Although listed in the index, some information is not publicly available, *e.g.,* confidential business information (CBI) or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, is not placed on the Internet and will be publicly available only in hard copy form. Publicly available docket materials are available electronically through *http://www.regulations.gov.*

FOR FURTHER INFORMATION CONTACT: Carole Cook, Climate Change Division, Office of Atmospheric Programs (MC–6207A), Environmental Protection Agency, 1200 Pennsylvania Ave. NW., Washington, DC 20460; telephone number: (202) 343–9263; fax number: (202) 343–2342; email address: *GHGReportingRule@epa.gov.* For technical information, please go to the Greenhouse Gas Reporting Rule Web site, *http://www.epa.gov/ghgreporting/.* To submit a question, select Help Center, followed by ''Contact Us.''

Worldwide Web (WWW). In addition to being available in the docket, an electronic copy of this final rule will also be available through the WWW. Following the Administrator's signature, a copy of this action will be posted on the EPA's Greenhouse Gas Reporting Rule Web site at *http://www.epa.gov/ghgreporting/index.html.*

SUPPLEMENTARY INFORMATION:

Regulated Entities. This final rule adds calculation methods, monitoring, and data reporting requirements and finalizes confidentiality determinations for the petroleum and natural gas systems source category of the Greenhouse Gas Reporting Rule (40 CFR part 98). The Administrator determined that 40 CFR part 98 is subject to the provisions of Clean Air Act (CAA) section 307(d). See CAA section 307(d)(1)(V) (the provisions of section 307(d) apply to ''such other actions as the Administrator may determine''). Entities affected by this final rule are owners and operators of petroleum and natural gas systems that directly emit GHGs, which include those listed in Table 1 of this preamble:

TABLE 1—EXAMPLES OF AFFECTED ENTITIES BY CATEGORY

Category	NAICS [a]	Examples of affected facilities
Petroleum and Natural Gas Systems	211111	Crude petroleum and natural gas extraction.
	211112	Natural gas liquid extraction.
	221210	Natural gas distribution.
	486210	Pipeline transportation of natural gas.

[a] North American Industry Classification System.

Table 1 of this preamble is not intended to be exhaustive, but rather provides a guide for readers regarding facilities likely to be affected by this action. Types of facilities other than those listed in the table could also be subject to reporting requirements. To determine whether you are affected by this action, you should carefully examine the applicability criteria found in 40 CFR part 98, subpart A and 40 CFR part 98, subpart W. If you have questions regarding the applicability of this action to a particular facility, consult the person listed in the preceding **FOR FURTHER INFORMATION CONTACT** section.

What is the effective date? The final rule is effective on January 1, 2016.

Judicial Review. Under CAA section 307(b)(1), judicial review of this final rule is available only by filing a petition for review in the U.S. Court of Appeals for the District of Columbia Circuit (the Court) by December 21, 2015. Under CAA section 307(d)(7)(B), only an objection to this final rule that was raised with reasonable specificity during the period for public comment can be raised during judicial review. Section 307(d)(7)(B) of the CAA also provides a mechanism for the EPA to convene a proceeding for reconsideration, ''[i]f the person raising an objection can demonstrate to the EPA that it was impracticable to raise such objection within [the period for public comment] or if the grounds for such objection arose after the period for public comment (but within the time specified for judicial review) and if such objection is of central relevance to the outcome of the rule.'' Any person seeking to make such a demonstration to us should submit a Petition for Reconsideration to the Office of the Administrator, Environmental Protection Agency, Room 3000, William Jefferson Clinton Building, 1200 Pennsylvania Ave. NW., Washington, DC 20460, with a copy to the person listed in the preceding **FOR FURTHER INFORMATION CONTACT** section, and the Associate General Counsel for the Air and Radiation Law Office, Office of General Counsel (Mail Code 2344A), Environmental Protection Agency, 1200 Pennsylvania Ave. NW., Washington, DC 20004. Note that under CAA section 307(b)(2), the requirements established by this final rule may not be challenged separately in any civil or criminal proceedings brought by the EPA to enforce these requirements.

I. Background

A. Organization of This Preamble

Section I of this preamble provides background information regarding the origin of the final amendments. This section also discusses the EPA's legal authority under the CAA to promulgate and amend 40 CFR part 98 of the Greenhouse Gas Reporting Rule (hereafter referred to as ''part 98'') as well as the legal authority for making confidentiality determinations for the data to be reported. Section II of this preamble contains information on the final amendments to part 98, subpart W (Petroleum and Natural Gas Systems) (hereafter referred to as ''subpart W''), including a summary of the major comments that the EPA considered in the development of this final rule. Section III of this preamble discusses the final confidentiality determinations for new data reporting elements. Section IV of this preamble discusses the impacts of the final amendments to subpart W. Finally, Section V of this preamble describes the statutory and executive order requirements applicable to this action.

B. Background on This Action

The EPA's Greenhouse Gas Reporting Program (GHGRP) requires annual reporting of GHG data and other relevant information from large sources and suppliers in the United States. On October 30, 2009, the EPA published part 98 for collecting information regarding GHG emissions from a broad range of industry sectors (74 FR 56260). Although reporting requirements for petroleum and natural gas systems were originally proposed to be part of part 98 (75 FR 16448; April 10, 2009), the final October 2009 rule did not include the petroleum and natural gas systems source category as one of the 29 source categories for which reporting requirements were finalized. The EPA re-proposed subpart W in 2010 (79 FR 18608; April 12, 2010), and a subsequent final rule was published on November 30, 2010, with the requirements for the petroleum and natural gas systems source category at 40 CFR part 98, subpart W (75 FR 74458) (hereafter referred to as ''the final subpart W rule''). Following promulgation, the EPA finalized actions revising subpart W (76 FR 22825, April 25, 2011; 76 FR 59533, September 27, 2011; 76 FR 80554, December 23, 2011; 77 FR 51477, August 24, 2012; 78 FR 25392, May 1, 2013; 78 FR 71904, November 29, 2013; 79 FR 63750, October 24, 2014; 79 FR 70352, November 25, 2014).

On December 9, 2014, the EPA proposed ''2015 Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' (79 FR 76267) to require the reporting of GHG emissions from several sources that had not previously been included in subpart W. These sources include completions and workovers of oil wells with hydraulic fracturing, petroleum and natural gas gathering and boosting systems, and transmission pipeline blowdowns between compressor stations. The reporting requirements for completions and workovers of oil wells with hydraulic fracturing were proposed to be included as part of the existing Onshore Petroleum and Natural Gas Production industry segment. For the other sources, the EPA proposed two new industry segments: The Onshore Petroleum and Natural Gas Gathering and Boosting segment for petroleum and natural gas gathering and boosting facilities, and the Onshore Natural Gas Transmission Pipeline segment for transmission pipeline blowdowns between compressor stations. The EPA also proposed to require the reporting of a well identification number for oil and gas wells covered in the Onshore Petroleum and Natural Gas Production segment. In addition, the EPA proposed confidentiality determinations for new data elements contained in the proposed amendments. The public comment period for these proposed rule amendments ended on February 24, 2015, following a 2-week extension of the original comment period end date (80 FR 6495; February 5, 2015).

In this action, the EPA is finalizing additions and revisions to the subpart W calculation, monitoring, and reporting requirements for new sources, with some changes made in response to public comments. Responses to comments submitted on the proposed amendments can be found in sections II, III, and IV of this preamble as well as in ''Response to Public Comments on Greenhouse Gas Reporting Rule: 2015 Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' in Docket ID No. EPA–HQ–OAR–2014–0831. As noted in the preamble to the proposed amendments (79 FR 73148; December 9, 2014), these additions and revisions further the EPA's goals of improving the completeness, quality, accuracy, and transparency of data from this sector, and improving the ability of agencies and the public to use these GHG data to analyze emissions and understand emission trends.

The *Strategy to Reduce Methane Emissions* in the President's *Climate Action Plan* summarizes the sources of methane (CH_4) emissions, commits to new steps to cut emissions of this potent GHG, and outlines the Administration's efforts to improve the measurement of these emissions. The strategy builds on progress to date and takes steps to further cut CH_4 emissions from several sectors, including the oil and natural gas sector. In the strategy, the EPA was tasked to review regulatory requirements to address potential gaps in coverage, improve methods, and help ensure high quality data reporting.[1] The final revisions to subpart W covered in this action are responsive to this task by addressing data gaps in subpart W, specifying methods for measuring CH_4 emissions, and providing data that can be used to further analyze CH_4 emissions in this industry.

This action also addresses a petition the EPA received from a group of non-government organizations (NGOs) requesting that the EPA collect data from emissions sources not currently included in subpart W, including well completion emissions from oil wells that co-produce natural gas, facilities and pipelines in the gathering and boosting segment, and transmission pipeline blowdown events (''Petition for Rulemaking'').[2] Table 2 of this preamble summarizes how the EPA has responded to the Petition for Rulemaking. These revisions, and previously finalized revisions where noted in Table 2, reflect the EPA's complete response to the Petition for Rulemaking. It is our position that we have fully responded to the NGO petition, however, any requests included in the petition that have not been responded to in Table 2 are considered denied.

TABLE 2—EPA RESPONSE TO PETITION FOR RULEMAKING

Request in petition	EPA's response	Final rule citations (40 CFR)
Clarify that oil wells that co-produce natural gas (''co-producing wells''), specifically wells in tight-oil formations like the Bakken and Eagle Ford, are subject to the completion reporting requirements as currently written. Expand the well completion reporting requirements to all wells, ensuring co-producing wells in any formation type are required to report completion emissions.	The EPA is not changing the definition of ''gas well'' or ''oil well.'' Instead, the EPA is amending subpart W to require the reporting of GHG emissions from completions and workovers with hydraulic fracturing for wells in the Onshore Petroleum and Natural Gas Production segment, regardless of whether their primary product is oil or natural gas.	98.232(c)(6) 98.232(c)(8) 98.236(g)
Require reporting from facilities and pipelines in the gathering and boosting segment of the natural gas industry.	The EPA is finalizing the proposal to amend subpart W to add a new industry segment, Onshore Petroleum and Natural Gas Gathering and Boosting, which covers emissions from equipment used by gathering pipeline systems that move petroleum and natural gas from the well to either larger gathering pipeline systems, natural gas processing plants, natural gas transmission pipelines, or natural gas distribution pipelines.	98.230(a)(9) 98.232(j) 98.233 (various) 98.236(a)(9)
Require reporting from transmission pipeline blowdown events.	The EPA is finalizing the proposal to add reporting requirements for emissions from natural gas transmission pipeline blowdowns between compressor stations in a new Onshore Natural Gas Transmission Pipeline segment.	98.230(a)(10) 98.232(m) 98.236(aa)(11)
Require reporters to include API well identification numbers along with their submissions to help the public and policymakers understand which sources are reporting and how the threshold may be adjusted to most effectively provide emissions information.	The EPA is requiring the reporting of well identification numbers for the Onshore Petroleum and Natural Gas Production segment for information related specifically to wells.	98.236(f), (g), (h), (l), and (m) 98.238
Phase out the use of best available monitoring methods (BAMM), which will further help to ensure Subpart W data are rigorous, and comprehensive.	Prior to these amendments, BAMM was discontinued for all sources except specific sources that were affected by the amendments finalized on November 25, 2014 (79 FR 70352); those BAMM provisions will be unavailable after December 31, 2015. Reporters will be allowed to use BAMM for the 2016 reporting year for only the new industry segments and emission sources included in this action. The EPA is not allowing the use of BAMM beyond 2016.	98.234(f) and (g)

TABLE 2—EPA RESPONSE TO PETITION FOR RULEMAKING—Continued

Request in petition	EPA's response	Final rule citations (40 CFR)
Consider including advanced innovative monitoring methods as a way to accelerate development and deployment of real-time continuous CH_4 emission monitoring in the oil and natural gas sector.	The agency is assessing the potential opportunities for application of remote sensing technologies and other innovations in measurement or monitoring technology to identifying and calculating emissions from affected sources under subpart W and requested comment in the proposal. The EPA received multiple comments in response to the request for comments on the feasibility, possible regulatory approaches, and provisions necessary to incorporate or allow the use of advanced measurement or monitoring methods in subpart W. All of the comments received are included in "Response to Public Comments on Greenhouse Gas Reporting Rule: 2015 Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems" in Docket ID No. EPA–HQ–OAR–2014–0831. The EPA is not including provisions related to advanced measurement or monitoring methods in this rule and is not responding to these comments in this rulemaking. Instead, following review of the data and information received in comments, the EPA may propose amendments related to the use of innovative technologies in reporting to the GHGRP in a future rulemaking.	

Legal Authority

The EPA is finalizing these rule amendments under its existing CAA authority provided in CAA section 114. As stated in the preamble to the 2009 final GHG reporting rule (74 FR 56260; October 30, 2009), CAA section 114(a)(1) provides the EPA broad authority to require the information to be gathered by this rule because such data would inform and are relevant to the EPA's carrying out a wide variety of CAA provisions. See the preambles to the proposed (74 FR 16448; April 10, 2009) and final GHG reporting rule (74 FR 56260; October 30, 2009) for further information.

In addition, pursuant to sections 114, 301, and 307 of the CAA, the EPA is publishing final confidentiality determinations for the new data elements required by these amendments. Section 114(c) requires that the EPA make information obtained under section 114 available to the public, except for information that qualifies for confidential treatment. The Administrator has determined that this action is subject to the provisions of section 307(d) of the CAA.

D. How do these amendments apply to 2015 and 2016 reports?

These amendments are effective on January 1, 2016. Thus, beginning on January 1, 2016, facilities must follow the revised methods in subpart W, as amended, to calculate emissions occurring during the 2016 calendar year (*i.e.,* reporting year 2016). The first annual reports of emissions calculated using the amended requirements will be those submitted by March 31, 2017, covering reporting year 2016. For reporting year 2015, reporters will continue to calculate emissions and other relevant data for the reports that are submitted according to the requirements in part 98 that are applicable to reporting year 2015 (*i.e.,* the requirements in place until the effective date of this final rule).

For reporting year 2016 only, we are allowing the use of best available monitoring methods (BAMM) on a short-term transitional basis for facilities new to reporting under subpart W as well as reporters of facilities subject to new monitoring requirements associated with these revisions. Reporters have the option of using BAMM for only the new industry segments and emission sources included in this action from January 1, 2016, to December 31, 2016, without seeking prior EPA approval. The EPA will not accept requests for an extension for the use of BAMM beyond the time periods listed above. The EPA is not allowing the use of BAMM for the new well identification number provisions in the Onshore Petroleum and Natural Gas Production segment because the well identification number is not a parameter that requires monitoring equipment to be measured and, therefore, does not meet the requirements for BAMM. In addition, reporters should already have well identification numbers readily available for all wells and associated equipment to which this reporting requirement applies. See section II.E of this preamble for more information.

II. Summary of Final Revisions and Other Amendments to Subpart W and Responses to Public Comment

In this action, the EPA is amending subpart W to require the reporting of GHG emissions from completions and workovers of oil wells with hydraulic fracturing as part of the existing Onshore Petroleum and Natural Gas Production industry segment. The EPA is also adding requirements for two new industry segments: the Onshore Petroleum and Natural Gas Gathering and Boosting segment for petroleum and natural gas gathering and boosting systems, and the Onshore Natural Gas Transmission Pipeline segment for transmission pipeline blowdowns between compressor stations. Finally, the EPA is requiring the reporting of well identification numbers for oil and gas well-specific information (*e.g.,* completions and workovers, associated gas venting and flaring) reported in the Onshore Petroleum and Natural Gas Production segment. The comments received on this rule generally did not dispute the merit of adding these new segments and sources to subpart W, but they did provide a number of suggestions regarding the technical details of monitoring, reporting, and applicability.

Sections II.A through II.E of this preamble describe the requirements and other amendments that we are finalizing in this rulemaking. Section II.A describes the final amendments for the

reporting of GHG emissions from completions and workovers of oil wells with hydraulic fracturing. Section II.B describes the final amendments for the reporting of GHG emissions from sources in the new Onshore Petroleum and Natural Gas Gathering and Boosting segment. Section II.C describes the final amendments for the reporting of GHG emissions from sources in the new Onshore Natural Gas Transmission Pipeline segment. Section II.D describes the requirements for reporting well identification numbers for the Onshore Petroleum and Natural Gas Production segment. Finally, section II.E provides a summary of the final amendments to the best available monitoring method requirements. The amendments described in each section are followed by a summary of the major comments on those amendments and the EPA's responses. See ''Response to Public Comments on Greenhouse Gas Reporting Rule: 2015 Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' in Docket ID No. EPA–HQ–OAR–2014–0831 for a complete listing of all comments and the EPA's responses.

Finally, in the preamble to the proposed rule, the EPA stated that the agency is ''assessing the potential opportunities for applying remote sensing technologies and other innovations in measurement or monitoring technology to identifying and calculating emissions from affected sources under subpart W'' (79 FR 73148; December 9, 2014). The EPA did not propose, and therefore is not finalizing, any amendments to subpart W to this effect, but the EPA did request comment on the feasibility, possible regulatory approaches, provisions necessary to incorporate or allow the use of advanced measurement or monitoring methods in subpart W, and methods to ensure compliance with those provisions in an efficient manner. The EPA also requested comment on the memorandum ''Discussion Paper on Potential Implementation of Alternative Monitoring under the GHGRP'' in Docket ID No. EPA–HQ–OAR–2014–0831. All of the comments received are included in ''Response to Public Comments on Greenhouse Gas Reporting Rule: 2015 Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' in Docket ID No. EPA–HQ–OAR–2014–0831. The EPA will consider these comments in the context of any future action related to alternative monitoring.

The amendments in this action will advance EPA's goal of maximizing rule effectiveness. For example, these amendments provide clear monitoring, calculation and reporting requirements for new segments and sources in subpart W, thus enabling government, regulated entities, and the public to easily identify and understand rule requirements. In addition, specific changes such as increasing the flexibility and time period for transitional BAMM will make compliance easier than non-compliance.

These amendments will also improve the EPA's ability to assess compliance by adding reporting elements that allow the EPA to more thoroughly verify greenhouse gas data and understand trends in emissions. For example, the requirement for the Onshore Petroleum and Natural Gas Production segment to report well identification numbers will allow the EPA to link GHGRP data with other data sources and assess the completeness and representativeness of the data collected relative to all activity in the U.S. oil and gas production sector. Lastly, these amendments further advance the ability of the GHGRP to provide access to quality data on greenhouse gas emissions by adding key petroleum and natural gas emission sources to this program. One example is the addition of the Onshore Petroleum and Natural Gas Gathering and Boosting segment, a significant greenhouse gas emissions segment that had not been previously covered under the GHGRP.

A. Summary of Final Amendments for Oil Wells With Hydraulic Fracturing

1. Summary of Final Amendments

The EPA is amending subpart W to require the reporting of GHG emissions from completions and workovers with hydraulic fracturing for wells in the Onshore Petroleum and Natural Gas Production segment, regardless of whether their primary product is oil or natural gas. In general, commenters supported inclusion of emissions from completions and workovers of oil wells with hydraulic fracturing in subpart W, and a few commenters provided targeted technical edits and suggestions for this source. Consistent with the requirements for completions and workovers of gas wells with hydraulic fracturing, and consistent with the proposed requirements, the new provisions include the reporting of activity data on the number of completions and workovers of oil wells with hydraulic fracturing and on the use of flaring and reduced emission completions (RECs). In response to public comments, the final monitoring and reporting amendments do not apply to completions and workovers of oil wells with hydraulic fracturing that have a gas to oil ratio (GOR) of less than 300 standard cubic feet per stock tank barrel (scf/STB).

The EPA is also amending the equations and definitions in 40 CFR 98.233(g) to reflect applicability to completions and workovers of all gas and oil wells with hydraulic fracturing. As in the proposal, the final amendments require the use of either Equation W–10A or W–10B for calculating GHG emissions from completions and workovers of oil wells with hydraulic fracturing. Equation W–10A is used to calculate emissions from wells using inputs obtained from a representative sample of wells within a sub-basin and the ratio of the gas flowback rate to the production flow rate, and Equation W–10B is used to calculate emissions using inputs obtained from all wells within a sub-basin and the flow rate and flow volume of the gas vented or flared. As proposed, the EPA is finalizing that emissions be calculated and reported separately for gas wells and oil wells by sub-basin and well type combination.[3] Furthermore, as proposed, the final amendments require the use of Calculation Method 1 for calculating inputs to Equations W–12A and W–12B for oil wells. Calculation Method 1 relies on direct measurement of gas flow rate during flowback to develop calculation inputs; the requirements for the location of the flow meter used to measure the gas flow rate for oil wells are the same as the location requirements for gas wells. Other provisions that apply to completions and workovers of gas wells with hydraulic fracturing also apply to completions and workovers of oil wells with hydraulic fracturing, including the determination of wells that constitute a representative sample for use in Equation W–10A.

For oil wells that do not meter gas production, such as some wells with a relatively low GOR, the EPA is adding a new Equation W–12C as proposed to calculate, rather than measure, the value of $PR_{s,p}$ (the average gas production flow rate during the first 30 days of production after the completion or workover), which is used as an input to Equation W–10A. In this Equation W–12C, the value of $PR_{s,p}$ is calculated by multiplying the GOR of the well by the measured oil production rate over the

[3] Within subpart W, an individual well is labeled an ''oil well'' or ''gas well'' depending on the formation type reported for that well. If wells produce from more than one formation type, then the well is classified into only one type based on the formation type with the most contribution to production as determined by the reporter's engineering knowledge. See the definition of ''Sub-basin category, for onshore natural gas production'' in 40 CFR 98.238.

first 30 days of production after the completion or workover.

2. Summary of Comments and Responses

Comment: Several commenters responded to the EPA's request for comment on whether to establish a minimum GOR threshold such that oil wells with a very low GOR would not be subject to the monitoring and reporting requirements for GHG emissions from completions and workovers with hydraulic fracturing. Most of these commenters supported establishment of a cutoff for wells with very low emissions. One commenter urged the EPA to require monitoring and reporting for all completions and workovers with hydraulic fracturing but stated that if a threshold is set, it should be set at a level that ensures that all significant emissions sources are included and that sources are able to clearly determine whether they are required to report. Three commenters supported setting a minimum GOR threshold. One commenter suggested a minimum GOR threshold of 300 and stated that, based on industry experience, oil wells with GOR values less than 300 do not have sufficient gas to operate a separator. The second commenter agreed that operators should only have to monitor and report emissions if the GOR is great enough to operate a separator and direct measurement is possible. The third commenter supporting a minimum GOR threshold did not provide a suggestion for a specific numeric threshold but stated that the emissions from wells with a low GOR are insignificant, and the time and resources involved in measuring the flowback and reporting emissions for wells expected to have minimal emissions would outweigh any contribution of these emissions to the overall source category totals. This commenter supported the inclusion of a threshold so that only significant sources of emissions would be included.

Response: The EPA agrees that including a minimum GOR threshold will help minimize reporting burden while still capturing most of the emissions from this source. Energy Information Administration data show that the number of ''oil only'' wells drilled from 2007–2012 was less than 20 percent of all new wells.[4] These wells would have a GOR approaching zero and, therefore, would be expected to have low emissions. We believe that having no threshold may create an unnecessary burden for operators to report emissions for these wells with just a trace of gas. Given that the EPA is finalizing the proposed requirement that the oil well flow meter be located downstream of the separator, the separator must be operating for the owner or operator to be able to measure the flow rate and estimate emissions from completions and workovers of oil wells with hydraulic fracturing. One commenter, an industry trade association, suggested a threshold of 300 scf/STB based on the industry trade association's experience that separators typically do not operate at a GOR less than 300 scf/STB.

The primary concern when determining the level for a threshold is volatility; the threshold must be low enough that the oil produced is considered non-volatile. Non-volatile ''black oils'' (*i.e.,* oil likely to not have gases or light hydrocarbons associated with it) are generally defined as having GOR values in the range of 200 to 900 scf/STB.[5] Oil wells with a GOR less than the 300 scf/STB suggested by the commenter are at the lower end of this range, and completions and workovers with hydraulic fracturing of these wells will not likely have enough gas associated that can be separated. Therefore, the final monitoring and reporting requirements do not apply to completions and workovers of oil wells with hydraulic fracturing that have a GOR of less than 300 scf/STB.

Comment: Several commenters responded to the EPA's request for comment on whether to establish a minimum well pressure threshold such that oil wells with a very low well pressure would not be subject to the monitoring and reporting requirements for GHG emissions from completions and workovers with hydraulic fracturing. Most of these commenters supported establishment of a cutoff for wells with very low well pressure. One commenter urged the EPA to require monitoring and reporting for all completions and workovers with hydraulic fracturing but stated that if a threshold is set, it should be set at a level that ensures that all significant emissions sources are included and that sources are able to clearly determine whether they are required to report. Three commenters supported setting a minimum well pressure threshold. One commenter suggested a minimum well pressure threshold of 0.4645 pounds per square inch per foot (psi/ft) because this is the vertical pressure gradient needed for a well to flow back, based on experience with the Natural Gas STAR program. The second commenter suggested that operators should only have to monitor and report emissions if the pressure of the reservoir during oil well completions and workovers is greater than the pressure gradient of 0.433 psi/ft and noted that the pressure needed varies based on the density of the materials in the column and the depth of the well. The third commenter supporting a minimum well pressure threshold did not provide a suggestion for a threshold but supported the inclusion of a threshold so that only significant sources of emissions would be included.

Response: The EPA evaluated the commenters' suggestions and has decided not to include a minimum well pressure threshold. Both commenters who suggested a specific value noted in their comments that these pressure gradients are the minimum needed for the well to produce. In other words, according to the commenters' rationale, wells with pressures below the suggested pressure thresholds would not have any production, regardless of whether a threshold is included in the final rule. As a result, specifying that reporting of emissions from completions and workovers of oil wells with hydraulic fracturing is not required below those pressures is redundant. Therefore, the final rule does not include a minimum well or reservoir pressure threshold for completions and workovers of oil wells with hydraulic fracturing.

B. Summary of Final Amendments for the Onshore Petroleum and Natural Gas Gathering and Boosting Segment

The EPA is amending subpart W to add a new industry segment, Onshore Petroleum and Natural Gas Gathering and Boosting, that covers emissions from equipment used by gathering pipeline systems that move petroleum and natural gas from the well to either larger gathering pipeline systems, natural gas processing plants, natural gas transmission pipelines, or natural gas distribution pipelines. A gathering and boosting system is a single network of pipelines, compressors and process equipment, including equipment to perform natural gas compression, dehydration, and acid gas removal, that has one or more well-defined connection points to gas and oil production and a well-defined downstream endpoint, typically a gas

[4] In this analysis, all hydrocarbon production in the liquid state at the wellhead was considered oil. J. Lieskovsky and S. Gorgen. ''Drilling often results in both oil and natural gas production.'' *Today in Energy,* U.S. Energy Information Administration, October 29, 2013. *http://www.eia.gov/todayinenergy/detail.cfm?id=13571.* Accessed June 9, 2015.

processing plant or transmission pipeline. Gathering pipelines are pipelines used to transport gas from the furthermost downstream point in an onshore production facility to certain endpoints, generally either a gas processing facility or point of connection to a transmission pipeline. Compressors located along the gathering and boosting system are used to control or ''boost'' the pressure of the gas in the pipeline and keep the gas moving downstream. Commenters generally supported inclusion of gathering and boosting system emissions in subpart W, and many commenters suggested targeted revisions concerning definitions, what emission sources should be included in the segment and methods for individual emission sources.

The remainder of this section describes the final reporting requirements for this new industry segment, including the segment description, definitions, calculation methods, and information to be reported. The amendments described in each section are followed by a summary of the major comments, if any, on those amendments and the EPA's responses. See ''Response to Public Comments on Greenhouse Gas Reporting Rule: 2015 Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' in Docket ID No. EPA–HQ–OAR–2014–0831 for a complete listing of all comments and the EPA's responses.

1. Segment Description for the Onshore Petroleum and Natural Gas Gathering and Boosting Segment

a. Summary of Final Amendments

The EPA is finalizing the definition of the Onshore Petroleum and Natural Gas Gathering and Boosting segment in 40 CFR 98.230 as gathering pipelines and other equipment used to collect petroleum and/or natural gas from onshore production gas or oil wells and used to compress, dehydrate, sweeten, or transport the petroleum and/or natural gas to a natural gas processing facility, a natural gas transmission pipeline, or a natural gas distribution pipeline. Gathering and boosting equipment includes, but is not limited to, gathering pipelines, separators, compressors, acid gas removal (AGR) units, dehydrators, pneumatic devices/pumps, storage vessels, engines, boilers, heaters, and flares. The Onshore Petroleum and Natural Gas Gathering and Boosting segment does not include equipment and pipelines that are reported under any other industry segment defined in subpart W. The segment definition is being finalized as proposed, except that the final amendments provide two clarifications regarding gathering pipelines. First, gathering pipelines operating on a vacuum are not included because they would not be expected to have emissions. Second, to address comments regarding the inclusion of liquid and multiphase streams in the segment, the definition clarifies that gathering pipelines with a GOR less than 300 scf/STB are not a part of the segment.

b. Summary of Comments and Responses

Comment: Commenters requested that the EPA remove ''Petroleum and'' from the proposed segment name, ''Onshore Petroleum and Natural Gas Gathering and Boosting.'' The commenters asserted that the removal would provide a clear demarcation between onshore petroleum and natural gas production and onshore natural gas gathering and boosting. They also stated that such a change would be more consistent with the segment definition, which includes pipelines and equipment ''used to compress, dehydrate, sweeten, or transport the gas to a natural gas processing facility, a natural gas transmission pipeline or to a natural gas distribution pipeline.'' The commenter stated that the type of equipment included in the gathering and boosting segment is ''synonymous'' with gas gathering and boosting systems, not liquid or petroleum, and they noted that the emission factor for equipment leaks from gathering pipelines is not applicable to gathering pipelines that carry mostly liquid.

Commenters also specifically requested that the EPA exclude petroleum gathering pipelines from the gathering and boosting segment because the fugitive gas emissions from these gathering pipelines would be negligible. Both commenters stated that the proposed emission factor for gathering pipeline leaks is only applicable to gas gathering pipelines. Two commenters also requested that multi-phase flow lines from wells to a centralized production facility where initial separation occurs be retained in the Onshore Petroleum and Natural Gas Production segment rather than included in the new gathering and boosting segment.

Response: The EPA is finalizing the segment name as proposed and not removing ''Petroleum and'' from the segment name or moving multiphase gathering pipelines to the Onshore Petroleum and Natural Gas Production segment. We proposed including ''Petroleum and'' in the segment name to reflect the complex nature of upstream operations where wells can produce oil, natural gas, or a mixture of both and to signify the inclusion of GHG emissions from gathering and boosting systems moving high volatility liquids in this new segment. Even in wells that produce primarily liquids at surface temperature and pressure conditions, there is often a volatile gaseous component. This associated gas is usually considered wet due to the high content of natural gas liquids (volatile components) to go along with gaseous CH_4. Similarly, the inclusion of all petroleum gathering pipelines in the Onshore Petroleum and Natural Gas Gathering and Boosting segment, including multiphase pipelines, is appropriate, because gathering lines are a key component to gathering and boosting systems. Therefore, all gathering pipelines that collect petroleum and/or natural gas from onshore production gas or oil wells and transport the petroleum and/or natural gas to a natural gas processing facility, a natural gas transmission pipeline or to a natural gas distribution pipeline are considered part of the final Onshore Petroleum and Natural Gas Gathering and Boosting segment.

However, the EPA does agree that gathering pipelines carrying mostly oil have a low potential for GHG emissions. We note that the ratio of CH_4 to volatile components increases as the GOR increases. Therefore, to clarify our intent to exclude gathering pipelines containing oil, the final rule clarifies that the Onshore Petroleum and Natural Gas Gathering and Boosting segment does not include gathering pipelines with a GOR of less than 300 scf/STB. Operators of gathering pipelines below that threshold are not required to include those pipelines in their gathering and boosting facility. See section II.B.5 of this preamble for additional discussion.

Finally, as part of evaluating this comment, the EPA reviewed the proposed definitions related to the Onshore Petroleum and Natural Gas Gathering and Boosting segment and recognizes that two of them referred to ''the gas'' rather than ''the petroleum and/or natural gas.'' One was the proposed description of the Onshore Petroleum and Natural Gas Gathering and Boosting segment in 40 CFR 98.230, as identified by the commenters, and the other was the definition of ''gathering and boosting system owner or operator'' in 40 CFR 98.238. For consistency throughout the final rule with the intent stated in this response, the final description of the Onshore

Petroleum and Natural Gas Gathering and Boosting segment in 40 CFR 98.230 refers to ''petroleum and/or natural gas'' and the final definition of ''gathering and boosting system owner or operator'' in 40 CFR 98.238 refers to ''the petroleum or natural gas transported.''

Comment: One commenter stated that there may be confusion regarding which equipment should be reported in the different industry segments, which could lead to emissions being mistakenly excluded or double-counted. For example, gathering and boosting equipment located on a single well pad or associated with a single well pad could be double-counted, especially if it is operated by one entity but owned by another. The commenter also noted that confusion over the proper segment for this type of equipment could make the difference between reporting emissions or not reporting emissions if a facility is close to the reporting threshold of 25,000 metric tons carbon dioxide equivalent (CO_2e). Therefore, the commenter requested that the EPA incorporate by reference the U.S. Department of Transportation's Pipeline and Hazardous Materials Safety Administration (PHMSA) federally defined boundaries of production, gathering and boosting, and transmission segments to ensure state/federal transparency and consistency.

Response: The EPA is not changing the segment description for the Onshore Petroleum and Natural Gas Production segment in 40 CFR 98.230(a)(2) or the Onshore Natural Gas Processing segment in 40 CFR 98.230(a)(3). As stated at proposal, the EPA decided not to make any changes to the existing segment descriptions to provide consistency for reporters in that segment. This decision allows the EPA to ensure that the data gap in subpart W related to gathering and boosting systems is addressed while minimizing confusion over changes to other segments. Instead, the EPA is reiterating the intention for the Onshore Petroleum and Natural Gas Gathering and Boosting segment to cover equipment and emission sources not included in reporting for the existing Onshore Petroleum and Natural Gas Production or Onshore Natural Gas Processing segments.

The EPA does not agree that emissions from the same equipment will be reported under more than one industry segment in a given reporting year; however, we acknowledge that similar equipment may exist in adjacent industry segments as defined in subpart W. The owner or operator of the equipment in question should first determine if that equipment is subject to reporting in another segment of subpart W, such as the Onshore Petroleum and Natural Gas Production or Onshore Natural Gas Processing segments. If the equipment is not subject to reporting in another segment of subpart W, then the owner or operator should evaluate whether or not the equipment is included in the Onshore Petroleum and Natural Gas Gathering and Boosting source category. For example, if a gathering and boosting owner or operator also owns or operates equipment on or associated with a single well pad (40 CFR 98.230(a)(2)), that equipment is part of the Onshore Petroleum and Natural Gas Production segment, not the Onshore Petroleum and Natural Gas Gathering and Boosting segment. Therefore, emissions from that equipment should not be included when determining if the gathering and boosting facility exceeds the reporting threshold.

Comment: One commenter requested that the EPA clarify the proper segment for AGR units and revise the rule accordingly. The commenter suggested that the Natural Gas Processing segment should explicitly exclude sulfur dioxide and carbon dioxide (CO_2) removal units, so that it is clear that those units do not report under both the Natural Gas Processing segment and the Onshore Petroleum and Natural Gas Gathering and Boosting segment. The commenter stated that this revision would be more consistent with the definition of gas processing plant in other EPA rules. If the EPA does not make this change, the commenter stated that AGR units should not be included in the Onshore Petroleum and Natural Gas Gathering and Boosting segment because they are already included in the Natural Gas Processing segment. The commenter noted that AGR units are specifically defined in 40 CFR 98.238 as a process unit that separates hydrogen sulfide and/or CO_2 from sour natural gas using liquid or solid absorbents or membrane separators.

Response: The EPA agrees that emissions from a particular acid gas removal unit should not be reported under both the Natural Gas Processing segment and the Onshore Petroleum and Natural Gas Gathering and Boosting segment. However, as noted previously in this preamble, the EPA is not changing the segment description for the Onshore Petroleum and Natural Gas Production segment in 40 CFR 98.230(a)(2) or the Onshore Natural Gas Processing segment in 40 CFR 98.230(a)(3). Instead, the EPA is reiterating the intention for the Onshore Petroleum and Natural Gas Gathering and Boosting segment to cover equipment and emission sources not included in reporting for the Onshore Petroleum and Natural Gas Production or Onshore Natural Gas Processing segments. The final segment description for the Onshore Petroleum and Natural Gas Gathering and Boosting segment in 40 CFR 98.230(a)(10) specifies that gathering and boosting equipment does not include equipment reported under any other industry segment defined in 40 CFR 98.230(a), which should address the commenter's concern about reporting under multiple segments.

Regarding the commenter's suggestion to exclude AGR units from the Onshore Petroleum and Natural Gas Gathering and Boosting segment, the EPA believes AGR units should be reported under subpart W and that the current requirements, coupled with the revisions in this rulemaking, allow for a clear demarcation of where they should be included and reported. While most AGR units will be included in the Onshore Natural Gas Processing segment, the EPA does not agree that the Onshore Natural Gas Processing segment includes all AGR vents, particularly those in processes that do not fractionate gas liquids with an annual average throughput of less than 25 million scf per day. Therefore, the final Onshore Petroleum and Natural Gas Gathering and Boosting segment includes AGR vents that do not meet the segment descriptions for the Onshore Petroleum and Natural Gas Production segment in 40 CFR 98.230(a)(2) or the Onshore Natural Gas Processing segment in 40 CFR 98.230(a)(3) but do meet the Onshore Petroleum and Natural Gas Gathering and Boosting segment description in 40 CFR 98.230(a)(10).

2. Definitions

a. Summary of Final Amendments

The EPA is finalizing the definition of ''gathering and boosting system'' as proposed and is finalizing the definition of ''gathering and boosting system owner or operator'' as proposed with a clarification that the fluid being transported may be petroleum or natural gas. Specifically, a gathering and boosting system is a single network of pipelines, compressors and process equipment, including equipment to perform natural gas compression, dehydration, and acid gas removal, that has one or more connection points to gas and oil production and a downstream endpoint, typically a gas processing plant, transmission pipeline, local distribution company (LDC) pipeline, or other gathering and boosting system. A gathering and

boosting system owner or operator is any person that: (1) Holds a contract in which they agree to transport petroleum or natural gas from one or more onshore petroleum and natural gas production wells to a natural gas processing facility, another gathering and boosting system, a natural gas transmission pipeline, or a distribution pipeline; or (2) is responsible for custody of the petroleum or natural gas transported. In complex ownership scenarios, the owner/operator assigns a designated representative responsible for reporting consistent with 40 CFR 98.4.

The EPA is also finalizing the definition of ''facility with respect to onshore petroleum and natural gas gathering and boosting'' in 40 CFR 98.238 as proposed. A facility with respect to onshore petroleum and natural gas gathering and boosting is all gathering pipelines and other equipment located along those pipelines that are under common ownership or common control by a gathering and boosting system owner or operator and that are located in a single hydrocarbon basin as defined in 40 CFR 98.238. Where a person owns or operates more than one gathering and boosting system in a basin (for example, separate gathering lines that are not connected), then all gathering and boosting systems and equipment that the person owns or operates in the basin are considered one facility. Any gathering and boosting equipment that is associated with a single gathering and boosting system, including leased, rented, or contracted activities, is considered to be under common control of the owner or operator of the gathering and boosting system. Emissions from an onshore petroleum and natural gas gathering and boosting facility only need to be reported if the collection of emission sources emits 25,000 metric tons CO_2e or more per year.

b. Summary of Comments and Responses

Comment: Multiple commenters provided comments on the definition of ''facility with respect to onshore petroleum and natural gas gathering and boosting.'' Some commenters supported the basin-level approach that the EPA proposed, although a few asked the EPA to clarify how to report their emissions if their gathering and boosting system is in more than one basin. Other commenters disagreed with the basin-level approach and suggested that the EPA should use the definition of facility in 40 CFR 98.6. These commenters asserted that the basin-level approach would result in an expansive definition of facility that includes huge numbers of emissions sources and that this approach is not consistent with how a facility is defined elsewhere in the GHGRP or with traditional notions of aggregation under the CAA. One commenter asserted that defining a facility in a way that is not consistent with other CAA programs will make it difficult for the EPA to use the GHGRP data to inform future policy decisions. The commenter also stated that the EPA has not provided any explanation of why basin-wide aggregation is a reasonable data request under section 114 of the CAA.

Commenters opposing the basin-level facility definition noted that the Onshore Petroleum and Natural Gas Gathering and Boosting segment has very different characteristics from the Onshore Petroleum and Natural Gas Production segment, which also uses the basin-level approach to defining a facility. One commenter specifically noted that production sources are located at well-defined, discrete locations, owners and operators of production sites know where the wells are physically located and how many operate in a single production basin. In contrast, the commenter stated, the gathering and boosting operations of one owner or operator in a single hydrocarbon basin may include hundreds or thousands of miles of pipelines with multiple sites, including interconnects, meter stations, scrubber stations, pigging stations, compressor stations, and gas treating plants. Another commenter stated that gathering and boosting sites have the ability to boost and move gas from multiple basins within the same site, whereas production typically maintains operations and moves gas within one basin.

Another commenter also disagreed with the basin-level approach, noting that the term ''basin'' is not common terminology that is used in the gathering and boosting industry segment. The commenter suggested that the EPA use a county- or parish-level approach with an equipment threshold (to determine which equipment should be counted when determining if the 25,000 metric tons CO_2e reporting threshold has been exceeded).

Response: The EPA is finalizing the definition of ''facility with respect to onshore petroleum and natural gas gathering and boosting'' as proposed. As noted in the preamble to the proposed amendments, the basin-level approach to defining a facility for the Onshore Petroleum and Natural Gas Gathering and Boosting segment is expected to achieve a balance of providing geographically specific information while also reducing burden on reporters. This approach also recognizes the fact that gathering and boosting facilities are more dispersed than processing facilities and are geographically similar to the Onshore Petroleum and Natural Gas Production segment in size and number of sources because, by their nature, they are needed to process and transport the petroleum and natural gas produced in a given basin. While some gathering and boosting operations may span multiple basins or may only be present in a portion of a basin, as will some onshore production operations, the EPA has concluded that a basin-level facility definition is the best reflection of how this industry is organized operationally.

In ''Greenhouse Gas Reporting Rule: Technical Support for 2015 Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems; Proposed Rule'' (Docket Item No. EPA–HQ–OAR–2014–0831–0018), we evaluated the option of using the definition of ''facility'' found in 40 CFR 98.6 for gathering and boosting facilities, and we found that this definition would provide limited data on the proposed Onshore Petroleum and Natural Gas Gathering and Boosting segment compared to the basin-level approach, due to the fact that fewer facilities would exceed the 25,000 metric tons CO_2e reporting threshold. It would also likely be more burdensome overall to reporters, because a larger number of facilities would have to be evaluated to determine whether they exceed the 25,000 metric tons CO_2e reporting threshold, and a larger number of ''facility'' reports would be required for each owner or operator. The commenters did not provide any new information that would enable us to re-evaluate this conclusion. A county- or parish-level approach would similarly result in a larger number of smaller facilities to be evaluated to determine whether they exceed the reporting threshold than the basin-level approach. This approach would result in fewer facilities reporting than a basin-level definition, especially if an equipment threshold were defined as requested by the commenter, as well as a higher burden for owners or operators with multiple facilities in a basin that exceed the 25,000 metric tons CO_2e reporting threshold. Therefore, the EPA concluded that these options would not achieve the goals that were articulated in the preamble to the proposed rule of ''having a thorough data set and transparent, complete information for this sector while minimizing burden to reporters'' (79 FR 73156; December 9,

2014). For more detail on this analysis, see ''Greenhouse Gas Reporting Rule: Technical Support for Final 2015 Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' in Docket ID No. EPA–HQ–OAR–2014–0831. We disagree with the comment that aggregation of data would not provide a data set that the EPA can use to inform future policy decisions. The purpose of this rule is to collect emissions and activity data for this industry and understand the relative emission sources, which we anticipate the aggregated data will help to promote. Therefore, the aggregated data can still inform future GHG policy. As we have pointed out previously, the EPA's definition of ''facility'' for purposes of part 98 in no way impacts the ''facility'' definition for similar sources under existing CAA programs.[6] Information collected under part 98 can inform a number of different CAA programs and the Agency's authority under CAA section 114 as the basis for part 98 is independent from the EPA's authority for other CAA programs.

To address the commenters' question about reporting a system in two basins, we are confirming in this response that reporters should submit one report per basin (*i.e.,* per facility as it is defined in subpart W) and that the 25,000 metric tons CO_2e per year reporting threshold applies to each basin/facility separately. In other words, the reporter should determine the emissions from the portion of gathering and boosting system associated with each basin. If the total emissions in each basin exceed the 25,000 metric tons CO_2e per year reporting threshold, then the reporter submits two reports. If the total emissions in one basin exceed the 25,000 metric tons CO_2e threshold, but the emissions in the other basin are below the threshold, then the reporter submits one report (for the facility that exceeds the threshold).

Regarding the commenter's question regarding the reasonableness of collecting data at the basin-level under the CAA, the EPA established its basis for collecting basin-level data in the final subpart W rule, when the EPA finalized the requirements for the Onshore Petroleum and Natural Gas Production segment. Additionally, as noted earlier in this section, more granular collection of data for this segment would result in higher burden for owners or operators with multiple operations in a basin that exceed the 25,000 metric tons CO_2e reporting threshold. See also, ''Greenhouse Gas Emissions Reporting from the Petroleum and Natural Gas Industry, Background Technical Support Document (Docket Item No. EPA–HQ–OAR–2009–0923–3610) and ''Mandatory Greenhouse Gas Reporting Rule Subpart W—Petroleum and Natural Gas: EPA's Response to Public Comments'' (Docket Item No. EPA–HQ–OAR–2009–0923–3608).

3. Blowdown Vent Stacks

a. Summary of Final Amendments

The EPA is finalizing the requirements for blowdowns of equipment in the Onshore Petroleum and Natural Gas Gathering and Boosting segment with some clarifications from proposal. Emissions should be calculated using the same methods that are used for the Onshore Natural Gas Processing segment. The same exemptions, including those for volumes less than 50 cubic feet (ft^3) and for desiccant dehydrator reloading, apply to the Onshore Petroleum and Natural Gas Gathering and Boosting segment. In response to comments that the segment is geographically dispersed and blowdowns may occur without personnel on-site or nearby, making it difficult to determine emissions from a blowdown event, the final amendments specify that for emergency blowdowns, reporters may use engineering estimates based on best available information to determine the temperature and pressure used in Equation W–14A.

b. Summary of Comments and Responses

Comment: Commenters stated that the EPA should not include reporting of blowdown vent stack emissions due to the large burden on the reporter. Instead, the commenters stated, blowdowns in the Onshore Petroleum and Natural Gas Gathering and Boosting segment should be treated similarly to blowdowns in the Onshore Petroleum and Natural Gas Production segment, where they are excluded because they are not located at consolidated facility sites and are not manned. Commenters also stated that blowdowns from gathering and boosting systems contribute minimally to overall GHG emissions. One commenter noted that while there is an exemption for any blowdown of a volume less than 50 ft^3, there is also a burden to determine if the physical volume meets this reporting threshold. To reduce the burden, some commenters suggested only including emissions from blowdown vent stacks located at a facility site (*e.g.,* compressor station, central tank battery). Other commenters stated if blowdowns remain in the segment, the EPA should allow reporters to use an emission factor approach to calculate emissions. Another commenter stated that the EPA's supporting documentation focuses on gathering pipeline blowdowns, but the regulatory text appears to include all the blowdowns occurring within a basin, including individual equipment blowdowns. The commenter requested that the EPA clarify its intent if blowdowns remain in the segment.

Response: The EPA has evaluated these comments and has decided to finalize the reporting requirements for blowdowns in the Onshore Petroleum and Natural Gas Gathering and Boosting segment with some revisions to address the commenters' concerns. While the EPA does recognize that many gathering and boosting systems are geographically dispersed, as noted by the commenters, the nature of the Onshore Petroleum and Natural Gas Gathering and Boosting segment is such that the amount of fluid passing through a gathering and boosting system will be much greater than the amount of fluid at individual well pads. Therefore, the EPA has determined that the potential for emissions from blowdowns in the Onshore Petroleum and Natural Gas Gathering and Boosting segment is higher than blowdowns in the Onshore Petroleum and Natural Gas Production segment, and they should not be excluded. However, the EPA acknowledges that the geographic dispersion of the segment, and the fact that some blowdowns occur without facility personnel on site, may make it difficult to measure emissions from blowdowns, particularly emergency blowdowns. Therefore, the final amendments include a provision specifying that for emergency blowdowns, reporters may use engineering estimates based on best available information to determine the temperature at actual conditions in the unique physical volume and absolute pressure at actual conditions in the unique physical volume for use in Equation W–14A.

To respond to the commenter's request regarding whether only gathering pipeline blowdowns or all equipment blowdowns should be included, the EPA is clarifying that the intent is to include emissions from the ''blowdown vent stacks'' source type as defined in subpart A of part 98. The focus on blowdown vent stacks located on gathering pipelines in the supporting documentation was not intended to imply that only gathering pipeline blowdowns should be reported. On the

[6] Mandatory Greenhouse Gas Reporting Rule: EPA's Response to Public Comments, Subpart W: Petroleum and Natural Gas Systems, Docket Id. No. EPA–HQ–OAR–2009–0923.

contrary, the proposal supporting documentation reflects the fact that the EPA expected that blowdown vent stacks located at boosting stations would be similar to blowdown vent stacks in other industry segments and conducted a separate evaluation to determine whether the same calculation methods would be appropriate for gathering pipeline blowdown vent stacks. The final rule supporting documentation more clearly reflects this intent. The EPA also notes that while measuring equipment to determine whether it exceeds the 50 ft^3 physical volume threshold for reporting may create an initial burden on reporters, the threshold will lead to a burden reduction as reporters become familiar with the identification process.

4. Storage Tank Vented Emissions

a. Summary of Final Amendments

The EPA is finalizing the same methods for calculating emissions for atmospheric storage tanks located in the Onshore Petroleum and Natural Gas Gathering and Boosting segment as in the Onshore Petroleum and Natural Gas Production segment, as proposed but with a few clarifications. Specifically, the EPA is clarifying some of the language within 40 CFR 98.233(j) and 40 CFR 98.236(j) that was originally written to apply to Onshore Petroleum and Natural Gas Production facilities and not proposed to be amended to also apply to storage tanks in the Onshore Petroleum and Natural Gas Gathering and Boosting segment. In particular, references to a ''wellhead separator'' have been clarified to refer simply to a ''separator,'' which is a defined term in 40 CFR 98.238. To accommodate Onshore Petroleum and Natural Gas Gathering and Boosting storage tanks that do not receive hydrocarbon liquids from a separator or well, Calculation Methods 1 and 2 have been amended to specify how to estimate emissions if liquids are received from non-separator equipment. In addition, certain instances of ''sub-basin'' have been amended to refer to ''county'' to clarify the requirements for Onshore Petroleum and Natural Gas Gathering and Boosting reporters. All other provisions in 40 CFR 98.233(j) apply to the Onshore Petroleum and Natural Gas Gathering and Boosting segment, including the 10 barrels per day threshold for determining which calculation method may be used for estimating emissions.

b. Summary of Comments and Responses

Comment: One commenter stated that combining the requirements for storage tanks in the Onshore Petroleum and Natural Gas Gathering and Boosting segment and the Onshore Petroleum and Natural Gas Production segment results in confusing terminology and unclear requirements. In particular, the commenter noted that the terms ''separator(s),'' ''gas-liquid separator(s),'' ''wellhead separator(s),'' and ''wellhead gas-liquid separator(s),'' appear throughout the storage tank requirements. The commenter asked whether the EPA intended all of these terms to refer to the same equipment. The commenter also noted that not all gathering and boosting system storage tanks receive liquids directly from separators, and no gathering and boosting storage tanks receive liquids directly from wellhead separators. Therefore, the commenter stated, the requirements for storage tanks in the Onshore Petroleum and Natural Gas Gathering and Boosting segment are unclear.

The commenter also noted inconsistency between use of the terms ''oil,'' ''sales oil,'' and ''stabilized oil'' in 40 CFR 98.233(j) and 40 CFR 98.236(j). The commenter stated that Onshore Petroleum and Natural Gas Gathering and Boosting facilities may process condensate but not oil, and the commenter asked the EPA to clarify how those terms should be applied to the Onshore Petroleum and Natural Gas Gathering and Boosting segment.

Finally, the commenter noted that Calculation Method 1 for storage tanks requires use of the latest available analysis that is representative of produced crude oil or condensate from the sub-basin category. The commenter stated that the term ''sub-basin'' has no relevance to the Onshore Petroleum and Natural Gas Gathering and Boosting segment because the composition of condensate processed at a compressor station may have little relationship to the oil or gas formation below the compressor station.

Response: The EPA agrees that the language in 40 CFR 98.233(j) and 40 CFR 98.236(j) should be clear for all Onshore Petroleum and Natural Gas Production facilities and all Onshore Petroleum and Natural Gas Gathering and Boosting facilities to which it applies. The existing definition of ''separator'' in 40 CFR 98.238 is a vessel in which streams of multiple phases are gravity separated into individual streams of single phase. This general definition and the general term ''gas-liquid separator'' apply to both Onshore Petroleum and Natural Gas Production facilities and all Onshore Petroleum and Natural Gas Gathering and Boosting facilities. Therefore, the EPA has reviewed the language and is amending references to a ''well,'' ''well pad,'' or ''wellhead,'' which are terms that are not expected to apply to most Onshore Petroleum and Natural Gas Gathering and Boosting facilities. The final provisions in 40 CFR 98.233(j) and 40 CFR 98.236(j) refer more generally to separators or gas-liquid separators. To address the comment that not all gathering and boosting system storage tanks receive liquids directly from separators, the EPA has amended 40 CFR 98.233(j)(1) and (2) to specify how those calculation methodologies may be used for Onshore Petroleum and Natural Gas Gathering and Boosting storage tanks receiving hydrocarbon liquids from non-separator equipment (*i.e.,* without a well or separator directly upstream of the storage tank).

Regarding the particular material being stored in storage tanks, the EPA agrees that there is inconsistency in some of the terms that could cause some confusion. The EPA is clarifying in this response that for the Onshore Petroleum and Natural Gas Gathering and Boosting segment, the intent is for ''oil'' to refer more generally to hydrocarbon liquids, which is consistent with the statement in 40 CFR 98.233(j) that reporters are required to calculate emissions ''from atmospheric pressure fixed roof storage tanks receiving hydrocarbon produced liquids.'' The proposed separate reporting requirements for quantity of produced oil throughput and produced condensate throughput in 40 CFR 98.236(aa)(10) have been revised, and the final rule requires reporting of the hydrocarbon liquids received by the facility and the hydrocarbon liquids leaving the facility. Finally, the EPA notes that the term ''sales oil'' is already defined in Subpart A to include ''produced crude oil or condensate,'' so there is no further clarification needed.

Regarding the term ''sub-basin,'' the EPA agrees with the commenter that the definition of ''sub-basin category, for onshore natural gas production'' in 40 CFR 98.238 is not relevant for Onshore Petroleum and Natural Gas Gathering and Boosting facilities. The EPA also agrees that the operations within a section of a gathering and boosting system may not be related to the formation type below the surface of the ground at that location, especially as the material travels further from the wells supplying gas and hydrocarbon liquids to the system. As a result of this comment, the EPA reviewed the use of the term ''sub-basin'' as it was proposed to apply to Onshore Petroleum and Natural Gas Gathering and Boosting facilities. In 40 CFR 98.233(j), the calculation methods provide options to

estimate unknown parameters using information from a previous analysis of the composition in the sub-basin category. In these cases, the intent is to estimate unknown parameters from a representative unit (*e.g.,* well, separator). To reflect a similar intent for Onshore Petroleum and Natural Gas Gathering and Boosting facilities, 40 CFR 98.233(j)(1)(vii)(B) and 40 CFR 98.233(j)(1)(vii)(C) in Calculation Method 1 clarify that representative separators or non-separator equipment are located within the same county for Onshore Petroleum and Natural Gas Gathering and Boosting reporters. For Calculation Method 2, the term ''sub-basin category'' is used to describe calculation of emissions for flow to storage tanks directly from wells. The final rule includes a new paragraph 40 CFR 98.233(j)(2)(iii) to address calculation of emissions from flow to a tank from equipment other than a well or separator (such as a stabilizer or slug catcher), and this paragraph also clarifies that representative analyses should come from other non-separator equipment located within the same county. Finally, there are reporting requirements for a ''sub-basin ID'' in 40 CFR 98.236. The final rule specifies that for Onshore Petroleum and Natural Gas Gathering and Boosting, the information to be reported is the county in which the equipment is located.

5. Gathering Pipelines

a. Summary of Final Amendments

The EPA is finalizing the requirements for calculating emissions from gathering pipelines defined to be included in the Onshore Petroleum and Natural Gas Gathering and Boosting segment as proposed. The methodology is similar to the approach used for equipment leaks in the Onshore Petroleum and Natural Gas Production segment. For gathering lines, reporters use the population count and emission factor approach in 40 CFR 98.233(r). The emission factors in Table W–1A for gathering pipelines are whole gas emission factors based on the U.S. GHG Inventory. The population count is the miles of gathering pipeline, similar to the approach used for calculating emissions from natural gas distribution pipelines in the Natural Gas Distribution segment. As noted in section II.B.1.a of this preamble, gathering pipelines with a GOR less than 300 scf/STB are not included in this segment.

b. Summary of Comments and Responses

Comment: One commenter asserted that the EPA should revise the proposed emission factor of 2.81 standard cubic feet (scf)/hour/mile for leaks from gathering pipelines to be based on characteristics of currently operating gathering pipelines rather than distribution pipelines or older data on gathering pipelines. The commenter also noted that this emission factor is not applicable to gathering pipelines that carry primarily liquids, as there is no gas stream until after separation. The commenter identified gathering pipeline-specific data from PHMSA and used the data to calculate a suggested emission factor of 2.23 scf/hour/mile.

Response: We reviewed the underlying data used to develop the proposed emission factor, and we agree with the commenter that the proposed emission factor could better account for differences between pipeline types and for currently operating gathering pipelines. In the 1996 Gas Research Institute (GRI)/EPA report that is the basis of the emission factor, material-specific emissions factors for gathering lines were developed using data from direct measurement of distribution pipelines conducted in the 1990s, not gathering pipelines. These material-specific emission factors are the same emission factors used by the commenter as the starting point for their revised emission factor.

We agree with the commenter that the emission factors should better represent currently operating gathering pipelines; however, there is significant variability in gathering pipelines and gathering system configurations. Owners and operators currently report the mileage of pipeline by gathering pipeline type to PHMSA.[7] Therefore, rather than calculate a single emission factor for gathering pipelines based on a distribution of gathering pipeline materials, as was done at proposal, the EPA determined that the most appropriate approach is to develop gathering pipeline emission factors for four pipeline material types: Protected steel, unprotected steel, plastic, and cast iron. (For more information about the development of these emission factors, see ''Greenhouse Gas Reporting Rule: Technical Support for Final 2015 Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' in Docket ID No. EPA–HQ–OAR–2014–0831.) The final amendments require reporters to estimate emissions using material-specific emission factors provided in the rule and to report gathering pipeline mileage by material type.

The EPA also notes that reporters will not need to calculate emissions from gathering pipelines that carry hydrocarbon liquids if they are below the minimum GOR threshold for the Onshore Petroleum and Natural Gas Gathering and Boosting segment.

6. Other Emission Sources

a. Summary of Final Amendments

The EPA is finalizing the requirements for natural gas pneumatic devices and pneumatic pumps located in the Onshore Petroleum and Natural Gas Gathering and Boosting segment as proposed. Gathering and boosting reporters will use the same methods for calculating emissions as in the Onshore Petroleum and Natural Gas Production segment. The EPA is also finalizing the requirements for acid gas removal units, dehydrators, and flare stacks as proposed. The methods are the same as the methods for these sources in both the Onshore Petroleum and Natural Gas Production segment and the Onshore Natural Gas Processing segment. The EPA is also finalizing the requirements for compressors and equipment leaks as proposed, with one clarification regarding how to count ''meters/piping'' for equipment leaks. Gathering and boosting reporters use the same method as in the Onshore Petroleum and Natural Gas Production segment. Specifically, a reporter will need to establish an inventory of the components or equipment subject to the population counts, apply the emission factors, and then update the inventory each year to account for new or retired components or equipment.

b. Summary of Comments and Responses

Comment: Two commenters stated that the major equipment categories for calculating equipment leaks by population count are not clear for the Onshore Petroleum and Natural Gas Gathering and Boosting segment. Both commenters requested that the EPA clarify how to count ''meters/piping'' for the Onshore Petroleum and Natural Gas Gathering and Boosting segment. One commenter also requested clarification regarding separators, compressors, and in-line heaters (specifically, whether small heating systems used to ensure a temperate environment for a meter are considered in-line heaters). The

[7] U.S. Department of Transportation Pipeline and Hazardous Materials Safety Administration. Natural and Other Gas Transmission and Gathering Pipeline Systems: Annual Report for Calendar Year. Form PHMSA F 7100.2–1 (rev 10–2014). OMB No. 2137–0522, Expires: 10/31/2016.

commenter also noted that there was limited time to evaluate the appropriateness of the emission factors in Table W–1A and the component counts in Table W–1B for gathering and boosting systems.

Response: The categories in Table W–1B represent the types of equipment that are generally expected to be found in the field for Onshore Petroleum and Natural Gas Production and Onshore Petroleum and Natural Gas Gathering and Boosting facilities.[8] For the Onshore Petroleum and Natural Gas Gathering and Boosting segment, the EPA realizes that reporters will only use those categories that apply (*e.g.,* reporters will not include wellheads, as that equipment type is specific to Onshore Petroleum and Natural Gas Production facilities).

Most of the major equipment categories are described by function in the rule. For the example of a separator, 40 CFR 98.238 defines a separator as ''a vessel in which streams of multiple phases are gravity separated into individual streams of single phase.'' Any device meeting this functional definition will fall into this major equipment category. Other major categories are described in the rule by their functional role, including dehydrators and compressors. For the in-line heater example for which the commenter requested clarification, the equipment described is not located in line with the fluid flow and therefore would not be considered in this equipment category.

The EPA agrees with both commenters that the measurement of meters/piping in the Onshore Petroleum and Natural Gas Gathering and Boosting segment was not clear as proposed. The final rule specifies that reporters in the Onshore Petroleum and Natural Gas Gathering and Boosting segment should count the number of meters in the facility and use that as the count for ''meters/piping.''

Comment: Two commenters supported the use of calculation methods that include emission factors for the Onshore Petroleum and Natural Gas Gathering and Boosting segment because they are less burdensome to the industry. However, the commenters also requested that the EPA allow reporters the option to use any available data/information that provides the best representation of emissions from their specific sources, including manufacturer data, test data, measurement and/or monitoring data. The commenters compared this option to the approach in state-level emissions inventories that require an emissions reporting hierarchy. The commenters noted that this approach will provide the EPA with more accurate emissions data that could be used to update the emission factors for the Onshore Petroleum and Natural Gas Gathering and Boosting segment.

Response: The calculation methods provided in subpart W were selected to minimize burden on industry while maintaining the necessary quality and consistency of data to inform policy. Therefore, outside of the BAMM provisions being finalized in this rulemaking, the EPA does not agree to allow reporters to use customized, individual information for their emission sources at this time. The EPA is currently investigating additional calculation methods for subpart W sources and may propose additional calculation methods in the future.

C. Summary of Final Amendments for the Onshore Natural Gas Transmission Pipeline Segment

1. Summary of Final Amendments

The EPA is finalizing the proposal to add reporting requirements for emissions from natural gas transmission pipeline blowdowns between compressor stations in a new Onshore Natural Gas Transmission Pipeline segment. Commenters generally had no objections to the merit of including this segment in subpart W but did suggest technical edits and clarifications for targeted provisions. As noted in the preamble to the proposed amendments, a blowdown is the release of gas from transmission pipelines that causes a reduction in system pressure or a complete depressurization. The EPA is clarifying that for the purposes of the Onshore Natural Gas Transmission Pipeline segment, the blowdowns that must be reported are blowdowns of a pipeline or section of pipeline.

The EPA is finalizing clarifications to the proposed definition of onshore natural gas transmission pipeline owner or operator. For interstate pipelines, the onshore natural gas transmission pipeline owner or operator is the person identified as the transmission pipeline owner or operator on the Certificate of Public Convenience and Necessity issued under 15 U.S.C. 717f, as proposed. For intrastate pipelines, the onshore natural gas transmission pipeline owner or operator is the person identified as the owner or operator on the transmission pipeline's Statement of Operating Conditions under section 311 of the Natural Gas Policy Act (NGPA). If the intrastate pipeline is not subject to section 311 of the NGPA, the onshore natural gas transmission pipeline owner or operator is the person identified as the owner or operator on reports to the state regulatory body regulating rates and charges for the sale of natural gas to consumers. Finally, the owner or operator of a pipeline that falls under the ''Hinshaw Exemption'' is the person identified as the owner or operator on blanket certificates issued under 18 CFR 284.224.

The EPA is finalizing the definition of facility for the new Onshore Natural Gas Transmission Pipeline segment as proposed; the facility is the total U.S. mileage of natural gas transmission pipelines owned or operated by an onshore natural gas transmission pipeline owner or operator. If an owner or operator has multiple pipelines in the United States, the facility is considered the aggregate of those pipelines, even if they are not interconnected.

The EPA is finalizing the requirement that reporters use the methods in 40 CFR 98.233(i) to calculate or measure emissions from pipeline blowdown events as proposed. One method allows a reporter to calculate emissions based on the volume of the pipeline segment between isolation valves that is blown down and the pressure and temperature of the gas within the pipeline. The second method allows the reporter to measure the emissions from the blowdown using a flow meter on the blowdown vent stack. In both methods, the reporter calculates both CH_4 and CO_2 emissions from the volume of natural gas vented using either default gas composition or engineering estimates of composition as specified in 40 CFR 98.233(u)(2)(iii).

The EPA is not finalizing the proposed requirement to report the emissions and location (latitude and longitude) of each blowdown event. Instead, the EPA is requiring that Onshore Natural Gas Transmission Pipeline reporters report the total CH_4 and CO_2 emissions in each state, the number of blowdowns in each state, and the miles of pipeline in each state. In addition, instead of requiring Onshore Natural Gas Transmission Pipeline reporters to use the same equipment and event type categories as other industry segments reporting blowdown emissions, the EPA is including reporting categories specific to the Onshore Natural Gas Transmission Pipeline segment.

[8] See the memorandum ''Equipment-Level Population Emission Factors for Onshore Production,'' Docket Item No. EPA–HQ–OAR–2009–0923–3582, for more information regarding the derivation of this table.

NMED Exhibit 97 - 0014

2. Summary of Comments and Responses

Comment: Several commenters noted that not all intrastate pipelines are subject to section 311 of the NGPA and asked the EPA to clarify which intrastate pipelines are subject to reporting. One commenter requested that the EPA clarify that intrastate pipelines not subject to the NGPA are not required to report under subpart W. Another commenter suggested revising the definition of owner or operator to state that if section 311 of the NGPA does not apply, the intrastate transmission pipeline owner or operator is the owner or operator identified on required reports with the appropriate state agency.

Response: It was our intent to include transmission pipelines (including intrastate pipelines) that meet the already existing subpart W definition of ''transmission pipeline'' in the Onshore Natural Gas Transmission Pipeline segment. A transmission pipeline in subpart W is defined in 40 CFR 98.238 as a Federal Energy Regulatory Commission (FERC) rate-regulated Interstate pipeline, a state rate-regulated Intrastate pipeline, or a pipeline that falls under the ''Hinshaw Exemption'' as referenced in section 1(c) of the Natural Gas Act, 15 U.S.C. 717–717 (w)(1994). After reviewing the comments on the proposed rule, we re-reviewed section 311 of the NGPA and found that only operators of some intrastate pipelines, including those that transport natural gas on behalf of an interstate pipeline or sell natural gas to an interstate pipeline, are required to prepare a Statement of Operating Conditions for compliance under section 311 of the NGPA. Therefore, to clarify how to determine the owner and operator of intrastate transmission pipelines, the finalized definition of ''onshore natural gas transmission pipeline owner or operator'' specifies that for intrastate transmission pipelines not subject to section 311 of the NGPA, the owner or operator is the person identified as the owner or operator on reports to the state regulatory body regulating rates and charges for the sale of natural gas to consumers. The EPA also found that the proposed definition of ''onshore natural gas transmission pipeline owner or operator'' did not specify how to determine the owner or operator of pipelines that fall under the ''Hinshaw Exemption.'' The EPA notes that similar to intrastate pipelines, pipelines that fall under the ''Hinshaw Exemption'' must apply for a ''blanket certificate'' under 18 CFR 284.224 in order to transport petroleum or natural gas on behalf of interstate pipelines. Therefore, the finalized definition of ''onshore natural gas transmission pipeline owner or operator'' also specifies that for a pipeline that falls under the ''Hinshaw Exemption,'' the owner or operator is the person identified as the owner or operator on blanket certificates issued under 18 CFR 284.224.

Comment: Commenters appreciated that the EPA provided a threshold of 50 ft^3 of physical volume for blowdown emissions reporting but requested several changes. Commenters requested that the EPA include a list of ancillary equipment, such as metering and/or regulating stations, pipeline interconnects, and pig launchers and receivers, that would be excluded from reporting of blowdown emissions. One commenter suggested that, alternatively, the physical volume threshold could be increased to 3,000 thousand cubic feet to clearly exclude blowdowns of ancillary facilities along the pipeline. Another commenter stated that it is not feasible to establish a specific *de minimis* volume threshold to exclude all ancillary equipment.

Response: The EPA is finalizing the reporting threshold of 50 ft^3 of physical volume for blowdowns in the Onshore Natural Gas Transmission Pipeline segment as proposed. This threshold excludes smaller blowdown sources that have little contribution to emissions, consistent with other industry segments within subpart W that must report blowdown stack vent emissions. The EPA is not increasing the physical volume reporting threshold to account for blowdowns from ancillary equipment, as this would be inconsistent with the EPA's previous analysis in ''Equipment Threshold for Blowdowns'' (see Docket Item No. EPA–HQ–OAR–2009–0923–3581), and commenters were divided on whether increasing the threshold would even address their primary concern.

The EPA agrees that the emphasis for the Onshore Natural Gas Transmission Pipeline segment is on calculating and reporting blowdown emissions from pipeline segments, not ancillary equipment. However, any list of ancillary equipment that would be excluded from blowdown reporting could be incomplete, resulting in reporting of emissions from other equipment that is ancillary but not on the list in the rule. In addition, some of the equipment identified as ''ancillary'' in this segment is not considered ancillary in other industry segments, which could lead to confusion among reporters. Instead, the final rule clarifies that facilities in the Onshore Natural Gas Transmission Pipeline segment report pipeline blowdown emissions from blowdown vent stacks. If the blowdown does not include a pipeline segment or has a physical volume of less than 50 ft^3, then that blowdown is not required to be reported.

Comment: Several commenters stated that the blowdown equipment and event type categories in 40 CFR 98.233(i)(2) were developed for compressor station blowdowns and would not provide meaningful information regarding pipeline blowdowns in the Onshore Natural Gas Transmission Pipeline segment. The commenters provided suggestions for categories that would be more applicable to Onshore Natural Gas Transmission Pipeline blowdowns and would provide more valuable information than relying on the categories in the existing rule.

Response: The EPA agrees with the commenters that the rule should include blowdown categories specific to blowdowns in the Onshore Natural Gas Transmission Pipeline segment. The final rule specifies that blowdowns must be grouped into one of the following categories: Pipeline integrity work (*e.g.,* the preparation work of modifying facilities, ongoing assessments, maintenance or mitigation), traditional operations or pipeline maintenance, equipment replacement or repair (*e.g.,* valves), pipe abandonment, new construction or modification of pipelines including commissioning and change of service, operational precaution during activities (*e.g.* excavation near pipelines), emergency shutdowns including pipeline incidents as defined by PHMSA, and all other pipeline segments with a physical volume greater than or equal to 50 ft^3.

Comment: Commenters requested that the EPA not finalize the requirement to report latitude and longitude for each blowdown event. The commenters indicated this requirement would be burdensome, such data are not currently collected, the requirement is inconsistent with the Paperwork Reduction Act, and the data would not be useful in determining the inventory. Some commenters also suggested aggregating emissions at the state level or only at the national/facility level.

Response: The requirement to report latitude and longitude of each blowdown was included in the proposed rule to help characterize the emissions from the new Onshore Natural Gas Transmission Pipeline segment on a more granular level than the nationwide facility. The EPA evaluated this comment and has noted the commenters' assertion that the latitude and longitude of each

blowdown is not information currently reported elsewhere and may result in additional burden. Therefore, the EPA is not finalizing the requirement to report the emissions or latitude and longitude for each individual blowdown. Instead, the EPA is finalizing requirements for reporters to aggregate blowdown emissions by state and report the number of blowdowns and mileage of pipeline per state.

Comment: Two commenters questioned the requirement to report the data elements in proposed 40 CFR 98.236(aa)(11). Two commenters noted that the quantities of natural gas in this section are duplicative of information reported to FERC annually in FERC Form 2, although the units of measure are dekatherms rather than thousand standard cubic feet. One commenter noted that for the GHGRP reporting, they would assume 1 dekatherm is equivalent to 1,000 scf of natural gas, based on the approximate heat value of natural gas. The other commenter opposed these reporting requirements because they are duplicative and inconsistent with the requirements of the PRA, which is intended to reduce the information burden imposed by the federal government by requiring that agencies ensure that reported information is not duplicative of other available data and has a practical utility. This commenter stated that the EPA has not followed the PRA. The commenter also stated that the requested information is irrelevant to assisting EPA in verifying pipeline blowdown emissions; in particular, the information cannot be used to calculate pipeline blowdown volumes.

Response: As the EPA has noted elsewhere, the data collected in the GHGRP will be used to inform future policy decisions. As such, information regarding emissions and the inputs needed to verify those emissions is only part of the information that is needed. It is important to understand that, to inform future policy, activity data is often as useful as emissions estimates. The EPA has determined that data elements in 40 CFR 98.236(aa)(11) are activity data that will be used to determine how to use the emissions data to inform future policy decisions. It is essential that reporters provide and certify the data they gather under this rule so that EPA has a complete inventory from all sources under this rule and can directly relate the activity data to the emissions data reported, which will provide for appropriate verification of the emissions data reported.

The EPA agrees with the first commenter that for purposes of reporting the data elements in 40 CFR 98.236(aa)(11), reporters may consider 1 dekatherm equal to 1,000 scf.

Comment: Several commenters asserted that the EPA has not been consistent in its decisions on whether to include pipeline leaks across the subpart W industry segments. Some commenters supported the EPA's proposal not to include leaks from transmission pipelines and noted the decision was consistent with the Onshore Petroleum and Natural Gas Production segment. Conversely, one commenter stated that transmission pipeline leaks should be reported, consistent with the new Onshore Petroleum and Natural Gas Gathering and Boosting segment. This commenter noted that accidental leaks at these facilities can be a significant source of CH_4 emissions, as evidenced by the magnitude of emissions from pipeline incidents reported to PHMSA, and leaks at remote locations may not be noticed or repaired immediately.

Response: The EPA previously considered fugitive emissions that result from leaks in transmission pipelines in the re-proposal of subpart W in April 2010 (75 FR 18616; April 12, 2010) but did not include provisions for these emissions in either the proposed or final rules. The April 2010 preamble explained that the EPA did not propose reporting requirements for fugitive emissions from leaks in natural gas pipeline segments between compressor stations due to the dispersed nature of the fugitive emissions and the fact that, once fugitives are found, the leaks causing the emissions are usually addressed quickly for safety reasons (75 FR 18616; April 12, 2010). The EPA also noted in the proposal preamble for these amendments (79 FR 76267; December 9, 2014) that larger fugitive leaks are currently reported to PHMSA as part of 49 CFR 191.3. Under this provision, any pipeline incident that results in unintentional gas loss of 3 million ft^3 or more must be reported. The commenter that noted that emissions can be significant cited the emissions reported to PHMSA under this provision, and the EPA does not find it necessary to require owners and operators to report this same information under the GHGRP. The focus of the PHMSA reporting requirements is to identify major safety-related incidents that are not a part of typical operations. Therefore, the EPA is not finalizing a requirement to report fugitive emissions from transmission pipeline leaks but will continue to review this source as part of the EPA's ongoing effort to ensure comprehensive, high quality data in subpart W.

D. Summary of Final Amendments for Well Identification Numbers

1. Summary of Final Amendments

The EPA is finalizing some of the proposed amendments to 40 CFR 98.236 to add reporting requirements for well identification numbers to improve data quality by enabling identification of wells. These well identification numbers will be reported for the first time in the report covering 2016 emissions; reporters will not be required to report well identification numbers for previous years. For the majority of wells, the well identification number reported will be the US Well Number (formerly referred to as the API Well Number, or API Number).[9] For any well that does not already have a US Well Number, the reporter will be required to provide the unique well number assigned by the permitting authority for drilling of oil and gas wells. Commenters varied in their level of support for the proposed provisions regarding well identification numbers. The EPA is adjusting the final provisions in response to concerns about these reporting provisions raised in comments.

The EPA is requiring the reporting of well identification numbers for the Onshore Petroleum and Natural Gas Production segment only for information related specifically to wells. For reporters in the Onshore Petroleum and Natural Gas Production segment that report emissions using input data that are calculated from measurements at individual wells or equipment associated with individual wells (*e.g.,* if Equation W–10A was used to calculate emissions from oil well completions and workovers with hydraulic fracturing, well testing emissions), the report must include the well identification number for which those measurements were made and the well identification number(s) of other wells to which the measurements will be applied. This includes a list of the well identification numbers by sub-basin for the producing wells at the end of the calendar year as well as lists of the well identification numbers for the wells acquired, divested, completed, and permanently taken out of production during the calendar year. The EPA is not finalizing the proposed requirement that reporters in the Onshore Petroleum and Natural Gas Production segment report a list of well identification numbers associated with different emission

[9] The Professional Petroleum Data Management Association. *The US Well Number Standard: An Identifier for Petroleum Industry Wells in the USA.* Version 2013 rev 1, published June 19, 2014. Available at *http://dl.ppdm.org/dl/1147.*

sources for all wells in a sub-basin included in the reported emissions data.

The EPA is finalizing the proposed change to update references to the ''API well number'' in subpart W to ''well identification number.'' The EPA is not otherwise changing the well identification reporting requirements finalized in 2014 (79 FR 70352; November 25, 2014). Reporters will still need to report well identification numbers for liquids unloading and for any exploratory wells for which reporting has been delayed for 2 years.

2. Summary of Comments and Responses

Comment: While one commenter supported the addition of well identification number reporting, most commenters opposed the proposal to require reporting of well identification numbers. These commenters asserted that requiring reporting of well identification numbers is an overreach of the EPA's authority for the reporting program under CAA section 114 and that the EPA has not provided a reasoned basis for the departure from the previous EPA approach that well-specific data was not necessary under Subpart W. Commenters also noted that well identification numbers are not needed to validate reported emissions. One commenter noted that the EPA has not questioned the data collected from wells thus far; nor has the EPA stated that the data already collected are insufficient to inform policy without addition of well identification numbers, so with this proposal, the EPA is no longer balancing data collection with reporting burdens. Commenters stated that mapping and maintaining a database of well identification numbers is more burdensome than the EPA estimated, and one commenter stated that it would be arbitrary and capricious to require companies to expend the resources necessary to report these data. Commenters also noted that it is not clear how to interpret the term ''associated with'' in all cases. One commenter stated that matching specific wells with emissions in the GHGRP could cause security concerns.

Response: The EPA disagrees that requiring reporting of well identification numbers is an overreach of our authority. The EPA has determined that these data elements are useful and necessary for the verification of existing data and for characterizing the emissions from the industry segment. This final revision will allow the EPA to link the GHGRP data to other databases (*i.e.* state permitting databases) to more easily match the data reported under the GHGRP with other data sources and will improve the accuracy and transparency of subpart W. Additionally, being able to match the GHGRP data to other data sources will provide the EPA with more options for analysis of the GHGRP data to better inform future policy decisions related to GHG emissions from the oil and natural gas production sector. The reporting of the well identification numbers will also allow the EPA to assess the completeness and representativeness of the data collected under the GHGRP as a portion of all activity in the oil and natural gas production sector. The EPA reiterates that CAA section 114 provides the EPA with the authority to collect emissions data, which includes information about the location of the source of emissions. Section 114 generally authorizes the EPA to gather information from any person who owns or operates an emissions source, who is subject to a requirement of the CAA, who manufactures control or process equipment, or who the Administrator believes has information necessary for the purposes of section 114(a). The EPA may gather information for purposes of establishing implementation plans or emissions standards, determining compliance, or ''carrying out any provision'' of the CAA. For these reasons, the Administrator may request that a person, on a one-time, periodic or continuous basis, establish and maintain records, make reports, install and operate monitoring equipment and, among other things, provide such information the Administrator may reasonably require. This language has been interpreted to grant the EPA broad authority. See, *e.g.,* Dow Chemical Co. v. U.S., 467 U.S. 227, 233 (1986) (''Regulatory and enforcement authority generally carries with it all modes of inquiring and investigation traditionally employed or useful to execute the authority granted.''). See, generally *Mandatory Greenhouse Gas Reporting Rule: EPA's Response to Public Comments, Volume No.: 9, Legal Issues* (Docket Item No. EPA–HQ–OAR–2008–0508–2264). The requirement to report well identification numbers for well-specific data clearly fits within EPA's statutory authority. We also believe, for the reasons stated above, that we are exercising this authority reasonably in furtherance of the purposes of the Clean Air Act. Further, the EPA disagrees that this is a deviation from our previous approach to collecting data. As discussed in section II.B of this preamble, the EPA is finalizing the requirement to report Onshore Petroleum and Natural Gas Gathering and Boosting facilities at the basin-level, which is consistent with our previous approach to the Onshore Petroleum and Natural Gas Production segment.

Therefore, the EPA is finalizing the requirements to report the well identification number for well-specific data as proposed. Specifically, for reporters in the Onshore Petroleum and Natural Gas Production segment that report emissions using input data that are calculated from measurements at individual wells or equipment or operations associated with individual wells (*e.g.,* if Equation W–10A is used to calculate emissions from oil well completions and workovers with hydraulic fracturing, well testing emissions, liquids unloading), the report must include the well identification number for which those measurements were made, or for which the equipment or operations are associated. In addition, the EPA is finalizing the requirements in 40 CFR 98.236(aa)(1)(ii)(D) through (H) to include a list of the well identification numbers by sub-basin for the producing wells at the end of the calendar year and lists of the well identification numbers for the wells acquired, divested, completed, and permanently taken out of production during the calendar year. The EPA continues to expect that this is a low burden to reporters because reporters already track and maintain well identification numbers associated with measurements used for the GHGRP input data.

To respond to the comment that well identification numbers may not be available for or assigned to equipment other than wells, the EPA reviewed the permits and requirements in seven different states. Although most of the states assign unique identifiers to each emission source, the EPA found that only two of the seven states have a tracking system that links individual emission sources to specific wells and well identification numbers, and these two states are not consistent in their approach. (See ''Greenhouse Gas Reporting Rule: Technical Support for 2015 Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems; Final Rule'' in Docket ID No. EPA–HQ–OAR–2014–0831 for more information on this analysis.) While it may be straightforward to assign some emission sources directly to one well, particularly if there is only one well on the single well pad and the reporter does not operate any other wells nearby, the EPA's review of state requirements shows that there may be multiple scenarios in which a reporter does not know which well or wells are associated with a particular emission source. For

example, there may be multiple wells on a single well pad and multiple storage tanks associated with that well pad, and the tanks may have the ability to receive hydrocarbon liquids from several of those wells. Therefore, in light of the potential burden of requiring facilities to develop new tracking systems that would assign and track emissions to well identification numbers for the purposes of part 98, the EPA is not requiring facilities in this rulemaking to report well identification numbers for every emission source in a facility in the Onshore Petroleum and Natural Gas Production segment.

E. Summary of Final Amendments to Best Available Monitoring Methods

1. Summary of Final Amendments

As proposed, reporters will be allowed to use BAMM for the 2016 reporting year for the new industry segments and emission sources included in this action. These include calculating and reporting emissions from oil well completions and workovers with hydraulic fracturing, from onshore petroleum and natural gas gathering and boosting systems, and for transmission pipeline blowdown emissions. Reporters are allowed to use BAMM to estimate inputs to emission equations for the newly finalized emission sources for cases where the monitoring of these inputs would not be possible beginning on January 1, 2016. The use of BAMM is not allowed for the reporting of well identification numbers because reporters should already have well identification numbers readily available for all wells and associated equipment to which this reporting requirement applies and because the well identification number is not a parameter that requires monitoring equipment to be measured and, therefore, does not meet the requirements for BAMM.

For these sources, the EPA is finalizing a longer timeline for BAMM than was proposed. Reporters have the option of using BAMM for the new industry segments and emission sources included in this action from January 1, 2016, to December 31, 2016, without seeking prior EPA approval. The provision providing a set amount of automatic transitional BAMM will allow reporters to prepare for data collection while automatically being able to use BAMM, which is consistent with the approach of prior part 98 rulemakings. This additional time for reporters to comply with the revised monitoring methods in subpart W will allow facilities to install the necessary monitoring equipment during other planned (or unplanned) process unit downtime, thus avoiding process interruptions, and is responsive to comments received on the proposed rule provisions.

The EPA is not finalizing the proposed provision to allow reporters the opportunity to request an extension for the use of BAMM. The EPA will not accept requests for an extension for the use of BAMM beyond the time periods listed above. As proposed, the EPA also is not providing transitional BAMM for these new requirements beyond December 31, 2016.

The EPA is not allowing the use of BAMM beyond 2016 and does not anticipate that BAMM will be needed beyond 2016 for the new segments and emissions sources being finalized in this rule.

2. Summary of Comments and Responses

Comment: Several commenters stated that only 3 months of automatic BAMM and 1 year of transitional BAMM is not enough time to implement the monitoring and measurement requirements for facilities newly subject to subpart W and newly added emission sources. The commenter stated that adding a new segment is a significant amendment and the EPA has set the precedent of providing at least 1 year of automatic BAMM when adding a new segment to subpart W. The commenters noted that not all gathering and boosting reporters are already reporting as Onshore Petroleum and Natural Gas Production facilities, so they will not necessarily all be familiar with the monitoring and calculation methodologies. The commenters also noted that nearly all reporters will be spending the first month working on BAMM requests for the rest of 2016.

The commenters had a variety of suggestions for how long the EPA should provide BAMM for these new emission sources. Several commenters suggested 1 year (through the end of 2016) for automatic BAMM. Another commenter suggested March 31, 2017 (*i.e.,* 1 year in addition to the EPA's proposed 3 months), and another stated that 3 years would be consistent with the length of time provided when the Onshore Petroleum and Natural Gas Production segment was added to subpart W. Some commenters addressed the length of transitional BAMM with the EPA's approval. One commenter noted that a new reporter/facility could become subject to one of the new segments beyond the end of 2016, so there should be no deadline for submitting a request for BAMM to the EPA. Another requested transitional BAMM through the end of 2018.

Response: The EPA recognizes that most of the amendments being finalized in this rulemaking are new requirements rather than clarifications of existing reporting requirements for facilities already subject to subpart W and may require the development and implementation of new systems of data collection and monitoring. Therefore, the EPA is finalizing 1 year of automatic transitional BAMM in place of the proposed 3 months of automatic transitional BAMM. This additional time for reporters to comply with the revised monitoring methods in subpart W will allow facilities to install the necessary monitoring equipment and implement any new systems of data collection that may be required. Because the amount of time for which automatic BAMM is available should be sufficient time to comply with the requirements of subpart W for the new segments and emission sources, the EPA will not provide additional BAMM beyond the automatic BAMM provisions in 40 CFR 98.234(g).

We note that 40 CFR 98.235(e) and(f) provides 6 months of reporting flexibility for facilities that become subject to subpart W or acquire new sources after reporting year 2016. Reporters may also refer to the provisions of 40 CFR 98.235 after reporting year 2016 for guidance on reporting emissions if certain required data are not collected.

III. Confidentiality Determinations

A. Summary of Final Confidentiality Determinations for New Subpart W Data Elements

In the proposed rule, we assigned new data elements to the appropriate direct emitter data categories created in the 2011 Final CBI Rule based on the type and characteristics of each data element.[10] For data elements the EPA assigned to a direct emitter category with a categorical determination, the EPA proposed that the categorical determination for the category be applied to the proposed new data element. For data elements assigned to the ''Unit/Process 'Static' Characteristics that Are Not Inputs to Emission Equations'' and ''Unit/Process Operating Characteristics that Are Not Inputs to Emission Equations,'' we proposed confidentiality determinations on a case-by-case basis taking into

[10] ''Confidentiality Determinations for Data Required Under the Mandatory Greenhouse Gas Reporting Rule and Amendments to Special Rules Governing Certain Information Obtained Under the Clean Air Act'' (76 FR 30782, May 26, 2011).

NMED Exhibit 97 - 0018

consideration the criteria in 40 CFR 2.208, consistent with the approach used for data elements previously assigned to these two data categories. We also proposed individual confidentiality determinations for six new data elements without making a data category assignment. Refer to the preamble to the proposed rule (79 FR 76267; December 9, 2014) for additional information regarding the proposed confidentiality determinations.

With consideration of the data provided by commenters, the EPA is finalizing the confidentiality determinations as proposed. Specifically, the EPA is finalizing the proposed decision to require each of the new data elements to be designated as ''not CBI.''

The EPA proposed to provide reporters with the option to delay reporting of five data elements for 2 reporting years in situations where exploratory wells are the only wells in a sub-basin. We received comment requesting that the EPA provide the same 2-year delay for additional data elements associated with exploratory wells. The comment and the EPA's response are included in section III.B of this preamble. Based on consideration of the comment and consistent with the EPA's previous decisions related to exploratory wells under part 98 (79 FR 63750, October 24, 2014; 79 FR 70352, November 25, 2014), the EPA is finalizing provisions to provide reporters with the option to delay reporting of five data elements as proposed and, based on comments received, an additional two data elements for 2 reporting years in situations where exploratory wells are the only wells in a sub-basin. For a given sub-basin, in situations where wildcat wells and/or delineation wells are the only wells in a sub-basin that can be used for the required measurement, the following seven data elements associated with the delineation or wildcat well may be delayed for 2 reporting years: (1) The cumulative gas flowback time, in hours, for each sub-basin, from when gas is first detected until sufficient quantities are present to enable separation (40 CFR 98.236(g)(5)(i)); (2) the cumulative flowback time, in hours, for each sub-basin, after sufficient quantities of gas are present to enable separation (40 CFR 98.236(g)(5)(i)); (3) the measured flowback rate, in standard cubic feet per hour, for each sub-basin (40 CFR 98.236(g)(5)(ii)); (4) the gas to oil ratio for the well (40 CFR 98.236(g)(5)(iii)(A)); (5) the volume of oil produced during the first 30 days of production after completions of each newly drilled well or well workover using hydraulic fracturing (40 CFR 98.236(g)(5)(iii)(B)); (6) the total annual gas-liquid separator oil volume that is sent to applicable onshore storage tanks, in barrels (40 CFR 98.236(j)(1)(iii)); and (7) the total annual oil throughput that is sent to all atmospheric tanks, in barrels (40 CFR 98.236(j)(2)(i)(A).

Four of the seven data elements for which reporting may be delayed by 2 years are inputs to emission equations and the EPA provided the same option in the EPA's previous decisions related to exploratory wells under part 98 (79 FR 63750, October 24, 2014). Two of the seven data elements are inputs only when the applicable data are related to a single well (the two data elements in 40 CFR 98.236(g)(5)(i)), and one data element is never an input (40 CFR 98.236(j)(2)(i)(A)). Where the EPA agrees that there are early disclosure concerns related to exploratory wells, the EPA decided to treat those early disclosure concerns consistently throughout subpart W by providing the option to delay reporting by 2 years to all seven data elements listed above.

At proposal, in cases where the two data elements in 40 CFR 98.236(g)(5)(i)) are not inputs to equations, they were assigned to the ''Unit/Process Operating Characteristics that are Not Inputs to Emission Equations'' category and were proposed to be ''not CBI.'' The EPA is finalizing this determination as proposed. Specifically, the ''not CBI'' determination applies to all situations except for when the data elements are inputs to equations.

For the situations when the data elements are used as inputs to equations, the EPA is assigning them to the ''Inputs to Emission Equations'' data category and is not making confidentiality determinations for these data. The EPA evaluated and summarized any potential disclosure concerns with the reporting of the data elements assigned to the ''Inputs to Emission Equations'' data category in the memo titled ''Review for Potential Disclosure Concerns for Inputs to Emission Equations Affected by the 2015 Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' available in Docket ID No. EPA–HQ–OAR–2014–0831. Other than the exception of the early disclosure concerns for certain data elements related to exploratory wells discussed earlier in this section, the EPA has concluded that there are no disclosure concerns with the reporting of these data elements.

The data element collected under 40 CFR 98.236(j)(2)(i)(A) was proposed as ''not CBI'' and was not assigned to a data category. The EPA is finalizing this determination as proposed as well. For the data elements reported under 40 CFR 98.236(g)(5)(i)) (in cases where they are not inputs to equations) and 40 CFR 98.236(j)(2)(i)(A), the ''not CBI'' determinations will apply once the data are reported to the EPA following the 2-year delay.

B. Summary of Comments and Responses

This section summarizes the major comments and responses related to the proposed categorical assignments and confidentiality determinations. See ''Response to Public Comments on Greenhouse Gas Reporting Rule: 2015 Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' in Docket ID No. EPA–HQ–OAR–2014–0831 for a complete listing of all comments and responses. See the memorandum ''Final Data Category Assignments and Confidentiality Determinations for Data Elements (excluding inputs to emission equations) in the 'Greenhouse Gas Reporting Rule: 2015 Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems; Final Rule' '' in Docket ID No. EPA–HQ–OAR–2014–0831 for a complete listing of final data category assignments and confidentiality determinations, and a discussion of changes since proposal.

Comment: One commenter requested that the EPA reconsider the determination that the quantity of produced gas throughput in the calendar year and the quantity of produced gas consumed by the facility in the calendar year are ''not CBI.'' The commenter noted that the quantity of natural gas received and the quantity of processed gas leaving processing plants was maintained as CBI in the 2014 amendments (79 FR 70352; November 25, 2014). The commenter also stated that information on fuel consumed at gathering and boosting facilities is not typically publically available, and when this information is combined with the quantity of produced gas throughput, it directly indicates the fuel efficiency of a station. The commenter noted that while the EPA is correct that the agreements are long-term for a given well, revealing information about one facility's fuel efficiency could cause competitive harm by affecting contracts for other facilities owned by that company, especially if there are smaller gathering and boosting facilities in the area that do not have to report this information to the GHGRP.

The commenter also requested that the EPA clarify a number of the reporting elements in 40 CFR

98.236(aa)(10). Specifically, the commenter requested clarification of the terms ''produced gas,'' ''produced condensate,'' ''produced oil,'' ''throughput,'' and ''consumed'' as they are used in proposed 40 CFR 98.236(aa)(10). The commenter also asserted that the data element in 40 CFR 98.236(aa)(10)(ii) (''quantity of produced gas consumed'') would be redundant with subpart C and should not be finalized. Finally, the commenter stated that the requirement to report the ''quantity of gas flared, vented and/or unaccounted for in the calendar year'' in 40 CFR 98.236(10)(aa)(v) would undermine over 5 years of rule development, public comment, reconsiderations, and petitioner negotiations because it would require reporting of emissions that are otherwise exempted (*e.g.,* blowdowns below 50 ft^3).

Response: The EPA reviewed these comments and has clarified the reporting elements in 40 CFR 98.236(aa)(10) for the final rule. The final reporting requirements include: (1) The quantity of gas received by the gathering and boosting facility in the calendar year, in thousand standard cubic feet; (2) the quantity of gas transported to a natural gas processing facility, a natural gas transmission pipeline, a natural gas distribution pipeline, or another gathering and boosting facility in the calendar year, in thousand standard cubic feet; (3) the quantity of all hydrocarbon liquids received by the gathering and boosting facility in the calendar year, in barrels; and (4) the quantity of all hydrocarbon liquids transported to a natural gas processing facility, a natural gas transmission pipeline, a natural gas distribution pipeline, or another gathering and boosting facility in the calendar year, in barrels. The EPA has determined that these quantities will be easily accessible for all reporters and are more consistent with the reporting requirements for the Onshore Natural Gas Processing segment. The EPA is finalizing the CBI determinations for these quantities as ''not CBI,'' as proposed.

The final reporting requirements do not include the terms ''produced gas,'' ''produced condensate,'' ''produced oil,'' ''throughput,'' or ''consumed,'' so no clarification regarding the use of those terms is needed. In particular, the final rule does not include a requirement to report the quantity of produced gas consumed by the facility. The difference between the quantities received by a gathering and boosting facility and the quantities exiting the gathering and boosting facility is expected to include the quantity of gas consumed by the facility as well as the quantity of gas flared or vented in one lump sum. Therefore, the reporting requirements do not directly indicate the fuel efficiency of the stations in a gathering and boosting facility.

Comment: One commenter reiterated previously stated concerns over the disclosure of information for exploratory wells, especially when they are located in stepout areas where no prior reporting exists for a given sub-basin. The commenter supported the EPA's proposal to defer reporting of data elements related to oil well completions and workovers with hydraulic fracturing for exploratory wells, but expressed concern that EPA has not provided such a delay in reporting for all emissions data and data elements that are associated with exploratory wells. Specifically, the commenter stated that the EPA failed to provide a necessary 2-year deferral in reporting for the following data elements, which are as business sensitive and confidential as the other information for which the EPA proposed to defer reporting for 2 years:

- 40 CFR 98.236(g)(5)(iii)(A)—If you used Equation W–12C to calculate the average gas production rate for an oil well, the gas to oil ratio for the well in standard cubic feet of gas per barrel of oil.
- 40 CFR 98.236(g)(5)(iii)(B)—If you used Equation W–12C to calculate the average gas production rate for an oil well, the volume of oil produced during the first 30 days of production after completions of each newly drilled well or well workover using hydraulic fracturing, in barrels.
- 40 CFR 98.236(g)(6)(i)—If you used Equation W–10B to calculate annual volumetric total gas emissions for completions that vent gas to the atmosphere, the vented natural gas volume, in standard cubic feet, for each well in the sub-basin.
- 40 CFR 98.236(g)(6)(ii)—If you used Equation W–10B to calculate annual volumetric total gas emissions for completions that vent gas to the atmosphere, the flow rate at the beginning of the period of time when sufficient quantities of gas are present to enable separation, in standard cubic feet per hour, for each well in the sub-basin.
- 40 CFR 98.236(g)(7)—For each oil well completion or workover and well type combination, annual gas emissions.
- 40 CFR 98.236(g)(8)—For each oil well completion or workover and well type combination, annual CO_2 emissions.
- 40 CFR 98.236(g)(9)—For each oil well completion or workover and well type combination, annual CH_4 emissions.
- 40 CFR 98.236(g)(10)—For each oil well completion or workover and well type combination, the total N_2O emissions, if the well emissions were vented to a flare.

Response: The EPA reviewed the data elements identified by the commenter as having disclosure concerns for exploratory wells (delineation wells and wildcat wells). Consistent with the EPA's previous decisions related to exploratory wells under part 98 (79 FR 63750, October 24, 2014; 79 FR 70352, November 25, 2014), the EPA has determined that, for gas well completions or workovers with hydraulic fracturing of wildcat wells and/or delineation wells, early public disclosure of some of the additional data elements identified by the commenter could reveal the well productivity of wildcat wells and/or delineation wells, thereby resulting in the loss of investment value.

The additional data elements that could reveal well productivity for wildcat and/or delineation wells are as follows:

- The gas to oil ratio for the well (40 CFR 98.236(g)(5)(iii)(A))
- The volume of oil produced during the first 30 days of production after completions of each newly drilled well or well workover using hydraulic fracturing (40 CFR 98.236(g)(5)(iii)(B))

As the EPA has previously noted (79 FR 70352, November 25, 2014), in the interim period before these data are reported to the EPA, the EPA will be able to verify the majority of the emissions using data elements that will be reported to the EPA. For the seven total data elements that may be delayed for 2 years, the EPA will verify emissions using other data reported to the EPA, and will conclude verification upon receipt of the data. The EPA agrees with the commenter that a 2-year delay of reporting is sufficient to prevent early public disclosure of these data and will provide sufficient time for the reporter to thoroughly conduct an assessment of the well. Given the results of this evaluation, the EPA determined that, for these data elements, in those cases where delineation wells or wildcat wells are the only wells in a sub-basin, reporters should be provided an option to delay reporting of the given data element for 2 reporting years starting in 2015. In such cases, if the 2-year delay in reporting is used, the reporter must indicate for each delayed reporting element that wildcat wells and/or delineation wells are the only wells in a sub-basin that can be used for the measurement in the current reporting year. In addition, when reporters report the delayed data elements after the 2-year delay, they must also report the well identification numbers for the applicable wildcat and/or delineation wells in the sub-basin for which the reporting element was delayed. For example, if a delineation or wildcat well is completed in 2015 in a sub-basin that

has only delineation or wildcat wells or these are the only wells for which measurements can be made, then the reporter may: (1) Elect to report these seven data elements in their 2016 annual report submitted by March 31, 2017, or (2) elect to delay reporting of these data elements for up to 2 years. If the reporter elects to delay reporting, then the well identification numbers for the wildcat and delineation wells in the sub-basin for which reporting has been delayed and the data elements delayed from reporting must be reported no later than March 31, 2019.

The following inputs meet the definition of emission data in 40 CFR 2.301(a)(2)(i) because they indicate the amount or frequency of gas emitted by the facility: Volume of natural gas vented (reported under 40 CFR 98.236(g)(6)(i)) and flow rate at the beginning of the period of time when sufficient quantities of gas are present to enable separation (reported under 40 CFR 98.236(g)(6)(ii)). Without corresponding activity data, such as a count of the exploratory wells in a sub-basin or production or flow rate data for a sub-basin containing only exploratory wells, there is no potential to disclose business sensitive information based on these data elements. Therefore, the EPA is not providing an option to delay reporting of these data elements for 2 reporting years.

Similarly, the data element annual gas emissions (reported under 40 CFR 98.236(g)(7)) meets the definition of emission data in 40 CFR 2.301(a)(2)(i) and is assigned to the ''Emissions'' data category because it indicates the amount of gas emitted by the facility. In addition, the following data elements meet the definition of emission data in 40 CFR 2.301(a)(2)(i) and are assigned to the ''Emissions'' data category because they are emissions of pollutants emitted by the source: annual CO_2 emissions (reported under 40 CFR 98.236(g)(8)), annual CH_4 emissions (reported under 40 CFR 98.236(g)(9)), and annual nitrous oxide (N_2O) emissions if the well emissions were vented to a flare (reported under 40 CFR 98.236(g)(10)). For these data elements that are assigned to the ''Emissions'' data category, the commenter did not claim or provide any justification for why these data elements do not meet the definition of emission data. Without corresponding activity data, such as a count of the exploratory wells in a sub-basin or production or flow rate data for a sub-basin containing only exploratory wells, there is no potential to disclose business sensitive information based on these data elements. Therefore, the EPA is not providing an option to delay reporting of these data elements for 2 reporting years.

IV. Impacts of the Final Amendments to Subpart W

A. Impacts of the Final Amendments

The final amendments to subpart W add monitoring and reporting requirements for reporters in three industry segments: Onshore Petroleum and Natural Gas Production, Onshore Petroleum and Natural Gas Gathering and Boosting, and Onshore Natural Gas Transmission Pipeline. The EPA is adding 213 new data elements to the reporting requirements. The new data elements impose additional burden and costs because, for each of the new data elements that are required to be reported, reporters are required to calculate the data element using readily available data and report the value to the EPA via e-GGRT as part of the annual report currently required under part 98.

The EPA calculated the increase in reporting and recordkeeping burden associated with the new data elements by adjusting labor hours upwards per reporter for all affected industry segments. For all three segments, an estimate of 10 hours per year per reporter was allotted for reporting via e-GGRT and 10 hours per year per reporter was allotted for recordkeeping.

Costs to reporters associated with this rulemaking are expressed as labor costs (*i.e.,* the cost of labor by facility staff to comply with the amendments), capital costs for equipment and travel, and operation and maintenance (O&M) costs.

Reporters in the Onshore Petroleum and Natural Gas Production segment have to monitor and report emissions and data elements associated with oil well completions and workovers with hydraulic fracturing. Reporters in this segment also have to report the well identification numbers associated with individual oil and gas wells. The addition of the requirement to report emissions associated with oil well completions and workovers with hydraulic fracturing is expected to cause an increase in the amount of emissions that count towards determining applicability under subpart W. The addition of reporting requirements for oil wells with hydraulic fracturing is expected to affect 246 existing reporters and to cause approximately 50 new reporters to exceed the reporting threshold for the onshore petroleum and natural gas production facility. These numbers have not changed from proposal.

The 50 new reporters will be required to estimate and report emissions data and related data elements associated with several different emission sources within this new industry segment, including acid gas removal units, associated natural gas venting and flaring, storage tanks, dehydrators, equipment leaks, liquids unloading, and pneumatic devices.

Reporters in the Onshore Petroleum and Natural Gas Gathering and Boosting segment must estimate and report emissions data and related data elements associated with several different emission sources within this new industry segment, including acid gas removal units, storage tanks, blowdown vents, dehydrators, equipment leaks, flare stacks, and pneumatic devices. Approximately 200 new reporters are expected to be subject to subpart W due to the amendments for the Onshore Petroleum and Natural Gas Gathering and Boosting segment in this rulemaking. This number has not changed from proposal.

Reporters in the Onshore Natural Gas Transmission Pipeline segment will need to estimate and report emissions data and related data elements associated with transmission pipeline blowdown activities. Approximately 183 new reporters in this segment are expected to be subject to subpart W. This number increased from 150 to 183 since proposal due to public comment.

The EPA received multiple comments regarding the impacts of the proposed amendments. After evaluating these comments and reviewing other changes from proposal, the EPA revised the impacts assessment slightly from proposal. The final amendments to subpart W are not expected to significantly change the burden calculated at proposal.

The EPA has determined that the cost associated with this final action will be $7,190,235 each year and has worked to minimize burden to reporters where practicable. See the memorandum, ''Assessment of Impacts of the 2015 Final Revisions to Subpart W'' in Docket ID No. EPA–HQ–OAR–2014–0831 for additional information.

B. Summary of Comments and Responses

This section summarizes the major comments and responses related to the impacts of the proposed amendments to subpart W of part 98. We note that numerous commenters asserted that the burden was underestimated, and some provided suggestions for improvement, but most of those comments did not include the detailed information the EPA needed to assess the comment

fully, such as a suggestion for a revised burden estimate, support for the suggestion, and an explanation of why the suggested value is representative of all sources subject to the same requirements. See ''Response to Public Comments on Greenhouse Gas Reporting Rule: 2015 Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' in Docket ID No. EPA–HQ–OAR–2014–0831 for a complete listing of all comments and responses.

Comment: One commenter asked for an explanation for the estimate of 200 respondents in the Onshore Petroleum and Natural Gas Gathering and Boosting segment. The commenter noted that the EPA estimated the number of reporters in the Onshore Natural Gas Processing industry segment as 291 reporters. The commenter stated by the nature of the industry, any company with a processing plant will most likely also have an associated gathering system subject to reporting and suggested that the number of reporters in the Onshore Petroleum and Natural Gas Gathering and Boosting industry segment should total 291, at minimum, but potentially more.

Response: Due to differences in the definitions of the two industry segments, the EPA disagrees that the number of reporters in the Onshore Petroleum and Natural Gas Gathering and Boosting segment should match the number of reporters in the Onshore Natural Gas Processing segment. The EPA estimate of 200 respondents was based on the regulatory analysis for Office of Pipeline Safety (OPS) safety regulations. In the analysis, it was estimated that 50 percent of the 400 natural gas gathering pipeline operators under regulation are small entities operating small diameter, low pressure (Type B) gathering lines and fifty percent are large diameter, high pressure lines (Type A) potentially subject to the safety regulation (depending upon proximity to population centers).[11]

Comment: One commenter noted that the EPA estimated that there are 150 reporters for Onshore Natural Gas Transmission Pipeline facilities at proposal. However, the commenter stated that the EPA should expect 183 reporters in the segment based on the number of operators that are required to complete a PHMSA annual report (PHMSA F–7100–2) or are regulated by FERC under section 311 of the NGPA.

Response: The EPA agrees with the suggested change. The preamble to the final amendments, the final Supporting Statement, and the memorandum ''Assessment of Impacts of the 2015 Final Revisions to Subpart W'' (see Docket ID No. EPA–HQ–OAR–2014–0831) have been updated to reflect the change from 150 reporters to 183 reporters in the Onshore Natural Gas Transmission Pipeline segment.

Comment: Two commenters objected to the collection of well identification numbers. One commenter noted that collection would require significant resources and would be unduly burdensome on operators. The other commenter stated that the burdens associated with collecting and reporting this data far outweigh any minimal benefits in data quality.

Response: The EPA is finalizing the well identification number reporting requirements for well-specific data as proposed, but the EPA is not requiring well identification numbers to be reported in this rulemaking for equipment other than wells. See section II.D of this preamble for additional discussion responding to this comment.

V. Statutory and Executive Order Reviews

A. Executive Order 12866: Regulatory Planning and Review and Executive Order 13563: Improving Regulation and Regulatory Review

This action is not a significant regulatory action and was therefore not submitted to the Office of Management and Budget (OMB) for review.

In addition, the EPA prepared an analysis of the potential costs associated with the final amendments to subpart W. This analysis is contained in the memorandum ''Assessment of Impacts of the 2015 Final Revisions to Subpart W.'' A copy of the analysis is available in the docket for this action (see Docket ID No. EPA–HQ–OAR–2014–0831) and the analysis is briefly summarized in section IV of this preamble.

B. Paperwork Reduction Act (PRA)

The information collection activities in this rule have been submitted for approval to the OMB under the PRA. The Information Collection Request (ICR) document that the EPA prepared has been assigned EPA ICR number 2300.16. You can find a copy of the ICR in the docket for this rule, and it is briefly summarized here. The information collection requirements are not enforceable until OMB approves them.

This action adds monitoring and reporting requirements for reporters in three industry segments: Onshore Petroleum and Natural Gas Production, Onshore Petroleum and Natural Gas Gathering and Boosting, and Onshore Natural Gas Transmission Pipeline. Data collection complements the *Inventory of U.S. Greenhouse Gas Emissions and Sinks* (Inventory) and provides a critical tool for communities to identify nearby sources of GHGs and provide information to state and local governments. The data can be used to complement atmospheric GHG studies and inform updates to emission inventories. Various activity data are collected that can be used to improve understanding of the occurrence of emissions from a variety of sources.

Data collected must be made available to the public unless the data qualify for CBI treatment under the CAA and EPA regulations. All data determined by the EPA to be CBI are safeguarded in accordance with regulations in 40 CFR chapter 1, part 2, subpart B.

Respondents/Affected Entities: The respondents in this information collection include owners and operators of petroleum and natural gas systems facilities that must report their GHG emissions to the EPA to comply with subpart W of part 98.

Respondent's Obligation To Respond: The respondent's obligation to respond is mandatory under the authority provided in CAA section 114.

Estimated Number of Respondents: Approximately 3,300 respondents per year.

Frequency of Response: Annual.

Total Estimated Burden: 317,100 hours (per year). Burden is defined at 5 CFR 1320.3(b).

Total Estimated Cost: $29.2 million (per year), includes $1.1 million annualized capital and 2.8 million operation & maintenance costs.

An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information unless it displays a currently valid OMB control number. The OMB control numbers for the EPA's regulations in 40 CFR are listed in 40 CFR part 9. When OMB approves this ICR, the Agency will announce that approval in the **Federal Register** and publish a technical amendment to 40 CFR part 9 to display the OMB control number for the approved information collection activities contained in this final rule.

C. Regulatory Flexibility Act (RFA)

I certify that this action will not have a significant economic impact on a substantial number of small entities under the RFA. The small entities

[11] U.S. Department of Transportation. Pipeline and Hazardous Materials Safety Administration. *Draft Regulatory Evaluation, Regulated Natural Gas Gathering Lines, Regulatory Analysis,* Docket RSPA–1998–4868. Available at *www.viadata.com/pipeliner/library_docs/Gatheringanalysis.pdf.*

subject to the requirements of this action are: (1) A small business as defined by the Small Business Administration's regulations at 13 CFR 121.201; (2) a small governmental jurisdiction that is a government of a city, county, town, school district or special district with a population of less than 50,000; and (3) a small organization that is any not-for-profit enterprise which is independently owned and operated and is not dominant in its field.

The Agency has determined that a few small businesses may experience an insignificant impact. Details of this analysis are presented in section IV.B of the preamble to the proposed amendments (79 FR 76267; December 9, 2014).

Although this final rule will not have a significant economic impact on a substantial number of small entities, the EPA nonetheless has tried to reduce the impact of this rule on small entities. As part of the process of finalizing the subpart W 2010 final rule, the EPA took several steps to evaluate the effect of the rule on small entities. For example, the EPA determined appropriate thresholds that reduced the number of small businesses reporting. In addition, the EPA supports a ''help desk'' for the rule, which is available to answer questions on the provisions in the rule. Finally, the EPA continues to conduct significant outreach on the GHG reporting rule and maintains an ''open door'' policy for stakeholders to help inform the EPA's understanding of key issues for the industries.

D. Unfunded Mandates Reform Act (UMRA)

This action does not contain an unfunded mandate of $100 million or more as described in UMRA, 2 U.S.C. 1531–1538, and does not significantly or uniquely affect small governments. This action imposes no enforceable duty on any state, local, or tribal governments or the private sector.

E. Executive Order 13132: Federalism

This action does not have federalism implications. It will not have substantial direct effects on the states, on the relationship between the national government and the states, or on the distribution of power and responsibilities among the various levels of government.

F. Executive Order 13175: Consultation and Coordination With Indian Tribal Governments

This action has tribal implications. However, it will neither impose substantial direct compliance costs on federally recognized tribal governments, nor preempt tribal law. This regulation will apply directly to petroleum and natural gas facilities that emit GHGs. Although few facilities that will be subject to the rule are likely to be owned by tribal governments, the EPA has sought opportunities to provide information to tribal governments and representatives during the development of the proposed and final subpart W that was promulgated on November 30, 2010 (75 FR 74458).

The EPA consulted with tribal officials under the EPA Policy on Consultation and Coordination with Indian Tribes early in the process of developing this regulation to permit them to have meaningful and timely input into its development. A summary of that consultation is provided in section IV.F of the preamble to the re-proposal of subpart W published on April 12, 2010 (75 FR 18608), and section IV.F of the preamble to the subpart W 2010 final rule published on November 30, 2010 (75 FR 74458).

G. Executive Order 13045: Protection of Children From Environmental Health Risks and Safety Risks

The EPA interprets Executive Order 13045 as applying only to those regulatory actions that concern environmental health or safety risks, that the EPA has reason to believe may disproportionately affect children, per the definition of ''covered regulatory action'' in section 2–202 of the Executive Order. This action is not subject to Executive Order 13045 because it does not concern an environmental health risk or safety risks.

H. Executive Order 13211: Actions That Significantly Affect Energy Supply, Distribution, or Use

This action is not subject to Executive Order 13211, because it is not a significant regulatory action under Executive Order 12866.

I. National Technology Transfer and Advancement Act (NTTAA)

This rulemaking does not involve technical standards.

J. Executive Order 12898: Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations

The EPA believes the human health or environmental risk addressed by this action will **not** have potential disproportionately high and adverse human health or environmental effects on minority, low-income or indigenous populations because it does not affect the level of protection provided to human health or the environment. Instead, this rule addresses information collection and reporting procedures.

K. Congressional Review Act (CRA)

This action is subject to the CRA, and the EPA will submit a rule report to each House of the Congress and to the Comptroller General of the United States. This action is not a ''major rule'' as defined by 5 U.S.C. 804(2).

List of Subjects in 40 CFR Part 98

Environmental protection, Administrative practice and procedure, Greenhouse gases, Reporting and recordkeeping requirements.

Dated: October 1, 2015.

Gina McCarthy,

Administrator.

For the reasons stated in the preamble, title 40, chapter I, of the Code of Federal Regulations is amended as follows:

PART 98—MANDATORY GREENHOUSE GAS REPORTING

■ 1. The authority citation for part 98 continues to read as follows:

Authority: 42 U.S.C. 7401, *et seq.*

Subpart W—Petroleum and Natural Gas Systems

■ 2. Section 98.230 is amended by adding paragraphs (a)(9) and (10) to read as follows:

§ 98.230 Definition of the source category.

(a) * * *

(9) *Onshore petroleum and natural gas gathering and boosting.* Onshore petroleum and natural gas gathering and boosting means gathering pipelines and other equipment used to collect petroleum and/or natural gas from onshore production gas or oil wells and used to compress, dehydrate, sweeten, or transport the petroleum and/or natural gas to a natural gas processing facility, a natural gas transmission pipeline or to a natural gas distribution pipeline. Gathering and boosting equipment includes, but is not limited to gathering pipelines, separators, compressors, acid gas removal units, dehydrators, pneumatic devices/pumps, storage vessels, engines, boilers, heaters, and flares. Gathering and boosting equipment does not include equipment reported under any other industry segment defined in this section. Gathering pipelines operating on a vacuum and gathering pipelines with a GOR) less than 300 standard cubic feet per stock tank barrel (scf/STB) are not included in this industry segment (oil

here refers to hydrocarbon liquids of all API gravities).

(10) *Onshore natural gas transmission pipeline.* Onshore natural gas transmission pipeline means all natural gas transmission pipelines as defined in § 98.238.

* * * * *

■ 3. Section 98.231 is amended by revising paragraph (a) to read as follows:

§ 98.231 Reporting threshold.

(a) You must report GHG emissions under this subpart if your facility contains petroleum and natural gas systems and the facility meets the requirements of § 98.2(a)(2), except for the industry segments in paragraphs (a)(1) through (4) of this section.

(1) Facilities must report emissions from the onshore petroleum and natural gas production industry segment only if emission sources specified in § 98.232(c) emit 25,000 metric tons of CO_2 equivalent or more per year.

(2) Facilities must report emissions from the natural gas distribution industry segment only if emission sources specified in § 98.232(i) emit 25,000 metric tons of CO_2 equivalent or more per year.

(3) Facilities must report emissions from the onshore petroleum and natural gas gathering and boosting industry segment only if emission sources specified in § 98.232(j) emit 25,000 metric tons of CO_2 equivalent or more per year.

(4) Facilities must report emissions from the onshore natural gas transmission pipeline industry segment only if emission sources specified in § 98.232(m) emit 25,000 metric tons of CO_2 equivalent or more per year.

* * * * *

■ 4. Section 98.232 is amended by:
■ a. Revising paragraphs (a) and (c)(6) and (8);
■ b. Adding paragraph (j);
■ c. Revising paragraph (k); and
■ d. Adding paragraph (m).

The revisions and additions read as follows:

§ 98.232 GHGs to report.

(a) You must report CO_2, CH_4, and N_2O emissions from each industry segment specified in paragraphs (b) through (j) and (m) of this section, CO_2, CH_4, and N_2O emissions from each flare as specified in paragraphs (b) through (j) of this section, and stationary and portable combustion emissions as applicable as specified in paragraph (k) of this section.

* * * * *

(c) * * *

(6) Well venting during well completions with hydraulic fracturing that have a GOR of 300 scf/STB or greater (oil here refers to hydrocarbon liquids produced of all API gravities).

* * * * *

(8) Well venting during well workovers with hydraulic fracturing that have a GOR of 300 scf/STB or greater (oil here refers to hydrocarbon liquids produced of all API gravities).

* * * * *

(j) For an onshore petroleum and natural gas gathering and boosting facility, report CO_2, CH_4, and N_2O emissions from the following source types:

(1) Natural gas pneumatic device venting.

(2) Natural gas driven pneumatic pump venting.

(3) Acid gas removal vents.

(4) Dehydrator vents.

(5) Blowdown vent stacks.

(6) Storage tank vented emissions.

(7) Flare stack emissions.

(8) Centrifugal compressor venting.

(9) Reciprocating compressor venting.

(10) Equipment leaks from valves, connectors, open ended lines, pressure relief valves, pumps, flanges, and other equipment leak sources (such as instruments, loading arms, stuffing boxes, compressor seals, dump lever arms, and breather caps).

(11) Gathering pipeline equipment leaks.

(12) You must use the methods in § 98.233(z) and report under this subpart the emissions of CO_2, CH_4, and N_2O from stationary or portable fuel combustion equipment that cannot move on roadways under its own power and drive train, and that is located at an onshore petroleum and natural gas gathering and boosting facility as defined in § 98.238. Stationary or portable equipment includes the following equipment, which are integral to the movement of natural gas: Natural gas dehydrators, natural gas compressors, electrical generators, steam boilers, and process heaters.

(k) Report under subpart C of this part (General Stationary Fuel Combustion Sources) the emissions of CO_2, CH_4, and N_2O from each stationary fuel combustion unit by following the requirements of subpart C except for facilities under onshore petroleum and natural gas production, onshore petroleum and natural gas gathering and boosting, and natural gas distribution. Onshore petroleum and natural gas production facilities must report stationary and portable combustion emissions as specified in paragraph (c) of this section. Natural gas distribution facilities must report stationary combustion emissions as specified in paragraph (i) of this section. Onshore petroleum and natural gas gathering and boosting facilities must report stationary and portable combustion emissions as specified in paragraph (j) of this section.

* * * * *

(m) For onshore natural gas transmission pipeline, report pipeline blowdown CO_2 and CH_4 emissions from blowdown vent stacks.

■ 5. Section 98.233 is amended by:
■ a. Revising the parameters ''EF_t'' and ''GHG_i'' of Equation W–1 in paragraph (a);
■ b. Revising paragraph (a)(2);
■ c. Revising the parameter ''EF'' of Equation W–2 in paragraph (c);
■ d. Revising paragraph (d)(8)(iii);
■ e. Revising paragraphs (g) introductory text, (g)(1) introductory text, (g)(1)(i), and paragraph (g)(1)(ii) heading;
■ f. Revising the parameters ''FRM_s,'' ''$FR_{s,p}$'' and ''$PR_{s,p}$'' of Equation W–12A in paragraph (g)(1)(iii);
■ g. Revising the parameters ''$FRM_{i,}$'' and ''$PR_{s,p}$'' of Equation W–12B in paragraph (g)(1)(iv);
■ h. Revising paragraphs (g)(1)(v) and (vi);
■ i. Adding paragraph (g)(1)(vii);
■ j. Revising paragraph (g)(2) introductory text;
■ k. Adding paragraph (g)(2)(iv);
■ l. Revising paragraph (g)(4) introductory text;
■ m. Revising paragraph (i)(2) introductory text;
■ n. Revising the parameters ''T_a'' and ''P_a'' of Equation W–14A in paragraph (i)(2)(i);
■ o. Revising paragraphs (j) introductory text, (j)(1) through (3), and (j)(6);
■ p. Revising paragraph (n)(2)(i);
■ q. Revising paragraphs (o) introductory text and (o)(10);
■ r. Revising paragraphs (p) introductory text and (p)(10);
■ s. Revising paragraphs (r) introductory text, (r)(2) introductory text, and (r)(2)(i);
■ t. Revising paragraphs (u)(2)(i) and (iii); and
■ x. Revising paragraphs (z) introductory text and (z)(1)(ii).

The revisions and additions read as follows:

§ 98.233 Calculating GHG emissions.

* * * * *

(a) * * *

* * * * *

EF_t = Population emission factors for natural gas pneumatic device vents (in standard cubic feet per hour per device) of each type ''t'' listed in Tables W–1A, W–3, and W–4 of this subpart for onshore petroleum and natural gas production,

onshore natural gas transmission compression, and underground natural gas storage facilities, respectively. Onshore petroleum and natural gas gathering and boosting facilities must use the population emission factors listed in Table W–1A of this subpart.

GHG_i = For onshore petroleum and natural gas production facilities, onshore petroleum and natural gas gathering and boosting facilities, onshore natural gas transmission compression facilities, and underground natural gas storage facilities, concentration of GHG_i, CH_4 or CO_2, in produced natural gas or processed natural gas for each facility as specified in paragraphs (u)(2)(i), (iii), and (iv) of this section.

* * * * *

(2) For the onshore petroleum and natural gas production industry segment, you have the option in the first two consecutive calendar years to determine ''$Count_t$'' for Equation W–1 of this section for each type of natural gas pneumatic device (continuous high bleed, continuous low bleed, and intermittent bleed) using engineering estimates based on best available data. For the onshore petroleum and natural gas gathering and boosting industry segment, you have the option in the first two consecutive calendar years to determine ''$Count_t$'' for Equation W–1 for each type of natural gas pneumatic device (continuous high bleed, continuous low bleed, and intermittent bleed) using engineering estimates based on best available data.

* * * * *

(c) * * *

* * * * *

EF = Population emissions factors for natural gas driven pneumatic pumps (in standard cubic feet per hour per pump) listed in Table W–1A of this subpart for onshore petroleum and natural gas production and onshore petroleum and natural gas gathering and boosting facilities.

* * * * *

(d) * * *

(8) * * *

(iii) If a continuous gas analyzer is not available or installed, you may use the outlet pipeline quality specification for CO_2 in natural gas.

* * * * *

(g) *Well venting during completions and workovers with hydraulic fracturing.* Calculate annual volumetric natural gas emissions from gas well and oil well venting during completions and workovers involving hydraulic fracturing using Equation W–10A or Equation W–10B of this section. Equation W–10A applies to well venting when the gas flowback rate is measured from a specified number of example completions or workovers and Equation W–10B applies when the gas flowback vent or flare volume is measured for each completion or workover. Completion and workover activities are separated into two periods, an initial period when flowback is routed to open pits or tanks and a subsequent period when gas content is sufficient to route the flowback to a separator or when the gas content is sufficient to allow measurement by the devices specified in paragraph (g)(1) of this section, regardless of whether a separator is actually utilized. If you elect to use Equation W–10A, you must follow the procedures specified in paragraph (g)(1). If you elect to use Equation W–10B, you must use a recording flow meter installed on the vent line, downstream of a separator and ahead of a flare or vent, to measure the gas flowback. For either equation, emissions must be calculated separately for completions and workovers, for each sub-basin, and for each well type combination identified in paragraph (g)(2) of this section. You must calculate CH_4 and CO_2 volumetric and mass emissions as specified in paragraph (g)(3) of this section. If emissions from well venting during completions and workovers with hydraulic fracturing are routed to a flare, you must calculate CH_4, CO_2, and N_2O annual emissions as specified in paragraph (g)(4) of this section.

$$E_{s,n} = \sum_{p=1}^{W} \left[T_{p,s} \times FRM_s \times PR_{s,p} - EnF_{s,p} + \left[T_{p,i} \times FRM_i \div 2 \times PR_{s,p} \right] \right] \quad \text{(Eq. W-10A)}$$

$$E_{s,n} = \sum_{p=1}^{W} \left[FV_{s,p} - EnF_{s,p} + \left[T_{p,i} \times FR_{p,i} \div 2 \right] \right] \quad \text{(Eq. W-10B)}$$

Where:

$E_{s,n}$ = Annual volumetric natural gas emissions in standard cubic feet from gas venting during well completions or workovers following hydraulic fracturing for each sub-basin and well type combination.

W = Total number of wells completed or worked over using hydraulic fracturing in a sub-basin and well type combination.

$T_{p,s}$ = Cumulative amount of time of flowback, after sufficient quantities of gas are present to enable separation, where gas vented or flared for the completion or workover, in hours, for each well, p, in a sub-basin and well type combination during the reporting year. This may include non-contiguous periods of venting or flaring.

$T_{p,i}$ = Cumulative amount of time of flowback to open tanks/pits, from when gas is first detected until sufficient quantities of gas are present to enable separation, for the completion or workover, in hours, for each well, p, in a sub-basin and well type combination during the reporting year. This may include non-contiguous periods of routing to open tanks/pits but does not include periods when the oil well ceases to produce fluids to the surface.

FRM_s = Ratio of average gas flowback, during the period when sufficient quantities of gas are present to enable separation, of well completions and workovers from hydraulic fracturing to 30-day production rate for the sub-basin and well type combination, calculated using procedures specified in paragraph (g)(1)(iii) of this section.

FRM_i = Ratio of initial gas flowback rate during well completions and workovers from hydraulic fracturing to 30-day gas production rate for the sub-basin and well type combination, calculated using procedures specified in paragraph (g)(1)(iv) of this section, for the period of flow to open tanks/pits.

$PR_{s,p}$ = Average gas production flow rate during the first 30 days of production after completions of newly drilled wells or well workovers using hydraulic fracturing in standard cubic feet per hour of each well p, that was measured in the sub-basin and well type combination. If applicable, $PR_{s,p}$ may be calculated for oil wells using procedures specified in paragraph (g)(1)(vii) of this section.

$EnF_{s,p}$ = Volume of N_2 injected gas in cubic feet at standard conditions that was injected into the reservoir during an energized fracture job or during flowback for each well, p, as determined by using an appropriate meter according to methods described in § 98.234(b), or by using receipts of gas purchases that are used for the energized fracture job or injection during flowback. Convert to standard conditions using paragraph (t) of this section. If the fracture process did

not inject gas into the reservoir or if the injected gas is CO_2 then $EnF_{s,p}$ is 0.

$FV_{s,p}$ = Flow volume of vented or flared gas for each well, p, in standard cubic feet measured using a recording flow meter (digital or analog) on the vent line to measure gas flowback during the separation period of the completion or workover according to methods set forth in § 98.234(b).

$FR_{p,i}$ = Flow rate vented or flared of each well, p, in standard cubic feet per hour measured using a recording flow meter (digital or analog) on the vent line to measure the flowback, at the beginning of the period of time when sufficient quantities of gas are present to enable separation, of the completion or workover according to methods set forth in § 98.234(b).

(1) If you elect to use Equation W–10A of this section on gas wells, you must use Calculation Method 1 as specified in paragraph (g)(1)(i) of this section, or Calculation Method 2 as specified in paragraph (g)(1)(ii) of this section, to determine the value of FRM_s and FRM_i. If you elect to use Equation W–10A of this section on oil wells, you must use Calculation Method 1 as specified in paragraph (g)(1)(i) to determine the value of FRM_s and FRM_i. These values must be based on the flow rate for flowback gases, once sufficient gas is present to enable separation. The number of measurements or calculations required to estimate FRM_s and FRM_i must be determined individually for completions and workovers per sub-basin and well type combination as follows: Complete measurements or calculations for at least one completion or workover for less than or equal to 25 completions or workovers for each well type combination within a sub-basin; complete measurements or calculations for at least two completions or workovers for 26 to 50 completions or workovers for each sub-basin and well type combination; complete measurements or calculations for at least three completions or workovers for 51 to 100 completions or workovers for each sub-basin and well type combination; complete measurements or calculations for at least four completions or workovers for 101 to 250 completions or workovers for each sub-basin and well type combination; and complete measurements or calculations for at least five completions or workovers for greater than 250 completions or workovers for each sub-basin and well type combination.

(i) *Calculation Method 1.* You must use Equation W–12A of this section as specified in paragraph (g)(1)(iii) of this section to determine the value of FRM_s. You must use Equation W–12B of this section as specified in paragraph (g)(1)(iv) of this section to determine the value of FRM_i. The procedures specified in paragraphs (g)(1)(v) and (vi) of this section also apply. When making gas flowback measurements for use in Equations W–12A and W–12B of this section, you must use a recording flow meter (digital or analog) installed on the vent line, downstream of a separator and ahead of a flare or vent, to measure the gas flowback rates in units of standard cubic feet per hour according to methods set forth in § 98.234(b).

(ii) *Calculation Method 2 (for gas wells).* * * *

(iii) * * *

* * * * *

FRM_s = Ratio of average gas flowback rate, during the period of time when sufficient quantities of gas are present to enable separation, of well completions and workovers from hydraulic fracturing to 30-day gas production rate for each sub-basin and well type combination.

$FR_{s,p}$ = Measured average gas flowback rate from Calculation Method 1 described in paragraph (g)(1)(i) of this section or calculated average flowback rate from Calculation Method 2 described in paragraph (g)(1)(ii) of this section, during the separation period in standard cubic feet per hour for well(s) p for each sub-basin and well type combination. Convert measured and calculated FR_a values from actual conditions upstream of the restriction orifice (FR_a) to standard conditions ($FR_{s,p}$) for each well p using Equation W–33 in paragraph (t) of this section. You may not use flow volume as used in Equation W–10B of this section converted to a flow rate for this parameter.

$PR_{s,p}$ = Average gas production flow rate during the first 30 days of production after completions of newly drilled wells or well workovers using hydraulic fracturing, in standard cubic feet per hour for each well, p, that was measured in the sub-basin and well type combination. For oil wells for which production is not measured continuously during the first 30 days of production, the average flow rate may be based on individual well production tests conducted within the first 30 days of production. Alternatively, if applicable, $PR_{s,p}$ may be calculated for oil wells using procedures specified in paragraph (g)(1)(vii) of this section.

* * * * *

(iv) * * *

* * * * *

FRM_i = Ratio of initial gas flowback rate during well completions and workovers from hydraulic fracturing to 30-day gas production rate for the sub-basin and well type combination, for the period of flow to open tanks/pits.

* * * * *

$PR_{s,p}$ = Average gas production flow rate during the first 30-days of production after completions of newly drilled wells or well workovers using hydraulic fracturing, in standard cubic feet per hour of each well, p, that was measured in the sub-basin and well type combination. For oil wells for which production is not measured continuously during the first 30 days of production, the average flow rate may be based on individual well production tests conducted within the first 30 days of production. Alternatively, if applicable, $PR_{s,p}$ may be calculated for oil wells using procedures specified in paragraph (g)(1)(vii) of this section.

* * * * *

(v) For Equation W–10A of this section, the ratio of gas flowback rate during well completions and workovers from hydraulic fracturing to 30-day gas production rate are applied to all well completions and well workovers, respectively, in the sub-basin and well type combination for the total number of hours of flowback and for the first 30 day average gas production rate for each of these wells.

(vi) For Equations W–12A and W–12B of this section, calculate new flowback rates for well completions and well workovers in each sub-basin and well type combination once every two years starting in the first calendar year of data collection.

(vii) For oil wells where the gas production rate is not metered and you elect to use Equation W–10A of this section, calculate the average gas production rate ($PR_{s,p}$) using Equation W–12C of this section. If GOR cannot be determined from your available data, then you must use one of the procedures specified in paragraph (g)(1)(vii)(A) or (B) of this section to determine GOR. If GOR from each well is not available, use the GOR from a cluster of wells in the same sub-basin category.

$$PR_{s,p} = GOR_p * \frac{V_p}{720} \qquad \text{(Eq. W-12C)}$$

Where:

$PR_{s,p}$ = Average gas production flow rate during the first 30 days of production after completions of newly drilled wells or well workovers using hydraulic fracturing in standard cubic feet per hour of well p, in the sub-basin and well type combination.

GOR_p = Average gas to oil ratio during the first 30 days of production after completions of newly drilled wells or workovers using hydraulic fracturing in standard cubic feet of gas per barrel of oil for each well p, that was measured in the sub-basin and well type combination; oil here refers to hydrocarbon liquids produced of all API gravities.

V_p = Volume of oil produced during the first 30 days of production after completions of newly drilled wells or well workovers using hydraulic fracturing in barrels of each well p, that was measured in the sub-basin and well type combination.

720 = Conversion from 30 days of production to hourly production rate.

(A) You may use an appropriate standard method published by a consensus-based standards organization if such a method exists.

(B) You may use an industry standard practice as described in § 98.234(b).

(2) For paragraphs (g) introductory text and (g)(1) of this section, measurements and calculations are completed separately for workovers and completions per sub-basin and well type combination. A well type combination is a unique combination of the parameters listed in paragraphs (g)(2)(i) through (iv) of this section.

* * * * *

(iv) Oil well or gas well.

* * * * *

(4) Calculate annual emissions from well venting during well completions and workovers from hydraulic fracturing where all or a portion of the gas is flared as specified in paragraphs (g)(4)(i) and (ii) of this section.

* * * * *

(i) * * *

(2) *Method for determining emissions from blowdown vent stacks according to equipment or event type.* If you elect to determine emissions according to each equipment or event type, using unique physical volumes as calculated in paragraph (i)(1) of this section, you must calculate emissions as specified in paragraph (i)(2)(i) of this section and either paragraph (i)(2)(ii) or, if applicable, paragraph (i)(2)(iii) of this section for each equipment or event type. For industry segments other than onshore natural gas transmission pipeline, equipment or event types must be grouped into the following seven categories: Facility piping (*i.e.,* piping within the facility boundary other than physical volumes associated with distribution pipelines), pipeline venting (*i.e.,* physical volumes associated with distribution pipelines vented within the facility boundary), compressors, scrubbers/strainers, pig launchers and receivers, emergency shutdowns (this category includes emergency shutdown blowdown emissions regardless of equipment type), and all other equipment with a physical volume greater than or equal to 50 cubic feet. If a blowdown event resulted in emissions from multiple equipment types and the emissions cannot be apportioned to the different equipment types, then categorize the blowdown event as the equipment type that represented the largest portion of the emissions for the blowdown event. For the onshore natural gas transmission pipeline segment, pipeline segments or event types must be grouped into the following eight categories: Pipeline integrity work (*e.g.,* the preparation work of modifying facilities, ongoing assessments, maintenance or mitigation), traditional operations or pipeline maintenance, equipment replacement or repair (*e.g.,* valves), pipe abandonment, new construction or modification of pipelines including commissioning and change of service, operational precaution during activities (*e.g.* excavation near pipelines), emergency shutdowns including pipeline incidents as defined in 49 CFR 191.3, and all other pipeline segments with a physical volume greater than or equal to 50 cubic feet. If a blowdown event resulted in emissions from multiple categories and the emissions cannot be apportioned to the different categories, then categorize the blowdown event in the category that represented the largest portion of the emissions for the blowdown event.

(i) * * *

* * * * *

T_a = Temperature at actual conditions in the unique physical volume (°F). For emergency blowdowns at onshore petroleum and natural gas gathering and boosting facilities, engineering estimates based on best available information may be used to determine the temperature.

* * * * *

P_a = Absolute pressure at actual conditions in the unique physical volume (psia). For emergency blowdowns at onshore petroleum and natural gas gathering and boosting facilities, engineering estimates based on best available information may be used to determine the pressure.

* * * * *

(j) *Onshore production and onshore petroleum and natural gas gathering and boosting storage tanks.* Calculate CH_4, CO_2, and N_2O (when flared) emissions from atmospheric pressure fixed roof storage tanks receiving hydrocarbon produced liquids from onshore petroleum and natural gas production facilities and onshore petroleum and natural gas gathering and boosting facilities (including stationary liquid storage not owned or operated by the reporter), as specified in this paragraph (j). For gas-liquid separators or onshore petroleum and natural gas gathering and boosting non-separator equipment (*e.g.,* stabilizers, slug catchers) with annual average daily throughput of oil greater than or equal to 10 barrels per day, calculate annual CH_4 and CO_2 using Calculation Method 1 or 2 as specified in paragraphs (j)(1) and (2) of this section. For wells flowing directly to atmospheric storage tanks without passing through a separator with throughput greater than or equal to 10 barrels per day, calculate annual CH_4 and CO_2 emissions using Calculation Method 2 as specified in paragraph (j)(2) of this section. For hydrocarbon liquids flowing to gas-liquid separators or non-separator equipment or directly to atmospheric storage tanks with throughput less than 10 barrels per day, use Calculation Method 3 as specified in paragraph (j)(3) of this section. If you use Calculation Method 1 or Calculation Method 2 for separators, you must also calculate emissions that may have occurred due to dump valves not closing properly using the method specified in paragraph (j)(6) of this section. If emissions from atmospheric pressure fixed roof storage tanks are routed to a vapor recovery system, you must adjust the emissions downward according to paragraph (j)(4) of this section. If emissions from atmospheric pressure fixed roof storage tanks are routed to a flare, you must calculate CH_4, CO_2, and N_2O annual emissions as specified in paragraph (j)(5) of this section.

(1) *Calculation Method 1.* Calculate annual CH_4 and CO_2 emissions from onshore production storage tanks and onshore petroleum and natural gas gathering and boosting storage tanks using operating conditions in the last gas-liquid separator or non-separator equipment before liquid transfer to storage tanks. Calculate flashing emissions with a software program, such as AspenTech HYSYS® or API 4697 E&P Tank, that uses the Peng-Robinson equation of state, models flashing emissions, and speciates CH_4 and CO_2 emissions that will result when the oil from the separator or non-separator equipment enters an atmospheric pressure storage tank. The following parameters must be determined for typical operating

conditions over the year by engineering estimate and process knowledge based on best available data, and must be used at a minimum to characterize emissions from liquid transferred to tanks:

(i) Separator or non-separator equipment temperature.

