Operators in the gathering and boosting and transmission and storage parts of the industry typically do not own the natural gas they transport; rather, the operators receive payment for the transportation service they provide. As a result, the unit-level cost and emission reduction analyses supporting BSER decisions in the preamble (and is presented in Volume 1 of the TSD) do not include estimates of revenue

[123] Natural gas savings calculated using the CH_4 reductions and assuming a methane to natural gas volume ration of 82.9% for upstream facilities (well sites, gathering & boosting) and a methane to natural gas volume ratio of 92.8% for downstream facilities (transmission, storage).

NMED Exhibit 70

from natural gas recovery as offsets to compliance costs. From a social perspective, however, the increased financial returns from natural gas recovery accrues to entities somewhere along the natural gas supply chain and should be accounted for in the national impacts analysis. An economic argument can be made that, in the long run, no single entity is going to bear the entire burden of the compliance costs or fully receive the financial gain of the additional revenues associated with natural gas recovery. The change in economic surplus resulting from natural gas recovery is going to be spread out amongst different agents via price mechanisms. Therefore, the most simple and transparent option for allocating these revenues would be to keep the compliance costs and associated revenues together in a given source category and not add assumptions regarding the allocation of these revenues across agents. This is the approach followed in Volume 2 of the TSD, as well as in the RIA. Table 9-2 also summarizes the nationwide cost impacts for the projected years 2020 and 2025 for implementation of regulatory Option 1.

Regulatory Option 2 include semiannual monitoring of fugitive emissions components using OGI and repair of fugitive emissions components that are found to be leaking during the survey. The annual costs for these surveys (as summarized in Table 9-3) include the costs for having a contractor perform the semiannual OGI survey, activities planning, repair costs, preparation and submittal of an annual report and the amortization of the capital costs over 8 years at 7 percent interest. The potential natural gas savings from the implementation of a semiannual OGI monitoring and repair program were calculated to be 191 Mscf/yr for a natural gas production well site, 96 Mscf/yr for an oil production well site with a GOR > 300, and 43 Mscf/yr for an oil production well site with a GOR < 300. For the compressor stations, the potential natural gas savings were calculated to be 1,222 Mscf/yr for gathering and boosting stations, 1,255 Mscf/yr for transmission stations, and 4,424 Mscf/yr for storage facilities.[124] Table 9-3 summarizes the nationwide cost impacts for the projected years 2020 and 2025 for implementation of regulatory Option 2.

Regulatory Option 3 for well sites and compressor stations include quarterly monitoring of fugitive emissions components using OGI and repair of fugitive emissions components that are found to be leaking during the survey. The annual costs for these surveys (as summarized in Table 9-4) include the costs for having a contractor perform the quarterly OGI survey, activities planning, repair costs, preparation and submittal of an annual report and the amortization of the capital costs over 8 years at 7 percent interest. The potential natural gas saved from the implementation of a quarterly OGI monitoring and repair

[124] Ibid.

NMED Exhibit 70

program at well sites was calculated to be 255 Mscf/yr for a natural gas production well site, 127 Mscf/yr for an oil well site with a GOR > 300, and 57 Mscf/yr for an oil production well site with a GOR < 300. The potential natural gas savings at compressor stations were calculated to be 1,629 Mscf/yr for gathering and boosting stations, 1,673 Mscf/yr for transmission stations, and 5,899 Mscf/yr for storage facilities.[125] Table 9-4 summarizes the nationwide cost impacts for the projected years 2020 and 2025 for implementation of regulatory Option 3.

9.1.4.3 Low Producing Natural Gas and Oil Wells

For the proposed rule, the EPA evaluated an alternative nationwide impact scenario that accounts for well sites that produce relatively little crude oil and/or natural gas. The EPA had proposed that low producing wells not be subject to fugitive emissions monitoring provisions. While there were several criteria for defining a low-producing well, the EPA believed the definition of a "stripper well" in Internal Revenue Services (IRS) regulations, was consistent with the type of well which would be considered low-producing under that scenario. Under the IRS regulations, a stripper well property “means, with respect to any calendar year, any property with respect to which the amount determined by dividing—(i) the average daily production of domestic crude oil and domestic natural gas from producing wells on such property for such calendar year, by (ii) the number of such wells, is 15 barrel equivalents or less". [126] This proposal was based on our belief at the time that low production wells have inherently low emissions from well completions and that many are owned and operated by small businesses. The EPA was concerned about the burden of the well completion requirement on small businesses, in particular if there is little emission reduction to be achieved.

However, based on information provided in the comments for the proposed rule, the EPA determined that fugitive emissions from low production wells may be comparable to fugitive emissions from other production wells. The low production well sites have the same type of equipment (e.g., separators, storage vessels) and components (e.g., valves, flanges, connectors) as production well sites with production greater than 15 boe per day. This indicates that the component counts for low production well sites are similar to that of non-low production well sites, and hence the potential fugitive emissions from both types of well sites are comparable. The comments on the proposed rule stated that many of these well sites are developed for leasing purposes and are typically unmanned and not visited as often as

[125] Ibid.
[126] 26 U.S.C. 613A(c)(6)(E).

NMED Exhibit 70

other well sites. This may potentially allow fugitive emissions to go unnoticed longer. No data were provided in the comments on the proposed rule that shows low production well sites have lower GHG (principally as methane) or VOC emissions than normal production well sites. In fact, the data that were provided indicated that the potential emissions from these well sites could be as significant as the emissions from non-low production well sites since the type of equipment and the well pressures are more than likely the same. In addition, discussions with the industry indicated that well site fugitive emissions are not based on production, but rather on the number of equipment and components. Therefore, the EPA believes that the emissions from low production and non-low production well sites are likely comparable and are included as affected sources for fugitive emissions.

NMED Exhibit 70

10.0 NATIONWIDE IMPACTS FOR PNEUMATIC CONTROLLERS

10.1 Nationwide Emissions from New Sources

10.1.1 Approach

Nationwide emissions from newly installed natural gas pneumatic devices for a typical year were calculated by estimating the number of pneumatic devices installed in a typical year and multiplying by the estimated annual emissions per device listed in Table 5-2. The number of new pneumatic devices installed for a typical year was determined using the methodologies described in section 10.1.2 of this chapter.

10.1.2 Population of Controllers Installed Annually

The number of pneumatic controllers installed in the transmission and storage segment was approximated using the Inventory of U.S. GHG Emissions and Sinks: 1990-2012. The number of new devices installed in a given year was estimated by subtracting the prior year (e.g., 2011) from the given years total (e.g., 2012). This difference was assumed to be the number of new devices installed in the latter year (e.g., Number of new devices installed during 2012 equals pneumatics in 2012 minus pneumatics in 2011). A 10-year average was calculated based on the number of new controllers installed in 2003 through 2012 in order to determine the average number of new devices installed in a typical year. An average was taken of all years. Where the year change was negative, the average calculation treated it as zero.

The number of facilities estimated to be subject to regulation was undeterminable due to the magnitude of new sources estimated and the lack of sufficient data that could indicate the number of controllers that would be installed in states that may have regulations requiring low-bleed controllers, such as in Wyoming and Colorado. Therefore, the EPA considered all facilities to be unregulated for this analysis.

Once the population counts for the number of pneumatics in each segment were established, this population count was further refined to account for the number of intermittent controllers that would be installed versus a bleed controller. This estimate of the percent of intermittent and bleed controllers was based on data from the GRI study, where 32 percent of the pneumatic controllers are bleed devices in the production segment, and 32 percent of the pneumatic controllers are bleed devices in the transmission and

NMED Exhibit 70

storage segment.[127] The distinction between the number of high-bleed and low-bleed devices was not estimated because this analysis assumes it is not possible to predict or ensure where low bleeds will be used in the future. Table 10-1 summarizes the estimated number of new devices installed per year.

Table 10-1. Estimated Number of Pneumatic Controllers Installed in a Typical Year in the Natural Gas Transmission and Storage Segment

Number of New Controllers Estimated for a Typical Year[a, b]		
Intermittent	**Bleed-Devices**	**Total**
256	120	376

a. National averages of population counts from the Inventory were refined to include the difference in intermittent and bleed devices based on raw data found in the GRI/EPA study. This is based on the assumption that 32 percent of the pneumatic controllers are bleed devices in the transmission and storage segment.
b. The number of pneumatics controllers estimated for the transmission and storage segment was approximated from comparing a 10 year average of new controllers installed in 2003 through 2012 in order to establish an average number of pneumatics being installed in this industry segment in a typical year. This analysis was performed using the Inventory of U.S. GHG Emissions and Sinks: 1990-2012.

10.1.3 Nationwide Emission Estimates

Nationwide baseline emission estimates for pneumatic devices for new sources in a typical year are summarized in Table 10-2. This analysis assumed for the nationwide emission estimate that all bleed-devices have the high-bleed emission rates estimated in Table W-3 of the GHG Reporting Rule, Subpart W since it cannot be predicted which sources would install a low bleed versus a high bleed controller.

Table 10-2. Nationwide Baseline Emissions from Representative Pneumatic Controller Installed in a Typical Year in Natural Gas Transmission and Storage Segment[a, b]

Baseline Emissions from Representative New Continuous Bleed Controller (tpy)		Number of New Continuous Bleed Controllers Expected Per Year	Nationwide Baseline Emissions from New Continuous Bleed Controller (tpy)	
Methane	**VOC**		**Methane**	**VOC**
3.013	0.083	120	362	10

a. Baseline emissions were based on the bleed rates for a high-bleed controllers.
b. To estimate VOC emissions, the weight ratio of 0.0277 lbs VOC per pound methane was used.

10.2 Nationwide Cost Impacts of Regulatory Options

Operators in the gathering and boosting and transmission and storage parts of the industry typically do not own the natural gas they transport; rather, the operators receive payment for the transportation service they provide. As a result, the unit-level cost and emission reduction analyses supporting BSER decisions in the preamble (and is presented in Volume 1 of the TSD) do not include estimates of revenue from natural gas recovery as offsets to compliance costs. From a social perspective,

[127] *See footnote 57.*

NMED Exhibit 70

however, the increased financial returns from natural gas recovery accrues to entities somewhere along the natural gas supply chain and should be accounted for in the national impacts analysis. An economic argument can be made that, in the long run, no single entity is going to bear the entire burden of the compliance costs or fully receive the financial gain of the additional revenues associated with natural gas recovery. The change in economic surplus resulting from natural gas recovery is going to be spread out amongst different agents via price mechanisms. Therefore, the most simple and transparent option for allocating these revenues would be to keep the compliance costs and associated revenues together in a given source category and not add assumptions regarding the allocation of these revenues across agents. This is the approach followed in Volume 2 of the TSD, as well as in the RIA.

Table 10-3 summarizes the nationwide emission reductions and nationwide costs impacts of the selected regulatory option for the natural gas transmission and storage segment. It is estimated to affect 96 new transmission and storage pneumatic controllers per year and 480 new affected sources through 2020 and 960 affected sources through 2025. The nationwide capital cost for projected year 2020 is estimated to be $109,073 and annual costs of $11,976 without considering value of gas saved. With consideration of gas savings from recovered gas, the annual cost for projected year 2020 is a net savings of $270,264. The nationwide capital cost for projected year 2025 is estimated to be $218,146 and annual costs of $23,951 without considering savings from gas saved. With consideration of gas savings from recovered gas, the annual cost for projected year 2025 is a net savings of $540,529.

NMED Exhibit 70

Table 10-3. Nationwide Cost and Emission Reduction Impacts for Pneumatic Controllers for Transmission and Storage for the Projected Years 2020 and 2025

Number of Affected Facilities[a]	Capital Cost Per Controller[b]	Annual Costs		Nationwide Emission Reductions				Total Nationwide Costs ($/year)		
		w/o savings	w/savings	(tpy)			(metric tonnes)	Capital Cost	Annualized Cost	
	(2012)	($/year)		Methane	VOC	HAP	CO2e		w/o savings	w/savings
Projected Year 2020										
480	$227	$25	($563)	1,338	37	1	30,335	$109,073	$11,976	($270,264)
Projected Year 2025										
960	$227	$25	($563)	2,675	74	2	60,671	$218,146	$23,951	($540,529)

a. The number of sources subject to NSPS for the natural gas transmission and storage segment represent the number of new controllers expected per year (120) reduced by 20 percent. This is consistent with the assumption that 80 percent of high bleed controllers can be replaced with a low bleed device. It is assumed all new sources would be installed as a high bleed for these segments.
b. The capital cost is equal to the incremental cost of a low bleed device versus a new high bleed device.
c. Based on the global potential warming of methane equal to 25.
Note: Negative numbers reflect a net savings.

NMED Exhibit 70

11.0 NATIONWIDE IMPACTS FOR PNEUMATIC PUMPS

11.1 Nationwide Emissions from New Sources

11.1.1 Approach

Nationwide emissions from newly installed natural gas pneumatic pumps for a typical year were calculated by estimating the count of pneumatic pumps installed in a typical year and multiplying by the estimated annual emissions per device listed in Table 6-2. The count of new pneumatic pumps installed for a typical year was determined for each natural gas production and natural gas processing. The methodologies that determined the estimated count of new pneumatic pumps installed in a typical year is provided below.

11.1.2 Population of Pneumatic Pumps Installed Annually

For the natural gas production segment the count of new pneumatic pumps installed in a typical year was estimated by reviewing the annual count of pneumatic pumps from the year 1990 to 2012 reported in the GHG Inventory for the natural gas and oil production facilities and determining the rate of change in the count of pneumatic pumps in each inventory over this period. For all the years, the annual counts of new pneumatic pumps installed between two years were not consistent. The average change for the entire period was estimated to be 877 for natural gas facilities and (-161) for oil facilities. Additionally, the average change over the last 10 years was estimated to be 1,480 for natural gas facilities and 803 for oil facilities. Because of the fluctuation in the count of new pneumatic pumps from the years 1990 to 2012, it was assumed that the 10-year average change represented a better estimate of the current growth of pneumatic pumps. For proposal the EPA calculated the average change excluding years where there was a negative change in the number of pneumatic pumps IPs. Based on comments received, the EPA changed the methodology to include the years where there was a negative change as zero in the averaging calculation. Based on this methodology, the counts of new pneumatic pumps that would be affected sources under the proposed NSPS for a typical year was estimated to be 1,184 for natural gas facilities and 241 for oil facilities.

To forecast the count of pneumatic pumps replaced in a *typical* year, age and count of gas and oil wells for 2012 were extracted from DI Desktop®. The age of the pneumatic pump was assumed to be the age of the well. The average lifetime of a pneumatic pump was assumed to be 10 years. Therefore, a portion of CIPs that reached 10 years in a particular year were assumed to be replaced that year. For a typical year for this analysis, the replacement count for pneumatic pumps was estimated to be 340

NMED Exhibit 70

diaphragm pumps and 340 piston pumps for gas wells with the same replacement pump counts for oil wells.

The GHG Inventory[128] does not estimate any emissions from pneumatic pumps for the natural gas processing, natural gas transmission and storage segments. Pneumatic pump data are not reported in GHGRP for these segments. For this analysis, the EPA assumed that pneumatic pumps are not used in these segments.

Once the population counts of pneumatic pumps in each segment were established, the count of pneumatic pumps was split into diaphragm and piston. Similar to the assumption used in the EPA/GRI Report,[129] for new and replaced pumps for each segment the EPA assumed 50 percent of the pumps to be diaphragm and 50 percent of the pumps to be piston pumps. Table 11-1 below summarizes the estimated count of new pumps installed per year.

Table 11-1. Estimated Count of Pneumatic Pumps Installed in a Typical Year

Segment/Pump Type	Number of New Pumps
Production/Diaphragm	1,052
Production/Piston	1,052
Processing/Diaphragm and Piston	0
Transmission/Diaphragm and Piston	0
Storage/Diaphragm and Piston	0

11.1.3 Nationwide Emission Estimates

Nationwide baseline emission estimates for pneumatic pumps for new sources in a typical year are summarized in Table 11-2 by industry segment and pump type.

[128] *See footnote 81.*
[129] *See footnote 82.*

Total Processing				0	0
Total Transmission				0	0
Total Storage				0	0

a. From Table 7-3.
b. From Table 7-2.

11.2 Nationwide Emission Reductions and Cost Impacts of Selected Regulatory Options

The EPA calculated the nationwide impacts of the selected options by considering the estimated affected population for each of the target years, the estimated emission reductions per pneumatic pump controlled by the regulatory option and the annualized cost associated with that control option for that pump in that segment.

For Option 1, based on the activity analysis presented above, the EPA estimated there will be no new pneumatic pumps installed in the natural gas processing segment in either of the projected years 2020 or 2025. Therefore, there will be zero nationwide emission reductions and costs associated with Option 1.

For Option 3 for the final rule, the EPA estimated that there will be 1,052 new, modified, or reconstructed diaphragm pumps installed in a typical year. As noted above, due to inherently low emissions, piston pumps were removed from coverage under the final rule. In addition, for the final rule, the EPA included a provision that allowed for an exemption from control where it is determined to be technically infeasible to connect the pump to an existing control device or process at a non-greenfield site or where the a pump is limited use. The EPA has no data that provides information on the number of pumps located at sites where a control device or process is available. Further, the EPA have no data that indicates how often conditions with respect to the pump and/or the control device would be such that it would be technically infeasible to connect the pump to an existing control device or process or where a pump is limited use. In order to estimate impacts that account for these circumstances that would remove

NMED Exhibit 70

control requirements for the pumps under the NSPS, the EPA has estimated that 75 percent of the new pumps will be able to be connect to an existing control device or process. Based on this estimate, 789 pumps in a typical year would be subject to control requirements under the rule.

For nationwide impacts, the EPA estimated that a total of 3,946 new or replaced diaphragm pumps will be installed in the production segment from 2016 through and including the projected year 2020, assumed to still be in operation in 2020. For the projected year 2025, the EPA determined the affected population as those affected facilities from the years 2016 through and including 2025, assumed to still be in operation in 2025. Therefore, the EPA estimated that 7,892 new diaphragm pumps will be installed in the production segment by 2025. Table 12-3 summarizes the estimated number of pumps that would be subject to the final rule provisions for the projected years 2020 and 2025.

Table 11-3. Estimated Count of Pneumatic Pumps Installed Subject to NSPS for 2020 and 2025

Segment/Pump Type	Estimated Number of New Pumps			
	Pumps Per Year[a]	Controlled Per Year Under NSPS	Controlled Under NSPS 2020	Controlled Under NSPS 2025
Production/Diaphragm	1,052	789	3,946	7,892
Production/Piston	1,052	0	0	0
Processing/Diaphragm and Piston	0	0	0	0

a. This number includes all newly installed, modified, and reconstructed pumps.

Based on these activity numbers, the nationwide emission reductions in 2020 are estimated to be 12,970 tons per year of methane and 3,605 tons per year of VOC from diaphragm pumps. The total nationwide emission reductions, for the projected year 2025, are estimated to be 25,940 tons per year of methane and 7,210 tons per year of VOC from diaphragm pumps.

The nationwide costs are based only on the Option 3 costs related to routing pump emissions to an existing combustion device or a VRU. The EPA estimated that the annualized cost for routing pump emissions either to a combustion device or a VRU would be $774. Based on the estimated affected population of 3,946 pneumatic pumps in 2020, the EPA estimated the nationwide cost to be approximately $3.1 million in 2020. The nationwide costs are estimated to be approximately $6.1 million in 2025. Table 11-4 summarizes the nationwide emission reduction and cost impacts for projected years 2020 and 2025.

NMED Exhibit 70

Secondary emissions impacts for Option 3 would include emissions resulting from the combustion of the recovered gas. Table 11-5 summarizes the nationwide secondary emissions for the projected year 2020 and 2025 for Option 3.

Table 11-4. Nationwide Impacts for Gas-Driven Diaphragm Pumps for Projected Years 2020 and 2025

Segment/ Affected Facility	Number of Pumps Subject to NSPS[a]	Annualized Cost[b]	Nationwide Emission Reductions[c] (tpy)			(metric (tonnes)[d]	Nationwide Costs
		($)	Methane	VOC	HAP	CO_2e	(million $)

a. Total hydrocarbons - based on combustion of natural gas stream and AP-42 Total Hydrocarbons emission factors for industrial flares.
b. Carbon monoxide - based on combustion of natural gas stream and AP-42 Carbon Monoxide emission factors for industrial flares.
c. Carbon Dioxide - based on combustion of natural gas stream and 40 CFR Part 98, subpart Y, Equation Y-2.
d. Nitrous Oxides - based on combustion of natural gas stream and AP-42 Nitrogen Oxides emission factors for industrial flares.
e. Particulate Matter - based on combustion of natural gas stream and AP-42 Particulate Matter emission factors for industrial flares. Assumes a "lightly smoking" flare.

NMED Exhibit 70

12.0 NATIONWIDE IMPACTS FOR COMPRESSORS

12.1 Nationwide Emissions from New Sources

12.1.1 Overview of Approach

The number of new affected facilities in the oil and natural gas source category was estimated using data from the GHG Inventory.[130] The nationwide emissions estimates for new sources were then determined by multiplying the number of new sources for each oil and natural gas segment by the expected emissions per compressor based on the emission factor data presented in Table 7-3. A summary of the number of new, modified, and reconstructed reciprocating and centrifugal compressors for transmission and storage segment is presented in Table 7-4.

12.1.2 Nationwide Activity Data for Compressors in Transmission and Storage

The number of reciprocating compressors and wet seal centrifugal compressors installed in the transmission and storage segment was estimated using the GHG Inventory. The number of new reciprocating compressors, wet seal centrifugal compressors, and dry seal centrifugal compressors installed in a given year was estimated by subtracting the prior year (e.g., 2011) from the given year's (e.g., 2012) total as represented in the Inventory. This difference was assumed to be the number of new compressors installed in the latter year (e.g., number of new compressors installed during 2012 equals the compressors reported in 2012 minus the compressors reported in 2011). A 10-year average was calculated based on the number of new compressors installed in 2003 through 2012 in order to determine the average number of new compressors installed in a typical year. Where the data indicated a decrease in new compressors, the average calculation counted those years as zero. An average was taken of all years and rounded to the nearest whole number. The results of this analysis are shown in Table 12-1.

Table 12-1. Approximate Number of New Compressors in the Transmission and Storage Segment in a Typical Year[a]

Compressor Location	Number of New Reciprocating Compressors	Number of New Centrifugal Compressors	
		Wet Seal	Dry Seal
Transmission	15	0	2
Storage	17	1	5

[130] See footnote 4.

NMED Exhibit 70

a. Estimates of the number of new compressors were rounded to the nearest whole number.

12.1.3 Nationwide Emission Estimates

Nationwide baseline emission estimates for new reciprocating and centrifugal compressors are summarized in Table 12-2 by industry segment.

Table 12-2. Nationwide Baseline Emissions for New Reciprocating and Centrifugal Compressors for Projected Years 202 and 2025

Compressor Location/Compressor Type	Nationwide Baseline Emissions (tpy)	
	Methane	VOC
Projected Year 2020		
Transmission		
Reciprocating Compressors	2,035	56
Wet Seal Centrifugal Compressors	0	0
Storage		
Reciprocating Compressors	2,401	675
Wet Seal Centrifugal Compressors	585	16
Projected Year 2025		
Transmission		
Reciprocating Compressors	4,070	113
Wet Seal Centrifugal Compressors	0	0
Storage		
Reciprocating Compressors	,4802	133
Wet Seal Centrifugal Compressors	1,169	32

12.2 Nationwide Emission Reductions and Cost Impacts of Selected Regulatory Options

Tables 12-3 and 12-4 summarize the impacts of the selected regulatory options by industry segment. Regulatory Option 1 is estimated to affect 15 reciprocating compressors at transmission facilities and 17 reciprocating compressors at underground storage facilities in a typical year. The nationwide impacts for projected year 2020 are based on a typical year. The projected affected number of compressors for projected year 2020 is calculated as all compressors affected from 2016 through and including 2020 and for 2025 as all compressors affected from 2016 through and including 2025, assumed to still be in operation in the analysis years. A summary of the capital and annual costs and emission reductions for this option is presented in Table 12-3.

Operators in the gathering and boosting and transmission and storage parts of the industry typically do not own the natural gas they transport; rather, the operators receive payment for the transportation

NMED Exhibit 70

service they provide. As a result, the unit-level cost and emission reduction analyses supporting BSER decisions in the preamble (and is presented in Volume 1 of the TSD) do not include estimates of revenue from natural gas recovery as offsets to compliance costs. From a social perspective, however, the increased financial returns from natural gas recovery accrues to entities somewhere along the natural gas supply chain and should be accounted for in the national impacts analysis. An economic argument can be made that, in the long run, no single entity is going to bear the entire burden of the compliance costs or fully receive the financial gain of the additional revenues associated with natural gas recovery. The change in economic surplus resulting from natural gas recovery is going to be spread out amongst different agents via price mechanisms. Therefore, the most simple and transparent option for allocating these revenues would be to keep the compliance costs and associated revenues together in a given source category and not add assumptions regarding the allocation of these revenues across agents. This is the approach followed in Volume 2 of the TSD, as well as in the RIA.

Regulatory Option 3 is expected to affect 1 new wet-seal centrifugal compressor in the transmission and storage segment (specifically at a storage facility) each year. The number of affected centrifugal compressors is low because the historical rate of growth in the overall number of wet seal centrifugal compressors in the segment has been low, indicating few new compressors are being installed. In addition, most new centrifugal compressors are expected to use dry seals, which would not be affected facilities. EPA did not change these activity numbers for the final rule. A summary of the capital and annual costs and emission reductions for this option is presented in Table 12-4. A summary of the nationwide secondary combustion-related emissions from Option 2 are summarized in Table 12-5.

NMED Exhibit 70

Table 12-3. Nationwide Cost Impacts for Regulatory Option 1

Compressor Location	Number of New Sources	Nationwide Emission Reductions (tpy)		Total Nationwide Costs	Annualized Cost ($/year)	
		Methane	VOC	Capital Cost ($)	Without Savings	With Savings
Projected Year 2020						
Transmission	75	1,626	45	$423,769	$131,066	($205,534)
Storage	85	1,856	51	$654,915	$159,594	($207,676)
Projected Year 2025						
Transmission	150	3,252	90	$847,537	$262,132	($411,068)
Storage	170	3,712	103	$1,309,830	$353,049	($415,351)

Note: Negative number indicates net savings.

Table 12-4. Nationwide Cost Impacts for Regulatory Option 3

Compressor Location	Number of New Sources	Nationwide Emission Reductions (tpy)		Nationwide Costs			
		Methane	VOC	Capital Cost New CD[a] ($)	Capital Cost Existing CD[b] ($)	Annual Cost New CD[a] ($/year)	Annual Cost Existing CD[b] ($/year)
Projected Year 2020							
Transmission	0	0	0	$0	$0	$0	$0
Storage	5	555	21	$358,914	$116,260	$570,728	$16,553

Projected Year 2025					
Storage	5.8	13	5,496	2.8	0.10

a. Based on combustion of natural gas stream and AP-42 Total Hydrocarbons emission factors for industrial flares.
b. Based on combustion of natural gas stream and AP-42 Carbon Monoxide emission factors for industrial flares.
c. Based on combustion of natural gas stream and 40 CFR Part 98, subpart Y, Equation Y-2.
d. Based on combustion of natural gas stream and AP-42 Nitrogen Oxides emission factors for industrial flares.
e. Based on combustion of natural gas stream and AP-42 Particulate Matter emission factors for industrial flares. Assumes a "lightly smoking" flare.

NMED Exhibit 70

13.0 NATURAL GAS SAVINGS

Affected facilities under the NSPS may recover natural that would have otherwise been vented or combusted as a result of controlling emissions. This section presents the value of recovered gas nationally.[131] With respect to the regulatory options presented above, there are several opportunities for gas savings to be realized, as noted below:

- For oil well completions, with implementation of a REC, the EPA estimated that 899 Mcf of natural gas is recovered during the average 3-day completion event.
- For equipment leaks, with implementation of the semiannual OGI monitoring and repair of leaks found, the EPA estimate that the average annual gas saved would be 43 Mcf for oil wells with GOR < 300, 96 Mcf for oil wells with GOR > 300, 191 Mcf for gas wells, 1,222 Mcf for gathering and boosting stations, 1,255 Mcf for transmission stations, and 4,424 for storage facilities. For quarterly monitoring and repair, the EPA estimate for average annual gas saved would be 57 Mcf for oil wells with GOR < 300, 127 Mcf for oil wells with GOR > 300, 255 Mcf for gas wells, 1,629 Mcf for gathering and boosting stations, 1,673 Mcf for transmission stations, and 5,899 for storage facilities.
- For pneumatic controllers, the EPA estimate the use of low-bleed controllers instead of high-bleed controllers will save 147 Mcf of natural gas per year.
- For reciprocating compressors, the EPA estimate that the replacement of rod packing every 26,000 hours of operations (or every three years) will avoid the loss of, for each reciprocating compressor, 1,122 Mcf per year for transmission facilities and 1,130 Mcf per year for storage facilities.[132]
- For centrifugal compressors, the EPA estimates that the replacement of one wet seal compressor with a dry seal compressor will save 5,290 Mcf per year.[133]

Based on the above per unit natural gas savings and the new source activity counts anticipated for the projected years 2020 and 2025 for the affected facilities, the EPA calculated

[131] Note that operators in the gathering and boosting and transmission and storage segments of the industry typically do not own the natural gas they transport; rather, the operators receive payment for the transportation service they provide. As a result, the unit-level cost supporting BSER decisions in the preamble (and is presented in Volume 1 of this TSD) do not include estimates of revenue from natural gas recovery as offsets to compliance costs. This section addresses all gas savings regardless of presumed ownership.
[132] See footnote 2.
[133] See footnote 2.

NMED Exhibit 70

the nationwide gas savings for each of the regulatory options discussed in the sections above for the projected years 2020 and 2025. Table 13-1 presents the estimated gas savings for these affected facilities.

Table 13-1. Estimated Nationwide Natural Gas Savings for Selected Regulatory Options

Affected Facility	Number of Affected Facilities Subject to NSPS[a]	Volume of Gas Saved (MMcf)	Value of Gas Saved ($ million)
Projected Year 2020			
Well Completions			
Development Oil Wells	19,703	5,738	$23
Equipment Leaks			
Oil Well Site[b]	76,759	5,633	$22.5
Gas Well Site[b]	16,819	3,214	$12.9

Pneumatic Pumps	7,892	0	$0
Reciprocating Compressors - Transmission	150	168	$0.67
Reciprocating Compressors - Storage	170	192	$0.77
Centrifugal Compressors - Storage	10	53	$0.21
Total Projected Year 2025	230,407	26,676	$107

a. Reflects only the number of affected facilities subject to the NSPS that will have potential gas savings (not all sources will have potential for gas savings).
b. For oil wells, the activity number reflects both oil well sites with GOR < 300 and oil well sites with GOR > 300. The gas savings for well sites are based on semiannual monitoring and repair.
c. The gas savings for compressor stations are based on quarterly monitoring and repair.

NMED Exhibit 70

14.0 POTENTIAL NATIONWIDE CO_2 Eq. and HAP IMPACTS

Because methane is of concern for global warming effects, the EPA also calculated the global warming potential expressed as CO_2 Eq. for the methane reductions from the proposed regulatory options. For the purposes of this analysis, one ton of methane is equal to 25 tons of CO_2 Eq. The EPA have converted the CO_2 Eq. values to metric tonnes consistent with the presentation of CO_2 Eq.in the GHG Inventory.

In addition, there may be important HAP emission co-reductions a resulting from the application of emission controls under the NSPS. For the purposes of the NSPS, the EPA estimate HAP emissions by applying a ratio to the methane emissions. The ratio used is based on the gas composition analysis conducted for the NSPS.[134] Because gas composition was determined to vary between industry segments and between the various affected facilities, different ratios were used accordingly. Table 14-1 summarizes the HAP-to-methane ratios used for the various affected facilities in the various segments. Based on the methane emission reductions estimated in the above sections for the respective affected facilities and regulatory options, the EPA estimated the HAP emissions.

Table 14-2 summarizes the CO_2 Eq. and HAP emission reductions calculated for the affected facilities based on the finalized regulatory options.

Table 14-1. HAP-to-Methane Ratios Used to Estimate HAP Emissions

Segment	Affected Facility	HAP-to-Methane Ratio

NMED Exhibit 70

15.0 COMPARISON OF TOTAL COST IMPACTS TO OVERALL INDUSTRY CAPITAL EXPENDITURES AND RECEIPTS

In order to provide another perspective on the reasonableness of the estimated cost of control as determined in our evaluation of BSER for the final standards as presented in Volume 1 of this TSD, we analyzed the total cost of the rule for each type of affected facility (as presented in Volume 2 of this TSD) under two additional approaches using industry economic data.

First, we compared the total nationwide capitals costs that would be incurred for each type of affected facility to comply with the final standards to the industry's estimated new annual capital expenditures. This analysis allowed us to compare the capital costs that would be incurred to comply with the final standards to the level of new capital expenditures that the industry is incurring in the absence of the final standards. Capital expenditure data for relevant NAICS codes covered by the rule were obtained from the U.S. Census 2013 Annual Capital Expenditures Survey[135]. For the capital expenditures analysis, we determined the estimated nationwide capital costs estimated to be incurred by each type of affected facility to comply with the final standards[136], then divided the nationwide capital costs by the new capital expenditures (census data) for the appropriate NAICS code(s) to determine the percentage that the nationwide capital costs represent of the capital expenditures. For example, we used the total estimated capital cost (nationwide) for hydraulically fractured development oil well completions and compared that to the total capital expenditures the NAICs codes that correspond to oil and natural gas production segment. Table 15-1 below summarizes the capital expenditure data used for our analysis.

For fugitive emissions standards at well sites and compressor stations, there are no actual capital cost identified in the TSD. Instead, for the purposes of this portion of the analysis, we used the first-year corporate-based costs for these standards.

[135] Capital Expenditures for Structures and Equipment for Companies With Employees by Industry: 2013, Table 4a. See http://www.census.gov/econ/aces/xls/2013/full_report.html

[136] The total capital cost estimate is based on the number of estimated affected facilities within the year and the capital cost per facility, however, the capital expenditure may not actually be incurred in that year.

NMED Exhibit 70

In the second approach, we compared the annualized costs that would be incurred to comply with the standards to the industry's estimated annual revenues. This analysis allowed us determine whether the annualized costs appears reasonable as a percentage of the revenues being generated by the industry. The annualized cost, as calculated for the rule, includes capital cost annualized using a seven percent discount rate plus any annually incurred cost for implementation of a control technology. We included, where applicable, the cost savings realized from recovered natural gas. The annual revenue data for relevant NAICS codes were obtained from the U.S. Census 2012 County Business Patterns and 2012 Economic Census[137]. For the annual revenues analysis, we determined the estimated nationwide annualize costs incurred by each type of affected facility to comply with the final standards[138], then divided the nationwide annualized costs by the annual revenues (Census data) for the appropriate NAICS code(s) to determine the percentage that the nationwide annualized costs represent of annual revenues. For example, we used the total annual cost (nationwide) for hydraulically fractured development oil well completions and compared that to the total receipts for the NAICs codes that correspond to oil and natural gas production segment. Table 15-2 below summarizes the revenue data used for our analysis.

For the capital expenditures, the production segment was represented with the NAICS codes 21111 " Crude Petroleum and Natural Gas Extraction" and 213111 and 213112 " Support Activities for Oil and Gas Operations". The transmission and storage segment was represented with the NAICS code 4862 "Pipeline transportation of natural gas". For revenue, the production segment was represented with the NAICS codes 21111 " Crude Petroleum and Natural Gas Extraction" and 213112 " Support Activities for Oil and Gas Operations". The transmission and storage segment was represented with the NAICS code 486210 "Pipeline transportation of natural gas". Although there is not a one-to-one correspondence between NAICS codes and the

[137] Number of Firms, Number of Establishments, Employment, Annual Payroll, and Estimated Receipts by Enterprise Employment Size for the United States, All Industries: 2012. Release date: 6/22/2015. 2012 County Business Patterns and 2012 Economic Census. For information on confidentiality protection, sampling error, and nonsampling error, see http://www.census.gov/econ/susb/methodology.html. For definitions of estimated receipts and other definitions, see http://www.census.gov/econ/susb/definitions.html.

[138] The estimated nationwide annualized costs were determined based on the estimated number of affected facilities in that year, however, these annualized costs are not necessarily incurred within that same year.

NMED Exhibit 70

industry segments we used in the development of the analysis, we believe there is enough similarity to draw accurate conclusions.

Because we are aware the different owners or operators are generally involved in the different industry segments, we conducted the analysis at the affected facility level to ensure proper characterization of the impact. We also conducted the analysis for all sources in the production segment and in the transmission and storage segment. Table 15-3 summarizes the result of our analysis. In all cases we found that the rule impacts in comparison to either capital expenditures or revenues represent a fraction of one percent.

Table 15-1. NAICS-Based Capital Expenditure Data

MEMORANDUM

Development of the Low Pressure Well Equation for Determining REC Requirements at Hydraulically Fractured Oil and Gas Wells

MEMORANDUM

FROM: ICF International

THRU: Graham Fitzsimons, EC/R

TO: Ravi Srivastava, U.S. EPA

DATE: April 29, 2016

SUBJECT: Technical Development of the Low Pressure Well Equation for Assessing REC Feasibility at Hydraulically Fractured Oil and Gas Wells

---

This memorandum documents the method for estimating flowback pressure during completion for a hydraulically fractured petroleum well to assess whether a Reduced Emissions Completion (REC) can be implemented. If the well does not have adequate pressure to push the produced natural gas into the flow line then the well is deemed a low pressure well. The memo provides background on low pressure wells, the technical development of the low pressure well equation (LPWE) and related correlations, comparison of LPWE predictions with those from an established well flow model, and an example calculation using the LPWE. A brief summary then follows the main body of this memo.

1. Background on Low Pressure Well Equation

REC is a practice in which the natural gas produced during a well completion is captured and routed through the flow line, following hydraulic fracturing. To successfully perform an REC, the pressure of the gas needs to be sufficiently high to push the gas into the flow line. If a well does not have adequate pressure to push the gas into the flow line then the well is deemed a low pressure well.

NMED Exhibit 70

In the March 2015 New Source Performance Standards (NSPS) proposal, EPA proposed to use the definition for low pressure gas well provided in the 2012 final NSPS rule for all wells (i.e. oil and/or gas). According to this definition, the pressure of the flowback fluid, immediately before it enters the flow line, is calculated by the following equation:

$$P_L\ (psia) = 0.445 \cdot P_R - 0.038 \cdot L + 67.578 \quad (1)$$

Where P_L (psia) is predicted flow line pressure (sales line pressure is sometimes used interchangeably with flow line pressure), P_R (psia) is reservoir pressure (synonymous with formation pressure), and L (ft) is true vertical depth of the well.

If the P_L calculated using the above equation is less than the available actual flow line pressure, the well would be considered to be a low pressure well. Such a well cannot implement an REC during completion flowback.

The above equation is not appropriate for application to oil wells. This effort was undertaken to develop an equation for predicting pressure of the flowback fluid just before the fluid enters the flow line and essentially modifies equation (1) to account for additional pressure drop due to flows of oil and water.

While detailed models are available for calculating multiphase flow in oil and gas wells, these models typically require many inputs, often complex, from an experienced user, the values of some of which may not be readily available before well completion activity is undertaken. The LPWE described in this memorandum uses only those inputs for which estimates are understood to be available before well completion activity starts including:

- Wellhead production rates (gas, oil, and water);
- Wellhead oil gravity;
- Reservoir pressure and bottomhole temperature; and
- True vertical well depth.

NMED Exhibit 70

The three flow regimes typically encountered during the flowback event include:

a. **Fracture fluid flow.** After hydraulic fracture (frack) of a new or existing well, the well tubing is filled with large quantities of frack fluid which consists of injected liquid (i.e., water plus additives) and proppant (typically sand). This material must be evacuated to prepare the well for production.

   During the initial flowback, virtually all of the flow output from the well consists of the frack material itself, rather than hydrocarbons from the formation, given that the well tubing is filled with the frack fluid. As the frack fluid reaches the surface, it is typically directed to atmospheric pressure storage, typically a tank.

b. **Slug flow.** As the column of frack fluid flows to the surface, it is followed by hydrocarbons (gas and oil) and water from the formation and any inert gas introduced during the frack. Because of the differences in density and viscosity of the various flowback components (oil, water, gas, and frack fluid), at this point the flowing fluid typically has multi-phase slugs of gas and liquid. As the slug flow reaches the surface, it is directed to temporary storage where the liquids portion of the slug flow is contained while the gas portion of the slug flow is typically vented to the atmosphere or sent to a completion combustion device.

c. **Steady flow.** Over time (on the order of hours to days), the slug flow transitions to a steady flow condition where the frack fluid slugs in the tubing have been largely evacuated and there is a reasonably steady flow of hydrocarbons (oil and gas) and water. For energized fracks, this steady flow of vapor may, for a time, contain a significant percentage of the inert gas introduced into the formation during the frack, and over time, (on the order of hours) the steady flow transitions to primarily hydrocarbons and water from the formation. Depending upon the pressure of the fluid (oil, gas, and water) downstream of the wellhead, the steady flow of fluid can be directed to surface equipment and then to the flow line or a completion combustion device.

NMED Exhibit 70

The LPWE developed in this document applies to the steady flow of hydrocarbons encountered during the separation flowback stage[1]. Under this flow regime, gas may be separated and routed to the flow line.

2. Development of the Low Pressure Well Equation

Prior to developing the LPWE, research was performed to identify flow correlation models that adequately estimate the pressure drop across the well depth. In literature, a multitude of flow correlation models exist, ranging from simple pressure gradient models to complex mechanistic models. No flow correlation model is perfect and there is no model that can be applied to every situation. The hydrostatic pressure drop is typically the dominant component of pressure drop in wells. This component varies significantly with the gas-to-oil ratio, with higher volumes of oil significantly increasing the pressure drop due to oil having a higher density than gas. The frictional losses in wells constitute a small fraction of the total pressure drop across the entire well. Therefore, even for wells with horizontal section(s), it is the vertical section that determines the overall pressure drop characteristics. Hence for characterizing pressure drop in a well, it was important to focus on models that perform adequately for vertical wells. In general, the Hagedorn and Brown model[2] performs well for vertical wells, and is typically a good choice for such wells[3].

All flow correlation models, including Hagedorn and Brown, typically require many inputs, often complex, from an experienced user, the values of some of which may not be readily available before well completion activity is undertaken. Therefore use of such models for determining REC requirements

[1] Separation flowback stage means the period during a well completion operation when it is technically feasible for a separator to function. The separation flowback stage ends either at the startup of production, or when the well is shut in and permanently disconnected from the flowback equipment.

NMED Exhibit 70

could pose practical limitations. Consequently, a need was identified to develop a simpler model that could be used to determine whether an REC can be performed. The LPWE developed in this work uses only those inputs for which estimates are understood to be available before well completion activity starts.

The development of the LPWE starts from an energy balance that takes into account the two main components of pressure drop for oil and gas wells – hydrostatic and frictional. As such, the LPWE developed in this work modifies equation (1) to account for these components of pressure drop resulting from flow of oil and water in a well.

Under steady flow conditions during flow back, the flow of oil, gas, water, and proppant in well tubing can be visualized as a column of fluid[4] experiencing[5]:

- The hydrostatic pressure drop due to the weight of the fluid column in the well tubing;
- Frictional pressure drop due to friction at the tubing walls opposing the flow to the surface;
- The pressure of the hydrocarbons and water at bottom hole conditions; and
- The pressure of the hydrocarbons and water at the well head.

Consequently[6],

$$P_{WH} = P_{BH} - \left(\Delta P_g\right)_h - (\Delta P_o)_h - (\Delta P_w)_h - \Delta P_f \quad (2)$$

[4] Pressure drop from horizontal sections of a well is assumed to be negligible compared to the vertical sections of the same well due to the hydrostatic pressure drop being the dominant component of total pressure drop compared to the frictional component in the lateral sections.
[5] An additional force due to fluid acceleration is also present. Since this force contributes a negligible amount to total pressure drop across the well tubing, the impact of this force is ignored.
[6] Hydrostatic pressure drop due to small amounts of proppant during separation flowback is implicit in the hydrostatic drop due to water.

NMED Exhibit 70

Where P_{WH} is well-head pressure, P_{BH} is bottomhole pressure, $(\Delta P_g)_h$ is total hydrostatic pressure drop due to the gas phase, $(\Delta P_o)_h$ is total hydrostatic pressure drop due to the oil phase, $(\Delta P_w)_h$ is total hydrostatic pressure drop due to the water phase, and ΔP_f is total frictional pressure drop.

The pressure drop due to friction typically contributes a small amount to the overall total pressure drop, and it can be expressed as a percentage, x(%), of the total pressure drop:

$$\Delta P_f = x(\%).\left[\left(\Delta P_g\right)_h + (\Delta P_o)_h + (\Delta P_w)_h + \Delta P_f\right]$$

Simplifying and solving for pressure drop due to frictional losses:

$$\Delta P_f = \frac{x(\%).\left[\left(\Delta P_g\right)_h + (\Delta P_o)_h + (\Delta P_w)_h\right]}{[100 - x(\%)]} \quad (3)$$

Substituting equation (3) into equation (2) yields:

$$P_{WH} = P_{BH} - \left(\Delta P_g\right)_h - (\Delta P_o)_h - (\Delta P_w)_h - \frac{x(\%).\left[\left(\Delta P_g\right)_h + (\Delta P_o)_h + (\Delta P_w)_h\right]}{[100 - x(\%)]}$$

Simplifying further yields:

$$P_{WH} = P_{BH} - \left[\frac{100}{100 - x(\%)}\right]\left[\left(\Delta P_g\right)_h + (\Delta P_o)_h + (\Delta P_w)_h\right] \quad (4)$$

Now the pressure drops due to flow of gas, oil, and water can be expressed in terms of respective pressure gradients across the well. Then equation (4) can be written as,

$$P_{WH}\,(psia) = P_{BH}(psia) - \left[\frac{100}{100 - x(\%)}\right]\left[\left(\frac{\Delta P_g}{L}\right)_h + \left(\frac{\Delta P_o}{L}\right)_h + \left(\frac{\Delta P_w}{L}\right)_h\right]\left(\frac{psi}{ft}\right) \cdot L(ft) \quad (5)$$

Where L is the true vertical depth of the well, expressed in feet.

In the previous evaluation conducted for the 2012 NSPS, the flow line and bottom hole pressures for a gas well were expressed as:

$$P_L\,(psia) = \frac{P_{WH}}{1.01}(psia) \quad (6)$$

NMED Exhibit 70

and

$$P_{BH}\ (psia) = \frac{P_R}{2}(psia) \quad (7)$$

These relationships are assumed to be generally applicable to flow in petroleum wells. Then, using these equations in equation (5) yields:

$$P_L\ (psia) = 0.495 \cdot P_R(psia) - 0.99\left[\frac{100}{100-x(\%)}\right]\left[\left(\frac{\Delta P_g}{L}\right)_h + \left(\frac{\Delta P_o}{L}\right)_h + \left(\frac{\Delta P_w}{L}\right)_h\right](\frac{psi}{ft}) \cdot L(ft) \quad (8)$$

Rewriting (8) in terms of densities (pounds/cubic foot) and the related volume fractions,

$$P_L\ (psia) = 0.495 \cdot P_R(psia) - \frac{0.99}{144}^{7} \cdot \left[\frac{100}{100-x(\%)}\right]\left[\frac{q_g}{q_g+q_o+q_w}\rho_g + \frac{q_o}{q_g+q_o+q_w}\rho_o + \frac{q_w}{q_g+q_o+q_w}\rho_w\right](\frac{psi}{ft}) \cdot L(ft) \quad (9)$$

Where q_g, q_o, and q_w are the volumetric flowrates of gas, oil, and water in the well, respectively, expressed in cubic feet per second, and ρ_g, ρ_o, ρ_w, are the densities for the gas, oil, and water phases in the well, respectively, expressed in pounds per cubic feet.

2.1 Determination of hydrostatic and frictional pressure gradient due to gas flow

Under conditions of gas flow only, equation (9) becomes

$$P_L\ (psia) = 0.495 \cdot P_R(psia) - \frac{0.99}{144} \cdot \left[\frac{100}{100-x(\%)}\right]\rho_g(\frac{psi}{ft}) \cdot L(ft) \quad (10)$$

Comparing equations (1) and (10), we get,

$$0.445 \cdot P_R(psia) - 0.038 \cdot L(ft) + 67.578 = 0.495 \cdot P_R(psia) - \frac{0.99}{144} \cdot \left[\frac{100}{100-x(\%)}\right]\rho_g(\frac{psi}{ft}) \cdot L(ft)$$

Simplifying,

[7] 144 inches squared per foot squared.

NMED Exhibit 70

$$\frac{0.99}{144}\cdot\left[\frac{100}{100-x(\%)}\right]\rho_g\cdot L = 0.05\cdot P_R + 0.038\cdot L(ft) - 67.578\ (psi) \quad (11)$$

Substituting equation (11) into equation (9),

$$P_L\ (psia) = 0.495\cdot P_R(psia) - \frac{q_g}{q_g+q_o+q_w}[0.05\cdot P_R + 0.038\cdot L(ft) - 67.578] - \frac{0.99}{144}\cdot$$

$$\left[\frac{100}{100-x(\%)}\right]\left[\frac{q_o}{q_g+q_o+q_w}\rho_o + \frac{q_w}{q_g+q_o+q_w}\rho_w\right](\frac{psi}{ft})\cdot L(ft) \quad (12)$$

2.2 Determination of hydrostatic pressure gradient due to water flow

Generally a well can produce significant amounts of water while producing oil and gas. Therefore, it was important to take the water pressure gradient (psi/ft) into consideration when developing the LPWE. In the development of the LPWE the fresh water gradient of 0.433 psi/foot is used for calculating the hydrostatic pressure drop due to water[8].

Then,

$$\frac{1}{144}\left[\frac{q_w}{q_g+q_o+q_w}\rho_w\right]\left(\frac{psi}{ft}\right) = \left[\frac{q_w}{q_g+q_o+q_w}0.433\right](\frac{psi}{ft}) \quad (13)$$

Substituting (13) in (12) yields:

$$P_L\ (psia) = 0.495\cdot P_R(psia) - \frac{q_g}{q_g+q_o+q_w}[0.05\cdot P_R + 0.038\cdot L(ft) - 67.578] - 0.99\cdot$$

$$\left[\frac{100}{100-x(\%)}\right]\left[\frac{q_o}{q_g+q_o+q_w}\cdot\frac{\rho_o}{144} + \frac{q_w}{q_g+q_o+q_w}0.433\right](\frac{psi}{ft})\cdot L(ft) \quad (14)$$

2.3 Determination of Estimated Frictional Pressure Drop (%)

As mentioned above, the Hagedorn and Brown flow model performs well for vertical wells and predicts both hydrostatic and frictional components of pressure drop based on the input conditions provided to

[8] American Association of Petroleum Geologists: http://wiki.aapg.org/Hydrostatic_pressure-depth_plot_construction.

NMED Exhibit 70

the model[9]. This model, henceforth referred to as the Hagedorn and Brown model, was coded in Excel by EPA and provided to ICFI. ICF checked the model and used it for validating the results of the LPWE. To evaluate the relative contribution of pressure drop due to frictional losses, an experimental matrix of model runs was created using known ranges of data from the DI Desktop™ commercial well database. These ranges are understood to cover the spectrum of oil and gas well characteristics relevant to the U.S[10]. The experimental matrix is summarized in Table 1 below.

Table 1: Experimental Matrix of Input Variables for All Model Runs

Input Variable	**Units**	**Values Used for All Model Runs**
Oil Production Rate	Standard barrel per day	100, 200, 400, 800, 1000, 2000
Gas Production Rate	Million standard cubic feet per day	0.1, 0.3, 0.5, 1, 2, 3, 5, 10
Pressure Gradient[11]	psi per foot of well depth	0.35, 0.433, 0.5, 0.6, 0.75
Well Depth	Feet	500, 1000, 2500, 5000, 7000, 9000, 13000, 17000, 20000
Oil Wellhead Gravity	API	20, 30, 40, 50

Hagedorn and Brown model runs were completed and the pressure drop due to frictional losses was calculated as a percent of total pressure drop (hydrostatic and frictional). After evaluating over 7,560

[9] The Hagedorn and Brown model used in this work calculates pressure drop gradient in psi/ft and multiplies the gradient by the well depth.

[10] For purposes of this work, wells with Gas to Oil Ratios of 300 or less were excluded from the model runs. Additionally, few model runs with negative predicted values from either Hagedorn and Brown or the LPWE were considered infeasible and removed from the results.

[11] Increments of pressure gradient were multiplied against values of well depth to produce values of bottomhole pressure for each model run.

NMED Exhibit 70

dynamic model runs[12], it was found that pressure drop due to frictional losses was close to 0.64% on average with a median value of 0.24%. As a conservative estimate, a value of 1% (i.e., x% = 1%) was assumed in this work to adequately characterize frictional pressure drop for operations typically encountered in U.S. oil production.

2.4 The Final Low Pressure Well equation

Assuming an average frictional component to total pressure drop ratio of 1% (i.e., x% = 1%) and substituting the value into (14), the final form of the LPWE becomes:

$$P_L\,(psia) = 0.495 * P_R(psia) - \frac{q_g}{q_g+q_o+q_w}[0.05 \cdot P_R + 0.038 \cdot L(ft) - 67.578] -$$

$$\left[\frac{q_o}{q_g+q_o+q_w} \cdot \frac{\rho_o}{144} + \frac{q_w}{q_g+q_o+q_w} 0.433\right] (\frac{psi}{ft}) \cdot L(ft) \qquad (15)$$

The procedures for calculating oil, gas, and water flow rates and oil density to be used with the LPWE are described in Section 2.5.

Note under conditions of gas flow only (i.e., *qo = qw = 0*), equation (15) reduces to equation (1), the equation for gas wells. Also note that equation (15) for line pressure is derived using a vertical well. It is known that inclined wells exist in the field, which will experience a somewhat higher frictional drop due to longer flow length. Nonetheless, it expected that equation (15) would be able to account for minor increases in pressure drop due to increased frictional drop at inclined wells because frictional pressure drop component contributes a small amount to the total pressure drop (about 1% on average) and conservative assumptions were used in deriving equation (15) – notably bottom hole pressure = ½ of formation pressure.

[12] In this work, two models were used: (1) a "dynamic model" including above-the-bubble point calculations, and (2) a "simplified dynamic model" (e.g. without above-the-bubble point calculations and with a constant value for dissolved gas gravity.)_ See Section 4 for more details.

NMED Exhibit 70

In summary, equation (15) constitutes the LPWE developed in this work. This equation predicts the fluid pressure immediately upstream of the flow line. If this predicted pressure is higher than the available flow line pressure, the well can do an REC.

2.5 Determination of Oil Density, Oil Flow Rate, and Gas Flow Rate for Use in the LPWE[13]

2.5.1 Determination of Oil Density and Flow Rate

Oil density used in calculating the hydrostatic pressure drop for oil is defined as an arithmetic average of the oil density at bottomhole and the oil density at the wellhead. This accounts for the fact that the density of oil increases as the hydrocarbons move up the well and dissolved gases come out of the oil. The oil flow rate used in the LPWE corresponds to the flow rate at bottomhole conditions. In essence, starting with the bottomhole flow rate, the pressure drop across the well is calculated using this flowrate and the average oil density, and then the pressure at the wellhead is determined. This "marching" calculation procedure is also used in more complex multiphase flow models.

The oil density and volumetric flow rate at bottomhole conditions are calculated using the known values of oil API gravity and oil production rate (STBO/day) at a well site and the widely used correlations provided in Vasquez and Beggs (1980).[14] This calculation procedure is described below[15].

[13] Equations marked by asterisks (*) are not original work developed by ICF and the relevant citations are provided. ICF received an approval through EPA from the Society of Petroleum Engineers on March 14th, 2016 for reproduction and use of equations and correlations from publications in their journals.

[14] Vasquez, M. and Beggs, H.D., "Correlations for fluid physical property prediction," JPT, June 1980, 968. This paper provides correlations for oil properties including dissolved gas-oil ratio and oil formation volume factor based on approximately 6000 data points - measured over large ranges of pressure, temperature, oil gravity and gas gravity.
https://www.onepetro.org/journal-paper/SPE-6719-PA

[15] The calculation procedure uses correlations for flow conditions at or below bubble point. Runs of the Hagedorn and Brown model (see Table 1), with above-bubble-point correlations revealed that above-bubble-point conditions were met in less than 10% of all dynamic model runs (see Section 4) and above-bubble-point corrections amounted to oil density corrections on the order of 4% or less. Thus, the overall impact to predicted line pressure is considered to be relatively negligible and for simplicity above-bubble-point calculations are not included in the calculation procedure.

NMED Exhibit 70

Step 1: Determine the value of the bottom hole pressure, P_{BH}, based on available information at the well site, or by calculating it using the reservoir pressure, $P_R\ (psia)$, in the following equation:

$$P_{BH}\ (psia) = \frac{1}{2} P_R$$

Step 2: Determine the value of the bottom hole temperature, $T_{BH}\ (F)$, based on available information at the well site, or by calculating it using the true vertical depth of the well, *L(ft)*, in the following equation[16]:

$$T_{BH}\ (F) = 0.014 \times L\ + 79.081$$

Step 3: Calculate the value of the applicable natural gas specific gravity that would result from a separator pressure of 100 psig, γ_{gs}, using the following equation from Vasquez and Beggs (1980) [14] with: separator at standard conditions (pressure, $p = 14.7\ (psia)$, temperature, T $= 60\ (F)$); the API oil gravity at the well site, γ_o; and the oil specific gravity at the separator under standard conditions, $\gamma_{gp} = 0.75$:[17]

$$\gamma_{gs} = \gamma_{gp} \cdot \left(1.0 + 5.912\ x\ 10^{-5} \cdot \gamma_o \cdot T \cdot log\left(\frac{p}{114.7}\right)\right)^*$$

Step 4: Calculate the value of the applicable dissolved GOR, *Rs (scf/STBO)*, using the following equation from Vasquez and Beggs (1980)[14] with: the bottom hole pressure, $P_{BH}\ (psia)$, determined in Step 1 above; the bottom hole temperature, $T_{BH}\ (F)$, determined in Step 2 above;

[16] Temperature gradient data from the United States Geological Service were regressed across the sedimentary basins in the US and modeled as a function of well depth. Data is derived from USGS Open-File Report 2010-1303 titled "Comprehensive Database of Wellbore Temperatures and Drilling Mud Weight Pressures by Depth for Judge Digby Field".
https://pubs.er.usgs.gov/publication/ofr20101303.

[17] The value of 0.75 is based on expert opinion considering the average natural gas concentration data referenced in the technical memo titled "Composition of Natural Gas for Use in the Oil and Natural Gas Sector Rulemaking," July, 2011, available in the NSPS OOOO rule making docket: https://www.regulations.gov/#!documentDetail;D=EPA-HQ-OAR-2010-0505-0084.

the gas gravity at separator pressure of 100 psig, γ_{gs}, calculated in Step 3 above; the oil API gravity, γ_o, at the well site; and the constants, C1, C2, and C3, found in Table 2:

$$R_s(\frac{scf}{STBO}) = C1 \cdot \gamma_{gs} \cdot {P_{BH}}^{C2} \cdot exp\left[C3\left(\frac{\gamma_o}{T_{BH} + 460}\right)\right]^*$$

Table 2. Coefficients for the Vasquez and Beggs Correlation for R_s.

Constant	$\gamma_{API} \leq 30$	$\gamma_{API} > 30$
C1	0.0362	0.0178
C2	1.0937	1.1870
C3	25.7240	23.931

Step 5: Calculate the value of the oil formation volume factor, *Bo (bbl/STBO)*, using the following equation from Vasquez and Beggs (1980)[14] with: the bottom hole temperature, $T_{BH}\ (F)$,, determined in Step 2 above; the gas gravity at separator pressure of 100 psig, γ_{gs}, calculated in Step 3 above; the dissolved GOR, Rs (scf/STBO), calculated in Step 4 above; the oil API gravity, γ_o, at the well site; and the constants, C1, C2, and C3, found in Table 3:

$$B_o\left(\frac{bbl}{STBO}\right) = 1.0 + C1 \cdot R_s + (T_{BH} - 60)\left(\frac{\gamma_o}{\gamma_{gs}}\right) \cdot (C2 + C3 \cdot R_s)^*$$

Table 3. Coefficients for the Vasquez and Beggs Correlation for B_o

Constant	$\gamma_{API} \leq 30$	$\gamma_{API} > 30$
C1	4.677×10^{-4}	4.670×10^{-4}
C2	1.751×10^{-5}	1.100×10^{-5}

NMED Exhibit 70

C3	-1.811×10^{-8}	1.337×10^{-9}

Step 6: Calculate the density of oil at the wellhead, ρ_{WH} $(\frac{lbm}{cu\ ft})$, using the following equation with the value of the oil API gravity, γ_o, at the well site:

$$\rho_{WH}\ (\frac{lbm}{cu\ ft}) = \frac{141.5}{\gamma_o + 131.5} \times 62.4$$

Step 7: Calculate the density of oil at bottom hole conditions, ρ_{BH} $(\frac{lbm}{cu\ ft})$, using the following equation with: the dissolved GOR, Rs (scf/STBO), calculated in Step 4 above; the oil formation volume factor, Bo (bbl/STBO), calculated in Step 5 above; the oil density at the wellhead, ρ_{WH} $(\frac{lbm}{cu\ ft})$, calculated in Step 6 above; and the dissolved gas gravity, $\gamma_{gd} = 0.77$[18]:

$$\rho_{BH}\ (\frac{lbm}{cu\ ft}) = \frac{\rho_{WH} + 0.0136 \times Rs \times \gamma_{gd}}{Bo}$$

Step 8: Calculate the density of oil in the well, ρ_o $(\frac{lbm}{cu\ ft})$, using the following equation with the density of oil at the wellhead, ρ_{WH} $(\frac{lbm}{cu\ ft})$, calculated in Step 6 above; and the density of oil at bottom hole conditions, ρ_{BH} $(\frac{lbm}{cu\ ft})$, calculated in Step 7 above:

$$\rho_o\ (\frac{lbm}{cu\ ft}) = 0.5 \times (\rho_{WH} + \rho_{BH})$$

[18] Figure B-10 (Katz diagram) from Brill, J.P. and Mukherjee, H., "Multiphase Flow in Wells", Monograph Volume 17, SPE, 1999 was used to calculate the values of this variable in the model runs described in Section 2.4. It was found that dissolved gas gravity, γ_{gd} , did not have a significant impact on predicted flow line pressure. Therefore a value of 0.77 is recommended to be used for $\gamma_{gd.}$ This value is the average of the values used in the dynamic model runs (see Section 4).

NMED Exhibit 70

Step 9: Calculate the oil flow rate, $q_o\ (cu\ ft/sec)$, using the following equation with: the oil formation volume factor, *Bo* (bbl/STBO), calculated in Step 4 above; and the estimated oil production rate at the well head, *Qo* (STBO/day):

$$q_o\left(\frac{cu\ ft}{sec}\right) = \text{Qo}\ \left(\frac{\text{STBO}}{\text{day}}\right) \times \text{Bo}\ \left(\frac{\text{bbl}}{\text{STBO}}\right) \times 5.614(\frac{cu\ ft}{\text{bbl}}) \times \frac{1}{24 \times 60 \times 60}(\frac{day}{sec})$$

2.5.2 Determination of Gas Flow Rate

As oil-gas-water mixture flows upwards in a well to a lower pressure location, gas volume changes and some of the dissolved gas evolves out of solution in oil. This results in gas volumetric flow (and therefore pressure gradient) changing with well depth.

The gas volumetric flow at bottomhole conditions is calculated in a sequential fashion, first evaluating terms to estimate gas compressibility factor, z. The Standing and Katz correlation and z-factor chart[19] was used to estimate critical pressure and temperature at bottomhole conditions. Then, adjustments were made to the critical pressure and temperature according to the Carr/Kobayashi[20] method to account for potential impurities in the natural gas. Finally, the Brill and Beggs correlation for compressibility[21] was utilized to estimate the z-factor. This calculation procedure is described below in detail:

Step 10: Calculate the critical pressure, P_c (psia), and critical temperature, T_c (R), using the aforementioned Standing and Katz correlation and Carr/Kobayashi adjustment with specific

[19] Standing, M.B. and Katz, D.L., "Density of Natural Gases," Transactions of the AIME, SPE, December, 1942, 146.
https://www.onepetro.org/journal-paper/SPE-942140-G.

[20] To derive the equations, first adjustment factors for N2, CO2, and H2S were obtained from Figure 8 in Carr, N. L., Kobayashi, R., and Burrows, D.B., "Viscosity of Hydrocarbon Gases Under Pressure," JPT, SPE, October, 1954, 6 . Then these factors were applied to Standing and Katz correlations for Pc and Tc.
https://www.onepetro.org/journal-paper/SPE-297-G.

[21] Guo, B., Ghalambor, A., "Natural Gas Engineering Handbook," Gulf Publishing Company, 2005, ISBN 0976511339, Chapter 2 equations 2.28 to 2.33.

NMED Exhibit 70

gravity of gas at standard conditions (p=14.7 psia and T = 60 F), SG = 0.75; and where the mole fractions in the gas of nitrogen, carbon dioxide and hydrogen sulfide are: $X_{N_2} = 0.168225$, $X_{CO_2} = 0.013163$, and $X_{H_2S} = 0.013680$[22]. The equations below for critical temperature and critical pressure represent the combined Standing correlation and Carr/Kobayashi adjustments into one form.

$$P_c(psia) = 678 - 50 \cdot (SG - 0.5) - 206.7 \cdot X_{N_2} + 440 \cdot X_{CO_2} + 606.7 \cdot X_{H_2S}^{*}$$

$$T_c(R) = 326 + 315.7 \cdot (SG - 0.5) - 240 \cdot X_{N_2} - 83.3 \cdot X_{CO_2} + 133.3 \cdot X_{H_2S}^{*}$$

Step 11: Calculate reduced pressure, P_r, and reduced temperature, T_r, using the following equations with: the bottom hole pressure, P_{BH} (psia), as determined in Step 1 above; the bottom hole temperature, T_{BH} (F), as determined in Step 2 above in the following equations:

$$P_r = \frac{P_{BH}}{P_c}$$

$$T_r = \frac{(T_{BH} + 460)}{T_c}$$

Step 12: Calculate the gas compressibility factor, *Z*, using the following Brill and Beggs correlation with the reduced pressure, P_r, calculated in Step 10 above:

$$z = A + \frac{(1-A)}{e^B} + C \cdot p_r^{D*}$$

The values for A, B, C, D in the above equation, are calculated using the following equations with the reduced pressure, P_r, and reduced temperature, T_r, calculated in Step 10 above:

$$A = 1.39 \cdot (T_r - 0.92)^{0.5} - 0.36 \cdot T_r - 0.10$$

[22] The mole fractions are the averages for compositions in oil and gas wells and are based on information in Table 8 in the technical memo titled "Composition of Natural Gas for Use in the Oil and Natural Gas Sector Rulemaking,", July, 2011, available in the NSPS OOOO rule making docket https://www.regulations.gov/#!documentDetail;D=EPA-HQ-OAR-2010-0505-0084.

NMED Exhibit 70

$$B = (0.62 - 0.23 \cdot T_r) \cdot P_r + \left(\frac{0.066}{(T_r - 0.86)} - 0.037\right) \cdot P_r^2 + \frac{0.32}{10^{9 \cdot (T_r - 1)}} \cdot P_r^6$$

$$C = (0.132 - 0.32 \cdot \log(T_r))$$

$$D = 10^{0.3106 - 0.49 \cdot T_r + 0.1824 \cdot T_r^2}$$

Step 13: Calculate the gas formation volume factor, $B_g \left(\frac{cuft}{scf}\right)$, using the real gas law below with the bottom hole pressure, $P_{BH}\ (psia)$, as determined in Step 1 above; and the bottom hole temperature, $T_{BH}\ (F)$, as determined in Step 2 above:

$$B_g \left(\frac{cuft}{scf}\right) = 0.0283 \cdot \frac{Z \cdot (T_{BH} + 460)}{P_{BH}} *$$

Step 14: Calculate the gas flow rate, $q_g \left(\frac{cu\,ft}{sec}\right)$, using the following equation with: the value of gas formation volume factor, $B_g \left(\frac{cuft}{scf}\right)$, calculated in Step 12 above; the estimated gas production rate, Qg (scf/day); the estimated oil production rate, Qo (STBO/day); and the dissolved GOR, Rs (scf/STBO), as calculated in Step 4 above:

$$q_g \left(\frac{cf}{sec}\right) = (Q_g - R_s \cdot Q_o) \cdot B_g \cdot \frac{1}{24x60x60}$$

2.5.3 Determination of Water Flow Rate

Step 15: Generally, water is relatively incompressible and gas solubility in water is negligible. Therefore, $q_w\ (\frac{cf}{sec})$, the flow rate of water in the well, is calculated using the following equation with the water production rate Qw (bbl/day) at the well site:

$$q_w \left(\frac{cf}{sec}\right) = \text{Qw} \left(\frac{\text{STB}}{\text{day}}\right) \times 5.614 (\frac{\text{cf}}{\text{bbl}}) \times \frac{1}{24 \times 60 \times 60} (\frac{day}{sec})$$

NMED Exhibit 70

4. Comparison of the Low Pressure Oil Well Equation Results with those from the Hagedorn and Brown Model

As discussed previously, the Hagedorn and Brown flow correlation method generally predicts pressure drop for vertical wells better than the other models. The Hagedorn and Brown model was used for validating the results of the LPWE, equation (15). For validation purposes, model runs were completed using the experimental matrix shown in Table 1 above.

Over 7,560 model runs were performed using the coded Hagedorn and Brown model and simultaneously corresponding calculations were made with the LPWE (equation (15). In this version of the Hagedorn and Brown model, called the dynamic model, certain calculations (i.e., bubble point pressure corrections and dissolved gas gravity) were completed using established correlations. While completing experimental matrix runs with the dynamic model, it was observed that correction for above-the-bubble point pressure and changes in dissolved gas gravity did not have a significant impact on model results (see footnotes 15 and 18). Consequently, a simplified dynamic model was created without above-the-bubble point calculations and with a fixed value for dissolved gas gravity (footnote 18). Subsequently, the same 7,560 model runs as above were completed with the simplified dynamic model. Results for line pressure from Hagedorn and Brown model runs are compared with corresponding results from the LPWE (equation (15) in Figure 1 for the dynamic model case and in Figure 2 for the simplified dynamic model case.

NMED Exhibit 70

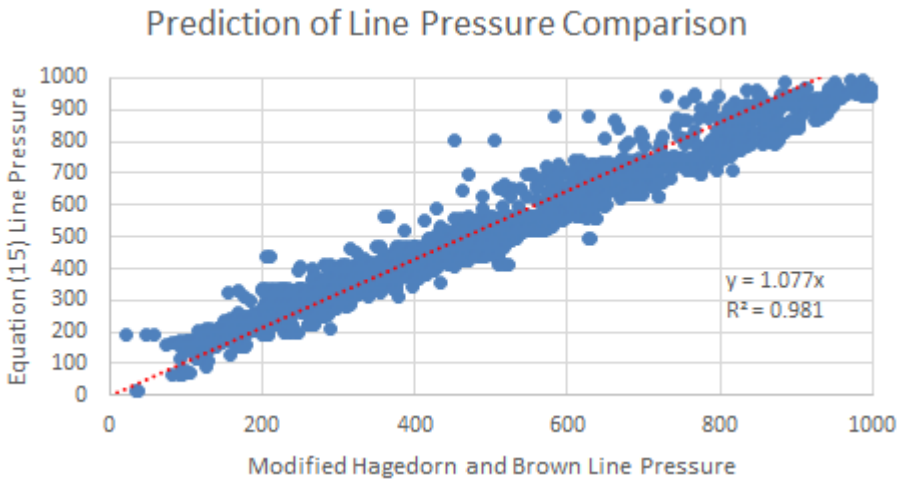

Figure 1: Comparison of Line Pressure Prediction for the Dynamic Model

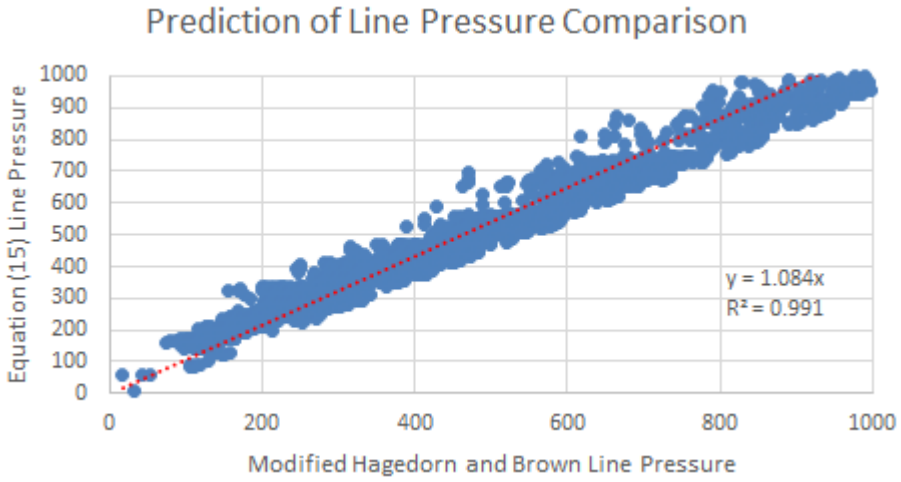

Figure 2: Comparison of Line Pressure Prediction for the Simplified Dynamic Model

Since the difference between Figure 1 and Figure 2 is negligible, the LPWE related calculation procedure described in Section 2.5 is appropriate. Finally, in addition to the comparison plots shown above, a multiple linear regression for line pressure predictions below 1000 psia was performed for data in Figure 2 and a standard error of 41 psia was observed[23]. These results indicate that the LPWE estimates pressure drops comparable to the Hagedorn and Brown model.

[23] The standard error in this context represents an over-prediction of line pressure by 41 psia on average for equation (15) when compared to the Hagedorn and Brown method.

5. Example Calculation

For the example calculation with the LPWE, input conditions (illustrative example) are defined as follows:

- Well depth, L = 7,900 feet
- Reservoir pressure, P_R = 2,700 psia
- Bottomhole temperature, T_{BH} = 180 °F
- Oil production rate, Qo = 465 STBOD
- Water production rate, Qw = 45 STBOD
- Gas production rate, Qg = 570,000 scf/day
- API gravity, γ_o = 25
- Available flow line pressure= 150 psia

Calculation of Oil Density and Flow Rate

Step 1. Calculate the bottomhole pressure using (Step 1, Section 2.5):

$$P_{BH}(psia) = \frac{1}{2}(2{,}700\ psia) = 1{,}350 psia$$

Step 2. Determine the bottomhole temperature (Step 2, Section 2.5):

From the information provided,

$$T_{BH}(F) = 180\ \text{F}$$

Step 3. Calculate gas gravity at from a separator pressure of 100 psig, γ_{gs} (Step 3, Section 2.5):

$$\gamma_{gs} = (0.75) \cdot \left(1.0 + 5.912\ x\ 10^{-5} \cdot 25 \cdot 60°F \cdot log\left(\frac{14.7\ psia}{114.7}\right)\right) = 0.691$$

Step 4. Calculate dissolved GOR, R_s (Step 4, Section 2.5):

NMED Exhibit 70

$$R_s\left(\frac{scf}{STBO}\right) = (0.0362)\cdot(0.691)\cdot(1{,}350\ psia)^{1.0937}\cdot exp\left[25.7240\cdot\left(\frac{25}{180°F+460}\right)\right]$$

$$= 181.14\left(\frac{scf}{STBO}\right)$$

Step 5. Calculate the volume formation factor for oil, B_o (Step 5, Section 2.5):

$$B_o\left(\frac{bbl}{STBO}\right) = 1.0 + (4.677 * 10^{-4}\cdot 181.14\left(\frac{scf}{STBO}\right) + (180°F - 60)\left(\frac{25}{0.691}\right)$$

$$\cdot\left(1.751 * 10^{-5} - 1.811\cdot 10^{-8}\cdot 181.14\left(\frac{scf}{STBO}\right)\right) = 1.147\left(\frac{bbl}{STBO}\right)$$

Step 6. Calculate the density of oil at the wellhead (Step 6, Section 2.5):

$$\rho_{WH} = \frac{141.5}{25+131.5}\cdot 62.4 = 56.42\left(\frac{lb_m}{cuft}\right)$$

Step 7. Calculate the density of oil at bottomhole (Step 7, Section 2.5):

$$\rho_{BH}\left(\frac{lb_m}{cuft}\right) = \frac{56.42 + 0.0136\cdot 181.14\left(\frac{scf}{STBO}\right)\cdot 0.77}{1.147\left(\frac{bbl}{STBO}\right)} = 50.86\left(\frac{lb_m}{cuft}\right)$$

Step 8. Calculate the average oil density, ρ_o (Step 8, Section 2.5):

$$\rho_o\left(\frac{lb_m}{cuft}\right) = \frac{1}{2}\left[56.42\left(\frac{lb_m}{cuft}\right) + 50.86\ \left(\frac{lb_m}{cuft}\right)\right] = 53.64\left(\frac{lb_m}{cuft}\right)$$

Step 9: Calculate the oil flow rate at bottomhole conditions (Step 9, Section 2.5):

$$q_o\left(\frac{cuft}{sec}\right) = 465\ \frac{STBO}{Day}\cdot 1.147\left(\frac{bbl}{STBO}\right)\cdot\left(\frac{5.614}{24*60*60}\right) = 0.0346\left(\frac{cuft}{sec}\right)$$

Calculation of Gas Flow Rate

Step 10. Calculate critical pressure and temperature (Step 10, Section 2.5):

NMED Exhibit 70

$$P_c = 678 - 50 \cdot (0.75 - 0.5) - 206.7 \cdot 0.168225 + 440 \cdot 0.013163 + 606.7 \cdot 0.01368$$

$$= 644.819\ psia$$

$$T_c = 326 + 315.7 \cdot (0.75 - 0.5) - 240 \cdot 0.168225 - 83.3 \cdot 0.013163 + 133.3 \cdot 0.01368$$

$$= 365.278\ °R$$

Step 11. Calculate reduced pressure and temperature (Step 11, Section 2.5):

$$P_r = \frac{1{,}350\ psia}{644.819\ psia} = 2.094$$

$$T_r = \frac{640\ °R}{365.278\ °R} = 1.752$$

Step 12. Calculate gas compressibility factor, z (Step 12, Section 2.5):

$$A = 1.39 \cdot (1.753 - 0.92)^{0.5} - 0.36 \cdot 1.753 - 0.101 = 0.536$$

$$B = (0.62 - 0.23 \cdot 1.752) \cdot 2.094 + \left(\frac{0.066}{(1.752 - 0.86)} - 0.037\right) \cdot (2.094)^2 + \frac{0.32}{10^{9 \cdot (1.752-1)}}$$

$$\cdot (2.094)^6 = 0.616$$

$$C = (0.132 - 0.32 \cdot \log(1.752)) = 0.054$$

$$D = 10^{0.3106 - 0.49 \cdot (1.752) + 0.1824 \cdot (1.752)^2} = 1.028$$

$$z = 0.537 + \frac{(1 - 0.537)}{e^{0.245}} + 0.054 \cdot (0.968)^{1.028} = 0.902$$

Step 13. Calculate the gas formation volume factor, B_g (Step 13, Section 2.5):

$$B_g \left(\frac{cuft}{scuft}\right) = 0.0283 \cdot \left(\frac{0.902 * 640\ °R}{1{,}350\ psia}\right) = 0.0121 \left(\frac{cuft}{scuft}\right)$$

Step 14. Calculate the volumetric flow rate of the gas (Step 14, Section 2.5):

$$q_g \left(\frac{cuft}{sec}\right) = \left(570{,}000 \left(\frac{scf}{day}\right) - 181.14 \left(\frac{scf}{STBO}\right) \cdot 465\ stbod\right) \cdot 0.0121 \left(\frac{cuft}{scuft}\right) \cdot \left(\frac{1}{24 \cdot 60 \cdot 60}\right)$$

$$= 0.0680 \left(\frac{cuft}{sec}\right)$$

Step 15. Express water flow rate in cu ft/sec (Step 13, Section 2.5):

NMED Exhibit 70

$$q_w\left(\frac{cuft}{sec}\right) = 45\ \frac{STBO}{Day} \cdot \left(\frac{5.614}{24 * 60 * 60}\right) = 0.0029\left(\frac{cuft}{sec}\right)$$

Finally, the line pressure can be evaluated using equation (15) to determine predicted flow line pressure.

$$P_L\ (psia) = 0.495 \cdot 2{,}700(psia)$$

$$- \frac{0.068\left(\frac{cuft}{s}\right)}{\left(0.068\left(\frac{cuft}{s}\right) + 0.0.0346\left(\frac{cuft}{s}\right) + 0.0029\left(\frac{cuft}{s}\right)\right)}\left[0.05 \cdot 2{,}700(psia)\right.$$

$$\left. + 0.038\left(\frac{psia}{ft}\right) \cdot 7{,}900(ft) - 67.578(psia)\right]$$

$$- 1.00\left[\frac{0.0346\left(\frac{cuft}{s}\right)}{\left(0.068\left(\frac{cuft}{s}\right) + 0.0346\left(\frac{cuft}{s}\right) + 0.0029\left(\frac{cuft}{s}\right)\right)} \cdot \frac{53.641\left(\frac{lb_m}{cuft}\right)}{144\left(\frac{psia}{\left(\frac{lb_m}{ft^2}\right)}\right)}\right.$$

$$\left. + \frac{0.0029\left(\frac{cuft}{s}\right)}{\left(0.068\left(\frac{cuft}{s}\right) + 0.0346\left(\frac{cuft}{s}\right) + 0.0029\left(\frac{cuft}{s}\right)\right)} \cdot 0.433\left(\frac{psia}{ft}\right)\right]$$

$$\cdot 7{,}900(ft) = 39.7(psia)$$

Since $P_L = 39.7\ psia < available\ flow\ line\ pressure = 150\ psia$, the well may not be able to perform an REC. On the other hand, if the sales line pressure is below 39.7 psia, then the operator may be able to perform an REC within operational constraints.

NMED Exhibit 70

6. Summary

This memo describes the development of the low pressure well equation, LPWE, appropriate for use at well sites to determine whether or not a well can implement an REC. This equation uses only those inputs for which estimates are understood to be available before well completion activity starts to calculate the flowback fluid pressure immediately upstream of the flow line. If the well does not have adequate pressure to push the produced natural gas into the flow line then the well can be deemed a low pressure well and may not be able to perform REC. The equation was tested against an established and widely used multiphase flow model using a range of conditions representative of wells in the U.S. The results from the equation were generally consistent with those from the established Hagedorn and Brown model.

NMED Exhibit 70

Appendix

Additional analysis was performed to characterize oil and gas wells with respect to the low pressure well equation. The analysis informs assumptions about the proportion of hydraulically fractured well completions that would be considered low pressure using the low pressure well equation.

This document analyzes roughly 37,800 oil and gas wells across the United States and applies the low pressure well equation to each of the wells to determine a prediction of flow line pressure. Based on various filters described below, the wells were characterized in a set of tables. Finally, in addition to evaluating flow line pressure using the draft low pressure well equation, data from the Green House Gas Reporting Program (GHGRP) was utilized to determine average separator pressure and API gravity according to basin.

For all subsequent tables, wells were classified as low pressure wells if the predicted flow line pressure was less than the average separator pressure for the associated basin as reported in the GHGRP Subpart W for 2014. If the flow line pressure was greater than the average separator pressure, the well was classified as a high pressure well. Although in some cases there will be a dehydrator or other equipment downstream of the separator, which will result in a pressure drop, the separator pressure is the closest metric available to the flowline pressure, and was therefore used in this analysis.

Table 1 shows the distribution of oil and gas wells (identified using a GOR threshold of 100,000 scf/bbl) and whether the wells would be considered high pressure (HP) or low pressure (LP) using the LPWE. Table 2 performs the same analysis but excludes wells with GOR < 300 scf/bbl. Table 3 provides the oil and gas well splits with additional detail on basin type. Tables 1 through 3 are generated based on 2014 annual oil and gas production values[24].

[24] Values obtained from the DI Desktop™ commercial well database for well completions in 2014.

NMED Exhibit 70

We assume that hydraulically fractured oil well completions occur in shale oil basins. While variations from this assumption are very likely, we believe this is a reasonable assumption for this analysis. **Based on this assumption and according to this analysis, about 40 percent (3,717 of 9,227 completions) for shale oil wells with GOR>300 scf/bbl would be considered low pressure using the low pressure well equation.**

Table 1: Oil and Gas Well Splits with Gas Well Cutoff of 100,000 scf/bbl including all GORs

Well Type	Total Count	HP Well Count	LP Well Count
Oil Well	35,793	14,583	21,210
Gas Well	2,015	1,918	97

Table 2: Oil and Gas Well Splits with Gas Well Cutoff of 100,000 scf/bbl excluding GORs <300

Well Type	Total Count	HP Well Count	LP Well Count
Oil Well	22,093	13,701	8,392
Gas Well	2,015	1,918	97

Table 3: Oil and Gas Well Splits by Basin Type for GORs > 300 with Gas Well Cutoff of 100,000 scf/bbl[25]

Basin Type	Total Count	HP Well Count	LP Well Count
Conventional	12,505	8,770	3,735
Oil	*11,288*	*7,616*	*3,672*
Gas	*1,217*	*1,154*	*63*
Shale Oil	9,227	5,510	3,717
Tight Gas	1,953	972	981
Shale Gas	417	361	56
Coal Bed Methane	5	5	0

[25] The categories of shale oil, tight gas, and shale gas are based on the DI Database basin type designation. With the 100,000 scf/bbl cutoff, some of these wells could be classified as oil or gas wells but were not reclassified and the basin type designation was used to classify these wells.

NMED Exhibit 71

1 EXECUTIVE SUMMARY

The Colorado Air Pollution Control Division's ("Division's") proposed revisions to the Air Quality Control Commission's ("Commission's") Regulation Numbers 3, 6, and 7, collectively expand the air emission control requirements on oil and gas facilities in Colorado. They were developed after the Division's extensive, year-long stakeholder process leading up to the Commission's rulemaking hearing, including input from diverse industry, environmental and governmental stakeholders. The proposal has received the support of several industry and environmental leaders, including Anadarko Petroleum, Noble Energy, Encana Oil and Gas, and the Environmental Defense Fund. The proposal affects not only the oil and gas industry and supporting businesses in Colorado, but the Regulation Number 3 revisions broadly affect all businesses in Colorado. Further, the proposal broadly benefits all persons in Colorado, especially those who live and work in the proximity of oil and gas operations, given the anticipated emissions reductions that will be achieved and the reasonable associated cost of implementation. The Division estimates that the proposed strategies will result in substantial reductions of hydrocarbon emissions from the oil and gas industry. More specifically, the Division estimates the proposed strategies will reduce volatile organic compound (VOC) emissions by 93,500 tons per year, and methane/ethane emissions by 64,000 tons per year. The Division conservatively estimates that the annual net costs to industry of the Division's proposal will be $42.4 million per year. This translates to approximately $453 per ton of VOC reduced, which is very reasonable when compared to other air pollution reduction strategies adopted by the Colorado Commission and the U.S. Environmental Protection Agency (EPA). In prehearing submittals to the Commission, the supporters of the proposal have concluded that the Division's costs estimates methodology and cost estimates are reasonable. Some opponents of the proposal have asserted that the costs may be much higher. The Commission will consider the Division's proposal and any alternate proposals at the rulemaking hearing commencing February 19, 2014.

2 INTRODUCTION

On December 13, 2013, interested parties, stakeholders, and state representatives filed eleven separate requests for both a Cost Benefit Analysis and a Regulatory Analysis ("Requests") with the Division, per C.R.S. §24-4-103(2.5), C.R.S. §24-4-103(4.5) and the Commission's Procedural Rules, 5 CCR 1001-1, §V.E.13. This document satisfies the requirements for a Regulatory Analysis, and is separate from the related Cost-Benefit Analysis. Similarly, this Regulatory Analysis is different from, but related to, the required Economic Impact Analysis, C.R.S. §25-7-110.5(4). The Requests were specific to proposed revisions to the Commission's Regulation Numbers 3, Parts A, B, and C ("Regulation 3"); Regulation 6, Part A ("Regulation 6"); and Regulation Number 7 ("Regulation 7").

NMED Exhibit 71

The Colorado Administrative Procedure Act ("APA")[1] serves as the legal authority for this rulemaking process, and sets forth requirements for both cost-benefit and regulatory analyses. Under the APA, any person may request an agency engaged in a rulemaking to prepare a regulatory analysis.[2] The regulatory analysis must include:

- A description of the classes of persons who will be affected by the proposed rule, including classes that will bear the costs of the proposed rule and classes that will benefit from the proposed rule;
- To the extent practicable, a description of the probable quantitative and qualitative impact of the proposed rule, economic or otherwise, upon affected classes of persons;
- The probable costs to the agency and to any other agency of the implementation and enforcement of the proposed rule and any anticipated effect on state revenues;
- A comparison of the probable costs and benefits of the proposed rule to the probable costs and benefits of inaction;
- A determination of whether there are less costly methods or less intrusive methods for achieving the purpose of the proposed rule; and
- A description of any alternative methods for achieving the purpose of the proposed rule that were seriously considered by the agency and the reasons why they were rejected in favor of the proposed rule.
- To the extent practicable, a quantification of the data used in the analysis; the analysis must take into account both short-term and long-term consequences.[3]

So long as the regulatory analysis is undertaken in good faith, it satisfies the APA.[4]

This Regulatory Analysis evaluates the Division's November 15, 2013 proposed revisions to Regulations 3, 6, and 7, as amended on January 30, 2014, using information gathered through the Division's Cost Benefit Analysis, and Economic Impact Analyses, and other documents associated with the administrative record for the February 19-23, 2014 Commission Hearing.

The Division's proposed revisions to Regulation 3, 6, and 7 are part of an overall effort to fully adopt federal Standards of Performance for Crude Oil and Natural Gas Production, Transmission, and Distribution found in 40 C.F.R. Part 60, Subpart OOOO ("NSPS OOOO"), by incorporating them into Regulation Number 6, Part A, and making the corresponding revisions to the Regulation Number 3 catch-all provisions to address barriers that prevented full adoption of NSPS OOOO. The proposal also revises Regulation Number 7 to address differences and overlaps between NSPS OOOO and Regulation Number 7 oil and gas control requirements, and to further reduce hydrocarbon emissions and leaks from oil and gas facilities. These revisions include:

1. Expanding Colorado's adoption of NSPS OOOO, such that it is adopted in full (Regulation 6);
2. Removing "catch-all" provisions (Regulation 3);

[1] *See* C.R.S. § 24-4-101 *et. seq*.
[2] *Id. at* § 24-4-103(4.5)
[3] *Id.*
[4] *Id. at* § 24-4-103(2.5)(d) & § 24-4-103(4.5)(d).

NMED Exhibit 71

3. Removing crude oil storage tank permitting exemptions (Regulation 3);
4. Expanding condensate tank control requirements state-wide, including establishing storage tank emission monitoring ("STEM") requirements (Regulation 7);
5. Expanding dehydration unit ("dehy") control requirements state-wide (Regulation 7);
6. Establishing leak detection and repair ("LDAR") requirements for components at well production facilities and natural gas compressor stations state-wide (Regulation 7);
7. Establishing well maintenance and liquids unloading requirements state-wide (Regulation 7); and
8. Expanding pneumatic controller requirements state-wide (Regulation 7).

In addition to these more prominent revisions, these proposals also correct minor administrative errors, and make typographical, grammatical, and formatting changes in Regulation 3, 6, and 7. This Regulatory Analysis focuses on the more significant revisions and does not address typographical, grammatical, and formatting changes.

This analysis represents information gathered from various stakeholders in an effort to generate the most complete and accurate assessment of the costs and benefits of the proposed strategies. Where data was not reasonably available, the Division utilized assumptions that are set forth in this analysis.

3 ANALYSIS

3.1 Regulation Number 6

3.1.1 Proposed Revisions

The proposed revisions to Regulation 6 fully incorporate by reference the federal NSPS OOOO into Regulation Number 6, Part A, including the provisions not incorporated during the Commission's partial adoption. In late 2012, the Commission partially adopted the Standards of Performance for Crude Oil and Natural Gas Production, Transmission, and Distribution found in 40 C.F.R. Part 60, Subpart OOOO ("NSPS OOOO"), such that Colorado currently administers NSPS OOOO, for all affected facilities under NSPS OOOO including centrifugal compressors, reciprocating compressors, pneumatic controllers, storage vessels, process unit equipment, and sweetening units, except for natural gas wells (well completion requirements) and equipment that emits less than current reporting and permitting thresholds. At that time, the Commission directed the Division to consider full adoption of NSPS OOOO, as well as other improvements to Colorado's oil and gas emission regulations.

It appears that all parties to the Commission rulemaking support the proposed revisions to Regulation 6.

NMED Exhibit 71

3.1.2 Class of Persons Affected

"A description of the classes of persons who will be affected by the proposed rule, including classes that will bear the costs of the proposed rule and classes that will benefit from the proposed rule."

There is limited impact associated with this proposal, in that NSPS OOOO is already in effect on a federal level and the Commission has already partially adopted NSPS OOOO for Colorado. The classes of persons affected by the proposed full adoption of NSPS OOOO include oil and gas companies operating in Colorado, and businesses that support the oil and gas industry in Colorado. Also, citizens statewide are impacted by the proposal. In all cases, it is simpler and less confusing to no longer have to deal with federal and state agencies administering the same requirements.

Full adoption of NSPS OOOO does not have an additional cost impact on any affected classes of persons because this rule is currently in effect and federally enforceable. Full adoption of NSPS OOOO does not provide additional health or economic benefits to classes of persons affected by the proposal because NSPS OOOO is currently in effect and federally enforceable. However, affected classes of persons will benefit from the proposed full adoption of NSPS OOOO due to having Colorado implement and enforce NSPS OOOO for all sources subject to NSPS OOOO in Colorado.

Further, full adoption of NSPS OOOO benefits the United States Environmental Protection Agency ("EPA") by relieving the agency of the primary responsibility to implement and enforce NSPS OOOO in Colorado.

The Colorado Oil and Gas Conservation Commission ("COGCC") does have well completion requirements that are different but similar to NSPS OOOO requirements. However this proposal to fully adopt NSPS OOOO does not change the fact that there are two different requirements that may apply to natural gas wells. The Division continues to work with the COGCC to address this issue and coordinate implementation of these rules.

3.1.3 Quantitative and Qualitative Impacts

"To the extent practicable, a description of the probable quantitative and qualitative impact of the proposed rule, economic or otherwise, upon affected classes of persons."

There are few if any additional quantitative impacts of the Regulation 6 proposal because these rules are already in effect on a federal level. The qualitative impact of the proposed rule upon affected classes of persons includes Colorado's implementation and enforcement of NSPS OOOO, using Division staff much more familiar with Colorado's oil and gas issues than EPA staff. Full adoption of NSPS OOOO does not provide any other additional costs or benefits beyond those affected by NSPS OOOO.

NMED Exhibit 71

3.1.4 Probable Agency Costs

"The probable costs to the agency and to any other agency of the implementation and enforcement of the proposed rule and any anticipated effect on state revenues."

The probable costs to the Division of implementing and enforcing the NSPS OOOO requirements for affected facilities below current Air Pollutant Emission Notice ("APEN") reporting and minor source permitting thresholds, as well as implementing and enforcing the NSPS OOOO well completion requirements, are unknown at this time. These sources are not currently subject to Colorado's reporting and permitting requirements.

The Division will largely implement the provisions of its proposal through its oil and gas inspection team. This team currently consists of nine full time inspectors and four term limited inspectors. In 2012, in response to the growth in the oil and gas industry in Colorado, the legislature approved increasing the size of the inspection team from six inspectors to nine. In 2013, the legislature appropriated additional funds to hire four term limited inspectors to conduct IR camera inspections at well production facilities in Colorado. The term for these positions runs through June of 2015, but could be extended by the legislature if warranted. The additional inspectors provided during the 2012 and 2013 legislative sessions has significantly expanded the capabilities of the oil and gas inspection team, which will further enable the Division to implement and enforce the proposed requirements if the Commission chooses to adopt the Division's proposal. The total projected annual cost to the Division for the oil and gas inspection team in fiscal year 2013-14 is $1,305,304, which includes salary costs, fringe benefits, operating costs (including vehicles, field equipment, and office equipment), travel training and indirect costs.

There is no anticipated effect on state revenues because the proposal does not assess any additional emissions reporting or permitting fees than those that already apply.

3.1.5 Comparison to Inaction

"A comparison of the probable costs and benefits of the proposed rule to the probable costs and benefits of inaction."

If the Commission does not fully adopt NSPS OOOO, EPA and the Division will continue to share the implementation and enforcement responsibilities for NSPS OOOO. However, regardless of partial or full adoption, NSPS OOOO remains effective and federally enforceable.

Importantly, the Division does not advocate full adoption of NSPS OOOO without removing the catch-all provisions in Regulation Number 3 due to the reporting and permitting impacts on both the regulated community and the Division.

NMED Exhibit 71

3.1.6 Less Costly Methods/Less Intrusive Methods

"A determination of whether there are less costly methods or less intrusive methods for achieving the purpose of the proposed rule."

There are no less costly or intrusive methods for achieving full adoption of NSPS OOOO. Retaining partial adoption of NSPS OOOO will not resolve the issue of shared implementation responsibilities between EPA and the Division.

3.1.7 Alternative Methods

"A description of any alternative methods for achieving the purpose of the proposed rule that were seriously considered by the agency and the reasons why they were rejected in favor of the proposed rule."

The Division did not consider any alternative methods for achieving full adoption of NSPS OOOO.

3.1.8 Quantification of Data

"To the extent practicable, a quantification of the data used in the analysis; the analysis must take into account both short-term and long-term consequences."

The short and long term consequences of the full adoption of NSPS OOOO are full implementation and enforcement by Colorado, instead of split implementation and enforcement between EPA and Colorado. The Division did not further quantify the short- or long-term consequences of the Regulation 6 proposal to fully adopt NSPS OOOO beyond what was already performed by EPA.

3.2 Regulation Number 3

3.2.1 Proposed Revisions

The Division is proposing revisions to Regulation 3's reporting and permitting requirements in order to improve the efficiency of Colorado's air quality reporting and permitting system.

The proposed revisions remove the requirement for sources subject to either a federal New Source Performance Standard ("NSPS") or federal National Emission Standards for Hazardous Air Pollutant ("NESHAP")/Maximum Available Control Technology ("MACT") adopted into Regulation Number 6, Part A or Number 8, Parts A, C, D, and E to file an APEN and obtain a minor source permit regardless of whether their emissions exceed the reporting or permitting thresholds ("catch-all provisions"). As a result, sources subject to a NSPS incorporated into Regulation Number 6, Part A or a NESHAP/MACT incorporated into Regulation Number 8,

NMED Exhibit 71

Parts A, C, D, or E are subject to APEN reporting and permitting **only** if their emissions exceed the applicable APEN and permitting thresholds.

In addition, the proposed revisions simplify the Appendix A non-criteria reportable pollutant de minimis determination to 250 pounds per year of any individual non-criteria reportable pollutant. The proposed revisions also remove the crude oil storage tank permitting exemptions.

Finally, the proposed revisions correct an inadvertent error to the minor source permitting exemption for crude oil and condensate truck loading equipment. This revision is administrative in nature, as the Division currently implements the provision as it was originally intended.

It appears that all parties to the Commission rulemaking support the proposed revisions to Regulation 3, and some parties have submitted alternative proposals requesting additional revisions (see Section 3.2.7 in this Regulatory Analysis).

3.2.2 Class of Persons Affected

"A description of the classes of persons who will be affected by the proposed rule, including classes that will bear the costs of the proposed rule and classes that will benefit from the proposed rule."

The classes of persons affected by the proposed revisions to Regulation 3 are broad. Revisions to the catch-all provisions affect any stationary source subject to an NSPS adopted into Regulation Number 6 or NESHAP/MACT adopted into Regulation Number 8 that has emissions below the APEN reporting and minor source permitting thresholds. To demonstrate the breadth of impact, some examples of business and industry that are affected include dry cleaners, aggregate mining operations, grain elevators, natural gas compressor stations, surface coating operations, and power plants. Those activities subject to an NSPS or NESHAP/MACT, whose emissions fall below current reporting and permitting thresholds, will no longer have to report emissions and obtain minor source permits.

The proposed revisions to the non-criteria reportable pollutant de minimis threshold will affect stationary sources with emissions of non-criteria reportable pollutants greater than 250 pounds per year. This revision also has a broad impact, as most sources emit some degree of hazardous air pollutants or other non-criteria reportable pollutants.

Further, the revisions to the crude oil storage tank permit exemptions affect owners and operators of crude oil storage tanks with capacities of 40,000 gallons or less. The correction to the minor source permitting exemption for crude oil and condensate truck loading equipment is administrative in nature and affects oil and natural gas operations.

3.2.3 Quantitative and Qualitative Impacts

"To the extent practicable, a description of the probable quantitative and qualitative impact of the proposed rule, economic or otherwise, upon affected classes of persons."

NMED Exhibit 71

Quantitative and qualitative consequences for each revision are discussed below. Short- and long-term consequences include the continued delay in adopting NSPS OOOO in full, as well as other federal NSPS and NESHAP/MACT that apply to small sources in Colorado. There are minimal if any costs to the regulated community due to these revisions, and in some cases, cost savings are anticipated. Further, the Division anticipates that there will be no significant environmental impact associated with the proposal.

3.2.3.1 Catch-all Provisions

There are no anticipated costs to either the regulated community or the government associated with these proposed revisions. Removal of the catchall provisions will actually reduce reporting, permitting, and associated cost burdens for the regulated community. By reducing reporting and permitting activities, the proposed revision will also reduce costs to the Division associated with these activities.

The Division conducted a permit tracking project from February, 2013 to September, 2013 to understand the impact of this proposal. All pre-construction permits issued were evaluated to determine if they would have required an APEN and permit under this proposal. The Division's permit tracking project indicated that 7% (167 of 2,355) permits processed required permits solely due to the catch-all provision, accounting for approximately 0.03% of the total uncontrolled actual criteria pollutant emissions and 0.003% of statewide uncontrolled actual criteria pollutant emissions. The total hourly permit processing fees for these permits was approximately $50,000.[5] This cost estimate does not include the time saved by the sources by no longer having to complete and submit an APEN or minor source permit application.

The environmental impacts of revising the catch-all provisions are minimal. Further, no emissions increases are anticipated from these sources that would no longer require a permit because these revisions will not exempt them from having to comply with the requirements of an applicable NSPS or NESHAP/MACT.

3.2.3.2 Non-criteria Reportable Pollutants

Some stationary sources affected by the proposed revisions to the non-criteria reportable pollutant thresholds may have new costs related to reporting emissions previously below reporting thresholds, including filing and annual fees. Revision of the threshold for non-criteria reportable pollutants could result in ether cost savings or additional costs to the regulated community depending on the source. Sources that are required to report hazardous air pollutants (a subset of non-criteria reportable pollutants) must pay an emission fee of $152.90 per ton. Currently Regulation Number 3 contains a complex reporting formula involving multiple and different thresholds, some of which are above and some of which are below the proposed 250 pound threshold. Accordingly, changing the threshold will reduce costs for some sources, while increasing costs for other sources. Based on an analysis of reported emissions, the proposed threshold change will reduce industry fees paid to the Division by $47,702 per year. Because the emissions from sources that are not currently reporting is unknown it is not possible to calculate

[5] Permit cost savings were calculated using an average of 4 hours spent per permit, as determined by the time spent on permits processed due to the catch-all provisions in the Division's permit tracking project, multiplied by the Division billing rate of $76.45 an hour.

NMED Exhibit 71

the additional costs to sources that will be required to report for the first time under the new proposed threshold. Based on the relative prevalence of different emissions, however, the Division believes that there will be a small net savings to the regulated community.

Additionally, beyond the actual emission fees, the current reporting system is very complex resulting in numerous hours being spent by both the regulated community and Division staff in determining whether reporting is required. Simplifying the reporting system will eliminate the costs associated with this analysis.

Some stationary sources affected by the proposed revisions would benefit because they would no longer be required to report their non-criteria reportable pollutant emissions, thus saving filing and possibly annual fees. The revised threshold of 250 pounds per year preserves at least 96% of the Division's current inventory of non-criteria reportable pollutants. Other sources may have new costs related to having to report emissions that were previously below reporting thresholds, including filing and annual fees. This impact is unknown at this time because these sources are not currently subject to Colorado's reporting and permitting requirements. While EPA does not require States to report hazardous air pollutant emissions, EPA utilizes this data to annually populate the National Emissions Inventory. Accordingly, Colorado will continue to provide a robust set of data while also serving an important regulatory streamlining purpose.

3.2.3.3 Crude Oil Storage Tanks

Owners and operators of crude oil storage tanks may have new costs related to obtaining permits for previously permit-exempt equipment. There are minimal direct costs projected for the affected businesses and industrial sector associated with the removal of the crude oil storage tank permitting exemption. Stationary sources with crude oil storage tanks whose uncontrolled actual emissions exceed the minor source or operating permit thresholds would be required to obtain a permit. In 2008, the Commission removed the reporting exemption for crude oil storage tanks to improve the inventory of uncontrolled actual emissions. While the Division believes there are many crude oil storage tanks in Colorado, the Division's APEN inventory only identifies 64 crude oil storage tanks with a design capacity of 40,000 gallons or less in Colorado. Removal of the crude oil storage tank minor source permitting exemption would require these tanks to obtain minor source permits at a cost of approximately $19,500.

3.2.3.4 Minor Source Permitting Correction

No practical impact is anticipated as a result of this revision, as the Division continues to implement the provision as was originally intended.

3.2.4 Probable Agency Costs

"The probable costs to the agency and to any other agency of the implementation and enforcement of the proposed rule and any anticipated effect on state revenues."

The Division does not anticipate any negative effect on state revenues. Any potential Full Time Equivalent ("FTE") personnel savings will be redirected to addressing the current permitting backlog. Any loss in permitting fees, will be offset by the processing of backlog permits. In

NMED Exhibit 71

addition, the crude oil storage tank permitting exemption revisions will slightly increase the submission of permitting fees. Similarly, the Division anticipates the reduction in filing and annual fees due to the approximately 4% reduction in current non-criteria reportable pollutant reporting to be offset by the increased reporting and associated fees by stationary sources with non-criteria reportable pollutant emissions greater than 250 pounds per year.

3.2.4.1 Catch-all Provisions

The revisions to the catch-all provisions will reduce the administrative burden on both the Division and the regulated community. The Division estimated through the permit tracking project that the staffing of approximately 0.6 FTE would be saved due to the revisions. However, revising the catch-all provisions does not change the applicability or enforcement of the NSPS or NESHAP/MACT.

3.2.4.2 Non-criteria Reportable Pollutants

The revisions to the non-criteria reportable pollutant threshold establish a simplified, standard reporting threshold of 250 pounds per year for all non-criteria reportable pollutants. This eliminates the complicated matrix system and streamlines the process for sources, and for the Division, both in explaining the process to sources and reviewing reported emissions. The work associated with any increased reporting will be absorbed by existing Division staff or potentially offset by the approximately 4% reduction in current non-criteria reportable pollutant reporting.

3.2.4.3 Crude Oil Storage Tanks

The Division's APEN inventory currently identifies 64 crude oil storage tanks with a design capacity of 40,000 gallons or less. The work associated with permitting and inspecting these, and potentially more, sources will be absorbed by existing Division staff.

3.2.4.4 Minor Source Permitting Correction

There are no additional agency costs incurred as a result of this revision, as the Division continues to implement the provision as was originally intended.

3.2.5 Comparison to Inaction

"A comparison of the probable costs and benefits of the proposed rule to the probable costs and benefits of inaction."

If the Commission does not adopt at least the proposed revisions to the catchall provisions, the Division would not recommend full adoption of NSPS OOOO. Further, absent adoption of the proposed revisions to the catchall provisions, the Division's permitting backlog will be negatively impacted. Finally, the public, regulated community, and other agencies will continue to experience the complexity and confusion of the APEN reporting thresholds and Appendix A de minimis levels applicability determinations. If the Commission does not adopt the proposed crude oil storage tank exemption revisions, a potentially significant source of emissions will continue to be exempt from permitting requirements. If the Commission does not make the minor source permitting correction, the provision will not align with the Commission's intent at the time of adoption nor the Division's current implementation of the provision. The purposes of the proposed revisions to Regulation 3 include allowing full adoption of NSPS OOOO,

NMED Exhibit 71

streamlining and clarifying reporting and permitting, and requiring permits for a potentially significant source of emissions.

3.2.5.1 Catch-all Provisions

The revisions to the catch-all provisions reduce reporting and permitting costs. If the Commission does not adopt the proposed revisions, the regulated community and the Division will retain those reporting and permitting costs. Further, if the Commission adopts NSPS OOOO, and other NSPS and NESHAP/MACT similarly affecting very small sources, in full without removing the catch-all provisions, the increase in APEN reporting and minor source permitting would overwhelm both the Division and the regulated community.

3.2.5.2 Non-criteria Reportable Pollutants

The revisions to the non-criteria reportable pollutant thresholds may reduce costs for some sources and increase costs for other sources. However, all sources will benefit from the increased clarity of the de minimis reporting determination. If the Commission does not adopt the proposed revisions, the public, regulated community, and the Division will continue to deal with a complex and confusing reporting determination.

3.2.5.3 Crude Oil Storage Tanks

The costs of the proposed revisions to the crude oil storage tank permit exemptions include the costs to the regulated community of obtaining permits and the costs to the Division of permitting and inspecting subject tanks. Removing the permitting exemptions also increases the consistency of Colorado's regulations with NSPS OOOO by requiring these sources to also be subject to Colorado's notification, recordkeeping, and control requirements. If the Commission does not adopt the proposed crude oil storage tank exemption revisions, there will not be costs associated with permitting but a potentially significant source of emissions will continue to be exempt from permitting requirements.

3.2.5.4 Minor Source Permitting Correction

No costs are anticipated with the proposed revisions, as the Division will continue to implement the provision as was originally intended.

3.2.6 Less Costly Methods/Less Intrusive Methods

"A determination of whether there are less costly methods or less intrusive methods for achieving the purpose of the proposed rule."

The Division does not believe that there are less costly or less intrusive methods to fully adopt NSPS OOOO than the Division's proposal.

3.2.6.1 Catchall Provisions

The Division believes that the revisions to the catch-all provisions are necessary to adopt NSPS OOOO, and other NSPS and NESHAP/MACT similarly affecting very small sources, due to the anticipated extensive number of APENs and minor source permit applications that would be required. Consider how the current catch-all provisions would apply if the Commission adopts MACT JJJJJJ, which applies to a multitude of small boilers. Under the catch-all provisions,

NMED Exhibit 71

every boiler providing electricity, steam, or hot water in a hotel, restaurant, laundry, medical center, research center, institution of higher education, or manufacturing, processing, mining, or refining facility would be required to file an APEN and obtain a minor source permit, even if the source had emissions less than the reporting and permitting thresholds. Other examples of rules similarly affecting very small sources include NSPS JJJJ, which applies to numerous stationary spark ignition internal combustion engines; MACT M, which applies to all perchloroethylene dry cleaning facilities; MACT HHHHHH, which applies to paint stripping and spray applications of greater than three motor vehicles or mobile equipment; and MACT SSSSSS, which applies to all glass manufacturing facilities. Under the current catch-all provisions, all of these facilities would require APENs and minor source permits, even if emissions are below the reporting and permitting thresholds.

If NSPS OOOO is adopted in full without the corresponding adoption of the proposed revisions to the catch-all provisions, the regulated community will be required to file APENs and obtain minor source permits for every NSPS OOOO affected facility. In turn, the Division's permitting backlog will likely grow and industry's ability to obtain timely permits will be negatively impacted. In comparison, if NSPS OOOO is adopted in full along with the proposed revisions to the catch-all provisions, only NSPS OOOO affected facilities with emissions greater than the reporting and minor source permitting thresholds will be required to report emissions and obtain minor source permits. This is currently how the partial adoption of NSPS OOOO is implemented. Thus, the Division does not believe there are less costly or intrusive methods than the proposed catch-all provisions revisions to reduce the administrative impact of full adoption of NSPS OOOO.

Similarly, the Division does not believe there are less costly or intrusive methods than the proposed catch-all provisions revisions to improve the efficiency of Colorado's reporting and permitting system for NSPS or NESHAP/MACT subject sources with emissions below the reporting and permitting thresholds, especially since these revisions will save costs for both the Division and the regulated community.

3.2.6.2 Appendix A

The purpose of the revisions to the non-criteria reportable pollutant thresholds is to simplify a complex and confusing reporting determination.

The Division cannot quantify the costs of unknown non-criteria reportable pollutants but considers the true cost savings of the proposed revision to the non-criteria reportable pollutant threshold the savings in time and effort of the public and regulated community in determining applicability under the revised Appendix A. While some sources non-criteria reportable pollutant reporting will increase, the Division does not believe there is a less costly or intrusive method to streamline the non-criteria reportable pollutant reporting determination while still maintaining a robust non-criteria reportable pollutant inventory.

3.2.6.3 Crude Oil Tank Permit Exemption

Requiring permits for crude oil storage tanks, a potentially significant source of emissions, cannot be accomplished in any less costly or less intrusive method. Further, some sources will

NMED Exhibit 71

want enforceable permit limits on their crude oil storage tanks so as to be exempt from NSPS OOOO storage vessel requirements.

3.2.6.4 Minor Source Permitting Correction

There are no less costly or no less intrusive methods, as the Division will continue to implement the provision as was originally intended.

3.2.7 Alternative Methods

"A description of any alternative methods for achieving the purpose of the proposed rule that were seriously considered by the agency and the reasons why they were rejected in favor of the proposed rule."

In addition to the Division's proposal, various parties to the rulemaking have submitted different alternative proposals for the Commission to consider. Some of these proposals request that the Commission adopt additional requirements, increasing APEN reporting and permitting thresholds, as well as change how emissions are reported to the Division.

The Division considered revising the APEN and minor source permitting thresholds to further simplify and clarify APEN reporting and minor source permitting. However, the Division decided not to pursue revising the APEN and minor source permitting thresholds at this time, in order to avoid diverting focus from the important emission reductions associated with the proposed revisions to Regulation Number 7, and provide additional time to work with EPA on the potential development of a sufficient noninterference demonstration for such revisions.

Further, the Division considered alternative thresholds for the proposed revisions to the non-criteria reportable threshold. The Division selected the 250 pound per year threshold due to concerns about higher thresholds and the retention of approximately 96% of the Division's current non-criteria reportable pollutant inventory under the proposed revision.

The Division did not consider any alternatives concerning the proposed revisions to the crude oil storage tank permitting exemptions or the minor source permitting correction.

3.2.8 Quantification of Data

"To the extent practicable, a quantification of the data used in the analysis; the analysis must take into account both short-term and long-term consequences."

The Division quantified the short-term consequences and used them to project long-term consequences of the Regulation 3 proposal.

3.2.8.1 Catch-all Provisions

The Division tracked all pre-construction permits, which includes permits processed for point sources at both major stationary sources and minor sources, between mid-February and September, 2013. The permit tracking project indicates that 7% (167 of 2,355) of those permits

NMED Exhibit 71

processed required permits because of the catch-all provision. In addition, the potentially eliminated emissions in comparison to statewide emissions are all much less than 1%, as illustrated in **Table 1** below.

Table 1: Emissions from Sources Potentially No Longer Requiring Permits due to the Catch-all Revisions (State-wide)

Pollutant	Uncontrolled actual emissions of potentially eliminated permits during tracking project (tpy, % of statewide emissions)	Uncontrolled actual emissions statewide[6] (tpy)
CO	45 (0.05%)	99,929
NOx	110 (0.07%)	165,192
Total PM[7]	32 (0.0004%)	7,385,720
SO2	0.2 (0.0002%)	115,715
VOC	24 (0.005%)	469,396
TOTAL	211.2 (0.003%)	8,235,952

Further, 4% (87 of 2,355) of the permits processed that required permits because of the catch-all provision are in the nonattainment area ("NAA"). The potentially eliminated emissions in comparison to NAA emissions are also much less than 1%, as illustrated in **Table 2** below.

Table 2: Emissions from Sources Potentially No Longer Requiring Permits due to the Catch-all Revisions (8-Hour Ozone NAA)

Pollutant	Uncontrolled actual emissions of potentially eliminated permits during tracking project in the NAA (tpy, % of NAA emissions)	NAA uncontrolled actual emissions[8] (tpy)
CO	19 (0.1%)	19,110
NOx	90 (0.24%)	37,831
Total PM[9]	15 (0.003%)	441,084
SO2	0.1 (0.0004%)	23,994
VOC	5 (0.004%)	140,463
TOTAL	129.1 (0.02%)	662,482

Importantly, these tables represent point source emissions, and do not include mobile source or area source emissions. Therefore, the percentage of emissions potentially eliminated from

[6] January-November, 2013, total emissions.
[7] Includes PM, PM10, and PM2.5.
[8] January-November, 2013, total emissions.
[9] Includes PM, PM10, and PM2.5.

NMED Exhibit 71

permitting due to the removal of the catch-all provisions is even less, if the total emissions inventory, including point, mobile and area source emissions, were used.

The revisions to the catch-all provisions reduce costs to affected classes of persons, due to fewer sources being required to file APENs and obtain minor source permits. The Division's permit tracking project shows that 7% (167 of 2,355) of the permits processed between mid-February and September, 2013, were permitted due to the catch-all provision. The total hourly permit processing fees for these permits was approximately $50,000[10]. This cost estimate does not include the time saved by the sources by no longer having to complete and submit an APEN or minor source permit application.

The environmental impacts of revising the catch-all provisions are minimal and no emissions increases are anticipated because these revisions will not exempt any source from complying with the requirements of an applicable NSPS or NESHAP/MACT. The Division's permit tracking project shows that the 7% of permits processed between mid-February 14, and September 30, 2013, accounted for approximately 0.03% of the total uncontrolled actual criteria pollutant emissions during the tracking project and 0.003% of statewide uncontrolled actual criteria pollutant emissions.[11]

3.2.8.2 Appendix A

There are potential increased costs to the affected classes of persons associated with the revisions to Appendix A, however the full extent is unknown. This revision may increase the reporting requirements for a currently unknown quantity of Bin B and Bin C non-criteria reportable pollutants because the revised threshold is lower than the current lowest de minimis reporting thresholds of 500 and 1,000 pounds per year, respectively. This revision may also decrease the reporting requirements for some Bin A pollutants because the revised threshold is higher than the current lowest de minimis reporting threshold of 50 pounds per year. Sources will save emission fees of $152.90 per ton of non-criteria reportable pollutant no longer required to report, not including the time saved by the sources due to not collecting the emissions data for and submitting APENs.

The environmental impacts of revising the catch-all provisions are minimal and no emissions increases are anticipated because these revisions will not exempt any source from complying with applicable requirements. In addition, the Division estimates that the proposed reporting thresholds of 250 pounds per year will retain at least 96% of the Division's current non-criteria reportable pollutant tracking for inventory purposes, which will continue to provide data to the EPA for the National Emissions Inventory, as well as to external custormers such as environmental groups and the public. In addition, because the proposed reporting threshold is less than the current thresholds for many of the current scenarios, the revision will result in additional emissions of Bin B and Bin C pollutants being reported.

---

[10] Permit cost savings were calculated using an average of 4 hours spent per permit, as determined by the time spent on permits processed due to the catch-all provisions in the Division's permit tracking project, multiplied by the Division billing rate of $76.45 an hour.

[11] See the Division's January 29, 2014, CAA § 110(l) Noninterference Demonstration for a more detailed discussion of noninterference with the NAAQS.

NMED Exhibit 71

3.2.8.3 Crude Oil Tank Permit Exemption

There are anticipated costs to the affected classes of persons associated with the removal of the crude oil storage tank permitting exemptions. The Division's APEN inventory currently only identifies 64 crude oil storage tanks with a design capacity of 40,000 gallons or less in Colorado. Removal of the crude oil storage tank minor source permitting exemption would requires these tanks to obtain minor source permits at a cost of approximately $19,500.

The emissions from crude oil storage tanks can be significant and permitting exemptions are meant to be limited to emission points with negligible impacts on air quality. The environmental impacts of revising the crude oil storage tank permitting exemptions may be significant, however, due to data limitations that impact is known.

The short term consequences of the proposed catch-all revisions include allowing the Commission to fully adopt NSPS OOOO. The long term consequences of the proposed catch-all revisions include potentially allowing the Commission to adopt other NSPS and NESHAP/MACT similarly affecting very small sources.

The short term consequences of the proposed revisions to the non-criteria reportable pollutant threshold include simplifying the non-criteria reportable pollutant reporting determinations for both the Division and the regulated community and reducing the Division's current non-criteria reportable pollutant inventory by approximately 4%. The long term consequences of the proposed revisions to the non-criteria reportable pollutant threshold are unknown.

The short-term consequences of the proposed crude oil storage tank permit exemptions include requiring existing crude oil storage tanks with a capacity of 40,000 gallons or less to obtain permits. The long term consequences of the proposed crude oil storage tank permit exemptions include requiring new crude oil storage tanks to obtain permits.

3.2.8.4 Minor Source Permitting Correction

Short- and long-term consequences of the proposed correction include aligning the provision with the Commission's original intent. No data was quantified relating to this revision.

3.3 Regulation Number 7

3.3.1 Discussion of Proposed Revisions

The Regulation 7 rulemaking package proposes revisions that expand existing oil and gas control requirements and establish additional monitoring, recordkeeping and reporting requirements. These proposed revisions include the following:

1) Enhancing the existing control program for petroleum storage tanks by:
    a. Lowering the control requirement threshold for condensate storage tanks from 20 to 6 tons per year of uncontrolled actual volatile organic compound (VOC) emissions;

NMED Exhibit 71

    b. Requiring controls for crude oil and produced water storage tanks with uncontrolled actual VOC emissions that are equal or greater than 6 tons per year; and
    c. Expanding NAA requirements for tank controls during the first 90 days of production to the rest of the state;
2) Establishing requirements to ensure that emissions from controlled storage tanks are captured and routed to the control device;
3) Enhancing the existing control program for dehys by:
    a. Increasing the control requirements from 90% to 95%;
    b. Increasing designed destruction efficiency requirements from 95% to 98%;
    c. Establising more stringent requirements for individual dehys located in proximity to a building unit or designated outside activity area;
4) Establishing LDAR requirements for compressor stations and well production facilities, including requirements to reduce emissions from compressor seals and open ended lines consistent with current federal requirements;
5) Expanding the existing 8-hour ozone NAA requirements for auto-igniters on flare devices to the rest of the state;
6) Expanding the existing NAA requirements for low bleed pneumatic devices to the rest of the state and where feasible requiring no-bleed pneumatic devices; and
7) Requiring that the gas stream at newly constructed well production facilities either be connected to a pipeline or routed to a control device from the date of first production.

If adopted, these proposed revisions will result in substantial reduction of hydrocarbon emissions including volatile organic compounds (VOCs) and methane.

Several industry and environmental parties fully support the Division's proposed revisions to Regulation 7. Conversely, some parties request that the Commission adopt additional requirements that go beyond the Division's proposal, while other alternatives request that the Commission limit aspects of the Division's proposed revisions. See Section 3.3.7 of this Regulatory Analysis for details on the parties' alternative proposals.

3.3.2 Class of Persons Affected

"A description of the classes of persons who will be affected by the proposed rule, including classes that will bear the costs of the proposed rule and classes that will benefit from the proposed rule."

The proposal affects the oil and gas industry and supporting businesses in Colorado. Further, the proposal broadly benefits all persons in Colorado, especially those who live and work in the proximity of oil and gas operations. Companies that will bear the costs of this rule change include the oil and gas companies operating, drilling, recompleting or otherwise stimulating wells in the NAA, as well as well production facilities, compressor stations and dehys. Revisions to Regulation 7 may require installation of controls to reduce hydrocarbon emissions from storage tanks, dehys, and separators on newly constructed, hydraulically fractured or recompleted wells. Typically flares are used as control equipment, but vapor recovery units ("VRUs") and other

NMED Exhibit 71

Division-approved pollution prevention devices may be used. Use of best management practices or controls may also be required for well maintenance and liquids unloading activities. Regulation 7 revisions may also require installation of auto-igniters on combustion devices and installation of low- or no-bleed pneumatic controllers. In addition, compressor stations and well production facilities may be required to monitor components for emissions and repair leaks. Owners and operators of well production facilities or compressor stations that include compressor seals and open-ended lines may have to comply with additional work practice standards.

The proposed Regulation 7 will benefit those companies that manufacture and/or distribute flare control devices, VRUs, auto-igniters or low- and no-bleed pneumatic controllers. Companies that manufacture hydrocarbon monitoring equipment, including infra-red ("IR") cameras, photo-ionization detectors, flame ionization detectors and other Division-approved monitoring methods, as well as those companies that provide or support monitoring services may also benefit from these proposed revisions.

Given that VOCs are precursors to ozone, the citizens in the NAA will benefit from the proposed rule through reduced ozone precursor emissions. State-wide, persons living or working in proximity to storage tanks, dehys, wells, well production facilities or compressor stations will benefit from reduced air emissions. See Section 3.3.3 of this Regulatory Analysis for a more comprehensive review of public health impacts.

Thus, all persons in the State benefit from the proposed revisions.

3.3.3 Quantitative and Qualitative Impacts

"To the extent practicable, a description of the probable quantitative and qualitative impact of the proposed rule, economic or otherwise, upon affected classes of persons."

The proposed changes to Regulation Number 7 are projected to result in substantial reductions of hydrocarbon emissions (including both VOCs and methane/ethane) from the oil and gas industry. The Division estimates approximately 93,500 tons per year VOC, or 257 tons per day, and approximately 64,000 tons per year methane/ethane will be reduced.

Qualitative impacts of this Regulation 7 proposal are closely related to Colorado's air quality and economy. During the past ten years, Colorado has been a leader in developing and implementing requirements to reduce air emissions from the oil and gas sector. As a result of these efforts, Colorado now has in place a series of cost-effective requirements that significantly reduce air emissions from Colorado oil and gas facilities. Despite this success, however, the tremendous growth of oil and gas production in Colorado continues to threaten the air quality gains that we have achieved. Since 2004 gas production in Colorado has increased by 50% while oil production has more than doubled. While this growth has provided important economic benefits for Colorado, increased air emissions can have a negative impact on Colorado's public health and environment.

NMED Exhibit 71

Specifically, VOC emissions contribute to the formation of ground level ozone. Ozone is photochemical oxidant and known respiratory irritant. Ground level ozone is a secondary pollutant produced through the reaction of VOCs, nitrogen oxides and sunlight. Elevated levels of ground level ozone have been linked to a variety of adverse health effects including decreased lung function, increased respiratory symptoms, serious indicators of respiratory morbidity including emergency visits and hospital admissions, as well as total non-accidental and cardio-respiratory mortality. According to EPA, ground-level ozone also damages vegetation and ecosystems. It leads to reduced agricultural crop and commercial forest yields, reduced growth and survivability of tree seedlings, and increased susceptibility to diseases, pests and other stresses such as harsh weather. In the United States alone, ground-level ozone is responsible for an estimated $500 million in reduced crop production each year. Ground-level ozone also damages the foliage of trees and other plants, affecting the landscape of cities, national parks and forests, and recreation areas.[12]

The U.S. EPA has set the current National Ambient Air Quality Standards ("NAAQS") for ground level ozone at 75 parts per billion (ppb) averaged over an 8-hour period. Based on a review of the then current health literature, the Clean Air Scientific Advisory Committee concluded in 2008 that the 75 ppb standard was not sufficiently protective of public health, and recommended that the standard be set at between 60 ppb and 70 ppb. EPA is in the process of considering whether to lower the ozone standard.

Currently, the Denver Metro/North Front Range area is out of attainment with federal health-based ground level ozone standards. This includes much of the Denver/Julesberg oil field. Other areas of the state have also experienced elevated ozone levels recently, with one monitor in Western Colorado showing concentrations above 75 ppb and a number of other monitors showing levels between 60 ppb and 75 ppb.

Addressing oil and gas emissions is a critical component of Colorado's efforts to lower ozone levels since this sector represents the largest source of VOC emissions in the state. Based on the most recent inventory (2011), 54% of the anthropogenic VOC emissions in the state come from the oil and gas sector, which is roughly triple the amount of emissions from the next largest source. Moreover, because of the ongoing growth in the oil and gas industry and the projected decline in VOC emissions from other sectors, the share of VOC emissions attributable to the oil and gas sector will likely increase over the foreseeable future. The proposed emission reduction strategies will further enhance existing public health and environment protections on both a local and regional scale.

In addition to VOC emissions, oil and gas operations are a large source of methane. Methane is a potent greenhouse gas, which contributes to global climate change. In addition to reducing VOCs that contribute to regional ozone pollution, the Division's proposed strategies will reduce methane, and thereby play a role in Colorado's overall efforts to reduce greenhouse gas emissions. Finally, the proposed strategies will reduce the exposure of people that live and work

[12] See EPA website, "Ozone – Good Up High Bad Nearby." http://www.epa.gov/oar/aqps/gooduphigh/bad.html. February 11, 2014.

NMED Exhibit 71

near oil and gas production sites to VOC emissions. Methane is also a valuable natural resource (natural gas), and reducing leaks will benefit Colorado's environment and economy.

The Division assesses the direct and indirect costs to the regulated community for each of the proposed strategies in Regulation Number 7 in Section 3.3.8 of this Regulatory Analysis. Equipment costs, labor costs, maintenance costs, supervision costs, travel costs, and costs associated with recordkeeping and reporting are all evaluated. The Division estimates that the total annual costs to the regulated community as a result of the proposed strategies will be approximately $59.2 million. Further, the proposed strategies are expected to result in the capture of additional product worth approximately $16.8 million, for a total net cost of $42.4 per year. In addition to these direct costs, implementation of the proposed strategies could result in the shut-in of certain marginally producing wells, resulting in indirect costs in the form of lost revenues to oil and gas companies, loss of jobs associated with these facilities, lost royalty payments, and lost severance taxes. Based on available information the Division cannot reasonably calculate the amount of additional oil and gas that would be shut-in due to the proposed rules, but believes that the amount is likely to be very small due to the low costs attributable to small, marginally producing facilities.[13] An analysis by an economist hired by certain industry parties has suggested that these indirect costs could be quite large.[14] This information will be considered by the Commission as part of the rulemaking hearing.

The Division recognizes that the oil and gas industry plays an important role in Colorado's economy in the evaluation of qualitative impacts of the Regulation 7 proposal. The industry is a significant employer of highly skilled and well-paid employees. The industry generates large revenues and pays significant taxes in the state. It produces valuable domestic resources that help keep prices low while adding to national stability and security. At the same time, emissions from the oil and gas industry represent a significant portion of the total VOC emissions both in the NAA and throughout the rest of the state. The Division's proposal is intended to achieve significant reductions in air emissions without imposing unreasonable costs that could stifle economic activity.

As discussed above, the Division's proposal is projected to result in a net annual cost to the industry of approximately $42.4 million. As with any increase in costs, the costs associated with the Division's proposal could have some adverse impact on economic activity associated with the oil and gas industry in Colorado. However, over the past decade Colorado's oil and gas industry has experienced unprecedented growth, even as Colorado has enacted regulatory measures to ensure that development continues in a protective and responsible manner. Moreover, given the relative size of the costs of the current proposal to the overall size of the industry, the total impact of these costs will likely be minimal. In 2012, for example, oil and gas producers in Colorado sold 48,450,717 barrels of oil and 1,661,073,176 MCF of natural gas.

Based on the current price of oil, $96 per barrel, and assuming a price for natural gas of

[13] See discussion in Section 3.3.8 of this Regulatory Analysis.
[14] See Attached Exhibit A.

NMED Exhibit 71

$3.5/MCF[15], annual revenue from the sale of oil and gas in Colorado based on 2012 production levels is approximately $10.5 billion. Accordingly, the net cost of the Division's proposal is approximately 0.4% of the annual revenues. Given this small percentage, the Division's proposal is unlikely to have any appreciable impact on the economic competitiveness of the industry as a whole. This conclusion is bolstered by the fact that several of the largest oil and gas companies in the state (Anadarko Petroleum Corp., Noble Energy, Inc., Encana Oil and Gas USA, and DCP Midstream) fully support the Division's proposed revisions. Collectively, the Division estimates that these companies will bear approximately 75% of the total annual cost of the proposed rules.

While it is unlikely that the costs associated with the proposed revisions will have any meaningfully adverse impacts on the competitiveness of the industry as a whole in Colorado, the costs could incrementally add to the current costs associated with operating marginally producing wells. This could potentially lead to some wells being shut in and the resultant economic consequences of these shut-ins including lost production revenue, lost royalties, lost severance taxes and potentially lost jobs. To mitigate against this possibility, the Division's has crafted a tiered proposal that triggers requirements based on emission thresholds that are directly tied to production. Based on this, the truly small facilities are subject to less requirements and less costs; for example, only a one-time instrument-based leak inspection, which the Division estimates will cost approximately $712.

Finally, it does not appear that the costs associated with the Division's proposal will have any meaningful negative impact on the general public or small businesses that purchase natural gas and other petroleum products. Oil and natural gas are sold on international and national markets, making it extremely unlikely that any increase in production costs in Colorado will be reflected in prices for Colorado consumers.

3.3.4 Probable Agency Costs

"The probable costs to the agency and to any other agency of the implementation and enforcement of the proposed rule and any anticipated effect on state revenues."

The Division will largely implement the provisions of its proposal through its oil and gas inspection team. This team currently consists of nine full time inspectors and four term limited inspectors. In 2012, in response to the growth in the oil and gas industry in Colorado, the legislature approved increasing the size of the inspection team from six inspectors to nine. In 2013, the legislature appropriated additional funds to hire four term limited inspectors to conduct IR camera inspections at well production facilities in Colorado. The term for these positions runs through June of 2015, but could be extended by the legislature if warranted. The additional inspectors provided during the 2012 and 2013 legislative sessions has significantly expanded the capabilities of the oil and gas inspection team, which will further enable the Division to implement and enforce the proposed requirements if the Commission chooses to adopt the Division's proposal. The total projected annual cost to the Division for the oil and gas inspection

[15] The Division assumed a price per MCF of $3.50 throughout its analysis; however, natural gas prices are currently around $5 per MCF, suggesting that the Division has underestimated the value of gas saved by the proposal.

NMED Exhibit 71

team in fiscal year 2013-14 is $1,305,304, which includes salary costs, fringe benefits, operating costs (including vehicles, field equipment, and office equipment), travel training and indirect costs.

The Division does not anticipate state revenues to be affected because the proposal does not assess any additional emissions reporting or permitting fees beyond those that already apply. However, state revenues could potentially be affected by implementation of the proposed strategies, in that they could potentially result in the shut-in of a few marginally producing wells, resulting in indirect costs in the form of lost revenues to oil and gas companies, loss of jobs associated with these facilities, lost royalty payments, and lost severance taxes. Based on available information the Division cannot reasonably calculate the amount of oil and gas that could be shut-in due to the proposed rules, but believes that the amount is likely to be very small due to the low costs attributable to small, marginally producing facilities.

3.3.5 Comparison to Inaction

"A comparison of the probable costs and benefits of the proposed rule to the probable costs and benefits of inaction."

The Division estimates the proposed strategies will reduce volatile organic compound (VOC) emissions by 93,500 tons per year, and methane/ethane emissions by 64,000 tons per year. The Division conservatively estimates that the annual net costs to industry of the Division's proposal will be $42.4 million per year. This translates to approximately $453 per ton of VOC reduced. Costs and benefits of the proposed Regulation 7 revisions are detailed in Section 3.3.8.

Conversely, inaction would mean that the above emissions reductions are not realized, that the associated captured methane (natural gas), a valuable natural resource, is lost to the ambient air and that the estimated cost savings in captured product that can be sold at a profit is not realized. Further, emissions from this sector are projected to grow substantially, especially in shale gas/oil development.[16]

The forecast growth in shale gas/oil development will result in increased emissions of VOC and other hydrocarbons including greenhouse gases, unless additional controls are implemented. This could result in increases in ozone formation and the development of additional State Implementation Plan requirements to meet current and future NAAQS requirements. According to EPA, attaining the current ozone standard throughout the nation will result in between $6.9 billion and $18 billion in annual health benefits. For lower standards the health benefits are even greater. For example, EPA projects that achieve a 70 ppb standard will result in between $13 billion and $37 billion in annual health benefits, and for a 65 ppb standard the benefits will increase to between $22 billion and $61 billion per year. EPA does not report these health benefits by state, but since the population of the Denver Metropolitan Area/North Front Range NAA accounts for approximately 2.5% of the total national population living in areas that are in

[16] U. S. Energy Information Administration. "Annual Energy Outlook 2013". April 15-May 2, 2013.

NMED Exhibit 71

violation of the current NAAQS, the health benefits attributable to Colorado are likely to be substantial.

The proposed rules will also produce substantial benefits associated with reducing greenhouse gases. As part of this rulemaking the Environmental Defense Fund has engaged an expert to analyze the benefits of the rulemaking based on the social cost of carbon. Based on this analysis, EDF projects that the total annual benefit from the projected methane reductions is between $104 million and $318 million in 2016 and between $132 million and $404 million in 2025.[17]

In addition to the benefits associated with reductions of VOCs and methane, the proposed rules will produce additional economic benefits in the form increased product capture and the creation of new jobs associated with the implementation of the new requirements.

3.3.6 Less Costly Methods/Less Intrusive Methods

"A determination of whether there are less costly methods or less intrusive methods for achieving the purpose of the proposed rule."

In 2004, 2006 and again in 2008, the Commission established oil and gas industry specific emissions control requirements in an effort to reduce VOC emissions in the 8-hour ozone NAA. The tremendous growth of oil and gas production in Colorado and the associated emissions continue to threaten the air quality gains that have been achieved. Since 2004 gas production in Colorado has increased by 50% while oil production has more than doubled. Since then, the oil and gas industry has grown significantly (more than predicted), and changes in drilling technologies and other advancements have further supported growth in this industry. The oil and gas industry continues to be the largest VOC emitter in Colorado (illustrated in Figure 1, below).

Several industry alternative proposals identify less costly and/or less intrusive methods to reduce emissions (see Section 3.3.7 of this Regulatory Analysis). The Division made several clarifications based on these alternatives, but did not substantially revise the Division's Regulation 7 proposal. The Division believes the Regulation 7 proposal secures more emissions reductions than those alternatives, and those additional emission reductions are cost effective. Moreover, several parties have proposed more costly and/or more intrusive methods to reduce emissions. The Division believes that its proposal strikes a proper balance and achieves substantial emissions reductions in a cost effective manner.

[17] See Attached Exhibit B.

NMED Exhibit 71

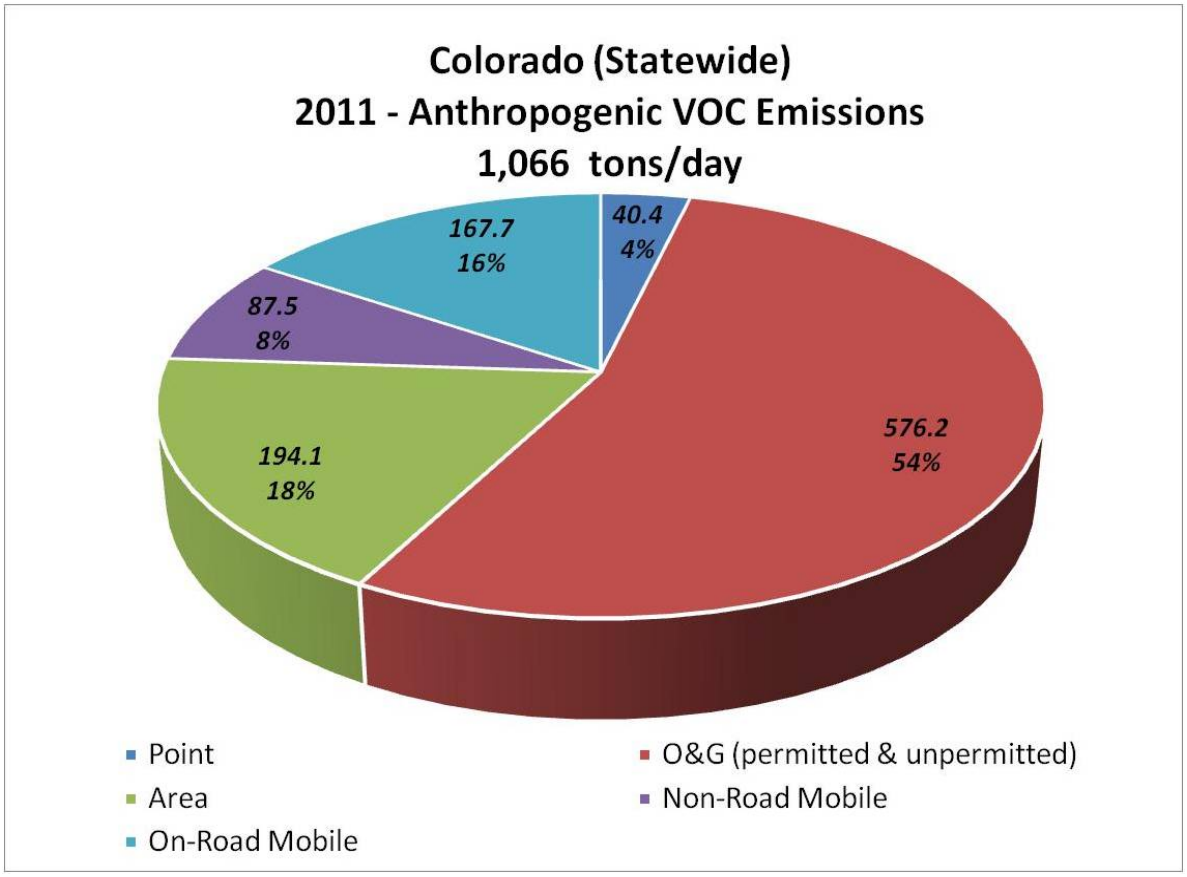

Figure 1 - Colorado Statewide Anthropogenic VOC Emissions (2011)

3.3.7 Alternative Methods

"A description of any alternative methods for achieving the purpose of the proposed rule that were seriously considered by the agency and the reasons why they were rejected in favor of the proposed rule."

In addition to the Division's proposal, various parties to the rulemaking have submitted 6 different alternative proposals for the Commission to consider. Some of these proposals request that the Commission adopt additional requirements that go beyond the Division's proposal, while other alternatives request that the Commission limit aspects of the Division's proposed revisions. In some cases, the parties submitting the proposals included analyses estimating the costs and benefits associated with their proposals. Copies of each of these proposals along with any economic impact analysis that the parties submitted identifying the projected costs and benefits of their particular proposals are attached to this Regulatory Analysis as exhibits. Upon evaluation of these proposals, and other parties' comments, the Division made several clarifications to but did not substantially revise the Division's Regulation 7 proposal. The Division believes the Regulation 7 proposal strikes an appropriate balance between the various alternatives.

NMED Exhibit 71

The section below identifies each of the submitted proposals, discusses how the proposals differ from the Division's proposal, and addresses the projected costs and benefits of each proposal.[18]

3.3.7.1 Joint Industry Work Group

A collection of oil and gas companies and industry trade groups have submitted an alternative proposal seeking to limit the requirements set forth in the Division's proposal.[19] Specifically, the Joint Industry Work Group request that the Commission limit the Division's proposal in the following respects: 1) restrict all proposed requirements to the Denver Metropolitan Area/North Front Range 8-hour ozone NAA; 2) reduce the required frequency proposed for leak inspection and repair; 3) eliminate the proposed requirements for dehydrators; 4) limit proposed requirements for compressor seals and open-ended lines to compressor stations; and 5) eliminate proposed requirements related to well maintenance and liquids unloading. In addition to these proposed limitations, the Joint Industry Work Group have proposed a number of additional changes, which could have some minimal additional impacts on the costs and benefits of the proposal.

Since the Joint Industry Group did not submit an economic analysis detailing the projected costs and benefits of their alternative proposal,[20] the Division has conducted an analysis of the Joint Industry Work Group alternative proposal utilizing the same methodologies and assumptions detailed in Section 3.3.8 of this Regulatory Analysis. Based on this analysis, the Division estimates that the Joint Industry Work Group alternative proposal would have a net cost[21] to the regulated community of approximately $32.2 million, and would reduce emissions of VOCs by 56,525 tons per year and methane/ethane by 33,058 tons per year. The decrease in net costs should have some positive impact on the indirect costs associated with potential well shut-ins, but the Division is unable to reasonably calculate this impact. The decrease in costs relative to the Division's proposal includes a decrease in the number of facility inspections, which would result in fewer new inspector jobs attributable to the proposal. Finally, because the Joint Industry Work Group proposal would result in less VOC and methane emission reductions, the economic benefits associated with these reductions discussed in Section 3.3.8 of this Regulatory Analysis would be reduced.

---

[18] In instances where a party submitted an analysis of the costs and benefits associated with their proposal such analysis is attached. Where parties submitted proposal without an analysis of their own proposal the Division has endeavored to analyze the costs and benefits of these proposals using the same methodologies used to analyze the costs and benefits of the Division's proposal.

[19] A copy of this alternative proposal is attached to this Regulatory Analysis as Exhibit C.

[20] The group did submit an analysis of the Division's proposal showing substantially higher costs than reflected in the Division's analysis. A copy of this analysis is attached hereto as Exhibit A. It should be noted that while the Joint Industry Work Group predicts much higher costs from the Division's proposals, Anadarko Petroleum Corporation, Noble Energy, Inc. and Encana Oil and Gas USA have submitted information during the rulemaking supporting the reasonableness of the Division's cost and benefit calculations. Submissions from these companies can be found at the following link: ftp://ft.dphe.state.co.us/apc/aqcc/REBUTTAL%20STATEMENTS,%20EXHIBITS%20%26%20ALT%20PROPOSAL%20REVISIONS/

[21] Net cost reflects the cost of implementing the proposed strategy less the value of the additional product captured as a result of the proposed strategies.

NMED Exhibit 71

3.3.7.2 WPX Energy

WPX is the largest natural gas producer in the state. In the current rulemaking WPX has offered an alternative proposal that would decrease the total number of leak inspections by allowing well production facilities with low leak rates during two consecutive inspections to reduce inspection frequency from monthly to quarterly, or from quarterly to annually depending on the size of the facility.[22] While it is difficult to predict in advance how many facilities would be able to take advantage of this reduced inspection rate, for the purposes of this Regulatory Analysis the Division assumes that one half of the facilities would be able to utilize the reduced frequency. Based on this assumption, adoption of WPX's alternative proposal would reduce the total net annual cost of the proposed revisions from approximately $42.4 million to approximately $36.8 million. This change would also decrease the amount of emission reductions from the Division's proposal by 1,845 tons per year of VOC and 2,757 tons per year of methane/ethane.

The decrease in net costs should have some positive impact on the indirect costs associated with potential well shut-ins, but the Division is unable to reasonably calculate this impact. Given the relatively small difference in net costs between the two proposals, any positive impact should be fairly small. The decrease in costs relative to the Division's proposal includes a decrease in the number of facility inspections, which would result in fewer new inspector jobs attributable to the proposal. Based on the number of inspection hours for each proposal, the number of new inspector jobs would decrease. Finally, because the WPX proposal would result in less VOC and methane emission reductions, the economic benefits associated with these reductions discussed in Section 3.3.8 of this Regulatory Analysis would be reduced.

3.3.7.3 Conservation Groups

As part of the rulemaking a number of conservation groups have submitted an alternative proposal requiring additional leak detection inspections for well production facilities and compressor stations relative to the Division's proposal. In addition, the Conservation Groups' alternative proposal increases the number of pneumatic devices that would need to be retrofitted. A copy of the Conservation Groups' alternative proposal is attached as Exhibit D. Additionally, their analysis of the costs and benefits associated with their alternative proposal is attached as Exhibit E.

3.3.7.4 Local Community Organizations

A group of local community organizations have submitted an alternative proposal aimed at increasing the stringency of the Division's proposal for facilities that are located within 1,320 feet of a building unit or designated outdoor activity area. Specifically, for such facilities the Local Community Organizations' alternative proposal would decrease the threshold for controls from petroleum storage tanks from 6 tons per year (as proposed by the Division) to two tons per year. Additionally, facilities located within 1,320 feet of these designated areas would be subject to a more stringent leak inspection schedule. Copies of the Local Community Organizations'

[22] In addition to this change, WPX has proposed a limited number of additional changes and clarifications that do not impact the cost and benefit calculations conducted for the Division's proposal. A copy of WPX's alternative proposal is attached as Exhibit F.

NMED Exhibit 71

alternative proposal and their assessment of costs and emission reduction benefits are attached as Exhibits G and H.

3.3.7.5 Local Government Coalition

The Local Government Coalition consists of a number of county and city governments including Adams County, Boulder County, La Plata County, Pitkin County and San Miguel County, Fort Collins, the City of Boulder, and the City and County of Denver. In their alternative proposal, the Local Government Coalition seeks to increase the number of leak detection inspections for compressor stations and well production facilities relative to the Division's proposal. The Local Government Coalition also seeks to require that well production facilities be tied in to a gas gathering line within 90 days after the date of first production, unless the Division approves an extension of this deadline. Copies of the Local Government Coalition's alternative proposal and documents assessing the costs and benefits of that proposal are attached hereto as Exhibits I through M.

3.3.7.6 Worldwide Liquid Solutions, LLC

Worldwide Liquid Solutions (WLS) is a manufacturer of emission reduction technology designed to control VOC emissions from petroleum storage tanks. According to WLS, their emission reduction technology cannot control methane and ethane and therefore cannot meet the control standards for tanks reflected in the Division proposal. To address this, WLS has submitted an alternative proposal that would only require reductions of VOCs from tanks and not methane/ethane. As an alternative to their alternative, WLS has proposed rejecting all of the proposed changes to Regulation No. 7 set forth in the Division's proposal. Copies of WLS' alternative proposal and their assessment of costs and emission reduction benefits are attached as Exhibits N and O.

3.3.8 Quantification of Data

"To the extent practicable, a quantification of the data used in the analysis; the analysis must take into account both short-term and long-term consequences."

As set forth below, the Division has assessed the direct and indirect costs to the regulated community for each of the proposed strategies in Regulation Number 7. The Division estimates revisions to Regulation 7 will reduce VOC emissions by 93,500 tons per year, and methane/ethane emissions by 64,000 tons per year. The Division conservatively estimates that the annual net costs to industry of the Division's proposal will be $42.4 million per year. This translates to approximately $453 per ton of VOC reduced, which is very reasonable when compared to other air pollution reduction strategies adopted by the Colorado Commission and the EPA. The Division estimates that the total annual costs to the regulated community as a result of the proposed strategies will be approximately $59.2 million. Further, the proposed strategies are expected to result in the capture of additional product worth approximately $16.8 million, for a total net cost of $42.4 million per year. In addition to these direct costs, implementation of the proposed strategies could potentially result in the shut-in of certain marginally producing wells, resulting in indirect

NMED Exhibit 71

costs in the form of lost revenues to oil and gas companies, loss of jobs associated with these facilities, lost royalty payments, and lost severance taxes. Based on available information the Division cannot reasonably calculate the amount of oil and gas that could be shut-in due to the proposed rules, but believes that the amount is likely to be very small due to the low costs attributable to small, marginally producing facilities. To mitigate against this possibility, the Division's has crafted a tiered proposal that triggers requirements based on emission thresholds that are directly tied to production. Based on this, the truly small facilities are subject to less requirements and less costs; for example, only a one-time instrument-based leak inspection, which the Division estimates will cost approximately $712. An analysis by an economist hired by certain industry parties has suggested that these indirect costs could be quite large.[23] This information will be considered by the Commission as part of the rulemaking hearing.

The detailed discussions below largely focus on short-term consequences of the proposal. Long term consequences potentially include having to establish greater and potentially more extreme control measures in the future to address the current mass of emissions and anticipated growth in emissions. The oil and gas industry is expected to continue to grow significantly, especially in shale gas/oil development.[24]

This continued growth in shale gas/oil development will result in increased emissions of VOC and other hydrocarbons including methane and ethane, unless additional controls are implemented. This could result in increases in ozone formation and additional State Implementation Plan requirements to meet current and future NAAQS requirements. According to EPA, attaining the current ozone standard throughout the nation will result in between $6.9 billion and $18 billion in annual health benefits. For lower standards the health benefits are even greater. For example, EPA projects that achieving a 70 ppb standard will result in between $13 billion and $37 billion in annual health benefits, and for a 65 ppb standard the benefits will increase to between $22 billion and $61 billion per year. EPA does not report these health benefits by state, but since the population of the Denver Metropolitan Area/North Front Range NAA accounts for approximately 2.5% of the total national population living in areas that are in violation of the current NAAQS, the health benefits attributable to Colorado are likely to be substantial.

3.3.8.1 Control Requirements for Petroleum Storage Tanks

Commencing in 2004 the Commission has adopted a series of requirements aimed at reducing emissions from petroleum storage tanks at well production facilities, compressor stations and gas processing plants. Currently, condensate tanks with uncontrolled actual emissions of 20 tons per year or greater of VOC must be equipped with a control device that has a control efficiency of at least 95%. Additionally, with certain exceptions, operators in the NAA must achieve a 90% system-wide reduction of VOC emissions from condensate tanks during the period from May 1 through September 30, and 70% during the period from October 1 through April 30. These current requirements only apply to tanks that store condensate, which is defined in the Commission's Common Provisions regulation as "hydrocarbon liquids . . . with an API gravity

[23] See Attached Exhibit A.
[24] U. S. Energy Information Administration. "Annual Energy Outlook 2013". April 15-May 2, 2013.

NMED Exhibit 71

of 40 degrees or greater." While most of the petroleum liquid produced in Colorado qualifies as condensate, there are heavier hydrocarbon liquids, typically referred to as crude oil, with an API gravity below 40 degrees that are not subject to the current control requirements. Additionally, there are a number of high volume produced water tanks that have VOC emissions above 6 tons per year that are not currently regulated under the existing requirements.

While Colorado has achieved considerable success in controlling emissions from condensate tanks since 2004, petroleum storage tanks at oil and gas production and midstream facilities continue to be the most significant source of VOC emissions from this sector. To address this emission source the Division is proposing the following strategies: 1) reducing the control threshold from 20 tons per year VOC to 6 tons per year; 2) eliminating the distinction between condensate and other liquids and requiring controls strictly based on emission levels; and 3) extending the current requirement that all condensate tanks in the NAA be controlled during the first 90 days of production to storage tanks throughout the state. In order to meet each of these three strategies, the Division assumes that owners and operators will equip tanks with enclosed flares, as is the typical practice under the existing tank control requirements. The estimated costs associated with installing and maintaining an enclosed flare are set forth in subsection 3.3.8.1.1 of this Regulatory Analysis. Utilizing the calculated flare costs, the estimated costs and benefits for each of the three tank control strategies are discussed in subsections 3.3.8.1.2 – 3.3.8.1.4 of this Regulatory Analysis.

3.3.8.1.1 General Cost Estimates for Flares

The estimated cost for a flare control device is based on identified costs from a 2008 oil and gas cost study[25] adjusted for inflation. Based on this data, the estimated annualized cost of a flare control device with auto-igniter[26] is about $6,287.[27]

[25] See "Oil & Gas Emissions Reduction Strategies Cost Analysis and Control Efficiency Determination," Lesair Environmental, Inc., June 2008. Information from this study was previously submitted to the Commission as part of the 2008 Ozone Action Plan process. For reference or background purposes, the Division has cited herein certain information that has been submitted to the Commission as part of the rulemaking; however, it is not necessarily included with this Regulatory Analysis as an exhibit.

[26] Currently only flares in the NAA are required to have auto-igniters. Under the current proposal, the auto-igniter requirement would be extended statewide. For the purposes of this cost analysis, it is assumed that auto-igniters will be required statewide. The cost and benefits associated with equipping existing flares outside the non-attainment with auto-igniters are discussed below in Section 3.3.8.1.7.

[27] Certain parties to the rulemaking have asserted that the actual cost per combustion device is higher based on EPA's cost analysis conducted in accordance with NSPS OOOO. Based on a review of EPA's analysis it appears that additional costs were included for surveillance systems that are not applicable to the proposed rule. Additionally, unlike the analysis in NSPS OOOO, the costs that the Division has identified are based on a Colorado specific cost analysis.

NMED Exhibit 71

*Table 1: Flare Control Device with Auto Igniter – Annualized Cost Analysis**				
Item	Capital Costs (one time)	Non-Recurring Costs (one time)	O&M Costs (recurring)	Annualized Total Costs
Flare	$18,169			
Freight/Engineering		$1,648		
Flare Installation		$6,980		
Auto Igniter	$1,648			
Pilot Fuel**			$768	
Maintenance			$2,197	
Subtotal Costs	$19,817	$8,628	$2,965	
Annualized Costs***	$2,747	$575	$2,965	$6,287

**Control cost evaluation based on 2008 Ozone Rulemaking cost survey and producer data. Control device costs were developed based on an oil and gas cost study and information submitted by industry in 2008. However, those costs were escalated by 9.85% to reflect CPI-U increases that have occurred since 2008.*[28]
*** Pilot fuel costs $3.41/MMBtu (Henry Hub Spot Price - Aug. 2013)*
**** Annualized over 15 years at 5% ROR*

3.3.8.1.2 Lowering Statewide Condensate Tank Control Threshold (from 20 tpy to 6 tpy)

The Division is proposing to lower the uncontrolled VOC emission control threshold from 20 tpy down to 6 tpy on condensate storage tanks statewide. Based on an analysis of the Air Pollution Emissions Notice (APEN) database, the Division estimates that statewide there are 588 uncontrolled condensate tank batteries with VOC emissions over six tons per year. Of these 588 tanks, 396 are outside the NAA and the remaining 192 are within the current NAA.

Table 2: Condensate Tank Battery Analysis				
Tank Battery Type	Ozone NAA [count]	Outside NAA [count]	Cancelled Tanks [count]	Total Statewide Tanks [count]
Controlled Tanks	4,971	490		5,461
Uncontrolled Tanks	1,451	1,132	36	2,619
All Tanks	6,422	1,622	36	8,080
Uncontrolled Tanks (≥ 6 tpy)	192	396		588

Based on the reported uncontrolled actual VOC emissions for these 588 tanks, and assuming both that 75% of the VOC emissions are captured and sent to the flare,[29] and that the flare has a 95% destruction efficiency, the total VOC emission reduction associated with lowering the condensate tank threshold statewide is 5,162 tons per year.

[28] It has been suggested that the Division should have used the Producer Price Index to calculate an escalation from 2008 to 2013 costs. From 2008 to 2013, however, the Producer Price Index for the oil and gas field equipment sector grew at a slower rate than the CPI. Accordingly, the Division's analysis may actually overstate the increase in cost from 2008 to 2013.

[29] The costs and benefits associated with improving the capture percentage for controlled storage tanks are discussed below in Section 3.3.8.1.5.

NMED Exhibit 71

Table 3: Condensate Tank Battery Emissions Analysis for Lowering Statewide Threshold			
Tank Battery Type	Uncontrolled VOC Emissions [tons/year]	Controlled VOC Emissions [tons/year]	VOC Emission Reduction [tons/year]
NAA Uncontrolled Tanks (≥6 tpy)	2,355	677*	1,678
Outside NAA Uncontrolled Tanks (≥6 tpy)	4,890	1,406*	3,484
Totals:	7,245	2,083	5,162

**Emission reduction estimated by accounting for 75% capture and 95% destruction efficiency.*

The annualized cost of installing 588 flare control devices is about $3.7 million dollars with an average cost effectiveness of about $716 per ton of VOC reduced. For the smallest individual tank battery subject to controls (6 tons/year), the flare cost effectiveness is estimated at $1,471 per ton of VOC reduced.

Table 4: Tanks over 6 tpy – Control Cost Estimates for Flare Control Devices				
Affected Tanks [count]	Each Flare Annualized Cost	Total Annualized Costs	VOC Reduction [tons/year]	Control Costs [$/ton]
588	$6,286.8	$3,696,638	5,162	$716

In addition to VOC reductions, this strategy will significantly reduce methane and ethane emissions from currently uncontrolled tanks. To calculate methane and ethane emission reductions, the Division determined the relative proportion of VOCs to methane and ethane based on reported average values from 30 natural gas liquid analyses submitted to the Division. Based on these analyses, methane/ethane emissions from condensate storage tanks are about 38% of the VOC emissions by weight. Accordingly, projected methane/ethane emission reductions from this proposed strategy are 1,963 tons per year or $1,884 per ton of methane/ethane reduced.

3.3.8.1.3 Requiring Controls for Produced Water and Crude Oil Tanks

As discussed above, the Division is proposing to eliminate the distinction between condensate tanks and other storage tanks. If the Commission adopts this proposal, crude oil tanks and produced water tanks with uncontrolled actual VOC emissions of six tons per year or greater will require controls. Because produced water and crude oil tanks are identified separately in the Division's APEN data base, the costs and benefits for these two types of storage tanks are broken out separately.

The Division is proposing that all statewide produced water tanks with uncontrolled VOC emissions over 6 tons/year be required to install emission controls. Some uncontrolled produced water tanks could be co-located at sites with condensate or crude oil tanks that have flare controls, but pressure and flow differences may require the installation of a separate flare control device for the water tank. Consequently, the control costs are based on the assumption that each water tank battery will install a new flare control device. Based on an analysis of the APEN

NMED Exhibit 71

database, the Division estimates that statewide there are 52 uncontrolled produced water tank batteries with VOC emissions over 6 tons/year.

Table 5: Produced Water Tank Battery Analysis	
Tank Battery Type	Total Statewide Water Tanks
Controlled Water Tanks:	338
Uncontrolled Water Tanks:	530
Total:	868
Uncontrolled Tanks (≥6 tpy)	52

Based on the reported uncontrolled actual emissions, the Division estimates that the total VOC emission reduction associated with controlling these produced water tanks statewide is 457 tons per year.

Table 6: Produced Water Tank Battery – Emissions Analysis			
Tank Battery Type	Uncontrolled VOC Emissions [tons/year]	Controlled VOC Emissions [tons/year]	VOC Emission Reduction [tons/year]
Uncontrolled Tanks (≥6tpy)	641.4	184.4*	457

**Emission reduction estimated by accounting for 75% capture and 95% destruction efficiency.*

The annualized cost of installing 52 flare control devices is about $327,000, with an average cost effectiveness of about $715 per ton of VOC reduced. For the smallest individual tank battery (6 tons/year), the flare cost effectiveness is estimated at $1,471 per ton of VOC reduced.

Table 7: Produced Water Tanks – Control Cost Estimates for Flare Control Devices					
Tank Size	Affected Tanks [count]	Each Flare Annualized Cost	Total Annualized Costs	VOC Reduction [tons/year]	Control Costs [$/ton]
≥ 6tpy	52	$6,286.8	$326,914	457	$715

The Division is proposing that all statewide hydrocarbon liquid storage tanks with VOC emissions over six tons/year must install emission controls. Based on a recent analysis of 2013 APEN data, there are 67 reported crude oil tanks batteries statewide. Thirty seven of the tank batteries are already equipped with controls. Of the remaining thirty, eight are over the proposed six tons/year threshold. Given that approximately 5% of the total wells in the state report crude oil production to the Colorado Oil and Gas Conservation Commission (COGCC),[30] it appears

[30] Based on an analysis of 2010 COGCC data.

NMED Exhibit 71

likely that the Division's APEN database may be undercounting crude oil tanks, either because these tanks have not been reported or because they are being reported as condensate tanks.[31]

Table 8: Crude Oil Tank Battery Analysis	
Tank Battery Type	Total Statewide Crude Oil Tanks
Controlled Crude Oil Tanks	36
Uncontrolled Crude Oil Tanks	29
Total:	65
Uncontrolled Tanks (≥6 tpy)	8

The total VOC emission reduction associated with controlling these 8 crude oil tanks statewide is 118 tons per year.

Table 9: Crude Oil Tank Battery – Emissions Analysis			
Tank Battery Type	Uncontrolled VOC Emissions [tons/year]	Controlled VOC Emissions [tons/year]	VOC Emission Reduction [tons/year]
Uncontrolled Tanks (≥6tpy)	165.2	47.5*	117.7

**Emission reduction estimated by accounting for 75% capture and 95% destruction efficiency.*

The annualized cost of installing eight flare control devices is about $50,294 dollars with an average cost effectiveness of about $427 per ton of VOC reduced. For the smallest individual tank battery (6 tons/year), the flare cost effectiveness is estimated at $1,471 per ton of VOC reduced.

Table 10: Crude Oil Tanks – Control Cost Estimates for Flare Control Devices					
Tank Size	Affected Tanks [count]	Each Flare Annualized Cost	Total Annualized Costs	VOC Reduction [tons/year]	Control Costs [$/ton]
≥ 6tpy	8	$6,286.8	$50,294.4	117.7	$427

3.3.8.1.4 Requiring Controls During the First 90 Days of Production Statewide

Under current requirements owners and operators of new and modified storage tanks outside the NAA have 90 days after the date of first production to determine if emissions from the tank trigger the requirement to install a control. Because production is typically at its highest during this initial period, significant emissions can occur before controls are installed. To address this

[31] Prior to 2008 crude oil storage tanks were exempt from APEN reporting requirements, which may explain in part the small numbers of tanks identified in the system.

NMED Exhibit 71

issue in the NAA, the Commission mandated in the 2008 Ozone Action Plan that all condensate tanks be controlled during the first 90 days. The Division is now proposing to expand this requirement to storage tanks throughout the state.

To calculate the cost effectiveness of this strategy, the Division first determined the number of new and modified storage tanks outside the NAA based on reported APEN data for the period of 2010-2012. Based on this APEN data, there are on average 141 new and modified tanks each year, with yearly reported uncontrolled actual emissions of 7,370 tons VOC. Assuming that emissions during the first 90 days equal 1/4th of the annual reported emissions,[32] total uncontrolled actual VOC emissions from these tanks during the first 90 days is 1,842.5 tons. Assuming enhanced capture efficiency for these new tanks (see subsection 3.3.8.1.5 of this Regulatory Analysis) the flare control efficiency is 95%, and thus the calculated benefit from expanding the first 90 day control requirement to tanks outside the NAA will be 1,750.4 tons per year.

While the Division estimates that there are 141 new and modified storage tanks outside the NAA each year, the majority of these, 84, will require control devices regardless of this strategy since their uncontrolled actual emissions are over six tpy. For these 84 tanks, the cost of operating a flare during the first 90 days will be approximately 25% of the total annualized cost, or $1,571.70 per tank. For the remaining 57 tanks with emissions less than six tons/year, because controls for these tanks will only need to be in place for 90 days, the Division assumes that each flare can control 3 tanks per year, which means that 19 new flares are required to comply with this proposed strategy. For other applications, the annualized cost of a flare is estimated to be $6,287. Since flares required for this application will be relocated three times a year, the Division assumes an additional $3,000 in annual relocation costs, for a total annualized cost of about $9,287 per flare. Based on the emission reductions calculated above, the total cost effectiveness of this requirement is $176/ton of VOC reduction.

Table 11: Control Cost Estimates for Flare Control Devices Required During the First 90 Days of Production

Storage Tank Threshold [tpy]	Number of New Storage Tanks	Number of New Flares	Annualized Cost Each Flare	Total Flare Cost	Total VOC Reduction [tons/year]	VOC Control Cost [$/ton]
<6	57	19	$9,286.8	$176,449.2	44.7	$3,947
≥6	84	84	$1,571.7	$132,022.8	1,705.7	$77
	141			$308,472	1,750.4	$176

Using the methodology discussed in subsection 3.3.8.1.2 of this Regulatory Analysis, the projected methane/ethane emission reductions from this strategy is 665.5 tons per year or $464 per ton of methane/ethane reduced.

[32] Because reported emissions typically are based on a calculation assuming a standard rate of production decline after the first 90 days, actual emissions during the first 90 days could be much higher.

NMED Exhibit 71

3.3.8.1.5 Emission Capture Requirements for Controlled Petroleum Storage Tanks

In order for storage tank control requirements to be effective, emissions from the tank must be routed to the control device. Historically the Division has assumed that 100% of a tank's emissions will be captured and routed to the control device, typically a flare, resulting in a 95% reduction of emissions. Field observations using IR cameras and other methodologies indicate that in actuality emissions from controlled storage tanks often escape through the thief hatches and pressure relief valves (PRV) and therefore are not being combusted in the flare. This occurs when the tank cannot adequately contain the flashing emissions that occur when pressurized liquids from the separator are dumped into the atmospheric tank. To address this issue, the Division is proposing new regulatory language clarifying that all emissions from controlled storage tanks must be routed to the control device and that these tanks must be operated without venting emissions from thief hatches, PRVs and other openings, except when venting is reasonably necessary for maintenance, gauging, or safety of personnel and equipment.

To assure compliance with these capture standards, the Division's proposal requires that owners and operators of controlled storage tanks implement a STEM plan. Pursuant to the STEM plan, owners and operators must evaluate and employ appropriate control technologies and/or operational practices designed to meet the proposed capture requirements, and certify that these technologies and/or operational practices are designed to minimize emissions from the tank. The Division's STEM proposal also requires implementation of a two-pronged monitoring strategy involving a weekly[33] auditory, visual, and olfactory (AVO) inspection for all controlled tanks, and a periodic instrument based monitoring for tanks using EPA Reference Method 21, an IR camera or other Division approved monitoring device or method. As proposed, the frequency of this instrument based monitoring will depend on the level of uncontrolled actual emissions from the tank.

Table 12: Proposed Tiering for Instrument Based Tank Inspections

Tank Uncontrolled Actual VOC Emissions	Inspection Frequency
≥ 6 tpy to ≤ 12 tpy	Annually
> 12 tpy to ≤ 50 tpy	Quarterly
> 50 tpy	Monthly

In assessing the cost effectiveness of the proposed requirements, the Division first calculated the costs associated with implementing technological and/or operational changes at controlled tanks. For the purposes of this analysis the Division assumed that all tanks with uncontrolled actual emissions greater than or equal to 6 tons per year would need to be controlled consistent with the Division's proposal discussed in Section 3.3.1 of this Regulatory Analysis. Based on reported data, there are currently 5,310 storage tanks statewide with emissions greater than or equal to 6 tons per year. While the Division's proposal does not specify the type of technology or operational practices that operators will use, for the purposes of this analysis the Division

[33] There is an exception for the weekly inspection requirement where the operator loads out liquids from the storage tank on less than a weekly basis. In these circumstances the operator must conduct the inspection whenever liquids are loaded out, but no less often than every 30 days. Typically liquids are loaded out multiple times in a given week, meaning that for the majority of the tanks AVO inspections will be required weekly.

NMED Exhibit 71

assumed that buffer bottle technology would be installed on each of the subject tanks.[34] The buffer bottle technology utilizes a small tank that is installed after the separator which allows for a secondary flash of pressurized liquids prior to dumping into the storage tank. The second-stage flash reduces the pressure of the liquids going to the tank and thereby helps to ensure that the tank can adequately handle the flashing emissions that occur when the liquids are brought to atmospheric pressure. Based on industry provided information, the estimated annual cost of a buffer bottle is set forth in Table 13.[35]

Table 13: Annualized Cost Analysis for Buffer Bottle

Item	Capital Costs (one time)	Non-Recurring Costs (one time)	O&M Costs (recurring)	Annualized Total Costs
Buffer Bottle	$11,500			
Freight/Engr		$600		
Installation		$2,280		
Maintenance			$2,500	
Subtotal Costs	$11,500	$2,880	$2,500	
Annualized Costs*	$1,593.8	$192	$2,500	$4,285.8

** Annualized over 15 years at 5% ROR*

The Division also calculated the costs associated with conducting enhanced inspections. Based on the proposed tiering, operators will need to conduct 24,840 tank inspections per year.[36]

Assuming that each inspection takes two hours and utilizing a $103/hour [37] in-house inspection cost and a $134/hour contractor inspection cost (30% profit added to in-house rate), the total annual cost associated with conducting enhanced inspections under the proposed rule is $5,392,010, which equates to $1,015.4 per year for each tank that will be subject to STEM.

[34] Based on discussions with industry representatives during the stakeholder process there may be other less costly technologies and operational practices that could be used to ensure good emission capture from tanks such as replacing seals, more frequent maintenance, changing the size of piping going to the storage tank, and timing well dumps to avoid overloading the separator. There may also be other options for new facilities that allow for the capture and sale of additional gas such as the installation of high-low pressure separators or utilizing a liquids gathering system that eliminates atmospheric storage tanks at well sites.

[35] For this Regulatory Analysis, the Division increased the capital and maintenance costs for buffer bottles based on input from industry stakeholders.

[36] In practice, many operators are already conducting IR camera inspections at storage tanks, however, the Division does not have information regarding how many inspections are currently occurring.

[37] The hourly inspection cost is discussed below in Table 20.

NMED Exhibit 71

Table 14: Instrument Based Tank Inspections Based on Proposed Tiering					
Tank Uncontrolled Actual VOC Emissions	Inspection Type/Hourly Rate	Number of Tanks	Inspection Frequency	Number of Inspections	STEM Inspection Costs
>6 tpy to ≤ 12 tpy	In-House/$103	1,085	Annually	1,085	$223,510
>12 tpy to ≤ 50 tpy	In-House/$103	2,595	Quarterly	10,380	$2,138,280
> 50 tpy	In-House/$103	745	Monthly	8,940	$1,841,640
	Subtotal:	***4,425***		***20,405***	***$4,203,430***
>6 tpy to ≤ 12 tpy	Contractor/$134	323	Annually	323	$86,564
>12 tpy to ≤ 50 tpy	Contractor/$134	329	Quarterly	1,316	$352,688
> 50 tpy	Contractor/$134	233	Monthly	2,796	$749,328
	Subtotal:	***885***		***4,435***	***$1,188,580***
	Total:	**5,310**		**24,840**	**$5,392,010**

The Division also considered whether additional costs should be included for conducting periodic AVO inspections. Because these activities are already required for controlled storage tanks under existing regulation, the Division did not include these costs in determining the total cost of the proposed capture requirements. The Division also did not include costs associated with certifying that selected technologies and/or operational practices are designed to minimize emissions, since costs for certifying capture efficiency are already included in the annualized cost of required flares.[38] Accordingly, the total projected annual cost of the proposed capture requirements based on the use of a buffer bottle and enhanced monitoring requirements is $5,301.2 per tank.

To calculate the projected emissions reduction from the proposed capture requirements, the Division assumed a current capture rate of 75% for controlled tanks based on analytical work that the Division, EPA and others have performed. Based on this capture rate, the Division calculated the emissions reduction that would occur if the capture rate were increased to 100% using the following equation:

Emission reduction = [uncontrolled VOC*(1-(0.75*0.95))] – [uncontrolled VOC *(1-0.95)],

Using this equation as applied to the reported uncontrolled actual emissions from the 5,310 storage tanks statewide with emissions greater than or equal to six tons per day, the projected emission reduction from the proposed capture requirements is 53,386 tons per year. Included in the total are 33 existing crude oil tanks with flare controls (>6 tpy) and 8 crude oil tanks that would need flare controls (>6 tpy).

[38] See "Oil & Gas Emissions Reduction Strategies Cost Analysis and Control Efficiency Determination," Lesair Environmental, Inc., June 2008, at pg. 8.

NMED Exhibit 71

Table 15: STEM Emission Control Analysis (Statewide)				
Number of Tanks ≥6 tpy	Uncontrolled VOC [tons/year]	Controlled VOC (@ 71.25% Control) [tons/year]	Controlled VOC (@ 95% Control) [tons/year]	VOC Reduction [tons/year]
5,269	221,569	63,701	11,078	52,623
41	3,213	924	161	763
5,310	224,782	64,625	11,239	53,386

Applying this reduction to the costs calculated above, the cost effectiveness of these proposed requirements is $527/ton of VOC.

Table 16: STEM Control Cost Estimates (Statewide)					
Type of Technology	Number of Tanks	Each Device Annualized Costs [$/year]	Total Annualized Costs	VOC Reduction [tons/year]	Control Costs [$/ton]
Buffer Bottle	5,310	$5,301.2	$28,149,372	53,386	$527.3

Using the average ratio of VOC to methane/ethane emissions from storage tanks, the projected methane/ethane reduction from this strategy is 20,287 tons per year, which equates to $1,388 per ton of methane/ethane reduced.

During the Division's stakeholder process leading up to the Commission's rulemaking hearing, certain parties have raised questions about the Division's assumption that currently controlled tanks have a 75% capture efficiency. In light of this the Division has also calculated cost effectiveness based on the assumption that current capture efficiency is 50% and 95%. For the 50% case, current controlled emissions would be 118,011 tpy VOC. Accordingly, the emission reduction benefit from increasing capture to 100% would be 106,772 tons per year (118,011-11,239) and the cost effectiveness would be $264/ton VOC[39]. For the 95% capture scenario, current controlled emissions would be 21,916 tons per year VOC and the emission reduction would be 10,677 tons per year (21,916-11,239). Under this scenario, the cost effectiveness would be $2,636/ton VOC[40].

While the buffer bottle technology offers a good alternative in a retrofit situation for reducing pressures to the tank and increasing emission capture, for new facilities, installation of a high-low pressure (HLP) separator to satisfy STEM may prove to be a better performing option. This equipment allows for two stages of separation of the gas and the liquids instead of the single stage separation accomplished in traditional separators. By adding a second stage of separation, the pressure of the liquids sent to the tank is significantly reduced, thereby helping to ensure

[39] This may overestimate the cost effectiveness given that if the current capture rate were only 50% additional costs could be required to increase the capture rate to 100%.
[40] This is a conservative calculation given that if the current capture rate were 95% it is likely that the control costs to increase the capture rate to 100% would be significantly less.

NMED Exhibit 71

complete capture of flashing emissions instead of venting a portion of the emission stream through the thief hatch or PRV. Additionally, rather than being routed to the flare, as in the case of the buffer bottle technology, gas from the second stage of separation can be sent to a vapor recovery unit (VRU), recompressed and sent to the sales line, resulting in increased product recovery. Based on information provided from industry, the Division has calculated that the annual cost of a HLP separator w/VRU is about $19,341.

Table 17: Annualized Cost Analysis for HLP Separator

Item	Capital Costs (one time)	Non-Recurring Costs (one time)	O&M Costs (recurring)	Annualized Total Costs
HLP/VRU	$90,000			
Freight/Engr		$1,648		
HLP/VRU Installation		$11,154		
Maintenance			$9,396	
VRU Recovered NG *			$(3,382)	
Subtotal Costs	$90,000	$12,802	$6,014	
Annualized Costs**	$12,474	$853	$6,014	$19,341

** Recovered NG fuel costs $3.5/MCF (Henry Hub Spot Price - Aug. 2013) and average tank battery size of 63.2 tpy – based on 3-yr average of APEN data on storage tanks ≥6 tpy (uncontrolled VOC).*

*** Annualized over 15 years at 5% ROR*

Unlike the retrofit situation analyzed above where the emission controls are already in place, it is appropriate in new installations to aggregate the cost of the HLP separator w/VRU with the costs of the control unit (flare) to determine the overall cost of controlling emissions from the tank. Based on the $6,286.8 annual cost of a flare and annual instrument based monitoring costs of $1,015.4 per tank, the total annual control costs for a new tank will be $26,643 per year.

Based on an analysis of reported data for new tanks during the past three years, the average uncontrolled actual emissions of a new tank is 63.2 tpy. Assuming a 95% overall control efficiency, equipping a tank with an HLP separator and a flare will reduce the emissions from an average new tank by 60 tpy. This yields a cost effectiveness of $444 per ton VOC reduced. If instead, the highest cost scenario (using a six tpy tank) is assumed, the cost effectiveness is $4,674 per ton VOC. For methane ethane the cost per ton is $1,168 per ton reduced on average.

3.3.8.1.6 LDAR Requirements for Compressor Stations and Well Production Facilities

Commission Regulation Number 7 requires owners and operators of gas processing plants in Colorado to implement LDAR programs to identify and repair fugitive emission leaks from components at these facilities. Under this requirement, owners and operators must conduct periodic inspections using EPA Reference Method 21[41] and repair leaks within a prescribed time frame.

[41] While EPA Reference Method 21 sets performance standards for inspection equipment rather than specifying technology, typically Method 21 inspections utilize photo ionization detectors (PIDs) to assess leak levels.

NMED Exhibit 71

Although component leaks at compressor stations and well production facilities in Colorado are also a significant source of VOC and methane emissions, Regulation No. 7 does not currently include LDAR requirements for these facilities.[42] To address these emissions, the Division is proposing regulatory changes that would establish LDAR requirements for compressor stations and well production facilities. Pursuant to this proposal, owners and operators of compressor stations and well production facilities will be required to conduct periodic leak inspections, and repair identified leaks. As specified, required inspections may be done either in accordance with EPA Reference Method 21 or utilizing an IR camera. The proposed language also allows the Division to approve other inspection methods as new leak detection technologies are demonstrated to be effective.

The proposed regulation establishes a tiered system to determine inspection frequency. For compressor stations the tiering is based on the uncontrolled actual leak emissions at the facility as follows:

Table 18: Proposed Tiering for Leak Inspections at Compressor Stations

Component Leak Uncontrolled Actual VOC Emissions	Inspection Frequency
≤ 12 tpy	Annually
>12 tpy to ≤ 50 tpy	Quarterly
> 50 tpy	Monthly

For well production facilities the proposed tiering is based on uncontrolled actual emissions from the largest emitting storage tank at the facility as set forth in Table 19. The tiering is based on tank emissions rather than uncontrolled actual leak emissions in order to create an EPA Reference Method 21/IR camera monitoring schedule that is consistent with the monitoring schedule proposed as part of STEM emission capture requirements.[43]

[42] Although leak detection is not currently required at most of these facilities, some operators currently conduct voluntary leak detection and repair programs. Additionally, the Division has issued a limited number of permits that include some leak detection requirements. For the purposes of this analysis, however, the Division assumes that there is no leak detection occurring at well production facilities and compressor stations. Accordingly the actual additional costs that operators may incur may be less than the costs calculated in this analysis.

[43] Because there may be a limited number of instances where well production facilities don't have storage tanks, the proposal also provides that for tank-less facilities, the inspection schedule will be based on the facility's total VOC emissions. This provision is intended to apply to large facilities that utilize a liquids gathering system for transporting petroleum liquids to a centralized facility. These facilities are not included in the facility count used in this Regulatory Analysis, but because the number of these facilities in Colorado is extremely small this exclusion should have a negligible impact on the overall costs and emission reduction benefits of the proposed LDAR requirement. Additionally, because the costs and benefits from the proposed LDAR program increase at roughly the same rate, the cost effectiveness of the program for these facilities should mirror the cost effectiveness of the program as applied to facilities with tanks.

NMED Exhibit 71

Table 19: Proposed Tiering for Leak Inspections at Well Production Facilities	
Tank Uncontrolled Actual VOC Emissions	Inspection Frequency
< 6 tpy	One Time (and Monthly AVO)
≥ 6 tpy to ≤ 12 tpy	Annually
>12 tpy to ≤ 50 tpy	Quarterly
> 50 tpy	Monthly

The Division utilized a multi-step process to calculate the estimated costs and benefits associated with the proposed LDAR requirements. First, the Division calculated an hourly inspection rate based on the total annual cost for each inspector divided by an assumed 1,880 annual work hours.[44] To calculate the total annual cost for each inspector, the Division included salary and fringe benefits for each inspector, annualized equipment and vehicle costs, and add-ons to account for supervision, overhead, travel, record keeping, and reporting. Based on the assumptions set forth in Table 20 below, the total annual cost for each inspector will be $193,629, which equates to an hourly inspection rate of $103.

