(2) If you start up your new or reconstructed stationary RICE with a site rating of more than 500 brake HP located at a major source of HAP emissions before August 16, 2004, you must comply with the applicable emission limitations and operating limitations in this subpart no later than August 16, 2004.

(3) If you start up your new or reconstructed stationary RICE with a site rating of more than 500 brake HP located at a major source of HAP emissions after August 16, 2004, you must comply with the applicable emission limitations and operating limitations in this subpart upon startup of your affected source.

(4) If you start up your new or reconstructed stationary RICE with a site rating of less than or equal to 500 brake HP located at a major source of HAP emissions before January 18, 2008, you must comply with the applicable emission limitations and operating limitations in this subpart no later than January 18, 2008.

(5) If you start up your new or reconstructed stationary RICE with a site rating of less than or equal to 500 brake HP located at a major source of HAP emissions after January 18, 2008, you must comply with the applicable emission limitations and operating limitations in this subpart upon startup of your affected source.

(6) If you start up your new or reconstructed stationary RICE located at an area source of HAP emissions before January 18, 2008, you must comply with the applicable emission limitations and operating limitations in this subpart no later than January 18, 2008.

(7) If you start up your new or reconstructed stationary RICE located at an area source of HAP emissions after January 18, 2008, you must comply with the applicable emission limitations and operating limitations in this subpart upon startup of your affected source.

(b) *Area sources that become major sources.* If you have an area source that increases its emissions or its potential to emit such that it becomes a major source of HAP, the compliance dates in paragraphs (b)(1) and (2) of this section apply to you.

(1) Any stationary RICE for which construction or reconstruction is commenced after the date when your area source becomes a major source of HAP must be in compliance with this subpart upon startup of your affected source.

(2) Any stationary RICE for which construction or reconstruction is commenced before your area source becomes a major source of HAP must be in compliance with the provisions of this subpart that are applicable to RICE located at major sources within 3 years after your area source becomes a major source of HAP.

(c) If you own or operate an affected source, you must meet the applicable notification requirements in §63.6645 and in 40 CFR part 63, subpart A.

[69 FR 33506, June 15, 2004, as amended at 73 FR 3604, Jan. 18, 2008; 75 FR 9675, Mar. 3, 2010; 75 FR 51589, Aug. 20, 2010; 78 FR 6701, Jan. 30, 2013]

EMISSION AND OPERATING LIMITATIONS

Back to Top

§63.6600 What emission limitations and operating limitations must I meet if I own or operate a stationary RICE with a site rating of more than 500 brake HP located at a major source of HAP emissions?

Compliance with the numerical emission limitations established in this subpart is based on the results of testing the average of three 1-hour runs using the testing requirements and procedures in §63.6620 and Table 4 to this subpart.

(a) If you own or operate an existing, new, or reconstructed spark ignition 4SRB stationary RICE with a site rating of more than 500 brake HP located at a major source of HAP emissions, you must comply with the emission limitations in Table 1a to this subpart and the operating limitations in Table 1b to this subpart which apply to you.

(b) If you own or operate a new or reconstructed 2SLB stationary RICE with a site rating of more than 500 brake HP located at major source of HAP emissions, a new or reconstructed 4SLB stationary RICE with a site rating of more than 500 brake HP located at major source of HAP emissions, or a new or reconstructed CI stationary RICE with a site rating of more than 500 brake HP located at a major source of HAP emissions, you must comply with the emission limitations in Table 2a to this subpart and the operating limitations in Table 2b to this subpart which apply to you.

(c) If you own or operate any of the following stationary RICE with a site rating of more than 500 brake HP located at a major source of HAP emissions, you do not need to comply with the emission limitations in Tables 1a, 2a, 2c, and 2d to this subpart or operating limitations in Tables 1b and 2b to this subpart: an existing 2SLB stationary RICE; an existing 4SLB stationary RICE; a

stationary RICE that combusts landfill gas or digester gas equivalent to 10 percent or more of the gross heat input on an annual basis; an emergency stationary RICE; or a limited use stationary RICE.

(d) If you own or operate an existing non-emergency stationary CI RICE with a site rating of more than 500 brake HP located at a major source of HAP emissions, you must comply with the emission limitations in Table 2c to this subpart and the operating limitations in Table 2b to this subpart which apply to you.

[73 FR 3605, Jan. 18, 2008, as amended at 75 FR 9675, Mar. 3, 2010]

Back to Top

§63.6601 What emission limitations must I meet if I own or operate a new or reconstructed 4SLB stationary RICE with a site rating of greater than or equal to 250 brake HP and less than or equal to 500 brake HP located at a major source of HAP emissions?

Compliance with the numerical emission limitations established in this subpart is based on the results of testing the average of three 1-hour runs using the testing requirements and procedures in §63.6620 and Table 4 to this subpart. If you own or operate a new or reconstructed 4SLB stationary RICE with a site rating of greater than or equal to 250 and less than or equal to 500 brake HP located at major source of HAP emissions manufactured on or after January 1, 2008, you must comply with the emission limitations in Table 2a to this subpart and the operating limitations in Table 2b to this subpart which apply to you.

[73 FR 3605, Jan. 18, 2008, as amended at 75 FR 9675, Mar. 3, 2010; 75 FR 51589, Aug. 20, 2010]

Back to Top

§63.6602 What emission limitations and other requirements must I meet if I own or operate an existing stationary RICE with a site rating of equal to or less than 500 brake HP located at a major source of HAP emissions?

If you own or operate an existing stationary RICE with a site rating of equal to or less than 500 brake HP located at a major source of HAP emissions, you must comply with the emission limitations and other requirements in Table 2c to this subpart which apply to you. Compliance with the numerical emission limitations established in this subpart is based on the results of testing the average of three 1-hour runs using the testing requirements and procedures in §63.6620 and Table 4 to this subpart.

[78 FR 6701, Jan. 30, 2013]

Back to Top

§63.6603 What emission limitations, operating limitations, and other requirements must I meet if I own or operate an existing stationary RICE located at an area source of HAP emissions?

Compliance with the numerical emission limitations established in this subpart is based on the results of testing the average of three 1-hour runs using the testing requirements and procedures in §63.6620 and Table 4 to this subpart.

(a) If you own or operate an existing stationary RICE located at an area source of HAP emissions, you must comply with the requirements in Table 2d to this subpart and the operating limitations in Table 2b to this subpart that apply to you.

(b) If you own or operate an existing stationary non-emergency CI RICE with a site rating of more than 300 HP located at an area source of HAP that meets either paragraph (b)(1) or (2) of this section, you do not have to meet the numerical CO emission limitations specified in Table 2d of this subpart. Existing stationary non-emergency CI RICE with a site rating of more than 300 HP located at an area source of HAP that meet either paragraph (b)(1) or (2) of this section must meet the management practices that are shown for stationary non-emergency CI RICE with a site rating of less than or equal to 300 HP in Table 2d of this subpart.

(1) The area source is located in an area of Alaska that is not accessible by the Federal Aid Highway System (FAHS).

(2) The stationary RICE is located at an area source that meets paragraphs (b)(2)(i), (ii), and (iii) of this section.

(i) The only connection to the FAHS is through the Alaska Marine Highway System (AMHS), or the stationary RICE operation is within an isolated grid in Alaska that is not connected to the statewide electrical grid referred to as the Alaska Railbelt Grid.

(ii) At least 10 percent of the power generated by the stationary RICE on an annual basis is used for residential purposes.

(iii) The generating capacity of the area source is less than 12 megawatts, or the stationary RICE is used exclusively for backup power for renewable energy.

(c) If you own or operate an existing stationary non-emergency CI RICE with a site rating of more than 300 HP located on an offshore vessel that is an area source of HAP and is a nonroad vehicle that is an Outer Continental Shelf (OCS) source as defined in 40 CFR 55.2, you do not have to meet the numerical CO emission limitations specified in Table 2d of this subpart. You must meet all of the following management practices:

(1) Change oil every 1,000 hours of operation or annually, whichever comes first. Sources have the option to utilize an oil analysis program as described in §63.6625(i) in order to extend the specified oil change requirement.

(2) Inspect and clean air filters every 750 hours of operation or annually, whichever comes first, and replace as necessary.

(3) Inspect fuel filters and belts, if installed, every 750 hours of operation or annually, whichever comes first, and replace as necessary.

(4) Inspect all flexible hoses every 1,000 hours of operation or annually, whichever comes first, and replace as necessary.

(d) If you own or operate an existing non-emergency CI RICE with a site rating of more than 300 HP located at an area source of HAP emissions that is certified to the Tier 1 or Tier 2 emission standards in Table 1 of 40 CFR 89.112 and that is subject to an enforceable state or local standard that requires the engine to be replaced no later than June 1, 2018, you may until January 1, 2015, or 12 years after the installation date of the engine (whichever is later), but not later than June 1, 2018, choose to comply with the management practices that are shown for stationary non-emergency CI RICE with a site rating of less than or equal to 300 HP in Table 2d of this subpart instead of the applicable emission limitations in Table 2d, operating limitations in Table 2b, and crankcase ventilation system requirements in §63.6625(g). You must comply with the emission limitations in Table 2d and operating limitations in Table 2b that apply for non-emergency CI RICE with a site rating of more than 300 HP located at an area source of HAP emissions by January 1, 2015, or 12 years after the installation date of the engine (whichever is later), but not later than June 1, 2018. You must also comply with the crankcase ventilation system requirements in §63.6625(g) by January 1, 2015, or 12 years after the installation date of the engine (whichever is later), but not later than June 1, 2018.

(e) If you own or operate an existing non-emergency CI RICE with a site rating of more than 300 HP located at an area source of HAP emissions that is certified to the Tier 3 (Tier 2 for engines above 560 kilowatt (kW)) emission standards in Table 1 of 40 CFR 89.112, you may comply with the requirements under this part by meeting the requirements for Tier 3 engines (Tier 2 for engines above 560 kW) in 40 CFR part 60 subpart IIII instead of the emission limitations and other requirements that would otherwise apply under this part for existing non-emergency CI RICE with a site rating of more than 300 HP located at an area source of HAP emissions.

(f) An existing non-emergency SI 4SLB and 4SRB stationary RICE with a site rating of more than 500 HP located at area sources of HAP must meet the definition of remote stationary RICE in §63.6675 on the initial compliance date for the engine, October 19, 2013, in order to be considered a remote stationary RICE under this subpart. Owners and operators of existing non-emergency SI 4SLB and 4SRB stationary RICE with a site rating of more than 500 HP located at area sources of HAP that meet the definition of remote stationary RICE in §63.6675 of this subpart as of October 19, 2013 must evaluate the status of their stationary RICE every 12 months. Owners and operators must keep records of the initial and annual evaluation of the status of the engine. If the evaluation indicates that the stationary RICE no longer meets the definition of remote stationary RICE in §63.6675 of this subpart, the owner or operator must comply with all of the requirements for existing non-emergency SI 4SLB and 4SRB stationary RICE with a site rating of more than 500 HP located at area sources of HAP that are not remote stationary RICE within 1 year of the evaluation.

[75 FR 9675, Mar. 3, 2010, as amended at 75 FR 51589, Aug. 20, 2010; 76 FR 12866, Mar. 9, 2011; 78 FR 6701, Jan. 30, 2013]

Back to Top

§63.6604 What fuel requirements must I meet if I own or operate a stationary CI RICE?

(a) If you own or operate an existing non-emergency, non-black start CI stationary RICE with a site rating of more than 300 brake HP with a displacement of less than 30 liters per cylinder that uses diesel fuel, you must use diesel fuel that meets the requirements in 40 CFR 80.510(b) for nonroad diesel fuel.

(b) Beginning January 1, 2015, if you own or operate an existing emergency CI stationary RICE with a site rating of more than 100 brake HP and a displacement of less than 30 liters per cylinder

that uses diesel fuel and operates or is contractually obligated to be available for more than 15 hours per calendar year for the purposes specified in §63.6640(f)(2)(ii) and (iii) or that operates for the purpose specified in §63.6640(f)(4)(ii), you must use diesel fuel that meets the requirements in 40 CFR 80.510(b) for nonroad diesel fuel, except that any existing diesel fuel purchased (or otherwise obtained) prior to January 1, 2015, may be used until depleted.

(c) Beginning January 1, 2015, if you own or operate a new emergency CI stationary RICE with a site rating of more than 500 brake HP and a displacement of less than 30 liters per cylinder located at a major source of HAP that uses diesel fuel and operates or is contractually obligated to be available for more than 15 hours per calendar year for the purposes specified in §63.6640(f)(2)(ii) and (iii), you must use diesel fuel that meets the requirements in 40 CFR 80.510(b) for nonroad diesel fuel, except that any existing diesel fuel purchased (or otherwise obtained) prior to January 1, 2015, may be used until depleted.

(d) Existing CI stationary RICE located in Guam, American Samoa, the Commonwealth of the Northern Mariana Islands, at area sources in areas of Alaska that meet either §63.6603(b)(1) or §63.6603(b)(2), or are on offshore vessels that meet §63.6603(c) are exempt from the requirements of this section.

[78 FR 6702, Jan. 30, 2013]

Back to Top

GENERAL COMPLIANCE REQUIREMENTS

Back to Top

§63.6605 What are my general requirements for complying with this subpart?

(a) You must be in compliance with the emission limitations, operating limitations, and other requirements in this subpart that apply to you at all times.

(b) At all times you must operate and maintain any affected source, including associated air pollution control equipment and monitoring equipment, in a manner consistent with safety and good air pollution control practices for minimizing emissions. The general duty to minimize emissions does not require you to make any further efforts to reduce emissions if levels required by this standard have been achieved. Determination of whether such operation and maintenance procedures are being used will be based on information available to the Administrator which may include, but is not limited to, monitoring results, review of operation and maintenance procedures, review of operation and maintenance records, and inspection of the source.

[75 FR 9675, Mar. 3, 2010, as amended at 78 FR 6702, Jan. 30, 2013]

Back to Top

TESTING AND INITIAL COMPLIANCE REQUIREMENTS

Back to Top

§63.6610 By what date must I conduct the initial performance tests or other initial compliance demonstrations if I own or operate a stationary RICE with a site rating of more than 500 brake HP located at a major source of HAP emissions?

If you own or operate a stationary RICE with a site rating of more than 500 brake HP located at a major source of HAP emissions you are subject to the requirements of this section.

(a) You must conduct the initial performance test or other initial compliance demonstrations in Table 4 to this subpart that apply to you within 180 days after the compliance date that is specified for your stationary RICE in §63.6595 and according to the provisions in §63.7(a)(2).

(b) If you commenced construction or reconstruction between December 19, 2002 and June 15, 2004 and own or operate stationary RICE with a site rating of more than 500 brake HP located at a major source of HAP emissions, you must demonstrate initial compliance with either the proposed emission limitations or the promulgated emission limitations no later than February 10, 2005 or no later than 180 days after startup of the source, whichever is later, according to §63.7(a)(2)(ix).

(c) If you commenced construction or reconstruction between December 19, 2002 and June 15, 2004 and own or operate stationary RICE with a site rating of more than 500 brake HP located at a major source of HAP emissions, and you chose to comply with the proposed emission limitations when demonstrating initial compliance, you must conduct a second performance test to demonstrate compliance with the promulgated emission limitations by December 13, 2007 or after startup of the source, whichever is later, according to §63.7(a)(2)(ix).

(d) An owner or operator is not required to conduct an initial performance test on units for which a performance test has been previously conducted, but the test must meet all of the conditions described in paragraphs (d)(1) through (5) of this section.

(1) The test must have been conducted using the same methods specified in this subpart, and these methods must have been followed correctly.

(2) The test must not be older than 2 years.

(3) The test must be reviewed and accepted by the Administrator.

(4) Either no process or equipment changes must have been made since the test was performed, or the owner or operator must be able to demonstrate that the results of the performance test, with or without adjustments, reliably demonstrate compliance despite process or equipment changes.

(5) The test must be conducted at any load condition within plus or minus 10 percent of 100 percent load.

[69 FR 33506, June 15, 2004, as amended at 73 FR 3605, Jan. 18, 2008]

Back to Top

§63.6611 By what date must I conduct the initial performance tests or other initial compliance demonstrations if I own or operate a new or reconstructed 4SLB SI stationary RICE with a site rating of greater than or equal to 250 and less than or equal to 500 brake HP located at a major source of HAP emissions?

If you own or operate a new or reconstructed 4SLB stationary RICE with a site rating of greater than or equal to 250 and less than or equal to 500 brake HP located at a major source of HAP emissions, you must conduct an initial performance test within 240 days after the compliance date that is specified for your stationary RICE in §63.6595 and according to the provisions specified in Table 4 to this subpart, as appropriate.

[73 FR 3605, Jan. 18, 2008, as amended at 75 FR 51589, Aug. 20, 2010]

Back to Top

§63.6612 By what date must I conduct the initial performance tests or other initial compliance demonstrations if I own or operate an existing stationary RICE with a site rating of less than or equal to 500 brake HP located at a major source of HAP emissions or an existing stationary RICE located at an area source of HAP emissions?

If you own or operate an existing stationary RICE with a site rating of less than or equal to 500 brake HP located at a major source of HAP emissions or an existing stationary RICE located at an area source of HAP emissions you are subject to the requirements of this section.

(a) You must conduct any initial performance test or other initial compliance demonstration according to Tables 4 and 5 to this subpart that apply to you within 180 days after the compliance date that is specified for your stationary RICE in §63.6595 and according to the provisions in §63.7(a)(2).

(b) An owner or operator is not required to conduct an initial performance test on a unit for which a performance test has been previously conducted, but the test must meet all of the conditions described in paragraphs (b)(1) through (4) of this section.

(1) The test must have been conducted using the same methods specified in this subpart, and these methods must have been followed correctly.

(2) The test must not be older than 2 years.

(3) The test must be reviewed and accepted by the Administrator.

(4) Either no process or equipment changes must have been made since the test was performed, or the owner or operator must be able to demonstrate that the results of the performance test, with or without adjustments, reliably demonstrate compliance despite process or equipment changes.

[75 FR 9676, Mar. 3, 2010, as amended at 75 FR 51589, Aug. 20, 2010]

Back to Top

§63.6615 When must I conduct subsequent performance tests?

If you must comply with the emission limitations and operating limitations, you must conduct subsequent performance tests as specified in Table 3 of this subpart.

Back to Top

§63.6620 What performance tests and other procedures must I use?

(a) You must conduct each performance test in Tables 3 and 4 of this subpart that applies to you.

(b) Each performance test must be conducted according to the requirements that this subpart specifies in Table 4 to this subpart. If you own or operate a non-operational stationary RICE that is subject to performance testing, you do not need to start up the engine solely to conduct the performance test. Owners and operators of a non-operational engine can conduct the performance test when the engine is started up again. The test must be conducted at any load condition within plus or minus 10 percent of 100 percent load for the stationary RICE listed in paragraphs (b)(1) through (4) of this section.

(1) Non-emergency 4SRB stationary RICE with a site rating of greater than 500 brake HP located at a major source of HAP emissions.

(2) New non-emergency 4SLB stationary RICE with a site rating of greater than or equal to 250 brake HP located at a major source of HAP emissions.

(3) New non-emergency 2SLB stationary RICE with a site rating of greater than 500 brake HP located at a major source of HAP emissions.

(4) New non-emergency CI stationary RICE with a site rating of greater than 500 brake HP located at a major source of HAP emissions.

(c) [Reserved]

(d) You must conduct three separate test runs for each performance test required in this section, as specified in §63.7(e)(3). Each test run must last at least 1 hour, unless otherwise specified in this subpart.

(e)(1) You must use Equation 1 of this section to determine compliance with the percent reduction requirement:

View or download PDF

Where:

C_i = concentration of carbon monoxide (CO), total hydrocarbons (THC), or formaldehyde at the control device inlet,

C_o = concentration of CO, THC, or formaldehyde at the control device outlet, and

R = percent reduction of CO, THC, or formaldehyde emissions.

(2) You must normalize the CO, THC, or formaldehyde concentrations at the inlet and outlet of the control device to a dry basis and to 15 percent oxygen, or an equivalent percent carbon dioxide (CO_2). If pollutant concentrations are to be corrected to 15 percent oxygen and CO_2 concentration is measured in lieu of oxygen concentration measurement, a CO_2 correction factor is needed. Calculate the CO_2 correction factor as described in paragraphs (e)(2)(i) through (iii) of this section.

(i) Calculate the fuel-specific F_o value for the fuel burned during the test using values obtained from Method 19, Section 5.2, and the following equation:

View or download PDF

Where:

F_o = Fuel factor based on the ratio of oxygen volume to the ultimate CO_2 volume produced by the fuel at zero percent excess air.

0.209 = Fraction of air that is oxygen, percent/100.

F_d = Ratio of the volume of dry effluent gas to the gross calorific value of the fuel from Method 19, dsm^3/J ($dscf/10^6$ Btu).

F_c = Ratio of the volume of CO_2 produced to the gross calorific value of the fuel from Method 19, dsm^3/J ($dscf/10^6$ Btu)

(ii) Calculate the CO_2 correction factor for correcting measurement data to 15 percent O_2, as follows:

View or download PDF

Where:

X_{CO2} = CO_2 correction factor, percent.

5.9 = 20.9 percent O_2—15 percent O_2, the defined O_2 correction value, percent.

(iii) Calculate the CO, THC, and formaldehyde gas concentrations adjusted to 15 percent O_2 using CO_2 as follows:

View or download PDF

Where:

C_{adj} = Calculated concentration of CO, THC, or formaldehyde adjusted to 15 percent O_2.

C_d = Measured concentration of CO, THC, or formaldehyde, uncorrected.

X_{CO2} = CO_2 correction factor, percent.

$\%CO_2$ = Measured CO_2 concentration measured, dry basis, percent.

(f) If you comply with the emission limitation to reduce CO and you are not using an oxidation catalyst, if you comply with the emission limitation to reduce formaldehyde and you are not using NSCR, or if you comply with the emission limitation to limit the concentration of formaldehyde in the stationary RICE exhaust and you are not using an oxidation catalyst or NSCR, you must petition the Administrator for operating limitations to be established during the initial performance test and continuously monitored thereafter; or for approval of no operating limitations. You must not conduct the initial performance test until after the petition has been approved by the Administrator.

(g) If you petition the Administrator for approval of operating limitations, your petition must include the information described in paragraphs (g)(1) through (5) of this section.

(1) Identification of the specific parameters you propose to use as operating limitations;

(2) A discussion of the relationship between these parameters and HAP emissions, identifying how HAP emissions change with changes in these parameters, and how limitations on these parameters will serve to limit HAP emissions;

(3) A discussion of how you will establish the upper and/or lower values for these parameters which will establish the limits on these parameters in the operating limitations;

(4) A discussion identifying the methods you will use to measure and the instruments you will use to monitor these parameters, as well as the relative accuracy and precision of these methods and instruments; and

(5) A discussion identifying the frequency and methods for recalibrating the instruments you will use for monitoring these parameters.

(h) If you petition the Administrator for approval of no operating limitations, your petition must include the information described in paragraphs (h)(1) through (7) of this section.

(1) Identification of the parameters associated with operation of the stationary RICE and any emission control device which could change intentionally (*e.g.,* operator adjustment, automatic controller adjustment, etc.) or unintentionally (*e.g.,* wear and tear, error, etc.) on a routine basis or over time;

(2) A discussion of the relationship, if any, between changes in the parameters and changes in HAP emissions;

(3) For the parameters which could change in such a way as to increase HAP emissions, a discussion of whether establishing limitations on the parameters would serve to limit HAP emissions;

(4) For the parameters which could change in such a way as to increase HAP emissions, a discussion of how you could establish upper and/or lower values for the parameters which would establish limits on the parameters in operating limitations;

(5) For the parameters, a discussion identifying the methods you could use to measure them and the instruments you could use to monitor them, as well as the relative accuracy and precision of the methods and instruments;

(6) For the parameters, a discussion identifying the frequency and methods for recalibrating the instruments you could use to monitor them; and

(7) A discussion of why, from your point of view, it is infeasible or unreasonable to adopt the parameters as operating limitations.

(i) The engine percent load during a performance test must be determined by documenting the calculations, assumptions, and measurement devices used to measure or estimate the percent load in a specific application. A written report of the average percent load determination must be included in the notification of compliance status. The following information must be included in the written report: the engine model number, the engine manufacturer, the year of purchase, the manufacturer's site-rated brake horsepower, the ambient temperature, pressure, and humidity during the performance test, and all assumptions that were made to estimate or calculate percent load during the performance test must be clearly explained. If measurement devices such as flow meters, kilowatt meters, beta analyzers, stain gauges, etc. are used, the model number of the measurement device, and an estimate of its accurate in percentage of true value must be provided.

[69 FR 33506, June 15, 2004, as amended at 75 FR 9676, Mar. 3, 2010; 78 FR 6702, Jan. 30, 2013]

Back to Top

§63.6625 What are my monitoring, installation, collection, operation, and maintenance requirements?

(a) If you elect to install a CEMS as specified in Table 5 of this subpart, you must install, operate, and maintain a CEMS to monitor CO and either O_2 or CO_2 according to the requirements in paragraphs (a)(1) through (4) of this section. If you are meeting a requirement to reduce CO emissions, the CEMS must be installed at both the inlet and outlet of the control device. If you are meeting a requirement to limit the concentration of CO, the CEMS must be installed at the outlet of the control device.

(1) Each CEMS must be installed, operated, and maintained according to the applicable performance specifications of 40 CFR part 60, appendix B.

(2) You must conduct an initial performance evaluation and an annual relative accuracy test audit (RATA) of each CEMS according to the requirements in §63.8 and according to the applicable performance specifications of 40 CFR part 60, appendix B as well as daily and periodic data quality checks in accordance with 40 CFR part 60, appendix F, procedure 1.

(3) As specified in §63.8(c)(4)(ii), each CEMS must complete a minimum of one cycle of operation (sampling, analyzing, and data recording) for each successive 15-minute period. You must have at least two data points, with each representing a different 15-minute period, to have a valid hour of data.

(4) The CEMS data must be reduced as specified in §63.8(g)(2) and recorded in parts per million or parts per billion (as appropriate for the applicable limitation) at 15 percent oxygen or the equivalent CO_2 concentration.

(b) If you are required to install a continuous parameter monitoring system (CPMS) as specified in Table 5 of this subpart, you must install, operate, and maintain each CPMS according to the requirements in paragraphs (b)(1) through (6) of this section. For an affected source that is complying with the emission limitations and operating limitations on March 9, 2011, the requirements in paragraph (b) of this section are applicable September 6, 2011.

(1) You must prepare a site-specific monitoring plan that addresses the monitoring system design, data collection, and the quality assurance and quality control elements outlined in paragraphs (b)(1)(i) through (v) of this section and in §63.8(d). As specified in §63.8(f)(4), you may request approval of monitoring system quality assurance and quality control procedures alternative to those specified in paragraphs (b)(1) through (5) of this section in your site-specific monitoring plan.

(i) The performance criteria and design specifications for the monitoring system equipment, including the sample interface, detector signal analyzer, and data acquisition and calculations;

(ii) Sampling interface (*e.g.,* thermocouple) location such that the monitoring system will provide representative measurements;

(iii) Equipment performance evaluations, system accuracy audits, or other audit procedures;

(iv) Ongoing operation and maintenance procedures in accordance with provisions in §63.8(c)(1)(ii) and (c)(3); and

(v) Ongoing reporting and recordkeeping procedures in accordance with provisions in §63.10(c), (e)(1), and (e)(2)(i).

(2) You must install, operate, and maintain each CPMS in continuous operation according to the procedures in your site-specific monitoring plan.

(3) The CPMS must collect data at least once every 15 minutes (see also §63.6635).

(4) For a CPMS for measuring temperature range, the temperature sensor must have a minimum tolerance of 2.8 degrees Celsius (5 degrees Fahrenheit) or 1 percent of the measurement range, whichever is larger.

(5) You must conduct the CPMS equipment performance evaluation, system accuracy audits, or other audit procedures specified in your site-specific monitoring plan at least annually.

(6) You must conduct a performance evaluation of each CPMS in accordance with your site-specific monitoring plan.

(c) If you are operating a new or reconstructed stationary RICE which fires landfill gas or digester gas equivalent to 10 percent or more of the gross heat input on an annual basis, you must monitor and record your fuel usage daily with separate fuel meters to measure the volumetric flow rate of each fuel. In addition, you must operate your stationary RICE in a manner which reasonably minimizes HAP emissions.

(d) If you are operating a new or reconstructed emergency 4SLB stationary RICE with a site rating of greater than or equal to 250 and less than or equal to 500 brake HP located at a major source of HAP emissions, you must install a non-resettable hour meter prior to the startup of the engine.

(e) If you own or operate any of the following stationary RICE, you must operate and maintain the stationary RICE and after-treatment control device (if any) according to the manufacturer's emission-related written instructions or develop your own maintenance plan which must provide to the extent practicable for the maintenance and operation of the engine in a manner consistent with good air pollution control practice for minimizing emissions:

(1) An existing stationary RICE with a site rating of less than 100 HP located at a major source of HAP emissions;

(2) An existing emergency or black start stationary RICE with a site rating of less than or equal to 500 HP located at a major source of HAP emissions;

(3) An existing emergency or black start stationary RICE located at an area source of HAP emissions;

(4) An existing non-emergency, non-black start stationary CI RICE with a site rating less than or equal to 300 HP located at an area source of HAP emissions;

(5) An existing non-emergency, non-black start 2SLB stationary RICE located at an area source of HAP emissions;

(6) An existing non-emergency, non-black start stationary RICE located at an area source of HAP emissions which combusts landfill or digester gas equivalent to 10 percent or more of the gross heat input on an annual basis.

(7) An existing non-emergency, non-black start 4SLB stationary RICE with a site rating less than or equal to 500 HP located at an area source of HAP emissions;

(8) An existing non-emergency, non-black start 4SRB stationary RICE with a site rating less than or equal to 500 HP located at an area source of HAP emissions;

(9) An existing, non-emergency, non-black start 4SLB stationary RICE with a site rating greater than 500 HP located at an area source of HAP emissions that is operated 24 hours or less per calendar year; and

(10) An existing, non-emergency, non-black start 4SRB stationary RICE with a site rating greater than 500 HP located at an area source of HAP emissions that is operated 24 hours or less per calendar year.

(f) If you own or operate an existing emergency stationary RICE with a site rating of less than or equal to 500 brake HP located at a major source of HAP emissions or an existing emergency stationary RICE located at an area source of HAP emissions, you must install a non-resettable hour meter if one is not already installed.

(g) If you own or operate an existing non-emergency, non-black start CI engine greater than or equal to 300 HP that is not equipped with a closed crankcase ventilation system, you must comply

with either paragraph (g)(1) or paragraph (2) of this section. Owners and operators must follow the manufacturer's specified maintenance requirements for operating and maintaining the open or closed crankcase ventilation systems and replacing the crankcase filters, or can request the Administrator to approve different maintenance requirements that are as protective as manufacturer requirements. Existing CI engines located at area sources in areas of Alaska that meet either §63.6603(b)(1) or §63.6603(b)(2) do not have to meet the requirements of this paragraph (g). Existing CI engines located on offshore vessels that meet §63.6603(c) do not have to meet the requirements of this paragraph (g).

(1) Install a closed crankcase ventilation system that prevents crankcase emissions from being emitted to the atmosphere, or

(2) Install an open crankcase filtration emission control system that reduces emissions from the crankcase by filtering the exhaust stream to remove oil mist, particulates and metals.

(h) If you operate a new, reconstructed, or existing stationary engine, you must minimize the engine's time spent at idle during startup and minimize the engine's startup time to a period needed for appropriate and safe loading of the engine, not to exceed 30 minutes, after which time the emission standards applicable to all times other than startup in Tables 1a, 2a, 2c, and 2d to this subpart apply.

(i) If you own or operate a stationary CI engine that is subject to the work, operation or management practices in items 1 or 2 of Table 2c to this subpart or in items 1 or 4 of Table 2d to this subpart, you have the option of utilizing an oil analysis program in order to extend the specified oil change requirement in Tables 2c and 2d to this subpart. The oil analysis must be performed at the same frequency specified for changing the oil in Table 2c or 2d to this subpart. The analysis program must at a minimum analyze the following three parameters: Total Base Number, viscosity, and percent water content. The condemning limits for these parameters are as follows: Total Base Number is less than 30 percent of the Total Base Number of the oil when new; viscosity of the oil has changed by more than 20 percent from the viscosity of the oil when new; or percent water content (by volume) is greater than 0.5. If all of these condemning limits are not exceeded, the engine owner or operator is not required to change the oil. If any of the limits are exceeded, the engine owner or operator must change the oil within 2 business days of receiving the results of the analysis; if the engine is not in operation when the results of the analysis are received, the engine owner or operator must change the oil within 2 business days or before commencing operation, whichever is later. The owner or operator must keep records of the parameters that are analyzed as part of the program, the results of the analysis, and the oil changes for the engine. The analysis program must be part of the maintenance plan for the engine.

(j) If you own or operate a stationary SI engine that is subject to the work, operation or management practices in items 6, 7, or 8 of Table 2c to this subpart or in items 5, 6, 7, 9, or 11 of Table 2d to this subpart, you have the option of utilizing an oil analysis program in order to extend the specified oil change requirement in Tables 2c and 2d to this subpart. The oil analysis must be performed at the same frequency specified for changing the oil in Table 2c or 2d to this subpart. The analysis program must at a minimum analyze the following three parameters: Total Acid Number, viscosity, and percent water content. The condemning limits for these parameters are as follows: Total Acid Number increases by more than 3.0 milligrams of potassium hydroxide (KOH) per gram from Total Acid Number of the oil when new; viscosity of the oil has changed by more than 20 percent from the viscosity of the oil when new; or percent water content (by volume) is greater than 0.5. If all of these condemning limits are not exceeded, the engine owner or operator is not required to change the oil. If any of the limits are exceeded, the engine owner or operator must change the oil within 2 business days of receiving the results of the analysis; if the engine is not in operation when

the results of the analysis are received, the engine owner or operator must change the oil within 2 business days or before commencing operation, whichever is later. The owner or operator must keep records of the parameters that are analyzed as part of the program, the results of the analysis, and the oil changes for the engine. The analysis program must be part of the maintenance plan for the engine.

[69 FR 33506, June 15, 2004, as amended at 73 FR 3606, Jan. 18, 2008; 75 FR 9676, Mar. 3, 2010; 75 FR 51589, Aug. 20, 2010; 76 FR 12866, Mar. 9, 2011; 78 FR 6703, Jan. 30, 2013]

Back to Top

§63.6630 How do I demonstrate initial compliance with the emission limitations, operating limitations, and other requirements?

(a) You must demonstrate initial compliance with each emission limitation, operating limitation, and other requirement that applies to you according to Table 5 of this subpart.

(b) During the initial performance test, you must establish each operating limitation in Tables 1b and 2b of this subpart that applies to you.

(c) You must submit the Notification of Compliance Status containing the results of the initial compliance demonstration according to the requirements in §63.6645.

(d) Non-emergency 4SRB stationary RICE complying with the requirement to reduce formaldehyde emissions by 76 percent or more can demonstrate initial compliance with the formaldehyde emission limit by testing for THC instead of formaldehyde. The testing must be conducted according to the requirements in Table 4 of this subpart. The average reduction of emissions of THC determined from the performance test must be equal to or greater than 30 percent.

(e) The initial compliance demonstration required for existing non-emergency 4SLB and 4SRB stationary RICE with a site rating of more than 500 HP located at an area source of HAP that are not remote stationary RICE and that are operated more than 24 hours per calendar year must be conducted according to the following requirements:

(1) The compliance demonstration must consist of at least three test runs.

(2) Each test run must be of at least 15 minute duration, except that each test conducted using the method in appendix A to this subpart must consist of at least one measurement cycle and include at least 2 minutes of test data phase measurement.

(3) If you are demonstrating compliance with the CO concentration or CO percent reduction requirement, you must measure CO emissions using one of the CO measurement methods specified in Table 4 of this subpart, or using appendix A to this subpart.

(4) If you are demonstrating compliance with the THC percent reduction requirement, you must measure THC emissions using Method 25A, reported as propane, of 40 CFR part 60, appendix A.

(5) You must measure O_2 using one of the O_2 measurement methods specified in Table 4 of this subpart. Measurements to determine O_2 concentration must be made at the same time as the measurements for CO or THC concentration.

(6) If you are demonstrating compliance with the CO or THC percent reduction requirement, you must measure CO or THC emissions and O_2 emissions simultaneously at the inlet and outlet of the control device.

[69 FR 33506, June 15, 2004, as amended at 78 FR 6704, Jan. 30, 2013]

CONTINUOUS COMPLIANCE REQUIREMENTS

Back to Top

§63.6635 How do I monitor and collect data to demonstrate continuous compliance?

(a) If you must comply with emission and operating limitations, you must monitor and collect data according to this section.

(b) Except for monitor malfunctions, associated repairs, required performance evaluations, and required quality assurance or control activities, you must monitor continuously at all times that the stationary RICE is operating. A monitoring malfunction is any sudden, infrequent, not reasonably preventable failure of the monitoring to provide valid data. Monitoring failures that are caused in part by poor maintenance or careless operation are not malfunctions.

(c) You may not use data recorded during monitoring malfunctions, associated repairs, and required quality assurance or control activities in data averages and calculations used to report emission or operating levels. You must, however, use all the valid data collected during all other periods.

[69 FR 33506, June 15, 2004, as amended at 76 FR 12867, Mar. 9, 2011]

Back to Top

§63.6640 How do I demonstrate continuous compliance with the emission limitations, operating limitations, and other requirements?

(a) You must demonstrate continuous compliance with each emission limitation, operating limitation, and other requirements in Tables 1a and 1b, Tables 2a and 2b, Table 2c, and Table 2d to this subpart that apply to you according to methods specified in Table 6 to this subpart.

(b) You must report each instance in which you did not meet each emission limitation or operating limitation in Tables 1a and 1b, Tables 2a and 2b, Table 2c, and Table 2d to this subpart that apply to you. These instances are deviations from the emission and operating limitations in this subpart. These deviations must be reported according to the requirements in §63.6650. If you change your catalyst, you must reestablish the values of the operating parameters measured during

the initial performance test. When you reestablish the values of your operating parameters, you must also conduct a performance test to demonstrate that you are meeting the required emission limitation applicable to your stationary RICE.

(c) The annual compliance demonstration required for existing non-emergency 4SLB and 4SRB stationary RICE with a site rating of more than 500 HP located at an area source of HAP that are not remote stationary RICE and that are operated more than 24 hours per calendar year must be conducted according to the following requirements:

(1) The compliance demonstration must consist of at least one test run.

(2) Each test run must be of at least 15 minute duration, except that each test conducted using the method in appendix A to this subpart must consist of at least one measurement cycle and include at least 2 minutes of test data phase measurement.

(3) If you are demonstrating compliance with the CO concentration or CO percent reduction requirement, you must measure CO emissions using one of the CO measurement methods specified in Table 4 of this subpart, or using appendix A to this subpart.

(4) If you are demonstrating compliance with the THC percent reduction requirement, you must measure THC emissions using Method 25A, reported as propane, of 40 CFR part 60, appendix A.

(5) You must measure O_2 using one of the O_2 measurement methods specified in Table 4 of this subpart. Measurements to determine O_2 concentration must be made at the same time as the measurements for CO or THC concentration.

(6) If you are demonstrating compliance with the CO or THC percent reduction requirement, you must measure CO or THC emissions and O_2 emissions simultaneously at the inlet and outlet of the control device.

(7) If the results of the annual compliance demonstration show that the emissions exceed the levels specified in Table 6 of this subpart, the stationary RICE must be shut down as soon as safely possible, and appropriate corrective action must be taken (e.g., repairs, catalyst cleaning, catalyst replacement). The stationary RICE must be retested within 7 days of being restarted and the emissions must meet the levels specified in Table 6 of this subpart. If the retest shows that the emissions continue to exceed the specified levels, the stationary RICE must again be shut down as soon as safely possible, and the stationary RICE may not operate, except for purposes of startup and testing, until the owner/operator demonstrates through testing that the emissions do not exceed the levels specified in Table 6 of this subpart.

(d) For new, reconstructed, and rebuilt stationary RICE, deviations from the emission or operating limitations that occur during the first 200 hours of operation from engine startup (engine burn-in period) are not violations. Rebuilt stationary RICE means a stationary RICE that has been rebuilt as that term is defined in 40 CFR 94.11(a).

(e) You must also report each instance in which you did not meet the requirements in Table 8 to this subpart that apply to you. If you own or operate a new or reconstructed stationary RICE with a site rating of less than or equal to 500 brake HP located at a major source of HAP emissions (except new or reconstructed 4SLB engines greater than or equal to 250 and less than or equal to 500 brake HP), a new or reconstructed stationary RICE located at an area source of HAP emissions, or any of the following RICE with a site rating of more than 500 brake HP located at a major source of HAP emissions, you do not need to comply with the requirements in Table 8 to this subpart: An existing

2SLB stationary RICE, an existing 4SLB stationary RICE, an existing emergency stationary RICE, an existing limited use stationary RICE, or an existing stationary RICE which fires landfill gas or digester gas equivalent to 10 percent or more of the gross heat input on an annual basis. If you own or operate any of the following RICE with a site rating of more than 500 brake HP located at a major source of HAP emissions, you do not need to comply with the requirements in Table 8 to this subpart, except for the initial notification requirements: a new or reconstructed stationary RICE that combusts landfill gas or digester gas equivalent to 10 percent or more of the gross heat input on an annual basis, a new or reconstructed emergency stationary RICE, or a new or reconstructed limited use stationary RICE.

(f) If you own or operate an emergency stationary RICE, you must operate the emergency stationary RICE according to the requirements in paragraphs (f)(1) through (4) of this section. In order for the engine to be considered an emergency stationary RICE under this subpart, any operation other than emergency operation, maintenance and testing, emergency demand response, and operation in non-emergency situations for 50 hours per year, as described in paragraphs (f)(1) through (4) of this section, is prohibited. If you do not operate the engine according to the requirements in paragraphs (f)(1) through (4) of this section, the engine will not be considered an emergency engine under this subpart and must meet all requirements for non-emergency engines.

(1) There is no time limit on the use of emergency stationary RICE in emergency situations.

(2) You may operate your emergency stationary RICE for any combination of the purposes specified in paragraphs (f)(2)(i) through (iii) of this section for a maximum of 100 hours per calendar year. Any operation for non-emergency situations as allowed by paragraphs (f)(3) and (4) of this section counts as part of the 100 hours per calendar year allowed by this paragraph (f)(2).

(i) Emergency stationary RICE may be operated for maintenance checks and readiness testing, provided that the tests are recommended by federal, state or local government, the manufacturer, the vendor, the regional transmission organization or equivalent balancing authority and transmission operator, or the insurance company associated with the engine. The owner or operator may petition the Administrator for approval of additional hours to be used for maintenance checks and readiness testing, but a petition is not required if the owner or operator maintains records indicating that federal, state, or local standards require maintenance and testing of emergency RICE beyond 100 hours per calendar year.

(ii) Emergency stationary RICE may be operated for emergency demand response for periods in which the Reliability Coordinator under the North American Electric Reliability Corporation (NERC) Reliability Standard EOP-002-3, Capacity and Energy Emergencies (incorporated by reference, see §63.14), or other authorized entity as determined by the Reliability Coordinator, has declared an Energy Emergency Alert Level 2 as defined in the NERC Reliability Standard EOP-002-3.

(iii) Emergency stationary RICE may be operated for periods where there is a deviation of voltage or frequency of 5 percent or greater below standard voltage or frequency.

(3) Emergency stationary RICE located at major sources of HAP may be operated for up to 50 hours per calendar year in non-emergency situations. The 50 hours of operation in non-emergency situations are counted as part of the 100 hours per calendar year for maintenance and testing and emergency demand response provided in paragraph (f)(2) of this section. The 50 hours per year for non-emergency situations cannot be used for peak shaving or non-emergency demand response, or to generate income for a facility to supply power to an electric grid or otherwise supply power as part of a financial arrangement with another entity.

(4) Emergency stationary RICE located at area sources of HAP may be operated for up to 50 hours per calendar year in non-emergency situations. The 50 hours of operation in non-emergency situations are counted as part of the 100 hours per calendar year for maintenance and testing and emergency demand response provided in paragraph (f)(2) of this section. Except as provided in paragraphs (f)(4)(i) and (ii) of this section, the 50 hours per year for non-emergency situations cannot be used for peak shaving or non-emergency demand response, or to generate income for a facility to an electric grid or otherwise supply power as part of a financial arrangement with another entity.

(i) Prior to May 3, 2014, the 50 hours per year for non-emergency situations can be used for peak shaving or non-emergency demand response to generate income for a facility, or to otherwise supply power as part of a financial arrangement with another entity if the engine is operated as part of a peak shaving (load management program) with the local distribution system operator and the power is provided only to the facility itself or to support the local distribution system.

(ii) The 50 hours per year for non-emergency situations can be used to supply power as part of a financial arrangement with another entity if all of the following conditions are met:

(A) The engine is dispatched by the local balancing authority or local transmission and distribution system operator.

(B) The dispatch is intended to mitigate local transmission and/or distribution limitations so as to avert potential voltage collapse or line overloads that could lead to the interruption of power supply in a local area or region.

(C) The dispatch follows reliability, emergency operation or similar protocols that follow specific NERC, regional, state, public utility commission or local standards or guidelines.

(D) The power is provided only to the facility itself or to support the local transmission and distribution system.

(E) The owner or operator identifies and records the entity that dispatches the engine and the specific NERC, regional, state, public utility commission or local standards or guidelines that are being followed for dispatching the engine. The local balancing authority or local transmission and distribution system operator may keep these records on behalf of the engine owner or operator.

[69 FR 33506, June 15, 2004, as amended at 71 FR 20467, Apr. 20, 2006; 73 FR 3606, Jan. 18, 2008; 75 FR 9676, Mar. 3, 2010; 75 FR 51591, Aug. 20, 2010; 78 FR 6704, Jan. 30, 2013]

NOTIFICATIONS, REPORTS, AND RECORDS

Back to Top

§63.6645 What notifications must I submit and when?

(a) You must submit all of the notifications in §§63.7(b) and (c), 63.8(e), (f)(4) and (f)(6), 63.9(b) through (e), and (g) and (h) that apply to you by the dates specified if you own or operate any of the following;

(1) An existing stationary RICE with a site rating of less than or equal to 500 brake HP located at a major source of HAP emissions.

(2) An existing stationary RICE located at an area source of HAP emissions.

(3) A stationary RICE with a site rating of more than 500 brake HP located at a major source of HAP emissions.

(4) A new or reconstructed 4SLB stationary RICE with a site rating of greater than or equal to 250 HP located at a major source of HAP emissions.

(5) This requirement does not apply if you own or operate an existing stationary RICE less than 100 HP, an existing stationary emergency RICE, or an existing stationary RICE that is not subject to any numerical emission standards.

(b) As specified in §63.9(b)(2), if you start up your stationary RICE with a site rating of more than 500 brake HP located at a major source of HAP emissions before the effective date of this subpart, you must submit an Initial Notification not later than December 13, 2004.

(c) If you start up your new or reconstructed stationary RICE with a site rating of more than 500 brake HP located at a major source of HAP emissions on or after August 16, 2004, you must submit an Initial Notification not later than 120 days after you become subject to this subpart.

(d) As specified in §63.9(b)(2), if you start up your stationary RICE with a site rating of equal to or less than 500 brake HP located at a major source of HAP emissions before the effective date of this subpart and you are required to submit an initial notification, you must submit an Initial Notification not later than July 16, 2008.

(e) If you start up your new or reconstructed stationary RICE with a site rating of equal to or less than 500 brake HP located at a major source of HAP emissions on or after March 18, 2008 and you are required to submit an initial notification, you must submit an Initial Notification not later than 120 days after you become subject to this subpart.

(f) If you are required to submit an Initial Notification but are otherwise not affected by the requirements of this subpart, in accordance with §63.6590(b), your notification should include the information in §63.9(b)(2)(i) through (v), and a statement that your stationary RICE has no additional requirements and explain the basis of the exclusion (for example, that it operates exclusively as an emergency stationary RICE if it has a site rating of more than 500 brake HP located at a major source of HAP emissions).

(g) If you are required to conduct a performance test, you must submit a Notification of Intent to conduct a performance test at least 60 days before the performance test is scheduled to begin as required in §63.7(b)(1).

(h) If you are required to conduct a performance test or other initial compliance demonstration as specified in Tables 4 and 5 to this subpart, you must submit a Notification of Compliance Status according to §63.9(h)(2)(ii).

(1) For each initial compliance demonstration required in Table 5 to this subpart that does not include a performance test, you must submit the Notification of Compliance Status before the close of business on the 30th day following the completion of the initial compliance demonstration.

(2) For each initial compliance demonstration required in Table 5 to this subpart that includes a performance test conducted according to the requirements in Table 3 to this subpart, you must submit the Notification of Compliance Status, including the performance test results, before the close of business on the 60th day following the completion of the performance test according to §63.10(d)(2).

(i) If you own or operate an existing non-emergency CI RICE with a site rating of more than 300 HP located at an area source of HAP emissions that is certified to the Tier 1 or Tier 2 emission standards in Table 1 of 40 CFR 89.112 and subject to an enforceable state or local standard requiring engine replacement and you intend to meet management practices rather than emission limits, as specified in §63.6603(d), you must submit a notification by March 3, 2013, stating that you intend to use the provision in §63.6603(d) and identifying the state or local regulation that the engine is subject to.

[73 FR 3606, Jan. 18, 2008, as amended at 75 FR 9677, Mar. 3, 2010; 75 FR 51591, Aug. 20, 2010; 78 FR 6705, Jan. 30, 2013]

Back to Top

§63.6650 What reports must I submit and when?

(a) You must submit each report in Table 7 of this subpart that applies to you.

(b) Unless the Administrator has approved a different schedule for submission of reports under §63.10(a), you must submit each report by the date in Table 7 of this subpart and according to the requirements in paragraphs (b)(1) through (b)(9) of this section.

(1) For semiannual Compliance reports, the first Compliance report must cover the period beginning on the compliance date that is specified for your affected source in §63.6595 and ending on June 30 or December 31, whichever date is the first date following the end of the first calendar half after the compliance date that is specified for your source in §63.6595.

(2) For semiannual Compliance reports, the first Compliance report must be postmarked or delivered no later than July 31 or January 31, whichever date follows the end of the first calendar half after the compliance date that is specified for your affected source in §63.6595.

(3) For semiannual Compliance reports, each subsequent Compliance report must cover the semiannual reporting period from January 1 through June 30 or the semiannual reporting period from July 1 through December 31.

(4) For semiannual Compliance reports, each subsequent Compliance report must be postmarked or delivered no later than July 31 or January 31, whichever date is the first date following the end of the semiannual reporting period.

(5) For each stationary RICE that is subject to permitting regulations pursuant to 40 CFR part 70 or 71, and if the permitting authority has established dates for submitting semiannual reports

pursuant to 40 CFR 70.6(a)(3)(iii)(A) or 40 CFR 71.6 (a)(3)(iii)(A), you may submit the first and subsequent Compliance reports according to the dates the permitting authority has established instead of according to the dates in paragraphs (b)(1) through (b)(4) of this section.

(6) For annual Compliance reports, the first Compliance report must cover the period beginning on the compliance date that is specified for your affected source in §63.6595 and ending on December 31.

(7) For annual Compliance reports, the first Compliance report must be postmarked or delivered no later than January 31 following the end of the first calendar year after the compliance date that is specified for your affected source in §63.6595.

(8) For annual Compliance reports, each subsequent Compliance report must cover the annual reporting period from January 1 through December 31.

(9) For annual Compliance reports, each subsequent Compliance report must be postmarked or delivered no later than January 31.

(c) The Compliance report must contain the information in paragraphs (c)(1) through (6) of this section.

(1) Company name and address.

(2) Statement by a responsible official, with that official's name, title, and signature, certifying the accuracy of the content of the report.

(3) Date of report and beginning and ending dates of the reporting period.

(4) If you had a malfunction during the reporting period, the compliance report must include the number, duration, and a brief description for each type of malfunction which occurred during the reporting period and which caused or may have caused any applicable emission limitation to be exceeded. The report must also include a description of actions taken by an owner or operator during a malfunction of an affected source to minimize emissions in accordance with §63.6605(b), including actions taken to correct a malfunction.

(5) If there are no deviations from any emission or operating limitations that apply to you, a statement that there were no deviations from the emission or operating limitations during the reporting period.

(6) If there were no periods during which the continuous monitoring system (CMS), including CEMS and CPMS, was out-of-control, as specified in §63.8(c)(7), a statement that there were no periods during which the CMS was out-of-control during the reporting period.

(d) For each deviation from an emission or operating limitation that occurs for a stationary RICE where you are not using a CMS to comply with the emission or operating limitations in this subpart, the Compliance report must contain the information in paragraphs (c)(1) through (4) of this section and the information in paragraphs (d)(1) and (2) of this section.

(1) The total operating time of the stationary RICE at which the deviation occurred during the reporting period.

(2) Information on the number, duration, and cause of deviations (including unknown cause, if applicable), as applicable, and the corrective action taken.

(e) For each deviation from an emission or operating limitation occurring for a stationary RICE where you are using a CMS to comply with the emission and operating limitations in this subpart, you must include information in paragraphs (c)(1) through (4) and (e)(1) through (12) of this section.

(1) The date and time that each malfunction started and stopped.

(2) The date, time, and duration that each CMS was inoperative, except for zero (low-level) and high-level checks.

(3) The date, time, and duration that each CMS was out-of-control, including the information in §63.8(c)(8).

(4) The date and time that each deviation started and stopped, and whether each deviation occurred during a period of malfunction or during another period.

(5) A summary of the total duration of the deviation during the reporting period, and the total duration as a percent of the total source operating time during that reporting period.

(6) A breakdown of the total duration of the deviations during the reporting period into those that are due to control equipment problems, process problems, other known causes, and other unknown causes.

(7) A summary of the total duration of CMS downtime during the reporting period, and the total duration of CMS downtime as a percent of the total operating time of the stationary RICE at which the CMS downtime occurred during that reporting period.

(8) An identification of each parameter and pollutant (CO or formaldehyde) that was monitored at the stationary RICE.

(9) A brief description of the stationary RICE.

(10) A brief description of the CMS.

(11) The date of the latest CMS certification or audit.

(12) A description of any changes in CMS, processes, or controls since the last reporting period.

(f) Each affected source that has obtained a title V operating permit pursuant to 40 CFR part 70 or 71 must report all deviations as defined in this subpart in the semiannual monitoring report required by 40 CFR 70.6 (a)(3)(iii)(A) or 40 CFR 71.6(a)(3)(iii)(A). If an affected source submits a Compliance report pursuant to Table 7 of this subpart along with, or as part of, the semiannual monitoring report required by 40 CFR 70.6(a)(3)(iii)(A) or 40 CFR 71.6(a)(3)(iii)(A), and the Compliance report includes all required information concerning deviations from any emission or operating limitation in this subpart, submission of the Compliance report shall be deemed to satisfy any obligation to report the same deviations in the semiannual monitoring report. However, submission of a Compliance report shall not otherwise affect any obligation the affected source may have to report deviations from permit requirements to the permit authority.

(g) If you are operating as a new or reconstructed stationary RICE which fires landfill gas or digester gas equivalent to 10 percent or more of the gross heat input on an annual basis, you must submit an annual report according to Table 7 of this subpart by the date specified unless the Administrator has approved a different schedule, according to the information described in paragraphs (b)(1) through (b)(5) of this section. You must report the data specified in (g)(1) through (g)(3) of this section.

(1) Fuel flow rate of each fuel and the heating values that were used in your calculations. You must also demonstrate that the percentage of heat input provided by landfill gas or digester gas is equivalent to 10 percent or more of the total fuel consumption on an annual basis.

(2) The operating limits provided in your federally enforceable permit, and any deviations from these limits.

(3) Any problems or errors suspected with the meters.

(h) If you own or operate an emergency stationary RICE with a site rating of more than 100 brake HP that operates or is contractually obligated to be available for more than 15 hours per calendar year for the purposes specified in §63.6640(f)(2)(ii) and (iii) or that operates for the purpose specified in §63.6640(f)(4)(ii), you must submit an annual report according to the requirements in paragraphs (h)(1) through (3) of this section.

(1) The report must contain the following information:

(i) Company name and address where the engine is located.

(ii) Date of the report and beginning and ending dates of the reporting period.

(iii) Engine site rating and model year.

(iv) Latitude and longitude of the engine in decimal degrees reported to the fifth decimal place.

(v) Hours operated for the purposes specified in §63.6640(f)(2)(ii) and (iii), including the date, start time, and end time for engine operation for the purposes specified in §63.6640(f)(2)(ii) and (iii).

(vi) Number of hours the engine is contractually obligated to be available for the purposes specified in §63.6640(f)(2)(ii) and (iii).

(vii) Hours spent for operation for the purpose specified in §63.6640(f)(4)(ii), including the date, start time, and end time for engine operation for the purposes specified in §63.6640(f)(4)(ii). The report must also identify the entity that dispatched the engine and the situation that necessitated the dispatch of the engine.

(viii) If there were no deviations from the fuel requirements in §63.6604 that apply to the engine (if any), a statement that there were no deviations from the fuel requirements during the reporting period.

(ix) If there were deviations from the fuel requirements in §63.6604 that apply to the engine (if any), information on the number, duration, and cause of deviations, and the corrective action taken.

(2) The first annual report must cover the calendar year 2015 and must be submitted no later than March 31, 2016. Subsequent annual reports for each calendar year must be submitted no later than March 31 of the following calendar year.

(3) The annual report must be submitted electronically using the subpart specific reporting form in the Compliance and Emissions Data Reporting Interface (CEDRI) that is accessed through EPA's Central Data Exchange (CDX) (*www.epa.gov/cdx*). However, if the reporting form specific to this subpart is not available in CEDRI at the time that the report is due, the written report must be submitted to the Administrator at the appropriate address listed in §63.13.

[69 FR 33506, June 15, 2004, as amended at 75 FR 9677, Mar. 3, 2010; 78 FR 6705, Jan. 30, 2013]

§63.6655 What records must I keep?

(a) If you must comply with the emission and operating limitations, you must keep the records described in paragraphs (a)(1) through (a)(5), (b)(1) through (b)(3) and (c) of this section.

(1) A copy of each notification and report that you submitted to comply with this subpart, including all documentation supporting any Initial Notification or Notification of Compliance Status that you submitted, according to the requirement in §63.10(b)(2)(xiv).

(2) Records of the occurrence and duration of each malfunction of operation (*i.e.,* process equipment) or the air pollution control and monitoring equipment.

(3) Records of performance tests and performance evaluations as required in §63.10(b)(2)(viii).

(4) Records of all required maintenance performed on the air pollution control and monitoring equipment.

(5) Records of actions taken during periods of malfunction to minimize emissions in accordance with §63.6605(b), including corrective actions to restore malfunctioning process and air pollution control and monitoring equipment to its normal or usual manner of operation.

(b) For each CEMS or CPMS, you must keep the records listed in paragraphs (b)(1) through (3) of this section.

(1) Records described in §63.10(b)(2)(vi) through (xi).

(2) Previous (*i.e.,* superseded) versions of the performance evaluation plan as required in §63.8(d)(3).

(3) Requests for alternatives to the relative accuracy test for CEMS or CPMS as required in §63.8(f)(6)(i), if applicable.

(c) If you are operating a new or reconstructed stationary RICE which fires landfill gas or digester gas equivalent to 10 percent or more of the gross heat input on an annual basis, you must keep the records of your daily fuel usage monitors.

(d) You must keep the records required in Table 6 of this subpart to show continuous compliance with each emission or operating limitation that applies to you.

(e) You must keep records of the maintenance conducted on the stationary RICE in order to demonstrate that you operated and maintained the stationary RICE and after-treatment control device (if any) according to your own maintenance plan if you own or operate any of the following stationary RICE;

(1) An existing stationary RICE with a site rating of less than 100 brake HP located at a major source of HAP emissions.

(2) An existing stationary emergency RICE.

(3) An existing stationary RICE located at an area source of HAP emissions subject to management practices as shown in Table 2d to this subpart.

(f) If you own or operate any of the stationary RICE in paragraphs (f)(1) through (2) of this section, you must keep records of the hours of operation of the engine that is recorded through the non-resettable hour meter. The owner or operator must document how many hours are spent for emergency operation, including what classified the operation as emergency and how many hours are spent for non-emergency operation. If the engine is used for the purposes specified in §63.6640(f)(2)(ii) or (iii) or §63.6640(f)(4)(ii), the owner or operator must keep records of the notification of the emergency situation, and the date, start time, and end time of engine operation for these purposes.

(1) An existing emergency stationary RICE with a site rating of less than or equal to 500 brake HP located at a major source of HAP emissions that does not meet the standards applicable to non-emergency engines.

(2) An existing emergency stationary RICE located at an area source of HAP emissions that does not meet the standards applicable to non-emergency engines.

[69 FR 33506, June 15, 2004, as amended at 75 FR 9678, Mar. 3, 2010; 75 FR 51592, Aug. 20, 2010; 78 FR 6706, Jan. 30, 2013]

Back to Top

§63.6660 In what form and how long must I keep my records?

(a) Your records must be in a form suitable and readily available for expeditious review according to §63.10(b)(1).

(b) As specified in §63.10(b)(1), you must keep each record for 5 years following the date of each occurrence, measurement, maintenance, corrective action, report, or record.

(c) You must keep each record readily accessible in hard copy or electronic form for at least 5 years after the date of each occurrence, measurement, maintenance, corrective action, report, or record, according to §63.10(b)(1).

[69 FR 33506, June 15, 2004, as amended at 75 FR 9678, Mar. 3, 2010]

OTHER REQUIREMENTS AND INFORMATION

Back to Top

§63.6665 What parts of the General Provisions apply to me?

Table 8 to this subpart shows which parts of the General Provisions in §§63.1 through 63.15 apply to you. If you own or operate a new or reconstructed stationary RICE with a site rating of less than or equal to 500 brake HP located at a major source of HAP emissions (except new or reconstructed 4SLB engines greater than or equal to 250 and less than or equal to 500 brake HP), a new or reconstructed stationary RICE located at an area source of HAP emissions, or any of the following RICE with a site rating of more than 500 brake HP located at a major source of HAP emissions, you do not need to comply with any of the requirements of the General Provisions specified in Table 8: An existing 2SLB stationary RICE, an existing 4SLB stationary RICE, an existing stationary RICE that combusts landfill or digester gas equivalent to 10 percent or more of the gross heat input on an annual basis, an existing emergency stationary RICE, or an existing limited use stationary RICE. If you own or operate any of the following RICE with a site rating of more than 500 brake HP located at a major source of HAP emissions, you do not need to comply with the requirements in the General Provisions specified in Table 8 except for the initial notification requirements: A new stationary RICE that combusts landfill gas or digester gas equivalent to 10 percent or more of the gross heat input on an annual basis, a new emergency stationary RICE, or a new limited use stationary RICE.

[75 FR 9678, Mar. 3, 2010]

Back to Top

§63.6670 Who implements and enforces this subpart?

(a) This subpart is implemented and enforced by the U.S. EPA, or a delegated authority such as your State, local, or tribal agency. If the U.S. EPA Administrator has delegated authority to your State, local, or tribal agency, then that agency (as well as the U.S. EPA) has the authority to implement and enforce this subpart. You should contact your U.S. EPA Regional Office to find out whether this subpart is delegated to your State, local, or tribal agency.