(ii) Separator or non-separator equipment pressure.

(iii) Sales oil or stabilized oil API gravity.

(iv) Sales oil or stabilized oil production rate.

(v) Ambient air temperature.

(vi) Ambient air pressure.

(vii) Separator or non-separator equipment oil composition and Reid vapor pressure. If this data is not available, determine these parameters by using one of the methods described in paragraphs (j)(1)(vii)(A) through (C) of this section.

(A) If separator or non-separator equipment oil composition and Reid vapor pressure default data are provided with the software program, select the default values that most closely match your separator or non-separator equipment pressure first, and API gravity secondarily.

(B) If separator or non-separator equipment oil composition and Reid vapor pressure data are available through your previous analysis, select the latest available analysis that is representative of produced crude oil or condensate from the sub-basin category for onshore petroleum and natural gas production or from the county for onshore petroleum and natural gas gathering and boosting.

(C) Analyze a representative sample of separator or non-separator equipment oil in each sub-basin category for onshore petroleum and natural gas production or each county for onshore petroleum and natural gas gathering and boosting for oil composition and Reid vapor pressure using an appropriate standard method published by a consensus-based standards organization.

(2) *Calculation Method 2.* Calculate annual CH_4 and CO_2 emissions using the methods in paragraph (j)(2)(i) of this section for gas-liquid separators with annual average daily throughput of oil greater than or equal to 10 barrels per day. Calculate annual CH_4 and CO_2 emissions using the methods in paragraph (j)(2)(ii) of this section for wells with annual average daily oil production greater than or equal to 10 barrels per day that flow directly to atmospheric storage tanks in onshore petroleum and natural gas production and onshore petroleum and natural gas gathering and boosting (if applicable). Calculate annual CH_4 and CO_2 emissions using the methods in paragraph (j)(2)(iii) of this section for non-separator equipment with annual average daily hydrocarbon liquids throughput greater than or equal to 10 barrels per day that flow directly to atmospheric storage tanks in onshore petroleum and natural gas gathering and boosting.

(i) *Flow to storage tank after passing through a separator.* Assume that all of the CH_4 and CO_2 in solution at separator temperature and pressure is emitted from oil sent to storage tanks. You may use an appropriate standard method published by a consensus-based standards organization if such a method exists or you may use an industry standard practice as described in § 98.234(b) to sample and analyze separator oil composition at separator pressure and temperature.

(ii) *Flow to storage tank direct from wells.* Calculate CH_4 and CO_2 emissions using either of the methods in paragraph (j)(2)(ii)(A) or (B) of this section.

(A) If well production oil and gas compositions are available through a previous analysis, select the latest available analysis that is representative of produced oil and gas from the sub-basin category and assume all of the CH_4 and CO_2 in both oil and gas are emitted from the tank.

(B) If well production oil and gas compositions are not available, use default oil and gas compositions in software programs, such as API 4697 E&P Tank, that most closely match the well production gas/oil ratio and API gravity and assume all of the CH_4 and CO_2 in both oil and gas are emitted from the tank.

(iii) *Flow to storage tank direct from non-separator equipment.* Calculate CH_4 and CO_2 emissions using either of the methods in paragraph (j)(2)(iii)(A) or (B) of this section.

(A) If other non-separator equipment liquid and gas compositions are available through a previous analysis, select the latest available analysis that is representative of liquid and gas from non-separator equipment in the same county and assume all of the CH_4 and CO_2 in both hydrocarbon liquids and gas are emitted from the tank.

(B) If non-separator equipment liquid and gas compositions are not available, use default liquid and gas compositions in software programs, such as API 4697 E&P Tank, that most closely match the non-separator equipment gas/liquid ratio and API gravity and assume all of the CH_4 and CO_2 in both hydrocarbon liquids and gas are emitted from the tank.

(3) *Calculation Method 3.* Calculate CH_4 and CO_2 emissions using Equation W–15 of this section:

$$E_{s,i} = EF_i * Count * 1000 \qquad \text{(Eq. W-15)}$$

Where:

$E_{s,i}$ = Annual total volumetric GHG emissions (either CO_2 or CH_4) at standard conditions in cubic feet.

EF_i = Population emission factor for separators, wells, or non-separator equipment in thousand standard cubic feet per separator, well, or non-separator equipment per year, for crude oil use 4.2 for CH_4 and 2.8 for CO_2 at 60 °F and 14.7 psia, and for gas condensate use 17.6 for CH_4 and 2.8 for CO_2 at 60 °F and 14.7 psia.

Count = Total number of separators, wells, or non-separator equipment with annual average daily throughput less than 10 barrels per day. Count only separators, wells, or non-separator equipment that feed oil directly to the storage tank.

1,000 = Conversion from thousand standard cubic feet to standard cubic feet.

* * * * *

(6) If you use Calculation Method 1 or Calculation Method 2 in paragraph (j)(1) or (2) of this section, calculate emissions from occurrences of gas-liquid separator liquid dump valves not closing during the calendar year by using Equation W–16 of this section.

$$E_{s,i,o} = \left(CF_n * \frac{E_n}{8760} * T_n \right) \qquad \text{(Eq. W-16)}$$

Where:

$E_{s,i,o}$ = Annual volumetric GHG emissions at standard conditions from each storage tank in cubic feet that resulted from the dump valve on the gas-liquid separator not closing properly.

E_n = Storage tank emissions as determined in paragraphs (j)(1), (j)(2) and, if applicable, (j)(4) of this section in standard cubic feet per year.

T_n = Total time a dump valve is not closing properly in the calendar year in hours. Estimate T_n based on maintenance, operations, or routine separator inspections that indicate the period of time when the valve was malfunctioning in open or partially open position.

CF_n = Correction factor for tank emissions for time period T_n is 2.87 for crude oil production. Correction factor for tank emissions for time period T_n is 4.37 for gas condensate production.

8,760 = Conversion to hourly emissions.

* * * * *

(n) * * *

(2) * * *

(i) For onshore natural gas production and onshore petroleum and natural gas gathering and boosting, determine the GHG mole fraction using paragraph (u)(2)(i) of this section.

* * * * *

(o) *Centrifugal compressor venting.* If you are required to report emissions from centrifugal compressor venting as specified in § 98.232(d)(2), (e)(2), (f)(2), (g)(2), and (h)(2), you must conduct volumetric emission measurements specified in paragraph (o)(1) of this section using methods specified in paragraphs (o)(2) through (5) of this section; perform calculations specified in paragraphs (o)(6) through (9) of this section; and calculate CH_4 and CO_2 mass emissions as specified in paragraph (o)(11) of this section. If emissions from a compressor source are routed to a flare, paragraphs (o)(1) through (11) do not apply and instead you must calculate CH_4, CO_2, and N_2O emissions as specified in paragraph (o)(12) of this section. If emissions from a compressor source are captured for fuel use or are routed to a thermal oxidizer, paragraphs (o)(1) through (12) do not apply and instead you must calculate and report emissions as specified in subpart C of this part. If emissions from a compressor source are routed to vapor recovery, paragraphs (o)(1) through (12) do not apply. If you are required to report emissions from centrifugal compressor venting at an onshore petroleum and natural gas production facility as specified in § 98.232(c)(19) or an onshore petroleum and natural gas gathering and boosting facility as specified in § 98.232(j)(8), you must calculate volumetric emissions as specified in paragraph (o)(10); and calculate CH_4 and CO_2 mass emissions as specified in paragraph (o)(11).

* * * * *

(10) *Method for calculating volumetric GHG emissions from wet seal oil degassing vents at an onshore petroleum and natural gas production facility or an onshore petroleum and natural gas gathering and boosting facility.* You must calculate emissions from centrifugal compressor wet seal oil degassing vents at an onshore petroleum and natural gas production facility or an onshore petroleum and natural gas gathering and boosting facility using Equation W–25 of this section.

$$E_{s,i} = Count * EF_{i,s} \qquad \text{(Eq. W-25)}$$

Where:

$E_{s,i}$ = Annual volumetric GHG_i (either CH_4 or CO_2) emissions from centrifugal compressor wet seals, at standard conditions, in cubic feet.

Count = Total number of centrifugal compressors that have wet seal oil degassing vents.

$EF_{i,s}$ = Emission factor for GHG_i. Use 1.2×10^7 standard cubic feet per year per compressor for CH_4 and 5.30×10^5 standard cubic feet per year per compressor for CO_2 at 60 °F and 14.7 psia.

* * * * *

(p) *Reciprocating compressor venting.* If you are required to report emissions from reciprocating compressor venting as specified in § 98.232(d)(1), (e)(1), (f)(1), (g)(1), and (h)(1), you must conduct volumetric emission measurements specified in paragraph (p)(1) of this section using methods specified in paragraphs (p)(2) through (5) of this section; perform calculations specified in paragraphs (p)(6) through (9) of this section; and calculate CH_4 and CO_2 mass emissions as specified in paragraph (p)(11) of this section. If emissions from a compressor source are routed to a flare, paragraphs (p)(1) through (11) do not apply and instead you must calculate CH_4, CO_2, and N_2O emissions as specified in paragraph (p)(12) of this section. If emissions from a compressor source are captured for fuel use or are routed to a thermal oxidizer, paragraphs (p)(1) through (12) do not apply and instead you must calculate and report emissions as specified in subpart C of this part. If emissions from a compressor source are routed to vapor recovery, paragraphs (p)(1) through (12) do not apply. If you are required to report emissions from reciprocating compressor venting at an onshore petroleum and natural gas production facility as specified in § 98.232(c)(11) or an onshore petroleum and natural gas gathering and boosting facility as specified in § 98.232(j)(5), you must calculate volumetric emissions as specified in paragraph (p)(10); and calculate CH_4 and CO_2 mass emissions as specified in paragraph (p)(11).

* * * * *

(10) *Method for calculating volumetric GHG emissions from reciprocating compressor venting at an onshore petroleum and natural gas production facility or an onshore petroleum and natural gas gathering and boosting facility.* You must calculate emissions from reciprocating compressor venting at an onshore petroleum and natural gas production facility or an onshore petroleum and natural gas gathering and boosting facility using Equation W–29D of this section.

$$E_{s,i} = Count * EF_{i,s} \qquad \text{(Eq. W-29D)}$$

Where:

$E_{s,i}$ = Annual volumetric GHG_i (either CH_4 or CO_2) emissions from reciprocating compressors, at standard conditions, in cubic feet.

Count = Total number of reciprocating compressors.

$EF_{i,s}$ = Emission factor for GHG_i. Use 9.48×10^3 standard cubic feet per year per compressor for CH_4 and 5.27×10^2 standard cubic feet per year per compressor for CO_2 at 60 °F and 14.7 psia.

* * * * *

(r) *Equipment leaks by population count.* This paragraph (r) applies to emissions sources listed in § 98.232 (c)(21), (f)(5), (g)(3), (h)(4), (i)(2), (i)(3), (i)(4), (i)(5), (i)(6), (j)(10), and (j)(11) on streams with gas content greater than 10 percent CH_4 plus CO_2 by weight. Emissions sources in streams with gas content less than or equal to 10 percent CH_4 plus CO_2 by weight are exempt from the requirements of this paragraph (r) and do not need to be reported. Tubing systems equal to or less than one half inch diameter are exempt from the requirements of paragraph (r) of this section and do not need to be reported. You must calculate emissions from all emission sources listed in this paragraph using Equation W–32A of this section, except for natural gas distribution facility emission sources listed in § 98.232(i)(3). Natural gas distribution facility emission sources listed in § 98.232(i)(3) must calculate emissions using Equation W–32B of this section and according to paragraph (r)(6)(ii) of this section.

$$E_{s,e,i} = Count_e * EF_{s,e} * GHG_i * T_e \quad \text{(Eq. W-32A)}$$

$$E_{s,MR,i} = Count_{MR} * EF_{s,MR,i} * T_{w,avg} \quad \text{(Eq. W-32B)}$$

Where:

$E_{s,e,i}$ = Annual volumetric emissions of GHG_i from the emission source type in standard cubic feet. The emission source type may be a component (*e.g.* connector, open-ended line, etc.), below grade metering-regulating station, below grade transmission-distribution transfer station, distribution main, distribution service, or gathering pipeline.

$E_{s,MR,i}$ = Annual volumetric emissions of GHG_i from all meter/regulator runs at above grade metering regulating stations that are not above grade transmission-distribution transfer stations or, when used to calculate emissions according to paragraph (q)(9) of this section, the annual volumetric emissions of GHG_i from all meter/regulator runs at above grade transmission-distribution transfer stations, in standard cubic feet.

$Count_e$ = Total number of the emission source type at the facility. For onshore petroleum and natural gas production facilities and onshore petroleum and natural gas gathering and boosting facilities, average component counts are provided by major equipment piece in Tables W–1B and Table W–1C of this subpart. Use average component counts as appropriate for operations in Eastern and Western U.S., according to Table W–1D of this subpart. Onshore petroleum and natural gas gathering and boosting facilities must also count the miles of gathering pipelines by material type (protected steel, unprotected steel, plastic, or cast iron). Underground natural gas storage facilities must count each component listed in Table W–4 of this subpart. LNG storage facilities must count the number of vapor recovery compressors. LNG import and export facilities must count the number of vapor recovery compressors. Natural gas distribution facilities must count: (1) The number of distribution services by material type; (2) miles of distribution mains by material type; and (3) number of below grade metering-regulating stations, by pressure type; as listed in Table W–7 of this subpart.

$Count_{MR}$ = Total number of meter/regulator runs at above grade metering-regulating stations that are not above grade transmission-distribution transfer stations or, when used to calculate emissions according to paragraph (q)(9) of this section, the total number of meter/regulator runs at above grade transmission-distribution transfer stations.

$EF_{s,e}$ = Population emission factor for the specific emission source type, as listed in Tables W–1A and W–4 through W–7 of this subpart. Use appropriate population emission factor for operations in Eastern and Western U.S., according to Table W–1D of this subpart.

$EF_{s,MR,i}$ = Meter/regulator run population emission factor for GHG_i based on all surveyed above grade transmission-distribution transfer stations over ''n'' years, in standard cubic feet of GHG_i per operational hour of all meter/regulator runs, as determined in Equation W–31 of this section.

GHG_i = For onshore petroleum and natural gas production facilities and onshore petroleum and natural gas gathering and boosting facilities, concentration of GHG_i, CH_4, or CO_2, in produced natural gas as defined in paragraph (u)(2) of this section; for onshore natural gas transmission compression and underground natural gas storage, GHG_i equals 0.975 for CH_4 and 1.1×10^{-2} for CO_2; for LNG storage and LNG import and export equipment, GHG_i equals 1 for CH_4 and 0 for CO_2; and for natural gas distribution, GHG_i equals 1 for CH_4 and 1.1×10^{-2} CO_2.

T_e = Average estimated time that each emission source type associated with the equipment leak emission was operational in the calendar year, in hours, using engineering estimate based on best available data.

$T_{w,avg}$ = Average estimated time that each meter/regulator run was operational in the calendar year, in hours per meter/regulator run, using engineering estimate based on best available data.

* * * * *

(2) Onshore petroleum and natural gas production facilities and onshore petroleum and natural gas gathering and boosting facilities must use the appropriate default whole gas population emission factors listed in Table W–1A of this subpart. Major equipment and components associated with gas wells and onshore petroleum and natural gas gathering and boosting systems are considered gas service components in reference to Table W–1A of this subpart and major natural gas equipment in reference to Table W–1B of this subpart. Major equipment and components associated with crude oil wells are considered crude service components in reference to Table W–1A of this subpart and major crude oil equipment in reference to Table W–1C of this subpart. Where facilities conduct EOR operations the emissions factor listed in Table W–1A of this subpart shall be used to estimate all streams of gases, including recycle CO_2 stream. The component count can be determined using either of the calculation methods described in this paragraph (r)(2), except for miles of gathering pipelines by material type, which must be determined using Component Count Method 2 in paragraph (r)(2)(ii) of this section. The same calculation method must be used for the entire calendar year.

(i) *Component Count Method 1.* For all onshore petroleum and natural gas production operations and onshore petroleum and natural gas gathering and boosting operations in the facility perform the following activities:

(A) Count all major equipment listed in Table W–1B and Table W–1C of this subpart. For meters/piping, use one meters/piping per well-pad for onshore petroleum and natural gas production operations and the number of meters in the facility for onshore petroleum and natural gas gathering and boosting operations.

(B) Multiply major equipment counts by the average component counts listed in Table W–1B of this subpart for onshore natural gas production and onshore petroleum and natural gas gathering and boosting; and Table W–1C of this subpart for onshore oil production. Use the appropriate factor

in Table W–1A of this subpart for operations in Eastern and Western U.S. according to the mapping in Table W–1D of this subpart.

* * * * *

(u) * * *

(2) * * *

(i) *GHG mole fraction in produced natural gas for onshore petroleum and natural gas production facilities and onshore petroleum and natural gas gathering and boosting facilities.* If you have a continuous gas composition analyzer for produced natural gas, you must use an annual average of these values for determining the mole fraction. If you do not have a continuous gas composition analyzer, then you must use an annual average gas composition based on your most recent available analysis of the sub-basin category or facility, as applicable to the emission source.

* * * * *

(iii) *GHG mole fraction in transmission pipeline natural gas that passes through the facility for the onshore natural gas transmission compression industry segment and the onshore natural gas transmission pipeline industry segment.* You may use either a default 95 percent methane and 1 percent carbon dioxide fraction for GHG mole fraction in natural gas or site specific engineering estimates based on best available data.

* * * * *

(z) *Onshore petroleum and natural gas production, onshore petroleum and natural gas gathering and boosting, and natural gas distribution combustion emissions.* Calculate CO_2, CH_4, and N_2O combustion-related emissions from stationary or portable equipment, except as specified in paragraphs (z)(3) and (4) of this section, as follows:

(1) * * *

(ii) Emissions from fuel combusted in stationary or portable equipment at onshore petroleum and natural gas production facilities, at onshore petroleum and natural gas gathering and boosting facilities, and at natural gas distribution facilities will be reported according to the requirements specified in § 98.236(z) and not according to the reporting requirements specified in subpart C of this part.

* * * * *

■ 6. Section 98.234 is amended by adding paragraph (g) to read as follows:

§ 98.234 Monitoring and QA/QC requirements.

* * * * *

(g) *Special reporting provisions for best available monitoring methods in reporting year 2016*—(1) *Best available monitoring methods.* From January 1, 2016, to December 31, 2016, you must use the calculation methodologies and equations in § 98.233 but you may use the best available monitoring method as described in paragraph (g)(2) of this section for any parameter specified in paragraphs (g)(3) through (6) of this section for which it is not reasonably feasible to acquire, install, and operate a required piece of monitoring equipment by January 1, 2016. Starting no later than January 1, 2017, you must discontinue using best available methods and begin following all applicable monitoring and QA/QC requirements of this part. For onshore petroleum and natural gas production, this paragraph (g)(1) only applies if emissions from well completions and workovers of oil wells with hydraulic fracturing cause your facility to exceed the reporting threshold in § 98.231(a)(1).

(2) Best available monitoring methods means any of the following methods:

(i) Monitoring methods currently used by the facility that do not meet the specifications of this subpart.

(ii) Supplier data.

(iii) Engineering calculations.

(iv) Other company records.

(3) *Best available monitoring methods for well-related measurement data for oil wells with hydraulic fracturing.* You may use best available monitoring methods for any well-related measurement data that cannot reasonably be measured according to the monitoring and QA/QC requirements of this subpart for venting during well completions and workovers of oil wells with hydraulic fracturing.

(4) *Best available monitoring methods for measurement data for onshore petroleum and natural gas gathering and boosting facilities.* You may use best available monitoring methods for any leak detection and/or measurement data that cannot reasonably be measured according to the monitoring and QA/QC requirements of this subpart for acid gas removal vents as specified in § 98.233(d).

(5) *Best available monitoring methods for measurement data for natural gas transmission pipelines.* You may use best available monitoring methods for any measurement data for natural gas transmission pipelines that cannot reasonably be obtained according to the monitoring and QA/QC requirements of this subpart for blowdown vent stacks.

(6) *Best available monitoring methods for specified activity data.* You may use best available monitoring methods for activity data as listed in paragraphs (g)(6)(i) through (iii) of this section that cannot reasonably be obtained according to the monitoring and QA/QC requirements of this subpart for well completions and workovers of oil wells with hydraulic fracturing, onshore petroleum and natural gas gathering and boosting facilities, or natural gas transmission pipelines.

(i) Cumulative hours of venting, days, or times of operation in § 98.233(e), (g), (o), (p), and (r).

(ii) Number of blowdowns, completions, workovers, or other events in § 98.233(g) and (i).

(iii) Cumulative volume produced, volume input or output, or volume of fuel used in paragraphs § 98.233(d), (e), (j), (n), and (z).

* * * * *

■ 7. Section 98.236 is amended by:

■ a. Revising paragraph (a) introductory text;

■ b. Adding paragraphs (a)(9) and (10);

■ c. Revising paragraphs (d)(1)(i) and (vi);

■ d. Revising paragraphs (e)(1)(i) and (xviii);

■ e. Revising paragraphs (f)(1)(ii), (f)(1)(xi)(A), (f)(1)(xii)(A), and (f)(2)(i);

■ f. Revising paragraphs (g) introductory text, (g)(1), (g)(2), (g)(5), and (g)(6);

■ g. Revising paragraphs (h)(1)(i) and (iv), (h)(2)(i) and (iv), (h)(3)(i), and (h)(4)(i);

■ h. Revising paragraphs (i) introductory text and (i)(1) introductory text;

■ i. Adding paragraph (i)(3);

■ j. Revising paragraphs (j) introductory text and (j)(1) introductory text;

■ k. Revising paragraphs (j)(1)(i), (iii), (iv) (v), (vii), and (viii);

■ l. Revising paragraphs (j)(2)(i) introductory text, (j)(2)(i)(A) through (C), (j)(2)(ii), (j)(2)(iii) introductory text, (j)(2)(iii)(A) and (B), and (j)(3) introductory text;

■ m. Revising paragraph (l)(1) introductory text;

■ n. Redesignating paragraphs (l)(1)(ii) through (vi) as paragraphs (l)(1)(iii) through (vii), respectively;

■ o. Adding paragraph (l)(1)(ii);

■ p. Revising newly designated paragraph (l)(1)(v);

■ q. Revising paragraph (l)(2) introductory text;

■ r. Redesignating paragraphs (l)(2)(ii) through (vii) as paragraphs (l)(2)(iii) through (viii), respectively;

■ s. Adding paragraph (l)(2)(ii);

■ t. Revising newly designated paragraph (l)(2)(v);

■ u. Revising paragraph (l)(3) introductory text;

■ v. Redesignating paragraphs (l)(3)(ii) through (v) as paragraphs (l)(3)(iii) through (vi), respectively;

■ w. Adding paragraph (l)(3)(ii);

■ x. Revising newly designated paragraph (l)(3)(iv);

■ y. Revising paragraph (l)(4) introductory text;
■ a. Redesignating paragraphs (l)(4)(ii) through (vi) as paragraphs (l)(4)(iii) through (vii), respectively;
■ aa. Adding paragraph (l)(4)(ii);
■ bb. Revising newly designated paragraph (l)(4)(iv);
■ cc. Revising paragraphs (m)(1), (m)(5), (m)(6), (m)(7)(i), (m)(8)(i);
■ dd. Revising paragraph (n)(1);
■ ee. Revising paragraphs (o) introductory text and (o)(5) introductory text;
■ ff. Revising paragraphs (p) introductory text and (p)(5) introductory text;
■ gg. Revising paragraphs (r)(1) introductory text, (r)(1)(i), (r)(3) introductory text, and (r)(3)(ii) introductory text;
■ hh. Revising paragraph (z) introductory text;
■ ii. Revising paragraphs (aa) introductory text and (aa)(1)(ii)(D) through (H);
■ jj. Adding paragraphs (aa)(10) and (11); and
■ kk. Revising paragraph (cc).

The revisions and additions read as follows:

§ 98.236 Data reporting requirements.

* * * * *

(a) The annual report must include the information specified in paragraphs (a)(1) through (10) of this section for each applicable industry segment. The annual report must also include annual emissions totals, in metric tons of each GHG, for each applicable industry segment listed in paragraphs (a)(1) through (10), and each applicable emission source listed in paragraphs (b) through (z) of this section.

* * * * *

(9) *Onshore petroleum and natural gas gathering and boosting.* For the equipment/activities specified in paragraphs (a)(9)(i) through (xi) of this section, report the information specified in the applicable paragraphs of this section.

(i) *Natural gas pneumatic devices.* Report the information specified in paragraph (b) of this section.

(ii) *Natural gas driven pneumatic pumps.* Report the information specified in paragraph (c) of this section.

(iii) *Acid gas removal units.* Report the information specified in paragraph (d) of this section.

(iv) *Dehydrators.* Report the information specified in paragraph (e) of this section.

(v) *Blowdown vent stacks.* Report the information specified in paragraph (i) of this section.

(vi) *Storage tanks.* Report the information specified in paragraph (j) of this section.

(vii) *Flare stacks.* Report the information specified in paragraph (n) of this section.

(viii) *Centrifugal compressors.* Report the information specified in paragraph (o) of this section.

(ix) *Reciprocating compressors.* Report the information specified in paragraph (p) of this section.

(x) *Equipment leaks by population count.* Report the information specified in paragraph (r) of this section.

(xi) *Combustion equipment.* Report the information specified in paragraph (z) of this section.

(10) *Onshore natural gas transmission pipeline.* For blowdown vent stacks, report the information specified in paragraph (i) of this section.

* * * * *

(d) * * *

(1) * * *

(i) A unique name or ID number for the acid gas removal unit. For the onshore petroleum and natural gas production and the onshore petroleum and natural gas gathering and boosting industry segments, a different name or ID may be used for a single acid gas removal unit for each location it operates at in a given year.

* * * * *

(vi) Sub-basin ID that best represents the wells supplying gas to the unit (for the onshore petroleum and natural gas production industry segment only) or name of the county that best represents the equipment supplying gas to the unit (for the onshore petroleum and natural gas gathering and boosting industry segment only).

* * * * *

(e) * * *

(1) * * *

(i) A unique name or ID number for the dehydrator. For the onshore petroleum and natural gas production and the onshore petroleum and natural gas gathering and boosting industry segments, a different name or ID may be used for a single dehydrator for each location it operates at in a given year.

* * * * *

(xviii) Sub-basin ID that best represents the wells supplying gas to the dehydrator (for the onshore petroleum and natural gas production industry segment only) or name of the county that best represents the equipment supplying gas to the dehydrator (for the onshore petroleum and natural gas gathering and boosting industry segment only).

* * * * *

(f) * * *

(1) * * *

(ii) Well tubing diameter and pressure group ID and a list of the well ID numbers associated with each sub-basin and well tubing diameter and pressure group ID.

* * * * *

(xi) * * *

(A) Well ID number of tested well.

* * * * *

(xii) * * *

(A) Well ID number.

* * * * *

(2) * * *

(i) Sub-basin ID and a list of the well ID numbers associated with each sub-basin.

* * * * *

(g) *Completions and workovers with hydraulic fracturing.* You must indicate whether your facility had any well completions or workovers with hydraulic fracturing during the calendar year. If your facility had well completions or workovers with hydraulic fracturing during the calendar year, then you must report information specified in paragraphs (g)(1) through (10) of this section, for each sub-basin and well type combination. Report information separately for completions and workovers.

(1) Sub-basin ID and a list of the well ID numbers associated with each sub-basin that had completions or workovers with hydraulic fracturing during the calendar year.

(2) Well type combination (horizontal or vertical, gas well or oil well).

* * * * *

(5) If you used Equation W–10A of § 98.233 to calculate annual volumetric total gas emissions, then you must report the information specified in paragraphs (g)(5)(i) through (iii) of this section.

(i) Cumulative gas flowback time, in hours, from when gas is first detected until sufficient quantities are present to enable separation, and the cumulative flowback time, in hours, after sufficient quantities of gas are present to enable separation (sum of ''$T_{p,i}$'' and sum of ''$T_{p,s}$'' values used in Equation W–10A of § 98.233). You may delay the reporting of this data element if you indicate in the annual report that wildcat wells and/or delineation wells are the only wells included in this number. If you elect to delay reporting of this data element, you must report by the date specified in § 98.236(cc) the total number of hours of flowback from all wells during completions or workovers and the well ID number(s) for the well(s) included in the number.

(ii) For the measured well(s), the flowback rate, in standard cubic feet per

hour (average of ''$FR_{s,p}$'' values used in Equation W–12A of § 98.233), and the well ID numbers of the wells for which it is measured. You may delay the reporting of this data element if you indicate in the annual report that wildcat wells and/or delineation wells are the only wells that can be used for the measurement. If you elect to delay reporting of this data element, you must report by the date specified in § 98.236(cc) the measured flowback rate during well completion or workover and the well ID number(s) for the well(s) included in the measurement.

(iii) If you used Equation W–12C of § 98.233 to calculate the average gas production rate for an oil well, then you must report the information specified in paragraphs (g)(5)(iii)(A) and (B) of this section.

(A) Gas to oil ratio for the well in standard cubic feet of gas per barrel of oil (''GOR_p'' in Equation W–12C of § 98.233). You may delay the reporting of this data element if you indicate in the annual report that wildcat wells and/or delineation wells are the only wells that can be used for the measurement. If you elect to delay reporting of this data element, you must report by the date specified in § 98.236(cc) the gas to oil ratio for the well and the well ID number for the well.

(B) Volume of oil produced during the first 30 days of production after completions of each newly drilled well or well workover using hydraulic fracturing, in barrels (''V_p'' in Equation W–12C of § 98.233). You may delay the reporting of this data element if you indicate in the annual report that wildcat wells and/or delineation wells are the only wells that can be used for the measurement. If you elect to delay reporting of this data element, you must report by the date specified in § 98.236(cc) the volume of oil produced during the first 30 days of production after well completion or workover and the well ID number for the well.

(6) If you used Equation W–10B of § 98.233 to calculate annual volumetric total gas emissions, then you must report the information specified in paragraphs (g)(6)(i) through (iii) of this section.

(i) Vented natural gas volume, in standard cubic feet, for each well in the sub-basin (''$FV_{s,p}$'' in Equation W–10B of § 98.233).

(ii) Flow rate at the beginning of the period of time when sufficient quantities of gas are present to enable separation, in standard cubic feet per hour, for each well in the sub-basin (''$FR_{p,i}$'' in Equation W–10B of § 98.233).

(iii) The well ID number for which vented natural gas volume was measured.

* * * * *

(h) * * *

(1) * * *

(i) Sub-basin ID and a list of the well ID numbers associated with each sub-basin for gas well completions without hydraulic fracturing and without flaring.

* * * * *

(iv) Average daily gas production rate for all completions without hydraulic fracturing in the sub-basin without flaring, in standard cubic feet per hour (average of all ''V_p'' used in Equation W–13B of § 98.233). You may delay reporting of this data element if you indicate in the annual report that wildcat wells and/or delineation wells are the only wells that can be used for the measurement. If you elect to delay reporting of this data element, you must report by the date specified in § 98.236(cc) the measured average daily gas production rate for all wells during completions and the well ID number(s) for the well(s) included in the measurement.

* * * * *

(2) * * *

(i) Sub-basin ID and a list of the well ID numbers associated with each sub-basin for gas well completions without hydraulic fracturing and with flaring.

* * * * *

(iv) Average daily gas production rate for all completions without hydraulic fracturing in the sub-basin with flaring, in standard cubic feet per hour (the average of all ''V_p'' from Equation W–13B of § 98.233). You may delay reporting of this data element if you indicate in the annual report that wildcat wells and/or delineation wells are the only wells that can be used for the measurement. If you elect to delay reporting of this data element, you must report by the date specified in § 98.236(cc) the measured average daily gas production rate for all wells during completions and the well ID number(s) for the well(s) included in the measurement.

* * * * *

(3) * * *

(i) Sub-basin ID and a list of the well ID numbers associated with each sub-basin for gas well workovers without hydraulic fracturing and without flaring.

* * * * *

(4) * * *

(i) Sub-basin ID and a list of well ID numbers associated with each sub-basin for gas well workovers without hydraulic fracturing and with flaring.

* * * * *

(i) *Blowdown vent stacks.* You must indicate whether your facility has blowdown vent stacks. If your facility has blowdown vent stacks, then you must report whether emissions were calculated by equipment or event type or by using flow meters or a combination of both. If you calculated emissions by equipment or event type for any blowdown vent stacks, then you must report the information specified in paragraph (i)(1) of this section considering, in aggregate, all blowdown vent stacks for which emissions were calculated by equipment or event type. If you calculated emissions using flow meters for any blowdown vent stacks, then you must report the information specified in paragraph (i)(2) of this section considering, in aggregate, all blowdown vent stacks for which emissions were calculated using flow meters. For the onshore natural gas transmission pipeline segment, you must also report the information in paragraph (i)(3) of this section.

(1) *Report by equipment or event type.* If you calculated emissions from blowdown vent stacks by the seven categories listed in § 98.233(i)(2) for industry segments other than the onshore natural gas transmission pipeline segment, then you must report the equipment or event types and the information specified in paragraphs (i)(1)(i) through (iii) of this section for each equipment or event type. If a blowdown event resulted in emissions from multiple equipment types, and the emissions cannot be apportioned to the different equipment types, then you may report the information in paragraphs (i)(1)(i) through (iii) of this section for the equipment type that represented the largest portion of the emissions for the blowdown event. If you calculated emissions from blowdown vent stacks by the eight categories listed in § 98.233(i)(2) for the onshore natural gas transmission pipeline segment, then you must report the pipeline segments or event types and the information specified in paragraphs (i)(1)(i) through (iii) of this section for each ''equipment or event type'' (*i.e.,* category). If a blowdown event resulted in emissions from multiple categories, and the emissions cannot be apportioned to the different categories, then you may report the information in paragraphs (i)(1)(i) through (iii) of this section for the ''equipment or event type'' (*i.e.,* category) that represented the largest portion of the emissions for the blowdown event.

* * * * *

(3) *Onshore natural gas transmission pipeline segment.* Report the information in paragraphs (i)(3)(i) through (iii) of this section for each state.

(i) Annual CO_2 emissions in metric tons CO_2.

(ii) Annual CH_4 emissions in metric tons CH_4.

(iii) Annual number of blowdown events.

(j) *Onshore production and onshore petroleum and natural gas gathering and boosting storage tanks.* You must indicate whether your facility sends produced oil to atmospheric tanks. If your facility sends produced oil to atmospheric tanks, then you must indicate which Calculation Method(s) you used to calculate GHG emissions, and you must report the information specified in paragraphs (j)(1) and (2) of this section as applicable. If you used Calculation Method 1 or Calculation Method 2 of § 98.233(j), and any atmospheric tanks were observed to have malfunctioning dump valves during the calendar year, then you must indicate that dump valves were malfunctioning and you must report the information specified in paragraph (j)(3) of this section.

(1) If you used Calculation Method 1 or Calculation Method 2 of § 98.233(j) to calculate GHG emissions, then you must report the information specified in paragraphs (j)(1)(i) through (xvi) of this section for each sub-basin (for onshore production) or county (for onshore petroleum and natural gas gathering and boosting) and by calculation method. Onshore petroleum and natural gas gathering and boosting facilities do not report the information specified in paragraphs (j)(1)(ix) and (xi) of this section.

(i) Sub-basin ID (for onshore production) or county name (for onshore petroleum and natural gas gathering and boosting).

* * * * *

(iii) The total annual oil volume from gas-liquid separators and direct from wells or non-separator equipment that is sent to applicable onshore production and onshore petroleum and natural gas gathering and boosting storage tanks, in barrels. You may delay reporting of this data element for onshore production if you indicate in the annual report that wildcat wells and delineation wells are the only wells in the sub-basin with oil production greater than or equal to 10 barrels per day and flowing to gas-liquid separators or direct to storage tanks. If you elect to delay reporting of this data element, you must report by the date specified in § 98.236(cc) the total volume of oil from all wells and the well ID number(s) for the well(s) included in this volume.

(iv) The average gas-liquid separator or non-separator equipment temperature, in degrees Fahrenheit.

(v) The average gas-liquid separator or non-separator equipment pressure, in pounds per square inch gauge.

* * * * *

(vii) The minimum and maximum concentration (mole fraction) of CO_2 in flash gas from onshore production and onshore natural gas gathering and boosting storage tanks.

(viii) The minimum and maximum concentration (mole fraction) of CH_4 in flash gas from onshore production and onshore natural gas gathering and boosting storage tanks.

* * * * *

(2) * * *

(i) Report the information specified in paragraphs (j)(2)(i)(A) through (F) of this section, at the basin level, for atmospheric tanks where emissions were calculated using Calculation Method 3 of § 98.233(j). Onshore gathering and boosting facilities do not report the information specified in paragraphs (j)(2)(i)(E) and (F) of this section.

(A) The total annual oil/condensate throughput that is sent to all atmospheric tanks in the basin, in barrels. You may delay reporting of this data element for onshore production if you indicate in the annual report that wildcat wells and delineation wells are the only wells in the sub-basin with oil/condensate production less than 10 barrels per day and that send oil/condensate to atmospheric tanks. If you elect to delay reporting of this data element, you must report by the date specified in § 98.236(cc) the total annual oil/condensate throughput from all wells and the well ID number(s) for the well(s) included in this volume.

(B) An estimate of the fraction of oil/condensate throughput reported in paragraph (j)(2)(i)(A) of this section sent to atmospheric tanks in the basin that controlled emissions with flares.

(C) An estimate of the fraction of oil/condensate throughput reported in paragraph (j)(2)(i)(A) of this section sent to atmospheric tanks in the basin that controlled emissions with vapor recovery systems.

* * * * *

(ii) Report the information specified in paragraphs (j)(2)(ii)(A) through (D) of this section for each sub-basin (for onshore production) or county (for onshore petroleum and natural gas gathering and boosting) with atmospheric tanks whose emissions were calculated using Calculation Method 3 of § 98.233(j) and that did not control emissions with flares.

(A) Sub-basin ID (for onshore production) or county name (for onshore petroleum and natural gas gathering and boosting).

(B) The number of atmospheric tanks in the sub-basin (for onshore production) or county (for onshore petroleum and natural gas gathering and boosting) that did not control emissions with flares.

(C) Annual CO_2 emissions, in metric tons CO_2, from atmospheric tanks in the sub-basin (for onshore production) or county (for onshore petroleum and natural gas gathering and boosting) that did not control emissions with flares, calculated using Equation W–15 of § 98.233(j) and adjusted for vapor recovery, if applicable.

(D) Annual CH_4 emissions, in metric tons CH_4, from atmospheric tanks in the sub-basin (for onshore production) or county (for onshore petroleum and natural gas gathering and boosting) that did not control emissions with flares, calculated using Equation W–15 of § 98.233(j) and adjusted for vapor recovery, if applicable.

(iii) Report the information specified in paragraphs (j)(2)(iii)(A) through (E) of this section for each sub-basin (for onshore production) or county (for onshore petroleum and natural gas gathering and boosting) with atmospheric tanks whose emissions were calculated using Calculation Method 3 of § 98.233(j) and that controlled emissions with flares.

(A) Sub-basin ID (for onshore production) or county name (for onshore petroleum and natural gas gathering and boosting).

(B) The number of atmospheric tanks in the sub-basin (for onshore production) or county (for onshore petroleum and natural gas gathering and boosting) that controlled emissions with flares.

* * * * *

(3) If you used Calculation Method 1 or Calculation Method 2 of § 98.233(j), and any gas-liquid separator liquid dump values did not close properly during the calendar year, then you must report the information specified in paragraphs (j)(3)(i) through (iv) of this section for each sub-basin (for onshore production) or county (for onshore petroleum and natural gas gathering and boosting).

* * * * *

(l) * * *

(1) If you used Equation W–17A of § 98.233 to calculate annual volumetric natural gas emissions at actual

conditions from oil wells and the emissions are not vented to a flare, then you must report the information specified in paragraphs (l)(1)(i) through (vii) of this section.

* * * * *

(ii) Well ID numbers for the wells tested in the calendar year.

* * * * *

(v) Average flow rate for well(s) tested, in barrels of oil per day. You may delay reporting of this data element if you indicate in the annual report that wildcat wells and/or delineation wells are the only wells that are tested. If you elect to delay reporting of this data element, you must report by the date specified in § 98.236(cc) the measured average flow rate for well(s) tested and the well ID number(s) for the well(s) included in the measurement.

* * * * *

(2) If you used Equation W–17A of § 98.233 to calculate annual volumetric natural gas emissions at actual conditions from oil wells and the emissions are vented to a flare, then you must report the information specified in paragraphs (l)(2)(i) through (viii) of this section.

* * * * *

(ii) Well ID numbers for the wells tested in the calendar year.

* * * * *

(v) Average flow rate for well(s) tested, in barrels of oil per day. You may delay reporting of this data element if you indicate in the annual report that wildcat wells and/or delineation wells are the only wells that are tested. If you elect to delay reporting of this data element, you must report by the date specified in § 98.236(cc) the measured average flow rate for well(s) tested and the well ID number(s) for the well(s) included in the measurement.

* * * * *

(3) If you used Equation W–17B of § 98.233 to calculate annual volumetric natural gas emissions at actual conditions from gas wells and the emissions were not vented to a flare, then you must report the information specified in paragraphs (l)(3)(i) through (vi) of this section.

* * * * *

(ii) Well ID numbers for the wells tested in the calendar year.

* * * * *

(iv) Average annual production rate for well(s) tested, in actual cubic feet per day. You may delay reporting of this data element if you indicate in the annual report that wildcat wells and/or delineation wells are the only wells that are tested. If you elect to delay reporting of this data element, you must report by the date specified in § 98.236(cc) the measured average annual production rate for well(s) tested and the well ID number(s) for the well(s) included in the measurement.

* * * * *

(4) If you used Equation W–17B of § 98.233 to calculate annual volumetric natural gas emissions at actual conditions from gas wells and the emissions were vented to a flare, then you must report the information specified in paragraphs (l)(4)(i) through (vii) of this section.

* * * * *

(ii) Well ID numbers for the wells tested in the calendar year.

* * * * *

(iv) Average annual production rate for well(s) tested, in actual cubic feet per day. You may delay reporting of this data element if you indicate in the annual report that wildcat wells and/or delineation wells are the only wells that are tested. If you elect to delay reporting of this data element, you must report by the date specified in § 98.236(cc) the measured average annual production rate for well(s) tested and the well ID number(s) for the well(s) included in the measurement.

* * * * *

(m) * * *

(1) Sub-basin ID and a list of well ID numbers for wells for which associated gas was vented or flared.

* * * * *

(5) Volume of oil produced, in barrels, in the calendar year during the time periods in which associated gas was vented or flared (the sum of "$V_{p,q}$" used in Equation W–18 of § 98.233). You may delay reporting of this data element if you indicate in the annual report that wildcat wells and/or delineation wells are the only wells from which associated gas was vented or flared. If you elect to delay reporting of this data element, you must report by the date specified in § 98.236(cc) the volume of oil produced for well(s) with associated gas venting and flaring and the well ID number(s) for the well(s) included in the measurement.

(6) Total volume of associated gas sent to sales, in standard cubic feet, in the calendar year during time periods in which associated gas was vented or flared (the sum of "SG" values used in Equation W–18 of § 98.233(m)). You may delay reporting of this data element if you indicate in the annual report that wildcat wells and/or delineation wells from which associated gas was vented or flared. If you elect to delay reporting of this data element, you must report by the date specified in § 98.236(cc) the measured total volume of associated gas sent to sales for well(s) with associated gas venting and flaring and the well ID number(s) for the well(s) included in the measurement.

(7) * * *

(i) Total number of wells for which associated gas was vented directly to the atmosphere without flaring and a list of their well ID numbers.

* * * * *

(8) * * *

(i) Total number of wells for which associated gas was flared and a list of their well ID numbers.

* * * * *

(n) * * *

(1) Unique name or ID for the flare stack. For the onshore petroleum and natural gas production and onshore petroleum and natural gas gathering and boosting industry segments, a different name or ID may be used for a single flare stack for each location where it operates at in a given calendar year.

* * * * *

(o) *Centrifugal compressors.* You must indicate whether your facility has centrifugal compressors. You must report the information specified in paragraphs (o)(1) and (2) of this section for all centrifugal compressors at your facility. For each compressor source or manifolded group of compressor sources that you conduct as found leak measurements as specified in § 98.233(o)(2) or (4), you must report the information specified in paragraph (o)(3) of this section. For each compressor source or manifolded group of compressor sources that you conduct continuous monitoring as specified in § 98.233(o)(3) or (5), you must report the information specified in paragraph (o)(4) of this section. Centrifugal compressors in onshore petroleum and natural gas production and onshore petroleum and natural gas gathering and boosting are not required to report information in paragraphs (o)(1) through (4) of this section and instead must report the information specified in paragraph (o)(5) of this section.

* * * * *

(5) *Onshore petroleum and natural gas production and onshore petroleum and natural gas gathering and boosting.* Centrifugal compressors with wet seal degassing vents in onshore petroleum and natural gas production and onshore petroleum and natural gas gathering and boosting must report the information specified in paragraphs (o)(5)(i) through (iii) of this section.

* * * * *

(p) *Reciprocating compressors.* You must indicate whether your facility has reciprocating compressors. You must report the information specified in

paragraphs (p)(1) and (2) of this section for all reciprocating compressors at your facility. For each compressor source or manifolded group of compressor sources that you conduct as found leak measurements as specified in § 98.233(p)(2) or (4), you must report the information specified in paragraph (p)(3) of this section. For each compressor source or manifolded group of compressor sources that you conduct continuous monitoring as specified in § 98.233(p)(3) or (5), you must report the information specified in paragraph (p)(4) of this section. Reciprocating compressors in onshore petroleum and natural gas production and onshore petroleum and natural gas gathering and boosting are not required to report information in paragraphs (p)(1) through (4) of this section and instead must report the information specified in paragraph (p)(5) of this section.

* * * * *

(5) *Onshore petroleum and natural gas production and onshore petroleum and natural gas gathering and boosting.* Reciprocating compressors in onshore petroleum and natural gas production and onshore petroleum and natural gas gathering and boosting must report the information specified in paragraphs (p)(5)(i) through (iii) of this section.

* * * * *

(r) * * *

(1) You must indicate whether your facility contains any of the emission source types required to use Equation W–32A of § 98.233. You must report the information specified in paragraphs (r)(1)(i) through (v) of this section separately for each emission source type required to use Equation W–32A that is located at your facility. Onshore petroleum and natural gas production facilities and onshore petroleum and natural gas gathering and boosting facilities must report the information specified in paragraphs (r)(1)(i) through (v) separately by component type, service type, and geographic location (*i.e.,* Eastern U.S. or Western U.S.).

(i) Emission source type. Onshore petroleum and natural gas production facilities and onshore petroleum and natural gas gathering and boosting facilities must report the component type, service type and geographic location.

* * * * *

(3) Onshore petroleum and natural gas production facilities and onshore petroleum and natural gas gathering and boosting facilities must also report the information specified in paragraphs (r)(3)(i) and (ii) of this section.

* * * * *

(ii) Onshore petroleum and natural gas production facilities and onshore petroleum and natural gas gathering and boosting facilities must report the information specified in paragraphs (r)(3)(ii)(A) and (B) of this section, for each major equipment type, production type (*i.e.,* natural gas or crude oil), and geographic location combination in Tables W–1B and W–1C of this subpart.

* * * * *

(z) *Combustion equipment at onshore petroleum and natural gas production facilities, onshore petroleum and natural gas gathering and boosting facilities, and natural gas distribution facilities.* If your facility is required by § 98.232(c)(22), (i)(7), or (j)(12) to report emissions from combustion equipment, then you must indicate whether your facility has any combustion units subject to reporting according to paragraph (a)(1)(xvii), (a)(8)(i), or (a)(9)(xi) of this section. If your facility contains any combustion units subject to reporting according to paragraph (a)(1)(xvii), (a)(8)(i), or (a)(9)(xi) of this section, then you must report the information specified in paragraphs (z)(1) and (2) of this section, as applicable.

* * * * *

(aa) Each facility must report the information specified in paragraphs (aa)(1) through (11) of this section, for each applicable industry segment, by using best available data. If a quantity required to be reported is zero, you must report zero as the value.

(1) * * *

(ii) * * *

(D) The number of producing wells at the end of the calendar year and a list of the well ID numbers (exclude only those wells permanently taken out of production, *i.e.,* plugged and abandoned).

(E) The number of producing wells acquired during the calendar year and a list of the well ID numbers.

(F) The number of producing wells divested during the calendar year and a list of the well ID numbers.

(G) The number of wells completed during the calendar year and a list of the well ID numbers.

(H) The number of wells permanently taken out of production (*i.e.,* plugged and abandoned) during the calendar year and a list of the well ID numbers.

* * * * *

(10) For onshore petroleum and natural gas gathering and boosting facilities, report the quantities specified in paragraphs (aa)(10)(i) through (iv) of this section.

(i) The quantity of gas received by the gathering and boosting facility in the calendar year, in thousand standard cubic feet.

(ii) The quantity of gas transported to a natural gas processing facility, a natural gas transmission pipeline, a natural gas distribution pipeline, or another gathering and boosting facility in the calendar year, in thousand standard cubic feet.

(iii) The quantity of all hydrocarbon liquids received by the gathering and boosting facility in the calendar year, in barrels.

(iv) The quantity of all hydrocarbon liquids transported to a natural gas processing facility, a natural gas transmission pipeline, a natural gas distribution pipeline, or another gathering and boosting facility in the calendar year, in barrels.

(11) For onshore natural gas transmission pipeline facilities, report the quantities specified in paragraphs (aa)(11)(i) through (vi) of this section.

(i) The quantity of natural gas received at all custody transfer stations in the calendar year, in thousand standard cubic feet. This value may include meter corrections, but only for the calendar year covered by the annual report.

(ii) The quantity of natural gas withdrawn from in-system storage in the calendar year, in thousand standard cubic feet.

(iii) The quantity of natural gas added to in-system storage in the calendar year, in thousand standard cubic feet.

(iv) The quantity of natural gas transferred to third parties such as LDCs or other transmission pipelines, in thousand standard cubic feet.

(v) The quantity of natural gas consumed by the transmission pipeline facility for operational purposes, in thousand standard cubic feet.

(vi) The miles of transmission pipeline for each state in the facility.

* * * * *

(cc) If you elect to delay reporting the information in paragraph (g)(5)(i), (g)(5)(ii), (g)(5)(iii)(A), (g)(5)(iii)(B), (h)(1)(iv), (h)(2)(iv), (j)(1)(iii), (j)(2)(i)(A), (l)(1)(iv), (l)(2)(iv), (l)(3)(iii), (l)(4)(iii), (m)(5), or (m)(6) of this section, you must report the information required in that paragraph no later than the date 2 years following the date specified in § 98.3(b) introductory text.

■ 8. Section 98.238 is amended by adding definitions for ''Facility with respect to onshore petroleum and natural gas gathering and boosting for purposes of reporting under this subpart and for the corresponding subpart A requirements,'' ''Facility with respect to the onshore natural gas transmission pipeline segment,'' ''Gathering and

boosting system,'' ''Gathering and boosting system owner or operator,'' ''Onshore natural gas transmission pipeline owner or operator,'' and ''Well identification (ID) number'' in alphabetical order to read as follows:

§ 98.238 Definitions.

* * * * *

Facility with respect to onshore petroleum and natural gas gathering and boosting for purposes of reporting under this subpart and for the corresponding subpart A requirements means all gathering pipelines and other equipment located along those pipelines that are under common ownership or common control by a gathering and boosting system owner or operator and that are located in a single hydrocarbon basin as defined in this section. Where a person owns or operates more than one gathering and boosting system in a basin (for example, separate gathering lines that are not connected), then all gathering and boosting equipment that the person owns or operates in the basin would be considered one facility. Any gathering and boosting equipment that is associated with a single gathering and boosting system, including leased, rented, or contracted activities, is considered to be under common control of the owner or operator of the gathering and boosting system that contains the pipeline. The facility does not include equipment and pipelines that are part of any other industry segment defined in this subpart.

* * * * *

Facility with respect to the onshore natural gas transmission pipeline segment means the total U.S. mileage of natural gas transmission pipelines, as defined in this section, owned and operated by an onshore natural gas transmission pipeline owner or operator as defined in this section. The facility does not include pipelines that are part of any other industry segment defined in this subpart.

* * * * *

Gathering and boosting system means a single network of pipelines, compressors and process equipment, including equipment to perform natural gas compression, dehydration, and acid gas removal, that has one or more connection points to gas and oil production and a downstream endpoint, typically a gas processing plant, transmission pipeline, LDC pipeline, or other gathering and boosting system.

Gathering and boosting system owner or operator means any person that holds a contract in which they agree to transport petroleum or natural gas from one or more onshore petroleum and natural gas production wells to a natural gas processing facility, another gathering and boosting system, a natural gas transmission pipeline, or a distribution pipeline, or any person responsible for custody of the petroleum or natural gas transported.

* * * * *

Onshore natural gas transmission pipeline owner or operator means, for interstate pipelines, the person identified as the transmission pipeline owner or operator on the Certificate of Public Convenience and Necessity issued under 15 U.S.C. 717f, or, for intrastate pipelines, the person identified as the owner or operator on the transmission pipeline's Statement of Operating Conditions under section 311 of the Natural Gas Policy Act, or for pipelines that fall under the ''Hinshaw Exemption'' as referenced in section 1(c) of the Natural Gas Act, 15 U.S.C. 717–717 (w)(1994), the person identified as the owner or operator on blanket certificates issued under 18 CFR 284.224. If an intrastate pipeline is not subject to section 311 of the Natural Gas Policy Act (NGPA), the onshore natural gas transmission pipeline owner or operator is the person identified as the owner or operator on reports to the state regulatory body regulating rates and charges for the sale of natural gas to consumers.

* * * * *

Well identification (ID) number means the unique and permanent identification number assigned to a petroleum or natural gas well. If the well has been assigned a US Well Number, the well ID number required in this subpart is the US Well Number. If a US Well Number has not been assigned to the well, the well ID number is the identifier established by the well's permitting authority.

* * * * *

■ 9. Revise Table W–1A of subpart W of part 98 to read as follows:

TABLE W–1A TO SUBPART W OF PART 98—DEFAULT WHOLE GAS EMISSION FACTORS FOR ONSHORE PETROLEUM AND NATURAL GAS PRODUCTION FACILITIES AND ONSHORE PETROLEUM AND NATURAL GAS GATHERING AND BOOSTING FACILITIES

Onshore petroleum and natural gas production and Onshore petroleum and natural gas gathering and boosting	Emission factor (scf/hour/component)

RIN 2060–AS73

Greenhouse Gas Reporting Rule: Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: The Environmental Protection Agency is finalizing revisions and confidentiality determinations for the petroleum and natural gas systems source category of the Greenhouse Gas Reporting Program. In particular, this action adds new monitoring methods for detecting leaks from oil and gas equipment in the petroleum and natural gas systems source category consistent with the fugitive emissions monitoring methods in the recently finalized new source performance standards for the oil and gas industry. This action also adds emission factors for leaking equipment to be used in conjunction with these monitoring methods to calculate and report greenhouse gas emissions resulting from equipment leaks. Finally, this action finalizes reporting requirements and confidentiality determinations for nine new or substantially revised data elements contained in these amendments.

DATES: This final rule is effective on January 1, 2017.

ADDRESSES: The EPA has established a docket for this action under Docket ID No. EPA–HQ–OAR–2015–0764. All documents in the docket are listed on the *http://www.regulations.gov* Web site. Although listed in the index, some information is not publicly available, *e.g.,* confidential business information (CBI) or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, is not placed on the Internet and will be publicly available only in hard copy form. Publicly available docket materials are available electronically through *http://www.regulations.gov.*

FOR FURTHER INFORMATION CONTACT: Carole Cook, Climate Change Division, Office of Atmospheric Programs (MC–6207A), Environmental Protection Agency, 1200 Pennsylvania Ave. NW., Washington, DC 20460; telephone number: (202) 343–9334; fax number: (202) 343–2342; email address: *GHGReporting@epa.gov.* For technical information, please go to the Greenhouse Gas Reporting Rule Web site, *http://www.epa.gov/ghgreporting/.* To submit a question, select Help Center, followed by ''Contact Us.''

Worldwide Web (WWW). In addition to being available in the docket, an electronic copy of this final rule will also be available through the WWW. Following the Administrator's signature, a copy of this action will be posted on the EPA's Greenhouse Gas Reporting Rule Web site at *http://www.epa.gov/ghgreporting/index.html.*

SUPPLEMENTARY INFORMATION:

Regulated Entities. These revisions affect entities that must submit annual greenhouse gas (GHG) reports under the Greenhouse Gas Reporting Program (GHGRP), codified in the Code of Federal Regulations (CFR) at 40 CFR part 98. This rule applies to all petroleum and natural gas systems facilities that are subject to 40 CFR part 98, regardless of the facility's location, and ensures that all these facilities across the United States (U.S.) report GHG data consistently, and therefore is ''nationally applicable'' within the meaning of section 307(b)(1) of the Clean Air Act (CAA). Further, the Administrator has determined that rules codified in 40 CFR part 98 are subject to the provisions of CAA section 307(d). (See CAA section 307(d)(1)(V) (the provisions of section 307(d) apply to ''such other actions as the Administrator may determine'').) These are amendments to existing regulations. These amended regulations affect owners or operators of petroleum and natural gas systems that directly emit GHGs. Regulated categories and entities include, but are not limited to, those listed in Table 1 of this preamble:

TABLE 1—EXAMPLES OF AFFECTED ENTITIES BY CATEGORY

Category	NAICS [a]	Examples of affected facilities
Petroleum and Natural Gas Systems	486210	Pipeline transportation of natural gas.
	221210	Natural gas distribution.
	211111	Crude petroleum and natural gas extraction.
	211112	Natural gas liquid extraction.

[a] North American Industry Classification System.

Table 1 of this preamble is not intended to be exhaustive, but rather provides a guide for readers regarding facilities likely to be affected by this action. Other types of facilities than those listed in the table could also be subject to reporting requirements. To determine whether you are affected by this action, you should carefully examine the applicability criteria found in 40 CFR part 98, subpart A and 40 CFR part 98, subpart W. If you have questions regarding the applicability of this action to a particular facility, consult the person listed in the preceding **FOR FURTHER INFORMATION CONTACT** section.

What is the effective date? The final rule is effective on January 1, 2017. Section 553(d) of the Administrative Procedure Act (APA), 5 U.S.C. Chapter 5, generally provides that rules may not take effect earlier than 30 days after they are published in the **Federal Register**. The EPA is issuing this final rule under section 307(d)(1) of the Clean Air Act, which states: ''The provisions of section 553 through 557 * * * of Title 5 shall not, except as expressly provided in this section, apply to actions to which this subsection applies.'' Thus, section 553(d) of the APA does not apply to this rule. The EPA is nevertheless acting consistently with the purposes underlying APA section 553(d) in making the first set of amendments to this rule effective on January 1, 2017. Section 553(d) allows an effective date less than 30 days after publication for a rule that ''grants or recognizes an exemption or relieves a restriction'' or ''as otherwise provided by the agency for good cause found and published with the rule.'' As explained below, the EPA finds that there is good cause for the first set of amendments to this rule to become effective on January 1, 2017, even though this may result in an effective date fewer than 30 days from date of publication in the **Federal Register**.

While this action is being signed prior to December 1, 2016, there is likely to

be a significant delay in the publication of this rule as it contains complex equations and tables and is relatively long. As an example, the EPA Administrator signed the Greenhouse Gas Reporting Rule: 2015 Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems final rule on October 1, 2015, but the rule was not published in the **Federal Register** until October 22, 2015 (80 FR 64262). The purpose of the 30-day waiting period prescribed in 5 U.S.C. 553(d) is to give affected parties a reasonable time to adjust their behavior and prepare before the final rule takes effect. To employ the APA section 553(d)(3) ''good cause'' exemption, an agency must balance the necessity for immediate implementation against principles of fundamental fairness which require that all affected persons be afforded a reasonable amount of time to prepare for the effective date of its ruling.[1] Where, as here, the final rule will be signed and made available on the EPA Web site more than 30 days before the effective date, but where the publication is likely to be delayed due to the complexity and length of the rule, the regulated entities are afforded this reasonable amount of time. We balance these circumstances with the need for the amendments to be effective by January 1, 2017; a delayed effective date would result in regulatory uncertainty, program disruption, and an inability to have the amendments effective for the 2017 reporting year. Accordingly, we find good cause exists to make this rule effective on January 1, 2017, consistent with the purposes of APA section 553(d)(3).

Judicial Review. Under CAA section 307(b)(1), judicial review of this final rule is available only by filing a petition for review in the U.S. Court of Appeals for the District of Columbia Circuit (the Court) by January 30, 2017 Under CAA section 307(d)(7)(B), only an objection to this final rule that was raised with reasonable specificity during the period for public comment can be raised during judicial review. Section 307(d)(7)(B) of the CAA also provides a mechanism for the EPA to convene a proceeding for reconsideration, ''[i]f the person raising an objection can demonstrate to the EPA that it was impracticable to raise such objection within [the period for public comment] or if the grounds for such objection arose after the period for public comment (but within the time specified for judicial review) and if such objection is of central relevance to the outcome of the rule.'' Any person seeking to make such a demonstration to us should submit a Petition for Reconsideration to the Office of the Administrator, Environmental Protection Agency, Room 3000, William Jefferson Clinton Building, 1200 Pennsylvania Ave. NW., Washington, DC 20460, with a copy to the person listed in the preceding **FOR FURTHER INFORMATION CONTACT** section, and the Associate General Counsel for the Air and Radiation Law Office, Office of General Counsel (Mail Code 2344A), Environmental Protection Agency, 1200 Pennsylvania Ave. NW., Washington, DC 20004. Note that under CAA section 307(b)(2), the requirements established by this final rule may not be challenged separately in any civil or criminal proceedings brought by the EPA to enforce these requirements.

I. Background

A. Organization of This Preamble

Section I of this preamble provides background information regarding the origin of the final amendments. This section also discusses the EPA's legal authority under the CAA to promulgate and amend 40 CFR part 98 of the Greenhouse Gas Reporting Rule (hereafter referred to as ''part 98'') as well as the legal authority for making confidentiality determinations for the data to be reported. Section II of this preamble contains information on the final amendments to part 98, subpart W (Petroleum and Natural Gas Systems) (hereafter referred to as ''subpart W''), including a summary of the major comments that the EPA considered in the development of this final rule. Section III of this preamble discusses the final confidentiality determinations for new or substantially revised data

[1] *Omnipoint Corp.* v. *FCC*, 78 F3d 620, 630 (D.C. Cir. 1996), quoting *U.S.* v. *Gavrilovic*, 551 F.2d 1099, 1105 (8th Cir. 1977).

reporting elements. Section IV of this preamble discusses the impacts of the final amendments to subpart W. Finally, section V of this preamble describes the statutory and executive order requirements applicable to this action.

B. Background on This Action

The EPA's GHGRP requires annual reporting of GHG data and other relevant information from large sources and suppliers in the United States. On October 30, 2009, the EPA published part 98 in the **Federal Register** (FR) for collecting information regarding GHG emissions from a broad range of industry sectors (74 FR 56260). Although reporting requirements for petroleum and natural gas systems were originally proposed to be part of part 98 (74 FR 16448, April 10, 2009), the final October 2009 rulemaking did not include the petroleum and natural gas systems source category as one of the 29 source categories for which reporting requirements were finalized. The EPA re-proposed subpart W in 2010 (75 FR 18608; April 12, 2010), and a subsequent final rulemaking was published on November 30, 2010, with the requirements for the petroleum and natural gas systems source category at 40 CFR part 98, subpart W (75 FR 74458). Following promulgation, the EPA finalized several actions revising subpart W (76 FR 22825, April 25, 2011; 76 FR 53057, August 25, 2011; 76 FR 59533, September 27, 2011; 76 FR 80554, December 23, 2011; 77 FR 51477, August 24, 2012; 78 FR 25392, May 1, 2013; 78 FR 71904, November 29, 2013; 79 FR 70352, November 25, 2014; 80 FR 64262, October 22, 2015).[2]

The Strategy to Reduce Methane Emissions in the President's Climate Action Plan summarizes the sources of CH_4 emissions, commits to new steps to cut emissions of this potent GHG, and outlines the Administration's efforts to improve the measurement of these emissions. The strategy builds on progress to date and takes steps to further cut CH_4 emissions from several sectors, including the oil and natural gas sector. In the strategy, the EPA was specifically tasked with continuing to review GHGRP regulatory requirements to address potential gaps in coverage, improve methods, and ensure high quality data reporting.[3] On January 14, 2015, the Obama administration provided additional direction to the EPA to ''explore potential regulatory opportunities for applying remote sensing technologies and other innovations in measurement and monitoring technology to further improve the identification and quantification of emissions'' in the oil and natural gas sector, such as the emissions submitted as part of GHGRP annual reporting.[4]

Under subpart W, GHGs that must be reported by each industry segment and applicable source types are specified in 40 CFR 98.232, including equipment leaks from listed component types. In order to fulfill these equipment leak emissions reporting requirements, reporters must utilize one of two calculation methodologies [5] to calculate GHG emissions from equipment leaks as specified in 40 CFR 98.233: (1) Calculation methodology based on equipment leak surveys (40 CFR 98.233(q)), or (2) calculation methodology based on population counts (40 CFR 98.233(r).[6] For example, facilities in the Onshore Natural Gas Processing and Onshore Natural Gas Transmission Compression industry segments use the calculation methodology based on equipment leak surveys for most components at their facilities. If 40 CFR 98.233(q) specifies that an equipment leak survey is required for the subsection of listed component types in 40 CFR 98.232, reporters must use one of the monitoring methods specified in 40 CFR 98.234 when conducting those equipment leak surveys to detect leaking components at the facility. The calculation methodology based on equipment leak surveys requires that the reporter then determine the total amount of time each component was assumed to be leaking and multiply that by the concentration of the methane (CH_4) and carbon dioxide (CO_2) in the gas and the applicable emission factor (referred to as a ''leaker emission factor''), listed in Table W–1E and Table W–2 through Table W–7, to calculate emissions. Finally, 40 CFR 98.236 specifies the data elements that must be reported to the EPA.

On January 29, 2016, the EPA proposed ''Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' (81 FR 4987) to add new monitoring methods for detecting leaks from oil and gas equipment, to revise which industry segments and sources use the calculation methodology based on equipment leak surveys or the calculation methodology based on population counts, to clarify how the definition of fugitive emission components in the new source performance standards (NSPS) for the oil and natural gas sector (40 CFR part 60, subpart OOOOa, at 81 FR 35824) (hereafter referred to as the ''NSPS subpart OOOOa'') aligns with the equipment components subject to subpart W, to add leaker emission factors for multiple industry segments, and to add reporting requirements and confidentiality determinations for new or substantially revised data elements. Under those proposed amendments, facilities with fugitive emissions components at a well site or compressor station subject to the NSPS subpart OOOOa would use data derived from the NSPS subpart OOOOa fugitive emissions requirements (*i.e.*, which components were determined to have fugitive emissions) along with the subpart W leaker emission factors to calculate and report GHG emissions to the GHGRP. The proposed revisions provided the opportunity for owners and operators of sources not subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions standards (*e.g.,* sources participating in a voluntarily implemented program) and not already required to conduct leak surveys under subpart W to optionally use the calculation methodology at 40 CFR 98.233(q) to calculate and report their GHG emissions to the GHGRP. The EPA also proposed that facilities that are already required to conduct leak surveys under subpart W would be able to use the newly proposed monitoring method(s) in 40 CFR 98.234. In addition, the EPA proposed new reporting requirements for all reporters using the calculation methodology

[2] See Greenhouse Gas Reporting Program, Historical Rulemakings. Available at *https://www.epa.gov/ghgreporting/rulemaking-notices-ghg-reporting.*

[3] Climate Action Plan—Strategy to Reduce Methane Emissions. The White House, Washington, DC, March 2014. Available at *http://www.whitehouse.gov/sites/default/files/strategy_to_reduce_methane_emissions_2014-03-28_final.pdf.*

[4] FACT SHEET: Administration Takes Steps Forward on Climate Action Plan by Announcing Actions to Cut Methane Emissions. The White House, Office of the Press Secretary, January 14, 2015. Available at *https://www.whitehouse.gov/the-press-office/2015/01/14/fact-sheet-administration-takes-steps-forward-climate-action-plan-anno-1.*

[5] Throughout this preamble, the term ''calculation methodology'' refers to the procedures used to calculate emissions (*e.g.,* ''calculation methodology based on equipment leak surveys'' refers to the methodology described in 40 CFR 98.233(q)) and ''monitoring method'' refers to the technology, test method, or other method of determining whether an individual component is leaking (see 40 CFR 98.234(a)). The term ''leak detection method'' that is used in the 40 CFR part 98 subpart W regulatory text has the same meaning as ''monitoring method'' used in this preamble.

[6] Reporters using the calculation methodology based on population counts determine the total number of all components in the facility and multiply that count by the average estimated time of operation, the concentration of the CH_4 and CO_2 in the gas, and the applicable emission factor (referred to as a ''population emission factor'') to calculate emissions.

based on equipment leak surveys and proposed to require reporters using the calculation methodology for the first time to begin reporting the information associated with that methodology. Finally, the EPA proposed confidentiality determinations for nine new or substantially revised data elements. The public comment period for these proposed rule amendments ended on March 15, 2016, following a 15-day extension of the original comment period end date (81 FR 9797; February 26, 2016). On June 3, 2016, the EPA published the final NSPS subpart OOOOa requirements (81 FR 35824).

In this action, the EPA is finalizing revisions to subpart W largely as proposed, with some changes made after consideration of public comments. Summaries of significant comments submitted on the proposed amendments and the EPA's responses to those comments can be found in sections II, III, and IV of this preamble. All comments submitted on the proposed amendments and the EPA's additional responses to the comments can be found in ''Response to Public Comments on Greenhouse Gas Reporting Rule: Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' in Docket ID No. EPA–HQ–OAR–2015–0764.

As further detailed in the preamble to the proposed amendments, these revisions advance the EPA's goal of maximizing rule effectiveness by providing a mechanism for facilities to use the NSPS subpart OOOOa monitoring results for purposes of GHGRP subpart W reporting. This alignment reduces burden for entities subject to the fugitive emissions/equipment leak detection method requirements in both programs, and, when combined with the other amendments being finalized in this revision, provides clear monitoring methods, equipment leak survey and calculation methodologies and emission factors, and reporting requirements in subpart W, thus enabling government, regulated entities, and the public to easily identify and understand regulatory requirements. These amendments also further advance the ability of the GHGRP to provide access to high quality data on GHG emissions by adding the ability for reporters to use data collected during equipment leak surveys and to perform site-specific equipment leak calculations.

C. Legal Authority

The EPA is finalizing these rule amendments under its existing CAA authority provided in CAA section 114. As stated in the preamble to the 2009 final GHG reporting rule (74 FR 56260; October 30, 2009), CAA section 114(a)(1) provides the EPA broad authority to require the information to be gathered by this rule because such data will inform and are relevant to the EPA's carrying out a wide variety of CAA provisions. See the preambles to the proposed (74 FR 16448; April 10, 2009) and final GHG reporting rule (74 FR 56260; October 30, 2009) for further information.

In addition, pursuant to sections 114, 301, and 307 of the CAA, the EPA is publishing final confidentiality determinations for the new or substantially revised data elements required by these amendments. Section 114(c) requires that the EPA make information obtained under section 114 available to the public, except for information (excluding emission data) that qualifies for confidential treatment. The Administrator has determined that this action is subject to the provisions of section 307(d) of the CAA. Section 307(d) contains a set of procedures relating to the issuance and review of certain CAA rules.

D. How do these amendments apply to 2016 and 2017 reports?

These amendments are effective on January 1, 2017. Starting with the 2017 reporting year, facilities must follow the revised methods to detect equipment leaks (if applicable) and to calculate and report their annual equipment leak emissions. The first annual reports of emissions calculated using the amended requirements will be those submitted by April 2, 2018, covering reporting year 2017. For reporting year 2016, reporters will calculate emissions according to the requirements in part 98 that are applicable to reporting year 2016 (*i.e.,* the requirements in place until the effective date of this final rule).

II. Summary of Final Revisions and Other Amendments to Subpart W and Responses to Public Comment

Sections II.A through II.F of this preamble describe the revisions that we are finalizing in this rulemaking. Section II.A provides a general summary of the final amendments to subpart W. Section II.B describes the final amendments to the requirement to use the calculation methodology based on equipment leak surveys. Section II.C describes the final amendments to the subpart W monitoring methods. Section II.D describes the final amendments for component types to be surveyed. Section II.E describes the final amendments to the subpart W leaker emission factors. Finally, section II.F provides a summary of the final amendments to the subpart W reporting requirements. The amendments described in each section are followed by a summary of the major comments on those amendments and the EPA's responses. See ''Response to Public Comments on Greenhouse Gas Reporting Rule: Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' in Docket ID No. EPA–HQ–OAR–2015–0764 for a complete listing of all comments and the EPA's responses.

A. Summary of Final Amendments—General

1. Summary of Final Amendments

In this action, the EPA is amending subpart W to add new monitoring methods for detecting leaks from oil and gas equipment in the petroleum and natural gas systems source category consistent with the NSPS subpart OOOOa. The EPA is also specifying that facilities with a collection of fugitive emissions components at a well site or compressor station subject to the NSPS subpart OOOOa (40 CFR 60.5397a) would be required to survey those components, except as otherwise specified in this subpart W final rule, for the subpart W calculation methodology based on equipment leak surveys using one of the new monitoring methods being added to subpart W. In practice, this means that facilities can use the results of the NSPS subpart OOOOa-required fugitive emissions monitoring survey to fulfill these subpart W requirements. The EPA is adding leaker emission factors to be used in conjunction with the calculation methodology based on equipment leak surveys to calculate and report GHG emissions. The revisions provide the opportunity for owners and operators of sources not subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions standards (*e.g.,* sources participating in a voluntarily implemented program) and not already required to conduct leak surveys under subpart W to optionally use the calculation methodology at 40 CFR 98.233(q) to calculate and report their GHG emissions, and to use the new monitoring methods in 40 CFR 98.234 to do so.

Facilities in certain subpart W industry segments [7] that are already required to conduct leak surveys will be able to use the new monitoring methods

[7] These segments are Onshore Natural Gas Transmission Compression, Underground Natural Gas Storage, LNG Storage, and LNG Import and Export Equipment.

in 40 CFR 98.234. If they use either of the two new monitoring methods in 40 CFR 98.234(a)(6) or (7) that are consistent with the NSPS subpart OOOOa, then in addition to surveying the components currently subject to the survey requirements in subpart W, they must also survey all other components that are fugitive emissions components in the NSPS subpart OOOOa, with limited exceptions, as specified in 40 CFR 98.232 (see sections II.C and II.D of this preamble). If they use any of the monitoring methods currently in 40 CFR 98.234(a)(1) through (5), then in addition to surveying the components currently subject to the survey requirements in subpart W, they may elect to survey the other components specified in 40 CFR 98.232.

The comments received on this rule generally do not dispute the merit of allowing the use of new monitoring methods in subpart W, but they do include issues related to the adequacy of the notice and comment process, the calculation methodology based on equipment leak surveys, reporting, and applicability.

2. Summary of Comments and Responses

Comment: Numerous commenters stated that the EPA's reference to the proposed NSPS subpart OOOOa included in the subpart W proposal was premature, and substantively and procedurally flawed. According to these commenters, by relying on a proposed action, the EPA did not provide the opportunity for notice or comment on how the rule would ultimately affect stakeholders. These commenters stated that at the very least the EPA made it difficult and increased burden for stakeholders to evaluate scope and impacts and to provide comment. Commenters stated that they could only comment on the effect of the incorporation of the NSPS subpart OOOOa proposed requirements, as they could not review and comment on the effect of the finalized NSPS subpart OOOOa requirements on subpart W prior to closure of the comment period for the subpart W proposal. Specifically, the commenters expressed concern that because the EPA received so many comments on the proposed NSPS subpart OOOOa, the final NSPS subpart OOOOa provisions would likely be significantly different in certain aspects and that those details were unknowable at the time of comment. Noting that the EPA expressed intent in the preamble to the subpart W proposed amendments to incorporate the final NSPS subpart OOOOa provisions in the final subpart W rule, the commenters stated they inherently would have no formal opportunity to meaningfully comment on the effect those final NSPS subpart OOOOa provisions would have on subpart W reporters. Several commenters stated that this created substantive and procedural flaws in the proposed rule, as the EPA provided neither the ''terms or substance'' nor a ''description of the subjects and issues involved'' of the proposed rule as required for notice and comment rulemaking under the Administrative Procedure Act, 5 U.S.C. 553(b), nor did the EPA meet the more stringent notice and comment requirements of CAA section 307. Several commenters stated that EPA similarly did not consider changes that might be made to the final NSPS subpart OOOOa through the judicial review process.

Several commenters requested that the EPA either finalize, or re-propose or re-open the public comment period for, the proposed alignment of subpart W with the NSPS subpart OOOOa only after the NSPS subpart OOOOa is finalized. Other commenters requested that the EPA withdraw the proposal to amend subpart W and reconsider whether any revisions are necessary once the NSPS subpart OOOOa is in effect.

Response: The EPA disagrees that the proposed rule for this subpart W revision was premature, or substantively and procedurally flawed. This action is focused on aligning the subpart W requirements, to the extent possible, with the finalized NSPS subpart OOOOa fugitive emission requirements so that facilities may use the results of the NSPS subpart OOOOa-required fugitive emissions monitoring surveys to fulfill subpart W requirements, and does so through revisions that incorporate final NSPS subpart OOOOa monitoring methods into subpart W and make their use mandatory in subpart W surveys for most components subject to NSPS subpart OOOOa. The proposed rule for subpart W clearly specified that only a monitoring method finalized in the NSPS subpart OOOOa rule would be finalized for subpart W, which ensured that no requirement would reference any monitoring method that was merely at proposal stage. The proposed rule provided adequate notice and opportunity to comment on how the rule will affect stakeholders, and thus this final rule is in compliance with the relevant requirements of CAA section 307(d). Multiple commenters cited the Administrative Procedure Act (APA), including 5 U.S.C. 553(b)(3), which requires that a notice of proposed rulemaking shall include ''either the terms or substance of the proposed rule or a description of the subjects and issues involved.'' The EPA notes that our process is also consistent with the notice and comment requirements of the APA, 5 U.S.C. 551–559. In the preamble to the proposed and final rule, as well as in ''Response to Public Comments on Greenhouse Gas Reporting Rule: Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' in Docket ID No. EPA–HQ–OAR–2015–0764, the EPA describes at length the statement and purpose of the revisions, provides explanations for any changes in the rule, and responds to all comments submitted.

Specifically, in regards to the proposed rule referencing the then proposed NSPS subpart OOOOa monitoring method(s) and fugitive emissions component definition,[8] the EPA disagrees that the proposed rule did not give adequate notice and therefore the EPA did not re-propose or re-open the comment period for this action. The proposed rule clearly laid out the EPA's proposal and requested comment regarding alternatives, as well as the detailed reasoning behind and goals of the proposal. The EPA provided this detailed explanation to ensure that commenters had ample notice of the revisions under consideration, and provided 45 days for the public comment period. This process accords with proper notice and comment procedure. Commenters posit that referencing the then proposed NSPS subpart OOOOa standard in the proposed rule renders this notice premature and inadequate, and the EPA respectfully disagrees. First, in proposing to add the NSPS subpart OOOOa equipment leak detection methods as approved monitoring methods for subpart W surveys, the EPA was not proposing to require any new collection of data under subpart W, as the data on fugitive emissions components would already be collected to meet the requirements of NSPS subpart OOOOa. Instead, the EPA proposed to add these new monitoring methods under subpart W so that reporters would be able to use, for the purpose of compliance with the proposed mandatory subpart W equipment leak survey, calculation, and reporting requirements, whatever data would already be collected as a result of complying with the monitoring method(s) that would be finalized in the NSPS subpart OOOOa. Similarly, while the EPA proposed to include all fugitive emissions components subject to the

[8] The NSPS subpart OOOOa rule has since been finalized. 81 FR 35824 (June 3, 2016).

final NSPS subpart OOOOa monitoring methods within subpart W emissions reporting requirements, with some exceptions, which would mean that additional components would fall within the scope of subpart W applicability, these data would already be collected under the NSPS subpart OOOOa, meaning that no new data would need to be collected for subpart W that was not already required by another CAA program. As such, the substance of the monitoring method(s) and fugitive emission component definition was not at issue for purposes of subpart W within these revisions, as that process took place within the NSPS subpart OOOOa rulemaking. Rather, the EPA ensured that reporters were provided notice of the proposal to add the monitoring methods and scope of components that would be finalized under the NSPS OOOOa as additional monitoring methods and applicable components for subpart W, provided notice of the proposed additional subpart W equipment leak survey, calculation, and reporting requirements for equipment components subject to the NSPS subpart OOOOa, and made clear that the intent of these revisions was to align the programs so that reporters would use the data gathered in complying with the finalized NSPS subpart OOOOa to comply with their subpart W requirements. The proposed rule further explained the purpose behind this proposed revision, as detailed in the proposed rule (81 FR 4987; January 29, 2016), including reducing burden on reporters by minimizing the potential equipment leak surveys required at a given facility across CAA programs. As noted earlier, the proposed rule for subpart W clearly specified that only a monitoring method finalized in the NSPS subpart OOOOa rule would be finalized for subpart W, which ensured that no requirement would reference any monitoring method that was merely at proposal stage. In fact, the proposed rule for subpart W clearly detailed the NSPS subpart OOOOa proposed monitoring method, and identified that the NSPS subpart OOOOa proposal included a potential alternative monitoring method, and furthermore explained that any method(s) added in this final subpart W action would be the method(s) that were finalized in the NSPS subpart OOOOa.

Furthermore, Subpart W currently includes an optical gas imaging (OGI) method (see 40 CFR 98.234(a)(1)) and Method 21 (40 CFR 98.234(a)(2)) in the subpart W list of monitoring methods. While there are differences in the application of the methods between the current subpart W and the final NSPS subpart OOOOa,[9] necessitating this revision, current use of OGI and Method 21 for purposes of subpart W provides support that the methods at issue provide reliable data for use in subpart W emissions reporting.

This final rule incorporates the monitoring methods finalized in the NSPS subpart OOOOa with some changes from proposal. To the extent the specifics of how this final subpart W rule is adding method(s) in accordance with the NSPS subpart OOOOa differ from the specifics in the subpart W proposal, as explained further in section II.C of this preamble, these changes are consistent with the purpose detailed in the proposed rule and were made to ensure only those portions of the final NSPS subpart OOOOa that are essential to the integrity of the methods are referenced within the requirements of subpart W. This final rule revises applicable components subject to subpart W to include all components subject to the final NSPS subpart OOOOa, except for the finalized as proposed exclusion of certain components, as further detailed in section II.D of this preamble. The EPA notes that while we finalized the reference to the NSPS subpart OOOOa with certain exceptions regarding applicable components as proposed, the final NSPS subpart OOOOa definition of fugitive emission components was narrower in scope than that rule's proposal. This final rule also includes revisions, with some changes from proposal as detailed in Sections II.B, II.D, II.E, and II.F of this preamble, to how reporters must use the data obtained in accordance with the methods finalized in the NSPS subpart OOOOa for subpart W reporting.

Although the EPA's own reasoned consideration and its assessment of public comment have resulted in some modifications to the final rule, as explained further in sections II.B through II.F of this preamble, such changes reflect the goals and alternatives in the EPA's original proposal, and the proposed rule ensured that interested parties were ''fairly apprised'' of the elements ultimately included in this final rulemaking. See, *e.g.,* United Steelworkers of America v. Schuylkill Metals, 828 F.2d 314 (5th Cir. 1987).

While some changes occurred to the NSPS subpart OOOOa requirements from proposal to final in that rulemaking, including changes to the substance of the monitoring methods and the fugitive emission component definition, those substantive changes are out of scope of this subpart W rulemaking that is intended to align with the final NSPS subpart OOOOa requirements; however, commenters were provided full notice and opportunity to comment within that NSPS subpart OOOOa rulemaking, as fully explained within those proposed and final preambles, the EPA's response to comments, and the docket of that action.[10]

The commenter is correct that the EPA did not consider changes that may be made to the final NSPS subpart OOOOa through the judicial review process. Any such potential, future changes are premature to consider at this time.

B. Summary of Final Amendments to the Requirement To Use the Calculation Methodology Based on Equipment Leak Surveys

1. Summary of Final Amendments

As noted in section I.B of this preamble, subpart W presently requires reporters with sources in certain industry segments to use the calculation methodology based on population counts according to 40 CFR 98.233(r). For example, reporters in the Onshore Petroleum and Natural Gas Production and the Onshore Petroleum and Natural Gas Gathering and Boosting industry segments are required either to count the number of equipment components of each type (*e.g.,* valve, connector, open-ended line, or pressure relief valve) or to count the number of major equipment at the facility and then calculate the number of equipment components of each type using default average component counts for each piece of major equipment in Tables W–1B and W–1C to subpart W (40 CFR 98.233(r)(2)). The resulting equipment component counts are then multiplied by default ''population emission factors'' in Table W–1A to subpart W to calculate emissions from equipment leaks.

Other reporters are required to use the calculation methodology based on equipment leak surveys according to 40 CFR 98.233(q) using one of the monitoring methods in 40 CFR 98.234(a). For example, reporters in the Onshore Natural Gas Transmission Compression industry segment must conduct at least one equipment leak survey in a calendar year for the compressor and non-compressor components in gas service listed in Table W–3A to subpart W. These reporters then use the number of leaking

[9] See section II.C of this preamble.

[10] Docket ID No. EPA–HQ–OAR–2010–0505.

components in the calendar year, the average amount of time each component was leaking, and the default ''leaker emission factors'' in Table W–3A to subpart W to calculate emissions according to Equation W–30.

The EPA is finalizing the proposal to apply the calculation methodology based on equipment leak surveys in 40 CFR 98.233(q) to additional reporters in subpart W. Specifically, reporters in any subpart W industry segment with a well site(s) and/or compressor station(s) required to conduct fugitive emissions monitoring to comply with the NSPS subpart OOOOa will be required to use the calculation methodology based on equipment leak surveys for those components [11] under subpart W using the new monitoring methods consistent with the NSPS subpart OOOOa (see section II.C of this preamble). While these are new calculation methodology and equipment leak survey requirements for the subpart W reporting of these components, reporters may meet the survey requirements by counting the actual number of components with fugitive emissions identified through implementation of the NSPS subpart OOOOa as leaks for purposes of subpart W and use those counts with the calculation methodologies specified in 40 CFR 98.233(q) to determine equipment leak emissions for those components.

We received extensive comment regarding the proposed revisions to require facilities in the Onshore Natural Gas Processing industry segment to use the results of the leak surveys conducted to comply with the NSPS subpart OOOOa equipment leak requirements for reporting under subpart W. We are still reviewing those comments and are not taking final action on those revisions at this time.

For other sources of equipment leaks (*i.e.,* those not subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions standards),[12] the amended subpart W requirements depend on whether the component types are currently required to be reported using the calculation methodology based on equipment leak surveys (40 CFR 98.233(q)) or the calculation methodology based on population counts (40 CFR 98.233(r)). For components at facilities in industry segments that are currently required to use the calculation methodology based on equipment leak surveys to comply with subpart W, the EPA is finalizing as proposed that reporters must continue to conduct equipment leak surveys as required by subpart W but may use any monitoring method in 40 CFR 98.234(a). If they use either of the two new monitoring methods in 40 CFR 98.234(a)(6) or (7) that are consistent with the NSPS subpart OOOOa, then in addition to surveying the components currently subject to the survey requirements in subpart W, they must also survey all other components that are fugitive emissions components in the NSPS subpart OOOOa, with limited exceptions, as specified in 40 CFR 98.232 (see sections II.C and II.D of this preamble). If they use any of the monitoring methods currently in 40 CFR 98.234(a)(1) through (5), then in addition to surveying the components currently subject to the survey requirements in subpart W, they may elect to survey the other components specified in 40 CFR 98.232.

For components at facilities in industry segments that are currently required to use the calculation methodology based on population counts, the reporter may continue to use that methodology. Alternatively, the EPA is finalizing as proposed the option that the reporter may elect to use the calculation methodology based on equipment leak surveys (40 CFR 98.233(q)(1)(iv)) in lieu of the calculation methodology based on population counts (40 CFR 98.233(r)). If this option is selected, then the reporter must use any of the monitoring methods in 40 CFR 98.234(a). If they use a monitoring method in 40 CFR 98.234(a)(6) or (7), then they must survey all components that would otherwise be subject to the calculation methodology based on population counts, and they must also survey all other components that are fugitive emissions components in the NSPS subpart OOOOa, with limited exceptions, as specified in 40 CFR 98.232. If they use any of the monitoring methods currently in 40 CFR 98.234(a)(1) through (5), then in addition to surveying the components that would otherwise be subject to the calculation methodology based on population counts, they may elect to survey the other specified in 40 CFR 98.232. The intent of the new provision in 40 CFR 98.233(q)(1)(iv) is to allow flexibility for reporters currently required to use the calculation methodology based on population counts for components that are not subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions standards.

The burden of using the calculation methodology based on equipment leak surveys will be similar to using the existing subpart W calculation methodology based on population counts, and the results will be more representative of the number of leaks at the facility than the calculation methodology based on population counts. Table 2 of this preamble provides a summary of the equipment leak calculation methodologies and monitoring methods that will be available to each industry segment covered by subpart W under these amendments.

TABLE 2—FINAL EQUIPMENT LEAK REQUIREMENTS FOR SUBPART W

Subpart W industry segments [a]	Components subject to 40 CFR 60.5397a of the NSPS subpart OOOOa		Components not subject to 40 CFR 60.5397a of the NSPS subpart OOOOa	
	Subpart W calculation methodology [b]	Subpart W monitoring method for leak detection [c]	Subpart W calculation methodology	Subpart W monitoring method for leak detection [d]
Onshore Petroleum and Natural Gas Production.	Leak survey (40 CFR 98.233(q)).	OGI or Method 21 as specified in the NSPS subpart OOOOa.	Leak survey (40 CFR 98.233(q)); OR Population count (40 CFR 98.233(r)).	Any method in 40 CFR 98.234(a). N/A.
Onshore Natural Gas Transmission Compression; Underground Natural Gas Storage: Storage stations, gas service.	Leak survey (40 CFR 98.233(q)).	OGI or Method 21 as specified in the NSPS subpart OOOOa.	Leak survey (40 CFR 98.233(q)) [e].	Any method in 40 CFR 98.234(a).

[11] See section II.D of this preamble.

[12] Except for onshore natural gas processing and natural gas distribution.

TABLE 2—FINAL EQUIPMENT LEAK REQUIREMENTS FOR SUBPART W—Continued

Subpart W industry segments [a]	Components subject to 40 CFR 60.5397a of the NSPS subpart OOOOa		Components not subject to 40 CFR 60.5397a of the NSPS subpart OOOOa	
	Subpart W calculation methodology [b]	Subpart W monitoring method for leak detection [c]	Subpart W calculation methodology	Subpart W monitoring method for leak detection [d]
Underground Natural Gas Storage: Storage wellheads, gas service.	Leak survey (40 CFR 98.233(q)).	OGI or Method 21 as specified in the NSPS subpart OOOOa.	Leak survey (40 CFR 98.233(q)); OR Population count (40 CFR 98.233(r)).	Any method in 40 CFR 98.234(a). N/A.
LNG [f] Storage: LNG Service; LNG Import and Export Equipment: LNG Service.	Leak survey (40 CFR 98.233(q)).	OGI or Method 21 as specified in the NSPS subpart OOOOa.	Leak survey (40 CFR 98.233(q)).	Any method in 40 CFR 98.234(a).
LNG Storage: Gas Service; LNG Import and Export Equipment: Gas Service.	Leak survey (40 CFR 98.233(q)).	OGI or Method 21 as specified in the NSPS subpart OOOOa.	Leak survey (40 CFR 98.233(q)); OR Population count (40 CFR 98.233(r)) [g].	Any method in 40 CFR 98.234(a). N/A.

[a] Onshore Natural Gas Processing and Natural Gas Distribution are not included in this table because we are not revising the calculation methodology and monitoring method for leak detection for these industry segments in this action. The current requirements are still applicable to components in these industry segments.

[b] The term "calculation methodology" refers to the procedures used to calculate emissions (*e.g.,* "calculation methodology based on equipment leak surveys" refers to the methodology described in 40 CFR 98.233(q)) and "monitoring method" refers to the technology, test method, or other method of determining whether an individual component is leaking (see 40 CFR 98.234(a)).

[c] OGI as specified in the NSPS subpart OOOOa is codified in subpart W at 40 CFR 98.234(a)(6) and Method 21 as specified in the NSPS subpart OOOOa is codified in subpart W at 40 CFR 98.234(a)(7).

[d] "Any method in 40 CFR 98.234(a)" means any of the following methods: OGI as specified in 40 CFR 60.18 (40 CFR 98.234(a)(1)), Method 21 with a leak definition of 10,000 parts per million by volume (ppmv)(40 CFR 98.234(a)(2)), Infrared laser beam illuminated instrument (40 CFR 98.234(a)(3)), Acoustic leak detection device (40 CFR 98.234(a)(5)), OGI as specified in the NSPS subpart OOOOa (40 CFR 98.234(a)(6)) or Method 21 with a leak definition of 500 ppmv (40 CFR 98.234(a)(7)).

[e] Reporting is required for emissions from valves, connectors, open-ended lines, pressure relief valves, and meters but is optional for instruments and other components unless the reporter elects to use either OGI or Method 21 as specified in the NSPS subpart OOOOa (40 CFR 98.234(a)(6) or (7)), in which case reporting is also required for instruments and other fugitive emissions components.[13]

[f] LNG = liquefied natural gas.

[g] Reporting is only required for emissions from vapor recovery compressors if this option is chosen.

2. Summary of Comments and Responses

Comment: Several commenters stated that facilities in the Onshore Petroleum and Natural Gas Production and Onshore Petroleum and Natural Gas Gathering and Boosting industry segments should not be required to use the NSPS subpart OOOOa results to calculate GHG emissions to comply with subpart W. They stated that the proposed NSPS subpart OOOOa leak detection program was limited to one monitoring method, which is inconsistent with the current flexibility for reporters conducting equipment leak surveys for subpart W to choose any monitoring method within 40 CFR 98.234(a). The commenters asserted that this requirement will result in some subpart W reporters having to manage multiple equipment leak survey programs within one facility, especially if the facility is located within a state with a different leak detection program, and this result is overly burdensome. In addition, the commenters stated that the equipment leak survey results will be internally inconsistent if they use different methods, and a facility's emissions could appear to increase one year simply because the number of sites subject to the NSPS subpart OOOOa increases, requiring the reporter to use the OGI method in the NSPS subpart OOOOa for an increased number of components. Instead, the reporters suggested, use of the calculation methodology based on equipment leak surveys, including the selection of monitoring method within 40 CFR 98.234(a), should be voluntary for all facilities not currently required to conduct leak surveys under subpart W.

In contrast, another commenter requested that the EPA require all subpart W reporters to detect leaks using direct equipment leak detection technologies such as OGI. The commenter stated that leak detection using OGI can produce more accurate data than current subpart W methods and that the EPA's approach is consistent with the EPA's stated goals to enhance the rigor and transparency of subpart W data. In addition, the commenter stated that applying OGI detection uniformly across subpart W sources will produce data that is readily comparable across facilities and will allow the EPA to assess the performance of facilities over time.

Response: For facilities that have affected sources required to conduct fugitive emissions monitoring to comply with the NSPS subpart OOOOa well site or compressor station fugitive emissions standards, the EPA is finalizing as proposed that these components must meet the subpart W calculation methodology based on equipment leak survey requirements. In practice, this means reporters can meet these requirements by counting the actual number of components with fugitive emissions identified through implementation of the NSPS subpart OOOOa as leaks for purposes of subpart W. This requirement will achieve the EPA's stated goal of alignment with the NSPS subpart OOOOa and will assist in providing the EPA with a greater understanding of emission reductions.

At this time, we are not requiring all subpart W facilities to perform a leak detection survey using direct equipment leak detection technologies such as OGI. Rather this action is focused on aligning the subpart W requirements, to the extent possible, with the NSPS subpart OOOOa fugitive emission requirements so that facilities may use the results of the NSPS subpart OOOOa-required

[13] See section II.D.1 of this preamble for the EPA's decision on the final subpart W requirements for components not subject to 40 CFR 60.5397a of the NSPS Subpart OOOOa from affected facilities in the Onshore Natural Gas Transmission Compression industry segment, and storage stations in gas service within the Underground Natural Gas Storage industry segment.

fugitive emissions monitoring surveys to fulfill subpart W requirements.

The EPA does not agree that a subpart W requirement to use the results of a previously completed leak survey within the subpart W calculation methodology based on equipment leak surveys will result in an undue burden to these reporters. For components subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions standards, there is little to no burden associated with using the number of components found to have fugitive emissions as the number of leaking components in the subpart W calculation methodology based on equipment leak surveys. The only additional piece of information these reporters need to calculate emissions is the amount of time each component was leaking, and this is a straightforward determination based on the dates of the equipment leak surveys. See section IV.B of this preamble for information and responses to comments related to the EPA's burden estimates for these amendments.

C. Summary of Final Amendments to Monitoring Methods

1. Summary of Final Amendments

The EPA is finalizing the proposal to add OGI, as specified in the NSPS subpart OOOOa, to the list of monitoring methods in 40 CFR 98.234(a). The addition of this specific OGI method to subpart W at 40 CFR 98.234(a)(6) aligns the methods in the two rulemakings and allows subpart W facilities to directly use information derived from the implementation of the fugitive emissions monitoring conducted under the NSPS subpart OOOOa to calculate and report equipment leak emissions to the GHGRP.

The EPA has made changes to the proposed subpart W amendments after consideration of public comment and/or to be consistent with the final revisions made to the corresponding proposed NSPS subpart OOOOa specifications. The proposed subpart W amendments cross-referenced the proposed 40 CFR 60.5397a(b) through (e) and (g) through (i), which included the requirements to: (1) Develop a corporate-wide fugitive emissions monitoring plan; (2) develop a site-specific monitoring plan; (3) observe each fugitive emissions component for fugitive emissions; (4) conduct monitoring surveys semiannually; and (5) adjust the frequency of monitoring surveys based on the percent of the fugitive emissions components detected to have fugitive emissions. For the reasons described below, the final amendments to subpart W for the OGI method cross-reference a portion of the NSPS subpart OOOOa requirements to develop the fugitive emissions monitoring plan and the NSPS subpart OOOOa requirements to observe each fugitive emissions component for fugitive emissions.

The final NSPS subpart OOOOa requires an emissions monitoring plan that covers the affected sources within each company-defined area. This monitoring plan includes information about the survey frequency, monitoring method and instrument selected, repair procedures and timeframes, recordkeeping, and procedures for calibrating the monitoring instrument and verifying that it can detect fugitive emissions at the required levels.

For the final subpart W amendments, the EPA evaluated the NSPS subpart OOOOa requirements for the monitoring plan along with the level of detail in the existing monitoring methods in 40 CFR 98.234(a). The EPA determined that information about the monitoring instrument selected and procedures for calibrating the monitoring instrument and verifying that it can detect fugitive emissions at the required levels is necessary to ensure the OGI monitoring is performed correctly. Therefore, the new OGI detection method in subpart W does include the NSPS subpart OOOOa requirement to develop a monitoring plan that describes the OGI instrument (40 CFR 60.5397a(c)(3)) and how the OGI survey will be conducted to ensure that fugitive emissions can be imaged effectively (40 CFR 60.5397a(c)(7)). The EPA determined that the NSPS subpart OOOOa survey frequency should not be cross-referenced in subpart W because cross-referencing these frequencies would override the current annual survey requirement in subpart W regardless of whether the use of the new monitoring methods is voluntary or mandatory. The EPA determined that the repair procedures and timeframes should not be cross-referenced because subpart W is part of a reporting program and does not require repair of detected leaks. The EPA also determined that the NSPS subpart OOOOa recordkeeping requirements should not be cross-referenced because they include provisions that are not applicable to greenhouse gas reporting, such as records related to repairs. Applicable recordkeeping requirements for all leak detection methods in subpart W are specified at 40 CFR 98.237.

The final site-specific monitoring plan in the NSPS subpart OOOOa includes three items specific to the OGI method: (1) A sitemap; (2) a defined observation path for the operator that ensures that all fugitive emissions components are within sight of the path; and (3) a monitoring plan for difficult-to-monitor and unsafe-to-monitor fugitive emissions components. The EPA has reviewed these elements as well and determined not to cross-reference these three elements in subpart W. The observation path and the sitemap ensure that the OGI operator visualizes all of the components that must be surveyed, analogous to requirements in some rules to identify all of the equipment that must be monitored using Method 21 (*e.g.,* 40 CFR 60.486a(e)(1) and 40 CFR 63.162(c)). Subpart W does not include these identification requirements as part of the Method 21 requirements in 40 CFR 98.234(a)(2), so it would be inconsistent to require the observation path as part of the new OGI method. However, while we are not finalizing the explicit requirement to define the observation path the operator will follow during their survey, we do note that 40 CFR part 98, subpart A requires a written GHG monitoring plan for all facilities subject to the GHGRP (see 40 CFR 98.4(g)(5)). Defining an observation path is one item that could be included in the GHG monitoring plan to meet the requirement to describe ''procedures and methods that are used for quality assurance . . . of all . . . other instrumentation'' used to collect data to comply with the GHGRP (40 CFR 98.3(g)(5)(i)(C)).

The EPA is finalizing the proposed requirement to observe each fugitive emissions component for fugitive emissions (40 CFR 60.5397a(e)).[14] The EPA considers surveying all fugitive emissions components (instead of just the current list of equipment in subpart W for a particular industry segment) to be an inherent part of the NSPS subpart OOOOa OGI method.

The EPA is not cross-referencing the semi-annual (well sites) and quarterly (compressor stations) monitoring frequencies of the final NSPS subpart OOOOa. As noted above, cross-referencing these monitoring frequencies would override the current annual survey requirement in subpart W regardless of whether the use of the new monitoring methods is voluntary or mandatory. The EPA is instead clarifying that for reporters with components subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions requirements and for which surveys are required or elected, the results from each equipment leak

[14] See section II.D.1 of this preamble for details regarding the specific NSPS subpart OOOOa-defined fugitive emissions components that are not considered sources of ''equipment leaks'' in subpart W.

survey must be used to calculate GHG emissions for subpart W. The EPA is further clarifying that it is not our intent to require reporters that are not subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions requirements to conduct more than one equipment leak survey in a calendar year for purposes of GHGRP reporting, solely because they choose to use the OGI method. The EPA also notes that the proposed NSPS subpart OOOOa provisions for adjusting the frequency of equipment leak surveys based on the percent of the fugitive emissions components detected to have fugitive emissions were not included in the final NSPS subpart OOOOa and therefore are not cross-referenced in the final subpart W revisions.

Finally, consistent with the final NSPS subpart OOOOa, the EPA is finalizing the use of Method 21 as an alternative monitoring method to OGI (as specified in the NSPS subpart OOOOa) at 40 CFR 98.234(a)(7). As the EPA noted in the preamble for this proposed revision to subpart W (81 FR 4989; Jan. 29, 2016), the NSPS subpart OOOOa proposal identified EPA Method 21 as a monitoring method that may also be used to conduct resurveys of repaired components when fugitive emissions are detected (80 FR 56612 (well sites) and 80 FR 56612 (compressor stations)), and the EPA requested comment on including in the final rule the use of Method 21 for fugitive emissions monitoring as well (80 FR 56638 (well sites) and 80 FR 56643 (compressor stations)). The EPA also made clear in the preamble to these proposed revisions to subpart W that, consistent with the goal of aligning the methods in the two rulemakings (subpart W and the NSPS subpart OOOOa), the EPA expected that the final amendments to subpart W for monitoring methods would reference the final version of the method(s) in the NSPS subpart OOOOa, including any changes made to the NSPS subpart OOOOa in response to comments on the proposed monitoring method(s) (81 FR 4991). Accordingly, the EPA is finalizing the use of Method 21 as an alternative monitoring method to OGI (as specified in the NSPS subpart OOOOa) at 40 CFR 98.234(a)(7).

For reporters that elect to use Method 21 as specified in 40 CFR 98.234(a)(7), either for components that are subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions requirements or voluntarily, a leak is detected if an instrument reading of 500 ppmv or greater is measured. As explained in this section regarding the NSPS subpart OOOOa OGI monitoring method, we determined that the requirements in 40 CFR 60.5397a(b) are consistent with the requirements of subpart W regarding the development of an emissions monitoring plan; this monitoring plan is required to include verification that the procedures of Method 21 are followed consistent with the requirements in 40 CFR 60.5397a(c)(8). Also, as with the NSPS subpart OOOOa OGI method, the EPA is requiring in subpart W observation of each fugitive emissions component for fugitive emissions consistent with the requirements in 40 CFR 60.5397a(e); the EPA considers surveying all fugitive emissions components to be an inherent part of the NSPS subpart OOOOa Method 21 alternative to the OGI method and is consistent with requirements in subpart W to conduct a complete equipment leak survey.

At this time, the EPA is not adding any other monitoring methods to subpart W. We will continue to evaluate equipment leak detection methods and technologies [15] and may amend subpart W to allow the use of additional methods in the future.

2. Summary of Comments and Responses

Comment: Many commenters disagreed with the EPA's proposal to add only the OGI method as specified in the NSPS subpart OOOOa to 40 CFR 98.234(a) of subpart W. They asserted that while OGI is an effective method for finding the majority of emissions more quickly than EPA Method 21, it is also a costly technology that cannot quantify emissions. The commenters stated that OGI has other limitations, especially in non-ideal weather conditions; one commenter also stated that use of the OGI camera requires a hot work permit in many instances.

Response: Due to similar comments on the proposed NSPS subpart OOOOa, the final NSPS subpart OOOOa provides owners and operators of new, modified, or reconstructed well sites or compressor stations with the option of using EPA Method 21 with a repair threshold of 500 ppmv if they elect not to use the OGI method (40 CFR 60.5397a). As discussed in section II.C.1 of this preamble, the final amendments to subpart W provide for the use of EPA Method 21 where a leak is detected for purposes of subpart W if an instrument reading of 500 ppmv or greater is measured. This amendment to subpart W maintains the alignment with the NSPS subpart OOOOa well site and compressor station fugitive emissions monitoring requirements, so that reporters can directly use the NSPS subpart OOOOa monitoring results to count the number of leaks under subpart W.

Comment: Many commenters stated that leak detection technology is a rapidly growing field and there are many alternative technologies and new technologies in development that may be more accurate and less costly than OGI. Some commenters noted that recent emphasis on CH_4 emissions has caused vendors to focus on CH_4 leak detection. Therefore, according to the commenters, some of those technologies may be better options for the purpose of reporting emissions under subpart W than other leak detection programs. The commenters stated that the EPA's proposal to limit leak surveys to a prescriptive list of methods could limit development of these new technologies.

Commenters provided a variety of suggestions for incorporation of new and emerging technologies into subpart W. Three commenters recommended that the EPA establish a clear process for industry, vendors, and/or the EPA to evaluate the efficacy and accuracy of alternative CH_4 monitoring technologies and approve the use of those technologies. One of these commenters noted that any technology evaluation process should be straightforward and more streamlined than the years-long process needed to approve emissions control devices or continuous emissions monitoring systems. Another of these commenters suggested that the EPA model a technology evaluation process after the vendor testing program for flares and combustors, in which the EPA sets testing protocols and vendors demonstrate that they can meet specific criteria. A fourth commenter suggested that the EPA develop a pilot program to incentivize the accelerated development and deployment of advanced monitoring and detection technologies and to compare the effectiveness of these approaches to periodic, OGI-based surveys.

Response: The EPA agrees with the commenters that emissions monitoring in the oil and gas sector is a field of emerging technology, and major advances are expected in the near future. We are seeing a rapidly growing push to develop and produce low-cost monitoring technologies to find fugitive CH_4 emissions sooner and at lower levels than current technology allows, thus enhancing the ability of operators to detect fugitive emissions. The EPA agrees that continued development of these cost-effective technologies is

[15] For example, the EPA has issued a voluntary request for information inviting all parties to provide information on innovative technologies to detect, measure, and mitigate emissions from the oil and gas industry. See 81 FR 46670 (July 18, 2016).

important. However, the EPA does not have enough information at this time to evaluate specific technologies to determine if they are equivalent to or better than the monitoring methods provided in and being added to 40 CFR 98.234(a). The EPA may evaluate new options as they become available and determine if they are equivalent to existing methods. For example, the final NSPS subpart OOOOa provides a process for the EPA to determine that a technology can be used as an ''alternative means of emission limitation.'' [16] As technologies are approved through this process, the EPA anticipates that it would contemporaneously incorporate these monitoring methods in subpart W to ensure continued alignment between the NSPS subpart OOOOa and subpart W through future notice and comment rulemaking.

Comment: Multiple commenters addressed the proposed requirement to consider any fugitive emissions observed using OGI during the NSPS subpart OOOOa fugitive emissions monitoring as a leak for purposes of subpart W. Most of these commenters objected to the proposal and stated that the definition of a leak for subpart W should be 10,000 ppmv, regardless of the monitoring method used. These commenters asserted that setting the leak definition consistent with the current methods in subpart W would ensure that the new methods result in new information being collected and reported consistently within a facility and consistent with the equipment leak data already in the GHGRP. One commenter noted that defining a leak as emissions at a set concentration is much less subjective than defining a leak as any emissions observed with OGI, and setting the leak definition at 10,000 ppmv rather than a lower concentration would allow operators to focus on finding (and fixing) large leaks instead of spending resources to identify many small leaks that do not contribute much to overall emissions. Another commenter noted that a leak definition of 10,000 ppmv is consistent with the leaker emission factors currently provided in subpart W as well as the proposed new leaker emission factors.

One commenter agreed with a subpart W leak being defined as any fugitive emissions observed using OGI during the NSPS subpart OOOOa fugitive emissions monitoring or emissions above 500 ppmv detected via EPA Method 21, but the commenter asserted that the leak definition for any new or emerging technologies used in a voluntary leak survey should be 5,000 ppmv. The commenter noted that these new technologies are likely to be more sensitive and detect emissions at lower concentrations than OGI, and companies that are employing more accurate instruments should not be ''penalized'' by having to report more leaks than if they used OGI.

Response: Subpart W already includes OGI and EPA Method 21 with a leak definition of 10,000 ppmv for use by reporters currently required to conduct leak surveys for subpart W. The final amendments also provide for use of these methods by reporters electing to conduct an equipment leak survey voluntarily (*i.e.,* for sources currently required to use the calculation methodology based on population counts that are not subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions requirements). The EPA is adding the methods used for fugitive emissions monitoring in the NSPS subpart OOOOa to 40 CFR 98.234(a), as approved monitoring methods for subpart W leak surveys. This addition facilitates alignment with the NSPS subpart OOOOa and will allow reporters to directly use the NSPS subpart OOOOa monitoring results to count the number of leaks under subpart W. Finally, as noted in section II.C.1 of this preamble, the EPA is not adding any other monitoring methods to subpart W at this time, so it is not necessary to consider a different leak definition for new or emerging technologies.

The EPA disagrees that using a leak definition other than 10,000 ppmv would undermine the quality of the data reported to the GHGRP. First, subpart W currently includes an OGI monitoring method in 40 CFR 98.234(a)(1). While this monitoring method allows facilities to screen the observed leaks using Method 21, it does not require it, and we do not expect that many reporters actively use dual monitoring methods in their leak surveys to screen all OGI-detected leaks using Method 21.

Second, we are also finalizing, consistent with the final NSPS subpart OOOOa rule, the ability to use Method 21 with a leak definition of 500 ppmv as an alternative to the OGI method. We agree with commenters that the average emissions rate of leaks identified using Method 21 with a leak definition of 500 ppmv would be less than the average emissions rate of leaks identified using Method 21 with a leak definition of 10,000 ppmv. To address this issue, we are also finalizing separate leaker factors that are appropriate for reporters using this alternative method (Method 21 with a leak definition of 500 ppmv). As described in further detail in section II.E.1 of this preamble and in the document ''Greenhouse Gas Reporting Rule: Technical Support for Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems Final Rule'' in Docket ID No. EPA–HQ–OAR–2015–0764, these additional emission factors were developed from the same data set that was used to develop the original population emission factors and the proposed leaker factors.[17] Therefore, this additional Method 21 monitoring method, which includes a different leak definition than the other Method 21-based method already available in subpart W at 40 CFR 98.234(a)(2), has been specifically considered and new emission factors are provided in the final rule to ensure that this new monitoring method's leak definition will not undermine the quality of the emissions reported under subpart W.

If the EPA did not provide the ability for reporters to use the monitoring methods required by the NSPS subpart OOOOa within subpart W, reporters would not be able to use the NSPS subpart OOOOa monitoring results directly; instead, they would have to measure each occurrence of fugitive emissions individually to determine if it is a leak for purposes of subpart W, which would increase the burden for those reporters.

D. Summary of Final Amendments for Components To Be Surveyed

1. Summary of Final Amendments

The EPA proposed to align the subpart W equipment components with the NSPS subpart OOOOa definition of ''fugitive emissions component,'' with certain exceptions.[18] After careful consideration of comments, the EPA is finalizing that provision consistent with the final NSPS subpart OOOOa definition of ''fugitive emissions component'' with certain exceptions consistent with the proposal, as described in further detail in this section below. A ''fugitive emissions component'' is defined in 40 CFR 60.5430a of the final NSPS subpart

[16] See 40 CFR 60.5398a titled ''What are the alternative means of emission limitations for GHG and volatile organic compounds from well completions, reciprocating compressors, the collection of fugitive emissions components at a well site and the collection of fugitive emissions components at a compressor station?''

[17] This data set was developed from monitoring conducted using Method 21 with a leak definition of 10,000 ppmv.

[18] See 81 FR 4994 for a discussion of the differences between the proposed definition of ''fugitive emissions component'' and the proposed components subject to equipment leak reporting in subpart W.

OOOOa to include any component that has the potential to emit fugitive emissions of CH4 or volatile organic compounds at a well site or compressor station, including but not limited to valves, connectors, pressure relief devices, open-ended lines, flanges, covers and closed vent systems not subject to 40 CFR 60.5411a, thief hatches or other openings on a controlled storage vessel not subject to 40 CFR 60.5395a, compressors, instruments, and meters. Devices that vent as part of normal operations, such as natural gas-driven pneumatic controllers or natural gas-driven pumps, are not fugitive emissions components, as the natural gas discharged from the device's vent is not considered a fugitive emission. Emissions originating from a location other than the vent are considered fugitive emissions.

As noted in the preamble to the proposed subpart W amendments, some of the components listed in the NSPS subpart OOOOa definition of fugitive emissions component are already included as part of the subpart W equipment leaks calculation methodologies (either based on equipment leak surveys or on population counts), while other fugitive emissions components are specifically addressed in other calculation methodologies in subpart W. As part of developing the proposed amendments for subpart W, we compared the list of components in the NSPS subpart OOOOa proposed definition of fugitive emissions component with the current methodologies in subpart W to identify which fugitive emissions components were already covered by an existing requirement in subpart W and which fugitive emissions components would be specifically covered in subpart W when using the OGI method as specified in the proposed NSPS subpart OOOOa.

Table 3 of this preamble provides a summary of the applicable subpart W calculation methodologies for components subject to the fugitive emissions standards in the final NSPS subpart OOOOa. The basis for excluding certain components that are subject to the fugitive emissions standards in the final NSPS subpart OOOOa from the final equipment leak survey requirements in 40 CFR 98.233(q) is discussed below.

TABLE 3—FINAL SUBPART W CALCULATION METHODOLOGY REQUIREMENTS FOR COMPONENTS SUBJECT TO THE FUGITIVE EMISSIONS STANDARDS IN NSPS SUBPART OOOOa

Type of component in definition of fugitive emissions component and subject to the fugitive emissions standards in NSPS subpart OOOOa	Applicable GHG emissions calculation methodology in subpart W by industry segment for components that are also subject to the fugitive emissions standards for well sites or compressor stations in the NSPS subpart OOOOa[a]		
	Onshore petroleum and natural gas production, onshore petroleum and natural gas gathering and boosting	Underground natural gas storage, LNG storage, LNG import and export equipment	Onshore natural gas transmission compression
Thief hatches or other openings on controlled storage vessels not subject to 40 CFR 60.5395a.	• 40 CFR 98.233(j)	• 40 CFR 98.233(q) (use factor for "other" components in Tables W–4A, W–5A, and W–6A to subpart W)[b].	• 40 CFR 98.233(k).
Compressors, excluding emissions from vents that are part of normal operations (*i.e.,* wet seal oil degassing vents).	• 40 CFR 98.233(q) for blowdown valve leakage and isolation valve leakage (use factor for "open-ended line" in Table W–1E to subpart W)[b]. • 40 CFR 98.233(q) for all other leaks from the housing (use factor for "other" components in Table W–1E to subpart W)[b]. • 40 CFR 98.233(p)(10) for rod packing venting from reciprocating compressors.	• 40 CFR 98.233(o) for blowdown valve leakage and isolation valve leakage from centrifugal compressors. • 40 CFR 98.233(p) for blowdown valve leakage, isolation valve leakage, and rod packing venting from reciprocating compressors. • 40 CFR 98.233(q) for all other leaks from the housing (use factor for "other" components in Table W–4A, W–5A, and W–6A to subpart W)[b].	• 40 CFR 98.233(o) for blowdown valve leakage and isolation valve leakage from centrifugal compressors • 40 CFR 98.233(p) for blowdown valve leakage, isolation valve leakage, and rod packing venting from reciprocating compressors • 40 CFR 98.233(q) for all other leaks from the housing (use factor for "other" components in Tables W–3A, to subpart W)[b]
All other components	• 40 CFR 98.233(q) (use factors for applicable component types in Table W–1E to subpart W)[b].	• 40 CFR 98.233(q) (use factors for applicable component types in Tables W–4A, W–5A, and W–6A to subpart W)[c].	• 40 CFR 98.233(q) (use factors for applicable component types in Table W–3A to subpart W)[c].

[a] Onshore Natural Gas Processing and Natural Gas Distribution are not included in this table because we are not revising the calculation methodology and monitoring method for leak detection for these industry segments in this action. The current requirements are still applicable to components in these industry segments.

[b] The leaker emission factors for "other" components are being finalized in this revision.

[c] The leaker emission factors include both factors in the current rule and factors that are being finalized in this action, depending on the specific component and the monitoring method used to conduct the survey, as discussed in section II.E.1 of this preamble.

At proposal, we determined that the subpart W calculation methodology for storage tanks in 40 CFR 98.233(j) already includes emissions from thief hatches or other openings on storage vessels in the Onshore Petroleum and Natural Gas Production and Onshore Petroleum and Natural Gas Gathering and Boosting industry segments. However, we requested comment on whether the agency should consider separate approaches for controlled storage tanks and uncontrolled storage tanks. The final definition of "fugitive emissions component" in the NSPS subpart OOOOa (40 CFR 60.5430a) includes only thief hatches or other openings on a controlled storage vessel; it does not specifically list openings on uncontrolled storage vessels. We reviewed the subpart W calculation methodology specifically for storage tanks with a vapor recovery system (40 CFR 98.233(j)(4)) and storage tanks with a flare (40 CFR 98.233(j)(5)). The procedure for determining emissions from a tank with a vapor recovery system instructs reporters to adjust the storage tank emissions downward by the magnitude of emissions recovered using

a vapor recovery system as determined by engineering estimate based on best available data (40 CFR 98.233(j)(4)(i)). The procedure for determining emissions from a tank with a flare references 40 CFR 98.233(n), which instructs reporters to use engineering calculations based on process knowledge, company records, and best available data to determine the flow to the flare if the flare does not have a continuous flow measurement device. If a reporter sees fugitive emissions from a thief hatch or other opening on a controlled storage vessel during an equipment leak survey conducted using OGI, the reporter should consider that information as part of the ''best available data'' used to calculate emissions from that storage tank. Therefore, we have concluded that emissions from thief hatches or other openings on storage vessels in the Onshore Petroleum and Natural Gas Production and Onshore Petroleum and Natural Gas Gathering and Boosting industry segments are already included in the subpart W storage tank emission calculations in 40 CFR 98.233(j) and are finalizing, consistent with the proposal, that they are not to be considered when determining emissions from equipment leaks for purposes of subpart W.

We are also finalizing as proposed the exclusion of thief hatches and other openings on transmission storage tanks from the equipment leak reporting requirements.[19] We note that, for purposes of subpart W reporting, a leaking thief hatch or other opening is functionally a secondary vent, and thus subject to annual screening on an uncontrolled tank according to 40 CFR 98.233(k)(1). If screening shows vapors from the thief hatch or opening are continuous for 5 minutes, then a method in 40 CFR 98.233(k)(2) must be used to quantify the leak rate, and this amount must be combined with any other vent leak rates for reporting.

We are also finalizing the proposed distinction between equipment leak emissions and compressor emissions. Specifically, for centrifugal compressors, emission sources include wet seal oil degassing vents (for centrifugal compressors with wet seals), blowdown valve leakage, and isolation valve leakage. For reciprocating compressors, emission sources include reciprocating compressor rod packing vents, blowdown valve leakage, and isolation valve leakage.

For compressors in the Onshore Petroleum and Natural Gas Production and the Onshore Petroleum and Natural Gas Gathering and Boosting industry segments under subpart W, the compressor methodologies only cover emissions from centrifugal compressor wet seal oil degassing vents and from reciprocating compressor rod packing vents. Thus, the EPA is finalizing as proposed, for these industry segments, that blowdown valve leakage and isolation valve leakage are considered equipment leaks (*i.e.,* open-ended lines), and finalizing as proposed that emissions from centrifugal compressor wet seal oil degassing vents and from reciprocating compressor rod packing vents are not considered equipment leaks when using the calculation methodology based on equipment leak surveys in 40 CFR 98.233(q).[20]

For the Onshore Natural Gas Transmission Compression, Underground Natural Gas Storage, LNG Storage, and LNG Import and Export Equipment segments, subpart W requires reporters to make ''as found'' or continuous measurements for compressor emission sources, so the reporters will have either direct measurement data or site-specific emission factors by which to calculate emissions from all of the compressor sources listed above (*i.e.,* wet seal oil degassing vents for centrifugal compressors with wet seals, rod packing vents for reciprocating compressors, and blowdown valve leakage and isolation valve leakage for both centrifugal and reciprocating compressors). Therefore, we are finalizing as proposed to exclude these compressor emission sources from the requirements in the calculation methodology based on equipment leak surveys so that reporters do not double-count emissions from these sources in their GHGRP reports.

Finally, as noted in section II.C.1 of this preamble, we are finalizing the proposed determination that for purposes of subpart W, all other fugitive emissions components as defined in the NSPS subpart OOOOa not specifically identified above (*e.g.,* thief hatches or other openings on a controlled storage vessel, compressor sources with explicit calculation methodologies in subpart W) will be considered equipment components when conducting an equipment leak survey using the OGI method as specified in the NSPS subpart OOOOa or EPA Method 21 with a leak definition of 500 ppmv. In other words, we consider the provision requiring monitoring of fugitive emissions components as defined in the NSPS subpart OOOOa in 40 CFR 60.5397a(e) to be an inherent part of the NSPS subpart OOOOa OGI method and EPA Method 21 with a leak definition of 500 ppmv. Therefore, if a reporter with components not subject to the NSPS subpart OOOOa well site or compressor station fugitive emission requirements elects to use the NSPS subpart OOOOa OGI method or EPA Method 21 with a leak definition of 500 ppmv for purposes of subpart W, they are also electing to survey these additional components.

2. Summary of Comments and Responses

Comment: Several commenters stated that the NSPS subpart OOOOa proposed definition of ''fugitive emissions component'' is too expansive. Because it includes many more emission sources than a more traditional definition of equipment, the commenters asserted that it is inconsistent with current subpart W requirements. The commenters stated that aligning subpart W with the NSPS subpart OOOOa in this respect will complicate the question of which components must be monitored at subpart W facilities and will result in facilities having higher numbers of leaks than they would have if they used any other equipment leak detection method in subpart W. Some commenters stated that even for well sites and compressor station sites subject to the NSPS subpart OOOOa, component types considered to be equipment under subpart W should be consistent with a more traditional definition of equipment. Other commenters requested that equipment under subpart W only include component types for which the EPA can provide specific population factors and leaker emission factors.

Response: As noted in section II.D.1 of this preamble, the final definition of ''fugitive emissions component'' in the NSPS subpart OOOOa (40 CFR 60.5430a) does not list as many explicit individual component types, as originally proposed. The EPA is finalizing, with the exceptions discussed in section II.D.1 of this preamble and consistent with the extent proposed, this alignment with the NSPS subpart OOOOa, so that reporters may directly use the NSPS subpart OOOOa monitoring results to count the number of leaks under subpart W. Reporters using the calculation methodology based on equipment leak surveys for

[19] The exceptions to equipment leak reporting requirements were included in Tables W–1E and W–3 through W–6 of the proposal. The final rule moves these exceptions to 40 CFR 98.232, to increase clarity and reduce confusion while achieving the same purpose and effect.

[20] 40 CFR 98.233(q) specifies which subsections in 40 CFR 98.232 (*i.e.,* which components) must follow the calculation methodology based on equipment leak surveys in 40 CFR 98.233(q), and 40 CFR 98.232 subsections identify exceptions from the list of components for which equipment leak reporting is required.

components not subject to the NSPS subpart OOOOa may choose which monitoring method to use. If a reporter chooses to use one of the monitoring methods listed in 40 CFR 98.234(a)(1) through (5), that reporter would use the current list of equipment components for the appropriate industry segment in 40 CFR 98.232 (*e.g.,* the list of equipment at 40 CFR 98.232(e)(7) for the Onshore Natural Gas Transmission Compression industry segment). If a reporter chooses to use the OGI method as specified in the NSPS subpart OOOOa or EPA Method 21 with a leak definition of 500 ppmv, the reporter would use both the current list and the newly added list of equipment components for the appropriate industry segment in 40 CFR 98.232, which in conjunction include the NSPS subpart OOOOa definition of ''fugitive emissions component'' in 40 CFR 60.5430a with the exceptions discussed in section II.D.1 of this preamble (*e.g.,* the list of equipment at 40 CFR 98.232(e)(7) and (8) for the Onshore Natural Gas Transmission Compression industry segment).

E. Summary of Final Amendments to Leaker Emission Factors and the Calculation Methodology Based on Equipment Leak Surveys

1. Summary of Final Amendments

To quantify emissions from leaking equipment components, subpart W includes leaker emission factors for each component type in each industry segment currently required to use the calculation methodology based on equipment leak surveys. In contrast to the population emission factors, which are multiplied by the total facility component counts, leaker emission factors are multiplied by the actual number of leaks for each component type, as identified by the equipment leak survey. These amendments increase the component types that are required or may elect to use the calculation methodology based on equipment leak surveys, including most of the component types currently using the subpart W calculation methodology based on population counts.[21] Therefore, new leaker emission factors are being added so that reporters can calculate their GHG emissions for these new component types.

Specifically, the EPA proposed to add new sets of leaker emission factors to subpart W for: (1) The Onshore Petroleum and Natural Gas Production industry segment; (2) the Onshore Petroleum and Natural Gas Gathering and Boosting industry segment; (3) storage wellheads in gas service in the Underground Natural Gas Storage industry segment; (4) LNG storage components in gas service in the LNG Storage industry segment; and (5) LNG terminals components in gas service for the LNG Import and Export Equipment industry segment. For industry segments that already include a set of leaker emission factors, the EPA also proposed to expand that set of leaker emission factors to include certain additional components to better align with the definition of fugitive emissions components in the NSPS subpart OOOOa. See the document ''Greenhouse Gas Reporting Rule: Technical Support for Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' in Docket Item No. EPA–HQ–OAR–2015–0764–0028, for more information on the development of the proposed leaker emission factors.

We are finalizing the leaker emission factors for the Onshore Petroleum and Natural Gas Production and the Onshore Petroleum and Natural Gas Gathering and Boosting industry segments as proposed, with clarifications for flanges and connectors noted below. We are also finalizing the following leaker emission factors as proposed: (1) The leaker emission factors for ''other'' components in Tables W–3A, W–4A, W–5A, and W–6A to subpart W; (2) the leaker emission factors for storage wellhead equipment in gas service within Table W–4A to subpart W; and (3) the leaker emission factors for equipment in gas service for LNG storage components within Table W–5A to subpart W and for LNG terminal components within Table W–6A to subpart W. We are also finalizing the proposal to expand the existing leaker emission factor for meters to also include instruments in Tables W–3A and W–4A to subpart W for the Onshore Natural Gas Transmission Compression and Underground Natural Gas Storage industry segments, respectively. All but one of the proposed leaker factors for flanges in Tables W–3 through W–6 to subpart W (Tables W–3A, W–4A, W–5A, and W–6A to subpart W in these final amendments) were the same as the leaker factors for connectors; the exception was for flanges in gas service associated with storage wellheads at Underground Natural Gas Storage facilities, which had a proposed leaker factor that differed from the proposed leaker factor for connectors in the same service. Flanges are a type of connector, which means the proposed flange factors that were identical to the existing connector factors were redundant. Therefore, we have not finalized the proposed separate factors for flanges where the factor was the same as the factor for connectors and are finalizing that flanges must use the final connector factor, meaning the effect of the final amendments is the same as the proposal. The separate factors for connectors and flanges for storage wellheads in gas service at Underground Natural Gas Storage facilities are finalized as proposed, but to clarify that the factor for connectors applies only to all types of connectors other than flanges, the component name has been changed from ''connector'' in the proposal to ''connector (other)'' in Table W–4A of the final amendments. This change also makes the terminology in Table W–4A consistent with the terminology in Tables W–1A and W–1E, which also specify factors for flanges that differ from the factors for other types of connectors.

We are not finalizing the proposed addition of pumps to the leaker factors in Table W–2 for the Onshore Natural Gas Processing industry segment. As described in section II.B.1 of this preamble, we are not taking final action on the Onshore Natural Gas Processing revisions at this time.

In addition to finalizing nearly all of the proposed leaker factors, we are also finalizing an additional set of emission factors corresponding to the average emissions rates of components identified using Method 21 with a leak definition of 500 ppmv. The proposed leaker factors were developed based on Method 21 monitoring using a leak definition of 10,000 ppmv and were to be applied by all reporters regardless of the leak survey monitoring method used. As noted in section II.C of this preamble, the final NSPS subpart OOOOa includes an additional alternative that allows reporters to use Method 21 with a leak definition of 500 ppmv. On average, the emissions from a leak identified with a Method 21 reading above 500 ppmv are less than the emissions from a leak identified with a Method 21 reading of 10,000 ppmv or higher. Consequently, the leaker factor (which is the average emissions rate) for leaks identified when using a leak definition of 500 ppmv is smaller than the leaker factor for leaks identified when using a leak definition of 10,000 ppmv. Therefore, in order to use the NSPS subpart OOOOa survey results directly to calculate equipment leak emissions for subpart W when Method 21 with a leak definition of 500

[21] The NSPS subpart OOOOa fugitive emission requirements do not apply to fugitive emissions components in the Natural Gas Distribution industry segment.

NMED Exhibit 98 - 0014

ppmv is used, leaker factors were developed consistent with the average emissions rate of a ''leak'' defined as a measurement reading of 500 ppmv or more using Method 21. We developed these new leaker factors using data from EPA's Protocol for Equipment Leak Emissions Estimates [22] consistent with the data used to develop the proposed leaker factors for Onshore Petroleum and Natural Gas Production and the Onshore Petroleum and Natural Gas Gathering and Boosting industry segments. See the document ''Greenhouse Gas Reporting Rule: Technical Support for Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems Final Rule'' in Docket ID No. EPA–HQ–OAR–2015–0764, which provides more information on the development of the final leaker emission factors. The inclusion of leaker factors specific to Method 21 with a leak definition of 500 ppmv is consistent with our proposal to align subpart W calculation methodologies with the monitoring requirements in the NSPS subpart OOOOa.

We are also finalizing the proposed amendments to the time variable $T_{p,z}$ in Equation W–30 to clarify the total time a surveyed component found leaking is assumed to be leaking and operational. The previous language for the definition of the time variable specifically considers a first leak survey and a last leak survey in the year but does not provide specific language with respect to the duration of any ''intermediate'' survey conducted between the first and last survey. Therefore, the EPA proposed to amend the definition of the time variable to clarify how to determine the duration of a leak if more than two leak surveys are conducted in a year and to instruct reporters to sum the individual durations to determine the total time the component was leaking during the year.

The EPA is finalizing this amendment as proposed. The amendments to the time variable $T_{p,z}$ define each equipment leak survey as covering a unique, non-overlapping time period and we are clarifying our intent that a leak detected in the first or any intermediate survey is not considered to continue leaking past the date of that specific equipment leak survey. For the last survey conducted in the calendar year, the leak is assumed to continue until the end of the year. For example, if a reporter conducts three equipment leak surveys in a calendar year and a particular component is found to be leaking in the first and second surveys but not the third, the total leak duration is the sum of the time from January 1 to the date of the second survey. If a reporter conducts three equipment leak surveys in a calendar year and a particular component is found to be leaking in the first and last surveys but not the second, then the total leak duration is the sum of the time from January 1 to the date of the first survey and the time from the date of the second survey to December 31.

See ''Response to Public Comments on Greenhouse Gas Reporting Rule: Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' in Docket ID No. EPA–HQ–OAR–2015–0764 for all comments and the EPA's responses to comments on other aspects of the time variable $T_{p,z}$ in Equation W–30.

Finally, 40 CFR 98.233(q) includes a provision requiring reporters to conduct one equipment leak survey in a calendar year (which must include ''all component types'' subject to 40 CFR 98.233(q)) or multiple ''complete'' equipment leak surveys in a calendar year. In response to comments as part of the 2010 subpart W final rule, the EPA noted that subsequent equipment leak surveys should be ''conducted for an entire facility.'' [23]

The EPA has reviewed how this interpretation could interact with these final amendments for components subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions requirements and finds that additional clarification is necessary. For example, a facility in the Onshore Petroleum and Natural Gas Production industry segment or the Onshore Petroleum and Natural Gas Gathering and Boosting industry segment may have some components that are subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions requirements and some components that are not. In such a case, multiple equipment leak surveys would be conducted for the components subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions requirements, to fulfill the requirements of the NSPS subpart OOOOa for those components, that would be consistent with subpart W monitoring methods under these final revisions.

However, under the current interpretation of a ''complete'' survey, it would appear that these reporters would either: (1) Be unable to use the NSPS subpart OOOOa fugitive emissions monitoring results as directed, because they did not survey all components at the facility; or (2) be forced to monitor all components at the facility on the same frequency as the components subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions requirements to meet the subpart W requirement to use all additional leak surveys conducted in accordance with NSPS OOOOa. The first interpretation would render these final amendments useless, and the second interpretation would increase the burden beyond the EPA's intentions, and could also have unintended consequences for the components subject to the NSPS subpart OOOOa (*e.g.*, a subpart W facility with some components subject to the NSPS subpart OOOOa well site fugitive emissions requirements and others subject to the NSPS subpart OOOOa compressor station fugitive emissions requirements could end up being required to monitor the fugitive emissions components at a well site four times a year instead of twice). Therefore, the EPA is clarifying in 40 CFR 98.233(q)(2)(i) that any monitoring conducted pursuant to and in compliance with the NSPS subpart OOOOa well site or compressor station fugitive emissions requirements constitutes a ''complete'' survey for purposes of subpart W and must be used for subpart W reporting. The EPA is further clarifying that, to meet the requirements of 40 CFR 98.233(q), at least one equipment leak survey must be conducted in a calendar year.

2. Summary of Comments and Responses

Comment: Several commenters addressed the EPA's proposed leaker emission factors. Some of the commenters indicated that the EPA/Gas Research Institute (GRI) data set upon which the proposed factors are based is an older data set and asserted that it may not be representative of operating practices and procedures that have changed significantly over the past 20 years. In addition, the commenters stated that the EPA/GRI data set includes a limited population of measurements, so the proposed leaker emission factors may not account for operational variability on a regional or national level. Some commenters requested that the EPA consider newer studies, including those cited in

[22] U.S. Environmental Protection Agency. *Protocol for Equipment Leak Emissions Estimates.* EPA–453/R–95–017. November 1995. Docket Item No. EPA–HQ–OAR–2009–0927–0043.

[23] U.S. Environmental Protection Agency. *Mandatory Greenhouse Gas Reporting Rule Subpart W—Petroleum and Natural Gas: EPA's Response to Public Comments.* November 2010. Docket Item No. EPA–HQ–OAR–2009–0923–3608. Response to Comment Number EPA–HQ–OAR–2009–0923–1014–9, pp. 1281–1282.

NMED Exhibit 98 - 0015

''Greenhouse Gas Reporting Rule: Technical Support for Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' (Docket Item No. EPA–HQ–OAR–2015–0764–0028) either instead of or in combination with the EPA/GRI data set.

Several commenters urged the EPA to work with the regulated community to improve the default leaker emission factors in subpart W. One commenter noted that the proposed leaker emission factors may be a viable interim solution but recommended that the EPA analyze more robust data sets consisting of the combined results of all studies for each industry segment and evaluate whether the subpart W leaker emission factors should be revised.

Response: As described in the preamble to the proposed rule and the document ''Greenhouse Gas Reporting Rule: Technical Support for Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems Final Rule'' (Docket ID No. EPA–HQ–OAR–2015–0764), the EPA has determined that the EPA/GRI data set is appropriate to base leaker emission factors in these subpart W amendments. We note that the EPA/GRI data set provides sufficient data to develop leaker emission factors and that using this data set for the leaker emission factors provides consistency with the population emission factors used by reporters that do not conduct equipment leak surveys.

The EPA agrees that there are numerous recent studies that could be used to either replace or supplement the EPA/GRI study data, and many of these are described in the technical support document. The EPA evaluated these other studies and found that the leaker emission factors determined from these data sets agreed reasonably well with the leaker emission factors developed from the EPA/GRI data set, suggesting that the EPA/GRI leaker emission factors are still valid. Commenters that supported a different basis for the leaker emission factors than the EPA/GRI data set did not provide specific information explaining why another study would be a better basis or address any of the specific considerations listed above, although the comments received suggest that stakeholders are interested in further involvement in the assessment of the available data. Therefore, for the reasons stated in the preamble to the proposed rule and the document ''Greenhouse Gas Reporting Rule: Technical Support for Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems Final Rule'' in Docket ID No. EPA–HQ–OAR–2015–0764, the EPA is finalizing the leaker emission factors as proposed.

The EPA appreciates the commenters' interest in providing a thorough review of the available study data to develop an accurate set of leaker emission factors. The EPA is committed to working with stakeholders to ensure that GHGRP requirements and calculation methods are based upon the most robust data available. If the EPA determines that revisions to the subpart W leaker emission factors are appropriate in the future based on additional information, we anticipate that we will propose to amend the rule accordingly.

Comment: Numerous commenters stated that reporters should be allowed to use site-specific leak quantification data if available, either directly for each individual leak (*i.e.,* direct measurement data) or to develop their own leaker emission factors on a facility-specific, company-specific, or product-specific basis. Most of these commenters supported the EPA's proposal to include default leaker emission factors, but stated that reporters should not be limited to using them if the facility has more accurate, site-specific information. Some commenters further noted that the site-specific data reported to the GHGRP could be used to improve the default leaker emission factors in the future. One commenter also requested that the EPA require quantification of any leak that a reporter elects not to repair.

Response: The EPA did not propose and, after review and consideration of comments, is not finalizing provisions allowing reporters to use site-specific information to calculate equipment leak emissions for subpart W. While we agree that direct measurement has the potential to provide more accurate emissions data than using emission factors, we would need to develop criteria and guidelines for using direct measurement data consistently across subpart W reporters for calculating equipment leak emissions. Similarly, we agree that using site-specific emission factors can provide more accurate emissions data than using default emission factors, but a robust set of requirements would be needed for reporters to use when developing their own emission factors to ensure that those factors are as unbiased and representative as possible. In addition, if reporters are using direct measurement or their own emission factors, we would most likely need to amend the reporting requirements (*e.g.*, to require reporters to provide site-specific emission factors), and we would need to consider whether any other amendments would be needed to enable us to review and verify reported data. In either of these cases, we would provide the opportunity for the public to comment on those amended requirements before finalizing them within subpart W.

F. Summary of Final Amendments to Reporting Requirements

1. Summary of Final Amendments

The EPA is finalizing largely as proposed the new reporting requirements for facilities conducting equipment leak surveys under subpart W. Reporters in the Onshore Petroleum and Natural Gas Production and the Onshore Petroleum and Natural Gas Gathering and Boosting industry segments, reporters with storage wellheads in the Underground Natural Gas Storage industry segment, and reporters with components in gas service in the LNG Storage and LNG Import and Export Equipment industry segments that begin using the calculation methodology based on equipment leak surveys must report the information currently listed in 40 CFR 98.236(q)(1) and (2), which includes the number of equipment leak surveys, component types, number of leaking components, average time the components were assumed to be leaking, and annual CO_2 and CH_4 emissions. Facilities that conduct surveys using the new monitoring methods in 40 CFR 98.234(a)(6) or (7) must also report the data elements in 40 CFR 98.236(q)(2) for additional component types specified in 40 CFR 98.232. Reporters may elect to report the data elements in 40 CFR 98.236(q)(2) for the additional component types if they conduct surveys using a monitoring method in 40 CFR 98.234(a)(1) through (5).