Table 20: LDAR Inspector – Annualized Cost Analysis			
Item	Capital Costs (one time)	Annual Costs	Annualized Total Costs
FLIR Camera	$122,000		
FLIR Camera Maintenance/Repair		$7,500	
Photo Ionization Detector	$5,000		
Vehicle (4x4 Truck)	$22,000		
Inspection Staff		$75,000	
Supervision (@ 20%)		$15,000	
Overhead (@10%)		$7,500	
Travel (@15%)		$11,250	
Recordkeeping (@10%)		$7,500	
Reporting (@10%)		$7,500	
Fringe (@30%)		$22,500	
Subtotal Costs	$149,000	$153,750	
Annualized Costs*	$39,879	$153,750	$193,629
**over 5 years at 6% ROR*		Annualized Hourly Rate	$103

Initially, the Division assumed that conducting inspections in-house would be the lowest cost option since it would not involve additional profit to be paid to a contractor. For smaller companies that cannot fully utilize an IR camera, however, conducting inspections in-house may not be the most cost effective option. To account for this in this Regulatory Analysis, the Division assumed a 30% profit margin for contractors, which it added to the calculated hourly rate in instances where it appeared that contractors would be used to conduct the inspection ($134 per hour).

[44] This assumes a 40 hour work week with ten holidays, two weeks of vacation, and one week of sick leave.

NMED Exhibit 71

Second, the Division calculated the average amount of time that it would take to conduct an EPA Reference Method 21 inspection at compressor stations and well production facilities based on the number of components to be inspected and assuming that a component could be inspected every 30 seconds. The proposed rule also allows owners and operators to use IR cameras either as the sole inspection tool, or as a screening tool to identify potential leaking components followed by a Method 21 inspection. An IR camera inspection or IR Camera/Method 21 hybrid inspection can be conducted more quickly than a Method 21 inspection of each component. While the Division does not currently have actual data regarding how much faster an inspection could be completed using an IR camera, for the purpose of this analysis the Division assumed that an IR camera based inspection would take 50% of the time required for a Method 21 inspection.[45]

For compressor stations, the Division used reported component counts for compressor stations within each of the tiers identified in Table 18 above. Based on these counts, and the inspection times per component discussed above, the Division calculated that the total inspection time per compressor station facility tier are as follows:

Table 21: Calculated Inspection Time Compressor Station Leak Inspections

Component Leak Uncontrolled Actual VOC Emissions	Method 21 Inspection	IR Camera/ Hybrid Inspection
≤ 12 tpy	21.2 hours	10.6 hours
>12 tpy to ≤ 50 tpy	56.2 hours	28.1 hours
> 50 tpy*		

* *there are currently no compressor stations in Colorado with calculated leaks at this level*

For well production facilities, the Division has limited data on the number of components per facility. Based on this limitation, the Division did not attempt to calculate a separate inspection time for each of the proposed facility tiers, and instead used the overall average component count. Based on the limited available data, however, there does appear to be a distinction between component numbers at well production facilities in the NAA and well production facilities outside the NAA. Accordingly, the Division calculated separate inspection times for well production facilities by area as set forth in Table 22.

Table 22: Calculated Inspection Times for Well Production Facility Leak Inspections

Area	Method 21 Inspection	IR Camera/ Hybrid Inspection
NAA	12.2 hours	6.1 hours
Rest of the State	6.8 hours	3.4 hours

[45] Based on the Division's own IR camera inspections, and reports from various parties during the stakeholder and prehearing process it appears that the Division's assumption may significantly overstate the actual time needed to conduct an IR camera inspection.

NMED Exhibit 71

In addition to the travel costs that are built into the hourly inspection rate as set forth in Table 20, for the purposes of this Regulatory Analysis the Division also assumed an additional three hours in travel time for each inspection outside the NAA. This assumption reflects the fact that certain well sites in basins outside the NAA may be remote, requiring additional travel.

Next, the Division calculated the projected inspection costs for both compressor stations and well production facilities. To make this calculation the Division used industry reported emission data to determine the number of facilities that will be subject to annual, quarterly and monthly inspections to determine the total number of inspections for each tier, and multiplied these inspections by the calculated inspection time and projected hourly inspection rate. For compressor stations the Division assumed that all inspections would be conducted by 3rd party contractors. For well production facilities, the Division assumed that any company with 500 or more inspections per year would conduct inspections in-house, and that companies with less than 500 inspections per year would use contractors.[46] Because the proposed rule also requires owners and operators of well production facilities that are not subject to monthly instrument monitoring to conduct monthly AVO inspections the Division considered whether additional costs should be included for these inspections. Based on information provided during the Division's stakeholder process leading up to the Commission's rulemaking hearing it appears that operators already routinely conduct such inspections and repair leaks identified during these AVO inspections. Additionally, while the proposed rule may impose recordkeeping and reporting requirements associated with these AVO inspections, given the relatively small number of leaks that are expected to be identified, and the fact that any recordkeeping can be readily included in existing inspection and maintenance records the Division believes that any additional recordkeeping and reporting costs will be nominal relative to the overall cost of the LDAR program.

In its Initial EIA, the Division did not include the cost to repair leaking components or re-monitor these components post-repair to verify that the repair was effective, assuming that the cost to repair and re-monitor would be offset by the cost savings from capturing additional product as a result of repairs. Based on information that the Conservation Groups submitted as part of their Pre-Hearing Statement to the Commission, it appears that the Division's assumption in the Initial EIA was reasonable. See Exhibit A to CG-PHS, Testimony of David McCabe at pg. 8. Nevertheless, for this Regulatory Analysis, the Division has included both repair costs and estimated product savings from conducting leak detection activities. To calculate repair costs, the Division used EPA information regarding leaking component rates, component repair times, and hourly repair rates. Specifically, the Division assumed a $66.24 hourly rate to repair components, and an average repair time of between 0.17 hours and 16 hours, depending on the both type of component and the complexity of the repair.[47] To calculate the number of leaking components the Division used industry reported component counts and assumed a 1.18% leaking

[46] Based on this assumption, 3,545 inspections per year will be conducted using 3rd party contractors.
[47] See "Equipment Leak Emission Reduction and Cost Analysis for Well Pads, Gathering and Boosting Stations, and Transmission and Storage Facilities Using Emission and Cost Data From the Uniform Standards," Bradley Nelson and Heather Brown, April 17, 2012; "Analysis of Emissions Reduction Techniques for Equipment Leaks," Cindy Hancy, December 21, 2011.

NMED Exhibit 71

component rate for facilities subject to annual inspections.[48] To account for the projected additional emission reductions from quarterly and monthly inspection schedules the Division used annual leaking component rates of 1.77% for facilities with quarterly inspection schedules and 2.36% for facilities with monthly inspection schedules. To calculate the value of the additional product captured, the Division converted the amount of VOC and methane/ethane reduced to MCF of natural gas, with a price of $3.50/MCF. With respect to re-monitoring, the Division determined that because of the small number of components that will require repair and the fact that re-monitoring can be undertaken at the same time as repair, any additional costs associated with re-monitoring are negligible.

Based on this methodology, the calculated annual inspection costs for compressor stations are set forth in Table 23.

Table 23: Compressor Station Leak Inspection Costs Using IR Camera/Method 21 Hybrid

Compressor Station Fugitive VOC Tier [tpy]	Number of Compressor Stations	Annual Inspection Frequency	Time per IR Camera Inspection [hours]	Total Annual Inspection Time [hours]	Total Annual Inspection Cost
≤ 12 tpy	147	1	10.6	1,558.2	$208,799
>12 to ≤ 50 tpy	53	4	28.1	5,957.2	$798,265
≥ 50 tpy	0	12			
Total:	200			7,515.4	$1,007,064

Repair costs associated with these inspections are set forth in Table 24 and fuel savings associated with these repairs are set forth in Table 25.

Table 24: Compressor Station Leak Repair Costs

Compressor Station Fugitive VOC Tier [tpy]	Number of Compressor Stations	Leak Repair Rate [$/hr]	Number of Leaks per Compressor Station	Total Leak Repair Time per CS [hours]	Total Annual Repair Cost
≤ 12 tpy	147	$66.24	30.1	23.0	$223,957.4
>12 to ≤ 50 tpy	53	$66.24	119.4	85.2	$299,113.3
≥ 50 tpy	0	$66.24	-	-	-
Total:	200				$523,071

[48] This leaking component rate is consistent with the rate that the Louis Berger Group used in their Initial Economic Impact Analysis for Industry's Proposed Revisions to Colorado's Air Quality Control Commission Regulation No. 7 (DGS-PHS Ex. C), and is based on the leak rate utilized by Nelson and Brown in their analysis of leak reduction costs and benefits (See footnote 41).

NMED Exhibit 71

Table 25: Compressor Station Recovered Natural Gas Value from Leak Repairs					
Compressor Station Fugitive VOC Tier [tpy]	Number of Compressor Stations	Total Recovered Natural Gas per CS [tons/year]	Value of Natural Gas [$/MCF]	Conversion Factor [MCF/ton]	Total Annual Value of Recovered Natural Gas
≤ 12 tpy	147	10.2	$3.5	35.8	$187,875
>12 to ≤ 50 tpy	53	36.4	$3.5	35.8	$241,729
≥ 50 tpy	0		$3.5	35.8	-
Total:	200				$429,604

The total net costs for compressor station LDAR are set forth in Table 26.

Table 26: Compressor Station Net Leak Inspection and Repair Costs					
Compressor Station Fugitive VOC Tier [tpy]	Number of Compressor Stations	Total Annual Inspection Cost	Total Annual Repair Cost	Total Annual Value of Recovered Natural Gas	Net Annual Leak Inspection and Repair Costs
≤ 12 tpy	147	$208,799	$223,957.4	$187,875	$244,882
>12 to ≤ 50 tpy	53	$798,265	$299,113.3	$241,729	$855,650
≥ 50 tpy	0		-	-	-
Total:	200	$1,007,064	$523,071	$429,604	$1,100,531

For well production facilities the estimated annual inspection costs are set forth in Table 27.

> 50	ROS	$909,696	$535,142	$170,356	$190,418	$1,424,776
	Subtotal:	$1,487,815	$1,162,905	$578,957	$646,886	$2,582,791
	Total:	**$13,456,302**	**$2,943,202**	**$5,751,016**	**$4,503,532**	**$17,646,988**

Additionally, based on information in the Division's APEN reporting system, there are 2,799 well production facilities with uncontrolled actual storage tank emissions less than or equal to 6 tons per year that will be subject to a one-time instrument based inspection. The one-time cost for inspecting these facilities is estimated to be $1,639,239.[49]

Table 31: Well Production Facility Leak Inspection Costs Using IR Camera/Method 21 Hybrid					
Uncontrolled VOC at Storage Tank Battery Tier [tpy]	O&G Basin	Number of Facilities and Inspections	Inspection Time Per Inspection [hours]	Inspection Type/Hourly Rate	Total Annual Inspection Cost
≤ 6	DJ/NAA	1,598	6.1	In-House/$103	$1,004,023
≤ 6	ROS	500	3.4	In-House/$103	$175,100
	Subtotal:	2,098			$1,179,123
≤ 6	DJ/NAA	389	6.1	Contractor/$134	$317,969
≤ 6	ROS	312	3.4	Contractor/$134	$142,147
	Subtotal:	701			$460,116
	Total:	**2,799**			**$1,639,239**

[49] To calculate these costs the Division used the same methodology applicable to periodic inspection costs, except that it did not include additional travel time for facilities outside the NAA based on the assumption that companies could coordinate these one-time inspections with visits to the facilities for other purposes.

NMED Exhibit 71

The Division recognizes that there are likely additional facilities not included in the APEN database that will be subject to this one-time inspection requirement, thereby increasing the overall cost of the one-time inspection requirement. Roughly speaking the additional cost for one-time inspections will be proportional to the number of additional facilities, so that if there are twice the number of facilities, the overall cost will be approximately double. However, because the expected emission reduction benefit will increase roughly at the same rate as the cost of inspections the overall cost-effectiveness of the one-time inspection requirement should remain approximately the same regardless of the number of facilities.

Finally, the Division calculated the cost effectiveness of the proposed LDAR requirements based on the costs identified above and the projected emission reductions. To determine emission reductions the Division first calculated pre-inspection program VOC and methane emissions based on the reported component counts, standard emission factors for these components, and the average fraction of VOC and non-VOC emissions (methane/ethane). Based on EPA reported information, the Division calculated a 40% reduction for annual inspections, a 60% reduction for quarterly inspections, and an 80% reduction for monthly inspections.

Using this information the Division calculated that the total emission reductions from leaks at compressor stations will be 1,107 tpy VOC and 2,321 tons per year methane/ethane.

Table 32: Compressor Station Leak Inspection Emission Reductions

Comp. Station Fugitive VOC Tier [tpy]	Number of Comp Stations	LDAR Program Reduction %	Fugitive VOC Emissions for each CS tier [tpy]	Total VOC Reduction [tpy]	Fugitive Methane-Ethane Emissions for each CS tier [tpy]	Total Methane-Ethane Reduction [tpy]
≤ 12	147	40%	10.1	588.0	15.5	911.4
> 12 to ≤ 50	53	60%	16.4	519.4	44.3	1,409.8
> 50		80%				
	200			1,107.4		2,321.1

Based on these reductions, the cost effectiveness of conducting leak inspections at compressor stations is estimated to be $994/ton VOC and $474/ton methane/ethane.

NMED Exhibit 71

Table 33: Compressor Station Leak Inspection Cost Effectiveness using IR Camera/Method 21							
Comp. Station Fugitive VOC Tier [tpy]	Number of Comp Stations	Total Net Annual Inspection & Repair Cost	LDAR Program Reduction %	Total VOC Reduction [tpy]	VOC Control Cost [$/ton]	Total Methane-Ethane Reduction [tpy]	Methane -Ethane Control Cost [$/ton]
≤ 12	147	$244,882	40%	588.0	$416	911.4	$269
> 12 to ≤ 50	53	$855,650	60%	519.4	$1,647	1,409.8	$607
> 50			80%				
	200	$1,100,531		1,107.4	$994	2,321.2	$474

For well production facilities the total emission reductions is estimated to be 14,015 tpy VOC and 21,927 tpy methane/ethane.

Table 34: Well Production Facility Leak Inspection Emission Reductions						
Uncontrolled VOC at Tank Battery Tier [tpy]	Number of Facilities	LDAR Program Reduction %	Fugitive VOC Emissions for each Tank Battery [tpy]	Total VOC Reduction [tpy]	Fugitive Methane-Ethane Emissions for each Tank Battery [tpy]	Total Methane-Ethane Reduction [tpy]
DJ/NAA						
> 6 to ≤ 12	1,095	40%	4.6	1,971.0	7.0	3,066.0
> 12 to ≤ 50	2,600	60%	4.6	7,280.0	7.0	10,920.0
> 50	811	80%	4.6	3,000.7	7.0	4,541.6

Additionally, for the 2,799 well production facilities with uncontrolled actual storage tank emissions equal to or less than 6 tons per year that will be subject to a one-time instrument based inspection, the calculated one-time benefit is 4,876 tons VOC and 8,000 tons methane/ethane, assuming a 40% reduction. Based on these reductions, for the one-time inspections of well production facilities with tanks that are less than six tons per year the cost effectiveness of the proposed rule is calculated to be $409/ton VOC and $249/ton methane/ethane.

In addition to the component LDAR requirements for compressor stations and well production facilities, the Division's proposal includes additional requirements designed to reduce leaks from open ended lines and valves, reciprocating compressors, and wet seal centrifugal compressors. These requirements mirror existing cost-effective requirements set forth in NSPS OOOO and other federal rules.

For open ended valves and lines at well production facilities and compressor stations, the proposal requires that each such valve or line be equipped with a cap, blind flange, plug or second valve commencing January 1, 2015. Alternatively, the Division's proposal allows operators to treat open-ended lines and valves as components and monitor them in accordance with the proposed LDAR requirements. As part of its LDAR cost effectiveness analysis detailed above, the Division included the costs of inspecting and repairing open ended lines and valves in its overall calculation. While the Division has not identified specific information regarding the costs and emission reduction benefits from equipping open ended lines with a cap, blind flange, plug or second valve it notes that the requirement has been included in a multitude of federal air quality rules, including NSPS VV, NSPS VVa, MACT H, MACT CC, MACT TT, MACT YY, MACT GGG, MACT III, and MACT MMM, dating back as far as 1983. Based on this

NMED Exhibit 71

widespread prevalence in federal rules the Division believes that the proposal represents a simple and cost-effective strategy to reduce emissions from open-ended lines and valves. However, to the extent that it is not cost effective in a specific case operators can employ the monitoring option allowed for under the proposed rule.

For centrifugal compressors, the Division's proposal requires that hydrocarbon emissions from wet seal fluid degassing systems be reduced by 95% beginning January 1, 2015. In its updated technical support document for NSPS OOOO, EPA analyzed the cost-effectiveness of this strategy and found that accounting revenues from the capture of additional product, implementation of this strategy would on a per unit basis reduce VOC emissions by 19.5 tpy, methane emissions by 216.2 tpy, and result in a net cost savings of $46,974.[50]

With respect to reciprocating compressors, the Division's proposal requires that commencing January 1, 2015, the rod packing for reciprocating compressors located at compressor stations be replaced every 26,000 hours of operation or every 36 months. As with the requirement for centrifugal compressors, EPA analyzed this proposed strategy as part of the adoption of NSPS OOOO and found that it was a cost-effective way to reduce VOC and methane emissions. Specifically, EPA found that per compressor the strategy reduces VOC emissions by 1.9 tons per year and methane emissions by 6.8 tons per year, at a net cost of $43 per ton of VOC reduced and $12 per ton of methane reduced.[51]

3.3.8.1.7 Auto Igniter Requirements on Existing Flare Control Devices Outside the NAA

Unlike the NAA, flares used to control emissions at condensate tank batteries and glycol dehydration units outside the NAA are not required to have auto-igniters. The Division is proposing that all flares used to control emissions at condensate tank batteries and glycol dehydration units statewide should have auto igniters. Based on an analysis of the APEN database, the Division estimates the statewide number of existing flare control devices without auto-igniters on condensate tank batteries, glycol dehydration, produced water tanks, and crude oil tanks is 796. The reported uncontrolled actual emissions from these units are 53,101.1 tons per year VOC.

The estimated annualized cost for an auto-igniter is $475 based on information that the industry provided to the Division in 2008, adjusted for inflation.[52]

[50] See APCD-PHS Ex. HHHH pp. 6-1—6-3
[51] See initial technical support document for NSPS OOOO (submitted as DGS-PHS Ex. NN) at pp. 6-12—6-17.
[52] See "Oil & Gas Emissions Reduction Strategies Cost Analysis and Control Efficiency Determination," Lesair Environmental, Inc., June 2008.

NMED Exhibit 71

Table 36: Auto Igniter Control Device – Retrofit Cost Analysis				
Item	Capital Costs (one time)	Non-Recurring Costs (one time)	O&M Costs (recurring)	Annualized Total Costs
Auto Igniter	$1,648			
Freight/Engineering		$200		
Flare Installation		$500		
Maintenance			$200	
Subtotal Costs	$1,648	$700	$200	
Annualized Costs*	$228.4	$46.7	$200	$475

** Annualized over 15 years at 5% ROR*

The Division estimates that a flare without an auto-igniter could experience about 3% pilot light downtime (262.8 hours) over a one year period. During the downtime period, any VOC emissions routed to the flare control device are uncontrolled. Based on the total uncontrolled actual emissions of 53,101.1tons per year VOC from units equipped with flares without auto-igniters, the emissions during this downtime period will be 1,593.1 tons of VOC. The Division assumes that as a result of the installation of an auto-igniter, the amount of downtime can be eliminated, for a total emission reduction of 1,251.7 tons/year. Given that the annualized cost of installing 796 auto-igniters is about $378,100 the estimated cost effectiveness of this strategy is about $302 per ton of VOC reduced.

Table 37: Auto Igniter Emission Reduction Estimates				
Source Type for Existing Flare Controls	Number of Auto Igniters	Uncontrolled VOC [tpy]	Uncontrolled VOC Using 3% Downtime [tpy]	Total VOC Reduction [tpy]
Condensate Tanks	490	31,170.6	935.1	666.3
Dehydrators	131	16,372.0	491.2	466.6
Produced Water Tanks	172	4,842.2	145.3	103.5
Crude Oil Tanks	3	716.3	21.5	15.3
	796	53,101.1	1,593.1	1251.7

** Dehydrator flares assumed to have 100% capture and 95% destruction – thus 95% control. Tank flares are assumed to have 75% capture and 95% destruction – thus 71.25% control.*

Table 38: Auto Igniter Control Cost Estimates (Outside NAA)				
Number	Each Auto-Igniter Annualized Costs	Total Annualized Costs	VOC Reduction* [tons/year]	Control Costs [$/ton]
796	$475	$378,100	1,251.7	$302

NMED Exhibit 71

3.3.8.2 Expanding Low Bleed Pneumatics Requirements Statewide

As part of the 2008 Ozone Action Plan the Commission adopted regulatory requirements mandating the use of low bleed pneumatic controllers in the NAA. The current proposal would expand this requirement statewide.

To estimate the costs and benefits of this proposed strategy, the Division estimated the number of high-bleed pneumatic devices based on Independent Petroleum Association of the Mountain States (IPAMS) survey data from 2006, which identified the average number of such devices per well. The Division then scaled this number up based on 2012 COGCC well count data. Based on this methodology, there are 9,877 high-bleed pneumatic devices outside the NAA. Assuming a 95% replacement rate, the proposed rule will result in the replacement of 9,384 high bleed devices with low bleed devices. Based on this count, and the average emission reductions per device replaced identified in the IPAMS survey, the projected benefit from the proposed expansion of the current NAA low bleed pneumatic rule will be approximately 14,921 tons per year VOC (40.9 tons per day). Based on this information and assuming an 80/20 ratio of methane/ethane to VOC by volume, the estimated methane/ethane reduction from this strategy is 17,100 tons per year.

The average retrofit cost of a high-bleed pneumatic device is based on costs from the 2008 cost study[53] adjusted for inflation. Utilizing this methodology, the annualized cost for each replaced device is $169. However, because the reduced bleed rate results in more natural gas being sold, operators will receive additional revenue as a result of the installation of a low bleed device. Based on the emission reduction data from the IPAMS survey and August 2013 spot prices for natural gas, the estimated average value of the recovered gas will be $1,268 for each device replaced. As a result, the net annual gain is $1,084 per replaced device. Based on this projected net gain, this strategy will pay for itself in approximately one year and two months.

Table 39: Replace High-Bleed Pneumatics with Low-Bleed Pneumatics – Annualized Cost Analysis*

Item	Capital Costs (one time)	Non-Recurring Costs (one time)	O&M Costs (recurring)	Annualized Total Costs
Low/No Bleed Device*	$1,033			
Labor		$387		
Value of NG Saved**			$(1,268)	
Maintenance			$16	
Subtotal Costs	$1,033	$387	$(1,253)	
Annualized Costs***	$143	$26	$(1,253)	$(1,084)

** Control device costs were developed based on an Oil and Gas Cost Study and information submitted by industry in 2008. However, those costs were escalated by 9.85% to reflect CPI-U increases that have occurred since 2008.*
*** Recovered NG fuel costs $3.5/MCF (Henry Hub Spot Price - Aug. 2013)*
**** Annualized over 15 years at 5% ROR*

[53] See "Oil & Gas Emissions Reduction Strategies Cost Analysis and Control Efficiency Determination," Lesair Environmental, Inc., June 2008.

NMED Exhibit 71

Assuming 9,384 total devices replaced, adoption of this strategy will result in $10,169,441 in annual cost savings.

Table 40: Low Bleed Pneumatic Control Cost Estimates (Outside NAA)				
Number	Each Device Annualized Costs	Total Annualized Costs	VOC Reduction [tons/year]	Control Costs [$/ton]
9,384	$(1,084)	$(10,169,441)	14,921	NA

The proposed rule also requires the use of no-bleed pneumatic devices if it is technically and economically feasible and where on-site electrical grid power is being used. Use of no-bleed pneumatic devices will further reduce emissions relative to the use of low bleed devices. Since the Division does not have information indicating the number of no-bleed pneumatic devices that could be required, it is not possible to calculate the cost effectiveness of this particular provision. However, because the proposed requirement expressly provides that use of no-bleed pneumatics is only required where economically feasible the Division assumes that any use of no-bleed pneumatic devices pursuant to the proposed rule will be cost effective.

3.3.8.3 Require Newly Constructed Gas Wells be Connected to a Pipeline or Route Emissions to a Control Device

Currently in Colorado, natural gas produced at oil and gas sites is typically routed to a transmission pipeline. With the advent of new drilling technologies, additional areas of the state without established pipeline infrastructure may experience oil and gas exploration and production. This can lead to instances where produced gas is vented or flared instead of being put into a transmission line. To date the Division has identified 61 instances in Colorado where this is occurring. To address this, the proposed regulation provides that for newly constructed, hydraulically fractured, or recompleted wells, the gas stream must either be connected to a pipeline or routed to a control device achieving 95% control efficiency. Currently all of the sites that are not routed to a pipeline are flaring their gas. Additionally, because venting the gas at such sites would create a safety issue, the Division assumes that in the limited future instances where the gas stream is not routed to a pipeline, operators will route the emissions to a flare or other control device. Accordingly, adoption of this portion of the proposed regulation will likely not result in any additional costs.

3.3.8.4 Control Requirements for Glycol Dehydrators

The Division is proposing to revise the control requirements applicable to glycol natural gas dehydrators statewide. Currently any glycol natural gas dehydrator with uncontrolled actual VOC emissions of 2 tons per year or greater that is located at a facility where the sum of uncontrolled actual emissions from all of the dehydrators at the facility is greater than 15 tons per year, must be equipped with a control device that reduces emissions by at least 90%. Under the Division's proposal, all existing dehydrators with uncontrolled actual emissions of 6 tons per year or greater VOC must be controlled with air pollution control equipment achieving at least 95% reduction. The proposal also provides that existing dehydrators with uncontrolled actual emissions of two tons per year or greater VOC must be controlled if they are located within

NMED Exhibit 71

1,320 feet of a building unit or designated outside activity area. Finally, the proposal requires that all new dehydrators with uncontrolled actual emissions of two tons per year or greater VOC be controlled. The Division assumes that newly subject glycol dehydrators will be controlled using flares that achieve a 95% destruction efficiency. The annual cost for these units is $6,286.80 per unit.

Based on industry reported APEN data, there are currently 433 uncontrolled dehydrators at sites with total dehydrator uncontrolled actual VOC emissions below 15 tpy. Of these, 217 have uncontrolled actual emissions greater than or equal to two tons per year. The total uncontrolled actual emissions for these 217 dehydrators are 1,827.5 tpy VOC. There are 148 dehydrators with uncontrolled actual VOC emissions greater than or equal to 6 tons per year. The total uncontrolled actual emissions for these 148 dehydrators are 1,549.7 tpy VOC. Currently, the Division does not have information regarding the location of these uncontrolled dehydrators relative to a building unit or designated outside activity area. Assuming, however, that all of the 2 to 6 ton dehydrators are located within 1,320 feet of a building unit or designated outside activity area and thus will require a control, the proposed requirement will reduce 1,736 tpy of VOC at a cost effectiveness of $786/ton VOC. For the smallest dehydrator subject to the proposed rule (2 ton/year) the cost effectiveness is estimated to be $3309 per ton of VOC reduced.

Table 41: Dehydrator Control Cost Estimates (2 TPY Control Threshold)

Number	Each Device Annualized Costs	Total Annualized Costs	VOC Reduction [tons/year]	Control Costs [$/ton]
217	$6,286.8	$1,364,236	1,736	$786

Conversely, if it is assumed that none of the 2 to 6 ton existing dehydrators will require controls the proposed requirement will reduce 1,472 tpy of VOC at a cost effectiveness of $632/ton VOC.

Table 42: Dehydrator Control Cost Estimates (6 TPY Control Threshold)

Number	Each Device Annualized Costs	Total Annualized Costs	VOC Reduction [tons/year]	Control Costs [$/ton]
148	$6,286.8	$930,446	1,472	$632

3.3.8.5 Control Requirements for Downhole Well Maintenance and Liquids Unloading Events

Historically, Colorado has not regulated air emissions from temporary activities such as well completions and well maintenance at well production sites. Recently, however, EPA, Colorado and other jurisdictions have identified these activities as potentially large sources of emissions from the oil and gas sector. In recognition of this, the Colorado Oil and Gas Conservation Commission and more recently EPA have adopted requirements for green completions to reduce hydrocarbon emissions during well completion activities. The Division is now proposing additional regulatory requirements designed to reduce emissions during well maintenance.

NMED Exhibit 71

Well maintenance is required when, over time, liquids build up inside the well and reduce gas and oil flow out of the well. To remove these liquids and improve flow, the liquids are blown out of the well under pressure. This process is typically referred to as liquids load-out or well blow-down. Historically emissions from well blow-downs are vented to the atmosphere. EPA has established emission factors for liquid unloading based on fluid equilibrium calculations to calculate the amount of gas needed to blow down a column of fluids blocking a well and Natural Gas STAR partner data on the amount of additional venting after a blow-down. Based on its calculations, EPA estimated that in the United States the combined methane emissions for liquid unloading and well completions in 2009, was 217 billion cubic feet, and that liquid unloading may account for 33% of the uncontrolled methane emissions from the natural gas industry.[54] For Colorado, the Division has calculated that emissions from well blow-downs in 2008 were approximately 9,306 tons of VOC per year.

To address these emissions, the Division is proposing a two pronged requirement aimed at reducing the number of required liquids unloading events and reducing the amount of emissions vented to the atmosphere during these events. Under the Division's proposal operators shall use best management practices to minimize the need for venting associated with downhole maintenance and liquids unloading. For example, EPA's Gas Star program advocates the use of a plunger lift system to reduce the need for liquids unloading. According to EPA, use of a plunger lift will on average pay for itself in less than one year through the capture of additional product. The Division's proposal also provides that emissions during well maintenance and liquids unloading shall be captured or controlled using best management practices to limit venting during well blow-downs to the maximum extent practicable. Based on information provided by Environmental Defense Fund, application of these requirements could result in annual VOC reductions of 2,881 tons and methane reductions of 19,207 tons per year. Given the wide variety of practices that this could entail, the Division currently does not have information about the precise cost-effectiveness of this provision. Given the fact that the proposal only requires use of best management practices, which takes into account the cost of the practices in a given situation, the Division assumes that the proposed strategy will be cost effective.

4 CLOSING SUMMARY

On December 13, 2013, interested parties, stakeholders and state representatives filed requests for a Regulatory Analysis. This Regulatory Analysis is a careful and considerate response to those Requests and is a good faith effort on the part of the Division.

The Division has addressed, to the best of its ability, issues related to the entirety of proposed revisions to Regulation 3, 6, and 7. The Division believes that the proposal before the Commission reflects a balanced approach that includes proven and cost effective strategies to reduce emissions from the oil and gas sector, while enabling the sector to continue to grow in a responsible and protective manner. The Division looks forward to the Commission's consideration of its proposal and alternate proposals of other parties at the February 2014 hearing.

Executive Summary

This document provides an economic analysis of the proposed revisions to Colorado Air Quality Control Commission (AQCC) Rules. This analysis is focused on specific parts of the regulations, including the costs for flares and auto-igniters, pneumatic controllers, storage tank emission management (STEM), and LDAR for well production facilities and compressor stations. Louis Berger has also estimated the value of the product saved as a result of the LDAR programs for well production facilities and compressor stations. Additionally, Louis Berger analyzed the impacts to marginally producing wells as they become less economically viable and are shut in or plugged as regulatory costs increase, resulting in loss of production, operator revenues, royalties, and severance taxes. Finally, Louis Berger provides estimates on the costs to the state to implement the proposed rules and regulations. This document also provides support for industry's proposed language.

Economic Impact Analysis

Important results of the analysis are summarized in table ES-1 and described in the bullets below.

- Louis Berger estimated pollution control costs using information obtained from industry sources. Total costs to add flares and auto-igniters to tanks between 6 and 20 TPY uncontrolled VOC emissions are estimated to be $5.8 million, $511,680, and $7,872 for condensate, produced water, and crude oil tanks, respectively. Annualized costs of buffer bottles are estimated to be $5,850, with a total annual cost of $31.1 million.
- LDAR programs result in decreased emission reduction benefits after the initial year of program implementation. That is, after initial monitoring, leaks are found and fixed, resulting in reduced leak frequencies and emissions. These decreased leak frequencies in subsequent years affect the cost effectiveness of the regulations. As emissions reductions decline in subsequent years, LDAR annualized costs decrease by a smaller proportion; therefore, costs per ton of VOC reduced in subsequent years are significantly higher in subsequent years compared to the initial year of implementation. Figure ES-1 shows how the emission reductions decline while LDAR costs per ton of VOC increase after the initial year. This figure also demonstrates the disparity in costs for the facilities with differing levels of uncontrolled emissions, with lower emitting tanks having a much higher cost per ton of VOC reduced than the higher emitting tanks.

JIWG-REB EX. B

NMED Exhibit 71

Figure ES-1: STEM Emission Reductions and Cost Per Ton of VOC Reduced

- STEM costs are estimated to be $77.1 million in the initial year and $73.9 million in subsequent years, while the cost per ton of VOC reduced is $1,250 in the initial year and $5,097 in subsequent years, on a recurring annual basis.
- Inspections and LDAR programs are more expensive to implement in the attainment area in comparison to the relatively dense operations in the non-attainment area due to the additional travel time, travel expenses, and fewer inspections possible on an annual basis in the attainment area. The STEM costs show that across all tank levels, the attainment area tanks have $1,000 higher costs per tank per year than in the non-attainment area to implement this program. Similar results occur for well production facilities, with LDAR costs per facility in the initial year higher in the attainment area than non-attainment area for each level of monitoring required.
- LDAR costs for well production facilities are considerable, with initial year costs of $136.7M ($16,778 per facility) and subsequent recurring annual costs of $58.2 million ($7,138 per facility). The cost per ton of VOC reduced is $8,590 in the initial year and $19,354 in the subsequent years on an annual recurring basis.
- LDAR costs for compressor stations are $15.4 million in the initial year ($77,033 per compressor station) and subsequent recurring annual costs of $6.5 million ($32,336 per compressor station). The cost per ton of VOC reduced is $8,641 in the initial year and $15,416 in the subsequent years on an annual recurring basis.
- The total cost to expand the regulatory mandate to modify or retrofit high-bleed pneumatic devices statewide was estimated to be $32 million. This includes the cost to replace an

estimated 9,800 high-bleed devices that are located at facilities outside the nonattainment area. When considering the amount of gas that can be recovered with the low-bleed devices, payback of the costs are expected to occur within 2.8 years. .

- Louis Berger estimated the product savings that can be expected from LDAR requirements for well production facilities and compressor stations. In the initial year, the value of the product captured represents approximately 8.7 percent of the LDAR costs. In subsequent years, the value of the natural gas captured represents 4 and 5 percent of the LDAR costs in subsequent years for well production facilities and compressor stations, respectively. The Economic Impact Analysis requires an assessment of the cost for the Division to implement the proposed rule changes. Oversight of an LDAR program, STEM plans, and annual report review of 5,312 tank batteries, 5,312 well production facilities, and 200 compressor stations with possibly hundreds of thousands of components would require additional Division manpower. Louis Berger reviewed the revised (November 21, 2013) Regulations 3, 6 and 7 to understand the implementation costs to the Division associated with the new rules. The net increase in the number of labor hours at the Division as result of the proposed regulations is anticipated to be approximately 12,282 labor hours annually. Notably, the Division would need 5,600 hours to review and approve initial STEM plans required under Regulation 7, the largest estimated time commitment for the Division. This represents approximately 6.1 FTEs of additional staff for the Division to review, oversee, inspect, manage, and approve various requirements associated with the proposed rules. Therefore, Louis Berger concludes that the Division would incur additional net costs to implement the proposed requirements beyond current expenditures.

In order to gain an understanding of the potential indirect costs to businesses, in particular small businesses if the proposed rules were implemented, Louis Berger evaluated the impacts on small, marginally producing wells within the state. Marginally producing wells with production less than 2 BOPD represent over half (55 percent) of the total producing wells in the state (46,495) as of 2013. Under current economic and regulatory conditions, the economic limit for marginally producing wells was estimated to be 0.43 BOPD, which is the point at which revenues would no longer cover operating expenses and the well would be shut in. Additional operating costs associated with the proposed rules were estimated per well production facility and tank and included in the analysis. Over time, the additional cost burden would result in as much as 128.6 million barrels of oil being left in place and not produced. The calculated present values for these losses include $1.9 billion in lost revenue to producers, $384 million in lost royalties and $96 million in lost severance taxes.

- Support of Industry's Proposed Language

The results of the final economic impact analysis presented here support the industry's key suggested revisions to the Division's proposed rule. Specifically, the proposed revisions will allow similar emission reductions to be achieved in a cost effective, achievable, and reasonable manner. Key points to the analysis include:

- Diminishing marginal benefits associated with LDAR programs implies decreasing cost effectiveness after initial rounds of inspections and repairs. Reducing the monitoring to reflect

JIWG-REB EX. B

NMED Exhibit 71

successful LDAR implementation reduces costs and improves the cost effectiveness of the proposed rule compared to the Division's proposal while maintaining program integrity through realized emission reductions. The "step-down" of monitoring frequency, which rewards companies with four inspections with no leaks, is an example of how the industry changes to the proposed rule would provide incentives for industry to maintain compliance and reduce costs for good behavior.

- Generally, compliance costs of STEM and LDAR for small tanks and well production facilities are more burdensome than for larger facilities on a cost per ton basis. As such, requiring a one-time LDAR inspection and monthly AVO for all facilities (including all well production facilities) with uncontrolled emissions between 2 and 6 TPY would improve the overall cost effectiveness of the proposed rule by limiting the very high costs per ton of VOC reduced incurred by very small facilities with very small VOC fugitive emissions.
- Compliance costs are higher for operations outside of the non-attainment area as the distance among facilities and tanks increases inspection travel time and expenses. Limiting the geographic scope to the non-attainment area will improve the cost effectiveness of the proposed rule.
- Allowing for the use of other established technology, such as the tunable diode laser absorption spectroscopy technology (TDLAS) as an option for inspection monitoring, would reduce costs to industry with faster inspections and reduced camera training requirements, among other factors.

NMED Exhibit 71

Economic Impact Analysis

This document provides an economic analysis of the proposed revisions to Colorado Air Quality Control Commission (AQCC) Regulation Number 3, 6 and 7. This analysis is focused on the specific parts of the regulation, including the costs for flares and auto-igniters, STEM, LDAR for well production facilities and compressor stations, and pneumatic controllers. Louis Berger has also estimated the value of the product saved as a result of the LDAR programs for well production facilities and compressor stations. Additionally, Louis Berger analyzed the impacts to marginally producing wells as they become less economically viable and are shut in or plugged as compliance costs increase resulting in a loss of production, operator revenues, royalties, and severance taxes. Finally, Louis Berger provided estimates on the costs to the state to implement the proposed rules and regulations.

Lowering Statewide Tank Control Threshold (from 20 tpy to 6 tpy)

Louis Berger evaluated the costs to industry associated with installing flares and auto-igniters on condensate tanks with uncontrolled emissions between 6 TPY and 20 TPY. The analysis used the state's estimate of 588 condensate tanks that that would be affected by the change in the regulatory threshold, along with updated costs estimated by the EPA and in the industry survey.

Louis Berger developed cost estimates for flares and auto-igniters using data and information obtained from an industry survey conducted in 2013 and data from the EPA. The capital, non-recurring and annual costs were obtained from the EPA.[1] Because the costs were reported in 2008 dollars they were escalated to 2013 dollars using the GDP price index obtained from the U.S. Office of Management and Budget.[2] These costs were annualized for an 11-year life of the equipment based on information obtained from the industry survey at a 5 percent interest rate. The annual cost for the flare is estimated to be $9,840 (Table 1).

Table 1: Estimated Cost for Flares and Auto-Igniters

Item	Estimated Cost (2013$)
Capital and Non-Recurring Cost	$35,070
Annual Costs	$5,823
Annualized Capital Costs	$4,018
Total Annual Costs	**$9,840**

The Division estimated the cost per ton of VOC emission reductions by lowering the statewide tank control threshold from 20 TPY to 6 TPY. According to the Division's analysis, there are 588 condensate tanks that would be affected by this rule change and that by adding flares to these particular tanks, VOC emissions would decline by 5,162 TPY. Louis Berger analyzed the cost of lowering the threshold from 20 tpy to 6 tpy using the flare cost estimate summarized above. The results are summarized in Table 2.

JIWG-REB EX. B

NMED Exhibit 71

When the costs are separated by uncontrolled emissions, the differences are significant. For tanks with lower uncontrolled emissions (6 to 10 TPY), the control costs are double what they are for the higher emitting tanks (between 10 and 20 TPY). Average cost per ton of VOC reduced is estimated to be $1,121.

Table 2: Estimated Cost Per Ton of VOCs Reduced for Condensate Water Tanks

Uncontrolled Emissions	Number of Tank Batteries Affected	Average Uncontrolled Emissions per tank	Total Uncontrolled Emissions	Emission Reduction with Flare and Auto-Igniter	Total Cost of Flares Per Tank Category	Cost Per Ton of VOC Reduced Per Tank Category
(1)	(2)	(3)	(4) = (3) * (2)	(5) = (4) * 0.7125	(6) = (2) * $9,840	(7) = (6)/(5)
6 to 10	235	7.35	1,729	1,232	$2,314,368	$1,879
10 to 20	353	13.98	4,932	3,514	$3,471,552	$988
Total Affected (State Estimate)	**588**	**12.32**	**7,244**	**5,161**	**$5,785,920**	**$1,121**

Using the same logic and data as described for condensate tanks, the controls for produced water tanks and crude oil tanks yields the following results. According to the Division's analysis, there are 52 produced water tanks and 8 crude oil tanks. Louis Berger believes that there are considerably more crude oil tanks than are reported in the APEN. However, without additional data, Louis Berger used the Division's estimate of 8. Cost per ton of VOC reduced for produced water and crude oil tanks are estimated to be $1,121 and $670, respectively.

Table 3: Estimated Cost Per Ton of VOCs for Produced Water Tanks

Emission Capture Requirements for Controlled Petroleum Storage Tanks

This section of the analysis evaluates requirements under the Storage Tank Emissions Management (STEM) plan, including costs of adding a buffer bottle and implementing a LDAR program. With data collected from the industry survey conducted in 2013, Louis Berger estimated an annual cost for buffer bottles of $5,850, as described in Table 5.

Table 5: Estimated Cost for Buffer Bottles

Item	Estimated Cost (2013$)
Capital and Non-Recurring Cost	$25,000
Annual O&M Costs	$2,500
Annualized Capital Costs*	$3,350
Total Annual Costs	**$5,850**

*Capital costs and non-recurring costs were annualized over 9 years, the estimate life of the control technology.

The STEM program would require instrument based monitoring. The monitoring frequency would be based on the uncontrolled emissions of various tanks as reported in the APEN database. Louis Berger estimated the LDAR costs using data and information obtained through an operator survey and follow up interviews. Table 6 summarizes the cost assumptions for the analysis.

Travel and per diem costs (AA Condensate)	$40					$40/inspection
Supervision	$100 (annual, quarterly) $200 (monthly)		Tank			$100/tank/year $200/tank/year
Compiling data, record-keeping and reporting	$1,530 (annual, quarterly) $3,060 (monthly)		Tank			$1,530/tank/year $3,060/tank/year

*Camera and set up costs annualized at 5% over 5 year-life of the equipment.

Louis Berger estimated the repair costs using information from a Canadian study and a Trihydro report that provide estimates of the number of components, potential number of leaks, and average leak

JIWG-REB EX. B

NMED Exhibit 71

frequency for production tanks.[3] Louis Berger assumed for this cost estimate that the typical production tank in Colorado has 38 components (Clearstone Engineering 2013) with an initial leak rate of 1.7 percent (Trihydro 2014), which equates to 0.65 components discovered leaking during each inspection. The Trihydro report indicates that subsequent leak frequencies associated with quarterly LDAR drop to 0.4 percent (0.15 leaking components per production tank), which was used to estimate the number of leaks repaired and re-monitored in subsequent years. Costs to repair components were obtained from Nelson and Brown (2012) and include only the labor needed to repair the leak, not materials and equipment costs.[4] Data and cost assumptions for the repair and re-monitoring costs are summarized in table 7. The re-monitoring cost was assumed to apply to the 25 percent of leaks, and the inspection and travel costs were obtained from the operator survey, with a cost estimate of $480 per inspection in the non-attainment area and $640 in the attainment area.

Table 7: Repair and Re-monitoring Cost Assumptions

Percent of Leaks	Type of repair	Repair Time (hours)	Hourly Rate	Re-monitor Cost (per leak)
75%	On-line	1	$75	-
25%	On the ground	4	$75	$480 (NAA) $640 (AA)

The total estimated cost of the proposed STEM program, which includes the costs for the inspections and the buffer bottles, are summarized in the following two tables. Total STEM costs include annualized capital costs, recurring inspection, operations, and maintenance costs, buffer bottle costs, repair costs, and re-monitoring costs. Total costs for all storage tanks are estimated to be $77.1 million, of which the non-attainment area tanks account for $64.1 million. When comparing the costs per condensate tank in the attainment area and non-attainment area over all the different types of tanks, costs per tank in the attainment area are approximately $1,000 higher than tanks in the non-attainment. The higher costs in the attainment area due to longer travel times and per diem costs, as ability to perform fewer inspections on an annual basis. For the greater than 50 TPY tanks, the STEM costs are $23,676 per tank in attainment area compared with the non-attainment area STEM costs of $20,966 per tank. The STEM costs are provided in Tables 8.1 and 8.2.

As a result of initial implementation of a LDAR program, it has been shown that leak frequencies decrease from 1.7 percent to 0.4 percent (Trihydro 2014). Therefore, in subsequent years, the number of leaks was adjusted to reflect the reduced leak frequency. The reduced leak repair and re-monitoring costs with the adjusted number of leaks were estimated and shown in table 9. It is assumed that subsequent LDAR and AVO capital (annualized), recurring annual, and annualized buffer bottle costs would remain as estimated in the initial year (table 8), while the number of repairs and re-monitoring needed would fall as the leak rate frequency also falls in subsequent years (table 9). The total STEM costs for subsequent years, shown in table 9, include the capital, inspection and O&M costs, and buffer bottle costs in table 8, with the adjusted leak repair and re-monitoring costs in table 9.

To better understand the costs per ton of VOCs reduced across the different levels of uncontrolled emissions, Louis Berger queried data from the APEN database provided by the Division to identify the uncontrolled emissions for the various tanks which is summarized in table 10.[5]

[5] The following Exhibits were analyzed on the state's rulemaking ftp site: APCD-PHS EX TT (produced water tanks), APCD-PHS-EX-LL (condensate tanks), APCD -PHS- EX - MM (crude oil tanks), APCD-PHS EX- (STEM emission control).

Table 10: Uncontrolled Emissions for Tanks

The approach used by Louis Berger for the initial emission reductions (year 1) is very similar to that of the Division's: the uncontrolled emissions less the control for the flares (71.25%) or 0.2876 percent of the uncontrolled emissions, times 95 percent. *Note that the Division's efficiency rate for the flare and auto-igniter of 71.25 percent is not supported by empirical data or industry literature, nor is it consistent with EPA guidance regarding the estimated effectiveness of such control requirements for air quality planning purposes[6]. These sources would suggest that the control efficiency of flares is considerably higher than the estimates by the Division, and the effectiveness of such control requirements is also higher (83% under EPA's noted revised rule effectiveness guidance, not 75%). As such, the emission reductions attributed to STEM in this analysis (as well as in the Division's analysis) are likely overestimated. The cost per ton of VOC reduced associated with STEM are therefore likely to be higher than estimated in this analysis due to the higher efficiency factor of the flare, with fewer fugitive emissions to capture with STEM.*

The initial year results reveal an average of $1,250 per ton of VOC reduced. Emission reductions in subsequent years are much smaller than initial reductions, especially with leak definitions as low as 500 and 2,000 PPM. The Clearstone study has indicated that annual leak detection and monitoring emissions factors result in a net reduction of 75.3 percent compared to what would occur without instrument monitoring.[7] This is consistent with Trihydro's estimated drop in leak rate frequencies after quarterly LDAR from 1.7 percent to 0.4 percent (Trihydro 2014). Louis Berger assumed that the emissions

[6] Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Regulations, Appendix B, Doc.No. EPA-454/R-05-001 (August 2005).
[7] See Clearstone Engineering study previously cited, page 19.

JIWG-REB EX. B

NMED Exhibit 71

reductions captured in subsequent years would be consistent with this decline in leak frequency. For example, if STEM was assumed to reduce emissions by 100 TPY in the initial year, the subsequent emissions reductions would be 23.5 percent (0.4/1.7) of the initial reduction.

It should be noted that the smaller tanks incur significantly larger costs per ton of VOC reduced. In the initial year, these costs per ton are $4,800 for tanks between 6 and 12 TPY uncontrolled emission, while tanks above 50 TPY, the initial year cost is $555 per ton reduced. Across all tanks, the subsequent year cost per ton of VOC reduced is approximately ***four times as high*** as the initial year cost, with the average cost in the subsequent years of $5,097 per ton of VOC reduced compared to the initial year cost per ton of VOC reduced of $1,250. This is due primarily to the effectiveness of the initial year LDAR in reducing fugitive emissions to a quarter of initial year rate. Despite the relatively higher travel and inspection costs in the attainment area, since the non-attainment area is where the overwhelming majority of tanks are located, there is not a considerable difference in the cost per ton of VOC reduced between these two geographic regions. However, as shown in Table 9, the tank STEM costs are more than $1,000 higher for attainment area tanks when compared to non-attainment tanks (for all tank uncontrolled emissions). Table 11 shows the initial year and subsequent total costs, emission reductions, and costs per ton of VOC reduced.

Figure 1 shows how the emission reductions decline after the initial year while LDAR costs per ton of VOC increase after the initial years. This figure also demonstrates the disparity in costs for facilities with different levels of uncontrolled emissions, with the lower emitting tanks having a much higher cost per ton of VOC reduced than higher emitting tanks. Over time, STEM for the tanks with the smallest uncontrolled emissions control the least amount of VOC emissions with the highest cost per ton of VOC ($20,172), while STEM for the tanks with the highest uncontrolled emissions capture the greatest amount of emissions and have the lowest cost per ton of VOC reduced ($2,192).

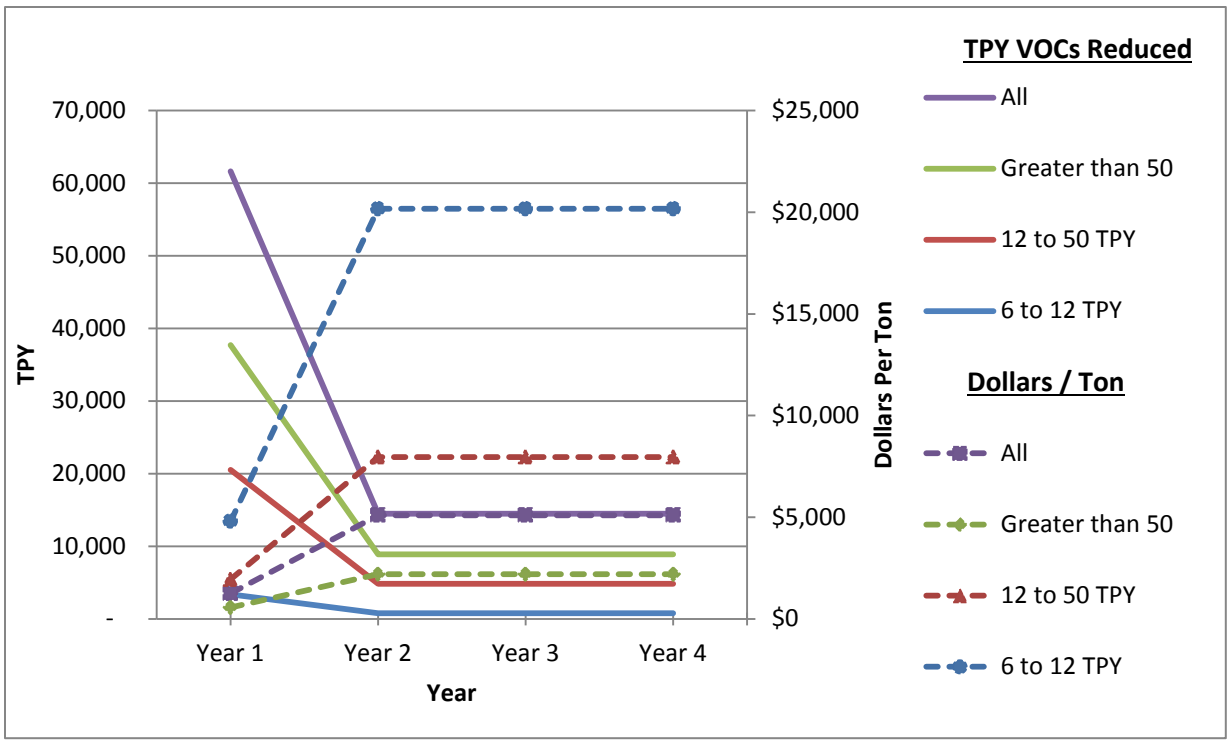

Figure 1: STEM Costs and Emission Reductions Over Time

Leak Detection and Repair Requirements for Well Production Facilities

The Division's proposed regulations include leak detection and repair requirements for well production facilities. The Division has based the LDAR monitoring frequency associated with these facilities on the uncontrolled VOC emissions with associated tanks. However, the Division's well production facility data (Exhibit RR) indicates that the tank VOC uncontrolled emissions do not correlate with fugitive emissions from well production facilities. The correlation coefficient is 0.19 indicating a weak positive correlation among the well production facilities and tank VOC uncontrolled emissions. For example, one tank had uncontrolled VOC emissions of 1,000 TPY, while the well production facilities accompanying the tank had a reported 2.4 TPY of VOC uncontrolled emissions. Regardless, the Division is requiring LDAR monitoring at various frequencies based on tank VOC uncontrolled emissions levels, and this section provides an estimate of the costs of these requirements to industry.

Louis Berger estimated LDAR inspection costs for well production facilities with a similar approach as described above for tanks. The Division has indicated that well production facilities would take on average 4.75 hours to inspect, which is consistent with Louis Berger's estimate of two facilities could be inspected per day in the non-attainment area. However, it is assumed that facilities in the attainment area would require an additional hour for travel time due to more remote operations and greater distance to access operations. Table 12 summarizes these assumptions for well production facilities.

*Camera and set up costs annualized at 5% over 5 year-life of the equipment.

Similar to the storage tank analysis, data on costs to repair components for well production facilities were obtained from Nelson and Brown (2012).[8] The initial and subsequent year leak frequency rates were assumed to be 1.7 percent and 0.4 percent, respectively, consistent with the Trihydro report (2014) and Clearstone Engineering (2013) study. The number of components was consistent with the

[8] Nelson, Bradley and Heather Brown. 2012. Equipment Leak Emission Reduction and Cost Analysis for Well Pads, Gathering and Boosting Stations, and Transmission and Storage Facilities Use Emission and Cost Data from the Uniform Standards. Memorandum to Greg Nizich and Bruce Moore, EPA. April. See attachments 3 and 4.

JIWG-REB EX. B

NMED Exhibit 71

analysis in the EPA technical memorandum, based on the well pad model plant 2, with an average number of components of 592.[9] As shown in the Division's analysis of its 40 well production facilities (Exhibit RR), the uncontrolled emissions of the tanks do not correlate with the components and uncontrolled emissions of the well production facilities. Additionally, information on 40 well production facilities does not provide a representative sample of well production facilities across the state, accounting for facilities in only five counties. As a result, without further information on the well production facilities, we used a constant number of components and uncontrolled emissions factors for all the well production facilities based on the EPA technical report (2011), consistent with information obtained from communications with industry representatives.

LDAR costs for well production facilities for the first year were estimated by Louis Berger using the approach described above to be $136.7 million, of which 81 percent of the cost is attributed to well production facilities in the non-attainment area. For each of the various tank uncontrolled emissions levels, the costs per well production facility are greater in the attainment area when compared to those in the non-attainment area. However, when averaged across all the facilities, since there are more higher cost tanks (in the 12-50 TPY and over 50 TPY) in the non-attainment area than in the attainment area, the per well production facility cost is actually higher in the non-attainment area. The LDAR costs are summarized in Tables 13.1 and 13.2.

Similar to the storage tank STEM analysis, following the initial implementation of a LDAR program, leak frequencies decrease, and as a result, the number of leaking components also decrease along with repair and re-monitoring costs, when compared to the initial year. Therefore, in subsequent years, the number of leaks was adjusted to reflect the reduced leak frequency (0.4%). As a result, reduced leak repair and re-monitoring costs with the adjusted number of leaks were estimated and shown in table 14. The total LDAR costs for subsequent years include the capital, and inspection and O&M costs in table 13 with the adjusted leak repair and re-monitoring costs in table 14. The exception is for well production facilities with tanks less than 6 TPY, which have been adjusted to include costs for a one-time LDAR inspection and monthly AVO.

To better estimate the potential uncontrolled emissions from these facilities, uncontrolled emission factors from the well pad model number 2 were used from the EPA technical document.[10] As described above, the tank uncontrolled emissions factors do not correlate with uncontrolled emissions associated with the well production facilities.[11] Additionally, the Division has utilized a very small sample of the well production facilities in the state for its analysis. As a result, Louis Berger used the VOC uncontrolled emissions per well production facility of 2.56 TPY associated with well pad model number 2 (592 components), which we believe more accurately reflects the types of facilities operating in Colorado based on communication with industry representatives. Table 15 summarizes the uncontrolled emissions for well production facilities.

[10] See EPA (2011) previously cited, tables 8-2, 8-3, and 8-10.
[11] See Division's analysis of 40 well production facilities in Exhibit RR in the rulemaking documents.

Louis Berger again uses an approach which utilizes a Canadian study, described above, and assumes an across the board reduction of 75.3 percent of uncontrolled emissions in the initial year with a one-time and annual LDAR program. The quarterly LDAR program is assumed to reduce emissions in the initial year by 76.5, consistent with the report by Trihydro (2013), and monthly LDAR is assumed to be even more effective, reducing emissions by 80 percent in the initial year. The average initial year cost per ton of VOC reduced across all well production facilities was estimated to be $8,590 per ton.

As with the STEM program, subsequent emission reductions in future years are expected to be much lower than in the initial year. The emission reductions in subsequent years are assumed to decline by the same proportion as the decline in leak frequency (0.4/1.7). The emission reductions were then divided by total annual costs in subsequent years to estimate the cost per ton of VOC reduced. In subsequent years, the average cost is $19,354 per ton of VOC reduced, approximately twice the initial year cost. Since uncontrolled emissions per well production facility are assumed constant across all of the tank uncontrolled emissions levels, the costs per tons of VOC reduced increase significantly with the higher tank VOC uncontrolled emissions levels (greater than 50 TPY) as more monitoring is required of these facilities. The cost per ton of VOC reduced for well production facilities is $45,855 in subsequent years for the greater than 50 TPY, while 12 to 20 TPY facilities incur a cost of $20,261 per ton of VOC reduced in subsequent years.

JIWG-REB EX. B

NMED Exhibit 71

When comparing across the geographies, the costs per ton reduced are approximately $1,000 more in the attainment area when compared to costs in the non-attainment area. Table 16 and Figure 2 shows the initial and subsequent year total costs, emission reductions, and cost per ton of VOC reduced.

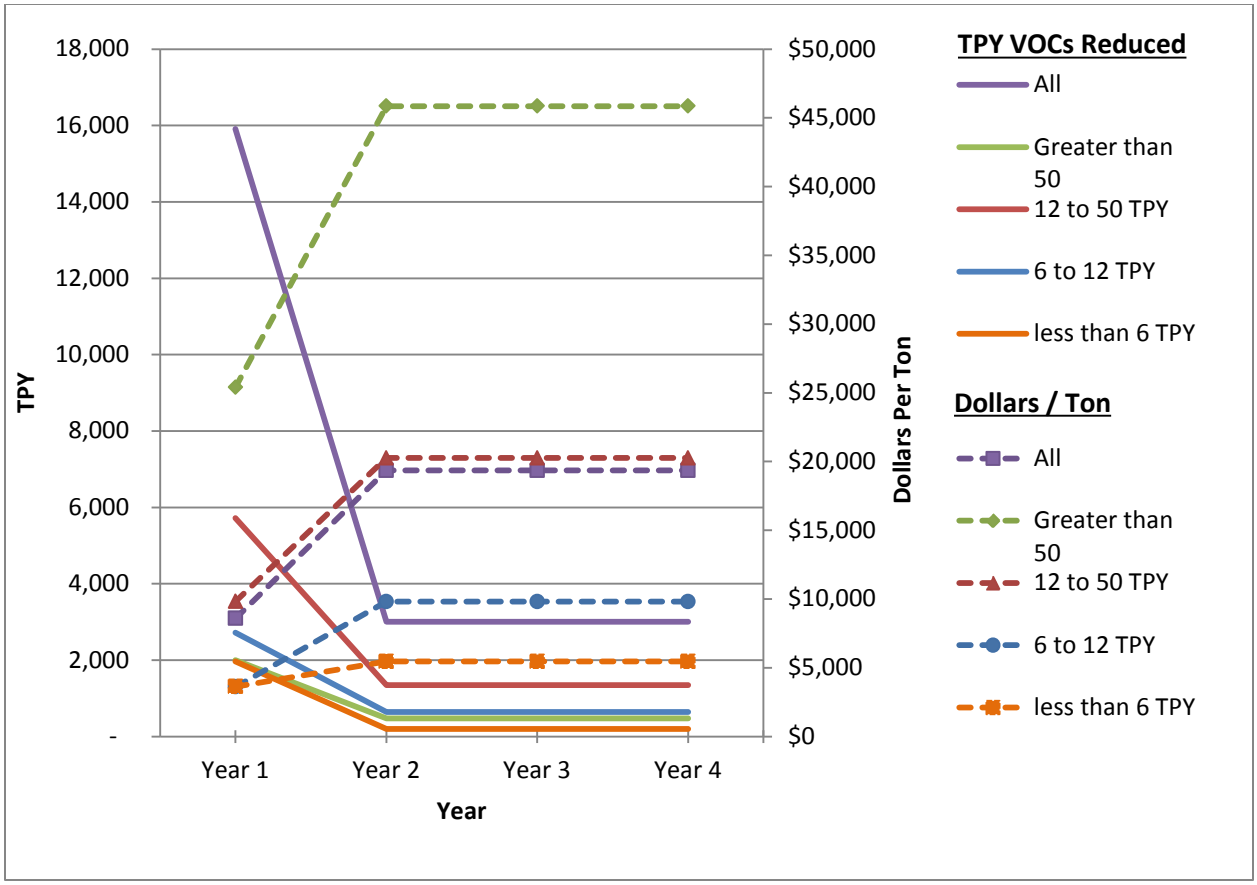

Figure 2: Well Production Facilities LDAR Costs and Emission Reductions Over Time

LDAR Costs for Compressor Stations

Louis Berger estimated LDAR costs for compressor stations with a similar approach as described above using the Division's estimates of the number of compressor stations affected by the proposed regulations. Louis Berger assumed two and four days per inspection for small and large compressor stations, respectively. Table 17 summarizes these assumptions.

JIWG-REB EX. B

NMED Exhibit 71

Table 17: Compressor Station LDAR Cost Assumptions (2013$)

Item	Estimated Cost	Annualized*	Unit Cost
Capital and Non-Recurring Costs			
Camera	$122,000	$28,179	$282 per inspection for small CS and $564 for large CS
Vehicle	$30,000	$6,929	$69 per inspection for small CS and $139 for large CS
Program set up costs (i.e., Tagging, software, travel, etc.)	$13,688 for small compressor stations, and $27,272 for large CS	$1,319 for small CS and $2,627 for large CS	$1,319/small CS and $2,627/large CS
Assume inspections would take 2 days to inspect for smaller facilities, 100 inspections with one camera per year; inspections would take 4 days for larger facilities, 50 inspections with one camera per year.			
Inspection, Operations and Maintenance costs			
Small CS with Annual LDAR	$6,468		$6,468/year/CS
Large CS with Quarterly LDAR	$32,683		$32,683/year/CS
Travel and per diem costs	$32		$32/Inspection
Supervision	$200		$200/CS
Camera Repair	$12,500		$12,500/year/camera
Camera Training	$7,500		$7,500 per 100 CS
Record-keeping and reporting of comments	$1,530 for small CS $3,060 for large CS		$1,540/small CS $3,060/large CS

*Camera and vehicle costs annualized at 5% over 5 year-life of the equipment. Program set up costs are annualized over 15 years at 5%.

Similar to the previous analysis, data on costs to repair components were obtained from Nelson and Brown (2012).[12] The initial year leak frequency rate was assumed to be 1.17 percent, consistent with the Trihydro study (2014). The number of components was assumed to be 2,544 for small compressor stations and 6,744 for large compressor stations. Cost assumptions for repairs and re-monitoring are similar to those described above.

Tables 18.1 and 18.2 summarize the LDAR costs for compressor stations. LDAR costs for 200 compressor stations were estimated to be $15.4 million. Small compressor stations are estimated to incur $26,353 per facility in the initial year, while larger compressor stations would incur $217,599 per facility in the initial year.

Similar to the storage tank STEM analysis, following the initial implementation of a LDAR program, leak frequencies decrease, and as a result, the number of leaking components also decrease along with repair and re-monitoring costs, when compared to the initial year. Therefore, in subsequent years, the number of leaks was adjusted to reflect the reduced leak frequency (0.4%). As a result, reduced leak repair and re-monitoring costs with the adjusted number of leaks were estimated and shown in table 19. The total LDAR costs for subsequent years include the capital, and inspection and O&M costs in table 18 with the adjusted leak repair and re-monitoring costs in table 19.

JIWG-REB EX. B

NMED Exhibit 71

Table 19: Compressor Station LDAR Cost Analysis for Subsequent Years

Compressor Stations Uncontrolled VOC Emissions	Monitoring Frequency	Number of Components	Annual Number of Leaks	Leak Repair Costs (3)	Re-monitor Costs (4)	LDAR Costs for Compressor Stations in Subsequent Years (Annual Cost) (1+2+3+4)	Per Compressor Station Cost, Subsequent Years
Less than 12	annual	2,544	1,496	$196,333	$373,968	$2,020,457	$13,745
12 to 50 TPY	quarterly	6,744	5,719	$750,607	$1,429,728	$4,446,685	$83,900

Total	**-**	**9,288**	**7,215**	**$946,940**	**$1,803,696**	**$6,467,142**	**$32,336**

The Division has identified an average uncontrolled emission rate for compressor stations of 10.1 TPY of VOCs for small compressor stations and 16.4 for large compressor stations, respectively. Louis Berger used these assumptions for uncontrolled emissions for the analysis as summarized in Table 20.

Table 20: Uncontrolled Emissions for Compressor Stations

Compressor Stations Uncontrolled VOC Emissions	Monitoring Frequency	Number of Compressor Stations	Uncontrolled VOC Emissions per Compressor Station (TPY)	Total Uncontrolled VOC Emissions (TPY)
Less than 12 TPY	annual	147	10.1	1,485
12 to 50 TPY	quarterly	53	16.4	869
Greater than 50	monthly	-	-	-
Total	**-**	**200**	**-**	**2,354**

Similar to the analyses on storage tanks and well production facilities, Louis Berger again uses the emission reductions associated with annual LDAR from the Clearstone Engineering, Ltd. study, described above, which estimates 75.3 percent emissions reductions associated with the annual LDAR program. Quarterly LDAR monitoring is assumed to be slightly more effective, reducing emissions by 76.5 percent, consistent with declining leak frequencies documented in the Trihydro report (2014).

As with tanks and well production facilities, Louis Berger accounts for subsequent year emission reductions with LDAR for compressor stations. The emission reductions in subsequent years are assumed to decrease by the proportion based on the reduction in leak frequency (0.4/1.7). The subsequent year costs were then divided by emission reductions in subsequent years to estimate the cost per ton of VOC reduced. Initial year cost per ton of VOC reduced is $8,641, while in subsequent years, the cost per ton of VOC reduced increases to $15,416. Table 21 shows the initial year and subsequent year total costs, emission reductions, and cost per ton of VOC reduced.

Expanding Low Bleed Pneumatics Requirements Statewide

The Division is proposing to expand statewide the regulatory requirements mandating the use of low bleed pneumatic controls that were adopted for the nonattainment area in 2008. This section estimates the cost of the requirement to industry.

Under the proposed rules, high-bleed pneumatic controllers shall be replaced or retrofitted with low-bleed pneumatic devices by May 1, 2015. It is assumed that the Division would define a low-bleed pneumatic device as one that emits less than or equal to 6 standard cubic feet per hour (scfh), while high-bleed devices bleed at a rate greater than 6 scfh. The Division has estimated that 9,877 high-bleed pneumatic devices are being utilized outside the nonattainment area. Louis Berger utilizes this estimate of the number of devices that will need to be replaced to comply with the proposed rule.

The EPA through their Natural Gas Star Program, has evaluated the effectiveness of reducing methane emissions through the replacement of high-bleed pneumatic devices with low-bleed pneumatics. In the document titled, "Options for Reducing Methane Emissions from Pneumatic Devices in the Natural Gas Industry", EPA provides estimates of costs, service life, benefits and decision process for determining the feasibility of replacing high-bleed pneumatics.[13] The costs of several models of pneumatic devices are summarized in Appendix B and range from $380 to $3,500 in 2006 dollars. In addition, EPA reported the average cost of a low-bleed pneumatic device of $2,553 in 2008 dollars. Based on this information, Louis Berger assumes the cost of low-bleed pneumatic devices averages $2,775 adjusted to 2013 dollars. In addition, the analysis assumes a service life of 5 years[14] and cost are annualized at a 5 percent interest rate.

Replacement of pneumatic devices would require an initial assessment of the devices used at various facilities. The EPA suggests that a system-wide or facility-specific pneumatic survey would need to record for each device "location, function, make and model, condition, age, estimated remaining useful

[13]U.S. EPA, "Options for Reducing Methane Emissions from Pneumatic Devices in the Natural Gas Industry", October, 2006.

JIWG-REB EX. B

NMED Exhibit 71

life, and bleed rate characteristics (volume and whether intermittent or continuous)."[i] Louis Berger has estimated the cost of conducting a pneumatic survey in the cost of the regulatory mandate as summarized in Table 22. Total cost of the mandate is estimated to be $32 million.

Table 22: Estimated Cost of Low-Bleed Pneumatic Devices

Item	Estimated Cost	Annualized*
Capital and Non-Recurring Costs		
Low-Bleed Pneumatic Devices	$2,775	$641
Pneumatic Survey	$500	$115
Total Cost	**$3,275**	**$756**

*Annualized at 5% over a five year service life.

Replacing high-bleed pneumatics with low-bleed devices will likely result in gas savings and the value of these savings per device are estimated in Table 23. Payback period is estimated to be 2.8 years.

Table 23: Gas Savings Associated with Low-Bleed Pneumatic Devices

Estimated Annual Bleed Emission Reductions (Methane) (Tons)[ii]	Gas Volume (Mcf)	Gas Price ($/Mcf)	Value of Gas Recovered
(1)	(2) = (1)*40.49 Mcf/ton	(3)	(4) = (3) * (2)
6.65	269	$4.34	$1,168

Recovered Product Estimates Attributable to proposed STEM and LDAR Requirements

In their analysis of cost effectiveness of LDAR requirements, the Division "…assumes that the costs savings from additional product capture will be equal or greater than the cost of repair and re-inspection."[15] In order to test the validity of this assumption, Louis Berger estimated the product savings that can be expected from LDAR requirements for well production facilities and compressor stations.

Gas Savings Attributed to LDAR – Well Production Facilities

Product savings attributable to the LDAR program as it relates to well production facilities in the initial year are estimated as shown in Table 24. Column 1 shows that 15,913 tons of VOCs are estimated to be detected and captured by the LDAR program for all well production facilities in the initial year of the program (see Table 16). Louis Berger used a Gas/VOC ratio (22.4%) reported by the Division in their analysis of LDAR costs of well production facilities to estimate the amount of gas that would be captured by the controls. In this case, 71,040 tons of gas is expected to be captured by the LDAR program at well production facilities in the initial year. The gas mass was then converted to a volume metric using a

[15]Colorado Air Quality Control Commission 2014. Updated Economic Impact Analysis for Proposed Revisions to AQCC Regulations Number 7. Submitted with Pre-Hearing Statement on January 6, 2014. Page 17.

JIWG-REB EX. B

NMED Exhibit 71

natural gas density factor and results in 2,876,121Mcf of gas recovered. The value of the recovered gas was estimated at $12.4 million for the initial year using a recent natural gas price of$4.34 Mcf. The value of the product savings equates to 8.8 percent of the total LDAR costs ($136 million) for the initial year of implementation.

Table 24: Product Savings Attributable to the LDAR Program for Well Production Facilities for the Initial Year

Tons of VOCs Captured by LDAR Program at WPF	Average Gas/VOC Ratio[1]	Tons of Methane Captured by LDAR Program for WPF (Tons)	Natural Gas Volume Recovered (MCF)[2]	Natural Gas Price ($/Mcf)[3]	Value of Recovered Gas
(1)	(2)	(3) = (1) / (2)	(4) = (3)/0.0247 ton/mcf	(5)	(6) = (4) * (5)
15,913	22.4%	71,040	2,876,121	$4.34	$12,482,363

[2] Natural gas volumes calculated by assuming a gas density of 0.791 kg/m3 and converted to English units.

[3] Henry Hub Natural Gas Spot Price for December, 2013. Obtain from the Energy Information Agency at http://www.eia.gov/dnav/ng/hist/rngwhhdm.htm.

For subsequent years, the LDAR program at well production facilities is expected to realize product savings though they are expect to decline from the initial year. An estimate of the amount and value of the product saved is estimated as shown in Table 25. Using the same approach as used for the initial year, the amount of natural gas expected to be recovered in subsequent years is estimated to be 543,125 Mcf and is valued at $2.3 million which is less than four percent of the total annual LDAR costs in subsequent years.

Table 25: Product Savings Attributable to the LDAR Program for Well Production Facilities for Subsequent Years

Tons of VOCs Captured by LDAR Program at WPF	Average Gas/VOC Ratio[1]	Tons of Methane Captured by LDAR Program for WPF (Tons)	Natural Gas Volume Recovered (MCF)[2]	Natural Gas Price ($/Mcf)[3]	Value of Recovered Gas
(1)	(2)	(3) = (1) / (2)	(4) = (3)/0.0247 ton/mcf	(5)	(6) = (4) * (5)
3,005	22.4%	13,415	543,125	$4.34	$2,357,161

[1] Taken from the Division's calculation on LDAR costs for well production facilities. Spreadsheet titled "APCD-PHS EX-RR.xlsx"; sheet: statewide wells model FAC.

[2] Natural gas volumes calculated by assuming a gas density of 0.791 kg/m3 and converted to English units.

[3] Henry Hub Natural Gas Spot Price for December, 2013. Obtain from the Energy Information Agency at http://www.eia.gov/dnav/ng/hist/rngwhhdm.htm.

The Division's assertion that product captured and sold would offset costs of repair and re-monitoring is not supported by this analysis. Well production facility LDAR repair and re-monitoring costs in the initial year are estimated to be $90.0 million (see table 13), while the value of the recovered gas is estimated to be $12.4 million in the initial year, or 13.8 percent of the repair and re-monitoring cost. In subsequent years, the value of the gas recovered would offset 10.9 percent of the repair and re-monitoring costs.

Gas Savings Attributed to LDAR – Compression Stations

Gas savings attributable to the LDAR program as it relates to compressor stations in the initial year are estimated as shown in Table 26. The amount of gas that is expected to be detected and captured by a successful LDAR program at compressor stations during the initial year is 322,260 Mcf and is valued at $1.3 million. This value represents 8.6 percent of the total cost of the LDAR program during the initial year. It is worth noting that Louis Berger believes the estimated product savings for compressor stations may be conservatively high. This opinion is based on the likelihood that the gas/VOC ratio is not as high for compressor stations as it is for well production facilities.

Table 26: Product Savings Attributable to the LDAR Program for Compressor Stations for the Initial Year

Tons of VOCs Captured by LDAR Program for Compressor Stations	Average Gas/VOC Ratio[1]	Tons of Methane Captured by LDAR Program for Compressor Stations (Tons)	Natural Gas Volume Recovered (MCF)[2]	Natural Gas Price ($/Mcf)[3]	Value of Recovered Gas
(1)	(2)	(3) = (1) / (2)	(4) = (3)/0.0247 ton/mcf	(5)	(6) = (4) * (5)
1,783	22.4%	7,960	322,260	$4.34	$1,398,608

[1] Taken from the Division's calculation on LDAR costs for well production facilities. Spreadsheet titled "APCD-PHS EX-RR.xlsx"; sheet: statewide wells model FAC.

[3] Henry Hub Natural Gas Spot Price for December, 2013. Obtain from the Energy Information Agency at http://www.eia.gov/dnav/ng/hist/rngwhhdm.htm.

For subsequent years, the LDAR program at compressor stations is also expected to generate gas savings though these savings are expected to decline from the initial year. An estimate of the amount and value of the project saved is shown in Table 27. The amount of natural gas expected to be recovered in subsequent years is estimated to be 1,875Mcf and is valued at $329,453 which represents 5 percent of total annual costs of the program in subsequent years.

JIWG-REB EX. B

NMED Exhibit 71

Table 27: Product Savings Attributable to the LDAR Program for Compressor Stations for Subsequent Years

420	22.4%	1,875	75,911	$4.34	$329,453

[1] Taken from the Division's calculation on LDAR costs for well production facilities. Spreadsheet titled "APCD-PHS EX-RR.xlsx"; sheet: statewide wells model FAC.

[2] Natural gas volumes calculated by assuming a gas density of 0.791 kg/m3 and converted to English units.

[3] Henry Hub Natural Gas Spot Price for December, 2013. Obtain from the Energy Information Agency at http://www.eia.gov/dnav/ng/hist/rngwhhdm.htm.

The Division's assertion that product captured and sold would offset costs of repair and re-monitoring is not supported by this analysis. Compressor station LDAR repair and re-monitoring costs in the initial year are estimated to be $11.7 million (see table 13), while the value of the recovered gas is estimated to be $1.4 million in the initial year, or 12.0 percent of the repair and re-monitoring cost. In subsequent years, the value of the gas recovered would also offset only 12.0 percent of the repair and re-monitoring costs.

Indirect Costs of Regulations on Small Operators and Marginally Producing Wells

In order to gain an understanding of the potential indirect costs to businesses, in particular small businesses, if the proposed rules were implemented, Louis Berger evaluated the impacts on small operators and marginally producing wells within the state. Evaluation of historical production and well count data maintained by the Colorado Oil and Gas Conservation Commission (COGCC) indicates that 25,463 conventionally completed wells produce approximately 1.57 million barrels of oil per month (BOPM) or on average two barrels of oil per day as of mid-year 2013. These marginally producing wells represent over half (55 percent) of the total producing wells in the state (46,495) as of 2013. Given the likelihood that smaller operations would be negatively impacted by the increased costs of the proposed rules and regulations as well as the large percentage of these wells that occur within the state, small and marginally producing operations are the focus of this analysis.

Louis Berger first evaluated the economic limit (in barrels per day) that marginally producing wells would realize under current economic and regulatory conditions. The economic limit is defined as the point that production levels are no longer economic given a number of factors (price of oil, lease costs, tax rates, etc.). Relevant assumptions for this analysis are as follows:

- Current Rate of Production – 2 BOPD
- Oil Price - $90 ($/BO)
- Severance Tax Rate – 5%

JIWG-REB EX. B

NMED Exhibit 71

- Net Return on Investment (NRI) (well income minus royalties) – 80%
- Lease Operating Expense ($/well/month) (includes ad valorem taxes) - $900
- Number of Tanks per lease – 2
- Number of Wells per lease – 4
- Production Decline Rate – 2.5%

The economic limit in barrels of oil per day (BOPD) was calculated for wells using the following equation.

$$\textit{Economic Limit (BOPD)} = \frac{\text{Lease Operating Expense (LOE)}}{\textit{(Oil Price) * (30.4 days) * (NRI * (1- severance tax))}}$$

Implementation of the new air quality rules would have an impact on lease operating expenses for each well. The increase costs would change the economic limit for each well as shown in Figure 3. Under current economic and regulatory conditions, the economic limit for marginally producing wells was estimated to be 0.43 BOPD. In other words, when production falls below 0.43 BOPD, the well is no longer economic and will be shut it or plugged. If lease operating costs increase, the economic limit increases, causing wells to be shut in earlier than planned. This leads to oil left in place as shown in Figure 3.

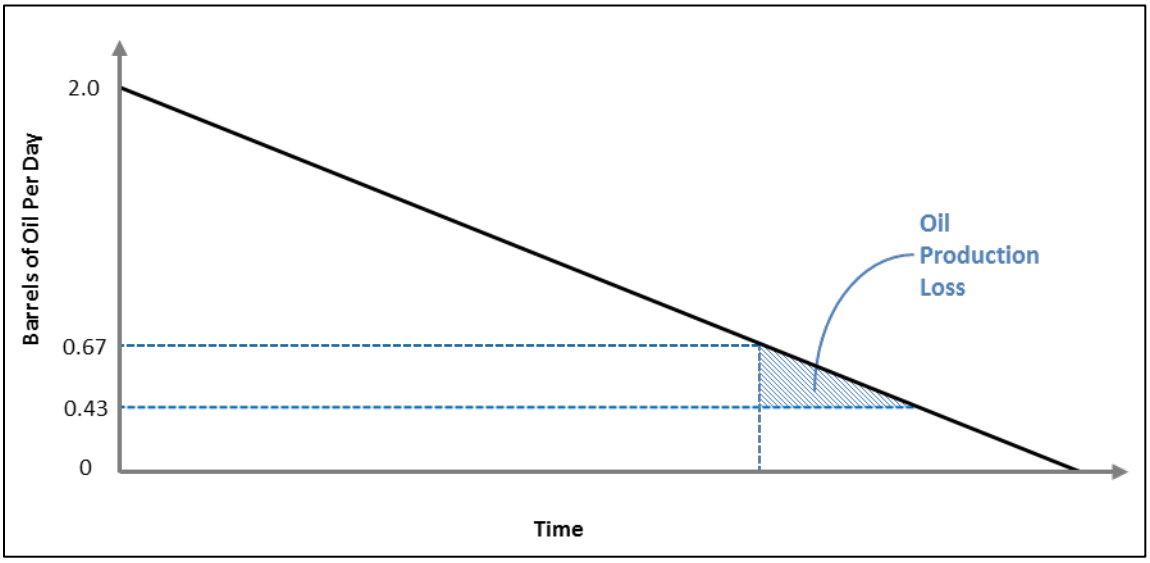

Figure 3: Oil Production Loss with an Increase in the Economic Limit

The amount of production that would result under different economic limits was calculated as follows.

$$\textbf{Remaining Oil} = \frac{(Q_i - Q_f) * 365}{\text{Limit } (1 - \text{Decline Rate})}$$

Where:

Q_i = *Current Production Rate = 2 BOPD*
Q_f = *Calculated Economic Limit*

Louis Berger estimated the economic limit for marginally producing wells if the air regulations relevant to oil and gas operations were implemented as proposed by the Division. The STEM costs for tanks and the LDAR costs for well production facilities were included as additional monthly unit costs in the lease operating expenses, increasing these costs for operators. The results are summarized in Table 19. Changes in lease operating costs due to the regulations were estimated for different sizes of facilities. Costs are expected to increase from $22 to $1,290 per month with an average of $729 for all facilities. The increase costs are expected to increase the economic limit from 0.44 to 1.05 BOPD, depending on the size of facilities.

The additional cost burden would result in as much as 128.6 million barrels of oil being left in place and not produced over time. Assuming a price per barrel of oil is $90, this would equate in $11.6 billion in lost revenue to producers, $2.3 billion in lost royalties and $579 million in lost severance taxes. Present values for these losses are $1.9 billion in lost revenue, $384 million in lost royalties and $96 million in lost severance taxes.[16]

[16] Present value analysis assumed a 10 percent discount rate over 60 years.

Lost Royalties ($)	-	$24,359,432	$305,001,869	$826,355,781	$491,783,676	$2,315,006,074
Lost Severance Taxes ($)	-	$6,089,858	$76,250,467	$206,588,945	$122,945,919	$578,751,519

*Values in the table have not been discounted and reflect revenues and costs over the life of the well.

JIWG-REB EX. B

NMED Exhibit 71

Costs to Division to Implement Proposed Rules

The Economic Impact Analysis requires an assessment of the cost for the Division to implement the proposed rule changes. Oversight of an LDAR program, STEM plans, and annual report review of 5,312 tank batteries, 5,312 well production facilities, and 200 compressor stations with possibly hundreds of thousands of components would require additional Division manpower. Louis Berger reviewed the revised (November 21, 2013) Regulations 3, 6 and 7 to understand the implementation costs to the Division associated with the new rules. A summary of potential cost implications for the Division, as result of the rule changes, is provided in Table 29. The rationale for the estimated additional costs or cost savings is provided after the table.

Table 29: Summary of Potential Implementation Costs to the Division with Proposed Changes in Regulation 3, 6, and 7

Regulation Subpart	Description	Cost Impact	Estimated Savings/Cost
Regulation 3			
Minor Source Permits	Facilities with emissions less than the APEN no longer have to file for a minor source permit.	Cost Savings	An estimated 882 hours per year in labor would be saved from not having to review and approve minor source permits.
Standardization of de minimis Reporting Threshold	The de minimis reporting threshold would be set to a standard of 250 pounds per year. This increases the clarity of reporting requirements.	Cost Savings	An undetermined amount of savings would be realized by the Division.
Crude Oil Storage Tank Permitting	Additional permits would now be required for crude oil tanks as the tank permitting exemptions are removed.	Cost Increase	An estimated 128 hours per year in additional labor would be required to review and approve permits.
Regulation 6			
Adoption of NSPS OOOO	This regulation adopts NSPS OOOO. No additional impacts beyond the minimum required by federal law would occur.	No Impact	No Impact
Regulation 7			
Evaluation of Operation and Maintenance of Air Pollution Control Equipment	The Division would be required to make determinations on the acceptableness of operating and maintenance procedures used to control Air Pollution Control Equipment.	Cost Increase	An estimated 1,062 hours per year in additional labor would be required to review and monitor o&m procedures.
Approval of STEM Plans	The Division would be required to review and approve STEM plans for compliance with regulatory requirements.	Cost Increase	An estimated 5,600 hours in additional labor would be required for review and approval of STEM plans.

JIWG-REB EX. B

NMED Exhibit 71

Ongoing Management of STEM Program	The Division would incur labor costs for review of records that would be retained by each operator or owner as part of their STEM plan compliance.	Cost Increase	An estimated 1,062 hours per year in additional labor would be required.to manage the STEM program
Division Approval of Monitoring Devices or Methods	When the Division is required to approve monitoring devices or methods not mentioned in these regulations it is anticipated that additional labor costs to the Division would occur.	Cost Increase	An undetermined additional cost would be incurred by the Division.
Recordkeeping Requirements	The owner or operator of each facility is required to keep records of various tests and repairs. It anticipated that the Division would review a percentage of these records annually.	Cost Increase	An estimated 1,062 hours per year in additional labor would be required.
Reporting Requirements	Each owner or operator is required to submit an annual report summarizing the inspection and maintenance activities of all facilities during the previous year. It is anticipated that the Division would review a percentage of these annual reports.	Cost Increase	An estimated 2,125 hours per year in additional labor would be required to review annual reports.
Venting Recordkeeping Requirements	Each owner or operator is required to record venting statistics and make them available to the Division upon request. Additionally, the Division may be called upon to make a determination on the visibility of venting. It is anticipated that the Division would commit a certain amount of time annually to reviewing these venting records and making visibility determinations on venting events.	Cost Increase	An estimated 2,125 hours per year in additional labor would be required for review and monitoring.

The following section provides an explanation of the implementation cost analysis summarized in Table 29 for each proposed rule change.

Regulation 3

Minor Source Permits

Under Regulation 3, the Division is proposing that NSPS OOOO affected facilities with uncontrolled actual emissions that are less than the APEN and minor source permit thresholds no longer automatically have to file APENs and obtain minor source permits. As such, it expected that the Division would realize an implementation cost savings with this proposed rule change. As a result of this revision, up to 441 facilities would be exempt from submitting an APEN. If it is assumed that it requires two hours to process each APEN application, then this rule change could save the Division up to 882 hours of processing time. This would allow the Division to reallocate permitting resources to more complicated sources with greater impact to Colorado air quality, as well as develop and maintain other guidance and compliance assistance tools.

JIWG-REB EX. B

NMED Exhibit 71

Standardization of de minimis Reporting Threshold

The Division is proposing to revise method (Part A, Appendix A) for determining non-criteria reportable pollutant de minimis levels in order to standardize the de minimis reporting threshold and set a 250 pounds per year threshold for all non-criteria reportable pollutants, regardless of the pollutant, height of release point or distance to property boundary. This revision increases regulatory clarity and reduces the administrative reporting burdens on both sources and the Division by simplifying the process. This revision is therefore anticipated to reduce costs to the Division though it is uncertain what the cost savings would be for this rule change.

Crude Oil Storage Tank Permitting

The Division is proposing to remove the crude oil storage tank permitting exemptions in Part B, Section II.D.1.n. and Part C, Section II.E.3.ddd. It is estimated that up to 64 additional crude oil tanks would be required to obtain a permit under this revision. If it is assumed that it takes approximately two hours to review and issue each permit, it is anticipated that this would result in up to 128 hours of additional labor for the Division each year to implement this rule.

Regulation 6

This regulation adopts NSPS OOOO; therefore, this rule makes NSPS OOOO enforceable under Colorado law and is not anticipated to impose additional requirements beyond the minimum required by federal law. The revised changes to this regulation are not anticipated to impact regulation implementation costs to the Division.

Regulation 7

It is anticipated that several new provisions of the revised Regulation 7 would require owners or operators of facilities to prepare reports and documentation or perform tasks that would require review, approval and inspection by the Division. These additional tasks are expected to result in an increase in the implementation costs to the Division.

Evaluation of Operation and Maintenance of Air Pollution Control Equipment

The revised regulations would require that air pollution control equipment be maintained and operated in a manner consistent with good air pollution practices. A determination on whether or not acceptable operating and maintenance procedures are being used at a facility would be based on information provided to the Division by the owner or operator of the facility. This information could include, but would not be limited to: monitoring results, opacity observations, review of operating and maintenance procedures, and inspection of the source. The requirement for the Division to make a determination on the acceptability of operating and maintenance procedures is expected to take 2 hours per facility per year. The Division has reported that there are 5,312 facilities that would be affected by this rule. If it is assumed that the Division would review approximately 10 percent of these records annually, then the rule change would require an additional 1,062 labor hours per year for implementation.

JIWG-REB EX. B

NMED Exhibit 71

Approval of STEM Plans

Owners or operators of storage tanks would be required to develop, certify and implement a Storage Tank Emission Management System (STEM) plan to identify appropriate strategies to minimize emissions from venting at thief hatches (or other access points to a storage tank) and pressure relief devices during normal operation under the revised Regulation 7. It has been estimated that approximately 5,312 storage tanks under the revised regulations would have to meet the STEM requirements. Assuming that a STEM plan could be developed for sites with multiple tanks (2), at most, 2,800 STEM plans would be developed and require review by the Division. Assuming the Division would review and approve each plan and it would require 2 hours per review would result in an additional 5,600 hours to initially review and approve the individual STEM plans, resulting in additional implementation costs as a result of the revised regulation.

Ongoing Management of STEM Program

As each owner or operator of a storage tank subject to section XII.D or XVII.C under the revised regulation must maintain records of STEM, including the plan, any updates, and the certification; and as these records should be made available to the Division upon request, it is anticipated that the Division would incur additional implementation costs as a result of this requirement. Further document retention requirements under the revised regulation would include retention of the AIRS ID for the storage tank; the date and duration of any period where the thief hatch, pressure relief device, or other access point are found to be venting hydrocarbon emissions; the date and duration of any period where the air pollution control equipment is not operating, or where a flare or other combustion device is being used; the date and result of any Method 22 test, as well as the timing of and efforts made to eliminate venting, restore operation of air pollution control equipment, and mitigate visible emissions. While the Division is not required to review this information, the requirement for the retention of this information would allow it to be reviewed. It is anticipated that the Division would review approximately 10 percent of these records annually. As there would be at most 5,312 facilities under the revised regulations subject to these requirements and each would take an assumed 2 hours of review per set of records, this would require, at most, 1,062 hours per year, resulting in additional implementation costs as a result of the revised regulation.

Division Approval of Monitoring Devices or Methods

Under section XVII.F.6, the Division may be required to approve monitoring devices or methods not mentioned in these regulations, resulting in additional time and funding costs to the Division.

Recordkeeping Requirements

As a result of recordkeeping requirements under the proposed regulation, the owner or operator of each facility subject to inspection and maintenance requirements under Section XVII.F is required to maintain documentation of the pre-start-up pressure tests for new well production facilities; date and site information for each inspection; a list of leaking components and monitoring method used to determine the presence of the leak; the date of the first attempt to repair the leak and additional

JIWG-REB EX. B

NMED Exhibit 71

attempts; the date the leak was repaired; the delayed repair list; the date the leak was re-monitored to verify effectiveness of the repair and the results of re-monitoring effort; and a list of identification numbers for the components designated as unsafe or inaccessible to monitor, as well as an explanation for each component stating why the component was so designated and the plan for monitoring such components for a period of two years and make them available to the Division upon request. It is anticipated that the Division would review approximately 10 percent of these records annually. As there would be at most 5,312 facilities under the revised regulations subject to these requirements and it is assumed to take approximately 2 hours of review per set of records, this would require, at most, 1,062 hours per year in additional labor. This would result in increased implementation costs of Regulation 7.

Reporting Requirements

In addition to recordkeeping, the owner or operator of each facility subject to the inspection and maintenance requirements in Section XVII.F would be required to submit a single annual report each year summarizing the inspection and maintenance activities at all of their subject facilities during the previous year. This report would contain at least the number of facilities inspected as well as the total number of inspections, leaks identified, categorized by component type and the number of leaks repaired. It would also require the identification of the number of leaks on the delayed repair list at the end of the calendar year. Additionally, each of these reports would be required to be accompanied by a self-certification form certifying the accuracy of the information in the report. It is anticipated that review of one annual report by the Division would require 4 hours. As there would be at most 5,312 annual reports, depending on the ownership of individual facilities in the state of Colorado, this new requirement is anticipated to add an additional amount of 2,125 hours, at most, of labor to the Division each year. This would result in increased implementation costs of Regulation 7.

Venting Recordkeeping Requirements

Records of the cause, date, time, and duration of venting events under Section XVII.H would be required to be kept and made available to the Division upon request under the revised regulation. Regarding visible emissions, the Commission expects that both Division inspectors and the regulated community will, if any smoke is observed, determine whether the emissions are considered visible emissions for purposes of Regulation Number 7. When the venting event records are reviewed by the Division or if the Division makes a determination on the visibility of emissions this would result in additional implementation costs as a result of the revised regulation. It is anticipated that the average time required to determine the visibility of emissions or review the records of a facility would be four hours per facility. As there would be, at most, 5,312 facilities that may require review by an inspector annually and assuming 10 percent of these facilities require monitoring per year it is anticipated that up to 2,125 labor hours would be required. This would result in increased implementation costs of Regulation 7.

JIWG-REB EX. B

NMED Exhibit 71

Conclusions

The net increase in the number of labor hours at the Division as result of the proposed regulations is anticipated to be approximately 12,282 labor hours annually. Notably, the Division would need 5,600 hours to review and approve initial STEM plans required under Regulation 7, the largest estimated time commitment for the Division. This represents approximately 6.1 FTEs of additional staff for the Division to review, oversee, inspect, manage, and approve various requirements associated with the proposed rules. Therefore, Louis Berger concludes that the Division would incur significant additional net costs to implement the proposed requirements beyond current expenditures, contrary to the Division's assertions to date.

Support of Industry's Proposed Language

The results of the initial economic impact analysis presented here support the industry's key suggested revisions to the Division's proposed rule. Specifically, the proposed revisions will allow similar emission reductions to be achieved in a much more cost effective manner than the regulatory approach proposed by the Division. Key points to the analysis include:

- Diminishing marginal benefits associated with LDAR programs implies increasing costs per ton of VOC reduced after initial rounds of inspections and repairs. Reducing the monitoring to reflect successful LDAR implementation reduces costs and improves the cost effectiveness of the proposed rule compared to the Division's proposal while maintaining program integrity through realized emission reductions. The "step-down" of monitoring frequency, which rewards companies with four inspections with no leaks, is an example of how the industry changes to the proposed rule would provide incentives for industry to maintain compliance and reduce costs for good performance.
- Generally, compliance costs of STEM and LDAR for small tanks and well production facilities are more burdensome than for larger facilities on a cost per ton basis. As such, requiring a one-time LDAR inspection and monthly AVO for all facilities (including all well production facilities) with uncontrolled emissions between 2 and 6 TPY would improve the overall cost effectiveness of the proposed rule by limiting the very high costs per ton of VOC reduced incurred by very small facilities with very small VOC fugitive emissions.
- Compliance costs are higher for operations outside of the non-attainment area as the distance among facilities and tanks increases inspection travel time and expenses. Limiting the geographic scope to the non-attainment area will improve the cost effectiveness of the proposed rule.
- Allowing for the use of other established technology, such as the tunable diode laser absorption technology (TDLAS), as an option for inspection monitoring, would reduce costs to industry with faster inspections, reduced camera training requirements, among other factors.

Expert Introduction: Dr. Gernot Wagner

My name is Gernot Wagner, Ph.D., and I am a senior economist at EDF, where I co-lead the office of economic policy and analysis to advocate for market-based solutions to a wide range of environmental problems. I teach energy economics as adjunct faculty at Columbia's School of International and Public Affairs, and I am the author of *But Will the Planet Notice?* (Hill & Wang/Farrar, Strauss & Giroux, 2011) and, joint author with Harvard University's Martin Weitzman, of the forthcoming *Climate Shock* (Princeton University Press). I am a research associate at the Harvard Kennedy School and a term member of the Council on Foreign Relations. Prior to EDF, I worked for the Boston Consulting Group and served on the editorial board of the *Financial Times*. I hold a Ph.D. and M.A. in Political Economy and Government as well as an A.B. in Environmental Science and Public Policy, and Economics (*magna cum laude* with highest honors in the field) from Harvard University, and an M.A. in Economics from Stanford University. A copy of my cv is attached as Exhibit A to this expert report and testimony.

The following is my written testimony on the topics covered in this report, based on my education, research, and expertise on the topic of the Social Cost of Carbon and related issues.

Summary of Written Testimony and Expert Opinion

Calculating the social costs of greenhouse gas pollutants has a long tradition in the academic literature. In 2010, the United States' Interagency Working Group ("IWG") calculated the Social Cost of Carbon ("SCC") in a transparent, well-reviewed inter-agency process involving a dozen federal agencies and entities. A routine update in 2013, reflecting the latest changes in the peer-reviewed literature resulted in a central estimate for the SCC of $37 per ton of carbon dioxide emitted in 2015. Converting the value into one reflecting the social cost of methane – and making conservative assumptions every step along the way – results in a central value of the social benefit of methane reductions for the proposed oil and gas rule in Colorado per year: over $104,000,000 when fully implemented in 2016 and increasing to $132,000,000 in 2025. The upper range of the central estimate reaches over $318,000,000 per year in 2016 and over $404,000,000 per year in 2025.

Social Cost of Carbon

The SCC is a monetary measure of the incremental damage to the climate resulting from carbon dioxide emissions. The SCC assigns a net present value to the marginal impact of one additional ton of carbon dioxide emissions released at a specific point in time. The SCC is based on a large and growing body of research regarding the quantitative economic damages that would result from unmitigated climate change. These economic estimates are typically based on the results of integrated assessment models, in which a scientific model of the predicted physical impacts of climate change is paired with a socio-economic model that evaluates the economic impact of these effects.

The most comprehensive effort to calculate the SCC is the work published by the IWG. The IWG is a group of numerous federal agencies/departments, including the Council of Economic Advisers, Council on Environmental Quality, Department of Agriculture, Department of Commerce, Department of Energy, Department of Transportation, Environmental Protection Agency, National Economic Council, Office of Management and Budget, Office of Science and Technology Policy, and the Department of the Treasury. The IWG developed the SCC through an open and transparent process, involving extensive meetings, public comment and peer review. The SCC developed by the IWG is widely used in regulatory rulemakings in the United States.[1]

[1] The SCC has been used in numerous notice-and-comment rulemakings by various agencies since it was published in 2010, and each of these occasions has provided opportunity for public comment on the SCC. *See, e.g.*, Energy Conservation Program: Energy Conservation Standards for Residential Clothes Washers, 77 Fed. Reg. 32,381 (May 31, 2012); Energy Conservation Program: Energy Conservation Standards for Residential Dishwashers, 77 Fed. Reg. 31,964 (May 30, 2012); Energy Conservation Program: Energy Conservation for Battery Chargers and External Power Supplies, 77 Fed. Reg. 18,478 (Mar. 27, 2012); Energy Conservation Program: Energy Conservation Standards for Standby Mode and Off Mode for Microwave Ovens, 77 Fed. Reg. 8526 (Feb. 14, 2012); Energy Conservation Program: Energy Conservation Standards for Distribution Transformers, 77 Fed. Reg. 2356 (Jan. 17, 2012); 2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards, 76 Fed. Reg. 74,854 (Dec. 1, 2011); Oil and Natural Gas Sector: New Source Performance Standards and National Emission Standards for Hazardous Air Pollutants Reviews, 76 Fed. Reg. 52,738 (Aug. 23, 2011); Energy Conservation Program: Energy Conservation Standards for Residential Furnaces and Residential Central Air Conditioners and Heat Pumps, 76 Fed. Reg. 37,549 (June 27, 2011); Energy Conservation Program: Energy Conservation Standards for Residential Clothes Dryers and Room Air Conditioners, 76 Fed. Reg. 22,324 (Apr. 21, 2011); Energy Conservation Program: Energy Conservation Standards for Fluorescent Lamp Ballasts, 76 Fed. Reg. 20,090 (Apr. 11, 2011); National Emission Standards for Hazardous Air Pollutants: Mercury Emissions from Mercury Cell Chlor-Alkali Plants, 76 Fed. Reg. 13,852 (Mar. 14, 2011); Greenhouse Gas Emissions Standards

The IWG's most recent value for the social cost of carbon is $37/ton (central value for a ton released in 2015, assuming a 3% discount rate).[2] The SCC is derived from running three state-of-the-art, peer-reviewed Integrated Assessment Models ("IAMs") that quantify the costs of climate change to the economy. They project future economic output with and without climate change using five reference scenarios and three constant discount rates of 2.5, 3, and 5 percent. The use of three models, three discount rates, and five scenarios produces a number of distributions for the SCC. The final $37 number is the average of the monetized effect found by all three models under the central model run, assuming a 3% discount rate. SCC values rise over time, reflecting the increased costs of unmitigated climate change over time. A ton emitted in 2020 is calculated to come with a social cost of $43; a ton emitted in 2025 will cost $47 (Table 1).

This central value is conservative because it does not reflect a declining discount rate, fully value impacts associated with catastrophic events, or include non-monetized benefits. The latter may be the most significant omission, since quantifying the full cost of climate damages is difficult. The IWG also presents a value for the 95th-percentile of the SCC distribution as a conservative proxy for including the value of extreme events (Table 1). This estimate can only be seen as a proxy and is likely a large underestimate of the actual damages in extreme situations.[3]

Using the Social Cost of Carbon to Calculate Damage associated with Methane Emissions

Each greenhouse gas has its own potential to force changes to the climate, and those impacts can also differ over time. To evaluate the SCC of a non CO2 greenhouse gas, such as methane, it is necessary to convert those emissions to the same units as the SCC, using the Global Warming Potential ("GWP") of the gas at issue. GWP is a measure of the climate forcing potential of a gas (such as methane) relative to CO2.

The most recent Intergovernmental Panel on Climate Change ("IPCC") establishes the 100-year GWP for methane at a figure of at least 28, which means that methane is 28 times more potent

than CO2 over a 100-year period.[4] However, because methane causes greater climate damage over shorter time frames than over longer time frames, choosing a 100-year GWP will undervalue the short-term impacts of methane. Accordingly, the benefits of methane reductions should also be valued using the most-recent 20-year GWP for methane, which is at least 84.

These GWP values for methane (28 long term and 84 short term) are conservative because they do not include climate-carbon ("cc") feedbacks (which are feedbacks between climate change and the carbon cycle). The latest IPCC report concludes that, when cc is considered, methane has an even higher GWP on both 100- and 20-year timeframes of 34 and 86, respectively.[5] Other scientific analyses have likewise determined that methane is an even more potent climate forcer.[6]

Table 2 below shows the GWP of methane in the short and long term from the most recent IPCC report, both with and without climate-carbon feedback.

Table 2—Global Warming Potential (GWP) of methane relative to one metric ton of CO_2

	Global Warming Potential (GWP) relative to CO_2
100-year GWP without cc feedbacks	28
100-year GWP with cc feedbacks	34
20-year GWP without cc feedbacks	84
20-year GWP with cc feedbacks	86

This conversion yields a conservative estimate—undervaluing the benefits of methane reductions by up to 36%.[7]

Calculating the Benefits of Anticipated Methane Reductions from Proposed Changes to Air Pollution Control Regulations in Colorado

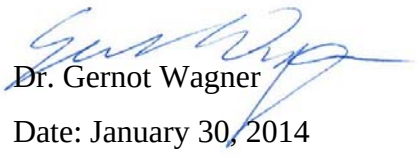
An expert retained by EDF, WZI Inc., estimates that the proposed rule will reduce methane emissions by around 112,000 short tons per year once fully implemented (EDF-PHS-WZI Expert Report, Table 7-1). Table 3, below, calculates the value of avoided methane emissions in 2007 dollars for 2015, 2020, and 2025 by using central values for the social cost of carbon (at the central 3% discount rate). This table results from the IWG values for SCC, the IPCC values for GWP of methane, and the WZI estimate of methane reductions. Benefits are calculated using both 100- and 20-year GWPs for methane, and GWPs with and without climate-carbon feedbacks. The calculations are performed by multiplying the SCC (shown in the top row) by the GWP of methane (shown in the column on the left) times the tons of methane reduced (112,000 short tons based on current oil and gas production activity in Colorado, equal to 102,000 metric tons).

In 2015, the central value for calculated benefits is $104,000,000, going as high as $318,000,000. In 2025, the central value for calculated benefits is $132,000,000, going as high as $404,000,000 (Table 3).

The values below almost certainly understate the actual SCC associated with these emissions. Among other things:

- The values are stated in 2007 dollars, so the values are understated in terms of current dollars.

[7] EDF-REB-GW-EX H. Marten, Alex L., and Stephen C. Newbold. "Estimating the social cost of non-CO2 GHG emissions: Methane and nitrous oxide." *Energy policy* 51 (2012): 957-972, at 964;Marten, A. L., and Newbold, S. C. (2011), "Estimating the Social Cost of Non-CO2 GHG Emissions: Methane and Nitrous Oxide," EPA NCEE Working Paper # 11-01, at 16, available at http://www.sciencedirect.com/science/article/pii/S0301421512008555.



- The 2025 reductions only account for the existing rates of production. Production is projected to increase, so the actual reductions compared to the business as usual case would be greater than indicated below.
- This estimate does not include the monetary impact of extreme climate events. IWG prepared an SCC that includes these factors (shown as the "95th percentile" value in Table 1 above). The estimate for these factors would increase the values below by approximately a factor of three.
- The conversion of the SCC to the social cost of methane using GWP is likely conservative, resulting in a further underestimate.[8]

Table 3—Benefits of Methane reductions from Proposed Oil and Gas Rule (in 2007 dollars)

	2015	2020	2025
	3.0% Average (SCC: $37)	3.0% Average (SCC: $43)	3.0% Average (SCC: $47)
100-year GWP without cc feedbacks (GWP: 28)	$104 million	$120 million	$132 million
100-year GWP with cc feedbacks (GWP: 34)	$126 million	$146 million	$160 million
20-year GWP without cc feedbacks (GWP: 84)	$311 million	$361 million	$395 million
20-year GWP with cc feedbacks (GWP: 86)	$318 million	$370 million	$404 million

[8] See footnote 7 above.

I, Gernot Wagner, of proper age, state that the above-testimony has been prepared by me, or under my supervision and control, and that it is true and correct to the best of my knowledge, and belief, and would be the same if given orally under oath.

Dr. Gernot Wagner

TO THE JOINT INDUSTRY WORK GROUP REBUTTAL STATEMENT

REVISED COLLECTIVE PROPOSED REVISIONS

DEPARTMENT OF PUBLIC HEALTH AND ENVIRONMENT

Air Quality Control Commission

REGULATION NUMBER 3

STATIONARY SOURCE PERMITTING AND AIR POLLUTANT EMISSION NOTICE REQUIREMENTS

5 CCR 1001-5

>>>>>>>>

PART A CONCERNING GENERAL PROVISIONS APPLICABLE TO REPORTING AND PERMITTING

>>>>>>>>

II. Air Pollutant Emission Notice (APEN) Requirements

>>>>>>>>

II.B.3. APEN Applicability

For the purposes of Air Pollutant Emission Notice applicability, a source will be considered to be an individual emission point, or group of points pursuant to Section II.B.4. of this Part A.

II.B.3.a. Criteria Pollutants

For criteria pollutants, Air Pollution Emission Notices are required for: ~~each individual emission point in a nonattainment area with uncontrolled action emissions of one ton per year or more of any criteria pollutant (pollutants are not summed) for which the area is nonattainment;~~ each individual emission point ~~in an attainment or attainment/maintenance area~~ with uncontrolled actual emissions of two tons per year or more of any individual criteria pollutant (pollutants are not summed)~~;~~ and each individual emission point with uncontrolled actual emissions of lead greater than one hundred pounds per year, regardless of where of where the source is located.

II.B.3.b. Non-criteria Reportable Pollutants

For non-criteria reportable pollutants, Air Pollutant Emission Notices are required for each individual emission point with uncontrolled actual emissions equal to or greater than 250 pounds per year or more of any individual non-criteria reportable pollutant (pollutants are not summed) ~~that exceed the de minimis levels as determined following the procedures set forth in Appendix A.~~

>>>>>>>>

II.D. Exemptions from Air Pollutant Emission Notice Requirements

II.D.1. ~~Notwithstanding the exemptions contained in Section II.D.1., Air Pollutant Emission Notices must be filed for all emission units specifically identified in the applicability section of any subpart of Part A of Regulation Number 6 (New Source Performance Standards) and/or Regulation Number 8 (Hazardous Air Pollutants), Parts A,C,D, and E. However, Air Pollutant Emission Notices need not be filed for wet screening operations subject to Subpart OOO of the New Source Performance Standards if the exemption in Section II.D.1.cccc. is applicable.~~

Stationary sources having emission units that are exempt from the requirement to file an Air Pollutant Emission Notice must nevertheless comply with all requirements that are otherwise applicable specifically to the exempted emission units, including, but not limited to: Title V, Prevention of Significant Deterioration, nonattainment New Source Review, opacity limitations, odor limitations, particulate matter limitations, and volatile organic compounds controls.

An applicant may not omit any information regarding APEN exempt emission units in any permit application if such information is needed to determine the applicability of Title V (Part C of this Regulation Number 3), Prevention of Significant Deterioration (Section VI., Part D of this Regulation Number 3), or nonattainment New Source Review (Section V., Part D of this Regulation Number 3).

The following sources are exempt from the requirement to file Air Pollutant Emission Notices because by themselves, or cumulatively as a category, they are deemed to have a negligible impact on air quality.

II.D.1.a. Individual emission points ~~in nonattainment areas having uncontrolled actual emissions of any criteria pollutant of less than one ton per year, and individual emission points in attainment or attainment/maintenance areas~~ having uncontrolled actual emissions of any criteria pollutant of less than two tons per year~~,~~ and each individual emission point with uncontrolled actual emissions of lead less than one hundred pounds per year~~, regardless of where the sources is located~~.

II.D.1.b. Individual emission points ~~of non-criteria reportable pollutants~~ having uncontrolled actual emissions of any individual non-criteria reportable pollutant less than ~~the de minimis levels as determined following the procedures set forth in Appendix A~~ 250 pounds per year.

>>>>>>>>

APPENDIX A
APPENDIX A
~~**Method For Determining**~~ **De Minimis Levels For Non-Criteria Reportable Pollutants**

An Air Pollutant Emission Notice must be filed for each emission point (individual or grouped) that has uncontrolled actual emissions equal to or greater than 250 pounds per year of any non-criteria reportable pollutant listed in Appendix B.

If a non-criteria pollutant is not listed in Appendix B, it does not have to be reported unless it is included in a chemical compound group.

~~**The following procedures must be followed in order to determine the appropriate de minimis (minimum) reporting level for each pollutant that is emitted from each emission point at a contiguous site. If you do not wish to use the three-scenario approach at your facility, you may elect to use Scenario 1 for all emission points.**~~

Definitions

~~Release Point - the lowest height above ground level from which the pollutants are emitted to the atmosphere.~~

~~Property Boundary - the distance from the base of the release point to the nearest property boundary.~~

Point - an individual emission point or a group of individual emission points reported on one Air Pollutant Emission Notice as provided for in Part A, Section II.B.4.

~~**Methodology**~~

~~To determine the de minimis level for a single pollutant being emitted from a point (single or grouped).~~

~~**STEP 1:**~~

~~Determine which of the three scenarios below applies to the emission point. If different scenarios can be applied to the same emission point, use the highest numbered scenario that applies. In the case of grouped emission points, use the lowest scenario number (for the entire group) that applies to any of the single emission points within the group.~~

~~Scenario 1: Release point less than 10 meters or property boundary less than 100 meters;~~

~~Scenario 2: Release point equal to or greater than 10 meters, but less than 50 meters, or property boundary equal to or greater than 100 meters, but less than 500 meters; or~~

~~Scenario 3: Release point equal to or greater than 50 meters, or property boundary equal to or greater than 500 meters.~~

~~**STEP 2:**~~

~~Use Appendix B to identify which of the three bins (Bin A, B, or C) the chemical is listed under.~~

~~If the pollutant is not listed, it does not have to be reported unless it is included in a chemical compound group.~~

~~**STEP 3:**~~

~~Use the table below to determine the de minimis level.~~

~~All values are in pounds per year.~~

	~~**Scenario 1**~~	~~**Scenario 2**~~	~~**Scenario 3**~~
~~Chemical Bin~~	~~De Minimis~~	~~De Minimis~~	~~De Minimis~~
~~Bin A~~	~~50~~	~~125~~	~~250~~

~~Bin B~~	~~500~~	~~1250~~	~~2500~~
~~Bin C~~	~~1000~~	~~2500~~	~~5000~~

~~**STEP 4:**~~

~~Repeat the above steps for each pollutant emitted from each emission point (single or grouped). One Air Pollutant Emission Notice must be filed for each emission point that emits one or more chemicals above the de minimis level.~~

>>>>>>>>

PART B CONCERNING CONSTRUCTION PERMITS

>>>>>>>>

II. General Requirements For Construction Permits

>>>>>>>>

II.A.5. Construction permits are required for hazardous air pollutants if:

II.A.5.a. The source is subject to Colorado Maximum Achievable Control Technology or Generally Available Control Technology~~; or~~

~~II.A.5.b. The source is subject to Federal National Emission Standards for Hazardous Air Pollutants; or~~

~~II.A.5.c. The source is subject to Federal Maximum Achievable Control Technology or Generally Available Control Technology standards; or~~

~~II.A.5.d. The source is subject to Regulation Number 8, Part E, where the more specific requirements of Regulation Number 8, Part E, take precedence over requirements in this regulation.~~

>>>>>>>>

II.D. Exemption from Construction Permit Requirements

~~None of the exemptions listed below in Sections II.D.1. through II.D.4. shall apply if a source is subject to Part A of Regulation Number 6 (New Source Performance Standards) and/or Regulation Number 8 (Hazardous Air Pollutants), Parts A,C, D, and E.~~ Permit exemptions taken under this section do not affect the applicability of ~~the~~ any State or Federal ~~r~~regulations that are otherwise applicable to the source.

An applicant may not omit any information regarding APEN or permit exempt emission units in any application if such information is needed to determine the applicability of Title V (Part C of this Regulation Number 3), Prevention of Significant Deterioration (Section VI. of Part D of this Regulation Number 3), or Nonattainment New Source Review (Section V. of Part D of this Regulation Number 3).

II.D.1. The following sources are exempt because by themselves, or cumulatively as a category, they are deemed to have a negligible impact on air quality:

>>>>>>>>

II.D.1.l. Crude oil truck loading equipment at exploration and production sites where the loading rate does not exceed 10,000 gallons of crude oil per day averaged on an annual basis. Condensate truck loading equipment at exploration and production sites that splash fill less than 6750 barrels of condensate per year or that submerge fill less than 16308 barrels of condensate per year. ~~Crude oil or condensate loading truck equipment at crude oil production sites where the loading rate does not exceed 10,000 gallons per day averaged over any thirty-day period.~~

>>>>>>>>

II.D.1.n. Exemption Repealed ~~Crude oil storage tanks with a capacity of 40,000 gallons or less.~~

II.D.2. ~~Facilities located in a nonattainment area for any criteria pollutant for which the area is nonattainment; with t~~Total facility-wide uncontrolled actual emissions ~~(potential emissions at actual operating hours)~~ that are less than the following amounts:

II.D.2.a. ~~Two~~ Twenty five tons per year of volatile organic compounds.

II.D.2.b. ~~One ton per year PM10~~Twenty five tons per year of any other criteria pollutant, except for lead.

~~II.D.2.c. One ton per year PM2.5.~~

~~II.D.2.d. Five tons per year total suspended particulate.~~

~~II.D.2.e. Five tons per year carbon monoxide.~~

~~II.D.2.f. Five tons per year sulfur dioxide.~~

~~II.D.2.g. Facilities located in attainment or attainment/maintenance areas for all criteria pollutants with total facility uncontrolled actual emissions less (potential emissions at actual operating hours) than the following amounts:~~

~~II.D.3. Facilities located in attainment or attainment/maintenance areas for all criteria pollutants with total facility uncontrolled actual emissions less (potential emissions at actual operating hours) than the following amounts:~~

~~II.D.3.a. Five tons per year volatile organic compounds.~~

~~II.D.3.b. Five tons per year PM10.~~

~~II.D.3.c. Five tons per year PM2.5.~~

~~II.D.3.d. Ten tons per year total suspended particulate.~~

~~II.D.3.e. Ten tons per year carbon monoxide.~~

~~II.D.3.f. Ten tons per year sulfur dioxide.~~

~~II.D.3.g. Ten tons per year nitrogen oxides.~~

~~II.D.3.h. Two hundred pounds per year lead.~~

II.D.34. Facilities that emit any other criteria pollutant that is not listed in Sections II.D.2. and II.D.3., above (flourides, sulfuric acid mist, hydrogen sulfide, total reduced sulfur, reduced sulfur compounds, and municipal waste combustor engines), with total facility uncontrolled actual emissions of such pollutants that are less than two twenty five tons per year.

II.D.55. When a facility that was previously exempt from permit requirements exceeds one of the permit de minimis levels stated in Sections II.D.2. through II.D.4., above, due to the addition of new emission points or an increase in uncontrolled actual emissions, the Division will issue either a facility-wide permit for all non-grandfathered emission units above that require Air Pollutant Emission Notices de minimis levels=, or individual emission permits for those emission units that are not otherwise permit exempt.

>>>>>>>>

PART C CONCERNING OPERATING PERMITS

>>>>>>>>

II.E. Insignificant Activities and Exemptions from Operating Permit Requirements

>>>>>>>>

The following sources are exempt from the requirement to obtain an operating permit pursuant to this Part C:

>>>>>>>>

II.E.3.ddd. Exemption Repealed *Crude oil storage tanks with a capacity of 40,000 gallons or less.

>>>>>>>>

PART D CONCERNING MAJOR STATIONARY SOURCE NEW SOURCE REVIEW AND PREVENTION OF SIGNIFICANT DETERIORATION

>>>>>>>>

XV. Actuals PALs

>>>>>>>>

XV.F. Contents of the PAL permit.

>>>>>>>>
XV.F.5. A requirement that, once the PAL expires, the major stationary source is subject to the requirements of Section XV.H.

REGULATION NUMBER 7

CONTROL OF OZONE VIA OZONE PRECURSORS ~~AND CONTROL OF HYDROCARBONS VIA OIL AND GAS EMISSIONS~~

(EMISSIONS OF VOLATILE ORGANIC COMPOUNDS AND NITROGEN OXIDES)

5 CCR 1001-9

[The Joint Industry Work Group proposes that all Division Proposed Rules as well as any changes made in this Revised Collective Proposed Revisions document apply only in the ozone nonattainment area]

>>>>>>>>

II. General Provisions

>>>>>>>>

II.B. Exemptions

Emissions of the organic compounds listed as having negligible photochemical reactivity in the common provisions definition of Negligibly Reactive Volatile Organic Compound are exempt from the provisions of this regulation.

~~(State Only) Notwithstanding the foregoing exemption, hydrocarbon emissions from oil and gas operations, including methane and ethane, are subject to this regulation as set forth in Sections XVII. and XVIII.~~

>>>>>>>>

XVII. (State Only, except Section XVII.E.3.a. which was submitted as part of the Regional Haze SIP) Statewide Controls for Oil and Gas Operations and Natural Gas-Fired Reciprocating Internal Combustion Engines

XVII.A. (State Only) Definitions

XVII.A.1 "Air Pollution Control Equipment," as used in this Section XVII, means a combustion device or vapor recovery unit. Air pollution control equipment also means alternative emissions control equipment and pollution prevention devices and processes intended to reduce uncontrolled actual emissions that comply with the requirements of Section XVII.B.2.e.

XVII.A.2. ~~"~~"Approved Instrument ~~Based~~ Monitoring Method" or "AIMM"~~," as used in this Section XVII."~~ means an infra-red camera with cooled InSb focal plane array with non-dispersive infra-red filter, tunable diode laser absorption spectroscopy ("TDLAS"), flame ionization detector, optical methane detector, infra-red controlled interference polarization spectrometer, cavity ring-down spectroscopy, mid-infra-red laser-based differential absorption light detection and ranging ("LIDAR"), pulsed infra-red laser, three-channel

non-dispersive gas correlation infra-red spectrometer, EPA Method 21, or other Division approved instrument ~~based~~ monitoring, device or method. If an owner~~/~~ or operator elects to use ~~a~~ Division approved ~~Continuous Emission Monitoring program~~continuous emission monitoring, the Division may approve a streamlined inspection and reporting program for such operations. ~~Any instrument based monitoring method approved by the Division under this definition must be at least as effective as Method 21 or an infra-red camera.~~

XVII.A.~~2.~~ ~~"Atmospheric", when used to modify the term "condensate storage tank", means a type of condensate storage tank that vents, or is designed to vent, to the atmosphere.~~3. ~~"~~"Auto-Igniter" means a device which will automatically attempt to relight the pilot flame in the combustion chamber of a control device in order to combust ~~volatile organic compound~~ VOC emissions.

XVII.A.4. "Centrifugal Compressor" means any machine used for raising the pressure of natural gas by drawing in low pressure natural gas and discharging significantly higher pressure natural gas by means of mechanical rotating vanes or impellers. Screw, sliding vane, and liquid ring compressors are not centrifugal compressors for the purposes of this subpart.

XVII.A.5. "Component" means each pump seal, ~~compressor seal~~, flange, pressure relief device, connector, ~~open ended line~~, and valve that contains or contacts a process stream with ~~hydrocarbons~~at least 10 percent VOCs by weight. For the purpose of Section IXVII., ~~P~~process stream~~s~~ does not include those streams consisting of glycol, amine, produced water, or methanol ~~are not components for purposes of this Section XVII~~.

XVII.A.~~5~~6. "Connector" means flanged, screwed, or other joined fittings used to connect two pipes or a pipe and a piece of process equipment or that close an opening in a pipe that could be connected to another pipe. Jointed fittings welded completely around the circumference of the interface are not considered connectors.

XVII.A.~~3~~6. "~~Condensate Storage Tank" means any production tank or series~~Date of First Production" means the date reported to the COGCC as the "~~first~~ date of first production ~~tanks that are manifolded together that store condensate~~."

XVII.A.~~7~~8. "Glycol Natural Gas Dehydrator" means any device in which a liquid glycol (including ethylene glycol, diethylene glycol, or triethylene glycol) absorbent directly contacts a natural gas stream and absorbs water.

XVII.A.9 "Intermediate Hydrocarbon Liquid" means any naturally occurring, unrefined petroleum liquid, as defined in 40 CFR Part 60, Subpart OOOO.

~~XVII.A.89. "Multi-Well Site" means a common well pad from which multiple wells may be drilled to various bottomhole locations.~~

XVII.A.~~9~~10. "Natural Gas Compressor Station" means a facility, located downstream of well production facilities, which contains one or more compressors designed to compress natural gas from well pressure to gathering system pressure ~~and recompress~~ prior to the inlet of a natural gas ~~prior to~~ processing plant.

XVII.A.~~10~~11. "Normal Operation" means all periods of operation, excluding malfunctions as defined in Section I.G. of the Common Provisions regulation. ~~For storage tanks at well production facilities, normal operation includes, but is not limited to, liquid dumps from the separator.~~

~~XVII.A.11~~XVII.A.12. "Open-Ended Valve or Line" means any valve, except safety relief valves, having one side of the valve seat in contact with process fluid and one side open to the atmosphere, either directly or through open piping.

XVII.A.13. "Reciprocating Compressor" means a piece of equipment that increases the pressure of process gas by positive displacement, employing linear movement of the driveshaft.

XVII.A.14. "Stabilized" when used to refer to crude oil, condensate, intermediate hydrocarbon liquids, or produced water means that the vapor pressure of the liquid is sufficiently low to prevent the production of vapor phase upon transferring the liquid to an atmospheric pressure in a storage tank, and that any emissions that occur are limited to those commonly referred to within the industry as working, breathing, and standing losses.

XVII.A.~~12~~15. "Storage Tank" means any permanent fixed roof storage vessel or series of storage vessels that are manifolded together via liquid line. Storage vessel is as defined in 40 CFR Part 60, Subpart OOOO. Storage tanks may be located at a well production facility or other location.

~~XVII.A.1316. "Unsafe to Monitor" means a component is unsafe to inspect because inspecting personnel would be exposed to an imminent or potentialimmediate danger as a consequence of such monitoring.~~

XVII.A.16. "Uncontrolled Release" means emissions from thief hatches (or other access points to the storage tank) and pressure relief devices at a storage tank that result from inadequate design, operation, or maintenance, except for those emissions that are necessary for the safety of personnel and equipment. Emissions during routine maintenance, tank gauging, and loadout operations shall not be considered Uncontrolled Releases.

XVII.A.~~14~~17. "Visible Emissions" means observations of smoke for any period or periods of duration greater than or equal to one (1) minute in any fifteen (15) minute period during normal operation pursuant to EPA Method 22. Visible emissions do not include radiant energy or water vapor. This definition also applies to Visible Emissions as referred to in XII of this Regulation Number 7.

XVII.A.~~15~~18. "Well Production Facility" means all permanent equipment co-located at a single stationary source directly associated with one or more oil ~~wells~~ or gas production wells. This equipment includes, but is not limited to, equipment used for storage, separation, treating, dehydration, artificial lift, combustion, compression, pumping, metering, monitoring, and flowline located at the inlet to the separator through the point of Custody Transfer. Oil and gas production wells located on the same surface disturbance as the single stationary source are included in the Well Production Facility. "Custody Transfer" means the transfer of produced crude oil and/or condensate, after processing and/or treating in the producing operations, from Storage Tanks or automatic transfer facilities to sales pipelines or any other forms of post-sales transportation or the point at which natural gas passes from Well Production Facilities to natural gas gathering lines through which gathered natural gas is conveyed to Compressor Stations.

XVII.B. (State Only) General Provisions

These Regulations shall not apply to any lands within the exterior boundaries of the Southern Ute Indian Reservation, as agreed in, and defined by, that Intergovernmental Agreement between the Southern Ute Indian Tribe and the State of Colorado Concerning Air Quality Control on the Southern Ute Indian

Reservation, codified at Colorado Revised Statutes Section 24-62-101 (2013); (see also C.R.S. § 25-7-1301 (2013)); and approved by the United States Environmental Protection Agency on March 2, 2012 at 77 Fed. Reg. 15267 (March 14, 2012).

XVII.B.1. General requirements for prevention of emissions and good air pollution control ~~equipment, prevention of leakage, and flares and combustion devices.~~practices for all ~~oil and gas exploration and production operations,~~ well production facilities, natural gas compressor stations, and natural gas processing plants.

XVII.B.1.a. All intermediate hydrocarbon liquids collection, storage, processing, and handling operations, regardless of size, shall be designed, operated, and maintained so as to minimize leakage of ~~volatile organic compounds~~VOCs and other hydrocarbons to the atmosphere to the extent reasonably practicable.

XVII.B.1.b. At all times, including periods of start-up and shutdown, the facility and air pollution control equipment ~~shall~~must be maintained and operated in a manner consistent with good air pollution control practices for minimizing VOC emissions. Determination of whether or not acceptable ~~operating~~operation and maintenance procedures are being used will be based on information available to the Division, which may include, but is not limited to, monitoring results, opacity observations, review of ~~operating~~operation and maintenance procedures, and inspection of the source.

XVII.B.2. General requirements for air pollution control equipment~~, flares, and combustion devices used~~ required to comply with Section XVII.

XVII.B.~~1~~2.a. All air pollution control equipment ~~required by this Section XVII~~ shall be operated and maintained pursuant to ~~manufacturer~~the manufacturing specifications or equivalent to the extent practicable, and consistent with technological limitations and good engineering and maintenance practices. The owner or operator shall keep manufacturer specifications or equivalent on file. In addition, all such air pollution control equipment shall be adequately designed and sized to achieve the control efficiency rates ~~required by this Section XVII~~ and to handle reasonably foreseeable fluctuations in emissions of ~~volatile organic compounds~~VOCs ~~and other hydrocarbons~~ during normal operations. Fluctuations in emissions that occur when the separator dumps into the tank are reasonably foreseeable.

~~XVII.B.1.b. All condensate collection, storage, processing and handling operations, regardless of size, shall be designed, operated and maintained so as to minimize leakage of volatile organic compounds to the atmosphere to the extent reasonably practicable.~~

XVII.B.~~1~~2.~~c~~b. If a ~~flare or other~~ combustion device is used to control emissions of ~~volatile organic compounds to comply with Section XVII~~VOCs ~~and other hydrocarbons~~ from storage tanks subject to Section XVII.C. and glycol natural gas dehydrators subject to Section XVII.D., it shall be enclosed except as described below in Section XVII.B.2.f., have no visible emissions during normal ~~operations~~operation, and be designed so ~~than~~that an observer can, by means of visual observation from the outside of the enclosed flare or combustion device, or by other ~~convenient~~ means approved by the Division, determine whether it is operating properly. An owner or operator that installed a combustion device prior to [insert date of promulgation] with Division approval, either express or implied,

is not required to replace or retrofit the control device unless the combustion device is modified after [insert date of promulgation].

XVII.B.~~1~~2.~~d~~c. Any of the effective dates for installation of controls on ~~condensate~~storage tanks, glycol natural gas dehydrators, and/or internal combustion engines may be extended at the ~~air pollution control~~ Division's discretion for good cause shown.

XVII.B.2.d. Auto-igniters: All combustion devices used to control emissions of ~~hydrocarbons~~ VOCs from storage tanks subject to Section XVII.C. and glycol natural gas dehydrators subject to Section XVII.D. ~~shall~~must be equipped with and operate an auto-igniter as follows:

XVII.B.2.d.(i) All such combustion devices installed on or after ~~May~~ January 1, 201~~5~~4, ~~will~~must be equipped with an operational auto-igniter upon installation of the combustion device~~.~~; and

XVII.B.2.d.(ii) All such combustion devices installed before ~~May~~ January 1, 201~~5~~4, ~~will~~must be equipped with an operational auto-igniter by or before May 1, 2016, or after the next combustion device planned shutdown, whichever comes first.

XVII.B.2.e. Alternative emissions control equipment shall qualify as air pollution control equipment, and may be used in lieu of, or in combination with, combustion devices and vapor recovery units to achieve the emission reductions required by this Section XVII, if the Division approves the equipment, device or process. ~~As part of the approval process the Division, at its discretion, may specify a different control efficiency than the control efficiencies required by this Section XVII.~~

XVII.B.2.f. An owner or operator may install a non-enclosed flare that otherwise meets the requirements of XVII.B.2.b. to control volatile organic compounds as follows:

XVII.B.2.f.(i) If the flare will control emissions at a Well Production Facility, Compressor Station, or natural gas processing plant and the required design capacity exceeds the reasonably available capacity for an enclosed combustor;

XVII.B.2.f.(ii) If the flare will serve as a backup to the primary means of control;

XVII.B.2.f. (iv) If the flare is located more than 1,320 feet from a Residential Area. For purposes of this Section XVII.B.2.f., Residential Area means an area where six (6) or more occupied residential homes are within a 1,320 foot radius of the Well Production Facility, Compressor Station, or natural gas processing plant at which the flare is located. The presence of a Residential Area shall be determined at the time the non-enclosed flare is installed. Owners and operators shall not be required to replace or retrofit the non-enclosed flare in the event that a Residential Area is later established within 1,320 feet of the Well Production Facility, Compressor Station, or natural gas processing plant.

(v) An owner or operator that installed a flare subject to one of the exceptions at XVII.B.2.f.(i). through (iv). or with prior division approval, either express

or implied, is not required to retrofit or replace the flare unless modified, pursuant to Regulation 3, and a cost-benefit analysis reasonably justifies retrofit or replacement.

XVII.B.2.g. In the event that a control device is inoperable or malfunctioning, the owner or operator may choose to shut-in operations to the source or site as an air pollution control alternative, in lieu of, emergency recordkeeping and reporting requirements. Only records of the shut-in and control device maintenance must be maintained.

XVII.B.3. Requirements for compressor seals and open-ended valves or lines at natural gas compressor stations only.

XVII.B.3.a. Beginning January 1, 2015, each open-ended valve or line at ~~well production facilities and~~ natural gas compressor stations must be equipped with a cap, blind flange, plug, or a second valve that seals the open end at all times except during operations requiring process fluid flow through the open-ended valve or line. Open-ended valves or lines in an emergency shutdown system which are designed to open automatically in the event of a process upset are exempt from the requirement to seal the open end of the valve or line.

XVII.B.3.b. Beginning January 1, 2015, uncontrolled actual ~~hydrocarbon~~ VOC emissions from wet seal fluid degassing systems on wet seal centrifugal compressors at natural gas compressor stations must be reduced by at least 95%, unless the centrifugal compressor is subject to 40 C.F.R. Part 60, Subpart OOOO on that date or thereafter.

XVII.B.3.c. Beginning January 1, 2015, at natural gas compressor stations, the rod packing on any reciprocating compressor installed must be replaced every 26,000 hours of operation or every thirty six (36) months, unless the reciprocating compressor is subject to 40 C.F.R. Part 60, Subpart OOOO on that date or thereafter or if the vent gas from the rod packing is being captured, controlled or put to other beneficial use. The measurement of accumulated hours of operation (26,000) or months elapsed (36) begins on January 1, 2015.

X.V.II.B.4. Oil refineries are not subject to ~~this section of the rule~~Section XVII.

XVII.B.45. ~~Condensate tanks,~~Glycol natural gas dehydrators and internal combustion engines that are subject to an emissions control requirement in a federal maximum achievable control technology ("MACT") standard under 40 CFR Part 63, a Best Available Control Technology ("BACT") limit, or a New Source Performance Standard ("NSPS") under 40 CFR Part 60 are not subject to ~~this~~ Section XVII.

XVII.C. (State Only) Emission reduction from ~~condensate~~ storage tanks at ~~oil and gas exploration and production operations, natural gas compressor stations~~well production facilities, natural gas ~~drip~~compressor stations, and natural gas processing plants.

XVII.C.1. Control and monitoring requirements for storage tanks

XVII.C.1.a. Beginning May 1, 2008, owners or operators of all ~~atmospheric condensate~~ storage tanks storing condensate with uncontrolled actual emissions of ~~volatile organic compounds~~VOCs equal to or greater than twenty (20) tons per year based on a rolling twelve-month total ~~shall~~must operate air pollution control equipment that has an average control efficiency of at least 95% for VOCs ~~on such tanks~~.

XVII.C.~~2~~1.b. ~~For condensate~~Owners or operators of all storage tanks with ~~past,~~ uncontrolled actual emissions of ~~volatile organic compounds~~VOCs ~~of less~~equal to or greater than ~~20~~six (6) tons per year based on a rolling twelve-month total ~~that may become subject to Section XVII.C.1. by virtue of the addition of a newly drilled well or the recompletion or stimulation of an existing well, owners or operators of such tanks shall have until 90 days after the date of 1st production of the newly drilled, recompleted or stimulated well to install and~~must operate ~~any required~~ air pollution control equipment~~. If the owner or operator determines that emissions of volatile organic compounds will be below the 20 ton per year threshold, the owner or operator shall notify the Division of this determination in writing and include an explanation of the methodology used to make this determination.~~ that achieves an average ~~hydrocarbon~~ VOC control efficiency of 95%. If a combustion device is used, it ~~shall~~must have a design destruction efficiency of at least 98% for ~~hydrocarbons~~VOCs.

XVII.C.1.b.(i) Control requirements of Section XVII.C.1.b. must be achieved in accordance with the following schedule:

XVII.C.1.b.(i)(a) A storage tank constructed on or after ~~May~~ January 1, 201~~4~~5, must be in compliance ~~by~~within ninety (90) days from the date that the storage tank commences operation.

XVII.C.1.b.~~(ii)~~(i)(b) A storage tank ~~constructed~~ that began operating before ~~May~~ January 1, 201~~4~~5, must be in compliance by May 1, 201~~6~~5.

XVII.C.1.b.~~(iii)~~(i)(~~d~~c) A storage tank not otherwise subject to Sections XVII.C.1.b.(i)(a) or XVII.C.1.b.(i)(b)~~(ii), above~~, that increases uncontrolled actual emissions to six (6) tons per year VOC or more ~~per year~~ on a rolling twelve month basis after ~~May~~ January 1, 201~~4~~5, must be in compliance within sixty ~~days~~ (60) days of discovery of the emissions increase.

XVII.C.1.c. Control requirements within ninety (90) days of the date of first production.

XVII.C.1.c.(i) Beginning ~~May~~ January 1, 201~~4~~5, owners or operators of storage tanks at well production facilities ~~shall~~must collect and control emissions by routing emissions to operating air pollution control equipment during the first ninety (90) calendar days after the date of first production. The air pollution control equipment ~~shall~~must achieve an average ~~hydrocarbon~~ VOC control efficiency of 95%. If a combustion device is used, it ~~shall~~must have a design destruction efficiency of at least 98% for ~~hydrocarbons~~VOCs. ~~Except that this~~This control requirement does not apply to storage tanks that are reasonably projected to have emissions less than 1.5 tons of VOC during the first ninety (90) days after the date of first production.

XVII.C.1.c.(ii) The air pollution control equipment and any associated monitoring equipment required pursuant to Section XVII.C.1.c.~~, above~~(i), may be removed at any time after the first 90 calendar days as long as the source can demonstrate that uncontrolled actual emissions from the storage tank are reasonably expected to be below the threshold in Section XVII.C.1.b~~., above~~.

~~XVII.C.2. Capture requirements for storage tanks that are fitted with air pollution control equipment as required by Sections XII.D. or~~ XVII.C.1.

XVII.C.2.a. Beginning onJanuaryMay 1, 20154, or the applicable compliance date specified in Section XVII.C.1.b.(i), whichever comes later, owners andor operators of storage tanks shall route all hydrocarbon emissionssubject to air pollution control equipment, and shall operate without venting hydrocarbon emissions from the thief hatch (or other access point to the tank) or pressure relief device during normal operation unless venting is reasonably required for maintenance, gauging, or safety of personnel and equipment.

XVII.C.2.b. Beginning on the applicable compliance date specified in section XVII.C.1.b., owners and operators of storage tanks shall develop, certify, and implement a document Storage Tank Emission Management System (STEM) plan to identify appropriate strategies to minimize emissions from venting at thief hatches (or other access points to a storage tank) and pressure relief devices during normal operation. As part of STEM, owners and operators shall evaluate and employ appropriate control technologies, monitoring practices, operational practices, and/or other strategies designed to meet the requirements set forth in Section XVII.C.2.a., above, and will update the STEM plan as necessary to achieve or maintain compliance. Owners and operators are not required to develop and implement STEM for storage tanks containing only stabilized liquids. The minimum elements of STEM are listed below.

XVII.C.2.1.b.(i) STEM must include a monitoring strategy that incorporates the minimum monitoring frequency set forth in Section XVII.F.5.e., procedures for evaluating ongoing storage tank emission capture performance, and, if applicable, the selected strategies.

XVII.C.2.b.(ii) STEM must include a certification by the owner or operator that the selected STEM strategy or strategies are designed to minimize emissions from storage tanks and associated equipment components at the facility or facilities, including thief hatches and pressure relief devices.

XVII.C.3. Monitoring: The monitoring strategy of each STEM plan must include monitoring in accordance with Approved Instrument Based Monitoring Methods, as specified in Section XVII.F.5.

XVII.C.3.a. In addition to any applicable Approved Instrument Based Monitoring Methods, conduct audio, visual, olfactory ("AVO") inspection and additional visual inspections of the storage tank and any associated equipment (i.e. separator, air pollution control equipment, or other pressure reducing equipment), must be completed) as oftenat the same frequency as liquids are loaded out from the storage tank. However, AVO inspection isThese inspections are required no more frequently than every seven (7) days or less frequently than every thirty-one (310) days. AVO monitoring is not required for components and storage tanks or associated equipment that are unsafe, difficult, or inaccessible to monitor. AVO inspection, as defined in Section XVII.C.1.e. The additional visualAVO inspections must include, at a minimum:

XVII.C.3.a.1.d.(i) Visual inspection of any storage tank thief hatch, pressure relief valve, or other access point to ensure that they are enclosed and properly sealed;

XVII.C.3.a.1.d.(ii) Visual inspection or monitoring of the storage tank air pollution control equipment to ensure that it is operating, including that the pilot light is lit on combustion devices used as air pollution control equipment;

XVII.C.~~3.a.~~1.d.(iii) If a ~~flare or other~~ combustion device is used, visual inspection of the auto-igniter and valves for piping of gas to the pilot light, to ensure they are functioning properly;

XVII.C.~~3.a.~~1.d.(iv) Visual inspection of the air pollution control equipment to ensure that the valves for the piping from the storage tank to the air pollution control equipment are open; and

XVII.C.~~3.~~1.d.(v) ~~Monitoring: The owner or operator of any condensate storage tank that is required to control volatile organic compound emissions pursuant to this Section XVII.C. shall visually inspect or monitor the Air Pollution Control Equipment to ensure that it is operating at least as often as condensate is loaded out from the tank, unless a more frequent inspection or monitoring schedule is followed. In addition, if~~a.(v) If a ~~flare or~~ other combustion device is used, ~~the owner or operator shall visually inspect~~inspection of the device for the presence ~~of~~ or absence of smoke. If smoke is observed, either the equipment ~~will~~must be immediately shut-in to investigate ~~that~~the potential cause for smoke and perform repairs, as necessary, or EPA Method 22 ~~shall~~must be conducted to determine whether visible emissions are present for a period of at least ~~as often as condensate is loaded out from the tank~~one (1) minute in fifteen (15) minutes.

XVII.C.1.e. If equipment associated with the storage tank is unsafe, difficult, or inaccessible to monitor, the owner or operator ~~is~~ shall not be required to monitor such equipment ~~until it becomes feasible to do so~~.

XVII.C.1.e.(i) ~~—~~Difficult to monitor equipment are those that ~~means it~~ cannot be monitored without elevating the monitoring personnel more than two meters above a supported surface or is unable to be reached via a wheeled scissor-lift or hydraulic type scaffold that allows access up to 7.6 meters (25 feet) above the ground.

XVII.C.1.e.(ii) ~~-~~Unsafe to monitor means ~~it~~ equipment is unsafe to monitor because ~~cannot be monitored without exposing~~ monitoring personnel would be exposed to ~~an~~ imminent and potential ~~immediate~~ danger as a consequence of completing the monitoring.

XVII.C.1.e.(iii) ~~-~~Inaccessible to monitor equipment means equipment that is buried, insulated, or obstructed by equipment or piping that prevents access to the equipment by monitoring personnel.

XVII.C.2. Capture and monitoring requirements for storage tanks that are fitted with air pollution control equipment as required by Sections XII.D. or XVII.C.1.

XVII.C.2.a. Owners or operators of storage tanks must ~~route all hydrocarbon emissions to air pollution control equipment, and must~~ operate ~~without~~ to minimize ~~venting hydrocarbon emissions~~ uncontrolled releases to the maximum extent practicable from the thief hatches (or other access point to the tank) or pressure relief device ~~during normal operation, unless venting is reasonably required for maintenance, gauging, or safety of personnel and equipment. Compliance must be achieved~~ in accordance with the schedule in Section XVII.C.2.b.(ii).

XVII.C.2.b. Beginning on January 1, 2015, or the applicable compliance date in Section XVII.C.1.b.(i), whichever comes later, ~~O~~owners or operators of storage

tanks subject to control requirements of Sections XII.D.2., XVII.C.1.a. or XVII.C.1.b. must develop, certify, and implement a documented Storage Tank Emission Management System (STEM) plan to identify, evaluate, and employ appropriate control technologies, monitoring practices, operational practices, and/or other strategies designed to meet the requirements set forth in Section XVII.C.2.a. An owner or operator may develop a STEM plan applicable to multiple Storage Tanks across some or all of the owner or operators' assets and operations within Colorado. ~~-~~Owners or operators must update the STEM plan as necessary to achieve or maintain compliance. Owners or operators are not required to develop and implement STEM for storage tanks containing only stabilized liquids. The minimum elements of STEM are listed below.

XVII.C.2.b.(i) The STEM plan must include selected control technologies, monitoring practices, operational practices, and/or other strategies; procedures for evaluating ongoing storage tank emission capture performance; and monitoring in accordance with ~~approved instrument based monitoring methods~~AIMM following the applicable monitoring frequency in Table 1.

XVII.C.2.b.(ii) Owners or operators must achieve the requirements of Sections XVII.C.2.a. ~~and XVII.C.2.b.~~ and begin implementing the required ~~approved instrument based monitoring~~AIMM method in accordance with the following schedule:

XVII.C.2.b.(ii)(a) A storage tank constructed on or after ~~May~~ January 1, 201~~5~~4, must comply with the requirements of Sections XVII.C.2.a. ~~and XVII.C.2.b.~~ by the date that the storage tank commences operation. Approved instrument based monitoring method inspections must begin within ninety (90) days after the tank commences operation.

XVII.C.2.b.(ii)(b) A storage tank constructed before ~~May~~ January 1, 201~~5~~4, must comply with the requirements of Sections XVII.C.2.a. and XVII.C.2.b. by May 1, 201~~5~~6. Approved instrument based monitoring method inspections must begin within ninety (90) days of the Phase-In Schedule in Table 1, or within thirty (30) days for storage tanks with uncontrolled actual VOC emissions > 50 tons per year.

XVII.C.2.b.(ii)(c) A storage tank not otherwise subject to Sections XVII.C.2.b.(ii)(a) or XVII.C.2.b.(ii)(b) that increases uncontrolled actual emissions to six (6) tons per year VOC or more on a rolling twelve month basis after ~~May~~ January 1, 201~~5~~4, must be in compliance with Sections XVII.C.2.a. and XVII.C.2.b. and implement the required ~~approved instrument based monitoring~~AIMM method within sixty (60) days of discovery of the emissions increase.

XVII.C.2.b.(ii)(d) Following the first approved instrument based monitoring method inspection, owners or operators must continue conducting ~~approved instrument based monitoring~~AIMM method inspections in accordance with the Inspection Frequency in Table 1.

Table 1 – Storage Tank Inspections		
Threshold: Storage Tank Uncontrolled Actual VOC Emissions (tpy)	Approved Instrument Based Monitoring Method Inspection Frequency	Phase-In Schedule
> 6 and ≤< 12	Annually	January 1, 2016
> 12 and ≤< 50	Quarterly	July 1, 2015
> 50	Monthly	January 1, 2015

XVII.C.2.b.(iii) Owners or operators are not required to monitor storage tanks and associated equipment that are unsafe, difficult, or inaccessible to monitor, as defined in Section XVII.C.1.e.

XVII.C.2.b.(iv) STEM must include a certification by the owner or operator that the selected STEM strategy or strategies are designed to minimize emissions from storage tanks and associated equipment at the facility or facilities, including thief hatches and pressure relief devices.

XVII.C.3. Recordkeeping: The owner or operator of each condensate storage tank ~~shall~~subject to Sections XII.D. or XVII.C.1.b. must maintain ~~the following~~ records of STEM ~~as~~if applicable, including the plan, any updates, and the certification, ~~to be made~~and make them available to the Division upon request. In addition, for a period of ~~five~~two years, the owner or operator must maintain records of any required monitoring and make them available to the Division upon request, including:

XVII.C.~~4~~3.a. ~~Monthly condensate production from the~~The AIRS ID for the storage tank.

XVII.C.~~4~~3.b. The date and duration of any period where uncontrolled releases are discovered at the storage tank thief hatch, pressure relief device, or other access point ~~are found to be venting hydrocarbon emissions~~.

XVII.C.~~4.~~3~~b~~c. ~~For any condensate storage tank required to be controlled pursuant to this Section XVII.C., the~~The date~~, time~~ and duration of any period where the air pollution control equipment is not operating. ~~The duration of a period of non-operation shall be from the time that the air pollution control equipment was last observed to be operating until the time the equipment recommences operation.~~

XVII.C.~~4~~3.c~~d~~. ~~For tanks where~~Where a ~~flare or other~~ combustion device is being used, the date and ~~time of any instances where visible emissions are observed from the device~~result of any EPA Method 22 test or investigation pursuant to Section XVII.C.4.1.d.(v).

XVII.C.3.e. The timing of and efforts made to eliminate ~~venting~~an uncontrolled release, restore operation of air pollution control equipment, and to mitigate visible emissions.

XVII.C.3.f. A list of equipment that ~~identification numbers for components that are~~is designated as unsafe, difficult, or inaccessible to monitor, as described in Section

XVII.C.1.e., an explanation stating why the equipment~~component~~ is so designated, and the plan for monitoring such equipment~~component(s)~~.

XVII.D. (State Only) Emission reductions from glycol natural gas dehydrators

XVII.D.1. Beginning May 1, 2008, still vents and vents from any flash separator or flash tank on a glycol natural gas dehydrator located at ~~an oil and gas exploration and production operation~~a well production facility, natural gas compressor station, ~~drip station or~~ or natural gas gas-processing plant subject to control requirements pursuant to Section XVII.D.2., shall reduce uncontrolled actual emissions of volatile organic compounds by at least 90 percent through the use of ~~a condenser or~~ air pollution control equipment.

XVII.D.2. The control requirement in Section XVII.D.1. shall apply where:

XVII.D.2.a. Actual uncontrolled emissions of volatile organic compounds from the glycol natural gas dehydrator are equal to or greater than two tons per year; and

XVII.D.2.b. The sum of actual uncontrolled emissions of volatile organic compounds from any single glycol natural gas dehydrator or grouping of glycol natural gas dehydrators at a single stationary source is equal to or greater than 15 tons per year. To determine if a grouping of dehydrators meets or exceeds the 15 tons per year threshold, sum the total actual uncontrolled emissions of volatile organic compounds from all individual dehydrators at the stationary source, including those with emissions less than two tons per year.

~~XVII.D.3. Beginning May 1, 2015, still vents and vents from any flash separator or flash tank on a glycol natural gas dehydrator located at an oil and gas exploration and production operation, natural gas compressor station, and drip station or gas-processing plant subject to control requirements pursuant to Section XVII.D.4., shall reduce uncontrolled actual emissions of hydrocarbons by at least 95 percent on a rolling twelve-month basis through the use of a condenser or air pollution control equipment. If a combustion device is used, it shall have a design destruction efficiency of at least 98% for hydrocarbons, except where:~~

~~XVII.D.3.a. The combustion device has been authorized by permit prior to May 1, 2014; and~~

~~XVII.D.3.b. A building unit or designated outside activity area is not located within 1,320 feet of the facility at which the natural gas glycol dehydrator is located.~~

~~XVII.D.4. The control requirement in Section XVII.D.3. shall apply where:~~

~~XVII.D.4.a. Actual uncontrolled emissions Owners or operators of volatile organic compounds from a single newa glycol natural gas dehydrator are constructed on or after May 1, 2015, with uncontrolled actual emissions of VOCs equal to or greater than two (2) tons per year must be in compliance with Section XVII.D.3. by the date that the glycol natural gas dehydrator commences operation; or~~

~~XVII.D.4.b. Actual uncontrolled Uncontrolled actual emissions of volatile organic compoundsVOCs from a single existing glycol natural gas dehydrator constructed before May 1, 2015, are equal to or greater than six (6) tons per year, or two (2) tons per year if the glycol natural gas dehydrator is located within 1,320 feet of a building unit or designated outside activity area.~~

~~XVII.D.4.c. For purposes of Section~~Sections XVII.D.3. and XVII.D.4.:

~~XVII.D.4.c.(i) Building Unit shall mean a residential building unit, and every five thousand (5,000) square feet of building floor area in commercial facilities or every fifteen thousand (15,000) square feet of building floor area in warehouses that are operating and normally occupied during working hours.~~

~~XVII.D.4.c.(ii) A designated outside activity area~~Designated Outside Activity Area shall mean an outdoor venue or recreation area, such as a playground, permanent sports field, amphitheater, or other similar place of public assembly owned or operated by a local government, which the local government seeks to have established as a ~~Designated Outside Activity~~designated outside activity area by the COGCC ~~Area~~; or an outdoor venue or recreation area where ingress to or egress from could be impeded in the event of an emergency condition at an oil and gas location less than three hundred and fifty (350) feet from the venue due to the configuration of the venue and the number of persons known or expected to simultaneously occupy the venue on a regular basis.

XVII.E. Control of emissions from new, modified, existing, and relocated natural gas fired reciprocating internal combustion engines.

XVII.E.1. (State Only) The requirements of this Section XVII.E. shall not apply to any engine having actual uncontrolled emissions below permitting thresholds listed in Regulation Number 3, Part B.

XVII.E.2. (State Only) New, Modified and Relocated Natural Gas Fired Reciprocating Internal Combustion Engines

XVII.E.2.a. Except as provided in Section XVII.E.2.b. below, the owner or operator ~~on~~of any natural gas fired reciprocating internal combustion engine that is either constructed or relocated to the state of Colorado from another state, on or after the date listed in the table below shall operate and maintain each engine according to the manufacturer's written instructions or procedures to the extent practicable and consistent with technological limitations and good engineering and maintenance practices over the entire life of the engine so that it achieves the emission standards required in Section XVII.E.2.b. Table ~~1~~2 below.

XVII.E.2.b. Actual emissions from natural gas fired reciprocating internal combustion engines shall not exceed the emission performance standards in Table ~~1~~2 below as expressed in units of grams per horsepower-hour (G/hp-hr)

TABLE ~~1~~2

Maximum Engine Hp	Construction or Relocation Date	Emission Standards is G/hp-hr		
		NOx	CO	VOC
< 100 Hp	Any	NA	NA	NA
≥100 Hp	On or after January 1, 2008	2.0	4.0	1.0

and < 500 Hp	On or after January 1, 2011	1.0	2.0	0.7
≥500 Hp	On or after July 1, 2007	2.0	4.0	1.0
	On or after July 1, 2010	1.0	2.0	0.7

XVII.E.3. Existing Natural Gas Fired Reciprocating Internal Combustion Engines

XVII.E.3.a. (Regional Haze SIP) Rich Burn Reciprocating Internal Combustion Engines

XVII.E.3.a.(i) Except as provided in Sections XVII.3.1.(i)(b) and (c) and XVII.E.3.a.(ii), all rich burn reciprocating internal combustion engines with a manufacturer's name plate design rate greater than 500 horsepower, constructed or modified before February 1, 2009 shall install and operate both a non-selective catalytic reduction system and an air fuel controller by July 1, 2010. A rich burn reciprocating internal combustion engine is one with a normal exhaust oxygen concentration of less than 2% by volume.

XVII.E.3.a.(i)(a) All control equipment required by this Section XVII.E.3.a. shall be operated and maintained pursuant to manufacturer specifications or equivalent to the extent practicable, and consistent with technological limitations and good engineering and maintenance practices. The owner or operator shall keep manufacturer specifications or equivalent on file.

XVII.E.3.a.(i)(b) Internal combustion engines that are subject to an emissions control requirement in a federal maximum achievable control technology ("MACT") standard under 40 CFR Part 63, a Best Available Control Technology ("BACT") limit, or a New Source Performance Standard under 40 CFR Part 60 are not subject to this Section XVII.E.3.a.

XVII.E.3.a.(i)(c) The requirements of this Section XVII.E.3.a. shall not apply to any engine having actual uncontrolled emissions below permitting thresholds listed in Regulation Number 3, Part B.

XVII.E.3.a.(ii) Any rich burn reciprocating internal combustion engine constructed or modified before February 1, 2009, for which the owner or operator demonstrates to the Division that retrofit technology cannot be installed at a cost of less than $ 5,000 per ton of combined volatile organic compound and nitrogen oxides emission reductions (this value shall be adjusted for future applications according to the current day consumer price index) is exempt complying with Section XVII.E.3.a. Installation costs and the best information available for determining control efficiency shall be considered in determining such costs. In order to qualify for such exemption, the owner or operator must submit an application making such a demonstration, together with all supporting documents, to the Division by August 1,2009.

XVII.E.3.b. (State Only) Lean Burn Reciprocating Internal Combustion Engines

XVII.E.3.b.(i) Except as provided in Section XVII.E.3.b.(ii), all lean burn reciprocating internal combustion engines with a manufacturer's nameplate design rate greater than 500 horsepower shall install and operate an oxidation catalyst by July 1, 2010. A lean burn reciprocating internal combustion engine is one with a normal exhaust oxygen concentration of 2% by volume, or greater.

XVII.E.3.b.(ii) Any lean burn reciprocating internal combustion engine constructed or modified before February 1, 2009, for which the owner or operator demonstrates to the Division that retrofit technology cannot be installed at a cost of less than $ 5,000 per ton of volatile organic compound emission reduction (this value shall be adjusted for future applications according to the current day consumer price index) is exempt complying with Section XVII.E.3.b.(i). Installation costs and the best information available for determining control efficiency shall be considered in determining such costs. In order to qualify for such exemption, the owner or operator must submit an application making such a demonstration, together with all supporting documents, to the Division by August 1, 2009.

XVII.F. (State Only) Leak detection and repair program for components at well production facilities~~,~~ ~~storage tanks,~~ and natural gas compressor stations, excluding storage tank thief hatches, pressure relief devices, and access points subject to STEM. Natural gas processing plants, including Components, Storage Tanks and Compressor Stations at natural gas processing plants, are not subject to this Section XVII.F.

XVII.F.1. Beginning ~~January 1, 2015~~the date the well production facility or natural gas compressor station becomes subject to this Section XVII.F., owners ~~and~~or operators of components at well production facilities ~~and~~or natural gas compressor stations ~~will~~must identify and repair leaks from such components ~~at these facilities~~ in accordance with the requirements of this ~~this~~ Section XVII.F. The ~~following~~ provisions of Section XVII.F. shall apply in lieu of any directed inspection and maintenance program requirements established pursuant to Regulation Number 3, Part B, Section III.D.2.

XVII.F.2. Owners ~~and~~or operators of components at well production facilities or natural gas compressor stations that monitor components as part of ~~this~~ Section XVII.F. may ~~opt to~~ estimate uncontrolled actual emissions from components for the purpose of evaluating the applicability of component fugitive emissions to Regulation Number 3 by utilizing the emission factors defined as less than 10,000 ppmv of Table 2-8 of the 1995 EPA Protocol for Equipment Leak Emission Estimates (Document EPA-453/R-95-017).

~~XVII.F.3. Owners andor operators of well production facilities or natural gas compressor stations shall utilizemust implement the Approved Instrument Based Monitoring Method approved instrument based monitoring method and AVO programinspections as outlined in Section XVII.F. AVO monitoringMonitoring is not required offor components and tanks that are unsafe to monitor, difficult, or inaccessible to monitor, pursuant toas defined in Section XVII.F.5.g6.~~

XVII.F.3. If upon the completion of four consecutive semi-annual AIMM inspection events, no leaks requiring repair are detected, AIMM inspection shall be conducted annually for that well production facility or natural gas compressor station. If upon the completion of four consecutive quarterly AIMM inspection events, no leaks requiring repair are detected, AIMM inspection shall be conducted semi-annually for that well production facility or natural gas compressor station. If two or more leaks requiring repair are

detected during subsequent AIMM inspection events, then the inspection frequency shall revert back to the original frequency for that well production facility or natural gas compressor station until the terms of this provision are again met.

XVII.F.3.a. An owner or operator may skip the next AIMM inspection event where the owner or operator demonstrates in the previous AIMM inspection event that less than or equal to 2 percent of components required repair for all well production facilities or natural gas compressor stations in a basin belonging to the same threshold class as set forth in Tables 2 and 3. An owner or operator may estimate a facility's component count using the Default Average Component Counts in 40 CFR Part 98, Subpart W, Tables W-1B and W-1C for equipment located at natural gas production facilities and oil production facilities, respectively.

XVII.F.4. ~~Inspection schedules for natural gas compressor stations: Beginning January 1, 2015, owners and~~ Leak detection for components at natural gas compressor stations.

XVII.F.4.a. Beginning January 1, 2016, within 180 days of startup of a new natural gas compressor station, ~~O~~owners or operators of natural gas compressor stations ~~shall~~must inspect components for leaks using an ~~Approved Instrument Based Monitoring Method approved instrument based monitoring~~AIMM ~~method~~, in accordance with ~~the following~~ Table ~~2~~3, except under the conditions described in XVII.F.6. ~~for components subject tothat are unsafe, difficult, or inaccessible to monitor, as defined in Section XVII.F.5.g~~6.

XVII.F.4.b. Owners or operators of existing natural gas compressor stations shall inspect components for leaks as set forth in Table 3, except under the conditions described in Section XVII.F.6.

XVII.F.4.c. ~~–~~For purposes of ~~this~~ Section XVII.F.4., fugitive VOC emissions ~~shall~~must be calculated using the emission factors of Table 2-4 of the 1995 EPA Protocol for Equipment Leak Emission Estimates (Document EPA-453/R-95-017), ~~off~~or other Division approved method.

~~Table 2~~Table 3

Fugitive VOC Emissions (tpy)	AIMM Inspection Frequency (calendar basis)	Beginning of Phase-In Schedule for Existing Compressor Stations[1]
> 2 and < 6	One time, within five years of applicable phase-in or implementation date	July 1, 2016
>~~60~~ and < 20~~12~~	Annually	January 1, 2016
> ~~12~~ 20 and < 50	~~Quarterly~~Semi-annually	July 1, 2015
> 50	~~Monthly~~Quarterly	January 1, 2015

[1] As set forth in XVII.F.4.a., owners and operators of new Compressor Stations shall initiate compliance with this Table 2 within 180 days after the commenced construction date (i.e., the implementation date).

XVII.F.5. ~~Requirements~~ Leak detection for components at ~~for~~ well production facilities ~~and/or storage tanks~~

~~XVII.F.5.a. Beginning August 1, 2014, all new~~All well production facilities ~~shall~~constructed ~~on or after August 1, 2014, must have a documented pressure test performed on all equipment and piping prior to start up. Documentation of this 90 day testing and monitoring shallinitial pressure test must be provided in the first annual report to the Division, as required by Section XVII.F.910.~~

XVII.F.5.a~~b~~. ~~Beginning January 1, 2015, within 90 days of startup of all new~~Owners or operators of well production facilities ~~and/or storage tanks, owners and/or operators shall~~ constructed on or after January 1, 201~~56~~, must ~~identify~~ inspect components for leaks using as set forth in Table 4 no later than 180 days after the date of first production, except under the conditions described in Section XVII.F.6.~~and repair leaks from components using an Approved Instrument Based Monitoring Method. Such action shall qualify as an inspection pursuant to approved instrument based monitoring method within ninety (90) days after the inspection frequencyfacility commences operation and in accordance with the Inspection Frequency schedule in Table 3~~. To the extent that pursuant to Table 4 an AIMM inspection and an AVO monitoring would occur simultaneously, then the AIMM inspection satisfies the requirement to conduct AVO for that inspection.

4. XVII.F.5.c. ~~Consistent with the provisions of XVII.F.5.f., owners and~~ Owners or operators of ~~existing~~ well production facilities ~~and/or storage tanks shall identify and repair leaks using an Approved Instrument Based Monitoring Method, in accordance with the implementation schedule in XVII.F.5.e. Inspection frequency shall be determined according to Table 3.~~

~~XVII.F.5.d. Consistent with the provisions of XVII.F.5.f., owners and operators of new well production facilities and/or storage tanks shall identify and repair~~ constructed before January 1, 201~~65~~, must ~~identify~~ inspect components for leaks as set forth in Table 4, except under the conditions described in Section XVII.F.6.~~from components using an Approved Instrument Based Monitoring Method beginning on January 1, 2015. approved instrument based monitoring method within ninety (90) days of the Phase-In Schedule in Table 4, within thirty (30) days for > 50 tons per year, or by July 1, 2016, for > 0 and < 6 tons per year tanks. Thereafter, approved instrument based monitoring method and AVO inspections must be conducted in accordance with the Inspection frequency shall be determined according to Frequency in Table 3~~4. To the extent that pursuant to Table 4 an AIMM inspection and an AVO monitoring would occur simultaneously, then the AIMM inspection satisfies the requirement to conduct AVO for that inspection.

XVII.F.5.e~~d~~. For purposes of this Section XVII.F.5., ~~T~~the VOC thresholds shall be calculated using the estimated uncontrolled actual emissions from the largest single storage tank~~s~~ as set forth in Table 4. ~~determine the frequency at which inspections must be performed.~~ If no storage tanks storing oil or condensate are located at the well production facility ~~or multi-well site, owners or operators will~~must rely on VOC thresholds shall be calculated using the potential to emit of VOC for all of the emissions sources, including emissions from components located at the. ~~facility.~~

XVII.F.5.e. ~~All components at a~~ Inspection of components at a well production facility ~~or storage tank must be inspected~~ shall be conducted as set forth in Table 4:

~~Table 3~~Table 4
~~—~~Well Production Facility Component Inspections

VOC Threshold (per XVII.F.5.ed.) ~~VOC Emissions (tpy, uncontrolled actual for sites with tanks or PTE for sites without tanks~~)	AIMM Inspection Frequency (calendar basis)	AVO Monitoring Frequency (calendar basis)	Beginning of Phase-In Schedule For Existing Well Production Facilities[2]
> 2 and < 6	One time, within five years of phase-in or implementation date ~~using Approved Instrument Based Monitoring Method~~approved ~~instrument based monitoring methods and thereafter using monthly AVO~~	Annual	July 1, 2016
> 6 and < ~~12~~20	Annually ~~with monthly AVO~~	Semi-annual	January 1, 2016
> ~~12~~ 20 and < 50	~~Quarterly with monthly AVO~~Semi-annually	Quarterly	July 1, 2015
> 50	~~Monthly~~Quarterly	Monthly	January 1, 2015
~~Multi~~Well production facilities ~~or multi-well sites~~ without storage tanks ~~after April 15, 2014,~~storing oil or condensate that have a ~~PTE~~potential to emit > 20 tpy VOC	~~Monthly~~Quarterly	Monthly	January 1, 2015

~~XVII.F.~~5.f. ~~Phase-in of Approved Instrument Based Monitoring Methods: Owners and operators of existing well production facilities and/or storage tanks shall identify and repair leaks from components using an Approved Instrument Based Monitoring Method, in accordance with the following schedule:~~

~~XVII.F.5.f.(i) Beginning January 1, 2015, facilities with uncontrolled actual VOC emissions greater than 50 tpy or multi-well sites.~~

~~XVII.F.5.f.(ii) Beginning July 1, 2015, facilities with uncontrolled actual VOC emissions greater than 20 tpy but less than or equal to 50 tpy.~~

~~XVII.F.5.f.(iii) Beginning January 1, 2016, facilities with uncontrolled actual VOC emissions greater than 6 tpy but less than or equal to 20 tpy.~~

~~XVII.F.5.g.(iv) By July 1, 2016, facilities with uncontrolled actual VOC emissions less than or equal to 6 tpy.~~

~~XVII.F.5.g.~~XVII.F.6. If a component is unsafe, difficult~~, unsafe~~, or inaccessible to monitor, the owner or operator ~~shall~~is not ~~be~~ required to monitor the component or equipment~~until it becomes feasible to do so~~.

[2] As set forth in XVII.F.6.a., owners and operators of new Well Production Facilities installed after January 1, 2016 shall comply with this Table 3 within 180 days after the Date of First Production (i.e., the implementation date).

XVII.F.~~5.g.(i)~~6.a. Difficult to monitor components or equipment are those that cannot be monitored without elevating the monitoring personnel more than two (2) meters above a supported surface or are unable to be reached via a wheeled scissor-lift or hydraulic type scaffold that allows access to components up to 7.6 meters (25 feet) above the ground.

XVII.F.~~5.g.(ii)~~6.b. Unsafe to monitor means a component or equipment that is unsafe because inspectings ~~are those that cannot be monitored without exposing monitoring~~ personnel would be exposed to ~~an~~ immediate danger as a consequence of completing the monitoring, which includes weather conditions preventing access to the site, or that endanger monitoring personnel or equipment, or prevent use of AIMM (such as reflection due to precipitation).

XVII.F.~~5.g.(iii)~~6.c. Inaccessible to monitor components or equipment are those that are buried, insulated ~~in a manner that prevents access to the components by a monitor probe~~, or obstructed by equipment or piping that prevents AIMM inspection or AVO monitoring access to the components by ~~a monitor probe~~monitoring personnel.

XVII.F.~~6~~7 Leaks ~~detection~~ requiring repair: Leaks at components that are not otherwise designed to leak ~~shall~~must be identified utilizing the methods listed in ~~this~~ Section XVII.F.~~6.a. through XVII.F.6.d~~7. Only leaks detected pursuant to ~~this~~ Section ~~XVIII~~XVII.F.~~6. shall~~ 7, require repair under Section XVII.F.8.

XVII.F.~~6~~7.a. For EPA Method 21 or other quantitative AIMMs, monitoring at ~~existing~~ well production facilities and natural gas compressor stations constructed before ~~May~~ January 1, 201~~5~~4, a leak is any concentration of VOC above 10,000ppm ~~hydrocarbon above 2,000 parts per million (ppm), except for existing well production facilities where a leak is defined as any concentration of hydrocarbon above 500 ppm~~.

~~XVII.F.67.b. For EPA Method 21 monitoring at facilities constructed on or after May 1, 2014, a leak is any concentration of hydrocarbon above 500 ppm.~~

XVII.F.~~6~~7.c. For ~~infra-red camera and~~ AVO monitoring or other non-quantitative AIMMs such as Infra-red camera, a leak is any detectable VOC emissions except as described in XVII.F.7.d ~~emissions not associated with normal equipment operation, such as pneumatic device actuation and crank case ventilation~~.

~~XVII.F.67.d. For other Division approved monitoring devices or methods, leak identification requiring repair will be established as set forth in the Division's approval.~~

XVII.F.7.d For leaks identified using AVO, or other non-quantitative AIMM, owners and operators have the option of either repairing the leak in accordance with the repair schedule set forth in Section XVII.F.8. or conducting follow-up monitoring using EPA Method 21 within fifteen (15) working days of the day the leak was detected. If the follow-up EPA Method 21 monitoring shows that the leak concentration is less than or equal to 10,000 ppm volatile organic compound for well production facilities or natural gas compressor stations, then the emissions shall not be considered a leak for purposes of this Section and shall not require repair.

XVII.F.7.e. If a leak is identified using AIMM or AVO and the leak is immediately repaired (within the same working day), any such leak does not constitute a leak under this Section XVII.F.7. and is not subject to the Repair and Re-monitoring or Recordkeeping and Reporting requirements at Sections XVII.F.8. through XVII.F.10.

XVII.F.~~7~~8. Repair and remonitoring

XVII.F.~~7~~8.a. First attempt to repair a leak that requires repair pursuant to XVII.F.7. ~~shall~~must be made no later than ~~five~~ fifteen (15) working days after discovery, unless parts are unavailable, the equipment requires shutdown to complete repair, or other good cause exists. If parts are unavailable, they ~~shall~~must be ordered promptly and the repair ~~shall~~must be made within ~~fifteen~~ thirty (~~15~~30) working days of receipt of the parts. If shutdown is required, the leak ~~shall~~must be repaired during the next scheduled shutdown. If delay is attributable to other good cause, repairs ~~shall~~must be completed within ~~fifteen~~ thirty (30~~15~~) working days after the owner or operator has reason to believe the cause of delay ceases to exist.

XVII.F.~~7~~8.b. Within ~~fifteen~~ thirty (30~~15~~) working days of completion of a repair, the ~~leaks shall~~leak that is repaired according to Section XVII.F.7. must be remonitored to verify the repair was effective utilizing AIMM.

XVII.F.~~7~~8.c. Leaks discovered pursuant to the leak detection methods of Section XVII.F.7. shall not be a violation of the Air Quality Control Commission's Rules or subject to enforcement by the Division unless the owner or operator fails to perform the required repairs in accordance with Section XVII.F.~~7~~8.

~~XVII.F.7.d. For leaks identified using an Approved Instrument Based Monitoring Method approved instrument based monitoring method, owners and or operators have the option of either repairing the leak in accordance with the repair schedule set forth in Section XVII.F.78. or conducting follow-up monitoring using EPA Method 21 within five (5) working days of the leak detecteddetection. If the follow-up EPA Method 21 monitoring shows that the leak concentration is less than or equal to 2,000 ppm hydrocarbon for existing facilities (other than existing well production facilities), or 500 ppm for new facilities or existing well production facilities, then the emission shall not be consideredis a leak for purposes of thisas defined in Section XVII.F.7., the leak must be repaired and remonitored in accordance with Section XVII.F.8.~~

XVII.F.~~8~~9. Recordkeeping: The owner or operator of each well production facility or natural gas compressor station subject to the ~~inspection~~leak detection and ~~maintenance~~repair requirements in ~~this~~ Section XVII.F. ~~shall~~must maintain the following records for a period of two (2) years and make them available to the Division upon request.

~~XVII.F.89.a. Documentation of the pre-start-up pressure tests for new well production facilities;~~

XVII.F.~~8~~9.~~a~~b. The date and site information for each inspection;

XVII.F.~~8~~9.~~c~~b. A list of the leaking components and the monitoring method used to determine the presence of the leak;

XVII.F.~~8~~9.~~d~~c. The date of first attempt to repair the leak and, if necessary, any additional attempt to repair the leak;

XVII.F.~~8~~9.~~d~~e. The date the leak was ~~repair~~repaired;

XVII.F.~~8~~9.~~d~~f. The delayed repair list including the basis for placing leaks on the list;

XVII.F.~~8~~9.~~f~~g. The date the leak was remonitored to verify the effectiveness of the repair, and the results of the remonitoring; and

XVII.F.~~8~~9.~~g~~h. A list of ~~identification numbers for~~ components that are designated as unsafe, difficult, or inaccessible to monitor, as described in Section XVII.F.~~5.g~~6., and an explanation ~~for each component~~ stating why the component is so designated~~, and the plan for monitoring such component(s)~~.

XVII.F.~~9~~10. Reporting: The owner or operator of each well production facility and natural gas compressor station subject to the ~~inspection~~leak detection and ~~maintenance~~repair requirements in this Section XVII.F. ~~shall~~must submit a single annual report on or before ~~April 30th~~May 31st of each year ~~summarizing~~ that includes the following information regarding inspection and maintenance ~~inspection~~~~leak detection and~~ ~~maintenance~~repair activities at all of their subject facilities during the previous calendar year~~. This report shallmust contain, at a minimum, the following information~~:

XVII.F.~~9~~10.a. The number of facilities inspected;

XVII.F.~~9~~10.b. The total number of inspections;

XVII.F.~~9~~10.c. The total number of leaks identified that require repair, broken out by component type;

XVII.F.~~9~~10.d. The total number of leaks repaired;

XVII.F.~~9~~10.e. The number of leaks on the delayed repair list as of December 31st; and

XVII.F.~~9~~10.f. Each report shall be accompanied by a self-certification form. The form shall contain a certification by an authorized representative ~~responsible official~~ of the truth, accuracy, and completeness of such form, report, or certification stating that, based on information and belief formed after reasonable inquiry, the statements and information in the document are true, accurate, and complete.

XVII.G. (State Only) Control of emissions from well production facilities

~~XVII.G.1. Well Operation and Maintenance:~~ On or after August 1, 2014, ~~during normal operation~~ gas coming off a separator, produced during normal operation from any newly constructed, hydraulically fractured, or recompleted oil and gas well must either be routed to a gas gathering line or controlled from the date of first production by air pollution control equipment that achieves an average ~~hydrocarbon~~ VOC control efficiency of 95~~% from the date of first production.~~%. If a combustion device is used, it ~~shall~~must have a design destruction efficiency ~~of~~for at least 98% of ~~hydrocarbons~~VOCs.

~~XVII.H. (State Only) Venting during downhole well maintenance and unloading events~~

~~XVII.H.1. Well Maintenance: Beginning May 1, 2014, hydrocarbon emissions from flowing wells must be captured or controlled during downhole well maintenance or servicing activities, unless venting is necessary for safety.~~

~~XVII.H.1.a. Operators shallOwners or operators must use best management practices to minimize the need for well venting associated with downhole well~~

maintenance and liquids unloading. During liquids unloading events, any means of creating differential pressure willmust first be used to attempt to unload the liquids from the well without venting. If these methods are not successful in unloading the liquids from the well, the well may be vented to the atmosphere to create the necessary differential pressure to bring the liquids to the surface.

XVII.H.1.b. Venting willmust be minimized to the extent possible, using best management practices during the well maintenance and liquids unloading events in XVII.H.1.a. The owner and/or operator shallmust be present on-site during any planned well maintenance and liquids unloading event in XVII.H.1.a. and shallmust ensure that any venting to the atmosphere is limited to the maximum extent practicable.

XVII.H.1.c. Records of the cause, date, time, and duration of venting events under this Section XVII.H. willmust be kept and made available to the Division upon request.

XVIII. (State Only) Natural Gas-Actuated Pneumatic Controllers Associated with Oil and Gas Operations in the 8-Hour Ozone Control Area or Any Ozone Nonattainment or Attainment/Maintenance Area

XVIII.A. Applicability

This section applies to pneumatic controllers that are actuated by natural gas, and located at, or upstream of natural gas processing plants (upstream activities include: oil and gas exploration and production operationswell production facilities, and natural gas compressor stations, and/or natural gas drip stations) in the 8-Hour Ozone Control Area or any Ozone Nonattainment or Attainment/Maintenance Area.

XVIII.B. Definitions

XVIII.B.1. "Affected Operations" shall mean pneumatic controllers that are actuated by natural gas, and located at, or upstream of natural gas processing plants (upstream activities include: oil and gas exploration and production operationswell production facilities, and natural gas compressor stations, and/or natural gas drip stations).

XVIII.B.2. "Enhanced Maintenance" is specific to high-bleed devices and shall include but is not limited to cleaning, tuning, and repairing leaking gaskets, tubing fittings, and seals; tuning to operate over a broader range of proportional band; and eliminating unnecessary valve positioners.

XVIII.B.3. "High-Bleed Pneumatic Controller" shall mean a pneumatic controller that is designed to have a constant bleed rate that emits in excess of 6 standard cubic feet per hour (scfh) of natural gas to the atmosphere.

XVIII.B.4. "Low-Bleed Pneumatic controller" shall mean a pneumatic controller that is designed to have a constant bleed rate that emits less than or equal to 6 scfh of natural gas to the atmosphere.

XVIII.B.5. "Natural Gas Processing Plant" shall mean any processing site engaged in the extraction of natural gas liquids from field gas, fractionation of mixed natural gas liquids to natural gas products, or both.

XVIII.B.6. "No-bleedBleed Pneumatic Controller" shall mean any pneumatic controller that is not using hydrocarbon gas as the valve's actuating gas.

XVIII.B.~~6~~7. "Pneumatic Controller" shall mean a~~n~~ continuous bleed instrument that is actuated using ~~natural~~pressurized gas ~~pressure~~ and used to control or monitor process parameters such as liquid level, gas level, pressure, valve position, liquid flow, gas flow and temperature.

XVIII.C. Emission Reduction Requirements

The owners and operators of affected operations shall reduce emissions of volatile organic compounds from pneumatic controllers associated with affected operations as follows:

XVIII.C.1. In the 8-Hour Ozone Control Area:

XVIII.C.1.a. All pneumatic controllers placed in service on or after February 1, 2009, shall emit VOCs in an amount equal to or less than a low-bleed pneumatic controller, unless allowed pursuant to Section XVIII.C.~~3~~1.c.

XVIII.C.~~2~~1.b. All high-bleed pneumatic controllers in service prior to February 1, 2009 shall be replaced or retrofit such that VOC emissions are reduced to an amount equal to or less than a low-bleed pneumatic controller, by May 1, 2009, unless allowed pursuant to Section XVIII.C.~~3~~1.c.

XVIII.C.~~3~~1.c. All high-bleed pneumatic controllers that must remain in service due to safety and/or process purposes must have Division approval and comply with Sections XVIII.D. and XVIII.E.

XVIII.C.~~3~~1.~~a~~c.(i) For high-bleed pneumatic controllers in service prior to February 1, 2009, the owner/operator shall submit justification for high-bleed pneumatic controllers to remain in service due to safety and /or process purposes by March 1, 2009. The Division shall be deemed to have approved the justification if it does not object to the owner/operator within 30-days upon receipt.

XVIII.C.~~3~~1.~~b~~c.(ii) For high-bleed pneumatic controllers placed in service on or after February 1, 2009, the owner/operator shall submit justification for high-bleed pneumatic controllers to be installed due to safety and /or process purposes prior to installation. The Division shall be deemed to have approved the justification if it does not object to the owner/operator within 30-days upon receipt.~~XVIII.D. Monitoring~~

XVIII.C.2. Statewide:

XVIII.C.2.a. All continuous bleed pneumatic controllers placed in service on or after May 1, 2014, shall:

XVIII.C.2.~~c~~a.(i) Emit VOCs in an amount equal to or less than a low-bleed pneumatic controller, unless allowed pursuant to Section XVIII.C.2.c.; or

XVIII.C.2.~~c~~a.(ii) Where the operator is using on-site electrical grid power and where use of ~~Utilize~~ no-bleed pneumatic controllers ~~where on-site electrical grid power is being used and~~ is technically and economically feasible, operators shall employ no-bleed pneumatic controllers. Nothing in this provision shall require an operator to bring electrical grid power to the location in order to meet this requirement or replace or retrofit low-bleed pneumatic controllers upon availability of electrical grid power to the location.

XVIII.C.2.b. All high-bleed pneumatic controllers in service prior to May 1, 2014, shall be replaced or retrofitted by May 1, 2015, such that VOC emissions are reduced to an amount equal to or less than a low-bleed pneumatic controller, unless allowed pursuant to Section XVIII.C.2.c.

XVIII.C.2.c. All high-bleed pneumatic controllers that must remain in service due to safety and/or process purposes must have Division approval and comply with Sections XVIII.D. and XVIII.E.

XVIII.C.2.c.(i) ~~All~~For high-bleed pneumatic controllers in service prior to May 1, 2014, the owner/operator shall submit justification for high-bleed pneumatic controllers to remain in service due to safety and/or process purposes by March 1, 2015. The Division shall be deemed to have approved the justification if it does not object to the owner/operator within 30-days upon receipt.

XVIII.C.2.c.(ii) For high-bleed pneumatic controllers placed in service on or after May 1, 2014, the owner/operator shall submit justification for high-bleed pneumatic controllers to be installed due to safety and/or process purposes prior to installation. The Division shall be deemed to have approved the justification if it does not object to the owner/operator within 30-days upon receipt.