(b) In delegating implementation and enforcement authority of this subpart to a State, local, or tribal agency under 40 CFR part 63, subpart E, the authorities contained in paragraph (c) of this section are retained by the Administrator of the U.S. EPA and are not transferred to the State, local, or tribal agency.

(c) The authorities that will not be delegated to State, local, or tribal agencies are:

(1) Approval of alternatives to the non-opacity emission limitations and operating limitations in §63.6600 under §63.6(g).

(2) Approval of major alternatives to test methods under §63.7(e)(2)(ii) and (f) and as defined in §63.90.

(3) Approval of major alternatives to monitoring under §63.8(f) and as defined in §63.90.

(4) Approval of major alternatives to recordkeeping and reporting under §63.10(f) and as defined in §63.90.

(5) Approval of a performance test which was conducted prior to the effective date of the rule, as specified in §63.6610(b).

Back to Top

§63.6675 What definitions apply to this subpart?

Terms used in this subpart are defined in the Clean Air Act (CAA); in 40 CFR 63.2, the General Provisions of this part; and in this section as follows:

Alaska Railbelt Grid means the service areas of the six regulated public utilities that extend from Fairbanks to Anchorage and the Kenai Peninsula. These utilities are Golden Valley Electric Association; Chugach Electric Association; Matanuska Electric Association; Homer Electric Association; Anchorage Municipal Light & Power; and the City of Seward Electric System.

Area source means any stationary source of HAP that is not a major source as defined in part 63.

Associated equipment as used in this subpart and as referred to in section 112(n)(4) of the CAA, means equipment associated with an oil or natural gas exploration or production well, and includes all equipment from the well bore to the point of custody transfer, except glycol dehydration units, storage vessels with potential for flash emissions, combustion turbines, and stationary RICE.

Backup power for renewable energy means an engine that provides backup power to a facility that generates electricity from renewable energy resources, as that term is defined in Alaska Statute 42.45.045(l)(5) (incorporated by reference, see §63.14).

Black start engine means an engine whose only purpose is to start up a combustion turbine.

CAA means the Clean Air Act (42 U.S.C. 7401 *et seq.,* as amended by Public Law 101-549, 104 Stat. 2399).

Commercial emergency stationary RICE means an emergency stationary RICE used in commercial establishments such as office buildings, hotels, stores, telecommunications facilities, restaurants, financial institutions such as banks, doctor's offices, and sports and performing arts facilities.

Compression ignition means relating to a type of stationary internal combustion engine that is not a spark ignition engine.

Custody transfer means the transfer of hydrocarbon liquids or natural gas: After processing and/or treatment in the producing operations, or from storage vessels or automatic transfer facilities

or other such equipment, including product loading racks, to pipelines or any other forms of transportation. For the purposes of this subpart, the point at which such liquids or natural gas enters a natural gas processing plant is a point of custody transfer.

Deviation means any instance in which an affected source subject to this subpart, or an owner or operator of such a source:

(1) Fails to meet any requirement or obligation established by this subpart, including but not limited to any emission limitation or operating limitation;

(2) Fails to meet any term or condition that is adopted to implement an applicable requirement in this subpart and that is included in the operating permit for any affected source required to obtain such a permit; or

(3) Fails to meet any emission limitation or operating limitation in this subpart during malfunction, regardless or whether or not such failure is permitted by this subpart.

(4) Fails to satisfy the general duty to minimize emissions established by §63.6(e)(1)(i).

Diesel engine means any stationary RICE in which a high boiling point liquid fuel injected into the combustion chamber ignites when the air charge has been compressed to a temperature sufficiently high for auto-ignition. This process is also known as compression ignition.

Diesel fuel means any liquid obtained from the distillation of petroleum with a boiling point of approximately 150 to 360 degrees Celsius. One commonly used form is fuel oil number 2. Diesel fuel also includes any non-distillate fuel with comparable physical and chemical properties (*e.g.* biodiesel) that is suitable for use in compression ignition engines.

Digester gas means any gaseous by-product of wastewater treatment typically formed through the anaerobic decomposition of organic waste materials and composed principally of methane and CO_2.

Dual-fuel engine means any stationary RICE in which a liquid fuel (typically diesel fuel) is used for compression ignition and gaseous fuel (typically natural gas) is used as the primary fuel.

Emergency stationary RICE means any stationary reciprocating internal combustion engine that meets all of the criteria in paragraphs (1) through (3) of this definition. All emergency stationary RICE must comply with the requirements specified in §63.6640(f) in order to be considered emergency stationary RICE. If the engine does not comply with the requirements specified in §63.6640(f), then it is not considered to be an emergency stationary RICE under this subpart.

(1) The stationary RICE is operated to provide electrical power or mechanical work during an emergency situation. Examples include stationary RICE used to produce power for critical networks or equipment (including power supplied to portions of a facility) when electric power from the local utility (or the normal power source, if the facility runs on its own power production) is interrupted, or stationary RICE used to pump water in the case of fire or flood, etc.

(2) The stationary RICE is operated under limited circumstances for situations not included in paragraph (1) of this definition, as specified in §63.6640(f).

(3) The stationary RICE operates as part of a financial arrangement with another entity in situations not included in paragraph (1) of this definition only as allowed in §63.6640(f)(2)(ii) or (iii) and §63.6640(f)(4)(i) or (ii).

Engine startup means the time from initial start until applied load and engine and associated equipment reaches steady state or normal operation. For stationary engine with catalytic controls, engine startup means the time from initial start until applied load and engine and associated equipment, including the catalyst, reaches steady state or normal operation.

Four-stroke engine means any type of engine which completes the power cycle in two crankshaft revolutions, with intake and compression strokes in the first revolution and power and exhaust strokes in the second revolution.

Gaseous fuel means a material used for combustion which is in the gaseous state at standard atmospheric temperature and pressure conditions.

Gasoline means any fuel sold in any State for use in motor vehicles and motor vehicle engines, or nonroad or stationary engines, and commonly or commercially known or sold as gasoline.

Glycol dehydration unit means a device in which a liquid glycol (including, but not limited to, ethylene glycol, diethylene glycol, or triethylene glycol) absorbent directly contacts a natural gas stream and absorbs water in a contact tower or absorption column (absorber). The glycol contacts and absorbs water vapor and other gas stream constituents from the natural gas and becomes “rich” glycol. This glycol is then regenerated in the glycol dehydration unit reboiler. The “lean” glycol is then recycled.

Hazardous air pollutants (HAP) means any air pollutants listed in or pursuant to section 112(b) of the CAA.

Institutional emergency stationary RICE means an emergency stationary RICE used in institutional establishments such as medical centers, nursing homes, research centers, institutions of higher education, correctional facilities, elementary and secondary schools, libraries, religious establishments, police stations, and fire stations.

ISO standard day conditions means 288 degrees Kelvin (15 degrees Celsius), 60 percent relative humidity and 101.3 kilopascals pressure.

Landfill gas means a gaseous by-product of the land application of municipal refuse typically formed through the anaerobic decomposition of waste materials and composed principally of methane and CO_2.

Lean burn engine means any two-stroke or four-stroke spark ignited engine that does not meet the definition of a rich burn engine.

Limited use stationary RICE means any stationary RICE that operates less than 100 hours per year.

Liquefied petroleum gas means any liquefied hydrocarbon gas obtained as a by-product in petroleum refining of natural gas production.

Liquid fuel means any fuel in liquid form at standard temperature and pressure, including but not limited to diesel, residual/crude oil, kerosene/naphtha (jet fuel), and gasoline.

Major Source, as used in this subpart, shall have the same meaning as in §63.2, except that:

(1) Emissions from any oil or gas exploration or production well (with its associated equipment (as defined in this section)) and emissions from any pipeline compressor station or pump station shall not be aggregated with emissions from other similar units, to determine whether such emission points or stations are major sources, even when emission points are in a contiguous area or under common control;

(2) For oil and gas production facilities, emissions from processes, operations, or equipment that are not part of the same oil and gas production facility, as defined in §63.1271 of subpart HHH of this part, shall not be aggregated;

(3) For production field facilities, only HAP emissions from glycol dehydration units, storage vessel with the potential for flash emissions, combustion turbines and reciprocating internal combustion engines shall be aggregated for a major source determination; and

(4) Emissions from processes, operations, and equipment that are not part of the same natural gas transmission and storage facility, as defined in §63.1271 of subpart HHH of this part, shall not be aggregated.

Malfunction means any sudden, infrequent, and not reasonably preventable failure of air pollution control equipment, process equipment, or a process to operate in a normal or usual manner which causes, or has the potential to cause, the emission limitations in an applicable standard to be exceeded. Failures that are caused in part by poor maintenance or careless operation are not malfunctions.

Natural gas means a naturally occurring mixture of hydrocarbon and non-hydrocarbon gases found in geologic formations beneath the Earth's surface, of which the principal constituent is methane. Natural gas may be field or pipeline quality.

Non-selective catalytic reduction (NSCR) means an add-on catalytic nitrogen oxides (NO_x) control device for rich burn engines that, in a two-step reaction, promotes the conversion of excess oxygen, NO_x, CO, and volatile organic compounds (VOC) into CO_2, nitrogen, and water.

Oil and gas production facility as used in this subpart means any grouping of equipment where hydrocarbon liquids are processed, upgraded (*i.e.,* remove impurities or other constituents to meet contract specifications), or stored prior to the point of custody transfer; or where natural gas is processed, upgraded, or stored prior to entering the natural gas transmission and storage source category. For purposes of a major source determination, facility (including a building, structure, or installation) means oil and natural gas production and processing equipment that is located within the boundaries of an individual surface site as defined in this section. Equipment that is part of a facility will typically be located within close proximity to other equipment located at the same facility. Pieces of production equipment or groupings of equipment located on different oil and gas leases, mineral fee tracts, lease tracts, subsurface or surface unit areas, surface fee tracts, surface lease tracts, or separate surface sites, whether or not connected by a road, waterway, power line or pipeline, shall not be considered part of the same facility. Examples of facilities in the oil and natural gas production source category include, but are not limited to, well sites, satellite tank batteries, central tank batteries, a compressor station that transports natural gas to a natural gas processing plant, and natural gas processing plants.

Oxidation catalyst means an add-on catalytic control device that controls CO and VOC by oxidation.

Peaking unit or engine means any standby engine intended for use during periods of high demand that are not emergencies.

Percent load means the fractional power of an engine compared to its maximum manufacturer's design capacity at engine site conditions. Percent load may range between 0 percent to above 100 percent.

Potential to emit means the maximum capacity of a stationary source to emit a pollutant under its physical and operational design. Any physical or operational limitation on the capacity of the stationary source to emit a pollutant, including air pollution control equipment and restrictions on hours of operation or on the type or amount of material combusted, stored, or processed, shall be treated as part of its design if the limitation or the effect it would have on emissions is federally enforceable. For oil and natural gas production facilities subject to subpart HH of this part, the potential to emit provisions in §63.760(a) may be used. For natural gas transmission and storage facilities subject to subpart HHH of this part, the maximum annual facility gas throughput for storage facilities may be determined according to §63.1270(a)(1) and the maximum annual throughput for transmission facilities may be determined according to §63.1270(a)(2).

Production field facility means those oil and gas production facilities located prior to the point of custody transfer.

Production well means any hole drilled in the earth from which crude oil, condensate, or field natural gas is extracted.

Propane means a colorless gas derived from petroleum and natural gas, with the molecular structure C_3H_8.

Remote stationary RICE means stationary RICE meeting any of the following criteria:

(1) Stationary RICE located in an offshore area that is beyond the line of ordinary low water along that portion of the coast of the United States that is in direct contact with the open seas and beyond the line marking the seaward limit of inland waters.

(2) Stationary RICE located on a pipeline segment that meets both of the criteria in paragraphs (2)(i) and (ii) of this definition.

(i) A pipeline segment with 10 or fewer buildings intended for human occupancy and no buildings with four or more stories within 220 yards (200 meters) on either side of the centerline of any continuous 1-mile (1.6 kilometers) length of pipeline. Each separate dwelling unit in a multiple dwelling unit building is counted as a separate building intended for human occupancy.

(ii) The pipeline segment does not lie within 100 yards (91 meters) of either a building or a small, well-defined outside area (such as a playground, recreation area, outdoor theater, or other place of public assembly) that is occupied by 20 or more persons on at least 5 days a week for 10 weeks in any 12-month period. The days and weeks need not be consecutive. The building or area is considered occupied for a full day if it is occupied for any portion of the day.

(iii) For purposes of this paragraph (2), the term pipeline segment means all parts of those physical facilities through which gas moves in transportation, including but not limited to pipe, valves, and other appurtenance attached to pipe, compressor units, metering stations, regulator stations, delivery stations, holders, and fabricated assemblies. Stationary RICE located within 50 yards (46 meters) of the pipeline segment providing power for equipment on a pipeline segment are part of the pipeline segment. Transportation of gas means the gathering, transmission, or distribution of gas by pipeline, or the storage of gas. A building is intended for human occupancy if its primary use is for a purpose involving the presence of humans.

(3) Stationary RICE that are not located on gas pipelines and that have 5 or fewer buildings intended for human occupancy and no buildings with four or more stories within a 0.25 mile radius around the engine. A building is intended for human occupancy if its primary use is for a purpose involving the presence of humans.

Residential emergency stationary RICE means an emergency stationary RICE used in residential establishments such as homes or apartment buildings.

Responsible official means responsible official as defined in 40 CFR 70.2.

Rich burn engine means any four-stroke spark ignited engine where the manufacturer's recommended operating air/fuel ratio divided by the stoichiometric air/fuel ratio at full load conditions is less than or equal to 1.1. Engines originally manufactured as rich burn engines, but modified prior to December 19, 2002 with passive emission control technology for NO_x (such as pre-combustion chambers) will be considered lean burn engines. Also, existing engines where there are no manufacturer's recommendations regarding air/fuel ratio will be considered a rich burn engine if the excess oxygen content of the exhaust at full load conditions is less than or equal to 2 percent.

Site-rated HP means the maximum manufacturer's design capacity at engine site conditions.

Spark ignition means relating to either: A gasoline-fueled engine; or any other type of engine with a spark plug (or other sparking device) and with operating characteristics significantly similar to the theoretical Otto combustion cycle. Spark ignition engines usually use a throttle to regulate intake air flow to control power during normal operation. Dual-fuel engines in which a liquid fuel (typically diesel fuel) is used for CI and gaseous fuel (typically natural gas) is used as the primary fuel at an annual average ratio of less than 2 parts diesel fuel to 100 parts total fuel on an energy equivalent basis are spark ignition engines.

Stationary reciprocating internal combustion engine (RICE) means any reciprocating internal combustion engine which uses reciprocating motion to convert heat energy into mechanical work and which is not mobile. Stationary RICE differ from mobile RICE in that a stationary RICE is not a non-road engine as defined at 40 CFR 1068.30, and is not used to propel a motor vehicle or a vehicle used solely for competition.

Stationary RICE test cell/stand means an engine test cell/stand, as defined in subpart PPPPP of this part, that tests stationary RICE.

Stoichiometric means the theoretical air-to-fuel ratio required for complete combustion.

Storage vessel with the potential for flash emissions means any storage vessel that contains a hydrocarbon liquid with a stock tank gas-to-oil ratio equal to or greater than 0.31 cubic meters per liter and an American Petroleum Institute gravity equal to or greater than 40 degrees and an actual annual average hydrocarbon liquid throughput equal to or greater than 79,500 liters per day. Flash

emissions occur when dissolved hydrocarbons in the fluid evolve from solution when the fluid pressure is reduced.

Subpart means 40 CFR part 63, subpart ZZZZ.

Surface site means any combination of one or more graded pad sites, gravel pad sites, foundations, platforms, or the immediate physical location upon which equipment is physically affixed.

Two-stroke engine means a type of engine which completes the power cycle in single crankshaft revolution by combining the intake and compression operations into one stroke and the power and exhaust operations into a second stroke. This system requires auxiliary scavenging and inherently runs lean of stoichiometric.

[69 FR 33506, June 15, 2004, as amended at 71 FR 20467, Apr. 20, 2006; 73 FR 3607, Jan. 18, 2008; 75 FR 9679, Mar. 3, 2010; 75 FR 51592, Aug. 20, 2010; 76 FR 12867, Mar. 9, 2011; 78 FR 6706, Jan. 30, 2013]

Back to Top

Table 1a to Subpart ZZZZ of Part 63—Emission Limitations for Existing, New, and Reconstructed Spark Ignition, 4SRB Stationary RICE >500 HP Located at a Major Source of HAP Emissions

As stated in §§63.6600 and 63.6640, you must comply with the following emission limitations at 100 percent load plus or minus 10 percent for existing, new and reconstructed 4SRB stationary RICE >500 HP located at a major source of HAP emissions:

For each . . .	You must meet the following emission limitation, except during periods of startup . . .	During periods of startup you must . . .
1. 4SRB stationary RICE	a. Reduce formaldehyde emissions by 76 percent or more. If you commenced construction or reconstruction between December 19, 2002 and June 15, 2004, you may reduce formaldehyde emissions by 75 percent or more until June 15, 2007 or	Minimize the engine's time spent at idle and minimize the engine's startup time at startup to a period needed for appropriate and safe loading of the engine, not to exceed 30 minutes, after which time the non-startup emission limitations apply.[1]
	b. Limit the concentration of formaldehyde in the stationary RICE exhaust to 350 ppbvd or less at 15 percent O_2	

[1] Sources can petition the Administrator pursuant to the requirements of 40 CFR 63.6(g) for alternative work practices.

[75 FR 9679, Mar. 3, 2010, as amended at 75 FR 51592, Aug. 20, 2010]

Table 1b to Subpart ZZZZ of Part 63—Operating Limitations for Existing, New, and Reconstructed SI 4SRB Stationary RICE >500 HP Located at a Major Source of HAP Emissions

As stated in §§63.6600, 63.6603, 63.6630 and 63.6640, you must comply with the following operating limitations for existing, new and reconstructed 4SRB stationary RICE >500 HP located at a major source of HAP emissions:

For each . . .	You must meet the following operating limitation, except during periods of startup . . .
1. existing, new and reconstructed 4SRB stationary RICE >500 HP located at a major source of HAP emissions complying with the requirement to reduce formaldehyde emissions by 76 percent or more (or by 75 percent or more, if applicable) and using NSCR; or existing, new and reconstructed 4SRB stationary RICE >500 HP located at a major source of HAP emissions complying with the requirement to limit the concentration of formaldehyde in the stationary RICE exhaust to 350 ppbvd or less at 15 percent O_2 and using NSCR;	a. maintain your catalyst so that the pressure drop across the catalyst does not change by more than 2 inches of water at 100 percent load plus or minus 10 percent from the pressure drop across the catalyst measured during the initial performance test; and b. maintain the temperature of your stationary RICE exhaust so that the catalyst inlet temperature is greater than or equal to 750 °F and less than or equal to 1250 °F.[1]
2. existing, new and reconstructed 4SRB stationary RICE >500 HP located at a major source of HAP emissions complying with the requirement to reduce formaldehyde emissions by 76 percent or more (or by 75 percent or more, if applicable) and not using NSCR; or	Comply with any operating limitations approved by the Administrator.
existing, new and reconstructed 4SRB stationary RICE >500 HP located at a major source of HAP emissions complying with the requirement to limit the concentration of formaldehyde in the stationary RICE exhaust to 350 ppbvd or less at 15 percent O_2 and not using NSCR.	

[1]Sources can petition the Administrator pursuant to the requirements of 40 CFR 63.8(f) for a different temperature range.

Table 2a to Subpart ZZZZ of Part 63—Emission Limitations for New and Reconstructed 2SLB and Compression Ignition Stationary RICE >500 HP and New and Reconstructed 4SLB Stationary RICE ≥250 HP Located at a Major Source of HAP Emissions

As stated in §§63.6600 and 63.6640, you must comply with the following emission limitations for new and reconstructed lean burn and new and reconstructed compression ignition stationary RICE at 100 percent load plus or minus 10 percent:

For each . . .	You must meet the following emission limitation, except during periods of startup . . .	During periods of startup you must . . .
1. 2SLB stationary RICE	a. Reduce CO emissions by 58 percent or more; or b. Limit concentration of formaldehyde in the stationary RICE exhaust to 12 ppmvd or less at 15 percent O_2. If you commenced construction or reconstruction between December 19, 2002 and June 15, 2004, you may limit concentration of formaldehyde to 17 ppmvd or less at 15 percent O_2 until June 15, 2007	Minimize the engine's time spent at idle and minimize the engine's startup time at startup to a period needed for appropriate and safe loading of the engine, not to exceed 30 minutes, after which time the non-startup emission limitations apply.[1]
2. 4SLB stationary RICE	a. Reduce CO emissions by 93 percent or more; or	
	b. Limit concentration of formaldehyde in the stationary RICE exhaust to 14 ppmvd or less at 15 percent O_2	
3. CI stationary RICE	a. Reduce CO emissions by 70 percent or more; or	
	b. Limit concentration of formaldehyde in the stationary RICE exhaust to 580 ppbvd or less at 15 percent O_2	

[1]Sources can petition the Administrator pursuant to the requirements of 40 CFR 63.6(g) for alternative work practices.

Table 2b to Subpart ZZZZ of Part 63—Operating Limitations for New and Reconstructed 2SLB and CI Stationary RICE >500 HP Located at a Major Source of HAP Emissions, New and Reconstructed 4SLB Stationary RICE ≥250 HP Located at a Major Source of HAP Emissions, Existing CI Stationary RICE >500 HP

As stated in §§63.6600, 63.6601, 63.6603, 63.6630, and 63.6640, you must comply with the following operating limitations for new and reconstructed 2SLB and CI stationary RICE >500 HP located at a major source of HAP emissions; new and reconstructed 4SLB stationary RICE ≥250 HP located at a major source of HAP emissions; and existing CI stationary RICE >500 HP:

For each . . .	You must meet the following operating limitation, except during periods of startup . . .
1. New and reconstructed 2SLB and CI stationary RICE >500 HP located at a major source of HAP emissions and new and reconstructed 4SLB stationary RICE ≥250 HP located at a major source of HAP emissions complying with the requirement to reduce CO emissions and using an oxidation catalyst; and New and reconstructed 2SLB and CI stationary RICE >500 HP located at a major source of HAP emissions and new and reconstructed 4SLB stationary RICE ≥250 HP located at a major source of HAP emissions complying with the requirement to limit the concentration of formaldehyde in the stationary RICE exhaust and using an oxidation catalyst.	a. maintain your catalyst so that the pressure drop across the catalyst does not change by more than 2 inches of water at 100 percent load plus or minus 10 percent from the pressure drop across the catalyst that was measured during the initial performance test; and b. maintain the temperature of your stationary RICE exhaust so that the catalyst inlet temperature is greater than or equal to 450 °F and less than or equal to 1350 °F.[1]
2. Existing CI stationary RICE >500 HP complying with the requirement to limit or reduce the concentration of CO in the stationary RICE exhaust and using an oxidation catalyst	a. maintain your catalyst so that the pressure drop across the catalyst does not change by more than 2 inches of water from the pressure drop across the catalyst that was measured during the initial performance test; and
	b. maintain the temperature of your stationary RICE exhaust so that the catalyst inlet temperature is greater than or equal to 450 °F and less than or equal to 1350 °F.[1]
3. New and reconstructed 2SLB and CI stationary RICE >500 HP located at a major source of HAP emissions and new and reconstructed 4SLB stationary RICE ≥250 HP located at a major source of HAP emissions complying with the requirement to reduce CO emissions and not using an oxidation catalyst; and	Comply with any operating limitations approved by the Administrator.
New and reconstructed 2SLB and CI stationary RICE >500 HP located at a major source of HAP emissions and new and reconstructed 4SLB stationary RICE ≥250 HP located at a major source	

of HAP emissions complying with the requirement to limit the concentration of formaldehyde in the stationary RICE exhaust and not using an oxidation catalyst; and	
existing CI stationary RICE >500 HP complying with the requirement to limit or reduce the concentration of CO in the stationary RICE exhaust and not using an oxidation catalyst.

Table 2c to Subpart ZZZZ of Part 63—Requirements for Existing Compression Ignition Stationary RICE Located at a Major Source of HAP Emissions and Existing Spark Ignition Stationary RICE ≤500 HP Located at a Major Source of HAP Emissions

As stated in §§63.6600, 63.6602, and 63.6640, you must comply with the following requirements for existing compression ignition stationary RICE located at a major source of HAP emissions and existing spark ignition stationary RICE ≤500 HP located at a major source of HAP emissions:

For each . . .	You must meet the following requirement, except during periods of startup . . .	During periods of startup you must . . .
1. Emergency stationary CI RICE and black start stationary CI RICE[1]	a. Change oil and filter every 500 hours of operation or annually, whichever comes first.[2] b. Inspect air cleaner every 1,000 hours of operation or annually, whichever comes first, and replace as necessary; c. Inspect all hoses and belts every 500 hours of operation or annually, whichever comes first, and replace as necessary.[3]	Minimize the engine's time spent at idle and minimize the engine's startup time at startup to a period needed for appropriate and safe loading of the engine, not to exceed 30 minutes, after which time the non-startup emission limitations apply.[3]

2. Non-Emergency, non-black start stationary CI RICE <100 HP	a. Change oil and filter every 1,000 hours of operation or annually, whichever comes first.[2] b. Inspect air cleaner every 1,000 hours of operation or annually, whichever comes first, and replace as necessary; c. Inspect all hoses and belts every 500 hours of operation or annually, whichever comes first, and replace as necessary.[3]	
3. Non-Emergency, non-black start CI stationary RICE 100≤HP≤300 HP	Limit concentration of CO in the stationary RICE exhaust to 230 ppmvd or less at 15 percent O_2.	
4. Non-Emergency, non-black start CI stationary RICE 300<HP≤500	a. Limit concentration of CO in the stationary RICE exhaust to 49 ppmvd or less at 15 percent O_2; or b. Reduce CO emissions by 70 percent or more.	
5. Non-Emergency, non-black start stationary CI RICE >500 HP	a. Limit concentration of CO in the stationary RICE exhaust to 23 ppmvd or less at 15 percent O_2; or b. Reduce CO emissions by 70 percent or more.	
6. Emergency stationary SI RICE and black start stationary SI RICE.[1]	a. Change oil and filter every 500 hours of operation or annually, whichever comes first;[2] b. Inspect spark plugs every 1,000 hours of operation or annually, whichever comes first, and replace as necessary; c. Inspect all hoses and belts every 500 hours of	

	operation or annually, whichever comes first, and replace as necessary.[3]	
7. Non-Emergency, non-black start stationary SI RICE <100 HP that are not 2SLB stationary RICE	a. Change oil and filter every 1,440 hours of operation or annually, whichever comes first;[2] b. Inspect spark plugs every 1,440 hours of operation or annually, whichever comes first, and replace as necessary;	
	c. Inspect all hoses and belts every 1,440 hours of operation or annually, whichever comes first, and replace as necessary.[3]	
8. Non-Emergency, non-black start 2SLB stationary SI RICE <100 HP	a. Change oil and filter every 4,320 hours of operation or annually, whichever comes first;[2] b. Inspect spark plugs every 4,320 hours of operation or annually, whichever comes first, and replace as necessary;	
	c. Inspect all hoses and belts every 4,320 hours of operation or annually, whichever comes first, and replace as necessary.[3]	
9. Non-emergency, non-black start 2SLB stationary RICE 100≤HP≤500	Limit concentration of CO in the stationary RICE exhaust to 225 ppmvd or less at 15 percent O_2.	
10. Non-emergency, non-black start 4SLB stationary RICE 100≤HP≤500	Limit concentration of CO in the stationary RICE exhaust to 47 ppmvd or less at 15 percent O_2.	

11. Non-emergency, non-black start 4SRB stationary RICE 100≤HP≤500	Limit concentration of formaldehyde in the stationary RICE exhaust to 10.3 ppmvd or less at 15 percent O_2.	
12. Non-emergency, non-black start stationary RICE 100≤HP≤500 which combusts landfill or digester gas equivalent to 10 percent or more of the gross heat input on an annual basis	Limit concentration of CO in the stationary RICE exhaust to 177 ppmvd or less at 15 percent O_2.	

[1]If an emergency engine is operating during an emergency and it is not possible to shut down the engine in order to perform the work practice requirements on the schedule required in Table 2c of this subpart, or if performing the work practice on the required schedule would otherwise pose an unacceptable risk under federal, state, or local law, the work practice can be delayed until the emergency is over or the unacceptable risk under federal, state, or local law has abated. The work practice should be performed as soon as practicable after the emergency has ended or the unacceptable risk under federal, state, or local law has abated. Sources must report any failure to perform the work practice on the schedule required and the federal, state or local law under which the risk was deemed unacceptable.

[2]Sources have the option to utilize an oil analysis program as described in §63.6625(i) or (j) in order to extend the specified oil change requirement in Table 2c of this subpart.

[3]Sources can petition the Administrator pursuant to the requirements of 40 CFR 63.6(g) for alternative work practices.

[78 FR 6708, Jan. 30, 2013, as amended at 78 FR 14457, Mar. 6, 2013]

Table 2d to Subpart ZZZZ of Part 63—Requirements for Existing Stationary RICE Located at Area Sources of HAP Emissions

As stated in §§63.6603 and 63.6640, you must comply with the following requirements for existing stationary RICE located at area sources of HAP emissions:

For each . . .	You must meet the following requirement, except during periods of startup . . .	During periods of startup you must . . .
1. Non-Emergency, non-black start CI stationary RICE ≤300 HP	a. Change oil and filter every 1,000 hours of	Minimize the engine's time spent at idle and minimize the

	operation or annually, whichever comes first;[1] b. Inspect air cleaner every 1,000 hours of operation or annually, whichever comes first, and replace as necessary; c. Inspect all hoses and belts every 500 hours of operation or annually, whichever comes first, and replace as necessary.	engine's startup time at startup to a period needed for appropriate and safe loading of the engine, not to exceed 30 minutes, after which time the non-startup emission limitations apply.
2. Non-Emergency, non-black start CI stationary RICE 300<HP≤500	a. Limit concentration of CO in the stationary RICE exhaust to 49 ppmvd at 15 percent O_2; or	
	b. Reduce CO emissions by 70 percent or more.	
3. Non-Emergency, non-black start CI stationary RICE >500 HP	a. Limit concentration of CO in the stationary RICE exhaust to 23 ppmvd at 15 percent O_2; or	
	b. Reduce CO emissions by 70 percent or more.	
4. Emergency stationary CI RICE and black start stationary CI RICE.[2]	a. Change oil and filter every 500 hours of operation or annually, whichever comes first;[1]	
	b. Inspect air cleaner every 1,000 hours of operation or annually, whichever comes first, and replace as necessary; and	
	c. Inspect all hoses and belts every 500 hours	

	of operation or annually, whichever comes first, and replace as necessary.	
5. Emergency stationary SI RICE; black start stationary SI RICE; non-emergency, non-black start 4SLB stationary RICE >500 HP that operate 24 hours or less per calendar year; non-emergency, non-black start 4SRB stationary RICE >500 HP that operate 24 hours or less per calendar year.[2]	a. Change oil and filter every 500 hours of operation or annually, whichever comes first;[1]; b. Inspect spark plugs every 1,000 hours of operation or annually, whichever comes first, and replace as necessary; and c. Inspect all hoses and belts every 500 hours of operation or annually, whichever comes first, and replace as necessary.	
6. Non-emergency, non-black start 2SLB stationary RICE	a. Change oil and filter every 4,320 hours of operation or annually, whichever comes first;[1]	
	b. Inspect spark plugs every 4,320 hours of operation or annually, whichever comes first, and replace as necessary; and	
	c. Inspect all hoses and belts every 4,320 hours of operation or annually, whichever comes first, and replace as necessary.	
7. Non-emergency, non-black start 4SLB stationary RICE ≤500 HP	a. Change oil and filter every 1,440 hours of operation or annually, whichever comes first;[1]	
	b. Inspect spark plugs every 1,440 hours of	

	operation or annually, whichever comes first, and replace as necessary; and	
	c. Inspect all hoses and belts every 1,440 hours of operation or annually, whichever comes first, and replace as necessary.	
8. Non-emergency, non-black start 4SLB remote stationary RICE >500 HP	a. Change oil and filter every 2,160 hours of operation or annually, whichever comes first;[1]	
	b. Inspect spark plugs every 2,160 hours of operation or annually, whichever comes first, and replace as necessary; and	
	c. Inspect all hoses and belts every 2,160 hours of operation or annually, whichever comes first, and replace as necessary.	
9. Non-emergency, non-black start 4SLB stationary RICE >500 HP that are not remote stationary RICE and that operate more than 24 hours per calendar year	Install an oxidation catalyst to reduce HAP emissions from the stationary RICE.	
10. Non-emergency, non-black start 4SRB stationary RICE ≤500 HP	a. Change oil and filter every 1,440 hours of operation or annually, whichever comes first;[1]	
	b. Inspect spark plugs every 1,440 hours of operation or annually, whichever comes first, and replace as necessary; and	

	c. Inspect all hoses and belts every 1,440 hours of operation or annually, whichever comes first, and replace as necessary.	
11. Non-emergency, non-black start 4SRB remote stationary RICE >500 HP	a. Change oil and filter every 2,160 hours of operation or annually, whichever comes first;[1]	
	b. Inspect spark plugs every 2,160 hours of operation or annually, whichever comes first, and replace as necessary; and	
	c. Inspect all hoses and belts every 2,160 hours of operation or annually, whichever comes first, and replace as necessary.	
12. Non-emergency, non-black start 4SRB stationary RICE >500 HP that are not remote stationary RICE and that operate more than 24 hours per calendar year	Install NSCR to reduce HAP emissions from the stationary RICE.	
13. Non-emergency, non-black start stationary RICE which combusts landfill or digester gas equivalent to 10 percent or more of the gross heat input on an annual basis	a. Change oil and filter every 1,440 hours of operation or annually, whichever comes first;[1] b. Inspect spark plugs every 1,440 hours of operation or annually, whichever comes first, and replace as necessary; and	
	c. Inspect all hoses and belts every 1,440 hours of operation or annually, whichever comes first, and replace as necessary.	

[1]Sources have the option to utilize an oil analysis program as described in §63.6625(i) or (j) in order to extend the specified oil change requirement in Table 2d of this subpart.

[2]If an emergency engine is operating during an emergency and it is not possible to shut down the engine in order to perform the management practice requirements on the schedule required in Table 2d of this subpart, or if performing the management practice on the required schedule would otherwise pose an unacceptable risk under federal, state, or local law, the management practice can be delayed until the emergency is over or the unacceptable risk under federal, state, or local law has abated. The management practice should be performed as soon as practicable after the emergency has ended or the unacceptable risk under federal, state, or local law has abated. Sources must report any failure to perform the management practice on the schedule required and the federal, state or local law under which the risk was deemed unacceptable.

[78 FR 6709, Jan. 30, 2013]

Table 3 to Subpart ZZZZ of Part 63—Subsequent Performance Tests

As stated in §§63.6615 and 63.6620, you must comply with the following subsequent performance test requirements:

For each . . .	Complying with the requirement to . . .	You must . . .
1. New or reconstructed 2SLB stationary RICE >500 HP located at major sources; new or reconstructed 4SLB stationary RICE ≥250 HP located at major sources; and new or reconstructed CI stationary RICE >500 HP located at major sources	Reduce CO emissions and not using a CEMS	Conduct subsequent performance tests semiannually.[1]
2. 4SRB stationary RICE ≥5,000 HP located at major sources	Reduce formaldehyde emissions	Conduct subsequent performance tests semiannually.[1]
3. Stationary RICE >500 HP located at major sources and new or reconstructed 4SLB stationary RICE 250≤HP≤500 located at major sources	Limit the concentration of formaldehyde in the stationary RICE exhaust	Conduct subsequent performance tests semiannually.[1]
4. Existing non-emergency, non-black start CI stationary RICE >500 HP that are not limited use stationary RICE	Limit or reduce CO emissions and not using a CEMS	Conduct subsequent performance tests every 8,760 hours or 3 years, whichever comes first.

5. Existing non-emergency, non-black start CI stationary RICE >500 HP that are limited use stationary RICE	Limit or reduce CO emissions and not using a CEMS	Conduct subsequent performance tests every 8,760 hours or 5 years, whichever comes first.

[1]After you have demonstrated compliance for two consecutive tests, you may reduce the frequency of subsequent performance tests to annually. If the results of any subsequent annual performance test indicate the stationary RICE is not in compliance with the CO or formaldehyde emission limitation, or you deviate from any of your operating limitations, you must resume semiannual performance tests.

[78 FR 6711, Jan. 30, 2013]

Back to Top

Table 4 to Subpart ZZZZ of Part 63—Requirements for Performance Tests

As stated in §§63.6610, 63.6611, 63.6620, and 63.6640, you must comply with the following requirements for performance tests for stationary RICE:

For each . . .	Complying with the requirement to . . .	You must . . .	Using . . .	According to the following requirements . . .
1. 2SLB, 4SLB, and CI stationary RICE	a. reduce CO emissions	i. Select the sampling port location and the number/location of traverse points at the inlet and outlet of the control device; and		(a) For CO and O_2 measurement, ducts ≤6 inches in diameter may be sampled at a single point located at the duct centroid and ducts >6 and ≤12 inches in diameter may be sampled at 3 traverse points located at 16.7, 50.0, and 83.3% of the measurement line (`3-point long line'). If the duct is >12 inches in diameter *and* the sampling port location meets the two and half-diameter criterion of Section 11.1.1 of Method 1 of 40 CFR part 60, appendix A-1, the duct may be sampled at `3-

				point long line'; otherwise, conduct the stratification testing and select sampling points according to Section 8.1.2 of Method 7E of 40 CFR part 60, appendix A-4.
		ii. Measure the O_2 at the inlet and outlet of the control device; and	(1) Method 3 or 3A or 3B of 40 CFR part 60, appendix A-2, or ASTM Method D6522-00 (Reapproved 2005)[a] [c] (heated probe not necessary)	(b) Measurements to determine O_2 must be made at the same time as the measurements for CO concentration.
		iii. Measure the CO at the inlet and the outlet of the control device	(1) ASTM D6522-00 (Reapproved 2005)[a] [b] [c] (heated probe not necessary) or Method 10 of 40 CFR part 60, appendix A-4	(c) The CO concentration must be at 15 percent O_2, dry basis.
2. 4SRB stationary RICE	a. reduce formaldehyde emissions	i. Select the sampling port location and the number/location of traverse points at the inlet and outlet of the control device; and		(a) For formaldehyde, O_2, and moisture measurement, ducts ≤6 inches in diameter may be sampled at a single point located at the duct centroid and ducts >6 and ≤12 inches in diameter may be sampled at 3 traverse points located at 16.7, 50.0, and 83.3% of the measurement line (`3-point long line'). If the duct is >12 inches in diameter *and* the sampling port location meets the two and half-diameter criterion of Section 11.1.1 of Method 1 of 40 CFR part 60, appendix A, the duct may be sampled at `3-point

				long line'; otherwise, conduct the stratification testing and select sampling points according to Section 8.1.2 of Method 7E of 40 CFR part 60, appendix A.
		ii. Measure O_2 at the inlet and outlet of the control device; and	(1) Method 3 or 3A or 3B of 40 CFR part 60, appendix A-2, or ASTM Method D6522-00 (Reapproved 2005)[a] (heated probe not necessary)	(a) Measurements to determine O_2 concentration must be made at the same time as the measurements for formaldehyde or THC concentration.
		iii. Measure moisture content at the inlet and outlet of the control device; and	(1) Method 4 of 40 CFR part 60, appendix A-3, or Method 320 of 40 CFR part 63, appendix A, or ASTM D 6348-03[a]	(a) Measurements to determine moisture content must be made at the same time and location as the measurements for formaldehyde or THC concentration.
		iv. If demonstrating compliance with the formaldehyde percent reduction requirement, measure formalde-hyde at the inlet and the outlet of the control device	(1) Method 320 or 323 of 40 CFR part 63, appendix A; or ASTM D6348-03[a], provided in ASTM D6348-03 Annex A5 (Analyte Spiking Technique), the percent R must be greater than or equal to 70 and less than or equal to 130	(a) Formaldehyde concentration must be at 15 percent O_2, dry basis. Results of this test consist of the average of the three 1-hour or longer runs.
		v. If demonstrating compliance with the THC percent reduction requirement, measure THC at the inlet and the outlet of the control device	(1) Method 25A, reported as propane, of 40 CFR part 60, appendix A-7	(a) THC concentration must be at 15 percent O_2, dry basis. Results of this test consist of the average of the three 1-hour or longer runs.

3. Stationary RICE	a. limit the concentra-tion of formalde-hyde or CO in the stationary RICE exhaust	i. Select the sampling port location and the number/location of traverse points at the exhaust of the stationary RICE; and		(a) For formaldehyde, CO, O_2, and moisture measurement, ducts ≤6 inches in diameter may be sampled at a single point located at the duct centroid and ducts >6 and ≤12 inches in diameter may be sampled at 3 traverse points located at 16.7, 50.0, and 83.3% of the measurement line (`3-point long line'). If the duct is >12 inches in diameter *and* the sampling port location meets the two and half-diameter criterion of Section 11.1.1 of Method 1 of 40 CFR part 60, appendix A, the duct may be sampled at `3-point long line'; otherwise, conduct the stratification testing and select sampling points according to Section 8.1.2 of Method 7E of 40 CFR part 60, appendix A. If using a control device, the sampling site must be located at the outlet of the control device.
		ii. Determine the O_2 concentration of the stationary RICE exhaust at the sampling port location; and	(1) Method 3 or 3A or 3B of 40 CFR part 60, appendix A-2, or ASTM Method D6522-00 (Reapproved 2005)[a] (heated probe not necessary)	(a) Measurements to determine O_2 concentration must be made at the same time and location as the measurements for formaldehyde or CO concentration.
		iii. Measure moisture content of the station-ary RICE exhaust at the	(1) Method 4 of 40 CFR part 60, appendix A-3, or Method 320 of 40	(a) Measurements to determine moisture content must be made at the same time and

		sampling port location; and	CFR part 63, appendix A, or ASTM D 6348-03[a]	location as the measurements for formaldehyde or CO concentration.
		iv. Measure formalde-hyde at the exhaust of the station-ary RICE; or	(1) Method 320 or 323 of 40 CFR part 63, appendix A; or ASTM D6348-03[a], provided in ASTM D6348-03 Annex A5 (Analyte Spiking Technique), the percent R must be greater than or equal to 70 and less than or equal to 130	(a) Formaldehyde concentration must be at 15 percent O_2, dry basis. Results of this test consist of the average of the three 1-hour or longer runs.
		v. measure CO at the exhaust of the station-ary RICE	(1) Method 10 of 40 CFR part 60, appendix A-4, ASTM Method D6522-00 (2005)[a c], Method 320 of 40 CFR part 63, appendix A, or ASTM D6348-03[a]	(a) CO concentration must be at 15 percent O_2, dry basis. Results of this test consist of the average of the three 1-hour or longer runs.

[a]You may also use Methods 3A and 10 as options to ASTM-D6522-00 (2005). You may obtain a copy of ASTM-D6522-00 (2005) from at least one of the following addresses: American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959, or University Microfilms International, 300 North Zeeb Road, Ann Arbor, MI 48106.

[b]You may obtain a copy of ASTM-D6348-03 from at least one of the following addresses: American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959, or University Microfilms International, 300 North Zeeb Road, Ann Arbor, MI 48106.

Table 5 to Subpart ZZZZ of Part 63—Initial Compliance With Emission Limitations, Operating Limitations, and Other Requirements

As stated in §§63.6612, 63.6625 and 63.6630, you must initially comply with the emission and operating limitations as required by the following:

For each . . .	Complying with the requirement to . . .	You have demonstrated initial compliance if . . .
1. New or reconstructed non-emergency 2SLB stationary RICE >500 HP located at a major source of HAP, new or reconstructed non-emergency 4SLB stationary RICE ≥250 HP located at a major source of HAP, non-emergency stationary CI RICE >500 HP located at a major source of HAP, and existing non-emergency stationary CI RICE >500 HP located at an area source of HAP	a. Reduce CO emissions and using oxidation catalyst, and using a CPMS	i. The average reduction of emissions of CO determined from the initial performance test achieves the required CO percent reduction; and ii. You have installed a CPMS to continuously monitor catalyst inlet temperature according to the requirements in §63.6625(b); and iii. You have recorded the catalyst pressure drop and catalyst inlet temperature during the initial performance test.
2. Non-emergency stationary CI RICE >500 HP located at a major source of HAP, and existing non-emergency stationary CI RICE >500 HP located at an area source of HAP	a. Limit the concentration of CO, using oxidation catalyst, and using a CPMS	i. The average CO concentration determined from the initial performance test is less than or equal to the CO emission limitation; and
		ii. You have installed a CPMS to continuously monitor catalyst inlet temperature according to the requirements in §63.6625(b); and
		iii. You have recorded the catalyst pressure drop and catalyst inlet temperature during the initial performance test.
3. New or reconstructed non-emergency 2SLB stationary RICE >500 HP located at a major source of HAP, new or reconstructed non-emergency 4SLB stationary RICE ≥250 HP located at a major source of HAP, non-emergency stationary CI RICE >500 HP located at a major source of HAP, and existing non-emergency stationary CI RICE >500 HP located at an area source of HAP	a. Reduce CO emissions and not using oxidation catalyst	i. The average reduction of emissions of CO determined from the initial performance test achieves the required CO percent reduction; and ii. You have installed a CPMS to continuously monitor operating parameters approved by the Administrator (if any) according to the requirements in §63.6625(b); and iii. You have recorded the approved operating parameters (if any) during the initial performance test.
4. Non-emergency stationary CI RICE >500 HP located at a major	a. Limit the concentration of CO,	i. The average CO concentration determined from the initial

source of HAP, and existing non-emergency stationary CI RICE >500 HP located at an area source of HAP	and not using oxidation catalyst	performance test is less than or equal to the CO emission limitation; and ii. You have installed a CPMS to continuously monitor operating parameters approved by the Administrator (if any) according to the requirements in §63.6625(b); and
		iii. You have recorded the approved operating parameters (if any) during the initial performance test.
5. New or reconstructed non-emergency 2SLB stationary RICE >500 HP located at a major source of HAP, new or reconstructed non-emergency 4SLB stationary RICE ≥250 HP located at a major source of HAP, non-emergency stationary CI RICE >500 HP located at a major source of HAP, and existing non-emergency stationary CI RICE >500 HP located at an area source of HAP	a. Reduce CO emissions, and using a CEMS	i. You have installed a CEMS to continuously monitor CO and either O_2 or CO_2 at both the inlet and outlet of the oxidation catalyst according to the requirements in §63.6625(a); and ii. You have conducted a performance evaluation of your CEMS using PS 3 and 4A of 40 CFR part 60, appendix B; and
		iii. The average reduction of CO calculated using §63.6620 equals or exceeds the required percent reduction. The initial test comprises the first 4-hour period after successful validation of the CEMS. Compliance is based on the average percent reduction achieved during the 4-hour period.
6. Non-emergency stationary CI RICE >500 HP located at a major source of HAP, and existing non-emergency stationary CI RICE >500 HP located at an area source of HAP	a. Limit the concentration of CO, and using a CEMS	i. You have installed a CEMS to continuously monitor CO and either O_2 or CO_2 at the outlet of the oxidation catalyst according to the requirements in §63.6625(a); and
		ii. You have conducted a performance evaluation of your CEMS using PS 3 and 4A of 40 CFR part 60, appendix B; and
		iii. The average concentration of CO calculated using §63.6620 is less than or equal to the CO emission limitation. The initial test comprises

		the first 4-hour period after successful validation of the CEMS. Compliance is based on the average concentration measured during the 4-hour period.
7. Non-emergency 4SRB stationary RICE >500 HP located at a major source of HAP	a. Reduce formaldehyde emissions and using NSCR	i. The average reduction of emissions of formaldehyde determined from the initial performance test is equal to or greater than the required formaldehyde percent reduction, or the average reduction of emissions of THC determined from the initial performance test is equal to or greater than 30 percent; and
		ii. You have installed a CPMS to continuously monitor catalyst inlet temperature according to the requirements in §63.6625(b); and
		iii. You have recorded the catalyst pressure drop and catalyst inlet temperature during the initial performance test.
8. Non-emergency 4SRB stationary RICE >500 HP located at a major source of HAP	a. Reduce formaldehyde emissions and not using NSCR	i. The average reduction of emissions of formaldehyde determined from the initial performance test is equal to or greater than the required formaldehyde percent reduction or the average reduction of emissions of THC determined from the initial performance test is equal to or greater than 30 percent; and
		ii. You have installed a CPMS to continuously monitor operating parameters approved by the Administrator (if any) according to the requirements in §63.6625(b); and
		iii. You have recorded the approved operating parameters (if any) during the initial performance test.

9. New or reconstructed non-emergency stationary RICE >500 HP located at a major source of HAP, new or reconstructed non-emergency 4SLB stationary RICE 250≤HP≤500 located at a major source of HAP, and existing non-emergency 4SRB stationary RICE >500 HP located at a major source of HAP	a. Limit the concentration of formaldehyde in the stationary RICE exhaust and using oxidation catalyst or NSCR	i. The average formaldehyde concentration, corrected to 15 percent O_2, dry basis, from the three test runs is less than or equal to the formaldehyde emission limitation; and ii. You have installed a CPMS to continuously monitor catalyst inlet temperature according to the requirements in §63.6625(b); and
		iii. You have recorded the catalyst pressure drop and catalyst inlet temperature during the initial performance test.
10. New or reconstructed non-emergency stationary RICE >500 HP located at a major source of HAP, new or reconstructed non-emergency 4SLB stationary RICE 250≤HP≤500 located at a major source of HAP, and existing non-emergency 4SRB stationary RICE >500 HP located at a major source of HAP	a. Limit the concentration of formaldehyde in the stationary RICE exhaust and not using oxidation catalyst or NSCR	i. The average formaldehyde concentration, corrected to 15 percent O_2, dry basis, from the three test runs is less than or equal to the formaldehyde emission limitation; and ii. You have installed a CPMS to continuously monitor operating parameters approved by the Administrator (if any) according to the requirements in §63.6625(b); and
		iii. You have recorded the approved operating parameters (if any) during the initial performance test.
11. Existing non-emergency stationary RICE 100≤HP≤500 located at a major source of HAP, and existing non-emergency stationary CI RICE 300<HP≤500 located at an area source of HAP	a. Reduce CO emissions	i. The average reduction of emissions of CO or formaldehyde, as applicable determined from the initial performance test is equal to or greater than the required CO or formaldehyde, as applicable, percent reduction.
12. Existing non-emergency stationary RICE 100≤HP≤500 located at a major source of HAP, and existing non-emergency stationary CI RICE 300<HP≤500 located at an area source of HAP	a. Limit the concentration of formaldehyde or CO in the stationary RICE exhaust	i. The average formaldehyde or CO concentration, as applicable, corrected to 15 percent O_2, dry basis, from the three test runs is less than or equal to the formaldehyde or CO emission limitation, as applicable.
13. Existing non-emergency 4SLB stationary RICE >500 HP located at	a. Install an oxidation catalyst	i. You have conducted an initial compliance demonstration as

an area source of HAP that are not remote stationary RICE and that are operated more than 24 hours per calendar year		specified in §63.6630(e) to show that the average reduction of emissions of CO is 93 percent or more, or the average CO concentration is less than or equal to 47 ppmvd at 15 percent O_2;
		ii. You have installed a CPMS to continuously monitor catalyst inlet temperature according to the requirements in §63.6625(b), or you have installed equipment to automatically shut down the engine if the catalyst inlet temperature exceeds 1350 °F.
14. Existing non-emergency 4SRB stationary RICE >500 HP located at an area source of HAP that are not remote stationary RICE and that are operated more than 24 hours per calendar year	a. Install NSCR	i. You have conducted an initial compliance demonstration as specified in §63.6630(e) to show that the average reduction of emissions of CO is 75 percent or more, the average CO concentration is less than or equal to 270 ppmvd at 15 percent O_2, or the average reduction of emissions of THC is 30 percent or more;
		ii. You have installed a CPMS to continuously monitor catalyst inlet temperature according to the requirements in §63.6625(b), or you have installed equipment to automatically shut down the engine if the catalyst inlet temperature exceeds 1250 °F.

Table 6 to Subpart ZZZZ of Part 63—Continuous Compliance With Emission Limitations, and Other Requirements

As stated in §63.6640, you must continuously comply with the emissions and operating limitations and work or management practices as required by the following:

For each . . .	Complying with the requirement to . . .	You must demonstrate continuous compliance by . . .
1. New or reconstructed non-emergency 2SLB stationary RICE >500 HP located at a major source of HAP, new or reconstructed non-emergency 4SLB stationary RICE ≥250 HP located at a major source of HAP, and new or reconstructed non-emergency CI stationary RICE >500 HP located at a major source of HAP	a. Reduce CO emissions and using an oxidation catalyst, and using a CPMS	i. Conducting semiannual performance tests for CO to demonstrate that the required CO percent reduction is achieved[a]; and ii. Collecting the catalyst inlet temperature data according to §63.6625(b); and iii. Reducing these data to 4-hour rolling averages; and
		iv. Maintaining the 4-hour rolling averages within the operating limitations for the catalyst inlet temperature; and
		v. Measuring the pressure drop across the catalyst once per month and demonstrating that the pressure drop across the catalyst is within the operating limitation established during the performance test.
2. New or reconstructed non-emergency 2SLB stationary RICE >500 HP located at a major source of HAP, new or reconstructed non-emergency 4SLB stationary RICE ≥250 HP located at a major source of HAP, and new or reconstructed non-emergency CI stationary RICE >500 HP located at a major source of HAP	a. Reduce CO emissions and not using an oxidation catalyst, and using a CPMS	i. Conducting semiannual performance tests for CO to demonstrate that the required CO percent reduction is achieved[a]; and ii. Collecting the approved operating parameter (if any) data according to §63.6625(b); and iii. Reducing these data to 4-hour rolling averages; and
		iv. Maintaining the 4-hour rolling averages within the operating limitations for the operating parameters established during the performance test.
3. New or reconstructed non-emergency 2SLB stationary RICE >500 HP located at a major source of HAP, new or reconstructed non-emergency 4SLB stationary RICE ≥250 HP located at a major source	a. Reduce CO emissions or limit the concentration of CO in the stationary RICE exhaust, and using a CEMS	i. Collecting the monitoring data according to §63.6625(a), reducing the measurements to 1-hour averages, calculating the percent reduction or concentration of CO emissions according to §63.6620;

of HAP, new or reconstructed non-emergency stationary CI RICE >500 HP located at a major source of HAP, and existing non-emergency stationary CI RICE >500 HP		and ii. Demonstrating that the catalyst achieves the required percent reduction of CO emissions over the 4-hour averaging period, or that the emission remain at or below the CO concentration limit; and
		iii. Conducting an annual RATA of your CEMS using PS 3 and 4A of 40 CFR part 60, appendix B, as well as daily and periodic data quality checks in accordance with 40 CFR part 60, appendix F, procedure 1.
4. Non-emergency 4SRB stationary RICE >500 HP located at a major source of HAP	a. Reduce formaldehyde emissions and using NSCR	i. Collecting the catalyst inlet temperature data according to §63.6625(b); and
		ii. Reducing these data to 4-hour rolling averages; and
		iii. Maintaining the 4-hour rolling averages within the operating limitations for the catalyst inlet temperature; and
		iv. Measuring the pressure drop across the catalyst once per month and demonstrating that the pressure drop across the catalyst is within the operating limitation established during the performance test.
5. Non-emergency 4SRB stationary RICE >500 HP located at a major source of HAP	a. Reduce formaldehyde emissions and not using NSCR	i. Collecting the approved operating parameter (if any) data according to §63.6625(b); and
		ii. Reducing these data to 4-hour rolling averages; and
		iii. Maintaining the 4-hour rolling averages within the operating limitations for the operating parameters established during the performance test.

6. Non-emergency 4SRB stationary RICE with a brake HP ≥5,000 located at a major source of HAP	a. Reduce formaldehyde emissions	Conducting semiannual performance tests for formaldehyde to demonstrate that the required formaldehyde percent reduction is achieved, or to demonstrate that the average reduction of emissions of THC determined from the performance test is equal to or greater than 30 percent.[a]
7. New or reconstructed non-emergency stationary RICE >500 HP located at a major source of HAP and new or reconstructed non-emergency 4SLB stationary RICE 250≤HP≤500 located at a major source of HAP	a. Limit the concentration of formaldehyde in the stationary RICE exhaust and using oxidation catalyst or NSCR	i. Conducting semiannual performance tests for formaldehyde to demonstrate that your emissions remain at or below the formaldehyde concentration limit[a]; and ii. Collecting the catalyst inlet temperature data according to §63.6625(b); and
		iii. Reducing these data to 4-hour rolling averages; and
		iv. Maintaining the 4-hour rolling averages within the operating limitations for the catalyst inlet temperature; and
		v. Measuring the pressure drop across the catalyst once per month and demonstrating that the pressure drop across the catalyst is within the operating limitation established during the performance test.
8. New or reconstructed non-emergency stationary RICE >500 HP located at a major source of HAP and new or reconstructed non-emergency 4SLB stationary RICE 250≤HP≤500 located at a major source of HAP	a. Limit the concentration of formaldehyde in the stationary RICE exhaust and not using oxidation catalyst or NSCR	i. Conducting semiannual performance tests for formaldehyde to demonstrate that your emissions remain at or below the formaldehyde concentration limit[a]; and ii. Collecting the approved operating parameter (if any) data according to §63.6625(b); and
		iii. Reducing these data to 4-hour rolling averages; and
		iv. Maintaining the 4-hour rolling averages within the operating limitations for the operating

		parameters established during the performance test.
9. Existing emergency and black start stationary RICE ≤500 HP located at a major source of HAP, existing non-emergency stationary RICE <100 HP located at a major source of HAP, existing emergency and black start stationary RICE located at an area source of HAP, existing non-emergency stationary CI RICE ≤300 HP located at an area source of HAP, existing non-emergency 2SLB stationary RICE located at an area source of HAP, existing non-emergency stationary SI RICE located at an area source of HAP which combusts landfill or digester gas equivalent to 10 percent or more of the gross heat input on an annual basis, existing non-emergency 4SLB and 4SRB stationary RICE ≤500 HP located at an area source of HAP, existing non-emergency 4SLB and 4SRB stationary RICE >500 HP located at an area source of HAP that operate 24 hours or less per calendar year, and existing non-emergency 4SLB and 4SRB stationary RICE >500 HP located at an area source of HAP that are remote stationary RICE	a. Work or Management practices	i. Operating and maintaining the stationary RICE according to the manufacturer's emission-related operation and maintenance instructions; or ii. Develop and follow your own maintenance plan which must provide to the extent practicable for the maintenance and operation of the engine in a manner consistent with good air pollution control practice for minimizing emissions.
10. Existing stationary CI RICE >500 HP that are not limited use stationary RICE	a. Reduce CO emissions, or limit the concentration of CO in the stationary RICE exhaust, and using oxidation catalyst	i. Conducting performance tests every 8,760 hours or 3 years, whichever comes first, for CO or formaldehyde, as appropriate, to demonstrate that the required CO or formaldehyde, as appropriate, percent reduction is achieved or that your emissions remain at or below the CO or formaldehyde concentration limit; and

		ii. Collecting the catalyst inlet temperature data according to §63.6625(b); and
		iii. Reducing these data to 4-hour rolling averages; and
		iv. Maintaining the 4-hour rolling averages within the operating limitations for the catalyst inlet temperature; and
		v. Measuring the pressure drop across the catalyst once per month and demonstrating that the pressure drop across the catalyst is within the operating limitation established during the performance test.
11. Existing stationary CI RICE >500 HP that are not limited use stationary RICE	a. Reduce CO emissions, or limit the concentration of CO in the stationary RICE exhaust, and not using oxidation catalyst	i. Conducting performance tests every 8,760 hours or 3 years, whichever comes first, for CO or formaldehyde, as appropriate, to demonstrate that the required CO or formaldehyde, as appropriate, percent reduction is achieved or that your emissions remain at or below the CO or formaldehyde concentration limit; and
		ii. Collecting the approved operating parameter (if any) data according to §63.6625(b); and
		iii. Reducing these data to 4-hour rolling averages; and
		iv. Maintaining the 4-hour rolling averages within the operating limitations for the operating parameters established during the performance test.
12. Existing limited use CI stationary RICE >500 HP	a. Reduce CO emissions or limit the concentration of CO in the stationary RICE exhaust, and using an oxidation catalyst	i. Conducting performance tests every 8,760 hours or 5 years, whichever comes first, for CO or formaldehyde, as appropriate, to demonstrate that the required CO or formaldehyde, as appropriate, percent reduction is achieved or that

		your emissions remain at or below the CO or formaldehyde concentration limit; and
		ii. Collecting the catalyst inlet temperature data according to §63.6625(b); and
		iii. Reducing these data to 4-hour rolling averages; and
		iv. Maintaining the 4-hour rolling averages within the operating limitations for the catalyst inlet temperature; and
		v. Measuring the pressure drop across the catalyst once per month and demonstrating that the pressure drop across the catalyst is within the operating limitation established during the performance test.
13. Existing limited use CI stationary RICE >500 HP	a. Reduce CO emissions or limit the concentration of CO in the stationary RICE exhaust, and not using an oxidation catalyst	i. Conducting performance tests every 8,760 hours or 5 years, whichever comes first, for CO or formaldehyde, as appropriate, to demonstrate that the required CO or formaldehyde, as appropriate, percent reduction is achieved or that your emissions remain at or below the CO or formaldehyde concentration limit; and
		ii. Collecting the approved operating parameter (if any) data according to §63.6625(b); and
		iii. Reducing these data to 4-hour rolling averages; and
		iv. Maintaining the 4-hour rolling averages within the operating limitations for the operating parameters established during the performance test.
14. Existing non-emergency 4SLB stationary RICE >500 HP located at an area source of HAP that are not	a. Install an oxidation catalyst	i. Conducting annual compliance demonstrations as specified in §63.6640(c) to show that the average

remote stationary RICE and that are operated more than 24 hours per calendar year		reduction of emissions of CO is 93 percent or more, or the average CO concentration is less than or equal to 47 ppmvd at 15 percent O_2; and either ii. Collecting the catalyst inlet temperature data according to §63.6625(b), reducing these data to 4-hour rolling averages; and maintaining the 4-hour rolling averages within the limitation of greater than 450 °F and less than or equal to 1350 °F for the catalyst inlet temperature; or iii. Immediately shutting down the engine if the catalyst inlet temperature exceeds 1350 °F.
15. Existing non-emergency 4SRB stationary RICE >500 HP located at an area source of HAP that are not remote stationary RICE and that are operated more than 24 hours per calendar year	a. Install NSCR	i. Conducting annual compliance demonstrations as specified in §63.6640(c) to show that the average reduction of emissions of CO is 75 percent or more, the average CO concentration is less than or equal to 270 ppmvd at 15 percent O_2, or the average reduction of emissions of THC is 30 percent or more; and either ii. Collecting the catalyst inlet temperature data according to §63.6625(b), reducing these data to 4-hour rolling averages; and maintaining the 4-hour rolling averages within the limitation of greater than or equal to 750 °F and less than or equal to 1250 °F for the catalyst inlet temperature; or iii. Immediately shutting down the engine if the catalyst inlet temperature exceeds 1250 °F.