The data elements in 40 CFR 98.236(q)(1) and (2) are already required to be reported by facilities conducting equipment leak surveys in the Onshore Natural Gas Transmission Compression, Underground Natural Gas Storage (storage stations), and LNG Storage and LNG Import and Export Equipment (components in LNG service) industry segments. However, facilities in those segments conducting equipment leak surveys using the new OGI method or Method 21, as specified in the NSPS subpart OOOOa (finalized in subpart W as 40 CFR 98.234(a)(6) or (7)), must begin reporting the data elements in 40 CFR 98.236(q)(2) for component types with the new leaker emission factors, including component types that are not currently subject to reporting. Facilities conducting equipment leak surveys using a monitoring method in 40 CFR

98.234(a)(1) through (5) may elect to begin reporting the data elements in 40 CFR 98.236(q)(2) for other components that are not currently subject to reporting.

In addition, the EPA is finalizing as proposed three new reporting requirements for facilities conducting equipment leak surveys in all of the above segments as well as the Onshore Natural Gas Processing and Natural Gas Distribution segments. First, facilities in those segments will be required to report the monitoring method(s) in 40 CFR 98.234(a) used to conduct the survey(s). Second, facilities in the above segments except for Onshore Natural Gas Processing and Natural Gas Distribution will be required to indicate whether any of their component types are subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions requirements. Finally, facilities with components for which the calculation methodology based on equipment leak surveys is optional (*e.g.,* facilities in the Onshore Petroleum and Natural Gas Production segment) will be required to indicate whether they elected to use the calculation methodology based on equipment leak surveys for any of their component types at the facility.

Additionally, in reviewing specific reporting requirements while responding to public comments, we recognized that the reporting requirements at 40 CFR 98.236(r)(3)(ii) were unclear, and could be misinterpreted with respect to how this reporting element relates to the calculated emissions. Therefore, we are revising 40 CFR 98.236(r)(3)(ii) by adding the phrase ''. . . for which equipment leak emissions are calculated using the methodology in § 98.233(r)'' to clarify our original intent that the major equipment counts reported under this requirement are specific to equipment for which emissions are calculated using the population count methodology.

2. Summary of Comments and Responses

Comment: Two commenters addressed the proposed requirement in 40 CFR 98.236(q)(1)(iii) to indicate whether any component types at a facility are subject to the NSPS subpart OOOOa. One commenter opposed the addition, stating that it is overly burdensome to require reporters to delineate reporting of emission sources subject to the NSPS subpart OOOOa, especially if this is intended to be a numeric response regarding the number of individual components subject to the NSPS subpart OOOOa. Another commenter asserted that it is not clear if the response to proposed 40 CFR 98.236(q)(1)(iii) is a single yes or no for each facility or if the EPA will be expecting a yes or no response for each component type.

Response: In the final rule, the EPA has revised the proposed requirement in 40 CFR 98.236(q)(1)(iii) (indicate whether any component types are subject to the NSPS subpart OOOOa) to be clear that the EPA expects only one yes or no response for an entire facility. While the EPA understands that the number of leaking components and equipment leak emissions may increase as the number of components subject to the NSPS subpart OOOOa increases, this response will allow the EPA to provide transparent data related to changes in emissions for facilities with components subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions requirements over time. This data element will also support verification that the appropriate GHGRP monitoring method was used by the facility.

III. Confidentiality Determinations

A. Summary of Final Confidentiality Determinations for New Subpart W Data Elements

As noted in the proposed rule, we are applying the same approach as previously used for making confidentiality determinations for data elements reported under the GHGRP. In the ''Confidentiality Determinations for Data Required Under the Mandatory Greenhouse Gas Reporting Rule and Amendments to Special Rules Governing Certain Information Obtained Under the Clean Air Act'' (hereafter referred to as ''2011 Final CBI Rulemaking'') (76 FR 30782, May 26, 2011), the EPA grouped part 98 data elements for which EPA was determining confidentiality status through that rulemaking into 22 data categories (11 direct emitter data categories and 11 supplier data categories) with each of the 22 data categories containing data elements that are similar in type or characteristics. The EPA then made categorical confidentiality determinations for eight direct emitter data categories and eight supplier data categories and applied the categorical confidentiality determination to all data elements assigned to the category. Of these data categories with categorical determinations, the EPA determined that four direct emitter data categories are comprised of those data elements that meet the definition of ''emission data,'' as defined at 40 CFR 2.301(a), and are, therefore, not entitled to confidential treatment under section 114(c) of the CAA.[24] The EPA determined that the other four direct emitter data categories and the eight supplier data categories do not meet the definition of ''emission data.'' For these data categories that are determined not to be emission data, the EPA determined categorically that data in three direct emitter data categories and five supplier data categories are eligible for confidential treatment as CBI, and that the data in one direct emitter data category and three supplier data categories are ineligible for confidential treatment as CBI. For two direct emitter data categories, ''Unit/Process 'Static' Characteristics that Are Not Inputs to Emission Equations'' and ''Unit/Process Operating Characteristics that Are Not Inputs to Emission Equations,'' and three supplier data categories, ''GHGs Reported,'' ''Production/Throughput Quantities and Composition,'' and ''Unit/Process Operating Characteristics,'' the EPA determined in the 2011 Final CBI Rulemaking that the data elements assigned to those categories are not emission data, but the EPA did not make categorical CBI determinations for them. Rather, the EPA made CBI determinations for each individual data element included in those categories on a case-by-case basis taking into consideration the criteria in 40 CFR 2.208. The EPA did not make a final confidentiality determination for data elements assigned to the inputs to emission equation data category (a direct emitter data category) in the 2011 Final CBI Rulemaking. However, the EPA has since proposed and finalized an approach for addressing disclosure concerns associated with inputs to emissions equations.[25]

In the proposed rule, we assigned the nine proposed new or substantially revised data elements to the appropriate direct emitter data categories created in the 2011 Final CBI Rulemaking based on the type and characteristics of each data element. For the seven data elements the EPA assigned to a direct emitter category with a categorical determination, the EPA proposed that the categorical determination for the category be applied to the proposed new or substantially revised data elements,

[24] Direct emitter data categories that meet the definition of ''emission data'' in 40 CFR 2.301(a) are ''Facility and Unit Identifier Information,'' ''Emissions,'' ''Calculation Methodology and Methodological Tier,'' and ''Data Elements Reported for Periods of Missing Data that are not Inputs to Emission Equations.''

[25] Revisions to Reporting and Recordkeeping Requirements, and Confidentiality Determinations Under the Greenhouse Gas Reporting Program; Final Rule. (79 FR 63750, October 24, 2014).

as shown in Table 4 of this preamble. For the two data elements assigned to the ''Unit/Process Operating Characteristics that Are Not Inputs to Emission Equations,'' we proposed confidentiality determinations on a case-by-case basis taking into consideration the criteria in 40 CFR 2.208, consistent with the approach used for data elements previously assigned to these two data categories, as shown in Table 5 of this preamble. Refer to the preamble to the proposed rule (81 FR 4987; January 29, 2016) for additional information regarding the proposed confidentiality determinations.

With consideration of the information provided by commenters, the EPA is finalizing the confidentiality determinations as proposed. Specifically, the EPA is finalizing the proposed determination for each of the nine new or substantially revised data elements to be designated as ''emission data'' or ''not CBI.''

TABLE 4—FINAL DATA CATEGORY ASSIGNMENTS AND CONFIDENTIALITY DETERMINATIONS FOR NEW DATA ELEMENTS ASSIGNED TO CATEGORIES WITH CATEGORICAL DETERMINATIONS

Citation	Data element	Final category assignment	Categorical determination (as established in 2011)[26]
§ 98.236(q)(1)(i)	The number of complete equipment leak surveys performed during the calendar year.	Test and Calibration Methods.	Not Emission Data and Not CBI.
§ 98.236(q)(1)(iii)	Whether any component types were subject to 40 CFR part 60, subpart OOOOa.	Facility and Unit Identifier Information.	Emission Data.
§ 98.236(q)(1)(iv)	Whether you elected to comply with § 98.233(q) per § 98.233(q)(1)(iii).	Facility and Unit Identifier Information.	Emission Data.
§ 98.236(q)(1)(v)	Each type of method described in § 98.234(a) that was used to conduct leak surveys.	Test and Calibration Methods.	Not Emission Data and Not CBI.
§ 98.236(q)(2)(i)	For each component type that is located at your facility, component type.	Facility and Unit Identifier Information.	Emission Data.
§ 98.236(q)(2)(iv)	For each component type that is located at your facility, annual CO_2 emissions, in metric tons CO_2.	Emissions	Emission Data.
§ 98.236(q)(2)(v)	For each component type that is located at your facility, annual CH_4 emissions, in metric tons CH_4.	Emissions	Emission Data.

TABLE 5—FINAL CONFIDENTIALITY FOR DATA ELEMENTS ASSIGNED TO THE ''UNIT/PROCESS OPERATING CHARACTERISTICS THAT ARE NOT INPUTS TO EMISSION EQUATIONS'' DATA CATEGORY

Citation	Data element	Final confidentiality determination and rationale
§ 98.236(q)(2)(ii)	For each component type that is located at your facility, total number of the surveyed component type that were identified as leaking in the calendar year (''x_p'' in Equation W–30).	Not Emission Data (Categorical Determination as Established in 2011). Not CBI. The term ''equipment leaks'' refers to those emissions which could not reasonably pass through a stack, chimney, vent, or other functionally-equivalent opening. Leaking components at a facility may have a correlation to the level of maintenance at a facility. However, there is no direct correlation between the level of maintenance and process efficiency, *i.e.,* a higher number of leaks in one facility do not indicate that the processes have been running longer or more frequently than those processes at another facility that has a lower number of leaks. Furthermore, Department of Transportation (DOT) regulations require natural gas distribution companies and transmission pipeline companies to conduct periodic leak detection and fix any leaking equipment. The number of leaks detected and fixed is reported to the DOT and is publicly available. Finally, 40 CFR part 60, subpart OOOOa requires reporting for each component with visible emissions at affected well sites and compressor station sites. The EPA is finalizing that this data element is not confidential; and that it will be considered ''not CBI.''
§ 98.236(q)(2)(iii)	For each component type that is located at your facility, average time the surveyed components are assumed to be leaking and operational, in hours (average of ''T_p,z'' from Equation W–30).	Not Emission Data (Categorical Determination as Established in 2011). Not CBI. This data element will provide information on the amount of time operational components were found to be leaking. This information provides little insight into maintenance practices at a facility because it does not identify the cause of the leaks or the nature and cost of repairs. Therefore, this information would not be likely to cause substantial competitive harm to reporters. For this reason, we are finalizing the average time operational components were found leaking be designated as ''not CBI.''

B. Summary of Comments and Responses

This section summarizes the major comments and responses related to the proposed categorical assignments and confidentiality determinations. See ''Response to Public Comments on Greenhouse Gas Reporting Rule: Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' in Docket ID No. EPA–HQ–OAR–2015–

[26] The categorical confidentiality determinations for the data categories listed in this table were finalized on May 26, 2011 (see 76 FR 30782).

0764 for a complete listing of all comments and responses. See the memorandum ''Final Data Category Assignments and Confidentiality Determinations for Data Elements in the 'Greenhouse Gas Reporting Rule: Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems; Final Rule' '' in Docket ID No. EPA–HQ–OAR–2015–0764 for a complete listing of final data category assignments and confidentiality determinations.

Comment: One commenter stated that the EPA should reconsider the proposed determination of ''not CBI'' for the number of components identified as leaking in a calendar year and the average time the surveyed components are assumed to be leaking. The commenter asserted that designating this information as CBI would encourage more reporters to voluntarily conduct leak surveys. The commenter also noted that this information is publically available for some sources and suggested that the rule provide an exception from classification as CBI for components subject to State programs or NSPS that already require public disclosure. Another commenter requested that the EPA protect the community's right to know and not allow companies to keep the public from finding out about leaks from hydrocarbon facilities.

Response: While it is possible that the requirement to report the number of leaking components and the average time those components were leaking could discourage some reporters from conducting voluntary equipment leak surveys, this is not a valid reason to allow reporters to claim these data elements as confidential. As noted in section III.C of the preamble to the proposed rule, the EPA proposed that disclosure of these data elements is unlikely to cause substantial harm to a business's competitive position, and the commenter did not indicate that the EPA's determination was incorrect. Therefore, the EPA is finalizing the confidentiality determinations for these data elements as ''not CBI.''

IV. Impacts of the Final Amendments to Subpart W

A. Impacts of the Final Amendments

The final amendments to subpart W revise costs associated with the use of the monitoring methods and the calculation methodology based on equipment leak surveys for reporters in the following industry segments: Onshore Petroleum and Natural Gas Production, Onshore Petroleum and Natural Gas Gathering and Boosting, Onshore Natural Gas Transmission Compression, Underground Natural Gas Storage, LNG Storage, and LNG Import and Export Equipment. Reporters in these industry segments are required to use the results of fugitive emissions component monitoring required for well sites and compressor stations under the NSPS subpart OOOOa. Reporters in these segments with components not subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions requirements and for which they are currently required to use the calculation methodology based on population counts under subpart W may voluntarily use the calculation methodology based on equipment leak surveys for those components if the equipment leak survey is conducted following a monitoring method listed in subpart W.

The EPA received comments from one commenter regarding the specific impacts of the proposed amendments. After evaluating these comments and reviewing other changes from proposal, the EPA revised the impacts assessment from proposal. The EPA estimates that the costs of the final amendments to subpart W are slightly more burdensome than we estimated at proposal, but they do not significantly change the overall burden to subpart W reporters. The EPA estimated that the additional costs to subpart W reporters in the Onshore Petroleum and Natural Gas Production and the Onshore Petroleum and Natural Gas Gathering and Boosting industry segments to transition their existing equipment leak recordkeeping, calculating, and reporting systems to use the calculation methodology based on equipment leak surveys and to determine which components are subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions requirements and which are not, will be approximately $110,000 per year, or about $410 per reporter. The EPA estimated that the additional costs for subpart W reporters in the other industry segments (*i.e.,* Onshore Natural Gas Transmission Compression, Underground Natural Gas Storage, Liquefied Natural Gas (LNG) Storage, and LNG Import and Export Equipment) to add a few new emission factors to their existing systems (rather than transitioning their recordkeeping, calculating, and reporting systems) and to determine which components are covered by the NSPS subpart OOOOa well site or compressor station fugitive emissions requirements and which are not, will be approximately $20,000 per year or about $110 per reporter. The total costs are approximately $128,400 per year for all reporters, or about $286 per reporter. See the memorandum, ''Assessment of Impacts of the Final Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' in Docket ID No. EPA–HQ–OAR–2015–0764 for additional information.

B. Summary of Comments and Responses

This section summarizes the major comments and responses related to the impacts of the proposed amendments to subpart W of part 98. We note that while several commenters asserted that the proposed rule would be burdensome for many operators and suggested revisions to the rule requirements that would reduce the burden, only one commenter provided comments on the EPA's impacts estimate and supporting statement, and that commenter's major comments are summarized in this section. See ''Response to Public Comments on Greenhouse Gas Reporting Rule: Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' in Docket ID No. EPA–HQ–OAR–2015–0764 for a complete listing of all comments and responses.

Comment: One commenter stated that the EPA's estimate of two hours of labor and $198 per reporter significantly underestimates and misrepresents the amount of time and effort that goes into implementing a new rule. The commenter provided a cost estimate that assumes more labor hours than in the EPA's memorandum ''Assessment of Impacts of the Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' (Docket Item No. EPA–HQ–OAR–2015–0764–0025). The commenter noted that as more sites become subject to the NSPS subpart OOOOa at a facility, the costs of managing the data and processing it into a usable format for the GHGRP will increase each year for that reporter. The commenter also noted that the EPA was incorrect in assuming that there would be no costs for facilities in the Onshore Natural Gas Processing segment.

Response: The EPA has evaluated the comments and has made changes to the estimate of burden in the supporting statement. The following paragraphs address each of the points in the commenter's detailed cost estimate included with the comment letter and explain how the points are being addressed in the final burden and cost estimate.

The commenter suggested adding burden of two hours in the first year related to the initial monitoring plan development and burden of 0.5 hours in subsequent years related to yearly monitoring plan revisions. The EPA did not include costs at proposal related to the monitoring plan because the subpart W amendments do not require the development of a separate monitoring plan. Instead, the subpart W amendments cross reference the monitoring plan that is already being developed according to the NSPS subpart OOOOa. The EPA recognizes that reporters that are not subject to the NSPS subpart OOOOa would not already be required to develop a monitoring plan under the NSPS subpart OOOOa; however, reporters that elect to use one of the new leak detection methods are also electing to incur the burden of developing a monitoring plan. Therefore, there is no monitoring plan burden associated with the subpart W amendments and the final burden and cost estimate has not changed from proposal as a result of this comment.

The commenter suggested changing the number of hours to revise the reporting system to five hours and to allow one hour for maintenance in each subsequent year. At proposal, the EPA estimated that revising the reporting system to use the calculation methodology based on equipment leak surveys would require two hours. The commenter did not provide the basis for their estimate of five hours to update the data management system. The overall reporting costs for compliance already include a burden of ten hours per year and the EPA disagrees that updating the data management system would encompass half of that allotment because EPA anticipates that reporters would only need to add a few emission factors for leaking components to their existing system, rather than something more time-intensive such as creating a new data management system. We reviewed the revisions expected to be needed in the data management system. While we maintain that two hours are sufficient to implement the calculation methodology based on equipment leak surveys into a reporter's existing system, we recognize that this process will also require quality assurance reviews and testing to ensure the data are stored properly and the calculations are performed correctly. Therefore, we increased the number of hours estimated to revise the reporting system from two hours to 3.5 hours to account for these additional quality reviews of the data management system. However, the EPA has made no changes to burden associated with maintenance of the revised reporting system because the EPA asserts that any reporting system maintenance related to subpart W is already reflected in the twenty hours per year allotted to each subpart W reporter for recordkeeping and reporting activities.

The commenter suggested that the EPA adjust the proposed burden and cost estimate by adding the following activities and burden estimates: (1) Time for staff to process the survey data resulting from the calculation methodology based on equipment leak surveys and to enter it into the GHGRP system at a burden of three hours per year; (2) time for staff training at a burden of two hours for initial training and one hour per year in subsequent years; and (3) time for staff to review the data for quality assurance, follow missing data requirements, report data to the EPA, and retain all records at a burden of four total hours per year.

At proposal, the EPA did not include burden related to these activities because they are covered by the twenty hours per year already accounted for in the overall subpart W reporter burden for recordkeeping and reporting activities. Therefore, the final burden and cost estimate has not changed from proposal as a result of these comments.

However, at proposal, the EPA did not account for the time associated with determining which components in the reporting system are covered by the NSPS subpart OOOOa well site or compressor station fugitive emissions requirements and which are not. As a result, the EPA has added 0.5 hours per reporter in the first year that the reporter has an affected collection of fugitive emissions components subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions requirements and 0.1 hours per reporter in subsequent years.

Finally, for the reasons described in section II.B.2 of this preamble, the final rule language specifies that the requirement to use the NSPS subpart OOOOa results as part of the calculation methodology based on equipment leak surveys only applies to components subject to the NSPS subpart OOOOa well site or compressor station fugitive emissions requirements. The subpart W equipment leak survey requirements for facilities in the Onshore Natural Gas Processing segment do not change as a result of these amendments. Therefore, the EPA is not including any burden estimate for Onshore Natural Gas Processing reporters (i.e., the revisions to the burden estimate described in this response do not apply to the Onshore Natural Gas Processing segment).

Overall, the burden and cost estimate has been revised as discussed above from 502 hours and $50,000 per year at proposal to approximately 1,295 hours and $128,400 per year for all reporters.

V. Statutory and Executive Order Reviews

Additional information about these statutes and Executive Orders can be found at *http://www2.epa.gov/laws-and-executive orders.*

A. Executive Order 12866: Regulatory Planning and Review and Executive Order 13563: Improving Regulation and Regulatory Review

This action is not a significant regulatory action and was therefore not submitted to the Office of Management and Budget (OMB) for review.

B. Paperwork Reduction Act (PRA)

The information collection activities in this rule have been submitted for approval to the OMB under the PRA. The Information Collection Request (ICR) document that the EPA prepared has been assigned EPA ICR number 2300.19. You can find a copy of the ICR in the docket for this rule, and it is briefly summarized here. The information collection requirements are not enforceable until OMB approves them.

This action increases burden for industry segments that conduct equipment leak surveys. These revisions are expected to increase respondent burden for subpart W reporters that become subject to the NSPS subpart OOOOa well site or compressor station fugitive requirements. To accommodate the new methods and emission factors added by these final amendments, the EPA expects that each affected subpart W reporter will either revise their reporter-specific calculation mechanism (i.e., calculation spreadsheet, recordkeeping database, etc.) or add a few new emission factors to the reporter-specific calculation mechanism, when and if the reporter becomes subject to the NSPS subpart OOOOa well site or compressor station fugitive requirements. The recordkeeping and reporting requirements are being finalized as proposed. Impacts associated with the final revisions to the recordkeeping and reporting requirements are detailed in the memorandum ''Assessment of Impacts of the Final Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems''

(see Docket ID No. EPA–HQ–OAR–2015–0764).

Data collection provides a critical tool for communities to identify nearby sources of GHGs and provides information to state and local governments. The data can be used to complement atmospheric GHG studies and inform updates to emission inventories such as the *Inventory of U.S. Greenhouse Gas Emissions and Sinks* (Inventory). Various activity data are collected that can be used to improve understanding of the occurrence of emissions from a variety of sources.

Data collected must be made available to the public unless the data qualify for CBI treatment under the CAA and EPA regulations. All data determined by the EPA to be CBI are safeguarded in accordance with regulations in 40 CFR chapter 1, part 2, subpart B.

Respondents/affected entities: The respondents in this information collection include owners and operators of petroleum and natural gas systems facilities that report their GHG emissions from equipment leaks to the EPA to comply with subpart W.

Respondent's obligation to respond: The respondent's obligation to respond is mandatory under the authority provided in CAA section 114.

Estimated number of respondents: Approximately 899 respondents per year.

Frequency of response: Annual.

Total estimated burden: 1,295 hours (per year). Burden is defined at 5 CFR 1320.3(b).

Total estimated cost: $128,400 (per year), includes $0 annualized capital or operation and maintenance costs.

An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information unless it displays a currently valid OMB control number. The OMB control numbers for the EPA's regulations in 40 CFR are listed in 40 CFR part 9. When OMB approves this ICR, the EPA will announce that approval in the **Federal Register** and publish a technical amendment to 40 CFR part 9 to display the OMB control number for the approved information collection activities contained in this final rule.

C. Regulatory Flexibility Act (RFA)

I certify that this action will not have a significant economic impact on a substantial number of small entities under the RFA. The small entities directly regulated by this final rule include small businesses in the petroleum and natural gas industry. The EPA has determined that some small businesses will be affected because their production processes emit GHGs exceeding the reporting threshold. This action includes amendments that may result in a small burden increase on some subpart W reporters, but the EPA has determined that the increased cost of less than $286 per reporter is not a significant impact. Details of this analysis are presented in ''Assessment of Impacts of the Final Leak Detection Methodology Revisions and Confidentiality Determinations for Petroleum and Natural Gas Systems'' in Docket ID No. EPA–HQ–OAR–2015–0764.

D. Unfunded Mandates Reform Act (UMRA)

This action does not contain an unfunded mandate of $100 million or more as described in UMRA, 2 U.S.C. 1531–1538, and does not significantly or uniquely affect small governments. As shown in sections IV.A and V.B of this preamble, the annual cost of this action is $128,400, which is well under $100 million per year.

E. Executive Order 13132: Federalism

This action does not have federalism implications. It will not have substantial direct effects on the states, on the relationship between the national government and the states, or on the distribution of power and responsibilities among the various levels of government.

F. Executive Order 13175: Consultation and Coordination With Indian Tribal Governments

This action has tribal implications. However, it will neither impose substantial direct compliance costs on federally recognized tribal governments, nor preempt tribal law. This regulation will apply directly to petroleum and natural gas facilities that emit GHGs. Although few facilities that will be subject to the rule are likely to be owned by tribal governments, the EPA sought opportunities to provide information to tribal governments and representatives during the development of the proposed and final subpart W that was promulgated on November 30, 2010 (75 FR 74458).

The EPA consulted with tribal officials under the EPA Policy on Consultation and Coordination with Indian Tribes early in the process of developing this regulation to permit them to have meaningful and timely input into its development. A summary of that consultation is provided in section IV.F of the preamble to the re-proposal of subpart W published on April 12, 2010 (75 FR 18608), and section IV.F of the preamble to the subpart W 2010 final rule published on November 30, 2010 (75 FR 74458).

G. Executive Order 13045: Protection of Children From Environmental Health Risks and Safety Risks

The EPA interprets Executive Order 13045 as applying only to those regulatory actions that concern environmental health or safety risks that the EPA has reason to believe may disproportionately affect children, per the definition of ''covered regulatory action'' in section 2–202 of the Executive Order. This action is not subject to Executive Order 13045 because it does not concern an environmental health risk or safety risk.

H. Executive Order 13211: Actions That Significantly Affect Energy Supply, Distribution, or Use

This action is not subject to Executive Order 13211, because it is not a significant regulatory action under Executive Order 12866.

I. National Technology Transfer and Advancement Act (NTTAA)

This rulemaking does not involve technical standards.

J. Executive Order 12898: Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations

The EPA believes that this action is not subject to Executive Order 12898 (59 FR 7629, February 16, 1994) because it does not establish an environmental health or safety standard. Instead, this rule addresses information collection and reporting and verification procedures.

K. Congressional Review Act (CRA)

This action is subject to the CRA, and the EPA will submit a rule report to each House of the Congress and to the Comptroller General of the United States. This action is not a ''major rule'' as defined by 5 U.S.C. 804(2).

List of Subjects in 40 CFR Part 98

Environmental protection, Administrative practice and procedure, Greenhouse gases, Reporting and recordkeeping requirements.

Dated: November 10, 2016.

Gina McCarthy,

Administrator.

For the reasons stated in the preamble, title 40, chapter I, of the Code of Federal Regulations is amended as follows:

PART 98—MANDATORY GREENHOUSE GAS REPORTING

■ 1. The authority citation for part 98 continues to read as follows:

Authority: 42 U.S.C. 7401–7671q.

Subpart W—Petroleum and Natural Gas Systems

■ 2. Section 98.232 is amended by:
■ a. Revising paragraph (c)(21);
■ b. Adding paragraph (e)(8);
■ c. Revising paragraph (f)(5);
■ d. Adding paragraphs (f)(6) through (8);
■ e. Revising paragraphs (g)(3) and (4);
■ f. Adding paragraphs (g)(5) through (7);
■ g. Revising paragraphs (h)(4) and (5);
■ h. Adding paragraphs (h)(6) through (8); and
■ i. Revising paragraph (j)(10).

The revisions and additions read as follows:

§ 98.232 GHGs to report.

* * * * *

(c) * * *

(21) Equipment leaks from valves, connectors, open ended lines, pressure relief valves, pumps, flanges, and other components (such as instruments, loading arms, stuffing boxes, compressor seals, dump lever arms, and breather caps, but does not include components listed in paragraph (c)(11) or (19) of this section, and it does not include thief hatches or other openings on a storage vessel).

* * * * *

(e) * * *

(8) Equipment leaks from all other components that are not listed in paragraph (e)(1), (2), or (7) of this section and are either subject to the well site or compressor station fugitive emissions standards in § 60.5397a of this chapter or you elect to survey using a leak detection method described in § 98.234(a)(6) or (7). The other components subject to this paragraph (e)(8) also do not include thief hatches or other openings on a storage vessel. If these other components are not subject to the well site or compressor station fugitive emissions standards in § 60.5397a of this chapter, you may also elect to report emissions from these other components if you elect to survey them using a leak detection method described in § 98.234(a)(1) through (5).

(f) * * *

(5) Equipment leaks from valves, connectors, open ended lines, pressure relief valves, and meters associated with storage stations.

(6) Equipment leaks from all other components that are associated with storage stations, are not listed in paragraph (f)(1), (2), or (5) of this section, and are either subject to the well site or compressor station fugitive emissions standards in § 60.5397a of this chapter or you elect to survey using a leak detection method described in § 98.234(a)(6) or (7). If these other components are not subject to the well site or compressor station fugitive emissions standards in § 60.5397a of this chapter, you may also elect to report emissions from these other components if you elect to survey them using a leak detection method described in § 98.234(a)(1) through (5).

(7) Equipment leaks from valves, connectors, open-ended lines, and pressure relief valves associated with storage wellheads.

(8) Equipment leaks from all other components that are associated with storage wellheads, are not listed in paragraph (f)(1), (2), or (7) of this section, and are either subject to the well site or compressor station fugitive emissions standards in § 60.5397a, of this chapter or you elect to survey using a leak detection method described in § 98.234(a)(6) or (7). If these other components are not subject to the well site or compressor station fugitive emissions standards in § 60.5397a of this chapter, you may also elect to report emissions from these other components if you elect to survey them using a leak detection method described in § 98.234(a)(1) through (5).

(g) * * *

(3) Flare stack emissions.

(4) Equipment leaks from valves, pump seals, connectors, and other equipment leak sources in LNG service.

(5) Equipment leaks from vapor recovery compressors, if you do not survey components associated with vapor recovery compressors in accordance with paragraph (g)(6) of this section.

(6) Equipment leaks from all components in gas service that are associated with a vapor recovery compressor, are not listed in paragraph (g)(1) or (2) of this section, and that are either subject to the well site or compressor station fugitive emissions standards in § 60.5397a of this chapter or you elect to survey using a leak detection method described in § 98.234(a).

(7) Equipment leaks from all components in gas service that are not associated with a vapor recovery compressor, are not listed in paragraph (g)(1) or (2) of this section, and are either subject to the well site or compressor station fugitive emissions standards in § 60.5397a of this chapter or you elect to survey using a leak detection method described in § 98.234(a)(6) or (7). If these components are not subject to the well site or compressor station fugitive emissions standards in § 60.5397a of this chapter, you may also elect to report emissions from these components if you elect to survey them using a leak detection method described in § 98.234(a)(1) through (5).

(h) * * *

(4) Flare stack emissions.

(5) Equipment leaks from valves, pump seals, connectors, and other equipment leak sources in LNG service.

(6) Equipment leaks from vapor recovery compressors, if you do not survey components associated with vapor recovery compressors in accordance with paragraph (h)(7) of this section.

(7) Equipment leaks from all components in gas service that are associated with a vapor recovery compressor, are not listed in paragraph (h)(1) or (2) of this section, and that are either subject to the well site or compressor station fugitive emissions standards in § 60.5397a of this chapter or you elect to survey using a leak detection method described in § 98.234(a).

(8) Equipment leaks from all components in gas service that are not associated with a vapor recovery compressor, are not listed in paragraph (h)(1) or (2) of this section, and that are either subject to the well site or compressor station fugitive emissions standards in § 60.5397a of this chapter or you elect to survey using a leak detection method described in § 98.234(a)(6) or (7). If these components are not subject to the well site or compressor station fugitive emissions standards in § 60.5397a of this chapter, you may also elect to report emissions from these components if you elect to survey them using a leak detection method described in § 98.234(a)(1) through (5).

* * * * *

(j) * * *

(10) Equipment leaks from valves, connectors, open ended lines, pressure relief valves, pumps, flanges, and other components (such as instruments, loading arms, stuffing boxes, compressor seals, dump lever arms, and breather caps, but does not include components in paragraph (j)(8) or (9) of this section, and it does not include thief hatches or other openings on a storage vessel).

* * * * *

■ 3. Section 98.233 is amended by:
■ a. Revising the parameter EF_t of Equation W–1 in paragraph (a) introductory text, and paragraph (q);

■ b. Removing the first two sentences of paragraph (r) introductory text and adding four sentences in their place; and

■ c. Revising the parameters $Count_e$ and $EF_{s,e}$ of Equation W–32A in paragraph (r) introductory text, and paragraphs (r)(3) through (5).

The revisions read as follows:

§ 98.233 Calculating GHG emissions.

* * * * *

(a) * * *

* * * * *

EF_t = Population emission factors for natural gas pneumatic device vents (in standard cubic feet per hour per device) of each type ''t'' listed in Tables W–1A, W–3B, and W–4B to this subpart for onshore petroleum and natural gas production, onshore natural gas transmission compression, and underground natural gas storage facilities, respectively. Onshore petroleum and natural gas gathering and boosting facilities must use the population emission factors listed in Table W–1A to this subpart.

* * * * *

(q) *Equipment leak surveys.* For the components identified in paragraphs (q)(1)(i) through (iii) of this section, you must conduct equipment leak surveys using the leak detection methods specified in paragraphs (q)(1)(i) through (iii) of this section. For the components identified in paragraph (q)(1)(iv) of this section, you may elect to conduct equipment leak surveys, and if you elect to conduct surveys, you must use a leak detection method specified in paragraph (q)(1)(iv) of this section. This paragraph (q) applies to components in streams with gas content greater than 10 percent CH_4 plus CO_2 by weight. Components in streams with gas content less than or equal to 10 percent CH_4 plus CO_2 by weight are exempt from the requirements of this paragraph (q) and do not need to be reported. Tubing systems equal to or less than one half inch diameter are exempt from the requirements of this paragraph (q) and do not need to be reported.

(1) *Survey requirements.* (i) For the components listed in § 98.232(e)(7), (f)(5), (g)(4), and (h)(5), that are not subject to the well site or compressor station fugitive emissions standards in § 60.5397a of this chapter, you must conduct surveys using any of the leak detection methods listed in § 98.234(a) and calculate equipment leak emissions using the procedures specified in paragraph (q)(2) of this section.

(ii) For the components listed in § 98.232(d)(7) and (i)(1), you must conduct surveys using any of the leak detection methods listed in § 98.234(a)(1) through (5) and calculate equipment leak emissions using the procedures specified in paragraph (q)(2) of this section.

(iii) For the components listed in § 98.232(c)(21), (e)(7), (e)(8), (f)(5), (f)(6), (f)(7), (f)(8), (g)(4), (g)(6), (g)(7), (h)(5), (h)(7), (h)(8), and (j)(10) that are subject to the well site or compressor station fugitive emissions standards in § 60.5397a of this chapter, you must conduct surveys using any of the leak detection methods in § 98.234(a)(6) or (7) and calculate equipment leak emissions using the procedures specified in paragraph (q)(2) of this section.

(iv) For the components listed in § 98.232(c)(21), (e)(8), (f)(6), (f)(7), (f)(8), (g)(6), (g)(7), (h)(7), (h)(8), or (j)(10), that are not subject to fugitive emissions standards in § 60.5397a of this chapter, you may elect to conduct surveys according to this paragraph (q), and, if you elect to do so, then you must use one of the leak detection methods in § 98.234(a).

(A) If you elect to use a leak detection method in § 98.234(a)(1) through (5) for the surveyed component types in § 98.232(c)(21), (f)(7), (g)(6), (h)(7), or (j)(10) in lieu of the population count methodology specified in paragraph (r) of this section, then you must calculate emissions for the surveyed component types in § 98.232(c)(21), (f)(7), (g)(6), (h)(7), or (j)(10) using the procedures in paragraph (q)(2) of this section.

(B) If you elect to use a leak detection method in § 98.234(a)(1) through (5) for the surveyed component types in § 98.232(e)(8), (f)(6), (f)(8), (g)(7), and (h)(8), then you must use the procedures in paragraph (q)(2) of this section to calculate those emissions.

(C) If you elect to use a leak detection method in § 98.234(a)(6) or (7) for any elective survey under this subparagraph (q)(1)(iv), then you must survey the component types in § 98.232(c)(21), (e)(8), (f)(6), (f)(7), (f)(8), (g)(6), (g)(7), (h)(7), (h)(8), and (j)(10) that are not subject to fugitive emissions standards in § 60.5397a of this chapter, and you must calculate emissions from the surveyed component types in § 98.232(c)(21), (e)(8), (f)(6), (f)(7), (f)(8), (g)(6), (g)(7), (h)(7), (h)(8), and (j)(10) using the emission calculation requirements in paragraph (q)(2) of this section.

(2) *Emission calculation methodology.* For industry segments listed in § 98.230(a)(2) through (9), if equipment leaks are detected during surveys required or elected for components listed in paragraphs (q)(1)(i) through (iv) of this section, then you must calculate equipment leak emissions per component type per reporting facility using Equation W–30 of this section and the requirements specified in paragraphs (q)(2)(i) through (xi) of this section. For the industry segment listed in § 98.230(a)(8), the results from Equation W–30 are used to calculate population emission factors on a meter/regulator run basis using Equation W–31 of this section. If you chose to conduct equipment leak surveys at all above grade transmission-distribution transfer stations over multiple years, ''n,'' according to paragraph (q)(2)(x)(A) of this section, then you must calculate the emissions from all above grade transmission-distribution transfer stations as specified in paragraph (q)(2)(xi) of this section.

$$E_{s,p,i} = GHG_i * EF_{s,p} * \sum_{z=1}^{x_p} T_{p,z} \qquad \text{(Eq. W-30)}$$

Where:

$E_{s,p,i}$ = Annual total volumetric emissions of GHGi from specific component type ''p'' (in accordance with paragraphs (q)(1)(i) through (iv) of this section) in standard (''s'') cubic feet, as specified in paragraphs (q)(2)(ii) through (x) of this section.

x_p = Total number of specific component type ''p'' detected as leaking in any leak survey during the year. A component found leaking in two or more surveys during the year is counted as one leaking component.

$EF_{s,p}$ = Leaker emission factor for specific component types listed in Tables W–1E, W–2, W–3A, W–4A, W–5A, W–6A, and W–7 to this subpart.

GHG_i = For onshore petroleum and natural gas production facilities and onshore petroleum and natural gas gathering and boosting facilities, concentration of GHG_i, CH_4, or CO_2, in produced natural gas as defined in paragraph (u)(2) of this section; for onshore natural gas processing facilities, concentration of GHG_i, CH_4 or CO_2, in the total hydrocarbon of the feed natural gas; for onshore natural gas transmission compression and underground natural

gas storage, GHG_i equals 0.975 for CH_4 and 1.1×10^{-2} for CO_2; for LNG storage and LNG import and export equipment, GHG_i equals 1 for CH_4 and 0 for CO_2; and for natural gas distribution, GHG_i equals 1 for CH_4 and 1.1×10^{-2} CO_2.

$T_{p,z}$ = The total time the surveyed component ''z,'' component type ''p,'' was assumed to be leaking and operational, in hours. If one leak detection survey is conducted in the calendar year, assume the component was leaking for the entire calendar year. If multiple leak detection surveys are conducted in the calendar year, assume a component found leaking in the first survey was leaking since the beginning of the year until the date of the survey; assume a component found leaking in the last survey of the year was leaking from the preceding survey through the end of the year; assume a component found leaking in a survey between the first and last surveys of the year was leaking since the preceding survey until the date of the survey; and sum times for all leaking periods. For each leaking component, account for time the component was not operational (*i.e.,* not operating under pressure) using an engineering estimate based on best available data.

(i) You must conduct at least one leak detection survey in a calendar year. The leak detection surveys selected must be conducted during the calendar year. If you conduct multiple complete leak detection surveys in a calendar year, you must use the results from each complete leak detection survey when calculating emissions using Equation W–30. For components subject to the well site and compressor station fugitive emissions standards in § 60.5397a of this chapter, each survey conducted in accordance with § 60.5397a of this chapter will be considered a complete leak detection survey for purposes of this section.

(ii) Calculate both CO_2 and CH_4 mass emissions using calculations in paragraph (v) of this section.

(iii) Onshore petroleum and natural gas production facilities must use the appropriate default whole gas leaker emission factors for components in gas service, light crude service, and heavy crude service listed in Table W–1E to this subpart.

(iv) Onshore petroleum and natural gas gathering and boosting facilities must use the appropriate default whole gas leaker factors for components in gas service listed in Table W–1E to this subpart.

(v) Onshore natural gas processing facilities must use the appropriate default total hydrocarbon leaker emission factors for compressor components in gas service and non-compressor components in gas service listed in Table W–2 to this subpart.

(vi) Onshore natural gas transmission compression facilities must use the appropriate default total hydrocarbon leaker emission factors for compressor components in gas service and non-compressor components in gas service listed in Table W–3A to this subpart.

(vii) Underground natural gas storage facilities must use the appropriate default total hydrocarbon leaker emission factors for storage stations or storage wellheads in gas service listed in Table W–4A to this subpart.

(viii) LNG storage facilities must use the appropriate default methane leaker emission factors for LNG storage components in LNG service or gas service listed in Table W–5A to this subpart.

(ix) LNG import and export facilities must use the appropriate default methane leaker emission factors for LNG terminals components in LNG service or gas service listed in Table W–6A to this subpart.

(x) Natural gas distribution facilities must use Equation W–30 of this section and the default methane leaker emission factors for transmission-distribution transfer station components in gas service listed in Table W–7 to this subpart to calculate component emissions from annual equipment leak surveys conducted at above grade transmission-distribution transfer stations. Natural gas distribution facilities are required to perform equipment leak surveys only at above grade stations that qualify as transmission-distribution transfer stations. Below grade transmission-distribution transfer stations and all metering-regulating stations that do not meet the definition of transmission-distribution transfer stations are not required to perform equipment leak surveys under this section.

(A) Natural gas distribution facilities may choose to conduct equipment leak surveys at all above grade transmission-distribution transfer stations over multiple years ''n,'' not exceeding a five year period to cover all above grade transmission-distribution transfer stations. If the facility chooses to use the multiple year option, then the number of transmission-distribution transfer stations that are monitored in each year should be approximately equal across all years in the cycle.

(B) Use Equation W–31 of this section to determine the meter/regulator run population emission factors for each GHG_i. As additional survey data become available, you must recalculate the meter/regulator run population emission factors for each GHG_i annually according to paragraph (q)(2)(x)(C) of this section.

$$EF_{s,MR,i} = \frac{\sum_{y=1}^{n}\sum_{p=1}^{7} E_{s,p,i,y}}{\sum_{y=1}^{n}\sum_{w=1}^{Count_{MR,y}} T_{w,y}} \qquad \text{(Eq. W-31)}$$

Where:

$EF_{s,MR,i}$ = Meter/regulator run population emission factor for GHG_i based on all surveyed above grade transmission-distribution transfer stations over ''n'' years, in standard cubic feet of GHG_i per operational hour of all meter/regulator runs.

$E_{s,p,i,y}$ = Annual total volumetric emissions at standard conditions of GHG_i from component type ''p'' during year ''y'' in standard (''s'') cubic feet, as calculated using Equation W–30 of this section.

p = Seven component types listed in Table W–7 to this subpart for transmission-distribution transfer stations.

$T_{w,y}$ = The total time the surveyed meter/regulator run ''w'' was operational, in hours during survey year ''y'' using an engineering estimate based on best available data.

$Count_{MR,y}$ = Count of meter/regulator runs surveyed at above grade transmission-distribution transfer stations in year ''y''.

y = Year of data included in emission factor ''$EF_{s,MR,i}$'' according to paragraph (q)(2)(x)(C) of this section.

n = Number of years of data, according to paragraph (q)(2)(x)(A) of this section, whose results are used to calculate emission factor ''$EF_{s,MR,i}$'' according to paragraph (q)(2)(x)(C) of this section.

(C) The emission factor ''$EFs_{,MR,i,}$'' based on annual equipment leak surveys at above grade transmission-distribution transfer stations, must be calculated

annually. If you chose to conduct equipment leak surveys at all above grade transmission-distribution transfer stations over multiple years, ''n,'' according to paragraph (q)(2)(x)(A) of this section and you have submitted a smaller number of annual reports than the duration of the selected cycle period of 5 years or less, then all available data from the current year and previous years must be used in the calculation of the emission factor ''$EF_{s,MR,i}$'' from Equation W–31 of this section. After the first survey cycle of ''n'' years is completed and beginning in calendar year (n+1), the survey will continue on a rolling basis by including the survey results from the current calendar year ''y'' and survey results from all previous $(n-1)$ calendar years, such that each annual calculation of the emission factor ''$EF_{s,MR,i}$'' from Equation W–31 is based on survey results from ''n'' years. Upon completion of a cycle, you may elect to change the number of years in the next cycle period (to be 5 years or less). If the number of years in the new cycle is greater than the number of years in the previous cycle, calculate ''$EF_{s,MR,i}$'' from Equation W–31 in each year of the new cycle using the survey results from the current calendar year and the survey results from the preceding number years that is equal to the number of years in the previous cycle period. If the number of years, ''n_{new},'' in the new cycle is smaller than the number of years in the previous cycle, ''n,'' calculate ''$EF_{s,MR,i}$'' from Equation W–31 in each year of the new cycle using the survey results from the current calendar year and survey results from all previous $(n_{new}-1)$ calendar years.

(xi) If you chose to conduct equipment leak surveys at all above grade transmission-distribution transfer stations over multiple years, ''n,'' according to paragraph (q)(2)(x)(A) of this section, you must use the meter/regulator run population emission factors calculated using Equation W–31 of this section and the total count of all meter/regulator runs at above grade transmission-distribution transfer stations to calculate emissions from all above grade transmission-distribution transfer stations using Equation W–32B in paragraph (r) of this section.

(r) * * * This paragraph (r) applies to emissions sources listed in § 98.232(c)(21), (f)(7), (g)(5), (h)(6), and (j)(10) if you are not required to comply with paragraph (q) of this section and if you do not elect to comply with paragraph (q) of this section for these components in lieu of this paragraph (r). This paragraph (r) also applies to emission sources listed in § 98.232(i)(2), (i)(3), (i)(4), (i)(5), (i)(6), and (j)(11). To be subject to the requirements of this paragraph (r), the listed emissions sources also must contact streams with gas content greater than 10 percent CH plus CO_2 by weight. Emissions sources that contact streams with gas content less than or equal to 10 percent CH_4 plus CO_2 by weight are exempt from the requirements of this paragraph (r) and do not need to be reported. * * *

* * * * *

$Count_e$ = Total number of the emission source type at the facility. For onshore petroleum and natural gas production facilities and onshore petroleum and natural gas gathering and boosting facilities, average component counts are provided by major equipment piece in Tables W–1B and Table W–1C to this subpart. Use average component counts as appropriate for operations in Eastern and Western U.S., according to Table W–1D to this subpart. Onshore petroleum and natural gas gathering and boosting facilities must also count the miles of gathering pipelines by material type (protected steel, unprotected steel, plastic, or cast iron). Underground natural gas storage facilities must count each component listed in Table W–4B to this subpart. LNG storage facilities must count the number of vapor recovery compressors. LNG import and export facilities must count the number of vapor recovery compressors. Natural gas distribution facilities must count: (1) The number of distribution services by material type; (2) miles of distribution mains by material type; and (3) number of below grade metering-regulating stations, by pressure type; as listed in Table W–7 to this subpart.

* * * * *

$EF_{s,e}$ = Population emission factor for the specific emission source type, as listed in Tables W–1A, W–4B, W–5B, W–6B, and W–7 to this subpart. Use appropriate population emission factor for operations in Eastern and Western U.S., according to Table W–1D to this subpart.

* * * * *

(3) Underground natural gas storage facilities must use the appropriate default total hydrocarbon population emission factors for storage wellheads in gas service listed in Table W–4B to this subpart.

(4) LNG storage facilities must use the appropriate default methane population emission factor for LNG storage compressors in gas service listed in Table W–5B to this subpart.

(5) LNG import and export facilities must use the appropriate default methane population emission factor for LNG terminal compressors in gas service listed in Table W–6B to this subpart.

* * * * *

■ 4. Section 98.234 is amended by:

■ a. Revising paragraph (a) introductory text, the paragraph (a)(1) heading, and the fourth sentence in paragraph (a)(2); and

■ b. Adding paragraphs (a)(6) and (7).

The revisions and additions read as follows:

* * * * *

§ 98.234 Monitoring and QA/QC requirements.

(a) You must use any of the methods described in paragraphs (a)(1) through (5) of this section to conduct leak detection(s) of through-valve leakage from all source types listed in § 98.233(k), (o), and (p) that occur during a calendar year. You must use any of the methods described in paragraphs (a)(1) through (7) of this section to conduct leak detection(s) of equipment leaks from components as specified in § 98.233(q)(1)(i) that occur during a calendar year. You must use any of the methods described in paragraphs (a)(1) through (5) of this section to conduct leak detection(s) of equipment leaks from components as specified in § 98.233(q)(1)(ii) that occur during a calendar year. You must use one of the methods described in paragraph (a)(6) or (7) of this section to conduct leak detection(s) of equipment leaks from components as specified in § 98.233(q)(1)(iii). If electing to comply with § 98.233(q) as specified in § 98.233(q)(1)(iv), you must use any of the methods described in paragraphs (a)(1) through (7) of this section to conduct leak detection(s) of equipment leaks from component types as specified in § 98.233(q)(1)(iv) that occur during a calendar year.

(1) Optical gas imaging instrument as specified in § 60.18 of this chapter. * * *

* * * * *

(2) * * * If the equipment leak detection methods in this paragraph cannot be used, you must use alternative leak detection devices as described in paragraph (a)(1) of this section to monitor inaccessible equipment leaks or vented emissions.

* * * * *

(6) Optical gas imaging instrument as specified in § 60.5397a of this chapter. Use an optical gas imaging instrument for equipment leak detection in accordance with § 60.5397a(b), (c)(3), (c)(7), and (e) of this chapter and paragraphs (a)(6)(i) through (iii) of this section. Unless using methods in paragraph (a)(7) of this section, an optical gas imaging instrument must be used for all source types that are inaccessible and cannot be monitored without elevating the monitoring

personnel more than 2 meters above a support surface.

(i) For the purposes of this subpart, any visible emissions from a component listed in § 98.232 observed by the optical gas imaging instrument is a leak.

(ii) For the purposes of this subpart, the term ''fugitive emissions component'' in § 60.5397a of this chapter means ''component.''

(iii) For the purpose of complying with § 98.233(q)(1)(iv), the phrase ''the collection of fugitive emissions components at well sites and compressor stations'' in § 60.5397a(b) of this chapter means ''the collection of components for which you elect to comply with § 98.233(q)(1)(iv).''

(7) Method 21 as specified in § 60.5397a of this chapter. Use the equipment leak detection methods in appendix A–7 to part 60 of this chapter, Method 21, in accordance with § 60.5397a(b), (c)(8), and (e) of this chapter and paragraphs (a)(7)(i) through (iii) of this section. Inaccessible emissions sources, as defined in part 60 of this chapter, are not exempt from this subpart. If the equipment leak detection methods in this paragraph cannot be used, you must use alternative leak detection devices as described in paragraph (a)(6) of this section to monitor inaccessible equipment leaks.

(i) For the purposes of this subpart, any instrument reading from a component listed in § 98.232 of this chapter of 500 ppm or greater using Method 21 is a leak.

(ii) For the purposes of this subpart, the term ''fugitive emissions component'' in § 60.5397a of this chapter means ''component.''

(iii) For the purpose of complying with § 98.233(q)(1)(iv), the phrase ''the collection of fugitive emissions components at well sites and compressor stations'' in § 60.5397a(b) of this chapter means ''the collection of components for which you elect to comply with § 98.233(q)(1)(iv).''

* * * * *

■ 5. Section 98.236 is amended by:
■ a. Redesignating paragraphs (a)(1)(xiv) through (xvii) as paragraphs (a)(1)(xv) through (xviii), respectively;
■ b. Adding new paragraph (a)(1)(xiv);
■ c. Redesignating paragraphs (a)(9)(x) and (xi) as paragraphs (a)(9)(xi) and (xii), respectively;
■ d. Adding new paragraph (a)(9)(x);
■ e. Revising paragraph (q) introductory text, paragraph (q)(1), paragraph (q)(2) introductory text, paragraph (r)(3)(ii) introductory text, and the second sentence of paragraph (z) introductory text.

The revisions and additions read as follows:

§ 98.236 Data reporting requirements.

* * * * *

(a) * * *

(1) * * *

(xiv) Equipment leak surveys. Report the information specified in paragraph (q) of this section.

* * * * *

(9) * * *

(x) Equipment leak surveys. Report the information specified in paragraph (q) of this section.

* * * * *

(q) Equipment leak surveys. For any components subject to or complying with the requirements of § 98.233(q), you must report the information specified in paragraphs (q)(1) and (2) of this section. Natural gas distribution facilities with emission sources listed in § 98.232(i)(1) must also report the information specified in paragraph (q)(3) of this section.

(1) You must report the information specified in paragraphs (q)(1)(i) through (v) of this section.

(i) Except as specified in paragraph (q)(1)(ii) of this section, the number of complete equipment leak surveys performed during the calendar year.

(ii) Natural gas distribution facilities performing equipment leak surveys across a multiple year leak survey cycle must report the number of years in the leak survey cycle.

(iii) Except for onshore natural gas processing facilities and natural gas distribution facilities, indicate whether any equipment components at your facility are subject to the well site or compressor station fugitive emissions standards in § 60.5397a of this chapter. Report the indication per facility, not per component type.

(iv) For facilities in onshore petroleum and natural gas production, onshore petroleum and natural gas gathering and boosting, onshore natural gas transmission compression, underground natural gas storage, LNG storage, and LNG import and export equipment, indicate whether you elected to comply with § 98.233(q) according to § 98.233(q)(1)(iv) for any equipment components at your facility.

(v) Report each type of method described in § 98.234(a) that was used to conduct leak surveys.

(2) You must indicate whether your facility contains any of the component types subject to or complying with § 98.233(q) that are listed in § 98.232(c)(21), (d)(7), (e)(7), (e)(8), (f)(5), (f)(6), (f)(7), (f)(8), (g)(4), (g)(6), (g)(7), (h)(5), (h)(7), (h)(8), (i)(1), or (j)(10) for your facility's industry segment. For each component type that is located at your facility, you must report the information specified in paragraphs (q)(2)(i) through (v) of this section. If a component type is located at your facility and no leaks were identified from that component, then you must report the information in paragraphs (q)(2)(i) through (v) of this section but report a zero (''0'') for the information required according to paragraphs (q)(2)(ii) through (v) of this section.

* * * * *

(r) * * *

(3) * * *

(ii) Onshore petroleum and natural gas production facilities and onshore petroleum and natural gas gathering and boosting facilities must report the information specified in paragraphs (r)(3)(ii)(A) and (B) of this section, for each major equipment type, production type (*i.e.,* natural gas or crude oil), and geographic location combination in Tables W–1B and W–1C to this subpart for which equipment leak emissions are calculated using the methodology in § 98.233(r).

* * * * *

(z) * * * If your facility contains any combustion units subject to reporting according to paragraph (a)(1)(xviii), (a)(8)(i), or (a)(9)(xii) of this section, then you must report the information specified in paragraphs (z)(1) and (2) of this section, as applicable.

* * * * *

■ 6. Add Table W–1E to subpart W of part 98 in numerical order to read as follows:

TABLE W–1E TO SUBPART W OF PART 98—DEFAULT WHOLE GAS LEAKER EMISSION FACTORS FOR ONSHORE PETROLEUM AND NATURAL GAS PRODUCTION AND ONSHORE PETROLEUM AND NATURAL GAS GATHERING AND BOOSTING

Equipment components	Emission factor (scf/hour/component)	
	If you survey using any of the methods in § 98.234(a)(1) through (6)	If you survey using Method 21 as specified in § 98.234(a)(7)
Leaker Emission Factors—All Components, Gas Service [1]		
Valve	4.9	3.5
Flange	4.1	2.2
Connector (other)	1.3	0.8
Open-Ended Line [2]	2.8	1.9
Pressure Relief Valve	4.5	2.8
Pump Seal	3.7	1.4
Other [3]	4.5	2.8
Leaker Emission Factors—All Components, Light Crude Service [4]

BILLING CODE 6560–50–P

Convert Gas Pneumatic Controls To Instrument Air

Executive Summary

Pneumatic instrument systems powered by high-pressure natural gas are often used across the natural gas and petroleum industries for process control. Typical process control applications include pressure, temperature, liquid level, and flow rate regulation. The constant bleed of natural gas from these controllers is collectively one of the largest sources of methane emissions in the natural gas industry, estimated at approximately 51 billion cubic feet (Bcf) per year in the production sector, 14 Bcf per year in the transmission sector, and <1 Bcf from processing.

Companies can achieve significant cost savings and methane emission reductions by converting natural gas-powered pneumatic control systems to compressed instrument air systems. Instrument air systems substitute compressed air for the pressurized natural gas, eliminating methane emissions and providing additional safety benefits. Cost effective applications, however, are limited to those field sites with available electrical power, either from a utility or self-generated.

Natural Gas STAR Partners have reported savings of up to 70,000 thousand cubic feet (Mcf) per year per facility by replacing natural gas-powered pneumatic systems with instrument air systems, representing annual savings of up to $490,000 per facility. Partners have found that most investments to convert pneumatic systems pay for themselves in just over one year. Individual savings will vary depending on the design, condition and specific operating conditions of the controllers.

Technology Background

The natural gas industry uses a variety of process control devices to operate valves that regulate pressure, flow, temperature, and liquid levels. Most instrumentation and control equipment falls into one of three categories: (1) pneumatic; (2) electrical; or (3) mechanical. In the vast majority of applications, the natural gas industry uses pneumatic devices, which make use of readily available high-pressure natural gas to provide the required energy and control signals. Pneumatic instrument systems powered by high-pressure natural gas are used throughout the natural gas industry. In the production sector, an estimated 400,000 pneumatic devices control and monitor gas and liquid flows and levels in dehydrators and separators, temperature in dehydrator regenerators, and pressure in flash tanks. Most processing plants already use instrument air, but some use gas pneumatics, and including the gathering/booster stations that feed these processing plants, there are about 13,000 gas pneumatic devices in this sector. In the transmission sector, an estimated 85,000 pneumatic devices actuate isolation valves and regulate gas flow and pressure at compressor stations, pipelines, and storage facilities. Non-bleed pneumatic devices are also found on meter runs at distribution company gate stations and distribution grids where they regulate flow and pressure.

Exhibit 1 depicts a pneumatic control system powered by natural gas. The pneumatic control system consists of the process control instruments and valves that are operated by natural gas regulated at approximately 20-30 pounds

Economic and Environmental Benefits

Method for Reducing Natural Gas Losses	Volume of Natural Gas Savings (Mcf/year)	Value of Natural Gas Savings ($/year)			Implementation Cost ($)[a]	Payback (Months)		
		$3 per Mcf	$5 per Mcf	$7 per Mcf		$3 per Mcf	$5 per Mcf	$7 per Mcf
Replace Gas with Air in Pneumatic Systems (per facility)	20,000	$60,000	$100,000	$140,000	$60,000	12	8	6

General Assumptions:
[a] Cost of installing compressor, dryer and other accessories, and annual electricity requirements.

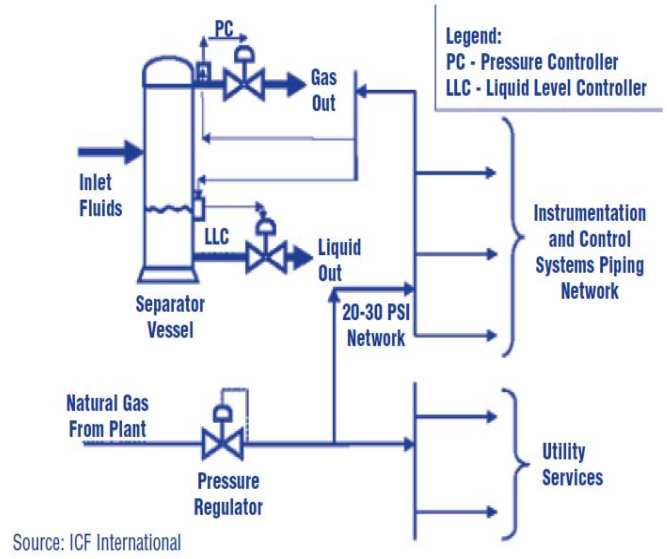

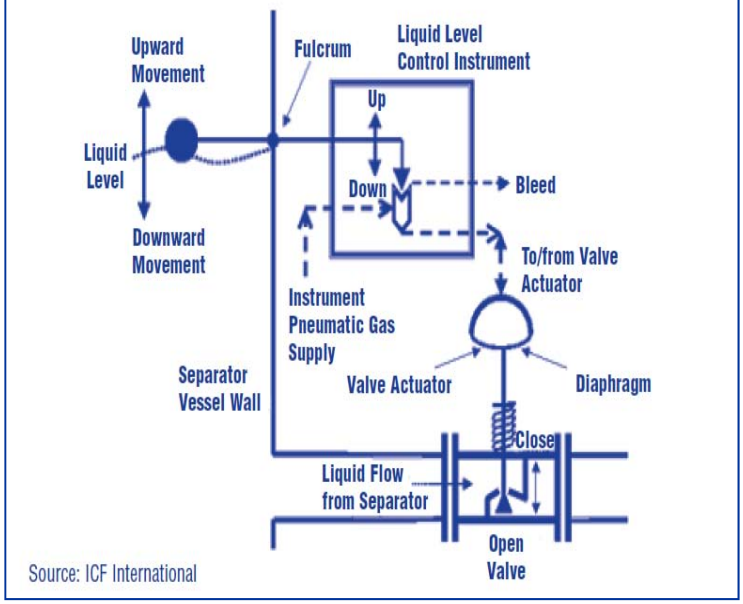

Exhibit 2: Signal and Actuation Schematics

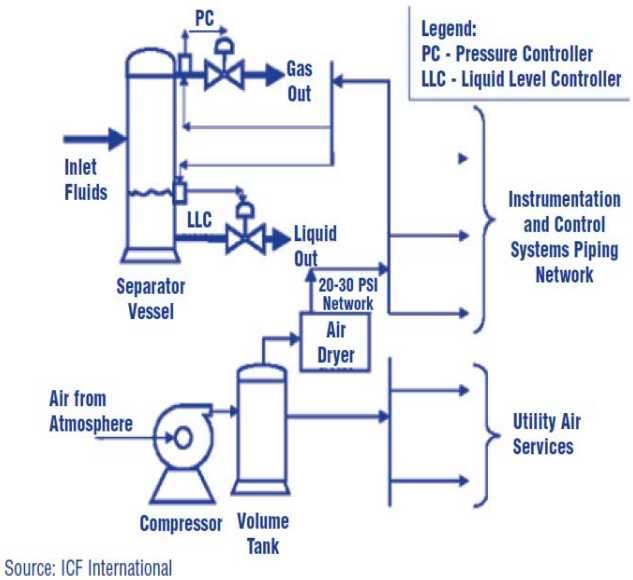
per square inch (psi), and a network of distribution tubing to supply all of the control instruments. Natural gas is also used for a few "utility services," such as small pneumatic pumps, compressor motor starters, and isolation shutoff valves. Exhibit 2 shows a simplified diagram of a pneumatic control loop. A process condition, such as liquid level in a separator vessel, is monitored by a float that is mechanically linked to the liquid level controller outside the vessel. A rise or fall in liquid level moves the float upward or downward, which is translated to small needle valves inside the controller. Pneumatic supply gas is either directed to the valve actuator by the needle valve pinching off an orifice, or gas pressure is bled off the valve actuator. Increasing gas pressure on the valve actuator pushes down a diaphragm connected by a rod to the valve plug, causing the plug to open and increasing the flow of liquid draining out of the separator vessel. Gas pressure relieved from the valve actuator allows a spring to push the valve plug closed.



As part of normal operation, natural gas powered pneumatic devices release or bleed gas to the atmosphere and, consequently, are a major source of methane emissions from the natural gas industry. Pneumatic control systems emit methane from tube joints, controls, and any number of points within the distribution tubing network. The actual bleed rate or emissions level largely depends on the design of the device. In general, controllers of similar design have similar steady-state bleed rates regardless of brand name. The methane emission rate will also vary with the pneumatic gas supply pressure, actuation frequency, and age or condition of the equipment.

Many Partners have found that it is economic to substitute compressed air for natural gas in pneumatic systems. The use of instrument air eliminates methane emissions and leads to increased gas sales. In addition, by eliminating the use of a flammable substance, operational safety is significantly increased. The primary costs associated with conversion to instrument air systems are initial capital expenditures for installing compressors and related equipment and operating costs for electrical energy to power the compressor motor. Existing pneumatic gas supply piping, control instruments, and valve actuators of the gas pneumatic system can be reused in an instrument air system.

A compressed instrument air system is shown in Exhibit 3. In these systems, atmospheric air is compressed, stored in a volume tank, filtered and dried for instrument use. Air used for utility services (e.g. small pneumatic pumps, gas compressor motor starters, pneumatic tools, sand blasting) does not need to be dried. All other parts of a gas pneumatic system will work the same way with air as they do with gas.

The major components of an instrument air conversion project include the compressor, power source, dehydrator, and volume tank. The following are descriptions of each of

Exhibit 3: Compressed Instrument Air System

Source: ICF International

these components along with important installation considerations.

- **Compressor.** Compressors used for instrument air delivery are available in various types and sizes, from rotary screw (centrifugal) compressors to positive displacement (reciprocating piston) types. The size of the compressor depends on the size of the facility, the number of control devices operated by the system, and the typical bleed rates of these devices. The compressor is usually driven by an electric motor that turns on and off, depending on the pressure in the volume tank. For reliability, a full spare compressor is normally installed.

- **Power Source.** A critical component of the instrument air control system is the power source required to operate the compressor. Because high-pressure natural gas is abundant and readily available, gas pneumatic systems can run uninterrupted on a 24-hour, 7-day per week schedule. The reliability of an instrument air system, however, depends on the reliability of the compressor and electric power supply. Most large natural gas plants have either an existing electric power supply or have their own power generation system. For smaller facilities and remote locations, however, a reliable source of electric power can be difficult to assure. In some instances, solar-powered battery-operated air compressors can be cost effective for remote locations, which reduces both methane emissions and energy consumption. Small natural gas powered fuel cells are also being developed.

- **Dehydrators.** Dehydrators, or air dryers, are an integral part of the instrument air compressor system. Water vapor present in atmospheric air condenses when the air is pressurized and cooled, and can cause a number of problems to these systems, including corrosion of the instrument parts and blockage of instrument air piping and controller orifices. For smaller systems, membrane dryers have become economic. These are molecular filters that allow oxygen and nitrogen molecules to pass through the membrane, and hold back water molecules. They are very reliable, with no moving parts, and the filter element can be easily replaced. For larger applications, desiccant (alumina) dryers are more cost effective.

- **Volume Tank.** The volume tank holds enough air to allow the pneumatic control system to have an uninterrupted supply of high pressure air without having to run the air compressor continuously. The volume tank allows a large withdrawal of compressed air for a short time, such as for a motor starter, pneumatic pump, or pneumatic tools, without affecting the process control functions.

Economic and Environmental Benefits

Reducing methane emissions from pneumatic devices by converting to instrument air control and instrumentation systems can yield significant economic and environmental benefits for natural gas companies including:

- **Financial Return From Reducing Gas Emission Losses.** Assuming a natural gas price of $7.00 per Mcf, savings from reduced emissions can be estimated at $840 per year per device or $490,000 or more per year per facility. In many cases, the cost of converting to instrument air can be recovered in less than a year.

- **Increased Life of Control Devices and Improved Operational Efficiency.** Natural gas used in pneumatic control devices and instruments often contains corrosive gases (such as carbon dioxide and hydrogen sulfide) that can reduce the effective operating life of these devices. In addition, natural

gas often produces by-products of iron oxidation, which can plug small orifices in the equipment resulting in operational inefficiencies or hazards. When instrument air is used, and properly filtered and dried, system degradation is reduced and operating life is extended.

★ **Avoided Use Of Flammable Natural Gas.** Using compressed air as an alternative to natural gas eliminates the use of a flammable substance, significantly increasing the safety of natural gas processing plants and transmission and distribution systems. This can be particularly important at offshore installations, where risks associated with hazardous and flammable materials are greater.

★ **Lower Methane Emissions.** Reductions in methane emissions have been reported as high as 70,000 Mcf per facility annually, depending on the device(s) and the type of control application.

Decision Process

The conversion of natural gas pneumatics to instrument air system is applicable to all natural gas facilities and plants. To determine the most cost-effective applications, however, requires a technical and economic feasibility study. The six steps outlined below, and the practical example with cost tables, equations, and factors, can help companies to evaluate their opportunities.

Step 1: Identify Possible Locations For Instrument Air System Installations.

Most natural gas-operated pneumatic control systems can be replaced with instrument air. Instrument air systems will require new investments for the compressor, dehydrator, and other related equipment, as well as a supply of electricity. As a result, a first step in a successful instrument air conversion project is screening existing facilities to identify locations that are most suitable for cost effective projects. In general, three main factors should be considered during this process.

Decision Process for Converting Gas Pneumatic Devices to Instrument Air:

1. Identify possible locations for system installations.
2. Determine optimal system capacity.
3. Estimate the project costs.
4. Estimate gas savings.
5. Evaluate the economics.
6. Develop an implementation plan.

Methane Content of Natural Gas

The average methane content of natural gas varies by natural gas industry sector. The Natural Gas STAR Program assumes the following methane content of natural gas when estimating methane savings for Partner Reported Opportunities.

Production	79 %
Processing	87 %
Transmission and Distribution	94 %

★ **Facility Layout.** The layout of a natural gas facility can significantly affect equipment and installation costs for an instrument air system. For example, conversion to instrument air might not be cost effective at decentralized facilities where tank batteries are remote or widely scattered. Instrument air is most appropriate when used at offshore platforms and onshore facilities where pneumatics are consolidated within a relatively small area.

★ **Number Of Pneumatics.** The more pneumatic controllers converted to instrument air, the greater the potential for reduced emissions and increased company savings. Conversion to instrument air is most profitable when a company is planning a facility -wide change.

★ **Available Power Supply.** Since most instrument air systems rely on electric power for operating the compressor, a cost-effective, uninterrupted electrical energy source is essential. While major facilities often have an existing power supply or their own power generation system, many smaller and remote facilities do not. For these facilities, the cost of power generation generally makes the use of instrument air unprofitable. In addition, facilities with dedicated generators need to assess whether the generators have enough available capacity to support an air compression system, as the cost of a generator upgrade can be prohibitive. Remote facilities should examine alternatives for power generation, which range from microturbines to solar power.

Step 2: Determine Optimal System Capacity.

Once project sites have been identified, it is important to determine the appropriate capacity of the new instrument air system. The capacity needed is a direct function of the amount of compressed air needed to both operate the pneumatic instrumentation and meet any utility air requirements.

★ **Instrument Air Requirements.** The compressed air needs for the pneumatic system are equivalent to the volume of gas being used to run the existing instrumentation—adjusted for air losses during the drying process. The current volume of gas usage can be determined by a direct meter reading (if a meter has been installed). In nonmetered systems, a conservative rule-of-thumb for sizing air systems is one cubic foot per minute (cfm) of instrument air for each control loop (consisting of a pneumatic controller and a control valve).

Rule-of-Thumb

1 cfm air/control loop

The initial estimate of instrument air needs should then be adjusted to account for air losses during the drying process. Typically, the membrane filters in the air dryer consume about 17 percent of the air input. As a result, the estimated volume of instrument air usage is 83 percent of the total compressed air supply: i.e., divide estimated air usage by 83 percent. Desiccant dryers do not consume air and therefore require no adjustment.

Rule-of-Thumb

17 percent of air input is consumed by the membrane dryer

★ **Utility Air Requirements.** It is common to use compressed air for utility purposes, such as engine starters, pneumatic driven pumps, pneumatic tools (e.g., impact wrenches), and sand blasting. Unlike instrument air, utility air does not have to be dried. The frequency and volumes of such utility air uses are additive. Companies will need to evaluate these other compressed air services on a site-specific basis, allowing for the possibility of expansion at the site. A general rule-of-thumb is to assume that the maximum rate of compressed air needed periodically for utility purposes will be double the steady rate used for instrument air.

Rule-of-Thumb

Pneumatic air uses: 1/3 for instrument air; 2/3 for utility air

Exhibit 4 illustrates how the instrument air compressor size can be estimated. Using the rule-of-thumb of 1 cfm/ control loop, the current gas usage would translate to approximately 35 cfm of dry instrument air. Adjusting for the dryer's air consumption (17 percent of air input), the total instrument air supply requirement will be 42 cfm. Factoring in utility air needs of about 70 cfm, the project would require a total of 112 cfm of compressed air.

Exhibit 4: Calculate Compressor Size for Converting Gas Pneumatics to Instrument Air

Given:	For an average size production site with pneumatics, glycol dehydration, compression, 35 control loops, and an average of 10 cfm utility gas usage for pneumatic pumps and compressor engine starting.
A IAu IAs UAs L	= Total Compressed Air = Instrument air use = Instrument air supply = Utility air supply = Control loops
	Rule-of-thumb: 1 cfm per control loop for estimating instrument air systems. Rule-of-thumb: 17% of air is bypassed in membrane dryers. Rule-of-thumb: 1/3 of total air used for instruments, 2/3 of total air used for utility services.
	Calculate: A = Air compressor capacity required.
A IAu IAs UAs A	= IAs + UAs = L * (1 cfm/loop) = IAu/(100% - % air bypassed in dryer) = IAu * (fraction of utility air use) / (fraction of instrument air use) = (35*1) / (100% - 17%) + (35*1) * (2/3) / (1/3) = 112 cfm

Step 3: Estimate the Project Costs.

The major costs associated with installing and operating an instrument air system are the installation costs for compressors, dryers, and volume tanks, and energy costs. The actual installation costs will be a function of the size, location, and other location specific factors. A typical conversion of a natural gas pneumatic control system to compressed instrument air costs approximately $45,000 to $75,000.

To estimate the cost for a given project, all expenses associated with the compressor, dryer, volume tank, and power supply must be calculated. Most vendors are willing to provide estimates of the equipment costs and installation requirements (including compressor size, motor horsepower, electrical power requirements, and storage capacity). Alternatively, operators can use the following information on the major system components to estimate the total installed cost of the instrument air system.

★ **Compressor Costs.** It is common to install two compressors at a facility (one operating and one stand-by spare) to ensure reliability and allow for maintenance and overhauls without service interruptions. The capacity for each of the compressors must be sufficient to handle the total expected compressed air volume for the project (i.e., both instrument and utility air). Exhibit 5 presents

cost estimates for purchasing and servicing small, medium, and large compressors. For screw-type compressors, operators should expect to overhaul the unit every 5 to 6 years. This normally involves exchanging the compressor core for a rebuilt compressor at a cost of approximately $3,929, with an additional $720 in labor expense and a $650 core exchange credit.

Exhibit 5: Air Compressor Costs

Service Size	Air Volume (cfm)	Compressor Type	Horsepower	Equipment Costs ($)	Annual Service ($/yr)	Service Life (yrs)
Small	30	Reciprocating	10	3,275[a]	434	1
Medium	125	Screw	30	16,371	868	5-6[b]
Large	350	Screw	75	28,812	868	5-6[b]

[a] Cost included package compressor with a volume tank.
[b] Rebuilt compressor costs $3,929 plus $500 labor minus $500 core exchange credit.

★ **Volume Tank.** Compressed air supply systems include a volume tank, which maintains a steady pressure with the on-off operation of the air compressor. The rule-of-thumb in determining the size of the volume tank is 1-gallon capacity for each cfm of compressed air. Exhibit 6 presents equipment costs for small, medium, and large volume tanks. Volume tanks have essentially no operating and maintenance costs.

Rule-of-Thumb

1 gallon tank capacity/1 cfm air

★ **Air Dryer Costs.** Because instrument air must be very dry to avoid plugging and corrosion, the compressed air is commonly put through a dryer. The most common dryer used in small to medium applications is a permeable membrane dryer. Larger air systems can use multiple membrane dryers, or, more cost effectively, alumina bed desiccant dryers. Membrane dryers filter out oil mist and particulate solids and have no moving parts. As a result, annual operating costs are kept low. Exhibit 7 presents equipment and service cost data for different size dryers. The appropriate sized dryer would need to accommodate the expected volume of gas needed for the instrument air system.

Exhibit 6: Volume Tank Costs

Service Size	Air Volume (gallons)	Equipment Cost ($)
Small[a]	80	655
Medium	400	1,964
Large	1,000	3,929

[a] Small reciprocating air compressors, 10 horsepower and less, are commonly supplied with a surge tank.

Exhibit 7: Air Dryer Costs

Service Size	Air Volume (cfm)	Dryer Type	Equipment Cost ($)	Annual Service ($/yr)
Small	30	membrane	1,964	724
Medium	60[a]	membrane	5,893	2,894
Large	350	alumina	13,096	4,341

[a] Largest membrane size; use multiple units, larger volumes.

Using the equipment information described above, the total installed cost for a project can be calculated. Exhibit 8 illustrates this using the earlier example of a medium-sized production facility with an instrument air requirement of 42 cfm and a maximum utility air requirement of 70 cfm (for a total of 112 cfm of compressed air). To estimate the installed cost of equipment, it is a common practice in industry to assume that installation labor is equivalent to equipment purchase cost (i.e. double equipment purchase cost to estimate the installed cost). This would be suitable for large, desiccant dried instrument air systems, but for small, skid-mounted instrument air systems a factor of 1.5 is used to estimate the total installed cost (installation labor is half the cost of equipment).

In addition to the facility costs, it is also necessary to estimate the energy costs associated with operating the system. The most significant operating cost of an air compressor is electricity, unless the site has excess self-generation capacity. To continue the example from above, assuming that electricity is purchased at 7.5 cents per kilowatt-hour (kWh) and that one compressor is in standby while the other compressor runs at full capacity half the time (a 50 percent operating factor), the electrical power

Exhibit 8: Calculate Total Installation Costs	
Given:	
Compressors (2) Volume Tanks (2-small) Membrane Dryer Installed Cost Factor	= $32,742 (Exhibit 5) = $1,310 (Exhibit 6) = $5,893 (Exhibit 7) = 1.5
Calculate Total Installed Cost:	
Equipment Cost	= Compressor Cost + Tank Cost + Dryer Cost = $32,742 + $1,310 + $5,893 = $39,945
Total Cost	= Equipment Cost * Installation Cost Factor = $39,945 * 1.5 = $59,917

cost amounts to $13,140 per year. This calculation is shown in Exhibit 9.

Step 4: Estimate Gas Savings.

To estimate the gas savings that result from the installation of an instrument air system, it is important to determine the normal bleed rates (continuous leak from piping networks, control devices, etc.), as well as the peak bleed rates (associated with movements in the control devices). One approach is to list all the control devices,

Exhibit 9: Calculate Electricity Cost	
Given:	
Engine Power Operating Factor (OF) Electricity Cost	= 30 HP = 50 percent = $0.075/kwh
Calculate Required Power:	
Electrical Power	= Engine Power * OF * Electricity Cost = [30 HP * 8,760 hrs/yr * 0.5 * $0.075/kwh] / 0.75 HP/kw = $13,140/yr

assess their normal and peak bleed rates, frequency of actuation, and estimates of leakage from the piping networks. Manufacturers of the control devices usually publish the emission rates for each type of device, and for each type of operation. Rates should be increased by 25 percent for devices that have been in service without overhaul for five to 10 years, and by about 50 percent for devices that have not been overhauled for more than 10 years to account for increased leakage associated with wear and tear. Alternatively, installing a meter can be more accurate, provided monitoring occurs over a long enough period of time to take account of all the utility uses of gas (i.e., pumps, motor starters, activation of isolation valves).

EPA's *Lessons Learned: Options for Reducing Methane Emissions from Pneumatic Devices in the Natural Gas Industry*, provides brand name, model, and gas consumption information for a wide variety of currently used pneumatic devices. Manufacturer information and actual field measurement data, wherever available, are provided as well (see Appendix of that report). To simplify the calculation of gas savings for the purpose of this lesson learned analysis, we can use the earlier rules-of-thumb to estimate the gas savings. The gas savings for the medium-sized production facility example in Exhibit 4 include the conservatively estimated 35 cfm used in the 35 gas pneumatic controllers plus the gas used occasionally for compressor motor starters and small pneumatic chemical and transfer pumps. (Note that replacing these gas usages will result in direct savings of gas emissions.) Natural gas is not used for pneumatic tools or sand blasting, so additional compressed air provided for these services does not reduce methane emissions. Assuming an annual average of 10 cfm gas use for natural gas powered non-instrument services, the gas savings would be 45 cfm. As shown in Exhibit 10, this is equivalent to 23,652 Mcf per year and annual savings of $165,600.

Step 5: Evaluate the Economics.

The cost effectiveness of replacing the natural gas pneumatic control systems with instrument air systems

Exhibit 10: Calculate Gas Savings	
Given:	
Pneumatic instrument gas usage Other non-instrument gas usage	= 35 cfm = 10 cfm
Calculate Value of Gas Saved:	
Volume of Natural Gas Saved	= Instrument Usage + Other Usage = 35 cfm + 10 cfm = 45 cfm
Annual Volume of Gas Saved	= 45 cfm * 525,600 min/yr / 1000 = 23,652 Mcf/yr
Annual Value of Gas Saved	= volume * $7.00/Mcf = 23,652 Mcf/yr * $7.00/Mcf = $165,600/year

can be evaluated using straightforward cost-benefit economic analyses.

Exhibit 11 illustrates a cost-benefit analysis for the medium-sized production facility example. The cash flow over a five-year period is analyzed by showing the magnitude and timing of costs from Exhibits 8 and 9 (shown in parentheses) and benefits from Exhibit 10. The annual maintenance costs associated with the compressors and air dryer, from Exhibits 5 and 7, are accounted for, as well as a five-year major overhaul of a compressor per Exhibit 5. The net present value (NPV) is equal to the benefits minus the costs accrued over five years and discounted by 10 percent each year. The Internal Rate of Return (IRR) reflects the discount rate at which the NPV generated by the investment equals zero.

Nelson Price Indexes

In order to account for inflation in equipment and operating & maintenance costs, Nelson-Farrar Quarterly Cost Indexes (available in the first issue of each quarter in the *Oil and Gas Journal*) are used to update costs in the Lessons Learned documents.

The "Refinery Operation Index" is used to revise operating costs while the "Machinery: Oilfield Itemized Refining Cost Index" is used to update equipment costs.

To use these indexes in the future, simply look up the most current Nelson-Farrar index number, divide by the February 2006 Nelson-Farrar index number, and, finally multiply by the appropriate costs in the Lessons Learned.

Step 6: Develop an Implementation Plan.

After determining the feasibility and economics of converting to an instrument air system, develop a systematic plan for implementing the required changes. This can include installing a gas measuring meter in the gas supply line, making an estimate of the number of control loops, ensuring an uninterrupted supply of electric energy for operating the compressors, and replacing old, obsolete and high-bleed controllers. It is recommended that all necessary changes be made at one time to minimize labor costs and disruption of operations. This might include a parallel strategy to install low-bleed devices in conjunction with the switch to instrument air systems. There are similar economic savings for conserving instrument air use as for conserving methane emissions with low bleed pneumatic devices. Whenever specific pneumatic devices are being replaced, such as in the case of alternative mechanical and/or electronic

Exhibit 11: Economic Analysis of Instrument Air System Conversion

	Year 0	Year 1	Year 2	Year 3	Year 4	Year 5
Implementation Cost ($)	(59,917)					
O&M Cost ($)		(13,140)[a] (4,630)[b]	(13,140) (4,630)	(13,140) (4,630)	(13,140) (4,630)	(13,140) (4,630)
Overhaul Cost ($)	0	0	0	0	0	(6,286)[c]
Total Cost ($)	(59,917)	(17,770)	(17,770)	(17,770)	(17,770)	(24,057)
Gas Savings ($)	0	165,600[d]	165,600	165,600	165,600	165,600
Annual Cash Flow ($)	(59,917)	147,830	147,830	147,830	147,830	141,543
Cumulative Cash Flow ($)	(59,917)	87,912	235,742	383,571	531,401	672,944
					Payback Period (months)	5
					IRR	246%
					NPV[e]	$496,570

[a] Electrical power at 7.5 cents per kilowatt-hour.
[b] Maintenance costs include $1,736 compressor service and $2,894 air dryer membrane replacement.
[c] Compressor overhaul cost of $3,929, inflated at 10% per year.
[d] Value of gas = $7.00/Mcf.
[e] Net Present Value (NPV) based on 10% discount rate for 5 years.

systems, the existing pneumatic devices should be replaced on a similar economic basis as discussed in the companion document *Lessons Learned: Options for Reducing Methane Emissions from Pneumatic Devices in the Natural Gas Industry*.

When assessing options for converting gas pneumatic controls to instrument air, natural gas price may influence the decision making process. Exhibit 12 shows an economic analysis installing two 30 hp compressors, two medium sized volume tanks, and a medium sized membrane dryer at different natural gas prices.

Partner Experiences

Several EPA Natural Gas Star Partners have reported the conversion of natural gas pneumatic control systems to compressed instrument air systems as the single most significant source of methane emission reduction and a source of substantial cost savings. Exhibit 13 below highlights the accomplishments that several Natural Gas STAR Partners have reported.

Exhibit 12: Gas Price Impact on Economic Analysis

	$3/Mcf	$5/Mcf	$7/Mcf	$8/Mcf	$10/Mcf
Value of Gas Saved	$70,971	$118,286	$165,600	$189,257	$236,571
Payback Period (months)	14	8	5	5	4
Internal Rate of Return (IRR)	84%	166%	246%	286%	365%
Net Present Value (*i*=10%)	$137,853	$317,211	$496,570	$586,249	$765,607

Other Technologies

The majority of Partners' experiences in substituting natural gas-powered pneumatic devices and control instrumentation with alternative controllers have involved

Exhibit 13: Partner Reported Experience

Gas STAR Partner	Description of Project	Project Cost ($)	Annual Emissions Reductions (Mcf/yr)	Annual Savings ($/yr)[a]	Payback (months)[b]
Unocal[c] (now Chevron)	Installed an air compression system in its Fresh Water Bayou facility in southern Vermillion Parish, Louisiana	$79,000	69,350	$485,450	2
Texaco[c] (now Chevron)	Installed compressed air system to drive pneumatic devices in 10 South Louisiana facilities	$52,000	23,000	$161,000	4
Chevron[c]	Converted pneumatic controllers to compressed air, including new installations	$227,000 over 2 years	31,700	$221,900	7
ExxonMobil[d]	Installed instrument air systems at 3 production satellites and 1 central tank battery at Postle CO_2 unit	$72,000	19,163	$134,141	7
Shell	Used instrument air operated devices on over 4,300 valves at off-shore platforms	Not available	532,800	$3,729,600	Not available
Marathon	Installed 15 instrument air systems in New Mexico facilities	Not available	120 - 38,000 per facility	$840 - 226,000	Not available

[a] Value of gas = $7.00/Mcf.
[b] Calculated based on Partner-reported costs and gas savings updated to 2006 costs.
[c] Data for this report were collected prior to the Chevron-Texaco and Chevron-Unocal mergers.
[d] Data for this report were collected prior to the Exxon/Mobil merger in 1999.

the installation of compressed instrument air systems. Some additional alternatives to gas pneumatics implemented by Partners are described below:

- ★ **Liquid Nitrogen.** In a system using liquid nitrogen, the volume tank, air compressor, and dryer are replaced with a cylinder containing cryogenic liquid nitrogen. A pressure regulator allows expansion of the nitrogen gas into the instrument and control-piping network at the desired pressure. Liquid nitrogen bottles are replaced periodically. Liquid nitrogen-operated devices require handling of cryogenic liquids, which can be expensive as well as a potential safety hazard. Large volume demands on a liquid nitrogen system require a vaporizer.

- ★ **Mechanical Controls and Instrumentation System.** Mechanical instrument and control devices have a long history of use in the natural gas and petroleum industry. They are usually distinguished by the absence of pneumatic and electric components, are simple in design, and require no power source. Such equipment operates using springs, levers, baffles, flow channels, and hand wheels. They have several disadvantages, such as limited application, the need for continuous calibration, lack of sensitivity, inability to handle large variations, and potential for sticking parts.

- ★ **Electric and Electro-Pneumatic Devices.** As a result of advanced technology and increasing sophistication, the use of electronic instrument and control devices is increasing. The advantage of these devices is that they require no compression devices to supply energy to operate the equipment; a simple 120 -volt electric supply is used for power. Another advantage is that the use of electronic instrument and control devices is far less dangerous than using combustible natural gas or cryogenic liquid nitrogen cylinders. The disadvantage of these devices is their reliance on an uninterrupted source of electric supply, and significantly higher costs.

Although these options have advantages, systems using air instead of natural gas are the most widely employed alternative in replacing natural gas-operated pneumatic control devices. It is important to note that maintaining a constant, reliable supply of dry, compressed air in a plant environment is a significant cost, albeit more economic than natural gas. Therefore, a parallel strategy to install low-bleed devices in conjunction with the switch to instrument air systems (refer to *Lessons Learned: Options for Reducing Methane Emissions from Pneumatic Devices in the Natural Gas Industry*), and to design a maintenance schedule to keep the instruments and control devices in tune, is often economic. Such actions can significantly reduce the consumption of instrument air in the overall system and, therefore, minimize both the size of the compression system and the electricity consumption over the life of the plant.

Lessons Learned

The lessons learned from Natural Gas STAR Partners are:

- ★ Installing instrument air systems has the potential to increase revenues and substantially reduce methane emissions.

- ★ Instrument air systems can extend the life cycle of system equipment, which can accumulate trace amounts of sulfur and various acid gases when controlled by natural gas, thus adding to the potential savings and increasing operational efficiencies.

- ★ Remote locations and facilities without a reliable source of electric supply often need to evaluate alternate power generation sources. When feasible, solar-powered air compressors provide an economical and ecologically beneficial alternative to expensive electricity in remote production areas. On site generation using microturbines running on natural gas is another alternative.

- ★ A parallel strategy of installing low-bleed devices in conjunction with the switch to instrument air systems is often economic.

- ★ Existing infrastructure can be used; therefore, no pipe replacement is needed. However, existing piping and tubing should be flushed clear of accumulated debris.

- ★ Rotary air compressors are normally lubricated with oil, which must be filtered to maintain the life and proper performance of membrane dryers.

- ★ Use of instrument air will eliminate safety hazards associated with flammable natural gas usage in pneumatic devices.

- ★ Nitrogen-drive systems may be an alternative to instrument air in special cases, but tends to be

NMED Exhibit 99 - 0010

expensive and handling of cryogenic gas is a safety concern.

★ Report reductions in methane emissions from converting gas pneumatic controls to instrument air in your Natural Gas STAR Annual Report.

October 2006

EPA provides the suggested methane emissions estimating methods contained in this document as a tool to develop basic methane emissions estimates only. As regulatory reporting demands a higher-level of accuracy, the methane emission estimating methods and terminology contained in this document may not conform to the Greenhouse Gas Reporting Rule, 40 CFR Part 98, Subpart W methods or those in other EPA regulations.

ENVIRONMENTAL PROTECTION AGENCY

40 CFR Parts 51, 52, 60 and 61

[FRL–5691–2]

RIN 2020–AA27

Credible Evidence Revisions

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: In an October 22, 1993 Federal Register, EPA solicited public comment on a proposal to amend 40 CFR Parts 51, 52, 60 and 61 to eliminate language that has been read to provide for exclusive reliance on reference test methods as the means of demonstrating compliance with various emission limits under the Clean Air Act (''CAA'' or ''Act''). These revisions—generally referred to as the ''credible evidence'' revisions—were designed to clarify that non-reference test data can be used in enforcement actions, and to remove any potential ambiguity regarding this data's use for compliance certifications under Section 114 and Title V of the Act. In the same document, EPA proposed an ''enhanced monitoring'' rule under Section 114 and Title V. EPA subsequently decided to suspend development of the original enhanced monitoring rule and develop a compliance assurance monitoring (''CAM'') approach to serve the same statutory goals as the original enhanced monitoring proposal. Today's rulemaking finalizes the previously proposed credible evidence revisions to Parts 51, 52, 60 and 61. EPA will take final action regarding enhanced monitoring and CAM in a separate rulemaking.

DATES: *Effective Date:* April 25, 1997. *Judicial Review:* Under CAA section 307(b)(1), judicial review of this nationally applicable final action is available only by the filing of a petition for review in the U.S. Court of Appeals for the District of Columbia Circuit within 60 days of today's publication of this rule. Under CAA section 307(b)(2), the regulations that are the subject of today's rule may not be challenged later in civil or criminal proceedings brought by EPA in reliance on them.

ADDRESSES: *Docket.* Supporting information used in developing this rulemaking is contained in Public Docket No. A–91–52. This docket is available for public inspection and copying between 8:00 a.m. and 5:30 p.m. on weekdays, excluding federal holidays, at the EPA Air and Radiation Docket and Information Center, Room M–1500, Waterside Mall, 401 M Street SW., Washington, DC 20460; telephone (202) 260–7548. A reasonable fee may be charged for photocopying docket materials.

FOR FURTHER INFORMATION CONTACT: Gregory Jaffe, Air Enforcement Division (Mailcode 2242–A), Office of Regulatory Enforcement, U.S. Environmental Protection Agency, 401 M Street, SW, Washington, D.C. 20460; telephone (202) 564–2260.

SUPPLEMENTARY INFORMATION: The contents of the preamble are listed in the following outline:

I. Background
A. Statutory and Regulatory Authority
B. Benefits of the Credible Evidence Revisions
C. Public Participation
II. Summary of Final Rule
A. 40 CFR Part 51, § 51.212
B. 40 CFR Part 52, § 52.12
C. 40 CFR Part 52, § 52.30
D. 40 CFR Part 60, § 60.11
E. 40 CFR Part 61, § 61.12
III. Major Issues
A. Use of Credible Evidence in Enforcement Actions
B. Use of Credible Evidence in Compliance Certifications
C. EPA's Authority To Promulgate the Credible Evidence Revisions
1. Statutory Authority
2. The *Kaiser Steel* Decision Does Not Constrain EPA's Authority To Amend its Regulations
3. Despite Commenters' Claims, Clean Air Act Case Law Does Not Mandate Exclusive Reference Tests
4. The 1990 CAA Amendments Further Support EPA's Authority
5. Commenters' Attempts To Narrow the Scope of Sections 113(e) and 113(a) Are Unpersuasive
6. EPA Can Promulgate the Credible Evidence Revisions Without Reproposal
D. Stringency
1. Emissions Limits Require Continuous Compliance (Consistent With Any Averaging Times) Except During Periods Where Compliance is Specifically Excused
2. Commenters' Advocacy of Noncontinuous Compliance Would Lead to Numerous Anomalies
3. Comments Regarding Continuous Compliance Are Not Directed at Today's Action, but Rather at Underlying Emission Standards
4. Enforcement Using Continuous Monitoring Data Does Not Increase the Stringency of Applicable Requirements
5. Sources Must Comply Both With Good Operation and Maintenance Requirements and With Emission Limits
E. SIP Call
IV. Administrative Requirements
A. Docket
B. Office of Management and Budget (OMB) Review
C. Unfunded Mandates Reform Act
D. Regulatory Flexibility Act
E. Paperwork Reduction Act
F. Submission to Congress and the General Accounting Office

I. Background

A. Statutory and Regulatory Authority

The credible evidence revisions are based on EPA's long-standing authority under the Act, and on amplified authority provided by the 1990 CAA Amendments. Section 113(a) of the Act authorizes EPA to bring an administrative, civil or criminal enforcement action ''on the basis of any information available to the Administrator.'' In this provision, which predates the 1990 CAA Amendments, Congress gave EPA clear statutory authority to use any available information—not just data from reference tests or other federally promulgated or approved compliance methods—to prove CAA violations. (The preamble will generally use the phrase ''reference tests'' to include all these compliance methods. Where appropriate, the phrase ''reference tests'' will also include test conditions specified in individual regulations.)

In the 1990 CAA Amendments, Congress included an enforcement title (Title VII) to enhance EPA's compliance and enforcement authorities. Among other things, Congress revised Section 113(e)(1) of the Act to overrule a federal court decision (*Kaiser Steel*, discussed below) that had held that only specified reference test data could prove violations. Thus, although the pre-existing authority of Section 113(a) forms the principal basis for today's action, the credible evidence revisions are also supported by the language, history and intent of the 1990 CAA Amendments. *See also* Section III.C. below.

In addition to clarifying EPA's, states' and citizens' enforcement authorities under the Act, the credible evidence revisions eliminate any potential ambiguity regarding the use of non-reference test data as a basis for Title V compliance certifications. Such potential ambiguity could arise from comparing the draft compliance assurance monitoring (CAM) approach and associated Part 70 changes, which would allow sources to include CAM data as a basis for certifying compliance, with various EPA regulations that could be read on their face to specify reference test methods as the sole means of determining compliance.

B. Benefits of the Credible Evidence Revisions

As a preliminary matter, EPA wishes to clearly state that this rulemaking merely addresses an evidentiary issue. The credible evidence revisions are not

intended to and will not serve to affect the stringency of underlying emission standards by amending the nature of the compliance obligation. This rulemaking does not amend existing emission standards nor does it modify generic regulations affecting the compliance obligation such as exceptions for startup, shutdown, and malfunctions. See, e.g., 40 CFR 60.8(c). This regulation also does not designate any particular data as probative of a violation of an emission standard. Rather, this regulation merely removes what some have construed to be a regulatory bar to the admission of non-reference test data to prove a violation of an emission standard, no matter how credible and probative those data are that a violation has occurred. The credible evidence revisions do not affect the compliance obligation and thus do not affect the stringency of existing emission standards. What compliance obligation is imposed by any given emission standard remains an issue ultimately to be determined based on that emission standard and not this rulemaking.

For these reasons, we do not believe that this rulemaking affects whether emission standards require intermittent or continuous compliance. However, as made clear below, and in the detailed response to comments document, EPA's position continues to be that an emission standard requires continuous compliance unless the emission standard specifically provides otherwise.

Today's credible evidence revisions will benefit sources, state environmental agencies, EPA and the public. EPA, states and citizens will be able to use credible evidence to assess a source's compliance status and respond to noncompliance. This will help ensure that the government and citizens alike can respond to sources that are not complying with air pollutant emission standards on an ongoing basis, thus furthering the protection of public health and the environment. At the same time, sources will be able to use credible evidence for contesting allegations of noncompliance in enforcement actions. Accordingly, today's rulemaking exemplifies EPA's ''common sense'' approach to environmental protection, which encourages smarter, cheaper and more flexible means of achieving environmental goals without compromising the fundamental health and environmental protections provided by federal environmental laws.

In the past, state regulatory authorities and EPA have relied primarily on infrequent on-site inspections and even more infrequent reference tests in order to check compliance with emission limits at major stationary sources. According to a September, 1990, General Accounting Office (GAO) report, these on-site inspections were performed approximately once a year; the reference tests, typically once every five years. ''Air Pollution: Improvements Needed in Detecting and Preventing Violations,'' GAO, No. GAO/RCED–90–155, September 1990, at 12, 19. These methods are inadequate to ensure that sources continuously stay within their emission limits: for example, Pennsylvania officials have estimated that, in comparison with continuous emissions monitoring, on-site inspections may be 50 times less likely to detect non-compliance. *Id.* at 18. Reference tests may not yield a representative emissions picture because the sources typically schedule, set up and run the tests themselves. This allows sources to ''fine tune'' their operations and emissions control processes prior to the tests, and generate results that may not be typical of day-to-day source operations. *Id.* at 19–20. Reference tests can also be expensive and burdensome: They can cost up to $100,000, and take a week or more to complete. *See, e.g.*, 43 FR 7568, 7571 (1978).

In contrast to the above approach, today's rule will make it clear that various kinds of information other than reference test data, much of which is already available and utilized for other purposes, may be used to demonstrate compliance or noncompliance with emission standards. (The preamble generally refers to this other information as ''non-reference test data''). EPA, state agencies and industry routinely rely on many types of information, including engineering calculations, indirect estimates of emissions, and direct measurement of emissions by a variety of means, in order to assess compliance with CAA requirements. Where available, continuous emission monitoring (CEM) data and well-chosen parametric monitoring data, such as the operating temperature and air flow rate of a regenerative thermal oxidizer, generally provide accurate data regarding a source's compliance with emission limits and standards. These data also generally cover a greater percentage of a source's time in operation and are more representative of a source's ongoing compliance status than sporadic performance testing.

Under today's rule both sources and potential enforcers will be put on the same evidentiary footing in an enforcement action. Further, since 1992, EPA's Part 70 operating permit regulations have allowed the use of this data in compliance certifications. Today's action reaffirms this approach, and removes any potential ambiguity regarding the use of such data for this purpose.

Today's action reflects EPA's efforts to make existing regulatory programs work better rather than creating additional requirements. By ensuring greater compliance with existing emissions limits, the credible evidence revisions will help minimize the need for further requirements to achieve air quality goals. *See* the October, 1993, proposal, 58 FR 54654.

C. Public Participation

The final credible evidence revisions were developed with the benefit of insight from many parties that will be affected by the regulations, including State and local air pollution control agencies, large and small industries, trade associations and environmental organizations. Many comments regarding credible evidence issues were received during the development and after the proposal of the original enhanced monitoring rule, in 1991 through 1995. Many additional comments were received after the Agency announced that it was continuing to go forward with the credible evidence revisions in 1996.

To obtain the views of all interested parties at the early stages of developing the enhanced monitoring rulemaking, EPA published a notice in the Federal Register on August 8, 1991, to make available a Public Information Document on enhanced monitoring and to provide notice of a public meeting to be held on August 22, 1991, on the subject (56 FR 37700–37701, August 8, 1991). In response to the public meeting, EPA received many comments which were included in the docket for the proposed regulations.

Over the next four years, EPA held over one hundred informal informational and discussion sessions with representatives of interested organizations to receive their views on enhanced monitoring, as well as a second informational meeting with approximately fifty attendees held on August 12, 1993. Following publication of the proposed enhanced monitoring regulations on October 22, 1993 at 58 FR 54648, EPA conducted a public hearing in Washington, D.C., on November 19, 1993. Testimony was given by twelve individuals, representing industry and environmental organizations.

In addition, during the public comment period, which was first scheduled to close on December 30, 1993, and was extended until January 31, 1994, in response to requests for

extension, EPA received comments from a wide variety of interested parties concerning the enhanced monitoring proposal, including numerous comments on credible evidence issues. In the fall of 1994, EPA held a series of informational meetings with interested parties affected by the rule. The Agency then reopened the public comment period on specific issues to solicit additional comments, and held an additional stakeholder meeting. In response to the reopened public comment period, EPA received over 200 additional comment letters.

In April, 1995, EPA announced that it was suspending development of the enhanced monitoring rule while it developed the CAM approach to serve the same statutory goals. In a September, 1995, public draft of the CAM approach, EPA stated that it would hold further discussions with stakeholders before it proceeded to finalize the credible evidence revisions. On March 8, 1996, EPA announced that a public meeting on credible evidence issues would be held on April 2, 1996. To focus the meeting's discussion, EPA released a paper on March 21, 1996, entitled ''The Use of Information Other Than Reference Test Results for Determining Compliance With the Clean Air Act'' (sometimes referred to as the ''Credible Evidence White Paper''). EPA distributed this paper by electronic bulletin board to the same stakeholders who were involved in the enhanced monitoring and CAM rulemakings, further distributed it to various other interested parties, and made it generally available to the public.

The public meeting was held on April 2, 1996, where twenty-three organizations and individuals presented oral statements and written comments. At the meeting, EPA announced that, although the rulemaking docket would not formally be re-opened, additional written comments would be accepted for at least another 30 days. Moreover, EPA stated that it would meet with any interested parties to discuss the credible evidence rules. As a result, many additional written comments have been received, and numerous additional EPA/stakeholder meetings have been held.

Section III of this preamble contains a description of the most significant public comments and EPA's responses to them. Summaries of other public comments on the credible evidence revisions received over the past five years, together with the Agency's responses, are available in the docket in a document entitled ''Credible Evidence Revisions: Detailed Response to Comments Document'' (referred to in this preamble as the ''Detailed Response Document'').

II. Summary of Final Rule

The credible evidence revisions consist of various changes to 40 CFR 51.212, 52.12, 52.30, 60.11 and 61.12. These revisions provide minor modifications to existing regulatory provisions to clearly allow for the use of any credible evidence—that is, both reference test and comparable non-reference test data—to prove or disprove violations of the Act in enforcement actions. These revisions make clear that enforcement authorities can prosecute actions based exclusively on any credible evidence, without the need to rely on any data from a particular reference test. The revisions also have the effect of eliminating any potential ambiguity regarding the use of non-reference test data as a basis for Title V compliance certifications. The credible evidence revisions do not call for the creation or submission of any new emissions or parametric data, but rather address the role of existing data in enforcement actions and compliance certifications. As such, today's final action is distinct and separable from the bulk of the proposed enhanced monitoring rule, which addressed new monitoring requirements.

By clearly providing that federally approved SIP test methods or Agency reference test methods are not the exclusive means of establishing noncompliance or compliance, EPA in no way intends to alter the underlying emission standards. The Agency will still use the reference methods for exactly what they are: test methods of reference against which to compare information generated by means other than the reference tests. The National Bureau of Standards maintains a number of standards against which other measuring devices, used in scientific or commercial applications, are calibrated. Similarly, where a SIP, New Source Performance Standard or permit specifies EPA Method 25A, for example, for determining the amount of volatile organic compounds (''VOCs'') that are emitted, the ''other evidence'' that could establish compliance would have to relate to the likely measurement of VOCs that would be obtained by a Method 25A measurement. This could include, for example, consideration of key operating parameters for the facility as correlated with emissions during a Method 25A test.

A. 40 CFR Part 51, § 51.212

Section 51.212(c) is revised to clarify that the inclusion in a state implementation plan (SIP) of enforceable test methods for SIP emissions limits does not preclude enforcement based on other credible evidence or information, relevant to whether a source would have been in compliance with applicable requirements if the appropriate performance or compliance test procedures or methods had been performed. This revision does not affect the existing requirements in §§ 51.212(a) and (b) for periodic testing and inspections, and establishment of a system of violation detection and investigation.

The proposed revisions to § 51.212 contained detailed lists of ''presumptively credible evidence'' and ''presumptively credible monitoring methods.'' After consideration of public comments, EPA has decided to delete these lists because they are potentially confusing and unnecessary. While EPA continues to believe that the listed evidence and monitoring methods are indeed credible, the Agency recognizes that both judicial and administrative tribunals routinely make determinations concerning the admissibility and weight of evidence on a case-by-case basis.

B. 40 CFR Part 52, § 52.12

Section 52.12(c) is revised to clarify that, for purposes of federal enforcement, any credible evidence relevant to whether a source would have been in compliance with applicable requirements if the appropriate performance or compliance test procedures or methods had been performed may be used to establish whether or not SIP violations have occurred. As with § 51.212 above, EPA has deleted the proposed lists of presumptively credible evidence and monitoring methods for the same reasons stated above. Under today's final action, where an emission limitation specifies a particular monitoring or testing method approved by EPA for use in the SIP to determine compliance, data from such method will continue to be the benchmark against which other emissions or parametric data, or engineering analyses, will be measured. Similarly, where there are no approved SIP methods, the test methods specified in part 60 of this chapter will remain the standard against which other such information will be evaluated.

C. 40 CFR Part 52, § 52.30

Proposed § 52.30(a), which concerned compliance certifications, has been revised in accordance with § 51.212 above, and the same comments apply. The enforcement-related § 52.30(b) is rendered unnecessary by today's final § 52.12(c), which effectively

NMED Exhibit 101 - 0003

encompasses it. Finally, the entire section has been renumbered as § 52.33.

D. 40 CFR Part 60, § 60.11

Similar to the existing regulation, § 60.11(a) states that compliance with Part 60 standards shall be determined in accordance with the applicable performance tests and performance testing provisions in this part. A new § 60.11(g) clarifies that nothing in § 60.11 precludes the use, including exclusive use, of any credible evidence or information, relevant to whether a source would have been in compliance with applicable requirements if the appropriate performance or compliance test or procedure had been performed, for purposes of submitting compliance certifications or establishing whether or not a source has violated or is in violation of any Part 60 standard, including opacity standards.

The first sentence in today's final § 60.11(a) has been modified from the proposal. EPA has decided to use mandatory phrasing in the first sentence (''Compliance with standards * * * shall be determined in accordance with the applicable performance tests * * *'') as is included in the existing regulation, rather than adopt the permissive language proposed in 1993 (''Compliance with standards * * * may be determined by performance tests * * *). The rationale for retaining this mandatory language is to make clear that, although the regulation is being modified to clarify that it does not establish an exclusive method of determining compliance, the reference tests remain the benchmark against which other emissions or parametric data, engineering analyses, or other information will be evaluated. For similar reasons, EPA included in § 60.11(g) the requirement that evidence or information gathered by other means than the reference tests be ''relevant to whether a source would have been in compliance with applicable requirements if the appropriate performance or compliance test or procedure had been performed''. This phrase means that the evidence or information must bear on whether a facility would have been found to be in compliance, during the time period in question, if the appropriate performance test had been conducted. It does not mean that, to prove a violation occurred, ideal testing conditions, for example the sun light at a certain angle to the tester for an opacity reading, must exist if other credible evidence, such as continuous opacity monitor data, can establish that a violation occurred. These changes have been made in response to comments that EPA's proposal did not give full recognition to the role of reference tests in determining compliance with emission standards. Section 60.11(g) combines the requirements of the proposed subsections (g) and (h) with the exception of presumptions included in those sections which have been deleted. The clarifying language in § 60.11(g) renders unnecessary the previously proposed language in § 60.11(b). Accordingly, the proposed language for that subsection is deleted from today's rule. The proposed changes to subsection (e) have been deleted as unnecessary due to changes to subsections (a) and (g). Finally, § 60.11(f) is revised so as to clarify that it does not countermand subsection (g).

Under today's revisions, information generated from an appropriate and properly conducted test method established under the general provisions of Part 60 or in the applicable subpart will still generally be the best method for determining a source's compliance during the test period. Other emissions or parametric data, or engineering analyses, may be considered if relevant to the results that would have been obtained by the appropriate, properly conducted reference test methods.

E. 40 CFR Part 61, § 61.12

Today's revisions to § 61.12 generally mirror the revisions to § 60.11, largely for the same reasons. Section 61.12(b) remains unchanged from its current promulgated version because credible evidence has always been used to establish violations of these standards.

III. Major Issues

Throughout the development of this rulemaking, various commenters have expressed concerns regarding the proposed rule's potential effects on CAA enforcement, compliance certifications and emissions standards. The most significant of these comments, together with EPA's responses, are discussed below.

A. Use of Credible Evidence in Enforcement Actions

Commenters raised various concerns regarding the potential use of credible evidence in enforcement actions. Some commenters argued that the use of such evidence would be unconstitutional, unprecedented and unfair. Others expressed concern that EPA, states or citizen groups would use credible evidence to bring enforcement actions for insignificant violations. These comments are addressed below.

Industry commenters have argued that the use of credible evidence in enforcement actions would violate sources' constitutional right to due process. Specifically, the commenters argue that EPA must comprehensively identify the precise types of information that can be used as credible evidence, or else sources will not have sufficient ''fair warning'' regarding potential enforcement. EPA rejects this view. ''Fair warning'' jurisprudence holds that regulated sources must have adequate notice identifying ''the standards with which the agency expects parties to conform.'' *General Electric Co.* v. *U.S. EPA,* 53 F.3d 1324, 1329 (D.C. Cir. 1995). Today's rule does not establish or alter standards with which sources regulated under the CAA must comply. Rather, today's rule only concerns the evidence that can be used to prove violations of a standard, giving full recognition to the role of reference test methods under the standards. The Federal Rules of Evidence govern the admission of evidence in all federal district court litigation, including CAA enforcement actions, without any discernible constitutional infirmity. Similar evidentiary rules govern federal administrative and state environmental actions. Our legal system provides that a federal or administrative law judge will be the ultimate, independent arbitrator of the evidence's admissibility and credibility.

Credible evidence is far from a new concept in judicial and administrative actions. In private lawsuits such as contract disputes, and in governmental and citizen enforcement actions brought under environmental laws other than the CAA, litigants can and do use a wide variety of information to prove their claims, or to refute the claims of opposing parties. In all these lawsuits, the judge acts as the final, independent arbitrator of what constitutes credible and admissible evidence. Today's final rule addresses problems arising from certain CAA regulations, which predate the 1990 Amendments to the CAA, containing language that has been read to allow only a very limited amount of information, i.e., data from reference test methods, to be used as evidence of violations. As such, the rule merely corrects an anomaly that has been read into these regulations, and brings their potential enforcement into line with that of other CAA requirements such as the ''general duty obligations'' in 40 CFR 60.11(d) (for NSPS standards) and 40 CFR 61.22(c) (for National Emission Standards for Hazardous Air Pollutants (NESHAPs)), and with other environmental statutes. It should be emphasized that the determination that evidence or information is credible is merely a threshold determination that

the evidence or information in question is technically relevant, and therefore, legally admissible in an enforcement action. In light of section 113(a) providing that the Administrator may bring an enforcement action based on ''any information'', EPA believes that Congress intended this threshold to be a low one.

Industry commenters have also argued that using credible evidence in enforcement actions is unfair because sources will not know what credible evidence may be used against them. EPA believes that this claim lacks merit. This issue is no different in CAA enforcement than in any civil or criminal matter resolved by our nation's courts. Further, EPA disagrees with the notion that sources will likely be faced with an unknown and unlimited array of evidence. To the contrary, with regard to sources subject to Title V permits, EPA generally expects that most if not all of the data that EPA would consider as potentially credible evidence of an emission violation at a unit subject to monitoring under the agency's proposed CAM rule would be generated through means of appropriate, well-designed parametric or emission monitoring submitted by the source itself and approved by the permitting authority, or through other requirements in the source's permit. Sources not subject to CAM should still be readily able to discern the information, for example information about the operation of pollution control devices, that is relevant to their compliance with applicable regulation.

Some industry representatives have expressed concern that the use of credible evidence in compliance determinations will reveal multiple minor violations for which EPA, the states or citizens will bring lawsuits. It is not EPA's intent to foster frivolous lawsuits, and EPA does not expect that such lawsuits will occur as the result of today's action. As EPA explained in the Credible Evidence March 1996 memorandum, EPA generally focuses its judicial enforcement resources on violations that (1) may threaten or result in harm to public health or the environment, (2) are of significant duration or magnitude, (3) represent a pattern of noncompliance, (4) involve a refusal to provide specifically requested compliance information, (5) involve criminal conduct, or (6) allow a source to reap an economic windfall. *See* March 1996 Memorandum, p. 5.

An examination of EPA's judicial enforcement cases over the past few years reveals that EPA has focused its judicial enforcement resources on large, significant cases rather than a large number of relatively minor matters. The Credible Evidence March 1996 memorandum contains several examples that illustrate this point. In contrast, EPA's approach to minor unexcused violations generally has been to exercise prosecutorial discretion and use tools such as notices of violation and administrative compliance and penalty orders. In every case, EPA considers the nature and extent of the violation and all other circumstances surrounding the violation in determining whether and what kind of enforcement response is appropriate. Further, for any type of noncompliance, EPA generally will not bring a federal enforcement action where a state or local permitting authority has taken timely and appropriate action under existing policies to resolve the violations. Finally, for all violations, EPA will apply all other existing specific enforcement policies, such as the May, 1996, *Policy on Compliance Incentives for Small Businesses*, in accordance with their terms. EPA does not intend to use credible evidence to change any of these policies.

EPA has a balanced enforcement program that seeks to assure compliance using the mix of the compliance and enforcement tools available to it. Deterrence is also an overall goal of the program. Judicial enforcement against minor CAA violations generally is a lower enforcement priority, because EPA believes its other enforcement and compliance assistance tools allow it to respond to such violations without the need to file an action in federal court. Accordingly, in considering whether to bring a judicial action, or whether to use some other enforcement or compliance tool, EPA generally takes into consideration such factors as number and duration of the exceedances, harm or risk posed by the exceedance, potential for recurrence, the source's compliance history, and other circumstances surrounding the violation. For example, if a source were installing a new unit subject to an NSPS standard and had some difficulty getting the control equipment to operate properly after the ''shakedown'' period permitted before the initial performance test (*see* 40 CFR 60.8(a)) but solved the problem promptly after the test, this generally would be a low enforcement priority, absent other circumstances indicating a need for judicial action.

These same general policies regarding EPA's use of judicial and administrative enforcement actions were discussed in Section I.D. of the August 2, 1996, CAM draft approach. Therein, EPA provided various specific examples of circumstances where the Agency was or was not likely to take compliance or enforcement action based on the examination of CAM data.

Finally, the NSPS general provisions and many SIPs generally excuse sources from compliance with emissions limits during periods of startup, shutdown or malfunction. *See* 40 CFR 60.11(c). Some specific NSPS standards additionally excuse sources from compliance during certain operating periods. Exceedances monitored during any of these specifically excused periods are not violations of the emission limit. Moreover, some NSPS standards specify averaging periods for determining compliance and noncompliance. As a result, many short term emissions values when averaged with other values in the relevant averaging period, will not constitute violations. The credible evidence proposal does not change any of these general or specific periods of excused noncompliance, or any averaging periods, or any of their effects on compliance.

Regarding citizen suits, in February, 1996, EPA performed a review of citizen enforcement actions under the Clean Water Act (CWA), and found that citizen enforcers generally do not focus on sporadic, inconsequential violations. This analysis was summarized in the Credible Evidence White Paper, and is included in the Air Docket. Although to date there have been far fewer CAA citizen suits than CWA citizen suits, there have been at least two notable CAA citizen cases involving serious violations: *National Wildlife Federation* v. *Copper Range Co.*, Civil Action No. 2:92–CV–186 (W.D. Michigan), involving one of the largest sources of particulate matter in Michigan's Upper Peninsula, which was emitting particulates at 230 lbs/hour (over five times its permitted limit) and toxic air pollutants including mercury, arsenic, cadmium and lead; and *Sierra Club* v. *Public Service Company*, 894 F. Supp. 1455 (D.C. Col. 1995), involving a power plant that had committed over 19,000 opacity emission violations, which had allegedly affected a nearby wilderness area. Both of these suits were ultimately settled (with the United States an intervenor) for multi-million dollar penalties and significant injunctive relief, including the installation of appropriate pollution controls.

EPA notes that today's rule creates no new rights or powers for citizen enforcers; instead, the rule clarifies existing EPA regulations. Citizens have been free to use credible evidence in Clean Air Act enforcement, and have won at least two court cases using it. *See Sierra Club* v. *PSC*, cited above, and *Unitek Environmental Services* v.

Hawaiian Cement, Civ. No. 95–00723 (D. Hawaii 1996). Also, EPA is aware of no increase in citizen suits in any of the five states—Kansas, Iowa, Nebraska, North Dakota and Georgia—whose SIPs, based on EPA's SIP Call, have specifically clarified that credible evidence can be used for enforcement, or in those states that have credible evidence provisions in other parts of their state law.

Finally, EPA takes this opportunity to further elaborate on certain credible evidence and enforcement issues that were discussed in the August, 1996, draft CAM approach preamble. Therein, EPA explained that ''the CAM rule cannot and does not replace a source's obligation to comply with otherwise applicable emission limits.'' Nonetheless, as a practical matter, ''EPA expects that a unit that is operating within appropriately established indicator ranges as part of an approved CAM plan will, in fact, be in compliance with its applicable limits.'' (*See* draft CAM rule § 64.6(c), which requires that ''the ranges shall be established so as to provide a reasonable assurance of compliance with emission limitations or standards for the anticipated range of operations at a pollutant-specific emissions unit.'') Such a unit generally will not be an enforcement target. However, if the Agency obtains information that the unit is in fact exceeding its applicable emission limit even though it is operating within its approved indicator ranges, the Agency will consider whether or not to take compliance or enforcement action in accordance with its general enforcement policies. Further, under the CAM approach, the source has such information, it would have to promptly remedy the exceedance and notify the permitting authority and submit a proposed permit modification to correct its CAM monitoring as required under draft CAM rule § 64.3(b)(5).

Under today's rule, the legal burdens regarding the establishment of violations or compliance in an enforcement action are not changed. The means of meeting these burdens will vary in different circumstances. Today's rule provides that where information (such as non-reference emissions data, parametric data or engineering analyses) is equivalent to information generated by reference test methods, the former may be used to establish compliance or noncompliance in an enforcement action. There is no need to establish that every test condition specified in a reference test method has been matched by a surrogate condition in the method used to generate the comparable information. Typically, reference test methods (and any additional test conditions specified in individual regulations) quantify the presence of particular physical attributes—for example, mass or concentration of a chemical or group of chemicals—over a specified period of time. As long as these two elements—quantification and specified time period—are retained and the data from the alternate method is related to the reference test, information generated by alternate methods yield data bearing on what the results of a reference test would have been, and the use of such information to establish compliance or noncompliance in an enforcement action will not affect the stringency of the underlying standard. Of course, non-reference data that is already quantified in the same units as the underlying standard, e.g., emissions data generated by properly operating and calibrated non-reference CEMs, should generally be comparable to reference test data, with all specified averaging periods still applying.

For example, Method 9, the NSPS reference method for opacity, requires that a trained visible emissions observer (VEO) view a smoke plume with the sun at a certain angle to the plume in order to properly illuminate it. In contrast, a continuous opacity monitor (COM) contains a calibrated light source that provides for accurate and precise measurement of opacity at all times. Notably, EPA uses COM data to certify and re-certify the credentials of VEOs under Method 9. Accordingly, since a comparable light source is provided by a COM, if COM data were offered in an enforcement action to prove or disprove opacity violations, there would be no need to establish that the sun was shining during the period the COM data was collected. Where a reference test method or test requirements in an individual regulation include plant operating conditions, e.g., a requirement that testing be conducted at a specified percentage of maximum plant capacity, this does not mean that the underlying standard applies only when the plant is operating at that capacity or that the ''other information'' would have to show that the plant was operating at the specified capacity during the period that the other ''credible evidence'' was obtained.

Where a party seeks to introduce other sorts of information in an enforcement action, for example, expert testimony as to whether a unit was able to meet its emission limit based on the operation or nonoperation of its control equipment during the period of alleged violation, the information would still need to be relevant to reference test data in the sense that it must be related to reference test data in some fashion. In the expert testimony example, this might be accomplished by a qualified expert opinion that a reference test would have demonstrated noncompliance in these same circumstances. Finally, where general burdens of proof for the proponent of this information are reduced through statutory provisions or other means, the same reduced burdens will apply in circumstances where EPA uses non-reference test data to assert noncompliance. *See, e.g.*, CAA section 113(e)(2).

B. Use of Credible Evidence in Compliance Certifications

Some commenters argued that today's final action will create new uncertainties and burdens for sources, because sources will not know what information they must consider before certifying compliance with Title V permit requirements. Previously, these commenters argue, sources would have needed to consider only the results of any specified reference tests, whereas under the credible evidence revisions almost any information could be potentially relevant to determining compliance. Thus, as a practical matter sources would need to ''go through every file drawer'' and examine a great deal of additional information before certifying compliance. Even then, sources would not know whether they had reviewed all compliance information that was potentially credible. According to some commenters, even if the source determined its compliance using a reference method, the source would still be uncertain as to whether it could certify compliance during that period, because other contemporaneous information might still indicate noncompliance. Still other commenters argue that allowing a broad array of information to be considered in compliance certifications would render the certification requirement void for vagueness.

At the outset, EPA notes that today's action merely eliminates any potential ambiguity or conflict between Parts 51, 52, 60, and 61 and Part 70 regarding the ability of sources to use non-reference test data in compliance certifications. Consistent with the congressional intent reflected in Title V and section 114(a)(3), Part 70 already contemplates use of non-reference test data in compliance certifications. There are other pending rulemakings—specifically, pending actions involving the CAM approach and Part 70—that are

proposing to modify existing Part 70 requirements to provide additional detail as to what information sources must consider when certifying compliance. Nothing in these rule revisions is meant to specify what degree of correlation there must be between CAM monitoring data and emissions violations or compliance certifications; rather this issue will be discussed in the CAM rulemaking.

In addition, EPA believes that the commenters have greatly exaggerated the purported uncertainties and burdens in certifying compliance under Part 70 and notes that facilities routinely determine their compliance with numerous statutory or regulatory obligations without government imposed ''checklists.'' Under Title V, the source's substantive CAA obligations (i.e., the source's applicable requirements) are clearly set forth in the source's CAA operating permit.

Contrary to the commenters' claims, sources that are certifying compliance using properly conducted continuous reference methods may generally certify compliance based solely on the continuous reference method data, although naturally such sole reliance would be inappropriate in the face of obvious contrary information or fraud as discussed below.

Of course, if a source becomes aware of other material information that indicates that an emission unit has experienced deviations (as that term is defined in the draft CAM approach) or may otherwise be out of compliance with an applicable requirement even though the unit's permit-identified data indicates compliance, the source must consider this information, identify and address it in the compliance certification, and certify accordingly. This ensures, among other things, that sources will not certify compliance in circumstances where doing so would constitute a violation of CAA section 113(c) and 18 U.S.C. Section 1001, which prohibits sources from knowingly making a false certification or omitting material information, or a violation of other prohibitions on fraud. EPA emphasizes, however, that its purpose here is to make clear that sources may not ignore obvious relevant information. EPA does not view compliance certification requirements as imposing a duty on the source to search out and review every possible document to determine its relevance on the issue of the source's compliance.

Following on the above discussion, the Agency takes this opportunity to restate that while a Title V permit can include a ''permit shield'' protecting it from allegations that it has failed to satisfy CAA *monitoring* requirements, such shield does not relieve the source of its obligation to comply with the underlying emission limits or other applicable requirements being monitored. In other words, even where a source receives a ''shield'' providing that the monitoring provisions set forth in its Title V permit constitute compliance with all monitoring requirements of the CAA, the source would not be shielded from allegations of noncompliance with the underlying substantive requirements (e.g., emission limits) being monitored even if the source's required monitoring failed to detect the violation. *See also* the October, 1993, proposal, 58 FR 54678.

Industry commenters argued that allowing credible evidence in Title V compliance certifications would render the certification requirement constitutionally void for vagueness. According to these commenters, reference test methods are necessary to define, in a consistent and reproducible manner, the level of performance that constitutes compliance; without a reference method, an emission limit would be incomplete. As discussed above, EPA in no way intends to eliminate reference tests or to alter their methodology. Instead, these tests, performed as specified under EPA and state regulations, will remain the benchmark against which to compare other emissions or parametric data, or engineering analyses, regarding source compliance.

Finally, numerous commenters argued that allowing credible evidence in compliance certifications and enforcement actions would disrupt the Title V permit process and cause substantial delays in the issuance of these permits because local permitting authorities would have to adjust many of the sources' emission limits, which the commenters contend were not intended to be complied with continuously. Such Title V gridlock could occur only if today's action in fact changed the stringency of emission standards.

C. EPA's Authority To Promulgate the Credible Evidence Revisions

1. Statutory Authority

Today's rulemaking and related SIP call are based primarily on EPA's existing authority prior to the 1990 CAA Amendments. Section 113(a) of the Act authorizes EPA to bring an administrative, civil or criminal enforcement action ''on the basis of any information available to the Administrator.'' This provision provides the Agency with clear statutory authority to use any available information to prove violations of requirements under the Act, and demonstrates that Congress did not intend to limit EPA to using reference test method results in bringing enforcement actions. The language of Section 113(a), together with the fact that the Act nowhere prohibits the use of information other than reference test results to prove violations, indicates that the Act does not limit the use of any information to prove a violation. Therefore, by law the Agency is limited only by general evidentiary rules in what it can use to prove a violation alleged in an enforcement action.

2. The Kaiser Steel Decision Does Not Constrain EPA's Authority To Amend Its Regulations

Although the Act sets no inherent limits on EPA's authority to use any type of information to prove a violation, some EPA regulations provide for specific test methods for determining compliance and have been read by some to constrain EPA's enforcement authority. In *United States* v. *Kaiser Steel Corp.,* No. CV–82–2623 IH (C.D. Cal. Jan. 17, 1984), the district court construed the language of EPA's regulations at 40 CFR 60.11 as limiting the admissible evidence of violations of opacity standards to observations utilizing Method 9, the opacity reference test method. Thus, when the Agency attempted to use expert testimony pertaining to opacity to prove the existence of violations without Method 9 test data, the court rejected the evidence and held that EPA could prove violations only on those days where the Method 9 test was conducted. This decision—which interpreted only EPA's existing regulations, not the Act—was specifically overruled by Congress in the 1990 CAA Amendments. Today's rulemaking is intended to clarify that EPA's regulations do not constrain EPA to using reference tests to prove a violation of an emission standard. Rather, EPA retains its full authority under Section 113(a) to use ''any information'' as the basis for an enforcement action.

3. Despite Commenters' Claims, Clean Air Act Case Law Does Not Mandate Exclusive Reference Tests

At least one commenter has asserted that the decision in *Portland Cement Ass'n* v. *Ruckelshaus,* 486 F.2d 375, 399 (D.C. Cir. 1973), *cert. denied,* 417 U.S. 921 (1974), stands for the proposition that CAA emission standards may be enforced only through an exclusive reference test method. First, the commenter relies on the court's ruling

that a reference test method must make measurements with ''reasonable accuracy'' and be ''objective.'' 486 F.2d at 401 & n. 103. Second, the commenter cited the court's concern with deviations between sampling methods used in gathering data to set an emission standard and sampling methods used in reference methods. The court stated that ''a significant difference between techniques used by the agency in arriving at standards, and requirements presently prescribed for determining compliance with standards [i.e., the reference method], raises serious questions about the validity of the standards.'' 486 F.2d at 396. EPA disagrees with this reading of *Portland Cement.*

These holdings, individually or together, do not support the conclusion that violations of an emission standard may only be demonstrated by an exclusive reference method. The court's statements regarding the reliability of reference methods were made in context of a challenge to an opacity standard. The industry petitioner argued that testing compliance with that standard, inspector observations, is inaccurate and therefore arbitrary. The court agreed that the evidence called the reliability of inspector observations into question and remanded to EPA for it to determine if there was a way to measure compliance with the standard with ''reasonable accuracy.'' In no way did the court imply that the opacity standard had to have an exclusive reference test but simply rejected the test EPA proposed to use as insufficiently supported.

The *Portland Cement* court's discussion of a compliance method that differed from the test method used to develop the standard also lends no support to the conclusion that an exclusive test method is required. It is true that the court mentioned reference methods ''outlined by regulation.'' However, the mere description of an agency practice (here, the inclusion of a reference test in a regulation setting an emission standard) does not transform that practice into a statutory requirement. Moreover, the thrust of the court's remarks was to caution EPA that, where EPA has established by regulation a reference method for sources to demonstrate compliance, the best data EPA can put forth to show that a standard is in fact achievable is data generated by the reference method. The D.C. Circuit, however, has specifically rejected the assertion that standards can only be supported by reference test data. *See National Lime Ass'n* v. *EPA,* 627 F.2d 416, 446, fn.103 (D.C. Cir. 1980). None of this, thus, supports the commenter's claim that a standard's supporting data must be generated using the reference method, and its supposed corollary that only reference method data can be used to enforce the standard, especially where, as here, that other information must be related back to a reference test method. At best, the commenter's arguments would apply only in the context of an original standard-setting, where an emission limitation or other standard newly promulgated by EPA was being challenged on the basis that the standard's supporting data was inadequate. Today's rule sets no new emission or work-practice standards, and amends no existing ones.

Thus, the commenter is mistaken. Neither of the two passages in *Portland Cement* cited by the commenter address whether exclusive reference tests are necessary, much less mandate establishment of such tests. Further, EPA regulations are inconsistent with the exclusivity argument of the commenter. For example, section 60.8(a) of Title 40 of the CFR provides a whole string of circumstances under which a source can alter or completely replace the reference test required by the regulation. Finally, today's final action regarding the use of non-reference test data in enforcement is fully consistent with the court's requirement that reference testing be conducted in a nonarbitrary manner.

4. The 1990 CAA Amendments Further Support EPA's Authority

Various provisions of the 1990 CAA Amendments provide additional support for EPA's position that reference tests are not the exclusive means of proving violations. As noted above, Congress specifically reversed the *Kaiser Steel* decision in Section 113(e) of the Amendments by providing that the duration of a violation may be established ''by any credible evidence (including evidence other than the applicable test method).'' The legislative history for this provision shows that Congress meant to clarify that in an enforcement action courts are not restricted to reference test method data, but may consider any evidence of violation or compliance admissible under relevant evidentiary rules. *See* S. Rep. No. 228, 101st Cong., 1st Sess. 1, 358 (1989) (''Senate Report''), *reprinted in* 1990 U.S. Code Cong. & Admin. News 3385, 3741 (''Reprint'').

Other provisions of the 1990 CAA Amendments also evidence Congressional intent that reference test methods should not be used as the exclusive means for assessing compliance with CAA emission limits. Most pointedly, the requirements in Section 114(a)(3) for enhanced monitoring and for compliance certifications based on a determination of whether compliance was continuous or intermittent presumes that data other than reference tests would be used for these purposes. As explained in the October, 1993, proposal, the use of non-reference test data is also consistent with the monitoring, compliance assurance, and compliance certification requirements in Sections 504(a), 504(c), and 503(b)(2) of the Act. *See* 58 FR 54649–50. In addition, Section 504(b) of the Act grants discretionary authority to the Administrator to prescribe procedures and methods for monitoring, and provides that continuous emission monitoring systems need not be required ''if alternative methods are available that provide sufficiently reliable and timely information for determining compliance.'' In sum, Congress' repeated emphasis on providing reliable and timely compliance information is inconsistent with the notion that only data from infrequently performed reference tests is relevant to compliance certifications and enforcement actions.

5. Commenters' Attempts To Narrow the Scope of Sections 113(e) and 113(a) Are Unpersuasive

Several industry commenters have claimed that the legislative history of the 1990 CAA Amendments shows that section 113(e)(1) does not provide authority for today's final action. Additionally, these commenters have asserted that the section's legislative history upon which EPA has relied is ambiguous.

In the October, 1993, proposal, EPA cited to the Senate Report's discussion of Section 113(e)(1). The Senate Report stated:

> This title of the bill enhances the ability of the Environmental Protection Agency * * * by making clear that the Agency may rely upon any credible evidence of violations in pursuing alleged violations.

Senate Report at 358, Reprint at 3741. The Report further explained:

> [T]he amendment clarifies that courts may consider any evidence of violation or compliance admissible under the Federal Rules of Evidence, and that they are not limited to consideration of evidence that is based solely on the applicable test method in the State implementation [plan] or regulation. For example, courts may consider evidence from continuous emission monitoring systems, expert testimony, and bypassing and control equipment malfunctions, even if these are not the applicable test methods. Thus, this amendment overrules the ruling in *United States v. Kaiser Steel Corp.,* No. 82–2623 (C.D. Cal. January 17, 1984) to the extent that

the court in that case excluded the consideration of such evidence.

Senate Report at 366, Reprint at 3749. Finally, the Report notes that data from enhanced monitoring and compliance certifications ''will facilitate enforcement, due in part to the fact that such data and certifications can be used as evidence.'' Senate Report at 368, Reprint at 3751.

The commenters, in turn, rely on the views of Senator Chafee regarding S. 1630, inserted into the Congressional Record at the time the legislation was introduced. Senator Chafee stated with regard to Section 113(e)(1):

> Subsection 113(e) also clarifies and confirms that once EPA establishes evidence of a violation using a formal test method, EPA can use other credible evidence to prove additional violations, or that violation has continued.

135 Cong. Rec. S 9650, 9655 (August 3, 1989).

EPA believes that the best reading of the legislative history still supports its interpretation of Section 113(e)(1). First, there is no ambiguity in the Senate Report, the language of which unreservedly supports enforcement actions brought on the basis of non-reference test data. Second, EPA does not believe that Senator Chafee's floor statement outweighs the clear statement in the Senate Report. The Senate Report is a more authoritative reflection of congressional intent than a floor statement produced at the beginning of the legislative process.

Various commenters also objected to EPA's reliance on Section 113(a) as a basis for today's action. One commenter argued that Section 113(a) does not preempt regulatorily specified reference test methods. Several commenters asserted that EPA's construction of Section 113(a) would render superfluous the new language in Section 113(e)(1) concerning credible evidence. These commenters claim that, under EPA's interpretation of Section 113(a), Congress could have ''fixed'' the *Kaiser Steel* decision simply by clarifying the scope of EPA's authority under Section 113(a).

These various commenters have misunderstood EPA's interpretation of Section 113(a). EPA has not asserted that Section 113(a) preempts reference test methods. Rather, EPA believes that Section 113(a) provides authority to amend current regulations to make clear that data from reference test methods are not the exclusive means of establishing noncompliance or compliance in enforcement actions. Given this interpretation of Section 113(a), Congress's passage of Section 113(e)(1) cannot be described as superfluous—particularly in light of the decision in *Kaiser Steel.*

6. EPA Can Promulgate the Credible Evidence Revisions Without Reproposal

Several commenters have argued that finalization of the proposed changes in Parts 51, 52, 60 and 61 without first reproposing those changes violates the Administrative Procedure Act (APA), the CAA, and due process. The commenters' main argument is based on EPA's presumed change in course on implementing the requirement in Section 114(a)(3) concerning enhanced monitoring and compliance certification. As noted above, the changes to Parts 51, 52, 60 and 61 were proposed in the same rulemaking that proposed an enhanced monitoring and compliance certification program. Since that proposal, EPA has re-evaluated its approach to enhanced monitoring and has made publicly available and has sought comment on a revised approach—the CAM approach—for satisfying the same statutory goals as the original enhanced monitoring proposal. Some commenters contend that switching to CAM will fundamentally change their view of the proposed changes to Parts 51, 52, 60 and 61 because those proposed changes were evaluated only in terms of how they would be implemented under the October, 1993, proposal on enhanced monitoring. Until CAM is formally proposed, these commenters assert, they cannot give meaningful comments on the credible evidence revisions. Further, the commenters argue that the proposed revisions provided insufficient notice and opportunity to comment because EPA has not adequately defined the term ''credible evidence.''

EPA believes today's rule has no procedural infirmities. EPA is today finalizing the enforcement-related portions of the proposal it made in 1993 with only minor changes.

The commenters' claim that they cannot meaningfully comment on credible evidence revisions prior to proposal of the CAM approach is not well-taken for two reasons. First, EPA does not believe that any knowledge of the draft CAM approach is necessary to comment on today's rulemaking. In today's final rule, EPA has removed any presumptions regarding the credibility of any specific data. If and when the draft CAM approach is finally adopted, CAM data will be treated under today's rule like any other potential source of compliance information. Thus, knowledge of the draft CAM approach is not critical to commenting on this rulemaking. In any event, the nature of the draft CAM approach has been generally available in some detail since September, 1995—well before EPA renewed its request for comment on today's rulemaking. Further, EPA has sought and received additional comment on the enforcement consequences of the draft CAM approach by distribution of a revision of the CAM approach in August, 1996. The revised approach specifically discussed the relationship of the draft CAM approach and today's action.

Second, the October, 1993, proposed rulemaking gave interested parties sufficient notice of the issues raised by the proposed changes to Parts 51, 52, 60 and 61. The Agency made clear that these revisions were designed to remove any potential ambiguity regarding the use of enhanced monitoring data in compliance certifications, and to clarify that any credible evidence of a violation of an emission standard was admissible to prove (or disprove) such a violation. *See* 58 FR 54677. To clarify that these credible evidence revisions extended beyond the data gathered under an enhanced monitoring program, EPA gave two specific examples of evidence collected outside the enhanced monitoring program that under the revised regulations could be used to prove a violation. *See* 58 FR 54676–54677. Thus, the October, 1993, proposal clearly put interested parties on notice that the credible evidence revisions were not merely an adjunct to the enhanced monitoring program. In fact, industry commenters on the October, 1993, proposal clearly understood the central issue posed by the proposed credible evidence changes, and they commented on it extensively. Today's final action promulgates revisions to *existing* regulations, and are not contingent upon *future* promulgation of the CAM approach or any other form of enhanced monitoring requirement.

Neither is this rulemaking procedurally deficient for not providing an express regulatory definition of the term ''credible evidence''—a term which Congress itself inserted, without definition, into the Act. The issues of credibility, admissibility and weight of evidence have been exhaustively addressed by federal and state court evidentiary rules regarding evidence, and the thousands of cases decided under them. Today's final action defers to those regulations and makes clear that there are no bars in regulations under the CAA which prevent the use of evidence or information other than reference test methods in compliance certifications and enforcement actions. Of course, in judicial enforcement

proceedings, what evidence is credible and admissible will be determined by the court taking into account how the evidence was gathered and the specifics of the emission standard and any associated reference method.

Finally, EPA believes that it has taken extensive steps, detailed in Section I.C. above, to ensure that the concerns of affected parties were fully aired. None of the additional public outreach actions that EPA undertook in 1996 were required by the APA or the CAA; instead, EPA undertook them voluntarily to ensure full input by interested parties regarding the credible evidence rules.

D. Stringency

Industry commenters have presented several arguments in support of their position that this rulemaking requires sources to be in continuous compliance and thus would effectively increase the stringency of underlying requirements, including SIP limits and standards established by EPA under the NSPS and NESHAP programs.