XVIII.D. Monitoring

This section applies only to high-bleed pneumatic controllers identified in ~~Section~~Sections XVIII.C.~~3~~1.c. and XVIII.C.2.c.

XVIII.D.1. In the 8-Hour Ozone Control Area

XVIII.D.1.a. Effective May 1, 2009, each high-bleed pneumatic controller shall be physically tagged by the owner/operator identifying it with a unique high-bleed pneumatic controller number that is assigned and maintained by the owner/operator.

XVIII.D.~~2~~1.b. Effective May 1, 2009, each high-bleed pneumatic controller shall be inspected on a monthly basis, perform necessary enhanced maintenance as defined in Section XVIII.B.2~~.~~., and maintain the device according to manufacturer specifications to ensure that the controller's VOC emissions are minimized.

XVIII.D.2. Statewide:

XVIII.D.2.a. Effective May 1, 2015, each high-bleed pneumatic controller shall be physically tagged by the owner/operator identifying it with a unique high-bleed pneumatic controller number that is assigned and maintained by the owner/operator.

XVIII.D.2.b. Effective May 1, 2015, each high-bleed pneumatic controller shall be inspected on a monthly basis, ~~perform~~undergo necessary enhanced maintenance as defined in Section XVIII.B.2 , and ~~maintain the device~~be maintained according to manufacturer specifications to ensure that the controller's VOC emissions are minimized.

XVIII.E. Recordkeeping

This section applies only to high-bleed pneumatic controllers identified in ~~Section~~Sections XVIII.C.~~3~~1.c. and XVIII.C.2.c.

XVIII.E.1. The owner or operator of affected operations shall maintain a log of the total number of high-bleed pneumatic controllers and their associated controller numbers per facility, the total number of high-bleed pneumatic controllers per company and the associated justification that the high-bleed pneumatic controllers must be used pursuant to ~~Section~~Sections XVIII.C.~~3~~1.c. and XVIII.C.2.c. The log shall be updated on a monthly basis.

XVIII.E.2. The owner or operator shall maintain a log of enhanced maintenance which shall include, at a minimum, inspection dates, the date of the maintenance activity, high-bleed pneumatic controller number, description of the maintenance performed, results and date of any corrective action taken, and the printed name and signature of the individual performing the maintenance. The log shall be updated on a monthly basis.

XVIII.E.3. Records of enhanced maintenance of pneumatic controllers shall be maintained for a minimum of three years and readily made available to the ~~division~~Division upon request.

DEPARTMENT OF PUBLIC HEALTH AND ENVIRONMENT
Air Quality Control Commission

REGULATION NUMBER 7

CONTROL OF OZONE VIA OZONE PRECURSORS AND CONTROL OF HYDROCARBONS VIA OIL AND GAS EMISSIONS

(EMISSIONS OF VOLATILE ORGANIC COMPOUNDS AND NITROGEN OXIDES)

5 CCR 1001-9

>>>>>>>>

II. General Provisions

>>>>>>>>

II.B. Exemptions

Emissions of the organic compounds listed as having negligible photochemical reactivity in the common provisions definition of Negligibly Reactive Volatile Organic Compound are exempt from the provisions of this regulation.

(State Only) Notwithstanding the foregoing exemption, hydrocarbon emissions from oil and gas operations, including methane and ethane, are subject to this regulation as set forth in Sections XVII. and XVIII.

>>>>>>>>

XVII. (State Only, except Section XVII.E.3.a. which was submitted as part of the Regional Haze SIP) Statewide Controls for Oil and Gas Operations and Natural Gas-Fired Reciprocating Internal Combustion Engines

XVII.A. (State Only) Definitions

XVII.A.1 "Air Pollution Control Equipment," as used in this Section XVII, means a combustion device or vapor recovery unit. Air pollution control equipment also means alternative emissions control equipment and pollution prevention devices and processes intended to reduce uncontrolled actual emissions that comply with the requirements of Section XVII.B.2.e.

XVII.A.2. "Approved Instrument Based Monitoring Method," as used in this Section XVII. means an infra-red camera, Method 21, or other Division approved instrument based monitoring device or method. If an owner/operator elects to use a Division approved

Continuous Emission Monitoring program, the Division may approve a streamlined inspection and reporting program for such operations. Any instrument based monitoring method approved by the Division under this definition must be at least as effective as Method 21 or an infra-red camera.

XVII.A.3. "Auto-Igniter" means a device which will automatically attempt to relight the pilot flame in the combustion chamber of a control device in order to combust volatile organic compound emissions.

XVII.A.4. "Component" means each pump seal, compressor seal, flange, pressure relief device, connector, open ended line, and valve that contains or contacts a process stream with hydrocarbons. Process streams consisting of glycol, amine, produced water, or methanol are not components for purposes of this Section XVII.

XVII.A.5. "Connector" means flanged, screwed, or other joined fittings used to connect two pipes or a pipe and a piece of process equipment or that close an opening in a pipe that could be connected to another pipe. Jointed fittings welded completely around the circumference of the interface are not considered connectors.

XVII.A.6. "Date of First Production" means the date reported to the COGCC as the "first date of production."

XVII.A.7. "Glycol Natural Gas Dehydrator" means any device in which a liquid glycol (including ethylene glycol, diethylene glycol, or triethylene glycol) absorbent directly contacts a natural gas stream and absorbs water.

XVII.A.8. "Multi-Well Site" means a common well pad from which multiple wells may be drilled to various bottomhole locations.

XVII.A.9. "Natural Gas Compressor Station" means a facility which contains one or more compressors designed to compress natural gas from well pressure to gathering system pressure and recompress natural gas prior to processing, as well as well as compressors located downstream of processing plants.

XVII.A.10. "Normal Operation" means all periods of operation, excluding malfunctions as defined in Section I.G. of the Common Provisions regulation. For storage tanks at well production facilities, normal operation includes but is not limited to liquid dumps from the separator.

XVII.A.11. "Stabilized" when used to refer to crude oil, condensate, intermediate hydrocarbon liquids, or produced water means that the vapor pressure of the liquid is sufficiently low to prevent the production of vapor phase upon transferring the liquid to an atmospheric pressure in a storage tank, and that any emissions that occur are limited to those commonly referred to within the industry as working, breathing, and standing losses.

XVII.A.12. "Storage Tank" means any fixed roof storage vessel or series of storage vessels that are manifolded together via liquid line. Storage vessel is as defined in 40 CFR Part 60, Subpart OOOO. Storage tanks may be located at a well production facility or other location.

XVII.A.13. "Unsafe to Monitor" means a component is unsafe to inspect because inspecting personnel would be exposed to an imminent or potential danger as a consequence of such monitoring.

XVII.A.14. "Visible Emissions" means observations of smoke for any period or periods of duration greater than or equal to one (1) minute in any fifteen (15) minute period during normal operation. Visible emissions do not include radiant energy or water vapor.

XVII.A.15. "Well Production Facility" means all equipment at a single stationary source directly associated with one or more oil wells or gas wells. This equipment includes, but is not limited to, equipment used for storage, separation, treating, dehydration, artificial lift, combustion, compression, pumping, metering, monitoring, and flowline.

XVII.B. (State Only) General Provisions

XVII.B.1. General requirements for prevention of emissions and good air pollution control practices for all oil and gas exploration and production operations, well production facilities, natural gas compressor stations, and natural gas processing plants.

XVII.B.1.a. All intermediate hydrocarbon liquids collection, storage, processing, and handling operations, regardless of size, shall be designed, operated, and maintained so as to minimize leakage of volatile organic compounds to the atmosphere to the extent reasonably practicable.

XVII.B.1.b. At all times, including periods of start-up and shutdown, the facility and air pollution control equipment shall be maintained and operated in a manner consistent with good air pollution control practices for minimizing emissions. Determination of whether or not acceptable operating and maintenance procedures are being used will be based on information available to the Division, which may include, but is not limited to, monitoring results, opacity observations, review of operating and maintenance procedures, and inspection of the source.

XVII.B.2. General requirements for air pollution control equipment, flares, and combustion devices used to comply with Section XVII.

XVII.B.2.a. All air pollution control equipment shall be operated and maintained pursuant to the manufacturing specifications or equivalent to the extent practicable, and consistent with technological limitations and good engineering and maintenance practices. The owner or operator shall keep manufacturer specifications or equivalent on file. In addition, all such air pollution control equipment shall be adequately designed and sized to achieve the control efficiency rates and to handle reasonably foreseeable fluctuations in emissions of volatile organic compounds and hydrocarbons during normal operations. Fluctuations in emissions that occur when the separator dumps into the tank are reasonably foreseeable.

XVII.B.2.b. If a flare or other combustion device is used to control emissions of hydrocarbons, it shall be enclosed, have no visible emissions during normal operations, and be designed so that an observer can, by means of visual observation from the outside of the enclosed flare or combustion device, or by other means approved by the Division, determine whether it is operating properly.

XVII.B.2.c. Any of the effective dates for installation of controls on storage tanks, dehydrators, and/or internal combustion engines may be extended at the Division's discretion for good cause shown.

XVII.B.2.d. Auto-igniters: All combustion devices used to control emissions of hydrocarbons shall be equipped with and operate an auto-igniter as follows:

XVII.B.2.d.(i) All combustion devices installed on or after May 1, 2014, will be equipped with an operational auto-igniter upon installation of the combustion device.

XVII.B.2.d.(ii) All combustion devices installed before May 1, 2014, will be equipped with an operational auto-igniter by or before May 1, 2015~~6~~, or after the next combustion device planned shutdown, whichever comes first.

XVII.B.2.e. Alternative emissions control equipment shall qualify as air pollution control equipment, and may be used in lieu of, or in combination with, combustion devices and vapor recovery units to achieve the emission reductions required by this Section XVII, if the Division approves the equipment, device or process. As part of the approval process the Division, at its discretion, may specify a different control efficiency than the control efficiencies required by this Section XVII.

XVII.B.3. Oil refineries are not subject to Section XVII.

XVII.B.4. Glycol natural gas dehydrators and internal combustion engines that are subject to an emissions control requirement in a federal maximum achievable control technology ("MACT") standard under 40 CFR Part 63, a Best Available Control Technology ("BACT") limit, or a New Source Performance Standard ("NSPS") under 40 CFR Part 60 are not subject to this Section XVII.

XVII.C. (State Only) Emission reduction from storage tanks at oil and gas exploration and production operations, well production facilities, natural gas compressor stations, and natural gas processing plants.

XVII.C.1. Control requirements for storage tanks

XVII.C.1.a. Beginning May 1, 2008, owners or operators of all storage tanks storing condensate with uncontrolled actual emissions of volatile organic compounds equal to or greater than twenty (20) tons per year based on a rolling twelve-month total must operate air pollution control equipment that has an average control efficiency of at least 95% for VOCs.

XVII.C.1.b. Owners or operators of all storage tanks with uncontrolled actual emissions of volatile organic compounds equal to or greater than six (6) tons per year based on a rolling twelve-month total must operate air pollution control equipment that achieves an average hydrocarbon control efficiency of 95%. If a combustion device is used, it shall have a design destruction efficiency of at least 98% for hydrocarbons.

XVII.C.1.b.(i) A storage tank constructed on or after May 1, 2014, must be in compliance by the date that the storage tank commences operation.

XVII.C.1.b.(ii) A storage tank constructed before May 1, 2014, must be in compliance by May 1, 2015.

XVII.C.1.b.(iii) A storage tank not otherwise subject to Sections XVII.C.1.b.(i) or XVII.C.1.b.(ii), above, that increases uncontrolled actual emissions to six tons VOC or more per year on a rolling twelve month basis after May 1, 2014, must be in compliance within sixty days of discovery of the emissions increase.

XVII.C.1.c. Control requirements within 90 days of the date of first production.

XVII.C.1.c.(i) Beginning May 1, 2014, owners or operators of storage tanks at well production facilities shall collect and control emissions by routing emissions to operating air pollution control equipment during the first 90 calendar days after the date of first production. The air pollution control equipment shall achieve an average hydrocarbon control efficiency of 95%. If a combustion device is used, it shall have a design

destruction efficiency of at least 98% for hydrocarbons. Except that this requirement does not apply where the Division has approved a demonstration that the~~to~~ storage tanks ~~that are projected to~~ will have emissions less than 1.5 tons of VOC during the first 90 days after the date of first production.

XVII.C.1.c.(ii) The air pollution control equipment and any associated monitoring equipment required pursuant to Section XVII.C.1.c., above, may be removed at any time after the first 90 calendar days as long as the source can demonstrate that uncontrolled actual emissions from the storage tank are below the threshold in Section XVII.C.1.b., above.

XVII.C.2. Capture requirements for storage tanks that are fitted with air pollution control equipment as required by Sections XII.D. or XVII.C.1.

XVII.C.2.a. Beginning on the applicable compliance date specified in Section XVII.C.1.b., owners and operators of storage tanks shall route all hydrocarbon emissions to air pollution control equipment, and shall operate without venting hydrocarbon emissions from the thief hatch (or other access point to the tank) or pressure relief device during normal operation unless venting is reasonably required for maintenance, gauging, or safety of personnel and equipment.

XVII.C.2.b. Beginning on the applicable compliance date specified in section XVII.C.1.b., owners and operators of storage tanks shall develop, certify, and implement a document Storage Tank Emission Management System (STEM) plan to identify appropriate strategies designed to meet the requirements of XVII.C.2.a. ~~minimize emissions from venting at thief hatches (or other access points to a storage tank) and pressure relief devices during normal operation~~. As part of STEM, owners and operators shall evaluate and employ appropriate control technologies, monitoring practices, operational practices, and/or other strategies ~~designed to meet the requirements set forth in Section XVII.C.2.a., above,~~ and will update the STEM plan as necessary to achieve or maintain compliance. Owners and operators are not required to develop and implement STEM for storage tanks containing only stabilized liquids. The minimum elements of STEM are listed below.

XVII.C.2.b.(i) STEM must include a monitoring strategy that incorporates the minimum monitoring frequency set forth in Section XVII.F.5.e., procedures for evaluating ongoing storage tank emission capture performance, and, if applicable, the selected strategies.

XVII.C.2.b.(ii) STEM must include a certification by the owner or operator that the selected STEM strategy or strategies are designed to meet the requirements of XVII.C.2.a.~~minimize emissions from storage tanks and~~

~~associated equipment components at the facility or facilities, including thief hatches and pressure relief devices~~.

XVII.C.3. Monitoring: The monitoring strategy of each STEM plan must include monitoring in accordance with Approved Instrument Based Monitoring Methods, as specified in Section XVII.F.5.

XVII.C.3.a. In addition to any applicable Approved Instrument Based Monitoring Methods, audio, visual, olfactory ("AVO") inspection of the storage tank and any associated equipment (i.e. separator, air pollution control equipment, or other pressure reducing equipment), must be completed as often as liquids are loaded out from the storage tank. However, AVO inspection is required no more frequently than every seven (7) days or less frequently than every thirty (30) days. AVO monitoring is not required for components and tanks that are unsafe to monitor. AVO inspection must include, at a minimum:

XVII.C.3.a.(i) Visual inspection of any thief hatch, pressure relief valve, or other access point to ensure that they are enclosed and properly sealed;

XVII.C.3.a.(ii) Visual inspection or monitoring of the air pollution control equipment to ensure that it is operating, including that the pilot light is lit on combustion devices used as air pollution control equipment;

XVII.C.3.a.(iii) If a flare or other combustion device is used, visual inspection of the auto-igniter and valves for piping of gas to the pilot light, to ensure they are functioning properly;

XVII.C.3.a.(iv) Visual inspection of the air pollution control equipment to ensure that the valves for the piping from the storage tank to the air pollution control equipment are open; and

XVII.C.3.a.(v) If a flare or other combustion device is used, inspection of the device for the presence of absence of smoke. If smoke is observed, either the equipment will be immediately shut-in to investigate that potential cause for smoke and perform repairs, as necessary, or Method 22 shall be conducted to determine whether visible emissions are present for a period of at least one (1) minute in fifteen (15) minutes.

XVII.C.4. Recordkeeping and Reporting: The owner or operator of each storage tank subject to XII.D. or XVII.C. must maintain records of STEM as applicable, including the plan, any updates, and the certification, and submit them to the Division by the applicable compliance date specified in section XVII.C.1.b.~~to be made available to the Division upon request~~. In addition, for a period of five~~two~~ years, the owner or operator

must maintain records of any required monitoring and make them available to the Division upon request, including:

XVII.C.4.a. The AIRS ID for the storage tank.

XVII.C.4.b. The date and duration of any period where the thief hatch, pressure relief device, or other access point are found to be venting hydrocarbon emissions.

XVII.C.4.c. The date and duration of any period where the air pollution control equipment is not operating.

XVII.C.4.d. Where a flare or other combustion device is being used, the date and result of any Method 22 test.

XVII.C.4.e. The timing of and efforts made to eliminate venting, restore operation of air pollution control equipment, and mitigate visible emissions.

XVII.D. (State Only) Emission reductions from glycol natural gas dehydrators

XVII.D.1. Beginning May 1, 2008, still vents and vents from any flash separator or flash tank on a glycol natural gas dehydrator located at an oil and gas exploration and production operation, natural gas compressor station, drip station or gas-processing plant subject to control requirements pursuant to Section XVII.D.2., shall reduce uncontrolled actual emissions of volatile organic compounds by at least 90 percent through the use of a condenser or air pollution control equipment.

XVII.D.2. The control requirement in Section XVII.D.1. shall apply where:

XVII.D.2.a. Actual uncontrolled emissions of volatile organic compounds from the glycol natural gas dehydrator are equal to or greater than two tons per year; and

XVII.D.2.b. The sum of actual uncontrolled emissions of volatile organic compounds from any single glycol natural gas dehydrator or grouping of glycol natural gas dehydrators at a single stationary source is equal to or greater than 15 tons per year. To determine if a grouping of dehydrators meets or exceeds the 15 tons per year threshold, sum the total actual uncontrolled emissions of volatile organic compounds from all individual dehydrators at the stationary source, including those with emissions less than two tons per year.

XVII.D.3. Beginning May 1, 2015, still vents and vents from any flash separator or flash tank on a glycol natural gas dehydrator located at an oil and gas exploration and production operation, natural gas compressor station, and drip station or gas-processing plant subject to control requirements pursuant to Section XVII.D.4., shall reduce

uncontrolled actual emissions of hydrocarbons by at least 95 percent on a rolling twelve-month basis through the use of a condenser or air pollution control equipment. If a combustion device is used, it shall have a design destruction efficiency of at least 98% for hydrocarbons.

XVII.D.4. The control requirement in Section XVII.D.3. shall apply where:

XVII.D.4.a. Actual uncontrolled emissions of volatile organic compounds from a single new glycol natural gas dehydrator are equal to or greater than two tons per year; or

XVII.D.4.b. Actual uncontrolled emissions of volatile organic compounds from a single existing glycol natural gas dehydrator are equal to or greater than six (6) tons per year, or two (2) tons per year if the glycol natural gas dehydrator is located within 1,320 feet of a building unit or designated outside activity area.

XVII.D.4.c. For purposes of Section XVII.D.4.:

XVII.D.4.c.(i) Building Unit shall mean a residential building unit, and every five thousand (5,000) square feet of building floor area in commercial facilities or every fifteen thousand (15,000) square feet of building floor area in warehouses that are operating and normally occupied during working hours.

XVII.D.4.c.(ii) A designated outside activity area shall mean an outdoor venue or recreation area, such as a playground, permanent sports field, amphitheater, or other similar place of public assembly owned or operated by a local government, which the local government seeks to have established as a Designated Outside Activity Area; or an outdoor venue or recreation area where ingress to or egress from could be impeded in the event of an emergency condition at an oil and gas location less than three hundred and fifty (350) feet from the venue due to the configuration of the venue and the number of persons known or expected to simultaneously occupy the venue on a regular basis.

XVII.E. Control of emissions from new, modified, existing, and relocated natural gas fired reciprocating internal combustion engines.

XVII.E.1. (State Only) The requirements of this Section XVII.E. shall not apply to any engine having actual uncontrolled emissions below permitting thresholds listed in Regulation Number 3, Part B.

XVII.E.2. (State Only) New, Modified and Relocated Natural Gas Fired Reciprocating Internal Combustion Engines

XVII.E.2.a. Except as provided in Section XVII.E.2.b. below, the owner or operator on any natural gas fired reciprocating internal combustion engine that is either constructed or relocated to the state of Colorado from another state, on or after the date listed in the table below shall operate and maintain each engine according to the manufacturer's written instructions or procedures to the extent practicable and consistent with technological limitations and good engineering and maintenance practices over the entire life of the engine so that it achieves the emission standards required in Section XVII.E.2.b. Table 1 below.

XVII.E.2.b. Actual emissions from natural gas fired reciprocating internal combustion engines shall not exceed the emission performance standards in Table 1 below as expressed in units of grams per horsepower-hour (G/hp-hr)

TABLE 1

Maximum Engine Hp	Construction or Relocation Date	Emission Standards is G/hp-hr		
		NOx	CO	VOC
< 100 Hp	Any	NA	NA	NA
≥100 Hp and < 500 Hp	On or after January 1, 2008	2.0	4.0	1.0
	On or after January 1, 2011	1.0	2.0	0.7
≥500 Hp	On or after July 1, 2007	2.0	4.0	1.0
	On or after July 1, 2010	1.0	2.0	0.7

XVII.E.3. Existing Natural Gas Fired Reciprocating Internal Combustion Engines

XVII.E.3.a. (Regional Haze SIP) Rich Burn Reciprocating Internal Combustion Engines

XVII.E.3.a.(i) Except as provided in Sections XVII.3.1.(i)(b) and (c) and XVII.E.3.a.(ii), all rich burn reciprocating internal combustion engines with a manufacturer's name plate design rate greater than 500 horsepower, constructed or modified before February 1, 2009 shall install and operate both a non-selective catalytic reduction system and an air fuel controller by July 1, 2010. A rich burn reciprocating internal

combustion engine is one with a normal exhaust oxygen concentration of less than 2% by volume.

XVII.E.3.a.(i)(a) All control equipment required by this Section XVII.E.3.a. shall be operated and maintained pursuant to manufacturer specifications or equivalent to the extent practicable, and consistent with technological limitations and good engineering and maintenance practices. The owner or operator shall keep manufacturer specifications or equivalent on file.

XVII.E.3.a.(i)(b) Internal combustion engines that are subject to an emissions control requirement in a federal maximum achievable control technology ("MACT") standard under 40 CFR Part 63, a Best Available Control Technology ("BACT") limit, or a New Source Performance Standard under 40 CFR Part 60 are not subject to this Section XVII.E.3.a.

XVII.E.3.a.(i)(c) The requirements of this Section XVII.E.3.a. shall not apply to any engine having actual uncontrolled emissions below permitting thresholds listed in Regulation Number 3, Part B.

XVII.E.3.a.(ii) Any rich burn reciprocating internal combustion engine constructed or modified before February 1, 2009, for which the owner or operator demonstrates to the Division that retrofit technology cannot be installed at a cost of less than $ 5,000 per ton of combined volatile organic compound and nitrogen oxides emission reductions (this value shall be adjusted for future applications according to the current day consumer price index) is exempt complying with Section XVII.E.3.a. Installation costs and the best information available for determining control efficiency shall be considered in determining such costs. In order to qualify for such exemption, the owner or operator must submit an application making such a demonstration, together with all supporting documents, to the Division by August 1,2009.

XVII.E.3.b. (State Only) Lean Burn Reciprocating Internal Combustion Engines

XVII.E.3.b.(i) Except as provided in Section XVII.E.3.b.(ii), all lean burn reciprocating internal combustion engines with a manufacturer's nameplate design rate greater than 500 horsepower shall install and operate an oxidation catalyst by July 1, 2010. A lean burn reciprocating internal combustion engine is one with a normal exhaust oxygen concentration of 2% by volume, or greater.

XVII.E.3.b.(ii) Any lean burn reciprocating internal combustion engine constructed or modified before February 1, 2009, for which the owner or operator demonstrates to the Division that retrofit technology cannot be installed at a cost of less than $ 5,000 per ton of volatile organic compound emission reduction (this value shall be adjusted for future applications according to the current day consumer price index) is exempt complying with Section XVII.E.3.b.(i). Installation costs and the best information available for determining control efficiency shall be considered in determining such costs. In order to qualify for such exemption, the owner or operator must submit an application making such a demonstration, together with all supporting documents, to the Division by August 1, 2009.

XVII.F. (State Only) Leak detection and repair program for well production facilities, storage tanks, and compressor stations

XVII.F.1. Beginning January 1, 2015, owners and operators of well production facilities and compressor stations will identify and repair leaks from components at these facilities in accordance with the requirements of this Section XVII.F. The following shall apply in lieu of any directed inspection and maintenance program requirements established pursuant to Regulation Number 3, Part B, Section III.D.2.

XVII.F.2. Owners and operators of well production facilities or natural gas compressor stations that monitor components as part of this Section XVII.F. may opt to estimate emissions from components for the purpose of evaluating the applicability of component fugitive emissions to Regulation Number 3 by utilizing the emission factors defined as less than 10,000 ppmv of Table 2-8 of the 1995 EPA Protocol for Equipment Leak Emission Estimates (Document EPA-453/R-95-017).

XVII.F.3. Owners and operators of well production facilities or natural gas compressor stations shall utilize the Approved Instrument Based Monitoring Method and AVO program as outlined in Section XVII.F. AVO monitoring is not required of components and tanks that are unsafe to monitor or inaccessible to monitor, pursuant to XVII.F.5.g.

XVII.F.4. Inspection schedules for natural gas compressor stations: Beginning January 1, 2015, owners and operators of natural gas compressor stations shall inspect components for leaks using an Approved Instrument Based Monitoring Method, in accordance with the following Table 2, except for components subject to XVII.F.5.g. ~~For purposes of this Section XVII.F.4., fugitive emissions shall be calculated using the emission factors of Table 2-4 of the 1995 EPA Protocol for Equipment Leak Emission Estimates (Document EPA-453/R-95-017), or other Division approved method~~.

Table 2	
~~Fugitive VOC Emissions (tpy)~~ VOC Emissions – PTE (tpy)	Inspection Frequency
>0 and ≤ 12	Annually with monthly AVO
> 12 and ≤ 50	Quarterly with monthly AVO
> 50	Monthly

XVII.F.5. Requirements for well production facilities and/or storage tanks

XVII.F.5.a. Beginning August 1, 2014, all new well production facilities shall have a documented pressure test performed on all equipment and piping prior to start up. Documentation of this 90 day testing and monitoring shall be provided in the first annual report to the Division, as required by Section XVII.F.9.

XVII.F.5.b. Beginning January 1, 2015, within 90 days of startup of all new well production facilities and/or storage tanks, owners and/or operators shall identify and repair leaks from components using an Approved Instrument Based Monitoring Method. Such action shall qualify as an inspection pursuant to the inspection frequency schedule in Table 3.

XVII.F.5.c. ~~Consistent with the provisions of XVII.F.5.f.~~Beginning January 1, 2015, owners and operators of existing well production facilities and/or storage tanks shall identify and repair leaks using an Approved Instrument Based Monitoring Method, in accordance with the ~~implementation~~ schedule in XVII.F.5.e. Inspection frequency shall be determined according to Table 3.

XVII.F.5.d. Consistent with the provisions of XVII.F.5.f., owners and operators of new well production facilities and/or storage tanks shall identify and repair leaks from components using an Approved Instrument Based Monitoring Method beginning on January 1, 2015. Inspection frequency shall be determined according to Table 3.

XVII.F.5.e. The estimated uncontrolled actual emissions from storage tanks determine the frequency at which inspections must be performed. If no storage tanks are located at the well production facility or multi-well site, operators will rely on the potential to emit of VOC for all of the emissions sources, including emissions from components located at the facility. All components at a well production facility or storage tank must be inspected:

Table 3	
Threshold (per XVII.F.5.e.) VOC Emissions (tpy, uncontrolled actual for sites with tanks or PTE for sites without tanks)	Inspection Frequency
> 0 and ≤ 12~~6~~	Annually with monthly AVO~~One time using Approved Instrument Based Monitoring Method and thereafter using monthly AVO~~
~~> 6 and ≤ 12~~	~~Annually with monthly AVO~~
> 12 and ≤ 50	Quarterly with monthly AVO
> 50	Monthly
Multi-well sites without storage tanks after April 15, 2014, that have a PTE > 20 tpy VOC	Monthly

~~XVII.F.5.f. Phase-in of Approved Instrument Based Monitoring Methods: Owners and operators of existing well production facilities and/or storage tanks shall identify and repair leaks from components using an Approved Instrument Based Monitoring Method, in accordance with the following schedule:~~

~~XVII.F.5.f.(i) Beginning January 1, 2015, facilities with uncontrolled actual VOC emissions greater than 50 tpy or multi-well sites.~~

~~XVII.F.5.f.(ii) Beginning July 1, 2015, facilities with uncontrolled actual VOC emissions greater than 20 tpy but less than or equal to 50 tpy.~~

~~XVII.F.5.f.(iii) Beginning January 1, 2016, facilities with uncontrolled actual VOC emissions greater than 6 tpy but less than or equal to 20 tpy.~~

~~XVII.F.5.g.(iv) By July 1, 2016, facilities with uncontrolled actual VOC emissions less than or equal to 6 tpy.~~

XVII.F.5.g. If a component is difficult, unsafe, or inaccessible to monitor, the owner or operator shall not be required to monitor the component until it becomes feasible to do so.

XVII.F.5.g.(i) Difficult to monitor components are those that cannot be monitored without elevating the monitoring personnel more than two meters above a supported surface or are unable to be reached via a wheeled scissor-lift or hydraulic type scaffold that allows access to components up to 7.6 meters (25 feet) above the ground.

XVII.F.5.g.(ii) Unsafe to monitor components are those that cannot be monitored without exposing monitoring personnel to an immediate danger as a consequence of completing the monitoring.

XVII.F.5.g.(iii) Inaccessible to monitor components are those that are buried, insulated in a manner that prevents access to the components by a monitor probe, or obstructed by equipment or piping that prevents access to the components by a monitor probe.

XVII.F.6 Leak detection requiring repair: Leaks shall be identified utilizing the methods listed in this Section XVII.F.6.a. through XVII.F.6.d. Only leaks detected pursuant to this Section XVIII.F.6. shall require repair under Section XVII.F.

XVII.F.6.a. For Method 21 monitoring at existing facilities, a leak is any concentration of hydrocarbon above 2,000 parts per million (ppm), except for existing well production facilities where leak is defined as any concentration of hydrocarbon above 500 ppm.

XVII.F.6.b. For Method 21 monitoring at facilities constructed after May 1, 2014, a leak is any concentration of hydrocarbon above 500 ppm.

XVII.F.6.c. For infra-red camera and AVO monitoring, a leak is any detectable emissions not associated with normal equipment operation, such as pneumatic device actuation and crank case ventilation.

XVII.F.6.d. For other Division approved monitoring devices or methods, leak identification requiring repair will be established as set forth in the Division's approval.

XVII.F.7. Repair and remonitoring

XVII.F.7.a. First attempt to repair a leak shall be made no later than five (5) working days after discovery, unless parts are unavailable or, the equipment requires shutdown to complete repair~~, or other good cause exists~~. If parts are unavailable, they shall be ordered promptly and the repair shall be made within five (5)~~fifteen (15)~~ working days of receipt of the parts. If shutdown is required, the leak shall be repaired during the next scheduled shutdown. ~~If delay is attributable to other good cause,~~

~~repairs shall be completed within fifteen (15) working days after the cause of delay ceases to exist.~~

XVII.F.7.b. Within fifteen (15) working days of completion of a repair, the leaks shall be remonitored to verify the repair was effective.

XVII.F.7.c. Leaks discovered pursuant to the leak detection methods of Section XVII.F. shall not be subject to enforcement by the Division unless the owner or operator fails to perform the required repairs in accordance with Section XVII.F.7.

XVII.F.7.d. For leaks identified using an Approved Instrument Based Monitoring Method, owners and operators have the option of either repairing the leak in accordance with the repair schedule set forth in Section XVII.F.7. or conducting follow-up monitoring using Method 21 within five (5) working days of the leak detected. If the follow-up Method 21 monitoring shows that the leak concentration is less than or equal to 2,000 ppm hydrocarbon for existing facilities (other than existing well production facilities), or 500 ppm for new facilities or existing well production facilities, then the emission shall not be considered a leak for purposes of this Section.

XVII.F.8. Recordkeeping: The owner or operator of each facility subject to the inspection and maintenance requirements in this Section XVII.F. shall maintain the following for a period of five (5) ~~two (2)~~ years and make them available to the Division upon request.

XVII.F.8.a. Documentation of the pre-start-up pressure tests for new well production facilities;

XVII.F.8.b. The date and site information for each inspection;

XVII.F.8.c. A list of the leaking components and the monitoring method used to determine the presence of the leak;

XVII.F.8.d. The date of first attempt to repair the leak and, if necessary, any additional attempt to repair the leak;

XVII.F.8.e. The date the leak was repair;

XVII.F.8.f. The delayed repair list including the basis for placing leaks on the list;

XVII.F.8.g. The date the leak was remonitored to verify the effectiveness of the repair, and the results of the remonitoring; and

XVII.F.8.h. A list of identification numbers for components that are designated as unsafe or inaccessible to monitor, as described in Section XVII.F.5.g., an

explanation for each component stating why the component is so designated, and the plan for monitoring such component(s).

XVII.F.9. Reporting: The owner or operator of each facility subject to the inspection and maintenance requirements in Section XVII.F. shall submit a single annual report on or before April 30th of each year summarizing inspection and maintenance activities at all of their subject facilities during the previous calendar year. This report shall contain at a minimum the following information:

XVII.F.9.a. The number of facilities inspected;

XVII.F.9.b. The total number of inspections;

XVII.F.9.c. The total number of leaks identified, broken out by component type;

XVII.F.9.d. The total number of leaks repaired;

XVII.F.9.e. The number of leaks on the delayed repair list as of December 31st; and

XVII.F.9.f. Each report shall be accompanied by a self-certification form. The form shall contain a certification by a responsible official of the truth, accuracy, and completeness of such form, report, or certification stating that, based on information and belief formed after reasonable inquiry, the statements and information in the document are true, accurate, and complete.

XVII.G. (State Only) Control of emissions from well production facilities

XVII.G.1. Well Operation and Maintenance: On or after August 1, 2014, during normal operation gas coming off a separator produced from any newly constructed, hydraulically fractured, or recompleted oil and gas well must either be routed to a gas gathering line or controlled by air pollution control equipment that achieves an average hydrocarbon control efficiency of 95% from the date of first production. If a combustion device is used, it shall have a design destruction efficiency of at least 98% of hydrocarbons.

XVII.H. (State Only) Venting during downhole well maintenance and unloading events

XVII.H.1. Well Maintenance: Beginning May 1, 2014, hydrocarbon emissions from flowing wells must be captured or controlled during downhole well maintenance or servicing activities, unless venting is necessary for safety.

XVII.H.1.a. Operators shall use best management practices to minimize the need for well venting associated with downhole well maintenance and liquids unloading. During liquids unloading events, any means of creating differential pressure will first be used to attempt to unload the liquids from the well without venting. If these methods are not successful in unloading the liquids from the

well, the well may be vented to the atmosphere to create the necessary differential pressure to bring the liquids to the surface.

XVII.H.1.b. Venting will be minimized to the extent possible, using best management practices during the well maintenance and liquids unloading events in XVII.H.1.a. The owner and/or operator shall be present on-site during any planned well maintenance and liquids unloading event in XVII.H.1.a. and shall ensure that any venting to the atmosphere is limited to the maximum extent practicable.

XVII.H.1.c. Records of the best management practices employed under this Section XVII.H., and the cause, date, time, and duration of venting events ~~under this Section XVII.H.,~~ will be kept and submitted annually ~~made available~~ to the Division ~~upon request~~.

XVIII. (State Only) Natural Gas-Actuated Pneumatic Controllers Associated with Oil and Gas Operations

XVIII.A. Applicability

This section applies to pneumatic controllers that are actuated by natural gas, and located at, or upstream of natural gas processing plants (upstream activities include: oil and gas exploration and production operations, natural gas compressor stations, and/or natural gas drip stations).

XVIII.B. Definitions

XVIII.B.1. "Affected Operations" shall mean pneumatic controllers that are actuated by natural gas, and located at, or upstream of natural gas processing plants (upstream activities include: oil and gas exploration and production operations, natural gas compressor stations, and/or natural gas drip stations).

XVIII.B.2. "Enhanced Maintenance" is specific to high-bleed devices and shall include but is not limited to cleaning, tuning, and repairing leaking gaskets, tubing fittings, and seals; tuning to operate over a broader range of proportional band; and eliminating unnecessary valve positioners.

XVIII.B.3. "High-Bleed Pneumatic Controller" shall mean a pneumatic controller that is designed to have a constant bleed rate that emits in excess of 6 standard cubic feet per hour (scfh) of natural gas to the atmosphere.

XVIII.B.4. "Low-Bleed Pneumatic controller" shall mean a pneumatic controller that is designed to have a constant bleed rate that emits less than or equal to 6 scfh of natural gas to the atmosphere.

XVIII.B.5. "Natural Gas Processing Plant" shall mean any processing site engaged in the extraction of natural gas liquids from field gas, fractionation of mixed natural gas liquids to natural gas products, or both.

XVIII.B.6. "No-bleed Pneumatic Controller" shall mean any pneumatic controller that is not using hydrocarbon gas as the valve's actuating gas.

XVIII.B.7. "Pneumatic Controller" shall mean an instrument that is actuated using natural gas pressure and used to control or monitor process parameters such as liquid level, gas level, pressure, valve position, liquid flow, gas flow and temperature.

XVIII.C. Emission Reduction Requirements

The owners and operators of affected operations shall reduce emissions of volatile organic compounds from pneumatic controllers associated with affected operations as follows:

XVIII.C.1. In the 8-Hour Ozone Control Area:

XVIII.C.1.a. All pneumatic controllers placed in service on or after February 1, 2009, shall emit VOCs in an amount equal to or less than a low-bleed pneumatic controller, unless allowed pursuant to Section XVIII.C.1.c.

XVIII.C.1.b. All high-bleed pneumatic controllers in service prior to February 1, 2009 shall be replaced or retrofit such that VOC emissions are reduced to an amount equal to or less than a low-bleed pneumatic controller, by May 1, 2009, unless allowed pursuant to Section XVIII.C.1.c.

XVIII.C.1.c. All high-bleed pneumatic controllers that must remain in service due to safety and/or process purposes must have Division approval and comply with Sections XVIII.D. and XVIII.E.

XVIII.C.1.c.(i) For high-bleed pneumatic controllers in service prior to February 1, 2009, the owner/operator shall submit justification for high-bleed pneumatic controllers to remain in service due to safety and /or process purposes by March 1, 2009. The Division shall be deemed to have approved the justification if it does not object to the owner/operator within 30-days upon receipt.

XVIII.C.1.c.(ii) For high-bleed pneumatic controllers placed in service on or after February 1, 2009, the owner/operator shall submit justification for high-bleed pneumatic controllers to be installed due to safety and /or process purposes prior to installation. The Division shall be deemed to have approved the justification if it does not object to the owner/operator within 30-days upon receipt.

XVIII.C.2. Statewide:

XVIII.C.2.a. All pneumatic controllers placed in service on or after May 1, 2014, shall:

XVIII.C.2.c.(i) Emit VOCs in an amount equal to or less than a low-bleed pneumatic controller, unless allowed pursuant to Section XVIII.C.2.c.; or

XVIII.C.2.c.(ii) Utilize no-bleed pneumatic controllers where on-site electrical grid power is being used and is technically and economically feasible.

XVIII.C.2.b. All ~~high-bleed~~ pneumatic controllers in service prior to May 1, 2014 with VOC emissions greater than a low-bleed pneumatic controller~~,~~ shall be replaced or retrofitted by May 1, 2015, such that VOC emissions are reduced to an amount equal to or less than a low-bleed pneumatic controller, unless allowed pursuant to Section XVIII.C.2.c.

XVIII.C.2.c. All ~~high-bleed~~ controllers with VOC emissions greater than a low-bleed pneumatic controller that must remain in service due to safety and/or process purposes must have Division approval and comply with Sections XVIII.D. and XVIII.E.

XVIII.C.2.c.(i) A~~For~~l~~l high-bleed~~ pneumatic controllers in service prior to May 1, 2014, the owner/operator shall submit justification for ~~high-bleed~~ all pneumatic controllers with VOC emissions greater than a low-bleed pneumatic controller to remain in service due to safety and/or process purposes by March 1, 2015. The Division shall be deemed to have approved the justification if it does not object to the owner/operator within 30-days upon receipt.

XVIII.C.2.c.(ii) For ~~high-bleed~~ pneumatic controllers placed in service on or after May 1, 2014, the owner/operator shall submit justification for ~~high-bleed~~ all pneumatic controllers with VOC emissions greater than a low-bleed pneumatic controller to be installed due to safety and/or process purposes prior to installation. The Division shall be deemed to have approved the justification if it does not object to the owner/operator within 30-days upon receipt.

XVIII.D. Monitoring

This section applies only to high-bleed pneumatic controllers identified in Sections XVIII.C.1.c. and XVIII.C.2.c.

XVIII.D.1. In the 8-Hour Ozone Control Area

XVIII.D.1.a. Effective May 1, 2009, each high-bleed pneumatic controller shall be physically tagged by the owner/operator identifying it with a unique high-bleed pneumatic controller number that is assigned and maintained by the owner/operator.

XVIII.D.1.b. Effective May 1, 2009, each high-bleed pneumatic controller shall be inspected on a monthly basis, perform necessary enhanced maintenance as defined in Section XVIII.B.2 , and maintain the device according to manufacturer specifications to ensure that the controller's VOC emissions are minimized.

XVIII.D.2. Statewide:

XVIII.D.2.a. Effective May 1, 2015, each ~~high-bleed~~ pneumatic controller with VOC emissions greater than a low-bleed pneumatic controller shall be physically tagged by the owner/operator identifying it with a unique ~~high-bleed~~ pneumatic controller number that is assigned and maintained by the owner/operator.

XVIII.D.2.b. Effective May 1, 2015, each ~~high-bleed~~ pneumatic controller with VOC emissions greater than a low-bleed pneumatic controller shall be inspected on a monthly basis, perform necessary enhanced maintenance as defined in Section XVIII.B.2 , and maintain the device according to manufacturer specifications to ensure that the controller's VOC emissions are minimized.

XVIII.E. Recordkeeping

This section applies only to ~~high-bleed~~ pneumatic controllers with VOC emissions greater than a low-bleed pneumatic controller identified in Sections XVIII.C.1.c. and XVIII.C.2.c.

XVIII.E.1. The owner or operator of affected operations shall maintain a log of the total number of ~~high-bleed~~ pneumatic controllers with VOC emissions greater than a low-bleed pneumatic controller and their associated controller numbers per facility, the total number of ~~high-bleed~~ such pneumatic controllers per company and the associated justification that those ~~high-bleed~~ pneumatic controllers must be used pursuant to Sections XVIII.C.1.c. and XVIII.C.2.c. The log shall be updated on a monthly basis.

XVIII.E.2. The owner or operator shall maintain a log of enhanced maintenance which shall include, at a minimum, inspection dates, the date of the maintenance activity, ~~high-bleed~~ pneumatic controller number, description of the maintenance performed, results and date of any corrective action taken, and the printed name and signature of the individual performing the maintenance. The log shall be updated on a monthly basis.

XVIII.E.3. Records of enhanced maintenance of pneumatic controllers shall be maintained for a minimum of five (5) ~~three~~ years and readily made available to the Division upon request.

NMED Exhibit 71

FINAL
ECONOMIC IMPACT ANALYSIS
PER § 25-7-110.5(4), C.R.S.

For Conservation Groups' Alternate Proposal modifying proposed revisions to
Colorado Air Quality Control Commission
Regulation Number 7 (5 CCR 1001-9)

I. INTRODUCTION

This economic analysis addresses the impact of the Conservation Groups' alternate proposal on the Division-proposed revisions to Regulation 7. The alternate proposal includes the following changes covered in this analysis:[1]

1. Leak detection requirements for compressors should be expanded in two ways:

   a. The definition of "Natural Gas Compressor Station" in Rule XVII.A.10 should be expanded so that it is not limited to those compressors upstream of processing facilities.

   b. The inspection frequencies for compressor stations in Rule XVII.F should be calculated based on <u>total</u> VOC emissions (potential to emit), similar to the approach for well production facilities, rather than based only on <u>fugitive</u> VOC emissions.

2. For well production facilities and tanks with uncontrolled actual emissions of less than 6 tpy, the leak detection schedule in Rule XVII.F should require an instrument-based inspection on an annual basis – not just a single time.

3. Under Rule XVIII.C, the requirement to retrofit existing high-bleed pneumatic controllers should be clarified to ensure that it requires retrofitting <u>all</u> pneumatics emitting VOCs at a rate higher than a low-bleed pneumatic. This would include retrofitting <u>intermittent-bleed</u> pneumatics.

---

[1] The alternate proposal includes several other proposed changes, such as shortening excessively long phase-in periods and requiring that records be kept for a longer time period. These proposed requirements are not separately analyzed in the discussion below because they are not expected to involve any material costs to companies. This is consistent with the approach taken by the Division in its initial economic analysis, which does not alter its analysis of a requirement's cost-effectiveness based on when the requirement takes effect, or how long records must be retained, for example.

NMED Exhibit 71

The discussion below uses the relevant sections from the Division's initial economic analysis, with modifications reflecting the limited changes proposed by the Conservation Groups.

II. COST/BENEFIT ANALYSIS:

A. Leak Detection and Repair Requirements for Compressor Stations and Well Production Facilities

AQCC Regulation Number 7 requires owners and operators of gas processing plants in Colorado to implement leak detection and repair programs to identify and repair fugitive emission leaks from components at these facilities. Under this requirement, owners and operators must conduct periodic inspections using EPA Reference Method 21[2] and repair leaks within a prescribed time frame.

Although component leaks at compressor stations and well production facilities in Colorado are also a significant source of VOC and methane emissions, Regulation No. 7 does not currently include leak detection and repair requirements for these facilities.[3] To address these emissions, the Division is proposing regulatory changes that would establish leak detection and repair requirements for compressor stations and well production facilities. Pursuant to this proposal, owners and operators of compressor stations and well production facilities will be required to conduct periodic leak inspections, and repair identified leaks. As specified, required inspections may be done either in accordance with Method 21 or utilizing an IR camera. The proposed language also allows the Division to approve other inspection methods as new leak detection technologies are demonstrated to be effective.

The Division's Proposal would establish a tiered system to determine inspection frequency. For well production facilities, the tiering is based on the uncontrolled actual emissions from the largest storage tank at the facility.[4] This approach creates a Method 21/IR camera monitoring schedule that is consistent with the monitoring schedule proposed as part of the STEM emission capture requirements. The Conservation Groups would use the same approach, but require that facilities with emissions under 6 tpy conduct annual instrument-based inspections (instead of just a one-time inspection as proposed by the Division). For compressor stations, the Division proposes tiers based on the station's fugitive emissions. The Conservation Groups tiering is based instead on the facility's potential to emit (PTE) VOCs.

---

[2] While Method 21 sets performance standards for inspection equipment rather than specifying technology, typically Method 21 inspections utilize photo ionization detectors (PIDs) to assess leak levels.

[3] Although leak detection is not currently required at most of these facilities, some operators currently conduct voluntary leak detection and repair programs. Additionally, the Division has issued a limited number of permits that include some leak detection requirements. For the purposes of this analysis, however, the Division assumes that there is no leak detection occurring at well production facilities and compressor stations. Accordingly the actual additional costs that operators may incur may be less than the costs calculated in this analysis.

[4] Because there may be instances where facilities do not have storage tanks, the proposal also provides that for tank-less facilities, the inspection schedule will be based on the facility's potential to emit (PTE) VOC.

NMED Exhibit 71

For compressor stations and well production facilities, the frequencies proposed by the Conservation Groups are described as follows in Tables 1-2:

Table 1: Conservation Groups' Proposed Tiering for Leak Inspections at Compressor Stations	
PTE VOCs	Inspection Frequency
≤ 12 tpy	Annually, with monthly AVO
>12 tpy to ≤ 50 tpy	Quarterly, with monthly AVO
> 50 tpy	Monthly

Table 2: Conservtion Groups' Proposed Tiering for Leak Inspections at Well Production Facilities	
Tank Uncontrolled Actual VOC Emissions or PTE	Inspection Frequency
≤ 12 tpy	Annually (and monthly AVO)
>12 tpy to ≤ 50 tpy	Quarterly (and monthly AVO)
> 50 tpy	Monthly

1. Well production facilities

To evaluate the cost-effectiveness of the alternate proposal with regard to well production facilities, the Conservation Groups followed the approach used by the Division in its initial economic analysis. The Division utilized a multi-step process to calculate the estimated costs and benefits associated with the proposed leak detection and repair requirements. First, the Division calculated an hourly inspection rate based on the total annual cost for each inspector divided by an assumed 1,880 annual work hours.[5] To calculate the total annual cost for each inspector, the Division included salary and fringe benefits for each inspector, annualized equipment and vehicle costs, and add-ons to account for supervision, overhead, travel, record keeping, and reporting. Based on the assumptions set forth in the Division's EIA Table 20 (reproduced below), the total annual cost for each inspector will be $186,129, which equates to an hourly inspection rate of $99.

Leak Detection and Repair (LDAR) Inspector – Annualized Cost Analysis (Division EIA Table 20)			
Item	Capital Costs (one time)	Annual Costs	Annualized Total Costs
FLIR Camera	$122,000		
Photo Ionization Detector	$5,000		
Vehicle (4x4 Truck)	$22,000		
Inspection Staff		$75,000	
Supervision (@ 20%)		$15,000	
Overhead (@10%)		$7,500	
Travel (@15%)		$11,250	

[5] This assumes a 40 hour work week with ten holidays, two weeks of vacation, and one week of sick leave.

NMED Exhibit 71

Recordkeeping (@10%)		$7,500	
Reporting (@10%)		$7,500	
Fringe (@30%)		$22,500	
Subtotal Costs	$149,000	$146,250	
Annualized Costs*	$39,879	$146,250	$186,129
**over 5 years at 6% ROR*		Annualized Hourly Rate	$99

Second, the Division calculated the average amount of time that it would take to conduct a Method 21 inspection at well production facilities based on the number of components to be inspected and assuming that a component could be inspected every 30 seconds. The proposed rule also allows owners and operators to use IR cameras either as the sole inspection tool, or as a screening tool to identify potential leaking components followed by a Method 21 inspection. An IR camera inspection or IR Camera/Method 21 hybrid inspection can be conducted more quickly than a Method 21 inspection of each component. While the Division does not currently have actual data regarding how much faster an inspection could be completed using an IR camera, for the purpose of its analysis the Division assumed that an IR camera based inspection would take 50% of the time required for a Method 21 inspection. Discussions with multiple private contractors that perform these inspections at well production and oil and gas processing facilities indicates that, on average, the value of 30 seconds per component for camera-based inspections errs on the side of over-estimation of time. One contractor with extensive experience with camera-based inpsections stated that inspections can be conducted for 300 to 400 components per hour, when components are generally accessible.

For well production facilities, the Division has limited data on the number of components per facility. Based on this limitation, the Division did not attempt to calculate a separate inspection time for each of the proposed facility tiers, and instead used the overall average component count. Based on this overall average component count each Method 21 inspection will take 9.5 hours and each IR camera based inspection will take 4.75 hours.

Next, the Division calculated the projected inspection costs for well production facilities. To make this calculation the Division used industry reported emission data to determine the number of facilities that will be subject to annual, quarterly and monthly inspections to determine the total number of inspections for each tier, and multiplied these inspections by the calculated inspection time and projected hourly inspection rate. The calculated inspection costs for well production facilities do not include the cost to repair leaking components or re-monitor these components post-repair to verify that the repair was effective. Conversely, the calculated costs also do not account for the cost savings from capturing additional product as a result of repairs. For the purposes of its initial cost analysis the Division assumes that the cost savings from additional product capture will be equal to or greater than the cost of repair and re-inspection. The Division's estimated annual inspection costs for well production facilities are set forth in its EIA Table 23.[6]

[6] The Division's proposal also requires monthly AVO inspections at facilities. Based on information provided during the stakeholder process, the Division reports that AVO inspections are part of current standard operational practice. Accordingly, the regulatory provisions should not result in additional costs.

NMED Exhibit 71

Taking the same approach, the Conservation Groups' estimated annual inspection costs for well production facilities are set forth in Table 3.

Table 3: Well Production Facility Leak Inspection Costs Using IR Camera/Method 21 Hybrid

Uncontrolled Tank Battery VOCs/PTE Tier [tpy]	Number of Facilities	Annual Inspection Frequency	Inspection Time Per Inspection [hours]	Total Inspection Time [hours]	Total Annual Inspection Cost
≤12	4,200	1	4.75	19,950	$1,975,050
> 12 to ≤ 50	2,916	4	4.75	55,404.0	$5,484,996
> 50	964	12	4.75	54,498.0	$5,439,852
Total:	8,080			129,852	$12,899,898

Finally, the Division calculated the cost effectiveness of the proposed leak detection and repair requirements based on the costs identified above and the projected emission reductions. To determine emission reductions the Division first calculated pre-inspection program VOC and methane emissions based on the reported component counts, standard emission factors for these components, and the average fraction of VOC and non-VOC emissions (methane/ethane). Based on EPA reported information, the Division calculated a 40% reduction for annual inspections, a 60% reduction for quarterly inspections, and an 80% reduction for monthly inspections. The Division estimated total emissions reductions at well production facilities from its proposal would be 14,153 tpy VOC and 22,461 tpy methane/ethane. This resulted in a Division estimate that its proposal would cost $818/ton VOC controlled, and $516/ton methane/ethane controlled, at well production facilities. These were calculated in Tables 26-27 of the Division's EIA.

The Conservation Groups have used a similar approach. The total emissions reductions and cost-effectiveness at well production facilities from the alternate proposal are set forth in Tables 4-5. Under the alternate proposal, the cost effectiveness of conducting ongoing instrument based inspections at well production facilities is estimated to be $668/ton VOC and $421/ton methane/ethane. Thus, the Conservation Groups' alternate proposal for well production facilities is more cost-effective than the Division proposal.

NMED Exhibit 71

Table 4: Well Production Facility Leak Inspection Emission Reductions						
Uncontrolled Tank Battery VOCs/PTE Tier [tpy]	Number of Facilities	LDAR Program Reduction %	Fugitive VOC Emissions for each Tank Battery [tpy]	Total VOC Reduction [tpy]	Fugitive Methane-Ethane Emissions for each Tank Battery [tpy]	Total Methane-Ethane Reduction [tpy]
≤ 12	4,200	40%	4.6	7,728	7.3	12,264
> 12 to ≤ 50	2,916	60%	4.6	8,048.2	7.3	12,772.1
> 50	964	80%	4.6	3,547.5	7.3	5,629.8
Total:	8,080			19,323.7		30,665.9

Table 5: Well Production Facility Leak Cost-Effectiveness Using IR Camera/Method 21							
Uncont. Tank Battery VOCs/PTE Tier [tpy]	Number of Tanks	Total Annual Inspection Cost	LDAR Program Reduction %	Total VOC Reduction [tpy]	VOC Control Cost [$/ton]	Total Methane-Ethane Reduction [tpy]	Methane -Ethane Control Cost [$/ton]
≤ 12	4,200	$1,975,050	40%	7,728	$256	12,264	$161
> 12 to ≤ 50	2,919	$5,484,996	60%	8,048.2	$682	12,772.1	$429
> 50	964	$5,439,852	80%	3,547.5	$1533	5,629.8	$966
Total:	8,080	$12,899,898		19,323	$668	30,665.9	$421

Finally, it should be noted that the Division's methodology for calculating the cost-effectiveness of LDAR at well production facilities is conservative in several respects. An analysis by the Clean Air Task Force of data from actual inspections found that costs are lower than those estimated by the Division. Testimony of David McCabe at 7-8.

2. Compressor stations

The Division's analysis of cost-effectiveness for compressor stations was similar to its analysis for well production facilities. It concluded that VOCs would be controlled at a cost of $667/ton, and methane/ethane controlled for $321/ton. These estimates are summarized in Table 25 of the Division's initial EIA.

Division Proposal - Compressor Station Leak Inspection Cost Effectiveness using IR Camera/Method 21 (Division EIA Table 25)							
Comp. Station Fugitive VOC Tier	Number of Comp Stations	Total Annual Inspection Cost	LDAR Program Reduction %	Total VOC Reduction [tpy]	VOC Control Cost [$/ton]	Total Methane-Ethane Reduction	Methane-Ethane Control Cost [$/ton]

NMED Exhibit 71

[tpy]						[tpy]	
≤ 12	147	$154,262	40%	593.9	$260	911.4	$169
> 12 to ≤ 50	53	$589,763	60%	521.5	$1,131	1,408.7	$419
> 50			80%				
	200	$744,025		1,115.4	$667	2,320.1	$321

For compressor stations, the Conservation Groups do not have data that allows for a comparable calculation of the cost-effectiveness of their alternate proposal. Testimony of Maureen Barrett at 3-4. As a result, the Conservation Groups cannot provide numeric estimates of: (a) how many additional facilities would be affected if the LDAR provisions cover compressor stations downstream of processing plants; (b) how many compressor stations would fall into each inspection tier based on total VOCs (instead of fugitive VOCs); and (c) the potential to emit of each compressor station.

With regard to the estimated 200 compressor stations upstream of processing plants, the Conservation Groups expect that their alternate proposal will be cost-effective. For these compressors, the alternate proposal is expected to require more frequent inpections because total facility VOC emissions are typically much greater than the fugitive emissions counted by the Division Proposal. Barrett testimony at 2-3. While the increased inspections will result in greater costs, that expense will be offset by greater reductions of VOCs and methane/ethane at compressors than would result from the Division Proposal. An analysis by Clean Air Task Force estimates that quarterly instrument-based inspections of compressor stations controls VOC emissions at a cost of $800/metric ton, and the cost for monthly insepctions is under $3,500/metric ton. See McCabe testimony at 8. The control costs for methane are only about $10/metric ton with quarterly inspections, and just over $50/metric ton for monthly inspections. Id. at 4.

With regard to compressor stations downstream of processing plants, the cost of controlling methane/ethane reductions is likely to be even lower than for their upstream counterparts. The CATF figures indicate that methane control costs at transmission compressor stations are somewhat lower than those for gathering stations. McCabe testimony at 8-9.[7]

The cost per ton of VOC reductions for transmission compressor stations, however, likely would be greater than for compressors upstream of processing plants. Limited data is available, but the Title V permits for two such compressor stations, Kerr McGee's Fort Lupton station and DCP Midstream's Enterprise station, include limits for VOC fugitive emissions that allow for a conservative estimate of cost-effectiveness. The Kerr-McGee permit has a limit of 30.8 tpy fugitive VOCs, Supp. Testimony of Maureen Barrett at 2, and the DCP permit has a limit of 18.22 tpy fugitive VOCs. The Conservation Groups' alternate proposal would subject these two facilities to monthly instrument-based inspections. Assuming that such inspections reduce

[7] If the value of gas conserved by LDAR programs is not considered in the analysis of abatement costs for transmission compressor stations (because the facility owners may not own the gas), the methane abatement cost for those facilities is slightly higher than for gathering compressor stations, but still very reasonable (under $3/ metric ton CO_2e). McCabe testimony at 9 n. 5.

BEFORE THE COLORADO AIR QUALITY CONTROL COMMISSION
COLORADO DEPARTMENT OF PUBLIC HEALTH AND ENVIRONMENT

WPX ENERGY ROCKY MOUNTAIN, LLC'S AND WPX ENERGY PRODUCTION, LLC'S PROPOSED REGULATION TEXT – WPX REB EX A

IN THE MATTER OF OIL & GAS RULEMAKING EFFORTS REGARDING PROPOSED REVISIONS TO:
REGULATION NUMBER 3, PARTS A, B, AND C;
REGULATION NUMBER 6, PART A;
REGULATION NUMBER 7

WPX ENERGY ROCKY MOUNTAIN, LLC and WPX ENERGY PRODUCTION, LLC (collectively "WPX") respectfully submit to the Colorado Air Quality Control Commission ("Commission") WPX's final proposed regulation text to accompany WPX's alternate proposal[1] pursuant to Procedural Rule § V.C.3.c.

Based on the revised language of the Proposed Regulation Text circulated by the Division on January 24, 2014, please see the attached revised alternate proposal by WPX indicated by the redlined attachment. *See* attached WPX ALT EX D REVISED. For clarity, WPX has only included here the sections for which it proposes changes, and has indicated such changes in the attached redline.

[1] Note that WPX does not believe that the minor changes it proposed on January 6, 2014, rise to the level of an alternate proposal. However, out of an abundance of caution, WPX filed its proposed revisions to the Division rules as an alternate proposal with the documents described in 5 CCR 1001-1 ("Procedural Rules") Section V.C.3.a through k.

DEPARTMENT OF PUBLIC HEALTH AND ENVIRONMENT

Air Quality Control Commission

REGULATION NUMBER 7

CONTROL OF OZONE PRECURSORS AND CONTROL OF HYDROCARBONS VIA OIL AND GAS EMISSIONS

XVII.C.1.e.(ii) (new section) Unsafe to monitor means it cannot be monitored without exposing monitoring personnel to an immediate danger as a consequence of completing the monitoring, which includes weather conditions preventing access to the site, or that endanger monitoring personnel or equipment, or prevent use of Approved Instrument Based Monitoring Methods (such as reflection due to precipitation).

XVII.F.5.c. Owners or operators of well production facilities constructed before January 1, 2015, must identify leaks from components using an approved instrument based monitoring method within ninety (90) days of the Phase-In Schedule in Table 4, within thirty (30) days for > 50 tons per year, or by July 1, 2016, for > 0 and < 6 tons per year tanks. Thereafter, approved instrument based monitoring method and AVO inspections must be conducted in accordance with the Inspection Frequency in Table ~~4.~~4 or when a reduced LDAR demonstration is made, the frequency may be determined by Alternative Table 4A pursuant to Section XVII.F.5.d.

XVII.F.5.~~e~~d. The largest estimated uncontrolled actual emissions from a single storage ~~tanks determine~~tank batterys determines the frequency at which inspections must be performed. If no storage tanks storing oil or condensate are located at the well production facility or multi-well site, owners or operators must rely on the potential to emit of VOC for all of the emissions sources, including emissions from components located at the well production facility~~.~~ in accordance with Table 4 of Alternative Table 4A.

Table 4 – Well Production Facility Component Inspections

Threshold (per XVII.F.5.d.) VOC Emissions (tpy)	Inspection Frequency	Phase-In Schedule
> 0 and < 6	One time using approved Instrument based monitoring method and thereafter using monthly AVO	July 1, 2016
> 6 and < 12	Annually with monthly AVO	January 1, 2016
> 12 and < 50	Quarterly with monthly AVO	July 1, 2015
> 50	Monthly	January 1, 2015
Well production facilities or multi-well sites without storage tanks storing oil or condensate that have a potential to emit > 20 tpy VOC	Monthly	January 1, 2015

An alternative inspection frequency schedule pursuant to Alternative Table 4A may be implemented once a reduced LDAR demonstration is made. A reduced LDAR demonstration requires that an owner or operator identify fewer than either (1) the specified number of leaking components listed in "Demonstration of Reduced LDAR – Monitoring History" in Alternative Table 4A or (2) two percent of the total components for that facility during a single monitoring event, for at least two consecutive monitoring events.

Once the reduced LDAR demonstration is made pursuant to this Section, the alternative inspection frequency pursuant to Alternative Table 4A may remain in place until, during any monitoring event under the alternative inspection frequency, more leaks are indentified than allowed under Alternative Table 4A's "Demonstration of Reduced LDAR – Monitoring History." Using the alternative inspection frequency identified in Alternative Table 4A, during any monitoring event, if more leaks are identified than listed in the "Demonstration of Reduced LDAR – Monitoring History," then the original monitoring frequency identified in Table 4 shall become applicable until or if the operator can make another reduced LDAR demonstration for that facility.

Alternative Table 4A		
Threshold (per XVII.F.5.e.) VOC Emissions (tpy, uncontrolled actual for sites with tanks or PTE for sites without tanks)	Demonstration of Reduced LDAR - Monitoring History	Alternative Inspection Frequency
> 0 and < 6		One time using Approved Instrument Based Monitoring Method and thereafter using monthly AVO
> 6 and < 12		Annually with monthly AVO
> 12 and < 50	5 or less component leaks (or 2% of total components) identified in each of two consecutive monitoring events.	Annually with monthly AVO
> 50	10 or less component leaks (or 2% of total components) identified in each of two consecutive monitoring events.	Quarterly with monthly AVO
Multi-well sites without storage tanks after April 15, 2014, that have a PTE > 20 tpy VOC	10 or less component leaks (or 2% of total components) identified in each of two consecutive monitoring events.	Quarterly with monthly AVO

XVII.F.~~5.g.(ii)~~6.b. Unsafe to monitor components are those that cannot be monitored without exposing monitoring personnel to an immediate danger as a consequence of completing the monitoring, which includes weather conditions preventing access to the site, or that endanger monitoring personnel or equipment, or prevent use of Approved Instrument Based Monitoring Methods (such as reflection due to precipitation).

XVII.F.~~6.~~7.a. For EPA Method 21 monitoring at facilities constructed before May 1, 2014, a leak is any concentration of hydrocarbon above 2,000 parts per million (ppm), except for existing well production facilities where a leak is defined as any concentration of hydrocarbon above 500 ppm~~.~~ after January 1, 2016.

XVII.F.~~6.~~7.b. For EPA Method 21 monitoring at facilities constructed on or after ~~May~~January 1, ~~2014,~~2016, a leak is any concentration of hydrocarbon above 500 ppm.

REGULATION NUMBER 7

CONTROL OF OZONE VIA OZONE PRECURSORS AND CONTROL OF HYDROCARBONS VIA OIL AND GAS EMISSIONS

(EMISSIONS OF VOLATILE ORGANIC COMPOUNDS AND NITROGEN OXIDES)

5 CCR 1001-9

>>>>>>>>

II. General Provisions

>>>>>>>>

II.B. Exemptions

Emissions of the organic compounds listed as having negligible photochemical reactivity in the common provisions definition of Negligibly Reactive Volatile Organic Compound are exempt from the provisions of this regulation.

(State Only) Notwithstanding the foregoing exemption, hydrocarbon emissions from oil and gas operations, including methane and ethane, are subject to this regulation as set forth in Sections XVII. and XVIII.

>>>>>>>>

XVII. (State Only, except Section XVII.E.3.a. which was submitted as part of the Regional Haze SIP) Statewide Controls for Oil and Gas Operations and Natural Gas-Fired Reciprocating Internal Combustion Engines

XVII.A. (State Only) Definitions

XVII.A.1 "Air Pollution Control Equipment," as used in this Section XVII, means a combustion device or vapor recovery unit. Air pollution control equipment also means alternative emissions control equipment and pollution prevention devices and processes intended to reduce uncontrolled actual emissions that comply with the requirements of Section XVII.B.2.e.

XVII.A.2. "Approved Instrument Based Monitoring Method," as used in this Section XVII. means an infra-red camera, Method 21, or other Division approved instrument based monitoring device or method. If an owner/operator elects to use a Division approved Continuous Emission Monitoring program, the Division may approve a streamlined inspection and reporting program for such operations. Any instrument based monitoring method approved by the Division under this definition must be at least as effective as Method 21 or an infra-red camera.

XVII.A.3. ”Auto-Igniter” means a device which will automatically attempt to relight the pilot flame in the combustion chamber of a control device in order to combust volatile organic compound emissions.

XVII.A.4. “Building Unit” shall mean a residential building unit, and every five thousand (5,000) square feet of building floor area in commercial facilities or every fifteen thousand (15,000) square feet of building floor area in warehouses that are operating and normally occupied during working hours.

XVII.A.5~~4~~. “Component” means each pump seal, compressor seal, flange, pressure relief device, connector, open ended line, and valve that contains or contacts a process stream with hydrocarbons. Process streams consisting of glycol, amine, produced water, or methanol are not components for purposes of this Section XVII.

XVII.A.6~~5~~. “Connector” means flanged, screwed, or other joined fittings used to connect two pipes or a pipe and a piece of process equipment or that close an opening in a pipe that could be connected to another pipe. Jointed fittings welded completely around the circumference of the interface are not considered connectors.

XVII.A.7~~6~~. “Date of First Production” means the date reported to the COGCC as the “first date of production.”

XVII.A.8. “Designated Outside Activity Area” shall mean an outdoor venue or recreation area, such as a playground, permanent sports field, amphitheater, or other similar place of public assembly owned or operated by a local government, which the local government seeks to have established as a Designated Outside Activity Area; or an outdoor venue or recreation area where ingress to or egress from could be impeded in the event of an emergency condition at an oil and gas location less than three hundred and fifty (350) feet from the venue due to the configuration of the venue and the number of persons known or expected to simultaneously occupy the venue on a regular basis.

XVII.A.9~~7~~. “Glycol Natural Gas Dehydrator” means any device in which a liquid glycol (including ethylene glycol, diethylene glycol, or triethylene glycol) absorbent directly contacts a natural gas stream and absorbs water.

XVII.A.10. “Major Gas Leak” shall mean any leak greater than 10,000 ppm hydrocarbon concentration above background as determined through an approved instrument based monitoring method.

XVII.A.11~~8~~. “Multi-Well Site” means a common well pad from which multiple wells may be drilled to various bottomhole locations.

XVII.A.12~~9~~. “Natural Gas Compressor Station” means a facility which contains one or more compressors designed to compress natural gas from well pressure to gathering system pressure and recompress natural gas prior to processing.

XVII.A.13~~0~~. “Normal Operation” means all periods of operation, excluding malfunctions as defined in Section I.G. of the Common Provisions regulation. For storage tanks at well production facilities, normal operation includes but is not limited to liquid dumps from the separator.

XVII.A.14~~1~~. “Stabilized” when used to refer to crude oil, condensate, intermediate hydrocarbon liquids, or produced water means that the vapor pressure of the liquid is sufficiently low to prevent the production of vapor phase upon transferring the liquid to an atmospheric pressure in a storage tank, and that any emissions that occur are limited to

those commonly referred to within the industry as working, breathing, and standing losses.

XVII.A.15~~2~~. "Storage Tank" means any fixed roof storage vessel or series of storage vessels that are manifolded together via liquid line. Storage vessel is as defined in 40 CFR Part 60, Subpart OOOO. Storage tanks may be located at a well production facility or other location.

XVII.A.16~~3~~. "Unsafe to Monitor" means a component is unsafe to inspect because inspecting personnel would be exposed to an imminent or potential danger as a consequence of such monitoring.

XVII.A.17~~4~~. "Visible Emissions" means observations of smoke and/or hydrocarbon vapors for any period or periods of duration greater than or equal to one (1) minute in any fifteen (15) minute period during normal operation. Visible emissions do not include radiant energy ~~or water vapor~~.

XVII.A.18~~5~~. "Well Production Facility" means all equipment at a single stationary source directly associated with one or more oil wells or gas wells. This equipment includes, but is not limited to, equipment used for storage, separation, treating, dehydration, artificial lift, combustion, compression, pumping, metering, monitoring, and flowline.

XVII.B. (State Only) General Provisions

XVII.B.1. General requirements for prevention of emissions and good air pollution control practices for all oil and gas exploration and production operations, well production facilities, natural gas compressor stations, and natural gas processing plants.

XVII.B.1.a. All intermediate hydrocarbon liquids collection, storage, processing, and handling operations, regardless of size, shall be designed, operated, and maintained so as to minimize leakage of volatile organic compounds to the atmosphere to the extent reasonably practicable.

XVII.B.1.b. At all times, including periods of start-up and shutdown, the facility and air pollution control equipment shall be maintained and operated in a manner consistent with ~~good air pollution control~~best management practices for minimizing emissions. Determination of whether or not acceptable operating and maintenance procedures are being used will be based on information available to the Division, which may include, but is not limited to, monitoring results, opacity observations, review of operating and maintenance procedures, and inspection of the source.

XVII.B.2. General requirements for air pollution control equipment, flares, and combustion devices used to comply with Section XVII.

XVII.B.2.a. All air pollution control equipment shall be operated and maintained pursuant to the manufacturing specifications or equivalent. ~~to the extent practicable,~~ and consistent with technological limitations and ~~good~~ best engineering and maintenance practices. The owner or operator shall keep manufacturer specifications or equivalent on file. In addition, all such air pollution control equipment shall be adequately designed and sized to achieve the control efficiency rates and to handle reasonably foreseeable fluctuations in emissions of volatile organic compounds and hydrocarbons during normal operations.

Fluctuations in emissions that occur when the separator dumps into the tank are reasonably foreseeable.

XVII.B.2.b. If a flare or other combustion device is used to control emissions of hydrocarbons, it shall be enclosed, have no visible emissions during normal operations, and be designed so that an observer can, by means of visual observation from the outside of the enclosed flare or combustion device, or by other means approved by the Division, determine whether it is operating properly.

XVII.B.2.c. Any of the effective dates for installation of controls on storage tanks, dehydrators, and/or internal combustion engines may be extended at the Division's discretion for good cause shown.

XVII.B.2.d. Auto-igniters: All combustion devices used to control emissions of hydrocarbons shall be equipped with and operate an auto-igniter as follows:

XVII.B.2.d.(i) All combustion devices installed on or after May 1, 2014, will be equipped with an operational auto-igniter upon installation of the combustion device.

XVII.B.2.d.(ii) All combustion devices installed before May 1, 2014, will be equipped with an operational auto-igniter by or before May 1, 2016, or after the next combustion device planned shutdown, whichever comes first.

XVII.B.2.e. Alternative emissions control equipment shall qualify as air pollution control equipment, and may be used in lieu of, or in combination with, combustion devices and vapor recovery units to achieve the emission reductions required by this Section XVII, if the Division approves the equipment, device or process. As part of the approval process the Division, at its discretion, may specify a different control efficiency than the control efficiencies required by this Section XVII.

XVII.B.3. Oil refineries are not subject to Section XVII.

XVII.B.4. Glycol natural gas dehydrators and internal combustion engines that are subject to an emissions control requirement in a federal maximum achievable control technology ("MACT") standard under 40 CFR Part 63, a Best Available Control Technology ("BACT") limit, or a New Source Performance Standard ("NSPS") under 40 CFR Part 60 are not subject to this Section XVII.

XVII.C. (State Only) Emission reduction from storage tanks at oil and gas exploration and production operations, well production facilities, natural gas compressor stations, and natural gas processing plants.

XVII.C.1. Control requirements for storage tanks

XVII.C.1.a. Beginning May 1, 2008, owners or operators of all storage tanks storing condensate with uncontrolled actual emissions of volatile organic compounds equal to or greater than twenty (20) tons per year based on a rolling twelve-month total must operate air pollution control equipment that has an average control efficiency of at least 95% for VOCs.

XVII.C.1.b. Owners or operators of all storage tanks with uncontrolled actual emissions of volatile organic compounds, based on a rolling twelve-month total, equal to or greater than six (6) tons per year, ~~based on a rolling twelve-month total~~ or two (2) tons per year if the storage tanks is located within 1,320 feet of a building unit or designated outside activity area, must operate air pollution control equipment that achieves an average hydrocarbon control efficiency of no less than 95%. If a combustion device is used, it shall have a design destruction efficiency of at least 98% for hydrocarbons.

XVII.C.1.b.(i) A storage tank constructed on or after May 1, 2014, must be in compliance by the date that the storage tank commences operation.

XVII.C.1.b.(ii) A storage tank constructed before May 1, 2014, must be in compliance by May 1, 2015.

XVII.C.1.b.(iii) A storage tank not otherwise subject to Sections XVII.C.1.b.(i) or XVII.C.1.b.(ii), above, that increases uncontrolled actual emissions to six (6) tons VOC or more per year on a rolling twelve month basis after May 1, 2014, or two tons VOC or more per year if located within 1,320 feet of a building unit or designated outside activity area, must be in compliance within sixty days of discovery of the emissions increase.

XVII.C.1.c. Control requirements within 90 days of the date of first production.

XVII.C.1.c.(i) Beginning May 1, 2014, owners or operators of storage tanks at well production facilities shall collect and control emissions by routing emissions to operating air pollution control equipment during the first 90 calendar days after the date of first production. The air pollution control equipment shall achieve an average hydrocarbon control efficiency of 95%. If a combustion device is used, it shall have a design destruction efficiency of at least 98% for hydrocarbons. Except that this requirement does not apply to storage tanks that are projected to have emissions less than 1.5 tons of VOC during the first 90 days after the date of first production, or 0.5 tons of VOC emissions during the first 90 days after the date of first production if located 1,320 feet from a building unit or designated outdoor activity area.

XVII.C.1.c.(ii) The air pollution control equipment and any associated monitoring equipment required pursuant to Section XVII.C.1.c., above, may be removed at any time after the first 90 calendar days as long as the source can demonstrate that uncontrolled actual emissions from the storage tank are below the thresholds in Section XVII.C.1.b., above.

XVII.C.2. Capture requirements for storage tanks that are fitted with air pollution control equipment as required by Sections XII.D. or XVII.C.1.

XVII.C.2.a. Beginning on the applicable compliance date specified in Section XVII.C.1.b., owners and operators of storage tanks shall route all hydrocarbon emissions to air pollution control equipment, and shall operate without venting hydrocarbon emissions from the thief hatch (or other access point to the tank) or pressure relief device during normal operation unless venting is reasonably required for maintenance, gauging, or safety of personnel and equipment.

XVII.C.2.b. Beginning on the applicable compliance date specified in section XVII.C.1.b., owners and operators of storage tanks shall develop, certify, and

implement a document Storage Tank Emission Management System (STEM) plan to identify appropriate strategies to minimize emissions from venting at thief hatches (or other access points to a storage tank) and pressure relief devices during normal operation. As part of STEM, owners and operators shall evaluate and employ appropriate control technologies, monitoring practices, operational practices, and/or other strategies designed to meet the requirements set forth in Section XVII.C.2.a., above, and will update the STEM plan as necessary to achieve or maintain compliance. Owners and operators are not required to develop and implement STEM for storage tanks containing only stabilized liquids. The minimum elements of STEM are listed below.

XVII.C.2.b.(i) STEM must include a monitoring strategy that incorporates the minimum monitoring frequency set forth in Section XVII.F.5.e., procedures for evaluating ongoing storage tank emission capture performance, and, if applicable, the selected strategies.

XVII.C.2.b.(ii) STEM must include a certification by the owner or operator that the selected STEM strategy or strategies are designed to minimize emissions from storage tanks and associated equipment components at the facility or facilities, including thief hatches and pressure relief devices.

XVII.C.3. Monitoring: The monitoring strategy of each STEM plan must include monitoring in accordance with Approved Instrument Based Monitoring Methods, as specified in Section XVII.F.5.

XVII.C.3.a. In addition to any applicable Approved Instrument Based Monitoring Methods, audio, visual, olfactory ("AVO") inspection of the storage tank and any associated equipment (i.e. separator, air pollution control equipment, or other pressure reducing equipment), must be completed as often as liquids are loaded out from the storage tank. However, AVO inspection is required no more frequently than every seven (7) days or less frequently than every thirty (30) days. AVO monitoring is not required for components and tanks that are unsafe to monitor. AVO inspection must include, at a minimum:

XVII.C.3.a.(i) Visual inspection of any thief hatch, pressure relief valve, or other access point to ensure that they are enclosed and properly sealed;

XVII.C.3.a.(ii) Visual inspection or monitoring of the air pollution control equipment to ensure that it is operating, including that the pilot light is lit on combustion devices used as air pollution control equipment;

XVII.C.3.a.(iii) If a flare or other combustion device is used, visual inspection of the auto-igniter and valves for piping of gas to the pilot light, to ensure they are functioning properly;

XVII.C.3.a.(iv) Visual inspection of the air pollution control equipment to ensure that the valves for the piping from the storage tank to the air pollution control equipment are open; and

XVII.C.3.a.(v) If a flare or other combustion device is used, inspection of the device for the presence ~~of~~ or absence of smoke or vapors. If smoke or vapors are ~~is~~ observed, either the equipment will be immediately shut-in to investigate that potential cause for smoke and perform repairs, as necessary, or Method 22 shall be conducted to determine whether visible

emissions are present for a period of at least one (1) minute in fifteen (15) minutes.

XVII.C.4. Recordkeeping: The owner or operator of each storage tank subject to XII.D. or XVII.C. must maintain records of STEM as applicable, including the plan, any updates, and the certification, to be made available to the Division upon request. In addition, for a period of two years, the owner or operator must maintain records of any required monitoring and make them available to the Division upon request, including:

XVII.C.4.a. The AIRS ID for the storage tank.

XVII.C.4.b. The date and duration of any period where the thief hatch, pressure relief device, or other access point are found to be venting hydrocarbon emissions.

XVII.C.4.c. The date and duration of any period where the air pollution control equipment is not operating.

XVII.C.4.d. Where a flare or other combustion device is being used, the date and result of any Method 22 test.

XVII.C.4.e. The timing of and efforts made to eliminate venting, restore operation of air pollution control equipment, and mitigate visible emissions.

XVII.D. (State Only) Emission reductions from glycol natural gas dehydrators

XVII.D.1. Beginning May 1, 2008, still vents and vents from any flash separator or flash tank on a glycol natural gas dehydrator located at an oil and gas exploration and production operation, natural gas compressor station, drip station or gas-processing plant subject to control requirements pursuant to Section XVII.D.2., shall reduce uncontrolled actual emissions of volatile organic compounds by at least 90 percent through the use of a condenser or air pollution control equipment.

XVII.D.2. The control requirement in Section XVII.D.1. shall apply where:

XVII.D.2.a. Actual uncontrolled emissions of volatile organic compounds from the glycol natural gas dehydrator are equal to or greater than two tons per year; and

XVII.D.2.b. The sum of actual uncontrolled emissions of volatile organic compounds from any single glycol natural gas dehydrator or grouping of glycol natural gas dehydrators at a single stationary source is equal to or greater than 15 tons per year. To determine if a grouping of dehydrators meets or exceeds the 15 tons per year threshold, sum the total actual uncontrolled emissions of volatile organic compounds from all individual dehydrators at the stationary source, including those with emissions less than two tons per year.

XVII.D.3. Beginning May 1, 2015, still vents and vents from any flash separator or flash tank on a glycol natural gas dehydrator located at an oil and gas exploration and production operation, natural gas compressor station, and drip station or gas-processing plant subject to control requirements pursuant to Section XVII.D.4., shall reduce uncontrolled actual emissions of hydrocarbons by at least 95 percent on a rolling twelve-month basis through the use of a condenser or air pollution control equipment. If a combustion device is used, it shall have a design destruction efficiency of at least 98% for hydrocarbons.

XVII.D.4. The control requirement in Section XVII.D.3. shall apply where:

XVII.D.4.a. Actual uncontrolled emissions of volatile organic compounds from a single new glycol natural gas dehydrator are equal to or greater than two (2) tons per year; or

XVII.D.4.b. Actual uncontrolled emissions of volatile organic compounds from a single existing glycol natural gas dehydrator are equal to or greater than six (6) tons per year, or two (2) tons per year if the glycol natural gas dehydrator is located within 1,320 feet of a building unit or designated outside activity area.

~~XVII.D.4.c. For purposes of Section XVII.D.4.:~~

~~XVII.D.4.c.(i) Building Unit shall mean a residential building unit, and every five thousand (5,000) square feet of building floor area in commercial facilities or every fifteen thousand (15,000) square feet of building floor area in warehouses that are operating and normally occupied during working hours.~~

~~XVII.D.4.c.(ii) A designated outside activity area shall mean an outdoor venue or recreation area, such as a playground, permanent sports field, amphitheater, or other similar place of public assembly owned or operated by a local government, which the local government seeks to have established as a Designated Outside Activity Area; or an outdoor venue or recreation area where ingress to or egress from could be impeded in the event of an emergency condition at an oil and gas location less than three hundred and fifty (350) feet from the venue due to the configuration of the venue and the number of persons known or expected to simultaneously occupy the venue on a regular basis.~~

XVII.E. Control of emissions from new, modified, existing, and relocated natural gas fired reciprocating internal combustion engines.

XVII.E.1. (State Only) The requirements of this Section XVII.E. shall not apply to any engine having actual uncontrolled emissions below permitting thresholds listed in Regulation Number 3, Part B.

XVII.E.2. (State Only) New, Modified and Relocated Natural Gas Fired Reciprocating Internal Combustion Engines

XVII.E.2.a. Except as provided in Section XVII.E.2.b. below, the owner or operator on any natural gas fired reciprocating internal combustion engine that is either constructed in or relocated to the state of Colorado from another state, on or after the date listed in the table below shall operate and maintain each engine according to the manufacturer's written instructions or procedures to the extent practicable and consistent with technological limitations and good engineering and maintenance practices over the entire life of the engine so that it achieves the emission standards required in Section XVII.E.2.b. Table 1 below.

XVII.E.2.b. Actual emissions from natural gas fired reciprocating internal combustion engines shall not exceed the emission performance standards in Table 1 below as expressed in units of grams per horsepower-hour (G/hp-hr)

TABLE 1

Maximum Engine Hp	Construction or Relocation Date	Emission Standards is G/hp-hr		
		NOx	CO	VOC
< 100 Hp	Any	NA	NA	NA
≥100 Hp and < 500 Hp	On or after January 1, 2008	2.0	4.0	1.0
	On or after January 1, 2011	1.0	2.0	0.7
≥500 Hp	On or after July 1, 2007	2.0	4.0	1.0
	On or after July 1, 2010	1.0	2.0	0.7

XVII.E.3. Existing Natural Gas Fired Reciprocating Internal Combustion Engines

XVII.E.3.a. (Regional Haze SIP) Rich Burn Reciprocating Internal Combustion Engines

XVII.E.3.a.(i) Except as provided in Sections XVII.3.1.(i)(b) and (c) and XVII.E.3.a.(ii), all rich burn reciprocating internal combustion engines with a manufacturer's name plate design rate greater than 500 horsepower, constructed or modified before February 1, 2009 shall install and operate both a non-selective catalytic reduction system and an air fuel controller by July 1, 2010. A rich burn reciprocating internal combustion engine is one with a normal exhaust oxygen concentration of less than 2% by volume.

XVII.E.3.a.(i)(a) All control equipment required by this Section XVII.E.3.a. shall be operated and maintained pursuant to manufacturer specifications or equivalent to the extent practicable, and consistent with technological limitations and best~~good~~ engineering and maintenance practices. The owner or operator shall keep manufacturer specifications or equivalent on file.

XVII.E.3.a.(i)(b) Internal combustion engines that are subject to an emissions control requirement in a federal maximum achievable control technology ("MACT") standard under 40 CFR Part 63, a Best Available Control Technology ("BACT") limit, or a New Source Performance Standard under 40 CFR Part 60 are not subject to this Section XVII.E.3.a.

XVII.E.3.a.(i)(c) The requirements of this Section XVII.E.3.a. shall not apply to any engine having actual uncontrolled emissions below permitting thresholds listed in Regulation Number 3, Part B.

XVII.E.3.a.(ii) Any rich burn reciprocating internal combustion engine constructed or modified before February 1, 2009, for which the owner or operator demonstrates to the Division that retrofit technology cannot be installed at a cost of less than $ 5,000 per ton of combined volatile

organic compound and nitrogen oxides emission reductions (this value shall be adjusted for future applications according to the current day consumer price index) is exempt complying with Section XVII.E.3.a. Installation costs and the best information available for determining control efficiency shall be considered in determining such costs. In order to qualify for such exemption, the owner or operator must submit an application making such a demonstration, together with all supporting documents, to the Division by August 1,2009.

XVII.E.3.b. (State Only) Lean Burn Reciprocating Internal Combustion Engines

XVII.E.3.b.(i) Except as provided in Section XVII.E.3.b.(ii), all lean burn reciprocating internal combustion engines with a manufacturer's nameplate design rate greater than 500 horsepower shall install and operate an oxidation catalyst by July 1, 2010. A lean burn reciprocating internal combustion engine is one with a normal exhaust oxygen concentration of 2% by volume, or greater.

XVII.E.3.b.(ii) Any lean burn reciprocating internal combustion engine constructed or modified before February 1, 2009, for which the owner or operator demonstrates to the Division that retrofit technology cannot be installed at a cost of less than $ 5,000 per ton of volatile organic compound emission reduction (this value shall be adjusted for future applications according to the current day consumer price index) is exempt complying with Section XVII.E.3.b.(i). Installation costs and the best information available for determining control efficiency shall be considered in determining such costs. In order to qualify for such exemption, the owner or operator must submit an application making such a demonstration, together with all supporting documents, to the Division by August 1, 2009.

XVII.F. (State Only) Leak detection and repair program for well production facilities, storage tanks, and compressor stations

XVII.F.1. Beginning January 1, 2015, owners and operators of well production facilities and compressor stations will identify and repair leaks from components at these facilities in accordance with the requirements of this Section XVII.F. The following shall apply in lieu of any directed inspection and maintenance program requirements established pursuant to Regulation Number 3, Part B, Section III.D.2.

XVII.F.2. Owners and operators of well production facilities or natural gas compressor stations that monitor components as part of this Section XVII.F. may opt to estimate emissions from components for the purpose of evaluating the applicability of component fugitive emissions to Regulation Number 3 by utilizing the emission factors defined as less than 10,000 ppmv of Table 2-8 of the 1995 EPA Protocol for Equipment Leak Emission Estimates (Document EPA-453/R-95-017).

XVII.F.3. Owners and operators of well production facilities or natural gas compressor stations shall utilize the Approved Instrument Based Monitoring Method and AVO program as outlined in Section XVII.F. AVO monitoring is not required of components and tanks that are unsafe to monitor or inaccessible to monitor, pursuant to XVII.F.5.g.

XVII.F.4. Inspection schedules for natural gas compressor stations: Beginning January 1, 2015, owners and operators of natural gas compressor stations shall inspect components for leaks using an Approved Instrument Based Monitoring Method, in accordance with the following Table 2, except for components subject to XVII.F.5.g. For purposes of this

Section XVII.F.4., fugitive emissions shall be calculated using the emission factors of Table 2-4 of the 1995 EPA Protocol for Equipment Leak Emission Estimates (Document EPA-453/R-95-017), of other Division approved method.

Table 2	
Fugitive VOC Emissions (tpy)	Inspection Frequency
>0 and ≤ 12	Annually
> 12 and ≤ 50	Quarterly
> 50	Monthly

XVII.F.5. Requirements for well production facilities and/or storage tanks

XVII.F.5.a. Beginning August 1, 2014, all new well production facilities shall have a documented pressure test performed on all equipment and piping prior to start up. Documentation of this 90 day testing and monitoring shall be provided in the first annual report to the Division, as required by Section XVII.F.9.

XVII.F.5.b. Beginning January 1, 2015, within 90 days of startup of all new well production facilities and/or storage tanks, owners and/or operators shall identify and repair leaks from components using an Approved Instrument Based Monitoring Method. Such action shall qualify as an inspection pursuant to the inspection frequency schedule in Table 3.

XVII.F.5.c. Consistent with the provisions of XVII.F.5.f., owners and operators of existing well production facilities and/or storage tanks shall identify and repair leaks using an Approved Instrument Based Monitoring Method, in accordance with the implementation schedule in XVII.F.5.e. Inspection frequency shall be determined according to Table 3.

XVII.F.5.d. Consistent with the provisions of XVII.F.5.f., owners and operators of new well production facilities and/or storage tanks shall identify and repair leaks from components using an Approved Instrument Based Monitoring Method beginning on January 1, 2015. Inspection frequency shall be determined according to Table 3.

XVII.F.5.e. The estimated uncontrolled actual emissions from storage tanks determine the frequency at which inspections must be performed. If no storage tanks are located at the well production facility or multi-well site, operators will rely on the potential to emit of VOC for all of the emissions sources, including emissions from components located at the facility. All components at a well production facility or storage tank must be inspected:

Table 3		
Threshold (per XVII.F.5.e.) VOC	Threshold within 1,320 feet of a building	Inspection Frequency

Emissions (tpy, uncontrolled actual for sites with tanks or PTE for sites without tanks)	unit or designated outside activity area (per XVII.F.5.e.) VOC Emissions (tpy, uncontrolled actual for sites with tanks or PTE for sites without tanks)	
> 0 and ≤ 6		One time using Approved Instrument Based Monitoring Method and thereafter using monthly AVO
> 6 and ≤ 12	> 0 and < 6	Annually with monthly AVO
> 12 and ≤ 50	> 6 and < 12	Quarterly with monthly AVO
> 50	> 12	Monthly
Multi-well sites without storage tanks after April 15, 2014, that have a PTE > 20 tpy VOC	Multi-well sites without storage tanks after April 15, 2014, that have a PTE > 12 tpy VOC	Monthly

XVII.F.5.f. Phase-in of Approved Instrument Based Monitoring Methods: Owners and operators of existing well production facilities and/or storage tanks shall identify and repair leaks from components using an Approved Instrument Based Monitoring Method, in accordance with the following schedule:

XVII.F.5.f.(i) Beginning January 1, 2015, facilities with uncontrolled actual VOC emissions greater than 50 tpy or multi-well sites.

XVII.F.5.f.(ii) Beginning July 1, 2015, facilities with uncontrolled actual VOC emissions greater than 20 tpy but less than or equal to 50 tpy.

XVII.F.5.f.(iii) Beginning January 1, 2016, facilities with uncontrolled actual VOC emissions greater than 6 tpy but less than or equal to 20 tpy.

XVII.F.5.g.(iv) By July 1, 2016, facilities with uncontrolled actual VOC emissions less than or equal to 6 tpy.

XVII.F.5.g. If a component is difficult, unsafe, or inaccessible to monitor, the owner or operator shall not be required to monitor the component until it becomes feasible to do so.

XVII.F.5.g.(i) Difficult to monitor components are those that cannot be monitored without elevating the monitoring personnel more than two meters above a supported surface or are unable to be reached via a wheeled scissor-lift or hydraulic type scaffold that allows access to components up to 7.6 meters (25 feet) above the ground.

XVII.F.5.g.(ii) Unsafe to monitor components are those that cannot be monitored without exposing monitoring personnel to an immediate danger as a consequence of completing the monitoring.

XVII.F.5.g.(iii) Inaccessible to monitor components are those that are buried, insulated in a manner that prevents access to the components by a

monitor probe, or obstructed by equipment or piping that prevents access to the components by a monitor probe.

XVII.F.6 Leak detection requiring repair: Leaks shall be identified utilizing the methods listed in this Section XVII.F.6.a. through XVII.F.6.d. Only leaks detected pursuant to this Section XVIII.F.6. shall require repair under Section XVII.F.

XVII.F.6.a. For Method 21 monitoring at existing facilities, a leak is any concentration of hydrocarbon above 2,000 parts per million (ppm), except for existing well production facilities where leak is defined as any concentration of hydrocarbon above 500 ppm.

XVII.F.6.b. For Method 21 monitoring at facilities constructed after May 1, 2014, a leak is any concentration of hydrocarbon above 500 ppm.

XVII.F.6.c. For infra-red camera and AVO monitoring, a leak is any detectable emissions not associated with normal equipment operation, such as pneumatic device actuation and crank case ventilation.

XVII.F.6.d. For other Division approved monitoring devices or methods, leak identification requiring repair will be established as set forth in the Division's approval.

XVII.F.7. Repair and remonitoring

XVII.F.7.a. Except as provided in Section XVII.F.7.b. below, the f~~F~~irst attempt to repair a leak shall be made no later than five (5) working days after discovery, unless parts are unavailable, the equipment requires shutdown to complete repair, or other good cause exists. If parts are unavailable, they shall be ordered promptly and the repair shall be made within fifteen (15) working days of receipt of the parts. If shutdown is required, the leak shall be repaired during the next scheduled shutdown. If delay is attributable to other good cause, repairs shall be completed within fifteen (15) working days after the cause of delay ceases to exist.

XVII.F.7.b. Repairs to major gas leaks that are discovered within 1,320 feet of a building unit or designated outside activity area shall be made no later than 24 hours after discovery. If a repair is not possible with 24 hours, the well shall be shut down until a repair can be made. If shutting down the well will not stop the leak, demonstrable efforts should be made to minimize the leak within the first 24 hours.

XVII.F.7.c~~b~~. Within fifteen (15) working days of completion of a repair, the leaks shall be remonitored to verify the repair was effective.

XVII.F.7.d~~c~~. Leaks discovered pursuant to the leak detection methods of Section XVII.F. shall not be subject to enforcement by the Division unless the owner or operator fails to perform the required repairs in accordance with Section XVII.F.7.

XVII.F.7.e~~d~~. For leaks identified using an Approved Instrument Based Monitoring Method, owners and operators have the option of either repairing the leak in accordance with the repair schedule set forth in Section XVII.F.7. or conducting follow-up monitoring using Method 21 within five (5) working days of the leak detected. If the follow-up Method 21 monitoring shows that the leak concentration is less than or equal to 2,000 ppm hydrocarbon for existing

facilities (other than existing well production facilities), or 500 ppm for new facilities or existing well production facilities, then the emission shall not be considered a leak for purposes of this Section.

XVII.F.8. Recordkeeping: The owner or operator of each facility subject to the inspection and maintenance requirements in this Section XVII.F. shall maintain the following for a period of two (2) years and make them available to the Division upon request.

XVII.F.8.a. Documentation of the pre-start-up pressure tests for new well production facilities;

XVII.F.8.b. The date and site information for each inspection;

XVII.F.8.c. A list of the leaking components and the monitoring method used to determine the presence of the leak;

XVII.F.8.d. The date of first attempt to repair the leak and, if necessary, any additional attempt to repair the leak;

XVII.F.8.e. The date the leak was repaired;

XVII.F.8.f. The delayed repair list including the basis for placing leaks on the list;

XVII.F.8.g. The date the leak was remonitored to verify the effectiveness of the repair, and the results of the remonitoring; and

XVII.F.8.h. A list of identification numbers for components that are designated as unsafe or inaccessible to monitor, as described in Section XVII.F.5.g., an explanation for each component stating why the component is so designated, and the plan for monitoring such component(s).

XVII.F.9. Reporting: The owner or operator of each facility subject to the inspection and maintenance requirements in Section XVII.F. shall submit a single annual report on or before April 30th of each year summarizing inspection and maintenance activities at all of their subject facilities during the previous calendar year. Reports will be made publicly available on the APCD Website and searchable by API well number, APEN permit number, operator, date, and geographic area. In addition to this information, ~~This~~ the report shall also contain ~~at a minimum~~ the following information:

XVII.F.9.a. The number of facilities inspected;

XVII.F.9.b. The total number of inspections;

XVII.F.9.c. The total number of leaks identified, broken out by component type;

XVII.F.9.d. The total number of leaks repaired;

XVII.F.9.e. Each major gas leak discovered and how quickly it was repaired;

XVII.F.9.f~~e~~. The number of leaks on the delayed repair list as of December 31st; and

XVII.F.9.g~~f~~. Each report shall be accompanied by a self-certification form. The form shall contain a certification by a responsible official of the truth, accuracy, and completeness of such form, report, or certification stating that, based on

information and belief formed after reasonable inquiry, the statements and information in the document are true, accurate, and complete.

XVII.G. (State Only) Control of emissions from well production facilities

XVII.G.1. Well Operation and Maintenance: On or after August 1, 2014, during normal operation gas coming off a separator produced from any newly constructed, hydraulically fractured, or recompleted oil and gas well must either be routed to a gas gathering line or controlled by air pollution control equipment that achieves an average hydrocarbon control efficiency of 95% from the date of first production. If a combustion device is used, it shall have a design destruction efficiency of at least 98% of hydrocarbons.

XVII.H. (State Only) Venting during downhole well maintenance and unloading events

XVII.H.1. Well Maintenance: Beginning May 1, 2014, hydrocarbon emissions from flowing wells must be captured or controlled during downhole well maintenance or servicing activities, unless venting is necessary for safety.

XVII.H.1.a. Operators shall use best management practices to minimize the need for well venting associated with downhole well maintenance and liquids unloading. During liquids unloading events, any means of creating differential pressure will first be used to attempt to unload the liquids from the well without venting. If these methods are not successful in unloading the liquids from the well, the well may be vented to the atmosphere to create the necessary differential pressure to bring the liquids to the surface.

XVII.H.1.b. Venting will be minimized to the extent possible, using best management practices during the well maintenance and liquids unloading events in XVII.H.1.a. The owner and/or operator shall be present on-site during any planned well maintenance and liquids unloading event in XVII.H.1.a. and shall ensure that any venting to the atmosphere is limited to the maximum extent practicable.

XVII.H.1.c. Records of the cause, date, time, and duration of venting events under this Section XVII.H. will be kept and made available to the Division upon request.

XVIII. (State Only) Natural Gas-Actuated Pneumatic Controllers Associated with Oil and Gas Operations

XVIII.A. Applicability

This section applies to pneumatic controllers that are actuated by natural gas, and located at, or upstream of natural gas processing plants (upstream activities include: oil and gas exploration and production operations, natural gas compressor stations, and/or natural gas drip stations).

XVIII.B. Definitions

XVIII.B.1. “Affected Operations” shall mean pneumatic controllers that are actuated by natural gas, and located at, or upstream of natural gas processing plants (upstream activities include: oil and gas exploration and production operations, natural gas compressor stations, and/or natural gas drip stations).

XVIII.B.2. “Enhanced Maintenance” is specific to high-bleed devices and shall include but is not limited to cleaning, tuning, and repairing leaking gaskets, tubing fittings, and seals; tuning to operate over a broader range of proportional band; and eliminating unnecessary valve positioners.

XVIII.B.3. “High-Bleed Pneumatic Controller” shall mean a pneumatic controller that is designed to have a constant bleed rate that emits in excess of 6 standard cubic feet per hour (scfh) of natural gas to the atmosphere.

XVIII.B.4. “Low-Bleed Pneumatic controller” shall mean a pneumatic controller that is designed to have a constant bleed rate that emits less than or equal to 6 scfh of natural gas to the atmosphere.

XVIII.B.5. “Natural Gas Processing Plant” shall mean any processing site engaged in the extraction of natural gas liquids from field gas, fractionation of mixed natural gas liquids to natural gas products, or both.

XVIII.B.6. “No-bleed Pneumatic Controller” shall mean any pneumatic controller that is not using hydrocarbon gas as the valve’s actuating gas.

XVIII.B.7. “Pneumatic Controller” shall mean an instrument that is actuated using natural gas pressure and used to control or monitor process parameters such as liquid level, gas level, pressure, valve position, liquid flow, gas flow and temperature.

XVIII.C. Emission Reduction Requirements

The owners and operators of affected operations shall reduce emissions of volatile organic compounds from pneumatic controllers associated with affected operations as follows:

XVIII.C.1. In the 8-Hour Ozone Control Area:

XVIII.C.1.a. All pneumatic controllers placed in service on or after February 1, 2009, shall emit VOCs in an amount equal to or less than a low-bleed pneumatic controller, unless allowed pursuant to Section XVIII.C.1.c.

XVIII.C.1.b. All high-bleed pneumatic controllers in service prior to February 1, 2009 shall be replaced or retrofit such that VOC emissions are reduced to an amount equal to or less than a low-bleed pneumatic controller, by May 1, 2009, unless allowed pursuant to Section XVIII.C.1.c.

XVIII.C.1.c. All high-bleed pneumatic controllers that must remain in service due to safety and/or process purposes must have Division approval and comply with Sections XVIII.D. and XVIII.E.

XVIII.C.1.c.(i) For high-bleed pneumatic controllers in service prior to February 1, 2009, the owner/operator shall submit justification for high-bleed pneumatic controllers to remain in service due to safety and /or process purposes by March 1, 2009. The Division shall be deemed to have approved the justification if it does not object to the owner/operator within 30-days upon receipt.

XVIII.C.1.c.(ii) For high-bleed pneumatic controllers placed in service on or after February 1, 2009, the owner/operator shall submit justification for high-bleed pneumatic controllers to be installed due to safety and /or process purposes prior to installation. The Division shall be deemed to have approved the justification if it does not object to the owner/operator within 30-days upon receipt.

XVIII.C.2. Statewide:

XVIII.C.2.a. All pneumatic controllers placed in service on or after May 1, 2014, shall:

XVIII.C.2.c.(i) Emit VOCs in an amount equal to or less than a low-bleed pneumatic controller, unless allowed pursuant to Section XVIII.C.2.c.; or

XVIII.C.2.c.(ii) Utilize no-bleed pneumatic controllers where on-site electrical grid power is being used and is technically and economically feasible.

XVIII.C.2.b. All high-bleed pneumatic controllers in service prior to May 1, 2014, shall be replaced or retrofitted by May 1, 2015, such that VOC emissions are reduced to an amount equal to or less than a low-bleed pneumatic controller, unless allowed pursuant to Section XVIII.C.2.c.

XVIII.C.2.c. All high-bleed controllers that must remain in service due to safety and/or process purposes must have Division approval and comply with Sections XVIII.D. and XVIII.E.

XVIII.C.2.c.(i) All high-bleed pneumatic controllers in service prior to May 1, 2014, the owner/operator shall submit justification for high-bleed pneumatic controllers to remain in service due to safety and/or process purposes by March 1, 2015. The Division shall be deemed to have approved the justification if it does not object to the owner/operator within 30-days upon receipt.

XVIII.C.2.c.(ii) For high-bleed pneumatic controllers placed in service on or after May 1, 2014, the owner/operator shall submit justification for high-bleed pneumatic controllers to be installed due to safety and/or process purposes prior to installation. The Division shall be deemed to have approved the justification if it does not object to the owner/operator within 30-days upon receipt.

XVIII.D. Monitoring

This section applies only to high-bleed pneumatic controllers identified in Sections XVIII.C.1.c. and XVIII.C.2.c.

XVIII.D.1. In the 8-Hour Ozone Control Area

XVIII.D.1.a. Effective May 1, 2009, each high-bleed pneumatic controller shall be physically tagged by the owner/operator identifying it with a unique high-bleed pneumatic controller number that is assigned and maintained by the owner/operator.

XVIII.D.1.b. Effective May 1, 2009, each high-bleed pneumatic controller shall be inspected on a monthly basis, perform necessary enhanced maintenance as defined in Section XVIII.B.2 , and maintain the device according to manufacturer specifications to ensure that the controller's VOC emissions are minimized.

XVIII.D.2. Statewide:

XVIII.D.2.a. Effective May 1, 2015, each high-bleed pneumatic controller shall be physically tagged by the owner/operator identifying it with a unique high-bleed pneumatic controller number that is assigned and maintained by the owner/operator.

XVIII.D.2.b. Effective May 1, 2015, each high-bleed pneumatic controller shall be inspected on a monthly basis, perform necessary enhanced maintenance as defined in Section XVIII.B.2 , and maintain the device according to manufacturer specifications to ensure that the controller's VOC emissions are minimized.

XVIII.E. Recordkeeping

This section applies only to high-bleed pneumatic controllers identified in Sections XVIII.C.1.c. and XVIII.C.2.c.

XVIII.E.1. The owner or operator of affected operations shall maintain a log of the total number of high-bleed pneumatic controllers and their associated controller numbers per facility, the total number of high-bleed pneumatic controllers per company and the associated justification that the high-bleed pneumatic controllers must be used pursuant to Sections XVIII.C.1.c. and XVIII.C.2.c. The log shall be updated on a monthly basis.

XVIII.E.2. The owner or operator shall maintain a log of enhanced maintenance which shall include, at a minimum, inspection dates, the date of the maintenance activity, high-bleed pneumatic controller number, description of the maintenance performed, results and date of any corrective action taken, and the printed name and signature of the individual performing the maintenance. The log shall be updated on a monthly basis.

XVIII.E.3. Records of enhanced maintenance of pneumatic controllers shall be maintained for a minimum of three years and readily made available to the Division upon request.

>>>>>>>>

XIX. Statements of Basis, Specific Statutory Authority and Purpose

The Local Community Organizations adopt the Statement of Basis and Purpose proposed by the APCD.

EXHIBIT I.

LOCAL COMMUNITY ORGANIZATIONS' FINAL ECONOMIC IMPACT ANALYSIS PER § 25-7-110.5(4), C.R.S.

For proposed revisions to
Colorado Air Quality Control Commission
Regulation Number 7 (5 CCR 1001-9)

I. INTRODUCTION

This final economic impact analysis will cover only the changes the Local Community Organizations have made to the Air Quality Control Division's (APCD) proposal. The Local Community Organizations appreciate the assistance from the APCD in the creation of this final economic impact analysis.

II. OVERVIEW OF PROPOSED REGULATORY CHANGES

The Local Community Organizations are proposing revisions to the APCD's proposed AQCC Regulation Number 7. This Regulation Number 7 rulemaking package adopts nearly all of the changes proposed by the Colorado Air Pollution Control Division but amends specific sections to accomplish the following:

1) Reduce nearby residents' exposure to air toxics by requiring operators of facilities within 1,320 feet of a building unit or outdoor activity area to

    a. control VOCs down to 2 TPY,
    b. conduct more frequent inspections, and
    c. repair "major leaks" within 24 hours.

2) Increase transparency by requiring annual inspection reports to be posted online and accessible by the public.

III. COST/BENEFIT ANALYSIS:

A. Control Requirements for Petroleum Storage Tanks

The Local Community Organizations have proposed changes to require that tanks within 1,320 feet (1/4 mile) of a building unit or designated outdoor activity area must utilize air pollution control equipment if the tanks have uncontrolled actual emissions of equal or greater than two (2) tons per year.

The proposed APCD regulations would require operators with tanks that have uncontrolled emissions of at least **six (6) tons** per year to use emission control devices capable of achieving 95% control efficiency of volatile organic compounds (VOCs). Currently, the Colorado Oil and Gas Conservation Commission (COGCC) requires all tanks with uncontrolled emissions of VOCs

of five (5) tons per year or greater that are located within 1,320 feet of a Building Unit, or a Designated Outside Activity Area to use an emission control device capable of achieving 95% control efficiency of VOCs. (COGCC Rule 805.b.(2)). Therefore, this change only will affect those tanks that emit from 2-5 tons of VOCs per year.

1. General Cost Estimates for Flares

Using the data obtained from the APCD Initial Economic Impact Analysis, we assume that the estimated annualized cost of a flare control device with auto-igniter is about $6,287.

2. Annualized Cost for Buffer Bottles

As reported in the Division's initial economic impact analysis, the annualized costs for buffer bottles is $3,024 per unit.

3. Lowering Statewide Condensate Tank Control Threshold (from 6(5) tpy to 2 tpy)

The Local Community Organization is proposing to lower the uncontrolled VOC emission control threshold from the state-proposed 6 tpy to 2 tpy on all tanks within 1,320 feet of a Building Unit, or a Designated Outside Activity Area.

As stated above, the COGCC currently requires tanks to control VOCs to five (5) tons per year within 1,320 feet of a home so the regulation only affects those tanks that emit two (2) to five (5) tpy.

Using numbers obtained from the APCD, there are 1,506 tanks that are emitting between 2-5 tpy VOCs.

Of this number, at least 2/3 of the tanks would not be located within 1,320 feet of a home or designated outdoor recreation area. The COGCC supplied data during the setback hearing that indicated that approximately 26% of new and expanded well sites were located within 1,000 feet of a building unit. (COGCC analysis is attached). Expanding the area from 1,000 to 1,320 feet we have allowed for the percentage of wells affected to climb to 1/3 or 33%. Therefore, 2/3 of the potential tanks affected will not be affected by this regulation and are listed in Table 1 as "cancelled tanks".

Using the assumption of 33% of tanks being within 1,230 feet of a building unit we get 497 tanks.

Table 1: Tank Battery Analysis

	2-3 TPY	3-4 TPY	4-5 TPY	5-6 TPY	Total Tanks 2-5 TPY	Total Tanks 2-6 TPY
Tanks	610	485	411	374	1,506	1,880
Cancelled Tanks	409	325	275	251	1,009	1,260
TOTAL AFFECTED TANKS (2-5 tpy)	201	160	136	123	497	620

The annual cost of installing 497 flare control devices is about $3,125,000 with an average cost effectiveness of about $1,884.5 per ton of VOCs reduced. See Table 2. VOC reduction in the 497 tanks that are within 1,320 feet of a building unit or designated outside activity area AND emit =>2 tpy of VOCS but less than 5 tpy of VOCs was calculated by summing the VOC emissions of ALL tanks that emit =>2 tpy but less than 5 tpy and then multiplying this sum by 0.33, assuming only 33% of all such tanks lie within 1,320 feet of a building unit or designated outside activity area. The emission data came from the APCD.

Table 2: Tanks over 6 tpy – Control Cost Estimates for Flare Control Devices (inc. buffer bottle)

Affected Tanks [count]	Each Flare + buffer bottle Annualized Cost	Total Annualized Costs	VOC Reduction [tons/year]	Control Costs [$/ton]
497	$9,310.8	$4,627,467.6	1,658	$2,791

B. Emission Capture Requirements for Controlled Petroleum Storage Tanks

In order to prevent leaks and ensure that oil and gas facilities closest to homes and schools are being properly maintained, the Local Community Organizations are proposing that tanks within 1,320 feet of a building unit or designated outdoor recreation area be subject to more frequent instrument based monitoring using Method 21, an IR camera or other Division approved monitoring device or method. As proposed by the APCD, the frequency of this instrument based monitoring will depend on the level of uncontrolled actual emissions from the tank.

Table 3: Proposed Tiering for Instrument Based Tank Inspections - ¼ mile of building units

Tank Uncontrolled Actual VOC Emissions	Number of Tanks Affected	Inspection Frequency	Additional Number of Inspections	Additional Inspection Costs
≥ 2 tpy to ≤ 6 tpy	497	Annually	497	$98,406
>6 tpy to ≤ 12 tpy	459	Quarterly	1,376	$272,448
>12 tpy to 50 tpy	962	Monthly	7,698	$1,524,204

In assessing the cost-effectiveness of the proposed requirements, the Local Community Organizations first calculated the number of tanks that would be affected (1/3 in each category of tanks) and then the additional inspections necessary. That is, going from annual inspection to quarterly inspections would require an additional three inspections, quarterly to monthly would require an additional eight inspections per tank. These figures were then multiplied by the state's estimate of $198 per inspection to come up with the figures in Table 3.

C. Leak Detection and Repair Requirements for Compressor Stations and Well Production Facilities

The Local Community Organizations have requested that major leaks of over 10,000 ppm within 1,320 feet of building units should be repaired within 24 hours. We do not believe there will be

any additional costs associated with this practice since the leaks would already have to be repaired within five days and most operators will make immediate repairs if major leaks are discovered for safety purposes and to conserve the oil and gas.

D. Require the APCD to Place Annual Inspection Reports on their Website

The Local Community Organizations have requested that the APCD assist in finalizing this economic impact analysis. They hope to receive that information as to the cost of this provision in the coming weeks. In the meantime, we would expect that the COGCC would be willing to post the annual inspection reports on its website. The cost to post on the COGCC website would be much less given the website is already set-up to allow the public to search by API well number.

IV. CONCLUSION

The Local Community Organizations estimate that their requested revisions to increase tank controls within 1,320 feet of building units will cost $4,627,467– reducing 1,658 tpy of VOCs at a cost of $2,791 tons/year. The total cost for the increased inspection schedules within 1,320 feet of homes is $1,895,058.

The cost to the APCD for design and maintenance of a website that will contain annual inspection reports is still to be determined.

LGC EXHIBIT A. ALTERNATIVE PROPOSED REGULATION

AMENDED REVISIONS BY THE LGC TO:

DEPARTMENT OF PUBLIC HEALTH AND ENVIRONMENT
Air Quality Control Commission

REGULATION NUMBER 7

CONTROL OF OZONE VIA OZONE PRECURSORS AND CONTROL OF HYDROCARBONS VIA OIL AND GAS EMISSIONS

(EMISSIONS OF VOLATILE ORGANIC COMPOUNDS AND NITROGEN OXIDES)

Field Code Changed

5 CCR 1001-9

>>>>>>>>

II. General Provisions

>>>>>>>>

II.B. Exemptions

Emissions of the organic compounds listed as having negligible photochemical reactivity in the common provisions definition of Negligibly Reactive Volatile Organic Compound are exempt from the provisions of this regulation.

(State Only) Notwithstanding the foregoing exemption, hydrocarbon emissions from oil and gas operations, including methane and ethane, are subject to this regulation as set forth in Sections XVII. and XVIII.

>>>>>>>>

XVII. (State Only, except Section XVII.E.3.a. which was submitted as part of the Regional Haze SIP) Statewide Controls for Oil and Gas Operations and Natural Gas-Fired Reciprocating Internal Combustion Engines

XVII.A. (State Only) Definitions

XVII.A.1 "Air Pollution Control Equipment," as used in this Section XVII, means a combustion device or vapor recovery unit. Air pollution control equipment also means alternative emissions control equipment and pollution prevention devices and processes intended to reduce uncontrolled actual emissions that comply with the requirements of Section XVII.B.2.e.

XVII.A.2. ”Approved Instrument Based Monitoring Method,” as used in this Section XVII. means an infra-red camera, Method 21, or other Division approved instrument based monitoring device or method. If an owner/operator elects to use a Division approved Continuous Emission Monitoring program, the Division may approve a streamlined inspection and reporting program for such operations. Any instrument based monitoring method approved by the Division under this definition must be at least as effective as Method 21 or an infra-red camera.

XVII.A.3. ”Auto-Igniter” means a device which will automatically attempt to relight the pilot flame in the combustion chamber of a control device in order to combust volatile organic compound emissions.

XVII.A.4. “Component” means each pump seal, compressor seal, flange, pressure relief device, connector, open ended line, and valve that contains or contacts a process stream with hydrocarbons. Process streams consisting of glycol, amine, produced water, or methanol are not components for purposes of this Section XVII.

XVII.A.5. “Connector” means flanged, screwed, or other joined fittings used to connect two pipes or a pipe and a piece of process equipment or that close an opening in a pipe that could be connected to another pipe. Jointed fittings welded completely around the circumference of the interface are not considered connectors.

XVII.A.6. “Date of First Production” means the date reported to the COGCC as the “first date of production.”

XVII.A.7. “Glycol Natural Gas Dehydrator” means any device in which a liquid glycol (including ethylene glycol, diethylene glycol, or triethylene glycol) absorbent directly contacts a natural gas stream and absorbs water.

XVII.A.8. “Multi-Well Site” means a common well pad from which multiple wells may be drilled to various bottomhole locations.

XVII.A.9. “Natural Gas Compressor Station” means a facility which contains one or more compressors designed to compress natural gas from well pressure to gathering system pressure and recompress natural gas prior to processing.

XVII.A.10. “Normal Operation” means all periods of operation, excluding malfunctions as defined in Section I.G. of the Common Provisions regulation. For storage tanks at well production facilities, normal operation includes but is not limited to liquid dumps from the separator.

XVII.A.11. “Stabilized” when used to refer to crude oil, condensate, intermediate hydrocarbon liquids, or produced water means that the vapor pressure of the liquid is sufficiently low to prevent the production of vapor phase upon transferring the liquid to an atmospheric pressure in a storage tank, and that any emissions that occur are limited

to those commonly referred to within the industry as working, breathing, and standing losses.

XVII.A.12. "Storage Tank" means any fixed roof storage vessel or series of storage vessels that are manifolded together via liquid line. Storage vessel is as defined in 40 CFR Part 60, Subpart OOOO. Storage tanks may be located at a well production facility or other location.

XVII.A.13. "Unsafe to Monitor" means a component is unsafe to inspect because inspecting personnel would be exposed to an imminent or potential danger as a consequence of such monitoring.

XVII.A.14. "Visible Emissions" means observations of smoke for any period or periods of duration greater than or equal to one (1) minute in any fifteen (15) minute period during normal operation. Visible emissions do not include radiant energy or water vapor.

XVII.A.15. "Well Production Facility" means all equipment at a single stationary source directly associated with one or more oil wells or gas wells. This equipment includes, but is not limited to, equipment used for storage, separation, treating, dehydration, artificial lift, combustion, compression, pumping, metering, monitoring, and flowline.

XVII.B. (State Only) General Provisions

XVII.B.1. General requirements for prevention of emissions and good air pollution control practices for all oil and gas exploration and production operations, well production facilities, natural gas compressor stations, and natural gas processing plants.

XVII.B.1.a. All intermediate hydrocarbon liquids collection, storage, processing, and handling operations, regardless of size, shall be designed, operated, and maintained so as to minimize leakage of volatile organic compounds to the atmosphere to the extent reasonably practicable.

XVII.B.1.b. At all times, including periods of start-up and shutdown, the facility and air pollution control equipment shall be maintained and operated in a manner consistent with good air pollution control practices for minimizing emissions. Determination of whether or not acceptable operating and maintenance procedures are being used will be based on information available to the Division, which may include, but is not limited to, monitoring results, opacity observations, review of operating and maintenance procedures, and inspection of the source.

XVII.B.2. General requirements for air pollution control equipment, flares, and combustion devices used to comply with Section XVII.

XVII.B.2.a. All air pollution control equipment shall be operated and maintained pursuant to the manufacturing specifications or equivalent to the extent practicable, and consistent with technological limitations and good engineering and maintenance practices. The owner or operator shall keep manufacturer specifications or equivalent on file. In addition, all such air pollution control equipment shall be adequately designed and sized to achieve the control efficiency rates and to handle reasonably foreseeable fluctuations in emissions of volatile organic compounds and hydrocarbons during normal operations. Fluctuations in emissions that occur when the separator dumps into the tank are reasonably foreseeable.

XVII.B.2.b. If a flare or other combustion device is used to control emissions of hydrocarbons, it shall be enclosed, have no visible emissions during normal operations, and be designed so that an observer can, by means of visual observation from the outside of the enclosed flare or combustion device, or by other means approved by the Division, determine whether it is operating properly.

XVII.B.2.c. Any of the effective dates for installation of controls on storage tanks, dehydrators, and/or internal combustion engines may be extended at the Division's discretion for good cause shown.

XVII.B.2.d. Auto-igniters: All combustion devices used to control emissions of hydrocarbons shall be equipped with and operate an auto-igniter as follows:

XVII.B.2.d.(i) All combustion devices installed on or after May 1, 2014, will be equipped with an operational auto-igniter upon installation of the combustion device.

XVII.B.2.d.(ii) All combustion devices installed before May 1, 2014, will be equipped with an operational auto-igniter by or before May 1, 2016, or after the next combustion device planned shutdown, whichever comes first.

XVII.B.2.e. Alternative emissions control equipment shall qualify as air pollution control equipment, and may be used in lieu of, or in combination with, combustion devices and vapor recovery units to achieve the emission reductions required by this Section XVII, if the Division approves the equipment, device or process. As part of the approval process the Division, at its discretion, may specify a different control efficiency than the control efficiencies required by this Section XVII.

XVII.B.3. Oil refineries are not subject to Section XVII.

XVII.B.4. Glycol natural gas dehydrators and internal combustion engines that are subject to an emissions control requirement in a federal maximum achievable control technology ("MACT") standard under 40 CFR Part 63, a Best Available Control Technology ("BACT") limit, or a New Source Performance Standard ("NSPS") under 40 CFR Part 60 are not subject to this Section XVII.

XVII.C. (State Only) Emission reduction from storage tanks at oil and gas exploration and production operations, well production facilities, natural gas compressor stations, and natural gas processing plants.

XVII.C.1. Control requirements for storage tanks

XVII.C.1.a. Beginning May 1, 2008, owners or operators of all storage tanks storing condensate with uncontrolled actual emissions of volatile organic compounds equal to or greater than twenty (20) tons per year based on a rolling twelve-month total must operate air pollution control equipment that has an average control efficiency of at least 95% for VOCs.

XVII.C.1.b. Owners or operators of all storage tanks with uncontrolled actual emissions of volatile organic compounds equal to or greater than six (6) tons per year based on a rolling twelve-month total must operate air pollution control equipment that achieves an average hydrocarbon control efficiency of 95%. If a combustion device is used, it shall have a design destruction efficiency of at least 98% for hydrocarbons.

XVII.C.1.b.(i) A storage tank constructed on or after May 1, 2014, must be in compliance by the date that the storage tank commences operation.

XVII.C.1.b.(ii) A storage tank constructed before May 1, 2014, must be in compliance by May 1, 2015.

XVII.C.1.b.(iii) A storage tank not otherwise subject to Sections XVII.C.1.b.(i) or XVII.C.1.b.(ii), above, that increases uncontrolled actual emissions to six tons VOC or more per year on a rolling twelve month basis after May 1, 2014, must be in compliance within sixty days of discovery of the emissions increase.

XVII.C.1.c. Control requirements within 90 days of the date of first production.

XVII.C.1.c.(i) Beginning May 1, 2014, owners or operators of storage tanks at well production facilities shall collect and control emissions by routing emissions to operating air pollution control equipment during the first 90 calendar days after the date of first production. The air pollution

control equipment shall achieve an average hydrocarbon control efficiency of 95%. If a combustion device is used, it shall have a design destruction efficiency of at least 98% for hydrocarbons. Except that this requirement does not apply to storage tanks that are projected to have emissions less than 1.5 tons of VOC during the first 90 days after the date of first production.

XVII.C.1.c.(ii) The air pollution control equipment and any associated monitoring equipment required pursuant to Section XVII.C.1.c., above, may be removed at any time after the first 90 calendar days as long as the source can demonstrate that uncontrolled actual emissions from the storage tank are below the threshold in Section XVII.C.1.b., above.

XVII.C.2. Capture requirements for storage tanks that are fitted with air pollution control equipment as required by Sections XII.D. or XVII.C.1.

XVII.C.2.a. Beginning on the applicable compliance date specified in Section XVII.C.1.b., owners and operators of storage tanks shall route all hydrocarbon emissions to air pollution control equipment, and shall operate without venting hydrocarbon emissions from the thief hatch (or other access point to the tank) or pressure relief device during normal operation unless venting is reasonably required for maintenance, gauging, or safety of personnel and equipment.

XVII.C.2.b. Beginning on the applicable compliance date specified in section XVII.C.1.b., owners and operators of storage tanks shall develop, certify, and implement a document Storage Tank Emission Management System (STEM) plan to identify appropriate strategies to minimize emissions from venting at thief hatches (or other access points to a storage tank) and pressure relief devices during normal operation. As part of STEM, owners and operators shall evaluate and employ appropriate control technologies, monitoring practices, operational practices, and/or other strategies designed to meet the requirements set forth in Section XVII.C.2.a., above, and will update the STEM plan as necessary to achieve or maintain compliance. Owners and operators are not required to develop and implement STEM for storage tanks containing only stabilized liquids. The minimum elements of STEM are listed below.

XVII.C.2.b.(i) STEM must include a monitoring strategy that incorporates the minimum monitoring frequency set forth in Section XVII.F.5.e., procedures for evaluating ongoing storage tank emission capture performance, and, if applicable, the selected strategies.

XVII.C.2.b.(ii) STEM must include a certification by the owner or operator that the selected STEM strategy or strategies are designed to minimize emissions from storage tanks and associated equipment components at

the facility or facilities, including thief hatches and pressure relief devices.

XVII.C.3. Monitoring: The monitoring strategy of each STEM plan must include monitoring in accordance with Approved Instrument Based Monitoring Methods, as specified in Section XVII.F.5.

XVII.C.3.a. In addition to any applicable Approved Instrument Based Monitoring Methods, audio, visual, olfactory ("AVO") inspection of the storage tank and any associated equipment (i.e. separator, air pollution control equipment, or other pressure reducing equipment), must be completed as often as liquids are loaded out from the storage tank. However, AVO inspection is required no more frequently than every seven (7) days or less frequently than every thirty (30) days. AVO monitoring is not required for components and tanks that are unsafe to monitor. AVO inspection must include, at a minimum:

XVII.C.3.a.(i) Visual inspection of any thief hatch, pressure relief valve, or other access point to ensure that they are enclosed and properly sealed;

XVII.C.3.a.(ii) Visual inspection or monitoring of the air pollution control equipment to ensure that it is operating, including that the pilot light is lit on combustion devices used as air pollution control equipment;

XVII.C.3.a.(iii) If a flare or other combustion device is used, visual inspection of the auto-igniter and valves for piping of gas to the pilot light, to ensure they are functioning properly;

XVII.C.3.a.(iv) Visual inspection of the air pollution control equipment to ensure that the valves for the piping from the storage tank to the air pollution control equipment are open; and

XVII.C.3.a.(v) If a flare or other combustion device is used, inspection of the device for the presence of absence of smoke. If smoke is observed, either the equipment will be immediately shut-in to investigate that potential cause for smoke and perform repairs, as necessary, or Method 22 shall be conducted to determine whether visible emissions are present for a period of at least one (1) minute in fifteen (15) minutes.

XVII.C.4. Recordkeeping: The owner or operator of each storage tank subject to XII.D. or XVII.C. must maintain records of STEM as applicable, including the plan, any updates, and the certification, to be made available to the Division upon request. In addition, for a period of two years, the owner or operator must maintain records of any required monitoring and make them available to the Division upon request, including:

XVII.C.4.a. The AIRS ID for the storage tank.

XVII.C.4.b. The date and duration of any period where the thief hatch, pressure relief device, or other access point are found to be venting hydrocarbon emissions.

XVII.C.4.c. The date and duration of any period where the air pollution control equipment is not operating.

XVII.C.4.d. Where a flare or other combustion device is being used, the date and result of any Method 22 test.

XVII.C.4.e. The timing of and efforts made to eliminate venting, restore operation of air pollution control equipment, and mitigate visible emissions.

XVII.D. (State Only) Emission reductions from glycol natural gas dehydrators

XVII.D.1. Beginning May 1, 2008, still vents and vents from any flash separator or flash tank on a glycol natural gas dehydrator located at an oil and gas exploration and production operation, natural gas compressor station, drip station or gas-processing plant subject to control requirements pursuant to Section XVII.D.2., shall reduce uncontrolled actual emissions of volatile organic compounds by at least 90 percent through the use of a condenser or air pollution control equipment.

XVII.D.2. The control requirement in Section XVII.D.1. shall apply where:

XVII.D.2.a. Actual uncontrolled emissions of volatile organic compounds from the glycol natural gas dehydrator are equal to or greater than two tons per year; and

XVII.D.2.b. The sum of actual uncontrolled emissions of volatile organic compounds from any single glycol natural gas dehydrator or grouping of glycol natural gas dehydrators at a single stationary source is equal to or greater than 15 tons per year. To determine if a grouping of dehydrators meets or exceeds the 15 tons per year threshold, sum the total actual uncontrolled emissions of volatile organic compounds from all individual dehydrators at the stationary source, including those with emissions less than two tons per year.

XVII.D.3. Beginning May 1, 2015, still vents and vents from any flash separator or flash tank on a glycol natural gas dehydrator located at an oil and gas exploration and production operation, natural gas compressor station, and drip station or gas-processing plant subject to control requirements pursuant to Section XVII.D.4., shall reduce uncontrolled actual emissions of hydrocarbons by at least 95 percent on a rolling twelve-month basis through the use of a condenser or air pollution control equipment. If a combustion device is used, it shall have a design destruction efficiency of at least 98% for hydrocarbons.

XVII.D.4. The control requirement in Section XVII.D.3. shall apply where:

XVII.D.4.a. Actual uncontrolled emissions of volatile organic compounds from a single new glycol natural gas dehydrator are equal to or greater than two tons per year; or

XVII.D.4.b. Actual uncontrolled emissions of volatile organic compounds from a single existing glycol natural gas dehydrator are equal to or greater than six (6) tons per year, or two (2) tons per year if the glycol natural gas dehydrator is located within 1,320 feet of a building unit or designated outside activity area.

XVII.D.4.c. For purposes of Section XVII.D.4.:

XVII.D.4.c.(i) Building Unit shall mean a residential building unit, and every five thousand (5,000) square feet of building floor area in commercial facilities or every fifteen thousand (15,000) square feet of building floor area in warehouses that are operating and normally occupied during working hours.

XVII.D.4.c.(ii) A designated outside activity area shall mean an outdoor venue or recreation area, such as a playground, permanent sports field, amphitheater, or other similar place of public assembly owned or operated by a local government, which the local government seeks to have established as a Designated Outside Activity Area; or an outdoor venue or recreation area where ingress to or egress from could be impeded in the event of an emergency condition at an oil and gas location less than three hundred and fifty (350) feet from the venue due to the configuration of the venue and the number of persons known or expected to simultaneously occupy the venue on a regular basis.

XVII.E. Control of emissions from new, modified, existing, and relocated natural gas fired reciprocating internal combustion engines.

XVII.E.1. (State Only) The requirements of this Section XVII.E. shall not apply to any engine having actual uncontrolled emissions below permitting thresholds listed in Regulation Number 3, Part B.

XVII.E.2. (State Only) New, Modified and Relocated Natural Gas Fired Reciprocating Internal Combustion Engines

XVII.E.2.a. Except as provided in Section XVII.E.2.b. below, the owner or operator on any natural gas fired reciprocating internal combustion engine that is either constructed or relocated to the state of Colorado from another state, on or after the date listed in the table below shall operate and maintain each engine according to the manufacturer's written instructions or procedures to the

extent practicable and consistent with technological limitations and good engineering and maintenance practices over the entire life of the engine so that it achieves the emission standards required in Section XVII.E.2.b. Table 1 below.

XVII.E.2.b. Actual emissions from natural gas fired reciprocating internal combustion engines shall not exceed the emission performance standards in Table 1 below as expressed in units of grams per horsepower-hour (G/hp-hr)

TABLE 1				
Maximum Engine Hp	Construction or Relocation Date	Emission Standards is G/hp-hr		
		NOx	CO	VOC
< 100 Hp	Any	NA	NA	NA
≥100 Hp and < 500 Hp	On or after January 1, 2008	2.0	4.0	1.0
	On or after January 1, 2011	1.0	2.0	0.7
≥500 Hp	On or after July 1, 2007	2.0	4.0	1.0
	On or after July 1, 2010	1.0	2.0	0.7

XVII.E.3. Existing Natural Gas Fired Reciprocating Internal Combustion Engines

XVII.E.3.a. (Regional Haze SIP) Rich Burn Reciprocating Internal Combustion Engines

XVII.E.3.a.(i) Except as provided in Sections XVII.3.1.(i)(b) and (c) and XVII.E.3.a.(ii), all rich burn reciprocating internal combustion engines with a manufacturer's name plate design rate greater than 500 horsepower, constructed or modified before February 1, 2009 shall install and operate both a non-selective catalytic reduction system and an air fuel controller by July 1, 2010. A rich burn reciprocating internal combustion engine is one with a normal exhaust oxygen concentration of less than 2% by volume.

XVII.E.3.a.(i)(a) All control equipment required by this Section XVII.E.3.a. shall be operated and maintained pursuant to manufacturer specifications or equivalent to the extent

practicable, and consistent with technological limitations and good engineering and maintenance practices. The owner or operator shall keep manufacturer specifications or equivalent on file.

XVII.E.3.a.(i)(b) Internal combustion engines that are subject to an emissions control requirement in a federal maximum achievable control technology ("MACT") standard under 40 CFR Part 63, a Best Available Control Technology ("BACT") limit, or a New Source Performance Standard under 40 CFR Part 60 are not subject to this Section XVII.E.3.a.

XVII.E.3.a.(i)(c) The requirements of this Section XVII.E.3.a. shall not apply to any engine having actual uncontrolled emissions below permitting thresholds listed in Regulation Number 3, Part B.

XVII.E.3.a.(ii) Any rich burn reciprocating internal combustion engine constructed or modified before February 1, 2009, for which the owner or operator demonstrates to the Division that retrofit technology cannot be installed at a cost of less than $ 5,000 per ton of combined volatile organic compound and nitrogen oxides emission reductions (this value shall be adjusted for future applications according to the current day consumer price index) is exempt complying with Section XVII.E.3.a. Installation costs and the best information available for determining control efficiency shall be considered in determining such costs. In order to qualify for such exemption, the owner or operator must submit an application making such a demonstration, together with all supporting documents, to the Division by August 1,2009.

XVII.E.3.b. (State Only) Lean Burn Reciprocating Internal Combustion Engines

XVII.E.3.b.(i) Except as provided in Section XVII.E.3.b.(ii), all lean burn reciprocating internal combustion engines with a manufacturer's nameplate design rate greater than 500 horsepower shall install and operate an oxidation catalyst by July 1, 2010. A lean burn reciprocating internal combustion engine is one with a normal exhaust oxygen concentration of 2% by volume, or greater.

XVII.E.3.b.(ii) Any lean burn reciprocating internal combustion engine constructed or modified before February 1, 2009, for which the owner or operator demonstrates to the Division that retrofit technology cannot be installed at a cost of less than $ 5,000 per ton of volatile organic compound emission reduction (this value shall be adjusted for future applications according to the current day consumer price index)

is exempt complying with Section XVII.E.3.b.(i). Installation costs and the best information available for determining control efficiency shall be considered in determining such costs. In order to qualify for such exemption, the owner or operator must submit an application making such a demonstration, together with all supporting documents, to the Division by August 1, 2009.

XVII.F. (State Only) Leak detection and repair program for well production facilities, storage tanks, and compressor stations

XVII.F.1. Beginning January 1, 2015, owners and operators of well production facilities and compressor stations will identify and repair leaks from components at these facilities in accordance with the requirements of this Section XVII.F. The following shall apply in lieu of any directed inspection and maintenance program requirements established pursuant to Regulation Number 3, Part B, Section III.D.2.

XVII.F.2. Owners and operators of well production facilities or natural gas compressor stations that monitor components as part of this Section XVII.F. may opt to estimate emissions from components for the purpose of evaluating the applicability of component fugitive emissions to Regulation Number 3 by utilizing the emission factors defined as less than 10,000 ppmv of Table 2-8 of the 1995 EPA Protocol for Equipment Leak Emission Estimates (Document EPA-453/R-95-017).

XVII.F.3. Owners and operators of well production facilities or natural gas compressor stations shall utilize the Approved Instrument Based Monitoring Method and AVO program as outlined in Section XVII.F. AVO monitoring is not required of components and tanks that are unsafe to monitor or inaccessible to monitor, pursuant to XVII.F.5.g.

XVII.F.4. Inspection schedules for natural gas compressor stations: Beginning January 1, 2015, owners and operators of natural gas compressor stations shall inspect components for leaks using an Approved Instrument Based Monitoring Method, in accordance with the following Table 2, except for components subject to XVII.F.5.g. For purposes of this Section XVII.F.4., fugitive emissions shall be calculated using the emission factors of Table 2-4 of the 1995 EPA Protocol for Equipment Leak Emission Estimates (Document EPA-453/R-95-017), of other Division approved method.

Table 2	
Fugitive VOC Emissions (tpy)	Inspection Frequency
>0 and ≤ 12	Semi-~~A~~annually

> 12 and ≤ 50	Quarterly
> 50	Monthly

XVII.F.5. Requirements for well production facilities and/or storage tanks

XVII.F.5.a. Beginning August 1, 2014, all new well production facilities shall have a documented pressure test performed on all equipment and piping prior to start up. Documentation of this 90 day testing and monitoring shall be provided in the first annual report to the Division, as required by Section XVII.F.9.

XVII.F.5.b. Beginning January 1, 2015, within 90 days of startup of all new well production facilities and/or storage tanks, owners and/or operators shall identify and repair leaks from components using an Approved Instrument Based Monitoring Method. Such action shall qualify as an inspection pursuant to the inspection frequency schedule in Table 3.

XVII.F.5.c. Consistent with the provisions of XVII.F.5.f., owners and operators of existing well production facilities and/or storage tanks shall identify and repair leaks using an Approved Instrument Based Monitoring Method, in accordance with the implementation schedule in XVII.F.5.e. Inspection frequency shall be determined according to Table 3.

XVII.F.5.d. Consistent with the provisions of XVII.F.5.f., owners and operators of new well production facilities and/or storage tanks shall identify and repair leaks from components using an Approved Instrument Based Monitoring Method beginning on January 1, 2015. Inspection frequency shall be determined according to Table 3.

XVII.F.5.e. The estimated uncontrolled actual emissions from storage tanks determine the frequency at which inspections must be performed. If no storage tanks are located at the well production facility or multi-well site, operators will rely on the potential to emit of VOC for all of the emissions sources, including emissions from components located at the facility. All components at a well production facility or storage tank must be inspected:

Table 3	
Threshold (per XVII.F.5.e.) VOC Emissions (tpy, uncontrolled actual for sites with	Inspection Frequency

tanks or PTE for sites without tanks)	
> 0 and ≤ 6	~~One time using Approved Instrument Based Monitoring Method and thereafter using monthly AVO~~Every two years with monthly AVO
> 6 and ≤ 12	Semi-a~~A~~nnually with monthly AVO
> 12 and ≤ 50	Quarterly with monthly AVO
> 50	Monthly
Multi-well sites without storage tanks after April 15, 2014, that have a PTE > 20 tpy VOC	Monthly

XVII.F.5.f. Phase-in of Approved Instrument Based Monitoring Methods: Owners and operators of existing well production facilities and/or storage tanks shall identify and repair leaks from components using an Approved Instrument Based Monitoring Method, in accordance with the following schedule:

XVII.F.5.f.(i) Beginning January 1, 2015, facilities with uncontrolled actual VOC emissions greater than ~~50~~ 6 tpy or multi-well sites.

~~XVII.F.5.f.(ii) Beginning July January May 1, 2015, facilities with uncontrolled actual VOC emissions greater than 20 6 tpy but less than or equal to 50 tpy.~~

XVII.F.5.f.(ii~~i~~) Beginning January 1, 2016, facilities with uncontrolled actual VOC emissions ~~greater~~ less than or equat to~~than~~ 6 tpy ~~but less than or equal to 20 tpy~~.

~~XVII.F.5.g.(iv) By July 1, 2016, facilities with uncontrolled actual VOC emissions less than or equal to 6 tpy.~~

XVII.F.5.g. If a component is difficult, unsafe, or inaccessible to monitor, the owner or operator shall not be required to monitor the component until it becomes feasible to do so.

XVII.F.5.g.(i) Difficult to monitor components are those that cannot be monitored without elevating the monitoring personnel more than two meters above a supported surface or are unable to be reached via a

wheeled scissor-lift or hydraulic type scaffold that allows access to components up to 7.6 meters (25 feet) above the ground.

XVII.F.5.g.(ii) Unsafe to monitor components are those that cannot be monitored without exposing monitoring personnel to an immediate danger as a consequence of completing the monitoring.

XVII.F.5.g.(iii) Inaccessible to monitor components are those that are buried, insulated in a manner that prevents access to the components by a monitor probe, or obstructed by equipment or piping that prevents access to the components by a monitor probe.

XVII.F.6 Leak detection requiring repair: Leaks shall be identified utilizing the methods listed in this Section XVII.F.6.a. through XVII.F.6.d. Only leaks detected pursuant to this Section XVIII.F.6. shall require repair under Section XVII.F.

XVII.F.6.a. For Method 21 monitoring at existing facilities, a leak is any concentration of hydrocarbon above 2,000 parts per million (ppm), except for existing well production facilities where leak is defined as any concentration of hydrocarbon above 500 ppm.

XVII.F.6.b. For Method 21 monitoring at facilities constructed after May 1, 2014, a leak is any concentration of hydrocarbon above 500 ppm.

XVII.F.6.c. For infra-red camera and AVO monitoring, a leak is any detectable emissions not associated with normal equipment operation, such as pneumatic device actuation and crank case ventilation.

XVII.F.6.d. For other Division approved monitoring devices or methods, leak identification requiring repair will be established as set forth in the Division's approval.

XVII.F.7. Repair and remonitoring

XVII.F.7.a. First attempt to repair a leak shall be made no later than five (5) working days after discovery, unless parts are unavailable, the equipment requires shutdown to complete repair, or other good cause exists. If parts are unavailable, they shall be ordered promptly and the repair shall be made within fifteen (15) working days of receipt of the parts. If shutdown is required, the leak shall be repaired during the next scheduled shutdown. If delay is attributable to other good cause, repairs shall be completed within fifteen (15) working days after the cause of delay ceases to exist.

XVII.F.7.b. Within fifteen (15) working days of completion of a repair, the leaks shall be remonitored to verify the repair was effective.

XVII.F.7.c. Leaks discovered pursuant to the leak detection methods of Section XVII.F. shall not be subject to enforcement by the Division unless the owner or operator fails to perform the required repairs in accordance with Section XVII.F.7.

XVII.F.7.d. For leaks identified using an Approved Instrument Based Monitoring Method, owners and operators have the option of either repairing the leak in accordance with the repair schedule set forth in Section XVII.F.7. or conducting follow-up monitoring using Method 21 within five (5) working days of the leak detected. If the follow-up Method 21 monitoring shows that the leak concentration is less than or equal to 2,000 ppm hydrocarbon for existing facilities (other than existing well production facilities), or 500 ppm for new facilities or existing well production facilities, then the emission shall not be considered a leak for purposes of this Section.

XVII.F.8. Recordkeeping: The owner or operator of each facility subject to the inspection and maintenance requirements in this Section XVII.F. shall maintain the following for a period of two (2) years and make them available to the Division upon request.

XVII.F.8.a. Documentation of the pre-start-up pressure tests for new well production facilities;

XVII.F.8.b. The date and site information for each inspection;

XVII.F.8.c. A list of the leaking components and the monitoring method used to determine the presence of the leak;

XVII.F.8.d. The date of first attempt to repair the leak and, if necessary, any additional attempt to repair the leak;

XVII.F.8.e. The date the leak was repair;

XVII.F.8.f. The delayed repair list including the basis for placing leaks on the list;

XVII.F.8.g. The date the leak was remonitored to verify the effectiveness of the repair, and the results of the remonitoring; and

XVII.F.8.h. A list of identification numbers for components that are designated as unsafe or inaccessible to monitor, as described in Section XVII.F.5.g., an explanation for each component stating why the component is so designated, and the plan for monitoring such component(s).

XVII.F.9. Reporting: The owner or operator of each facility subject to the inspection and maintenance requirements in Section XVII.F. shall submit a single annual report on or before April 30th of each year summarizing inspection and maintenance activities at all

of their subject facilities during the previous calendar year. This report shall contain at a minimum the following information:

XVII.F.9.a. The number of facilities inspected;

XVII.F.9.b. The total number of inspections;

XVII.F.9.c. The total number of leaks identified, broken out by component type;

XVII.F.9.d. The total number of leaks repaired;

XVII.F.9.e. The number of leaks on the delayed repair list as of December 31st; and

XVII.F.9.f. Each report shall be accompanied by a self-certification form. The form shall contain a certification by a responsible official of the truth, accuracy, and completeness of such form, report, or certification stating that, based on information and belief formed after reasonable inquiry, the statements and information in the document are true, accurate, and complete.

XVII.G. (State Only) Control of emissions from well production facilities

XVII.G.1Control Standards

XVII.G.1.A Well Operation and Maintenance: On or after ~~August~~ January 1, 201~~5~~4, ~~during normal operation~~ gas coming off a separator produced from any newly ~~–~~constructed, hydraulically fractured, or recompleted oil and gas well must either ~~,~~ be routed to a gas gathering line or controlled by air pollution control equipment ~~,~~ ~~t~~that achieves an average hydrocarbon control efficiency of 95% from the date of first production. If a combustion device is used, it shall have a design destruction efficiency of at least 98% of hydrocarbons.

Formatted: Indent: Left: 0.5", Hanging: 1"

XVII.G.1.B Unless otherwise approved by the Division, on or before 90 days from the date of first production from the well or [January 1, 2015], whichever is later, the well must be connected to a gas gathering line. In determining whether to approve an extension of the 90 day period, the Division will consider the economic feasibility of connecting the well to a gas gathering line, the amount of gas being routed to air pollution equipment, the economic feasibility of alternative uses of the gas, the owner/operators' future plans for connecting the well to a gas line, and any other relevant information from the owner or operator. The division will also consider input received from the Colorado Oil & Gas Conservation Commission and will assess economic feasibility subject to a feasibility criterior of $2,500 per ton.

XVII.G.2 Monitoring: The owner or operator of any well production facility that is using air pollution control equipment to comply with section XVII.G.1.A. shall visually inspect or monitor the air pollution control equipment to ensure that it is operating. In addition, if a flare or other combustion device is used, the owner or operator shall visually inspect the device for visible emissions. These inspections shall occur as often as liquids are loaded out from the well production facility. However, these inspections are required no more frequently than every seven days or less frequently than every 90 days.

XVII.G.3 Recordkeeping: The owner or operator of an oil or gas well shall maintain the following records for a period of five years and make them available to the Division upon request.

XVII.G.3.A The date of each visual inspection required under Section XVII.G.2

XVII.G.3.B The date, time and duration of any period where the air pollution control equipment is not operating. The duration of a period of non-operation is from the time that the air pollution control equipment was last observed to be operating until the time the equipment recommences operation.

XVII.G.3.C Where a flare or other combustion device is being used, the date and time of any instances where visible emissions are observed from the device.

Formatted: Normal

Formatted: Font: (Default) Calibri, Underline, All caps

XVII.H. (State Only) Venting during downhole well maintenance and unloading events

XVII.H.1. Well Maintenance: Beginning May 1, 2014, hydrocarbon emissions from flowing wells must be captured or controlled during downhole well maintenance or servicing activities, unless venting is necessary for safety.

XVII.H.1.a. Operators shall use best management practices to minimize the need for well venting associated with downhole well maintenance and liquids unloading. During liquids unloading events, any means of creating differential pressure will first be used to attempt to unload the liquids from the well without venting. If these methods are not successful in unloading the liquids from the well, the well may be vented to the atmosphere to create the necessary differential pressure to bring the liquids to the surface.

XVII.H.1.b. Venting will be minimized to the extent possible, using best management practices during the well maintenance and liquids unloading events in XVII.H.1.a. The owner and/or operator shall be present on-site during any planned well maintenance and liquids unloading event in XVII.H.1.a. and

shall ensure that any venting to the atmosphere is limited to the maximum extent practicable.

XVII.H.1.c. Records of the cause, date, time, and duration of venting events under this Section XVII.H. will be kept and made available to the Division upon request.

XVIII. (State Only) Natural Gas-Actuated Pneumatic Controllers Associated with Oil and Gas Operations

XVIII.A. Applicability

This section applies to pneumatic controllers that are actuated by natural gas, and located at, or upstream of natural gas processing plants (upstream activities include: oil and gas exploration and production operations, natural gas compressor stations, and/or natural gas drip stations).

XVIII.B. Definitions

XVIII.B.1. "Affected Operations" shall mean pneumatic controllers that are actuated by natural gas, and located at, or upstream of natural gas processing plants (upstream activities include: oil and gas exploration and production operations, natural gas compressor stations, and/or natural gas drip stations).

XVIII.B.2. "Enhanced Maintenance" is specific to high-bleed devices and shall include but is not limited to cleaning, tuning, and repairing leaking gaskets, tubing fittings, and seals; tuning to operate over a broader range of proportional band; and eliminating unnecessary valve positioners.

XVIII.B.3. "High-Bleed Pneumatic Controller" shall mean a pneumatic controller that is designed to have a constant bleed rate that emits in excess of 6 standard cubic feet per hour (scfh) of natural gas to the atmosphere.

XVIII.B.4. "Low-Bleed Pneumatic controller" shall mean a pneumatic controller that is designed to have a constant bleed rate that emits less than or equal to 6 scfh of natural gas to the atmosphere.

XVIII.B.5. "Natural Gas Processing Plant" shall mean any processing site engaged in the extraction of natural gas liquids from field gas, fractionation of mixed natural gas liquids to natural gas products, or both.

XVIII.B.6. "No-bleed Pneumatic Controller" shall mean any pneumatic controller that is not using hydrocarbon gas as the valve's actuating gas.

XVIII.B.7. "Pneumatic Controller" shall mean an instrument that is actuated using natural gas pressure and used to control or monitor process parameters such as liquid level, gas level, pressure, valve position, liquid flow, gas flow and temperature.

XVIII.C. Emission Reduction Requirements

The owners and operators of affected operations shall reduce emissions of volatile organic compounds from pneumatic controllers associated with affected operations as follows:

XVIII.C.1. In the 8-Hour Ozone Control Area:

XVIII.C.1.a. All pneumatic controllers placed in service on or after February 1, 2009, shall emit VOCs in an amount equal to or less than a low-bleed pneumatic controller, unless allowed pursuant to Section XVIII.C.1.c.

XVIII.C.1.b. All high-bleed pneumatic controllers in service prior to February 1, 2009 shall be replaced or retrofit such that VOC emissions are reduced to an amount equal to or less than a low-bleed pneumatic controller, by May 1, 2009, unless allowed pursuant to Section XVIII.C.1.c.

XVIII.C.1.c. All high-bleed pneumatic controllers that must remain in service due to safety and/or process purposes must have Division approval and comply with Sections XVIII.D. and XVIII.E.

XVIII.C.1.c.(i) For high-bleed pneumatic controllers in service prior to February 1, 2009, the owner/operator shall submit justification for high-bleed pneumatic controllers to remain in service due to safety and /or process purposes by March 1, 2009. The Division shall be deemed to have approved the justification if it does not object to the owner/operator within 30-days upon receipt.

XVIII.C.1.c.(ii) For high-bleed pneumatic controllers placed in service on or after February 1, 2009, the owner/operator shall submit justification for high-bleed pneumatic controllers to be installed due to safety and /or process purposes prior to installation. The Division shall be deemed to have approved the justification if it does not object to the owner/operator within 30-days upon receipt.

XVIII.C.2. Statewide:

XVIII.C.2.a. All pneumatic controllers placed in service on or after May 1, 2014, shall:

XVIII.C.2.c.(i) Emit VOCs in an amount equal to or less than a low-bleed pneumatic controller, unless allowed pursuant to Section XVIII.C.2.c.; or

XVIII.C.2.c.(ii) Utilize no-bleed pneumatic controllers where on-site electrical grid power is being used and is technically and economically feasible.

XVIII.C.2.b. All high-bleed pneumatic controllers in service prior to May 1, 2014, shall be replaced or retrofitted by May 1, 2015, such that VOC emissions are reduced to an amount equal to or less than a low-bleed pneumatic controller, unless allowed pursuant to Section XVIII.C.2.c.

XVIII.C.2.c. All high-bleed controllers that must remain in service due to safety and/or process purposes must have Division approval and comply with Sections XVIII.D. and XVIII.E.

XVIII.C.2.c.(i) All high-bleed pneumatic controllers in service prior to May 1, 2014, the owner/operator shall submit justification for high-bleed pneumatic controllers to remain in service due to safety and/or process purposes by March 1, 2015. The Division shall be deemed to have approved the justification if it does not object to the owner/operator within 30-days upon receipt.

XVIII.C.2.c.(ii) For high-bleed pneumatic controllers placed in service on or after May 1, 2014, the owner/operator shall submit justification for high-bleed pneumatic controllers to be installed due to safety and/or process purposes prior to installation. The Division shall be deemed to have approved the justification if it does not object to the owner/operator within 30-days upon receipt.

XVIII.D. Monitoring

This section applies only to high-bleed pneumatic controllers identified in Sections XVIII.C.1.c. and XVIII.C.2.c.

XVIII.D.1. In the 8-Hour Ozone Control Area

XVIII.D.1.a. Effective May 1, 2009, each high-bleed pneumatic controller shall be physically tagged by the owner/operator identifying it with a unique high-bleed pneumatic controller number that is assigned and maintained by the owner/operator.

XVIII.D.1.b. Effective May 1, 2009, each high-bleed pneumatic controller shall be inspected on a monthly basis, perform necessary enhanced maintenance as defined in Section XVIII.B.2 , and maintain the device according to manufacturer specifications to ensure that the controller's VOC emissions are minimized.

XVIII.D.2. Statewide:

XVIII.D.2.a. Effective May 1, 2015, each high-bleed pneumatic controller shall be physically tagged by the owner/operator identifying it with a unique high-bleed

pneumatic controller number that is assigned and maintained by the owner/operator.

XVIII.D.2.b. Effective May 1, 2015, each high-bleed pneumatic controller shall be inspected on a monthly basis, perform necessary enhanced maintenance as defined in Section XVIII.B.2 , and maintain the device according to manufacturer specifications to ensure that the controller's VOC emissions are minimized.

XVIII.E. Recordkeeping

This section applies only to high-bleed pneumatic controllers identified in Sections XVIII.C.1.c. and XVIII.C.2.c.

XVIII.E.1. The owner or operator of affected operations shall maintain a log of the total number of high-bleed pneumatic controllers and their associated controller numbers per facility, the total number of high-bleed pneumatic controllers per company and the associated justification that the high-bleed pneumatic controllers must be used pursuant to Sections XVIII.C.1.c. and XVIII.C.2.c. The log shall be updated on a monthly basis.

XVIII.E.2. The owner or operator shall maintain a log of enhanced maintenance which shall include, at a minimum, inspection dates, the date of the maintenance activity, high-bleed pneumatic controller number, description of the maintenance performed, results and date of any corrective action taken, and the printed name and signature of the individual performing the maintenance. The log shall be updated on a monthly basis.

XVIII.E.3. Records of enhanced maintenance of pneumatic controllers shall be maintained for a minimum of three years and readily made available to the Division upon request.

XIX. Statements of Basis, Specific Statutory Authority and Purpose

XIX.N. February 21, 2014 (Sections II., XVII., and XVIII.)

This Statement of Basis, Specific Statutory Authority, and Purpose complies with the requirements of the Colorado Administrative Procedure Act Sections 24-4-103(4), the Colorado Air Pollution Prevention and Control Act, C.R.S. §§ 25-7-110 and 25-7-110.5., and the Air Quality Control Commission's ("Commission") Procedural Rules.

Basis

The oil and gas industry is a source of volatile organic compounds ("VOCs"), an ozone precursor. Additionally, oil and gas operations are a source of other hydrocarbon emissions, such as methane, through the leaking and venting of natural gas.

On October 18, 2012, the Commission partially adopted federal Standards of Performance for Crude Oil and Natural Gas Production, Transmission, and Distribution found in 40 C.F.R. Part 60, Subpart OOOO ("NSPS OOOO") into Regulation Number 6, Part A. During the partial adoption of NSPS OOOO, the Commission requested the Air Pollution Control Division ("Division") to consider full adoption at a later date and directed the Division to identify additional oil and gas control measures that complement and expand upon NSPS OOOO. This rulemaking is the result.

The Commission supports the EPA's development of NSPS OOOO, and believes that additional hydrocarbon control measures are warranted in Colorado for several reasons. The Denver Metropolitan Area/North Front Range is in nonattainment with EPA's current 8-Hour Ozone National Ambient Air Quality Standard ("NAAQS"). It is also likely that EPA will lower the ozone NAAQS in the near future. In addition, Colorado has seen significant growth of oil and gas development in recent years, and that growth is expected to continue in the foreseeable future. The oil and gas industry is a significant source of VOC emissions (an ozone precursor). This is particularly true of oil and gas storage tanks. Oil and gas operations also emit methane, a negligibly reactive ozone precursor and a potent greenhouse gas. Division air monitors and other sampling indicate elevated levels of oil and gas related compounds in oil and gas development areas. Improved technologies and business practices can reduce emissions of hydrocarbons such as VOCs and methane in a cost effective manner. Many Colorado operators are already utilizing such technologies and practices to some degree including, without limitation, auto-igniters, low- or no-bleed pneumatic controllers, stabilized liquids or reduced tank pressures, flares achieving at least 98% destruction efficiency, and leak detection and repair (including the use of infrared ("IR") cameras). These technologies and practices have the added benefit of reducing several types of hydrocarbon emissions at the same time.

Colorado has vast experience with the regulation of oil and gas sources. In 2004, 2006, and 2008, the Commission established oil and gas industry emissions controls in Regulation Number 7, Sections XII., XVII., and XVIII. In March 2004, the Commission required condensate tank, controlled under the system-wide approach in what was known as the 8-Hour Ozone Control Area, to meet a 95% control efficiency requirement. This provision was approved into the State Implementation Plan ("SIP"). In December 2006, the Commission determined that on a state-wide, state-only basis, all (new and existing) condensate storage tanks must install air pollution control equipment and meet 95% destruction of VOC, if the total VOC emissions from the tank were equal to or greater than twenty (20) tons per year ("tpy"). Due to "flash," operators have had difficulty consistently meeting this 95% control requirement.

For these reasons and more, the Commission believes additional control measures beyond the current requirements in Regulation Number 7 and NSPS OOOO are appropriate. These regulations apply on a state-wide, state-only basis, and are not a part of Colorado's SIP. This approach gives the Commission, the Division, and stakeholders the opportunity to further assess the implementation and effectiveness of these requirements, to better inform future actions.

Statutory Authority

The Colorado Air Pollution Prevention and Control Act, C.R.S. §§ 25-7-101, et seq., ("Act"), C.R.S. § 25-7-105(1) directs the Commission to promulgate such rules and regulations as are consistent with the legislative declaration set forth in Section 25-7-102 and are necessary for the proper implementation and administration of Article 7. The Act broadly defines air pollutant and provides the Commission broad authority to regulate air pollutants. Section 25-7-106 provides the Commission maximum flexibility in developing an effective air quality program and promulgating such combination of regulations as may be necessary or desirable to carry out that program. Section 25-7-106 also authorizes the Commission to promulgate emission control regulations applicable to the entire state, specified areas or zones, or a specified class of pollution. Section 109(1)(a), (2), and (3) of the Act authorize the Commission to promulgate regulations requiring effective and practical air pollution controls for significant sources and categories of sources, emission control regulations pertaining to nitrogen oxides and hydrocarbons, and emissions control regulations pertaining to the storage and transfer of petroleum products and other VOCs. Section 25-7-109(2)(c), in particular, provides broad authority to regulate hydrocarbons.

Purpose

The Commission adopts revisions throughout Regulation Number 7 to address hydrocarbon emissions from oil and gas facilities, including well production facilities and compressor stations. The revisions expand existing oil and gas control requirements and establish additional monitoring, recordkeeping, and reporting requirements. For example, regarding oil and gas storage tanks, the revisions increase control requirements and improve capture efficiency requirements. The Commission also seeks to minimize fugitive emissions from leaking components at compressor stations and well production facilities. Further, the Commission intends to minimize emissions at new and modified oil and gas wells, and wells undergoing maintenance. The Commission also expands control requirements for pneumatic devices and glycol dehydrators. The Commission believes that this combination of revisions is appropriate to fully adopt NSPS OOOO, and to further reduce emissions produced by the oil and gas industry.

Among other things, these revisions:

- Expressly address hydrocarbon emissions in Section XVII. and XVIII.;
- Amend definitions in Section XVII.A. and XVIII.B.;
- Strengthen good air pollution control practices, require use of auto-igniters, and remove the off-ramp for condensate tanks if subject to NSPS, MACT, or BACT in Section XVII.B.;
- Expand condensate tank control requirements to apply state-wide, to all hydrocarbon liquid storage tanks, and to smaller storage tanks in Section XVII.C.;

- Limit venting and establish a storage tank emissions monitoring system ("STEM"), and associated recordkeeping and reporting requirements in Section XVII.C.;
- Expand glycol dehydrator control requirements in Section XVII.D.;
- Establish a leak detection and repair program for compressor stations and well production facilities in Section XVII.F.;
- Establish control measures for oil and gas wells in Section XVII.G.;
- Limit venting during well maintenance in Section XVII.H.; and
- Expand pneumatic device requirements in Section XVII.

The revisions also correct typographical, grammatical, and formatting errors found through the regulation.

The Commission intends that all the revisions to Regulation Number 7, are state-only requirements.

The following explanations provide further insight into the Commission's intention for certain revisions.

Joint Applicability of NSPS OOOO and Regulation Number 7 Sections XII. and XVII.

It is possible for storage tanks to be subject to NSPS OOOO and Regulation Number 7, Sections XII. and XVII. While this creates an overlap between the different requirements, the requirements secure different emissions reductions. Regulation Number 7, Section XII. applies to condensate storage tanks in the 8-Hour Ozone Nonattainment Area, whereas NSPS OOOO applies to storage vessels that contain more than just condensate, such as produced water and crude oil storage vessels. NSPS OOOO also applies to individual storage vessels, whereas Regulation Number 7, Sections XII. and XVII. apply to single tanks and, if manifolded together, the series of tanks in tank batteries. In addition, NSPS OOOO applies to storage vessels with 6 tpy of controlled actual VOC emissions, whereas Regulation Number 7, Sections XII. and XVII. base applicability on uncontrolled actual emissions. For these reasons, and considering that portions of Regulation Number 7, Section XII. are approved in Colorado's SIP, the Commission intends for the federal and state rules to jointly apply to storage tanks in Colorado. Thus, the Commission intentionally removed storage tanks from the exemption in Section XVII.B.4. that allowed sources subject to an NSPS, MACT, or BACT requirement to avoid having to comply with overlapping requirements in Section XVII.

Furthermore, because NSPS OOOO allows oil and gas operators to avoid applicability by establishing enforceable emission limits below NSPS OOOO applicability thresholds through a state, federal, or local requirement, most storage tanks subject to Regulation Number 7 will not be subject to NSPS OOOO monitoring or recordkeeping requirements. In those limited cases where storage tanks are subject to

both NSPS OOOO and current Regulation Number 7 control requirements, Regulation Number 7 will require some additional emissions monitoring.

However, joint applicability is anticipated to be limited to those storage tanks whose uncontrolled actual VOC emissions are one hundred and twenty (120) tpy (the equivalent of six (6) tpy VOC on a controlled actual basis). While this means that more storage tanks are regulated under Regulation Number 7, Section XVII., they are regulated on a state-only basis, and are not federally enforceable like NSPS OOOO. Thus, the Commission believes joint applicability is necessary.

It is the Commission's intent that compliance with Sections XII. and XVII. shall serve to establish legally and practically enforceable limits for the purpose of estimating emissions.

Applicability of Parts of Regulation Number 7 to Hydrocarbons

Many of the control measures set forth in these revisions have the benefit of reducing both VOC emissions and emissions of other hydrocarbons such as methane. Sections XVII. and XVIII. have been revised to reflect the Commission's intent that the provisions contained therein reduce emissions of the broader category of hydrocarbons.

Visible Emissions

Regulation Number 7, Sections XII. and XVII. have historically contained a prohibition on visible emissions from combustion devices, such as flares. The Commission is not proposing to relax this requirement. To address comments from diverse stakeholders, the Commission is clarifying how the Division inspectors and the regulated community are to determine compliance with the prohibition on visible emissions going forward. The Commission has qualified that visible emissions are emissions of smoke that are observed for a period in duration of one (1) minute during a fifteen (15) minute time period. The Commission expects that both Division inspectors and the regulated community will, if any smoke is observed, determine whether the emissions are considered visible emissions for purposes of Regulation Number 7.

Definitions (Section XVII.A.)

The Commission has revised or added definitions for several terms. Further explanation for a few of these terms is set forth below.

"Normal operation" is considered to include all operation, including maintenance and other activities, as long as the operation does not meet the definition of "malfunction" as set forth in the Common Provision regulations.

"Date of first production" is meant to coincide with the date reported to the Colorado Oil and Gas Conservation Commission's ("COGCC") as the "date of first production," as currently used in COGCC Form 5A. The Commission intends for oil and gas sources to use only one date for compliance with both the COGCC and Commission requirements.

"Storage tank," means a single tank, as well as a tank battery if the tanks are manifolded together. In recent years, it has become more common for multiple tank batteries, sometimes containing different hydrocarbon liquids, to be manifolded at the emissions line and routed to a common control device. To further clarify the concept of manifolded within the definition of "storage tank," the Commission revises the definition of storage tank to specify that a tank battery must be manifolded by liquid line, and not just be gas or emission line. This revision is in keeping with the rationale that a single tank could have been used to capture liquids in place of multiple small tanks in a battery. The Commission's definition differs from EPA's definition of "storage vessel" and the description of an affected storage vessel facility in NSPS OOOO. EPA considers each individual tank, even those in a battery manifolded by liquid line, to be a storage vessel for comparison against the applicability threshold. However, this approach differs from how Colorado has required emissions reporting and permitting for storage tanks, and the Commission intends to maintain that distinction. The Commission, therefore, deletes the previously used definition of "atmospheric condensate storage tank" and creates a new definition of "storage tank" which expands upon the definition of storage vessel in NSPS OOOO to include storage vessels manifolded together by liquid line.

"Well production facilities" are subject to leak detection and maintenance requirements. This definition is meant to include all of the emission points, as well as any other equipment and associated piping and components, located at the same stationary source (a defined term specific to permitting).

Good Air Pollution Control Practices (Section XVII.B.)

The Commission intends that all oil and gas sources, including those below the control threshold or even below Regulation Number 3 APEN and permitting thresholds, be required to adhere to good general air pollution control practices. Examples of what the Commission considers to be a good air pollution control practice include, but are not limited to:

- Keeping the thief hatch, pressure relief valve, or other access point on storage tanks closed and properly sealed during normal operation, unless being actively used during periods of maintenance or liquids loadout from the storage tank;
- Inspecting and repairing seals on their hatches, access points, or other openings of storage tanks;
- Initiating timely action to address leaks or unpermitted emissions; and
- Maintaining equipment and facility in good operating condition.

Controls for Storage Tanks Over 6 tpy (Section XVII.C.)

EPA established a six (6) tpy VOC threshold for applying storage vessel controls. This threshold differs from Regulation Number 7, Section XVII. in that it applies to individual tanks on a controlled actual emissions basis. In contrast, Colorado uses the sum total emissions from a tank battery, where multiple tanks are manifolded together, on an uncontrolled actual emissions basis for reporting, permitting, and

control requirements. This means that the EPA's six (6) tpy threshold on a controlled actual emissions basis applies to individual tanks having the equivalent of one hundred and twenty (120) tpy VOC on an uncontrolled actual basis. Thus, more storage tanks are regulated under Regulation Number 7, Section XVII. than under NSPS OOOO.

The Commission intends that under Regulation Number 7, Section XVII., air pollution control devices can be removed if the following conditions are met: (1) storage tank (including manifolded tanks) emissions are below the uncontrolled actual six (6) tpy threshold, on a rolling twelve month basis and (2) controls are not required by other applicable requirements. Conversely, if storage tank emissions increase above the six (6) tpy threshold, control equipment must be installed within sixty (60) days of discovery of the increase.

Control Efficiency (Section XVII.C.)

The Commission expands the 95% control efficiency requirement to apply to storage tanks containing any hydrocarbon liquids (including condensate, crude oil, produced water, and intermediate hydrocarbon liquids), for consistency with NSPS OOOO. Produced water and crude oil storage tanks, which in years past were thought to have insignificant emissions, can instead by significant sources of emissions. This rule change is also a result, in part, of the removal of the APEN exemption in 2008 for tanks containing crude oil and less than 1% crude. The Commission intends that the air pollution control equipment achieve an average hydrocarbon control efficiency of at least 95%, and if a combustion device is used, it must have a design destruction efficiency of at least 98%. The Commission recognizes and expects that most flares can control hydrocarbon emissions by 98% or more than properly operated.

Venting vs. Leaking (Sections XVII.B., XVII.C., and XVII.F.)

The Commission believes that emissions caused by over pressurization of oil and gas equipment are foreseeable, are not adequately addressed by NSPS OOOO, and should be addressed in Colorado specific regulations. Venting includes emissions from equipment such as a storage tank at the thief hatch, pressure relief valve, or other access point. Access points are not limited to points of entry of liquids or gas into the storage tank, but include any route from which emissions can escape. However, there are limited circumstances which should not be considered venting, such as where storage tanks emit in emergency situations, during maintenance, gauging, or where necessary to ensure the safety of personnel and equipment. For example, an unplanned third party outage resulting in increased pressure along the system may be the type of malfunction or scenario where venting may be necessary for safety purposes. Inadequate design of a storage tank emissions capture system is not a legitimate reason for venting. The Commission intends that the burden remain on the owner/operator to demonstrate that an emission should not be considered venting as provided in Section XVII.C.2.

The Commission further intends that the malfunction affirmative defense in the Common Provisions regulation continue to be available to operators, provided that the operators demonstrate that the elements of the malfunction affirmative defense have been met. The Commission recognizes that pressure release valves and other devices are meant to operate as safety devices, and not as emission

devices. Nothing in this revision is intended to increase risk or compromise safety of personnel and equipment. The Commission recognizes that venting for safety purposes may occur due to sudden, unavoidable equipment failures or surges beyond normal or usual activities that could not have been reasonably foreseeable, avoided, or planned.

In contrast with venting, leaking as used in Section XVII.F. more specifically relates to unintended emissions from components at well production facilities and compressor stations. Identification and repair of leaks in accordance with these revisions benefits the public, the environment, and the oil and gas industry. The Commission has determined that leaks discovered pursuant to the detection methods specified in Section XVII.F. shall not be subject to enforcement by the Division under certain circumstances. For example, if an operator has identified a leak and is in the process of timely and properly addressing the leak in accordance with these revisions, the Division should afford the operator the opportunity to fix the leak absent enforcement. However, by this provision, the Commission does not intend to exempt owners and operators from their obligation to operate without venting or to utilize good air pollution control practices at all times.

Storage Tank Emission Management System (STEM) Plan, Monitoring, and Recordkeeping (Section XVII.C.)

All owners and operators of any storage tank not containing only stabilized liquid must develop, certify, and implement a STEM plan designed, in part, to ensure compliance with the "without venting" requirement of Section XVII.C., among other requirements. Through STEM, owners and operators must evaluate and employ appropriate control technologies and monitoring, maintenance, and operational practices, to avoid venting of emissions from storage tanks. The Commission intends that sources have flexibility in the development of individualized STEM plans. STEM plans may be developed on an individual basis for each storage tank or may be developed for a swath of similarly designed or sized tanks. However, upon request, the owner or operator must be able to identify to the Division what STEM plan applies to a storage tank and make that plan available for review.

Owners and operators of storage tanks containing only stabilized liquids are not required to develop and implement a STEM plan. However, these tanks must still comply with applicable control, capture, monitoring, and recordkeeping requirements.

For purposes of clarification, the STEM plan is intended to include the following elements:

- A monitoring strategy with a minimum of the applicable inspection frequency and methodology;
- An identification of the personnel conducting the monitoring, and any training program, materials, or training schedule for such personnel. This element does not require training, but ensures that any training by documented to permit the operator to demonstrate the quality and achievements of its STEM plan;

- The calibration methodology and schedule for emission detection equipment used in the monitoring;
- An analysis of the engineering design of the storage tank and air pollution control equipment, and where applicable, the technological or operational methods employed to preventing venting;
- An identification of the procedures to be employed to evaluate ongoing capture performance after implementation of the STEM plan;
- A procedures to update the STEM plan when capture performance is not adequate, the STEM design is not operating properly, when otherwise desired by the owner or operator, or when required by the Division; and
- The certification made by the appropriate personnel with actual knowledge of the STEM design for each storage tank.

Monitoring for storage tanks must be conducted utilizing an Approved Instrument Based Monitoring Method, on a frequency schedule that is tied to an emissions from the tank. In addition to any applicable Approve Instrument Based Monitoring Method, the Commission intends that all owners or operators of a storage tank (whether or not it contains stabilized liquids) conduct applicable audio, visual, olfactory ("AVO") monitoring. AVO inspection is not required to occur at the same time as loadout. Instead, loadout triggers the requirement for AVO inspection, and indicates the frequency with which AVO inspection is required.

Documentation of the STEM plan should be maintained by the owner or operator for the life of the storage tank, while records of STEM monitoring only need to be retained for a period of two years. Upon sale or transfer of ownership of a storage tank, the relevant documentation and records should be transferred with the ownership. Owners and operators are encouraged to reevaluate any existing STEM plan for the storage tank upon purchase or acquisition of the storage tank.

Glycol dehydrators (Section XVII.D.)

The Commission expanded the state-wide control requirements for glycol natural gas dehydrators. Currently, any glycol natural gas dehydrator with uncontrolled actual VOC emissions of two tons per year or greater that is located at a facility where the sum of uncontrolled actual VOC emissions from all of the dehydrators at the facility is greater than fifteen tpy must be equipped with a control device that reduces emissions by at least 90%. This revision requires that all existing dehydrators with uncontrolled actual emissions of six (6) tpy or greater VOC must be controlled with air pollution control equipment achieving at least 95% reduction. This revision also provides that existing dehydrator with uncontrolled actual emissions of two (2) tpy or greater VOC must be controlled if they are located within 1,320 feet of a building unit or designated outside activity area. The definitions for building unit and designated outside activity area are taken from COGCC regulations. Finally, this revision requires that all new dehydrators with uncontrolled actual emissions of two (2) tpy or greater VOC must be controlled. The

Commission intends that the air pollution control equipment achieves an average hydrocarbon control efficiency of at least 95%, and if a combustion device is uses, it must have a design destruction efficiency of at least 98%. The Commission recognizes and expects that most flares can control hydrocarbon emissions by 98% or more when properly operated.

Leak Detection and Repair Requirements (Section XVII.F.)

The Commission believes the detection and timely repair of leaks is important in the efforts to reduce hydrocarbon emissions. The use of appropriate inspection instruments and methods, such as IR cameras, enhances the detection and reduction of emissions. STEM targets venting from storage tanks, while the detection and repair program more broadly target leaks from components at compressor stations and well production facilities, even if they do not include storage tanks. The use of an Approved Instrument Based Monitoring Method as it relates to leak detection and repair frequency is generally intended to complement the STEM monitoring schedule. The Commission has created a phased schedule and tiered approach for leak detection and repair that is based on emissions, recognizing that smaller operators and facilities may need or want additional time to comply and may have lower emissions. Owner and operators have flexibility in how to meet the leak detection and repair requirements, including utilizing their own equipment and personnel or hiring a third party contractor.

The Commission has defined a leak in a manner that is dependent on the monitoring methodology used in detection. Leak detection methodologies have varied abilities to identify emission quantity and chemical makeup. EPA Reference Method 21, for example, detects and quantifies hydrocarbon emission concentration, but does not speciate hydrocarbons (e.g., methane from other hydrocarbons) or identifies the emission rate. IR cameras are becoming much more prevalent as a more affordable, time-saving, and user-friendly tool, but they also do not speciate hydrocarbons or quantify the emission concentration. The Commission provides owners and operators flexibility in choosing instrument based detection methodology.

If Method 21 is utilized, the Commission has set the threshold at which component leaks must be repaired at 2,000 parts per million ("ppm") hydrocarbons for existing compressor stations and 500 ppm for new (constructed after May 1, 2014) compressor stations and new and existing well production facilities. Where IR camera or AVO monitoring is used, a leak is any detectable emission not associated with normal equipment operation. These values were determined based in part on a review of current federal or state leak detection and repair requirements for natural gas processing plants, refineries, and other oil and gas sources. Leak detection values have decreased over time, in recognition of improved technologies and business practices. NSPS OOOO establishes leak detection at natural gas processing component type. Prior to NSPS OOOO, leaks were identified in other New Source Performance Standards (NSPS KKK and NSPS VVa) at 10,000 ppm. In addition, California, Wyoming, and Pennsylvania have varying leak detection and repair requirements and approaches to defining a leak. Some California air quality districts generally define a minor leak as between 1,000 and 10,000 ppm. Wyoming does not have a numerical limit. Pennsylvania essentially defines a leak at a well pad as anything with detectable emissions utilizing Method 21, as more than 2.5% methane or 500 ppm VOC, or no visible leaks using an

IR camera. Upon consideration of all of the evidence presented, the Commission chose to define component leak at the foregoing thresholds.

The Commission anticipates that many operators will choose to utilize IR cameras, in light of their relative ease of use and increased reliance by both by industry and regulators within Colorado and across the country. The Commission expects that leaks that are not located specifically at a component will be addressed and repaired, in accordance with the general requirements to minimize emissions and employ good air pollution control practices.

The Commission expects that in most instances the leak detection and repair requirements of this regulation will apply in lieu of leak detection and repair requirements in existing permits. The Commission recognizes that leak detection and repair requirements in a few state permits may be federally enforceable, and this state-only regulation cannot supersede federal requirements. The Commission expects the Division and operators to work cooperatively on the efficient implementation of leak detection and repair requirements, in those rare instances where there may be duplicative or competing requirements.

Well Maintenance and Unloading (Section XVII.H.)

Over time, liquids build up inside a well and reduce flow out of the well. These liquids can slow and even block gas flow in wet gas wells and are removed during a well blowdown, also called liquids unloading. As a result of recent information, EPA has significantly increased their emission factor for liquids unloading. The uncontrolled emission factor is based upon fluid equilibrium calculations used to estimate the amount of gas needed to blow down a column of fluids blocking a well and Natural Gas STAR partner data on the amount of additional venting after a blowdown. Similar to the issues with well completion emissions, considerable uncertainty for liquid unloading emissions arises from the limited data sources used and the applicability of Natural Gas STAR program activities to calculate industry baseline emissions. This is especially important as liquid unloading is estimated to comprise 33% of the uncontrolled methane emissions from the natural gas industry in the latest greenhouse gas inventory. EPA's Natural Gas STAR program advocates the use of a plunger lift system to reduce the need for liquids unloading, and indicates that such systems may pay for themselves in about one year. The Commission has determined that the use of technologies and practices to minimize venting, including plunger lift systems, are available and economically feasible, and encourages their use in Colorado.

Pneumatic Controllers (Section XVIII.)

The Commission recognized in a December 2008 rulemaking that pneumatic devices are a significant source of emissions. In addition, a 2013 University of Texas study concluded that methane emissions from pneumatics are higher than EPA previously estimated. Therefore, expanding the current low-bleed pneumatic device requirements statewide and further reducing emissions is appropriate and cost-effective. While the use of low-bleed pneumatics will result in a significant reduction of VOC and methane emissions from Colorado oil and gas facilities, no-bleed pneumatic controllers are currently commercially available to further reduce emissions from these sources. However, because these devices can only be used at facilities with adequate electric power, and given the high cost of electrifying

a facility, the Commission is requiring the use of no-bleed pneumatics at facilities that are connected to the electric grid and using electricity to power equipment, but only where technically and economically feasible.

ADDITIONAL CONSIDERATIONS

In accordance with C.R.S. §§ 25-7-105.1 and 25-7-133(3) the Commission states the rules in Section XVII. and XVIII. of Regulation Number 7 adopted in this rulemaking are state-only requirements and are not intended as additions or revisions to be incorporated into Colorado's SIP at this time.

In accordance with C.R.S. § 25-7-110.5(5)(b), the Commission determines:

I. The revisions to Regulation Number 7 address hydrocarbon emissions from oil and gas facilities, including well production facilities and compressor stations. The majority of sources subject to the revised rules will not also be subject to NSPS OOOO or other federal law for such emissions. One goal of the revisions is to address individual sources below NSPS OOOO thresholds, yet that collectively contribute significantly to ozone formation in Colorado. Additionally, it is the Commission's determination that the venting of emissions from storage tanks at oil and gas facilities, caused primarily by over pressurization, is not adequately addressed under NSPS OOOO and therefore warrants Colorado-specific regulations. Moreover, leaks or fugitive emissions of hydrocarbons, such as VOCs and methane, particularly from well production facilities and compressor stations, are not adequately addressed under NSPS OOOO. Thus, Colorado specific regulations are appropriate. Finally, some very large sources (e.g. storage vessels emitting 120 tpy uncontrolled VOC) will be subject to both the revised rules and NSPS OOOO, including the reporting and monitoring requirements.

   In addition to NSPS OOOO, several other federal NSPS, as well as National Emission Standards for Hazardous Air Pollutants ("NESHAP") that apply Maximum Achievable Control Technologies ("MACT") may apply to the tanks, dehydrators, leaking components, and pneumatic devices at oil and gas facilities subject to these revisions. These include, but are not limited to, NSPS Kb and NSPS KKK (which incorporate NSPS VV or VVa) and NESHAP HH and HHH. However, the Regulation Number 7 revisions apply on a broader basis to more tanks, dehydrators, leaking components, and pneumatic devices, and address more hydrocarbon emissions. Some examples include: tank and dehydrator control measures that apply at lower thresholds; leak detection and repair requirements applicable to components beyond gas processing plants; and pneumatic device provisions that require the use of lower emitting devices.

II. NSPS OOOO is primarily technology-based in that it largely prescribes the use of specific technologies in order to comply. EPA has provided some flexibility by allowing a storage vessel to avoid being subject to NSPS OOOO if the storage vessel is subject to any state, federal, or local requirement that brings the storage vessel's emissions below the NSPS OOOO threshold (greater than or equal to 6 tpy controlled actual VOCs). The

Commission chose to set the revised Regulation Number 7 controls at 6 tpy on an uncontrolled actual emissions basis, and therefore provide Colorado's oil and gas operators a limit for calculating the controlled PTE of their storage vessels, which may be used to avoid NSPS OOOO applicability.