[a]After you have demonstrated compliance for two consecutive tests, you may reduce the frequency of subsequent performance tests to annually. If the results of any subsequent annual performance test indicate the stationary RICE is not in compliance with the CO or formaldehyde emission limitation, or you deviate from any of your operating limitations, you must resume semiannual performance tests.

Table 7 to Subpart ZZZZ of Part 63—Requirements for Reports

As stated in §63.6650, you must comply with the following requirements for reports:

For each . . .	You must submit a . . .	The report must contain . . .	You must submit the report . . .
1. Existing non-emergency, non-black start stationary RICE 100≤HP≤500 located at a major source of HAP; existing non-emergency, non-black start stationary CI RICE >500 HP located at a major source of HAP; existing non-emergency 4SRB stationary RICE >500 HP located at a major source of HAP; existing non-emergency, non-black start stationary CI RICE >300 HP located at an area source of HAP; new or reconstructed non-emergency stationary RICE >500 HP located at a major source of HAP; and new or reconstructed non-emergency 4SLB stationary RICE 250≤HP≤500 located at a major source of HAP	Compliance report	a. If there are no deviations from any emission limitations or operating limitations that apply to you, a statement that there were no deviations from the emission limitations or operating limitations during the reporting period. If there were no periods during which the CMS, including CEMS and CPMS, was out-of-control, as specified in §63.8(c)(7), a statement that there were not periods during which the CMS was out-of-control during the reporting period; or	i. Semiannually according to the requirements in §63.6650(b)(1)-(5) for engines that are not limited use stationary RICE subject to numerical emission limitations; and ii. Annually according to the requirements in §63.6650(b)(6)-(9) for engines that are limited use stationary RICE subject to numerical emission limitations.
		b. If you had a deviation from any emission limitation or operating limitation during the reporting period, the information in §63.6650(d). If there were periods during which the CMS, including CEMS and CPMS, was out-of-control, as specified in §63.8(c)(7),	i. Semiannually according to the requirements in §63.6650(b).

		the information in §63.6650(e); or	
		c. If you had a malfunction during the reporting period, the information in §63.6650(c)(4).	i. Semiannually according to the requirements in §63.6650(b).
2. New or reconstructed non-emergency stationary RICE that combusts landfill gas or digester gas equivalent to 10 percent or more of the gross heat input on an annual basis	Report	a. The fuel flow rate of each fuel and the heating values that were used in your calculations, and you must demonstrate that the percentage of heat input provided by landfill gas or digester gas, is equivalent to 10 percent or more of the gross heat input on an annual basis; and	i. Annually, according to the requirements in §63.6650.
		b. The operating limits provided in your federally enforceable permit, and any deviations from these limits; and	i. See item 2.a.i.
		c. Any problems or errors suspected with the meters.	i. See item 2.a.i.
3. Existing non-emergency, non-black start 4SLB and 4SRB stationary RICE >500 HP located at an area source of HAP that are not remote stationary RICE and that operate more than 24 hours per calendar year	Compliance report	a. The results of the annual compliance demonstration, if conducted during the reporting period.	i. Semiannually according to the requirements in §63.6650(b)(1)-(5).
4. Emergency stationary RICE that operate or are contractually obligated to be available for more than 15 hours per year for the purposes specified in §63.6640(f)(2)(ii) and (iii) or that operate for the purposes specified in §63.6640(f)(4)(ii)	Report	a. The information in §63.6650(h)(1)	i. annually according to the requirements in §63.6650(h)(2)-(3).

Table 8 to Subpart ZZZZ of Part 63—Applicability of General Provisions to Subpart ZZZZ.

As stated in §63.6665, you must comply with the following applicable general provisions.

General provisions citation	Subject of citation	Applies to subpart	Explanation
§63.1	General applicability of the General Provisions	Yes.	
§63.2	Definitions	Yes	Additional terms defined in §63.6675.
§63.3	Units and abbreviations	Yes.	
§63.4	Prohibited activities and circumvention	Yes.	
§63.5	Construction and reconstruction	Yes.	
§63.6(a)	Applicability	Yes.	
§63.6(b)(1)-(4)	Compliance dates for new and reconstructed sources	Yes.	
§63.6(b)(5)	Notification	Yes.	
§63.6(b)(6)	[Reserved]		
§63.6(b)(7)	Compliance dates for new and reconstructed area sources that become major sources	Yes.	
§63.6(c)(1)-(2)	Compliance dates for existing sources	Yes.	
§63.6(c)(3)-(4)	[Reserved]		
§63.6(c)(5)	Compliance dates for existing area sources that become major sources	Yes.	
§63.6(d)	[Reserved]		
§63.6(e)	Operation and maintenance	No.	
§63.6(f)(1)	Applicability of standards	No.	

§63.6(f)(2)	Methods for determining compliance	Yes.	
§63.6(f)(3)	Finding of compliance	Yes.	
§63.6(g)(1)-(3)	Use of alternate standard	Yes.	
§63.6(h)	Opacity and visible emission standards	No	Subpart ZZZZ does not contain opacity or visible emission standards.
§63.6(i)	Compliance extension procedures and criteria	Yes.	
§63.6(j)	Presidential compliance exemption	Yes.	
§63.7(a)(1)-(2)	Performance test dates	Yes	Subpart ZZZZ contains performance test dates at §§63.6610, 63.6611, and 63.6612.
§63.7(a)(3)	CAA section 114 authority	Yes.	
§63.7(b)(1)	Notification of performance test	Yes	Except that §63.7(b)(1) only applies as specified in §63.6645.
§63.7(b)(2)	Notification of rescheduling	Yes	Except that §63.7(b)(2) only applies as specified in §63.6645.
§63.7(c)	Quality assurance/test plan	Yes	Except that §63.7(c) only applies as specified in §63.6645.
§63.7(d)	Testing facilities	Yes.	
§63.7(e)(1)	Conditions for conducting performance tests	No.	Subpart ZZZZ specifies conditions for conducting performance tests at §63.6620.
§63.7(e)(2)	Conduct of performance tests and reduction of data	Yes	Subpart ZZZZ specifies test methods at §63.6620.
§63.7(e)(3)	Test run duration	Yes.	
§63.7(e)(4)	Administrator may require other testing under section 114 of the CAA	Yes.	

§63.7(f)	Alternative test method provisions	Yes.	
§63.7(g)	Performance test data analysis, recordkeeping, and reporting	Yes.	
§63.7(h)	Waiver of tests	Yes.	
§63.8(a)(1)	Applicability of monitoring requirements	Yes	Subpart ZZZZ contains specific requirements for monitoring at §63.6625.
§63.8(a)(2)	Performance specifications	Yes.	
§63.8(a)(3)	[Reserved]		
§63.8(a)(4)	Monitoring for control devices	No.	
§63.8(b)(1)	Monitoring	Yes.	
§63.8(b)(2)-(3)	Multiple effluents and multiple monitoring systems	Yes.	
§63.8(c)(1)	Monitoring system operation and maintenance	Yes.	
§63.8(c)(1)(i)	Routine and predictable SSM	No	
§63.8(c)(1)(ii)	SSM not in Startup Shutdown Malfunction Plan	Yes.	
§63.8(c)(1)(iii)	Compliance with operation and maintenance requirements	No	
§63.8(c)(2)-(3)	Monitoring system installation	Yes.	
§63.8(c)(4)	Continuous monitoring system (CMS) requirements	Yes	Except that subpart ZZZZ does not require Continuous Opacity Monitoring System (COMS).
§63.8(c)(5)	COMS minimum procedures	No	Subpart ZZZZ does not require COMS.
§63.8(c)(6)-(8)	CMS requirements	Yes	Except that subpart ZZZZ does not require COMS.
§63.8(d)	CMS quality control	Yes.	
§63.8(e)	CMS performance evaluation	Yes	Except for §63.8(e)(5)(ii), which applies to COMS.
		Except that §63.8(e) only applies as	

		specified in §63.6645.	
§63.8(f)(1)-(5)	Alternative monitoring method	Yes	Except that §63.8(f)(4) only applies as specified in §63.6645.
§63.8(f)(6)	Alternative to relative accuracy test	Yes	Except that §63.8(f)(6) only applies as specified in §63.6645.
§63.8(g)	Data reduction	Yes	Except that provisions for COMS are not applicable. Averaging periods for demonstrating compliance are specified at §§63.6635 and 63.6640.
§63.9(a)	Applicability and State delegation of notification requirements	Yes.	
§63.9(b)(1)-(5)	Initial notifications	Yes	Except that §63.9(b)(3) is reserved.
		Except that §63.9(b) only applies as specified in §63.6645.	
§63.9(c)	Request for compliance extension	Yes	Except that §63.9(c) only applies as specified in §63.6645.
§63.9(d)	Notification of special compliance requirements for new sources	Yes	Except that §63.9(d) only applies as specified in §63.6645.
§63.9(e)	Notification of performance test	Yes	Except that §63.9(e) only applies as specified in §63.6645.
§63.9(f)	Notification of visible emission (VE)/opacity test	No	Subpart ZZZZ does not contain opacity or VE standards.
§63.9(g)(1)	Notification of performance evaluation	Yes	Except that §63.9(g) only applies as specified in §63.6645.

§63.9(g)(2)	Notification of use of COMS data	No	Subpart ZZZZ does not contain opacity or VE standards.
§63.9(g)(3)	Notification that criterion for alternative to RATA is exceeded	Yes	If alternative is in use.
		Except that §63.9(g) only applies as specified in §63.6645.	
§63.9(h)(1)-(6)	Notification of compliance status	Yes	Except that notifications for sources using a CEMS are due 30 days after completion of performance evaluations. §63.9(h)(4) is reserved.
			Except that §63.9(h) only applies as specified in §63.6645.
§63.9(i)	Adjustment of submittal deadlines	Yes.	
§63.9(j)	Change in previous information	Yes.	
§63.10(a)	Administrative provisions for recordkeeping/reporting	Yes.	
§63.10(b)(1)	Record retention	Yes	Except that the most recent 2 years of data do not have to be retained on site.
§63.10(b)(2)(i)-(v)	Records related to SSM	No.	
§63.10(b)(2)(vi)-(xi)	Records	Yes.	
§63.10(b)(2)(xii)	Record when under waiver	Yes.	
§63.10(b)(2)(xiii)	Records when using alternative to RATA	Yes	For CO standard if using RATA alternative.
§63.10(b)(2)(xiv)	Records of supporting documentation	Yes.	
§63.10(b)(3)	Records of applicability determination	Yes.	

§63.10(c)	Additional records for sources using CEMS	Yes	Except that §63.10(c)(2)-(4) and (9) are reserved.
§63.10(d)(1)	General reporting requirements	Yes.	
§63.10(d)(2)	Report of performance test results	Yes.	
§63.10(d)(3)	Reporting opacity or VE observations	No	Subpart ZZZZ does not contain opacity or VE standards.
§63.10(d)(4)	Progress reports	Yes.	
§63.10(d)(5)	Startup, shutdown, and malfunction reports	No.	
§63.10(e)(1) and (2)(i)	Additional CMS Reports	Yes.	
§63.10(e)(2)(ii)	COMS-related report	No	Subpart ZZZZ does not require COMS.
§63.10(e)(3)	Excess emission and parameter exceedances reports	Yes.	Except that §63.10(e)(3)(i)(C) is reserved.
§63.10(e)(4)	Reporting COMS data	No	Subpart ZZZZ does not require COMS.
§63.10(f)	Waiver for recordkeeping/reporting	Yes.	
§63.11	Flares	No.	
§63.12	State authority and delegations	Yes.	
§63.13	Addresses	Yes.	
§63.14	Incorporation by reference	Yes.	
§63.15	Availability of information	Yes.

Appendix A to Subpart ZZZZ of Part 63—Protocol for Using an Electrochemical Analyzer to Determine Oxygen and Carbon Monoxide Concentrations From Certain Engines

1.0 Scope and Application. What is this Protocol?

This protocol is a procedure for using portable electrochemical (EC) cells for measuring carbon monoxide (CO) and oxygen (O_2) concentrations in controlled and uncontrolled emissions from existing stationary 4-stroke lean burn and 4-stroke rich burn reciprocating internal combustion engines as specified in the applicable rule.

1.1 Analytes. What does this protocol determine?

This protocol measures the engine exhaust gas concentrations of carbon monoxide (CO) and oxygen (O_2).

Analyte	CAS No.	Sensitivity
Carbon monoxide (CO)	630-08-0	Minimum detectable limit should be 2 percent of the nominal range or 1 ppm, whichever is less restrictive.
Oxygen (O_2)	*7782-44-7*	

1.2 Applicability. When is this protocol acceptable?

This protocol is applicable to 40 CFR part 63, subpart ZZZZ. Because of inherent cross sensitivities of EC cells, you must not apply this protocol to other emissions sources without specific instruction to that effect.

1.3 Data Quality Objectives. How good must my collected data be?

Refer to Section 13 to verify and document acceptable analyzer performance.

1.4 Range. What is the targeted analytical range for this protocol?

The measurement system and EC cell design(s) conforming to this protocol will determine the analytical range for each gas component. The nominal ranges are defined by choosing up-scale calibration gas concentrations near the maximum anticipated flue gas concentrations for CO and O_2, or no more than twice the permitted CO level.

1.5 Sensitivity. What minimum detectable limit will this protocol yield for a particular gas component?

The minimum detectable limit depends on the nominal range and resolution of the specific EC cell used, and the signal to noise ratio of the measurement system. The minimum detectable limit should be 2 percent of the nominal range or 1 ppm, whichever is less restrictive.

2.0 Summary of Protocol

In this protocol, a gas sample is extracted from an engine exhaust system and then conveyed to a portable EC analyzer for measurement of CO and O_2 gas concentrations. This method provides measurement system performance specifications and sampling protocols to ensure reliable data. You may use additions to, or modifications of vendor supplied measurement systems (e.g., heated or unheated sample lines, thermocouples, flow meters, selective gas scrubbers, etc.) to meet the design specifications of this protocol. Do not make changes to the measurement system from the as-verified configuration (Section 3.12).

3.0 DEFINITIONS

3.1 Measurement System. The total equipment required for the measurement of CO and O_2 concentrations. The measurement system consists of the following major subsystems:

3.1.1 Data Recorder. A strip chart recorder, computer or digital recorder for logging measurement data from the analyzer output. You may record measurement data from the digital data display manually or electronically.

3.1.2 Electrochemical (EC) Cell. A device, similar to a fuel cell, used to sense the presence of a specific analyte and generate an electrical current output proportional to the analyte concentration.

3.1.3 Interference Gas Scrubber. A device used to remove or neutralize chemical compounds that may interfere with the selective operation of an EC cell.

3.1.4 Moisture Removal System. Any device used to reduce the concentration of moisture in the sample stream so as to protect the EC cells from the damaging effects of condensation and to minimize errors in measurements caused by the scrubbing of soluble gases.

3.1.5 Sample Interface. The portion of the system used for one or more of the following: sample acquisition; sample transport; sample conditioning or protection of the EC cell from any degrading effects of the engine exhaust effluent; removal of particulate matter and condensed moisture.

3.2 Nominal Range. The range of analyte concentrations over which each EC cell is operated (normally 25 percent to 150 percent of up-scale calibration gas value). Several nominal ranges can be used for any given cell so long as the calibration and repeatability checks for that range remain within specifications.

3.3 Calibration Gas. A vendor certified concentration of a specific analyte in an appropriate balance gas.

3.4 Zero Calibration Error. The analyte concentration output exhibited by the EC cell in response to zero-level calibration gas.

3.5 Up-Scale Calibration Error. The mean of the difference between the analyte concentration exhibited by the EC cell and the certified concentration of the up-scale calibration gas.

3.6 Interference Check. A procedure for quantifying analytical interference from components in the engine exhaust gas other than the targeted analytes.

3.7 Repeatability Check. A protocol for demonstrating that an EC cell operated over a given nominal analyte concentration range provides a stable and consistent response and is not significantly affected by repeated exposure to that gas.

3.8 Sample Flow Rate. The flow rate of the gas sample as it passes through the EC cell. In some situations, EC cells can experience drift with changes in flow rate. The flow rate must be monitored and documented during all phases of a sampling run.

3.9 Sampling Run. A timed three-phase event whereby an EC cell's response rises and plateaus in a sample conditioning phase, remains relatively constant during a measurement data phase, then declines during a refresh phase. The sample conditioning phase exposes the EC cell to

the gas sample for a length of time sufficient to reach a constant response. The measurement data phase is the time interval during which gas sample measurements can be made that meet the acceptance criteria of this protocol. The refresh phase then purges the EC cells with CO-free air. The refresh phase replenishes requisite O_2 and moisture in the electrolyte reserve and provides a mechanism to de-gas or desorb any interference gas scrubbers or filters so as to enable a stable CO EC cell response. There are four primary types of sampling runs: pre- sampling calibrations; stack gas sampling; post-sampling calibration checks; and measurement system repeatability checks. Stack gas sampling runs can be chained together for extended evaluations, providing all other procedural specifications are met.

3.10 Sampling Day. A time not to exceed twelve hours from the time of the pre-sampling calibration to the post-sampling calibration check. During this time, stack gas sampling runs can be repeated without repeated recalibrations, providing all other sampling specifications have been met.

3.11 Pre-Sampling Calibration/Post-Sampling Calibration Check. The protocols executed at the beginning and end of each sampling day to bracket measurement readings with controlled performance checks.

3.12 Performance-Established Configuration. The EC cell and sampling system configuration that existed at the time that it initially met the performance requirements of this protocol.

4.0 INTERFERENCES.

When present in sufficient concentrations, NO and NO_2 are two gas species that have been reported to interfere with CO concentration measurements. In the likelihood of this occurrence, it is the protocol user's responsibility to employ and properly maintain an appropriate CO EC cell filter or scrubber for removal of these gases, as described in Section 6.2.12.

5.0 SAFETY. [RESERVED]

6.0 EQUIPMENT AND SUPPLIES.

6.1 What equipment do I need for the measurement system?

The system must maintain the gas sample at conditions that will prevent moisture condensation in the sample transport lines, both before and as the sample gas contacts the EC cells. The essential components of the measurement system are described below.

6.2 Measurement System Components.

6.2.1 Sample Probe. A single extraction-point probe constructed of glass, stainless steel or other non-reactive material, and of length sufficient to reach any designated sampling point. The sample probe must be designed to prevent plugging due to condensation or particulate matter.

6.2.2 Sample Line. Non-reactive tubing to transport the effluent from the sample probe to the EC cell.

6.2.3 Calibration Assembly (optional). A three-way valve assembly or equivalent to introduce calibration gases at ambient pressure at the exit end of the sample probe during calibration checks. The assembly must be designed such that only stack gas or calibration gas flows in the sample line and all gases flow through any gas path filters.

6.2.4 Particulate Filter (optional). Filters before the inlet of the EC cell to prevent accumulation of particulate material in the measurement system and extend the useful life of the components. All filters must be fabricated of materials that are non-reactive to the gas mixtures being sampled.

6.2.5 Sample Pump. A leak-free pump to provide undiluted sample gas to the system at a flow rate sufficient to minimize the response time of the measurement system. If located upstream of the EC cells, the pump must be constructed of a material that is non-reactive to the gas mixtures being sampled.

6.2.8 Sample Flow Rate Monitoring. An adjustable rotameter or equivalent device used to adjust and maintain the sample flow rate through the analyzer as prescribed.

6.2.9 Sample Gas Manifold (optional). A manifold to divert a portion of the sample gas stream to the analyzer and the remainder to a by-pass discharge vent. The sample gas manifold may also include provisions for introducing calibration gases directly to the analyzer. The manifold must be constructed of a material that is non-reactive to the gas mixtures being sampled.

6.2.10 EC cell. A device containing one or more EC cells to determine the CO and O_2 concentrations in the sample gas stream. The EC cell(s) must meet the applicable performance specifications of Section 13 of this protocol.

6.2.11 Data Recorder. A strip chart recorder, computer or digital recorder to make a record of analyzer output data. The data recorder resolution (i.e., readability) must be no greater than 1 ppm for CO; 0.1 percent for O_2; and one degree (either °C or °F) for temperature. Alternatively, you may use a digital or analog meter having the same resolution to observe and manually record the analyzer responses.

6.2.12 Interference Gas Filter or Scrubber. A device to remove interfering compounds upstream of the CO EC cell. Specific interference gas filters or scrubbers used in the performance-established configuration of the analyzer must continue to be used. Such a filter or scrubber must have a means to determine when the removal agent is exhausted. Periodically replace or replenish it in accordance with the manufacturer's recommendations.

7.0 Reagents and Standards. What calibration gases are needed?

7.1 Calibration Gases. CO calibration gases for the EC cell must be CO in nitrogen or CO in a mixture of nitrogen and O_2. Use CO calibration gases with labeled concentration values certified by the manufacturer to be within ±5 percent of the label value. Dry ambient air (20.9 percent O_2) is acceptable for calibration of the O_2 cell. If needed, any lower percentage O_2 calibration gas must be a mixture of O_2 in nitrogen.

7.1.1 Up-Scale CO Calibration Gas Concentration. Choose one or more up-scale gas concentrations such that the average of the stack gas measurements for each stack gas sampling run are between 25 and 150 percent of those concentrations. Alternatively, choose an up-scale gas that does not exceed twice the concentration of the applicable outlet standard. If a measured gas value exceeds 150 percent of the up-scale CO calibration gas value at any time during the stack gas sampling run, the run must be discarded and repeated.

7.1.2 Up-Scale O_2 Calibration Gas Concentration.

Select an O_2 gas concentration such that the difference between the gas concentration and the average stack gas measurement or reading for each sample run is less than 15 percent O_2. When the average exhaust gas O_2 readings are above 6 percent, you may use dry ambient air (20.9 percent O_2) for the up-scale O_2 calibration gas.

7.1.3 Zero Gas. Use an inert gas that contains less than 0.25 percent of the up-scale CO calibration gas concentration. You may use dry air that is free from ambient CO and other combustion gas products (e.g., CO_2).

8.0 Sample Collection and Analysis

8.1 Selection of Sampling Sites.

8.1.1 Control Device Inlet. Select a sampling site sufficiently downstream of the engine so that the combustion gases should be well mixed. Use a single sampling extraction point near the center of the duct (e.g., within the 10 percent centroidal area), unless instructed otherwise.

8.1.2 Exhaust Gas Outlet. Select a sampling site located at least two stack diameters downstream of any disturbance (e.g., turbocharger exhaust, crossover junction or recirculation take-off) and at least one-half stack diameter upstream of the gas discharge to the atmosphere. Use a single sampling extraction point near the center of the duct (e.g., within the 10 percent centroidal area), unless instructed otherwise.

8.2 Stack Gas Collection and Analysis. Prior to the first stack gas sampling run, conduct that the pre-sampling calibration in accordance with Section 10.1. Use Figure 1 to record all data. Zero the analyzer with zero gas. Confirm and record that the scrubber media color is correct and not exhausted. Then position the probe at the sampling point and begin the sampling run at the same flow rate used during the up-scale calibration. Record the start time. Record all EC cell output responses and the flow rate during the “sample conditioning phase” once per minute until constant readings are obtained. Then begin the “measurement data phase” and record readings every 15 seconds for at least two minutes (or eight readings), or as otherwise required to achieve two continuous minutes of data that meet the specification given in Section 13.1. Finally, perform the “refresh phase” by introducing dry air, free from CO and other combustion gases, until several minute-to-minute readings of consistent value have been obtained. For each run use the “measurement data phase” readings to calculate the average stack gas CO and O_2 concentrations.

8.3 EC Cell Rate. Maintain the EC cell sample flow rate so that it does not vary by more than ±10 percent throughout the pre-sampling calibration, stack gas sampling and post-sampling calibration check. Alternatively, the EC cell sample flow rate can be maintained within a tolerance range that does not affect the gas concentration readings by more than ±3 percent, as instructed by the EC cell manufacturer.

9.0 Quality Control (Reserved)

10.0 Calibration and Standardization

10.1 Pre-Sampling Calibration. Conduct the following protocol once for each nominal range to be used on each EC cell before performing a stack gas sampling run on each field sampling day. Repeat the calibration if you replace an EC cell before completing all of the sampling runs. There is no prescribed order for calibration of the EC cells; however, each cell must complete the measurement data phase during calibration. Assemble the measurement system by following the manufacturer's recommended protocols including for preparing and preconditioning the EC cell.

Assure the measurement system has no leaks and verify the gas scrubbing agent is not depleted. Use Figure 1 to record all data.

10.1.1 Zero Calibration. For both the O_2 and CO cells, introduce zero gas to the measurement system (e.g., at the calibration assembly) and record the concentration reading every minute until readings are constant for at least two consecutive minutes. Include the time and sample flow rate. Repeat the steps in this section at least once to verify the zero calibration for each component gas.

10.1.2 Zero Calibration Tolerance. For each zero gas introduction, the zero level output must be less than or equal to ±3 percent of the up-scale gas value or ±1 ppm, whichever is less restrictive, for the CO channel and less than or equal to ±0.3 percent O_2 for the O_2 channel.

10.1.3 Up-Scale Calibration. Individually introduce each calibration gas to the measurement system (e.g., at the calibration assembly) and record the start time. Record all EC cell output responses and the flow rate during this "sample conditioning phase" once per minute until readings are constant for at least two minutes. Then begin the "measurement data phase" and record readings every 15 seconds for a total of two minutes, or as otherwise required. Finally, perform the "refresh phase" by introducing dry air, free from CO and other combustion gases, until readings are constant for at least two consecutive minutes. Then repeat the steps in this section at least once to verify the calibration for each component gas. Introduce all gases to flow through the entire sample handling system (i.e., at the exit end of the sampling probe or the calibration assembly).

10.1.4 Up-Scale Calibration Error. The mean of the difference of the "measurement data phase" readings from the reported standard gas value must be less than or equal to ±5 percent or ±1 ppm for CO or ±0.5 percent O_2, whichever is less restrictive, respectively. The maximum allowable deviation from the mean measured value of any single "measurement data phase" reading must be less than or equal to ±2 percent or ±1 ppm for CO or ±0.5 percent O_2, whichever is less restrictive, respectively.

10.2 Post-Sampling Calibration Check. Conduct a stack gas post-sampling calibration check after the stack gas sampling run or set of runs and within 12 hours of the initial calibration. Conduct up-scale and zero calibration checks using the protocol in Section 10.1. Make no changes to the sampling system or EC cell calibration until all post-sampling calibration checks have been recorded. If either the zero or up-scale calibration error exceeds the respective specification in Sections 10.1.2 and 10.1.4 then all measurement data collected since the previous successful calibrations are invalid and re-calibration and re-sampling are required. If the sampling system is disassembled or the EC cell calibration is adjusted, repeat the calibration check before conducting the next analyzer sampling run.

11.0 Analytical Procedure

The analytical procedure is fully discussed in Section 8.

12.0 Calculations and Data Analysis

Determine the CO and O_2 concentrations for each stack gas sampling run by calculating the mean gas concentrations of the data recorded during the "measurement data phase".

13.0 Protocol Performance

Use the following protocols to verify consistent analyzer performance during each field sampling day.

13.1 Measurement Data Phase Performance Check. Calculate the mean of the readings from the "measurement data phase". The maximum allowable deviation from the mean for each of the individual readings is ±2 percent, or ±1 ppm, whichever is less restrictive. Record the mean value and maximum deviation for each gas monitored. Data must conform to Section 10.1.4. The EC cell flow rate must conform to the specification in Section 8.3.

Example: A measurement data phase is invalid if the maximum deviation of any single reading comprising that mean is greater than ±2 percent *or* ±1 ppm (the default criteria). For example, if the mean = 30 ppm, single readings of below 29 ppm and above 31 ppm are disallowed).

13.2 Interference Check. Before the initial use of the EC cell and interference gas scrubber in the field, and semi-annually thereafter, challenge the interference gas scrubber with NO and NO_2 gas standards that are generally recognized as representative of diesel-fueled engine NO and NO_2 emission values. Record the responses displayed by the CO EC cell and other pertinent data on Figure 1 or a similar form.

13.2.1 Interference Response. The combined NO and NO_2 interference response should be less than or equal to ±5 percent of the up-scale CO calibration gas concentration.

13.3 Repeatability Check. Conduct the following check once for each nominal range that is to be used on the CO EC cell within 5 days prior to each field sampling program. If a field sampling program lasts longer than 5 days, repeat this check every 5 days. Immediately repeat the check if the EC cell is replaced or if the EC cell is exposed to gas concentrations greater than 150 percent of the highest up-scale gas concentration.

13.3.1 Repeatability Check Procedure. Perform a complete EC cell sampling run (all three phases) by introducing the CO calibration gas to the measurement system and record the response. Follow Section 10.1.3. Use Figure 1 to record all data. Repeat the run three times for a total of four complete runs. During the four repeatability check runs, do not adjust the system except where necessary to achieve the correct calibration gas flow rate at the analyzer.

13.3.2 Repeatability Check Calculations. Determine the highest and lowest average "measurement data phase" CO concentrations from the four repeatability check runs and record the results on Figure 1 or a similar form. The absolute value of the difference between the maximum and minimum average values recorded must not vary more than ±3 percent or ±1 ppm of the up-scale gas value, whichever is less restrictive.

14.0 Pollution Prevention (Reserved)

15.0 Waste Management (Reserved)

16.0 Alternative Procedures (Reserved)

Subpart JJJJ—Standards of Performance for Stationary Spark Ignition Internal Combustion Engines

SOURCE: 73 FR 3591, Jan. 18, 2008, unless otherwise noted.

Back to Top

WHAT THIS SUBPART COVERS

Back to Top

§60.4230 Am I subject to this subpart?

(a) The provisions of this subpart are applicable to manufacturers, owners, and operators of stationary spark ignition (SI) internal combustion engines (ICE) as specified in paragraphs (a)(1) through (6) of this section. For the purposes of this subpart, the date that construction commences is the date the engine is ordered by the owner or operator.

(1) Manufacturers of stationary SI ICE with a maximum engine power less than or equal to 19 kilowatt (KW) (25 horsepower (HP)) that are manufactured on or after July 1, 2008.

(2) Manufacturers of stationary SI ICE with a maximum engine power greater than 19 KW (25 HP) that are gasoline fueled or that are rich burn engines fueled by liquefied petroleum gas (LPG), where the date of manufacture is:

(i) On or after July 1, 2008; or

(ii) On or after January 1, 2009, for emergency engines.

(3) Manufacturers of stationary SI ICE with a maximum engine power greater than 19 KW (25 HP) that are not gasoline fueled and are not rich burn engines fueled by LPG, where the manufacturer participates in the voluntary manufacturer certification program described in this subpart and where the date of manufacture is:

(i) On or after July 1, 2007, for engines with a maximum engine power greater than or equal to 500 HP (except lean burn engines with a maximum engine power greater than or equal to 500 HP and less than 1,350 HP);

(ii) On or after January 1, 2008, for lean burn engines with a maximum engine power greater than or equal to 500 HP and less than 1,350 HP;

(iii) On or after July 1, 2008, for engines with a maximum engine power less than 500 HP; or

(iv) On or after January 1, 2009, for emergency engines.

(4) Owners and operators of stationary SI ICE that commence construction after June 12, 2006, where the stationary SI ICE are manufactured:

(i) On or after July 1, 2007, for engines with a maximum engine power greater than or equal to 500 HP (except lean burn engines with a maximum engine power greater than or equal to 500 HP and less than 1,350 HP);

(ii) on or after January 1, 2008, for lean burn engines with a maximum engine power greater than or equal to 500 HP and less than 1,350 HP;

(iii) on or after July 1, 2008, for engines with a maximum engine power less than 500 HP; or

(iv) on or after January 1, 2009, for emergency engines with a maximum engine power greater than 19 KW (25 HP).

(5) Owners and operators of stationary SI ICE that are modified or reconstructed after June 12, 2006, and any person that modifies or reconstructs any stationary SI ICE after June 12, 2006.

(6) The provisions of §60.4236 of this subpart are applicable to all owners and operators of stationary SI ICE that commence construction after June 12, 2006.

(b) The provisions of this subpart are not applicable to stationary SI ICE being tested at an engine test cell/stand.

(c) If you are an owner or operator of an area source subject to this subpart, you are exempt from the obligation to obtain a permit under 40 CFR part 70 or 40 CFR part 71, provided you are not required to obtain a permit under 40 CFR 70.3(a) or 40 CFR 71.3(a) for a reason other than your status as an area source under this subpart. Notwithstanding the previous sentence, you must continue to comply with the provisions of this subpart as applicable.

(d) For the purposes of this subpart, stationary SI ICE using alcohol-based fuels are considered gasoline engines.

(e) Stationary SI ICE may be eligible for exemption from the requirements of this subpart as described in 40 CFR part 1068, subpart C (or the exemptions described in 40 CFR parts 90 and 1048, for engines that would need to be certified to standards in those parts), except that owners and operators, as well as manufacturers, may be eligible to request an exemption for national security.

(f) Owners and operators of facilities with internal combustion engines that are acting as temporary replacement units and that are located at a stationary source for less than 1 year and that have been properly certified as meeting the standards that would be applicable to such engine under the appropriate nonroad engine provisions, are not required to meet any other provisions under this subpart with regard to such engines.

[73 FR 3591, Jan. 18, 2008, as amended at 76 FR 37972, June 28, 2011]

Back to Top

EMISSION STANDARDS FOR MANUFACTURERS

Back to Top

§60.4231 What emission standards must I meet if I am a manufacturer of stationary SI internal combustion engines or equipment containing such engines?

(a) Stationary SI internal combustion engine manufacturers must certify their stationary SI ICE with a maximum engine power less than or equal to 19 KW (25 HP) manufactured on or after July 1, 2008 to the certification emission standards and other requirements for new nonroad SI engines in 40 CFR part 90 or 1054, as follows:

If engine displacement is * * *	and manufacturing dates are * * *	the engine must meet emission standards and related requirements for nonhandheld engines under * * *
(1) below 225 cc	July 1, 2008 to December 31, 2011	40 CFR part 90.
(2) below 225 cc	January 1, 2012 or later	40 CFR part 1054.
(3) at or above 225 cc	July 1, 2008 to December 31, 2010	40 CFR part 90.
(4) at or above 225 cc	January 1, 2011 or later	40 CFR part 1054.

(b) Stationary SI internal combustion engine manufacturers must certify their stationary SI ICE with a maximum engine power greater than 19 KW (25 HP) (except emergency stationary ICE with a maximum engine power greater than 25 HP and less than 130 HP) that use gasoline and that are manufactured on or after the applicable date in §60.4230(a)(2), or manufactured on or after the applicable date in §60.4230(a)(4) for emergency stationary ICE with a maximum engine power greater than or equal to 130 HP, to the certification emission standards and other requirements for new nonroad SI engines in 40 CFR part 1048. Stationary SI internal combustion engine manufacturers must certify their emergency stationary SI ICE with a maximum engine power greater than 25 HP and less than 130 HP that use gasoline and that are manufactured on or after the applicable date in §60.4230(a)(4) to the Phase 1 emission standards in 40 CFR 90.103, applicable to class II engines, and other requirements for new nonroad SI engines in 40 CFR part 90. Stationary SI internal combustion engine manufacturers may certify their stationary SI ICE with a maximum engine power less than or equal to 30 KW (40 HP) with a total displacement less than or equal to 1,000 cubic centimeters (cc) that use gasoline to the certification emission standards and other requirements for new nonroad SI engines in 40 CFR part 90 or 1054, as appropriate.

(c) Stationary SI internal combustion engine manufacturers must certify their stationary SI ICE with a maximum engine power greater than 19 KW (25 HP) (except emergency stationary ICE with a

maximum engine power greater than 25 HP and less than 130 HP) that are rich burn engines that use LPG and that are manufactured on or after the applicable date in §60.4230(a)(2), or manufactured on or after the applicable date in §60.4230(a)(4) for emergency stationary ICE with a maximum engine power greater than or equal to 130 HP, to the certification emission standards and other requirements for new nonroad SI engines in 40 CFR part 1048. Stationary SI internal combustion engine manufacturers must certify their emergency stationary SI ICE greater than 25 HP and less than 130 HP that are rich burn engines that use LPG and that are manufactured on or after the applicable date in §60.4230(a)(4) to the Phase 1 emission standards in 40 CFR 90.103, applicable to class II engines, and other requirements for new nonroad SI engines in 40 CFR part 90. Stationary SI internal combustion engine manufacturers may certify their stationary SI ICE with a maximum engine power less than or equal to 30 KW (40 HP) with a total displacement less than or equal to 1,000 cc that are rich burn engines that use LPG to the certification emission standards and other requirements for new nonroad SI engines in 40 CFR part 90 or 1054, as appropriate.

(d) Stationary SI internal combustion engine manufacturers who choose to certify their stationary SI ICE with a maximum engine power greater than 19 KW (25 HP) and less than 75 KW (100 HP) (except gasoline and rich burn engines that use LPG and emergency stationary ICE with a maximum engine power greater than 25 HP and less than 130 HP) under the voluntary manufacturer certification program described in this subpart must certify those engines to the certification emission standards for new nonroad SI engines in 40 CFR part 1048. Stationary SI internal combustion engine manufacturers who choose to certify their emergency stationary SI ICE greater than 25 HP and less than 130 HP (except gasoline and rich burn engines that use LPG), must certify those engines to the Phase 1 emission standards in 40 CFR 90.103, applicable to class II engines, for new nonroad SI engines in 40 CFR part 90. Stationary SI internal combustion engine manufacturers may certify their stationary SI ICE with a maximum engine power less than or equal to 30 KW (40 HP) with a total displacement less than or equal to 1,000 cc (except gasoline and rich burn engines that use LPG) to the certification emission standards for new nonroad SI engines in 40 CFR part 90 or 1054, as appropriate. For stationary SI ICE with a maximum engine power greater than 19 KW (25 HP) and less than 75 KW (100 HP) (except gasoline and rich burn engines that use LPG and emergency stationary ICE with a maximum engine power greater than 25 HP and less than 130 HP) manufactured prior to January 1, 2011, manufacturers may choose to certify these engines to the standards in Table 1 to this subpart applicable to engines with a maximum engine power greater than or equal to 100 HP and less than 500 HP.

(e) Stationary SI internal combustion engine manufacturers who choose to certify their stationary SI ICE with a maximum engine power greater than or equal to 75 KW (100 HP) (except gasoline and rich burn engines that use LPG) under the voluntary manufacturer certification program described in this subpart must certify those engines to the emission standards in Table 1 to this subpart. Stationary SI internal combustion engine manufacturers may certify their stationary SI ICE with a maximum engine power greater than or equal to 75 KW (100 HP) that are lean burn engines that use LPG to the certification emission standards for new nonroad SI engines in 40 CFR part 1048. For stationary SI ICE with a maximum engine power greater than or equal to 100 HP (75 KW) and less than 500 HP (373 KW) manufactured prior to January 1, 2011, and for stationary SI ICE with a maximum engine power greater than or equal to 500 HP (373 KW) manufactured prior to July 1, 2010, manufacturers may choose to certify these engines to the certification emission standards for new nonroad SI engines in 40 CFR part 1048 applicable to engines that are not severe duty engines.

(f) Manufacturers of equipment containing stationary SI internal combustion engines meeting the provisions of 40 CFR part 1054 must meet the provisions of 40 CFR part 1060, to the extent they apply to equipment manufacturers.

(g) Notwithstanding the requirements in paragraphs (a) through (c) of this section, stationary SI internal combustion engine manufacturers are not required to certify reconstructed engines; however manufacturers may elect to do so. The reconstructed engine must be certified to the emission standards specified in paragraphs (a) through (e) of this section that are applicable to the model year, maximum engine power and displacement of the reconstructed stationary SI ICE.

[73 FR 3591, Jan. 18, 2008, as amended at 73 FR 59175, Oct. 8, 2008; 76 FR 37973, June 28, 2011; 78 FR 6697, Jan. 30, 2013]

Back to Top

§60.4232 How long must my engines meet the emission standards if I am a manufacturer of stationary SI internal combustion engines?

Engines manufactured by stationary SI internal combustion engine manufacturers must meet the emission standards as required in §60.4231 during the certified emissions life of the engines.

Back to Top

EMISSION STANDARDS FOR OWNERS AND OPERATORS

Back to Top

§60.4233 What emission standards must I meet if I am an owner or operator of a stationary SI internal combustion engine?

(a) Owners and operators of stationary SI ICE with a maximum engine power less than or equal to 19 KW (25 HP) manufactured on or after July 1, 2008, must comply with the emission standards in §60.4231(a) for their stationary SI ICE.

(b) Owners and operators of stationary SI ICE with a maximum engine power greater than 19 KW (25 HP) manufactured on or after the applicable date in §60.4230(a)(4) that use gasoline must comply with the emission standards in §60.4231(b) for their stationary SI ICE.

(c) Owners and operators of stationary SI ICE with a maximum engine power greater than 19 KW (25 HP) manufactured on or after the applicable date in §60.4230(a)(4) that are rich burn engines that use LPG must comply with the emission standards in §60.4231(c) for their stationary SI ICE.

(d) Owners and operators of stationary SI ICE with a maximum engine power greater than 19 KW (25 HP) and less than 75 KW (100 HP) (except gasoline and rich burn engines that use LPG) must comply with the emission standards for field testing in 40 CFR 1048.101(c) for their non-emergency stationary SI ICE and with the emission standards in Table 1 to this subpart for their emergency

stationary SI ICE. Owners and operators of stationary SI ICE with a maximum engine power greater than 19 KW (25 HP) and less than 75 KW (100 HP) manufactured prior to January 1, 2011, that were certified to the standards in Table 1 to this subpart applicable to engines with a maximum engine power greater than or equal to 100 HP and less than 500 HP, may optionally choose to meet those standards.

(e) Owners and operators of stationary SI ICE with a maximum engine power greater than or equal to 75 KW (100 HP) (except gasoline and rich burn engines that use LPG) must comply with the emission standards in Table 1 to this subpart for their stationary SI ICE. For owners and operators of stationary SI ICE with a maximum engine power greater than or equal to 100 HP (except gasoline and rich burn engines that use LPG) manufactured prior to January 1, 2011 that were certified to the certification emission standards in 40 CFR part 1048 applicable to engines that are not severe duty engines, if such stationary SI ICE was certified to a carbon monoxide (CO) standard above the standard in Table 1 to this subpart, then the owners and operators may meet the CO certification (not field testing) standard for which the engine was certified.

(f) Owners and operators of any modified or reconstructed stationary SI ICE subject to this subpart must meet the requirements as specified in paragraphs (f)(1) through (5) of this section.

(1) Owners and operators of stationary SI ICE with a maximum engine power less than or equal to 19 KW (25 HP), that are modified or reconstructed after June 12, 2006, must comply with emission standards in §60.4231(a) for their stationary SI ICE. Engines with a date of manufacture prior to July 1, 2008 must comply with the emission standards specified in §60.4231(a) applicable to engines manufactured on July 1, 2008.

(2) Owners and operators of stationary SI ICE with a maximum engine power greater than 19 KW (25 HP) that are gasoline engines and are modified or reconstructed after June 12, 2006, must comply with the emission standards in §60.4231(b) for their stationary SI ICE. Engines with a date of manufacture prior to July 1, 2008 (or January 1, 2009 for emergency engines) must comply with the emission standards specified in §60.4231(b) applicable to engines manufactured on July 1, 2008 (or January 1, 2009 for emergency engines).

(3) Owners and operators of stationary SI ICE with a maximum engine power greater than 19 KW (25 HP) that are rich burn engines that use LPG, that are modified or reconstructed after June 12, 2006, must comply with the same emission standards as those specified in §60.4231(c). Engines with a date of manufacture prior to July 1, 2008 (or January 1, 2009 for emergency engines) must comply with the emission standards specified in §60.4231(c) applicable to engines manufactured on July 1, 2008 (or January 1, 2009 for emergency engines).

(4) Owners and operators of stationary SI natural gas and lean burn LPG engines with a maximum engine power greater than 19 KW (25 HP), that are modified or reconstructed after June 12, 2006, must comply with the same emission standards as those specified in paragraph (d) or (e) of this section, except that such owners and operators of non-emergency engines and emergency engines greater than or equal to 130 HP must meet a nitrogen oxides (NO_x) emission standard of 3.0 grams per HP-hour (g/HP-hr), a CO emission standard of 4.0 g/HP-hr (5.0 g/HP-hr for non-emergency engines less than 100 HP), and a volatile organic compounds (VOC) emission standard of

1.0 g/HP-hr, or a NO_x emission standard of 250 ppmvd at 15 percent oxygen (O_2), a CO emission standard 540 ppmvd at 15 percent O_2 (675 ppmvd at 15 percent O_2 for non-emergency engines less than 100 HP), and a VOC emission standard of 86 ppmvd at 15 percent O_2, where the date of manufacture of the engine is:

(i) Prior to July 1, 2007, for non-emergency engines with a maximum engine power greater than or equal to 500 HP (except lean burn natural gas engines and LPG engines with a maximum engine power greater than or equal to 500 HP and less than 1,350 HP);

(ii) Prior to July 1, 2008, for non-emergency engines with a maximum engine power less than 500 HP;

(iii) Prior to January 1, 2009, for emergency engines;

(iv) Prior to January 1, 2008, for non-emergency lean burn natural gas engines and LPG engines with a maximum engine power greater than or equal to 500 HP and less than 1,350 HP.

(5) Owners and operators of stationary SI landfill/digester gas ICE engines with a maximum engine power greater than 19 KW (25 HP), that are modified or reconstructed after June 12, 2006, must comply with the same emission standards as those specified in paragraph (e) of this section for stationary landfill/digester gas engines. Engines with maximum engine power less than 500 HP and a date of manufacture prior to July 1, 2008 must comply with the emission standards specified in paragraph (e) of this section for stationary landfill/digester gas ICE with a maximum engine power less than 500 HP manufactured on July 1, 2008. Engines with a maximum engine power greater than or equal to 500 HP (except lean burn engines greater than or equal to 500 HP and less than 1,350 HP) and a date of manufacture prior to July 1, 2007 must comply with the emission standards specified in paragraph (e) of this section for stationary landfill/digester gas ICE with a maximum engine power greater than or equal to 500 HP (except lean burn engines greater than or equal to 500 HP and less than 1,350 HP) manufactured on July 1, 2007. Lean burn engines greater than or equal to 500 HP and less than 1,350 HP with a date of manufacture prior to January 1, 2008 must comply with the emission standards specified in paragraph (e) of this section for stationary landfill/digester gas ICE that are lean burn engines greater than or equal to 500 HP and less than 1,350 HP and manufactured on January 1, 2008.

(g) Owners and operators of stationary SI wellhead gas ICE engines may petition the Administrator for approval on a case-by-case basis to meet emission standards no less stringent than the emission standards that apply to stationary emergency SI engines greater than 25 HP and less than 130 HP due to the presence of high sulfur levels in the fuel, as specified in Table 1 to this subpart. The request must, at a minimum, demonstrate that the fuel has high sulfur levels that prevent the use of aftertreatment controls and also that the owner has reasonably made all attempts possible to obtain an engine that will meet the standards without the use of aftertreatment controls. The petition must request the most stringent standards reasonably applicable to the engine using the fuel.

(h) Owners and operators of stationary SI ICE that are required to meet standards that reference 40 CFR 1048.101 must, if testing their engines in use, meet the standards in that section applicable to field testing, except as indicated in paragraph (e) of this section.

[73 FR 3591, Jan. 18, 2008, as amended at 76 FR 37973, June 28, 2011]

Back to Top

§60.4234 How long must I meet the emission standards if I am an owner or operator of a stationary SI internal combustion engine?

Owners and operators of stationary SI ICE must operate and maintain stationary SI ICE that achieve the emission standards as required in §60.4233 over the entire life of the engine.

Back to Top

OTHER REQUIREMENTS FOR OWNERS AND OPERATORS

Back to Top

§60.4235 What fuel requirements must I meet if I am an owner or operator of a stationary SI gasoline fired internal combustion engine subject to this subpart?

Owners and operators of stationary SI ICE subject to this subpart that use gasoline must use gasoline that meets the per gallon sulfur limit in 40 CFR 1090.205.

[73 FR 3591, Jan. 18, 2008, as amended at 85 FR 78463, Dec. 4, 2020]

Back to Top

§60.4236 What is the deadline for importing or installing stationary SI ICE produced in previous model years?

(a) After July 1, 2010, owners and operators may not install stationary SI ICE with a maximum engine power of less than 500 HP that do not meet the applicable requirements in §60.4233.

(b) After July 1, 2009, owners and operators may not install stationary SI ICE with a maximum engine power of greater than or equal to 500 HP that do not meet the applicable requirements in §60.4233, except that lean burn engines with a maximum engine power greater than or equal to 500 HP and less than 1,350 HP that do not meet the applicable requirements in §60.4233 may not be installed after January 1, 2010.

(c) For emergency stationary SI ICE with a maximum engine power of greater than 19 KW (25 HP), owners and operators may not install engines that do not meet the applicable requirements in §60.4233 after January 1, 2011.

(d) In addition to the requirements specified in §§60.4231 and 60.4233, it is prohibited to import stationary SI ICE less than or equal to 19 KW (25 HP), stationary rich burn LPG SI ICE, and stationary gasoline SI ICE that do not meet the applicable requirements specified in paragraphs (a), (b), and (c) of this section, after the date specified in paragraph (a), (b), and (c) of this section.

(e) The requirements of this section do not apply to owners and operators of stationary SI ICE that have been modified or reconstructed, and they do not apply to engines that were removed from one existing location and reinstalled at a new location.

Back to Top

§60.4237 What are the monitoring requirements if I am an owner or operator of an emergency stationary SI internal combustion engine?

(a) Starting on July 1, 2010, if the emergency stationary SI internal combustion engine that is greater than or equal to 500 HP that was built on or after July 1, 2010, does not meet the standards applicable to non-emergency engines, the owner or operator must install a non-resettable hour meter.

(b) Starting on January 1, 2011, if the emergency stationary SI internal combustion engine that is greater than or equal to 130 HP and less than 500 HP that was built on or after January 1, 2011, does not meet the standards applicable to non-emergency engines, the owner or operator must install a non-resettable hour meter.

(c) If you are an owner or operator of an emergency stationary SI internal combustion engine that is less than 130 HP, was built on or after July 1, 2008, and does not meet the standards applicable to non-emergency engines, you must install a non-resettable hour meter upon startup of your emergency engine.

Back to Top

COMPLIANCE REQUIREMENTS FOR MANUFACTURERS

Back to Top

§60.4238 What are my compliance requirements if I am a manufacturer of stationary SI internal combustion engines ≤19 KW (25 HP) or a manufacturer of equipment containing such engines?

Stationary SI internal combustion engine manufacturers who are subject to the emission standards specified in §60.4231(a) must certify their stationary SI ICE using the certification procedures required in 40 CFR part 90, subpart B, or 40 CFR part 1054, subpart C, as applicable, and must test their engines as specified in those parts. Manufacturers of equipment containing stationary SI internal combustion engines meeting the provisions of 40 CFR part 1054 must meet the provisions of 40 CFR part 1060, subpart C, to the extent they apply to equipment manufacturers.

[73 FR 59176, Oct. 8, 2008]

Back to Top

§60.4239 What are my compliance requirements if I am a manufacturer of stationary SI internal combustion engines >19 KW (25 HP) that use gasoline or a manufacturer of equipment containing such engines?

Stationary SI internal combustion engine manufacturers who are subject to the emission standards specified in §60.4231(b) must certify their stationary SI ICE using the certification procedures required in 40 CFR part 1048, subpart C, and must test their engines as specified in that part. Stationary SI internal combustion engine manufacturers who certify their stationary SI ICE with a maximum engine power less than or equal to 30 KW (40 HP) with a total displacement less than or equal to 1,000 cc to the certification emission standards and other requirements for new nonroad SI engines in 40 CFR part 90 or 40 CFR part 1054, and manufacturers of stationary SI emergency engines that are greater than 25 HP and less than 130 HP who meet the Phase 1 emission standards in 40 CFR 90.103, applicable to class II engines, must certify their stationary SI ICE using the certification procedures required in 40 CFR part 90, subpart B, or 40 CFR part 1054, subpart C, as applicable, and must test their engines as specified in those parts. Manufacturers of equipment containing stationary SI internal combustion engines meeting the provisions of 40 CFR part 1054 must meet the provisions of 40 CFR part 1060, subpart C, to the extent they apply to equipment manufacturers.

[73 FR 59176, Oct. 8, 2008]

Back to Top

§60.4240 What are my compliance requirements if I am a manufacturer of stationary SI internal combustion engines >19 KW (25 HP) that are rich burn engines that use LPG or a manufacturer of equipment containing such engines?

Stationary SI internal combustion engine manufacturers who are subject to the emission standards specified in §60.4231(c) must certify their stationary SI ICE using the certification procedures required in 40 CFR part 1048, subpart C, and must test their engines as specified in that part. Stationary SI internal combustion engine manufacturers who certify their stationary SI ICE with a maximum engine power less than or equal to 30 KW (40 HP) with a total displacement less than or equal to 1,000 cc to the certification emission standards and other requirements for new nonroad SI engines in 40 CFR part 90 or 40 CFR part 1054, and manufacturers of stationary SI emergency engines that are greater than 25 HP and less than 130 HP who meet the Phase 1 emission standards in 40 CFR 90.103, applicable to class II engines, must certify their stationary SI ICE using the certification procedures required in 40 CFR part 90, subpart B, or 40 CFR part 1054, subpart C, as applicable, and must test their engines as specified in those parts. Manufacturers of equipment containing stationary SI internal combustion engines meeting the provisions of 40 CFR part 1054 must meet the provisions of 40 CFR part 1060, subpart C, to the extent they apply to equipment manufacturers.

[73 FR 59176, Oct. 8, 2008]

Back to Top

§60.4241 What are my compliance requirements if I am a manufacturer of stationary SI internal combustion engines participating in the voluntary certification program or a manufacturer of equipment containing such engines?

(a) Manufacturers of stationary SI internal combustion engines with a maximum engine power greater than 19 KW (25 HP) that do not use gasoline and are not rich burn engines that use LPG can choose to certify their engines to the emission standards in §60.4231(d) or (e), as applicable, under the voluntary certification program described in this subpart. Manufacturers who certify their engines under the voluntary certification program must meet the requirements as specified in paragraphs (b) through (g) of this section. In addition, manufacturers of stationary SI internal combustion engines who choose to certify their engines under the voluntary certification program, must also meet the requirements as specified in §60.4247.

(b) Manufacturers of engines other than those certified to standards in 40 CFR part 90 or 40 CFR part 1054 must certify their stationary SI ICE using the certification procedures required in 40 CFR part 1048, subpart C, and must follow the same test procedures that apply to large SI nonroad engines under 40 CFR part 1048, but must use the D-1 cycle of International Organization of Standardization 8178-4: 1996(E) (incorporated by reference, see 40 CFR 60.17) or the test cycle requirements specified in Table 3 to 40 CFR 1048.505, except that Table 3 of 40 CFR 1048.505 applies to high load engines only. Stationary SI internal combustion engine manufacturers who certify their stationary SI ICE with a maximum engine power less than or equal to 30 KW (40 HP) with a total displacement less than or equal to 1,000 cc to the certification emission standards and other requirements for new nonroad SI engines in 40 CFR part 90 or 40 CFR part 1054, and manufacturers of emergency engines that are greater than 25 HP and less than 130 HP who meet the Phase 1 standards in 40 CFR 90.103, applicable to class II engines, must certify their stationary SI ICE using the certification procedures required in 40 CFR part 90, subpart B, or 40 CFR part 1054, subpart C, as applicable, and must test their engines as specified in those parts. Manufacturers of equipment containing stationary SI internal combustion engines meeting the provisions of 40 CFR part 1054 must meet the provisions of 40 CFR part 1060, subpart C, to the extent they apply to equipment manufacturers.

(c) Certification of stationary SI ICE to the emission standards specified in §60.4231(d) or (e), as applicable, is voluntary, but manufacturers who decide to certify are subject to all of the requirements indicated in this subpart with regard to the engines included in their certification. Manufacturers must clearly label their stationary SI engines as certified or non-certified engines.

(d) Manufacturers of natural gas fired stationary SI ICE who conduct voluntary certification of stationary SI ICE to the emission standards specified in §60.4231(d) or (e), as applicable, must certify their engines for operation using fuel that meets the definition of pipeline-quality natural gas. The fuel used for certifying stationary SI natural gas engines must meet the definition of pipeline-quality natural gas as described in §60.4248. In addition, the manufacturer must provide information to the owner and operator of the certified stationary SI engine including the specifications of the pipeline-

quality natural gas to which the engine is certified and what adjustments the owner or operator must make to the engine when installed in the field to ensure compliance with the emission standards.

(e) Manufacturers of stationary SI ICE that are lean burn engines fueled by LPG who conduct voluntary certification of stationary SI ICE to the emission standards specified in §60.4231(d) or (e), as applicable, must certify their engines for operation using fuel that meets the specifications in 40 CFR 1065.720.

(f) Manufacturers may certify their engines for operation using gaseous fuels in addition to pipeline-quality natural gas; however, the manufacturer must specify the properties of that fuel and provide testing information showing that the engine will meet the emission standards specified in §60.4231(d) or (e), as applicable, when operating on that fuel. The manufacturer must also provide instructions for configuring the stationary engine to meet the emission standards on fuels that do not meet the pipeline-quality natural gas definition. The manufacturer must also provide information to the owner and operator of the certified stationary SI engine regarding the configuration that is most conducive to reduced emissions where the engine will be operated on gaseous fuels with different quality than the fuel that it was certified to.

(g) A stationary SI engine manufacturer may certify an engine family solely to the standards applicable to landfill/digester gas engines as specified in §60.4231(d) or (e), as applicable, but must certify their engines for operation using landfill/digester gas and must add a permanent label stating that the engine is for use only in landfill/digester gas applications. The label must be added according to the labeling requirements specified in 40 CFR 1048.135(b).

(h) For purposes of this subpart, when calculating emissions of volatile organic compounds, emissions of formaldehyde should not be included.

(i) For engines being certified to the voluntary certification standards in Table 1 of this subpart, the VOC measurement shall be made by following the procedures in 40 CFR 1065.260 and 1065.265 in order to determine the total NMHC emissions by using a flame-ionization detector and non-methane cutter. As an alternative to the nonmethane cutter, manufacturers may use a gas chromatograph as allowed under 40 CFR 1065.267 and may measure ethane, as well as methane, for excluding such levels from the total VOC measurement.

[73 FR 3591, Jan. 18, 2008, as amended at 73 FR 59176, Oct. 8, 2008; 76 FR 37974, June 28, 2011]

Back to Top

§60.4242 What other requirements must I meet if I am a manufacturer of stationary SI internal combustion engines or equipment containing stationary SI internal combustion engines or a manufacturer of equipment containing such engines?

(a) Stationary SI internal combustion engine manufacturers must meet the provisions of 40 CFR part 90, 40 CFR part 1048, or 40 CFR part 1054, as applicable, as well as 40 CFR part 1068 for engines that are certified to the emission standards in 40 CFR part 1048 or 1054, except that engines certified pursuant to the voluntary certification procedures in §60.4241 are subject only to the provisions

indicated in §60.4247 and are permitted to provide instructions to owners and operators allowing for deviations from certified configurations, if such deviations are consistent with the provisions of paragraphs §60.4241(c) through (f). Manufacturers of equipment containing stationary SI internal combustion engines meeting the provisions of 40 CFR part 1054 must meet the provisions of 40 CFR part 1060, as applicable. Labels on engines certified to 40 CFR part 1048 must refer to stationary engines, rather than or in addition to nonroad engines, as appropriate.

(b) An engine manufacturer certifying an engine family or families to standards under this subpart that are identical to standards applicable under 40 CFR part 90, 40 CFR part 1048, or 40 CFR part 1054 for that model year may certify any such family that contains both nonroad and stationary engines as a single engine family and/or may include any such family containing stationary engines in the averaging, banking and trading provisions applicable for such engines under those parts. This provision also applies to equipment or component manufacturers certifying to standards under 40 CFR part 1060.

(c) Manufacturers of engine families certified to 40 CFR part 1048 may meet the labeling requirements referred to in paragraph (a) of this section for stationary SI ICE by either adding a separate label containing the information required in paragraph (a) of this section or by adding the words "and stationary" after the word "nonroad" to the label.

(d) For all engines manufactured on or after January 1, 2011, and for all engines with a maximum engine power greater than 25 HP and less than 130 HP manufactured on or after July 1, 2008, a stationary SI engine manufacturer that certifies an engine family solely to the standards applicable to emergency engines must add a permanent label stating that the engines in that family are for emergency use only. The label must be added according to the labeling requirements specified in 40 CFR 1048.135(b).

(e) All stationary SI engines subject to mandatory certification that do not meet the requirements of this subpart must be labeled according to 40 CFR 1068.230 and must be exported under the provisions of 40 CFR 1068.230. Stationary SI engines subject to standards in 40 CFR part 90 may use the provisions in 40 CFR 90.909. Manufacturers of stationary engines with a maximum engine power greater than 25 HP that are not certified to standards and other requirements under 40 CFR part 1048 are subject to the labeling provisions of 40 CFR 1048.20 pertaining to excluded stationary engines.

(f) For manufacturers of gaseous-fueled stationary engines required to meet the warranty provisions in 40 CFR 90.1103 or 1054.120, we may establish an hour-based warranty period equal to at least the certified emissions life of the engines (in engine operating hours) if we determine that these engines are likely to operate for a number of hours greater than the applicable useful life within 24 months. We will not approve an alternate warranty under this paragraph (f) for nonroad engines. An alternate warranty period approved under this paragraph (f) will be the specified number of engine operating hours or two years, whichever comes first. The engine manufacturer shall request this alternate warranty period in its application for certification or in an earlier submission. We may approve an alternate warranty period for an engine family subject to the following conditions:

(1) The engines must be equipped with non-resettable hour meters.

(2) The engines must be designed to operate for a number of hours substantially greater than the applicable certified emissions life.

(3) The emission-related warranty for the engines may not be shorter than any published warranty offered by the manufacturer without charge for the engines. Similarly, the emission-related warranty for any component shall not be shorter than any published warranty offered by the manufacturer without charge for that component.

[73 FR 3591, Jan. 18, 2008, as amended at 73 FR 59177, Oct. 8, 2008]

Back to Top

COMPLIANCE REQUIREMENTS FOR OWNERS AND OPERATORS

Back to Top

§60.4243 What are my compliance requirements if I am an owner or operator of a stationary SI internal combustion engine?

(a) If you are an owner or operator of a stationary SI internal combustion engine that is manufactured after July 1, 2008, and must comply with the emission standards specified in §60.4233(a) through (c), you must comply by purchasing an engine certified to the emission standards in §60.4231(a) through (c), as applicable, for the same engine class and maximum engine power. In addition, you must meet one of the requirements specified in (a)(1) and (2) of this section.

(1) If you operate and maintain the certified stationary SI internal combustion engine and control device according to the manufacturer's emission-related written instructions, you must keep records of conducted maintenance to demonstrate compliance, but no performance testing is required if you are an owner or operator. You must also meet the requirements as specified in 40 CFR part 1068, subparts A through D, as they apply to you. If you adjust engine settings according to and consistent with the manufacturer's instructions, your stationary SI internal combustion engine will not be considered out of compliance.