EPA believes that industry's arguments on this point are fundamentally wrong. It is not EPA's intent that these rules should increase the stringency of any applicable requirement. These rules do not do so because they maintain the focus of the compliance determination on whether or not the appropriate reference test would have shown a violation.

The commenters' arguments regarding increased stringency are as follows: applicable requirements are accompanied by specified reference tests. Any departure from past practice regarding the use of these tests, including the use of other credible information to directly assess compliance, particularly on a more frequent basis, will inevitably change the results of an inquiry into the compliance status of any source compared to exclusive reliance on the infrequent performance of the reference tests. Therefore, industry argues, using credible evidence would change the underlying applicable requirements—usually in a manner that makes them more stringent—without going through the necessary rulemaking procedures.

Industry's argument hinges on the premise that adoption of an emission standard that includes a particular form of reference test—one that is not required to be performed continuously as a matter of course—limits the compliance obligation. The scope of the compliance obligation is not at issue in this rulemaking. The scope of the compliance obligation prescribed by any particular standard shall be based on the emission standard and not this rulemaking. However, to fully respond to industry comments, and to give notice of the position EPA will take in future enforcement proceedings, EPA believes it is necessary to address in some detail the nature of the compliance obligation under emission standards with particular emphasis on the compliance obligation as it pertains to emission standards which have a reference test method that is not required to be performed continuously.

While the bulk of the commenters' concerns were expressed with respect to NSPS, the same concerns also apply in most cases to NESHAPs and SIPs. Likewise, EPA's responses focus on NSPS, but are generally applicable to other emissions limits as well.

1. Emissions Limits Require Continuous Compliance (Consistent With Any Averaging Times) Except During Periods Where Compliance Is Specifically Excused

To resolve commenters' claims of increased stringency, the nature of the compliance obligation facing owners and operators of sources of air pollution under the Act must be addressed. Under the CAA, its regulations, and the case law, a source's compliance with emission limitations must be continuous (consistent with any averaging times) except where a particular emission standard specifically provides for periods of noncompliance.

The Statute. The Clean Air Act defines the terms ''emission limitation'' and ''emission standard'' as meaning ''a requirement established by the State or the Administrator which limits the quantity, rate, or concentration of emissions of air pollutants on a *continuous* basis * * *.'' CAA section 302(k) (emphasis added). In accordance with this clear statutory statement, the Act authorizes penalties for multiple days of violation should a source fail to meet its continuing obligation. *See also* CAA sections 113(e)(2) (providing that ''a penalty may be assessed for each day of violation,'' and establishing a presumption of continuing violation if certain conditions are met) and 113(e)(1).

CAA Regulations. The Act's general requirement of continuous compliance is mirrored in the NSPS regulations, which generally require that sources comply with established emission limits except during certain defined time periods. NSPS provisions typically specify that compliance with stated limits is required ''on and after the date'' of an initial performance test conducted in accordance with 40 CFR 60.8. *See, e.g.,* 40 CFR 60.502. The need for continuous compliance is also discussed in the preambles to numerous NSPS, including many older ones. For example, in proposing standards for glass manufacturing plants (Subpart CC), EPA stressed the need for effective monitoring to assure that affected facilities are ''continuing to maintain the emission reduction observed during the performance test.'' 48 FR 50670, 50675 (1983). EPA has also made this point clear in publicly-available guidance memoranda. *See* Detailed Response Document at Section 4.

In addition to requirements for continuous compliance, NSPS regulations also typically contain specifically excused periods of noncompliance. These periods confirm that compliance is required at other times. They also confirm the basic reasonableness of this compliance scheme—that is, sources must generally comply continuously with their numerical emission limits, but not during periods of specifically excused noncompliance, and only in accordance with any specified averaging periods. For example, for many standards, compliance is not required during periods of startup, shutdown or malfunction. This exception is contained in the NSPS general provisions and in individual standards. *See* 40 CFR 60.8(c); *see also, e.g.,* 40 CFR 60.46a.

Case Law. In various judicial decisions, courts have approved of the basic NSPS regulatory scheme of continuous compliance accompanied by limited, specified exceptions for noncompliance. The courts have stated that the specified exceptions are needed because sources must comply at all other times. *See, e.g., Portland Cement,* 486 F.2d at 399 (court noted EPA's then-proposed ''startup, shutdown and malfunction'' compliance exclusion regulation with approval, suggested that it was a ''limited safety valve'' and stated that it imparts a construction of ''reasonableness'' to the standards as a whole and adopts a more flexible system of regulation that can be had by a system devoid of ''give''; (*Essex Chemical Corp.* v. *Ruckelshaus,* 486 F.2d. 427, 433 (D.C. Cir. 1973), *cert. denied,* 416 U.S. 969 (1974) (in a challenge to sulfuric acid plant and coal-fired steam generator NSPS standards, the court again noted with approval the proposed start-up, shutdown and malfunction exception and remanded the rule stating that ''such variant provisions appear necessary to preserve the reasonableness of the standards as a whole and that the record does not support the ''never to be

exceeded'' standard currently in force'') (emphasis added); and *Bunker Hill Co.* v. *EPA,* 572 F.2d 1286, 1301–02 (9th Cir. 1977) (in challenge to SIP sulfur dioxide standard, court observed that EPA regulations required that the standard be met ''all of the time,'' and thus EPA must typically promulgate upset provisions to excuse noncompliance beyond the source's control). Similarly, the proposition that compliance must be continuous is reflected in numerous judicial decisions involving challenges to various NSPS rulemakings. In these cases, both the D.C. Circuit Court and industry petitioners have emphasized that for an emission standard to be achievable it must be able to be continuously complied with over wide operating ranges at varied facilities. *See, e.g., Portland Cement, Essex Chemical, National Lime,* and *Sierra Club* v. *Costle,* 657 F.2d 298 (D.C. Cir. 1981). In *National Lime,* for example, the lime industry's trade association itself complained that the data underlying the promulgated numerical emission standards were insufficient to show that the standards were ''in fact achievable on a continuous basis.'' 627 F.2d at 430. In holding that EPA had not adequately demonstrated the achievability of the standards for the industry as a whole, the court explained that ''to be achievable, we think a uniform standard must be capable of being met under most adverse conditions that can reasonably be expected to recur . . . .'' *Id.* at 431. In *Sierra Club* v. *Costle,* various electric utility companies challenged a particulate standard on the basis that ''the data reflect only short term performance while the standard requires long term continuous compliance.'' 657 F.2d at 377 (emphasis added). This challenge was rejected by the court based on data showing that certain sources had ''consistently complied with the standard.'' *Id.* at 382.

2. Commenters' Advocacy of Noncontinuous Compliance Would Lead to Numerous Anomalies

Some industry commenters have argued that numerous emissions limitations do not require continuous compliance or, alternatively, that ''continuous'' does not have the straightforward meaning suggested above. The commenters' argument centers on NSPS standards issued under CAA section 111. In the commenters' view, many such standards do not contemplate that facilities will operate in compliance on a continuous basis with stated emissions limits, but rather require only an initial demonstration of compliance with stated limits upon start-up or shortly thereafter. After an initial performance test, continuous compliance is required only with respect to operation and maintenance ''in a manner consistent with good air pollution control practice'' as specified in 40 CFR 60.11(d). As to numerical emissions limits, commenters suggest that these must be met only on those infrequent occasions that a subsequent performance test is conducted. So long as any such performance test is passed, the source is in ''continuous'' compliance with numerical emissions limits without regard to whether its emissions in fact exceeded the numerical limit during the time between the tests, no matter how long that may be.

EPA rejects this view of the nature of the obligation to comply with NSPS and other emission limits under the CAA. *See* Detailed Response Document. EPA and the courts have long held that emission limits must be complied with continuously, consistent with any associated averaging periods, except where a particular limit provides otherwise. Adopting the commenters' view of compliance would lead to numerous anomalies.

In the April 2, 1996, public meeting and in follow-up written comments, several commenters argued that many reference test methods were selected specifically because they would only be performed infrequently—for example, on a yearly basis. These once a year tests would be proper for their associated emission standards, which in the commenters' view were intended to be complied with only 95% of the time. Specifically, performing a reference test once a year would yield ''acceptable'' compliance results, because on average a source would be found out of compliance only 5% of the time—that is, in one in twenty tests, or once every twenty years. According to these commenters, testing for compliance more frequently would be unfair, because it would increase the likelihood that the source would be found out of compliance during periods where the standard itself contemplated noncompliance. In order to avoid being found in noncompliance, sources would have to continuously stay below their emission limits—which in these commenters' view would effectively increase the stringency of the emission standard.

EPA disagrees with the commenters' notion that sources must meet their legal numerical air emission limits only seldomly. Further, EPA rejects as inconsistent with the Act and its underlying purposes the notion that sources can somehow be in routine ''compliance'' without staying within these limits on an ongoing basis. The fundamental goal of the CAA and the emission standards established under it, is to achieve clean air. Moreover, many emission standards, such as hazardous air pollutant standards under Section 112 and emission standards in State Implementation Plans designed to implement national ambient air quality standards, have a direct relationship to the protection of human health. Routine compliance with numerical emission standards is critical to achieving this goal. The commenters' view that such compliance is somehow not required would completely undercut these public health and safety goals.

If the commenters' view was correct, any EPA or state targeting of a specific source by requiring the source to perform more frequent reference tests would be unfair and presumably illegal, because any such increased frequency in reference testing would destroy the delicate balance of frequent noncompliance and infrequent testing that the commenters claim is contemplated by the rules. Under this view, EPA and states might not be able to require an apparently violating source to conduct a previously unscheduled reference test, because it would improperly raise the source's chances of being found in noncompliance and thereby ''increase the stringency of the underlying standards.''

The commenters'' argument is also inconsistent with the language, structure, and purpose of the CAA. For example, if the frequency of testing must be limited to meet the intent of the emission limits, to be fair to all sources EPA's regulations should have required that the tests be performed only at infrequent intervals. EPA's rules contain no such restrictions; rather, CAA section 114(a)(1)(D) grants EPA broad discretion to order reference tests whenever the Administrator deems it appropriate. Moreover, commenters'' argument is inconsistent with CAA section 113(e)(1), which even on its narrowest reading (note that EPA's reading is considerably broader) specifically provides for use of non-reference test data to prove continuing additional days of violation after an initial violation is established by reference test data, and by CAA section 113(e)(2), which establishes a presumption of continuing violation after notice of the violation has been given to the source, provided that EPA can make a prima facie showing that ''the conduct or events giving rise to the violation are likely to have continued or recurred past the date of notice.'' This presumption continues until the violator ''establishes that continuous compliance has been achieved.''

Likewise, sections 114(a)(3) and 504(a)-(c) regarding enhanced monitoring and certification as to whether compliance is continuous or intermittent, and prompt reporting of deviations, are simply inconsistent with a regulatory regime that would require only occasional demonstrations of compliance with emission limits. Taken together, these provisions, represent a fundamental statutory rejection of the commenters' argument. *See* Detailed Response Document, Section 4, which discusses other reasons why these comments are without merit.

3. Comments Regarding Continuous Compliance Are Not Directed at Today's Action, but Rather at Underlying Emission Standards

Industry commenters have argued that the quality and quantity of the data used in establishing emissions limitations, such as those under the NSPS and NESHAP programs, reflect a conscious decision by EPA that compliance with such standards would need to be demonstrated only periodically. It follows that requiring continuous compliance with stated limits at this juncture would effectively increase the stringency of the standards. As discussed above, EPA believes that the commenters' general arguments strain common sense. Commenters have pointed to various NSPS standards to support their views, but EPA finds these examples unpersuasive.

In particular, commenters have pointed to the NSPS for kraft pulp mills, 40 CFR Part 60, Subpart BB, and for steam electric generators constructed between 1971 and 1978, Subpart D, as reflecting a general acknowledgment by EPA that national standards need not be complied with at all times. EPA believes that, to the contrary, Subparts BB and D and other cases demonstrate that where EPA intended to allow affected sources to exceed stated emissions limits, the standards in question expressly so provide. It is true that in the development of some NSPS and NESHAP standards, EPA was concerned with the limited number and distribution of test runs and the inherent variability in levels of emissions from even well-controlled facilities. Where appropriate, EPA addressed those concerns by adjusting the numerical value of the standard, providing excess emissions allowances and provisions for noncompliance during certain upset conditions, or through changes in averaging times. With other standards, EPA did not provide for any departure from the general requirement that compliance must be continuous. Examples of all these approaches, and specific responses to comments regarding Subparts D and BB, are provided in the Detailed Response Document.

The commenters' assertions that sources cannot comply on a continuous basis are really directed not to the propriety of today's rules, but rather to the adequacy of the underlying NSPS and other emission standards that are not at issue in this rulemaking. To the extent there is any documentation that a well-run facility cannot comply consistently with underlying national emission standards, or applicable SIP requirements, such documentation would be relevant only to those existing standards, not to today's rule. EPA notes that despite several requests to commenters to identify any standards that cannot be complied with on a regular basis, no specific information has been provided to this rulemaking docket that demonstrates that well operated and maintained facilities employing pollution control technologies of the types upon which the underlying emission standards were based cannot comply with those standards on a continuing basis. The most that was submitted was a statistical re-analysis of the data relied upon by EPA in promulgating several emission standards and a one page graph purporting to show that an industrial boiler could not comply with the NO_X emission limit at low levels.

The agency has considered this comment concerning the Subpart D NO_X standard carefully, as it does not intend to impose requirements that are impossible for well-designed sources to meet, but believes that this concern is largely theoretical. The information provided by the commenter to EPA was vague and did not prove that the undisclosed source could not comply with the emission standard. Further, if a standard was impossible to achieve under some circumstance, EPA and citizens are not likely to bring enforcement cases in such instances. In reviewing CAA enforcement actions the agency has been unable to identify any case where either the agency or a citizen sought to enforce a standard that was impossible to achieve. The agency was also unable to identify any case in which a defendant established that compliance was not possible at the time of the alleged violation. This appears to be the case even in those states and localities that have had ''credible evidence'' rules for years.

Additionally, should it be determined that a standard could not be met during some relatively infrequent or inconsequential period of source activity, the potential for significant adverse impact on that source is remote. The agency has previously expressed its policy that, generally, judicial enforcement is not the appropriate vehicle to redress sporadic, infrequent violations with no environmental consequence. Further, it is unlikely that a citizen could prevail in enforcing a theoretically impossible standard since Courts will not issue an injunction where there is nothing to be done. Similarly, where one cannot establish that a source failed to act in a manner required by law a significant penalty will not be imposed by the courts. The agency is not aware of any situation in which it has filed, and one should not anticipate large numbers of citizen suits being filed, where there is nothing the source could have done or could do to achieve a greater degree of compliance. Moreover, the courts today have additional tools, including fee awards and sanctions available under the Federal Rules of Civil Procedure and other statutes to address meritless suits.

In further response to these industry comments, EPA has included in the record a 1993 study conducted by EPA Region V that shows that almost all (95%) of sources with sulfur dioxide CEMs were meeting their federal and state sulfur dioxide emission limits approximately 97% of the time, with excess emission periods totaling only 3%. *See* Region V Study, Figure 2. Because this 3% figure included excess emissions recorded during periods in which compliance is specifically not required, such as startup and shutdown, the percentage of operating time in noncompliance with the standard is even smaller and may mean that most sources are in compliance all the time. EPA Region V sources with continuous opacity monitors showed similar results: the average source's percentage of opacity exceedances was less than 2%, with 95% of sources at or below approximately 4%. *See* Study, Figure 1. As with the sulfur dioxide data, opacity exceedances during periods of startup, shutdown and other excused periods were not excluded. Accordingly, the percentage of actual noncompliance with opacity limits was even smaller. Note that these figures are for the average (50th percentile) and worst (95th percentile) facilities. The best run facilities have fewer excess emissions reports.

Additional CEM data from EPA Region V that focused specifically on exceedances from NSPS Subpart D SO_2 emission standards shows similar results. This data shows that Subpart D sources report few or no excess SO_2 emissions. Approximately two-thirds of the sources report no excess emissions

at all, during any three month reporting period. Further, since 1990, the vast majority of sources (95%) have reported total excess emissions averaging less than 2.5% of operating time; since 1993, less than 1.7%. Since these figures include all excess emission periods, including periods that are probably excused, the actual SO_2 exceedance rates were even lower.

These data show that there are not ''fundamental flaws'' in the subject standards such that the standard cannot be met. *Indeed,* the data demonstrate that most sources do comply all or nearly all of the time.

If the regulated community believes that a standard cannot be met across some meaningful range of normal operating conditions, or if specific exemptions beyond those currently provided are proper, we believe the appropriate action is for the affected industry to file a petition for amendment of the standard at issue or propose more specific permit conditions so that the matter can be fully assessed and addressed through the regulatory process. However, the information submitted by the commenters does not show that there currently exists a significant ''impossibility'' issue that is so widespread as to outweigh the benefits of the proposed rule.

4. Enforcement Using Continuous Monitoring Data Does Not Increase the Stringency of Applicable Requirements

Industry commenters have argued that the stringency of emission standards will be increased if enforceable data is obtained more frequently than has been ordinarily obtained in the past through reference testing. Further, the commenters argue that direct enforceability of this data would contradict EPA's stated positions in adopting standards under the NSPS and NESHAP programs because EPA intended that continuous monitoring would only show compliance with good operation and maintenance procedures, i.e., general duty requirements, and would not be otherwise used in enforcement. (*See, e.g.,* 38 FR 10820 (1973) (preamble to proposed startup, shutdown and malfunction regulation); 43 FR 7571 (1978) (preamble to final kraft pulp mill standards).

Because the NSPS and NESHAP emission standards must be met continuously, consistent with any averaging times and except during periods where compliance is specifically excused, any more frequent or continuous monitoring of the standards and any enforcement based on violations uncovered thereby have no effect on the stringency of the standards. To take a simple analogy, allowing the use of radar guns or increasing the number of police checking for speeding may raise the chance that a speeder will be detected, but this does not alter the legal stringency of a posted speed limit.

In some early NSPS, the agency required the installation of what were styled ''indicator monitors'' and provided policy guidance that such monitoring data would not be used as the sole basis of enforcement actions absent further rulemaking. 38 FR 10820. To the extent that the CAA Amendments of 1990 did not supersede this policy statement, today's action is that future rulemaking. These policy statements, like today's rulemaking, pertain only to the kinds of evidence EPA uses to prove violations. The policy change that was contemplated in our 1993 proposal and 1996 memorandum are supported by technological advances in the accuracy and reliability of continuous emission monitors, deficiencies in EPA's previous practices identified by GAO and others, and the language and intent of the Act and the 1990 CAA Amendments.

EPA's past statements regarding limitations on the use of data derived from continuous monitoring methods for purposes of enforcing standards were motivated in part by concerns over the cost and availability of such methods and their ability to accurately determine compliance. *See, e.g., National Lime,* 627 F.2d at 450 (responding to petitioners' argument that there was no adequately demonstrated technology for monitoring opacity, EPA stated that the continuous monitoring data would not be used to determine compliance with the opacity standard but ''to keep a check on the operation and maintenance of the control equipment,'' and that the monitors were reliable enough to perform this limited function). For example, in the 1973 startup, shutdown and malfunction regulation proposal, EPA noted that while continuous monitoring data would not, at that time, be used to determine compliance as a general matter, such data could be used if ''approved as [an] equivalent or alternative method for performance testing.'' 38 FR 10820. Indeed, the NSPS general provisions have long provided that in lieu of performance tests using reference methods, a source could demonstrate compliance using an approved equivalent or alternative method, and that EPA can waive reference tests where the source has otherwise satisfactorily demonstrated compliance. *See* 40 CFR 60.8(b).

Since the 1970s, the availability, cost and accuracy of methods that enable determinations of compliance on a continuous basis has improved markedly. *See, e.g.,* 1990 GAO report at 19, 22–23 (1986 and 1988 EPA studies showed CEM data highly reliable); *Continuous Emission Monitoring,* 1993, Jahake, Thomas Publishing Co. For these reasons, EPA believes it is appropriate as a technical matter to allow information derived from these methods to be used in compliance certifications and enforcement actions. In fact, more recent national standards issued by EPA provide for determining and enforcing compliance directly by use of continuous monitoring data.

5. Sources Must Comply Both With Good Operation and Maintenance Requirements and With Emission Limits

Industry commenters have claimed that as to the NSPS program, the only goal of the program was to insure that best demonstrated technology was employed, such that once an initial reference test demonstrated that compliance with the standards could be achieved, it need not be demonstrated thereafter, and that an affected source's only ongoing obligation was its ''general duty'' to employ good operation and maintenance practices to minimize emissions in accordance with 40 CFR 60.11(d).

EPA agrees that proper operation and maintenance of an emissions unit and any associated pollution controls in accordance with 40 CFR 60.11(d) is vital to complying with emission standards. However, while it is true that sources have a continuing duty to employ good operations and maintenance practices, this duty does not substitute for the sources' obligation to comply with its emission limits. The two obligations, while related, are separate requirements in the NSPS regulations and in legal effect.

EPA has made these points plain as far back as 1973 in the proposed NSPS startup, shutdown and malfunction rulemaking:

> It is anticipated that the initial performance test and subsequent performance tests will ensure that equipment is installed which will permit the standards to be attained and that such equipment is not allowed to deteriorate to the point where the standards are no longer maintained. In addition, the proposed regulation requires that the plant operator use maintenance and operating procedures designed to minimize emissions in excess of the standard.

38 FR 10820 (1973) (emphasis added). This preamble text clearly states both that proper equipment maintenance is vital to remaining within an emission

standard (otherwise equipment would deteriorate to the point where standards were not met) and that the general operation and maintenance obligation is a separate regulatory requirement. Additional discussion of the distinction between the emission limits and good operating practice requirements can be in the Detailed Response Document. These statements make it clear that good operating practices requirements are separate and distinct from the need to continuously comply with emissions limits.

E. SIP Call

In the October, 1993, proposal, EPA announced that it planned to call for States to amend their applicable implementation plans to ensure that owners or operators may use enhanced monitoring (or other monitoring approved for the source pursuant to part 70) for compliance certification purposes, and that data from this monitoring, along with any other credible evidence, may be used as evidence of a violation of an applicable plan. 58 FR 54660. In December, 1993, and February, 1994, the Office of Air and Radiation's Stationary Source Compliance Division, the division then responsible for writing and implementing the enhanced monitoring rules, issued memoranda to EPA's Regional offices instructing them to conduct the SIP call. As of September, 1996, fifteen states and local air pollution control districts, together with the Commonwealth of Puerto Rico, had responded to the call and submitted SIP amendments for EPA approval. Kansas, Iowa, Nebraska, North Dakota, Georgia and Puerto Rico had received approval; the other states and districts' revisions were pending.

For substantially the same reasons that allow EPA to go forward with today's final rule, EPA has the authority to initiate and continue this SIP call. EPA's decision to forego the enhanced monitoring approach in favor of the CAM proposal has no effect on the basic goals of the SIP call, which are to clarify that non-reference test data can be used in enforcement actions, and to remove any potential ambiguity regarding this data's use for Title V compliance certifications.

Today's action ensures that the evidentiary rules for CAA violations are consistent in all fifty states. EPA has surveyed those states that have responded to the SIP call and has determined that the credible evidence changes have not created the difficulties forecast by the commenters.

IV. Administrative Requirements

A. Docket

Today's final rulemaking action is subject to Section 307(d) of the Act. Accordingly, EPA has established a docket (No. A–91–52), which consists of an organized and complete file of all information submitted to, or otherwise considered by, EPA in the development of today's action and the CAM approach. The docket includes all memoranda and studies cited by EPA in this preamble. The principal purposes of the docket are: (1) to allow interested parties a means to identify and locate documents so that they can effectively participate in the rulemaking process, and (2) to serve as the record in case of judicial review. The docket is available for public inspection at EPA's Air Docket, which is listed under the **ADDRESSES** section of this document.

B. Office of Management and Budget (OMB) Review

Today's rulemaking is not a ''significant regulatory action'' because the revisions make only evidentiary changes and do not impose any additional implementation costs on regulated sources. Nevertheless, EPA submitted this final rule to OMB for review. Changes made in response to OMB suggestions and recommendations will be documented in the public record.

C. Unfunded Mandates Reform Act

Under section 202 of the Unfunded Mandates Reform Act of 1995 (UMRA), Public Law 104–4, EPA generally must prepare a budgetary impact statement to accompany any proposed or final rule that includes a Federal mandate that may result in expenditure by State, local, or tribal governments in the aggregate, or by the private sector, of $100 million or more. Before promulgating a rule for which such a statement is needed, section 205 of the UMRA generally requires EPA to identify and consider a reasonable number of regulatory alternatives and adopt the least costly, most cost-effective or least burdensome alternative that achieves the objectives of the rule. The provisions of section 205 do not apply when they are inconsistent with applicable law. Section 203 requires the Agency to establish a plan for obtaining input from and informing, educating, and advising any small governments that may be significantly or uniquely affected by the rule.

EPA has determined that this rule does not contain a Federal mandate that may result in expenditures of $100 million or more for State, local, and tribal governments, in the aggregate, or the private sector in any one year. Today's rulemaking makes only evidentiary changes and does not impose any additional costs on regulated sources or State, local, or tribal governments. For the same reason, these evidentiary changes will not significantly or uniquely affect small governments. Accordingly, this rulemaking is not subject to the requirements of sections 202, 203, and 205 of the UMRA.

D. Regulatory Flexibility Act

EPA has determined that it is not necessary to prepare a regulatory flexibility analysis in connection with this final rule. EPA has also determined that this rule will not have a significant economic impact on a substantial number of small entities. As explained above, this rulemaking does not impose any additional implementation costs on small or large entities.

E. Paperwork Reduction Act

The information collection requirements for the proposed enhanced monitoring rule were previously submitted for approval to OMB under the Paperwork Reduction Act (PRA), 44 U.S.C. 3501 *et seq.* In contrast, today's rule does not contain any information collection requirements subject to OMB review under the PRA.

F. Submission to Congress and the General Accounting Office

Under 5 U.S.C. 801(a)(1)(A) of the Small Business Regulatory Enforcement Fairness Act of 1996 (Pub. L. 104–121, 110 Stat. 847), EPA submitted a report containing this rule and other required information to the U.S. Senate, the U.S. House of Representatives and the Controller General of the General Accounting Office prior to publication of this rule in today's Federal Register. For the same reasons that this rulemaking is not a ''significant regulatory action'' under Executive Order 12866, this rule is not a ''major rule'' as defined by 5 U.S.C. 804(2).

List of Subjects

40 CFR Part 51

Environmental protection, Air pollution control.

40 CFR Part 52

Air pollution control.

40 CFR Part 60

40 CFR Part 61

Air pollution control.

Dated: February 13, 1997.

Carol M. Browner,

Administrator, U.S. Environmental Protection Agency.

For the reasons set out in the preamble, 40 CFR Chapter I is amended as follows:

PART 51—REQUIREMENTS FOR PREPARATION, ADOPTION, AND SUBMITTAL OF IMPLEMENTATION PLANS

1. The authority citation for part 51 is revised to read as follows:

Authority: 42 U.S.C. 7401, 7411, 7412, 7413, 7414, 7470–7479, 7501–7508, 7601, and 7602.

2. Section 51.212 is amended by revising paragraph (c) to read as follows:

§ 51.212 Testing, inspection, enforcement, and complaints.

* * * * *

(c) Enforceable test methods for each emission limit specified in the plan. For the purpose of submitting compliance certifications or establishing whether or not a person has violated or is in violation of any standard in this part, the plan must not preclude the use, including the exclusive use, of any credible evidence or information, relevant to whether a source would have been in compliance with applicable requirements if the appropriate performance or compliance test or procedure had been performed. As an enforceable method, States may use:

(1) Any of the appropriate methods in appendix M to this part, Recommended Test Methods for State Implementation Plans; or

(2) An alternative method following review and approval of that method by the Administrator; or

(3) Any appropriate method in appendix A to 40 CFR part 60.

PART 52—APPROVAL AND PROMULGATION OF IMPLEMENTATION PLANS

1. The authority citation for part 52 is revised to read as follows:

Authority: 42 U.S.C. 7401 *et seq.*

2. Section 52.12 is amended by revising paragraph (c) to read as follows:

§ 52.12 Source surveillance.

* * * * *

(c) For purposes of Federal enforcement, the following test procedures and methods shall be used, provided that for the purpose of establishing whether or not a person has violated or is in violation of any provision of the plan, nothing in this part shall preclude the use, including the exclusive use, of any credible evidence or information, relevant to whether a source would have been in compliance with applicable requirements if the appropriate performance or compliance test procedures or methods had been performed:

(1) Sources subject to plan provisions which do not specify a test procedure and sources subject to provisions promulgated by the Administrator will be tested by means of the appropriate procedures and methods prescribed in part 60 of this chapter unless otherwise specified in this part.

(2) Sources subject to approved provisions of a plan wherein a test procedure is specified will be tested by the specified procedure.

3. Subpart A is amended by adding a new § 52.33 to read as follows:

§ 52.33 Compliance certifications.

(a) For the purpose of submitting compliance certifications, nothing in this part or in a plan promulgated by the Administrator shall preclude the use, including the exclusive use, of any credible evidence or information, relevant to whether a source would have been in compliance with applicable requirements if the appropriate performance or compliance test had been performed.

(b) For all federal implementation plans, paragraph (a) of this section is incorporated into the plan.

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

1. The authority citation for part 60 is revised to read as follows:

Authority: 42 U.S.C. 7401, 7411, 7413, 7414, 7416, 7601 and 7602.

2. Section 60.11 is amended by revising paragraphs (a) and (f) and by adding paragraph (g) to read as follows:

§ 60.11 Compliance with standards and maintenance requirements.

(a) Compliance with standards in this part, other than opacity standards, shall be determined in accordance with performance tests established by § 60.8, unless otherwise specified in the applicable standard.

* * * * *

(f) Special provisions set forth under an applicable subpart shall supersede any conflicting provisions in paragraphs (a) through (e) of this section.

(g) For the purpose of submitting compliance certifications or establishing whether or not a person has violated or is in violation of any standard in this part, nothing in this part shall preclude the use, including the exclusive use, of any credible evidence or information, relevant to whether a source would have been in compliance with applicable requirements if the appropriate performance or compliance test or procedure had been performed.

PART 61—NATIONAL EMISSION STANDARDS FOR HAZARDOUS AIR POLLUTANTS

1. The authority citation for part 61 is revised to read as follows:

Authority: 42 U.S.C. 7401, 7412, 7413, 7414, 7416, 7601 and 7602.

2. Section 61.12 is amended by revising paragraph (a) and adding paragraph (e) to read as follows:

§ 61.12 Compliance with standards and maintenance requirements.

(a) Compliance with numerical emission limits shall be determined in accordance with emission tests established in § 61.13 or as otherwise specified in an individual subpart.

* * * * *

(e) For the purpose of submitting compliance certifications or establishing whether or not a person has violated or is in violation of any standard in this part, nothing in this part shall preclude the use, including the exclusive use, of any credible evidence or information, relevant to whether a source would have been in compliance with applicable requirements if the appropriate performance or compliance test had been performed.

BILLING CODE 6560–50–P

NMED Exhibit 101 - 0015

STATE OF NEW MEXICO
ENVIRONMENTAL IMPROVEMENT BOARD

IN THE MATTER OF PROPOSED NEW REGULATION,
20.2.50 NMAC – *Oil and Gas Sector – Ozone Precursor Pollutants* **No. EIB 21-27 (R)**

DIRECT TESTIMONY OF SUSAN DAY AND ELIZABETH BISBEY-KUEHN

Susan Day

My name is Susan Day, and I am the Senior Economist with ERG, Inc. I have been asked to provide testimony in support of the New Mexico Environment Department's ("Department" or "NMED") proposed new air quality regulations at 20.2.50 NMAC ("Part 50"). My testimony is set forth in Sections I.A and III below, and addresses the compilation of the data used to develop the proposed definition of "small business facility" in 20.2.50.7.OO.

Elizabeth Bisbey-Kuehn

My name is Elizabeth Bisbey-Kuehn. I am the Bureau Chief of the Department's Air Quality Bureau ("Bureau"). My testimony is set forth in Sections I.B, II, and IV below, and addresses the basis for the proposed definition of "small business facility" in 20.2.50.7.OO, and the regulatory requirements for such facilities in Section 20.2.50.125.

I. QUALIFICATIONS

A. Susan Day

I hold a BA in Economics from Colby College and an MS in Resource Economics from the University of Rhode Island. I am an economist and project manager with 34 years of experience conducting and managing economic, regulatory, and data analyses that support environmental regulations under the Toxic Substances Control Act, Emergency Planning and Community Right-to-Know Act, Pollution Prevention Act, Clean Water Act, and the Safe Drinking Water Act. I have

also conducted benefit cost analyses in support of worker health and safety regulations for the U.S. Occupational Safety and Health Administration. My work includes preparing pre-rulemaking options analyses; estimating regulatory compliance costs; characterizing potential benefits associated with regulatory and nonregulatory options; evaluating small business impacts in accordance with Small Business Regulatory Enforcement Fairness Act requirements; tracking, organizing, and summarizing public comments; and preparing information collection requests.

My full background and qualifications are set forth in my resume, which is marked as NMED Exhibit 103.

B. Elizabeth Bisbey-Kuehn

A summary of my background and qualifications is provided in my other pre-filed testimony at NMED Exhibit 5. My full background and qualifications are set forth in my resume, which is marked as NMED Exhibit 6.

II. SMALL BUSINESS FACILITY DEFINITION (Kuehn)

Under the proposed rule, a small business facility is defined as a source that is independently owned or operated by a company that is a not a subsidiary or a division of another business, that employs no more than 10 employees at any time during the calendar year, and that has a gross annual revenue of less than $250,000. Employees include part-time, temporary, or limited-service workers.

III. DATA ANALYSIS FOR SMALL BUSINESS FACILITY DEFINITION (Day)

The small business definition proposed in 20.2.50.7.OO includes, among other factors, an indication of the position of the facility (highest level) in the overall corporate hierarchy. For the purposes of the analysis conducted by ERG, the term “global ultimate parent company” is used to define the highest level in the corporate family tree. As discussed below, in conducting this

analysis ERG identified the global ultimate parent associated with a list of New Mexico Oil and Gas well owners/operators potentially subject to the proposed rulemaking. Additionally, ERG obtained information on the revenues and employment associated with these global ultimate parent companies.

A. Master List of Well Owners/Operators, and Other Affected Facilities

NMED provided ERG with the names and addresses for well owners/operators and other affected facilities compiled from the NMED Equipment Data and NM Oil Conservation Division data.[1] Using this data, ERG created a master list of 535 well owners/operators and owners/operators of other affected facilities (hereafter collectively referred to as "owners/operators") by combining the two lists and eliminating duplicate entries. *See* NMED Exhibit. 104 – Owner Address List Final Spreadsheet.

Global Ultimate Parent Data

As input to the determination of whether facilities can be classified as "small business facilities" under Part 50, information on ownership by a global ultimate parent company and the revenue and employment data linked to each global ultimate parent company is required. Using information on industry classification signified by North American Industry Classification System ("NAICS") code, as well as name and address, facilities can be identified and linked to global ultimate parent companies in commercially available business databases such as Dun and Bradstreet ("D&B"). Information on revenues and employment for global ultimate parent companies can also be obtained from D&B. D&B is a fee for service operation, typically dealing in transactions for large scale queries (e.g., an entire industry sector). Due to the limited size of the universe of facilities covered by Part 50, it was cost effective for ERG to purchase the needed

[1] http://gotech.nmt.edu/gotech/Petroleum_Data/allwells.aspx

D&B data from another vendor called NAICS Association, LLC ("NAICS Association"). This process involved the following steps:

Step 1 – Submit the master list of New Mexico owners/operators to NAICS Association.

Step 2 – NAICS Association links the master list of owners/operators to D&B data and develops a dataset of facility records.

Step 3 – Review the dataset returned by NAICS Association, which includes the following categories of data:

- Name and address of the owner/operator identified as matching each facility on the master list of New Mexico owners/operators.
- Match fields including match method, match grade and confidence code.
- Facility identification including D&B number, facility sales (which is used as a proxy for revenues) and employment, industry sector designation (NAICS and SIC codes), and organization type (e.g., subsidiary).
- Global ultimate parent company identification including name, location, D&B number, sales (which is used as a proxy for revenues) and employment, and industry sector designation (NAICS and SIC codes) for the global ultimate parent.

NAICS Association used a matching algorithm to identify each New Mexico owner/operator or other affected facility in their data. Standard Matches are based on company name, address, and phone number, while Company Name Only matching is based on company name and country (no address). Where a match was made, NAICS Association appended D&B numbers and confidence codes for each matched record showing the degree of confidence they have in that particular match. The confidence codes range from 10, which is a perfect match, down to 4, which is a loose match. Following NAICS Association recommendations, only

matches above 7 were retained for ERG's analysis. Of matches with a confidence code of 8, 9, and 10, the matches were further categorized by match method (standard, name only) and match grade (in the form of letter grades A, B, F, and Z). For both standard and name-only matches, match grade can be interpreted in the following manner:

A - Same: ABC WIDGET MFG vs. ABC Widgeting MFG

B - Similar: ABC Widget MFG vs. ABC MFG

F - Different: ABC Widget MFG vs. XYZ MFG

Z - Null: One or Both are Null (Blank)

Match grade is shown in the NAICS Association dataset as a sequence in which the match grade string reflects the following data elements:

1. Business Name
2. Street Address Number
3. Street Name
4. City
5. State
6. PO
7. Phone

For example, a match grade sequence could be AAAAAZA, with each letter representing the match grade for each data element.

Of the 535 owners/operators ERG submitted to NAICS Association, 404 were identified using a standard match with a confidence code of 8 or above; 80 were identified using a name-only match (i.e., only the "business name" data element is the same between the NM facility and the facility identified by NAICS Association), and 51 could not be matched at all. ERG reviewed

all 80 name-only matched facilities and accepted 56 matches where enough information could be located through google searches on either the original name from NMED or the matched name suggested by NAICS Association to confidently conclude that they were the same facility. The remaining 24 matches were rejected where sufficient information could not be located.

For the 460 matched New Mexico facilities (404 standard matches plus 56 name-only matches confirmed by further research), NAICS Association attempted to identify a global ultimate parent company associated with the facility. Where a separate global ultimate parent was not identified, the owner/operator or other affected facility was not a subsidiary of a company and was considered to be the global ultimate parent for the purpose of this analysis (e.g., the facility itself could own other locations but was not itself owned by another entity). Of the 460 "matched" owners/operators, global ultimate parent companies were identified for 154 facilities. The remaining 306 facilities were considered to be their own global ultimate parent.

B. U.S. Small Business Administration Definition of "Small Business"

The U.S. Small Business Administration ("SBA") is a federal government agency that was created by federal legislation to support small businesses. SBA is responsible for defining industry size standards that identify threshold values below which firms in individual industries are classified as small businesses. These size standards are the basis for qualifying firms for preference in government contracting, and define eligibility criteria for loans at attractive rates under government lending programs.

SBA's small business size standards vary by industry sector and are set by NAICS code. In establishing size standards, SBA considers a number of economic and market characteristics that may allow a business of concern to exercise dominance in an industry sector. Size standards are based on criteria – such as annual receipts or number of employees – that represent a measure

of these characteristics. The standards define the largest size a for-profit enterprise (together with its affiliates) can be and still qualify as a "small business." As such, the size standard is established at the parent company level, encompassing all identified sites under a common ownership structure.

For context in this rulemaking, ERG included the SBA size standards for potentially affected owners/operators and other facilities and, using global ultimate parent company information identified for each facility, identified how that global ultimate parent would be classified based on the SBA size definition. *See* NMED Exhibit 105 – Preliminary Results NAICS.COM Updated Spreadsheet. Note that this analysis required NAICS code, revenue, and employment data. Accounting for the 22 facilities that were linked to the same global ultimate parent as at least one other affected facility, ERG counted 406 unique ultimate parents with revenue and employment data, and 24 ultimate parents that did not have revenue or employment data. The 406 unique global ultimate parent companies are associated with 436 owners/operators.

A comparison of these data to the SBA size definition (revenue or employment, depending on the NAICS code) resulted in 355 (87%) global ultimate parent companies that meet the SBA definition of "small business", and 51 (13%) global ultimate parent companies that do not meet that definition (i.e., "not small"), associated with 436 owners/operators and other facilities with usable data (revenue and employment). The 355 small global ultimate parent companies are associated with 359 small owners/operators, and the 51 not small global ultimate parent companies are associated with 77 not small owners/operators.

C. Estimation of Revenue Per Well and Total Gas/Oil Value Per Well

ERG obtained oil and gas well production data for New Mexico owner/operators and other affected facilities from the Go-Tech website.[2] The Go-Tech website presents historical oil and gas production data, updated monthly for the state of New Mexico. The production data on the website is obtained primarily from the New Mexico Oil Conservation Division, and the website is sponsored by the State of New Mexico; the U.S. Department of Energy's Office of Fossil Energy and the National Energy Technology Laboratory; and the New Mexico Petroleum Recovery Research Center, a division of the New Mexico Institute of Mining and Technology. These data include information on the number of stripper and non-stripper wells[3] per owner/operator, as well as the total MSCF of gas and BBLS of oil produced by the owner/operator in the 18-month time period between January 2019 and June 2020. Production data were available for 399 (75%) of the 535 owner/operators. ERG used these data to calculate an estimate of "value" per well using two methods, as described below.

Method 1: ERG estimated average revenue per well for each owner/operator by dividing the global ultimate parent revenues associated with the owner/operator by the total number of wells reported in the GO-TECH data for that owner/operator. The distribution of average global

---

[2] Available at: http://gotech.nmt.edu/gotech/Petroleum_Data/allwells.aspx

[3] Stripper wells are defined in the New Mexico Natural Gas and Crude Oil Incentive Act at NMSA 1978, § 7-29B-2(L), as follows:

> "stripper well property" means a crude oil or natural gas producing property that is assigned a single production unit number by the department and:
>
> (1) if a crude oil producing property, produced an average daily production of less than ten barrels of oil per eligible well per day for the preceding calendar year;
>
> (2) if a natural gas producing property, produced an average daily production of less than sixty thousand cubic feet of natural gas per eligible well per day during the preceding calendar year; or
>
> (3) if a property with wells that produce both crude oil and natural gas, produced an average daily production of less than ten barrels of oil per eligible well per day for the preceding calendar year, as determined by converting the volume of natural gas produced by the well to barrels of oil by using a ratio of six thousand cubic feet to one barrel of oil.

.

ultimate parent revenue per well ranges from a low of $38 per well to a high of $3,314,250,000 per well. It should be noted that the global ultimate parent revenue for many ultimate parent companies can come from other sources besides oil and gas well production, including sources entirely outside the oil and gas production industry. Therefore, the global ultimate parent revenue per well can be highly variable.

Note also that 22 global ultimate parent companies are associated with more than one well owner/operator. As such, the estimate of average revenue per well associated with the individual owner/operator is overstated in these 22 instances because the number of wells only includes those wells associated with the individual owner/operator, while the revenue is for the global ultimate parent, which is associated with multiple owner/operators.

Method 2: ERG estimated the average value of the oil and gas production per well for each owner/operator. Production data were available for an 18-month period including all of 2019 and the first 6 months of 2020. Using dollars per barrel (BBLS) for oil, and dollars per million BTU (MMBTU) for gas, ERG calculated the average value of the production from wells of each type per owner/operator. Production volumes were multiplied by 12/18ths to convert from 18 months to annual estimates. Price information was taken from the following:

- New Mexico Crude Oil First Purchase Price (Dollars per BBLS) – US Energy Information Administration[4] 24-Month average (February 2019 - January 2021) = **$45/BBLS**
- Henry Hub Natural Gas Spot Price (Dollars per MMBTU) - US Energy Information Administration[5] 24-Month average (March 2019 - February 2021) = **$2.39/MMBTU**

[4]Available at: https://www.eia.gov/dnav/pet/hist/LeafHandler.ashx?n=PET&s=F003035__3&f=M
[5] http://www.eia.gov/dnav/ng/hist/rngwhhdm.htm

See NMED Exhibit 105 – Preliminary Results NAICS.COM Updated Spreadsheet.

To estimate the average oil and gas value per well, ERG calculated the total production value (oil and gas) for all wells owned by each owner/operator then divided that value by the total number of wells per owner/operator as reported in the GO-TECH data. The distribution of average oil and gas value per well ranges from a low of $30 per well to a high of $5,306,080 per well.

IV. BASIS FOR SMALL BUSINESS FACILITY DEFINITION AND REQUIREMENTS OF SUBPART 125 (Kuehn)

The Department structured the overall requirements of Part 50 such that there is a baseline set of requirements applicable to all owners and operators, and a tiered set of requirements that apply based upon the equipment or source type, the PTE of the equipment or source, and whether a facility meets the definition of a small business facility as defined in this rule. All owners and operators are required to calculate the PTE of equipment and have that calculation certified by a professional engineer and conduct equipment leak monitoring and find and repair leaking components by specified deadlines. The monitoring frequency is determined by the facility PTE. An owner or operator of a facility that meets the definition of a small business facility must comply with the requirements of Sections 20.2.50.111 and 125. If a facility does not meet the definition of a small business facility, the owner or operator must comply with the other sections of Part 50 applicable to the particular sources at the facility.

The Department developed the definition of a small business facility to recognize the unique challenges smaller independent operators may face in determining applicability of complex regulations and financing the initial and ongoing costs of compliance with Part 50. Both the federal Clean Air Act and the Board's air quality construction permit fee regulations at 20.2.75 NMAC contain provisions to assist to small businesses by providing compliance

assistance and a tiered fee schedule that gives a 50% reduction in initial and annual permit fees. These programs were developed because small businesses frequently lack the technical expertise and financial resources necessary to evaluate complex regulations, to finance the initial and ongoing compliance requirements, and to pay the full cost of recurring permitting fees.

A. Use of Data Complied by ERG

In developing the definition of small business facility in Part 50, the Department evaluated the report prepared by ERG and sorted the companies by the annual Global Ultimate (GULT) Parent revenue and staffing levels. The thresholds established in the rule were chosen because the data compiled by ERG indicated that those thresholds balanced the costs of compliance with Part 50 against a company's ability to finance the costs of compliance, and would not put the majority of companies at risk of becoming insolvent and therefore cause wells to be abandoned without remediation.

The Department estimated the annual average cost of compliance for a representative well site facility to determine the number of companies that could finance those compliance costs. The representative facility was assumed to have facility-wide emissions greater than 5 TPY VOC, requiring quarterly LDAR monitoring under Section 20.2.50.116; a storage vessel emitting greater than 2 TPY, requiring a control device, and an annual inspection of the storage vessel under Section 20.2.50.123. The annual average cost of compliance for the representative facility was estimated at $37,945 (based on an average cost of $32,400 to control a storage vessel, $4,385 for quarterly LDAR monitoring, and $1,160 for an annual inspection). Because the cost estimates are based on the average cost of compliance for companies operating throughout the sector, the cost estimates are conservative and may overestimate the true cost of compliance for an individual facility. The Department then ranked the companies by GULT

revenue from highest to lowest revenue and screened the companies that reported $1,000,000 or less and $250,000 or less to determine how many of those companies had per well site revenue less than the cost of compliance for the representative facility. Based on this review, the Department determined that 96 companies reporting a GULT revenue of $1,000,000 and less had a calculated revenue per well less than $37,945. These companies operate approximately 9,277 wells or 18% of the total wells (9,277/50,866). The Department determined that 54 companies reporting a GULT revenue of $250,000 and less had a calculated revenue per well less than $37,945. These companies operate approximately 4,638 wells or 9% of the total wells (4,638/50,866).

The Department then determined the average annual cost of compliance for a facility meeting the small business definition at $4,385 (based on a conservative quarterly LDAR monitoring requirement). According to the report, few companies have a revenue of less than $4,385 per well.

Based on the above, the Department established $250,000 as the revenue threshold to meet the small business definition. This is based on the need to require robust emission reduction requirements for a majority of wells and facilities; to tailor the requirements for companies with low annual revenue; and to reduce the potential early abandonment of wells that will result in increased uncontrolled air emissions and significant public cost to remediate those wells.

Based on the ERG report and the proposed definition, a total of 82 companies that operate 4,638 wells would qualify as small business facilities under the thresholds established in the rule. Therefore, under the proposed definition, 15% of the total number of companies (82/535) subject to Part 50 would be considered owners/operators of small business facilities,

and 9% of the total number of wells (4,638/50,866) would be considered small business facilities.

The Department also estimated the revenue from a well producing 7.5 bbl of oil per day, (7.5 bbl oil/day * 365 days/year * $60.00/bbl of crude oil) as $164,250 per year (or $450 per day). Comparing this estimated revenue with the estimated cost of complying with the small business provisions of Part 50 (estimated at $4,385), it would cost companies approximately 2.6% of total revenue to comply. The estimated cost of compliance for the representative facility (estimated at $37,945) as a percentage of the total estimated revenue is approximately 23% of total revenue.

B. Rationale for Proposed Small Business Facility Provisions

As detailed above, Part 50 establishes a baseline set of requirements for all owners and operators and then a tiered set of requirements depending on the PTE, type of equipment, and if a facility meets the definition of a small business facility. The rationale for the definition of a small business is provided below.

The proposed definition is based upon three principal criteria that help delineate between small, independent businesses and large, vertically integrated companies. The first criterion is ownership structure, which was used to distinguish companies that are independently owned and operated and are not a subsidiary or division of another company from larger corporations. The differences between small and large companies include the size of the business, number of employees, revenue, legal structures, and financing and tax requirements. Small and large companies may both operate within the same industrial sector, however, the differences in how these companies operate, their ability to access and finance capital, and their overall size affect their operations.

The second criterion is the total number of staff employed by the company, which is an indication of the company's personnel and staff resource capacity to interpret and implement the requirements of the rule. Larger companies have the financing capacity to employ dedicated environmental, health, and safety specialists; these staff typically monitor the company's compliance with numerous state and federal environmental regulations. Small companies employing fewer numbers of employees typically do not have the staffing or funding capacity to finance dedicated environmental compliance specialists.

The third criterion is annual revenue. The Department recognizes that the cost of complying with the requirements of Part 50 may disproportionately impact the smallest companies and may result in early abandonment of small business-owned wells, which, in turn, may result in increased uncontrolled air emissions from abandoned wells. Thus, by establishing a definition for small business facility, the Department is rightsizing the rule to require robust equipment and emission monitoring for smaller, independent operations, while simultaneously balancing those requirements against the unintended negative environmental consequences resulting from early abandonment.

C. Proposed Requirements for Small Business Facilities

The definition of small business facility in Part 50 distinguishes those companies that are independently owned, have low annual revenues (less than $250,000), and a small number of employees (10 or fewer), from those companies with larger annual revenues ($250,000 or greater) and a greater number of employees (more than 10 employees). As discussed previously in the testimony of Susan Day, the Department established the definition of small business facility based on ownership, revenue, and staffing information obtained from NAICS Association, LLC.

Sections 20.2.50.111 and 125 require the owner or operator of a small business facility to comply with emission reduction, monitoring, and operational requirements. The requirements of Section 20.2.50.111 include estimating the facility's PTE and having those emissions calculations certified by a professional engineer.

The requirements of Section 20.2.50.125 include operating equipment in accordance with manufacturer specifications and keeping those specifications on file; calculating the annual VOC and NOx emissions from each facility using the actual production and processing rates; maintaining a company-wide database of emission calculations for all subject facilities; complying with third party verification requirements if requested by the Department; conducting fugitive leak monitoring requirements as required in Subsections C and D of Section 20.2.50.116; repairing equipment leaks as required under Subsection E of Section 20.2.50.116; submitting an initial certification certifying that the small business facility meets the definition of small business facility in Part 50, and annual certifications thereafter.

Subsection G of Section 20.2.50.125 contains an important provision that triggers the applicability of the remaining sections and requirements of Part 50 if the Secretary finds, based on credible evidence, that the facility presents an imminent threat to public health or welfare or to the environment; is not being operated in a manner that minimizes emissions of air contaminants; or has violated another requirement of Section 20.2.50.125 NMAC. This provision incentivizes owners and operators of small business facilities to fully comply with Section 20.2.50.125 providing for an applicability onramp for the other sections of Part 50 if they fail to do so. The annual emissions data collected and reported to the Department will be used in air quality planning projects, air dispersion modeling analyses, air emissions databases and emissions inventories, and in other air quality related projects.

Susan Day
Economist

A seasoned economist and program manager with extensive experience in data collection and analysis supporting development of federal regulations

- Has extensive experience with all aspects of the regulatory development process and has estimated compliance costs/savings, characterized benefits, and evaluated the potential for small business impacts for more than 30 rulemakings related to worker safety, toxic chemicals, water quality standards, and government mandated electronic reporting.
- Has more than two decades of experience managing contracts and large and small projects, as well as coordinating the work of multiple subcontractors and consultants.
- Currently leading ERG's team providing a range of economic, engineering, and data analyses in support of the proposed Toxic Substances Control Act (TSCA) Chemical Data Reporting (CDR) Revisions Rule.

EMPLOYMENT

2017–present
Senior Economist, ERG, Lexington, MA

2014–2017
Principal Associate, Abt Associates Inc.

1987–2014
Various Positions, Abt Associates Inc.

1985–1987
Graduate Research Assistant, Department of Resource Economics, University of Rhode Island

1985–1986
Research Assistant, Economic Analysis Inc.

B.A., Economics, Colby College, 1983

RELEVANT PROJECTS

Economic Support for TSCA CDR Revisions Rule

Client: U.S. EPA OCSPP. Currently leading ERG's team providing a range of economic, engineering, and data analyses in support of the proposed TSCA CDR Revisions Rule. Developed a model to estimate reporting burden and cost for multiple future CDR reporting scenarios and changes to reporting requirements. Prepared regulatory options for potential changes to small business definitions under section 8(a) of TSCA. Responsible for developing reporting burden estimates, modeling total burden, and preparing the full suite of regulatory documents for the proposed rule.

Economic and Regulatory Analyses of Toxics Release Inventory (TRI) Reporting Requirements

Client: U.S. EPA OPPT. For the TRI program, from 1990 to 2017, prepared more than 50 economic and regulatory analyses supporting options selection and rulemaking packages for several industry and chemicals expansion regulations. Prepared industry profiles, estimates of potentially affected universe, compliance cost estimates, characterization of small entities affected by rulemakings, benefits, sensitivity analyses, SBREFA analyses (using cost impact ratios compared to thresholds), and analyses of other statutory and EO requirements. Incorporated results from models such as RSEI to assess potential distributional impacts. Oversaw literature reviews related to topics

such as industry trends, specific industrial processes, and the value of information. Also developed a rapid, low-cost screening analysis approach that is appropriate for use when compliance costs are minor. For several rulemakings, also organized and tracked public comments, summarizing key themes and assisting in the preparation of responses to comments.

Regulatory Support for CAA Section 112(r) (RMP), CERCLA and EPCRA Regulations, Lists of Chemicals and Guidance Documents

Client: U.S. EPA OEM. Leading ERG's team to provide support for the development and modification of regulations, as well as the revision of lists of chemicals and reporting thresholds under CAA Section 112(r) ("RMP"), CERCLA, and EPCRA. Oversaw the update of existing EPA guidance on CERCLA Section 103 continuous release reporting. Prepared a regulatory impact analysis (RIA) in support of adjustments to reportable quantities (RQ) for ammonia and hydrogen sulfide continuous releases from animal farms under CERCLA and EPCRA. This task was a quick-turnaround engagement (two weeks) to prepare and deliver all analyses (and final RIA document), including estimation of the number of farms that would no longer report under the higher RQs, estimation of reporting burden and cost averted, agency burden and costs averted, benefits, and small entity impacts.

As part of the development of the economic analysis supporting this rulemaking, evaluated whether other statutory and executive order (EO) requirements needed to be addressed, including EO 12866, Regulatory Planning and Review; EO 13563, Improving Regulation and Regulatory Review; EO 13771, Reducing Regulations and Controlling Regulatory Costs, Paperwork Reduction Act (PRA), Regulatory Flexibility Act (RFA), Unfunded Mandates Reform Act (UMRA); EO 13132: Federalism; EO 13175, Consultation and Coordination with Indian Tribal Governments; EO 13045, Protection of Children from Environmental Health Risks and Safety Risks; EO 13211, Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution or Use, National Technology Transfer and Advancement Act (NTTAA); and EO 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations. Developed language demonstrating how the rulemaking addressed each, using the economic analysis where appropriate.

Other tasks include 1) preparing an ICR Renewal for the Episodic Releases of Oil and Hazardous Substances data collection. Conducted informal interview of reporters to estimate their reporting burden; 2) responding to multiple quick turnaround requests for data mining (ERNS data) and economic analysis, 3) In support of the Amendment to Emergency Release Notification Regulations on Reporting Exemption for Air Emissions from Animal Waste at Farms; Emergency Planning and Community Right-to-Know Act, organized, tracked, and summarized 87,000 comments received on the proposed rule.

Telecommunications Structures Small Entity Representative (SER) Background Document

Client: OSHA. Led the development of SER background document for the Telecommunications Structures Standard covering both maintenance and construction activities. Estimated the number of antenna-supporting structures in the United States as well as the number of structures constructed and dismantled. Further, estimated the number of establishments and climbing employees potentially affected by the proposed standard. Estimated the number of entities and employees by NAICS code and size category for use in the estimation of small business impacts. Estimated unit compliance costs for components of the standard including rule familiarization, training, recordkeeping, job hazard analysis, rigging plans, weather monitoring, structural modifications, communication, fall protection and 100% tie-off, and inspections. Prepared unit labor costs (wage rates) for relevant labor categories (e.g., authorized climber, competent rigger) using BLSOES occupational costs and wage categories.

STATE OF NEW MEXICO
ENVIRONMENTAL IMPROVEMENT BOARD

IN THE MATTER OF PROPOSED NEW REGULATION,
20.2.50 NMAC – *Oil and Gas Sector – Ozone Precursor Pollutants* **No. EIB 21-27 (R)**

DIRECT TESTIMONY OF RALPH MORRIS

My name is Ralph E. Morris, and I am the Managing Principal of Ramboll's Environment and Health ("REH") Central West Business Unit ("CWBU") with offices in Northern California, Utah, and Colorado. I have been asked to provide testimony on the air quality impacts of the New Mexico Environmental Department's ("Department" or "NMED") proposed new air quality regulations at 20.2.50 NMAC ("Part 50") to control ozone precursor emissions from oil and gas ("O&G") sources in New Mexico. My testimony will address the potential future year ozone air quality impacts from the implementation of the emissions controls for ozone precursor emissions on oil and gas sources due to NMED's proposed new air quality regulations.

I. Qualifications

As Managing Principal of the REH CWBU, I am responsible for the business operations for approximately 140 Ramboll employees in the San Francisco Bay Area, Salt Lake City, and Denver offices. REH is a 2,600 person environmental and health consulting group that is part of Ramboll Group A/S that consists of ~16,000 employees in ~250 offices in ~30 countries with headquarters in Copenhagen, Denmark.

I am part of REH's Air Sciences Group where I direct a variety of air quality studies including air quality model development and application, emissions inventory development and control strategy evaluation, meteorological modeling, and analysis and regulatory air issues

studies. With over 40 years of air quality consulting experience, I am one of the original developers of many of the photochemical air quality models that are or have been used for regulatory decision making in the United States and around the world, including one of the leaders in the development of Ramboll's Comprehensive Air-quality Model with extensions ("CAMx")[1] that was used to evaluate the ozone impacts of Part 50.

In the 1980s I led, or was a key person in, the development of the ozone models Reactive Plume Model ("RPM"), Regional Transport Model ("RTM") and Urban Airshed Model ("UAM"), and I was ultimately responsible for the delivery of the UAM photochemical grid model ("PGM") to the U.S. Environmental Protection Agency ("EPA") in 1990. EPA subsequently designated the UAM as the EPA-recommended model for ozone air quality planning in their air quality modeling guidelines at 40 CFR Part 51, Appendix W. During the early 1990s I directed the development of the variable grid version of UAM ("UAM-V") that was used in the Ozone Transport Assessment Group ("OTAG") and subsequent EPA NOx State Implementation Plan ("SIP") Call, the first regional NOx control strategy for the eastern United States. And in the mid-1990s I was one of the leaders in the development of the CAMx PGM that has been used in numerous ozone and $PM_{2.5}$ SIPs, as well as by EPA for national rules such as the Cross State Air Pollution Rule ("CSAPR")[2].

I directed the application of regional particulate matter ("PM"), ozone, and visibility modeling using EPA's Community Multiscale Air Quality ("CMAQ") modeling system and CAMx PGMs for the southeastern ("VISTA/ASIP"), western ("WRAP") and central ("CENRAP") US Regional Planning Organizations ("RPOs") for the development of the first round of regional haze SIPs that were due to EPA in 2007. I directed the development of an

[1] https://www.camx.com/
[2] https://www.epa.gov/csapr

updated Pollutants in the ATmosphere for Hong Kong ("PATH") air quality modeling system (the air quality component of PATH used the CMAQ and CAMx models) for the Hong Kong Environmental Protection Department, and applied it to Southeast Asia to assess regional transport and urban ozone and particulate matter formation. I was an original member of EPA's ozone and particulate matter modeling guidance workgroups, the Community Modeling and Analysis System,[3]Models-3/CMAQ External Advisory Committee, and I am currently a member of the Scientific Technical Modeling Peer Review Advisory Group for the South Coast Air Quality Management District ("SCAQMD"), offering advice on South Coast (Los Angeles) Air Basin ozone and PM air quality issues for over 15 years. I was formerly a member of the Air Quality Modeling Subcommittee of the Science Advisory Board that advised EPA on their air modeling studies.

I have been assisting EPA in developing air quality modeling techniques for over 30 years, which included addressing near-source, far-field and photochemical modeling issues. Currently, I am leading the air quality modeling efforts of the western states to develop their Regional Haze SIPs due in July of 2021, and have just finished leading the air quality modeling efforts for the Denver Serious ozone SIP and starting the Denver Severe/Moderate ozone SIP modeling efforts under the 2008 and 2015 ozone national ambient air quality standards ("NAAQS"). Because of my expertise in air quality modeling, over the last 15 years I have served as an expert witness in numerous litigation cases, many related to violations of the Clean Air Act, with the last time I testified at a trial being in St. Louis in April of 2019 in the Ameren Rush Island coal-fired power plant case.

[3] https://www.cmascenter.org/

My full background and qualifications are set forth in my resume, which is marked as NMED Exhibit 107.

II. Fundamentals of Ozone Air Pollution

Ozone is a molecule composed of three oxygen atoms (O_3) and is the main component of smog. Ozone occurs in both the Earth's upper atmosphere (stratospheric ozone) and at ground-level (tropospheric ozone). Stratospheric ozone in the upper atmosphere is good ozone because it shields us from harmful ultraviolet rays from the sun. However, ozone at ground-level is harmful to human health and the environment. Elevated levels of ground-level ozone can cause breathing difficulties, coughing and scratchy throat, aggravate lung disease such as asthma, emphysema and chronic bronchitis and make the lungs more susceptible to infection. Ozone can also harm plants, especially during the growing season, and cause material damage. Ozone is one of six criteria pollutants for which EPA sets NAAQS, with the primary NAAQS set to protect public health with a margin of safety, and the secondary NAAQS set to protect public welfare, which includes decreased visibility and damage to animals, crops, vegetation, and buildings. Currently, the primary and secondary ozone NAAQS are set to the same value. In 2008 and 2015 EPA promulgated ozone NAAQS with thresholds of, respectively, 75 and 70 parts per billion (ppb). The relevant ozone NAAQS metric is the ozone design value ("DV"), which is defined as the three-year average of the fourth highest maximum daily average 8-hour ozone concentration.

Ozone is not directly emitted but instead is formed in the atmosphere through a set of complex photochemical reactions involving volatile organic compounds ("VOC") and oxides of nitrogen ("NO_X") in the presence of sunlight. Elevated ozone concentrations typically occur on hot summer days under low wind speed and/or ground-level trapping inversions that allow the VOC and NO_X concentrations to build up. There have, however, been occurrences of winter high

ozone concentrations in Wyoming and Utah oil and gas fields in locations with strong trapping inversions that produce very high VOC and NO_X concentrations and white snow on the ground with high albedo that reflects the sunlight resulting in near-ground ultraviolet light comparable to the summer. NO_X emissions are produced by combustion where the heat converts the naturally occurring nitrogen and oxygen in the air[4] to NO_X emissions. NO_X is primarily produced by anthropogenic (man-made) sources through fuel combustion of coal, gasoline, diesel, oil, natural gas, and biomass burning. Natural sources of NO_X include wildfires, lightning, and soils. Anthropogenic sources of VOCs include mobile sources, chemical plants and refineries, oil and gas production, consumer products and other sources. On a region-wide basis, biogenic VOCs from plants are the largest VOC contributor, but in locations of large amounts of anthropogenic VOC emission sources, such as urban areas, oil and gas production fields or industrial complexes, biogenic VOC may not be the largest source sector but is usually still a large component of the total VOC emissions.

Emission control plans designed to mitigate high ozone concentrations reduce anthropogenic VOC and/or NO_X emissions. Ozone formation can be more sensitive to NO_X or VOC emissions, but usually has some sensitivity to both ozone precursors. Reducing VOC emissions almost always reduces ozone concentrations or has no effect. Reducing NO_X emissions can reduce ozone concentrations, but can also have localized ozone increases, a case known as "NO_X disbenefits." There are two causes of NO_X disbenefits. Most NO_X is emitted as nitric oxide (NO), some of which is quickly converted to nitrogen dioxide (NO_2) in the ozone titration reaction ($NO + O_3 \rightarrow NO_2 + O_2$). When NO_X emissions are reduced there is less ozone titrated by NO, resulting in a localized increase in ozone concentrations. The second way NO_X disbenefits occur

[4] Air in the earth's atmosphere is made up of approximately 78% nitrogen and 21% oxygen.

is due to the NO_X inhibition effect on ozone formation, where high NO_X concentrations can terminate the radical cycle that drives photochemical reactions. The reduction in NO_X emissions can result in an increase in the hydroxyl radical OH due to less of them being reacted away by the lower NO_2 concentrations ($NO_2 + OH + M \rightarrow HNO_3 + M$). NO_X disbenefits occur in areas with high NO_X concentrations where ozone formation is more VOC sensitive, such as urban areas and NO_X point source plumes. NO_X disbenefits were the cause of the "weekend effect" where, in urban areas like Los Angles, higher ozone concentrations were more likely to occur on weekend days than weekdays due to the lower morning NO_X emissions since there is no morning commute on weekend days.

With climate change, there are more hot days with higher temperatures that promote ozone formation resulting in higher ozone levels, as well as a lengthening of the ozone season resulting in more ozone exceedance days in the spring and fall than there have been in the past. Ozone attainment VOC/NO_X emission control plans designed to achieve the ozone NAAQS for a region under current climate conditions may be insufficient in the future under climate change, a phenomenon known as the "climate penalty."

III. Fundamentals of Ozone Modeling

Ozone modeling is usually conducted using a photochemical grid model ("PGM"). A PGM divides the region to be modeled into three-dimensional ("3-D") arrays of boxes (grid cells) that is shown schematically in Figure 1. There are three main inputs for a PGM: (1) 3-D meteorological fields that are usually produced by a prognostic meteorological model such as the Weather Research Forecast ("WRF")[5] model; (2) hourly speciated emission inputs that consist of gridded surface layer emissions that are emitted into layer 1 of the PGM (e.g., mobile sources and biogenic

[5] https://www.mmm.ucar.edu/weather-research-and-forecasting-model

emissions) and point source emissions that are emitted in an appropriate upper layer grid cell of the PGM based on its plume rise[6] (e.g., power plants and industrial point sources); and (3) Boundary Condition ("BC") species concentrations that are defined around the boundaries of the modeling domain (i.e., transport from outside of the PGM modeling domain). PGM emission inputs are prepared by processing county-level and point source emissions using an emissions model, such as the Sparse Matrix Operator Kernel Emissions ("SMOKE")[7] modeling system. PGM BC inputs are usually defined using output from a global chemistry model, such as GEOS-Chem.[8] Unlike air quality dispersion models (e.g., AERMOD) that are applied for a single source or small group of sources, PGMs must include all sources of air pollution, and so are more intensive and costly to apply.

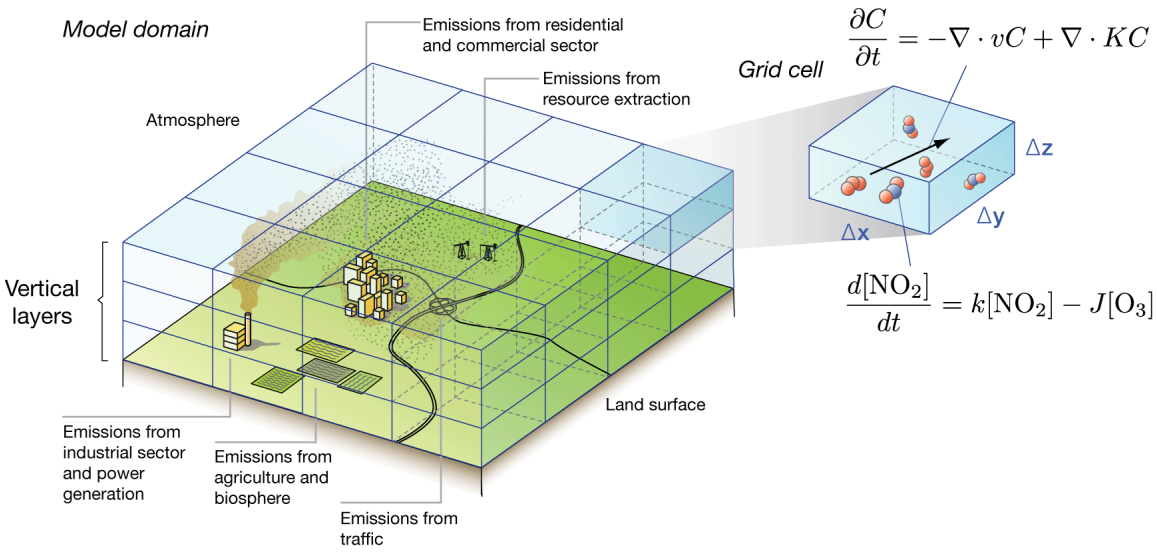

Figure 1. Schematic illustration of a PGM modeling domain that is divided up into a three-dimensional array of grid cells (Source: AWMA Environmental Manager magazine, July 2012 issue on AQMEII, D. Steyn, P. Builtjes, M. Schaap and G. Yarwood).

[6] Point source emissions usually have buoyancy through an exit velocity out of the stack and/or higher temperatures of the emitted effluent than the ambient air that causes the emissions to rise in the atmosphere after their release.
[7] https://www.cmascenter.org/smoke/
[8] http://acmg.seas.harvard.edu/geos/

A PGM will first be set-up for a historical base year (e.g., 2014), or in the case of an ozone modeling PGM application, an ozone season period of a past year. A PGM base year base case simulation is conducted that is subjected to a model performance evaluation ("MPE") that compares the modeled concentrations with concurrent observations. Graphical and statistical techniques are used in the MPE, the results of which are also compared to model performance goals and criteria based on past well-performing PGM applications to help put the PGM MPE in context. Diagnostic sensitivity tests may also be conducted to improve the PGM model performance through alternative model inputs or model options.

A typical PGM application will then project the anthropogenic emissions to a future year with all other inputs typically held constant the same as used in the base year.[9] Anthropogenic emissions are then controlled and future year PGM simulations made to determine the types and levels of emissions controls required to meet the air quality objectives under study (e.g., attainment of the ozone NAAQS).

IV. Overview of PGM Modeling to Support the NMED's Ozone Attainment Initiative

The Department contracted with a team consisting of the Western States Air Resource Council ("WESTAR") and Ramboll US Consulting, Inc. ("Ramboll") to conduct PGM modeling in support of the Department's Ozone Attainment Initiative ("OAI"). The OAI PGM study was conducted from April 2020 to May 2021, with results and progress of the study continuously documented on a website[10] as the study evolved. Although the OAI PGM study was not part of the development of an ozone SIP, it was conducted following EPA's 2018 photochemical modeling guidance for ozone SIPs ("EPA 2018 PCM Guidance"). *See* NMED Exhibit 108 – *Modeling Guidance for Demonstrating Air Quality Goals for Ozone, PM2.5, and Regional Haze*,

[9] In some application, future year BC inputs may be used based on future year global chemistry model simulations.
[10] https://www.wrapair2.org/NMOAI.aspx

EPA 454/R-18-009 (November 2018). This included preparing a Modeling Protocol (Ramboll and WESTAR, 2020a)[11] at the outset of the study (May 2020) that provided a roadmap for how the study would be conducted, and allow NMED and other interested parties to comment on the study approach prior to conducting the OAI PGM study.

The OAI PGM study used the Comprehensive Air-quality Model with extensions (CAMx[12]) PGM on a 36/12/4-km grid resolution nested modeling domains shown in Figure 2 with the 4-km domain covering New Mexico and nearby regions (e.g., the San Juan and Permian O&G development regions). The CAMx 2014 36/12/4-km modeling platform was developed for the May-August 2014 base year period. The CAMx 2014 36/12/4-km modeling platform was based on the Western Regional Air Partnership ("WRAP") and Western Air Quality Study ("WAQS") CAMx 2014 36/12-km annual modeling platform.[13] Boundary Conditions for the OAI PGM study CAMx 36/12/4-km simulation were based on output from the WRAP-WAQS 2014 GEOS-Chem global chemistry model simulation. The OAI study conducted two Weather Research Forecast ("WRF") 2014 36/12/4-km meteorological model simulations that differed in the analysis fields used to initialize, provide BCs, and used in the four dimensional data assimilation ("FDDA") that nudges the WRF meteorological model predictions to the observations. Details on the OAI PGM study 2014 WRF meteorological modeling are contained in Chapter 2 of the 2014v2 base case modeling report[14] and the Air Quality Technical Support Document ("AQ Technical Support Document").[15]

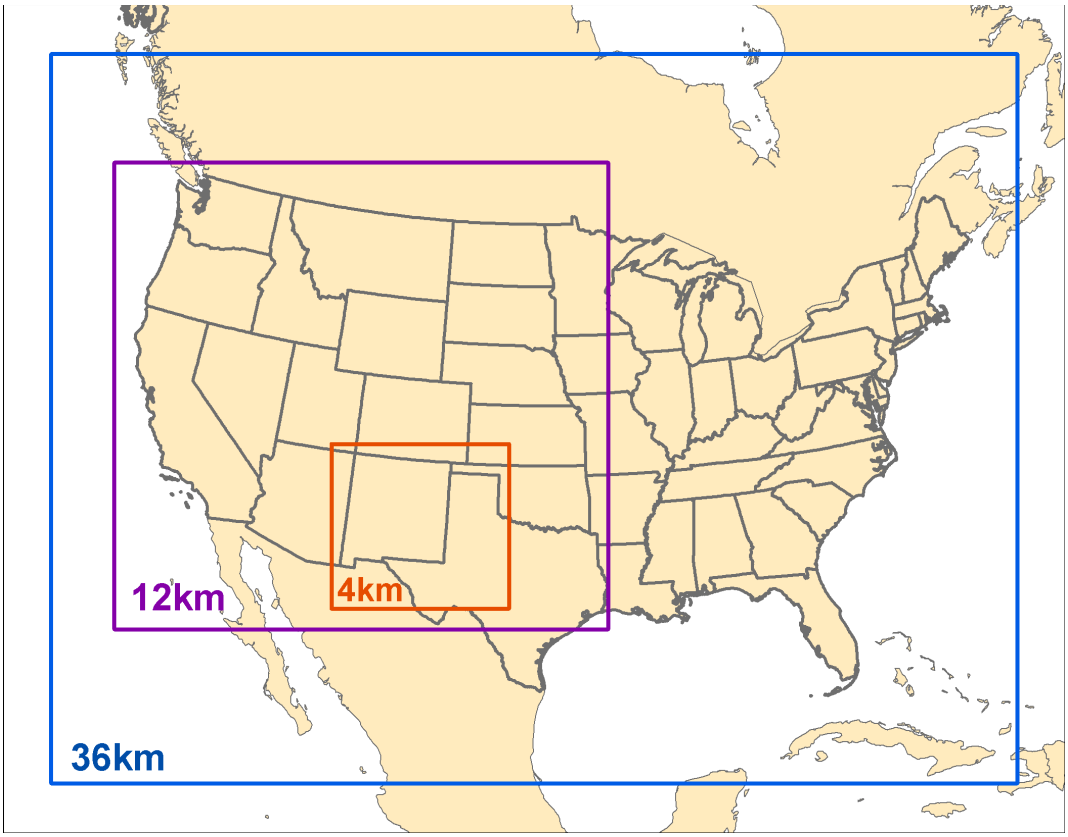

Figure 2. CAMx 36/12/4-km modeling domains used in the OAI PGM study.

A CAMx 2014v2 base case simulation and model performance evaluation was conducted and documented in an addendum[16] to the 2014 base case modeling report and the OAI PGM study AQ Technical Support Document, cited above. A 2028 base case emissions scenario was developed that was based on the WRAP-WAQS 2028 on-the-books (2028OTBa2) scenario with updated 2028 New Mexico base case O&G emissions. A 2028 O&G control strategy scenario was developed that reduced the New Mexico 2028 base case O&G emissions accounting for the estimated effects of Part 50, as determined by Eastern Research Group ("ERG") under separate contract with NMED. CAMx 2028 base case and 2028 O&G control strategy simulations were conducted, and the resultant ozone estimates were analyzed to determine the effect that the

[16] http://wrapair2.org/pdf/NM_OAI_Addendum_2014v2_MPE_v2.pdf

requirements in Part 50 would have on ozone concentrations if implemented. Ozone source apportionment modeling for the 2028 O&G control strategy was also conducted.

V. Summary of Modeled Ozone Impacts from Implementation of Part 50

Section IX below and Chapter 8 of the OAI PGM study AQ Technical Support Document present details on the ozone impacts of the NMED proposed O&G ozone precursor regulations. In this section I briefly summarize the key results of the estimated effects of Part 50 on ozone concentrations in New Mexico, with the remainder of my testimony going into details on how the OAI PGM study was carried out and its results.

The requirements of Part 50 are estimated to reduce projected 2028 future year ozone design values ("DVF") at New Mexico monitoring sites by between -0.2 to -1.5 ppb (see Table 5 in Section IX). The largest reductions in 2028 ozone DVFs occurs at the Navajo Lake (-1.5 ppb) and Substation (-1.2 ppb) monitoring sites in San Juan County in the San Juan Basin. The largest reductions in 2028 ozone DVFs in the Permian Basin occur at the Hobbs monitor (-0.7 ppb) in Lea County and the Carlsbad monitor (-0.3 ppb) in Eddy County.

The requirements of Part 50 are estimated to reduce daily MDA8 ozone concentrations across wide areas in New Mexico. On some days there are also isolated areas of increases in MDA8 ozone concentrations due to VOC and NO_X emissions reductions from Part 50 that are due to NO_X disbenefits. Figures 8-3 through 8-8 of the OAI PGM study AQ Technical Support Document display the ozone impacts of the 2028 O&G control strategy across the 4-km New Mexico domain for 6 example higher ozone days, which show that the extent of the ozone reductions due to the O&G controls are much greater than the extent of ozone increases due to the controls. In Figure 15 in Section IX below I present results for two example days. On June 5th the CAMx 2028 base case simulation estimates there are MDA8 ozone concentrations in excess of the 70 ppb 2015 ozone NAAQS in the San Juan Basin with a MDA8 ozone peak of 74.0 ppb that are reduced to

below the 70 ppb 2015 ozone NAAQS in the 2028 O&G control strategy simulation. And on July 24 there is a 2028 base case estimated MDA8 ozone peak of 71.3 ppb on the Colorado side of the San Juan Basin that is brought to below the 70 ppb 2015 ozone NAAQS in the 2028 O&G control strategy. However, on July 24th the 2028 O&G control strategy is also estimated to cause increases MDA8 ozone concentrations in portions of San Juan County with a maximum ozone increase of 6.4 ppb that was sufficient to increase the MDA8 ozone in a single grid cell to 71.0 ppb in the 2028 O&G control strategy scenario that exceeds the 70 ppb 2015 ozone NAAQS.

In summary, proposed Part 50 is estimated to reduce 2028 ozone DVFs and MDA8 ozone concentrations across New Mexico, with the largest ozone reductions occurring within the San Juan and Permian Basins. On some days there are also areas of ozone increases due to the O&G controls, although the area of ozone increases are much less than the areas of ozone decreases, and the magnitudes of the ozone increases are also usually less than the magnitudes of the ozone decreases. The area of reductions in projected 2028 ozone DVFs due to the O&G emission reductions are also much greater in extent and magnitudes than the areas of ozone DVF increases that appear to occur in 7 isolated grid cells whose ozone increases are presumed to be due to localized NO_X disbenefits due to the NO_X controls on O&G sources.

Ozone source apportionment modeling was also conducted for the 2028 O&G control strategy emissions scenario to examine source sector ozone contributions. This modeling found, among other things, that even with implementation of Part 50, New Mexico O&G emissions still had substantial contributions to ozone concentrations. For example, O&G emissions in the New Mexico portions of the San Juan and Permian Basins contributed as much as 3.0 and 2.0 ppb to the projected 2028 ozone DVF in the 2028 O&G control strategy (Table 8 in Section XI). And the

highest contribution of New Mexico O&G emissions to MDA8 ozone concentrations in the 2028 O&G control strategy emissions scenario exceeded 10 ppb (Figure 19 in Section XI).

A second CAMx ozone source apportionment simulation was conducted to examine whether ozone formation under the 2028 O&G control strategy emissions scenario was more sensitive to VOC or NO_X. Although ozone formation in New Mexico was mostly highly NO_X sensitive across most of New Mexico, frequently the highest MDA8 ozone concentrations in New Mexico were more evenly divided between VOC and NO_X sensitive ozone formation conditions. This was especially true in the San Juan Basin (e.g., see Figure 20 in Section XII).

VI. Development of the 2014 and 2028 Base Case Emission Scenarios

The emissions inventories for the OAI PGM study CAMx 2014v2 base case modeling were based on the WRAP-WAQS 2014v2 emissions inventory[17] that in turn was based on EPA's 2014 National Emissions Inventory ("2014NEI")[18] with updates made by the western states. Within the 36-km North American and 12-km western U.S. domains (Figure 1), the WRAP-WAQS CAMx 2014v2 base case emission inputs were used as is without any changes. For the 4-km New Mexico domain, the WRAP-WAQS 2014v2 emissions were reviewed and updated as needed by NMED and processed by the SMOKE emissions model to generate gridded hourly speciated emission inputs for the 4-km New Mexico domain. Biogenic VOC and NO_X emissions were initially based on the MEGAN v3.1 biogenic emissions model but were ultimately replaced by biogenic emissions from the BEIS biogenic emissions model because MEGAN v3.1 required data filling for the Leaf Area Index ("LAI") input for the urban land use type that was beyond the scope of the OAI PGM study. The final CAMx 2014v2 base case, 2028 base case and 2028 O&G control strategy CAMx simulations used the BEIS biogenic emission inputs.

[17] https://views.cira.colostate.edu/iwdw/docs/WRAP_WAQS_2014v2_MPE.aspx
[18] https://www.epa.gov/air-emissions-inventories/2014-national-emissions-inventory-nei-data

The OAI PGM study future year 2028 base case emissions were based on the WRAP 2028OTBa2[19] emissions inventory with updated New Mexico O&G emissions and use of 2014 actual fires instead of the Representative Baseline fires used in 2028OTBa2. The 2028OTBa2 CAMx-ready anthropogenic emission inputs for the 36/12-km domains were used as is. For the 4-km NM domain, the 2028OTBa2 emissions were processed using the SMOKE emissions model substituting the new 2028 New Mexico oil and gas O&G emissions developed in the OAI PGM study for the New Mexico O&G emissions used in the 2028OTBa2 emissions scenario.

A circa 2028 New Mexico O&G emission inventory was developed in the OAI PGM study for the 2028 base case emission scenario. The basis of the forecast 2028 New Mexico O&G emission inventory is circa 2028 O&G activity estimates provided by the Bureau of Land Management ("BLM")[20] that was used to project the O&G activity from the 2023 future year New Mexico O&G activity data developed by the WRAP Oil and Gas Working Group ("OGWG")[21] for the 2028OTBa2 emission inventory.[22] The 2028 New Mexico O&G emission base case inventory includes wellsite, gathering, and processing subsectors. The BLM New Mexico O&G future year forecast factors were used to project New Mexico O&G emissions to 2028. Table 1 compares the New Mexico O&G activity data for the WRAP 2014 and 2023 emission scenarios with the OAI PGM study 2028 O&G activity data that was based on BLM forecasts. Except for spud count, the 2028 New Mexico O&G activity is greater than 2014.

A comparison of the WRAP OGWG 2014 and 2023 New Mexico O&G emissions with the 2028 base case New Mexico O&G emissions from the OAI PGM study is shown in Table 2.

[19]https://views.cira.colostate.edu/docs/iwdw/platformdocs/WRAP_2014/EmissionsSpecifications_WRAP_RepBase2_and_2028OTBa2_RegionalHazeModelingScenarios_Sept30_2020.pdf

Across New Mexico, 2028 base case O&G NO_x and VOC emissions are, respectively, 29% and 15% higher than in 2014. In the Permian Basin, New Mexico 2028 base case O&G NO_x emissions are 64% higher than 2014, with VOC emissions 19% higher. The 2028 and 2014 New Mexico O&G emissions in the San Juan Basin are more comparable, with 2028 base case NO_x and VOC emissions, respectively, 1% and 10% higher than 2014.

Table 1. Comparison of WRAP OGWG 2014 and 2023 New Mexico O&G activity data used in the WRAP 2014v2 and 2028OTBa2 emission scenarios with the OAI PGM study 2028 base case New Mexico O&G activity data based on BLM forecast.

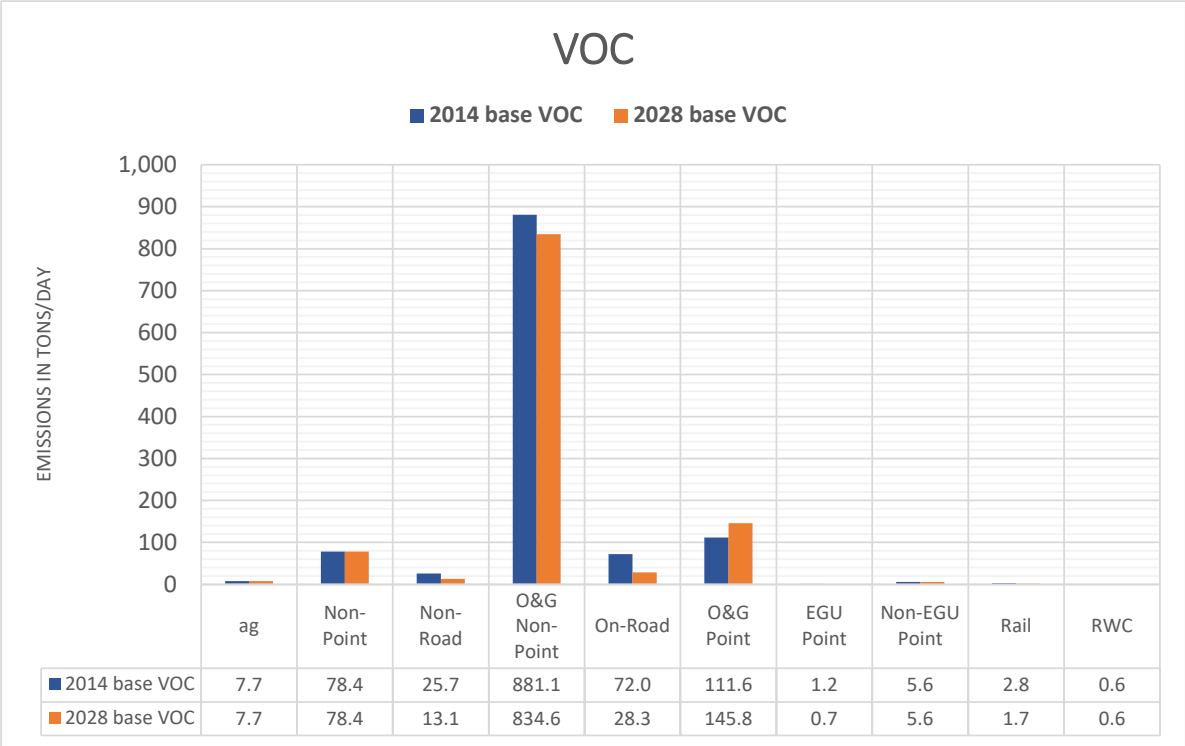
Figures 3 and 4 compare anthropogenic emissions in New Mexico by source sector for the 2014 and 2028 base case emission scenarios. Total anthropogenic NO_x emissions in New Mexico are estimated to be reduced by -28% between 2014 and 2028, with the largest reductions coming from on-road mobile (-72%), EGU point (-69%), and non-road mobile (-51%) source sectors (Figure 3). These NO_x emission reductions were offset somewhat by increases in NO_X emissions between the 2014 and 2028 base cases from the O&G point (+40%) and non-point (+36%) source sectors.

Oil and gas emission sources are typically divided into "non-point" and "point" sources. Non-point oil and gas emission sources generally consist of emissions from upstream well-sites during both exploration and production phases. Typical non-point oil and gas emission sources include drilling rigs, hydraulic fracturing engines, and completion venting during the exploration phase, and sources such as wellhead engines, oil tanks, condensate tanks, produced water tanks, fugitive components, pneumatic controllers, pneumatic pumps, dehydrators, heaters, liquid unloading, and workover engines during the production phase. Representative, process-specific inputs specific to each non-point emission source category are used to estimate emissions from numerous sources in a given county or oil and gas basin. Point oil and gas emission sources generally include midstream gathering and treating facilities, such as compressor stations and gas plants, because midstream facilities typically have larger per facility emissions than well-sites and are more likely to be compelled to report their criteria and/or hazardous air pollutant emissions to state and/or federal agencies under regulatory requirements such as Title V. Emission processes at oil and gas point sources may include such categories as large spark-ignition engines, turbines, fugitive components, amine units, heaters, dehydrators, and tanks.



Facility owner/operator engineering estimates of process -level emissions are typically submitted to the permitting authority and included directly in the emissions inventory.

Although there are large reductions in on-road (-61%) and non-road (-49%) mobile source VOC emissions between the 2014 and 2028 base cases, the total reduction in New Mexico VOC emissions between 2014 and 2028 is only -6% because non-point O&G dominates (~75%) anthropogenic VOC emissions in New Mexico and they are only reduced by -5% between 2014 and 2028.

	Non-Point	Non-Road	O&G Non-Point	On-Road	O&G Point	EGU Point	Non-EGU Point	Rail	RWC
2014 base NOX	16.3	20.1	124.6	207.8	85.3	118.0	10.5	55.1	0.1
2028 base NOX	16.3	9.9	169.8	59.2	119.1	36.7	11.3	39.7	0.1

Figure 3. Comparison of 2014 and 2028 base cases New Mexico anthropogenic NOx emissions by source sector.

	ag	Non-Point	Non-Road	O&G Non-Point	On-Road	O&G Point	EGU Point	Non-EGU Point	Rail	RWC
2014 base VOC	7.7	78.4	25.7	881.1	72.0	111.6	1.2	5.6	2.8	0.6
2028 base VOC	7.7	78.4	13.1	834.6	28.3	145.8	0.7	5.6	1.7	0.6

Figure 4. Comparison of 2014 and 2028 base cases New Mexico anthropogenic VOC emissions by source sector.

Figure 5 displays the spatial distribution of differences in NO_X emissions between the 2014 and 2028 base case emission scenarios (2028 – 2014) across the 4-km New Mexico domain for four source sectors: (a) on-road mobile; (b) non-road mobile; (c) non-point O&G; and (d) point O&G. Except for Mexico (e.g. Juarez), mobile source NO_X emissions are reduced (Figures 5a and 5b), with the largest reductions occurring in the major urban areas (e.g., Albuquerque, Las Cruces, El Paso) and, for on-road mobile, along the major highways. Within New Mexico, 2028 non-point O&G NO_X emissions are greater than in 2014 in both the San Juan and Permian Basins, although on the Texas side of the Permian Basin the future year O&G non-point NO_X emissions are mainly lower than in 2014 (Figure 5c). 2028 point source O&G emissions are greater than 2014 in the Permian Basin, but mostly less in the San Juan Basin (Figure 5d). Figure 6 is like Figure 5 only for VOC emissions. Except for Mexico, mobile source VOC emissions are reduced across the 4-km New Mexico domain between 2014 and 2028 (Figures 6a and 6b). Non-

point O&G emissions are increased in northeast San Juan and northwest Rio Arriba Counties in the San Juan Basin, with a mixture of increases and decreases in the New Mexico portion of the Permian Basin and mainly increases in the Texas portion of the Permian Basin.

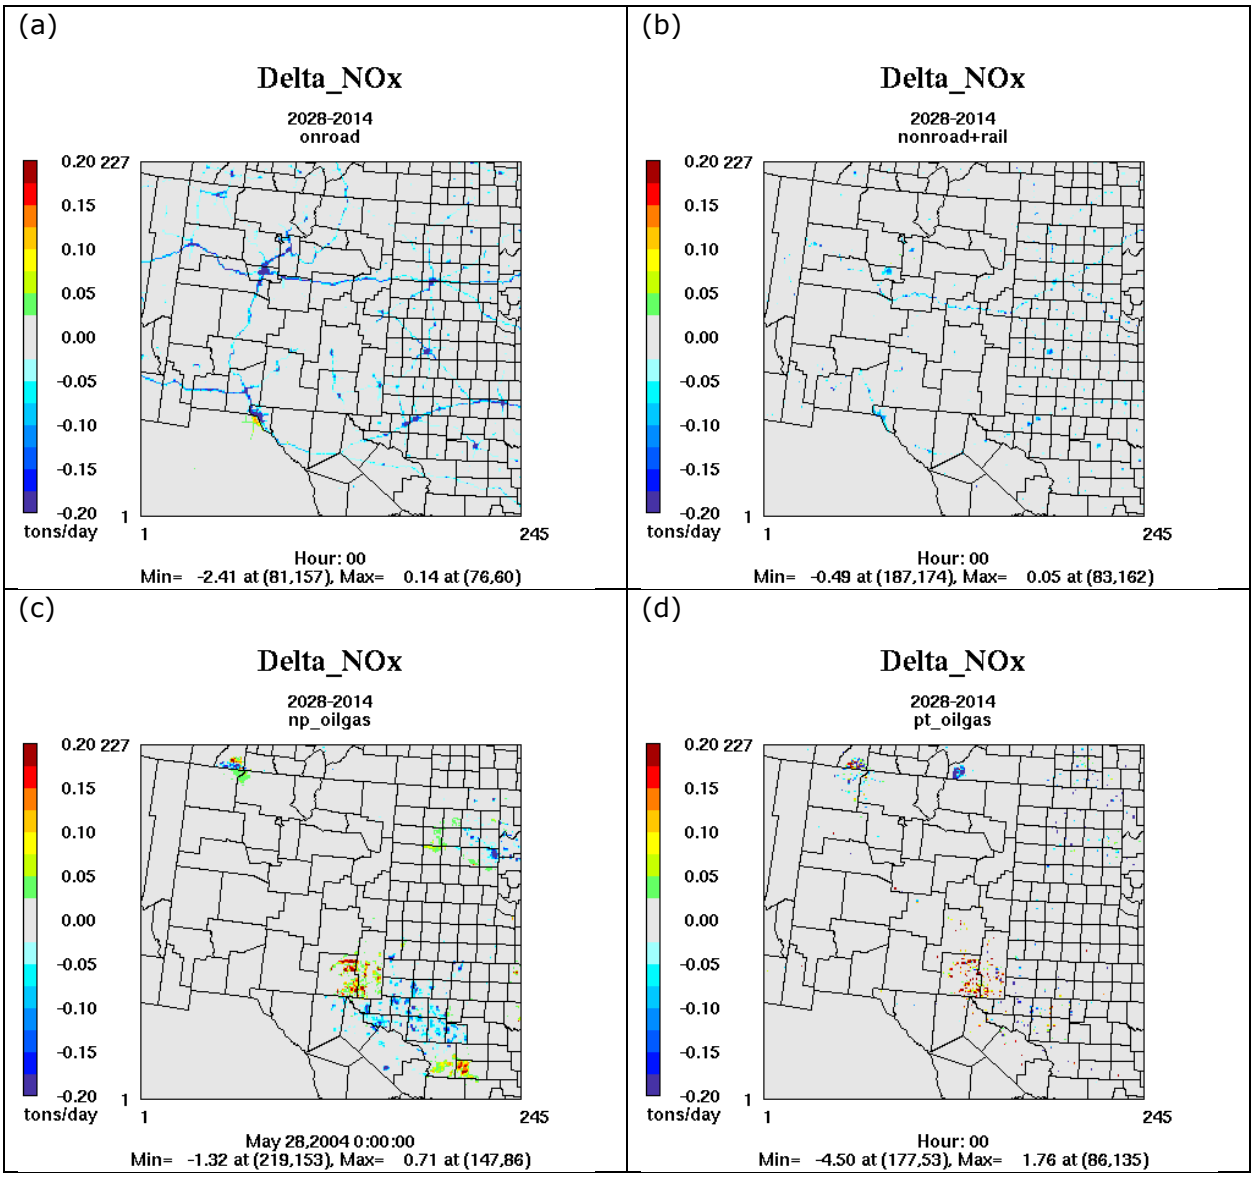


Figure 5. Differences in 2028 and 2014 base case NOx emissions (2028-2014) within the 4-km New Mexico domain for: (a) on-road mobile; (b) non-road mobile; (c) non-point oil and gas; and (d) point oil and gas source sectors.

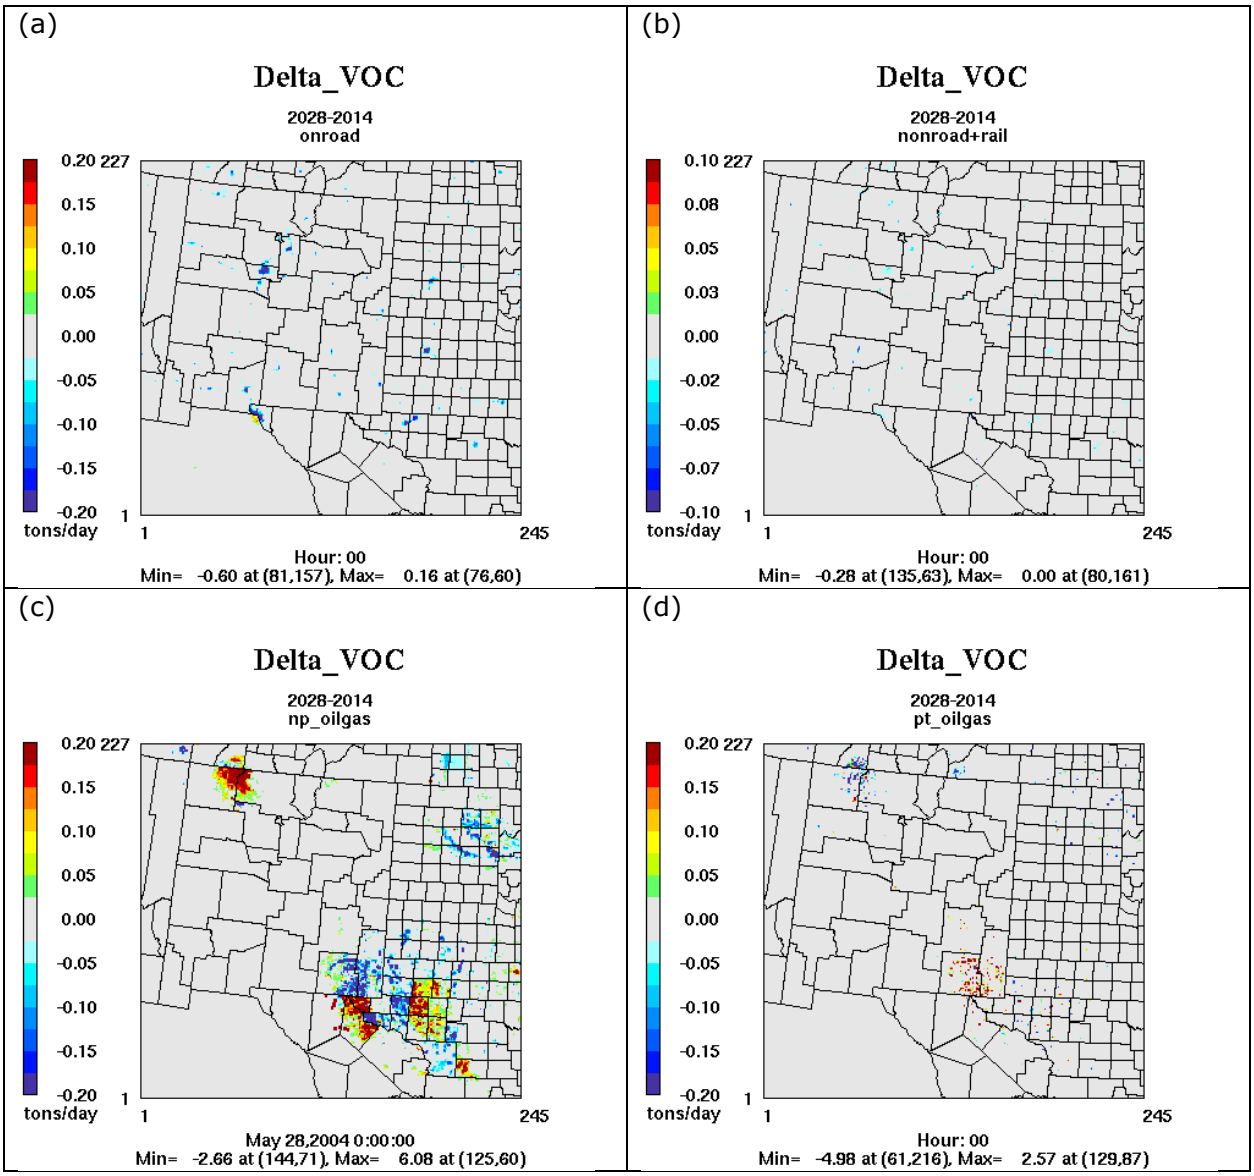

Figure 6. Differences in 2028 and 2014 base case VOC emissions (2028-2014) within the 4-km New Mexico domain for: (a) on-road mobile; (b) non-road mobile; (c) non-point oil and gas; and (d) point oil and gas source sectors.

VII. Development of 2028 New Mexico Oil and Gas Control Strategy Emissions

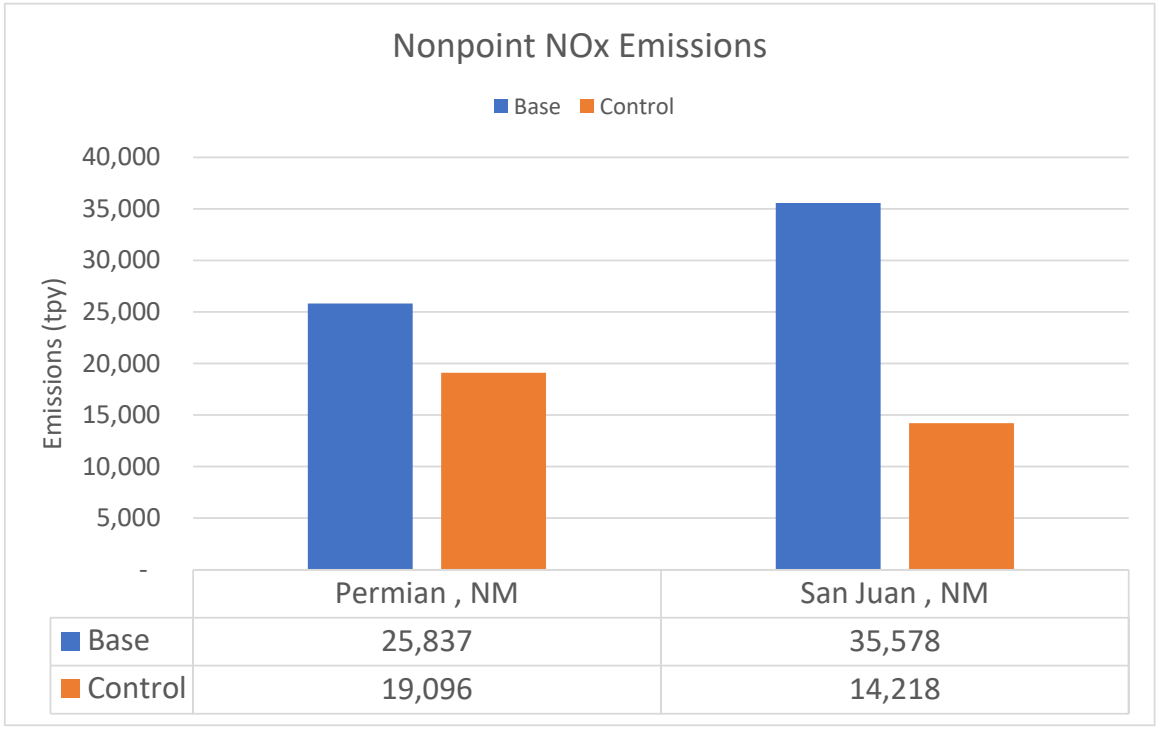
The WESTAR/Ramboll Team provided the New Mexico 2028 base case O&G emissions to the Department. ERG, under separate contract with NMED, estimated the reductions in the 2028 New Mexico O&G emissions from implementation of emission controls based on their

interpretation of the proposed requirements in Part 50.[23] The 2028 O&G Control Strategy reduced O&G emissions in seven New Mexico counties.

The 2028 NM O&G controlled emissions were processed by SMOKE and substituted for the 2028 NM O&G base case emissions to create the 2028 O&G control strategy emissions scenario. The only difference between the OAI PGM study 2028 base case and 2028 O&G control strategy emission scenarios were the controls on O&G emissions in New Mexico as implemented by ERG to reflect the proposed O&G ozone precursor regulations.

Table 3 displays the New Mexico state-wide O&G emissions for the 2028 base case and 2028 O&G control strategy. State-wide O&G NO_x emissions are reduced by approximately -45% with similar percent reductions from both the point and non-point O&G source sectors. State-wide O&G VOC emission are reduced by approximately -50% with more reductions coming from the non-point (-53%) than point (-35%) source sectors.

Table 3. New Mexico NO_x and VOC O&G emissions (tons per year, TPY) for the 2028 Base Case and 2028 NM O&G control strategy.



Source Sector	NO_x Emissions (TPY)			VOC Emissions (TPY)		
	Base	Control	Diff	Base	Control	Diff
Non-Point	61,245	33,144	-46%	181,252	85,564	-53%
Point	41,066	22,872	-44%	30,340	19,608	-35%
Total	102,311	56,016	-45%	211,592	105,172	-50%

Figures 7 and 8 display the changes in, respectively, NO_x and VOC O&G emissions in the Permian and San Juan Basins between the 2028 base and 2028 control strategy cases by point and non-point source sectors. In the Permian Basin, O&G NO_x emissions are estimated to be reduced by approximately 21,000 tons per year ("TPY") (-64%). In the San Juan Basin, O&G NO_x emissions are estimated to be reduced by approximately 25,000 TPY (-44%). 2028 VOC

[23] https://www.env.nm.gov/new-mexico-methane-strategy/wp-content/uploads/sites/15/2020/07/Draft-Ozone-Precursor-Rule-for-Oil-and-Natural-Gas-Sector-Version-Date-7.20.20.pdf

O&G emissions in the Permian and San Juan Basins are estimated to be reduced by approximately 53,000 TPY each (-46% and -55% reduction, respectively).

Figure 9 shows the spatial distribution of the differences in non-point and point O&G NO_x and VOC emissions between the 2028 base case and 2028 O&G control strategy scenario. The O&G emission reductions are restricted to the New Mexico portions of the San Juan and Permian Basins.

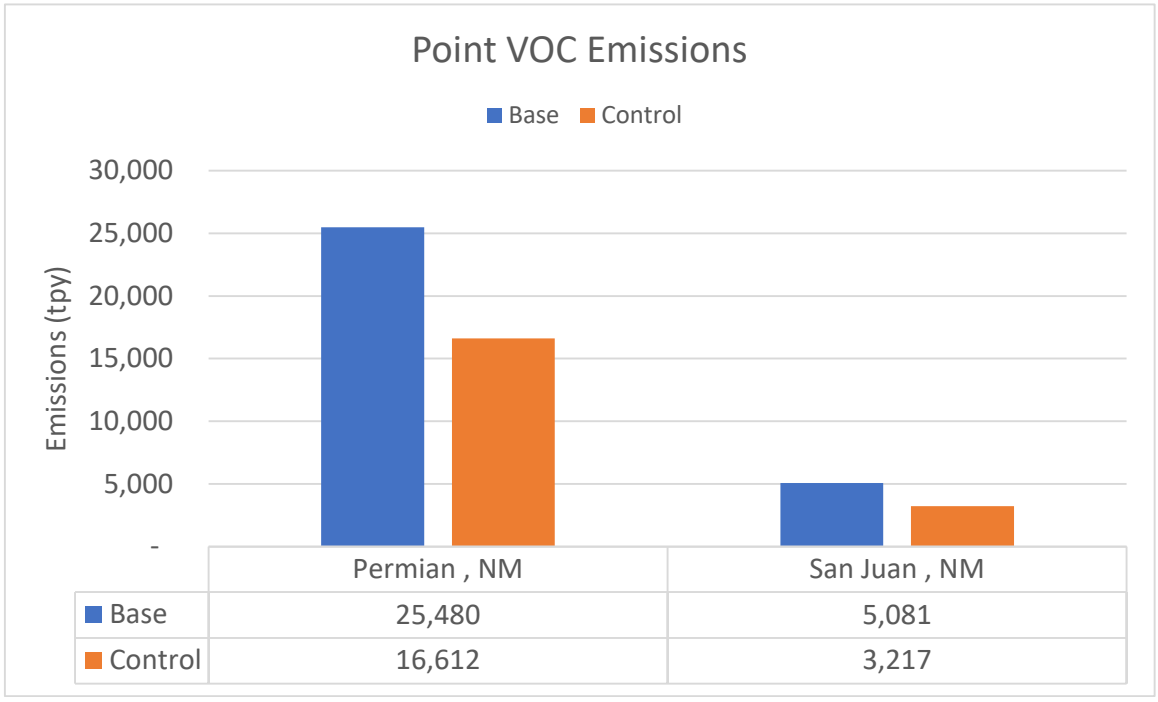

Figure 8. Comparison of 2028 Base Case and 2028 NM O&G control strategy VOC emissions for the non-point (top) and point (bottom) source sectors and the Permian (left) and San Juan (right) basins.

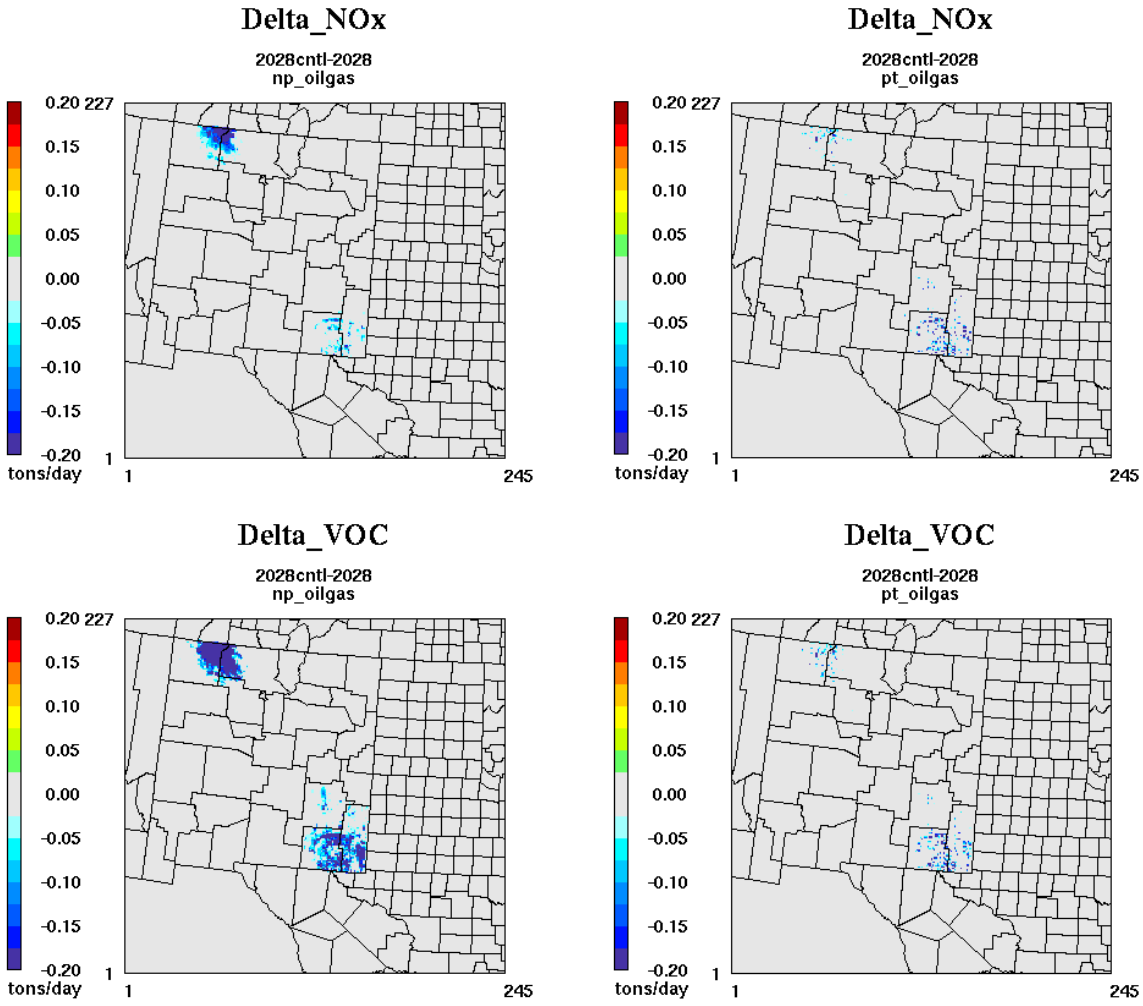

Figure 9. Differences between 2028 O&G Control Strategy and 2028 Base Case O&G NO_x (top) and VOC (bottom) emissions for the non-point (left) and point (right) source sectors.

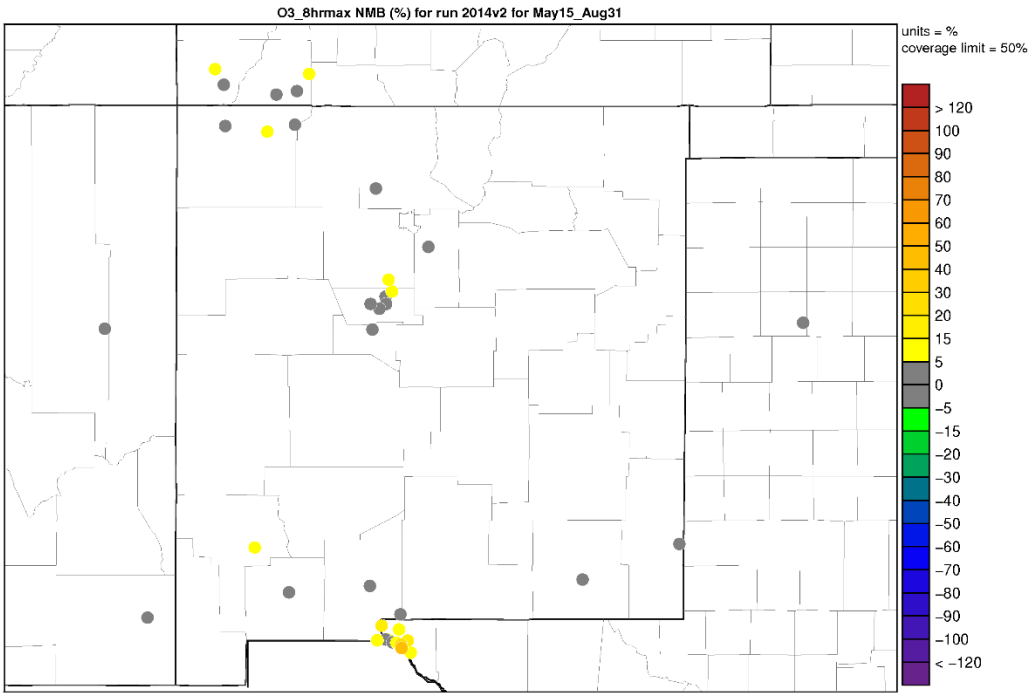

VIII. CAMx 2014v2 Base Case Modeling and Model Performance Evaluation

Four CAMx 2014 diagnostic sensitivity tests were conducted using different sets of meteorological inputs based on the OAI PGM study 2014 WRF meteorological model output. The CAMx ozone model performance for the four sensitivity tests was evaluated and the meteorological inputs from the best performing sensitivity test were selected for use in the final CAMx 2014v2 base case and 2028 future year modeling.

The CAMx final 2014v2 36/12/4-km base case simulation ozone estimates were evaluated by comparing them against concurrent observed ozone concentrations matched by time and

location. Both graphical and statistical measures of ozone model performance were used in the CAMx 2014v2 base case model performance evaluation ("MPE"), with the statistical performance metrics compared against ozone model performance goals and criteria developed from the peer reviewed literature[24] that were based on good ozone performing PGMs. Ozone model performance goals and criteria are not pass/fail tests; rather, they are used to help put the model performance in context. Model performance statistics for bias, error, and correlation were calculated across the domain and at each monitoring site using all predicted and observed maximum daily average 8-hour ("MDA8") ozone pairs and using just predicted and observed MDA8 ozone pairs when the observed MDA8 ozone concentration is above a 60 ppb cutoff value in order to evaluate how well the model is predicting observed higher MDA8 ozone concentrations. Figure 10 displays the spatial distribution of the Normalized Mean Bias ("NMB") performance statistic for MDA8 ozone concentrations at monitoring sites in the 4-km New Mexico domain with and without using the 60 ppb observed ozone cutoff. The NMB are colored grey when they achieve the NMB performance goal (≤±5%), and bright yellow or bright green when they fall between the performance goal and performance criteria (i.e., between ±5% and ±15%). Without using the 60 ppb ozone cutoff, NMB at all sites in New Mexico achieve the performance criteria with most sites also achieving the NMB performance goal (Figure 10, top). When a 60 ppb ozone cutoff is used, almost all sites in New Mexico achieve the ozone bias performance criteria, with approximately half the sites also achieving the ozone bias performance goal.

[24] https://www.tandfonline.com/doi/full/10.1080/10962247.2016.1265027

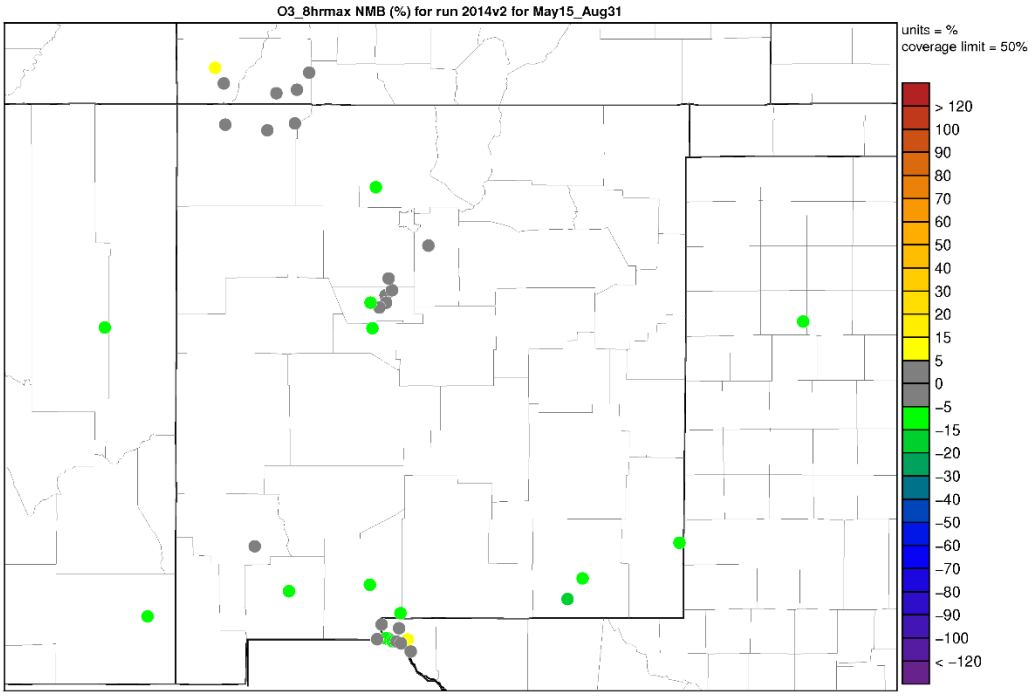

Figure 10. Normalized Mean Bias (NMB) for MDA8 ozone concentrations at monitoring sites in the 4-km New Mexico domain without (top) and with using a 60 ppb observed ozone cutoff.

Figure 11 displays scatter plots of predicted and observed MDA8 ozone concentrations for monitoring sites in the 4-km New Mexico domain from EPA's Air Quality System ("AQS") and the more rural CASTNet networks. The NMB across both the AQS (4.4%) and CASTNet (-1.4%) achieves the ozone bias performance goal (≤±5%) with the Normalized Mean Error ("NME") across both networks (10.9% and 7.9%) achieving the ozone error performance goal (≤15%). The ozone model performance of the final CAMx 2014v2 base case simulation was quite good; more details on the OAI PGM study CAMx 2014v2 base case MPE are provided in the addendum[25] to the 2014 base case modeling report and Chapter 6 of the AQ Technical Support Document.[26]

[25] http://wrapair2.org/pdf/NM_OAI_Addendum_2014v2_MPE_v2.pdf

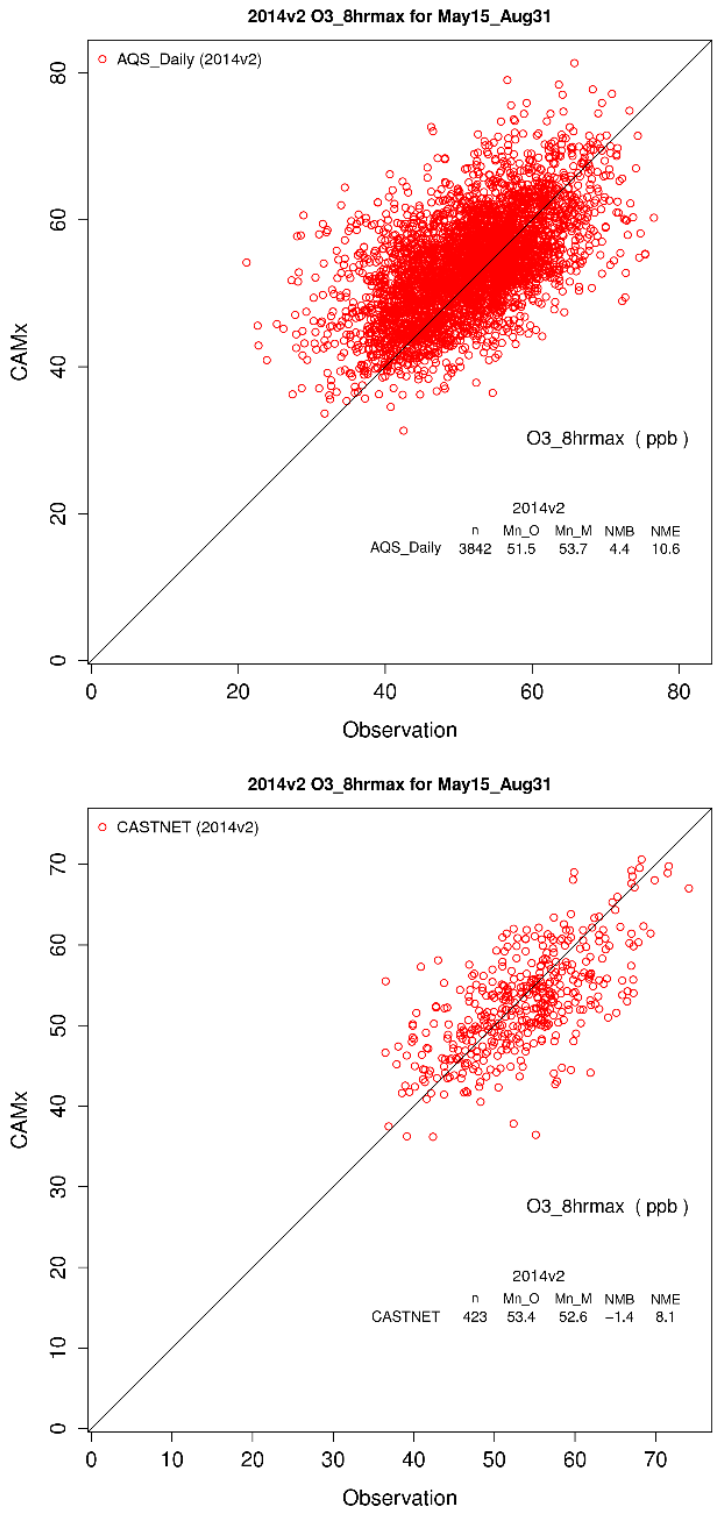

Figure 11. Scatter plots of predicted and observed MDA8 ozone concentrations for AQS (top) and CASTNet (bottom) monitoring sites within the 4-km New Mexico domain and the final 2014v2 CAMx base case simulation.

VIII. CAMx 2028 Base Case Modeling Results

A CAMx 2028 36/12/4-km base case simulation was conducted whose emissions were based on the WRAP-WAQS 2028OTBa2 emissions scenario only using updated 2028 O&G emissions for New Mexico and 2014 actual fires. 2028 future year ozone design values ("DVF") were estimated by projecting observed current year ozone design values ("DVC") using the CAMx 2014v2 and 2028 base cases modeling results following the EPA 2018 PCM Guidance (NMED Exhibit 108) for making future year ozone DVF projections.

EPA recommends using PGM modeling results in a relative fashion to scale the observed current year ozone DVC to estimate the future year ozone DVF. The model derived scaling factors are called Relative Response Factors ("RRF") and are the ratio of future (2028) to base (2014v2) year ozone modeling results averaged over the 10 days with the highest base year base case modeled MDA8 ozone concentrations:

$$RRF = \sum \text{Model MDA8 Ozone}_{2028} / \sum \text{Model MDA8 Ozone}_{2014}$$

$$DVF = DVC \times RRF$$

The EPA 2018 PCM Guidance recommends that the DVC be calculated as the average of three-years of observed ozone design values (DV)[27] centered on the base modeling year, which is 2014 in this case:

$$DVC_{2012\text{-}2016} = (DV_{2012\text{-}2014} + DV_{2013\text{-}2015} + DV_{2014\text{-}2016}) / 3$$

The EPA 2018 PCM Guidance recommends for the RRFs that the highest modeled base year MDA8 ozone be selected within a 3x3 array of grid cells centred on the monitor. For the future year, the MDA8 ozone is selected from the same grid cell in the 3x3 array centered on the monitor as used in the base year.

[27] An ozone DV is defined as the three-year average of the fourth highest observed MDA8 ozone concentrations at a monitoring site.

The EPA 2018 PCM Guidance recommends using the 10 highest modeled base year MDA8 ozone concentrations days with MDA8 ozone greater than 60 ppb in the RRFs. If there are less than 10 modeled days with base year MDA8 ozone greater than 60 ppb, the EPA 2018 PCM Guidance states that RRFs can still be calculated if there are at least 5 days with MDA8 ozone greater than 60 ppb. EPA has codified their recommended ozone DVF projection approach in the Software for the Modeled Attainment Test ("SMAT")[28]. The SMAT tool was used to make 2028 ozone DVF projections in the OAI PGM study. The default SMAT parameters that follow the EPA 2018 PCM Guidance were used, except that the minimum number of days needed to calculated an RRF was lowered from 5 to 4 in order to obtain 2028 ozone DV projections at all sites in New Mexico as one site only had 4 days with 2014v2 MDA8 ozone greater than 60 ppb (Hobbs in Lea County).

Table 4 displays the current year ozone $DVC_{2012\text{-}2016}$ and projected 2028 ozone DVFs at monitoring sites in New Mexico for the 2028 base case simulation and their differences. There are two sites in Doña Ana County with current year ozone $DVC_{2012\text{-}2016}$ above the 70 ppb 2015 ozone NAAQS: Desert View (72.0 ppb) and Santa Teresa (71.3 ppb). The 2028 base case ozone DVFs at monitoring sites in New Mexico are projected to be -2.0 ppb to -5.7 ppb lower than the observed $DVC_{2012\text{-}2016}$. Following the EPA 2018 PCM Guidance, the 2028 ozone DVF at all monitoring sites in New Mexico are projected to be below the 70 ppb 2015 ozone NAAQS with the two highest values being 67.0 ppb at Desert View in Doña Ana County and 66.7 ppb at Carlsbad in Eddy County, both in southern New Mexico.

EPA's SMAT tool has an ozone DVF Unmonitored Area Analysis ("UAA") feature that was used to make 2028 ozone DVF projections across the 4-km New Mexico domain. The SMAT UAA tool first spatially interpolates the observed ozone $DVC_{2012-2016}$ at the monitoring sites to each 4-km grid cell in the New Mexico modeling domain, where an option exists in SMAT to use the modeled ozone concentration gradients in the interpolation procedure. I do not present the SMAT UAA results using the option to use the modeled concentrations gradients in the spatial

interpolation procedure in this testimony, as it produced spurious results due to high modeled ozone concentrations caused by wildfires, although those results are available in the OAI PGM study AQ Technical Support Document. The SMAT UAA procedure then makes the 2028 ozone DVF projections in each 4-km grid cell using the CAMx 2014v2 and 2028 base case modeling results in the same relative fashion as used to project 2028 ozone DVF at the monitoring sites described above, only instead of using the modeling results from a 3x3 array of grid cells centered on the monitor it uses the modeling results in the 4-km grid cell in question.

Figure 12 displays the SMAT UAA projected 2028 ozone DVFs and the differences between in the projected 2028 ozone DVF and the observed current year $DVC_{2012\text{-}2016}$ across the 4-km New Mexico modeling domain. The highest SMAT UAA 2028 ozone DVF in the 2028 base case is 67.9 ppb, which occurs within the Permian Basin, with 2028 ozone DVF exceeding 65 ppb in the San Juan Basin (Figure 12, top). The differences between the SMAT UAA 2028 ozone DVF and current year ozone $DVC_{2012\text{-}2016}$ show ozone reductions across most of New Mexico except for small area of ozone increases in the Permian Basin and larger area of ozone increases in the San Juan Basin (Figure 12, bottom). These are areas where there were increases in O&G emissions between 2014 and 2028 (see Figures 5 and 6).

Figure 13 displays spatial maps of daily MDA8 ozone concentrations for the 2014v2 base case, 2028 base case and their differences for two example days during the May-August 2014 modeling period. The OAI PGM study AQ Technical Support Document contains MDA8 ozone results for additional example days. For the 2014v2 base case, the highest CAMx estimated MDA8 ozone concentration on June 5, 2014 (Figure 13, top left panel) is 72.9 ppb which occurs in El Paso, and there is a small area in northeastern San Juan County that exceeds the 70 ppb 2015 ozone NAAQS that is indicated by the yellow shading (i.e., MDA8 ozone between 71 and 73 ppb). The highest estimated MDA8 ozone on June 5th for the 2028 base case is 74.0 ppb and occurs in the San Juan Basin just over the border of New Mexico in southern Colorado, with MDA8 ozone above the 2015 ozone NAAQS in northeast San Juan and northwest Rio Arriba counties (Figure 13, middle left). The difference plot in MDA8 ozone between 2028 and 2014 base cases on June 5th, shown in the bottom right panel of Figure 13, show that the 2028 base case has higher MDA8 ozone than the 2014 base case within the Permian and San Juan Basins due to higher O&G emissions in the 2028 base case emissions scenario than in the 2014v2 base case (see Figures 5 and 6). However, outside the San Juan and Permian Basins, the 2028 base case has lower MDA8 ozone concentrations on June 5th due to lower mobile source and other non-O&G source sector emissions.

The 2028 and 2014 base case daily MDA8 ozone concentrations and their differences on July 24, 2014 are shown in the right panels in Figure 13. On July 24th the 2014v2 base case has a peak MDA8 ozone value of 74.7 ppb in the San Juan Basin just across the border in Colorado, with areas in San Juan County, New Mexico above the 2015 ozone NAAQS (Figure 13, top right). In 2028 the MDA8 ozone peak across the border from New Mexico in Colorado on July 24th is reduced to 71.3 and the area above the 2015 ozone NAAQS in the 2014v2 scenario (indicated by

yellow in Figure 13, top right) is reduced to below the NAAQS in the 2028 base case scenario (indicated by green in Figure 13, middle left). The 2028 minus 2014v2 MDA8 ozone difference plot on July 24th show more wide-spread and higher magnitudes of ozone decreases in the future year that appear to be due in part to lower ozone concentrations in the 2028 than 2014 base case emission scenarios being transported into New Mexico from Texas.

The differences between the MDA8 ozone concentrations in the 2014v2 and 2028 base case simulations vary day-to-day, as illustrated in the two example days shown in Figure 13. In general, there is higher ozone in the San Juan and Permian Basins due to increases in O&G emission between 2014v2 and 2028, but lower ozone everywhere else due to lower emissions in the other source sectors (e.g., mobile). Whether there is a net increase in MDA8 ozone concentrations in the two O&G basins depends on whether the ozone reductions due to emission reductions in the non-O&G source sectors is sufficient to offset the ozone increases due to increases in O&G emissions between 2014v2 and 2028.

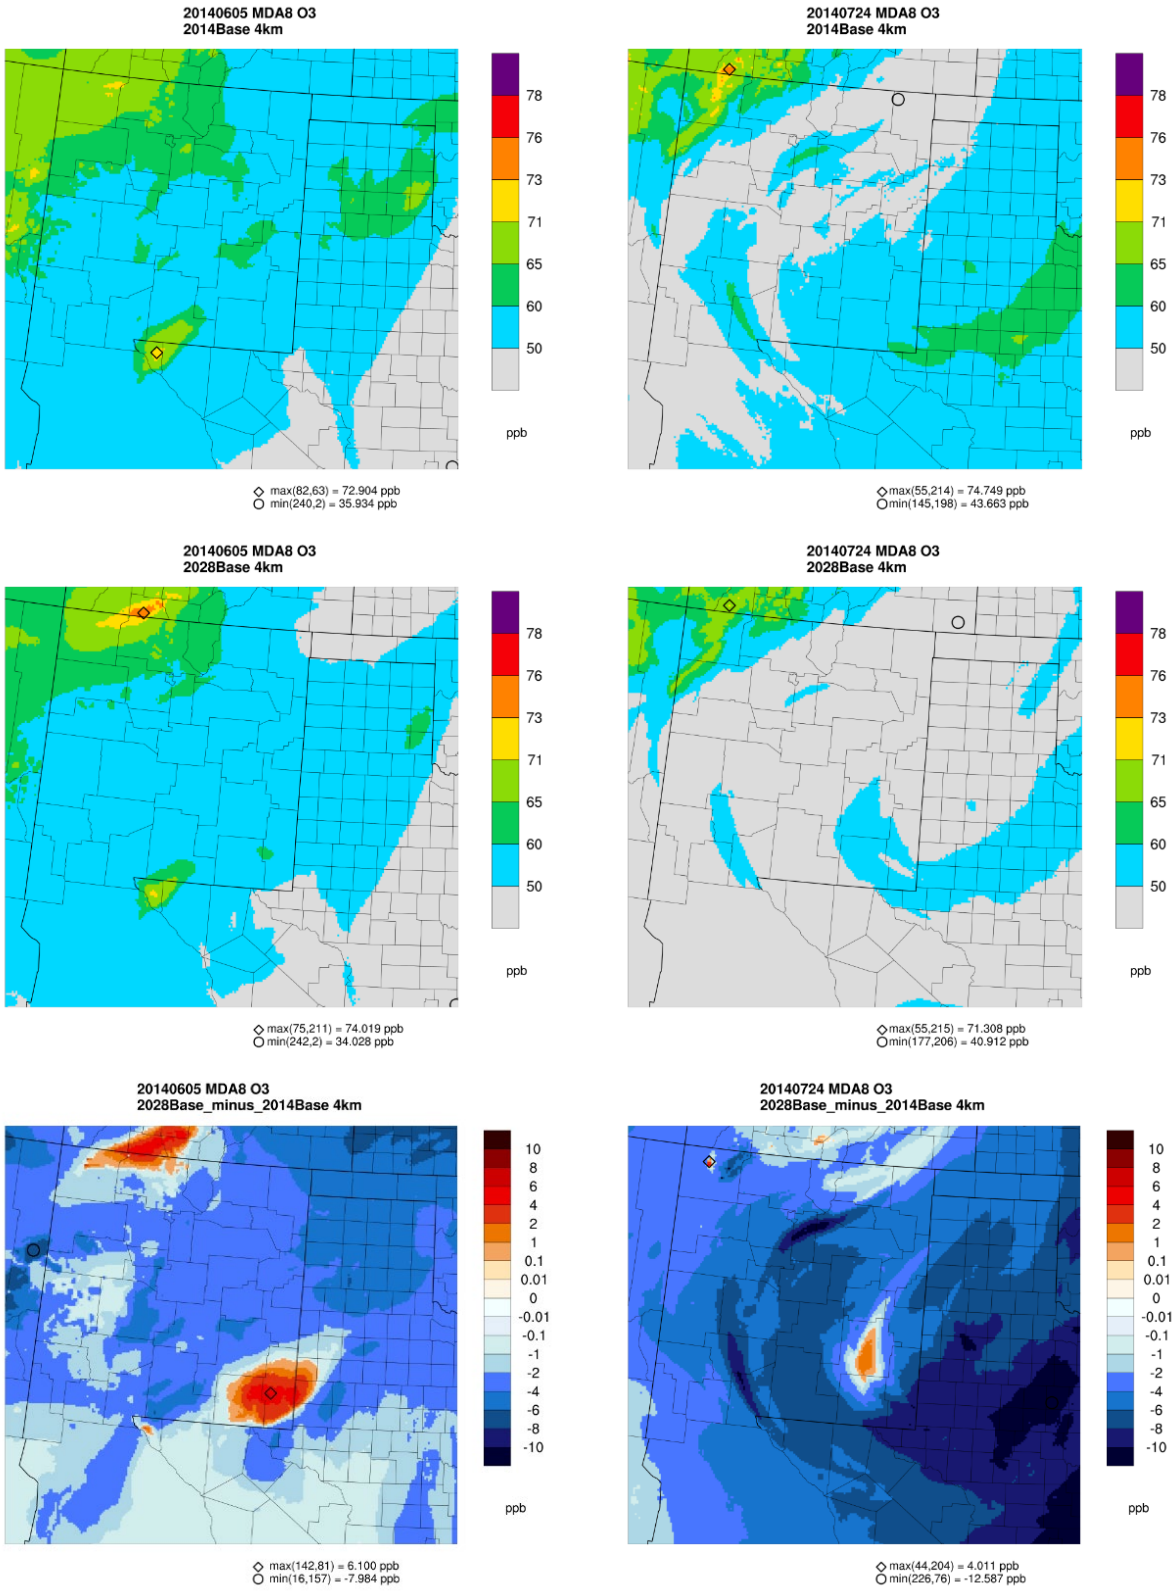

Figure 13. MDA8 ozone concentrations (ppb) on June 5, 2014 (left) and July 24, 2014 (right) for the 2014v2 base case (top), 2028 base case (middle) and their differences (bottom).

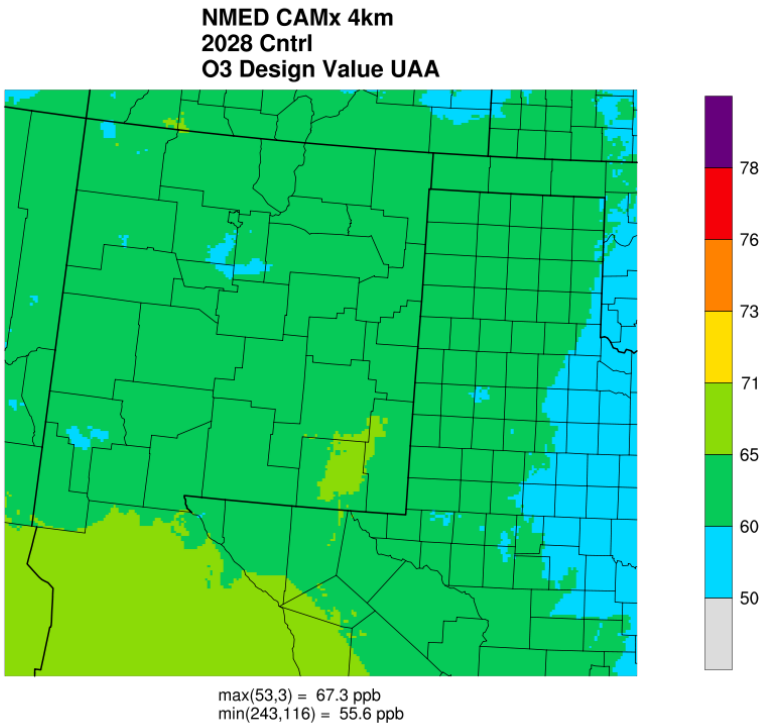

IX. 2028 New Mexico Oil and Gas Control Strategy Ozone Results

Future year 2028 ozone DVF projections were made using the 2014v2 and 2028 O&G control strategy CAMx modeling results (DVF_{Cntl}) following the same EPA-recommended procedures as used to make projections for the 2028 base case (DVF_{Base}), described above only substituting the CAMx 2028 O&G control strategy results for the 2028 base case results. Table 5 compares the projected 2028 ozone DVFs for the 2028 base case and 2028 O&G control strategy and their differences at monitoring sites in New Mexico. The O&G control strategy reduces the 2028 base case ozone DVF_{Base} at the monitoring sites from -0.1 ppb to -1.5 ppb. The largest reductions in 2028 ozone DVF_{Base} due to the O&G control strategy occur at Navajo Lake (-1.5 ppb) and Substation (-1.2) monitoring sites in San Juan County in northwestern New Mexico. The largest reductions in 2028 ozone DVF_{Base} due to the O&G control strategy in southern New Mexico occurs at the Hobbs (-0.7 ppb) and Carlsbad (-0.3 ppb) monitoring sites in the Permian Basin.