III. There are no federal requirements related to the revisions to Regulation Number 7 that specifically and fully address the issues of concern to Colorado, or take into account concerns that are unique to Colorado. NSPS OOOO addresses VOC emissions and certain co-benefits of reducing such emissions, but does not address hydrocarbon emissions in the more comprehensive manner addressed by these revisions. Following these revisions, Regulation Number 7 will surpass federal requirements in several ways, including, without limitation: (a) Regulation Number 7 will apply to a broader class of tanks than NSPS OOOO; (b) Regulation Number 7 will require a leak detection and repair program for more categories and components that NSPS OOOO; and (c) Regulation Number 7 will require storage tanks with uncontrolled actual emissions equal to or greater than 6 tpy VOC to control emissions with 95% efficiency, while NSPS OOOO's threshold is 6 tpy controlled actual emissions (i.e. 120 tpy uncontrolled actual emissions). It is the Commission's determination that, given the current and projected levels of oil and gas development in Colorado, combined with the advances in technology and business practices utilized by oil and gas operators, the revisions to Regulation Number 7 are appropriate to address hydrocarbon emissions from this sector. Such emission reductions will, among other things, protect public health and the environment, address current and future ozone concerns specific to Colorado, reduce greenhouse gas emissions, and ensure the maximum beneficial use of a valuable natural resource.

IV. Compliance with the control requirements in the revisions to Regulation Number 7 provide Colorado's oil and gas operators a limit for calculating the controlled potential to emit of their storage vessels, thereby allowing many of these sources to avoid regulation under NSPS OOOO. Additionally, the revisions may prevent or reduce the need for more costly retrofits at a later date. The Denver Metro/North Front Range area is currently in nonattainment with the ozone NAAQS. Other areas in the State are seeing elevated ozone levels, including areas of increasing oil and gas development. Colorado may also be required to comply with a future ozone NAAQS that is lower than the current standard. The revised rules are intended to reduce ozone levels now by utilizing controls and techniques already being used or readily available. Utilizing these controls and techniques may prevent the need for more costly retrofitting in the future by addressing ozone precursor emissions now and not waiting until after ozone levels have increased.

V. Adoption at this time allows many of Colorado's oil and gas operators to utilize the controls established in the revisions to Regulation Number 7 to avoid being subject to

NSPS OOOO storage vessel requirements. Postponement of adoption would potentially subject these sources to compliance with NSPS OOOO and then compliance with State requirements once State controls become effective.

VI. The revisions to Regulation Number 7 do not place limits on the growth of Colorado's oil and gas industry. Instead, the rules address hydrocarbon emissions from the sector to assure air quality is maintained while also allowing for continued growth of Colorado's oil and gas industry. Indeed, the oil and gas industry has already grown in Colorado while widely utilizing many of the technologies and practices set forth in these revisions.

VII. The revisions to Regulation Number 7 establish reasonably equity for oil and gas facilities subject to these rules by providing the same standards for similarly situated sources. The revisions to Regulation Number 7 were proposed after a lengthy stakeholder process. Rules of general applicability have been developed along with tiered requirements and exclusions that tailor the rules to the regulated sources within the oil and gas sector.

VIII. The oil and gas industry is a large anthropogenic stationary source of VOCs, a precursor pollutant to ozone. If the revisions to Regulation Number 7 are not adopted, other aspects of oil and gas operations or other sectors may be looked to for additional emission reductions.

IX. The majority of sources subject to the revised rules in Regulation Number 7 will not be subject to federal procedural, reporting, or monitoring requirements. Those few sources subject to both NSPS OOOO and Regulation Number 7 will be required to comply with both regulations. The procedural, reporting, and monitoring requirements of Regulation Number 7, to the extent different than federal requirements, are necessary to achieve the Commission's goals while maintaining flexibility for the operators.

X. Demonstrated technology is available to comply with the revisions to Regulation Number 7. Some of the revisions expand requirements already applicable in the 8-Hour Ozone Nonattainment Area state-wide, such as the auto-igniters and pneumatic devices. In addition, many oil and gas operators are already using the control devices and techniques intended to be used to comply with these revisions. The lead-in time provides operators time to install control devices and develop plans for compliance. Should unanticipated events occur, such as a lack of availability of control devices, the rules provide for Division approved extensions to compliance.

XI. As set forth in the Economic Impact Analysis, the revisions to Regulation Number 7 will contribute to the prevention of hydrocarbon emissions in a cost-effective manner. Significantly, the Commission expressly finds that the cost-effectiveness of the VOC emission reductions alone supports the revisions to Regulation Number 7. The

reductions of other hydrocarbon emissions such as methane add to the already cost-effective and appropriate emission reduction requirements.

XII. Alternative rules requiring differing or additional controls for oil and gas facilities could also provide reductions in hydrocarbon emissions. The Commission could adopt some or all of these proposed revisions. However, the revisions to Regulation Number 7 were proposed after a lengthy stakeholder process and provide a balanced approach, reducing emissions from the oil and gas industry while allowing the sector to continue to play a critical role in Colorado's economy and the nation's energy independence. A no action alternative would very likely only delay future reductions in hydrocarbon emissions, including ozone precursors pollutants, necessary for attaining or maintaining the ozone NAAQS in Colorado.

XIII. The Commission has taken into consideration any evidence submitted regarding the factors set forth in C.R.S. § 25-7-109(1)(b).

The incorporation by reference of NSPS OOOO in Regulation Number 6 does not affect the requirements of these revisions to Regulation Number 7. Instead, these revisions to Regulation Number 7 are designed and intended to address the differences and overlaps between NSPS OOOO and current state requirements, and to include additional emission control measures for oil and gas production and equipment. To the extent that C.R.S. § 25-7-110.8 requirements apply to this rulemaking, the Commission hereby makes the determination that:

I. These rules are based upon reasonably available, validated, reviewed, and sound scientific methodologies, and the Commission has considered all information submitted by interested parties.

II. Evidence in the record supports the finding that the rules shall result in a demonstrable reduction of hydrocarbon emissions.

III. Evidence in the record supports the finding that the rules shall being about reductions in risks to human health and the environment that justify the costs to implement and comply with the rules.

IV. The rules are the most cost-effective to achieve the necessary and desired results, provide the regulated community flexibility, and achieve the necessary reduction in air pollution.

V. The selected regulatory alternative will maximize the air quality benefits of regulation in the most cost-effective manner.

LEAK DETECTION AND REPAIR (LDAR) INSPECTION PROGRAM - ESTIMATED TRAVEL, EQUIPMENT AND LABOR COSTS

1.0 INTRODUCTION

There is economic burden for oil and gas (O&G) companies in the State of Colorado to implement leak detection and repair (LDAR) programs for their Colorado O&G facilities. Recently, a proposed amendment to Regulation 7 of the Colorado Department of Public Health and Environment (CDPHE), Air Pollution and Control Division (APCD) air regulations would lower the volatile organic compound (VOC) emissions threshold for which LDAR would be required. For this task, Boulder County requested that Terracon analyze the estimated travel time, labor and equipment costs for three typical mid-size Colorado O&G companies with multiple well production facilities (with the potential to emit 6 to 12 tons of uncontrolled VOC emissions per year per facility) and assuming that the company would self-perform its LDAR inspection program with leased monitoring equipment.

Terracon's task was to prepare geographical information system (GIS) simulations to estimate O&G company travel times, labor and equipment costs to self-perform LDAR inspections for their well production facilities in Colorado. Three "mid-sized" O&G companies (2013 statewide gas production volumes of 1.2 to 42 million MCF of gas) in Colorado were evaluated. Production values were obtained from the Colorado Oil and Gas Conservation Commission (COGCC) online database.

2.0 MODELING APPROACH

The initial modeling approach was to evaluate one worst-case scenario where an O&G company would conduct LDAR inspections for its well production facilities in both "urban" and "rural" settings. For purposes of this model, an "urban" setting includes the Denver-Julesburg (DJ) Basin north of Denver, and a "rural" setting includes the Piceance or Paradox Basins on the western slope. Additionally, the modeling approach was intended to evaluate two O&G companies in "rural" settings. However, based on our review of the COGCC database, we were unable to identify companies with well production facilities in the 6 to 12 tons per year uncontrolled VOC emissions range in only "rural" areas. Therefore, the remaining two modeling approaches included two companies with 6 to 12 ton emission well production facilities in "urban" Colorado.

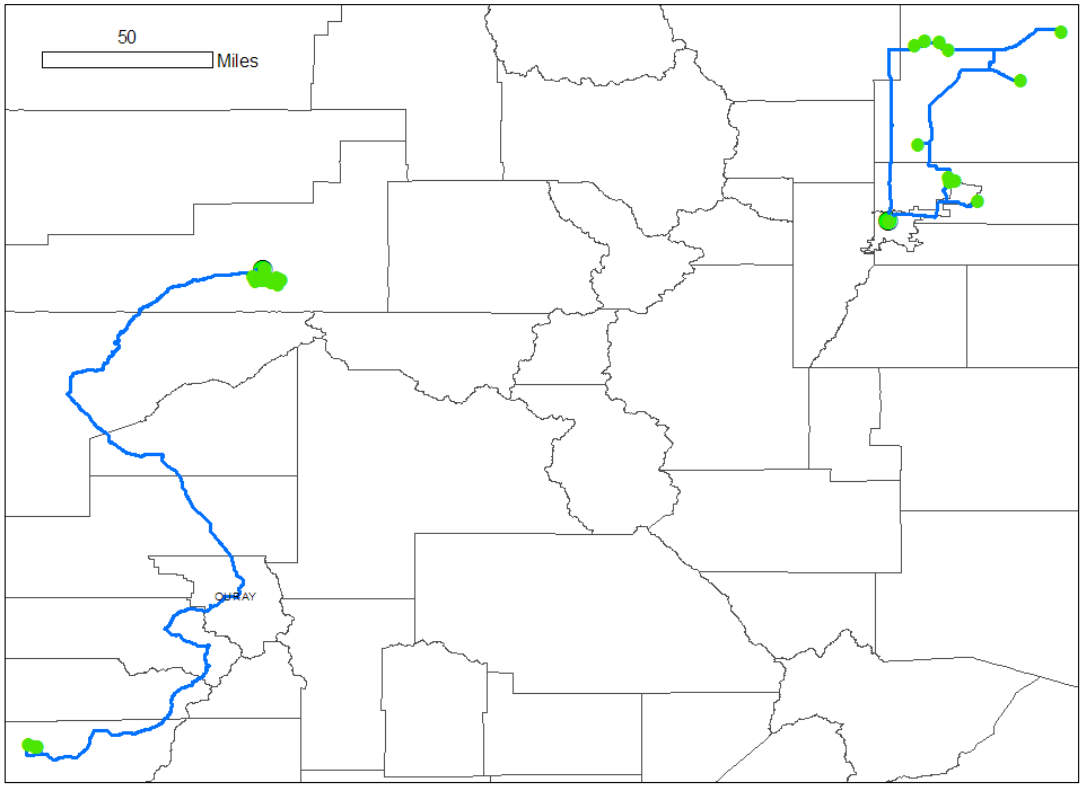
For these simulations, Terracon used ESRI's Network Analyst to compute a least-cost (least-time) path using ESRI's Detailed Streets Layer (2007) and well production facility locational information provided by CDPHE.

DRAFT

3.0 MODELING ASSUMPTIONS AND ATTRIBUTES

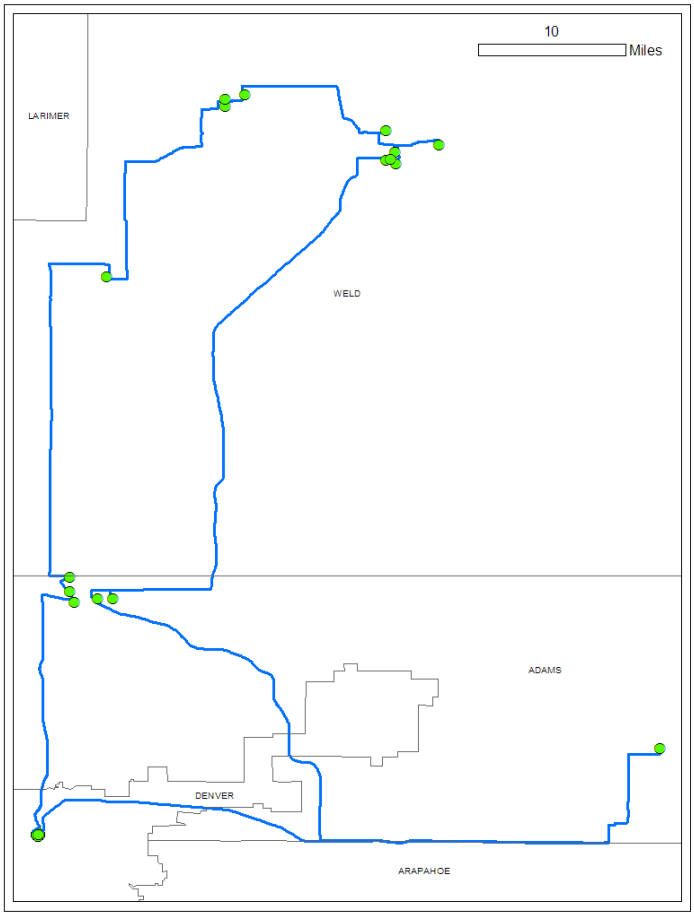
The following assumptions were made in preparing the following LDAR inspection travel time and cost estimates:

1. An LDAR inspection/monitoring loop consists of a round trip circuit to each well production facility containing equipment with uncontrolled VOC emissions ranging from 6 to 12 tons per year.
2. Each O&G operator self-performs the LDAR inspections using rented monitoring equipment, either a total vapor analyzer (TVA) or an infrared (IR) camera.
3. An average of three hours of monitoring time are required at each facility regardless of the instrument used. This time estimate is based on discussions with several LDAR vendors in Colorado.
4. One technician and one LDAR monitoring instrument is used
5. The ESRI 2007 street network is conservative for estimating distances between sites.
6. Although actual well production facility location information was provided by CDPHE, minor modifications to the latitude and/or longitude values were inputted into the GIS to preserve the anonymity of the O&G companies used for the GIS evaluation.



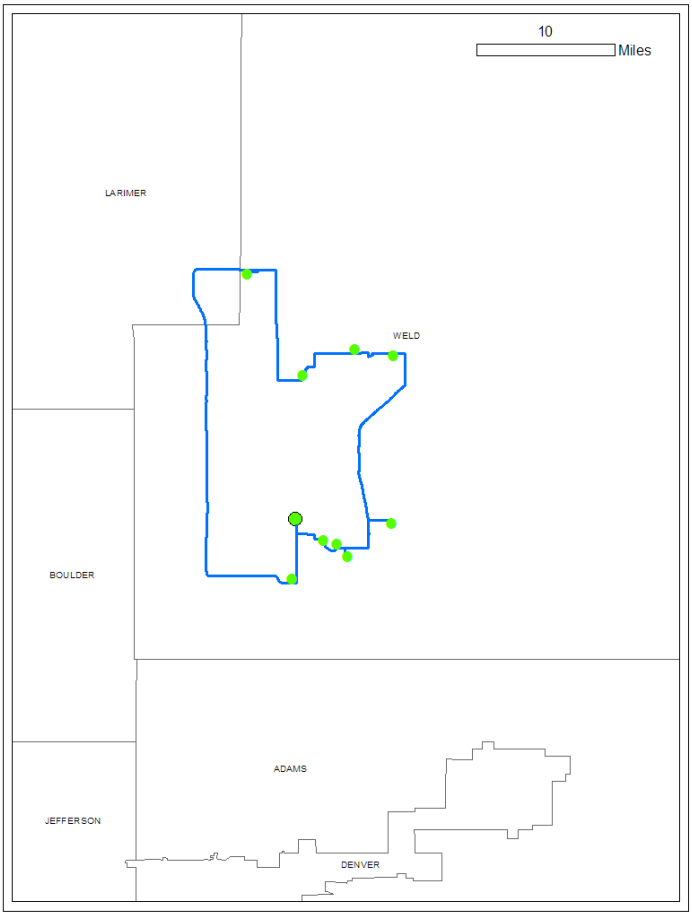
The following attributes were used to prepare ESRI's Detailed North America Street Map into a network dataset with least-cost routing capability.

Name	Usage	Units	Data Type
Length	Cost	Miles	Double
Oneway	Restriction	Unknown	Boolean
RoadClass	Descriptor	Unknown	Integer
Minutes	Cost	Minutes	Double
Hierarchy	Hierarchy	Unknown	Integer



DRAFT

Figure 1 – Optimized Travel Routes for Companies A, B and C



Company A

Company B

Company C

Map Legend

1. Green points represent well production facilities with tanks or equipment with 6 - 12 tons per year in uncontrolled VOC emissions.
2. The Blue route lines between points represent the calculated shortest distance along the road network between every facility, starting and finishing at a point of origin.
3. Company A has two loops. One loop in the DJ Basin. The second loop in the Piceance and Paradox Basins with a starting point at an office in proximity to the Basin.
4. Companies B and C each have one loop with their starting points originating near Denver.

4.0 CALCULATION OF ESTIMATED LDAR INSPECTION PROGRAM LABOR AND EQUIPMENT COSTS

The total time to complete one LDAR monitoring loop includes the travel time between well production sites and the LDAR monitoring time at each site. The total labor cost, in dollars, is the total time to complete one LDAR monitoring loop times the monitoring technician's hourly rate. The total equipment cost is the total time to complete one LDAR monitoring loop times the daily rental rate for the monitoring equipment. Table 1 (see Attachment A) provides a summary of estimated labor and equipment costs for Companies A, B and C to complete one LDAR inspection and annual LDAR inspection costs assuming biannual inspections.

4.1 Method 21 – TVA 1000B Instrument

As indicated in Table 1 (Attachment A), one-time estimated LDAR inspection costs with a TVA 1000B instrument ranged from $2,094 for Company C ("rural" setting) to $8,891 for Company A ("rural" and "urban" setting). Annual LDAR inspection costs using a TVA 1000B instrument, assuming two inspections per year, ranged from $4,188 for Company C ("rural" setting) to $17,782 for Company A ("rural" and "urban" setting).

4.2 Method 21 – IR Camera

As indicated in Table 1 (Attachment A), one-time estimated LDAR inspection costs with an IR camera ranged from $4,494 for Company C ("rural" setting) to $18,491 for Company A ("rural" and "urban" setting). Annual LDAR inspection costs using an IR camera, assuming two inspections per year, ranged from $8,988 for Company C ("rural" setting) to $36,982 for Company A ("rural" and "urban" setting). Inspection times with an IR camera were assumed to be the same as a TVA 1000B (3 hours per site). Actual inspection times may be less using an IR camera, but are not quantified in this analysis.

4.3 Cost Exceptions

The estimated costs do not include the following:

1. LDAR program development costs
2. Method 21 certification or employee LDAR training
3. Purchase of leak detection Instruments
4. Preparation of LDAR reports for submittal to CDPHE
5. Repair or replacement of faulty equipment
6. Internal auditing
7. Per diem (meals and lodging) expenses
8. Supervisor and administrative support
9. Equipment calibration or accessories

DRAFT

5.0 CONCLUSIONS

Terracon used GIS simulations to estimate travel time and costs for three O&G companies to self-perform LDAR inspections for multiple well production facilities in Colorado. The analysis only included facilities with uncontrolled VOC emissions between 6 to 12 tons per year. Three companies were evaluated; one "rural and urban" company (Company A) with facilities in the DJ, Piceance and Paradox Basins and two "urban" companies (Companies B and C) with facilities only in the DJ Basin area.

One-time estimated LDAR inspection costs with a TVA 1000B instrument ranged from $2,094 for Company C ("rural" setting) to $8,891 for Company A ("rural" and "urban" setting). Annual LDAR inspection costs using a TVA 1000B instrument, assuming two inspections per year, ranged from $4,188 for Company C ("rural" setting) to $17,782 for Company A ("rural" and "urban" setting).

One-time estimated LDAR inspection costs with an IR camera ranged from $4,494 for Company C ("rural" setting) to $18,491 for Company A ("rural" and "urban" setting). Annual LDAR inspection costs using an IR camera, assuming two inspections per year, ranged from $8,988 for Company C ("rural" setting) to $36,982 for Company A ("rural" and "urban" setting).

6.0 QUALIFICATIONS AND LIMITATIONS

GIS simulations were developed to provide Boulder County with estimates of reasonable costs that may potentially be incurred by three mid-sized O&G companies to conduct LDAR inspections at Colorado well production facilities with tanks having uncontrolled VOC emissions ranging from 6 to 12 tons per year. This is an order-of-magnitude evaluation that provides the basis for more detailed cost evaluations. Our estimates are based on metropolitan and field office origination points, use of a least-time travel route, and average labor and equipment rates provided by LDAR inspection vendors. An actual LDAR inspection cost proposal could be obtained from a vendor provided that the number and locations of facilities and number of components at each facility are specified.

Terracon has endeavored to use a reasonable cost estimate approach to derive the conceptual LDAR inspection cost estimates given the stated assumptions. Potential inspection costs that were not evaluated or estimated are stated in our assumptions section of this report. In preparing this analysis, our scope was strictly limited to an evaluation of costs associated with travel, equipment and labor for LDAR inspections, and we are not providing opinions as to the cost burden for full implementation of the proposed amendments to Regulation 7 of the APCD CDPHE air regulations.

(Unions, Couplings, Elbows and Valves)

NMED Exhibit 71

What causes some leaks to occur?

- Threaded Connections:
  - Improper selection and/or application of thread tape can lead to material degradation or inability to create a seal. Thread tapes rated for greater than operating pressure and temperature should be chosen;
  - Inadequate support to pipes can lead to vibrations during pressure variations in the system, resulting in leaks; and
  - Connections near or under the ground in the presence of water may expand unevenly resulting in leaks.

Why do leaks occur? (cont..)

- Valves, Pressure Relief Valves (PRVs), Compressors, Pumps and Meters
  - Debris in the flow system can prevent the valve from completely closing allowing gas or oil to escape from the system downstream from the valve;
  - A damaged valve seat or seal;
  - Not performing scheduled re-greasing and/or equipment inspections per manufacturer recommendations; and
  - Lack or implementation of a regular operations and maintenance (O&M) program.

Why do leaks occur? (cont..)

- Inadequate O&M program may fail to identify:
  - Damage from impact;
  - Excessive corrosion;
  - Cracked seals;
  - Metal fatigue and stress cracks from hydrogen sulfide attack; and
  - Over-pressurization of storage vessel from inoperable PRV.

Potential Benefits of Implementing an LDAR Program*

- Reducing Product Losses,
- Decreasing exposure to surrounding community, and
- Potentially reducing emission fees

* Per EPA "Leak Detection and Repair-A Best Practices Guide"

LDAR SERVICE VENDORS OVERVIEW

Prepared for

Boulder County
Colorado

NMED Exhibit 71

VENDOR CONTACT & INFORMATION COLLECTION

- Several subcontractors contacted that provide LDAR monitoring services to the oil and gas industry in Colorado.
- The objective was to approximate costs charged for LDAR monitoring.
- Of the companies contacted, four companies provided responses.

TYPICAL LDAR SERVICES VENDOR COST BREAKDOWN

VENDORS[1]	LDAR TECHNICIAN HOURLY COST[2]	LDAR SUPERVISOR HOURLY COST	EQUIPMENT CHARGES PER DAY [3]	MILEAGE CHARGE PER MILE	NOTES
Vendor 1	$ 35.00	$ 45.00	Included for Method 21	Did not provide	---
Vendor 2	$ 60.00	NA	$ 200.00 (Equipment and vehicle charge)	Did not provide	---
Vendor 3	$ 42.00	$ 46.00	Included for Method 21	$ 0.56	IR Camera - $ 750.00 per day additional charge
Vendor 4[4]	$ 48.00	$ 65.00	Included for Method 21	$ 1.00	IR Camera - $ 750.00 per day additional charge

1 Actual vendor names not provided as site specific information was not provided and to protect vendor competitive interests. Vendors have also indicated that pricing may vary based on site specific factors.

2 Technician hourly cost does not include food/per diem expenses, overtime, hotel expenses or other travel expenses.

3 Method 21 does not specify an instrument detector type, but the detector used must satisfy the performance criteria specified in the method. The detector can use catalytic oxidation, flame ionization, infrared absorption, or photoionization. Vendors 1, 2 and 4 indicated that for LDAR inspection as per Method 21, there will be no additional equipment charges. However, if IR cameras are employed, there will be additional charges. Vendors may charge additional for tag sets, wires and cables.

4 Vendor 4 indicated that if only IR camera is used for leak detection then the LDAR technician hourly cost will be $ 67.50 and Supervisor hourly cost will be $ 90.00.

Notes from Vendor discussions

- IR cameras approved for Method 21 may not be readily available because of cost.
- Due to differences in training required for IR cameras, technician charges are usually higher.
- IR cameras approved for Method 21 are typically used to detect high concentrations or larger leaks and other Method 21 equipment is typically used for lower concentrations. Some vendors indicated that they could use a combination of Method 21 equipment and IR cameras based on the size of the site and number of potential fugitive emission sources.
- Most commonly used equipment for Method 21 is Thermo Toxic Vapor (TVA) Analyzer, TVA-1000B. As per research, rental cost for the equipment averages around $ 150 per day, not including accessories or other miscellaneous parts/calibration kits.
- Most commonly used Infrared Camera was FLIR GasFindIR MW camera. As per research, rental cost for the camera averages around $750 per day.

NMED Exhibit 71

The next worksheet is the final EIA for the 6-12 TPY well production facility (WPF) changes that the LGC alternate proposal addresses.

The main difference between the LGC alternate proposal and the Division's is that WPFs in the 6-12 TPY category get inspected twice per year in the LGC alternate proposal versus once per year in the Division's.

The initial EIA cost estimates for compressor stations in the 0-12 TPY category and the WPFs in the 0-6 TPY category, also proposed by the LGC to be inspected more frequently than the Division's proposal, remain as stated within the LGC - PHS.

The costs on the following worksheet are based off of data the LGC commissioned Terracon to develop for WPFs in the 6-12 TPY uncontrolled VOC range. The assumptions and results are included as rebuttal exhibits LGC - REB EXH A1, A2, and A3. These costs supersede the values for the 6-12 TPY facilities in the initial EIA, contained within the LGC - PHS.

Economic Impact Analysis for Biannual Inspections of Well Production Facilities as Recommended by the LGC

Number of Facilities	1412	6-12 TPY threshold
Inspections per facility per year	2	
VOC per facility - uncontrolled (6-12 TPY range)	9	TPY
Cumulative VOC - uncontrolled	12708	TPY
Current VOC capture rate	71.25%	(CDPHE EIA - Table 15)
Current VOC emissions - controlled	3654	TPY
Intended VOC capture rate	95%	(CDPHE EIA - Table 15)
Intended VOC emissions (with STEM and LDAR)	635	TPY (@ 95% effectiveness)
Potential VOC emissions avoided (w/ STEM & LDAR)	3018	TPY (going from 71.25% to 95% effectiveness)
Potential WPF VOC emissions avoided (w/ LDAR)	2598	TPY (CDPHE EIA Table 26, 6-12 TPY)
Total LDAR inspection costs @ 2x/year	$1,503,547	using TVA1000B rental costs (see below)
Total LDAR inspection costs @ 2x/year	**$2,350,747**	using FLIR camera rental costs (see below)
Total LDAR inspection costs @ 2x/year	**$1,327,986**	CDPHE EIA (Table 27, 6-12 TPY); multiplied $663K by 2 to compare with proposed LGC semi-annual inspections vs annual
Total LDAR inspection costs @ 2x/year	**$6,042,560**	DGS Client Group PHS EX C (Table 12 Part I, 6-12 TPY); multiplied $3M by 2 to compare with proposed LGC semi-annual inspections vs annual
Annual LDAR inspection costs per facility @ 2x/year	$1,065	(w/ TVA 1000B)
Annual LDAR inspection costs per facility @ 2x/year	$1,665	(w/ FLIR Camera)
Annual LDAR inspection costs per facility @ 2x/year	**$1,365**	Average of TVA and FLIR
Annual LDAR inspection costs per facility @ 1x/year	$926	(CDPHE EIA w/ FLIR - Table 14)
Cost per ton of VOC reductions (w/ LDAR)	$579	(using TVA 1000B costs)
Cost per ton of VOC reductions @2x per year (w/ LDAR)	**$905**	(using FLIR camera costs)
Cost per ton of VOC reductions (LDAR)	**$512**	CDPHE EIA (Table 27, 6-12 TPY); multiplied $256 by 2 to compare with proposed LGC semi-annual inspections vs annual
Cost per ton of VOC reductions (LDAR)	**$3,702**	DGS EIA (Table 14, 6-12 TPY); multiplied $1851 (Year 1) by 2 to compare with proposed LGC semi-annual inspections vs annual

Supporting data used to estimate LDAR inspection costs:

LDAR Inspection time	3	hours (per LGC REB EXH A1)
Avg daily round trip distance	90	miles (@ 2 inspections per day)
Per mile costs	0.56	per mile rate (2014 GSA)
Avg speed	50	mph
Travel time per inspection	0.9	hours
Technician hourly rate	$50	
Additional staff costs multiplier	1.55	(CDPHE EIA - Table 20)
Overhead multiplier	1.10	(CDPHE EIA - Table 20)
Fringe multiplier	1.30	(CDPHE EIA - Table 20)
Labor costs per inspection w/travel time	$432	
Mileage costs per inspection	$25	
Total Labor and mileage costs per Inspection	$457	
Total Annual Labor and Mileage Costs	**$1,291,747**	(@ 2 inspections per year per facility)
Total number of inspections	2824	LGC @ 2x per year
Inspections per day	2	LGC estimate
Number of days	1412	to complete
TVA equipment costs (rental)	$150	per day (Terracon)
FLIR equipment costs (rental)	$750	per day (Terracon)
	$211,800	**Annual TVA Costs (LGC)**
	$1,059,000	**Annual FLIR Costs (LGC)**
	$1,503,547	**Total Annual Inspection Costs with TVA (LGC)**
	$2,350,747	**Total Annual Inspection Costs FLIR Costs (LGC)**

BEFORE THE COLORADO AIR QUALITY CONTROL COMMISSION
COLORADO DEPARTMENT OF PUBLIC HEALTH AND ENVIRONMENT

WORLDWIDE LIQUID SOLUTIONS, LLC ALTERNATIVE PROPOSALS

IN THE MATTER OF OIL & GAS RULEMAKING EFFORTS:
REGULATION NUMBER 3, PARTS A, B AND C
REGULATION NUMBER 6, PART A and
REGULATION NUMBER 7

Worldwide Liquid Solutions, LLC, by and through its attorney, Dan E. Wilson, Attorney at Law, LLC, files its Alternative Proposals in the above referenced matter.

1. In its initial Request for Party Status, Worldwide Liquid Solutions ("WLS") suggested the alternative of deleting ethane and methane from proposed Rule. 7 (5CCR 10001-9), to wit:

   a. In II. B. Exemptions, strike all proposed language for addition to the rule (specifically striking the addition of methane and ethane in Sections XVII and XVIII).

   b. Consistent with this change, change all references throughout the draft proposed rule noted as "hydrocarbons" to "volatile organic compounds". A more accurate description would be to identify them as precursors to ozone producing compounds within the definition of the rules.

   c. In XVII.C.4.c. Recordkeeping, please be informed that a properly functioning passive volatile organic compound absorption filter ("PVOCAF") will continue to capture VOCs in an upset condition until such filter is filled or replaced under a service schedule. This rule needs to be modified to reflect a release of "volatile organic compounds" released to the atmosphere, or to note repair of the "burp valve", or when the passive absorption filter is replaced.

2. Upon further review, WLS would suggest the complete incorporation of 40 CFR Part 60, subpart OOOO as revised through 9/23/2013.

   a. Such incorporation would likely be made into Rule 6, Part A. Rule 3, Parts A, B and C could be promulgated. If done, Rule 7 would be stricken in its entirety.

b. Such action would bring the Air Quality Control Commission ("AQCC") current from its partial incorporation of 40 CFR Part 60, subpart OOOO on October 12, 2012.

3. A good faith argument can be made to limit the application of proposed Rule 7 to the Denver Metropolitan/North Front Range nonattainment areas. Such an effort would require a major effort to compile the necessary data supporting analyses to support Rule 7 even in these non-attainment areas. The analyses will not likely support the addition of the de minimis, negligibly reactive compounds of ethane and methane for pollution purposes but may prove more cost effective in these locations.

Respectfully submitted this 6th day of January, 2014.

Dan E. Wilson
Dan Wilson, Attorney at Law
607 25 Road, Suite 201
Grand Junction, CO 81505

BEFORE THE COLORADO AIR QUALITY CONTROL COMMISSION
COLORADO DEPARTMENT OF PUBLIC HEALTH AND ENVIRONMENT

WORLDWIDE LIQUID SOLUTIONS, LLC – ECONOMIC IMPACT ANALYSIS STATEMENT

IN THE MATTER OF OIL & GAS RULEMAKING EFFORTS:
REGULATION NUMBER 3, PARTS A, B AND C
REGULATION NUMBER 6, PART A and
REGULATION NUMBER 7

Worldwide Liquid Solutions, LLC, by and through its attorney, Dan E. Wilson, Attorney at Law, LLC, files its Economic Impact Analysis in the above referenced matter.

A. SUMMARY

Worldwide Liquid Solutions ("WLS") participated as a stakeholder in the above referenced rulemaking process. However, despite repeated promises by the Colorado Department of Public Health and Environment ("CDPHE" or "Division") to hold technical working group sessions to evaluate emerging technical solutions, no such meetings were ever held by CDPHE, nor alternative solutions evaluated in connection with the proposed rules.

WLS manufactures a passive volatile organic compound ("VOC") absorption filter ("PVOCAF"). The filter is passive and requires no outside source for electrical power to operate. Wind turbines or solar collection devices are adequate power sources for small storage tank filters to maintain negative pressure. The filters are housed in a non-absorptive, recyclable 'short stack' which holds a filter of absorptive carbon material that captures VOC compounds as they pass up the stack.

The PVOCAF is entirely constructed of material that can be recycled into a fresh filter. A WLS vendor will recover the captured VOCs and regenerate the carbon filtering material for reuse. Development of a full scale carbon recovery program is possible with a significant percentage of participants within the oil and gas industry.

The PVOCAF offers a low cost, low energy, carbon capturing, recyclable alternative to flaring and combustion devices without creating additional, secondary pollution. However, PVOCAF will not capture ethane and methane, not currently regulated by Quad O. The inclusion of ethane and methane in the draft Colorado Rule 7 will render this advanced technology unusable in Colorado.

When compared to published data from EPA, the PVOCAF demonstrates a cost savings advantage over flares and combustion devices for VOC emissions from storage tanks in many scenarios. The cost effectiveness of the PVOCAF is extended in remote areas where there is no electrical service or where generators would be required to power a flare or combustion device.

NMED Exhibit 71

The PVOCAF offers an additional advantage over flares and combustion devices because it consumes no fuel (ethane and methane) to operate, reducing the cost of fuel and avoiding the secondary pollution of NOx, CO, methane and primarily CO2 created by these devices. Currently, EPA has set the Best System of Emission Reduction ("BSER") at 4 tpy VOC under Quad O determining that below this limit, flares and combustion devices are no longer cost effective, will create additional pollution and environmental impacts and consume too much energy to be effective. WLS is working with Wyoming, Texas, Utah, and U. S. EPA for use of the PVOCAF as an alternative to flaring. The PVOCAF may revolutionize the BSER for the oil and gas industry because it can cost effectively capture VOCs well below the current BSER limits.

B. ECONOMIC IMPACT ANALYSIS

WLS estimates that it can provide passive volatile organic compound absorption filters ("PVOCAF") for storage tanks at the initial start-up investment of $1,000 per filter and $1,100 per ton of VOC removal. This cost will include the initial potential to emit analysis, including VOC testing and gas chromatography. Actual VOC monitoring of the PVOCAF should be set at monthly to quarterly schedules depending on the initial potential to emit ("PET") determination or changes in tank usage. These estimates include maintenance, monitoring and filter replacement costs.

VOC (tpy)	PVOCAF	EPA	CDPHE
1	$2100 per ton		
2	$1600 per ton	$10,000 per ton	
3	$1433 per ton	$6900 per ton	
4	$1350 per ton	$5100 per ton	
5	$1300 per ton		
6	$1267 per ton		
7	$1243 per ton		
8	$1225 per ton		
9	$1211 per ton		
10	$1200 per ton		
11	$1191 per ton		
12	$1183 per ton		

The chart above is based upon the cost estimates provided by WLS and what has been most currently published by EPA in connection with the Quad O revisions, 78 FR 58416, at page 58429 (9/23/13). The CDPHE cost projections have not yet been submitted as part of the rulemaking process. However, it should be noted that EPA has expressed concern over CDPHE's costs being used in the current rulemaking process. See, 78 FR at page 58429.

Please keep in mind that there is no secondary pollution or fuel cost to operate the PVOCAF, so there is no corresponding BSER limit. In other words, the PVOCAF can cost

effectively capture VOCs below the 4 tpy BSER limit established by EPA for flares and combustion devices.

WLS submits that the PVOCAF is a cost effective alternative to flares and combustion devices that should be utilized to capture VOCs in Colorado. The device has the potential to reduce VOC emissions below the current EPA BSER limit of 4 tpy VOC and could cost effectively be used in areas where VOC capture needs to occur below these limits, such as to protect residents in close proximity to VOC emissions or help achieve VOC compliance in non-attainment areas.

Respectfully submitted this 30th day of January, 2014.

NMED Exhibit 72

1. Executive Summary

Our Nation's Energy Future Coalition (ONE Future) [1] commissioned ICF to conduct this analysis of the marginal abatement cost (MAC) of various methane emission abatement technologies and work practices for the natural gas industry. The goal of this MAC analysis is threefold: (1) to identify the emission sources that provide the greatest opportunity for methane emission reduction from the natural gas system, (2) to develop a comprehensive listing of known emission abatement technologies for each of the identified emission sources, and (3) to calculate the cost of deploying each emission abatement technology and to develop a MAC curve for these emission reductions. The findings of this report will be utilized by ONE Future to develop segment-specific methane emission reduction goals that, when combined, will achieve a collective 1% (or less) emission target in the most cost-effective manner. This report will also assist each ONE Future member to customize its abatement strategy to fit its particular emission profile.

This analysis is based on a MAC curve model developed by ICF for the Environmental Defense Fund (EDF) in 2014. The current study incorporates more recent information on emissions and equipment costs and modified assumptions provided by the One Future participants. Appendix A summarizes and compares the key assumptions and results for the two studies. The study utilized the following approach:

- The baseline for methane emissions from the natural gas sector was established as the U.S. EPA Inventory of Greenhouse Gas Emissions for 2012 to match the baseline year employed in the U.S. methane emissions reduction goals.[2]
- A review of existing literature and additional analysis was conducted to identify the largest emission reduction opportunities; a cost-benefit estimate for each of the mitigation technologies was calculated.
- Interviews with One Future members, industry, technology innovators, and equipment vendors were conducted with a specific focus on identifying additional mitigation options and characterizing the cost and performance of the options.
- Information from the analysis was used to develop MAC curves for the methane reduction opportunities.

The analysis estimates reductions for each segment of the natural gas industry. The MAC analysis identified reductions totaling 88.3 Bcf/year of methane at a total annualized cost of $296 million or $3.35/Mcf of methane reduced for all segments except the distribution segment. The reductions for the distribution segment were calculated separately, and total 8.9 Bcf. An additional 12.3 Bcf of reductions were projected for the application of reduced emission completions for gas wells with hydraulic

[1] ONE Future is a coalition of companies that aims to achieve an average rate of methane emissions across the entire natural gas value chain that is one percent or less of total natural gas production.

[2] This analysis was completed prior to the updates to the methodologies incorporated into the U.S. Greenhouse Gas Inventory (GHGI) on April, 15, 2016.

NMED Exhibit 72

fracturing. This was not required in 2012 but is now legally required, and was therefore included as a reduction from the baseline but not as part of the MAC analysis. This brings the total industry-wide methane reduction to 109.5 Bcf from the 2012 baseline emissions.

NMED Exhibit 72

2. Approach and Methodology

2.1. Overview of Methodology

This section provides an overview of the methodology applied for this study. The major steps were:

- **Establish the 2012 Baseline for analysis** – the analysis started with the U.S. EPA inventory of methane emissions in the EPA Inventory of U.S. GHG Emissions (GHGI) published in April 2014 with data for 2012[3]. The most recent edition of the Inventory, released in April 2016, includes significant revisions, which are not included in this analysis. ICF expects future inventories will be updated to incorporate additional emissions and activity data collected from activities include:
  - Greenhouse Gas Reporting Program (GHGRP) inventory data collected in 2016 from companies in the gathering and boosting segment;
  - Information Collection Request (ICR)[4] for additional regulations, which will require operators to provide key activity and emissions data; and
  - Private and Government-sponsored scientific studies, including several multi-million dollar research projects focused on methane emissions from oil and gas operations sponsored by Department of Energy[5]

  Potential future updates to the GHGI may require a future update of this analysis to include those changes.

- **Identification of major sources and key mitigation options** – the next step was to identify the largest emitting sources in the inventory and the mitigation options that would be most effective and cost-effective for these sources.
- **Characterization of emission reduction technologies** – a key part of the study was to review and update information on the cost and performance of the selected mitigation technologies. Information was gathered from ONE Future Members, equipment manufacturers, other oil and gas companies, and other knowledgeable parties.
- **Development of the marginal abatement cost curves** – the technology information was applied to the emissions inventory to calculate the potential emission reduction and cost. The results were displayed in a series of marginal abatement cost curves.

The analysis calculates the annualized cost of emission reductions based on the capital and operating costs of the emission reduction technologies and the value of recovered gas in the production segment. This annualized cost is divided by the emission reductions to calculate the primary figure of merit -

[3] U.S. EPA, "Inventory of U.S. Greenhouse Gas Emissions And Sinks: 1990-2012", http://www.epa.gov/climatechange/ghgemissions/usinventoryreport.html
[4] https://www3.epa.gov/airquality/oilandgas/methane.html
[5] http://www.netl.doe.gov/research/oil-and-gas/project-summaries/natural-gas-resources

NMED Exhibit 72

$/unit of emissions reduced. This is expressed as $/Mcf methane reduced, $/tonne methane reduced, or $/tonne CO_2 equivalent reduced. This figure of merit is consistent with the format used in other pollution control programs (SO_2, NO_x, VOC, etc.), which typically focus on $/ton of pollutant reduced.

In the 2014 report for EDF, ICF concluded that the weighted average methane reduction cost was $0.66/Mcf of methane reduced. The annual costs were also presented as normalized by gross natural gas production, dividing the annual cost by total U.S. natural gas production. Since methane emissions are only a few percent of total production, this value is very small – less than $0.01/Mcf of gas produced in the U.S., depending on the specific assumptions. However this second metric is different from the approach typically used by industry and regulators to characterize the cost-effectiveness of emission reduction technologies and should not be compared to a $/unit of methane reduced. In addition, the ONE Future sponsor companies reported that the metric that focuses on methane reduced is more useful to companies operating in different segments in assessing technologies and opportunities at new and existing facilities within each segment. Therefore, this report employs only the more commonly used weighted annual cost per methane reduced.

2.2. Identification of Targeted Emission Sources

Table 2-1 summarizes the largest emitting source categories for the oil and gas sectors by major source category in the EPA inventory for 2012. Due to the lack of specific data on the emission sources for offshore oil and gas production, the study focused on onshore production and offshore emissions are excluded from this list. The top 24 source categories account for nearly 90% of the total 2012 onshore methane emissions of 353 Bcf and were the primary focus of this analysis. The remaining 100+ categories each account for 1% or less of the total emissions. Although there are demonstrated methane reduction technologies that can provide cost-effective reductions for many of these smaller sources, these source categories were not included in this analysis due to their relative minor contribution to the overall emissions and reduction opportunity. In addition, the 2014 inventory for 2012 has a limited representation[6] of the gathering segment and therefore the analysis likely does not represent the full potential reductions that could be achieved from this segment.

The distribution of emission sources is shown in Table 2-1 and Figure 2-1. Fugitive emissions are the largest emission source category overall across the oil and natural gas systems. Vented emissions from pneumatic controllers and pumps, and venting from wet seal centrifugal compressors are some of the significant methane emissions venting sources from the natural gas industry. Completion emissions from hydraulic fracturing were a significant source at this time however have since been regulated.

NMED Exhibit 72

2.3. Selected Mitigation Technologies

The following sections describe the mitigation measures included in this analysis to address the high-emitting source categories identified in Table 2-1. The smaller sources individually were judged to have an insignificant effect on the overall emissions analysis even if cost-effective mitigation technologies were available. Much of the cost and performance data for the technologies is based on information from the EPA Natural Gas STAR program[7] but was updated and augmented with information provided by industry and equipment vendor sources consulted during the EDF study. Further updates and information were provided by ONE Future members for this study.

This analysis attempts to define reasonable estimates of average cost and performance based on the available data and experiences of operators, including ONE Future members. The costs and performance of an actual individual project may not be directly comparable to the averages employed in this analysis because implementation costs and technology effectiveness are highly site-specific. Some technologies, like the efficiency of plunger-lifts for liquids unloading to reduce emissions, depend on the operating conditions of the well. Further, certain low-production or lower utilized compressor stations may have lower emissions. Costs for specific actual facilities could be higher or lower than the averages used in this analysis.

Several of the sources identified in Table 2-1 do not have commercially available mitigation technologies (e.g., engine exhaust) or are not currently cost-effective (e.g. cast iron main replacement). ICF analyzed various mitigation options for each of the 24 sources based on cost, reduction potential and market-penetration and considered 16 sources and mitigation measures for further modeling and evaluation.

Table 2-2 summarizes the mitigation measures applied in the analysis for each of the 16 major emission sources.

Table 2-2 - Summary of Mitigation Measures Modeled

Source	Mitigation Measure
Condensate Tanks w/o Control Devices	Install vapor recovery units
Wellhead Oil Tanks w/o Control Devices	Install vapor recovery units
Liquids Unloading - Wells w/o Plunger Lifts	Install plunger lift systems in gas wells
High Bleed Pneumatic Devices	Early replacement of high-bleed devices with low-bleed devices
Intermittent Bleed Pneumatic Devices	Replace with instrument air systems – intermittent
Chemical Injection Pumps	Replace pneumatic chemical injection pumps with Solar electric pumps
Kimray Pumps	Replace Kimray pumps with electric pumps

[7] http://www.epa.gov/gasstar/

NMED Exhibit 72

Source	Mitigation Measure
Pipeline Venting	Pipeline pump-down before maintenance
Centrifugal Compressors (wet seals)	Wet seal gas capture or dry seals
Transmission Station Venting	Redesign blowdown systems and alter ESD practice
Gas Well Completions - with Fracturing	Install flares – portable
Reciprocating Compressor Rod Packing	Replacement of compressor rod packing systems
Reciprocating Compressor Fugitives[8]	Leak detection and repair (LDAR)[9]
Compressor Station Fugitives[10]	Leak detection and repair (LDAR)
Well Fugitives	Leak detection and repair (LDAR)
Gathering Station Fugitives	Leak detection and repair (LDAR)

[8] Includes blowdown and unit isolation valves, connectors, other valves, meters, open-ended lines, and PRVs that are associated with the compressors.

[9] LDAR here is used generically to mean a wide range of leak detection, inspection, and repair activities.

[10] Includes valves, connectors, meters, open-ended lines, and pressure reducing valves (PRVs) that are located throughout the station and not associated with the compressors.

NMED Exhibit 72

Table 2-3 summarizes the key characteristics (i.e. capital costs, operating costs and reduction efficiency) of the 16 measures modeled. (The assumptions and analytical approach for LDAR are addressed further below.) The costs are for U.S. Gulf Coast and are adjusted by regional cost factors in the MAC curve analysis in Section 3. The sources and derivation of these values are listed in Appendix B. Table 2-4 shows the baseline cost effectiveness ($/Mcf, tonnes, or CO_2e of methane removed) for each measure modeled with and without credit for any recovered gas. The credit applies where emission reduction measures result in gas being recovered by the company. In the production segment, gas that is recovered can be sold and therefore has an economic value. In that case, the value of recovered gas is subtracted from the annual operating costs.

In the transmission and distribution segments, rate regulation typically requires pipeline and distribution companies to pass any cost reductions, including reduced losses, along to customers, thus the companies typically cannot capture the financial benefit of recovered gas. The contractual provisions for gathering, processing, and storage are variable but the ONE Future members reported that these companies typically do not take ownership of the gas but rather are paid a fee for their service. Reduced losses could result in increased throughput and increased recovery of the fee (which is much less than the value of the gas itself) but only if the metering point is downstream of the potential gas recovery.

NMED Exhibit 72

Table 2-3 - Summary of Mitigation Measure Characteristics (Gulf-Coast Cost Basis)

Mitigation strategy	Capital Cost	Operating Cost	Percent Reduction
Early replacement of high-bleed devices with low-bleed devices	$3,000	$0	78%
Replacement of Reciprocating Compressor Rod Packing Systems	$6,600	$0	31%
Install Flares-Portable	$30,000	$6,000	98%
Install Plunger Lift Systems in Gas Wells	$20,000	$2,400	95%
Install Vapor Recovery Units	$50,636	$9,166	95%
Replace Pneumatic Chemical Injection Pumps with Solar Electric Pumps	$5,000	$75	100%
Replace Kimray Pumps with Electric Pumps	$10,000	$2,000	100%
Pipeline Pump-Down Before Maintenance	$0	$30,155	80%
Redesign Blowdown Systems and Alter ESD Practices	$15,000	$0	95%
Wet Seal Degassing Recovery System for Centrifugal Compressors	$70,000	$0	95%
Replace with Instrument Air Systems - Intermittent	$60,000	$17,770	100%

The members also reported that the metering for most of these facilities is at the entry point of the facility, thus preventing the operator from capturing the value of recovered gas. Based on this information, the value of recovered gas was included only for the production sector in this study. This is a change from the 2014 EDF study. The gas price was assumed to be $3/Mcf[11], reduced by 25% to account for royalties and fees, for a net value of $2.25/Mcf[12].

[11] EIA Short Term Energy Outlook, March 9, 2016, Henry Hub spot prices are forecast to average $3.11/MMBtu in 2017.
[12] A fuel price sensitivity analysis is included in Appendix A.

* Gas recovery credit is applied only for the Production Segment

** GWP=25

NMED Exhibit 72

The annual cost was calculated as the annual amortized capital cost over the equipment life plus annual operating costs. This was divided by annual methane reductions to calculate the cost-effectiveness without credit for recovered gas. Where gas can be recovered and monetized by the operating company, the value of that gas was subtracted from the annual cost to calculate the cost-effectiveness with credit for recovered gas. The costs shown here are the baseline costs, which are adjusted for regional cost variation in the later MAC analysis. As noted earlier, these are average costs that may not reflect site-specific conditions at individual facilities.

Fugitive emissions are the unplanned loss of methane from pipes, valves, flanges, and other types of equipment. Fugitive emissions from reciprocating compressors, compressor stations (transmission, storage, and gathering), wells, and LDC metering and regulator equipment are the largest combined emission category, accounting for over 30% of the highlighted sources. The potential size and nature of these fugitive emissions can vary widely by industry segment and even by site.

Leak Detection and Repair (LDAR) is the generic term for the process of locating and repairing these fugitive leaks. There are a variety of techniques and types of equipment that can be used to locate and quantify these fugitive emissions. The analysis of LDAR cost and effectiveness for this study is a little different from the treatment of other measures because it is largely a function of labor required for inspections and repairs.

Extensive work has been done by EPA and others to document and describe these techniques, both in the Gas STAR reference materials and in several regulatory analyses, including for the EPA's NSPS Subpart OOOO[13] and the Colorado Air Quality Control Commission Regulation Number 7 (5 CCR 1001-9)[14]. This study used both the Colorado regulatory analysis and the EPA Technical Support Document (TSD) [15] for NSPS Subpart OOOO as the basis for the analytical framework. Additional cost information was provided by ONE Future members.

The key factors in the analysis are how much time it takes an inspector to survey each facility, how many inspections are required each year, how much reduction can be achieved, and how much time is required for repairs. ICF adapted the structure (but not all of the specific inputs) of the Colorado analysis, which calculates the capital and labor cost to field a full-time inspector, including allowances for travel and record-keeping (Table 2-5). Specific cost factors were updated based on input from the ONE Future member companies. The combined hourly cost was the basis for the cost estimates. The capital cost includes a variety of leak detection and measurement equipment, a truck and the cost of a record-keeping system. These are estimated average costs and are highly variable depending on site-

NMED Exhibit 72

specific conditions and scale. In addition, the Gathering and Boosting segment is included in the Production segment in these analysis due to the design of the EPA inventory.

Table 2-5 - LDAR Hourly Cost Calculation

Labor			Capital and Initial Costs	
Inspection Staff	$86,155		FLIR Thermal Camera	$122,200
Supervision (@ 20%)	$17,231		Remote Methane Leak Detector (RMLD)	$20,000
Overhead (@10%)	$8,616		Photo Ionization Detector	$5,000
Travel (@0%)	$0		Flame Ionization Detector	$12,000
Recordkeeping (@5%)	$4,308		Hi-Flow Sampler	$21,450
Reporting (@0%)	$0		Miscellaneous	$3,000
Fringe (@50%)	$43,078		Truck	$22,000
Subtotal Costs	$159,387		Monitoring system	$14,500
			Total	$220,150
Hours/yr.	1880		Training Dollars	$6,782
Hourly Rate	$84.78		Amortized Capital+Training	$59,864
			Annual Labor	$207,203
Training Hours	80		Annual Total	$267,067
Training Dollars	$6,782			
			Total Hourly Rate	$142.06

Many analyses have used facility component counts and historical data on the time required to inspect each component to estimate facility survey times. However, the use of the infrared camera technology allows much shorter survey times[16] and the EPA and Colorado time estimates have been criticized as too long. The estimates here are based on ICF and ONE Future company experience. ICF added additional time for training relative to the Colorado analysis.

ICF then adopted the baseline emission values for wells, gathering and transmission stations, and processing stations from the EPA NSPS analysis[15]. The 2014 EDF analysis had very limited data for LDC

[16] Robinson, D, et. al., "Refinery Evaluation of Optical Imaging to Locate Fugitive Emissions". Journal of the Air & Waste Management Association. Volume 57 June 2007.

NMED Exhibit 72

programs and resulted in very high reduction costs. Since a different approach was taken for the LDC segment in this analysis (see below) LDCs were not included here.

Table 2-6 summarizes the assumptions for the overall LDAR calculation. This analysis assumes annual emission surveys for all facilities. The reduction is assumed to be a 40% reduction, consistent with the experience of ONE Future members. In addition to the surveys, the estimate includes one initial visit to each site to inventory the equipment (equivalent hours to two inspection visits for each site with cost averaged over five years) and additional visits for repairs. Gas processing plants are already subject to some LDAR requirements for conventional pollutants, which result in co-benefit methane reductions. The miscellaneous fugitive emissions for gas processing were below the size threshold for this analysis but the costs developed here for gas processing are applied to compressors in that segment.

Table 2-6 – Cost Calculation – Annual LDAR

	Well Pads	Processing	Transmission
Methane Mcf/yr[15]	3,057	5,986	3,605
% Reduction	40%	40%	40%
Reduction Mcf	1,223	2,394	1,442
Hours each Inspection (includes survey, travel, recordkeeping, review and training)	5.5	40	32
Frequency (per year)	1	1	1
Annual Inspection Cost	$781	$5,682	$4,546
Initial Set-Up	$156	$1,136	$909
Repair Labor Cost	$781	$5,682	$4,546
Total Cost/yr	$1,719	$12,501	$10,001
Recovered Gas Value*	$3,303	NA	NA
Net Cost	-$1,584	$12,501	$10,001
Cost Effectiveness ($/Mcf CH_4 reduced)	-$1.30	$5.22	$6.94

*Gas at $3/Mcf minus royalty = $2.25/Mcf

Some repairs can be made at the time of the survey, such as tightening valve packing or flanges, but others will require additional repair time. This analysis assumes repair time equivalent to one survey visit for each facility for repairs each year. The capital cost of larger repairs is not included on the assumption that these repairs would need to be made anyway and the LDAR program is simply alerting the operator to the need. This lower repair estimate takes into account that:

NMED Exhibit 72

- These are average values across facilities – not every facility will require repairs.
- These are average values over time – not every facility will need repairs every year while being monitored on a continuing basis.
- Some or all of cost of major repairs is assumed to be part of regular facility maintenance.

Replacement costs for large diameter, high pressure components are significantly greater than these average annual repair costs. The replacement frequency for large diameter, high pressure components at any individual facility cannot be accurately predicted or estimated.

The value of reduced gas losses is credited to the program for production only. These final reduction cost values were used for the analysis.

2.4. Treatment of LDC Reductions

The 2014 EDF study found that methane emission reductions from LDCs were extremely expensive, mostly due to the low baseline emissions and the high capital cost of some options, such as cast iron pipe replacement. Cast iron mains have been identified is a significant emission source, however they are primarily located in congested urban areas where replacement or repair is very expensive, reported as $1 million to $3 million per mile. This makes for a very expensive control option based purely on emission reduction. Moreover, these expenditures must be approved by state utility commissions, whose purview typically does not extend to environmental remediation of this type. That said, approximately 3% of cast iron mains are being replaced each year for safety reasons, so the emissions are gradually declining.

For this study, a separate analysis of emission reductions was developed for the LDC segment to account for reductions that will be undertaken even though they may not be cost-effective as emission control measures alone. The analysis assumed three types of activities:

- Cast iron main replacement at 3% per year
- Unprotected steel pipe replacement at 3% per year
- Miscellaneous other emission reduction measures such as: service line replacement, blowdown gas recovery, hot tapping, M&R Station upgrades, and dig-in mitigations, assumed to be 6% of the remaining emissions (excluding cast iron and unprotected steel mains) between 2012 and 2025.

Using the baseline emissions and the emission factors from the EPA 2012 inventory, these emission reductions were calculated as:

- Cast iron main replacement – 2.9 Bcf
- Unprotected steel pipe replacement – 2.5 Bcf
- Miscellaneous other emission reduction measures – 3.5 Bcf

NMED Exhibit 72

2.5. Completion Emissions from Hydraulic Fracturing

Gas well completion emissions from hydraulic fracturing were estimated at 13.1 Bcf in the 2012 inventory. These emissions were regulated during the second half of 2012 and are assumed to be controlled going forward. Therefore they are not included in the MAC analysis but are counted as a reduction of 12.3 Bcf in the overall reductions from the base year.

2.6. Source Categories Not Addressed

Several source categories with relatively large emissions were not addressed in the analysis. The sources and the reasons for their treatment are summarized below.

- **Off-shore oil and gas production** – As noted earlier, the EPA inventory provides very limited data on offshore emissions, which were not adequate to apply the methodology used for other sources. This is an area in which further analysis would probably yield additional opportunities for reduction.
- **Engine exhaust** – The exhaust from gas-burning engines and turbines contains a small amount of unburned methane from incomplete combustion of the fuel. While it is a small percentage, it is significant in aggregate. Oxidation catalyst devices are used to reduce unburned emissions of other hydrocarbons in the exhaust but they are not effective at reducing emissions of methane due to its lower reactivity. However, new catalysts are being developed, in part for natural gas vehicles, which may be applicable to these sources. This is a topic for further research and technology deployment.
- **Other sources** – There are additional cost-effective measures for methane reduction that have been identified by the EPA Gas STAR program and others. They are not included here because this report focuses only on the largest emitting sources. However, their omission should not be taken to indicate that the measures listed here are the only cost-effective methane reduction measures.
- **Gathering and Boosting** – The gathering and boosting segment is not called out as a separate segment in the 2014 edition of the EPA inventory for 2012 and therefore was not addressed as a separate source of potential reductions in this study. The 2016 edition has developed new emission factors and significantly increased the activity counts in the gathering segment, however these higher emissions and potential reductions were not included in this analysis, which was completed prior to that release. Since the GHGRP now mandates reporting of emissions data from such facilities, and with the data to be gathered by EPA pursuant to the ICR process, we expect further updates in future GHGI releases. Further, several key government-sponsored studies of emissions from gathering and boosting facilities will be published by the end of 2016. All of this data will support future updates to the methane emissions profile from this segment and available abatement potential.

NMED Exhibit 72

3. Analytical Results

3.1. Development of Emission Control Cost Curves

Section 2 identified 16 discrete control technologies and the associated costs, reduction potential, and cost-effectiveness in terms of annualized cost per ton or Mcf of methane reduced based on Gulf Coast region capital costs. In this Section 3, we model the cumulative reductions and marginal abatement costs from a 2012 U.S. methane emissions baseline for the oil and natural gas sector, employing the technology-level data generated in Section 2. Employing data from the EPA 2012 Greenhouse Gas Inventory and source/control technology data presented in Section 2, adjusted for regional cost differences, ICF computed the methane abatement potential from the natural gas sector from a 2012 baseline.

The model developed for this task includes the individual source categories for each segment of the oil and gas industry. Mitigation technologies are matched to each source or individual measure in various segments of the oil and gas value chain. The model calculates the reduction achieved for each source within each segment and calculates the cost of control based on the capital and operating costs, the equipment life, and where appropriate, the value of recovered gas. Key global input assumptions include: whether a particular segment is able to monetize the value of recovered gas, the value of gas, and the discount rate/cost of capital. As discussed above, the value of recovered gas was included only for the production segment and the gas price was assumed to be $3/Mcf minus 25% for royalties and fees, for a net value of $2.25/Mcf. A 10% discount rate was used for the analysis. These calculations include two factors that were not included in the baseline costs presented in Section 2:

- A construction cost index is used to account for regional cost differences, which averages 15% higher than the baseline Gulf Coast costs.
- The methane content is adjusted depending on whether the application is upstream or downstream in the value chain. This adjustment affects the value of recovered gas where the gas value can be monetized.

These two factors result in some of the costs in the MAC curve results presented in this chapter being higher than the baseline costs presented in Section 2. These and other key assumptions are listed in Appendix A.

Table 3-1 lists the emission reduction measures by industry segment with their reduction and cost, depicted in several formats. The total reduction is 88.3 Bcf/year of methane from the U.S. oil and gas segment at a total annualized cost of $296 million or $3.35/Mcf of methane reduced from the 2012 baseline. The reductions for the LDC segment calculated separately total 8.9 Bcf and the reductions from reduced emission well completions result in a total reduction of 109.5 Bcf of methane reduction.

NMED Exhibit 72

The results can also be presented as a Marginal Abatement Cost Curve (MAC curve), shown in Figure 3-1. This representation shows the emission reductions sorted from lowest to highest cost-of-reduction and shows the amount of emission reduction available at each cost level. The vertical axis shows the cost per unit in $/Mcf of methane reduced. A negative cost-of-reduction indicates that the measure has a positive financial return, i.e. saves money for the operator. The horizontal width of the bars shows the amount of reduction. The area within the bars is the total cost per year. The area below the horizontal axis represents savings and the area above the axis represents cost. The net sum of the two is the total net cost per year.

Figure 3-1 – Example MAC Curve

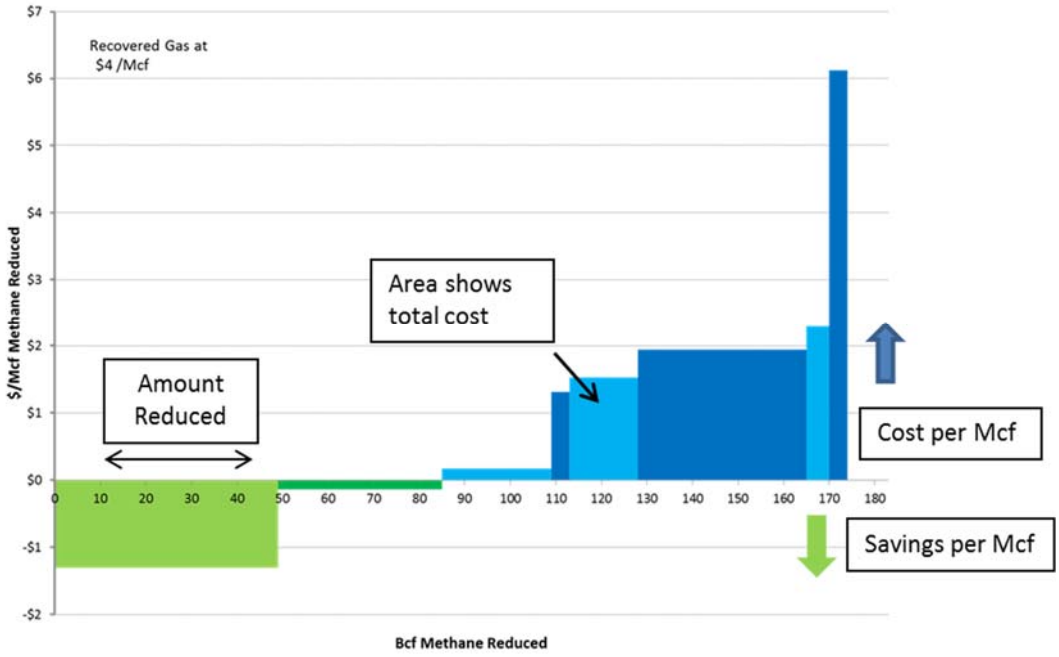

Figure 3-2 shows the reduction for each measure across all industry segments in the MAC curve format. Figure 3-3 shows the reduction in methane emissions by industry segment. The transmission and production sectors have the greatest reductions. The costs for each sector depend on the particular mitigation options available in each and their aggregate cost.

Appendix A.
Summary and Comparison of Assumptions and Results

This section summarizes and compares the key assumptions and results for this study and the 2014 EDF study. The assumptions for each study were largely specified by the clients for each. Table A-1 summarizes some of the key assumptions and results. The primary difference in total reduction volume is the lower reduction from less frequent LDAR and the smaller baseline in the current study due to a different base year and exclusion of the distribution segment.

Table A-1 - Summary of Baseline Assumptions and MAC Curve Results

	ONE Future 2016	EDF 2014
Inventory Baseline	EPA Inventory 2012 – 353 Bcf methane	EPA Inventory 2011 modified and projected to 2018 – 404 Bcf methane
Natural Gas Price	$2.25/Mcf ($3/Mcf – 25% royalty and fee payments)	$4/Mcf
LDAR Frequency and reduction	Annual – 40%	Quarterly – 60%
Gas Value Credit for Reductions	Production segment only	All except transmission and distribution
Net Annualized Cost	$296 million	$108 million
Annual reduction	88.3 Bcf methane	163 Bcf methane
Average cost of reduction	$3.35/Mcf methane reduced	$0.66/Mcf methane reduced

The primary drivers of the difference in the average cost of reduction between the two studies are the different gas price and the assumptions on which sectors can monetize the value of recovered gas. Table A-2 provides a sensitivity analysis of the gas price effect on the annualized cost of reduction per Mcf.

Table A-2 – Cost per Mcf of Methane Reduced – Gas Price Sensitivity

Gas Price	ONE Future 2016	EDF 2014
$2.25/Mcf	$3.35	
$3.00/Mcf	$3.01	$1.48
$4.00/Mcf	$2.55	$0.66
$5.00/Mcf		-$0.15

NMED Exhibit 72

Data Sources

The follow notes explain the sources and derivation of the capital cost (Capex), operating cost (Opex), and emission reduction potential of the emission reduction options assessed in this study. The primary sources are a variety of EPA sources – particularly data from the Gas STAR program, the Greenhouse Gas Reporting, and support documents from NSPS OOOO, as well as industry comments received during the 2014 EDF study, and comments from the ONE Future sponsors of this study. Each emission reduction option is discussed below:

- **Early replacement of high-bleed devices with low-bleed devices** – Capex $3,000, Opex $0, Reduction 78%. The Capex and Opex were based on Gas STAR data updated by industry review in both studies. There is no incremental Opex for pneumatic devices. The reduction estimate was based on the performance of high bleed and low bleed pneumatic devices found in two field measurement studies completed by the University of Texas [17, 18] and sponsored by industry participants and EDF.
- **Replacement of Reciprocating Compressor Rod Packing Systems –** Capex $6,600, Opex $0, Reduction 31%. The Capex was based on Gas STAR data updated by industry in both studies. There is no incremental Opex for this measure. The reduction estimate was based on an analysis by ICF that calculates the reductions due to more frequent replacement of rod packing seals relative to less frequent replacement.
- **Install Flares-Portable** – Capex $30,000, Opex $6,000, Reduction 98%. The Capex and Opex were based on industry input during both the EDF and ONE Future studies. The reduction is an EPA Gas STAR/inventory assumption of 98% flare combustion efficiency. Additional information was derived from GHGRP Subpart W.
- **Install Plunger Lift Systems in Gas Wells** – Capex - $20,000, Opex $2,400, Reduction 95%. These values were based on industry input during both studies. They do not include the value of increased production, which is typically the primary driver for liquids unloading. The cost and effectiveness of plunger lifts are highly variable depending on the well characteristics. Plunger lifts can be an effective mitigation measure for certain wells at certain times over their operating life but may not

[17] Allen, David T. et al. "Measurements of Methane Emissions at Natural Gas Production Sites in the United States." *Proceedings of the National Academy of Sciences of the United States of America* 110.44 (2013): 17768–17773.

[18] Methane Emissions from Process Equipment at Natural Gas Production Sites in the United States: Pneumatic Controllers. David T. Allen et al. Environmental Science & Technology 2015 49 (1), 633-640. DOI: 10.1021/es5040156. Available online at: http://pubs.acs.org/doi/abs/10.1021/es5040156

NMED Exhibit 72

be effective or feasible for other wells or even for the same well at a different point in its operating life. Applicability information was derived from GHGRP subpart W.

- **Install Vapor Recovery Units –** Capex $50,636, Opex $9,166, Reduction 95%. These values were based on EPA Gas STAR data, independent ICF analysis, and updates from vendors and industry commenters in both studies.
- **Replace Pneumatic Chemical Injection Pumps with Solar Electric Pumps -** Capex $5,000, Opex $75, Reduction 100%. These values were based on EPA Gas STAR data with updates from vendors and industry commenters in both studies.
- **Replace Kimray Pumps with Electric Pumps** – Capex $10,000, Opex $2,000, Reduction 100%. These values were based on EPA Gas STAR data with updates from vendors and industry commenters in both studies.
- **Pipeline Pump-Down Before Maintenance** – Capex $0, Opex $30,155, Reduction 80%. These values were based on EPA Gas STAR data with updates from vendors and industry commenters in both studies. The required equipment is typically leased so there is no Capex.
- **Redesign Blowdown Systems and Alter ESD Practices** - Capex $15,000, Opex $0, Reduction 95%. These values were based on EPA Gas STAR data with updates from vendors and industry commenters in both studies.
- **Wet Seal Degassing Recovery System for Centrifugal Compressors** – Capex $70,000, Opex $0, reduction 95%. These values were based on EPA Gas STAR data with updates from vendors and industry commenters in both studies.
- **Replace with Instrument Air Systems – Intermittent** – Capex $60,000, Opex $17,770, Reduction 100%. These values were based on EPA Gas STAR data with updates from vendors and industry commenters in both studies.
- **LDAR Costs** – The structure of the LDAR cost analysis is different from the other measures, as discussed in the body of the report. The cost analysis structure is based on the regulatory analysis for the Colorado methane rule but most of the values have been updated. The ONE Future sponsors provided extensive input on the labor and instrumentation costs. The baseline labor costs were increased and the number of measurement devices was increased from the Colorado assumptions. The time allocated for inspections was also increased relative to the 2014 EDF report based on input from the sponsors. The baseline emissions were from the EPA Technical Support Document for NSPS OOOO.

NMED Exhibit 72

Options for Removing Accumulated Fluid and Improving Flow in Gas Wells

Executive Summary

When first completed, many natural gas wells have sufficient reservoir pressure to flow formation fluids (water and liquid hydrocarbon) to the surface along with the produced gas. As gas production continues, the reservoir pressure declines, and as pressure declines, the velocity of the fluid in the well tubing decreases. Eventually, the gas velocity up the production tubing is no longer sufficient to lift liquid droplets to the surface. Liquids accumulate in the tubing, creating additional pressure drop, slowing gas velocity, and raising pressure in the reservoir surrounding the well perforations and inside the casing. As the bottom well pressure approaches reservoir shut-in pressure, gas flow stops and all liquids accumulate at the bottom of the tubing. A common approach to temporarily restore flow is to vent the well to the atmosphere (well "blowdown"), which produces substantial methane emissions. The *U.S. Inventory of Greenhouse Gas Emissions and Sinks 1990—2008* estimates 9.6 billion cubic feet (Bcf) of annual methane emissions from venting of low pressure gas wells.

At different stages in the life of a gas well, various alternatives to repeated well venting can be deployed to move accumulated liquids to the surface. These options include:

- ★ Foaming agents or surfactants
- ★ Velocity tubing
- ★ Plunger lift, operated manually or with 'smart' well automation
- ★ Downhole pumps, which include reciprocating (beam) pumps and rotating (progressive cavity) pumps.

Natural Gas STAR Partners report significant methane emission reductions and economic benefits from implementing one or more lift options to remove accumulated liquids in gas wells. Not only are vented methane emissions reduced or eliminated, but these lift techniques can provide the additional benefit of increased gas production.

Economic and Environmental Benefits

Method for Reducing Natural Gas Losses	Volume of Natural Gas Savings and Incremental Production[1] (Mcf/well/year)	Value of Natural Gas Savings and Additional Production (Mcf/well/year)			Implementation Cost[1] (2010 $/Well)	Project Payback (years)

[1]Based on results reported by Natural Gas STAR Partners
[2]Does not include incremental gas production. Includes only potential gas savings from avoided well venting.

NMED Exhibit 73 - 0001

By avoiding or reducing well blowdowns, Partners report annual methane emissions savings that range from 500 thousand cubic feet (Mcf) per well to more than 27,000 Mcf/well. The benefit of increased gas production will vary considerably among individual wells and reservoirs, but can be substantial. For example, Partners report that increased gas production following plunger lift installation yielded as much as 18,250 Mcf per well.

Technology Background

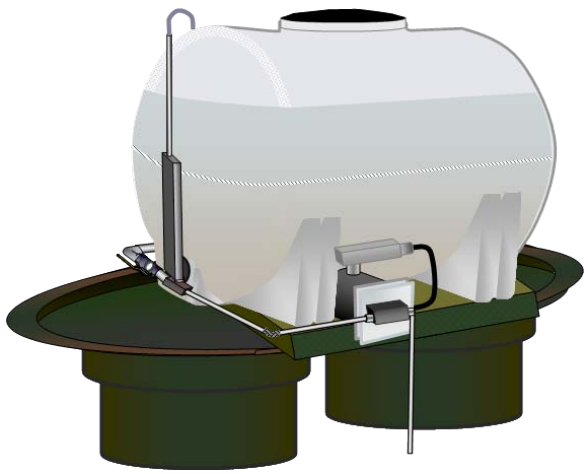
Most gas wells will have liquid loading occur at some point during the productive life of the well. When this occurs, a common course of action to improve gas flow includes:

- ★ Shutting–in the well to allow bottom hole pressure to increase,
- ★ Swabbing the well to remove accumulated fluids,
- ★ Venting the well to the atmosphere (well blowdown),
- ★ Installing an artificial lift system.

'No-Emissions' Solutions for Liquid Loading in Gas Wells:

- ★ Foaming Agents/ Surfactants
  - – Low cost/ low volume lift method
  - – Applied early in production decline, when the bottom hole pressure still generates sufficient velocity to lift liquid droplets
- ★ Velocity Tubing
  - – Low maintenance, effective for low volumes lifted
  - – Somewhat expensive to acquire and install
  - – Often deployed in combination with foaming agents
- ★ Plunger Lift
  - – Long lasting
  - – Less expense to install and operate than a pumping unit
  - – Often, plunger lift cannot produce a well to its economic limit (abandonment).
  - – Challenging to operate effectively; requires more time and expertise to manage.
- ★ Rod Pumping Units
  - – Can be deployed in applications to remove greater liquid volumes than plunger lift.

Swabbing and "blowing down" a well to temporarily restore production can vent significant methane emissions, from 80 to 1600 Mcf/year per well. The process must be repeated as fluids reaccumulate, resulting in additional methane emissions. Operators may wait until well blowdown becomes increasingly ineffective before implementing some type of artificial lift. At this point, the cumulative methane emissions from a well could be substantial.



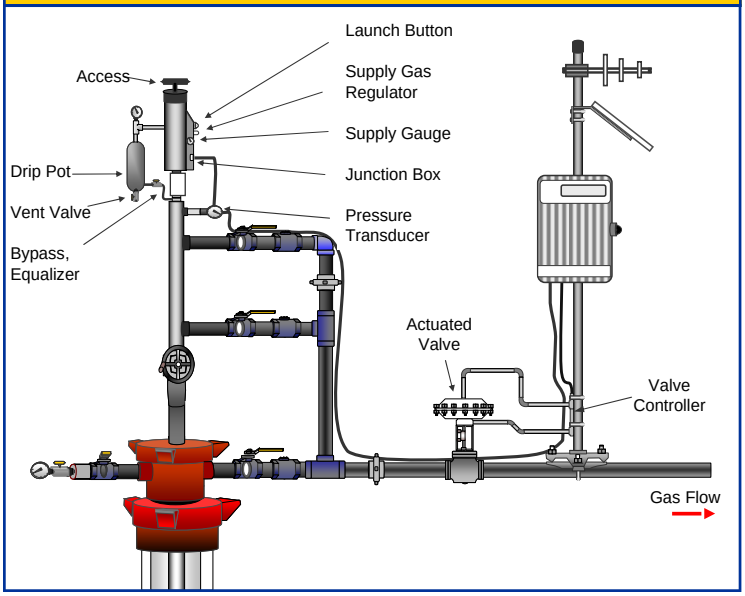
Natural Gas STAR Partners have found that applying artificial lift options early in the life of a well offers significant emissions savings and economic benefits. Each method for lifting liquid in a well has advantages and disadvantages for prolonging the economic life of a well. Total gas savings and methane emission reductions that result from reducing or eliminating well venting will vary for each well depending on flow line operating pressure, reservoir pressure, liquid volume, specific gravity and the number of blowdowns eliminated.

Fluid Removal Options for Gas Wells

Foaming Agents

The use of foam produced by surfactants can be effective for gas wells that accumulate liquid at low rates (Exhibit 1). Foam reduces the density and surface tension of the fluid column, which reduces the critical gas velocity needed to lift fluids to surface and aids liquid removal from the well. Compared to other artificial lift methods, foaming agents are one of the least costly applications for unloading gas wells. Foaming agents work best if the fluid in the well is at least 50 percent water. Surfactants are not

Exhibit 1: Liquid Foaming Agent



Source: S. Bumgardner, Advanced Resources International, inc.

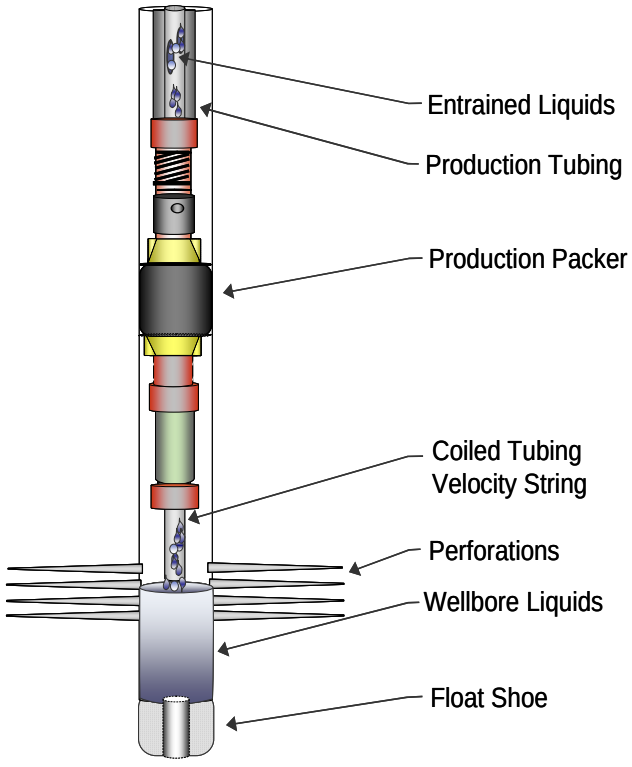
NMED Exhibit 73 - 0002

effective for natural gas liquids or liquid hydrocarbons.

Surfactants are delivered to the well as soap sticks or as a liquid injected directly into the casing-tubing annulus or down a capillary tubing string. For shallow wells, the surfactant delivery can be as simple as the operator periodically pouring surfactant down the annulus of the well through an open valve. For deep wells, a surfactant injection system requires the installation of surface equipment, as well as regular monitoring. The surface equipment includes a surfactant or 'soap' reservoir, an injection pump, a motor valve with a timer (depending on the installation design), and a power source for the pump (Exhibit 2). No equipment is required in the well, although foaming agents and velocity tubing may be more effective when used in combination.

Exhibit 2: Soap Stick Launcher with Automatic Controller

Source: S. Bumgardner, Advanced Resources International, inc.



Electric pumps can be powered by AC power where available or by solar power to charge batteries. Other pump choices include mechanical pumps that are actuated by the movement of another piece of equipment or pneumatic pumps actuated by gas pressure. Different pump types have different advantages with respect to reliability, precision, remote operation, simplicity, maintenance frequency, efficiency, and equipment compatibility.

Velocity Tubing

The velocity at which gas flows through pipe determines the capacity to lift liquids. When the gas flow velocity in a well is not sufficient to move reservoir fluids, the liquids will build up in the well tubing and eventually block gas flow from the reservoir. One option to overcome liquid loading is to install smaller diameter production tubing or 'velocity tubing'. The cross-sectional area of the conduit through which gas is produced determines the velocity of flow and can be critical for controlling liquid loading. A velocity string reduces the cross-sectional area of flow and increases the flow velocity, achieving liquid removal while limiting blowdowns to the atmosphere.

Exhibit 3 shows that the conduit for gas flow up a wellbore can be either production tubing, the casing-tubing annulus or simultaneous flow through both the tubing and the annulus. In any case, a 2004 study estimated that gas velocity must be at least 5 to 10 ft/sec (300 to 600 ft/min) to effectively remove hydrocarbon liquids from a well, and at least 10 to 20 ft/ sec (600 to 1200 ft/min) to move produced water. As a rule of thumb, gas flow velocity of 1,000 feet per minute is needed to remove liquid. These figures assume used pipe in good condition with low relative roughness of the pipe wall.

Exhibit 3: Velocity Tubing

Source: S. Bumgardner, Advanced Resources International, inc.

The installation of a velocity string is relatively simple and requires calculation of the proper tubing diameter to achieve the required velocity at the inlet and outlet pressures of the tubing. Velocity tubing to facilitate liquid removal can be successfully deployed in low volume gas wells upon initial completion or near the end of their productive lives. Candidate wells include marginal gas wells producing less than 60 Mfcd. Installation of velocity tubing requires a well workover rig to remove the existing production tubing and place the smaller diameter tubing string in the well.

Coiled tubing may also be used, allowing for easier installation and the application of a greater range of tubing diameters as small as 0.25 inches. Coiled tubing can be applied in wells with lower velocity gas production due to better relative roughness characteristics of the tubing and the absence of pipe joint connections. Studies indicate that seamed coiled tubing provides better lift characteristics due to the elimination of turbulence in the flow stream because the seam acts as a "straightening vane".

Plunger Lift with 'Smart' Well Automation

Plunger lifts are commonly used to lift fluids from gas wells. A plunger lift system is a form of intermittent gas lift that uses gas pressure buildup in the casing-tubing annulus to push a steel plunger and a column of fluid above the plunger up the well tubing to the surface. Exhibit 4 shows a conventional plunger lift installation on a gas well.

Exhibit 4: Plunger Lift

Source: Chesapeake Energy

The operation of a plunger lift system relies on pressure buildup in a gas well during the time that the well is shut-in (not producing). The well shut-in pressure must significantly exceed the sales line pressure in order to lift the plunger and load of accumulated fluid to the surface against the sales line backpressure. A companion Lessons Learned paper, *Installing Plunger Lift Systems in Gas Wells,* discusses the installation, gas savings and economics of plunger lift systems. The focus of the present Lessons Learned paper are the incremental gas savings obtained from installing 'smart' automation systems to better manage the operation of plunger lift installations on a field-wide or basin-wide scale.

Most plunger systems operate on a fixed time cycle or on a preset differential pressure. Regardless of activation system (manual, fixed time cycle, or preset pressure differential), a valve mechanism and controller at the surface cause gas volume and pressure to build up in the wellbore initiating the plunger release cycle. At this point, the surface valve closes and the plunger drops to the bottom of the well. Once adequate pressure is reached, the surface valve opens and the plunger rises to the surface with the liquid load. Insufficient reservoir energy, or too much fluid buildup can overload a plunger lift. When that occurs, venting the well to the atmosphere (well blowdown) instantaneously reduces the backpressure on the plunger and usually allows the plunger to return to the surface.

Automated control systems optimize plunger lift and well unloading operations to prevent overloading (plunger cannot overcome backpressure and rise to the surface) and underloading (plunger rises to quickly, possibly damaging equipment) therefore reducing or eliminating well venting. "Smart" automated control systems combine customized control software with standard well control hardware such as remote terminal units (RTUs) and programmable logic controllers (PLCs) to cycle the plunger system and lift fluids out of the tubing. The artificial intelligence component of a smart automation system monitors the tubing and sales line pressures and allows the PLC to "learn" a well's performance characteristics (such as flow rate and plunger velocity) and to build an inflow performance relationship (IPR) curve for the well. The frequency and duration of the plunger cycle is then modified to optimize well performance.

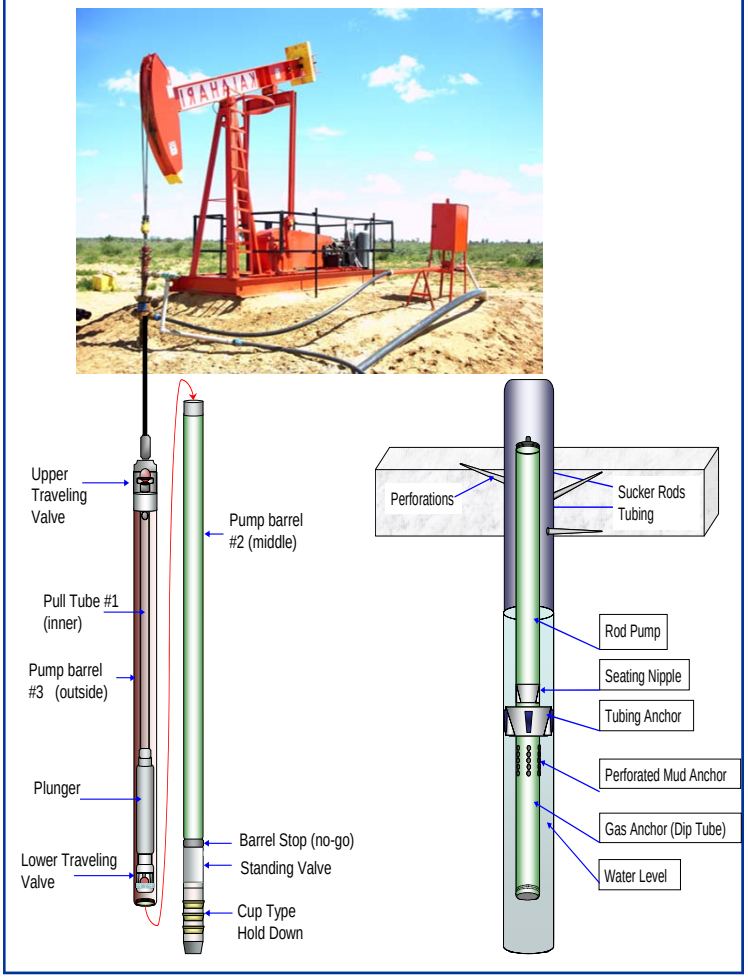
Data analysis combined with wellhead control technology is the key to an effective gas well "smart" automation system. A smart automation system stores historical well production data allowing the program to learn from experience by monitoring and analyzing wellhead instrument data. The control system relays wellhead

instrument data to a central computer, tracks venting times, and reports well problems and high-venting wells, all of which allow custom management of field production.

The components of a smart well automation system that must be installed on each gas well include:

- ★ remote terminal unit with PLC,
- ★ tubing and casing transmitters,
- ★ gas measurement equipment,
- ★ control valve, and
- ★ plunger detector.

Automated controllers at the wellhead monitor well parameters and adjust plunger cycling. These typically operate on low-voltage, solar batteries. Exhibit 5 illustrates typical wellhead equipment and telemetry for plunger lift automated control systems. A host system capable of retrieving and presenting data is also required for continuous data logging and remote data transition. Operators configure all controls and send them to the RTU from the host system. Engineering time is needed to customize the control software and optimize the system. Field operating practices and protocols must be flexible to quickly address well performance deficiencies and operating problems.



Partners have found that optimized plunger lift cycling to remove liquids can decrease the amount of gas vented by up to 90+ percent. Methane emission savings from reduced well venting is a significant benefit that can add up to huge volumes when applied on a field or basin scale.

Exhibit 6: Diagram of a Sucker Rod Pump and Pump Jack

Source: S. Bumgardner, Advanced Resources International, inc.

Rod Pumps and Pumping Units

A downhole positive displacement, reciprocating rod pump with surface pump unit can be deployed in the later stages of a well's life to remove liquids from the wellbore and maximize production until the well is depleted (Exhibit 6). Pumping units can be installed when there is insufficient reservoir pressure to operate a plunger lift. The units can be manually controlled by the field pumper, or very low volume wells may be operated with a timer.

Pumping units not only eliminate the need to vent the well to unload fluids but also extend the productive life of a well. Methane emissions can be further reduced by operating pumping units with electric motors, rather than natural gas-fueled engines. The annual fuel requirement for a typical pumping unit is approximately 1,500 Mcf per unit, of which 0.5 percent is emitted as unburned methane (8 Mcf per unit per year).

A well workover rig is required to install the downhole rod pump, rods, and tubing in the well. Field personnel must be trained for rod pump operations and proper maintenance of the surface equipment. Excessive wear of the rods and tubing can be a major expense for rod pump applications where solids are produced or down hole corrosion is a problem.

A common problem with reciprocating pumps in gas wells is gas locking of the rod pump valves, which prevents the pump from delivering fluid to the surface at the design rate. The presence of free gas in the subsurface sucker rod pump decreases the volumetric pump efficiency and can prevent the pump from lifting fluid. This is not a problem found in progressive cavity pumps as there are no valves to gas lock.

Economic and Environmental Benefits

Implementation of fluid removal options and artificial lift provide economic and environmentally beneficial alternatives to well blowdown. The major benefit of the various fluid removal options is extending the productive life of a well. The full scope of environmental and economic benefits depend on the type of artificial lift system and the remaining productive capacity of the well. Several benefits described below, are realized with the progressive application of fluid removal options in gas wells.

- ★ **Improved gas production rates and extended well life.** Fluid removal and artificial lift systems conserve reservoir energy and boost gas production. Regular fluid removal generally extends the economic life of declining wells resulting in more continuous gas production, improved gas production rates, and incremental ultimate recovery.

- ★ **Reclaims vented gas to sales.** Avoiding well blowdown reclaims the value of gas that would otherwise be vented to the atmosphere.

- ★ **Reduced pollution.** Eliminating well blowdown and gas venting eliminates a significant source of methane and other air pollutant emissions.

- ★ **Lower well maintenance costs and fewer remedial treatments.** Overall well maintenance costs can be reduced by eliminating the cost of a workover rig for swabbing wells. Other savings occur when well blowdowns are significantly reduced or eliminated.

Four Steps for Evaluating Artificial Lift Options:

1. **Determine the technical feasibility of various artificial lift options.**
2. **Determine the cost of various options.**
3. **Estimate the natural gas savings and production increase.**
4. **Evaluate and compare the economics of artificial lift options.**

Decision Process

The decision to implement any type of liquid removal option during the life-cycle of a gas well should be made when the value of the estimated incremental gas production exceeds the cost of the fluid removal option. When one fluid removal approach becomes ineffective and uneconomic, another can be deployed. If venting a well is the current fluid removal approach, the application of foaming agents, velocity tubing or plunger lift should be evaluated before well blowdowns become too frequent, less effective and costly. Natural Gas STAR Partners can use the following decision process as a guide to evaluate the application, safety, and cost effectiveness of fluid removal and artificial lift installations.

Step 1: Determine the technical feasibility of a fluid removal option or artificial lift installation.

Various data and criteria should be evaluated to select a fluid removal approach that is both technically feasible and cost effective. These data include IPR (inflow

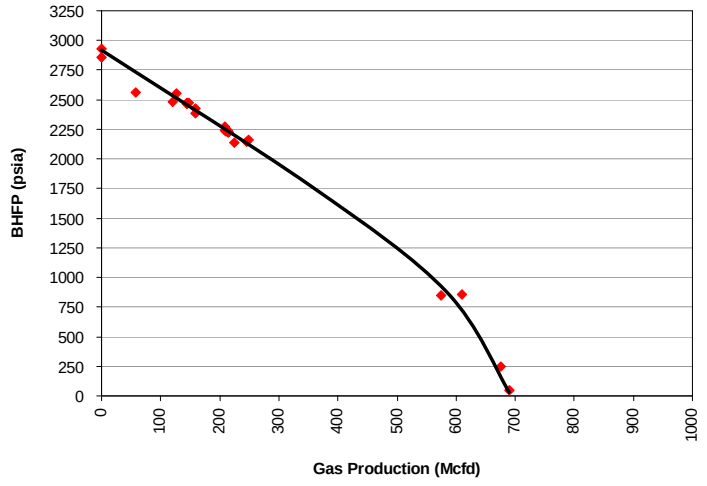
NMED Exhibit 73 - 0006

performance relationship) curves; reservoir pressure; gas and fluid production flow rates; fluid levels in the well; the desired flowing bottom hole pressure and casing pressure; production tubing size, the downhole condition of the well; other mechanical limitations of the well and production site; and the capabilities and training of field personnel.

Appendix A (Exhibit A1 and A2) shows the Turner relationship and Lee relationship between critical flow rate (critical gas velocity), and flowing pressure for various sizes of production tubing. If the relationship between flow rate and pressure falls below a line specifying a size of production tubing, a well will not flow liquids to the surface for the indicated tubing size. If flow rate vs pressure falls on or above the line for a specified tubing size, a well meets or exceeds the critical flow rate for the specified tubing size and the well is able to unload fluid to the surface. Exhibits A1 and A2 can be used as starting points to estimate whether a fluid removal or artificial lift option is likely to be effective. Following are some technical considerations that enter into the decision process for each fluid removal option:

- ★ **Foaming Agents.** Partners typically use foaming agents early in the life of gas wells when the wells begin to load with formation water and the liquid production rate is comparatively low. Foaming works best if the liquid in the wellbore is mainly water, and condensate content is less than 50 percent. Foaming agents may also be used in combination with other well treatments that reduce salt and scale build up, or may be applied in combination with velocity tubing.

- ★ **Velocity Tubing**. Velocity tubing strings are appropriate for natural gas wells with relatively small liquid production and higher reservoir pressure. Low surface pipeline pressure relative to the reservoir pressure is also necessary to create the pressure drop that will achieve an adequate flow rate. The depth of the well affects the overall cost of the installation, but is usually offset by the higher pressure and gas volume in deeper wells. Velocity tubing can also be a good option for deviated wells and crooked well bores. Rod pumped wells with deviation and or dog legs that become uneconomic due to high failure rates and servicing costs may also be candidates for velocity strings.



Determining the feasibility of installing a velocity tubing string is relatively straightforward. An inflow performance relationship (IPR curve) is calculated to establish the flow regime in the well tubing, as shown in Exhibit 7. The diagram shown in Exhibit 7 illustrates the relationship between gas production and the bottom hole flowing pressure (BHFP). Gas flow is evaluated and the velocity relationships for various sizes of tubing are developed to determine the appropriate diameter for use in each well. As a rule of thumb, a gas flow velocity of approximately 1,000 feet per minute is the minimum necessary to remove fresh water. Condensate requires less velocity due to its lower density while more dense brine requires a higher velocity.

Once the velocity string is installed, no other artificial lift equipment is required until the reservoir pressure declines to the point that

Indicators of Liquid Loading in Gas Wells:

1. Construct an IPR curve and evaluate the production efficiency of the well.
2. Monitor production curves for each well on a regular basis. Liquid loading is indicated if the curve for a normally declining well becomes erratic and the production rate drops.
3. Compute the critical gas velocity (flow rate) at which liquid can no longer be lifted in the tubing (see Appendix)
4. Critical velocity vs. flowing tubing pressure can be constructed for various tubing diameters.

Exhibit 7: Example of Inflow Performance Relationship Curve for Evaluating Fluid Removal Options

Source: S. Bumgardner, Advanced Resources International, inc.

velocities of 1,000 feet per minute are no longer possible in the tubing. The introduction of a foaming agent to the bottom of a tubing string will extend the effective life of a velocity string below the 1,000 feet per minute velocity required to lift water by reducing the density of the column that is lifted. This only applies to water lifted from the well tubing since condensate is not affected by a surfactant.

★ **"Smart" Well Automation of Plunger Lift.** Candidate wells for plunger lift generally do not have adequate downhole pressure for the well to flow freely into a gas gathering system. Like pumping units, plunger lifts are used to extend the productive life of a well. Installation is less expensive than rod pumps, but plunger lifts may be difficult to operate.

Conventional plunger lift operations rely upon manual, on-site adjustments to tune a plunger cycle time. When a plunger lift becomes overloaded, the well must be manually vented to the atmosphere to restart the plunger. A "smart" well automation system enhances plunger performance by monitoring parameters such as tubing and casing pressure, well flow rate and plunger cycle frequency (travel time). Data for each well are relayed to a host computer where operators review the data and address any performance deficiencies or operating problems. This helps to optimize plunger lift performance, improve gas production, and reduce well venting.

Optimum plunger lift performance generally occurs when the plunger cycle is frequent and set to lift the smallest liquid loads. Small liquid loads require lower operating bottom hole pressure, which allows for better inflow performance. As with velocity tubing, a desirable velocity for a plunger to ascend in tubing is in the range of 500 to 1,000 ft per minute.

★ **Pumping Units.** Rod pump installations for gas wells can be costly to install and operate, but can extend well life, increase ultimate recovery, increase profits and reduce methane emissions. A rod pumping application for gas wells must be carefully designed to ensure trouble-free installation of the pumping units, minimize installation costs, and maximize operating cost savings by reducing mechanical wear and the need for well servicing.

Technical considerations for a rod pump application include the amount of pump capacity required, the pump setting depth in the well, and the type and gravity of the fluid in the hole (brine, fresh water, hydrocarbon, hydrogen sulfide, carbon dioxide, etc.). These factors influence the components of a rod pump installation, including rod pump materials, rod string size and grade, pumping unit design, size of the prime mover (motor), pump speed and stroke length. Resources available for evaluating and designing rod pump applications for gas wells include American Petroleum Institute and various Society of Petroleum Engineers publications; commercial pumping unit vendors; and computer design models. In general, rod pump installations for gas wells have lower fluid volumes than for oil wells. Operating costs can be minimized by correctly sizing the artificial lift and pumping as slow as possible while maintaining a pumped-off condition. The use of pump-off controllers are also effective by matching the pump displacement to the volume of fluid entering the well bore.

Methane Content of Natural Gas

The average methane content of natural gas varies by natural gas industry sector. The Natural Gas STAR Program assumes the following methane content of natural gas when estimating methane savings for Partner Reported Opportunities.

Production	79 %
Processing	87 %
Transmission and Distribution	94 %

Step 2. Determine the cost of fluid removal options.

Costs associated with the various fluid removal options include capital, start-up and labor expenditures to purchase and install the equipment, as well as ongoing costs to operate and maintain the systems.

★ **Foaming Agents.** Partners report upfront capital and start-up costs to install soap launchers ranging from $500 to $3,880 per well. Monthly cost for the foaming agent is $500 per well, or approximately $6,000 per year. As such, typical costs can vary between $500 and $9,880.

★ **Velocity Tubing.** One Partner reports total capital and installation costs of at least $25,000 per well, which includes the workover rig time, downhole tools, tubing connections and supervision. Another Partner has deployed velocity tubing in more than 100 wells and reports total installation costs ranging from $8,100 per well to $30,000 per well. Based on Partner experiences, typical costs will vary between $7,000 and $64,000 per well.

NMED Exhibit 73 - 0008

- **"Smart" Well Automation of Plunger Lift.** Two Partners report implementing "smart" automation systems to control plunger lift operations. One operation is fairly small, consisting of 21 wells. The second is a basin-wide deployment on more than 2,150 wells. Reported upfront costs for the smaller installation is $6,300 per well. Total cost over 5 years reported for the larger automation project is $12,200,000 or approximately $5,700 per well. Typical costs will vary between $5,700 and $18,000 depending on the complexity of the "smart" automation system. These costs would be incremental over the cost of installing a plunger lift system.

- **Pumping Units.** Capital and installation costs include the use of a workover rig and crew, for approximately one day, sucker rods, rod guides and pump costs, and the cost of the pumping unit and motor. Other start-up costs can include miscellaneous clean out operations to prepare the well to receive a down hole pump and sucker rods.

  Partners report that location preparation, well clean out, artificial lift equipment, and a pumping unit can be installed for approximately $41,000 to $62,000 per well. The reported average cost of the pumping unit alone appears to range from approximately $17,000 to $27,000. Most companies have surplus units in stock that can be deployed at the expense of transportation and repair, or may purchase used units.

Step 3. Estimate the savings from various fluid removal options.

The total savings associated with any of the fluid removal and artificial lift options include:

- Revenue from incremental increased gas production;
- Revenue from avoided emissions;
- Additional avoided costs such as well treatment and workover costs, and reduced fuel and electricity;
- Salvage value.

Revenue from Increased Production

The most significant benefit of deploying foaming agents, velocity tubing or a pumping unit is to extend the productive life of the well by decreasing the abandonment pressure of the reservoir and increasing the cumulative gas production. The benefit of automating a plunger lift system is to optimize the plunger cycle. Most of the increase in gas production is realized by the initial decision to install plunger lifts. Installing a 'smart' automated control system provides some incremental increase in gas production over a plunger lift system operated manually or by a timer, but the most significant benefit is the emissions avoided from repeated well blowdowns and the reduction in personnel time required at the well.

The fluid removal options are evaluated based on the incremental gas production predicted by well blowdowns. For wells that are not on production decline, the incremental gas production from installing velocity tubing or artificial lift can be estimated by assuming the average peak production after a well blowdown event represents the incremental peak production that will be achieved after the fluid removal option is implemented in the well.

The more common evaluation is for a well already experiencing production decline. In such a case, estimating incremental gas production from implementing a fluid removal/ artificial lift method is more complex and requires generating a new "expected" production and decline curve that would result from reducing the back pressure at the well perforations. This requires well-specific reservoir engineering analyses, a basic example of which is provided in Appendix B.

Once the incremental gas production from implementing a fluid removal approach is estimated, operators can

Exhibit 8: Gas Production Increase from Application of Foaming Agents — One Partner's Experience

- One Gas STAR Partner reports injecting foaming agent into 15 wells using soap sticks.
- Incremental gas production of individual wells increased an average of 513 Mcf per well per year.
- Annual incremental gas production for the entire project was 7,700 Mcf.
- Total cost for the project was $8,871 in 2010 dollars.
- At nominal gas prices ranging from $3.00/ Mcf to $5.00/ Mcf, the value incremental gas production ranges from approximately $23,100 to $38,500/ year and project payback occurs in 3 to 5 months.

NMED Exhibit 73 - 0009

calculate the value of the incremental gas and estimate the economics of the application. Exhibit 8 is an example of the potential revenue from increased gas production using foaming agents. Note that Exhibit 8 does not include other benefits such as avoided blowdown emissions and operations cost savings.

Revenue from Avoided Emissions

Emissions from venting gas to the atmosphere vary in both frequency and flow rates, and are entirely well and reservoir specific. The volume of natural gas emissions avoided by reducing or eliminating well blow-downs will vary due to individual characteristics such as sales line pressure, well shut-in pressure, fluid accumulation rate, and well dimensions (such as depth and casing and tubing diameters). Another key variable is an operator's normal practice for venting wells. Some operators put wells on automatic vent timers. Some wells are vented manually with personnel standing by monitoring the blow-down. In some cases, wells are open to vent and unattended for hours or days, depending upon the time it typically takes the well to clear liquids. The economic benefits of avoided emissions will vary considerably, and some projects will have significantly shorter payback periods than others.

Partner-reported annual emissions attributable to well blowdowns vary from 1 Mcf per well to several thousand Mcf per well, so methane emissions savings attributable to avoided emissions will also vary according to the characteristics and available data for the particular wells being vented. Exhibit 9 illustrates the range of avoided emissions reported by various Partners after applying specific fluid removal and artificial lift strategies in their operations.

Revenue from avoided emissions can be calculated by multiplying the sales price of the gas by the volume of vented gas. If well emissions have not been measured, they can be estimated. The volume of emissions from well venting can be estimated by constructing an IPR curve to predict the open flow potential of the well based on reservoir pressure, depth, tubular sizes, and fluid constituents. Other operator methods are discussed in Appendix C. The volume of gas released during well blow-down is dependent on the duration of the event, wellhead temperature and pressure, size of the vent line, the properties of the gas, and the quantity of water produced.

Four approaches to estimating well blow-down emissions are provided in Appendix C. None of the estimations discussed in Appendix C provide the "exact" result in an absolute sense, but they are accurate enough for effective management of producing gas wells. One emission estimation approach calculates well blow-down volume as a function of venting time, normal production rate, well volume and gas properties. Another approach uses

Exhibit 9: Comparison of Partner-Reported Costs and Emissions Savings for Fluid Removal / Artificial Lift Options

Fluid Removal Approach	Installation Costs ($/well)	Incremental Gas Production (Mcf/well/year)	Avoided Methane Emissions from Swabbing/ Blowdown[2] (Mcf/Well/Year)	Other Potential Cost Savings ($/well)
Use Foaming Agents	$500 - $9,880 *(installation of soap launcher);* $500/month *(surfactant)*	365 – 1,095	178 – 7,394	$2,000 *(eliminate well swabbing)*
Install Velocity Tubing	$7,000 - $64,000	9,125 – 18,250	146 – 7,394	$2,000 - $13,200 *(eliminate well swabbing & blowdown)*
"Smart" Well Automated Controls for Plunger Lift[1]	Partner reported average cost = $5,700 - $18,000	Not reported by Partners (*5,000 Mcf estimated for average U.S. gas well by assuming a 10-20% increase in production)*	Partner reported = 630 – 900 (500 Mcf estimated *for average U.S. well by assuming 1 % of annual production)*	$7,500 *(reduces labor cost to monitor plunger lift installations in the field)*
Install Rod Pumps and Pumping Units	$41,000 - $62,000	Not reported	769 – 1,612	$22,994 *(salvage value at end of well life)*

[1]Incremental cost, gas production and methane emissions savings for installation of automated plunger lift control system.
[2]Assumes methane content of natural gas at wellhead is 79 percent, unless reported otherwise.

NMED Exhibit 73 - 0010

pressure transient analysis to extrapolate gas flow rate from wellhead pressure. A final approach installs an orifice meter on a vent line and measures specific vent volume over time. The resulting vent rates expressed in Mcf/minute are averaged by producing formation and extrapolated from the initial subset of wells measured to the larger well population.

Avoided Costs and Other Benefits

Avoided costs and additional benefits depend on the type of fluid removal/ artificial lift system currently applied in the well and the new system to be deployed. These can include avoided chemical treatments, fewer well workovers, lower fuel costs and lower daily operations and maintenance costs. Partners report using foaming agents to replace well swabbing for a savings of approximately $2,000 annually per well. EPA's Natural Gas STAR Partners report that "smart" well automated control systems for plunger lifts have reduced the labor cost for field monitoring by approximately $7,500 per well. Velocity tubing eliminates well swabbing, well blowdowns and chemical treatments, the cost of which are reported to range from a few thousand to more than $13,000 per treatment.

Step 4. Evaluate the economics of fluid removal options.

Basic cash flow analysis can be used to compare the costs and benefits of the various fluid removal options. Exhibit 9 is a summary of the installation costs, gas savings and reduced methane losses associated with each fluid removal approach that have been reported by Natural Gas STAR Partners. Cash flow analyses based on Partner-reported experience and data are provided in Exhibit 10 for installing velocity tubing strings and in Exhibit 11 for "smart" well automated control systems for plunger lift.

Partner Experience

This section highlights specific experiences reported by Gas STAR Partners with the selected fluid removal options for gas wells.

Install Velocity Tubing Strings.

One Partner reported installation of velocity tubing in two Gulf Coast wells during 2008. Total installation cost in 2008 was $25,000 per well, which included a workover rig to remove and replace tubing, downhole tools, connections and supervision. Due to low inflation between years 2008 and 2010, the installation cost in 2010 dollars is only slightly higher than 2008.

The velocity tubing installation in these wells improved gas production by 25 Mcfd to 50 Mcfd, which equates to annual incremental gas production of approximately 9,125 Mcf to 18,250 Mcf per well. In addition, gas savings from eliminating well swabbing is 160 Mcf per year per well. Methane content of gas at the well head is 91 percent, so the estimated reduction in methane losses are 146 Mcf per well. Velocity tubing also eliminated annual swabbing costs of approximately $2000 per well per year. Exhibit 10

Exhibit 10: Economic Analysis of Velocity Tubing Installation Replacing Periodic Swabbing

	Year 0	Year 1	Year 2	Year 3	Year 4	Year 5
Value of Gas from Increased Production[1]		$36,500	$36,500	$36,500	$36,500	$36,500
Value of Gas from Avoided Emissions[2]		$640	$640	$640	$640	$640
Velocity Tubing Installation Cost	($25,000)					
Avoided Swabbing Cost		$2,000	$2,000	$2,000	$2,000	$2,000
Net Annual Cash Flow	**($25,000)**	**$39,140**	**$39,140**	**$39,140**	**$39,140**	**$39,140**

provides a cash flow analysis of this Partner's velocity tubing installation replacing well swabbing.

Install "Smart" Automated Control Systems on Plunger Lifts

Two Partners have applied "smart" well automated control systems at plunger lift installations. One Partner—BP—initiated an automation project in 2000, and in 2001 began installing automated plunger lift control systems across their San Juan Basin operations. BP justified the project based on gas and methane emissions savings resulting from a 50 percent reduction in well venting between 2000 and 2004. By 2007, BP implemented automated control systems for more than 2,150 wells equipped with plunger lift which resulted in average methane emissions savings of 900 Mcf per well. Total cost for the "smart" automation systems was $12.2 million. Total gas venting was reduced from approximately 4 billion cubic feet of gas per year (Bcf) to approximately 0.8 Bcf.

Another Natural Gas STAR Partner found that a substantially smaller application of "smart" automated controls for plunger lift can be similarly effective. An automated control system was implemented for 21 wells equipped with plunger lifts. Total gas savings are 16,800 Mcf per year, or 800 Mcf per well. Assuming a methane content of 79 percent, estimated annual methane emissions savings are 632 Mcf per well.

The wide range in upfront capital and installation costs for components of plunger lift automated control systems are indicated in Exhibit 9. The host computer and communication system can be quite costly ($50,000 to $750,000) depending upon the size of the project, but as more plunger lift-equipped wells are added, the unit cost for the automated control system is significantly reduced. The two Natural Gas STAR Partners report approximate unit costs for plunger lift automated control systems of $6,800 and $5,950 per well, respectively. Exhibit 11 provides a basic cash flow analysis of "smart" well automated control systems for plunger lift based on

Exhibit 11: Economic Analysis of "Smart" Well Automated Control Systems for Plunger Lift for Hypothetical Onshore Gas Field[1]

	Year 0	Year 1	Year 2	Year 3	Year 4	Year 5

NMED Exhibit 73 - 0012

generic assumptions about potential increased gas production and methane emissions savings for the average onshore natural gas well in the United States.

Install Pumping Units on Wells Lifting Low Water Volumes

ConocoPhillips installed pumping units on 45 low-pressure gas wells in 2003 to remove low water volumes from the wells and prevent them from loading up. This installation eliminated routine venting of the wells for up to one hour per day. The primary benefit of installing pumping units on these wells is the incremental gas production gained by extending the productive life of the wells. The Partner reported gas savings of 973 Mcf per well from the elimination of well blowdowns as a secondary, but not insignificant, benefit. The pump jacks at this installation are powered by electric motors rather than natural gas engines, which contributes to fewer methane emissions and lower maintenance costs.

ConocoPhillips reported total gas savings of 43,780 Mcf for the project or approximately 973 Mcf per well per year. At a nominal gas price of $4.00 to $5.00/Mcf, this corresponds to savings of approximately $3,892 to $4,865 per unit, or $175,140 to $218,900 per year for the entire project consisting of 45 wells. Assuming a methane content of 79 percent, this project has reduced methane losses by 34,586 Mcf per year.

Total capital and installation costs for the downhole pumps and surface pumping units were estimated to be $62,000 per well in 2003 or the equivalent of $73,332 in 2010 dollars. The total cost in 2003 included $45,000 for site preparation, downhole equipment, and installation plus an average cost of $17,000 per pumping unit. The project was expanded in subsequent years. ConocoPhillips reported a total of 100 pumping units installed from 2005 through 2007. During this time, the average reported upfront installation cost declined to approximately $38,000 per unit in 2010 dollars. Assuming a nominal gas price of $4, the vented gas savings alone pays back the typical pumping unit installation for this project in less than 10 years.

Nelson Price Indexes

In order to account for inflation in equipment and operating & maintenance costs, Nelson-Farrar Quarterly Cost Indexes (available in the first issue of each quarter in the *Oil and Gas Journal*) are used to update costs in the Lessons Learned documents.

The "Refinery Operation Index" is used to revise operating costs while the "Machinery: Oilfield Itemized Refining Cost Index" is used to update equipment costs.

To use these indexes in the future, simply look up the most current Nelson-Farrar index number, divide by the February 2006 Nelson-Farrar index number, and, finally multiply by the appropriate costs in the Lessons Learned.

Lessons Learned

- ★ For natural gas wells, a progression of fluid removal options are available to unload accumulated fluid, boost gas production, extend well life and reduce or eliminate the need for well venting.
- ★ Options for removing accumulated wellbore fluids from gas wells range from relatively low cost application of surfactants, appropriate for wells with low fluid production and significant remaining reservoir energy, to installing pumping units and downhole rod pumps on wells with depleted reservoir pressure and significant water production.
- ★ The best approach will depend on the where a well is performing along the continuum of its productive life.
- ★ Well blowdown and swabbing can release large volumes of natural gas to the atmosphere, producing significant methane emissions and gas losses.
- ★ Fluid removal approaches presented in this paper can reduce the amount of remedial work needed during the lifetime of a well, eliminate well blowdowns, and increase the ultimate recovery of the well while minimizing methane emissions to the atmosphere.
- ★ If a well is in production decline, the fluid removal alternatives discussed here will increase gas production in most cases or at least arrest the decline.
- ★ This increased gas production should be captured in analyses of cash flow and future economic benefit when evaluating fluid removal options for gas wells. In most cases, increased gas production is the primary benefit from implementing any or all of the fluid removal options.

NMED Exhibit 73 - 0013

★ Methane emissions and gas savings from the elimination of well venting is generally a secondary, but significant, benefit, which may cover all or most of the upfront installation costs for a fluid removal technology.

Exhibit A2: Lee Unloading Rate for Well Producing Water

Source: S. Bumgardner, Advanced Resources International, inc.

APPENDIX B: Estimating Incremental Production for Declining Wells

From Dake's Fundamentals of Reservoir Engineering (1978) the following analytical model can be used to estimate increased gas flow into a well in response to reducing back pressure on the perforations by removing accumulated liquids. The semi-steady state inflow equation is:

$$m(p_{avg})-m(p_{wf})=[(1422 \times Q \times T)/(k \times h)] \times [\ln(r_e/r_w)-3/4+S)] \times (8.15)$$

Where,

$m(p_{avg})$ = real gas pseudo pressure average

$m(p_{wf})$ = real gas pseudo pressure well flowing

Q = gas production rate

T = absolute temperature

k = permeability

h = formation height

r_e = external boundary radius

r_w = wellbore radius

S = mechanical skin factor

Incremental production achieved by implementing various artificial lift options can be estimated by solving this equation for `Q' calculated for retarded flow with fluids in the hole (current conditions and current decline curve), and comparing to `Q' calculated for the condition of no fluids in the hole (artificial lift active and improved decline curve). This discussion is intended as a guide for estimating the potential impact of fluid removal alternatives, and is not a substitute for thorough reservoir engineering analyses of specific wells.

APPENDIX C: Alternate Techniques for Estimating Avoided Emissions When Replacing Blowdowns

Simple Vent Volume Calculation

A conservative estimate of well venting volumes can be made using the following equation:

Annual Vent Volume, Mscf/yr = (0.37×10^{-6})*(Casing Diameter^2)*(Well Depth)*(Shut-in Pressure)*# of Annual Vents)

Where, casing diameter is in inches, well depth is in feet and shut-in pressure is in psia. If the shut-in pressure is not known, a suitable surrogate is the casing pressure at the surface.

This is the minimum volume of gas that would be vented to atmospheric pressure from a well that has stopped flowing to the sales line because a head of liquid has accumulated in the tubing equal to the pressure difference between the sales line pressure and well shut-in pressure.

If the well shut-in pressure is more than 1.5 times the sales line pressure, as required for a plunger lift installation, then the volume of gas in the well casing at shut-in pressure should be minimally sufficient to push the liquid in the tubing to the surface in slug-flow when back-pressure is reduced to sales line pressure.

Partners can estimate the minimum time needed to vent the well by using this volume and the Weymouth gas-flow formula (worked out for common pipe diameters, lengths and pressure drops in Tables 3, 4 and 5 in *Pipeline Rules of Thumb Handbook*, Fourth Edition, pages 283 and 284). If a Partner's practice is to open and vent the wells for a longer time than calculated by these methods, the Annual Vent Volume calculated by this equation can be scaled up according to the ratio of the actual vent time versus the minimum vent time calculated using the Weymouth equation.

Natural Gas STAR Partner, BP, has reported three approaches to estimating well venting and completion emissions, which include: 1) a more detailed version of the vent volume calculation method above, 2) pressure transient analysis, and 3) installing an orifice meter on the vent line.

Detailed Vent Volume Calculation

The detailed vent volume calculation is a function of venting time, normal production rate, and "well blowdown value" that represents the volume of gas in a well under an assumption of line pressure.

Vent Volume(Mcf) =
((Vent Time – 30 min)*(1/1440)* Production Rate) + (Well Blowdown Volume)

Well Blowdown Volume (Mcf) =
(well depth*3.1416*(casing diameter/2)^2) * ((tubing press + atmospheric press)/14.7) * (520/(Temp+460))/ Z/ 1000

Variables:

- production rate, Mcf per day
- well depth, ft
- atmospheric pressure, psia
- shut-in tubing pressure, psig
- temperature of gas in pipeline, ^{o}F
- diameter of production casing, ft
- compressibility, Z

A limitation of the vent volume calculation method is that it does not account for either the volume or weight of a column of fluid in the wellbore at the time of venting.

Pressure Transient Analysis

This method is based on observations of wellhead pressure versus flow rate for a specific set of wells which are used to develop a linear expression of gas flow rate versus wellhead pressure. This relationship is then applied to pressure transient data during blowdown to extrapolate Mcf versus time for the venting period. All data are evaluated using pressure data analysis software to extrapolate total vented volumes based on the blowdown time, pipe diameter and the decline in well head pressure during the process. An advantage of this approach is that it accounts for choke flow and is tailored to specific wells. Limitations of the approach are that it fails to account for very large influx into the reservoir and the observations data set may not be representative of the formation. To make the data set more representative, it is recommended that the data include at least one point within the following 5 ranges:

- ★ $P \leq 25$ psia
- ★ 25 psia $< P \leq 60$ psia

NMED Exhibit 73 - 0016

- ★ 60 psia < P ≤ 110 psia
- ★ 110 psia < P ≤ 200 psia
- ★ 200 psia < P

Orifice Metering of Blow Down

For this approach, an orifice meter is installed on a vent line and flow rates are measured directly during blowdown. An advantage of this approach is the precision of the data that are obtained, potentially offering meaningful comparisons of vent volumes between well types, well completions or producing formations.

A limitation of the approach is that results obtained from a 'study population' or small subset of producing wells will likely be extrapolated to a larger field or producing area, and the original study wells may not be representative of field operations as a whole.

2011

EPA provides the suggested methane emissions estimating methods contained in this document as a tool to develop basic methane emissions estimates only. As regulatory reporting demands a higher-level of accuracy, the methane emission estimating methods and terminology contained in this document may not conform to the Greenhouse Gas Reporting Rule, 40 CFR Part 98, Subpart W methods or those in other EPA regulations.

Installing Plunger Lift Systems In Gas Wells

Executive Summary

In mature gas wells, the accumulation of fluids in the well can impede and sometimes halt gas production. Gas flow is maintained by removing accumulated fluids through the use of a beam pump or remedial treatments, such as swabbing, soaping, or venting the well to atmospheric pressure (referred to as "blowing down" the well). Fluid removal operations, particularly well blowdowns, may result in substantial methane emissions to the atmosphere.

Installing a plunger lift system is a cost-effective alternative for removing liquids. Plunger lift systems have the additional benefit of increasing production, as well as significantly reducing methane emissions associated with blowdown operations. A plunger lift uses gas pressure buildup in a well to lift a column of accumulated fluid out of the well. The plunger lift system helps to maintain gas production and may reduce the need for other remedial operations.

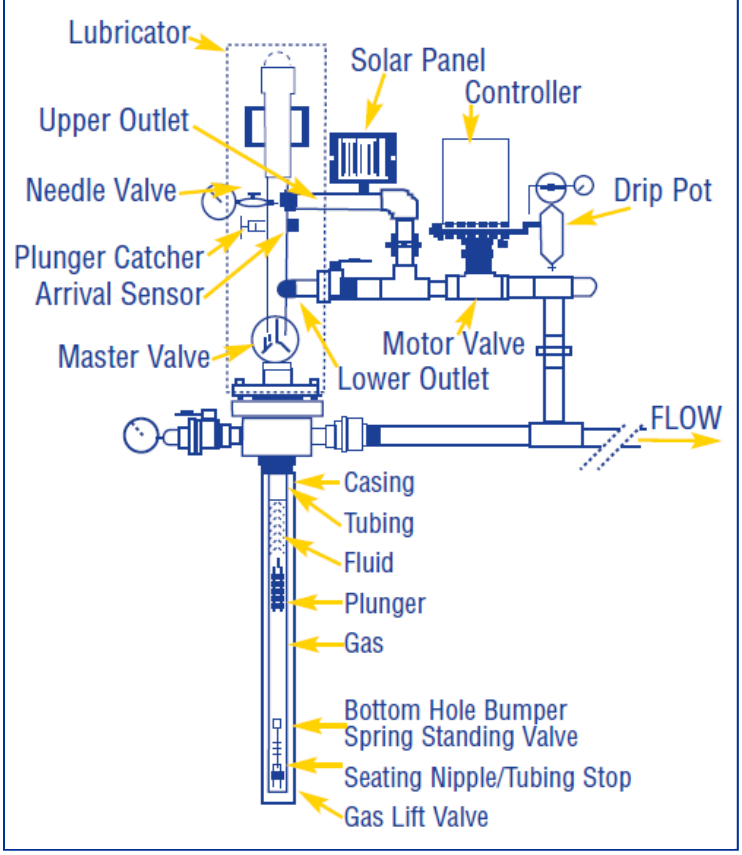
Natural Gas STAR Partners report significant economic benefits and methane emission reductions from installing plunger lift systems in gas wells. Companies have reported annual gas savings averaging 600 thousand cubic feet (Mcf) per well by avoiding blowdowns. In addition, increased gas production following plunger lift installation has yielded total gas benefits of up to 18,250 Mcf per well, worth an estimated $127,750. Benefits from both increased gas production and emissions savings are well- and reservoir-specific and will vary considerably.

Technology Background

Liquid loading of the wellbore is often a serious problem in aging production wells. Operators commonly use beam lift pumps or remedial techniques, such as venting or "blowing down" the well to atmospheric pressure, to remove liquid buildup and restore well productivity. These techniques, however, result in gas losses. In the case of blowing down a well, the process must be repeated over time as fluids reaccumulate, resulting in additional methane emissions.

Plunger lift systems are a cost-effective alternative to both beam lifts and well blowdowns and can significantly reduce gas losses, eliminate or reduce the frequency of future well treatments, and improve well productivity. A plunger lift system is a form of intermittent gas lift that uses gas pressure buildup in the casing-tubing annulus to push a steel plunger, and the column of fluid ahead of it, up the well tubing to the surface. The plunger serves as a piston between the liquid and the gas, which minimizes liquid fallback, and as a scale and paraffin scraper. Exhibit 1 depicts a typical plunger lift system.

The operation of a plunger lift system relies on the natural buildup of pressure in a gas well during the time that the well is shut-in (not producing). The well shut-in pressure must be sufficiently higher than the sales-line pressure to lift the plunger and liquid load to the surface. A valve mechanism, controlled by a microprocessor, regulates gas input to the casing and automates the process. The controller is normally powered by a solar recharged battery and can be a simple timer-cycle or have solid state



Economic and Environmental Benefits

Method for Reducing Natural Gas Losses	Potential Gas Savings from Increased Gas Production and Avoided Emissions (Mcf)	Value of Natural Gas Production and Savings ($)			Implementation Cost ($)	Payback (Months)		
		$3 per Mcf	$5 per Mcf	$7 per Mcf		$3 per Mcf	$5 per Mcf	$7 per Mcf
Install a Plunger Lift System	4,700 - 18,250[a] per year per well	$14,100 - $54,750 per year	$23,500 - $91,250 per year	$32,900 - $127,750 per year	$2,591 - $10,363 per year per well	1 - 9	1 - 6	1 - 4

General Assumptions:
[a] Based on results reported by Natural Gas STAR Partners.

NMED Exhibit 74 - 0001

Exhibit 1: Plunger Lifts

memory and programmable functions based on process sensors.

Operation of a typical plunger lift system involves the following steps:

1. The plunger rests on the bottom hole bumper spring located at the base of the well. As gas is produced to the sales line, liquids accumulate in the well-bore, creating a gradual increase in backpressure that slows gas production.

2. To reverse the decline in gas production, the well is shut-in at the surface by an automatic controller. This causes well pressure to increase as a large volume of high pressure gas accumulates in the annulus between the casing and tubing. Once a sufficient volume of gas and pressure is obtained, the plunger and liquid load are pushed to the surface.

3. As the plunger is lifted to the surface, gas and accumulated liquids above the plunger flow through the upper and lower outlets.

4. The plunger arrives and is captured in the lubricator, situated across the upper lubricator outlet.

5. The gas that has lifted the plunger flows through the lower outlet to the sales line.

6. Once gas flow is stabilized, the automatic controller releases the plunger, dropping it back down the tubing.

7. The cycle repeats.

New information technology systems have streamlined plunger lift monitoring and control. For example, technologies such as smart automation, online data management and satellite communications allow operators to control plunger lift systems remotely, without regular field visits. Operators visit only the wells that need attention, which increases efficiency and reduces cost. For more information regarding this technology and other artificial lift systems, see the Lessons Learned document titled "Options for Removing Accumulated Fluid and Improving Flow in Gas Wells".

Economic and Environmental Benefits

The installation of a plunger lift system serves as a cost-effective alternative to beam lifts and well blowdown and yields significant economic and environmental benefits. The extent and nature of these benefits depend on the liquid removal system that the plunger lift is replacing.

- ★ **Lower capital cost versus installing beam lift equipment.** The costs of installing and maintaining a plunger lift are generally lower than the cost to install and maintain beam lift equipment.

- ★ **Lower well maintenance and fewer remedial treatments.** Overall well maintenance costs are reduced because periodic remedial treatments such as swabbing or well blowdowns are reduced or no longer needed with plunger lift systems.

- ★ **Continuous production improves gas production rates and increases efficiency.** Plunger lift systems can conserve the well's lifting energy and increase gas production. Regular fluid

removal allows the well to produce gas continuously and prevent fluid loading that periodically halts gas production or "kills" the well. Often, the continuous removal of fluids results in daily gas production rates that are higher than the production rates prior to the plunger lift installation.

★ **Reduced paraffin and scale buildup.** In wells where paraffin or scale buildup is a problem, the mechanical action of the plunger running up and down the tubing may prevent particulate buildup inside the tubing. Thus, the need for chemical or swabbing treatments may be reduced or eliminated. Many different types of plungers are manufactured with "wobble-washers" to improve their "scraping" performance.

★ **Lower methane emissions.** Eliminating repetitive remedial treatments and well workovers also reduces methane emissions. Natural Gas STAR Partners have reported annual gas savings averaging 600 Mcf per well by avoiding blowdown and an average of 30 Mcf per year by eliminating workovers.

★ **Other economic benefits.** In calculating the economic benefits of plunger lifts, the savings from avoided emissions are only one of many factors to consider in the analysis. Additional savings may result from the salvage value of surplus production equipment and the associated reduction in electricity and work over costs. Moreover, wells that move water continuously out of the well bore have the potential to produce more condensate and oil.

Decision Process

Operators should evaluate plunger lifts as an alternative to well blowdown and beam lift equipment. The decision to install a plunger lift system must be made on a case-by-case basis. Partners can use the following decision process as a guide to evaluate the applicability and cost-effectiveness of plunger lift systems for their gas production wells.

Step 1: Determine the technical feasibility of a plunger lift installation.

Plunger lifts are applicable in gas wells that experience liquid loading and have sufficient gas volume and excess shut-in pressure to lift the liquids from the reservoir to the surface. Exhibit 2 lists four common well characteristics that are good indicators of plunger lift applicability. Vendors often will supply written materials designed to help operators ascertain whether a particular well would benefit from the installation of a plunger lift system. As an example, a well that is 3,000 feet deep, producing to a sales line at 100 psig, has a shut-in pressure of 150 psig and must be vented to the atmosphere daily to expel and average of three barrels per day of water accumulation. This well has sufficient excess shut-in pressure and would have to produce 3,600 scf per day (400 scf/bbl/1000 feet of depth times 3000 feet of depth, times 3 barrels of water per day) to justify use of a plunger lift.

Four Steps for Evaluating Plunger Lift Systems:
1. Determine the technical feasibility of a plunger lift installation;
2. Determine the cost of a plunger lift system;
3. Estimate the savings of a plunger lift; and
4. Evaluate the plunger lift's economics.

Exhibit 2: Common Requirements for Plunger Lift Applications

★ Well blowdowns and other fluid removal techniques are necessary to maintain production.

★ Wells must produce at least 400 scf of gas per barrel of fluid per 1,000 feet of depth.

★ Wells with shut-in wellhead pressure that is 1.5 times the sales line pressure.

★ Wells with scale or paraffin buildup.

Step 2: Determine the cost of a plunger lift system.

Costs associated with plunger lifts include capital, start-up and labor expenditures to purchase and install the equipment, as well as ongoing costs to operate and maintain the system. These costs include:

★ **Capital, installation, and start-up costs.** The basic plunger lift installation costs approximately $1,900 to $7,800. In contrast, installation of surface pumping equipment, such as a beam lift, costs between $26,000 and $52,000. Plunger lift installation costs include installing the piping, valves, controller and power supply on the wellhead and setting the down-hole plunger bumper assembly assuming the well tubing is open and clear. The largest variable in the installation cost is running a wire-line to gauge the tubing (check for internal blockages) and test run a plunger from top to bottom (broaching) to assure that the plunger will move freely up and down the tubing string. Other start-up costs can include a well depth survey, swabbing to

NMED Exhibit 74 - 0003

Nelson Price Indexes

In order to account for inflation in equipment and operating & maintenance costs, Nelson-Farrar Quarterly Cost Indexes (available in the first issue of each quarter in the *Oil and Gas Journal*) are used to update costs in the Lessons Learned documents.

The "Refinery Operation Index" is used to revise operating costs while the "Machinery: Oilfield Itemized Refining Cost Index" is used to update equipment costs.

To use these indexes in the future, simply look up the most current Nelson-Farrar index number, divide by the February 2006 Nelson-Farrar index number, and, finally multiply by the appropriate costs in the Lessons Learned.

remove well bore fluids, acidizing to remove mineral scale and clean out perforations, fishing-out debris in the well, and other miscellaneous well clean out operations. These additional start-up costs can range from $700 to more than $2,600.

Operators considering a plunger lift installation should note that the system requires continuous tubing string with a constant internal diameter in good condition. The replacement of the tubing string, if required, can add several thousands of dollars more to the cost of installation, depending upon the depth of the well.

★ **Operating costs.** Plunger lift maintenance requires routine inspection of the lubricator and plunger. Typically, these items need to be replaced every 6 to 12 months, at an approximate cost of $700 to $1,300 per year. Other system components are inspected annually.

Step 3: Estimate the savings of a plunger lift.

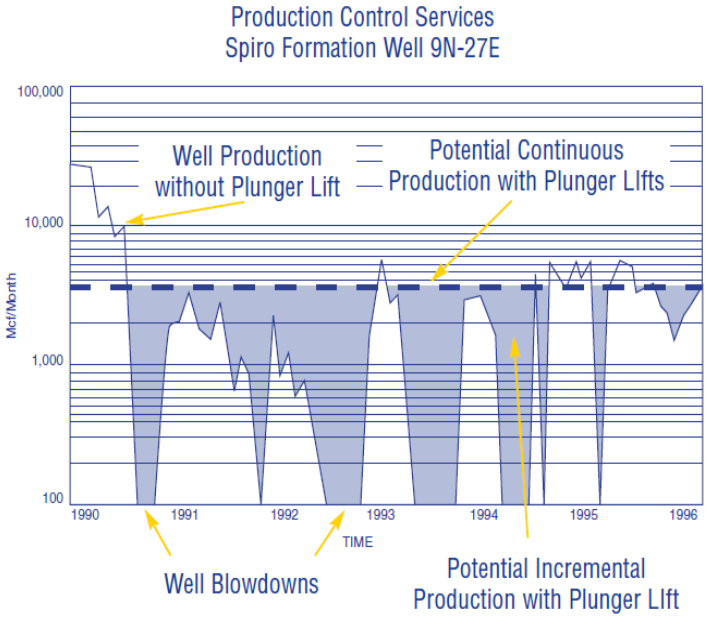
The savings associated with a plunger lift include:

★ Revenue from increased production;

★ Revenue from avoided emissions;

★ Additional avoided costs—well treatment costs, reduced electricity costs, workover costs; and

★ Salvage value.



Revenue from Increased Production

The most significant benefit of plunger lift installations is the resulting increase in gas production. During the decision process, the increase in production cannot be measured directly and must be estimated. The methodology for estimating this expected incremental production varies depending on the state of the well. The methodology for continuous or non-declining wells is relatively straightforward. In contrast, the methodology for estimating the incremental production for wells in decline is more complex.

★ **Estimating incremental gas production for non-declining wells.** The incremental gas production from a plunger lift installation may be estimated by assuming that the average peak production rate achieved after blowdown is near the potential peak production rate for the well with fluid removed. A well log, like that illustrated in Exhibit 3, can be used to estimate the potential production increase.

In this exhibit, the solid line shows well production rate gradually, then steeply declining as liquids accumulate in the tubing. Production is restored by venting the well to the atmosphere, but then declines again with reaccumulation of liquids. Note that the production rate scale, in thousands of cubic feet per month, is a log scale. The dashed line shows the

Exhibit 3: Incremental Production for Non-Declining Wells

average peak production rate after liquids unloading. This is assumed to be equal to the potential peak production rate that could be achieved with a plunger lift system, typically at least 80 percent of the peak production rate after blowdown. The shaded area between the potential production (dashed-line) and the actual well production (solid-line) represents the estimate of incremental increase in gas production that can be achieved with a plunger lift system.

★ **Estimating incremental production for declining wells or for situations in which the maximum production level after blowdown is not known.** Wells that are in decline or operated without periodic blowdowns require more detailed methods for estimating incremental production under plunger lift systems. Plunger lift installations on declining wells, for example, will require generating an improved declining curve resulting from decreased pressure at perforations. Operators should seek the assistance of a reservoir engineer to aid in these determinations (see Appendix).

Once incremental production from a plunger lift installation is estimated, operators can calculate the value of incremental gas and estimate the economics of the plunger lift installation. Exhibit 4 presents an example of potential financial returns at different levels of increase in gas production. It is important to recognize that local costs and conditions may vary. Note also that the example in Exhibit 4 does not take into account other financial benefits of a plunger lift installation project, such as avoided emissions and decreased electricity and chemical treatment costs, which are described later in this Lessons Learned. Consideration of these additional benefits may improve the already excellent financial returns of a plunger lift installation.

Exhibit 4: Example of Estimated Financial Returns for Various Levels of Incremental Gas Production from a Plunger Installation

Incremental Gas Production (Mcfd)	Payout Time (months)	Internal Rate of Return (%)
3	14	71
5	8	141
10	4	309
15	3	475
20	2	640
25	2	804
30	2	969

Assumptions:
Value of gas = $7.00/Mcf.
Plunger system cost of $7,772 including start-up cost.
Lease operating expense of $790/year.
Production decline of 6%/year.

Revenue from Avoided Emissions

The amount of natural gas emissions reduced following plunger lift installation will vary greatly from well to well, based on the individual well and reservoir characteristics such as sales line pressure, well shut-in pressure, liquids accumulation rate, and well dimensions (depth, casing diameter, tubing diameter). The most important variable, however, is the normal operating practice of venting wells. Some operators put wells on automatic vent timers, while others manually vent the wells with the operator standing by monitoring the vent, and still others open the well vent and leave, returning in hours or up to days, depending on how long it typically takes the well to clear liquids. Thus, the economic benefits from avoided emissions will also vary considerably. Such wide variability means that some projects will have much shorter payback periods than others. While most plunger lift installations will be justified by increased gas production rates alone, methane emissions reductions can provide an additional revenue stream.

★ **Avoided emissions when replacing blowdowns.** In wells where plunger lift systems are installed, emissions from blowing down the well can be reduced. Blowdown emissions vary widely in both their frequency and flow rates and are entirely well and reservoir specific. Emissions attributable to blowdown activities have been reported from 1 Mcf per year to thousands of Mcf per year per well. Therefore, the savings attributable to avoided emissions will vary greatly based on the data for the particular well being rehauled.

Revenue from avoided emissions can be calculated by multiplying the market value of the gas by the volume of avoided emissions. If the emissions per well per blowdown have not been measured, they must be estimated. In the example below, the amount of gas that is vented from a low pressure gas well at each blowdown is estimated as 0.5625 times the sustained flow gas rate. This emission factor assumes that the integrated average flow over the blowdown period is 56.25 percent of full well flow. Using this assumption, Exhibit 5 demonstrates that

NMED Exhibit 74 - 0005

for an unloaded well producing 100 Mcf per day, the gas vented to the atmosphere can be estimated at 2 Mcf per hour of blowdown.

Exhibit 5: Example—Estimate Avoided Emissions from Blowdowns

Avoided Emissions per Hour of Blowdown[a]	= (0.56251 x Sustained Daily Flow Rate) / 24 hrs/day
Avoided Emissions[b]	= (0.5625 x 100 Mcfd) / 24 = 2 Mcf per hour of blowdown
Annual Value of Avoided Emissions[c]	= 2 Mcf x 12 x $7.00/Mcf = $168 per year

[a] Recommended methane emission factor reported in the joint GRI/EPA study, Methane Emissions From the Natural Gas Industry, Volume 7: Blow and Purge Activities (June 1995). The study estimated that at the beginning of a blowdown event, gas flow is restricted by fluids in the well to 25 percent of full flow. By the end of the blowdown event, gas flow is returned to 100 percent. The integrated average flow over the blowdown period is 56.25 percent of full well flow.
[b] Assuming a sustained daily production rate of 100 Mcfd.
[c] Assuming 1 blowdown per month lasting 1 hour.

This method is simple to use, but anecdotal evidence suggests that it produces estimates of methane emissions avoided that are unrealistically low. For an alternate method for estimating avoided emissions from blowdowns, see the Appendix.

Given the high degree of variability in emissions based on well and reservoir specific characteristics, measurement is the preferred method for determining avoided emissions. Field measurements can provide the data necessary to accurately determine the savings attributable to avoided emissions.

★ **Avoided emissions when replacing beam lifts.** In cases where plunger lifts replace beam lifts rather than blowdowns, emissions will be avoided due to reduced workovers for mechanical repairs, to remove debris and cleanout perforations, to remove mineral scale and paraffin deposits from the sucker rods. The average emissions associated with workovers have been reported as approximately 2 Mcf per workover; the frequency of workovers has been reported to range from 1 to 15 per year. Due to well-specific characteristics such as flow during workover, duration of workover, and frequency of workover, avoided emissions can vary greatly.

Avoided Costs and Additional Benefits

Avoided costs depend on the type of liquid removal systems currently in place, but can include avoided well treatment, reduced electricity costs, and reduced workover costs. Avoided well treatment costs are applicable when plunger lifts replace beam lifts or other remedial techniques such as blowdown, swabbing, or soaping. Reduced electricity costs, reduced workovers, and recovered salvage value are only applicable if plunger lifts replace beam lifts.

★ **Avoided well treatment costs.** Well treatment costs include chemical treatments, microbial cleanups, and removal of rods and scraping the borehole. Information from shallow 1,500-foot wells show well remediation costs including rod removal and tubing rehabilitation at more than $14,500 per well. Chemical treatment costs (inhibitors, solvents, dispersants, hot fluids, crystal modifiers, and surfactants) are reported in the literature at a minimum of $13,200 per well per year. Microbial costs to reduce paraffin have been shown to be $6,600 per well per year (note that microbial treatments do not address the fluids influx problem). Each of these treatment costs increases as the severity of the scale or paraffin increases, and as the depth of the well increases.

★ **Reduced electricity costs compared to beam lifts.** Reduced electric operating costs further increase the economic return of plunger lifts. No electrical costs are associated with plunger lifts, because most controllers are solar-powered with battery backup. Exhibit 6 presents a range of avoided electricity costs reported by operators who have installed plunger lifts. Assuming 365 days of operation, avoided electricity costs range from $1,000 to $7,300 per year.

★ **Reduced workover costs compared to beam lifts.** Workover costs associated with beam lifts have been reported as $1,300 per day. While typical

Exhibit 6: Electricity Costs[a] Avoided by Using a Plunger Lift in Place of a Beam Lift

Motor Size (BHP)	Operation Cost ($/day)
10	3
20	7
30	10
40	13
50	17
60	20

[a] Electricity cost assumes 50 percent of full load, running 50 percent of the time, with cost of 7.5 cents/kWh.

NMED Exhibit 74 - 0006

workovers may take one day, wells more than 8,000 feet deep will require more than one day of workover time. Depending on the well, from 1 to 15 workovers can be required per year. These costs are avoided by using a plunger lift.

★ **Recovered salvage value when replacing a beam lift.** If the plunger being installed is replacing a beam lift, extra income and a better economic return are realized from the salvage value of the old production hardware. Exhibit 7 shows the salvage value that may be obtained by selling the surplus pumping units. In some cases, salvage sales alone may pay for the installation of plunger lifts.

Exhibit 7: Salvage Value[a] of Legacy Equipment When Converting from Beam Lift to Plunger Lift Operations

Capital Savings from Salvaging Equipment	
Size of Pumping Unit (inch-lbs torque)	**Equipment Salvage Value ($)**
114,000	12,300
160,000	16,800
228,000	21,300
320,000	27,200
456,000	34,300
640,000	41,500

[a] Salvage costs include low estimate sale value of pumping unit, electric motor, and rod string.

Step 4: Evaluate the plunger lift's economics.

A basic cash flow analysis can be used to compare the costs and benefits of a plunger lift with other liquid removal options. Exhibit 8 shows a summary of the costs associated with each option.

★ **Economics of Replacing a Beam Lift with a Plunger Lift.** In Exhibit 9 the data from Exhibit 8 is used to model a hypothetical 100 Mcfd well and to evaluate the economics of plunger lift installation. The increase in production is 20 Mcf per day, yielding an annual increase in production of 7,300 Mcf. Assuming one workover per year prior to installation, the switch to a plunger lift also provides 2 Mcf of avoided emissions per year. The project profits greatly from the salvage value of the surplus beam lift equipment, yielding an immediate payback. Even if the salvage value is not recovered, the project may yield payback after only a few months depending on the well's productivity.

Methane Content of Natural Gas

The average methane content of natural gas varies by natural gas industry sector. The Natural Gas STAR Program assumes the following methane content of natural gas when estimating methane savings for Partner Reported Opportunities.

Production	79 %
Processing	87 %
Transmission and Distribution	94 %

★ **Economics of Avoiding Blowdown with a Plunger Lift.** Exhibit 10 uses data from Exhibit 8 to evaluate the economics of a hypothetical 100 Mcfd well at which a plunger lift is installed to replace blowdown as the method for removing liquid from the well. Assuming the increased production is 20 Mcf per day, the annual increase in production is 7,300 Mcf. In addition, there will be savings from avoided emissions during blowdown. Assuming 12 one-hour blowdowns per year, the avoided emissions are 24 Mcf per year.

Exhibit 8: Cost Comparison of Plunger Lift vs. Other Options

Cost Category	Plunger Lift	Traditional Beam Lift	Remedial Treatment[a]
Capital and Startup Costs	$1,943 - $7,772	$25,907 - $51,813	$0
Implementation Costs:			
Maintenance[b]	$1,300/yr	$1,300 - $19,500/yr	$0
Well Treatment[c]	$0	$13,200+	$13,200+
Electrical[d]	$0	$1,000 - $7,300/yr	$0
Salvage	$0	($12,000 - $41,500)	$0

[a] Includes soaping, swabbing, and blowing down.
[b] For traditional beam lift, maintenance costs include workovers and assume 1 to 15 workovers per year at $1,300 per workover.
[c] Costs may vary depending on the nature of the liquid.
[d] Electricity costs for plunger lift: assume the lift is solar and well powered.

Case Studies

BP (formerly Amoco) Midland Farm Field

Amoco Corporation, a Natural Gas STAR charter Partner (now merged with BP), documented its success in replacing beam lift, rod pump well production equipment with plunger lifts at its Midland Farm field. Prior to installing plunger lift systems, Amoco used beam lift installations with fiberglass rod strings. The lift equipment was primarily 640 inch-lb pumping units powered by 60 HP motors. Operations personnel noted that wells at the field were having problems with paraffin plating the well bore and sucker rods, which blocked fluid flow and interfered with fiberglass sucker rod movement. Plunger lifts were seen as a possible solution to inhibit the accumulation of paraffin downhole.

Amoco began its plunger lift replacement program with a single-well pilot project. Based on the success of this initial effort, Amoco then expanded the replacement process to the entire field. As a result of the success in the Midland Farm field, Amoco installed 190 plunger lift units at its Denver City and Sundown, Texas locations, replacing other beam lift applications.

Costs and Benefits

Amoco estimated that plunger lift system installation costs -including plunger equipment and tubing conversion costs- averaged $13,000 per well (initial pilot costs were higher than average during the learning phase, and the cost of tubing conversion is included).

Amoco then calculated savings resulting from avoided costs in three areas—electricity, workover, and chemical treatment. Overall, Amoco estimated that the avoided costs of electricity, workover, and paraffin control averaged $24,000 per well per year.

- **Electricity.** Cost savings were estimated based on 50 percent run times. Using the costs from Exhibit 6, the estimated electrical cost savings were estimated to be $20 per day.
- **Workover.** On average, Amoco had one workover per year per well to fix rod parts. With the old beam lift systems, the cost of this operation was $4,000, averaging about $11 per day.
- **Chemical treatment.** The biggest savings were realized from avoided chemical treatment. Amoco was able to save the approximately $13,000 per well per year for paraffin control because the plunger operation removed paraffin accumulation in the tubing.

Increased Gas Production and Revenue

For the initial plunger lift installation, Amoco realized an increase in gas production of more than 400 Mcf per day. Upon expansion of the plunger lift installation to the entire field, the company realized notable success in many wells—although some showed little or no production increase during the 30 day evaluation period. Total production increase (including both incremental production and non-emitted gas) across all wells where plunger lifts were installed was 1,348 Mcf per day. The average annual gas savings, which assumes a 6 percent production decline, was 11,274 Mcf per well or approximately $78,918 per well at 2006 prices. Exhibit 12 and Exhibit 13 summarize the initial results and first year economics of Amoco's Midland Farm plunger lift installation. In addition to the gas savings and cost savings from the plunger lift installations, Amoco realized a one-time gain from the sale of surplus pumping units

and motors, resulting in additional revenue of $41,500 per installation.

Analysis

A summary of the costs and benefits associated with Amoco's plunger lift installation program is provided below in Exhibit 13. For the first year of operation, the company realized an average annual savings of approximately $90,200 per well at 2006 prices. In addition the company realized approximately $41,500 per well from salvage of the beam lift equipment at 2006 costs.

ExxonMobil Big Piney Field

At Big Piney Field in Wyoming, Natural Gas STAR charter Partner Mobil Oil Corporation (now merged with Exxon) has installed plunger lift systems at 19 wells. The first two plunger lifts were installed in 1995, and the remaining wells were equipped in 1997. As a result of these installations, Mobil reduced overall blowdown gas emissions by 12,164 Mcf per year. In addition to the methane emission reduction, the plunger lift system reduced the venting of ethane (6 percent by volume), C3 hydrocarbons + VOCs (5 percent), and inerts (2 percent). Exhibit 14 shows the emission reductions for each well after plunger lift installation.

Installation Tips

The following suggestions can help ensure trouble-free installation of a plunger lift system:

- ★ **Do not use a completion packer, because it limits the amount of gas production per plunger trip.** Without a completion packer, the entire annular void space is available to create a large compressed gas supply. The greater the volume of gas, the larger the volume of water that can be lifted.

- ★ **Check for tubing obstructions with a gauge ring before installation.** Tubing obstructions hinder plunger movement and may require replacement of production tubing.

- ★ **Capture the plunger after the first trip.** Inspection of the plunger for the presence of any damage, sand, or scale will help prevent any subsequent plunger lift operational difficulties, permitting immediate operational repair while the crew and installation equipment are mobilized.

Lessons Learned

Plunger lift systems offer several advantages over other remedial treatments for removing reservoir fluids from wells: increased gas sales, increased well life, decreased well maintenance, and decreased methane emissions. The following should be considered when installing a plunger lift system:

- ★ Plunger lift installations can offer quick paybacks and high return on investments whether replacing a beam lift or blowdowns.

- ★ Plunger lift installations can greatly reduce the amount of remedial work needed throughout the

Exhibit 14: Plunger Lift Program at Big Piney, Wyoming

lifetime of the well and the amount of methane vented to the atmosphere.

- ★ An economic analysis of plunger lift installation should include the incremental boost in productivity as well as the associated extension in well life.
- ★ Even when the well pressure declines below that necessary to lift the plunger and liquids against sales line back pressure, a plunger is more efficient in removing liquids with the well vented to the atmosphere than simply blowing the well without a plunger lift.
- ★ Include methane emission reductions from installing plunger lift systems in annual reports submitted as part of the Natural Gas STAR Program.

Appendix

Estimating incremental production for declining wells.

From Dake's *Fundamentals of Reservoir Engineering* (1982) we can use the following equation to calculate the increase in downhole flow for reduced pressure that may be seen when using a plunger lift. A semi-steady state inflow equation can be expressed as:

$m(p_{avg}) - m(p_{wf}) = [(1422 \times Q \times T)/(k \times h)] \times [\ln(r_e/r_w) - 3/4 + S)] \times (8.15)$

Where,

$m(p_{avg})$ = real gas pseudo pressure average

$m(p_{wf})$ = real gas pseudo pressure well flowing

Q = gas production rate

T = absolute temperature

k = permeability

h = formation height

r_e = external boundary radius

r_w = wellbore radius

S = mechanical skin factor

After the reservoir parameters are gathered, this equation can be solved for Q for the retarded flow with fluids in the hole (current conditions and current decline curve), and Q for no fluids in the hole (plunger lift active and improved decline curve). This is a guideline, and operators are reminded to use a reservoir engineer to aid in this determination.

Alternate technique for calculating avoided emissions when replacing blowdowns.

A conservative estimate of well venting volumes can be made using the following equation:

Annual Vent Volume, Mscf/yr = $(0.37 \times 10^{-6}) \times$ (Casing Diameter)^2 × Well Depth × Shut-in Pressure × Annual Vents

Where casing diameter is in inches, well depth is in feet and shut-in pressure is in psig. Exhibit A1 shows an example calculation.

Exhibit A1: Example—Estimate Avoided Emissions from Blowdowns

Casing Diameter	8 inches
Well Depth	10,000 feet
Shut-in Pressure	214.7 psig
Annual Vents	52 (weekly venting)

Annual Vent Volume = $(0.37 \times 10^{-6}) \times 8^2 \times 10{,}000 \times 214.7 \times 52$ = 2,644 Mscf/yr

This is the minimum volume of gas that would be vented to atmospheric pressure from a well that has stopped flowing to the sales line because a head of liquid has accumulated in the tubing equal to the pressure difference between the sales line pressure and well shut-in pressure. If the well shut-in pressure is more than 1.5 times the sales line pressure, as required for a plunger lift installation in Exhibit 2, then the volume of gas in the well casing at shut-in pressure should be minimally sufficient to push the liquid in the tubing to the surface in slug-flow when back-pressure is reduced to zero psig. Partners can estimate the minimum time to vent the well by using this volume and the Weymouth gas-flow formula (worked out for common pipe diameters, lengths and pressure drops in Tables 3, 4 and 5 in *Pipeline Rules of Thumb Handbook*, Fourth Edition, pages 283 and 284). If the Partner's practice and experience is to vent the wells a longer time than calculated by these methods, the conservative Annual Vent Volume can be increased by a simple ratio of the actual vent times and the minimum vent time calculated using the Weymouth equation.

MEMORANDUM

DATE: December 21, 2006

SUBJECT: Impacts of Applying Management Practices to a Single Oil and Natural Gas Production Area Source Facility

FROM: Heather P. Brown, P.E.

TO: Greg Nizich, EPA/OAQPS/SPPD/CCG

I. INTRODUCTION AND BACKGROUND

On July 8, 2005, (70 FR 39443), the United States Environmental Protection Agency (EPA) issued a supplemental proposal to the February 6, 1998 (63 FR 6288), proposed standards for oil and natural gas production area sources. In response to comments received on the two proposals, EPA is requiring certain triethylene glycol (TEG) dehydration units located at area source oil and natural gas production facilities to reduce emissions by implementing the management practice of optimizing the glycol circulation rate.

Most dehydration systems use TEG as an absorbent to remove water from natural gas. As the TEG absorbs water, it also absorbs methane and any other hazardous air pollutants (HAP) or volatile organic compounds (VOC) entrained in the methane. As the TEG is regenerated in the reboiler, any absorbed compounds (i.e., methane, HAP, and VOC) are vented to the atmosphere. The amount of methane absorbed and vented is directly proportional to the TEG circulation rate. According to the Natural Gas STAR Partners, many wells operate below their original design capacity but continue to circulate the TEG at rates two to three times higher than needed for a particular water removal rate.[a] Therefore, by reducing the glycol circulation rate, HAP emissions can be reduced.

In addition to reducing HAP emissions, reducing the glycol circulation rate also reduces the TEG circulation rate has the added benefit of reducing the amount of natural gas absorbed by the TEG and subsequently emitted through the reboiler vent thereby resulting in a natural gas savings. Furthermore, optimizing the TEG circulation rate can be achieved without sacrificing the performance of the TEG dehydration unit, does not require the presence of an on-site operator to maintain, can be optimized for minimal capital cost (e.g., a new pump may be required), and could result in an annual cost savings due to the reduction of the natural gas losses. The purpose of this memorandum is to estimate air emission and cost impacts associated with reducing the glycol circulation rate to an optimized level for a single TEG dehydration unit.

[a] Lessons Learned: From Natural Gas STAR Partners. "Optimize Glycol Circulation and Install Flash Tank Separators in Glycol Dehydrators." http://www.epa.gov/gasstar/pdf/lessons/ll_flashtanks3.pdf

II. AIR EMISSIONS IMPACTS

In order to estimate the air emissions impact from reducing the TEG circulation rate to an optimum level, GRI-GLYCalc Version 4.0 (GLYCalc) was used to estimate baseline emissions and emissions from the optimized TEG circulation rate.

Table 1 presents baseline emissions estimated using the following inputs for GLYCalc:

- The glycol recirculation ratio was set at the industry average of 5.9 gallons of glycol per pound of water removed (gal TEG/lb H_2O).[b] This corresponds to a circulation rate of approximately 37 gallons of TEG per hour (gal TEG/hr).
- Because emissions are proportional to the natural gas throughput, the emission reduction is not impacted by the throughput level (i.e., TEG dehydration units with a natural gas throughputs of 3 MMSCF/D and 5 MMSCF/D have the same emission reduction of 45 percent). Therefore, the natural gas throughput was set at the applicability cutoff of 3 million standard cubic feet per day (MMSCF/D).
- According to Natural Gas STAR Partners, smaller and older units are not equipped with a flash tank. Therefore, no flash tank was used.[c]
- According to Natural Gas STAR Partners, remote gas fields do not have electrical power and instead use energy-exchange (or gas injection) pumps. Therefore, the pump type was set as a gas injection pump.[d]
- Other program inputs were chosen to be consistent with values used in previous impacts calculations.[e]

Attachment 1 contains the summary of input values and emissions data generated by the GLYCalc program for baseline emissions.

To calculate emissions at the optimal glycol circulation rate, a glycol recirculation ratio of 3 gal TEG/lb H_2O was used. This ratio is considered the rule-of-thumb for the industry[f] and corresponds to a TEG circulation rate of approximately 19 gal TEG/hr. The remaining inputs were the same as those used to estimate baseline emissions. Emissions at the optimal glycol circulation rate are also presented in Table 1 (a summary of input values and emissions data is presented in Attachment 2).

As shown in Table 1, optimizing the glycol circulation rate reduces HAP emission by approximately 45 percent. Likewise, VOC emissions were reduced by 48 percent and benzene emissions were reduced by 47 percent.

Table 1. Emissions Impacts of Reducing TEG Circulation Rate for a Single TEG Dehydration Unit[1]

Pollutant	Emissions at Baseline Circulation Rate (tpy)[2]	Emissions at Optimized Circulation Rate (tpy)[3]	Emission Reduction (%)
HAP	6.1482	3.376	45
VOC	15.281	7.9982	48
Benzene	1.8076	0.9498	47

[1] Emissions for the baseline circulation rate and optimized circulation rate were generated using GLYCalc. Input summaries and emissions results are presented in Attachments 1 and 2, respectively.

[2] Baseline circulation rate = 37 gal/hr (corresponding to a baseline recirculation ratio of 5.9 gal TEG/lb H_2O).

[3] Optimized circulation rate = 19 gal/hr (corresponding to an optimal recirculation ratio of 3 gal TEG/lb H_2O).

NMED Exhibit 76 - 0003

III. COST IMPACTS

While some facilities may be able to adjust the circulation rate without replacing equipment, it was assumed that at a minimum, the glycol pump would have to be replaced. Therefore, cost impacts were generated to represent the costs related to pump replacement.

Equipment costs were developed based on information from Kimray, Inc., a pump vendor (See Attachment 3).[g] Table 2 presents the capital costs for installing a new pump to achieve the optimized TEG circulation rate. The total capital investment for installing a new pump was estimated to be $1,540. The annual costs were estimated to be $914 per year for a single unit and are presented in Table 3. For sources that do not have to purchase a new pump to meet the optimal circulation rate, the only costs associated with the implementing the optimal TEG circulation rate are related to operational costs. The annual cost of implementing the optimal circulation rate without replacing the pump was approximately $600 per year and is presented in Table 4.

EQUIPMENT REPORTS:

ABSORBER

NOTE: Because the Calculated Absorber Stages was below the minimum allowed, GRI-GLYCalc has set the number of Absorber Stages to 1.25 and has calculated a revised Dry Gas Dew Point.

Calculated Absorber Stages: 1.25
Calculated Dry Gas Dew Point: 2.90 lbs. H2O/MMSCF

Temperature:	90.0 deg. F
Pressure:	700.0 psig
Dry Gas Flow Rate:	3.0000 MMSCF/day
Glycol Losses with Dry Gas:	0.0180 lb/hr
Wet Gas Water Content:	Saturated
Calculated Wet Gas Water Content:	56.75 lbs. H2O/MMSCF
Specified Lean Glycol Recirc. Ratio:	5.90 gal/lb H2O

Component	Remaining in Dry Gas	Absorbed in Glycol
Water	5.09%	94.91%
Carbon Dioxide	99.77%	0.23%
Methane	99.98%	0.02%
Ethane	99.95%	0.05%
Propane	99.91%	0.09%
n-Butane	99.82%	0.18%
n-Pentane	99.76%	0.24%
n-Hexane	99.59%	0.41%
Other Hexanes	99.69%	0.31%
Heptanes	99.22%	0.78%
2,2,4-Trimethylpentane	99.66%	0.34%
Benzene	84.70%	15.30%
Toluene	77.99%	22.01%
Ethylbenzene	70.79%	29.21%
Xylenes	61.83%	38.17%

REGENERATOR

No Stripping Gas used in regenerator.

Component	Remaining in Glycol	Distilled Overhead
Water	43.33%	56.67%

GRI-GLYCalc, Version 4.0 Input Summary and Aggregate Emissions Summary for Optimized Glycol Circulation Rate (3 gal TEG/lb H_2O)

GRI-GLYCalc VERSION 4.0 - SUMMARY OF INPUT VALUES

Case Name: BMP Case
File Name: D:\My Documents\Oil and Gas\Promulgation\Condenser Operation\GLYCalc\BMP runs\3mmscf per day flash tank 3 recirc.ddf
Date: December 08, 2006

DESCRIPTION:

Description: 3 mmscf/d actual throughput
BTEX content = 200 ppmv; Recirc Rate 3
No Flash Tank
Gas Injection Pump

Annual Hours of Operation: 8760.0 hours/yr

WET GAS:

Temperature: 90.00 deg. F
Pressure: 700.00 psig
Wet Gas Water Content: Saturated

Component	Conc. (vol %)
Carbon Dioxide	1.0000
Methane	90.0240
Ethane	5.3000
Propane	1.3000
n-Butane	1.2000
n-Pentane	1.0000
n-Hexane	0.0420
Other Hexanes	0.0840
Heptanes	0.0100
2,2,4-Trimethylpentane	0.0200
Benzene	0.0104
Toluene	0.0056
Ethylbenzene	0.0006
Xylenes	0.0034

DRY GAS:

Flow Rate: 3.0 MMSCF/day
Water Content: 7.0 lbs. H2O/MMSCF

LEAN GLYCOL:

Glycol Type: TEG
Water Content: 1.5 wt% H2O
Recirculation Ratio: 3.0 gal/lb H2O

PUMP:

Glycol Pump Type: Gas Injection
Gas Injection Pump Volume Ratio: 0.080 acfm gas/gpm glycol

MEMORANDUM

DATE: June 25, 2005

SUBJECT: Revised Impacts for Area Sources in the Oil and Natural Gas Production Source Category

FROM: Heather P. Brown, P.E.

TO: Greg Nizich, EPA/OAQPS/ESD/WCPG

On February 6, 1998 (63 FR 6288), the United States Environmental Protection Agency (EPA) proposed standards for major and area sources in the Oil and Natural Gas Production Source Category. When the major source rule was finalized on June 17, 1999 (64 FR 32610) under 40 CFR part 63, subpart HH, the regulation of oil and natural production area source facilities was deferred. EPA is now proposing amendments to subpart HH to add regulatory language for area sources. The proposed amendments require area sources to reduce HAP emissions from each triethylene glycol (TEG) dehydration unit with a natural gas throughput greater than or equal to 3 million standard cubic feet per day (MMscf/d) or with benzene emissions greater than or equal to 1 ton per year (tpy) by 95 percent or to a level such that benzene emissions are less than 1 tpy.

The purpose of this memorandum is to present the revised impacts for area source TEG units in the oil and natural gas production source category. The impacts presented include primary air impacts, secondary environmental impacts (air pollution, water and solid waste impacts), energy impacts, and cost impacts. In addition, the incremental cost effectiveness evaluation is documented in this memorandum.

PRIMARY ENVIRONMENTAL IMPACTS

This section presents the revised nationwide primary air pollution impacts (i.e., the reduction of HAP emissions) associated with the proposed area source standards. EPA estimated that there are potentially 38,067 area source TEG dehydration units in the United States. Throughput categories were established and the number of TEG dehydration units were distributed across these categories. The basis for the distribution of facilities is presented in another memorandum.[1] Table 1 presents the throughput categories and the number of units within each category.

>2 and ≤ 3	3	884	796	88
>3 and ≤ 4	4	732	659	73
>4 and ≤ 5	5	606	545	61
	Total	38,067	34,261	3,806

For the purposes of estimating baseline emissions, EPA estimated that 10 percent of the existing TEG dehydration units would be equipped with a flash tank.[2] The number of units within each throughput category with and without flash tanks are also presented in Table 1 as well as the average throughput for each category.

Baseline emissions were estimated using GRI-GLYCalc (Version 4.0)©. Attachment A contains the input summary files for each run. The following inputs were used for each GRI-GLYCalc© run:

- Temperature = 90^{O}F;
- Pressure = 700 psig;
- Dry gas water content = 7 lb/MMscf/d; and
- Glycol Circulation rate = 5.9 gal glycol/lb water removed

Table 2 presents baseline HAP, VOC, and benzene emissions for a single TEG dehydration unit within each throughput category.

Nationwide baseline emissions were estimated based on the number of TEG units per throughput category (Table 1) and baseline single unit emissions (Table 2). Nationwide baseline emissions are presented in Table 3.

Controlled emissions were estimated for area source TEG dehydration units that would be subject to area source standards. Each area source TEG dehydration unit with a throughput greater than or equal to 3 MMscf/d or benzene emissions greater than or equal to 1 tpy must choose between two control scenarios. Under Control Scenario 1, TEG dehydration units would reduce emissions by 95 percent. Area sources also have the option of reducing emissions to a level such that benzene emissions are less than 1 tpy, defined as Control Scenario 2. Controlled emissions are presented for Control Scenario 1 in Table 3 (95-percent emission reduction) and for Control Scenario 2 in Table 4 (1 tpy benzene). Table 5 presents the total emission reductions for each control scenario.

NMED Exhibit 78 - 0007

SECONDARY ENVIRONMENTAL IMPACTS

Although the intent of the area source standards is to reduce HAP emissions, the application of control technologies can lead to other secondary environmental impacts. These secondary impacts can have a positive environmental impact, such as the reduction of VOC emissions, or a negative impact. Negative impacts may result from air pollutants emitted as a result of combustion sources (e.g., flares) or generation of a solid or liquid waste stream. The secondary impacts on air pollution and water and solid waste are discussed in this section.

Air Pollution

The primary method of HAP control from area source TEG dehydration units is the installation of a condenser and, if not present, a gas condensate glycol separator (GCG separator or flash tank). The secondary air pollution impacts associated with the application of this type of control are the decreased VOC emissions resulting from capture and control of HAP emissions.

Other secondary environmental impacts are those associated with the operation of certain air emission control devices, (i.e., flares). If a facility does not have the ability to handle the collected vapor for use as a fuel or recycle the collected vapor back into the process. In such cases, the collected vapors may be directed to an on-site flare. EPA estimated that 10 percent of the facilities would direct all collected vapors to an on-site flare.[3] The adverse secondary air impacts resulting from the use of a flare would be minimal in comparison to the primary HAP reduction benefits from implementing the proposed control options for area sources. Table 6 presents the secondary air impacts due to the use of flares for area sources.

Water and Solid Waste Impacts

The water impacts associated the installation of a condenser system for the TEG dehydration unit reboiler vent would be minimal. The condensed water collected with the hydrocarbon condensate can be directed back into the system for reprocessing with the hydrocarbon condensate or, if separated, combined with produced water for disposal by reinjection.[4]

There is no solid waste generated from the control of HAP emissions using a condenser. Therefore, we do not anticipate any adverse solid waste impacts from the implementation of the area source standards.

Pollutant	Estimated Emissions per Flare (lb/yr)[a]	Estimated Number of Units Installing a Flare	Nationwide Emissions (tpy)
SO_X	2	222	<1
NO_X	106	222	12
CO	22	222	2

[a]Reference 2, page 5-7.

NMED Exhibit 78 - 0009

ENERGY IMPACTS

Energy impacts are those energy requirements associated with the operation of emission control devices. There would be no national energy demand increase from the operation of any of the control options analyzed under the proposed oil and natural gas production standards for area sources. The proposed area source standards encourage the use of emission controls that recover hydrocarbon products, such as methane and condensate, that can be used on-site as fuel or reprocessed, within the production process, for sale. Thus, the proposed standards have a positive impact associated with the recovery of non-renewable energy resources.

COST IMPACTS

The cost impacts due to the application of control devices to meet the proposed area source standards include the cost of the control equipment that must be purchased, along with the cost of the installation of that control equipment. There are also costs for the operation and maintenance of the equipment. Finally, there are costs associated with the required monitoring, inspection, recordkeeping, and reporting (MIRR). This section presents the estimated costs associated with compliance with the area source standards. These cost estimates apply to both control scenarios.

Cost estimates for condensers were developed for the 1998 proposal and are documented in the Background Information Document (BID).[5] The original cost estimates were based on 1993 cost data. Therefore, these estimates were revised to reflect 2004 prices. The following tables present these revised cost estimates. Equipment costs were updated to represent 2004 prices using the Chemical Engineering[6] cost index. In addition, labor rates were updated to 2004 prices using information from the Bureau of Labor Statistics.[7,8] Table 7 presents the updated capital costs for installing a condenser on a TEG dehydration unit that does not have existing flash tanks and must install a flash tank to comply with the area source standards. Table 8 presents a summary of the updated capital costs for installing a condenser on a TEG dehydration units that are equipped with a flash tank. Table 9 presents the updated annual cost for condensers and Table 10 presents the costs associated with MIRR. Finally, Table 11 presents the nationwide costs for the oil and natural gas production industry.

Table 10. Annual MIRR Costs per Glycol Dehydration Unit

Activity	Technical hours per activity (A)	Number of activities per year (B)	Activity cost parameters Technical hours per year (C)	Management hours per activity (D)	Clerical hours per activity (E)	Total annual costs in $ per year (F)
Read rule and instructions	1.5	2	3	0.15	0.3	$ 137.88
Plan activities	3	1	3	0.15	0.3	$ 137.88
Training	1	1	1	0.05	0.1	$ 45.96
Testing/Development	20	1	20	1	2	$ 919.22
Monitoring/Inspection	0.1	52	5.2	0.26	0.52	$ 239.00
Process/Review	1.5	1	1.5	0.08	0.15	$ 69.25
Complete reports	5	1	5	0.25	0.5	$ 229.80
Record/Report	0.5	6	3	0.15	0.3	$ 137.88
Store/Maintain data	0.5	12	6	0.3	0.6	$ 275.76
Totals[a]			47.7	2.39	4.77	$ 2,192.64

Activity cost parameters

C = A x B
D = 0.05 x C
E = 0.10 x C
F = ($tech x C) + ($mgmt x D) + ($clerical x E)

a - Total hours are rounded to nearest hour and total dollars rounded to nearest $100.

Technical Labor Hourly Rate = 39.75
Management Labor Hourly Rate = 62.39
Clerical Labor Hourly Rate = 30.92
(Reference 14. All labor rates are multiplied by 1.5 to account for overhead)

[14]Bureau of Labor Statistics (http://www.bls.gov/news.release/pdf/ecec.pdf) Table 11. March 2004

NMED Exhibit 78 - 0014

Table 11. Nationwide Cost Impacts for Area Sources

	National Revised Costs	
	TEG-A	**TEG-A'**
Estimated Number of Impacted Units	2,000	222
Capital Costs	17,220	14,410
Annualized Capital Costs	1,891	1,582
O&M	8,816	8,816
Other Annual Costs (Admin., taxes, ins.)	4,940	4,828
Product Recovery	(141)	(141)
MIRR (c)	2,193	2,193
Cost Impact Summary for one Model Unit		
Total Capital Investment	17,220	14,410
Total Annual Cost	17,699	17,278
Nationwide Impacts		
Total Capital Investment	34,440,000	3,199,020
Total Annual Cost	35,397,951	3,835,724
	39,233,675	

a- Costs for the proposed rule are in July 1993 dollars

b- Revised costs are in April 2004 dollars

c- Labor cost for MIRR was updated based on March 2004 data f

REGULATORY ACTION LEVELS

In the preamble to the proposed area source standard (63 FR 6288), four regulatory alternatives were evaluated. Each regulatory alternative was characterized in terms of an action level, above which HAP emissions must be controlled. Action levels were expressed as the actual annual average flow rate of natural gas to the TEG dehydration unit (MMscf/d). For the proposed amendments, four similar action levels were evaluated for Control Scenarios 1 and 2 (95-percent control and 1-tpy benzene emissions, respectively). Table 12 presents the regulatory action levels for Control Scenario 1 (reduce emissions by 95 percent). Table 13 presents the regulatory action levels for Control Scenario 2 (control emissions so that benzene emissions are less than 1 tpy).

Tables 12 and 13 also present the cost effectiveness of each regulatory action level as well as the incremental cost effectiveness. As shown in Table 12, the incremental cost effectiveness between the 3-MMscf/d action level and the 2-MMscf/d is approximately $4,600 per ton for sources that would apply 95 percent control (Control Scenario 1). However, when considering the incremental cost effectiveness between the same to action levels for Control Scenario 2 (reducing benzene emissions to less than 1 tpy), the value is approximately $27,000 per ton. Since it is more likely that sources will opt for Control Scenario 2, which is less stringent than Control Scenario 1, the 3-MMScf/d regulatory action level is appropriate.

NMED Exhibit 78 - 0016

Table 12. Regulatory Action Levels for Area Source Glycol Dehydration Units - Control Scenario 1[1]

Size-Based Action Level (MMSCF/D)	Number of Units Impacted	HAP Reduction (1,000 tpy)	Total Capital Costs ($million)	Annual Costs ($million)	MIRR Costs ($million)	Total Annual Costs ($million)	Cost Effectiveness ($/ton HAP)	Incremental Cost Effectiveness ($/ton HAP)
4	1,338	11.35	22.7	20.7	2.9	23.6	2,082	--
3	2,222	16.40	37.6	34.4	4.9	39.2	2,392	3,089
2	3,289	20.46	55.7	50.9	7.2	58.1	2,838	4,634
0.3	25,180	43.59	426.5	389.3	55.2	444.5	10,198	16,713

[1] Control Scenario 1 - Reduce emissions by 95 percent.

Table 13. Regulatory Action Levels for Area Source Glycol Dehydration Units - Control Scenario 2[1]

Size-Based Action Level (MMSCF/D)	Number of Units Impacted	HAP Reduction (1,000 tpy)	Total Capital Costs ($million)	Annual Costs ($million)	MIRR Costs ($million)	Total Annual Costs ($million)	Cost Effectiveness ($/ton HAP)	Incremental Cost Effectiveness ($/ton HAP)
4	1,338	7.46	22.7	20.7	2.9	23.6	3,168	--
3	2,222	9.81	37.6	34.4	4.9	39.2	3,999	6,633
2	3,289	10.51	55.7	50.9	7.2	58.1	5,525	26,896
0.3	3,289	10.51	55.7	50.9	7.2	58.1	5,525	--

[1] Control Scenario 2 - Units with benzene emissions greater than or equal to 1 tpy of benzene will reduce emissions such that benzene emissions are less than 1 tpy.

DRY GAS:

Flow Rate: 0.3 MMSCF/day
Water Content: 7.0 lbs. H2O/MMSCF

LEAN GLYCOL:

Glycol Type: TEG
Water Content: 1.5 wt% H2O
Recirculation Ratio: 5.9 gal/lb H2O

PUMP:

Glycol Pump Type: Electric/Pneumatic

FLASH TANK:

Flash Control: Vented to atmosphere
Temperature: 160.0 deg. F
Pressure: 28.0 psig

GRI-GLYCalc VERSION 4.0 - SUMMARY OF INPUT VALUES

Case Name: .5 mmscf/d Dehy
File Name: D:\My Documents\Oil and Gas\number of area sources\GRI Runs\actual throughput\0.5mmscf per day flash tank.ddf
Date: November 08, 2004

DESCRIPTION:

Description: Dehydration unit with a .5 mmscf/d actual throughput
BTEX content = 200ppmv
Flash Tank
Production Unit

Annual Hours of Operation: 8760.0 hours/yr

WET GAS:

Temperature: 90.00 deg. F
Pressure: 700.00 psig
Wet Gas Water Content: Saturated

Component	Conc. (vol %)
Carbon Dioxide	1.0000
Methane	90.0240
Ethane	5.3000
Propane	1.3000
n-Butane	1.2000
n-Pentane	1.0000
n-Hexane	0.0420
Other Hexanes	0.0840
Heptanes	0.0100
2,2,4-Trimethylpentane	0.0200
Benzene	0.0104
Toluene	0.0056
Ethylbenzene	0.0006
Xylenes	0.0034

DRY GAS:

Flow Rate: 0.5 MMSCF/day
Water Content: 7.0 lbs. H2O/MMSCF

LEAN GLYCOL:

Glycol Type: TEG
Water Content: 1.5 wt% H2O
Recirculation Ratio: 5.9 gal/lb H2O

PUMP:

Glycol Pump Type: Electric/Pneumatic

FLASH TANK:

Flash Control: Vented to atmosphere
Temperature: 160.0 deg. F
Pressure: 28.0 psig

GRI-GLYCalc VERSION 4.0 - AGGREGATE CALCULATIONS REPORT

Case Name: .6 mmscf/d Dehy
File Name: D:\My Documents\Oil and Gas\number of area sources\GRI Runs\actual throughput\0.6mmscf per day no flash tank.ddf
Date: November 08, 2004

DESCRIPTION:

Description: Dehydration unit with a .6 mmscf/d actual throughput
BTEX content = 200ppmv
No Flash Tank
Production Unit

Annual Hours of Operation: 8760.0 hours/yr

EQUIPMENT REPORTS:

ABSORBER

NOTE: Because the Calculated Absorber Stages was below the minimum allowed, GRI-GLYCalc has set the number of Absorber Stages to 1.25 and has calculated a revised Dry Gas Dew Point.

Calculated Absorber Stages: 1.25
Calculated Dry Gas Dew Point: 2.90 lbs. H2O/MMSCF

Temperature: 90.0 deg. F
Pressure: 700.0 psig
Dry Gas Flow Rate: 0.6000 MMSCF/day
Glycol Losses with Dry Gas: 0.0036 lb/hr
Wet Gas Water Content: Saturated
Calculated Wet Gas Water Content: 56.75 lbs. H2O/MMSCF
Specified Lean Glycol Recirc. Ratio: 5.90 gal/lb H2O

Component	Remaining in Dry Gas	Absorbed in Glycol
Water	5.09%	94.91%
Carbon Dioxide	99.77%	0.23%
Methane	99.98%	0.02%
Ethane	99.95%	0.05%
Propane	99.91%	0.09%
n-Butane	99.82%	0.18%
n-Pentane	99.76%	0.24%
n-Hexane	99.59%	0.41%
Other Hexanes	99.69%	0.31%
Heptanes	99.22%	0.78%
2,2,4-Trimethylpentane	99.66%	0.34%
Benzene	84.70%	15.30%
Toluene	77.99%	22.01%
Ethylbenzene	70.79%	29.21%
Xylenes	61.83%	38.17%

REGENERATOR

No Stripping Gas used in regenerator.

GRI-GLYCalc VERSION 4.0 - SUMMARY OF INPUT VALUES

Case Name: .7 mmscf/d Dehy
File Name: D:\My Documents\Oil and Gas\number of area sources\GRI Runs\actual throughput\0.7mmscf per day no flash tank.ddf
Date: November 08, 2004

DESCRIPTION:

Description: Dehydration unit with a .7 mmscf/d actual throughput
BTEX content = 200ppmv
No Flash Tank
Production Unit

Annual Hours of Operation: 8760.0 hours/yr

WET GAS:

Temperature: 90.00 deg. F
Pressure: 700.00 psig
Wet Gas Water Content: Saturated

Component	Conc. (vol %)
Carbon Dioxide	1.0000
Methane	90.0240
Ethane	5.3000

GRI-GLYCalc VERSION 4.0 - SUMMARY OF INPUT VALUES

Case Name: .7 mmscf/d Dehy
File Name: D:\My Documents\Oil and Gas\number of area sources\GRI Runs\actual throughput\0.7mmscf per day flash tank.ddf
Date: November 08, 2004

DESCRIPTION:

Description: Dehydration unit with a .7 mmscf/d actual throughput
BTEX content = 200ppmv
Flash Tank
Production Unit

Annual Hours of Operation: 8760.0 hours/yr

WET GAS:

Temperature: 90.00 deg. F
Pressure: 700.00 psig
Wet Gas Water Content: Saturated

Component	Conc. (vol %)
Carbon Dioxide	1.0000
Methane	90.0240
Ethane	5.3000
Propane	1.3000
n-Butane	1.2000
n-Pentane	1.0000
n-Hexane	0.0420
Other Hexanes	0.0840
Heptanes	0.0100
2,2,4-Trimethylpentane	0.0200
Benzene	0.0104
Toluene	0.0056
Ethylbenzene	0.0006
Xylenes	0.0034

DRY GAS:

Flow Rate: 0.7 MMSCF/day
Water Content: 7.0 lbs. H2O/MMSCF

LEAN GLYCOL:

Glycol Type: TEG
Water Content: 1.5 wt% H2O
Recirculation Ratio: 5.9 gal/lb H2O

PUMP:

Glycol Pump Type: Electric/Pneumatic

FLASH TANK:

Flash Control: Vented to atmosphere
Temperature: 160.0 deg. F
Pressure: 28.0 psig

GRI-GLYCalc VERSION 4.0 - AGGREGATE CALCULATIONS REPORT

Case Name: 0.8 mmscf/d Dehy
File Name: D:\My Documents\Oil and Gas\number of area sources\GRI Runs\actual throughput\0.8mmscf per day no flash tank.ddf
Date: November 08, 2004

DESCRIPTION:

Description: Dehydration unit with a .8 mmscf/d actual throughput
BTEX content = 200ppmv
No Flash Tank
Production Unit

Annual Hours of Operation: 8760.0 hours/yr

EQUIPMENT REPORTS:

ABSORBER

NOTE: Because the Calculated Absorber Stages was below the minimum allowed, GRI-GLYCalc has set the number of Absorber Stages to 1.25 and has calculated a revised Dry Gas Dew Point.

Calculated Absorber Stages: 1.25
Calculated Dry Gas Dew Point: 2.90 lbs. H2O/MMSCF

Temperature: 90.0 deg. F
Pressure: 700.0 psig
Dry Gas Flow Rate: 0.8000 MMSCF/day
Glycol Losses with Dry Gas: 0.0048 lb/hr
Wet Gas Water Content: Saturated
Calculated Wet Gas Water Content: 56.75 lbs. H2O/MMSCF
Specified Lean Glycol Recirc. Ratio: 5.90 gal/lb H2O

Component	Remaining in Dry Gas	Absorbed in Glycol
Water	5.09%	94.91%
Carbon Dioxide	99.77%	0.23%
Methane	99.98%	0.02%
Ethane	99.95%	0.05%
Propane	99.91%	0.09%
n-Butane	99.82%	0.18%
n-Pentane	99.76%	0.24%
n-Hexane	99.59%	0.41%
Other Hexanes	99.69%	0.31%
Heptanes	99.22%	0.78%
2,2,4-Trimethylpentane	99.66%	0.34%
Benzene	84.70%	15.30%
Toluene	77.99%	22.01%
Ethylbenzene	70.79%	29.21%
Xylenes	61.83%	38.17%

REGENERATOR

No Stripping Gas used in regenerator.

Component	Remaining in Glycol	Distilled Overhead
Water	43.37%	56.63%

STREAM REPORTS:

MEMORANDUM

DATE: December 21, 2006

SUBJECT: Impacts of the Final Standards for Oil and Natural Gas Production Area Sources

FROM: Heather P. Brown, P.E.