(2) If you do not operate and maintain the certified stationary SI internal combustion engine and control device according to the manufacturer's emission-related written instructions, your engine will be considered a non-certified engine, and you must demonstrate compliance according to (a)(2)(i) through (iii) of this section, as appropriate.

(i) If you are an owner or operator of a stationary SI internal combustion engine less than 100 HP, you must keep a maintenance plan and records of conducted maintenance to demonstrate compliance and must, to the extent practicable, maintain and operate the engine in a manner consistent with good air pollution control practice for minimizing emissions, but no performance testing is required if you are an owner or operator.

(ii) If you are an owner or operator of a stationary SI internal combustion engine greater than or equal to 100 HP and less than or equal to 500 HP, you must keep a maintenance plan and records of conducted maintenance and must, to the extent practicable, maintain and operate the engine in a manner consistent with good air pollution control practice for minimizing emissions. In addition, you must conduct an initial performance test within 1 year of engine startup to demonstrate compliance.

(iii) If you are an owner or operator of a stationary SI internal combustion engine greater than 500 HP, you must keep a maintenance plan and records of conducted maintenance and must, to the extent practicable, maintain and operate the engine in a manner consistent with good air pollution control practice for minimizing emissions. In addition, you must conduct an initial performance test within 1 year of engine startup and conduct subsequent performance testing every 8,760 hours or 3 years, whichever comes first, thereafter to demonstrate compliance.

(b) If you are an owner or operator of a stationary SI internal combustion engine and must comply with the emission standards specified in §60.4233(d) or (e), you must demonstrate compliance according to one of the methods specified in paragraphs (b)(1) and (2) of this section.

(1) Purchasing an engine certified according to procedures specified in this subpart, for the same model year and demonstrating compliance according to one of the methods specified in paragraph (a) of this section.

(2) Purchasing a non-certified engine and demonstrating compliance with the emission standards specified in §60.4233(d) or (e) and according to the requirements specified in §60.4244, as applicable, and according to paragraphs (b)(2)(i) and (ii) of this section.

(i) If you are an owner or operator of a stationary SI internal combustion engine greater than 25 HP and less than or equal to 500 HP, you must keep a maintenance plan and records of conducted maintenance and must, to the extent practicable, maintain and operate the engine in a manner consistent with good air pollution control practice for minimizing emissions. In addition, you must conduct an initial performance test to demonstrate compliance.

(ii) If you are an owner or operator of a stationary SI internal combustion engine greater than 500 HP, you must keep a maintenance plan and records of conducted maintenance and must, to the extent practicable, maintain and operate the engine in a manner consistent with good air pollution control practice for minimizing emissions. In addition, you must conduct an initial performance test and conduct subsequent performance testing every 8,760 hours or 3 years, whichever comes first, thereafter to demonstrate compliance.

(c) If you are an owner or operator of a stationary SI internal combustion engine that must comply with the emission standards specified in §60.4233(f), you must demonstrate compliance according paragraph (b)(2)(i) or (ii) of this section, except that if you comply according to paragraph (b)(2)(i) of this section, you demonstrate that your non-certified engine complies with the emission standards specified in §60.4233(f).

(d) If you own or operate an emergency stationary ICE, you must operate the emergency stationary ICE according to the requirements in paragraphs (d)(1) through (3) of this section. In order

for the engine to be considered an emergency stationary ICE under this subpart, any operation other than emergency operation, maintenance and testing, emergency demand response, and operation in non-emergency situations for 50 hours per year, as described in paragraphs (d)(1) through (3) of this section, is prohibited. If you do not operate the engine according to the requirements in paragraphs (d)(1) through (3) of this section, the engine will not be considered an emergency engine under this subpart and must meet all requirements for non-emergency engines.

(1) There is no time limit on the use of emergency stationary ICE in emergency situations.

(2) You may operate your emergency stationary ICE for any combination of the purposes specified in paragraphs (d)(2)(i) through (iii) of this section for a maximum of 100 hours per calendar year. Any operation for non-emergency situations as allowed by paragraph (d)(3) of this section counts as part of the 100 hours per calendar year allowed by this paragraph (d)(2).

(i) Emergency stationary ICE may be operated for maintenance checks and readiness testing, provided that the tests are recommended by federal, state or local government, the manufacturer, the vendor, the regional transmission organization or equivalent balancing authority and transmission operator, or the insurance company associated with the engine. The owner or operator may petition the Administrator for approval of additional hours to be used for maintenance checks and readiness testing, but a petition is not required if the owner or operator maintains records indicating that federal, state, or local standards require maintenance and testing of emergency ICE beyond 100 hours per calendar year.

(ii) Emergency stationary ICE may be operated for emergency demand response for periods in which the Reliability Coordinator under the North American Electric Reliability Corporation (NERC) Reliability Standard EOP-002-3, Capacity and Energy Emergencies (incorporated by reference, see §60.17), or other authorized entity as determined by the Reliability Coordinator, has declared an Energy Emergency Alert Level 2 as defined in the NERC Reliability Standard EOP-002-3.

(iii) Emergency stationary ICE may be operated for periods where there is a deviation of voltage or frequency of 5 percent or greater below standard voltage or frequency.

(3) Emergency stationary ICE may be operated for up to 50 hours per calendar year in non-emergency situations. The 50 hours of operation in non-emergency situations are counted as part of the 100 hours per calendar year for maintenance and testing and emergency demand response provided in paragraph (d)(2) of this section. Except as provided in paragraph (d)(3)(i) of this section, the 50 hours per year for non-emergency situations cannot be used for peak shaving or non-emergency demand response, or to generate income for a facility to an electric grid or otherwise supply power as part of a financial arrangement with another entity.

(i) The 50 hours per year for non-emergency situations can be used to supply power as part of a financial arrangement with another entity if all of the following conditions are met:

(A) The engine is dispatched by the local balancing authority or local transmission and distribution system operator;

(B) The dispatch is intended to mitigate local transmission and/or distribution limitations so as to avert potential voltage collapse or line overloads that could lead to the interruption of power supply in a local area or region.

(C) The dispatch follows reliability, emergency operation or similar protocols that follow specific NERC, regional, state, public utility commission or local standards or guidelines.

(D) The power is provided only to the facility itself or to support the local transmission and distribution system.

(E) The owner or operator identifies and records the entity that dispatches the engine and the specific NERC, regional, state, public utility commission or local standards or guidelines that are being followed for dispatching the engine. The local balancing authority or local transmission and distribution system operator may keep these records on behalf of the engine owner or operator.

(ii) [Reserved]

(e) Owners and operators of stationary SI natural gas fired engines may operate their engines using propane for a maximum of 100 hours per year as an alternative fuel solely during emergency operations, but must keep records of such use. If propane is used for more than 100 hours per year in an engine that is not certified to the emission standards when using propane, the owners and operators are required to conduct a performance test to demonstrate compliance with the emission standards of §60.4233.

(f) If you are an owner or operator of a stationary SI internal combustion engine that is less than or equal to 500 HP and you purchase a non-certified engine or you do not operate and maintain your certified stationary SI internal combustion engine and control device according to the manufacturer's written emission-related instructions, you are required to perform initial performance testing as indicated in this section, but you are not required to conduct subsequent performance testing unless the stationary engine is rebuilt or undergoes major repair or maintenance. A rebuilt stationary SI ICE means an engine that has been rebuilt as that term is defined in 40 CFR 94.11(a).

(g) It is expected that air-to-fuel ratio controllers will be used with the operation of three-way catalysts/non-selective catalytic reduction. The AFR controller must be maintained and operated appropriately in order to ensure proper operation of the engine and control device to minimize emissions at all times.

(h) If you are an owner/operator of an stationary SI internal combustion engine with maximum engine power greater than or equal to 500 HP that is manufactured after July 1, 2007 and before July 1, 2008, and must comply with the emission standards specified in sections 60.4233(b) or (c), you must comply by one of the methods specified in paragraphs (h)(1) through (h)(4) of this section.

(1) Purchasing an engine certified according to 40 CFR part 1048. The engine must be installed and configured according to the manufacturer's specifications.

(2) Keeping records of performance test results for each pollutant for a test conducted on a similar engine. The test must have been conducted using the same methods specified in this subpart and these methods must have been followed correctly.

(3) Keeping records of engine manufacturer data indicating compliance with the standards.

(4) Keeping records of control device vendor data indicating compliance with the standards.

(i) If you are an owner or operator of a modified or reconstructed stationary SI internal combustion engine and must comply with the emission standards specified in §60.4233(f), you must demonstrate compliance according to one of the methods specified in paragraphs (i)(1) or (2) of this section.

(1) Purchasing, or otherwise owning or operating, an engine certified to the emission standards in §60.4233(f), as applicable.

(2) Conducting a performance test to demonstrate initial compliance with the emission standards according to the requirements specified in §60.4244. The test must be conducted within 60 days after the engine commences operation after the modification or reconstruction.

[73 FR 3591, Jan. 18, 2008, as amended at 76 FR 37974, June 28, 2011; 78 FR 6697, Jan. 30, 2013]

Back to Top

TESTING REQUIREMENTS FOR OWNERS AND OPERATORS

Back to Top

§60.4244 What test methods and other procedures must I use if I am an owner or operator of a stationary SI internal combustion engine?

Owners and operators of stationary SI ICE who conduct performance tests must follow the procedures in paragraphs (a) through (f) of this section.

(a) Each performance test must be conducted within 10 percent of 100 percent peak (or the highest achievable) load and according to the requirements in §60.8 and under the specific conditions that are specified by Table 2 to this subpart.

(b) You may not conduct performance tests during periods of startup, shutdown, or malfunction, as specified in §60.8(c). If your stationary SI internal combustion engine is non-operational, you do not need to startup the engine solely to conduct a performance test; however, you must conduct the performance test immediately upon startup of the engine.

(c) You must conduct three separate test runs for each performance test required in this section, as specified in §60.8(f). Each test run must be conducted within 10 percent of 100 percent peak (or the highest achievable) load and last at least 1 hour.

(d) To determine compliance with the NO_x mass per unit output emission limitation, convert the concentration of NO_x in the engine exhaust using Equation 1 of this section:

View or download PDF

Where:

ER = Emission rate of NO_x in g/HP-hr.

C_d = Measured NO_x concentration in parts per million by volume (ppmv).

1.912×10^{-3} = Conversion constant for ppm NO_x to grams per standard cubic meter at 20 degrees Celsius.

Q = Stack gas volumetric flow rate, in standard cubic meter per hour, dry basis.

T = Time of test run, in hours.

HP-hr = Brake work of the engine, horsepower-hour (HP-hr).

(e) To determine compliance with the CO mass per unit output emission limitation, convert the concentration of CO in the engine exhaust using Equation 2 of this section:

View or download PDF

Where:

ER = Emission rate of CO in g/HP-hr.

C_d = Measured CO concentration in ppmv.

1.164×10^{-3} = Conversion constant for ppm CO to grams per standard cubic meter at 20 degrees Celsius.

Q = Stack gas volumetric flow rate, in standard cubic meters per hour, dry basis.

T = Time of test run, in hours.

HP-hr = Brake work of the engine, in HP-hr.

(f) For purposes of this subpart, when calculating emissions of VOC, emissions of formaldehyde should not be included. To determine compliance with the VOC mass per unit output emission limitation, convert the concentration of VOC in the engine exhaust using Equation 3 of this section:

View or download PDF

Where:

ER = Emission rate of VOC in g/HP-hr.

C_d = VOC concentration measured as propane in ppmv.

1.833×10^{-3} = Conversion constant for ppm VOC measured as propane, to grams per standard cubic meter at 20 degrees Celsius.

Q = Stack gas volumetric flow rate, in standard cubic meters per hour, dry basis.

T = Time of test run, in hours.

HP-hr = Brake work of the engine, in HP-hr.

(g) If the owner/operator chooses to measure VOC emissions using either Method 18 of 40 CFR part 60, appendix A, or Method 320 of 40 CFR part 63, appendix A, then it has the option of correcting the measured VOC emissions to account for the potential differences in measured values between these methods and Method 25A. The results from Method 18 and Method 320 can be corrected for response factor differences using Equations 4 and 5 of this section. The corrected VOC concentration can then be placed on a propane basis using Equation 6 of this section.

View or download PDF

Where:

RF_i = Response factor of compound i when measured with EPA Method 25A.

C_{Mi} = Measured concentration of compound i in ppmv as carbon.

C_{Ai} = True concentration of compound i in ppmv as carbon.

View or download PDF

Where:

C_{icorr} = Concentration of compound i corrected to the value that would have been measured by EPA Method 25A, ppmv as carbon.

C_{imeas} = Concentration of compound i measured by EPA Method 320, ppmv as carbon.

$$C_{Eq} = 0.6098 \times C_{icorr} \quad \text{(Eq. 6)}$$

View or download PDF

Where:

C_{Peq} = Concentration of compound i in mg of propane equivalent per DSCM.

Back to Top

NOTIFICATION, REPORTS, AND RECORDS FOR OWNERS AND OPERATORS

Back to Top

§60.4245 What are my notification, reporting, and recordkeeping requirements if I am an owner or operator of a stationary SI internal combustion engine?

Owners or operators of stationary SI ICE must meet the following notification, reporting and recordkeeping requirements.

(a) Owners and operators of all stationary SI ICE must keep records of the information in paragraphs (a)(1) through (4) of this section.

(1) All notifications submitted to comply with this subpart and all documentation supporting any notification.

(2) Maintenance conducted on the engine.

(3) If the stationary SI internal combustion engine is a certified engine, documentation from the manufacturer that the engine is certified to meet the emission standards and information as required in 40 CFR parts 90, 1048, 1054, and 1060, as applicable.

(4) If the stationary SI internal combustion engine is not a certified engine or is a certified engine operating in a non-certified manner and subject to §60.4243(a)(2), documentation that the engine meets the emission standards.

(b) For all stationary SI emergency ICE greater than or equal to 500 HP manufactured on or after July 1, 2010, that do not meet the standards applicable to non-emergency engines, the owner or operator of must keep records of the hours of operation of the engine that is recorded through the non-resettable hour meter. For all stationary SI emergency ICE greater than or equal to 130 HP and less than 500 HP manufactured on or after July 1, 2011 that do not meet the standards applicable to non-emergency engines, the owner or operator of must keep records of the hours of operation of the engine that is recorded through the non-resettable hour meter. For all stationary SI emergency ICE greater than 25 HP and less than 130 HP manufactured on or after July 1, 2008, that do not meet the standards applicable to non-emergency engines, the owner or operator of must keep records of the hours of operation of the engine that is recorded through the non-resettable hour meter. The owner or operator must document how many hours are spent for emergency operation, including what classified the operation as emergency and how many hours are spent for non-emergency operation.

(c) Owners and operators of stationary SI ICE greater than or equal to 500 HP that have not been certified by an engine manufacturer to meet the emission standards in §60.4231 must submit

an initial notification as required in §60.7(a)(1). The notification must include the information in paragraphs (c)(1) through (5) of this section.

(1) Name and address of the owner or operator;

(2) The address of the affected source;

(3) Engine information including make, model, engine family, serial number, model year, maximum engine power, and engine displacement;

(4) Emission control equipment; and

(5) Fuel used.

(d) Owners and operators of stationary SI ICE that are subject to performance testing must submit a copy of each performance test as conducted in §60.4244 within 60 days after the test has been completed. Performance test reports using EPA Method 18, EPA Method 320, or ASTM D6348-03 (incorporated by reference—see 40 CFR 60.17) to measure VOC require reporting of all QA/QC data. For Method 18, report results from sections 8.4 and 11.1.1.4; for Method 320, report results from sections 8.6.2, 9.0, and 13.0; and for ASTM D6348-03 report results of all QA/QC procedures in Annexes 1-7.

(e) If you own or operate an emergency stationary SI ICE with a maximum engine power more than 100 HP that operates or is contractually obligated to be available for more than 15 hours per calendar year for the purposes specified in §60.4243(d)(2)(ii) and (iii) or that operates for the purposes specified in §60.4243(d)(3)(i), you must submit an annual report according to the requirements in paragraphs (e)(1) through (3) of this section.

(1) The report must contain the following information:

(i) Company name and address where the engine is located.

(ii) Date of the report and beginning and ending dates of the reporting period.

(iii) Engine site rating and model year.

(iv) Latitude and longitude of the engine in decimal degrees reported to the fifth decimal place.

(v) Hours operated for the purposes specified in §60.4243(d)(2)(ii) and (iii), including the date, start time, and end time for engine operation for the purposes specified in §60.4243(d)(2)(ii) and (iii).

(vi) Number of hours the engine is contractually obligated to be available for the purposes specified in §60.4243(d)(2)(ii) and (iii).

(vii) Hours spent for operation for the purposes specified in §60.4243(d)(3)(i), including the date, start time, and end time for engine operation for the purposes specified in §60.4243(d)(3)(i). The

report must also identify the entity that dispatched the engine and the situation that necessitated the dispatch of the engine.

(2) The first annual report must cover the calendar year 2015 and must be submitted no later than March 31, 2016. Subsequent annual reports for each calendar year must be submitted no later than March 31 of the following calendar year.

(3) The annual report must be submitted electronically using the subpart specific reporting form in the Compliance and Emissions Data Reporting Interface (CEDRI) that is accessed through EPA's Central Data Exchange (CDX) (*www.epa.gov/cdx*). However, if the reporting form specific to this subpart is not available in CEDRI at the time that the report is due, the written report must be submitted to the Administrator at the appropriate address listed in §60.4.

[73 FR 3591, Jan. 18, 2008, as amended at 73 FR 59177, Oct. 8, 2008; 78 FR 6697, Jan. 30, 2013; 81 FR 59809, Aug. 30, 2016]

Back to Top

General Provisions

Back to Top

§60.4246 What parts of the General Provisions apply to me?

Table 3 to this subpart shows which parts of the General Provisions in §§60.1 through 60.19 apply to you.

Back to Top

Mobile Source Provisions

Back to Top

§60.4247 What parts of the mobile source provisions apply to me if I am a manufacturer of stationary SI internal combustion engines or a manufacturer of equipment containing such engines?

(a) Manufacturers certifying to emission standards in 40 CFR part 90, including manufacturers certifying emergency engines below 130 HP, must meet the provisions of 40 CFR part 90. Manufacturers certifying to emission standards in 40 CFR part 1054 must meet the provisions of 40 CFR part 1054. Manufacturers of equipment containing stationary SI internal combustion engines meeting the provisions of 40 CFR part 1054 must meet the provisions of 40 CFR part 1060 to the extent they apply to equipment manufacturers.

(b) Manufacturers required to certify to emission standards in 40 CFR part 1048 must meet the provisions of 40 CFR part 1048. Manufacturers certifying to emission standards in 40 CFR part 1048

pursuant to the voluntary certification program must meet the requirements in Table 4 to this subpart as well as the standards in 40 CFR 1048.101.

(c) For manufacturers of stationary SI internal combustion engines participating in the voluntary certification program and certifying engines to Table 1 to this subpart, Table 4 to this subpart shows which parts of the mobile source provisions in 40 CFR parts 1048, 1065, and 1068 apply to you. Compliance with the deterioration factor provisions under 40 CFR 1048.205(n) and 1048.240 will be required for engines built new on and after January 1, 2010. Prior to January 1, 2010, manufacturers of stationary internal combustion engines participating in the voluntary certification program have the option to develop their own deterioration factors based on an engineering analysis.

[73 FR 3591, Jan. 18, 2008, as amended at 73 FR 59177, Oct. 8, 2008]

Back to Top

DEFINITIONS

Back to Top

§60.4248 What definitions apply to this subpart?

As used in this subpart, all terms not defined herein shall have the meaning given them in the CAA and in subpart A of this part.

Certified emissions life means the period during which the engine is designed to properly function in terms of reliability and fuel consumption, without being remanufactured, specified as a number of hours of operation or calendar years, whichever comes first. The values for certified emissions life for stationary SI ICE with a maximum engine power less than or equal to 19 KW (25 HP) are given in 40 CFR 90.105, 40 CFR 1054.107, and 40 CFR 1060.101, as appropriate. The values for certified emissions life for stationary SI ICE with a maximum engine power greater than 19 KW (25 HP) certified to 40 CFR part 1048 are given in 40 CFR 1048.101(g). The certified emissions life for stationary SI ICE with a maximum engine power greater than 75 KW (100 HP) certified under the voluntary manufacturer certification program of this subpart is 5,000 hours or 7 years, whichever comes first. You may request in your application for certification that we approve a shorter certified emissions life for an engine family. We may approve a shorter certified emissions life, in hours of engine operation but not in years, if we determine that these engines will rarely operate longer than the shorter certified emissions life. If engines identical to those in the engine family have already been produced and are in use, your demonstration must include documentation from such in-use engines. In other cases, your demonstration must include an engineering analysis of information equivalent to such in-use data, such as data from research engines or similar engine models that are already in production. Your demonstration must also include any overhaul interval that you recommend, any mechanical warranty that you offer for the engine or its components, and any relevant customer design specifications. Your demonstration may include any other relevant information. The certified emissions life value may not be shorter than any of the following:

(i) 1,000 hours of operation.

(ii) Your recommended overhaul interval.

(iii) Your mechanical warranty for the engine.

Certified stationary internal combustion engine means an engine that belongs to an engine family that has a certificate of conformity that complies with the emission standards and requirements in this part, or of 40 CFR part 90, 40 CFR part 1048, or 40 CFR part 1054, as appropriate.

Combustion turbine means all equipment, including but not limited to the turbine, the fuel, air, lubrication and exhaust gas systems, control systems (except emissions control equipment), and any ancillary components and sub-components comprising any simple cycle combustion turbine, any regenerative/recuperative cycle combustion turbine, the combustion turbine portion of any cogeneration cycle combustion system, or the combustion turbine portion of any combined cycle steam/electric generating system.

Compression ignition means relating to a type of stationary internal combustion engine that is not a spark ignition engine.

Date of manufacture means one of the following things:

(1) For freshly manufactured engines and modified engines, date of manufacture means the date the engine is originally produced.

(2) For reconstructed engines, date of manufacture means the date the engine was originally produced, except as specified in paragraph (3) of this definition.

(3) Reconstructed engines are assigned a new date of manufacture if the fixed capital cost of the new and refurbished components exceeds 75 percent of the fixed capital cost of a comparable entirely new facility. An engine that is produced from a previously used engine block does not retain the date of manufacture of the engine in which the engine block was previously used if the engine is produced using all new components except for the engine block. In these cases, the date of manufacture is the date of reconstruction or the date the new engine is produced.

Diesel fuel means any liquid obtained from the distillation of petroleum with a boiling point of approximately 150 to 360 degrees Celsius. One commonly used form is number 2 distillate oil.

Digester gas means any gaseous by-product of wastewater treatment typically formed through the anaerobic decomposition of organic waste materials and composed principally of methane and carbon dioxide (CO_2).

Emergency stationary internal combustion engine means any stationary reciprocating internal combustion engine that meets all of the criteria in paragraphs (1) through (3) of this definition. All emergency stationary ICE must comply with the requirements specified in §60.4243(d) in order to be considered emergency stationary ICE. If the engine does not comply with the requirements specified in §60.4243(d), then it is not considered to be an emergency stationary ICE under this subpart.

(1) The stationary ICE is operated to provide electrical power or mechanical work during an emergency situation. Examples include stationary ICE used to produce power for critical networks or equipment (including power supplied to portions of a facility) when electric power from the local utility (or the normal power source, if the facility runs on its own power production) is interrupted, or stationary ICE used to pump water in the case of fire or flood, etc.

(2) The stationary ICE is operated under limited circumstances for situations not included in paragraph (1) of this definition, as specified in §60.4243(d).

(3) The stationary ICE operates as part of a financial arrangement with another entity in situations not included in paragraph (1) of this definition only as allowed in §60.4243(d)(2)(ii) or (iii) and §60.4243(d)(3)(i).

Engine manufacturer means the manufacturer of the engine. See the definition of "manufacturer" in this section.

Four-stroke engine means any type of engine which completes the power cycle in two crankshaft revolutions, with intake and compression strokes in the first revolution and power and exhaust strokes in the second revolution.

Freshly manufactured engine means an engine that has not been placed into service. An engine becomes freshly manufactured when it is originally produced.

Gasoline means any fuel sold in any State for use in motor vehicles and motor vehicle engines, or nonroad or stationary engines, and commonly or commercially known or sold as gasoline.

Installed means the engine is placed and secured at the location where it is intended to be operated.

Landfill gas means a gaseous by-product of the land application of municipal refuse typically formed through the anaerobic decomposition of waste materials and composed principally of methane and CO_2.

Lean burn engine means any two-stroke or four-stroke spark ignited engine that does not meet the definition of a rich burn engine.

Liquefied petroleum gas means any liquefied hydrocarbon gas obtained as a by-product in petroleum refining or natural gas production.

Manufacturer has the meaning given in section 216(1) of the Clean Air Act. In general, this term includes any person who manufactures a stationary engine for sale in the United States or otherwise introduces a new stationary engine into commerce in the United States. This includes importers who import stationary engines for resale.

Maximum engine power means maximum engine power as defined in 40 CFR 1048.801.

Model year means the calendar year in which an engine is manufactured (see "date of manufacture"), except as follows:

(1) Model year means the annual new model production period of the engine manufacturer in which an engine is manufactured (see "date of manufacture"), if the annual new model production period is different than the calendar year and includes January 1 of the calendar year for which the model year is named. It may not begin before January 2 of the previous calendar year and it must end by December 31 of the named calendar year.

(2) For an engine that is converted to a stationary engine after being placed into service as a nonroad or other non-stationary engine, model year means the calendar year or new model production period in which the engine was manufactured (see "date of manufacture").

Natural gas means a naturally occurring mixture of hydrocarbon and non-hydrocarbon gases found in geologic formations beneath the Earth's surface, of which the principal constituent is methane. Natural gas may be field or pipeline quality.

Other internal combustion engine means any internal combustion engine, except combustion turbines, which is not a reciprocating internal combustion engine or rotary internal combustion engine.

Pipeline-quality natural gas means a naturally occurring fluid mixture of hydrocarbons (e.g., methane, ethane, or propane) produced in geological formations beneath the Earth's surface that maintains a gaseous state at standard atmospheric temperature and pressure under ordinary conditions, and which is provided by a supplier through a pipeline. Pipeline-quality natural gas must either be composed of at least 70 percent methane by volume or have a gross calorific value between 950 and 1,100 British thermal units per standard cubic foot.

Rich burn engine means any four-stroke spark ignited engine where the manufacturer's recommended operating air/fuel ratio divided by the stoichiometric air/fuel ratio at full load conditions is less than or equal to 1.1. Engines originally manufactured as rich burn engines, but modified prior to June 12, 2006, with passive emission control technology for NO_x (such as pre-combustion chambers) will be considered lean burn engines. Also, existing engines where there are no manufacturer's recommendations regarding air/fuel ratio will be considered a rich burn engine if the excess oxygen content of the exhaust at full load conditions is less than or equal to 2 percent.

Rotary internal combustion engine means any internal combustion engine which uses rotary motion to convert heat energy into mechanical work.

Spark ignition means relating to either: a gasoline-fueled engine; or any other type of engine with a spark plug (or other sparking device) and with operating characteristics significantly similar to the theoretical Otto combustion cycle. Spark ignition engines usually use a throttle to regulate intake air flow to control power during normal operation. Dual-fuel engines in which a liquid fuel (typically diesel fuel) is used for compression ignition and gaseous fuel (typically natural gas) is used as the primary fuel at an annual average ratio of less than 2 parts diesel fuel to 100 parts total fuel on an energy equivalent basis are spark ignition engines.

Stationary internal combustion engine means any internal combustion engine, except combustion turbines, that converts heat energy into mechanical work and is not mobile. Stationary ICE differ from mobile ICE in that a stationary internal combustion engine is not a nonroad engine as defined at 40 CFR 1068.30 (excluding paragraph (2)(ii) of that definition), and is not used to propel a motor vehicle, aircraft, or a vehicle used solely for competition. Stationary ICE include reciprocating ICE, rotary ICE, and other ICE, except combustion turbines.

Stationary internal combustion engine test cell/stand means an engine test cell/stand, as defined in 40 CFR part 63, subpart PPPPP, that tests stationary ICE.

Stoichiometric means the theoretical air-to-fuel ratio required for complete combustion.

Subpart means 40 CFR part 60, subpart JJJJ.

Two-stroke engine means a type of engine which completes the power cycle in single crankshaft revolution by combining the intake and compression operations into one stroke and the power and exhaust operations into a second stroke. This system requires auxiliary scavenging and inherently runs lean of stoichiometric.

Volatile organic compounds means volatile organic compounds as defined in 40 CFR 51.100(s).

Voluntary certification program means an optional engine certification program that manufacturers of stationary SI internal combustion engines with a maximum engine power greater than 19 KW (25 HP) that do not use gasoline and are not rich burn engines that use LPG can choose to participate in to certify their engines to the emission standards in §60.4231(d) or (e), as applicable.

[73 FR 3591, Jan. 18, 2008, as amended at 73 FR 59177, Oct. 8, 2008; 76 FR 37974, June 28, 2011; 78 FR 6698, Jan. 30, 2013]

Table 1 to Subpart JJJJ of Part 60—NO_x, CO, and VOC Emission Standards for Stationary Non-Emergency SI Engines ≥100 HP (Except Gasoline and Rich Burn LPG), Stationary SI Landfill/Digester Gas Engines, and Stationary Emergency Engines >25 HP

Engine type and fuel	Maximum engine power	Manufacture date	Emission standards[a]					
			g/HP-hr			ppmvd at 15% O_2		
			NO_x	CO	VOC[d]	NO_x	CO	VOC[d]
Non-Emergency SI Natural Gas[b] and Non-Emergency SI Lean Burn LPG[b]	100≤HP<500	7/1/2008	2.0	4.0	1.0	160	540	86
		1/1/2011	1.0	2.0	0.7	82	270	60

Non-Emergency SI Lean Burn Natural Gas and LPG	500≤HP<1,350	1/1/2008	2.0	4.0	1.0	160	540	86
		7/1/2010	1.0	2.0	0.7	82	270	60
Non-Emergency SI Natural Gas [BP1]and Non-Emergency SI Lean Burn LPG (except lean burn 500≤HP<1,350)	HP≥500	7/1/2007	2.0	4.0	1.0	160	540	86
	HP≥500	7/1/2010	1.0	2.0	0.7	82	270	60
Landfill/Digester Gas (except lean burn 500≤HP<1,350)	HP<500	7/1/2008	3.0	5.0	1.0	220	610	80
		1/1/2011	2.0	5.0	1.0	150	610	80
	HP≥500	7/1/2007	3.0	5.0	1.0	220	610	80
		7/1/2010	2.0	5.0	1.0	150	610	80
Landfill/Digester Gas Lean Burn	500≤HP<1,350	1/1/2008	3.0	5.0	1.0	220	610	80
		7/1/2010	2.0	5.0	1.0	150	610	80
Emergency	25<HP<130	1/1/2009	[c]10	387	N/A	N/A	N/A	N/A
	HP≥130		2.0	4.0	1.0	160	540	86

[a]Owners and operators of stationary non-certified SI engines may choose to comply with the emission standards in units of either g/HP-hr or ppmvd at 15 percent O_2.

[b]Owners and operators of new or reconstructed non-emergency lean burn SI stationary engines with a site rating of greater than or equal to 250 brake HP located at a major source that are meeting the requirements of 40 CFR part 63, subpart ZZZZ, Table 2a do not have to comply with the CO emission standards of Table 1 of this subpart.

[c]The emission standards applicable to emergency engines between 25 HP and 130 HP are in terms of NO_x + HC.

[d]For purposes of this subpart, when calculating emissions of volatile organic compounds, emissions of formaldehyde should not be included.

[76 FR 37975, June 28, 2011]

Table 2 to Subpart JJJJ of Part 60—Requirements for Performance Tests

As stated in §60.4244, you must comply with the following requirements for performance tests within 10 percent of 100 percent peak (or the highest achievable) load].

For each	Complying with the requirement to	You must	Using	According to the following requirements
1. Stationary SI internal combustion engine demonstrating compliance according to §60.4244	a. Limit the concentration of NO_x in the stationary SI internal combustion engine exhaust	i. Select the sampling port location and the number/location of traverse points at the exhaust of the stationary internal combustion engine;	(1) Method 1 or 1A of 40 CFR part 60, appendix A-1, if measuring flow rate	(a) Alternatively, for NO_x, O_2, and moisture measurement, ducts ≤6 inches in diameter may be sampled at a single point located at the duct centroid and ducts >6 and ≤12 inches in diameter may be sampled at 3 traverse points located at 16.7, 50.0, and 83.3% of the measurement line (`3-point long line'). If the duct is >12 inches in diameter *and* the sampling port location meets the two and half-diameter criterion of Section 11.1.1 of Method 1 of 40 CFR part 60, Appendix A, the duct may be sampled at `3-point long line'; otherwise, conduct the stratification testing and select sampling points according to Section 8.1.2 of Method 7E of 40 CFR part 60, Appendix A.
		ii. Determine the O_2 concentration of the stationary internal combustion engine exhaust at the sampling port location;	(2) Method 3, 3A, or 3B[b] of 40 CFR part 60, appendix A-2 or ASTM Method D6522-00 (Reapproved 2005)[ad]	(b) Measurements to determine O_2 concentration must be made at the same time as the measurements for NO_x concentration.

		iii. If necessary, determine the exhaust flowrate of the stationary internal combustion engine exhaust;	(3) Method 2 or 2C of 40 CFR part 60, appendix A-1 or Method 19 of 40 CFR part 60, appendix A-7	(c) Measurements to determine the exhaust flowrate must be made (1) at the same time as the measurement for NO_x concentration or, alternatively (2) according to the option in Section 11.1.2 of Method 1A of 40 CFR part 60, Appendix A-1, if applicable.
		iv. If necessary, measure moisture content of the stationary internal combustion engine exhaust at the sampling port location; and	(4) Method 4 of 40 CFR part 60, appendix A-3, Method 320 of 40 CFR part 63, appendix A,[e] or ASTM Method D6348-03[de]	(d) Measurements to determine moisture must be made at the same time as the measurement for NO_x concentration.
		v. Measure NO_x at the exhaust of the stationary internal combustion engine; if using a control device, the sampling site must be located at the outlet of the control device	(5) Method 7E of 40 CFR part 60, appendix A-4, ASTM Method D6522-00 (Reapproved 2005),[ad] Method 320 of 40 CFR part 63, appendix A,[e] or ASTM Method D6348-03[de]	(e) Results of this test consist of the average of the three 1-hour or longer runs.
	b. Limit the concentration of CO in the stationary SI internal combustion engine exhaust	i. Select the sampling port location and the number/location of traverse points at the exhaust of the stationary internal combustion engine;	(1) Method 1 or 1A of 40 CFR part 60, appendix A-1, if measuring flow rate	(a) Alternatively, for CO, O_2, and moisture measurement, ducts ≤6 inches in diameter may be sampled at a single point located at the duct centroid and ducts >6 and ≤12 inches in diameter may be sampled at 3 traverse points located at 16.7, 50.0, and 83.3% of the measurement line (`3-

				point long line'). If the duct is >12 inches in diameter *and* the sampling port location meets the two and half-diameter criterion of Section 11.1.1 of Method 1 of 40 CFR part 60, Appendix A, the duct may be sampled at `3-point long line'; otherwise, conduct the stratification testing and select sampling points according to Section 8.1.2 of Method 7E of 40 CFR part 60, Appendix A.
		ii. Determine the O_2 concentration of the stationary internal combustion engine exhaust at the sampling port location;	(2) Method 3, 3A, or 3B[b] of 40 CFR part 60, appendix A-2 or ASTM Method D6522-00 (Reapproved 2005)[ad]	(b) Measurements to determine O_2 concentration must be made at the same time as the measurements for CO concentration.
		iii. If necessary, determine the exhaust flowrate of the stationary internal combustion engine exhaust;	(3) Method 2 or 2C of 40 CFR 60, appendix A-1 or Method 19 of 40 CFR part 60, appendix A-7	(c) Measurements to determine the exhaust flowrate must be made (1) at the same time as the measurement for CO concentration or, alternatively (2) according to the option in Section 11.1.2 of Method 1A of 40 CFR part 60, Appendix A-1, if applicable.
		iv. If necessary, measure moisture content of the stationary internal combustion engine exhaust at the	(4) Method 4 of 40 CFR part 60, appendix A-3, Method 320 of 40 CFR part 63, appendix A,[e] or	(d) Measurements to determine moisture must be made at the same time as the measurement for CO concentration.

		sampling port location; and	ASTM Method D6348-03[de]	
		v. Measure CO at the exhaust of the stationary internal combustion engine; if using a control device, the sampling site must be located at the outlet of the control device	(5) Method 10 of 40 CFR part 60, appendix A4, ASTM Method D6522-00 (Reapproved 2005),[ade] Method 320 of 40 CFR part 63, appendix A,[e] or ASTM Method D6348-03[de]	(e) Results of this test consist of the average of the three 1-hour or longer runs.
	c. Limit the concentration of VOC in the stationary SI internal combustion engine exhaust	i. Select the sampling port location and the number/location of traverse points at the exhaust of the stationary internal combustion engine;	(1) Method 1 or 1A of 40 CFR part 60, appendix A-1, if measuring flow rate	(a) Alternatively, for VOC, O_2, and moisture measurement, ducts ≤6 inches in diameter may be sampled at a single point located at the duct centroid and ducts >6 and ≤12 inches in diameter may be sampled at 3 traverse points located at 16.7, 50.0, and 83.3% of the measurement line (`3-point long line'). If the duct is >12 inches in diameter *and* the sampling port location meets the two and half-diameter criterion of Section 11.1.1 of Method 1 of 40 CFR part 60, Appendix A, the duct may be sampled at `3-point long line'; otherwise, conduct the stratification testing and select sampling points according to Section 8.1.2 of Method 7E of 40 CFR part 60, Appendix A.

		ii. Determine the O_2 concentration of the stationary internal combustion engine exhaust at the sampling port location;	(2) Method 3, 3A, or 3B[b] of 40 CFR part 60, appendix A-2 or ASTM Method D6522-00 (Reapproved 2005)[ad]	(b) Measurements to determine O_2 concentration must be made at the same time as the measurements for VOC concentration.
		iii. If necessary, determine the exhaust flowrate of the stationary internal combustion engine exhaust;	(3) Method 2 or 2C of 40 CFR 60, appendix A-1 or Method 19 of 40 CFR part 60, appendix A-7	(c) Measurements to determine the exhaust flowrate must be made (1) at the same time as the measurement for VOC concentration or, alternatively (2) according to the option in Section 11.1.2 of Method 1A of 40 CFR part 60, Appendix A-1, if applicable.
		iv. If necessary, measure moisture content of the stationary internal combustion engine exhaust at the sampling port location; and	(4) Method 4 of 40 CFR part 60, appendix A-3, Method 320 of 40 CFR part 63, appendix A,[e] or ASTM Method D6348-03[dc]	(d) Measurements to determine moisture must be made at the same time as the measurement for VOC concentration.
		v. Measure VOC at the exhaust of the stationary internal combustion engine; if using a control device, the sampling site must be located at the outlet of the control device	(5) Methods 25A and 18 of 40 CFR part 60, appendices A-6 and A-7, Method 25A with the use of a hydrocarbon cutter as described in 40 CFR 1065.265, Method 18 of 40 CFR part 60, appendix A-6,[ce] Method 320 of 40 CFR part 63, appendix A,[e] or	(e) Results of this test consist of the average of the three 1-hour or longer runs.

			ASTM Method D6348-03[de]	

[a]Also, you may petition the Administrator for approval to use alternative methods for portable analyzer.

[b]You may use ASME PTC 19.10-1981, Flue and Exhaust Gas Analyses, for measuring the O_2 content of the exhaust gas as an alternative to EPA Method 3B. AMSE PTC 19.10-1981 incorporated by reference, see 40 CFR 60.17

[c]You may use EPA Method 18 of 40 CFR part 60, appendix A-6, provided that you conduct an adequate pre-survey test prior to the emissions test, such as the one described in OTM 11 on EPA's website (*http://www.epa.gov/ttn/emc/prelim/otm11.pdf*).

[d]Incorporated by reference; see 40 CFR 60.17.

[e]You must meet the requirements in §60.4245(d).

Table 3 to Subpart JJJJ of Part 60—Applicability of General Provisions to Subpart JJJJ

[As stated in §60.4246, you must comply with the following applicable General Provisions]

General provisions citation	Subject of citation	Applies to subpart	Explanation
§60.1	General applicability of the General Provisions	Yes	
§60.2	Definitions	Yes	Additional terms defined in §60.4248.
§60.3	Units and abbreviations	Yes	
§60.4	Address	Yes	
§60.5	Determination of construction or modification	Yes	
§60.6	Review of plans	Yes	
§60.7	Notification and Recordkeeping	Yes	Except that §60.7 only applies as specified in §60.4245.

§60.8	Performance tests	Yes	Except that §60.8 only applies to owners and operators who are subject to performance testing in subpart JJJJ.
§60.9	Availability of information	Yes	
§60.10	State Authority	Yes	
§60.11	Compliance with standards and maintenance requirements	Yes	Requirements are specified in subpart JJJJ.
§60.12	Circumvention	Yes	
§60.13	Monitoring requirements	No	
§60.14	Modification	Yes	
§60.15	Reconstruction	Yes	
§60.16	Priority list	Yes	
§60.17	Incorporations by reference	Yes	
§60.18	General control device requirements	No	
§60.19	General notification and reporting requirements	Yes

Table 4 to Subpart JJJJ of Part 60—Applicability of Mobile Source Provisions for Manufacturers Participating in the Voluntary Certification Program and Certifying Stationary SI ICE to Emission Standards in Table 1 of Subpart JJJJ

[As stated in §60.4247, you must comply with the following applicable mobile source provisions if you are a manufacturer participating in the voluntary certification program and certifying stationary SI ICE to emission standards in Table 1 of subpart JJJJ]

Mobile source provisions citation	Subject of citation	Applies to subpart	Explanation
1048 subpart A	Overview and Applicability	Yes	
1048 subpart B	Emission Standards and Related Requirements	Yes	Except for the specific sections below.
1048.101	Exhaust Emission Standards	No	

1048.105	Evaporative Emission Standards	No	
1048.110	Diagnosing Malfunctions	No	
1048.140	Certifying Blue Sky Series Engines	No	
1048.145	Interim Provisions	No	
1048 subpart C	Certifying Engine Families	Yes	Except for the specific sections below.
1048.205(b)	AECD reporting	Yes	
1048.205(c)	OBD Requirements	No	
1048.205(n)	Deterioration Factors	Yes	Except as indicated in 60.4247(c).
1048.205(p)(1)	Deterioration Factor Discussion	Yes	
1048.205(p)(2)	Liquid Fuels as they require	No	
1048.240(b)(c)(d)	Deterioration Factors	Yes	
1048 subpart D	Testing Production-Line Engines	Yes	
1048 subpart E	Testing In-Use Engines	No	
1048 subpart F	Test Procedures	Yes	
1065.5(a)(4)	Raw sampling (refers reader back to the specific emissions regulation for guidance)	Yes	
1048 subpart G	Compliance Provisions	Yes	
1048 subpart H	Reserved		
1048 subpart I	Definitions and Other Reference Information	Yes	
1048 appendix I and II	Yes		
1065 (all subparts)	Engine Testing Procedures	Yes	Except for the specific section below.
1065.715	Test Fuel Specifications for Natural Gas	No	
1068 (all subparts)	General Compliance Provisions for Nonroad Programs	Yes	Except for the specific sections below.

1068.245	Hardship Provisions for Unusual Circumstances	No	
1068.250	Hardship Provisions for Small-Volume Manufacturers	No	
1068.255	Hardship Provisions for Equipment Manufacturers and Secondary Engine Manufacturers	No

A/F	Air-to-Fuel
AVO	Auditory, Visual, and Olfactory Inspections
BAT	Best Available Technology
bhp	Brake Horsepower
BMP	Best Management Practices
BTEX	Benzene, Toluene, Ethylbenzene, and Xylene
CFR	Code of Federal Regulations
CO	Carbon Monoxide
CO_2	Carbon Dioxide
CPI	Consumer Price Index
DEA	Diethanolamine
DEP	Pennsylvania Department of Environmental Protection
EGR	Exhaust Gas Recirculation
EPA	U.S. Environmental Protection Agency
g/bhp-h	Grams per Brake Horsepower-Hour
GHG	Greenhouse Gas(es)
GP	General Plan Approval/General Operating Permit
GP-5	General Plan Approval/General Operating Permit for Natural Gas Compression Stations, Processing Plants, and Transmission Stations
GP-5A	General Plan Approval/General Operating Permit for Unconventional Natural Gas Well Site Operations and Remote Pigging Stations
H_2O	Water
H_2S	Hydrogen Sulfide
HAP	Hazardous Air Pollutant
HCHO	Formaldehyde
GPU	Gas Production Unit
MEA	Monoethanolamine
Mcf	Thousand Cubic Feet
MMBtu	Million British Thermal Units
MMBtu/h	Million British Thermal Units per Hour
N_2	Molecular Nitrogen
NAAQS	National Ambient Air Quality Standard
NESHAP	National Emission Standards for Hazardous Air Pollutants
NGL	Natural Gas Liquid
NGStar	The Natural Gas Star Program
NMNEHC	Non-Methane, Non-Ethane Hydrocarbon
NO	Nitrogen Oxide
NO_2	Nitrogen Dioxide
NO_X	Oxides of Nitrogen
NSCR	Non-Selective Catalytic Reduction
NSPS	New Source Performance Standard
OGI	Optical Gas Imaging Camera
PennDOT	Pennsylvania Department of Transportation
PM	Particulate Matter
$PM_{2.5}$	Particulate Matter with an Aerodynamic Diameter Less Than 2.5 Microns
PM_{10}	Particulate Matter with an Aerodynamic Diameter Less Than 10 Microns
ppmvd	Parts Per Million, Dry, by Volume

NMED Exhibit 52

ppmv	Parts Per Million by Volume
PRO	Partner Reported Opportunities
PTE	Potential to Emit
RBLC	RACT/BACT/LAER Clearinghouse
REC	Reduced Emission Completion
scf	Standard Cubic Feet
SCR	Selective Catalytic Reduction
SI-RICE	Spark Ignition Reciprocating Internal Combustion Engine
SO_2	Sulfur Dioxide
SO_X	Oxides of Sulfur
THC	Total Hydrocarbons
tpy	Tons Per Year
TSD	Technical Support Document
VOC	Volatile Organic Compound

NMED Exhibit 52

V. Executive Summary

This technical support document (TSD) was prepared by the Pennsylvania Department of Environmental Protection (Department or DEP) to include background information about the General Plan Approval and General Operating Permit for Unconventional Natural Gas Well Site Operations and Remote Pigging Stations (GP-5A) and the General Plan Approval and General Operating Permit for Natural Gas Compression Stations, Processing Plants, and Transmission Stations (GP-5) released on *June 9, 2018.* The TSD includes the rationale for the air permitting requirements for air pollution sources and the associated air pollution controls covered by the General Permits. The TSD also describes sources common to all types of facilities, sources specific to GP-5A-eligible facilities, and sources specific to GP-5-eligible facilities.

According to 25 Pa. Code § 127.1, air contamination sources must be regulated to protect the public welfare, and new sources shall control air pollutant emissions to the maximum extent consistent with Best Available Technology (BAT) as determined by the Department. The federal New Source Performance Standards (NSPS) are incorporated into the Department's regulations by reference in 25 Pa. Code § 122.3, and the federal National Emissions Standards for Hazardous Air Pollutants (NESHAP) regulations are incorporated by reference in 25 Pa. Code § 127.35. Additionally, the current requirements of the U.S. Environmental Protection Agency's (EPA) NSPS for Crude Oil and Natural Gas Facilities (40 CFR Part 60, Subparts OOOO and OOOOa) and other federal requirements are incorporated by reference into the General Permits when the conditions are no different than the conditions determined by the Department to be BAT.

VI. Introduction

GP-5A and GP-5 have been developed under the authority of Section 6.1(f) of the Pennsylvania Air Pollution Control Act (APCA, 35 P.S § 4006.1) and under section 504(d) of the Clean Air Act (CAA, 42 U.S.C. § 7661c(d)) which authorizes the establishment of a general permit program to regulate air contamination sources. *See also* 25 Pa. Code Chapter 127, Subchapter H. Additionally, section 6.6(c) of the APCA, 35 P.S. § 4006.6(c), authorizes the Department to require new sources to control air pollution through the use of BAT at the time of plan approval. *See also* 25 Pa. Code § 127.1.

The Department's regulatory General Permit program and BAT provisions were established in 1994. (24 Pa.B. 5899 (November 26, 1994)). These regulations were subsequently approved by EPA as part of Pennsylvania's State Implementation Plan (SIP) in 1996. (61 Fed. Reg. 39594 (July 30, 1996)). Currently, the Department has 18 air quality General Permits that regulate air contamination sources in several industrial categories, including small boilers, burn off ovens, storage tanks, lithographic printing, mineral processing, petroleum dry cleaning, powder metal sintering furnaces, and natural gas production.

A General Permit is a pre-approved plan approval and operating permit which applies to a specific category of sources, if the Department determines that those sources can be adequately regulated using standardized specifications and conditions. (35 P.S. § 4006.1(f)). As part of the General Permit process, the Department establishes BAT requirements for new sources. Those BAT requirements can include equipment, devices, methods, or techniques as determined by the Department, which will prevent, reduce, or control air emissions to the maximum degree possible and which are available or may be made available. (25 Pa. Code § 121.1). BAT is not a regulation but an analysis of control techniques that are determined at the time of the issuance of a plan approval. The Pennsylvania Environmental Hearing Board (EHB) has indicated that the requirement to conduct a BAT analysis for new sources extends to greenhouse gases (GHGs), including methane. (*Snyder v. DEP*, 2015 EHB 027). Moreover,

NMED Exhibit 52

the Commonwealth Court has endorsed the Department's position that the General Assembly, through the APCA, gave the agency the authority to reduce GHG emissions. (*Wolf v. Funk,* 144 A.3d 228, 250 (Pa. Cmwlth. 2016)).

On September 21, 1996, the Department published the Air Quality Permit Exemptions, which specified sources or classes of sources that were determined to be exempt from the plan approval and permitting requirements of the APCA, 35 P.S. §4001 *et seq.* and 25 Pa. Code Chapter 127, which included crude oil and natural gas wells. The Department issued GP-5 on March 10, 1997, for natural gas production facilities. This established BAT for stationary natural gas-fired spark ignition reciprocating internal combustion engines (engines) rated from 100 brake horsepower (bhp) to 1,500 bhp and for glycol dehydrators with an uncontrolled potential to emit (PTE) volatile organic compounds (VOC) in excess of 10 tons per year (tpy) at natural gas production facilities. On July 27, 2006, DEP revised the GP-5 to expand the applicability to natural gas, coal bed methane, and gob gas production or recovery facilities, including gathering stations.

EPA has developed several regulations applicable to oil and natural gas production sites, natural gas compression stations, processing plants, and transmissions stations; these are 40 CFR Part 60, Subparts KKK, JJJJ, KKKK, OOOO, and OOOOa and 40 CFR Part 60 Subparts HH, HHH, and ZZZZ. Some of these regulations require the control of methane emissions from sources at these facilities. Other pollutants that are regulated under these standards include VOC and hazardous air pollutants (HAP). The federal regulations apply to all oil and gas operations in the U.S. The Department is required to implement these federal regulations under Section 4 of the APCA, 35 P.S. §4004. In addition, these federal regulations are incorporated by reference into the *Pennsylvania Code* and, as a result, are Pennsylvania law. *See* 25 Pa. Code §§122.1, 124.1, and 127.35(b).

On February 2, 2013, the Department changed the applicability of GP-5 to natural gas compression and/or processing facilities, and established BAT requirements for engines, stationary natural gas-fired simple cycle turbines (turbines), natural gas compressors, storage vessels, glycol dehydrators, natural gas fractionation units, equipment leaks, pneumatic controllers, and sweetening units. The Air Quality Permit Exemptions were amended by the Department on August 10, 2013, to change the unconditional exemption of all crude oil and natural gas wells to the unconditional exemption of sources located at conventional well sites and a conditional exemption for sources located at unconventional natural gas well sites.

In 2009, based on a large body of scientific evidence, EPA issued an "Endangerment Finding" under the Clean Air Act (CAA) section 202(a)(1), 42 U.S.C. § 7521(a)(1), related to GHGs.[1] EPA found that six well-mixed GHGs — carbon dioxide, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride — endanger both the public health and the public welfare of current and future generations by causing or contributing to climate change.[2] New scientific assessments and observations strengthen the conclusions of this Endangerment Finding that GHGs endanger public health and the environment.[3] Methane traps 86 times more heat in the atmosphere than carbon dioxide in the short-term, increasing the consequences of climate change. Additionally, methane is often accompanied by toxic air pollutants such as benzene, formaldehyde, and ethylbenzene.

[1] ''Endangerment and Cause or Contribute Findings for Greenhouse Gases Under Section 202(a) of the Clean Air Act,'' 74 Fed. Reg. 66496 (December 15, 2009) (''Endangerment Finding'').
[2] *Id.*
[3] "Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources," 81 Fed. Reg. 35824 (June 3, 2016).

Methane is also a precursor to ground level ozone, which can cause a number of harmful effects on public health and the environment.[4] Exposure to ozone can cause respiratory system effects such as difficulty breathing and airway inflammation.[5] In addition, long-term exposure to ozone is likely to result in harmful respiratory effects, including respiratory symptoms and the development of asthma.[6]

There are also independent peer-reviewed studies which indicate that shale gas development is associated with the production of secondary pollutants such as tropospheric (ground-level) ozone, formed through the interaction of methane, VOC, and nitrogen oxides (NO_X) in the presence of sunlight.[7,8] Tropospheric ozone is a strong respiratory irritant associated with increased respiratory and cardiovascular morbidity and mortality.[9] Although toxicological data suggest that pure methane is not by itself health damaging (excluding its role as an asphyxiant and an explosive), it is a precursor to global tropospheric ozone.[10]

Based on all the information reviewed by the Department, which it adopts as its own, and incorporates by reference into this TSD, there is a strong scientific basis to show that methane meets the definition of air contaminant, air contamination, and air pollution under section 3 of the APCA. As a GHG and ozone precursor, methane is, among other things, inimical or may be inimical to the public health, safety, or welfare.

According to the U.S. Energy Information Agency (EIA), Pennsylvania was the nation's second-largest natural gas producer for the fourth consecutive year. The largest key sources of anthropogenic methane emissions in Pennsylvania include natural gas and oil systems (30.5 percent), coal mining (30.3 percent), landfills (21.1 percent), enteric fermentation from domestic livestock (9.9 percent), wastewater (3.9 percent), and manure management (2.3 percent). Of these major categories, natural gas and oil systems are the only areas that show significant growth, increasing threefold from the 1990s. The other major categories are either flat or slightly down from the 1990s. This shows that the oil and gas industry is therefore the largest category for methane emissions.

Based on information from the Department's emission inventory, there are approximately 31,224 sources at 4,960 well pad facilities and 4,285 sources at 493 compressor stations. The overall methane emissions from this source category in 2015 amounted to approximately 123,081 tons in Pennsylvania, which is an increase from 2014 levels. One peer-reviewed study indicates that new emissions data suggest that the recently instituted Pennsylvania methane emissions inventory substantially underestimates measured facility-level methane emissions by 10-40 times.[11]

Pennsylvania Governor Tom Wolf introduced a methane reduction strategy on January 19, 2016. The four-point plan included the following strategies:

NMED Exhibit 52

- To reduce leaks at new unconventional natural gas well pads, DEP will develop a new General Permit for oil and gas exploration, development, and production facilities, requiring BAT for equipment and processes, better recordkeeping, and quarterly monitoring inspections.
- To reduce leaks at new compression stations and processing facilities, DEP will revise its current General Permit, updating BAT requirements and applying more stringent leak detection and repair (LDAR) and other requirements to minimize leaks.
- To reduce leaks at existing oil and natural gas facilities, DEP will develop a regulation for existing sources for consideration by the Environmental Quality Board.
- To reduce emissions along production, gathering, transmission and distribution lines, DEP will establish best management practices (BMP), including LDAR programs.

On February 4, 2017, the Department published notice in the *Pennsylvania Bulletin* of the availability of the Proposed General Plan Approval and/or General Operating Permit No. 5A for Unconventional Natural Gas Well Site Operations or Remote Pigging Stations ("GP-5A") and Proposed Modifications to General Plan Approval and/or General Operating Permit No. 5 for Natural Gas Compressor Stations, Processing Plants and Transmission Stations ("GP-5") and proposed revisions to the Air Quality Permit Exemptions document (TGD Document No. 275-2101-003) for public review and comment. (47 Pa.B. 733). The public comment period was originally scheduled to close on March 22, 2017. However, due to increased public and legislative interest, the comment period was extended until June 5, 2017. (47 Pa.B. 1235). Then on March 31, 2018, the Department published another *Pennsylvania Bulletin* notice announcing an additional opportunity to submit comments on the draft final GPs until May 15, 2018. (48 Pa.B. 1902).

The final General Permits set forth standardized terms and conditions related to BAT, compliance certification, notification, recordkeeping, reporting, and source testing requirements. In addition, the General Permits require permittees to comply with any applicable federal NSPS. Under the final GPs, the Department determined that BAT for certain new sources is more stringent than the applicable NSPS, and, in other cases, the Department determined that BAT is the same as the applicable NSPS limit for certain new sources. A BAT standard does not replace a NSPS, but is in addition to a NSPS. The Department made its determinations based on a technical and economic feasibility analysis contained in this TSD. For instance, under GP-5, the Department made 13 separate BAT determinations for 13 separate sources, nine of which were more stringent than the applicable NSPS. Under GP-5A, the Department made 11 separate BAT determinations for 11 separate sources, of which eight were more stringent than the applicable NSPS.

The BAT emission reductions in Table 1 and Table 2 below are from sources that may be located at an unconventional well site or a mid-stream compressor station and are scientifically-based estimates. Actual emissions at an individual site depend on a case-by-case analysis that accounts for: gas production or throughput; type of equipment; management practices; and composition of the gas or liquids. Estimates of reductions are based on changes due to BAT requirements from the previous GP-5 and Exemption 38 to the final GP-5A and GP-5.

The new GP-5A is applicable to the sources located at unconventional natural gas well site operations and remote pigging stations, and the revised GP-5 is applicable to sources located at natural gas compression stations, processing plants, and transmission stations. The use of the GP-5 and GP-5A are restricted to facilities with actual emissions less than 100 tpy of criteria pollutants (NO_X, CO, SO_2, PM_{10}, and $PM_{2.5}$), less than 50 tpy of VOC, less than 10 tpy of any single HAP, and less than 25 tpy of total HAPs. For facilities located in Philadelphia, Bucks, Chester, Montgomery, or Delaware Counties, the NO_X and VOC emissions thresholds are less than 25 tpy each.

NMED Exhibit 52

While the terms and conditions of both General Permits incorporate both federal and state requirements, it is the duty of the Responsible Official to ensure that the facility is in compliance with all applicable federal, state, and local laws and regulations, including 25 Pa. Code, Subpart C, Article III. Nothing in these General Permits relieves the Responsible Official from this obligation to comply.

NMED Exhibit 52

Table 1 - Emissions Reduction Estimates for Sources at Unconventional Natural Gas Wells Sites

Source	Emissions Reduction Estimate									
	CH_4 (tpy)		VOC (tpy)		HAP (lbpy)		NO_X (tpy)		CO (tpy)	
Glycol Dehydration Units	1.04[3]	29%	No Change		No Change		NA		NA	
Lean-Burn Engines (100 hp ≤ rating ≤ 500 hp)	NA		1.93	57%	NA		No Change		6.27	65%
Lean-Burn Engines (500 hp < rating < 2,370 hp)	NA		10.28	64%	NA		11.43	50%	40.00	88%
Lean-Burn Engines (rating ≥ 2,370 hp, 0.3 g/bhp-h NO_X)	NA		10.29	64%	NA		16.01	70%	40.01	88%
Lean-Burn Engines (rating ≥ 2,370 hp, SCR)	NA		10.29	64%	NA		21.72	95%	40.01	88%
Rich-Burn Engines (100 hp ≤ rating ≤ 500 hp)	NA		2.41	71%	NA		3.62	75%	8.20	85%
Rich-Burn Engines (rating > 500 hp)	NA		2.42	71%	NA		3.87	80%	8.22	85%
Reciprocating Compressors (EPA Emission Factors)	0.04	80%	0[4]	80%	0[4]	80%	NA		NA	
Reciprocating Compressors (UT Average Emission Factors)	3.03	80%	0.16	80%	0.07	80%	NA		NA	
Storage Vessels	1.04[3]	29%	No Change		No Change		NA		NA	
Fugitive Emissions Components	6.36	20%	0.33	20%	0.15	20%	NA		NA	
Pigging Operations[1] (Monthly Frequency)	No Change[5]									
Pigging Operations[1] (Monthly Frequency – BMP reduces pressure to 125 psi)	1.57	90%	0.08	90%	0.04	90%	NA		NA	
Pigging Operations[1] (Daily Frequency	50.41	95%	2.62	95%	1.18	95%	NA		NA	
Wellbore Liquids Unloading[2] (Monthly Frequency – BMP halves volume)	27.91	50%	1.45	50%	0.65	50%	NA		NA	
Wellbore Liquids Unloading[2] (Monthly Frequency – routed to control)	53.03	95%	2.76	95%	1.24	95%	NA		NA	

[1] Pigging Operations were assumed to emit a volume of 90 ft^3 at 1,250 psi.
[2] Wellbore Liquids Unloading Operations were assumed to emit a volume of 4,500 ft^3 at 800 psi.
[3] Methane emissions reductions based on assumed 93% destruction efficiency correlated to operating temperature for 95% VOC destruction efficiency.
[4] Even though the table shows zero tons reduced, emissions are reduced by the following percentage.
[5] Pigging Operations at the assumed volume and pressure to not exceed the control threshold at the monthly frequency.

NMED Exhibit 52

Table 2 - Emissions Reduction Estimates for Sources at Natural Gas Compression Stations

Source	Emissions Reduction Estimate									
	CH_4 (tpy)		VOC (tpy)		HAP (lbpy)		NO_X (tpy)		CO (tpy)

Lean-Burn Engines (rating ≥ 2,370 hp, SCR)	NA		No Change		NA		10.29	90%	No Change	
Storage Vessels	5.48[2]	68%	0.17[3]	55%	0.07[3]	55%	NA		NA	
Tanker Truck Load-Out Operations	0.83[3]	55%	0.04[3]	55%	0.02[3]	55%	NA		NA	
Pigging Operations[1] (Monthly Frequency)	No Change[4]									
Pigging Operations[1] (Monthly Frequency – BMP reduces pressure to 125 psi)	1.57	90%	0.08	90%	0.04	90%	NA		NA	
Pigging Operations[1] (Daily Frequency	50.41	95%	2.62	95%	1.18	95%	NA		NA	
Natural Gas-Fired Combustion Units (rating ≥ 10 MMBtu/h)	NA		NA		NA		0.80	50%	5.49	57%
Turbine (5,000 hp ≤ rating <15,900 hp)	NA		4.96	44%	NA		No Change		11.81	60%
Turbine (rating ≥ 15,900 hp – 9 ppm NO_X)	NA		No Change		NA		11.40	40%	No Change	
Turbine (rating ≥ 15,900 hp – SCR)	NA		No Change		NA		25.65	90%	No Change	
Centrifugal Compressor (Wet Seal Degassing Systems)	9.52[2]	29%	No Change		No Change		NA		NA	

[1] Pigging Operations were assumed to emit a volume of 90 ft^3 at 1,250 psi.
[2] Methane emissions reductions based on assumed 93% destruction efficiency correlated to operating temperature for 95% VOC destruction efficiency.
[3] Emissions reduction primarily based on reduction in control threshold.
[4] Pigging Operations at the assumed volume and pressure to not exceed the control threshold at the monthly frequency.