Figure 14 displays the spatial distribution of the SMAT UAA ozone DVFs for the 2028 O&G Control Strategy where the SMAT UAA was applied without using concentration gradients in the spatial interpolation of the $DVC_{2012\text{-}2016}$. As shown in Figure 12 (top), within New Mexico, the projected 2028 DVF_{Base} tends to be mostly in the 60-71 ppb range, with the highest ozone concentrations (65-71 ppb) occurring in the San Juan and Permian Basins as indicated by the lighter green shading. When the O&G control strategy is applied, the 2028 ozone DVF_{Cntl} in the San Juan Basin is lower (i.e., in the 60-65 ppb range with the light green shading completely gone in Figure 14, top) and the area of ozone DVF_{Base} in the 65-71 ppb range is greatly reduced for the ozone DVF_{Cntl} case.

Table 5. Observed ozone $DVC_{2012-2016}$ and projected 2028 ozone DVFs for the 2028 Base Case and 2028 O&G Control strategy and differences in the 2028 ozone DVFs ($DVF_{Cntl} - DVF_{Base}$).

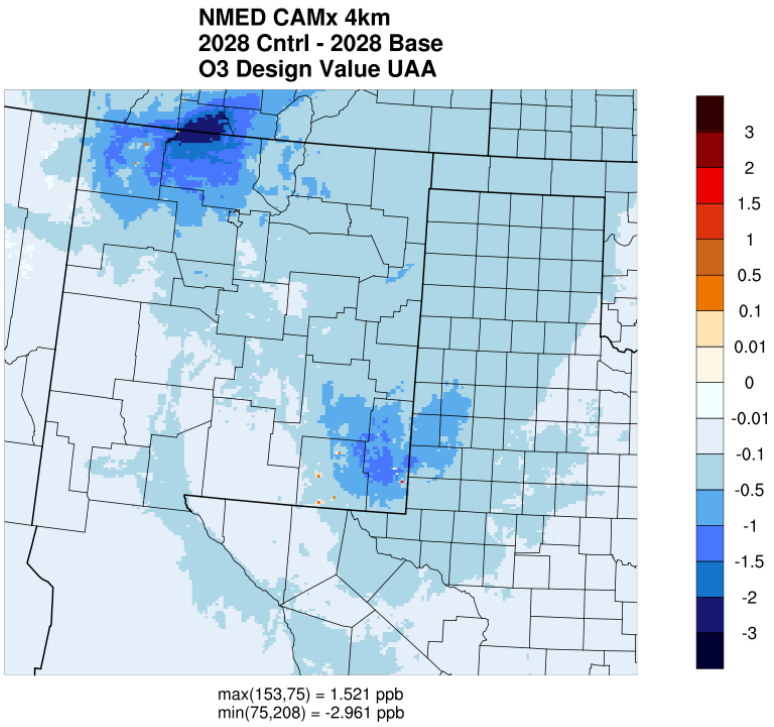

Figure 14. Projected 2028 ozone DVF_{Cntl} for the 2028 O&G control strategy (top) and differences between the projected 2028 ozone DVFs for the 2028 base case and 2028 O&G control strategy ($DVF_{Cntl} - DVF_{Base}$) (bottom) across the 4-km New Mexico modeling domain.

The spatial map of the differences in SMAT UAA projected 2028 ozone DVFs are shown in the bottom panel of Figure 14 (i.e., $DVF_{Cntl} - DVF_{Base}$). Within the Permian Basin, the 2028 O&G control strategy reduces the ozone DVF_{Base} by -0.5 to -1.5 ppb with the largest reductions (-1.0 to -1.5 ppb) mostly occurring in Lea County. The 2028 O&G control strategy has a bigger reduction effect on the 2028 ozone DVF in the San Jun Basin with reductions of -1.0 to -3.0 ppb, with the largest reductions (-2.0 to -3.0 ppb) straddling the New Mexico/Colorado state line, and includes the northern portions of Rio Arriba County. There are also isolated grid cells of SMAT UAA ozone DVF increases in the Permian and San Juan Basins due to the 2028 O&G Control Strategy (i.e., red dots in Figure 14, bottom). These ozone DVF increases appear to be several isolated 4-km grid cells and are likely due to NO_X disbenefits that occur at the locations of O&G NO_x emission reductions due to the 2028 O&G control strategy.

Figure 15 displays the spatial distribution of daily MDA8 ozone concentrations for the 2028 base case, the 2028 O&G control strategy case, and their differences for two days with additional days presented in the AQ Technical Support Document. On June 5, 2014, the 2028 base case has CAMx-estimated MDA8 ozone concentrations in excess of the 70 ppb 2015 ozone NAAQS in northeast San Juan and northwest Rio Arriba Counties, with a peak MDA8 ozone of 74 ppb on the border with and just inside of Colorado (Figure 15, top left). The 2028 O&G control strategy is very effectively reducing these high MDA8 ozone exceedances in the San Juan Basin, with ozone reductions of up to -4.6 ppb that reduce the MDA8 ozone concentrations that were above the 2015 ozone NAAQS in San Juan and Rio Arriba Counties in the 2028 base case to below the 2015 ozone NAAQS in the 2028 O&G control strategy case. MDA8 ozone is also reduced in the Permian Basin, although not to the extent as in the San Juan Basin on this

day. There are also very small areas of ozone increases due to the 2028 O&G control strategy on June 5th that are as high as 0.4 ppb in New Mexico.

On July 24th the 2028 base case has elevated MDA8 ozone concentrations approaching, but below, the 2015 ozone NAAQS in San Juan County, but right across the border in Colorado there is an MDA8 ozone peak of 71.3 ppb that is above the NAAQS (Figure 15, top right). Although the 2028 O&G control strategy reduces the MDA8 ozone across wide areas of New Mexico on this day, with ozone reductions as high as -2.8 ppb in the Permian Basin, there are areas of estimated increases in MDA8 ozone in San Juan County due to the O&G control strategy. These MDA8 ozone increases on July 24th in San Juan County due to the 2028 O&G control strategy are as high as +6.4 ppb. The ozone increases in San Juan County due to the 2028 O&G control strategy are sufficient to increase the MDA8 ozone concentration in one grid cell to 71.0 ppb that exceeds the 2015 ozone NAAQS.

In conclusion, the O&G control strategy results in wide areas of reductions in daily MDA8 ozone concentrations and projected 2028 ozone DVFs across large portions of New Mexico, with the largest ozone reductions occurring in the San Juan and Permian Basins. There are also areas of ozone increases (NO_X disbenefits) in MDA8 ozone and projected 2028 ozone DVFs due to the O&G Control Strategy that usually occur in isolated locations within and near the San Juan and Permian Basins. The size of the areas and magnitudes of the ozone reductions due to the 2028 O&G Control Strategy scenario are much greater than the ozone increases. Using the EPA 2018 PCM Guidance, the projected 2028 ozone DVF were below the 2008 and 2015 ozone NAAQS for both the 2028 base case and 2028 O&G control strategy scenarios.

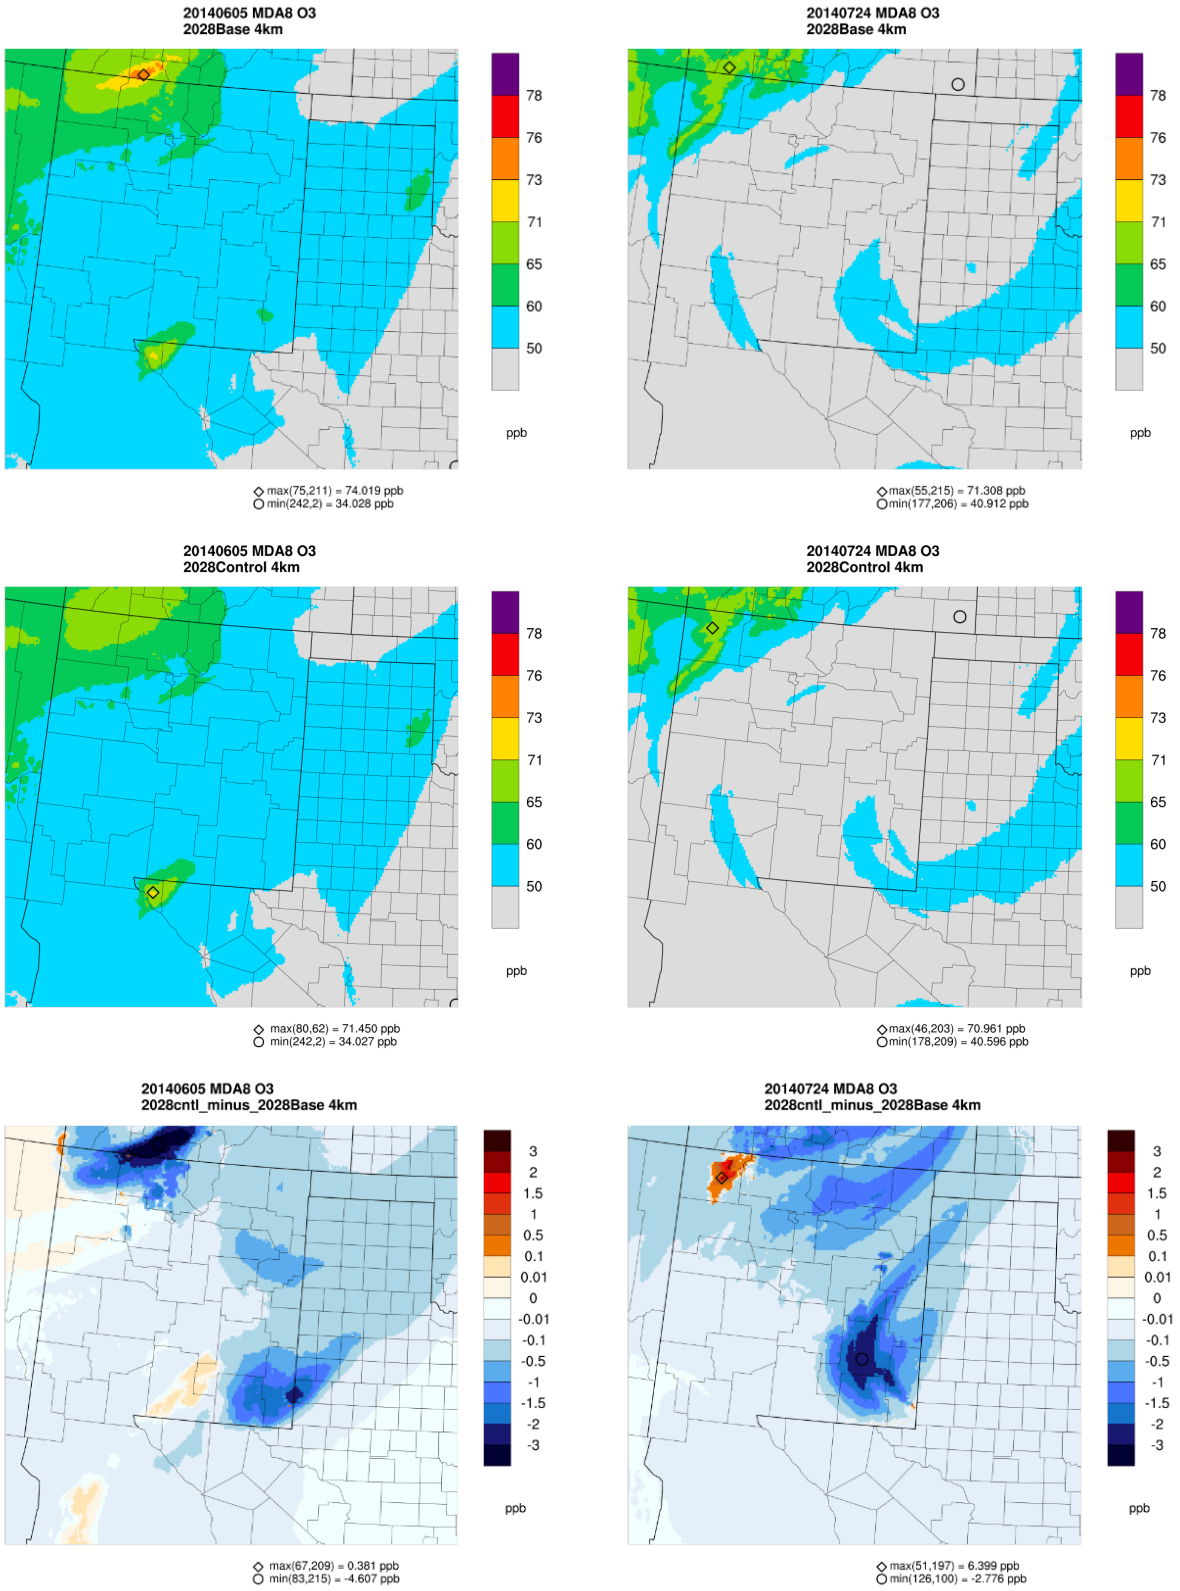

Figure 15. Daily MDA8 ozone concentrations (ppb) on June 5, 2014 (left) and July 24, 2014 (right) for the 2028 base case (top), 2028 O&G control strategy (middle) and their differences (bottom).

X. Sensitivity of the 2028 Ozone DVF Projections to Current Year Ozone DVC

Although the projected 2028 ozone DVF for the 2028 base and 2028 O&G control strategy cases are below the 70 ppb 2015 ozone NAAQS at all monitoring sites in New Mexico when using the current year DVC from 2012-2016 ($DVC_{2012\text{-}2016}$) following EPA's 2018 modeling guidance, in more recent years there has been an increase in observed ozone DVs at some monitoring sites in southern New Mexico. For example, at the Desert View site in Doña Ana County the most recent $DV_{2017\text{-}2019}$ is 77 ppb, which is 5 ppb higher than the $DVC_{2012\text{-}2016}$ (72.0 ppb) used in the 2028 ozone DVF projections when following the EPA 2018 PCM Guidance. And the most recent $DV_{2017\text{-}2019}$ at the Carlsbad site in Eddy County (79 ppb) is 7.7 ppb higher than the $DVC_{2012\text{-}2016}$ (71.3 ppb). Thus, I examined the sensitivity of the 2028 ozone DVF projections to the observed current year DVC. Instead of using the $DVC_{2012\text{-}2016}$ as the starting point for the 2028 ozone DVF projections, I used an average of three ozone design values from 2015-2019 5-year period (i.e., $DVC_{2015\text{-}2019}$) as well as the DV from 2017-2019 (i.e., $DVC_{2017\text{-}2019}$). Note that the CAMx 2014v2 Base Case modeling results used in the denominator of the RRFs to make the 2028 ozone DVF projections does not account for the changes in emissions between 2014 and the more recent years (i.e., 2015-2019 and 2017-2019) that affect the magnitude of the ozone $DVC_{2015\text{-}2019}$ and $DVC_{2017\text{-}2019}$. This includes emission reductions from mobile sources, as well as emission increases from O&G sources. Thus, because the 2014 emission conditions used in the CAMx 2014v2 base case do not represent the emissions conditions that produced the observed current year $DVC_{2015\text{-}2019}$ and $DVC_{2017\text{-}2019}$, the DVC sensitivity analysis of projected 2028 ozone DVFs has additional uncertainties and will likely overstate 2028 ozone DVFs in and near the Permian Basin where the more current year O&G emissions are higher than they were in 2014, and understate the DVFs in areas not affected by

O&G emissions away from the Permian Basin that are more affected by reductions in mobile source emissions in the more recent years.

The 2028 projected ozone DVFs for the 2028 base case using the $DVC_{2015\text{-}2019}$ have one monitoring site that exceeds the 2015 ozone NAAQS, 71.2 ppb at Carlsbad (Table 6). The next highest 2028 ozone DVFs for the 2028 Base Case are 69.3 ppb at Carlsbad Caverns NP and 69.1 ppb at Desert View. The emissions controls in the 2028 O&G control strategy are sufficient to reduce the 2028 Base Case ozone DVF at Carlsbad (71.2 ppb) to below the ozone NAAQS (70.9 ppb) using the $DVC_{2015\text{-}2019}$ current year design value in the 2028 ozone DVF projections.

Table 6. Projected 2028 ozone DVFs for the 2015-2019 current year design value $DVC_{2015\text{-}2019}$ sensitivity analysis.

AQS_ID	2015-19	Projected 2028 DVF			Site Name	County
	DVC (ppb)	Base (ppb)	Cntl (ppb)	Cntl - Base

350153001	71.0	69.3	69.3	0.0	Carlsbad Caverns NP	Eddy
350250008	69.3	67.2	66.5	-0.7	Hobbs Jefferson	Lea
350390026	66.3	63.0	62.2	-0.8	Coyote Ranger Dist	Rio Arriba
350431001	67.0	61.2	60.9	-0.3	Bernalillo (E Avenida)	Sandoval
350450009	67.0	63.6	62.8	-0.8	Bloomfield	San Juan
350450018	69.0	66.7	65.2	-1.5	Navajo Lake	San Juan
350451005	67.3	64.2	62.9	-1.3	Substation	San Juan
350490021	65.0	61.2	61.0	-0.2	Santa Fe Airport	Santa Fe
350610008	66.7	62.6	62.3	-0.3	Los Lunas (Los Lentes)	Valencia

Table 7 shows the results of the 2028 ozone DVF projection current year ozone design value sensitivity analysis using the latest 2017-2019 ozone design value ($DVC_{2017\text{-}2019}$) as the starting point for the 2028 ozone DVF projections. There are three monitors in New Mexico with

$DVC_{2017\text{-}2019}$ above the 75 ppb 2008 ozone NAAQS: Desert View (77.0 ppb), Santa Teresa (76.0 ppb) and Carlsbad (79 ppb). These $DV_{2017\text{-}2019}$ values are, respectively, 5.0, 4.7 and 10.0 ppb higher than the $DVC_{2012\text{-}2016}$ used as the ozone projection starting point in the 2028 ozone DVF projections presented previously following the EPA 2018 PCM Guidance. There are an additional three sites with $DVC_{2017\text{-}2019}$ above the 70 ppb 2015 ozone NAAQS but below the 75 ppb 2008 ozone NAAQS.

For the 2028 base case, there are two sites with projected 2028 ozone DVFs with values above the 70 ppb 2015 ozone NAAQS in the $DVC_{2017\text{-}2019}$ current year design value sensitivity test: 71.6 ppb at Desert View and 76.4 ppb at Carlsbad. The 76.0 ppb $DV_{2017\text{-}2019}$ at Santa Teresa is reduced to 70.5 ppb under the 2028 Base Case, so attains the 2015 ozone NAAQS.

The projected 2028 ozone DVF using the $DVC_{2017\text{-}2019}$ as the current year DVC under the 2028 O&G control strategy are 71.4 ppb at Desert View and 76.0 at Carlsbad, so still exceed the 2015 ozone NAAQS. In fact, the Carlsbad 76.0 ppb ozone DVF even exceeds the 2008 ozone NAAQS.

In addition to the uncertainties and bias in the 2028 ozone DVF projections introduced by using the ozone $DVC_{2015\text{-}2019}$ and $DVC_{2017\text{-}2019}$ that do not overlap with the 2014 base modeling year, the $DVC_{2017\text{-}2019}$ 2028 ozone DVF projection sensitivity analysis has additional uncertainties as it is only based on 3-years of ozone monitoring data and EPA recommends using 5-years of observed ozone concentrations in the DVC to help mitigate the effects of year-to-year variability in the observed ozone concentrations.

Table 7. Projected 2028 ozone DVFs for the 2017-2019 current year design value $DVC_{2017-2019}$ sensitivity analysis.

XI. CAMx 2023 Source Sector APCA Ozone Source Apportionment Modeling

The CAMx 2023 Source Sector APCA ozone source apportionment obtained separate ozone contributions due to emissions from several source regions (e.g., New Mexico) and source sectors (e.g., O&G point sources) using the Anthropogenic Precursor Culpability Assessment ("APCA") version of the CAMx ozone source apportionment tool and the 2028 O&G control strategy emissions scenario. Separate ozone contributions were obtained for the following 9 source categories:

1. NAT: Natural (biogenic, lightning NO_x, windblown dust and oceanic [sea salt and dimethyl sulfide]).
2. FIR: Fires (U.S. wildfires, wildland prescribed burns and agricultural burning and other [Mexico/Canada] fires).

3. O&GPT: Oil and gas point sources (surrogate for midstream O&G).
4. O&GNP: Oil and gas non-point sources (surrogate for upstream O&G).
5. EGU: Electrical Generating Unit point sources.
6. NonEGU: Non-EGU point sources.
7. OnRoad: On-road mobile.
8. NonRoad: Non-road mobile.
9. OAnth: Remainder anthropogenic.

The ozone contributions due to New Mexico anthropogenic emissions for each source sector were removed from the CAMx 2028 O&G control strategy ozone results and SMAT was used to estimate the New Mexico source sector contributions to the projected 2028 ozone DVFs that are shown in Table 8. Sites in northern New Mexico have the highest contributions from O&G sources and EGU point sources due to being in or near the San Juan Basin and in close proximity to the Four Corners Power Plant that is assumed to still be operating in 2028. Sites in central New Mexico (e.g., Bernalillo County) tend to have higher ozone contributions associated with sources related to population (e.g., mobile sources and other anthropogenic) due to being in or within proximity of Albuquerque, New Mexico's largest city. Sites in southern New Mexico include those in southern Doña Ana County on the border with Texas that tend to have mostly small contributions from New Mexico source sectors with the exception of EGU (0.7 to 0.9 ppb), due to the proximity of the Rio Grande Power Plant to some of the sites, and on-road mobile (0.4-0.5 ppb) due to population centers along I-25, with the Solano monitor having higher ozone contributions from mobile sources due to being close to emissions from the City of Las Cruces, the second largest city in New Mexico. Finally, the Carlsbad and Hobbs monitors are within the Permian Basin so have relatively high contributions from New Mexico O&G sources.

Table 8. Reduction in 2028 O&G control strategy ozone DVFs due to the elimination of ozone contributions due to New Mexico emissions from 7 anthropogenic emissions source sectors.

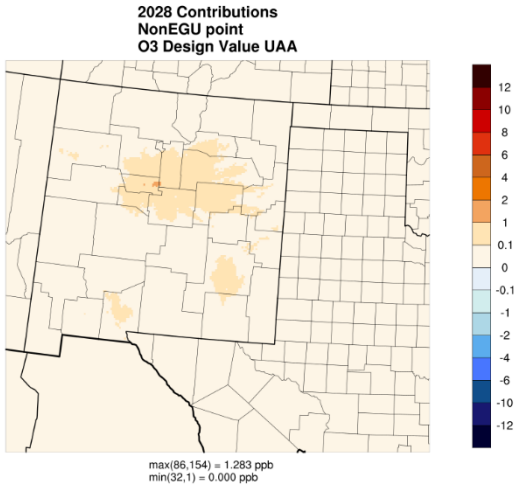
The SMAT UAA feature was used to estimate the spatial distribution 2028 ozone DVFs across the 4-km New Mexico domain for the 2028 O&G control scenario without New Mexico emissions from each of the 7 anthropogenic emission source sectors as shown in Figures 17 and 18. Removing New Mexico EGU emissions results in a reduction in the 2028 ozone DVF by as much as 3.1 ppb in San Juan County with ozone reductions of 0.1 to 1.0 ppb in the upper half of New Mexico and from Doña Ana to Lea Counties in southern New Mexico (Figure 17a). The removal of New Mexico Non-EGU Point emissions results in a reduction of 1.3 ppb in eastern



Bernalillo County and reductions of 0.1 to 1.0 in adjacent counties, with little effect over the rest of New Mexico away from Bernalillo County (Figure 17b). New Mexico on-road mobile contributes as much as 2.6 ppb to the 2028 ozone DVF, with reductions of 1-2 ppb stretching from Albuquerque to Santa Fe and in Las Cruces (Figure 17c). New Mexico non-road mobile contributes as much as 2.1 ppb in Bernalillo County (Figure 17d). New Mexico Non-Point O&G has large (> 2 ppb) contributions to the 2028 ozone DVF in the San Juan and Permian Basins (Figure 18a). Whereas, New Mexico Point O&G contributes as much as 1-2 ppb in the Permian Basin but less than 1 ppb in the San Juan Basin (Figure 18b). The Other Anthropogenic Source Sector contributions has a similar distribution to the two mobile Source Sectors with the highest ozone contributions centered on Bernalillo County (Figure 18c).

(c)

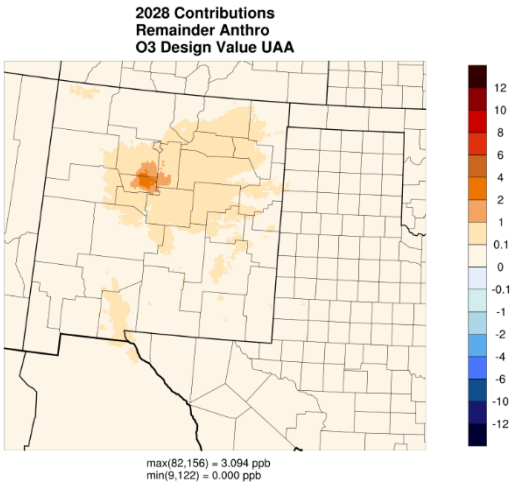

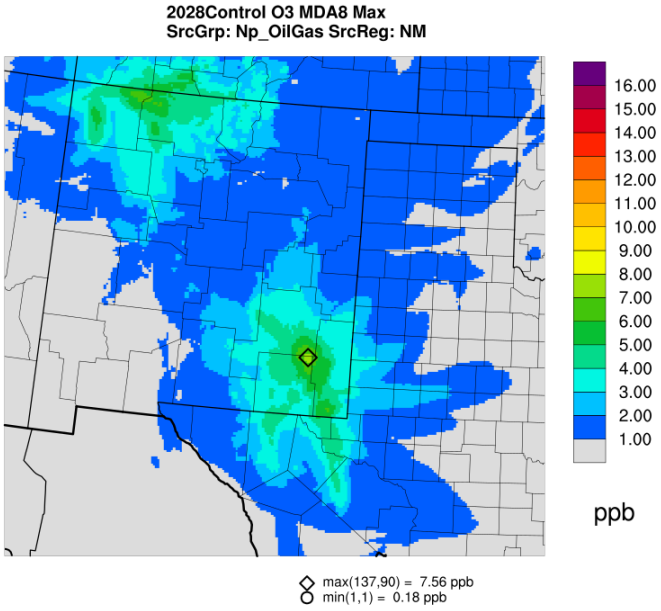

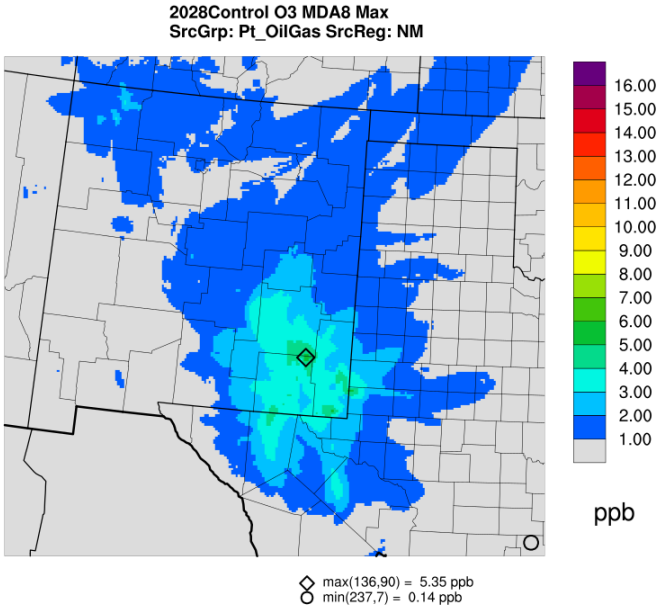

Figure 18. Reduction in 2028 O&G control strategy ozone DVF due to removal of New Mexico Source Sector emissions for: (a) Non-Point O&G; (b) Point O&G; and (c) Other Anthropogenic.

Figure 19 displays the episode maximum MDA8 ozone contributions due to emissions in New Mexico from the non-point and point O&G source sectors. There are substantial ozone contributions (e.g., > 5 ppb) to MDA8 ozone due to non-point O&G in both the Permian and San Juan Basins, with a maximum value of 7.6 ppb in the northeast corner of Eddy County in the Permian Basin. The New Mexico point O&G source sector has lower contributions than non-point O&G, especially in the San Juan Basin, with a peak MDA8 ozone contribution of 5.4 ppb

at the same location in the northeast corner of Eddy County that the non-point O&G peak occurred (i.e., total episode maximum O&G contribution of 13 ppb). Thus, even with implementation of the proposed requirements in Part 50, New Mexico O&G emissions in 2028 are still estimated to have substantial contributions to MDA8 ozone concentrations in New Mexico.

XII. CAMx 2028 VOC/NO_X Sensitivity OSAT Ozone Source Apportionment Modeling

A second CAMx 2028 O&G control strategy ozone source apportionment simulation was conducted to examine whether ozone formation resulting in high ozone concentrations in New Mexico is more sensitive to VOC or NO_X emissions. The VOC/NOx sensitivity ozone source apportionment simulation used the Ozone Source Apportionment Technology ("OSAT") version of the CAMx ozone source apportionment tool. When ozone is formed in CAMx, OSAT determines whether ozone formation is more VOC or NOx sensitive, and assigns a fraction of the ozone formed to either the OSAT source group's O3V (VOC sensitive) or O3N (NO_X sensitive) ozone tracers based on the relative contribution of the source group's limiting precursor contribution (i.e., VOC or NO_X). Thus, comparing the OSAT O3V and O3N tracers provides an indication of whether ozone formation is more sensitive to VOC or NO_X precursors. I developed the percent contribution of NO_x sensitive ozone formation metric (%NOxSens) to display the degree that ozone formation is more sensitive to VOC or NO_X as follows:

$$\text{Percent } NO_x \text{ Sensitive Ozone (\%NOxSens)} = 100 \times \sum O3N_i / \sum (O3V_i + O3N_i)$$

where the sum is performed over the source groups (i) being analyzed. In the displays below I present spatial maps of the %NOxSens metric for the following summed source groups:

- All emission source groups in the 36/12/4-km modeling domains (anthropogenic and natural);
- Anthropogenic emission source groups in the 36/12/4-km modeling domains (U.S. and international); and
- New Mexico anthropogenic emission source groups.

To interpret the %NOxSens for the above three summed source groups, I also present the MDA8 ozone contribution of the summed source groups to understand whether the level VOC

and NO_X ozone formation sensitivity occurs under elevated MDA8 ozone conditions or not. Example %NOxSens results are presented below for the three source groups listed above and two example days in detail and then 15 days for the total anthropogenic emissions source group.

On June 5, 2014 CAMx estimates high MDA8 ozone concentrations in excess of the 70 ppb ozone NAAQS in the San Juan Basin and El Paso under the 2028 O&G control strategy scenario (Figure 20a). In these high ozone locations, ozone formation is split approximately equally between VOC and NO_x sensitive ozone formation conditions (Figure 20b). When looking at just anthropogenic emissions, ozone formation tends to be more NO_x sensitive with %NOxSens ranging from 60-85% in El Paso and 70-85% in San Juan Basin (Figure 20d). Ozone from New Mexico anthropogenic emissions is mainly NO_x sensitive in El Paso on June 5th, but in the San Juan Basin there is more VOC sensitive ozone formation, with New Mexico anthropogenic emissions ozone contribution ranging from 1 to 4 ppb (Figure 20e and 20f). In particular, there are large areas of blue shaded %NOxSens ozone in San Juan County due to New Mexico anthropogenic emissions indicating that New Mexico VOC and NO_x anthropogenic emissions are approximately equally important to ozone formation in San Juan County on this day (Figure 20f). On the other hand, ozone formation within the Permian Basin appears to be more NO_x sensitive on June 5th.

On July 24th, the peak MDA8 ozone in the 4-km domain is above the NAAQS (71.1 ppb) and occurs in San Juan County (Figure 21a). Although ozone formation is primarily NO_x sensitive across the 4-km NM domain, the largest VOC sensitive ozone (23%) due to all emissions (%NOxSens = 77%) occurs at the location of the peak ozone in San Juan County (Figure 21b).

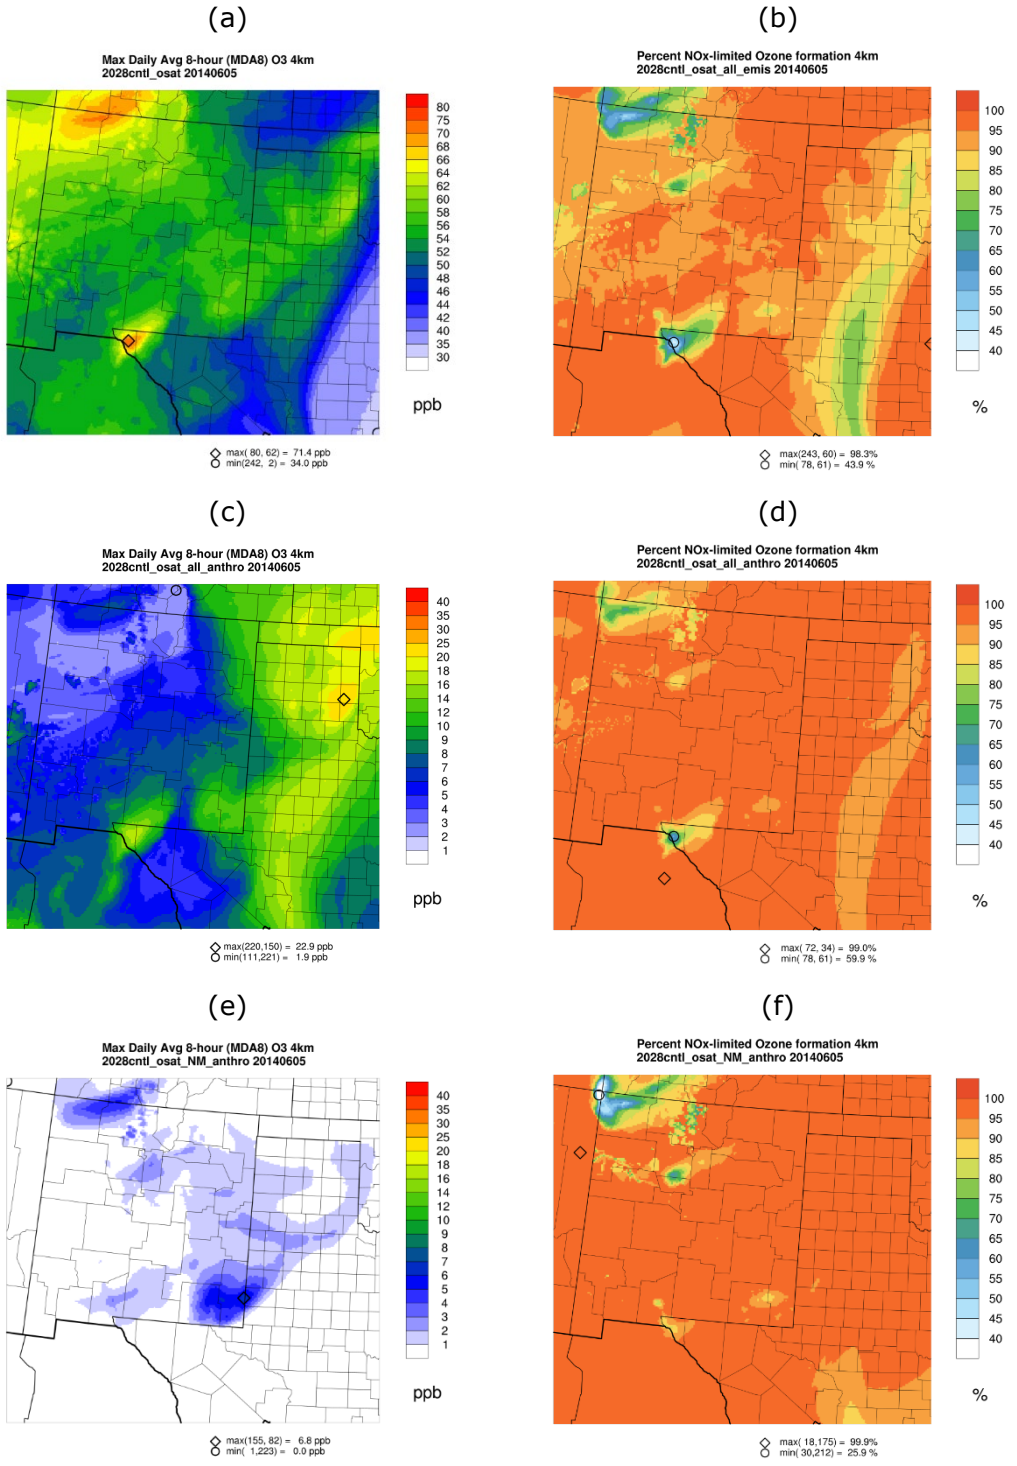

Figure 20. 2028 O&G control strategy MDA8 ozone (left) and Percent NOx Sensitive Ozone (right) on June 5, 2014 for: (a) total MDA8 ozone; (c) ozone due to anthropogenic emissions; (e) ozone due to New Mexico anthropogenic emissions; (b) %NOxSens for all emissions; (d) %NOxSens for all anthropogenic emissions; and (f) %NOxSens for New Mexico anthropogenic emissions.

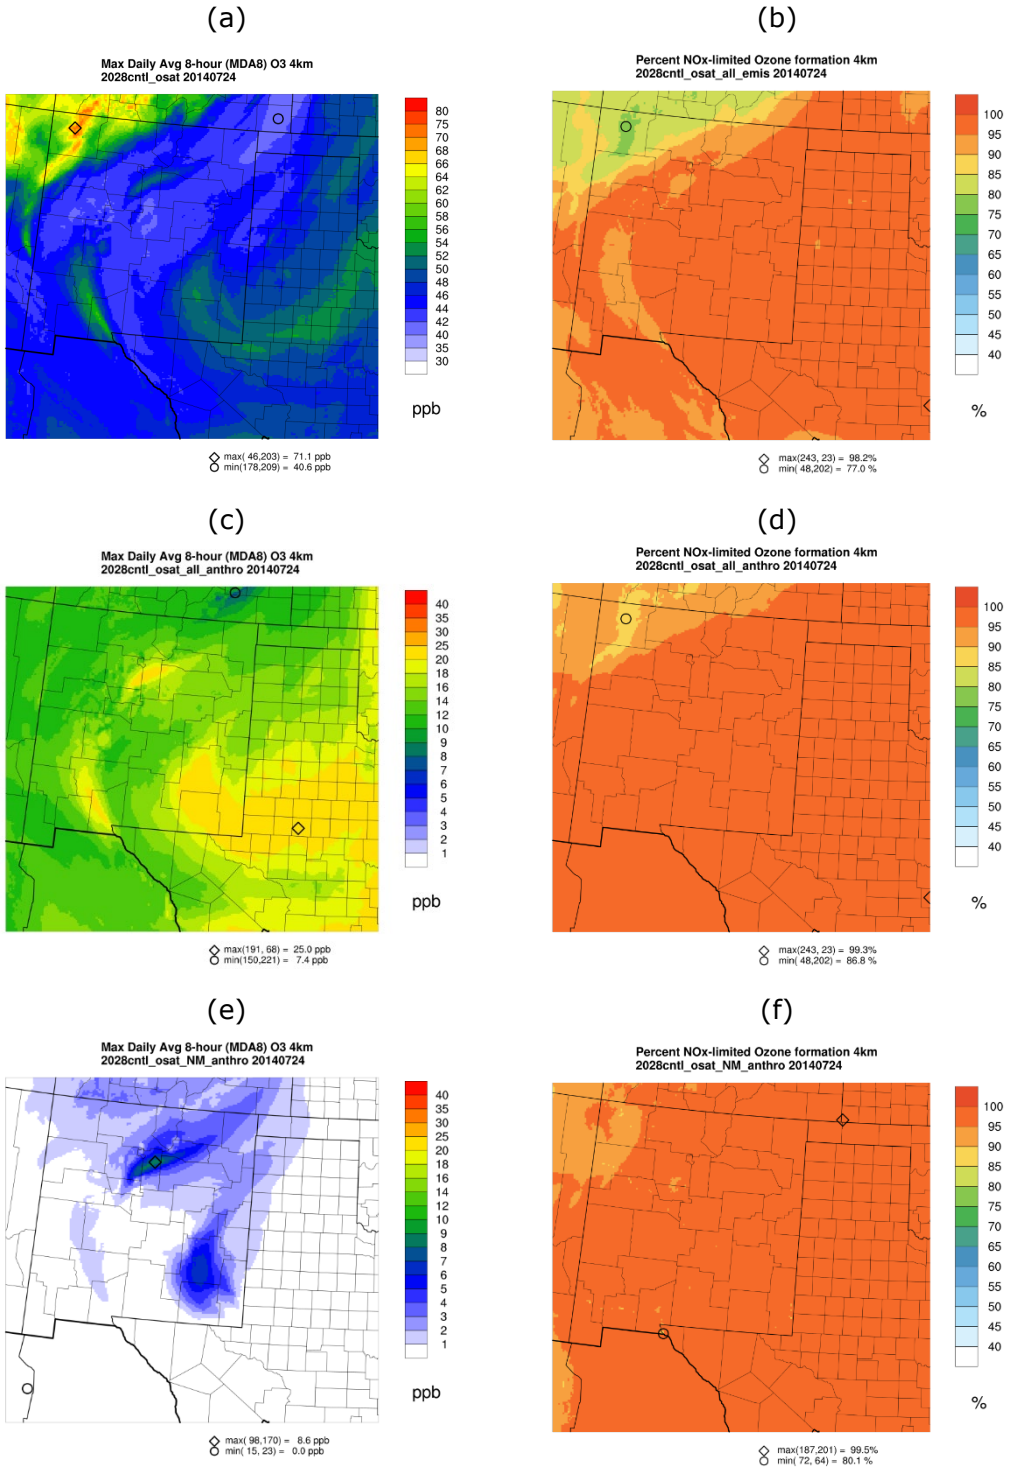

Figure 21. 2028 O&G control strategy MDA8 ozone (left) and Percent NOx Sensitive Ozone (right) on July 24, 2014 for: (a) total MDA8 ozone; (c) ozone due to anthropogenic emissions; (e) ozone due to New Mexico anthropogenic emissions; (b) %NOxSens for all emissions; (d) %NOxSens for all anthropogenic emissions; and (f) %NOxSens for New Mexico anthropogenic emissions.

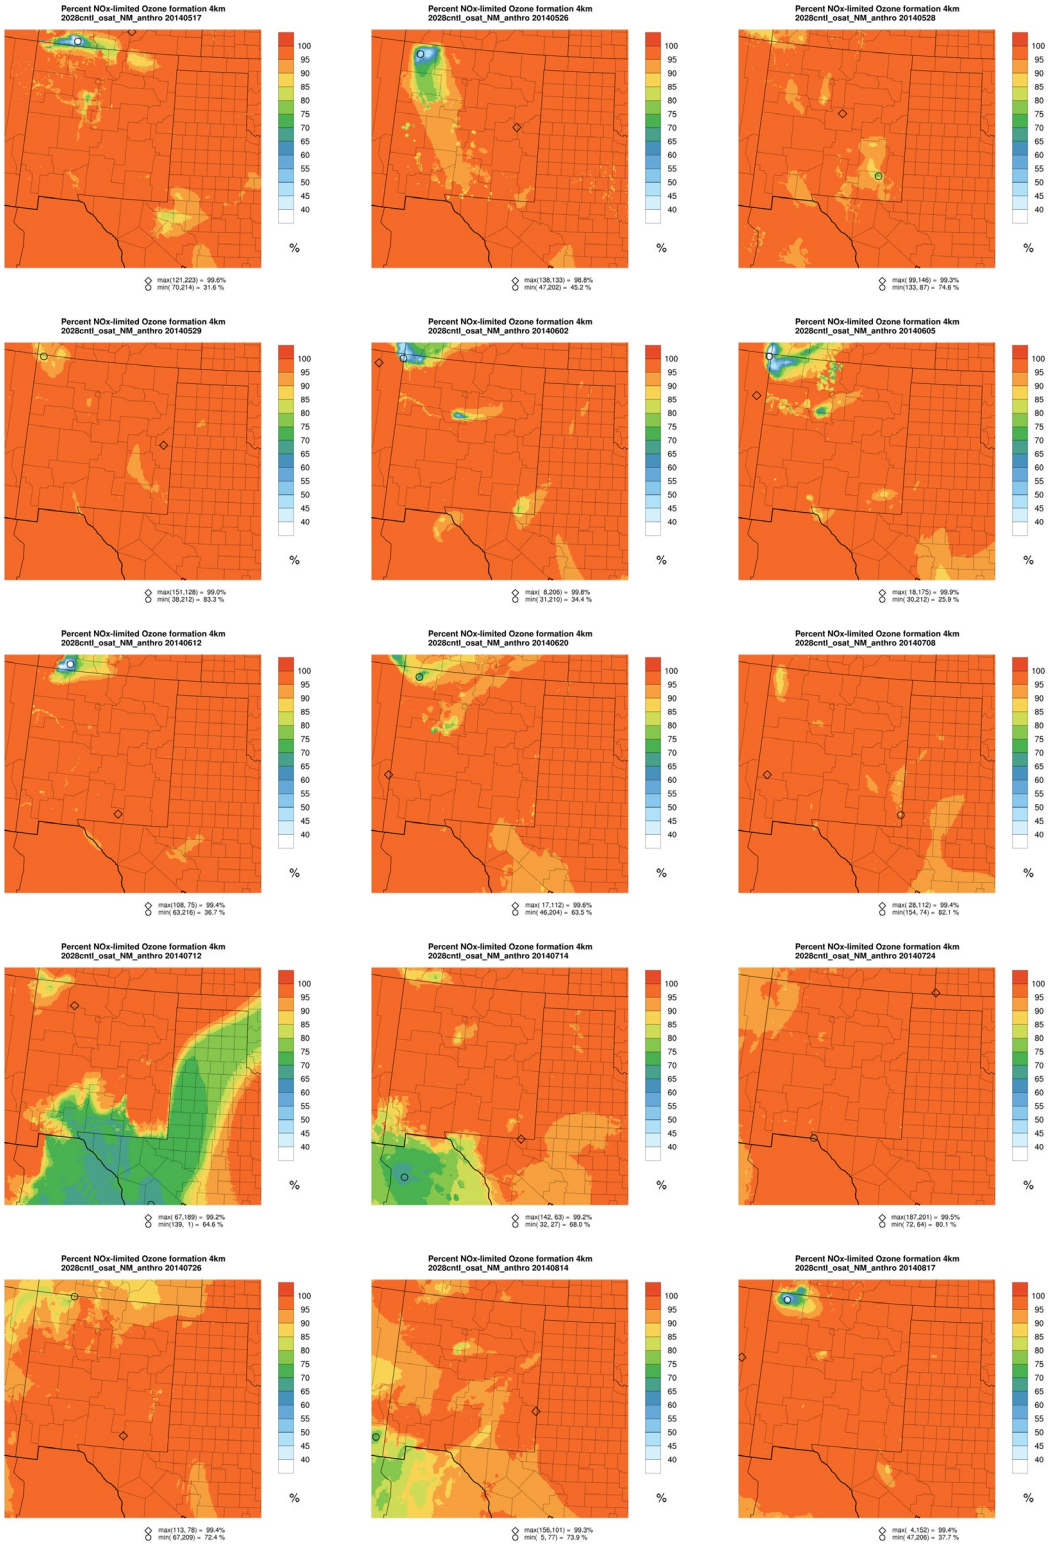
Figure 22 displays the spatial distribution of the %NOxSens metric due to 2028 O&G control strategy New Mexico anthropogenic emissions for 15 example days from the May-August 2014 modeling episode. As expected, given its mostly rural nature, the CAMx OSAT simulation estimates that ozone formation due to New Mexico anthropogenic emissions is primarily NO_x sensitive across most of New Mexico. However, there are several locations where ozone formation is estimated to have relatively higher VOC sensitive ozone formation conditions. The San Juan Basin consistently has higher VOC sensitive ozone formation conditions due to New Mexico anthropogenic emissions. Albuquerque also has higher VOC sensitive ozone formation conditions due to New Mexico anthropogenic emissions, and occasionally, ozone formation in the Permian Basin also has relatively higher VOC sensitive ozone formation. The highest MDA8 ozone concentrations also tend to have relatively higher VOC sensitive ozone formation conditions. For example, at the location of the relatively high (58 ppb) MDA8 ozone in San Juan County on May 26th the fraction of VOC sensitive ozone is 32% for all emissions, 31% for all anthropogenic emissions and 55% for New Mexico anthropogenic emissions (Figure 22, top middle). On May 28th an ozone peak in the Permian Basin is split 75%/25% NO_X/VOC sensitive ozone (Figure 22, top right). June 5th is a day where there is high MDA8 ozone in San Juan and Rio Arriba Counties that is approaching the NAAQS that is split approximately equally between VOC and NO_X sensitive ozone (Figure 20 and Figure 22, second row right). On August 14th the modeled ozone peak exceeds the ozone NAAQS in El Paso and ~70% of the ozone was formed under NOx sensitive conditions (Figure 22, bottom middle).



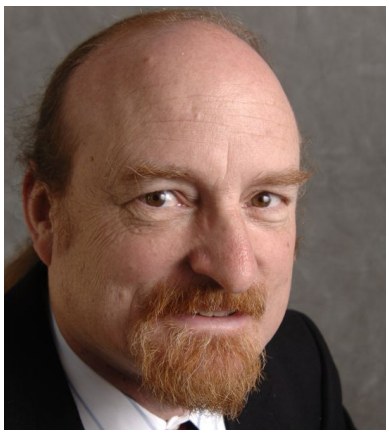


Figure 22. Spatial distribution of Percent NO_x Sensitive Ozone due to New Mexico anthropogenic emissions across the 4-km New Mexico domain for 15 days of relatively higher MDA8 ozone concentrations.

RALPH E MORRIS

Managing Principal

Ralph Morris is the Managing Principal at Ramboll's North California, Utah and Colorado Offices, where he directs air quality modeling and analysis, emission inventory development, control strategy evaluation, and regulatory air issues projects. With over 40 years of air quality consulting experience, Ralph is one of the original developers of many of the photochemical air quality models that are being or have been used for regulatory decision making in the United States and around the world, including co-developer of Ramboll's Comprehensive Air Quality Model with extensions (CAMx) as well as the UAM and UAM-V models.

In the late 1970s and 1980s, Ralph was one of the pioneers in modeling air pollution in Los Angeles using one of the first ever photochemical grid models (PGM), the Urban Airshed Model (UAM). In the late 1980s, Ralph performed the EPA Five Cities UAM Study for the United States Environmental Protection Agency (USEPA) that demonstrated the use the UAM PGM for ozone air quality planning culminating in the delivery of the UAM to USEPA in 1990 as the USEPA-recommended (Appendix W) ozone model. In the late 1980s and early 1990s, Ralph developed the next generation variable grid PGM (UAM-V) that treats urban and regional transport issues within the same nested grid model that was used by the Ozone Transport Assessment Group (OTAG) to define the first regional control strategies designed to reduce the contributions of ozone transport in the eastern U.S. (i.e., NO_X SIP Call). Ralph also led the development of ozone and $PM_{2.5}$ State Implemental Plans (SIPs) for numerous cities to allow them to achieve clean air. After joining Ramboll in 1994 (then called ENVIRON), Ralph was one of the leaders in the development of the Comprehensive Air-quality Model with extensions (CAMx) PGM that is still being used today around the world for air quality planning, including for USEPA's transport rules. During the 1990s Ralph was involved in numerous ozone and $PM_{2.5}$ SIP modeling studies and analyzed long-range transport of air pollutants.

In the 2000s, Ralph directed the development of an updated Pollutants in the ATmosphere for Hong Kong (PATH) air quality modeling system for the Hong Kong Environmental Protection Department (HKEPD) and applied it to southeast Asia to assess regional transport and urban ozone and particulate matter formation. During this time he also directed the application of regional particulate matter (PM), ozone and visibility modeling using CMAQ and CAMx photochemical grid models for the southeastern (VISTA/ASIP), western (WRAP) and central (CENRAP) U.S. Regional Planning Organizations (RPOs) for the development of the first round of regional haze State Implementation Plans (SIPs) due in 2007.

For almost two decades, Ralph led regional air quality modeling for Alberta Environment for a variety of issues including to assess the air and ecological impacts of oil sands, development of modeling databases for various regions in Alberta and most recently to model the high winter $PM_{2.5}$ occurrences in Edmonton and Red Deer. He led or is leading the application of the CMAQ and CAMx models to address

numerous ozone and $PM_{2.5}$ State implementation Plans (SIPs), as well as to address other air quality and air quality-related value (AQRV) issues associated with oil and gas development projects. Ralph has also addressed NO_2 and SO_2 issues including SIPs. Ralph was an original member of USEPA's ozone and fine particulate guidance workgroup and the CMAS Models-3/CMAQ External Advisory Committee (EAC).

Ralph is currently leading the WRF meteorological, SMOKE emissions and CAMx and CMAQ photochemical modeling effort for the Western Regional Air Partnership (WRAP) to develop the western states Regional Haze SIPs. He is also currently leading the WRF/SMOKE/CAMx modeling efforts for the Denver ozone SIPs to address both the 2008 and 2015 ozone NAAQS as well as the Fairbanks Alaska $PM_{2.5}$ SIP efforts.

EXPERIENCE

Over the last 40+ years, Ralph has been involved in thousands of air quality studies. These studies include the development of clean air plans for cities and states so that they attain the health-based air quality standards and the evaluation of the air quality impacts of numerous types of sources. any of the studies involved photochemical modeling, usually using CMAQ and/or CAMx, that required WRF meteorological and SMOKE emissions modeling as well. A few examples for some of Ralph's projects are provided below.

- **WRAP Regional Haze Photochemical Modeling**. Ralph led the development of photochemical modeling databases for western states used in the second round of regional haze SIPs due July 2021. For the Western Regional Air Partnership (WRAP), Ralph has set up the CMAQ and CAMx models for the 2014 calendar year and conducted model performance evaluation and 2028 future year modeling.
- **Denver 2020 and 2023 SIPs Ozone Attainment Demonstration Modeling.** Ralph just finished the 2020 Denver Serious ozone SIP modeling and is just starting the 2023 Denver ozone SIP ozone attainment demonstration modeling for the 2023 and 2026 future years. The CAMx PGM

was set-up for the 2016 summer ozone season using WRF meteorology and will be used for the 2023 and 2026 future year attainment demonstration modeling to address attainment of the 2015 and 2008 ozone NAAQS, respectively.

- **Allegheny County Annual $PM_{2.5}$ State Implementation Plan.** Project Director for performing the air quality modeling to define emissions control strategy to demonstrate that Allegheny County (Pittsburgh), Pennsylvania will attain the annual $PM_{2.5}$ National Ambient Air Quality Standard (NAAQS). Performed 36/12/4/1.30.444 km WRF meteorological modeling for the 2011 year. SMOKE emissions modeling for 2011 and 2021. CAMx regional 36/12 km modeling to provided boundary conditions for mesoscale 4/1.33 km PM source apportionment modeling for 2011 base and 2021 future years. 2021 PM control strategy evaluation.
- **Evaluation of USEPA's 2011 National Air Toxics Assessment (NATA**). Evaluated and assessed USEA's 2011 NATA modeling approach and results for modeling hundreds of air toxics compounds on a national scale. The 2011 NATA combined CMAQ national modeling results for reactive and non-reactive pollutants at 12 km grid cell resolution with AERMOD local-scale non-reactive modeling results by using the AERMOD results for receptors in the 12 km grid cell in a relative fashion to scale the CMAQ 12 km average concentrations. This unique method of model fusion of the CMAQ and AERMOD modeling results overcomes some of the issues associated with other techniques (e.g., CMAQ zero-out runs) when combining modeling results with disparate formulations.
- **Dynamic Evaluation of Ozone Models for the South Coast (Los Angeles) Air Basin (SoCAB).** Project Manager for conducting a dynamic evaluation of the CMAQ photochemical grid model in the SoCAB (Los Angeles, California region) using a 2008 and 2012 CMAQ modeling database. The dynamic evaluation compared the CMAQ modeled ozone trends over a long period (1990-2015) with the observed ozone trends and found the CMAQ model underestuimat6ed the observed rate of ozone reductions over time. Potential reasons for this included the likely underestimation of VOC or overestimation of NOx emissions in the region.
- **Denver 2017 Ozone SIP Modeling.** For almost two decades, Ralph has led the Denver ozone SIP modeling for the 2003, 2008 and 2017 Denver ozone SIPs. For the Denver 2017 ozone SIP modeling we developed 2011 CAMx PGM modeling database using WRF meteorological and SMOKE emissions modeling. This included high-resolution mobile source emissions for the Denver region using link-based activity data from a Transportation Demand Model (TDM) and mobile source emission factors from MOVES2014. Conducted CAMx 2011 base case modeling and model performance evaluation. Projected emission to 2017 and 2023 and conducted emission reduction control strategy modeling to demonstrate attainment of the ozone standard.
- **Allegheny County 1-Hour SO_2 State Implementation Plan.** Project Manager for performing the air quality modeling to define emissions control strategy to demonstrate that Allegheny County (Pittsburgh), Pennsylvania will attain the 1-hour SO_2 National Ambient Air Quality Standard (NAAQS). Perform 36/12/4/1.3 km WRF meteorological modeling for multiple years. Conduct model shoot-out using multiple models (e.g., AERMOD, CALPUFF and SCICHEM) and model configurations to determine best performing model for simulating SO_2 and use model to demonstrate attainment of the SO2 NAAQS.
- **BLM Environmental Impact Statement and Resource Management Plan for Oklahoma, Texas and Kansas.** Project Manager for preparing the air quality and climate change sections of the Environmental Impact Statement (EIS)/ Resource Management Plan (RMP) for the U.S. Bureau of Land Management (BLM) and Bureau of Indian Affairs (BIA) to guide the management of BLM- and BIA-administered lands in the states of Oklahoma, Texas and Kansas
- **Navajo Generating Station Environmental Impact Statement.** Project Manager for coordinating the Environmental Impact Statement (EIS) required under the National Environmental Policy Act (NEPA) for the Navajo Generating Station coal-fired power plant and Kayenta Coal Mine Complex in Arizona. Technical services include air quality modeling and analysis of air monitoring data for criteria and hazardous air pollutants, assessments of human health risk and ecological risk due to atmospheric deposition from the emission sources, and preparation of Technical Support Documents for the EIS.
- **Western Air Quality Study (WAQS).** Project Manager for WRF meteorological, SMOKE emissions and CMAQ/CAMx air quality modeling of the western U.S. to develop the next generation air quality

modeling databases to address ozone, $PM_{2.5}$, visibility and deposition issues in the western U.S.. Develop new 2008, 2011 and 2014 regional modeling platforms and distribute using the Intermountain West Data Warehouse (IWDW). Assess the role of regional transport on ozone, PM, and visibility issues in western U.S. states.

- **Air Quality Impacts of Off-Shore Oil and Gas Production.** Ralph led the photochemical modeling for two studies for BOEM to estimate the on-shore air quality impacts due to off-shore oil and gas development in the Arctic Sea north of Alaska and the Gulf of Mexico. This multi-year multi-million dollar study projected future year emissions and air quality impacts and developed emission exception screening thresholds.
- **Air Quality Impacts of Fires**. Project Manager of studies to assess the contributions of wildfires, prescribed burns and agricultural burning to ozone and PM air quality throughout the USA. Developed fire emission inventories and use the CAMx photochemical grid model source apportionment tool to calculate the contributions of fires to ozone and PM air quality. Results are used to identify exceptional events and assist planners in fire management practices.
- **BLM Montana/Dakotas Photochemical Grid Model Modeling Study.** Project Manager for the BLM Montana/Dakotas PGM modeling study to assess the air quality and AQRV impacts due to oil and gas development. The Bakken Shale formation in the Montana/Dakotas region is one of the most rapidly growing oil and gas development area in the U.S. Under this study, Ramboll is developing a comprehensive oil and gas emissions inventory and performing base year 2012/2013 and future year 2032 modeling using the CAMx photochemical grid model.
- **Allegheny County 24-Hour $PM_{2.5}$ SIP Modeling.** The $PM_{2.5}$ problem in Allegheny County (Pittsburgh), Pennsylvania is due to a combination of regional transport from upwind states and local sources within a river valley complex terrain environment. Ralph Morris led the Allegheny County $PM_{2.5}$ SIP modeling effort that used the CAMx photochemical grid model with a 36 km CONUS, 12 km Midwest, 4 km southeastern Pennsylvania and 0.8 km Allegheny County grid nests to demonstrate the area would achieve the 24-hour $PM_{2.5}$ standard by 2010. CAMx was run on the 36/12/4/0.8 km grids using two-way grid nesting. Local sources were treated using the CAMx subgrid-scale Plume-in-Grid treatment.
- **Development of Air Quality Modeling System for Hong Kong**. Ralph was Project Manager and led the development of a new air quality modeling system for Hong Kong. The WRF/MM5 meteorological, SMOKE/CONCEPT emissions and CMAQ/CAMx air quality models were set up for a 27/9/3/1 km modeling domain with the 36 km domain covering Asia and the 1 km domain focused on Hong Kong. The modeling system was delivered to the HKEPD as a turn-key system.
- **St. Louis Ozone and $PM_{2.5}$ SIP.** Ralph led the air quality modeling efforts for the development of clean air plans for St. Louis, Missouri that were included in the St. Louis ozone and $PM_{2.5}$ State Implementation Plans (SIPs). He worked with the states of Missouri and Illinois to identify the optimal control plan for the region and performed air quality modeling to demonstrate that St. Louis would achieve the ozone and $PM_{2.5}$ standards.
- **Air Quality Assessments in Alberta, Canada**. For over a decade, Ralph Morris has been leading air quality studies for Alberta Environment to address Canada wide standards and Province air quality goals and objectives. These activities have included developing emission inventories for the Alberta oil sands region and urban areas, conducting meteorological modeling and performing air quality modeling using the CMAQ model to address ozone, $PM_{2.5}$, SO_2, NO_2, exposure and deposition issues in the Province.
- **Expert Testimony for Air Quality Related Issues**. Because of Ralph's vast expertise in air quality issues and in particular air quality modeling, for over two decades he has served as an expert witness in numerous litigation cases.
  - Ameren Rush Island: Ralph was an expert witness and testified at trial in St. Louis April 2019 in a case where the Rush Island coal-fired power plant was accused of causing health effect impacts due to alleged illegal emissions since it failed to obtain a PSD permit and install BACT.
  - LG&E Cane Run Class Action Suit: Starting in 2015, Mr. Morris served as an expert witness led by Hunton and Williams in a Class Action case involving nuisance dust deposition from the Louisville Gas and Electric Cane Run coal-fired EGU. He discovered a fatal flaw in the opposing experts AERMOD modeling analysis that undermined the class action arguments.

- Minnesota Power Plant Damage Assessment: During 2015, Ralph performed air quality modeling of the potential damages and costs associated with fossil-fueled power generation in Minnesota and prepared testimony.
- Mead Westvaco Luke Mill: Expert witness and testified at trial in a case where a Maryland paper mill was accused of violating the Clean Air Act (CAA) and emitting illegal emissions (2012-2016).
- DTE Energy Monroe: In 2010-2011 Ralph was retained as an expert witness by Hunton and Williams and prepared expert report and attended trial in Detroit for the USDOJ CAA NOV case against the Monroe coal-fired power plant in the Detroit, Michigan region.
- AEP NOV: Ralph was an expert witness for American Electric Power (AEP) from 2003-2006 through Sidley Austin in the US DOJ CAA NOV charges against 9 coal-fired power plants in the Midwestern US.
- Illinois Power/Dynegy Baldwin NOV: Ralph was an expert witness for Illinois Power through Akin Gump in the US DOJ CAA NOV case against the Baldwin Power Plant in Illinois. Ralph prepared expert reports and was deposed on the ozone and PM impacts of the alleged excess emissions including a review and critique of the plaintiffs CALPUFF modeling that found errors and omissions.
- First Energy Sammis: Expert witness for the Sammis coal fired power plant in Ohio NOV case.
- Louisiana Generating Big Cajun 2: Ralph was an expert witness for a USDOJ CAA NOV case against the Big Cajun 2 coal-fired power plant in Baton Rouge, Louisiana during 2012.
- WE Energies Power the Future: In 2004, Ralph performed air quality modeling using CAMx and testified in front of a judge in Madison, WI on the Wisconsin Electric's plans to retire an old and build a new coal fired power plant at the Oak Creek facility. Testimony also included a critical review of CALPUFF modeling performed by the opponents.
- Minnesota Acid Rain Legislation: In the early 1980s Ralph performed modeling and testified in Minneapolis, MN in front of a judge for Northern States Power regarding the impacts of local sources in Minnesota on acid deposition in Minnesota.

CALPUFF Modeling Experience. Ralph has been directing and using the CALPUFF model, and its predecessor MESOPUFF, for over 35 years. In fact, the Diagnostic Wind Model (DWM), which is the wind model component of CALMET that is part of the CALPUFF modeling system, was developed under Ralph's direction as part of the UAM modeling system and implemented in CALMET as part of its original development for the California Air Resources Board. Ralph's Experience with CALPUFF includes the following:

Mount Zirkel Visibility Study (MZVS): In the 1995-1997 period, Ralph led the CALPUFF modeling component of the MZVS that was assessing the visibility impacts of the Hayden and Craig coal-fired power plants in northern Colorado on visibility impairment at the Mount Zirkel Class I Area.

PSD Permitting Of New Sources: Ralph has directed and conducted CALPUFF model applications for numerous proposed new sources as part permitting under the U.S. Prevention of Significant Deterioration (PSD) program. CALPUFF was used to model the long-range transport of pollutants and assess their impacts at Class I and sensitive Class II areas for comparison against Significant Impact Levels (SILs) and PSD Increments as well as the Assessment of Air Quality Related Values (AQRVs, e.g., visibility and acid deposition). Example CALPUFF permitting for PSD applications include applications for

LSPower (e.g., Doswell Energy, Hanover, Virginia; White Pine Energy Development near Ely, Nevada; High Plains Energy Project northeast of Denver, Colorado; Sunrise River, Minnesota; Plum Point Unit II in Arkansas; West Deptford Energy Station in New Jersey

Holcim (now LaFarge) Ste. Genevieve Cement Plant: Holcim proposed to build the largest cement plan in the U.S. south of St. Louis and Ralph led the CALPUFF modeling component of the PSD permit.

NEPA Air Quality Modeling: In the U.S., proposed development on Federal land must disclose their environmental impacts under the National Environmental Policy Act (NEPA).

Ralph has led numerous NEPA air quality assessment that have included CALPUFF modeling for a variety types of sources, including oil and gas and energy development.
EPA Modeling Techniques: Ralph has assisted USEPA in developing and evaluating numerous air quality modeling techniques for 35 years. In 2012 Ralph published the results of several the definitive long-range transport model evaluation studies[1] that included the evaluation of CALPUFF and 5 other models against regional tracer test field experiments[2] that helped formulate EPA's latest January 2017 air quality modeling guidelines[3]. Ralph was also Principal-in-Charge in the development of the Mesoscale Model Interface (MMIF[4]) program the generates CALPUFF meteorological inputs directly from WRF model output without the need of CALMET.
Litigation Support: Ralph has used and critiqued the CALPUFF modeling system in several litigation cases, including the Illinois Power Baldwin coal-fired power plant case where Ralph's identification of errors introduced in the model by the Plaintiff's expert modifications resulted in them pulling their expert report.

- **Oil and Gas Environmental Impact Statements.** Ralph has led the air quality modeling component of several oil and gas Environmental Impact Statements to assess the air quality, visibility and deposition impact of oil and gas development in Colorado, Utah, Wyoming and New Mexico. These activities includes near-source AERMOD modeling and frequently regional PGM modeling.
- **Air Quality Permitting Studies.** As part of the permitting process, Ralph has conducted numerous air quality modeling studies to demonstrate that new sources would be compliant with air quality standard and thresholds of concern. Sources evaluated include coal and natural gas powered electricity generation; cement plans and oil and gas production, distribution and refining.
- **Air Quality Impacts of Mobile Sources**. Ralph has performed numerous studies to assess the air quality impacts of alternative engine technologies and fuels. In the 1980s he modeled the air quality impacts of alternative fuels in five cities for the USEPA. In the 1990s he led the air quality modeling component of the $20M Auto/Oil Program for the automobile manufacturers and oil companies. He also led the assessment of the air quality impacts of hybrid vehicles for a joint study by General Motors and Toyota. More recently he evaluated air quality impacts of passenger vehicles for Toyota and the air quality impacts in California due to the use of biodiesel in on-road and non-road diesel engines.
- **Technical Assistance to USEPA.** For over three decades, Ralph has provided technical assistance to the USEPA to assist them in implementing their air program and developing the USEPA air quality modeling techniques and guidelines. This assistance included developing guidance for plume modeling, demonstrating how photochemical grid models (PGMs) can be used in ozone air quality planning and delivering the UAM PGM to USEPA in 1990 as a turn-key PGM ozone modeling system. In 2012 Ralph evaluated six long range transport (LRT) models using atmospheric field study tracer tests, evaluated chemical dispersion models using aircraft data and demonstrated how a PGM can be used for single-source modeling that helped EPA formulate their latest January 2017 air quality modeling guidelines. More recently he is assisting USEPA to update the chemical mechanisms in the CAMx and CMAQ models and implement improved aqueous-chemistry and secondary organic aerosol modules.
- **Various Clients.** Prior to joining Ramboll, Ralph worked for over 15 years at Systems Applications International (SAI) in San Rafael (now part of ICF Consulting), California, where he was Director of the Advanced Modeling Program, managed model development activities and air quality modeling and analysis studies. His work at SAI included the development and application of the RPM, UAM, UAM-V and REMSAD modeling systems.

OFFICE OF
AIR QUALITY PLANNING
AND STANDARDS

MEMORANDUM

SUBJECT: Modeling Guidance for Demonstrating Air Quality Goals for Ozone, $PM_{2.5}$ and Regional Haze

FROM: Richard A. Wayland, Division Director
Air Quality Assessment Division

TO: Regional Air Division Directors, Regions 1 – 10

The Environmental Protection Agency (EPA) is issuing the attached *Modeling Guidance for Demonstrating Air Quality Goals for Ozone, $PM_{2.5}$ and Regional Haze*. This document reflects the EPA's recommendations for how air agencies should conduct air quality modeling and related technical analyses to satisfy model attainment demonstration requirements for the 2015 ozone and 2012 $PM_{2.5}$ National Ambient Air Quality Standards (NAAQS), as well as for regional haze reasonable progress analyses. This document updates the previous draft version of the modeling guidance, which was released in December 2014.

This document does not substitute for provisions or regulations of the Clean Air Act (CAA), nor is it a regulation itself. As the term "guidance" suggests, it provides recommendations on how to implement the modeling requirements. Thus, it does not impose binding, enforceable requirements on any party, nor does it assure that the EPA will approve all instances of its application, as the guidance may not apply to a particular situation based upon the circumstances. Final decisions by the EPA regarding a particular State Implementation Plan (SIP) demonstration will only be made based on the statute and applicable regulations and will only be made following a final submission by air agencies and after notice and opportunity for public review and comment.

In December 2014, the EPA released a draft version of this guidance for public review and comment. A total of 13 substantive comments were received. After considering the comments, the EPA made changes which are reflected in this updated version of the guidance. Major guidance updates include responding to the public comments as well as updates to reflect requirements in the most recent NAAQS implementation rules and regional haze rule.

NMED Exhibit 108

Similar to the draft guidance, the updated guidance is divided into two main sections. The first part describes how to setup and apply a photochemical modeling platform (including meteorological, emissions, and air quality modeling), and the second part describes how to use the air quality modeling results to show whether future attainment of the ozone and/or $PM_{2.5}$ NAAQS is likely. The guidance also describes how to use photochemical grid modeling to evaluate reasonable progress goals for regional haze.

Many of guidance updates are in the form of revised and reorganized text. In addition, numerous references have been added and/or updated. The updated guidance reflects the requirements contained in the 2015 ozone NAAQS SIP requirements rule (November 2018)[1], the 2012 $PM_{2.5}$ NAAQS SIP requirements rule (August 2016)[2], and the regional haze rule (January 2017)[3].

Specific updates to the draft guidance include:

- Reorganization of the document including removal of outdated language and references.
- The 2014 draft guidance updates to the recommended 8-hour ozone attainment test (relative response factors using the top ten modeled days) were finalized, and now also apply to the 2015 ozone NAAQS.
- Consistent with the 2017 regional haze rule revisions, the reasonable progress goals methodology has been updated to reference the 20 percent "most anthropogenically impaired" days and 20 percent "clearest" days.
- The emissions modeling section has been extensively updated to account for new and improved emissions models, techniques, and input data, and has been closely coordinated with the SIP emissions inventory guidance, "*Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Regulations*," available at: https://www.epa.gov/air-emissions-inventories/air-emissions-inventory-guidance-implementation-ozone-and-particulate.

Please share this guidance with air agencies in your Region. If you have any questions concerning this document, please contact Brian Timin at (919) 541-1850 or *timin.brian@epa.gov*. The guidance document is available electronically on the EPA's website: https://www.epa.gov/scram/state-implementation-plan-sip-attainment-demonstration-guidance.

NMED Exhibit 108

1.0 Introduction

This document describes how to estimate the impacts of an emissions control strategy on air quality for purposes of demonstrating attainment of the annual average and 24-hour average national ambient air quality standards (NAAQS) for particles smaller than 2.5 µm in diameter ($PM_{2.5}$) and the 8-hour NAAQS for ozone. We also describe how to use modeled and monitored air quality data to estimate future visibility conditions in *Class I areas* (e.g., national parks, wilderness areas) as part of the development of reasonable progress goals (RPGs) that reflect the long-term strategy in a regional haze state implementation plan (SIP).[1]

This document describes how to apply air quality models to generate the predictions used to evaluate attainment and/or to set RPGs for regional haze. Modeling to show attainment of the NAAQS primarily applies to nonattainment areas[2] for which modeling is required, or desired. Modeling to assess reasonable progress for regional haze applies to all states, the District of Columbia, and the U.S. Virgin Islands.[3]

This guidance is designed to implement national policy on air quality modeling requirements as embodied in the Clean Air Act (CAA), the Ozone SIP Requirements Rule[4], the $PM_{2.5}$ SIP Requirements Rule[5], and the Regional Haze Rule[6]. In addition, the United States Environmental Protection Agency (EPA) revised 40 CFR part 51, Appendix W (Guideline on Air Quality Models) (U.S. EPA, 2017a), hereafter referred to as "Appendix W," in 2017 to provide general information about the types of model approaches that may be appropriate for the purposes of demonstrating attainment with the ozone and $PM_{2.5}$ NAAQS (section 5) and projecting visibility impacts at Class I areas (section 6). Appendix W is a regulation and, as such, contains binding requirements. However, the Appendix W photochemical modeling requirements related to SIP

[1] Modeling to determine RPGs as described in this document is part of the development of a regional haze SIP. However, unlike the NAAQS, the Regional Haze program does not involve fixed air quality standards that must be achieved. The ways that RPGs are used in the development of a regional haze SIP are described in more detail in section 5.

[2] While this guidance document is primarily directed at modeling applications in nonattainment areas, it may also be useful as a guide for modeling to support NEPA analyses, maintenance plans or to support other rules or provisions of the Clean Air Act.

[3] *See* 40 CFR 51.300(b).

[4] *See* Implementation of the 2015 National Ambient Air Quality Standards for Ozone: Nonattainment Area State Implementation Plan Requirements; [Final rule signed November 7, 2018]

[5] *See* Fine Particulate Matter National Ambient Air Quality Standards: State Implementation Plan Requirements ($PM_{2.5}$ SIP Requirements Rule), 81 FR 58101 (Aug. 24, 2016).

[6] The Regional Haze Rule was revised by a final rule published on January 10, 2017 (82 FR 3078). This version of the modeling guidance reflects that revision of the rule. Additional revisions may be made to this guidance to be consistent with any future regional haze rule and/or guidance issued by EPA.

NMED Exhibit 108

attainment demonstration modeling and regional haze modeling do not proscribe any particular models or modeling techniques. As such, this modeling guidance provides additional details about how to set up and run photochemical models that may be useful to air agencies that are required to submit SIP attainment demonstrations and/or regional haze modeling.

This guidance is intended for use by the EPA headquarters and Regional offices; federal land managers of mandatory Class I federal areas; state, local and tribal air quality management authorities, and the general public. This document does not substitute for provisions or regulations of the CAA enumerated above, nor is it a regulation itself. As the term "guidance" suggests, it provides recommendations on how to implement the modeling requirements. Thus, it does not impose binding, enforceable requirements on any party, nor does it assure that the EPA will approve all instances of its application, as the guidance may not apply to a particular situation based upon the circumstances.

The EPA and state, local, and tribal air agencies (hereinafter referred simply as "air agency" or "air agencies") retain the discretion to adopt approaches on a case-by-case basis that differ from this guidance where appropriate. Final decisions by the EPA regarding a particular SIP submission that includes a modeling demonstration will ultimately be made based on the statute and applicable regulations and will only be made following a final submission by air agencies and after notice and opportunity for public review and comment. Interested parties are free to raise questions and objections about the appropriateness of the application of this guidance to a particular situation; the EPA and air agencies should consider whether or not the recommendations in this guidance are appropriate in that situation.

1.1 What Is the Purpose of This Document?

This document has two purposes. The first purpose is to describe how to apply an air quality model to produce results needed to support an attainment demonstration or to calculate RPGs for a regional haze reasonable progress analysis in a scientifically appropriate manner. The second is to explain how to interpret whether results of modeling and other analyses support a conclusion that attainment of the ozone and/or $PM_{2.5}$ NAAQS will occur by the appropriate date for an area, and/or to assess progress towards the national visibility goal of the regional haze program.

1.2 Does the Guidance in This Document Apply to Me?

This guidance applies to all air agencies that are required to submit a State Implementation Plan (SIP), or Tribal Implementation Plan (TIP) submission with an attainment plan designed to

NMED Exhibit 108

achieve attainment of the ozone and/or $PM_{2.5}$ NAAQS. The guidance also applies to air agency SIP submissions developed to address Regional Haze Rule requirements. Air agencies required to submit an attainment demonstration and/or a reasonable progress analysis for regional haze are encouraged to follow the procedures described in this document. Details on when a state is required to submit a modeled attainment demonstration can be found in the Ozone SIP Requirements Rule[7] and the $PM_{2.5}$ SIP Requirements Rule[8]. Details on when a state is required to submit a regional haze SIP that includes RPGs can be found in the Regional Haze Rule[9].

1.3 Outline

Part 1 of this guidance provides an overview of the modeling and attainment demonstration process. Part 2 describes how to build a "modeling platform" and apply air quality models. A "modeling platform" consists of the building blocks of an air quality modeling demonstration. This includes emissions modeling[10], meteorological modeling, and the development of all other inputs needed to run an air quality model. The model platform development process consists of the following steps as outlined in section 2:

Section 2.1	Development of a conceptual description of the problem to be addressed
Section 2.2	Develop a modeling protocol
Section 2.3	Select appropriate meteorological time periods to model
Section 2.4	Choose an appropriate area to model with appropriate horizontal/vertical resolution
Section 2.5	Select an appropriate model to support the demonstration
Section 2.6	Generate meteorological inputs to the air quality model
Section 2.7	Generate emissions inputs to the air quality model
Section 2.8	Develop initial and lateral boundary conditions that are suitable for the application

Typically, the air quality modeling process starts with the development of base year emissions and meteorology for input to an air quality model to evaluate model performance. Section 3

[7] *See* 40 CFR 51.1308.
[8] *See* 40 CFR 51.1011.
[9] *See* 40 CFR 51.308. Sections 308(d) and (e) apply for SIPs for the first implementation period only. States that followed section 51.309 (which is also part of the Regional Haze Rule) in the first implementation period were not required to develop RPGs. Section 51.308(f) applies to all Regional Haze SIPs due in 2021 and later.
[10] Additional emissions inventory requirements and details on emissions modeling are contained in "Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Regulations."

NMED Exhibit 108

describes the process for evaluating model performance and performing diagnostic analyses. After evaluating the model and making any necessary input changes or adjustments, the model is run for a future year, which corresponds to the appropriate attainment year for the area or to the future year modeled for regional haze planning purposes. Sections 2 and 3 apply to both ozone and $PM_{2.5}$ modeling and modeling to set RPGs for regional haze SIPs.

Section 4 describes how the air quality model outputs are then used to apply the modeled attainment test to support an attainment demonstration for ozone or $PM_{2.5}$. We explain what is meant by a *modeled attainment demonstration*, a *modeled attainment test*, and a *weight of evidence demonstration*. Modeled attainment tests are described for the 8-hr ozone NAAQS and the annual and 24-hour $PM_{2.5}$ NAAQS. Section 5 addresses aspects of modeling specific to regional haze SIPs.

Model applications require a substantial effort. Air agencies are encouraged to work closely with the appropriate EPA Regional office(s) in executing each step of the modeling and attainment demonstration or regional haze planning process. This will increase the likelihood of approval of the demonstration at the end of the process.

NMED Exhibit 108

2.0 Building a Model Platform

2.1 Conceptual Description

The first step in developing an attainment demonstration is to construct a conceptual description of the problem that is being addressed. Conceptual descriptions, which are also referred to as conceptual models, are comprehensive summaries of the "state of the knowledge" regarding the influence of emissions, meteorology, transport, and other relevant atmospheric processes on air quality in the area (Vickery, 2004). For a conceptual description to be informative, it should identify what processes and sources, in the generic sense, are most responsible for the air quality issue being simulated. Well-constructed conceptual models can substantially inform the design of the attainment demonstration modeling (e.g., episode selection, choice of domain, emissions priorities, evaluation focus) and should be conducted in advance of the development of a modeling protocol. It is worth noting that conceptual descriptions can be valuable in other air quality planning efforts besides attainment demonstrations, such as determining nonattainment area boundaries, investigating emissions control program impacts, interstate transport analyses, and monitoring network design, among others.

The following bullets describe some of the key building blocks in developing a conceptual model. The process steps discussed below are meant to illustrate one possible template for building a conceptual model to inform an air quality modeling demonstration; there may be alternate approaches that better suit individual study areas or issues, which air agencies should discuss with the appropriate EPA Regional office.

- Introduce the general nature of the air quality problem addressed by the conceptual model:
    - What are the pollutants of concern in the area?
    - What are the current air quality levels in the area?
    - What is the attainment/nonattainment status of the area?
    - What is the geographical scope of poor air quality?
    - What is the temporal scope of poor air quality?
    - What are the air quality trends in the area? Is the problem getting better or worse?
    - What are the suspected mechanisms for formation of poor air quality levels?
    - What are the sources of emissions that may contribute to poor air quality?
    - Are there unique meteorological influences on local air quality levels?

- Describe the ambient monitoring network used for the conceptual model:
    - Develop a map of monitor sites and types (e.g., FRM, FEM, CSN, IMPROVE, CASTNET, etc.).

NMED Exhibit 108

- Describe characteristics of individual monitoring sites (scale, frequency, etc.).

- Describe the status and trends of air quality in the area:
  - Summarize the relevant monitoring data for the air quality problem being studied.
  - Identify locations that are in violation of the NAAQS.
  - Describe the spatial pattern in pollutant and precursor pollutant levels.
  - Describe the temporal pattern in pollutant and precursor pollutant levels.
  - Describe the annual trends in concentrations over the period of interest.
  - If appropriate, develop fused ambient/model surfaces to fill any gaps within the monitoring network.

- Investigate possible relationships between emissions and air quality:
  - Examine emissions estimates for the main sector/source categories.
  - Compare emission trends for annual and or seasonal/episodic periods to corresponding air quality trends.
  - Identify key emission sources or source categories.
  - Assess the historical effectiveness of control programs.
  - Consider how future emissions growth or reductions may affect air quality.
  - List control programs that are in place, or will soon be implemented, that may impact emissions sources in the area.

- Investigate possible relationships between meteorology and air quality (AQ):
  - Describe meteorological characteristics on poor air quality days (e.g., wind speed/direction, temperatures, relative humidity levels, inversion indicators, etc.).
  - Identify any distinct meteorological phenomena that coincide with poor air quality days.
  - Prepare pollution roses, HYSPLIT back-trajectories (Draxler, 1998), or any other relevant analysis needed to link poor air quality days to specific meteorological patterns and sources of transported pollutants.
  - Assess the impact from pollutant transport into area based on meteorological data and ambient air quality data.

- Synthesize all the relevant information into a detailed conceptual model:
  - Aggregate all elements of the conceptual model and provide the key findings resulting from the analyses completed.
  - Characterize the potential factors that influence air quality in the area and where possible rank the importance of those influences.

- Identify issues that require further investigation, either in terms of data collection or chemical transport modeling.
- Discuss how the subsequent SIP modeling and associated protocol is impacted by this conceptual description.

2.1.1 Example Applications of Conceptual Models

The idea of developing a modeling protocol based upon a conceptual description of the sources and processes that lead to poor air quality is well-established (U.S. EPA, 2007a). Numerous excellent conceptual models of local and regional air quality issues have been developed over the past decade. Table 2-1 provides a non-comprehensive list of example conceptual models that have been developed since the last release of the guidance that may be useful in orienting future SIP modeling applications.

Table 2.1 Examples of recently developed conceptual models

Air quality issue	**Reference**
$PM_{2.5}$ / Regional Haze (Northeast U.S.)	MANE-VU (2013)
$PM_{2.5}$ (Midwest U.S.)	Lake Michigan Air Directors Consortium (LADCO) (2009)
Ozone (Austin TX)	McGaughey *et al.* (2010)
Ozone (Wyoming)	Stoeckenius (2010)
$PM_{2.5}$ (Southeast Michigan)	Turner (2008)

2.2 Modeling Protocol and Supporting Documentation

As with any technical support document designed to inform air quality planning, an attainment demonstration or regional haze analysis should be supported by documentation that sufficiently describes the procedures used in the analysis. In order to facilitate the process of EPA Regional office review and approval, we recommend the preparation of two separate supporting documents for ozone and $PM_{2.5}$ SIPs: one before the modeling analyses are initiated (modeling protocol) and one after the analyses have been completed (attainment demonstration package). We recommend a similar approach during the development of regional haze SIPs.

2.2.1 Modeling Protocol

Developing and implementing a modeling protocol is an important part of a modeling demonstration. The protocol should detail and formalize the procedures for conducting all

NMED Exhibit 108

phases of the modeling study, such as describing the background and objectives for the study, creating a schedule and organizational structure for the study, selection of appropriate period(s) for modeling, developing the input data, conducting model performance evaluations, interpreting modeling results, describing procedures for using the model to demonstrate whether proposed strategies are sufficient to attain the NAAQS and/or regional haze goals, and producing documentation to be submitted for EPA Regional office review and approval. The most important function of the modeling protocol is to serve as a blueprint for planning how the modeled demonstration will be performed. The protocol should be a valuable communication device by which air agencies, EPA, and other stakeholders can assess the applicability of default recommendations and develop area-specific alternatives, where needed, prior to conducting the work to build the modeling system. A suitable protocol should lead to extensive participation by stakeholders in developing the demonstration. It should also reduce the risk of spending time and resources on efforts that are unproductive or inconsistent with EPA rules, policy, and guidance. While the modeling protocol is initially developed at the beginning of a modeling exercise to foster communication, it is advisable to modify the document as needed throughout the modeling process when alterations from the original modeling plan are necessary. Again, any changes to the protocol should be fully communicated between affected air agencies, stakeholders, and the EPA.

Meaningful protocols should fully communicate the expected scope of the analysis and provide a blueprint for carrying out the needed analyses. There is no “one-size-fits-all” format for a sufficient modeling protocol, as different individual areas may require specific points of emphasis. However, past attainment demonstrations have yielded several excellent protocol examples that could serve as templates for any groups developing new modeling protocols. While not exhaustive, potentially valuable protocol references include attainment demonstration modeling efforts completed in the Dallas/Fort Worth area (Environ, 2003), the Denver region (Morris, 2011), and the San Joaquin Valley (CARB, 2012). Based on past experience, the EPA recommends that the following topics be core elements of any modeling protocol:

- Overview of the air quality issue being considered including historical background
- List of the planned participants in the analysis and their expected roles
- Schedule for completion of key steps in the analysis and final documentation
- Description of the conceptual model for the area
- Description of periods to be modeled, how they comport with the conceptual model, and why they are sufficient
- Models to be used in the demonstration and why they are appropriate
- Description of model inputs and their expected sources (e.g., emissions, meteorology, etc.)

NMED Exhibit 108

- Description and justification of the domain to be modeled (expanse and resolution)
- Process for evaluating base year model performance (meteorology, emissions, and air quality) and demonstrating that the model is an appropriate tool for the intended use
- Description of the future years to be modeled and how projection inputs will be prepared
- Description of the NAAQS attainment test procedures and (if known) planned weight of evidence, and/or description of the procedures for calculating RPGs from the modeling outputs, as applicable.
- Expected diagnostic or supplemental analyses needed to develop weight of evidence analyses
- Commitment to specific deliverables fully documenting the completed analysis

2.2.2 Attainment Demonstration and/or Reasonable Progress Goals Modeling Documentation Package

Whereas the modeling protocol describes the planned scope of the analysis, the final modeling documentation package summarizes the actual analysis conducted (including procedures used) to show that an area will likely meet the NAAQS and/or RPGs under a specific set of future conditions. This document can follow the same basic outline as the modeling protocol, highlighting those aspects of the modeling that may have changed from the original plans. Additionally, the modeling documentation package should have detailed information on any emission reduction strategies that will be implemented as part of an attainment or regional haze SIP. Ultimately, the modeling documentation package should provide a narrative that fully describes the technical rationale behind the projection of a specific air quality goal in an area. Based on past experience, the EPA recommends that the following topics be core elements of any modeling documentation package:

- Executive summary that provides an overview of the analysis and the key conclusions
- Reference to the modeling protocol noting any major deviations from the original plans
- List of the institutional participants in the attainment demonstration and their roles
- Description of air quality in the area and describe how that shaped the analysis
- Justification for the model, episodes, domain, and grid(s) used in the analysis
- Description of the development of the emissions inputs used in the base year modeling, including, at a minimum, tabular summaries by state/county, as appropriate

NMED Exhibit 108

- Description of the development of meteorological inputs used in the base year modeling
- Description of all other base year modeling inputs
- Evaluation of base year model performance (meteorology, emissions, and air quality), including a description of the observational database used in the evaluation and any diagnostic or sensitivity tests used to improve the model
- Description of the strategy used to demonstrate attainment and/or RPGs, including speciated emissions summaries for the future year and identification of authority for implementing these strategies
- Description of the attainment test inputs and results
- Description of any supplemental analyses designed to bolster the original attainment test results
- Detailed summary of the entire analysis that leads to the conclusion that the selected attainment demonstration strategy is likely to produce attainment of the NAAQS by the required date and/or leads to the calculation of the RPGs
- Appendices that contain more detailed information on the model inputs and outputs (emissions, meteorology, etc.), model performance, and attainment demonstration, including charts, tables, and descriptive text

All model input and output files (in electronic format) should be made available upon request by the EPA and/or stakeholders.

2.3 Episode Selection

The modeled attainment test and the recommended procedure for setting RPGs for regional haze both adjust observed ambient concentrations during a base case period (e.g., 2012-2016) to a future period (e.g., 2023) using model-derived "relative response factors" (RRFs). It is important that emissions used in the attainment modeling correspond with the period reflected by the chosen baseline design value period (e.g., 2012-2016).[11] Deviations from this constraint will diminish the credibility of the RRFs. The base year modeling inventory typically corresponds to the middle year of the baseline average design value period (e.g. 2014 for a 2012-2016 average design value period). Alternatively, the base year emissions can reflect multi-year average emissions from the base year period (e.g. average emissions for the 2013-2015 period). But in

[11] The regional haze program does not use design values. However, in an analogous approach, this guidance recommends the use of 5 years of historical visibility data (non-weighted) in a manner similar to the approach in the modeled attainment test for ozone and $PM_{2.5}$. For this reason and for brevity, sections 2 and 3 use the "design value" terminology in some explanations that apply to both ozone and $PM_{2.5}$ attainment modeling and to the setting of regional haze RPGs. That is, for regional haze purposes, "design values" can be understood to mean "visibility data."

NMED Exhibit 108

either case, the emissions year or years should be representative of the 5-year design value window.

There is no recommended default base year for modeling. However, it is recommended to use a relatively recent base period so that the emissions projection period is as short as possible and the base year ambient data is as current as possible. For example, projecting emissions from 2014 to 2023 (using a 2012-2016 base year average design value) should be less uncertain than projecting emissions from 2005 to 2023 (using a 2003-2007 base year average design value). The most recent ambient design values reflect actual emissions changes that have occurred over time. It is, therefore, better to use recent design values, which are actual measurements, combined with modeled emissions changes to project future concentrations, then to use older ambient data to estimate the change in design values. When selecting a base modeling year, air agencies should review recent ambient data and consider the factors in the following section.

2.3.1 Choosing Time Periods to Model

In the past, the choice of modeled episode days has been limited by the speed of computers and the ability to store model output files. With the advancement in computer technology over the past two decades, computer speed and storage issues are no longer an impediment to modeling long time periods. In fact, the majority of recent regulatory assessment modeling platforms have been inclusive of entire summers and/or full years (as appropriate) for ozone, $PM_{2.5}$, and regional haze (Boylan and Russell, 2006; Morris et al., 2006; Rodriguez et al., 2009; Simon et al., 2012; Tesche et al., 2006; U.S. EPA, 2011a, 2011b, 2016a).

Ozone-based research has shown that model performance evaluations and the response to emissions controls need to consider modeling results from relatively long time periods, in particular, full synoptic cycles or even full ozone seasons (Hogrefe et al., 2000; Vizuete et al., 2011). In order to examine the response to ozone control strategies, it may not be necessary to model a full ozone season (or seasons), but, at a minimum, modeling "longer" episodes that encompass full synoptic cycles is advisable. Time periods which include a ramp-up to a high ozone period and a ramp-down to cleaner conditions allow for a more complete evaluation of model performance under a variety of meteorological conditions.

Most model applications for the annual $PM_{2.5}$ NAAQS have modeled a full year (Morris et al., 2006; Tesche et al., 2006; U.S. EPA, 2011a, 2011b, 2017b). This is a logical goal since every monitored day of the year is included in the calculation of the annual NAAQS. The annual $PM_{2.5}$ NAAQS is unique because each and every ambient observation is included in the average. It is,

NMED Exhibit 108

therefore, likely that a full year of modeled data is needed to adequately represent the annual average $PM_{2.5}$ NAAQS.

Eight-hour ozone and 24-hour $PM_{2.5}$ episode selection criteria are similar because both standards are based on short-term peak concentration periods. Regional haze calculations are based on an average of 20 or more days per year (20% clearest and 20% most impaired days). Therefore, regional haze episode selection will likely include more days throughout the year.

At a minimum, several criteria should be used to select time periods that are appropriate to model:

- Model time periods that are close to the most recently compiled and quality assured National Emission Inventory (NEI). These comprehensive inventories are typically generated every 3 years (e.g. 2011, 2014, 2017, etc.), but often contain year-specific data for the intermediate years. Since NEI years will have a nationwide complete and comprehensive inventory, selecting a base modeling year that is also an NEI year may save resources. However, other factors should be considered when selecting a base modeling year, such as the availability and magnitude of observed ambient data, meteorology, and availability of special study data. After consideration of all factors, the most appropriate base year may or may not be an NEI year. See section 2.7 for more information on base year inventory selection issues.

- Model time periods in which observed concentrations are close to the appropriate base year design value or level of visibility impairment and ensure there are a sufficient number of days so that the modeled test applied at each monitor is based on multiple days.

- Model time periods both before and following elevated pollution concentration (poor air quality) episodes to ensure the modeling system appropriately characterizes low pollution periods, development of elevated periods, and transition back to low pollution periods through synoptic cycles.

- Simulate a variety of meteorological conditions conducive to elevated/poor air quality.

Primary Ozone (8-Hour Ozone) - Choose time periods which reflect a variety of meteorological conditions that frequently correspond with observed 8-hour daily maxima concentrations greater than the level of the NAAQS at monitoring sites in the nonattainment area.

NMED Exhibit 108

24-Hour $PM_{2.5}$ - Choose time periods that reflect a variety of meteorological conditions that frequently correspond with observed 24-hour average concentrations greater than the level of the NAAQS at monitoring sites in the nonattainment area.
Annual $PM_{2.5}$ - The best way to represent the meteorological variability within a season and over an entire year is to model an entire year that has meteorology generally conducive to elevated $PM_{2.5}$ concentrations.
Regional Haze - Choose time periods that reflect the variety of meteorological conditions that represent visibility impairment on the 20% clearest and 20% most impaired days in the Class I areas being modeled (high and low concentrations necessary). This is best accomplished by modeling a full year.
Long-term or seasonal ozone – Since long-term (seasonal) ozone assessments are based on accumulated ozone over multiple months during the ozone season, the most appropriate way to represent the variability in high and low ozone is to model an entire ozone season that is representative of long-term values. [**Note:** This analysis is only applicable if seasonal ozone assessments are necessary (e.g. to support ozone benefits calculations). Currently, there are no long-term or seasonal ozone NAAQS (primary or secondary).]

2.3.2 Future Year Selection

For ozone and $PM_{2.5}$, future emissions should be projected to the attainment year or appropriate time period based on the area's classification. The Ozone SIP Requirements Rule provides a schedule for implementing emission reductions needed to ensure attainment by the area's attainment date. Specifically, it states that emission reductions needed for attainment must be implemented no later than the beginning of the attainment year ozone season.[12] The $PM_{2.5}$ Implementation Rule contains similar provisions. It states that emissions reductions should be in place no later than the beginning of the year containing the applicable attainment date.[13]

As part of demonstrating attainment of the ozone and $PM_{2.5}$ NAAQS, air agencies are required to conduct a Reasonably Available Control Measures (RACM) analysis to determine if the attainment date can be advanced by at least a year. Since areas are required to attain as expeditiously as practicable, results of the RACM analysis may indicate attainment can be achieved earlier.

[12] *See* 40 CFR 51.1308(d).
[13] *See* 40 CFR 51.1011(a)(5) and 40 CFR 51.1011(b)(5).

NMED Exhibit 108

There are varying requirements related to attainment year and RACM analyses for ozone and $PM_{2.5}$ nonattainment areas, depending on classifications and other factors. Please see the appropriate ozone and/or $PM_{2.5}$ implementation rule for more details and information.[14]

For regional haze SIPs, RPGs must reflect the visibility conditions that are projected to be achieved by the end of the applicable implementation period.[15] Therefore, the modeling should be based on emissions forecasted for the end year of the implementation period addressed by the SIP. These end years are 2018, 2028, etc.

2.4 Modeling Domain Selection

A modeling domain identifies the geographical bounds of the area to be modeled. Horizontal resolution is the geographic size of individual grid cells within the modeling domain. Vertical resolution is specified in terms of multiple layers of the atmosphere between the surface and top of the model (usually near the tropopause).

2.4.1 Domain Size

The principal determinants of model domain size are the nature of the ozone, $PM_{2.5}$ and/or regional haze problem being modeled, and the spatial scale of the emissions that impact the nonattainment or Class I area. Establishment of a sufficiently large model domain that utilizes the output from a larger regional or global modeling simulation to feed hourly lateral boundary conditions is a preferred approach (see section 2.8 for more information on boundary conditions). However, regardless of the size of the modeling domain, sources outside the modeling domain may have an important influence on concentrations within nonattainment areas or Class I areas. Therefore, boundary conditions need to be well characterized. The grid containing the key emissions sources and receptors needs to have sufficiently fine-scale to resolve local gradients and have a large enough spatial extent to capture recirculation due to shifting wind directions. An alternative to a single large domain to capture recirculation is to apply a chemical transport model with a large coarse domain with a smaller-domain, nested fine grid with feedback between the grids (i.e., 2-way nesting). This option allows pollutants from the fine grid to move into the coarser domain and back into the fine grid depending on wind patterns.

Global models are routinely used to supply regional chemical transport models with temporally and spatially variant lateral boundary conditions. Since regional and urban model applications

[14] *See* 40 CFR 51.1009 (moderate $PM_{2.5}$), 40 CFR 51.1010 (serious $PM_{2.5}$) and 40 CFR 51.1312 (ozone).
[15] See 40 CFR 51.308(f)(3)(i).

NMED Exhibit 108

for attainment demonstration purposes are typically less than or equal to 12 km sized grid cells, it may be worthwhile to apply the regional scale model at a coarser grid resolution (e.g. 36 km) to downscale global model estimates to the regional model. The coarser simulation results provide a better transition from the global simulation to the nested urban or urban/regional area of interest both at the boundaries near the surface and in the free troposphere. See section 2.8 for more information on using global and/or regional models to derive initial and lateral boundary conditions.

Isolated nonattainment areas that have limited impacts from regional transport of ozone and/or $PM_{2.5}$ and its precursors may be able to use a relatively small domain. The modeling domain should be designed so that all major upwind source areas that influence the downwind nonattainment area are included in the modeling domain. It is also important to be able to directly capture the impact of future year emissions increases or decreases from upwind areas. In addition, all monitors that are currently or recently (within any of the years included in the base year period) violating the NAAQS or close to violating[16] the NAAQS in the nonattainment area should be contained in the modeling domain far enough from the edge to minimize complications associated with air mass recirculation and to minimize lateral boundary influence. Similarly, all Class I areas to be evaluated in a regional haze modeling application should be sufficiently distant from the edge of the modeling domain.

2.4.2 Vertical Layer Configuration

There is no correct maximum or minimum number of vertical layers needed in attainment demonstration modeling. However, the specification of the air quality model vertical layer structure should closely match the vertical layer structure of the meteorological model used to generate inputs for the air quality model. It is best to have an air quality model's vertical layers align with the layers in the meteorological model matching one-to-one. However, resource constraints sometimes preclude direct vertical layer mapping. When vertical layer collapsing is necessary, use the highest resolution where the conceptual model suggests it is most needed.

The top of the modeling domain should typically be set above the tropopause at the 50 or 100 millibar level. The lowest layer (surface layer) in the air quality model should be no more than ~40 meters thick. The vertical resolution between the surface layer and model top will vary

[16] A monitor that is "close to violating" the NAAQS in a base year may be modeled to violate in the future due to projected emissions increases or modeled "dis-benefits" due to non-linear chemistry. Air agencies should consult with the appropriate EPA Regional office if there are questions regarding the interpretation of "close to violating" and which monitors should be included in the modeling analysis.

NMED Exhibit 108

depending on the application. Layer thickness should monotonically increase or be the same size as altitude increases.

In view of the importance of carefully specifying the temporal variation in mixing height, high precision below and near the anticipated maximum afternoon mixing height is ideal. In addition, near-surface vertical resolution is important to capture overnight stable conditions. Layers above the boundary layer are important for characterizing clouds and precipitation and layers near the tropopause are important to create a realistic stratification of strongly variant pollutant concentrations in the stratosphere and free troposphere (Emery et al., 2011).

There are some model applications that may not need to consider the full extent of the troposphere. These applications typically use vertical domains, which extend up to 4 or 5 km. These types of applications may cover episodes of elevated pollutant concentrations associated with strong surface-based inversions that occur in isolated areas. However, in almost all cases, the EPA encourages the use of full-scale one-atmosphere models that account for all atmospheric processes throughout the extent of the troposphere.

2.4.3 Horizontal Grid Cell Size

Recent chemical transport modeling applications for ozone, $PM_{2.5}$, and regional haze have commonly used grid cell sizes ranging from 4 km to 12 km resolution (Morris et al., 2006; Rodriguez et al., 2009; Simon et al., 2012; U.S. EPA, 2011b, 2016a; Vizuete et al., 2010). Urban scale assessments have used chemical transport grid models at 1 to 2 km resolution (Vizuete et al., 2011). Intuitively, one would expect to get more accurate results in urban applications with smaller grid cells (e.g., ~1 or 4 km) provided the spatial details in the emissions and meteorological inputs support making such predictions. However, model performance at 4 km resolution is not always better than 12 km resolution (Simon et al., 2012).

For coarse portions of the regional grids, a grid cell size of 12 km is generally recommended. For urban areas, it may be desirable to use grid cells sized ~1 to 4 km, but not larger than 12 km. The relative importance of using a domain with grid cells as small as ~1 km should be weighed on a case-by-case basis. If the conceptual model indicates that there are atmospheric, physical, or chemical processes related to the air quality issue that require a specific minimum resolution to simulate (e.g., localized emissions, complex terrain, land-water interfaces, etc.), then that resolution should be utilized in the model. For example, it is likely that spatial gradients in concentrations are higher for primary pollutants (e.g., primary particulate matter, or PM) than for secondary pollutants because physical processes dominate concentration rather than chemical processes. Although it is clear that spatial resolution of primary pollutants will impact

NMED Exhibit 108

the predicted concentrations, it is not clear how it will impact the relative change in concentrations due to emissions changes. Areas that have large gradients in primary $PM_{2.5}$ may need to use finer resolution (approximately ~1 to 4 km) or may need to supplement the grid modeling with dispersion modeling. This is particularly true if violating monitors are strongly impacted by local sources of primary $PM_{2.5}$ emissions.

The most important factor to consider when establishing grid cell size is model response to emissions controls. Analysis of ambient data, sensitivity modeling, and past modeling results can be used to evaluate the expected response to emissions controls at various horizontal resolutions for ozone, $PM_{2.5}$, and regional haze. If model response is expected to be different (and presumably more accurate) at higher resolution, then higher resolution modeling should be considered. If model response is expected to be similar at both high and low(er) resolution, then high resolution modeling may not be necessary. The use of grid resolution finer than 12 km would generally be more appropriate for areas with a combination of complex meteorology, strong gradients in emissions sources, and/or land-water interfaces in or near the nonattainment area(s).

Sensitivity tests comparing relative response factors in predicted 8-hour daily maximum ozone at sites in the eastern United States indicate relatively small unbiased differences (< 4%, in RRF difference in 95% of the comparisons) using a grid with 12 km versus 4 km sized grid cells (Arunachalam, 2006). The largest difference in the relative response of secondary pollutants at varying resolution is likely to occur in oxidant limited areas (areas that are more sensitive to VOC reductions than NOx reductions). In such areas, horizontal resolution may have a large impact on the spatial distribution and magnitude of modeled NOx "disbenefits" (i.e., ozone increases in oxidant limited areas when NOx emissions are reduced).

2.5 Air Quality Model Selection

Chemical transport models address the physical processes and chemistry that form ozone and PM. Air quality models continue to evolve and each has its own strengths and weakness (Galmarini et al., 2012; Pirovano et al., 2012; Russell, 2008; Simon et al., 2012). The most commonly used chemical transport models for attainment demonstrations are the Community Multiscale Air Quality Model (CMAQ) (Byun and Schere, 2006; Foley et al., 2010) and the Comprehensive Air Quality Model with Extensions (CAMx) (Baker and Scheff, 2007; Vizuete et al., 2011). The mention of CMAQ and CAMx is not intended to be a comprehensive list of available chemical transport models and omittance from this discussion does not imply that a different model cannot be used to support a modeled attainment demonstration or reasonable

NMED Exhibit 108

progress assessment. In the same way, inclusion in this discussion does not imply that a model is "preferred" for a particular type of application.

A modeling-based demonstration of the impacts of an emissions control scenario for attainment of the ozone or $PM_{2.5}$ NAAQS, or as part of a regional haze assessment, usually necessitates the application of a chemical transport grid model. However, it is not necessary to use a model that considers atmospheric chemistry in addressing changes in primary $PM_{2.5}$ components. Either a numerical grid or a Lagrangian (such as a Gaussian dispersion) model or other empirical techniques could potentially be used for this purpose. In general, modeling primary $PM_{2.5}$ components with a grid model is acceptable, but dispersion modeling may be necessary in areas with large spatial gradients of primary $PM_{2.5}$. Depending on the nature of the problem, an air agency may choose to use a regional chemical transport grid model to address both primary and secondary components of PM or they may need to use a chemical transport model to address secondary $PM_{2.5}$ and regional primary PM and an inert model applied over a more limited domain to address fine scale primary components of PM. In addition, the EPA recognizes that in some cases, more simplistic modeling techniques (such as dispersion, receptor, rollback, and/or box models) may suffice to demonstrate that an area will attain the $PM_{2.5}$ NAAQS, especially in areas that are dominated by primary $PM_{2.5}$ emissions (e.g., residential wood smoke).

A model should meet several general criteria in order to be considered for use in an attainment demonstration or reasonable progress assessment. These general criteria are consistent with requirements in Appendix W (U.S. EPA, 2017a). Appendix W does not identify a "preferred model" for use in attainment demonstrations of the NAAQS for ozone or $PM_{2.5}$ or reasonable progress assessments for regional haze. Therefore, at this time, the EPA is not recommending a specific model for use in ozone or $PM_{2.5}$ attainment demonstrations or regional haze uniform rate of progress assessments. Instead, models used for these purposes should meet requirements for "alternative models" in Appendix W, section 3.2. Air agencies should use a non-proprietary model, which is a model whose source code is available for free (or for a reasonable cost). Furthermore, the user should be able to revise the source code to perform diagnostic analyses and/or to improve the model's ability to describe observations in a credible manner. Several additional prerequisites should be met for a model to be used to support an attainment demonstration or reasonable progress assessment (see Appendix W, section 3.2.2(e), as well as sections 5 and 6 for more general secondary pollutant modeling requirements):

1) The model or technique has received a scientific peer review.

   An air quality model may be considered to have undergone "scientific peer review" if each of the major components of the modeling system has been

NMED Exhibit 108

described and tested, and the results have been documented and reviewed by one or more disinterested third parties, and the model has been revised in response to the review. This review is not the responsibility of the EPA. Air agencies should reference available documentation to gain acceptance of an air quality model for use in a modeled attainment demonstration.

2) The model or technique can be demonstrated to be applicable to the problem on a theoretical basis.
    - The model should be scientifically appropriate and applicable for the intended purpose.

3) Databases, which are necessary to perform the analysis, are available and adequate.

4) Appropriate performance evaluations of the model or technique have shown that the model or technique is not inappropriately biased for regulatory application.
    - Prior to use of a selected model's results in an attainment demonstration or regional haze analysis, the model should be shown to perform adequately for the specific application.
    - If the application is the first for a particular model, then the air agency should demonstrate that the new model is expected to perform sufficiently. For a model to be used in an attainment demonstration, evidence should be presented that it has been found acceptable for estimating hourly and 8-hourly ozone concentrations and/or hourly and 24-hour average $PM_{2.5}$ and $PM_{2.5}$ component concentrations. In addition to ozone and/or $PM_{2.5}$, the model should be acceptable for estimating precursor species, important chemical intermediates, and in the case of $PM_{2.5,}$ the main chemical constituents. Preference should be given to models exhibiting satisfactory past performance under a variety of conditions.

5) A protocol on methods and procedures to be followed has been established (such as described in section 2.2.1).

In addition to the criteria in Appendix W, the EPA also recommends the following criteria and considerations:

1) A user's guide (including a benchmark example and outputs) and technical description of the model should be available.

NMED Exhibit 108

2) The advanced technical features available in a model could be a consideration when other criteria are satisfied. Models are often differentiated by their available advanced science features and tools. For example, some models include advanced probing tools that allow tracking of downwind impacts from upwind emissions sources. Availability of probing tools and/or science algorithms is a legitimate reason to choose one equally capable model over another.

3) When other criteria are satisfied, resource considerations may be important. This is a legitimate criterion provided the other listed criteria are met.

The EPA has prepared an "alternative model" demonstration for both CMAQ and CAMx for the purposes of supporting ozone or $PM_{2.5}$ attainment demonstrations and regional haze assessments (Fox, 2017). This document is also a useful template for others seeking to provide a similar type of demonstration for another photochemical modeling system.

2.6 Meteorological Inputs

In order to solve for the pollutant concentrations over time and space, air quality models require accurate meteorological inputs to properly simulate the formation, transport, and removal of pollutant material. The required meteorological inputs can vary by air quality model, but all models require parameters such as wind, vertical mixing, temperature, humidity, and solar radiation. While model inputs can be created strictly from ambient measurements, a more credible technical approach is to use off-line, dynamic, meteorological grid models to provide the necessary inputs. When these models are applied retrospectively (i.e., for historical time periods), they are able to blend ambient data with model predictions via four-dimensional data assimilation (FDDA), thereby providing temporally and spatially complete data sets that are grounded by actual observations.

This section provides recommendations for generating the meteorological data sets needed for regional air quality modeling purposes. In many ways, the development of meteorological inputs parallels the steps needed to conduct the air quality modeling. A meteorological model platform (episodes, domain, model selection, model configuration, input data, etc.) must be established and then evaluated. Because of the strong sensitivity of the eventual air quality results to the input meteorology (Appel, 2007; Appel, 2010), it is recommended that air agencies spend extensive effort in developing and evaluating the meteorological inputs.

NMED Exhibit 108

2.6.1 Developing Base Year Meteorological Fields

The recommended approach for generating the base year meteorological data needed to conduct the attainment or regional haze demonstration is to apply off-line, dynamic meteorological models with FDDA. These models use the fundamental equations of momentum, thermodynamics, and moisture to determine the evolution of specific meteorological variables from a given initial state. When modeling historic episodes, the use of data assimilation helps to "nudge" solutions so that they do not diverge greatly from the actual observed meteorological fields. A major benefit of using dynamic meteorological models is that they provide a way of consistently characterizing conditions at times and locations where observations do not exist.

The Weather Research and Forecasting (WRF) (Skamarock, 2008) model is a community supported mesoscale numerical prediction model that replaced the previous community supported mesoscale meteorological model v5 (MM5) model. The MM5 model is no longer being updated or supported. Meteorological models other than the WRF can be used as long as they are appropriate for the situation being modeled and are properly evaluated. A number of recent studies (Appel et al., 2010; de Meij et al., 2009; Gilliam et al., 2010; Matichuk et al., 2017; Pleim et al., 2016) have compared the ability of the WRF and MM5 models to reproduce past meteorological conditions and their suitability for use in air quality modeling. Generally speaking, comparative evaluation efforts have shown that the WRF model outputs represent equivalent or better statistical skill over a variety of meteorological conditions. An additional advantage of the WRF model is that there is a large community of WRF users and developers. As a result, the code is both maintained and frequently updated as new science emerges. The EPA recommends the use of a well-supported gridded mesoscale meteorological model for generating meteorological inputs to regional air quality model attainment demonstrations.

In some cases, however, there may be legitimate reasons for using an approach other than well-supported gridded mesoscale meteorological models to provide the requisite meteorological data. For instance, there may be long-standing local experience for a given domain and/or episode with a different meteorological model. In other cases, dynamic meteorological models may not adequately capture key meteorological elements of an airshed's conceptual model (e.g., source-receptor transport vectors to key monitoring locations). In rare cases such as these, it may be appropriate to blend the dynamic model data with wind data from an objective analysis of observed wind fields. The guiding factor in determining which meteorological model or approach to use should be an assessment of which set of inputs will best capture the key meteorological conditions that led to poor air quality. It is recommended that a description of the methods used to generate the meteorological fields be

NMED Exhibit 108

included in the modeling protocol. For those cases in which an off-line prognostic meteorological model is not used, it is recommended that a detailed description of the alternate technique that will be used to generate the three-dimensional meteorological fields be shared with the appropriate EPA Regional office(s) prior to conducting the meteorological analysis and air quality modeling analysis.

As with other parts of the air quality modeling system, choices made regarding how to configure the meteorological modeling can affect the quality and suitability of the air quality model predictions. Decisions regarding the configuration of complex dynamic meteorological models can be particularly challenging because of the amount of flexibility available to the user. The goal in establishing the proper configuration for meteorological modeling should be to obtain the best possible meteorological model performance, especially for those parameters identified as most important in the conceptual description. As part of the overall chemical transport modeling system evaluation process, performance issues in the chemical transport model can sometimes be explained by options chosen in the meteorological simulation. Therefore, a feedback between the meteorological model evaluation and the air quality model evaluation can be highly beneficial.

2.6.1.1 Selecting a Model Domain

The selection of the meteorological modeling domain should closely match the air quality domain. The outermost grid should capture all upwind areas that can reasonably be expected to influence local concentrations of ozone and/or $PM_{2.5}$. In terms of selecting an appropriate meteorological modeling domain, one should extend the grid at least 3 to 6 cells beyond the domains of each air quality modeling grid to avoid boundary effects. It is recommended that the vertical and horizontal grid structures, including geographic datum and projected coordinate definitions, be generally consistent within the meteorological and air quality models to minimize interpolation and aggregation issues associated with the post-processing of meteorological model outputs into air quality model inputs.

2.6.1.2 Selecting Physics Options

Meteorological models have a suite of physics options that allow users to configure how a given meteorological effect will be simulated. For example, there may be several options for specifying the planetary boundary layer scheme or how sub-grid cumulus clouds will be handled. In many situations, the "optimal" configuration cannot be determined without performing an initial series of sensitivity tests, which consider various combinations of physics options over specific time periods and regions. While these tests may not ultimately conclude that any one configuration is clearly superior at all times and in all areas, it is recommended

NMED Exhibit 108

that these sensitivity tests be completed, as they should lead to a modeling analysis that is best suited for the domain and period being simulated. An optimal starting point of physics options may be selected from another modeling application that has a similar set of meteorological conditions that lead to elevated pollutant levels. Typically, the model configuration that yields predictions that provide the best statistical match with observed data over the most cases (episodes, regions, etc.) is the one that should be chosen, although other more qualitative information can also be considered. Additionally, model configurations should be designed to account for the pollutants and time periods that are of most interest, per the conceptual description.

2.6.1.3 Use of Data Assimilation

As noted above, the use of FDDA helps to keep the model predictions from widely diverging from what was actually observed to occur at a particular point in time/space. Studies have shown that the incorporation of FDDA into atmospheric models improves meteorological simulations (Otte, 2008a and b; Pleim and Gilliam, 2009; Gilliam and Pleim, 2010). In particular, these studies have shown that better representation of the atmospheric fields aloft through assimilation of data from nationwide atmospheric profiler networks can aid in reproducing certain meteorological features (e.g., low-level jets) (Godowitch et al., 2011; Gilliam et al., 2012). However, if used improperly, FDDA can significantly degrade overall model performance and introduce computational artifacts (Tesche and McNally, 2001). Inappropriately strong nudging coefficients can distort the magnitude of the physical terms in the underlying atmospheric thermodynamic equations and result in "patchwork" meteorological fields with strong gradients between near-site grid cells and the remainder of the grid. Additionally, if specific meteorological features are expected to be important for predicting the location and amount of pollution formed, based on an area's conceptual model, then the meteorological modeling should be set up to ensure that FDDA does not prevent the model from forming these features (e.g., lake/sea breeze circulations).

In general, analysis nudging strengths should be no greater than 3.0×10^{-4} for winds and temperatures and 1.0×10^{-5} for water vapor mixing ratio. In the case of observation nudging (i.e., FDDA based on individual observations as opposed to analysis fields), it is recommended that the resultant meteorological fields be examined to ensure that the results over the entire domain are still consistent. Further, based on past experience, we recommend against using FDDA within the boundary layer for thermodynamic variables like temperature and water vapor mixing ratio because of the potential for spurious convection. If the dynamic model is applied without FDDA, it is suggested that the simulation durations be no longer than 24 hours. As with selecting physics options, it is often valuable to conduct sensitivity testing of various FDDA approaches to help determine the optimal nudging configuration for any specific case.

NMED Exhibit 108

Along with application of the meteorological modeling, users should be careful when translating the meteorological model outputs into air quality modeling inputs. A number of air quality model pre-processors (which are meteorological model post-processors) exist to conduct this off-line coupling, including the Meteorology-Chemistry Interface Processor (MCIP) (Otte and Pleim, 2010) and wrfcamx (Ramboll-Environ, 2017). These meteorological post-processors generate the complete set of meteorological data needed for the air quality simulation by accounting for issues related to:

1) Data format translation;
2) Conversion of parameter units;
3) Extraction of data for appropriate window domains;
4) Reconstruction of the meteorological data on different grid and layer structures; and
5) Calculation of additional variables.

As noted above, most meteorological modeling applications should be set up to minimize the influence of the pre-processing software. For instance, it is recommended that the horizontal grid structures be consistent within the meteorological and air quality models to minimize issues associated with interpolation and aggregation. While it is often not feasible to run the air quality model with the same vertical layer structure as the meteorological model, it is recommended that vertical layer collapsing between the models be minimized (preferably with no layer collapsing), to the extent possible.

While the traditional approach for attainment and regional haze demonstration modeling is to convert "off-line" meteorological model outputs into air quality model inputs via specific pre-processing tools, there have been recent efforts to couple "on-line" meteorological models within air quality model applications, such as WRF-Chem (Grell et al., 2005; Wilczak et al., 2009), NOAA-EPA CMAQ (Davidson et al., 2007), and WRF-CMAQ (Wong et al., 2012). The advantage of an on-line meteorological model is that one can simulate impacts that air quality changes might have on meteorological conditions (and vice versa) through direct and indirect feedback mechanisms. In most cases, the EPA does not expect emissions reductions from local SIP reductions to appreciably affect future meteorological conditions. Therefore, off-line meteorological approaches, where the same meteorological fields are used for multiple emissions scenarios, are expected to be sufficient for the majority of SIP modeling exercises.

2.6.2 Assessing Impacts of Future Year Meteorology

Traditionally, SIP meteorology simulations have not accounted for the impact of global emissions of carbon dioxide and other climate forcers on future meteorological conditions. However, ozone concentrations have a high correlation with daily maximum temperatures over many areas in the U.S. (Camalier et al., 2007), suggestive of a potential climate connection.

NMED Exhibit 108

Recent research, taking into account temperature and other meteorological variables, indicates that in certain populated regions of the country, climate change could lead to higher future ozone concentrations (often called a "climate penalty") (Jacob and Winner, 2009; Bloomer et al., 2009; U.S. EPA, 2009; CARB 2010; Fiore, 2012; Fann, 2016). Assuming climate change does lead to higher ozone concentrations, there could potentially be a need for more stringent emissions reductions to counteract the higher ozone potential from warmer conditions. However, there are significant uncertainties regarding the precise location and timing of climate change impacts on air quality. Generally, climate projections are more robust for periods at least several decades in the future because the forcing mechanisms that drive near-term natural variability in climate patterns (e.g., El Nino, North American Oscillation) have substantially larger signals over short time spans than the driving forces related to long-term climate change. In contrast, projections for SIP purposes are generally for time spans of less than 20 years. Given the relatively short time span between base and future year meteorology in most SIP demonstrations, the EPA does not recommend that air agencies explicitly account for long-term climate change in attainment demonstrations. However, air agencies are welcome to consider potential climate impacts in their specific areas, especially where and when there is evidence of significant potential impacts.

2.6.3 Evaluation of Base Year Meteorological Fields

While the air quality models used in attainment and regional haze demonstrations have consistently been subjected to a rigorous performance assessment, in many cases the meteorological inputs to these models have received less rigorous evaluation, even though this component of the modeling is quite complex and has the potential to substantially affect air quality predictions (Tesche, 2002). The EPA recommends that air agencies devote appropriate effort to the process of evaluating the meteorological inputs to the air quality model as we believe good meteorological model performance will yield more confidence in predictions from the air quality model. One of the objectives of this evaluation should be to determine if the meteorological model output fields represent a reasonable approximation of the actual meteorology that occurred during the modeling period. Further, because it will never be possible to exactly simulate the actual meteorological fields at all points in space/time, a second objective of the evaluation should be to identify and quantify the existing biases and errors in the meteorological predictions in order to allow for a downstream assessment of how the air quality modeling results are affected by issues associated with the meteorological data. To address both objectives, it will be necessary to complete both an operational evaluation (i.e., quantitative, statistical, and graphical comparisons) as well as a more phenomenological assessment (i.e., generally qualitative comparisons of observed features versus their depiction in the model data).

NMED Exhibit 108

2.6.3.1 Operational Evaluation

The operational evaluation results should focus on the values and distributions of specific meteorological parameters as paired with and compared to observed data. It is recommended that the observation-model matching be paired as closely as possible in space and time. Typical statistical comparisons of the key meteorological parameters will include: comparisons of the means, mean bias, normalized mean bias, mean absolute error, normalized mean error, and root mean square error. For modeling exercises over large domains and entire ozone seasons or years, it is recommended that the operational evaluation be broken into individual segments such as geographic subregions and/or months/seasons to allow for a more comprehensive assessment of the meteorological strengths and weaknesses. It may also be useful to break out model performance aloft, at the surface, during individual episodes (e.g., high ozone/$PM_{2.5}$ days), over the diurnal cycle, and as a function of synoptic regime. Modelers are also encouraged to set aside a portion of the ambient data strictly for evaluation purposes (i.e., data not used in the FDDA). Examples of observed meteorological data sets available for operational evaluations include (some of these data sets are not typically used in FDDA and, therefore, may be serve as an "independent" source of evaluation data):

1. TDL U.S and Canada Surface Hourly Observations (http://rda.ucar.edu/datasets/ds472.0);
2. Cooperative Agency Profilers (https://madis-data.noaa.gov/cap/);
3. NOAA Profiler Network (http://profiler.noaa.gov/npn/);
4. Individual State Climate Office Observation Networks; and
5. PRISM Climate Group Precipitation Analysis (http://www.prism.oregonstate.edu/).

While these data are readily available, it is up to the air agency to determine if the data have undergone appropriate quality assurance/quality control (QA/QC) procedures through the provider.

It may be helpful when calculating domainwide and/or regional summary statistics to compare the results against previously generated meteorological model performance "benchmarks" (Emery et al., 2001). However, because of concerns about potentially misleading comparisons of model performance findings across different analyses with differing model configurations and FDDA strengths, the EPA does not recommend using these benchmarks as a "pass/fail" indicator of the acceptability of a model simulation. The benchmarks should only be used as a means of assessing general confidence in the meteorological model data. Statistical results that are outside the range of the compiled benchmarks may indicate a performance issue that should be given further examination. In some cases, adjustment of input data and/or model settings may be needed in order to improve model performance. The Atmospheric Model

NMED Exhibit 108

Evaluation Tool (AMET) was designed for use in the assessment of meteorological and chemical transport models. AMET provides a method of pairing observed and simulated values and performing common analysis techniques to evaluate the performance and suitability of atmospheric models.

2.6.3.2 Phenomenological Evaluation

As discussed in section 2.1, it is recommended that a conceptual description of the area's air quality problem be developed prior to the initiation of any air modeling study. Within the conceptual description, it is recommended that the specific meteorological parameters that influence air quality be identified and qualitatively ranked in importance. When evaluating meteorological models or any other source of meteorological data, the focus of the phenomenological evaluation should be on those specific meteorological phenomena that are thought to strongly affect air pollution formation and transport within the geographic area of interest. This event-oriented evaluation should summarize model performance in terms of statistical metrics such as probability of detection and false alarm rate. As an example of a potential phenomenological analysis, many regional air quality modeling exercises attempt to assess the effects of transport of pollutants from one area to a downwind area with the intent of establishing source-receptor relationships. For these types of analyses, accurate transport wind trajectories are needed to properly establish these source-receptor linkages. A useful event-based meteorological evaluation would be to compare model-derived trajectories versus those based on ambient data to determine what error distance can be associated with the model fields. Other examples of phenomenological evaluations would be the replication by the model of low level nocturnal jets, cold pool conditions, fog events, or land/sea breezes.

2.7 How Are the Emission Inputs Developed?

Air quality modeling for 8-hour ozone, $PM_{2.5}$, and regional haze requires emissions data for a base year and future modeling years. While not explicitly a requirement of the implementation rules, the emissions data for modeling are a necessary input to the modeling that is required by the implementation rules as part of the modeled attainment demonstration and for regional haze analyses.

A separate EPA guidance document describes the planning inventories that are specifically required for SIPs and provides an overview of all emission inventory requirements, resources, and techniques. That guidance is the "Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Regulations" (U.S. EPA, 2017b), and is used as a key reference throughout this section.

NMED Exhibit 108

Many of the issues associated with the planning inventories are also relevant for modeling inventories. We will refer to that guidance here as the "EI SIP Guidance."

Table 1 of the EI SIP Guidance provides a list of emissions estimation resources for emissions inventories. In addition to the resources listed there, the EPA also provides emissions data used in modeling analyses in support of rulemakings. The current available "emissions platforms" are based on 2005, 2007, 2008, 2011, and 2014 base years. These platforms are available publicly on the Emissions Modeling Clearinghouse website. The emissions modeling data and other data included in these platforms can be a starting point for air agencies in developing their own capabilities for preparing emissions for use in air quality models.

2.7.1 What Emissions Inventory Years Should I use for Base and Future Modeling?

For the base year, the EPA does not require a particular modeling year for $PM_{2.5}$ and ozone SIP attainment plans, and regional haze plans. However, for several reasons, it is technically appropriate to use a recent year as the base year. In addition, there are certain regulatory requirements for selecting an appropriate base year for planning inventories. See ozone NAAQS inventory requirements at 40 CFR 51.1315 and $PM_{2.5}$ NAAQS inventory requirements at 40 CFR 51.1008.[17] Currently, the most recent base National Emissions Inventory (NEI) is 2014 (U.S. EPA 2016c), and NEI data are developed every 3 years (the next NEI year will be 2017). In most cases, the most recent NEI year will be the most appropriate year to use for base case modeling. In some cases, other years (either before or after the most recent NEI year) may be more appropriate for modeling in view of unusual meteorology, transport patterns, exceptional events (i.e. large wildfires), lack of air pollution events, or other factors that may vary from year to year. See section 2.3.1 for more information on episode selection. The choice of the base year should be discussed with the appropriate EPA Regional office as part of the SIP planning process for the attainment demonstration.

For attainment planning in particular, the choice of a future year for an inventory depends on the nonattainment classification of the nonattainment area, as described in section 2.3.2. For ozone and $PM_{2.5}$, in most cases the future modeling year will be the expected attainment year. Requirements for selecting appropriate future years for modeling are provided in the ozone and $PM_{2.5}$ NAAQS implementation rules. For regional haze, the future year will depend on the end-date of the planning period being examined.

[17] There are additional regulations related to reasonable further progress (RFP) requirements for both the ozone and $PM_{2.5}$ NAAQS.

NMED Exhibit 108

2.7.2 What Base Year Emission Inventory Data Are Needed to Support Air Quality Models?

Air quality models require hourly emissions of modeled species for each grid cell and model layer in the modeling domain. For the base year, the inventories are called the *base year inventory for modeling.* To meet the input requirements of models, the inventory must have pollutants that are the scientific precursors (pollutants that impact the relevant chemistry) to the ozone, $PM_{2.5}$, and/or regional haze being addressed in the modeling demonstration. The time frame of the emissions inventory should be consistent with the period being modeled. The inventory should include states, counties, and tribes that are covered by the spatial extent of the modeling domain. Additionally, the emissions sources included should be comprehensive, including emissions from all source categories. As explained with additional detail below, this includes point sources, non-point stationary sources, on-road and nonroad mobile sources, fires, and biogenic sources.

2.7.3 What Pollutants Should Be Included in Base Year Inventories?

Because many sources emit more than one of the precursor pollutants, and because the precursor pollutants have the potential to be transported across state boundaries, the EPA encourages air agencies to develop comprehensive inventories to support integrated, regional-scale modeling, and control strategy development for ozone, $PM_{2.5}$, and regional haze. However, there are some considerations for which pollutants to include in inventories for the purpose of supporting air quality modeling.

For 8-hour ozone NAAQS modeling, the pollutants to be inventoried for modeling are VOC, NO_X, and CO. For $PM_{2.5}$ NAAQS modeling, the pollutants to be inventoried are primary emissions of $PM_{2.5}$ and PM_{10} (including both the filterable and condensable portions) and emissions of SO_2, NH_3, VOC, NO_X, and CO. While certain $PM_{2.5}$ precursors may not be considered precursors for planning purposes in some nonattainment areas[18], inclusion of all precursors is a prerequisite for appropriate application of air quality models for modeled attainment demonstrations. For regional haze, the pollutants to be inventoried include all of the pollutants and precursor pollutants identified for ozone and $PM_{2.5}$. While CO does not need to be included in the *planning inventories* associated with ozone and/or $PM_{2.5}$ SIP submissions (as described in the EI SIP Guidance), it should be included for modeling purposes because CO plays an important role in atmospheric chemistry.

[18] See the $PM_{2.5}$ SIP requirements rule for detailed information on the definition of "planning" precursors for $PM_{2.5}$ nonattainment areas.

NMED Exhibit 108

For modeling purposes, emissions inventories of these pollutants undergo many transformations to prepare the inventories for use in air quality models. These transformations include chemical speciation, which is described below in section 2.7.8.2. As part of the chemical transformations of VOC, in particular, total organic gases (TOG) are calculated to include lower reactivity compounds that are not included in the regulatory definition of VOC, but nonetheless have some role in ozone and/or $PM_{2.5}$ formation.

2.7.4 What Temporal Resolution Should Be Used for Base Year Inventories?

The emissions inventories should cover the time periods associated with the modeled time period. Different approaches to accomplishing this goal arise because of the nature of ozone, $PM_{2.5}$, and regional haze problems.

For ozone, the episodic nature of 8-hour ozone exceedances leads to inventories that may reflect a specific period being modeled. For this reason, the *planning* inventories should be provided as an ozone season day inventory[19] (as described in the EI SIP Guidance). For the nonattainment area, the planning ozone season day inventories are also often used for modeling inventories.

For $PM_{2.5}$, both annual and daily NAAQS result in different inventory temporal possibilities for the modeling episode, depending on which NAAQS a particular nonattainment area must address in the SIP. As a result, the *planning* inventories may be annual, seasonal, or both. Like ozone, the planning inventories may also be used as the starting point for the modeling inventories. For example, an annual planning inventory will need to be temporally allocated to the days and hours of the time period used for $PM_{2.5}$ modeled attainment demonstrations. This is the case for both annual modeling and when the air agency has chosen to use a seasonal demonstration as part of a 24-hour demonstration.

Modeling inventories also include areas outside the nonattainment area, for which ozone season day or average season day (for $PM_{2.5}$) emissions may not be readily available. In these instances, air agencies may elect to start with an annual inventory and use an emissions model to adjust the annual emissions to reflect the modeling period. This may not be advisable in every case; in particular, mobile source emissions are highly variable with meteorology and day of the week, and are often available on a monthly or even daily basis that reflects variability in temperature, traffic patterns, and other factors. In addition, more detailed temporal data from electric generating units (EGUs), biogenic sources, windblown dust, sea salt, lighting, wildfires,

[19] The definition of "ozone season day" emissions specifies weekday emissions and is intended to reflect the periods of emissions associated with monitored ambient ozone exceedances.

NMED Exhibit 108

prescribed fires, agricultural burning, or other sources should be used when available to enhance the technical quality of the modeled attainment demonstration.

For regional haze, the use of annual emissions inventories is appropriate given the nature of the regional haze problem. However, the same considerations apply for the inventory's temporal aspects as they do in the cases above; more detailed temporal data should be used as the inventory starting point when it is available for important sources of the pollutants included in the inventory.

2.7.5 What Spatial Coverage Is Needed for Base Year Inventories?

Modeling inventories must cover all areas of the modeling domain, which will include areas outside of a nonattainment area and Class I areas and most often includes areas in neighboring states or tribes. This subsection addresses areas within and outside the nonattainment area separately.

2.7.5.1 Areas Within the Nonattainment Area

As mentioned above, planning inventories (which are a CAA and regulatory requirement for ozone and $PM_{2.5}$ SIPs) include emissions within the nonattainment area. The EPA expects that modeling inventories will be consistent with those planning inventories; however, some exceptions may exist. Where possible, the planning inventories (which are typically annual or seasonal) can be a sum (for annual data) or average (for ozone or $PM_{2.5}$ season day data) of day-specific or hour-specific data used for modeling. In some cases, however, this approach may not be sufficient for modeling purposes. For example, greater spatial and temporal detail are needed for on-road mobile modeling inventories as compared to the base year (planning) inventory for the nonattainment area. For the planning inventory, one goal is to allow for the repeatability of the approach in order to create average, seasonal, or annual inventories for use in rule requirements, such as reasonable further progress or conformity demonstrations. That goal is not necessarily compatible with the modeling need for spatial and temporal detail. In cases where some differences between planning and modeling inventories are unavoidable, air agencies should attempt to promote consistency where feasible. More information on the temporal basis of inventories is provided in section 4.5 of the EI SIP Guidance.

2.7.5.2 Areas Outside of the Nonattainment Area

For air quality modeling, emissions inventories are often needed for areas outside the nonattainment area. Developing modeling inventories for these areas should be relatively straightforward and can be included as part of the SIP planning inventories. For areas outside of

NMED Exhibit 108

the air agency's jurisdiction, however, it can be more difficult for air agencies to develop the inventories themselves. In these cases, the EPA encourages participation in regional modeling efforts, which are designed to allow sharing of data and help promote consistent approaches across state boundaries. When those organizations lack the needed inventories, the EPA recommends using the EPA's publicly available emissions, as described in the next section.

2.7.5.3 Areas Outside of the United States

In some cases, the modeling domain may need to extend into areas of Canada and/or Mexico. In this case, emissions modelers will need to include emissions from these countries in their modeling domain. Both Canada and Mexico have emission inventory programs that provide inventories that can be used in modeling, and the EPA includes the latest available inventories from these countries in its national emissions modeling platform. States are encouraged to use the latest available data for these countries. While the EPA is one source for that data, states may work directly with other countries or work with their EPA Regional office to try to get inventories that are more current or otherwise improved over what is available directly from the EPA.

2.7.6 How Can the National Emission Inventory Be Used by Air Agencies?

The EPA recommends that state, local, and tribal agencies start with available inventories suitable for air quality modeling of the selected time period(s). If no such inventories are available from a prior state or tribal effort, from regional modeling groups, or from some other source, air agencies may choose to derive an inventory suitable for use with models from EPA-provided information. Two sources of information are available, as described below. In both cases, the EPA expects that air agencies will only use such data after additional review to ensure the appropriate quality of the data for SIP planning purposes.

First, the National Emission Inventory (NEI) provides criteria air pollutant and hazardous air pollutant emissions as annual emissions totals for most (if not all) sources of emissions relevant for ozone, $PM_{2.5}$, and regional haze implementation purposes. Air agencies may use the most recent public release of the NEI as a starting point for inventory development. The data and documentation are available from the NEI Website.

Additionally, the EPA provides emissions modeling "platforms" that are based on the NEI and can be a starting point for air agencies. The modeling platform data provide additional information not available from the NEI, such as daily EGU and fire emissions, monthly nonroad emissions, biogenic emissions and/or input to biogenic emissions models, and inputs to mobile source models. Furthermore, these modeling platforms usually include future-year emissions

NMED Exhibit 108

projections. Both base and future-year data are provided in a format used by emissions models and can, therefore, be more readily adopted by air agencies that need to process emissions for use in air quality models. The data and documentation are available from the latest platform release at the Air Emissions Modeling Website.

The detail and accuracy of the EPA emissions inventories and platforms may or may not be sufficient for use in any particular SIP. Air agencies should review the emissions and associated documentation and make improvements where deficiencies exist. Such improvements will often be necessary to demonstrate appropriate model performance, as described in section 3. Additional degrees of review are needed for areas closer to the nonattainment area. For example, EPA data may be sufficient for estimating emissions in states that are hundreds of kilometers upwind or downwind of the nonattainment area, but may not be sufficient for estimating emissions closer to the nonattainment area because those emissions can have a greater impact on the final results of the attainment demonstration.

2.7.7 How Should Base Year Emissions Be Created?

Emission inventory data from at least five general categories are needed to support air quality modeling: stationary point-source emissions, stationary area-source emissions (also called non-point), emissions for on-road mobile sources, emissions for nonroad mobile sources (including railroad and marine vessels), and biogenic/geogenic emissions. A sixth category of wildland fires also exists and includes day-specific emissions from wildfires and prescribed burns. These fire emissions are included as an "event" source in the NEI. Emissions inventories are expected to include "all" sources of emissions; if an air agency wishes to exclude a particular source (e.g., because it is a very small contributor), then the air agency should document the reasons such omissions are acceptable. In addition, some "traditional" nonroad mobile sources (e.g., airports and rail yards) can also be included in inventories as a point source. For example, in the NEI, airports and rail yards are included as point sources and railroad and marine vessel emissions as part of the nonpoint data category.