TO: Greg Nizich, EPA/OAQPS/SPPD/CCG

I. INTRODUCTION AND BACKGROUND

On July 8, 2005, (70 FR 39441), the United States Environmental Protection Agency (EPA) issued a supplemental proposal to the February 6, 1998 (63 FR 6288), proposed standards for oil and natural gas production area sources. Impacts were developed for the July 2005 supplemental proposed action based on regulating area sources on a nationwide basis.[1] For the final rule, EPA has created three subcategories of sources: (1) triethylene glycol (TEG) dehydration units with either an annual average natural gas flow rate less than 3 million standard cubic feet per day (MMSCF/D) or benzene emissions less than 1 ton per year (tpy); (2) TEG dehydration units with an annual average natural gas flow rate equal to or greater than 3 MMSCF/D and benzene emissions equal to or greater than 1 tpy and located within areas of higher population densities with 10,000 people or more; and (3) TEG dehydration units with an annual average natural gas flow rate equal to or greater than 3 MMSCF/D and benzene emissions equal to or greater than 1 tpy and located outside areas of higher population densities with 10,000 people or more.

The purpose of this memorandum is to present the regulatory alternatives considered, as well as the impacts for the final standards for oil and natural gas production. The impacts presented include primary air impacts, secondary environmental impacts (air pollution, water, and solid waste impacts), energy impacts, and cost impacts.

II. REGULATORY ALTERNATIVES

The oil and natural gas production source category is unique compared to many source categories since the location of the facilities is dictated by the location of the natural resources, rather than a need to serve a particular population center. For this reason, many sources are located in remote or rural areas. Further, these sources do not require on-site operators and are usually not manned by large staff, if manned at all. Finally, the operation of these sources is not

[1] Memorandum from Brown, H., EC/R Incorporated, to Nizich, G., US Environmental Protection Agency. Revised Impacts for Area Sources in the Oil and Natural Gas Production Source Category. June 25, 2005. Docket No. EPA-HQ-OAR-2004-0238-0002, 0003.

dependant on being close to populated areas. Based on these factors, EPA explored two regulatory alternatives for applying add-on controls to TEG dehydration units in the two subcategories of sources with an annual average natural gas flow rate equal to or greater than 3 MMSCF/D and benzene emissions equal to or greater than 1 tpy. The first alternative was to apply add-on control requirements to TEG dehydration units nationwide. The second alternative was to apply add-on control requirements to units located in areas of high population densities.

A. Regulatory Alternative 1: Apply Add-on Control Requirements Nationwide

Under this regulatory alternative, each subject TEG dehydration unit at an area source is required to: (1) reduce hazardous air pollutant (HAP) emissions by 95 percent or more; (2) reduce HAP emissions to an outlet concentration of 20 parts per million by volume (ppmv); or (3) reduce benzene emissions to a level less than 1.0 tpy. For the purposes of this memorandum, an emission reduction of 77.5 percent was assumed.

In the July 2005 supplemental proposal, EPA estimated that there are potentially 38,067 area source TEG dehydration units in the United States. Of the 38,067 potential TEG dehydration units, EPA estimates that 2,222 have actual annual average natural gas throughputs greater than 3 MMSCF/D and benzene emission greater than 1.0 tpy. Baseline HAP emissions of 49,635 tpy (14,803 tpy benzene) were estimated using GRI-GLYCalc© (version 4.0).[2] Reducing emissions by 77.5 percent resulted in an emission reduction of 13,377 tpy HAP (3,989 tpy benzene).

Using an approach consistent with that used in the July 2005 proposal (70 FR 39446), EPA evaluated the affected TEG dehydration units relative to the populations contained in the top 13 natural gas producing States (Alabama, Alaska, California, Colorado, Kansas, Louisiana, Michigan, Mississippi, New Mexico, Oklahoma, Texas, Utah, and Wyoming). EPA estimated that these 2,222 TEG dehydration units were located in States with a combined population of 92 million people.[3] The annual cost for this option was estimated to be $39 million.[4]

B. Regulatory Alternative 2: Apply Add-on Control Requirements to Units Located in Areas of High Population Densities

Under this regulatory alternative, TEG units located in areas of higher population densities with 10,000 people or more would be required to apply add-on controls (see Regulatory Alternative 1). EPA defines areas of higher population densities with 10,000 people or more as including the area occupied by each urban cluster[5] (UC) with 10,000 or more (referred to as UC

[2] See footnote 1.
[3] Memorandum from Brown, H., EC/R Incorporated, to Nizich, G., US Environmental Protection Agency. Evaluation of Number of Sources Potentially Affected within Census Designated Geographies for 13 States Responsible for the Highest Oil and Natural Gas Production. June 29, 2006. Docket No. . EPA-HQ-OAR-2004-0238-0013.
[4] See footnote 1.
[5] An Urban Cluster refers to o Census 2000 Urban Cluster, which is defined in the *Urban Area Criteria for Census 2000,* 67 FR 11667 (March 15, 2002). Essentially, an UC consists of densely settled territory with at least 2,500 people but fewer than 50,000 people.

NMED Exhibit 79 - 0002

≥ 10,000) and each urbanized area[6] (UA) plus the area located two miles or less from each UA boundary,[7] referred to by the phrase "UA plus offset." Based on this definition, EPA estimates that 50 TEG dehydration units would be required to apply add-on controls.[8] Baseline emissions from a single TEG dehydration unit are presented in another memorandum.[9] Table 1 presents baseline emissions from the 50 TEG dehydration units located within UC ≥ 10,000 and UA plus offset boundaries as well as emissions after reducing benzene emissions by 77.5 percent tpy by applying add-on controls. Emission reductions were estimated to be 301 tpy HAP (90 tpy of benzene).

EPA estimated that these 50 units are located in urban areas with a combined population of 76 million people.[10] Annual costs for a single unit without a flash tank were estimated to be $17,700 per year and for those with a flash tank annual costs were estimated to be $17,280 per year.[11] Assuming that 45 units do not have a flash tank and 5 units have a flash tank,[12] the annual costs for the 50 TEG dehydration units located within UC ≥ 10,000 and UA plus offset boundaries were estimated to be approximately $880 thousand per year.

C. Results of Regulatory Alternative Evaluation

Table 2 presents a cost comparison of Regulatory Alternatives 1 and 2. As shown in Table 2, extending the add-on control requirement to sources outside UC ≥ 10,000 and UA plus offset boundaries would result in an additional annual cost exceeding $38 million per year in an area with a combined population of 16 million people. This analysis shows that the overall cost of controlling units outside UC ≥ 10,000 and UA plus offset boundaries was much higher for a lower total population. Therefore, impacts were developed for Regulatory Alternative 2: apply the add-on control requirement to those TEG dehydration units located within UC ≥ 10,000 and UA plus offset boundaries.

III. PRIMARY AIR IMPACTS

This purpose of this section is to present the primary air pollution impacts (i.e., the reduction of HAP emissions) associated with the area source standards for existing and new sources.

---

[6] An Urbanized Area refers to Census 2000 Urbanized Area, which is defined in the *Urban Area Criteria for Census 2000*, 67 FR 11663, 11667 (March 15, 2002). Essentially, an UA consists of densely settled territory with a population of at least 50,000 people.

Affected Population in 13 States (million)	92	76
Annual Cost ($million)	39	0.880

NMED Exhibit 79 - 0005

Existing Sources

As previously stated, EPA has estimated that there are potentially 38,067 existing area source TEG dehydration units in the U.S. Of these, EPA has identified 35,845 TEG dehydration units that fall within the subcategory of sources with either an annual average natural gas flow rate less than 3 MMSCF/D or benzene emissions less than 1.0 tpy. Baseline emissions for these units were estimated to be 32,375 tpy. [13] For this subcategory, EPA has determined that GACT is no control.

There are 2,222 TEG dehydration units with annual average natural gas flow rates equal to or greater than 3 MMSCF/D and benzene emissions equal to or greater than 1.0 tpy and are subject to emission reduction requirements. There are two subcategories within this group of sources. One subcategory consists of the 50 TEG dehydration units identified as being located within UC $\geq$ 10,000 and UA plus offset boundaries. EPA determined that these sources are subject to the add-on controls requirements of Regulatory Alternative 2.

The remaining 2,172 TEG dehydration units fall within the subcategory of sources located outside of UC $\geq$ 10,000 and UA plus offset boundaries. These units would be required to implement management practices by reducing their glycol circulation rate to an optimum rate. Impacts of implementing management practices for a single unit were developed in a separate memorandum.[14] It was determined that reducing the glycol circulation rate to an optimum level would result in a HAP emission reduction of 45 percent (47 percent for benzene). To estimate national impacts, the same relative distribution used to estimate impacts at proposal[15] was used to determine how many TEG units fall within each throughput category (3, 4, and 5 MMSCF/D). Tables 3 and 4 present the HAP and benzene air emission impacts, respectively, associated with applying Regulatory Alternative 2 plus implementing management practices. The overall emission reduction was estimated to be 7,909 tpy HAP (2,455 tpy benzene).

New Sources

EPA has estimated that there will be 423 new TEG dehydration units (141 each year) that will come into service during the first three years after promulgation (from 2007 to 2009).[16] Assuming the same location distribution of existing sources, it was estimated that 3 new TEG dehydration units (2.2 percent of 141) would be located within UC $\geq$ 10,000 and UA plus offset boundaries, and would be subject to add-on control requirements. Additionally, it was estimated that 138 new TEG dehydration units would be required to implement management practices.

Tables 5 and 6 present the HAP and benzene air emission impacts, respectively, for new sources. The overall emission reduction associated with the regulation of new sources was estimated to be 501 tpy HAP (155 tpy benzene).

IV. SECONDARY ENVIRONMENTAL IMPACTS

Although the intent of the area source standards is to reduce HAP emissions, the application of control technologies can lead to other secondary environmental impacts. These secondary impacts can have a positive environmental impact, such as the reduction of volatile organic compounds (VOC) emissions, or a negative impact. Negative impacts may result from air pollutants emitted as a result of combustion sources (e.g., flares) or generation of a solid or liquid waste stream. The secondary impacts on air pollution and water and solid waste are discussed in this section.

A. Air Pollution Impacts

The primary method of HAP control from area source TEG dehydration units located within UC $\geq$ 10,000 and UA plus offset boundaries is the installation of a condenser and, if not present, a gas condensate glycol separator (GCG separator or flash tank). The secondary air pollution impacts associated with the application of this type of control are the decreased VOC emissions resulting from capture and control of HAP emissions. For TEG dehydration units located outside of UC $\geq$ 10,000 and UA plus offset boundaries, reducing the glycol circulation rate to the optimum level also decreases VOC emissions. Table 7 presents the total VOC emissions reduction (approximately 16,004 tpy) for existing area sources. Table 8 presents the VOC emissions reduction (approximately 1,013 tpy) for new sources.

Other secondary air pollution impacts are those associated with the operation of certain air emission control devices (i.e., flares). For facilities located within UC $\geq$ 10,000 and UA plus offset areas EPA assumed that 90 percent of the facilities would install condensers. Of these, EPA estimated that 45 percent of impacted facilities would be able to recycle the non-condensable vapors into a low pressure header system for combination with other hydrocarbon streams handled at the facilities and 45 percent of impacted facilities would use the non-condensable portion of the emission stream as a supplemental fuel for the glycol reboiler.[17] Therefore, for 90 percent of the impacted facilities there is no net change in energy use associated with the application of this control technology for facilities that incorporate this design and no net change in combustion-related emissions. In some cases, a facility does not have the ability to handle the collected vapor for use as a fuel or recycle the collected vapor back into the process. In such cases, the collected vapors may be directed to an on-site flare. EPA estimated that 10 percent of the facilities required to install add-on controls would direct all collected non-condensable vapors to an on-site flare.[18] The adverse secondary air impacts resulting from the use of a flare would be minimal in comparison to the primary HAP reduction

NMED Exhibit 79 - 0013

benefits from implementing the proposed control options for area sources. The secondary air impacts due to the use of flares are presented in Table 9 for existing area sources and Table 10 for new sources.

B. Water and Solid Waste Impacts

The water impacts associated the installation of a condenser system for the TEG dehydration unit reboiler vent would be minimal. The condensed water collected with the hydrocarbon condensate can be directed back into the system for reprocessing with the hydrocarbon condensate or, if separated, combined with produced water for disposal by reinjection.[19]

There is no solid waste generated from the control of HAP emissions using a condenser. Therefore, we do not anticipate any adverse solid waste impacts from the implementation of the area source standards.

V. ENERGY IMPACTS

Energy impacts are those energy requirements associated with the operation of emission control devices. There would be no national energy demand increase from the operation of any of the control options analyzed under the oil and natural gas production standards for area sources. The area source standards (1) encourage the use of emission controls that recover hydrocarbon products, such as methane and condensate, which can be used on-site as fuel or reprocessed within the production process and sold and (2) require management practices that result in a natural gas savings. Thus, the standards have a positive impact associated with the recovery of non-renewable energy resources.

VI. COST IMPACTS

The cost impacts due to the final area source standards include the cost of equipment that must be purchased, along with the cost of the installation of the equipment. There are also costs for the operation and maintenance of the equipment. Finally, there are costs associated with the required monitoring, inspection, recordkeeping, and reporting (MIRR). This section presents the estimated costs associated with compliance with the area source standards.

Existing Sources

The total capital investment and total annual costs associated with the installation of add-on controls for a single unit were estimated during the development of the July 2005 proposal and are summarized in Table 11.[20] Table 11 also presents the nationwide impacts for total capital investment ($847 thousand) and total annual cost ($883 thousand) for the 50 existing sources located within UC $\geq$ 10,000 and UA plus offset boundaries.

Total	na	**2,172**	**$ 1,646,546**

Table 13. Cost Impacts for Existing Sources and New Sources

Cost Parameter	Existing Sources	New Sources
Total Capital Investment		
Add-On Controls	$846,952	$37,590
Management Practices	$1,671,409	$106,195
Total	$2,518,361	$143,785
Total Annual Cost		
Add-On Controls	$882,846	$50,989
Management Practices	$14,249,503	$905,355
Gas Savings (Due to management practices)	($12,602,957)	($800,740)
Total	$2,529,392	$155,604

The total capital investment and total annual costs, as well as the gas savings, associated with the implementation of management practices for a single unit are presented in another memorandum.[21] Table 12 presents a summary of these impacts for the 2,172 existing sources estimated to be located outside of UC $\geq$ 10,000 and UA plus offset boundaries. It was assumed that 50 percent of these existing sources (1,086) would be required to install a new pump.

Table 13 presents the combined impacts for existing sources associated with the application of add-on controls and the implementation of management practices.

New Sources

To estimate the impacts of the area source standards on new sources, it was assumed that no new sources would be constructed without flash tanks. Therefore, total capital investment and total annual cost associated with applying add-on controls to new sources was calculated only for those already with flash tanks for the 3 new sources assumed to be located within UC $\geq$ 10,000 and UA plus offset boundaries. A summary of the cost impact calculations associated with the installation of add-on controls is presented in Table 14. A retrofit factor of 15 percent was assumed for existing sources.[22] Therefore, the new source capital investment values are 1.15 times lower than those presented in Table 11. The annual costs were calculated using the same methodology as used to estimate existing source annual costs.[23]

To estimate the cost impacts of applying management practices to new sources, the total capital investment and total annual cost associated with the reduction of the glycol circulation rate are the same as for existing sources.[24] Table 15 presents a summary of these impacts. The national impacts presented in Table 15 were estimated for the 138 new sources determined to be located outside of UC $\geq$ 10,000 and UA plus offset boundaries. Of these, 69 (50 percent of 138) were assumed to require the installation of a new pump and the remaining 69 were assumed to be able to design the TEG dehydration unit to achieve the optimum glycol circulation rate.

Table 13 also presents the combined impacts for new sources associated with the application of add-on controls and the implementation of management practices.

National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters; Final Rule

ENVIRONMENTAL PROTECTION AGENCY

40 CFR Part 63

[EPA–HQ–OAR–2002–0058; FRL–9676–8]

RIN 2060–AR13

National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule; notice of final action on reconsideration.

SUMMARY: In this action the EPA is taking final action on its reconsideration of certain issues in the emission standards for the control of hazardous air pollutants from new and existing industrial, commercial, and institutional boilers and process heaters at major sources of hazardous air pollutants, which were issued under section 112 of the Clean Air Act. As part of this action, the EPA is making technical corrections to the final rule to clarify definitions, references, applicability and compliance issues raised by petitioners and other stakeholders affected by this rule. On March 21, 2011, the EPA promulgated national emission standards for this source category. On that same day, the EPA also published a notice announcing its intent to reconsider certain provisions of the final rule. Following these actions, the Administrator received several petitions for reconsideration. After consideration of the petitions received, on December 23, 2011, the EPA proposed revisions to certain provisions of the March 21, 2011, final rule, and requested public comment on several provisions of the final rule. The EPA is now taking final action on the proposed reconsideration.

DATES: The May 18, 2011 (76 FR28661), delay of the effective date revising subpart DDDDD at 76 FR 15451 (March 21, 2011) is lifted January 31, 2013. The amendments in this rule to 40 CFR part 63, subpart DDDDD are effective as of April 1, 2013.

ADDRESSES: The EPA established a single docket under Docket ID No. EPA–HQ–OAR–2002–0058 for this action. All documents in the docket are listed on the *http://www.regulations.gov* Web site. Although listed in the index, some information is not publicly available, e.g., confidential business information or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, is not placed on the Internet and will be publicly available only in hard copy form. Publicly available docket materials are available either electronically through *http://www.regulations.gov* or in hard copy at the EPA's Docket Center, Public Reading Room, EPA West Building, Room 3334, 1301 Constitution Avenue NW., Washington, DC 20004. This Docket Facility is open from 8:30 a.m. to 4:30 p.m., Monday through Friday, excluding legal holidays. The telephone number for the Public Reading Room is (202) 566–1744, and the telephone number for the Air Docket is (202) 566–1742.

FOR FURTHER INFORMATION CONTACT: Mr. Jim Eddinger, Energy Strategies Group, Sector Policies and Programs Division, (D243–01), Office of Air Quality Planning and Standards, U.S. Environmental Protection Agency, Research Triangle Park, North Carolina 27711; Telephone number: (919) 541–5426; Fax number (919) 541–5450; Email address: *eddinger.jim@epa.gov*.

SUPPLEMENTARY INFORMATION:

Executive Summary

Purpose of This Regulatory Action

The EPA is taking final action on its proposed reconsideration of certain provisions of its March 21, 2011, final rule that established standards for new and existing industrial, commercial, and institutional boilers and process heaters at major sources of hazardous air pollutants. Section 112(d) of the CAA requires the EPA to regulate HAP from major stationary sources based on the performance of MACT. Section 112(h) of the CAA allows the EPA to establish work practice standards in lieu of numerical emission limits only in cases where the agency determines that it is not feasible to prescribe or enforce an emission standard, including circumstances in which the agency determines that the application of measurement methodology is not practicable due to technological and economic limitations. The EPA is revising certain MACT standards established in March 2011 for boilers and process heaters, including standards for CO—as a surrogate for organic HAP; HCl—as a surrogate for acid gas HAP; Hg; TSM or filterable PM—as a surrogate for non-Hg metallic HAP; and dioxin/furan.

This final rule amends certain provisions of the final rule issued by the EPA on March 21, 2011. The EPA delayed the effective date of the 2011 rule in a May 18, 2011, notice, but that delay notice was vacated by the U.S. District Court for the District of Columbia on January 9, 2012, and the March 2011 final rule was, therefore, in effect until publication of this action.

Summary of Major Reconsideration Provisions

In general, this final rule requires facilities classified as major sources of HAP with affected boilers or process heaters to reduce emissions of harmful toxic air emissions from these combustion sources. This will improve air quality and protect public health in communities where these facilities are located.

Recognizing the diversity of this source category and the multiple sectors of the economy this final rule effects, the EPA is revising certain subcategories for boilers and process heaters in this action that were established in the March 2011 final rule, based on the design of the combustion equipment. These revisions result in 19 subcategories for the boilers and process heaters source category. Numerical emission limits are established for most of the subcategories for five pollutants, CO, HCl, Hg, and PM or TSM. The review of existing data and consideration of new data have resulted in changes to some of the emission limits contained in the March 2011 final rule. Overall, for both new and existing affected units, about 30 percent of the emission limits are more stringent, half are less stringent, and 20 percent unchanged as compared to the March 2011 final rule. Also, based on its review and analysis of new data submissions, the EPA is establishing an alternative emission standard for CO, based on CEMS data for several subcategories with CO CEMS data available. This alternative standard is based on a 30-day rolling average for subcategories for which sufficient CEMS data were available for more than a 30-day period, or a 10-day rolling average for subcategories for which CEMS data were available for less than a 30-day period, and provides additional compliance flexibility to sources. All of the subcategories are subject to periodic tune-up work practices for dioxin/furan emissions.

The compliance dates for the rule are January 31, 2016, for existing sources and, January 31, 2013, or upon startup, whichever is later, for new sources. New sources are defined as sources that began operation on or after June 4, 2010.

Costs and Benefits

The final rule affects 1,700 existing major source facilities with an estimated 14,136 boilers and process heaters and the EPA projects an additional 1,844 new boilers and process heaters to be subject to this final rule over the next 3

years. This final rule affects multiple sectors of the economy including small entities. Table 1 summarizes the costs and benefits associated with this final rule. A more detailed discussion of the costs and benefits of this final rule is provided in section VI of this preamble.

TABLE 1—SUMMARY OF THE MONETIZED BENEFITS, SOCIAL COSTS AND NET BENEFITS FOR THE FINAL BOILER MACT RECONSIDERATION IN 2015

[Millions of 2008$] [1]

	3 percent discount rate	7 percent discount rate
Total Monetized Benefits [2]	$27,000 to $67,000	$25,000 to $61,000.
Total Social Costs [3]	$1,400 to $1,600	$1,400 to $1,600.
Net Benefits	$26,000 to $65,000	$23,000 to $59,000.
Non-monetized Benefits	Health effects from exposure to HAP (39,000 tons of HCl, 500 tons of HF, 3,100 to 5,300 pounds of Hg and 2,500 tons of other metals). Health effects from exposure to other criteria pollutants (180,000 tons of CO and 572,000 tons of SO_2). Ecosystem effects. Visibility impairment.	

[1] All estimates are for the implementation year (2015), and are rounded to two significant figures.

[2] The total monetized co-benefits reflect the human health benefits associated with reducing exposure to $PM_{2.5}$ through reductions of $PM_{2.5}$ precursors such as directly emitted particles, SO_2, and NO_X and reducing exposure to ozone through reductions of VOC. It is important to note that the monetized benefits include many but not all health effects associated with $PM_{2.5}$ exposure. Monetized benefits are shown as a range from Pope et al. (2002) to Laden et al. (2006). These models assume that all fine particles, regardless of their chemical composition, are equally potent in causing premature mortality because the scientific evidence is not yet sufficient to support the development of differential effects estimates by particle type. These estimates include the energy disbenefits valued at $24 million (using the 3 percent discount rate), which do not change the rounded totals. CO_2-related disbenefits were calculated using the ''social cost of carbon,'' which is discussed further in the RIA.

[3] The methodology used to estimate social costs for one year in the multimarket model using surplus changes results in the same social costs for both discount rates.

Organization of this Document. The information presented in this preamble is organized as follows:

I. General Information
A. Does this action apply to me?
B. Where can I get a copy of this document?
C. Judicial Review
II. Background Information
A. Chronological History of Related Actions
III. Summary of This Final Rule
A. What is an affected source?
B. What are the subcategories of boilers and process heaters?
C. What emission limits and work practice standards are being finalized?
D. What are the requirements during periods of startup and shutdown?
E. What are the testing and initial compliance requirements?
F. What are the continuous compliance requirements?

G. What are the compliance dates?
IV. Summary of Significant Changes Since Proposal
A. Applicability
B. Subcategories
C. Performance Test Requirements
D. Emission Limits
E. Work Practice Requirement
F. Averaging Times Definitions
G. Energy Assessment
H. Startup and Shutdown Definitions
I. Fuel Sampling Frequency
J. Affirmative Defense
V. Other Actions We Are Taking
VI. Impacts of This Final Rule
A. What are the incremental air impacts?
B. What are the incremental water and solid waste impacts?
C. What are the incremental energy impacts?
D. What are the incremental cost impacts?
E. What are the economic impacts?
F. What are the benefits of this final rule?
G. What are the incremental secondary air impacts?
VII. Statutory and Executive Order Reviews
A. Executive Order 12866: Regulatory Planning and Review and Executive Order 13563: Improving Regulation and Regulatory Review
B. Paperwork Reduction Act
C. Regulatory Flexibility Act
D. Unfunded Mandates Reform Act
E. Executive Order 13132: Federalism
F. Executive Order 13175: Consultation and Coordination with Indian Tribal Governments
G. Executive Order 13045: Protection of Children from Environmental Health Risks and Safety Risks
H. Executive Order 13211: Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution, or Use
I. National Technology Transfer and Advancement Act
J. Executive Order 12898: Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations
K. Congressional Review Act

I. General Information

A. Does this action apply to me?

The regulated categories and entities potentially affected by this action include:

TABLE 2—POTENTIAL REGULATED CATEGORIES AND ENTITIES AFFECTED

Category	NAICS code[1]	Examples of potentially regulated entities
Any industry using a boiler or process heater as defined in the final rule	211	Extractors of crude petroleum and natural gas.
	321	Manufacturers of lumber and wood products.
	322	Pulp and paper mills.
	325	Chemical manufacturers.
	324	Petroleum refineries, and manufacturers of coal products.
	316, 326, 339	Manufacturers of rubber and miscellaneous plastic products.
	331	Steel works, blast furnaces.
	332	Electroplating, plating, polishing, anodizing, and coloring.
	336	Manufacturers of motor vehicle parts and accessories.
	221	Electric, gas, and sanitary services.
	622	Health services.
	611	Educational services.

[1] North American Industry Classification System.

This table is not intended to be exhaustive, but rather provides a guide for readers regarding entities likely to be regulated by this reconsideration action. To determine whether your facility may be affected by this reconsideration action, you should examine the applicability criteria in 40 CFR 63.7485 of subpart DDDDD (National Emission Standards for Hazardous Air Pollutants (NESHAP) for Industrial, Commercial, and Institutional Boilers and Process Heaters). If you have any questions regarding the applicability of this final rule to a particular entity, consult either the air permitting authority for the entity or your EPA regional representative, as listed in 40 CFR 63.13 of subpart A (General Provisions).

B. Where can I get a copy of this document?

In addition to being available in the docket, an electronic copy of this action will also be available on the WWW through the TTN. Following signature, a copy of the action will be posted on the TTN's policy and guidance page for newly proposed or promulgated rules at the following address: *http://www.epa.gov/ttn/oarpg/*. The TTN provides information and technology exchange in various areas of air pollution control.

C. Judicial Review

Under the CAA section 307(b)(1), judicial review of this final rule is available only by filing a petition for review in the U.S. Court of Appeals for the District of Columbia Circuit by April 1, 2013. Under CAA section 307(d)(7)(B), only an objection to this final rule that was raised with reasonable specificity during the period for public comment can be raised during judicial review. Note, under CAA section 307(b)(2), the requirements established by this final rule may not be challenged separately in any civil or criminal proceedings brought by the EPA to enforce these requirements.

II. Background Information

A. Chronological History of Related Actions

On March 21, 2011, the EPA issued final standards for new and existing industrial, commercial, and institutional boilers and process heaters, pursuant to its authority under section 112 of the CAA. On the same day as the final rule was issued, the EPA stated in a separate notice that it planned to initiate a reconsideration of several provisions of the final rule. This reconsideration notice identified several provisions of the March 2011 final rule where additional public comment was appropriate. This notice also identified several issues of central relevance to the rulemaking where reconsideration was appropriate under CAA section 307(d).

On May 18, 2011, the EPA issued a notice to postpone the effective date of the March 21, 2011 final rule. Following promulgation of the final rule, the EPA received petitions for reconsideration from the following organizations

(''Petitioners''): AIE, USCHPA, Alyeska Pipeline, ACC, AHFA, AISI, ACCCI, AMP, API, NPRA, AIF, Citizens Energy Group (CEG), CIBO, CMI, District Energy St. Paul, FSI, GPSP, Hovensa L.L.C., Tesoro Hawaii Corp., Industry Coalition (AF&PA *et al.*), JELD–WEN Inc., MSU, PSU, Purdue University, Renovar Energy Corp., RPU, Sierra Club, Southeastern Lumber Manufacturers Association, State of Washington Department of Ecology, BCSE, UARG, US Sugar, WM and WEPCO. Copies of these petitions are provided in the docket (see Docket ID No. EPA–HQ–OAR–2002–0058). Petitioners, pursuant to CAA section 307(d)(7)(B), requested that the EPA reconsider numerous provisions in the rule. On December 23, 2011, the EPA granted the petitions for reconsideration on certain issues, and proposed certain revisions to the final rule in response to the reconsideration petitions and to address the issues that the EPA previously identified as warranting reconsideration. That proposal solicited comment on several specific aspects of the rule, including:

- Revising the proposed subcategories.
- Solicitation of new data or corrections to existing data to revise emission standards calculations.
- Establishing an alternative TSM limit.
- Appropriateness of an alternative TSM limit for the liquid subcategories.
- Establishing work practice standards for dioxin/furan emissions.
- Revising the efficiency assumptions for the alternative output-based emission standards.
- Accommodating emissions averaging provisions in the alternative output-based emission standards.
- Establishing a mercury fuel specification through which gas-fired boilers that use a fuel other than natural gas or refinery gas may be considered Gas 1 units.
- Establishing a work practice standard for limited use units.
- Providing an affirmative defense for malfunction events.
- Revisions to the monitoring requirements for oxygen in the March 2011 final rule.
- Establishing a full-load stack test requirement for carbon monoxide coupled with continuous oxygen (oxygen trim) monitoring.
- Revising PM monitoring requirements from CEMS to CPMS and exempting biomass units from PM CPMS requirements.
- Revising mercury monitoring requirements to allow for an alternative mercury CEMS.
- Considering use of SO_2 CEMS to demonstrate compliance with HCl limits.
- Minimum data availability provisions.
- Averaging times for monitored parameters and pollutants.
- Revised methods for computing minimum detection levels.
- Providing an alternative CO emission limit based on CO CEMS data.
- Soliciting additional data to set MACT floor emission limits for non-continental liquid units.
- Selecting a 99 percent confidence interval for setting the CO emission limit.
- Tune-up frequencies, timing of initial tune-ups and adjusted tune-up requirements for shutdown units.
- Scope and duration of the energy assessment and deadline for completing the assessment.
- Revising work practices during startup and shutdown.
- Revisions to certain exemptions, including units serving as control devices, waste heat process heaters, units firing comparable fuels and residential units.
- Revisions to reduced testing frequency for emission limits that are established at minimum detection levels.
- Removing fuel analysis requirements for gas 1 fuels at co-fired units.
- Revisions to automating techniques for coal sampling.
- Revisions to emissions averaging across subcategories when units opt to switch to natural gas.
- Consideration of a new subcategory for units installed and used in place of flares.

In this action, the EPA is finalizing multiple changes to the March 2011 final rule after considering public comments on the items under reconsideration.

III. Summary of This Final Rule

As stated above, the December 23, 2011 proposed rule addressed specific issues and provisions the EPA identified for reconsideration. This summary of the final rule reflects the changes to 40 CFR part 63, subpart DDDDD (March 21, 2011 final rule) in regards to those provisions identified for reconsideration and on other discrete matters identified in response to comments or data received during the comment period. Information on other provisions and issues not proposed for reconsideration is contained in the notice and record for the 2011 final rule. [See 76 FR 15608]

This section summarizes the requirements of this action. Section IV below provides a summary of the significant changes to the March 21, 2011 final rule.

A. What is an affected source?

This final rule revises the list of exemptions in § 63.7491 to include residential boilers that may be located at an industrial, commercial or institutional major source. The exemption for boilers or process heaters used specifically for research and development has been revised to include boilers used for certain testing purposes.

B. What are the subcategories of boilers and process heaters?

In this final rule, we are finalizing separate subcategories for heavy liquid-fired, light liquid-fired and liquid-fired units in non-continental locations for PM and CO, pollutants that are dependent on combustor design. In addition, a new subcategory for coal-fired fluidized bed boilers with integrated fluidized bed heat exchangers has been included in the final rule for CO which is dependent on boiler design. Finally, we are finalizing the subcategory for PM at coal/fossil solid units across all coal combustor designs.

C. What emission limits and work practice standards are being finalized?

You must meet the emission limits presented in Table 3 of this preamble for each subcategory of units listed in the table. This final rule includes 19 subcategories, which are based on unit design. New and existing units in three of the subcategories are subject to work practices standards in lieu of emission limits for all pollutants. Numeric emission limits are finalized for new and existing sources in each of the other 16 subcategories.

The changes associated with the emission limits are due to new data, corrections to old data, and inventory changes. In summary, for existing subcategories, for the HCl emission limits, 10 are more stringent, 3 are less stringent and 1 remained the same from the March 21, 2011 final rule; for the mercury emission limits, 3 are more stringent and 11 are less stringent from the March 21, 2011 final rule; for the PM emission limits, 2 are more stringent, 7 are less stringent and 5 are unchanged from the March 21, 2011 final rule; and for the CO emission limits, 4 are more stringent and 10 are less stringent from the March 21, 2011 final rule. For new subcategories, for the HCl emission limits, 13 are less stringent and 1 is unchanged from the March 21, 2011 final rule; for the mercury emission limits, 11 are more

stringent, 2 are less stringent and 1 is unchanged from the March 21, 2011 final rule; for the PM emission limits, 9 are less stringent and 5 are unchanged from the March 21, 2011 final rule; and for the CO emission limits, 3 are more stringent and 11 are less stringent from the March 21, 2011 final rule.

TABLE 3—EMISSION LIMITS FOR BOILERS AND PROCESS HEATERS

[lb/MMBtu heat input basis unless noted; alternative output based limits are not shown in the summary table below]

Subcategory	Filterable PM (or total selected metals) (lb per MMBtu of heat input) [a]	HCl (lb per MMBtu of heat input) [a]	Mercury (lb per MMBtu of heat input) [a]	CO (ppm @3% oxygen) [a]	Alternate CO CEMS limit, (ppm @3% oxygen) [b]
Existing—Coal Stoker	0.040 (5.3E–05)	0.022	5.7E–06	160	340

New—Light Liquid	0.0011 (2.9E–05)	4.4E–04	4.8E–07	130	ND
New—Non-Continental Liquid	0.023 (8.6E–04)	4.4E–04	4.8E–07	130	ND
New—Gas 2 (Other Process Gases)	0.0067 (2.1E–04)	0.0017	7.9E–06	130	ND

NA-Not applicable; ND-No data available
[a] 3-run average, unless otherwise noted.
[b] 30-day rolling average, unless otherwise noted.
[c] 10-day rolling average.

We also are finalizing a work practice standard for dioxin/furan emissions from all subcategories.

D. What are the requirements during periods of startup and shutdown?

We are finalizing revised work practice standards for periods of startup and shutdown to better reflect the maximum achievable control technology during those periods. In addition, we are finalizing definitions of startup and shutdown. We are defining startup as the period between the state of first-firing of fuel in the unit after a shutdown to the period where the unit first supplies steam. We are defining shutdown as the period that begins when no more steam is supplied or at the point of no fuel being fired in the unit. For periods of startup and shutdown, we are finalizing the following work practice standard: You must operate all continuous monitoring systems during startup and shutdown. For startup, you must use one or a combination of the listed clean fuels. Once you start firing coal/solid fossil fuel, biomass/bio-based solids, heavy liquid fuel, or gas 2 (other) gases, you must engage all of the applicable control devices except limestone injection in FBC boilers, dry scrubber, fabric filter, SNCR and SCR. You must start your limestone injection in FBC boilers, dry scrubber, fabric filter, SNCR and SCR systems as expeditiously as possible. During shutdown while firing coal/solid fossil fuel, biomass/bio-based solids, heavy liquid fuel, or gas 2 (other) gases during shutdown, you must operate all applicable control devices, except limestone injection in FBC boilers, dry scrubber, fabric filter, SNCR and SCR. You must comply with all applicable emissions and operating limits at all times the unit is in operation except for periods that meet the definitions of startup and shutdown in this subpart, during which times you must comply with these work practices. You must keep records during periods of startup or shutdown. You must keep records concerning the date, duration, and fuel usage during startup and shutdown.

E. What are the testing and initial compliance requirements?

We are requiring that the owner or operator of a new or existing boiler or process heater conduct performance tests to demonstrate compliance with all applicable emission limits. This final rule adds the requirement to conduct initial and annual stack tests to determine compliance with the TSM emission limits using EPA Method 29 for those subcategories with alternate TSM limits.

F. What are the continuous compliance requirements?

This final rule removes the requirement for units combusting biomass with heat input capacities of 250 MMBtu/hr or greater to install, certify, maintain and operate a CEMS measuring PM emissions. This final rule requires units combusting solid fossil fuel or heavy liquid with heat input capacities of 250 MMBtu/hr or greater to install, certify, maintain, and operate PM CPMS. Moreover, owners or operators of units combusting solid fossil fuel or heavy liquid with heat input capacities of 250 MMBtu/hr or greater are allowed to install, certify, maintain and operate PM CEMS as an alternative to the use of PM CPMS, consistent with regulations for similarly-sized commercial and industrial solid waste incinerators units and EGUs subject to the MATS. Just as units using PM CPMS will not be required to conduct parameter monitoring for PM, units using PM CEMS will not be required to conduct parameter monitoring for PM.

This final rule also includes an alternative method of demonstrating continuous compliance with the HCl emission limit. This method allows using SO_2 emissions as an alternate operating limit. This method of demonstrating continuous compliance will be allowed only on a unit that utilizes a SO_2 CEMS and an acid-gas control technology including wet scrubber, dry scrubbers and duct sorbent injection. Boilers or process heaters subject to an HCl emission limit that demonstrate compliance with an SO_2 CEMS would be required to maintain the 30-day rolling average SO_2 emission rate at or below the highest hourly average SO_2 concentration measured during the most recent HCl performance test.

G. What are the compliance dates?

For existing sources, the EPA is establishing a compliance date of January 31, 2016. New sources must comply by January 31, 2013, or upon startup, whichever is later. New sources are defined as sources which commenced construction or reconstruction on or after June 4, 2010 pursuant to section 112(a)(4).

Commenters have argued that the 3-year compliance deadline the EPA is establishing for existing sources to meet the standards does not provide them with sufficient time to meet the standards in view of the large number of sources that will be competing for the needed resources and materials from engineering consultants, permitting authorities, equipment vendors, construction contractors, financial institutions, and other critical suppliers.

As an initial matter, we note that many sources subject to the emission standards in the final rule should be able to meet the standards within three years, even those that need to install pollution control technologies to do so. In addition, many sources subject to the rule are gas fired units or small boilers (less than 10 MMBtu/hr) and will not need to install controls in order to demonstrate compliance, as these sources are subject to work practice standards. For these sources, the 3-year compliance deadline is highly unlikely to be problematic either in general, or with respect to the claims commenters have made about the possibility that the demand for resources related to control technology will exceed the supply.

At the same time, the CAA allows title V permitting authorities to grant sources, on a case-by-case basis, extensions to the compliance time of up to one year if such time is needed for the installation of controls. *See* CAA section 112(i)(4)(i)(A). Permitting authorities are already familiar with, and in many cases have experience with, applying the 1-year extension authority under section 112(i)(4)(A) since the provision applies to all NESHAP. We believe that should the range of circumstances that commenters have cited as impeding sources' ability to install controls within three years materialize, then it is reasonable for permitting authorities to take those circumstances into consideration when evaluating a source's request for a 1-year extension, and where such applications prove to be well-founded, it is also reasonable for permitting authorities to make the 1-year extension available to applicants.

In making a determination as to whether an extension is appropriate, we believe it is also reasonable for permitting authorities to consider the large number of pollution control retrofit projects being undertaken for purposes of complying either with the standards in this rule or with those of other rules such as MATS for the power sector that may be competing for similar resources.

Further, commenters have pointed out that in some cases operators of existing sources that are subject to these standards and that generate energy may opt to meet the standards by terminating operations at these sources and building new sources to replace the energy generation at the shut-down sources. While the ultimate discretion to provide a 1-year extension lies with the permitting authority, the EPA believes that it is reasonable for permitting authorities to allow the fourth year extension for the installation of replacement sources of energy generation at the site of a facility applying for an extension for that purpose. Specifically, the EPA believes where an applicant demonstrates that it is building replacement sources of energy generation for purposes of meeting the requirements of these standards such a replacement project could be deemed to constitute the ''installation of controls'' under section 112(i)(3)(B).

In a case where pollution controls are being installed or onsite replacement energy generation is being constructed to allow for retirement of older, under-controlled energy generation units, a determination that an extra year is necessary for compliance should be relatively straightforward. In order to install controls, companies are likely to undertake a number of steps relatively soon after the effective date of the rule, including obtaining necessary building and environmental permits and hiring contractors to perform the construction of the emission controls or replacement energy generation units. This should provide sufficient information for a permitting authority to determine that emission controls are being installed or that replacement energy generation is being constructed. As a result, a permitting authority will be in a position to make a determination as to whether a source's compliance schedule will exceed 3 years and to quickly make a determination as to when an extension is appropriate.

In sum, the EPA believes that although most, if not all, units will be able to fully comply with the standards within 3 years, the fourth year that permitting authorities are allowed to grant for installation of controls is an important flexibility that will address situations where an extra year is necessary. Of course in situations where EPA is the permitting authority, we would also consider the above circumstances when acting on a permit application.

IV. Summary of Significant Changes Since Proposal

The EPA has made numerous changes in this final rule from the proposal after consideration of the public comments received. Most are changes to clarify applicability and implementation issues raised by the commenters. The public comments received on the proposed changes and the responses to them can be viewed in the memorandum ''Response to Comments for Industrial, Commercial, and Institutional Boilers

and Process Heaters National Emission Standards for Hazardous Air Pollutants'' located in the docket.

A. Applicability

Since proposal, the EPA has made certain changes to the applicability of this final rule. We have clarified that the exemption for boilers and process heaters used for research and development includes boilers used for testing the propulsion systems on military vessels. This is consistent with the intent of the exemption in that these test boilers do not provide steam for heating, to a process, or other non-propulsion related uses but are used exclusively to test the propulsion systems of nuclear-powered aircraft carriers that are undergoing repair, overhaul, or installation.

B. Subcategories

As described in the preamble to the proposed reconsideration rule, within the basic unit types of boilers and process heaters there are different designs and combustion systems that, while having a minor effect on fuel-dependent HAP emissions, have a much larger effect on pollutants whose emissions depend on the combustion conditions in a boiler or process heater. In the case of boilers and process heaters, the combustion-related pollutants are the organic HAP. In the proposed rule, we identified the following 17 subcategories for organic HAP: (1) Pulverized coal units; (2) stokers designed to burn coal; (3) fluidized bed units designed to burn coal; (4) stokers designed to burn wet biomass; (5) stokers designed to burn kiln-dried biomass; (6) fluidized bed units designed to burn biomass; (7) suspension burners designed to burn biomass; (8) dutch ovens/pile burners designed to burn biomass; (9) fuel cells designed to burn biomass; (10) hybrid suspension grate units designed to burn biomass; (11) units designed to burn heavy liquid fuel; (12) units designed to burn light liquid fuel; (13) non-continental liquid units; (14) units designed to burn natural gas/refinery gas; (15) units designed to burn other gases; (16) metal process furnaces; and (17) limited-use units.

In this final rule, we are also adding a separate subcategory for fluidized bed units with a fluidized bed heat exchanger designed to burn coal and adjusted the definition of the limited use subcategory.

Fluidized bed boilers are designed to combust fuel with relatively low heating value and high ash compared to other combustor designs. Two fuel properties of coal are heating values and ash content. As the heating value of the coal decreases, ash content increases. Fluidized bed boilers are designed to have large tube surface areas to transfer heat from the fuel through the process of conduction and convection, but in some cases the amount of tube surface area in the furnace for heat transfer is insufficient. In order to overcome insufficient heat exchange, certain fluidized bed boilers adopt a fluidized bed heat exchanger design to achieve heat transfer. The fluidized bed heat exchanger is located at the exit of the cyclone section of the unit. This design allows the boiler to combust coal with a lower heating value than a coal-fired fluidized bed boiler without a fluidized bed heat exchanger. Therefore, because this boiler design does have different combustion-related HAP emission characteristics, a new subcategory of coal fluidized bed with integrated heat exchanger was added to the final rule.

The EPA is also revising the definition of the limited use subcategory. Many affected units operate on standby mode or low loads for periods longer than the proposed definition for limited use units, which limited operation to 876 hours per year. By converting to a capacity-factor approach, we are allowing more flexibility on unit operations without increasing emissions or harm to human health and the environment. For example, units operating at 10 percent load for 8,760 hours per year would emit the same amount of emissions as units operating at full load for 876 hours per year. Further, it is technically infeasible to schedule stack testing for these limited use units since these units serve as back up energy sources and their operating schedules can be intermittent and unpredictable. The limited use subcategory was adjusted to be based on units with a federally enforceable operating limit of less than or equal to 10 percent of an average annual capacity factor.

C. Performance Test Requirements

Table 5 of this final rule has been revised to add performance test procedures for conducting performance stack tests for demonstrating compliance with the alternate TSM emission limits. In the reconsideration proposal, we proposed emissions limits for TSM (i.e., arsenic, beryllium, cadmium, chromium, lead, manganese, nickel and selenium) as an alternative to the proposed PM emission limits for many of the subcategories. In the preamble to the proposed rule, we added procedures in Table 6 of the rule for conducting fuel analysis for total selected metals but we inadvertently failed to add performance test requirements for stack sampling of TSM emissions in Table 5 of the rule.

D. Emission Limits

One significant change since proposal is related to the PM emission limits for the coal subcategories. Several petitioners disagreed with EPA's position to set different PM limits for subcategories of boilers and process heaters based on the fuel used, and instead offered information to support the position that PM should be considered a combustion-based pollutant. The differences in PM particle size, fouling characteristics and feasibility of certain control technologies on certain unit designs suggested that PM is more appropriately classified as a combustion-based pollutant, but only for the coal subcategories. After assessing the points raised by the petitioners, the EPA agreed that PM emissions are influenced by unit design, and fuel type, and proposed to create combustion-based pollutant subcategories for coal and solid fuels and create fuel-based subcategories for liquid and biomass fuel units. The EPA is finalizing a single PM limit for all coal/solid fossil fuel subcategories, and is also finalizing emissions limits based on PM as a combustion-based pollutant for the biomass and liquid fuel subcategories.

Another change from proposal is that the alternative TSM emission limits are now applicable to the three liquid fuel subcategories. Several commenters provided data and comments supporting these alternative emission standards for non-mercury metallic HAP. After assessing the revised data and the points made by the commenters, the EPA agrees that the limited data available for liquid fuel units are not unique to this subcategory. Based on the EPA agreeing with the commenters, the EPA re-calculated the TSM emission limits for the liquid fuel subcategories and included them in the final rule.

The CO emission limit for several subcategories, both new and existing, have been revised to reflect a CO level that is consistent with MACT for organic HAP reduction. Several commenters recommended that the EPA evaluate a minimum CO standard (i.e., 100 ppm corrected to 7 percent oxygen) to serve as a lower bound surrogate for organic HAP. Commenters also provided data and information to support such a standard, and noted that the EPA has taken a similar approach in other emission standards under section 112.

The EPA evaluated whether there is a minimum CO level for boilers and

process heaters below which there is no further benefit in organic HAP reduction/destruction. Specifically, we evaluated the relationship between CO and formaldehyde using the available data obtained during the rulemaking. Formaldehyde was selected as the basis of the organic HAP comparison because it is the most prevalent organic HAP in the emission database and a large number of paired tests existed for boilers and process heaters for CO and formaldehyde. The paired data show decreasing formaldehyde emissions with decreasing CO emissions down to CO levels around 300 ppm, supporting the selection of CO as a surrogate for organic HAP emissions. A slight increase in formaldehyde emissions is observed at CO levels below around 200 ppm, suggesting a breakdown in the CO-formaldehyde relationship at low CO levels. At levels lower than 150 ppm, the mean levels of formaldehyde appear to increase, as does the overall maximum value of and variability in formaldehyde emissions. However, we are aware of no reason why CO concentrations would continue to decrease and formaldehyde concentrations would increase as combustion conditions improve. It is possible that imprecise formaldehyde measurements at low concentrations (i.e., 1–2 ppm) may account for this slight increase in formaldehyde emissions observed at CO levels below 100 ppm corrected to 7 percent oxygen. Based on this, we do not believe that such measurements are sufficiently reliable to use as a basis for establishing an emissions limit.

Therefore, based on the above analysis, we are promulgating a minimum MACT floor level for CO of 130 ppm corrected to 3 percent oxygen (which is equivalent to 100 ppm corrected to 7 percent oxygen). We note this is the same approach used to establish the CO emission limit of 100 ppm corrected to 7 percent oxygen for the Burning of Hazardous Waste in Boilers and Industrial Furnaces rule. Additional discussion of the rationale for this approach can be found in the memorandum ''Revised MACT Floor Analysis (August 2012) for Industrial, Commercial, Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants—Major Source.''

Subcategories where the initial MACT floor 99 percent UPL calculations for CO were less than 100 ppm corrected to 7 percent oxygen (or equivalently 130 ppm corrected to 3 percent oxygen) are as follows:

- New and Existing Subcategories: Coal-FB, Coal-PC, Heavy Liquid, Light Liquid, Non-Continental Liquid, Process Gas
- New Subcategories: Coal-Stoker

We believe a CO level of 130 ppm corrected to 3 percent oxygen is an appropriate minimum MACT floor level. Although some measurements show CO levels below 130 ppm corrected to 3 percent oxygen, it is not appropriate to establish a lower floor level because CO is a conservative surrogate for organic HAP. In other words, organic HAP emissions are extremely low when sources operate under the good combustion conditions required to achieve CO levels in the range of zero to 100 ppm. As such, lowering the CO floor below 100 ppm will not provide reductions in organic HAP emissions. There are myriad factors that affect combustion efficiency and, as a function of combustion efficiency, CO emissions. As combustion conditions improve and hydrocarbon levels decrease, the larger and easier to combust compounds are oxidized to form smaller compounds that are, in turn, oxidized to form CO and water. As combustion continues, CO is then oxidized to form carbon dioxide and water. Because CO is a difficult to destroy refractory compound (*i.e.,* oxidation of CO to carbon dioxide is the slowest and last step in the oxidation of hydrocarbons), it is a conservative surrogate for destruction of hydrocarbons, including organic HAP.

The conservative nature of CO as an indicator of good combustion practices is supported by our data. At CO levels less than 100 ppm corrected to 7 percent oxygen, our data indicate that there is no apparent relationship between CO and organic HAP (i.e., formaldehyde). For example, a source with a CO level of 20 ppm may have the same measured formaldehyde as a source achieving a CO emission level of 100 ppm corrected to 7 percent oxygen. Sources are required to establish operating requirements based on operating levels that were demonstrated during the test. Sources must comply with these operating requirements on a continuous basis. Compliance with these requirements adequately assures sources will be controlling organic HAP emissions to MACT levels.

As detailed in the docketed memorandum ''Beyond the Floor Technology Analysis for Major Source Boilers and Process Heaters (Revised August 2012),'' we reviewed the emission limits that are becoming less stringent since the March 2011 final rule in order to assess whether a beyond the floor option was technically achievable and cost effective. As a result of this review, the PM emission limits for several new biomass subcategories have been changed to reflect a beyond the floor limit of 0.03 lb/MMBtu, based on the limit for new biomass boilers in 40 CFR part 60 subparts Db and Dc. Due to the low mercury emission limits for new solid fuel boilers, these new biomass units are expected to install a fabric filter level of control in order to meet the new source mercury limits for the solid fuel subcategory. This mercury control has the co-benefit of reducing PM emissions down to levels of 0.03 lb/MMBtu so there is no incremental cost to achieve these additional reductions in PM for the biomass units that have a design heat input capacity between 10 and 30 MMBtu/hr. For units with a design heat input capacity of 30 MMBtu/hr or greater, these units are already subject to a PM limit of 0.03 lb/MMBtu and adjusting these new source limits to this level of control makes the limits consistent between both rules, without adding additional costs. We did not identify any beyond the floor options for existing source PM limits or new and existing limits for other pollutants as technically feasible or cost effective.

The other changes associated with the other emission limits are due to new data, corrections to old data, and inventory changes. In summary, compared to the December 23, 2011 proposed limits for existing units, the final HCl emission limits remained the same; for the final mercury emission limits, 3 are more stringent, 10 are less stringent and 1 is unchanged; for the final PM emission limits, 3 are more stringent, 5 are less stringent and 6 are unchanged; and for the final CO emission limits, 3 are more stringent and 11 are less stringent. For new units, compared to the proposed emission limits, 3 of the final HCl emission limits are more stringent and 11 remained the same; for the final mercury emission limits, 10 are more stringent and 4 are unchanged; for the final PM emission limits, 5 are more stringent, 2 are less stringent and 7 are unchanged; and for the final CO emission limits, 2 are more stringent, 11 are less stringent and 1 is unchanged.

E. Work Practice Requirement

In this final rule several changes have been made to the work practice requirement to conduct a tune-up. First, the requirement to inspect the burner has been revised to allow units that sell electricity to schedule the burner inspection, as well as the air-to-fuel system inspection, at the time of the first outage but not to exceed 36 months from the previous inspection. This

change is being made to this final rule because commenters stated that large boilers that serve electricity for sale may not require annual outages and would, therefore, need to be taken off-line for the sole purpose of an annual tune-up. This frequency is consistent with the requirements of the NESHAP for electric utility boilers (40 CFR part 63, subpart UUUUU).

Also, for units where entry into a piece of process equipment or into a storage vessel is required to complete the tune-up inspections, inspections are required only during planned entries into the storage vessel or into process equipment. Commenters indicated that some process heaters are installed inside tanks and entry into the tank to access the heater may not occur within a 5 year period.

The requirement to optimize total emissions of CO has been revised to require that this optimization not only be consistent with the manufacturer's specifications but also with any NO_X emission requirement to which the unit is subject. Some commenters indicated that many boilers need different tune-up criteria due to their requirement to also comply with low NO_X emission limits. We are also aware that several states have boiler tune-up requirements to minimize NO_X emissions first and then optimize CO emissions.

We have added boilers or process heaters that have a continuous oxygen trim system to the types of boilers or process heaters that must conduct a tune-up every 5 years. These units do not need to be tuned as frequently because the trim system is designed to continuously measure and maintain an optimum air to fuel ratio which is the purpose of a tune-up.

F. Averaging Times Definitions

We revised the definitions of ''30-day rolling average'' and ''daily block average'' to exclude periods of startup and shutdown or downtime from the arithmetic mean. Commenters requested that the EPA specify how a 30-day rolling average is calculated and whether it includes the previous 720 hours of valid operating data and that the valid data exclude hours during startup and shutdown as well as unit down time. We agree with the commenters that the definitions need clarification and that these periods should not be included in calculating the 30-day rolling average. Therefore, we have revised the definitions accordingly.

We have also included in the final rule a definition of ''10-day rolling average'' that is consistent with the revised definition of ''30-day rolling average.''

G. Energy Assessment

In this final rule, we have revised the definition of energy assessment per the requirements of Table 3 of this final rule by providing duration for performing the energy assessment for large fuel use facilities. In numbered paragraph (3) in the definition of ''Energy assessment'' in § 63.7575, which is for facilities with units having a combined heat input capacity greater than 1 TBtu/yr, we added time duration/size ratio and included a cap to the maximum number of on-site technical hours that should be used in the energy assessment. This addition of a duration for large fuel use facilities is being made to be consistent with durations specified for small [paragraph (1) in the definition of ''Energy assessment''] and medium [paragraph (2) in the definition of ''Energy assessment''] fuel use facilities. The energy assessment for facilities with affected boilers and process heaters having a combined heat input capacity greater than 1.0 TBtu/yr will be up to 24 on-site technical labor hours for the first TBtu/yr plus 8 technical labor hours for every additional 1.0 TBtu/yr not to exceed 160 technical hours, but may be longer at the discretion of the owner or operator.

The revised definition of energy assessment also clarifies our intentions that the scope of assessment is based on energy use by discrete segments of a facility and not by a total aggregation of all individual energy using elements of a facility. The applicable discrete segments of a facility could vary significantly depending on the site and its complexity. We have added the following paragraph (4), to the energy assessment definition to help resolve current problems in identifying the scope of the various energy use systems in a large industrial complex and allow for more streamlined assessments:

''(4) The on-site energy use systems serving as the basis for the percent of affected boiler(s) and process heater(s) energy output in (1), (2) and (3) above may be segmented by production area or energy use area as most logical and applicable to the specific facility being assessed (e.g., product X manufacturing area; product Y drying area; Building Z).''

We have also revised paragraph 4 of Table 3 of the final rule to allow a source that is operating under an energy management program established through energy management systems compatible with ISO 50001, which includes the affected units, to satisfy the energy assessment requirement. We consider these energy management programs to be equivalent to the one-time energy assessment because facilities having these programs operate under a set of practices and procedures designed to manage energy use on an ongoing basis. These programs contain energy performance measurements and tracking plans with periodic reviews.

The definition of ''Energy use system'' has also been revised in this final rule to clarify that energy use systems are only those systems using energy clearly produced by affected boilers and process heaters.

H. Startup and Shutdown Definitions

A number of commenters indicated that the proposed load specifications (i.e., 25 percent load) within the definitions of ''startup'' and ''shutdown'' were inconsistent with either safe or normal (proper) operation of the various types of boilers and process heaters encountered within the source category. As the basis for defining periods of startup and shutdown, a number of commenters suggested alternative load specifications based on the specific considerations of their boilers; other commenters suggested the achievement of various steady-state conditions.

We have reviewed these comments and believe adjustments are appropriate in the definition of ''startup'' and ''shutdown.'' These adjustments are tailored for industrial boilers and are consistent with the definitions of ''startup'' and ''shutdown'' contained in the 40 CFR part 63, subpart A General Provisions. We believe these revised definitions address the comments and are rational based on the fact that industrial boilers function to provide steam or, in the case of cogeneration units, electricity; therefore, industrial boilers should be considered to be operating normally at all times steam of the proper pressure, temperature, and flow rate is being supplied to a common header system or energy user(s) for use as either process steam or for the cogeneration of electricity. The definitions of ''startup'' and ''shutdown'' have been revised in the final rule as follows:

''*Startup* means either the first-ever firing of fuel in a boiler or process heater for the purpose of supplying steam or heat for heating and/or producing electricity, or for any other purpose, or the firing of fuel in a boiler or process heater after a shutdown event for any purpose. Startup ends when any of the steam or heat from the boiler or process heater is supplied for heating and/or producing electricity, or for any other purpose.''

''*Shutdown* means the cessation of operation of a boiler or process heater for any purpose. Shutdown begins either when none of the steam and heat from the boiler or process heater is supplied for heating and/or producing electricity, or for any other purpose, or at the point of no fuel being fired in the boiler or process heater, whichever is earlier. Shutdown ends when there is both no steam or heat being supplied and no fuel being fired in the boiler or process heater.''

The EPA is requiring sources to vent emissions to the main stack(s) and operate all control devices necessary to meet the normal operating standards under this final rule (with the exception of limestone injection in FBC boilers, dry scrubber, fabric filter, SNCR and SCR) when firing coal/solid fossil fuel, biomass/bio-based solids, heavy liquid fuel or gas 2 (other) gases in the boiler or process heater during startup or shutdown. It is the responsibility of the operators of affected boilers and process heaters to start their limestone injection in FBC boilers, dry scrubber, fabric filter, SNCR and SCR systems appropriately to comply with relevant standards applicable during normal operation. Startup ends and normal operating standards apply when heat or steam is supplied for any purpose.

The EPA carefully considered fuels and potential operational constraints of APCD when designing its work practices for periods of startup and shutdown. The EPA notes that there is no technical barrier to burning clean fuels (e.g., natural gas, distillate oil) for longer portions of startup or shutdown periods at a boiler and the HAP emission reduction benefits warrant additional utilization of such fuels until the temperature and stack emissions pressure is sufficient to engage the APCD. The EPA is aware that SNCR and SCR systems with ammonia injection need to be operated within a prescribed and relatively narrow temperature window to provide NO_X reductions. Further, the EPA is aware that dry scrubbers also need to be operated close to flue gas saturation temperature, and that fabric filters need to be operated at temperatures above the acid dew point. Because these devices have specific temperature requirements for proper operation, the EPA notes in its work practices that it is the responsibility of the operators of affected boilers and process heaters to start their SNCR, SCR, fabric filter and dry scrubber systems appropriately to comply with relevant standards applicable during normal operation.

I. Fuel Sampling Frequency

The sampling frequency for gaseous fuel-fired units that elected to demonstrate that the unit meets the specification for mercury for the unit designed to burn gas 1 subcategory has been revised in this final rule. If the initial mercury constituents in the gaseous fuels are measured to be equal to or less than half of the mercury specification, no further sampling is required. If the initial mercury constituents are greater than half but equal to or less than 75 percent of the mercury specification, only semi-annual sampling need to be conducted. If the initial mercury constituents are greater than 75 percent of the mercury specification, monthly sampling is required.

J. Affirmative Defense

In the proposal, we used terms such as ''exceedance'' or ''excess emissions'' in § 63.7501, which created unnecessary confusion as to when the affirmative defense could be used. In the final amended rule, we have eliminated those terms and used the word ''violation'' to make clear that the affirmative defense to civil penalties is available only where an event that causes a violation of the emissions standard meets the definition of malfunction under § 63.2.

We have also eliminated the 2-day notification requirement that was included in 40 CFR 63.7501(b) at proposal because we expect to receive sufficient notification of malfunction events that result in violations in other required compliance reports, such as the malfunction report required under 40 CFR 63.7550(c). In addition, we have revised the 45-day affirmative defense reporting requirement that was included in 40 CFR 63.7501(b) at proposal to require sources to include the report in the first compliance, deviation or excess emission report due after the initial occurrence of the violation, unless the compliance, deviation or excess emission report is due less than 45 days after the violation. In that case, the affirmative defense report may be included in the second compliance, deviation or excess emission report due after the initial occurrence of the violation. Because the affirmative defense report is now included in a subsequent compliance, deviation or excess emission report, there is no longer a need for the proposed 30-day extension for submitting a stand-alone affirmative defense report. Consequently, we are not including this provision in the final amended rule. We have also re-evaluated the language concerning the use of off-shift and overtime labor to the extent practicable and believe that the language is not necessary. Thus, we have deleted that phrase from section 63.7501(a)(2).

V. Other Actions We Are Taking

Section 307(d)(7)(B) of the CAA states that ''[o]nly an objection to a rule or procedure which was raised with reasonable specificity during the period for public comment (including any public hearing) may be raised during judicial review. If the person raising an objection can demonstrate to the Administrator that it was impracticable to raise such objection within such time or if the grounds for such objection arose after the period for public comment (but within the time specified for judicial review) and if such objection is of central relevance to the outcome of the rule, the Administrator shall convene a proceeding for reconsideration of the rule and provide the same procedural rights as would have been afforded had the information been available at the time the rule was proposed. If the Administrator refuses to convene such a proceeding, such person may seek review of such refusal in the United States court of appeals for the appropriate circuit (as provided in subsection (b)).''

As to the first procedural criterion for reconsideration, a petitioner must show why the issue could not have been presented during the comment period, either because it was impracticable to raise the issue during that time or because the grounds for the issue arose after the period for public comment (but within 60 days of publication of the final action). The EPA is denying the petitions for reconsideration on a number of issues because this criterion has not been met. In many cases, the petitions reiterate comments made on the proposed June 2011 rule during the public comment period for that rule. On those issues, the EPA responded to those comments in the final rule and made appropriate revisions to the proposed rule after consideration of public comments received. It is well-established that an agency may refine its proposed approach without providing an additional opportunity for public comment. See *Community Nutrition Institute* v. *Block,* 749 F.2d at 58 and *International Fabricare Institute* v. *EPA,* 972 F.2d 384, 399 (D.C. Cir. 1992) (notice and comment is not intended to result in ''interminable back-and-forth[,]'' nor is agency required to provide additional opportunity to comment on its response to comments) and *Small Refiner Lead Phase-Down Task Force* v. *EPA,* 705 F.2d 506, 547 (D.C. Cir. 1983) (''notice requirement

should not force an agency endlessly to repropose a rule because of minor changes'')

In the EPA's view, an objection is of central relevance to the outcome of the rule only if it provides substantial support for the argument that the promulgated regulation should be revised. See *Union Oil* v. *EPA,* 821 F.2d 768, 683 (D.C. Cir. 1987) (court declined to remand rule because petitioners failed to show substantial likelihood that final rule would have been changed based on information in petition). See also the EPA's *Denial of the Petitions to Reconsider the Endangerment and Cause or Contribute Findings for Greenhouse Gases under Section 202 of the Clean Air Act,* 75 FR at 49556, 49561 (August 13, 2010). See also, 75 FR at 49556, 49560–49563 (August 13, 2010) and 76 FR at 4780, 4786–4788 (January 26, 2011) for additional discussion of the standard for reconsideration under CAA section 307(d)(7)(B).

We are denying reconsideration on the following 57 issues contained in the petitions for reconsideration because they failed to meet the standard described above for reconsideration under CAA section 307(d)(7)(B). Specifically, on these issues, the petitioner has failed to show the following: that it was impracticable to raise their objections during the comment period or that the grounds for their objections arose after the close of the comment period; and/or that their concern is of central relevance to the outcome of the rule. Therefore, the EPA is denying the petitions for reconsideration on the issues for the reasons described below.

Issue: Delist gas units.

The petitioners (API, NPRA) requested that the EPA remove gas-fired units from the section 112(c) list of source categories for which the EPA is required to establish emissions standards under section 112(d). The EPA is denying the petition for reconsideration for the following reasons. First, the issue is outside the scope of this rulemaking, which establishes emissions standards for new and existing units within the major source boilers and process heaters source category. The EPA did not solicit comment in the proposed rule regarding the scope of the subcategory. Further, petitioners provide no information to support delisting gas units under section 112(c)(9), which requires the EPA to make certain findings before delisting any sources. In addition, the petition does not address the D.C. Circuit's decision in *NRDC* v. *EPA,* 489 F.3d 1364 (2007), regarding the EPA's ability to delist subcategories of a source category pursuant to section 112(c)(9). For these reasons, the petitions do not provide support for the argument that the regulation should be changed. For this reason, the petition does not demonstrate that the issue is of central relevance to the outcome of the final rule and the EPA is denying the request for reconsideration.

Issue: Exempt natural gas hot water heaters with tanks greater than 120 gallons.

The petitioner (AIF) requested that the EPA exempt natural gas hot water heaters with tanks greater than 120 gallons. While the EPA disagrees with the petitioner regarding whether such units should be subject to the emissions standards in this rule, the petitioner has not demonstrated that it lacked the opportunity to comment on whether such units should be required to meet emissions standards. The EPA proposed work practice standards for such units in its June 2010 proposal, and the petitioner had the opportunity to comment on whether such standards should be applied to such units at all. Therefore, the EPA is denying the request for reconsideration.

Issue: Exempt natural gas and distillate oil-fired circulating hot water systems with a design capacity of 10 MMBtu/hr or less.

The petitioner (CIBO) requested that the EPA exempt natural gas and distillate oil-fired circulation hot water systems that are not greater than 10 MMBtu/hr. While the EPA disagrees with the petitioner regarding whether such units should be subject to the emissions standards in this rule, the petitioner has not demonstrated that it lacked the opportunity to comment on whether such units should be required to meet emissions standards. The EPA proposed emissions standards for such units, and the petitioner had the opportunity to comment on whether such standards should be applied to such units at all. In addition, the petition does not provide any information to demonstrate that these units should be delisted pursuant to section 112(c)(9). Therefore, the EPA is denying the request for reconsideration.

Issue: Confirm in definitions that open flame heaters (e.g., asphalt tank heaters) are not process heaters.

The petitioners (API, NPRA) requested that the EPA clarify in the definition of ''process heater'' that open flame heaters do not meet the definition. While the EPA disagrees with the petitioners whether clarification is needed in regards to open flame heaters, the petitioners have not demonstrated that it lacked the opportunity to comment on the proposed definition. The definition that the EPA proposed clearly states that process heaters are enclosed devices in which the combustion gases do not come into contact with process materials, and as such, does not include open flame heaters. Therefore, the EPA is denying reconsideration.

Issue: For blast furnace fuel-fired boiler exemption, compute the 90 percent BFG by volume threshold to exclude periods of BFG curtailment.

The petitioners (AISI, ACCCI) requested that the EPA revise the exemption for BFG fuel-fired boilers to exclude periods of BFG curtailment. While the EPA disagrees with the petitioners regarding revising the exemption, the petitioners have not demonstrated that it lacked the opportunity to comment on the proposed exemption for BFG fuel-fired boilers. The EPA proposed the exemption for these boilers, and petitioners therefore had the opportunity to comment on whether the exemption should apply to periods of BFG curtailment. Therefore, the EPA is denying the request for reconsideration.

Issue: Exempt boilers whose flue gases are used in direct-fired process heaters subject to other NESHAP.

The petitioner (CMI) requested that the EPA exempt from the rule boilers whose flue gases are used in direct-fired process heaters that are subject to other NESHAP. The final rule does not apply to such units if they are subject to another NESHAP. The EPA does not see a need for further clarification. Since the final rule does in fact exempt these units, the EPA is denying the request for reconsideration.

Issue: Work practice standards do not meet EPA obligations under 112(c)(6).

The petitioner (Sierra Club) requested that the EPA establish numeric emissions limits for Gas 1 units rather than work practice standards. Specifically, the petitioner alleges that the work practice standards do not meet the EPA's obligations under section 112(c)(6) of the CAA, and that it was not the case that data were below the detection level for all HAP emitted from these units. The EPA is denying the request for reconsideration on this issue. While the EPA disagrees with the petitioner's arguments regarding the legal authority to establish work practice standards for Gas 1 units and the basis for such standards, the petitioner has not demonstrated that it lacked the opportunity to comment on this issue. The EPA proposed work practice standards for Gas 1 units and explained in the proposal its rationale for such standards, including the fact that a significant portion of the

emissions data were below the detection level. 75 *FR* at 32024–25. Therefore, the petitioner had the opportunity to comment on this issue, and did in fact submit comments regarding the EPA's legal authority to establish work practice standards for Gas 1 units. Therefore, the EPA is denying reconsideration on this issue.

Issue: Work practices for small units are not justified by 112(h) since small units were not given their own subcategory.

The petitioner (Sierra Club) requested that the EPA require small units, those having a heat input capacity of less than 10 MMBtu/hr, to meet numeric emissions limits rather than work practice standards. The EPA is denying the request for reconsideration on this issue because the petitioner has not demonstrated that it lacked the opportunity to comment on this issue. The EPA proposed work practice standards for these units and explained in the proposal its rationale for such standards. 75 *FR* at 32024–25. The EPA did in fact receive comments regarding the proposed standards, to which it responded in the final rule. 76 *FR* at 15640. Moreover, the EPA notes that nothing in section 112(h) limits the EPA's discretion to establish work practice standards to the establishment of such standards for an entire category or subcategory. Therefore, the EPA is denying the request for reconsideration.

Issue: PM is not an adequate surrogate for non-mercury metallic HAP.

The petitioner (Sierra Club) requested that the EPA remove the PM standard as a surrogate for non-mercury metallic HAP and instead adopt a numeric limit for non-mercury metallic HAP because PM is not an appropriate surrogate. The EPA is denying the request for reconsideration on this issue. While the EPA disagrees with the petitioner's argument regarding the suitability of PM as a surrogate for non-mercury metallic HAP, the petitioner has not demonstrated that it lacked the opportunity to comment on this issue. The EPA proposed PM standards as a surrogate for non-mercury metallic HAP and explained in the proposal the agency's basis for concluding that PM was an appropriate surrogate. 75 *FR* at 32018. Therefore, the EPA is denying the request for reconsideration.

Issue: Establish direct limits on organics or select a surrogate besides CO.

The petitioner (Sierra Club) requested that the EPA remove the CO standard as a surrogate for organic HAP and instead adopt a numeric limit for these HAP, because CO is not an appropriate surrogate. The EPA is denying the request for reconsideration on this issue. While the EPA disagrees with the petitioner's argument regarding the suitability of CO as a surrogate for organic HAP, the petitioner has not demonstrated that it lacked the opportunity to comment on this issue. The EPA proposed CO standards as a surrogate for organic HAP and explained in the proposal the agency's basis for concluding that CO was an appropriate surrogate. 75 *FR* at 32018. The EPA received comments on this issue, including comments stating that CO is not an appropriate surrogate for organic HAP. Therefore, the EPA is denying the request for reconsideration.

Issue: Adopt an alternative THC emission standard.

The petitioner (CIBO) requested that the EPA adopt a THC emissions standard as an alternative to the CO standard. The EPA is denying the request for reconsideration on this issue. While the EPA disagrees with the petitioner's argument regarding whether a THC alternative standard is appropriate as a surrogate for non-dioxin organic HAP, the petitioner has not demonstrated that it lacked the opportunity to comment on this issue. The EPA raised in the proposal the possibility of THC as a surrogate for non-dioxin organic HAP, and explained why the use of CO as a surrogate was preferable. 75 *FR* at 32018. In addition, the EPA did not receive any comments or data during the public comment period on the proposed rule that would have enabled the agency to establish a THC alternative standard, including THC emissions data, nor did the petitioner provide any such data. Therefore, the petition does not provide substantial support for its argument that the final rule should be changed. For these reasons, the EPA is denying the petition for reconsideration on this issue.

Issue: Regulation of Total dioxin/furans exceeds statutory authority as only 2 compounds are in 112(b)(1).

The petitioners (AISI, ACCCI, AF&PA) alleged that the EPA lacks statutory authority to regulate total dioxin/furans under CAA section 112, and that the EPA's response in the final rule explaining why it is issuing a total dioxin/furan standard was not a logical outgrowth of the proposed rule. The EPA is denying the request for reconsideration on this issue. First, the EPA disagrees that the final rule is not a logical outgrowth of the proposal. The EPA proposed emissions standards for total dioxin/furans and adopted a final emissions standard for the same pollutant. Therefore, the commenter had the opportunity to provide its views during the public comment period regarding the EPA's proposed emissions standard, including its views regarding the EPA's authority to regulate the pollutant at issue. The fact that the EPA responded to those comments does not mean that the petitioner lacked the opportunity to comment—in fact, the petitioner did provide such comments. 76 *FR* at 15640. For this reason, the EPA is denying the petition for reconsideration.

Issue: HCl is an inadequate surrogate for all acid gases.

The petitioner (Sierra Club) requested that the EPA remove the HCl standard as a surrogate for acid gases and instead adopt a numeric limit for these HAP, because HCl is not an appropriate surrogate. The EPA is denying the request for reconsideration on this issue. While the EPA disagrees with the petitioner's argument regarding the suitability of HCl as a surrogate for acid gases, the petitioner has not demonstrated that it lacked the opportunity to comment on this issue. The EPA proposed HCl standards as a surrogate for acid gases and explained in the proposal the agency's basis for concluding that HCl was an appropriate surrogate. 75 *FR* at 32018. While the EPA had emission data for HCl from hundreds of affected units upon which to establish standards, the EPA did not have sufficient data on the other acid gases to do so (hydrogen fluoride, hydrogen cyanide and chlorine). The petitioner did not refer to any such data and, therefore, the issue is not of central relevance to the outcome of the final rule. Therefore, the EPA is denying the request for reconsideration.

Issue: Establish work practice for other organic HAP instead of using CO as a surrogate.

The petitioners (AMP, JELD–WEN) requested that the EPA adopt a work practice standard for organic HAP rather than a numeric emissions limit based on CO as a surrogate for organic HAP. The EPA is denying the request for reconsideration on this issue. While the EPA disagrees that a work practice standard is appropriate for such HAP for the subcategories for which the EPA adopted a numeric CO limit in the final rule, the petitioners have not demonstrated that they lacked the opportunity to comment on this issue. The EPA proposed numeric CO limits rather than a work practice, and the petitioners had the opportunity to provide their views during the public comment period on the proposed rule regarding why it believed a work practice standard should instead be

finalized. Therefore, the EPA is denying the petition for reconsideration.

Issue: Allow health based compliance alternatives for HCl, other acid gases and manganese.

The petitioners (AMP, AF&PA, AHFA, AISI, ACCCI, RPU, CIBO) requested that the EPA adopt a HBES for HCl and other acid gases as well as for manganese, pursuant to section 112(d)(4). The petitioners also requested that the EPA grant reconsideration on this issue to better address the comments and data submitted during the public comment period for the proposed rule. The EPA is denying the request for reconsideration of this issue. The EPA did not propose a HBES for any pollutants, but did solicit public comment on such standards, explaining its concerns regarding health-based standards, including the lack of available data on which to base such standards. 75 *FR* at 32030. The EPA received comments addressing those concerns and responded to them in the final rule. 76 *FR* at 15642. Therefore, the petitioners have not demonstrated that it lacked the opportunity to comment on this issue. Further, the EPA received no data during the public comment period for the proposed rule on which it could base a HBES for HCl, other acid gases or manganese. Therefore, the petitions do not provide substantial support to demonstrate that the final rule should be changed. For these reasons, the EPA is denying the petition for reconsideration.

Issue: Provide additional compliance alternatives according to Executive Order 13563 (additional subcategories and HBES).

The petitioner (AHFA) requested that the EPA provide additional compliance alternatives in the final rule pursuant to Executive Order 13563 (Improving Regulation and Regulatory Review), including HBES. The EPA is denying the request for reconsideration on this issue because it is not of central relevance. First, nothing in Executive Order 13563 affects the EPA's discretion to establish HBES under the CAA. Additionally, the petition does not provide any information to address our concerns regarding HBES or data to establish such standards.

Issue: Remove energy assessment requirements.

The petitioners (AHFA, AISI, ACCCI, API, NPRA, AIF, CIBO, AF&PA, U.S. Sugar) requested that the EPA remove from the final rule the requirement that existing sources conduct an energy assessment. The EPA is denying the request for reconsideration on this issue. The EPA proposed an energy assessment requirement as a beyond-the-floor standard, and petitioners commented on that proposal. The EPA addressed those comments in the final rule, and petitioners have not demonstrated that they lacked the opportunity to comment on whether the EPA should require an energy assessment, including the EPA's legal authority to do so. 76 *FR* at 15631. Therefore, the EPA is denying the petition for reconsideration. The EPA continues to believe that an energy assessment is not only authorized by the CAA but required as a cost-effective beyond-the-floor standard in accordance with section 112(d)(2).

Issue: Require energy assessment to be conducted every 5 years.

The petitioner (Washington Dept. of Ecology) requested that the EPA require more frequent energy assessments. The EPA proposed a one-time assessment (75 *FR* at p. 32036) and the petitioner has not demonstrated it lacked the opportunity to comment on the frequency of the assessment requirement. Therefore, the EPA is denying the petition.

Issue: Modify cost analysis to include potential fuel savings from implementing assessment findings.

The petitioners (AIE, USCHPA) requested that the EPA modify its cost impacts analysis to include potential fuel savings from implementing energy assessment findings. The EPA is denying the petition. The impacts analysis, including specific mention of how cost savings for energy assessments were handled quantitatively, was explained in the proposal (see 75 FR 32026), and the petitioner therefore had the opportunity to comment on this issue. For this reason, the EPA is denying the petition for reconsideration on this issue.

Issue: Reconsider definition of ''cost effective.''

The petitioners (AIE, USCHPA) requested that the EPA reconsider the definition of ''cost-effective'' in the final rule. The EPA is denying the request for reconsideration on this issue. The EPA proposed to define cost-effective energy conservation measures as any measure with return of investment period of two years or less. 75 *FR* at 32036. The petitioners have not demonstrated it lacked the opportunity to comment on the proposed definition. Therefore, the EPA is denying the petition for reconsideration.

Issue: Establish work practice for other organic HAP instead of using CO surrogate.

The petitioners (AMP, JELD–WEN) requested that the EPA establish work practice standards for controlling organic HAP instead of using CO as a surrogate for organic HAP and establishing CO emission limits. The EPA is denying the request for reconsideration on this issue. Use of CO as a surrogate for organic HAP was subject to notice and comment. (75 FR 32018, 75 FR 32041). Responses to comment on this topic were provided in RTC document, Volume 2, EPA–HQ–OAR–2002–0058–3289, see section ''Choice of Regulated Pollutants: THC vs. CO vs. Other Organic HAP''.

Issue: Provide alternative format for units of measure for CO emission limits to allow sources to use their existing monitoring equipment.

The petitioners (UARG, CIBO) requested that the EPA provide an alternative format (ppm at X percent CO_2) for units of measure for CO emissions in addition to ppm at 3 percent oxygen. The EPA is denying the petition because the petitioners do not demonstrate that it was impracticable to comment on this issue. The format for units of measure for the limits was provided in the proposed rule, and petitioners could have commented on whether the proposed units were appropriate.

Issue: New source emission limits are unachievable and the EPA should collect additional fuel variability data from top performing units to adjust the limits.

The petitioner (AF&PA) requested that the EPA adjust the emissions limits for new sources by collecting additional data from the best performing units that they believed would result in increased variability. The petitioners have not demonstrated that they lacked the opportunity to comment. We proposed standards based on the data we had, including data collected during the ICR process in which petitioners participated, and that data were available for public review. Therefore, petitioners could have commented on this issue. Second, the CAA requires that we base the standards on the sources for which we have emissions information. Petitioners are always free to provide more information to us and the EPA specifically requested new data at each stage of the rulemaking to support the development of emission limits for each subcategory. (75 FR 32041, 76 FR 28663, 76 FR 80612). The EPA has incorporated revised data corrections or new data submittals in its analysis for the final rule. The EPA is denying the request for reconsideration.

Issue: Adjust the methodology for computing MACT floors to address statistical errors and variability concerns.

The petitioners (AISI, ACCCI, AF&PA) requested that the EPA adjust the

methodology for computing MACT floors to address statistical errors and variability concerns, including: (1) Dataset reflects the ''best of the best'' units; (2) misapplication of statistical formulae to address distribution, confidence limits, and variability; and (3) failure to address variability in emissions from one unit over time. The methods used to compute the MACT floors were subject to notice and comment. Where new data or data corrections have been submitted that might alter data distributions, identifying best performers or application of fuel variability factors, these changes have been made in the final rule, but the general methodology remains the same. See *Solite Corp.* v. *EPA,* 952 F.2d 473, 485 (D.C. Cir. 1991) (public had sufficient notice of final rule threshold calculations where methodology did not change significantly from proposed rule). The EPA explained the MACT floor methodology in the proposed rule, and addressed comments received on the proposed methodology in the final rule (75 FR 32019–26, 32027–29, 76 15621–30, 76 FR 80614). Therefore, the EPA is denying the request for reconsideration.

Issue: Modify the basis for ranking the top performing units.

The petitioner (WEPCO) requested that the EPA modify the basis for ranking the top performing units, especially for new units, according to the average performance of the unit. The EPA is denying the petition. The methods used to rank units to establish the MACT floors were subject to notice and comment. The EPA explained its methodology in the proposed rule and addressed comments received on the ranking of data for computing the MACT floor in the final rule (75 FR 32019–26, 32027–29, 76 FR 15627).

Issue: Do not use a pollutant-by-pollutant approach to establish MACT floors.

The petitioners (AISI, ACCCI, AF&PA) requested that the EPA not use a pollutant-by-pollutant approach to establish MACT floors. The petitioners stated that this method is not a reasonable interpretation of Section 112(d)(3) of the CAA and that MACT floors should reflect levels achieved in practice, not aspirational controls. The EPA is denying the petition for reconsideration on this issue because it does not demonstrate that it was impracticable to comment on the issue. The EPA proposed MACT floors based on the pollutant-by-pollutant methodology, and therefore petitioners could, and in fact did, provide comments opposing this approach. See 75 FR 32021, 32029. The EPA addressed comments received on this approach in the final rule (76 FR 15621–23). Therefore, the EPA is denying the petition.

Issue: Revise approach to establish MACT floors where there is non-detect data.

The petitioner (Sierra Club) requested that the EPA not use the approach it used in the final rule based on the representative detection level (RDL) to establish MACT floors because it does not reflect actual emissions of any source within the subcategory. Further, the petitioner questioned the basis of the selected detection level, and whether or not other variability adjustments (e.g., UPL analysis) sufficiently account for measurement imprecision. The EPA is denying the petition. The three times representative detection level approach was subject to notice and comment. The EPA explained its rationale for this approach in the proposed rule (75 FR 32021) and responded to comments received in the final rule (76 FR 15623, 76 FR 80611).

Issue: The approach used to set MACT floor limits for dioxin/furan emissions is flawed and the EPA should establish an isomer-specific approach.

The petitioner (WEPCO) requested that the EPA establish an isomer-specific approach for dioxin/furan emissions because the three times detection level approach for dioxin/furan emissions is flawed. The EPA is denying the petition. This approach was subject to notice and comment. Rationale and responses to comments on this approach were provided at (75 FR 32021, 32041, 76 FR 15623). Further, the methods for establishing a representative detection level for dioxin/furan have been revised to account for the sensitivity of individual isomers, see rationale provided at (76 FR 80606).

Issue: Incorporate a fuel variability factor for PM based on the ash content of the fuel used by best performing units.

The petitioners (WEPCO, CIBO) requested that the EPA incorporate a fuel variability factor for PM based on the ash content of the fuel used by best performing units. The MACT floor methodology was explained in the June 4, 2010 proposal which included fuel variability factors that did not reflect the ash content of the fuel. Therefore, the petitioner could have commented recommending that the EPA do so, and, in fact, comments were provided on this issue. The EPA is denying the petition for reconsideration on this issue because it does not demonstrate that it was impracticable to comment on the issue. Responses to comment on this topic were provided in RTC document, Volume 1, EPA–HQ–OAR–2002–0058–3289, see section ''MACT Floor Methodology: Fuel Analysis Variability''.

Issue: Allow energy assessors to determine the time needed to conduct assessment.

The petitioner (Washington Dept. of Ecology) requested that the EPA allow the energy assessor to determine the time needed to conduct the energy assessment. The EPA is denying the petition. The duration of energy assessments was subject to notice and comment and the duration remains up to the affected source. Specific concerns with maximum duration requirements included in the March 21, 2011 final rule were clarified in the December 23, 2011 proposed notice of reconsideration. (76 FR 80615)

Issue: The unit designed to burn gas 1 subcategory should allow for limited use of liquid fuels.

The petitioners (ACC, CEG, API, NPRA) requested that the EPA allow units in the Gas 1 subcategory for limited use of liquid fuels; for example, units with a federally enforceable permit on back up fuels or units burning 10 percent or less of its heat input from liquid fuels should qualify as gas 1 units. The EPA is denying the petition because it does not demonstrate that it was impracticable to comment on the issue. The EPA proposed definitions of the various subcategories, and petitioners had the opportunity to comment on those definitions, including the proposed definition of the Gas 1 subcategory which did allow for the limited use of liquid fuels. The EPA addressed comments received on this issue in the final rule (76 FR 15620).

Issue: The unit designed to burn gas 1 subcategory should automatically include other gaseous fuels such as petrochemical process gas and landfill gas.

The petitioners (ACC, AIF, WM) requested that the EPA redefine the unit designed to burn gas 1 subcategory to automatically include other gaseous fuels such as petrochemical process gas and LFG, especially when the LFG is routed to a treatment system prior to use or sale. The EPA proposed definitions of units designed to burn gas 1 and units designed to burn gas 2 (other), and therefore the petitioner had the opportunity to comment on these definitions and to recommend that other gases be included in the definition of the Gas 1 subcategory (75 FR 32017, 32065). The EPA addressed comments received on this issue in the final rule (76 FR 15638). Therefore, the EPA is denying the petition.

Issue: Reconsider the emission standards established for the unit designed to burn gas 2 subcategory.

Petitioners (AIF, CIBO, WM, CEG) requested that the EPA reconsider the emission standards for the unit designed to burn gas 2 subcategory in light of what they feel was a limited dataset and lack of data from a diverse set of fuel types. The EPA is denying the petition. The MACT floor methodology was open to notice and comment in the June 4, 2010 proposal. The EPA proposed emissions standards for this subcategory and the petitioners had an opportunity to comment on the proposed standards and the data on which the standards were based. The EPA further notes that the CAA requires that the MACT standards be based on the best performing sources for which the Administrator has emissions information.

Issue: Adjust the ''metal process furnaces'' subcategory definition to include any gas-fired process furnace.

The petitioners (AISI, ACCCI) requested that the EPA adjust the ''metal process furnaces'' subcategory definition to include any gas-fired process furnace. The EPA is denying the petition. The definition of the subcategory for metal process furnaces was subject to notice and comment. (75 FR 32064, 76 FR 15620).

Issue: The designed to burn rationale for subcategorization is arbitrary.

The petitioner (Sierra Club) alleged that the designed to burn rationale for subcategorization is arbitrary, especially considering the large number of co-fired units in the inventory. The EPA proposed subcategories based on boiler design, and the petitioner has not demonstrated that it was impracticable to comment on the issue. In fact, the petitioner did submit comments on the proposed rule opposing the EPA's proposed subcategorization approach. Therefore, the EPA is denying the petition.

Issue: The EPA should consider exempting units from NSR.

The petitioners (MSU, PSU, Purdue, Citizens Thermal Energy) requested that the EPA consider exempting units from NSR who switch fuels, install pollution controls, or construct energy efficiency projects to meet the requirements of this rule because complying with the rule requirements will trigger NSR. The EPA is denying the petition. The applicability of NSR is outside the scope of this rulemaking. Moreover, it was not impracticable to comment on this issue during the 2011 rulemaking, in fact, comments were submitted on this issue, to which the EPA responded. See RTC document, Volume 2, EPA–HQ–OAR–2002–0058–3289, DCN EPA–HQ–OAR–2002–0058–2729.1, excerpt 17.

Issue: Remove the 10 percent penalty for sources opting to use the emission averaging compliance alternative.

The petitioners (AMP, MSU, PSU, Purdue, RPU, U.S. Sugar, Citizens Thermal Energy) requested that the EPA remove the 10 percent penalty for sources opting to use the emission averaging compliance alternative. The EPA is denying the petition. The EPA proposed an emissions averaging approach that included the 10 percent adjustment factor. (75 FR 32035) Therefore, the petition does not demonstrate that it was impracticable to comment on this issue. Responses to comment on this topic were provided in RTC document, Volume 2, EPA–HQ–OAR–2002–0058–3289, see section ''Emissions Averaging.''

Issue: Allow emissions averaging across subcategories.

The petitioners (MSU, PSU, Purdue, RPU, Citizens Thermal Energy) requested that the EPA allow emissions averaging across subcategories. The EPA is denying the petition. The EPA proposed an emissions averaging approach that did not allow averaging across subcategories, and petitioners therefore had the opportunity to comment recommending that the EPA allow such averaging. Responses to comment on this topic were provided in RTC document, Volume 2, EPA–HQ–OAR–2002–0058–3289, DCN EPA–HQ–OAR–2002–0058–3213.1, excerpt 175.

Issue: Allow a source's actual heat input instead of the maximum design heat input to be used in the emissions averaging provisions.

The petitioner (CIBO) requested that the EPA allow a source's actual heat input instead of the maximum design heat input to be used in the emissions averaging provisions of the final rule. The EPA proposed an emissions averaging approach that was based on the maximum rated heat input capacity, and petitioners therefore had the opportunity to comment recommending that the EPA base the averaging on actual heat input. Therefore, the EPA is denying the petition.

Issue: Reduce stack testing frequency to once every five years to reduce burden on facilities.

The petitioners (ACC, CIBO, JELD–WEN) requested that the EPA reduce stack testing frequency to once every 5 years and rely on the extensive set of continuous parameter monitoring in order to reduce burden on facilities. The EPA is denying the petition. The EPA proposed to require stack testing every year. The petition does not demonstrate that it was impracticable to comment on this issue, and the petitioners could have submitted comments requesting less frequent stack testing.

Issue: Incorporate detailed fuel sampling procedures using incorporation by reference mechanisms instead of detailing sampling procedures in the regulatory language.

The petitioner (CIBO) requested that the EPA incorporate detailed fuel sampling procedures using incorporation by reference mechanisms and citing credible literature (e.g., American Society for Testing and Materials) instead of detailing sampling procedures in the regulatory language since sampling procedures are subject to change over time. The EPA is denying the petition because the petitioner has not demonstrated that it was impracticable to comment on this issue. The EPA proposed fuel sampling procedures in the regulatory text in the June 4, 2010 proposal, and the petitioner therefore had the opportunity to comment recommending its preferred approach.

Issue: Remove the advanced submittal requirement for site-specific fuel monitoring plans before each analysis.

The petitioner (UARG) requested that the EPA remove the advanced submittal requirement for site-specific fuel monitoring plans before each analysis, especially if monthly frequency is maintained. If the fuel monitoring plan requirement remains, the petitioner requests that the EPA remove the requirement to report things that might change, such as unanticipated fuel use (based on unanticipated fuel changes). The EPA is denying the petition and disagrees with the commenter. First, the EPA proposed a fuel monitoring plan, and petitioners had the opportunity to comment on the plan requirement. The final rule requires submittal of a fuel monitoring plan 60 days before demonstrating initial compliance. The rule does not require re-submittal of this plan before each monthly analysis, see 40 CFR section 63.7521(b)(1).

Issue: Allow EPA Method 5B to demonstrate compliance with PM emission limits.

The petitioner (UARG) requested that the EPA allow EPA Method 5B to demonstrate compliance with PM emission limits. The EPA is denying the petition because it does not demonstrate that it was impracticable to comment on this issue. The EPA proposed methods to demonstrate compliance in the June 4, 2010 proposal and did not propose to allow Method 5B for PM compliance demonstrations. Therefore, the petitioner had the opportunity to submit comments recommending that the EPA allow the use of this method. For this

reason, the EPA is denying the petition on this issue.

Issue: Remove or make references to Methods 2, 2F, 2G and 4 optional.

The petitioner (UARG) requested that the EPA remove or make references to EPA Methods 2, 2F, 2G and 4 optional. The EPA is denying the petition because it does not demonstrate that it was impracticable to comment on this issue. The EPA proposed methods to demonstrate compliance in the June 4, 2010 proposal and did not propose to make EPA Methods 2, 2F, 2G and 4 optional. Therefore, the petitioner had the opportunity to submit comments recommending that the EPA make the use of these methods optional. For this reason, the EPA is denying the petition on this issue.

Issue: Allow sources to petition for alternative PM monitoring requirements based on source-specific limitations.

The petitioner (CEG) requested that the EPA allow sources to petition for alternative PM monitoring requirements based on source-specific limitations (e.g., common stacks with more than one subcategory). The EPA is denying this petition because it is not of central relevance to this rulemaking. The General Provisions at 40 CFR 63.8 allow sources to petition the EPA for alternative monitoring plans. Therefore, no such provision is needed in this final rule.

Issue: Allow sources with overlapping CEMS regulations to comply with existing QA/QC plans or 40 CFR part 75 Appendices A and B.

The petitioners (CIBO, CMI) requested that the EPA allow sources with overlapping CEMS regulations to comply with existing QA/QC plans or 40 CFR part 75 Appendices A and B. The EPA is denying this petition because it is not of central relevance to this rulemaking.

Issue: No justification or discussion was provided on why the EPA selected 12 hours as the averaging time period and also why the EPA selected block averages instead of rolling averages.

The petitioner (Sierra Club) alleges that the EPA provided no justification or discussion explaining why the EPA selected 12 hours as the averaging time period and why the EPA selected block averages instead of rolling averages for parameter monitor. The petitioner requested that the EPA clarify that the averaging times for continuous parameter monitoring should be the same as the averaging times during the most recent performance test. Averaging times were open to notice and comment in the June 4, 2010 proposal. In the June 2010 proposal, we required that parameters be set based on 4-hour block averages during the compliance test, and that continuous compliance be demonstrated by monitoring 12-hour block average values for most parameters. We selected this averaging period to reflect operating conditions during the performance test to ensure the control system is continuously operating at the same or better level as during a performance test demonstrating compliance with the emission limits. Therefore, the EPA is denying the petition.

Issue: The EPA position regarding treatment of ''out-of-control'' and ''maintenance'' periods as deviations is not supported or explained.

The petitioner (UARG) alleges that the EPA position regarding treatment of ''out-of-control'' and ''maintenance'' periods as deviations is not supported or explained. The petitioner requested that the EPA revise the definition of ''deviation'' to be consistent with how deviation is treated with respect to CO CEMS and CPMS. The EPA is denying the petition. The definition of deviations was open to notice and comment in the June 4, 2010 proposal.

Issue: Require checks of pressure monitoring taps only if reading is abnormal.

The petitioner (CMI) requested that the EPA require checks of pressure monitoring taps only if reading is abnormal. The requirement to check pressure tap pluggage daily was open to notice and comment in the June 2010 proposal. In addition, the EPA is denying this petition because it is not of central relevance to this rulemaking.

Issue: The EPA has not sufficiently correlated emission limits to operating parameters and should not set enforceable limits on maximum and minimum control device operating parameters.

The petitioners (UARG, AMP, CIBO) alleges that the EPA has not sufficiently correlated emission limits to operating parameters and requested the EPA not to set enforceable limits on maximum and minimum control device operating parameters. One petitioner (CIBO) requested that the rule should allow sources to set their own ESP secondary voltage requirement based on load and coal quality since power consumption by an ESP is influenced by factors other than operating load, including ESP design, amount of PM collected, and resistivity of the PM. Other petitioners (UARG and AMP) also indicate that the limits set on control devices inhibit the flexibility to operate control devices with a margin of safety. The EPA is denying the petition. Operating limits were open to notice and comment in the June 4, 2010 proposal.

Issue: The EPA should delay incorporating PS 17 in this rule until the revisions for PS 17 are completed.

The petitioner (UARG) requested that the EPA delay incorporating PS 17 in this rule, which outlines how to select and install CPMS, until the revisions for PS 17 are completed.

The EPA is denying this petition. The final rule did not incorporate PS 17, or any other PS, in the provision regarding selection and installation of CPMS and ongoing quality assurance of data from CPMS. Comments related to revising PS 17 are outside the scope of this rulemaking. (RTC document, Chapter 11, EPA–HQ–OAR–2002–0058–3289, DCN EPA–HQ–OAR–2002–0058–2960.1, excerpt 150).

Issue: The EPA should not set an enforceable operating limit on opacity.

The petitioner (UARG) alleged that there is insufficient correlation between opacity and PM emissions and requested that the EPA not set an enforceable operating limit on opacity. The EPA is denying the petition. The EPA proposed opacity limits in the June 4, 2010 proposal and the petitioner therefore had the opportunity to comment on the proposed limits, including comments requesting that no limit be established.

Issue: Update outdated BLDS Guidance.

The petitioner (UARG) requested that the EPA update the outdated BLDS Guidance that is currently incorporated by reference. The EPA is denying this petition. The current guidance document is the most recent guidance available and comments related to revising the guidance document are outside the scope of this rulemaking. (RTC document, Chapter 11, EPA–HQ–OAR–2002–0058–3289, DCN EPA–HQ–OAR–2002–0058–2997.1, excerpt 10).

Issue: The EPA should reconsider emission limits for HCl on coal-fired boilers using a hot-side ESP for particulate control.

The petitioners (MSU, PSU, Purdue, Citizens Thermal Energy) requested that the EPA reconsider emission limits for HCl on coal-fired boilers using a hot-side ESP for particulate control. The petitioners are unaware of any HCl control devices that are compatible with a hot-side ESP. The EPA is denying the petition. The basis for subcategorization was subject to notice and comment. The EPA did not propose a separate subcategory for such units, and the petitioner could have commented recommending that the agency do so. (75 FR 32012, 76 FR 15617–18, 76 FR 80607) Further, the EPA disagrees with the petitioner that the subcategories

could be based on the level of controls installed on the unit.

Issue: The EPA should change electronic reporting requirements to avoid WebFIRE and ERT shortcomings.

The petitioner (UARG) requested that the EPA change the electronic reporting requirements to avoid WebFIRE and ERT shortcomings. The petitioner requested that to meet the EPA's obligations under the Paperwork Reduction Act the EPA specify each individual data item requested in the ERT. The petitioner also requests that the EPA explain how the ERT electronic signature mechanisms will meet the requirements of the Cross-Media Electronic Reporting Rule.

The EPA is denying the petition because it does not demonstrate that it was impracticable to comment on this issue. The EPA proposed to require the use of the ERT and WebFIRE, and the petitioner therefore had the opportunity to comment on any concerns with the proposed approach.

Issue: Eliminate gas curtailment notification requirements or adjust the frequency of these notifications to be consistent with the reporting requirements in the Title V program.

The petitioner (AIF) requested that the EPA eliminate the gas curtailment notification requirements or adjust the frequency of these notifications to be consistent with the semi-annual reporting requirements in the Title V program. The EPA is denying the petition. Reporting requirements were open to notice and comment in the June 4, 2010 proposal.

Issue: Allow facilities to become area or synthetic minor sources instead of installing controls.

The petitioner (GPSP) requested that the EPA allow facilities to become area or synthetic minor sources instead of installing controls. The EPA is denying the petition. Whether or not sources elect to become area or synthetic minor sources is not of central relevance to this rulemaking, as nothing in this rule affects whether or how a source can become a synthetic minor source (RTC document, EPA–HQ–OAR–2002–0058–3289, Volume 1, DCN EPA–HQ–OAR–2002–0058–3176.2, excerpt 4).

VI. Impacts of This Final Rule

A. What are the incremental air impacts?

Table 4 of this preamble illustrates, for each basic fuel subcategory, the total emissions reductions achieved by the final amended rule (i.e., the difference in emissions between a boiler or process heater controlled to the amended floor level of control and boilers or process heaters at the current baseline) for new and existing sources. Nationwide emissions of selected HAP (i.e., HCl, HF, mercury, metals, and VOC) will be reduced by 44,300 tpy. This is an incremental increase of 4,000 tpy in HAP reductions compared to the estimates in the March 2011 final rule. This increase is due mainly to changes in the inventory (336 units were added since the March 2011 inventory). Excluding the changes in the inventory, the amendments to the regulatory provisions themselves resulted in a decrease of 1,100 tpy of estimated reductions, part of this incremental reduction in HAP is contributed to edits to the baseline emission data received since the March 2011 final rule, as well as changes to the subcategories and emission limits as a result of this amended rule. The amendments to the final rule are expected to result in an additional 4,600 tpy of reductions in HCl emissions. The amendments are also expected to have a modest effect on mercury, estimated to range from a slight decrease of 0.12 tpy up to a slight increase of 0.96 tpy in emission reductions as a result of the changes to the regulatory requirements. Reductions in emissions of filterable PM will decrease by 18,500 tpy due to the final amended rule. Reductions in emissions of non-mercury metals (i.e., antimony, arsenic, beryllium, cadmium, chromium, cobalt, lead, manganese, nickel, and selenium) will decrease by 260 tpy. In addition, the amendments are estimated to result in an additional 50,100 tpy of reductions in SO_2 emissions. A discussion of the methodology used to estimate emissions, emissions reductions, and incremental emission reductions is presented in ''Revised (August 2012) Methodology for Estimating Cost and Emission Impacts for Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP—Major Source'' in the docket.

TABLE 4—SUMMARY OF TOTAL EMISSIONS REDUCTIONS FOR THE FINAL AMENDED RULE

[tons/yr]

Source	Subcategory	HCl	PM	Non mercury metals [a]	Mercury [b]	VOC
Existing Units	Limited Use	1	2	0.42	2.1E–04	0.48
	Solid units	36,737	21,367	147	0.4 to 1.5	1,619
	Liquid units	2,143	9,434	2,315	0.9 to 1	620
	Non-Continental Liquid units	35	3	1	0.01 to 0.02	23
	Gas 1 (NG/RG) units	20	117	0.3	0.01	88
	Gas 1 Metallurgical Furnaces	0.4	3	0.02	0.001	27
	Gas 2 (other) units	4	8	0.06	3.8E–03 to 4.6E–03.	40
New Units	Solid units	0	351	5	0.02	0
	Liquid units	0	0	0	0	0
	Gas 1 units	0	0	0	0	0
	Gas 1 Metallurgical Furnaces	0	0	0	0	0
	Gas 2 (other) units	0	0	0	0	0

[a] Includes antimony, arsenic, beryllium, cadmium, chromium, cobalt, lead, manganese, nickel, and selenium.

[b] Mercury reductions are presented as a range due to adjustments on reported fractions and limits of detection. See memorandum entitled ''Revised (March 2012) Methodology for Estimating Cost and Emissions Impacts for Industrial, Commercial, Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants—Major Source'' for a description of the two methods for estimating mercury reductions.

B. What are the incremental water and solid waste impacts?

The EPA estimated the additional water usage that would result from installing wet scrubbers to meet the amended emission limits for HCl would be 556 million gallons per year for existing sources compared to the current baseline. In addition to the increased water usage, an additional 160 million gallons per year of wastewater would be produced for existing sources. Only half of these incremental changes are due to changes in the regulatory provisions. The other half is due to changes in the number of identified existing units and projected new units. The annual costs of treating the additional wastewater are $1.2 million. These additional costs are accounted for in the incremental control cost estimates.

The EPA estimated the additional solid waste that would result due to the amendments to be 138,000 tpy, with nearly all due to changes in the regulatory provisions. Solid waste is generated from flyash and dust captured in PM and mercury controls as well as from spent carbon that is injected into exhaust streams or used to filter gas streams. The costs of handling the additional solid waste generated are $5.8 million. These costs are also accounted for in the incremental control costs estimates.

A discussion of the methodology used to estimate incremental impacts is presented in ''Revised (August 2012) Methodology for Estimating Cost and Emission Impacts for Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP—Major Source'' in the docket.

C. What are the incremental energy impacts?

The EPA estimated that the March 2011 final rule would result in an increase of about 1.4 billion kWh/yr in national energy usage from the electricity required to operate control devices, such as wet scrubbers, electrostatic precipitators and fabric filters which are expected to be installed to meet the final rule. The amendments are expected to decrease energy usage by a net 143 million kWh/yr compared to the March 2011 rule. These reductions are driven by the regulatory provisions of these amendments. Additionally, the EPA expects these amendments will result in a decrease of 4.4 million MMBtu/yr in fuel savings, compared with the estimates in the March 2011 final rule.

D. What are the incremental cost impacts?

For these final amendments, we estimated the incremental difference between the national costs impacts for the final amended rule and the March 2011 final rule. First, we determined the control measures, work practices, and monitoring and testing requirements that would be required by boilers and process heaters located at major source facilities to comply with the final amended rule. To estimate the national cost impacts of the final amended rule for existing sources, we used the identical methodology used to estimate the cost impacts for the March 2011 final rule with one exception. In this revised analysis, it was assumed that several liquid fuel units that reported natural gas firing capability would switch to natural gas as a compliance option instead of installing add-on controls to demonstrate compliance with the emission limits. Thus, the only costs to these units would be the tune-up work practice costs. A discussion of the methodology used to estimate cost impacts is presented in ''Revised (August 2012) Methodology for Estimating Cost and Emission Impacts for Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP—Major Source'' in the docket.

The resulting total national cost impact of the final amended rule is $4.7 billion in capital expenditures and $1.5 billion per year in total annual costs, considering fuel savings. The total capital expenditures are slightly lower than estimated for the March 2011 final rule, but the total annual costs are slightly higher than estimated for the March 2011 final rule. See 76 FR 15651. The total capital and annual costs include costs for control devices, work practices, testing and monitoring.

In order to determine the incremental cost impacts of the amended requirements and emission limits, we first estimated the cost impacts of the additional existing boilers and process heaters added to the Boiler MACT inventory database since promulgation of the March 2011 final rule and the revised number of new boilers and process heaters that could be potentially constructed. Since the March 2011 final rule, we became aware of 72 major source facilities that were not previously in the Boiler MACT inventory database. Adding the boilers and process heaters located at these newly identified major source facilities resulted in 73 additional coal-fired units, 32 additional biomass-fired units, 82 additional oil-fired units, and 149 additional gas-fired units. Our revised number of new boilers and process heaters included 82 additional biomass units, 1,728 additional gas 1 units and 13 fewer liquid units.

The resulting cost impact for these additional existing and new boilers and process heaters is $1.0 billion in capital expenditures and $0.31 billion per year in total annual costs, considering fuel savings.

Therefore, discounting the added costs for the additional boilers and process heaters included in the costs analysis, the estimated incremental cost impacts for these amended requirements on existing and new boilers and process heaters are $1.0 billion in capital expenditures and $0.13 billion per year in total annual costs less than the costs estimated in the March 2011 rule.

Table 5 of this preamble shows the total capital and annual cost impacts of the final amended rule for each subcategory. Costs include testing and monitoring costs, but not recordkeeping and reporting costs.

TABLE 5—SUMMARY OF TOTAL CAPITAL AND ANNUAL COSTS FOR NEW AND EXISTING SOURCES FOR THE FINAL AMENDED RULE

Source	Subcategory	Estimated/ projected number of affected units	Capital costs (10^6 $)	Testing and monitoring annualized costs (10^6 $/yr)	Annualized cost (10^6 $/yr) (considering fuel savings)
Existing Units	Coal units	621	2,554	46	904
	Biomass units	502	405	29	109
	Heavy Liquid units	319	761	5.4	221
	Light Liquid units	615	712	4.2	166
	Non-Continental Liquid units	21	62	0.8	17
	Gas 1 (NG/RG) units	11,929	77	0.9	(295)

TABLE 5—SUMMARY OF TOTAL CAPITAL AND ANNUAL COSTS FOR NEW AND EXISTING SOURCES FOR THE FINAL AMENDED RULE—Continued

Source	Subcategory	Estimated/ projected number of affected units	Capital costs (10^6 $)	Testing and monitoring annualized costs (10^6 $/yr)	Annualized cost (10^6 $/yr) (considering fuel savings)
	Gas 2 (other) units	129	138	2.3	58
Energy Assessment	ALL	1,700 (Facilities).	N/A	N/A	28
New Units	Coal units	0	0	0	0
	Biomass units	82	381	5.6	[a] 99
	Liquid units	0	0	0	0
	Gas 1 (NG/RG) units	1,762	11	0	[a] 5.1
	Gas 2 (other) units	0	0	0	0

[a] Total annualized costs for new units do not account for fuel savings since no fuel savings are estimated in the first year for new units.

Potential control device cost savings and increased recordkeeping and reporting costs associated with the emissions averaging provisions in the final rule are not accounted for in either the capital or annualized cost estimates.

A discussion of the methodology used to estimate cost impacts is presented in ''Revised (August 2012) Methodology for Estimating Cost and Emission Impacts for Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP—Major Source'' in the docket.

E. What are the economic impacts?

The EPA analyzed the economic impacts of this final amended rule using the methodology that was discussed in the March 2011 final rule RIA and in the preamble to the March 2011 final rule. See FR 76 15651. The market impact results are very similar to the results presented in the March 2011 final rule and the RIA. The agency's economic model suggests the average national price increases for industrial sectors are less than 0.01 percent, while average annual domestic production may fall by less than 0.01 percent.

Because of higher domestic prices, imports slightly rise. The results for sales tests for small businesses were somewhat reduced than those calculated for the March 2011 final rule. For the sales tests using small companies identified in the Combustion Survey, the mean cost to receipts dropped from 4 percent in the RIA to 3 percent for this final amended rule and the median was 0.2 percent for the RIA and also 0.2 percent for this final amended rule. The number of parent companies with sales tests exceeding 3 percent dropped from 8 in the RIA to 5 for this final amended rule. There was no change in the results for small public entities. Median cost is still about $1.1 million and representative small major public entities would have cost-to-revenue ratios above 10 percent. The change in employment estimates between the RIA and the final amended rule is minimal. In the RIA for the March 2011 final rule, we estimated employment changes ranging between −3,100 to +6,500 employees, with a central estimate of +1,700. For this final amended rule we estimate employment changes ranging between −2,600 to +5,400 employees, with a central estimate of +1,400. These estimated annual employment changes compared to the baseline employment, and are for the time period for which the annualized cost applies (2015 to 2029).

F. What are the benefits of this final rule?

We calculated health benefits using the methodology described in the RIA prepared for the March 21, 2011 final rule. We incorporated the revised emission reductions estimated for this reconsideration final rule into the analysis. We were unable to estimate the benefits from reducing exposure to HAP and ozone, ecosystem impairment and visibility impairment, including reducing 180,000 tons of carbon monoxide, 39,000 tons of HCl, 500 tons of HF, 2,500 tons of other metals and 3,100 to 5,300 pounds of mercury. Please refer to the full description of the unquantified benefits as well as technical details of the analysis and its limitations and uncertainties in the final Boiler RIA (March 2011). These monetized benefits are approximately 23 percent higher than the March 2011 final rule benefits due to the increase in SO_2 emission reductions associated with the additional units affected by the rule and the revised HCl limit. We estimate the total monetized benefits of this final regulatory action to be $27 billion to $67 billion at a 3 percent discount rate and $25 to $61 billion at a 7 percent discount rate. All estimates are for the implementation year (2015) in 2008$. A summary of the monetized benefits estimates at discount rates of 3 percent and 7 percent is provided in Table 6 of this preamble. A summary of the avoided health incidences is provided in Table 7 of this preamble.

TABLE 6—SUMMARY OF THE MONETIZED BENEFITS ESTIMATES FOR THE FINAL BOILER MACT

[millions of 2008$] [a b]

Pollutant	Emissions reductions (tons)	Total monetized benefits (at 3% discount rate)	Total monetized benefits (at 7% discount rate)
$PM_{2.5}$-related benefits			
Direct $PM_{2.5}$	14,139	$1,200 to $2,900	$1,100 to $ $2,700
SO_2	572,000	$26,000 to $64,000	$24,000 to $61,000

TABLE 6—SUMMARY OF THE MONETIZED BENEFITS ESTIMATES FOR THE FINAL BOILER MACT—Continued

[millions of 2008$] [a b]

Pollutant	Emissions reductions (tons)	Total monetized benefits (at 3% discount rate)	Total monetized benefits (at 7% discount rate)
Total		$27,000 to $67,000	$25,000 to $61,000.

[a] All estimates are for the implementation year (2015), and are rounded to two significant figures so numbers may not sum across rows. All fine particles are assumed to have equivalent health effects because the scientific evidence is not yet sufficient to allow differentiation of effect estimates by particle type. Benefits from reducing hazardous air pollutants (HAP) are not included. These estimates do not include energy disbenefits valued at $24 million (using a 3 percent discount rate). These benefits reflect existing boilers and new boilers anticipated to come on-line by 2015.

[b] There are some slight differences in the emission reductions used in the RIA and those used in the air impacts section of this preamble due to some late changes in the data that were received after the RIA was completed. Refer to the memoranda ''Revised (August 2012) Methodology for Estimating Cost and Emission Impacts for Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP—Major Source'' for a discussion of the differences.

TABLE 7—SUMMARY OF THE AVOIDED HEALTH INCIDENCES FOR THE FINAL BOILER MACT [a]

	Avoided health incidences
Premature Mortality	3,000–7,900
Morbidity	
Chronic Bronchitis	2,000
Acute Myocardial Infarction	5,000
Hospital Admissions, Respiratory	750
Hospital Admissions, Cardiovascular	1,600
Emergency Room Visits, Respiratory	3,000
Acute Bronchitis	4,600
Work Loss Days	390,000
Asthma Exacerbation	51,000
Minor Restricted Activity Days	2,300,000
Lower Respiratory Symptoms	55,000
Upper Respiratory Symptoms	41,000

[a] All estimates are for the implementation year (2015), and are rounded to two significant figures. All fine particles are assumed to have equivalent health effects because the scientific evidence is not yet sufficient to allow differentiation of effect estimates by particle type. Benefits from reducing HAP are not included. These benefits reflect existing boilers and new boilers anticipated to come online by 2015.

G. What are the incremental secondary air impacts?

For units adding controls to meet the amended emission limits, we anticipate very minor secondary air impacts. The combustion of fuel needed to generate additional electricity would yield slight increases in emissions, including NO_X, CO, PM and SO_2 and an increase in CO_2 emissions. Since NO_X and SO_2 are covered by capped emissions trading programs and methodological limitations prevent us from quantifying the change in CO and PM, we do not estimate an increase in secondary air impacts for this final rule from additional electricity demand. We do estimate greenhouse gas impacts, which result from increased electricity consumption, to be 859,200 tpy from existing units and 79,700 tpy from new units. This is 19,200 tpy less than the estimated greenhouse gas impacts associated with the March 2011 final rule.

VII. Statutory and Executive Order Reviews

A. Executive Order 12866: Regulatory Planning and Review and Executive Order 13563: Improving Regulation and Regulatory Review

Under section 3(f)(1) of Executive Order 12866 (58 FR 51735, October 4, 1993), this action is an ''economically significant regulatory action'' because it is likely to have an annual effect on the economy of $100 million or more or adversely affect in a material way the economy, a sector of the economy, productivity, competition, jobs, the environment, public health or safety, or state, local, or tribal governments or communities. Accordingly, the EPA submitted this action to the OMB for review under Executive Orders 12866 and 13563 (76 FR 3821, January 21, 2011) and any changes made in response to the OMB recommendations have been documented in the docket for this action.

The EPA did prepare a new RIA for this action. The EPA prepared an assessment of the changes in the costs and benefits of this final rule compared to the costs and benefits associated with the March 21, 2011, final rule. Overall, the costs and impacts are estimated to be similar to the costs and impacts associated with the previous final rule, although the distribution is somewhat different and the number of affected units in the inventory has increased by about 302 units. When comparing the costs using only those sources that were part of the final rule inventory, the costs have decreased. The EPA re-ran the multimarket model to assess changes in economic impacts, and this analysis confirmed that the overall economic impacts are similar to the previous final rule. The benefits are projected to increase by about 20 percent because of the increase in the estimated SO_2 reductions. A summary of the costs and benefits of the previous final rule is provided in the preamble to the previous final rule (*see* 76 FR 15658) and the detailed analysis for the previous final rule is provided in the RIA for the previous final rule. In addition, memoranda are provided in the docket to document the changes in costs, economic impacts, and benefits associated with this final rule, shown in Table 8.

TABLE 8—SUMMARY OF THE MONETIZED BENEFITS, SOCIAL COSTS AND NET BENEFITS FOR THE FINAL BOILER MACT RECONSIDERATION IN 2015

[Millions of 2008$] [1]

	3 percent discount rate	7 percent discount rate
Total Monetized Benefits [2]	$27,000 to $67,000	$24,000 to $61,000.
Total Social Costs [3]	$1,400 to $1,600	$1,400 to $1,600.
Net Benefits	$26,000 to $65,000	$23,200 to $59,000.

TABLE 8—SUMMARY OF THE MONETIZED BENEFITS, SOCIAL COSTS AND NET BENEFITS FOR THE FINAL BOILER MACT RECONSIDERATION IN 2015—Continued

[Millions of 2008$] [1]

	3 percent discount rate	7 percent discount rate
Non-monetized Benefits	Health effects from exposure to HAP (39,000 tons of HCl, 500 tons of HF, 3,100 to 5,300 pounds of mercury, and 2,500 tons of other metals). Health effects from exposure to other criteria pollutants (180,000 tons of CO and 572,000 tons of SO_2). Ecosystem effects. Visibility impairment.	

[1] All estimates are for the implementation year (2015), and are rounded to two significant figures.
[2] The total monetized co-benefits reflect the human health benefits associated with reducing exposure to $PM_{2.5}$ through reductions of $PM_{2.5}$ precursors such as directly emitted particles, SO_2, and NO_X and reducing exposure to ozone through reductions of VOC. It is important to note that the monetized benefits include many but not all health effects associated with $PM_{2.5}$ exposure. Monetized benefits are shown as a range from Pope et al. (2002) to Laden et al. (2006). These models assume that all fine particles, regardless of their chemical composition, are equally potent in causing premature mortality because the scientific evidence is not yet sufficient to support the development of differential effects estimates by particle type. These estimates include the energy disbenefits valued at $24 million (using the 3 percent discount rate), which do not change the rounded totals. CO_2-related disbenefits were calculated using the ''social cost of carbon'', which is discussed further in the RIA.
[3] The methodology used to estimate social costs for one year in the multimarket model using surplus changes results in the same social costs for both discount rates.

B. Paperwork Reduction Act

The OMB has approved the information collection requirements contained in the March 21, 2011 final rule under the provisions of the *Paperwork Reduction Act,* 44 U.S.C. 3501 *et seq.* and has assigned OMB control number 2060–0551. The EPA has updated the supporting statement to reflect the final inventory and burden estimates associated with this action since some of the monitoring, recordkeeping and reporting requirements have changed since the March 21, 2011 final rule. These revised estimates have been sent to OMB for review and approval.

The information requirements are based on notification, recordkeeping, and reporting requirements in the NESHAP General Provisions (40 CFR part 63, subpart A), which are mandatory for all operators subject to national emission standards. These recordkeeping and reporting requirements are specifically authorized by section 114 of the CAA (42 U.S.C. 7414). All information submitted to the EPA pursuant to the recordkeeping and reporting requirements for which a claim of confidentiality is made is safeguarded according to agency policies set forth in 40 CFR part 2, subpart B.

This final rule will require maintenance inspections of the control devices but will not require any notifications or reports beyond those required by the General Provisions aside from a notification of intent to commence burning solid waste materials and notification of alternative fuel use for those units that are in the Gas 1 subcategory but burn liquid fuels for periodic testing, or during periods of gas curtailment or gas supply emergencies. The recordkeeping requirements require only the specific information needed to determine compliance.

The revised annual monitoring, reporting and recordkeeping burden for this collection (averaged over the first 3 years after the effective date of the standards) is estimated to be $95.3 million which is about the same as estimated for the March 2011 final rule. This includes 323,130 labor hours per year at a total labor cost of $30.6 million per year, and total non-labor capital costs of $64.7 million per year. This estimate includes initial and annual performance test, conducting and documenting an energy assessment, conducting fuel specifications for Gas 1 units, repeat testing under worst-case conditions for solid fuel units, conducting and documenting a tune-up, semiannual excess emission reports, maintenance inspections, developing a monitoring plan, notifications and recordkeeping. Monitoring, testing, tune-up and energy assessment costs and cost were also included in the cost estimates presented in the control costs impacts estimates in section VI.D of this preamble. The total burden for the federal government (averaged over the first 3 years after the effective date of the standard) is estimated to be 100,608 hours per year at a total labor cost of $5.3 million per year. Burden is defined at 5 CFR 1320.3(b).

An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information unless it displays a currently valid OMB control number. The OMB control numbers for the EPA's regulations in 40 CFR are listed in 40 CFR part 9. In addition, the EPA is amending the table in 40 CFR part 9 of currently approved OMB control numbers for various regulations to list the regulatory citations for the information requirements contained in this final rule.

C. Regulatory Flexibility Act

The RFA generally requires an agency to prepare a regulatory flexibility analysis of any rule subject to notice and comment rulemaking requirements under the Administrative Procedure Act or any other statute unless the agency certifies that the rule will not have a significant economic impact on a substantial number of small entities.[1] The RFA also allows an agency to ''consider a series of closely related rules as one rule for the purposes of sections'' 603 (initial regulatory flexibility analysis) and 604 (final regulatory flexibility analysis) in order to avoid ''duplicative action.'' 5 U.S.C. § 605(c). This final rule is closely related to the final major source rule, which the EPA signed on February 21, 2011. The EPA prepared a final regulatory flexibility analyses in connection with the major source rule. Therefore,

[1] Small entities include small businesses, small organizations, and small governmental jurisdictions. For purposes of assessing the impacts of today's rule on small entities, small entity is defined as: (1) A small business according to Small Business Administration (SBA) size standards by the North American Industry Classification System category of the owning entity. The range of small business size standards for the affected industries ranges from 500 to 1,000 employees, except for petroleum refining and electric utilities. In these latter two industries, the size standard is 1,500 employees and a mass throughput of 75,000 barrels/day or less, and 4 million kilowatt-hours of production or less, respectively; (2) a small governmental jurisdiction that is a government of a city, county, town, school district or special district with a population of less than 50,000; and (3) a small organization that is any not-for-profit enterprise which is independently owned and operated and is not dominant in its field.

pursuant to § 605(c), the EPA is not required to complete a final regulatory flexibility analysis for this rule.

The EPA has been concerned with potential small entity impacts since it began developing the major source rule. The EPA conducted outreach to small entities and, pursuant to § 609 of RFA, convened a Small Business Advocacy Review Panel to obtain advice and recommendations from small entity representatives.

Pursuant to the RFA, the EPA used the Panel's report and prepared both an initial regulatory flexibility analysis and a final regulatory flexibility analysis in connection with the closely related major source rule. Convening an additional Panel and preparing an additional final regulatory flexibility analysis would be procedurally duplicative and is unnecessary given that the issues here are within the scope of those considered by the Panel. In addition, this final action would decrease capital and annualized costs on small entities by about 3 percent and 10 percent, respectively, relative to the closely related final rule.

D. Unfunded Mandates Reform Act

Title II of the UMRA of 1995, 2 U.S.C. 1531–1538, requires federal agencies, unless otherwise prohibited by law, to assess the effects of their regulatory actions on state, local and tribal governments and the private sector. Federal agencies must also develop a plan to provide notice to small governments that might be significantly or uniquely affected by any regulatory requirements. The plan must enable officials of affected small governments to have meaningful and timely input in the development of the EPA regulatory proposals with significant Federal intergovernmental mandates and must inform, educate, and advise small governments on compliance with the regulatory requirements.

Both this rule and the March 21, 2011 final rule contain a federal mandate that may result in expenditures of $100 million or more for state, local and tribal governments, in the aggregate, or the private sector in any one year. Accordingly, the EPA prepared under section 202 of the UMRA a written statement for the final rule. This final rule also contains a federal mandate that may result in expenditures of $100 million or more for state, local, and tribal governments, in the aggregate, or the private sector in any one year. The discussion below has been updated to reflect the changes.

1. Statutory Authority

As discussed in the March 21, 2011, final rule, the statutory authority for this final rulemaking is section 112 of the CAA. Title III of the CAA Amendments was enacted to reduce nationwide air toxic emissions. Section 112(b) of the CAA lists the 188 chemicals, compounds, or groups of chemicals deemed by Congress to be HAP. These toxic air pollutants are to be regulated by NESHAP.

Section 112(d) of the CAA directs us to develop NESHAP which require existing and new major sources to control emissions of HAP using MACT based standards. This NESHAP applies to all boilers and process heaters located at major sources of HAP emissions.

2. Social Costs and Benefits

The regulatory impact analysis prepared for the March 21, 2011 final rule, which we have revised for this final rule, including the agency's assessment of costs and benefits, is detailed in the ''Regulatory Impact Analysis for the Final Industrial Boilers and Process Heaters MACT (2011)'' and in the ''Regulatory Impact Results for the Reconsideration Final Rule for National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters at Major Sources'' in the docket. Based on estimated compliance costs associated with this final rule and the predicted change in prices and production in the affected industries, the estimated social costs of this rule are $1.4 to 1.6 billion (2008 dollars).

It is estimated that 3 years after implementation of this final rule, HAP would be reduced by 45,000 tpy, including reductions in HCl, hydrogen fluoride, metallic HAP including mercury, and several other organic HAP from boilers and process heaters. Studies have determined a relationship between exposure to these HAP and the onset of cancer, however, the agency is unable to provide a monetized estimate of the HAP benefits at this time. In addition, there are significant annual reductions in fine particulate matter ($PM_{2.5}$) and in SO_2 that would occur, including 25 thousand tons of $PM_{2.5}$ and 558 thousand tons of SO_2. These reductions occur within 3 years after the implementation of the final regulation and are expected to continue throughout the life of the affected sources. The major health effect associated with reducing $PM_{2.5}$ and $PM_{2.5}$ precursors (such as SO_2) are a reduction in premature mortality. Other health effects associated with $PM_{2.5}$ emission reductions include avoiding cases of chronic bronchitis, heart attacks, asthma attacks and work-lost days (i.e., days when employees are unable to work). While we are unable to monetize the benefits associated with the HAP emissions reductions, we are able to monetize the benefits associated with the $PM_{2.5}$ and SO_2 emissions reductions. For SO_2 and $PM_{2.5}$, we estimated the benefits associated with health effects of PM but were unable to quantify all categories of benefits (particularly those associated with ecosystem and visibility effects). Our estimates of the monetized benefits in 2015 associated with the implementation of the final regulatory action range from $27 billion (2008 dollars) to $67 billion (2008 dollars) when using a 3 percent discount rate (or from $25 billion (2008 dollars) to $61 billion (2008 dollars) when using a 7 percent discount rate). This estimate, at a 3 percent discount rate, is about $25 billion (2008 dollars) to $65 billion (2008 dollars) higher than the estimated social costs shown earlier in this section. The general approach used to value benefits is discussed in more detail earlier in this preamble. For more detailed information on the benefits estimated for the rulemaking, refer to the RIA and the memos updating the impacts and benefits in the docket.

3. Future and Disproportionate Costs

The UMRA requires that we estimate, where accurate estimation is reasonably feasible, future compliance costs imposed by this final rule and any disproportionate budgetary effects. Our estimates of the future compliance costs of the rule are discussed previously in this preamble.

We do not believe that there will be any disproportionate budgetary effects of this final rule on any particular areas of the country, state or local governments, types of communities (e.g., urban, rural) or particular industry segments. See the results of the ''Regulatory Impact Analysis for the Final Industrial Boilers and Process Heaters MACT (2011).''

4. Effects on the National Economy

The UMRA requires that we estimate the effect of this final rule on the national economy. To the extent feasible, we must estimate the effect on productivity, economic growth, full employment, creation of productive jobs and international competitiveness of the U.S. goods and services, if we determine that accurate estimates are reasonably feasible and that such effect is relevant and material.

The nationwide economic impact of this final rule is presented in the

''Regulatory Impact Analysis for the Final Industrial Boilers and Process Heaters MACT (2011)'' and a memoranda that are included in the docket, entitled ''Regulatory Impact Results for the Reconsideration Final Rule for National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters at Major Sources which update the RIA analyses. This analysis provides estimates of the effect of this rule on some of the categories mentioned above. The results of the economic impact analysis are summarized previously in this preamble. The results show that there will be a small impact on prices and output, and little impact on communities that may be affected by this final rule. In addition, there should be little impact on energy markets (in this case, coal, natural gas, petroleum products and electricity). Hence, the potential impacts on the categories mentioned above should be small.

5. Consultation With Government Officials

The UMRA requires that we describe the extent of the agency's prior consultation with affected state, local and tribal officials, summarize the officials' comments or concerns, and summarize our response to those comments or concerns. In addition, section 203 of the UMRA requires that we develop a plan for informing and advising small governments that may be significantly or uniquely impacted by a final rule. We consulted with state and local air pollution control officials during the development of the final rule. We have also held meetings on this final rule with many of the stakeholders from numerous individual companies, institutions, environmental groups, consultants and vendors, labor unions and other interested parties. We have added materials to the docket to document these meetings.

Consistent with section 205, the EPA has identified and considered a reasonable number of regulatory alternatives. Additional information on the costs and environmental impacts of these regulatory alternatives is presented in the docket.

The regulatory alternative upon which the emission limits in this final rule are based represents the MACT floors for all subcategories and, as a result, it is the least costly and least burdensome alternative.

This rule is not subject to the requirements of section 203 of UMRA because it contains no regulatory requirements that might significantly or uniquely affect small governments. While some small governments may have some sources affected by this final rule, the impacts are not expected to be significant. Therefore, this final rule is not subject to the requirements of section 203 of the UMRA.

E. Executive Order 13132: Federalism

This action does not have federalism implications. It will not have substantial direct effects on the states, on the relationship between the national government and the states, or on the distribution of power and responsibilities among the various levels of government, as specified in Executive Order 13132. This final rule will not impose direct compliance costs on state or local governments, and will not preempt state law. Thus, Executive Order 13132 does not apply to this action.

F. Executive Order 13175: Consultation and Coordination With Indian Tribal Governments

This action does not have tribal implications, as specified in Executive Order 13175 (65 FR 67249, November 9, 2000). It will not have substantial direct effects on tribal governments, on the relationship between the federal government and Indian tribes, or on the distribution of power and responsibilities between the federal government and Indian tribes, as specified in Executive Order 13175. Thus, Executive Order 13175 does not apply to this action.

G. Executive Order 13045: Protection of Children From Environmental Health Risks and Safety Risks

The EPA interprets Executive Order 13045 (62 FR 19885, April 23, 1997) as applying to those regulatory actions that concern health or safety risks, such that the analysis required under section 5–501 of the Order has the potential to influence the regulation. This action is not subject to EO 13045 because it is based solely on technology performance.

H. Executive Order 13211: Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution, or Use

This action is not a ''significant energy action'' as defined in Executive Order 13211 (66 FR 28355, May 22, 2001), because it is not likely to have a significant adverse effect on the supply, distribution, or use of energy. For the March 21, 2011, final rule, we estimated a 0.05 percent price increase for the energy sector and a −0.02 percent percentage change in production. We estimated a 0.09 percent increase in energy imports. For more information on the estimated energy effects, please refer to the ''Regulatory Impact Analysis for the Final Industrial Boilers and Process Heaters MACT (2011).'' The analysis is available in the public docket. While we did not recreate the RIA for this final action, the energy impacts for existing sources decreased slightly, and the energy impacts for new source increased due to the increased number of new sources that is now projected. Overall, the projected energy use increased slightly but would not change the analysis that was conducted for the previous final rule. Therefore, we conclude that this final rule when implemented is not likely to have a significant adverse effect on the supply, distribution, or use of energy.

I. National Technology Transfer and Advancement Act

Section 12(d) of the NTTAA, Public Law 104–113, 12(d) (15 U.S.C. 272 note) directs the EPA to use VCS in its regulatory activities unless to do so would be inconsistent with applicable law or otherwise impractical. VCS are technical standards (e.g., materials specifications, test methods, sampling procedures, and business practices) that are developed or adopted by VCS bodies. NTTAA directs the EPA to provide Congress, through the OMB, explanations when the agency decides not to use available and applicable VCS.

This action does not involve any new technical standards from those contained in the March 21, 2011 final rule. Therefore, the EPA did not consider the use of any VCS. See 76 FR 15660–15662 for the NTTAA discussion in the March 21, 2011 final rule.

J. Executive Order 12898: Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations

Executive Order 12898 (59 FR 7629, February 16, 1994) establishes federal executive policy on environmental justice. Its main provision directs federal agencies, to the greatest extent practicable and permitted by law, to make environmental justice part of their mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority populations and low-income populations in the United States.

For the March 2011 final rule, the EPA determined that the rule would not have disproportionately high and adverse human health or environmental effects on minority or low-income populations because it increases the

level of environmental protection for all affected populations without having any disproportionately high and adverse human health or environmental effects on any population, including any minority or low-income population. Compared to the previous final rule, while the amendments are somewhat less stringent for some subcategories of units and more stringent for some others, the overall increased health benefits demonstrate that the conclusions from the environmental justice analysis conducted for the previous final rule are still valid. Therefore, the EPA has determined this final rule will not have disproportionately high and adverse human or environmental effects on minority or low-income populations.

K. Congressional Review Act

The Congressional Review Act, 5 U.S.C. 801 *et seq.,* as added by the Small Business Regulatory Enforcement Fairness Act of 1996, generally provides that before a rule may take effect, the agency promulgating the rule must submit a rule report, which includes a copy of the rule, to each House of the Congress and to the Comptroller General of the United States. EPA will submit a report containing this final rule and other required information to the U.S. Senate, the U.S. House of Representatives, and the Comptroller General of the United States prior to publication of the rule in the **Federal Register**. A major rule cannot take effect until 60 days after it is published in the **Federal Register**. This action is a ''major rule'' as defined by 5 U.S.C. 804(2). With the exception of the May 18, 2011 (76 FR 28661), delay of the effective date revising subpart DDDDD at 76 FR 15451 (March 21, 2011) being lifted January 31, 2013, this rule will be effective April 1, 2013.

List of Subjects in 40 CFR Part 63

Environmental protection, Administrative practice and procedure, Air pollution control, Hazardous substances, Incorporation by reference, Intergovernmental relations, Reporting and Recordkeeping requirements.

Dated: December 20, 2012

Lisa P. Jackson,

Administrator.

For the reasons cited in the preamble, title 40, chapter I, part 63 of the Code of Federal Regulations is amended as follows:

PART 63—[AMENDED]

■ 1. The authority for part 63 continues to read as follows:

Authority: 42 U.S.C. 7401, *et seq.*

■ 2. Effective January 31, 2013, the May 18, 2011 (76 FR 28661), delay of the effective date revising subpart DDDDD at 76 FR 15451 (March 21, 2011) is lifted.

Subpart A—[Amended]

■ 3. Section 63.14 is amended by:
■ a. Revising paragraphs (b)(19), (b)(23), (b)(35), (b)(40), (b)(69), and (b)(70).
■ b. Removing and reserving paragraph (b)(53).
■ c. Adding paragraphs (b)(46), (b)(55), and (b)(76) through (83).
■ d. Adding paragraphs (p)(12) through (20).
■ e. Adding paragraph (r).

The revisions and additions read as follows:

§ 63.14 Incorporations by reference.

* * * * *

(b) * * *

(19) ASTM D95–05 (Reapproved 2010), Standard Test Method for Water in Petroleum Products and Bituminous Materials by Distillation, approved May 1, 2010, IBR approved for § 63.10005(i) and table 6 to subpart DDDDD.

* * * * *

(23) ASTM D4006–11, Standard Test Method for Water in Crude Oil by Distillation, including Annex A1 and Appendix X1, approved June 1, 2011, IBR approved for § 63.10005(i) and table 6 to subpart DDDDD.

* * * * *

(35) ASTM D6784–02 (Reapproved 2008) Standard Test Method for Elemental, Oxidized, Particle-Bound and Total Mercury in Flue Gas Generated from Coal-Fired Stationary Sources (Ontario Hydro Method), approved April 1, 2008, IBR approved for table 1 to subpart DDDDD of this part, table 2 to subpart DDDDD of this part, table 5 to subpart DDDDD, table 11 to subpart DDDDD of this part, table 12 to subpart DDDDD of this part, table 13 to subpart DDDDD of this part, and table 4 to subpart JJJJJJ of this part.

* * * * *

(40) ASTM D396–10 Standard Specification for Fuel Oils, approved October 1, 2010, IBR approved for § 63.7575 and § 63.11237.

* * * * *

(46) ASTM D4606–03 (2007), Standard Test Method for Determination of Arsenic and Selenium in Coal by the Hydride Generation/Atomic Absorption Method, approved October 1, 2007, IBR approved for table 6 to subpart DDDDD.

* * * * *

(55) ASTM D6357–11, Test Methods for Determination of Trace Elements in Coal, Coke, and Combustion Residues from Coal Utilization Processes by Inductively Coupled Plasma Atomic Emission Spectrometry, approved April 1, 2011, IBR approved for table 6 to subpart DDDDD.

* * * * *

(69) ASTM D4057–06 (Reapproved 2011), Standard Practice for Manual Sampling of Petroleum and Petroleum Products, including Annex A1, approved June 1, 2011, IBR approved for § 63.10005(i) and table 6 to subpart DDDDD.

(70) ASTM D4177–95 (Reapproved 2010), Standard Practice for Automatic Sampling of Petroleum and Petroleum Products, including Annexes A1 through A6 and Appendices X1 and X2, approved May 1, 2010, IBR approved for § 63.10005(i) and table 6 to subpart DDDDD.

* * * * *

(76) ASTM D6751–11b, Standard Specification for Biodiesel Fuel Blend Stock (B100) for Middle Distillate Fuels, approved July 15, 2011, IBR approved for § 63.7575 and § 63.11237.

(77) ASTM D975–11b, Standard Specification for Diesel Fuel Oils, approved December 1, 2011, IBR approved for § 63.7575.

(78) ASTM D5864–11 Standard Test Method for Determining Aerobic Aquatic Biodegradation of Lubricants or Their Components, approved March 1, 2011, IBR approved for table 6 to subpart DDDDD.

(79) ASTM D240–09 Standard Test Method for Heat of Combustion of Liquid Hydrocarbon Fuels by Bomb Calorimeter, approved July 1, 2009, IBR approved for table 6 to subpart DDDDD.

(80) ASTM D4208–02 (2007) Standard Test Method for Total Chlorine in Coal by the Oxygen Bomb Combustion/Ion Selective Electrode Method, approved May 1, 2007, IBR approved for table 6 to subpart DDDDD.

(81) ASTM D5192–09 Standard Practice for Collection of Coal Samples from Core, approved June 1, 2009, IBR approved for table 6 to subpart DDDDD.

(82) ASTM D7430–11ae1, Standard Practice for Mechanical Sampling of Coal, approved October 1, 2011, IBR approved for table 6 to subpart DDDDD.

(83) ASTM D6883–04, Standard Practice for Manual Sampling of Stationary Coal from Railroad Cars, Barges, Trucks, or Stockpiles, approved June 1, 2004, IBR approved for table 6 to subpart DDDDD.

* * * * *

(p) * * *

(12) Method 5050 (SW–846–5050), Bomb Preparation Method for Solid Waste, Revision 0, September 1994, in

EPA Publication No. SW–846, Test Methods for Evaluating Solid Waste, Physical/Chemical Methods, Third Edition IBR approved for table 6 to subpart DDDDD.

(13) Method 9056 (SW–846–9056), Determination of Inorganic Anions by Ion Chromatography, Revision 1, February 2007, in EPA Publication No. SW–846, Test Methods for Evaluating Solid Waste, Physical/Chemical Methods, Third Edition, IBR approved for table 6 to subpart DDDDD.

(14) Method 9076 (SW–846–9076), Test Method for Total Chlorine in New and Used Petroleum Products by Oxidative Combustion and Microcoulometry, Revision 0, September 1994, in EPA Publication No. SW–846, Test Methods for Evaluating Solid Waste, Physical/Chemical Methods, Third Edition, IBR approved for table 6 to subpart DDDDD.

(15) Method 1631 Revision E, Mercury in Water by Oxidation, Purge and Trap, and Cold Vapor Atomic Absorption Fluorescence Spectrometry, Revision E, EPA–821–R–02–019, August 2002, IBR approved for table 6 to subpart DDDDD.

(16) Method 200.8, Determination of Trace Elements in Waters and Wastes by Inductively Coupled Plasma—Mass Spectrometry, Revision 5.4, 1994, IBR approved for table 6 to subpart DDDDD.

(17) Method 6020A (SW–846–6020A), Inductively Coupled Plasma-Mass Spectrometry, Revision 1, February 2007, in EPA Publication No. SW–846, Test Methods for Evaluating Solid Waste, Physical/Chemical Methods, Third Edition, IBR approved for table 6 to subpart DDDDD.

(18) Method 6010C (SW–846–6010C), Inductively Coupled Plasma-Atomic Emission Spectrometry, Revision 3, February 2007, in EPA Publication No. SW–846, Test Methods for Evaluating Solid Waste, Physical/Chemical Methods, Third Edition, IBR approved for table 6 to subpart DDDDD.

(19) Method 7060A (SW–846–7060A), Arsenic (Atomic Absorption, Furnace Technique), Revision 1, September 1994, in EPA Publication No. SW–846, Test Methods for Evaluating Solid Waste, Physical/Chemical Methods, Third Edition, IBR approved for table 6 to subpart DDDDD.

(20) Method 7740 (SW–846–7740), Selenium (Atomic Absorption, Furnace Technique), Revision 0, September 1986, in EPA Publication No. SW–846, Test Methods for Evaluating Solid Waste, Physical/Chemical Methods, Third Edition, IBR approved for table 6 to subpart DDDDD.

(r) The following material is available for purchase from the Technical Association of the Pulp and Paper Industry (TAPPI), 15 Technology Parkway South, Norcross, GA 30092, (800) 332–8686, *http://www.tappi.org.*

(1) TAPPI T 266, Determination of Sodium, Calcium, Copper, Iron, and Manganese in Pulp and Paper by Atomic Absorption Spectroscopy (Reaffirmation of T 266 om-02), Draft No. 2, July 2006, IBR approved for table 6 to subpart DDDDD.

(2) [Reserved]

Subpart DDDDD—[Amended]

■ 4. Section 63.7485 is revised to read as follows:

§ 63.7485 Am I subject to this subpart?

You are subject to this subpart if you own or operate an industrial, commercial, or institutional boiler or process heater as defined in § 63.7575 that is located at, or is part of, a major source of HAP, except as specified in § 63.7491. For purposes of this subpart, a major source of HAP is as defined in § 63.2, except that for oil and natural gas production facilities, a major source of HAP is as defined in § 63.7575.

■ 5. Section 63.7490 is amended by adding paragraph (e) to read as follows:

§ 63.7490 What is the affected source of this subpart?

* * * * *

(e) An existing electric utility steam generating unit (EGU) that meets the applicability requirements of this subpart after the effective date of this final rule due to a change (e.g., fuel switch) is considered to be an existing source under this subpart.

■ 6. Section 63.7491 is amended by:
■ a. Revising the introductory text.
■ b. Revising paragraph (a).
■ c. Revising paragraph (c).
■ d. Revising paragraph (h)
■ e. Revising paragraph (i).
■ f. Revising paragraph (m).
■ g. Revising paragraph (n).

The revisions read as follows:

§ 63.7491 Are any boilers or process heaters not subject to this subpart?

The types of boilers and process heaters listed in paragraphs (a) through (n) of this section are not subject to this subpart.

(a) An electric utility steam generating unit (EGU) covered by subpart UUUUU of this part.

* * * * *

(c) A boiler or process heater that is used specifically for research and development, including test steam boilers used to provide steam for testing the propulsion systems on military vessels. This does not include units that provide heat or steam to a process at a research and development facility.

* * * * *

(h) Any boiler or process heater that is part of the affected source subject to another subpart of this part, such as boilers and process heaters used as control devices to comply with subparts JJJ, OOO, PPP, and U of this part.

(i) Any boiler or process heater that is used as a control device to comply with another subpart of this part, or part 60, part 61, or part 65 of this chapter provided that at least 50 percent of the average annual heat input during any 3 consecutive calendar years to the boiler or process heater is provided by regulated gas streams that are subject to another standard.

* * * * *

(m) A unit that burns hazardous waste covered by Subpart EEE of this part. A unit that is exempt from Subpart EEE as specified in § 63.1200(b) is not covered by Subpart EEE.

(n) Residential boilers as defined in this subpart.

* * * * *

■ 7. Section 63.7495 is amended by:
■ a. Revising paragraph (a).
■ b. Revising paragraph (b).
■ c. Adding paragraphs (e), (f), and (g).

The revisions and additions read as follows:

§ 63.7495 When do I have to comply with this subpart?

(a) If you have a new or reconstructed boiler or process heater, you must comply with this subpart by January 31, 2013, or upon startup of your boiler or process heater, whichever is later.

(b) If you have an existing boiler or process heater, you must comply with this subpart no later than January 31, 2016, except as provided in § 63.6(i).

* * * * *

(e) If you own or operate an industrial, commercial, or institutional boiler or process heater and would be subject to this subpart except for the exemption in § 63.7491(l) for commercial and industrial solid waste incineration units covered by part 60, subpart CCCC or subpart DDDD, and you cease combusting solid waste, you must be in compliance with this subpart and are no longer subject to part 60, subparts CCCC or DDDD beginning on the effective date of the switch as identified under the provisions of § 60.2145(a)(2) and (3) or § 60.2710(a)(2) and (3).

(f) If you own or operate an existing EGU that becomes subject to this subpart after January 31, 2013, you must

be in compliance with the applicable existing source provisions of this subpart on the effective date such unit becomes subject to this subpart.

(g) If you own or operate an existing industrial, commercial, or institutional boiler or process heater and would be subject to this subpart except for a exemption in § 63.7491(i) that becomes subject to this subpart after January 31, 2013, you must be in compliance with the applicable existing source provisions of this subpart within 3 years after such unit becomes subject to this subpart.

■ 8.Section 63.7499 is amended by revising paragraphs (d) and (f) through (l) and adding paragraphs (p) through (u) to read as follows:

§ 63.7499 What are the subcategories of boilers and process heaters?

* * * * *

(d) Stokers/sloped grate/other units designed to burn kiln dried biomass/bio-based solid.

* * * * *

(f) Suspension burners designed to burn biomass/bio-based solid.

(g) Fuel cells designed to burn biomass/bio-based solid.

(h) Hybrid suspension/grate burners designed to burn wet biomass/bio-based solid.

(i) Stokers/sloped grate/other units designed to burn wet biomass/bio-based solid.

(j) Dutch ovens/pile burners designed to burn biomass/bio-based solid.

(k) Units designed to burn liquid fuel that are non-continental units.

(l) Units designed to burn gas 1 fuels.

* * * * *

(p) Units designed to burn solid fuel.

(q) Units designed to burn liquid fuel.

(r) Units designed to burn coal/solid fossil fuel.

(s) Fluidized bed units with an integrated fluidized bed heat exchanger designed to burn coal/solid fossil fuel.

(t) Units designed to burn heavy liquid fuel.

(u) Units designed to burn light liquid fuel.

■ 9. Section 63.7500 is amended by:
■ a. Revising paragraph (a).
■ b. Revising paragraph (c).
■ c. Adding paragraph (d).
■ d. Adding paragraph (e).
■ e. Adding paragraph (f).

§ 63.7500 What emission limitations, work practice standards, and operating limits must I meet?

(a) You must meet the requirements in paragraphs (a)(1) through (3) of this section, except as provided in paragraphs (b), through (e) of this section. You must meet these requirements at all times the affected unit is operating, except as provided in paragraph (f) of this section.

(1) You must meet each emission limit and work practice standard in Tables 1 through 3, and 11 through 13 to this subpart that applies to your boiler or process heater, for each boiler or process heater at your source, except as provided under § 63.7522. The output-based emission limits, in units of pounds per million Btu of steam output, in Tables 1 or 2 to this subpart are an alternative applicable only to boilers and process heaters that generate steam. The output-based emission limits, in units of pounds per megawatt-hour, in Tables 1 or 2 to this subpart are an alternative applicable only to boilers that generate electricity. If you operate a new boiler or process heater, you can choose to comply with alternative limits as discussed in paragraphs (a)(1)(i) through (a)(1)(iii) of this section, but on or after January 31, 2016, you must comply with the emission limits in Table 1 to this subpart.

(i) If your boiler or process heater commenced construction or reconstruction after June 4, 2010 and before May 20, 2011, you may comply with the emission limits in Table 1 or 11 to this subpart until January 31, 2016.

(ii) If your boiler or process heater commenced construction or reconstruction after May 20, 2011 and before December 23, 2011, you may comply with the emission limits in Table 1 or 12 to this subpart until January 31, 2016.

(iii) If your boiler or process heater commenced construction or reconstruction after December 23, 2011 and before January 31, 2013, you may comply with the emission limits in Table 1 or 13 to this subpart until January 31, 2016.

(2) You must meet each operating limit in Table 4 to this subpart that applies to your boiler or process heater. If you use a control device or combination of control devices not covered in Table 4 to this subpart, or you wish to establish and monitor an alternative operating limit or an alternative monitoring parameter, you must apply to the EPA Administrator for approval of alternative monitoring under § 63.8(f).

(3) At all times, you must operate and maintain any affected source (as defined in § 63.7490), including associated air pollution control equipment and monitoring equipment, in a manner consistent with safety and good air pollution control practices for minimizing emissions. Determination of whether such operation and maintenance procedures are being used will be based on information available to the Administrator that may include, but is not limited to, monitoring results, review of operation and maintenance procedures, review of operation and maintenance records, and inspection of the source.

* * * * *

(c) Limited-use boilers and process heaters must complete a tune-up every 5 years as specified in § 63.7540. They are not subject to the emission limits in Tables 1 and 2 or 11 through 13 to this subpart, the annual tune-up, or the energy assessment requirements in Table 3 to this subpart, or the operating limits in Table 4 to this subpart.

(d) Boilers and process heaters with a heat input capacity of less than or equal to 5 million Btu per hour in the units designed to burn gas 2 (other) fuels subcategory or units designed to burn light liquid fuels subcategory must complete a tune-up every 5 years as specified in § 63.7540.

(e) Boilers and process heaters in the units designed to burn gas 1 fuels subcategory with a heat input capacity of less than or equal to 5 million Btu per hour must complete a tune-up every 5 years as specified in § 63.7540. Boilers and process heaters in the units designed to burn gas 1 fuels subcategory with a heat input capacity greater than 5 million Btu per hour and less than 10 million Btu per hour must complete a tune-up every 2 years as specified in § 63.7540. Boilers and process heaters in the units designed to burn gas 1 fuels subcategory are not subject to the emission limits in Tables 1 and 2 or 11 through 13 to this subpart, or the operating limits in Table 4 to this subpart.

(f) These standards apply at all times the affected unit is operating, except during periods of startup and shutdown during which time you must comply only with Table 3 to this subpart.

■ 10. Section 63.7501 is revised to read as follows:

§ 63.7501 Affirmative Defense for Violation of Emission Standards During Malfunction.

In response to an action to enforce the standards set forth in § 63.7500 you may assert an affirmative defense to a claim for civil penalties for violations of such standards that are caused by malfunction, as defined at § 63.2. Appropriate penalties may be assessed if you fail to meet your burden of proving all of the requirements in the affirmative defense. The affirmative defense shall not be available for claims for injunctive relief.

(a) *Assertion of affirmative defense.* To establish the affirmative defense in

any action to enforce such a standard, you must timely meet the reporting requirements in paragraph (b) of this section, and must prove by a preponderance of evidence that:

(1) The violation:

(i) Was caused by a sudden, infrequent, and unavoidable failure of air pollution control equipment, process equipment, or a process to operate in a normal or usual manner; and

(ii) Could not have been prevented through careful planning, proper design, or better operation and maintenance practices; and

(iii) Did not stem from any activity or event that could have been foreseen and avoided, or planned for; and

(iv) Was not part of a recurring pattern indicative of inadequate design, operation, or maintenance; and

(2) Repairs were made as expeditiously as possible when a violation occurred; and

(3) The frequency, amount, and duration of the violation (including any bypass) were minimized to the maximum extent practicable; and

(4) If the violation resulted from a bypass of control equipment or a process, then the bypass was unavoidable to prevent loss of life, personal injury, or severe property damage; and

(5) All possible steps were taken to minimize the impact of the violation on ambient air quality, the environment, and human health; and

(6) All emissions monitoring and control systems were kept in operation if at all possible, consistent with safety and good air pollution control practices; and

(7) All of the actions in response to the violation were documented by properly signed, contemporaneous operating logs; and

(8) At all times, the affected source was operated in a manner consistent with good practices for minimizing emissions; and

(9) A written root cause analysis has been prepared, the purpose of which is to determine, correct, and eliminate the primary causes of the malfunction and the violation resulting from the malfunction event at issue. The analysis shall also specify, using best monitoring methods and engineering judgment, the amount of any emissions that were the result of the malfunction.

(b) *Report.* The owner or operator seeking to assert an affirmative defense shall submit a written report to the Administrator with all necessary supporting documentation, that it has met the requirements set forth in § 63.7500 of this section. This affirmative defense report shall be included in the first periodic compliance, deviation report or excess emission report otherwise required after the initial occurrence of the violation of the relevant standard (which may be the end of any applicable averaging period). If such compliance, deviation report or excess emission report is due less than 45 days after the initial occurrence of the violation, the affirmative defense report may be included in the second compliance, deviation report or excess emission report due after the initial occurrence of the violation of the relevant standard.

■ 11. Section 63.7505 is amended by:
■ a. Revising paragraph (a).
■ b. Revising paragraph (c).
■ c. Revising paragraphs (d) introductory text, (d)(1) introductory text, and (d)(1)(iii).

§ 63.7505 What are my general requirements for complying with this subpart?

(a) You must be in compliance with the emission limits, work practice standards, and operating limits in this subpart. These limits apply to you at all times the affected unit is operating except for the periods noted in § 63.7500(f).

* * * * *

(c) You must demonstrate compliance with all applicable emission limits using performance stack testing, fuel analysis, or continuous monitoring systems (CMS), including a continuous emission monitoring system (CEMS), continuous opacity monitoring system (COMS), continuous parameter monitoring system (CPMS), or particulate matter continuous parameter monitoring system (PM CPMS), where applicable. You may demonstrate compliance with the applicable emission limit for hydrogen chloride (HCl), mercury, or total selected metals (TSM) using fuel analysis if the emission rate calculated according to § 63.7530(c) is less than the applicable emission limit. (For gaseous fuels, you may not use fuel analyses to comply with the TSM alternative standard or the HCl standard.) Otherwise, you must demonstrate compliance for HCl, mercury, or TSM using performance testing, if subject to an applicable emission limit listed in Tables 1, 2, or 11 through 13 to this subpart.

(d) If you demonstrate compliance with any applicable emission limit through performance testing and subsequent compliance with operating limits (including the use of CPMS), or with a CEMS, or COMS, you must develop a site-specific monitoring plan according to the requirements in paragraphs (d)(1) through (4) of this section for the use of any CEMS, COMS, or CPMS. This requirement also applies to you if you petition the EPA Administrator for alternative monitoring parameters under § 63.8(f).

(1) For each CMS required in this section (including CEMS, COMS, or CPMS), you must develop, and submit to the Administrator for approval upon request, a site-specific monitoring plan that addresses design, data collection, and the quality assurance and quality control elements outlined in § 63.8(d) and the elements described in paragraphs (d)(1)(i) through (iii) of this section. You must submit this site-specific monitoring plan, if requested, at least 60 days before your initial performance evaluation of your CMS. This requirement to develop and submit a site specific monitoring plan does not apply to affected sources with existing CEMS or COMS operated according to the performance specifications under appendix B to part 60 of this chapter and that meet the requirements of § 63.7525. Using the process described in § 63.8(f)(4), you may request approval of alternative monitoring system quality assurance and quality control procedures in place of those specified in this paragraph and, if approved, include the alternatives in your site-specific monitoring plan.

* * * * *

(iii) Performance evaluation procedures and acceptance criteria (e.g., calibrations, accuracy audits, analytical drift).

* * * * *

■ 12. Section 63.7510 is revised to read as follows:

§ 63.7510 What are my initial compliance requirements and by what date must I conduct them?

(a) For each boiler or process heater that is required or that you elect to demonstrate compliance with any of the applicable emission limits in Tables 1 or 2 or 11 through 13 of this subpart through performance testing, your initial compliance requirements include all the following:

(1) Conduct performance tests according to § 63.7520 and Table 5 to this subpart.

(2) Conduct a fuel analysis for each type of fuel burned in your boiler or process heater according to § 63.7521 and Table 6 to this subpart, except as specified in paragraphs (a)(2)(i) through (iii) of this section.

(i) For each boiler or process heater that burns a single type of fuel, you are not required to conduct a fuel analysis for each type of fuel burned in your boiler or process heater according to

§ 63.7521 and Table 6 to this subpart. For purposes of this subpart, units that use a supplemental fuel only for startup, unit shutdown, and transient flame stability purposes still qualify as units that burn a single type of fuel, and the supplemental fuel is not subject to the fuel analysis requirements under § 63.7521 and Table 6 to this subpart.

(ii) When natural gas, refinery gas, or other gas 1 fuels are co-fired with other fuels, you are not required to conduct a fuel analysis of those fuels according to § 63.7521 and Table 6 to this subpart. If gaseous fuels other than natural gas, refinery gas, or other gas 1 fuels are co-fired with other fuels and those gaseous fuels are subject to another subpart of this part, part 60, part 61, or part 65, you are not required to conduct a fuel analysis of those fuels according to § 63.7521 and Table 6 to this subpart.

(iii) You are not required to conduct a chlorine fuel analysis for any gaseous fuels. You must conduct a fuel analysis for mercury on gaseous fuels unless the fuel is exempted in paragraphs (a)(2)(i) and (ii) of this section.

(3) Establish operating limits according to § 63.7530 and Table 7 to this subpart.

(4) Conduct CMS performance evaluations according to § 63.7525.

(b) For each boiler or process heater that you elect to demonstrate compliance with the applicable emission limits in Tables 1 or 2 or 11 through 13 to this subpart for HCl, mercury, or TSM through fuel analysis, your initial compliance requirement is to conduct a fuel analysis for each type of fuel burned in your boiler or process heater according to § 63.7521 and Table 6 to this subpart and establish operating limits according to § 63.7530 and Table 8 to this subpart. The fuels described in paragraph (a)(2)(i) and (ii) of this section are exempt from these fuel analysis and operating limit requirements. The fuels described in paragraph (a)(2)(ii) of this section are exempt from the chloride fuel analysis and operating limit requirements. Boilers and process heaters that use a CEMS for mercury or HCl are exempt from the performance testing and operating limit requirements specified in paragraph (a) of this section for the HAP for which CEMS are used.

(c) If your boiler or process heater is subject to a carbon monoxide (CO) limit, your initial compliance demonstration for CO is to conduct a performance test for CO according to Table 5 to this subpart or conduct a performance evaluation of your continuous CO monitor, if applicable, according to § 63.7525(a). Boilers and process heaters that use a CO CEMS to comply with the applicable alternative CO CEMS emission standard listed in Tables 12, or 11 through 13 to this subpart, as specified in § 63.7525(a), are exempt from the initial CO performance testing and oxygen concentration operating limit requirements specified in paragraph (a) of this section.

(d) If your boiler or process heater is subject to a PM limit, your initial compliance demonstration for PM is to conduct a performance test in accordance with § 63.7520 and Table 5 to this subpart.

(e) For existing affected sources (as defined in § 63.7490), you must complete the initial compliance demonstration, as specified in paragraphs (a) through (d) of this section, no later than 180 days after the compliance date that is specified for your source in § 63.7495 and according to the applicable provisions in § 63.7(a)(2) as cited in Table 10 to this subpart, except as specified in paragraph (j) of this section. You must complete an initial tune-up by following the procedures described in § 63.7540(a)(10)(i) through (vi) no later than the compliance date specified in § 63.7495, except as specified in paragraph (j) of this section. You must complete the one-time energy assessment specified in Table 3 to this subpart no later than the compliance date specified in § 63.7495, except as specified in paragraph (j) of this section.

(f) For new or reconstructed affected sources (as defined in § 63.7490), you must complete the initial compliance demonstration with the emission limits no later than July 30, 2013 or within 180 days after startup of the source, whichever is later. If you are demonstrating compliance with an emission limit in Tables 11 through 13 to this subpart that is less stringent (that is, higher) than the applicable emission limit in Table 1 to this subpart, you must demonstrate compliance with the applicable emission limit in Table 1 no later than July 29, 2016.

(g) For new or reconstructed affected sources (as defined in § 63.7490), you must demonstrate initial compliance with the applicable work practice standards in Table 3 to this subpart within the applicable annual, biennial, or 5-year schedule as specified in § 63.7540(a) following the initial compliance date specified in § 63.7495(a). Thereafter, you are required to complete the applicable annual, biennial, or 5-year tune-up as specified in § 63.7540(a).

(h) For affected sources (as defined in § 63.7490) that ceased burning solid waste consistent with § 63.7495(e) and for which the initial compliance date has passed, you must demonstrate compliance within 60 days of the effective date of the waste-to-fuel switch. If you have not conducted your compliance demonstration for this subpart within the previous 12 months, you must complete all compliance demonstrations for this subpart before you commence or recommence combustion of solid waste.

(i) For an existing EGU that becomes subject after January 31, 2013, you must demonstrate compliance within 180 days after becoming an affected source.

(j) For existing affected sources (as defined in § 63.7490) that have not operated between the effective date of the rule and the compliance date that is specified for your source in § 63.7495, you must complete the initial compliance demonstration, if subject to the emission limits in Table 2 to this subpart, as specified in paragraphs (a) through (d) of this section, no later than 180 days after the re-start of the affected source and according to the applicable provisions in § 63.7(a)(2) as cited in Table 10 to this subpart. You must complete an initial tune-up by following the procedures described in § 63.7540(a)(10)(i) through (vi) no later than 30 days after the re-start of the affected source and, if applicable, complete the one-time energy assessment specified in Table 3 to this subpart, no later than the compliance date specified in § 63.7495.

■ 13. Section 63.7515 is revised to read as follows:

§ 63.7515 When must I conduct subsequent performance tests, fuel analyses, or tune-ups?

(a) You must conduct all applicable performance tests according to § 63.7520 on an annual basis, except as specified in paragraphs (b) through (e), (g), and (h) of this section. Annual performance tests must be completed no more than 13 months after the previous performance test, except as specified in paragraphs (b) through (e), (g), and (h) of this section.

(b) If your performance tests for a given pollutant for at least 2 consecutive years show that your emissions are at or below 75 percent of the emission limit (or, in limited instances as specified in Tables 1 and 2 or 11 through 13 to this subpart, at or below the emission limit) for the pollutant, and if there are no changes in the operation of the individual boiler or process heater or air pollution control equipment that could increase emissions, you may choose to conduct performance tests for the pollutant every third year. Each such performance test must be conducted no more than 37 months after the previous performance test. If you elect to

demonstrate compliance using emission averaging under § 63.7522, you must continue to conduct performance tests annually. The requirement to test at maximum chloride input level is waived unless the stack test is conducted for HCl. The requirement to test at maximum mercury input level is waived unless the stack test is conducted for mercury. The requirement to test at maximum TSM input level is waived unless the stack test is conducted for TSM.

(c) If a performance test shows emissions exceeded the emission limit or 75 percent of the emission limit (as specified in Tables 1 and 2 or 11 through 13 to this subpart) for a pollutant, you must conduct annual performance tests for that pollutant until all performance tests over a consecutive 2-year period meet the required level (at or below 75 percent of the emission limit, as specified in Tables 1 and 2 or 11 through 13 to this subpart).

(d) If you are required to meet an applicable tune-up work practice standard, you must conduct an annual, biennial, or 5-year performance tune-up according to § 63.7540(a)(10), (11), or (12), respectively. Each annual tune-up specified in § 63.7540(a)(10) must be no more than 13 months after the previous tune-up. Each biennial tune-up specified in § 63.7540(a)(11) must be conducted no more than 25 months after the previous tune-up. Each 5-year tune-up specified in § 63.7540(a)(12) must be conducted no more than 61 months after the previous tune-up. For a new or reconstructed affected source (as defined in § 63.7490), the first annual, biennial, or 5-year tune-up must be no later than 13 months, 25 months, or 61 months, respectively, after the initial startup of the new or reconstructed affected source.

(e) If you demonstrate compliance with the mercury, HCl, or TSM based on fuel analysis, you must conduct a monthly fuel analysis according to § 63.7521 for each type of fuel burned that is subject to an emission limit in Tables 1, 2, or 11 through 13 to this subpart. You may comply with this monthly requirement by completing the fuel analysis any time within the calendar month as long as the analysis is separated from the previous analysis by at least 14 calendar days. If you burn a new type of fuel, you must conduct a fuel analysis before burning the new type of fuel in your boiler or process heater. You must still meet all applicable continuous compliance requirements in § 63.7540. If each of 12 consecutive monthly fuel analyses demonstrates 75 percent or less of the compliance level, you may decrease the fuel analysis frequency to quarterly for that fuel. If any quarterly sample exceeds 75 percent of the compliance level or you begin burning a new type of fuel, you must return to monthly monitoring for that fuel, until 12 months of fuel analyses are again less than 75 percent of the compliance level.

(f) You must report the results of performance tests and the associated fuel analyses within 60 days after the completion of the performance tests. This report must also verify that the operating limits for each boiler or process heater have not changed or provide documentation of revised operating limits established according to § 63.7530 and Table 7 to this subpart, as applicable. The reports for all subsequent performance tests must include all applicable information required in § 63.7550.

(g) For affected sources (as defined in § 63.7490) that have not operated since the previous compliance demonstration and more than one year has passed since the previous compliance demonstration, you must complete the subsequent compliance demonstration, if subject to the emission limits in Tables 1, 2, or 11 through 13 to this subpart, no later than 180 days after the re-start of the affected source and according to the applicable provisions in § 63.7(a)(2) as cited in Table 10 to this subpart. You must complete a subsequent tune-up by following the procedures described in § 63.7540(a)(10)(i) through (vi) and the schedule described in § 63.7540(a)(13) for units that are not operating at the time of their scheduled tune-up.

(h) If your affected boiler or process heater is in the unit designed to burn light liquid subcategory and you combust ultra low sulfur liquid fuel, you do not need to conduct further performance tests if the pollutants measured during the initial compliance performance tests meet the emission limits in Tables 1 or 2 of this subpart providing you demonstrate ongoing compliance with the emissions limits by monitoring and recording the type of fuel combusted on a monthly basis. If you intend to use a fuel other than ultra low sulfur liquid fuel, natural gas, refinery gas, or other gas 1 fuel, you must conduct new performance tests within 60 days of burning the new fuel type.

(i) If you operate a CO CEMS that meets the Performance Specifications outlined in § 63.7525(a)(3) of this subpart to demonstrate compliance with the applicable alternative CO CEMS emission standard listed in Tables 1, 2, or 11 through 13 to this subpart, you are not required to conduct CO performance tests and are not subject to the oxygen concentration operating limit requirement specified in § 63.7510(a).

■ 14. Section § 63.7520 is amended by revising paragraphs (a), (c), (d), and (e) and adding paragraph (f) to read as follows:

§ 63.7520 What stack tests and procedures must I use?

(a) You must conduct all performance tests according to § 63.7(c), (d), (f), and (h). You must also develop a site-specific stack test plan according to the requirements in § 63.7(c). You shall conduct all performance tests under such conditions as the Administrator specifies to you based on the representative performance of each boiler or process heater for the period being tested. Upon request, you shall make available to the Administrator such records as may be necessary to determine the conditions of the performance tests.

* * * * *

(c) You must conduct each performance test under the specific conditions listed in Tables 5 and 7 to this subpart. You must conduct performance tests at representative operating load conditions while burning the type of fuel or mixture of fuels that has the highest content of chlorine and mercury, and TSM if you are opting to comply with the TSM alternative standard and you must demonstrate initial compliance and establish your operating limits based on these performance tests. These requirements could result in the need to conduct more than one performance test. Following each performance test and until the next performance test, you must comply with the operating limit for operating load conditions specified in Table 4 to this subpart.

(d) You must conduct a minimum of three separate test runs for each performance test required in this section, as specified in § 63.7(e)(3). Each test run must comply with the minimum applicable sampling times or volumes specified in Tables 1 and 2 or 11 through 13 to this subpart.

(e) To determine compliance with the emission limits, you must use the F-Factor methodology and equations in sections 12.2 and 12.3 of EPA Method 19 at 40 CFR part 60, appendix A–7 of this chapter to convert the measured particulate matter (PM) concentrations, the measured HCl concentrations, the measured mercury concentrations, and the measured TSM concentrations that result from the performance test to pounds per million Btu heat input emission rates.

(f) Except for a 30-day rolling average based on CEMS (or sorbent trap monitoring system) data, if measurement results for any pollutant are reported as below the method detection level (e.g., laboratory analytical results for one or more sample components are below the method defined analytical detection level), you must use the method detection level as the measured emissions level for that pollutant in calculating compliance. The measured result for a multiple component analysis (e.g., analytical values for multiple Method 29 fractions both for individual HAP metals and for total HAP metals) may include a combination of method detection level data and analytical data reported above the method detection level.

■ 15. Section 63.7521 is revised to read as follows:

§ 63.7521 What fuel analyses, fuel specification, and procedures must I use?

(a) For solid and liquid fuels, you must conduct fuel analyses for chloride and mercury according to the procedures in paragraphs (b) through (e) of this section and Table 6 to this subpart, as applicable. For solid fuels and liquid fuels, you must also conduct fuel analyses for TSM if you are opting to comply with the TSM alternative standard. For gas 2 (other) fuels, you must conduct fuel analyses for mercury according to the procedures in paragraphs (b) through (e) of this section and Table 6 to this subpart, as applicable. (For gaseous fuels, you may not use fuel analyses to comply with the TSM alternative standard or the HCl standard.) For purposes of complying with this section, a fuel gas system that consists of multiple gaseous fuels collected and mixed with each other is considered a single fuel type and sampling and analysis is only required on the combined fuel gas system that will feed the boiler or process heater. Sampling and analysis of the individual gaseous streams prior to combining is not required. You are not required to conduct fuel analyses for fuels used for only startup, unit shutdown, and transient flame stability purposes. You are required to conduct fuel analyses only for fuels and units that are subject to emission limits for mercury, HCl, or TSM in Tables 1 and 2 or 11 through 13 to this subpart. Gaseous and liquid fuels are exempt from the sampling requirements in paragraphs (c) and (d) of this section and Table 6 to this subpart.

(b) You must develop a site-specific fuel monitoring plan according to the following procedures and requirements in paragraphs (b)(1) and (2) of this section, if you are required to conduct fuel analyses as specified in § 63.7510.

(1) If you intend to use an alternative analytical method other than those required by Table 6 to this subpart, you must submit the fuel analysis plan to the Administrator for review and approval no later than 60 days before the date that you intend to conduct the initial compliance demonstration described in § 63.7510.

(2) You must include the information contained in paragraphs (b)(2)(i) through (vi) of this section in your fuel analysis plan.

(i) The identification of all fuel types anticipated to be burned in each boiler or process heater.

(ii) For each anticipated fuel type, the notification of whether you or a fuel supplier will be conducting the fuel analysis.

(iii) For each anticipated fuel type, a detailed description of the sample location and specific procedures to be used for collecting and preparing the composite samples if your procedures are different from paragraph (c) or (d) of this section. Samples should be collected at a location that most accurately represents the fuel type, where possible, at a point prior to mixing with other dissimilar fuel types.

(iv) For each anticipated fuel type, the analytical methods from Table 6, with the expected minimum detection levels, to be used for the measurement of chlorine or mercury.

(v) If you request to use an alternative analytical method other than those required by Table 6 to this subpart, you must also include a detailed description of the methods and procedures that you are proposing to use. Methods in Table 6 shall be used until the requested alternative is approved.

(vi) If you will be using fuel analysis from a fuel supplier in lieu of site-specific sampling and analysis, the fuel supplier must use the analytical methods required by Table 6 to this subpart.

(c) At a minimum, you must obtain three composite fuel samples for each fuel type according to the procedures in paragraph (c)(1) or (2) of this section, or the methods listed in Table 6 to this subpart, or use an automated sampling mechanism that provides representative composite fuel samples for each fuel type that includes both coarse and fine material.

(1) If sampling from a belt (or screw) feeder, collect fuel samples according to paragraphs (c)(1)(i) and (ii) of this section.

(i) Stop the belt and withdraw a 6-inch wide sample from the full cross-section of the stopped belt to obtain a minimum two pounds of sample. You must collect all the material (fines and coarse) in the full cross-section. You must transfer the sample to a clean plastic bag.

(ii) Each composite sample will consist of a minimum of three samples collected at approximately equal one-hour intervals during the testing period for sampling during performance stack testing. For monthly sampling, each composite sample shall be collected at approximately equal 10-day intervals during the month.

(2) If sampling from a fuel pile or truck, you must collect fuel samples according to paragraphs (c)(2)(i) through (iii) of this section.

(i) For each composite sample, you must select a minimum of five sampling locations uniformly spaced over the surface of the pile.

(ii) At each sampling site, you must dig into the pile to a uniform depth of approximately 18 inches. You must insert a clean shovel into the hole and withdraw a sample, making sure that large pieces do not fall off during sampling; use the same shovel to collect all samples.

(iii) You must transfer all samples to a clean plastic bag for further processing.

(d) You must prepare each composite sample according to the procedures in paragraphs (d)(1) through (7) of this section.

(1) You must thoroughly mix and pour the entire composite sample over a clean plastic sheet.

(2) You must break large sample pieces (e.g., larger than 3 inches) into smaller sizes.

(3) You must make a pie shape with the entire composite sample and subdivide it into four equal parts.

(4) You must separate one of the quarter samples as the first subset.

(5) If this subset is too large for grinding, you must repeat the procedure in paragraph (d)(3) of this section with the quarter sample and obtain a one-quarter subset from this sample.

(6) You must grind the sample in a mill.

(7) You must use the procedure in paragraph (d)(3) of this section to obtain a one-quarter subsample for analysis. If the quarter sample is too large, subdivide it further using the same procedure.

(e) You must determine the concentration of pollutants in the fuel (mercury and/or chlorine and/or TSM) in units of pounds per million Btu of each composite sample for each fuel type according to the procedures in

Table 6 to this subpart, for use in Equations 7, 8, and 9 of this subpart.

(f) To demonstrate that a gaseous fuel other than natural gas or refinery gas qualifies as an other gas 1 fuel, as defined in § 63.7575, you must conduct a fuel specification analyses for mercury according to the procedures in paragraphs (g) through (i) of this section and Table 6 to this subpart, as applicable, except as specified in paragraph (f)(1) through (4) of this section.

(1) You are not required to conduct the fuel specification analyses in paragraphs (g) through (i) of this section for natural gas or refinery gas.

(2) You are not required to conduct the fuel specification analyses in paragraphs (g) through (i) of this section for gaseous fuels that are subject to another subpart of this part, part 60, part 61, or part 65.

(3) You are not required to conduct the fuel specification analyses in paragraphs (g) through (i) of this section on gaseous fuels for units that are complying with the limits for units designed to burn gas 2 (other) fuels.

(4) You are not required to conduct the fuel specification analyses in paragraphs (g) through (i) of this section for gas streams directly derived from natural gas at natural gas production sites or natural gas plants.

(g) You must develop and submit a site-specific fuel analysis plan for other gas 1 fuels to the EPA Administrator for review and approval according to the following procedures and requirements in paragraphs (g)(1) and (2) of this section.

(1) If you intend to use an alternative analytical method other than those required by Table 6 to this subpart, you must submit the fuel analysis plan to the Administrator for review and approval no later than 60 days before the date that you intend to conduct the initial compliance demonstration described in § 63.7510.

(2) You must include the information contained in paragraphs (g)(2)(i) through (vi) of this section in your fuel analysis plan.

(i) The identification of all gaseous fuel types other than those exempted from fuel specification analysis under (f)(1) through (3) of this section anticipated to be burned in each boiler or process heater.

(ii) For each anticipated fuel type, the notification of whether you or a fuel supplier will be conducting the fuel specification analysis.

(iii) For each anticipated fuel type, a detailed description of the sample location and specific procedures to be used for collecting and preparing the samples if your procedures are different from the sampling methods contained in Table 6 to this subpart. Samples should be collected at a location that most accurately represents the fuel type, where possible, at a point prior to mixing with other dissimilar fuel types. If multiple boilers or process heaters are fueled by a common fuel stream it is permissible to conduct a single gas specification at the common point of gas distribution.

(iv) For each anticipated fuel type, the analytical methods from Table 6 to this subpart, with the expected minimum detection levels, to be used for the measurement of mercury.

(v) If you request to use an alternative analytical method other than those required by Table 6 to this subpart, you must also include a detailed description of the methods and procedures that you are proposing to use. Methods in Table 6 to this subpart shall be used until the requested alternative is approved.

(vi) If you will be using fuel analysis from a fuel supplier in lieu of site-specific sampling and analysis, the fuel supplier must use the analytical methods required by Table 6 to this subpart.

(h) You must obtain a single fuel sample for each fuel type according to the sampling procedures listed in Table 6 for fuel specification of gaseous fuels.

(i) You must determine the concentration in the fuel of mercury, in units of microgram per cubic meter, dry basis, of each sample for each other gas 1 fuel type according to the procedures in Table 6 to this subpart.

■ 16. Section § 63.7522 is revised by:
■ a. Revising paragraphs (a) through (d).
■ b. Revising paragraphs (e)(1) and (2).
■ c. Revising paragraphs (f) introductory text and (f)(1) and (2).
■ d. Revising paragraphs (g) introductory text, (g)(2)(i), (g)(2)(iv), (g)(2)(vi)(B), (g)(3) introductory text, (g)(4) introductory text, and (g)(4)(ii).
■ e. Revising paragraph (h).
■ f. Revising paragraph (i).
■ g. Revising paragraph (j)(1).
■ h. Revising paragraph (k).

The revisions read as follows:

§ 63.7522 Can I use emissions averaging to comply with this subpart?

(a) As an alternative to meeting the requirements of § 63.7500 for PM (or TSM), HCl, or mercury on a boiler or process heater-specific basis, if you have more than one existing boiler or process heater in any subcategories located at your facility, you may demonstrate compliance by emissions averaging, if your averaged emissions are not more than 90 percent of the applicable emission limit, according to the procedures in this section. You may not include new boilers or process heaters in an emissions average.

(b) For a group of two or more existing boilers or process heaters in the same subcategory that each vent to a separate stack, you may average PM (or TSM), HCl, or mercury emissions among existing units to demonstrate compliance with the limits in Table 2 to this subpart as specified in paragraph (b)(1) through (3) of this section, if you satisfy the requirements in paragraphs (c) through (g) of this section.

(1) You may average units using a CEMS or PM CPMS for demonstrating compliance.

(2) For mercury and HCl, averaging is allowed as follows:

(i) You may average among units in any of the solid fuel subcategories.

(ii) You may average among units in any of the liquid fuel subcategories.

(iii) You may average among units in a subcategory of units designed to burn gas 2 (other) fuels.

(iv) You may not average across the units designed to burn liquid, units designed to burn solid fuel, and units designed to burn gas 2 (other) subcategories.

(3) For PM (or TSM), averaging is only allowed between units within each of the following subcategories and you may not average across subcategories:

(i) Units designed to burn coal/solid fossil fuel.

(ii) Stokers/sloped grate/other units designed to burn kiln dried biomass/bio-based solids.

(iii) Stokers/sloped grate/other units designed to burn wet biomass/bio-based solids.

(iv) Fluidized bed units designed to burn biomass/bio-based solid.

(v) Suspension burners designed to burn biomass/bio-based solid.

(vi) Dutch ovens/pile burners designed to burn biomass/bio-based solid.

(vii) Fuel Cells designed to burn biomass/bio-based solid.

(viii) Hybrid suspension/grate burners designed to burn wet biomass/bio-based solid.

(ix) Units designed to burn heavy liquid fuel.

(x) Units designed to burn light liquid fuel.

(xi) Units designed to burn liquid fuel that are non-continental units.

(xii) Units designed to burn gas 2 (other) gases.

(c) For each existing boiler or process heater in the averaging group, the emission rate achieved during the initial compliance test for the HAP being averaged must not exceed the emission level that was being achieved on

January 31, 2013 or the control technology employed during the initial compliance test must not be less effective for the HAP being averaged than the control technology employed on January 31, 2013.

(d) The averaged emissions rate from the existing boilers and process heaters participating in the emissions averaging option must not exceed 90 percent of the limits in Table 2 to this subpart at all times the affected units are operating following the compliance date specified in § 63.7495.

(e) * * *

(1) You must use Equation 1a or 1b or 1c of this section to demonstrate that the PM (or TSM), HCl, or mercury emissions from all existing units participating in the emissions averaging option for that pollutant do not exceed the emission limits in Table 2 to this subpart. Use Equation 1a if you are complying with the emission limits on a heat input basis, use Equation 1b if you are complying with the emission limits on a steam generation (output) basis, and use Equation 1c if you are complying with the emission limits on a electric generation (output) basis.

$$AveWeightedEmissions = 1.1 \times \sum_{i=1}^{n} (Er \times Hm) \div \sum_{i=1}^{n} Hm \qquad \text{(Eq. 1a)}$$

Where:

AveWeightedEmissions = Average weighted emissions for PM (or TSM), HCl, or mercury, in units of pounds per million Btu of heat input.

Er = Emission rate (as determined during the initial compliance demonstration) of PM (or TSM), HCl, or mercury from unit, i, in units of pounds per million Btu of heat input. Determine the emission rate for PM (or TSM), HCl, or mercury by performance testing according to Table 5 to this subpart, or by fuel analysis for HCl or mercury or TSM using the applicable equation in § 63.7530(c).

Hm = Maximum rated heat input capacity of unit, i, in units of million Btu per hour.

n = Number of units participating in the emissions averaging option.

1.1 = Required discount factor.

$$AveWeightedEmissions = 1.1 \times \sum_{i=1}^{n} (Er \times So) \div \sum_{i=1}^{n} So \qquad \text{(Eq. 1b)}$$

Where:

AveWeightedEmissions = Average weighted emissions for PM (or TSM), HCl, or mercury, in units of pounds per million Btu of steam output.