NMED Exhibit 52

I. Definitions

Words and terms that are not otherwise defined in the General Permits have the meanings set forth in Section 3 of the APCA (35 P.S. § 4003) and Title 25, Article III, including 25 Pa. Code § 121.1 (relating to definitions), unless the context indicates otherwise. The meanings set forth in applicable definitions codified in the Code of Federal Regulations including 40 CFR Part 60 Subparts JJJJ, KKKK, OOOO, and OOOOa or 40 CFR Part 63 Subparts HH and ZZZZ also apply to these General Permits.

Coal bed methane – Methane that is extracted from a coal bed and the surrounding rock strata by extraction wells drilled in advance of a mining operation, which is typically of pipeline quality.

Fugitive Emissions Component – Any component that has the potential to emit fugitive emissions of methane, VOC, or HAP at a facility, but not limited to, valves, connectors, pressure relief devices, open-ended lines, flanges, compressors, instruments, meters, covers, and closed vent systems. Devices that vent as part of normal operations are not considered fugitive sources unless the emission originates from a place other than the vent.

Gob gas – Methane that is mixed with air from a mine ventilation system due to the mining operation reaching the area of an extraction well, which is typically below pipeline quality.

Leak – A leak is defined as any release of gaseous hydrocarbons that is detected by Auditory, Visual, or Olfactory (AVO) inspection; an optical gas imaging (OGI) camera calibrated according to 40 CFR §60.18 and a detection sensitivity level of 60 g/h; a gas leak detector that meets the requirements of 40 CFR Part 60, Appendix A-7, Method 21 that detects a concentration of 500 ppm calibrated as methane or greater; or other leak detection methods approved by the Department's Division of Source Testing and Monitoring. However, a release from any equipment or component designed by the manufacturer to protect the equipment, controller, or personnel or to prevent groundwater contamination, gas migration, or an emergency situation is not considered a leak.

Natural Gas Compression Station – A facility that compresses and/or processes natural gas, coal bed methane, or gob gas prior to the point of custody transfer using processes including, but not limited to, gas dehydration, compression, pigging, and storage.

Natural Gas Processing Plant – A facility that engages in the extraction of natural gas liquids from field gas, the fractionation of mixed natural gas liquids to natural gas products, or both extracts and fractionates natural gas liquids.

Natural Gas Transmission Station – A facility that compresses and/or processes natural gas after the point of custody transfer using processes including, but not limited to, gas dehydration, compression, pigging, and storage.

Pigging Operations – The process of removing and collecting condensed liquids including condensate, intermediate hydrocarbons, or produced water from a pipeline using a spherical or bullet-shaped device, known as a pig, forced through the pipeline by natural gas pressure. The liquids are then collected at their eventual destination in a storage tank, often referred to as a slug tank. This process also includes operation conducted for pipeline integrity evaluation.

Point of Custody Transfer – The location after the processing and/or treatment of natural gas in the production sector, typically after a natural gas processing plant, where control and/or ownership of the natural gas is transferred from one owner or operator to another.

NMED Exhibit 52

Remote Pigging Station – A facility where pigging operations are conducted that is not located at an unconventional natural gas well site, natural gas compression station, natural gas processing plant, or natural gas transmission station and which meets or exceeds the exemption criteria in Category 38(c) of the Air Quality Permit Exemptions List.

Sour Gas – Natural gas where the Hydrogen Sulfide (H_2S) content is in excess of 4 ppmv at standard temperature and pressure.

Start of Production – The beginning of initial flow following the end of flowback when there is continuous recovery of salable quality gas and separation and recovery of any crude oil, condensate, or produced water. A well whose owner or operator is selling gas through temporary equipment designed for flowback shall not be considered in production until either the sales continue through the temporary equipment for more than 30 days or the gas is routed to a permanent production separator.

Unconventional Natural Gas Well – A well drilled to produce natural gas from shale formations below the Elk Group or its geologic equivalent stratigraphic interval, where recovery of the resource is generally not economic without the bores being stimulated by hydraulic fracturing, multilateral well bores, or other techniques to expose more of the formation to the well bore.

Unconventional Natural Gas Well Site – A location with one or more unconventional natural gas wells at which unconventional natural gas well site operations are conducted.

Unconventional Natural Gas Well Site Operations – Equipment and processes at unconventional natural gas well sites including, but not limited to, well completion, gas dehydration, tanker truck load-out, wellbore liquids unloading, gas compression, pigging, and storage.

Wellbore Liquids Unloading – The process of removing accumulated liquids from a natural gas well in order to restore well pressure and natural gas production.

VII. Applicability/Scope

GP-5A authorizes the construction, modification, and/or operation of sources located at an unconventional natural gas well site or remote pigging station. The applicability of the GP-5A may include one or more of the following operations or emissions sources:

- Glycol Dehydration Units
- Stationary Natural Gas-Fired Spark Ignition Internal Combustion Engines
- Reciprocating Compressors
- Storage Vessels
- Tanker Truck Load-Out Operations
- Fugitive Emissions Components
- Controllers
- Pumps
- Enclosed Flares and Other Control Devices
- Pigging Operations
- Wellbore Liquids Unloading Operations

GP-5 authorizes the construction, modification, and/or operation of sources located at natural gas compression station, processing plant, or transmission station. The applicability of the GP-5 may include one or more of the following operations or emissions sources:

NMED Exhibit 52

- Glycol Dehydration Units
- Stationary Natural Gas-Fired Spark Ignition Internal Combustion Engines
- Reciprocating Compressors
- Storage Vessels
- Tanker Truck Load-Out Operations
- Fugitive Emissions Components
- Controllers
- Pumps
- Enclosed Flares and Other Control Devices
- Pigging Operations
- Natural Gas-Fired Combustion Units
- Stationary Natural Gas-Fired Combustion Turbines
- Centrifugal Compressors

An Application for Authorization to Use GP-5 or GP-5A may be submitted for the operation of an eligible source if the source is exempted from plan approval requirements under 25 Pa. Code §127.14. If any source located at a facility cannot be regulated under the appropriate General Permit, a plan approval and/or an operating permit issued in accordance with 25 Pa. Code, Chapter 127, Subchapter B and/or Subchapter F will be required.

VIII. Prohibited Use of GP-5 and GP-5A

The proposed GP-5 and GP-5A are different from many other General Permits issued by the Department. The General Permit program typically establishes a general plan approval/general operating permit with requirements for a specific type of **source**, and can be used at Title V facilities when they are adding that type of source to the facility. However, GP-5 and 5A are eligible for sources located at non-major facilities. Since 1997, Authorizations to Use GP-5 issued for natural gas facilities were applicable only for sources located at non-major facilities. The sources located at Title V or major facilities must obtain a site-specific plan approval and operating permit.

In addition, because most of the natural gas production in the Marcellus Shale and Utica Shale Region is not sour gas, the GP-5 and 5A are prohibited for use by those facilities that produce or process sour gas. This removes the necessity to include the sweetening unit requirements and means many of the federal SO_2 requirements in 40 CFR Part 60 are presumptively met.

The owner or operator of a facility is also prohibited from circumventing the requirements for Title V applicability, the prevention of significant deterioration, or non-attainment new source review by allowing a pattern of ownership or development that conceals that the facility would otherwise be required to submit a plan approval or operating permit application. This includes specifically phasing, staging, delaying, or engaging in incremental construction over the geographical extent of the facility or using a device, stack height that exceeds good engineering practice, dispersion technique, or other technique to conceal or dilute emissions of air contaminants without reducing the amount of emissions in order to appear to qualify for the General Permit when the facility should actually be authorized under a plan approval or operating permit.

IX. Authorization to Use the General Permits

The general procedure to apply for an Authorization to Use the General Permit; the terms; expiration and reauthorization procedure; transfer of ownership; administrative amendment; and conditions relating

NMED Exhibit 52

to the modification, suspension, or revocation of the General Permit or an Authorization to Use the General Permit are detailed in Condition 6 of the General Permits. Application Instructions and Application Forms for the General Permits can be found in the Department's e-Library. In addition, electronic applications can be submitted using the Department's e-Permitting system, accessible through DEP's Greenport.

Another important modification to this Condition is the Transfer of Ownership procedure. In previous versions of the GP-5, the new owner or operator was required to submit a new application form within 30 days of the transfer of ownership. The new procedure, which is available in both GP-5 and GP-5A, is for the new owner or operator to file the appropriate form; for a transfer of ownership that does not modify any existing source, is not adding a new source, and is not subject to a new Single Source Determination the owner or operator may submit the Transfer of Ownership Form with the appropriate fee. For a transfer of ownership that does not modify any existing source, is not adding a new source, but requires a new Single Source Determination (i.e., equipment or activities located on the same site or on sites that share equipment and are within ¼ mile of each other) the new owner or operator shall submit an application for Authorization to Use the General Permit as a General Plan Approval with the appropriate fee. For a transfer of ownership that modifies an existing source or adds a new source, the new owner or operator shall submit an application for Authorization to Use the General Permit using the standard procedure.

X. General Permit Fees

The fees related to the General Permits are detailed in Condition 7. All fees are assessed in accordance with 25 Pa. Code Chapter 127 Subchapter I.

XI. Applicable Laws

The terms and conditions of the proposed GP-5 and 5A incorporate both federal and state requirements. It is the duty of the Responsible Official to ensure that the facility is in compliance with all applicable laws and regulations, and nothing in the General Permits relieves the Responsible Official of that duty. Therefore, it is suggested that owners and operators carefully review the listed sources and the federal, state, and local requirements applicable to them and compare them to the terms and conditions of the General Permit.

The Department's review has found that the applicable federal regulations include the following NSPS and NESHAP subparts:

(a) **40 CFR Part 60, Subpart JJJJ – Standards of Performance for Stationary Spark Ignition Internal Combustion Engines.** This subpart establishes emission standards and compliance requirements for the control of emissions from stationary spark ignition internal combustion engines that commenced construction, modification or reconstruction after June 12, 2006, where the SI-RICE are manufactured on or after specified manufacture trigger dates. The manufacture trigger dates are based on the engine type, fuel used, and maximum engine horsepower. The state BAT requirements for engines at natural gas compression and/or processing facilities under the current GP-5 are either equivalent or more stringent than the federal requirements.

(b) **40 CFR Part 60, Subpart KKKK – Standards of Performance for Stationary Combustion Turbines.** This subpart establishes emission standards and compliance schedules for the control of emissions from stationary combustion turbines with a heat input at peak load equal to or greater than 10 million British thermal units per hour (MMBtu/h) that commenced construction,

NMED Exhibit 52

modification or reconstruction after February 18, 2005. The pollutants regulated by this subpart are NO_X and sulfur dioxide (SO_2). However, the SO_2 requirements can be met by fuel composition analysis, and the prohibition of using the General Permits for facilities that produce or process sour gas ensures that the fuel composition analysis will be met.

(c) **40 CFR Part 60, Subpart OOOO – Standards of Performance for Crude Oil and Natural Gas Production, Transmission, and Distribution for which Construction, Modification, or Reconstruction Commenced after August 23, 2011, and on or before September 18, 2015.** This subpart establishes emission standards and compliance schedules for the control of VOC and SO_2 emissions from affected facilities. In Subpart OOOO, the only SO_2 emission source is the sweetening unit typically located at natural gas processing plants. The prohibition of using the General Permits for facilities that produce or process sour gas makes it unlikely that a sweetening unit will produce significant SO_2 emissions, so the requirements for the sweetening unit were not included.

(d) **40 CFR Part 60, Subpart OOOOa – Standards of Performance for Crude Oil and Natural Gas Facilities for which Construction, Modification, or Reconstruction Commenced After September 18, 2015.** This subpart establishes emission standards and compliance schedules for the control of the pollutant greenhouse gases (GHG). The GHG standard in this subpart is in the form of a limitation on emissions of methane. This subpart also establishes emission standards and compliance schedules for the control of VOC and SO_2 emissions. As for Subpart OOOO, the prohibition of using the General Permits for facilities that produce or process sour gas makes it unlikely that a sweetening unit will produce significant SO_2 emissions, so the requirements for the sweetening unit were not included.

(e) **40 CFR Part 63, Subpart HH – National Emission Standards for Hazardous Air Pollutants from Oil and Natural Gas Production Facilities.** This subpart applies to the owners and operators of affected units located at natural gas production facilities that are major or area sources of HAPs and that process, upgrade, or store natural gas prior to the point of custody transfer, or that process, upgrade, or store natural gas prior to the point at which natural gas enters the natural gas transmission and storage source category or is delivered to a final end user. Because the GP-5 and 5A require that the facility is non-major with respect to air pollution, only the area source requirements apply. Area sources are broken down into two categories, those located within an Urbanized Area (UA) plus offset or an Urbanized Cluster (UC) and those not located within a UA plus offset or UC.

(f) **40 CFR Part 63, Subpart ZZZZ – National Emission Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines (RICE).** This rule establishes national emission limitations and operating limitations for HAPs emitted from stationary RICE. This rule applies to owners or operators of new and reconstructed stationary RICE of any horsepower rating which are located at a major or area source of HAP emissions. While all stationary RICE located at major or area sources are subject to the final rule, in the context of these General Permits, only four-stroke engines above 500 bhp have BACT requirements; all others have work practice requirements. In addition, for engines that commenced construction, modification or reconstruction after June 12, 2006, compliance with 40 CFR Part 60, Subpart JJJJ meets the requirements of this subpart.

NMED Exhibit 52

XII. Best Available Technology Requirements

New sources are required to control emissions of air pollutants to the maximum extent, consistent with BAT as determined by the Department as of the date of issuance of the plan approval for the new source as required under 25 Pa. Code §127.1. Condition 1 (BAT Compliance Requirements) in Sections B through L of GP-5A and in Sections B through N of GP-5 are determined to meet the BAT requirements.

XIII. Compliance Requirements and Compliance Certification

These General Permits function as a plan approval and operating permit only for a synthetic minor or natural minor facility. The Conditions of Section A lay out general terms and conditions to ensure that a facility remains a minor facility. The primary requirement to use these GPs is that the emissions from all sources and associated air pollution control equipment located at a facility must not exceed the major source thresholds on a 12-month rolling sum basis.

The owner or operator must constrain the facility throughput, hours of operation, and/or emissions from sources at the facility to ensure that the major source thresholds are not exceeded and keep records adequate to demonstrate compliance.

This Condition also contains requirements that all sources and associated air pollution control equipment are operated so as not to cause air pollution, operated and maintained in accordance with the manufacturer's specifications, operated and maintained in accordance with the fugitive emission requirements, and operated and maintained to limit the detection of malodors outside the property boundary. The addition of the fugitive emission requirements clause in the revised permit replaces the proposed version's Section B. Fugitive Particulate Matter, which was removed from both the GP-5 and GP-5A.

Another key compliance requirement is that the General Permits cannot be used to relax BAT previously established through the air quality permitting process. The owner and operator may not obtain a General Permit if BAT requirements in their current permit are more stringent than those in the revised General Permits. However, an owner or operator may elect to obtain a General Permit in lieu of their current plan approval or operating permit if they demonstrate they will be able to meet the applicable General Permit BAT requirements.

Finally, the Responsible Official must sign and submit a Certification of Compliance with the annual report.

XIV. Notification Requirements

There are several notifications that the owner or operator of a facility must perform, including a municipal notification to the local governments where the air pollution source is to be located. A copy of this notification is required to be included in the Application for Authorization to Use GP-5 or GP-5A. The notification to the local governments should include a description of the proposed sources and/or modification of existing sources to be authorized under the application.

Notifications to the Department for individual sources include prior notification of the commencement of operation of a source, which must include the completion of construction date. Notification of malfunctions are performed according to the GP-5 Malfunction Reporting Instructions (See Appendix I

NMED Exhibit 52

– GP-5 Malfunction Reporting Instructions). All notices must be submitted to the Air Program Manager of the appropriate DEP Regional Office.

XV. Recordkeeping Requirements

Any records generated as part of the terms and conditions of the General Permits are required to be maintained on site or at the nearest local field office for a minimum of 5 years and may be maintained in electronic format. The key records generated and maintained by the owner or operator of a facility authorized under the General Permit are those that show the facility is in compliance with the facility-wide emission limits on a 12-month rolling basis. All records, reports, or other information obtained by the Department under the General Permit is publicly available unless the owner or operator of the facility shows cause that the information is confidential. Under no circumstance are records of emission data eligible for confidentiality as set forth in Section 13.2 of the APCA. 35 P.S. § 4013.2.

XVI. Reporting Requirements

In order to manage the federal and state reporting requirements, the Department merged all reporting requirements into a single annual report that is required to be sent to the Department no later than 60 days from the anniversary of the Authorization to Use the General Permit. The owner or operator may send a copy of the annual report to the EPA as all federal requirements are included, or the owner or operator may send a version that redacts all state requirements at their discretion. The annual report serves as the basis for the Compliance Certification, which the Responsible Official must sign. The annual report must be submitted either in electronic format or by hand-delivery, courier, or sent by certified mail, return receipt requested, to the Air Program Manager of the appropriate DEP Regional Office. The owner or operator of the facility must also submit an annual emissions inventory via AES*Online or AES*XML to the Department by March 1st of each year.

XVII. Source Testing Requirements

All submittals, including all reports, protocols, and test completion notifications and excluding periodic monitoring data, related to Source Testing must include one hard copy and one electronic copy sent to the Air Program Manager of the appropriate DEP Regional Office and one hard copy and one electronic copy sent to the PSIMS Administrator for the Source Testing Section in DEP Central Office.

The submission of a test protocol must be done at least 60 days prior to the performance of a source test to demonstrate compliance with the General Permits. An operator may request an approval from the Department for a test protocol that covers testing of all currently operated sources in service at that operator's various facilities. In such a request, the operator will submit the test protocol that includes a list of currently permitted sources and that meets the applicable requirements specified in the most current version of the Department's Source Testing Manual for review and approval. In the case that the owner or operator has a test protocol previously approved by the Department (including the testing contractor), a new test protocol is not required provided that there are no changes, and the owner or operator agrees to comply with all conditions of acceptance in the letter approving the protocol.

The frequency of the tests required is based on federal and state requirements. In most cases, the requirements are identical; however, in the case of engines, there are some discrepancies in the timing and frequency of the tests. These discrepancies are outlined in Table 3, with the caveats noted below the table.

Table 3 - Engine Source Testing Requirements

Engine Size	Initial Compliance Performance Test	Continuous Compliance Performance Test	Periodic Monitoring
<100 hp	None Required	None Required	Every 2,500 hours of operation
100 hp ≤ ER ≤ 500 hp	Within 180 days of startup of the engine	Within 180 days of each reauthorization	Every 2,500 hours of operation
>500 hp and not subject to 40 CFR Part 60 Subpart ZZZZ	Within 180 days of startup of the engine	Every 8,760 hours of operation **or** every three years **and** within 180 days of each reauthorization	Every 2,500 hours of operation
> 500 hp and subject to 40 CFR Part 60, Subpart ZZZZ	Not Applicable	Every year	Every 2,500 hours of operation

For an engine rated greater than or equal to 100 hp and less than or equal to 500 hp, if the engine is certified by the manufacturer in accordance with 40 CFR Part 60, Subpart JJJJ and the owner or operator operates and maintains the engine in accordance with the manufacturer's instructions, the performance testing requirements are waived.

For an engine rated greater than 500 hp, if the engine is certified by the manufacturer in accordance with 40 CFR Part 60, Subpart JJJJ and the owner or operator operates and maintains the engine in accordance with the manufacturer's instructions, the continuous compliance performance testing requirements every 8,760 hours of operation or every three years are waived.

There are also some differences between the federal and state requirements for testing for combustion turbines, primarily which pollutants are analyzed during the test. The Department requires testing for NO_X, CO, and NMNEHC (as propane) while the federal regulation requires testing of NO_X and SO_2 only. It is the Department's determination that SO_2 testing is not required based on 40 CFR §60.4415(a)(1) if the fuel used is either pipeline quality gas or field gas that does not meet the definition of sour gas. There is also a frequency difference in that the federal regulations require annual testing for turbines that do not use water or steam injection for NO_X control. The annual requirement can be waived if the owner or operator installs a continuous monitoring system.

In all cases and for all sources, the Department may alter the frequency of performance testing for reauthorization based on available performance data from the source, unless the performance tests are required by federal regulation.

XVIII. General Methodology of Determining Best Available Technology

New sources are required to control the emission of air pollutants to the maximum extent, consistent with BAT as determined by the Department. BAT is defined in 25 Pa. Code §121.1 as equipment, devices, methods, or techniques as determined by the Department which will prevent, reduce, or control emissions of air contaminants to the maximum degree possible and which are available or may be made available. The applicable emission limits of federal NSPS and NESHAPs serve as minimum

NMED Exhibit 52

requirements for determining BAT. The resources utilized in the determination of BAT include the conditions established for similar sources in Category 38 of the Air Quality Permit Exemptions; the current GP-5; the data in EPA's RACT/BACT/LAER Clearinghouse (RBLC); case-by-case BAT determined in recently issued plan approvals; and permits recently issued by other states. The Department also evaluated vendors' guaranteed emission limits, available stack test data for the applicable sources, and documents related to EPA's Natural Gas Star (NGStar) program. The emission limitations included in the General Permits must be technically and economically feasible and must be sustainable during the life of the air pollution source.

The general classes of air emissions from the sources at facilities covered by GP-5 and GP-5A include NO_X, CO, VOC, HAP, SO_X, PM_{10}, $PM_{2.5}$, CO_2, and methane. These pollutants are described in more detail below.

A. Oxides of Nitrogen

Oxides of nitrogen are a family of compounds which includes nitrogen oxide (NO) and nitrogen dioxide (NO_2) that are produced as a byproduct of the combustion of fuel and air. The heat of combustion causes the molecular nitrogen (N_2) in the combustion air to disassociate and oxidize, forming NO and NO_2. NO_X is a criteria pollutant, but it is also a precursor to acid rain, ozone, and $PM_{2.5}$; NO_X emissions are typically expressed as NO_2.

There are three types of NO_X created during combustion: thermal, fuel, and prompt. Thermal NO_X is produced at very high temperatures by the reaction of atmospheric oxygen and nitrogen and is heavily influenced by combustion temperature. Fuel NO_X results from oxidation of nitrogen contained in the fuel. Prompt NO_X is formed from molecular nitrogen in the air combining with fuel in fuel-rich conditions.

Strategies for the control of NO_X include combustion control and post-combustion control. In combustion control, the combustion temperature is lowered in order to limit the disassociation of molecular nitrogen through premixing, staging, or excess air. Post-combustion control typically includes an add-on device, such as nonselective catalytic reduction (NSCR) systems or selective catalytic reduction (SCR) systems. Both systems are described in greater detail in the individual source BAT analysis.

B. Carbon Monoxide

Carbon monoxide is a colorless, odorless gas that results from the incomplete combustion of carbon. CO is formed when insufficient oxygen or poor mixing interferes with the combustion reaction to produce CO_2. CO formation is greatest when the air-to-fuel (A/F) mixture is rich; however, CO also forms when a very fuel-lean mixture cannot sustain complete combustion.

Techniques for control of carbon monoxide also include combustion control and post-combustion controls. As for combustion control, a balance must be sought with NO_X control as lower combustion temperatures that prevent thermal NO_X formation can lead to incomplete combustion and therefore increase CO formation. Post-combustion controls include NSCR systems and oxidation catalysts. Individual source BAT analyses tend to favor minimizing NO_X production through combustion control techniques even though there may be an increase of CO, and then use post-combustion controls to mitigate the CO impact because Pennsylvania is a non-attainment state in the Ozone Transport Region.

NMED Exhibit 52

C. Volatile Organic Compounds

VOCs are defined in 25 Pa Code §121.1. For engines and turbines, the Department uses non-methane, non-ethane hydrocarbons (NMNEHC) expressed as propane, excluding formaldehyde, in lieu of VOC. Also, the final General Permits include a separate emission limit for formaldehyde (HCHO), which is both a VOC and a HAP, for engines.

Techniques for the control of VOC are different depending on whether they are byproducts of combustion, due to venting or processing natural gas, or a result of fugitive emissions. Control techniques considered for the reduction of post-combustion VOC include NSCR systems and oxidation catalysts. The primary control technique considered for the reduction of venting or process emissions is the installation of a closed vent system routed to a process or a control. The primary control technique considered for the reduction of fugitive emissions is an LDAR program.

D. Hazardous Air Pollutants

HAPs are air pollutants known to cause cancer or to have other serious health impacts. There are currently 187 listed HAPs. While combustion accounts for a portion of HAP emissions, HAPs are also released through fugitive emissions, venting, and the processing of natural gas. The HAPs of primary concern at unconventional natural gas well site operations, remote pigging stations, natural gas compression stations, processing plants, and transmission stations are n-hexane; benzene, toluene, ethylbenzene, xylenes (collectively known as BTEX); and formaldehyde. Formaldehyde is of interest because it is the predominant HAP component of combustion emissions, resulting from the incomplete combustion of methane.

Similar to the control of VOC, the techniques for mitigating HAP emissions are dependent on whether the emissions are byproducts of combustion, due to venting or processing natural gas, or a result of fugitive emissions. The techniques to reduce HAP in these cases are the same as those used to reduce VOCs.

E. Oxides of Sulfur

Oxides of sulfur are the byproduct of combustion of a fuel that contains sulfur. In the Marcellus Shale region, natural gas does not contain sulfur above trace amounts. The Department has determined that for a typical combustion process using natural gas, SO_2 emissions are of minor significance. Therefore, neither GP-5 nor GP-5A include SO_2 emission limitations or SO_2 stack testing requirements for combustion sources. An example of this determination of minor significance is given in the calculation below.

$$\left|\frac{4\ lb\cdot mol\ H_2S}{10^6\ lb\cdot mol\ natural\ gas}\right|\left|\frac{lb\cdot mol\ SO_2}{lb\cdot mol\ H_2S}\right|\left|\frac{64.07\ lb\ SO_2}{lb\cdot mol\ SO_2}\right|\left|\frac{lb\cdot mol\ natural\ gas}{386.8\ scf\ natural\ gas}\right|\left|\frac{scf\ natural\ gas}{1{,}030\ Btu}\right|\left|\frac{10^6\ Btu}{MMBtu}\right|$$
$$= 6.42\times10^{-4}\frac{lb\ SO_2}{MMBtu} < 6.00\times10^{-2}\ \frac{lb\ SO_2}{MMBtu}\left(40\ CFR\ §60.4330(a)(2)\right)$$

Another example is the sweetening unit sulfur feed rate, where the lowest applicable limit is two long tons per day. Using the equations provided in 40 CFR §60.5406a(b)(1) and assuming the 4 ppm H_2S limit, the "acid gas" flow rate would have to be nearly 13,500 MMscf/day to reach a sulfur feed rate of

two long tons of sulfur per day. According to a EIA report,[12] an average transmission station moves approximately 700 MMscf/day and the largest compression station at the time moves as much as 4,600 MMscf/day. Neither type of facility would reach the required sulfur feed rate for control under 40 CFR §60.5405(a). This is also true for gathering stations as they are generally smaller than transmission stations.

F. Particulate Matter

There are many types of particulate matter emissions, with classifications based on size (i.e., PM_{10} and $PM_{2.5}$) and state (i.e., filterable and condensable). Some particles are emitted directly from a source, such as construction sites, unpaved roads, or combustion, and are called primary particles. Others are formed in complicated reactions in the atmosphere from SO_2 and NO_X and are called secondary particles. The clearing, grading, and construction of a site as well as the drilling of a well can create primary particle emissions. The combustion of natural gas produces very little primary particle emissions, and the control of precursor emissions helps reduce secondary particle emissions. Because the primary particle emissions from combustion sources are of minor significance, and the primary precursor emissions are either of minor significance or well controlled, GP-5 and GP-5A do not include PM emission limitations or stack testing requirements from most combustion sources.[13]

G. Carbon Dioxide

Carbon dioxide is sometimes present in natural gas in significant quantities and is also a primary byproduct of combustion. CO_2 is a greenhouse gas; however, since the explicit control of CO_2 emissions such as carbon capture and sequestration (CCS) from minor facilities such as sources covered by these General Permits are not readily available. However, many of the BMP, maintenance requirements, and operating limitations included in the General Permits have the co-benefit of increasing the source's efficiency and therefore reducing CO_2 on an output basis.

H. Methane

Methane is the primary component of natural gas and represents a major portion of the emissions from unconventional natural gas well site operations, remote pigging stations, natural gas compression stations, processing plants, and transmission stations. While methane is harmless in low concentrations, it can explode when the concentration reaches the lower explosive limit. Methane is also a greenhouse gas and a precursor to ground level ozone.

Based on the 2015 Air Emissions Inventory for unconventional natural gas operations, methane emissions from 2011 through 2015 ranged from 107,375 tpy to 122,589 tpy. The sources of methane emissions included dehydration units, fugitive sources such as connectors, flanges, pump lines, pump seals, valves, heaters, pneumatic pumps, stationary engines, tanks, venting, blowdowns, well completions and pigging operations. Details of methane emissions from the above sources are shown in Table 4 and Table 5.

[13] Technical Report: Development of Fine Particulate Emission Factors and Speciation Profiles for Oil and Gas-fired Combustion Systems, Update: Critical Review of Source Sampling and Analysis Methodologies for Characterizing Organic Aerosol and Fine Particulate Source Emission Profiles, February 2004, Gas Research Institute, *et.al.*

NMED Exhibit 52

The Exemption 38, finalized in 2013, required 95% control of any emission unit exceeding emission thresholds of 2.7 tpy of VOC, 0.5 tpy of single HAP, and 1.0 tpy of total HAP. It should be noted that not a single plan approval was submitted for an unconventional natural gas well site despite the requirement to install 95% VOC control on storage vessels and other equipment. This means either the installation of control is cost effective, or that the sources in question emit less than 2.7 tpy of VOC, 0.5 tpy of single HAP, and 1.0 tpy of total HAP.

The control of methane emissions in the earlier GP-5s and Exemption 38 were addressed as a collateral benefit due to the control of VOC emissions; however, because of the great success with the 2.7 tpy VOC threshold in Exemption 38, the Department decided to do something similar with methane related to a cost-effective control threshold under BAT. In addition, the leak definition for oil and gas operations included in GP-5 and Exemption 38 expressly addressed methane emissions from fugitive sources. As previously discussed in the Introduction, Governor Wolf's Methane Reduction Strategy sought to explicitly address the control of methane from the oil and gas industry. Also, as previously discussed in the Introduction, the EHB indicated to the Department that BAT also applies to GHG. Therefore, BAT for methane control was determined for sources authorized under the final General Permits to satisfy both regulatory and policy requirements.

Table 4 - Methane Emissions from Unconventional Well Site Operations in Pennsylvania

Source Type	2012		2013		2014		2015		2016

The Department originally proposed a BAT methane control threshold of 200 tpy based on calculating the amount of methane based on the VOC control threshold and an average gas composition as shown in Table 15 of Appendix A – Average Gas Composition Analysis. To calculate the BAT methane control threshold, the Department used a standard mass-balance calculation; the general methodology for determining the methane control threshold was to calculate the amount of methane in a natural gas release relative to the amount of VOC that reaches the VOC control threshold. Using twelve different gas samples, the BAT methane control thresholds ranged from a minimum of 21.2 tpy to a maximum of 1,615.3 tpy. The average of the twelve calculated control thresholds is 714.9 tpy, which is 17,872 tpy of CO_{2e}. This value is nearly 25% of the 75,000 tpy of CO_{2e} major modification facility threshold for greenhouse gases.

Therefore, the Department calculated an average gas composition from the twelve samples and followed the same methodology for determining the methane control threshold with a result of 191.6 tpy. The Department conservatively used 200 tpy methane to account for the scientific uncertainty due to the limited number of gas samples used in the calculation, which is equivalent to 5,000 tpy CO_{2e}. This is approximately 7% of the facility greenhouse gas threshold.

Several commentators stated that the Department's calculated average gas composition was not representative of natural gas in Pennsylvania because of its small sample size and limited geographic scope. To improve the average gas composition calculation, the Department decided to expand the scope of the analysis; for every county with wells displayed on eMapPA, the Department attempted to obtain at least five reasonable representative gas analyses, two from compressor stations or processing plants, and three from unconventional natural gas well sites. The Department then calculated a county average gas composition for each county, and a state average gas composition by averaging the county average gas compositions.

The average composition for the counties with at least one representative gas analysis and the calculated state average gas composition are shown in Table 16 of Appendix A – Average Gas Composition Analysis. The Department believes that this state average gas composition is representative of the regions where oil and gas operations are occurring. The same process was followed as in the previous analysis, where methane emissions were calculated based on a standard mass-balance and the VOC control threshold of 2.7 tpy for each county. The methane control thresholds ranged from 5.8 tpy for Mercer County and 1,474.8 tpy for Somerset County with an average methane control threshold of 444.0 tpy. While this value is lower than the 714.9 tpy value of the previous analysis, the Department determined that it is unreasonable to be used as a control threshold; this is because it is approximately 15% of the major modification facility threshold for GHG. For the calculated state average composition, the methane control threshold is calculated to be 51.9 tpy; this is lower than in the previous calculation because there were more representative gas analyses with VOC weight percentages higher than 2%.

In the first analysis, there were only two samples with VOC weight percentages over 2% and one of them was questionable due to the high nitrogen content; this means only 10% - 17% of the samples had a VOC weight percentage over 2%. In the second analyses, approximately 25% of the samples had VOC weight percentages over 2%; half of those samples had VOC weight percentages over 5% and one

NMED Exhibit 52

had a VOC weight percentage over 25%. This higher VOC weight percentage had the effect of lowering the methane emissions calculated from the mass-balance and increasing the VOC weight percentage of the state average gas composition from 1.25% in the first analysis to 4.47% in the second analysis. The 51.9 tpy methane control threshold calculated from the state average gas composition is approximately 2% of the major modification facility threshold for GHG meaning it is appropriate to use it as a control threshold in the permit. However, as is shown in the analysis in Appendix D – Cost Analysis for Combustion Control Devices, control of methane at 51.9 tpy is not cost-effective.

The average gas composition determined in the second analysis is comparable to other sources such as E $^{C}/_{R}$ Incorporated's memorandum[14] to EPA, which was used in establishing the requirements of 40 CFR Part 60 Subparts OOOO and OOOOa. In most cases the cost-effectiveness threshold for methane control was determined to be $1,000/ton of methane reduced, which is based on an analysis of EPA's technical support document for Subpart OOOOa where the cost-effectiveness threshold appeared to be $1,000/ton based on which methane control techniques were implemented and which were not. The $1,000/ton of methane reduced also coincides with the central estimate of the Social Cost of Methane as determined by EPA in 2012.

As shown in Appendix D – Cost Analysis for Combustion Control Devices, the BAT methane control is cost-prohibitive at $2,239/ton of methane reduced when considering the 51.9 tpy calculated control threshold. Even though methane control is cost-effective at approximately 163 tpy methane based on the $1,000/ton reduced threshold based on a linear interpolation, the 200 tpy BAT methane control threshold previously proposed is maintained for new or modified unconventional natural gas sources at $581/ton of methane reduced. One reason for conservatively establishing the BAT methane control threshold is due to the scientific uncertainty inherent in any analysis, including the second analysis discussed above and in Appendix A – Average Gas Composition Analysis and the site-specific uncertainty in the control costs from Appendix D – Cost Analysis for Combustion Control Devices. BAT control measures for methane must be implemented for sources with emissions that meet or exceed 200 tpy methane; this requirement is also included in the exemption criteria for facilities seeking exemption under Category 38(c). For those sources that wish to forgo controls, they can use methods or techniques to reduce methane emissions below the BAT control threshold.

Another reason in establishing the BAT 200 tpy methane control threshold is that, according to the Air Emissions Inventory, between 2012 and 2016 various sources at natural gas production, compression, and processing facilities have emissions exceeding 200 tpy of methane. While the number of sources fluctuate, generally speaking the number of sources have increased from year to year; details are shown in Table 6.

Table 6 - Reported Methane Emissions Greater Than 200 tpy

Source	Number of Sources				
	2012	2013	2014	2015	2016
Pumps	9	12	5	8	22
Heaters				2	1
Pigging				2	
Blowdowns	4	6	14	25	17
Completions	52	10	1	6	11
Dehydrators	33	40	37	28	30

[14] Memorandum on Composition of Natural Gas for use in the Oil and Natural Gas Sector Rulemaking, E $^{C}/_{R}$ Incorporated, July 28, 2011.

Fugitive			3	9	7

It should be noted, however, that even when not explicitly stated for control of methane, such as for sources that were constructed prior to August 8, 2018, the BMP, maintenance requirements, operating limitations, and control requirements often have a co-benefit of reducing methane emissions. As an illustration of this co-benefit, assume the 95% control requirement for VOC from a storage vessel authorized under Category Number 38(b) is met using an enclosed flare. Assuming a pre-control VOC emission rate of 10 tpy, the updated average gas composition as determined in Table 16 of Appendix A – Average Gas Composition Analysis, a methane destruction efficiency of 95%, and that 100% of the destroyed methane becomes CO_2, it is possible to calculate the greenhouse gas reduction in CO_{2e}. The following equation shows the amount of methane emissions that coincide with the 10 tpy VOC assumption:

$$\left|\frac{10 \text{ ton VOC}}{\text{year}}\right|\left|\frac{1 \text{ ton natural gas}}{0.0447 \text{ ton VOC}}\right|\left|\frac{0.8603 \text{ ton } CH_4}{1 \text{ ton natural gas}}\right| = 192.5 \text{ tpy } CH_4$$

The next calculation shows the amount of CO_2 generated by combusting the methane in the control device, using the 95% destruction efficiency and 100% conversion assumptions:

$$\left|\frac{192.5 \text{ tons } CH_4}{\text{year}}\right|\left|\frac{2000 \text{ lb } CH_4}{1 \text{ ton } CH_4}\right|\left|\frac{1 \text{ lb} \cdot \text{mol } CH_4}{16.04 \text{ lb } CH_4}\right|\left|\frac{0.95 \text{ lb} \cdot \text{mol } CH_4}{1 \text{ lb} \cdot \text{mol } CH_4}\right|\left|\frac{1 \text{ lb} \cdot \text{mol } CO_2}{1 \text{ lb} \cdot \text{mol } CH_4}\right|\left|\frac{44.02 \text{ lb } CO_2}{\text{lb} \cdot \text{mol } CO_2}\right|\left|\frac{1 \text{ ton } CO_2}{2000 \text{ lb } CO_2}\right|$$
$$= 501.8 \text{ tpy } CO_2 \text{ produced from the combustion of methane}$$

The final equation shows the total amount of CO_{2e} reduced by showing the amount of CO_{2e} equivalent to the reduced methane and subtracting the CO_{2e} of the CO_2 emissions produced in the combustion process:

$$(0.95)(192.5 \text{ tpy } CH_4)\left(\frac{25 \text{ tpy } CO_{2e}}{1 \text{ tpy } CH_4}\right) - (501.8 \text{ tpy } CO_2)\left(\frac{1 \text{ tpy } CO_{2e}}{1 \text{ tpy } CO_2}\right)$$
$$= 4{,}070.1 \text{ tpy } CO_{2e} \text{ eliminated by the combustion of methane}$$

Techniques for the control of methane emissions differ depending on whether they are due to venting, processing natural gas, or fugitive emissions. The primary control technique considered for the reduction of venting or process emissions is the installation of a closed vent system routed to a process or control. The primary control technique considered for the reduction of fugitive emissions is an LDAR program.

XIX. Sources Common to GP-5 and GP-5A

A. Glycol Dehydration Units and Associated Equipment

All natural gas well streams contain water vapor as they leave the reservoir, and this water is produced along with the natural gas. As the natural gas travels up the well bore, it cools as a result of pressure reduction and the conduction of heat through the casing to cooler formations. Therefore, since the ability of gas to hold water vapor decreases as the gas temperature decreases, natural gas is nearly always saturated with water vapor when it reaches surface equipment. Additional cooling of the saturated gas will cause the formation of free water. The process for removal of water vapor from natural gas is known as dehydration.

NMED Exhibit 52

Dehydrators are designed to remove water from the natural gas vapor stream, thereby reducing corrosion and preventing the formation of hydrates, which are solid compounds that can cause flow restrictions and plugging in valves and even pipelines. The water-lean glycol usually flows downward in an absorption tower, counter-current to the natural gas. The glycol absorbs most of the water from the natural gas, but it also absorbs other materials present in the gas stream. The dried natural gas exits the top of the tower. The water-rich glycol leaves the bottom of the tower and flows to the regenerator. The regenerator heats the glycol to drive off water vapor, and the water vapor is usually vented directly to the atmosphere through the regenerator vent stack. While water has a boiling point of 212 degrees Fahrenheit, glycol does not boil until 400 degrees Fahrenheit. This difference in the boiling points allows for the easy removal of water from the glycol. The water-lean glycol is then returned to the absorber. Glycol has a high affinity for water and a relatively low affinity for non-aromatic hydrocarbons, which makes it a very good absorbent fluid for drying natural gas. However, the glycol does absorb small amounts of methane and other hydrocarbons from the natural gas. The hydrocarbons are released to the atmosphere along with the water vapor from the regenerator vent.

Some glycol dehydrators have additional equipment. Two common additions are flash tanks and regenerator vent emissions control equipment. The flash tank is placed in the rich glycol loop between the absorber and the regenerator. The glycol line pressure is dropped in the flash tank, causing most of the light hydrocarbons to flash into the vapor phase. The flash gas is usually routed to the regenerator burner as fuel. The methane emissions from the regenerator vent can be significantly reduced by using a flash tank. Regenerator vent control devices on units reduce emissions of BTEX and VOC to the atmosphere. These compounds are absorbed from the gas stream and driven off with the water in the regenerator vent. Control devices usually condense the water and hydrocarbons (containing BTEX and heavier VOC), then decant the hydrocarbons for sale and the water for disposal.

Emissions from glycol dehydration units are often controlled by using a condenser on the regenerator still vent and then venting to the atmosphere or to the regenerator firebox, other heaters, or a flare. Emissions from water-rich glycol flash tank vents are often controlled by combustion or by recycling back to low-pressure inlet gas streams. These systems have been shown to recover 90 to 99 percent of methane that would otherwise be flared into the atmosphere.[15]

1. Emission Limits for Glycol Dehydrators

a. Existing Glycol Dehydrators

The owner or operator of each existing glycol dehydrator located at an unconventional natural gas well site, remote pigging station, natural gas compression station, natural gas processing plant, or natural gas transmission station shall comply with the applicable requirements established in 40 CFR Part 63, Subpart HH, which are incorporated by reference in the General Permits. It is important to note that the locations listed in the technical support documents of 40 CFR Part 63, Subpart HH as urbanized areas and urban clusters were updated in the 2010 Census. The new list can be found in Appendix F.

The owner or operator of each existing glycol dehydrator installed prior to February 2, 2013, which has a total uncontrolled PTE of VOC in excess of 10 tpy, shall be controlled by at least 85% with a condenser, enclosed flare, or other air cleaning device approved by the Department.

The owner or operator of each existing glycol dehydrator installed on or after February 2, 2013, but before August 8, 2018 at a natural gas compression station or processing plant, which has a total

[15] NaturalGas.org, last accessed on May 24, 2018.

NMED Exhibit 52

uncontrolled PTE of VOC in excess of 5 tpy, shall be controlled by at least 95% with a condenser, enclosed flare or other air cleaning device approved by the Department.

The owner or operator of each existing glycol dehydrator installed on or after August 10, 2013, but before August 8, 2018 at an unconventional natural gas well site or remote pigging station, which has a total uncontrolled VOC emission rate greater than or equal to 2.7 tpy, an uncontrolled single HAP emission rate greater than or equal to 0.5 tpy, or a total HAP emission rate greater than or equal to 1.0 tpy, shall be controlled by at least 95%.

b. New Glycol Dehydrators

The owner or operator of each new glycol dehydrator located at an unconventional natural gas well site, remote pigging station, natural gas compression station, processing plant, or transmission station shall comply with the applicable requirements established in 40 CFR Part 63, Subpart HH, which are incorporated by reference in the General Permits.

For new glycol dehydrators whose emissions are greater than or equal to the control thresholds for methane of 200 tpy, VOC of 2.7 tpy, single HAP of 0.5 tpy, **or** combined HAP of 1.0 tpy, emission must be controlled by at least 95%. A cost analysis was done by the Department for sources that emit above the control thresholds and included in Appendix D – Cost Analysis for Combustion Control Devices. A revised analysis was done based on comments received and is also included in Appendix D – Cost Analysis for Combustion Control Devices. The control requirements are summarized in Table 7.

Table 7 - Glycol Dehydrator Control Thresholds and Control Requirements

Uncontrolled VOC PTE	Still Vent Control Level
Permitted Under GP-5 Prior to Feb 2, 2013	
>10 tpy	85%
Permitted Under GP-5 On or After Feb 2, 2013 but Prior to Aug 8, 2018	
>5 tpy	95%
Permitted on or After Aug 8, 2018	
≥2.7 tpy	95%

B. Stationary Natural Gas-Fired Spark Ignition Internal Combustion Engines

In an engine, a mixture of air and fuel is burned within the engine cylinder and the energy of expanding gases is converted into mechanical work at the engine crank shaft. The relative proportions of air and fuel in the combusted mixture is called the air-to-fuel (A/F) ratio. The A/F ratio is called "stoichiometric" if the mixture contains the precise amount of air that supplies sufficient oxygen for complete combustion of the fuel with no oxygen or fuel left over after combustion.

Reciprocating engines are grouped into two general categories based on the combustion model used in their design: “rich-burn” and “lean-burn.” The primary distinction between the two is the amount of excess air admitted prior to combustion. Rich-burn engines operate with a minimum amount of air required for combustion and lean-burn engines use 50% to 100% more air than is necessary for combustion.

NMED Exhibit 52

In the natural gas industry, engines are used as prime movers to drive compressors or vapor recovery units and as electric generators. Both rich-burn and lean-burn engines are used in the natural gas industry.

1. Emissions from Lean-Burn and Rich-Burn Engines

The main pollutants emitted from the exhaust of SI-RICE are NO_X, CO, NMNEHC, formaldehyde, SO_X, PM, and methane, depending on the composition of the fuel used. Natural gas is the only fuel authorized by GP-5A and GP-5.

2. Emission Control Technology

Control technologies that may be used on engines primarily fall into two categories, combustion control and post-combustion control.

a. Combustion Control

Control of combustion temperature is the principal focus of combustion process control in natural gas-fired engines. Combustion control requires tradeoffs – higher temperatures favor complete consumption of the fuel and lower residual hydrocarbons and CO but result in increased NO_X formation. Lean combustion dilutes the fuel mixture and reduces combustion temperatures and therefore reduces NO_X formation. This allows a higher compression ratio or peak firing pressures resulting in higher efficiency. However, if the mixture is too lean, misfiring and incomplete combustion may occur, increasing CO and VOC emissions.[16]

Because the NO_X produced by SI-RICE is primarily thermal NO_X, reducing the combustion temperature will result in less NO_X production. Thus, the most common strategy for NO_X control is to control the combustion temperature. This is most easily done by adding more air than what is required for complete combustion of the fuel. This raises the heat capacity of the gases in the cylinder so that for a given amount of energy released in the combustion reaction, the maximum temperature will be reduced.

Combustion temperature can also be controlled to some extent in reciprocating engines by one or more of the following techniques:

- Diluting the fuel-air mixture with exhaust gas recirculation (EGR), which replaces some of the air and contains water vapor that has a relatively high heat capacity and absorbs some of the heat of combustion.
- Modifying valve timing, compression ratio, turbocharging, and the combustion chamber configuration.

b. Post-Combustion Emission Reduction Technology for Rich-Burn Engines

i. Three-Way Catalyst (for NO_X, CO, and NMNEHC reduction)

In rich-burn engines, an after-treatment system such as NSCR, also known as a three-way catalyst, can be added to reduce NO_X, CO, and NMNEHC emission levels. Three-way catalysts use oxygen to treat exhaust emissions. However, three-way catalysts do not use unburned combustion oxygen to reduce emissions. They make use of the oxygen within the constituent compounds. Oxygen from NO_X is used

[16] Technical Report: Technology Characterization: Reciprocating Engines, March 2015, Prepared by Darrow, K. *et al.*, of ICF International on behalf of the EPA and US DOE.

to oxidize the CO and NMNEHC. This converts the three pollutants into N_2, CO_2 and H_2O. Catalysts may be used in series to obtain lower emission levels. Typically, the reduction level for NO_X is > 95%, CO is >95%, and NMNEHC is >50%. For this analysis, the Department has determined that an NSCR is economically feasible for engines if the cost per ton of NO_X, CO, and NMNEHC removal is approximately $5,000; see Appendix C – Oxidation Catalyst and NSCR Cost Analysis for Engines and Turbines.

c. Post-Combustion Emission Reduction Technology for Lean-Burn Engines

i. Oxidation Catalyst (for CO and NMNEHC reduction)

On lean-burn engines, oxidation catalysts using platinum and palladium are effective for lowering CO and NMNEHC levels in exhaust emissions. Methane that is not combusted in the engine is exhausted with the other products of combustion; however, methane is difficult to oxidize at exhaust temperatures provided by lean-burn engines. Therefore, the control efficiency for methane using an oxidation catalyst can be very low, and no specific emission limit for methane is included in the final General Permits for engines. No A/F ratio control system is required with this type of catalyst and it can be applied to either rich-burn or lean-burn engines. For this analysis, the Department has determined that an oxidation catalyst is economically feasible for engines if the cost per ton of CO and NMNEHC removal is approximately $5,000; see Appendix C – Oxidation Catalyst and NSCR Cost Analysis for Engines and Turbines.

ii. Selective Catalytic Reduction (for NO_X reduction)

SCR is an exhaust gas after-treatment that specifically targets the NO_X in engine exhaust and converts it to N_2 and H_2O. Unlike the three-way catalyst which uses oxygen from the exhaust stream to treat emissions, SCR injects a compound into the exhaust stream to start the reaction. The process begins when a small amount of urea is injected into the exhaust stream. After hydrolysis, the urea becomes ammonia and reacts with NO_X. On closed-loop control systems SCR can reduce natural gas-fired engine NO_X emissions by 90% as per the SCR system manufacturers.[17]

In the GP-5 issued on February 2, 2013, the Department required add-on control for CO emissions which also controls VOC and HCHO emissions. The Department also established an uncontrolled NO_X emission limit of 0.5 grams per brake horsepower-hour (g/bhp-h) for lean-burn engines rated at greater than 500 brake horsepower (bhp) based on vendor's guaranteed emission rates. The Department evaluated the economic feasibility of SCR for engines and determined that SCR is economically cost-prohibitive for engines rated below 4,000 bhp. The Department did not evaluate SCR for larger engines at that time because the information received from natural gas compression facility owners led us to believe that the typical engine sizes were between 1,300 bhp and 4,000 bhp.

The Department has reviewed the manufacturers' current guaranteed level for NO_X emissions for lean-burn engines and found that some manufacturers now offer a guaranteed emissions rate of 0.30 g/bhp-h NO_X for certain engines rated greater than or equal to 1,875 bhp. For the current analysis, the Department has determined that SCR is economically feasible for engines if the cost per ton of NO_X removal is approximately $10,000; see the updated Appendix B – SCR Cost Analysis for Engines and Turbines.

[17] Emails from Vendor A and Vendor B, as referenced in Appendix B – SCR Cost Analysis for Engines and Turbines of this document.

NMED Exhibit 52

3. Engine Size Grouping

The Department chose the engine size groups based on information for various engine makes and models available. The General Permits group the engines into the following categories:

- Less than 100 bhp;
- Greater than or equal to 100 bhp and less than 500 bhp;
- Greater than or equal to 500 bhp and less than 2,370 bhp; and
- Greater than or equal to 2,370 bhp.

The groupings are comparable to the bhp categories in 40 CFR Part 60, Subpart JJJJ. The Department made BAT determinations for these categories.

4. Engine Emission Limits

The BAT for most of the engine size categories in the proposed GP-5A and GP-5 is adapted from the current GP-5 for Natural Gas Compression and/or Processing Facilities, revised January 16, 2015. For engines rated above a certain size, the Department evaluated uncontrolled emissions, control efficiency of various controls and associated costs, and stack test results for SI-RICE to establish BAT.

It should be noted that there were engines permitted through GP-5 prior to February 2, 2013, which could include sources at natural gas well sites. The scope of the revised GP-5, issued on February 2, 2013, did not include sources at natural gas well sites. Therefore, specific categories for these existing engines authorized to operate under previous versions of GP-5 and their emissions limits have been included in GP-5A.

a. Rich-Burn Engines Less Than 100 bhp

Due to the limited available emissions data for rich-burn engines less than 100 hp, the Department determined BAT for rich-burn engines less than 100 bhp equivalent to the emissions standards specified in 40 CFR Part 60 Subpart JJJJ. The emission limits included in the final General Permits are 1.0 g/bhp-h of NO_X, 2.0 g/bhp-h of CO, and 0.70 g/bhp-h of NMNEHC.

b. Rich-Burn Engines Greater Than or Equal To 100 bhp but Less Than 500 bhp

Vendor data for rich-burn engines greater than or equal to 100 bhp but less than 500 bhp indicate weighted average emission rates[18] of 15.9 g/bhp-h for NO_X, 8.3 g/bhp-h for CO, 1.5 g/bhp-h for THC, and 0.3 g/bhp-h for NMNEHC. Both the weighted average emission rates and BAT emission rates were used in the BAT analysis.

All NSCR cost estimations were based on an analysis by E $^{C}/_{R}$ Incorporated[19], where they determined total annual costs based on vendor data. The equations are for retrofitted technology and give the cost in 2009 dollars. The total annual cost in the cost analysis was then multiplied by the consumer price index (CPI) of 1.12 for inflating 2009 dollars to 2016 dollars. Because the equations were designed as a retrofit, it is assumed that it is a conservative cost estimate for new installations. It was assumed that the control efficiencies for NO_X and CO are 95% and for NMNEHC is 50%.

[18] The weighted average emission rates for all engine categories is based on data gathered by the Department and included in the Excel Spreadsheet titled GP-5 NG Engine Data 03152018.

[19] Memorandum on Control Costs for Existing Stationary SI-RICE, E $^{C}/_{R}$ Incorporated, June 29, 2010.

NMED Exhibit 52

Using the weighted average emission rates and the BAT emission rates, the assumed control efficiencies, and assuming full-year operation, the control cost for rich-burn engines greater than or equal to 100 bhp but less than 500 bhp is estimated between $138 and $11,480 per ton of pollutants reduced. The $11,480 per ton of pollutants reduced figure is for a 100 hp engine operating at the BAT emissions rate, which presumes installation of NSCR. Discarding this point, the control cost for an NSCR is then estimated to be between $138 and $5,126 per ton of pollutant reduced, which are within the cost-effectiveness benchmark (~$5,000/ton of pollutant removed). Therefore, the Department determines NSCR to be BAT for rich-burn engines greater than or equal to 100 bhp but less than 500 bhp where emission limits of 0.25 g/bhp-h for NO_X, 0.30 g/bhp-h for CO, and 0.20 g/bhp-h for NMNEHC remains as in the previously issued GP-5.

c. Rich-Burn Engines Greater Than or Equal To 500 bhp

Vendor data for rich-burn engines greater than or equal to 500 bhp indicate uncontrolled weighted average emission rates of 15.4 g/bhp-h for NO_X, 8.2 g/bhp-h for CO, 1.7 g/bhp-h for THC, and 0.3 g/bhp-h for NMNEHC. Both the weighted average emission rates and BAT emission rates were used in the BAT analysis.

Using the weighted average emission rates and the BAT emissions rates, the assumed control efficiencies, and assuming full-year operation, the control cost for rich-burn engines greater than or equal to 500 bhp is estimated between $30 and $3,256 per ton of pollutants reduced, which are within the cost-effectiveness benchmark (~$5,000/ton of pollutant removed). Therefore, the Department determines NSCR to be BAT for rich-burn engines greater than or equal to 500 bhp where emission limits of 0.20 g/bhp-h for NO_X, 0.30 g/bhp-h for CO, and 0.20 g/bhp-h for NMNEHC remains as in the previously issued GP-5.

d. Lean-Burn Engines Less Than 100 bhp

Due to the limited available emissions data for lean-burn engines less than 100 hp, the Department determined BAT for lean-burn engines less than 100 bhp equivalent to the emissions standards specified in 40 CFR Part 60 Subpart JJJJ. The emission limits included in the final General Permits are 1.0 g/bhp-h of NO_X, 2.0 g/bhp-h of CO, and 0.70 g/bhp-h of NMNEHC.

e. Lean-Burn Engines Greater Than or Equal To 100 bhp but Less Than 500 bhp

Vendor data for lean-burn engines greater than or equal to 100 bhp but less than 500 bhp indicate uncontrolled weighted average emission rates of 7.8 g/bhp-h for NO_X, 6.7 g/bhp-h for CO, 1.9 g/bhp-h for THC, and 0.6 g/bhp-h for NMNEHC. Both the weighted average emission rates and BAT emission rates were used in the BAT analysis.

Using the weighted average emission rates and BAT emission rates, the assumed control efficiencies, and assuming full-year operation, the control cost for an oxidation catalyst for lean-burn engines greater than or equal to 100 bhp but less than 500 bhp is estimated between $286 and $1,956 per ton of pollutants reduced, which are within the cost-effectiveness benchmark (~$5,000/ton of pollutant removed). Therefore, the Department determines oxidation catalyst to be BAT for lean-burn engines greater than 100 bhp but less than 500 bhp with emission limits of 0.70 g/bhp-h for CO and 0.30 g/bhp-h for NMNEHC based on the weighted average emission factors and the given control efficiencies.

In the previous analysis, using the BAT emission rates, the assumed control efficiencies, and assuming full-year operation, the control cost for SCR for lean-burn engines greater than or equal to 100 bhp but

NMED Exhibit 52

less than 500 bhp is estimated between $25,843 and $62,940 per ton of NO_X reduced. In the revised analysis, using the BAT emission rates, the assumed control efficiencies, and assuming full-year operation, the control cost for SCR for lean-burn engines greater than or equal to 100 bhp but less than 500 bhp is estimated between $22,183 and $71,821 per ton of NO_X reduced. The Department maintains the determination that SCR is not BAT for lean-burn engines greater than or equal to 100 bhp but less than 500 bhp because it is not economically feasible; therefore, the Department established emission limit of 1.00 g/bhp-h NO_X remains as in the previously issued GP-5.

f. Lean-Burn Engines Greater Than or Equal To 500 bhp but Less Than 2,370 bhp

Vendor data for lean-burn engines greater than or equal to 500 bhp but less than 2,370 bhp indicate uncontrolled weighted average emission rates of 1.4 g/bhp-h for NO_X, 2.0 g/bhp-h for CO, 4.0 g/bhp-h for THC, and 0.5 g/bhp-h for NMNEHC. Both the weighted average emission rates and the current uncontrolled BAT for NO_X were used in the BAT analysis.

In the previous analysis, using the weighted average emission rates and BAT emission rates, the assumed control efficiencies, and assuming full-year operation, the control cost for an oxidation catalyst for lean-burn engines greater than or equal to 500 bhp but less than 1,875 bhp is estimated between $232 and $2,081 per ton of pollutants reduced. Under the new category, using the previous analysis, the control cost for an oxidation catalyst for lean-burn engines greater than or equal to 500 bhp but less than 2,370 bhp is estimated between $185 and $2,081 per ton of pollutants reduced, which are within the cost-effectiveness benchmark (~$5,000/ton of pollutant removed). Therefore, the Department maintains the determination that oxidation catalyst is BAT for engines greater than 500 bhp but less than 2,370 bhp with an emission limit of 0.25 g/bhp-h for CO based on the weighted average emission factor and the given control efficiencies and an emission limit of 0.25 g/bhp-h for NMNEHC as in the previously issued GP-5.

In the previous analysis, using the BAT emission rates, the assumed control efficiencies, and assuming full-year operation, the control cost for SCR for lean-burn engines greater than or equal to 500 bhp but less than 1,875 bhp is estimated between $10,466 and $13,477 per ton of NO_X reduced. In the revised analysis, using the BAT emission rates, the assumed control efficiencies, and assuming full-year operation, the control cost for SCR for lean-burn engines greater than or equal to 500 bhp but less than 2,370 bhp is estimated between $11,792 and $24,541 per ton of NO_X reduced. Therefore, the Department determines that SCR is not BAT for lean-burn engines greater than or equal to 500 bhp but less than 2,370 bhp because it is not economically feasible, and the emission limit remains 0.50 g/bhp-h for NO_X as in the previously issued GP-5.

g. Lean-Burn Engines Greater Than or Equal To 2,370 bhp

Vendor data for lean-burn engines greater than or equal to 2,370 bhp indicate uncontrolled weighted average emission rates of 0.7 g/bhp-h for NO_X, 2.1 g/bhp-h for CO, 5.7 g/bhp-h for THC, and 0.8 g/bhp-h for NMNEHC.

In the previous analysis, using the weighted average emission rates and BAT emission rates, the assumed control efficiencies, and assuming full-year operation, the control cost for an oxidation catalyst for lean-burn engines greater than or equal to 1,875 bhp is estimated between $123 and $873 per ton of pollutants reduced. Under the new category, using the previous analysis, the control cost for an oxidation catalyst for lean-burn engines greater than or equal to 2,370 bhp is estimated between $123 and $781 per ton of pollutants reduced, which are within the cost-effectiveness benchmark (~$5,000/ton of pollutant removed). Therefore, the Department determined oxidation catalyst to be BAT for lean-

NMED Exhibit 52

burn engines greater than 2,370 bhp with an emission limit of 0.25 g/bhp-h for CO based on the weighted average emission factor and the given control efficiency and an emission limit of 0.25 g/bhp-h for NMNEHC as in the previously issued GP-5.

In the previous analysis, using the BAT emission rate of 0.50 g/bhp-h as baseline, the assumed control efficiency, and assuming full-year operation, the control cost effectiveness for SCR for lean-burn engines greater than 1,875 bhp was estimated to be less than $8,818 per ton of NO_X reduced. In the revised analysis, lean-burn engines rated below 2,370 bhp were included in the previous category. However, the Department learned in recent conversations with Caterpillar that engines rated at 1,875 bhp are from a special class of engine designed to emit 0.30 g NO_X/bhp-h. Engines of the same model designation, but not of the same class as the 1,875 bhp model, are rated at 1,775 bhp. SCR is estimated to be $11,792 per ton of NO_X reduced for the 1,775 bhp model and $19,178 per ton of NO_X reduced for the 1,875 bhp model, therefore, SCR is a cost-prohibitive option for lean-burn engines designed to emit 0.30 g NOx/bhp-h. This was one reason for changing the engine categories.