The EI SIP Guidance (U.S. EPA, 2017b) addresses numerous details about emissions inventory development. Readers are encouraged to refer to information in that document as a resource for building base year emissions inventories. That guidance contains additional information on the definitions of the data categories (point sources, nonpoint sources, etc.), provides more information about emissions estimation for each data category, includes a process for prioritization of inventory development, and includes quality assurance recommendations. All of this information is highly relevant to inventories developed for air quality modeling. In the remainder of this section, we provide a basic description of the data categories and their base

NMED Exhibit 108

year emissions and additional information needed for their use in modeling applications where appropriate.

2.7.7.1 Point Sources

Point sources are emissions sources that are attributed to specific facilities and emissions release points within those facilities. The Air Emissions Reporting Rule (AERR) provides information on how to define which sources to include as specific point sources in the inventory. This definition is the same as the New Source Review program major source definition, with a lower potential-to-emit threshold for nonattainment areas. More information on the relationship between SIP inventories and the AERR and how that affects SIP inventories is available in the EI SIP Guidance. For modeling inventories, data developers may include sources with emissions smaller than the required reporting threshold, and should be careful to prevent double counting with nonpoint source categories that may overlap with some of these smaller sources. This is especially a concern when compiling point and nonpoint inventories from different sources, because a nonpoint inventory is compiled using certain assumptions about what an associated point source inventory includes. This issue is described as "nonpoint reconciliation" and is discussed further in the EI SIP Guidance.

Point source inventories for modeling should be compiled at a minimum by country, state/tribe, county, facility, unit, process or source category code (SCC) and by "release point" or stack (see references below to point-source inventory development). The point source data should include information on the location of the sources (e.g., latitude/longitude coordinates); their stack parameters (e.g., stack diameter and height, exit gas temperature and velocity); and operating schedules (e.g., monthly, day-of-week, and diurnal). Information on existing control device types, measures and associated emissions reductions are also useful to identify sources that might be further controlled and to prepare future year inventories.

For air quality modeling purposes, the precision of the latitude/longitude values can be very important, as it will determine the modeled grid cell of the source. It is recommended to use coordinates reported to one-ten-thousandth of a degree (four digits after the decimal point) to give a precision of approximately 30 feet. In addition, metadata about the latitude/longitude should ideally be collected, such as the horizontal reference datum code used (e.g., WGS84). The EPA provides a data standard for latitude/longitude which can be considered when collecting, storing, and reporting latitude and longitude data values (see here). When working with other states to share point source data, it may be useful to use the same horizontal reference datum across states, such as the World Geodetic System of 1984 (WGS84). Other datum codes listed on the EPA Data Element Registry Services include the North American Datum of 1927 (NAD27) and the North American Datum of 1983 (NAD83).

NMED Exhibit 108

For modeling needs, many point sources will also be post-processed for the estimation of plume rise of the emissions vertically through layers of the atmosphere as modeled by the air quality model. This plume rise depends on the stack parameters (listed above) and on meteorological conditions. Plume rise can be calculated by emissions models or as part of air quality models (either approach is acceptable and the results can be equivalent). In this latter case, inventory developers are responsible only for identifying for which sources' plume rise will be computed using tools available in emissions models.

Also, for modeling needs, hourly emissions data are usually a starting point for inventories of EGUs. In most cases, such data are readily available from Continuous Emissions Monitoring Systems (CEMS) installed as part of EPA trading programs[20] and include hourly emissions of NO_X, SO_2, CO_2, and heat input. The heat input data can be used to estimate hourly emissions of other pollutants (such of primary $PM_{2.5}$ emissions) using facility-specific emission factors or other emission factors. The EPA's modeling platforms also include these hourly data.

2.7.7.2 Nonpoint Sources

Nonpoint sources are also called "area sources." These sources collectively represent sources of emissions that have not been inventoried as specific point sources. The individual sources within the nonpoint emissions county totals are typically too small, numerous, or difficult to inventory using the methods for point sources. The nonpoint emissions data should be compiled by country, state/tribe, county, and SCC, and sometimes by emission type (e.g., hoteling and cruising for commercial marine emissions in the NEI) and Geographic Information Systems (GIS) shape (for locomotive and commercial marine emissions in the NEI). The specification of nonpoint emissions at a more detailed resolution than county is typically not necessary for modeling inventories, but can provide a more detailed spatial representation for areas where such an approach is needed. Spatial allocation of emissions with spatial surrogates (see section 2.7.8.3) can be equally effective.

2.7.7.3 On-Road Mobile

Emissions from on-road vehicles are the result of several emission processes, including the combustion of fuel while vehicles are starting, idling, and moving, evaporation of fuel from the fuel system and during refueling, and from brake wear and tire wear.

[20] CEM data are provided by the EPA's Clean Air Markets Division in a format suitable for use in emissions processing at the Air Markets Program Data Website. From this page, click the "Prepackaged data" tab and scroll to the bottom to download the data in a form that can be input into SMOKE.

NMED Exhibit 108

Mobile source inventory modelers should use the latest version of the Motor Vehicle Emission Simulator (MOVES) for on-road mobile source emissions. They should also subscribe to the MOVES email list to be notified of any bug fixes or updates to the MOVES model. For on-road emissions in California, the most recent EPA-approved version of the EMission FACtors model (EMFAC) should be used. In addition, the Sparse Matrix Operator Kernel Emissions (SMOKE) emissions modeling system includes tools that support the use of MOVES emission factors with SMOKE, and thereby allows modelers to account for the sensitivity of on-road emissions to temperature. SMOKE uses county-specific inputs and gridded hourly temperature and other meteorological information, which is typically based on the same meteorological data used for air quality modeling.

Emissions modelers have a choice in MOVES between "inventory" mode and "emission factors" mode (which creates emission factors that can be further processed using SMOKE-MOVES). Both approaches are valid for supporting air quality modeling for SIPs. More information on the different ways of running MOVES is provided in the MOVES documentation and guidance.

Modelers should consider using a refined approach (such as the SMOKE-MOVES system, day-specific MOVES runs, or some other approach) for use in emissions modeling needed for modeled attainment demonstrations. The SMOKE-MOVES approach first generates emissions rates from MOVES by process (running, start, vapor venting, refueling, etc.), vehicle type, road type, temperature, speed, and hour of day, according to specified fuel parameters and other inputs. Then, subsequent steps apply the appropriate MOVES emissions rates along with vehicle miles traveled (VMT) and vehicle population data for the counties and grid cells in the modeling domain for each hour of the modeling episode.

The MOVES model allows modelers to override default database settings to obtain a locality-specific on-road inventory, and EPA strongly encourages data developers to develop and use MOVES input databases that are specific to the states and counties within the modeling domain. The MOVES Technical Guidance[21] discusses when local data should be used in place of model default data, as well as potential sources of local data.

For some input parameters, there is overlap with the inputs needed for other models, such as the nonroad mobile models. For example, meteorology and fuels information is needed to drive both the mobile and non-road emissions models. Efforts should be made to use the same source of data across multiple categories when the inputs are shared by multiple models. Not doing so calls into question the validity of one or both approaches. Air agencies should explain

[21] The most current version of this document is available on the MOVES website.

NMED Exhibit 108

the use of shared inputs, or reasons for not using them, as part of the documentation prepared with their modeled attainment demonstration.

On-road emissions and VMT should be compiled at least at the country, state/tribe, county, and SCC level. Vehicle population data by county and vehicle type should also be compiled as well as idling hours, if available. For some inputs such as VMT, modelers may optionally compile and use data for individual road segments (called "links"). Link approaches require starting and ending coordinates for each road link. Link-based modeling is typically performed for fine scale (i.e., 4-km or finer) modeling studies. Travel Demand Models (TDMs) can be a source of data needed to develop link-based approaches. In regional scale modeling, county-level on-road emissions can be allocated onto road links using spatial surrogates that are generated based on link data and mapped into the modeling grid cells using appropriate weights.

2.7.7.4 Nonroad Mobile Equipment

Nonroad mobile equipment emissions result from the use of fuel in a diverse collection of vehicles and equipment, and the EPA's NONROAD emissions model estimates these emissions. The NONROAD model was originally a separate model, but has now been incorporated into the MOVES model (starting with MOVES2014a). Nonroad emissions should be compiled as country, state/tribe, county and SCC totals.

For the MOVES2014a version of MOVES and later versions, the MOVES model should be used to calculate nonroad source emissions. MOVES2014a (and newer versions) includes features not previously available in MOVES that simplify processing of emissions output and includes updated fuel input files that result in small changes in emission results. In addition, the prior tools available for nonroad emissions estimations (NONROAD2008 and NMIM2008) may no longer work with current operating systems, and the EPA cannot continue to provide technical support for these models. Therefore, the EPA recommends that for modeling nonroad emissions, MOVES2014a or newer versions be used for all new SIP development, although state and local agencies that have already completed significant work with MOVES2014, NONROAD2008, or NMIM2008 can continue to do so to allow for timely submission of the SIP. As a general matter, air agencies should review and possibly update and customize the MOVES model inputs to give better emissions estimates for their state.

Unlike models for onroad emissions, the EPA does not specifically "approve" nonroad models. However, use of alternative models can be justified as part of a SIP submission. For example, California has previously developed and used a state-specific approach for estimating its nonroad source emissions for SIP purposes, called OFFROAD2007. Although this model has now been replaced by category-specific methods for many categories, it is still the default approach for categories not listed with newer methods, as described on the OFFROAD website. Any use

NMED Exhibit 108

of such an alternative approach is subject to review by the EPA as part of the review of the SIP, and thus states are encouraged to coordinate with Regional offices on any use of alternative models. The MOVES nonroad capabilities include more than 80 basic and 260 specific types of nonroad equipment and further stratifies equipment types by horsepower rating. Fuel types include gasoline, diesel, compressed natural gas (CNG), and liquified petroleum gas (LPG). The nonroad capabilities of the MOVES model estimates emissions for all criteria pollutant and precursors from both exhaust and non-exhaust processes (diurnal, refueling spillage, vapor displacement, hot soak, running loss, take permeation, hose permeation, and crankcase emissions). MOVES supports many SIP-related inventory development needs, including support for partial counties and seasonal emissions.

Air agencies are encouraged to replace default model inputs with more representative data. Common input adjustments include equipment population, geographic allocations, and local growth rates. If agencies make changes to default model values, the agency should submit the input files to the EPA as well as a description of why the defaults were changed. As mentioned in the previous discussion of on-road mobile emissions, for some input parameters, there is overlap with the inputs needed for other models, such as the on-road mobile models (e.g., meteorology and fuels). Efforts should be made to use the same source of data across multiple categories when the inputs are shared. Not doing so calls into question the validity of one or both approaches. Air agencies should explain the use of shared inputs, or reasons for not using them, as part of the documentation provided with their inventories.

2.7.7.5 Nonroad Mobile: Commercial Marine Vessels, Locomotives, and Aircraft

Emissions from commercial marine vessels, locomotives, and aircraft are estimated in other ways as described in detail in the EI SIP Guidance. These sources can be particularly important for urban areas and in some Class I areas (especially in coastal areas). The EI SIP Guidance contains information about methods available to estimate emissions from these sources.

Commercial marine vessel emissions can be a particular challenge for nonattainment areas that include ports or are adjacent to major shipping lanes. While the level of emissions from these vessels can be outside of the control of state air agencies (coming under national rather than state jurisdiction), it is still important to accurately represent these emissions when they are significant contributors in the vicinity of a nonattainment area or Class I area. Vessels are divided into the largest ocean-going “category 3” (C3) vessels and the smaller “category 1” (C1) and “category 2” (C2) vessels such as tug boats, ferries, support vessels, fishing vessels, and others. Commercial marine emissions include both in-port emissions and underway emissions, with most (~90% of nationwide emissions) emissions associated with underway activity. For the planning inventories covered by the EI SIP Guidance, air agencies need to include only those

NMED Exhibit 108

emissions within state waters. For the modeling inventories, however, air agencies may also need to include emissions in Federal waters when the modeling domains extend more than a few miles offshore. This is especially important for coastal areas where offshore commercial marine emissions may be an important contributor to ozone and/or PM in the nonattainment area and/or visibility impairment in Class I areas.

The current EPA methods for estimating commercial marine emissions use a bottom-up approaches for C1, C2, and C3 vessels. The method uses activity data from Entrance and Clearance Waterbourne Commerce (both from the Army Corps of Engineers) and from a 2007 EPA census of C1 and C2 vessel activities. The most recent documentation for EPA methods is provided in the 2014 NEI v2 Technical Support Document, section 4.19.

Uncertainties in estimating commercial marine emissions with EPA's current methods remain. Thus, the EPA strongly encourages air agencies preparing modeling inventories to seek out, develop, and use local-specific information about their ports and waterway vessels to better compute emissions whenever possible, and particularly when the commercial marine sector is a major factor in emissions conditions that lead to nonattainment and/or visibility impairment in Class I areas.

2.7.7.5 Biogenic Emissions

Biogenic sources are a subset of natural emissions sources that may be an important component of the emissions inventory. Vegetation (i.e., forests and crops) is the predominant biogenic source of VOC and is typically the only source that is included in a biogenic VOC emissions inventory. Additionally, microbial activity in the soil contributes to biogenic NO emissions.

Biogenic emissions from vegetation and soils are computed using a model that utilizes spatial information on vegetation and land use and environmental conditions of temperature and solar radiation. The model inputs are typically horizontally allocated (gridded) data, and the outputs are gridded biogenic emissions which can then be speciated and utilized as input to chemical transport grid models. Several models exist, and are described more fully in section 2.7.9.2 and the EI SIP Guidance.

Modeled biogenic vegetation emissions are significant for understanding ozone formation, particularly in the Eastern U.S., and the dependence on meteorology makes using case-specific meteorology very important. In addition, the impact and model characterization of biogenic monoterpene and sequiterpene emissions on secondary aerosol formation is important in many areas of the U.S., most notably the Southeast. Therefore, biogenic emissions should be

NMED Exhibit 108

generated using hourly meteorology reflective of the time period being modeled to best capture important relationships between temperature, solar radiation, and biogenic emissions.

2.7.7.6 Geogenic and Other Natural Sources

Geogenic emissions are primarily the result of oil or natural gas seeps, soil wind erosion, and sea salt spray. In addition, lightning may also be an important contributor to natural NO emissions in an inventory area. Volcanoes and fumaroles (i.e., vapor or gas vents in a volcanic region) can be additional sources of geogenic emissions. SIP developers should consider these sources as part of their conceptual description. If geogenic sources are identified as potentially contributing to air quality, such emissions should be included in the modeling.

Oil or Natural Gas Seeps

The U.S. Geological Survey Bureau of Ocean Energy Management (BOEM) has documented emissions from oil and gas seeps in the Gulf of Mexico. The University of California Santa Barbara also provides inventory information about California- area seeps. This is an area of ongoing research.

Windblown Dust

Wind erosion may contribute substantially to PM emissions in an area. Emissions from wind erosion is an area of active research and development, and multiple approaches for estimating wind-blown dust emissions are available. For example, the EPA's CMAQ model includes a module that dynamically estimates hourly natural emissions of fine and coarse dust particles due to wind action over arid and agricultural land. The windblown dust approach is based on the work of J.S. Fu et al. (2016). Other examples of windblown dust approaches include Draxler, Ginoux and Stein (2010), Mansell et al. (2006), and Sundram et al. (2004).

Air agencies using any "in-line" approach for windblown dust emissions should evaluate the results of the approach to determine if it provides a reasonable representation of dust emissions in their modeling domains. Air quality models can have an option to output in-line emissions for evaluation, so that modelers can assess and quality assure the emission estimates directly.

Sea Salt and Other Ocean Emissions

The interaction of sea-salt particles in coastal environments with air chemistry can impact concentrations of $PM_{2.5}$ and gas-phase species in the atmosphere. Various emissions estimation methods are available to account for sea salt emissions. For example, the CMAQ model has been updated to account for these emissions, so that emission inventory developers are able to

NMED Exhibit 108

rely primarily on the air quality model to internally calculate sea-salt emissions. Additional information for CMAQ is available in Kelly et al., (2010) and Gantt et al., (2015). For CAMx, additional information on sea salt simulations is available in Athanasopoulou et al. (2008). When an in-line approach is used, emissions should be output from the model so that modelers can assess and quality assure the emission estimates directly. When an in-line approach is not used, modelers should consider the possible need for including sea salt emissions data as an input to the air quality model.

In addition to particulate impacts, ozone in coastal areas can be affected by ocean emissions of halogen compounds including chlorine, bromine, and iodine. Many approaches could be taken to represent those emissions. For example, Yarwood et al. (2014) describes an updated chemical mechanism to include halogen chemistry and a CAMx preprocessor that was used to estimate emissions of halogen precursors in coastal areas, and Sarwar (2015) describes a similar halogen chemistry implementation that has been used in CMAQ. Numerous other references are available in the peer reviewed literature that describe halogen chemistry impacts on ozone formation and modeling of that process.

Lightning

Another natural source of emissions is lightning, which produces NO that forms NO_2 in the presence of ozone or in a photochemically reactive atmosphere. The NO and NO_2 are formed in the mid-upper troposphere and can impact the vertical distribution of reactive nitrogen as well as ozone. Because lightning is not a direct source of NO_2, accounting for this source category is more important for air quality modeling purposes than for SIP planning inventory purposes.

Various methods for estimating lightning emissions could be used. For example, the EPA's CMAQ model includes a parameterized approach to estimate NO_X emissions and the vertical distribution that is generated from lightning. The peer reviewed literature contains both a description of the approach (Allen, 2012) and a model evaluation (Appel, 2010). In addition, Koo et al. (2010) describe estimating annual total lightning NO emissions for North America and then spatially and temporally allocating those emissions to model grid cells using convective precipitation activity as a surrogate.

Volcanoes and Fumaroles

Basic information on volcanic gas is available from the USGS. The USGS also has a monitoring program focused on predicting eruptions. Although this program does not include information on pollutant concentrations, the monitoring program website provides potentially useful maps of volcanos using the "Find a U.S. Volcano" pull-down menu near the top of the site. Finally, the publications related to volcanoes search allows for searching publications for pollutant

NMED Exhibit 108

keywords such as CO_2, SO_2, gas, hydrogen sulfide, and volcanic gas. Most of these emissions-related articles focus on information in California, Washington, Hawaii, and the Yellowstone area.

2.7.7.7 Wildland and Cropland Fires

Wildland fires are generally defined as any non-structure fire that occurs in wildland (an area in which human activity and development are essentially non-existent, except for roads, railroads, power lines, and similar transportation facilities and structures, if any, are widely scattered). Cropland fires are any non-structure fire that occurs on croplands. The Exceptional Events Rule[22] (which applies to NAAQS implementation) and the Regional Haze Rule define two types of fire that can occur on wildland:

- *Prescribed fire* means any fire intentionally ignited by management actions in accordance with applicable laws, policies, and regulations to meet specific land or resource management objectives.
- *Wildfire* means any fire started by an unplanned ignition caused by lightning; volcanoes; other acts of nature; unauthorized activity; or accidental, human-caused actions, or a prescribed fire that has developed into a wildfire. A wildfire that predominantly occurs on wildland is a natural event.

Inventories used for ozone, $PM_{2.5}$, and regional haze modeling purposes should include wildland (wild and prescribed) and cropland fire emissions. Wildland and cropland fires can emit large amounts of primary $PM_{2.5}$ as well as precursors that can react in the atmosphere to form ozone and secondary $PM_{2.5}$ downwind potentially impacting both urban and Class I areas. Thus, wildfire and prescribed fire emissions should be included in the nonattainment area inventories when and where these emissions occur within the modeling domain during time periods being modeled. Cropland fires can also be inventoried when and where these emissions occurred or as a nonpoint source.

Detailed information about how the EPA develops wildland and cropland (Pouliot et al, 2016) fire inventories can be found in the latest version of an NEI Technical Support Document, such as that provided with the 2014 NEI. The EPA's approach for wildland fires relies on a combination of satellite detection of fires merged with on-the-ground observational data where available. The EPA encourages the use of ground-based observations and local fuel information whenever possible, as these factors can have a large impact on the emissions. One option for obtaining fire date and location information includes the latest version of the

[22] *See* 81 FR 68216, October 3, 2016.

NMED Exhibit 108

Satellite Mapping Automated Reanalysis Tool for Fire Incident Reconciliation (SMARTFIRE) system (Du et al., 2013; Sullivan, et al., 2008). Detailed information on the SMARTFIRE system is available in Raffuse et al., 2007. Additional references and information are available as part of the 2014 NEI Technical Support Document. Other sources of fire location, size, duration, and emissions may be available and could be used instead of the SMARTFIRE approach. Examples of other approaches include the WRAP FETS (JFSP, 2013) and the Fire Inventory from NCAR (FINN).

Important aspects of wildland fire that impact resulting emissions estimates include the location of the fire, timing of the fire (start and end date/time), fire type (wild, prescribed, or cropland), fuel type, fuel loading, area burned, and fuel moisture. Daily emissions are allocated to hour of the day using profiles based on fire type. VOC and primary $PM_{2.5}$ emissions are speciated to specific compounds based on profiles generated from laboratory and field testing. The activity information noted is not just critically important for estimating emissions, it is also important toward estimating the heat flux of the fire and subsequent plume rise in the photochemical model. The estimated plume rise can have a large impact on how far downwind smoke can be transported (to a nonattainment area and/or Class I area). Combustion phase can also be an important consideration when modeling wildland fires in terms of emissions, plume rise, and vertical allocation of emissions. Fires that are largely smoldering (such as peat fires) can have different emission factors and have a different profile of VOC and primarily emitted $PM_{2.5}$ emissions.

Since fire emissions can be a large source of emissions, the treatment of fires should be discussed with the relevant EPA Regional office(s) as part of the modeling protocol development process.

2.7.8 What Other Data Are Needed to Support Emissions Modeling?

For modeling purposes, emission inventories need to be converted through emissions modeling from their original resolution (e.g., annual emissions by point source or count) to air quality model input files. Air quality models generally require emissions inputs to be specified by model grid cell, hour, and model chemical species. Modeling inventories also identify which point sources should have their plume rise computed. This section describes the ancillary data that modelers should collect and prepare to allow emissions models to convert the emission inventory data into air quality model inputs.

2.7.8.1 Temporal Allocation

Ancillary data for temporal allocation are necessary for stationary point, stationary area, and all mobile sources. To facilitate temporal allocation of the emissions, factors called “temporal

NMED Exhibit 108

profiles" should be created to convert annual emissions to specific months (i.e., monthly profiles), average-day emissions to a specific day of the week (i.e., weekly profiles), and daily emissions to hours of the day (i.e., hourly profiles). Additionally, a cross-reference file is needed to assign the temporal profiles to the inventory records by SCC, facility, geographic area such as state or county, or some other inventory characteristics. Where available, the operating information that may be available from the point-source inventory should be used to create inventory-specific temporal factors. The EPA provides a starting point for the temporal profiles and cross-reference files as part of the latest modeling platforms (previously described), available at the Air Emissions Modeling website.

The EPA has developed a SMOKE utility program (Gentpro) that estimates temporal profiles for residential wood combustion (RWC), agricultural NH_3 from animals, and other generic (user-defined) area sources by relating meteorology to air emission fluxes. Gentpro reads in hourly gridded meteorological data (temperature and wind) from the Meteorology-Chemistry Interface Processor (MCIP)[23] and a gridded spatial surrogate to produce temporal profiles and cross-reference data. Annual MCIP input data are required to calculate temporal profiles with Gentpro and the spatial surrogates are needed to identify the grid cells for computing county-averaged meteorology variables. The Gentpro program is described in the latest SMOKE User's Manual.

For RWC, Gentpro allocates emissions to specific days from annual totals based on a regression equation that was developed by relating daily minimum temperatures and chemical tracers of RWC. This approach results in more RWC emissions assigned to periods of colder temperatures using a user-defined temperature threshold that restricts RWC emissions to days with morning lows below a specific value. Air agencies that use EPA's emissions data for this category should note that this approach has been used to temporally allocate the RWC emissions.

For agricultural NH_3 from animals (i.e., from concentrated animal feeding operations, or CAFOs), Gentpro allocates annual, monthly or daily emissions to hourly emissions based on empirical equations derived from investigations of emissions from animal waste decomposition as a function of temperature and wind speed. The resolution of emissions input to Gentpro for this sector depends on the available data. Air agencies that use EPA's emissions data for this category should note that this approach has been used to temporally allocate agricultural NH_3 emissions from CAFOs.

[23] MCIP is a meteorology postprocessing program. It is typically used to convert WRF meteorological model output data to CMAQ input format. The latest version of MCIP can be found here.

NMED Exhibit 108

For point sources, hourly CEMS data are recommended for use in base year emissions modeling rather than temporal profiles, where such CEMS data are available, and with the following caveats. CEMS data are collected as part of emissions compliance and/or trading programs. Because these programs require complete hourly data, alternative emissions values are assigned to hours when CEMS devices are not functioning. These alternative values can be extremely high values (compared to actual emissions rates), in order to motivate CEMS operators to provide a complete data record to the extent possible. As a result, CEMS data may have some anomalies and should be reviewed prior to use in a modeling study. The CEMS data fields include an emissions method code, which identifies the hours with alternative values. Furthermore, CEMS data may be available for only part of a year; therefore, for annual modeling, users should be careful to ensure CEMS data are used for the appropriate periods and total annual emissions are temporally allocated to fill in the other hours of the year.

For wildland fire emissions, the EPA recommends using daily, location-specific fire data such as the NEI "events" sources. These sources can have a large impact on ambient levels of ozone and $PM_{2.5}$, and on regional haze. Although emissions from these sources are largely uncontrollable, the inclusion of all emissions sources (including biogenic and uncontrollable sources) is needed to accurately predict pollutant concentrations and derive relative response factors for both PM and ozone.

As a general matter, the temporal allocation approach should remain consistent between the base year modeling and the future year modeling. Consistency is important when using the RRF approach to make future year projections of ozone, $PM_{2.5}$ and/or visibility, because the results of that approach can be affected by changes in when emissions are modeled to occur. In general, this means that the temporal allocation will be the same between base and future years, except when an intentional change is made to reflect a real expected change in the temporal distribution. An example of such a change includes intentionally reducing emission peaks from units during incidents of poor air quality. In addition, modeling can be specially done for the current year with an emissions case which uses "typical" emissions temporal allocations for major sources, and this case may be different from the current year case, where actual source schedules are used to evaluate model performance.

For future-year modeling there are two choices for representing EGU emissions derived from CEMs data and wildfire emissions. Modelers can use day-specific emissions for both the base and future years, or a "typical year" temporal allocation (averaging) approach can be used to create representative emissions. If a typical year approach is used, it should include similar daily temporal variability as could be expected for any given year (in most cases, the daily temporal variability also needs to be consistent with the base year meteorology). Air agencies should

NMED Exhibit 108

discuss the temporal approach to fires (see also section 2.7.11) and point sources with the appropriate EPA Regional office as part of the modeling protocol development process.

2.7.8.2 Chemical Speciation

The emissions models also need information about the chemical species of the VOC, NOx, and $PM_{2.5}$ emissions for all emissions sources. These data are used to disaggregate the total VOC, NOx, and $PM_{2.5}$ emissions to the chemical species expected by the air quality model and are called speciation "factors" or "profiles."

The EPA provides a starting point for the VOC, NOx, and $PM_{2.5}$ speciation data, which are available with the EPA modeling platforms (previously described). The VOC and $PM_{2.5}$ speciation profiles are based on the SPECIATE database, which is available on the SPECIATE website. In addition to the speciation profiles, a speciation cross-reference file assigns speciation profiles. The default EPA speciation cross-reference assigns profiles to sources using SCCs. These speciation profiles in many cases are highly uncertain and should be assessed and improved where possible for emissions source categories that are critical to model performance.

For large or critical VOC and $PM_{2.5}$ sources in the modeling domain, air agencies should consider determining the individual chemical compounds contributing to the total VOC and $PM_{2.5}$. If collected, this information should then be used to compile speciation profiles for the critical facilities or source categories. These speciation profiles should be assigned to the facilities by updating the speciation cross-reference file to support a facility-specific or facility-SCC-specific assignment.

For VOC, low reactivity chemical components including methane have traditionally been calculated by applying a factor to the VOC emissions to calculate total organic gases (TOG). These TOG emissions are then split during emissions processing into the VOC model species that include methane. In limited situations, air agencies may want to investigate the extent that methane emissions and low volatility compounds play a role in ozone episodes and/or secondary $PM_{2.5}$ formation. Additional efforts going beyond the use of the default VOC-to-TOG profiles from the speciation profiles may develop over time.

In some limited cases, it may be of interest to include methane emissions inputs to air quality models to achieve sufficient model performance for a modeled attainment demonstration. Approaches can include incorporating methane emissions from other sources into emissions inventories used for modeled air quality. For example, the MOVES model estimates methane emissions directly, so there would be no need to use VOC speciation to estimate those emissions. Air agencies considering methane as a contributing factor should consult with their

NMED Exhibit 108

EPA Regional office to discuss the best sources for such data as this inventory development area is undergoing many changes at this time. Furthermore, more specific VOC-to-TOG factors and speciation profiles may be useful, particularly for analysis related to areas of very high methane emissions. Additionally, the EPA encourages the use of HAP emissions data when available to augment VOC speciation; therefore, we suggest using the inventory HAPs where criteria air pollutants (CAPs) and HAPs were provided by the same data source. When possible, the EPA's modeling platforms generally process the following HAPs rather than relying on VOC speciation: benzene, acetaldehyde, formaldehyde and methanol. These 4 HAPs are collectively known as "BAFM" and are removed from VOC speciation calculations for the remaining VOC HAPs needed for the air quality models. Ethanol can also be added to this "VOC integration" process where ethanol emissions are available. It is entirely up to the user to determine the "integration" status of specific sources in each inventory. A simple test for possible integration of VOC HAPs is the following. For each inventory unique source (i.e., a stack or nonpoint/mobile FIPS+SCC): 1) confirm that VOC HAPs and VOC were reported by the same data provider, and 2) compute VOC HAPs to ensure they are non-zero and less than inventory VOC. A detailed methodology is provided in section 3.2.1 of the 2011 emissions modeling platform technical support document.

County-specific speciation profile combinations are also available for cases where user-defined mixtures of two or more speciation profiles are needed. The "GSPRO_COMBO" feature in SMOKE can be applied by state and county and time period (e.g., month) and is currently used for on-road and nonroad mobile and gasoline-related stationary sources where the emissions sources use fuels with varying ethanol content (e.g., E0 and E10 profiles). Ethanol content varies spatially by state and county via nonattainment areas or local programs, temporally (e.g., during ozone season months), and by modeling year because future years have more ethanol. Certain source categories will require more careful review of speciation assignments. For example, the oil and gas sector (point, area and nonroad) inventories are generally constructed for specific drilling areas (i.e., drilling basins) which may include multiple counties with unique production gas characteristics. Knowledge of the type of gas (e.g., dry, wet, coal bed methane) or oil produced, flared and vented in these basin inventories is helpful for developing basin specific speciation assignments.

NO_x emission factors and, therefore, NO_x inventories are developed on a NO_2 weight basis. For air quality modeling, emissions processors must split NO_x to NO and NO_2 and in some cases HONO. Although emissions models allow using multiple speciation profiles for NO_x, historically only one split factor has been used of 90% NO and 10% NO_2. For mobile sources, the MOVES model calculates NO and NO_2 internally based on a more nuanced selection of factors and uses an NO_2 factor of 0.008 for onroad sources based on Sarwar (2008).

NMED Exhibit 108

One additional NO_x speciation data resource is stack test data of NO/NO_2 ratios for use in AERMOD modeling for the 1-hr NO_2 standard. These data are available here.

2.7.8.3 Spatial Allocation

For all source sectors that are compiled at a county resolution, the emissions models also need information about allocating the countywide emissions to individual grid cells that intersect the county boundaries. Such sectors include stationary area, nonroad mobile, and (non-link) on-road mobile sources. The spatial allocation process assigns fractions of county-total emissions to the model grid cells intersecting the county based on a "surrogate" data type (e.g., population, housing data). The appropriate types of surrogate data to use for each SCC in the inventories should be identified for this processing step. Spatial surrogates can be created using GIS to calculate the fraction of countywide emissions to allocate to each grid cell based on the surrogate type. These calculations can also be made using the EPA's Surrogate Tool, which is based on the Multimedia Integrated Modeling System (MIMS) Spatial Allocator. In addition, all SCCs needing spatial surrogates should be assigned a surrogate in a cross-reference file. Point sources do not need spatial surrogates, since the emissions models assign the grid location based on the latitude and longitude of the point sources. The EPA provides spatial surrogates and cross-references as part of its latest modeling platform. The same spatial surrogate data are normally used in both the base and future year modeling. However, emissions developers can choose to alter the spatial surrogate data based on predicted changes in land use patterns, population growth, and demographics, although the impacts and utility of such approaches are not well characterized,[24] so their use needs to be well documented and explained.

2.7.8.4 Other Ancillary Inputs

On-road emissions for fine-scale model grids (e.g., 4-km grid cells or smaller) may be based on a link-based approach as mentioned in section 2.7.7.3. The VMT and speed data needed for a link-based approach can be provided using a Travel Demand Model (TDM). These models require their own sets of inputs, which depend on the specific TDM used. The MOVES Technical Guidance provides general guidance on the development of MOVES inputs. Details on using TDMs for link-based on-road mobile emissions are available from the EIIP document "Use of Locality-Specific Transportation Data for the Development of Source Emission Inventories." An example of the use of TDMs can be found in "Use of Travel Demand Model Data to Improve Inventories in Philadelphia."

[24] At the time this document was written, tools to readily predict future-year land use patterns are not readily available in a form for use in emissions modeling.

NMED Exhibit 108

Emissions models have other input files that must be created. Previously, we noted that for point sources, emissions developers will have to identify which sources should be treated as elevated sources by an air quality model. To do this, data developers will select criteria such as stack height or a screening plume height value to allow an emissions model to flag point sources as elevated sources. In the SMOKE modeling system for example, the Elevpoint program can be used for this purpose.

The emissions models have a large number of files and settings which work together in fairly complex ways; therefore, users should be careful to select the appropriate files needed for the emissions model, and to prepare all input files in a way that will support using the emissions model for the specific air quality model application. A possible shortcut can be starting with the emissions modeling scripts included with the EPA's modeling platforms.

2.7.9 How Are Inventory Data Converted into Air Quality Model Input?

Emissions models are used to convert inventory data to inputs for air quality modeling. As described in section 2.7.8, as part of the emissions modeling process, additional ancillary data are needed to augment the raw emissions inventories. The emissions data for each of the six emissions sectors (point, area, on-road mobile, nonroad mobile, biogenics, and wildland fires) are temporally allocated, chemically speciated, and spatially allocated by the emissions model. The resulting hourly, gridded, and speciated emissions from all sectors are then combined before being used by an air quality model. In this section, we will provide information on several emissions models and summarize some key issues with the application of emissions models.

2.7.9.1 Emissions Models

Several emissions models are available for use in developing SIPs. While no single model has been specifically created for all situations, each model is generally capable of performing the necessary emissions processing steps including temporal, chemical, and spatial allocation. Users of such models are responsible for ensuring that the emissions processing steps transform the emission inventories as intended and are not changing the emissions in any unexpected way. Each model has different capabilities, limitations, and nuances. Therefore, when choosing an emissions model, it is worthwhile to discuss the choice with the developers of these systems and/or with EPA to determine which model is best suited for a particular application. Note that there are a number of programs that process emissions for individual source sectors. These are discussed below in the sector-specific subsections. Currently, SMOKE is the primary emissions

NMED Exhibit 108

model used to develop emissions data for input into chemical transport grid models. Other emissions models can also be used, such as the Emissions Preprocessing System (EPS).

SMOKE supports processing of criteria, mercury, and toxics inventories for stationary point, stationary area, mobile, and biogenic emissions. This emissions model can create input files for the CMAQ and CAM_X air quality models. Applications of SMOKE have been presented at several of the International Emissions Inventory Workshops (Houyoux, 2000; Strum, 2003, Zubrow, 2012, Baek, 2010, Adelman, 2008, Baek, 2007a, Baek, 2007b, Baek, 2006, Eyth, 2006, Pouliot, 2005). SMOKE is available for UNIX and Linux operating systems, but is not recommended for use on PCs running Windows. It does not require third party software. The SMOKE software and User's Guide are available on the SMOKE website.

Utilities for creating speciation profiles, biogenic land use, or spatial surrogates are not included within SMOKE. However, the Speciation Tool can create speciation profile inputs for SMOKE (Eyth, 2006), and biogenic land use and spatial surrogates can be built using the MIMS Spatial Allocator Tool along with the related Surrogate Tools.

2.7.9.2 Biogenic Emissions Models

There are several available biogenic emissions models that can be used to develop biogenic emissions for modeled attainment demonstrations and regional haze modeling. One such model is the Biogenic Emissions Inventory System, version 3.6 (BEIS3.6) (Bash et al, 2016). This model can be run both as part of a CMAQ model run and alternatively as a module of the SMOKE system. The CMAQ approach is described here. The latest documentation on the SMOKE approach to run BEIS is available here.

Another biogenic model commonly used to support air quality model applications is the Model of Emissions of Gases and Aerosols from Nature (MEGAN). The MEGAN model also uses meteorological data including temperature and solar radiation as input to generate biogenic emissions. MEGAN is distributed with vegetation/land-use data that includes all of North America. Other biogenic emissions models have been used to support air quality modeling, such as BEIGIS, which is a GIS-based biogenic emission model developed by the California Air Resources Board.

The BEIS modeling system uses land-use data from the Biogenic Emissions Land Use Database, version 4.1 (BELD4). BELD4 data provides data on the 230 vegetation classes at 1-km resolution over most of North America. These land use data can be created with the MIMS Spatial Allocator. Based on inputs from the emissions developer, the Spatial Allocator will select the 1-km grid cells from the BELD data that intersect the modeling domain and (if necessary)

aggregate to the grid resolution of the modeling domain. Air agencies can alternatively rely on the EPA's 12-km gridded data for modeling domains that overlap with the EPA national domain, provided with the EPA's latest modeling platform on the Emissions Modeling Clearinghouse.

In situations where air agencies consider biogenic emissions important for ozone, PM, or regional haze, the data used in these biogenic emission models could be updated to provide a better representation of vegetation and vegetation specific emission factors. For future-year modeling, land use data is typically held constant (same as the base case). Emissions developers can choose to change their land cover data based on predicted changes in land use patterns, however, the impact and utility of such approaches is not well characterized, so their use needs to be well documented and explained. Where fundamental changes are made to landuse/vegetation data or emission factors, those changes should be noted in the modeling protocol and/or final documentation package along with references to the source of updated/alternative data.

The meteorological data used as input to any biogenic emission model should be consistent with the data used for the air quality model. Biogenic emissions models are generally set up to use gridded hourly meteorological data, so inventory developers should be able to convert their meteorological inputs from air quality modeling inputs for use in their selected biogenics emissions model. Surface (or canopy level) temperature and solar radiation data can be obtained from modeled meteorological data, such as the WRF Model. Alternatively, solar radiation data could be obtained from satellite products.

Biogenic emission models evolve over time, so agencies using these models should evaluate the suitability of one model over the other as part of a modeling analysis. Once a choice has been made for modeling purposes, emissions should also be summed across the NAA for inclusion in the base year inventory for the NAA and/or the attainment projected inventory for the NAA.

2.7.10 Other Emissions Modeling Issues

In addition to the emissions modeling process and tools described above, there are several other important issues to consider. In the remainder of this section, we briefly address each of these issues.

NMED Exhibit 108

2.7.10.1 Elevated Point Sources

Point sources need to be assigned to an appropriate model layer[25] (the vertical modeling dimension). Depending on the air quality model that is being used, different emissions modeling steps can be taken. Models such as CMAQ and CAM_X expect input emissions files separately for surface level emissions versus the elevated point-source emissions.

2.7.10.2 Treatment of 'Atypical' Sources of Emissions

In the NEI, there are several sources of emissions that are reported by only one state or a small number of states. These sources typically have very low emissions, so whether they are included in the modeling inventory typically has little impact on air quality modeling. Examples of these sources include domestic and wild animal waste emissions (primarily NH_3), human perspiration and cigarette smoke, and swimming pools. In some inventories, large catastrophic/accidental releases are reported (e.g., car accidents, tire fires). It is generally considered inappropriate to include these sources in emissions processing for air quality models. However, some source categories may be important or unique to a particular area. Before removing seemingly unimportant source categories, the relative importance (e.g., as a percentage of emissions in the area) of each category should be evaluated.

Air agencies should also review and consider the draft EI SIP Guidance and the Ozone Implementation Rule regarding EGU emissions during High Electric Demand Day (HEDD) periods. Such emissions can be crucial for having a complete understanding of relevant emissions sources within a modeling domain. Where these emissions are important for assessing a nonattainment problem, air agencies should consider the potential impact of HEDD emissions when selecting time periods (e.g., episodes, season, year) to model.

2.7.10.3 Transport and Meteorology-based Reductions in Fugitive Dust Emissions

Fugitive dust emissions are another large source of primary $PM_{2.5}$ emissions. However, past modeling experience has shown modeled $PM_{2.5}$ concentration over-predictions from these emissions (Pouliot et al, 2010). Therefore, the EPA recommends reducing area-source fugitive dust emissions prior to air quality modeling to account for "capture" by the terrain (such as deposition on vegetation and buildings), changes in the emissions potential (such as frozen ground), and removal by meteorology (such as precipitation). These two components should be accounted for when adjusting the inventory PM emissions from PM sources such as paved and unpaved roads, construction, mining, agricultural activities, and industrial dust and other low-

[25] Point sources generally comprise most of the elevated emissions (above layer 1), although other sources, such as fires, ships, and aircraft may also have emissions assigned to elevated layers.

NMED Exhibit 108

level fugitive dust source categories. The "captured" portion of the reduction can be based on gridded land use data such as vegetation and building characteristics. The EPA has developed a methodology within SMOKE to adjust the fugitive dust emissions. The "meteorological" component of the reduction requires intermediate SMOKE processing scripts to merge hourly, gridded precipitation data and snow cover values to zero-out all fugitive dust emissions where appropriate. To avoid double-counting the precipitation-based reduction, the user should make sure that the inventory fugitive dust inventory does not already include a "MET-adjusted" reduction prior to these manipulations. This combined transport and met-based reduction approach is documented in Pouliot et al., 2010.

2.7.10.4 Quality Assurance

Quality assurance (QA) is a key component of any successful emissions modeling effort. A brief synopsis of appropriate QA approaches for emissions modeling is available in section 2.20 of the SMOKE manual. The purpose of QA for emissions modeling is to ensure that the inventories are correctly processed using the information the modeler intended. (It is assumed here that the inventory itself has already been QA'd and erroneous values and/or outliers removed through inventory QA procedures, as described in the EI SIP Guidance.)

Emissions modeling QA includes such activities as:

- Reviewing log files for errors and warnings and addressing problems;
- Comparing emissions between each of the processing stages (e.g., data import, speciation, temporal allocation) to ensure mass is conserved;
- Checking that the correct speciation, temporal allocation, and spatial allocation factors were applied; and
- Reviewing the modeling-specific parameters such as stack parameters.

It is also useful to compare air quality modeling-ready emissions summaries to previous emissions modeling efforts to verify expected emissions changes by source category(s) and geographic area(s) of interest. In addition, the process of running emissions inventories through emissions models and air quality models often provides insights into the emission inventories themselves. These insights can lead to inventory changes that improve the quality of inventories for additional modeling iterations.

In general, this guidance also encourages the use of graphical analysis and GIS for improved QA of emissions data and processing. A commonly used analysis tool for model-ready emissions data is the EPA-sponsored Visualization Environment for Rich Data Interpretation (VERDI) tool. The VERDI software package provides for efficient, flexible and modular capabilities of

NMED Exhibit 108

overlaying meteorology, emissions and air quality modeling data with GIS shapefiles. More information on VERDI is available on the VERDI website.

2.7.11 How Are Emissions Estimated for Future Years?

Emissions estimates for future years are called "emissions projections." The inventory developed for modeled attainment demonstrations is called the *attainment projected inventory for modeling.*[26] These emissions projections include emissions changes (due to increased or decreased activities), facility and/or unit-level shutdowns, and emissions controls (which can be due to, among other things, regulations, settlements or fuel-switching that reduce emissions in specific ways in the future). The goal in making projections is to obtain a reasonable estimate of future-year emissions that accounts for the key variables that will affect future emissions. Each air agency is encouraged to incorporate in its analysis the variables that have historically been shown to drive the economy and emissions within the modeling domain, as well as the changes in growth patterns and regulations that are expected to take place between the time of the base year and future years.

Complete guidance on emissions projections is provided in the EI SIP Guidance, with subsections on EGUs, non-EGU stationary sources, on-road mobile sources, nonroad mobile equipment, other nonroad mobile sources, and a list of other projection resources. The EI SIP Guidance includes a lengthy discussion about considerations that should be made for models or other tools that forecast EGU emissions. As noted in that guidance, "the states are advised to make sure that the tools meet the criteria laid out in this document because EPA will use these criteria to assess any EGU projection information submitted as part of SIPs." In addition, several additional issues are listed here for consideration for modeling inventories.

Emissions models (e.g., SMOKE, EPS) provide the capability to create future-year inventories using base year inventories and projection information. Emissions modelers will need to convert the projection data into specific formats for input to these models. Inventory developers should determine which emissions model will be used to perform the calculations and make sure that the type(s) of information needed by the model is being collected.

In the context of modeling for ozone and $PM_{2.5}$ purposes, for fires, it is recommended that the base year fires be held constant for use in the future year modeling. This approach allows for

[26] The name applies even if it turns out that the modeling shows that the area is not able to attain the standard by the latest applicable attainment date. Note that projected inventories are also used for regional haze modeling, however, the name "attainment projected inventory for modeling" applies specifically to attainment demonstrations.

NMED Exhibit 108

the impact of these fires to be minimized using the RRF approach, while still including realistic fire patterns that are relevant to ozone and $PM_{2.5}$ formation necessary for modeled attainment demonstrations. States have flexibility in how they estimate base year fires, but it is recommended that states should hold these constant in the future modeling case. Additional specific discussion of future-year fires as they relate to $PM_{2.5}$ SIPs is available in section IV.D.3.b of the preamble to the $PM_{2.5}$ SIP Requirements Rule. For regional haze purposes, air agencies should consult sections IV.E and IV.G of the 2017 Regional Haze Rule, 82 FR 3078 (Jan. 10, 2017), as well as their Regional EPA office as appropriate, to develop an approach for the treatment of emissions from fires.

Ancillary input files for inputs to emissions models, such as spatial surrogates, temporal allocation factors and especially speciation profiles may also need to be adjusted to reflect conditions expected in the future. The EPA modeling platforms, for example, consider the impact on speciation of fuels used in the future, which are expected to change over time due to regulations.

Once a future-year inventory and other data have been created, it should undergo the same steps as for the base-year modeling, including temporal allocation, speciation, spatial allocation, elevated source selection, special on-road mobile processing, any other custom processing steps (e.g. applying meteorology-based information to fugitive dust, agricultural NH_3 and residential wood combustion), and QA**.** Except where intentional, every attempt should be made to use consistent approaches between the future year and the base year for all of these modeling steps. Inconsistencies in approaches between the future-year modeling and the base-year modeling can lead to artificial differences in air quality modeling results that can affect conclusions.[27] Therefore, it is critical to avoid such differences whenever possible. If inconsistent base and future year approaches are necessary, they should be well documented and explained.

2.8 Initial and Lateral Boundary Conditions

Air quality models require chemical time and space boundary conditions in order to solve for concentrations within the modeled domain and time period. The time boundary or *initial condition* (IC) is provided at the beginning of the first simulated time step and the space boundary or *lateral boundary condition* (LBC) is provided at the outer edge of the modeling domain. As with other model inputs, the establishment of the IC and LBC data should be guided

[27] This is especially important due to the use of the "relative" change in modeled concentrations as part of the modeled attainment test. An inconsistency in base and future year emissions may lead to a very large modeled percent change in ozone and/or $PM_{2.5}$ concentrations.

NMED Exhibit 108

by the conceptual model of the air quality issue being simulated. For instance, more attention will be needed in developing accurate LBC for cases in which ambient data analyses (or previous modeling scenarios) have indicated the potential for long-range transport of pollutant material, compared to cases in which the air quality problem has been identified as largely local in nature. Numerous studies have highlighted the importance of accurately representing LBC in optimizing model performance and identifying the most effective path to attaining the NAAQS (Jacob *et al.*, 1999; Tang *et al.*, 2009; Hogrefe *et al.*, 2011).

Given limitations in available ambient data, it is impossible to exactly specify the complex three-dimensional chemical characteristics of the IC or LBC. As a result, two basic approaches to establishing these fields have been used within the modeling community. The first and preferred approach is to characterize the IC/LBC data as accurately as possible given the existing state of knowledge about ambient conditions at those times and in those locations. The second approach is to attempt to minimize the impacts of the IC and LBC by configuring the domain and modeling period such that the air quality concentrations in the locations and times of interest are largely unaffected by the IC/LBC inputs.

The impacts of the IC are most easily minimized when they are reasonably accurate. In most cases, it will be possible to minimize the impacts of the IC data via the use of a model "spin up" period. A spin up period is defined as some number of modeling days that precede the time period of actual interest. The model outputs for this spin up period are discarded from any analytical post-processing and evaluation, as they are potentially affected by the uncertain initial conditions. The length of the needed model spin-up period will vary as a function of: the domain size, prevailing meteorological conditions, and the chemical lifetimes of the pollutants being simulated. It is a simple modeling exercise to test the sensitivity of the key time periods to the initial conditions. Previous sensitivity modeling has determined that the IC are typically "washed out" of the system in as few as 3-5 days for a local-scale modeling analysis; approximately 10-20 days for a regional-scale analysis; and on the order of 6 months or more for a hemispheric-scale analysis (Berge *et al.*, 2001; U.S. EPA 2010; Anenberg et al., 2011). More recent work shows that 2 weeks is generally sufficient to reduce IC influence to under 1%, with more realistic IC decreasing the spin-up time (Hogrefe et al., 2017). Upper air (elevated layers in the model) takes longer to minimize the influence of IC, and as a result, some locations may require longer spin-up). If there is any question as to the appropriate length of the spin-up period, then sensitivity modeling tests should be conducted. Otherwise, the above guidelines should be sufficient for most ozone and $PM_{2.5}$ attainment demonstrations and regional haze assessments.

NMED Exhibit 108

In many cases, it will not be feasible to build a large enough domain to minimize the impacts from emissions outside the domain. For these cases, it will be necessary to downscale the requisite species concentration data from well-performing, coarser-grid, larger domain modeling runs. (In rare cases, it may be possible to assign LBC from detailed field study species data, but most domains will not have complete chemical profiles in space and time along the domain edges.). These larger "parent" grids may be generated by the same regional scale model at coarser resolution; or they can be generated via global or hemispheric models. In the last decade, several global/hemispheric air quality models have been used to generate regional LBC inputs. A sample of models used for LBC include: GEOS-Chem (Bey et al., 2001), the AM3 atmospheric component of the GFDL global coupled model (Donner, et al., 2011), the Model for Ozone And Related Tracers (MOZART, Emmons et al, 2010), the WRF-Chem model (Zhang, et al., 2012a), and the hemispheric CMAQ model (Byun and Schere, 2006; Fu et al., 2012). The EPA does not recommend any one particular global/hemispheric model. Each regional modeling exercise should individually assess whether the chosen global/hemispheric or coarse regional model accurately captures lateral boundary conditions.

For cases in which the LBC will be extracted from larger-scale regional/hemispheric modeling, the EPA recommends two efforts to optimize the LBC characterizations. First, modelers should try to minimize any disconnects in the downscaling process. Wherever possible, one should attempt to utilize the same species, chemical mechanism, layer depths, and meteorological inputs in the regional/hemispheric model as are being used in the finer-scale attainment demonstration modeling (Lam and Fu, 2009). This will minimize the number of uncertain translations needed to convert coarse-scale outputs to finer-scale LBC inputs. In particular, careful consideration of the stratosphere in the two modeling systems will be needed to ensure that regional/hemispheric ozone that is stratospheric in origin is not excessively mixed down to the surface in the finer-scale modeling due to disconnects between the two systems.[28] Second, there should be a comprehensive evaluation of the regional/hemispheric model performance (Bey *et al*., 2001). While there may not be a detailed data set available for model evaluation along the domain lateral boundaries in most cases, consideration of model performance across the domain will provide a first-order indication of the ability of the coarser-scale model to characterize air quality at the boundaries. Additionally, it may also be possible to infer

[28] In establishing the layer structure for both global and regional models, it is advisable to avoid selecting upper model layers that span both the upper troposphere and lower stratosphere. It has been seen that "hybrid" layers can allow for inappropriate diffusive mixing between those two generally decoupled sections of the atmosphere. In cases where stratospheric intrusions are not expected to influence ozone in the area, it may be appropriate to artificially cap stratospheric ozone concentrations to avoid ozone performance issues. This should be a "last resort" fix, only applied after detailed assessments of the vertical diffusion and vertical advection schemes within the model.

NMED Exhibit 108

information about the quality of the coarse-model estimates via comparisons with satellite data (Liu *et al.*, 2006, Henderson *et al.*, 2013).

In some situations, it may be possible to construct a modeling platform in which the LBC will not substantially influence the air quality issue under consideration. For instance, areas for which there is no evidence of pollutant transport from the far edges of the model domain to the local area may be able to demonstrate that the determination of LBC data will not impact the eventual modeling demonstration. As with the IC data, this conclusion can be proven via simple sensitivity tests in which the LBC are modified from a base state and the results between the two runs are compared (e.g., Appel *et al*, 2007). For situations in which alterations to the LBC data will not impact key findings, it is acceptable to use time-invariant profiles for LBC. Because there are many publicly available sources of modeled boundary conditions, this approach should only be used only when there is good reason.

Due to the potential impact of LBCs on model response to emissions controls, it is important to accurately characterize the relative influence of LBC versus local emissions. For example, if the impacts of LBC on local air quality are overestimated, it will be more difficult than it otherwise should be to show reductions in future design values from local controls. Conversely, if the modeling system underestimates the role of inflow air quality, local emissions reductions may appear more effective in the model than they will be in reality.

The selection of future year LBCs also has potentially important ramifications on the relative response factors derived from the modeling for the various control scenarios. If LBC are known to impact local air quality, then modelers may need to consider how these contributions will change between the base year and the attainment year (Adelman *et al.*, 2011). Ambient trends analyses for 1990-2010 have indicated that free tropospheric ozone levels above the western U.S. have increased by approximately 0.5 ppb/year over those two decades with increases seen at rural surface monitors in the west (Cooper et al., 2012; Cooper et al., 2010; Lin et al., 2017). More recent analysis focusing on 2000-2016 shows mixed trends in the free troposphere with only one high altitude surface monitor with a significant increase in its median or 95th percentile concentration. The most recent trends may suggest decreasing future ozone contributions from LBC due to international controls (e.g., van der A et al., 2017). It is left to the discretion of the air agency to determine whether varying future LBC are needed as part of an attainment demonstration. Updated future boundary conditions may be needed when emissions changes are expected outside the domain that will meaningfully change the LBC and impact the area(s) of interest within the domain. This decision should consider both the length of the projection period and the potential for significant air quality changes outside the modeling domain. Additionally, careful consideration of upstream emissions will be needed as

NMED Exhibit 108

part of any additional future-year regional/hemispheric modeling conducted to develop future LBC. If updated future year LBC are used, those data should be fully described and justified in the modeling protocol.

NMED Exhibit 108

3.0 Evaluating Model Performance

3.1 Overview of Model Performance Evaluation

The results of a model performance evaluation (MPE) should be considered prior to using modeling to support an attainment demonstration or regional haze assessment. The objective of the MPE is to demonstrate that the base case model can simulate observed pollution concentrations during historical pollution episodes, and to develop confidence that the model can reliably predict how future pollution levels will change in response to changes in emissions. A particular concern in photochemical models is that compensating errors in the model can cause the model to reproduce observed pollution concentrations in the base case while incorrectly representing the emissions, dispersion and chemistry processes that control pollution formation. Models that achieve good performance through compensating errors may not be reliable for predicting how pollution levels will respond to future emissions reductions. However, if an operational evaluation is conducted over a large enough spatial and temporal scale to incorporate a variety of meteorology and emissions conditions, good model performance is less likely the result of compensating error. Thus, a key goal of the MPE is to demonstrate that the model is getting good results for the right reason (Russell and Dennis, 2000) and to show that the model is able to capture pollution concentrations over the range of conditions that are relevant for the regulatory application being undertaken. In addition, the MPE can provide air agencies with tools to identify and fix causes of poor model performance such as problems in the meteorological, emissions, or boundary condition input files.

Dennis et al. (2010) describe an MPE framework that includes four different approaches that can be used to evaluate air quality models:

1. Operational evaluation techniques include statistical and graphical analyses aimed at determining whether the modeled simulated variables are comparable to measurements.
2. Diagnostic evaluation focuses on process-oriented analyses that determine whether the individual processes and components of the model system are working correctly, both independently and in combination.
3. Dynamic evaluation assesses the ability of the air quality model to predict changes in air quality given changes in source emissions or meteorology, the principal forces that drive the air quality model.
4. Probabilistic evaluation attempts to assess the level of confidence in the model predictions through techniques such as ensemble model simulations.

NMED Exhibit 108

The goal of the operational evaluation is to determine how well the model replicates observed concentrations of $PM_{2.5}$ components, ozone and their precursors. Diagnostic and dynamic evaluations are used to determine whether the model accurately represents the processes that determine pollutant concentrations, including emissions, dispersion, chemical reactions, and deposition (i.e., to determine if the model is getting good results for the right reason). For cases in which the model performs poorly in the operational evaluation, the diagnostic and dynamic evaluation can provide insights into the causes of the poor performance and to improve model performance. Ultimately, the goal of these evaluation methods is to assess the degree of confidence in the use of the model as a tool to inform the planning process, and more specifically, to determine how reliably the model predicts the response of ozone and/or $PM_{2.5}$ to changes in emissions. The modeled attainment and regional haze tests use models to predict the response of ozone and/or $PM_{2.5}$ to changes in emissions and then applies the resulting relative response factors (RRFs) to observed (rather than modeled) ambient data. Thus, while historically, most of the effort has focused on the operational evaluation, the relative test makes the diagnostic and dynamic evaluation also important.

At a minimum, a model used for air quality planning purposes should include a complete operational MPE using all available ambient monitoring data for the base case model simulation period. Section 3.2 describes the types of metrics and plots that are typically developed as part of an operational MPE, and section 3.3 describes ambient data that is available through continuously operating monitoring networks. If available, monitoring data from special field studies and other research data may also be used in the operational MPE.

Where practical, the MPE should also include some level of diagnostic evaluation. The use of sensitivity studies, process analysis, indicator ratios and source apportionment approaches for diagnostic evaluation, including dynamic and probabilistic evaluations are described in section 3.4. Given that air agencies might have limited resources and time to perform diagnostic and dynamic evaluation, the use of these methods may be limited in scope in a typical regulatory modeling application. However, more comprehensive diagnostic testing of the model can be a valuable component of the weight of evidence analysis used to support a SIP model attainment demonstration.

From an operational standpoint, the EPA recommends that air agencies compare their evaluation results against similar modeling exercises to ensure that the model performance approximates the quality of other applications. Recent literature reviews (Simon et al, 2012; Emery et al., 2017) summarize photochemical model performance for applications published in the peer-reviewed literature between 2006 and 2012. These reviews may serve as a resource for identifying typical model performance for state of the science modeling applications. It is clear that there is no single definitive test for evaluating model performance. All of the tests

NMED Exhibit 108

mentioned here have strengths and weaknesses. Further, even with a single performance test, it is not appropriate to assign "bright line" criteria that distinguish between adequate and inadequate model performance. In this regard, the EPA recommends that a "weight of evidence" approach be used to determine whether a particular modeling application is valid for assessing the future attainment status of an area. The EPA recommends that air agencies conduct a variety of performance tests and weigh them qualitatively to assess model performance. Provided suitable databases are available, greater weight should be given to those tests which assess the model capabilities most closely related to how the model is used (i.e., tests that provide insight into the accuracy of the model's relative response to emissions reductions should be given more weight). Generally, additional confidence should be attributed to model applications in which a variety of the tests described here are applied and the results indicate that the model is performing well.

3.2 Operational Evaluation

An operational evaluation is used to assess how accurately the model predicts observed concentrations. The underlying rationale is that if we are able to correctly characterize historical concentrations of ozone, PM and their precursors for a variety of meteorological conditions, this gives us some confidence that we can correctly characterize future concentrations under alternative emissions levels. Typically, this type of evaluation is comprised of statistical assessments of modeled versus observed data. Operational evaluations are generally accompanied by graphical and other qualitative descriptions of the model's ability to replicate historical air quality patterns. An operational evaluation provides a benchmark for model performance and can therefore identify model limitations and uncertainties that may require further model development/improvement and/or diagnostic evaluation

The robustness of an operational evaluation is directly related to the amount and quality of the ambient data available for comparison. An operational evaluation for ozone would ideally include co-located measurements of ozone precursors NOx and VOC and vertical profile measurements that can be used to determine the extent of vertical mixing of pollutants and the concentration of ozone and precursors above the boundary layer.

An operational evaluation for $PM_{2.5}$ and regional haze is similar to that for ozone; however, an important difference is that $PM_{2.5}$ consists of many component species and is typically measured with a 24-hour averaging time. The chemical components of $PM_{2.5}$ should be evaluated individually. In fact, in undertaking an operational assessment, it is more important to evaluate the components of $PM_{2.5}$ than to evaluate total $PM_{2.5}$. Apparent "good performance" for total $PM_{2.5}$ does not indicate whether the model is predicting the proper mix of components, which is important for the modeled attainment test or regional haze

NMED Exhibit 108

assessment. If performance of the major components is good, then it follows that performance for total $PM_{2.5}$ will also be good. In addition to measurements of VOC and NOx, which are precursors for organic aerosols and nitrate, a $PM_{2.5}$ model evaluation should also include measurements of gaseous precursors SO_2 and (where available) NH_3. Due to the influence of initial conditions, model predictions from the spin-up days should be excluded from the analysis of model performance.

3.2.1 Metrics

Operational evaluations quantify model performance through a variety of statistical metrics. Recommended metrics are described below and shown in Table 3.1. It is important to include multiple statistical measures in any operational evaluation to fully characterize model performance. At a minimum, we recommend evaluating: Mean Observed, Mean Model, Mean Bias, Mean Error and/or Root Mean Square Error, Normalized Mean Bias and/or Fractional Bias, Normalized Mean Error and/or Fractional Error, and the correlation coefficient. The equations for calculating each of these metrics are given in Table 3.1.

Mean Observed: The time-averaged mean observed value (in ppb or $\mu g/m^3$).

Mean Model: The time-averaged mean predicted value (in ppb or $\mu g/m^3$) paired in time and space with the observations.

Mean Bias (MB): This performance statistic averages the model/observation residual paired in time and space. A value of zero would indicate that the model over-predictions and model under predictions exactly cancel each other out. This metric is reported in the unit of measure (ppb or $\mu g/m^3$).

Mean (Gross) Error (ME/MGE): This performance statistic averages the absolute value of the model/observation residual paired in time and space. A value of zero would indicate that the model exactly matches the observed values at all points in space/time. This metric is reported in the unit of measure (ppb or $\mu g/m^3$).

Root Mean Square Error (RMSE): This performance statistic (in units of ppb or ug/m^3) is a measure of the average distance between predicted and observed values. It is calculated as the standard deviation of the difference between modeled and observed values.

Normalized Mean Bias (NMB): This statistic (given in units of percent) is used to normalize MB to the average observed value. NMB values range from -100% to +infinity. Consequently, negative and positive bias values using this metric are not symmetrical around 0.

Normalized Mean Error (NME): This performance statistic (given in units of percent) is used to normalize the mean error relative to the average observation. This statistic averages the

NMED Exhibit 108

absolute value of the difference (model - observed) over the sum of observed values. NME values range from 0 to +infinity.

(Mean) Fractional Bias (MFB/FB): Fractional bias is determined by normalizing the MB by the average of observed and modeled concentrations. The range of FB is -200% to +200%. The fractional bias for cases with factors of 2 under- and over-prediction are -67 and + 67 percent, respectively (as opposed to -50 and +100 percent, when using normalized bias). Fractional bias equally weights positive and negative bias estimates (underestimates and overestimates are symmetrical around 0).

(Mean) Fractional Error (MFE/FE): Fractional error is determined by normalizing the ME by the average of observed and modeled concentrations. The range of values for FE is 0 to 200%. It is similar to the fractional bias except the absolute value of the difference is used so that the error is always positive.

Correlation Coefficient (r) and Coefficient of Determination (R^2): These performance statistic measures the degree to which two variables are linearly related. A correlation coefficient of 1 indicates a perfect linear relationship; whereas a correlation coefficient of 0 means that there is no linear relationship between the variables. A correlation coefficient of less than 0 indicate anti-correlation. The Coefficient of Determination is always positive.

Table 3.1: Definitions of recommended statistical metrics

Abbreviation	Term	Definition
MB	mean bias	$\frac{1}{N}\sum(M_i - O_i)$
ME	mean error	$\frac{1}{N}\sum\lvert M_i - O_i\rvert$
RMSE	root mean squared error	$\sqrt{\frac{\sum(M_i - O_i)^2}{N}}$
FB	fractional bias	$100\% \times \frac{2}{N}\sum\frac{(M_i - O_i)}{(M_i + O_i)}$
FE	fractional error	$100\% \times \frac{2}{N}\sum\frac{\lvert M_i - O_i\rvert}{(M_i + O_i)}$
NMB	normalized mean bias	$100\% \times \frac{\sum(M_i - O_i)}{\sum O_i}$

NMED Exhibit 108

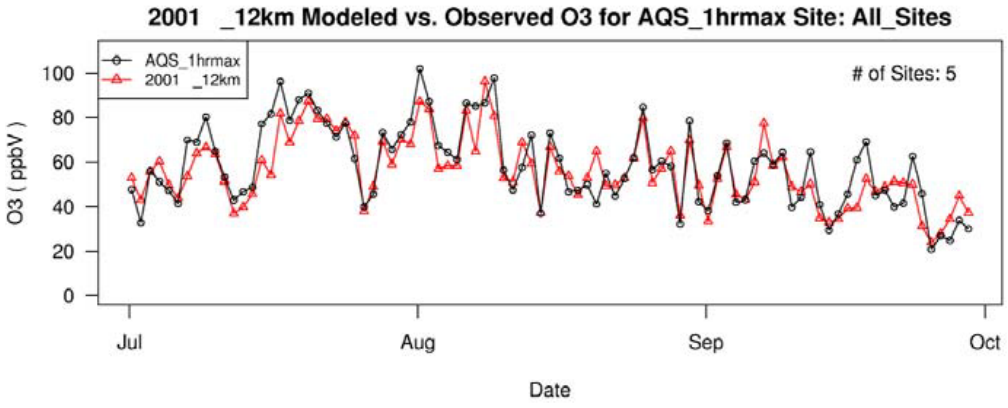
NME	normalized mean error	$100\% \times \frac{\sum \lvert M_i - O_i \rvert}{\sum O_i}$
r	Correlation coefficient	$\left(\frac{\sum_1^N \left((M_i - \bar{M}) \times (O_i - \bar{O}) \right)}{\sqrt{\sum_1^N (M_i - \bar{M})^2 \sum_1^N (O_i - \bar{O})^2}} \right)$
r^2	coefficient of determination	$\left(\frac{\sum_1^N \left((M_i - \bar{M}) \times (O_i - \bar{O}) \right)}{\sqrt{\sum_1^N (M_i - \bar{M})^2 \sum_1^N (O_i - \bar{O})^2}} \right)^2$

M_i = modeled concentration i. O_i = observed concentration i. N = number of paired obs/model concentrations. $\bar{M}$= mean modeled concentration. $\bar{O}$= mean observed concentration.

Observations and model predictions should initially be paired in time and space, matching the temporal resolution of the raw observation data. When matching in time, modelers should pay special attention to making sure that monitor and model data are both in local standard time. The units of time associated with model and observed concentrations can be 24-hour (usually for PM and its species), hourly (usually for species with continuous measurements, like ozone), or sometimes weekly (such as for CASTNet filter pack measurements). Temporal averaging is appropriate when used to match a relevant regulatory metric such as maximum 8-hr daily average ozone. As appropriate, air agencies should then aggregate the raw statistical results into meaningful groups of sub-regions or sub-periods. For example, examining model performance within and near the non-attainment area(s) of interest may be more important than performance in other parts of the modeling domain. For larger areas with more spatial variation, it may also be informative to evaluate sub-regions within the non-attainment area. In addition to any spatially aggregated statistics, model performance should also be evaluated at individual monitors within the nonattainment area. Similarly, priority may be placed on examination of the days that are potentially used in the attainment test (i.e., base period days with 8-hour ozone > 60 ppb). That is not to say that model performance evaluations should ignore performance on lower ozone days or in areas outside of the nonattainment areas. Model performance on lower concentration days and in areas outside of the nonattainment area are still important, but it is appropriate to give more attention to the model outputs that most directly impact the outcome of the attainment test. Unlike attainment demonstrations, model performance on days with low concentrations may be especially important for regional haze analyses. Some IMPROVE sites routinely measure extremely low PM species concentrations (even on the most impaired days).

In terms of pairing model predictions with monitored observations, the EPA recommends that the grid cell value in which the monitor resides be used for the calculations. It would also be acceptable to consider bi-linear interpolation of model predictions to specific monitoring

NMED Exhibit 108



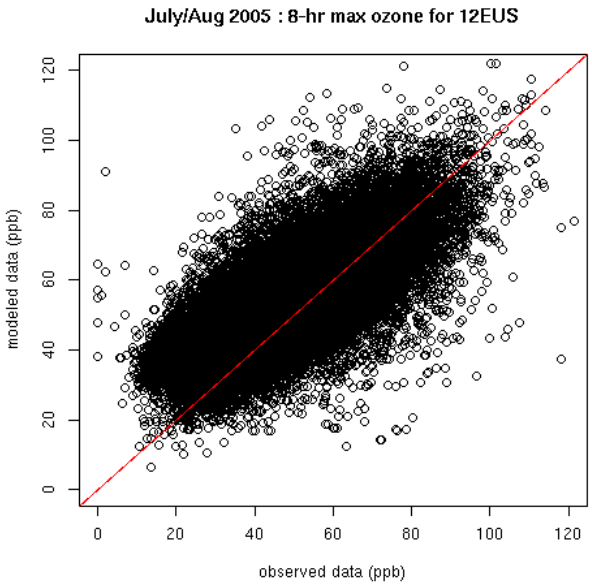
locations.[29] Air agencies should recognize that, even in the case of perfect model performance, model-observed residuals are unlikely to result in exact matches due to measurement uncertainty and differences in the spatial extent represented by model predictions, which are volume averages, and the observations, which are point values.

3.2.2 Plots

In addition to statistical summaries, graphical displays of data allow for a fuller characterization of model performance. Therefore, plots play a key role in any model performance evaluation. Below are examples of some types of plots which have been useful in past evaluations.

Time series plots of model and predicted hourly and/or daily concentrations (e.g., maximum 1-hour average, maximum 8-hour average, or 24-hour average) for each monitoring location in the nonattainment area, as well as key sites outside of the nonattainment area. These plots are especially important for examining performance at individual monitors and show how well the model captures temporal variations in pollutant concentrations at individual locations. Time series plots can indicate if there are particular times of day or days/episodes when the model performs especially poorly.

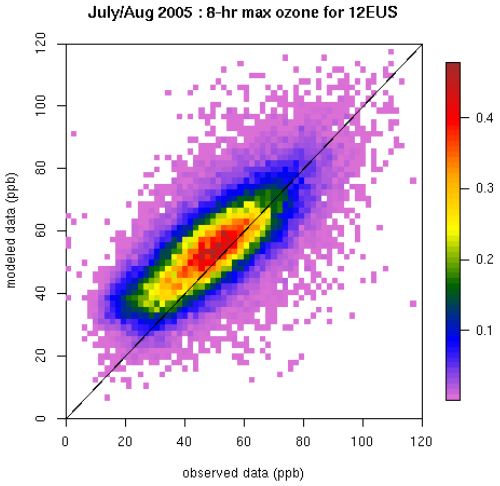
Figure 3.2.1 Example time series plot of daily 1-hour maximum ozone concentrations



Scatter plots of predicted and observed concentrations at each site. These plots are useful for indicating if there is a particular part of the distribution of observations that is poorly

[29]In certain instances, air agencies may also want to conduct performance evaluations using a "near the monitor" grid cell array (i.e., the best match within a 3X3 grid cell array centered on the monitor). A "near the monitor" analysis may be useful when strong ozone gradients are observed, such as in the presence of a sea breeze or in strongly oxidant limited conditions.

NMED Exhibit 108

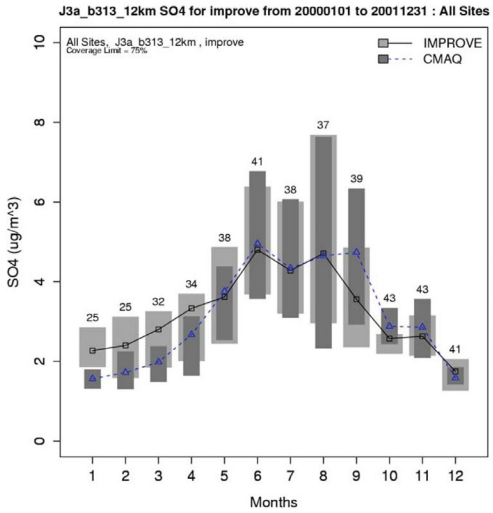


represented by the model. It may also be useful to develop separate plots for individual time periods or key sub-regions.

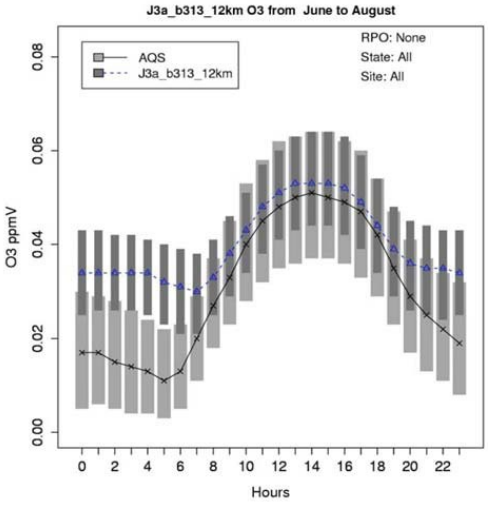
Figure 3.2.2 Example scatter plot of 8-hour daily maximum ozone concentrations

Density plots are a variation on scatter plots which are especially useful with large amounts of data when individual points overlap on a scatter plot. Density plots color code each point on the scatter plot based on the number of points falling in that location.

Figure 3.2.3 Example density plot of 8-hour daily maximum ozone concentrations

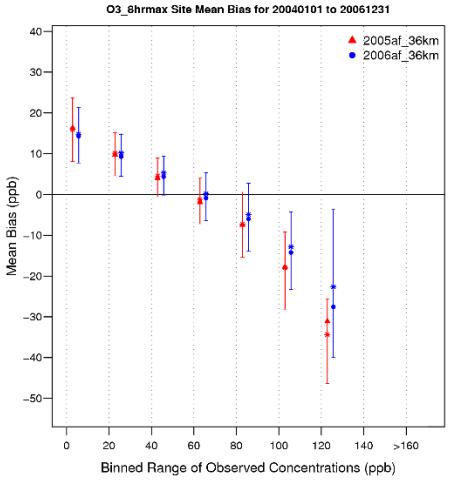


Box plots can be developed for model performance evaluation. These types of plots show the distribution of observations, model estimates, or performance metrics, which can be grouped



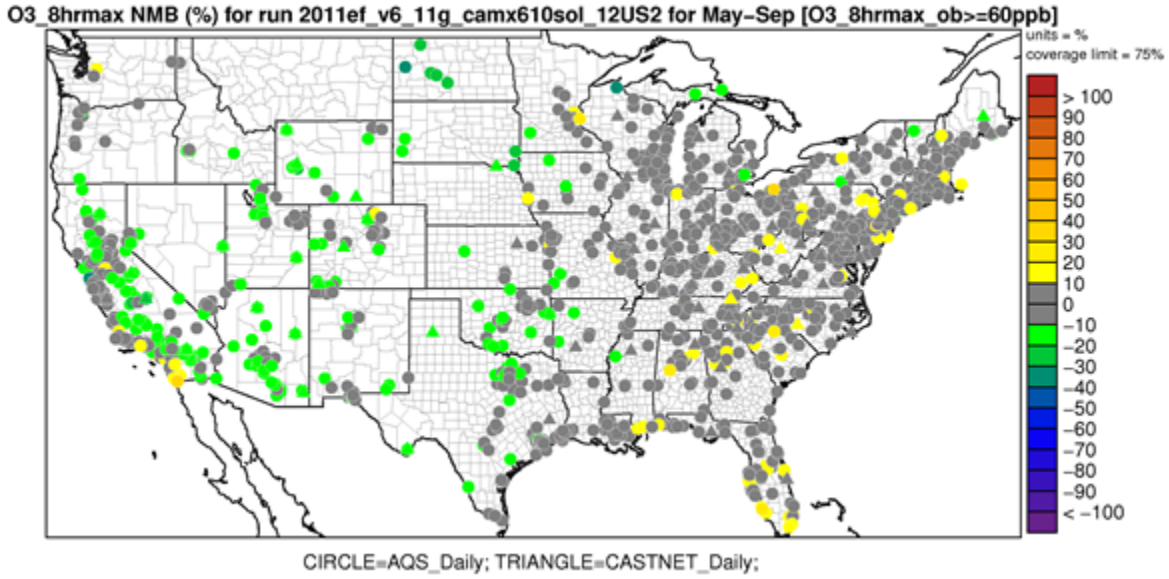
in a variety of ways, most commonly by observed ozone concentration, month, or hour of the day. Box plots can show several quantities: the 25% to 75% percentiles, the median values, and outliers. The monthly box plot can be used to quickly visualize model performance across the entire year, highlighting the seasonal change in model performance. The hourly or "diurnal" box plot is constructed using hourly data, and shows how the model predictions compare against observations throughout an entire day.

Figure 3.2.4 Example box plots of (a) monthly average sulfate concentrations, (b) daily diurnal average ozone concentrations, and (c) seasonal ozone bias binned by concentration range



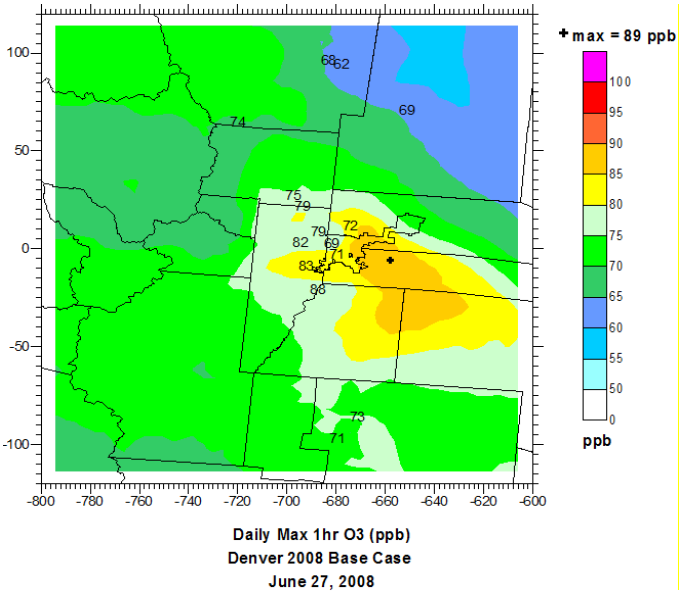
(a)

(b)



(c)

NMED Exhibit 108



Spatial plots of model performance at monitor locations provide an overall picture of the geographic patterns in model performance. Any performance metric can be plotted in this manner, but it is most common to include spatial plots of MB, ME, NMB, and NME. Spatial plots of correlation may also be useful. These plots are most useful when constructed on a monthly or seasonal basis. For ozone these plots may be constructed to include all days or only "high ozone days." For regional haze, these plots may be constructed to include only the 20% most impaired days or 20% clearest days.

Figure 3.2.5 Example of spatial plot of NMB at monitor locations for days with O_3 above 60 ppb during the 2011 ozone summer season (May-September).

Daily gridded tile plots of predicted concentrations across the modeling domain with the actual observations as an overlay. Plots should be prepared for relevant averaging time (i.e., 1-hour maxima, daily 8-hour maxima, 24-hour average, etc.). These plots can reveal locations where the model performs poorly. Superimposing observed concentrations on the predicted isopleths reveals useful information on the spatial alignment of predicted and observed plumes.

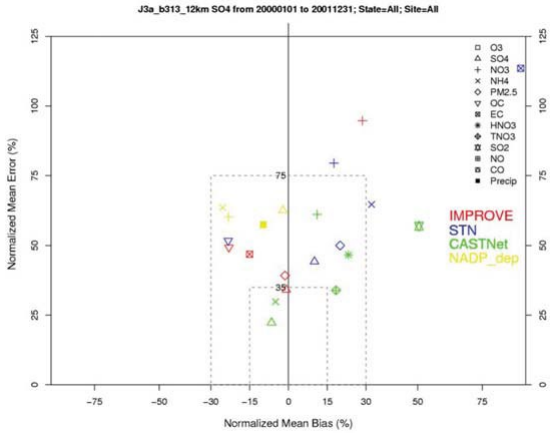


Figure 3.2.6 Example gridded tile plot of daily maximum 1-hour ozone concentrations (with overlaid observations)

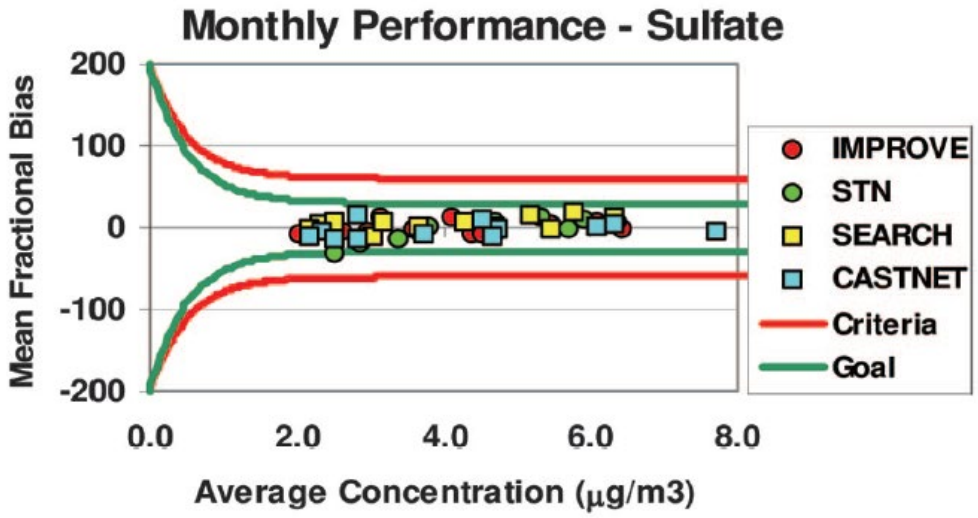
Animations of predicted hourly concentrations for all episode days or for certain periods of interest. Animations are useful for examining the timing and location of pollutant formation. Animations may also reveal transport patterns (especially when looking at aloft layers). Animations can also be used to qualitatively compare model outputs with the conceptual model of particular pollution episodes. These plots may also reveal whether an important feature was simulated but was spatially or temporally displaced.



The soccer plot (Tesche et al, 2006) is so named because the dotted lines illustrating performance goals resemble a soccer goal. The plot is a convenient way to visualize model performance of both bias and error on a single plot. As bias and error approach zero, the points are plotted closer to or within the "goal," represented by the dashed boxes.

Figure 3.2.7 Example soccer plot of sulfate normalized mean bias and error.

The bugle plot (Boylan and Russell, 2006; Tesche et al., 2006), named for the shape formed by the criteria and goal lines, is another plot available for model performance evaluation. The bugle plots are shaped as such because the goal and criteria lines are adjusted based on the average concentration of the observed species. As the average concentration becomes smaller, the criteria and goal lines become larger to adjust for the model's ability to predict at low concentrations.

Figure 3.2.8 Example bugle plot of sulfate mean fractional bias as a function of modeled concentration.

Source: Morris et al, 2005

3.2.3 Ozone Model Performance

It is recommended that, at a minimum, statistical performance metrics be calculated for hourly ozone and 8-hour ozone maxima for each day of the model simulation used to support the attainment demonstration. The EPA recommends that the metrics be calculated both for all pairs of modeled and observed data and for pairs in which the hourly or 8-hour daily max values are above 60 ppb. Another acceptable approach would be to estimate metrics binned by observed ozone concentration. This would allow for a thorough evaluation of the model tendencies to estimate ambient concentrations in different observed ranges of interest. Wherever possible, these types of performance measures should also be calculated for ozone precursors and related gas phase oxidants.

Ozone precursors and related gas-phase oxidants (partial list) are listed below.

- Total Volatile Organic Compounds (VOCs)
- Speciated VOC

NMED Exhibit 108

- Nitric acid (HNO_3)
- Nitric oxide (NO)
- Nitrogen dioxide (NO_2)
- Peroxyacetyl nitrate (PAN)
- NOy (NOx=NO+NO_2 and other oxidized nitrogen compounds)
- Carbon monoxide (CO)

3.2.4 $PM_{2.5}$ Model Performance

Performance metrics for PM and regional haze are similar to those calculated for ozone. Metrics should be estimated for components of $PM_{2.5}$ and PM precursors. Since modeling for $PM_{2.5}$ and regional haze will likely require modeling different times of year, season-specific statistics and graphical displays are helpful for evaluating and diagnosing model performance. Statistics and graphics can be averaged for various time scales depending on the model application. For example, statistical metrics and scatterplots can show daily averaged ambient-modeled pairs or annual average pairs for attainment demonstration of the daily and annual $PM_{2.5}$ standards respectively. In addition, the EPA recommends that daily pairs be grouped by season or month and statistics be given for different times of the year since different processes dominated $PM_{2.5}$ formation and fate in different seasons. Note that in this case, pairings should be performed on 24-hour average concentrations and statistics may then be reported for subgroups (seasons, regions etc.) of this data. This is different than pairing monthly or seasonally averaged data since statistics and plots tend to look "better" as the averaging time increases from daily to monthly to quarterly to annual. As such, daily pairs should always be examined to ensure a detailed look at model performance on the time scale of the measurements (24-hour average). Finally, air agencies may also want to subset the 20% clearest and most impaired visibility days at IMPROVE sites or the "high" modeled $PM_{2.5}$ days (e.g. the 10% highest modeled days in each quarter) to examine model performance on the days which will potentially be used to evaluate air quality goals.

Because $PM_{2.5}$ is a mixture, a meaningful performance evaluation should include an assessment of how well the model is able to predict individual chemical components that constitute $PM_{2.5}$. Components of $PM_{2.5}$ of interest include:

- Sulfate ion (SO_4)
- Nitrate ion (NO_3)
- Ammonium ion (NH_4)
- Elemental Carbon (EC)

NMED Exhibit 108

- Organic Carbon (OC) and/or Organic Carbon Mass[30]
- Crustal (weighted average of the most abundant trace elements in ambient air)
- Sea salt constituents (Na and Cl)[31]
- Other mass including Non-Carbon Organic Matter (NCOM) and metal oxides not captured by the crustal component

There are a number of gas-phase species that can be used to evaluate $PM_{2.5}$. Their presence may affect the formation of secondary PM and the response of secondary PM components to emissions strategies. Also, the model's performance in predicting certain gaseous species may provide diagnostic clues which help explain poor performance. Gas phase species of most interest for performance evaluation due to being a direct precursor to secondarily formed $PM_{2.5}$ are listed below:

- Nitric acid (HNO_3)
- Ammonia (NH_3)
- Sulfur dioxide (SO_2)
- Volatile Organic Compounds (VOCs)

Other related gas-phase oxidants (partial list) that indirectly influence $PM_{2.5}$ formation and destruction are listed below.

- Ozone (O_3)
- Nitric oxide (NO)
- Nitrogen dioxide (NO_2)
- Peroxyacetyl nitrate (PAN)
- NOy (sum of NOx and other oxidized compounds)
- Carbon monoxide (CO)
- Hydrogen peroxide (H_2O_2)

Some of the species listed above are currently available from either existing monitoring network systems and/or special studies. However, it is important to note that many of the species listed above are not routinely measured (e.g., H_2O_2, HNO_3, and NH_3) or measurements are not co-located with speciated PM measurements. Model performance can best be assessed using extensive databases, such as those obtained in major field studies. Where possible, model

[30] For predicted/observed comparisons, organic carbon is preferred over organic carbon mass to allow for transparency between model predictions and observed measurements. Ambient measurements will generally only account for the carbon portion of organic carbon. Organic carbon mass may include hydrogen, oxygen, and other components.

[31] White (2008) recommends the use of $1.8xCl^-$ to characterize ambient sea salt concentrations at coastal IMPROVE sites due to uncertainty in the XRF Na measurements.

NMED Exhibit 108

time periods can be prioritized to correspond to periods when field study or special study data was collected. However, it is recognized that many of the precursor species will not be available for every model application.

3.3 Ambient Measurement Networks

Provided below is an overview of some of the various ambient air monitoring networks currently available. Network methods and procedures are subject to change annually due to systematic review and/or updates to the existing monitoring network/program. Please note, there are other available monitoring networks which are not mentioned here and more details on these networks and measurements can be obtained from other sources, if necessary.

3.3.1 AQS

The Air Quality System (AQS) is a repository of ambient air pollution data and related meteorological data collected by EPA, state, local and tribal air pollution control agencies from tens of thousands of monitors (it is not an actual monitoring network). The monitoring data in AQS are the result of the various CAA requirements to provide a national database of ambient air pollution data. This information management system contains data on over 1,000 pollutants from 1957 through the present day. AQS contains all the routine hourly gaseous pollutant data collected from State and Local Air Monitoring Stations (SLAMS) sites. SLAMS is a dynamic network of monitors for state and local directed monitoring objectives (e.g., control strategy development) which consists of thousands of monitoring stations. The SLAMS network includes stations classified as NCore, PAMS, and Speciation, and stations formerly categorized as NAMS, but does not include Special Purpose Monitors (SPM) and other monitors used for non-regulatory or industrial monitoring purposes. AQS also contains data from the IMPROVE monitoring network, described separately in section 3.3.3 of this document.

The AQS database includes criteria pollutant data (SO_2, NO_2, O_3, CO, PM_{10}, $PM_{2.5}$, and Pb) and speciation data of particulate matter (SO_4, NO_3, NH_4, EC, OC, and crustal material), air toxic data, photochemical assessment data, and meteorological data. The data are measured and reported on an hourly or daily average basis. The AQS system continues to expand to include more ambient air pollutants. An overview of the AQS can be found here. For querying the database or viewing the data one can use the EPA's AirData website, which is a collection of user-friendly visualization tools for air quality analysts. The tools generate maps, graphs, and data tables dynamically. An AQS User's Guide is also available.

NMED Exhibit 108

3.3.2 NCore

The term "NCore monitoring network" (for national core) refers to a set of monitoring sites in major urban areas that generally started operating in 2011. These sites combine several advanced measurement systems for particles, pollutant gases and meteorology. Specifically, chemical measurements at these sites includes $PM_{2.5}$ speciation, continuous mass, 24-hr filter-based mass, ozone, CO, SO_2, NO, NOy. More information about this network is available here.

3.3.3 IMPROVE

The Interagency Monitoring of PROtected Visual Environments (IMPROVE) network began in 1985 as a cooperative visibility monitoring effort between EPA, federal land management agencies, and state air agencies (IMPROVE, 2011). Data are collected at Class I areas across the U.S., mostly at national parks, national wilderness areas, and national wildlife refuges. As of 2018, there were approximately 160 IMPROVE sites that have complete annual $PM_{2.5}$ mass and/or $PM_{2.5}$ species data. There are 110 IMPROVE monitoring sites which represent air quality at the 156 designated Class I areas. The additional IMPROVE sites are "IMPROVE protocol" sites, which are generally located in rural areas throughout the U.S., although there are also a handful of urban sites in the U.S. These protocol sites provide additional spatial information across the country, being generally located in areas where there are few Class I areas. The protocol sites use the IMPROVE monitoring samplers and collection routines. In addition to IMPROVE data that is available in AQS, the IMPROVE program provides summary datasets that contains information and pre-calculated data needed for Regional Haze Rule analyses. This includes daily average and annual data for the 20% most impaired and 20% clearest visibility days. The IMPROVE documentation and data can be found here. IMPROVE data advisories are posted here.

3.3.4 CASTNet

Established in 1987, the Clean Air Status and Trends Network (CASTNet) is a dry deposition monitoring network where PM data are collected and reported as weekly average data (U.S. EPA, 2012a). In addition, this network measures and reports hourly ozone concentrations. CASTNet provides atmospheric data on the dry deposition component of total acid deposition, ground-level ozone and other forms of atmospheric pollution. The data (except for ozone) are collected in filter packs that sample the ambient air continuously during the week. As of 2018, CASTNet is comprised of 95 monitoring stations across the U.S. The longest data records are primarily at eastern U.S. sites. More information can be obtained through the CASTNet website.

NMED Exhibit 108

3.3.5 CSN

The Chemical Speciation Network (formerly known as STN: The Speciation Trends Network) began operation in 1999 to provide nationally consistent speciated $PM_{2.5}$ data for the assessment of trends at representative sites in urban areas in the U.S. The CSN was established by regulation and is a companion network to the mass-based Federal Reference Method (FRM) network implemented in support of the $PM_{2.5}$ NAAQS. As part of a routine monitoring program, the CSN quantifies mass concentrations and $PM_{2.5}$ constituents, including numerous trace elements, ions (sulfate, nitrate, sodium, potassium, and ammonium), elemental carbon, and organic carbon. As of 2018, there were 52 trends sites in the CSN nationally. CSN trends sites are largely static urban monitoring stations with protocols for sampling methods that are dedicated to characterizing aerosol mass components in urban areas of the U.S. to discern long-term trends and provide an accountability mechanism to assess the effectiveness of control programs. In addition, in 2018, there were approximately 100 supplemental speciation sites that are also part of the CSN. The CSN data at trends sites are collected 1 in every 3 days, whereas supplemental sites collect data either 1 in every 3 days or 1 in every 6 days. Comprehensive information on the CSN and related speciation monitoring can be found here.

3.3.6 NADP

Initiated in the late 1970s, the National Acid Deposition Program (NADP) monitoring network began as a cooperative program between federal and state agencies, universities, electric utilities, and other industries to determine geographical patterns and trends in precipitation chemistry in the U.S. NADP collects and reports wet deposition measurements as weekly average data (NADP, 2013). The network is now known as NADP/NTN (National Trends Network), with nearly 200 sites in operation. The NADP analyzes the constituents important in precipitation chemistry, including those affecting rainfall acidity and those that may have ecological effects. The NTN measures sulfate, nitrate, hydrogen ion (measure of acidity), ammonia, chloride, and base cations (calcium, magnesium, potassium). Detailed information regarding the NADP/NTN monitoring network can be found here.

The Ammonia Monitoring Network (AMoN) is a NADP network that provides additional ambient and deposition ammonia data. The network began as part of a special study in 2007, was approved as an NADP network in 2010, and as of 2016 included approximately 50 monitoring sites across the U.S. AMoN monitors collect 2-week average data. More information can be found here.

NMED Exhibit 108

3.3.7 SEARCH

The South Eastern Aerosol Research and Characterization (SEARCH) monitoring network was established in 1998 and is a coordinated effort between the public and private sector to characterize the chemical and physical composition as well as the geographical distribution and long-term trends of $PM_{2.5}$ in the Southeastern U.S. (Edgerton, 2005; Hansen, 2003) The SEARCH network officially shut down in December 2016. However, SEARCH data are still useful for evaluating model performance for any simulations that included the Southeastern U.S. between 1998 and 2016. SEARCH data were collected and reported on an hourly/daily basis. A total of eight sites were operated at one time by SEARCH, although only six operated during SEARCH's final years: Birmingham, Alabama (urban), Centreville, Alabama (rural), Gulfport, Mississippi (urban), Jefferson Street, Atlanta, Georgia (urban), Oak Grove, Mississippi (rural) (not operational as of 2010), Yorkville, Georgia (rural) (not operational as of 2009), suburban Pensacola, Florida (suburban), and downtown Pensacola, Florida (urban). Historical SEARCH data from 1992-2016 can be accessed here.

3.3.8 Speciated $PM_{2.5}$ Data Summary

Speciated $PM_{2.5}$ data play an especially important role in performance evaluation, as the deterministic models predict exact chemical components which can be compared to some of the corresponding measured analytes. There are known positive and negative sampling artifacts as well as analysis artifacts associated with FRM and speciation monitors (Frank, 2006). Due to the complex nature of the measurements, a basic understanding of the various $PM_{2.5}$ and speciation monitoring technology and measurements are needed before undertaking a model evaluation.

Table 3.2: Known measurement artifacts for $PM_{2.5}$ and speciated PM for different monitoring networks.

Network	Measurement	Notes	Sampling Time
FRM	$PM_{2.5}$	- Negative artifacts: ammonium nitrate, organic carbon - Positive artifacts: organic carbon, water	24-hour average 1/3 days or 1/6 days (some daily sites)
	$PM_{2.5}$	- Negative artifacts: ammonium nitrate, organic carbon	

NMED Exhibit 108

Network	Measurement	Notes	Sampling Time
CSN (formally STN)		- Positive artifacts: organic carbon, water -Note that positive and negative artifacts for $PM_{2.5}$ may be different from artifacts for individual PM components because the speciated $PM_{2.5}$ samples are collected on different types of filters than are used for total $PM_{2.5}$ gravimetric measurements -CSN $PM_{2.5}$ mass may be different from FRM measurements due to differences in handling procedures	24-hour average 1/3 days or 1/6 days
	SO_4		
	NO_3		
	NH_4		
	OC	- Blank correction is needed to account for positive artifact[32] - Before 2007, OC/EC split was operationally defined using Thermal Optical Transmittance (TOT) method (NIOSH). CSN monitors switched to using the Thermal Optical Reflectance (TOR) method (consistent with	

[32] CSN OC measurements reported in AQS currently have artifact correction applied, although ambient data provided in SMAT-CE does already include a blank correction. The same artifact correction techniques are applied to measurements from CSN and IMPROVE networks. The CSN began implementing IMPROVE-like samplers and the IMPROVE analysis method in 2007. The implementation was fully completed in late 2009. Work by Malm et al (2011) suggests that CSN OC from 2005 and 2006 (before the switch in samplers) likely had a positive multiplicative bias of ~1.2 and a positive additive bias between 1.0 and 1.9 $\mu g/m^3$ depending on the time of year. We recommend using artifact corrected measurements where available and adjusting any uncorrected AQS CSN OC data by subtracting 1.4 $\mu g/m^3$ for measurement before the switch to IMPROVE-like measurements and by subtracting 0.12 $\mu g/m^3$ from measurements after the switch based on Frank (2012).

NMED Exhibit 108

Network	Measurement	Notes	Sampling Time
CSN (formerly STN) (con't.)		IMPROVE monitors) between 2007and 2009. [33]	
	EC	- Before 2007, OC/EC split was operationally defined using TOT method (NIOSH). CSN monitors switched to using the TOR method (consistent with IMPROVE monitors) between 2007 and 2009(see footnote 23)	
CASTNet	SO_4		weekly average
	NO_3	Split between NO_3 and HNO_3 may not be reliable in warm weather due to conversion from NO_3 to HNO_3. Recommend comparing total nitrate (NO_3 + HNO_3) between model and observations.	
	NH_4		
	SO_2		
	HNO_3	Split between NO_3 and HNO_3 may not be reliable in warm weather due to conversion from NO_3 to HNO_3. Recommend comparing total nitrate (NO_3 + HNO_3) between model and observations.	
	$PM_{2.5}$	- Negative artifacts: ammonium nitrate, organic carbon - Positive artifacts: organic carbon, water	

[33] The transition from TOT to TOR for CSN monitors occurred in shifts: 56 sites switched in May 2007, 63 sites switched in April 2009, and 78 sites switched in October 2009.

NMED Exhibit 108

Network	Measurement	Notes	Sampling Time
IMPROVE		-Note that positive and negative artifacts for $PM_{2.5}$ may be different from artifacts for individual PM components because the speciated $PM_{2.5}$ samples are collected on different types of filters than are used for total $PM_{2.5}$ gravimetric measurements	24-hour average 1/3 days
	SO_4 and S	-IMPROVE monitors measure both elemental S (by XRF) and ionic SO_4^- by ion chromatography. Generally, either measurement is reliable and may be used for model evaluation purposes although some caveats should be noted.[34]	
	NO_3		
	NH_4	-Only available at a limited number of sites for a limited number of years	
IMPROVE (con't.)	Organic Carbon	- OC/EC split is operationally defined using Thermal Optical Reflectance (TOR) analysis. - Blank corrections based on a median measured positive OC artifact from back-up filters at six sites are applied on a month-specific basis to all data before they are reported (Chow et al, 2010; Watson et al., 2009). Frank (2012) recommended changing blank	

[34] Hyslop et al (2012) report that XRF elemental sulfur measurements are somewhat affected by changes in XRF methodologies over time. Also, prior to 2000, filters used to collect sulfate for ion chromatography became clogged during high sulfate episodes. Changes in filter collection techniques eliminated this problem after 2000. In addition, recent literature by Tolocka and Turpin (2012) suggests that differences between XRF sulfur and ion chromatography sulfate are due to the presence of organic sulfur in aerosol (which would be measured by XRF but not IC). If this is the case, then the IC sulfate measurement is more appropriate for comparison with modeled sulfate which generally does not include formation of organic sulfur compounds.

NMED Exhibit 108

Network	Measurement	Notes	Sampling Time
		correction procedures for both IMPROVE and STN OC measurements. These recommendations have not yet been implemented.	
	Elemental Carbon	- OC/EC split is operationally defined using Thermal Optical Reflectance (TOR) analysis.	
	Sodium	XRF analysis is not as sensitive to sodium as other methods and generally under-reports sodium concentrations.	
	Silicon	XRF silicon measurements are unreliable at high sulfur conditions (when S/Si > about 7)	
	Aluminum	Elemental concentrations above the MDL can go undetected. IMPROVE has published an alternate soil calculation which estimates Al based on Si concentrations.[35]	

In general, the speciated $PM_{2.5}$ data can be directly compared to the model outputs. Of note, care should be taken in examining issues with blank corrections for organic carbon (especially when measured OC is low) as well as the EC/OC split. Prior to 2006, the CSN and IMPROVE networks used different analysis techniques when estimating EC and OC (CSN monitor locations switched to a similar method to IMPROVE between 2007 and 2009, depending on the monitor). The EC/OC analysis method will generally have a larger impact on EC concentrations than OC concentrations. The difference in OC/EC splits between the two techniques has been investigated in depth in the literature and by IMPROVE staff (Chow, 2001, Chow, 2010, White, 2007). It may not be appropriate to compare EC concentrations between networks for years prior to 2009 (although the data can still be used to evaluate model performance).

Total $PM_{2.5}$ mass measured gravimetrically at CSN and IMPROVE monitors is known to have several measurement artifacts (both positive and negative) (Frank, 2006, Simon et al., 2011,

[35] Due to difficulties in detecting Al, IMPROVE sometimes uses an alternative SOIL calculation which does not include Al: SOIL = 3.48*Si + 1.63*Ca + 2.42*Fe + 1.94*Ti (http://vista.cira.colostate.edu/improve/publications/SOPs/ucdavis_sops/sop351_V2.pdf).

Malm et al., 2011). Consequently, summing the mass of all $PM_{2.5}$ species components is not likely to give the same answer as the total measured $PM_{2.5}$ mass from a Teflon filter. Therefore, model evaluations should concentrate on comparisons with speciated $PM_{2.5}$ components at these sites, rather than total $PM_{2.5}$ mass.

FRM monitors do not measure all of the $PM_{2.5}$ in the air, and the speciation samplers don't measure $PM_{2.5}$ in the same way as the FRM monitors (Frank, 2006). Due to these positive and negative artifacts, the FRM data may not be directly comparable with model outputs without adjustment. The models predict PM species as they might be measured in the ambient air, but the FRM measurements may not always measure what is in the air (due to known positive and negative artifacts). As part of the $PM_{2.5}$ attainment test, we recommend default methodologies to adjust speciation (CSN and IMPROVE) data to better approximate the FRM data (see sections 4.4 and 4.5). A similar adjustment could be made to the model output data to allow the direct comparison to FRM measurements. However, as noted earlier, there may be limited value of information gained by evaluating daily average total measured $PM_{2.5}$ mass (as compared to $PM_{2.5}$ components). More meaningful information may be gleaned from continuous $PM_{2.5}$ ambient data.

Another issue to consider when comparing modeled and observed PM concentrations is the size definitions for PM. IMPROVE and CSN ambient monitors measure $PM_{2.5}$ using inlets which screen out any particles with aerodynamic diameters greater than 2.5 µm. Air quality models use varying schemes to characterize particulate matter size distributions. The two most common modeling schemes are the sectional treatment and the modal treatment. The default configuration for CAMx includes a sectional aerosol treatment while the default configuration for CMAQ includes a modal aerosol treatment, although other versions of these models exist with alternate aerosol treatments. Sectional aerosol modules split particles into bins defined using discrete size cut-points based on aerodynamic diameter (e.g., particles with aerodynamic diameters between 1 µm and 2.5 µm). One common sectional set-up includes 2 bins, one containing particles with aerodynamic diameters < 2.5 µm (fine PM) and one containing particles with aerodynamic diameters > 2.5 µm (coarse particles). Other models have split the fine PM into more than two bins (Nolte et al., 2008; Pandis et al., 1993). With sectional models, the comparison to measured $PM_{2.5}$ is straightforward so long as one of the PM bins has a cutoff at an aerodynamic diameter of 2.5 µm (i.e., add up PM mass in all bins less than 2.5 µm). The modal approach treats PM as occurring in distinct “modes,” each one having a lognormal distribution. Each PM mode is characterized by the geometric mean diameter and the geometric standard deviation of the diameter (the geometric mean and standard deviation can be tracked for particle number, surface area, mass or all three). With modal aerosol treatment, $PM_{2.5}$ can be estimated in several ways. One method is to simply sum the mass in the modes that generally contain fine PM. Another method would be to use the geometric mean and

NMED Exhibit 108

standard deviation to calculate the fraction of PM mass in each mode which is associated with particles less than 2.5 µm. However, there are several complicating factors with taking the second approach. First, the EPA's NEIy and many other inventories define $PM_{2.5}$ as being entirely less than 2.5 µm in diameter. If these primary emissions are injected into a modal model (generally into a fine PM mode), they are instantaneously mixed with existing aerosol mass in that mode. The tail of the fine PM mode will include particles greater than 2.5 µm. Therefore, a fraction of the PM that was operationally defined as primarily emitted $PM_{2.5}$ (diameter < 2.5 µm) would be incorrectly distributed into the > 2.5 µm size range based on the mode distribution. If primary emissions were quantified based on modes versus a discrete cut-point, then this would not be a problem. Secondly, some modal models have been shown to over-predict the peak-concentration diameter and distribution width of the fine PM mode (Kelly et al., 2011; Kelly et al., 2010). This would lead to under-predictions of the $PM_{2.5}$ fraction by increasing the mass fraction in the > 2.5 micron diameter range. Air agencies should consider these complications when deciding whether to calculate the fraction of PM mass in each mode below the 2.5 µm cut-point or to simply sum mass over the fine PM mode(s).

Finally, although we recommend weighing performance of speciated PM components more heavily than total PM, some additional insight can be gained by looking at Federal Equivalent Method (FEM) continuous $PM_{2.5}$ measurements[36]. Since speciated measurements are generally derived from filters, these measurements are usually taken as 24-hour averages. The FEM continuous measurements provide a diurnal profile of $PM_{2.5}$ concentrations that can be compared against hourly model outputs to determine whether the model is replicating the measured temporal pattern.

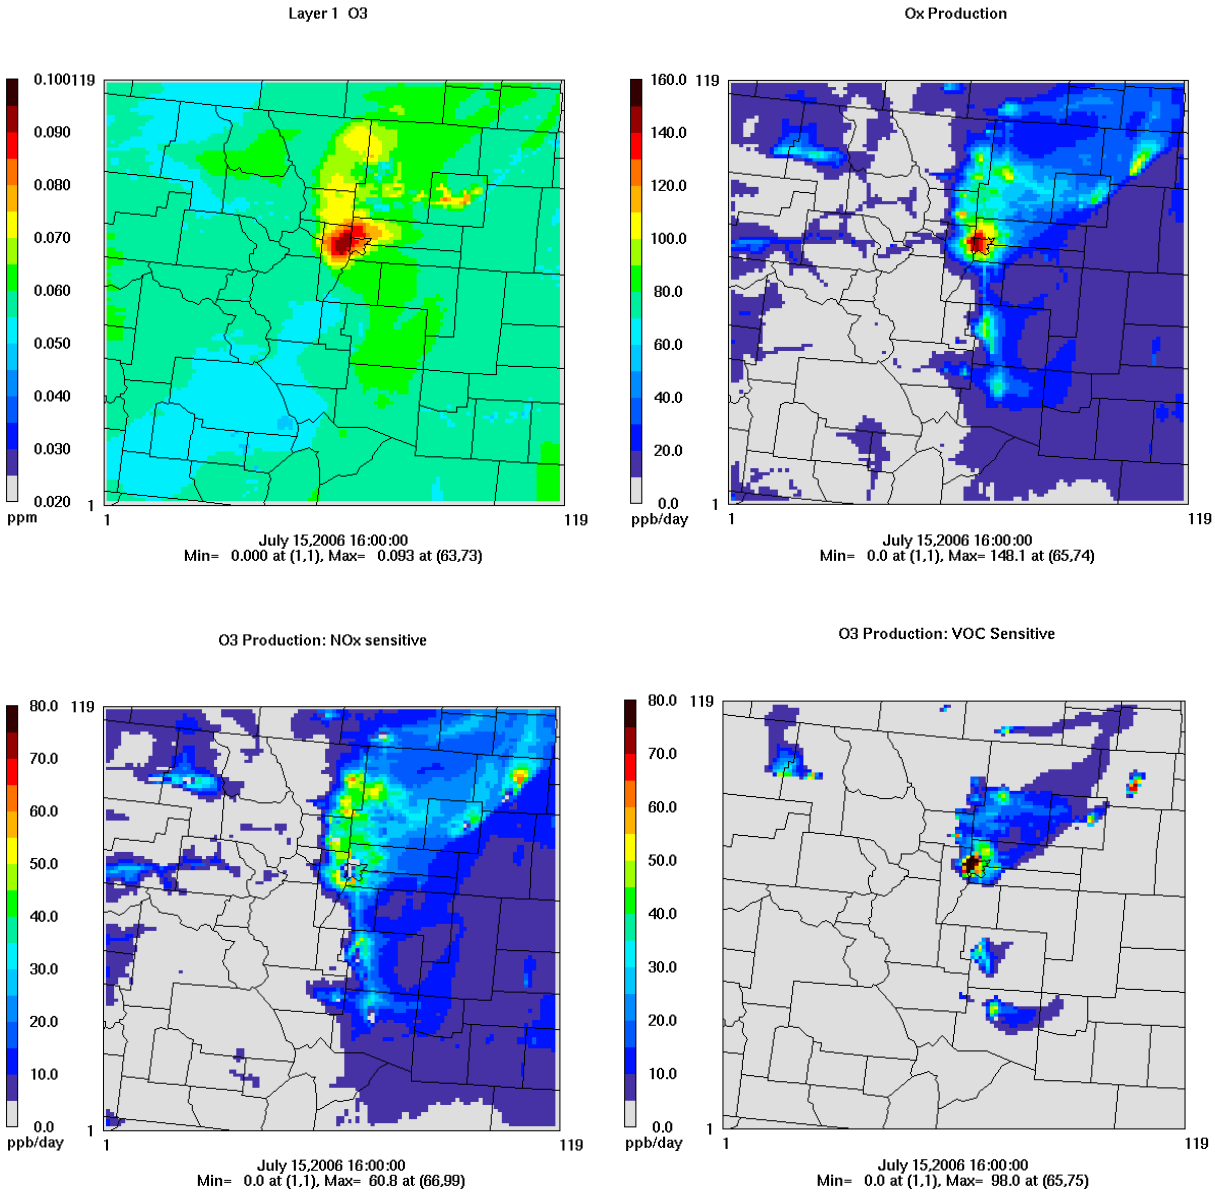
3.4 Diagnostic Evaluation

The goal of a diagnostic model evaluation is to determine whether the model correctly represents the physical and chemical processes that control the ambient concentrations of precursors and secondary pollutants. It is possible that a model can incorrectly represent the relative amount of primary emissions versus secondary production or that a model can incorrectly represent the importance of dispersion, deposition or chemical reaction as a sink. Thus, the ability of a model to accurately reproduce the observed concentration of a particular pollutant does not guarantee that the model correctly simulated the processes that determine the concentration of the pollutant. The goal of a diagnostic evaluation is to investigate the processes that determine the ambient concentrations of ozone, $PM_{2.5}$ and their precursors, and to develop confidence that the model can accurately predict how these concentrations will

[36] Monitoring of atmospheric air quality for purposes of determining compliance with the NAAQS generally requires the use of either Federal reference methods (FRM) or equivalent methods (FEM), as specified in Section 2.1 of Appendix C to 40 CFR part 58.

NMED Exhibit 108

change in the future (e.g., Arnold et al., 2006). It is likely that research grade measurements needed to perform a diagnostic evaluation will not be available in many SIP modeling studies, however, it can still be valuable to perform diagnostic analyses and compare the results with previous modeling research studies.



Several different tools and analysis methods are available for use in diagnostic model evaluation including process analysis, indicator ratios, source apportionment methods, model sensitivity studies, and retrospective studies.

3.4.1 Process Analysis

Both the CMAQ and CAMx models include a process analysis tool (Jeffries and Tonnesen, 1994) that provides additional diagnostic information on the chemical reactions and physical processes (e.g., emissions, deposition, advection, vertical mixing, and net change from chemistry) that determine species concentrations. Chemical reaction data can be output either as the hourly integrated reaction rate (IRR) for each reaction or as a summary of key reactions in the chemical process analysis (CPA). Physical processes can be output as hourly concentration changes in the integrated process rate (IPR) file. Detailed analysis off IRR and IPR outputs have been demonstrated in research studies (Jang et al., 1995; Vizuete et al., 2008; Henderson et al., 2011), but significant time and effort are required to complete these analyses. The CPA output provides a more limited set of chemical process information that is more accessible and that can be visualized using the same tools used to analyze model concentration output files. Minimal computational cost is required to produce the CPA files, and they are in the same format as the model concentration files and can be viewed using the same visualization tools. Below are examples of these plots comparing modeled ozone concentration, daily total Ox (Ox = O3 + O3P + O1D + NO2 +2*NO3 + PNA + PAN + 3*N2O5) production, and net ozone production in NOx limited and oxidant limited chemical regimes. The CPA tool can also provide information on the chemical reactions of VOC, NOy and radical species. The need for a process analysis evaluation and the specific processes investigated should be determined on a case-by-case basis.

NMED Exhibit 108

Figure 3.4.1 Chemical process analysis plots showing modeled ozone concentration, daily total Ox production, and net ozone production under VOC sensitive and NOx sensitive conditions.

3.4.2 Indicator Ratios

One way to evaluate the response of the model is to examine predicted and observed ratios of indicator species. Indicator species techniques have been developed for both ozone and secondary PM species (in particular nitrate) (Sillman, 1995, 1998; Ansari and Pandis, 1998;

Blanchard et al., 2000; Tonnesen and Dennis, 2000a and 2000b). If ratios of observed indicator species are very high or very low, they provide a sense of whether further ozone or secondary $PM_{2.5}$ production at the monitored location is likely to be limited by availability of NOx or VOC (or NH_3 in the case of particulate nitrate). Agreement between paired observed and predicted ratios suggests a model may correctly predict the sensitivity of ozone or secondary $PM_{2.5}$ at the monitored locations to emission control strategies. Thus, the use of indicator species aims to validate the modeled chemical regime and may help to build confidence in the RRFs predicted from the specific model application.

For ozone, measurements of certain "indicator species ratios" (e.g., comparisons between modeled and observed ratios: O_3/NO_y, O_3/HNO_3) are a potentially useful way to assess whether local ozone formation is VOC or NO_x limited at any particular point in space and time, as well as help reveal whether the model is correctly predicting the sensitivity of ozone to VOC and/or NO_x controls (Millford et al., 1994; Sillman, 1995, 1997, 1998, 2002; Lu and Chang, 1998). Tonnesen and Dennis (2000a and 2000b) distinguished between short lived indicators of instantaneous rates of production of ozone (PO_3) or odd oxygen (PO_x) versus long lived indicators of peak ozone concentration and found that the ratio of production of H_2O_2 to production of HNO_3 ($PH_2O_2/PHNO_3$) is strongly associated with PO_x sensitivity to VOC and NO_x. Tonnesen and Dennis also found that the ratio of formaldehyde to NO_2 was useful as an indicator of ozone sensitivity, and this ratio can be evaluated using satellite data (Martin et al., 2004; Duncan et al., 2010). For PM, such a comparison may reveal whether the model is predicting sensitivity of secondary components of $PM_{2.5}$ to changes in SO_2, NH_3, VOC and/or NO_x controls correctly (Ansari and Pandis, 1998; Blanchard et al., 2000; Pun and Seigneur, 1999, 2001). If a model accurately predicts observed indicator species relationships, then one can conclude with additional confidence that the predicted change in future year ozone or PM may be accurate.

Although ratios of indicator species have the potential to be quite useful, they should be used with caution since different studies have identified different ranges of values to characterize VOC and NOx limited regimes in different locations. Table 3.3 summarizes the range of values determined for 10 indicator species or ratios in various studies. In cases where the NOx and VOC limited ranges are broad or overlap, air agencies should attempt to use values from studies in the local area. Air agencies should be cautious with respect to the use of indicator species when the range of observed values does not provide a clear direction of control. When this occurs, agreement between predictions and observations does not necessarily imply that the response to controls as predicted by the model is correct (especially for secondary particulate matter to changes in precursors). If a model predicts observed values of indicator species relationships such that observed and predicted value fall within the same range, this provides

NMED Exhibit 108

some confidence that the predicted change in ozone or secondary particulate matter may be accurate.

A second precaution is that this method often requires more types of measurements than are commonly available. In some cases, it may be difficult to calculate meaningful indicator ratios from relatively imprecise measurements from routine monitoring networks.

Table 3.3: Ranges of indicator species/ratios that have been reported for VOC and NOx limited regimes.

indicator	median VOC-sensitive	transition	median NO_x-sensitive
O_3/NO_y	1.6 - 8.8[a,b,d,f-m]	6 – 15[c,d,m,n,q]	8.8 – 26[a,b,d,f-m]
O_3/NO_z	5.8 – 16[a,d,f,j-m]	7 – 100[c-f,n,q]	10.1 – 35[a,d,f,j-m]
O_3/NO_x	< 15	15 – 60[n,o,q,t]	> 40
O_3/HNO_3	7 - 33.9[a,d,j,k,m]	12 – 25[c,d]	17.2 - 62.9[a,d,j,k,m]
H_2O_2/HNO_3	0.3 - 1.5[d,j-m]	0.2 - 2.4[c,e,h,n-q]	0.4 - 3.6[d,j-m]
H_2O_2/NO_z	0.2 - 1.1[a,j]	0.2 - 0.25[c]	0.6 - 1.3[a,j]
H_2O_2/NO_y	0.2 - 0.4[a,j]	0.12 - 0.17[c]	0.6 - 1.0[a,j]
$HCHO/NO_2$	< 1	1-2[n,o,u]	> 2
NO_z/NO_y	< .5	0.5-0.6[f]	> 0.6
NOy	7.7 - 12.2[j]	5 -2 0[c,e,f,n,r,s]	3.2 - 5.7[j]

[a]Castell et al., 2009; [b]Xie et al., 2011; [c]Torres-Jardon and Keener, 2006; [d]Sillman and He, 2002; [e]Sillman, 1995; [f] Lu and Chang, 1998; [g]Stein et al, 2005; [h]Sillman et al., 1997; [i]Martilli et al., 2002; [j]Jimenez and Baldasano, 2004; [k]Torres-Jardon et al, 2009; [l]Chock et al, 1999; [m]Sillman et al., 2003; [n]Zhang et al, 2009; [o]Tonnesen and Dennis, 2000a; [p]Hammer et al., 2002; [q]Liang et al., 2006; [r]Milford et al, 1994; [s]Vogel et al, 1995; [t]Tonnesen and Dennis, 2000b; [u]Martin et al., 2004

Much of the work done to date with indicator species has focused on peak concentrations of ozone. Limited research has been conducted on development of indicator ratios for secondary PM. This includes work by Blanchard et al., (2000) who examined how indicator species might be used to assess whether particulate nitrate concentrations are limited by NOx or by ammonia

NMED Exhibit 108

emissions using mechanisms which incorporate reactions dealing with secondary PM. These authors identify several indicators which appear potentially useful for determining limiting precursors for secondary nitrate PM. The indicators include:

(1) excess NH_3 defined in Equation 3-1 (values greater than zero indicate NOx limited regimes and values less than 0 indicate ammonia limited regimes);

$$excess\ NH_3 = [\mathrm{NH3(g)}] + [\mathrm{NH4+(a)}] - 2 * [\mathrm{SO42-(a)}] - [\mathrm{NO3-(a)}] - [\mathrm{HNO3(g)}] - [\mathrm{HCl(g)}] + 2 * [\mathrm{Ca2+}] + 2 * [\mathrm{Mg2+}] + [\mathrm{Na+}] + [\mathrm{K+}] + [\mathrm{Cl-}] \quad [3\text{-}1]^{37}$$

(2) The ratio of particulate to total nitrate. Values above 0.9 at high temperatures indicate NOx limited regimes (values below 0.3 to 0.5 were indicative of ammonia limited regimes).

Ansari and Pandis (1998) also have suggested the use of the gas ratio (GS), defined in equation 3-2, as an indicator of PM formation regimes.

$$GS = \frac{NH_3^F}{HNO_3^T} \quad [3\text{-}2]^{38}$$

In summary, major challenges in evaluating indicator species include variability in the characteristic ratios for VOC and NOx limited regimes in different locations and the availability of ambient data. Despite these caveats, comparing predicted and observed relationships of indicator species provides a means of assessing a model's ability to accurately characterize the sensitivity of predicted ozone and predicted secondary components of $PM_{2.5}$ to changes in precursors.

3.4.3 Source Apportionment

Source apportionment methods and model sensitivity studies are two complementary approaches that can be used to identify emissions sources that contribute to high pollutant concentrations. While these tools do not directly diagnose the model's ability to replicate the real world, they are useful in their ability to further characterize the sources that are most important to high pollutant concentrations within the model. The CMAQ and CAMx models both include options to use source apportionment tools to identify sources that contribute to

[37] Concentrations are in µmol/m^3, (g) represent gas-phase and (a) represents aerosol phase.
[38] NH_3^F is free ammonia (total ammonia – 2*sulfate). HNO_3^T is total nitrate (gas + PM).

NMED Exhibit 108

the production of ozone (Ramboll, 2018; Kwok et al, 2014) and some components of $PM_{2.5}$, including sulfate, nitrate, ammonium and primary emissions of $PM_{2.5}$ (Ramboll, 2018; Kwok et al., 2013). Source apportionment tools employ a set of model tracers to attribute pollutant concentrations to user selected emissions source sectors and geographic areas. This approach can be useful both as a diagnostic tool to identify sources that contribute to ozone and $PM_{2.5}$ and also as an aid in regulatory analysis to identify emissions control measures that will be effective for attaining air quality standards. An advantage of source apportionment approaches is that tracers attribute the mass contribution from a source to a receptor and, therefore, this approach is less susceptible to the effects of non-linear chemistry, which can complicate the interpretation of model sensitivity simulations.

3.4.4 Sensitivity Studies

Model sensitivity simulations can be used to identify model inputs (IC/LBC, meteorological data, chemical reactions, and emissions) that have the greatest impact on model-predicted concentrations. The objective of sensitivity tests is to identify whether the inputs have a large enough influence that errors in these inputs could be a driving influence on the model predictions. In "brute-force" sensitivity simulations, the model input data is modified directly (e.g., increasing or decreasing emissions in the model input file). Brute-force simulations are relatively easy to implement but are resource intensive when many different inputs must be evaluated. The Direct Decoupled Method (DDM) is an approach that can be used to evaluate the first order sensitivity to multiple model inputs in a single model simulation (e.g., Cohan et al., 2005; Napelenok et al., 2006). Because of non-linearity in chemical reactions, first-order sensitivity is not always sufficient, and high-order DDM (HDDM) can be used to evaluate second order sensitivities to inputs that are subject to non-linear chemistry (Zhang et al., 2012b).

In cases where the model performs poorly in the base case, sensitivity simulation may be useful to identify potential causes for poor model performance. However, caution should be used in modifying inputs to achieve good model performance because arbitrarily "tuning" of model input data to fit the observations can introduce compensating errors. For example, if a model underestimates observed ozone because the meteorological data is overly dispersive, the model performance could be improved by increasing emissions or LBC concentrations, but this model would not be reliable for predicting future concentrations because its good performance in the base case was achieved through compensating errors in the input. An appropriate use of sensitivity approaches is to identify each of the processes or inputs that has a large effect on model predictions, and then perform additional analysis of those inputs to determine if they are accurately represented in the base case model.

NMED Exhibit 108

3.4.5 Dynamic Model Evaluation

A second method for assessing a model's performance in predicting the sensitivity of ozone or $PM_{2.5}$ species to changes in emissions is to perform a retrospective dynamic analysis. This involves comparing model predicted historical trends with observed trends. Retrospective analyses provide potentially useful means for diagnosing why a strategy did or did not work as expected. They also provide an important opportunity to evaluate model performance in a way that is closely related to how models are used to support an attainment demonstration.

A dynamic evaluation uses various analyses to assess the accuracy of the model in characterizing the sensitivity of ozone and/or $PM_{2.5}$ to changes in emissions. Although dynamic evaluation is always recommended, the measurements and resources needed for a dynamic evaluation may not be readily available to air agencies performing SIP modeling. Additional challenges for retrospective analyses include identifying appropriate case studies for which responses to emissions changes are large enough to be distinguished in ambient data, developing or obtaining equivalent and appropriate emissions for multiple historical years, and disentangling the confounding influences of year to year changes in meteorology and emissions.

A retrospective analysis is intended to examine the ability of the model to respond to emissions changes by comparing recent trends in observed ozone or $PM_{2.5}$ concentrations to the model-predicted trend over the same time period. The approach is a direct assessment of what is most important in an attainment demonstration: does the model accurately predict changes in air quality as a result of changes in emissions? As part of a retrospective analysis, the model is run for (a) current episodes or time periods and (b) episodes in one or more historical time periods using the emissions and meteorological inputs appropriate for each time period modeled.

While retrospective analyses may be useful, it may be difficult to obtain meteorological and emissions inputs for the historical time period(s) that are calculated using techniques and assumptions that are consistent with the calculation of these same inputs for the current time period. Using inconsistent inputs will confound the interpretation of the predicted trend. One method for ensuring consistent methodology for emissions estimates is to backcast emissions from the most recent year to the earliest year. The model should respond in a predictable way if the emissions changes are large enough. Hence, modeling an emissions change of only a few percent would not be viable. However, if NOx or SO_2 emissions have been reduced by a large percentage (e.g., 30% or more) over a relatively short time period, then that may be a good time period to test the response of the model.

Because differences in meteorology between years can confound the apparent change in pollutants, a complete retrospective analysis could include multiple sensitivity runs using both

NMED Exhibit 108

year-specific meteorology and constant meteorology. The year-specific meteorology would allow the modeler to compare modeled and observed trends most accurately, and the constant meteorology would help inform the analysis on what portion of the change in pollutant concentrations were due to emissions versus meteorological differences.

Retrospective analyses are one of the few tools that can be used to determine if the model is responding "adequately" or "correctly" to control measures. Recent efforts to perform this type of analysis have been undertaken by Zhou et al (2013), Gilliland et al. (2008), Godowitch et al. (2010), Pierce et al. (2010) and Foley et al. (2014). These published analyses may be used to better understand the ability of certain models to properly capture relationships between ambient pollution levels and emissions.

Another dynamic evaluation approach is to look at operational performance under varying conditions (e.g., by day of the week, by season, and by region) (Marr and Harley, 2002; Murphy et al, 2007; Harley et al, 2005). The mix of pollutants vary by day of the week and from area to area; when a model shows good operational performance across these different chemical environments, it supports the assertion that it will respond appropriately to changes in emissions. Two studies have performed model evaluations that focused on the model's ability to capture weekend/weekday changes (CRC, 2011; Pierce et al, 2010).

3.5 Evaluation Tools

There is available software and tools that can be used to process ambient and model data to create statistical output and plots for model performance evaluations. One example is the Atmospheric Model Evaluation Tool (AMET) (Appel, 2011). AMET is built on several open-source software packages and uses the MySQL database software to store paired observation and model output data. There are modules in AMET for evaluating both meteorological and air quality model output. AMET provides a useful set of scripts for creating various types of plots and statistics.

NMED Exhibit 108

4.0 Assessing Modeled Attainment for Ozone and $PM_{2.5}$

A *model attainment demonstration* usually consists of two key components: a) analyses which estimate whether a set of simulated emissions reductions corresponding to a control program scenario will result in ambient concentrations that meet the NAAQS and b) an identified set of control measures which will result in the required emissions reductions. This guidance focuses on the first component of a model attainment demonstration; that is, the completion and interpretation of analyses to estimate the amount of emission reduction needed to attain the NAAQS.

Air agencies should determine whether a control program scenario will provide sufficient emission reductions to demonstrate attainment of the NAAQS using the *modeled attainment test*. The modeled attainment test is a technical procedure in which an air quality model is used to simulate base year and future air pollutant concentrations for the purpose of demonstrating attainment of the relevant NAAQS. The recommended test uses model estimates in a "relative" rather than "absolute" sense to estimate future year design values. As explained in more detail in subsequent sections, the fractional changes in air pollutant concentrations between the model future year and model base year are calculated for all valid monitors. These ratios are called *relative response factors* (RRF). Future ozone and/or $PM_{2.5}$ design values are estimated at existing monitoring sites by multiplying the modeled relative response factor for each monitor by the monitor-specific base year design value. The resulting estimates of future concentrations are then compared to the NAAQS. If the future estimates of ozone and/or $PM_{2.5}$ design values do not exceed the NAAQS, then this provides evidence that attainment will be reached.

In addition to the modeled attainment test, air agencies should also consider performing a set of corroboratory analyses to further assess whether a proposed set of emission reductions is likely to lead to attainment of the NAAQS. As discussed later in this section (see section 6), the modeled attainment test and these supplemental analyses should be aggregated into a *weight of evidence determination* to evaluate whether the selected emissions reductions will yield attainment. The concept of relative response factors also applies to modeling for the purpose of setting RPGs for regional haze, the subject of section 5.

4.1 Overview of Modeled Attainment Test

There are four reasons why the recommended modeled attainment test is based on application of the model in a relative sense. First and foremost, this approach has the effect of anchoring the future concentrations to a "real" measured ambient value, which is important given model bias and error in the base year simulation(s). It is reasoned that factors causing bias (either under or over-predictions) in the base case will also affect the future case. While good model

NMED Exhibit 108

performance remains a prerequisite for use of a model for regulatory analyses, problems posed by imperfect model performance on individual days are expected to be reduced when using the relative approach. An internal EPA analysis (U.S. EPA, 2014a) considered whether daily ratios of model future/current maximum daily 8-hour ozone averages (MDA8) varied strongly as a function of site-specific base case model performance. This analysis was completed using a national model simulation that projected 2020 ozone concentrations from a 2007 base case. The analysis determined that when modeled, MDA8 ozone bias was relatively small (e.g., less than +/- 20 ppb), the average response ratios were not a strong function of the model MDA8 bias. This provides confidence that the model can detect the air quality response in the midst of reasonable levels of absolute bias and error. Second, the relative modeled attainment test allows for a future projection of 3-year average ozone and $PM_{2.5}$ design values or 5-year average visibility values without explicitly having to model a 3-year or 5-year period. Third, because $PM_{2.5}$ concentrations typically consist of a diverse mix of primary and secondary components, the modeled attainment test based on RRFs decreases the possibility of choosing ineffective control strategies based on inaccurate model estimations of $PM_{2.5}$ composition, by assessing component specific RRFs. Fourth, and finally, there is evidence, based on a retrospective modeling analysis of ozone changes between 2002 and 2005 (Foley et al, 2014) and 2002 and 2010 (Hogrefe et al, 2014), that using the model in a relative sense provides better estimates of future ozone design values than using the absolute future year simulation. The correlation between model-projected and actual design values, as well as the accuracy of model projections of attaining a 75 ppb NAAQS, appear to be slightly improved when a relative modeled attainment test is utilized.

Equation (4.1) describes the recommended modeled attainment test in its simplest form, which directly applies for ozone, as applied for monitoring site *i*:

$$(\mathrm{DVF})_{\mathrm{i}} = (RRF)_i * (DVB)_i \qquad [4.1]$$

where $\mathrm{DVF_i}$ is the estimated design value for the future year in which attainment is required at monitoring site *i*; $\mathrm{RRF_i}$ is the relative response factor at monitoring site *i*; and $\mathrm{DVB_i}$ is the *base design value* monitored at site *i*. Each of these terms is discussed in more detail below. For $PM_{2.5}$ and visibility, the modeled attainment test is more complicated in that each PM component (defined in a certain way) has its own RRF.

The EPA has developed the Software for Modeled Attainment Test-Community Edition (SMAT-CE) tool to enable completion of the modeled attainment tests for $PM_{2.5}$ and ozone, as well as for calculating changes in visibility in Class I areas. SMAT replaced the previous EPA attainment test software called MATS (Abt, 2014). SMAT can be found on the EPA's Support Center for Regulatory Atmospheric Modeling (SCRAM) website.

NMED Exhibit 108

4.1.1 Establishing the Base Design Value

The base design value for each monitoring site (DVB_i) is the anchor point for estimating future year projected concentrations. Because the modeling is being used in a relative sense to determine how the modeled emissions changes will affect air quality design values in an area, it is important to match the base design value as closely as possible to the base year for which future/base ratios will be assessed. That is, if one is estimating the expected air quality change from emissions reductions between 2016 and 2030, it is important to establish an air quality anchor that represents 2016 emissions levels as closely as possible. However, it is well-established that inter-annual variability in meteorological conditions often leads to year to year differences in design values, even with static emissions levels (U.S. EPA, 2012). In addition, there is also year to year variability in emissions due to economic factors (such as recessions) and compliance with regulations. We, therefore, recommend using the base design value approach described below.

For the modeled attainment tests for ozone and $PM_{2.5}$, we recommend using the average of the three design value periods, which include the base emissions inventory year. This average is expected to best represent the air quality resulting from base year emissions with consideration of meteorological and emissions variability. For example, if the modeled attainment test uses base year emissions from 2014, then the base design value (DVB) would be calculated as shown in equation 4.2 for each site *i*:

$$(DVB)i = \frac{((DV\ 2014)_i + (DV\ 2015)_i + (DV\ 2016)_i)}{3} \qquad [4.2]^{39}$$

This has the desired effect of weighting the projected ozone or $PM_{2.5}$ base design values towards the middle year of a five-year period (2012-2016); in this example, for a 2014 base emissions inventory year. Additionally, an average of three design values will be more stable (less year to year variability) than any single design value period. An EPA analysis of design values data at 761 ozone monitors over the period between 2002 and 2011 concluded that the median standard deviation of individual 3-year ozone design values was 5.3 ppb, whereas the standard deviation of the average of multiple 3-year ozone design values was only 4.0 ppb.

In cases in which there are less than 5 years of valid monitoring data at a site, we recommend that base design values be calculated only when there are at least 3 years of consecutive valid data (i.e., at least one complete design value). If a location has less than 3 consecutive years of

[39] For nomenclature purposes, the 3-year design value is referred to by the last year of the averaging period. That is, DV 2014 represents air quality data averaged over 2012, 2013, and 2014 for ozone and $PM_{2.5}$.

NMED Exhibit 108

valid data, then that site should not ordinarily be used in the modeled attainment test.[40] An example calculation for DVB is shown in Table 4.1 and includes the number of significant digits to include for ozone and each form of the $PM_{2.5}$ standard.

Table 4.1: Example illustrating the calculation of base design values.

	2014 DV	2015 DV	2016 DV	DVB
O3 NAAQS (ppb)[41]	76	76	78	76.7
Annual $PM_{2.5}$ NAAQS ($\mu g/m^3$)	12.9	13.1	12.6	12.87
24-hour $PM_{2.5}$ NAAQS ($\mu g/m^3$)	32	33	32	32.3

The measured 3-year average design values use the rounding/truncation rules established in 40 CFR part 50 Appendix U (8-hour ozone) and Appendix N ($PM_{2.5}$). The resultant 5-year weighted average DVB should carry one digit to the right of the decimal point for ozone and 24-hour $PM_{2.5}$ and two digits to the right of the decimal for annual $PM_{2.5}$.

The EPA also recognizes that the ambient data record may be modified under certain circumstances. For example, air agencies can request that the EPA agree to exclude event-influenced data by demonstrating that these data have been influenced by "exceptional" events and otherwise meet the criteria in the Exceptional Events Rule (81 FR 68216, October 3, 2016). Once an air agency submits an exceptional events demonstration and the EPA concurs with an air agency's request, the event-influenced data are officially noted and removed from AQS user reports (unless the AQS user specifically indicates that they should be included) and not used to calculate design values. In other cases, data may not qualify for exclusion under the Exceptional Events Rule but Appendix W to Part 51 may provide guidance on considering data which may be influenced by events that are not typical or expected to recur in the future (e.g., wildfires, construction, roadway repairs, or unusual agricultural activities) for certain modeling analyses. Potential event-influenced data may affect future year projections that are part of the modeled attainment demonstration. If potential event-influenced data from the historical

[40] Monitoring sites with less than 3 years of valid data cannot ordinarily be used to determine attainment status. Therefore, in most cases, those sites should not be used in the attainment demonstration or for regulatory analyses. However, there may be cases where a monitoring site with incomplete data indicates an area of high ozone or PM concentration. Further examination of the monitoring data and modeled response (RRF) in the area is recommended as part of either the monitor-based attainment test or an unmonitored area analysis, as appropriate.

[41] The current ozone NAAQS is defined in units of ppm. However, for ease of use, this document will use ppb units.

NMED Exhibit 108

record may affect regulatory outcomes, we encourage air agencies to consult with their EPA Regional office to determine how best to handle this situation.

In practice, the choice of the base design value can be critical to the determination of the estimated future year design values (Cohan, 2006) and careful consideration should be given to the selection of the years used in the calculation of base design values. There is no single methodology that can derive a "correct" base design value, but the 5-year weighted average value establishes a relatively stable value that is weighted towards the emissions and meteorological modeling year. In most cases, this provides an appropriate anchor point on which to base the future year design value calculations. Alternate, equally plausible, calculations of base design values may be considered with appropriate justification. Alternate base design values may also be considered as part of the corroborating analyses that comprise the aggregate weight of evidence determination. For instance, one may want to consider establishing the base design value on the highest of the relevant design values to ensure that the emissions measures will yield attainment even in periods with meteorological conditions especially conducive to poor air quality. In addition, in some cases, large year to year emissions changes or highly unusual meteorological conditions may make certain periods/years unsuitable for consideration in the base year period. Consideration of adjustments to the base design value(s) can be made, with appropriate justification, on a case-by-case basis and in consultation with the relevant EPA Regional office.

4.1.2 Calculation of Relative Response Factors

The relative response factor for each monitoring site $(RRF)_i$ is the fractional change in air quality concentrations that is simulated due to emissions changes between a base and a future year emissions scenario. The specific RRF calculation techniques vary by pollutant and are described in more detail in the remainder of section 4 below. The most important consideration associated with the RRF calculation is determining which model values are most representative of the expected air quality change for a given location. This requires consideration of all of the varying changes in hourly pollutant concentrations between the base and future cases and a determination of the most appropriate summary (average) value to apply to the base design value. As with the selection of a base design value, there may be plausible alternative means of calculating the RRFs that can differ from the approaches recommended below (e.g., Kulkarni et al., 2014, Porter et al., 2014). Where justified, alternate RRF calculation techniques can be included as corroborative analyses as part of a weight of evidence determination.