Er = Emission rate (as determined during the initial compliance demonstration) of PM (or TSM), HCl, or mercury from unit, i, in units of pounds per million Btu of steam output. Determine the emission rate for PM (or TSM), HCl, or mercury by performance testing according to Table 5 to this subpart, or by fuel analysis for HCl or mercury or TSM using the applicable equation in § 63.7530(c). If you are taking credit for energy conservation measures from a unit according to § 63.7533, use the adjusted emission level for that unit, Eadj, determined according to § 63.7533 for that unit.

So = Maximum steam output capacity of unit, i, in units of million Btu per hour, as defined in § 63.7575.

n = Number of units participating in the emissions averaging option.

1.1 = Required discount factor.

$$AveWeightedEmissions = 1.1 \times \sum_{i=1}^{n} (Er \times Eo) \div \sum_{i=1}^{n} Eo \qquad \text{(Eq. 1c)}$$

Where:

AveWeightedEmissions = Average weighted emissions for PM (or TSM), HCl, or mercury, in units of pounds per megawatt hour.

Er = Emission rate (as determined during the initial compliance demonstration) of PM (or TSM), HCl, or mercury from unit, i, in units of pounds per megawatt hour. Determine the emission rate for PM (or TSM), HCl, or mercury by performance testing according to Table 5 to this subpart, or by fuel analysis for HCl or mercury or TSM using the applicable equation in § 63.7530(c). If you are taking credit for energy conservation measures from a unit according to § 63.7533, use the adjusted emission level for that unit, Eadj, determined according to § 63.7533 for that unit.

Eo = Maximum electric generating output capacity of unit, i, in units of megawatt hour, as defined in § 63.7575.

n = Number of units participating in the emissions averaging option.

1.1 = Required discount factor.

(2) If you are not capable of determining the maximum rated heat input capacity of one or more boilers that generate steam, you may use Equation 2 of this section as an alternative to using Equation 1a of this section to demonstrate that the PM (or TSM), HCl, or mercury emissions from all existing units participating in the emissions averaging option do not exceed the emission limits for that pollutant in Table 2 to this subpart that are in pounds per million Btu of heat input.

$$AveWeightedEmissions = 1.1 \times \sum_{i=1}^{n} (Er \times Sm \times Cfi) \div \sum_{i=1}^{n} (Sm \times Cfi) \qquad \text{(Eq. 2)}$$

Where:

AveWeightedEmissions = Average weighted emission level for PM (or TSM), HCl, or mercury, in units of pounds per million Btu of heat input.

Er = Emission rate (as determined during the most recent compliance demonstration) of PM (or TSM), HCl, or mercury from unit, i, in units of pounds per million Btu of heat input. Determine the emission rate for PM (or TSM), HCl, or mercury by performance testing according to Table 5 to this subpart, or by fuel analysis for HCl or mercury or TSM using the applicable equation in § 63.7530(c).

Sm = Maximum steam generation capacity by unit, i, in units of pounds per hour.
Cfi = Conversion factor, calculated from the most recent compliance test, in units of million Btu of heat input per pounds of steam generated for unit, i.
1.1 = Required discount factor.

(f) After the initial compliance demonstration described in paragraph (e) of this section, you must demonstrate compliance on a monthly basis determined at the end of every month (12 times per year) according to paragraphs (f)(1) through (3) of this section. The first monthly period begins on the compliance date specified in § 63.7495. If the affected source elects to collect monthly data for up the 11 months preceding the first monthly period, these additional data points can be used to compute the 12-month rolling average in paragraph (f)(3) of this section.

(1) For each calendar month, you must use Equation 3a or 3b or 3c of this section to calculate the average weighted emission rate for that month. Use Equation 3a and the actual heat input for the month for each existing unit participating in the emissions averaging option if you are complying with emission limits on a heat input basis. Use Equation 3b and the actual steam generation for the month if you are complying with the emission limits on a steam generation (output) basis. Use Equation 3c and the actual steam generation for the month if you are complying with the emission limits on a electrical generation (output) basis.

$$AveWeightedEmissions = 1.1 \times \sum_{i=1}^{n} (Er \times Hb) \div \sum_{i=1}^{n} Hb \qquad \text{(Eq. 3a)}$$

Where:
AveWeightedEmissions = Average weighted emission level for PM (or TSM), HCl, or mercury, in units of pounds per million Btu of heat input, for that calendar month.
Er = Emission rate (as determined during the most recent compliance demonstration) of PM (or TSM), HCl, or mercury from unit, i, in units of pounds per million Btu of heat input. Determine the emission rate for PM (or TSM), HCl, or mercury by performance testing according to Table 5 to this subpart, or by fuel analysis for HCl or mercury or TSM according to Table 6 to this subpart.
Hb = The heat input for that calendar month to unit, i, in units of million Btu.
n = Number of units participating in the emissions averaging option.
1.1 = Required discount factor.

$$AveWeightedEmissions = 1.1 \times \sum_{i=1}^{n} (Er \times So) \div \sum_{i=1}^{n} So \qquad \text{(Eq. 3b)}$$

Where:
AveWeightedEmissions = Average weighted emission level for PM (or TSM), HCl, or mercury, in units of pounds per million Btu of steam output, for that calendar month.
Er = Emission rate (as determined during the most recent compliance demonstration) of PM (or TSM), HCl, or mercury from unit, i, in units of pounds per million Btu of steam output. Determine the emission rate for PM (or TSM), HCl, or mercury by performance testing according to Table 5 to this subpart, or by fuel analysis for HCl or mercury or TSM according to Table 6 to this subpart. If you are taking credit for energy conservation measures from a unit according to § 63.7533, use the adjusted emission level for that unit, E_{adj}, determined according to § 63.7533 for that unit.
So = The steam output for that calendar month from unit, i, in units of million Btu, as defined in § 63.7575.
n = Number of units participating in the emissions averaging option.
1.1 = Required discount factor.

$$AveWeightedEmissions = 1.1 \times \sum_{i=1}^{n} (Er \times Eo) \div \sum_{i=1}^{n} Eo \qquad \text{(Eq. 3c)}$$

Where:
AveWeightedEmissions = Average weighted emission level for PM (or TSM), HCl, or mercury, in units of pounds per megawatt hour, for that calendar month.
Er = Emission rate (as determined during the most recent compliance demonstration) of PM (or TSM), HCl, or mercury from unit, i, in units of pounds per megawatt hour. Determine the emission rate for PM (or TSM), HCl, or mercury by performance testing according to Table 5 to this subpart, or by fuel analysis for HCl or mercury or TSM according to Table 6 to this subpart. If you are taking credit for energy conservation measures from a unit according to § 63.7533, use the adjusted emission level for that unit, E_{adj}, determined according to § 63.7533 for that unit.
Eo = The electric generating output for that calendar month from unit, i, in units of megawatt hour, as defined in § 63.7575.
n = Number of units participating in the emissions averaging option.
1.1 = Required discount factor.

(2) If you are not capable of monitoring heat input, you may use Equation 4 of this section as an alternative to using Equation 3a of this section to calculate the average weighted emission rate using the actual steam generation from the boilers participating in the emissions averaging option.

$$AveWeightedEmissions = 1.1 \times \sum_{i=1}^{n} (Er \times Sa \times Cfi) \div \sum_{i=1}^{n} (Sa \times Cfi) \qquad \text{(Eq. 4)}$$

Where:
AveWeightedEmissions = average weighted emission level for PM (or TSM), HCl, or mercury, in units of pounds per million

Btu of heat input for that calendar month.

Er = Emission rate (as determined during the most recent compliance demonstration of PM (or TSM), HCl, or mercury from unit, i, in units of pounds per million Btu of heat input. Determine the emission rate for PM (or TSM), HCl, or mercury by performance testing according to Table 5 to this subpart, or by fuel analysis for HCl or mercury or TSM according to Table 6 to this subpart.

Sa = Actual steam generation for that calendar month by boiler, i, in units of pounds.

Cfi = Conversion factor, as calculated during the most recent compliance test, in units of million Btu of heat input per pounds of steam generated for boiler, i.

1.1 = Required discount factor.

* * * * *

(g) You must develop, and submit upon request to the applicable Administrator for review and approval, an implementation plan for emission averaging according to the following procedures and requirements in paragraphs (g)(1) through (4) of this section.

* * * * *

(2) * * *

(i) The identification of all existing boilers and process heaters in the averaging group, including for each either the applicable HAP emission level or the control technology installed as of January 31, 2013 and the date on which you are requesting emission averaging to commence;

* * * * *

(iv) The test plan for the measurement of PM (or TSM), HCl, or mercury emissions in accordance with the requirements in § 63.7520;

* * * * *

(vi) * * *

(B) A description of the methods and procedures that will be used to demonstrate that the parameter indicates proper operation of the control device; the frequency and content of monitoring, reporting, and recordkeeping requirements; and a demonstration, to the satisfaction of the Administrator, that the proposed monitoring frequency is sufficient to represent control device operating conditions; and

* * * * *

(3) The Administrator shall review and approve or disapprove the plan according to the following criteria:

* * * * *

(4) The applicable Administrator shall not approve an emission averaging implementation plan containing any of the following provisions:

* * * * *

(ii) The inclusion of any emission source other than an existing unit in the same subcategories.

* * * * *

(h) For a group of two or more existing affected units, each of which vents through a single common stack, you may average PM (or TSM), HCl, or mercury emissions to demonstrate compliance with the limits for that pollutant in Table 2 to this subpart if you satisfy the requirements in paragraph (i) or (j) of this section.

(i) For a group of two or more existing units in the same subcategories, each of which vents through a common emissions control system to a common stack, that does not receive emissions from units in other subcategories or categories, you may treat such averaging group as a single existing unit for purposes of this subpart and comply with the requirements of this subpart as if the group were a single unit.

(j) * * *

(1) Conduct performance tests according to procedures specified in § 63.7520 in the common stack if affected units from other subcategories vent to the common stack. The emission limits that the group must comply with are determined by the use of Equation 6 of this section.

$$En = \sum_{i=1}^{n} (ELi \times Hi) \div \sum_{i=1}^{n} Hi \qquad \text{(Eq. 6)}$$

Where:

En = HAP emission limit, pounds per million British thermal units (lb/MMBtu), parts per million (ppm), or nanograms per dry standard cubic meter (ng/dscm).

ELi = Appropriate emission limit from Table 2 to this subpart for unit i, in units of lb/MMBtu, ppm or ng/dscm.

Hi = Heat input from unit i, MMBtu.

* * * * *

(k) The common stack of a group of two or more existing boilers or process heaters in the same subcategories subject to paragraph (h) of this section may be treated as a separate stack for purposes of paragraph (b) of this section and included in an emissions averaging group subject to paragraph (b) of this section.

■ 17. Section 63.7525 is amended by:
■ a. Revising paragraph (a)
■ b. Revising paragraph (b).
■ c. Revising paragraph (c) introductory text.
■ d. Revising paragraphs (d) introductory text and paragraphs (d)(1) through (d)(4).
■ e. Revising paragraph (e)(2).
■ f. Revising paragraph (e)(3).
■ g. Revising paragraph (f)(2).
■ h. Revising paragraph (j).
■ i. Revising paragraph (k).
■ j. Adding paragraph (l).
■ k. Adding paragraph (m).

The revisions and additions read as follows:

§ 63.7525 What are my monitoring, installation, operation, and maintenance requirements?

(a) If your boiler or process heater is subject to a CO emission limit in Tables 1, 2, or 11 through 13 to this subpart, you must install, operate, and maintain an oxygen analyzer system, as defined in § 63.7575, or install, certify, operate and maintain continuous emission monitoring systems for CO and oxygen according to the procedures in paragraphs (a)(1) through (7) of this section.

(1) Install the CO CEMS and oxygen analyzer by the compliance date specified in § 63.7495. The CO and oxygen levels shall be monitored at the same location at the outlet of the boiler or process heater.

(2) To demonstrate compliance with the applicable alternative CO CEMS emission standard listed in Tables 1, 2, or 11 through 13 to this subpart, you must install, certify, operate, and maintain a CO CEMS and an oxygen analyzer according to the applicable procedures under Performance Specification 4, 4A, or 4B at 40 CFR part 60, appendix B, the site-specific monitoring plan developed according to § 63.7505(d), and the requirements in § 63.7540(a)(8) and paragraph (a) of this section. Any boiler or process heater that has a CO CEMS that is compliant with Performance Specification 4, 4A, or 4B at 40 CFR part 60, appendix B, a site-specific monitoring plan developed according to § 63.7505(d), and the requirements in § 63.7540(a)(8) and paragraph (a) of this section must use the CO CEMS to comply with the applicable alternative CO CEMS emission standard listed in Tables 1, 2, or 11 through 13 to this subpart.

(i) You must conduct a performance evaluation of each CO CEMS according to the requirements in § 63.8(e) and

according to Performance Specification 4, 4A, or 4B at 40 CFR part 60, appendix B.

(ii) During each relative accuracy test run of the CO CEMS, you must be collect emission data for CO concurrently (or within a 30- to 60-minute period) by both the CO CEMS and by Method 10, 10A, or 10B at 40 CFR part 60, appendix A–4. The relative accuracy testing must be at representative operating conditions.

(iii) You must follow the quality assurance procedures (e.g., quarterly accuracy determinations and daily calibration drift tests) of Procedure 1 of appendix F to part 60. The measurement span value of the CO CEMS must be two times the applicable CO emission limit, expressed as a concentration.

(iv) Any CO CEMS that does not comply with § 63.7525(a) cannot be used to meet any requirement in this subpart to demonstrate compliance with a CO emission limit listed in Tables 1, 2, or 11 through 13 to this subpart.

(v) For a new unit, complete the initial performance evaluation no later than July 30, 2013, or 180 days after the date of initial startup, whichever is later. For an existing unit, complete the initial performance evaluation no later than July 29, 2016.

(3) Complete a minimum of one cycle of CO and oxygen CEMS operation (sampling, analyzing, and data recording) for each successive 15-minute period. Collect CO and oxygen data concurrently. Collect at least four CO and oxygen CEMS data values representing the four 15-minute periods in an hour, or at least two 15-minute data values during an hour when CEMS calibration, quality assurance, or maintenance activities are being performed.

(4) Reduce the CO CEMS data as specified in § 63.8(g)(2).

(5) Calculate one-hour arithmetic averages, corrected to 3 percent oxygen from each hour of CO CEMS data in parts per million CO concentration. The one-hour arithmetic averages required shall be used to calculate the 30-day or 10-day rolling average emissions. Use Equation 19–19 in section 12.4.1 of Method 19 of 40 CFR part 60, appendix A–7 for calculating the average CO concentration from the hourly values.

(6) For purposes of collecting CO data, operate the CO CEMS as specified in § 63.7535(b). You must use all the data collected during all periods in calculating data averages and assessing compliance, except that you must exclude certain data as specified in § 63.7535(c). Periods when CO data are unavailable may constitute monitoring deviations as specified in § 63.7535(d).

(7) Operate an oxygen trim system with the oxygen level set no lower than the lowest hourly average oxygen concentration measured during the most recent CO performance test as the operating limit for oxygen according to Table 7 to this subpart.

(b) If your boiler or process heater is in the unit designed to burn coal/solid fossil fuel subcategory or the unit designed to burn heavy liquid subcategory and has an average annual heat input rate greater than 250 MMBtu per hour from solid fossil fuel and/or heavy liquid, and you demonstrate compliance with the PM limit instead of the alternative TSM limit, you must install, certify, maintain, and operate a PM CPMS monitoring emissions discharged to the atmosphere and record the output of the system as specified in paragraphs (b)(1) through (4) of this section. As an alternative to use of a PM CPMS to demonstrate compliance with the PM limit, you may choose to use a PM CEMS. If you choose to use a PM CEMS to demonstrate compliance with the PM limit instead of the alternative TSM limit, you must install, certify, maintain, and operate a PM CEMS monitoring emissions discharged to the atmosphere and record the output of the system as specified in paragraph (b)(5) through (8) of this section. For other boilers or process heaters, you may elect to use a PM CPMS or PM CEMS operated in accordance with this section in lieu of using other CMS for monitoring PM compliance (e.g., bag leak detectors, ESP secondary power, PM scrubber pressure). Owners of boilers and process heaters who elect to comply with the alternative TSM limit are not required to install a PM CPMS.

(1) Install, certify, operate, and maintain your PM CPMS according to the procedures in your approved site-specific monitoring plan developed in accordance with § 63.7505(d), the requirements in § 63.7540(a)(9), and paragraphs (b)(1)(i) through (iii) of this section.

(i) The operating principle of the PM CPMS must be based on in-stack or extractive light scatter, light scintillation, beta attenuation, or mass accumulation detection of PM in the exhaust gas or representative exhaust gas sample. The reportable measurement output from the PM CPMS must be expressed as milliamps.

(ii) The PM CPMS must have a cycle time (i.e., period required to complete sampling, measurement, and reporting for each measurement) no longer than 60 minutes.

(iii) The PM CPMS must be capable of detecting and responding to PM concentrations of no greater than 0.5 milligram per actual cubic meter.

(2) For a new unit, complete the initial performance evaluation no later than July 30, 2013, or 180 days after the date of initial startup, whichever is later. For an existing unit, complete the initial performance evaluation no later than July 29, 2016.

(3) Collect PM CPMS hourly average output data for all boiler or process heater operating hours except as indicated in § 63.7535(a) through (d). Express the PM CPMS output as milliamps.

(4) Calculate the arithmetic 30-day rolling average of all of the hourly average PM CPMS output data collected during all boiler or process heater operating hours (milliamps).

(5) Install, certify, operate, and maintain your PM CEMS according to the procedures in your approved site-specific monitoring plan developed in accordance with § 63.7505(d), the requirements in § 63.7540(a)(9), and paragraphs (b)(5)(i) through (iv) of this section.

(i) You shall conduct a performance evaluation of the PM CEMS according to the applicable requirements of § 60.8(e), and Performance Specification 11 at 40 CFR part 60, appendix B of this chapter.

(ii) During each PM correlation testing run of the CEMS required by Performance Specification 11 at 40 CFR part 60, appendix B of this chapter, you shall collect PM and oxygen (or carbon dioxide) data concurrently (or within a 30-to 60-minute period) by both the CEMS and conducting performance tests using Method 5 at 40 CFR part 60, appendix A–3 or Method 17 at 40 CFR part 60, appendix A–6 of this chapter.

(iii) You shall perform quarterly accuracy determinations and daily calibration drift tests in accordance with Procedure 2 at 40 CFR part 60, appendix F of this chapter. You must perform Relative Response Audits annually and perform Response Correlation Audits every 3 years.

(iv) Within 60 days after the date of completing each CEMS relative accuracy test audit or performance test conducted to demonstrate compliance with this subpart, you must submit the relative accuracy test audit data and performance test data to the EPA by successfully submitting the data electronically into the EPA's Central Data Exchange by using the Electronic Reporting Tool (see *http://www.epa.gov/ttn/chief/ert/erttool.html/*).

(6) For a new unit, complete the initial performance evaluation no later than July 30, 2013, or 180 days after the date of initial startup, whichever is later. For an existing unit, complete the

initial performance evaluation no later than July 29, 2016.

(7) Collect PM CEMS hourly average output data for all boiler or process heater operating hours except as indicated in § 63.7535(a) through (d).

(8) Calculate the arithmetic 30-day rolling average of all of the hourly average PM CEMS output data collected during all boiler or process heater operating hours.

(c) If you have an applicable opacity operating limit in this rule, and are not otherwise required or elect to install and operate a PM CPMS, PM CEMS, or a bag leak detection system, you must install, operate, certify and maintain each COMS according to the procedures in paragraphs (c)(1) through (7) of this section by the compliance date specified in § 63.7495.

* * * * *

(d) If you have an operating limit that requires the use of a CMS other than a PM CPMS or COMS, you must install, operate, and maintain each CMS according to the procedures in paragraphs (d)(1) through (5) of this section by the compliance date specified in § 63.7495.

(1) The CPMS must complete a minimum of one cycle of operation every 15-minutes. You must have a minimum of four successive cycles of operation, one representing each of the four 15-minute periods in an hour, to have a valid hour of data.

(2) You must operate the monitoring system as specified in § 63.7535(b), and comply with the data calculation requirements specified in § 63.7535(c).

(3) Any 15-minute period for which the monitoring system is out-of-control and data are not available for a required calculation constitutes a deviation from the monitoring requirements. Other situations that constitute a monitoring deviation are specified in § 63.7535(d).

(4) You must determine the 30-day rolling average of all recorded readings, except as provided in § 63.7535(c).

* * * * *

(e) * * *

(2) You must use a flow sensor with a measurement sensitivity of no greater than 2 percent of the design flow rate.

(3) You must minimize, consistent with good engineering practices, the effects of swirling flow or abnormal velocity distributions due to upstream and downstream disturbances.

* * * * *

(f) * * *

(2) Minimize or eliminate pulsating pressure, vibration, and internal and external corrosion consistent with good engineering practices.

* * * * *

(j) If you are not required to use a PM CPMS and elect to use a fabric filter bag leak detection system to comply with the requirements of this subpart, you must install, calibrate, maintain, and continuously operate the bag leak detection system as specified in paragraphs (j)(1) through (6) of this section.

(1) You must install a bag leak detection sensor(s) in a position(s) that will be representative of the relative or absolute PM loadings for each exhaust stack, roof vent, or compartment (e.g., for a positive pressure fabric filter) of the fabric filter.

(2) Conduct a performance evaluation of the bag leak detection system in accordance with your monitoring plan and consistent with the guidance provided in EPA–454/R–98–015 (incorporated by reference, see § 63.14).

(3) Use a bag leak detection system certified by the manufacturer to be capable of detecting PM emissions at concentrations of 10 milligrams per actual cubic meter or less.

(4) Use a bag leak detection system equipped with a device to record continuously the output signal from the sensor.

(5) Use a bag leak detection system equipped with a system that will alert plant operating personnel when an increase in relative PM emissions over a preset level is detected. The alert must easily recognizable (e.g., heard or seen) by plant operating personnel.

(6) Where multiple bag leak detectors are required, the system's instrumentation and alert may be shared among detectors.

(k) For each unit that meets the definition of limited-use boiler or process heater, you must keep fuel use records for the days the boiler or process heater was operating.

(l) For each unit for which you decide to demonstrate compliance with the mercury or HCl emissions limits in Tables 1 or 2 or 11 through 13 of this subpart by use of a CEMS for mercury or HCl, you must install, certify, maintain, and operate a CEMS measuring emissions discharged to the atmosphere and record the output of the system as specified in paragraphs (l)(1) through (8) of this section. For HCl, this option for an affected unit takes effect on the date a final performance specification for a HCl CEMS is published in the **Federal Register** or the date of approval of a site-specific monitoring plan.

(1) Notify the Administrator one month before starting use of the CEMS, and notify the Administrator one month before stopping use of the CEMS.

(2) Each CEMS shall be installed, certified, operated, and maintained according to the requirements in § 63.7540(a)(14) for a mercury CEMS and § 63.7540(a)(15) for a HCl CEMS.

(3) For a new unit, you must complete the initial performance evaluation of the CEMS by the latest of the dates specified in paragraph (l)(3)(i) through (iii) of this section.

(i) No later than July 30, 2013.

(ii) No later 180 days after the date of initial startup.

(iii) No later 180 days after notifying the Administrator before starting to use the CEMS in place of performance testing or fuel analysis to demonstrate compliance.

(4) For an existing unit, you must complete the initial performance evaluation by the latter of the two dates specified in paragraph (l)(4)(i) and (ii) of this section.

(i) No later than July 29, 2016.

(ii) No later 180 days after notifying the Administrator before starting to use the CEMS in place of performance testing or fuel analysis to demonstrate compliance.

(5) Compliance with the applicable emissions limit shall be determined based on the 30-day rolling average of the hourly arithmetic average emissions rates using the continuous monitoring system outlet data. The 30-day rolling arithmetic average emission rate (lb/MMBtu) shall be calculated using the equations in EPA Reference Method 19 at 40 CFR part 60, appendix A–7, but substituting the mercury or HCl concentration for the pollutant concentrations normally used in Method 19.

(6) Collect CEMS hourly averages for all operating hours on a 30-day rolling average basis. Collect at least four CMS data values representing the four 15-minute periods in an hour, or at least two 15-minute data values during an hour when CMS calibration, quality assurance, or maintenance activities are being performed.

(7) The one-hour arithmetic averages required shall be expressed in lb/MMBtu and shall be used to calculate the boiler 30-day and 10-day rolling average emissions.

(8) You are allowed to substitute the use of the PM, mercury or HCl CEMS for the applicable fuel analysis, annual performance test, and operating limits specified in Table 4 to this subpart to demonstrate compliance with the PM, mercury or HCl emissions limit, and if you are using an acid gas wet scrubber or dry sorbent injection control technology to comply with the HCl emission limit, you are allowed to substitute the use of a sulfur dioxide

(SO_2) CEMS for the applicable fuel analysis, annual performance test, and operating limits specified in Table 4 to this subpart to demonstrate compliance with HCl emissions limit.

(m) If your unit is subject to a HCl emission limit in Tables 1, 2, or 11 through 13 of this subpart and you have an acid gas wet scrubber or dry sorbent injection control technology and you use an SO_2 CEMS, you must install the monitor at the outlet of the boiler or process heater, downstream of all emission control devices, and you must install, certify, operate, and maintain the CEMS according to part 75 of this chapter.

(1) The SO_2 CEMS must be installed by the compliance date specified in § 63.7495.

(2) For on-going quality assurance (QA), the SO_2 CEMS must meet the applicable daily, quarterly, and semiannual or annual requirements in sections 2.1 through 2.3 of appendix B to part 75 of this chapter, with the following addition: You must perform the linearity checks required in section 2.2 of appendix B to part 75 of this chapter if the SO_2 CEMS has a span value of 30 ppm or less.

(3) For a new unit, the initial performance evaluation shall be completed no later than July 30, 2013, or 180 days after the date of initial startup, whichever is later. For an existing unit, the initial performance evaluation shall be completed no later than July 29, 2016.

(4) For purposes of collecting SO_2 data, you must operate the SO_2 CEMS as specified in § 63.7535(b). You must use all the data collected during all periods in calculating data averages and assessing compliance, except that you must exclude certain data as specified in § 63.7535(c). Periods when SO_2 data are unavailable may constitute monitoring deviations as specified in § 63.7535(d).

(5) Collect CEMS hourly averages for all operating hours on a 30-day rolling average basis.

(6) Use only unadjusted, quality-assured SO_2 concentration values in the emissions calculations; do not apply bias adjustment factors to the part 75 SO_2 data and do not use part 75 substitute data values.

■ 18. Section 63.7530 is amended by:
■ a. Revising paragraph (a).
■ b. Revising paragraph (b) introductory text.
■ c. Redesignating paragraph (b)(3) as paragraph (b)(4) and adding new paragraph (b)(3).
■ d. Revising newly designated paragraph (b)(4).
■ e. Revising paragraph (c), (c)(2) through (4).
■ f. Adding paragraph (c)(5).
■ g. Revising paragraphs (d), (e), (g), and (h).
■ h. Adding paragraph (i).

The revisions and additions read as follows:

§ 63.7530 How do I demonstrate initial compliance with the emission limitations, fuel specifications and work practice standards?

(a) You must demonstrate initial compliance with each emission limit that applies to you by conducting initial performance tests and fuel analyses and establishing operating limits, as applicable, according to § 63.7520, paragraphs (b) and (c) of this section, and Tables 5 and 7 to this subpart. The requirement to conduct a fuel analysis is not applicable for units that burn a single type of fuel, as specified by § 63.7510(a)(2)(i). If applicable, you must also install, operate, and maintain all applicable CMS (including CEMS, COMS, and CPMS) according to § 63.7525.

(b) If you demonstrate compliance through performance testing, you must establish each site-specific operating limit in Table 4 to this subpart that applies to you according to the requirements in § 63.7520, Table 7 to this subpart, and paragraph (b)(4) of this section, as applicable. You must also conduct fuel analyses according to § 63.7521 and establish maximum fuel pollutant input levels according to paragraphs (b)(1) through (3) of this section, as applicable, and as specified in § 63.7510(a)(2). (Note that § 63.7510(a)(2) exempts certain fuels from the fuel analysis requirements.) However, if you switch fuel(s) and cannot show that the new fuel(s) does (do) not increase the chlorine, mercury, or TSM input into the unit through the results of fuel analysis, then you must repeat the performance test to demonstrate compliance while burning the new fuel(s).

* * * * *

(3) If you opt to comply with the alternative TSM limit, you must establish the maximum TSM fuel input (TSMinput) for solid or liquid fuels during the initial fuel analysis according to the procedures in paragraphs (b)(3)(i) through (iii) of this section.

(i) You must determine the fuel type or fuel mixture that you could burn in your boiler or process heater that has the highest content of TSM.

(ii) During the fuel analysis for TSM, you must determine the fraction of the total heat input for each fuel type burned (Qi) based on the fuel mixture that has the highest content of TSM, and the average TSM concentration of each fuel type burned (TSMi).

(iii) You must establish a maximum TSM input level using Equation 9 of this section.

$$TSMinput = \sum_{i=1}^{n} (TSMi \times Qi) \qquad \text{(Eq. 9)}$$

Where:

TSMinput = Maximum amount of TSM entering the boiler or process heater through fuels burned in units of pounds per million Btu.

TSMi = Arithmetic average concentration of TSM in fuel type, i, analyzed according to § 63.7521, in units of pounds per million Btu.

Qi = Fraction of total heat input from fuel type, i, based on the fuel mixture that has the highest content of TSM. If you do not burn multiple fuel types during the performance testing, it is not necessary to determine the value of this term. Insert a value of ''1'' for Qi.

n = Number of different fuel types burned in your boiler or process heater for the mixture that has the highest content of TSM.

(4) You must establish parameter operating limits according to paragraphs (b)(4)(i) through (ix) of this section. As indicated in Table 4 to this subpart, you are not required to establish and comply with the operating parameter limits when you are using a CEMS to monitor and demonstrate compliance with the applicable emission limit for that control device parameter.

(i) For a wet acid gas scrubber, you must establish the minimum scrubber effluent pH and liquid flow rate as defined in § 63.7575, as your operating limits during the performance test during which you demonstrate compliance with your applicable limit. If you use a wet scrubber and you conduct separate performance tests for HCl and mercury emissions, you must establish one set of minimum scrubber effluent pH, liquid flow rate, and

pressure drop operating limits. The minimum scrubber effluent pH operating limit must be established during the HCl performance test. If you conduct multiple performance tests, you must set the minimum liquid flow rate operating limit at the higher of the minimum values established during the performance tests.

(ii) For any particulate control device (e.g., ESP, particulate wet scrubber, fabric filter) for which you use a PM CPMS, you must establish your PM CPMS operating limit and determine compliance with it according to paragraphs (b)(4)(ii)(A) through (F) of this section.

(A) Determine your operating limit as the average PM CPMS output value recorded during the most recent performance test run demonstrating compliance with the filterable PM emission limit or at the PM CPMS output value corresponding to 75 percent of the emission limit if your PM performance test demonstrates compliance below 75 percent of the emission limit. You must verify an existing or establish a new operating limit after each repeated performance test. You must repeat the performance test annually and reassess and adjust the site-specific operating limit in accordance with the results of the performance test.

(*1*) Your PM CPMS must provide a 4–20 milliamp output and the establishment of its relationship to manual reference method measurements must be determined in units of milliamps.

(*2*) Your PM CPMS operating range must be capable of reading PM concentrations from zero to a level equivalent to at least two times your allowable emission limit. If your PM CPMS is an auto-ranging instrument capable of multiple scales, the primary range of the instrument must be capable of reading PM concentration from zero to a level equivalent to two times your allowable emission limit.

(*3*) During the initial performance test or any such subsequent performance test that demonstrates compliance with the PM limit, record and average all milliamp output values from the PM CPMS for the periods corresponding to the compliance test runs (e.g., average all your PM CPMS output values for three corresponding 2-hour Method 5I test runs).

(B) If the average of your three PM performance test runs are below 75 percent of your PM emission limit, you must calculate an operating limit by establishing a relationship of PM CPMS signal to PM concentration using the PM CPMS instrument zero, the average PM CPMS values corresponding to the three compliance test runs, and the average PM concentration from the Method 5 or performance test with the procedures in paragraphs (b)(4)(ii)(B)(*1*) through (*4*) of this section.

(*1*) Determine your instrument zero output with one of the following procedures:

(*i*) Zero point data for *in-situ* instruments should be obtained by removing the instrument from the stack and monitoring ambient air on a test bench.

(*ii*) Zero point data for *extractive* instruments should be obtained by removing the extractive probe from the stack and drawing in clean ambient air.

(*iii*) The zero point may also be established by performing manual reference method measurements when the flue gas is free of PM emissions or contains very low PM concentrations (*e.g.,* when your process is not operating, but the fans are operating or your source is combusting only natural gas) and plotting these with the compliance data to find the zero intercept.

(*iv*) If none of the steps in paragraphs (b)(4)(ii)(B)(*1*)(*i*) through (*iii*) of this section are possible, you must use a zero output value provided by the manufacturer.

(*2*) Determine your PM CPMS instrument average in milliamps, and the average of your corresponding three PM compliance test runs, using equation 10.

$$\bar{x} = \frac{1}{n}\sum_{i=1}^{n} X_1 \, , \bar{y} = \frac{1}{n}\sum_{i=1}^{n} Y_1 \qquad \text{(Eq. 10)}$$

Where:

X_1 = the PM CPMS data points for the three runs constituting the performance test,

Y_1 = the PM concentration value for the three runs constituting the performance test, and

n = the number of data points.

(*3*) With your instrument zero expressed in milliamps, your three run average PM CPMS milliamp value, and your three run average PM concentration from your three compliance tests, determine a relationship of lb/MMBtu per milliamp with equation 11.

$$R = \frac{Y_1}{(X_1 - z)} \qquad \text{(Eq. 11)}$$

Where:

R = the relative lb/MMBtu per milliamp for your PM CPMS,

Y_1 = the three run average lb/MMBtu PM concentration,

X_1 = the three run average milliamp output from you PM CPMS, and

z = the milliamp equivalent of your instrument zero determined from (B)(i).

(*4*) Determine your source specific 30-day rolling average operating limit using the lb/MMBtu per milliamp value from Equation 11 in equation 12, below. This sets your operating limit at the PM CPMS output value corresponding to 75 percent of your emission limit.

$$O_l = z + \frac{0.75(L)}{R} \qquad \text{(Eq. 12)}$$

Where:

O_l = the operating limit for your PM CPMS on a 30-day rolling average, in milliamps.

L = your source emission limit expressed in lb/MMBtu,

z = your instrument zero in milliamps, determined from (B)(i), and

R = the relative lb/MMBtu per milliamp for your PM CPMS, from Equation 11.

(C) If the average of your three PM compliance test runs is at or above 75 percent of your PM emission limit you must determine your 30-day rolling average operating limit by averaging the PM CPMS milliamp output corresponding to your three PM performance test runs that demonstrate compliance with the emission limit using equation 13 and you must submit all compliance test and PM CPMS data according to the reporting requirements in paragraph (b)(4)(ii)(F) of this section.

$$O_h = \frac{1}{n}\sum_{i=1}^{n} X_1 \qquad \text{(Eq. 13)}$$

Where:

X_1 = the PM CPMS data points for all runs i,

n = the number of data points, and

O_h = your site specific operating limit, in milliamps.

(D) To determine continuous compliance, you must record the PM

CPMS output data for all periods when the process is operating and the PM CPMS is not out-of-control. You must demonstrate continuous compliance by using all quality-assured hourly average data collected by the PM CPMS for all operating hours to calculate the arithmetic average operating parameter in units of the operating limit (milliamps) on a 30-day rolling average basis, updated at the end of each new operating hour. Use Equation 14 to determine the 30-day rolling average.

$$30-\text{day} = \frac{\sum_{i=1}^{n} Hpv_i}{n} \qquad \text{(Eq. 14)}$$

Where:

30-day = 30-day average.

Hpvi = is the hourly parameter value for hour i

n = is the number of valid hourly parameter values collected over the previous 720 operating hours.

(E) Use EPA Method 5 of appendix A to part 60 of this chapter to determine PM emissions. For each performance test, conduct three separate runs under the conditions that exist when the affected source is operating at the highest load or capacity level reasonably expected to occur. Conduct each test run to collect a minimum sample volume specified in Tables 1, 2, or 11 through 13 to this subpart, as applicable, for determining compliance with a new source limit or an existing source limit. Calculate the average of the results from three runs to determine compliance. You need not determine the PM collected in the impingers (''back half'') of the Method 5 particulate sampling train to demonstrate compliance with the PM standards of this subpart. This shall not preclude the permitting authority from requiring a determination of the ''back half'' for other purposes.

(F) For PM performance test reports used to set a PM CPMS operating limit, the electronic submission of the test report must also include the make and model of the PM CPMS instrument, serial number of the instrument, analytical principle of the instrument (e.g. beta attenuation), span of the instruments primary analytical range, milliamp value equivalent to the instrument zero output, technique by which this zero value was determined, and the average milliamp signals corresponding to each PM compliance test run. (iii) For a particulate wet scrubber, you must establish the minimum pressure drop and liquid flow rate as defined in § 63.7575, as your operating limits during the three-run performance test during which you demonstrate compliance with your applicable limit. If you use a wet scrubber and you conduct separate performance tests for PM and TSM emissions, you must establish one set of minimum scrubber liquid flow rate and pressure drop operating limits. The minimum scrubber effluent pH operating limit must be established during the HCl performance test. If you conduct multiple performance tests, you must set the minimum liquid flow rate and pressure drop operating limits at the higher of the minimum values established during the performance tests.

(iii) For an electrostatic precipitator (ESP) operated with a wet scrubber, you must establish the minimum total secondary electric power input, as defined in § 63.7575, as your operating limit during the three-run performance test during which you demonstrate compliance with your applicable limit. (These operating limits do not apply to ESP that are operated as dry controls without a wet scrubber.)

(iv) For a dry scrubber, you must establish the minimum sorbent injection rate for each sorbent, as defined in § 63.7575, as your operating limit during the three-run performance test during which you demonstrate compliance with your applicable limit.

(v) For activated carbon injection, you must establish the minimum activated carbon injection rate, as defined in § 63.7575, as your operating limit during the three-run performance test during which you demonstrate compliance with your applicable limit.

(vi) The operating limit for boilers or process heaters with fabric filters that demonstrate continuous compliance through bag leak detection systems is that a bag leak detection system be installed according to the requirements in § 63.7525, and that each fabric filter must be operated such that the bag leak detection system alert is not activated more than 5 percent of the operating time during a 6-month period.

(vii) For a minimum oxygen level, if you conduct multiple performance tests, you must set the minimum oxygen level at the lower of the minimum values established during the performance tests.

(viii) The operating limit for boilers or process heaters that demonstrate continuous compliance with the HCl emission limit using a SO_2 CEMS is to install and operate the SO_2 according to the requirements in § 63.7525(m) establish a maximum SO_2 emission rate equal to the highest hourly average SO_2 measurement during the most recent three-run performance test for HCl.

(c) If you elect to demonstrate compliance with an applicable emission limit through fuel analysis, you must conduct fuel analyses according to § 63.7521 and follow the procedures in paragraphs (c)(1) through (5) of this section.

* * * * *

(2) You must determine the 90th percentile confidence level fuel pollutant concentration of the composite samples analyzed for each fuel type using the one-sided t-statistic test described in Equation 15 of this section.

$$P90 = mean + (SD \times t) \qquad \text{(Eq. 15)}$$

Where:

P90 = 90th percentile confidence level pollutant concentration, in pounds per million Btu.

Mean = Arithmetic average of the fuel pollutant concentration in the fuel samples analyzed according to § 63.7521, in units of pounds per million Btu.

SD = Standard deviation of the mean of pollutant concentration in the fuel samples analyzed according to § 63.7521, in units of pounds per million Btu. SD is calculated as the sample standard

deviation divided by the square root of the number of samples.

t = t distribution critical value for 90th percentile ($t_{0.1}$) probability for the appropriate degrees of freedom (number of samples minus one) as obtained from a t-Distribution Critical Value Table.

(3) To demonstrate compliance with the applicable emission limit for HCl, the HCl emission rate that you calculate for your boiler or process heater using Equation 16 of this section must not exceed the applicable emission limit for HCl.

$$HCl = \sum_{i=1}^{n} \left(Ci90 \times Qi \times 1.028 \right) \qquad \text{(Eq. 16)}$$

Where:

HCl = HCl emission rate from the boiler or process heater in units of pounds per million Btu.

Ci90 = 90th percentile confidence level concentration of chlorine in fuel type, i, in units of pounds per million Btu as calculated according to Equation 11 of this section.

Qi = Fraction of total heat input from fuel type, i, based on the fuel mixture that has the highest content of chlorine. If you do not burn multiple fuel types, it is not necessary to determine the value of this term. Insert a value of ''1'' for Qi.

n = Number of different fuel types burned in your boiler or process heater for the mixture that has the highest content of chlorine.

1.028 = Molecular weight ratio of HCl to chlorine.

(4) To demonstrate compliance with the applicable emission limit for mercury, the mercury emission rate that you calculate for your boiler or process heater using Equation 17 of this section must not exceed the applicable emission limit for mercury.

$$Mercury = \sum_{i=1}^{n} \left(Hgi90 \times Qi \right) \qquad \text{(Eq. 17)}$$

Where:

Mercury = Mercury emission rate from the boiler or process heater in units of pounds per million Btu.

Hgi90 = 90th percentile confidence level concentration of mercury in fuel, i, in units of pounds per million Btu as calculated according to Equation 11 of this section.

Qi = Fraction of total heat input from fuel type, i, based on the fuel mixture that has the highest mercury content. If you do not burn multiple fuel types, it is not necessary to determine the value of this term. Insert a value of ''1'' for Qi.

n = Number of different fuel types burned in your boiler or process heater for the mixture that has the highest mercury content.

(5) To demonstrate compliance with the applicable emission limit for TSM for solid or liquid fuels, the TSM emission rate that you calculate for your boiler or process heater from solid fuels using Equation 18 of this section must not exceed the applicable emission limit for TSM.

$$Metals = \sum_{i=1}^{n} \left(TSM90i \times Qi \right) \qquad \text{(Eq. 18)}$$

Where:

Metals = TSM emission rate from the boiler or process heater in units of pounds per million Btu.

TSMi90 = 90th percentile confidence level concentration of TSM in fuel, i, in units of pounds per million Btu as calculated according to Equation 11 of this section.

Qi = Fraction of total heat input from fuel type, i, based on the fuel mixture that has the highest TSM content. If you do not burn multiple fuel types, it is not necessary to determine the value of this term. Insert a value of ''1'' for Qi.

n = Number of different fuel types burned in your boiler or process heater for the mixture that has the highest TSM content.

(d) If you own or operate an existing unit with a heat input capacity of less than 10 million Btu per hour or a unit in the unit designed to burn gas 1 subcategory, you must submit a signed statement in the Notification of Compliance Status report that indicates that you conducted a tune-up of the unit.

(e) You must include with the Notification of Compliance Status a signed certification that the energy assessment was completed according to Table 3 to this subpart and is an accurate depiction of your facility at the time of the assessment.

* * * * *

(g) If you elect to demonstrate that a gaseous fuel meets the specifications of another gas 1 fuel as defined in § 63.7575, you must conduct an initial fuel specification analyses according to § 63.7521(f) through (i) and according to the frequency listed in § 63.7540(c) and maintain records of the results of the testing as outlined in § 63.7555(g). For samples where the initial mercury specification has not been exceeded, you will include a signed certification with the Notification of Compliance Status that the initial fuel specification test meets the gas specification outlined in the definition of other gas 1 fuels.

(h) If you own or operate a unit subject to emission limits in Tables 1 or 2 or 11 through 13 to this subpart, you must meet the work practice standard according to Table 3 of this subpart. During startup and shutdown, you must only follow the work practice standards according to item 5 of Table 3 of this subpart.

(i) If you opt to comply with the alternative SO_2 CEMS operating limit in Tables 4 and 8 to this subpart, you may do so only if your affected boiler or process heater:

(1) Has a system using wet scrubber or dry sorbent injection and SO_2 CEMS installed on the unit; and

(2) At all times, you operate the wet scrubber or dry sorbent injection for acid gas control on the unit consistent with § 63.7500(a)(3); and

(3) You establish a unit-specific maximum SO_2 operating limit by

collecting the minimum hourly SO_2 emission rate on the SO_2 CEMS during the paired 3-run test for HCl. The maximum SO_2 operating limit is equal to the highest hourly average SO_2 concentration measured during the most recent HCl performance test.

■ 19. Section 63.7533 is amended by:
■ a. Revising the section heading.
■ b. Revising paragraph (a).
■ c. Revising paragraphs (b)(1) and (4).
■ d. Revising paragraphs (c) introductory text, (c)(1)(i) and (ii), (c)(2)(i), and (c)(3).
■ e. Revising paragraph (d) through (f).
■ f. Adding paragraph (g).

The revisions and addition read as follows:

§ 63.7533 Can I use efficiency credits earned from implementation of energy conservation measures to comply with this subpart?

(a) If you elect to comply with the alternative equivalent output-based emission limits, instead of the heat input-based limits listed in Table 2 to this subpart, and you want to take credit for implementing energy conservation measures identified in an energy assessment, you may demonstrate compliance using efficiency credits according to the procedures in this section. You may use this compliance approach for an existing affected boiler for demonstrating initial compliance according to § 63.7522(e) and for demonstrating monthly compliance according to § 63.7522(f). Owners or operators using this compliance approach must establish an emissions benchmark, calculate and document the efficiency credits, develop an Implementation Plan, comply with the general reporting requirements, and apply the efficiency credit according to the procedures in paragraphs (b) through (f) of this section. You cannot use this compliance approach for a new or reconstructed affected boiler. Additional guidance from the Department of Energy on efficiency credits is available at: *http://www.epa.gov/ttn/atw/boiler/boilerpg.html.*

(b) * * *

(1) The benchmark from which efficiency credits may be generated shall be determined by using the most representative, accurate, and reliable process available for the source. The benchmark shall be established for a one-year period before the date that an energy demand reduction occurs, unless it can be demonstrated that a different time period is more representative of historical operations.

* * * * *

(4) Collect non-energy related facility and operational data to normalize, if necessary, the benchmark to current operations, such as building size, operating hours, etc. If possible, use actual data that are current and timely rather than estimated data.

(c) Efficiency credits can be generated if the energy conservation measures were implemented after January 1, 2008 and if sufficient information is available to determine the appropriate value of credits.

(1) The following emission points cannot be used to generate efficiency credits:

(i) Energy conservation measures implemented on or before January 1, 2008, unless the level of energy demand reduction is increased after January 1, 2008, in which case credit will be allowed only for change in demand reduction achieved after January 1, 2008.

(ii) Efficiency credits on shut-down boilers. Boilers that are shut down cannot be used to generate credits unless the facility provides documentation linking the permanent shutdown to energy conservation measures identified in the energy assessment. In this case, the bench established for the affected boiler to which the credits from the shutdown will be applied must be revised to include the benchmark established for the shutdown boiler.

(2) * * *

(i) Calculate annual credits for all energy demand points. Use Equation 19 to calculate credits. Energy conservation measures that meet the criteria of paragraph (c)(1) of this section shall not be included, except as specified in paragraph (c)(1)(i) of this section.

* * * * *

(3) Credits are generated by the difference between the benchmark that is established for each affected boiler, and the actual energy demand reductions from energy conservation measures implemented after January 1, 2008. Credits shall be calculated using Equation 19 of this section as follows:

(i) The overall equation for calculating credits is:

$$ECredits = \left(\sum_{i=1}^{n} EIS_{iactual} \right) \div EI_{baseline} \qquad \text{(Eq. 19)}$$

Where:

ECredits = Energy Input Savings for all energy conservation measures implemented for an affected boiler, expressed as a decimal fraction of the baseline energy input.

$EIS_{iactual}$ = Energy Input Savings for each energy conservation measure, i, implemented for an affected boiler, million Btu per year.

$EI_{baseline}$ = Energy Input baseline for the affected boiler, million Btu per year.

n = Number of energy conservation measures included in the efficiency credit for the affected boiler.

(ii) [Reserved]

(d) The owner or operator shall develop, and submit for approval upon request by the Administrator, an Implementation Plan containing all of the information required in this paragraph for all boilers to be included in an efficiency credit approach. The Implementation Plan shall identify all existing affected boilers to be included in applying the efficiency credits. The Implementation Plan shall include a description of the energy conservation measures implemented and the energy savings generated from each measure and an explanation of the criteria used for determining that savings. If requested, you must submit the implementation plan for efficiency credits to the Administrator for review and approval no later than 180 days before the date on which the facility intends to demonstrate compliance using the efficiency credit approach.

(e) The emissions rate as calculated using Equation 20 of this section from each existing boiler participating in the efficiency credit option must be in compliance with the limits in Table 2 to this subpart at all times the affected unit is operating, following the compliance date specified in § 63.7495.

(f) You must use Equation 20 of this section to demonstrate initial compliance by demonstrating that the emissions from the affected boiler participating in the efficiency credit compliance approach do not exceed the emission limits in Table 2 to this subpart.

$$E_{adj} = E_m \times (1 - ECredits) \quad \text{(Eq. 20)}$$

Where:

E_{adj} = Emission level adjusted by applying the efficiency credits earned, lb per million Btu steam output (or lb per MWh) for the affected boiler.

E_m = Emissions measured during the performance test, lb per million Btu steam output (or lb per MWh) for the affected boiler.

ECredits = Efficiency credits from Equation 19 for the affected boiler.

(g) As part of each compliance report submitted as required under § 63.7550, you must include documentation that the energy conservation measures implemented continue to generate the credit for use in demonstrating compliance with the emission limits.

■ 20. Section 63.7535 is amended by revising the section heading and paragraphs (b), (c), and (d) to read as follows:

§ 63.7535 Is there a minimum amount of monitoring data I must obtain?

* * * * *

(b) You must operate the monitoring system and collect data at all required intervals at all times that each boiler or process heater is operating and compliance is required, except for periods of monitoring system malfunctions or out of control periods (see § 63.8(c)(7) of this part), and required monitoring system quality assurance or control activities, including, as applicable, calibration checks, required zero and span adjustments, and scheduled CMS maintenance as defined in your site-specific monitoring plan. A monitoring system malfunction is any sudden, infrequent, not reasonably preventable failure of the monitoring system to provide valid data. Monitoring system failures that are caused in part by poor maintenance or careless operation are not malfunctions. You are required to complete monitoring system repairs in response to monitoring system malfunctions or out-of-control periods and to return the monitoring system to operation as expeditiously as practicable.

(c) You may not use data recorded during monitoring system malfunctions or out-of-control periods, repairs associated with monitoring system malfunctions or out-of-control periods, or required monitoring system quality assurance or control activities in data averages and calculations used to report emissions or operating levels. You must record and make available upon request results of CMS performance audits and dates and duration of periods when the CMS is out of control to completion of the corrective actions necessary to return the CMS to operation consistent with your site-specific monitoring plan. You must use all the data collected during all other periods in assessing compliance and the operation of the control device and associated control system.

(d) Except for periods of monitoring system malfunctions, repairs associated with monitoring system malfunctions, and required monitoring system quality assurance or quality control activities (including, as applicable, system accuracy audits, calibration checks, and required zero and span adjustments), failure to collect required data is a deviation of the monitoring requirements. In calculating monitoring results, do not use any data collected during periods when the monitoring system is out of control as specified in your site-specific monitoring plan, while conducting repairs associated with periods when the monitoring system is out of control, or while conducting required monitoring system quality assurance or quality control activities. You must calculate monitoring results using all other monitoring data collected while the process is operating. You must report all periods when the monitoring system is out of control in your annual report.

■ 21. Section 63.7540 is revised to read as follows:

§ 63.7540 How do I demonstrate continuous compliance with the emission limitations, fuel specifications and work practice standards?

(a) You must demonstrate continuous compliance with each emission limit in Tables 1 and 2 or 11 through 13 to this subpart, the work practice standards in Table 3 to this subpart, and the operating limits in Table 4 to this subpart that applies to you according to the methods specified in Table 8 to this subpart and paragraphs (a)(1) through (19) of this section.

(1) Following the date on which the initial compliance demonstration is completed or is required to be completed under §§ 63.7 and 63.7510, whichever date comes first, operation above the established maximum or below the established minimum operating limits shall constitute a deviation of established operating limits listed in Table 4 of this subpart except during performance tests conducted to determine compliance with the emission limits or to establish new operating limits. Operating limits must be confirmed or reestablished during performance tests.

(2) As specified in § 63.7550(c), you must keep records of the type and amount of all fuels burned in each boiler or process heater during the reporting period to demonstrate that all fuel types and mixtures of fuels burned would result in either of the following:

(i) Lower emissions of HCl, mercury, and TSM than the applicable emission limit for each pollutant, if you demonstrate compliance through fuel analysis.

(ii) Lower fuel input of chlorine, mercury, and TSM than the maximum values calculated during the last performance test, if you demonstrate compliance through performance testing.

(3) If you demonstrate compliance with an applicable HCl emission limit through fuel analysis for a solid or liquid fuel and you plan to burn a new type of solid or liquid fuel, you must recalculate the HCl emission rate using Equation 12 of § 63.7530 according to paragraphs (a)(3)(i) through (iii) of this section. You are not required to conduct fuel analyses for the fuels described in § 63.7510(a)(2)(i) through (iii). You may exclude the fuels described in § 63.7510(a)(2)(i) through (iii) when recalculating the HCl emission rate.

(i) You must determine the chlorine concentration for any new fuel type in units of pounds per million Btu, based on supplier data or your own fuel analysis, according to the provisions in your site-specific fuel analysis plan developed according to § 63.7521(b).

(ii) You must determine the new mixture of fuels that will have the highest content of chlorine.

(iii) Recalculate the HCl emission rate from your boiler or process heater under these new conditions using Equation 12 of § 63.7530. The recalculated HCl emission rate must be less than the applicable emission limit.

(4) If you demonstrate compliance with an applicable HCl emission limit through performance testing and you plan to burn a new type of fuel or a new mixture of fuels, you must recalculate the maximum chlorine input using Equation 7 of § 63.7530. If the results of recalculating the maximum chlorine input using Equation 7 of § 63.7530 are greater than the maximum chlorine input level established during the previous performance test, then you must conduct a new performance test within 60 days of burning the new fuel type or fuel mixture according to the

procedures in § 63.7520 to demonstrate that the HCl emissions do not exceed the emission limit. You must also establish new operating limits based on this performance test according to the procedures in § 63.7530(b). In recalculating the maximum chlorine input and establishing the new operating limits, you are not required to conduct fuel analyses for and include the fuels described in § 63.7510(a)(2)(i) through (iii).

(5) If you demonstrate compliance with an applicable mercury emission limit through fuel analysis, and you plan to burn a new type of fuel, you must recalculate the mercury emission rate using Equation 13 of § 63.7530 according to the procedures specified in paragraphs (a)(5)(i) through (iii) of this section. You are not required to conduct fuel analyses for the fuels described in § 63.7510(a)(2)(i) through (iii). You may exclude the fuels described in § 63.7510(a)(2)(i) through (iii) when recalculating the mercury emission rate.

(i) You must determine the mercury concentration for any new fuel type in units of pounds per million Btu, based on supplier data or your own fuel analysis, according to the provisions in your site-specific fuel analysis plan developed according to § 63.7521(b).

(ii) You must determine the new mixture of fuels that will have the highest content of mercury.

(iii) Recalculate the mercury emission rate from your boiler or process heater under these new conditions using Equation 13 of § 63.7530. The recalculated mercury emission rate must be less than the applicable emission limit.

(6) If you demonstrate compliance with an applicable mercury emission limit through performance testing, and you plan to burn a new type of fuel or a new mixture of fuels, you must recalculate the maximum mercury input using Equation 8 of § 63.7530. If the results of recalculating the maximum mercury input using Equation 8 of § 63.7530 are higher than the maximum mercury input level established during the previous performance test, then you must conduct a new performance test within 60 days of burning the new fuel type or fuel mixture according to the procedures in § 63.7520 to demonstrate that the mercury emissions do not exceed the emission limit. You must also establish new operating limits based on this performance test according to the procedures in § 63.7530(b). You are not required to conduct fuel analyses for the fuels described in § 63.7510(a)(2)(i) through (iii). You may exclude the fuels described in § 63.7510(a)(2)(i) through (iii) when recalculating the mercury emission rate.

(7) If your unit is controlled with a fabric filter, and you demonstrate continuous compliance using a bag leak detection system, you must initiate corrective action within 1 hour of a bag leak detection system alert and complete corrective actions as soon as practical, and operate and maintain the fabric filter system such that the periods which would cause an alert are no more than 5 percent of the operating time during a 6-month period. You must also keep records of the date, time, and duration of each alert, the time corrective action was initiated and completed, and a brief description of the cause of the alert and the corrective action taken. You must also record the percent of the operating time during each 6-month period that the conditions exist for an alert. In calculating this operating time percentage, if inspection of the fabric filter demonstrates that no corrective action is required, no alert time is counted. If corrective action is required, each alert shall be counted as a minimum of 1 hour. If you take longer than 1 hour to initiate corrective action, the alert time shall be counted as the actual amount of time taken to initiate corrective action.

(8) To demonstrate compliance with the applicable alternative CO CEMS emission limit listed in Tables 1, 2, or 11 through 13 to this subpart, you must meet the requirements in paragraphs (a)(8)(i) through (iv) of this section.

(i) Continuously monitor CO according to §§ 63.7525(a) and 63.7535.

(ii) Maintain a CO emission level below or at your applicable alternative CO CEMS-based standard in Tables 1 or 2 or 11 through 13 to this subpart at all times the affected unit is operating.

(iii) Keep records of CO levels according to § 63.7555(b).

(iv) You must record and make available upon request results of CO CEMS performance audits, dates and duration of periods when the CO CEMS is out of control to completion of the corrective actions necessary to return the CO CEMS to operation consistent with your site-specific monitoring plan.

(9) The owner or operator of a boiler or process heater using a PM CPMS or a PM CEMS to meet requirements of this subpart shall install, certify, operate, and maintain the PM CPMS or PM CEMS in accordance with your site-specific monitoring plan as required in § 63.7505(d).

(10) If your boiler or process heater has a heat input capacity of 10 million Btu per hour or greater, you must conduct an annual tune-up of the boiler or process heater to demonstrate continuous compliance as specified in paragraphs (a)(10)(i) through (vi) of this section. This frequency does not apply to limited-use boilers and process heaters, as defined in § 63.7575, or units with continuous oxygen trim systems that maintain an optimum air to fuel ratio.

(i) As applicable, inspect the burner, and clean or replace any components of the burner as necessary (you may delay the burner inspection until the next scheduled unit shutdown). Units that produce electricity for sale may delay the burner inspection until the first outage, not to exceed 36 months from the previous inspection. At units where entry into a piece of process equipment or into a storage vessel is required to complete the tune-up inspections, inspections are required only during planned entries into the storage vessel or process equipment;

(ii) Inspect the flame pattern, as applicable, and adjust the burner as necessary to optimize the flame pattern. The adjustment should be consistent with the manufacturer's specifications, if available;

(iii) Inspect the system controlling the air-to-fuel ratio, as applicable, and ensure that it is correctly calibrated and functioning properly (you may delay the inspection until the next scheduled unit shutdown). Units that produce electricity for sale may delay the inspection until the first outage, not to exceed 36 months from the previous inspection;

(iv) Optimize total emissions of CO. This optimization should be consistent with the manufacturer's specifications, if available, and with any NO_X requirement to which the unit is subject;

(v) Measure the concentrations in the effluent stream of CO in parts per million, by volume, and oxygen in volume percent, before and after the adjustments are made (measurements may be either on a dry or wet basis, as long as it is the same basis before and after the adjustments are made). Measurements may be taken using a portable CO analyzer; and

(vi) Maintain on-site and submit, if requested by the Administrator, an annual report containing the information in paragraphs (a)(10)(vi)(A) through (C) of this section,

(A) The concentrations of CO in the effluent stream in parts per million by volume, and oxygen in volume percent, measured at high fire or typical operating load, before and after the tune-up of the boiler or process heater;

(B) A description of any corrective actions taken as a part of the tune-up; and

(C) The type and amount of fuel used over the 12 months prior to the tune-up, but only if the unit was physically and legally capable of using more than one type of fuel during that period. Units sharing a fuel meter may estimate the fuel used by each unit.

(11) If your boiler or process heater has a heat input capacity of less than 10 million Btu per hour (except as specified in paragraph (a)(12) of this section), you must conduct a biennial tune-up of the boiler or process heater as specified in paragraphs (a)(10)(i) through (vi) of this section to demonstrate continuous compliance.

(12) If your boiler or process heater has a continuous oxygen trim system that maintains an optimum air to fuel ratio, or a heat input capacity of less than or equal to 5 million Btu per hour and the unit is in the units designed to burn gas 1; units designed to burn gas 2 (other); or units designed to burn light liquid subcategories, or meets the definition of limited-use boiler or process heater in § 63.7575, you must conduct a tune-up of the boiler or process heater every 5 years as specified in paragraphs (a)(10)(i) through (vi) of this section to demonstrate continuous compliance. You may delay the burner inspection specified in paragraph (a)(10)(i) of this section until the next scheduled or unscheduled unit shutdown, but you must inspect each burner at least once every 72 months.

(13) If the unit is not operating on the required date for a tune-up, the tune-up must be conducted within 30 calendar days of startup.

(14) If you are using a CEMS measuring mercury emissions to meet requirements of this subpart you must install, certify, operate, and maintain the mercury CEMS as specified in paragraphs (a)(14)(i) and (ii) of this section.

(i) Operate the mercury CEMS in accordance with performance specification 12A of 40 CFR part 60, appendix B or operate a sorbent trap based integrated monitor in accordance with performance specification 12B of 40 CFR part 60, appendix B. The duration of the performance test must be the maximum of 30 unit operating days or 720 hours. For each day in which the unit operates, you must obtain hourly mercury concentration data, and stack gas volumetric flow rate data.

(ii) If you are using a mercury CEMS, you must install, operate, calibrate, and maintain an instrument for continuously measuring and recording the mercury mass emissions rate to the atmosphere according to the requirements of performance specifications 6 and 12A of 40 CFR part 60, appendix B, and quality assurance procedure 6 of 40 CFR part 60, appendix F.

(15) If you are using a CEMS to measure HCl emissions to meet requirements of this subpart, you must install, certify, operate, and maintain the HCl CEMS as specified in paragraphs (a)(15)(i) and (ii) of this section. This option for an affected unit takes effect on the date a final performance specification for an HCl CEMS is published in the **Federal Register** or the date of approval of a site-specific monitoring plan.

(i) Operate the continuous emissions monitoring system in accordance with the applicable performance specification in 40 CFR part 60, appendix B. The duration of the performance test must be the maximum of 30 unit operating days or 720 hours. For each day in which the unit operates, you must obtain hourly HCl concentration data, and stack gas volumetric flow rate data.

(ii) If you are using a HCl CEMS, you must install, operate, calibrate, and maintain an instrument for continuously measuring and recording the HCl mass emissions rate to the atmosphere according to the requirements of the applicable performance specification of 40 CFR part 60, appendix B, and the quality assurance procedures of 40 CFR part 60, appendix F.

(16) If you demonstrate compliance with an applicable TSM emission limit through performance testing, and you plan to burn a new type of fuel or a new mixture of fuels, you must recalculate the maximum TSM input using Equation 9 of § 63.7530. If the results of recalculating the maximum TSM input using Equation 9 of § 63.7530 are higher than the maximum total selected input level established during the previous performance test, then you must conduct a new performance test within 60 days of burning the new fuel type or fuel mixture according to the procedures in § 63.7520 to demonstrate that the TSM emissions do not exceed the emission limit. You must also establish new operating limits based on this performance test according to the procedures in § 63.7530(b). You are not required to conduct fuel analyses for the fuels described in § 63.7510(a)(2)(i) through (iii). You may exclude the fuels described in § 63.7510(a)(2)(i) through (iii) when recalculating the TSM emission rate.

(17) If you demonstrate compliance with an applicable TSM emission limit through fuel analysis for solid or liquid fuels, and you plan to burn a new type of fuel, you must recalculate the TSM emission rate using Equation 14 of § 63.7530 according to the procedures specified in paragraphs (a)(5)(i) through (iii) of this section. You are not required to conduct fuel analyses for the fuels described in § 63.7510(a)(2)(i) through (iii). You may exclude the fuels described in § 63.7510(a)(2)(i) through (iii) when recalculating the TSM emission rate.

(i) You must determine the TSM concentration for any new fuel type in units of pounds per million Btu, based on supplier data or your own fuel analysis, according to the provisions in your site-specific fuel analysis plan developed according to § 63.7521(b).

(ii) You must determine the new mixture of fuels that will have the highest content of TSM.

(iii) Recalculate the TSM emission rate from your boiler or process heater under these new conditions using Equation 14 of § 63.7530. The recalculated TSM emission rate must be less than the applicable emission limit.

(18) If you demonstrate continuous PM emissions compliance with a PM CPMS you will use a PM CPMS to establish a site-specific operating limit corresponding to the results of the performance test demonstrating compliance with the PM limit. You will conduct your performance test using the test method criteria in Table 5 of this subpart. You will use the PM CPMS to demonstrate continuous compliance with this operating limit. You must repeat the performance test annually and reassess and adjust the site-specific operating limit in accordance with the results of the performance test.

(i) To determine continuous compliance, you must record the PM CPMS output data for all periods when the process is operating and the PM CPMS is not out-of-control. You must demonstrate continuous compliance by using all quality-assured hourly average data collected by the PM CPMS for all operating hours to calculate the arithmetic average operating parameter in units of the operating limit (milliamps) on a 30-day rolling average basis, updated at the end of each new boiler or process heater operating hour.

(ii) For any deviation of the 30-day rolling PM CPMS average value from the established operating parameter limit, you must:

(A) Within 48 hours of the deviation, visually inspect the air pollution control device (APCD);

(B) If inspection of the APCD identifies the cause of the deviation, take corrective action as soon as possible and return the PM CPMS measurement to within the established value; and

(C) Within 30 days of the deviation or at the time of the annual compliance test, whichever comes first, conduct a PM emissions compliance test to determine compliance with the PM emissions limit and to verify or re-establish the CPMS operating limit. You are not required to conduct additional testing for any deviations that occur between the time of the original deviation and the PM emissions compliance test required under this paragraph.

(iii) PM CPMS deviations from the operating limit leading to more than four required performance tests in a 12-month operating period constitute a separate violation of this subpart.

(19) If you choose to comply with the PM filterable emissions limit by using PM CEMS you must install, certify, operate, and maintain a PM CEMS and record the output of the PM CEMS as specified in paragraphs (a)(19)(i) through (vii) of this section. The compliance limit will be expressed as a 30-day rolling average of the numerical emissions limit value applicable for your unit in Tables 1 or 2 or 11 through 13 of this subpart.

(i) Install and certify your PM CEMS according to the procedures and requirements in Performance Specification 11—Specifications and Test Procedures for Particulate Matter Continuous Emission Monitoring Systems at Stationary Sources in Appendix B to part 60 of this chapter, using test criteria outlined in Table V of this rule. The reportable measurement output from the PM CEMS must be expressed in units of the applicable emissions limit (e.g., lb/MMBtu, lb/MWh).

(ii) Operate and maintain your PM CEMS according to the procedures and requirements in Procedure 2— Quality Assurance Requirements for Particulate Matter Continuous Emission Monitoring Systems at Stationary Sources in Appendix F to part 60 of this chapter.

(A) You must conduct the relative response audit (RRA) for your PM CEMS at least once annually.

(B) You must conduct the relative correlation audit (RCA) for your PM CEMS at least once every 3 years.

(iii) Collect PM CEMS hourly average output data for all boiler operating hours except as indicated in paragraph (i) of this section.

(iv) Calculate the arithmetic 30-day rolling average of all of the hourly average PM CEMS output data collected during all nonexempt boiler or process heater operating hours.

(v) You must collect data using the PM CEMS at all times the unit is operating and at the intervals specified this paragraph (a), except for periods of monitoring system malfunctions, repairs associated with monitoring system malfunctions, and required monitoring system quality assurance or quality control activities.

(vi) You must use all the data collected during all boiler or process heater operating hours in assessing the compliance with your operating limit except:

(A) Any data collected during monitoring system malfunctions, repairs associated with monitoring system malfunctions, or required monitoring system quality assurance or control activities conducted during monitoring system malfunctions in calculations and report any such periods in your annual deviation report;

(B) Any data collected during periods when the monitoring system is out of control as specified in your site-specific monitoring plan, repairs associated with periods when the monitoring system is out of control, or required monitoring system quality assurance or control activities conducted during out of control periods in calculations used to report emissions or operating levels and report any such periods in your annual deviation report;

(C) Any data recorded during periods of startup or shutdown.

(vii) You must record and make available upon request results of PM CEMS system performance audits, dates and duration of periods when the PM CEMS is out of control to completion of the corrective actions necessary to return the PM CEMS to operation consistent with your site-specific monitoring plan.

(b) You must report each instance in which you did not meet each emission limit and operating limit in Tables 1 through 4 or 11 through 13 to this subpart that apply to you. These instances are deviations from the emission limits or operating limits, respectively, in this subpart. These deviations must be reported according to the requirements in § 63.7550.

(c) If you elected to demonstrate that the unit meets the specification for mercury for the unit designed to burn gas 1 subcategory, you must follow the sampling frequency specified in paragraphs (c)(1) through (4) of this section and conduct this sampling according to the procedures in § 63.7521(f) through (i).

(1) If the initial mercury constituents in the gaseous fuels are measured to be equal to or less than half of the mercury specification as defined in § 63.7575, you do not need to conduct further sampling.

(2) If the initial mercury constituents are greater than half but equal to or less than 75 percent of the mercury specification as defined in § 63.7575, you will conduct semi-annual sampling. If 6 consecutive semi-annual fuel analyses demonstrate 50 percent or less of the mercury specification, you do not need to conduct further sampling. If any semi-annual sample exceeds 75 percent of the mercury specification, you must return to monthly sampling for that fuel, until 12 months of fuel analyses again are less than 75 percent of the compliance level.

(3) If the initial mercury constituents are greater than 75 percent of the mercury specification as defined in § 63.7575, you will conduct monthly sampling. If 12 consecutive monthly fuel analyses demonstrate 75 percent or less of the mercury specification, you may decrease the fuel analysis frequency to semi-annual for that fuel.

(4) If the initial sample exceeds the mercury specification as defined in § 63.7575, each affected boiler or process heater combusting this fuel is not part of the unit designed to burn gas 1 subcategory and must be in compliance with the emission and operating limits for the appropriate subcategory. You may elect to conduct additional monthly sampling while complying with these emissions and operating limits to demonstrate that the fuel qualifies as another gas 1 fuel. If 12 consecutive monthly fuel analyses samples are at or below the mercury specification as defined in § 63.7575, each affected boiler or process heater combusting the fuel can elect to switch back into the unit designed to burn gas 1 subcategory until the mercury specification is exceeded.

(d) For startup and shutdown, you must meet the work practice standards according to item 5 of Table 3 of this subpart.

■ 22. Section 63.7541 is amended by revising paragraphs (a)(3) and (4) to read as follows:

§ 63.7541 How do I demonstrate continuous compliance under the emissions averaging provision?

* * * * *

(a) * * *

(3) For each existing unit participating in the emissions averaging option that is equipped with a wet scrubber, maintain the 30-day rolling average parameter values at or above the operating limits established during the most recent performance test.

(4) For each existing unit participating in the emissions averaging option that has an approved alternative operating parameter, maintain the 30-day rolling

average parameter values consistent with the approved monitoring plan.

* * * * *

■ 23. Section 63.7545 is amended by:
■ a. Revising paragraphs (a) through (c).
■ b. Revising paragraphs (e) introductory text, (e)(1), (e)(2), (e)(3), (e)(4), (e)(5) introductory text, and (e)(5)(i).
■ c. Adding paragraph (e)(5)(ii).
■ d. Revising paragraphs (e)(8)(i) and (iii).
■ e. Revising paragraph (f) introductory text.
■ f. Revising paragraphs (g)(1) and (2).
■ g. Revising paragraphs (h) introductory text and (h)(1) and (3).
■ h. Removing paragraph (h)(4).

The revisions and addition read as follows:

§ 63.7545 What notifications must I submit and when?

(a) You must submit to the Administrator all of the notifications in §§ 63.7(b) and (c), 63.8(e), (f)(4) and (6), and 63.9(b) through (h) that apply to you by the dates specified.

(b) As specified in § 63.9(b)(2), if you startup your affected source before January 31, 2013, you must submit an Initial Notification not later than 120 days after January 31, 2013.

(c) As specified in § 63.9(b)(4) and (5), if you startup your new or reconstructed affected source on or after January 31, 2013, you must submit an Initial Notification not later than 15 days after the actual date of startup of the affected source.

* * * * *

(e) If you are required to conduct an initial compliance demonstration as specified in § 63.7530, you must submit a Notification of Compliance Status according to § 63.9(h)(2)(ii). For the initial compliance demonstration for each boiler or process heater, you must submit the Notification of Compliance Status, including all performance test results and fuel analyses, before the close of business on the 60th day following the completion of all performance test and/or other initial compliance demonstrations for all boiler or process heaters at the facility according to § 63.10(d)(2). The Notification of Compliance Status report must contain all the information specified in paragraphs (e)(1) through (8), as applicable. If you are not required to conduct an initial compliance demonstration as specified in § 63.7530(a), the Notification of Compliance Status must only contain the information specified in paragraphs (e)(1) and (8).

(1) A description of the affected unit(s) including identification of which subcategories the unit is in, the design heat input capacity of the unit, a description of the add-on controls used on the unit to comply with this subpart, description of the fuel(s) burned, including whether the fuel(s) were a secondary material determined by you or the EPA through a petition process to be a non-waste under § 241.3 of this chapter, whether the fuel(s) were a secondary material processed from discarded non-hazardous secondary materials within the meaning of § 241.3 of this chapter, and justification for the selection of fuel(s) burned during the compliance demonstration.

(2) Summary of the results of all performance tests and fuel analyses, and calculations conducted to demonstrate initial compliance including all established operating limits, and including:

(i) Identification of whether you are complying with the PM emission limit or the alternative TSM emission limit.

(ii) Identification of whether you are complying with the output-based emission limits or the heat input-based (i.e., lb/MMBtu or ppm) emission limits,

(3) A summary of the maximum CO emission levels recorded during the performance test to show that you have met any applicable emission standard in Tables 1, 2, or 11 through 13 to this subpart, if you are not using a CO CEMS to demonstrate compliance.

(4) Identification of whether you plan to demonstrate compliance with each applicable emission limit through performance testing, a CEMS, or fuel analysis.

(5) Identification of whether you plan to demonstrate compliance by emissions averaging and identification of whether you plan to demonstrate compliance by using efficiency credits through energy conservation:

(i) If you plan to demonstrate compliance by emission averaging, report the emission level that was being achieved or the control technology employed on January 31, 2013.

(ii) [Reserved]

* * * * *

(8) * * *

(i) ''This facility complies with the required initial tune-up according to the procedures in § 63.7540(a)(10)(i) through (vi).''

* * * * *

(iii) Except for units that burn only natural gas, refinery gas, or other gas 1 fuel, or units that qualify for a statutory exemption as provided in section 129(g)(1) of the Clean Air Act, include the following: ''No secondary materials that are solid waste were combusted in any affected unit.''

(f) If you operate a unit designed to burn natural gas, refinery gas, or other gas 1 fuels that is subject to this subpart, and you intend to use a fuel other than natural gas, refinery gas, gaseous fuel subject to another subpart of this part, part 60, 61, or 65, or other gas 1 fuel to fire the affected unit during a period of natural gas curtailment or supply interruption, as defined in § 63.7575, you must submit a notification of alternative fuel use within 48 hours of the declaration of each period of natural gas curtailment or supply interruption, as defined in § 63.7575. The notification must include the information specified in paragraphs (f)(1) through (5) of this section.

* * * * *

(g) * * *

(1) The name of the owner or operator of the affected source, as defined in § 63.7490, the location of the source, the boiler(s) or process heater(s) that will commence burning solid waste, and the date of the notice.

(2) The currently applicable subcategories under this subpart.

* * * * *

(h) If you have switched fuels or made a physical change to the boiler and the fuel switch or physical change resulted in the applicability of a different subcategory, you must provide notice of the date upon which you switched fuels or made the physical change within 30 days of the switch/change. The notification must identify:

(1) The name of the owner or operator of the affected source, as defined in § 63.7490, the location of the source, the boiler(s) and process heater(s) that have switched fuels, were physically changed, and the date of the notice.

* * * * *

(3) The date upon which the fuel switch or physical change occurred.

■ 24. Section 63.7550 is revised to read as follows:

§ 63.7550 What reports must I submit and when?

(a) You must submit each report in Table 9 to this subpart that applies to you.

(b) Unless the EPA Administrator has approved a different schedule for submission of reports under § 63.10(a), you must submit each report, according to paragraph (h) of this section, by the date in Table 9 to this subpart and according to the requirements in paragraphs (b)(1) through (4) of this section. For units that are subject only to a requirement to conduct an annual, biennial, or 5-year tune-up according to § 63.7540(a)(10), (11), or (12), respectively, and not subject to emission

limits or operating limits, you may submit only an annual, biennial, or 5-year compliance report, as applicable, as specified in paragraphs (b)(1) through (4) of this section, instead of a semi-annual compliance report.

(1) The first compliance report must cover the period beginning on the compliance date that is specified for each boiler or process heater in § 63.7495 and ending on July 31 or January 31, whichever date is the first date that occurs at least 180 days (or 1, 2, or 5 years, as applicable, if submitting an annual, biennial, or 5-year compliance report) after the compliance date that is specified for your source in § 63.7495.

(2) The first compliance report must be postmarked or submitted no later than July 31 or January 31, whichever date is the first date following the end of the first calendar half after the compliance date that is specified for each boiler or process heater in § 63.7495. The first annual, biennial, or 5-year compliance report must be postmarked or submitted no later than January 31.

(3) Each subsequent compliance report must cover the semiannual reporting period from January 1 through June 30 or the semiannual reporting period from July 1 through December 31. Annual, biennial, and 5-year compliance reports must cover the applicable 1-, 2-, or 5-year periods from January 1 to December 31.

(4) Each subsequent compliance report must be postmarked or submitted no later than July 31 or January 31, whichever date is the first date following the end of the semiannual reporting period. Annual, biennial, and 5-year compliance reports must be postmarked or submitted no later than January 31.

(c) A compliance report must contain the following information depending on how the facility chooses to comply with the limits set in this rule.

(1) If the facility is subject to a the requirements of a tune up they must submit a compliance report with the information in paragraphs (c)(5)(i) through (iv) and (xiv) of this section.

(2) If a facility is complying with the fuel analysis they must submit a compliance report with the information in paragraphs (c)(5)(i) through (iv), (vi), (x), (xi), (xiii), (xv) and paragraph (d) of this section.

(3) If a facility is complying with the applicable emissions limit with performance testing they must submit a compliance report with the information in (c)(5)(i) through (iv), (vi), (vii), (ix), (xi), (xiii), (xv) and paragraph (d) of this section.

(4) If a facility is complying with an emissions limit using a CMS the compliance report must contain the information required in paragraphs (c)(5)(i) through (vi), (xi), (xiii), (xv) through (xvii), and paragraph (e) of this section.

(5)(i) Company and Facility name and address.

(ii) Process unit information, emissions limitations, and operating parameter limitations.

(iii) Date of report and beginning and ending dates of the reporting period.

(iv) The total operating time during the reporting period.

(v) If you use a CMS, including CEMS, COMS, or CPMS, you must include the monitoring equipment manufacturer(s) and model numbers and the date of the last CMS certification or audit.

(vi) The total fuel use by each individual boiler or process heater subject to an emission limit within the reporting period, including, but not limited to, a description of the fuel, whether the fuel has received a non-waste determination by the EPA or your basis for concluding that the fuel is not a waste, and the total fuel usage amount with units of measure.

(vii) If you are conducting performance tests once every 3 years consistent with § 63.7515(b) or (c), the date of the last 2 performance tests and a statement as to whether there have been any operational changes since the last performance test that could increase emissions.

(viii) A statement indicating that you burned no new types of fuel in an individual boiler or process heater subject to an emission limit. Or, if you did burn a new type of fuel and are subject to a HCl emission limit, you must submit the calculation of chlorine input, using Equation 7 of § 63.7530, that demonstrates that your source is still within its maximum chlorine input level established during the previous performance testing (for sources that demonstrate compliance through performance testing) or you must submit the calculation of HCl emission rate using Equation 12 of § 63.7530 that demonstrates that your source is still meeting the emission limit for HCl emissions (for boilers or process heaters that demonstrate compliance through fuel analysis). If you burned a new type of fuel and are subject to a mercury emission limit, you must submit the calculation of mercury input, using Equation 8 of § 63.7530, that demonstrates that your source is still within its maximum mercury input level established during the previous performance testing (for sources that demonstrate compliance through performance testing), or you must submit the calculation of mercury emission rate using Equation 13 of § 63.7530 that demonstrates that your source is still meeting the emission limit for mercury emissions (for boilers or process heaters that demonstrate compliance through fuel analysis). If you burned a new type of fuel and are subject to a TSM emission limit, you must submit the calculation of TSM input, using Equation 9 of § 63.7530, that demonstrates that your source is still within its maximum TSM input level established during the previous performance testing (for sources that demonstrate compliance through performance testing), or you must submit the calculation of TSM emission rate, using Equation 14 of § 63.7530, that demonstrates that your source is still meeting the emission limit for TSM emissions (for boilers or process heaters that demonstrate compliance through fuel analysis).

(ix) If you wish to burn a new type of fuel in an individual boiler or process heater subject to an emission limit and you cannot demonstrate compliance with the maximum chlorine input operating limit using Equation 7 of § 63.7530 or the maximum mercury input operating limit using Equation 8 of § 63.7530, or the maximum TSM input operating limit using Equation 9 of § 63.7530 you must include in the compliance report a statement indicating the intent to conduct a new performance test within 60 days of starting to burn the new fuel.

(x) A summary of any monthly fuel analyses conducted to demonstrate compliance according to §§ 63.7521 and 63.7530 for individual boilers or process heaters subject to emission limits, and any fuel specification analyses conducted according to §§ 63.7521(f) and 63.7530(g).

(xi) If there are no deviations from any emission limits or operating limits in this subpart that apply to you, a statement that there were no deviations from the emission limits or operating limits during the reporting period.

(xii) If there were no deviations from the monitoring requirements including no periods during which the CMSs, including CEMS, COMS, and CPMS, were out of control as specified in § 63.8(c)(7), a statement that there were no deviations and no periods during which the CMS were out of control during the reporting period.

(xiii) If a malfunction occurred during the reporting period, the report must include the number, duration, and a brief description for each type of malfunction which occurred during the reporting period and which caused or

may have caused any applicable emission limitation to be exceeded. The report must also include a description of actions taken by you during a malfunction of a boiler, process heater, or associated air pollution control device or CMS to minimize emissions in accordance with § 63.7500(a)(3), including actions taken to correct the malfunction.

(xiv) Include the date of the most recent tune-up for each unit subject to only the requirement to conduct an annual, biennial, or 5-year tune-up according to § 63.7540(a)(10), (11), or (12) respectively. Include the date of the most recent burner inspection if it was not done annually, biennially, or on a 5-year period and was delayed until the next scheduled or unscheduled unit shutdown.

(xv) If you plan to demonstrate compliance by emission averaging, certify the emission level achieved or the control technology employed is no less stringent than the level or control technology contained in the notification of compliance status in § 63.7545(e)(5)(i).

(xvi) For each reporting period, the compliance reports must include all of the calculated 30 day rolling average values based on the daily CEMS (CO and mercury) and CPMS (PM CPMS output, scrubber pH, scrubber liquid flow rate, scrubber pressure drop) data.

(xvii) Statement by a responsible official with that official's name, title, and signature, certifying the truth, accuracy, and completeness of the content of the report.

(d) For each deviation from an emission limit or operating limit in this subpart that occurs at an individual boiler or process heater where you are not using a CMS to comply with that emission limit or operating limit, the compliance report must additionally contain the information required in paragraphs (d)(1) through (3) of this section.

(1) A description of the deviation and which emission limit or operating limit from which you deviated.

(2) Information on the number, duration, and cause of deviations (including unknown cause), as applicable, and the corrective action taken.

(3) If the deviation occurred during an annual performance test, provide the date the annual performance test was completed.

(e) For each deviation from an emission limit, operating limit, and monitoring requirement in this subpart occurring at an individual boiler or process heater where you are using a CMS to comply with that emission limit or operating limit, the compliance report must additionally contain the information required in paragraphs (e)(1) through (9) of this section. This includes any deviations from your site-specific monitoring plan as required in § 63.7505(d).

(1) The date and time that each deviation started and stopped and description of the nature of the deviation (i.e., what you deviated from).

(2) The date and time that each CMS was inoperative, except for zero (low-level) and high-level checks.

(3) The date, time, and duration that each CMS was out of control, including the information in § 63.8(c)(8).

(4) The date and time that each deviation started and stopped.

(5) A summary of the total duration of the deviation during the reporting period and the total duration as a percent of the total source operating time during that reporting period.

(6) A characterization of the total duration of the deviations during the reporting period into those that are due to control equipment problems, process problems, other known causes, and other unknown causes.

(7) A summary of the total duration of CMS's downtime during the reporting period and the total duration of CMS downtime as a percent of the total source operating time during that reporting period.

(8) A brief description of the source for which there was a deviation.

(9) A description of any changes in CMSs, processes, or controls since the last reporting period for the source for which there was a deviation.

(f) [Reserved]

(g) [Reserved]

(h) You must submit the reports according to the procedures specified in paragraphs (h)(1) through (3) of this section.

(1) Within 60 days after the date of completing each performance test (defined in § 63.2) as required by this subpart you must submit the results of the performance tests, including any associated fuel analyses, required by this subpart and the compliance reports required in § 63.7550(b) to the EPA's WebFIRE database by using the Compliance and Emissions Data Reporting Interface (CEDRI) that is accessed through the EPA's Central Data Exchange (CDX) (*www.epa.gov/cdx*). Performance test data must be submitted in the file format generated through use of the EPA's Electronic Reporting Tool (ERT) (see *http://www.epa.gov/ttn/chief/ert/index.html*). Only data collected using test methods on the ERT Web site are subject to this requirement for submitting reports electronically to WebFIRE. Owners or operators who claim that some of the information being submitted for performance tests is confidential business information (CBI) must submit a complete ERT file including information claimed to be CBI on a compact disk or other commonly used electronic storage media (including, but not limited to, flash drives) to the EPA. The electronic media must be clearly marked as CBI and mailed to U.S. EPA/OAPQS/CORE CBI Office, Attention: WebFIRE Administrator, MD C404–02, 4930 Old Page Rd., Durham, NC 27703. The same ERT file with the CBI omitted must be submitted to the EPA via CDX as described earlier in this paragraph. At the discretion of the Administrator, you must also submit these reports, including the confidential business information, to the Administrator in the format specified by the Administrator. For any performance test conducted using test methods that are not listed on the ERT Web site, the owner or operator shall submit the results of the performance test in paper submissions to the Administrator.

(2) Within 60 days after the date of completing each CEMS performance evaluation test (defined in 63.2) you must submit the relative accuracy test audit (RATA) data to the EPA's Central Data Exchange by using CEDRI as mentioned in paragraph (h)(1) of this section. Only RATA pollutants that can be documented with the ERT (as listed on the ERT Web site) are subject to this requirement. For any performance evaluations with no corresponding RATA pollutants listed on the ERT Web site, the owner or operator shall submit the results of the performance evaluation in paper submissions to the Administrator.

(3) You must submit all reports required by Table 9 of this subpart electronically using CEDRI that is accessed through the EPA's Central Data Exchange (CDX) (*www.epa.gov/cdx*). However, if the reporting form specific to this subpart is not available in CEDRI at the time that the report is due the report you must submit the report to the Administrator at the appropriate address listed in § 63.13. At the discretion of the Administrator, you must also submit these reports, to the Administrator in the format specified by the Administrator.

■ 25. Section 63.7555 is amended by:

■ a. Revising paragraphs (d) introductory text and (d)(2) through (6).

■ b. Adding paragraphs (d)(9) through (11).

■ c. Revising paragraphs (f) through (h).

■ d. Adding paragraphs (i) and (j).

The revisions and additions read as follows:

§ 63.7555 What records must I keep?

* * * * *

(d) For each boiler or process heater subject to an emission limit in Tables 1, 2, or 11 through 13 to this subpart, you must also keep the applicable records in paragraphs (d)(1) through (11) of this section.

* * * * *

(2) If you combust non-hazardous secondary materials that have been determined not to be solid waste pursuant to § 241.3(b)(1) and (2) of this chapter, you must keep a record that documents how the secondary material meets each of the legitimacy criteria under § 241.3(d)(1) of this chapter. If you combust a fuel that has been processed from a discarded non-hazardous secondary material pursuant to § 241.3(b)(4) of this chapter, you must keep records as to how the operations that produced the fuel satisfy the definition of processing in § 241.2 of this chapter. If the fuel received a non-waste determination pursuant to the petition process submitted under § 241.3(c) of this chapter, you must keep a record that documents how the fuel satisfies the requirements of the petition process. For operating units that combust non-hazardous secondary materials as fuel per § 241.4 of this chapter, you must keep records documenting that the material is listed as a non-waste under § 241.4(a) of this chapter. Units exempt from the incinerator standards under section 129(g)(1) of the Clean Air Act because they are qualifying facilities burning a homogeneous waste stream do not need to maintain the records described in this paragraph (d)(2).

(3) For units in the limited use subcategory, you must keep a copy of the federally enforceable permit that limits the annual capacity factor to less than or equal to 10 percent and fuel use records for the days the boiler or process heater was operating.

(4) A copy of all calculations and supporting documentation of maximum chlorine fuel input, using Equation 7 of § 63.7530, that were done to demonstrate continuous compliance with the HCl emission limit, for sources that demonstrate compliance through performance testing. For sources that demonstrate compliance through fuel analysis, a copy of all calculations and supporting documentation of HCl emission rates, using Equation 12 of § 63.7530, that were done to demonstrate compliance with the HCl emission limit. Supporting documentation should include results of any fuel analyses and basis for the estimates of maximum chlorine fuel input or HCl emission rates. You can use the results from one fuel analysis for multiple boilers and process heaters provided they are all burning the same fuel type. However, you must calculate chlorine fuel input, or HCl emission rate, for each boiler and process heater.

(5) A copy of all calculations and supporting documentation of maximum mercury fuel input, using Equation 8 of § 63.7530, that were done to demonstrate continuous compliance with the mercury emission limit for sources that demonstrate compliance through performance testing. For sources that demonstrate compliance through fuel analysis, a copy of all calculations and supporting documentation of mercury emission rates, using Equation 13 of § 63.7530, that were done to demonstrate compliance with the mercury emission limit. Supporting documentation should include results of any fuel analyses and basis for the estimates of maximum mercury fuel input or mercury emission rates. You can use the results from one fuel analysis for multiple boilers and process heaters provided they are all burning the same fuel type. However, you must calculate mercury fuel input, or mercury emission rates, for each boiler and process heater.

(6) If, consistent with § 63.7515(b), you choose to stack test less frequently than annually, you must keep a record that documents that your emissions in the previous stack test(s) were less than 75 percent of the applicable emission limit (or, in specific instances noted in Tables 1 and 2 or 11 through 13 to this subpart, less than the applicable emission limit), and document that there was no change in source operations including fuel composition and operation of air pollution control equipment that would cause emissions of the relevant pollutant to increase within the past year.

* * * * *

(9) A copy of all calculations and supporting documentation of maximum TSM fuel input, using Equation 9 of § 63.7530, that were done to demonstrate continuous compliance with the TSM emission limit for sources that demonstrate compliance through performance testing. For sources that demonstrate compliance through fuel analysis, a copy of all calculations and supporting documentation of TSM emission rates, using Equation 14 of § 63.7530, that were done to demonstrate compliance with the TSM emission limit. Supporting documentation should include results of any fuel analyses and basis for the estimates of maximum TSM fuel input or TSM emission rates. You can use the results from one fuel analysis for multiple boilers and process heaters provided they are all burning the same fuel type. However, you must calculate TSM fuel input, or TSM emission rates, for each boiler and process heater.

(10) You must maintain records of the calendar date, time, occurrence and duration of each startup and shutdown.

(11) You must maintain records of the type(s) and amount(s) of fuels used during each startup and shutdown.

* * * * *

(f) If you elect to use efficiency credits from energy conservation measures to demonstrate compliance according to § 63.7533, you must keep a copy of the Implementation Plan required in § 63.7533(d) and copies of all data and calculations used to establish credits according to § 63.7533(b), (c), and (f).

(g) If you elected to demonstrate that the unit meets the specification for mercury for the unit designed to burn gas 1 subcategory, you must maintain monthly records (or at the frequency required by § 63.7540(c)) of the calculations and results of the fuel specification for mercury in Table 6.

(h) If you operate a unit in the unit designed to burn gas 1 subcategory that is subject to this subpart, and you use an alternative fuel other than natural gas, refinery gas, gaseous fuel subject to another subpart under this part, other gas 1 fuel, or gaseous fuel subject to another subpart of this part or part 60, 61, or 65, you must keep records of the total hours per calendar year that alternative fuel is burned and the total hours per calendar year that the unit operated during periods of gas curtailment or gas supply emergencies.

(i) You must maintain records of the calendar date, time, occurrence and duration of each startup and shutdown.

(j) You must maintain records of the type(s) and amount(s) of fuels used during each startup and shutdown.

■ 26. Section 63.7570 is amended by revising paragraph (a) and paragraph (b) introductory text to read as follows:

§ 63.7570 Who implements and enforces this subpart?

(a) This subpart can be implemented and enforced by the EPA, or an Administrator such as your state, local, or tribal agency. If the EPA Administrator has delegated authority to your state, local, or tribal agency, then that agency (as well as the EPA) has the authority to implement and enforce this subpart. You should contact your EPA Regional Office to find out if this

subpart is delegated to your state, local, or tribal agency.

(b) In delegating implementation and enforcement authority of this subpart to a state, local, or tribal agency under 40 CFR part 63, subpart E, the authorities listed in paragraphs (b)(1) through (5) of this section are retained by the EPA Administrator and are not transferred to the state, local, or tribal agency, however, the EPA retains oversight of this subpart and can take enforcement actions, as appropriate.

* * * * *

■ 27. Section 63.7575 is amended by:

■ a. Adding in alphabetical order definitions for ''10-day rolling average,'' ''30-day rolling average,'' ''Annual capacity factor,'' ''Average annual heat input rate,'' ''Benchmark,'' ''Biodiesel,'' ''Daily block average,'' ''Efficiency credit,'' ''Energy management program,'' ''Fluidized bed boiler with an integrated fluidized bed heat exchanger,'' ''Heavy liquid,'' ''Light liquid,'' '' ''Major source for oil and natural gas production facilities,'' ''Minimum oxygen level,'' ''Other combustor'', ''Oxygen analyzer system'', ''Oxygen trim system'', ''Pile burner'', ''Regulated gas stream'', ''Residential boiler,'' ''Residual oil'', ''Secondary material,'' ''Shutdown'', ''Sloped grate'', ''Startup'', ''Stoker/sloped grate/other unit designed to burn kiln dried biomass,'' Stoker/sloped grate/other unit designed to burn wet biomass,'' ''Suspension burner,'' ''Total selected metals (TSM),'' ''Traditional fuel,'' ''Ultra low sulfur liquid fuel,'' ''Unit designed to burn heavy liquid subcategory,'' ''Unit designed to burn light liquid subcategory,'' and ''Vegetable oil.''

■ b. Revising the definitions for ''Boiler,'' ''Boiler system,'' ''Coal,'' Commercial/institutional boiler,'' ''Deviation,'' ''Distillate oil,'' ''Dry scrubber,'' ''Dutch oven,'' ''Electric utility steam generating unit,'' ''Energy assessment,'' ''Energy use system,'' ''Equivalent,'' ''Federally enforceable,'' ''Fluidized bed boiler'', ''Fuel cell,'' ''Fuel type,'' ''Gaseous fuel,'' ''Heat input,'' ''Hot water heater,'' ''Hybrid suspension grate boiler,'' ''Industrial boiler,'' ''Limited-use boiler or process heater,'' ''Liquid fuel,'' ''Load fraction,'' ''Metal process furnaces,'' ''Minimum activated carbon injection rate,'' ''Minimum scrubber liquid flow rate,'' ''Minimum sorbent injection rate,'' ''Natural gas,'' ''Other gas 1 fuel,'' ''Period of natural gas curtailment or supply interruption,'' ''Process heater,'' ''Qualified energy assessor,'' ''Residual oil,'' ''Solid fossil fuel,'' ''Steam output,'' ''Stoker,'' ''Temporary boiler,'' ''Tune-up,'' ''Unit designed to burn gas 1 subcategory,'' ''Unit designed to burn gas 2 (other) subcategory,'' ''Unit designed to burn liquid subcategory,'' ''Unit designed to burn liquid fuel that is a non-continental unit,'' ''Unit designed to burn solid fuel,'' ''Waste heat boiler,'' ''Waste heat process heater.''

■ c. Removing the definitions for ''Benchmarking,'' ''Emission credit,'' ''Liquid fuel subcategory,'' and ''Suspension boiler.''

The revisions read as follows:

§ 63.7575 What definitions apply to this subpart?

* * * * *

10-day rolling average means the arithmetic mean of the previous 240 hours of valid operating data. Valid data excludes hours during startup and shutdown, data collected during periods when the monitoring system is out of control as specified in your site-specific monitoring plan, while conducting repairs associated with periods when the monitoring system is out of control, or while conducting required monitoring system quality assurance or quality control activities, and periods when this unit is not operating. The 240 hours should be consecutive, but not necessarily continuous if operations were intermittent.

30-day rolling average means the arithmetic mean of the previous 720 hours of valid operating data. Valid data excludes hours during startup and shutdown, data collected during periods when the monitoring system is out of control as specified in your site-specific monitoring plan, while conducting repairs associated with periods when the monitoring system is out of control, or while conducting required monitoring system quality assurance or quality control activities, and periods when this unit is not operating. The 720 hours should be consecutive, but not necessarily continuous if operations were intermittent.

* * * * *

Annual capacity factor means the ratio between the actual heat input to a boiler or process heater from the fuels burned during a calendar year and the potential heat input to the boiler or process heater had it been operated for 8,760 hours during a year at the maximum steady state design heat input capacity.

Average annual heat input rate means total heat input divided by the hours of operation for the 12 months preceding the compliance demonstration.

* * * * *

Benchmark means the fuel heat input for a boiler or process heater for the one-year period before the date that an energy demand reduction occurs, unless it can be demonstrated that a different time period is more representative of historical operations.

Biodiesel means a mono-alkyl ester derived from biomass and conforming to ASTM D6751–11b, Standard Specification for Biodiesel Fuel Blend Stock (B100) for Middle Distillate Fuels (incorporated by reference, see § 63.14).

* * * * *

Boiler means an enclosed device using controlled flame combustion and having the primary purpose of recovering thermal energy in the form of steam or hot water. Controlled flame combustion refers to a steady-state, or near steady-state, process wherein fuel and/or oxidizer feed rates are controlled. A device combusting solid waste, as defined in § 241.3 of this chapter, is not a boiler unless the device is exempt from the definition of a solid waste incineration unit as provided in section 129(g)(1) of the Clean Air Act. Waste heat boilers are excluded from this definition.

Boiler system means the boiler and associated components, such as, the feed water system, the combustion air system, the fuel system (including burners), blowdown system, combustion control systems, steam systems, and condensate return systems.

* * * * *

Coal means all solid fuels classifiable as anthracite, bituminous, sub-bituminous, or lignite by ASTM D388 (incorporated by reference, see § 63.14), coal refuse, and petroleum coke. For the purposes of this subpart, this definition of ''coal'' includes synthetic fuels derived from coal, including but not limited to, solvent-refined coal, coal-oil mixtures, and coal-water mixtures. Coal derived gases are excluded from this definition.

* * * * *

Commercial/institutional boiler means a boiler used in commercial establishments or institutional establishments such as medical centers, nursing homes, research centers, institutions of higher education, elementary and secondary schools, libraries, religious establishments, governmental buildings, hotels, restaurants, and laundries to provide electricity, steam, and/or hot water.

* * * * *

Daily block average means the arithmetic mean of all valid emission concentrations or parameter levels recorded when a unit is operating measured over the 24-hour period from 12 a.m. (midnight) to 12 a.m. (midnight), except for periods of startup and shutdown or downtime.

Deviation.

(1) *Deviation* means any instance in which an affected source subject to this subpart, or an owner or operator of such a source:

(i) Fails to meet any applicable requirement or obligation established by this subpart including, but not limited to, any emission limit, operating limit, or work practice standard; or

(ii) Fails to meet any term or condition that is adopted to implement an applicable requirement in this subpart and that is included in the operating permit for any affected source required to obtain such a permit.

(2) A deviation is not always a violation.

* * * * *

Distillate oil means fuel oils that contain 0.05 weight percent nitrogen or less and comply with the specifications for fuel oil numbers 1 and 2, as defined by the American Society of Testing and Materials in ASTM D396 (incorporated by reference, see § 63.14) or diesel fuel oil numbers 1 and 2, as defined by the American Society for Testing and Materials in ASTM D975 (incorporated by reference, see § 63.14), kerosene, and biodiesel as defined by the American Society of Testing and Materials in ASTM D6751–11b (incorporated by reference, see § 60.14).

Dry scrubber means an add-on air pollution control system that injects dry alkaline sorbent (dry injection) or sprays an alkaline sorbent (spray dryer) to react with and neutralize acid gas in the exhaust stream forming a dry powder material. Sorbent injection systems used as control devices in fluidized bed boilers and process heaters are included in this definition. A dry scrubber is a dry control system.

Dutch oven means a unit having a refractory-walled cell connected to a conventional boiler setting. Fuel materials are introduced through an opening in the roof of the dutch oven and burn in a pile on its floor. Fluidized bed boilers are not part of the dutch oven design category.

Electric utility steam generating unit (EGU) means a fossil fuel-fired combustion unit of more than 25 megawatts electric (MWe) that serves a generator that produces electricity for sale. A fossil fuel-fired unit that cogenerates steam and electricity and supplies more than one-third of its potential electric output capacity and more than 25 MWe output to any utility power distribution system for sale is considered an electric utility steam generating unit. To be ''capable of combusting'' fossil fuels, an EGU would need to have these fuels allowed in their operating permits and have the appropriate fuel handling facilities on-site or otherwise available (e.g., coal handling equipment, including coal storage area, belts and conveyers, pulverizers, etc.; oil storage facilities). In addition, fossil fuel-fired EGU means any EGU that fired fossil fuel for more than 10.0 percent of the average annual heat input in any 3 consecutive calendar years or for more than 15.0 percent of the annual heat input during any one calendar year after April 16, 2012.

* * * * *

Efficiency credit means emission reductions above those required by this subpart. Efficiency credits generated may be used to comply with the emissions limits. Credits may come from pollution prevention projects that result in reduced fuel use by affected units. Boilers that are shut down cannot be used to generate credits unless the facility provides documentation linking the permanent shutdown to implementation of the energy conservation measures identified in the energy assessment.

Energy assessment means the following for the emission units covered by this subpart:

(1) The energy assessment for facilities with affected boilers and process heaters with a combined heat input capacity of less than 0.3 trillion Btu (TBtu) per year will be 8 on-site technical labor hours in length maximum, but may be longer at the discretion of the owner or operator of the affected source. The boiler system(s) and any on-site energy use system(s) accounting for at least 50 percent of the affected boiler(s) energy (e.g., steam, hot water, process heat, or electricity) production, as applicable, will be evaluated to identify energy savings opportunities, within the limit of performing an 8-hour on-site energy assessment.

(2) The energy assessment for facilities with affected boilers and process heaters with a combined heat input capacity of 0.3 to 1.0 TBtu/year will be 24 on-site technical labor hours in length maximum, but may be longer at the discretion of the owner or operator of the affected source. The boiler system(s) and any on-site energy use system(s) accounting for at least 33 percent of the energy (e.g., steam, hot water, process heat, or electricity) production, as applicable, will be evaluated to identify energy savings opportunities, within the limit of performing a 24-hour on-site energy assessment.

(3) The energy assessment for facilities with affected boilers and process heaters with a combined heat input capacity greater than 1.0 TBtu/year will be up to 24 on-site technical labor hours in length for the first TBtu/yr plus 8 on-site technical labor hours for every additional 1.0 TBtu/yr not to exceed 160 on-site technical hours, but may be longer at the discretion of the owner or operator of the affected source. The boiler system(s), process heater(s), and any on-site energy use system(s) accounting for at least 20 percent of the energy (e.g., steam, process heat, hot water, or electricity) production, as applicable, will be evaluated to identify energy savings opportunities.

(4) The on-site energy use systems serving as the basis for the percent of affected boiler(s) and process heater(s) energy production in paragraphs (1), (2), and (3) of this definition may be segmented by production area or energy use area as most logical and applicable to the specific facility being assessed (e.g., product X manufacturing area; product Y drying area; Building Z).

* * * * *

Energy management program means a program that includes a set of practices and procedures designed to manage energy use that are demonstrated by the facility's energy policies, a facility energy manager and other staffing responsibilities, energy performance measurement and tracking methods, an energy saving goal, action plans, operating procedures, internal reporting requirements, and periodic review intervals used at the facility. Facilities may establish their program through energy management systems compatible with ISO 50001.

Energy use system includes the following systems located on-site that use energy (steam, hot water, or electricity) provided by the affected boiler or process heater: process heating; compressed air systems; machine drive (motors, pumps, fans); process cooling; facility heating, ventilation, and air-conditioning systems; hot water systems; building envelop; and lighting; or other systems that use steam, hot water, process heat, or electricity provided by the affected boiler or process heater. Energy use systems are only those systems using energy clearly produced by affected boilers and process heaters.

Equivalent means the following only as this term is used in Table 6 to this subpart:

(1) An equivalent sample collection procedure means a published voluntary consensus standard or practice (VCS) or EPA method that includes collection of a minimum of three composite fuel samples, with each composite

consisting of a minimum of three increments collected at approximately equal intervals over the test period.

(2) An equivalent sample compositing procedure means a published VCS or EPA method to systematically mix and obtain a representative subsample (part) of the composite sample.

(3) An equivalent sample preparation procedure means a published VCS or EPA method that: Clearly states that the standard, practice or method is appropriate for the pollutant and the fuel matrix; or is cited as an appropriate sample preparation standard, practice or method for the pollutant in the chosen VCS or EPA determinative or analytical method.

(4) An equivalent procedure for determining heat content means a published VCS or EPA method to obtain gross calorific (or higher heating) value.

(5) An equivalent procedure for determining fuel moisture content means a published VCS or EPA method to obtain moisture content. If the sample analysis plan calls for determining metals (especially the mercury, selenium, or arsenic) using an aliquot of the dried sample, then the drying temperature must be modified to prevent vaporizing these metals. On the other hand, if metals analysis is done on an ''as received'' basis, a separate aliquot can be dried to determine moisture content and the metals concentration mathematically adjusted to a dry basis.

(6) An equivalent pollutant (mercury, HCl) determinative or analytical procedure means a published VCS or EPA method that clearly states that the standard, practice, or method is appropriate for the pollutant and the fuel matrix and has a published detection limit equal or lower than the methods listed in Table 6 to this subpart for the same purpose.

* * * * *

Federally enforceable means all limitations and conditions that are enforceable by the EPA Administrator, including, but not limited to, the requirements of 40 CFR parts 60, 61, 63, and 65, requirements within any applicable state implementation plan, and any permit requirements established under 40 CFR 52.21 or under 40 CFR 51.18 and 40 CFR 51.24.

Fluidized bed boiler means a boiler utilizing a fluidized bed combustion process that is not a pulverized coal boiler.

Fluidized bed boiler with an integrated fluidized bed heat exchanger means a boiler utilizing a fluidized bed combustion where the entire tube surface area is located outside of the furnace section at the exit of the cyclone section and exposed to the flue gas stream for conductive heat transfer. This design applies only to boilers in the unit designed to burn coal/solid fossil fuel subcategory that fire coal refuse.

* * * * *

Fuel cell means a boiler type in which the fuel is dropped onto suspended fixed grates and is fired in a pile. The refractory-lined fuel cell uses combustion air preheating and positioning of secondary and tertiary air injection ports to improve boiler efficiency. Fluidized bed, dutch oven, pile burner, hybrid suspension grate, and suspension burners are not part of the fuel cell subcategory.

Fuel type means each category of fuels that share a common name or classification. Examples include, but are not limited to, bituminous coal, sub-bituminous coal, lignite, anthracite, biomass, distillate oil, residual oil. Individual fuel types received from different suppliers are not considered new fuel types.

Gaseous fuel includes, but is not limited to, natural gas, process gas, landfill gas, coal derived gas, refinery gas, and biogas. Blast furnace gas and process gases that are regulated under another subpart of this part, or part 60, part 61, or part 65 of this chapter, are exempted from this definition.

Heat input means heat derived from combustion of fuel in a boiler or process heater and does not include the heat input from preheated combustion air, recirculated flue gases, returned condensate, or exhaust gases from other sources such as gas turbines, internal combustion engines, kilns, etc.

Heavy liquid includes residual oil and any other liquid fuel not classified as a light liquid.

* * * * *

Hot water heater means a closed vessel with a capacity of no more than 120 U.S. gallons in which water is heated by combustion of gaseous, liquid, or biomass/bio-based solid fuel and is withdrawn for use external to the vessel. Hot water boilers (i.e., not generating steam) combusting gaseous, liquid, or biomass fuel with a heat input capacity of less than 1.6 million Btu per hour are included in this definition. The 120 U.S. gallon capacity threshold to be considered a hot water heater is independent of the 1.6 MMBtu/hr heat input capacity threshold for hot water boilers. Hot water heater also means a tankless unit that provides on demand hot water.

Hybrid suspension grate boiler means a boiler designed with air distributors to spread the fuel material over the entire width and depth of the boiler combustion zone. The biomass fuel combusted in these units exceeds a moisture content of 40 percent on an as-fired annual heat input basis. The drying and much of the combustion of the fuel takes place in suspension, and the combustion is completed on the grate or floor of the boiler. Fluidized bed, dutch oven, and pile burner designs are not part of the hybrid suspension grate boiler design category.

Industrial boiler means a boiler used in manufacturing, processing, mining, and refining or any other industry to provide steam, hot water, and/or electricity.

Light liquid includes distillate oil, biodiesel, or vegetable oil.

Limited-use boiler or process heater means any boiler or process heater that burns any amount of solid, liquid, or gaseous fuels and has a federally enforceable average annual capacity factor of no more than 10 percent.

Liquid fuel includes, but is not limited to, light liquid, heavy liquid, any form of liquid fuel derived from petroleum, used oil, liquid biofuels, biodiesel, vegetable oil, and comparable fuels as defined under 40 CFR 261.38.

Load fraction means the actual heat input of a boiler or process heater divided by heat input during the performance test that established the minimum sorbent injection rate or minimum activated carbon injection rate, expressed as a fraction (e.g., for 50 percent load the load fraction is 0.5).

Major source for oil and natural gas production facilities, as used in this subpart, shall have the same meaning as in § 63.2, except that:

(1) Emissions from any oil or gas exploration or production well (with its associated equipment, as defined in this section), and emissions from any pipeline compressor station or pump station shall not be aggregated with emissions from other similar units to determine whether such emission points or stations are major sources, even when emission points are in a contiguous area or under common control;

(2) Emissions from processes, operations, or equipment that are not part of the same facility, as defined in this section, shall not be aggregated; and

(3) For facilities that are production field facilities, only HAP emissions from glycol dehydration units and storage vessels with the potential for flash emissions shall be aggregated for a major source determination. For facilities that are not production field facilities, HAP emissions from all HAP emission units shall be aggregated for a major source determination.

Metal process furnaces are a subcategory of process heaters, as defined in this subpart, which include natural gas-fired annealing furnaces, preheat furnaces, reheat furnaces, aging furnaces, heat treat furnaces, and homogenizing furnaces.

* * * * *

Minimum activated carbon injection rate means load fraction multiplied by the lowest hourly average activated carbon injection rate measured according to Table 7 to this subpart during the most recent performance test demonstrating compliance with the applicable emission limit.

Minimum oxygen level means the lowest hourly average oxygen level measured according to Table 7 to this subpart during the most recent performance test demonstrating compliance with the applicable emission limit.

* * * * *

Minimum scrubber liquid flow rate means the lowest hourly average liquid flow rate (e.g., to the PM scrubber or to the acid gas scrubber) measured according to Table 7 to this subpart during the most recent performance stack test demonstrating compliance with the applicable emission limit.

* * * * *

Minimum sorbent injection rate means:

(1) The load fraction multiplied by the lowest hourly average sorbent injection rate for each sorbent measured according to Table 7 to this subpart during the most recent performance test demonstrating compliance with the applicable emission limits; or

(2) For fluidized bed combustion, the lowest average ratio of sorbent to sulfur measured during the most recent performance test.

* * * * *

Natural gas means:

(1) A naturally occurring mixture of hydrocarbon and nonhydrocarbon gases found in geologic formations beneath the earth's surface, of which the principal constituent is methane; or

(2) Liquefied petroleum gas, as defined in ASTM D1835 (incorporated by reference, see § 63.14); or

(3) A mixture of hydrocarbons that maintains a gaseous state at ISO conditions. Additionally, natural gas must either be composed of at least 70 percent methane by volume or have a gross calorific value between 35 and 41 megajoules (MJ) per dry standard cubic meter (950 and 1,100 Btu per dry standard cubic foot); or

(4) Propane or propane derived synthetic natural gas. Propane means a colorless gas derived from petroleum and natural gas, with the molecular structure C_3H_8.

* * * * *

Other combustor means a unit designed to burn solid fuel that is not classified as a dutch oven, fluidized bed, fuel cell, hybrid suspension grate boiler, pulverized coal boiler, stoker, sloped grate, or suspension boiler as defined in this subpart.

Other gas 1 fuel means a gaseous fuel that is not natural gas or refinery gas and does not exceed a maximum concentration of 40 micrograms/cubic meters of mercury.

Oxygen analyzer system means all equipment required to determine the oxygen content of a gas stream and used to monitor oxygen in the boiler or process heater flue gas, boiler or process heater, firebox, or other appropriate location. This definition includes oxygen trim systems. The source owner or operator must install, calibrate, maintain, and operate the oxygen analyzer system in accordance with the manufacturer's recommendations.

Oxygen trim system means a system of monitors that is used to maintain excess air at the desired level in a combustion device. A typical system consists of a flue gas oxygen and/or CO monitor that automatically provides a feedback signal to the combustion air controller.

* * * * *

Period of gas curtailment or supply interruption means a period of time during which the supply of gaseous fuel to an affected boiler or process heater is restricted or halted for reasons beyond the control of the facility. The act of entering into a contractual agreement with a supplier of natural gas established for curtailment purposes does not constitute a reason that is under the control of a facility for the purposes of this definition. An increase in the cost or unit price of natural gas due to normal market fluctuations not during periods of supplier delivery restriction does not constitute a period of natural gas curtailment or supply interruption. On-site gaseous fuel system emergencies or equipment failures qualify as periods of supply interruption when the emergency or failure is beyond the control of the facility.

Pile burner means a boiler design incorporating a design where the anticipated biomass fuel has a high relative moisture content. Grates serve to support the fuel, and underfire air flowing up through the grates provides oxygen for combustion, cools the grates, promotes turbulence in the fuel bed, and fires the fuel. The most common form of pile burning is the dutch oven.

Process heater means an enclosed device using controlled flame, and the unit's primary purpose is to transfer heat indirectly to a process material (liquid, gas, or solid) or to a heat transfer material (e.g., glycol or a mixture of glycol and water) for use in a process unit, instead of generating steam. Process heaters are devices in which the combustion gases do not come into direct contact with process materials. A device combusting solid waste, as defined in § 241.3 of this chapter, is not a process heater unless the device is exempt from the definition of a solid waste incineration unit as provided in section 129(g)(1) of the Clean Air Act. Process heaters do not include units used for comfort heat or space heat, food preparation for on-site consumption, or autoclaves. Waste heat process heaters are excluded from this definition.

* * * * *

Qualified energy assessor means:

(1) Someone who has demonstrated capabilities to evaluate energy savings opportunities for steam generation and major energy using systems, including, but not limited to:

(i) Boiler combustion management.

(ii) Boiler thermal energy recovery, including

(A) Conventional feed water economizer,

(B) Conventional combustion air preheater, and

(C) Condensing economizer.

(iii) Boiler blowdown thermal energy recovery.

(iv) Primary energy resource selection, including

(A) Fuel (primary energy source) switching, and

(B) Applied steam energy versus direct-fired energy versus electricity.

(v) Insulation issues.

(vi) Steam trap and steam leak management.

(vi) Condensate recovery.

(viii) Steam end-use management.

(2) Capabilities and knowledge includes, but is not limited to:

(i) Background, experience, and recognized abilities to perform the assessment activities, data analysis, and report preparation.

(ii) Familiarity with operating and maintenance practices for steam or process heating systems.

(iii) Additional potential steam system improvement opportunities including improving steam turbine operations and reducing steam demand.

(iv) Additional process heating system opportunities including effective utilization of waste heat and use of proper process heating methods.

(v) Boiler-steam turbine cogeneration systems.

(vi) Industry specific steam end-use systems.

* * * * *

Regulated gas stream means an offgas stream that is routed to a boiler or process heater for the purpose of achieving compliance with a standard under another subpart of this part or part 60, part 61, or part 65 of this chapter.

Residential boiler means a boiler used to provide heat and/or hot water and/or as part of a residential combined heat and power system. This definition includes boilers located at an institutional facility (e.g., university campus, military base, church grounds) or commercial/industrial facility (e.g., farm) used primarily to provide heat and/or hot water for:

(1) A dwelling containing four or fewer families; or

(2) A single unit residence dwelling that has since been converted or subdivided into condominiums or apartments.

Residual oil means crude oil, fuel oil that does not comply with the specifications under the definition of distillate oil, and all fuel oil numbers 4, 5, and 6, as defined by the American Society of Testing and Materials in ASTM D396–10 (incorporated by reference, *see* § 63.14(b)).

* * * * *

Secondary material means the material as defined in § 241.2 of this chapter.

Shutdown means the cessation of operation of a boiler or process heater for any purpose. Shutdown begins either when none of the steam from the boiler is supplied for heating and/or producing electricity, or for any other purpose, or at the point of no fuel being fired in the boiler or process heater, whichever is earlier. Shutdown ends when there is no steam and no heat being supplied and no fuel being fired in the boiler or process heater.

Sloped grate means a unit where the solid fuel is fed to the top of the grate from where it slides downwards; while sliding the fuel first dries and then ignites and burns. The ash is deposited at the bottom of the grate. Fluidized bed, dutch oven, pile burner, hybrid suspension grate, suspension burners, and fuel cells are not considered to be a sloped grate design.

Solid fossil fuel includes, but is not limited to, coal, coke, petroleum coke, and tire derived fuel.

* * * * *

Startup means either the first-ever firing of fuel in a boiler or process heater for the purpose of supplying steam or heat for heating and/or producing electricity, or for any other purpose, or the firing of fuel in a boiler after a shutdown event for any purpose. Startup ends when any of the steam or heat from the boiler or process heater is supplied for heating, and/or producing electricity, or for any other purpose.

Steam output means:

(1) For a boiler that produces steam for process or heating only (no power generation), the energy content in terms of MMBtu of the boiler steam output,

(2) For a boiler that cogenerates process steam and electricity (also known as combined heat and power), the total energy output, which is the sum of the energy content of the steam exiting the turbine and sent to process in MMBtu and the energy of the electricity generated converted to MMBtu at a rate of 10,000 Btu per kilowatt-hour generated (10 MMBtu per megawatt-hour), and

(3) For a boiler that generates only electricity, the alternate output-based emission limits would be calculated using Equations 21 through 25 of this section, as appropriate:

(i) For emission limits for boilers in the unit designed to burn solid fuel subcategory use Equation 21 of this section:

$$EL_{OBE} = EL_T \times 12.7\ MMBtu/Mwh \quad (Eq.\ 21)$$

Where:

EL_{OBE} = Emission limit in units of pounds per megawatt-hour.

EL_T = Appropriate emission limit from Table 1 or 2 of this subpart in units of pounds per million Btu heat input.

(ii) For PM and CO emission limits for boilers in one of the subcategories of units designed to burn coal use Equation 22 of this section:

$$EL_{OBE} = EL_T \times 12.2\ MMBtu/Mwh \quad (Eq.\ 22)$$

Where:

EL_{OBE} = Emission limit in units of pounds per megawatt-hour.

EL_T = Appropriate emission limit from Table 1 or 2 of this subpart in units of pounds per million Btu heat input.

(iii) For PM and CO emission limits for boilers in one of the subcategories of units designed to burn biomass use Equation 23 of this section:

$$EL_{OBE} = EL_T \times 13.9\ MMBtu/Mwh \quad (Eq.\ 23)$$

Where:

EL_{OBE} = Emission limit in units of pounds per megawatt-hour.

EL_T = Appropriate emission limit from Table 1 or 2 of this subpart in units of pounds per million Btu heat input.

(iv) For emission limits for boilers in one of the subcategories of units designed to burn liquid fuels use Equation 24 of this section:

$$EL_{OBE} = EL_T \times 13.8\ MMBtu/Mwh \quad (Eq.\ 24)$$

Where:

EL_{OBE} = Emission limit in units of pounds per megawatt-hour.

EL_T = Appropriate emission limit from Table 1 or 2 of this subpart in units of pounds per million Btu heat input.

(v) For emission limits for boilers in the unit designed to burn gas 2 (other)

subcategory, use Equation 25 of this section:

$$EL_{OBE} = EL_T \times 10.4\ MMBtu/Mwh \quad (Eq.\ 25)$$

Where:
EL_{OBE} = Emission limit in units of pounds per megawatt-hour.
EL_T = Appropriate emission limit from Table 1 or 2 of this subpart in units of pounds per million Btu heat input.

Stoker means a unit consisting of a mechanically operated fuel feeding mechanism, a stationary or moving grate to support the burning of fuel and admit under-grate air to the fuel, an overfire air system to complete combustion, and an ash discharge system. This definition of stoker includes air swept stokers. There are two general types of stokers: Underfeed and overfeed. Overfeed stokers include mass feed and spreader stokers. Fluidized bed, dutch oven, pile burner, hybrid suspension grate, suspension burners, and fuel cells are not considered to be a stoker design.

Stoker/sloped grate/other unit designed to burn kiln dried biomass means the unit is in the units designed to burn biomass/bio-based solid subcategory that is either a stoker, sloped grate, or other combustor design and is not in the stoker/sloped grate/other units designed to burn wet biomass subcategory.

Stoker/sloped grate/other unit designed to burn wet biomass means the unit is in the units designed to burn biomass/bio-based solid subcategory that is either a stoker, sloped grate, or other combustor design and any of the biomass/bio-based solid fuel combusted in the unit exceeds 20 percent moisture on an annual heat input basis.

Suspension burner means a unit designed to fire dry biomass/biobased solid particles in suspension that are conveyed in an airstream to the furnace like pulverized coal. The combustion of the fuel material is completed on a grate or floor below. The biomass/biobased fuel combusted in the unit shall not exceed 20 percent moisture on an annual heat input basis. Fluidized bed, dutch oven, pile burner, and hybrid suspension grate units are not part of the suspension burner subcategory.

Temporary boiler means any gaseous or liquid fuel boiler that is designed to, and is capable of, being carried or moved from one location to another by means of, for example, wheels, skids, carrying handles, dollies, trailers, or platforms. A boiler is not a temporary boiler if any one of the following conditions exists:

(1) The equipment is attached to a foundation.

(2) The boiler or a replacement remains at a location within the facility and performs the same or similar function for more than 12 consecutive months, unless the regulatory agency approves an extension. An extension may be granted by the regulating agency upon petition by the owner or operator of a unit specifying the basis for such a request. Any temporary boiler that replaces a temporary boiler at a location and performs the same or similar function will be included in calculating the consecutive time period.

(3) The equipment is located at a seasonal facility and operates during the full annual operating period of the seasonal facility, remains at the facility for at least 2 years, and operates at that facility for at least 3 months each year.

(4) The equipment is moved from one location to another within the facility but continues to perform the same or similar function and serve the same electricity, steam, and/or hot water system in an attempt to circumvent the residence time requirements of this definition.

Total selected metals (TSM) means the sum of the following metallic hazardous air pollutants: arsenic, beryllium, cadmium, chromium, lead, manganese, nickel and selenium.

Traditional fuel means the fuel as defined in § 241.2 of this chapter.

Tune-up means adjustments made to a boiler or process heater in accordance with the procedures outlined in § 63.7540(a)(10).

* * * * *

Ultra low sulfur liquid fuel means a distillate oil that has less than or equal to 15 ppm sulfur.

* * * * *

Unit designed to burn gas 1 subcategory includes any boiler or process heater that burns only natural gas, refinery gas, and/or other gas 1 fuels. Gaseous fuel boilers and process heaters that burn liquid fuel for periodic testing of liquid fuel, maintenance, or operator training, not to exceed a combined total of 48 hours during any calendar year, are included in this definition. Gaseous fuel boilers and process heaters that burn liquid fuel during periods of gas curtailment or gas supply interruptions of any duration are also included in this definition.

Unit designed to burn gas 2 (other) subcategory includes any boiler or process heater that is not in the unit designed to burn gas 1 subcategory and burns any gaseous fuels either alone or in combination with less than 10 percent coal/solid fossil fuel, and less than 10 percent biomass/bio-based solid fuel on an annual heat input basis, and no liquid fuels. Gaseous fuel boilers and process heaters that are not in the unit designed to burn gas 1 subcategory and that burn liquid fuel for periodic testing of liquid fuel, maintenance, or operator training, not to exceed a combined total of 48 hours during any calendar year, are included in this definition. Gaseous fuel boilers and process heaters that are not in the unit designed to burn gas 1 subcategory and that burn liquid fuel during periods of gas curtailment or gas supply interruption of any duration are also included in this definition.

Unit designed to burn heavy liquid subcategory means a unit in the unit designed to burn liquid subcategory where at least 10 percent of the heat input from liquid fuels on an annual heat input basis comes from heavy liquids.

Unit designed to burn light liquid subcategory means a unit in the unit designed to burn liquid subcategory that is not part of the unit designed to burn heavy liquid subcategory.

Unit designed to burn liquid subcategory includes any boiler or process heater that burns any liquid fuel, but less than 10 percent coal/solid fossil fuel and less than 10 percent biomass/bio-based solid fuel on an annual heat input basis, either alone or in combination with gaseous fuels. Units in the unit design to burn gas 1 or unit designed to burn gas 2 (other) subcategories that burn liquid fuel for periodic testing of liquid fuel, maintenance, or operator training, not to exceed a combined total of 48 hours during any calendar year are not included in this definition. Units in the unit design to burn gas 1 or unit designed to burn gas 2 (other) subcategories during periods of gas curtailment or gas supply interruption of any duration are also not included in this definition.

Unit designed to burn liquid fuel that is a non-continental unit means an industrial, commercial, or institutional boiler or process heater meeting the definition of the unit designed to burn

liquid subcategory located in the State of Hawaii, the Virgin Islands, Guam, American Samoa, the Commonwealth of Puerto Rico, or the Northern Mariana Islands.

Unit designed to burn solid fuel subcategory means any boiler or process heater that burns only solid fuels or at least 10 percent solid fuel on an annual heat input basis in combination with liquid fuels or gaseous fuels.

Vegetable oil means oils extracted from vegetation.

* * * * *

Waste heat boiler means a device that recovers normally unused energy (i.e., hot exhaust gas) and converts it to usable heat. Waste heat boilers are also referred to as heat recovery steam generators. Waste heat boilers are heat exchangers generating steam from incoming hot exhaust gas from an industrial (e.g., thermal oxidizer, kiln, furnace) or power (e.g., combustion turbine, engine) equipment. Duct burners are sometimes used to increase the temperature of the incoming hot exhaust gas.

Waste heat process heater means an enclosed device that recovers normally unused energy (i.e., hot exhaust gas) and converts it to usable heat. Waste heat process heaters are also referred to as recuperative process heaters. This definition includes both fired and unfired waste heat process heaters.

* * * * *

■ 28. Table 1 to subpart DDDDD of part 63 is revised to read as follows:

As stated in § 63.7500, you must comply with the following applicable emission limits:

TABLE 1 TO SUBPART DDDDD OF PART 63—EMISSION LIMITS FOR NEW OR RECONSTRUCTED BOILERS AND PROCESS HEATERS

[Units with heat input capacity of 10 million Btu per hour or greater]

If your boiler or process heater is in this subcategory . . .	For the following pollutants . . .	The emissions must not exceed the following emission limits, except during startup and shutdown . . .	Or the emissions must not exceed the following alternative output-based limits, except during startup and shutdown . . .	Using this specified sampling volume or test run duration . . .
1. Units in all subcategories designed to burn solid fuel.	a. HCl	2.2E–02 lb per MMBtu of heat input.	2.5E–02 lb per MMBtu of steam output or 0.28 lb per MWh.	For M26A, collect a minimum of 1 dscm per run; for M26 collect a minimum of 120 liters per run.
	b. Mercury	8.0E–07 [a] lb per MMBtu of heat input.	8.7E–07 [a] lb per MMBtu of steam output or 1.1E–05 [a] lb per MWh.	For M29, collect a minimum of 4 dscm per run; for M30A or M30B, collect a minimum sample as specified in the method; for ASTM D6784 [b] collect a minimum of 4 dscm.
2. Units designed to burn coal/solid fossil fuel.	a. Filterable PM (or TSM)	1.1E–03 lb per MMBtu of heat input; or (2.3E–05 lb per MMBtu of heat input).	1.1E–03 lb per MMBtu of steam output or 1.4E–02 lb per MWh; or (2.7E–05 lb per MMBtu of steam output or 2.9E–04 lb per MWh).	Collect a minimum of 3 dscm per run.
3. Pulverized coal boilers designed to burn coal/solid fossil fuel.	a. Carbon monoxide (CO) (or CEMS).	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (320 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	0.11 lb per MMBtu of steam output or 1.4 lb per MWh; 3-run average.	1 hr minimum sampling time.
4. Stokers designed to burn coal/solid fossil fuel.	a. CO (or CEMS)	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (340 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	0.12 lb per MMBtu of steam output or 1.4 lb per MWh; 3-run average.	1 hr minimum sampling time.
5. Fluidized bed units designed to burn coal/solid fossil fuel.	a. CO (or CEMS)	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (230 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	0.11 lb per MMBtu of steam output or 1.4 lb per MWh; 3-run average.	1 hr minimum sampling time.
6. Fluidized bed units with an integrated heat exchanger designed to burn coal/solid fossil fuel.	a. CO (or CEMS)	140 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (150 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1.2E–01 lb per MMBtu of steam output or 1.5 lb per MWh; 3-run average.	1 hr minimum sampling time.
7. Stokers/sloped grate/others designed to burn wet biomass fuel.	a. CO (or CEMS)	620 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (390 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	5.8E–01 lb per MMBtu of steam output or 6.8 lb per MWh; 3-run average.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	3.0E–02 lb per MMBtu of heat input; or (2.6E–05 lb per MMBtu of heat input).	3.5E–02 lb per MMBtu of steam output or 4.2E–01 lb per MWh; or (2.7E–05 lb per MMBtu of steam output or 3.7E–04 lb per MWh).	Collect a minimum of 2 dscm per run.

NMED Exhibit 80 - 0057

TABLE 1 TO SUBPART DDDDD OF PART 63—EMISSION LIMITS FOR NEW OR RECONSTRUCTED BOILERS AND PROCESS HEATERS—Continued

[Units with heat input capacity of 10 million Btu per hour or greater]

If your boiler or process heater is in this subcategory . . .	For the following pollutants . . .	The emissions must not exceed the following emission limits, except during startup and shutdown . . .	Or the emissions must not exceed the following alternative output-based limits, except during startup and shutdown . . .	Using this specified sampling volume or test run duration . . .
8. Stokers/sloped grate/others designed to burn kiln-dried biomass fuel.	a. CO	460 ppm by volume on a dry basis corrected to 3 percent oxygen.	4.2E–01 lb per MMBtu of steam output or 5.1 lb per MWh.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	3.0E–02 lb per MMBtu of heat input; or (4.0E–03 lb per MMBtu of heat input).	3.5E–02 lb per MMBtu of steam output or 4.2E–01 lb per MWh; or (4.2E–03 lb per MMBtu of steam output or 5.6E–02 lb per MWh).	Collect a minimum of 2 dscm per run.
9. Fluidized bed units designed to burn biomass/bio-based solids.	a. CO (or CEMS)	230 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (310 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	2.2E–01 lb per MMBtu of steam output or 2.6 lb per MWh; 3-run average.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	9.8E–03 lb per MMBtu of heat input; or (8.3E–05 [a] lb per MMBtu of heat input).	1.2E–02 lb per MMBtu of steam output or 0.14 lb per MWh; or (1.1E–04 [a] lb per MMBtu of steam output or 1.2E–03 [a] lb per MWh).	Collect a minimum of 3 dscm per run.
10. Suspension burners designed to burn biomass/bio-based solids.	a. CO (or CEMS)	2,400 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (2,000 ppm by volume on a dry basis corrected to 3 percent oxygen, 10-day rolling average).	1.9 lb per MMBtu of steam output or 27 lb per MWh; 3-run average.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	3.0E–02 lb per MMBtu of heat input; or (6.5E–03 lb per MMBtu of heat input).	3.1E–02 lb per MMBtu of steam output or 4.2E–01 lb per MWh; or (6.6E–03 lb per MMBtu of steam output or 9.1E–02 lb per MWh).	Collect a minimum of 2 dscm per run.
11. Dutch Ovens/Pile burners designed to burn biomass/bio-based solids.	a. CO (or CEMS)	330 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (520 ppm by volume on a dry basis corrected to 3 percent oxygen, 10-day rolling average).	3.5E–01 lb per MMBtu of steam output or 3.6 lb per MWh; 3-run average.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	3.2E–03 lb per MMBtu of heat input; or (3.9E–05 lb per MMBtu of heat input).	4.3E–03 lb per MMBtu of steam output or 4.5E–02 lb per MWh; or (5.2E–05 lb per MMBtu of steam output or 5.5E–04 lb per MWh).	Collect a minimum of 3 dscm per run.
12. Fuel cell units designed to burn biomass/bio-based solids.	a. CO	910 ppm by volume on a dry basis corrected to 3 percent oxygen.	1.1 lb per MMBtu of steam output or 1.0E+01 lb per MWh.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	2.0E–02 lb per MMBtu of heat input; or (2.9E–05 [a] lb per MMBtu of heat input).	3.0E–02 lb per MMBtu of steam output or 2.8E–01 lb per MWh; or (5.1E–05 lb per MMBtu of steam output or 4.1E–04 lb per MWh).	Collect a minimum of 2 dscm per run.
13. Hybrid suspension grate boiler designed to burn biomass/bio-based solids.	a. CO (or CEMS)	1,100 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (900 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1.4 lb per MMBtu of steam output or 12 lb per MWh; 3-run average.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	2.6E–02 lb per MMBtu of heat input; or (4.4E–04 lb per MMBtu of heat input).	3.3E–02 lb per MMBtu of steam output or 3.7E–01 lb per MWh; or (5.5E–04 lb per MMBtu of steam output or 6.2E–03 lb per MWh).	Collect a minimum of 3 dscm per run.
14. Units designed to burn liquid fuel.	a. HCl	4.4E–04 lb per MMBtu of heat input.	4.8E–04 lb per MMBtu of steam output or 6.1E–03 lb per MWh.	For M26A: Collect a minimum of 2 dscm per run; for M26, collect a minimum of 240 liters per run.
	b. Mercury	4.8E–07 [a] lb per MMBtu of heat input.	5.3E–07 [a] lb per MMBtu of steam output or 6.7E–06 [a] lb per MWh.	For M29, collect a minimum of 4 dscm per run; for M30A or M30B, collect a minimum sample as specified in the method; for ASTM D6784 [b] collect a minimum of 4 dscm.

TABLE 1 TO SUBPART DDDDD OF PART 63—EMISSION LIMITS FOR NEW OR RECONSTRUCTED BOILERS AND PROCESS HEATERS—Continued

[Units with heat input capacity of 10 million Btu per hour or greater]

If your boiler or process heater is in this subcategory . . .	For the following pollutants . . .	The emissions must not exceed the following emission limits, except during startup and shutdown . . .	Or the emissions must not exceed the following alternative output-based limits, except during startup and shutdown . . .	Using this specified sampling volume or test run duration . . .
15. Units designed to burn heavy liquid fuel.	a. CO	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average.	0.13 lb per MMBtu of steam output or 1.4 lb per MWh; 3-run average.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	1.3E–02 lb per MMBtu of heat input; or (7.5E–05 lb per MMBtu of heat input).	1.5E–02 lb per MMBtu of steam output or 1.8E–01 lb per MWh; or (8.2E–05 lb per MMBtu of steam output or 1.1E–03 lb per MWh).	Collect a minimum of 3 dscm per run.
16. Units designed to burn light liquid fuel.	a. CO	130 ppm by volume on a dry basis corrected to 3 percent oxygen.	0.13 lb per MMBtu of steam output or 1.4 lb per MWh.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	1.1E–03 [a] lb per MMBtu of heat input; or (2.9E–05 lb per MMBtu of heat input).	1.2E–03 [a] lb per MMBtu of steam output or 1.6E–02 [a] lb per MWh; or (3.2E–05 lb per MMBtu of steam output or 4.0E–04 lb per MWh).	Collect a minimum of 3 dscm per run.
17. Units designed to burn liquid fuel that are non-continental units.	a. CO	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average based on stack test.	0.13 lb per MMBtu of steam output or 1.4 lb per MWh; 3-run average.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	2.3E–02 lb per MMBtu of heat input; or (8.6E–04 lb per MMBtu of heat input).	2.5E–02 lb per MMBtu of steam output or 3.2E–01 lb per MWh; or (9.4E–04 lb per MMBtu of steam output or 1.2E–02 lb per MWh).	Collect a minimum of 4 dscm per run.
18. Units designed to burn gas 2 (other) gases.	a. CO	130 ppm by volume on a dry basis corrected to 3 percent oxygen.	0.16 lb per MMBtu of steam output or 1.0 lb per MWh.	1 hr minimum sampling time.
	b. HCl	1.7E–03 lb per MMBtu of heat input.	2.9E–03 lb per MMBtu of steam output or 1.8E–02 lb per MWh.	For M26A, Collect a minimum of 2 dscm per run; for M26, collect a minimum of 240 liters per run.
	c. Mercury	7.9E–06 lb per MMBtu of heat input.	1.4E–05 lb per MMBtu of steam output or 8.3E–05 lb per MWh.	For M29, collect a minimum of 3 dscm per run; for M30A or M30B, collect a minimum sample as specified in the method; for ASTM D6784 [b] collect a minimum of 3 dscm.
	d. Filterable PM (or TSM)	6.7E–03 lb per MMBtu of heat input; or (2.1E–04 lb per MMBtu of heat input).	1.2E–02 lb per MMBtu of steam output or 7.0E–02 lb per MWh; or (3.5E–04 lb per MMBtu of steam output or 2.2E–03 lb per MWh).	Collect a minimum of 3 dscm per run.

[a] If you are conducting stack tests to demonstrate compliance and your performance tests for this pollutant for at least 2 consecutive years show that your emissions are at or below this limit, you can skip testing according to § 63.7515 if all of the other provisions of § 63.7515 are met. For all other pollutants that do not contain a footnote "a", your performance tests for this pollutant for at least 2 consecutive years must show that your emissions are at or below 75 percent of this limit in order to qualify for skip testing.

[b] Incorporated by reference, see § 63.14.

[c] If your affected source is a new or reconstructed affected source that commenced construction or reconstruction after June 4, 2010, and before January 31, 2013, you may comply with the emission limits in Tables 11, 12 or 13 to this subpart until January 31, 2016. On and after January 31, 2016, you must comply with the emission limits in Table 1 to this subpart.

■ 29. Table 2 to subpart DDDDD of part 63 is revised to read as follows:

As stated in § 63.7500, you must comply with the following applicable emission limits:

TABLE 2 TO SUBPART DDDDD OF PART 63—EMISSION LIMITS FOR EXISTING BOILERS AND PROCESS HEATERS

[Units with heat input capacity of 10 million Btu per hour or greater]

If your boiler or process heater is in this subcategory . . .	For the following pollutants . . .	The emissions must not exceed the following emission limits, except during startup and shutdown . . .	The emissions must not exceed the following alternative output-based limits, except during startup and shutdown . . .	Using this specified sampling volume or test run duration . . .
1. Units in all subcategories designed to burn solid fuel.	a. HCl	2.2E–02 lb per MMBtu of heat input.	2.5E–02 lb per MMBtu of steam output or 0.27 lb per MWh.	For M26A, Collect a minimum of 1 dscm per run; for M26, collect a minimum of 120 liters per run.

TABLE 2 TO SUBPART DDDDD OF PART 63—EMISSION LIMITS FOR EXISTING BOILERS AND PROCESS HEATERS—Continued

[Units with heat input capacity of 10 million Btu per hour or greater]

If your boiler or process heater is in this subcategory . . .	For the following pollutants . . .	The emissions must not exceed the following emission limits, except during startup and shutdown . . .	The emissions must not exceed the following alternative output-based limits, except during startup and shutdown . . .	Using this specified sampling volume or test run duration . . .
	b. Mercury	5.7E–06 lb per MMBtu of heat input.	6.4E–06 lb per MMBtu of steam output or 7.3E–05 lb per MWh.	For M29, collect a minimum of 3 dscm per run; for M30A or M30B, collect a minimum sample as specified in the method; for ASTM D6784 [b] collect a minimum of 3 dscm.
2. Units design to burn coal/solid fossil fuel.	a. Filterable PM (or TSM)	4.0E–02 lb per MMBtu of heat input; or (5.3E–05 lb per MMBtu of heat input).	4.2E–02 lb per MMBtu of steam output or 4.9E–01 lb per MWh; or (5.6E–05 lb per MMBtu of steam output or 6.5E–04 lb per MWh).	Collect a minimum of 2 dscm per run.
3. Pulverized coal boilers designed to burn coal/solid fossil fuel.	a. CO (or CEMS)	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (320 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	0.11 lb per MMBtu of steam output or 1.4 lb per MWh; 3-run average.	1 hr minimum sampling time.
4. Stokers designed to burn coal/solid fossil fuel.	a. CO (or CEMS)	160 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (340 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	0.14 lb per MMBtu of steam output or 1.7 lb per MWh; 3-run average.	1 hr minimum sampling time.
5. Fluidized bed units designed to burn coal/solid fossil fuel.	a. CO (or CEMS)	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (230 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	0.12 lb per MMBtu of steam output or 1.4 lb per MWh; 3-run average.	1 hr minimum sampling time.
6. Fluidized bed units with an integrated heat exchanger designed to burn coal/solid fossil fuel.	a. CO (or CEMS)	140 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (150 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1.3E–01 lb per MMBtu of steam output or 1.5 lb per MWh; 3-run average.	1 hr minimum sampling time.
7. Stokers/sloped grate/others designed to burn wet biomass fuel.	a. CO (or CEMS)	1,500 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (720 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1.4 lb per MMBtu of steam output or 17 lb per MWh; 3-run average.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	3.7E–02 lb per MMBtu of heat input; or (2.4E–04 lb per MMBtu of heat input).	4.3E–02 lb per MMBtu of steam output or 5.2E–01 lb per MWh; or (2.8E–04 lb per MMBtu of steam output or 3.4E–04 lb per MWh).	Collect a minimum of 2 dscm per run.
8. Stokers/sloped grate/others designed to burn kiln-dried biomass fuel.	a. CO	460 ppm by volume on a dry basis corrected to 3 percent oxygen.	4.2E–01 lb per MMBtu of steam output or 5.1 lb per MWh.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	3.2E–01 lb per MMBtu of heat input; or (4.0E–03 lb per MMBtu of heat input).	3.7E–01 lb per MMBtu of steam output or 4.5 lb per MWh; or (4.6E–03 lb per MMBtu of steam output or 5.6E–02 lb per MWh).	Collect a minimum of 1 dscm per run.
9. Fluidized bed units designed to burn biomass/bio-based solid.	a. CO (or CEMS)	470 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (310 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	4.6E–01 lb per MMBtu of steam output or 5.2 lb per MWh; 3-run average.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	1.1E–01 lb per MMBtu of heat input; or (1.2E–03 lb per MMBtu of heat input).	1.4E–01 lb per MMBtu of steam output or 1.6 lb per MWh; or (1.5E–03 lb per MMBtu of steam output or 1.7E–02 lb per MWh).	Collect a minimum of 1 dscm per run.

TABLE 2 TO SUBPART DDDDD OF PART 63—EMISSION LIMITS FOR EXISTING BOILERS AND PROCESS HEATERS—Continued

[Units with heat input capacity of 10 million Btu per hour or greater]

If your boiler or process heater is in this subcategory . . .	For the following pollutants . . .	The emissions must not exceed the following emission limits, except during startup and shutdown . . .	The emissions must not exceed the following alternative output-based limits, except during startup and shutdown . . .	Using this specified sampling volume or test run duration . . .
10. Suspension burners designed to burn biomass/bio-based solid.	a. CO (or CEMS)	2,400 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (2,000 ppm by volume on a dry basis corrected to 3 percent oxygen, 10-day rolling average).	1.9 lb per MMBtu of steam output or 27 lb per MWh; 3-run average.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	5.1E–02 lb per MMBtu of heat input; or (6.5E–03 lb per MMBtu of heat input).	5.2E–02 lb per MMBtu of steam output or 7.1E–01 lb per MWh; or (6.6E–03 lb per MMBtu of steam output or 9.1E–02 lb per MWh).	Collect a minimum of 2 dscm per run.
11. Dutch Ovens/Pile burners designed to burn biomass/bio-based solid.	a. CO (or CEMS)	770 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (520 ppm by volume on a dry basis corrected to 3 percent oxygen, 10-day rolling average).	8.4E–01 lb per MMBtu of steam output or 8.4 lb per MWh; 3-run average.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	2.8E–01 lb per MMBtu of heat input; or (2.0E–03 lb per MMBtu of heat input).	3.9E–01 lb per MMBtu of steam output or 3.9 lb per MWh; or (2.8E–03 lb per MMBtu of steam output or 2.8E–02 lb per MWh).	Collect a minimum of 1 dscm per run.
12. Fuel cell units designed to burn biomass/bio-based solid.	a. CO	1,100 ppm by volume on a dry basis corrected to 3 percent oxygen.	2.4 lb per MMBtu of steam output or 12 lb per MWh.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	2.0E–02 lb per MMBtu of heat input; or (5.8E–03 lb per MMBtu of heat input).	5.5E–02 lb per MMBtu of steam output or 2.8E–01 lb per MWh; or (1.6E–02 lb per MMBtu of steam output or 8.1E–02 lb per MWh).	Collect a minimum of 2 dscm per run.
13. Hybrid suspension grate units designed to burn biomass/bio-based solid.	a. CO (or CEMS)	2,800 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (900 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	2.8 lb per MMBtu of steam output or 31 lb per MWh; 3-run average.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	4.4E–01 lb per MMBtu of heat input; or (4.5E–04 lb per MMBtu of heat input).	5.5E–01 lb per MMBtu of steam output or 6.2 lb per MWh; or (5.7E–04 lb per MMBtu of steam output or 6.3E–03 lb per MWh).	Collect a minimum of 1 dscm per run.
14. Units designed to burn liquid fuel.	a. HCl	1.1E–03 lb per MMBtu of heat input.	1.4E–03 lb per MMBtu of steam output or 1.6E–02 lb per MWh.	For M26A, collect a minimum of 2 dscm per run; for M26, collect a minimum of 240 liters per run.
	b. Mercury	2.0E–06 lb per MMBtu of heat input.	2.5E–06 lb per MMBtu of steam output or 2.8E–05 lb per MWh.	For M29, collect a minimum of 3 dscm per run; for M30A or M30B collect a minimum sample as specified in the method, for ASTM D6784 [b] collect a minimum of 2 dscm.
15. Units designed to burn heavy liquid fuel.	a. CO	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average.	0.13 lb per MMBtu of steam output or 1.4 lb per MWh; 3-run average.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	6.2E–02 lb per MMBtu of heat input; or (2.0E–04 lb per MMBtu of heat input).	7.5E–02 lb per MMBtu of steam output or 8.6E–01 lb per MWh; or (2.5E–04 lb per MMBtu of steam output or 2.8E–03 lb per MWh).	Collect a minimum of 1 dscm per run.
16. Units designed to burn light liquid fuel.	a. CO	130 ppm by volume on a dry basis corrected to 3 percent oxygen.	0.13 lb per MMBtu of steam output or 1.4 lb per MWh.	1 hr minimum sampling time.
	b. Filterable PM (or TSM)	7.9E–03 lb per MMBtu of heat input; or (6.2E–05 lb per MMBtu of heat input).	9.6E–03 lb per MMBtu of steam output or 1.1E–01 lb per MWh; or (7.5E–05 lb per MMBtu of steam output or 8.6E–04 lb per MWh).	Collect a minimum of 3 dscm per run.
17. Units designed to burn liquid fuel that are non-continental units.	a. CO	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average based on stack test.	0.13 lb per MMBtu of steam output or 1.4 lb per MWh; 3-run average.	1 hr minimum sampling time.

TABLE 2 TO SUBPART DDDDD OF PART 63—EMISSION LIMITS FOR EXISTING BOILERS AND PROCESS HEATERS—Continued

[Units with heat input capacity of 10 million Btu per hour or greater]

If your boiler or process heater is in this subcategory . . .	For the following pollutants . . .	The emissions must not exceed the following emission limits, except during startup and shutdown . . .	The emissions must not exceed the following alternative output-based limits, except during startup and shutdown . . .	Using this specified sampling volume or test run duration . . .
	b. Filterable PM (or TSM)	2.7E–01 lb per MMBtu of heat input; or (8.6E–04 lb per MMBtu of heat input).	3.3E–01 lb per MMBtu of steam output or 3.8 lb per MWh; or (1.1E–03 lb per MMBtu of steam output or 1.2E–02 lb per MWh).	Collect a minimum of 2 dscm per run.
18. Units designed to burn gas 2 (other) gases.	a. CO	130 ppm by volume on a dry basis corrected to 3 percent oxygen.	0.16 lb per MMBtu of steam output or 1.0 lb per MWh.	1 hr minimum sampling time.
	b. HCl	1.7E–03 lb per MMBtu of heat input.	2.9E–03 lb per MMBtu of steam output or 1.8E–02 lb per MWh.	For M26A, collect a minimum of 2 dscm per run; for M26, collect a minimum of 240 liters per run.
	c. Mercury	7.9E–06 lb per MMBtu of heat input.	1.4E–05 lb per MMBtu of steam output or 8.3E–05 lb per MWh.	For M29, collect a minimum of 3 dscm per run; for M30A or M30B, collect a minimum sample as specified in the method; for ASTM D6784 [b] collect a minimum of 2 dscm.
	d. Filterable PM (or TSM)	6.7E–03 lb per MMBtu of heat input or (2.1E–04 lb per MMBtu of heat input).	1.2E–02 lb per MMBtu of steam output or 7.0E–02 lb per MWh; or (3.5E–04 lb per MMBtu of steam output or 2.2E–03 lb per MWh).	Collect a minimum of 3 dscm per run.

[a] If you are conducting stack tests to demonstrate compliance and your performance tests for this pollutant for at least 2 consecutive years show that your emissions are at or below this limit, you can skip testing according to § 63.7515 if all of the other provisions of § 63.7515 are met. For all other pollutants that do not contain a footnote a, your performance tests for this pollutant for at least 2 consecutive years must show that your emissions are at or below 75 percent of this limit in order to qualify for skip testing.

[b] Incorporated by reference, see § 63.14.

■ 30. Table 3 to subpart DDDDD of part 63 is revised to read as follows:

As stated in § 63.7500, you must comply with the following applicable work practice standards:

TABLE 3 TO SUBPART DDDDD OF PART 63—WORK PRACTICE STANDARDS

If your unit is . . .	You must meet the following . . .
1. A new or existing boiler or process heater with a continuous oxygen trim system that maintains an optimum air to fuel ratio, or a heat input capacity of less than or equal to 5 million Btu per hour in any of the following subcategories: unit designed to burn gas 1; unit designed to burn gas 2 (other); or unit designed to burn light liquid, or a limited use boiler or process heater.	Conduct a tune-up of the boiler or process heater every 5 years as specified in § 63.7540.
2. A new or existing boiler or process heater without a continuous oxygen trim system and with heat input capacity of less than 10 million Btu per hour in the unit designed to burn heavy liquid or unit designed to burn solid fuel subcategories; or a new or existing boiler or process heater with heat input capacity of less than 10 million Btu per hour, but greater than 5 million Btu per hour, in any of the following subcategories: unit designed to burn gas 1; unit designed to burn gas 2 (other); or unit designed to burn light liquid.	Conduct a tune-up of the boiler or process heater biennially as specified in § 63.7540.
3. A new or existing boiler or process heater without a continuous oxygen trim system and with heat input capacity of 10 million Btu per hour or greater.	Conduct a tune-up of the boiler or process heater annually as specified in § 63.7540. Units in either the Gas 1 or Metal Process Furnace subcategories will conduct this tune-up as a work practice for all regulated emissions under this subpart. Units in all other subcategories will conduct this tune-up as a work practice for dioxins/furans.
4. An existing boiler or process heater located at a major source facility, not including limited use units.	Must have a one-time energy assessment performed by a qualified energy assessor. An energy assessment completed on or after January 1, 2008, that meets or is amended to meet the energy assessment requirements in this table, satisfies the energy assessment requirement. A facility that operates under an energy management program compatible with ISO 50001 that includes the affected units also satisfies the energy assessment requirement. The energy assessment must include the following with extent of the evaluation for items a. to e. appropriate for the on-site technical hours listed in § 63.7575: a. A visual inspection of the boiler or process heater system.

TABLE 3 TO SUBPART DDDDD OF PART 63—WORK PRACTICE STANDARDS—Continued

If your unit is . . .	You must meet the following . . .
	b. An evaluation of operating characteristics of the boiler or process heater systems, specifications of energy using systems, operating and maintenance procedures, and unusual operating constraints. c. An inventory of major energy use systems consuming energy from affected boilers and process heaters and which are under the control of the boiler/process heater owner/operator. d. A review of available architectural and engineering plans, facility operation and maintenance procedures and logs, and fuel usage. e. A review of the facility's energy management practices and provide recommendations for improvements consistent with the definition of energy management practices, if identified. f. A list of cost-effective energy conservation measures that are within the facility's control. g. A list of the energy savings potential of the energy conservation measures identified. h. A comprehensive report detailing the ways to improve efficiency, the cost of specific improvements, benefits, and the time frame for recouping those investments.
5. An existing or new boiler or process heater subject to emission limits in Table 1 or 2 or 11 through 13 to this subpart during startup.	You must operate all CMS during startup. For startup of a boiler or process heater, you must use one or a combination of the following clean fuels: natural gas, synthetic natural gas, propane, distillate oil, syngas, ultra-low sulfur diesel, fuel oil-soaked rags, kerosene, hydrogen, paper, cardboard, refinery gas, and liquefied petroleum gas. If you start firing coal/solid fossil fuel, biomass/bio-based solids, heavy liquid fuel, or gas 2 (other) gases, you must vent emissions to the main stack(s) and engage all of the applicable control devices except limestone injection in fluidized bed combustion (FBC) boilers, dry scrubber, fabric filter, selective non-catalytic reduction (SNCR), and selective catalytic reduction (SCR). You must start your limestone injection in FBC boilers, dry scrubber, fabric filter, SNCR, and SCR systems as expeditiously as possible. Startup ends when steam or heat is supplied for any purpose. You must comply with all applicable emission limits at all times except for startup or shutdown periods conforming with this work practice. You must collect monitoring data during periods of startup, as specified in § 63.7535(b). You must keep records during periods of startup. You must provide reports concerning activities and periods of startup, as specified in § 63.7555.
6. An existing or new boiler or process heater subject to emission limits in Tables 1 or 2 or 11 through 13 to this subpart during shutdown.	You must operate all CMS during shutdown. While firing coal/solid fossil fuel, biomass/bio-based solids, heavy liquid fuel, or gas 2 (other) gases during shutdown, you must vent emissions to the main stack(s) and operate all applicable control devices, except limestone injection in FBC boilers, dry scrubber, fabric filter, SNCR, and SCR. You must comply with all applicable emissions limits at all times except for startup or shutdown periods conforming with this work practice. You must collect monitoring data during periods of shutdown, as specified in § 63.7535(b). You must keep records during periods of shutdown. You must provide reports concerning activities and periods of shutdown, as specified in § 63.7555.

■ 31. Table 4 to subpart DDDDD of part 63 is revised to read as follows:

As stated in § 63.7500, you must comply with the applicable operating limits:

TABLE 4 TO SUBPART DDDDD OF PART 63—OPERATING LIMITS FOR BOILERS AND PROCESS HEATERS

When complying with a Table 1, 2, 11, 12, or 13 numerical emission limit using . . .	You must meet these operating limits . . .
1. Wet PM scrubber control on a boiler not using a PM CPMS.	Maintain the 30-day rolling average pressure drop and the 30-day rolling average liquid flow rate at or above the lowest one-hour average pressure drop and the lowest one-hour average liquid flow rate, respectively, measured during the most recent performance test demonstrating compliance with the PM emission limitation according to § 63.7530(b) and Table 7 to this subpart.

TABLE 4 TO SUBPART DDDDD OF PART 63—OPERATING LIMITS FOR BOILERS AND PROCESS HEATERS—Continued

When complying with a Table 1, 2, 11, 12, or 13 numerical emission limit using . . .	You must meet these operating limits . . .
2. Wet acid gas (HCl) scrubber control on a boiler not using a HCl CEMS.	Maintain the 30-day rolling average effluent pH at or above the lowest one-hour average pH and the 30-day rolling average liquid flow rate at or above the lowest one-hour average liquid flow rate measured during the most recent performance test demonstrating compliance with the HCl emission limitation according to § 63.7530(b) and Table 7 to this subpart.
3. Fabric filter control on units not using a PM CPMS.	a. Maintain opacity to less than or equal to 10 percent opacity (daily block average); or b. Install and operate a bag leak detection system according to § 63.7525 and operate the fabric filter such that the bag leak detection system alert is not activated more than 5 percent of the operating time during each 6-month period.
4. Electrostatic precipitator control on units not using a PM CPMS.	a. This option is for boilers and process heaters that operate dry control systems (i.e., an ESP without a wet scrubber). Existing and new boilers and process heaters must maintain opacity to less than or equal to 10 percent opacity (daily block average); or b. This option is only for boilers and process heaters not subject to PM CPMS or continuous compliance with an opacity limit (i.e., COMS). Maintain the 30-day rolling average total secondary electric power input of the electrostatic precipitator at or above the operating limits established during the performance test according to § 63.7530(b) and Table 7 to this subpart.
5. Dry scrubber or carbon injection control on a boiler not using a mercury CEMS.	Maintain the minimum sorbent or carbon injection rate as defined in § 63.7575 of this subpart.
6. Any other add-on air pollution control type on units not using a PM CPMS.	This option is for boilers and process heaters that operate dry control systems. Existing and new boilers and process heaters must maintain opacity to less than or equal to 10 percent opacity (daily block average).
7. Fuel analysis	Maintain the fuel type or fuel mixture such that the applicable emission rates calculated according to § 63.7530(c)(1), (2) and/or (3) is less than the applicable emission limits.
8. Performance testing	For boilers and process heaters that demonstrate compliance with a performance test, maintain the operating load of each unit such that it does not exceed 110 percent of the highest hourly average operating load recorded during the most recent performance test.
9. Oxygen analyzer system	For boilers and process heaters subject to a CO emission limit that demonstrate compliance with an O_2 analyzer system as specified in § 63.7525(a), maintain the 30-day rolling average oxygen content at or above the lowest hourly average oxygen concentration measured during the most recent CO performance test, as specified in Table 8. This requirement does not apply to units that install an oxygen trim system since these units will set the trim system to the level specified in § 63.7525(a).
10. SO_2 CEMS	For boilers or process heaters subject to an HCl emission limit that demonstrate compliance with an SO_2 CEMS, maintain the 30-day rolling average SO_2 emission rate at or below the highest hourly average SO_2 concentration measured during the most recent HCl performance test, as specified in Table 8.

■ 32. Table 5 to subpart DDDDD of part 63 is amended by:
■ a. Revising the entry for ''1. Particulate matter.''
■ b. Remove the entry for ''5. Dioxins/Furans''.
■ c. Redesignating the entries for ''2. Hydrogen chloride,'' ''3. Mercury,'' and ''4. CO'' as ''3. Hydrogen chloride,'' ''4. Mercury,'' and ''5. CO,'' respectively.
■ d. Revising the newly redesignated entries for ''4. Mercury'' and ''5. CO.''
■ e. Add entry for ''2. Total selected metals.''

The revisions and addition read as follows:

As stated in § 63.7520, you must comply with the following requirements for performance testing for existing, new or reconstructed affected sources:

TABLE 5 TO SUBPART DDDDD OF PART 63—PERFORMANCE TESTING REQUIREMENTS

To conduct a performance test for the following pollutant . . .	You must . . .	Using . . .
1. Filterable PM	a. Select sampling ports location and the number of traverse points.	Method 1 at 40 CFR part 60, appendix A–1 of this chapter.
	b. Determine velocity and volumetric flow-rate of the stack gas.	Method 2, 2F, or 2G at 40 CFR part 60, appendix A–1 or A–2 to part 60 of this chapter.
	c. Determine oxygen or carbon dioxide concentration of the stack gas.	Method 3A or 3B at 40 CFR part 60, appendix A–2 to part 60 of this chapter, or ANSI/ASME PTC 19.10–1981.[a]
	d. Measure the moisture content of the stack gas.	Method 4 at 40 CFR part 60, appendix A–3 of this chapter.
	e. Measure the PM emission concentration	Method 5 or 17 (positive pressure fabric filters must use Method 5D) at 40 CFR part 60, appendix A–3 or A–6 of this chapter.
	f. Convert emissions concentration to lb per MMBtu emission rates.	Method 19 F-factor methodology at 40 CFR part 60, appendix A–7 of this chapter.
2. TSM	a. Select sampling ports location and the number of traverse points.	Method 1 at 40 CFR part 60, appendix A–1 of this chapter.

TABLE 5 TO SUBPART DDDDD OF PART 63—PERFORMANCE TESTING REQUIREMENTS—Continued

To conduct a performance test for the following pollutant . . .	You must . . .	Using . . .
	b. Determine velocity and volumetric flow-rate of the stack gas.	Method 2, 2F, or 2G at 40 CFR part 60, appendix A–1 or A–2 of this chapter.
	c. Determine oxygen or carbon dioxide concentration of the stack gas.	Method 3A or 3B at 40 CFR part 60, appendix A–1 of this chapter, or ANSI/ASME PTC 19.10–1981.[a]
	d. Measure the moisture content of the stack gas.	Method 4 at 40 CFR part 60, appendix A–3 of this chapter.
	e. Measure the TSM emission concentration ...	Method 29 at 40 CFR part 60, appendix A–8 of this chapter
	f. Convert emissions concentration to lb per MMBtu emission rates.	Method 19 F-factor methodology at 40 CFR part 60, appendix A–7 of this chapter.
3. HCl	a. Select sampling ports location and the number of traverse points.	Method 1 at 40 CFR part 60, appendix A–1 of this chapter.
	b. Determine velocity and volumetric flow-rate of the stack gas.	Method 2, 2F, or 2G at 40 CFR part 60, appendix A–2 of this chapter.
	c. Determine oxygen or carbon dioxide concentration of the stack gas.	Method 3A or 3B at 40 CFR part 60, appendix A–2 of this chapter, or ANSI/ASME PTC 19.10–1981.[a]
	d. Measure the moisture content of the stack gas.	Method 4 at 40 CFR part 60, appendix A–3 of this chapter.
	e. Measure the HCl emission concentration	Method 26 or 26A (M26 or M26A) at 40 CFR part 60, appendix A–8 of this chapter.
	f. Convert emissions concentration to lb per MMBtu emission rates.	Method 19 F-factor methodology at 40 CFR part 60, appendix A–7 of this chapter.
4. Mercury	a. Select sampling ports location and the number of traverse points.	Method 1 at 40 CFR part 60, appendix A–1 of this chapter.
	b. Determine velocity and volumetric flow-rate of the stack gas.	Method 2, 2F, or 2G at 40 CFR part 60, appendix A–1 or A–2 of this chapter.
	c. Determine oxygen or carbon dioxide concentration of the stack gas.	Method 3A or 3B at 40 CFR part 60, appendix A–1 of this chapter, or ANSI/ASME PTC 19.10–1981.[a]
	d. Measure the moisture content of the stack gas.	Method 4 at 40 CFR part 60, appendix A–3 of this chapter.
	e. Measure the mercury emission concentration.	Method 29, 30A, or 30B (M29, M30A, or M30B) at 40 CFR part 60, appendix A–8 of this chapter or Method 101A at 40 CFR part 61, appendix B of this chapter, or ASTM Method D6784.[a]
	f. Convert emissions concentration to lb per MMBtu emission rates.	Method 19 F-factor methodology at 40 CFR part 60, appendix A–7 of this chapter.
5. CO	a. Select the sampling ports location and the number of traverse points.	Method 1 at 40 CFR part 60, appendix A–1 of this chapter.
	b. Determine oxygen concentration of the stack gas.	Method 3A or 3B at 40 CFR part 60, appendix A–3 of this chapter, or ASTM D6522–00 (Reapproved 2005), or ANSI/ASME PTC 19.10–1981.[a]
	c. Measure the moisture content of the stack gas.	Method 4 at 40 CFR part 60, appendix A–3 of this chapter.
	d. Measure the CO emission concentration	Method 10 at 40 CFR part 60, appendix A–4 of this chapter. Use a measurement span value of 2 times the concentration of the applicable emission limit.

* * * * *

■ 33. Table 6 to subpart DDDDD of part 63 is revised to read as follows:

As stated in § 63.7521, you must comply with the following requirements for fuel analysis testing for existing, new or reconstructed affected sources. However, equivalent methods (as defined in § 63.7575) may be used in lieu of the prescribed methods at the discretion of the source owner or operator:

TABLE 6 TO SUBPART DDDDD OF PART 63—FUEL ANALYSIS REQUIREMENTS

To conduct a fuel analysis for the following pollutant . . .	You must . . .	Using . . .
1. Mercury	a. Collect fuel samples	Procedure in § 63.7521(c) or ASTM D5192[a], or ASTM D7430[a], or ASTM D6883[a], or ASTM D2234/D2234M[a](for coal) or EPA 1631 or EPA 1631E or ASTM D6323[a] (for solid), or EPA 821–R–01–013 (for liquid or solid), or ASTM D4177[a] (for liquid), or ASTM D4057[a] (for liquid), or equivalent.
	b. Composite fuel samples	Procedure in § 63.7521(d) or equivalent.
	c. Prepare composited fuel samples	EPA SW–846–3050B[a] (for solid samples), EPA SW–846–3020A[a] (for liquid samples), ASTM D2013/D2013M[a] (for coal), ASTM D5198[a] (for biomass), or EPA 3050[a] (for solid fuel), or EPA 821–R–01–013[a] (for liquid or solid), or equivalent.

TABLE 6 TO SUBPART DDDDD OF PART 63—FUEL ANALYSIS REQUIREMENTS—Continued

To conduct a fuel analysis for the following pollutant . . .	You must . . .	Using . . .
	d. Determine heat content of the fuel type	ASTM D5865[a] (for coal) or ASTM E711[a] (for biomass), or ASTM D5864[a] for liquids and other solids, or ASTM D240[a] or equivalent.
	e. Determine moisture content of the fuel type	ASTM D3173[a], ASTM E871[a], or ASTM D5864[a], or ASTM D240, or ASTM D95[a] (for liquid fuels), or ASTM D4006[a] (for liquid fuels), or ASTM D4177[a] (for liquid fuels) or ASTM D4057[a] (for liquid fuels), or equivalent.
	f. Measure mercury concentration in fuel sample.	ASTM D6722[a] (for coal), EPA SW–846–7471B[a] (for solid samples), or EPA SW–846–7470A[a] (for liquid samples), or equivalent.
	g. Convert concentration into units of pounds of mercury per MMBtu of heat content.	Equation 8 in § 63.7530.
	h. Calculate the mercury emission rate from the boiler or process heater in units of pounds per million Btu.	Equations 10 and 12 in § 63.7530.
2. HCl	a. Collect fuel samples	Procedure in § 63.7521(c) or ASTM D5192[a], or ASTM D7430[a], or ASTM D6883[a], or ASTM D2234/D2234M[a] (for coal) or ASTM D6323[a] (for coal or biomass), ASTM D4177[a] (for liquid fuels) or ASTM D4057[a] (for liquid fuels), or equivalent.
	b. Composite fuel samples	Procedure in § 63.7521(d) or equivalent.
	c. Prepare composited fuel samples	EPA SW–846–3050B[a] (for solid samples), EPA SW–846–3020A[a] (for liquid samples), ASTM D2013/D2013M§[a] (for coal), or ASTM D5198§[a] (for biomass), or EPA 3050[a] or equivalent.
	d. Determine heat content of the fuel type	ASTM D5865[a] (for coal) or ASTM E711[a] (for biomass), ASTM D5864, ASTM D240[a] or equivalent.
	e. Determine moisture content of the fuel type	ASTM D3173[a] or ASTM E871[a], or D5864[a], or ASTM D240[a], or ASTM D95[a] (for liquid fuels), or ASTM D4006[a] (for liquid fuels), or ASTM D4177[a] (for liquid fuels) or ASTM D4057[a] (for liquid fuels) or equivalent.
	f. Measure chlorine concentration in fuel sample.	EPA SW–846–9250[a], ASTM D6721[a], ASTM D4208[a] (for coal), or EPA SW–846–5050[a] or ASTM E776[a] (for solid fuel), or EPA SW–846–9056[a] or SW–846–9076[a] (for solids or liquids) or equivalent.
	g. Convert concentrations into units of pounds of HCl per MMBtu of heat content.	Equation 7 in § 63.7530.
	h. Calculate the HCl emission rate from the boiler or process heater in units of pounds per million Btu.	Equations 10 and 11 in § 63.7530.
3. Mercury Fuel Specification for other gas 1 fuels.	a. Measure mercury concentration in the fuel sample and convert to units of micrograms per cubic meter.	Method 30B (M30B) at 40 CFR part 60, appendix A–8 of this chapter or ASTM D5954[a], ASTM D6350[a], ISO 6978–1:2003(E)[a], or ISO 6978–2:2003(E)[a], or EPA–1631[a] or equivalent.
	b. Measure mercury concentration in the exhaust gas when firing only the other gas 1 fuel is fired in the boiler or process heater.	Method 29, 30A, or 30B (M29, M30A, or M30B) at 40 CFR part 60, appendix A–8 of this chapter or Method 101A or Method 102 at 40 CFR part 61, appendix B of this chapter, or ASTM Method D6784[a] or equivalent.
4. TSM for solid fuels	a. Collect fuel samples	Procedure in § 63.7521(c) or ASTM D5192[a], or ASTM D7430[a], or ASTM D6883[a], or ASTM D2234/D2234M[a] (for coal) or ASTM D6323[a] (for coal or biomass), or ASTM D4177[a],(for liquid fuels)or ASTM D4057[a] (for liquid fuels),or equivalent.
	b. Composite fuel samples	Procedure in § 63.7521(d) or equivalent.
	c. Prepare composited fuel samples	EPA SW–846–3050B[a] (for solid samples), EPA SW–846–3020A[a] (for liquid samples), ASTM D2013/D2013M[a] (for coal), ASTM D5198[a] or TAPPI T266[a] (for biomass), or EPA 3050[a] or equivalent.
	d. Determine heat content of the fuel type	ASTM D5865[a] (for coal) or ASTM E711[a] (for biomass), or ASTM D5864[a] for liquids and other solids, or ASTM D240[a] or equivalent.
	e. Determine moisture content of the fuel type	ASTM D3173[a] or ASTM E871[a], or D5864, or ASTM D240[a], or ASTM D95[a] (for liquid fuels), or ASTM D4006[a] (for liquid fuels), or ASTM D4177[a] (for liquid fuels) or ASTM D4057[a] (for liquid fuels), or equivalent.
	f. Measure TSM concentration in fuel sample ..	ASTM D3683[a], or ASTM D4606[a], or ASTM D6357[a] or EPA 200.8[a] or EPA SW–846–6020[a], or EPA SW–846–6020A[a], or EPA SW–846–6010C[a], EPA 7060[a] or EPA 7060A[a] (for arsenic only), or EPA SW–846–7740[a] (for selenium only).
	g. Convert concentrations into units of pounds of TSM per MMBtu of heat content.	Equation 9 in § 63.7530.
	h. Calculate the TSM emission rate from the boiler or process heater in units of pounds per million Btu.	Equations 10 and 13 in § 63.7530.

[a] Incorporated by reference, see § 63.14.

■ 34. Table 7 to subpart DDDDD of part 63 is amended by:
■ a. Revising the entry for ''1. Particulate matter or mercury,''.
■ b. Revising the entry for ''2. Hydrogen Chloride,''.
■ c. Revising the entry for ''3. Mercury,''.
■ d. Revising the entry for ''4. Carbon monoxide''.

The revisions read as follows:

As stated in § 63.7520, you must comply with the following requirements for establishing operating limits:

TABLE 7 TO SUBPART DDDDD OF PART 63—ESTABLISHING OPERATING LIMITS

If you have an applicable emission limit for . . .	And your operating limits are based on . . .	You must . . .	Using . . .	According to the following requirements
1. PM, TSM, or mercury	a. Wet scrubber operating parameters.	i. Establish a site-specific minimum scrubber pressure drop and minimum flow rate operating limit according to § 63.7530(b).	(1) Data from the scrubber pressure drop and liquid flow rate monitors and the PM or mercury performance test.	(a) You must collect scrubber pressure drop and liquid flow rate data every 15 minutes during the entire period of the performance tests. (b) Determine the lowest hourly average scrubber pressure drop and liquid flow rate by computing the hourly averages using all of the 15-minute readings taken during each performance test.
	b. Electrostatic precipitator operating parameters (option only for units that operate wet scrubbers).	i. Establish a site-specific minimum total secondary electric power input according to § 63.7530(b).	(1) Data from the voltage and secondary amperage monitors during the PM or mercury performance test.	(a) You must collect secondary voltage and secondary amperage for each ESP cell and calculate total secondary electric power input data every 15 minutes during the entire period of the performance tests. (b) Determine the average total secondary electric power input by computing the hourly averages using all of the 15-minute readings taken during each performance test.
2. HCl	a. Wet scrubber operating parameters.	i. Establish site-specific minimum pressure drop, effluent pH, and flow rate operating limits according to § 63.7530(b).	(1) Data from the pressure drop, pH, and liquid flow-rate monitors and the HCl performance test.	(a) You must collect pH and liquid flow-rate data every 15 minutes during the entire period of the performance tests. (b) Determine the hourly average pH and liquid flow rate by computing the hourly averages using all of the 15-minute readings taken during each performance test.
	b. Dry scrubber operating parameters.	i. Establish a site-specific minimum sorbent injection rate operating limit according to § 63.7530(b). If different acid gas sorbents are used during the HCl performance test, the average value for each sorbent becomes the site-specific operating limit for that sorbent.	(1) Data from the sorbent injection rate monitors and HCl or mercury performance test.	(a) You must collect sorbent injection rate data every 15 minutes during the entire period of the performance tests. (b) Determine the hourly average sorbent injection rate by computing the hourly averages using all of the 15-minute readings taken during each performance test. (c) Determine the lowest hourly average of the three test run averages established during the performance test as your operating limit. When your unit operates at lower loads, multiply your sorbent injection rate by the load fraction (e.g., for 50 percent load, multiply the injection rate operating limit by 0.5) to determine the required injection rate.
	c. Alternative Maximum SO_2 emission rate.	i. Establish a site-specific maximum SO_2 emission rate operating limit according to § 63.7530(b).	(1) Data from SO_2 CEMS and the HCl performance test.	(a) You must collect the SO_2 emissions data according to § 63.7525(m) during the most recent HCl performance tests.

TABLE 7 TO SUBPART DDDDD OF PART 63—ESTABLISHING OPERATING LIMITS—Continued

If you have an applicable emission limit for . . .	And your operating limits are based on . . .	You must . . .	Using . . .	According to the following requirements
				(b) The maximum SO_2 emission rate is equal to the lowest hourly average SO_2 emission rate measured during the most recent HCl performance tests.
3. Mercury	a. Activated carbon injection	i. Establish a site-specific minimum activated carbon injection rate operating limit according to § 63.7530(b).	(1) Data from the activated carbon rate monitors and mercury performance test.	(a) You must collect activated carbon injection rate data every 15 minutes during the entire period of the performance tests. (b) Determine the hourly average activated carbon injection rate by computing the hourly averages using all of the 15-minute readings taken during each performance test. (c) Determine the lowest hourly average established during the performance test as your operating limit. When your unit operates at lower loads, multiply your activated carbon injection rate by the load fraction (*e.g.,* actual heat input divided by heat input during performance test, for 50 percent load, multiply the injection rate operating limit by 0.5) to determine the required injection rate.
4. Carbon monoxide	a. Oxygen	i. Establish a unit-specific limit for minimum oxygen level according to § 63.7520.	(1) Data from the oxygen analyzer system specified in § 63.7525(a).	(a) You must collect oxygen data every 15 minutes during the entire period of the performance tests. (b) Determine the hourly average oxygen concentration by computing the hourly averages using all of the 15-minute readings taken during each performance test. (c) Determine the lowest hourly average established during the performance test as your minimum operating limit.
*	*	*	*	*	*	*

■ 35. Table 8 to subpart DDDDD of part 63 is revised to read as follows:

As stated in § 63.7540, you must show continuous compliance with the emission limitations for each boiler or process heater according to the following:

TABLE 8 TO SUBPART DDDDD OF PART 63—DEMONSTRATING CONTINUOUS COMPLIANCE

If you must meet the following operating limits or work practice standards . . .	You must demonstrate continuous compliance by . . .
1. Opacity	a. Collecting the opacity monitoring system data according to § 63.7525(c) and § 63.7535; and b. Reducing the opacity monitoring data to 6-minute averages; and c. Maintaining opacity to less than or equal to 10 percent (daily block average).
2. PM CPMS	a. Collecting the PM CPMS output data according to § 63.7525; b. Reducing the data to 30-day rolling averages; and c. Maintaining the 30-day rolling average PM CPMS output data to less than the operating limit established during the performance test according to § 63.7530(b)(4).
3. Fabric Filter Bag Leak Detection Operation	Installing and operating a bag leak detection system according to § 63.7525 and operating the fabric filter such that the requirements in § 63.7540(a)(9) are met.
4. Wet Scrubber Pressure Drop and Liquid Flow-rate.	a. Collecting the pressure drop and liquid flow rate monitoring system data according to §§ 63.7525 and 63.7535; and b. Reducing the data to 30-day rolling averages; and c. Maintaining the 30-day rolling average pressure drop and liquid flow-rate at or above the operating limits established during the performance test according to § 63.7530(b).
5. Wet Scrubber pH	a. Collecting the pH monitoring system data according to §§ 63.7525 and 63.7535; and

TABLE 8 TO SUBPART DDDDD OF PART 63—DEMONSTRATING CONTINUOUS COMPLIANCE—Continued

If you must meet the following operating limits or work practice standards . . .	You must demonstrate continuous compliance by . . .
	b. Reducing the data to 30-day rolling averages; and c. Maintaining the 30-day rolling average pH at or above the operating limit established during the performance test according to § 63.7530(b).
6. Dry Scrubber Sorbent or Carbon Injection Rate.	a. Collecting the sorbent or carbon injection rate monitoring system data for the dry scrubber according to §§ 63.7525 and 63.7535; and b. Reducing the data to 30-day rolling averages; and c. Maintaining the 30-day rolling average sorbent or carbon injection rate at or above the minimum sorbent or carbon injection rate as defined in § 63.7575.
7. Electrostatic Precipitator Total Secondary Electric Power Input.	a. Collecting the total secondary electric power input monitoring system data for the electrostatic precipitator according to §§ 63.7525 and 63.7535; and b. Reducing the data to 30-day rolling averages; and c. Maintaining the 30-day rolling average total secondary electric power input at or above the operating limits established during the performance test according to § 63.7530(b).
8. Emission limits using fuel analysis	a. Conduct monthly fuel analysis for HCl or mercury or TSM according to Table 6 to this subpart; and b. Reduce the data to 12-month rolling averages; and c. Maintain the 12-month rolling average at or below the applicable emission limit for HCl or mercury or TSM in Tables 1 and 2 or 11 through 13 to this subpart.
9. Oxygen content	a. Continuously monitor the oxygen content using an oxygen analyzer system according to § 63.7525(a). This requirement does not apply to units that install an oxygen trim system since these units will set the trim system to the level specified in § 63.7525(a)(2). b. Reducing the data to 30-day rolling averages; and c. Maintain the 30-day rolling average oxygen content at or above the lowest hourly average oxygen level measured during the most recent CO performance test.
10. Boiler or process heater operating load	a. Collecting operating load data or steam generation data every 15 minutes. b. Maintaining the operating load such that it does not exceed 110 percent of the highest hourly average operating load recorded during the most recent performance test according to § 63.7520(c).
11. SO_2 emissions using SO_2 CEMS	a. Collecting the SO_2 CEMS output data according to § 63.7525; b. Reducing the data to 30-day rolling averages; and c. Maintaining the 30-day rolling average SO_2 CEMS emission rate to a level at or below the minimum hourly SO_2 rate measured during the most recent HCl performance test according to § 63.7530.

■ 36. Table 9 to subpart DDDDD of part 63 is amended by revising the entry for ''1. Compliance report'' to read as follows:

As stated in § 63.7550, you must comply with the following requirements for reports:

TABLE 9 TO SUBPART DDDDD OF PART 63—REPORTING REQUIREMENTS

You must submit a(n)	The report must contain . . .	You must submit the report . . .
1. Compliance report	a. Information required in § 63.7550(c)(1) through (5); and	Semiannually, annually, biennially, or every 5 years according to the requirements in § 63.7550(b).
* * * * * * *		

■ 37. Table 10 to subpart DDDDD of part 63 is amended by:
■ a. Revising the entry for ''§ 63.6(i)''.
■ b. Revising the entry for ''§ 63.7(e)(1)''.
■ c. Revising the entry for ''63.8(g)''.
■ d. Revising the entry for ''§ 63.10(e) and (f)''.
■ e. Adding an entry for ''§ 63.10(e)''.
The revisions and addition read as follows.

As stated in § 63.7565, you must comply with the applicable General Provisions according to the following:

TABLE 10 TO SUBPART DDDDD OF PART 63—APPLICABILITY OF GENERAL PROVISIONS TO SUBPART DDDDD

Citation	Subject	Applies to subpart DDDDD
* * * * * * *		
§ 63.6(i)	Extension of compliance	Yes. Note: Facilities may also request extensions of compliance for the installation of combined heat and power, waste heat recovery, or gas pipeline or fuel feeding infrastructure as a means of complying with this subpart.