The Department previously relied on stack test data that shows that approximately 33% of engines rated greater than or equal to 1,875 bhp are capable of achieving a NO_X emissions rate of 0.35 g/bhp-h uncontrolled. Therefore, the Department performed the previous analysis using 0.35 g/bhp-h of NO_X as a baseline, the assumed control efficiency, and assuming full-year operation, and found the control cost effectiveness for SCR for lean-burn engines rated greater than or equal to 1,875 bhp but less than 3,000 bhp is estimated to increase to between $10,241 and $12,597. The control cost effectiveness for SCR for engines rated greater than or equal to 3,000 bhp, using a NO_X emissions rate of 0.35 g/bhp-h as the baseline, the assumed control efficiency, and assuming full-year operation, is estimated to be less than $9,064. The Department therefore determined that lean-burn engines greater than or equal to 1,875 bhp but less than 3,000 bhp would have a dual BAT where engines with a NO_X emission rate of 0.50 g/bhp-h required SCR and engines with a NO_X emission rate of 0.35 g/bhp-h did not require SCR based on economic feasibility. However, as many of the commentators pointed out, relying on stack test data to establish an uncontrolled emission rate based on 33% of sources tested basically means that two in three engines, or an engine in two out of three tests, would be incapable of meeting that emission rate. This was another reason for changing the engine categories.

The Department conducted a revised analysis based on available engine models. For engines with a NO_X emission rate of 0.50 g/bhp-h, the assumed control efficiencies, and assuming full-year operation, the control cost for SCR for lean-burn engines greater than or equal to 2,370 bhp is estimated between $7,611 and $10,451 per ton of NO_X reduced. This was the final reason for changing the engine categories.

For engines with a NO_X emission rate of 0.30 g/bhp-h, the assumed control efficiencies, and assuming full-year operation, the control cost for SCR for lean-burn engines greater than or equal to 2,370 bhp is estimated between $13,706 and $17,072 per ton of NO_X reduced. The Department therefore determined that lean-burn engines greater than or equal to 2,370 bhp have a dual BAT where engines with a NO_X emission rate of 0.50 g/bhp-h require SCR and engines with a NO_X emission rate of 0.30 do not require SCR based on economic feasibility. Based on the comments received, the Department has revised the ammonia slip limit to 10 ppmvd corrected to 15% O2 in the final general permits.

The BAT emission limits for the proposed General Permits are summarized in Table 8 and Table 9.

NMED Exhibit 52

Table 8 - BAT Emission Limits for Existing SI-RICE

Engine Type	Rated bhp	NO_X	CO	NMNEHC as propane (excluding HCHO)	HCHO
Permitted Under GP-5 Prior to Feb 2, 2013					
NG-fired Lean- and Rich-Burn Engines	<1,500	2.0 g/bhp-h	2.0 g/bhp-h	2.0 g/bhp-h	
Permitted Under GP-5 On or After Feb 2, 2013 but Prior to Aug 8, 2018					
NG-fired Lean- and Rich-burn Engines	≤100	2.0 g/bhp-h	2.0 g/bhp-h	-	-
NG-fired Lean-burn Engines	>100 to ≤500	1.0 g/bhp-h	2.0 g/bhp-h	0.70 g/bhp-h	-
NG-fired Lean-burn Engines	>500	0.50 g/bhp-h	47 ppmvd @ 15% O_2 **or** 93% reduction	0.25 g/bhp-h	0.05 g/bhp-h
NG-fired Rich-burn Engines	>100 to ≤500	0.25 g/bhp-h	0.30 g/bhp-h	0.20 g/bhp-h	
NG-fired Rich-burn Engines	>500	0.20 g/bhp-h	0.30 g/bhp-h	0.20 g/bhp-h	2.7 ppmvd @ 15% O_2 **or** 76% reduction

NMED Exhibit 52

Table 9 - Proposed BAT Emission Limits for New SI-RICE

Engine Type	Rated bhp	NO_X	CO	NMNEHC as propane (excluding HCHO)	HCHO
Permitted on or After Aug 8, 2018					
New NG-fired Lean-burn Engines	≤100	1.0 g/bhp-h	2.0 g/bhp-h	0.70 g/bhp-h	-
New NG-fired Lean-burn Engines	>100 to ≤500	1.0 g/bhp-h	0.70 g/bhp-h	0.30 g/bhp-h	-
New NG-fired Lean-burn Engines	>500 to <2,370	0.50 g/bhp-h	0.25 g/bhp-h	0.25 g/bhp-h	0.05 g/bhp-h
New NG-fired Lean-burn Engines	≥2,370	0.30 g/bhp-h Uncontrolled **or** 0.05 g/bhp-h with Control	0.25 g/bhp-h	0.25 g/bhp-h	0.05 g/bhp-h
New NG-fired Rich-burn Engines	≤100	1.0 g/bhp-h	2.0 g/bhp-h	0.70 g/bhp-h	-
New NG-fired Rich-burn Engines	>100 to ≤500	0.25 g/bhp-h	0.30 g/bhp-h	0.20 g/bhp-h	
New NG-fired Rich-burn Engines	>500	0.20 g/bhp-h	0.30 g/bhp-h	0.20 g/bhp-h	2.7 ppmvd @ 15% O_2 **or** 76% reduction

In addition, the engines shall comply with all applicable requirements specified in 40 CFR Part 60, Subpart JJJJ and 40 CFR Part 63, Subpart ZZZZ. For engines constructed on or after June 12, 2006, compliance with the requirements in Table 10 guarantees compliance with the requirements of 40 CFR Part 60 Subpart JJJJ and 40 CFR Part 63 Subpart ZZZZ.

Table 10 - 40 CFR Part 60 Subpart JJJJ Requirements

Engine Size	Manufacture Date	NO_X	NMNEHC (as propane) excluding HCHO	CO
≤25 bhp and <225 cc displacement	7/1/2008	12 g/bhp-h		387 g/bhp-h
	1/1/2012	7.5 g/bhp-h		455 g/bhp-h
≤25 bhp and ≥225 cc displacement	7/1/2008	10. g/bhp-h		387 g/bhp-h
	1/1/2011	6.0 g/bhp-h		455 g/bhp-h
25 bhp < ER < 100 bhp	1/1/2007	2.8 g/bhp-h		4.9 g/bhp-h
	1/1/2011	1.0 g/bhp-h	0.70 g/bhp-h	2.0 g/bhp-h
100 hp ≤ ER < 500 bhp	7/1/2008	2.0 g/bhp-h	1.0 g/bhp-h	4.0 g/bhp-h
	1/1/2011	1.0 g/bhp-h	0.70 g/bhp-h	2.0 g/bhp-h
≥500 bhp	7/1/2007	2.0 g/bhp-h	1.0 g/bhp-h	4.0 g/bhp-h
	7/1/2010	1.0 g/bhp-h	0.70 g/bhp-h	2.0 g/bhp-h

The Department's proposed BAT requirements are at least as or more stringent than those listed in the table above. Therefore, by complying with the Department's BAT requirements, the owner or operator of an engine will be guaranteed compliant with the applicable emission limits of 40 CFR Part 60 Subpart JJJJ and 40 CFR Part 63 Subpart ZZZZ for new engines.

For engines constructed prior to June 12, 2006, compliance with the requirements in Table 11 guarantees compliance with the requirements of 40 CFR Part 63 Subpart ZZZZ:

Table 11 - 40 CFR Part 63 Subpart ZZZZ Requirements

Engine Category	Oil and Filter Change	Spark Plug Inspection, Plugs Replaced as Necessary	Hose Inspection, Hoses Replaced as Necessary
Emergency SI-RICE; 4SRB and 4SLB > 500 hp that operate ≤ 24 hours per year	500 hours or annually	1,000 hours or annually	500 hours or annually
4SRB and 4SLB > 500 hp in remote locations	2,160 hours or annually	2,160 hours or annually	2,160 hours or annually
4SLB > 500 hp	Install Oxidation Catalyst to Reduce HAP Emissions		
4SRB > 500 hp	Install NSCR to Reduce HAP Emissions		
4SRB and 4SLB ≤ 500 hp	1,440 hours or annually	1,440 hours or annually	1,440 hours or annually
2SLB	4,320 hours or annually	4,320 hours or annually	4,320 hours or annually

Visible emissions shall not meet or exceed 10% opacity for a period or periods aggregating more than three minutes in any one hour nor meet or exceed 30% opacity at any time.

C. Reciprocating Natural Gas Compressors

Fluids, such as natural gas, travel naturally from areas of high pressure to areas of low pressure. Natural gas compressors take advantage of this property by increasing the pressure of natural gas at one location in a pipeline in order to promote the movement of the gas to a lower pressure area downstream. The pipeline pressure tends to drop over the length of a pipeline due to friction. This decrease in pressure is the reason why compression stations are located along the length of the pipeline.

Reciprocating natural gas compressors provide this increase of pressure by using a piston and cylinder arrangement. As the piston moves through the chamber, the pressure at the forward edge of the piston is increased as the volume in the cylinder is decreased. The high-pressure gas is then forced through a valve into the high-pressure section of the pipeline. On the reverse stroke, the pressure at the trailing edge of the piston is decreased as the volume in the cylinder is increased. This reduction in pressure allows the low-pressure gas in the pipeline to be drawn into the cylinder. The piston is connected to its prime mover by a rod, and the rod utilizes rod packings to reduce wear on the compressor components and to seal in the gas pressure. Over time, these packings can wear, resulting in methane, VOC, and HAP emissions.

It is not typical for reciprocating compressors to be installed at an unconventional natural gas well site. According to 40 CFR Part 60, Subparts OOOO and OOOOa, reciprocating compressors located at well sites are not affected facilities. Since reciprocating compressors located at well sites are air contaminant sources subject to BAT requirements, the final GP-5A requires reciprocating compressors located at well sites to meet the same requirements for reciprocating compressors located at compression stations as BAT; see Appendix H – Well Site Rod Packing Replacement Cost-Effectiveness Analysis.

1. Existing Reciprocating Natural Gas Compressors

40 CFR Part 60, Subpart OOOO provides two options for controlling VOC emissions from reciprocating natural gas compressors. The first is to replace the rod packings either every 26,000 hours of operation (operating hours must be monitored and documented) or every 36 months (monitoring and documentation of operating hours not required). The second is to utilize a rod packing emissions collection system that operates under negative pressure to route the rod packing emissions to a process through a closed vent system.

The previous GP-5 required the owner or operator of reciprocating compressors to meet the requirements of 40 CFR Part 60, Subpart OOOO. Therefore, the owner or operator of an existing reciprocating natural gas compressor shall continue to comply with the applicable requirements specified in 40 CFR Part 60, Subpart OOOO, which are incorporated by reference in the General Permit.

2. New Reciprocating Natural Gas Compressors

EPA finalized NSPS OOOOa on June 3, 2016, which requires reciprocating natural gas compressors to replace the rod packing on or before 26,000 hours of operation or 36 calendar months or route emissions from the rod packing to a process through a closed vent system under negative pressure. Based on the Department's evaluation, no additional requirements are needed. Therefore, the Department determines that the recently promulgated requirements of 40 CFR Part 60, Subpart OOOOa are determined to be BAT. Therefore, the owner or operator of a new reciprocating natural gas compressor at natural gas compression stations, processing plants, and transmission stations shall comply with the applicable requirements specified in 40 CFR Part 60, Subpart OOOOa, which are incorporated by reference in the GP-5.

NMED Exhibit 52

The Department examined whether the rod-packing replacement requirements of 40 CFR Part 60, Subpart OOOOa could also be applied to reciprocating compressors at unconventional natural gas well sites. Reciprocating compressors at these facilities are exempt based on EPA's determination in their Technical Support Document for Subpart OOOOa.[20] In their TSD, EPA determined that the cost to replace the rod-packings is $1,620 per cylinder in 2008 dollars. Adjusting to 2016 dollars using the CPI, using EPA's base assumptions for emissions and number of cylinders, and assuming 7% for future worth calculations, the Department calculates that the cost per ton of methane reduced and cost per ton of pollutant reduced is $15,802 and $12,365, respectively, based on the 0.271 scf/h emission factor from the TSD.

However, a more recent study by the University of Texas[21] (UT) lists compressor seal emission factors from different sources in Table 1-4 on pages 16 and 17 of the report including calculated emission factors from measurements conducted during the study. Table 1-4 of UT's report also includes EPA's methane emission factor of 0.271 scf/h for production sources, a natural gas emission factor of 0.343 scf/h per cylinder calculated from the methane emission factor using a default methane content of 78.8 mol%, and a natural gas emission factor of 42.2 scf/h per cylinder from a 1992 study by Picard. The UT study found the average rod packing emissions to be 241 Mscf/year, which translates to 27.5 scf/h per cylinder.

In Appendix H – Well Site Rod Packing Replacement Cost-Effectiveness Analysis, the costs associated with rod-packing replacement requirements identical to those in EPA's TSD for 40 CFR Part 60, Subpart OOOOa were reevaluated for unconventional natural gas well sites based on the additional natural gas emission factors from the UT study. Based on the emissions estimate using average emissions from the UT study, the requirement of rod-packing replacement was determined to be cost effective as BAT. The Center for Responsible Shale Development (CRSD) certifies participants, which includes energy companies such as Chevron, CNX, EQT, and Shell Appalachia, that conform to their performance standards. CRSD standard #14 also requires rod-packing replacement every 36 months or every 26,000 hours of operation at all new and existing sites, including those at the wellhead. The voluntary participation of natural gas producers in the CRSD performance standards supports the Department's determination that the rod-packing replacement requirement is technically and economically feasible and therefore BAT.

D. Storage Vessels

Storage vessels are used to collect and store condensate (also known as natural gas liquids or NGLs) and/or produced water that are byproducts of natural gas production. Most storage vessels in the natural gas industry are fixed-roof structures and are equipped with a variety of pressure equalization devices to protect the structural integrity of the tank.

There are several federal regulations that pertain to storage vessels including requirements found in 40 CFR Part 60, Subparts K, Ka, Kb, OOOO, and OOOOa and 40 CFR Part 63, Subpart HH. In addition, state regulations found in 25 Pa. Code §§ 129.56 and 129.57 have applicable requirements. 40

[20] E $^{C}/_{R}$ Incorporated/US Environmental Protection Agency. Oil and Natural Gas Sector: Standards for Crude Oil and Natural Gas Facilities. Background Technical Support Document for the Proposed Standards 40 CFR Part 60, Subpart OOOOa. August 2015.

[21] URS Corporation/University of Texas at Austin. 2011. Natural Gas Industry Methane Emission Factor Improvement Study, Final Report. December 2011. https://dept.ceer.utexas.edu/ceer/GHG/files/FReports/XA_83376101_Final_Report.pdf, last accessed May 24, 2018.

CFR Part 60, Subparts OOOO and OOOOa include inspection and monitoring requirements for storage vessels which are incorporated in the final General Permits by reference.

1. Emission Limits for Storage Vessels

a. Existing Storage Vessels

Existing storage vessels at crude oil and natural gas production (except unconventional natural gas facilities constructed on or after August 10, 2013 but prior to August 8, 2018), transmission, and distribution facilities constructed on or after August 23, 2011, but prior to August 8, 2018, with uncontrolled potential VOC emissions greater than or equal to 6.0 tpy are required to be controlled by 95% or more, install a fixed-roof tank with an internal floating roof, an external floating roof, or maintain the actual uncontrolled VOC emissions below 4.0 tpy as required by 40 CFR Part 60 Subparts OOOO and OOOOa.

Existing storage vessels at unconventional natural gas facilities constructed on or after August 10, 2013 but prior to August 8, 2018 are required to meet the conditions in Category 38(b) of the Air Quality Permit Exemptions document. This means that existing storage vessels at unconventional natural gas well sites shall be equipped with controls achieving VOC emission reductions of 95% or greater unless the facility's uncontrolled VOC emissions for all sources are below 2.7 tpy. If the storage vessels' HAP emissions are uncontrolled, they must also be included in the facility-wide uncontrolled single HAP emissions limit of 0.5 tpy and total uncontrolled HAP emissions limit of 1.0 tpy. The facility-wide uncontrolled emission limits do not include emissions from any source that is equipped with emission controls.

In addition, the owner or operator of any storage vessel, without regard to when it was constructed, must meet the applicable requirements of 25 Pa. Code §§129.56 and 129.57, which are incorporated by reference in the General Permits.

b. New Storage Vessels

Storage vessels at unconventional natural gas well sites constructed on or August 8, 2018, must meet the requirements of Category 38(c) of the Air Quality Permit Exemptions document.

Because the Department has not issued any plan approval for sources located at any unconventional natural gas well site, either the VOC and HAP emissions from each storage vessel installed at well sites on or after August 10, 2013 are below the control threshold requirement or emissions are being reduced by 95% or more. Therefore, based on the updated cost analysis in Appendix D – Cost Analysis for Combustion Control Devices and the lack of plan approvals for sources located at any unconventional natural gas well site, the Department has determined BAT for the General Permits to be the reduction of methane, VOC, and HAP emissions by 95% or more for a storage vessel that exceeds any control threshold of 200 tpy methane, 2.7 tpy VOC, 0.5 tpy of a single HAP, or 1.0 tpy of total HAP.

In addition, the owner or operator of any storage vessel, without regard to when it was constructed, must meet the applicable requirements of 25 Pa. Code §§129.56 and 129.57, which is incorporated by reference in the General Permits.

E. Tanker Truck Load-Out Operations

The storage tanks at unconventional natural gas well sites, natural gas compression facilities, and natural gas processing facilities must be unloaded on occasion. This is done by loading the liquids from the

NMED Exhibit 52

tanks into tanker trucks so the liquids may be transported to a processing facility. The unloading process may emit methane, VOC, and HAP based on the composition of the liquids.

Since August 10, 2013, in accordance with Category 38 of the Air Quality Permit Exemptions document tanker truck load out operations are required to be equipped with controls achieving VOC, and HAP emissions reductions of 95% or greater unless their uncontrolled VOC, single HAP, and total HAP emissions are below the control thresholds of 2.7 tpy, 0.5 tpy, and 1.0 tpy, respectively. Because the Department has not issued any plan approval for tanker truck load out operations, either VOC and HAP emissions from each tanker truck load out operation on or after August 10, 2013 is below the control threshold requirement or emissions are being reduced by 95% or more.

All tanker truck load-out operations were required to use a vapor recovery load-out system that meets the closed vent system requirements in Section N, Enclosed Flares and Other Control Devices, in the originally proposed General Permits. This was an error, which was pointed out by several commentators, as there should be no requirement to use a vapor recovery load-out system for tanks that handle produced water. This was not the Department's intent, and to be consistent with Exemption 38 and the Internal Implementation Instructions for Exemption Category No. 38, a source that is below the control thresholds is not required to install controls.

Therefore, in the final General Permits, only tanker truck load-out operations that take liquids from storage vessels with emissions above the control thresholds are required to use a vapor balancing system and ensure each truck used to unload liquids has passed one of the annual leak checks below.

When calculating the emissions from tanker truck load-out operations, the collection efficiency may be assumed to be 99.2% for tanker trucks that pass the MACT-level annual leak test and 98.7% for tanker trucks that pass the NSPS-level annual test. The MACT-level leak test is passed if the tanker does not indicate more than a 1" H_2O pressure change within 5 minutes after being pressurized to 18" H_2O and after being depressurized to 6" H_2O vacuum. The NSPS-level leak test is passed if the tanker does not indicate more than a 3" H_2O pressure change within 5 minutes after being pressurized to 18" H_2O and after being depressurized to 6" H_2O vacuum. A leak test performed in accordance with 49 CFR §180.407 – *Requirements for Test and Inspection of Specification Cargo Tanks*, or EPA Method 27 – *Determination of Vapor Tightness of Gasoline Delivery Tank Using Pressure Vacuum Test*, will be accepted as equivalent to an NSPS-level collection efficiency (i.e., 98.7%).

Originally, the Department required the owner or operator to keep records of the entire fleet of tanker trucks that collect liquids from the facility, including the date and rating of each leak test and an identification number for each truck. However, based on comments received, the Department decided to drop this recordkeeping requirement. Instead, the load-out records will identify the truck performing the load-out, identify the leak test classification, the date and time the load-out occurred, and the type and volume of liquids loaded. These records can then be used to calculate emissions due to the load-out operations for the emissions inventory.

F. Fugitive Emissions Components

Equipment leaks are typically low-level, unintentional losses of process gas from the sealed surfaces of above-ground process equipment. Equipment components that tend to leak include valves, flanges and other connectors, pump seals, compressor seals, pressure relief valves, open-ended lines, and sampling connections. These components represent mechanical joints, seals, and rotating surfaces, which in time tend to wear and develop leaks. However, a release from any equipment or component designed by the manufacturer to protect the equipment, controller, or personnel or to prevent groundwater

NMED Exhibit 52

contamination, gas migration, or an emergency situation is not considered a leak. The following requirements have been included to minimize and/or eliminate the equipment leaks.

In accordance with the Department's requirements under the previous version of GP-5, the owner or operator of a natural gas compression facility and/or natural gas processing facility shall, at a minimum on a monthly basis, perform an LDAR program which includes AVO inspections. This requirement is to be extended to unconventional natural gas well sites, remote pigging stations, and natural gas transmission stations covered by the final General Permits.

In the previous version of the GP-5, the owner or operator of the facility was required to use an OGI camera or other leak detection device to conduct an LDAR program inspection within 180 days after the initial startup of a source and at a minimum of once a quarter thereafter. This requirement has been changed to within 60 days after the initial startup of a source to meet the 40 CFR Part 60 Subpart OOOOa requirement and align with the LDAR requirements for unconventional natural gas well sites, which are required to perform an LDAR program inspection within 60 days of the start of production.

Based upon the cost-effectiveness analysis of Appendix E – LDAR Cost Analysis, the Department determined that quarterly inspections are BAT for unconventional natural gas well sites and remote pigging stations. An owner or operator of an unconventional natural gas well site or remote pigging station may track the number of leaking components in the LDAR program and reduce the inspection interval from once per quarter to semi-annually if the percentage of leaking components is less than 2.0% for two consecutive inspections. If the percentage of leaking components is higher than 2.0% in any inspection, the quarterly LDAR inspection interval must be resumed or maintained.

Consistent with 40 CFR Part 60, Subparts KKK, OOOO, and OOOOa, the LDAR requirements for natural gas processing plants are to use Method 21. As per 40 CFR §65.7(e), when a Method 21 inspection is required in any subpart of Parts 60, 61, 63, and 65, OGI camera inspections are an accepted alternative work practice for monitoring equipment for leaks. Therefore, the Department requires that all LDAR inspections covered by GP-5 and GP-5A use the same criteria, including those at natural gas processing plants under 40 CFR §§60.484 and 60.484a.

A leak is defined as any positive indication, whether audible, visual, or odorous, determined during an AVO inspection, any visible emission detected by an OGI camera calibrated according to 40 CFR §60.18 and a detection sensitivity level of 60 g/h, or a concentration of 500 ppm or greater calibrated as methane detected by an instrument that meets the requirements of 40 CFR Part 60, Appendix A-7, Method 21, regardless of source. However, a release from any equipment or component designed by the manufacturer to protect the equipment, controller, or personnel or to prevent groundwater contamination, gas migration, or an emergency situation is not considered a leak.

If any leak is detected, the owner or operator of the facility shall make a first attempt of repair within five days of the detection of the leak. The leak must be repaired no later than 15 days after the leak is detected, unless the repair requires the ordering of parts, in which case the repair must be completed no later than 10 days after receipt of the parts, or if the repair is technically infeasible without a vent blowdown, facility shutdown, or well shut-in or would be unsafe to repair during operation of the unit, in which case the repair must be completed at the earliest of the next scheduled facility shutdown, after a planned vent blowdown, or within two years.

Several commentators were concerned over the requirement that a repair that is technically infeasible without a blowdown, shutdown, or shut-in must be completed during an unscheduled blowdown. This was consistent with EPA's requirement in 40 CFR Part 60 Subpart OOOOa. The commentators were

NMED Exhibit 52

concerned that if the facility undergoes an emergency shutdown and parts are not on hand to complete the repair, the facility would have to remain shut down until the repair is completed. The commentators petitioned the EPA to change the requirement, which was granted; subsequently, the Department amended the final General Permits to reflect the change.

A leak is considered repaired if one of the following can be demonstrated:

- No detectable emissions consistent with 40 CFR Part 60, Appendix A-7, Method 21 Section 8.3.2;
- A concentration of less than 500 ppm calibrated as methane is detected when the gas leak detector probe inlet is placed at the surface of the component;
- No visible leak image when using an OGI camera calibrated in accordance with 40 CFR §60.18 with a detection sensitivity of 60 g/h; or
- No bubbling at leak interface using a soap solution bubble test specified in Section 8.3.3 of 40 CFR Part 60, Appendix A-7, Method 21.

LDAR is considered to have a fugitive emission control rate based on the frequency of the inspection. According to EPA and Colorado[22] the emissions reductions from annual LDAR is 40% and from quarterly LDAR is 60%. In 40 CFR Part 60, Subpart OOOOa, LDAR is required semi-annually for well pads and quarterly for compression stations and processing plants. Using 50% emissions reduction for semi-annual LDAR and 60% emission reduction for quarterly LDAR programs, the Department evaluated cost-effectiveness. As shown in Appendix E – LDAR Cost Analysis, the cost-effectiveness is $516 for well pad and $144 for transmission facilities. Therefore, the final GP-5A requires quarterly LDAR for sources at unconventional natural gas well sites or remote pigging stations and the final GP-5 requires quarterly LDAR for sources at natural gas compression, processing, and transmission facilities to minimize fugitive emissions.

The Department determined that the VOC and methane emissions remaining after the implementation of BAT requirements, including LDAR, are of minor significance with regard to causing air pollution, and will not, on their own merits, be preventing or interfering with the attainment or maintenance of an ambient air quality standard.

G. Controllers

Controllers are automated instruments used for maintaining liquid levels, pressure, and temperature at unconventional natural gas well sites, remote pigging stations, natural gas compression stations, natural gas processing plants, and natural gas transmission stations. These controllers often are powered by high-pressure natural gas and may release methane, VOC, and HAP with every valve movement (i.e., intermittent bleed), or continuously (i.e., continuous bleed) as part of their normal operations.

Existing controllers shall comply with the applicable requirements specified in 40 CFR Part 60, Subpart OOOO. For pneumatic controllers located at unconventional natural gas well sites, remote pigging stations, natural gas compression stations, and natural gas transmission stations this means they must be low-bleed controllers with an emission rate less than or equal to 6.0 standard cubic feet per hour unless a higher bleed rate is required for operational reasons such as speed, safety, or positive actuation.

[22] ICF International, Economic Analysis of Methane Emission Reduction Opportunities in the U.S. Onshore Oil and Natural Gas Industries, March 2014.

NMED Exhibit 52

The Department originally proposed that new controllers constructed on or after the effective date of the final General Permits should either be an electric controller if the facility has access to electricity on site or meet the requirements of 40 CFR Part 60 Subpart OOOOa if electricity is not available on site. Several commentators pointed out that electric controllers can compromise facility reliability because electric power can fail; using electric controllers could compromise safety. The Department removed the requirement to install electric controllers at facilities based on these safety and reliability concerns. However, pneumatic controllers must comply with Subpart OOOOa when located at unconventional natural gas well sites, remote pigging stations, natural gas compression stations, and natural gas transmission stations. This means they must be low-bleed controllers with an emission rate less than or equal to 6.0 standard cubic feet per hour unless a higher bleed rate is required for operational reasons as above.

The owner or operator of new and existing controllers located at a natural gas processing plant shall employ no-bleed pneumatic controllers. These can be electrically actuated controllers or pneumatic controllers driven by instrument air. Natural gas actuated controllers that route the emissions into the downstream pipeline can also be used.

H. Pumps

Pumps are primarily used at unconventional natural gas well sites, remote pigging stations, natural gas compression stations, processing plants, and transmission stations for glycol circulation or for injecting chemicals used in normal operations. Pneumatic pumps use pressurized air or natural gas to operate the pump; at natural gas facilities, it is common to use natural gas from the production stream to operate the pumps. The pressurized natural gas, after being used to operate the pump, is often vented to the atmosphere through the exhaust port. There are many options available to reduce or eliminate emissions to the atmosphere.

Pneumatic pumps had no standards in 40 CFR Part 60, Subpart OOOO other than the LDAR requirements for pumps at natural gas processing facilities. In 40 CFR Part 60, Subpart OOOOa, natural gas-driven diaphragm pumps have control requirements for GHG and VOC depending upon the type of facility at which they are located and the number of days they are operated. Subpart OOOOa does not have a requirement for pumps located at natural gas compression stations.

In the proposed GPs, the Department required that electric pumps be used at any facility other than a natural gas processing plant that has access to electricity on site. For facilities that do not have access to electricity on site, the Department proposed that the requirements of 40 CFR Part 60, Subpart OOOOa, which were detailed in the General Permit, are BAT for pumps located at unconventional natural gas well sites and natural gas processing plants. The Department also proposed that the requirements for pumps at well sites are also BAT for pumps located at remote pigging stations, natural gas compression stations, and transmission stations. The Department also proposed to collect information on other types of pneumatic pumps by having notification, recordkeeping, and reporting requirements for all pneumatic pumps.

However, based on comments received, and the current challenges to Subpart OOOOa, the Department reevaluated the requirements for pumps. Based on the cost analysis in Appendix D – Cost Analysis for Combustion Control Devices, the Department determined that pumps with emissions greater than or equal to the control thresholds for methane of 200 tpy, VOC of 2.7 tpy, a single HAP of 0.5 tpy, or combined HAP of 1.0 tpy must control methane, VOC, and HAP emissions by 95%. For pumps with methane, VOC, and HAP emissions below the control thresholds, they must meet the applicable

NMED Exhibit 52

requirements of 40 CFR Part 60 Subpart OOOOa. These requirements were incorporated into the General Permits by reference.

I. Enclosed Flares and Other Control Devices

Most of the BAT requirements for emissions sources are dependent on a control to reduce those emissions to the atmosphere. The conditions for operating, maintaining, and performance testing those control devices are included in this section of the General Permits. The proposed General Permits required 98% control efficiency which was based on the economic feasibility of combustion control devices, as shown in Appendix D – Cost Analysis for Combustion Control Devices. In addition, the Department demonstrated that at a combustion zone temperature of 1,600 °F a methane destruction of 98% is achievable.

However, in 40 CFR Part 60 Subparts OOOO and OOOOa, the operators have the option to purchase manufacturer-tested models, which require 95% VOC control efficiency. Therefore, the Department revised the methane, VOC, and HAP destruction efficiency required from 98% to 95% to enable the owners or operators to comply with the federal requirements and terms and conditions of the general permits using manufacturer-tested models. Even so, the manufacturer-tested models generally achieve higher than 95% destruction. The manufacturer-tested models also minimize the amount of performance tests required to be performed by the owner or operator relying instead on parametric monitoring to ensure compliance.

J. Pigging Operations

Pigging operations are undertaken to remove accumulated water and condensate liquids in natural gas gathering pipelines or to conduct pipeline integrity checks. These operations are done as necessary to maintain the optimal pressure in the pipeline that keeps the natural gas flowing and to push valuable condensate to tanks where it can be transported to a processing plant and ensure pipeline safety. The "pig" is a spherical or bullet-shaped device that travels through the pipeline to push the liquids to their eventual destination.

A pig must be loaded into the pipeline at a launching station and recovered at a receiving station. When the pig is launched and recovered, some of the natural gas in the chamber is vented to the atmosphere. This venting can be reduced by routing the gas to a vapor recovery unit, flare, or other control device. It can also be minimized in high-pressure pipelines by equalizing the high-pressure chamber with a low-pressure line before venting. Some of these technologies and techniques are employed in practice by MarkWest for their pigging operations. The EPA's Partner Reported Opportunities (PRO) for Reducing Methane Emissions, also called NGStar, PRO Fact Sheet No. 505, gives information on other ways to minimize emissions from pigging operations.

NMED Exhibit 52

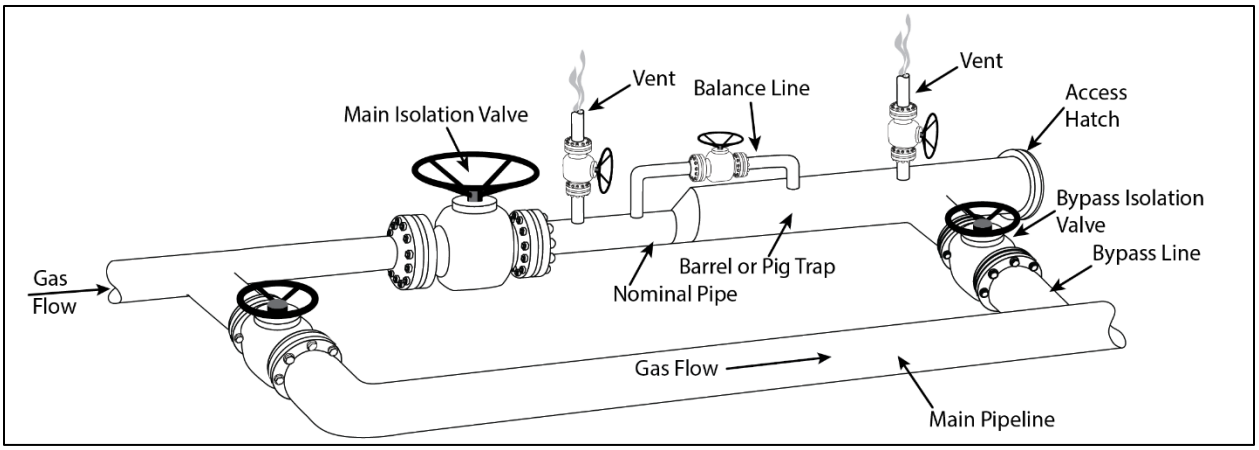

Figure 1: Drawing of a barrel type design of a pig launcher and receiver equipped with uncontrolled depressurization vents.[23]

Even though EPA is familiar with pigging operations through the NGStar program, they did not address emissions from pigging operations in 40 CFR Part 60 Subpart OOOOa. However, the Department has evaluated and set requirements for pigging operations. As part of the Annual Emissions Inventory reporting requirements, the Department requires that the owner or operator of each pigging-affected facility calculate the total annual emissions of VOC and methane using the Pigging Emissions Spreadsheet.

The owner or operator of a pigging operation shall minimize all emissions to the atmosphere to the highest extent possible. Originally, the Department required all pig receiver chambers to be equipped with a liquids drain and that all high-pressure pig launcher and receiver chambers be vented to a low-pressure pipeline or vessel if available in addition to any other best management practices (BMP) the operator decides to employ. The Department received comments recommending that DEP remove the proposed specific requirements and allow owners and operators to select all of the BMP they will implement for a specific operation. However, an owner or operator of a pigging operation whose emissions, after the application of BMP, still exceed the control thresholds for methane of 200 tpy, the total VOC of 2.7 tpy, the single HAP of 0.5 tpy, or the combined HAP of 1.0 tpy shall control methane, VOC, and HAP emissions by at least 95%.

XX. Sources Specific to GP-5A

A. Site Preparation, Well Drilling and Hydraulic Fracturing Operations

The first step in establishing a natural gas well is site preparation, which entails clearing, grading, and constructing access roads at the well site. This involves construction equipment which uses non-road engines that must meet the applicable non-road engine standards. The next step is the drilling phase; this typically entails drilling the wellbore in stages using either a diesel engine rig or a natural gas engine rig. Because the drill rig is on-site for a short period of time, the only standards that apply are that any drill rig engine must meet the applicable non-road engine standards. The owner or operator must provide at least 24 hours advance notification to the Department's Office of Oil and Gas Management before drilling. After the wellbore is completed and encased, the wellhead or "Christmas Tree" is installed.

[23] *Quantifying the Potential Impact of Natural Gas Condensate Holdup on Uncontrolled Volatile Organic Compound Emissions from Pig Receivers During Depressurization in Wet Gas Gathering Operations*, EPA Discussion Draft, May 2016.

After the installation of the wellhead, the well is ready for hydraulic fracturing. Large volumes of water mixed with chemicals and proppants are pumped into the formation to create and hold open fractures in the shale; this fracturing technique greatly enhances natural gas production. Again, the owner or operator must provide at least 24 hours advance notification to the Department's Office of Oil and Gas Management before fracture. The trucks responsible for mixing the fracturing fluid and pumping underground also use non-road engines and must meet the applicable non-road engine standards. These are summarized in the tables in Appendix G – Non-road Engine Standards.

Several commentators informed the Department that these temporary operations may be carried out a year or more in advance of the installation of any permanent air emissions source. The well drilling and hydraulic fracturing typically lasts from a few weeks to a few months. In addition, except for California, States are preempted from establishing emission standards for non-road engines under Section 209 of the CAA. However, these engines must comply with applicable EPA non-road engine standards at 40 CFR Parts 89, 1039, and 1048. Therefore, the Department has removed requirements related to site preparation, well drilling, hydraulic fracturing, and well completion from the final GP-5A and maintained the exemption for these temporary operations in Category 38(c) of the Air Quality Permit Exemptions document.

B. Well Completion Operations

After a natural gas well is hydraulically fractured, the well must be prepared to produce natural gas by removing the fluid used in the fracturing process from the well. During this process, equipment such as a separator is used to separate and remove the sand and water from the natural gas stream. The separated gas, instead of being vented, is either captured and routed to a sales pipeline, or is flared. By not directly venting the gas to the atmosphere, both methane and VOC emissions are greatly reduced. This method of completing a natural gas well is called reduced emission completion (REC) or green completion.

The owner or operator shall use REC methods in accordance with requirements specified in 40 CFR Part 60, Subpart OOOOa. Also, any existing well that is refractured after the applicability date of Subpart OOOOa subjects existing sources at a facility to the fugitive emissions components requirements in the final GP-5A. As stated above, these operations are also temporary in nature. While well completion is likely to occur much closer to the installation of permanent air emission sources, there may still be significant time between when the completion occurs and when air contamination sources are due to be installed. This could lead to inaccurate applications being submitted and many reauthorizations of the General Permit, increasing the administrative burden on the industry and the Department. Because the requirements for well completion operations are no different than those required by state and federal regulations, the Department removed these temporary operations from the final GP-5A and maintained the exemption for them in the Category 38(c). Even though these operations will not require an air permit, the operators will still be required to meet the applicable state and federal regulations, including notifying both the Air Program Manager of the appropriate Regional Office and the Department's Office of Oil and Gas Management 24 hours prior to the start of flowback.

C. Wellbore Liquids Unloading

Over time, liquids may accumulate in a producing natural gas well and may reduce the well pressure to the point where production is reduced, especially in wells located in the wet gas areas. When this happens, the accumulated fluids need to be removed in order to restore production through a process called liquids unloading. There are many techniques that can be used to accomplish this, including venting, soaping, swabbing, and using a plunger lift system. As indicated in EPA's white paper on Oil

and Natural Gas Sector Liquids Unloading Processes[24], the use of technologies like a plunger lift system can reduce the frequency of liquids unloading operations.

However, the basic criteria for the installation of a plunger lift, as found in EPA's NGStar program[25], are as follows:

- Wells must produce at least 400 scf of gas per barrel of fluid per 1,000 feet of depth.
- Wells with shut-in wellhead pressure that is 1.5 times the sales line pressure.
- Wells with scale or paraffin buildup.

These conditions may not be found at all wells covered by the GP-5A, so plunger lift systems remain an option but not a requirement for wellbore liquids unloading. Furthermore, in comments to EPA in the rulemaking for 40 CFR Part 60 Subpart OOOOa, the American Petroleum Institution (API) states that it is a misconception that plunger lift systems are the single emission control action for wells where venting for liquids unloading occurs.

> "This misconception is exacerbated by a lack of understanding, even among those purporting plunger lift systems as *the* solution to liquids unloading, of liquids loading or plunger lift systems and their appropriate uses, limitations, and efficacy. Plungers work by providing a mechanical barrier between a small volume of water and the gas that is used to transport it up the well-bore. The mechanical barrier isolates the gas from the liquids, prevents gas from moving up through the liquids hence making better use of the gas energy, and helps prevent liquids from falling back into the well-bore. If the gas could flow faster, then that mechanical barrier would not be necessary or helpful.
>
> Although plungers are among the most common tools used in middle stage deliquification, there is a misconception that plungers eliminate the need to vent to atmosphere. In many cases, wells are vented to atmosphere to generate the differential pressure necessary to lift the plunger and liquid column up the well-bore. While this can be controlled and minimized, it cannot be eliminated.
>
> As the API/ANGA report and the GHGRP data show, venting of wells to aid liquids unloading occurs in both plunger equipped wells and non-plunger equipped wells with plunger equipped wells having higher reported emissions overall."

There was another EPA white paper[26] that detailed other alternatives to repeated well venting to remove accumulated liquids including surfactants, velocity tubing, manual plunger lifts, automated plunger lifts, and downhole pumps. However, EPA did not address emissions from wellbore liquids unloading operations in 40 CFR Part 60 Subpart OOOOa. However, the Department evaluated emissions from

[24] U.S. EPA Office of Air Quality Planning and Standards, *Report for Oil and Natural Gas Sector Liquids Unloading Processes Review Panel,* April 2014, located at http://www.ourenergypolicy.org/wp-content/uploads/2014/04/epa-liquids-unloading.pdf, last accessed on May 24, 2018.
[25] U.S. EPA's Natural Gas STAR Program, *Lessons Learned from Natural Gas STAR Partners: Installing Plunger Lift Systems in Gas Wells,* October 2006, located at https://www.epa.gov/sites/production/files/2016-06/documents/ll_plungerlift.pdf, last accessed on May 24, 2018.
[26] U.S. EPA's Natural Gas STAR Program, *Lessons Learned from Natural Gas STAR Partners: Options for Removing Accumulated Fluid and Improving Flow in Gas Wells,* 2011, located at https://www.epa.gov/sites/production/files/2016-06/documents/ll_options.pdf, last accessed on May 24, 2018.

wellbore liquid operations to determine BAT. In general, there has been great support in the comments for including wellbore liquids unloading operations in the GP-5A.

The Department learned through conversations with some industry representatives, that one of the largest factors in emissions from wellbore liquids unloading events is the length of time that flow is directed to atmospheric pressure. Therefore, one of the most effective methods to reduce the time venting to atmospheric pressure would be to ensure that an operator remains on site for the duration of a manual unloading operation. However, one commentator stressed that the requirement to have an operator onsite for the entire duration of a wellbore liquids unloading operation is burdensome, especially to small businesses. An unloading operation can take a significant amount of time, which is typically spent by an operator travelling to another site to initiate another unloading operation. The operator then travels back to each site, ending each unloading operation in turn. The time spent by an operator onsite would necessitate hiring significant additional staff that small businesses cannot easily afford.

Therefore, the Department has removed the requirement that the owner or operator shall ensure that an operator remains on site for the duration of a manual unloading operation. The requirement that the owner or operator use BMP including, but not limited to, a plunger lift system, soaping, swabbing, or venting to atmospheric pressure to minimize methane and VOC emissions during wellbore liquids unloading operations to mitigate emissions. In all cases, where technically feasible, the owner or operator shall direct the gas to a separator, storage vessel, or control device, unless it is necessary to vent to the atmosphere for safety.

XXI. Sources Specific to GP-5

A. Natural Gas-Fired Combustion Units

There are many different combustion units used at natural gas production and processing facilities. Some are small integrated units, typically rated at less than 2.5 MMBtu/h, such as those found on gas production units (GPU), heated flash separators, or glycol dehydration units. Others are large units, some larger than 10 MMBtu/h, such as the fractionation column heaters found at natural gas processing plants.

Often when natural gas first exits the wellbore, it contains free water, condensate, and water vapor that must be removed from the natural gas stream. GPUs perform this task, and many have small boilers that facilitate the removal of natural gas from the liquids stream through flashing, which volatilizes the gas from the liquids. In dry-gas regions, the liquid is primarily water, and is referred to as produced water. In rich-gas regions, the high percentage of condensate in the natural gas stream often requires further processing to ensure that the water and condensate are separated. Heated flash separator units are used for this purpose and are also equipped with small boilers to facilitate the condensate removal from the water by flashing. The flow of the natural gas and liquids through the GPUs and heated flash separator units are often controlled by integrated controllers and pumps.

Combustion units with a rated capacity of less than 10 MMBtu/h of heat input fired on natural gas supplied by a public utility are exempt from plan approval and operating permit requirements by the Air Quality Permit Exemptions document. Under Category 39 of the final Air Quality Permit Exemptions document, combustion units rated at less than 10 MMBtu/h firing natural gas supplied by an independent producer shall be exempt from plan approval, and the General Permits may function as the required operating permit. Even though the combustion units are exempt from plan approval and/or operating permits, the owner or operator will be required to list these sources in the *Application for*

NMED Exhibit 52

Authorization to Use GP-5 or GP-5A for reference purposes to ensure compliance with the facility emissions limits. Any associated fugitive emissions components, controllers, and pumps will be subject to their respective requirements of the General Permit.

Table 12 identifies the applicable BAT emission limitations for combustion units rated greater than or equal to 10 MMBtu/h and less than or equal to 50 MMBtu/h:

Table 12 - BAT Emission Limits for Natural Gas-Fired Combustion Units

Constructed After:	NO_X (ppmvd @ 3% O_2)	CO (ppmvd @ 3% O_2)	PM (lb/MMBtu)	Opacity (No more than 3 minutes in an hour)	Opacity (At any time)
December 2, 1995	30	300	0.4	20%	60%
August 8, 2018	30	130	0.4	10%	30%

1. NO_X Limit

The Department has found that there are few vendors that offer natural gas-fired combustion units with a NOx emission rate of lower than 30 ppmvd corrected at 3% oxygen. These units are typically used in production facilities for producing steam. However, GP-5 includes combustion units including, but not limited to, heated flash separator units, evaporator units, fractionation column heaters, and glycol dehydrator reboilers. Typically, these combustion units are rated at less than 10 MMBtu/hr, which are exempted from permitting. Due to the availability of limited emissions data for units operating at natural gas production, compression and transmission facilities, the Department has established a NOx emission limit for natural gas-fired combustion units at 30 ppmvd corrected @ 3% oxygen. The Department will continue to evaluate NOx emissions data from these units.

2. CO Limit

The CO emission limit of 130 ppmvd corrected to 3% oxygen is consistent with the CO limit established in 40 CFR Part 63 Subpart DDDDD. Specifically, Table 1, Item 16 in Subpart DDDDD establishes for new or reconstructed boilers and process heaters the above-noted CO limit for "units designed to burn light liquid fuel." While this limit is specific to light liquid fuels, like No. 2 fuel oil, the Department proposed this limit for both No. 2 fuel oil and natural gas.

B. Natural Gas-Fired Simple Cycle Turbines

A simple cycle turbine is an internal combustion engine that operates with rotary rather than reciprocating motion. A turbine is composed of three major components: the compressor, the combustor, and the power turbine. In the compressor section, ambient air is drawn in and compressed up to 30 times the ambient pressure and directed to the combustor section where fuel is injected, ignited, and burned. The resultant gases are diluted with additional air from the compressor section and are expanded through the power turbine section, which consists of a series of rotors and stators to extract mechanical work via a shaft. A portion of the generated shaft power is used to drive the internal compressor; the rest is directed to external load. At natural gas compression stations, natural gas processing facilities, and natural gas transmission stations, turbines are used mainly as prime movers to drive centrifugal compressors or generators.

NMED Exhibit 52

1. Emissions from Natural Gas-Fired Turbines

Natural gas-fired turbines produce many of the same pollutants as SI-RICE which are emitted from the exhaust, depending on the composition of the fuel used. In addition, PM emissions are an issue for turbines due to the high exhaust flows. Since formaldehyde emissions from natural gas-fired turbines are on the order of 7.10×10^{-4} lb/MMBtu uncontrolled as per EPA's AP-42 Emissions Factors, a 30,000 hp simple cycle turbine may emit approximately 0.6 tpy. However, this size turbine is required to install an oxidation catalyst, which would also reduce formaldehyde by 85-90%. Therefore, the Department has not established a formaldehyde limit for simple cycle turbines. Natural gas is the primary fuel used by the natural gas industry and is the only fuel authorized by GP-5.

2. Emission Control Technology

Several technologies may be used to control emissions from turbines. They primarily fall into two categories: combustion control and post-combustion control.

a. Combustion Control

Control of combustion temperature has been the principal focus of combustion process control in turbines. Combustion control requires tradeoffs – higher temperatures favor complete consumption of the fuel and lower residual hydrocarbons and CO, but result in NO_X formation. Lean combustion dilutes the fuel mixture and reduces combustion temperatures and NO_X formation.

Because the NO_X produced by combustion turbines is primarily thermal NO_X, reducing the combustion temperature will result in less NO_X production. Thus, the most common strategy for NO_X control is to control the combustion temperature. This is often done by using wet methods, such as steam or water injection, or dry methods, such as lean combustion or two-stage combustion.

i. Steam or Water Injection

Steam or water injection has been demonstrated to effectively suppress NO_X emissions from turbines. The effect of steam or water injection is to increase the thermal mass by dilution and thereby reduce peak temperatures in the flame zone. Steam or water is typically injected at a water-to-fuel weight ratio of less than one. Depending on the initial NO_X levels, such rates of injection may reduce NO_X by 60% or more. Both CO and VOC emissions are increased by steam or water injection, and the level of increase will depend on the water-to-fuel weight ratio.

ii. Dry Controls

Since thermal NO_X is a function of both temperature and time, the basis of dry controls is to either lower the combustor temperature using lean mixtures of air and fuel, fuel staging, or decreasing the residence time of the combustor. A combination of these methods may also be used to reduce NO_X emissions.

Lean combustion involves increasing the A/F ratio of the mixture so that the peak and average temperatures within the combustor will be less than that of the stoichiometric mixture, thus suppressing thermal NO_X formation. Introducing excess air not only creates a leaner mixture, but also reduces residence time at peak temperatures.

Two-stage combustion can be broken down into lean/lean and rich/lean staging, which both serve to reduce NO_X. In lean/lean staging, the combustor is a fuel-staged premixed combustor that operates at an extremely lean A/F ratio. A small stoichiometric pilot flame ignites the premixed gas to provide flame

NMED Exhibit 52

stability. Because the NO_X emissions from the high temperature pilot flame are insignificant and the combustor is designed to operate at lower flame temperatures and to avoid localized "hot spots," low NO_X emission levels are achieved. In rich/lean staging, the combustor is an air-staged premixed combustor where the primary zone is operated fuel rich and the secondary zone is fuel lean. The fuel-rich zone operates at an A/F ratio less than one, which produces higher concentrations of CO and decreases the amount of NO_X due to a lack of available oxygen and lower flame temperatures. The exhaust from the primary zone is then quenched and mixed with large amounts of air, creating a lean mixture which is pre-ignited and introduced to the secondary zone where combustion is completed. The lower temperature and lean mixture results in low NO_X emission levels. Staged combustion is identified through a variety of names, including Dry-Low NO_X (DLN), Dry-Low Emissions (DLE), or $SoLoNO_X$.

b. Post-Combustion Emission Reduction Technology for Turbines

i. Oxidation Catalyst (for CO and NMNEHC reduction)

Oxidation catalysts using platinum and palladium are effective for lowering CO, NMNEHC, and formaldehyde levels in exhaust emissions from turbines. For this analysis, the Department has determined that an oxidation catalyst is economically feasible for turbines if the cost per ton of CO and NMNEHC removal is approximately $5,000; see Appendix C – Oxidation Catalyst and NSCR Cost Analysis for Engines and Turbines.

ii. Selective Catalytic Reduction (for NO_X reduction)

SCR is technically feasible on turbine exhaust streams, and the systems operate much like they do on engine exhaust streams. Urea or ammonia is typically used in SCR systems that control turbine NO_X emissions, which also results in ammonia emissions. For this analysis, the Department has determined that SCR is economically feasible for turbines if the cost per ton of NO_X removal is approximately $10,000; see Appendix B – SCR Cost Analysis for Engines and Turbines.

3. Turbine Size Grouping

The Department chose to slightly alter the turbine size groups for natural gas compression stations, natural gas processing plants, and natural gas transmission stations. In the previous GP-5, the turbines were placed into the following categories:

- Greater than or equal to 1,000 bhp but less than 5,000 bhp;
- Greater than or equal to 5,000 bhp but less than 15,000 bhp; and
- Greater than or equal to 15,000 bhp.

In the final GP-5, the turbines were placed into the following categories:

- Greater than or equal to 1,000 bhp but less than 5,000 bhp;
- Greater than or equal to 5,000 bhp but less than 15,900 bhp; and
- Greater than or equal to 15,900 bhp.

4. Turbine Emission Limits

New sources are required to control the emission of air pollutants to the maximum extent, consistent with BAT as determined by the Department. The Department evaluated uncontrolled emissions, control

NMED Exhibit 52

efficiency of various controls and associated costs, and stack test results for turbines to establish BAT. In the following sections, all references to the pollutant concentrations are given as ppm @ 15% O_2.

a. Turbines Rated Greater Than or Equal To 1,000 bhp but Less Than 5,000 bhp

Vendor data for turbines greater than or equal to 1,000 bhp but less than 5,000 bhp gave uncontrolled emission rates of 25 ppm NO_X, 25 ppm CO, and 25 ppm THC as methane. This was the basis of the BAT from the previous GP-5, and the THC emission rate was converted to NMNEHC as propane, establishing an emission rate of 9 ppm NMNEHC as propane.

SCR cost estimations were based on vendor quotes, cited as from Vendor A and Vendor B. It was assumed that the control efficiency for SCR is 90% for NO_X. All oxidation catalyst cost estimations were based on vendor data, with the costs quoted in 2007 dollars. The costs in the analysis were then multiplied by the CPI of 1.16 for inflating 2007 dollars to 2016 dollars. It was assumed that the control efficiencies for oxidation catalysts are 93% for CO and 50% for NMNEHC. See Appendix B – SCR Cost Analysis for Engines and Turbines and Appendix C – Oxidation Catalyst and NSCR Cost Analysis for Engines and Turbines for the analyses.

Using the uncontrolled and BAT emission rates, the assumed control efficiencies, and assuming full-year operation, the control cost for an oxidation catalyst for turbines greater than or equal to 1,000 bhp but less than 5,000 bhp is estimated between $8,142 and $13,810 per ton of pollutants reduced. The Department determines that an oxidation catalyst is not economically feasible based on the cost-effectiveness benchmark of approximately $5,000 per ton of pollutant reduced. Therefore, BAT for turbines greater than or equal to 1,000 bhp but less than 5,000 bhp are emission limits of 25 ppm for CO and 9 ppm for NMNEHC as in the previously issued GP-5.

Using the BAT emission rates, the assumed control efficiencies, and assuming full-year operation, the control cost for SCR for turbines greater than or equal to 1,000 bhp but less than 5,000 bhp is estimated between $11,622 and $18,853 per ton of NO_X reduced. The Department determines SCR is not BAT for turbines greater than or equal to 1,000 bhp but less than 5,000 bhp because it is not economically feasible based on a cost-effectiveness benchmark of $10,000 per ton of NO_X reduced and the emission limit remains 25 ppm for NO_X as in the previously issued GP-5.

b. Turbines Rated Greater Than or Equal To 5,000 bhp but Less Than 15,900 bhp

Vendor data for turbines greater than or equal to 5,000 bhp but less than 15,900 bhp gave uncontrolled emission rates of 25 ppm NO_X, 25 ppm CO, and 25 ppm THC as methane. This was the basis of the BAT from the previous GP-5 for CO and NMNEHC, and the THC emission rate was converted to NMNEHC as propane, establishing an emission rate of 9 ppm NMNEHC as propane. BAT for NO_X was established as 15 ppm based on stack test results.

Using the uncontrolled and BAT emission rates, the assumed control efficiencies, and assuming full-year operation, the control cost for an oxidation catalyst for turbines greater than or equal to 5,000 bhp but less than 15,900 bhp is estimated between $4,836 and $6,612 per ton of pollutants reduced. However, according to stack test data, emission rates of 10 ppm CO and 5 ppm NMNEHC are achievable without control. Using the stack test emission rates, the assumed control efficiencies, and assuming full-year operation, the control cost for an oxidation catalyst for turbines greater than or equal to 5,000 bhp but less than 15,900 bhp is estimated between $11,082 and $15,153 per ton of pollutants reduced. Therefore, it is the Department's determination that turbines greater than 5,000 bhp but less than 15,900 bhp have BAT criteria with emission limits of 10.00 ppm for CO and 5.00 ppm for

NMED Exhibit 52

NMNEHC whether attained through use of an oxidation catalyst or good combustion engineering practices.

Using the uncontrolled emission rates, the assumed control efficiencies, and assuming full-year operation, the control cost for SCR for turbines greater than or equal to 5,000 bhp but less than 15,900 bhp is estimated between $7,714 and $9,810 per ton of NO_X reduced. Using the BAT emission rates, the assumed control efficiencies, and assuming full-year operation, the control cost for SCR for turbines greater than or equal to 5,000 bhp but less than 15,900 bhp is estimated between $12,858 and $16,351 per ton of NO_X reduced. Therefore, it is the Department's determination that turbines greater than 5,000 bhp but less than 15,900 bhp have BAT criteria with emission limits of 15.00 ppm for NO_X whether attained through use of an SCR or good combustion engineering practices.

c. Turbines Rated Greater Than or Equal To 15,900 bhp

Vendor data for turbines greater than or equal to 15,900 bhp gave uncontrolled emission rates of 25 ppm NO_X, 25 ppm CO, and 25 ppm THC as methane. This was the basis of establishing oxidation catalysts as BAT from the previous GP-5 for CO and NMNEHC, and the THC emission rate was converted to NMNEHC as propane, establishing an emission rate of 9 ppm NMNEHC as propane. An alternative BAT of 10 ppm CO and 5 ppm NMNEHC based on stack test results was offered in the previous GP-5. BAT for NO_X was established as 15 ppm also based on stack test results.

Using the uncontrolled emission rates, the assumed control efficiencies, and assuming full-year operation, the control cost for an oxidation catalyst for turbines greater than or equal to 15,900 bhp is estimated between $3,576 and $4,321 per ton of pollutants reduced. Using the alternative BAT emission rates, the assumed control efficiencies, and assuming a full year of operation, the control cost for an oxidation catalyst for turbines greater than or equal to 15, 900 bhp is estimated between $8,243 and $9,903 per ton of pollutants reduced. Therefore, it is the Department's determination that turbines greater than 15,900 bhp have dual BAT criteria with emission limits of 10.00 ppm for CO uncontrolled or 1.75 ppm for CO through use of an oxidation catalyst. It is the Department's determination that turbines greater than 15,900 bhp have BAT criteria with emission limits of 5.00 ppm for NMNEHC whether attained through use of an oxidation catalyst or good combustion engineering practices.

Using the BAT emission rates, the assumed control efficiencies, and assuming full-year operation, the control cost for SCR for turbines greater than or equal to 15,900 bhp is estimated to be less than $11,466 per ton of NO_X reduced. The Department determines SCR is BAT for turbines greater than or equal to 15,900 bhp. However, recently issued permits and plan approval applications show turbines greater than or equal to 15,900 bhp are capable of achieving 9.0 ppm for NO_X uncontrolled. Using the 9.0 ppm emission rate, the assumed control efficiencies, and assuming full-year operation, the control cost for SCR for turbines greater than or equal to 15,900 bhp is estimated to be between $16,946 and $19,106 per ton of NO_X reduced.

Most SCR vendors guarantee NO_X emissions reduction of 90% or more and therefore, with an uncontrolled baseline NOx emission rate of 15 ppmvd corrected to 15% oxygen, which is established as achievable, the Department proposed a NO_X emission limit of 1.5 ppmvd @ 15% O_2. The Department has permitted several turbines equipped with SCR with emission limits of 2 to 2.5 ppmvd NO_X @ 15% O_2. The stack test results for these turbines show NOx emissions range from 1.6 to 1.8 ppmvd. Therefore, the Department has determined that 2.0 ppmvd NO_X @ 15% O_2 is BAT in the final GP-5 for turbines rated greater than or equal to 15, 900 hp.

NMED Exhibit 52

Therefore, it is the Department's determination that turbines greater than or equal to 15,900 bhp have dual BAT criteria with emission limits of 9.00 ppmvd for NO_X uncontrolled and 2.0 ppmvd for NO_X through use of SCR.

Table 13 - BAT Emission Limits for Existing Turbines

Turbine Rating (bhp)	NO_X (ppmvd @ 15% O_2)	CO (ppmvd @ 15% O_2)	NMNEHC (as propane) (ppmvd @ 15% O_2)	Total PM (lbs/MMBtu)
1,000 ≤ TR < 5,000	25	25	9.0	0.03
5,000 ≤ TR < 15,000	15	25	9.0	0.03
≥ 15,000	15	10. **or** 93% reduction	5.0 **or** 50% reduction	0.03

Table 14 - Proposed BAT Emission Limits for New Turbines

Turbine Rating (bhp)	NO_X (ppmvd @ 15% O_2)	CO (ppmvd @ 15% O_2)	NMNEHC (as propane) (ppmvd @ 15% O_2)	Total PM (lbs/MMBtu)
1,000 ≤ TR < 5,000	25	25	9.0	0.03
5,000 ≤ TR < 15,900	15	10.	5.0	0.03
≥ 15,900	9.0 Uncontrolled or 2.0 with Control	10. Uncontrolled or 1.8 with Control	5.0	0.03

In addition, the turbines shall comply with all applicable requirements specified in 40 CFR Part 60, Subpart KKKK.

However, for all previous versions of the GP-5, the Department's BAT requirements are more stringent than those required under Subpart KKKK. Therefore, by complying with the Department's BAT requirements, the owner or operator of a turbine will be guaranteed compliant with the applicable requirements of 40 CFR Part 60 Subpart KKKK.

Visible emissions shall not meet or exceed 10% opacity for a period or periods aggregating more than three minutes in any one hour nor meet or exceed 30% opacity at any time.

Based on the comments received, the Department added a provision that the owner or operator shall also operate the turbine and air pollution control equipment consistent with good air pollution control practices during periods of low ambient air temperature (at or below 0 °F) during which times the emission standards do not apply. This is consistent with the requirements of 40 CFR Part 60 Subpart KKKK.

5. Turbine Core Replacement

A turbine core must be done in accordance with the terms and conditions of the GP-5; these terms and conditions are consistent with turbine core replacement requirements established for landfill gas-fired turbines in GP-22.

C. Centrifugal Natural Gas Compressors

Like reciprocating natural gas compressors, centrifugal natural gas compressors are used to increase the pressure of natural gas in a pipeline in order to take advantage of the property of fluids moving from high-pressure to low-pressure areas. In a centrifugal compressor, however, rotary motion from the prime mover is used to drive an impeller that imparts energy into the gas which serves to increase its pressure. There can be multiple stages of impellers that can generate a large change in pressure.

Like the reciprocating natural gas compressor, the centrifugal compressor has a shaft that must be sealed to reduce wear and maintain gas pressure. These seals can be either dry or wet; the wet seal uses an oil film in its operation. However, the oil used in a wet seal system collects natural gas, which must be removed in order to maintain the seal effectiveness.