4.2 Modeled Attainment Test for the Primary Ozone Standard

The 8-hour ozone design value is currently calculated as the 3-year average of the annual fourth highest daily maximum 8-hour average concentration for a specific monitor. The standard is

NMED Exhibit 108

considered to be attained if the observed design value does not exceed the level of the ozone NAAQS[42]. Similarly, the modeled attainment test is considered satisfied when the $(\mathrm{DVF})_i$ is less than or equal to the current NAAQS level. The recommended test is described below.

4.2.1 Model Values to Use in the RRF Calculation

Given the formulation of the modeled attainment test, it is important to identify which model days are best suited for determining the expected air quality response resulting from a set of emissions changes. On any given modeled day, meteorological conditions may or may not be conducive to high concentrations at a monitor. If ozone predicted near a monitor on any particular day is much less than the design value, the model predictions for that day could be unresponsive to controls (e.g., the location could be upwind from most of the emissions in the nonattainment area on that day). If these days are included in the RRF calculation, they will likely lead to a higher RRF (closer to one) and a potential overestimation of the future design value.

Internal EPA analyses (U.S. EPA, 2014a) have shown that model response to decreasing emissions is generally most stable when the base ozone predictions are highest. The greater model response at higher concentrations is likely due to more "controllable" ozone at higher concentrations. In addition, the high model days are selected individually for each monitor. Meteorological conditions that lead to high ozone may differ between monitors in an area. For example, monitors that are typically "upwind" or "downwind" of an area may experience high ozone on different days, depending on the prevailing wind direction. In most urban areas, on days with high ozone concentrations, there is a relatively high percentage of locally generated ozone compared to days with low base case concentrations (U.S. EPA 2014b). Days with low ozone concentrations are more likely to have a high percentage of ozone due to background and boundary conditions. Since the form of the standard is also focused on the highest days of an ozone season (i.e., the fourth highest MDA8), the RRF calculation should also focus on days when the model predicts the highest ozone concentrations.

As the ozone NAAQS has been lowered, a key question is whether the attainment test should use an average RRF based on all modeled days that are greater than the NAAQS, as in the previous guidance approach. In some areas of the country, this could lead to RRF calculations that might include upwards of 100 days per ozone season. In these cases, including too many

[42] At the time of publication of this guidance, the ozone NAAQS is 0.070 ppm per 40 CFR 50.19. Design values for the 0.070 ppm NAAQS are truncated to the 3rd decimal digit. Therefore, 0.0709 ppm (70.9 ppb) is considered attainment and 0.0710 (71.0 ppb) is considered nonattainment. The same rounding/truncation procedures should be applied in the modeled attainment test. A detailed description of the methodology to calculate ambient ozone design values is provided in Appendix U to Part 50.

NMED Exhibit 108

days in the RRF calculation may lead to higher (closer to 1) RRFs. Using a reasonable number of the highest modeled days at each monitor is most likely to represent the response of the observed design value at a monitor. Since the design value is based on the seasonal 4th high observed values, we recommend selecting a set of modeled days that are likely to encompass a range of values that are somewhat higher than and somewhat lower than the 4th high value. We, therefore, recommend calculating the RRF based on the highest 10 modeled days in the simulated period (at each monitoring site). We believe this balances the desire to have enough days in the RRF to generate a robust calculation, but not so many days that the RRF does not represent days with concentrations near the observed design values. In addition, use of the highest 10 days (without an initial threshold) allows the attainment test to be easily adapted to any level of the NAAQS with little or no change in the methodology. In support of the revised recommendation, a recent assessment of modeled ozone changes between two ozone seasons (Foley et al., 2014) suggests that the use of the highest 10 days in the mean RRF calculation yields a slightly better estimate of the actual observed ozone change than the previous guidance approach.

The EPA recommends that the ozone RRF calculations be based on the 10 highest days in the base year modeling at the monitor location, as long as the base MDA8 value is greater than or equal to 60 ppb for that day. In cases for which the base model simulation does not have 10 days with MDA8 values greater than or equal to 60 ppb at a site, then EPA recommends using all days where MDA8 >= 60 ppb, as long as there are at least 5 days that meet the minimum threshold criteria. If there are less than 5 days with MDA8 >= 60 ppb, EPA recommends that air agencies do not calculate a DVF for the site.[43] If the modeled attainment test is based on less than 10 days, then other assessments in the aggregate weight of evidence demonstration will need to be more rigorous to counter the reduced robustness of the modeled attainment test.

In addition, as discussed by Vizuete et al. (2011), there can be days in which the modeled source-receptor relationships may not yield a representative response for a particular cell or array of grid cells. This can result from small inconsistencies between the model representation of transport patterns (or chemical formation) and what actually occurred on that day. In other situations, perhaps the high modeled ozone results from an atypical condition (e.g., in conjunction with a wildfire smoke plume) that is not representative of conditions that led to the area's design value. If there is compelling evidence to determine that a particular day, while being among the 10 highest MDA8 values at a location, is not representative of the expected source-receptor relationship at that location; then that day can be considered for removal from

[43] A scenario in which the 5th highest base model MDA8 values is less than 60 ppb either indicates an extremely low ozone site or a site with poor model performance. In either case, projections of DVF values are likely not reliable.

NMED Exhibit 108

the RRF calculation.[44] If a day or days are removed, we recommended adding the next-highest modeled day or days from outside the top 10 to maintain the use of 10 days in the RRF calculation. Air agencies should document the evidence that argues for the exclusion of any otherwise-eligible days. As noted earlier, poor model performance on individual days can lead to ratios of future to base ozone that may be biased on those days. For example, underprediction of ozone concentrations may lead to ratios that are unresponsive to emissions controls. Air agencies may want to examine the day- and site-specific model performance for days that are part of the RRF calculation to make sure that they can be appropriately used in calculating the expected response.

4.2.2 Grid Cells to Use in the RRF Calculation

It is recommended that ozone RRF calculations consider model response in grid cells immediately surrounding the monitoring site along with the grid cell in which the monitor is located. There are two primary reasons why we believe it is appropriate to include predictions from grid cells near a monitor rather than just the cell containing the monitor. First, limitations in the inputs and model physics can affect model precision at the grid cell level. Allowing some leeway in the precision of the predicted location of daily maximum ozone concentrations can help assure that possibly artificial, fine scale variations do not inadvertently impact an assessment of modeled ozone response. Second, some ozone monitors and important emission sources may be located very close to the border of a grid cell. Considering multiple cells near a monitor, rather than the single cell containing the monitor, diminishes the likelihood of inappropriate results which may occur from the artificial geometry of the superimposed grid system.

Based on the above considerations, it is recommended that the RRF be based on a 3 x 3 array of cells centered on the location of the grid cell containing the monitor. This is a change from the 2007 guidance (U.S. EPA, 2007), which pre-identified 15 km as an appropriate distance for grid cell proximity to a monitor and, therefore, recommended the selection of RRF grid cells to be contingent upon the chosen model grid resolution (i.e., a finer grid resolution considered a larger array of grid cells to maintain the pre-identified 15 km distance). The revised approach allows for small spatial differences in the response to be considered in the RRF calculation and presumes that the chosen model grid resolution is able to appropriately capture model response at the location of the monitoring site. Additionally, as described in section 4.2.3, the guidance now recommends that the grid cell with the highest base year MDA8 ozone value in the 3 x 3 array be used for both the base and future components of the RRF calculation, as opposed to the 2007 guidance approach, which recommended selecting the peak value in the

[44] Days that have been removed from the official record as exceptional events should be considered for removal from the RRF calculations.

NMED Exhibit 108

base and future cases even if they were in different grid cells. The rationale behind this change is that the goal of the modeling is to assess the ozone change at a specific location (i.e., a grid cell representative of a monitor location), independent of how the ozone peak may shift across an area. As the monitor location does not change between the base and future, it stands to reason that the future-year value should come from the same grid cell as the base case.

The selection of grid cells to use in the RRF calculation is especially important in "oxidant limited" areas (i.e., areas where incremental NOx decreases may lead to ozone increases) because these areas are likely to have grid cells that respond to VOC controls, with NOx sensitive grid cells nearby (perhaps even in the same 3 x 3 array). The 3 x 3 array methodology could lead to unrealistically small or large RRFs in these locations, depending on the specific case. Internal EPA analyses with a 12 km grid resolution have shown that on average, model-estimated future design values vary by less than 1 ppb when a 1x1 approach is used as opposed to the recommended array, although higher variability can occur (U.S. EPA, 2014a).

While the use of a 3 x 3 array of cells is the recommended approach for the modeled attainment test, air agencies are encouraged to consider the actual spatial scales of the monitors at which the modeled attainment test is being applied. Most ozone monitors are generally sited to be representative of an urban or neighborhood scale. In cases in which the spatial representativeness of a monitoring location is much smaller or larger than the area covered by the 3 x 3 array of cells, air agencies may consider assessing site-specific model response over an alternative grid cell array as part of corroborative analyses that inform the aggregate weight of evidence determination. Additionally, there may be cases where certain cells along the periphery of the 3 x 3 array have different modeled responses than what would be expected at the monitor location at the center of array due to a specific local topographic or geographical feature (e.g., a large water body or a significant elevation change). A potential example of this situation would be an array where several cells are over water and where the meteorological conditions and relevant emissions sources differ substantially from the land-based monitor location. Again, in these types of cases and with appropriate justification, air agencies could consider removing the unrepresentative cells from the calculation.

4.2.3 Sample Modeled Attainment Test Calculation

Once the appropriate RRF days are determined at each site, the calculation is straightforward. RRFs are not calculated on a daily basis, but instead are based on the mean 8-hour daily maximum values on all eligible calculation days. At the last step in the process, the final DVF should be calculated in accordance with the data handling conventions associated with the NAAQS (e.g., truncated to the third decimal in ppm units as per current Appendix U). An example is provided below for a 2016 base year and 2030 future year simulation based on an

NMED Exhibit 108

annual model simulation. This hypothetical modeled attainment test considers an area with three ozone monitors.

Step 1: Compute site-specific base year design values (DVBs) from observed data at all eligible sites in the area by calculating the average of the design value periods which include the base year inventory year. All averaged values should be rounded to the tenth of a ppb. See Table 4.2 for the calculation in this sample case. The base design value is the average of the 3-year design values for 2016, 2017, and 2018.

Table 4.2: Ambient ozone base design values in example calculation.

Monitoring site	2014 DV (ppb)	2015 DV (ppb)	2016 DV (ppb)	Base design value (ppb)
A	84	79	73	78.7
B	N/A	67	83	75.0
C	86	76	80	80.7

Step 2: Compute site-specific relative response factors (RRFs) from modeled data at all eligible sites (i.e., A, B, and C). This is done by first identifying the 10 days with the highest daily 8-hour maximum ozone concentrations greater than 60 ppb (or subset of days if there are 5-9 days greater than 60 ppb) in the base year. For each of these days, identify the grid cell with the highest base year MDA8 ozone in the 3 x 3 cell array surrounding the monitor cell location and use that value in the calculation of a multi-day average. 10-day averages (where possible) should be calculated for both the base and future simulations. The future case average should be based on MDA8 values paired to the same cell as used in the base average. Figure 4.1 below shows an abbreviated subset of the RRF calculation for 3 days at a single sample site. Model estimates of MDA8 (in ppb) should be calculated to at least four places to the right of the decimal, with the last digit truncated.

NMED Exhibit 108

Figure 4.1. Example demonstration of daily selections of 8-hour maxima to be used in RRF calculation.[45]

Base

6/21/2014		
60.24	68.15	66.20
73.41	**76.26**	71.27
67.62	74.02	73.24

6/26/2014		
76.20	75.35	77.41
78.51	76.79	75.92
76.66	75.95	77.21

7/17/2014		
50.22	58.55	56.22
53.47	56.22	51.28
57.76	**59.10**	53.29

Future

6/21/2014		
56.89	59.22	58.05
63.69	**68.46**	63.39
61.86	67.16	66.80

6/26/2014		
<u>69.84</u>	67.71	68.14
68.30	66.27	67.95
64.28	65.15	66.58

7/17/2014		
46.80	49.27	48.55
51.91	50.41	50.34
53.62	**54.10**	50.62

Day 1 (6/21) is straightforward. The daily maximum 8-hour average is > 60 ppb and is in the same cell in both the base and future case.

For day 2 (6/26), the peak location shifts from the base to another cell in the array in the future (underlined cell). However, the center left cell is used for base and future values (paired in space).

Day 3 (7/17) would not be eligible for the RRF calculation because there are no base values > 60 ppb.

Step 3: Once the MDA8 values are selected for each appropriate day for each monitoring site, they should be averaged together over the days while maintaining at least four places to the right of the decimal. The RRF is the ratio of the average future MDA8 values to the average base MDA8 values. Table 4.3 shows an example RRF calculation, using the results from days 1 and 2 from Figure 4.1, plus the other eight (top 10) days in which the daily model predictions were deemed appropriate for RRF calculation. RRF values should be estimated to four decimal places (rounded to the 4th decimal digit).

[45] Figure 4.1 depicts the modeled ozone in each cell with only two digits to the right of the decimal to make the formatting simpler. The actual cell values used in the calculation should carry at least 4 digits to the right of the decimal.

Table 4.3. Relative response factor (RRF) calculation in example calculation.

Date	Base (ppb)	Future (ppb)
6/21/2014	76.2632	68.4626
6/26/2014	78.5156	68.3089
6/27/2014	75.2235	65.4333
6/28/2014	70.0509	62.7618
7/11/2014	76.3311	68.1865
7/12/2014	81.6739	72.6237
7/13/2014	78.3132	64.5255
8/02/2014	73.6956	69.9670
8/03/2014	75.8379	65.0507
8/21/2014	71.4430	59.3647
Average	75.7348	66.4685
RRF_i	**0.8776**	

The last step of the process is to multiply all of the site-specific RRFs by the corresponding site-specific DVBs and compare the results against the current level of the ozone NAAQS. In the final step, as noted in footnote 34, the design values are truncated to the integer ppb unit. Table 4.4 shows those results, assuming that the sample RRF shown above is for site C in the example. The final DVF for this sample site would be 70 ppb or 0.070 ppm. This would be considered a passing modeled attainment test for an ozone NAAQS of 0.070 ppm.

Table 4.4. Calculation of DVF_i for the three sites in the sample exercise.

Monitoring site	Base design value (ppb)	RRF	Future design value, pre-truncation (ppb)	Final Future design value (ppb)
A	78.7	0.8933	70.3	70
B	75.0	0.9138	68.5	68
C	80.7	0.8776	70.8	70

Note: The "final" future year design value represents the truncated value to compare to the NAAQS. However, it is recommended to retain the tenths (of a ppb) digit in all documentation, so that small ozone changes can be gleaned from control strategy and sensitivity analyses.

4.3 Modeled Attainment Test for the Secondary Ozone Standard

At the time this guidance document was written, the secondary ozone NAAQS is the same as the primary NAAQS. However, in the past, EPA has considered setting a secondary ozone NAAQS that is based on a cumulative measure of ozone concentrations, as opposed to the 3-year average of the annual fourth-highest daily maxima. If EPA were to establish a distinct secondary standard, it is possible that air agencies would need to separately show that the planned emissions reductions would be sufficient to meet both the primary and secondary

NMED Exhibit 108

NAAQS. If a new secondary standard is subsequently developed, EPA will provide supplemental guidance on how to assess attainment of that new standard at the time of its promulgation.

4.4 What is the Modeled Attainment Tests for the Annual Average $PM_{2.5}$ NAAQS?

Because ambient $PM_{2.5}$ often consists of multiple PM species, the modeled attainment test for $PM_{2.5}$ utilizes both $PM_{2.5}$ and individual $PM_{2.5}$ component species. A separate RRF and a separate concentration representing the base period is calculated for each $PM_{2.5}$ species. In order to perform the recommended modeled attainment test, air agencies should divide observed mass concentrations of $PM_{2.5}$ into 8 components (plus passive mass):

- Sulfates
- Nitrates
- Ammonium
- Organic carbon
- Elemental carbon
- Particle bound water
- Salt
- "Other" primary inorganic particulate matter
- Passively collected mass (blank mass)

To apply the attainment test, air agencies must first have outputs from air quality model simulations for a base year and a future year emissions scenario. We recommend a modeled attainment test which has four basic steps, as described in this section.

Step 1. Compute *observed* quarterly mean $PM_{2.5}$ and quarterly mean composition for each monitor.

Derive base year period quarterly mean concentrations[46] for each of the major components of

[46]Concentrations should be calculated based on calendar quarters for two reasons. First, the NAAQS is calculated as an annual average of 3 calendar years, so it would be inconsistent to average the data by season (where the winter season would span two calendar years). Second, the monitored data used to calculate design values is averaged on a calendar quarter basis before calculating annual averages.

$PM_{2.5}$.[47] This is done by multiplying the monitored quarterly mean concentration of FRM derived $PM_{2.5}$ (40 CFR part 53) by the monitored fractional composition of $PM_{2.5}$ species for each calendar quarter (e.g., 20% sulfate x 15.0 µg/m^3 $PM_{2.5}$ = 3.0 µg/m^3 sulfate).

Step 2. Using air quality model results, derive component-specific relative response factors (RRF) at each monitor for each calendar quarter.

Use the air quality model predictions to calculate the quarterly mean concentration for each $PM_{2.5}$ component for the base year and future year scenario.[48] Take the ratio of future to base year predictions for each component. The result is a component-specific relative response factor (RRF).

The RRF for component j at a site i is given by the following expression:

$$(RRF)_{ij} = [C_{ij,\ projected}]/[C_{ij,\ base\ year}] \qquad [4.3]$$

where $C_{ij,\ base\ year}$ is the quarterly mean concentration predicted at or near the monitoring site[49] with emissions characteristic of the period used to calculate the base design value for annual $PM_{2.5.}$

$C_{ij,\ projected}$ is the future year quarterly mean concentration predicted at or near the monitoring site.

(e.g., given model predicted mean third quarter base year period sulfate of 10.12 µg/m^3 and future year mean third quarter concentration of 8.23 µg/$m^{3,}$ then the third quarter RRF for sulfate is 0.8132).

[47] The mean species concentrations should be representative of the base period. The default approach to calculate mean species concentrations in SMAT is to use the 3-year average, centered about the base modeling year. These values are used to calculate species fractions by quarter. This differs from the 5-year weighted average design values recommended for base year $PM_{2.5}$ values. However, it is expected that there will be less variation in the species fractions compared to the absolute measured $PM_{2.5}$ concentrations. Alternative species fractions calculations can be considered, as long as they are representative of the expected species fractions during base year period.

[48] The calculations assume that there is one full year of model outputs.

[49] For greater (coarser) than 12km grid resolution, use the single grid cell. For 12km or less grid resolution, use the mean of the 3 x 3 array of the grid cells surrounding the monitor.

Step 3. Apply the component specific RRFs to observed air quality to obtain projected quarterly species estimates.

For each quarter, multiply the base year period quarterly mean component concentration (step 1) times the component-specific RRF obtained in step 2. This leads to an estimated future quarterly mean concentration for each component (e.g., 3.0 µg/m^3 sulfate x 0.8132 = future sulfate of 2.44 µg/m^3).

Step 4. Calculate a future year annual average $PM_{2.5}$ estimate.

Sum the quarterly mean $PM_{2.5}$ components to get quarterly mean $PM_{2.5}$ values. Then average the quarterly mean $PM_{2.5}$ concentrations to get a future year annual average $PM_{2.5}$ estimate for each FRM site.

Compare the projected average annual arithmetic mean $PM_{2.5}$ concentration obtained in Step 4 with 12.0 µg/m^3. If the values at all FRM sites are $\leq$ 12.0 µg/m^3, the test is passed.

4.4.1 Ambient $PM_{2.5}$ Data Used in the Annual $PM_{2.5}$ Attainment Test

$PM_{2.5}$ data collected at FRM and FEM sites are used for nonattainment designations. Therefore, we recommend using FRM and FEM data as the base data for projecting future $PM_{2.5}$ concentrations. As can be seen from the list of steps, the modeled attainment test is critically dependent on the availability of species component mass at FRM sites. This raises several issues. First, the majority of FRM sites do not have co-located chemical speciation network (CSN[50]) samplers.[51] And second, the FRM filter measurements and $PM_{2.5}$ speciation measurements do not always measure the same mass (Frank, 2006). There are numerous known issues with positive and negative sampling artifacts. These issues are addressed below.

4.4.2 FRM Monitors that Do Not Have Speciation Data

Species concentration data and/or species fractions are needed in order to apply the $PM_{2.5}$ attainment test. There are approximately 1200 FRM and FEM $PM_{2.5}$ monitoring sites, but only ~200 urban speciation monitoring sites. This makes it difficult to apply the attainment test at

[50] References to CSN monitors in this document refers to the overall speciation network which includes both trends sites and SLAMS sites.
[51] There are ~1200 FRM measurement sites and ~200-250 urban speciation sites (trends and SLAMS).

the majority of FRM/FEM sites. There are several possible ways to estimate species concentrations at FRM monitors that lack speciation data. Among them are:

1) Use concurrent data from a nearby speciation monitor to estimate species concentrations and/or fractions at one or more FRM sites.
2) Use representative speciation data (from a different time period) collected in an area to estimates species data at FRM sites.
3) Use interpolation techniques to create spatial fields using ambient speciation data.
4) Use interpolation techniques to create spatial fields using ambient speciation data **and** gridded model outputs to adjust the species concentrations based on the modeled spatial gradients.

In general, we recommend using spatial interpolation techniques to estimate species concentrations at FRM sites that do not have speciation data (numbers 3 and 4 above). But in some cases, interpolating data from nearby sites may not be appropriate, may not be feasible, or simply may not be necessary. In the EPA's SMAT, a relatively simple interpolation technique is used to estimate species concentrations at all FRM sites in the country. The analysis uses a Voronoi Neighbor Averaging (VNA) technique (consistent with approach number 3 above). Other interpolations have been done using Kriging and other more complicated methodologies such as "Downscaler" (Berrocal, 2010a and 2010b). Air agencies are encouraged to explore techniques that are most appropriate for their area and situation. EPA's SMAT software is available for air agencies to use as a default technique.

For areas that contain one or more speciation sites, and where FRM sites exhibit very little spatial gradients, it may be appropriate to assume that the speciation site(s) is/are representative of the entire area. For areas that exhibit strong spatial gradients in $PM_{2.5}$ concentrations, air agencies should strongly consider using more sophisticated techniques to estimate species concentrations. Combining ambient data with model output concentrations (number 4 above) may help adjust concentrations in areas with strong gradients, but limited speciation data. This technique has been used extensively to create spatial fields of $PM_{2.5}$ concentrations for the purpose of generating health benefits calculations and other examinations of unmonitored areas (also see section 4.6), but it has generally not been used to generate species fractions at FRM sites. The technique is further limited by uncertainties in the representativeness of the model outputs and emissions inventories.

NMED Exhibit 108

4.4.3 $PM_{2.5}$ Species Calculations and Definitions

Data analyses (Frank, 2006) have noted that the FRM monitors do not measure the same components and do not retain all of the $PM_{2.5}$ that is measured by routine speciation samplers and, therefore, cannot be directly compared to speciation measurements from the Chemical Speciation Network (CSN).[52] The FRM mass measurement does not retain all ammonium nitrate and other semi-volatile materials (negative sampling artifacts) and includes particle bound water associated with sulfates, nitrates and other hygroscopic species (positive sampling artifacts). This results in FRM measured concentrations (and percent contributions to $PM_{2.5}$ mass), which may be different than the ambient levels of some measured $PM_{2.5}$ chemical constituents.

Because the FRM data are used to determine compliance with the NAAQS, it is critical to estimate the species composition as measured on the FRM filters. In addition, for the purposes of predicting changes in $PM_{2.5}$ components, constructed $PM_{2.5}$ mass should match the composition of mass retained by the FRM.

The goal is to reconstruct the measured species components so that they add up to the measured FRM mass. This concept can generally be represented by equation 4.4:

$RCFM_{FRM}$ = [Ammoniated Sulfate Mass] + [Retained Ammoniated Nitrate Mass] + [Retained Carbonaceous Mass] + [Other Primary $PM_{2.5}$] + [Other Components] [4.4]

In the above characterization, $RCFM_{FRM}$, or reconstructed fine mass, and all of the listed chemical components reflect those retained during sampling and equilibration on the FRM's Teflon filter. Sulfate and nitrate mass include associated ammonium, which may be different than assumed ammonium sulfate and ammonium nitrate compounds. Carbonaceous mass includes elemental carbon (EC), organic carbon (OC), and hundreds of different carbon compounds, which are not directly measured, and which may not match the carbon mass in speciated measurement data. Also, sulfates and nitrates include particle bound water associated with these hygroscopic aerosols. In this characterization, other primary $PM_{2.5}$ mass is intended to be a more general term that includes fine soil, and oxides that result from other PM emissions.

[52] The information in this section applies to the most common samplers in the CSN. The characteristics of the sampler and the analytical procedures used to produce chemical speciation data should be considered in determining which, if any, adjustments are appropriate to make the data useful for comparison to FRM and FEM data.

NMED Exhibit 108

4.4.4 Recommended Treatment of Species Data

We recommend an adjustment technique based on an FRM mass construction methodology, which results in reduced nitrates (relative to the amount measured by routine speciation networks), higher mass associated with sulfates and nitrates (reflecting water included in gravimetric FRM measurements), and a measure of organic carbonaceous mass, which is derived from the difference between measured $PM_{2.5}$ and its non-organic carbon components (Frank, 2006). This characterization of $PM_{2.5}$ mass also reflects "other" primary inorganic $PM_{2.5}$ and other minor constituents. Frank (2006) terms this approach "sulfate, adjusted nitrate, derived water, inferred carbonaceous material balance approach (SANDWICH)." The resulting characterization provides a complete mass balance. It does not have any unknown mass, which is sometimes presented as the difference between measured $PM_{2.5}$ mass and the characterized chemical components derived from routine speciation measurements. The recommended SANDWICH-based characterizations should yield more accurate assessments of future $PM_{2.5}$ concentrations as measured by FRM monitors, compared to using unadjusted CSN data.

4.4.4.1 Retained Nitrate Mass

The first step in the procedure for identifying FRM mass components is to estimate the retained nitrate mass on the FRM filters. The FRM does not capture all of the semi-volatile components of the ambient air, such as ammonium nitrate. The retained amount of nitrate ion, however, can be estimated by a simple thermodynamic model that involves 24-hr ambient nitrate speciation concentrations (as measured by a standard speciation sampler using a nylon filter preceded by a HNO_3 denuder) together with hourly ambient temperature and humidity. Atmospheric nitrates are highest during the cooler months. Retention on the FRM is also higher during the cooler months and essentially all the nitrates are lost during the summer. The retention does not appear to depend on ambient NH_3 or HNO_3 concentrations. More NO_3 is retained at low temperatures and high humidity, which varies by sampling location and time of year.

Because nitrate retention varies by site and season, a simple ammonium nitrate equilibrium model can be used to predict the amount of nitrates retained on the FRM Teflon filter. As used by Hering (Hering, 1999; Zhang, 1992),

$$\text{delta } NO_3\ (\mu g/m3) = 745.7/T_R * 1/24 * \sum_{i=1}^{24} (\mathbf{K}_i^{\frac{1}{2}}) \qquad [4.5]$$

where delta NO_3 is the amount of volatilized nitrate mass, T_R is the reference temperature for the sampled air volume in degrees Kelvin, and $\mathbf{K_i}$ is the dissociation constant for ammonium nitrate evaluated at the ambient temperature and relative humidity for hour i. The nitrate loss can be predicted for each day, based on hourly temperature and relative humidity data. It must be subtracted from the NO_3 measured at speciation sites to estimate the FRM retained nitrate. The SMAT software is populated with a speciation ambient data file with daily average retained nitrate pre-calculated for all CSN and IMPROVE sites. The analysis uses National Weather Service temperature and relative humidity data from the closest station. Other sources of meteorological data may also be appropriate. Further details on the nitrate loss calculations can be found in Frank (2006).

4.4.4.2 Ammonium Associated with Sulfates and Retained Nitrates

There are several ways to estimate ammonium mass for use in attainment test. The most direct way is to use measured ammonium concentrations from the CSN network (IMPROVE does not measure ammonium ion). A second, more indirect method is to estimate the ammonium associated with nitrate, and to calculate the ammonium associated with sulfate and the degree of neutralization of sulfate (DON), and then use the resulting information to calculate ammonium mass. Due to uncertainties associated with the ammonium measurements and the lack of ammonium measurements in rural areas, this indirect method is recommended as the default attainment test methodology.

To determine the mass associated with nitrates, we assume retained nitrate is all ammonium nitrate. Thus, using the ratio of the molecular weight of ammonium to that of nitrate, the ammonium associated with nitrates ($NH4_{NO3}$) can be derived directly from the estimated retained nitrate ($NO3_{FRM}$) as:

$$NH4_{NO3} = 0.29 * NO3_{FRM} \qquad [4.6]$$

The difference between total FRM NH_4 (amount associated with nitrates and sulfates), termed $NH4_{FRM}$, and the measured NH_4, termed NH_{4CSN}, is needed to determine the ammoniated form of sulfates as described by equation 4.4. A measurement study by Collett (Collett, 2004) shows that NH_4 may not be completely retained during collection on nylon filters preceded by a nitric acid denuder, such as are used at CSN sites. At several FRM study sites, the CSN NH_4 which is adjusted for evaporated NH_4NO_3 tends to more closely correspond to the measured NH_4 from the FRM Teflon filter. However, for other sites, the measured CSN NH_4 appears to agree with FRM NH_4.

NMED Exhibit 108

The available information suggests that using measured ammonium (assuming none is volatilized) may be the best assumption. We, therefore, recommend using unadjusted ammonium, but further analysis of this issue is warranted.

To calculate the ammonium associated with sulfate, we recommend using the degree of neutralization of sulfate (DON). This is defined as the ammonium associated with sulfate (i.e., total ammonium less the ammonium associated with nitrate), divided by sulfate. This reflects the degree to which sulfate has been neutralized by ammonium. The ambient data is such that nearly all of the ammonium data is from urban sites (CSN), but the sulfate and nitrate data is from both urban (CSN) and rural (IMPROVE) sites. This may lead to an overestimation of ammonium concentration in rural areas when ammonium is directly interpolated. Therefore, we recommend using calculated DON with SO_4 and $NO3_{FRM,}$ and interpolating to each FRM site to get quarterly average concentrations. The interpolated DON and species concentrations are used to calculate $NH4_{FRM}$ using the following equation:

$$NH4_{FRM} = DON * SO4 + 0.29*NO3_{FRM} \quad [4.7]$$

The indirect calculation of ammonium mass from interpolated fields tends to smooth out the gradients in mass. This is deemed to be beneficial, due to the uncertainty in the measurements.

4.4.4.3 Particle Bound Water

Because ammoniated sulfate and ammonium nitrate are hygroscopic, the retained sulfate and nitrate mass will include water. Particle bound water (PBW) can be estimated using an equilibrium model. The EPA developed an approach using the Aerosol Inorganic Model (AIM) (Clegg, 1998). PBW is derived from quarterly average FRM concentrations of sulfate, ammonium, and nitrate (as described above). Estimated hydronium ion, H+, needed to achieve ionic balance is derived from the latter values. The model enables the distribution of water and ions to be calculated between liquid, solid and vapor phases for specific temperature and relative humidity conditions. Typical FRM filter equilibration conditions of 35% RH and 22 deg C (295 deg K) temperature are used to estimate water concentrations at those conditions.

Application of AIM at the specified FRM filter equilibration conditions show that PBW is much more dependent on sulfate concentration compared to nitrate and that the relationship varies somewhat by season. There is proportionally less estimated PBW water for wintertime aerosol which has higher NO_3 and lower SO_4. The PBW concentrations are also sensitive to the degree

NMED Exhibit 108

of neutralization of the sulfate particles (determined by the relative concentration of $NH4_{FRM}$).

We recommend calculating PBW as a component of $PM_{2.5}$ mass. The AIM model (or other equilibrium models) can be used, or a regression equation can be developed to simplify the process. For computational convenience, EPA derived a polynomial regression equation fit to the calculated water mass from AIM and the three input values to AIM (sulfate, nitrate and ammonium). The polynomial equation is used in the SMAT software to calculate PBW. See the SMAT User's Guide for more details on the default PBW equation.

4.4.4.4 Salt

In the $PM_{2.5}$ attainment test methodology, salt is represented as a species which accounts primarily for sea salt at sites near the oceans. The salt species is estimated using the CSN measured Cl^+ ion concentration multiplied by 1.8. The multiplier accounts for the sodium contribution to the species. In areas distant from oceans, measured Cl^+ may represent PM mass that is not associated with salt water. For instance, there may be chloride emissions resulting from various industrial processes. Therefore, the use of measured salt in the attainment test calculations should be evaluated on an individual area/monitor basis.

Measured salt is included by default in the SMAT species ambient data file. The inclusion of modeled salt (and hence an RRF for salt) is optional and can be included if there are accurate modeled salt concentrations. If modeled salt is not included in the SMAT input files, an RRF of 1.0 used in the SMAT calculations.

4.4.4.5 Other Primary PM2.5

The terms "crustal," "fine soil," "major metal oxides," "inorganic particulates," and "other PM," are sometimes used interchangeably. For $PM_{2.5}$ design value calculations we will refer to this material as "other primary $PM_{2.5}$" (OPP). For regional haze calculations, we will continue to refer to this material as "fine soil."

For the purposes of estimating OPP for the $PM_{2.5}$ attainment test, all measured non-carbon mass that is not organic in nature (not associated with sulfate and/or nitrate) should be counted. As with the other $PM_{2.5}$ components measured on the FRM filter, there is uncertainty associated with this estimate. The "crustal" or "fine soil" definition from IMPROVE can be used

NMED Exhibit 108

to estimate OPP[53] or an alternative formula can be defined which better estimates the urban nature of the FRM measurements. The IMPROVE definition of "fine soil" accounts for the typical crustal components (and attached mass) that would be expected in remote Class I areas. Fine soil is represented as five elements (Al, Si, Fe, Ti, and Ca) with coefficients to represent various oxides and material, which may be attached to or associated with the major elements. In urban areas, inorganic PM, which is not elemental carbon or associated with sulfate or nitrate, may come from many sources such as re-suspended dust or industrial sources (stack or fugitives). It is generally "crustal" in nature (dominated by silicon), but urban PM is more likely to contain heavy metals and industrial components.

Although the composition of inorganic PM may differ between urban and rural (remote) areas, an alternative equation, similar to the IMPROVE fine soil equation, can be used to estimate OPP for the $PM_{2.5}$ attainment test. The alternative equation is suggested by (Frank, 2006) and uses only four elements. The equation removes aluminum (and accounts for associated mass by increasing the coefficient for Si), due to the fact that aluminum is often missing from the speciation measurements. This allows for more complete data.

The alternative "fine soil" equation is as follows:

$$\text{Other primary } PM_{2.5} \text{ mass} = 3.73 \times [Si] + 1.63 \times [Ca] + 2.42 \times [Fe] + 1.94 \times [Ti] \qquad [4.8]$$

4.4.4.6 Blank mass

The other quantifiable components of $PM_{2.5}$ mass include passively collected mass, represented by a field blank concentration (U.S. EPA, 2002). This appears to constitute a contamination of the filter resulting from handling or contact with the FRM cassette. This value is deemed to be an important constituent of $PM_{2.5}$ mass (it is assumed to not be dependent on pollutant emissions). Based on recently collected ambient QA data, we recommend using a default nominal blank mass value of 0.2 $\mu g/m^3$ (see the EPA QA website for more details). This value represents an approximate nationwide network median value. This value can be modified based on local FRM blank mass measurements. The blank mass is assumed to remain constant through time (RRF=1.0).

[53] IMPROVE estimates fine soil as: $2.2 \times [Al] + 2.49 \times [Si] + 1.63 \times [Ca] + 2.42 \times [Fe] + 1.94 \times [Ti]$

4.4.4.7 Calculation of Carbonaceous Mass

Organic carbon mass is typically estimated from blank corrected speciation data, where organic carbonaceous mass is first estimated by multiplying the organic carbon concentrations by 1.4 or alternative factors to account for the oxygen, hydrogen and other elements associated with ambient carbon particles.

There are many uncertainties in estimating carbonaceous mass from carbon measurements (Turpin, 2001; Chow, 2004). Uncertainties include differences in carbon measurement protocol between urban and rural monitoring locations; a relatively "bumpy" surface of urban carbon concentrations as derived from urban and rural organic carbon measurements; and lack of carbon measurements at all FRM locations. We, therefore, recommend an alternative approach to estimate the organic carbon contribution to $PM_{2.5}$ mass.

The recommended attainment test approach estimates organic carbon by *mass balance*. Precisely measured FRM $PM_{2.5}$ mass (U.S. EPA, 2003) is compared to the sum of its non-organic carbon components. The latter are sulfates, ammonium, nitrates, estimated particle bound water, elemental carbon, estimated other primary $PM_{2.5}$ material, salt, plus 0.2 µg/m3 blank mass as discussed earlier.

This approach estimates retained organic carbon FRM mass and explicitly accounts for the following important and difficult to estimate carbon mass properties: 1) regional and urban-rural differences in the mix of carbonaceous aerosols (i.e., the amount of oxygen, hydrogen, etc); 2) retained water associated with hygroscopic carbon compounds (Saxena, 1996; Yua, 2004*)*; 3) volatile carbonaceous material measured by speciation samplers, but not retained in FRM mass; and 4) uncertainties associated with blank corrections of measured organic carbon.

Organic Carbon Mass by mass balance **(OCM_{mb})** is defined as,

$$\mathbf{OCM_{mb}} = PM_{2.5} - \{ [SO4] + [NO3_{FRM}] + [NH4_{FRM}] + [water] + [EC] + [OPP] + [salt] + [0.2] \} \quad [4.9]$$

In this expression, all of the above components represent the mass retained on FRM Teflon filters.

NMED Exhibit 108

This approach completely accounts for FRM mass[54] and OCMmb is often greater than the amount that would be derived directly from speciation measurements. Because of uncertainties in speciation measurements and their estimates from interpolated surfaces, setting a lower limit (floor) may be necessary so that the OCMmb is not unreasonably low. In some cases, the OCMmb could be lower than the measured OC or OCM. Since measured OC (without accounting for mass associated with OC) is a conservative minimum estimate of OC mass, we recommend setting the OCMmb "floor" to be equal to measured OC.

There may also be situations where an OCMmb "ceiling" is needed. In remote urban areas with relatively high FRM concentrations that may be surrounded by rural background concentrations, the OC by mass balance technique may apportion 95%+ of the $PM_{2.5}$ mass to OCM. If this is not a reasonable assumption, then a ceiling may be needed to cap the OCM as a percentage of $PM_{2.5}$ mass. Based on measured data (FRM sites with co-located speciation data), it appears that on a quarterly average basis, OCM is rarely more than 80% of total $PM_{2.5}$ mass. This may be a reasonable default ceiling, but a lower value (or in rare circumstances, a higher value) may be more appropriate in some regions of the country.

4.4.4.8 Summary of $PM_{2.5}$ Composition Calculations

The terms of equation 4.10 reflect the final estimated composition of the particles measured by the FRM (for each quarter). Quarterly average FRM mass is equal to the sum of the eight species plus blank mass.

$$PM_{2.5FRM} = \{ [OCMmb] + [EC] + [SO4] + [NO3_{FRM}] + [NH4_{FRM}] + [water] + [OPP] + [salt] + [0.2] \} \quad [4.10]$$

The recommended order to generate the data is as follows:

1) Calculate adjusted nitrate using hourly meteorology and 24-hour average nitrate measurements.

[54] The OC by mass balance technique assumes that all other mass is accounted for and, therefore, all remaining mass is OCM. This may not always be a good assumption. The results of the technique should be carefully evaluated to ensure that OC mass is not overestimated (and, therefore, other mass components are underestimated). This may be an issue in areas that do not have nearby speciation data and have relatively large concentrations of primary $PM_{2.5}$. The OC by mass balance technique may inadvertently apportion mass to organic carbon, which may actually be EC or "other" primary $PM_{2.5}$ mass components (such as heavy metals). All available ambient data and modeling data should be used to evaluate the species apportionment results.

NMED Exhibit 108

2) Calculate quarterly averages for adjusted nitrate, sulfate, elemental carbon, ammonium (or degree of sulfate neutralization (DON)), OPP, salt, and measured OCM[55].

3) Quarterly average ammonium is calculated from the adjusted nitrate, sulfate, and DON values (if measured ammonium is not used directly).

4) Ammonium, sulfate, and nitrate concentrations are input into the polynomial water equation to derive particle bound water concentrations.

5) Carbon mass by difference (OMCmb) is calculated from the $PM_{2.5}$ mass, adjusted nitrate, ammonium, sulfate, water, elemental carbon, salt, other primary $PM_{2.5}$, and blank mass values. The sum of the eight species plus blank mass is equal to the FRM mass.

We illustrate application of the recommended test in example 4.4.1.

Example 4.4.1

Given: (1) Area "C" has 2 monitoring sites.

(2) Monitored FRM air quality data show the following average quarterly mean $PM_{2.5}$ concentrations based on a 5-year weighted average of observations from 2012-2016 at each site (values are in $\mu g/m^3$).

Table 4.4.1 Quarterly average $PM_{2.5}$ FRM mass concentration ($\mu g/m^3$) at 2 example sites

Site	Quarter 1	Quarter 2	Quarter 3	Quarter 4
1	17.21	16.34	20.00	14.76
2	15.39	17.98	18.23	13.76

(3) The area has 1 urban speciation site, which is co-located with FRM site 2. The speciation data is available for the entire time period, but the species concentrations for the 2013-2015 time period have been deemed to be most representative of the 2012-2016 5- year weighted average. Therefore, the species data for the average 3-year period (2013-2015) has been

[55]The measured OCM is only used to calculate the "floor" for OCMmb.

NMED Exhibit 108

interpolated to derive estimated species concentrations at each site. The species concentrations are matched up with FRM data for the same 2013-2015 period to derive representative species fractions. The average monitored air quality for the 3rd quarter of 2013-2015 at site 1 is as follows[56]:

Table 4.4.2 Average monitored 3rd quarter ambient data at site 1

FRM Mass (µg/m3)	Blank Mass (µg/m3)	Non-blank Mass (µg/m3)	Sulfate (µg/m3)	Nitrate (µg/m3)	Organic Carbon Mass (µg/m3)	Elemental Carbon (µg/m3)	Water (µg/m3)	Ammonium (µg/m3)	Salt (µg/m3)	OPP (µg/m3)
22.62	0 .2	22.42	8.51	1.11	5.21	0.91	2.31	3.31	0.35	0.71

The blank mass is subtracted before species fractions are calculated because the blank mass is held constant at 0.2 µg/m3 throughout the analysis. In the example, the measured FRM mass for quarter 3 is 22.62 µg/m3. The non-blank FRM mass is 22.42 µg/m3. The mass of the eight species add up to the non-blank mass.

(4) Species fractions are calculated for each quarter for each species. In the example below, a fraction of non-blank mass is calculated for each of the eight species. Blank mass remains fixed at 0.2 µg/m3.

Table 4.4.3 3rd quarter average species fractions for 2013-2015 at site 1

FRM Mass (µg/m3)	Blank Mass (µg/m3)	Non-blank Mass (µg/m3)	% Sulfate	% Nitrate	% Organic aerosol	% Elemental Carbon	% Water	% Ammonium	% Salt	% OPP
22.62	0 .2	22.42	37.96	4.95	23.24	4.06	10.30	14.76	1.56	3.17

The percentages in table 4.4.3 above are the relative composition for the 3rd quarter of 2013-2015. It is assumed that these species fractions are representative of the 2012-2016 time-period.[57]

[56] The species concentrations can be derived from co-located speciation data, nearby speciation data or from interpolated spatial fields. FRM mass is not interpolated.

[57] The default assumption is that the average of the middle 3 years of speciation data is representative of the 5-year weighted average FRM data. However, other assumptions (number of years of speciation

(5) The weighted quarterly average FRM design values are used as the base year FRM value for each monitoring site (2012-2016). The species fractions from the 2013-2015 speciation data were used to estimate the species concentrations for the base year FRM $PM_{2.5}$ data. The percentage compositions for 2013-2015 are applied to the quarterly weighted average design values as shown in table 4.4.4. In the example below, the weighted average design value for the 3rd quarter for the site from table 4.4.1 is 20.00 µg/m3. This leads to the following concentrations of $PM_{2.5}$ species:

Table 4.4.4 Calculation of the "base case" species concentrations at site 1

Weighted Avg. FRM Mass (µg/m3)	Blank Mass (µg/m3)	Non-blank Mass (µg/m3)	Sulfate (µg/m3)	Nitrate (µg/m3)	Organic aerosol (µg/m3)	Elemental Carbon (µg/m3)	Water (µg/m3)	Ammonium (µg/m3)	Salt	OPP (µg/m3)
20.00	0.2	19.80	7.52	0.98	4.60	0.80	2.04	2.92	0.31	0.63

This procedure is repeated for each $PM_{2.5}$ site and quarter to complete the calculation of base year ambient concentrations used as the basis for future estimates of $PM_{2.5}$ mass and its components.

data) can be used. It is generally assumed that the inter-annual variability of the species fractions is small compared to the variability of species concentrations.

NMED Exhibit 108

(6) Modeled results show the following relative response factors (RRF) for predicted mass of 5 components of $PM_{2.5}$ for the 3rd quarter[58]:

Table 4.4.5 3rd quarter modeled RRFs for site 1

RRF Sulfate	RRF Nitrate	RRF Organic aerosol	RRF Elemental Carbon	RRF Salt	RRF OPP
0.8761	0.9432	0.9713	0.9324	1.0	1.0423

(7) The quarterly mean RRFs from table 4.4.5 are multiplied by the weighted quarterly average species concentrations from table 4.4.4 to derive future year concentrations.

From the example above, the future year 3rd quarter concentrations are:

$Sulfate_{Future}$ = 7.52 * 0.8761 = 6.58 µg/m3
$Nitrate_{Future}$= 0.98 * 0.9432 = 0.92 µg/m3
Organic carbon $mass_{Future}$= 4.60 * 0.9713 = 4.47 µg/m3
Elemental $Carbon_{Future}$= 0.80 * 0.9324 = 0.75 µg/m3
$Salt_{Future}$=0.31*1.0 = 0.31 µg/m3
OPP_{Future}= 0.63 * 1.0423 = 0.65 µg/m3

(8) The future year concentrations derived above are used to calculate the future year concentration of ammonium (if the direct ammonium RRF is not used) and particle bound water.

The future year ammonium concentrations are calculated from the sulfate, nitrate, and (base year) DON values. Assuming that the DON is unchanged from the base year[59], the ammonium is

[58] The default assumption for the annual average $PM_{2.5}$ NAAQS test is to calculate RRFs from the mean of the 3 X 3 matrix of grid cells surrounding each FRM monitoring site.
[59] Due to the uncertainty in the ammonium measurements, by default, the DON is assumed to stay constant through time. The water calculation is sensitive to the ammonium (and, therefore, the DON value) concentrations. Holding the DON constant allows for the future year ammonium and water values to be solely a function of the change in sulfate and nitrate concentrations. Otherwise, the water concentration can go up when the sulfate and nitrate concentrations go down (and vice versa). This may occur if sulfate becomes more neutralized in the future. It is a somewhat illogical outcome (although scientifically possible) and is highly dependent on an uncertain measurement (ammonium). Therefore,

calculated using the following formula:

$NH4_{future}$ = DON * $SO4_{future}$ + 0.29*$NO3_{future}$, [4.7]

In the example above, assuming the base year DON is 0.336,

$Ammonium_{Future}$= 0.336 * 6.58 + 0.29 * 0.92 = 2.48 µg/m3

The $NH4_{future}$, $SO4_{future,}$ and $NO3_{future}$ concentrations can then be input into an equilibrium model (AIM or another alternative model) or through a polynomial regression equation to predict future year particle bound water concentration (based on the default equation, the future year water concentration in this case is 1.73 µg/m3).

(9) The future species concentrations at each FRM site are then summed over the eight species plus blank mass to estimate the future quarterly average $PM_{2.5}$ concentration.

In the example above, the total $PM_{2.5Future}$=
6.58 + 0.92 + 4.47 + 0.75 + 0.65 + 2.48 + 1.73 + 0.2 = 17.78 µg/m3

(10) The same calculations are completed for the other 3 quarters to get a future year $PM_{2.5}$ concentration for each quarter. The 4 quarters are then averaged to get a final future year annual average $PM_{2.5}$ concentration for each FRM site.

(11) The future year annual average concentration is compared to 12.0 µg/m^3.[60]

4.5 What Is the Recommended Modeled Attainment Test for the 24-Hour NAAQS?

Our recommended modeled attainment test for the 24-hour NAAQS for $PM_{2.5}$ is similar to the previously described test for the annual NAAQS in that it uses model predictions in a relative

use of a constant DON creates a more stable set of calculations. If the measured and modeled ammonium concentrations are believed to be accurate and respond in a reasonable way to emissions controls, then it would be more scientifically credible to use the model predicted change in ammonium. Otherwise, it is a reasonable assumption to keep the DON constant over time.

[60] In the final step, the future year concentration should be rounded to the tenths digit. A (rounded) value of 12.0 µg/m3 meets the NAAQS. A value of 12.1 µg/m3 or greater violates the NAAQS.

sense to reduce site-specific *observations* (averaged over 5 years). In the test, we are interested in reducing the base year design values at each site to $\leq$ 35 µg/m^3 (the 2006 24-hour $PM_{2.5}$ NAAQS). [61]

Ideally, the modeled attainment test should reflect model results obtained for days in each season having observed $PM_{2.5}$ concentrations above the design value. Even though the 24-hour NAAQS is based on the single 98th percentile value of all days in the year, it is important to perform the test on a seasonal basis, since $PM_{2.5}$ consists of a mixture of pollutants whose composition can vary substantially from season to season. There could be a substantial amount of uncertainty associated with predictions on any single day. Thus, our test is most likely to be reliable when relative response factors (RRFs) reflect composite responses from multiple days. Therefore, we recommend modeling as many days as feasible where observed $PM_{2.5}$ is greater than 35 µg/m^3. Alternatively, the test can focus on the high end of the distribution of days in each quarter[62] (e.g., the top 10% of $PM_{2.5}$ days[63]) assuming that the high days are representative of days that violate the NAAQS. As with the annual NAAQS (and for the same reasons), the preferred approach is to develop RRFs, which are quarter specific[64].

The 24-hour $PM_{2.5}$ attainment test should be based on the same 5-year weighted average methodology that was used for the annual standard, with some slight modifications. The 24-hour design values are calculated from the 98th percentile value for each year. In the 24-hour $PM_{2.5}$ calculations, the 98th percentile value from each year is used in the final calculations. Since the 98th percentile value can come from any day in the year, all quarters and years should be carried through to near the end of the calculations. To calculate final future year design

[61] *See* 71 FR 61224 and 40 CFR 50.13.

[62] Similar to the annual $PM_{2.5}$ NAAQS, the default recommended procedures for the 24-hr NAAQS assume handling of the ambient data and model data on a calendar quarter basis. However, in some nonattainment areas, 24-hr $PM_{2.5}$ NAAQS exceedances may occur during a very limited time of the year or season. Processing the data (both ambient and model) on a sub-quarterly basis may be appropriate in certain circumstances.

[63] For most sites, the top 10% of monitored days per quarter will represent between 3 and 8 ambient measurement days.

[64] In some areas it may not be necessary to model and evaluate the 24-hour NAAQS for all quarters. For example, if observed $PM_{2.5}$ concentrations only exceed the NAAQS in the 1st and 4th quarters, and concentrations in the 2nd and 3rd quarters are very low, then it may not be necessary to model the full year. But for areas that have monitored violations (or high values that are close to the NAAQS) in all four seasons, the entire year should be evaluated.

values, the 98th percentile day for each year is identified and then a 5-year weighted average of the 98th percentile values for each site is calculated to derive the future year design value.[65] In nonattainment areas that measure violations of the daily $PM_{2.5}$ NAAQS in multiple seasons (most often summer and winter), the highest PM days can sometimes shift between seasons when days are projected to the future. A consequence of this shift is that a base year 98th percentile winter day may have a higher future year concentration than a summer day that started with a higher concentration in the base year. Therefore, the recommended attainment test methodology has been designed so that the temporal distribution of high days in the base and future periods can shift between quarters.

In the 24-hour attainment test methodology (described below), the eight highest ambient $PM_{2.5}$ days in each quarter at each site are projected to the future (32 days per year) using species specific quarterly RRFs. After all 32 days are projected to the future, the days are re-ranked to determine the future year 98th percentile day.[66] The rank of the future year 98th percentile day is selected based on the rank of the observed 98th percentile day in the base year ambient data (which depends on the number of valid daily samples). For example, at monitoring site A, if there are 120 observations in year 1 then the 98th percentile day is the 3rd high observation day for the year. In that case, the future year 98th percentile day is selected as the 3rd high future day for the year (out of the 32 highest days).

Similar to the annual $PM_{2.5}$ attainment test, we recommend interpolation techniques for FRM monitors that do not have co-located speciation data. Because the 24-hour standard is a 98th percentile-based value, the species composition on high concentration days may be highly variable from day to day and from site to site. Therefore, while interpolation techniques may be needed, we strongly recommend collecting speciation data at all FRM sites that violate the 24-hour NAAQS. A precise estimate of the $PM_{2.5}$ components at violating sites will help reduce uncertainty in projecting the future year concentration estimates.

[65] Similar to the annual average $PM_{2.5}$ attainment test, design values are calculated for consecutive 3-year periods. From the 5-year base period, three design values are calculated and then averaged together to create a 5-year weighted average.

[66] The observed 98th percentile day is always between the 1st and 8th high for the year, depending on the sampling schedule. Therefore, projecting the 8 highest days in each quarter ensures that the observed 98th percentile day is always captured. Additional days could be projected, but a maximum of 32 days per year is needed to guarantee that the 98th percentile observation day at each site is projected to the future.

NMED Exhibit 108

We recommend a modeled attainment test for the 24-hour $PM_{2.5}$ NAAQS with the following steps.

Step 1. Identify the high observed $PM_{2.5}$ days at each FRM monitoring site for each year.

The first step in projecting the daily design value is to identify at each FRM site, the eight highest observed 24-hour $PM_{2.5}$ concentration days in each quarter for each year of the base period (up to 5 years), and identify the day rank of the observed 98th percentile value for each year based on the number of collected ambient samples (i.e., 3rd highest day of the year). This results in a data set containing 32 days of data for each year (for up to 5 years) for each site.[67]

The test should be performed for each monitoring site that meets the data completeness criteria for calculating a design value for the 24-hour NAAQS. There may not always be data available for all four quarters and all 5 years. We recommend using 8 days per quarter because the 98th percentile day for a year is always one of the 8 highest days of the year.[68] If all of the high days occur in a single quarter, then using the 8 highest days from each quarter will ensure that the actual 98th percentile day is always captured. This may result in processing more days than necessary, but effectively limits the future year design value calculations to a reasonably small number of days.

Step 2. Calculate "high days" species fractions for each quarter for each FRM monitor.

In this step, quarterly ambient species fractions on "high" days are calculated for each of the major component species of $PM_{2.5}$ (i.e., sulfate, nitrate, ammonium, elemental carbon, organic carbon mass, particle bound water, salt, and blank mass). This calculation is performed by dividing the average monitored concentrations of FRM-derived total $PM_{2.5}$ mass on the high $PM_{2.5}$ days at each site for each quarter, by the average monitored species concentration on the high $PM_{2.5}$ days for each quarter.[69] The default recommendation for identification of "high"

[67] The methodology does not assume that the temporal distribution of high days in the base and future periods will remain the same. We recommend projecting at least 8 ambient days per quarter from the base period to the future and then re-rank the entire set of days to find the new future year 98th percentile value (for each year).

[68] If there are 365 samples in a year, then the 98th percentile is the eighth high day.

[69] Similar to the annual average calculations, for FRM sites that do not have co-located species data, we recommend calculating the quarterly species fractions using interpolated species data. For the 24-hour species interpolations, we recommend interpolating the average of the highest 10% of monitor days in each quarter.

days is the top 10% of days in each quarter. This results in a relatively robust calculation, which typically uses between 3 and 9 days per quarter (depending on the sampling frequency). The end result is a set of quarterly "high days" species fractions for each FRM site.

Step 3. Calculate species concentrations for each of the high ambient days.

Multiply the quarterly "high day" species fractions from step 2 by the $PM_{2.5}$ mass concentration for the 8 high days per quarter identified in step 1. This results in a set of species concentrations for each of the 32 days per year identified in step 1.

Step 4. Calculate component specific RRFs for the high days in each quarter.

For each quarter, calculate the ratio of future year to base year modeled predictions for sulfate, nitrate, elemental carbon, organic carbon, salt, and OPP for the top 10 percent of modeled $PM_{2.5}$ days based on modeled concentrations of 24-hour average $PM_{2.5}$. The result is a set of species-specific "high day" RRFs for each quarter.

The relative response factor for component j at a site i is given by the following expression:

$$(RRF)_{ij} = ([C_{j,\ projected}]/[C_{j,\ base\ year}])_i$$

where $C_{j,\ base\ year}$ is the base year mean species concentration (for the high modeled $PM_{2.5}$ days for each quarter) predicted at the (single) grid cell which contains monitoring $site_i$.

$C_{j,\ projected}$ is the future year mean species concentration (for the high modeled days for each quarter) predicted at the (single) grid cell which contains monitoring $site_i$.

For example, assume that base year predicted sulfate mass on the 10 percent highest $PM_{2.5}$ days for quarter 3 for a particular location is 20.0 $\mu g/m^3$ and the future year modeled sulfate concentration is 16.0 $\mu g/m^3$, then the RRF for sulfate for quarter 3 is 16.0/20.0 or 0.80. Due to potentially large spatial and temporal gradients, we recommend 24-hour $PM_{2.5}$ NAAQS RRFs to be calculated based on the modeled concentrations at the single grid cell where the monitor is located.

NMED Exhibit 108

Step 5. Apply the component specific RRFs to observed air quality by quarter.

For each of the 8 days in each quarter, multiply the daily species concentrations from step 3 by the quarterly species-specific RRFs obtained in step 4. If there is 1 modeled base year, then there will be four quarterly RRFs at each monitor. The modeled quarterly RRF for quarter 1 is multiplied by the ambient data for quarter 1 (8 days in each year) for each of the 5 years of ambient data. For example, for day A, 21.0 $\mu g/m^3$ nitrate x 0.75 = future nitrate of 15.75 $\mu g/m^3$. The same procedure is applied for the 8 high days per quarter in the other 3 quarters. This leads to an estimated future concentration for each component for each day.

Step 6. Calculate remaining future year PM2.5 species.

The future year concentrations for the remaining species are then calculated for each of the days.[70] Similar to the annual $PM_{2.5}$ attainment test, we recommend that the future year ammonium is calculated based on the future year sulfate and nitrate concentrations, using a constant value for the degree of neutralization of sulfate (from the ambient data). The future year particle bound water concentration is then calculated from an empirical formula derived from the AIM model. The inputs to the formula are the future year concentrations of sulfate, nitrate, and ammonium calculated in step 5.

Step 7. Sum the species components to get total $PM_{2.5}$ concentrations for each day.

Sum the species concentrations for each day to obtain total $PM_{2.5}$ values for the 32 days per year per site.

Step 8. Determine future year 98th percentile concentrations for each site year.

Sort the 32 days for each site for each year by total $PM_{2.5}$ concentration. For each site year, the monitored 98th percentile rank (for each year) is used to identify the 98th percentile rank for each year.[71] For example, if the base year 98th percentile value for year 1 was the 3rd high concentration, then the future year 98th percentile concentration is identified as the 3rd high future year $PM_{2.5}$ concentration (out of the 32 days).

[70] If salt is not explicitly modeled, then the salt RRF should be held constant. Blank mass is assumed to be constant between the base and future year.

[71] This assumes that the ambient sampling schedule (and number of samples) would remain the same between base and future years.

Step 9. Calculate future 5-year weighted average 24-hour design values and compare to the NAAQS.

The estimated 98th percentile values for each of the 5 years are averaged over 3-year intervals to create 3-year average design values (e.g., the 98th percentile values from year 1, year 2, and year 3 are averaged. Then the 98th percentile values from year 2, year 3, and year 4 are averaged, etc.). These design values (up to 3) are then averaged to create a future year 5-year weighted average design value for each monitoring site.

The preceding steps for determining future year 24-hour $PM_{2.5}$ concentrations are applied for each FRM site. The 24-hour $PM_{2.5}$ design values are truncated after the first decimal place. This approach is consistent with the truncation and rounding procedures for the 24-hour $PM_{2.5}$ NAAQS. Any value that is greater than or equal to 35.5 µg/m^3 is rounded to 36 µg/m^3 and violates the 24-hour NAAQS. Similarly, a value of 35.4 µg/m^3 is rounded down to 34 µg/m^3 and is attaining the 24-hour NAAQS.

4.6 Local Area Analyses - Special Considerations for Primary $PM_{2.5}$

Primary PM does not undergo chemical transformation between being emitted and its arrival at a receptor location. Thus, high concentrations of primary PM can occur without relatively lengthy travel times from source to receptor. Unlike secondary PM or ozone, we would expect concentrations of primary PM to increase the closer one gets to the source(s) of emissions. Therefore, if a designated nonattainment area contains concentrated sources of primary PM, we would expect there to be relatively large spatial gradients near sources of the primary portion of the organic carbon, elemental carbon and other PM components of ambient $PM_{2.5}$ (these localized areas of high concentrations are often called “hotspots”).

Note that the $PM_{2.5}$ NAAQS ambient monitoring rule language[72] indicates that some monitoring locations may not be comparable to the annual $PM_{2.5}$ NAAQS. $PM_{2.5}$ measurement data from monitors that are not representative of “area-wide” air quality, but rather of relatively unique micro-scale, or localized hot spot, or unique middle-scale impact sites, are not eligible for comparison to the annual $PM_{2.5}$ NAAQS. The ambient air quality monitor siting rules define the appropriate scales of influence for the $PM_{2.5}$ monitoring network.[73]

[72] *See* 40 CFR 58.30.
[73] *See* 40 CFR part 58, Appendix E.

NMED Exhibit 108

4.6.1 Analysis of Primary $PM_{2.5}$ Impacts at Monitors

The majority of FRM and FEM $PM_{2.5}$ monitors are located at "urban scale" sites. These sites tend to represent relatively large spatial scales and do not have large gradients compared to other monitors in the area. Some sites are classified as "neighborhood" scale and may be influenced by more local sources. There are also near-road sites that have specifically been sited to measure gradients that may exist near heavily travelled roads. For reasons stated above, local influences creating large spatial gradients are likely to consist mostly of primary $PM_{2.5}$ (OC, EC, and OPP). These sources may be point sources, or they may be nearby roads or other mobile or area sources.

As part of the attainment demonstration modeling, it may be necessary to evaluate the local-scale impacts of primary $PM_{2.5}$ sources for contributions to the 24-hour and/or the annual NAAQS. As stated earlier, for the purposes of determining attainment with the NAAQS, it may not always be appropriate to compare ambient data from $PM_{2.5}$ monitoring sites that are dominated by point sources to the annual NAAQS. But there are numerous cases where local source contributions may not be dominant, but are a sizable contributor to total $PM_{2.5}$ (~10-30% of total annual average $PM_{2.5}$). In these cases, a more refined analysis of the contribution of local primary $PM_{2.5}$ sources to $PM_{2.5}$ at the monitor(s) will help explain the causes of nonattainment at and near the monitor and may lead to the more efficient ways to attain the NAAQS by controlling emissions from local sources which may be important contributors to the violating area.

There are several modeling tools that can be used to evaluate contributions of local $PM_{2.5}$ sources. A grid model can be run at very high horizontal resolution (1 or 2 km or finer) or a Gaussian dispersion model can be used. Grid based models simulate chemical transformation and complex meteorological conditions, while dispersion models are generally more simplistic; being limited to a local-scale, using Gaussian approximations with little or no chemistry. Therefore, while dispersion models may not be an appropriate tool for determining secondary $PM_{2.5}$ or ozone concentrations, they work well for use in determining local primary $PM_{2.5}$ impacts. The model(s) and model setup should be evaluated to determine the most appropriate tools for a specific situation. Regardless of which type of models are used to evaluate changes in primary $PM_{2.5}$ at monitoring locations, we recommend that the model results be used in a relative manner. This is consistent with the already described attainment tests. If a grid model is used at very high resolution, the attainment test as described in sections 4.4 and 4.5 should be followed. If a Gaussian dispersion model is used, then the application of the attainment test

NMED Exhibit 108

will vary slightly. The test will need to combine results from the chemical transport grid based modeled attainment test and the results from local-scale dispersion modeling. Because each nonattainment area has unique emissions sources and source-receptor relationships, air agencies should work closely with their EPA Regional office in developing local area analysis applications. The nature of the analyses and calculations of $PM_{2.5}$ concentrations (base and future) depend on the type(s) of local sources, measured PM gradients, the NAAQS being examined, and the model(s) used.

4.6.2 Analysis of Primary $PM_{2.5}$ Impacts at Monitors Using a Gaussian Dispersion Model

To apply a dispersion model in an attainment test, it is important to determine the local component of primary $PM_{2.5}$ at the monitor and the sources that are contributing to this component. There is no single, simple method for quantifying this contribution, but detailed analysis of ambient data and advanced data analysis techniques such as receptor modeling may help quantify the contribution. EPA provides software and information on the CMB, UNMIX, and PMF receptor models.

The simplest method for identifying the local component of $PM_{2.5}$ is to examine local ambient $PM_{2.5}$ concentrations. For this type of analysis, it is important to identify the local contributions from as small a source area as possible. This will make it easier to identify contributing sources. One aspect of this analysis is to examine monitored concentration differences between urban monitors (with the highest concentrations) and more suburban measurements. This is likely to provide a representative indication of the excess contribution from a relatively local area. "Urban excess" calculations which pair an urban monitor with an appropriate rural background monitor (U.S. EPA, 2004b) are likely to indicate "local" contributions that may be representative of a metropolitan area. In most cases, the local component will include contributions from more than one source.

Sources identified as contributing to the monitor through emissions analysis or data analysis (such as receptor modeling) can then be modeled with a dispersion model (or alternatively, a very high resolution grid model). It is common practice to run dispersion models for a limited number of major point sources or line sources in relatively small areas (out to a maximum

NMED Exhibit 108

distance of ~50 km).[74] Dispersion models can also be run for all sources of primary $PM_{2.5}$ in a limited area (including mobile, non-road, and area sources).

When applying a model to evaluate the impacts from emissions of primary $PM_{2.5}$, one should determine the $PM_{2.5}$ species that make up the local primary PM.[75] We recommend that the individual components of primary $PM_{2.5}$ be tracked separately. This will allow for a more thorough evaluation of the modeling results (comparing model output to speciated ambient data) and may aid in the development of primary $PM_{2.5}$ control strategies.

The majority of the primary $PM_{2.5}$ will consist of the primary portion of the organic carbon component, elemental carbon (EC), and the general category of "other primary particulate matter" (OPP). Speciated $PM_{2.5}$ measurements may be able to identify some of the more important "other" inorganic components such as heavy metals or salt. In some cases, directly emitted sulfate (and in rare cases nitrate) may also be a significant component of the local primary $PM_{2.5}$.

As part of a local-source impact analysis, an estimated concentration or fraction of primary OC may be needed. There are several methods available for estimating the primary versus secondary portion of ambient OC. Among these are the EC tracer method and receptor modeling. The EC tracer method is the most common method used to estimate secondary and primary OC concentrations (Turpin, 1995), (Strader, 1999), (Cabada, 2004), (Chu, 2005), (Saylor, 2006). The method uses measurements of OC and EC and calculated OC to EC ratios to identify periods when OC is likely to be mostly primary. This information is then used to calculate the secondary contribution to OC. Receptor models such as CMB and PMF have also been used to estimate secondary organic concentrations (Na, 2004), (Yuan, 2006).

Because each nonattainment area has unique emissions sources and source-receptor relationships, air agencies should work closely with their EPA Regional office in developing local area analysis applications.

---

[74] This guidance document only applies to $PM_{2.5}$ attainment demonstrations to satisfy requirements in CAA Section 189. Other guidance documents and procedures are applicable for SO_2, NO_2, CO, and/or Pb attainment demonstrations and/or $PM_{2.5}$ permitting applications.

[75] The $PM_{2.5}$ emissions should be broken out into individual species using the best information available. Typically, SCC specific speciation profiles are used to "speciate" the PM into individual components. Local, source specific information should be used whenever possible.

NMED Exhibit 108

4.6.2.1 Double Counting

Application of a local area analysis may result in double counting of local emissions sources and reductions. This can happen when a change in emissions is examined with both a dispersion model and a chemical transport model.

The potential for double counting can be evaluated by considering the grid resolution of the chemical transport model and the number of sources in the dispersion model. The finer the resolution of the grid model, the more double counting may be a problem (because the local sources will be more finely resolved). Additionally, the more sources that are run with the dispersion model, the more double counting may be a problem. If the grid cell size is relatively large (e.g., 12km) and the primary emissions are relatively small, it may be possible to assume that double counting is small enough to be ignored. But the nature of the issue should be evaluated on a case by case basis.

The simplest way to evaluate the magnitude of the problem is to run the chemical transport model with and without the sources from the dispersion model. This will indicate the maximum impact that the sources can have on the chemical transport modeling results. A very small impact means that double counting is not a problem. A large impact indicates that a more explicit analysis is needed in order to resolve double counting issues.

4.6.2.2 Analysis of Primary $PM_{2.5}$ at Monitors- Quality Assurance

As with any modeling exercise, it is important to quality assure the model inputs and outputs. In particular, we recommend focused quality assurance checks on emissions from sources flagged for a dispersion modeling analysis. Prior to applying a model, air agencies should review available information to ensure that there are no major discrepancies between modeled estimates and nearby monitored data for PM. The emission factors, activity data, and speciation profiles of the $PM_{2.5}$ emissions should also be analyzed for accuracy. If a speciation monitor exists, the speciated data from the monitor can be compared to the speciation profiles of the flagged sources. Receptor models can also be used as a QA tool. Discrepancies between receptor modeling results (which are based on analyzing ambient data) and speciated emissions may indicate a problem with the magnitude and/or the speciation of the emissions sources. If discrepancies are found, those implementing the modeling protocol (see section 2.1) should consult with the appropriate EPA Regional office to reach agreement on what, if any, adjustments should be made to the emissions estimates for the identified sources.

NMED Exhibit 108

It is also important to quality assure the model outputs. Modeling each species of primary $PM_{2.5}$ separately within the dispersion model should aid in this analysis, especially if the selected control strategies applied in the future year do not control each primary species to the same degree. If a speciation monitor exists, the speciated data from the monitor may also help quality assure the dispersion model results. However, the application of the dispersion model results in a relative sense will help to reduce the impact of possible over- or under-estimations by the dispersion model due to emissions, meteorology, or general selection of other model input parameters.

4.7 Estimating design values at unmonitored locations

High ozone and/or $PM_{2.5}$ concentrations can occur at (or near) existing ambient monitors or in unmonitored areas. The modeled attainment test is primarily a monitor-based test. As such, the focus of the attainment test is whether attainment can be reached at existing monitors.
An additional "unmonitored area analysis" can also be performed to examine ozone and/or $PM_{2.5}$ concentrations in unmonitored areas. The unmonitored area analysis is intended to be a means for identifying high ozone and/or $PM_{2.5}$ concentrations outside of traditionally monitored locations, particularly in nonattainment areas where modeling or other data analyses have indicated potential high concentration areas of ozone and/or $PM_{2.5}$ outside of the existing monitoring network. An unmonitored area analysis may also be more important in areas where the ozone or $PM_{2.5}$ monitoring networks just meet or minimally exceed the minimum required network in a nonattainment area.

This review can help ensure that a control strategy leads to reductions in ozone or $PM_{2.5}$ at other locations which could have base case (and future) design values exceeding the NAAQS were a monitor deployed there. In addition, analysis of concentrations in unmonitored areas may serve other purposes such as helping to site new (or move existing) monitors, examining health benefits from emissions reductions, and analyzing the impact of potential new or modified emissions sources. This document describes how an unmonitored area analysis can be performed for a particular area. See the respective ozone and $PM_{2.5}$ SIP Requirements Rules (including the preambles and response to comments documents) for more information on when an unmonitored area analysis is recommended or required.

We use the term "unmonitored area analysis" to describe an analysis that uses a combination of model output and ambient data to identify areas that might exceed the NAAQS in areas that are not currently monitored. An unmonitored area analysis for a particular nonattainment area is intended to address the potential for air quality problems within or near that nonattainment

NMED Exhibit 108

area. The analysis should include, at a minimum, all nonattainment counties and counties surrounding the nonattainment area, as appropriate. It is possible that unmonitored area violations may appear in counties far upwind or downwind of the local area of interest. In those cases, the distance to the nonattainment area and ability of the modeling to represent far downwind areas should be evaluated on a case-by-case basis.

The spatial resolution of the unmonitored area analysis should be consistent with the appropriate model resolution for the attainment demonstration. For example, if the attainment demonstration for ozone or $PM_{2.5}$ is conducted at 12km grid resolution, then in most cases, the unmonitored area analysis should also be performed at the same horizontal resolution.

4.7.1 Why does the unmonitored area analysis need to use both ambient data and model output?

When performing an unmonitored area analysis, it is recommended to use interpolated spatial fields of ambient data in combination with gridded modeled outputs (i.e., fused surfaces). Ambient data can be interpolated to provide a set of spatial fields. The resultant spatial fields will provide an indication of pollutant concentrations in monitored and unmonitored areas. But interpolated ambient data cannot identify unmonitored areas with higher concentrations than those measured at monitors. The interpolated concentration between monitors will generally be the same or lower than the measured concentration at the monitors (assuming that more sophisticated statistical techniques are not used). Simple interpolation techniques do not account for emissions or chemistry information that may be needed to identify high concentrations in unmonitored areas.

In addition to interpolated surfaces, gridded model output (absolute) concentrations (from a chemical transport model) can be used to examine unmonitored area concentrations. The model provides an hourly concentration output for every grid cell. The concentrations can be analyzed to determine unmonitored areas where the model predicts high values. But the absolute predictions from the model may not be entirely accurate (they may be biased high or low). But unlike the interpolated ambient data, the model explicitly accounts for emissions, chemistry, and meteorological processes over the entire domain.

Interpolated ambient data and absolute model outputs both have strengths and weaknesses. We can take advantage of the strengths of each dataset by combining the two types of data. Interpolated spatial fields of ambient data provide a strong basis for estimating accurate pollutant concentrations at and near monitor locations. And the model outputs can be used to

NMED Exhibit 108

adjust the interpolated spatial fields (either up or down) so that more accurate estimates can be derived in unmonitored areas.[76] A recommended way to use the modeling in the creation of fused surfaces is to adjust the ambient spatial fields using the concentration *gradients* derived from the model predictions. It is preferable to assume that the model is accurately predicting areas of generally high or low ozone or PM, rather than to assume that the absolute predictions from the model are correct. For example, in unmonitored locations where the model predicts relatively high ozone or PM concentrations, the spatial fields can be adjusted upward. In unmonitored locations where the model predicts relatively low ozone or PM concentrations, the spatial fields can be adjusted downward. In this way, it may be possible to predict unmonitored locations that may be likely to record high concentrations (were a monitor located there). We refer to this combination of interpolated spatial fields and modeled output as "gradient adjusted spatial fields."

4.7.2 Implementation of Gradient Adjusted Spatial Fields

A recommended methodology for developing gradient adjusted spatial fields is to first create base year fields. Future year estimates can then be created by applying gridded RRFs to the base year gradient adjusted spatial fields. The basic steps are as follows:

1) Interpolate base year ambient data to create a set of spatial fields.
2) Adjust the spatial fields using gridded model-based spatial gradients (base year values).
3) Apply gridded model-based RRFs to the gradient adjusted spatial fields.
4) Determine if any unmonitored areas are predicted to exceed the NAAQS in the future.

EPA's SMAT will spatially interpolate data, adjust spatial fields based on model output gradients, and multiply the fields by model calculated RRFs (steps 1-3 above) (U.S. EPA, 2018), (ABT, 2014). Air agencies can use the EPA-provided software or may wish to develop alternative techniques that may be appropriate for their area, situation, and/or purpose. Air Agencies should consult with the appropriate EPA Regional office to determine if and how an unmonitored area analysis should be conducted.

Step 1

The first step in developing an unmonitored area analysis is to interpolate ambient data. Ideally, design values should be interpolated. Either the 5-year weighted average design values

[76] The accuracy of interpolated fields can be evaluated by removing data from monitors (either in groups or one at a time) to see how well the interpolation scheme estimates known concentrations at ambient monitoring sites. This is known as a cross-validation.

that are used in the monitor based modeled attainment test or a single design value period can be used in the development of ambient spatial fields. Care should be taken so that the interpolated fields are not unduly influenced by monitoring sites that do not have complete valid data. Since the design values can vary significantly from year to year, it is important to use a consistent set of data.

We are not recommending a single interpolation technique. EPA's SMAT uses the Voronoi Neighbor Averaging (VNA) interpolation technique. Past analyses have used a Kriging interpolation technique (U.S.EPA, 2004).

For ozone analyses, a single spatial field of ozone values is needed. But for the $PM_{2.5}$ NAAQS, the EPA recommends creating interpolated spatial fields for $PM_{2.5}$ (FRM) and for each component species of $PM_{2.5}$. For the annual $PM_{2.5}$ NAAQS, a set of quarterly average spatial fields can be created. The four quarters are averaged to get an annual average set of fields.

For the 24-hour $PM_{2.5}$ standard, a spatial field can be created using the high end of the distribution of 24-hour $PM_{2.5}$ concentrations. This is best represented by interpolating the measured high values from each quarter. For the $PM_{2.5}$ component species, we recommend interpolating the high $PM_{2.5}$ days in each quarter. This can be based on the highest monitored days in each quarter.

Step 2

The second step in the process involves the use of gridded model output to adjust the spatial fields derived from ambient data. SMAT uses the eVNA technique, where the VNA interpolation is "enhanced" by adjusting the interpolated values based on the modeled ozone or PM (or PM species) gradient. See the SMAT user's guide for more details (U.S. EPA, 2018), (Abt, 2014). Other "model adjusted" spatial fields techniques include Hierarchical-Bayesian (McMillan, 2010) and "Downscaler" (Berrocal, 2010a and 2010b).

A specific metric is needed to determine the model predicted gradient in concentrations for each of the NAAQS. For ozone, a logical metric is the 4th highest ozone prediction in each grid cell.[77] For the annual $PM_{2.5}$ NAAQS, the model predicted quarterly mean concentrations for $PM_{2.5}$ and $PM_{2.5}$ species can be used to adjust the ambient spatial fields. For the 24-hour $PM_{2.5}$ NAAQS, the gradient adjusted fields can be derived from the high end of the distribution of

[77] The metric should approximate the measured design values at monitoring sites. Depending on the days modeled, other metrics, such as the average of the top 4 modeled days may be a better proxy for the design value.

NMED Exhibit 108

daily averages in each quarter. This could be for the top 10% of modeled days in each quarter or for all days with 24-hour average concentration > 35 µg/m3 (or some other relatively high value).

Step 3

The next step is to create future year spatial fields by multiplying the base year gradient adjusted spatial fields by model derived gridded RRFs. The RRFs for the unmonitored area analysis are calculated in the same way as the monitored based attainment test (except that the grid cell array is not typically used in the spatial fields based analysis). The future year concentrations are equal to the base year concentration multiplied by the RRF in each grid cell. For ozone, a single spatial field is multiplied by a single set of model derived RRFs. For $PM_{2.5}$, the RRFs for each of the species, for each quarter, are multiplied by the spatial fields for each species, for each year.

4.7.3 Using the Results of the Unmonitored Area Analysis

For ozone and/or $PM_{2.5}$ attainment demonstrations, the future year gradient adjusted spatial fields can be analyzed to determine if any grid cells are predicted to remain above the NAAQS. States should consult with their EPA Regional office to determine if an unmonitored area analysis should be conducted for a particular nonattainment area and, if so, how the analysis should be conducted and how the results should be used.

NMED Exhibit 108

5.0 What Is the Recommended Modeling Method for Developing Air Quality Goals for Regional Haze?

This section focuses on the modeling analysis needed to set RPGs that reflect the enforceable emission limitations, compliance schedules, and other measures included in the long-term strategy of a regional haze SIP.[78] In this section, we describe the recommended modeled analysis to assess visibility conditions at the end of an implementation period (i.e., the future end-point of a multi-year planning period under the regional haze program). The visibility analysis has many similarities to the $PM_{2.5}$ attainment tests described in sections 4.4 and 4.5. The recommended visibility analysis and the attainment tests both use monitored data to define base year air quality. They divide $PM_{2.5}$ into major species, and component-specific relative response factors are multiplied by base year monitored values to estimate future concentrations.

Section 5.1 provides background information on the requirements of the Regional Haze Rule and explains how RPGs are used in the regional haze program once they are set. The rest of the section describes the recommended modeling analysis to evaluate future year changes in visibility impairment. This document does not address how a state should develop its long-term strategy of emissions controls for regional haze or determine the uniform rate of progress for a Class I area.

5.1 Regional Haze Rule Background

The modeling results are used to quantify the amount of progress, expressed in deciviews of visibility improvement, anticipated to be made at individual Class I areas as of the end of an implementation period. Reasonable progress goals are calculated separately for the 20% most impaired days and the 20% clearest days at each Class I area. These values are then compared to visibility conditions in the "baseline period" (2000-2004 for most areas)[79] for the same type of

[78] The main regional haze section of the guidance is related to setting reasonable progress goals. However, the guidance methods may also be applicable to other regional haze related modeling, including, but not limited to, evaluation of visibility impacts from sources and/or source sectors (including international impacts).

[79] In the context of attainment demonstrations for ozone and $PM_{2.5}$, the term "baseline period" is commonly used to refer to the base period used for modeling. Because the Regional Haze Rule defines "baseline period" specifically as 2000-2004, this section uses "baseline" and "baseline period" only when referring to 2000-2004. The term "base period" is used when referring to a more recent 5-year period used in the modeling-based projection of RPGs.

days (i.e., most impaired and clearest) to verify that the SIP provides for an improvement in visibility on poor visibility days and allows no degradation in visibility on good visibility days. The RPGs for the most impaired days are also plotted against the uniform rate of progress that would be needed at individual Class I areas to achieve natural visibility conditions in 2064, starting at baseline visibility conditions for 2000-2004. The results of this comparison inform whether the SIP must contain an additional component demonstrating that no additional control measures are necessary to make reasonable progress.

Reasonable progress goals are a regulatory construction promulgated to implement the statutory requirements for visibility protection. Section 169A(a)(1) of the Clean Air Act states, "Congress hereby declares as a national goal the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory class I Federal areas which impairment results from manmade air pollution." This section later directs EPA to promulgate regulations to assure reasonable progress towards meeting this goal. Section 169B calls for EPA to "carry out the Administrator's regulatory responsibilities under [Section 169A], including criteria for measuring 'reasonable progress' toward the national goal."

In response to these mandates, EPA promulgated the Regional Haze Rule on July 1, 1999.[80] The rule was revised on January 10, 2017.[81] The regulations promulgated at 40 CFR 51.308(f) contain the relevant requirements for SIPs for the second and subsequent implementation periods, which are the SIPs that this guidance document addresses. Under section 51.308(f)(2), every state must determine the emission limitations, compliance schedules, and other measures that are necessary to make reasonable progress at Class I areas in the state and other Class I areas that may be affected by sources in the state. The collection of these measures is referred to as the long-term strategy. Under section 51.308(f)(3), a state in which a mandatory Class I Federal area is located must establish RPGs, one each for the 20% most impaired days and the 20% clearest days (expressed in deciviews) for each such area. These RPGs reflect the visibility conditions that are projected to be achieved by the end of the applicable implementation period as a result of its own and other states' long-term strategies, as well as the implementation of other requirements of the CAA. They are interim goals that represent the incremental visibility improvement achieved in each implementation period toward Congress's goal of eliminating visibility impairment from manmade emissions sources. The long-term strategy and the RPGs are developed in consultation with other affected air agencies and

[80] *See* 64 FR 35714.
[81] *See* 82 FR 3078.

NMED Exhibit 108

Federal Land Managers.[82]

The Regional Haze Rule contains the following requirements that involve the RPGs once they have been set.

> The reasonable progress goals (RPGs) must provide for an improvement in visibility for the 20% most anthropogenically impaired days relative to baseline visibility conditions and ensure no degradation in visibility for the 20% clearest days relative to baseline visibility conditions.[83] As explained in the RHR, the baseline for each Class I area is the average visibility (in deciviews) for the years 2000 through 2004.[84] The visibility conditions in these years are the benchmark for both the "provide for an improvement" and "no degradation" requirements.
>
> States are also required to determine the rate of improvement in visibility needed to reach natural conditions by 2064 for the 20% most anthropogenically impaired days, given the starting point of the 2000-2004 baseline.[85] The "glidepath," or uniform rate of progress (URP), is the amount of visibility improvement needed to stay on a linear path from the baseline period to natural conditions. Every state must compare its RPG for the 20% most anthropogenically impaired days to the point on the glidepath corresponding to the end of the implementation period. The results of this comparison determine whether a SIP must contain a demonstration that no additional emission reductions are needed to make reasonable progress towards achieving natural visibility conditions.

This section does not address the process of calculating the glidepath or determining the measures for inclusion in the long-term strategy.[86]

5.2 How is Regional Haze Measured?

Regional haze is measured by an *extinction coefficient* (b_{ext}) that represents light attenuation resulting from scattering and absorption of light from ambient PM plus scattering of light due to gas molecules in the air (i.e., Rayleigh scattering). Although b_{ext} can be estimated by several

[82] *See* 40 CFR 51.308(f)(2)(ii) and 51.308(i).

[83] *See* 40 CFR 51.308(f)(3)(i).

[84] *See* 40 CFR 51.308(f)(1) and definitions in 51.301.

[85] *See* 40 CFR 51.308(f)(1).

[86] For more details on calculating the URP and regional haze policy guidance, see draft guidance for the second implementation period [note that the draft guidance document will be updated in Spring 2019].

different methodologies, the RHR requires that it be estimated using measured ambient PM. This follows since, for a given set of meteorological conditions, visibility can be improved by reducing concentrations of ambient PM. Thus, deriving b_{ext} in this manner provides a direct link between regional haze and related pollutant concentrations.

5.2.1 IMPROVE Algorithm

The IMPROVE equation or algorithm reflects empirical relationships derived between measured mass of PM components and transmissometer measurements of b_{ext} at a subset of monitoring sites in Class I areas within the IMPROVE monitoring network. The IMPROVE program revised the IMPROVE algorithm in 2006 (Hand, 2006); (Pitchford, 2007). The revised algorithm is intended to reduce biases in light extinction estimates. The revised algorithm is as follows:

$$
\begin{aligned}
b_{ext} = {} & 2.2 \times f_s(RH) \times [\text{Small Sulfate}] + 4.8 \times f_L(RH) \times [\text{Large Sulfate}] \\
& + 2.4 \times f_s(RH) \times [\text{Small Nitrate}] + 5.1 \times f_L(RH) \times [\text{Large Nitrate}] \\
& + 2.8 \times [\text{Small Organic Mass}] + 6.1 \times [\text{Large Organic Mass}] \\
& + 10 \times [\text{Elemental Carbon}] \\
& + 1 \times [\text{Fine Soil}] \\
& + 1.7 \times f_{ss}(RH) \times [\text{Sea Salt}] \\
& + 0.6 \times [\text{Coarse Mass}] \\
& + \text{Rayleigh Scattering (site specific)} \\
& + 0.33 \times [NO_2 \text{ (ppb)}] \qquad \textbf{[5.1]}
\end{aligned}
$$

The numerical coefficients on the right hand side of the equation represent the light scattering or absorption efficiency, m^2/gm of the corresponding component of particulate matter,

$f_s(rh)$, $f_L(rh)$, $f_{ss}(rh)$ are relative humidity adjustment factors applied to the light scattering efficiency (to be described in greater detail shortly), dimensionless;

SO_4 is the mass associated with sulfates, $\mu g/m^3$;

NO_3 is the mass associated with nitrates, $\mu g/m^3$;

OC is the mass associated with organic carbon, $\mu g/m^3$;

EC is the mass associated with elemental carbon, $\mu g/m^3$;

NMED Exhibit 108

Fine Soil is inorganic primary particulate matter (excluding primary sulfate and nitrate particles) associated with soil components with aerodynamic diameter $\leq$ 2.5 µm, µg/m^3;

CM is coarse PM with aerodynamic diameter > 2.5 µm, but $\leq$ 10 µm, µg/m^3;

$b_{rayleigh}$ is light-scattering attributable to Rayleigh scattering, Mm^{-1} (i.e., inverse "mega-meters"); and

b_{ext} is the estimated extinction coefficient, Mm^{-1}.

The total sulfate, nitrate and organic mass concentrations are each split into two fractions, representing small and large size distributions of those components. The organic mass concentration is calculated as 1.8 times the measured IMPROVE organic carbon concentration, to adjust for organic mass from elements other than carbon. Terms are included for sea salt (important for coastal locations) and for absorption by NO_2 (only used where NO_2 data are available). Site-specific Rayleigh scattering is calculated based on the elevation and annual average temperature of each IMPROVE monitoring site.

The apportionment of the total concentration of sulfate compounds into the concentrations of the small and large size fractions is accomplished using the following equations:

[Large Sulfate] = [Total Sulfate]/20 µg/m^3 x [Total Sulfate], for [Total Sulfate] < 20 µg/m^3
[Large Sulfate] = [Total Sulfate], for [Total Sulfate] $\geq$ 20 µg/m^3

[Small Sulfate] = [Total Sulfate] - [Large Sulfate]

The same equations are used to apportion total nitrate and total organic mass concentrations into the small and large size fractions.

Sea salt is calculated as 1.8 x [Chloride] or 1.8 x [Chlorine] if the chloride measurement is below detection limits, missing or invalid. The algorithm also uses three water growth adjustment terms. They are for use with the small size distribution and the large size distribution sulfate and nitrate compounds and for sea salt (f_S(RH), f_L(RH) and f_{SS}(RH) respectively).

All or nearly all states used the revised algorithm in their SIPs for the first implementation period and the IMPROVE program has stopped reporting visibility data using the original

IMPROVE equation. Therefore, we now recommend using the revised IMPROVE equation for all reasonable progress related modeling calculations.

5.2.2 Deciview Haze Index

The RHR requires that reasonable progress is to be measured in terms of changes in a *deciview haze index* or simply "deciviews" (dv). Deciviews are defined as the natural logarithm of the ratio of the extinction coefficient to Rayleigh scattering (Pitchford and Malm, 1994).

$$\text{Deciview} = 10 \ln(b_{ext}/10) \qquad \textbf{[5.2]}$$

Where the units of b_{ext} and light scattering due to Rayleigh scattering[87] (i.e., the "10" in the denominator of the logarithmic expression) are both expressed in Mm^{-1}.

A *change* in deciviews, which is how progress is tracked, is given by Equation (5.3). A one deciview change is equivalent to ~10% change in b_{ext}.

$$\Delta dv = dv_{future} - dv_{base} \qquad \textbf{[5.3]}$$

A negative number indicates a reduction in deciviews, which is an improvement in visibility.

5.2.3 Estimating Mass Associated with Components of Particulate Matter

All Class I areas either have on-site speciated $PM_{2.5}$ measurements or have been assigned a representative IMPROVE monitoring site with measurements.[88] Therefore, it is generally not necessary to interpolate measured $PM_{2.5}$ species data to a site. The existing IMPROVE database of $PM_{2.5}$ measurements should be adequate to provide data for all Class I areas.[89]

FRM data is not used in the regional haze analysis and it is not necessary for the sum of species

[87] Even though the "revised" IMPROVE equation uses a site-specific Rayleigh scattering value, the denominator in the deciview equation should always be 10. In this way, the deciview calculation will be consistent across all Class I areas. When the site-specific Rayleigh scattering is less than 10 (at high elevation sites), the deciview value can be negative (on very clean days), but this should not be considered a problem.

[88] See U.S. EPA 2003b, Appendix A, Table A-2.

[89] There are some IMPROVE sites that do not have enough complete data to provide baseline condition information for the 2000-2004 period. Data substitution is addressed in 40 CFR 51.308(f)(1)(i) and also discussed in (U.S. EPA 2003b).

NMED Exhibit 108

components to equal gravimetric measurements obtained with a Federal Reference or equivalent method for measuring $PM_{2.5}$. Therefore, for regional haze calculations, it is not necessary to use the speciated data adjustment procedures introduced in section 4.4 (the "SANDWICH" adjustments).

Hand (2006) has developed a set of default assumptions for mass associated with each of the components of PM for Equation (5.1). These are presented in Table 5.1. The components in Table 5.1 are similar to those used in the modeled attainment demonstrations for the $PM_{2.5}$ NAAQS. Notice, however, that sulfate and nitrate mass are assumed to be fully neutralized (therefore, ammonium is not needed as a separate component); organic carbon is assumed to be equal to 1.8 times **measured** OC mass; there is no water component; and there is a term for coarse PM.

Table 5.1. Default Assumptions Used to Derive Aerosol Species Concentrations from IMPROVE Data for Estimating Extinction Coefficients

(1) Species	(2) Formula	(3) Assumptions
Sulfate	**1.375 *measured SO4**	**Sulfate is assumed to be fully neutralized (ammonium sulfate)**
Nitrate	**1.29 * measured nitrate**	**Denuder efficiency is ~100% & all nitrate is from ammonium nitrate**
EC	**high + low temperature EC**	**All high temperature carbon is elemental**
OC	**1.8 * organic carbon**	**Average organic molecule is 56% carbon**
Fine Soil	**2.2*Al + 2.49*Si + 1.63*Ca + 2.42*Fe + 1.94*Ti**	**(Soil K)=0.6(Fe), FeO & Fe_2O_3 are equally abundant, a factor of 1.16 is used for MgO, Na_2O, H_2O & CO_3**
Sea Salt	**1.8*Cl-**	**Sea salt is 55% chloride ion by weight**

$PM_{2.5}$		**-Measured gravimetrically -Represents dry ambient fine aerosol mass**
CM (coarse mass)	**(PM_{10}) - ($PM_{2.5}$)**	**Consists only of insoluble soil particles**

Throughout this section we make every attempt to be consistent (aside from the use of the revised IMPROVE algorithm) with corresponding parts of the "Guidance for Tracking Progress under the Regional Haze Program" (hereafter referred to as the "Tracking Guidance") (U.S. EPA, 2003b). It will be easier to interpret the modeling results and compare them to measured values if the modeled future year data are calculated in a manner similar to the ambient data.

5.2.4 Normalizing Trends in Regional Haze - f(rh) Factors

It is clear from equation 5.1 that relative humidity can have a substantial effect on estimated extinction coefficients, as well as the relative importance of changes in different components of PM on trends in regional haze. Because of the importance of relative humidity as a determinant of regional haze, it is necessary to normalize any apparent trend in the estimated extinction coefficient for differences in relative humidity. This enables an assessment of how much an emissions control strategy will reduce regional haze, without the confounding effects of different relative humidity levels during the base and future periods.

There are two possible approaches to normalize trends in visibility for changes in relative humidity between the past and future. The first is to assume that the same day-specific values for relative humidity which were observed in the base period calculations will occur in future years. Thus, one would use the relative humidity observations made on a specific day together with measured components of particulate matter on that day to compute the day-specific visibility extinction coefficient on that day in the future. However, the approach could lead to misleading conclusions if humidity observations were missing for some days or if the humidity observations are atypical in some way. Further, if an air agency wanted to perform visibility calculations in a number of Class I areas, it would need to obtain hourly relative humidity data for each area.

The second approach is to review relative humidity data over a long period of record to derive climatological estimates for relative humidity adjustment factors. These climatological estimates can then be used in Equation 5.1 to estimate visibility extinction coefficients. These

NMED Exhibit 108

estimates are more likely to reflect "typical" relative humidity at different times of year and, thus, expected future visibility extinction.

There are obvious advantages in using climatological f(rh) data for tracking progress of measured data. The measured relative humidity on the 20% most impaired days in a historical period will be different than the measured relative humidity in a future period. Therefore, the only way to normalize for relative humidity between the base and future years in the context of measured data is to use a single climatological value. However, in the context of modeling, there is a choice between climatological data or modeled (or measured) relative humidity data from a meteorological model. Since the modeled meteorological data is held constant when predicting future year air quality, the modeled relative humidity values would also be constant. This would be one way to normalize the data. But since the Tracking Guidance recommends tracking visibility using climatological f(rh) values, it will be easier to interpret the modeling results and compare them to future measured values if the data are calculated in a similar manner. Therefore, we recommend using climatological f(rh) values to calculate base period and future visibility. Appendix A (Table A-1) from the Tracking Guidance displays the relationship between relative humidity and f(rh) values. The f(rh) values were calculated from relative humidity data reported by Tang (1996). The f(rh) values are 1.00 up to 36% relative humidity and grow to a maximum value of 7.40 at a relative humidity of 95%.[90] These values were calculated using 10 years of meteorological data.

For calculations with the revised IMPROVE equation, three separate f(rh) curves are needed (small, large, and sea salt). These can be found in (Hand, 2006). The monthly f(rh) values for both the old and revised IMPROVE equations have been incorporated into pre-calculated daily extinction and deciview data that can be found on the IMPROVE website. The use of pre-calculated f(rh) and visibility data makes it easier for air agencies and regional organizations to calculate visibility changes and will also provide for more consistency.

5.3 How Do I Apply a Model to Calculate Changes in Visibility?

The purpose of a regional haze modeling assessment is to project future visibility conditions representing the RPGs, which are used to satisfy the requirements described in section 5.1. In

[90]For the regional haze calculations, the f(rh) factors have been capped at the f(rh) value associated with 95% relative humidity. Relative humidity value above 95% use the same value.

NMED Exhibit 108

the procedures below, the observed base period visibility data should be linked to the base modeling year. Similar to the ozone and $PM_{2.5}$ attainment tests, the 5-year ambient data period should be centered about the base modeling year. For example, for a base modeling year of 2014, the ambient IMPROVE data should be from the 2012-2016 period.[91] However, unlike the ozone and $PM_{2.5}$ attainment tests, the calculation is a 5-year mean where each year counts equally (unlike the 5-year weighted average values for the ozone and $PM_{2.5}$ attainment test). This is consistent with the regional haze rule ambient data calculations for the 20% most impaired days and 20% clearest days. The analysis we recommend has 6 steps.

1) For each Class I area, estimate anthropogenic impairment on each day using observed speciated $PM_{2.5}$ and PM_{10} data plus climatological f(rh) and Rayleigh scattering data for each of the 5 years comprising the base period (this estimation step is not addressed in this document), and rank the days on this indicator. This ranking will determine the 20% most anthropogenically impaired days and the 20% clearest days.
2) For each of the 5 years comprising the base period, calculate the mean deciviews for the 20% most anthropogenically impaired days and 20% clearest days. For each Class I area, calculate the 5-year mean deciviews for most impaired and clearest days from the 5 year-specific values.
3) Use an air quality model to simulate base period emissions and future emissions. Use the resulting information to develop RRFs for each component of PM identified on the right-hand side of Equation (5.1).
4) Multiply the RRFs by the measured species concentration data during the base period (for the measured 20% most impaired days and 20% clearest days). This results in daily future year species concentrations data.
5) Using the results in Step 4 and the IMPROVE algorithm (equation 5.1), calculate the future daily extinction coefficients for the 20% most impaired days and 20% clearest days in each of the 5 base years.
6) Calculate daily deciview values (from total daily extinction) and then compute the future average mean deciviews for the 20% most impaired days and 20% clearest days for each

[91] The *baseline period* for the regional haze program continues to be 2000-2004, and the uniform rate of progress is calculated using that historical data. However, the modeled reasonable progress visibility projections should use ambient data from a 5-year *base period* that corresponds to the modeled base year meteorological and emissions data. In addition, ambient data trends for the 5-year base period should be examined to make sure the base modeling year emissions are representative of the period. In some cases, an alternative base ambient data period may be more representative of a base modeling year.

NMED Exhibit 108

year. Average the 5 years together to get the final future year mean deciview values for the 20% most impaired days and 20% clearest days.

We describe each of these steps more fully below. The methodology follows the same basic procedures outlined in the Tracking Guidance, however, based on the revised regional haze rule, a draft methodology (for steps 1 and 2) is available for calculating the most anthropogenically impaired and clearest days (U.S. EPA, 2016d).[92] We conclude this subsection with an example illustrating the recommended modeled uniform rate of progress analysis.

Step 1. Using monitored data, rank base period visibility for each day with PM_{10}, $PM_{2.5}$ and speciated $PM_{2.5}$ measurements within a Class I area.

Ranking should be performed separately for each of the 5 years comprising the base period.[93] The deciview (dv) should serve as the basis for ranking. Day-specific observations for mass associated with SO_4, NO_3, OC, EC, soil, and CM, as defined in Table 5.1, should be used to calculate b_{ext} for each day. The appropriate month- and area-specific climatological relative humidity adjustment factor(s) (*f(rh)*) should be used. Total b_{ext} for all components should be converted to deciviews for each day to get a daily deciview value.

Step 2. Calculate the average base period deciviews for the 20% most anthropogenically impaired days and 20% clearest days.

For each of the 5 years in the base period, order all days considered in Step 1 from worst (highest deciview value) to best (lowest deciview value) visibility. For each year, note the 20% most impaired days and 20% clearest days. Calculate the arithmetic mean deciview value for the identified 20% most impaired days and 20% clearest days in each year. Average the resulting 5 yearly mean deciview values reflecting the most impaired days. This represents the value subject to improvement requirement (i.e., the value must decrease). Average the 5-yearly mean deciview values reflecting mean visibility on the clearest days. This is the value subject to the requirement of no degradation (i.e., the value cannot increase).

[92] A final recommendation is expected in Fall 2018.

[93] Pre-calculated and ranked anthropogenic impairment, extinction, and deciview calculations for all Class I areas is available on the IMPROVE website. This data can be used to satisfy steps 1 and 2. States may also choose to use an alternative methodology to calculate anthropogenic impairment for Class I areas, which may differ from the default EPA recommended methodology. States should consult with their EPA Regional office to discuss appropriate methodologies for alternative impairment calculations.

NMED Exhibit 108

Step 3. Estimate RRFs for each component of $PM_{2.5}$ and for CM.

The RRFs should be determined using results from air quality modeling of base year and future year emissions. These model simulations should be performed for a large number of days (presumably at least a full year; see section 2.3.1 for more details). The (temporal) arithmetic mean concentration for each $PM_{2.5}$ component (and coarse mass) computed near the Class I monitoring site from the future year modeling is divided by the corresponding arithmetic mean concentration for each component from the base year modeling. The resulting ratios are the component-specific RRF's. A separate set of RRF values are calculated for the 20% most impaired days and 20% clearest days identified in step 2. The RRFs are calculated using the model outputs corresponding to the *monitored* 20% most impaired days and 20% clearest days at each Class I area. This will likely be a different set of days at each monitor.

Step 4. Using the RRFs and ambient data, calculate future year daily concentration data for the clearest and most impaired days.

Multiply the RRFs derived in Step 3 by measured daily concentration data for each component of $PM_{2.5}$ and CM to get future daily estimates of species concentrations for $PM_{2.5}$ components and CM on the 20% most impaired days and 20% clearest days. These multiplications produce future concentration estimates for SO_4, NO_3, OC, EC, soil, sea salt, and CM for each of the previously selected 20% most impaired days and 20% clearest days. This calculation is performed for the 5-year period using an RRF for each PM component (a separate set of RRFs for the 20% most impaired days and 20% clearest days).

Step 5. Use the information developed in Step 4 to compute future year daily b_{ext} values for the 20% most impaired days and 20% clearest days.

Use the future year concentration data calculated in step 4 to calculate future year daily b_{ext} values for each PM component for each of the 20% most impaired days and 20% clearest days for the 5-year period. This is accomplished by applying the revised IMPROVE visibility algorithm (equation 5.1).

Step 6. Use the daily total b_{ext} values from step 5 to calculate future mean deciview values for the 20% most impaired days and 20% clearest days .

The total daily b_{ext} for each day is converted to deciviews. This gives a future year daily deciview value for each of the 20% most impaired days and 20% clearest days.

Next, compute the arithmetic mean future deciview value for the 20% most anthropogenically

impaired days and 20% clearest days for each year. This leads to five future estimated mean deciview values for the worst and five future estimated mean deciview values for the best visibility days. Compute the arithmetic mean of the five mean values for deciviews on the 20% most anthropogenically impaired days, and the arithmetic mean of the five mean deciview values estimated for the 20% clearest days. The resulting 5-year average mean values for deciviews on 20% most impaired days and 20% clearest days will be compared to the base period mean deciview values calculated in step 2. If the resulting change in deciviews is a negative number (future - base), this represents an improvement in visibility. The future year visibility value for the 20% most impaired days will also be compared to the glidepath to determine if the Class I area is expected to be on, above, or below the glidepath in the future implementation period.

Example 5.1

We use example 5.1 to illustrate the modeled visibility assessment. For ease of presentation, we assume there are only 10 speciated samples for PM in each of the 5 years comprising the base period. Since sampling occurs every third day, a typical sample size is ~120 days per year. We illustrate the calculations for the first base year and then furnish information regarding mean deciviews for the other 4 base years to illustrate subsequent steps in the test.

Given:

Ten days have measured components of PM in a Class I area during the first year of a 5-year base period. Table 5.2 below shows the measurements (in µg/m^3) for each of the 10 days. Table 5.2 also shows the date of each measurement and the corresponding climatological relative humidity adjustment factor (made up for this example) for the appropriate month and area.

Table 5.2 Example observed IMPROVE data at a Class I area

Day	Date	$f_S(RH)$	$f_L(RH)$	$F_{SS}(RH)$	Ammonium Sulfate (µg/m3)	$SO4_L$ (µg/m3)	$SO4_S$ (µg/m3)	Ammonium Nitrate (µg/m3)	$NO3_L$ (µg/m3)	$NO3_S$ (µg/m3)
1	1/7	3.82	2.75	3.91	2.004	0.201	1.804	1.050	0.055	0.995

Using the IMPROVE concentration data for the Class I area and modeled RRFs, calculate the future year extinction and deciview values for the 20% most impaired days and the 20% clearest days for the end of the implementation period addressed in the SIP.

Step 1. Using monitored data, rank base period visibility for each day with PM_{10}, $PM_{2.5}$, and speciated $PM_{2.5}$ measurements within a Class I area.

First, estimate the extinction coefficient for each day that has the needed PM measurements. This is done using the information in table 5.2 with Equation (5.1). For day 1 in year 1, the current extinction coefficient is:

b_{ext} = (2.2*3.82*1.804) + (4.8*2.75*0.201) + (2.4*3.82*0.995) + (5.1*2.75*0.055) + (2.8*2.567) + (6.1*0.457) + (10*0.345) + (1*0.106) + (1.7*3.91*0.214) + (0.6*+ 1.334) + 12

b_{ext} = 55.461 Mm^{-1}

Then convert extinction into deciviews:

dv = 10 * ln (55.461/10) = 17.131 dv

Base year extinction coefficients and deciviews for the remaining 9 days with monitored data in year 1 are calculated in a similar manner. The days are then ranked. The day with the highest impairment is given a rank of "1." The results of these calculations are displayed in the table 5.3 below. Based on these rankings, days 4 and 5 comprise the 20% most impaired. Days 2 and 8 comprise the 20% clearest days.[94]

[94] Note that this is an abbreviated example. The actual IMPROVE sampling schedule collects data every third day. Therefore, with a complete set of data, there will be ~121 samples per year at each site. Both the 20% most impaired days and 20% clearest days will be comprised of an average of ~24 sample days.

Table 5.3 Example observed IMPROVE extinction, deciviews, and rank at a Class I area

Day	Date	Rayleigh (Mm^{-1})	SO4 (Mm^{-1})	NO3 (Mm^{-1})	OM (Mm^{-1})	EC (Mm^{-1})	Soil (Mm^{-1})	CM (Mm^{-1})	Sea Salt (Mm^{-1})	B_{ext} [base period] (Mm^{-1})	Deciviews	Rank
1	1/7	12	17.809	9.897	9.975	3.447	0.106	0.801	1.425	55.461	17.131	5
2	2/24	12	17.777	3.621	3.195	1.500	0.058	1.203	0.891	40.244	13.924	9
3	4/15	12	23.049	11.139	7.702	2.411	0.589	3.557	2.231	62.678	18.354	3
4	6/20	12	43.421	4.905	7.967	2.815	0.367	2.129	0.857	74.460	20.077	1
5	7/14	12	27.743	4.327	12.249	2.969	0.343	3.751	1.118	64.499	18.641	2
6	8/10	12	36.711	1.687	5.467	2.680	0.134	1.194	0.187	60.061	17.928	4
7	8/28	12	23.369	2.351	5.481	1.624	0.190	1.512	1.199	47.726	15.629	7
8	9/18	12	18.556	4.546	3.117	1.234	0.112	2.328	5.473	47.366	15.553	8
9	10/21	12	15.695	1.577	3.811	0.943	0.218	1.198	0.607	36.048	12.823	10
10	12/14	12	19.267	8.817	4.418	2.475	0.170	1.248	0.328	48.723	15.836	6

Step 2. Calculate the average base year deciviews for the 20% most impaired days and 20% clearest days.

For year 1, mean deciview value for 20% most impaired days = (20.077 + 18.641) / 2 = 19.359 dv,
and mean deciview value for the 20% clearest days = (12.823 + 13.924) / 2 = 13.374 dv

Mean deciview values for the 20% most impaired and 20% clearest days for years 2-5 are provided in table 5.4.

Table 5.4 Example mean worst days visibility and best days visibility at a Class I area

Year	Mean $dv_{current}$ 20% Most Anthropogenically Impaired Days	Mean $dv_{current}$ 20% Clearest Days
1	19.35	13.37
2	20.32	12.54
3	19.21	11.78
4	18.93	12.32
5	18.34	12.91

The average mean base period visibility for the 20% most impaired and for the 20% clearest days is obtained by taking the arithmetic mean of these days for the 5 years. Thus, the 5-year mean of the average visibility for the 20% most impaired days is given by

$dv_{base\ period}$ = (19.35 + 20.32 + 19.21 + 18.93 + 18.34) / 5 = **19.23 dv**

The 5-year mean of the average visibility for the 20% clearest days is

$dv_{base\ period}$ = (13.37 + 12.54 + 11.78 + 12.32 + 12.91) / 5 = **12.58 dv**

Step 3. Apply a model to develop component specific RRF's for SO4, NO3, OC, EC, Soil and CM.

Tables 5.5 and 5.6 show the procedure for calculating component-specific relative response factors using an air quality model. The example shows the recommended calculation of RRFs for the 20% most impaired days in the year modeled (the abbreviated example assumes that the 20% most impaired days is represented by only 5 modeled days). The same calculation is repeated for the clearest days.

Table 5.5 Base year modeled species concentrations on the 20% most impaired days (in µg/m3)

Modeled Output	SO_4	NO_3	OC	EC	Soil	CM
Day 1	3.13	1.02	3.56	0.87	0.32	5.43
Day 2	5.21	3.11	4.67	1.23	0.34	4.68
Day 3	4.56	0.59	6.32	1.45	0.87	3.58
Day 4	5.51	1.67	4.56	0.54	1.07	4.67
Day 5	3.99	0.57	4.12	0.69	1.01	5.21
Mean Base Concentration	**4.48**	**1.39**	**4.65**	**0.96**	**0.72**	**4.71**

Table 5.6 Future year modeled species concentrations on 20% most anthropogenically impaired days (in µg/m3)

Modeled Output	SO_4	NO_3	OC	EC	Soil	CM
Day 1	2.45	0.91	3.54	0.82	0.36	5.51
Day 2	3.98	2.98	4.62	1.15	0.37	4.81
Day 3	3.56	0.50	6.30	1.32	0.92	3.76
Day 4	4.12	1.42	4.51	0.46	1.10	4.76
Day 5	2.87	0.39	4.07	0.61	1.08	5.34
Mean Future Concentration	**3.40**	**1.24**	**4.61**	**0.87**	**0.77**	**4.84**

Table 5.7 Component specific RRFs for the 20% most impaired days

Most Impaired days RRF	SO_4	NO_3	OC	EC	Soil	CM
RRF (mean future/mean base)	0.758	0.891	0.992	0.912	1.061	1.026

Step 4. Multiply the relative response factors times the measured daily species concentration data during the base period to compute future daily species concentrations.

In year 1, we previously identified days 4 and 5 as those included in the 20% most impaired days (i.e., see Step 1). Similarly, days 2 and 8 are the 20% clearest days (see Table 5.3). In this step, we estimate future concentrations for components of $PM_{2.5}$ and for CM for these two sets of days. This is done using information shown in tables presented in Steps 1 and 3 as well as the best days RRFs given in table 5.8 below:

Table 5.8 Component specific RRFs for the 20% clearest days

Clearest days RRF	SO_4	NO_3	OC	EC	Soil	CM
RRF (mean future/mean base)	0.780	0.752	0.956	0.768	1.022	1.043

NMED Exhibit 108

Most Anthropogenically Impaired Days

Day 4: $[SO_4]_{future} = (RRF)_{SO4}\ [SO_4]_{base\ period} = (0.758)\ [4.580] = 3.472\ \mu g/m^3$
$[NO_3]_{future} = (0.891)\ [0.528] = 0.470\ \mu g/m^3$
$[OC]_{future} = (0.992)\ [2.482] = 2.462\ \mu g/m^3$
$[EC]_{future} = (0.912)\ [0.282] = 0.257\ \mu g/m^3$
$[Soil]_{future} = (1.061)\ [0.367] = 0.389\ \mu g/m^3$
$[CM]_{future} = (1.026)\ [3.549] = 3.641\ \mu g/m^3$
$[Salt]_{future} = (1.00)\ [0.132] = 0.132\ \mu g/m^3$

Day 5: $[SO_4]_{future} = (0.758)\ [2.742] = 2.079\ \mu g/m^3$
$[NO_3]_{future} = (0.891)\ [0.416] = 0.371\ \mu g/m^3$
$[OC]_{future} = (0.992)\ [3.608] = 3.578\ \mu g/m^3$
$[EC]_{future} = (0.912)\ [0.297] = 0.271\ \mu g/m^3$
$[Soil]_{future} = (1.061)\ [0.343] = 0.364\ \mu g/m^3$
$[CM]_{future} = (1.026)\ [6.252] = 6.414\ \mu g/m^3$
$[Salt]_{future} = (1.00)\ [0.157] = 0.157\ \mu g/m^3$

Clearest Days

Day 2: $[SO_4]_{future} = (0.780)\ [2.290] = 1.786\ \mu g/m^3$
$[NO_3]_{future} = (0.752)\ [0.453] = 0.341\ \mu g/m^3$
$[OC]_{future} = (0.956)\ [1.073] = 1.026\ \mu g/m^3$
$[EC]_{future} = (0.768)\ [0.150] = 0.115\ \mu g/m^3$
$[Soil]_{future} = (1.022)\ [0.058] = 0.059\ \mu g/m^3$
$[CM]_{future} = (1.043)\ [2.004] = 2.090\ \mu g/m^3$
$[Salt]_{future} = (1.00)\ [0.150] = 0.150\ \mu g/m^3$

Day 8: $[SO_4]_{future} = (0.780)\ [1.759] = 1.372\ \mu g/m^3$
$[NO_3]_{future} = (0.752)\ [0.409] = 0.308\ \mu g/m^3$
$[OC]_{future} = (0.956)\ [1.049] = 1.003\ \mu g/m^3$
$[EC]_{future} = (0.768)\ [0.123] = 0.094\ \mu g/m^3$
$[Soil]_{future} = (1.022)\ [0.112] = 0.114\ \mu g/m^3$
$[CM]_{future} = (1.043)\ [3.880] = 4.047\ \mu g/m^3$
$[Salt]_{future} = (1.00)\ [0.725] = 0.725\ \mu g/m^3$

Similar calculations (using the same model derived component specific RRFs) are performed for each of the most impaired days and clearest days in each of the other 4 years in the base

period.[95]

Step 5. Using the results in Step 4, calculate the future year extinction coefficients for each of the 20% most impaired days and each of the 20% clearest days in each of the 5 base years.

Using future PM components obtained in Step 4, we can estimate future daily total b_{ext}.

For year 1

Most Impaired Days

Day 4: b_{ext} = (2.2*3.82*2.869) + (4.8*2.73*0.603) + (2.4*3.82*0.459) + (5.1*2.73*0.011) + (2.8*2.159) + (6.1*0.303) + (10*0.257) + (1*0.389) + (1.7*3.91*0.132) + (0.6*3.641) + 12 = 62.288 Mm^{-1}

Day 5: b_{ext} =(2.2*4.29*1.863) + (4.8*3.00*0.216) + (2.4*4.29*0.364) + (5.1*3.00*0.007) + (2.8*2.938) + (6.1*0.640) + (10*0.271) + (1*0.364) + (1.7*4.20*0.157) + (0.6*6.414) + 12 = 56.722 Mm^{-1}

Clearest Days

Day 2: b_{ext} = (2.2*3.29*1.627) + (4.8*2.46*0.160) + (2.4*3.29*0.335) + (5.1*2.46*0.006) + (2.8*0.973) + (6.1*0.053) + (10*0.115) + (1*0.059) + (1.7*3.49*0.150) + (0.6*2.090) + 12 = 34.786 Mm^{-1}

Day 8: b_{ext} = (2.2*4.59*1.278) + (4.8*3.17*0.094) + (2.4*4.59*0.303) + (5.1*3.17*0.005) + (2.8*953) + (6.1*0.050) + (10*0.094) + (1*0.114) + (1.7*4.44*0.725) + (0.6*4.047) + 12 = 41.682Mm^{-1}

Step 6. Use the daily total b_{ext} values from step 5 to calculate future mean deciview values for the 20% most impaired days and the 20% clearest days.

Calculate daily deciview values (from total daily extinction) and then compute the future mean

[95] Unless multiple meteorological years are being modeled, the same mean RRFs (for each component) are applied to the concentrations on all of the most impaired days for each of the 5 years of data. The mean RRFs are derived from the modeled days. A separate set of RRFs are derived (in the same manner) for the clearest days.

deciviews for the 20% most impaired days and the 20% clearest days for each year. Then average the 5 years together to get the final future mean deciview value for each set of days.

For Year 1

Most Impaired Days

Day 4: 62.288 Mm^{-1} = 10* ln (62.288/10) = 18.291 dv
Day 5: 56.722 Mm^{-1} = 10* ln (56.722/10) = 17.355 dv

Future mean visibility on most anthropogenically impaired days = (18.291 + 17.355) / 2 = 17.82 dv

Clearest Days

Day 2: 34.786 Mm^{-1} = 10* ln (34.786/10) = 12.466 dv
Day 8: 41.682 Mm^{-1} = 10* ln (41.682/10) = 14.274 dv

Future mean visibility on clearest days = (12.466 + 14.274) / 2 = 13.37 dv

Similar calculations are performed for previously selected 20% most impaired days and the 20% clearest days in each of years 2-5. Assume these other calculations yield the following estimates for future mean dv on these sets of days.

Table 5.9 Future year mean deciviews on the 20% most impaired days and the 20% clearest days for each of the 5 years

Year	Future Mean dv on 20% Most Impaired Days	Future Mean dv on 20% Clearest Days
1	17.82	13.37
2	18.17	12.45
3	16.78	12.91
4	18.65	11.52
5	18.21	12.31

Using results in table 5.9, we see that the estimated future average mean visibility for the most impaired days is

dv_{future} = (17.82 + 18.17 + 16.78 + 18.65 + 18.21) / 5 = **17.92 dv**

The estimated future average mean visibility for the clearest days is

dv_{future} = (13.37 + 12.45 + 12.91 + 11.52 + 12.31) / 5 = **12.51 dv**

The most impaired days result generated in step 6 can then be compared to the point on the Class I area-specific glidepath for the end of the implementation period. The most impaired days result is also compared to the baseline most impaired days to ensure that there has been improvement relative to the baseline period. The future year clearest days result is compared to the baseline (2000-2004) clearest days to ensure that visibility on the best days is not forecast to degrade relative to the same period.

This information is used to determine the predicted improvement in visibility that will result from implementation of an emissions strategy. It cannot itself determine the necessary content of the long-term strategy. See the Regional Haze Rule and related guidance documents for more information on the reasonable progress requirements.

5.4 How Do I Select Appropriate Inputs For Developing RPGs?

In section 5.3, we described the recommended regional modeling analysis to develop RPGs and to use them to evaluate progress relative to the glidepath and the baseline period. An important part of the analysis requires using component-specific RRFs, obtained with models, to estimate future concentrations of these components and, subsequently, future visibility. In this subsection, we address more details concerning the calculation of visibility RRFs. Additionally, there are several assumptions inherent in the recommended RPG analysis; we identify these assumptions and comment on their underlying rationale. More specifically, we address seven issues:

1. How to estimate base period air quality in a Class I area without monitored data;
2. How to handle a base year without data or with a small sample size;
3. Use of the same days to estimate changes in visibility for the most anthropogenically impaired days and a different set of same days to estimate changes in visibility for the clearest days;
4. Which predictions to use to derive RRFs;

NMED Exhibit 108

5. How many and what kind of days to use to develop RRF values;
6. RRFs when modeled species concentration are very low; and
7. Alternative RRF calculations.

Estimating baseline and base period visibility in a Class I area without monitors

There are 156 officially designated Class I areas subject to the Regional Haze Rule and 110 IMPROVE sites in or near Class I areas. Therefore, 46 Class I areas do not have co-located IMPROVE monitors. EPA's Tracking Guidance recommends using IMPROVE data from a nearby site to represent the visibility at each Class I area that does not have ambient data. Table A-2 in Appendix A of the Tracking Guidance lists the recommended monthly f(rh) values[96] for each Class I area as well as the representative site for each Class area. The representative IMPROVE site data will be used to track regional haze progress for the Class I areas. Therefore, it follows that visibility improvement for tracking purposes should be predicted at the location of the IMPROVE monitor, not at the actual Class I area. For the purposes of deriving ambient data for modeling, we recommend following the same representative site assignments contained in the Tracking Guidance. In this way, the needed visibility values can be derived for each Class I area from the network of 110 IMPROVE sites.[97] Similarly, the modeling results should be extracted for the location of the representative monitor, not the actual location of the Class I area.[98]

Considering a year in the base period with little or no monitored particulate matter or missing data

The Tracking Guidance recommends calculating base period visibility values for sites with at least 3 out of 5 complete years of data. It further contains recommendations for determining if a year has complete data. In general, a site should have 50% data completeness in all quarters and meet a 75% completeness criteria for the full year. There should be no periods with more than 30 consecutive days without data. The Tracking Guidance assumes that all IMPROVE sites

[96] The f(rh) values in the Tracking Guidance were developed for the "original" IMPROVE algorithm and should not be used to calculate visibility using the "revised" IMPROVE algorithm.

[97] Bering Sea Wilderness (Alaska) is the only Class I area that has no IMPROVE monitor **and** no representative IMPROVE site. On-site IMPROVE or representative IMPROVE data can be found for the other 155 Class I areas.

[98] There may be other reasons to calculate visibility improvement at the actual Class I area. The SMAT provides options for calculating visibility changes at both the Class I area grid cell center and at the representative IMPROVE monitoring site. It may be informative to compare model response at the representative IMPROVE site versus the grid cell center of the Class I area. Large differences in the model response may indicate that the "representative" site may not adequately represent visibility at the Class I area or across the entire Class I area.

will have at least 3 complete years in the base period (which may or may not be true). The Tracking Guidance also contains procedures for filling in missing data.

There are several data completeness issues that may cause problems within the visibility modeling analysis. First, a site may have less than 3 years of complete data. It is possible to calculate visibility improvement based on as little as 1 year of ambient data. Additionally, the IMPROVE program has procedures to utilize substituted and/or patched data to help minimize data incompleteness. States should work with their EPA Regional office and Federal Land Managers to determine how to estimate baseline visibility for these area(s).

Another issue that is a more specific problem for modeling analyses occurs when data is missing during the meteorological time period that was modeled. It is likely that most air agencies will only be modeling a single year of meteorology and it is possible that the ambient data at one or more Class I areas is incomplete during that year. Without ambient data, it is impossible to identify the 20% most anthropogenically impaired days and 20% clearest days, which are used to calculate modeled RRFs.

Again, if this occurs, states should work with their Regional office and Federal Land Managers to determine the best way to calculate visibility on these days. Potential options are to utilize substituted and/or patched data, data from another nearby IMPROVE site, nearby data from a different ambient data network, or interpolate ambient data to the site.

Using a constant sample of days to estimate base period and future visibility

For a typical Class I area, there will be about 120 days per year having measurements needed to estimate $(dv)_{\text{base period}}$ with Equation (5.1). Thus, there should be about 24 most anthropogenically impaired and 24 clearest days for each of the 5 years in the base period. It is conceivable that the identity of these days could change if emissions were altered to reflect net effects of controls and growth. The recommended test described in section 4.8 assumes that the identity of the most impaired and clearest days remains unchanged. This is done primarily to avoid having to perform iterative analyses to identify future most impaired and clearest visibility days and to keep the test relatively simple and more readily understood. This assumption could cause improvement in visibility to be overestimated for the most anthropogenically impaired days and could also cause the test to overestimate the difficulty in preventing deterioration of visibility on the clearest days. However, for the reasons described below, we do not believe the effects of this assumption are substantial.

NMED Exhibit 108

It is unlikely that there would be any wholesale change in the identity of most anthropogenically impaired or clearest days with future versus base year emissions. Analyses performed by Meyer, et al. (1997) have shown that the predicted ranked severity of high ozone days is largely unaffected by simulated controls and growth (i.e., highest days tend to remain the highest days after the effects of growth and controls are simulated). There is no reason to expect a different outcome for other secondary pollutants. If there are differences, we would expect these to occur near the borderline between the most impaired days and more moderate days.

Because the visibility analysis relies on *mean* visibility values on 20 or more most impaired visibility days and most of these days are unlikely to change, we would expect little difference in the outcome of the analysis. Further, because of the shape of the distribution of daily extinction coefficients, the mean of the most impaired days is often more heavily influenced by the very most impaired days rather than those on the borderline between 20% most impaired and more moderate light extinction. There could be differences in some of the clearest visibility days corresponding with pre- and post-control emissions. However, because the differences in concentrations of particulate matter on such days are likely to be relatively low, differences in the computed mean visibility for clearest days are likely to be small. It should be noted that any resulting difference in the projection of RPGs for clearest days would likely be in the direction of it being more difficult to pass the no degradation test compared to the baseline 2000-2004 period, in that some of the future days selected may be higher deciview-valued than they ought to be. If our recommended procedure leads to suspected problems in the outcome of a test, an air agency may wish to perform a more rigorous version of the analysis (in which the identity of pre-control and post-control days changes) as part of additional or supplemental analyses to support the RPG.

Selecting predictions to use in deriving RRF

RRFs should be developed for each Class I area. When a Class I area contains a monitoring site, the RRF estimates should be derived using predictions which are made "near" that site. For each day, daily average surface predictions of each component of PM made near a monitor should be estimated. Similar to the annual $PM_{2.5}$ NAAQS attainment test, nearby grid cells should be averaged. These nearby estimates should be spatially averaged to estimate a spatially representative daily concentration. For 12 km or finer resolution, we recommend averaging the modeled concentrations for a 3 x 3 array of grid cells surrounding the monitor. Note that for cells larger than 12 km on a side, no spatial averaging is necessary—states should just use the

NMED Exhibit 108

prediction in the cell containing the monitor. Spatially representative daily concentrations obtained for each modeled day with monitored data should then be temporally averaged. This final average should be used to compute the RRF. Thus, component-specific RRF values for a Class I area with a monitor are the ratio of the temporally averaged spatial mean of nearby concentrations predicted with future emissions to that predicted with base year emissions.

Selecting days to derive RRF values

It may often happen that a planning organization or a group of states decides to model the visibility impacts of a strategy for numerous Class I areas simultaneously. As we note in section 2.3.1, this may make it advisable to simulate (at least) a full year so that RRF values for each Class I area are based on a substantial number of observed best and worst days. For the most impaired days in the chosen year, the RRF for a component of PM should be estimated as the ratio of its modeled arithmetic mean predicted value on the 20% most impaired days with future emissions to that with base year emissions. Thus, in most cases, the RRF should reflect values averaged over ~ 24 most impaired days in that year. The same procedure is followed to derive RRFs over the ~24 clearest days in the year.

Since meteorological conditions and/or emissions may be markedly different on best visibility versus worst visibility days, we recommend calculation of a separate set of RRF values for the 20% clearest days. As with most impaired days, the preferred approach is to model an entire year and select an RRF value for concentrations averaged over the 20% clearest days for each Class I area. The RRF values are the ratios of the future to base year modeled averages. The appropriate RRF values should then be used in concert with each observed best day to estimate future concentrations for each component on each identified clearest day.

RRFs when modeled species concentrations are very low

In most cases, the RRFs derived for visibility components are either less than 1.0 or slightly more than 1.0. However, large RRFs (much greater than 1.0) can occur when the mean modeled concentration of a PM component on the 20% most impaired or clearest days is very small and the concentration of that component increases in the future year case. This most often occurs with the nitrate component. On both the 20% most impaired days and 20% clearest days, the modeled nitrate concentrations at Class I areas can be very small (i.e., < 0.01 µg/m3). These low modeled concentrations can sometimes increase in future year scenarios by orders of magnitude. This occurs most often in ammonia limited areas when sulfate concentrations are reduced in the future (due to SO_2 emissions reductions) causing nitrate

NMED Exhibit 108

increases due to an increase in available ammonia. Large RRFs should be closely examined to identify the cause of the issue. In many cases, large RRFs are caused by poor model performance (i.e., underpredicted base case nitrate concentrations) or instability in one or more model components (i.e., the nitrate partitioning model). One solution is to cap the RRF at 1.0 or close to 1 in cases where nitrate (or any other $PM_{2.5}$ component) increases in the future by an unrealistic amount due to very low modeled concentrations. Any adjustments to the default calculations should be documented and discussed with the appropriate EPA Regional office and the Federal Land Managers.

Alternative RRF calculations

The default analysis is relatively simple in that a single mean RRF is calculated for each PM component (separate RRFs on most impaired days and clearest days). A series of tests with more complicated methods has shown that: 1) the difference between various versions of the test are usually small and 2) each of the alternative tests has limitations in its applicability (Environ, 2005). Possible variations include the use of day specific RRFs, season (or quarter) specific RRFs, or climatologically based RRFs. In some cases, these more complicated techniques may provide different answers, but sometimes not. There are specific limitations with each of these alternatives noted in the indicated reference. We have chosen to keep the single mean RRF test as the default recommendation. States are encouraged to explore other methods for estimating RRFs if it is thought that the default recommendation is too simplistic to accurately capture the change in future visibility at any particular Class I area. The SIP analysis to develop RPGs should use the most appropriate method of projecting future concentrations for the characteristics of each Class I area.[99] Alternative methods should be discussed in the modeling protocol and discussed with the appropriate EPA Regional office and Federal Land Managers.

[99] In particular, issues may arise when dealing with visibility contributions from fires, coarse mass and fine soil (from wind-blown dust), and international transport (and possibly other issues). Each of these issues should be addressed in the modeling protocol and solutions should be discussed with the appropriate EPA Regional office(s) and Federal Land Managers on a case-by-case basis.

NMED Exhibit 108

6.0 How Can Additional Analyses Be Used to Support an Ozone or $PM_{2.5}$ Attainment Demonstration?

By definition, models are simplistic approximations of complex phenomena. The modeling analyses used to assess whether emission reduction measures will bring an individual area into attainment for the NAAQS contain many elements that are uncertain (e.g., emission projections, meteorological inputs, science formulations, etc.). These uncertain aspects of the analyses prevent definitive assessments of future attainment status. The confidence in the representativeness of the quantitative results from a modeled attainment test should be a function of the degree to which the uncertainties in the analysis were minimized. In general, by following the recommendations contained within this guidance document, EPA hopes that the attainment demonstrations will mitigate the uncertainty as much as possible given the current state of modeling inputs, procedures, and science. However, while air quality models represent the best tools for integrating emissions and meteorological information with atmospheric chemistry, and no single additional analysis can match the expected reliability of these models' results, EPA believes that all attainment demonstrations will be strengthened by additional analyses that can supplement the modeling to enhance the assessment of whether the planned emissions reductions are likely to result in attainment.

Supplemental evidence should accompany all model attainment demonstrations. Generally, those modeling analyses that show that attainment will be reached in the future with some margin of safety will need more limited supporting material. For other attainment cases in which the projected future design value is closer to the NAAQS, more rigorous supporting analyses should be completed. There may be some areas for which the supplemental evidence is persuasive enough to support a conclusion that the area can expect to achieve timely attainment despite failing the modeled attainment test, and other areas for which the modeled attainment test demonstrates attainment, but the supplemental evidence casts significant doubt on that result. This section of the guidance will discuss some specific information and additional analyses that can be used to supplement the model projections. Of particular interest are analyses that help determine whether the modeling-based projections are likely to provide a prediction of the *air quality improvement* that is likely to occur by the attainment date. Air agencies should review these supplemental analyses, in combination with the modeling analysis, in a "weight of evidence" assessment of whether each area is likely to achieve timely attainment. Again, it should be noted that no single supplemental analysis can serve as an adequate substitute for the air quality model. However, in aggregate, supplemental

NMED Exhibit 108

analyses may provide information which may provide further support for the outcome of the modeled test or may indicate a different outcome than the modeled test.

In considering the use of supplemental analyses, an important factor is the time (number of years) until the attainment date. In general, modeling and related analyses are the most useful corroborative analyses for areas with attainment dates which are more than several years in the future. In contrast, ambient data and emissions trends become more important (and hence model results become less important) the closer in time the area is to its attainment date. For example, if an area is only 1 or 2 years away from its attainment date, ambient data is in most cases the best predictor of likely air quality levels in the near future. However, this may not be true if there are large emissions reductions that are expected to occur in the near-term period. In that case, modeling is needed to estimate additional ozone and/or PM reductions that are likely to occur due to the emissions controls in the short term. Similarly, if the attainment date is 5 or 10 years or more in the future, appropriate modeling will likely be the most reliable indicator of future year ozone or PM levels. Emission changes over a relatively long period are likely to overwhelm the influence of ambient data trends and meteorological variability, making ambient data and emissions trends analyses relatively less important.

6.1 What Types of Additional Analyses Should Be Completed as Part of an Ozone or $PM_{2.5}$ Attainment Demonstration?

There are three basic types of analyses that are recommended to supplement the primary modeling analysis. They are:

1) Additional modeling analyses;

2) Analyses of trends in ambient air quality and emissions;

3) Additional emissions controls/reductions.

Note that air agencies are encouraged to consult with their EPA Regional office (and Federal Land Managers, when appropriate) in advance of initiating supplemental analyses to determine which additional analyses may be most appropriate for their particular area.

NMED Exhibit 108

6.1.1 Modeling Analyses

The relative attainment tests described in sections 4.2, 4.4, and 4.5 are the primary modeling tools used in an attainment demonstration. The application of a chemical transport grid model on a regional or local scale is the best tool available to judge the impacts of changes in future year emissions on concentrations. In addition to this "primary" modeling analysis, there are various other models, model applications, and tools that can be used to supplement the results of the modeled attainment test. These include, but are not limited to:

- Available regional or national scale modeling applications that are suitable[100] for the local area, for example, modeling in support of EPA rulemakings or regional, multi-jurisdictional organization modeling that may be available for the appropriate future year of interest. Modeling analyses may be available that used different models and/or inputs.

- Use of other appropriate local modeling that includes the nonattainment area of interest. This may include applications using alternative models and/or inputs or research-oriented analyses.

- Use of photochemical source apportionment, DDM, and/or process analysis modeling tools to help explain why attainment is (or is not) demonstrated.

- Use of multiple air quality models / model input data sets (e.g., multiple meteorological data sets, alternative chemical mechanisms or emissions inventories, etc.). Multiple model configurations can be used to estimate sensitivity and uncertainty of future year design value predictions.
    - For results to be most relevant to the way we recommend models be applied in attainment demonstrations, it is preferable that such procedures focus on the sensitivity of estimated RRFs and resulting projected design values to the variations in inputs and/or model formulations.

- Application of the attainment test with alternative procedures compared to the default recommendations in sections 4.2, 4.4, and 4.5 of this guidance. Any alternate approaches

[100] The resolution, emissions, meteorology, and other model inputs should be evaluated for applicability to the local nonattainment area. Additionally, model performance for the local nonattainment area should be examined before determining whether the regional model results are suitable for use in the local attainment demonstration.

NMED Exhibit 108

should be accompanied with a technical justification to explain why the approach is appropriate for the area in question and should be discussed with the appropriate EPA Regional office.

  - Alternative RRF calculations using non-default assumptions or more detailed temporal and spatial analysis of RRFs at one or more monitoring locations. If a sound technical argument can be made for why atypically high RRFs at any particular location are not reasonable, then these types of supplemental analyses would suggest that attainment is more likely to be achieved than the default modeling analysis alone would indicate.
  - Alternate base year design values that may differ from the 5-year weighted average value. Alternative values could include different methodologies for determining base year design values or removal of potential exceptional events data (see section 4.1.1).

- Use of dispersion models to address primary $PM_{2.5}$ contributions to $PM_{2.5}$ concentrations. In areas with large spatial gradients of primary $PM_{2.5}$, dispersion models are best suited to characterizing the change in primary $PM_{2.5}$ in the future. A local area analysis may be useful as a supplemental analysis (in either monitored or unmonitored areas, as appropriate) for areas that at least partially rely on local primary PM controls to reach attainment and did not otherwise perform and submit a local area analysis of part of the attainment demonstration.

The EPA has determined that the best approach to using models to demonstrate attainment of the NAAQS is to use a model in a relative mode. However, some types of "absolute" model results may be used to assess general progress towards attainment from the baseline inventory to the projected future inventory.[101] Example metrics include:

- Percent change in total amount of ozone or $PM_{2.5}$ >= NAAQS[102] within the nonattainment area
- Percent change in number of grid cells >= NAAQS within the nonattainment area
- Percent change in grid cell-hours (days) >= NAAQS within the nonattainment area
- Percent change in maximum modeled 8-hour ozone within the nonattainment area

[101] Care should be taken in interpreting absolute metrics if the model evaluation shows a large underprediction or overprediction of ozone or $PM_{2.5}$ concentrations. An underprediction of observed concentrations will make it artificially easy to show progress towards absolute attainment levels and an overprediction will make it artificially difficult to show progress towards attainment.

[102] For each of these metrics, the appropriate comparison to the level of the NAAQS is 70 ppb for 8-hour ozone; 35 µg/m3 for 24-hour $PM_{2.5}$; and 12 µg/m3 for annual $PM_{2.5}$.

While these metrics can be used to estimate the magnitude, frequency, and relative amount of ozone or $PM_{2.5}$ reductions from any given future emissions scenario, there are no threshold quantities of these metrics that can directly translate to an attainment determination. Generally, a large reduction in the frequency, magnitude, and relative amount of 8-hour ozone nonattainment (i.e., >= 71 ppb) or $PM_{2.5}$ nonattainment (24-hour and/or annual) is consistent with a conclusion that a proposed strategy would meet the NAAQS. In the context of a weight of evidence determination, these metrics could be used to suggest that a particular location may be "stiff" or relatively unresponsive to emissions controls, while the rest of the modeling domain/nonattainment area is projected to experience widespread reductions.

6.1.2 Analyses and Trends in Ambient Air Quality and Emissions

Generally, air quality models are regarded as the most appropriate tools for assessing the expected impacts of a change in emissions. However, it may also be possible to evaluate progress towards attainment of the ozone or $PM_{2.5}$ NAAQS based on measured historical trends of air quality and emissions. It may be possible to develop a relationship between past emissions changes and historical and current air quality. Once the relationship between past/present emissions and air quality is established, a response to the expected emissions reductions from a particular control strategy can be estimated. There are several elements to this analysis that are difficult to quantify. First, in most cases, the ambient data trends are best assessed by normalizing to account for year-to-year meteorological variations. Second, one must have an accurate accounting of the year-to-year changes in actual emissions (NOx, VOC, and/or SO_2 and NH_3) for the given area and any surrounding areas whose emissions may impact local concentrations. Third, one must have a solid conceptual model of how ozone or $PM_{2.5}$ is formed in the local area (e.g., influence of meteorology, NOx-limited, ammonia limited, transport-influenced, etc.).

If available, meteorologically adjusted ozone and $PM_{2.5}$ concentrations can be used to establish air quality trends. There are several techniques that have been used to examine the influence of meteorology on air quality. Among them are (a) statistical modeling (U.S. EPA, 2005b); (b) filtering techniques (Rao, 1995; Flaum, 1996; Milanchus, 1998; and Hogrefe, 2000), (c) using a probability distribution of meteorological severity based on climatological data (Cox and Chu, 1993, 1996), and (d) using CART analysis to identify meteorological classes and selecting days from each year so that the underlying frequency of the identified meteorological classes remains the same (Deuel and Douglas, 1996). Most of this work has examined the relationship between ozone and meteorology. Only recently have analyses examined the relationship between meteorology and $PM_{2.5}$. Additionally, compared to $PM_{2.5}$, the established relationship

NMED Exhibit 108

between ozone and meteorological variables is generally stronger (higher r-square values). In the case of $PM_{2.5}$, the relationship between concentration and meteorology is complicated by the fact that $PM_{2.5}$ components experience high concentrations at different times of the year and for different reasons. This makes it more difficult to meteorologically adjust $PM_{2.5}$ concentrations.