TABLE 10 TO SUBPART DDDDD OF PART 63—APPLICABILITY OF GENERAL PROVISIONS TO SUBPART DDDDD—Continued

Citation	Subject	Applies to subpart DDDDD
*	* * *	* * *
§ 63.7(e)(1)	Conditions for conducting performance tests	No. Subpart DDDDD specifies conditions for conducting performance tests at § 63.7520(a) to (c).
*	* * *	* * *
§ 63.8(g)	Reduction of monitoring data	Yes.
*	* * *	* * *
§ 63.10(e)	Additional reporting requirements for sources with CMS.	Yes.
§ 63.10(f)	Waiver of recordkeeping or reporting requirements.	Yes.
*	* * *	* * *

■ 38. Add Table 11 to subpart DDDDD of part 63 to read as follows:

TABLE 11 TO SUBPART DDDDD OF PART 63—ALTERNATIVE EMISSION LIMITS FOR NEW OR RECONSTRUCTED BOILERS AND PROCESS HEATERS THAT COMMENCED CONSTRUCTION OR RECONSTRUCTION AFTER JUNE 4, 2010, AND BEFORE MAY 20, 2011

If your boiler or process heater is in this subcategory . . .	For the following pollutants . . .	The emissions must not exceed the following emission limits, except during periods of startup and shutdown . . .	Using this specified sampling volume or test run duration . . .
1. Units in all subcategories designed to burn solid fuel.	a. HCl	0.022 lb per MMBtu of heat input	For M26A, collect a minimum of 1 dscm per run; for M26 collect a minimum of 120 liters per run.
2. Units in all subcategories designed to burn solid fuel that combust at least 10 percent biomass/bio-based solids on an annual heat input basis and less than 10 percent coal/solid fossil fuels on an annual heat input basis.	a. Mercury	8.0E–07 [a] lb per MMBtu of heat input	For M29, collect a minimum of 4 dscm per run; for M30A or M30B, collect a minimum sample as specified in the method; for ASTM D6784 [b] collect a minimum of 4 dscm.
3. Units in all subcategories designed to burn solid fuel that combust at least 10 percent coal/solid fossil fuels on an annual heat input basis and less than 10 percent biomass/bio-based solids on an annual heat input basis.	a. Mercury	2.0E–06 lb per MMBtu of heat input	For M29, collect a minimum of 4 dscm per run; for M30A or M30B, collect a minimum sample as specified in the method; for ASTM D6784 [b] collect a minimum of 4 dscm.
4. Units designed to burn coal/solid fossil fuel.	a. Filterable PM (or TSM).	1.1E–03 lb per MMBtu of heat input; or (2.3E–05 lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run.
5. Pulverized coal boilers designed to burn coal/solid fossil fuel.	a. Carbon monoxide (CO) (or CEMS).	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (320 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1 hr minimum sampling time.
6. Stokers designed to burn coal/solid fossil fuel.	a. CO (or CEMS)	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (340 ppm by volume on a dry basis corrected to 3 percent oxygen, 10-day rolling average).	1 hr minimum sampling time.
7. Fluidized bed units designed to burn coal/solid fossil fuel.	a. CO (or CEMS)	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (230 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1 hr minimum sampling time.

TABLE 11 TO SUBPART DDDDD OF PART 63—ALTERNATIVE EMISSION LIMITS FOR NEW OR RECONSTRUCTED BOILERS AND PROCESS HEATERS THAT COMMENCED CONSTRUCTION OR RECONSTRUCTION AFTER JUNE 4, 2010, AND BEFORE MAY 20, 2011—Continued

If your boiler or process heater is in this subcategory . . .	For the following pollutants . . .	The emissions must not exceed the following emission limits, except during periods of startup and shutdown . . .	Using this specified sampling volume or test run duration . . .
8. Fluidized bed units with an integrated heat exchanger designed to burn coal/solid fossil fuel.	a. CO (or CEMS)	140 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (150 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1 hr minimum sampling time.
9. Stokers/sloped grate/others designed to burn wet biomass fuel.	a. CO (or CEMS)	620 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (390 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	3.0E–02 lb per MMBtu of heat input; or (2.6E–05 lb per MMBtu of heat input).	Collect a minimum of 2 dscm per run.
10. Stokers/sloped grate/others designed to burn kiln-dried biomass fuel.	a. CO	560 ppm by volume on a dry basis corrected to 3 percent oxygen.	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	3.0E–02 lb per MMBtu of heat input; or (4.0E–03 lb per MMBtu of heat input).	Collect a minimum of 2 dscm per run.
11. Fluidized bed units designed to burn biomass/bio-based solids.	a. CO (or CEMS)	230 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (310 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	9.8E–03 lb per MMBtu of heat input; or (8.3E–05 [a] lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run
12. Suspension burners designed to burn biomass/bio-based solids.	a. CO (or CEMS)	2,400 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (2,000 ppm by volume on a dry basis corrected to 3 percent oxygen, 10-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	3.0E–02 lb per MMBtu of heat input; or (6.5E–03 lb per MMBtu of heat input).	Collect a minimum of 2 dscm per run.
13. Dutch Ovens/Pile burners designed to burn biomass/bio-based solids.	a. CO (or CEMS)	1,010 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (520 ppm by volume on a dry basis corrected to 3 percent oxygen, 10-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	8.0E–03 lb per MMBtu of heat input; or (3.9E–05 lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run.
14. Fuel cell units designed to burn biomass/bio-based solids.	a. CO	910 ppm by volume on a dry basis corrected to 3 percent oxygen.	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	2.0E–02 lb per MMBtu of heat input; or (2.9E–05 lb per MMBtu of heat input).	Collect a minimum of 2 dscm per run.
15. Hybrid suspension grate boiler designed to burn biomass/bio-based solids.	a. CO (or CEMS)	1,100 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (900 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	2.6E–02 lb per MMBtu of heat input; or (4.4E–04 lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run.
16. Units designed to burn liquid fuel ..	a. HCl	4.4E–04 lb per MMBtu of heat input ...	For M26A: Collect a minimum of 2 dscm per run; for M26, collect a minimum of 240 liters per run.

TABLE 11 TO SUBPART DDDDD OF PART 63—ALTERNATIVE EMISSION LIMITS FOR NEW OR RECONSTRUCTED BOILERS AND PROCESS HEATERS THAT COMMENCED CONSTRUCTION OR RECONSTRUCTION AFTER JUNE 4, 2010, AND BEFORE MAY 20, 2011—Continued

If your boiler or process heater is in this subcategory . . .	For the following pollutants . . .	The emissions must not exceed the following emission limits, except during periods of startup and shutdown . . .	Using this specified sampling volume or test run duration . . .
	b. Mercury	4.8E–07 [a] lb per MMBtu of heat input	For M29, collect a minimum of 4 dscm per run; for M30A or M30B, collect a minimum sample as specified in the method; for ASTM D6784 [b] collect a minimum of 4 dscm.
17. Units designed to burn heavy liquid fuel.	a. CO	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average.	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	1.3E–02 lb per MMBtu of heat input; or (7.5E–05 lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run.
18. Units designed to burn light liquid fuel.	a. CO	130 ppm by volume on a dry basis corrected to 3 percent oxygen.	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	2.0E–03 [a] lb per MMBtu of heat input; or (2.9E–05 lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run
19. Units designed to burn liquid fuel that are non-continental units.	a. CO	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average based on stack test.	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	2.3E–02 lb per MMBtu of heat input; or (8.6E–04 lb per MMBtu of heat input).	Collect a minimum of 4 dscm per run
20. Units designed to burn gas 2 (other) gases.	a. CO	130 ppm by volume on a dry basis corrected to 3 percent oxygen.	1 hr minimum sampling time.
	b. HCl	1.7E–03 lb per MMBtu of heat input ...	For M26A, collect a minimum of 2 dscm per run; for M26, collect a minimum of 240 liters per run.
	c. Mercury	7.9E–06 lb per MMBtu of heat input ...	For M29, collect a minimum of 3 dscm per run; for M30A or M30B, collect a minimum sample as specified in the method; for ASTM D6784 [b] collect a minimum of 3 dscm.
	d. Filterable PM (or TSM).	6.7E–03 lb per MMBtu of heat input; or (2.1E–04 lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run

[a] If you are conducting stack tests to demonstrate compliance and your performance tests for this pollutant for at least 2 consecutive years show that your emissions are at or below this limit, you can skip testing according to § 63.7515 if all of the other provisions of § 63.7515 are met. For all other pollutants that do not contain a footnote "a", your performance tests for this pollutant for at least 2 consecutive years must show that your emissions are at or below 75 percent of this limit in order to qualify for skip testing.
[b] Incorporated by reference, see § 63.14.

■ 39. Add Table 12 to subpart DDDDD of part 63 to read as follows:

TABLE 12 TO SUBPART DDDDD OF PART 63—ALTERNATIVE EMISSION LIMITS FOR NEW OR RECONSTRUCTED BOILERS AND PROCESS HEATERS THAT COMMENCED CONSTRUCTION OR RECONSTRUCTION AFTER MAY 20, 2011, AND BEFORE DECEMBER 23, 2011

If your boiler or process heater is in this subcategory . . .	For the following pollutants . . .	The emissions must not exceed the following emission limits, except during periods of startup and shutdown . . .	Using this specified sampling volume or test run duration . . .
1. Units in all subcategories designed to burn solid fuel.	a. HCl	0.022 lb per MMBtu of heat input	For M26A, collect a minimum of 1 dscm per run; for M26 collect a minimum of 120 liters per run.
	b. Mercury	3.5E–06 [a] lb per MMBtu of heat input	For M29, collect a minimum of 3 dscm per run; for M30A or M30B, collect a minimum sample as specified in the method; for ASTM D6784 [b] collect a minimum of 3 dscm.
2. Units design to burn coal/solid fossil fuel.	a. Filterable PM (or TSM).	1.1E–03 lb per MMBtu of heat input; or (2.3E–05 lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run.

TABLE 12 TO SUBPART DDDDD OF PART 63—ALTERNATIVE EMISSION LIMITS FOR NEW OR RECONSTRUCTED BOILERS AND PROCESS HEATERS THAT COMMENCED CONSTRUCTION OR RECONSTRUCTION AFTER MAY 20, 2011, AND BEFORE DECEMBER 23, 2011—Continued

If your boiler or process heater is in this subcategory . . .	For the following pollutants . . .	The emissions must not exceed the following emission limits, except during periods of startup and shutdown . . .	Using this specified sampling volume or test run duration . . .
3. Pulverized coal boilers designed to burn coal/solid fossil fuel.	a. Carbon monoxide (CO) (or CEMS).	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (320 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1 hr minimum sampling time.
4. Stokers designed to burn coal/solid fossil fuel.	a. CO (or CEMS)	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (340 ppm by volume on a dry basis corrected to 3 percent oxygen, 10-day rolling average).	1 hr minimum sampling time.
5. Fluidized bed units designed to burn coal/solid fossil fuel.	a. CO (or CEMS)	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (230 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1 hr minimum sampling time.
6. Fluidized bed units with an integrated heat exchanger designed to burn coal/solid fossil fuel.	a. CO (or CEMS)	140 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (150 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1 hr minimum sampling time.
7. Stokers/sloped grate/others designed to burn wet biomass fuel.	a. CO (or CEMS)	620 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (390 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	3.0E–02 lb per MMBtu of heat input; or (2.6E–05 lb per MMBtu of heat input).	Collect a minimum of 2 dscm per run.
8. Stokers/sloped grate/others designed to burn kiln-dried biomass fuel.	a. CO	460 ppm by volume on a dry basis corrected to 3 percent oxygen.	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	3.0E–02 lb per MMBtu of heat input; or (4.0E–03 lb per MMBtu of heat input).	Collect a minimum of 2 dscm per run.
9. Fluidized bed units designed to burn biomass/bio-based solids.	a. CO (or CEMS)	260 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (310 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	9.8E–03 lb per MMBtu of heat input; or (8.3E–05 [a] lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run.
10. Suspension burners designed to burn biomass/bio-based solids.	a. CO (or CEMS)	2,400 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (2,000 ppm by volume on a dry basis corrected to 3 percent oxygen, 10-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	3.0E–02 lb per MMBtu of heat input; or (6.5E–03 lb per MMBtu of heat input).	Collect a minimum of 2 dscm per run.
11. Dutch Ovens/Pile burners designed to burn biomass/bio-based solids.	a. CO (or CEMS)	470 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (520 ppm by volume on a dry basis corrected to 3 percent oxygen, 10-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	3.2E–03 lb per MMBtu of heat input; or (3.9E–05 lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run.

TABLE 12 TO SUBPART DDDDD OF PART 63—ALTERNATIVE EMISSION LIMITS FOR NEW OR RECONSTRUCTED BOILERS AND PROCESS HEATERS THAT COMMENCED CONSTRUCTION OR RECONSTRUCTION AFTER MAY 20, 2011, AND BEFORE DECEMBER 23, 2011—Continued

If your boiler or process heater is in this subcategory . . .	For the following pollutants . . .	The emissions must not exceed the following emission limits, except during periods of startup and shutdown . . .	Using this specified sampling volume or test run duration . . .
12. Fuel cell units designed to burn biomass/bio-based solids.	a. CO	910 ppm by volume on a dry basis corrected to 3 percent oxygen.	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	2.0E–02 lb per MMBtu of heat input; or (2.9E–05 lb per MMBtu of heat input).	Collect a minimum of 2 dscm per run.
13. Hybrid suspension grate boiler designed to burn biomass/bio-based solids.	a. CO (or CEMS)	1,500 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (900 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	2.6E–02 lb per MMBtu of heat input; or (4.4E–04 lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run.
14. Units designed to burn liquid fuel	a. HCl	4.4E–04 lb per MMBtu of heat input	For M26A: Collect a minimum of 2 dscm per run; for M26, collect a minimum of 240 liters per run.
	b. Mercury	4.8E–07 [a] lb per MMBtu of heat input	For M29, collect a minimum of 4 dscm per run; for M30A or M30B, collect a minimum sample as specified in the method; for ASTM D6784 [b] collect a minimum of 4 dscm.
15. Units designed to burn heavy liquid fuel.	a. CO	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average.	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	1.3E–02 lb per MMBtu of heat input; or (7.5E–05 lb per MMBtu of heat input).	Collect a minimum of 2 dscm per run.
16. Units designed to burn light liquid fuel.	a. CO	130 ppm by volume on a dry basis corrected to 3 percent oxygen.	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	1.3E–03 [a] lb per MMBtu of heat input; or (2.9E–05 lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run.
17. Units designed to burn liquid fuel that are non-continental units.	a. CO	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average based on stack test.	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	2.3E–02 lb per MMBtu of heat input; or (8.6E–04 lb per MMBtu of heat input).	Collect a minimum of 4 dscm per run.
18. Units designed to burn gas 2 (other) gases.	a. CO	130 ppm by volume on a dry basis corrected to 3 percent oxygen.	1 hr minimum sampling time.
	b. HCl	1.7E–03 lb per MMBtu of heat input	For M26A, Collect a minimum of 2 dscm per run; for M26, collect a minimum of 240 liters per run.
	c. Mercury	7.9E–06 lb per MMBtu of heat input	For M29, collect a minimum of 3 dscm per run; for M30A or M30B, collect a minimum sample as specified in the method; for ASTM D6784 [b] collect a minimum of 3 dscm.
	d. Filterable PM (or TSM).	6.7E–03 lb per MMBtu of heat input; or (2.1E–04 lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run.

[a] If you are conducting stack tests to demonstrate compliance and your performance tests for this pollutant for at least 2 consecutive years show that your emissions are at or below this limit, you can skip testing according to § 63.7515 if all of the other provision of § 63.7515 are met. For all other pollutants that do not contain a footnote ''a'', your performance tests for this pollutant for at least 2 consecutive years must show that your emissions are at or below 75 percent of this limit in order to qualify for skip testing.

[b] Incorporated by reference, see § 63.14.

■ 40. Add Table 13 to subpart DDDDD of part 63 to read as follows:

TABLE 13 TO SUBPART DDDDD OF PART 63—ALTERNATIVE EMISSION LIMITS FOR NEW OR RECONSTRUCTED BOILERS AND PROCESS HEATERS THAT COMMENCED CONSTRUCTION OR RECONSTRUCTION AFTER DECEMBER 23, 2011, AND BEFORE JANUARY 31, 2013

If your boiler or process heater is in this subcategory . . .	For the following pollutants . . .	The emissions must not exceed the following emission limits, except during periods of startup and shutdown . . .	Using this specified sampling volume or test run duration . . .
1. Units in all subcategories designed to burn solid fuel.	a. HCl	0.022 lb per MMBtu of heat input	For M26A, collect a minimum of 1 dscm per run; for M26 collect a minimum of 120 liters per run.
	b. Mercury	8.6E–07 [a] lb per MMBtu of heat input	For M29, collect a minimum of 4 dscm per run; for M30A or M30B, collect a minimum sample as specified in the method; for ASTM D6784 [b] collect a minimum of 4 dscm.
2. Pulverized coal boilers designed to burn coal/solid fossil fuel.	a. Carbon monoxide (CO) (or CEMS).	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (320 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	1.1E–03 lb per MMBtu of heat input; or (2.8E–05 lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run.
3. Stokers designed to burn coal/solid fossil fuel.	a. CO (or CEMS)	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (340 ppm by volume on a dry basis corrected to 3 percent oxygen, 10-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	2.8E–02 lb per MMBtu of heat input; or (2.3E–05 lb per MMBtu of heat input).	Collect a minimum of 2 dscm per run.
4. Fluidized bed units designed to burn coal/solid fossil fuel.	a. CO (or CEMS)	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (230 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	1.1E–03 lb per MMBtu of heat input; or (2.3E–05 lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run.
5. Fluidized bed units with an integrated heat exchanger designed to burn coal/solid fossil fuel.	a. CO (or CEMS)	140 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (150 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	1.1E–03 lb per MMBtu of heat input; or (2.3E–05 lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run.
6. Stokers/sloped grate/others designed to burn wet biomass fuel.	a. CO (or CEMS)	620 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (410 ppm by volume on a dry basis corrected to 3 percent oxygen, 10-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	3.0E–02 lb per MMBtu of heat input; or (2.6E–05 lb per MMBtu of heat input).	Collect a minimum of 2 dscm per run.
7. Stokers/sloped grate/others designed to burn kiln-dried biomass fuel.	a. CO	460 ppm by volume on a dry basis corrected to 3 percent oxygen.	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	3.2E–01 lb per MMBtu of heat input; or (4.0E–03 lb per MMBtu of heat input).	Collect a minimum of 2 dscm per run.
8. Fluidized bed units designed to burn biomass/bio-based solids.	a. CO (or CEMS)	230 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (310 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1 hr minimum sampling time.

TABLE 13 TO SUBPART DDDDD OF PART 63—ALTERNATIVE EMISSION LIMITS FOR NEW OR RECONSTRUCTED BOILERS AND PROCESS HEATERS THAT COMMENCED CONSTRUCTION OR RECONSTRUCTION AFTER DECEMBER 23, 2011, AND BEFORE JANUARY 31, 2013—Continued

If your boiler or process heater is in this subcategory . . .	For the following pollutants . . .	The emissions must not exceed the following emission limits, except during periods of startup and shutdown . . .	Using this specified sampling volume or test run duration . . .
	b. Filterable PM (or TSM).	9.8E–03 lb per MMBtu of heat input; or (8.3E–05 [a] lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run.
9. Suspension burners designed to burn biomass/bio-based solids.	a. CO (or CEMS)	2,400 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (2,000 ppm by volume on a dry basis corrected to 3 percent oxygen, 10-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	5.1E–02 lb per MMBtu of heat input; or (6.5E–03 lb per MMBtu of heat input).	Collect a minimum of 2 dscm per run.
10. Dutch Ovens/Pile burners designed to burn biomass/bio-based solids.	a. CO (or CEMS)	810 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (520 ppm by volume on a dry basis corrected to 3 percent oxygen, 10-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	3.6E–02 lb per MMBtu of heat input; or (3.9E–05 lb per MMBtu of heat input).	Collect a minimum of 2 dscm per run.
11. Fuel cell units designed to burn biomass/bio-based solids.	a. CO	910 ppm by volume on a dry basis corrected to 3 percent oxygen.	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	2.0E–02 lb per MMBtu of heat input; or (2.9E–05 lb per MMBtu of heat input).	Collect a minimum of 2 dscm per run.
12. Hybrid suspension grate boiler designed to burn biomass/bio-based solids.	a. CO (or CEMS)	1,500 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (900 ppm by volume on a dry basis corrected to 3 percent oxygen, 30-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	2.6E–02 lb per MMBtu of heat input; or (4.4E–04 lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run.
13. Units designed to burn liquid fuel ..	a. HCl	1.2E–03 lb per MMBtu of heat input ...	For M26A: Collect a minimum of 2 dscm per run; for M26, collect a minimum of 240 liters per run.
	b. Mercury	4.9E–07 [a] lb per MMBtu of heat input	For M29, collect a minimum of 4 dscm per run; for M30A or M30B, collect a minimum sample as specified in the method; for ASTM D6784 [b] collect a minimum of 4 dscm.
14. Units designed to burn heavy liquid fuel.	a. CO (or CEMS)	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average; or (18 ppm by volume on a dry basis corrected to 3 percent oxygen, 10-day rolling average).	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	1.3E–03 lb per MMBtu of heat input; or (7.5E–05 lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run.
15. Units designed to burn light liquid fuel.	a. CO (or CEMS)	130 [a] ppm by volume on a dry basis corrected to 3 percent oxygen; or (60 ppm by volume on a dry basis corrected to 3 percent oxygen, 1-day block average)..	1 hr minimum sampling time.
	b. Filterable PM (or TSM).	1.1E–03 [a] lb per MMBtu of heat input; or (2.9E–05 lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run.
16. Units designed to burn liquid fuel that are non-continental units.	a. CO	130 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-run average based on stack test; or (91 ppm by volume on a dry basis corrected to 3 percent oxygen, 3-hour rolling average).	1 hr minimum sampling time.

TABLE 13 TO SUBPART DDDDD OF PART 63—ALTERNATIVE EMISSION LIMITS FOR NEW OR RECONSTRUCTED BOILERS AND PROCESS HEATERS THAT COMMENCED CONSTRUCTION OR RECONSTRUCTION AFTER DECEMBER 23, 2011, AND BEFORE JANUARY 31, 2013—Continued

If your boiler or process heater is in this subcategory . . .	For the following pollutants . . .	The emissions must not exceed the following emission limits, except during periods of startup and shutdown . . .	Using this specified sampling volume or test run duration . . .
	b. Filterable PM (or TSM).	2.3E–02 lb per MMBtu of heat input; or (8.6E–04 lb per MMBtu of heat input).	Collect a minimum of 2 dscm per run.
17. Units designed to burn gas 2 (other) gases.	a. CO	130 ppm by volume on a dry basis corrected to 3 percent oxygen.	1 hr minimum sampling time.
	b. HCl	1.7E–03 lb per MMBtu of heat input	For M26A, Collect a minimum of 2 dscm per run; for M26, collect a minimum of 240 liters per run.
	c. Mercury	7.9E–06 lb per MMBtu of heat input	For M29, collect a minimum of 3 dscm per run; for M30A or M30B, collect a minimum sample as specified in the method; for ASTM D6784 [b] collect a minimum of 3 dscm.
	d. Filterable PM (or TSM).	6.7E–03 lb per MMBtu of heat input; or (2.1E–04 lb per MMBtu of heat input).	Collect a minimum of 3 dscm per run.

[a] If you are conducting stack tests to demonstrate compliance and your performance tests for this pollutant for at least 2 consecutive years show that your emissions are at or below this limit and you are not required to conduct testing for CEMS or CPMS monitor certification, you can skip testing according to § 63.7515 if all of the other provision of § 63.7515 are met. For all other pollutants that do not contain a footnote "a", your performance tests for this pollutant for at least 2 consecutive years must show that your emissions are at or below 75 percent of this limit in order to qualify for skip testing.

[b] Incorporated by reference, see § 63.14.

CORRECTION NOTICE

This document, EPA-456/F-99-006**a**, corrects errors found in the original document, EPA-456/F-99-006. These corrections are:

Page 8, fourth paragraph: "Destruction or Recovery Efficiency" has been changed to "Destruction or Removal Efficiency;"

Page 10, Method 2. Reducing Residence Time: This section has been rewritten to correct for an ambiguity in the original text.

Page 20, Table 4. Added Selective Non-Catalytic Reduction (SNCR) to the table and added acronyms for other technologies.

Page 29, last paragraph: This paragraph has been rewritten to correct an error in stating the configuration of a typical cogeneration facility.

Page30, Internal Combustion Reciprocating Engines: A sentence has been added to the end of this section to refer the readers to Table 13 for more information;

Page 41, third through seventh paragraphs: These paragraphs were renumbered to correct for a numbering error (numbers 6 and 7 were used twice).

NMED Exhibit 81

FORWARD

The **Clean Air Technology Center (CATC)** serves as a resource on all areas of emerging and existing air pollution prevention and control technologies, and provides public access to data and information on their use, effectiveness and cost. In addition, the CATC will provide technical support, including access to EPA's knowledge base, to government agencies and others, as resources allow, related to the technical and economic feasibility, operation and maintenance of these technologies.

ACKNOWLEDGMENTS

This technical bulletin was made possible through the diligent and persistent efforts of Lyndon Cox, Senior Environmental Employee with the Clean Air Technology Center (CATC). Lyndon did an exceptional job identifying information sources, gathering relative data and putting this bulletin together. The CATC also appreciates the helpful and timely comments and cooperation of the following peer reviewers:

Jim Eddinger, Combustion Group, Emission Standards Division, Office of Air Quality Planning and Standards, Office of Air and Radiation, U.S. EPA.

Doug Grano, Ozone Policy and Strategies Group, Air Quality Strategies and Standards Division, Office of Air Quality Planning and Standards, Office of Air and Radiation, U.S. EPA.

William Vatavuk, Innovative Strategies and Economics Group, Air Quality Strategies and Standards Division, Office of Air Quality Planning and Standards, Office of Air and Radiation, U.S. EPA.

Ravi Strivastava, Air Pollution Technology Branch, Air Pollution Prevention and Control Division, National Risk Management Research Laboratory, Office of Research and Development, U.S. EPA.

In addition, the CATC thanks the individuals, companies and institutions who supplied information on nitrogen oxide abatement technology used to prepare this Technical Bulletin. Contributors are indicated in the REFERENCES section of this bulletin.

Nitrogen Oxides (NOx), Why and How They Are Controlled

When we try to look only at one thing in Nature,
we find it connected to everything else.
John Muir

Nitrogen oxides (NOx) are a very interesting and important family of air polluting chemical compounds. This bulletin explains why NOx are important air pollutants and how NOx are formed and react in the atmosphere. This bulletin also discusses the principles on which all NOx control and pollution prevention technologies are based; available NOx technologies for various combustion sources; and performance and cost of NOx technologies..

WHY SHOULD WE CONTROL NOx?

NOx represent a family of seven compounds. Actually, EPA regulates only nitrogen dioxide (NO_2) as a surrogate for this family of compounds because it is the most prevalent form of NOx in the atmosphere that is generated by anthropogenic (human) activities. NO_2 is not only an important air pollutant by itself, but also reacts in the atmosphere to form ozone (O_3) and acid rain. It is important to note that the ozone that we want to minimize is tropospheric ozone; that is, ozone in the ambient air that we breathe. We are not talking about stratospheric ozone in the upper atmosphere that we cannot breathe. Stratospheric ozone protects us and the troposphere from ionizing radiation coming from the sun.

EPA has established National Ambient Air Quality Standards (NAAQS) for NO_2 and tropospheric ozone. The NAAQS define levels of air quality that are necessary, with a reasonable margin of safety, to protect public health (primary standard) and public welfare (secondary standard) from any known or anticipated adverse effects of pollution. The primary and secondary standard for NO_2 is 0.053 parts per million (ppm) (100 micrograms per cubic meter), annual arithmetic mean concentration.

Tropospheric ozone has been and continues to be a significant air pollution problem in the United States and is the primary constituent of smog. Large portions of the country do not meet the ozone NAAQS and thereby expose large segments of the population to unhealthy levels of ozone in the air. NO_2 reacts in the presence of air and ultraviolet light (UV) in sunlight to form ozone and nitric oxide (NO). The NO then reacts with free radicals in the atmosphere, which are also created by the UV acting on volatile organic compounds (VOC). The free radicals then recycle NO to NO_2. In this way, each molecule of NO can produce ozone multiple times.[40] This will continue until the VOC are reduced to short chains of carbon compounds that cease to be photo reactive (a reaction caused by light). A VOC molecule can usually do this about 5 times.

In addition to the NO_2 and Ozone NAAQS concerns, NOx and sulfur oxides (SOx) in the

NMED Exhibit 81

atmosphere are captured by moisture to form acid rain. Acid rain, along with cloud and dry deposition, severely affects certain ecosystems and directly affects some segments of our economy. All of these facts indicate an obvious need to reduce NOx emissions. However, to successfully do so, we must understand the generation and control of the NOx family of air pollutants.

WHAT IS A NITROGEN OXIDE?

Diatomic molecular nitrogen (N_2) is a relatively inert gas that makes up about 80% of the air we breathe. However, the chemical element nitrogen (N), as a single atom, can be reactive and have ionization levels (referred to as valence states) from plus one to plus five. Thus nitrogen can form several different oxides. Using the Niels Bohr model of the atom, valence state relates to the number of electrons which are either deficient (positive valence) or surplus (negative valence) in the ion when compared with the neutral molecule. The family of NOx compounds and their properties are listed in Table 1.

Table 1. Nitrogen Oxides (NOx)

Formula	Name	Nitrogen Valence	Properties
N_2O	nitrous oxide	1	colorless gas water soluble
NO N_2O_2	nitric oxide dinitrogen dioxide	2	colorless gas slightly water soluble
N_2O_3	dinitrogen trioxide	3	black solid water soluble, decomposes in water
NO_2 N_2O_4	nitrogen dioxide dinitrogen tetroxide	4	red-brown gas very water soluble, decomposes in water
N_2O_5	dinitrogen pentoxide	5	white solid very water soluble, decomposes in water

Oxygen ions are always at valence minus 2. Depending upon the number of oxygen ions (always balanced by the valence state of nitrogen), NOx can react to either deplete or enhance ozone concentrations. The nitrogen ion in these oxides really does a dance in which it has (at different times) various numbers of oxygen ions as partners. Nitrogen changes its number of partners when it changes its ionization energy level. This happens whenever NOx: (1) is hit with a photon of ionizing radiation (UV or a shorter wavelength light); (2) is hit with enough photons that together transfer enough energy to change its ionization level; (3) is catalyzed; (4) is stimulated sufficiently by thermal (IR) energy; (5) reacts with a chemically oxidizing or reducing radical (an ionized fragment of a molecule); or (6) reacts with a chemically oxidizing or reducing

ion (an atom with unbalanced electrical charge).

When any of these oxides dissolve in water and decompose, they form nitric acid (HNO_3) or nitrous acid (HNO_2). Nitric acid forms nitrate salts when it is neutralized. Nitrous acid forms nitrite salts. Thus, NOx and its derivatives exist and react either as gases in the air, as acids in droplets of water, or as a salt. These gases, acid gases and salts together contribute to pollution effects that have been observed and attributed to acid rain.

Nitrous oxide (N_2O), NO, and NO_2 are the most abundant nitrogen oxides in the air. N_2O (also known as laughing gas) is produced abundantly by biogenic sources such as plants and yeasts. It is only mildly reactive, and is an analgesic (i.e., unlike an anaesthetic you still feel pain, but you feel so good that you just don't mind it). N_2O is an ozone depleting substance which reacts with O_3 in both the troposphere (i.e., below 10,000 feet above sea level) and in the stratosphere (50,000 - 150,000 feet). N_2O has a long half-life, estimated at from 100 to 150 years.

Oxidation of N_2O by O_3 can occur at any temperature and yields both molecular oxygen (O_2) and either NO or two NO molecules joined together as its dimer, dinitrogen dioxide (N_2O_2). The NO or N_2O_2 then oxidizes quickly (in about two hours) to NO_2. The NO_2 then creates an ozone molecule out of a molecule of oxygen (O_2) when it gets hit by a photon of ionizing radiation from sunlight. N_2O is also a "Greenhouse Gas" which, like carbon dioxide (CO_2), absorbs long wavelength infrared radiation to hold heat radiating from Earth, and thereby contributes to global warming.

Emissions of NOx from combustion are primarily in the form of NO. According to the Zeldovich equations, NO is generated to the limit of available oxygen (about 200,000 ppm) in air at temperatures above 1,300°C (2,370°F). At temperatures below 760°C (1,400°F), NO is either generated in much lower concentrations or not at all. Combustion NO is generated as a function of air to fuel ratio and is more pronounced when the mixture is on the fuel-lean side of the stoichiometric ratio[50] (the ratio of chemicals which enter into reaction). The Zeldovich equations are:

$$N_2 + O \rightarrow NO + N$$
$$N + O_2 \rightarrow NO + O$$
$$N + OH \rightarrow NO + H$$

Except for NO from soils, lightning and natural fires, NO is largely anthropogenic (i.e., generated by human activity). Biogenic sources are generally thought to account for less than 10% of total NO emissions. NO produces the same failure to absorb oxygen into the blood as carbon monoxide (CO). However, since NO is only slightly soluble in water, it poses no real threat except to infants and very sensitive individuals.

NO_2 is present in the atmosphere and in acid rain. It produces nitric acid (HNO_3) when dissolved in water. When NO_2 reacts with a photon to make O_2 become O_3, NO_2 becomes NO. This NO is then oxidized within hours to NO_2 by radicals from the photo reaction of VOC. Therefore, our

present ozone concentration is the product of both NOx and VOC pollution.

Dinitrogen trioxide (N_2O_3) and dinitrogen tetroxide (N_2O_4) exist in very small concentrations in flue gas. However, they exist in such low concentrations in the atmosphere that both their presence and their effect are often ignored. N_2O_4 is two NO_2 molecules joined together (another dimer) and reacts like NO_2; so, the presence of N_2O_4 may be masked by the more abundant NO_2.

Dinitrogen pentoxide (N_2O_5) is the most highly ionized form of nitrogen oxide. It is generated in air in a very small concentration, unless it is emitted from a process (such as a nitric acid production facility) that is specifically designed to generate it. N_2O_5 is highly reactive, and forms nitric acid (HNO_3) when it decomposes in water.

Some experts feel that NO_2 is a good surrogate for NOx because NO is rapidly converted to NO_2, and N_2O has such a long life because it is not highly reactive. Others feel that due to their role in forming ozone, both NO and NO_2 should be considered NOx. Still others feel that all nitrogen oxides (including N_2O) need to be regulated. NO and NO_2 are certainly the most plentiful forms of NOx and they are largely (but not exclusively) from anthropogenic sources. N_2O is largely biogenic, and as such is not subject to regulation. For environmental purposes, using the concentration of NO_2 as a surrogate for the concentration of NOx has seemed to suffice, for it is the precursor for ozone.

WHERE DOES NOx COME FROM?

Automobiles and other mobile sources contribute about half of the NOx that is emitted. Electric power plant boilers produce about 40% of the NOx emissions from stationary sources.[34] Additionally, substantial emissions are also added by such anthropogenic sources as industrial boilers, incinerators, gas turbines, reciprocating spark ignition and Diesel engines in stationary sources, iron and steel mills, cement manufacture, glass manufacture, petroleum refineries, and nitric acid manufacture. Biogenic or natural sources of nitrogen oxides include lightning, forest fires, grass fires, trees, bushes, grasses, and yeasts.[1] These various sources produce differing amounts of each oxide. The anthropogenic sources are approximately shown as:

Mobile Sources	Electric Power Plants	Everything Else
50%	20%	30%

This shows a graphic portrayal of the emissions of our two greatest sources of NOx. If we could reduce the NOx emissions from just these two leading categories, we might be able to live with the rest. However, don't expect either of these categories to become zero in the foreseeable future. We cannot expect the car, truck, bus, and airplane to disappear. The zero-emission car is still on the drawing board and not on the production line. Also, social customs will have to change before consumption of electricity can be reduced.

NMED Exhibit 81

In all combustion there are three opportunities for NOx formation. They are:

1. Thermal NOx - The concentration of "thermal NOx" is controlled by the nitrogen and oxygen molar concentrations and the temperature of combustion. Combustion at temperatures well below 1,300°C (2,370°F) forms much smaller concentrations of thermal NOx.

2. Fuel NOx - Fuels that contain nitrogen (e.g., coal) create "fuel NOx" that results from oxidation of the already-ionized nitrogen contained in the fuel.

3. Prompt NOx - Prompt NOx is formed from molecular nitrogen in the air combining with fuel in fuel-rich conditions which exist, to some extent, in all combustion. This nitrogen then oxidizes along with the fuel and becomes NOx during combustion, just like fuel NOx. The abundance of prompt NOx is disputed by the various writers of articles and reports - probably because they each are either considering fuels intrinsically containing very large or very small amounts of nitrogen, or are considering burners that are intended to either have or not have fuel-rich regions in the flame.

HOW DOES NOx AFFECT THE ENVIRONMENT?

Because NOx are transparent to most wavelengths of light (although NO_2 has a brownish color and the rare N_2O_3 is black), they allow the vast majority of photons to pass through and, therefore, have a lifetime of at least several days. Because NO_2 is recycled from NO by the photo reaction of VOC to make more ozone, NO_2 seems to have an even longer lifetime and is capable of traveling considerable distances before creating ozone. Weather systems usually travel over the earth's surface and allow the atmospheric effects to move downwind for several hundred miles. This was noted in EPA reports more than twenty years ago. These reports found that each major city on the East coast has a plume of ozone that extends more than a hundred miles out to sea before concentrations drop to 100 parts per billion (ppb). Another report cited the same phenomenon for St. Louis. Therefore, this problem was not just on the sea coast. Since ozone in clean air has a lifetime of only a few hours, this phenomenon is a measure of the effect and the persistence of both VOC and NOx.

Differences in the distance estimates between the emission of NOx and the generation of ozone may be related to differences in plume transport (wind) speeds as well as other meteorological and air quality factors. It is important to note that, under the right conditions, power plant plumes may travel relatively long distances overnight with little loss of VOC, NO and NO_2 . These pollutants can thus be available to participate in photochemical reactions at distant locations on the following day.[41] Figure 1 shows a map of NOx concentration drawn by the Center for Air Pollution Impact and Trend Analysis (CAPITA) at Washington University in St. Louis and reported to the Ozone Transport Assessment Group, a national workgroup that addressed the problem of ground-level ozone (smog) and the long-range transport of air pollution across the Eastern United States. OTAG was a partnership among the EPA, the Environmental Council of the States (ECOS) and various industry and environmental groups with the goal of developing a thoughtful assessment and a consensus agreement for reducing ground-level ozone and the

pollutants that cause it. The animated version of Figure 1 shows the trajectory of NOx emissions moving with the weather over an 8 day period.

Figure 2 is a map of ozone concentration that shows the same trajectory over the 8 day period. The animated version shows concentrations of both NOx and ozone moving with the weather for several hundred miles.[5]

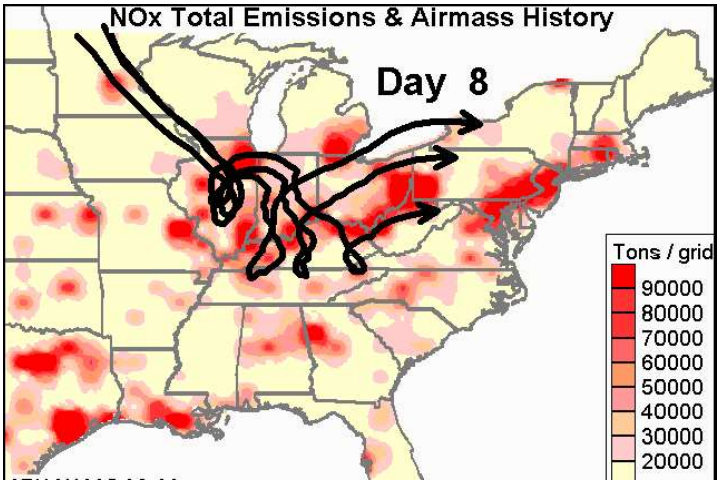

Figure 2 NOx Map

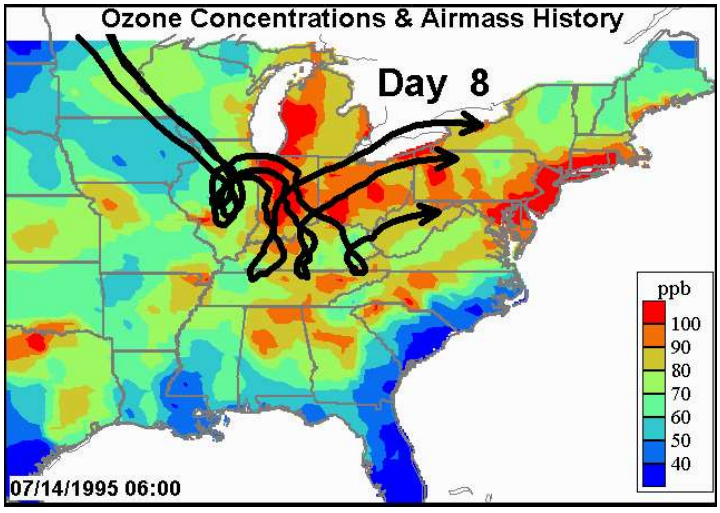

Figure 3 Ozone Map

Ozone is the primary constituent of smog. Between 1970 and 1990, we in the United States have tried to control ozone primarily by controlling the emissions of VOC. However, we have had mixed results, for although some areas reduced their VOC emissions and attained their ozone goals, others have not. It now appears that the communities that failed to meet their ozone goals

may not be completely at fault, for they appear to be affected by NOx and VOC emissions in the air coming to them. To meet the ozone NAAQS, EPA must now regulate emissions of NOx regionally.

ARE THERE OTHER NOx RELATED ISSUES?

Yes. Nutrient enrichment problems (eutrophication) occur in bodies of water when the availability of either nitrates or phosphates become too large. As a result, the ratios of nitrogen to phosphorus, silicon, and iron and other nutrients are altered. This alteration may induce changes in phytoplankton, produce noxious or toxic brown or red algal blooms (which are called "red tides"), or stimulate other plant growth. The algal blooms and plant growth produce a shadow and cause the death of other plants in the water, which depletes the oxygen content of the water (hypoxia) when the plants die, sink, and decay. Such eutrophication can make the bottom strata of water unihabitable for both marine animals (such as fish and shellfish) and aquatic plants. It can progress to virtually the complete depth of the water. It is estimated that between 12% and 44% of the nitrogen loading of coastal water bodies comes from the air.[40] Inland lakes are also affected in this way.

Another dimension of the problem is that high temperature combustion can convert sulfur in fuel to SO_2 and SO_3. While SO_2 is toxic and forms sulfurous acid when dissolved in water, SO_3 is both toxic and hygroscopic (moisture absorbing) and forms sulfuric acid by combining with moisture in the atmosphere. SO_2 and SO_3 form sulfites and sulfates when their acids are neutralized. Both of these acids can form solid particles by reacting with ammonia in air. SO_2 and SO_3 also contribute to pH (acidity) changes in water, which can adversely affect both land and aquatic life. Therefore, both NOx and SOx from combustion can kill plants and animals.

CAPITA has shown that there are about equal amounts by weight of sulfate/sulfite, nitrate and organic particles making up 90% of Particulate Matter less than 2.5 microns in aerodynamic diameter (PM-2.5). This was confirmed by Brigham Young University researchers. The Six Cities Study, published in the *New England Journal of Medicine* in 1990, has shown that illness and premature death are closely correlated with the amount of PM-2.5 in the air. Therefore, there is epidemiological data indicting nitrogen oxides, sulfur oxides, and/or organic compounds as PM-2.5 aerosols. There is currently no evidence that separately examines the health effects of each of these substances. PM-2.5 usually appear as smog, smoke, white overcast, haze, or fog which does not clear when air warms up. Brown smog is colored by nitrogen dioxide.

Because the nitric acid, sulfurous acid and sulfuric acid react with ammonia in air to form solid crystals that are much smaller than 2.5 microns and can be nucleation sites for particle growth, we need to be concerned about each of these pollutants. Some research indicates that even insoluble particles much smaller than 2.5 microns in size can exhibit severe toxic effects.[38] The smallest particles that have shown toxicity have a diameter of about 3% to 5% of the wavelength of any color of visible light. Therefore, these particles are too small to even scatter light and cannot even be detected optically.

Acid deposition occurs from airborne acidic or acidifying compounds, principally sulfates (SO_4^{-2}) and nitrates (NO_3^{-1}), that can be transported over long distances before returning to earth. This occurs through rain or snow (wet deposition), fog or cloud water (cloud deposition), or transfer of gases or particles (dry deposition). While severity of damage depends on the sensitivity of the receptor, acid deposition and NOx "represent a threat to natural resources, ecosystems, visibility, materials, and public health."(section 401(a)(1) of the Clean Air Act).[40]

WHAT ABATEMENT AND CONTROL PRINCIPLES APPLY?

NOx abatement and control technology is a relatively complex issue. We shall try to provide a structure to the spectrum of NOx pollution prevention and control technologies by first giving the principles that are used. Then we shall describe the more successful pollution prevention and emission control technologies and strategies.

Please note that abatement and control of NOx from nitric acid manufacturing and "pickling" baths differs from abatement and control at combustion sources. Combustion sources all have NOx in a large flow of flue gas, while nitric acid manufacturing plants and pickling baths try to contain the NOx. Wet scrubbers (absorbers) can control NOx emissions from acid plants and pickling, and can use either alkali in water, water alone, or hydrogen peroxide as the liquid that captures the NOx.[3] The wet scrubber operates by liquid flowing downward by gravity through a packing medium, opposed by an upward flow of gas. Scrubbers operate on the interchange of substances between gas and liquid. This requires that the height of the absorber, type of packing, liquid flow, liquid properties, gas properties, and gas flow should collectively cause a scrubber to have the desired control efficiency. Chapter 9 of the OAQPS Control Cost Manual provides guidance on the application, sizing, and cost of these scrubbers (referred to as gas absorbers). Also, Table 16 in this Bulletin presents some information for non-combustion NOx sources. Other then that, non-combustion NOx sources are not addressed in this Bulletin.

For combustion sources, this Bulletin defines abatement and emission control principles and states the Destruction or Removal Efficiency (DRE) that each successful technology is capable of achieving. The effectiveness of pollution prevention measures in reducing NO and NO_2 generation also is expressed in terms of relative DRE; i.e., the amount NOx generation is reduced by using a prevention technology compared to NOx generation when not using that technology. Then, specific boiler types and combustion systems and applicable NOx technologies for each system are discussed. Finally, the cost of these technologies is considered.

Many new combustion systems incorporate NOx prevention methods into their design and generate far less NOx then similar but older systems. As a result, considering DRE (even a relative DRE) for NOx may be inappropriate. Comparing estimated or actual NOx emissions from a new, well-designed system to NOx emitted by a similar well-controlled and operated older system may be the best way of evaluating how effectively a new combustion system minimizes NOx emissions.

Table 2 lists principles or methods that are used to reduce NOx. Basically there are six

NMED Exhibit 81

principles, with the seventh being an intentional combination of some subset of the six.

Table 2. NOx Control Methods [6,7]

Abatement or Emission Control Principle or Method	Successful Technologies	Pollution Prevention Method (P2) or Add-on Technology (A)
1. Reducing peak temperature	Flue Gas Recirculation (FGR) Natural Gas Reburning Low NOx Burners (LNB) Combustion Optimization Burners Out Of Service (BOOS) Less Excess Air (LEA) Inject Water or Steam Over Fire Air (OFA) Air Staging Reduced Air Preheat Catalytic Combustion	P2 P2 P2 P2 P2 P2 P2 P2 P2 P2 P2
2.Reducing residence time at peak temperature	Inject Air Inject Fuel Inject Steam	P2 P2 P2
3. Chemical reduction of NOx	Fuel Reburning (FR) Low NOx Burners (LNB) Selective Catalytic Reduction (SCR) Selective Non-Catalytic Reduction (SNCR)	P2 P2 A A
4. Oxidation of NOx with subsequent absorption	Non-Thermal Plasma Reactor Inject Oxidant	A A
5. Removal of nitrogen	Oxygen Instead Of Air Ultra-Low Nitrogen Fuel	P2 P2
6. Using a sorbent	Sorbent In Combustion Chambers Sorbent In Ducts	A A
7. Combinations of these Methods	All Commercial Products	P2 and A

Method 1. Reducing Temperature -- Reducing combustion temperature means avoiding the stoichiometric ratio (the exact ratio of chemicals that enter into reaction). Essentially, this technique dilutes calories with an excess of fuel, air, flue gas, or steam. Combustion controls use different forms of this technique and are different for fuels with high and low nitrogen content.

Control of NOx from combustion of high nitrogen content fuels (e.g., coal) can be understood by the net stoichiometric ratio. Control of the NOx from combustion of low nitrogen fuels (such as gas and oil) can be seen as lean versus rich fuel/air ratios. Either way, this technique avoids the ideal stoichiometric ratio because this is the ratio that produces higher temperatures that generate higher concentrations of thermal NOx.

Combustion temperature may be reduced by: (1) using fuel rich mixtures to limit the amount of oxygen available; (2) using fuel lean mixtures to limit temperature by diluting energy input; (3) injecting cooled oxygen-depleted flue gas into the combustion air to dilute energy; (4) injecting cooled flue gas with added fuel; or (5) injecting water or steam. Low-NOx burners are based partially on this principle.[8,9,10] The basic technique is to reduce the temperature of combustion products with an excess of fuel, air, flue gas, or steam. This method keeps the vast majority of nitrogen from becoming ionized (i.e., getting a non-zero valence).

Method 2. Reducing Residence Time -- Reducing residence time at high combustion temperatures can be done by ignition or injection timing with internal combustion engines. It can also be done in boilers by restricting the flame to a short region in which the combustion air becomes flue gas. This is immediately followed by injection of fuel, steam, more combustion air, or recirculating flue gas. This short residence time at peak temperature keeps the vast majority of nitrogen from becoming ionized. This bears no relationship to total residence time of a flue gas in a boiler.

Method 3. Chemical Reduction of NOx – This technique provides a chemically reducing (i.e., reversal of oxidization) substance to remove oxygen from nitrogen oxides. Examples include Selective Catalytic Reduction (SCR) which uses ammonia, Selective Non-Catalytic Reduction (SNCR) which use ammonia or urea, and Fuel Reburning (FR). Non-thermal plasma, an emerging technology, when used with a reducing agent, chemically reduces NOx. All of these technologies attempt to chemically reduce the valence level of nitrogen to zero after the valence has become higher.[11] Some low-NOx burners also are based partially on this principle.

Method 4. Oxidation of NOx -- This technique intentionally raises the valence of the nitrogen ion to allow water to absorb it (i.e., it is based on the greater solubility of NOx at higher valence). This is accomplished either by using a catalyst, injecting hydrogen peroxide, creating ozone within the air flow, or injecting ozone into the air flow. Non-thermal plasma, when used without a reducing agent, can be used to oxidize NOx. A scrubber must be added to the process to absorb N_2O_5 emissions to the atmosphere. Any resultant nitric acid can be either neutralized by the scrubber liquid and then sold (usually as a calcium or ammonia salt), or collected as nitric acid to sell to customers.[12, 49]

Method 5. Removal of nitrogen from combustion -- This is accomplished by removing nitrogen as a reactant either by: (1) using oxygen instead of air in the combustion process; or (2) using ultra-low nitrogen content fuel to form less fuel NOx. Eliminating nitrogen by using oxygen tends to produce a rather intense flame that must be subsequently and suitably diluted. Although Method 2 can lower the temperature quickly to avoid forming excessive NOx, it cannot

eliminate nitrogen oxides totally if air is the quench medium. Hot flue gas heats the air that is used to quench it and this heating generates some thermal NOx. This method also includes reducing the net excess air used in the combustion process because air is 80% nitrogen. Using ultra-low-nitrogen content fuels with oxygen can nearly eliminate fuel and prompt NOx.[13]

Method 6. Sorption, both adsorption and absorption -- Treatment of flue gas by injection of sorbents (such as ammonia, powdered limestone, aluminum oxide, or carbon) can remove NOx and other pollutants (principally sulfur). There have been successful efforts to make sorption products a marketable commodity. This kind of treatment has been applied in the combustion chamber, flue, and baghouse. The use of carbon as an adsorbent has not led to a marketable product, but it is sometimes used to limit NOx emissions in spite of this. The sorption method is often referred to as using a dry sorbent, but slurries also have been used. This method uses either adsorption or absorption followed by filtration and/or electrostatic precipitation to remove the sorbent.

Method 7. Combinations of these methods -- Many of these methods can be combined to achieve a lower NOx concentration than can be achieved alone by any one method. For example, a fuel-rich cyclone burner (Method 1) can be followed by fuel reburn (Method 3) and over-fire air (Method 1). This has produced as much as a 70% reduction in NOx.[55] Other control technologies that are intended to primarily reduce concentrations of sulfur also strongly affect the nitrogen oxide concentration. For example, the SOx-NOx-ROx-Box (SNRB) technology uses a limestone sorbent in the flue gas from the boiler to absorb sulfur. This is followed by ammonia injection and SCR using catalyst fibers in the baghouse filter bags. The sulfur is recovered from the sorbent and the sorbent regenerated by a Claus process. This has demonstrated removal of up to 90% of the NOx along with 80% of the SOx.[39, 42] EBARA of Japan reported that an electron beam reactor with added ammonia removed 80% of the SO_2 and 60% of the NOx for a utility boiler in China.[54] FLS Milo and Sons reported at the same symposium that 95% of the SO_2 and 70%-90% of the NOx were removed in several demonstrations of their SNAP technology, which is based upon an aluminum oxide adsorber with Claus regeneration.[56]

WHAT ABATEMENT TECHNOLOGIES ARE AVAILABLE?

In this report existing NOx abatement technologies are divided into two categories, external combustion applications (e.g., boilers, furnaces and process heaters) and internal combustion applications (e.g., stationary internal combustion engines and turbines). These categories are further subdivided into pollution prevention (which reduces NOx generation) and add-on control technologies (which reduces NOx emissions).

EXTERNAL COMBUSTION

For external combustion applicable technologies are shown in Table 3 (based on Table 2 in Select the Right NOx Control Technology, Stephen Wood, Chemical Engineering Progress, January 1994).

NMED Exhibit 81

Table 3. External Combustion NOx Limiting Technologies					
Technique	**Description**	**Advantages**	**Disadvantages**	**Impacts**	**Applicability**
Less Excess Air (LEA)	Reduces oxygen availability	Easy modification	Low NOx reduction	High CO Flame length Flame stability	All fuels
Off Stoichiometric a. Burners Out of Service (BOOS) b. Over Fire Air (OFA)	staged combustion	Low cost No capital cost for BOOS	a. Higher air flow for CO b. high capital cost	Flame length Fan capacity Header pressure	All fuels Multiple burners for BOOS
Low NOx Burner (LNB)	Internal staged combustion	Low operating cost Compatible FGR	Moderately high capital cost	Flame length Fan capacity Turndown stability	All fuels
Flue Gas Recirculation (FGR)	<30% flue gas recirculated with air, decreasing temperature	High NOx reduction potential for low nitrogen fuels	Moderately high capital cost and operating cost Affects heat transfer and system pressures	Fan capacity Furnace pressure Burner pressure drop Turndown stability	All fuels Low nitrogen fuels
Water/Steam Injection	Reduces flame temperature	Moderate capital cost NOx reduction similar to FGR	Efficiency penalty Fan power higher	Flame stability Efficiency penalty	All fuels as Low nitrogen fuels
Reduced Air Preheat	Air not preheated, reduces flame temperature	High NOx reduction potential	Significant efficiency loss (1% per 40°F)	Fan capacity Efficiency penalty	All fuels Low nitrogen fuels
Selective Catalytic reduction (SCR) (add-on technology)	Catalyst located in the air flow, promotes reaction between ammonia and NOx	High NOx removal	Very high capital cost High operating cost Catalyst siting Increased pressure drop Possible water wash required	Space requirements Ammonia slip Hazardous waste Disposal	All fuels

NMED Exhibit 81

Table 3. External Combustion NOx Limiting Technologies					
Technique	**Description**	**Advantages**	**Disadvantages**	**Impacts**	**Applicability**
Selective Non-Catalytic Reduction (SNCR) (add-on technology) a. urea b. ammonia	Inject reagent to react with NOx	a. Low capital cost Moderate NOx removal Non-toxic chemical b. Low operating cost Moderate NOx removal	a. Temperature dependent NOx reduction less at lower loads b. Moderately high capital cost Ammonia storage, handling, injection system	a. Furnace geometry Temperature profile b. Furnace geometry Temperature profile	All fuels
Fuel Reburning	Inject fuel to react with NOx	Moderate cost Moderate NOx removal	Extends residence time	Furnace temperature profile	All fuels (pulverized solid)
Combustion Optimization	Change efficiency of primary combustion	Minimal cost	Extends residence time	Furnace temperature profile	Gas Liquid fuels
Catalytic Combustion	Catalyst causes combustion to be at low temperature	Lowest possible NOx	Very high capital cost High operating cost Catalyst siting	Space requirements Disposal	Gas Liquid fuels
Non-Thermal Plasma	Reducing agent ionized or oxidant created in flow	Moderate cost Easy siting High NOx removal	Fouling possible Ozone emission possible	Uses electrical power	All fuels
Inject Oxidant	Chemical oxidant injected in flow	Moderate cost	Nitric acid removal	Add-on	All fuels
Oxygen instead of Air	Uses oxygen to oxidize fuel	Moderate to high cost Intense combustion	Eliminates prompt NOx Furnace alteration	Equipment to handle oxygen	All fuels
Ultra-Low Nitrogen Fuel	Uses low -nitrogen fuel	Eliminates fuel NOx No capital cost	Slight rise in operating cost	Minimal change	All ultra-low nitrogen fuels

NMED Exhibit 81

Table 3. External Combustion NOx Limiting Technologies					
Technique	**Description**	**Advantages**	**Disadvantages**	**Impacts**	**Applicability**
Use Sorbents (add-on technology) in: a. Combustion b. Duct to Baghouse c. Duct to Electrostatic Precipitator	Use a chemical to absorb NOx or an adsorber to hold it	Can control other pollutants as well as NOx Moderate operating cost	Cost of handling sorbent Space for the sorbent storage and handling	Add-on	All fuels
Air Staging	Admit air in separated stages	Reduce peak combustion temperature	Extend combustion to a longer residence time at lower temperature	Adds ducts and dampers to control air Furnace modification	All fuels
Fuel Staging	Admit fuel in separated stages	Reduce peak combustion temperature	Extend combustion to a longer residence time at lower temperature	Adds fuel injectors to other locations Furnace modification	All fuels

NMED Exhibit 81

EXTERNAL COMBUSTION: POLLUTION PREVENTION METHODS

LESS EXCESS AIR (LEA)

Excess air flow for combustion has been correlated to the amount of NOx generated. Limiting the net excess air flow to under 2% can strongly limit NOx content of flue gas. Although there are fuel-rich and fuel-lean zones in the combustion region, the overall net excess air is limited when using this approach.[43]

BURNERS OUT OF SERVICE (BOOS)

Multiple-burner equipment can have part of an array of burners with some "burners out of service" (not feeding fuel, but supplying air or flue gas). This allows the burners around them to supply fuel and air to air or flue gas flowing from the BOOS. The result is combustion by stages with temperature always lower than when all burners are in service. Thus, thermal NOx is lower. The degree to which NOx generation is reduced depends upon the spatial relationship of the BOOS to the other burners.[44]

OVER FIRE AIR (OFA)

When primary combustion uses a fuel-rich mixture, use of OFA completes the combustion. Because the mixture is always off-stoichiometric when combustion is occurring, the temperature is held down. After all other stages of combustion, the remainder of the fuel is oxidized in the over fire air. This is usually not a grossly excessive amount of air.

LOW NOx BURNERS (LNB)

A LNB provides a stable flame that has several different zones. For example, the first zone can be primary combustion. The second zone can be Fuel Reburning (FR) with fuel added to chemically reduce NOx. The third zone can be the final combustion in low excess air to limit the temperature. There are many variations on the LNB theme of reducing NOx. The LNB has produced up to 80% DRE.[17,18, 32, 33] This can be one of the least expensive pollution prevention technologies with high DRE. LNB have had problems with designs that had flame attaching to the burners, resulting in a need for maintenance. We believe that these design problems should now be a thing of the past.

FLUE GAS RECIRCULATION (FGR)

Recirculation of cooled flue gas reduces temperature by diluting the oxygen content of combustion air and by causing heat to be diluted in a greater mass of flue gas. Heat in the flue gas can be recovered by a heat exchanger. This reduction of temperature lowers the NOx concentration that is generated. If combustion temperature is held down to below 1,400 °F, the thermal NOx formation will be negligible.[50]

NMED Exhibit 81

WATER OR STEAM INJECTION

Injection of water or steam causes the stoichiometry of the mixture to be changed and adds steam to dilute calories generated by combustion. Both of these actions cause combustion temperature to be lower. If temperature is sufficiently reduced, thermal NOx will not be formed in as great a concentration.

REDUCED AIR PREHEAT

Air is usually preheated to cool the flue gases, reduce the heat losses, and gain efficiency. However, this can raise the temperature of combustion air to a level where NOx forms more readily. By reducing air preheat, the combustion temperature is lowered and NOx formation is suppressed. This can lower efficiency, but can limit NOx generation.

FUEL REBURNING (FR)

Recirculation of cooled flue gas with added fuel (this can be natural gas, pulverized coal, or even oil spray) causes dilution of calories, similar to FGR, and primary combustion temperature can be lowered. Also, when added as a secondary combustion stage, the presence of added fuel chemically reduces newly generated NOx to molecular nitrogen. Added fuel is only partially consumed in reducing NOx and burning is completed in a later stage using either combustion air nozzles or over-fire-air. This technique has been demonstrated to be effective with residence times from 0.2 seconds to 1.2 seconds and has achieved up to 76% DRE. [17]

COMBUSTION OPTIMIZATION

Combustion optimization refers to the active control of combustion. In a natural gas fired boiler, by decreasing combustion efficiency from 100% to 99%, NOx generation dropped to a much more acceptable level.[14,15] For coal-fired boilers a 20% to 60% reduction in NOx has been experienced. These active combustion control measures seek to find an optimum combustion efficiency and to control combustion (and hence emissions) at that efficiency. Another approach uses a neural network computer program to find the optimum control point.[16] Still another approach is to use software to optimize inputs for the defined output.[52,53]

One vendor decreases the amount of air that is pre-mixed with fuel from the stoichiometric ratio (ratio that produces the hottest flame) to lengthen the flame at the burner and reduce the rate of heat release per unit volume. This can work where the boiler tubes are far enough away from the burner. Carbon monoxide, unburned fuel, and partially burned fuel that result can then be subsequently oxidized in over-fire-air at a lower temperature. Combustion must be optimized for the conditions that are encountered. 50% DRE has been reported.[14]

AIR STAGING

Combustion air is divided into two streams. The first stream is mixed with fuel in a ratio that

NMED Exhibit 81

produces a reducing flame. The second stream is injected downstream of the flame and makes the net ratio slightly excess air compared to the stoichiometric ratio. DRE up to 99% have been reported.[51]

FUEL STAGING

This is staging of combustion using fuel instead of the air. Fuel is divided into two streams. The first stream feeds primary combustion that operates in a reducing fuel to air ratio. The second stream is injected downstream of primary combustion, causing the net fuel to air ratio to be only slightly oxidizing. Excess fuel in primary combustion dilutes heat to reduce temperature. The second stream oxidizes the fuel while reducing the NOx to N_2. This is reported to achieve a 50% DRE.[51]

OXYGEN INSTEAD OF AIR FOR COMBUSTION

An example of this is a cyclone burner where the flame is short and intense. Excess fuel air or steam, injected just after the combustion chamber per Method 2 is sufficient to rapidly quench the flue gas to below NOx formation temperature. Combustion can then be completed in over-fire air. Oxygen can now be separated from air at a low enough cost to make this economical.[13] This technique has reduced NOx by up to 20%[23] in burners using conventional fuel. This technique also is usable with low-NOx burners to prevent the prompt NOx from being formed.

INJECTION OF OXIDANT

The oxidation of nitrogen to its higher valence states makes NOx soluble in water. When this is done a gas absorber can be effective. Oxidants that have been injected into the air flow are ozone, ionized oxygen, or hydrogen peroxide. Non-thermal plasma generates oxygen ions within the air flow to achieve this. Other oxidants have to be injected and mixed in the flow. Nitric acid can be absorbed by water, hydrogen peroxide, or an alkaline fluid. Calcium or ammonia dissolved in the water can make an alkaline fluid that will react with nitric and sulfuric acids to produce a nitrate or sulfate salt that can be recovered. Alternatively, using water or hydrogen peroxide to absorb NOx can provide nitric acid for the commercial market.

CATALYTIC COMBUSTION

Use of a catalyst to cause combustion to occur below NO formation temperatures can provide a suitable means of limiting temperature. This technique is not used often because it is very load sensitive. However, where it is used, catalytic combustion can achieve less than a 1 ppm concentration of NOx in the flue gas.

ULTRA-LOW NITROGEN FUELS

These fuels can avoid NOx that results from nitrogen contained in conventional fuels. The result can be up to a 70% reduction in NOx emissions.[43] Now there are ultra-low-nitrogen liquid fuel

oils. These oils contain 15-20 times less nitrogen than standard No. 2 fuel oil. This oil is now commercially available and competitively priced. Ultra-low-nitrogen oil is most frequently used in Southern California where the air pollution is particularly a problem. Natural gas can be considered a low-nitrogen fuel. Coke (the quenched char from coal) can also be an ultra-low-nitrogen fuel because nitrogen in the volatile fraction of the coal is removed in making coke.

NON-THERMAL PLASMA

Using methane and hexane as reducing agents, non-thermal plasma has been shown to remove NOx in a laboratory setting with a reactor duct only 2 feet long. The reducing agents were ionized by a transient high voltage that created a non-thermal plasma. The ionized reducing agents reacted with NOx and achieved a 94% DRE. There are indications that an even higher DRE can be achieved. A successful commercial vendor uses ammonia as a reducing agent to react with NOx in an electron beam generated plasma. Such a short reactor can meet available space requirements for virtually any plant. The non-thermal plasma reactor could also be used without reducing agent to generate ozone and use that ozone to raise the valence of nitrogen for subsequent absorption as nitric acid.

EXTERNAL COMBUSTION: ADD-ON CONTROL TECHNOLOGY

Add-on controls are applicable to a broad range of sources and fuels. This differs from the pollution prevention techniques listed above in that the prevention techniques must be adapted to the circumstances of their use.

SELECTIVE CATALYTIC REDUCTION (SCR)

SCR uses a catalyst to react injected ammonia to chemically reduce NOx. It can achieve up to a 94% DRE[34] and is one of the most effective NOx abatement techniques. However, this technology has a high initial cost. In addition, catalysts have a finite life in flue gas and some ammonia "slips through" without being reacted. SCR has historically used precious metal catalysts, but can now also use base-metal and zeolite catalysts. The base-metal and zeolite catalysts operate at much different temperatures then the precious metal catalysts.[11]

SELECTIVE NON-CATALYTIC REDUCTION (SNCR)

In SNCR ammonia or urea is injected within a boiler or in ducts in a region where temperature is between 900°C and 1100°C. This technology is based on temperature ionizing the ammonia or urea instead of using a catalyst or non-thermal plasma. This temperature "window" – which is reported differently by various authors -- is important because outside of it either more ammonia "slips" through or more NOx is generated than is being chemically reduced. The temperature "window" is different for urea and ammonia. Reduction of the NOx by SNCR can have up to a 70% DRE.[23,35,43]

NMED Exhibit 81

SORPTION – BOTH ADSORPTION AND ABSORPTION

Several methods are used to inject and remove adsorbent or absorbent. One method sprays dry powdered limestone into the flue gas. The limestone then reacts with both sulfuric acid and nitric acid. There also is a spray dryer approach that sprays a slurry of powdered limestone and aqueous ammonia into the flue gas. The limestone preferentially reacts with the sulfur while the ammonia preferentially reacts with the NOx. In-duct injection of dry sorbents is another example of this technique and can reduce pollutants in three stages: (1) in the combustion chamber, (2) in the flue gas duct leading to the baghouse, and (3) in the flue gas duct leading to the electrostatic precipitator. The by products formed by sorption are gypsum (calcium sulfate) that is sold to make wallboard, and ammonium nitrate that can be sold to make either an explosive or a fertilizer. Sorption is reported to have up to a 60% DRE.[23, 31] Another version uses carbon injected into the air flow to finish the capture of NOx. The carbon is captured in either the baghouse or the ESP just like other sorbents. There are many absorbents and adsorbents available.

COMBINED TECHNOLOGY APPROACHES

Very seldom is only one method or principle used alone. The choice depends upon the type of combustion system, type of boiler or other energy conversion device, and type of fuel used. Available technologies will be narrowed by consideration of turndown ratio, stability of combustion, availability or access to burners, air supply controls, fuel impurities, and cost among other factors.

There are many examples and here are a few of them. Selective catalytic reduction of NOx to N_2 can be followed by selective oxidation of sulfur dioxide to sulfur trioxide. Then sulfuric acid is formed followed by scrubbing sulfuric acid from the flue gas.[30]

LNB can be used in conjunction with SCR or SNCR to achieve a greater overall DRE than any of these can achieve alone. Water/steam injection can be used with SCR to achieve a DRE greater than SCR can achieve alone. Fuel reburning and SCR can be used together as well as separately, to get the maximum NOx reduction.[57]

INTERNAL COMBUSTION

Now we turn to internal combustion, which usually occurs at elevated pressures. Again, we divide the technologies between pollution prevention techniques and add-on technologies. This is shown in Table 4.

These techniques can be used in combination. Pollution prevention techniques do not have to be used separately. Add-on techniques could be used sequentially after a pollution prevention technique when they do not impose conflicting demands on the process.

NMED Exhibit 81

Table 4. Internal Combustion NOx Limiting Technologies

Pollution Prevention	Add-On Control
Low-NOx Burners (LNB)	Selective Catalytic Reduction (SCR)
Steam/Water Injection	Selective Non-Catalytic Reduction (SNCR)
Catalytic Combustion	Non-Selective Catalytic Reduction (NSCR)
Air-Fuel Ratio and Ignition Type	Non-Thermal Plasma
Pre-Stratified Charge	
Lean Burn	

INTERNAL COMBUSTION: POLLUTION PREVENTION METHODS

LOW NOx BURNERS (LNB)

Combining the use of LNB with closely controlled air/fuel ratio and water/steam injection can yield emissions as low as 10 ppm from gas turbines.[46]

STEAM/ WATER INJECTION

To reduce combustion temperature, steam or water can be mixed with the air flow. This lowers combustion temperature to below 1,400°F to limit NOx generation to about 40 ppm.[46] This can cause the concentration of CO and unburned hydrocarbons emitted from a turbine to be increased. However, these can be burned by either a catalyst bed, afterburner, or another stage of combustion. This otherwise wasted fuel and heat can also be recovered in co-generation boilers.

CATALYTIC COMBUSTION

A catalyst is used to react fuel with air at a lower temperature than normal combustion at which generation of significant amounts of NOx does not occur. Emissions under 1 ppm NOx have been reported.[46] However, if this combustion is for a turbine, turbine efficiency may depend upon achieving a higher temperature. When a catalyst is present, you also need to assure that NOx will not be formed at the combustion temperature that results.

This technology has a relatively high capital and operation and maintenance cost because there is both a substantial initial investment and a replacement cost for the catalyst. The need for replacement and, therefore, replacement cost are usually driven by impurities in the fuel. However, catalytic combustion generates possibly the lowest level of thermal NOx.

AIR-FUEL RATIO AND IGNITION TYPE

For internal combustion reciprocating engines, retardation of injection or spark ignition, or an air-fuel ratio that departs from stoichiometric conditions will reduce peak temperature. Lower peak temperature will limit the amount of NOx formation. This technique can achieve up to 50% control efficiency.[19, 48]

When a three-way catalyst is used for spark ignition engines, exhaust gas must have no more than 0.5% oxygen. This technique can be up to 98% effective.

The use of plasma ignition (an alternating current or AC system) instead of a direct current (DC) spark ignition system can also allow a greater fuel-lean departure from the stoichiometric ratio. NOx emissions from internal combustion engines using plasma ignition have been reported to be reduced by up to 97%.[20,21, 45]

Delaying injection of fuel in a compression ignition (diesel) engine can reduce the NOx emissions. The amount of this reduction will depend upon the engine, valving, and fuel. Excessive timing retard can cause combustion instability or misfire.[48] However, some claims of high effectiveness are to be found with ostensibly excessive retard.

PRE-STRATIFIED CHARGE (PSC)

PSC refers to an engine equipped with a pre-combustion chamber that receives a rich enough air/fuel mixture to ignite dependably. This pre-combustion chamber fires a jet of flame into the main combustion chamber (cylinder). The main combustion chamber has a fuel-lean mixture that needs pre-combustion flame to ignite it reliably. The injected flame also produces a swirl in the main combustion chamber that acts like stratified charge combustion. This dependably ignites the lean main cylinder mixture. The PSC can achieve NOx emissions of 2 grams/horsepower-hour (g/hp-hr) or 140 ppm.[48]

LEAN BURN

Natural gas fueled engines that operate with a fuel-lean air/fuel ratio are capable of low NOx emissions. These can achieve less than 1.0 gram/brake horsepower-hour according to the RACT-BACT-LAER Clearinghouse (RBLC) (http://www.epa.gov/ttn/catc, then select RBLC).

INTERNAL COMBUSTION ADD-ON CONTROL TECHNOLOGY

SELECTIVE CATALYTIC REDUCTION (SCR)

As with boilers, SCR can be used to obtain up to a 90% DRE of NOx. When used with a LNB or steam/water injection, NOx can be reduced to 5-10 ppm.[46] With compression ignition engines, zeolite catalysts achieve a DRE of 90+%, while base-metal catalysts can achieve a 80% to 90% DRE.[48]

NON-SELECTIVE CATALYTIC REDUCTION (NSCR)

NSCR is the same technique used in automobile applications as a three-way catalytic converter. It does not require injection of a reducing agent because it uses unburned hydrocarbons as a reducing agent. The catalyst requires that exhaust have no more than 0.5% oxygen. This technique uses a fuel rich mixture that, combined with back pressure from exhaust flow through the catalyst, increases the brake specific fuel consumption of the engine. However, NOx control of 90% to 98% can be achieved.[48]

NON-THERMAL PLASMA REACTORS

This approach uses a non-thermal plasma to ionize ammonia, urea, hexane, methane or other reducing agents injected into a flue gas. Combined with the effect of temperature, non-thermal plasma ionizes the reducing agent that reacts with nitrogen oxides achieving a 94% DRE. This decreases the amount of reducing chemicals that "slips" through unreacted.[20,44] The use of non-thermal plasma was developed to ionize pollutants and act as a catalyst to control NOx in diesel exhaust.[36]

DO FUELS AND COMBUSTION TYPE AFFECT ABATEMENT?

Yes they do. Here again, we find a spectrum of types, almost enough to make every gas turbine, internal combustion engine, boiler, or furnace seem unique. The type of fuel can vary with the vein of the mine from which coal was obtained, the well in the oilfield from which crude oil came, the refinery for petroleum based fuels, or the supplier of natural gas. Thus the concentration of impurities will vary between sources, refineries, and suppliers. Even "natural gas" (methane) may contain some "supplier gas" (propane, butane, and carbon monoxide) which will cause the composition of "natural gas" to vary.

The type of combustion system (low-NOx burner, over-fire air, tangential firing, wall firing, etc) also will sometimes limit options. Each type of boiler, each type of fuel, each combustion system, and each construction of a boiler puts constraints on what is possible. It is not possible to treat each combination of combustion system and fuel in detail in this Technical Bulletin; however, we will try to show the picture while painting with broad strokes.

The choice of fuel and combustion system often depends upon: (1) what can or cannot be adjusted; (2) whether ducts are suitable for sorption; (3) what the effect on boiler maintenance will be; (4) the temperature profile in the flow: (5) how the combustion system can be modified; (6) what types of burners can be used; and (7) what can either be added or modified. The list does not end there, but continues. Let us consider some fuels with these limitations in mind.

SOLID FUELS

In burning a solid fuel (such as coal), combustion control is achieved by first getting the primary burner to gasify the volatile fraction of a fuel. The volatile fraction is carried away from char by

NMED Exhibit 81

air flow, oxidized in the air flow, and becomes flue gas. Char needs more combustion air to burn and provide further heat, part of which is used to volatilize additional fuel. To control combustion temperature, you traditionally would limit combustion air through the char fraction. The volatile fraction is oxidized in over-fire-air or a secondary stage of burner and must have its air separately controlled. The balance of combustion air between these stages must be adjusted for composition of fuel being used, boiler loading, and transient loads. Because all of these parameters will vary continually, provisions to make balancing adjustments dynamically are recommended.

Pulverized coal can be burned similar to oil. The flame is usually well defined and, depending on particle size, char may remain in suspension in flue gas throughout burning. The volatile fraction burns in air even as char is burned. If the particles are too coarse, char will continue burning on its trajectory after leaving the flame, but will stop burning at some point. The trade jargon for this is " unburned carbon (UBC)," "carbon in the ash (CIA)," or "loss of ignition (LOI)." These terms refer to carbon in char that does not burn along the trajectory. UBC is minimized by grinding particles finer and classifying particles so that larger ones are returned to the roller mill or grinder. Particles will become fly ash if they are small enough. UBC ranging from 0.5% to 5% is considered acceptable. Therefore, particle size at ignition is important. The major concerns are to control stoichiometry and combustion temperature to minimize unburned carbon in ash.

Biomass is another solid fuel, but burning biomass char is less of a concern than with coal. Biomass cannot be pulverized to small particles, but can burn to ash in a short time. As with the burning of all char, ash and fly ash are problems, but can be treated with a slag tap or ash pit, baghouse, and/or electrostatic precipitator.

LIQUID FUELS

Liquid fuels burn like the volatile fraction of solid fuel provided that the droplets are small enough. Liquid fuels usually have less nitrogen content than solid fuels. Combustion of liquids and gases can be controlled much more readily than char from solid fuel because combustion is less dependent on the history of the past few minutes of demand. Combustion is also completed essentially without residual ash. The fuel-air ratio can be used to control combustion temperature and can be adjusted to minimize NOx generation. The flame can be well-defined and combustion is essentially completed within the flame. Therefore, burning oil or liquid-from-coal or liquid-from-gas is different from burning coal because there is usually less nitrogen in the fuel, a lack of char, complete burning within the flame and a lack of ash.

SEMI-SOLID FUELS

Semi-solid fuels are residuals from refineries. They are not clean burning like distillates and often are not even liquid at room temperature. Many impurities typically found in crude oil are concentrated in semi-solid residual fuel. These fuels can contain more nitrogen than coal, but usually contain less sulfur.[50] Therefore, semi-solid fuels are intermediate between coal and oil. They often have somewhat less impurities than coal (although they can have more impurities),

NMED Exhibit 81

but they do produce ash.

GAS FUEL

Natural gas is desulfurized before it is sent in a pipeline. Therefore, natural gas has almost no sulfur, essentially no impurities, and no ash. The only thing that varies is heat content per cubic meter. This variance is caused by natural gas producers supplementing natural gas with propane, liquified petroleum gas (butane), carbon monoxide, or other gaseous fuel. As a result, air to fuel ratio must be controllable to allow for changes in the stoichiometric ratio.

COMBUSTION SYSTEMS

To take advantage of a specific NOx abatement technology, a combustion system must either have certain features in place, or needed system modifications must be technically and economically feasible. Therefore, when identifying applicable pollution prevention and emission control technologies, we must first consider combustion system design. The major types of combustion systems are shown in Table 5.[23]

Table 5. Common Combustion Systems

Type of Combustion Unit	Fuel
Dry bottom boilers - wall-fired, front-fired or opposed-fired	pulverized coal, gas, or liquid
Dry bottom boilers - tangentially fired	pulverized coal, gas, or liquid
Wet bottom (slag tap) boilers - cyclone-type burners	pulverized coal, gas, or liquid
Fluidized bed	coal
Stokers with traveling grate.	crushed coal
Stokers with spreader grate	crushed coal.
Gas turbines	gas and liquid
Internal combustion engines	gas and liquid

Each NOx abatement technology has different implementations, development histories, and, therefore, commercial status. Selection of a technology must occur after an engineering study to determine technical and economic feasibility of each NOx technology. This includes how each technology can be implemented and its cost. Options may be limited by inability to adjust combustion system air flow appropriately, ducts that are at the wrong temperature, or ducts that

NMED Exhibit 81

are too short to provide adequate mixing. These problems can be solved, but may require too much modification to make them economical.

DRY BOTTOM BOILERS - WALL-FIRED, FRONT-FIRED or OPPOSED-FIRED

Dry bottom pulverized coal, gas, and liquid fuel wall-fired boilers have used low-NOx burners to inject fuel and air from lower walls. Front-fired boilers have burners on one wall. Opposed-fired boilers have burners on front and back walls. These boilers typically use methods that reduce peak temperature, reduce residence time at peak temperature, or chemically reduce NOx (Methods 1, 2 & 3). These methods are used for large utility boilers in which combustion efficiency is all-important. NOx oxidation with absorption and removal of nitrogen (Methods 4 and 5) represent newer technologies that may be applied in the future. Using a sorbent (Method 6) is already in use for some boilers. See Table 6 for NOx technologies used for dry bottom wall-fired, front-fired or opposed-fired boilers.

Table 6: NOx technologies currently used for dry bottom wall-fired, front-fired or opposed-fired boilers.

NOx Abatement Method	Techniques Now Available	Efficiency
1. Reducing peak temperature	Flue Gas Recirculation (FGR) Natural Gas Reburning (NGR) Low NOx Burners (LNB) Combustion Optimization Burners Out Of Service (BOOS) Over Fire Air (OFA) Less Excess Air (LEA) Inject Water or Steam Reduced Air Preheat	50-70%
2.Reducing residence time at peak temperature	Air Staging of Combustion Fuel Staging of Combustion Inject Steam	50-70%
3. Chemical reduction of NOx	Selective Catalytic Reduction (SCR) Selective Non-Catalytic Reduction (SNCR) Fuel Reburning (FR) Low NOx Burners (LNB)	35-90%
4. Oxidation of NOx with subsequent absorption	Inject Oxidant Non-Thermal Plasma Reactor (NTPR)	60-80%
5. Removal of nitrogen	Ultra-Low Nitrogen Fuel	No Data
6. Using a sorbent	Sorbent In Combustion Chambers Sorbent In Ducts	60-90%

NMED Exhibit 81

DRY BOTTOM BOILERS - TANGENTIALLY FIRED

Dry bottom pulverized coal, gas, or liquid fuel tangentially-fired boilers use jets from each corner of a furnace to inject fuel and combustion air in a swirl. The injected mix of fuel and combustion air forms a fireball in the center of the boiler. This firing configuration is used in medium sized utility and large industrial boilers. This combustion technique holds flame temperatures down (Method 1). In addition, chemical reduction of NOx (Method 3) is frequently used. NOx oxidation (Method 4) techniques may be used in the future. Sorbents (Method 6) are already used for some boilers. See Table 7 for NOx technologies used for dry bottom tangentially fired boilers.

Table 7: NOx technologies currently used for dry bottom tangentially fired boilers.

NOx Abatement Method	Techniques Now Available	Efficiency
1. Reducing peak temperature	Flue Gas Recirculation (FGR) Natural Gas Reburning (NGR) Over Fire Air (OFA) Less Excess Air (LEA) Inject Water or Steam Reduced Air Preheat	50-70%
2.Reducing residence time at peak temperature	Air Staging of Combustion Fuel Staging of Combustion Inject Steam	50-70%
3. Chemical reduction of NOx	Selective Catalytic Reduction (SCR) Selective Non-Catalytic Reduction (SNCR) Fuel Reburning (FR)	35-90%
4. Oxidation of NOx with subsequent absorption	Non-Thermal Plasma Reactor (NTPR)	60-80%
5. Removal of nitrogen	Ultra-Low Nitrogen Fuel	No Data
6. Using a sorbent	Sorbent In Combustion Chambers Sorbent In Ducts	60-90%

WET BOTTOM (SLAG TAP) BOILERS

Wet bottom (slag tap) boilers use cyclone burners to create an intense flame. The flame is so hot that it melts ash, which then becomes slag that must be removed via a slag tap. These boilers are known to have higher NOx generation because combustion temperature is so high. As a result, this high temperature combustion technique is not widely used because the NOx concentration necessarily must be greater. Removal of non-fuel nitrogen as a reactant from the combustion process (Method 5) applies here. Reducing residence time at peak temperature, chemical

reduction of NOx, and NOx oxidation with absorption (Methods 2, 3 & 4) also apply to this combustion system. In addition, some slag tap boilers may be using sorbents (Method 6). There are recent reports that reducing peak temperature (Method 1) so that ash just melts has been used. See Table 8 for NOx technologies used for slag tap boilers.

Table 8: NOx technologies currently used for wet bottom (slag tap) boilers.

NOx Abatement Method	Techniques Now Available	Efficiency
1. Reducing peak temperature	Flue Gas Recirculation (FGR) Natural Gas Reburning (NGR) Over Fire Air (OFA) Less Excess Air (LEA) Inject Water or Steam Reduced Air Preheat	30-70%
2.Reducing residence time at peak temperature	Air Staging of Combustion Fuel Staging of Combustion Inject Steam	20-50%
3. Chemical reduction of NOx	Selective Catalytic Reduction (SCR) Selective Non-Catalytic Reduction (SNCR) Fuel Reburning (FR)	35-90%
4. Oxidation of NOx with subsequent absorption	Non-Thermal Plasma Reactor (NTPR)	60-80%
5. Removal of nitrogen	Use Oxygen Instead Of Air Ultra-Low Nitrogen Fuel	No Data
6. Using a sorbent	Sorbent In Combustion Chambers Sorbent In Ducts	60-90%

FLUIDIZED BED

Fluidized bed combustion occurs in a bed of crushed coal that has air flowing upward through it to make coal particles behave like a fluid. Boiler pipes can be either submerged in the bed or exposed to the hot gases after they leave the bed. The fluidized bed is temperature controlled (Method 1). The bed also is a chemically reducing region in which available oxygen is consumed by carbon (Method 3) that reduces ionization of nitrogen. Excess air is injected (Method 2) over the fluidized bed to complete combustion of CO and other burnables. This allows for the addition of pulverized limestone (Method 6) to coal in the fluidized bed. Sulfur oxides then react with the limestone to form gypsum, a marketable product. Gypsum must be separated from the ash. As a result, NOx generation can be essentially limited to prompt NOx and fuel NOx. See Table 9 for NOx technologies used for fluidized bed combustion units.

NMED Exhibit 81

Table 9: NOx techniques currently used for fluidized bed combustion.

NOx Abatement Method	Techniques Now Available	Efficiency
1. Reducing peak temperature	Flue Gas Recirculation (FGR) Natural Gas Reburning (NGR) Over Fire Air (OFA) Less Excess Air (LEA) Reduced Air Preheat	No Data
2.Reducing residence time at peak temperature	Inject Steam	No Data
3. Chemical reduction of NOx	Selective Catalytic Reduction (SCR) Selective Non-Catalytic Reduction(SNCR) Fuel Reburning (FR)	35-90%
4. Oxidation of NOx with subsequent absorption	Non-Thermal Plasma Reactor (NTPR)	60-80%
5. Removal of nitrogen	Ultra-Low Nitrogen Fuel	No Data
6. Using a sorbent	Sorbent In Combustion Chambers Sorbent In Ducts	60-90%

STOKERS WITH TRAVELING GRATE

Stokers with traveling grate cause the coal to move as it burns. Thus, char combustion is in one zone while volatiles are liberated and combusted in another zone. These stokers are commonly used with industrial boilers that are smaller than utility boilers. Reducing peak temperature, chemical reduction of NOx, and sorbents (Methods 1, 3 & 6) usually are applied. Perhaps NOx oxidation (Method 4) also will apply in the future. See Table 10 for NOx technologies used for stokers with traveling grates.

STOKERS WITH SPREADERS

Stokers with spreaders throw coal over the grate in a controlled manner. Coal is crushed, but particles are typically larger than pulverized coal. Therefore, combustion of volatiles begins while coal is in flight and combustion of char occurs on the grate. This system is used with somewhat larger boilers than stokers with traveling grates. It can be used in power plants, but this combustion system is used mainly for industrial boilers. Like stokers with traveling grates, reducing peak temperature, chemical reduction of NOx, and sorbents (Methods 1, 3, and 6) usually are applied. Perhaps NOx oxidation (Method 4) also will apply in the future. See Table 11 for NOx technologies used for stokers with Spreader grates.

NMED Exhibit 81

Table 10: NOx technologies currently used for stokers with traveling grates.

NOx Abatement Method	Technique Now Available	Efficiency
1. Reducing peak temperature	Flue Gas Recirculation (FGR) Natural Gas Reburning (NGR) Combustion Optimization Over Fire Air (OFA) Less Excess Air (LEA) Inject Water or Steam Reduced Air Preheat	35-50%
2.Reducing residence time at peak temperature	Air Staging of Combustion Fuel Staging of Combustion	50-70%
3. Chemical reduction of NOx	Selective Catalytic Reduction (SCR) Selective Non-Catalytic Reduction (SNCR) Fuel Reburning (FR)	55-80%
4. Oxidation of NOx with subsequent absorption	Inject Oxidant Non-Thermal Plasma Reactor (NTPR)	60-80%
5. Removal of nitrogen	Ultra-Low Nitrogen Fuel	No Data
6. Using a sorbent	Sorbent In Combustion Chambers Sorbent In Ducts	60-90%

GAS TURBINES

Gas turbines use the Brayton Cycle with a burner to raise temperature of gas after compression and before expansion through the turbine. Turbines mainly use reducing peak temperature and reducing residence time (Methods 1 and 2) approaches to limit NOx emissions. Because addition of particles to air flow entering the turbine would accelerate erosion of turbine blades, sorbents (Method 6) could only be applied after the expansion in the turbine. NOx reduction (Method 3) has been used to treat exhaust gases. Many turbine operators claim that they use "good combustion practices" that do reduce the particles that produce visible emissions (which they equate with pollution), but say nothing about the NOx emissions which are not visible.

Cogeneration units use a gas turbine to generate electricity and provide preheated combustion air for a boiler. Gas turbine exhaust is typically 10-15% oxygen and can be used to provide combustion air for a low pressure boiler. That boiler can be used to provide steam for another turbine, a process heater, a space heater, or some combination of these. If a steam turbine is used to generate electricity, it may constrain what can be done. Sorbent particles can be introduced to a flow after it leaves a gas turbine in order to control NOx. There has also been some success in reducing NOx concentrations when burning biomass fuels in a boiler. See Table 12 for NOx technologies used for gas turbines.

NMED Exhibit 81

Table 11: NOx technologies currently used for stokers with spreader grates.

NOx Abatement Method	Technique Now Available	Efficiency
1. Reducing peak temperature	Flue Gas Recirculation (FGR) Natural Gas Reburning (NGR) Low NOx Burners (LNB) Combustion Optimization Over Fire Air (OFA) Less Excess Air (LEA) Inject Water or Steam Reduced Air Preheat	50-65%
2.Reducing residence time at peak temperature	Air Staging of Combustion Fuel Staging of Combustion Inject Steam	50-65%
3. Chemical reduction of NOx	Selective Catalytic Reduction (SCR) Selective Non-Catalytic Reduction (SNCR) Fuel Reburning (FR)	35-80%
4. Oxidation of NOx with subsequent absorption	Inject Oxidant Non-Thermal Plasma Reactor (NTPR)	60-80%
5. Removal of nitrogen	Ultra-Low Nitrogen Fuel	No Data
6. Using a sorbent	Sorbent In Combustion Chambers Sorbent In Ducts	60-90%

INTERNAL COMBUSTION RECIPROCATING ENGINES

Internal combustion engines use air-to-fuel ratio and ignition/injection timing to control maximum temperature and residence time. This can reduce the concentration of NOx that is generated by reducing peak temperature (Method 1). Valve timing adjustments can reduce residence time at peak temperature (Method 2) to control NOx formation. Chemical reduction of NOx (Method 3) is used in catalytic converters to reduce NOx to N_2. Some stationary engines use both Method 3 and NOx oxidation (Method 4). A non-thermal plasma reactor was developed for treatment of diesel exhaust, but is not yet marketed to our knowledge. A plasma ignition system allows greater freedom in the air-fuel ratio and the ignition timing of spark ignition engines. See Table 13 for NOx technologies used for stationary internal combustion engines.

WHAT DOES NOx ABATEMENT AND CONTROL COST?

The cost of NOx abatement and control has been changing rapidly with dramatic reductions in recent years. Table 14 gives the 1993 cost as given in the Alternative Control Techniques

NMED Exhibit 81

Table 12: NOx technologies currently used for gas turbines.

NOx Abatement Method	Technique Now Available	Efficiency
1. Reducing peak temperature	Natural Gas Reburning (NGR) Low NOx Burners (LNB) Inject Water or Steam Reduced Air Preheat Catalytic Combustion	70-85%
2.Reducing residence time at peak temperature	Air Staging of Combustion Inject Steam	70-80%
3. Chemical reduction of NOx	Selective Catalytic Reduction (SCR) Selective Non-Catalytic Reduction (SNCR) Fuel Reburning (FR) Low NOx Burners (LNB)	70-90%
4. Oxidation of NOx with subsequent absorption	Non-Thermal Plasma Reactor (NTPR)	No Data
5. Removal of nitrogen	Ultra-Low Nitrogen Fuel	No Data
6. Using a sorbent	Sorbent In Ducts	60-90%

Table 13: NOx technologies currently used for stationary internal combustion engines.

NOx Abatement Method	Technique Now Available	Efficiency
1. Reducing peak temperature	Air/fuel Ratio Timing of Ignition/Type of Ignition Pre-Stratified Combustion	20-97%
2.Reducing residence time at peak temperature	Valve Timing	No Data
3. Chemical reduction of NOx	Selective Catalytic Reduction (SCR) Non-Selective Catalytic Reduction (NCSR)	80-90%
4. Oxidation of NOx with subsequent absorption	Non-Thermal Plasma Reactor (NTPR)	80-95%
5. Removal of nitrogen	Ultra-Low Nitrogen Fuel	No Data
6. Using a sorbent	Sorbent In Exhaust Ducts Adsorber in fixed Bed	60-90%

(1994 ESTIMATE)					700	1,300
SCR	2,400	20,000	1,500	5,800	1,810	10,900
(1994 ESTIMATE)					500	2,800

Document NOx Emissions from Industrial/Commercial/Institutional Boilers (EPA 453/R-94-022).
The EPA Region III Low-NOx Control Technology Study in 1994 said that low-NOx burners had both beneficial effects on operating costs and detrimental effects on the burners, their life expectancy, and the boilers in which they were installed. Coal quality and some boiler designs caused NOx to remain high even after low-NOx burners were in place. Capital costs ranged from $1.91 to $54.24 per kW. Operating costs ranged from $-23,000 (a profit) to $1,113,750 per year. Thus, no reliable cost estimates could be obtained regarding low-NOx burner operation. Coal quality, boiler capacity, and burner design were among the variables influencing this cost. Many plants could not even give an estimate. SNCR cost between $700 and $1,300 per ton of NOx reduced. SCR cost between $500 and $2,800 per ton of NOx reduced.[25] However, cost per ton of NOx removed for all technologies is apparently becoming smaller.

These costs vary by control technique; type of fuel; grade of fuel; size of boiler, engine or turbine; type of boiler, or turbine; and other factors. Other costs were also changing with time. Therefore you need to examine the costs of these NOx control technologies for a specific application and at a particular time.

These preliminary cost estimates will also be further reduced as operating experience is gained, competition sharpens, and design iterations eliminate the high-maintenance or life-shortening features. Confidence in this view of the future is based upon reports that some users of low-NOx burners had already seen in 1994 that operating costs could be reduced to make the changeover yield a net profit. SCR and SNCR costs may also have declined further, since there is now competition for these technologies.

NMED Exhibit 81

This analysis was supported by 1997 cost figures. These are presented in Table 15. This table is from the Analyzing Electric Power Generation Under the CAAA [26]. It appears that competition and improved designs are still driving the costs downward. The Table was presented in that publication and is presented here for your convenience.

Table 15. 1997 Costs of NOx Controls

Analyzing Electric Power Generation Under the CAAA -- Cost Estimates[26]					
Boiler Type	Control Type	Capital Cost	Fixed O & M	Variable O& M	% Control
		$/kW	$/kW/yr	mils/kWh	
Wall Fired	LNB w/o OFA	16.8	0.25	0.05	67.5
Wall Fired	LNB w/ OFA	22.8	0.35	0.07	67.5
Tang-Fired	LNB w/ OFA	32.3	0.49	0	47.3
Tang-Fired LNB w/ SOFA		34.7	0.53	0	52.3
Tang Fired LNB w/ BOFA		46.7	0.71	0.02	57.3
Cell Burners	Non Plug-In Comb. Ctl.	22.8	0.34	0.07	60
Cyclone	Coal Reburning	70.7	1.07	0.25	50
Wet Bottom	NOx Comb. Ctl.	9.6	0.14	0.05	50
Vert. Fired	NOx Comb. Ctl.	10.8	0.17	0.05	40
	SCR -Low NOx Rate	69.7	6.12	0.24	70
	SCR- High NOx Rate	71.8	6.38	0.4	80
	SNCR-Low NOx Rate	16.6	0.24	0.82	40
	SNCR-Cyclone	9.6	0.14	1.27	35
	SNCR-High NOx Rate	19	0.29	0.88	35
	Nat.Gas Reburn-Low	32.4	0.49		40
	Nat.Gas Reburn-High	32.4	0.49		50

Note that in Table 8 the following acronyms are used:

LNB is low-NOx burner
OFA is closed coupled overfire air
SOFA is separate over fire air
BOFA is both close coupled and over fire air
Comb. Ctl. is combined controls

The Institute of Clean Air Companies also suggests that in 1999 SCR will cost $50 - $80 per kW for retrofit to units, which relates to $400-$1800 per ton of NOx that is destroyed.[34] Their cost estimate for SNCR ranges from $5-$15 per kW, which relates to $400-$2000 per ton of NOx that is destroyed.[35] Cost-effectiveness does not correlate with boiler capacity alone - other variables such as type and quality of fuel, type of boiler, SNCR/SCR design, etc enter into the analysis.

While the "Performance of Selective Catalytic Reduction on Coal-fired Steam Generating Units" study was for Germany, it cited a recent cost range for SCR from $52 to $77 per kW with retrofit units tending to have lower costs. Thus, the costs in Germany were very similar to costs in the U.S.A., except that retrofit costs usually are greater in the United States.

Table 16, Unit Costs for NOx control Technologies for Non-Utility Stationary Sources, is from the report "Ozone Transport Rulemaking Non-Electricity Generating Unit Cost Analysis." The report was prepared for EPA by the Pechan-Avanti Group. It indicates efficiencies and cost estimates for various NOx technologies for the year 2007. This appears to be a conservative estimate of efficiency and cost. Efficiencies indicated in the table tend to be lower than currently demonstrated efficiencies. Costs were based on historical information and, therefore, should be high estimates because NOx technology costs appear to be declining over time. The table was included here to indicate the relative efficiency and cost of NOx technologies for specific types of combustion systems.

The Alternative Control Techniques Document NOx Emissions from Stationary Reciprocating Internal Combustion Engines contains cost algorithms for the pollution prevention techniques and control technology applied to internal reciprocating engines. Costs for NOx elimination run from $250/ton to $1,300/ton for engines larger than 1,000 horsepower. For smaller engines the cost runs from $400/ton to over $3,500/ton.

ARE THESE METHODS SUFFICIENT?

YES, these methods are sufficient to meet the present goal of reducing NOx emissions 2 million tons below 1980 emissions.[47] The goal appears to be set at a level that can be achieved based on the state of NOx technology in 1996. However, we will have to see whether achieving our present goal provides the needed relief. A still more stringent set of standards may become necessary at sometime in the future.

As a high-technology nation and with a large urban and suburban population, we depend on automobiles, buses, airplanes, railroads, and trucks for transportation. We also depend upon electric power for computers, lights, air conditioning, and commerce. Therefore, we seem caught in a dilemma, for, while we depend on transportation, vehicles produce most of our NOx. While we also consume electric power as part of our market economy, electric power generation also generates over 40% of our NOx from stationary sources in 1995.[34]

We also need to generate less NOx without regard to the ionization level of the nitrogen. In 1999, we are currently not capable of doing that. Therefore, we must do the best that we can,

NOTE: *Small source cost per ton values are used to estimate control costs for all sources with 1995 NO_x emissions below 1 ton per day. If the ozone season daily 1995 baseline NO_x value is 1 ton or more, the cost per ton value for large sources is used.
N/A = not applicable. The population of medium speed gas-fired IC engines are all considered small.

NMED Exhibit 81

and hope that we can endure while looking for the discovery and cost-reduction of the "better technology" that is capable of meeting the goal of sustainability. The reference literature suggests that the leading edge of pollution prevention and control technology in 1999 is capable of about 94%-99% control of NOx or 1 ppm-5 ppm of NOx.[27,28]

As we all know, the leading edge technology always costs more because engineering has not yet shifted from feasibility to cost-reduction, and competition in the technology is not fully developed. Therefore, we can expect technology to be more affordable with time and to also improve its capability. We should expect to see the goal change with time as the technology advances, and as the achievable goal becomes both more stringent and more economically feasible. At one time, the capabilities that we now have seemed beyond imagining, and the costs seemed prohibitive. We live in an interesting time when the NOx pollution prevention, abatement, and control technology is becoming more capable and more affordable.

CONCLUSIONS

1. Different fuels require different combustion, abatement and control techniques. Different coals have a varying content of volatile ingredients. The nitrogen content of fuel is important, as are the content of sulfur, lead, mercury and other contaminants. Ultra-low nitrogen content fuels have been developed and are already cost competitive. Thus, we can achieve some control of NOx from the lowered concentration of nitrogen in the fuel without investing in changed burner designs.[29]

2. The design of the boiler, internal combustion engine, or gas turbine has a major effect on the operation. NOx formation tends to increase with an increase in boiler capacity, because larger boilers tend to have more intense combustion with higher combustion temperatures and longer residence time for flue gases. The same appears to be true of engines and turbines.

3. Staging of the combustion is implicit in several pollution prevention techniques. Tandem application (or use of hybrid control technology) of NOx control techniques (first SNCR, then SCR in the duct, and then sorption before the ESP which is referred to as "polishing") have been used to achieve an overall reduction of 90+% in NOx and 80% in SOx, even without using low-NOx burners to lower NOx generation.

4. Combustion of natural gas and petroleum distillates can be controlled in much the same way as pulverized coal. The major differences between coal and natural gas or oil are that gas and oil: (1) generally are lower in sulfur and ash; (2) usually are lower in nitrogen; and (3) probably are lower in lead and mercury. Thus, gas and oil do not deactivate a catalyst used in Selective Catalytic Reduction (SCR) at the same rate that coal or semi-solid fuels do.

5. The semi-solid petroleum products can actually have higher levels of sulfur, nitrogen and other impurities than coal. They do not have as much char or ash as coal, but have more than the lighter distillates.

NMED Exhibit 81

6. We should expect the declining cost trend of control technology to continue as operating experience is gained, firing techniques are adapted to fuels, design flaws are corrected, and new designs appear. We should expect to see costs become less as they are driven down by competition between suppliers of successful technologies.

7. NOx control technology appears capable of more than just meeting EPA's present goal and this should provide emission credits that can be traded to those firms that choose to continue emitting poorly controlled emissions. The sale of these credits by those that over-corrected for the present goal should further offset any net costs in adopting these control technologies.

8. Commercially available NOx control systems are already available. The availability of these technologies was part of the basis of the recent NOx SIP Call and Title IV regulations.

9. There has been an economic incentive to make combustion more efficient and to innovate ways to control nitrogen oxides. However, the amount of time and money that must be invested for a full-scale test of a strategy is significant. Acceptance requires that a technology be tried and succeed before a larger scale test is even contemplated. This delays acceptance of improved techniques.

10. There seems to be no control technology which is clearly superior for all combustion systems, boilers, engines, or fuels. Lacking a clear winner, one must select fuels and control technology either from among those already proven, or from a growing number of new and promising ideas.

11. The end of the search for control technologies is not yet in sight, and the search must continue. Past research must of necessity give ambivalent answers, because there are so many conflicting factors. However, at under $150 per ton of NOx prevented and with up to 80% control efficiency, the low-NOx burner, where applicable, appears to be among the least expensive emission control technologies. SCR is more expensive, but can obtain up to 94% control efficiency. SNCR can be adopted without the initial cost of catalyst, although it is somewhat less effective. LNB, SCR and SNCR are all viable technologies across a wide spectrum of applications.

12. Research and development will have to continue to seek more effective answers and try to balance them against cost and efficiency. The cost will decrease as technology advances, operating experience is gained, competition becomes sharper, design flaws are corrected, and better designs become available. Reliability can only be gained with time. Cost will be reduced with time and experience. We also must expect that the level of pollution prevention and control technology effectiveness will improve with time.

16. ABSTRACT

The purpose of this document is to educate people about nitrogen oxides, how they are formed, the danger that they represent, and how emissions can be controlled. This knowledge is needed to make an informed choice of the control technology that is to be used.

Current through Bulletin 2021-13, July 1, 2021

Section R307-504-4 - Tank Truck Loading Requirements

(1) Tanker trucks used for intermediate hydrocarbon liquid or produced water shall be loaded using bottom filling or a submerged fill pipe.

(2) VOC emissions during truck loading operations shall be controlled at all times using a vapor capture line. The vapor capture line shall be connected from the tanker truck to a control device or process, resulting in a minimum 95 percent VOC destruction efficiency.

(a) Well sites in operation on January 1, 2018 shall comply with R307-504-4(2) no later than July 1, 2019.

WHEREAS, Plaintiffs the United States of America ("United States"), on behalf of the United States Environmental Protection Agency ("EPA"), and the Commonwealth of Pennsylvania, Department of Environmental Protection ("PADEP"), simultaneously with the lodging of this Consent Decree, filed a complaint pursuant to Section 113(b) of the Clean Air Act ("Act"), 42 U.S.C. § 7413(b). The complaint seeks injunctive relief and civil penalties for violations of the Clean Air Act's Prevention of Significant Deterioration ("PSD") provisions, 42 U.S.C. §§ 7490-7492; the Non-Attainment New Source Review ("NSR") provisions, 42 U.S.C. §§ 7501-7515; and the state implementation plans ("SIPs") adopted thereunder by the Commonwealth of Pennsylvania and the State of Ohio, and approved by EPA pursuant to Section 110 of the Act, 42 U.S.C. § 7410, at certain compressor stations and at stand-alone pigging stations ("stand-alone facilities") owned and operated by Defendants MarkWest Liberty Midstream & Resources, L.L.C. and Ohio Gathering Company, L.L.C., (collectively, "MarkWest") in the Marcellus Shale and Utica Shale formations in Pennsylvania and Ohio;

WHEREAS, PADEP is the agency of the Commonwealth of Pennsylvania charged with the implementation and enforcement of the Air Pollution Control Act, 35 P.S. § 4001 *et seq.*;

WHEREAS, MarkWest is engaged in natural gas gathering operations in western Pennsylvania and eastern Ohio;

WHEREAS, this is the first civil enforcement action brought by the United States or PADEP concerning emissions from natural gas pig launchers and receivers at compressor stations or at stand-alone facilities;

WHEREAS, MarkWest has investigated and evaluated the development, design, fabrication, and testing of new technologies for sampling and estimating volatile organic

compound ("VOC") emissions from pig launcher and receiver operations and alternatives for reducing VOC emissions from natural gas pig launchers and receivers at compressor stations and stand-alone facilities;

WHEREAS, MarkWest has undertaken numerous design enhancements of launchers and receivers at compressor stations and stand-alone facilities in Pennsylvania and Ohio that have substantially reduced VOC, methane, and ethane emissions, including the design, installation and/or operation of high-to-low pressure natural gas transfer lines, pig ramps, and liquid drains;

WHEREAS, MarkWest expressly denies and does not admit any liability to the United States or PADEP arising out of the conduct, transactions or occurrences alleged in the Complaint; and

WHEREAS, the Parties acknowledge that this Consent Decree has been negotiated by all Parties in good faith and will avoid litigation among the Parties, and the Court, by entering this Consent Decree, finds that this Consent Decree is fair, reasonable, and in the public interest.

NOW, THEREFORE, before the taking of any testimony, without the adjudication or admission of any issue of fact or law except as provided in Section I, and with the consent of the Parties,

IT IS HEREBY ADJUDGED, ORDERED, AND DECREED as follows:

I. JURISDICTION AND VENUE

1. This Court has jurisdiction over the subject matter of this action and over the Parties, pursuant to 28 U.S.C. §§ 1331, 1345, 1355 and 1367, and Section 113(b) of the Act, 42 U.S.C. § 7413(b). Venue is proper in this judicial district pursuant to Section 113(b) of the Act, 42 U.S.C. § 7413(b), and 28 U.S.C. §§ 1391(b) and (c), and 1395(a), because violations alleged

in the Complaint are alleged to have occurred, and MarkWest conducts business, in this judicial district. MarkWest consents to and shall not challenge entry of this Consent Decree or this Court's jurisdiction to enter and enforce this Decree, and further consents to venue in this judicial district solely for the purpose of entering and enforcing this Consent Decree.

2. For purposes of this Consent Decree, MarkWest agrees that the Complaint states claims upon which relief may be granted.

II. APPLICABILITY AND SALES OR TRANSFERS OF OWNERSHIP AND OPERATION INTERESTS

3. The obligations of this Consent Decree apply to and are binding upon the United States, PADEP, and MarkWest, and any of their respective successors or assigns, or other entities or persons otherwise bound by law.

4. In the event that MarkWest proposes to sell or transfer ownership or operation, in whole or in part, of any of the Covered Facilities, to an entity unrelated to MarkWest ("Third Party"), MarkWest shall notify the Third Party in writing of the existence of this Consent Decree prior to the closing of such sale or transfer. MarkWest shall send a copy of this written notification to the United States and PADEP pursuant to Section XVIII (Notices) prior to the proposed closing.

5. MarkWest shall condition any sale or transfer, in whole or part, of ownership or operation of any of the Covered Facilities upon the execution by the Third Party of a modification to this Consent Decree to make the terms and conditions of this Consent Decree related to the ownership or operation of the transferred Covered Facilities applicable to the Third Party. No earlier than thirty (30) Days after giving notice to a successor in interest pursuant to Paragraph 4, MarkWest may file a motion to modify this Consent Decree with the Court to make

the terms and conditions of the Consent Decree related to the ownership or operation of the transferred Covered Facilities applicable to the Third Party. MarkWest shall be released from the requirements of this Consent Decree with respect to the transferred Covered Facilities unless the Court finds that the Third Party does not have the financial or technical ability to comply with the requirements of this Consent Decree.

6. This Consent Decree shall not be construed to impede the sale or transfer of any asset or interest between MarkWest and any Third Party so long as the requirements of this Consent Decree are met.

7. Paragraphs 3-5 shall not be construed to affect or apply to mergers or other corporate transactions in which MarkWest is acquired by a Third Party and the surviving entity, by operation of law, assumes all of MarkWest's assets and liabilities pursuant to the Consent Decree relating to the Covered Facilities.

8. MarkWest shall (a) provide a copy of this Consent Decree to all officers of MarkWest and managers who will be responsible for implementation of the terms of this Consent Decree, and ensure that any employees and contractors whose duties might reasonably include compliance with any provision of this Consent Decree are made aware of those requirements of this Consent Decree that fall within such persons' duties; and (b) place an electronic version of the Consent Decree on its internal environmental website. MarkWest shall be responsible for ensuring that all employees and contractors involved in performing any work pursuant to this Consent Decree perform such work in compliance with the requirements of this Consent Decree.

9. In any action to enforce this Consent Decree, MarkWest shall not raise as a defense to liability or stipulated penalty the failure by any of its officers, directors, employees, agents, or contractors to take any actions necessary to comply with the provisions of this Consent Decree. This Section does not preclude MarkWest from holding any employee, agent, or contractor who is alleged to have not complied with this Consent Decree liable for their actions. Nothing herein shall preclude MarkWest, in an action to enforce this Consent Decree pursuant to Paragraph 78, from raising the failure of any contractor to take any actions necessary to comply with the provisions of this Consent Decree as a mitigating factor with regard to any non-injunctive relief sought.

III. DEFINITIONS

10. For purposes of this Consent Decree, every term expressly defined by this Section shall have the meaning given that term herein. Every other term used in this Decree that is defined in the Act, 42 U.S.C. § 7401 *et seq.*, or in the regulations promulgated pursuant to the Act, but not defined in this Section, shall mean in this Decree what such term means under the Act or those regulations.

a. "CD Emissions Reductions" shall mean any VOC emissions reductions that result from any projects, controls, or any other actions used to comply with this Consent Decree at any of the facilities listed on Appendices 1, 3 (with the exception of Route 18), or 4.

b. "Commercially and Operationally Appropriate" shall mean that: (1) fewer than 50% of anticipated pigging events at the pig launcher or receiver will be for pipeline inspection purposes; and (2) the costs of installing a shorter barrel at the pig launcher or receiver

would not be unreasonably disproportionate to the benefits of VOC emissions reductions achieved by use of a shorter barrel.

c. "Commercially Reasonable and Technically Feasible" shall mean that connection of a high pressure launcher or receiver to a low pressure line does not require MarkWest to: (1) use more than 100 feet of piping to achieve such a connection; (2) connect to a low pressure line located outside the fenceline of the facility where the high pressure launcher or receiver will be located; or (3) incur costs that would be unreasonably disproportionate to the benefits of VOC emissions reductions achieved by the installation and operation of such a connection to a low pressure line.

d. "Complaint" shall mean the complaint filed by the United States and PADEP in this action.

e. "Compressor Stations" shall mean the compressor stations identified in Appendices 1 and 4 to this Consent Decree.

f. "Consent Decree" or "Decree" shall mean this Decree and all appendices attached hereto (listed in Section XXVII (Appendices)).

g. "Covered Facilities" shall mean all MarkWest facilities identified in Appendices 1-5.

h. "Day" shall mean a calendar day unless expressly stated to be a business day. In computing any period of time under this Decree, where the last day would fall on a Saturday, Sunday, or federal holiday, the period shall run until the close of business of the next business day.

i. "EPA" shall mean the United States Environmental Protection Agency and any of its successor departments or agencies.

j. "Effective Date" shall have the definition provided in Section XIX (Effective Date).

k. "Flare" shall mean a combustion device used to control emissions from equipment in VOC service.

l. "Jumper Line" shall mean an enclosed piping system attached to the vent line of a pig launcher or receiver that routes the contents of a pig launcher or receiver into a lower pressure gathering system.

m. "Liquid or Residue Gas Service" shall refer to any pipelines downstream of a MarkWest processing plant that convey natural gas liquids or processed natural gas (residue gas).

n. "MarkWest" shall mean Ohio Gathering Company, L.L.C., and MarkWest Liberty Midstream & Resources, L.L.C.

o. "Mobile Flare" shall mean a trailer-mounted flare.

p. "Ohio SIP" shall mean the federally-approved State Implementation Plan ("SIP") adopted by the State of Ohio.

q. "Ohio VOC Permitting Threshold" shall mean, for Ohio air contaminant sources, actual VOC emissions exceeding 10 pounds per day from an air contaminant source, or potential VOC emissions from an air contaminant source alone or in combination with similar sources at the same facility in excess of 25 tons per year.

r. "PADEP" shall mean the Commonwealth of Pennsylvania, Department of Environmental Protection.

s. "Paragraph" shall mean a portion of this Decree identified by an Arabic numeral.

t. "Parties" shall mean the United States, PADEP, and MarkWest.

u. "Party" shall mean the United States, PADEP, or MarkWest.

v. "Pennsylvania SIP" shall mean the federally-approved State Implementation Plan ("SIP") adopted by the Commonwealth of Pennsylvania.

w. "Pigging" shall mean the process of introducing and subsequently removing a specialized device (called a "pig") into a natural gas pipeline to push liquids through the pipeline into a slug catcher and/or designated system.

x. "Pig Ramp" shall mean a device installed inside the barrel of a pig receiver designed and intended to prevent liquid accumulation in the barrel and minimize release of volatile liquids into the environment during retrieval of the pig.

y. "Project Dollars" shall mean MarkWest's direct costs incurred in implementing the Supplemental Environmental Projects identified in subparagraphs b. and c. of Paragraph 28 to the extent that such costs: (i) comply with the requirements set forth in Section VI and (ii) constitute MarkWest's direct payments associated with such projects or MarkWest's external costs for contractors, vendors, and equipment. Project Dollars shall not include MarkWest's internal personnel costs incurred to oversee the implementation of the Supplemental Environmental Projects identified in subparagraphs b. and c. of Paragraph 28.

z. "Real Gas Law" shall mean $PV = (m/M_w)RTZ$ where:

P = pressure inside the pipe (psfa) pound per square foot actual

V = actual volume of pipe (ft^3)

m = mass of material (lb)

M_w = molecular weight of the mixture (lb/lbmol)

R = universal gas constant (1545 psfa*ft3/lbmol*°R^{-1})

T = temperature of mixture (°R)

Z = compressibility factor (unitless)

Solving for mass yields: $m = PVM_w/(RTZ)$.

aa. "Section" shall mean a portion of this Decree identified by a Roman numeral.

bb. "Stand-Alone Facilities" shall mean the MarkWest sites where natural gas pig launchers and/or receivers are located that are identified in Appendices 3, 5, and 6.

cc. "System" shall mean all of MarkWest's pig launchers and receivers in Pennsylvania and Ohio.

dd. "United States" shall mean the United States of America, acting on behalf of EPA.

ee. "VOC" or "VOCs" shall mean volatile organic compounds, as defined in 40 C.F.R. § 51.100(s), and which does not include methane or ethane.

IV. INJUNCTIVE RELIEF

11. Emission Calculations. For purposes of compliance with the Consent Decree, MarkWest shall calculate the mass of VOC emissions from pigging operations at facilities listed in Appendices 1 through 5 using the Real Gas Law multiplied by a factor of 1.2.

12. Pennsylvania Compressor Stations. No later than the Effective Date, at the MarkWest Compressor Stations identified in Appendix 1, MarkWest shall:

a. connect each high pressure pig launcher and receiver by Jumper Lines to a low pressure gathering line;

b. operate Jumper Lines to depressurize such launchers and receivers prior to opening the launcher or receiver hatch; and

c. install and use Pig Ramps in pig receivers.

13. Pennsylvania Compressor Station Dehydrator Flares. At the MarkWest Compressor Stations identified in Appendix 2, MarkWest shall replace existing dehydrator flares with enclosed air-assisted flares. The replacement enclosed air-assisted flare system shall include a 3 horsepower blower (with a variable frequency drive), a single point burner tip, a gas enrichment stream and shutdown/startup control logic panels, and shall raise regenerator off-gas Btu value to ensure a clean burn. These flares shall achieve a minimum 98% destruction and removal efficiency ("DRE").

14. Pennsylvania Stand-Alone Facilities. No later than the Effective Date, MarkWest shall implement those elements of injunctive relief identified in this Paragraph that apply, as specified in Appendix 3, to each specific pig launcher and receiver located at each of the MarkWest Stand-Alone Facilities identified in Appendix 3. Where applicable, MarkWest shall:

a. connect high pressure pig launchers and receivers by Jumper Lines to a low pressure gathering line;

b. operate Jumper Lines to depressurize such launchers and receivers prior to opening the launcher or receiver hatch; and

c. install and use Pig Ramps in pig receivers.

15. Pennsylvania Launcher/Receiver Smith Tee Emissions Flare Replacement. At the Smith Tee Stand-Alone Facility (the location of which is identified in Appendix 3) in Pennsylvania**,** MarkWest shall replace the existing flare with a new "candlestick" flare. The replacement candlestick flare system shall be designed to (a) provide smokeless and low heat radiation flaring, (b) maintain its pilot light in winds up to 50 mph, and (c) generate a hydrocarbon gas-air mixture using an air inspirator ignition.

16. Loffert (Joe Cain) Pennsylvania Stand-Alone Facility. At the Loffert (Joe Cain) Stand-Alone Facility (the location of which is identified in Appendix 3)**,** MarkWest shall continue to operate the redesigned and modified discharge piping installed in 2016.

17. Closure of Drugmand, Stewart Route 50, and Graham Header Stations. No later than twelve (12) months after the Effective Date, MarkWest shall permanently close and cease operations of all launchers and receivers located at the Drugmand Station (located at 40.32917258600, -80.28226258100) and Stewart Route 50 Station (located at 40.28446667, -80.35458611) and all high pressure launchers and receivers located at the Graham Header Station (located at 40.83600748440, -80.08065377390). MarkWest shall permanently remove all pig launchers and receivers that are subject to this Paragraph. Until MarkWest permanently ceases operations of the referenced launchers and receivers, MarkWest shall continue to use the existing Pig Ramps, Jumper Lines, and Flares to reduce VOC emissions during pigging operations.

18. Ohio Compressor Stations. No later than the Effective Date, MarkWest shall implement those elements of injunctive relief identified in this Paragraph that apply, as specified

in Appendix 4, to each specific pig launcher and receiver located at each of the MarkWest Compressor Stations identified in Appendix 4. Where applicable, MarkWest shall:

a. connect high pressure pig launchers and receivers by Jumper Lines to a low pressure gathering line;

b. operate Jumper Lines to depressurize such launchers and receivers prior to opening the launcher or receiver hatch;

c. install and use Pig Ramps in pig receivers; and

d. when necessary to ensure that VOC emissions do not exceed the Ohio VOC Permitting Threshold, use a Mobile Flare to control VOC emissions.

19. Ohio Stand-Alone Facilities. No later than the Effective Date, MarkWest shall implement those elements of injunctive relief identified in this Paragraph that apply, as specified in Appendix 5, to each specific high pressure launcher and receiver located at each of the MarkWest Stand-Alone Facilities identified in Appendix 5. Where applicable, MarkWest shall:

a. connect high pressure pig launchers and receivers by Jumper Lines to a low pressure gathering line;

b. operate Jumper Lines to depressurize such launchers and receivers prior to opening the launcher or receiver hatch;

c. install and use Pig Ramps in pig receivers; and

d. when necessary to ensure compliance with the Ohio SIP, use a Mobile Flare to control VOC emissions.

20. New Launchers and Receivers. For pig launchers and receivers constructed in Pennsylvania and Ohio after the Effective Date and prior to Termination, MarkWest shall, subject to the exception in subparagraph e., below:

a. connect each high pressure pig launcher or receiver by Jumper Lines to a low pressure gathering line where such connection is Commercially Reasonable and Technically Feasible;

b. use Jumper Lines to depressurize such launchers and receivers prior to opening the launcher or receiver hatch;

c. at each new receiver, install and use a Pig Ramp or, with prior EPA written approval, technology that achieves equivalent emissions reductions;

d. at high pressure pig launchers and receivers, use shorter barrels than those presently used in the System, provided that the high pressure pig launcher or receiver is not in Liquid or Residue Gas Service and use of a shorter barrel is Commercially and Operationally Appropriate; and

e. in the event that MarkWest determines that any of the requirements in subparagraphs a., b., or d. above would pose a material adverse risk to worker safety, MarkWest may inform EPA of such risk and the reasons therefore, and upon written approval by EPA be excused from that requirement.

21. Existing Receivers. MarkWest shall install Pig Ramps in all pig receivers located at the Stand-Alone Facilities identified in Appendix 6.

22. At each high pressure pig launcher and receiver that MarkWest currently operates in Pennsylvania and Ohio that is not located at a Covered Facility, MarkWest shall connect such

high pressure pig launcher and receiver by pipe to a low pressure gathering line where such connection is Commercially Reasonable and Technically Feasible and operate such Jumper Lines to depressurize such launchers and receivers prior to opening the launcher or receiver hatch.

23. Liquid Containment Enhancement. For each launcher or receiver located at any MarkWest Compressor Station or Stand-Alone Facility identified in Appendices 1, 3, 4, 5, or 6, and each new launcher or receiver constructed after the Effective Date but prior to Termination in Pennsylvania and Ohio, MarkWest shall install and use liquid containers with grounded steel receptacles that are covered at all times when not in use.

V. CIVIL PENALTY

24. No later than thirty (30) Days after the Effective Date, MarkWest shall pay as a civil penalty $610,000. MarkWest shall pay 80% of this penalty to the United States, and 20% to PADEP. MarkWest shall pay interest on any amount past due, at the rate specified in 28 U.S.C. § 1961.

25. Federal Payment Instructions. MarkWest shall make the penalty payment to the United States at https://www.pay.gov to the U.S. Department of Justice account, in accordance with instructions provided to MarkWest by the Financial Litigation Unit ("FLU") of the United States Attorney's Office for the Western District of Pennsylvania after the Effective Date. The payment instructions provided by the FLU will include a Consolidated Debt Collection System ("CDCS") number that MarkWest shall use to identify this payment, as well as any others required to be made in accordance with this Consent Decree. The FLU will provide payment instructions to MarkWest to:

Christopher L. Rimkus
Managing Counsel – Operations
MarkWest Energy Partners, L.P.
1515 Arapahoe St., Suite 1600
Denver, CO 80202
Christopher.rimkus@markwest.com

MarkWest may change the individual to receive payment instructions on its behalf by providing written notice of such change in accordance with Section XVIII (Notices). At the time of payment, MarkWest shall send notice that payment has been made to the United States and EPA in accordance with Section XVIII (Notices). Such notice shall state that it is for the civil penalty owed pursuant to the Consent Decree, and shall reference the CDCS number, the civil action number, and DOJ Case No. 90-5-2-1-11374.

26. Pennsylvania Payment Instructions. The MarkWest penalty payment to Pennsylvania shall be made by Electronic Funds Transfer in accordance with instructions to be provided to MarkWest by PADEP. The payment instructions will include ABA and Account numbers that MarkWest shall use to identify all payments required to be made to PADEP in accordance with this Consent Decree. PADEP will provide the payment instructions to:

Christopher L. Rimkus
Managing Counsel – Operations
MarkWest Energy Partners, L.P.
1515 Arapahoe St., Suite 1600
Denver, CO 80202
Christopher.rimkus@markwest.com

MarkWest may change the individual to receive payment instructions on its behalf by providing written notice of such change in accordance with Section XVIII (Notices). At the time of payment, MarkWest shall send notice that payment has been made to PADEP. This notice shall include (a) the name, address, phone number and entity making payment, (b) the civil action

number of this case, (c) the reference/confirmation number and advice number of the transmittal, (d) the amount of the payment, (e) the date of the payment, and (f) the sending bank's Federal identification number.

27. Not Tax Deductible. MarkWest shall not deduct any penalties paid under this Section or Section XII (Stipulated Penalties) in calculating its federal, state, or local income tax.

VI. SUPPLEMENTAL ENVIRONMENTAL PROJECTS

28. MarkWest shall perform the following Supplemental Environmental Projects in accordance with all provisions of this Section:

a. Innovation Transfer and Emission Control Education. MarkWest will disseminate and make available for use by other oil and gas companies its proprietary design for Pig Ramps, which has been shown to reduce liquid accumulation and emissions from pig launcher and receiver operations. In order to promote the rapid adoption of this innovative device, MarkWest will make available on a public website, no later than six (6) months after the Effective Date, a royalty-free license and information on the Pig Ramp design. MarkWest will also provide educational presentations and host four demonstration or training sessions per year over a three-year period (for a total of 12 sessions), with technical staff available in-person at each session, to demonstrate and encourage the installation and adoption of the technologies developed by MarkWest to reduce VOC emissions from pig launchers and receivers throughout the oil and gas industry. In conjunction with such presentations and demonstrations, MarkWest will develop comprehensive and detailed educational materials on the effective installation, maintenance, and use of Pig Ramps and Jumper Lines to reduce VOC emissions from pig launchers and receivers. Within twelve (12) months of the Effective Date, MarkWest will make

any such materials available on the same website provided for in this Paragraph for the publication of a royalty-free Pig Ramp license and information on Pig Ramp design.

b. Humphreys Compressor Station Ambient Air Monitoring SEP. In accordance with Appendix 7, MarkWest shall install and operate, for a period of at least seven hundred twenty (720) days, one (1) meteorological station and two (2) air sampling stations for sampling and analyzing speciated and total VOCs and reduced sulfur compounds ("RSCs"). One air sampling station will be located upwind and the other downwind of the Humphreys Compressor Station ("HCS") in Barnesville, Ohio. Within one hundred twenty (120) days of the Effective Date, MarkWest shall submit a plan ("Humphreys Monitoring Plan") to EPA for approval to conduct an ambient air monitoring SEP ("Humphreys SEP") near the HCS in accordance with the requirements of this subparagraph and Appendix 7. Following EPA approval of the Humphreys Monitoring Plan, MarkWest shall install and operate the meteorological and air sampling stations in accordance with the approved Humphreys Monitoring Plan and Appendix 7. MarkWest shall submit quarterly information reports and annual reports to EPA as required by the approved Humphreys Monitoring Plan and Appendix 7.

c. Harmon Creek Ambient Air Monitoring SEP. In accordance with Appendix 8, MarkWest shall install and operate, for a period of at least seven hundred twenty (720) days, one (1) meteorological station and three (3) VOC air sampling stations located around the proposed Harmon Creek Gas Processing Plant ("Harmon Creek") in Smith Township, Washington County, Pennsylvania. Within one hundred twenty (120) days of the Effective Date, MarkWest shall submit a plan ("Harmon Creek Monitoring Plan") to EPA and PADEP, for approval by EPA in consultation with PADEP, to conduct an ambient air monitoring SEP near

Harmon Creek in accordance with the requirements of this subparagraph and Appendix 8. Following EPA approval (in consultation with PADEP) of the Harmon Creek Monitoring Plan, MarkWest shall install and operate the meteorological and air sampling stations in accordance with the approved Harmon Creek Monitoring Plan and Appendix 8. MarkWest shall submit quarterly information reports and annual reports to EPA and PADEP as required by the approved Harmon Creek Monitoring Plan and Appendix 8.

d. MarkWest shall spend not less than $2,000,000 in Project Dollars to implement the SEPs described in subparagraphs b. and c.

29. With regard to the SEPs identified in Paragraph 28, MarkWest certifies the truth and accuracy of each of the following:

a. That all cost information provided to EPA in connection with EPA's approval of the SEPs is complete and accurate and that MarkWest in good faith estimates that the cost to implement the SEPs is $2,400,000;

b. That, as of the date of executing this Consent Decree, MarkWest is not required to perform or develop the SEPs by any federal, state or local law, or regulation and is not required to perform or develop the SEPs by agreement, grant, or as injunctive relief awarded in any other action in any forum;

c. That the SEPs are not projects that MarkWest was planning or intending to construct, perform or implement other than in settlement of the claims resolved in this Decree;

d. That MarkWest has not received and will not receive credit for the SEPs in any other enforcement action;

e. That MarkWest will not receive any reimbursement for any portion of the SEPs from any other person;

f. That MarkWest is not a party to any open federal financial assistance transaction that is funding or could fund the same activity as the SEPs. For purposes of these certifications, the term "open federal financial assistance transaction" refers to a grant, cooperative agreement, loan, federally-guaranteed loan guarantee, or other mechanism for providing federal financial assistance whose performance period has not yet expired.

30. SEP Completion Report. Within thirty (30) Days after completion of a SEP, MarkWest shall submit a SEP Completion Report to the United States and PADEP in accordance with Section XVIII (Notices) of this Consent Decree. Each SEP Completion Report shall contain the following information:

a. A detailed description of the SEP as implemented;

b. A description of any problems encountered in completing the SEP and solutions thereto;

c. An itemized list of all eligible SEP costs expended;

d. Certification that the SEP has been fully implemented pursuant to the provisions of this Decree; and

e. To the extent feasible, a description of the environmental or public health benefits resulting from implementation of the SEPs.

31. The United States may, in its sole discretion, require MarkWest to provide information in addition to that described in Paragraph 30 ("SEP Completion Report") in order to evaluate MarkWest's SEP Completion Report.

32. After receiving a SEP Completion Report, the United States will notify MarkWest whether or not MarkWest has satisfactorily completed the SEP. If MarkWest has not completed the SEP in accordance with this Consent Decree, stipulated penalties may be assessed under Section XII (Stipulated Penalties) of this Consent Decree.

33. MarkWest may invoke dispute resolution under Section XIV of the Decree (Dispute Resolution) regarding EPA's determination of (i) whether MarkWest has satisfactorily performed a SEP and (ii) the amount of eligible SEP costs. No other disputes arising under this Section are subject to Dispute Resolution.

34. MarkWest shall ensure that each submission required under this Section is signed by a MarkWest official with knowledge of the SEP and bears the certification language set forth in Paragraph 63.

35. If MarkWest references the SEPs under this Consent Decree in any press conference, press release, or similar formal public statement, MarkWest shall include language in substantially the following form: "This project was undertaken in connection with the settlement of an enforcement action under the Clean Air Act brought by the United States and PADEP against certain MarkWest entities."

36. For federal income tax purposes, MarkWest agrees that it will neither capitalize into inventory or basis nor deduct any costs or expenditures incurred in performing the SEPs.

VII. COMMONWEALTH-ONLY COMMUNITY ENVIRONMENTAL PROJECT

37. In order to settle the matters contained herein, and in addition to the PADEP portion of the civil penalty identified in Section V (Civil Penalty), MarkWest shall, as a Commonwealth-Only Community Environmental Project ("CEP"), permanently transfer

ownership to PADEP of the equipment used in the Harmon Creek Ambient Air Monitoring SEP, identified in Paragraph 38, below (hereinafter "Monitoring Equipment CEP").

38. Within sixty (60) days of the completion of the Harmon Creek Ambient Air Monitoring SEP (Paragraph 28.c), MarkWest shall permanently transfer ownership of the following equipment ("Equipment") to PADEP, for PADEP's use within Pennsylvania:

Compound Analyzer	Consolidated Analytical Systems (CAS) AirmOzone Auto-Gas Chromatograph (GC) (along with ancillary equipment needed to operate it (i.e. stuff in the box))
Wind Speed/Direction	R.M. Young Model 05305 Wind Monitor AQ
Temperature and Delta Temperature	R.M. Young Platinum RTD Model 41342 ambient temperature sensor
Temperature and Delta Temperature	R.M. Young Model 43502 aspirated radiation shield
Relative Humidity	Campbell Scientific Inc (CSI) EE181 relative humidity/temperature probe
Solar Radiation	Hukseflux LP02
Net Radiation	Kipp & Zonen NR-LITE net radiometer
Barometric Pressure	CS106 Vaisala PTB110 barometer
10-Meter Tower	Model UT30 10-meter guyed aluminum tower
Telecommunications	Sierra Wireless RV50 modem (Verizon)
Data Acquisition System	Campbell Scientific, Inc. CR1000x data acquisition system

39. The Monitoring Equipment CEP falls within the definition of CEP in PADEP's "Policy for the Acceptance of Community Environmental Projects in Conjunction with Assessment of Civil Penalty" (Technical Guidance Document Number 012-4180-001).

40. PADEP has determined that the Monitoring Equipment CEP will provide a substantial public health and environmental benefit to Pennsylvania and that the Monitoring Equipment CEP is not something that MarkWest is otherwise legally required to do.

41. MarkWest shall not deduct any costs incurred in connection with or in any way associated with the Monitoring Equipment CEP for any tax purpose or otherwise obtain favorable tax treatment for those costs. If requested to do so by PADEP, MarkWest shall submit an affidavit of the corporate officer responsible for the financial affairs of MarkWest certifying that MarkWest has not deducted or otherwise obtained favorable tax treatment of any of the costs of the Monitoring Equipment CEP.

42. MarkWest agrees that whenever it publicizes, in any press conference, press release, or similar formal public statement, the Monitoring Equipment CEP, it will state that the Monitoring Equipment CEP was undertaken as part of the settlement of an enforcement action with PADEP.

VIII. PERMITS

43. Pennsylvania Appendix 1 and Appendix 3 Facilities. For each Pennsylvania Compressor Station identified on Appendix 1 with the exception of Baker, Redd, and Tupta Day, and each Pennsylvania Stand-Alone Facility identified on Appendix 3 with the exception of Route 18, MarkWest will submit complete applications to PADEP, using PADEP application forms, seeking to incorporate as "applicable requirements" the injunctive relief listed in Paragraphs 12 through 16 of this Consent Decree into non-Title V state-only operating permits ("SOOPs") for those Covered Facilities that are federally enforceable and will survive termination of this Consent Decree. VOC emissions from pigging operations in the SOOP

applications shall be determined in accordance with Paragraph 11. If, after the Effective Date, PADEP issues a revised version of its January 2015 General Plan Approval and/or General Operating Permit BAQ-GPA/GP-5 (Natural Gas Processing Stations, Processing Plants, and Transmission Stations) ("GP-5"), MarkWest will submit complete applications to PADEP, using PADEP application forms, seeking authorization to operate Baker, Redd, and Tupta Day Compressor Stations under the revised GP-5.

44. Permits to be Issued by PADEP. PADEP will review and act on such permit applications submitted by MarkWest. Any challenges to PADEP's issuance or denial of a permit application must be filed with the Pennsylvania Environmental Hearing Board.

45. Ohio Compressor Stations. For each Ohio Compressor Station identified on Appendix 4, MarkWest will submit complete applications to the Ohio Environmental Protection Agency ("OEPA") seeking to incorporate as "applicable requirements" the injunctive relief identified in Paragraph 18 (Ohio Compressor Stations) of the Consent Decree into non-Title V Permits to Install and Operate that are federally enforceable and will survive termination of this Consent Decree.

46. Other Covered Ohio Stand-Alone Facilities. For each pig launcher and receiver identified in Appendix 5, MarkWest will submit complete applications to OEPA seeking coverage under Ohio General Permit GP 21.1 (Pigging at an Oil and Gas Compressor Station/Other Site).

NMED Exhibit 85

IX. PROHIBITION ON NETTING CREDITS OR OFFSETS FROM REQUIRED CONTROLS

47. Prohibitions. MarkWest shall neither generate nor use any CD Emissions Reductions: (i) as netting reductions; (ii) as emissions offsets; or (iii) to apply for, obtain, trade, or sell any emission reduction credits in any permit application.

48. Outside the Scope of the Prohibitions. Nothing in this Section is intended to prohibit MarkWest from seeking to, nor PADEP or Ohio EPA from denying MarkWest's request to:

a. Use or generate emission reductions from emissions units that are covered by this Consent Decree to the extent that the proposed emissions reductions represent the difference between CD Emissions Reductions and more stringent control requirements that MarkWest may elect to accept for those emissions units in a permitting process, except as provided in this Paragraph;

b. Use or generate emissions reductions from emissions units that are not subject to an emission limitation or control requirement pursuant to this Consent Decree; or

c. Use CD Emissions Reductions for compliance with any rules or regulations designed to address regional haze or the non-attainment status of any area (excluding Prevention of Significant Deterioration and non-attainment New Source Review rules, but including, for example, Reasonably Achievable Control Technology ("RACT") rules that apply to MarkWest); provided, however, that MarkWest shall not be allowed to trade or sell any CD Emissions Reductions.

X. THIRD PARTY VERIFICATION

49. Third-Party Audit. MarkWest will retain, at its expense, a qualified third-party consultant, not employed by MarkWest or any of its subsidiary or affiliated companies (a "Third Party Auditor"), to lead an audit team to perform the audit described in this Section. The audit team shall include, for coordination of onsite inspection activities only, at least one MarkWest employee or contractor familiar with the Compressor Stations and Stand-Alone Facilities being audited. MarkWest shall make available to the Third-Party Auditor all of MarkWest's non-privileged records requested by the Third-Party Auditor that are reasonably related to the scope of the audit required under this Section. MarkWest may, however, require that the Third-Party Auditor execute a confidentiality agreement prior to providing any documents or records containing Confidential Business Information. MarkWest shall provide the Third-Party Auditor with access to those Compressor Stations and Stand-Alone Facilities that are the subject of the audit required by this Section and shall provide all reasonable assistance to allow the Third-Party Auditor to conduct the audit required by this Section, including making employees, affiliates, or contractors available to answer questions or provide information.

50. Third-Party Auditor Selection Process. Within sixty (60) Days after the Effective Date, MarkWest shall notify the United States and PADEP in writing of MarkWest's recommended Third-Party Auditor and provide statements of qualification for that consultant for performance of the services as Third-Party Auditor. Such statements of qualification shall identify those other services, in addition to those to be performed as Third-Party Auditor, that may be performed for MarkWest in the foreseeable future. EPA, in consultation with PADEP, may disapprove of MarkWest's recommended Third-Party Auditor if it determines that the

consultant lacks the necessary qualifications to serve as Third-Party Auditor. EPA shall state the reasons for its disapproval of the consultant as Third-Party Auditor in writing, and the MarkWest recommendation and EPA approval process will be repeated with MarkWest having thirty (30) Days from the date of disapproval to propose an alternate consultant and provide statements of qualification. In the event a consultant is not approved within thirty (30) Days of MarkWest's first submission under this Paragraph, all deadlines in this Section shall be extended by the total number of Days it takes to approve the consultant minus thirty (30) Days. For example, if it takes forty-five (45) Days to approve the consultant, MarkWest's deadlines would be extended by fifteen (15) Days (*i.e.*, 45 – 30 = 15).

51. MarkWest shall ensure that the Third-Party Auditor complies with the following terms: (a) the Third-Party Auditor shall provide written advance notice as soon as practicable to MarkWest, the United States, and PADEP in the event that the Third-Party Auditor is unable to continue to serve as the Third-Party Auditor under this Consent Decree; (b) the Third-Party Auditor shall provide EPA and PADEP with a written advance schedule of any facility visits, telephone calls, or other meetings with MarkWest or its agents or contractors and shall invite EPA and PADEP to participate in person or by teleconference; (c) the Third Party Auditor shall use the Real Gas Law, as defined herein, and calculate VOC emissions consistent with Paragraph 11 (Emission Calculations); (d) the Third-Party Auditor shall promptly disclose to the United States and PADEP any conflicts of interests for it or its subcontractors that may arise with respect to its performance of the audit and, in the event of a conflict, the Third-Party Auditor shall take any and all action to resolve such conflict; and (e) the individual Third-Party audit team personnel who conducted or otherwise participated in auditing services pursuant to this

Consent Decree shall not accept employment by MarkWest for a period of at least one (1) year following completion of the audit.

52. Scope of Audit. Within eighteen (18) months of the Effective Date, the Third-Party Auditor shall conduct an audit of the installation and operation of the injunctive relief required pursuant to Section IV to determine compliance with this Consent Decree at a total of five (5) of the Compressor Stations or Stand-Alone Facilities identified in Appendices 1 and 3, except the Baker, Redd, and Tupta Day Compressor Stations, and a total of five (5) Compressor Stations or Stand-Alone Facilities identified in Appendices 4 and 5.

53. Third-Party Audit Report. Within twenty-one (21) months of the Effective Date, the Third-Party Auditor shall simultaneously provide a draft Audit Report to MarkWest, EPA, and PADEP. Within forty-five (45) Days after receipt of the draft Audit Report, MarkWest shall provide comments on the draft Audit Report, if any, to the Third-Party Auditor, EPA, and PADEP. As part of such comments, MarkWest shall, if needed, identify within the draft Third-Party Audit Report any Confidential Business Information ("CBI"), and such information shall be designated by the Third-Party Auditor as CBI in the final Third-Party Audit Report submitted to EPA and PADEP. EPA and PADEP shall treat the draft Third-Party Audit Report, in its entirety, as CBI. The Third-Party Auditor shall provide in writing its basis for accepting or rejecting the comments of MarkWest on the draft Third-Party Audit Report. Within twenty-four (24) months of the Effective Date, the Third-Party Auditor shall submit a Third-Party Audit Report to MarkWest, EPA and PADEP. The Third-Party Audit Report shall identify any requirement of the injunctive relief specified in Section IV where MarkWest is not in compliance and, for each such requirement: (i) provide a detailed description of the basis for this conclusion

regarding noncompliance, including a summary of any relevant oral communications between the Third-Party Auditor and any of MarkWest's officers, agents, or employees; and (ii) attach relevant supporting documentation.

54. Response to Third-Party Audit Report. Within one hundred twenty (120) Days after receiving the Third-Party Audit Report, MarkWest shall (1) serve on the United States and PADEP a schedule for remedying any deficiencies identified in the Third-Party Audit Report, and/or (2) serve a notice on the United States and PADEP that MarkWest disputes the Third-Party Auditor's findings, in whole or part, and specifies the factual, technical, or legal basis of that disagreement. Any disagreement between the United States and MarkWest and/or PADEP and MarkWest over MarkWest's response to the Third-Party Audit Report shall be resolved according to the Dispute Resolution provisions of the Consent Decree in Section XIV.

55. The United States and PADEP shall not be bound by any Third-Party Audit Report generated pursuant to this Consent Decree. The United States and/or PADEP may accept or reject, in whole or in part, the Third-Party Auditor's findings, conclusions, and/or recommendations. If the United States or PADEP determines that MarkWest is in violation of any Consent Decree requirement for which stipulated penalties are provided under Section XII (Stipulated Penalties), MarkWest shall be subject to the assessment of such penalties, regardless of the Third-Party Audit Report, in accordance with the provisions of Section XII (Stipulated Penalties), and subject to MarkWest's right to invoke the provisions of Section XIV (Dispute Resolution).

56. MarkWest may terminate its contract with the Third-Party Auditor only for good cause shown and with the consent of the United States, in consultation with PADEP; such

consent not to be unreasonably withheld. For the purposes of this Paragraph, "good cause" includes, but is not limited to, incompetence, fraudulent actions, and any failure by the Third-Party Auditor to comply with all applicable laws and MarkWest policies relating to (1) worker health and safety, or (2) environmental compliance and protection. In the event MarkWest terminates its contract with the Third-Party Auditor, MarkWest shall select a new consultant consistent with the process in Paragraph 50.

57. Except as otherwise provided herein, the Third-Party Audit Report shall not be subject to any privilege or the attorney work product doctrine. Nothing in this Section shall prevent MarkWest from designating as CBI portions of the Third-Party Audit Report or other documents prepared by the Third-Party Auditor.

XI. RECORDKEEPING AND REPORTING

58. Status Reports. After the Effective Date and until termination of the Consent Decree, MarkWest shall submit periodic reports ("Status Reports") on the status of the injunctive relief and SEPs required by the Consent Decree. The first such Status Report shall cover the first six-month period after the Effective Date and shall be due within sixty (60) Days after the end of the six-month period. Each subsequent Status Report shall cover a one (1) year period and shall be due within sixty (60) Days after the end of annual period covered. Each Status Report shall contain the following information:

a. The date(s) of replacement of any Dehydrator Flares at compressor stations listed in Appendix 2 of this Decree, as required by Paragraph 13.

b. The date of the replacement of the candlestick flare at the Smith Tee facility, as required by Paragraph 15.

c. The status of the closure of launchers and receivers located at the Drugmand, Stewart Route 50, and Graham Header facilities. If the facility is closed, provide the date the facility ceased operation, as required by Paragraph 17.

d. The date of any SEP Completion Reports submitted under Paragraph 30. Also, identify for which SEP the completion report was submitted.

e. For any new launcher or receiver constructed after the Effective Date but prior to the Termination Date of this Decree, as provided in Paragraph 20, provide the date(s) and location of any:

i. Jumper Lines installed;

ii. Pig Ramps installed;

iii. An explanation for not installing Jumper Lines or Pig Ramps;

iv. Any instances where a Jumper Line was not used prior to opening the hatch;

v. An explanation for not using shorter barrels at high pressure launchers and receivers.

f. For each launcher or receiver subject to the requirements of Paragraphs 12, 14, 18 and 19, provide, as applicable to each specific pig launcher or receiver, the date(s) and locations of:

i. Jumper Lines installed;

ii. Pig Ramps installed; and

iii. Liquid Containment Vessels installed.

g. Copies of each permit application submitted to PADEP pursuant to Paragraph 43.

h. Copies of each permit application or application seeking coverage under a general permit submitted to OEPA pursuant to Paragraphs 45 and 46.

i. Date on which OEPA granted any permit or approval to operate under a general permit in response to applications submitted pursuant to Paragraphs 45 and 46.

j. Date that any Jumper Line was installed pursuant to the requirements of Paragraph 22.

k. Dates that Pig Ramps were installed for each receiver as required by Paragraph 21.

l. Dates that a Mobile Flare was operated as required by Paragraphs 18 and 19.

m. Status update for the HCS and Harmon Creek monitoring SEPs as set forth in Paragraph 28.b. and c. until those SEPs are completed.

59. Maintenance of Consent Decree Records. MarkWest shall maintain records necessary to demonstrate compliance with this Consent Decree.

60. Pigging Event Records. For each pigging event that occurs at a launcher or receiver subject to the requirements of Paragraphs 12, 14, 18, and 19, MarkWest shall maintain records of the following information:

a. Identification number of the launcher or receiver;

b. Location of the launcher or receiver;

c. Date and time of pigging;

d. The launcher or receiver pressure prior to venting to the atmosphere, and prior to routing emissions to a flare, where applicable;

e. Gas composition data representative of the composition of gas at the facility. This data shall be updated at least annually;

f. In the case of pig launchers and receivers identified in Appendices 4 and 5, whether a Mobile Flare was used as required by Paragraphs 18 and 19; and

g. In the case of pig launchers and receivers identified in Appendices 4 and 5, any additional records necessary to demonstrate that the emissions from each launcher and receiver did not exceed the emissions threshold applicable to each launcher and receiver under Paragraphs 18 and 19.

61. Whenever any violation of this Consent Decree, or any other event affecting MarkWest's performance under this Decree, may pose an immediate threat to public health or welfare or the environment, MarkWest shall notify EPA and PADEP orally or by electronic transmission as soon as possible, but no later than 24 hours after MarkWest first knew of the violation or event.

62. All reports pursuant to this Section shall be submitted to the persons designated in Section XVIII of this Consent Decree (Notices).

63. Certification. Each report submitted by MarkWest under this Decree shall be signed by an official of MarkWest and include the following certification:

> I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I have no personal knowledge that the information submitted is other than true, accurate, and complete. I am aware that there are significant

> penalties for submitting false information, including the possibility of fine and imprisonment for knowingly and willfully submitting a material false statement.

This certification requirement does not apply to emergency or similar notifications where compliance would be impractical.

64. The reporting requirements of this Consent Decree do not relieve MarkWest of any reporting obligations required by the Act or implementing regulations, or by any other federal, state, or local law, regulation, permit or requirement.

65. Any information provided pursuant to this Consent Decree may be used by the United States or PADEP in any proceeding to enforce the provisions of this Consent Decree and as otherwise permitted by law.

XII. STIPULATED PENALTIES

66. MarkWest shall be liable for stipulated penalties for violations of this Consent Decree as specified below, unless excused under Section XIII (Force Majeure) of the Decree, or reduced or waived by the United States or the United States and PADEP (in the case of violations at Facilities located in Pennsylvania) pursuant to Paragraph 72. For violations occurring at Facilities in Pennsylvania, stipulated penalties are due to both the United States and PADEP, with fifty percent (50%) of the total amount of stipulated penalties paid to the United States, and fifty percent (50%) to PADEP. For violations occurring at Facilities in Ohio, one hundred percent (100%) of the penalty shall be paid to the United States.

67. Tier 1 Stipulated Penalties. The following stipulated penalties shall accrue per violation per Day for each violation of the following requirements of this Consent Decree: (1) connection of high pressure to low pressure Jumper Lines under Paragraphs 12.a., 14.a., 18.a.,

and 19.a.; (2) use of Jumper Lines before depressurizing under Paragraphs 12.b., 14.b., 18.b., and 19.b; (3) installation of dehydrator flares at Compressor Stations pursuant to Paragraph 13; (4) replacement of the flare at the Smith Tee Stand-Alone Facility under Paragraph 15; (5) operation of the redesigned and modified discharge piping at Loffert (Joe Cain) Pennsylvania Stand-Alone Facility pursuant to Paragraph 16; and (6) closure of pig launchers and receivers at the Drugmand, Stewart Route 50, and Graham Header Stations pursuant to Paragraph 17.

Penalty Per Violation Per Day	Period of Noncompliance
$2,250	1st through 14th Day
$3,500	15th through 30th Day
$5,000	31st Day and beyond.

68. Tier 2 Stipulated Penalties. The following stipulated penalties shall accrue per violation per Day for each violation of each of the following requirements of this Consent Decree: (1) installation and use of Pig Ramps under Paragraphs 12.c., 14.c., 18.c., and 19.c.; and (2) timely submission of Status Reports under Paragraph 58:

Penalty Per Violation Per Day	Period of Noncompliance
$500	1st through 14th Day
$1,000	15th through 30th Day
$1,500	31st Day and beyond.

69. Stipulated Penalties for SEPs. The following stipulated penalties shall accrue per Day for each violation of the following SEP requirements, as set forth in Paragraph 28.a-c. of this Consent Decree: (1) failure to timely submit SEP work plans required by Paragraph 28.b and .c. (2) failure to timely make available on a public website a royalty-free license and/or

information on the Pig Ramp design; (3) failure to timely make available on a public website materials on the effective installation, maintenance, and use of Pig Ramps and Jumper Lines; (4) failure to install the air sampling or meteorological stations at HCS and Harmon Creek as required by Paragraph 28.b. and c.; (5) material failure to operate the monitoring or meteorological stations as required by Paragraph 28.b. and c.; (6) failure to timely provide the meteorological data and/or sampling data as set forth in Paragraph 28.b. and c.; and (7) failure to timely submit a SEP Completion Report pursuant to Paragraph 30:

Penalty Per Day of Violation	Period of Noncompliance
$500	1st through 14th Day
$1,000	15th through 30th Day
$2,500	31st Day and beyond.

70. Stipulated penalties under this Section shall begin to accrue on the Day after performance is due or on the Day a violation occurs, whichever is applicable, and shall continue to accrue until performance is satisfactorily completed or until the violation ceases. Stipulated penalties shall accrue simultaneously for separate violations of this Consent Decree. The penalties that accrue for each violation or failure to perform an obligation do not increase from one period of noncompliance to the next unless the violations or failures to perform are continuous.

71. MarkWest shall pay stipulated penalties to the United States and PADEP within thirty (30) Days of a written demand by the United States and/or PADEP.

72. Either the United States or PADEP may, in the unreviewable exercise of their respective discretion, reduce or waive stipulated penalties otherwise due them under this Consent Decree.

73. Stipulated penalties shall continue to accrue during any Dispute Resolution, but need not be paid until the following:

a. If the dispute is resolved by agreement or MarkWest does not seek judicial review of EPA's written position provided pursuant to Paragraph 87, MarkWest shall pay the stipulated penalties determined to be owing, together with interest, to the United States and PADEP within thirty (30) Days of the effective date of the agreement or the expiration of Paragraph 88's period for seeking judicial resolution of a dispute.

b. If the dispute is appealed to the Court and the United States and/or PADEP prevail, MarkWest shall pay all penalties determined by the Court to be owing, together with interest, within sixty (60) Days of receiving the Court's decision or order, except if the District Court's decision is appealed, and then as provided in Subparagraph c., below.

c. If any Party appeals the District Court's decision, MarkWest shall pay all penalties determined to be owing by the final decision of the appellate court, together with interest, within thirty (30) Days of receiving the final appellate court decision.

74. If MarkWest fails to pay stipulated penalties according to the terms of this Consent Decree, MarkWest shall be liable for interest on such penalties, as provided in 28 U.S.C. § 1961, accruing from the date payment became due until full payment is made.

75. MarkWest shall pay stipulated penalties owing to the United States in accordance with the procedures for payment of civil penalties specified in Paragraph 25. The transmittal letter required by Paragraph 25 shall specify that the payment is for stipulated penalties.

76. MarkWest shall pay stipulated penalties due under this Consent Decree to PADEP in accordance with the procedures for payment of civil penalties specified in Paragraph 26.

77. The payment of stipulated penalties and interest, if any, shall not alter in any way MarkWest's obligation to complete the performance of the requirements of this Consent Decree.

78. Subject to the provisions of Section XVI (Effect of Settlement/Reservation of Rights), the stipulated penalties provided for in this Consent Decree shall be in addition to any other rights, remedies, or sanctions available to the United States and PADEP for MarkWest's violations of this Consent Decree or applicable law. Where a violation of this Decree is also a violation of relevant statutory or regulatory requirements, MarkWest shall be allowed a credit for any stipulated penalties paid against any statutory penalties imposed for such violation under the applicable federal or state requirement.

XIII. FORCE MAJEURE

79. "Force majeure," for purposes of this Consent Decree, is defined as any event arising from a cause or causes beyond the control of MarkWest, of any entity controlled by MarkWest, or of MarkWest's contractors, that delays or prevents the performance of any obligation under this Decree despite MarkWest's best efforts to fulfill the obligation. The requirement that MarkWest exercise "best efforts to fulfill the obligation" includes using reasonable efforts to anticipate any potential force majeure event and best efforts to address the effects of any such event (a) as it is occurring and (b) after it has occurred in order to minimize

delay and any adverse effects of the delay to the greatest extent possible. Force majeure does not include MarkWest's financial inability to perform any obligation under this Decree.

80. If any event occurs or has occurred that may delay the performance of any obligation under this Consent Decree, for which MarkWest intends or may intend to assert a claim of force majeure, MarkWest shall provide notice orally or by electronic transmission within three (3) Days of when MarkWest first knew that the event might cause a delay to the addresses provided in Section XVIII of this Consent Decree (Notices). Within fifteen (15) Days of this initial notification, MarkWest shall provide in writing to EPA and, if the event involves a facility in Pennsylvania, PADEP, to the extent available: an explanation and description of the reasons for the delay; the anticipated duration of the delay; all actions taken or to be taken to prevent or minimize the delay; a schedule for implementation of any measures to be taken to mitigate the delay or the effect of the delay; and MarkWest's rationale for attributing such delay to a force majeure event if it intends to assert such a claim. MarkWest shall include with any notice all available documentation necessary to support the claim that the delay was attributable to a force majeure. Any material failure to comply with the above requirements that prejudices EPA's ability to assess MarkWest's claim of force majeure shall preclude MarkWest from asserting any claim of force majeure for that event for the period of time of such failure to comply.

81. If EPA agrees that the delay or anticipated delay is attributable to a force majeure, the time for performance of the obligations under this Consent Decree that are affected by the force majeure event will be extended by EPA for such time as is necessary to complete those obligations. An extension of the time for performance of the obligations affected by the force

majeure event shall not, of itself, extend the time for performance of any other obligation. EPA will notify MarkWest in writing of the length of the extension, if any, for performance of the obligations affected by the force majeure.

82. If EPA does not agree that the delay or anticipated delay has been or will be caused by a force majeure event, EPA will notify MarkWest in writing of its decision.

83. If MarkWest elects to invoke the dispute resolution procedures set forth in Section XIV (Dispute Resolution) of this Consent Decree with regard to a force majeure event, it shall do so no later than thirty (30) Days after receipt of EPA's notice. In any such proceeding, MarkWest bears the burden of demonstrating by a preponderance of the evidence that the delay or anticipated delay has been or will be caused by a force majeure, that the duration of the delay or the extension sought was or will be warranted under the circumstances, that best efforts were exercised to avoid and mitigate the effects of the delay, and that MarkWest complied with the requirements of Paragraphs 79 and 80. If MarkWest carries this burden, the delay at issue shall be deemed not to be a violation of the affected obligation of this Decree.

XIV. DISPUTE RESOLUTION

84. Unless otherwise expressly provided for in this Consent Decree, the dispute resolution procedures of this Section shall be the exclusive mechanism to resolve any dispute arising under or with respect to this Consent Decree.

85. Informal Dispute Resolution. Any dispute subject to dispute resolution under this Consent Decree shall first be the subject of informal negotiations. The dispute shall be considered to have arisen when MarkWest disputes a decision of the United States and sends the United States and PADEP a written Notice of Dispute. Such Notice of Dispute shall state clearly

the matter in dispute. The period of informal negotiations shall not exceed ninety (90) Days from the date the dispute arises, unless that period is modified by written agreement. If the Parties cannot resolve a dispute by informal negotiations, then the position advanced by the United States, after consultation with PADEP, shall be considered binding unless, within ninety (90) Days after the conclusion of the informal negotiation period, MarkWest invokes formal dispute resolution procedures as set forth below.

86. Formal Dispute Resolution. MarkWest shall invoke formal dispute resolution procedures, within the time period provided in the preceding Paragraph, by serving on the United States and PADEP a written Statement of Position regarding the matter in dispute. The MarkWest Statement of Position shall include, but need not be limited to, any factual data, analysis, or opinion supporting MarkWest's position and any supporting documentation relied upon by MarkWest.

87. The United States, after consultation with PADEP, shall serve its Statement of Position within forty-five (45) Days of receipt of MarkWest's Statement of Position. The United States' Statement of Position shall include, but need not be limited to, any factual data, analysis, or opinion supporting that position and any supporting documentation relied upon by the United States. The United States' Statement of Position shall be binding on MarkWest unless MarkWest files a motion for judicial review of the dispute in accordance with the following Paragraph.

88. MarkWest may seek judicial review of the dispute by filing with the Court and serving on the United States, in accordance with Section XVIII of this Consent Decree (Notices), a motion requesting judicial resolution of the dispute. The motion must be filed within thirty (30) Days of receipt of the United States' Statement of Position pursuant to the preceding Paragraph.

The motion shall contain a written statement of MarkWest's position on the matter in dispute, including any supporting factual data, analysis, opinion, or documentation, and shall set forth the relief requested and any schedule within which the dispute must be resolved for orderly implementation of the Consent Decree.

89. The United States shall respond to MarkWest's motion within the time period allowed by the Local Rules of this Court for responses to dispositive motions. MarkWest may file a reply memorandum to the extent permitted by the Local Rules.

90. Standard of Review.

a. Disputes Concerning Matters Accorded Record Review. Except as otherwise provided in this Consent Decree, in any dispute brought under Paragraph 85 and 86 above pertaining to a matter that involves EPA's exercise of discretion under this Consent Decree, MarkWest shall have the burden of proof based on the administrative record (including the Parties' Statements of Position) and the applicable standard of review as set forth in the Administrative Procedure Act, 5 U.S.C. § 500 *et seq*.

b. Other Disputes. Except as otherwise provided in this Consent Decree, in any other dispute brought under Paragraphs 85 and 86 above, MarkWest shall bear the burden of demonstrating that its position complies with this Consent Decree.

91. The invocation of dispute resolution procedures under this Section shall not, by itself, extend, postpone, or affect in any way any obligation of MarkWest under this Consent Decree, unless and until final resolution of the dispute so provides. Stipulated penalties with respect to the disputed matter shall continue to accrue from the first day of noncompliance, but payment shall be stayed pending resolution of the dispute as provided in Paragraph 73 above. If

MarkWest does not prevail on the disputed issue, subject to the Court's order, stipulated penalties shall be assessed and paid as provided in Section XII (Stipulated Penalties).

XV. INFORMATION COLLECTION AND RETENTION

92. The United States and PADEP, and their respective representatives, including attorneys, contractors, and consultants, shall have the right of entry into any facility identified on Appendices 1-6, at all reasonable times, upon presentation of proper credentials, to:

a. monitor the progress of activities required under this Decree;

b. verify any data or information submitted to the United States or PADEP in accordance with the terms of this Decree;

c. obtain samples and, upon request, splits of any samples taken by MarkWest or its representatives, contractors, or consultants related to MarkWest's performance of its obligations under this Decree;

d. obtain documentary evidence, including photographs and similar data; and

e. assess MarkWest's compliance with this Decree.

93. Upon request, MarkWest shall provide EPA, PADEP, or their authorized representatives, splits or duplicates of any samples taken by MarkWest in performing its obligations under this Decree. EPA or PADEP shall provide MarkWest splits of any samples taken by EPA or PADEP or their authorized representatives.

94. Until two (2) years after the termination of this Consent Decree, MarkWest shall retain, and shall instruct its contractors and agents performing work under this Consent Decree to preserve all non-identical copies of all documents, records, or other information (including documents, records, or other information in electronic form) in its or its contractors' or agents'

possession or control, or that come into its or its contractors' or agents' possession or control, and that relate in any manner to MarkWest's performance of its obligations under this Decree. This information-retention requirement shall apply regardless of any contrary corporate or institutional policies or procedures. At any time during this information-retention period, upon request by the United States or PADEP, MarkWest shall provide copies of any non-privileged documents, records, or other non-privileged information required to be maintained under this Paragraph to the United States or PADEP.

95. At the conclusion of the information-retention period provided in the preceding Paragraph, MarkWest shall notify the United States and PADEP at least sixty (60) days prior to the destruction of any records subject to the requirements of this Section and, upon request by the United States or PADEP, MarkWest shall deliver any such documents, records, or other information to EPA and PADEP.

96. MarkWest may assert that certain documents, records, or other information are privileged under the attorney-client privilege or any other privilege recognized by federal law. If MarkWest asserts such a privilege, it shall provide the following: (1) the title of the document, record, or information; (2) the date of the document, record, or information; (3) the name and title of each author of the document, record, or information; (4) the name and title of each addressee and recipient; (5) a description of the subject of the document, record, or information; and (6) the privilege asserted by MarkWest. However, no documents, records, or other information created or generated in order to comply with the requirements of this Consent Decree shall be withheld on grounds of privilege.

97. MarkWest may also assert that information required to be provided under this Section is protected as Confidential Business Information ("CBI") under 40 C.F.R. Part 2 or applicable state law. As to any information that MarkWest seeks to protect as CBI, MarkWest shall follow the procedures set forth in 40 C.F.R. Part 2 or applicable state law.

98. This Consent Decree in no way limits or affects any right of entry and inspection, or any right to obtain information, held by the United States or PADEP pursuant to applicable federal or state laws, regulations, or permits, nor does it limit or affect any duty or obligation of MarkWest to maintain documents, records, or other information imposed by applicable federal or state laws, regulations, or permits.

XVI. EFFECT OF SETTLEMENT/RESERVATION OF RIGHTS

99. This Consent Decree resolves the civil and administrative claims that the United States may have against MarkWest for the following violations of the Clean Air Act through the date of lodging:

a. With respect to the Pennsylvania Compressor Stations identified on Appendix 1, the Pennsylvania Stand-Alone Facilities (with the exception of Route 18) identified in Appendix 3, and the Drugmand, Stewart Route 50, and Graham Header Stations identified in Paragraph 17, failure to comply with (i) the PSD provisions, 42 U.S.C. §§ 7490-7492; (ii) the NSR provisions, 42 U.S.C. §§ 7501-7515; (iii) the Title V provisions, 42 U.S.C. §§ 7661-7661f; and (iv) provisions of the Pennsylvania SIP implementing Pennsylvania's PSD permitting program, NSR permitting program, Title V permitting program, and Plan Approval and Operating Permit programs;

b. With respect to the Pennsylvania Stand-Alone Facilities identified in Appendix 6 and the Route 18 Stand-Alone Facility identified in Appendix 3, failure to comply with the provisions of the Pennsylvania SIP implementing Pennsylvania's Plan Approval and Operating Permit programs;

c. With respect to the Ohio Compressor Stations identified on Appendix 4, failure to comply with (i) the PSD provisions with respect to VOC, 42 U.S.C. §§ 7490-7492; (ii) the Title V provisions, 42 U.S.C. §§ 7661-7661f; and (iii) the provisions of the Ohio SIP implementing Ohio's Title V operating permit program and Ohio's permit to install and operate program;

d. With respect to the Ohio Stand-Alone Facilities identified in Appendix 5, failure to comply with the provisions of the Ohio SIP implementing Ohio's minor source permit to install and operate program; and

e. With respect to the Ohio Stand-Alone Facilities identified in Appendix 6, failure to comply with the provisions of the Ohio SIP implementing Ohio's minor source permit to install and operate program, and failure to comply with the recordkeeping provisions of the Ohio SIP.

100. This Consent Decree resolves all of PADEP's civil claims against MarkWest pursuant to Sections 9.1 and 13.6(a) of the Air Pollution Control Act ("APCA"), 35 P.S. §§ 4009.1 and 4013.6(a), through the date of lodging for the following violations of the APCA and its implementing regulations:

a. With respect to the Pennsylvania Compressor Stations identified in Appendix 1, the Pennsylvania Stand-Alone Facilities (with the exception of Route 18) identified

in Appendix 3, and the Drugmand, Stewart Route 50, and Graham Header Stations identified in Paragraph 17, failure to comply with (i) the Plan Approval and Operating Permit programs; (ii) the PSD permitting program; (iii) the NSR permitting program; and (iv) the Title V permitting program.

b. With respect to the Pennsylvania Stand-Alone Facilities identified on Appendix 6 and the Route 18 Stand-Alone Facility identified in Appendix 3, failure to comply with the Plan Approval and Operating Permit programs.

101. The United States and PADEP reserve all legal and equitable remedies available to enforce the provisions of this Consent Decree, except as expressly stated in Paragraphs 78, 99 and 100. This Consent Decree does not limit the rights of the United States or PADEP to obtain penalties or injunctive relief under the Act or implementing regulations, or under other federal or state laws, regulations, or permit conditions, except as expressly specified in Paragraphs 99 and 100. The United States and PADEP further retain all legal and equitable remedies to address any imminent and substantial endangerment to the public health or welfare or the environment arising at, or posed by, any MarkWest facility, whether related to the violations addressed in this Decree or otherwise.

102. In any subsequent administrative or judicial proceeding initiated by the United States or PADEP for injunctive relief, civil penalties, or other appropriate relief relating to the facilities subject to this Consent Decree or MarkWest's alleged violations, MarkWest shall not assert, and may not maintain, any defense or claim based upon the principles of waiver, res judicata, collateral estoppel, issue preclusion, claim preclusion, claim-splitting, or other defenses based upon any contention that the claims raised by the United States or PADEP in the

subsequent proceeding were or should have been brought in the instant case, except with respect to claims that have been specifically resolved pursuant to Paragraphs 99 and 100.

103. This Consent Decree is not a permit, or a modification of any permit, under any federal, state, or local laws or regulations. MarkWest is responsible for achieving and maintaining complete compliance with all applicable federal, state, and local laws, regulations, and permits; and MarkWest's compliance with this Decree shall be no defense to any action commenced pursuant to any such laws, regulations, or permits, except as set forth herein. The United States and PADEP do not, by their consent to the entry of this Decree, warrant or aver in any manner that MarkWest's compliance with any aspect of this Decree will result in compliance with provisions of the Act, the APCA, or with any other provisions of federal, state, or local laws, regulations, or permits.

104. This Consent Decree does not limit or affect the rights of MarkWest, of the United States, or of PADEP against any third parties not party to this Decree, nor does it limit the rights of third parties not party to this Decree against MarkWest, except as otherwise provided by law.

105. This Consent Decree shall not be construed to create rights in, or grant any cause of action to, any third party not party to this Decree.

106. MarkWest expressly denies and does not admit any liability to the United States or PADEP arising out of the conduct, transactions or occurrences alleged in the Complaint. Nothing in this Consent Decree shall be construed as an admission of MarkWest's liability, nor shall MarkWest's performance of any obligation under this Decree be considered any admission

of liability. This Consent Decree shall not be admissible against MarkWest in any administrative or judicial proceeding, except in a proceeding initiated by the Parties to enforce this Decree.

XVII. COSTS

107. The Parties shall bear their own costs of this action, including attorneys' fees, except that the United States and PADEP shall be entitled to collect the costs (including attorneys' fees) incurred in any action necessary to collect any portion of the civil penalty or any stipulated penalties due, but not paid, by MarkWest.

XVIII. NOTICES

108. Unless otherwise specified herein, whenever notifications, submissions, statements of position, or communications are required by this Consent Decree (referred in this Paragraph as a "notice" or "notices"), they shall be made electronically as described below, unless such notices are unable to be uploaded to the CDX electronic system (in the case of EPA) or transmitted by email (in the case of any other party). For all notices to EPA, MarkWest shall register for the CDX electronic system and upload such notices at https://cdx.epa.gov/epa_home.asp. Any notice that cannot be uploaded or electronically transmitted via email shall be provided in writing to the addresses below:

109. Any Party may, by written notice to the other Parties, change its designated notice recipient or notice address provided above.

110. Notices submitted pursuant to this Section shall be deemed submitted upon electronic transmission or mailing, unless otherwise provided in this Consent Decree or by mutual agreement of the Parties in writing.

XIX. EFFECTIVE DATE

111. The Effective Date of this Consent Decree is the date upon which this Consent Decree is entered by the Court or a motion to enter the Decree is granted, whichever is first, as recorded by the Court's docket.

XX. RETENTION OF JURISDICTION

112. The Court shall retain jurisdiction over this case, until termination of this Consent Decree pursuant to Section XXII (Termination), for the purpose of (a) resolving disputes arising under this Decree pursuant to Section XIV (Dispute Resolution), (b) entering orders modifying this Decree pursuant to Section XXI (Modification), or (c) effectuating or enforcing compliance with the terms of this Decree.

XXI. MODIFICATION

113. The terms of this Decree, including any attached appendices, may be modified only by a subsequent written agreement signed by all the Parties. Where the modification constitutes a material change to this Decree, it shall be effective only upon approval by the Court.

114. Any disputes concerning modification of this Consent Decree shall be resolved pursuant to Section XIV (Dispute Resolution). The Party seeking the modification bears the burden of demonstrating that it is entitled to the requested modification in accordance with Federal Rule of Civil Procedure 60(b).

XXII. TERMINATION

115. After MarkWest has fulfilled its obligations to (a) pay the civil penalty in Paragraph 24, (b) implement all injunctive relief, (c) obtain permits pursuant to Section VIII (Permits); (d) implement the Third Party Verification program and submit a satisfactory Third-Party Audit Report; (e) complete all SEPs, (f) complete the Commonwealth-only Community Environmental Project, and (g) pay any stipulated penalties not waived or reduced by the United States or PADEP under Section XII (Stipulated Penalties) pursuant to Paragraph 72, MarkWest

may send to the United States and PADEP a Request for Termination, which shall be certified in accordance with Paragraph 63, stating that MarkWest has satisfied those requirements, together with all reasonably necessary supporting documentation.

116. Following receipt by the United States and PADEP of MarkWest's Request for Termination, the Parties shall confer informally concerning the Request and any disagreement that the Parties may have as to whether MarkWest has satisfactorily complied with the requirements for termination of this Consent Decree. If the United States, after consultation with PADEP, agrees that the Decree may be terminated, the Parties shall submit for the Court's approval a joint stipulation terminating the Decree.

117. If the United States, after consultation with PADEP, does not agree that the Decree may be terminated, MarkWest may invoke Dispute Resolution under Section XIV of this Decree (Dispute Resolution). However, MarkWest shall not seek Dispute Resolution of any dispute regarding termination until sixty (60) Days after service of its Request for Termination.

XXIII. PUBLIC PARTICIPATION

118. This Consent Decree will be lodged with the Court for a period of not less than thirty (30) Days for public notice and comment in accordance with 28 C.F.R. § 50.7. The United States reserves the right to withdraw or withhold its consent if the comments regarding the Consent Decree disclose facts or considerations indicating that the Decree is inappropriate, improper, or inadequate. MarkWest consents to entry of this Decree without modification without further notice and agrees not to withdraw from or oppose entry of this Decree by the Court or to challenge any provision of the Decree, unless the United States has notified MarkWest in writing that it no longer supports entry of the Decree or has modified the Decree.

XXIV. SIGNATORIES/SERVICE

119. Each undersigned representative of MarkWest, PADEP, and the Assistant Attorney General for the Environment and Natural Resources Division of the Department of Justice certifies that he or she is fully authorized to enter into the terms and conditions of this Consent Decree and to execute and legally bind the Party he or she represents to this document.

120. This Consent Decree may be signed in counterparts, and its validity shall not be challenged on that basis.

121. MarkWest agrees to accept service of process by mail with respect to all matters arising under or relating to this Consent Decree. MarkWest agrees to accept service in that manner and to waive the formal service requirements set forth in Rule 4 of the Federal Rules of Civil Procedure and any applicable Local Rules of this Court including, but not limited to, service of a summons. MarkWest need not file an answer to the Complaint in this action unless or until the Court expressly declines to enter this Decree.

XXV. INTEGRATION

122. This Consent Decree and its Appendices constitute the final, complete, and exclusive agreement and understanding among the Parties with respect to the settlement embodied in the Decree. There are no representations, agreements, or understandings relating to the settlement other than those expressly contained in this Consent Decree.

XXVI. FINAL JUDGMENT

123. Upon approval and entry of this Consent Decree by the Court, this Decree shall constitute a final judgment of the Court as to the United States, PADEP, and MarkWest under Fed. R. Civ. P. 54 and 58.

XXVII. 26 U.S.C. SECTION 162(f)(2)(A)(ii) IDENTIFICATION

124. For purposes of the identification requirement of Section 162(f)(2)(A)(ii) of the Internal Revenue Code, 26 U.S.C. § 162(f)(2)(A)(ii), performance of Section II (Applicability), Paragraph 8, Section IV (Injunctive Relief), Paragraphs 11 – 23, Section VIII (Permits), Paragraphs 43 - 46, Section X (Third Party Verification), Paragraphs 49 – 54, Section XI (Recordkeeping and Reporting), Paragraphs 58(a)-(c) and (e) – (l), 59 – 60, and 62 – 63, and Section XIV (Information Collection and Retention), Paragraphs 92 - 95, is restitution or required to come into compliance with law.

XXVIII. APPENDICES

125. The following appendices are attached to and part of this Consent Decree:

"Appendix 1" is a list of MarkWest compressor stations in Pennsylvania subject to Paragraph 12;

"Appendix 2" is a list of MarkWest compressor stations in Pennsylvania subject to Paragraph 13;

"Appendix 3" is a list of MarkWest Stand-Alone Facilities in Pennsylvania subject to Paragraph 14;

"Appendix 4" is a list of MarkWest Compressor Stations, and specific launchers and receivers at each of those Compressor Stations, in Ohio subject to Paragraph 18;

"Appendix 5" is a list of MarkWest Stand-Alone Facilities, and specific launchers and receivers at each of those Stand-Alone Facilities, in Ohio subject to Paragraph 19;

"Appendix 6" is a list of MarkWest Stand-Alone Facilities in Pennsylvania and in Ohio subject, as applicable, to Paragraphs 21 and 23;

"Appendix 7" is the Humphreys Ambient Air Monitoring SEP for the Humphreys Compressor Station in Ohio; and

"Appendix 8" is the Harmon Creek Ambient Air Monitoring SEP for the Harmon Creek Gas Processing Plant in Pennsylvania.

Dated and entered this _____ day of _____, 2018.

a. 513 to McGee Receiver	No	Yes	Yes	
b. McGee to Barnsville West Launcher	No	No	Yes	
c. Tri-County to McGee Receiver	No	Yes	Yes	
d. Brothers Receiver	No	Yes	No	
9. Neff Station				39.994326, -81.385291
a. Neff Launcher	No	No	Yes	
b. Shugert Daddy Receiver	No	Yes	No	
c. Onega Receiver	No	Yes	No	
d. Detweiler Receiver	No	Yes	No	
10. Oxford Siefert Station				40.028938, -81.305076
a. Flesher Launcher	No	No	Yes	
b. Karen Receiver	No	Yes	No	
11. Shannon				40.015606, -81.191986
a. Shannon to Tri-County Receiver	Yes	Yes	Yes	
b. Shannon to 70T Launcher	Yes	No	Yes	
Barnesville West 12" Receiver	Yes	Yes	Yes	
12. Scott Hill Station				40.213707, -81.199295
a. Scott Hill to Harrison West Launcher	No	No	No	

Stand-Alone Facility	¶ 19.a.-b. Apply? (Install and Use Jumper Line)	¶ 19.c. Applies? (Install Pig Ramp)	¶ 19.d. Applies? (Use of Mobile Flare as Necessary)	Coordinates
b. BK Stevens Receiver	No	Yes	No	
c. Scott Hill to Yoder Launcher	No	No	No	
13. Wheatley Station				39.910131, -81.201674
a. McCort to Wheatley Receiver	No	Yes	Yes	
b. Wheatley to Humphreys Launcher	No	No	Yes	

Appendix 6

Pennsylvania and Ohio Stand-Alone Facilities Subject to Paragraph 21

Pennsylvania

	Stand-Alone Facility	Coordinates	
1.	Airport L/R Site	40.37395927760,	-80.30305865130
2.	Amwell Meter Site	40.14614613440,	-80.20302966240
3.	Best Site L/R Site	40.23147156770,	-80.33893228910
4.	Brenckle Header	40.84400668670,	-80.01438657980
5.	Bowen Rd L/R Site	40.35620228600,	-80.29091780790
6.	Drugmand L/R Site	40.32121915270,	-80.30277507650
7.	Meter Site Greco	40.09104915880,	-80.20974335020

APPENDIX 7

HUMPHREYS AMBIENT AIR MONITORING SEP FOR THE HUMPHREYS COMPRESSOR STATION IN OHIO

A. General Requirements

1. Pursuant to Section VI of the Consent Decree, and in accordance with the specifications and provisions in this Appendix, MarkWest will install, operate, and maintain an ambient air monitoring system ("AAMS") at the Humphreys Compressor Station and provide data as required by this Appendix and the Consent Decree.

2. Within 120 Days of the Effective Date, MarkWest shall submit to EPA for review and approval a plan (the "Humphreys Monitoring Plan") that shall include, at a minimum:

   a. An identification of the location of the meteorological station required by this Appendix and how this location meets this Appendix's requirements.

   b. Compliance with the monitoring requirements in 40 C.F.R. Part 58, Appendix E, and in accordance with the NATTS guidance document available at https://www3.epa.gov/ttnamti1/files/ambient/airtox/NATTS%20TAD%20Revision%203_FINAL%20October%202016.pdf

   c. A Quality Assurance Project Plan ("QAPP") that describes the Quality Assurance/Quality Control procedures, specifications, and other technical activities to be implemented to ensure: (i) that the results of this SEP meet project specifications; and (ii) the accuracy, validity, representativeness, and usability of the data obtained by all monitoring equipment, including the stationary equipment and systems identified in Section B of this Appendix (Stationary Equipment Requirements). The QAPP shall follow the outline and guidance in the EPA publication entitled "QA Handbook for Air Pollution Measurement Systems, Volume II, Ambient Air Quality Monitoring Program," EPA-454/B-13-003, May 2013.

   d. A description of the implementation of Data Availability (Paragraph 17) requirements of this Appendix.

   e. A schedule, with a start date contingent upon approval of the Humphreys Monitoring Plan, for expeditiously purchasing, installing, upgrading, and commencing operation of specifically-identified systems and equipment that met all requirements of this Appendix.

3. Upon EPA approval of the Humphreys Monitoring Plan, in compliance with the

schedule in the approved Humphreys Monitoring Plan, MarkWest shall purchase or lease all equipment specified in the Humphreys Monitoring Plan, shall complete the installation of all such equipment, and shall upgrade all systems or stations as set forth in the approved Humphreys Monitoring Plan.

4. MarkWest shall promptly correct deficient implementation of its Humphreys Monitoring Plan. Any disputes related to the Humphreys Monitoring Plan or this Appendix shall be resolved pursuant to the procedures set forth in Section XIII (Dispute Resolution) of the Consent Decree.

5. MarkWest may seek EPA approval to modify the Humphreys Monitoring Plan at any time during the effective period of this Consent Decree.

B. Stationary Equipment Requirements

6. Overview. The AAMS shall include:

   a. A meteorological station to monitor meteorological parameters (Paragraph 7);

   b. Upwind and downwind stations to monitor air pollutants (Paragraphs 8-12); and

   c. A Data Acquisition System for all upwind, downwind, and meteorological stations (Paragraph 13).

7. Instruments for Measuring and Recording Wind Speed, Wind Direction, Ambient Temperature, and Barometric Pressure. Specific meteorological parameters will be continuously monitored to obtain data representative of the meteorological conditions at each facility. The data set produced shall be adequate to correlate hourly block average conditions and thirty-minute rolling average conditions (collected on a five-minute basis) with pollutant measurements and transport.

   a. Continuously measured meteorological parameters shall include hourly block average and thirty-minute rolling average horizontal wind speed and wind direction, the standard deviation of horizontal wind direction (sigma theta), air temperature, and barometric pressure. Wind speed and direction shall be measured at a height of approximately 10 meters. Temperature and barometric pressure shall be measured at a height of 2 to 3 meters. The sensors shall, to the extent practicable, be positioned away from, or above, obstructions such as buildings, trees, and process units that may interfere with wind direction measurements.

   b. Wind direction and sigma theta measurement data shall be auto-corrected to True North, rounded to the nearest whole degree. Wind speed data shall be reported in meters per second, rounded to the nearest tenth.

c. Air temperature data shall be reported in degrees Fahrenheit or Celsius, rounded to the nearest tenth of a degree.

d. Barometric pressure data may be in any unit of pressure.