It is not typical for centrifugal compressors to be installed at an unconventional natural gas well site. According to 40 CFR Part 60, Subparts OOOO and OOOOa, centrifugal compressors located at well sites are not affected facilities. The Department is therefore not proposing to authorize centrifugal compressors at unconventional well sites or remote pigging stations through the GP-5A; centrifugal compressors at natural gas compression stations, processing plants, and transmission stations are authorized in the GP-5.

1. Existing Centrifugal Natural Gas Compressors

The owner or operator of an existing wet seal centrifugal natural gas compressor shall continue to comply with the 95% control and other applicable requirements specified in 40 CFR Part 60, Subpart OOOO, which are incorporated by reference in the GP-5.

2. New Centrifugal Natural Gas Compressors

40 CFR Part 60, Subpart OOOOa requires centrifugal compressor to be equipped with dry seal or wet seal where methane and VOC emissions from the wet seal degassing system is reduced by 95% or more. Based on the Department's evaluation, no additional requirements are needed. Therefore, the Department determines that the recently promulgated requirements of 40 CFR Part 60, Subpart OOOOa are determined to be BAT.

D. Natural Gas Fractionation Process Units

Condensates, or NGLs, are an important product of natural gas production. In much of the production segment, the condensates are separated from the natural gas stream and stored in tanks before eventually being shipped to a processing plant via truck. However, condensates are still part of the natural gas stream and may fall out during transport in a pipeline. The fluid buildup can cause flow problems, which are typically cleaned through a pigging operation. In this case, the NGLs can be sent to a tank called a slug catcher which may be located at a compression station or processing plant. The liquids at a compression station are also commonly transported via a truck.

NMED Exhibit 52

Natural gas fractionation is the process of separating the various hydrocarbons in NGLs by extracting them in sequence in heated columns. Any methane, which is the lightest of the hydrocarbons, remaining in the condensate is separated first, and put into the pipeline for transmission and storage. Then ethane, propane, and butane are removed in turn and sent to their respective storage tanks; butane may be further divided into isobutane and n-butane. The heavier NGLs are called natural gasoline and will typically be sent to another plant for further refinement.

Potential emissions from natural gas fractionation units are from the process heaters and the fugitive emissions associated with piping, valves, flanges, pumps, compressors, and pressure relief devices. Process heaters for fractionation columns eligible for authorization under the GP-5 range in size up to 50 MMBtu/h. Combustion units rated less than 2.5 MMBtu/h are exempt from plan approval by 25 Pa. Code §127.14(a). Under Category 39 of the Air Quality Permit Exemptions document, combustion units rated less than 10 MMBtu/h firing natural gas supplied by an independent producer shall be given the same consideration given to similarly sized sources that fire natural gas provided by a public utility. Even though the process heaters described are exempt, these sources will be listed in the permit for reference purposes. However, emissions from these exempt units must be included in the facility emissions totals for tracking compliance with the General Requirements (i.e., the 12-month rolling sum must remain below the major source emissions thresholds) and in the annual emissions inventory.

Natural gas processing, which includes fractionation, is subject to federal requirements under 40 CFR Part 60, Subpart KKK for units which were constructed, reconstructed, or modified after January 20, 1984, and on or before August 23, 2011. After August 23, 2011, and on or before September 18, 2015, fractionation process units are subject to the requirements of 40 CFR Part 60, Subpart OOOO. After September 18, 2015, fractionation process units are subject to the requirements of 40 CFR Part 60, Subpart OOOOa. In all cases, the primary standards are monitoring for equipment leaks using 40 CFR Part 60, Appendix A-7, Method 21.

Because potential emission sources associated with natural gas fractionation are addressed individually, i.e. in the sections related to combustion units and fugitive emissions components, a separate section for natural gas fractionation units was not incorporated into the final General Permit.

E. Sweetening Units

Natural gas from some wells contains sulfur and carbon dioxide, which must be removed to protect personnel, the environment, and equipment. Sulfur typically exists in natural gas in the form of hydrogen sulfide (H_2S), and natural gas where the H_2S content exceeds 4 ppm is referred to as sour gas. The process for removing H_2S from sour gas is called sweetening the gas.

The primary process for sweetening sour gas is similar to the process of glycol dehydration. An amine solution is used to remove the H_2S by passing the sour gas through a tower where it contacts the solution and is absorbed. There are two primary amine solutions used, monoethanolamine (MEA) and diethanolamine (DEA). Either of these compounds, in liquid form, will absorb sulfur compounds and CO_2 from the sour gas leaving the effluent gas virtually free of these contaminants. Both MEA and DEA can be regenerated and the resultant gases can be used to feed a Claus process, which involves using thermal and catalytic reactions to extract elemental sulfur from the hydrogen sulfide solution.[27]

Potential emissions from sweetening units are from the process heaters; the fugitive emissions associated piping, valves, flanges, pumps, compressors, and pressure relief devices; and the tail gas of

[27] NaturalGas.org, last accessed on May 24, 2018.

NMED Exhibit 52

the Claus process. Process heaters for sweetening units are eligible for authorization under the GP-5 up to 50 MMBtu/h in size. Combustion units rated less than 2.5 MMBtu/h are exempt from plan approval by 25 Pa. Code §127.14(a). Under Category 39 of the Air Quality Permit Exemptions document, combustion units rated less than 10 MMBtu/h firing natural gas supplied by an independent producer shall be given the same consideration given to similarly sized sources that fire natural gas provided by a public utility. Even though the described process heaters are exempt, these sources will be listed in the permit for reference purposes. However, emissions from these exempt units must be included in the facility emissions totals for tracking compliance with the General Requirements (i.e., the 12-month rolling sum must remain below the major source emissions thresholds) and in the annual emissions inventory.

Sweetening units are subject to federal requirements under 40 CFR Part 60, Subpart LLL for units which were constructed, reconstructed, or modified after January 20, 1984, and on or before August 23, 2011. After August 23, 2011, and on or before September 18, 2015, sweetening units are subject to the requirements of 40 CFR Part 60, Subpart OOOO. After September 18, 2015, sweetening units are subject to the requirements of 40 CFR Part 60, Subpart OOOOa. The standards are for a target control efficiency for SO_2 emissions based on sulfur production.

Because the Authorization to Use the GP-5 and GP-5A cannot be granted to facilities that produce or process sour gas as shown in the basic calculations in the section on Oxides of Sulfur in General Methodology of Determining Best Available Technology, the SO_2 emissions limits from the federal regulations were not included in the General Permits. Should a sweetening unit be needed to remove excess CO_2, the potential emissions sources from the sweetening unit are addressed individually, i.e., in the sections on combustion units and fugitive emissions components, and therefore a separate section on sweetening units was not incorporated into the General Permits.

Average of Columns (C through N) Methane de minimis (TPY)					714.9								

The general methodology for determining the methane control threshold is to calculate the amount of methane in a natural gas release relative to the amount of VOC that reaches the VOC control threshold using a standard mass-balance calculation. Using twelve different gas samples, the methane control thresholds ranged from a minimum of 21.2 tpy to a maximum of 1,615.3 tpy. The average of the twelve calculated control thresholds is 714.9 tpy, which is 17,872 tpy of CO_{2e}. This value is nearly 25% of the 75,000 tpy CO_{2e} major modification facility threshold for greenhouse gases.

Therefore, the Department calculated an average gas composition from the twelve samples and followed the same methodology for determining the methane control threshold with a result of 191.6 tpy. The Department conservatively used 200 tpy methane to account for the scientific uncertainty due to the limited number of gas samples used in the calculation, which is equivalent to 5,000 tpy CO_{2e}. This is approximately 7% of the facility greenhouse gas threshold and is much more reasonable to use as the methane control threshold.

However, several commentators stated that the Department's calculated average gas composition was not representative of natural gas in Pennsylvania because of its small sample size and limited geographic scope. To improve the average gas composition calculation, the Department decided to expand the scope of the analysis. For every county with wells displayed on eMapPA, the Department attempted to obtain at least five reasonable representative gas analyses, two from compressor stations or processing plants, and three from unconventional natural gas well sites. The sample included 59 representative gas analyses across all of the regions with oil and gas activity including the Southwest, Northwest, North Central, and Northeast Regions of Pennsylvania. The Department then calculated a county average gas composition for each county, and a state average gas composition by averaging the county average gas compositions. Therefore, the Department reduced the scope of scientific uncertainty based on geographic location.

Average of per County Methane De Minimis					444.0																			

The average composition for the counties with at least one representative gas analysis and the calculated state average gas composition are shown in Table 16. The Department believes that this state average gas composition is representative of the regions where oil and gas operations are occurring. The same process was followed as in the previous analysis, where methane emissions were calculated based on a standard mass-balance and the VOC control threshold of 2.7 tpy for each county. The methane control thresholds ranged from 5.8 tpy for Mercer County and 1,474.8 tpy for Somerset County with an average methane control threshold of 444.0 tpy. While this value is lower than the 714.9 tpy value of the previous analysis, the Department determined that it is unreasonable to be used as a control threshold; this is because it is approximately 15% of the major modification facility threshold for GHG. For the calculated state average composition, the methane control threshold is calculated at 51.9 tpy; this is lower than in the previous calculation because there were more representative gas analyses with VOC weight percentages higher than 2%.

In the first analysis, there were only two samples with VOC weight percentages over 2% and one of them was questionable due to the high nitrogen content; this means only 10% - 17% of the samples had a VOC weight percentage over 2%. In the second analyses, approximately 25% of the samples had VOC weight percentages over 2%; half of those samples had VOC weight percentages over 5% and one had a VOC weight percentage over 25%. This higher VOC weight percentage had the effect of lowering the methane emissions calculated from the mass-balance and increasing the VOC weight percentage of the state average gas composition from 1.25% in the first analysis to 4.47% in the second analysis. The 51.9 tpy methane control threshold calculated from the state average gas composition is approximately 2% of the major modification facility threshold for GHG meaning it is appropriate to use it as a control threshold in the permit. However, as is shown in the analysis in Appendix D for Combustion Control Devices, control of methane at 51.9 tpy is not cost-effective.

Cost Per Ton	$18,853	$4,874	$7,329	$8,124	$12,215	$13,538	$20,355

Because the quotes furnished to the Department by the vendors were determined based on the assumption of 8,760 hours of operation, the Department proposes to determine cost effectiveness of the control of NO_X with an SCR system without regard to variability of hours of operation.

The Department proposed to use the average of the total annual costs for each engine size as determined in Table 17 and Table 18 above as a point on a line to determine the cost effectiveness of SCR for sizes for which a quote was not obtained. The reason for using the average total annual cost versus the average cost in dollars per ton is that the emission limit for NO_X emissions for engines rated equal to or less than 500 hp is 1.0 g/bhp-h while for engines rate greater than 500 hp the emission limit for NO_X is 0.5 g/bhp-h. This difference in emission limits would not be reflected using the average cost in dollars per ton, as can be seen in Table 20 below.

Table 20 - Calculated Cost per Ton NO_X Reduced vs Average Cost per Ton NO_X Reduced for Engines

Engine HP (All dollar values in 2016 dollars)	100	250	500	1,000	1,380	1,500	1,875	2,500	3,000	4,735	5,500
Average Total Annual Costs	$54,650	$56,097	$58,509	$63,334	$67,000	$68,158	$71,777	$77,807	$82,632	$99,373	$106,754
TPY of NO_X Emissions Reduced	0.87	2.17	4.34	4.34	5.99	6.51	8.14	10.85	13.02	20.56	23.88
Cost Per Ton	$62,940	$25,843	$13,477	$14,588	$11,183	$10,466	$8,818	$7,169	$6,344	$4,834	$4,471
Average Cost Per Ton	$13,603	$13,320	$12,847	$11,901	$11,182	$10,955	$10,245	$9,063	$8,117	$4,834	$3,387
TPY of NO_X Emissions Reduced, Alternative BAT							5.70	7.60	9.12	14.39	16.71
Alternative Cost Per Ton							$12,597	$10,241	$9,064	$6,906	$6,387

The Department proposed that installing an SCR system on lean-burn engines rated at or above 1,875 hp is BAT if the uncontrolled emission rate is 0.50 g/bhp-h, resulting in an emission limit of 0.05 g/bhp-h. However, engine stack test data shows that engines in this size range are capable of achieving an uncontrolled emissions rate of 0.35 g/bhp-h. As can be seen in Table 20 above, SCR is not economically feasible for an engine with uncontrolled emissions rate of 0.35 g/bhp-h until an engine is rated at or above 3,000 hp. Therefore, the Department proposed dual BAT criteria for lean-burn engines rated at or above 1,875 hp and less than 3,000 hp of 0.35 g/bhp-h uncontrolled or 0.05 g/bhp-h with control. The Department proposed a BAT criterion for lean-burn engines rated at or above 3,000 hp of 0.05 g/bhp-h.

Based on additional information submitted and comments received, the Department determined that the installation of SCR should be reevaluated for cost effectiveness. One of the issues raised is that the original BAT cost estimates did not include direct installation costs. Even though the EPA's Air Pollution Control Cost Manual 6th Edition Section 4.2 did not include direct installation costs in Table 2.5, and the 7th Edition Section 4.2 calculates the TCI based on operational parameters, the Department used vendor quotes and the standard cost estimate method from Section 1 of the 6th Edition to calculate cost effectiveness. There appears to be little difference in the method in Section 1 of the 7th Edition except for the use of the bank prime rate of 4.25% for the annualization of capital costs. The Department continues to use the 7% rate from the previous analysis for consistency.

Cost Per Ton								$3,495	$1,848						

[1] Quote included instrumentation.

[2] Company used interest rate and/or equipment life different than EPA directed 7.0% interest rate and 20 years equipment life.

[3] Quote included oxidation catalyst.

[4] Company made arithmetic error; listed PEC as $517,942 when $495,685 + $58,257 = $553,942.

[A] The Department orginially used the Capital Cost Factors from Table 2.5 in the October 2000 version of the Control Cost Manual. The updated chapter uses a base equation to calculate TCI. The Department uses the base OAQPS calculation method in the reanalysis, which may result in an overestimation of cost.

TPY of NO_X Emissions Reduced	13.70	14.39	13.70	14.39	14.39	14.39	11.74	12.33	12.90	13.94	12.90	13.94	12.90	13.94
Cost Per Ton	$17,315	$9,082	$26,869	$9,112	$6,890	$9,082	$19,370	$15,145	$17,009	$12,432	$19,497	$12,045	$18,935	$10,282
TPY of All Polutants Emissions Reduced									133.27	134.31				
Cost Per Ton									$1,646	$1,290				

[1] Quote included instrumentation.

[2] Company used interest rate and/or equipment life different than EPA directed 7.0% interest rate and 20 years equipment life.

[3] Quote included oxidation catalyst.

[4] Company made arithmetic error; listed PEC as $517,942 when $495,685 + $58,257 = $553,942.

[5] Company included sales tax in their calculation. Under 61 Pa. Code §32.35, pollution control devices are exempt from tax in mining operations, which includes oil and gas drilling. Under 61 Pa. Code §155.11, pollution control devices are deductable from property tax calculations.

[6] Company included $20,000 Testing and QA/QC costs in the Direct Annual Costs.

[7] Calculated NO_X reduction to limit of 0.05 g/bhp-h rather than by 90% control.

[8] Site Preparation Costs of $52,741 were included.

[9] The Department included the additional $2,340 for the Maintenance Pack listed in the scope of supply.

[10] The oxidation catalyst costs were removed from the system cost; however, the company did not pro-rate any other costs in their analysis. The Department prorated all costs based on the ratio of costs for the oxidation catalyst to the SCR system.

[A] The Department orginially used the Capital Cost Factors from Table 2.5 in the October 2000 version of the Control Cost Manual. The updated chapter uses a base equation to calculate TCI. The Department uses the base OAQPS calculation method in the reanalysis, which may result in an overestimation of cost.

Table 23 - Derivation of Average Total Annual Cost Parameters

Based on the costs determined in Table 24 above, and the cost-effectiveness threshold of $10,000 per ton of NO_X reduced, SCR is cost effective for engines greater than or equal to 2,370 hp if the starting NO_X emission rate is 0.50 g/bhp-h. Installation of SCR becomes economically infeasible for engines greater than or equal to 2,370 hp if the starting NO_X emission rate is 0.30 g/bhp-h. For this reason, the Department proposes a dual BAT criterion for lean burn engines greater than or equal to 2,370 hp of 0.30 g/bhp-h NO_X uncontrolled, or 0.05 g/bhp-h NO_X with control.

Following the original methodology described above for engines with the turbine data results in cost per ton and average cost per ton as summarized in Table 5 below. The BAT emissions limits of 25 ppm for NO_X for turbines below 5,000 bhp, of 15 ppm for turbines 5,000 bhp and above were used in the analysis.

Table 25 - Calculated Cost per Ton NO_X Reduced vs Average Cost per Ton NO_X Reduced for Turbines using BAT Emissions

Turbine HP (All dollar values in 2016 dollars)	1,000	1,590	3,000	5,000	6,130	7,500	11,150	15,900	17,500	20,000	25,000	30,000
Average Total Annual Costs	$107,277	$113,040	$130,449	$153,621	$166,713	$182,586	$224,875	$279,908	$298,446	$327,411	$385,341	$423,291
TPY of NO_X Emissions Reduced, Uncontrolled	6.79	6.00	11.22	15.66	18.95	21.21	29.15	42.75	43.39	48.93	60.02	69.38
Uncontrolled Cost Per Ton	$15,804	$18,853	$11,622	$9,810	$8,799	$8,611	$7,714	$6,547	$6,879	$6,691	$6,420	$6,101
Average Cost Per Ton	$15,912	$15,933	$15,987	$16,062	$16,104	$16,155	$16,292	$16,470	$16,530	$16,624	$16,812	$16,999
TPY of NO_X Emissions Reduced, BAT	6.79	6.00	11.22	9.40	11.37	12.72	17.49	25.65	26.03	29.36	36.01	41.62
BAT Cost Per Ton	$15,804	$18,853	$11,622	$16,351	$14,665	$14,352	$12,858	$10,913	$11,466	$11,153	$10,701	$10,170
TPY of NO_X Emissions Reduced, Alternative BAT								15.39	15.62	17.62	21.61	24.98
Alternative Cost Per Ton								$18,184	$19,106	$18,585	$17,832	$16,946

For turbines rated at 5,000 hp and above with uncontrolled emissions of 25 ppm NO_X, SCR is cost effective. However, for turbines rated 5,000 hp and above but below 15,900 hp and operating at 15 ppm NO_X uncontrolled, SCR is not cost effective. Therefore, for turbines rated at or above 5,000 hp and below 15,900 hp, the Department proposes an emission limit of 15 ppm NO_X. For turbines rated at or above 15,900 hp, SCR is cost effective even when the uncontrolled emission rate is 15 ppm NO_X. However, a recently issued permit in New York establishes a NO_X emission limit of 9 ppm for two Solar Mars Turbines which, according to the Solar Turbines website, are rated at 15,900 bhp. A recent plan approval application to the Department also proposes 9 ppm NO_X for combustion turbines. Based on the availability of these low-emission models, the Department proposes an emission limit of 9 ppm NO_X uncontrolled or 1.5 ppm NO_X with control for turbines greater than 15,900 hp.

XXIV. Appendix C – Oxidation Catalyst and NSCR Cost Analysis for Engines and Turbines

Unlike the methodology used in Appendix B – SCR Cost Analysis for Engines and Turbines for SCR, the Department relied on a memorandum from E $^{C}/_{R}$ Incorporated dated June 29, 2010, to Melanie King at EPA OAQPS/SPPD/ESG for engine emission control devices. The memorandum determined a linear equation for total annual cost for oxidation catalysts for lean-burn engines. The Department then calculated the cost per ton based on weighted average emission rates and on BAT emission rates.

Table 26 - Oxidation Catalyst Cost Analysis for Lean-Burn Engines - Weighted Average Emissions

Engine HP (All dollar values in 2016 dollars)	100	250	500	1,000	1,380	1,500	1,875	2,370	2,500	3,500	4,735	5,500

Cost Per Ton	$1,956	$841	$2,081	$1,257	$1,030	$983	$873	$781	$763	$669	$607	$583

The same memorandum also determined a linear equation for the total annual cost for NSCR for rich-burn engines. As for lean-burn engines, the Department calculated the cost per ton for NSCR on rich-burn engines using the cost per ton based on weighted average emission rates and on BAT emission rates.

Table 28 - NSCR Cost Analysis for Rich-Burn Engines - Weighted Average Emissions

Engine HP (All dollar values in 2016 dollars)	100	250	500	1,000	1,380	1,500	2,500	3,500	4,735	5,500
Total Annual Costs	$6,895	$7,696	$9,032	$11,703	$13,733	$14,374	$19,716	$25,059	$31,657	$35,744

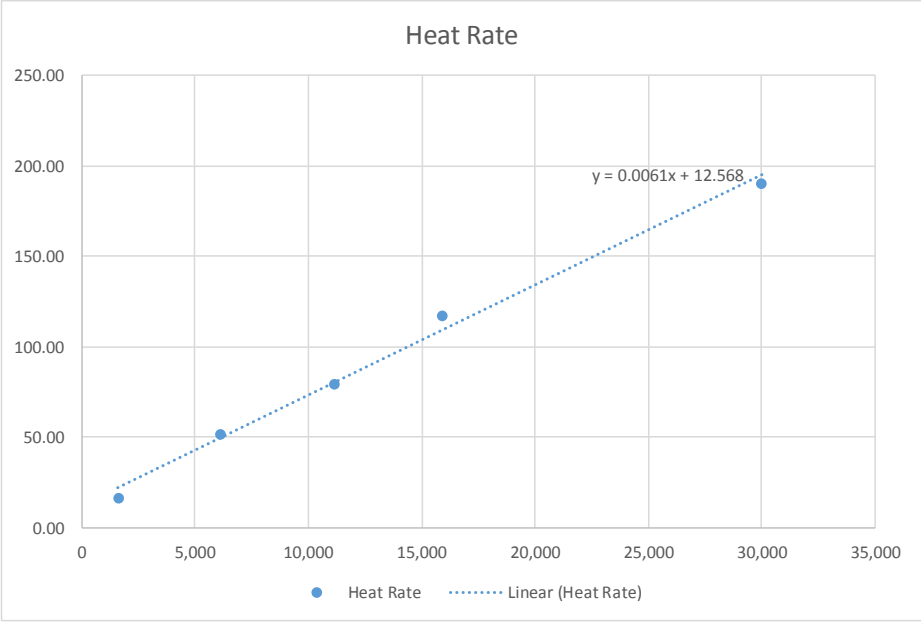
TPY of NMNEHC Emissions Reduced	0.14	0.36	0.72	1.45	2.00	2.17	3.62	5.06	6.85	7.96
Cost Per Ton	$309	$138	$83	$54	$46	$44	$36	$33	$31	$30

Table 29 - NSCR Cost Analysis for Rich-Burn Engines - BAT Emissions



Engine HP (All dollar values in 2016 dollars)	100	250	500	1,000	1,380	1,500	2,500	3,500	4,735	5,500
Total Annual Costs	$6,895	$7,696	$9,032	$11,703	$13,733	$14,374	$19,716	$25,059	$31,657	$35,744
TPY of NO_X Emissions Reduced	0.23	0.57	0.92	1.83	2.53	2.75	4.58	6.42	8.68	10.08
TPY of CO Emissions Reduced	0.27	0.69	1.37	2.75	3.79	4.12	6.87	9.62	13.02	15.12
TPY of NMNEHC Emissions Reduced	0.10	0.24	0.48	0.96	1.33	1.45	2.41	3.38	4.57	5.31
Cost Per Ton	$11,480	$5,126	$3,256	$2,110	$1,794	$1,727	$1,422	$1,291	$1,205	$1,172

For lean-burn engines, using both the weighted average emissions and the BAT emissions, the cost effectiveness of control was less than the cost-effectiveness threshold of $5,000 per ton of pollutant reduced was shown for engines rated at 100 bhp and above. Therefore, the Department determines that oxidation catalysts are required for all lean-burn engines rated greater than or equal to 100 bhp.

For rich-burn engines, using the BAT emissions shows that NSCR is not cost effective below 250 hp; however, NSCR was previously established as BAT for rich-burn engines rated greater than or equal to 100 bhp. Therefore, the Department determines that NSCR is required for all rich burn engines rated greater than or equal to 100 bhp.

Table 30 - Turbine Characteristics and Emissions Data

	Turbine A	Turbine B	Turbine C	Turbine D	Tubine E
Power (bhp)	1,590	6,130	11,150	15,900	30,000

NMNEHC Emission Rate (tpy)	2.30	7.25	11.16	9.09	14.76

Unfortunately, a convenient analysis for oxidation catalysts for turbines was not found. Instead, the Department relied on vendor quotes and performed an analysis similar to the one for SCR in Appendix B – SCR Cost Analysis for Engines and Turbines. Three independent quotes were given for different sized turbines, and those formed the basis for the extrapolation of total annual costs for turbines of other sizes.

Table 31 - Oxidation Catalyst Cost Data for Turbines

(All dollar values in 2016 dollars)	6,130	15,900	30,000
Oxidation Catalyst Purchased Equipment Costs	$96,785	$205,918	$215,090
Direct Installation Costs (0.30PEC)	$29,035	$61,775	$64,527
Total Indirect Installation Costs (0.27PEC)	$26,132	$55,598	$58,074
Project Contingency (0.15(DIC+IIC))	$8,275	$17,606	$18,390
Total Capital Investment	$160,227	$340,897	$356,082
Operating and Supervisory Labor Costs	$18,889	$18,889	$18,889
Maintenance Cost	$2,904	$6,178	$6,453
Natural Gas Penalty	$12,553	$28,325	$45,964
Catalyst Disposal	$130	$338	$637
Annual Catalyst Replacement Cost	$14,204	$36,841	$69,512
Direct Annual Costs	$48,679	$90,570	$141,454
Indirect Annual Costs	$34,609	$60,854	$63,060
Total Annual Costs	$83,288	$151,424	$204,514

The uncontrolled emissions rates assume 25 ppm for CO and total hydrocarbons, which when adjusted to NMNEHC as propane becomes 9 ppm. The BAT emissions rates, in ppm, were taken from the previous GP-5. The values for CO and NMNEHC are used in the table below for the turbine oxidation catalyst cost analysis.

Table 32 – Oxidation Catalyst Cost Analysis for Turbines - Uncontrolled Emissions

Turbine HP (All dollar values in 2016 dollars)	1,000	1,590	3,000	5,000	6,130	7,500	11,150	15,900	17,500	20,000	25,000	30,000
Total Annual Costs	$64,925	$67,866	$74,896	$84,868	$83,288	$97,333	$115,531	$151,424	$147,191	$159,655	$184,584	$204,514

Cost Per Ton	$11,670	$13,810	$8,142	$6,612	$5,363	$5,600	$4,836	$4,321	$4,139	$3,981	$3,752	$3,576

Table 33 - Oxidation Catalyst Cost Analysis for Turbines - BAT Emissions

Turbine HP (All dollar values in 2016 dollars)	1,000	1,590	3,000	5,000	6,130	7,500	11,150	15,900	17,500	20,000	25,000	30,000
Total Annual Costs	$64,925	$67,866	$74,896	$84,868	$83,288	$97,333	$115,531	$151,424	$147,191	$159,655	$184,584	$204,514
TPY of CO Emissions Reduced	4.26	3.77	7.05	9.84	11.90	13.32	18.31	10.74	10.90	12.29	15.08	17.43
TPY of NMNEHC Emissions Reduced	1.30	1.15	2.15	3.00	3.63	4.06	5.58	4.55	4.61	5.20	6.38	7.38
Cost Per Ton	$11,670	$13,810	$8,142	$6,612	$5,363	$5,600	$4,836	$9,903	$9,486	$9,123	$8,599	$8,243
TPY of CO Emissions Reduced, Alternative BAT				3.93	4.76	5.33	7.32					
TPY of NMNEHC Emissions Reduced, Alternative BAT				1.67	2.02	2.26	3.10					
Cost Per Ton				$15,153	$12,291	$12,834	$11,082					

As can be seen in Table 32 and Table 33 above, oxidation catalysts for turbines greater than or equal to 1,000 hp but less than 5,000 hp are not cost-effective; for turbines greater than or equal to 5,000 hp, oxidation catalysts are cost-effective based on a cost-effectiveness threshold of $5,000 per ton of pollutant reduced. It is important to point out that for turbines less than 15,000 hp, the uncontrolled emissions and the BAT emissions are identical, with identical results.

For turbines greater than or equal to 15,900 hp, oxidation catalysts are cost-effective if one considers the uncontrolled emission rates of 25 ppm CO and 9 ppm NMNEHC as propane as a baseline. However, if one considers the alternative BAT emissions rate established in the previous GP-5 of 10 ppm CO and 5 ppm NMNEHC, oxidation catalysts are not cost-effective. Oxidation catalysts are also cost prohibitive for turbines rated greater than or equal to 5,000 hp but less than 15,900 hp with uncontrolled emissions rates of 10 ppm CO and 5 ppm NMNEHC, which is achievable according to stack test data. Therefore, it is the Department's determination that turbines greater than or equal to 5,000 hp but less than 15,900 hp have BAT criteria of 10 ppm CO and 5 ppm NMNEHC and that turbines greater than or equal to 15,900 hp have dual BAT criteria with BAT of 10 ppm CO uncontrolled and 1.75 ppm CO with control and 5 ppm NMNEHC.

XXV. Appendix D – Cost Analysis for Combustion Control Devices

Table 34 - Combustion Control Device Cost Analysis

(All dollar values in 2016 dollars)	Vendor A	Sensitivity Analysis			
Combustor	$19,186				
Auto Ignitor	$1,740				
Surveilannce System	$4,176				
Total Purchased Equipment Cost	$25,102				
Freight and Design	$1,740				
Installation	$7,371				
Total Capital Investment	$34,213	$40,000	$50,000	$75,000	$100,000
Pilot Fuel	$2,201	$2,573	$3,216	$4,824	$6,432
Maintenance Cost	$2,320	$2,712	$3,391	$5,086	$6,781
Data Management	$1,160	$1,356	$1,695	$2,543	$3,391
Direct Annual Costs	$5,681	$6,641	$8,302	$12,453	$16,603
Indirect Annual Costs	$3,756	$4,392	$5,490	$8,235	$10,979
Total Annual Costs (7% Intrest, 15 Year Life)	$9,437	$11,033	$13,791	$20,687	$27,583
TPY of Methane	200.00	200.00	200.00	200.00	200.00
TPY of VOC	2.70	2.70	2.70	2.70	2.70
TPY of HAP	1.00	1.00	1.00	1.00	1.00
Cost Per Ton (95% Reduction)	$49	$57	$71	$107	$143
Cost Per Ton (95% Reduction, Excluding Methane)	$2,685	$3,139	$3,924	$5,885	$7,847
Cost Per Ton (98% Reduction)	$47	$55	$69	$104	$138
Cost Per Ton (98% Reduction, Excluding Methane)	$2,603	$3,043	$3,803	$5,705	$7,607

As can be seen from the table above, it is cost effective for a combustion control device that controls methane, VOC, and HAP based on the vendor quote and assuming an emission rate at the control threshold. In the sensitivity analysis, it is assumed that the annual costs scale relative to the increased total capital investment. If the cost-effectiveness threshold including methane is considered, it is cost-effective to install a combustion control device with a total capital investment of $100,000 (and arguably much more) because it is much less than the $1,000 per ton of pollutant reduced. If the cost-effectiveness threshold excluding methane is considered, combustion control devices are cost-effective up to a total capital investment of $75,000 because it is close to the $5,000 per ton of pollutant reduced.

Many commentators provided additional information on combustion control devices capabilities and cost, and so the Department conducted another cost analysis based on the new information. One aspect the Department explored was the effect of gas composition on the number of hours of operation an enclosed flare of the given characteristics would take to reach the proposed control thresholds. As seen in Table 35 below, the time varies for each pollutant, and establishes a range of operating hours. In Table 36 below, the emissions calculations were done based on the gas composition and the minimum and maximum operating hours calculated in Table 35.

Table 35 - Operating Hours to Reach Control Thresholds

Gas Composition Analysis	Original TSD Average Gas Composition	TSD Reanalysis Average Gas Composition	Rich Gas - Washington County Average	Dry Gas - Susquehanna County Average
Methane (vol%)			82.6%	97.4%
Methane (wt%)	88.8%	86.0%	67.3%	95.1%

Dollars Per Ton of All Pollutants Reduced Minimum ($/ton)	$598	$2,126	$6,816	$580

The cost effectiveness for all pollutants at both the minimum and maximum hours of operation show that regardless of gas composition, an enclosed combustion device is economically feasible for the control of methane, VOC, and HAP.

Another commentator pointed out that control devices need to be sized for the worst-case scenario, which drives up the cost of the system based on the maximum gas flow to the control. The commentator provided operational data, summarized in Table 37 below, that gives both volume flow rates and mass flow rates as well as hours of operation.

Table 37 - Gas Flow Rates and Annual Hours of Operation

	Purge Gas	Closed Drain Vapors	Pigging Vapors (30" Receiver)	Pigging Vapors (12" C3+ Launcher)	Amine Unit Flash Gas	Total Maximum Flow Rate		Total Minimum Flow Rate	
						scfh	Mscfd	scfh	Mscfd
Volume Flow Rate (scfh)	434	26	120,000	48,135	2,154	170,749	4,098	2,588	62
Volume Flow Rate %	0.25%	0.02%	70.28%	28.19%	1.26%				
Mass Rate (lb/h)	18.68	1.43	6,723.53	6,885.81	177.91	13,807		197	
Annual Hours of Operation	8,760	2,190	12	1	8,760				

Another consideration is the effect of the previously calculated methane control threshold versus the newly calculated methane control threshold; as seen in Table 38 below, there is a significant increase in the cost per ton of methane reduced, as well as the cost per ton of all pollutants reduced. Cost-effectiveness on the basis of methane alone at 51.9 tpy is significantly beyond EPA's threshold of approximately $1,000 per ton of methane reduced;

Table 38 - Cost-Effectiveness of Proposed vs. Recalculated Control Thresholds for Enclosed Combustion Devices

(All dollar values in 2016 dollars)	MSC Enclosed Oxidizer @ 250 Mscfd CH_4	MSC Enclosed Oxidizer @ 250 Mscfd CH_4	Vendor D Enclosed Flare @ 2,606 Mscfd	Vendor D Enclosed Flare @ 2,606 Mscfd	Vendor D Enclosed Flare @ 26,064 Mscfd	Vendor D Enclosed Flare @ 26,064 Mscfd
Total Annual Costs	$68,059	$68,059	$110,415	$110,415	$445,745	$445,745

Cost Per Ton	$352	$1,289	$571	$2,090	$2,303	$8,439

ranging from $1,380 to $9,041 per ton of methane reduced. However, considering all pollutants, an enclosed combustion device is still cost effective based on the cost-effectiveness threshold of $5,000 per ton of pollutant reduced, ranging from $1,289 to $8,439 per ton of pollutant reduced. The Department must maintain, however, that the control threshold of 51.9 tpy is cost-prohibitive because for dry gas regions, methane is the likely trigger

for control, and as there are insignificant amounts of VOC and HAP in the gas stream, only the cost per ton of methane reduced should be considered for determining the cost-effectiveness. Performing a linear interpolation between the 51.2 tpy control threshold and the 200 tpy control threshold for the 2,606 Mscfd enclosed flare, the $1,000 per ton of methane reduced threshold is approximately 163 tpy methane. This would provide a range from $441 to $2,886 per ton of methane reduced. However, the Department determines that BAT control measures for methane must be implemented for sources with emissions that meet or exceed 200 tpy methane; this requirement is also included in the exemption criteria for facilities seeking exemption under Category 38(c). One reason for conservatively establishing the methane control threshold at 200 tpy instead of 163 tpy is due to the inherent scientific uncertainty in the second analysis control threshold calculation discussed in Appendix A – Average Gas Composition Analysis and the site-specific uncertainty in the control costs from Appendix D – Cost Analysis for Combustion Control Devices.

For the primary BAT analysis, the Department determined the total annual flow through the enclosed flare based on the operational information from Table 37 and the average natural gas composition as determined in Table 16 of Appendix A – Average Gas Composition Analysis. Where the flow was given as a volume of methane, the Department used the methane density of 0.0416 lb/scf and the average gas composition density of 0.0442 lb/scf to determine the adjusted flow rate. For Vendor D, the flow was given in lb/h; the Department used the average gas composition density to determine the volume flow. The Department used EPA's Air Pollution Control Cost Manual to determine the total capital investment and total annual costs based on the purchased equipment prices provided by the commentators. The results can be seen in Table 39 below.

Cost Per Ton	$199	$730	$278	$1,018

As can be seen in Table 40, open flares are less expensive and have lower annual operating costs than enclosed flares, ranging from $203 to $283 per ton of methane reduced for the 200 tpy methane control threshold. At the recalculated 51.9 tpy methane control threshold, the costs range from $782 to $1,091 per ton of methane reduced which just meets EPA's Social Cost of Methane. However, the Department determines that BAT control measures for methane must be implemented for sources with emissions that meet or exceed 200 tpy methane; this requirement is also included in the exemption criteria for facilities seeking exemption under Category 38(c). One reason for conservatively establishing the methane control threshold at 200 tpy instead of 51.9 tpy is due to the inherent scientific uncertainty in the second analysis control threshold calculation discussed in Appendix A – Average Gas Composition Analysis and the site-specific uncertainty in the control costs from Appendix D – Cost Analysis for Combustion Control Devices.

For the primary BAT analysis, the Department determined the total annual flow through the open flare based on the operational information from Table 37 and the average natural gas composition as determined in Table 16 of Appendix A – Average Gas Composition Analysis. Where the flow was given as a volume of methane, the Department used the methane density of 0.0416 lb/scf and the average gas composition density of 0.0442 lb/scf to determine the adjusted flow rate. For Vendor D, the flow was given in lb/h; the Department used the average gas composition density to determine the volume flow. The Department used EPA's Air Pollution Control Cost Manual to determine the total capital investment and total annual costs based on the purchased equipment prices provided by the commentators. The results can be seen in Table 41 below.

Open flares are only authorized to be used at remote facilities and with infrequent operations.

XXVI. Appendix E – LDAR Cost Analysis

ICF has conducted two analyses on LDAR, one for the Environmental Defense Fund (EDF) in March of 2014[28] and one for ONE Future Inc. in May of 2016[29]. In both analyses, they broke down the costs associated with an LDAR program into an hourly cost number. This was an adaptation of the analysis used by Colorado in their rulemaking. In the March 2014 analysis, the determination was that the total cost as an hourly rate was $101.64 and that inspections would be performed on a quarterly basis. This resulted in an LDAR cost that ranged between $2.15 and $7.60 per Mcf of methane reduced, which approximates to between $95 and $336 per ton of methane reduced, when not counting the recovered gas value. In the May 2016 analysis, the determination was that the total cost as an hourly rate was $142.06 and that inspections would be performed annually. This resulted in an LDAR cost that ranged between $1.41 and $6.94 per Mcf of methane reduced, which approximates to between $62 and $306 per ton of methane, when not counting the recovered gas value.

The Department conducted two independent LDAR cost analyses, the first using the ICF analyses as a basis and a second based on two vendors' quotes. The Department's assumptions in the first analysis included a semi-annual and quarterly survey interval for unconventional natural gas well sites and a quarterly survey interval for natural gas compression stations, processing plants, and transmission stations. The semi-annual frequency is assumed to result in a 50% emissions reduction and the quarterly frequency is assumed to result in a 60% emissions reduction. The Department favored the ONE Future Equipment Costs as the basis of the cost analysis as it includes a high-flow system for leak quantification in the analysis.

Table 42 and Table 43 below represent the Department's assumptions on frequency with the respective assumptions on emissions and hours for each survey from the two ICF analyses.

Table 42 - LDAR Costs with ONE Future Equipment Costs and EDF Assumptions

	Wellpads	Wellpads	Gathering	Processing	Transmission

Total Cost per Year	$2,891	$5,782	$33,640	$42,050	$33,640
Cost of Reduction ($/Mcf)	$1.89	$3.15	$15.55	$11.71	$15.55
Cost of Reduction ($/ton)	$90.71	$151.19	$745.92	$561.53	$745.92

As can be seen in the tables, the cost of reduction in both cases is well within the cost-effective range of $1,000 per ton of methane reduced.

A. The Department's Independent LDAR Cost Analysis

Since the number of leaking components, amount of leakage from individual components, duration, and frequency is uncertain at an individual facility, it is impractical to perform a generic cost-analysis for LDAR requirements for static and rotating components (flanges, valves, joints, packing of compressor rods, etc.) at well sites, natural gas compression, processing or transmission facilities.

However, the Department contacted representatives of two companies that offer services for LDAR for the sources at well sites, and natural gas compression, processing or transmission facilities, to determine the estimated costs for leak detection, quantification, and repair tasks. Neither company offered quotes for repair costs since the costs for repairs vary significantly, depending on which components are leaking and what type of maintenance is required to repair the leaks. Therefore, the analysis is based only on the quoted costs for methane gas leak detections and quantifications.

According to the representative of the first company, a dry natural gas well pad contains approximately 1,000 components. Wet gas well pads, and compression, processing, or transmission facilities contain approximately 2,000 components. Typically, it takes one person and one day (10 hours) to complete the leak detection task using an OGI camera for a dry gas well pad. It takes one person two days to complete the leak detection using an OGI camera for a wet gas well pad, or natural gas compression, processing, or transmission station. The company charges $75 per hour for manpower, $400 per day for travel costs, $150 per day for camera rental, and $300 per day for gas leak detection device rental.

The company charges the same amount for labor for leak quantification, and assuming all components are leaking it takes two people three days to quantify leaks from all 1,000 components at a dry gas well pad, and two people six days to quantify leaks from all 2,000 components at a wet gas well pad, or natural gas compression, processing, or transmission facility. This yields a labor rate of 0.06 man-hours per component that is leaking, and in the analysis the Department will round up to the nearest full day.

The Department also contacted representatives of the second company to determine their costs for LDAR services, and they echoed the cost that was suggested by the first company. According to the company representatives, typically it costs $750 - $1,500 for any well pad or natural gas compression station for leak detection and quantification.

Based on the above information, the Department performed cost-effectiveness analysis for leak detection and quantification requirements stated for sources located at well pads, and natural gas compression, processing, or transmission facilities. The costs for leak detection were assumed to be at the full quoted cost and the costs for leak quantification were based on the amount of time to survey 1%, 2%, and 3% of the components rounded up to the nearest full day for sources at dry gas well pads, wet gas well pads, and natural gas compression, processing, and transmission facilities.

According to Method 21, the detector must have a sampling rate between $3.53x10^{-3}$ and 0.11 cf/min. At the maximum sampling rate, a 500 ppm indication on a Method 21 detector would be approximately equivalent to a 0.08 cf/day emission rate for a component if it is assumed that 100% of the leak is captured. For leaks above 500 ppm, it is less likely that 100% of the leak is captured, but for purposes of this analysis, it is assumed the detector does capture all of the emissions up to the 100,000 ppm level for a calculated leak rate of 15.84 cf/day. For any leak above 100,000 ppm on a Method 21 device, a high-flow sampler must be used for quantification. A high-flow device has a sampling rate of 10 cf/min and can detect leaks between 0.05 cf/min and 8.00 cf/min. This results in leak emission rates of 72.00 cf/day and 11,520 cf/day, respectively.

Based on the several leak studies, one vendor informed the Department that the majority of leak emissions come from a small percentage of "super-emitters." The Department assumes the "super-emitters" emit at the 11,520.00 cf/day rate and the total daily emission rate is based on the equation:

$$E = \frac{(P_{SE})(C_l)\left(11{,}520\ \frac{cf}{day}\right)}{(P_E)}$$

Where:

E = Total Daily Emission Rate
P_{SE} = Percentage of "Super-Emitters"
C_l = Number of Leaking Components
P_E = Percentage of Total Emissions Attributed to "Super-Emitters"

The following table outlines the calculated total daily emission rate for 1% of the total components at a dry gas well site found leaking.

Table 44 - Super-Emitter Study Data and LDAR Costs[30]

Study Author	Percent	Percent of Total Emissions	Calculated Total Daily Emission Rate	Annual Emissions	Annual Avoided Emissions	Cost per Ton of Methane Reduced
	"Super-Emitters"	(P_E)	(E)	(Mcf/y)	(TPY)	($/ton)
	(P_{SE})		(cf/day)			
Brandt, et. al.	5.00%	50%	11,520.00	4,204.80	52.6	$228.13
Rella, et. al.	6.60%	50%	15,206.40	5,550.30	69.4	$172.82
	22%	80%	9,642.60	3,519.50	44	$272.54
Clearstone Engineering	0.06%	58%	119.2	43.5	0.5	$22,047.27
British Columbia Oil & Gas	6.00%	80%	8,640.00	3,153.60	39.5	$304.17

The ONE Future emissions estimate from well sites is 3,057 Mcf/y, and the EDF emission estimate from well sites is 440 Mcf/y. Assuming the Department's costs and that the emissions estimates are from 1% of the total components, this results in costs of $313.78 per ton of methane reduced and $2,180.07 per ton of methane reduced, respectively. The British Columbia Oil & Gas and the Rella, *et al.* top 22% of leaks responsible for 80% of total emissions estimates are in line with ONE Future's emissions estimates from well sites.

Brandt, *et al.* and the Rella, *et al.* top 6.6% responsible for 50% of total emissions estimates are nearly 80% higher than ONE Future's emissions estimates. This serves to drive down the cost per ton of methane reduced. The Clearstone Engineering emissions estimate is approximately 1.5% of the ONE Future emission estimate, which serves to significantly drive up the cost per ton of methane reduced. The Department therefore focused on the British Columbia and Rella, *et al.* 22% cases in the cost analysis.

Based on our independent analysis, the Department determines that quarterly LDAR is technically and economically feasible for the control of methane emissions. The Department preserves the off-ramp originally proposed if less than 2% of components are found to be leaking in two consecutive inspections to help small businesses that operate effectively to reduce the frequency of inspections, and thereby reduce costs.

[30] The second line under Rella, et. al. is calculated assuming that 6.6% emit at the 11,520 cf/day rate and the remaining 15.4% emit at the 72.0 cf/day rate.

Table 45 - LDAR Costs from Vendor Quotes

TOTAL ANNUAL COST FOR LEAK DETECTION										
Facility	**~No. of Components**	**Leak Detection Duration (Days)**	**Labor Cost Per Man-Hour**	**Number of Hours/Day**	**Manpower**	**Travel Cost ($400/Day-Man)**	**Equipment Rental (OGI) ($150/Day-Man)**	**Contingency ($200/Day-Man)**	**Frequency per Year**	**Annual Cost for Leak Detection**

B. The Department's Revised LDAR Cost Analysis

Based on comments received, the Department has performed a brief reanalysis of LDAR costs, which are summarized in Table 47 below. Even with a leak rate at 0.13% of production or throughput, the mass and volume of emissions are very high. The corresponding costs, which are based on the Annual Costs for Leak Detection in Table 45, the assumed leak rate, and the assumed production and throughput rates yield cost effectiveness numbers well below EPA's Social Cost of Methane. Based on our revised analysis, the Department determines that quarterly LDAR is technically and economically feasible for the control of methane emissions. The Department preserves the off-ramp originally proposed if less than 2% of components are found to be leaking in two consecutive inspections to help small businesses that operate effectively to reduce the frequency of inspections, and thereby reduce costs.

Table 47 - Revised LDAR Cost Analysis

TOTAL ANNUAL COST FOR LEAK DETECTION[1]						
Facility	**Total Annual Cost**	**Total Flow Rate (CF/Day)**	**Undetected Annual PTE (CFY)**	**Avoided Emissions (CFY)**	**Mass of Avoided Emissions (TPY)**	**$/ton**
Wellpad (Dry Gas)[2]	$6,000	13,000	4,745,000	2,847,000	59.36	$101.08
Wellpad (Wet Gas)[2]	$12,000	13,000	4,745,000	2,847,000	59.36	$202.16
Compressor Station, Processing Plant, or Transmission Station[3]	$12,000	910,000	332,150,000	199,290,000	4,155.20	$2.89

[1] The Annual Cost reflects only leak detection, as the leak quantification requirements were removed.

[2] The assumed production was 10 MMcf/d, with an assumed leak rate of 0.13% of production.

[3] The assumed throughput was 700 MMcf/d based on the previously referenced U.S. EIA report (see page 26), with an assumed leak rate of 0.13% of throughput.

XXX. Appendix I – GP-5 Malfunction Reporting Instructions

GP-5 Malfunction Reporting Instructions

1. **Malfunction reporting to the PA Department of Environmental Protection (DEP or Department) under GP-5 must be conducted as follows:**

   a. The owner/operator authorized to use GP-5 shall report to DEP each malfunction that results in a potential exceedance of the GP-5 emissions limits. For GP-5 purposes, the term malfunction means any sudden, infrequent, and not reasonably preventable failure of air pollution control or process equipment, or, operating in a non-permitted manner, which results in, or may possibly be resulting in, the emission of air contaminants in excess of any applicable limitations specified in GP-5.

   b. The notification, recordkeeping and reporting requirements relating to performance testing, work practice and monitoring standards, equipment leaks or fugitive emissions noted in GP-5 are not subject to the malfunction reporting requirements.

   c. When the malfunction or incident poses an imminent and substantial danger to the public health and safety, and/or potential harm to the environment, the owner/operator shall report the incident to the Department and the County Emergency Management Agency immediately after the discovery of an incident. The owner/ operator shall submit a written report of instances of such malfunctions or incidents to the Department within three (3) business days of the telephone report.

      i. The Report shall include the following:
         a) name and location of the facility;
         b) nature and cause of the malfunction or incident;
         c) time when the malfunction, incident or breakdown was first observed;
         d) expected duration of increased emissions; and
         e) estimated rate of emissions

      ii. The Owner/Operator shall notify the Department immediately when corrective measures have been accomplished.

   d. Incidents covered by the notification, recordkeeping and reporting requirements relating to performance testing, work practice and monitoring standards, equipment leaks or fugitive emissions noted in this general permit are not subject to the reporting requirements of this section.

   e. Any malfunction or incident that is not subject to the notice requirements of paragraph (c) of this document shall be reported to the Department by telephone within 24 hours (or by 4:00 PM of the next business day, whichever is later) of discovery and in writing or e-mail within five days of discovery of the incident. The report shall contain the same information required by paragraph (c)(i).

   f. The Department may require, when a malfunction or other incident results in citizen complaints, the Owner/Operator to report the incident immediately to the Department. The Department will review the incident and determine if a written follow up report including corrective action is needed.

   g. Malfunctions shall be reported to the appropriate DEP Regional Office Air Program Manager.

NMED Exhibit 52

2. **Examples of Malfunctions or Incidents are provided below.**

   a. Malfunctions or incidents posing an imminent and substantial danger to the public health and safety.

      i. Reportable
         a) Fire;
         b) Explosion; or
         c) Explosive or other condition that may impact outside of the fence-line or require evacuations.

   b. Malfunctions or incidents that do not pose an imminent and substantial danger to public health and safety but may result in an exceedance of GP-5 emissions limits.

      i. Reportable Malfunctions or Incidents
         a) Process equipment incidents, or air pollution control equipment shutdown or reduction in control which results in VOC, NOX, CO, HAP, or Formaldehyde emissions in excess of the General Permit's emissions limits or permit requirements.
         b) Equipment or operation failure, or malfunctions in process or pollution control equipment that result in fugitive particulate emission or odor beyond the facility boundary.

      ii. Non-reportable Malfunctions or Incidents
         a) Air Pollution Control equipment shutdowns that are rectified by automatic restarts, other adjustments of the operation as per the manufacturer.
         b) Air Pollution Control equipment shutdowns which are manually restarted within one hour of the malfunction and do not result in emissions in excess of GP limitations.
         c) Malfunctions in process or pollution control equipment which result in odor or fugitive dust emissions which are contained within the facility's fence-line.
         d) Building fire eyes or gas detector trips that pose no harm to the public.
         e) False fire eyes or other safety device trips which do not pose harm to the public.
         f) Upset conditions within the site boundaries which do not pose a threat to the public provided that they do not result in a potential exceedance of the GP-5 emissions limits.

   c. Emergency Releases

      i. Reportable Releases
         a) Unplanned Emergency Shut-down events that result in a potential exceedance of permit emission limits or create an offsite risk.
         b) Relief valves that stay open, or frequently relieve and may result in a potential exceedance of permit limits.

      ii. Non- Reportable Releases
         a) Vents from pressure safety relief valves (PSVs) that do not result in a potential exceedance of permit limits or create an offsite risk. However, DEP should be notified by telephone if there is noise from the release that results in community complaints to the facility owner/operator, or there are multiple PSV incidents.

   d. Planned Compressor Vents, Engine Starters and Other Emissions Included in the Application

      i. Non-Reportable Releases
         a) Venting from compressors as described in the GP-5 Application that do not result in an exceedance of emission limits.

NMED Exhibit 52

b) Gas from engine starters as described in the application that do not result in an exceedance of emission limits. Planned or required ESDs included in the application that do not result in an exceedance of emission limits.
c) Rod packing or crankcase vent emissions – source of minor significance normally detailed in the permit application.

e. Malfunctions or Other Incidents That Result in Citizen Complaints – Courtesy Reporting

i. Incident Reporting
a) Noise from pressure relief valves or other safety devices that result in community complaints to the facility owner/operator.
b) Odors from an off-site source when detected in the area.
c) Issues that have received prior community complaints.
d) Emergency Response Drills held at the facility where a number of emergency vehicles may be present.

f. Dehydrators

i. Reportable Incidents
a) Still vent bypass or flash tank venting from freezing or process malfunction that has the potential to exceed permit emission limitations.
b) Malfunctions of process controls that may or may not result in exceedances of permit limits.

ii. Non-Reportable Incidents
a) Still vent or flash tank bypass of oxidizers or other controls during automated restart sequence, without any potential to exceed permit emission limits.

NOTE: Emissions (including emissions from malfunctions) from all sources must be included in the source reports submitted to DEP by March 1st each year as prescribed in 25 Pa. Code Chapter 135 (relating to reporting of sources).

1.0 INTRODUCTION

Congress, in the Clean Air Act Amendments of 1990 (CAAA), amended Title I of the Clean Air Act (CAA) to address ozone nonattainment areas. A new Subpart 2 was added to Part D of Section 103. Section 183(c) of the new Subpart 2 provides that:

> [w]ithin 3 years after the date of the enactment of the CAAA, the Administrator shall issue technical documents which identify alternative controls for all categories of stationary sources of...oxides of nitrogen which emit or have the potential to emit 25 tons per year or more of such air pollutant.

These documents are to be subsequently revised and updated as determined by the Administrator.

Stationary gas turbines have been identified as a category that emits more than 25 tons of nitrogen oxide (NO_x) per year. This alternative control techniques (ACT) document provides technical information for use by State and local agencies to develop and implement regulatory programs to control NO_x emissions from stationary gas turbines. Additional ACT documents are being developed for other stationary source categories.

Gas turbines are available with power outputs ranging from 1 megawatt (MW) (1,340 horsepower [hp]) to over 200 MW (268,000 hp) and are used in a broad scope of applications. It must be recognized that the alternative control techniques and the corresponding achievable NO_x emission levels presented in this document may not be applicable for every gas turbine application. The size and design of the turbine, the operating duty cycle, site conditions, and other site-specific factors must be taken into consideration, and the suitability of an

NMED Exhibit 53

alternative control technique must be determined on a case-by-case basis.

The information in this ACT document was generated through a literature search and from information provided by gas turbine manufacturers, control equipment vendors, gas turbine users, and regulatory agencies. Chapter 2.0 presents a summary of the findings of this study. Chapter 3.0 presents information on gas turbine operation and industry applications. Chapter 4.0 contains a discussion of NO_x formation and uncontrolled NO_x emission factors. Alternative control techniques and achievable controlled emission levels are included in Chapter 5.0. The cost and cost effectiveness of each control technique are presented in Chapter 6.0. Chapter 7.0 describes environmental and energy impacts associated with implementing the NO_x control techniques.

NMED Exhibit 53

2.0 SUMMARY

This chapter summarizes the more detailed information presented in subsequent chapters of this document. It presents a summary of nitrogen oxide (NO_x) formation mechanisms and uncontrolled NO_x emission factors, available NO_x emission control techniques, achievable controlled NO_x emission levels, the costs and cost effectiveness for these NO_x control techniques applied to combustion gas turbines, and the energy and environmental impacts of these control techniques. The control techniques included in this analysis are water or steam injection, dry low-NO_x combustors, and selective catalytic reduction (SCR).

Section 2.1 includes a brief discussion of NO_x formation and a summary of uncontrolled NO_x emission factors. Section 2.2 describes the available control techniques and achievable controlled NO_x emission levels. A summary of the costs and cost-effectiveness for each control technique is presented in Section 2.3. Section 2.4 reviews the range of controlled emission levels, capital costs, and cost effectiveness. Section 2.5 discusses energy and environmental impacts.

2.1 NO_x FORMATION AND UNCONTROLLED NO_x EMISSIONS

The two primary NO_x formation mechanisms in gas turbines are thermal and fuel NO_x. In each case, nitrogen and oxygen present in the combustion process combine to form NO_x. Thermal NO_x is formed by the dissociation of atmospheric nitrogen (N_2) and oxygen (O_2) in the turbine combustor and the subsequent formation of NO_x. When fuels containing nitrogen are combusted, this additional source of nitrogen results in fuel NO_x formation. Because most turbine installations burn natural gas or light

NMED Exhibit 53

distillate oil fuels with little or no nitrogen content, thermal NO_x is the dominant source of NO_x emissions. The formation rate of thermal NO_x increases exponentially with increases in temperature. Because the flame temperature of oil fuel is higher than that of natural gas, NO_x emissions are higher for operations using oil fuel than natural gas.

Uncontrolled NO_x emission levels were provided by gas turbine manufacturers in parts per million, by volume (ppmv). Unless stated otherwise, all emission levels shown in ppmv are corrected to 15 percent O_2. These emission levels were used to calculate uncontrolled NO_x emission factors, in pounds (lb) of NO_x per million British thermal units (Btu) (lb NO_x/MMBtu). Sample calculations are shown in Appendix A. These uncontrolled emission levels and emission factors for both natural gas and oil fuel are presented in Table 2-1

NMED Exhibit 53

[a]Based on emission levels provided by gas turbine manufacturers, corresponding to rated load at ISO conditions. NO_x emissions calculations are shown in Appendix A.

[b]Not available.

NMED Exhibit 53

. Uncontrolled NO_x emission levels range from 99 to 430 ppmv for natural gas fuel and from 150 to 680 ppmv for distillate oil fuel. Corresponding uncontrolled emission factors range from 0.397 to 1.72 lb NO_x/MMBtu and 0.551 to 2.50 lb NO_x/MMBtu for natural gas and distillate oil fuels, respectively. Because thermal NO_x is primarily a function of combustion temperature, NO_x emission rates vary with combustor design. There is no discernable correlation between turbine size and NO_x emission levels evident in Table 2-1.

2.2 CONTROL TECHNIQUES AND CONTROLLED NO_x EMISSION LEVELS

Reductions in NO_x emissions can be achieved using combustion controls or flue gas treatment. Available combustion controls are water or steam injection and dry low-NO_x combustion designs. Selective catalytic reduction is the only available flue gas treatment.

2.2.1 Combustion Controls

Combustion control using water or steam lowers combustion temperatures, which reduces thermal NO_x formation. Fuel NO_x formation is not reduced with this technique. Water or steam, treated to quality levels comparable to boiler feedwater, is injected into the combustor and acts as a heat sink to lower

NMED Exhibit 53

flame temperatures. This control technique is available for all new turbine models and can be retrofitted to most existing installations.

Although uncontrolled emission levels vary widely, the range of achievable controlled emission levels using water or steam injection is relatively small. Controlled NO_x emission levels range from 25 to 42 ppmv for natural gas fuel and from 42 to 75 ppmv for distillate oil fuel. Achievable guaranteed controlled emission levels, as provided by turbine manufacturers, are shown for individual turbine models in Figures 2-1 and 2-2

NMED Exhibit 53

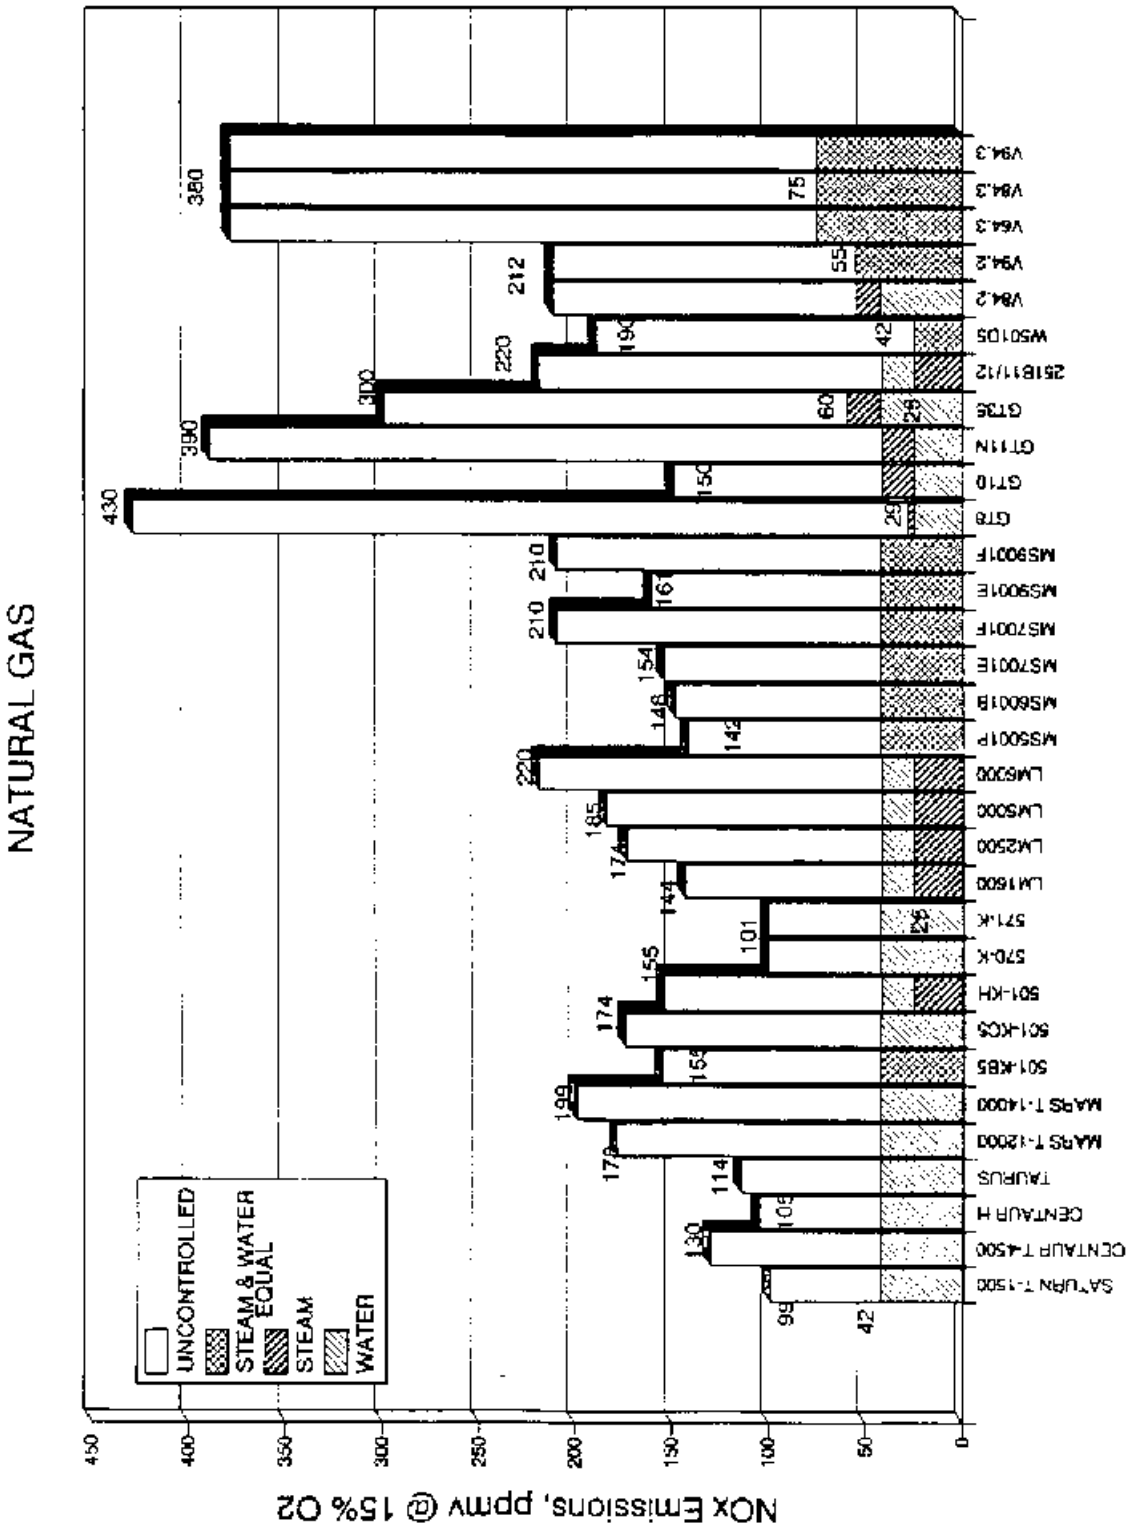

Figure 2-1. Uncontrolled NOx emission levels and gas turbine manufacturers' guaranteed controlled levels using wet injection. Natural gas fuel.