If a meteorologically adjusted trend in ozone or $PM_{2.5}$ can be estimated, then the information can be used to establish a link between emissions and air quality trends. This is not always straightforward due to the multitude of emissions precursors that may lead to high ozone and $PM_{2.5}$ concentrations. A careful analysis of (meteorologically adjusted) air quality trends and emissions trends of each of the ozone and PM precursors (as well as primary PM) is needed to fully establish relationships. Detailed emissions information as well as a solid understanding of the conceptual model of ozone or $PM_{2.5}$ formation is needed. If a trend can be established based on past emissions changes and air quality changes, then future year predicted emissions levels can be used to extrapolate future air quality.

Meteorologically adjusted trends in ozone and/or $PM_{2.5}$ attempt to adjust observed concentrations to levels which would have been observed during average meteorological conditions (Camalier, 2007). This makes it easier to observe trends primarily due to emissions changes and also allows identification of years with above average or below average meteorologically conducive conditions. Identification of "extreme" meteorological conditions, which are not likely to re-occur in a particular design value period, can be used as part of a weight of evidence analysis. For example, the presence of one or more "extreme" (high concentration) meteorological years in either the base year period or the most recent design value period may make it appear that an area is farther away from attaining the NAAQS than would otherwise be the case if more typical meteorological conditions had occurred. It is important to note that 1 or more years of meteorological conditions which are not conducive to ozone formation will have the opposite effect. An area may appear to be on track to attain the NAAQS (or close to attaining) but, in reality, may need substantial additional emissions reductions in order to attain under average or above average meteorological conditions. Meteorological adjusted concentration and/or design value calculations can help explain both of these situations. More information on meteorologically adjusted ozone trends can be found here.

A simpler (and more uncertain) way to qualitatively assess progress toward attainment is to examine recently observed air quality and emissions trends. Downward trends in observed concentrations and in emissions (past and projected) are consistent with progress towards

attainment. Strength of the evidence produced by emissions and air quality trends is increased if an extensive monitoring network exists and if there is a strong, positive and demonstrable, correlation between past emissions reductions and current trends in ozone or $PM_{2.5}$. Until recently, EPA prepared annual air quality trends reports for all criteria pollutants. The latest trends report analyzes ambient data through 2017 and can be found here.

The appropriate weight given to trend analyses depends on several factors. Analyses that use more air quality data and apply a greater variety of trend parameters typically provide more credible results. More weight can be placed on the results if the procedure used to normalize the trend for meteorological differences explains much of the variability attributable to these differences. In addition, trend analysis is usually more reliable if the extrapolation (as applicable) does not extend very far into the future. Finally, trend analysis is most credible if the contemplated strategy is similar to a past strategy (e.g., both strategies focus on reducing sulfates for PM or NOx for ozone). For example, if a past strategy focused on reducing sulfates, but a future one envisions controlling OC, there is no guarantee that ambient OC will respond similarly to changes in past emissions.

In addition to ambient data trends, further analysis of ambient data can provide information on ozone production efficiency, evidence of transport and assist in the quality assurance of emissions inputs. In particular, photochemical assessment monitoring station (PAMS) data, special study data, research and non-routine ambient data (i.e., NOy, and VOC data) can provide insights into the ozone and/or $PM_{2.5}$ concentrations observed in the nonattainment area and can help assess the accuracy of the modeling results and control strategies that are being relied upon for attainment.

6.1.3 Additional Emissions Controls/Reductions

Models are used to predict the future expected concentrations of ozone and/or $PM_{2.5}$, based on modeled emissions changes between a base year and future year. It is expected that emission inventories are as accurate as possible and represent emissions changes (including growth and controls) that are expected to occur. However, there may be various emissions sources and/or controls that are difficult to accurately represent in the modeling analysis, and the effects of some emissions controls may be difficult to quantify. Additionally, there may be uncertainty in how emissions controls may be implemented either in a nonattainment area, or in upwind regions which may contribute ozone to the nonattainment area.

NMED Exhibit 108

The following are some of the types of control measures that may be appropriate to include in a weight of evidence demonstration:

- Measures that are difficult to quantify or may not be enforceable in the SIP. Examples include:
    - Energy efficiency or renewable energy (EE/RE) programs may be implemented statewide (and in fact may be enforceable). However, emissions reductions from such programs are hard to quantify and it may be difficult to assign reductions to particular utility sources. EPA has provided an "EE/RE Roadmap Manual." The roadmap includes a weight of evidence "pathway" for air agencies that want to acknowledge the emissions benefits and potential reductions from EE/RE measures, but are unable to accurately quantify the emissions reductions in their SIP.
    - Smart growth initiatives such as land use planning and transportation planning.
    - Truck stop electrification.
    - Emissions reductions from idling regulations which may not be quantified in the mobile emissions modeling.
- Voluntary measures
    - Air agencies may have implemented voluntary measures that are not enforceable and therefore are not included in the SIP. These could include measures such as "ozone action days," voluntary no burn days, telework programs, idling reduction initiatives, etc. Even though these programs may be voluntary, they can still lead to positive actions in the nonattainment area that can lead to lower emissions. Voluntary measures should be documented to the fullest extent possible, including estimates of emissions benefits, where possible.

- Regional/super-regional and/or national programs that may not have been accounted for in the attainment demonstration.
    - Federal measures which were not accounted for in the modeling because they were proposed and/or finalized after the state modeling was completed.
    - Upwind regional, state, and/or local measures which were not known or not able to be quantified in the attainment demonstration due to timing or lack of information.

6.2 Weight of Evidence Summary

A weight of evidence (WOE) determination may examine results from a diverse set of analyses, including the outcome of the primary attainment test, and attempts to summarize the results into an aggregate conclusion with respect to whether a chosen set of control measures are

NMED Exhibit 108

likely to result in an area attaining the NAAQS by the applicable attainment date, notwithstanding what the air quality modeling may suggest in isolation. The supplemental analyses discussed above can be part of a WOE determination, although the level of detail required in a WOE submittal will vary as a function of many elements of the model application (e.g., model performance, degree of residual nonattainment in the modeled attainment test, amount of uncertainty in the model and its inputs, etc.). Each WOE determination will be subject to area-specific conditions and data availability. Area-specific factors may also affect the types of analyses that are feasible for a specific nonattainment area, as well as the significance of each. Thus, decisions concerning which analyses to perform, and how much credence to give each, need to be made on a case-by-case basis by those implementing the modeling/analysis protocol. Air agencies are encouraged to consult with their EPA Regional office (and Federal Land Managers, when appropriate) in advance of initiating supplemental analyses to determine which additional analyses may be most appropriate for their particular area for potential use as part of a WOE evaluation.

The most useful supplemental analyses are those providing the best evidence as to how much air quality improvement can be expected as compared to the improvement projected by the air quality modeling analysis. Each analysis is weighed qualitatively, depending on: 1) the capacity of the analysis to address the adequacy of a strategy and 2) the technical credibility of the analysis. If the overall WOE produced by the combination of the primary modeling analysis and the various supplemental analyses supports the attainment hypothesis, then the air agency can demonstrate attainment of the NAAQS proposed control strategy. The end product of a WOE determination is a document which describes analyses performed, databases used, key assumptions and outcomes of each analysis, and why an air agency believes that the evidence, viewed as a whole, supports a conclusion that the area will, or will not, attain the NAAQS. In conclusion, the basic criteria required for an attainment demonstration based on weight of evidence are as follows:

1) A fully-evaluated, high-quality modeling analysis that projects future values that are close to the NAAQS.
2) A description and explanation of each of the individual supplemental analyses, preferably from multiple categories. Analyses that utilize well-established analytical procedures and are grounded with sufficient data should be weighted accordingly higher.
3) A written description as to why the full set of evidence leads to a conclusive determination regarding the future attainment status of the area that differs from the results of the modeled attainment test alone.

NMED Exhibit 108

7.0 What Role Should Additional and/or Supplemental Analyses Play in Regional Haze Modeling Demonstrations?

We believe additional and/or supplemental analyses can be a useful tool for air agencies when developing RPGs and applying them in the ways described in section 5. In this subsection, we note some potential supplemental analyses that may be used in this context.

7.1 Additional air quality modeling

Sensitivity tests can be performed to see if conclusions about trends in the 20% most anthropogenically impaired days and 20% clearest days are robust. One example of such an analysis is applying a model with and without a more finely resolved nested grid near source areas or near Class I areas. A purpose of this would be to see whether conclusions are affected by the degree of detail in which nearby sources are considered. A second example of an analysis would be to consider alternative future emissions (including lateral boundary conditions) and/or differing growth rate assumptions. This may be a particular concern for regional haze analyses because the emissions projection period is generally longer than for most ozone and $PM_{2.5}$ attainment demonstrations. Uncertainty in emissions and growth rates become more important as the projection period is lengthened.

If the outcomes of the several comparisons described in section 5.1 are similar using sensitivity tests, alternative models and/or alternative modeling approaches, this finding supports conclusions reached in the main analysis.

7.2 Review of trends

A review of trends generally involves a comparison, sometimes qualitative, between past trends in reconstructed visibility and estimated changes in emissions (e.g., mid ‘00’s to mid ‘10's). This information could be used to confirm that additional reductions of previously controlled emissions of a component or its precursors is likely to result in the predicted visibility improvement. It may also be used to see whether certain PM components are becoming increasingly more or less important sources of light extinction.

7.3 Other models and tools

Trajectory models may be useful for identifying the types of meteorological conditions most often corresponding to observed worst and best visibility in various Class I areas. This, in turn,

NMED Exhibit 108

may enable air agencies to draw inferences about the areas containing sources most likely to influence visibility in a Class I area on days with “poor” and “good” visibility. Grid model-based techniques such as DDM or source apportionment may also be useful in identifying areas and emissions sources most responsible for visibility impairment on the most anthropogenically impaired days and clearest days.

7.4 Refinements to the recommended visibility analysis

A state may consider refining the recommended modeling analysis in some manner. Refinements are best made if they are based on local observations/analyses which suggest that some of the underlying assumptions in the recommended assessment may not be applicable. We list some potential refinements that could be considered. The list is intended to illustrate types of additional analyses that could be performed.

- Use an alternative light extinction equation or an area-specific version.
- The 20% most anthropogenically impaired days conceptually will not include days with high impacts from fires or dust storms because anthropogenic impairment relative to natural conditions will be low on such days. However, the particular method initially applied to identify the most anthropogenically impaired days may not implement this concept perfectly at a particular Class I area. Available speciated data and other information may be reviewed to see whether the outcome of the visibility analysis is being influenced by including one or more days with extraordinary events (e.g., a major wildfire lasting a number of days or transported dust events). If convincing arguments can be made that the event is a “natural” one, changes in the initial approach to estimate daily anthropogenic versus natural light extinction should be discussed with the appropriate EPA Regional office and Federal Land Managers.
- Daily component specific RRFs can be examined to determine if one or more days are responding in a different way compared to the majority of the clearest or most impaired days. Determining why days may be more or less responsive to emissions controls may lead to conclusions regarding the suitability of particular days to be represented in the mean response. It may be appropriate, in some cases, to re-calculate mean RRFs with suspect days removed.
- Re-rank future estimated light extinction (i.e., b_{ext} values) for all days that have current measurements and re-compute mean future most impaired and clearest days visibility (i.e., do not assume that the identity of clearest days remains the same between the base year and the future year).

NMED Exhibit 108

7.5 Concerns about modeling the clearest days

In some parts of the U.S., concentrations of the components of PM used in visibility calculations may be very close to background levels on the clearest days. Measurements and model estimates may be subject to more relative uncertainty (i.e., lower signal to noise ratio) on days where observed concentrations of PM are very low (and light extinction is also low). The utility of a WOE determination is heightened in such cases. An air agency should see whether a model's inability to accurately predict one or more individual components of PM has a substantial effect on the extinction coefficient calculated with Equation (5.1). If it does, and diagnostic tests are unable to resolve a performance problem, an air agency may need to address the "no degradation" requirement for the clearest days in the particular Class I area(s) without using results from a grid model.

1.0 INTRODUCTION

Congress, in the Clean Air Act Amendments of 1990 (CAAA), amended Title I of the Clean Air Act (CAA) to address ozone nonattainment areas. A new Subpart 2 was added to Part D of Section 103. Section 183(c) of the new Subpart 2 provides that:

> [w]ithin 3 years after the date of the enactment of the [CAAA], the Administrator shall issue technical documents which identify alternative controls for all categories of stationary sources of...oxides of nitrogen which emit, or have the potential to emit 25 tons per year or more of such air pollutant.

These documents are to be subsequently revised and updated as determined by the Administrator.

Process heaters have been identified as a category with emission sources that emit more than 25 tons of nitrogen oxide (NO_x) per year. This alternative control techniques (ACT) document provides technical information for use by State and local agencies to develop and implement regulatory programs to control NO_x emissions from process heaters. Additional ACT documents are being developed for other stationary source categories.

The information in this ACT document was generated through literature searches and contacts with process heater control equipment vendors, engineering firms, chemical plants, and petroleum refineries. Chapter 2.0 presents a summary of the findings of this study. Chapter 3.0 presents information on process heater operation and industry applications. Chapter 4.0 contains a discussion of NO_x formation and uncontrolled process heater NO_x emission factors. Alternative control techniques and achievable controlled emission levels are included in

NMED Exhibit 109

Chapter 5.0. The cost and cost effectiveness of each control technique are presented in Chapter 6.0 Chapter 7.0 describes environmental and energy impacts associated with implementing the NO_x control techniques.

NMED Exhibit 109

2.0 SUMMARY

This chapter presents a summary of the information contained in this document. Section 2.1 presents a summary of NO_x formation and uncontrolled NO_x emissions. Section 2.2 presents a summary of available NO_x emission control techniques and achievable NO_x emission reductions. Section 2.3 presents a summary of the capital costs and cost effectiveness for these NO_x control techniques. Process heaters are direct fired heaters used primarily in the petroleum refining and petrochemical industries. Process fluids are heated to temperatures in excess of 204°C (400°F) in the radiative and convective sections of the heaters. Flue gas entering the convective section is usually in excess of 800°C (1500°F) for most process heaters.

Due to the broad spectrum of process heater designs and capacities, this study uses a limited number of model heaters to evaluate the available NO_x control techniques for process heaters. The model heaters and uncontrolled emission factors are introduced in Chapter 4. The model heaters and uncontrolled emission factors are based on a refinery data base, published literature and data. The performance of the control techniques applied to model heaters is presented in Chapter 5 and is based on published literature and data. Costs and cost effectiveness of the control techniques applied to the model heaters are presented in Chapter 6 and are based on published cost methodologies.

2.1 UNCONTROLLED NO_x EMISSIONS

Nitrogen oxides are produced by three different formation mechanisms: thermal, fuel, and prompt NO_x. Thermal NO_x is primarily temperature-dependent, and fuel NO_x is primarily

NMED Exhibit 109

dependent on the presence of fuel-bound nitrogen and the local oxygen concentration. Prompt NO_x is the least understood formation mechanism. Most combustion control techniques are designed to reduce thermal and/or fuel NO_x. Post combustion techniques reduce NO_x in the flue gas regardless of the formation mechanism.

Thermal NO_x formation increases rapidly at temperatures exceeding 1540°C (2800°F) and is the primary source of NO_x in natural gas- and refinery fuel gas-fired heaters. Refinery fuel gas firing generally yields higher thermal NO_x formation than natural gas firing due to the higher flame temperatures caused by the higher hydrogen content of the refinery fuel gas.

Fuel NO_x formation is minimal in heaters that fire natural gas and refinery fuel gas, which contain little or no fuel-bound nitrogen. Fuel NO_x represents a considerable fraction of the total NO_x emissions in heaters burning nitrogen-bearing fuels, such as distillate and residual oils.

Uncontrolled emission factors for the model heaters are presented in Table 2-1. The uncontrolled NO_x emission factors for natural gas-fired, low- and medium-temperature model heaters are 0.098 and 0.197 pounds per million British thermal units (lb/MMBtu) for the natural draft (ND) and mechanical draft (MD) heaters, respectively. The uncontrolled NO_x emission factors for the ND oil-fired model heaters are 0.200 and 0.420 lb/MMBtu for distillate and residual oil-firing, respectively. The distillate and residual oil-fired MD model heaters have uncontrolled NO_x emission factors of 0.320 and 0.540, respectively. The uncontrolled emission factors for the pyrolysis model heaters are 0.135 and 0.162 lb/MMBtu for the natural gas-fired and high-hydrogen fuel gas-fired heaters, respectively.

The uncontrolled emission factors for MD model heaters are greater than for ND model heaters because the MD model heaters have combustion air preheat, which increases thermal NO_x emissions. The oil-fired model heaters have higher thermal NO_x emissions than the natural gas-fired model heaters, primarily due to the higher flame temperature for oil firing. Residual oil

NMED Exhibit 109

TABLE 2-1. UNCONTROLLED EMISSION FACTORS FOR MODEL HEATERS

Model heater type	Uncontrolled emission factor, lb/MMBtu		
	Thermal NO_x	Fuel NO_x	Total NO_x[a]
ND, natural gas-fired[b]	0.098	N/A	0.098
MD, natural gas-fired[b]	0.197	N/A	0.197
ND, distillate oil-fired	0.140	0.060	0.200
ND, residual oil-fired	0.140	0.280	0.420
MD, distillate oil-fired	0.260	0.060	0.320
MD, residual oil-fired	0.260	0.280	0.540
ND, pyrolysis, natural gas-fired	0.135	N/A	0.104
ND, pyrolysis, high-hydrogen fuel gas-fired[c]	0.162[d]	N/A	0.140

[a]Total NO_x = Thermal NO_x + Fuel NO_x

[b]Heaters firing refinery fuel gas with up to 50 mole percent hydrogen can have up to 20 percent higher NO_x emissions than similar heaters firing natural gas.

[c]High-hydrogen fuel gas is fuel gas with 50 mole percent or greater hydrogen content.

[d]Calculated assuming approximately 50 mole percent hydrogen.

N/A = Not applicable.

NMED Exhibit 109

contains a greater content of fuel-bound nitrogen and therefore has higher fuel NO_x emissions than the distillate oil-fired heaters.

2.2 AVAILABLE NO_x EMISSION CONTROL TECHNIQUES

The following NO_x control techniques are currently used in industry: low-NO_x burners (LNB's), ultra-low NO_x burners (ULNB's), selective noncatalytic reduction (SNCR), and selective catalytic reduction (SCR). Also, LNB's are used in combination with flue gas recirculation (FGR), SNCR, and SCR.

Combustion modifications such as LNB, ULNB and FGR inhibit NO_x formation by controlling the combustion process. Staging techniques are usually used by LNB and ULNB to supply excess air to cool the combustion process or to reduce available oxygen in the flame zone. Staged-air LNB's create a fuel-rich reducing primary combustion zone and a fuel-lean secondary combustion zone. Staged-fuel LNB's create a lean primary combustion zone that is relatively cool due to the presence of excess air, which acts as a heat sink to lower combustion temperatures. The secondary combustion zone is fuel-rich. Ultra-low-NO_x burners use staging techniques similar to staged-fuel LNB in addition to internal flue gas recirculation. Flue gas recirculation returns a portion of the flue gas to the combustion zone through ducting external to the firebox that reduces flame temperature and dilutes the combustion air supply with relatively inert flue gas.

Unlike combustion controls, SNCR and SCR do not reduce NO_x by inhibiting NO_x formation, but reduce NO_x in the flue gas. These techniques control NO_x by using a reactant that reduces NO_x to nitrogen (N_2) and water. The reactant, ammonia (NH_3) or urea for SNCR, and NH_3 for SCR, is injected into the flue gas stream. Temperature and residence time are the primary factors that influence the reduction reaction. Selective catalytic reduction uses a catalyst to facilitate the reaction.

The reduction efficiency of each control technique varies depending on the process heater application and design. The efficiencies for LNB, ULNB, and SCR are considered to be representative averages based on operating experience. Fuel NO_x

NMED Exhibit 109

reduction efficiencies and the reduction efficiencies for FGR, and SNCR are based on a Canadian Petroleum Products Institute report. Tables 2-2 and 2-3 present the reduction efficiencies for each NO_x control technique. The total effective reduction efficiencies for natural gas- and refinery fuel gas-fired heaters are shown in Table 2-2 and for low- and medium-temperature process heaters range from 50 percent for LNB to 88 percent for LNB plus SCR. The total effective percent reductions for pyrolysis furnaces are lower for control techniques that use LNB's or ULNB's compared to the low- and medium-temperature heaters, and range from 25 percent for LNB to 81 percent for LNB plus SCR. The total effective reduction efficiencies of the oil-fired heaters are shown in Table 2-3 and range from 27 percent for ND LNB on ND residual oil-fired heaters to 92 percent for MD LNB plus SCR on MD distillate oil-fired heaters. The total effective reduction efficiencies of the gas-fired heaters are the same for ND or MD operation. However, different reduction efficiencies for thermal and fuel NO_x emissions result in varying total effective reduction efficiencies for the oil-fired heaters.

2.3 CAPITAL COSTS AND COST EFFECTIVENESS

The capital costs and cost effectiveness for each of the NO_x control techniques discussed in Section 2.2 are presented in this section for the model heaters. Cost methodologies from reports published by the Canadian Petroleum Products Institute and the South Coast Air Quality Management District are used to estimate the capital and annual costs for the control techniques.

The cost of converting ND heaters to MD heaters is included in the cost analysis in which MD control techniques are used on ND model heaters. Natural draft-to-MD conversion is not considered a NO_x control technique and is usually performed to take advantage of thermal efficiency gains. These efficiency gains are site specific and are not included or quantified in this study. Therefore, the actual cost effectiveness of control

[a]Further discussion on the NO_x reduction efficiencies of each control technique is included in Chapter 5.
[b]Reduction efficiencies for ND or MD SNCR are equal

NMED Exhibit 109

techniques that include ND-to-MD conversion may be lower than shown in this study.

Cost effectiveness of the control techniques, in $/ton of NO_x removed, is calculated as the total annual cost divided by the annual NO_x reduction, in tons, for each control technique applied to each model heater. Tables 2-4 through 2-8 present the cost effectiveness of these control techniques for the ND natural gas-fired, MD natural gas-fired, ND oil-fired, MD oil-fired, and ND pyrolysis model heaters, respectively. Burner control techniques generally have the lowest cost effectiveness, with SCR having the highest. Ultra-low-NO_x burner cost effectiveness is lower than LNB in all cases because the additional reduction efficiency more than offsets the additional cost. The cost effectiveness of SNCR is greater than that of LNB in most cases because of the higher capital and operating costs for SNCR. Low-NO_x burners plus FGR have higher cost effectiveness than SNCR in most cases. The capital cost for SNCR are comparable to LNB plus FGR, but the higher operating costs result in higher cost-effectiveness values for SNCR. The highest reduction efficiencies are achieved by SCR and LNB plus SCR, but these techniques also have the highest cost effectiveness due to the relatively high capital and annual costs for SCR.

The lowest cost effectiveness is achieved with ULNB's and the highest with SCR for each model heater. The range of cost effectiveness for each of the five types of model heaters at a capacity factor of 0.9 are (1) $981/ton to $16,200/ton for the ND natural gas-fired heaters, (2) $813/ton to $10,600/ton for the MD natural gas-fired heaters, (3) $419/ton to $6,490/ton for the ND oil-fired heaters, (4) $245/ton to $4,160/ton for the MD oil-fired heaters, and (5) $1,790/ton to $14,100/ton for the ND pyrolysis heaters. Figures 2-1 through 2-5 graphically present the reduction efficiencies, capital cost, and cost effectiveness for the model heaters.

[a] NO_x reductions = Uncontrolled emission factor (lb/MMBtu) * Capacity(MMBtu/hr) * Effective reduction (%) * 1 ton/2,000lb * 8,760 hr/yr * Capacity factor.

[b] NO_x reductions in this column are calculated at a capacity factors of 1.0. To obtain reductions corresponding to particular capacity factors, substitute the desired capacity factor into the above equation.

[c] Cost effectiveness is calculated by dividing the total annual cost (TAC) by the NO_x reductions. Refer to Chapter 6 for the TAC.

2.4 IMPACTS OF NO_x CONTROLS

The use of NO_x control techniques may cause environmental and energy impacts. Environmental impacts associated with combustion controls include carbon monoxide (CO) and unburned hydrocarbon (HC) emissions. Environmental impacts of postcombustion techniques include NH_3, CO, and nitrous oxide (N_2O) emissions with the use of SNCR; NH_3 and sulfite (SO_3) emissions and solid waste disposal concerns with the use of SCR. Ammonia handling and storage also presents safety concerns with SNCR and SCR.

Energy impacts include additional electric energy requirements for fans or blowers and thermal efficiency losses. Thermal efficiency losses result in increased fuel consumption. These impacts are described briefly below.

Combustion controls, such as LNB, ULNB, and FGR, modify the combustion conditions to reduce the amount of NO_x formed. Combustion controls are usually operated in such a manner that reduces NO_x without producing unacceptable levels of CO and HC. Combustion controls reduce NO_x formation by reducing the peak flame temperature and/or O_2 concentrations in the flame zone. Reductions in NO_x formation achieved by reducing flame temperature and O_2 levels can increase CO and HC emissions if NO_x reductions by combustion controls are taken to extremes.

The use of SNCR results in emissions of unreacted NH_3 and increases in CO and N_2O emissions. Reactant-to-NO_x ratios of 1.25 to 2.0:1 are typical of SNCR systems. The high ratio results in unreacted NH_3 emissions, or NH_3 slip. Carbon monoxide and N_2O have been shown to be byproducts of urea injection. Unreacted NH_3 and N_2O are byproducts of NH_3 injection. Selective catalytic reduction NH_3 slip concentrations are generally less than SNCR NH_3 slip concentrations because the catalytic reactor allows a higher reaction rate and lower reactant-to-NO_x injection ratio (1.05:1 or less). Most catalysts used in SCR systems controlling process heaters in refinery service contain titanium and vanadium oxides. Catalyst formulations developed in the early 1980's tend to convert up to 5 percent of any sulfur

NMED Exhibit 109

dioxide (SO_2) present in high-sulfur fuels to SO_3, resulting in SO_3 emissions. Newer catalyst formulations that convert less than 1 percent SO_2 to SO_3 are available and have been demonstrated in utility applications.

Safety concerns for NH_3 storage and transport are due to the hazardous nature of concentrated NH_3 vapor. Aqueous NH_3 (NH_3 in a liquid solution at atmospheric pressure) is not considered as hazardous as anhydrous NH_3, which is stored as a concentrated pressurized vapor. Aqueous NH_3 is available for SCR and NH_3 SNCR processes.

State and local regulatory agencies may classify catalysts containing vanadium pentoxide as a hazardous waste, however, and require disposal of these catalyst materials in an approved hazardous waste disposal facility. Such disposal problems are not encountered with other catalyst materials, such as precious metals and zeolites, because these materials are not considered hazardous wastes.

Control techniques that require upgraded or newly installed fans and blowers increase the electrical energy consumption for process heaters using those control techniques. These control techniques are LNB plus SCR, LNB plus FGR and ND heaters converted to MD for MD LNB or MD ULNB use.

Current combustion controls balance NO_x reduction with acceptable fuel efficiency. Adding LNB, ULNB, and LNB plus FGR may cause flames instability and reduced combustion efficiency. However, these impacts are minimal in properly designed systems. Injecting reactants into the flue gas stream in SNCR systems produces approximately a 0.3 percent thermal efficiency loss. The injection of reactants and the pressure drop across the catalyst in SCR systems produces approximately a 1.5 percent thermal efficiency loss. Thermal efficiency losses generally result in increased fuel consumption.

NMED Exhibit 109

6.0 CONTROL COSTS

This chapter presents capital and annual costs and cost effectiveness for the NO_x emission control techniques described in Chapter 5. These control techniques are applied to the model heaters presented in Chapters 4 and 5. The NO_x control techniques are low-NO_x burners (LNB's), ultra low-NO_x burners (ULNB's), selective noncatalytic reduction (SNCR), selective catalytic reduction (SCR), LNB's combined with flue gas recirculation (FGR), LNB's combined with SNCR, and LNB's combined with SCR. These control techniques were selected because they are currently used to control NO_x emissions.

Cost estimates are highly variable, and accurate estimates can only be made on a case-by-case basis. The costs presented in this study give approximate costs of implementing the available control techniques. Costing methodologies from References 1 and 2 are used to estimate the costs. These methodologies estimate the costs of retrofitting control techniques on process heaters.[1,2] It is expected that the cost of incorporating a control technique in the design of a new process heater is less than retrofitting a similar heater with the same control technique.

Capital and annual cost methodologies for NO_x control techniques applied to the model heaters are presented in Section 6.1. The total annual costs (TAC) for the NO_x control techniques applied to the model heaters are presented in Section 6.2. The cost effectiveness of the NO_x control techniques applied to the model heaters is presented in Section 6.3. Radiant burner costs are discussed in Section 6.4; radiant burners are not included in the model heater cost

NMED Exhibit 109

analysis due to limited costing information. Section 6.5 lists the references used in this chapter.

6.1 CAPITAL AND ANNUAL COSTS METHODOLOGIES

The methodology used to develop capital costs is essentially the same for each NO_x control technique. Because available cost data for this study were limited, capital cost methodologies from References 1 and 2 were used to develop capital costs for each individual control technique. The capital costs were updated to 1991 U.S. dollars using the Chemical Engineering plant cost index.[3] Capital costs for combinations of controls are the sum of the capital costs of the individual control techniques.

The TAC for the NO_x control techniques comprises the annual operating costs of chemicals, electricity, fuel, and maintenance. The costs, in 1991 dollars, for electricity, fuel, chemical reactants, and maintenance are shown in Table 6-1. Capital and annual costs for LNB's, ULNB's, SNCR, SCR, FGR, LNB's plus SNCR, and LNB's plus SCR are presented in Sections 6.1.1 through 6.1.7, respectively. Each of these sections presents the methodology used to develop capital and annual costs. Natural draft (ND)-to-mechanical draft (MD) conversion is not considered a stand-alone control technique but is required to implement some control techniques. The capital and annual costs of ND-to-MD conversion are considerable and are presented in Section 6.1.8.

6.1.1 Costs of LNB's

6.1.1.1 Capital Costs of LNB's. The LNB capital cost methodology from Reference 1 was used to calculate the capital cost of applying LNB's to process heaters. The primary parameters affecting the capital cost include the following:

1. Heater capacity;
2. Number of burners;
3. Burner heat release rate; and
4. Natural or forced draft combustion air delivery system.[1]

The capital cost methodology from Reference 1 for ND heaters is:

$$TIC = 30,000 + HQ\ [5,230 - (622 \times BQ) + (26.1 \times BQ^2)]$$

NMED Exhibit 109

TABLE 6-1. UTILITY, CHEMICAL, AND MAINTENANCE COSTS

Electricity[a]	$0.06/kWh
Natural gas[b]	$2.00/MMBtu
Distillate fuel oil[c]	$5.54/MMBtu
Residual fuel oil[c]	$3.00/MMBtu
Ammonia[d]	$0.125/lb
Maintenance[e]	2.75% of capital cost

[a]Reference 4, Table 5-10.
[b]Reference 5.
[c]Reference 6.
[d]Reference 2.
[e]Reference 1.

NMED Exhibit 109

where:

TIC = total capital installed cost;

HQ = heater capacity (GJ/hr); and

BQ = burner heat release rate (GJ/hr)

and

$$BQ = HQ/NB \times (1.158 + 8/HQ)$$

where:

NB = number of burners.

The LNB capital cost for MD heaters is calculated to be 50 percent higher than the capital cost for ND heaters. This additional cost is added to account for the following:

1. Increased LNB cost;
2. Additional excess air control equipment; and
3. Combustion air plenum modification.[1]

The capital cost methodology for MD LNB's is:

$$TIC = 1.5 \times \{30,000 + HQ \times [5,230 - (622 \times BQ) + (26.1 \times BQ^2)]\}.$$

The cost methodologies give costs in Canadian average 1990 dollars. For this analysis, the capital costs have been escalated to U.S. average 1991 dollars using the Chemical Engineering plant cost index and an exchange rate of 1 U.S. dollar to 1.15 Canadian dollars.[3]

The cost of the burners, although substantial, represents a fraction of the actual installed costs. Large cost variations for LNB retrofit installations can occur when floor rebuilding is required and space limitations below the heater exist. Typical LNB's do not fit standard burner mounts and may require complete floor rebuilds and refractory replacement. Not all heaters can be retrofitted with current LNB designs. The primary variable influencing the feasibility of an LNB retrofit is the space requirement below the heater necessary to install the combustion air plenums.[8,9]

6.1.1.2 Operating Costs of LNB's. Maintenance costs of LNB's are calculated as 2.75 percent of the LNB's capital costs.[1,2] Installation of LNB's can improve heater efficiency, although this effect (if any) will be strongly heater-dependent.

NMED Exhibit 109

The potential increase in heater efficiency may lower fuel costs. Operational costs may be marginally increased due to the decrease in flame stability and the potential for flame-out.[1,8] These operational impacts will tend to offset one another in the cost analysis associated with LNB installation and minimize the effect of the current analysis.[1] These costs are site-specific and are not included in the cost analysis.

6.1.2 Cost of ULNB's

6.1.2.1 Capital Costs of ULNB's. The capital costs of ULNB's are affected by the same parameters as LNB's. The primary parameters that affect the capital costs include:

1. Heater capacity;
2. Number of burners;
3. Burner heat release rate; and
4. Natural or mechanical draft combustion air delivery system.

The capital cost methodology for ND ULNB's is:

$$TIC = 35{,}000 + \{HQ \times [5{,}230 - (622 \times BQ) + (26.1 \times BQ^2)]\}.$$

In the case of MD heaters, an additional 50 percent is added to the capital cost to account for the following:

1. Additional excess air control equipment; and
2. Increased combustion air plenum construction.

The capital cost methodology for MD ULNB's is:

$$TIC = 1.5 \times \{35{,}000 + HQ \times [5{,}230 - (622 \times BQ) + (26.1 \times BQ^2)]\}.$$

The cost methodologies give costs in Canadian average 1990 dollars. For this analysis, the capital costs have been escalated to U.S. average 1991 dollars using the Chemical Engineering plant index and an exchange rate of 1 U.S. dollar to 1.15 Canadian dollars.[3]

Similar to LNB's, large cost variations for ULNB's retrofit can exist. The cost variations and variables influencing the use of LNB's described in Section 6.1.1.1 also apply to ULNB's.

6.1.2.2 Operating Costs of ULNB's. Maintenance costs of ULNB's are calculated as 2.75 percent of the ULNB's capital

NMED Exhibit 109

costs.[1,2] Operating costs for LNB's described in Section 6.1.1.2 also apply to ULNB's.

6.1.3 Costs of SNCR

6.1.3.1 Capital Costs of SNCR. The SNCR capital cost methodology from Reference 1 has been used to calculate the capital cost of installing SNCR in process heaters. The cost methodology in Reference 1 uses data from Exxon's Thermal DeNO$_x$® (TDN®) process because Nalco Fuel Tech's process to date has been installed on only a limited number of refinery heaters. The major capital costs for SNCR systems are for the ductwork, reactant storage tank and injection system, insulation, control instrumentation, engineering, and installation. The capital cost methodology for SNCR from Reference 1 is:

$$TIC = 31,850\ (HQ)^{0.6}$$

where:

HQ is the heater capacity, in gigajoules per hour (GJ/hr).

The cost methodology gives costs in Canadian average 1990 dollars. For this analysis, capital costs have been escalated to U.S. average 1991 dollars using the Chemical Engineering plant index and an exchange rate of 1 U.S. Dollar to 1.15 Canadian dollars.[3]

6.1.3.2 Operating Costs of SNCR. The SNCR annual operating cost models from References 1 and 2 are used to calculate the annual operating costs of SNCR operation. Maintenance costs of SNCR are calculated as 2.75 percent of the SNCR capital costs.[1,2] The operating costs include the cost of ammonia reactant, additional electricity, and additional fuel. The Reference 2 cost model was used to calculate the operating costs for NH_3 and electricity. The fuel penalty results from a loss of heater thermal efficiency due to dilution of the hot flue gas with steam or cold distribution air, which lowers the convection section heat recovery.[1] The loss in efficiency is estimated to require a 0.3 percent increase in fuel firing. The cost of the fuel penalty is calculated as a 0.3 percent increase in firing rate.[9]

NMED Exhibit 109

The cost methodologies for the annual operating costs of SNCR are:

NH_3 cost = (Q) x (lb NO_x/MMBtu) x (1 mole NO_2/46 lb NO_2) x (17 lb NH_3/1 mole NH_3) x (mole NH_3/mole NO_x) x ($0.125/lb NH_3) x (8,760 hr/yr) x CF,

Electricity cost = (0.3 kWh/ton NH_3) x (ton NH_3/yr) x ($0.06/kWh) x CF

Fuel penalty cost = (0.03) x (Q) x (8,760 hr/yr) x (fuel cost $/MMBtu) x CF,

where:

Q = heater capacity, MMBtu/hr, and

CF = capacity factor expressed in decimal form.[1,2,10]

6.1.4 Costs of SCR

6.1.4.1 Capital Costs of SCR. The SCR capital cost methodology from Reference 2 was used to calculate the capital cost of installing SCR in process heaters. The major capital costs for SCR systems are for the reactor section (including catalyst), ductwork, ammonia storage tank and injection system, foundation, insulation, control instrumentation, engineering, and installation.[2,11] Selective catalytic reductions systems require mechanical draft operation due to the pressure drop across the catalyst. The costs for SCR applied to the ND model heaters includes the costs of converting to MD operation in addition to the SCR costs.[2]

The capital cost model from Reference 2 is:

$$TIC = 1{,}373{,}000 \times (Q/48.5)^{0.6} + 49{,}000 \times (Q/485),$$

where:

Q = heater capacity, MMBtu/hr.[2]

The cost methodology gives costs in U.S. average 1986 dollars. For this analysis, capital costs have been escalated to U.S. average 1991 dollars using the Chemical Engineering plant index.[3]

6.1.4.2 Operating Costs of SCR. The SCR annual operating costs were calculated using the methodologies from Reference 2. The operating costs include the cost of the ammonia reactant,

NMED Exhibit 109

catalyst replacement, additional electricity and additional fuel. The Reference 2 cost methodology was used to calculate the NH_3, catalyst replacement, and electricity costs. A 1 to 2 percent loss of heater thermal efficiency can be expected due to dilution of the hot flue gas with cold distribution air, which lowers convection section heat recovery. This loss of efficiency is represented by a fuel penalty; the cost of the fuel penalty is estimated to require a 1.5 percent increase in fuel consumption.[1]

The cost methodology for annual operating costs of SCR:

NH_3 cost = (Q) x (lb NO_x/MMBtu) x (1 mole NO_2/46 lb NO_2) x (17 lb NH_3/1 mole NH_3) x (mole NH_3/mole NO_x) x ($0.125/lb NH_3) x (8,760 hr/yr) x CF;

Catalyst replacement cost = 49,000 x (Q/48.5)/5 yr

Electricity cost = (0.3 kWh/ton NH_3) x (ton NH_3) x ($0.06/kWh) x CF, and

Fuel penalty cost = (0.015) x (Q) x (8,760 hr/yr) x (fuel cost $/MMBtu) x CF,

where:

Q = heater capacity, MMBtu/hr, and

CF = capacity factor expressed in decimal form.

Maintenance costs for SCR are calculated as 2.75 percent of the SCR capital cost.[1,2]

6.1.5 Costs of FGR

6.1.5.1 Capital Costs of FGR. The FGR capital cost methodology from Reference 1 is used to calculate the capital cost of installing an FGR system in process heaters. The capital cost model for FGR from Reference 1 is:

$$TIC = 12,800 (HQ)^{0.6}$$

where:

HQ = heater capacity, GJ/hr.[1]

The cost methodology gives cost in Canadian average 1990 dollars. For this analysis, the capital costs have been escalated to U.S. average 1991 dollars using the Chemical

NMED Exhibit 109

Engineering plant index and an exchange rate of 1 U.S. dollar to 1.15 Canadian dollars.[3]

As discussed in Chapter 5, FGR is not considered to be a stand-alone NO_x control technique but is typically combined with LNB's. Flue gas recirculation requires an MD combustion air supply. For ND heaters, implementing FGR as a NO_x control technique incurs the following capital costs: ND-to-MD conversion, MD LNB's, and the FGR system.

The cost methodology is based on boiler data because process heater applications of FGR are limited. An additional consideration for FGR is the high-temperature flue gas associated with process heaters. Boilers use economizers to recover a large amount of thermal energy from the flue gas in boilers. Process heaters do not have economizers and therefore have higher flue gas temperatures than do boilers. Flue gas recirculation fans capable of handling the high-temperature flue gas from process heaters may increase the cost of implementing FGR over the costs presented in this chapter.

6.1.5.2 Operating Costs of FGR. The FGR annual operating cost model from Reference 2 has been used to calculate the annual operating costs of FGR operation. The primary cost associated with FGR operation is the additional electrical energy required to operate the FGR fan. The annual cost model for FGR from Reference 2 is presented below:

Electric power cost = (motor hp) x (0.75 kW/hp) x (8,760 hr/yr) x ($0.06/kWh) x CF

where:

motor hp = FGR fan motor horsepower, (1/5) x (Q);
Q = process heater capacity in MMBtu/hr, and
CF = heater capacity factor.

Maintenance costs for FGR are calculated as 2.75 percent of the capital cost.[1,2]

6.1.6 Costs of LNB's Plus SNCR

6.1.6.1 Capital Costs of LNB's Plus SNCR. The capital cost of LNB's plus SNCR is the sum of the capital cost of LNB's, presented in Section 6.1.1.1, and the capital cost of SNCR,

NMED Exhibit 109

presented in Section 6.1.3.1. Selective noncatalytic reduction systems may be applied to ND or MD systems without modifications to the draft system. Therefore, either ND LNB's or MD LNB's may be combined with SNCR.

6.1.6.2 Operating Costs of LNB's Plus SNCR. The operating and maintenance costs of LNB's plus SNCR are the sum of the operating and maintenance costs for LNB's, presented in Section 6.1.1.2, and the operating and maintenance costs for SNCR, presented in Section 6.1.3.2.

6.1.7 Costs of LNB's Plus SCR

6.1.7.1 Capital Costs of LNB's Plus SCR. The capital cost of LNB's plus SCR is the sum of the capital cost of LNB's, presented in Section 6.1.1.1, and the capital cost of SCR, presented in Section 6.1.4.1. Selective catalytic reduction systems require MD operation. Therefore, ND heaters must be converted to MD operation for SCR.

6.1.7.2 Operating Costs of LNB's Plus SCR. The operating and maintenance costs of LNB's plus SCR are the sum of the operating and maintenance costs for LNB's, presented in Section 6.1.1.2, and the operating and maintenance costs for SCR, presented in Section 6.1.4.2.

6.1.8 Costs of ND-to-MD Conversion

6.1.8.1 Capital Costs of ND-to-MD Conversion. The ND-to-MD conversion capital cost methodology from Reference 1 is applied to calculate the capital cost of converting process heaters from ND to MD. The capital cost model for ND-to-MD conversion from Reference 1 is:

$$TIC = 21,350\ (HQ)^{0.6}$$

where:

HQ = heater capacity, GJ/hr.[1]

The cost methodology gives costs in Canadian average 1991 dollars. For this analysis, capital costs have been escalated to U.S. 1991 dollars using the Chemical Engineering plant indexes and an exchange rate of 1 U.S. dollar to 1.15 Canadian dollars.[3]

As discussed in Chapter 5, ND-to-MD conversion is generally not performed as a stand-alone NO_x control technique. The

NMED Exhibit 109

capital costs of converting ND heaters to MD heaters is added to the costs of control techniques where conversion from ND to MD is required. The control techniques that require ND heater conversion to MD are MD LNB's, MD ULNB's, MD SNCR, SCR, MD LNB's plus FGR, MD LNB's plus SNCR, and MD LNB's plus SCR.

6.1.8.2 Operating Costs of ND-to-MD Conversion. Maintenance costs for MD heaters are greater than for ND heaters. Maintenance costs associated with ND-to-MD conversion are calculated as 2.75 percent of the ND-to-MD capital cost.[1,2] Conversion from ND-to-MD increases heater thermal efficiency. Potential fuel reductions of 1.5 percent can lead to a yearly savings equivalent to about 4 to 8 percent of the capital cost to retrofit a medium sized heater ND heater to MD LNB's.[1] This efficiency gain is site-specific, however, and has not been included in the cost analysis.

6.2 TOTAL ANNUAL COST FOR MODEL HEATERS

The TAC for applying NO_x control techniques to model heaters is presented in this section. The TAC is the sum of the capital recovery cost and the annual cost. The capital recovery cost is estimated for each NO_x control technique by multiplying the capital costs by the capital recovery factor (CRF). The CRF is estimated by the following method:

$$CRF = [i \times (1+i)^n]/[(1+i)^{n-1}]$$

where:

i = pretax marginal rate of return (10 percent), and

n = equipment economic life (15 years).[4]

The capital and annual cost methodologies are presented in Section 6.1.

Sections 6.2.1 through 6.1.5 present the capital costs, capital recovery, annual costs, and TAC's for NO_x control techniques applied to the model heaters. Total annual costs are calculated for capacity factors of 0.1, 0.5, and 0.9. However, only TAC for the capacity factor of 0.9 are discussed in these sections. Sections 6.2.1 and 6.2.2 present these costs for the ND low- and medium-temperature and MD low- and medium-temperature gas-fired model heaters, respectively. Sections 6.2.3 and 6.2.4

NMED Exhibit 109

present these costs for the ND low- and medium-temperature and MD low- and medium-temperature oil-fired model heaters, respectively. Section 6.2.5 presents the capital costs, capital recovery, annual costs, and TAC's for the olefins pyrolysis model heaters. The ND-to-MD conversion costs are presented in Section 6.2.6.

6.2.1 Control Costs for the ND Gas-Fired, Low- and Medium-Temperature Model Heaters

Table 6-2 presents the capital costs, annual costs, and TAC's for the ND gas-fired, low-and medium-temperature model heaters. The capital costs of the control techniques range from $58,200 for ND LNB's used on the 17 MMBtu/hr heater to $4,650,000 for MD LNB's plus SCR used on the 186 MMBtu/hr heater. The TAC's range from $9,250/yr for ND LNB's on the 17 MMBtu/hr heater to $835,000/yr for MD LNB's plus SCR on the 186 MMBtu/hr heater.

6.2.2 Control Costs for MD Gas-Fired, Low- and Medium-Temperature Model Heaters

Table 6-3 presents the capital costs, annual costs, and TAC's for the MD gas-fired, low- and medium-temperature model heaters. The capital costs of the control techniques range from $130,000 for LNB's used on the 40 MMBtu/hr heater to $5,360,000 for LNB's plus SCR used on the 236 MMBtu/hr heater. The TAC's range from $20,700/yr for LNB's used on the 40 MMBtu/hr heater to $988,000/yr for LNB's plus SCR used on the 263 MMBtu/hr heater.

6.2.3 Control Costs for ND Oil-Fired, Low- and Medium-Temperature Model Heaters

Table 6-4 presents the capital costs, annual costs, and TAC's for the ND oil-fired, low- and medium-temperature model heaters. The capital costs of the control techniques range from $227,000 for ND LNB's to $2,580,000 for MD LNB's plus SCR. The TAC's range from $36,100/yr for ND LNB's to $463,000/yr for the MD LNB's plus SCR. These costs are the same for both distillate and residual oil-fired ND model heaters.

[c]Total annual cost = Capital recovery + operating and maintenance cost.

NMED Exhibit 109

6.2.4 Control Costs for MD Oil-Fired, Low- and Medium-Temperature Model Heaters

Table 6-5 presents the capital costs, annual costs, and TAC's for the MD oil-fired, low- and medium-temperature model heaters. The capital cost of the control techniques range from $319,000 for LNB's to $3,340,000 for LNB's plus SCR. The capital cost for both MD oil-fired heaters are the same. The TAC's range from $50,700/yr for LNB's used on the distillate oil-fired heater to $570,000 for LNB's plus SCR used on the residual oil-fired heater.

6.2.5 Control Costs for the Olefins Pyrolysis Model Heaters

Table 6-6 present the capital costs, annual costs, and TAC for the ND olefins pyrolysis model heaters. The capital costs of the control techniques range from $248,000 for LNB's to $2,900,000 for LNB's plus SCR on both pyrolysis model heaters. The TAC's range from $39,400/yr for LBN's on the natural gas-fired heater to $512,000 for LBN's plus SCR on the high-hydrogen fuel gas-fired heater.

6.2.6 Costs for ND-to-MD Conversion

Table 6-7 presents the capital, annual operating, and TAC of the ND-to-MD conversion for the model heaters. The capital costs range from $104,000 to $434,000; the annual operating cost range from $2,860/yr to $11,900/yr; and the TAC's range from $16,500/yr to $69,000/yr for the 17 and 185 MMBtu/hr natural gas-fired low- and medium-temperature heaters, respectively.

6.3 COST EFFECTIVENESS OF NO_x CONTROLS FOR PROCESS HEATERS

This section presents the cost effectiveness for the control techniques presented in Section 6.2. The cost effectiveness, in dollars per ton of NO_x removed ($/ton), is calculated by dividing the TAC's by the annual NO_x emission reduction, in tons.

Capacity factors of 0.1, 0.5, and 0.9 of heater operation, were included in the cost-effectiveness analysis. The capacity factor affects the operating costs but not the capital costs. The capacity factor also influences the tons per year of NO_x produced by a process heater. For example, approximately

NMED Exhibit 109

90 percent less NO_x is produced by a heater operating at a capacity factor of 0.1 as opposed to 1.0.

Cost effectiveness for ND natural gas-fired heaters is presented in Table 6-8. The cost-effectiveness range at a capacity factor of 0.9 is from $981/ton for ND ULNB's on the 77 MMBtu/hr heater to $16,200/ton for SCR on the 17 MMBtu/hr heater. The cost-effectiveness range for MD natural gas-fired heaters is shown in Table 6-9. At a capacity factor of 0.9, the cost effectiveness ranges from $813/ton for ULNB's on the 263 MMBtu/hr heater to $10,600/ton for SCR on the 40 MMBtu/hr heater.

The cost-effectiveness range for oil-fired ND heaters is shown in Table 6-10. For a capacity factor of 0.9, the cost effectiveness ranges from $419/ton for ND ULNB's on the residual oil-fired heater to $6,490/ton for SCR on the distillate oil-fired heater. The cost-effectiveness range for oil-fired MD heaters, shown in Table 6-11, is from $245/ton for ULNB's on the residual oil-fired heater to $4,160/ton for SCR on the distillate oil-fired heater at a capacity factor of 0.9.

The cost-effectiveness range for the ND olefins pyrolysis model heaters is shown in Table 6-12. At a capacity factor of 0.9, the cost effectiveness ranges from $1,490/ton for MD ULNB's on the high-hydrogen fuel gas-fired heater to $14,100/ton for LNB+SCR on the natural gas-fired heater.

The cost effectiveness of each control technique for the model heaters generally increases from ULNB to LNB, to LNB plus FGR, to SNCR, to LNB plus SNCR, to LNB plus SCR, to SCR. The cost-effectiveness values for the control techniques applied to the smaller model heaters are generally higher in comparison to the same control techniques applied to the larger heaters. This difference represents an economy of scale because for a given percent reduction, the quantity of NO_x emissions removed per year (tons/yr) from the smaller model heaters was lower than from other model heaters.

Table 6-13 is a summary of the cost effectiveness of selected NO_x emission control techniques as presented by the

NMED Exhibit 109

	90		4.53 to 10.2

[a]Escalated from 1986 $ to 1991 $ using the Chemical Engineering plant cost index.[3]

NMED Exhibit 109

California Air Resources Board (CARB).[12] The accuracy of the cost methodologies used in this study is estimated to be 30 percent plus or minus the actual cost.[1] The cost-effectiveness values of the control techniques for the model heaters are generally consistent with the ranges given in Table 6-13.

When comparing the cost effectiveness of combination control techniques in Table 6-13 to those in Tables 6-8 through 6-12, it is necessary to add the cost effectiveness of each component in Table 6-13. For example, the cost effectiveness of LNB's and SCR should be added to yield the total cost effectiveness of LNB's combined with SCR.

6.4 COST EFFECTIVENESS OF RADIANT BURNERS

This section presents the costs and cost-effectiveness values for a process heater using radiant burners. Data are insufficient to allow the development of model heaters with radiant burners. However, cost data for a new installation were provided for a 6 MMBtu/hr process heater using radiant burners. Retrofit costs are expected to be much higher for most process heater applications due to the major construction cost of modifying existing process heaters to accept radiant burners.[5] Refer to Section 5.1.8 for a discussion of radiant burners.

Emission reduction data for the 6 MMBtu/hr heater were presented in Table 5-6. The capital costs, capital recovery, annual costs, and cost-effectiveness values are presented in Table 6-14. The capital cost for radiant burners for this heater is $38,000. The annual costs range from $12,600/yr to $8,280/yr for capacity factors of 0.9 and 0.3, respectively. The cost effectiveness range from $7,600/ton to $17,600/ton for capacity factors of 0.9 and 0.3, respectively.[5]

NMED Exhibit 109

TABLE 6-14. RADIANT BURNER COST EFFECTIVENESS[5]

Heater capacity, MMBtu/hr	Capacity factor	Emission reduction, tons/yr[a]	Cost, $ 1991				Cost effectiveness, $/ton
			Capital	Capital recovery[b]	Annual operating	Total annual	
6	0.9	2.46	38,000	6,150	12,600	18,700	7,600
6	0.5	1.36	38,000	6,150	9,700	15,900	11,700
6	0.3	0.82	38,000	6,150	8,280	14,400	17,600

[a]Emission reduction compared to an MD heater with conventional burners.
[b]The capital recovery factor is 0.131.

Executive Summary

Natural gas-driven pneumatic controllers are used widely in the oil and natural gas industry to control liquid level, temperature, and pressure during the production, processing, transmission, and storage of natural gas and petroleum products. However, these devices release methane into the atmosphere. Pneumatic controllers are the second-largest source of methane from the US oil and gas industry, behind only component leaks, according to US EPA's Greenhouse Gas Inventory.

US Federal rules require that new continuous-bleed controllers be *low-bleed* (defined as designed to emit less than six standard cubic feet/hour) at production sites and compressor stations and be *zero-bleed* at processing plants. Unfortunately, recent measurements have demonstrated that many controllers currently in field use are emitting more than would be expected based on design specifications.

This study was undertaken to determine whether cost-effective non-emitting technologies are available to eliminate this major emissions source. We find that these technologies have evolved considerably over the past decade and are now available and actively in use in oil and gas fields in the United States and Canada. Two technologies are mature, proven, and in relatively wide use, and as we discuss in this report, these technologies provide a cost-effective way to eliminate emissions of methane and other pollutants from pneumatic controllers.

Major findings include:

- Zero emission technologies can virtually eliminate emissions from pneumatic devices.
- A number of technologies are available. The two most promising, which this report focuses on, are electronic controllers – both solar and grid powered – and instrument air**.**

  Electronic controllers can be installed both at sites connected to the electric grid and at sites isolated from the grid.

  Instrument air technology is a well-established, mature solution to run pneumatic control systems and is widely applied globally. The technology requires a reliable power supply, either from the grid or from generators on the site.
- Currently, electronic controllers are generally used at smaller sites while instrument air is used at larger sites, due to the technical limitations of air compressors. These two technologies are on the market today, from multiple suppliers.
- Due to the market conditions, providers of electronic controllers have so far focused mainly on the development of solutions for small sites in remote locations. There thus seems to be much less field experience with using electronic controllers at medium and large sites; however, no technical barriers were identified for this type of installation.
- A number of other zero emission solutions are available today with more limited applicability (e.g. self-contained devices) or fewer documented implementations (e.g. solar-powered instrument air). Depending on the site specificities, these options can represent useful alternatives to instrument air or electronic controllers.
- Operators have successfully installed hundreds of systems. They report positive experiences on both new and retrofit sites, valuing zero emission solutions for their low maintenance costs and reliability.
- An economic analysis, assuming conservative average emission factors for pneumatic controllers, was performed for 2032 site configurations with 1 to 40 controllers (excluding emergency

shutdown devices). Both retrofit and new installations, with and without electricity on-site, were considered.

- Zero emission solutions have abatement costs below the social cost of methane used by US EPA ($1354/tCH$_4$, mean value calculated for 2020 with a 3% discount rate in 2016 USD) in the vast majority of the site configurations considered (2008 out of 2032 site configurations).
- The abatement costs, calculated as described above, exceed the social cost of methane used by US EPA primarily at very small sites – those with less than three controllers (excluding emergency shutdown devices). However, if higher emission factors, as reported from recent field measurements, are used, the abatement costs at even the very small sites will fall below the social cost of methane.

Overall, we find that zero emission solutions are available today and are cost effective to implement in nearly every situation.

The following table presents a summary of both the technical applicability and economic attractiveness of the different zero emission technologies under different categories of sites. Though this analysis does not provide a detailed evaluation of the distribution of the sites in the US for each of the below categories, existing studies have suggested that the vast majority of the sites have less than 20 controllers.

Type of of site			**Both retrofit and new sites**					
		Number of controllers (excl. ESDs)	**1- 3**		**4-20**		**21-40**	
		Electricity on-site?	Yes	No	Yes	No	Yes	No
Main options: Electric controller Instrument air		**Description** (of the most economic option which is technically feasible)	Grid connected **electric** controller	Solar powered **electric** controller	Grid connected **electric** controller	Solar powered **electric** controller	Instrument **air**	
		Number of cases not cost effective (i.e. abatement cost > social cost of methane) **under central assumptions**	6 / 36	11 / 36	0 / 308	2 / 308	5/ 328	
		Cost effective for <u>every</u> site configuration if emissions factors are:*	> 5.6 scfh for retrofit > 2.8 scfh for new sites	> 7.2 scfh for retrofit > 4.4 scfh for new sites	> 3.6 scfh for retrofit > 1.4 scfh for new sites	> 4.2 scfh for retrofit > 1.8 scfh for new sites	> 4.5 scfh for retrofit > 1.8 scfh for new sites	
Other options potentially applicable depending on the local conditions	Limited applicability	Vent gas recovery	✓	✓	✓	✓	✓	✓
		Instrument air powered by gas	Not relevant	Not relevant	Not relevant	Not relevant	Not relevant	✓
		Self contained controllers	✓	✓	✓	✓	✓	✓
	Limited known implementations	Solar powered instrument air	Not relevant	✓	Not relevant	✓	✗	✗
		Electric controllers powered by other power sources (TEG, fuel cell)	Not relevant	Not relevant	Not relevant	Not relevant	Not relevant	✓
		Large solar powered electric controller (no known implementations)	Not relevant	Not relevant	Not relevant	Not relevant	Not relevant	Potential solution,** but no example known.

*Emissions factors threshold listed are determined for the site configuration with the highest abatement cost within the category.
** Based on other solar applications. No fundamental barrier identified.

Abbreviations and Notes on Units

CAPEX	Capital Expenditure
CH_4	Methane
CO_2eq	Carbon dioxide equivalent
EF	Emission Factor
ESD	Emergency shut down
GHGRP	Greenhouse Gas Reporting Program – US EPA
GOR	Gas/oil ratio
Mscf	Thousands standard cubic feet
MMscf	Million standard cubic feet
MMscfd	Million standard cubic feet per day
MMT	Million tons
OPEX	Operational expenditure
SCADA	Supervisory Control and Data Acquisition
Scfh	Standard cubic feet/hour
USD	US dollars
VOC	Volatile Organic compound
VRU	Vapor Recovery Unit

Notes on units:

All the data are presented in metric tons

All monetary figures are presented in US dollars, denoted as $

Social Cost of Methane: This report uses the social cost of methane, as reported by US EPA in recent regulatory analyses, as a benchmark for the cost-effectiveness of measures to abate methane emissions. We use the mean value calculated at the 3% discount rate for emissions in year 2020. EPA calculates this as $1300 per metric ton in 2012 USD. We have converted this to $1354 per metric ton in 2016 USD, using a cumulative rate of inflation of 4.2%.

1. Introduction

1.1 What is the problem?

Natural gas-driven pneumatic controllers are used widely in the oil and natural gas industry to control liquid level, temperature, and pressure during the production, processing, transmission, and storage of natural gas and petroleum products. However, these devices vent methane into the atmosphere. Pneumatic controllers are the second-largest source of methane from the US oil and gas industry, behind only component leaks, according to US EPA's Greenhouse Gas Inventory [1].

Over the last few years, regulators have worked to reduce the emission of methane and volatile organic compounds (VOCs) from pneumatic controllers. US Federal rules require that new continuous-bleed controllers be *low-bleed* (defined as designed to emit less than 6 scfh) at production sites and compressor stations and *zero-bleed* at processing plants. Wyoming goes further to include intermittent-vent controllers in its requirement that *all* new controllers are designed to emit less than 6 scfh. It also requires the replacement of existing high-emitting controllers in some areas and caps allowable emissions in other areas. Recently Colorado required that existing high-continuous-bleed controllers be replaced with low-bleed controllers statewide, and other states are currently considering similar measures. Finally, some operators have reported voluntary replacements of high-bleed controllers with low-bleed controllers to programs such as US EPA's Natural Gas STAR.

Unfortunately, recent measurement studies [2,3,4] have reported higher emissions from low-bleed controllers than expected. Some controllers that are considered low-bleed according to manufacturer specifications actually bleed above the low-bleed threshold of 6 scfh. Indeed, a number of controllers appear to malfunction, emitting significantly more than they are designed to emit.

Moreover, as a class, intermittent-vent controllers, which are largely unregulated, far outnumber continuous-bleed controllers, and EPA estimates that emissions from intermittent-vent controllers are considerably higher than emissions from continuous-bleed controllers [1]. Recent work has demonstrated that some controllers designed to emit intermittently fail and begin leaking natural gas continually [2,5].

Given the wide range of applications of pneumatic controllers, their typical installation in remote, unmanned sites, and the limited resources of air quality regulators, it is very challenging for air quality regulators to ensure compliance to emissions standards for pneumatic controllers. Currently, new continuous-bleed controllers are in compliance with EPA rules, if they are designed to emit below the EPA threshold of six cubic feet per hour. In practice, they may emit more depending on installation parameters (such as the pressure of the supply-gas), malfunctions, or even tampering, e.g. production workers modify controllers bleed rates when they believe that it will improve reliability [9]. Finally, it is inherently difficult to quantify the emissions from intermittent-vent controllers, as their actuation frequency is variable and may change over time.

1.2 Objective of this project

Zero emission technologies have the potential to virtually eliminate this emission source. They have evolved extensively over the last few years, as operators have gained experience using them. Yet, although zero emission technologies are often mentioned in best practices documentation and reports, there is very limited information on overall applicability and costs (with the exception of instrument air).

This report documents how zero emission technologies are being used in gas and oil fields, and discusses the zero emissions technologies that are suitable for wide usage in common applications at oil and gas production facilities and compressor stations. The main objectives include:

- Presentation of zero emission technologies that are currently available on the market.
- Discussion of the applicability and the technical barriers to the implementation of these technologies.
- Estimates of implementation and methane abatement costs of these technologies for new installations and retrofits.

1.3 Approach and methodology

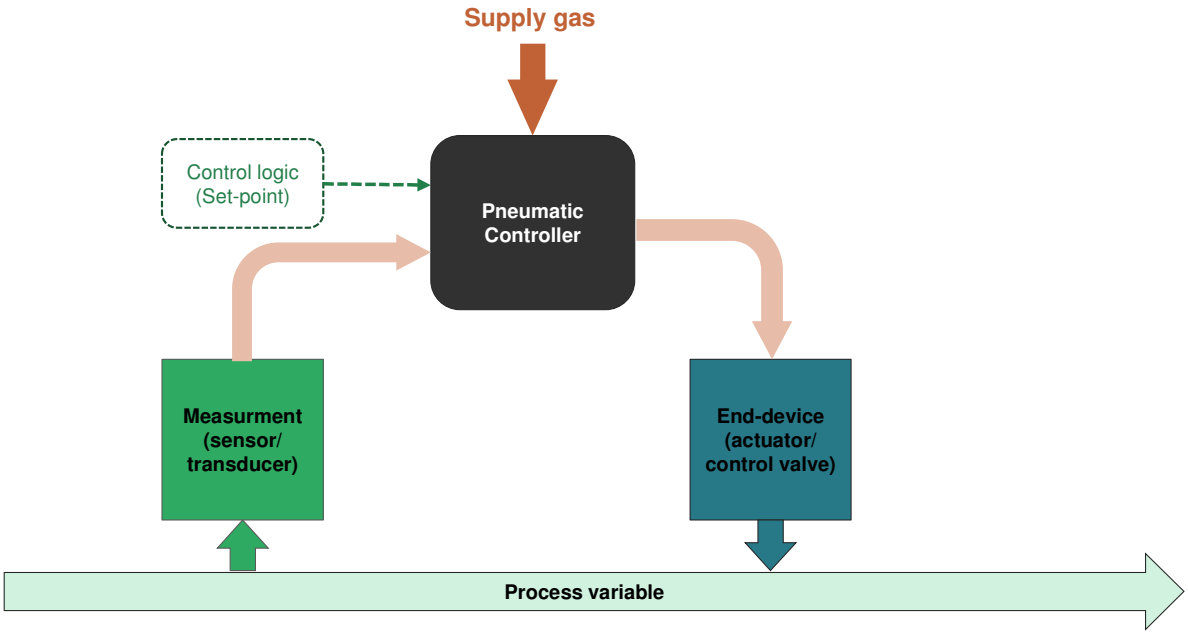
In addition to a comprehensive literature review, this report relies on interviews with a number of relevant stakeholders and a detailed cost-benefit analysis.

Interviews: Seventeen interviews were conducted. Nine were with technology providers, and eight with both small and large oil and gas companies. The interviews gathered information on field experience with the implementation of zero emission technologies, in particular on their applicability, technical barriers experienced, and actual costs and benefits.

Cost-benefit analysis of zero emission technology implementation: Based on the information gathered during the interviews, literature reviews, and online equipment quotes, a cost-benefit analysis was performed covering a wide range of possible site configurations.

The cost-benefit analysis is presented in section 4 of this report. Prior to that, section 2 includes an introduction to controller typologies, followed by a brief literature review of emissions from controllers. Section 3 presents the different zero emission controller technologies and includes a description of field experiences with these technologies. The report concludes with a brief overview of existing applicability and costs under a range of circumstances.

2. Gas Driven Pneumatic controllers – What are we talking about?



2.1 Definition

A process controller is a device that senses a physical state and then operates automatically to regulate that state[1], based on an established set-point in its control logic. Process controllers can regulate a variety of physical parameters – or *process variables* – including fluid pressure, liquid level, fluid temperature, and differential pressure. An example of a common type is a separator dump valve controller, which operates when it senses that liquid has reached a certain level. Process controllers can be electric, hydraulic, pneumatic or a combination of them. An example of a combination controller would be an electrohydraulic controller operating an electric valve to send liquid pressure to a hydraulic end-device.

Pneumatic controllers convert an input signal to a pneumatic pressure output using gas pressure. The end-device, i.e. the control valve, is adjusted by the actuator in response to signal from the controller. A pneumatic controller uses gas pressure to open or close a mechanical device, such as a valve, when it senses the need to regulate a process condition such as liquid level, pressure, temperature, or flow.

[1] In complex control systems, other process control variables might be modulated to regulate the *state* of that process variable.

Figure 1: Pneumatic Controller - concept sketch

2.2 Typology of controllers

Different typologies have been used in the literature to classify controllers, based on:

- The controller application (i.e. what the controller is used for, such as to control liquid level, pressure, or temperature)
- The emission pattern of the controller (continuous-bleed or intermittent vent)
- The end service (i.e. the way the controller regulate the parameter, such as *on/off* service or *throttle* service)

Controller application

Pneumatic controllers are widely used in upstream oil and gas operations, most commonly to regulate fluid level in separators and tanks, temperature of heaters and fans, pressure of vessels, and differential pressure of lines.

Emission pattern of the controllers

Pneumatic controllers can be designed to release supply-gas continuously or intermittently. Pneumatic controllers are thus classified as **continuous-bleed** or **intermittent-vent** (equivalent to intermittent bleed in all EPA documents), depending on whether or not they are *designed* to emit continuously.

In this study,

- emissions occurring from intermittent-vent controllers, where there is a physical barrier between the supply-gas and the end-device, are referred to as ***vent***; and
- emissions from continuous-bleed controllers, where the supply-gas provides required pressure to the end-device while the excess amount of gas is emitted, are referred to as ***bleed***.

The continuous-bleed controllers are classified into high-bleed and low-bleed in this report, depending on whether or not the controller is deemed to have a bleed rate above or below 6 scfh, in line with EPA regulations.[2]

The typology used in this report differs from the one presented in Allen et al. [2] where controllers are classified depending on their measured emissions pattern as opposed to their designed emissions pattern.

End-service typology

The end-device can be in *on/off* service or *throttle* service, depending on the process requirements. An example of on/off service is a dump-valve that controls the level of a vessel. In the "on" state, the valve is completely open to "dump" liquid. When the desired level has been achieved, the valve completely closes to its "off" state. An example of throttle service is a pressure control valve, which increases or decreases the flow of gas as needed to maintain line pressure at a fixed value. Both continuous-bleed and intermittent-vent controllers are commonly used to perform both on/off and throttling services.

A summary of pneumatic controller typology is presented in the table below. As this study focuses on eliminating emissions from these devices, only the emission pattern typology is used in the rest of the report.

Table 1: Summary of controller typology (mainly based on [6])

		Type of Service	
		On/Off	**Throttling**
Emission characteristics	**Intermittent-vent**	- Gas vented at de-actuation - Designed to emit no gas between de-actuation instances - De-actuation frequency depends on process variability	- Gas vented when end-device needs to throttle-off - Designed to emit no gas between throttle-off instances - Throttling frequency depends on process fluctuations
	High-bleed continuous controller	- Gas emitted continuously with higher bleed rates when end-device needs "off" service - Nevertheless, the average bleed amount is constant - Bleed rates are by definition deemed to be higher than 6 scfh	- Gas emitted continuously with higher bleed rates end-device needs to throttle-off - Nevertheless, the average bleed amount is constant - Bleed rates are by definition deemed to be higher than 6 scfh
	Low-bleed continuous controller	- Gas emitted continuously with higher bleed rates when end-device needs "off" service - Nevertheless, the average bleed amount is constant - Bleed rates are by definition deemed to be lower than 6 scfh	- Gas emitted continuously with higher bleed rates end-device needs to throttle-off - Nevertheless, the average bleed amount is constant - Bleed rates are by definition deemed to be lower than 6 scfh

2.3 Number of controllers and emission factors – Brief literature review.

Important work has been taking place over the last few years to measure and understand methane and VOC emissions from pneumatic controllers. This work includes measurement surveys [2,3,4,7], count of controllers per facility [1,2,8], and engineering calculations [8]. The methodology and the sampling approach vary significantly between different sources of information; thus comparisons should be made with particular care [8].

[2] It should be noted that the bleed rate is not a specification of the controller only, but also depends on the pressure and flow-rate of the supply-gas in addition to the size of the restriction orifice.

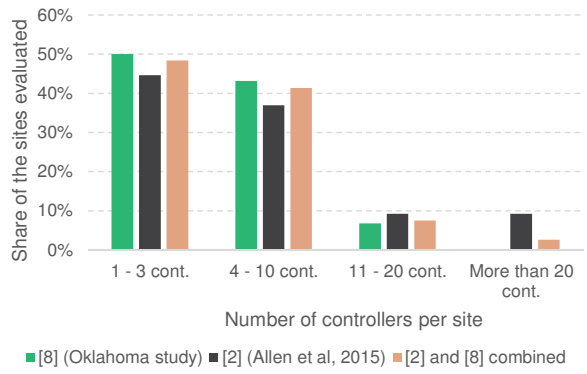
How many controllers per site?

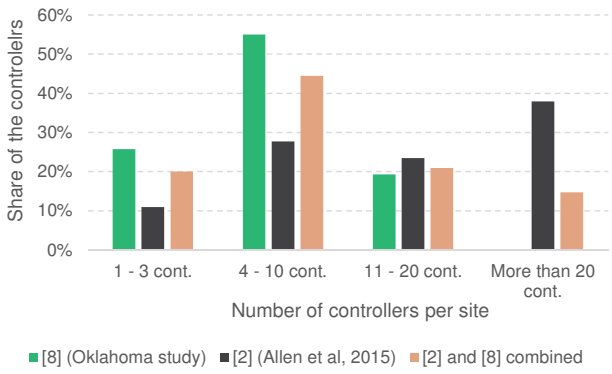
The number of controllers per site varies depending on the number of wells and more generally the number and type of equipment used. Recent studies have demonstrated that the vast majority of sites have less than 20 controllers.

Most of the existing studies have focused only on emitting controllers [3,5,7], thus underestimating the number of controllers reported for each site, since some intermittent-bleed controllers actuate infrequently (e.g., controllers for emergency shut-down valves) and are unlikely to do so while a site is being surveyed. Two studies have performed a thorough count of the number of controllers per site [2,8]. The distribution of controller functions reported by these studies varied, perhaps due to differences in the types of sites sampled in the studies, but the overall distribution of controller counts at production sites were quite similar (Figures 2 and 3):

- Very small and medium sites (with less than 20 controllers) account for the vast majority (97%) of the sites evaluated in both studies (Figure 2)
- These sites represent 85% of the controllers (Figure 3)

Figure 2: Share of the sites depending on the total number of controllers per site





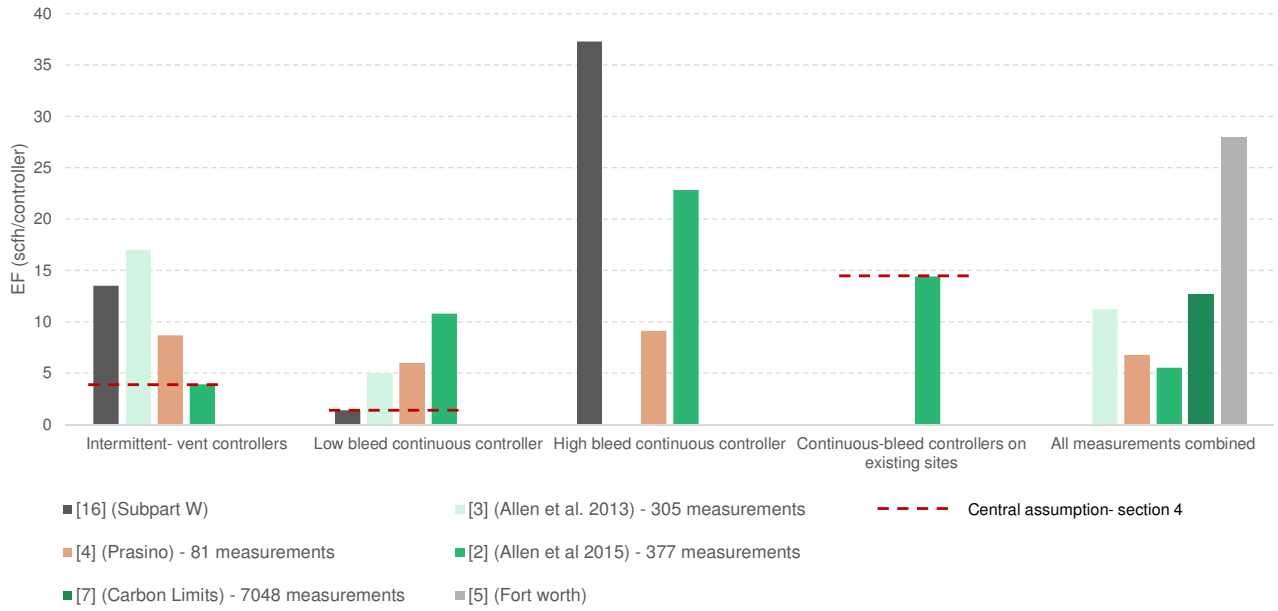


Figure 3: Share of the controllers depending on the total number of controllers per site

How much do controllers emit?

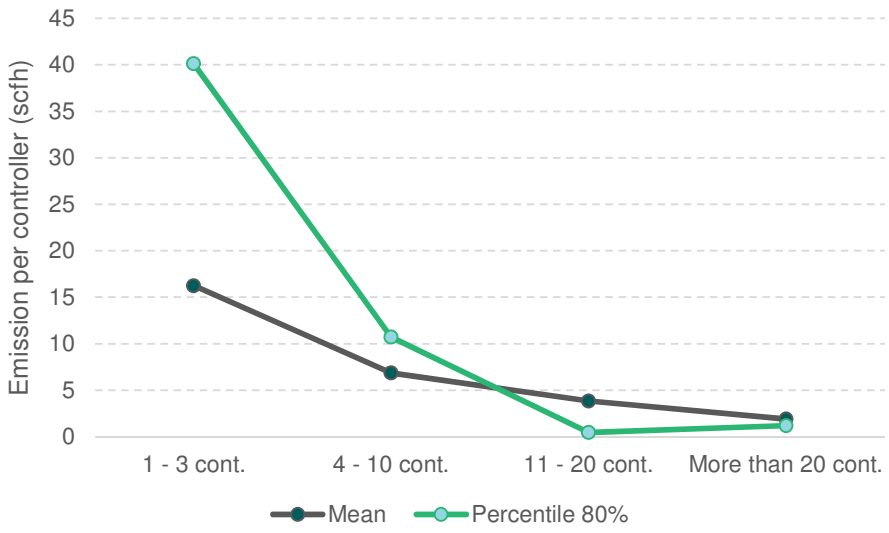
Despite the important work performed over the last few years, there is still significant uncertainty regarding emissions factors from controllers. The following figure summarizes the current emission estimates available for the different categories of controllers.

Figure 4: Emissions factors by controller category from different information sources[3]

A number of important conclusions can be drawn from the review of existing publications:

- Emissions from controllers vary between controller models and, for some models, for the same controller model between sites [2,4,7]
- A small subset of the controllers account for the vast majority of the emissions [2,7]
- Overall, recent research has demonstrated that a number of controllers behave differently than originally designed. In particular,
    - Average emission rates exceed the manufacturers' specifications [4], including some controllers designated low-bleed which emit above the threshold rate of 6 scfh [4,7]
    - Some controllers designed to emit intermittently fail and begin emitting natural gas continually [2,5]

In the analysis presented in the report, we have very conservatively adopted the lowest of the above average EFs for low-bleed in new installations and for intermittent-vent controllers. For continuous bleed controllers at existing sites, we have used the results of the recent measurement [2]. This average is consistent with a mix of low- and high-bleed in the field. The EFs are illustrated in Figure 4 and are described further in Section 4.1.



Do controllers from smaller sites emit more?

There is very little information available on how emission factors vary depending on the site's size. Analysis of recent measurements [2] suggests, however, that controllers are likely to emit much more in small than in large sites.

The following graph, plotting the mean and the eightieth percentile emission factors, shows a clear downward trend as the number of controllers per site increases. This trend could potentially be explained by the difference in terms of maintenance practices for small sites (typically unmanned and in remote area) and larger sites. In the follow-up analysis, a constant emission factor is assumed for both small and large sites.

[3] The data from [3] and [4] have been categorized and presented as described in [8]. The data from [2] have been categorized based on the "company classification into EPA category" (excluding ESD) and not based on the measured emission typology.

Figure 5: Average emission factors depending on the number of controllers per site [2]

3. Zero emission technologies – Description and technical applicability

This section provides an overview of a number of zero emission technologies available as an alternative to gas driven pneumatic controllers, based primarily on interviews and on a general literature review. A technology is considered "zero emission" if there is no methane or VOC emissions associated with its utilization.

3.1 Overview of the zero emission technology presented.

Five different technologies have been reviewed: Electronic controllers, instrument air provided by compressors (with electric power from the grid or existing on-site generation), solar-powered instrument air, vent recovery, and self-contained pneumatic controllers. Of these five different zero emission technologies, two – electronic controllers and instrument air – have reached a reliable level of maturity and are widely applicable. The remaining three technologies are either less mature (solar-powered instrument) or are applicable only in certain circumstances (self-contained pneumatic controllers and vent recovery).

The economic feasibility of the two mature and widely applicable technologies, electronic controllers and instrument air, is evaluated in detail in section 4 of this report.

The following table presents a brief summary of the different technologies evaluated.

Table 2: overview of the zero emission technologies presented

Technology	Maturity of the technology	Technical applicability limitations	Main strengths
Electronic controllers (ref section 3.2)	The technology has reached a reliable level of maturity, with hundreds of installations identified throughout this study.	Operators interviewed continue to use pneumatic ESDs. Some limitations with large numbers of controllers or high power demand chemical injection pumps.	• Can operate off grid • Reduced maintenance costs, in particular compared to wet gas driven controllers • Enables or simplifies automation of systems

Instrument air (ref section 3.3)	Extensive global experience for many years	Requires a reliable source of power Limited to installations with an air compressor > 5 HP	•	Reliability • Reduced maintenance costs, in particular compared to wet gas driven controllers
Solar-powered Instrument air (ref section 3.4)	Less than 100 installations identified	Compressor up to ~20 scfh	•	Operates off grid • Reduced maintenance costs, in particular compared to wet gas driven controllers
Vent Recovery (ref section 3.4)	The study identified less than 100 installations, with uncertain performance	Requires the presence of a VRU or a gas engine on site	•	Reliability
Self-contained pneumatic controllers (aka "Bleed to Pressure" or integral controllers) (ref section 3.4)	Although this solution has been deployed since early 2000s and is considered a relatively well-developed technology, controllers of this type are only available for certain specific applications	Applicability is limited by a number of conditions (e.g. pressure differential, downstream pressure, etc.)	•	Low-cost solution

3.2 Electronic controllers (solar powered and grid powered)

Electronic controllers adjust the position of the end-device by sending an electric signal to an electric actuator or positioner (as compared to pneumatic controllers which send a pneumatic signal to a pneumatic actuator or positioner). A motor powers the electric actuator to adjust the control valve to the desired position.

This section provides a description of the benefits, costs, and applicability of electronic controllers to both new sites and existing sites, where retrofits would be required. The description is based mainly on interviews with four oil and gas production companies that have installed these systems in their operations (from 3 to 40 installations per operator interviewed), complemented by interviews with technology providers.

Description of the technology

Electronic controllers can be installed both at sites connected to the electric grid, and at remote sites isolated from the grid. These systems typically include a control panel, electric actuators, electronic controllers, control valves, relevant switches (e.g. pressure, level or temperature switch) and a power source – connection to the grid, solar panels and batteries, or power generation on site. An electronic control system is generally designed to completely replace all pneumatically powered devices with electronic controls (with the exception of ESD, see below).

Electrically powered sites: Electronic controllers can be powered using 120 VAC or 220 VAC input from the grid or from on-site generation (three-phase power is not needed).

Remote sites: Solar control systems are driven by solar power cells that actuate mechanical devices using electric power. Systems can be customized for every application; those installed to date include up to three solar panels and eight batteries [9]. Use of solar-powered chemical injection pumps has become widespread over the past years.

Rationale for the use of electronic controllers:
For the operators interviewed, the two main drivers for project implementation were (i) to reduce methane and VOC emissions and conserve gas otherwise emitted and (ii) to reduce maintenance costs. Electronic systems have much lower maintenance costs than traditional gas-driven controller systems [10], in particular if the gas used is not perfectly dry and sweet.

Higher operating costs are also experienced for gas driven controller systems on sites where there is a need to purchase fuel gas from another source or use imported propane. These include sites with overly sour or wet gas, or with drastic drop in gas supply due to low gas/oil ratio (GOR) /low production.

Investment Costs
Each electronic control system is designed on a case-by-case basis. The investment costs depend on the number of controllers/pumps, but also on other factors such as pressure differential, pipeline diameter, and methanol volume requirement, which varies according to such factors as climate and production patterns[4]. The following table summarizes typical equipment costs for the cases evaluated:

Figure 6- Calscan pictures- Bear solar control system: Top: solar panel and control panel, bottom: Electric Actuator

Table 3: Electronic controllers – Typical investment costs for main equipment

Main items	**Approximate unit costs** USD
Level Controller & Level Control Valve	4000
Pressure Controller & Control Valve	4000
Chemical injection Pump	6000
Control panel	4000
Solar panel (140W unit)	500
Battery (100 Ah unit)	500

The operators interviewed experienced fairly smooth installations, with installation costs decreasing as they gained experience with the technology[5]. The installation costs vary by site, estimated at between $5000 and $8000 per well site. For a retrofit project, the well needs to be shut in for one or two days;

[4] Chemical injection pumps (e.g. methanol pumps) usually are the most important power consumer. Sites requiring high volumes of methanol volume injection would cause higher costs for scaled-up solar panel and batteries.
[5] After the first few sites installations.

NMED Exhibit 110

retrofit will generally take place when other maintenance is scheduled, to take advantage of that shut-down time. Solar powered electric systems do not require back-up generators[6].

Maintenance costs

The major maintenance costs include the replacement of batteries and panels. Most batteries last three to six years, while solar panels last twenty to thirty years. The operators interviewed highlighted that they experienced minimal maintenance costs on the sites converted to electronic controllers over the last five years.

Benefits of electronic controllers

Operators highlighted a number of benefits:

- Revenue from the sale of gas: Electronic controllers eliminate methane and VOC emissions and thus increase the volume of gas available for sale.
- Automation: Electronic control systems can provide additional benefits by enabling or simplifying the installation of automation systems (SCADA, Supervisory Control and Data Acquisition), though these systems are not required in order to use electronic controllers. This can potentially reduce the need for site inspections, reducing those costs for operators. For example, an alarm can be programmed to warn the operator if the dump has been open for more than 10 min. The system can be as sophisticated or as simple as required. (Note that we have not included any estimate of these cost reductions in the calculations of cost-effectiveness discussed in Section 4.)
- Reliability: As highlighted above, operators report that the electronic system is more reliable than a gas driven pneumatic control system, as operation of the latter with even slightly wet gas can lead to condensation issues, which over time will impact the performance of the system. One operator reported corrosion issues with sour gas used for pneumatic controllers and pumps.

Technical challenges with electronic controllers

- Snow: One operator reported that snow can be a problem with solar panel and battery lifetime.
- Theft or damage: Solar panels have reportedly been stolen or used as targets for shooting.
- Chemical injection pumps: Pumps consume far more energy than controllers/actuators. Sites with a large number of pumps or with pumps with high energy or power demand may represent a challenge for 100% solar powered electric systems. In addition, shortly after completion, some wells may require high volumes of methanol injection, and powering pumps to inject this high volume can strain these systems. Some of the operators interviewed reported that this technical barrier can be solved by bringing a portable stand-alone generator to the site for a few weeks to ensure that the power requirement is met.
- Safety considerations: Due to the very low voltage of the system, the safety risks are considered acceptable by the operator who evaluated this risk.

Applicability of electronic controllers

According to interviews with operators, this solution can technically be implemented on any well site. Generally, for the sites with these systems in place, the pressure differential is up to 2000 psi and the pipe diameters are between 2- 3 inches, but the system can be designed for larger pressure drops and larger diameters as required.

[6] When properly designed (e.g. with sufficient reserve margin in the batteries), recent solar powered electric systems do not require back-up generators, due to the reduced cost of solar-panels and the availability of low-power components. These systems are routinely installed without back-up generators in North America, including in Northern Canada where in winter there is only 1 to 2 hours of full sunlight a day. [9]

The only general limitation is the incremental costs. According to the operators, given the current gas prices, implementation costs are not compensated by the value of the gas saved. The project can be economical when other factors such as lower maintenance costs improve the return on investment.

Note on Emergency Shut-Down Valves (ESD): As a rule, electric controllers/actuators will stay in position if the system fails and power is lost, wires are cut, or other failures occur. This differs from some other solutions that can be designed so that valves close (or open) if the system fails (for example if the supply gas pressure is lost). Although Calscan is developing a "fail safe" electric ESD, operators have reportedly been using pneumatic or hydraulic ESD valves, as they are "fail-safe".

Sunlight: In northern latitudes (e.g. northern Alberta) and when the energy demand is high (e.g. several pumps), solar panels may not generate enough power, in particular for chemical injection pumps. Other power sources such as thermal electric generators or methanol fuel cells have been used in pilot implementations.

Electronic controllers at medium and large sites: Due to the market conditions, providers have so far focused mainly on the development of solutions for small sites in remote locations. There thus seems to be much less field experience with using electronic controllers at medium and large sites. No technical barriers were identified for the installation of electronic controllers in sites with available electricity. Given the recent progress in both solar panel technologies and large battery solutions, solar-powered solutions may also be appropriate for large sites without available power. However, we are not aware of any such installations. Therefore, to be conservative, we do not examine the use of electronic controllers at large sites without electricity available.
Medium or large sites may also be the result of a combination of a number of small sites (e.g. several well pads). In practice, several small independent electronic controller installations can thus be installed on one medium to large site.

Suppliers
The following table presents a non-exhaustive list of relevant providers:

Table 4: Non-exhaustive list of relevant providers:

Name of the suppliers	Website	Offer	Comments
Calscan	http://www.calscan.net/products_bearcontrol.html	Provide full customized system	Cascan's Bear Solar Electric Control System is designed mainly for well head separators, but it can also be used in other applications. It includes solar panels, batteries, electric actuators, control valves, switches, control panels and other control equipment.
Spartan	http://www.spartancontrols.com/	Provide full customized system	Spartan designs electronic control systems assembling a number of components including Emerson/Fisher electronic controllers and actuators.
Ameresco	http://www.amerescosolar.com/solar-power-solutions-oil-and-gas-industry	Provide full customized systems	Amaresco Solar designs customized off-grid solar power systems.

Exlar	http://exlar.com/	Manufacture elec. actuators	Exlar currently offer electric actuators that can replace pneumatic actuators.

3.3 Instrument air

Instrument air controllers are systems where pressurized natural gas is replaced with compressed air as a source of energy and signaling medium for pneumatic controllers and pneumatic actuators. Since controllers use air, instead of natural gas, they only vent air to the atmosphere, eliminating emissions from pneumatic controllers. Instrument air controllers are applicable to both new sites and existing sites; however, the technology can only be implemented when a reliable power supply is available.

This section provides a description of the benefits, the costs, and the applicability of instrument air controllers and is mainly based on interviews with oil companies, reviewing their recent experience installing instrument air systems.

Description of the technology

Instrument air technology is a well-established mature solution to run pneumatic control systems and is widely applied globally. In many countries (e.g. Norway, Iran, Kazakhstan [11]), the majority of the pneumatic control systems run on instrument air.

Systems typically include:

- Heavy-duty industrial air compressors. Two compressors are generally installed for redundancy, but for cost reasons, an operator has reported using only one.
- Air dryers - part of the air compressor package.
- Wet air receiver tank - part of the air compressor package.
- Dry air receiver tank - helps provide a buffer to secure longer system autonomy in the event of a power outage or demand surge.

Investment costs

Interviewers highlighted that the investment costs for instrument air installation vary significantly from site to site, depending on the layout and the type of equipment already on site. Investment costs can be classified as follows:

- Air compressor package: This includes the purchase of the main equipment (compressors, dryers and air receiver tanks). The size of compressors, dryers, and other equipment depends on the number of pneumatic controllers to be supplied with compressed air, and on their specifications (i.e., their demand for compressed air). A small compressor station would require around 5 HP of air compression capacity, while a larger facility would require up to 20 HP. This system can be purchased as individual components or as a package, for between $20,000 and $70,000 [12].
- Mechanical & installation costs: Mechanical and civil work may be required, depending on the layout of the existing facility. These costs are often higher for older facilities and can include:
    - Pipe cleaning and upgrades.
    - Trenching and tubing installation, since large sites may have several independent natural gas supply systems for controllers and pumps, and air would need to be piped through the full site.
- Electrical/instrumentation equipment and supplies: Depending on the site and the specific project requirement, this category may include:
    - Remote terminal unit or SCADA system installation or upgrade. The control system for some plants (e.g. shutdown/start-up, safety systems etc.) may have to be upgraded to accommodate the air compressor package.
    - Upgrades and wiring needed to add the additional electrical loads from the air compressor motors.
    - Repair/replacement of a controller in case of malfunctioning controller.
- Engineering/consulting: The site might require additional expenditures for electrical engineering and consulting.

Although air compressors and their auxiliary equipment represent a large part of the CAPEX, the engineering, preparation and installation costs can comprise up to 70% of the total upfront investment. Installation and preparation costs may include electrical and instrumentation supplies, mechanical and civil works, additional wiring, piping, valves and fittings. These costs are higher for older facilities that are not capable of handling the extra power, or don't have a suitable layout for utilities. Overall, the total cost for a project varies between $50,000 and $250,000 [10].

Maintenance costs

Maintenance costs typically include:

- Power consumption
- Air compressor servicing, generally every 6 months.

Benefits of instrument air controllers

Operators highlight a number of benefits:

- Revenue from the sale of gas: Instrument air eliminates methane and VOC emissions and thus increases the volume of gas available for sale.
- Reliability**:** The instrument air system is a highly reliable alternative to a natural gas driven pneumatic system for grid-connected facilities.
- Reduced maintenance costs**:** Although there are some additional operating costs with the deployment of air systems, some maintenance expenses are cut as a result of stopping the use of natural gas, particularly wellhead gas (or separator gas). Due to fluctuations in the GOR, some operators reported gas shortages on-site and thus they had to use other sources, such as propane, or to purchase gas from an adjacent field. Maintenance costs due to liquids condensing in the system or sour gas damage are also avoided by replacing untreated natural gas with air.

Applicability of instrument air controllers

Two main applicability limitations were identified during the interviews:

Size of the installation:

Instrument air controllers require heavy duty industrial air compressor packages designed for continuous duty (24/7). This in effect precludes the use of air compressors smaller than 5 HP, since available 2-3 HP air compressor packages present reliability problems. One operator reported that the one-year lifetime of a smaller compressors makes them unacceptable, so a minimum of 5 HP is assumed.

Access to power

Instrument air systems may only be used in locations with access to a sufficient and consistent supply of electrical power. Operators have used instrument air at:

- Grid connected sites.
- Sites with onsite power generation. Many sites (e.g. compressor plants) have power generation for other purposes: lighting, automation and control systems, etc. The same system can also be used for instrument air if generation capacity is available. We note that a sufficient, reliable, good quality gas stream is required for power generation. Wet or sour gas may not always be used for on-site power generation, depending on the specification of generator engines, etc.

In theory, diesel powered instrument air could be installed; however, this project identified no concrete examples of this technology. One operator stated he considered, and then rejected, the use of diesel to run air compressors, due to the high costs and low perceived environmental benefits.

3.4 Other technologies

This section reviews other "zero emission" technologies at various stages of maturity. In general these technical options are either (i) not widely applicable (such as self-contained controllers and vent gas recovery) or (ii) fewer than 100 installations were identified as part of this project (such as solar powered instrument air).

Solar powered instrument air
This study identified about 40 installations of small, energy efficient motor-compressors powered by solar panels/batteries, to replace natural gas with instrument air as the pneumatic medium. TRIDO industries, the technology provider interviewed as part of this study, indicated that these systems have a maximum capacity of ~20 scfh, making them suitable for some small to medium sites which use a few low-emitting controllers. High-bleed controllers have to be retrofitted to reduce air consumption in order to reach the feasible level. Despite the lack of extensive deployment so far, an attraction of this solution lies in the fact that controllers and actuators do not need to be replaced.

Instrument air powered by other power sources
Other power sources, such as thermal electric generators or methanol fuel cells, have been used in pilot implementations to power traditional instrument air systems.

Vent Gas Recovery
Re-routing to VRU
Vapor Recovery Units (VRUs) have a long, well-established track record in the upstream oil and gas industry to recover VOCs and methane from vented sources. Typically, they consist of capturing and piping equipment, a de-liquefaction drum, and compressor(s) to inject the recovered gas into pipelines. In theory, all vent lines can be connected to the VRU, including pneumatic controllers' lines.

Nevertheless, there have been limited implementations (only one example identified in this study) of well-site vent gas recovery projects using the recovered gas from pneumatic controllers in non-engine applications. SlipStream®, as further presented below, is a technology that facilitates recovery of the gas and use of it in gas-fired engines. Another technology, Cata-Dyne™, utilizes the recovered gas as a feed to a small, flameless appliance that converts natural gas or propane into infrared radiant heat that is usable if industrial heating is required.

SlipStream®
Spartan's SlipStream® system captures vented hydrocarbons and uses them as a supplementary fuel source for natural gas-fired engines, reducing fuel consumption. This technology can thus be applied only to sites with gas-fired engines, e.g. compressor engines. Despite concerns about costs, one operator emphasized specifically the reliability of the technology, as it reportedly does not interfere with normal operations. Nevertheless, if the volume of gas emitted by the combined vents (including the controllers) exceeds the engine fuel requirements, natural gas would still be vented or otherwise controlled.

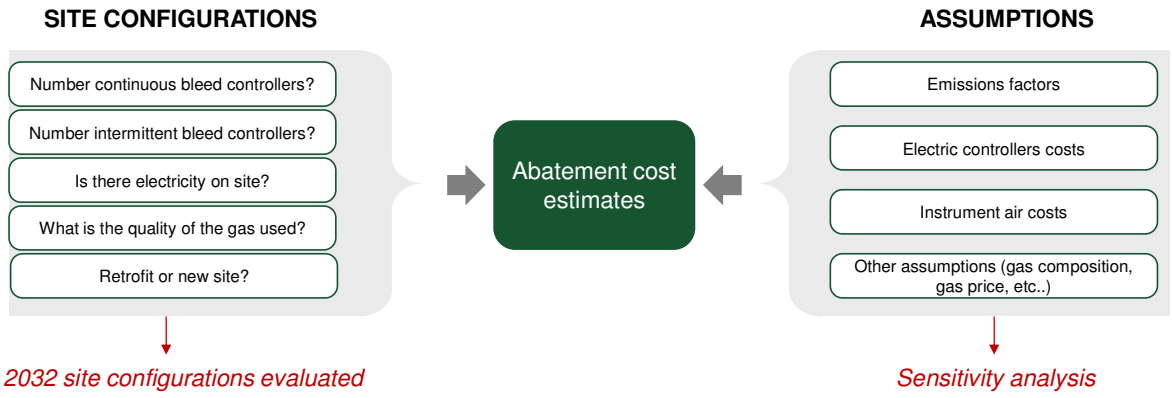
Self-contained (aka Bleed-to-Pressure or Integral Pneumatic Controllers)
Self-contained systems are designed to contain the gas typically vented from controllers and then discharge it to the control valve's downstream piping, thus resulting in zero emission.

A number of operational requirements limit the applicability of self-contained systems, the most important of which is the need for a high differential pressure across the control valve [6,13]. For instance, GE's Bleed-to-Pressure system requires more than 80 psi, and both GE and VRG Controls require a downstream pressure of maximum 300 psi [13]. Also, sour or untreated gas could cause disturbances in

the operation of self-contained controllers. Nevertheless, if applicable, the technology may be cost-effective or economical in cases where the total baseline emissions are high.[7]

Due to the limited applicability or the lack of widespread field experience, the technologies described above are not further analyzed in this report. However, depending on the site specifics, these options may be applicable and cost-effective, and can represent useful alternatives to instrument air or electronic controllers; thus they are presented as potential alternative options in section 4.4.

4. Cost effectiveness of electronic controllers and instrument air



This section presents an analysis of the *cost-effectiveness* – net cost in USD per ton of avoided pollution – of employing the two main zero emission technologies, air-driven pneumatic controllers and electronic controllers, instead of natural gas-driven pneumatic controllers at new and existing sites. These results are applicable at both oil and gas production sites (well pads) and compressor stations.

4.1 Analytical approach

The cost-effectiveness of zero emission technologies will vary with the number and type of controllers at a site, in addition to many other factors, as we discuss below. Given the variety of site configurations (number and type of controllers per site, connection to the grid, type of gas handled) across the US, and the lack of information on the frequency of occurrence of these configurations, we opted to carry out cost-effectiveness assessments for both electronic and instrument air controllers for a broad spectrum of permutations of those site configuration parameters.

A number of assumptions have been made for the analysis. Key assumptions are discussed in the section below; all assumptions are detailed in the Appendix.

Figure 7: Overview of the methodology

For each permutation of the site configuration parameters, a CH_4 abatement cost (cost per metric ton of avoided pollution) was estimated.

[7] A technology provider reports an average of less than $3000 per Bleed-to-Pressure control system, leading to a payback period of less than 2 years for replacing 8 controllers.

For this analysis, a zero emission technology implementation is considered
- "economical" if the CH_4 abatement cost is negative (i.e. if the project NPV is positive)
- "cost effective" if the CH_4 abatement cost (net cost per ton of abated pollution) is lower than the social cost of methane that EPA has used in recent regulatory analyses [19] (Social cost of methane for 2020, calculated with a 3% discount rate, $1354 (2016 USD). [8]

The following sections provide more insight on:
- The abatement cost calculation
- The main assumptions
- The site configurations evaluated.

Abatement cost calculation – methodology

For each site configuration, the following were estimated:
- The CAPEX and OPEX of the zero emission technology implementation (either electronic controllers or instrument air)
- The CAPEX and OPEX of the baseline scenario (i.e. the cost incurred by the operator if the conventional pneumatic technology had been used instead of zero emission systems)
- The emissions of CH_4 and VOC under the baseline scenario

Since methane and VOC emissions will be zero if the zero emission technology is used, the abatement cost (in \$/t CH_4) is then estimated as follows:

$$Abatement\ cost\ = -\frac{NPV(Cash\ flow_{zero\ emission\ project} - Cash\ flow_{baseline\ scanerio})}{NPV(Emission_{baseline\ scanerio})}$$

This approach, and its underlying assumptions, is compared to the annualized cost approach typically used by EPA in the appendix.

Main assumptions

The following table provides a list of the main assumptions applied. A full list of assumptions is available in the Appendix.

Table 5: Central assumptions

Description	Central Assumption	Comment
Gas price	2 \$/Mscf	The value of recovered gas has been assumed to be similar for all emission sources, independent of the composition of the gas. Gas values from 1 to 3 \$/Mcf have been assessed in sensitivity analyses.
Discount rate	7%	A 7% per year real term discount rate has been assumed. A sensitivity is presented for a 3% per year real term discount rate. This approach is consistent with EPA/BLM practice.
Remaining lifetime for a new project	15 years	The lifetime for new controller installation is assumed to be 15 years in line with EPA practice.
Remaining lifetime for retrofit project	10 years	The remaining lifetime for existing sites is assumed to be 10 years. A sensitivity is presented for a 5 years remaining lifetime.
Gas composition	0.0167 tCH_4/Mscf	Gas composition assumptions for dry gas (wet gas assumptions are presented in the Appendix)
	0.0046 tVOC/Mscf	

[8] EPA reports that the 2020 social cost of methane (mean value at 3% discount rate) is \$1300 / metric ton of methane in 2012 USD; this is adjusted to \$1354 / metric ton of methane in 2016 USD using a 4.2% cumulative inflation rate.

Average emissions factors assumptions

The emission factors used for this analysis are conservative averages based on the literature review (See section 2.3). The following table presents the emission factors used and the rationale for each value.

Table 6: Emission factors assumptions – central assumptions

Description	Central Assumption	Comment
Continuous-bleed controller(s) – retrofit sites only	14.4 scfh	This emission factor is applied for all the continuous bleed controllers on retrofit sites. Assumption based on [2] (Company classification into EPA categories excluding ESD)
Low bleed continuous controller (s)	1.39 scfh	This emission factor is applied for all the continuous bleed controllers on new sites. Current federal regulation (OOOO) requires that new continuous bleed controllers be low bleed. Assumption based on [16], most conservative average value between [16], [3], [4] and [2]
Intermittent-vent controller(s)	4.4 scfh	Assumption based on [2], most conservative average value between [16], [3], [4] and [2]
Chemical injection Pumps	13.3 scfh	Assumption based on [16], most conservative average value between [4], [7] and [16]
ESD	0.41 scfh	Assumption based on [2], average of the controllers classified as ESD

While measurements show that emission factors vary widely in the field, using conservative average emission factors, we are able to calculate conservative (i.e. high) abatement costs for widespread adoption of zero-emitting technologies. Sensitivity analyses are presented in the section 4.2 to reflect the field variability, which impact the site specific abatement costs.

Site configurations evaluated

As described above, we performed economic modeling on a total of 2032 permutations of site configuration parameters, covering a wide range of possible combinations of site parameters.

The following parameter inputs were used to construct the site configurations:

- Total number of controllers – from 1 to 40 controllers.
- A varying mix of continuous-bleed and intermittent-vent controllers (from 0% to 100% of intermittent-vent controllers).
- One emergency device (ESD) was added for every five controllers[9] (rounded up).
- New site (construction of new facilities) or retrofit (upgrade of existing facilities).
- Access to electricity or not.
- Whether pneumatic driven controllers currently operate on dry gas or wet gas.

To simplify the presentation of the results, the 2032 possible site configurations were then grouped into 20 larger categories depending on the total number of controllers, the presence of electricity on site, and whether the site is new or would need to be retrofit with zero emission controllers. The following table presents a matrix of the 20 different categories of site configurations evaluated, with the number of sites in each category presented in green. Each cell of this table includes a number of site configurations

[9] This number of ESDs has no impact on the final conclusion. Operators do not currently replace ESDs with electric controllers, so number and the emission factor of ESD have no effect on the cost-effectiveness of electric controllers. On the other hand, ESDs will generally be converted to instrument air, but the effect of including reasonable numbers of ESDs on the final cost-effectiveness is small due to the small air consumption of ESD. In this context, the assumption on the number of ESD did not affect the final number of sites with an abatement cost higher than the social cost of methane.

depending on the number of intermittent-vent or continuous-bleed controllers and the type of gas used to power the controllers.

Table 7: Site configurations categories (number of site configurations presented in green)

Number of Pumps	Number of controllers (excluding ESD)	New sites		Retrofit	
		No elec. on site	Elec. on site	No elec. on site	Elec. on site
0	1 to 3 controllers	18	18	18	18
	4 to 10 controllers	56	56	56	56
	11 to 20 controllers*	98	98	98	98
	21 to 40 controllers*		164		164
1	1 to 20 controllers*	172	172	172	172
	21 to 40 controllers*		164		164

* Based on the analysis presented in section 3, we did not model either technology for larger sites (≥21 controller excluding ESD) without electricity on-site

- Electronic controllers were modeled at sites of all sizes with electricity available, and smaller to medium sites (up to 20 controllers) with no electricity available. Medium and large sites with electricity on-site are presented, as no technical barriers were identified for the installation of electronic controllers in such installations. However, there seems to be much less field experience for these types of installations compared to smaller sites.
- Instrument air was presented at larger sites with electricity available. For sites smaller than 20 controllers, electronic controllers were always more cost efficient than instrument air (see below).

This approach reflects the current industry experience and practice as presented by the interviewees. It is, however, important to highlight that the threshold in terms of number of controllers (20 in the analysis), depends in reality on site-specific parameters, and should only be considered as an **illustrative** threshold based on information available.

4.2 Main findings – electronic controllers

The findings of the cost-benefit analysis for electronic controllers are presented in four different sections:

- First, the full cost-benefit analysis is presented for one site configuration, to illustrate the methodology by exploring one example in detail.
- Second, a sensitivity analysis is performed for the same site configuration to show the impact of the main assumptions.
- An overview of the results for all the site configurations evaluated is then presented.
- Finally, the impact of the emission factors assumptions is described.

Example of abatement cost estimate for one example site configuration

The following table presents a full analysis for an example site configuration. The project is the retrofit of an existing site with four different controllers (one continuous-bleed, two intermittent-vent, one ESD and no pump) which represents the most common number of controllers in [8,2]. The site is not connected to the grid and currently uses dry supply gas for the controllers.

Table 8 presents the CAPEX estimate for the conversion to electronic controllers. As the project is a retrofit project, the baseline CAPEX is zero.

The detailed assumptions for the size of the electronic system (such as number of solar panels and battery requirements) are presented in the appendix. Overall, the system is oversized and always includes, for example, 10 days of energy storage.

Table 8: CAPEX estimates for electronic controller implementation (central assumptions)

Item	Assumption	#	Total USD
Controllers	$ 4000/unit	3	12 000
Control Panel	$ 4000/unit	1	4 000
140 W Solar Panel	$500 /Unit	1	500
100 Amh battery	$400 /Unit	3	1 200
Installation and engineering costs	20% of equipment costs	NA	3 540
Total CAPEX			**21 240**

Table 9: Emissions estimates (central assumptions, new sites)

Whole gas emissions in scfh	EF assumption	#	Total
Intermittent – vent controllers	4.43	2	8.9
Continuous –bleed controller	14.4	1	14.4
Total gas emissions			**23.3**

In terms of OPEX, it is assumed that batteries are replaced every 4 years and solar panels every 10 years. Given the operators' reports of minimal maintenance for electronic controllers, it has thus been assumed, conservatively, that general maintenance costs for are similar to those for continuous-bleed controllers functioning properly[10]. We do not include any estimate of savings in inspection costs due to automation (conservative assumption). Table 9 above presents emission estimates for the baseline scenario and finally Table 10 includes the abatement costs estimated.

Table 10: Final results – central assumptions

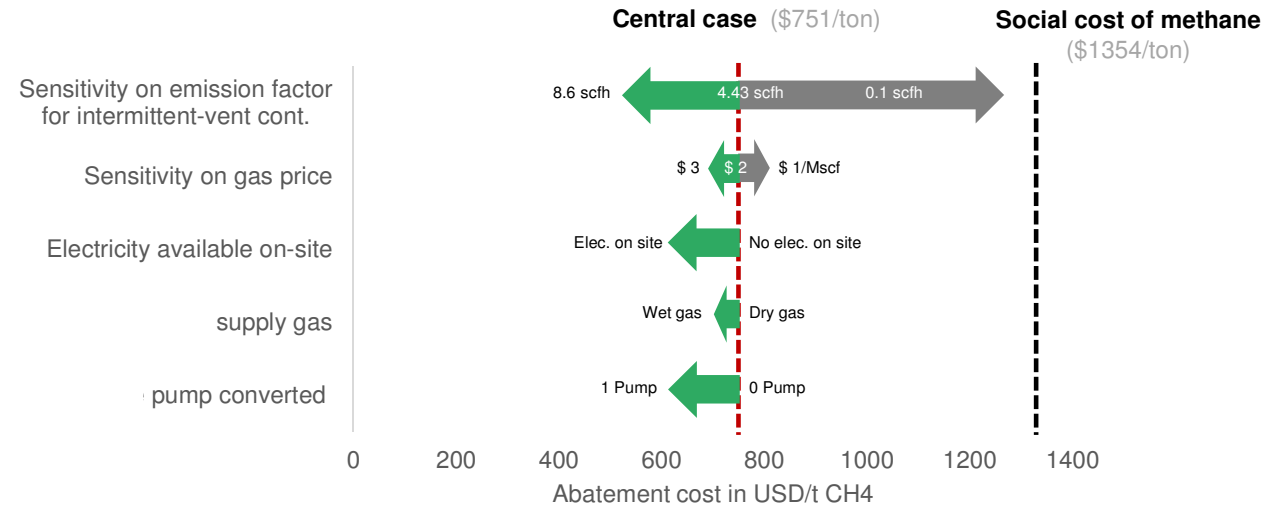
Item	Unit	Value USD
CAPEX	$	21 240
Value of the gas saved	$/year	408
NPV of the OPEX	$	1 672
NPV	$	-19 266
ABATEMENT COSTS	**$/tCH$_4$**	**751**

As presented in Table 10, for the small and remote site configuration presented, the abatement costs is well below the social cost of methane as defined above. The abatement cost for same site configuration, but at a new facility, as opposed to a retrofit, is estimated to be $847/ton CH_4. The difference is due to the difference in baseline costs and baseline emissions between new and retrofit sites (see below).

[10] Which is lower than the maintenance costs for continuous bleed controllers operating with wet supply gas.

Info Box 1: Electric conversion of pneumatic pumps

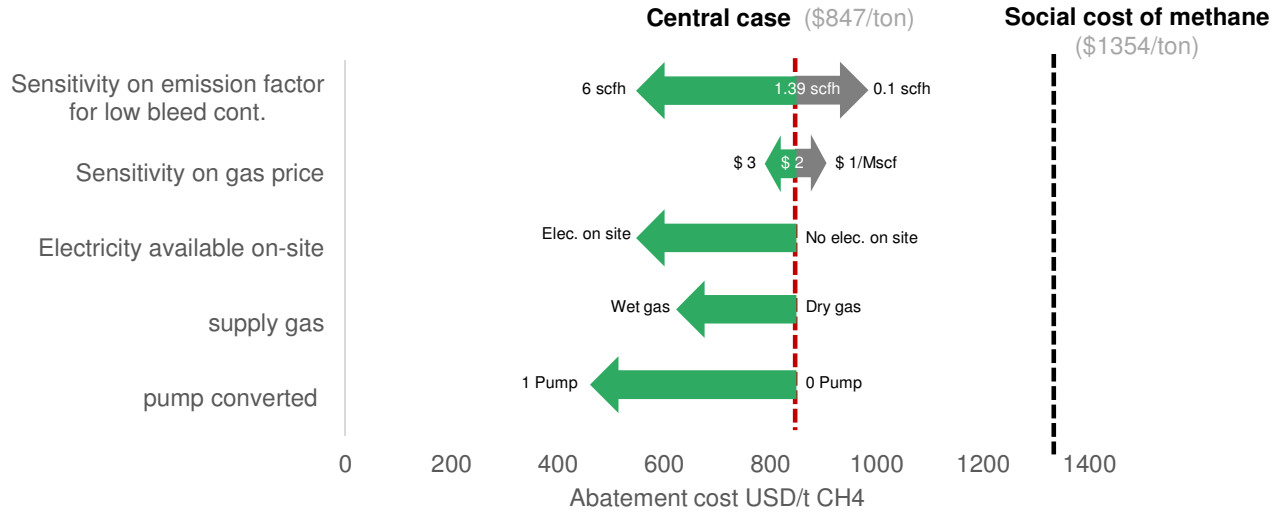
Pumps at well sites and well pads are typically used for methanol, corrosion inhibitor, de-waxing agents, or soap injection. Federal regulation (OOOOa) rules already require that emissions from new and modified chemical injection pumps be controlled in a number of circumstances.



As highlighted in Section 3, conversion of chemical injection pumps to electric is both a mature and a cost effective technology.

In the analysis presented in this section, the conversion of one chemical injection pump per site is presented as a potential added benefit for the project developer. In cases with many pumps, or of major energy requirements for the pumps, the conversion of pumps to zero emission technologies could be assessed as a separate emission reduction project.

Sensitivity analysis for one example site configuration



In this analysis, a number of assumptions have been made which impact the abatement cost. The following figures present sensitivity analyses for the site configuration described in the previous section, for both the retrofit case and the new site case. We examine the sensitivity of the abatement cost to changes to a few key sensitivities. A more exhaustive sensitivity analysis is presented in the appendix.

Figure 8: sensitivity analysis – electronic controllers - retrofit

The next figure presents a similar sensitivity for the same site configuration, but at a new facility as opposed to a retrofit.

Figure 9: sensitivity analysis – electronic controllers - new

The emission factor has by far the largest impact on the abatement cost and clearly heavily impacts the cost effectiveness of the option for retrofit sites. Excluding the emission factors, the other assumptions impact up to +33% of the abatement costs and no sensitivity leads to an abatement cost higher than the social cost of methane (see appendix).

In general terms, the abatement cost is more sensitive to changes for new sites than for retrofit sites. This is due to the fact that both the incremental costs and the emissions reductions are much smaller for new sites than for retrofit sites. A small change in either of these is thus relatively larger for new sites than for retrofit sites.

The following few paragraphs describes in more detail the impact of the main assumptions:

Electricity on site

The investment costs for sites without an electricity supply are higher than for sites with electricity due to the need to install solar panels and batteries. As a result, the abatement cost for site configurations with electricity is generally ten to one hundred percent lower than for site configurations without power. In a few site configurations the abatement cost is negative (i.e. NPV>0).

Wet versus dry supply gas

Operators have reported that the quality of the supply gas affects maintenance costs. Even slightly wet (or sour) gas can lead to condensation (or corrosion) issues, which over time will impact the performance of the system. The maintenance cost for sites with wet supply gas is estimated at $200/year/controller [10] compared to $80/year/controller for dry supply gas [18]. As a result, sites with wet gas have an abatement cost generally 5 to 100 % lower than sites with dry gas, and, in a few site configurations, the abatement cost is negative (i.e. NPV>0). Gas quality is also likely to impact the average emission rate. Due to the lack of quantitative data on this impact, however, this factor has not been taken into consideration during the analysis, but it would reduce the abatement costs of sites with wet gas even lower.

Chemical injection pumps

As pumps have high emissions factors, sites where one pump (or several) can be converted to electric power have much lower abatement costs than sites without. All the sites with one pump have an

abatement cost lower than the social cost of methane. In addition, the abatement cost of converting a single chemical injection pump (without any controller) to a solar powered electric pump is lower than the social cost of methane in all the sites configurations evaluated.

New versus retrofit sites

The costs and the emissions abatement structures differ greatly for new and for retrofit sites. The main differences include:

- The incremental CAPEX (i.e. the difference between the zero emission technology CAPEX and the baseline CAPEX) for a retrofit site is usually much higher than for a new site.
- Given the current regulatory framework, it is assumed that new sites use low-bleed continuous controllers as a default, and we conservatively use the EPA emissions factor [1] for these controllers, despite measurements showing higher emissions for low-bleed controllers [3,4]. The emissions reduction for retrofit sites is higher than for new sites, as we use an emissions factor based on actual measurement [2] for continuous-bleed controllers at existing sites.

The first difference makes the abatement cost higher for retrofit sites than new sites, while the second difference has the opposite effect. Overall, in the vast majority of the site configurations evaluated, the abatement cost for new sites is higher than for the equivalent retrofit site configuration.

Overview of the results for all the site configurations

Overall, the abatement costs for electronic controller installations at 2032 site configurations were estimated during this project. Under the central assumptions, 20 of the 2032 site configurations evaluated have abatement costs higher than the social cost of methane, $1354/t. The following table shows in red the number of site configurations with abatement costs higher than that figure for each category.

Table 11: Number of site configurations with abatement costs superior to the social cost of methane – central assumptions

Number of Pumps	Number of controllers (excluding ESD)	New sites		Retrofit	
		No elec. on site	Elec. On site	No elec. on site	Elec. On site
0	**1 to 3 controllers**	**6 / 18**	**4 / 18**	**5 / 18**	**2 / 18**
	4 to 10 controllers	**2 / 56**	**0 / 56**	**0 / 56**	**0 / 56**
	11 to 20 controllers*	**0 / 98**	**0 / 98**	**0 / 98**	**0 / 98**
	21 to 40 controllers*		0 / 164		0 / 164
1	**1 to 20 controllers***	**0 / 172**	**0 / 172**	**0 / 172**	**0 / 172**
	21 to 40 controllers*		0 / 164		0 / 164

* Sites with more than 10 controllers were presented for the installation of electronic controllers. However, there seems to be much less field experience for this type of installation, compared to smaller sites. Sites with more than 20 controllers and without electricity on-site were not modelled. Though no major technical barriers were identified, we could identify no examples of installations of solar powered electronic controllers on very large sites.

A number of conclusions can be drawn from this analysis. Under the central assumptions:

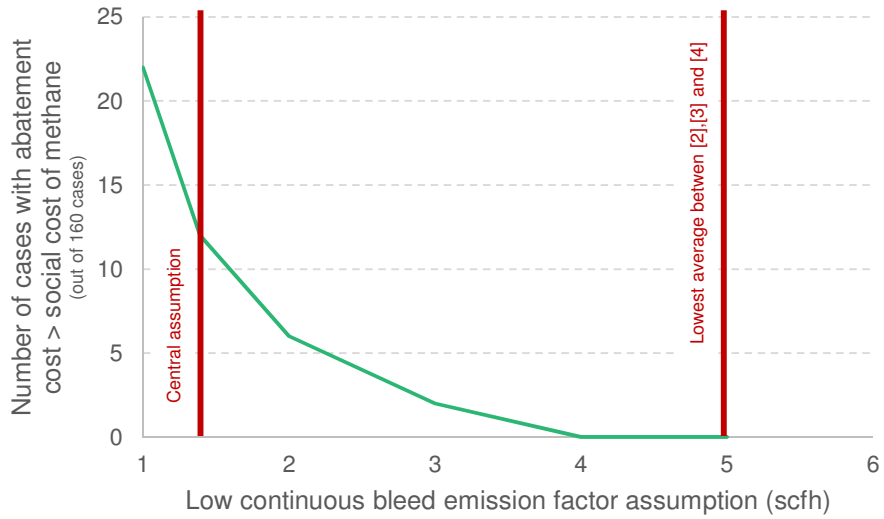
- For almost all the site configurations evaluated with four or more controllers (excluding ESDs), it is cost-effective to install electronic controllers.
- For all site configurations evaluated with one chemical injection pump, it is cost effective to install electronic controllers.

A site configuration is not cost effective if the volume of gas saved does not justify the cost of implementation. In general, for a given type of site configuration (wet/dry, on or off grid, new or existing, share of intermittent controllers), the cost-effectiveness improves (fewer $/ton) with the number of controllers.

NMED Exhibit 110

In addition, we can highlight the following patterns for the site configurations with abatement costs higher than the social cost of methane:

- For new facilities, these sites have only low-bleed continuous controllers (5 or fewer). The low bleed emission factor assumption has an important impact on the conclusion (see below).
- For retrofit facilities, these sites have only intermittent-vent controllers (3 or fewer). For retrofit sites, the emissions factor used for intermittent-vent controllers is less than that used for continuous bleed controllers (see section 4.1)



The full list of site configurations with an abatement cost higher than the social cost of methane is presented in the appendix.

Impact of the emission factors assumptions

The results of the analysis are quite dependent on the emissions factors used for the various types of pneumatic controllers.

The following graph illustrates the impact of the continuous low-bleed emission factor on the cost effectiveness of new sites with at least one continuous low-bleed device. This represents 12 of the 19 site configurations deemed not cost effective. The central assumption for the low-bleed emission factor is 1.39 scfh. But an emission factor of 4 scfh would make all sites with at least one continuous bleed controller cost effective. It is interesting to compare this figure to the results of past measurement campaigns presented in the Figure 4, which suggest that average emission factors for low-bleed devices are likely higher than 5 scfh.

Figure 10: Impact of the continuous low bleed emission factor on the cost effectiveness of new sites with at least one continuous low bleed device.

In a site without an electricity supply and with just a single controller, an electronic controller is cost-effective if the emissions from that single controller are more than 4.4 scfh for a new site and more than 7.2 scfh for a retrofit site. The point of cost-effectiveness is lower for sites with 2 or more controllers, for sites using wet supply gas, or for sites with on-site electricity. These thresholds should be compared with emissions factors observed in Figure 5 for small and very small sites.

As mentioned above, while emissions from pneumatic controllers vary widely from device to device, this analysis uses average emissions factors based on recent measurements, aiming at evaluating the cost-effectiveness of using electronic controllers on a widespread basis.

To conclude, the analysis shows that conversion to electronic controllers would be cost effective in most site configurations even using conservative average emissions assumptions. If higher emissions assumptions are considered -- as reflected in recent field measurements – virtually all site configurations evaluated would be fall below the social cost of methane

4.3 Main findings – Instrument air

As in the previous section, the finding of the analysis for instrument air is presented in three different sections:

- First, the full cost-benefit analysis is presented for one site configuration, to explain the methodology applied to one example.
- Secondly, a sensitivity analysis is performed for the same site configuration to illustrate the impact of the main assumptions.
- Finally, an overview of the results for all the site configurations evaluated is presented.

Contrary to electronic controllers, instrument air installation is only presented for site configurations with electricity available on-site.

Example of abatement cost estimate for one example site configuration
The following tables present a full analysis for an example site configuration. The project is retrofit of an existing site with 20 different controllers (5 continuous-bleed, 11 intermittent-vent, and 4 ESD). This configuration is illustrative; it is not known how representative it would be of larger sites. The site is connected to the grid or has power already generated on site, and currently uses dry gas for the controllers.

The first table presents the CAPEX estimate for the instrument air project. The detailed assumptions for the size of the instrument air system (share of the air bypassed in dryer, share of the utility air supply,[11] size of compressor, load of the compressor) are presented in the appendix. The approach in terms of system sizing proposed by Natural gas star has been applied [14], after having been quality checked against nine recently implemented projects. Overall, the system is oversized (as per the industry standard) and always includes, for example, one spare compressor. Equipment costs (including industrial grade compressors designed for 24/7 duty) have been assumed using online quotes.

As highlighted previously, installation costs for instrument air are highly site specific. Interviews have reported very low installation costs in particular when retrofitting many sites with similar designs. On the other side of the spectrum, operators have also reported high installation costs in cases where important investments, such as electric system upgrades and trenching between building or clusters of equipment, were required on the installations. The investment cost estimates presented below include some relatively conservative assumptions (i.e., high cost) in terms of equipment and installation costs. Some sensitivities are presented (appendix) to reflect the variability of the local circumstances.

[11] Because it is useful to have compressed air at a site for a variety of tasks and uses, operators typically oversize compressed air systems installed to drive pneumatic controllers. In this analysis, we assume that operators will do so, and consider the costs of the oversized system but do not make any estimate of the value of having compressed air available onsite. This approach is conservative (since operators do not strictly need oversize compression capacity for this purpose to use instrument air for pneumatic controllers), though the effect is not large.

Table 12: CAPEX estimates for instrument air controller implementation – central assumptions

Item	Assumption	Sizing /#	Value USD
Controllers and installation costs for the controllers	NA	retrofit projects (it is assumed that controller can be re-used)	0
Compressor package (Assuming 2 compressors, air drying unit and wet air receiver unit)	See list of assumption in the appendix [12]	10 HP	32 000
Other supplies costs (Instrumentation Supplies & Pipe/Valve/Fittings, electrical supplies, etc..)	1400 $/cont	20	28 000
Electrical, mechanical & civil Installation Costs, engineering	Retrofit: 100% New: 50% of equipment costs	NA	60 000
Total CAPEX			120 000

In terms of OPEX, it is assumed that compressors are replaced every 6 years. In addition, 4% of the equipment costs are accounted for normal compressor maintenance (typically every 6 months). Other OPEX costs include, for example, electricity costs.

Table 13 presents the emissions estimates while Table 14 present the final results.

Table 13: Emission estimates – central assumptions

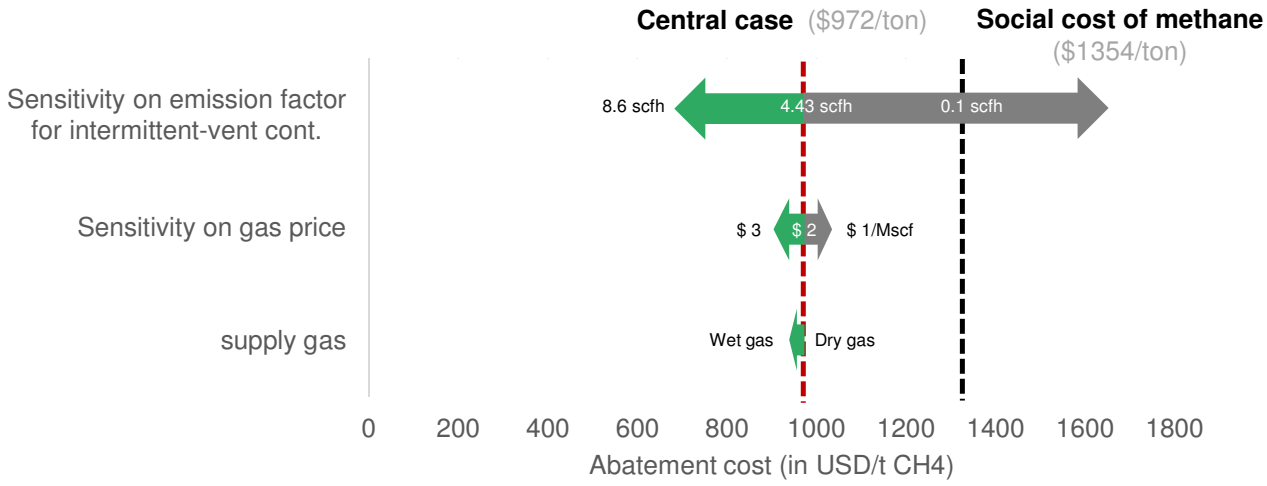
Emissions is scfh	EF assumption	#	total
Intermittent-vent Controllers	4.43	11	48.7
Continuous-bleed controllers	14.43	5	72.1
ESD	0.41	4	1.64
Total gas emissions			122.5

Table 14: Final results for the site configuration analyzed – central assumptions

Item	Unit	Value USD
CAPEX	$	120 000
Value of the gas saved	$/year	1073
NPV (Opex)	$	24 683
NPV	$	-121 652
ABATEMENT COSTS	$/tCH4	972

The abatement cost for the same site configuration, but at a new facility, as opposed to a retrofit, is estimated to be $886/ton CH_4. The difference is because the baseline costs are higher and the baseline emissions are lower for new sites than for retrofits.

Info Box 2: Conversion of pneumatic pumps to instrument air



Pneumatic pumps typically emit more per device than pneumatic controllers, so converting pumps to air can represent a large emission reduction and potentially reduce significantly the abatement cost of conversion. However converting pumps to instrument air is not always technically and/or economically feasible. For sites with access to reliable source of electricity, conversion to air is applicable and cost-effective for the majority of chemical injection pumps. However, even for grid-connected sites, conversion to instrument air is not always the preferred option, as electric pumps are proven effective and low-cost.

In summary, in a number of cases, emissions reduction for pumps could be considered as a separate project from controllers. In the follow up analysis, conversion of 1 pump to instrument air is only presented as part of the sensitivity analysis.

Sensitivity analysis for one example site configuration

The following figures present a sensitivity analysis for the same site configuration as in the section above. The CH_4 abatement cost for a few key sensitivities is compared to the abatement cost with the central assumptions. A more detailed sensitivity assessment is presented in the appendix.

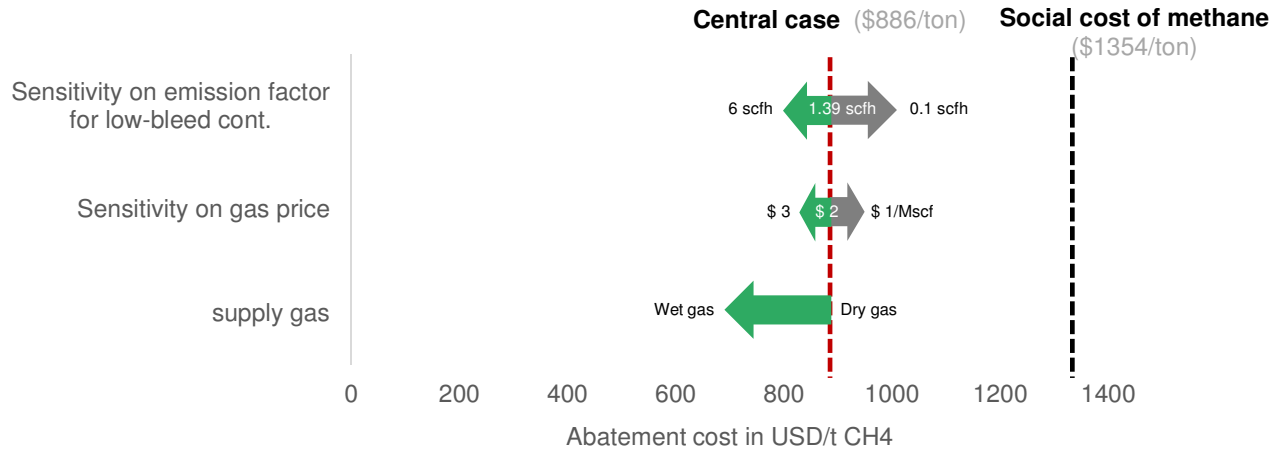


Figure 11: Sensitivity analysis – instrument air - retrofit

The next figure presents a similar sensitivity for the same site configuration but at a new facility.

NMED Exhibit 110

Figure 12: Sensitivity analysis – instrument air - new site

As with the electronic controllers, the emission factor heavily impacts the attractiveness of the option. Excluding the emission factor, no other assumption affects the abatement cost per ton by more than 30% (see appendix).

Wet versus dry supply gas

As with electronic controllers, sites with wet gas have an abatement cost generally 5% to 50 % lower than sites with dry gas due to the difference in maintenance costs.

Overview of the results for all the site configurations

The overall abatement costs for about 328 site configurations, all with an electricity supply and no pneumatic pump conversions, were estimated, with a total number of controllers ranging from 21 to 50 (in various permutations of intermittent-vent and continuous-bleed controllers). Sites with fewer than 20 controllers are not presented, as conversion to electric is cheaper (on a per ton basis) in most of the site configurations with fewer than 20 controllers.

In terms of CAPEX, the total investment for retrofit sites varies between $90,000 and $230,000, while the investment (excluding controllers and their installation) for new sites varies between $60,000 and $120,000.

Under the central assumptions, 5 of the 328 site configurations evaluated have abatement costs higher than the social cost of methane. The following table shows in red the number of sites with abatement costs higher than $1354 /t$CH_4$ for each category of sites.

Table 15: Number of site configurations with abatement costs higher than the social cost of methane – central assumptions

Number of Pumps	Number of controllers (Excluding ESD)	New Sites	Retrofit
0	**21 to 25 controllers**	**3 / 42**	**0 / 42**
	26 to 30 controllers	**2 / 40**	**0 / 40**
	31 to 40 controllers	**0 / 82**	**0 / 82**

A number of conclusions can be drawn from this analysis. Under the central assumptions:

- For almost all the site configurations evaluated with more than 21 controllers (excluding ESDs), it is cost effective to install instrument air.
- For all the retrofit site configurations evaluated, it is cost effective to install instrument air.
- In a few of the new site configurations considered, it is not cost effective to install instrument air.

A site configuration is not cost effective if the volume of gas saved does not justify the cost of implementation. The new site configurations with abatement costs greater than the social cost of methane have a vast majority of low bleed continuous controllers, which we have conservatively assumed have very low emissions (1.39 scfh emission factor, see Section 4.1).

The full list of site configurations with abatement costs higher than the social cost of methane is presented in the appendix.

4.4 Summary of the analysis

As described in the section above, an economic analysis assuming conservative average emission factors was performed for 2032 permutations of site configurations with 1 to 50 controllers. Both retrofit and new installations, with or without electricity, were considered. A number of key conclusions can be drawn:

- Zero emission solutions had abatement costs below the social cost of methane (for 2020) described in the EPA 2015 Regulatory Impact Analysis in the vast majority of site configurations considered.
- The abatement costs exceeded the social cost of methane mostly for small sites – those with less than three controllers (excluding ESDs). If higher emission factors, as reflected in field measurements, are used, the abatement costs at even the very small sites fall below the social cost of methane.

The following figure presents a summary of both the technical applicability and economic attractiveness of the different zero emission technologies under different categories of sites. Though this analysis does not provide a detailed evaluation of the distribution of the sites in the US for each of the categories below, existing studies have suggested that the vast majority of the sites have less than 20 controllers.

Table 16: Summary table

Type of of site		Both retrofit and new sites					
	Number of controllers (excl. ESDs)	1- 3		4-20		21-40	
	Electricity on-site?	Yes	No	Yes	No	Yes	No
Main options: Electric controller / Instrument air	**Description** (of the most economic option which is technically feasible)	Grid connected **electric** controller	Solar powered **electric** controller	Grid connected **electric** controller	Solar powered **electric** controller	Instrument **air**	
	Number of cases not cost effective (i.e. abatement cost > social cost of methane) **under central assumptions**	6 / 36	11 / 36	0 / 308	2 / 308	5/ 328	
	Cost effective for <u>every</u> site configuration if emissions factors are:*	> 5.6 scfh for retrofit > 2.8 scfh for new sites	> 7.2 scfh for retrofit > 4.4 scfh for new sites	> 3.6 scfh for retrofit > 1.4 scfh for new sites	> 4.2 scfh for retrofit > 1.8 scfh for new sites	> 4.5 scfh for retrofit > 1.8 scfh for new sites	
Other options potentially applicable depending on the local conditions	Vent gas recovery	✓	✓	✓	✓	✓	✓
Limited applicability	Instrument air powered by gas	Not relevant	Not relevant	Not relevant	Not relevant	Not relevant	✓
Limited applicability	Self contained controllers	✓	✓	✓	✓	✓	✓
Limited known implementations	Solar powered instrument air	Not relevant	✓	Not relevant	✓	✗	✗
Limited known implementations	Electric controllers powered by other power sources (TEG, fuel cell)	Not relevant	Not relevant	Not relevant	Not relevant	Not relevant	✓
Limited known implementations	Large solar powered electric controller (no known implementations)	Not relevant	Not relevant	Not relevant	Not relevant	Not relevant	Potential solution,** but no example known.

* Emissions factors thresholds listed are determined for the site configuration with the highest abatement cost within the category.
** Based on other solar applications.

The applicability of electronic controllers for small sites and instrument air for large sites reflects the current industry experience and practice as presented by the interviewees. It is, however, important to highlight that the threshold in terms of number of controllers (20 in the analysis), depends in reality on site-specific parameters, and should only be considered as an illustrative threshold based on information available.

Due to the market conditions, electronic controller providers have so far focused mainly on the development of solutions for small sites in remote locations. There thus seems to be much less field experience with using electronic controllers at medium and large sites; however, no technical barriers were identified for this type of installation.

These analyses indicate that the widespread adoption of zero-emitting technologies is cost effective in the vast majority of the site configurations considered. Furthermore, several factors listed should be considered:

- Conservative (low) average emissions factors have been used for low-bleed pneumatic controllers, even though recent research indicates that actual average emissions from those pneumatic controllers may be higher.
- Some of the important benefits of switching to zero-emitting technology, such as the ease of automation or remote operations associated with electrifying pneumatic controllers, are not included in our analysis of the cost-effectiveness of using zero emission technologies.
- Finally, pneumatic controllers emit natural gas, which includes (in varying amounts) other pollutants aside from methane, such as volatile organic compounds (VOCs), which are precursors to ground level smog, and toxic hazardous air pollutants (HAPs). Replacing natural-gas driven pneumatic controllers with zero-emitting technologies will eliminate emissions of these other

pollutants, in addition to emissions of methane, but we have not included the benefits of VOC or HAP abatement in our calculation of abatement costs for methane.

6.2 Other assumptions for the model

- General assumptions

- Retrofitting is assumed to be performed during a planned maintenance, hence retrofit activities do not cause production losses; thus, no potential revenue losses are accounted for in the estimates presented.

- Electronic controllers:
  - In all the site configurations, it is assumed that ESDs are gas driven pneumatic controllers.
  - Electronic controllers can reduce the need for site inspections. The subsequent reduced labour costs have not, however, been taken into consideration in the analysis. (conservative assumption)
- Instrument air
  - CO_2 emissions from power consumption (for non-solar powered options) have been neglected; this represents a very small volume of emissions compared to the CH_4 emissions (typically a few per cent, assuming a GWP of methane of 21).

6.3 Detailed sensitivity analysis

In the analysis presented, a number of assumptions have been made which affect the abatement cost. The following sections present the detailed sensitivity analysis performed.

Electronic controller – Retrofit

The following table presents a sensitivity analysis for the site configuration described in the section 4.2 (site with four controllers). The CH_4 abatement costs for a few key sensitivities should be compared to the abatement costs under the central assumption: $751/t CH_4. The abatement cost under all the sensitivities is below the social cost of methane.

Table 18: Sensitivity analysis – retrofit site with 4 controllers– results

Name of the parameter	Central assumption	Sensitivity value	Abatement cost in $/t CH_4
Number of pumps	0 pump	1 pump	614
Type of supply gas	Dry supply gas	Wet supply gas	702
Power on-site	No power on-site	Power on-site	611
Gas price	2 $/Mscf	1 $/Mscf	811
Gas price		3 $/Mscf	692
Discount rate	7%	3%	635
Emission factors intermittent-vent cont.	4.43 scfh	8.6 scfh	522
		0.1 scfh	1267
Control Panel equipment cost	$4000	$6000	845
Installation Costs	20% of Equipment Costs	40% of Equipment Costs	889
Battery replacement freq.	4 years	2 years	823
Average peak sun	4 hours	2 hours	775

Electronic controller – New

The following table presents a sensitivity analysis for the site configuration described in the section 4.2 (site with four controllers). The CH_4 abatement cost for a few key sensitivities should be compared to the

abatement costs under the central assumption: $847/t CH_4. The abatement costs for all the sensitivities are below the social cost of methane.

Table 19: Sensitivity analysis – New site with 4 controllers– results

Name of the parameter	Central assumption	Sensitivity value	Abatement cost in $/t CH_4
Number of pumps	0 pump	1 pump	459
Type of supply gas	Dry supply gas	Wet supply gas	624
Power on-site	No power on-site	Power on-site	548
Gas price	2 $/Mscf	1 $/Mscf	906
Gas price		3 $/Mscf	787
Discount rate	7%	3%	680