8. Air Pollutant Monitoring Stations: Equipment and Pollutant Measurement Capability. MarkWest shall install continuous auto-gas chromatographs for VOCs and separate continuous instruments for reduced sulfur compounds at each upwind and downwind monitoring station so that each station has each of the following:

a. Instruments capable of measuring and recording the concentrations of the following compounds in the air at a minimum detection level of 1.0 part per billion by volume (ppbV): propane, butane, pentane, hexane, benzene, toluene ethylbenzene, xylene and all of its isomers, and total VOCs. The data will be recorded as hourly block averages.

b. Instruments capable of measuring and recording the concentrations of reduced sulfur compounds at a minimum detection level of 1.0 ppbV. The data will be recorded as hourly block averages.

c. The continuous measurement of the compounds listed in Subparagraph 8.a. above, shall be accomplished using an auto-Gas Chromatograph ("GC"). The automated GCs shall be operated and maintained in accordance with the manufacturer's recommendations and shall have a measurement range of 1.0 to 500 ppbV for all gases.

d. The continuous measurement of reduced sulfur compounds, listed in Subparagraph 8.b. above, shall be accomplished using Teledyne API T102 Total Reduced Sulfur (TRS) analyzers. The instruments shall be operated and maintained in accordance with the manufacturer's recommendations, shall be operated in high sensitivity mode, and shall have a measurement range of 1.0 to 50 ppbV.

9. Air Pollutant Monitoring Stations: Temperature-Controlled Shelter: Each air pollutant monitoring station shall be operated inside a temperature-controlled equipment shelter.

a. The temperature within each shelter shall be continuously monitored and recorded using a calibrated resistance temperature detector ("RTD") and microprocessor or PC-based data acquisition system.

b. The climate control system for each monitoring shelter will be capable of maintaining a stable temperature within the range of 20ºC to 30ºC.

c. The monitoring shelters shall measure approximately 8 feet wide by 12 feet

long by 8 feet high.

d. Each shelter shall be anchored to the ground and be electrically grounded for safety.

e. The shelter walls and roofs will have a minimum insulation rating of R11.

f. Each shelter will be equipped with electrical service panels, interior electrical distribution circuits, lighting, workbench and sufficient space for housing, operating, and maintaining the monitoring instruments. All electrical wiring and appurtenances will conform to the National Electric Code (NEC).

10. Air Pollutant Monitoring Station Locations. The air pollutant monitoring stations shall be located at the following coordinates and identified as follows:

a. Humphreys Facility Upwind: Latitude: Longitude

b. Humphreys Facility Downwind: Latitude: Longitude

11. Air Pollutant Monitoring Systems Sampler Inlet Requirements. The sampler inlets for each monitoring station shall comply with the following requirements:

a. The sampler inlets should be 2 to 5 meters above ground and have unrestricted airflow 270 degrees around the sample inlet or 180 degrees if the sampler is on the side of a building.

b. The sampler inlets should be >20 meters from the dripline of any tree(s).

c. The sampler inlets should be >1 meter away from supporting structures and walls.

d. The distance from a sampler probe to an obstacle, such as a building, should be at least twice the height the obstacle protrudes above the sampler, probe, or monitoring path.

e. The sampler inlets should be away from minor sources, to avoid undue influences from minor sources. The separation distance is dependent on the height of the minor source's emission point, the type of fuel or waste burned, and the quality of the fuel.

12. Air Pollutant Monitoring Stations – Prohibition on Moving. MarkWest shall not move the pollutant monitoring stations to a new location without prior written approval by EPA. Movement of the pollutant monitoring station components for maintenance shall not be restricted by this Paragraph.

13. Data Acquisition System (DAS). A DAS will be used to log all numerical data generated by the air pollutant analyzers and weather instruments using a common time-stamp. The DAS also will be programmed to correct pollutant concentration data to standard temperature and pressure, and to automatically correlate pollutant data with wind direction. The DAS outputs shall be in a file format that can be used in common spreadsheet programs.

14. Nothing in this Appendix shall preclude the use of any other, additional fence line monitoring equipment and/or of monitoring other, additional pollutants at the fence line.

C. Operation of AAMS

15. MarkWest shall comply with all terms of this Appendix and the Humphreys Monitoring Plan, including but not limited to operating and maintaining the monitors, equipment, and systems described herein, for a period of no less than a total of 720 days.

16. Quality Assurance/Quality Control (QA/QC). MarkWest shall ensure that all data collected by the AAMS are subjected to the approved QA/QC procedures on a quarterly basis. The QA/QC procedures for a given quarter's data shall be completed by no later than the end of the quarter following the quarter within which the data were collected.

17. Data Submission. MarkWest shall provide Relevant Data on a quarterly basis, within 45 days of the end of each calendar quarter. For purposes of this Paragraph, "Relevant Data" shall mean the hourly block averages of propane, butane, pentane, hexane, benzene, toluene ethylbenzene, xylene and all of its isomers, total VOCs, and reduced sulfur compounds, wind speed, and wind direction that are collected during periods at all times. MarkWest shall submit the data in a manner that allows pollutant concentrations, wind speed, and wind direction to be viewed concurrently and indicate that these data meet the QA/QC procedures in Subparagraph C.16 of this Appendix. All numerical data shall be presented in a format that can be used in common spreadsheet programs. MarkWest shall maintain the Relevant Data collected through the AAMS as required by the Consent Decree.

18. Annual Reports. MarkWest shall prepare and submit at least two annual reports. These reports will detail the operation of the VOC, RSC, and meteorological equipment as well as any maintenance and service work performed at each monitoring location. These reports will contain data summaries, a summary of any problems encountered in the monitoring project and the status of any current problems and corrective actions performed, a summary of any meetings or correspondence addressing the monitoring program, a synopsis of percent recovery including brief explanations of missing data, overall data recovery, quality control, and all quality assurance documentation. Each report will include a fully quality□ assured hourly data file in Excel format and an Adobe Acrobat PDF copy of the

formalized report. Each report will be provided within 45 days of the end of each year-long monitoring period.

APPENDIX 8

AMBIENT AIR MONITORING SEP FOR THE HARMON CREEK GAS PROCESSING PLANT IN THE VICINITY OF SMITH TOWNSHIP, WASHINGTON COUNTY, PENNSYLVANIA

A. General Requirements

1. Pursuant to Section VI of the Consent Decree, and in accordance with the specifications and provisions in this Appendix, MarkWest will install, operate, and maintain an ambient air monitoring system in the vicinity of the proposed Harmon Creek Gas Processing Plant ("HC") in Smith Township, Washington County, Pennsylvania and provide data as required by this Appendix and the Consent Decree (hereinafter the "Harmon Creek Monitoring System").

2. Within 120 Days of the Effective Date, MarkWest shall submit to EPA and PADEP for review and, following consultation with PADEP, approval by EPA a plan (the "Harmon Creek Monitoring Plan") that shall include, at a minimum:

   a. The proposed location of the meteorological station required by this Appendix, a discussion of how the location meets the siting criteria discussed below, the specifications of the station, a discussion of how these specifications meet the data measurement criteria discussed below, and the proposed date for installation and operation. Before submitting the complete Harmon Creek Monitoring Plan, MarkWest may submit a separate plan for installing the meteorological station in order to speed installation and operation of the station.

   b. A description of the three VOC monitors to be installed, how this monitoring equipment meets the criteria discussed below, and a schedule for proposing the specific locations of this monitoring equipment.

   c. Compliance with the monitoring requirements in 40 C.F.R. Part 58, Appendix E, and in accordance with the NATTS guidance document available at https://www3.epa.gov/ttnamti1/files/ambient/airtox/NATTS%20TAD%20Revision%203_FINAL%20October%202016.pdf

   d. A Quality Assurance Project Plan ("QAPP") that describes the Quality Assurance/Quality Control procedures, specifications, and other technical activities to be implemented to ensure: (i) that the results of this SEP meet project specifications; and (ii) the accuracy, validity, representativeness, and usability of the data obtained by all monitoring equipment, including the stationary equipment and systems identified in Section B of this Appendix (Stationary Equipment Requirements). The QAPP shall follow the outline and guidance in the EPA publication entitled "QA Handbook for Air

Pollution Measurement Systems, Volume II, Ambient Air Quality Monitoring Program," EPA-454/B-13-003, May 2013.

e. A description of the implementation of Data Availability (Paragraph 17) requirements of this Appendix.

f. A schedule, with a start date contingent upon approval of the Harmon Creek Monitoring Plan, for (i) expeditiously purchasing, installing, upgrading, and commencing operation of specifically-identified systems and equipment that meet all requirements of this Appendix and (ii) completing the monitoring and submitting a final report to EPA and PADEP.

3. Upon EPA approval, after consultation with PADEP, of the Harmon Creek Monitoring Plan, MarkWest shall purchase all equipment specified in the plan, shall complete the installation of all such equipment, and shall upgrade all systems or stations as set forth in the schedule in the approved plan.

4. MarkWest shall promptly correct deficient implementation of its Harmon Creek Monitoring Plan. Any disputes related to the plan or this Appendix shall be resolved pursuant to the procedures set forth in Section XIII (Dispute Resolution) of the Consent Decree.

5. MarkWest may seek EPA approval to modify the Harmon Creek Monitoring Plan at any time during the effective period of this Consent Decree. EPA will consult with PADEP on any such request.

B. Stationary Equipment Requirements

6. Overview. The Harmon Creek Monitoring System shall include:

a. A meteorological station to monitor meteorological parameters (Paragraph 7);

b. Three air pollutant monitoring stations: one located a short distance upwind of HC ("Upwind Station"), one located a short distance downwind of HC ("Near Downwind Station"), and one located further downwind (approximately 1 – 3 km) of HC ("Far Downwind Station") (collectively referred to as "Air Pollutant Monitoring Stations") (Paragraphs 8-12); and

c. A Data Acquisition System for all Air Pollutant Monitoring Stations and the meteorological station (Paragraph 13).

7. Instruments for Measuring and Recording Wind Speed, Wind Direction, Ambient Temperature, and Barometric Pressure. Specific meteorological parameters will be continuously monitored to obtain data representative of the meteorological conditions at HC. The data set produced shall be adequate to correlate hourly block

average conditions and thirty-minute rolling average conditions (collected on a five-minute basis) with pollutant measurements and transport.

a. Continuously measured meteorological parameters shall include hourly block average and thirty-minute rolling average horizontal wind speed and wind direction, the standard deviation of horizontal wind direction (sigma theta), air temperature, and barometric pressure. Wind speed and direction shall be measured at a height of approximately 10 meters. Temperature and barometric pressure shall be measured at a height of 2 to 3 meters. The sensors shall, to the extent practicable, be positioned away from, or above, obstructions such as buildings, trees, and process units that may interfere with wind direction measurements.

b. Wind direction and sigma theta measurement data shall be auto-corrected to True North, rounded to the nearest whole degree. Wind speed data shall be reported in meters per second, rounded to the nearest tenth.

c. Air temperature data shall be reported in degrees Fahrenheit or Celsius, rounded to the nearest tenth of a degree.

d. Barometric pressure data may be in any unit of pressure.

8. Air Pollutant Monitoring Stations: Equipment and Pollutant Measurement Capability. MarkWest shall install the following equipment at each of the Air Pollutant Monitoring Stations:

a. Instruments capable of measuring and recording the concentrations of the following compounds in the air at a minimum detection level of 1.0 part per billion by volume (ppbV): C_2 to C_6 (i.e. from ethane through 1,3-butadiene up to benzene) and up to 32 compounds from C_6 to C_{12} (hexane, dimethylbutane, diethylbenzene, naphthalene, dodecane, BTEX, and halogen compounds), and total VOCs. The VOC data will be recorded as hourly averages.

b. An auto gas chromatograph ("GC") shall be employed to accomplish the continuous measurement of the compounds listed in Subparagraph 8.a. above. The automated GC shall be operated and maintained in accordance with the manufacturer's recommendations and shall have a measurement range of 1.0 to 500 ppbV for all gases.

9. Air Pollutant Monitoring Stations: Temperature-Controlled Shelter: Each air pollutant monitoring station shall be operated inside a temperature-controlled equipment shelter.

a. The temperature within each shelter shall be continuously monitored and recorded using a calibrated resistance temperature detector ("RTD") and

microprocessor or PC-based data acquisition system.

b. The climate control system for each monitoring shelter will be capable of maintaining a stable temperature within the range of 20ºC to 30ºC.

c. The monitoring shelters shall measure approximately 8 feet wide by 8 feet long by 8 feet high.

d. Each shelter shall be anchored to the ground and be electrically grounded for safety.

e. The shelter walls and roofs will have a minimum insulation rating of R11.

f. Each shelter will be equipped with electrical service panels, interior electrical distribution circuits, lighting, workbench and sufficient space for housing, operating, and maintaining the monitoring instruments. All electrical wiring and appurtenances will conform to the National Electric Code (NEC).

10. Air Pollutant Monitoring Systems Sampler Inlet Requirements. The sampler inlets for each monitoring station shall comply with the following requirements:

a. The sampler inlets should be 2 to 5 meters above ground and have unrestricted airflow 270 degrees around the sample inlet or 180 degrees if the sampler is on the side of a building.

b. The sampler inlets should be >20 meters from the dripline of any tree(s).

c. The sampler inlets should be >1 meter away from supporting structures and walls.

d. The distance from a sampler probe to an obstacle, such as a building, should be at least twice the height the obstacle protrudes above the sampler, probe, or monitoring path.

e. The sampler inlets should be away from minor sources, to avoid undue influences from minor sources. The separation distance is dependent on the height of the minor source's emission point, the type of fuel or waste burned, and the quality of the fuel.

f. Each Air Pollutant Monitoring System shall be housed in a climate controlled monitoring shelter and shall draw air through a sampling tube that meets the criteria at https://www3.epa.gov/ttn/amtic/files/ambient/pams/newtad.pd.

11. Air Pollutant Monitoring Stations – Prohibition on Moving. MarkWest shall not

move the pollutant monitoring stations to a new location without prior written approval by EPA, following consultation with PADEP. Movement of the pollutant monitoring station components for maintenance shall not be restricted by this Paragraph.

12. Data Acquisition System ("DAS"). A DAS will be used to log all numerical data generated by the air pollutant analyzers and weather instruments using a common time-stamp. The DAS also will be programmed to correct pollutant concentration data to standard temperature and pressure, and to automatically correlate pollutant data with wind direction. The DAS outputs shall be in a file format that can be used in common spreadsheet programs.

13. Nothing in this Appendix shall preclude the use of any other, additional fence line monitoring equipment and/or of monitoring other, additional pollutants at the fence line.

C. Operation of Harmon Creek Monitoring System

14. MarkWest shall comply with all terms of this Appendix and the Harmon Creek Monitoring Plan, including but not limited to operating and maintaining the monitors, equipment, and systems described herein, for a period of no less than a total of 720 days.

15. Quality Assurance/Quality Control ("QA/QC"). MarkWest shall ensure that all data collected by the Harmon Creek Monitoring System are subjected to the approved QA/QC procedures on a quarterly basis. The QA/QC procedures for a given quarter's data shall be completed by no later than 45 days following the end of the quarter in which the data were collected.

16. Quarterly Submissions. MarkWest shall provide Relevant Data on a quarterly basis, within 45 days of the end of each calendar quarter. For purposes of this Paragraph, "Relevant Data" shall mean the quality assured hourly block averages of compounds identified in Table A, attached, and all meteorological data collected (see Paragraph 7). MarkWest shall submit the data in a manner that allows pollutant concentrations and meteorological data to be viewed concurrently and indicate that these data meet the QA/QC procedures in Paragraph 15 of this Appendix. All numerical data shall be presented in a format that can be used in common spreadsheet programs. MarkWest shall maintain and retain the Relevant Data collected through the Harmon Creek Monitoring System as required by the Consent Decree. In addition to the Relevant Data, MarkWest shall provide the following information on a quarterly basis: a summary of any problems encountered in the monitoring project and the status of any current problems and corrective actions performed, a summary of any meetings or correspondence addressing the monitoring program, a synopsis of percent recovery including brief explanations of missing data, overall data recovery, quality control, and all quality assurance documentation, as well the results of any Performance Audits performed during the

quarter.

17. Final Report. Within 90 days of the conclusion of the monitoring period, MarkWest shall prepare and submit a Final Report. The Final Report shall describe the Harmon Creek Monitoring System sampling, compile all data collected, including meteorology, chemical compounds, and QA/QC, and interpret and analyze the data collected by the Harmon Creek Monitoring System.

GENERAL PERMIT 21.1 TEMPLATE

PIGGING OPERATION

B. Facility-Wide Terms and Conditions

The following are the terms and conditions for a General PTI to be issued to a **Title V** facility

1. All the facility-wide terms and conditions are federally enforceable with the exception of those listed below which are enforceable under state law only.

   a) B.2.

2. Modeling to demonstrate compliance with the “Toxic Air Contaminant Statute”, ORC 3704.03(F)(4)(b), is not necessary if/when the maximum annual emissions for each toxic air contaminant, as defined in OAC rule 3745-114-01, from all sources in the project, is less than 1.0 ton per year (or are subject to a standard under 40 CFR Part 63). OAC Chapter 3745-31 requires permittees to apply for and obtain a new or modified PTIO prior to making a "modification" as defined by OAC rule 3745-31-01. The permittee is hereby advised that changes in the composition of the materials or use of new materials that would cause the emissions of any toxic air contaminant to increase to above 1.0 ton per year may require the permittee to apply for and obtain a new PTIO.

3. Records related to this permit may be maintained at an off-site location (e.g. regional office), provided they are made accessible when the need arises, otherwise by the next business day upon Ohio EPA request (or made viewable electronically on-site and submitted to Ohio EPA within 24 hours).

C. Emissions Unit Terms and Conditions

1. Emissions Unit: Pigging Operation: P020

Operations, Property and/or Equipment Description:

One discrete pig launcher or receiver.

a) The following emissions unit terms and conditions are federally enforceable with the exception of those listed below which are enforceable under state law only.

(1) b)(1)b., b)(1)c., and b)(2)b.

b) Applicable Emissions Limitations and/or Control Requirements

(1) The specific operation(s), property, and/or equipment that constitute each emissions unit along with the applicable rules and/or requirements and with the applicable emissions limitations and/or control measures are identified below. Emissions from each unit shall not exceed the listed limitations, and the listed control measures shall be specified in narrative form following the table.

	Applicable Rules/Requirements	Applicable Emissions Limitations/Control Measures
a.	OAC rule 3745-31-05(A)(3) June 30, 2008	Volatile organic compound (VOC) emissions shall not exceed 0.27 ton per month, averaged over a rolling 12-month period. Use of add-on control (vapor recovery, flare/combustor or equivalent) to control emissions as needed to comply with the VOC emission limitations. If a flare is used, it must meet the requirements detailed in the permit for the flare emissions unit. See b)(2)a., b)(2)c. and c) below.
b.	OAC rule 3745-31-05(A)(3)(a)(ii) June 30, 2008	The Best Available Technology (BAT) requirements under OAC rule 3745-31-05(A)(3) do not apply to the VOC emissions from this air contaminant source since the calculated annual emissions rate is less than 10 tons/year, taking into account the voluntary restrictions from OAC rule 3745-31-05(E). See b)(2)b. below.
c.	OAC rule 3745-31-05(E) June 30, 2008	VOC emissions shall not exceed 0.27 ton per month, averaged over a rolling 12-month period. Use of add-on control (vapor recovery, flare/combustor or equivalent) to control emissions as needed to comply with the VOC emission limitations. If a flare is used, it must meet the requirements detailed in the permit for the flare emissions unit.

	Applicable Rules/Requirements	Applicable Emissions Limitations/Control Measures
		See b)(2)b., b)(2)c. and c) below.

(2) Additional Terms and Conditions

a. This Best Available Technology (BAT) emissions limit applies until U.S. EPA approves OAC rule 3745-31-05(A)(3)(a)(ii) (the less than 10 tons per year BAT exemption) into the Ohio SIP.

b. These requirements apply once U.S. EPA approves OAC paragraph 3745-31-05(A)(3)(a)(ii) (the less than 10 tons per year BAT exemption) as part of the Ohio SIP.

c) Operational Restrictions

(1) Access openings to the receivers shall be kept closed at all times, except when a pig is being placed into or removed from the receiver, or during active maintenance operations.

(2) The permittee shall install and operate add-on control (vapor recovery, flare/combustor or equivalent) for the control of VOC emissions as needed to comply with this permit's emission limits.

(3) In the event any needed add-on control is not operating in accordance with the manufacturer's recommendations, instructions, or operating manual, with any modifications deemed necessary by the permittee, add-on control shall be expeditiously repaired or otherwise returned to these documented operating conditions.

d) Monitoring and/or Recordkeeping Requirements

(1) The permittee shall collect the following information for each pigging event venting:

a. Date and time of the venting;

b. The calculated mass of the resulting VOC emissions where the mass is calculated using the following equation[1]:

VOC Mass = [(mw*PV/(RTZ)) * VOC Wt% + L + C] * (1 - capture efficiency * control efficiency) * (1 ton/2000 pounds)

Where:

mw = the molecular weight of the gas vented;

P = the absolute gas pressure of the gas in the pigging vessel prior to venting;

V = the actual volume of the pigging vessel and piping vented;

T = the temperature of the vented gas;

[1] Representative values may be used for this calculation as long as the values are updated with actual data at least on an annual basis.

Z = the gas compressibility factor of the vented gas;

R = the gas constant;

L = the chamber liquid phase released and volatilized (flash) as VOCs; and

C = the VOCs emitted in the re-sealed chamber purge gas flush.

(2) The permittee shall maintain monthly records of the following information:

a. the ton of VOC per month emitted from the pigging events (using the calculation provided in d)(1)), and

b. the ton of VOC per month emitted from all pigging events, averaged over a rolling, 12-month period (using the calculation provided in d)(1) and summing the current month with the previous 11 months and then dividing by 12 months).

(3) The permittee shall maintain documentation of the manufacturer's recommendations, instructions, or operating manuals for add-on control, along with documentation of any modifications deemed necessary by the permittee. These documents shall be maintained at the facility and shall be made available to the appropriate Ohio EPA District Office or local air agency upon request.

(4) The permittee shall conduct periodic inspections of the add-on control to determine whether it is operating in accordance with the manufacturer's recommendations, instructions, or operating manuals with any modifications deemed necessary by the permittee or operator.

(5) The permittee shall document each inspection (periodic and annual) of the add-on control and shall maintain the following information:

a. the date of the inspection;

b. a description of each/any problem identified and the date it was corrected;

c. a description of any maintenance and repairs performed; and

d. the name of person who performed the inspection.

These records shall be maintained at the facility for not less than five years from the date the inspection and any necessary maintenance or repairs were completed and shall be made available to the appropriate Ohio EPA District Office or local air agency upon request.

(6) The permittee shall maintain records that document any time periods when the add-on control was not in service when the emissions unit(s) was/were in operation, as well as, a record of all operations during which add-on control was not operated according to the manufacturer's recommendations with any documented modifications made by the permittee. These records shall be maintained for a period of not less than five years and shall be made available to the Ohio EPA upon request.

e) Reporting Requirements

(1) The permittee shall submit deviation reports that identify any of the following occurrences:

a. All exceedances of the ton of VOC per month, averaged over a rolling, 12-month period, and the other requirements under sections c)(1) through (3) and d)(1) through (6).

(2) The deviation reports shall be submitted in accordance with the reporting requirements of the Standard Terms and Conditions of this permit.

(3) Unless other arrangements have been approved by the Director, all notifications and reports shall be submitted through the Ohio EPA's eBusiness Center: Air Services online web portal.

f) Testing Requirements

(1) Compliance with the Emissions Limitations and/or Control Requirements specified in section b) of these terms and conditions shall be determined in accordance with the following methods:

Emission Limitation:

VOC emissions shall not exceed 0.27 ton per month, averaged over a rolling 12-month period.

Applicable Compliance Method:

Compliance shall be determined based on the records found in terms d)(1) and d)(2) above.

g) Miscellaneous Requirements

(1) None.

GENERAL PERMIT 21.1 TEMPLATE

PIGGING OPERATION

B. Facility-Wide Terms and Conditions

The following are the terms and conditions for a General PTIO to be issued to a **non-Title V** facility

1. This permit document constitutes a permit-to-install issued in accordance with ORC 3704.03(F) and a permit-to-operate issued in accordance with ORC 3704.03(G).

   a) For the purpose of a permit-to-install document, the facility-wide terms and conditions identified below are federally enforceable with the exception of those listed below which are enforceable under state law only.

      (1) B.2.

   b) For the purpose of a permit-to-operate document, the facility-wide terms and conditions identified below are enforceable under state law only with the exception of those listed below which are federally enforceable.

      (2) None.

2. Modeling to demonstrate compliance with the “Toxic Air Contaminant Statute”, ORC 3704.03(F)(4)(b), is not necessary if/when the maximum annual emissions for each toxic air contaminant, as defined in OAC rule 3745-114-01, from all sources in the project, is less than 1.0 ton per year (or are subject to a standard under 40 CFR Part 63). OAC Chapter 3745-31 requires permittees to apply for and obtain a new or modified PTIO prior to making a "modification" as defined by OAC rule 3745-31-01. The permittee is hereby advised that changes in the composition of the materials or use of new materials that would cause the emissions of any toxic air contaminant to increase to above 1.0 ton per year may require the permittee to apply for and obtain a new PTIO.

3. Records related to this permit may be maintained at an off-site location (e.g. regional office), provided they are made accessible when the need arises, otherwise by the next business day upon Ohio EPA request (or made viewable electronically on-site and submitted to Ohio EPA within 24 hours).

C. Emissions Unit Terms and Conditions

1. Emissions Unit: Pigging Operation: P020

Operations, Property and/or Equipment Description:

One discrete pig launcher or receiver.

a) This permit document constitutes a permit-to-install issued in accordance with ORC 3704.03(F) and a permit-to-operate issued in accordance with ORC 3704.03(G).

(1) For the purpose of a permit-to-install document, the emissions unit terms and conditions identified below are federally enforceable with the exception of those listed below which are enforceable under state law only.

a. b)(1)b., b)(1)c., and b)(2)b.

(2) For the purpose of a permit-to-operate document, the emissions unit terms and conditions identified below are enforceable under state law only with the exception of those listed below which are federally enforceable.

a. None.

b) Applicable Emissions Limitations and/or Control Requirements

(1) The specific operation(s), property, and/or equipment that constitute each emissions unit along with the applicable rules and/or requirements and with the applicable emissions limitations and/or control measures are identified below. Emissions from each unit shall not exceed the listed limitations, and the listed control measures shall be specified in narrative form following the table.

	Applicable Rules/Requirements	Applicable Emissions Limitations/Control Measures
a.	OAC rule 3745-31-05(A)(3) June 30, 2008	Volatile organic compound (VOC) emissions shall not exceed 0.27 ton per month, averaged over a rolling 12-month period. Use of add-on control (vapor recovery, flare/combustor or equivalent) to control emissions as needed to comply with the VOC emission limitations. If a flare is used, it must meet the requirements detailed in the permit for the flare emissions unit. See b)(2)a., b)(2)c. and c) below.
b.	OAC rule 3745-31-05(A)(3)(a)(ii) June 30, 2008	The Best Available Technology (BAT) requirements under OAC rule 3745-31-05(A)(3) do not apply to the VOC emissions from this air contaminant source since the calculated annual emissions rate is less than 10 tons/year, taking into account the voluntary restrictions from OAC rule 3745-31-05(E). See b)(2)b. below.

	Applicable Rules/Requirements	Applicable Emissions Limitations/Control Measures
c.	OAC rule 3745-31-05(E) June 30, 2008	VOC emissions shall not exceed 0.27 ton per month, averaged over a rolling 12-month period. Use of add-on control (vapor recovery, flare/combustor or equivalent) to control emissions as needed to comply with the VOC emission limitations. If a flare is used, it must meet the requirements detailed in the permit for the flare emissions unit. See b)(2)b., b)(2)c. and c) below.

(2) Additional Terms and Conditions

a. This Best Available Technology (BAT) emissions limit applies until U.S. EPA approves OAC rule 3745-31-05(A)(3)(a)(ii) (the less than 10 tons per year BAT exemption) into the Ohio SIP.

b. These requirements apply once U.S. EPA approves OAC paragraph 3745-31-05(A)(3)(a)(ii) (the less than 10 tons per year BAT exemption) as part of the Ohio SIP.

c) Operational Restrictions

(1) Access openings to the receivers shall be kept closed at all times, except when a pig is being placed into or removed from the receiver, or during active maintenance operations.

(2) The permittee shall install and operate add-on control (vapor recovery, flare/combustor or equivalent) for the control of VOC emissions as needed to comply with this permit's emission limits.

(3) In the event any needed add-on control is not operating in accordance with the manufacturer's recommendations, instructions, or operating manual, with any modifications deemed necessary by the permittee, add-on control shall be expeditiously repaired or otherwise returned to these documented operating conditions.

d) Monitoring and/or Recordkeeping Requirements

(1) The permittee shall collect the following information for each pigging event venting:

a. Date and time of the venting;

b. The calculated mass of the resulting VOC emissions where the mass is calculated using the following equation[1]:

[1] Representative values may be used for this calculation as long as the values are updated with actual data at least on an annual basis.

VOC Mass = [(mw*PV/(RTZ)) * VOC Wt% + L + C] * (1 - capture efficiency * control efficiency) * (1 ton/2000 pounds)

Where:

mw = the molecular weight of the gas vented;

P = the absolute gas pressure of the gas in the pigging vessel prior to venting;

V = the actual volume of the pigging vessel and piping vented;

T = the temperature of the vented gas;

Z = the gas compressibility factor of the vented gas;

R = the gas constant;

L = the chamber liquid phase released and volatilized (flash) as VOCs; and

C = the VOCs emitted in the re-sealed chamber purge gas flush.

(2) The permittee shall maintain monthly records of the following information:

a. the ton of VOC per month emitted from the pigging events (using the calculation provided in d)(1)), and

b. the ton of VOC per month emitted from all pigging events, averaged over a rolling, 12-month period (using the calculation provided in d)(1) and summing the current month with the previous 11 months and then dividing by 12 months).

(3) The permittee shall maintain documentation of the manufacturer's recommendations, instructions, or operating manuals for add-on control, along with documentation of any modifications deemed necessary by the permittee. These documents shall be maintained at the facility and shall be made available to the appropriate Ohio EPA District Office or local air agency upon request.

(4) The permittee shall conduct periodic inspections of the add-on control to determine whether it is operating in accordance with the manufacturer’s recommendations, instructions, or operating manuals with any modifications deemed necessary by the permittee or operator.

(5) The permittee shall document each inspection (periodic and annual) of the add-on control and shall maintain the following information:

a. the date of the inspection;

b. a description of each/any problem identified and the date it was corrected;

c. a description of any maintenance and repairs performed; and

d. the name of person who performed the inspection.

These records shall be maintained at the facility for not less than five years from the date the inspection and any necessary maintenance or repairs were completed and shall

be made available to the appropriate Ohio EPA District Office or local air agency upon request.

(6) The permittee shall maintain records that document any time periods when the add-on control was not in service when the emissions unit(s) was/were in operation, as well as, a record of all operations during which add-on control was not operated according to the manufacturer's recommendations with any documented modifications made by the permittee. These records shall be maintained for a period of not less than five years and shall be made available to the Ohio EPA upon request.

e) Reporting Requirements

(1) The permittee shall submit an annual Permit Evaluation Report (PER) to the Ohio EPA District Office or Local Air Agency by the due date identified in the Authorization section of this permit. The permit evaluation report shall cover a reporting period of no more than twelve months for each air contaminant source identified in this permit.

(2) The reports required by this permit may be submitted through the Ohio EPA's eBusiness Center: Air Services online web portal; or they may be mailed as a hard copy to the appropriate district office or local air agency.

f) Testing Requirements

(1) Compliance with the Emissions Limitations and/or Control Requirements specified in section b) of these terms and conditions shall be determined in accordance with the following methods:

Emission Limitation:

VOC emissions shall not exceed 0.27 ton per month, averaged over a rolling 12-month period.

Applicable Compliance Method:

Compliance shall be determined based on the records found in terms d)(1) and d)(2) above.

g) Miscellaneous Requirements

(1) None.

Recover Gas from Pipeline Pigging Operations

Technology/Practice Overview

Description

Gases rich in recoverable hydrocarbons tend to condense liquids in gathering systems upstream of gas gathering and processing plants. These systems are frequently pigged with spherical or bullet-shaped pigs to remove accumulated liquids and reduce the gathering system pressure drop. This improves gas flow and pipeline efficiency. The pigged liquids are separated from the gas ahead of the processing plant compressors, stored temporarily at gathering system pressure, and then sent to a low pressure storage tank. The liquids, recovered at pipeline pressure, flash and vent light hydrocarbon gases from the storage tanks.

Much of the gas that is vented can be recovered by installing a dedicated vapor recovery system. Recovering the flash gas resulting from the pressure drop between the pressurized liquid storage tanks and the atmospheric storage tanks can reduce emissions and add more gas to the sales line.

Operating Requirements

The required equipment to be installed includes an electric or a gas engine driven vapor recovery compressor. A liquid/vapor flash vessel and low pressure liquid pump may also be required depending on system design and/or ambient temperature and pressure. It is assumed that a pig launcher and receiver on gathering lines, vapor/liquid separation and pressurized liquid storage vessels, and low pressure liquid storage tanks would already be

Economic and Environmental Benefits

Methane Savings

Estimated annual methane emission reductions	*21,400 Mcf per year*

Economic Evaluation

Estimated Gas Price	Annual Methane Savings	Value of Annual Gas Savings*	Estimated Implementation Cost	Incremental Operating Cost	Payback (months)
$7.00/Mcf	21,400 Mcf	$159,400	$24,000	$1,000	2 Month
$5.00/Mcf	21,400 Mcf	$113,800	$24,000	$1,000	3 Month
$3.00/Mcf	21,400 Mcf	$68,300	$24,000	$1,000	5 Months

** Whole gas savings are calculated using a conversion factor of 94% methane in pipeline quality natural gas.*

Additional Benefits

- Addition of gas to the sales line (or plant fuel system)
- Recovery of valuable hydrocarbon liquids
- Safer operations

Recover Gas from Pipeline Pigging Operations (Cont'd)

present on site. Vapor recovery compressor sizing is affected by the variance of pigging operations; colder temperatures in the winter can require extra capacity that is not necessary in the summer months. This is because colder temperatures result in more condensation at constant pressure. Pipelines would therefore have to be pigged more often. In general, gathering lines that must be pigged frequently and recover a large volume of liquid at moderate to high pressure (150 to 300 psig or greater) are best suited for vapor recovery.

Applicability

Gas and condensate recovery is possible at any gas gathering station and processing plant that frequently must remove condensed liquids from its upstream gathering lines.

Methane Emissions

The methane emission savings are based on the design flow rate and operating time of a single vapor recovery compressor dedicated to the compression of the flash vapor from the pigged liquid (pressurized) storage tanks.

Economic Analysis

Basis for Costs and Emissions Savings

For example reported savings are based on a gathering system at 200-300 psig (pounds per square-inch, gage) that is pigged 30-40 times per year and collects approximately 3,000 barrels of condensate per year. A small vapor recovery system was installed with an electric compressor for $24,000 and has an annual operating and maintenance cost in excess of $1,000 per year.

Discussion

Gathering system pigging frequency depends on the gas composition as well as the ambient temperature conditions, and can vary greatly from one location to another and from season to season. The economics of recovering gas from pigging operations are dependent upon the methane through butane composition of the hydrocarbon liquid, which directly impact the energy content and value of the gas, and the amount of liquid collected.

Methane Content of Natural Gas

The average methane content of natural gas varies by natural gas industry sector. The Natural Gas STAR Program assumes the following methane content of natural gas when estimating methane savings for Partner Reported Opportunities.

Production	79 %
Processing	87 %
Transmission and Distribution	94 %

EPA provides the suggested methane emissions estimating methods contained in this document as a tool to develop basic methane emissions estimates only. As regulatory reporting demands a higher-level of accuracy, the methane emission estimating methods and terminology contained in this document may not conform to the Greenhouse Gas Reporting Rule, 40 CFR Part 98, Subpart W methods or those in other EPA regulations.

NMED Exhibit 87 - 0002

EPA United States Environmental Protection Agency

Office of Enforcement and Compliance Assurance

Enforcement Alert

Publication no. EPA 325-F-19-001

SEPTEMBER 2019

EPA Observes Air Emissions from Natural Gas Gathering Operations in Violation of the Clean Air Act

Purpose

EPA and state investigations have identified Clean Air Act (CAA) non compliance caused by unauthorized and/or excess emissions from depressurizing pig launchers and receivers in natural gas gathering operations. For example, EPA and Pennsylvania resolved CAA violations by MarkWest (described at the end of this Alert) in a consent decree in April 2018. The settlement provides an example of potential compliance issues that operators may experience if Volatile Organic Compound (VOC) emissions from depressurizing pig launchers and receivers in natural gas gathering operations are not properly controlled. This Alert discusses engineering, design, operations, and maintenance practices that EPA and state inspectors have found that can cause non-compliance and summarizes engineering solutions to reduce emissions and help alleviate potential safety issues. While this Alert provides information intended to help operators and state regulators identify and address compliance concerns, the solutions discussed in this Alert do not guarantee compliance with federal and state regulations, including, but not limited to requirements to obtain an air permit, keep records, and/or control emissions.

Non-Compliance Concerns

State and federal laws require owners and operators of certain facilities to register air emission sources, obtain authorization to emit from a registered source, including natural gas gathering operations, and design, install, operate, and maintain effective emission control measures. Such laws include state permitting and air pollution regulations—many of which are federally-enforceable and collectively referred to as the State Implementation Plan or "SIP"—and the federal New Source Review (NSR) air permitting regulations including the Prevention of Significant Deterioration (PSD) requirements.

Infrared Image of Compressor Station Pig Receiver Depressurization Event

EPA and state inspectors have observed numerous instances where depressurizing pig launchers and receivers in natural gas gathering operations emit unauthorized or excess VOC emissions, due to the company's failure to obtain an air permit for the pigging

NMED Exhibit 88 - 0001

equipment, to address deficiencies in the design of the pigging equipment, or to operate the pigging equipment in accordance with an air permit, air permit application or air permit registration.

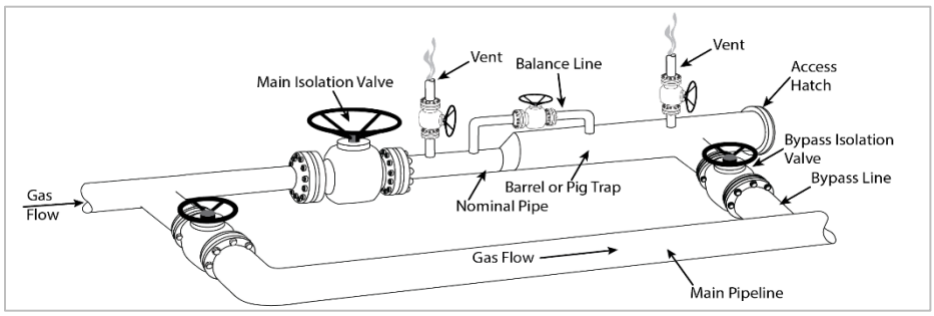

Figure 1. Conventional pig receiver.

In most jurisdictions, a company must determine the mass emissions of pollutants when registering a source, applying for an air permit, and/or claiming an air permit exemption; which are prerequisites to constructing a source. Failing to calculate the potential for VOC or HAP emissions from pigging operations or otherwise underestimating the mass of the pollutants released may result in a misrepresentation to the permit authority when the company applies for a permit or permit exemption. Depending on the state and local air permitting rules and regulations, a company's misrepresentation to the permit authority may mean that the emissions from the pigging operations are considered unauthorized or excess. In this situation, the non-compliance is caused by a company's failure to comply with federal and state permitting requirements, including, but not limited to: failure to register an air emission source, failure to obtain an air permit or obtain the correct air permit, or failure to adhere to representations in the air permit registration, failure to maintain records, and/or failure to control emissions. *See, e.g.,* 40 C.F.R. §§ 51.165 and 70.7(b); 25 Pa. Code §§ 127.11 and 127.402(a); Ohio Admin. Code 3745-31-02(A)(1)(a)-(b) and 3745-15-05(B), (D) and (E).

Emissions from Pigging Operations

Raw natural gas is transported from production wells to processing plants through networks of gathering pipelines. Although liquid separation may occur at the well pad, much of the raw natural gas passing through the gathering pipelines is saturated with hydrocarbons other than methane and may contain other components such as water, carbon dioxide, and hydrogen sulfide. During the transportation of this gas through gathering pipeline systems, the gas often experiences a temperature drop and pressure change that causes the hydrocarbons and other components to condense to a liquid phase. These natural gas condensates can accumulate in low elevation segments of the gathering pipelines, impeding the flow of natural gas. To maintain gas flow and operational integrity of the gathering pipelines, operators mechanically push these condensates out of the low elevations and down the pipeline by an operation called "pigging," which involves first inserting a device called a pig into a pig launcher upstream of the pipeline segment where condensates have accumulated. The gas flowing through the pipeline then pushes the pig through the pipeline, allowing the pig to sweep along the accumulated condensates. The pig is removed from the pipeline segment when it is caught in a pig receiver.

A conventional pig receiver is shown in Figure 1. Pig launchers are very similar in design. The pipeline at the rear of the barrel is called a "kicker line" on pig launchers and a "bypass line" on pig receivers; these lines direct the main gas flow through the barrel to launch or receive a pig, respectively.

Before a pig can be inserted or removed through the hatch of a pig launcher or a pig receiver, the pipeline gas in the launcher or receiver barrel must be removed, leading to potential emissions. This gas is under the same pressure as the pipeline and contains methane, ethane, and VOCs including benzene, toluene, ethylbenzene, and xylene. Pig receivers can also contain collected condensate liquid that had accumulated in the pipeline.

When the launcher and receiver barrels are depressurized (via a vent as shown in Figure 1) prior to opening the hatch for pig insertion or removal, the depressurization gases contain mixtures of methane, ethane, VOCs and hazardous air pollutants (HAPs). The barrel depressurization gases are often vented to the atmosphere but can be controlled or recovered to reduce emissions. When the hatch is opened, additional gas is released, and any liquids collected in a pig receiver that did not volatilize in the depressurization process may be spilled from the open hatch as the pig is withdrawn. These spilled liquids can fall to the ground or be collected in an open tub, either of which allow for further evaporation that contributes to emissions.

The amount of potential emissions from pigging operations depends on several factors including the launcher or receiver volume, pipeline pressure (higher pressure correlating with higher potential emissions), amount of liquid trapped in the pig receiver barrel prior to depressurization, frequency of pigging, and gas composition.

Depending on these system characteristics, the pigging operation may emit VOCs or HAPs in excess of federal or state limits.

Engineering Solutions

EPA inspectors have identified general characteristics of a pig launcher and receiver system that control and reduce emissions of air pollutants and may require less management. These systems: (1) minimize the total volume between the kicker and/or bypass isolation valves and the main isolation valve, so that less gas is trapped in the barrel; and (2) minimize the potential for liquid accumulation or hold-up in the receiver, and include features such as sloped receiver barrels and piping so that liquids collected in the barrel are gravity-drained through the bypass piping into the main pipeline for collection downstream. However, depending on the quantity of emissions released, a company may be required to implement additional design measures, and emissions capture and control approaches to comply with federal and state regulations.

The following sections discuss design alternatives to the conventional launcher/receiver system (i.e., pig ball valves and multi-pig launcher systems), considerations for receiver barrel design (i.e., condensate drains and pig ramps), and additional site modifications to capture or control emissions (i.e., jumper lines, combustion devices, rerouting low pressure systems, barrel pump-down systems, and enhanced liquid containment). In addition to reducing potential VOC emissions to alleviate potential non-compliance, application of these solutions reduces methane (a potent greenhouse gas) and generally improves safety of the pigging operation. The applicability and effectiveness of these engineering solutions are site-specific; solutions can generally be combined to effectively reduce emissions.

Install Pig Ball Valves

Pig ball valves are a design alternative to conventional launcher/receiver systems that result in fewer emissions

NMED Exhibit 88 - 0003

from pigging operations due to a smaller sized barrel (or chamber) that launches and receives the pig. A conventional pig launcher or receiver system can be retrofitted by replacing the conventional launcher and receiver barrels with special ball valves used to insert and remove the pig directly from the main pipeline. Figure 2 shows a pig ball valve installed in a pipeline, with a bypass loop around the pig ball valve for use when the pig ball valve is closed. By replacing the large volume barrel with the much smaller volume ball valve, the volume of gas vented during each pigging operation can be reduced by as much as 80% to 95% with a corresponding reduction in emissions and other risks associated with pipeline pigging operations.

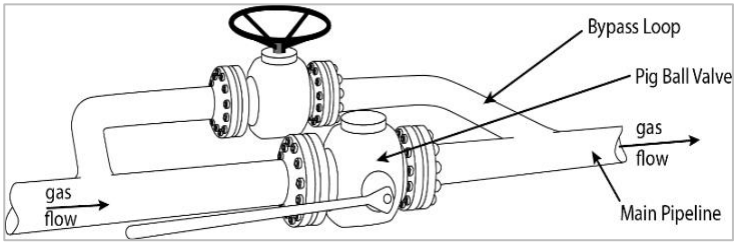

Figure 2. Pig Ball Valve Installation

Install Multi-Pig Launcher Systems

Multi-pig launcher systems are a design alternative to conventional launcher/receiver systems and reduce pigging emissions by reducing the frequency that launchers and receivers must be vented prior to pig insertion and removal. An example manufacturer design for a multi-pig launcher system is shown in Figure 3. The launcher barrel is designed to hold multiple spherical pigs, which are each held in place by gates or pins prior to release. Emission reductions are approximately proportional to the reduction in frequency of opening the launcher and receiver hatch.

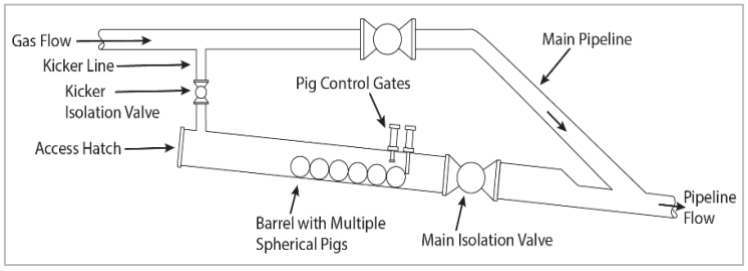

Figure 3. Multi-Pig Launcher System

Receiver Barrel Design: Condensate Drains

Drains can be installed in the bottom of receiver barrels and pig ball valves to ensure that all condensate is drained from the system prior to depressurization. These drains generally route the condensate back into the main pipelines, to onsite storage tanks, or to onsite processes via enclosed piping. Two drains are shown in Figure 4 which depicts a conventional receiver design, but additional drains can be used. These drains can be retrofitted to existing systems.

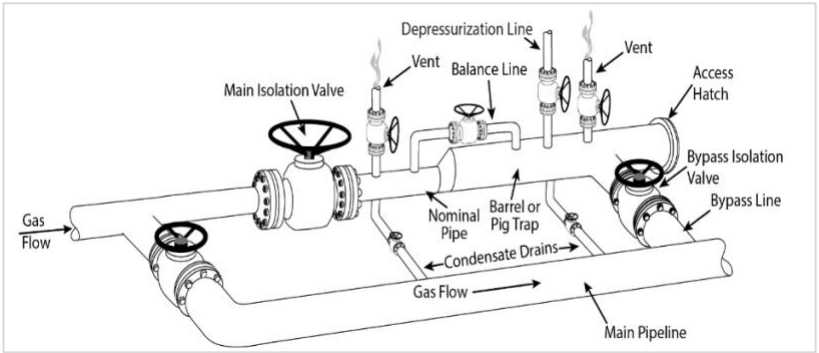

Figure 4. Conventional Pig Receiver with Condensate and Vapor Recovery

The effectiveness of condensate drains in controlling pigging emissions is based on the quantity of condensate trapped in the receiver system, and the subsequent ability of the drain to recover the full quantity of this condensate during each pigging operation, thereby preventing its volatilization during pig receiver depressurization or hatch opening.

NMED Exhibit 88 - 0004

Receiver Barrel Design: Pig Ramps

A pig ramp is a device that can be installed inside a receiver barrel to minimize the accumulation of condensate, or VOCs in the condensed liquid phase, in the receiver by directing the movement of the pig and liquid in the barrel. The pig ramp promotes the flow of liquid through the barrel and into the bypass line by preventing the pig from creating blockages in the receiver. By promoting the flow of liquid back into the pipeline system while the receiver is under pressure, pig ramps reduce the amount of condensed VOCs trapped in the barrel prior to depressurization which reduces the air emission that occur during depressurization and removal of the pig from the receiver. As part of MarkWest's recent settlement with EPA, pig ramps were installed at hundreds of barrels in its wet gas midstream pipeline systems. As discussed below, MarkWest will provide a royalty-free license to others interested in using their proprietary pig ramp design.

Route High Pressure Systems to Lower Pressure Lines (Install Jumper Lines)

The depressurization emissions from high pressure launchers and receivers can be reduced by routing the gases to a lower pressure system before venting the remaining gases to the atmosphere or to control equipment. Routing to a lower pressure system is achieved with a depressurization line (or, "jumper line") exiting the top of the barrel, as shown in Figure 4, or exiting the top of the pig ball valve. Compressor stations and gas plants have low pressure lines on the site that can receive these depressurization gases and recycle them through the process. Similarly, launchers and receivers along high pressure pipelines are occasionally located near low pressure pipelines that can receive depressurization gases exiting the barrel or pig ball valve.

Route Depressurization Gases to Combustion Devices

Depressurization gases from barrels and pig ball valves can be routed through the depressurization line (see Figure 4) to onsite combustion devices. Well-designed and operated combustion devices can achieve vapor destruction efficiencies as high as 95% to 98%. Combustion devices can be used in conjunction with engineering solutions discussed above that first reduce accumulation of or recover as much natural gas and condensate as possible before destroying the remaining vapors in the combustion device. An example would be to route high pressure systems to low pressure lines and drain barrel condensate, then route the remaining vapors to a combustion device. Large, high capacity combustion devices are typically available at compressor stations and processing plants and can be used to control pigging gases while meeting the other flaring needs of the facility. There are also numerous low capacity combustion devices available for serving remote launcher/receiver sites.

Route Low-Pressure Systems into Fuel Gas Systems or Vapor Recovery Unit (VRU)

Gases that remain in high pressure barrels after venting to low pressure systems and gases in low pressure barrels can be recovered during depressurization by discharging the gases to very low-pressure systems at the site (e.g., 10-15 psig). Two examples of very low-pressure systems at compressor stations are a fuel gas system and a condensate tank vapor recovery unit (VRU). Applying such an approach can reduce the gas pressure in the barrels to the pressure of the very low-pressure system (e.g., 10 psig), with a corresponding reduction in depressurization emissions.

NMED Exhibit 88 - 0005

Barrel Pump-down Systems

In barrel pump-down systems, small fixed or portable compressors are used to pump vapors in the receiver or a launcher barrel back into the main pipeline prior to venting and opening the barrel hatch. In barrel pump-down systems, the inlet of a gas compressor is connected to the receiver or launcher depressurization line, and the compressor discharge is connected into the main pipeline. Vapors exiting the depressurization line are pulled into the compression system and recovered back into the pipeline at system pressure. These control systems can recover greater than 99% of the depressurization vapors from pig launchers and receivers.

Enhanced Liquid Containment

Covering containers that collect liquids remaining in a receiver barrel after depressurization with a fitted impermeable material will reduce emissions from evaporation. Use of grounded steel receptacles additionally helps ensure safety.

Estimating Potential Emissions from Pigging Activities in Natural Gas Gathering Operations

The Real Gas Law has been used to estimate the emissions from depressurizing launcher and receiver barrels, where a gas compressibility factor is applied to account for non-ideal gas initial conditions (e.g., high pressure).

However, the fundamental assumption of the methodology guiding this approach is that the average pipeline gas profile accurately characterizes the contents of the barrel prior to depressurization. This assumption neglects changes in physical conditions along the pipeline which lead to compositional changes and potential formation of condensate liquid that can accumulate in and/or is swept into the pig receiver during pigging.

Therefore, when considering emissions from pig receivers, the Real Gas Law methodology accounts for depressurizing the natural gas mixture from pressurized conditions to atmospheric; however, the equation does not address the potential flash emissions from volatilization of condensates during depressurization. Using the Real Gas Law alone in circumstances with liquid accumulation can result in an underestimation of the calculated VOC emissions from the receiver.

A complete emissions estimation methodology for receivers would account for the impact of any liquid accumulation in receivers, as a supplement to estimates based on the Real Gas Law.

Enforcement Settlement with MarkWest

On April 24, 2018, the U.S. EPA, the U.S. Department of Justice, and the Pennsylvania Department of Environmental Protection announced a settlement with MarkWest that requires innovative solutions designed to evaluate and address VOC emissions from pigging operations at gathering compressor stations and stand-alone pigging stations. This settlement resulted from joint inspections conducted by the EPA and the Commonwealth of Pennsylvania. MarkWest failed to apply for, and comply with, the required permits and/or recordkeeping requirements under the Nonattainment New Source Review, Prevention of Significant Deterioration and Title V programs, and the Pennsylvania and Ohio State Implementation Plans, for natural gas pigging and venting activities that released excess VOC emissions. MarkWest is undertaking measures to help

NMED Exhibit 88 - 0006

ensure compliance with federal and state regulations and reduce emissions including:

- Operating jumper lines to depressurize launchers and receivers.
- Installing pig ramps in receivers.
- Using a mobile flare to control emissions during depressurization.
- Using shorter (smaller volume) barrels than those presently used in the system.
- Using liquid containers with grounded steel receptacles that are covered at all times when not in use.
- Using an estimation methodology that accounts for the flash emissions from condensates that accumulate in the pig barrel.

MarkWest additionally is performing the following environmental projects to further EPA's goal of protecting and enhancing the public health and the environment:

- Innovation transfer and emission control education: MarkWest will provide a royalty-free license and public educational sessions to promote rapid adoption of its proprietary pig ramp design. This project is aimed at increasing awareness of the emissions from pigging operations and sharing cost-effective methods to reduce these emissions. The adoption of this technology by other midstream operators will further benefit the environment by reducing emissions from pigging operations.
- Ambient air monitoring: MarkWest will install and operate air sampling stations to analyze VOCs downstream of two compressor stations over a period of at least two years. Air monitoring at these facilities is not required by law, but MarkWest agreed to conduct these supplemental environmental projects as part of the settlement to provide local communities, industry, regulators, and other stakeholders valuable information about air emissions generated during midstream operation and maintenance activities, and their impacts on local air quality.

Industry Emissions: Production, Gathering, and Boosting

Source: EPA. *Inventory of U.S. Greenhouse Gas Emissions and Sinks 1990 – 2006.* April, 2008. Available on the web at: epa.gov/climatechange/emissions/usinventoryreport.html

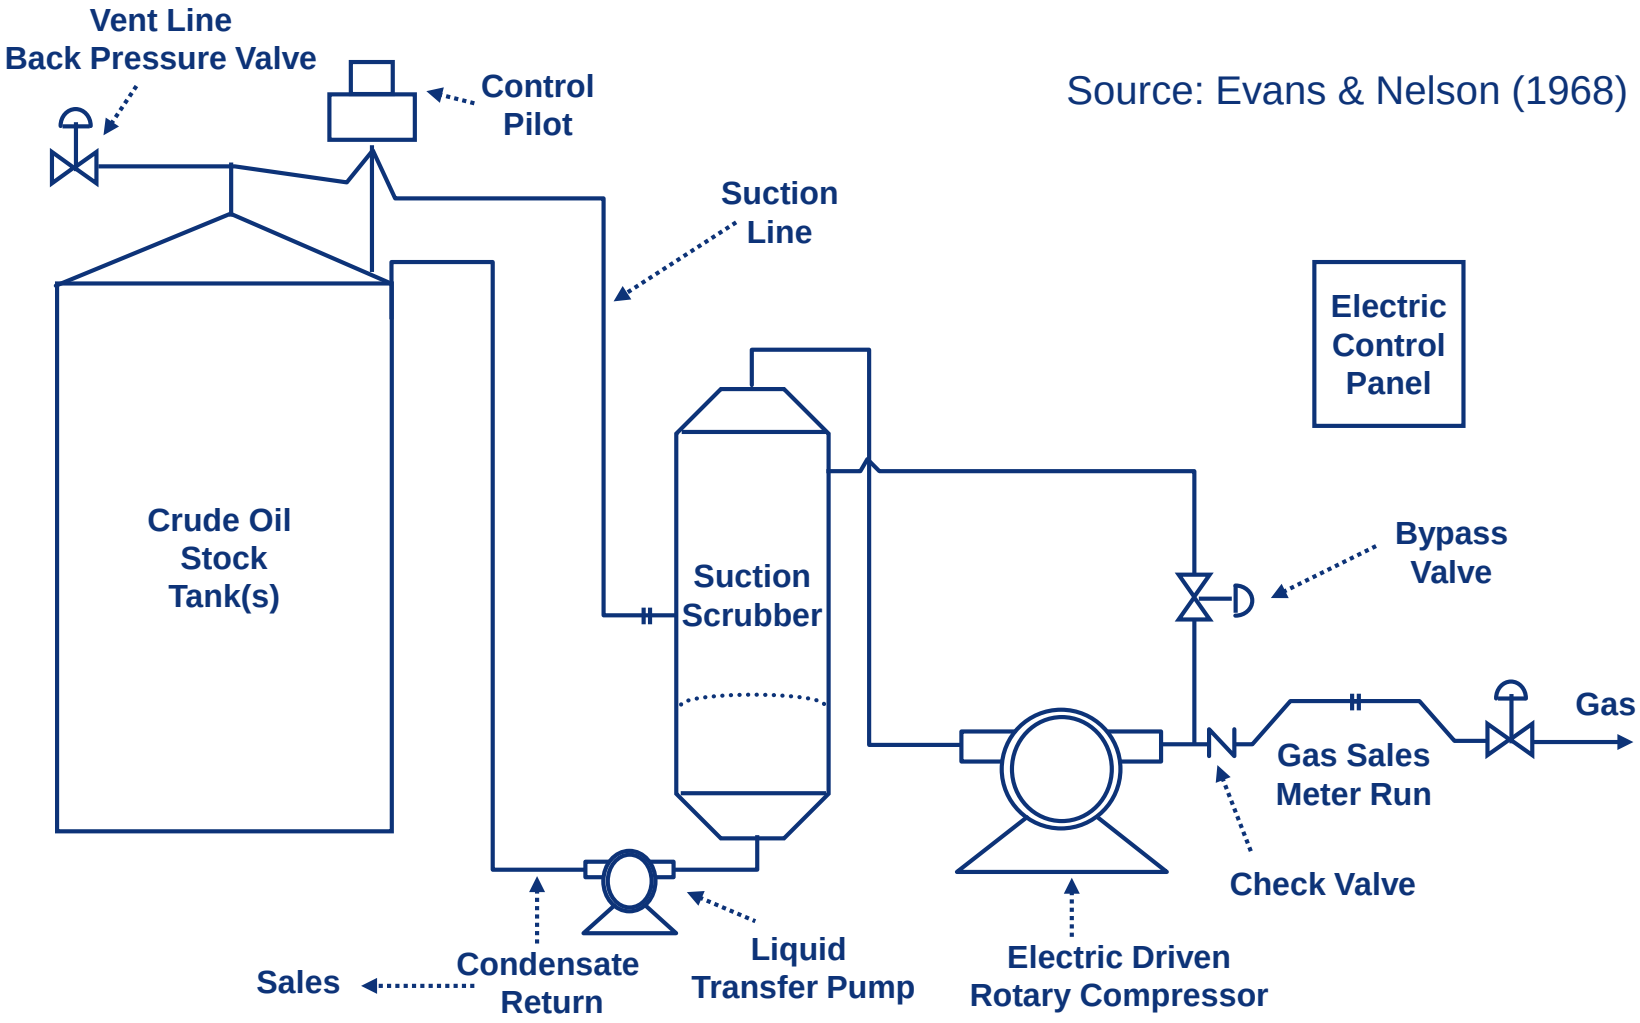
Note: Natural Gas STAR reductions from gathering and boosting operations are reflected in the production sector.

Vapor Recovery Units

- Methane Losses
- Methane Savings
- Is Recovery Profitable?
- Industry Experience
- Lessons Learned

Sources of Methane Losses

- A storage tank battery can vent 5,000 to 500,000 thousand cubic feet (Mcf) of natural gas and light hydrocarbon vapors to the atmosphere each year
  - Vapor losses are primarily a function of oil or condensate throughput, gravity, and gas-oil separator pressure
- Flash losses
  - Occur when crude oil or condensate is transferred from a gas-oil separator at higher pressure to a storage tank at atmospheric pressure
- Working losses
  - Occur when crude or condensate levels change and when liquid in tank is agitated
- Standing losses
  - Occur with daily and seasonal temperature and barometric pressure changes

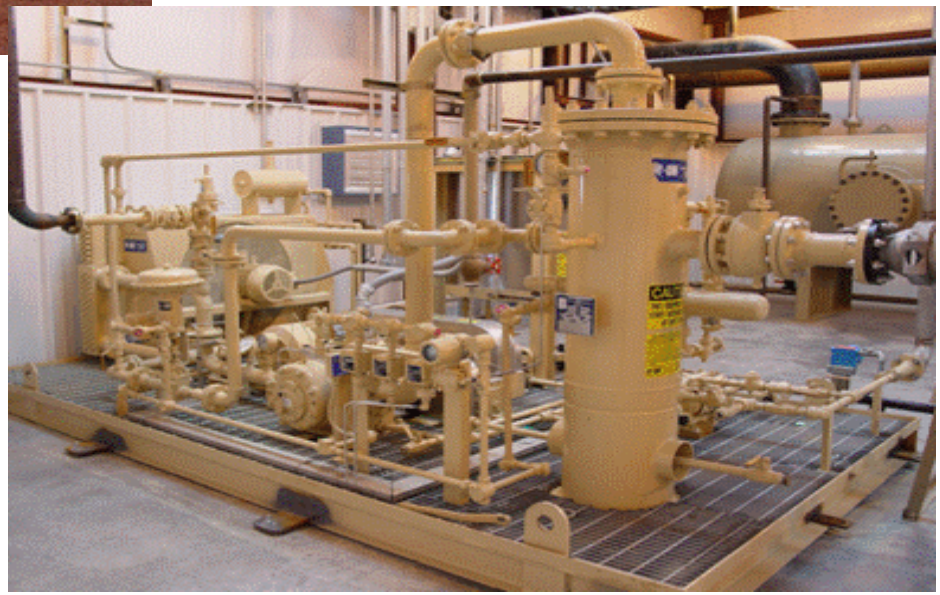


Methane Savings: Vapor Recovery

- Vapor recovery can capture up to 95% of hydrocarbon vapors from tanks
- Recovered vapors have higher heat content than pipeline quality natural gas
- Recovered vapors are more valuable than natural gas and have multiple uses
  - Re-inject into sales pipeline
  - Use as on-site fuel
  - Send to processing plants for recovering valuable natural gas liquids

Types of Vapor Recovery Units

- Conventional vapor recovery units (VRUs)
  - Use screw or vane compressor to suck vapors out of atmospheric pressure storage tanks
  - Scroll compressors are new to this market
  - Require electrical power or engine driver
- Venturi ejector vapor recovery units (EVRU™) or Vapor Jet
  - Use Venturi jet ejectors in place of rotary compressors
  - Contain no moving parts
  - EVRU™ requires a source of high pressure motive gas and intermediate pressure discharge system
  - Vapor Jet requires a high pressure water motive



Conventional Vapor Recovery Unit

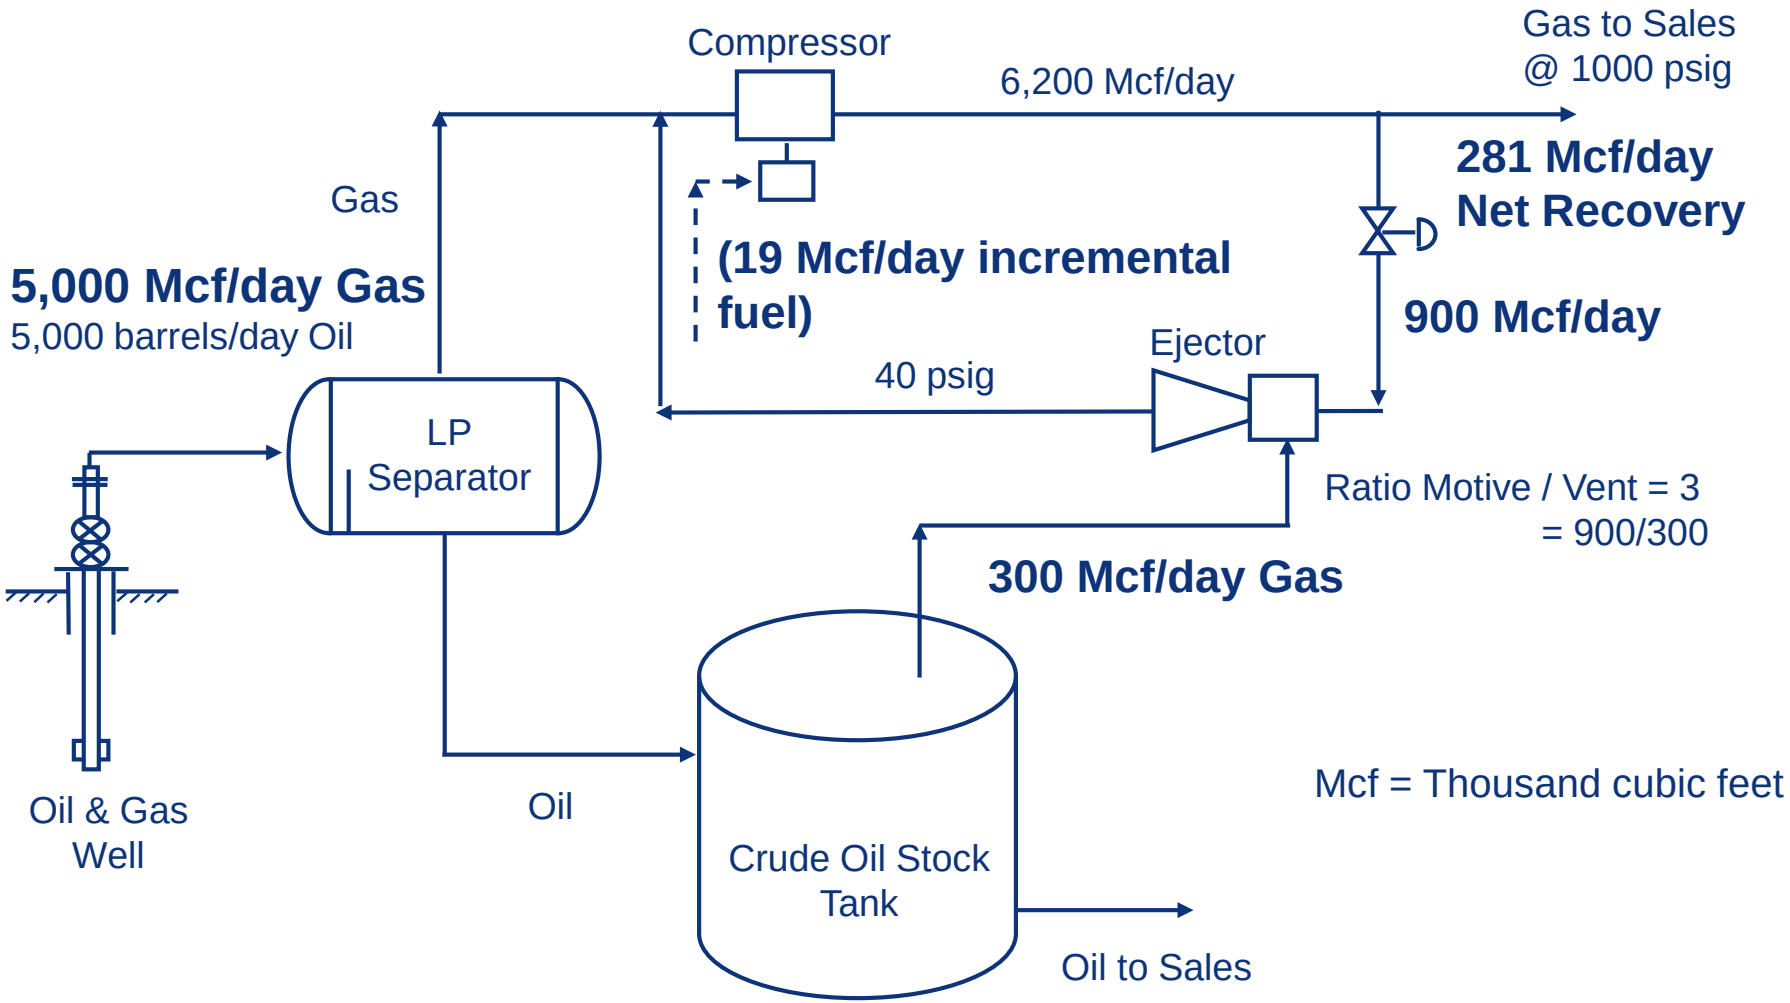
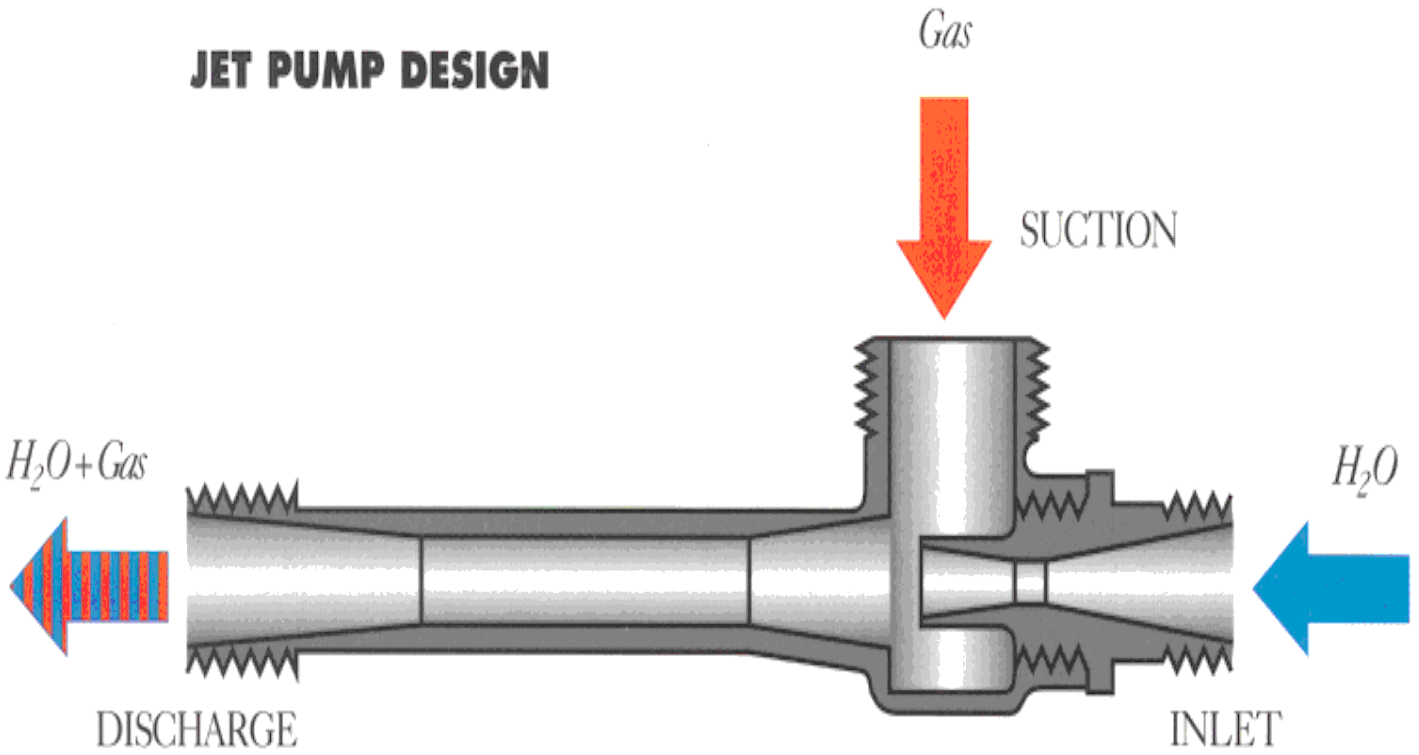
Vapor Recovery Installations



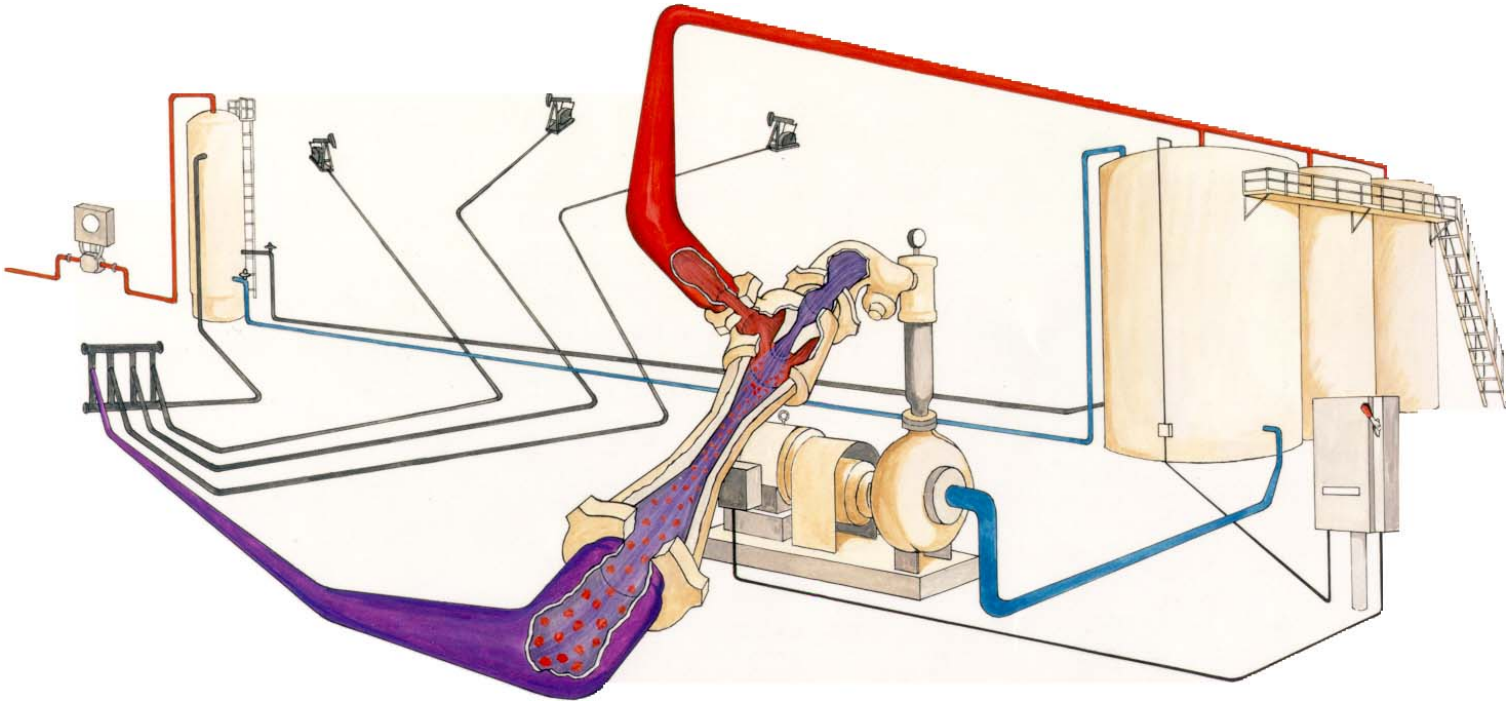
Venturi Jet Ejector*



*EVRU™ Patented by COMM Engineering

Adapted from SRI/USEPA-GHG-VR-19
psig = pound per square inch, gauge
psia = pounds per square inch, absolute

Vapor Recovery with Ejector



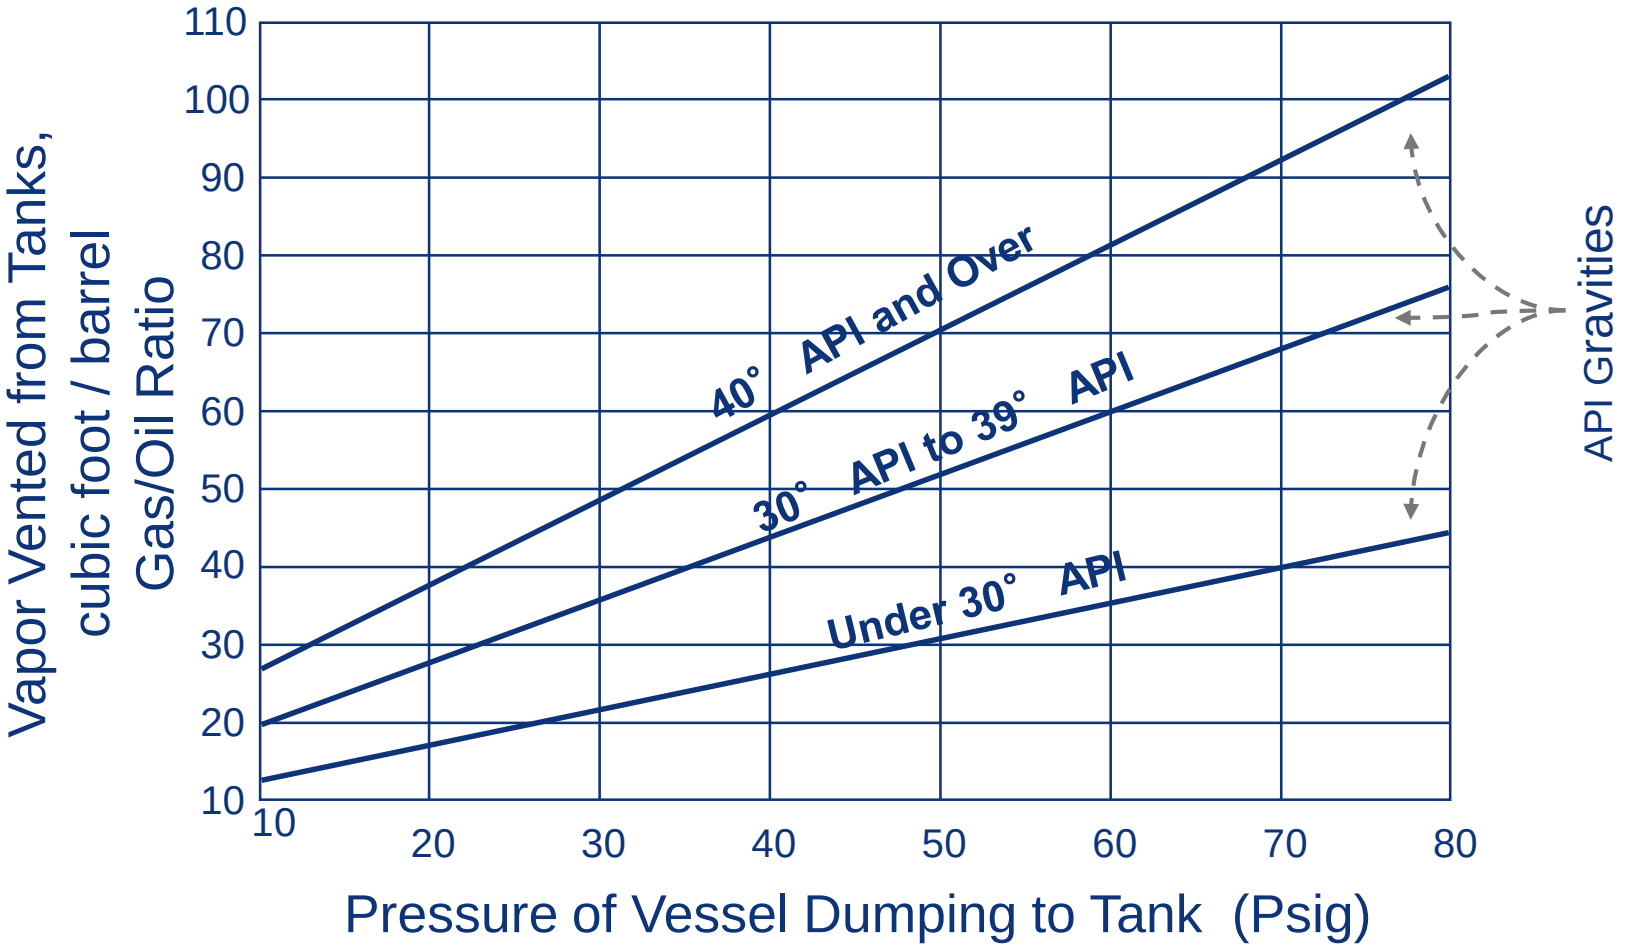
Vapor Jet System*

*Patented by Hy-Bon Engineering

Vapor Jet System*

- Utilizes produced water in closed loop system to effect gas gathering from tanks
- Small centrifugal pump forces water into Venturi jet, creating vacuum effect
- Limited to gas volumes of 77 Mcf/day and discharge pressure of 40 psig

*Patented by Hy-Bon Engineering



Criteria for Vapor Recovery Unit Locations

- Steady source and sufficient quantity of losses
  - Crude oil stock tank
  - Flash tank, heater/treater, water skimmer vents
  - Gas pneumatic controllers and pumps
  - Dehydrator still vent
  - Pig trap vent
- Outlet for recovered gas
  - Access to low pressure gas pipeline, compressor suction, or on-site fuel system
- Tank batteries not subject to air regulations

Quantify Volume of Losses

- Estimate losses from chart based on oil characteristics, pressure, and temperature at each location (± 50%)
- Estimate emissions using the E&P Tank Model (± 20%)
- Engineering Equations – Vasquez Beggs (± 20%)
- Measure losses using recording manometer and well tester or ultrasonic meter over several cycles (± 5%)
  - This is the best approach for facility design

Estimated Volume of Tank Vapors

° API = API gravity

Estimated Volume of Tank Vapors

- Atmospheric tanks may emit large amounts of tank vapors at relatively low separator pressure

Vasquez-Beggs Equation

$$GOR = A \times (G_{flash\ gas}) \times (P_{sep} + 14.7)^{B} \times \exp\left(\frac{C \times G_{oil}}{T_{sep} + 460}\right)$$

where,

GOR	=	Ratio of flash gas production to standard stock tank barrels of oil produced, in scf/bbl oil (barrels of oil corrected to 60°F)
$G_{flash\ gas}$	=	Specific gravity of the tank flash gas, where air = 1. A suggested default value for $G_{flash\ gas}$ is 1.22 (TNRCC; Vasquez, 1980)
G_{oil}	=	API gravity of stock tank oil at 60°F
P_{sep}	=	Pressure in separator, in psig
T_{sep}	=	Temperature in separator, °F

For $G_{oil} \leq 30$°API: A = 0.0362; B = 1.0937; and C = 25.724

For $G_{oil} > 30$°API: A = 0.0178; B = 1.187; and C = 23.931

psig – pounds per square inch, gauge
scf – standard cubic feet
bbl – barrels

What is the Recovered Gas Worth?

- Value depends on heat content of gas
- Value depends on how gas is used
  - On-site fuel
    - Valued in terms of fuel that is replaced
  - Natural gas pipeline
    - Measured by the higher price for rich (higher heat content) gas
  - Gas processing plant
    - Measured by value of natural gas liquids and methane, which can be separated
- Gross revenue per year = (Q x P x 365) + NGL
  - Q = Rate of vapor recovery (Mcf per day)
  - P = Price of natural gas
  - NGL = Value of natural gas liquids

Value of Natural Gas Liquids

Industry Experience: Anadarko

- Vapor Recover Tower (VRT)
  - Add separation vessel between heater treater or low pressure separator and storage tanks that operates at or near atmospheric pressure
    - Operating pressure range: 1 psi to 5 psi
  - Compressor (VRU) is used to capture gas from VRT
  - Oil/Condensate gravity flows from VRT to storage tanks
    - VRT insulates the VRU from gas surges with stock tank level changes
    - VRT more tolerant to higher and lower pressures
    - Stable pressure allows better operating factor for VRU

Industry Experience: Anadarko

- VRT reduces pressure drop from approximately 50 psig to 1-5 psig
  - Reduces flashing losses
  - Captures more product for sales
  - Anadarko netted between $7 to $8 million from 1993 to 1999 by utilizing VRT/VRU configuration
- Equipment Capital Cost: $11,000
- Standard size VRTs available based on oil production rate
  - 20” x 35’
  - 48” x 35’
- Anadarko has installed over 300 VRT/VRUs since 1993 and continues on an as needed basis

VRT/VRU Photos

Courtesy of Anadarko

Lessons Learned

- Vapor recovery can yield generous returns when there are market outlets for recovered gas
  - Recovered high heat content gas has extra value
  - Vapor recovery technology can be highly cost-effective in most general applications
  - Venturi jet models work well in certain niche applications, with reduced operating and maintenance costs
- Potential for reduced compliance costs can be considered when evaluating economics of VRU, EVRU™, or Vapor Jet

Lessons Learned (continued)

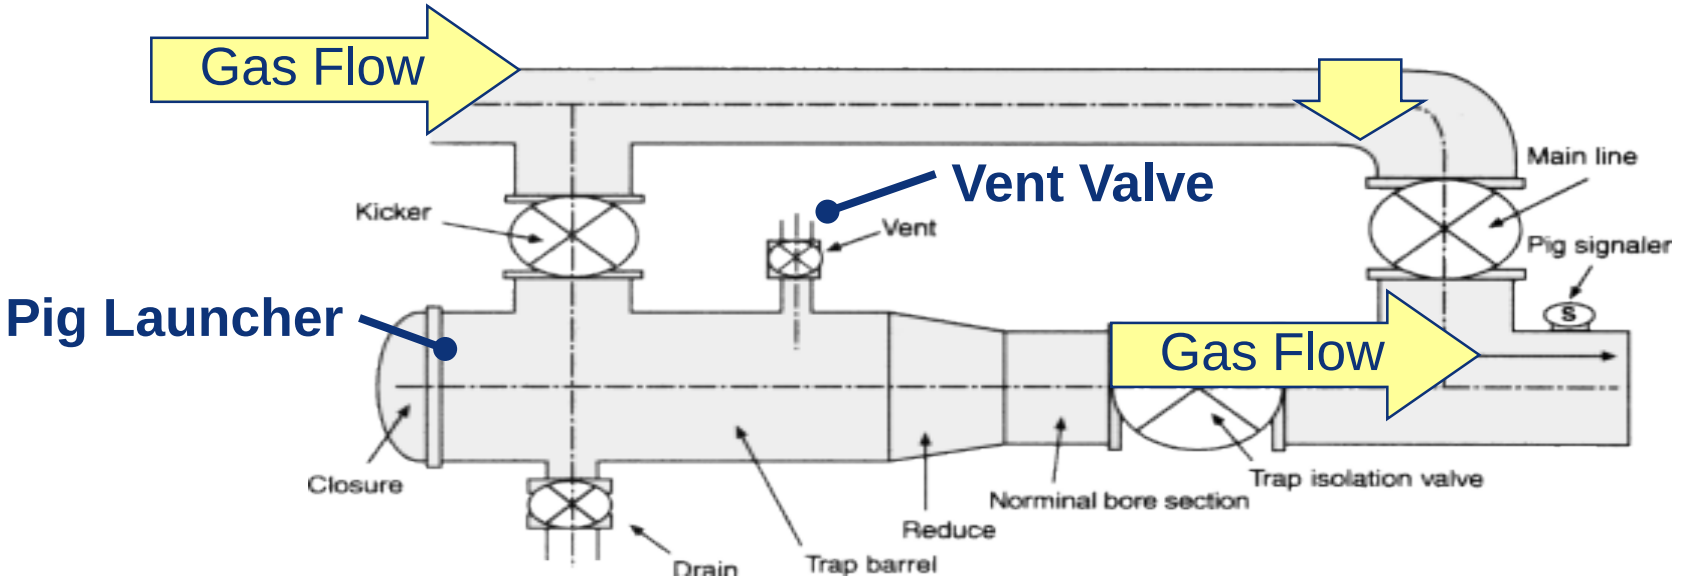
- VRU should be sized for maximum volume expected from storage tanks (rule-of-thumb is to double daily average volume)
- Rotary vane, screw or scroll type compressors recommended for VRUs where Venturi ejector jet designs are not applicable
- EVRU™ recommended where there is a high pressure gas compressor with excess capacity
- Vapor Jet recommended where there is produced water, less than 75 Mcf per day gas and discharge pressures below 40 psig

Methane Losses from Pipeline Pigging

- Gas lost when launching and receiving a pig
- Fugitive emissions from pig launcher/receiver valves
- Gas lost from storage tanks receiving condensate removed by pigging
- Gas vented from pipeline blowdowns

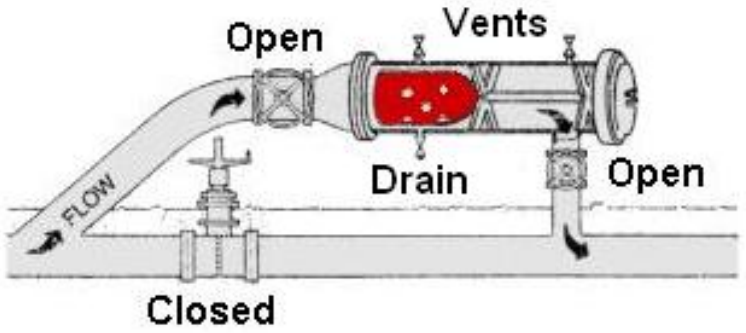
Pigging Pipelines

- Hydrocarbons and water condense inside pipelines, causing pressure drop and reducing gas flow
- Periodic line pigging removes liquids and debris to improve gas flow
  - Also inspect pipeline integrity
- Efficient pigging:
  - Keeps pipeline running continuously
  - Keeps pipeline near maximum throughput by removing debris
  - Minimizes product losses during launch/capture



Source: www.girardind.com/

How Does Pigging Vent Methane?



- Pig launchers have isolation valves for loading pigs, pressurizing pigs, and launching pigs with gas bypassed from the pipeline
- Launcher pressuring/depressuring loses methane out the vent valve

Source: www.girardind.com/

Pigging Vents Methane Twice

- Methane lost through vent valve on the launcher and again through vent valve on the receiver
  - Once receiver is isolated from the line, it must be depressured to remove the pig
  - Liquids ahead of the pig drain to a vessel or tank
- *MORE than twice:* isolation valve leaks may cause excessive venting to depressure

Source: www.girardind.com/

Methane Recovery

- Pipeline maintenance requires pipe section blowdown before work can begin
- Gas in pipeline is usually vented to the atmosphere
- Use inert gas and pig
- Route vent to vapor recovery system or fuel gas
  - One Partner reported connecting pig receiver vent to fuel gas to recover gas while working a tight isolation

Is Recovery Profitable?

- One partner pigged gathering lines 30 to 40 times per year, collecting several thousand barrels of condensate per application
- Partner reported saving 21,400 Mcf/year from recovering flash gases
- Dedicated vapor recovery unit (VRU) was installed with an electric compressor at an installation cost of $24,000 and an annual operating cost of $40,000 mostly for electricity
- Large gas savings and increasing gas prices will offset costs

Gas Price ($/Mcf)	$7.00
Gas Saved (Mcf/year)	21,400
Annual Savings ($/year)	$149,800
Installed Cost	$24,000
Operating Cost	$40,000
Payback Period (years)	0.3

Discussion

- Industry experience applying these technologies and practices
- Limitations on application of these technologies an practices
- Actual costs and benefits

Install Flares

Technology/Practice Overview

Description

Remote, unmanned production sites and compressor stations may vent low-pressure natural gas and vapors from storage tanks and other onsite equipment to the atmosphere. These gases, which contain methane and often volatile organic compounds (VOC), hydrogen sulfide, and hazardous air pollutants (HAP), can pose an environmental, health, and safety hazard. In order to reduce these emissions, Partners have reported installing flares to combust these gases instead of venting them to the atmosphere.

Partners have applied flaring technology typically consisting of a small flare stack with one or two pilots. Emissions sources, such as tank vents, compressor blowdown lines, low-pressure separator vents, overpressure relief valves, and other vent streams are piped directly to the flare.

Operating Requirements

If the heat content of the stream is below 300 Btu per scf, auxiliary fuel is needed. The average pilot gas consumption is 70 scf per hour per pilot burner.

Applicability

Flares can be applied to all point source vented emissions of combustible gas with minimal sulfur content.

Methane Emissions

The methane emissions reduction is uniquely dependent on the types and sizes of sources and the methane content of the flared gas. Wellhead gas may range from 70 to 90 percent methane while crude oil production tank vapors

Additional Benefits

- Safer operations

Install Flares (Cont'd)

may be as low as 50 percent methane. Partners have reported production site application for tank vents, relief valves, and compressor blow-down at 2,000 Mcf per year, low-pressure separators at 4,000 Mcf per year, and condensate tanks at 36,000 Mcf per year.

Economic Analysis

Basis for Costs and Emissions Savings

Methane emissions reductions of 2,000 Mcf per year apply to a single flare with a single pilot. Costs for a flare are estimated to be $3,000 based on partner experiences (which vary significantly and are often between $1,000 and $5,000). In addition, and there is a fuel cost of $1,800 per year for each pilot (at $3 per Mcf of gas).

Discussion

Flares are commonly installed on higher-pressure blowdown or emergency pressure relief valves for safety reasons. Low-pressure gas installations have been justified by environmental emissions control. There are no revenues from the gas as it is destroyed through combustion.

Methane Content of Natural Gas

The average methane content of natural gas varies by natural gas industry sector. The Natural Gas STAR Program assumes the following methane content of natural gas when estimating methane savings for Partner Reported Opportunities.

Production	79 %
Processing	87 %
Transmission and Distribution	94 %

EPA provides the suggested methane emissions estimating methods contained in this document as a tool to develop basic methane emissions estimates only. As regulatory reporting demands a higher-level of accuracy, the methane emission estimating methods and terminology contained in this document may not conform to the Greenhouse Gas Reporting Rule, 40 CFR Part 98, Subpart W methods or those in other EPA regulations.

PREFACE

On March 28, 2014 the Obama Administration released a key element called for in the President's Climate Action Plan: a Strategy to Reduce Methane Emissions. The strategy summarizes the sources of methane emissions, commits to new steps to cut emissions of this potent greenhouse gas, and outlines the Administration's efforts to improve the measurement of these emissions. The strategy builds on progress to date and takes steps to further cut methane emissions from several sectors, including the oil and natural gas sector.

This technical white paper is one of those steps. The paper, along with four others, focuses on potentially significant sources of methane and volatile organic compounds (VOCs) in the oil and gas sector, covering emissions and mitigation techniques for both pollutants. The Agency is seeking input from independent experts, along with data and technical information from the public. The EPA will use these technical documents to solidify our understanding of these potentially significant sources, which will allow us to fully evaluate the range of options for cost-effectively cutting VOC and methane waste and emissions.

The white papers are available at:

www.epa.gov/airquality/oilandgas/whitepapers.html

NMED Exhibit 91

1.0 INTRODUCTION

The oil and natural gas exploration and production industry in the U.S. is highly dynamic and growing rapidly. Consequently, the number of wells in service and the potential for greater emissions from oil and natural gas sources is also growing. There were an estimated 504,000 producing gas wells in the U.S. in 2011 (U.S. EIA, 2012a), and an estimated 536,000 producing oil wells in the U.S. in 2011 (U.S. EIA, 2012b). It is anticipated that the number of gas and oil wells will continue to increase substantially in the future because of the continued and expanding use of horizontal drilling combined with hydraulic fracturing (referred to here as simply hydraulic fracturing).

Due to the growth of this sector and the potential for increased air emissions, it is important that the U.S. Environmental Protection Agency (EPA) obtain a clear and accurate understanding of emerging data on emissions and available mitigation techniques. This paper presents the Agency's understanding of emissions and available emissions mitigation techniques from a potentially significant source of emissions in the oil and natural gas sector.

1.1 Definition of the Source

The focus of this white paper is natural gas-driven pneumatic controllers and natural gas-driven pneumatic pumps. Such pneumatic controllers and pumps are widespread in the oil and natural gas industry and emit natural gas, which contains methane and VOCs. In some applications, pneumatic controllers and pumps used in this industry may be driven by gases other than natural gas and, therefore, do not emit methane or VOCs.

1.1.1 Pneumatic Controllers

For the purposes of this white paper, a *pneumatic controller* means an automated instrument used for maintaining a process condition such as liquid level, pressure, pressure difference and temperature. Based on the source of power, two types of pneumatic controllers are defined for this paper:

NMED Exhibit 91

- *Natural gas-driven pneumatic controller* means a pneumatic controller powered by pressurized natural gas.
- *Non-natural gas-driven pneumatic controller* means an instrument that is actuated using other sources of power than pressurized natural gas; examples include solar, electric, and instrument air.

Natural gas-driven pneumatic controllers come in a variety of designs for a variety of uses. For the purposes of this white paper, they are characterized primarily by their emissions characteristics:

- *Continuous bleed pneumatic controllers* are those with a continuous flow of pneumatic supply natural gas to the process control device (e.g., level control, temperature control, pressure control) where the supply gas pressure is modulated by the process condition, and then flows to the valve controller where the signal is compared with the process set-point to adjust gas pressure in the valve actuator. For the purposes of this paper, continuous bleed controllers are further subdivided into two types based on their bleed rate:
    - *Low bleed*, having a bleed rate of less than or equal to 6 standard cubic feet per hour (scfh).
    - *High bleed*, having a bleed rate of greater than 6 scfh.
- *Intermittent pneumatic controller* means a pneumatic controller that vents non-continuously. These natural gas-driven pneumatic controllers do not have a continuous bleed, but are actuated using pressurized natural gas.
- *Zero bleed pneumatic controller* means a pneumatic controller that does not bleed natural gas to the atmosphere. These natural gas-driven pneumatic controllers are self-contained devices that release gas to a downstream pipeline instead of to the atmosphere.

NMED Exhibit 91

1.1.2 Pneumatic Pumps

Pneumatic pumps are devices that use gas pressure to drive a fluid by raising or reducing the pressure of the fluid by means of a positive displacement, a piston or set of rotating impellers. Pneumatic pumps are generally used at oil and natural gas production sites where electricity is not readily available (GRI/EPA, 1996d). The supply gas for these pumps can be compressed air, but most often these pumps use natural gas from the production stream (GRI/EPA, 1996e).

1.2 Background

1.2.1 Pneumatic Controllers

Pneumatic controllers are automated instruments used for maintaining a process condition such as liquid level, pressure, pressure differential, and temperature. In many situations, across all segments of the oil and gas industry, pneumatic controllers make use of the available high-pressure natural gas to operate control of a valve. In these natural gas-driven pneumatic controllers, natural gas is released with every actuation of the valve, i.e., valve movement. In some designs, natural gas is also released continuously from the valve control pilot. The rate at which the continuous release occurs is referred to as the bleed rate. Bleed rates are dependent on the design and operating characteristics of the device. Similar designs will have similar steady-state rates when operated under similar conditions. There are three basic designs of natural gas-driven pneumatic controllers: (1) continuous bleed controllers are used to modulate flow, liquid level, or pressure, and gas is vented continuously at a rate that may vary over time; (2) intermittent controllers release gas only when they open or close a valve or as they throttle the gas flow; and (3) zero bleed controllers, which are self-contained devices that release gas to a downstream pipeline instead of to the atmosphere (EPA, 2011a).

As noted above, intermittent controllers are devices that only emit gas during actuation and do not have a continuous bleed rate. Thus, the actual amount of emissions from an intermittent controller is dependent on the amount of natural gas vented per actuation and how often it is actuated. Continuous bleed controllers also vent an additional volume of gas during

NMED Exhibit 91

actuation, in addition to the device's continuous bleed stream. Thus, actual emissions from a continuous bleed device also depend, in part, on the frequency of activation and the amount of gas vented during activation. As the name implies, zero bleed controllers are considered to emit no natural gas to the atmosphere (EPA, 2011a).

In general, intermittent controllers serve functionally different purposes than bleed controllers and, therefore, cannot replace bleed controllers in most (but not all) applications. Furthermore, zero bleed controllers are "closed loop" systems that can be used only in applications with very low pressure and therefore may not be suitable to replace continuous bleed pneumatic controllers in many applications.

Non-natural gas-driven pneumatic controllers can be used in some applications. These controllers can be mechanically operated or use sources of power other than pressurized natural gas, such as compressed "instrument air." Instrument air systems are feasible only at oil and natural gas locations that have electrical service sufficient to power an air compressor. At sites without electrical service sufficient to power an instrument air compressor, mechanical or electrically powered pneumatic controllers can be used. Non-natural gas-driven controllers do not directly release methane or VOCs, but may have secondary impacts related to generation of required electrical power (EPA, 2011a).

1.2.2 Pneumatic Pumps

There are two types of pneumatic pumps that are commonly used in the oil and natural gas sector: piston and diaphragm (GRI/EPA, 1996d). These pumps have two major components, a driver side and a motive side, which operate in the same manner but with different reciprocating mechanisms. Pressurized gas provides energy to the driver side of the pump, which operates a piston or flexible diaphragm to draw fluid into the pump. The motive side of the pump delivers the energy to the fluid being moved in order to discharge the fluid from the pump. The natural gas leaving the exhaust port of the pump is either directly discharged into the atmosphere or is recovered and used as a fuel gas or stripping gas (GRI/EPA, 1996d).

NMED Exhibit 91

The majority of pneumatic pumps used in oil and natural gas production are used for chemical injection or glycol circulation (GRI/EPA, 1996d). Pneumatic pumps used for chemical injection are needed in oil and natural gas production to inject small amounts of chemicals to limit processing problems and protect equipment. Typical chemicals that are injected into the process include: biocides, demulsifiers, clarifiers, corrosion inhibitors, scale inhibitors, hydrate inhibitors, paraffin dewaxers, surfactants, oxygen scavengers and hydrogen sulfide scavengers (GRI/EPA, 1996d). These chemicals are normally injected using pneumatic pumps at the wellhead, and into gathering lines or at production separation facilities (GRI/EPA, 1996d). Pneumatic pumps, commonly referred to as "Kimray" pumps, used for glycol circulation recover energy from the high-pressure rich glycol/gas mixture leaving the absorber and use that energy to pump the low-pressure lean glycol back into the absorber (GRI/EPA, 1996e).

1.3 Purpose of the White Paper

This white paper provides a summary of the EPA's understanding of the emissions from natural gas-driven pneumatic controllers and pumps in the oil and natural gas sector, the mitigation techniques available to reduce these emissions, the efficacy of these techniques and the prevalence of these techniques in the field. Section 2 of this document provides the EPA's understanding of emissions from pneumatic controllers and pumps, and Section 3 provides our understanding of available mitigation techniques. Section 4 summarizes the EPA's understanding based on the information presented in Sections 2 and 3, and Section 5 presents a list of charge questions for reviewers to assist the EPA with obtaining a more comprehensive understanding of pneumatic controller and pump VOC and methane emissions and emission mitigation techniques.

2.0 AVAILABLE EMISSIONS DATA AND ESTIMATES

There are a number of studies that have been published that have estimated VOC and methane emissions from pneumatic controllers and pneumatic pumps in the oil and natural gas sector. These studies have used different methodologies to estimate these emissions including the use of equipment counts and emission factors and direct measurement of emissions. Section 2.1 discusses the studies relevant to pneumatic controllers, and Section 2.2 discusses the studies

NMED Exhibit 91

relevant to pneumatic pumps. These studies are listed in Table 2-1, along with an indication of the type of information contained in the study.

2.1 Discussion of Data Sources for Pneumatic Controllers

This section presents and discusses pertinent studies and data sources that estimate emissions from pneumatic controllers.

NMED Exhibit 91

2.1.1 Methane Emissions from the Natural Gas Industry (GRI/EPA, 1996c)

This report's main objective was to quantify annual methane emissions from pneumatic controllers from the natural gas production, processing, transmission, and distribution sectors. The methane emissions were determined by developing average annual emissions factors for the various types of pneumatic controllers used in each of the natural gas segments. The annual emission factors were then extrapolated to a national estimate using activity factors for each of the natural gas segments.

Production

The data used to develop emission factors for pneumatic controllers in the natural gas production sector were obtained from a study performed by the Canadian Petroleum Association (CPA)[1], manufacturers' data, measured emission rates[2], data collected from site visits, and literature data for methane composition.

The CPA study consisted of methane and VOC emission measurements from pneumatic controllers in two types of service: 19 in on/off service and 16 in throttling service.[3] The CPA study determined the average natural gas emission rate for on/off controllers was 213 standard cubic feet per day per device (scfd/device), and the average natural gas emission rate for throttling controllers was 94 scfd/device. For throttling controllers, the CPA study did not distinguish between the throttling controllers with intermittent bleed rates and throttling controllers with continuous bleed rates. In addition, only one throttling controller actuated during the emission measurement. Therefore, these measurements are lower in comparison to field measurements of similar devices in the U.S. (GRI/EPA, 1996c).

[3] Controllers in on/off service wait until a specific set point is reached before actuating (e.g., a high or low liquid level). Controllers in throttling service maintain a desired set point (e.g., pressure).

NMED Exhibit 91

The manufacturers' data were obtained from four manufacturers of pneumatic controllers and were based on laboratory testing of new controllers. The manufacturers' noted that emissions in the field can be higher due to operating condition, age, and wear of the device. The gas consumption rates for the manufacturers' pneumatic controllers ranged from 0 to 2,150 scfd. The manufacturers noted that the emissions from these controllers in the field may be higher than the reported maximum value (GRI/EPA, 1996c).

The measured emissions data[4] were collected by connecting a flow meter to the supply line between the pressure regulator and the controller to measure the gas consumption of the controller. The duration of the test depended on the operating conditions. For steady operating conditions, one data point was measured for 15-20 minutes. For variable operating conditions, several one-hour measurements were taken. The data set contained a total of 41 measurements from a combination of continuous bleed controllers from offshore and onshore production sites and transmission stations. The average gas emissions rates for continuous bleed controllers were determined to be 872 scfd/device for onshore and offshore production sites and 1,363 scfd/device for transmission stations.

The measured emission data[5] also provided data for intermittent bleed controllers that were measured using the same techniques that were used for the continuous bleed pneumatic controllers. A total of seven measurements were performed on intermittent bleed controllers located at onshore natural gas production sites. No measurements were available for intermittent bleed controllers in the offshore or transmission segments. The average natural gas emission rate for the intermittent pneumatic controllers was determined to be 511 scfd/device.

Site visit data were collected from a total of 22 sites to determine the number of pneumatic controllers located at natural gas production sites, and to determine the fraction of these controllers that were intermittent or continuous bleed. The study determined that 65% of

[4] Controller survey data provided by Tenneco Gas Transportation, 1994 and Chevron, 1995.
[5] Controller survey data provided by Tenneco Gas Transportation, 1994 and Chevron, 1995.

the pneumatic controllers were intermittent bleed and 35% of the pneumatic controllers were continuous bleed.

The measured emission data, the CPA study emissions data, and the pneumatic controller counts were used to develop a single emission factor for a "generic" pneumatic device. For the production segment, the "generic" pneumatic controller emission factor was calculated using:

- 323 scfd/device for intermittent bleed controllers,
- 654 scfd/device for continuous bleed controllers,
- a methane content of 78.8%, and
- the ratio of intermittent bleed to continuous bleed controllers at natural gas production sites.

The "generic" emission factor was determined to be 345 scfd/device of methane for a pneumatic controller at natural gas production sites.

Transmission

The transmission "generic" emission factor was calculated using data from three types of gas-operated pneumatic controllers: continuous bleed controllers and two types of intermittent bleed controllers used to operate isolation valves[6] (isolation valves with turbine operators and isolation valves with displacement-type pneumatic/hydraulic operators). The continuous bleed emission factor was obtained from the transmission station measured emission data, which was determined to be 1,363 scfd/device. The isolation valve with displacement-type pneumatic/hydraulic operators emission factor was determined using data provided by Shafer Valve Operating Systems[7,8] and the count of the isolation valves at four sites. Using these data,

[6] Isolation valves at transmission stations are very large and are most often actuated either pneumatically or by electric motor. Isolation valve pneumatic controllers only discharge gas when they are actuated and are considered to be intermittent.

[7] Shafer Valve Operating Systems. Gas Consumption Calculation Method for Rotary Vane, Gas/Hydraulic Actuators. Technical Bulletin Data, Bulletin GC-00693. June 1993.

the average annual emission factor was determined to be 5,627 standard cubic feet per year per device (scfy/device). For turbine-operated isolation valves, the natural gas emissions were estimated using information provided by Limitorque Corporation[9] and information from two transmission sites. This information was used to calculate an emission factor of 67,599 scfy/device. The above emission factors, a methane content of 93.4% and proportions of each of these controllers at transmission sites was used to calculate a "generic" emission factor of 162,197 scfy/device of methane for pneumatic controllers at transmission stations.

Processing

The site visit information from nine natural gas processing plants found that plants used compressed air to operate the majority of pneumatic controllers at the plants. Only one of the plants used natural gas-powered continuous bleed controllers, and five had natural gas-driven pneumatic controllers for the isolation valves on the main pipeline emergency shutdown system or isolation valves used for maintenance. The same type of pneumatic controllers used in the transmission sector are used at natural gas processing sites; therefore, the same emission factors were used to calculate a facility pneumatic emission factor. Using the survey data and the transmission sector pneumatic controller emission factors, the annual methane emissions were determined to be 165 thousand standard cubic feet per facility (Mscfy/facility).

Summary

A summary of the pneumatic controller emission factors, activity factors, and annual methane emission rates estimated by this report are provided in Table 2-2 for the natural gas production, processing and transmission segments. The total methane emissions from pneumatic controllers was estimated to be 45,634 million standard cubic feet per year (MMscfy) or 861,704 metric tons (MT).

2.1.2 Estimates of Methane Emissions from the U.S. Oil Industry (ICF Consulting, 1999)

ICF Consulting (ICF Consulting, 1999) prepared a report for the EPA that estimated methane emissions from crude oil production, transportation and refining, identified potential methane mitigation techniques and provided an analysis of the economics of reducing methane emissions. The report estimated that 97% of the annual methane emissions occur during crude oil production (59.1 billion cubic feet, Bcf or 1,116,000 MT) in 1995. The transportation and refining sectors generate 0.3 Bcf (5,700 MT) and 1.3 Bcf (24,500 MT) of the annual methane emissions, respectively. The annual methane emissions were estimated using methane emission factors and activity factors to calculate the annual methane emissions from the oil industry.

In the production segment, annual vented methane emissions from 13 sources account for 91% (53.8 Bcf or 1,016,000 MT) of the total 1995 methane emissions from crude oil production. Two of these sources: high bleed pneumatic controllers and low bleed pneumatic controllers account for 37% (19.9 Bcf or 376,000 MT) and 7% (3.7 Bcf or 69,900 MT) of the annual vented methane emissions, respectively.

The high bleed pneumatic controller methane emissions were calculated using an emission factor of 345 scfd (GRI/EPA, 1996c). The activity factor for high bleed pneumatic controllers was determined to be 157,581 and assumes that tank batteries with heater treaters have four pneumatic controllers (three level controllers and one pressure controller). Tank batteries without heater treaters were assumed to have three pneumatic controllers. In addition, it was assumed that 35% of the total pneumatic controllers were high bleed, which is based on the percentage of continuous bleed pneumatic controllers determined in the GRI/EPA study (GRI/EPA, 1996c).

The low bleed pneumatic controller methane emission factor was estimated to be 10% of the high bleed methane emission factor or 35 scfd.[10] The activity factor for low bleed controllers was calculated to be 292,650 controllers and was determined using the assumption that 65% of the total pneumatic controllers are intermittent bleed (GRI/EPA, 1996c), which this report assumed to be low bleed pneumatic devices.

No methane emissions from pneumatic controllers were estimated in this report for the transportation and refining segments of the oil industry.

2.1.3 Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2012 (U.S. EPA, 2014)

The EPA leads the development of the annual Inventory of U.S. Greenhouse Gas Emissions and Sinks (GHG Inventory). This report tracks total U.S. greenhouse gas (GHG) emissions and removals by source and by economic sector over a time series, beginning with 1990.

The U.S. submits the GHG Inventory to the United Nations Framework Convention on Climate Change (UNFCCC) as an annual reporting requirement. The GHG Inventory includes estimates of methane and carbon dioxide for natural gas systems (production through distribution) and petroleum systems (production through refining).

[10] EPA Natural Gas STAR default value for low bleed pneumatic controllers.

Table 2-3 summarizes the 2014 GHG Inventory's (published in 2014; containing emissions data for 1990-2012) estimates of 2012 national methane emissions from pneumatic controllers in the natural gas production, processing, transmission and storage segments and the petroleum production segment. Where presented in the GHG Inventory, the table includes potential emissions (i.e., emissions that would be released in the absence of controls), emission reductions and net emissions. For pneumatic controllers, the emission reductions reported to the Natural Gas STAR program are deducted from potential emission to calculate net emissions. In future years, the GHG Inventory will also account for regulatory reductions impacting emissions from pneumatic controllers that result from subpart OOOO.

Table 2-3. Summary of GHG Inventory 2012 Nationwide Emissions from Pneumatic Controllers

Industry Segment	Potential CH_4 Emissions (MT)	CH_4 Emission Reductions (MT)	Net CH_4 Emissions (MT)
Natural gas and petroleum production[a]	1,642,622	873,100	769,522
Natural gas processing	1,923	[b]	[b]
Natural gas transmission and storage	263,561	14,078	249,483

[a] In the GHG Inventory, all Natural Gas STAR reductions for pneumatic devices are removed from the natural gas systems estimate. As some of these reductions likely occur in petroleum systems, a combined number for production segment pneumatic devices in natural gas and petroleum systems is presented here.

[b] The GHG Inventory does not include a specific emission reduction for pneumatic controllers in the natural gas processing sector resulting from the Natural Gas STAR program although it is likely non-zero.

The GHG Inventory data estimates that pneumatic controller emissions are 13% of overall methane emissions from the oil and natural gas sectors. The following sections provide greater detail on the estimates given in Table 2-3.

2.1.3.1 Natural gas and petroleum production industry segment

Table 2-4 shows the 2014 GHG Inventory's estimates of 2012 methane emissions from pneumatic controllers in the natural gas and petroleum production industry segment. The table

NMED Exhibit 91

presents the population of pneumatic controllers, methane emission factors, potential methane emissions, and the estimated national total of pneumatic controllers and potential methane emissions. The natural gas production data are broken down by the Energy Information Agency's (EIA's) National Energy Modeling System (NEMS) regions. The table also presents the national total of methane emission reductions compiled from Natural Gas STAR reports and the resulting estimated national net methane emissions from pneumatic controllers.

Table 2-4. Estimated 2012 National and Regional Methane Emissions from Pneumatic Controllers in the Natural Gas and Petroleum Production Segment

NEMS Region	Population of Pneumatic Controllers[a]	CH_4 Potential Emission Factor (scfd/device)[a]	CH_4 Emissions (MT)
Potential Emissions-Natural Gas Systems			
North East	77,261	373	202,696
Midcontinent	167,589	362	426,133

[a] 1996 GRI/EPA report, extrapolated using ratios relating other factors for which activity data are available.
[b] In the GHG Inventory, all Natural Gas STAR reductions for pneumatic devices are removed from the natural gas systems estimate. As some of these reductions likely occur in petroleum systems, a combined number for production segment pneumatic devices in natural gas and petroleum systems is presented here.

Recent national activity data on pneumatic controllers are not available. To calculate national emissions for these sources for the GHG Inventory, a set of industry activity data drivers was developed and used to update activity data. For the natural gas production segment, pneumatic controllers were estimated each year by applying a regional factor for the number of pneumatic controllers per well to annual regional data on gas well population. These factors ranged from 0.5 to 1.6 pneumatic controllers per well. For the petroleum production segment, pneumatic controllers were estimated each year by applying a factor for the number of pneumatic controllers per heater/treater (4), and pneumatic controller per battery without a heater/treater (3).

The basis for the GHG Inventory's potential methane emission factors for pneumatic controllers in the natural gas and petroleum production industry segment is the 1996 GRI/EPA report. The factor for natural gas systems represents a mix of the average emissions from continuous bleed and intermittent natural gas-driven pneumatic controllers in the 1996 GRI/EPA report. The region-specific factors are developed using the GRI/EPA factor and regional gas composition data. For petroleum systems, it was then assumed that 65% of pneumatic controllers in the petroleum production segment are low bleed pneumatic controllers, and 35% of controllers are high bleed. The GRI/EPA factors for low and high bleed controllers are applied to these populations

According to the GHG Inventory, the 1996 GRI/EPA report "still represents the best available [emissions] data in many cases, [but] using these emission factors alone to represent actual emissions without adjusting for emissions controls would in many cases overestimate emissions. For this reason, 'potential emissions' are calculated using the [1996 GRI/EPA report] data, and then current data on voluntary and regulatory emission reduction activities are deducted to calculate actual emissions."

In the case of pneumatic controllers in the natural gas production industry segment, the GHG Inventory reduces the calculated potential emissions using voluntary emission reductions reported by industry partners to the Natural Gas STAR Program. The reductions undergo quality assurance and quality control checks to identify errors, inconsistencies, or irregular data before

being incorporated into the GHG Inventory. Future inventories are expected to reflect the subpart OOOO requirements for pneumatic controllers as they are implemented.

2.1.3.2 Natural gas processing industry segment

Table 2-5 shows the 2014 GHG Inventory's estimates of 2012 methane emissions from pneumatic controllers in the natural gas processing industry segment.

Table 2-5. Estimated 2012 National Methane Emissions from Pneumatic Controllers in the Natural Gas Processing Segment

Activity Factor	CH_4 Potential Emission Factor (scfy/plant)[b]	CH_4 Potential Emissions (MT)	CH_4 Emission Reductions (MT)	Net CH_4 Emissions (MT)
606 gas plants[a]	164,721	1,923	[c]	[c]

[a] *Oil and Gas Journal*, with available 2012 activity data.
[b] 1996 GRI/EPA report.
[c] Although voluntary Natural Gas STAR emission reductions are reported for this industry segment in the aggregate, no value is given specifically for pneumatic controllers.

The basis for the GHG Inventory's potential methane emission factors for pneumatic controllers in the natural gas processing segment is the 1996 GRI/EPA report. This potential emission factor is expressed in terms of standard cubic feet per year per processing plant (scfy/plant). The associated activity factor is the number of U.S. gas plants, which comes from the *Oil and Gas Journal*.

The GHG Inventory does not report emissions reductions specific to pneumatic controllers in this industry segment and, thus, there is no reported net emissions figure.

2.1.3.3 Natural gas transmission and storage segment

Table 2-6 shows the 2014 GHG Inventory's estimates of 2012 methane emissions from pneumatic controllers in the natural gas transmission and storage industry segment.

NMED Exhibit 91

Table 2-6. Estimated 2012 National Methane Emissions from Pneumatic Controllers in the Natural Gas Transmission and Storage Segment

Subsegment	Activity Factor (# of controllers)	CH_4 Potential Emission Factor (scfy/device)	CH_4 Potential Emissions (MT)	CH_4 Emission Reductions (MT)	Net CH_4 Emissions (MT)
Transmission	70,827	162,197[a]	221,257		
Storage	13,542	162,197[a]	42,304		
Total	84,369		263,561	-14,078[b]	249,483

[a] 1996 GRI/EPA report.
[b] Voluntary Natural Gas STAR emission reductions are reported for all pneumatic controllers in this industry segment, not split out by transmission and storage.

The basis for the GHG Inventory's potential methane emission factors for pneumatic controllers in the natural gas transmission and storage segment is the 1996 GRI/EPA report. In this case, the potential emission factor is expressed in terms of scfy/device. The associated activity factor is the number of pneumatic controllers. For transmission, the number of pneumatic controllers is calculated based on transmission pipeline length. For storage, the number of pneumatic controllers is calculated based on number of compressor stations in the storage segment.

The 2014 GHG Inventory includes voluntary emission reductions reported by industry partners to the Natural Gas STAR Program for pneumatic controllers in the natural gas transmission and storage industry segment.

2.1.4 Greenhouse Gas Reporting Program (U.S. EPA, 2013)

In October 2013, the EPA released 2012 GHG data for Petroleum and Natural Gas Systems collected under the Greenhouse Gas Reporting Program (GHGRP). The GHGRP, which was required by Congress in the FY2008 Consolidated Appropriations Act, requires facilities to report data from large emission sources across a range of industry sectors, as well as suppliers of certain GHGs and products that would emit GHGs if released or combusted.

When reviewing this data and comparing it to other data sets or published literature, it is important to understand the GHGRP reporting requirements and the impacts of these requirements on the reported data. The GHGRP covers a subset of national emissions from Petroleum and Natural Gas Systems; a facility in the Petroleum and Natural Gas Systems source category is required to submit annual reports if total emissions are 25,000 MT of CO_2 equivalent (MT CO_2e) or more. Facilities use uniform methods prescribed by the EPA to calculate GHG emissions, such as direct measurement, engineering calculations, or emission factors derived from direct measurement. In some cases, facilities have a choice of calculation methods for an emission source.

The GHGRP addresses petroleum and natural gas systems with implementing regulations at 40 CFR part 98, subpart W. The rules define three segments of the oil and natural gas industry sector that are required to report GHG emissions from pneumatic controllers: (1) onshore petroleum and natural gas production, (2) onshore natural gas transmission compression, and (3) underground natural gas storage. Facilities calculate emissions from pneumatic controllers by determining the number of each type of controller at the facility and applying emission factors. In the petroleum and natural gas production segment, facilities must apply facility-specific gas composition factors for methane and CO_2. In the natural gas transmission and storage segments, default gas composition factors are used. Subpart W emission factors for pneumatic controllers are located at 40 CFR Part 98, subpart W, Table W-1A (Onshore Petroleum and Natural Gas Production), Table W-3 (Onshore Natural Gas Transmission Compression), and Table W-4 (Underground Natural Gas Storage). These emission factors are based on the 2009 document *Compendium of Greenhouse Gas Emissions Methodologies for the Oil and Gas Industry* published by the American Petroleum Institute (API), which in turn is based on the 1996 GRI/EPA report.

Table 2-7 shows the number of reporting facilities[11] in each of the three industry segments, along with reported pneumatic controller methane emissions.

Table 2-7. Facilities and Reported Emissions from Pneumatic Controllers, 2012

Segment	Number of Reporting Facilities	Reported Methane Emissions (MT)[a]
Petroleum and NG Production	417	861,224
Transmission	330	7,582
Storage	38	4,493

[a] The reported methane MT CO2e emissions were converted to methane emissions in MT by dividing by a global warming potential (GWP) of methane (21).

2.1.5 Measurements of Methane Emissions at Natural Gas Production Sites in the United States (Allen et al., 2013)

A study completed by multiple academic institutions and consulting firms was conducted to gather methane emissions data at onshore natural gas sites in the U.S. and compare those emission estimates to the 2011 estimates reported in the 2013 GHG Inventory. The sources or operations tested included 305 pneumatic controllers located at 150 distinct natural gas production sites in four production regions (Appalachian, Gulf Coast, Midcontinent, and Rocky Mountain).

Testing was carried out using a Hi-Flow Sampler, which is a portable, battery-powered instrument designed to determine the rate of gas leakage around various pipe fittings, valve packings and compressor seals found in natural gas production, transmission, storage and processing facilities. To allow the quantity of methane to be separated out from other chemical

[11] In general, a "facility" for purposes of the GHGRP means all co-located emission sources that are commonly owned or operated. However, the GHGRP has developed a specialized facility definition for onshore production. For onshore production, the "facility" includes all emissions associated with wells owned or operated by a single company in a specific hydrocarbon-producing basin (as defined by the geologic provinces published by the American Association of Petroleum Geologists).

species, gas composition data were collected for each natural gas production site, typically provided by the site owner. The 305 sampled pneumatic controllers represented an estimated 41% of all the controllers associated with the wells that were sampled. The sampling time for each controller was not specified in the study. Table 2-8 shows the emission rates determined by the testing.

Table 2-8. Pneumatic Controller Methane Emission Rates Reported in the Allen Study

	Methane Emissions per Pneumatic Controller				
	Appalachian	Gulf Coast	Midcontinent	Rocky Mtn.	Total
Number sampled[a]	133	106	51	15	305
Emissions rate (scf methane/min/device)[b]	0.126 ± 0.043	0.268 ± 0.068	0.157 ± 0.083	0.015 ± 0.016	0.175 ± 0.034
Emissions rate (scf whole gas/min/device, based on site-specific gas composition)[b]	0.130 ± 0.044	0.289 ± 0.071	0.172 ± 0.086	0.021 ± 0.022	0.187 ± 0.036

[a] Intermittent and low bleed controllers are included in the total; no high bleed controllers were reported by companies providing controller type information

[b] Uncertainty characterizes the variability in the mean of the data set, rather than an instrumental uncertainty in a single measurement

The Allen study reports that the average whole gas emission rate was 11.2 scfh per pneumatic controller for the tested population, which consisted of a mix of intermittent and low bleed controllers. No high bleed controllers were reported by the companies that provided controller type information. The study also reports whole gas emission factors of 5.1 scfh for low bleed controllers and 17.4 scfh for intermittent controllers. These emission factors are based on measured emissions at the 24 sites where the site operators reported only low bleed controllers and the 55 sites reporting only intermittent controllers, where potential misidentification of controller type is less likely to be a confounding factor.

The study notes that there is significant geographical variability in the emissions rate from pneumatic controllers between production regions. Emissions per controller from the Gulf Coast are highest and are statistically different than emissions from controllers in the Rocky Mountain and Appalachian regions. The difference in average values is more than a factor of 10

between Rocky Mountain and Gulf Coast regions. The study provided the following discussion of these differences:

> Some of the regional differences in emissions may be explained by differences in practices for utilizing low bleed and intermittent controllers. For example, new controllers installed after February 1, 2009 in regions in Colorado that do not meet ozone standards, where most of the Rocky Mountain controllers were sampled, are required to be low bleed (or equivalent) where technically feasible (Colorado Air Regulation XVIII.C.1; XVIII.C.2; technical feasibility criterion under review as this is being written). However, observed differences in emission rates between intermittent and low bleed devices (roughly a factor of 3) are not sufficient to explain all of the regional differences. A number of additional hypotheses were examined to attempt to explain the differences in emissions. For datasets consisting entirely of intermittent or entirely of low-bleed devices, the volume of oil produced was not a good predictor of emissions. Wellhead and separator pressure were also not good predictors of emissions. The definition of low-bleed controllers may be [an] issue, however. All low bleed devices are required to have emissions below 6 scf/hr (0.1 scf/m), but there is not currently a clear definition of which specific controller designs should be classified as low bleed and reporting practices among companies can vary. Other possibilities for explaining the low-bleed emission rates observed in this work, that have not yet been investigated, but that may be pursued in follow-up work, include operating practices for the use of the controllers.

The study estimated 2011 national methane emissions from pneumatic controllers in the natural gas production industry segment at 570,000 MT (with a range of 510,000 – 812,000 MT based on the 95% confidence bounds of the emission factor) using the same number of controllers (447,379) used in the 2013 GHG Inventory for 2011. This estimate was computed using a regionally weighted emission factor of 67,400 scfy methane/device.

2.1.6 Determining Bleed Rates for Pneumatic Devices in British Columbia (Prasino Group 2013)

A study completed by the Prasino Group was conducted to determine the average bleed rate of pneumatic controllers when operating under field conditions in British Columbia (BC). Bleed rates were sampled from pneumatic controllers using a positive displacement bellows meter at upstream oil and gas facilities across a variety of producing fields in the Fort St. John, BC and surrounding areas. For this study, bleed rate was defined as "the amount of fuel gas released to the atmosphere per hour," including both continuous bleed (where applicable) and emissions during activation. The study centered on high bleed controllers, including both continuous bleed and intermittent controllers with emissions greater than 0.17 cubic meters per hour ($m^{3/}$hr) (e.g, > 6 scfh).[12] The study aimed to identify the most common high bleed pneumatic controllers in the field and test emissions from at least 30 units of each model. In identifying controllers to test, the study used a manufacturer-supplied emission rate of 0.119 m^3/hr as a cutoff to explore whether some models identified by manufacturers as low bleed perform at that level in the field.

Field measurements were carried out with a Calscan Hawk 9000 Vent Gas Meter, which uses a positive displacement diaphragm meter that detects flow rates down to zero, and can also effectively measure any type of vent gas (methane, air, or propane). (A few sampled devices ran on air at large sites using compressed air, or propane at sour sites using compressed propane; such samples were corrected using a density ratio to equivalent natural gas emissions rates.) This device uses "a precision pressure sensor, an external temperature probe, and industry standard gas flow measurement algorithms to accurately measure the gas rates and correct for pressure and temperature differences." The report notes that metering a device can affect the operation of the device when hooked up due to back pressure, adding that it is possible that certain controllers did not produce enough pressure when hooked up to overcome the back pressure, resulting in a

[12] This definition of "high bleed" is slightly different than the definition presented in Section 1.1.1 of this paper, because "intermittent bleed controllers" are included as "high bleed controllers" if their emissions are above the specified threshold. The definition presented in Section 1.1.1 places "intermittent bleed controllers" in their own category.

zero reading. The sample time for each controller was 30 minutes, so there was variability in the number of actuation events captured for each controller depending on operating conditions.

In addition to emission factors for individual models of pneumatic controllers, the study generated emission factors for "generic high bleed controllers" and "generic high bleed intermittent controllers." The study also included a regression analysis of the relationship between bleed rate and the pressure of the supply gas routed to the controller. Based on the analysis, the study found that the positive relationship between these parameters was strong enough to recommend use of a supply pressure coefficient to calculate the bleed rate for several controller models and for generic controllers. The generic emission factors and supply pressure coefficients are shown in Table 2-9.

Table 2-9. Generic Natural Gas Emission Factors and Supply Pressure Coefficients for High Bleed Pneumatic Controllers

Type of Pneumatic Controller	Average Bleed Rate (m^3/hr)[a]	Average Bleed Rate (scfh)[b]	Coefficient Related to Supply Pressure[c]
Generic High Bleed Controller	0.2605	9.199	0.0012
Generic High Bleed Intermittent Controller	0.2476	8.744	0.0012

[a] "Bleed rate" defined to include actuation emissions as well as continuous bleed.
[b] Calculated.
[c] Supply pressure apparently in kPa, although not clearly stated in the report.

Based on what it termed a "positive correlation," the Prasino study recommended the use of the supply pressure coefficients above for calculating emission rates for generic high bleed controllers and generic high bleed intermittent controllers. It should be noted that the coefficients of determination (R^2 values) for these supply pressure coefficients are 0.41 and 0.35 for high bleed and high bleed intermittent controllers, respectively.

2.1.7 Air Pollutant Emissions from the Development, Production, and Processing of Marcellus Shale Natural Gas (Roy et al., 2014)

A study by the Center for Atmospheric Particle Studies at Carnegie Mellon University was conducted to develop an emission inventory for the development, production, and processing of natural gas in the Marcellus Shale region for 2009 and 2020. (Note: The focus of this white paper is current emissions, therefore, the 2020 projections are not discussed further.) The inventory includes estimates for emissions of nitrogen oxides, VOC, and particulate matter less than 2.5 micrometers in diameter from major activities, including VOC emissions from pneumatic controllers associated with "wet" and "dry" gas wells. The study estimated VOC emissions from pneumatic controllers associated with Marcellus Shale natural gas wells to be on the order of 10 tons/day in 2009.

This study developed these emissions estimates by estimating the number of wet and dry wells in the region and establishing per-well emission factors for 2009. The per-well emission factors are shown in Table 2-10.

Table 2-10. Per-Well VOC Emissions from Pneumatic Controllers in 2009 (95% confidence interval)

Type of Well	VOC Emissions, 2009 (tons/producing well)
Dry Gas	0.5 (0.08 – 0.8)
Wet Gas	3.5 (2.4 – 4.4)

The per-well emission factors were based on assumptions regarding the type, number, and emission factors for pneumatic controllers associated with each natural gas well, which were drawn primarily from a 2008 ENVIRON report.[13] Table 2-11 shows these assumptions.

[13] Bar-Ilan, Amnon et al., ENVIRON International Corporation. *Recommendations for Improvement to the CENRAP States' Oil and Gas Emissions Inventories*. Prepared for the Central States Regional Air Partnership. November 13, 2008. This report also includes emission factors for positioners (15.2 scfh) and transducers

Table 2-11. Assumed Type, Number, and Emission Factors for Pneumatic Controllers Associated with Each Natural Gas Well

Type of Device	Number of Controllers	Emission Factor (scfh)[a]
Liquid Level Controller	2	31 (2009)
Pressure Controller	1	17 (2009)

[a] 2009 emission factors are from the 2008 ENVIRON report.

The emission factors from this study and the ENVIRON report are not comparable to the emission factors discussed above because they are provided for different classifications of pneumatic controllers. In addition, these emission factors differ from those discussed previously in that they are based on bleed rates provided by manufacturers rather than measured emissions.

2.1.8 Economic Analysis of Methane Emission Reduction Opportunities in the U.S. Onshore Oil and Natural Gas Industries (ICF, 2014)

The Environmental Defense Fund (EDF) commissioned ICF International (ICF) to conduct an economic analysis of methane emission reduction opportunities from the oil and natural gas industry to identify the most cost-effective approach to reduce methane emissions from the industry. The study projects the estimated growth of methane emissions through 2018 and focuses its analysis on 22 methane emission sources in the oil and natural gas industry (referred to as the targeted emission sources). These targeted emission sources represent 80% of their projected 2018 methane emissions from onshore oil and gas industry sources. Pneumatic devices are several of the 22 emission sources that are included in the study and include: high bleed pneumatic controllers, intermittent bleed pneumatic controllers, Kimray pumps, intermittent bleed pneumatic controllers – dump valves, and chemical injection pumps. The

(13.6 scfh). The emission factors in the report "were obtained from data gathered as part of the EPA's Natural Gas STAR program." Examination of Natural Gas STAR program materials clearly shows that these emission factors were derived from the manufacturer-supplied natural gas bleed rates for high bleed pneumatic controllers listed in Appendix A to *Options for Reducing Methane Emissions from Pneumatic Devices in the Natural Gas Industry*. The ENVIRON report also includes the number of controllers of each type associated with each gas well, said to be drawn from survey data in the CENRAP states. The numbers for liquid level controllers and pressure controllers are reflected in Table 2-15; the report found zero positioners and transducers per well.

methodology that was used for this analysis is based on the 2013 GHG Inventory and uses data from the GHGRP and the University of Texas/EDF gas production measurement study (Allen et al., 2013).

The study relied on the 2013 GHG Inventory for 1990-2011 for methane emissions data for the oil and natural gas sector. These emissions data were revised to include updated information from the GHG Inventory and the *Measurements of Methane Emissions at Natural Gas Production Sites in the United States* study (Allen et al., 2013). The revised 2011 baseline methane emissions estimate was used as the basis for projecting onshore methane emissions to 2018. (Note: The focus of this white paper is current emissions, therefore, the 2018 projections are not discussed further.)

The study used the 2013 GHG Inventory estimates for 2011 to develop new activity and emission factors for pneumatic controllers. The count of pneumatic controllers was calculated using the well counts and assuming 0.94 pneumatic controllers per well. The study did find that there are an additional 8.6 pneumatic controllers per gathering/boosting station that were not accounted for in the 2013 GHG Inventory. The study also used emission factors from subpart W, which reported pneumatic controllers in three categories: low bleed, intermittent bleed and high bleed controllers. To break out the number of pneumatic controllers in each of these categories, the emission data from subpart W were analyzed, and the study determined that the percentage of pneumatic controllers were 10% high bleed, 50% intermittent bleed and 40% low bleed. These percentages were applied to the pneumatic controller counts and the respective emission factor was used to calculate the emissions from these controllers. Intermittent pneumatic controllers were further segregated into two categories: dump valves and non-dump valve intermittent controllers. The dump valves represent intermittent controllers that do not continuously bleed and only emit during actuation. The study estimated that 75% of the total intermittent pneumatic controllers were dump valves. Based on the subpart W data and the assumptions above, the study used the following emission factors for each of the controllers: 320 Mcf/yr/device for high bleed, 120 Mcf/yr/device for non-dump intermittent, 20 Mcf/yr/device for dump intermittent and 11 Mcf/yr/device for low bleed pneumatic controllers. Using these factors, the study estimated an

NMED Exhibit 91

increase of 41% (26 Bcf or 491,000 MT) in methane emissions in comparison to the 2013 GHG Inventory.

Further information included in this study on the replacement of high bleed and intermittent bleed pneumatic controllers with low bleed pneumatic controllers, and the replacement of pneumatic pumps with electric pumps as mitigation or emission reduction techniques, methane control costs, and their estimates for the potential for VOC emissions co-control benefits from the replacement of these pneumatic controllers are presented in Section 3 of this document.

2.2 Discussion of Data Sources for Pneumatic Pumps

Many of the data sources for pneumatic pumps are the same as those for pneumatic controllers, therefore, the overall descriptions of these data sources are not repeated in this section and only the information relevant to pneumatic pumps is discussed.

2.2.1 Methane Emissions from the Natural Gas Industry (GRI/EPA, 1996c) (GRI/EPA, 1996e)

The methane emission estimates for pneumatic pumps are separated into two categories for the GRI/EPA reports; chemical injection pumps (GRI/EPA, 1996d) and gas-assisted glycol pumps (GRI/EPA, 1996f). A summary of each of these reports and the methane calculation methodologies are provided in the following sections.

2.2.1.1 Methane Emissions from the Natural Gas Industry – Chemical Injection Pumps (GRI/EPA, 1996c)

This report estimates emissions from two types of pumps that the oil and natural gas industry uses for chemical injection into process streams: piston pumps and diaphragm pumps. Four sources of information were used to develop an emission factor for chemical injection

pumps: a study by the CPA[14], data collected from site visits, literature data for methane composition, and data from pump manufacturers.

The CPA study provided natural gas emissions from five diaphragm chemical injection pumps using the "bagging" method. This method involves enclosing the pump and measuring the flow rate and concentration of the natural gas emissions from the pump. The measurements from this study reported natural gas emissions ranging from 254 to 499 standard cubic feet per day per pump (scfd/pump) with an average of 334 scfd/pump.

Data from site visits included: the total number of chemical injection pumps for a particular site, number of chemical injection pumps used in natural gas production, the energy source for the pump (e.g., natural gas, instrument air, electricity), frequency of operation (e.g., pumping rate in strokes per minute), number of pumps that are active or idle, pump operation schedule, size of the unit (e.g., volume displacement of the motive chamber), manufacturer and model number of the pump, and supply gas pressure. Table 2-12 provides a summary of the site visit data. The methane emission factor in Table 2-12 was calculated using a methane composition of 78.8% (GRI/EPA, 1996d).

Table 2-12. Summary of Chemical Injection Pump Site Visit Data

Chemical Injection Pump Data	All Data		Natural Gas Industry Data	
	Piston Pumps	Diaphragm Pumps	Piston Pumps	Diaphragm Pumps
Percent of Total Pumps	49.8 ± 38%	50.2 ± 38%	4.5 ± 678%	95.5 ± 32%
Pump Actuation Rate (strokes/min)	26.32 ± 29%	13.64 ± 49%	3.57 ± 42%	14.75 ± 61%
Number of Pump Actuation Measurements	32	8	15	5
Number of Sites with	7	5	2	4

[14] Canadian Petroleum Association. A Detailed Inventory of CH_4 and VOC Emissions from Upstream Oil and Gas Operations in Alberta, March 1992.

NMED Exhibit 91

Chemical Injection Pump Data	All Data		Natural Gas Industry Data	
	Piston Pumps	Diaphragm Pumps	Piston Pumps	Diaphragm Pumps
Pump Actuation Measurements				
Percent of Pumps Operating	44.6 ± 62%	40.0 ± 52%	77.5 ± 148%	58.0 ± 39%
Number of Sites with Pumps Operating	7	10	4	6
Methane Emissions Factor (scfd/pump)	248 ± 83%		668 ± 88%	

Manufacturers' data and the CPA data were used to determine the volume of gas released per pump stroke. This was done by using the natural gas usage data (amount of natural gas required to pump one gallon of liquid), stroke length, and stoke diameter to calculate volume of natural gas per pump stoke. For diaphragm pumps, the average natural gas usage was calculated to be 0.0719 standard cubic feet per stroke (scf/stroke). The piston pump average natural gas usage was calculated to be 0.0037 scf/stroke. These averages were then used to determine the emission factor for each of the pump types by multiplying the average frequency (strokes per day) by the operating time percentage. Note that the report uses the "all data" frequency and operating percentage to calculate the emission factor for each type of pump. The emission factor for diaphragm pumps was calculated to be 446 scfd/pump and the emission factor for piston pumps was calculated to be 48.9 scfd/pump.

The percentage of piston and diaphragm pumps and their respective emission factors were then used to calculate an average emission factor for chemical injection pumps. The average emission factor was determined to be 248 scfd/pump. The 1992 national emissions were then calculated using the average chemical injection pump emission factor (248 scfd/pump) and the activity factor for chemical injection pumps of 16,971 (GRI/EPA, 1996a). The resulting 1992 national emissions from chemical injection pumps for the natural gas production segment was calculated to be 1,536 MMscf/yr (29,008 MT).

2.2.1.2 Methane Emissions from the Natural Gas Industry – Gas-Assisted Glycol Pumps (GRI/EPA, 1996e)

For many glycol dehydrators in the natural gas industry, small gas-assisted pumps are used to circulate the glycol. These pumps use energy from the high-pressure rich glycol/gas mixture leaving the absorber to pump the low-pressure lean glycol back to the absorber. Natural gas is entrained in the rich glycol stream feeding the pump and is discharged from the pump at a lower pressure to the regenerator. If the glycol unit has a flash tank, most of the natural gas in the low-pressure stream can be recovered and used as a fuel or stripping gas. If the natural gas from the pump is used as a stripping gas, or if there is no flash tank, all of the pump exhaust gas will be vented through the regenerator's atmospheric vent stack (GRI/EPA, 1996e).

Methane emissions from these gas-assisted pumps were calculated using technical information from Kimray, a manufacturer of gas-assisted pumps. No direct measurements of pump gas usage were used in the calculations. Kimray reported that the natural gas usage ranges from 0.081 actual cubic feet per gallon of glycol pumped (acf/gal) for high-pressure pumps (>400 psig) to 0.130 acf/gal for low-pressure pumps (< 400 psig). These values convert to 3.73 standard cubic feet per gallon (scf/gal) at an operating pressure of 800 psig and 83 mole percent methane for high-pressure pumps and 2.31 scf/gal at an operating pressure of 300 psig and 83 mole percent methane for low-pressure pumps.

The gas usage rates were then converted to an amount of natural gas treated by assuming a typical high-pressure dehydrator would remove 53 pounds of water per million cubic feet of gas (lbs/MMscf), and a typical low-pressure dehydrator would remove 127 lbs/MMscf. The design glycol-to-gas ratio was assumed to be three gallons of glycol per pound of water removed and an overcirculation ratio of 2.1 was used to determine the emission factors for the pumps for the natural gas production segment. Using these factors and the fraction of dehydrators without flash tanks (0.735) and the fraction of dehydrators without combustion vent controls (0.988), the emission factor for the gas-assisted pumps in the natural gas production segment were calculated to be 904.5 standard cubic feet of methane per million standard cubic feet of natural gas treated (scf/MMscf) for high-pressure pumps, and 1342.2 scf/MMscf for low-pressure pumps. The final

emission factor for methane from an average gas-assisted glycol pump was determined assuming that 80% of these pumps are high-pressure and 20% are low-pressure. The average emission factor was calculated to be 992.0 scf/MMscf and was used to estimate methane emissions from the natural gas production segment.

For natural gas processing, the study assumed that only high-pressure gas-assisted glycol pumps are used. The emission factor was calculated using the high-pressure pump gas usage (3.73 scf/gal), the design glycol-to-gas ratio (3 gal glycol/lb water), the water removal rate for a high-pressure system (53 lbs/MMcsf), an overcirculation ratio of 1.0, the fraction of dehydrators without flash tanks (0.333) and the fraction of dehydrators without combustion vent controls (0.900). These values were used to calculate a methane emission factor of 177.8 scf/MMscf for gas-assisted pumps for the natural gas processing segment. The natural gas transmission and storage segments do not use gas-assisted glycol pumps.

The 1992 national methane emissions were calculated using data from site surveys to determine the natural gas throughput of dehydrators with gas-assisted pumps. The natural gas throughput of dehydrators with gas-assisted pumps was estimated to be 11.1 trillion standard cubic feet per year (Tscf/yr) for the natural gas production segment and 0.958 Tscf/yr for the natural gas processing segment. The 1992 national methane emissions from gas-assisted pumps were calculated to be 10,962 MMscf/yr (206,989 MT) for the natural gas production segment and 170 MMscf/yr (3,215 MT) for the natural gas processing segment.

2.2.2 Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2012 (U.S. EPA, 2014)

Table 2-13 summarizes the 2014 GHG Inventory estimates of 2012 national methane emissions from pneumatic pumps in the natural gas production and processing segments. (Note: The GHG inventory does not include estimates of emissions from pneumatic pumps in the natural gas transmission and storage segments.) The pneumatic pumps described in the GHG Inventory include: chemical injection pumps and Kimray pumps. The table includes potential emissions, emission reductions and net emissions. For pneumatic pumps, the emission reductions

NMED Exhibit 91

in this report are voluntary reductions through the Natural Gas STAR program. In future years, the GHG Inventory will also account for regulatory reductions that result from subpart OOOO.

Table 2-13. Summary of GHG Inventory 2012 Nationwide Emissions from Pneumatic Pumps

Industry Segment	Potential CH_4 Emissions (MT)	CH_4 Emission Reductions (MT)	Net CH_4 Emissions (MT)
Natural gas production	455,719	2,771	452,948
Petroleum Production	49,973	N/A	
Natural gas processing	5,011	N/A	

The 2014 GHG Inventory data estimates that pneumatic pump emissions are around 16% of overall methane emissions from the natural gas production and processing sectors.

Tables 2-14 and 2-15 show the 2014 GHG Inventory's estimates of 2012 methane emissions from chemical injection pumps and gas-assisted pumps (Kimray pumps) in the natural gas and petroleum production and processing industry segments. The tables present population of chemical injection and Kimray pumps, methane emission factors and potential methane emissions from these devices in each of the EIA's NEMS regions, and the estimated national total of chemical injection pumps, Kimray pumps and potential methane emissions. The activity factors for chemical injection pumps are based on the estimated count of chemical injection pumps in operation. For the production sector, a regional factor for pumps per well (ranging from 0.01 to 0.68) is applied to annual regional well counts to calculate chemical injection pumps each year for natural gas, and for petroleum systems it is estimated that around 20% of wells have pumps (based on 1996 GRI/EPA) and that 25% of pumps use gas. For the production sector, the activity factors for Kimray pumps are based on the total throughput of natural gas multiplied by the fraction of dehydrators using gas-driven pumps (0.9 for the production segment). For the processing segment, the activity factor for Kimray pumps is based the total processing plant throughput multiplied by the fraction of natural gas treated by dehydrators at

NMED Exhibit 91

gas plants (0.5) and then multiplied by the fraction of dehydrators that use a gas-driven pump (0.1 for the processing segment).

Table 2-14. Estimated 2012 National and Regional Methane Emissions from Chemical Injection Pumps in the Natural Gas Production Segment

[a] 1996 GRI/EPA report, extrapolated using ratios relating other factors for which activity data are available.
Note: The GHG Inventory did not list any Kimray pumps in the natural gas transmission or distribution sectors.

The basis for the GHG Inventory's potential methane emission factors for pneumatic pumps in the natural gas production and processing segments is the 1996 GRI/EPA report.

The region-specific factors used in the production segment are developed using the GRI/EPA factor and regional gas composition data.

2.2.3 Greenhouse Gas Reporting Program (U.S. EPA, 2013)

The GHGRP addresses petroleum and natural gas systems with implementing regulations at 40 CFR part 98, subpart W. The rule requires facilities in the onshore petroleum and natural gas production segment to report GHG emissions from pneumatic pumps. Facilities calculate emissions from pneumatic pumps by determining the number of pneumatic pumps at the facility and applying an emission factor of 13.3 scf/hour/pump. Facilities also apply a facility-specific gas composition factor for calculating emissions. For 2012, 343 facilities in the onshore petroleum and natural gas production industry segment reported emissions from pneumatic pumps, with total methane emissions of 135,227 metric tons.

2.2.4 Determining Bleed Rates for Pneumatic Devices in British Columbia (Prasino Group 2013)

The study used data from the Canadian Association of Petroleum Producers (2008), Pacific Carbon Trust (2011), Cap-Op Energy's Distributed Energy Efficiency Project Platform (DEEPP) database to compile a list of pneumatic pumps. The study notes that the total number of pneumatic pumps is unknown and the list only comprises a subset of the total population. In total, 184 samples were taken from chemical injection pumps. From the data collected, the study determined the average bleed rate for a piston-type pneumatic pumps to be 0.5917 m^3/hr

(approximately 20.9 scfh). For diaphragm-type pneumatic pumps, the bleed rate was calculated to be 1.0542 m^3/hr (approximately 37.2 scfh).

2.2.5 Economic Analysis of Methane Emission Reduction Opportunities in the U.S. Onshore Oil and Natural Gas Industries (ICF, 2014)

The analysis developed by ICF includes an inventory of methane emissions for 2011 using data from the 2013 GHG Inventory and the GHGRP (U.S. EPA, 2013), in addition to data from the EIA and GRI.

For pneumatic chemical injection pumps in the natural gas production segment, the 2011 ICF inventory updated the count of chemical injection pumps to reflect changes made to the well counts and applied the Natural Gas STAR estimated reductions associated with pneumatic pumps. These changes resulted in a 2011 methane estimate of 3 Bcf (56,600 MT) from chemical injection pumps in the natural production segment. Kimray pumps (gas-assisted glycol pumps) were estimated to be 17 Bcf (321,000 MT).

3.0 AVAILABLE PNEUMATIC DEVICE EMISSIONS MITIGATION TECHNIQUES

The following sections describe the different available emissions mitigations techniques that the EPA is aware of for pneumatic controllers and pneumatic pumps. The primary sources of information for mitigations techniques was the EPA's Natural Gas STAR Lessons Learned documents and the ICF economic analysis (ICF, 2014).

3.1 Available Pneumatic Controller Emissions Mitigation Techniques

Several techniques to reduce emissions from pneumatic controllers have been developed over the years. Table 3-1 provides a summary of these techniques for reducing emissions from pneumatic controllers including replacing high bleed controllers with low bleed or zero bleed

models, driving controllers with instrument air rather than natural gas, using non-gas-driven controllers, and enhanced maintenance.

Table 3-1. Summary of Alternative Mitigation Techniques for Pneumatic Controllers

Option	Description	Applicability	Costs	Efficacy and Prevalence
Install Zero Bleed Controller in Place of Continuous Bleed Controller (U.S. EPA, 2011a, GE Energy Services, 2012)	Zero bleed controllers are self-contained natural gas-driven devices that vent to the downstream pipeline, not the atmosphere. Provide the same functional control as continuous bleed controllers, where applicable (U.S. EPA, 2011a, GE Energy Services, 2012).	Applicable only for relatively low-pressure control valves, e.g., in gathering, metering and regulation stations, power plant and industrial feed, and city gate stations/distribution applications (U.S. EPA, 2011a).	The EPA does not have cost information on this technology.	100% emission reduction, where applicable. The EPA does not have information on the prevalence of this technology in the field, however, it is the EPA's understanding that applicability is limited.
Install Low Bleed Controller in Place of High Bleed Controller (U.S. EPA, 2006b)	Low bleed controllers provide the same functional control as a high bleed devices, while emitting less continuous bleed emissions (U.S. EPA, 2006b).	Applicability depends on the function of instrumentation for an individual device and whether the device is a level, pressure, or temperature controller. Not recommended for control of very large valves that require fast and/or precise response to process changes. These are found most frequently on large compressor discharge and bypass pressure controllers (U.S. EPA, 2006b).	Based on information from Natural Gas STAR (U.S. EPA, 2006b) and supplemental research conducted for subpart OOOO, low bleed devices cost, on average, around $165 more than high bleed versions. ICF report assumed a cost of $3,000 per replacement based on industry comments (ICF, 2014).	Estimated average reductions (U.S. EPA, 2011a): *Production segment:* 6.6 tpy methane *Transmission:* 3.7 tpy methane The EPA does not have information on the prevalence of this technology in the field.

NMED Exhibit 91

Table 3-1. Summary of Alternative Mitigation Techniques for Pneumatic Controllers

Option	Description	Applicability	Costs	Efficacy and Prevalence
Convert to Instrument Air (U.S. EPA, 2006c)	Compressed air may be substituted for natural gas in pneumatic systems without altering any of the parts of the pneumatic control. In this type of system, atmospheric air is compressed, stored in a tank, filtered and then dried for instrument use. Instrument air conversion requires additional equipment to properly compress and control the pressured air. This equipment includes a compressor, power source, air dehydrator and air storage vessel (U.S. EPA, 2006c).	Most applicable at facilities where there are a high concentration of pneumatic control valves and an operator present. Because the systems are powered by electric compressors, they require a constant source of electrical power or a backup natural gas pneumatic device (U.S. EPA, 2006c).	System costs are dependent on size of compressor, power supply needs, labor and other equipment (U.S. EPA, 2006c). A cost analysis is provided in Section 3.1.3 below.	100% emission reduction, where applicable. There are secondary emissions associated with electrical power generation. The EPA does not have information on the prevalence of this technology in the field.
Mechanical and Solar-Powered Systems in Place of Bleed Controller (U.S. EPA, 2006a, U.S. EPA, 2006b)	Mechanical controls operate using a simple design comprised of levers, hand wheels, springs and flow channels. The most common mechanical control device is the liquid-level float to the drain valve position with mechanical linkages. Electricity or small electrical motors (including solar-powered) have been used to operate valves. Solar control systems are driven by solar power cells that actuate mechanical devices using electric power. As such, solar cells require some type of backup power or storage to ensure reliability (U.S. EPA, 2006a).	Application of mechanical controls is limited because the control must be located in close proximity to the process measurement. Mechanical systems are also incapable of handling larger flow fluctuations. Electric-powered valves are only reliable with a constant supply of electricity (U.S. EPA, 2006a).	Depending on supply of power, costs can range from below $1,000 to $10,000 for entire systems (U.S. EPA, 2006a).	100% emission reduction, where applicable. The EPA does not have information on the prevalence of this technology in the field.

NMED Exhibit 91

Table 3-1. Summary of Alternative Mitigation Techniques for Pneumatic Controllers

Option	Description	Applicability	Costs	Efficacy and Prevalence
Enhanced Maintenance (U.S. EPA, 2006a)	Instrumentation in poor condition typically bleeds 5 to 10 scfh more than representative conditions due to worn seals, gaskets, diaphragms; nozzle corrosion or wear; or loose control tube fittings. This may not impact operations but does increase emissions. Proper methods of maintaining a device are highly variable (U.S. EPA, 2006a).	Enhanced maintenance to repair and maintain pneumatic controllers periodically can reduce emissions at many controllers (U.S. EPA, 2006a).	Variable based on labor, time, and fuel required to travel to many remote locations.	Natural gas emission reductions of 5 to 10 scfh (U.S. EPA, 2006a). The EPA does not have information on the prevalence of this practice in the field.

NMED Exhibit 91

The mitigation techniques summarized in Table 3-1 are discussed in more detail in the following sections.

3.1.1 Zero Bleed Pneumatic Controllers

Zero bleed pneumatic controllers are self-contained, "closed loop" natural gas-driven controllers that vent to the downstream pipeline rather than to the atmosphere (U.S. EPA, 2011a). These closed loop devices are considered to emit no natural gas to the atmosphere. However, they can be used only in applications with very low pressure and, therefore, may not be suitable to replace continuous bleed pneumatic controllers in many applications. Some applications where they may suitable include gathering, metering and regulation stations, power plant and industrial feed, and city gate stations/distribution (U.S. EPA, 2011a). To date, the EPA has not obtained any information on the cost of zero bleed controllers or their prevalence in the field.

3.1.2 Low Bleed Pneumatic Controllers

Description

Low bleed controllers provide similar functional control as high bleed controllers, but have lower continuous bleed emissions. It has been estimated on average that 6.6 tons of methane and 1.8 tons of VOC will be reduced annually in the production segment from installing a low bleed device in place of a high bleed device (U.S. EPA, 2011a). In the transmission segment, the average achievable reductions per device are estimated around 3.7 tons and 0.08 tons for methane and VOC, respectively (U.S. EPA, 2011a). As defined in this white paper, a low bleed controller can emit up to 6 scfh, but this is higher than the expected emissions from the typical low bleed controllers available on the current market.

NMED Exhibit 91

Applicability

There are certain situations in which replacing and retrofitting are not feasible, such as instances where a minimal response time is needed, cases where large valves require a high bleed rate to actuate, or a safety isolation valve is involved.

Replacing high bleed pneumatic with low bleed controllers is infeasible in situations where a process condition may require a fast or precise control response so that it does not stray too far from the desired set point (U.S. EPA, 2011a). A slower-acting controller could potentially result in damage to equipment and/or become a safety issue. An example of this is on a compressor where pneumatic controllers monitor the suction and discharge pressure and actuate a recycle when one or the other is out of the specified target range. Another scenario where fast and precise control is necessary includes transient (non-steady) situations where a gas flow rate may fluctuate widely or unpredictably (U.S. EPA, 2011a). In this case, a responsive high bleed device may be required to ensure that the gas flow can be controlled in all situations. Temperature and level controllers are typically present in control situations that are not prone to fluctuate as widely or where the fluctuation can be readily and safely accommodated by the equipment. Therefore, such processes may be appropriate for control from a low bleed device, which is slower acting and less precise.

Safety concerns can limit the appropriateness of low bleed controllers in specific situations where any amount of bleeding is unacceptable. Emergency valves are often not controlled with bleeding controllers (e.g., neither low bleed nor high bleed), because it may not be acceptable to have any amount of bleeding in emergency situations (U.S. EPA, 2011a). Pneumatic controllers are designed for process control during normal operations and to keep the process in a normal operating state. If an Emergency Shut Down (ESD) or Pressure Relief Valve (PRV) actuation occurs,[15] the equipment in place for such an event is spring-loaded, or otherwise not pneumatically powered. During a safety issue or emergency, it is possible that the pneumatic

[15] ESD valves either close or open in an emergency depending on the fail safe configuration. PRVs always open in an emergency.

NMED Exhibit 91

gas supply will be lost. For this reason, control valves are deliberately selected to either fail open or fail closed, depending on which option is the failsafe.

Costs

The costs described in this section are based on vendor research and information given in the appendices of the Natural Gas STAR Lessons Learned document on pneumatic controllers (U.S. EPA, 2006a). As Table 3-2 indicates, the average cost for a low bleed pneumatic is $2,553, while the average cost for a high bleed is $2,338.[16] Thus, the incremental cost of installing a low bleed device instead of a high bleed device is on the order of $165 per device. (Note: The ICF report assumed a cost of $3,000 to replace an existing high bleed pneumatic controller with a low bleed pneumatic controller based on industry comments (ICF, 2014).)

Table 3-2. Cost Projections for the Representative Pneumatic Controllers[a]

Device	Minimum cost ($)	Maximum cost ($)	Average cost ($)	Low Bleed Incremental Cost ($)
High bleed controller	366	7,000	2,388	$165
Low bleed controller	524	8,852	2,553	

[a] Major pneumatic controllers vendors were surveyed for costs, emission rates and any other pertinent information that would give an accurate picture of the present industry.

Monetary savings associated with additional gas captured to the sales line were estimated based on a natural gas value of $4.00 per Mcf (U.S. EIA, 2010).[17] The representative low bleed device is estimated to emit 6.65 tons, or 319 Mcf, (using the conversion factor of 0.0208 tons methane per 1 Mcf) of methane less than the average high bleed device per year. Assuming production quality gas is 82.8% methane by volume, this equals 385.5 Mcf natural gas recovered

[16] Costs are estimated in 2008 U.S. Dollars.

[17] The average market price for natural gas in 2010 was approximately $4.16 per Mcf. This is much less compared to the average price in 2008 of $7.96 per Mcf. Due to the volatility in the value, a conservative savings of $4.00 per Mcf estimate was projected for the analysis in order to not overstate savings.

per year (EC/R, 2011). Therefore, the value of recovered natural gas from one pneumatic controller in the production segment equates to approximately $1,500. While the owner of the transmission system is generally not the owner of the natural gas, the potentially lost gas still has value. The total value of the recovered gas from one pneumatic controller in the transmission segment is $1,375 assuming a natural gas value of $4.00 per Mscf and transmission natural gas is 92.8% methane by volume (EC/R, 2011).

3.1.3 Instrument Air Systems

Description

The major components of an instrument air conversion project include the compressor, power source, dehydrator, and volume tank. The following is a description of each component as described in the Natural Gas STAR document (U.S. EPA, 2006c), *Lessons Learned: Convert Gas Pneumatic Controls to Instrument Air:*

- Compressors used for instrument air delivery are available in various types and sizes, from centrifugal (rotary screw) compressors to reciprocating piston (positive displacement) types. The size of the compressor depends on the size of the facility, the number of control devices operated by the system and the typical bleed rates of these devices. The compressor is usually driven by an electric motor that turns on and off, depending on the pressure in the volume tank. For reliability, a full spare compressor is normally installed. A minimum amount of electrical service is required to power the compressors.
- A critical component of the instrument air control system is the power source required to operate the compressor. Because high-pressure natural gas is abundant and readily available, gas pneumatic systems can run uninterrupted on a 24-hour, 7-day per week schedule. The reliability of an instrument air system, however, depends on the reliability of the compressor and electric power supply. Most large natural gas plants have either an existing electric power supply or have their own power generation system. For smaller facilities and in remote locations, however, a reliable source of

electric power can be difficult to ensure. In some instances, solar-powered battery-operated air compressors can be effective for remote locations, which reduce both methane emissions and energy consumption. Small natural gas powered fuel cells are also being developed.

- Dehydrators, or air dryers, are also an integral part of the instrument air compressor system. Water vapor present in atmospheric air condenses when the air is pressurized and cooled, and can cause a number of problems to these systems, including corrosion of the instrument parts and blockage of instrument air piping and controller orifices.
- The volume tank holds enough air to allow the pneumatic control system to have an uninterrupted supply of high-pressure air without having to run the air compressor continuously. The volume tank allows a large withdrawal of compressed air for a short time, such as for a motor starter, pneumatic pump, or pneumatic tools, without affecting the process control functions.

Compressed air may be substituted for natural gas in pneumatic systems without altering any of the parts of the pneumatic control. The use of instrument air eliminates natural gas emissions from natural gas powered pneumatic controllers. All other parts of a gas pneumatic system will operate the same way with instrument air as they do with natural gas. A diagram of a natural gas pneumatic controller is presented in Figure 3-1. A diagram of a compressed instrument air system is presented in Figure 3-2.

Applicability

The use of instrument air eliminates natural gas emissions from the natural gas-driven pneumatic controllers; however, these systems may only be used in locations with access to a sufficient and consistent supply of electrical power. Instrument air systems are also usually installed at facilities where there is a high concentration of pneumatic control valves and the presence of an operator that can ensure the system is properly functioning (U.S. EPA, 2006c).

NMED Exhibit 91

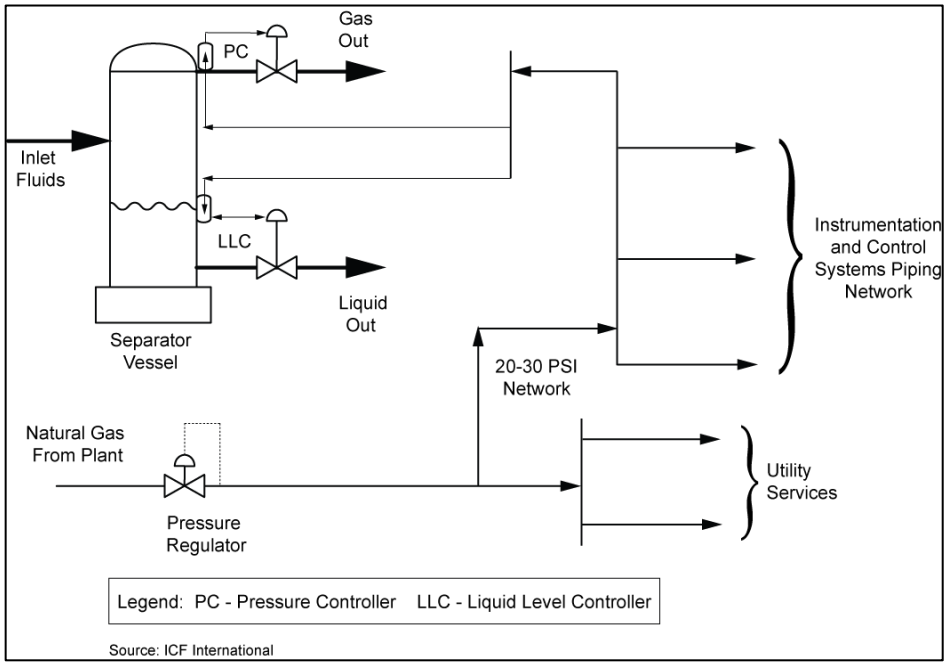

Figure 3-1 Natural Gas Pneumatic Control System

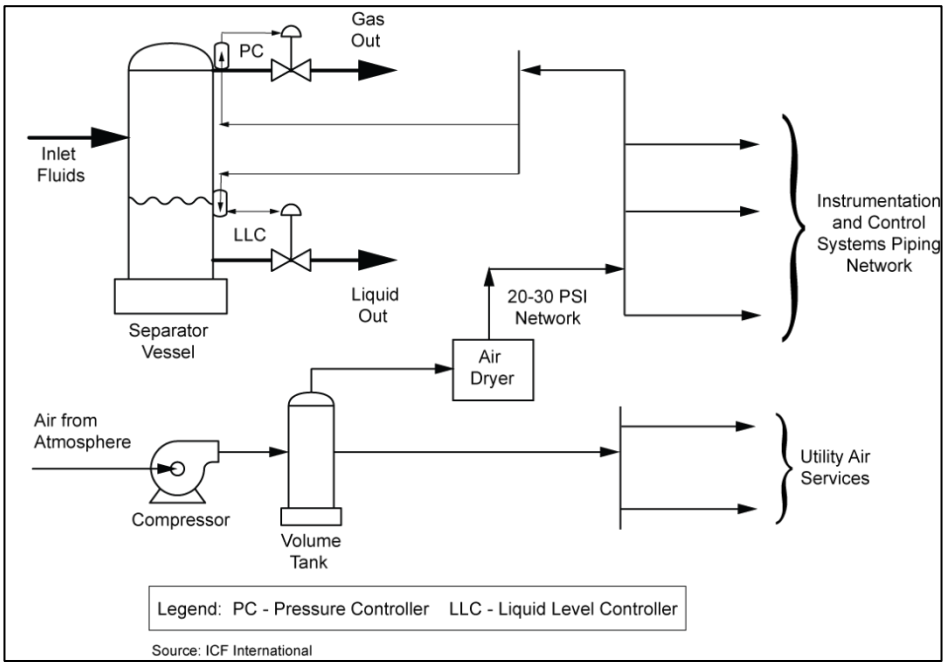

Figure 3-2. Compressed Instrument Air System

Costs

Instrument air conversion requires additional equipment to properly compress and control the pressured air. The size of the compressor will depend on the number of control loops present at a location. A control loop consists of one pneumatic controller and one control valve. The volume of compressed air supply for the pneumatic system is equivalent to the volume of gas used to run the existing instrumentation—adjusted for air losses during the drying process. The current volume of gas usage can be determined by direct metering if a meter is installed. Otherwise, an alternative rule of thumb for sizing instrument air systems is 1 cubic foot per minute (cfm) of instrument air for each control loop. As the system is powered by electric compressors, the system requires a constant source of electrical power or a backup pneumatic device. Table 3-3 outlines three different sized instrument air systems including the compressor power requirements, the flow rate provided from the compressor, and the associated number of control loops.

Table 3-3. Compressor Power Requirements and Costs for Various Sized Instrument Air Systems[a]

Compressor Power Requirements[b]			Flow Rate	Control Loops
Size of Unit	Hp	kW	(cfm)	Loops/Compressor
Small	10	13.3	30	15
Medium	30	40	125	63
Large	75	100	350	175

[a] Based on rules of thumb stated in the Natural Gas STAR document, *Lessons Learned: Convert Gas Pneumatic Controls to Instrument Air.*

[b] Power is based on the operation of two compressors operating in parallel (each assumed to be operating at full capacity 50% of the year).

The primary costs associated with conversion to instrument air systems are the initial capital expenditures for installing compressors and related equipment and the operating costs for electrical energy to power the compressor motor. This equipment includes a compressor, a power source, a dehydrator and a storage vessel. It is assumed that in either an instrument air solution or a natural gas pneumatic solution, gas supply piping, control instruments, and valve actuators of the gas pneumatic system are required. The total cost, including installation and labor, of three representative sizes of compressors based on assumptions found in the Natural Gas STAR

NMED Exhibit 91

document, “Lessons Learned: Convert Gas Pneumatic Controls to Instrument Air” are summarized in Table 3-4.

3.1.4 Mechanical and Solar-Powered Systems in Place of Bleed Controller

Description

Mechanical controls have been widely used in the natural gas and petroleum industry. They operate using a combination of levers, hand wheels, springs and flow channels with the most common mechanical control device being a liquid-level float to the drain valve position with mechanical linkages (U.S. EPA, 2006a). Another device that is increasing in use is electronic control instrumentation. Electricity or small electrical motors (including solar-powered) have been used to operate valves and therefore do not bleed natural gas into the atmosphere (U.S. EPA, 2006a). Solar control systems are driven by solar power cells that actuate mechanical devices using electric power. As such, solar cells require some type of backup power or storage to ensure reliability.

Applicability

Application of mechanical controls is limited because the control must be located in close proximity to the process measurement. Mechanical systems are also incapable of handling larger flow fluctuations (U.S. EPA, 2006c). Electric-powered valves are only reliable with a constant supply of electricity. These controllers can achieve 100% reduction in emissions where applicable.

Costs

Depending on supply of power, costs can range from below $1,000 to $10,000 for entire systems (U.S. EPA, 2006a).

NMED Exhibit 91

Table 3-4 Estimated Capital and Annual Costs of Various Sized Representative Instrument Air Systems

Instrument Air System Size	Compressor	Tank	Air Dryer	Total Capital[a]	Annualized Capital[b]	Labor Cost	Total Annual Costs[c]	Annualized Cost of Instrument Air System
Small	$3,772	$754	$2,262	$16,972	$2,416	$1,334	$8,674	$11,090
Medium	$18,855	$2,262	$6,787	$73,531	$10,469	$4,333	$26,408	$36,877
Large	$33,183	$4,525	$15,083	$135,750	$19,328	$5,999	$61,187	$80,515

[a] Total Capital includes the cost for two compressors, tank, an air dryer and installation. Installation costs are assumed to be equal to 1.5 times the cost of capital. Equipment costs were derived from the Natural Gas Star Lessons Learned document and converted to 2008 dollars from 2006 dollars using the Chemical Engineering Cost Index.

[b] The annualized cost was estimated using a 7% interest rate and 10-year equipment life.

[c] Annual Costs include the cost of electrical power as listed in Table 3-3 and labor.

3.1.5 Maintenance of Natural Gas-Driven Pneumatic Controllers

Manufacturers of pneumatic controllers indicate that emissions in the field can be higher than the reported gas consumption due to operating conditions, age, and wear of the device (U.S. EPA, 2006a). Examples of circumstances or factors that can contribute to this increase include:

- Nozzle corrosion resulting in more flow through a larger opening.
- Broken or worn diaphragms, bellows, fittings, and nozzles.
- Corrosives in the gas leading to erosion or corrosion of control loop internals.
- Improper installation.
- Lack of maintenance (maintenance includes replacement of the filter used to remove debris from the supply gas and replacement of O-rings and/or seals).
- Lack of calibration of the controller or adjustment of the distance between the flapper and nozzle.
- Foreign material lodged in the pilot seat.
- Wear in the seal seat.

Maintenance of pneumatics can correct many of these problems and can be an effective method for reducing emissions. Cleaning and tuning, in addition to repairing leaking gaskets, tubing fittings, and seals, can save 5 to 10 scfh per device. Tuning to operate over a broader range of proportional band often reduces bleed rates by as much as 10 scfh. Eliminating unnecessary valve positioners can save up to 18 scfh per device (U.S. EPA, 2006a).

However, proper methods of maintaining a device are highly variable, thus, costs are variable based on labor, time, and fuel required to travel to many remote locations.

3.2 Available Pneumatic Pump Emissions Mitigation Techniques

There are several techniques that are currently being used to reduce emissions from pneumatic pumps. Table 3-5 provides a summary of these techniques for reducing emissions

NMED Exhibit 91

from pneumatic pumps, which include chemical injection pumps and natural gas-assisted recirculation pumps.

3.2.1 Instrument Air Pump

Description

Circulation pumps in glycol dehydration processes and chemical injection pumps are often powered by pressurized natural gas at remote locations. As a result, these pumps vent natural gas to the atmosphere as part of their normal operation. To mitigate VOC and methane emissions, some companies are using instrument air to power these pumps. These companies have found that the use of instrument air increased operational efficiency, decreased maintenance and decreased costs, while eliminating emissions of methane and VOC (U.S. EPA, 2011b).

Applicability

Converting chemical injection pumps and glycol dehydration circulation pumps to instrument air can be applied to natural gas hydration operations across all gas industry sectors with excess capacity of its instrument air system. Because the systems are powered by electric compressors, they require a constant source of electrical power or a backup natural gas pneumatic device (U.S. EPA, 2011b).

Costs

The total cost to convert a natural gas pneumatic circulation pump to instrument air includes the installation of piping and an appropriate control system between the existing instrument air system and the glycol pump if the driver is independent of the circulation pump. If the driver is separated from the pump by O-rings, then the pump would need to also be replaced. The implementation capital costs are estimated to be $1,000 to $10,000, and the incremental operating costs are estimated to be $100 to $1,000 (U.S. EPA, 2011b). The potential annual

NMED Exhibit 91

Table 3-5. Summary of Alternative Mitigation Techniques for Pneumatic Pumps

Option	Description	Applicability	Costs	Efficacy and Prevalence
Replace natural gas-assisted pump with instrument air pump (U.S. EPA, 2011b)	Circulation pumps in glycol dehydration units and chemical injection pumps are retrofitted with instrument air to drive the pumps (U.S. EPA, 2011b).	Facilities with excess capacity of instrument air or facilities that can install an air compressor system. Because the systems are powered by electric compressors, they require a constant source of electrical power or a backup natural gas pneumatic pump (U.S. EPA, 2011b).	The installation of the piping from the air compressor system to the pump accounts for the bulk of the capital cost and typically ranges from $100 to $1,000 (U.S. EPA, 2011b).	100% emission reduction, where applicable. The Natural Gas STAR reports typical annual methane savings to be 2,500 Mcf for glycol circulation pumps and 183 Mcf for chemical injection pumps (U.S. EPA, 2011b). The EPA does not have information on the prevalence of this technology in the field.
Replacement of natural gas-assisted pump with solar-charged direct current pump (U.S. EPA, 2011b)	In field settings, low volume natural gas pneumatic pumps can be replaced with solar-charged DC pumps (U.S. EPA, 2011b).	Low volume solar-charged pneumatic pumps are limited to approximately 5 gallons per day discharge at 1,000 psig. Large volume solar pumps are available with maximum output of 38 to 100 gallons per day at maximum injection pressures of 1,200 to 3,000 psig (U.S. EPA, 2011b).	The reporting partners for Natural Gas STAR stated a replacement cost of $2,000 per pump, including the solar panels, storage batteries and pump (U.S. EPA, 2011b).	100% emission reduction, where applicable. The Natural Gas STAR reports typical annual methane savings to be 182.5 Mcf per chemical injection pump conversion (U.S. EPA, 2011b). The EPA does not have information on the prevalence of this technology in the field.

NMED Exhibit 91

Option	Description	Applicability	Costs	Efficacy and Prevalence
Replacement of natural gas-assisted pump with electric pump (ICF, 2014)	In settings where a constant supply of electricity is available, natural gas pneumatic pumps can be replaced with electric pumps (ICF, 2014).	These pumps require a constant source of electricity, thus, they are typically installed at processing plants or large dehydration facilities, which are normally equipped with electricity (U.S. EPA, 2011b).	Electrical pumps are estimated to cost roughly $10,000 per pump and the annual electrical usage cost was estimated to be $2,000 per year. (ICF, 2014)	100% emission reduction, where applicable. The annual methane reduction from replacing pneumatic pumps with electrical pumps is estimated to be 5,000 Mcf (ICF, 2014). The EPA does not have information on the prevalence of this technology in the field.

NMED Exhibit 91

natural gas savings are estimated to be 2,500 Mcf (U.S. EPA, 2011b) or $10,000 based on a natural gas value of $4.00 per Mcf (U.S. EIA, 2010). For chemical injection pumps, the implementation costs are the same, but the potential annual natural gas savings are estimated to be 183 Mcf per pump conversion (U.S. EPA, 2011b) or $732 based on a natural gas value of $4.00 per Mcf (U.S. EIA, 2010).

3.2.2 Solar Power Pump

Description

Solar power can be used to operate pumps located at remote sites where electricity is not available. These solar-powered pumps use electric power captured by solar panels to operate a DC-charged pump. Solar injection pumps can handle a range of throughputs and injection pressures. Low volume solar-charged DC pumps are limited to approximately 5 gallons per day discharge at 1,000 psig (U.S. EPA, 2011b). Large volume solar pumps are available with maximum output of 38 to 100 gallons per day at maximum injection pressures of 1,200 to 3,000 psig (U.S. EPA, 2011b). These pumps eliminate the methane and VOC emissions that would have resulted from the use of a pneumatic pump.

Applicability

These solar-powered pumps are generally used to replace low volume natural gas pneumatic pumps if sufficient sunlight is available to power the pumps and backup power is not required. These low volume pumps are typically used to inject methanol or corrosion inhibiters into producing wells and other field equipment. These chemical injection pumps are typically sized for 6 to 8 gallons of methanol injection per day. The large volume pumps can be used to replace gas-assisted circulation pumps for glycol dehydrators.

Costs

The Natural Gas STAR program reported the cost of replacing pneumatic pumps with solar-charged electric pumps to be approximately $2,000 per pump (U.S. EPA, 2011b). The solar

NMED Exhibit 91

panels and storage batteries are nearly maintenance free, and the solar panels have a life span of up to 15 years and the electric motors last approximately 5 years in continuous use (U.S. EPA, 2011b). The potential annual natural gas savings are estimated to be 2,500 Mcf or $10,000 based on a natural gas value of $4.00 per Mcf (U.S. EIA, 2010) for recirculation pumps (U.S. EPA, 2011b). For chemical injection pumps, the implementation costs are the same, but the potential annual natural gas savings are estimated to be 183 Mcf (U.S. EPA, 2011b) or $732 based on a natural gas value of $4.00 per Mcf (U.S. EIA, 2010). The ICF report estimates the cost of replacing chemical injection pneumatic pumps with solar-powered pumps to be $5,000 per pump with a natural gas savings of 180 Mcf per year (ICF, 2014) or $720 based on a natural gas value of $4.00 per Mcf (U.S. EIA, 2010).

3.2.3 Electric Power Pumps

Description

Electric power pumps are used to replace natural gas-assisted pneumatic used to recirculate glycol in gas dehydrators. These pumps eliminate the methane and VOC emissions that would have resulted from the use of a pneumatic pump.

Applicability

These pumps require a constant source of electricity, thus, they are typically installed at processing plants or large dehydration facilities, which are normally equipped with electricity.

Costs

Electrical pumps are estimated to cost roughly $10,000 per pump and the annual electrical usage cost was estimated to be $2,000 per year (ICF, 2014). The annual methane reduction from replacing pneumatic pumps with electrical pumps is estimated to be 5,000 Mcf (ICF, 2014) or $20,000 based on a natural gas value of $4.00 per Mcf (U.S. EIA, 2010).

NMED Exhibit 91

4.0 SUMMARY

The EPA has used the data sources, analyses and studies discussed in this paper to form the Agency's understanding of emissions from pneumatic controllers and pumps and the emissions mitigation techniques. The following are characteristics the Agency believes are important to understanding these sources of VOC and methane emissions.

4.1 Pneumatic Controllers

- The majority of recent emissions estimates for pneumatic controllers have focused on methane emissions and not VOC emissions.
- The GHG Inventory data estimates that pneumatic controller emissions are 13% of overall methane emissions from the oil and natural gas sectors.
- Recent emission measurement studies have resulted in a wide range of methane emission factors for natural gas-driven pneumatic controllers. The studies all show that emissions can vary depending on sector (e.g., production, transmission, or storage) and the type of gas-driven pneumatic controller.
- Natural gas-driven pneumatic controllers are particularly useful in segments of the oil and natural gas industry that involve remote locations where electrical power is not available or reliable.
- Low bleed gas-driven controllers can replace high bleed gas-driven controllers in many, but not all, applications.
- Where a reliable source of electrical power is available, instrument air systems can replace natural gas-driven pneumatic controllers, and result in no methane or VOC emissions.
- Zero bleed, mechanical, and solar-powered controllers can replace continuous bleed controllers in certain applications, but are not broadly applicable to all segments of the oil and natural gas industry.

NMED Exhibit 91

4.2 Pneumatic Pumps

- Pneumatic pumps in the oil and natural gas industry are used as chemical injection pumps and circulation pumps for glycol dehydrators. Pressure from the natural gas line is used to power these pumps and the natural gas is vented to the atmosphere.
- There are several mitigation techniques that can be used to reduce or eliminate emissions from pneumatic pumps and they include: instrument air pumps and electric pumps (both AC and DC powered).
- The 2014 GHG Inventory data estimates that pneumatic pump emissions are 16% of overall methane emissions from the natural gas production and processing sectors. The 2014 GHG Inventory estimated methane emissions from these sources to be 64,570 MT of methane for chemical injection pumps and 393,389 MT of methane for natural gas-assisted Kimray pumps. Chemical injection pumps at petroleum systems emitted 49,973 MT of methane, or around 3% of emissions from petroleum production.
- Natural gas-driven pneumatic pumps are particularly useful in segments of the oil and natural gas industry that involve remote locations where electrical power is not available or reliable.
- Where a reliable source of electrical power is available, instrument air systems are an effective replacement for natural gas-driven pneumatic pumps.

5.0 CHARGE QUESTIONS FOR REVIEWERS

1. Did this paper appropriately characterize the different studies and data sources that quantify emissions from pneumatic controllers and pneumatic pumps in the oil and gas sector?
2. Please discuss explanations for the wide range of emission rates that have been observed in direct measurement studies of pneumatic controller emissions (e.g., Allen et al., 2013 and Prasino 2013). Are these differences driven purely by the design of the monitored controllers or are there operational characteristics, such as supply pressure, that play a crucial role in determining emissions?

NMED Exhibit 91

3. Did this paper capture the full range of technologies available to reduce emissions from pneumatic controllers and pneumatic pumps oil and gas facilities?

4. Please comment on the pros and cons of the different emission reduction technologies. Please discuss efficacy, cost and feasibility for both new and existing pneumatics.

5. Please comment on the prevalence of the different emission control technologies and the different types of pneumatics in the field. What particular activities require high bleed pneumatic controllers and how prevalent are they in the field?

6. What are the barriers to installing instrument air systems for converting natural gas-driven pneumatic pumps and pneumatic controllers to air-driven pumps and controllers?

7. Are there situations where it may be infeasible to use air driven pumps and controllers in place of natural gas-driven pumps and controllers even where it is feasible to install an instrument air system?

8. Did this paper correctly characterize the limitations of electric-powered pneumatic controllers and pneumatic pumps? Are these electric devices applicable to a broader range of the oil and gas sector than this paper suggests?

9. Are there ongoing or planned studies that will substantially improve the current understanding of VOC and methane emissions from pneumatic controllers and pneumatic pumps and available techniques for increased product recovery and emissions reductions?