NMED Exhibit 53

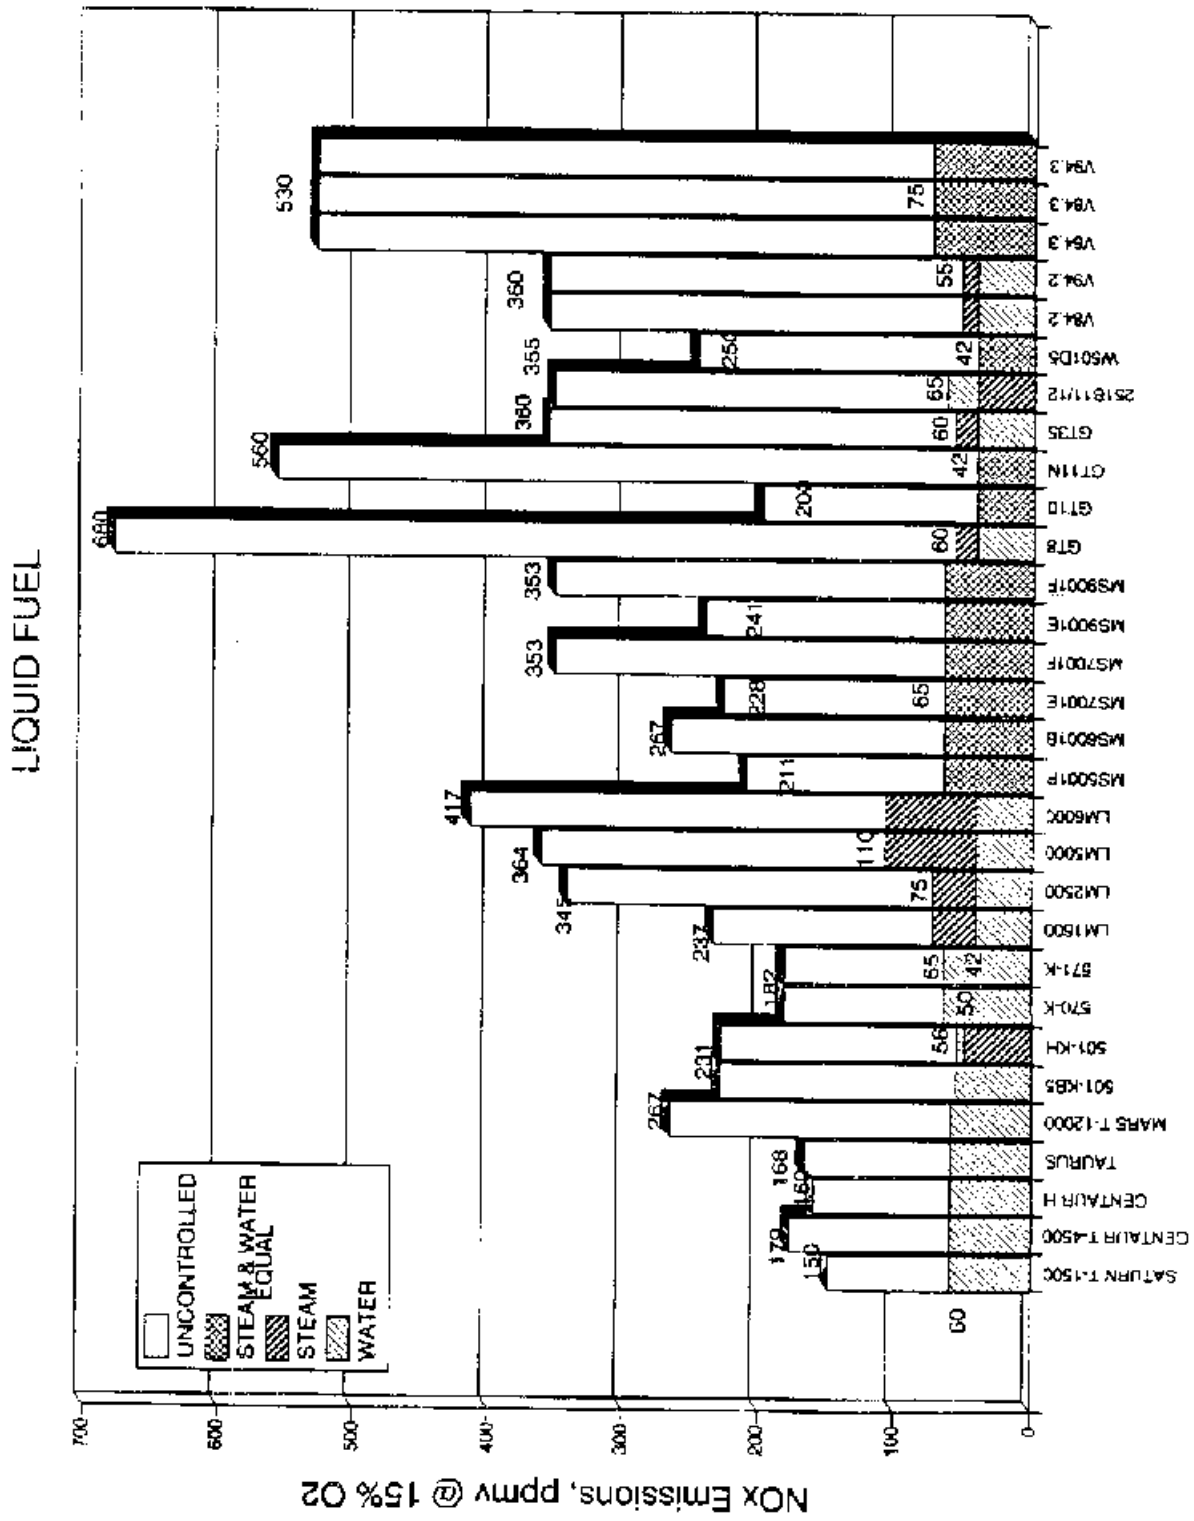

Figure 2-2. **Uncontrolled NO_x emission levels and gas turbine manufacturers' guaranteed controlled levels using wet injection. Distillate oil fuel.**

for natural gas and oil fuels, respectively.

The decision whether to use water versus steam injection for NO_x reduction depends on many factors, including the availability of steam injection nozzles and controls from the turbine manufacturer, the availability and cost of steam at the site, and turbine performance and maintenance impacts. This decision is usually driven by site-specific environmental and economic factors.

A system that allows treated water to be mixed with the fuel prior to injection is also available. Limited testing of water-in-oil emulsions injected into the turbine combustor have achieved NO_x reductions equivalent to direct water injection but at reduced water-to-fuel rates. The vendor reports a similar system is available for natural gas-fired applications.

Dry low-NO_x combustion control techniques reduce NO_x emissions without injecting water or steam. Two designs, lean premixed combustion and rich/quench/lean staged combustion have been developed.

Lean premixed combustion designs reduce combustion temperatures, thereby reducing thermal NO_x. Like wet injection, this technique is not effective in reducing fuel NO_x. In a conventional turbine combustor, the air and fuel are introduced at an approximately stoichiometric ratio and air/fuel mixing occurs simultaneously with combustion. A lean premixed combustor design premixes the fuel and air prior to combustion. Premixing results in a homogeneous air/fuel mixture, which minimizes

NMED Exhibit 53

localized fuel-rich pockets that produce elevated combustion temperatures and higher NO_x emissions. A lean air-to-fuel ratio approaching the lean flammability limit is maintained, and the excess air acts as a heat sink to lower combustion temperatures, which lowers thermal NO_x formation. A pilot flame is used to maintain combustion stability in this fuel-lean environment.

Lean premixed combustors are currently available from several turbine manufacturers for a limited number of turbine models. Development of this technology is ongoing, and availability should increase in the coming years. All turbine manufacturers state that lean premixed combustors are designed for retrofit to existing installations.

Controlled NO_x emission levels using dry lean premixed combustion range from 9 to 42 ppmv for operation on natural gas fuel. The low end of this range (9 to 25 ppmv) has been limited to turbines above 20 megawatts (MW) (27,000 horsepower [hp]); to date, three manufacturers have guaranteed controlled NO_x emission levels of 9 ppmv at one or more installations for utility-sized turbines. Controlled NO_x emissions from smaller turbines typically range from 25 to 42 ppmv. For operation on distillate oil fuel, water or steam injection is required to achieve controlled NO_x emissions levels of approximately 65 ppmv. Development continues for oil-fueled operation in lean premixed designs, however, and one turbine manufacturer reports having achieved controlled NO_x emission levels below 50 ppmv in limited testing on oil fuel without wet injection.

A second dry low-NO_x combustion design is a rich/quench/lean staged combustor. Air and fuel are partially combusted in a fuel-rich primary stage, the combustion products are then rapidly quenched using water or air, and combustion is completed in a fuel-lean secondary stage. The fuel-rich primary stage inhibits NO_x formation due to low O_2 levels. Combustion temperatures in the fuel-lean secondary stage are below NO_x formation temperatures as a result of the quenching process and the presence of excess air. Both thermal and fuel NO_x are controlled with this design. Limited testing with fuels including natural

NMED Exhibit 53

gas and coal have achieved controlled NO_x emissions of 25 ppmv. Development of this design continues, however, and currently the rich/quench/lean combustor is not available for production turbines.

2.2.2 Selective Catalytic Reduction

This flue gas treatment technique uses an ammonia (NH_3) injection system and a catalytic reactor to reduce NO_x. An injection grid disperses NH_3 in the flue gas upstream of the catalyst, and NH_3 and NO_x are reduced to N_2 and water (H_2O) in the catalyst reactor. This control technique reduces both thermal NO_x and fuel NO_x.

Ammonia injection systems are available that use either anhydrous or aqueous NH_3. Several catalyst materials are available. To date, most SCR installations use a base-metal catalyst with an operating temperature window ranging from approximately 260° to 400°C (400° to 800°F). The exhaust temperature from the gas turbine is typically above 480°C (900°F), so the catalyst is located within a heat recovery steam generator (HRSG) where temperatures are reduced to a range compatible with the catalyst operating temperature. This operating temperature requirement has, to date, limited SCR to cogeneration or combined-cycle applications with HRSG's to reduce flue gas temperatures. High-temperature zeolite catalysts, however, are now available and have operating temperature windows of up to 600°C (1100°F), which is suitable for installation directly downstream of the turbine. This high-temperature zeolite catalyst offers the potential for SCR applications with simple cycle gas turbines.

To achieve optimum long-term NO_x reductions, SCR systems must be properly designed for each application. In addition to temperature considerations, the NH_3 injection rate must be carefully controlled to maintain an NH_3/NO_x molar ratio that effectively reduces NO_x and avoids excessive NH_3 emissions downstream of the catalyst, known as ammonia slip. The selected catalyst formulation must be resistant to potential masking and/or poisoning agents in the flue gas.

NMED Exhibit 53

To date, most SCR systems in the United States have been installed in gas-fired turbine applications, but improvements in SCR system designs and experience on alternate fuels in Europe and Japan suggest that SCR systems are suitable for firing distillate oil and other sulfur-bearing fuels. These fuels produce sulfur dioxide (SO_2), which may oxidize to sulfite (SO_3) in the catalyst reactor. This SO_3 reacts with NH_3 slip to form ammonium salts in the low-temperature section of the HRSG and exhaust ductwork. The ammonium salts must be periodically cleaned from the affected surfaces to avoid fouling and corrosion as well as increased back-pressure on the turbine. Advances in catalyst formulations include sulfur-resistant catalysts with low SO_2 oxidation rates. By limiting ammonia slip and using these sulfur-resistant catalysts, ammonium salt formation can be minimized.

Catalyst vendors offer NO_x reduction efficiencies of 90 percent with ammonia slip levels of 10 ppmv or less. These emission levels are warranted for 2 to 3 years, and all catalyst vendors contacted accept return of spent catalyst reactors for recycle or disposal.

Controlled NO_x emission levels using SCR are typically 9 ppmv or less for gas-fueled turbine installations. With the exception of one site, all identified installations operate the SCR system in combination with combustion controls that reduce NO_x emission levels into the SCR to a range of 25 to 42 ppmv. Most continuous-duty turbine installations fire natural gas; there is limited distillate oil-fired operating experience in the United States. Several installations with SCR in the northeast United States that use distillate oil as a back-up fuel have controlled NO_x emission limits of 18 ppmv for operation on distillate oil fuel.

2.3 COSTS AND COST EFFECTIVENESS FOR NO_x CONTROL TECHNIQUES

Capital costs and cost effectiveness were developed for the available NO_x control techniques. Capital costs are presented in Section 2.3.1. Cost-effectiveness figures, in $/ton of NO_x

NMED Exhibit 53

removed, are shown in Section 2.3.2. All costs presented are in 1990 dollars.

2.3.1 Capital Costs

Capital costs are the sum of purchased equipment costs, taxes and freight charges, and installation costs. Purchased equipment costs were estimated based on information provided by equipment manufacturers, vendors, and published sources. Taxes, freight, and installation costs were developed based on factors recommended in the Office of Air Quality and Planning and Standards Control Cost Manual (Fourth Edition). Capital costs for combustion controls and SCR are presented in Sections 2.3.1.1 and 2.3.1.2, respectively.

2.3.1.1 Combustion Controls Capital Costs. Capital costs for wet injection include a mixed bed demineralizer and reverse-osmosis water treatment system and an injection system consisting of pumps, piping and hardware, metering controls, and injection nozzles. All costs for wet injection are based on the availability of water at the site; no costs have been included for transporting water to the site. These costs apply to new installations; retrofit costs would be similar except that turbine-related injection hardware and metering controls purchased from the turbine manufacturer may be higher for retrofit applications.

The capital costs for wet injection are shown in Figure 2-3, and range from $388,000 for a 3.3 MW (4,430 hp) turbine to $4,830,000 for a 161 MW (216,000 hp) turbine.

NMED Exhibit 53

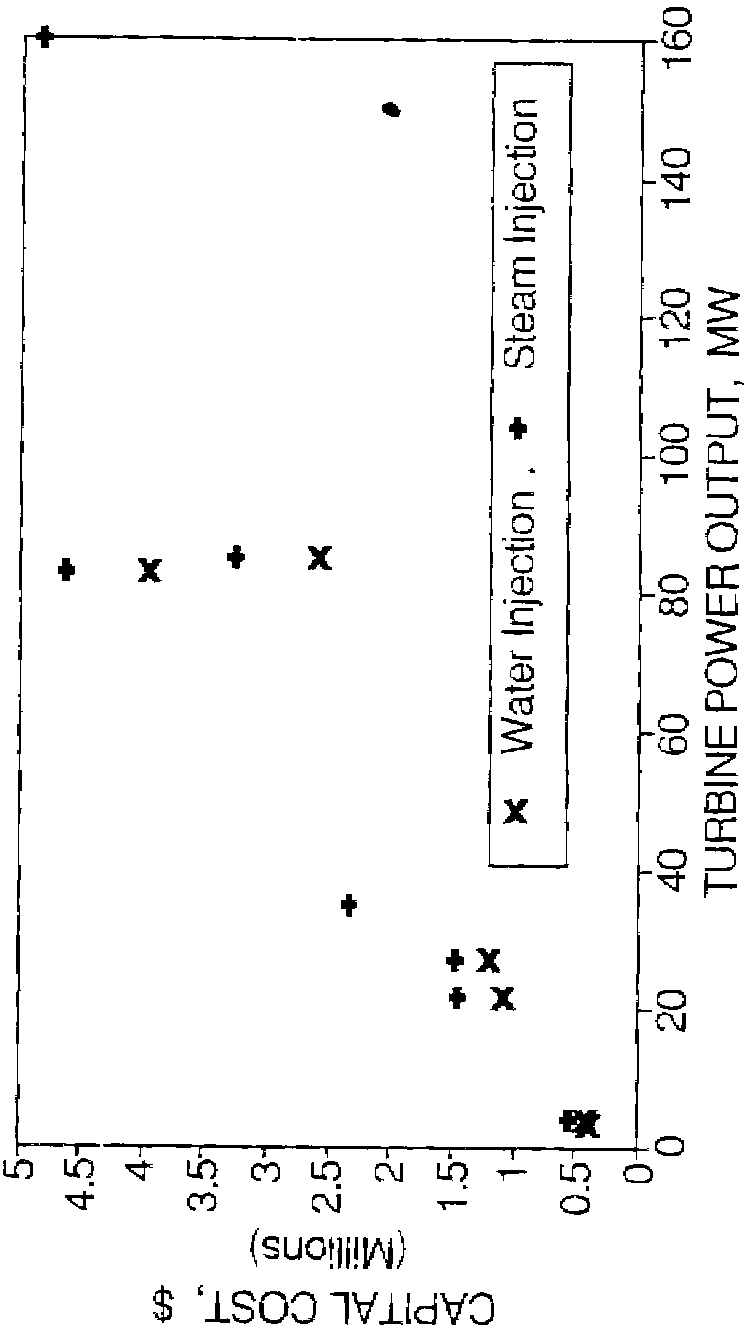

Figure 2-3. Capital costs for water or steam injection.

NMED Exhibit 53

These capital costs include both water and steam injection systems for use with either gas or distillate oil fuel applications. Figure 2-3 shows that the capital costs for steam injection are slightly higher than those for water injection for turbines in the 3 to 25 MW (4,000 to 33,500 hp) range.

The capital costs for dry low-NO_x combustors are the incremental costs for this design over a conventional combustor and apply to new installations. Turbine manufacturers estimate retrofit costs to be approximately 40 to 60 percent higher than new equipment costs. Incremental capital costs for dry low-NO_x

NMED Exhibit 53

combustion were provided by turbine manufacturers and are presented in Figure 2-4.

NMED Exhibit 53

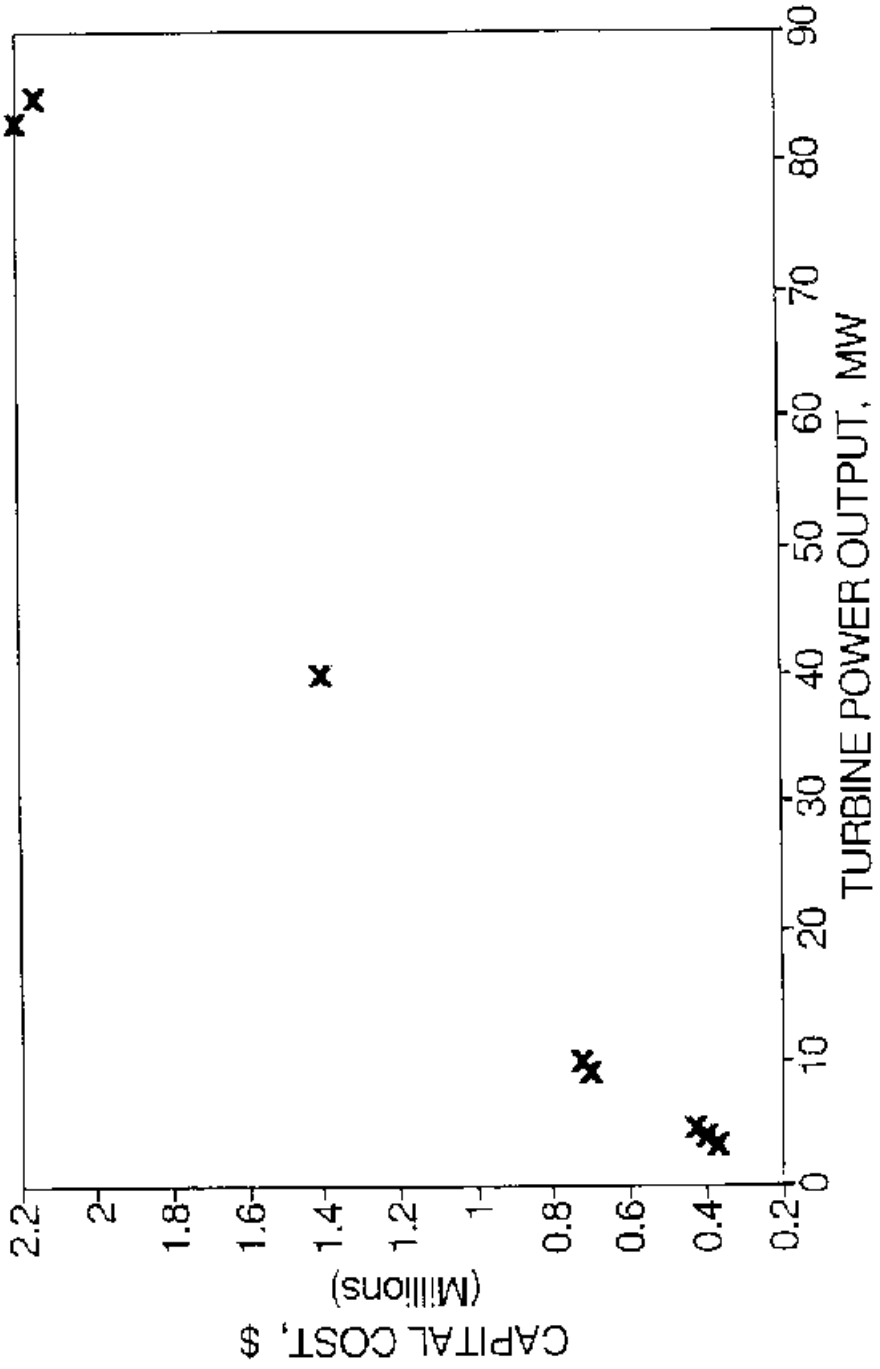

Figure 2-4. Capital costs for dry low-NO_x combustion.

NMED Exhibit 53

The incremental capital costs range from $375,000 for a 3.3 MW (4,430 hp) turbine to $2.2 million for an 85 MW (114,000 hp) machine. Costs were not available for turbines above 85 MW (114,000 hp).

When evaluated on a $/MW ($/hp) basis, the capital costs for wet injection or dry low-NO_x combustion controls are highest for the smallest turbines and decrease exponentially with increasing turbine size. The range of capital costs for combustion controls, in $/MW, and the effect of turbine size on capital costs are shown in Figure 2-5.

NMED Exhibit 53

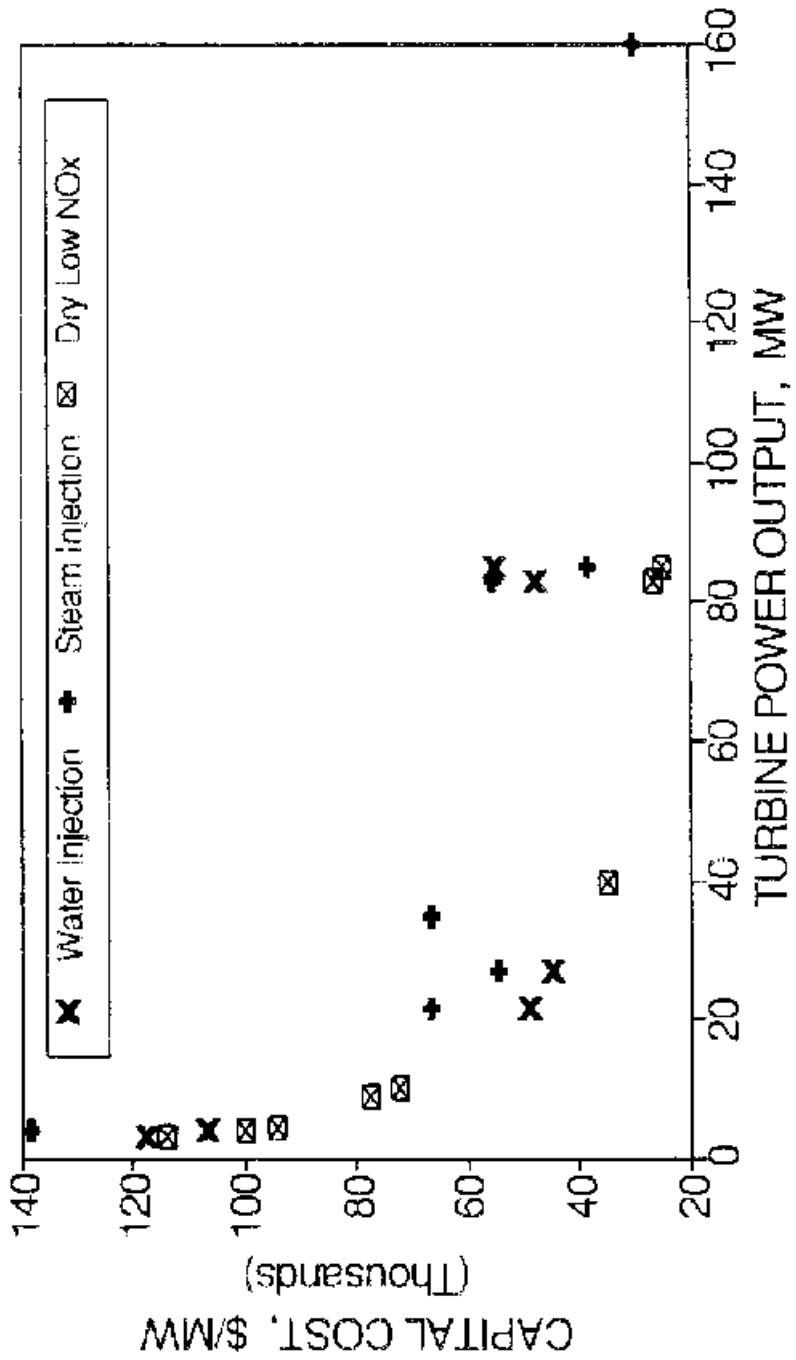

Figure 2-5. Capital costs, in $/MW, for cumbustion controls.

NMED Exhibit 53

For wet injection, the capital costs range from a high of $138,000/MW ($103/hp) for a 3.3 MW (4,430 hp) turbine to a low of $29,000/MW ($22/hp) for a 161 MW (216,000 hp) turbine. Corresponding capital cost figures for dry low-NO_x combustion range from $114,000/MW ($85/hp) for a 3.3 MW (4,430 hp) unit to $26,000/MW ($19/hp) for an 85 MW (114,000 hp) machine.

2.3.1.2 SCR Capital Costs. Capital costs for SCR include the catalyst reactor, ammonia storage and injection system, and controls and monitoring equipment. A comparison of available cost estimates for base-metal catalyst systems and high-temperature zeolite catalyst systems indicates that the costs for these systems are similar, so a single range of costs was developed that represents all SCR systems, regardless of catalyst type or turbine cycle (i.e., simple, cogeneration, or combined cycle).

The capital costs for SCR, shown in Figure 2-6, range from $622,000 for a 3.3 MW (4,430 hp) turbine to $8.46 million for a 161 MW (216,000 hp) turbine.

NMED Exhibit 53

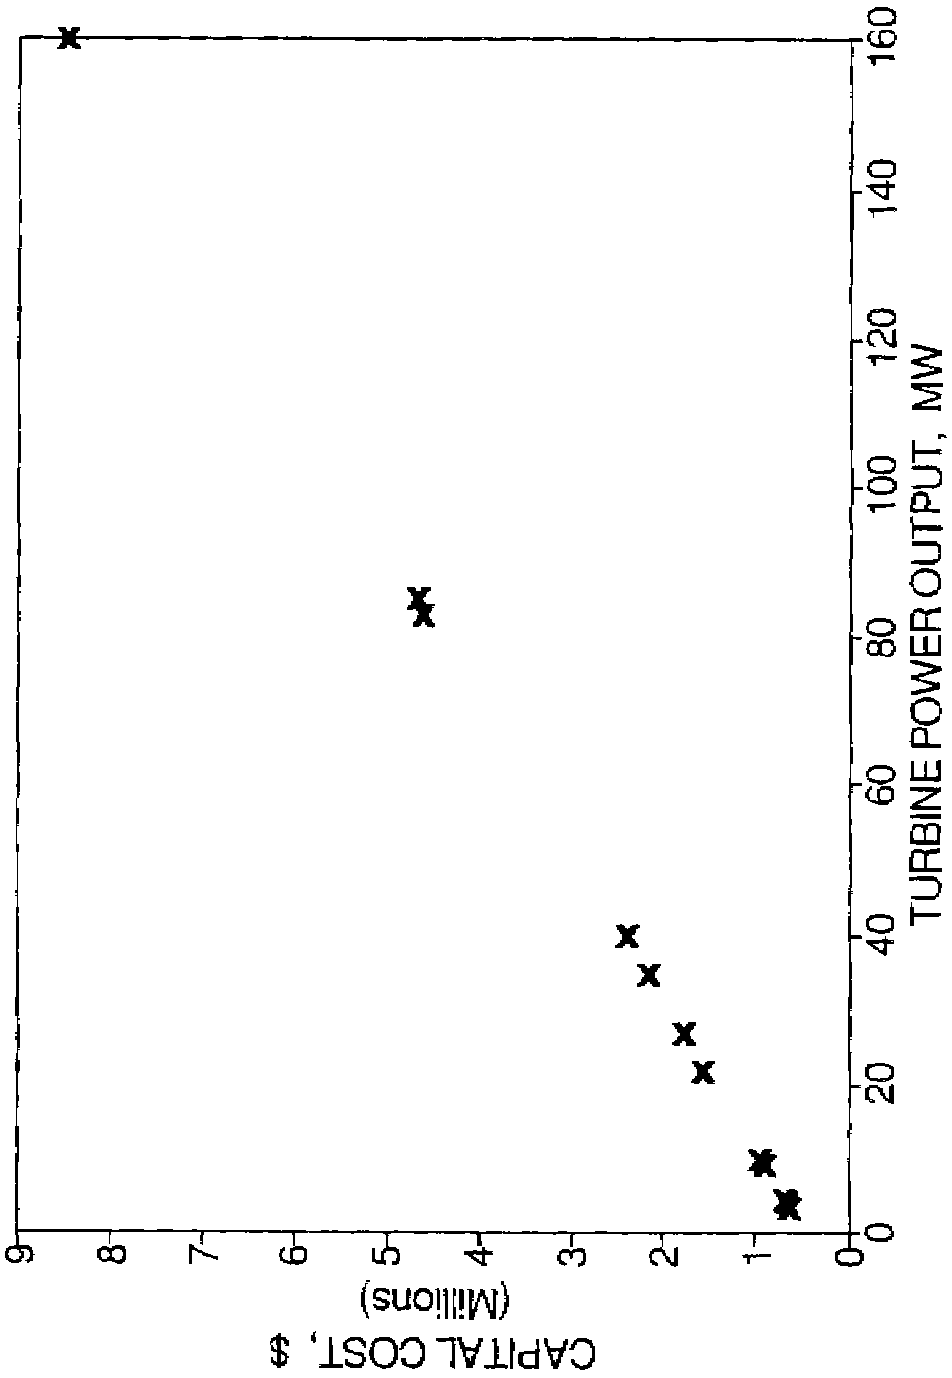

Figure 2-6. Capital costs for selective catalytic reduction.

NMED Exhibit 53

Figure 2-7 plots capital costs on a $/MW basis and shows that these costs are highest for the smallest turbine, at $188,000/MW ($140/hp) for a 3.3 MW (4,430 hp) unit, and decrease exponentially with increasing turbine size to $52/MW ($40/hp) for a 161 MW (216,000 hp) machine.

NMED Exhibit 53

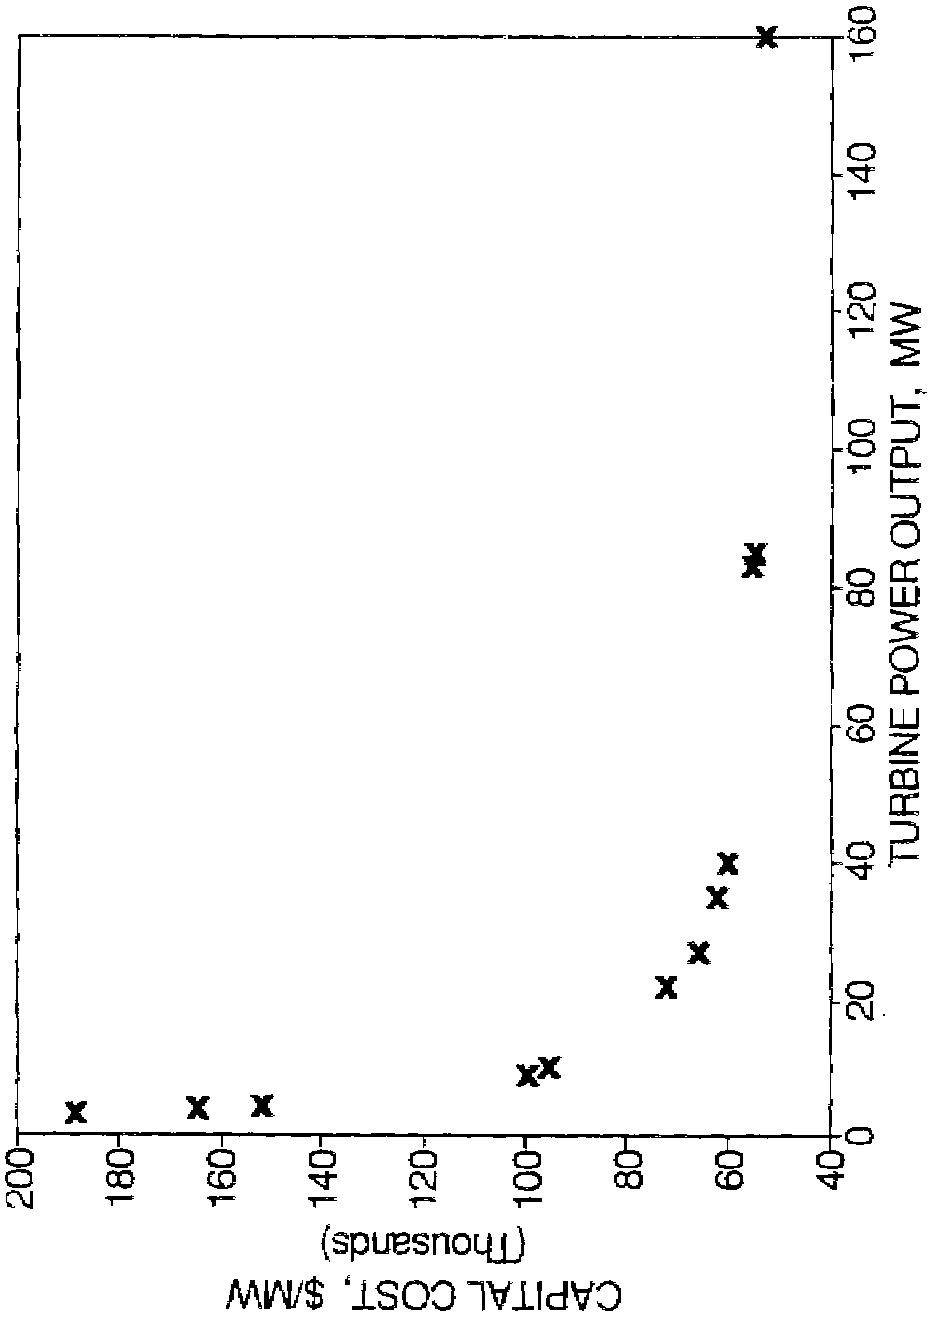

Figure 2-7. Capital costs, in $/MW, for selective catalytic reduction.

NMED Exhibit 53

These costs apply to new installations firing natural gas as the primary fuel. No SCR sites using oil as the primary fuel were identified, and costs were not available. For this

NMED Exhibit 53

reason, the costs for gas-fired applications were also used for oil-fired sites. Retrofit SCR costs could be considerably higher than those shown here for new installations, especially if an existing HRSG and ancillary equipment must be moved or modified to accommodate the SCR system.

2.3.2 Cost Effectiveness

The cost effectiveness, in $/ton of NO_x removed, was developed for each NO_x control technique. The cost effectiveness for a given control technique is calculated by dividing the total annual cost by the annual NO_x reduction, in tons. The cost effectiveness presented in this section correspond to 8,000 annual operating hours. Total annual costs were calculated as the sum of all annual operating costs and annualized capital costs. Annual operating costs include costs for incremental fuel, utilities, maintenance, applicable performance penalties, operating and supervisory labor, plant overhead, general and administrative, and taxes and insurance. Capital costs were annualized using the capital recovery factor method with an equipment life of 15 years and an annual interest rate of 10 percent. Cost-effectiveness figures for combustion controls and SCR are presented in Sections 2.3.2.1 and 2.3.2.2, respectively.

2.3.2.1 Combustion Controls Cost Effectiveness. Cost effectiveness for combustion controls is shown in Figure 2-8.

NMED Exhibit 53

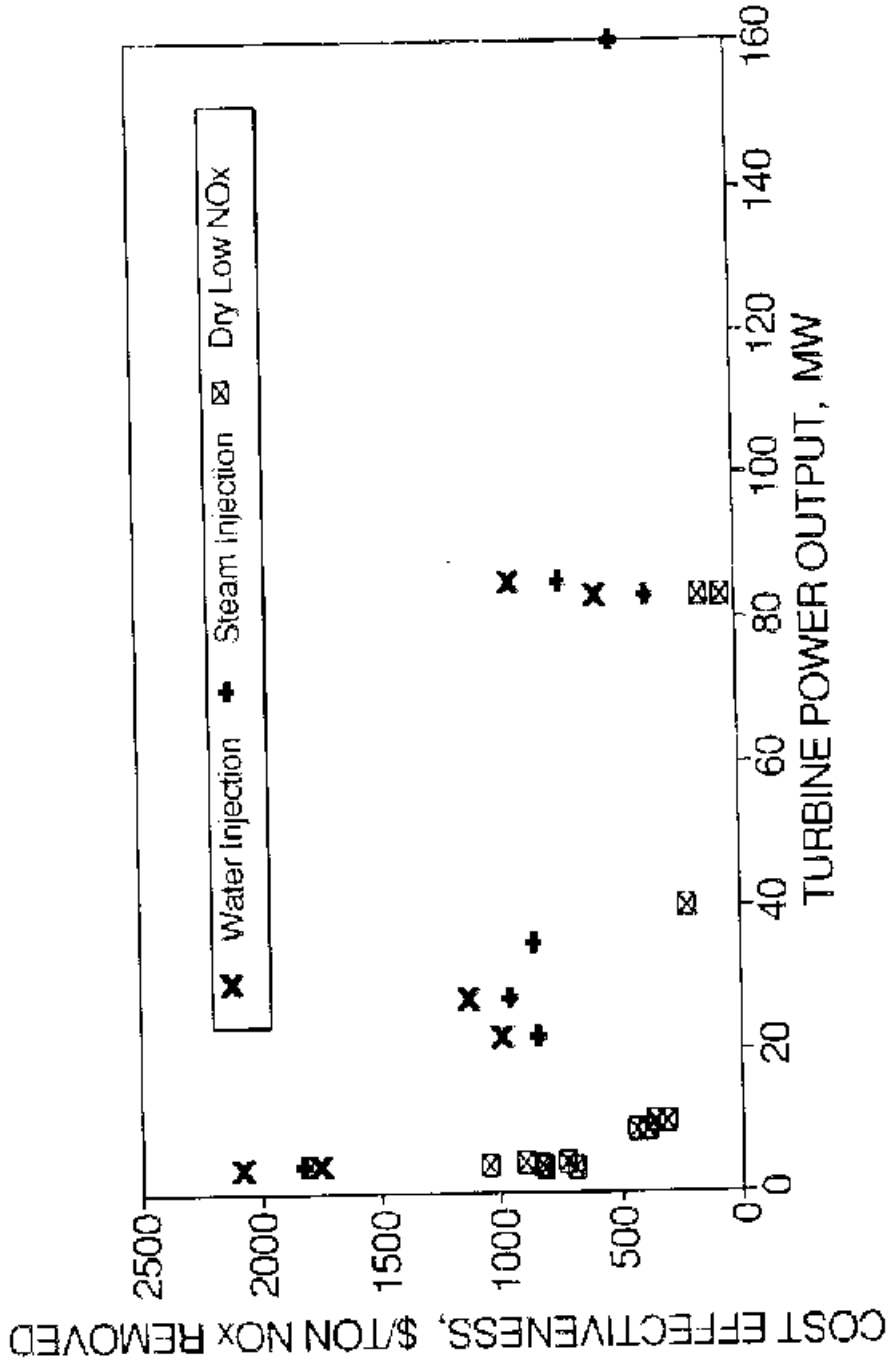

Figure 2-8. Cost effectiveness of combustion controls.

NMED Exhibit 53

Figure 2-8 indicates that cost effectiveness for combustion controls is highest for the smallest turbines and decreases exponentially with decreasing turbine size. Figure 2-8 also shows that the range of cost effectiveness for water injection is similar to that for steam injection, primarily because the total annual costs and achievable controlled NO_x emission levels for water and steam injection are similar. The cost-effectiveness range for dry low-NO_x combustion is lower than that for wet

$_x$ levels are similar (25 to 42 ppmv), due to the lower total annual costs for dry low-NO_x combustion.

NMED Exhibit 53

For water injection, cost effectiveness, in $/ton of NO_x removed, ranges from $2,080 for a 3.3 MW (4,430 hp) unit to $575 for an 83 MW (111,000 hp) turbine and $937 for an 85 MW (114,000 hp) turbine. For steam injection, cost effectiveness is $1,830 for a 3.3 MW (4,430 hp), decreasing to $375 for an 83 MW (111,000 hp) turbine, and increasing to $478 for a 161 MW (216,000 hp) turbine. The relatively low cost effectiveness for the 83 MW (111,000 hp) turbine is due to this particular turbine's high uncontrolled NO emissions, which result in a relatively high NO_x removal efficiency and lower cost effectiveness. The cost effectiveness shown in Figure 2-8

number of oil-fired applications with water injection indicates that the cost effectiveness ranges from 70 to 85 percent of the

NO_x removal efficiency achieved in oil-fired applications.

For dry low-NO_x combustion, cost effectiveness, in $/ton of NO_x removed, ranges from $1,060 for a 4.0 MW (5,360 hp) turbine down to $154 for an 85 MW (114,000 hp) machine. A cost effectiveness of $57 was calculated for the 83 MW (111,000 hp) unit. Again, the relatively high uncontrolled NO_x emissions and the resulting high NO_x removal efficiency for this turbine model yields a relatively low cost-effectiveness figure. Current dry low-NO_x combustion designs do not achieve NO_x reductions with oil fuels, so the cost-effectiveness values shown in this section apply only to gas-fired applications.

2.3.2.2 SCR Cost Effectiveness. Cost effectiveness for SCR was calculated based on the use of combustion controls upstream of the catalyst to reduce NO_x emissions to a range of 25 to 42 ppmv at the inlet to the catalyst. This approach was used because all available SCR cost information is for SCR applications used in combination with combustion controls and all but one of the 100+ SCR installations in the United States operate in combination with combustion controls. For this cost analysis, a 5-year catalyst life and a 9 ppmv controlled NO_x emission level was used to calculate cost effectiveness for SCR.

NMED Exhibit 53

Figure 2-9 presents SCR cost effectiveness. Figure 2-9 shows that, like combustion controls, SCR cost effectiveness is highest for the smallest turbines and decreases exponentially with decreasing turbine size.

NMED Exhibit 53

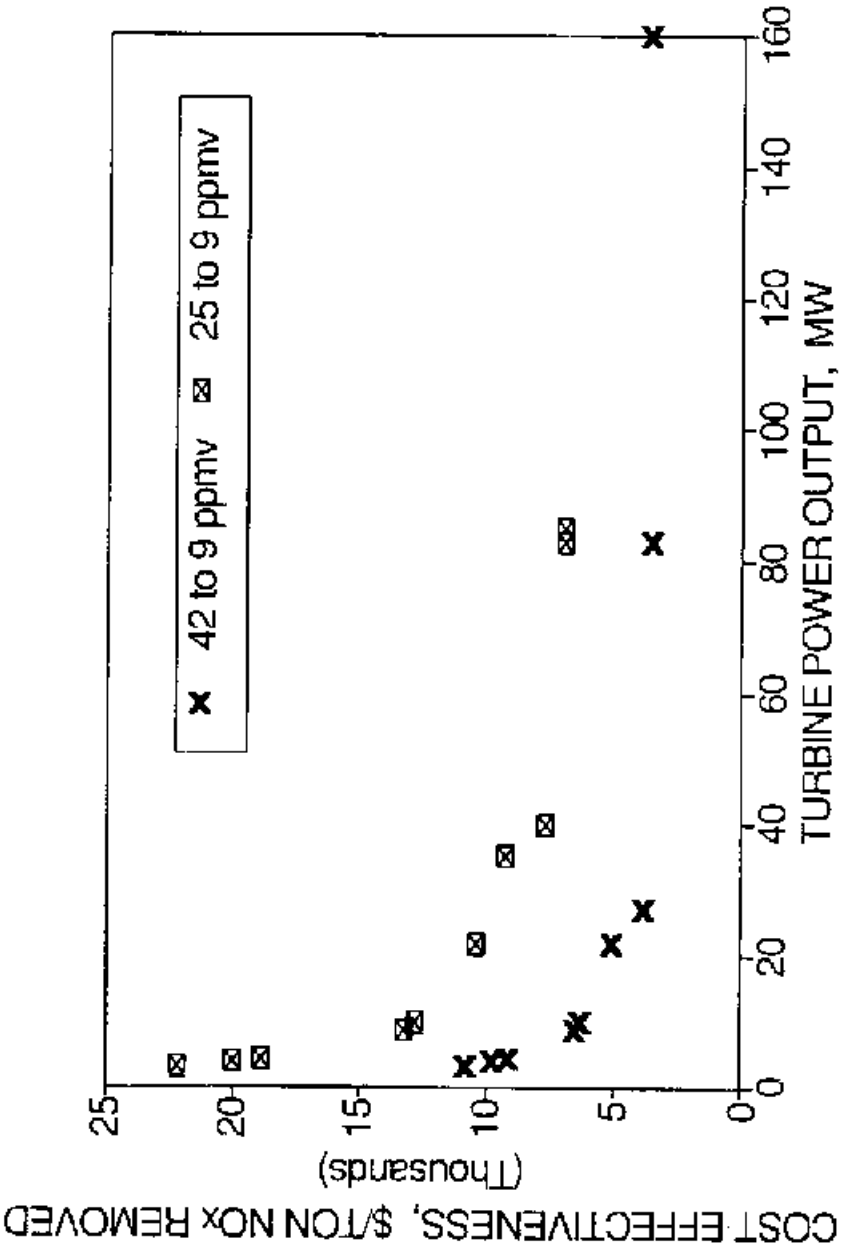

Figure 2-9. Cost effectiveness for selective catalytic reduction installed downstream of combustion controls.

NMED Exhibit 53

Also, because this cost analysis uses a 9 ppmv controlled NO_x emission level for SCR, NO_x reduction efficiencies are higher where the NO_x emission level into the SCR is 42 ppmv than for applications with a 25 ppmv level. Cost effectiveness corresponding to an inlet NO_x emission level of 42 ppmv, in $/ton of NO_x removed, ranges from a high of $10,800 for a 3.3 MW (4430 hp) turbine to $3,580 for a 161 MW (216,000 hp) turbine. For an inlet NO_x emission level of 25 ppmv, the cost-effectiveness range shifts higher, from $22,100 for a 3.3 MW (4,430 hp) installation to $6,980 for an 83 MW (111,000 hp) site.

The range of cost effectiveness for SCR shown in Figure 2-9 applies to gas-fired applications. Cost effectiveness developed for a limited number of oil-fired installations using capital costs from gas-fired applications yields cost-effectiveness values ranging from approximately 70 to 77 percent of those for gas-fired sites. The lower cost-effectiveness figures for oil-fired applications result primarily from the greater annual NO_x reductions for oil-fired applications; the gas-fired capital costs used for these oil-fired applications may understate the actual capital costs for these removal rates and actual oil-fired cost-effectiveness figures may be higher.

Combined cost-effectiveness figures, in $/ton of NO_x removed, were calculated for the combination of combustion controls plus SCR by dividing the sum of the total annual costs by the sum of the NO_x removed for both control techniques. The controlled NO_x emission level for the combination of controls is 9 ppmv. These combined cost-effectiveness figures are presented in Figure 2-10.

NMED Exhibit 53

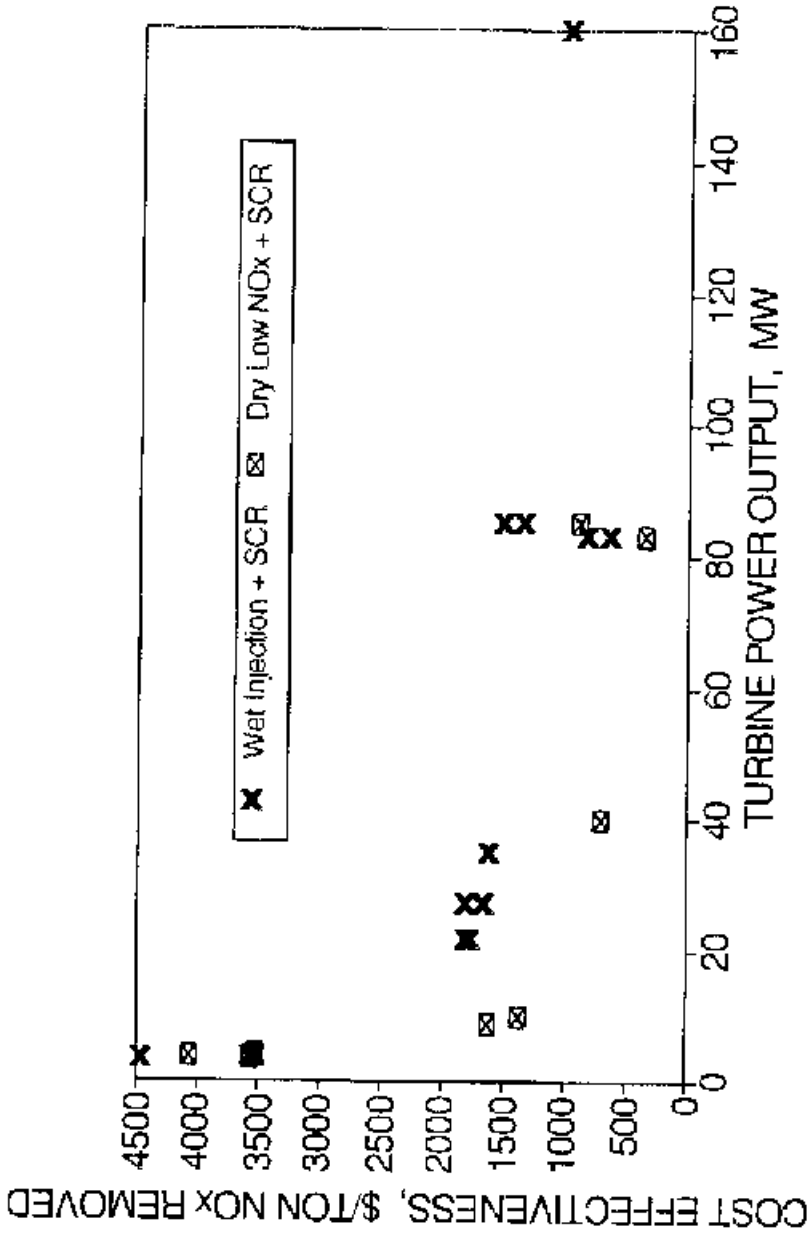

Figure 2-10. Combined cost effectiveness for combustion controls plus selective catalytic reduction.

For wet injection plus SCR, the combined cost effectiveness ranges from $4,460 for a 3.3 MW (4,430 hp) application to $988 for a 160 MW (216,000 hp) site. The $645 cost-effectiveness value for the 83 MW (111,000 hp) turbine is lower than the other turbine models shown in Figure 2-10 due to

NMED Exhibit 53

NMED Exhibit 53

the relatively high uncontrolled NO_x emission level for this turbine, which results in relatively high NO_x removal rates and a lower cost effectiveness. For dry low-NO_x combustion plus SCR, combined cost-effectiveness values range from $4,060 to $348 for this turbine size range.

2.4 REVIEW OF CONTROLLED NO_x EMISSION LEVELS AND COSTS

An overview of the performance and costs for available NO_x control techniques is presented in Figure 2-11.

NMED Exhibit 53

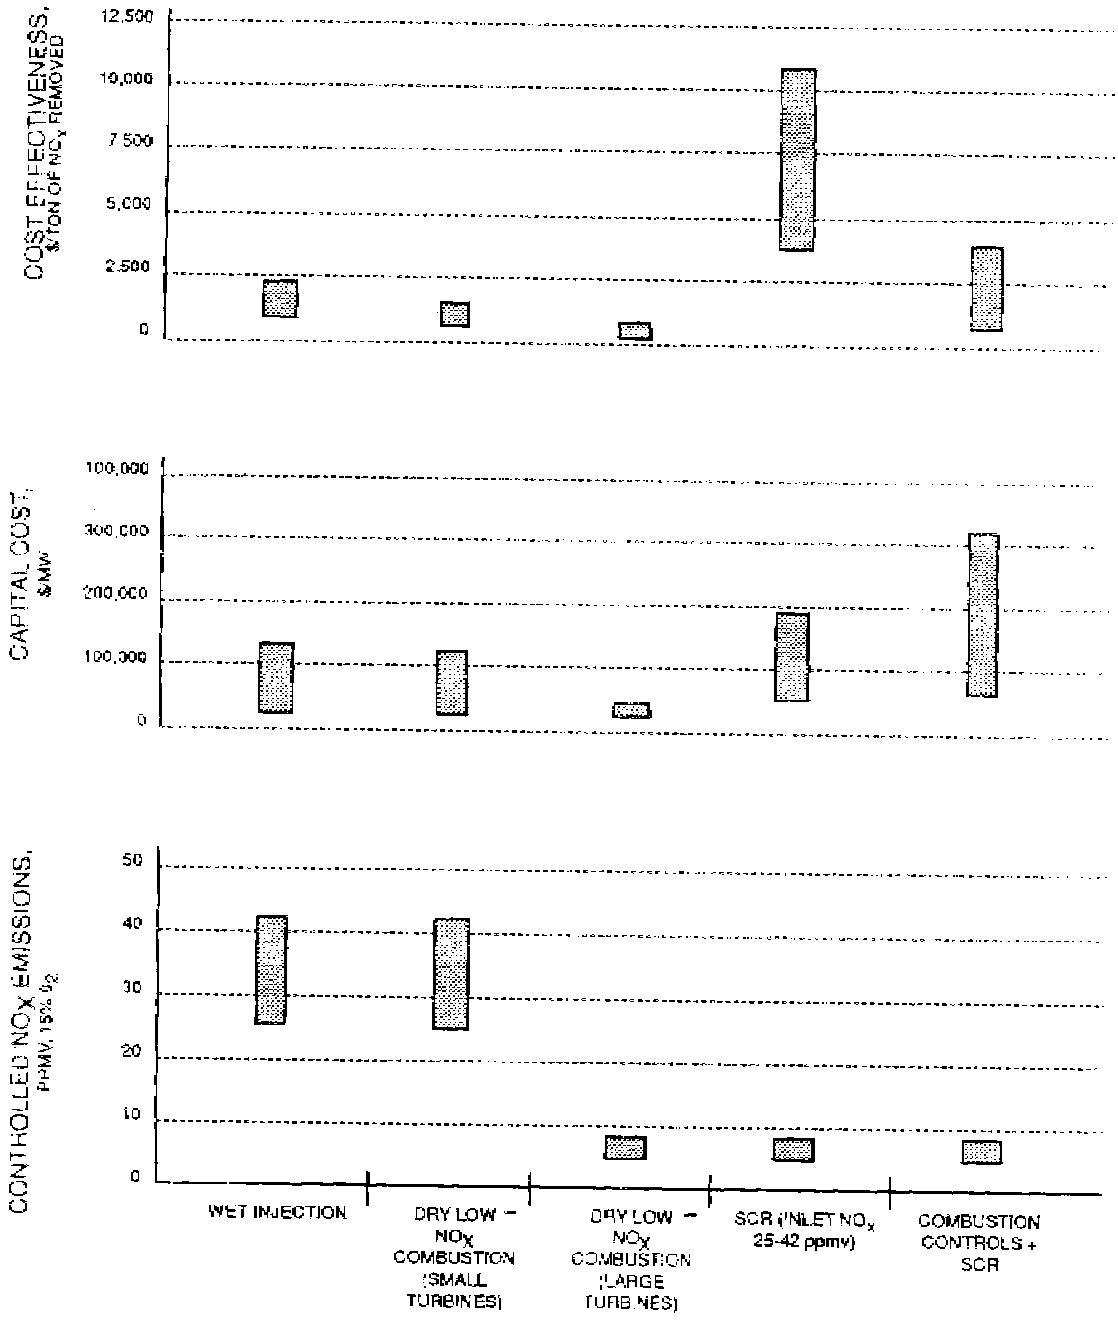

Figure 2-11. Controlled NO_x emission levels and associated capital costs and cost effectiveness for available NO_x control techniques. Natural gas fuel.

NMED Exhibit 53

Figure 2-11 shows relative achievable controlled NO_x emission levels, capital costs, and cost effectiveness for gas-fired turbine applications. Controlled NO_x emission levels of 25 to 42 ppmv can be achieved using either wet injection or, where available, dry low-NO_x combustion. Wet injection capital costs range from $30,000 to $140,000 per MW ($22 to $104 per hp), and cost effectiveness ranges from $375 to $2,100 per ton of NO_x removed. Dry low-NO_x combustion capital costs range from $25,000 to $115,000 per MW ($19 to $86 per hp), and cost effectiveness ranges from $55 to $1,050 per ton of NO_x removed.

A controlled NO_x emission level of 9 ppmv requires the addition of SCR, except for a limited number of large turbine models for which dry low-NO_x combustion designs can achieve this level. For turbine models above 40 MW (53,600 hp), the capital costs of dry low-NO_x combustion range from $25,000 to $36,000 per MW ($25 to $27 per hp), and the cost effectiveness ranges from $55 to $138 per ton of NO_x removed. Adding SCR to reduce NO_x emission levels from 42 or 25 ppmv to 9 ppmv adds capital costs ranging from $53,000 to $190,000 per MW ($40 to $142 per hp) and yields cost-effectiveness values ranging from $3,500 to $10,500 per ton of NO_x removed. The combination of combustion controls plus SCR yields combined capital costs ranging from $78,000 to $330,000 per MW ($58 to $246 per hp) and cost-effectiveness values ranging from $350 to $4,500 per ton of NO_x removed.

2.5 ENERGY AND ENVIRONMENTAL IMPACTS OF NO_x CONTROL TECHNIQUES

The use of the NO_x control techniques described in this document may affect the turbine performance and maintenance

NMED Exhibit 53

requirements and may result in increased emissions of carbon monoxide (CO), hydrocarbons (HC), and NH_3. These potential energy and environmental impacts are discussed in this section.

Water or steam injection affects turbine performance and in some turbines also affects maintenance requirements. The increased mass flow through the turbine resulting from water or steam injection increases the available power output. The quenching effect in the combustor, however, decreases combustion efficiency, and consequently the efficiency of the turbine decreases in most applications. The efficiency reduction is greater for water than for steam injection, largely because the heat of vaporization energy cannot be recovered in the turbine. In applications where the steam can be produced from turbine exhaust heat that would otherwise be rejected to the atmosphere, the net gas turbine efficiency is increased with steam injection. Injection of water or steam into the combustor increases the maintenance requirements of the hot section of some turbine models. Water injection generally has a greater impact than steam on increased turbine maintenance. Water or steam injection has the potential to increase CO and, to a lesser extent, HC emissions, especially at water-to-fuel ratios above 0.8.

Turbine manufacturers report no significant performance impacts for lean premixed combustors. Power output and efficiency are comparable to conventional designs. No maintenance impacts are reported, although long-term operating experience is not available. Impacts on CO emissions vary for different combustor designs. Limited data from three manufacturers showed minimal or no increases in CO emissions for controlled NO_x emission levels of 25 to 42 ppmv. For a controlled NO_x level of 9 ppmv, however, CO emissions increased in from 10 to 25 ppmv in one manufacturer's combustor design.

For SCR, the catalyst reactor increases the back-pressure on the turbine, which decreases the turbine power output by approximately 0.5 percent. The addition of the SCR system and associated controls and monitoring equipment increases plant maintenance requirements, but it is expected that these

NMED Exhibit 53

maintenance requirements are consistent with maintenance schedules for other plant equipment. There is no impact on CO or HC emissions from the turbine caused by the SCR system, but ammonia slip through the catalyst reactor results in NH_3 emissions. Ammonia slip levels are typically guaranteed by SCR vendors at 10 ppmv, and operating experience indicates actual NH_3 emissions are at or below this level.

NMED Exhibit 53

3.0 STATIONARY GAS TURBINE DESCRIPTION AND INDUSTRY APPLICATIONS

This section describes the physical components and operating cycles of gas turbines and how turbines are used in industry. Projected growth in key industries is also presented.

3.1 GENERAL DESCRIPTION OF GAS TURBINES

A gas turbine is an internal combustion engine that operates with rotary rather than reciprocating motion. A common example of a gas turbine is the aircraft jet engine. In stationary applications, the hot combustion gases are directed through one or more fan-like turbine wheels to generate shaft horsepower rather than the thrust propulsion generated in an aircraft engine. Often the heat from the exhaust gases is recovered through an add-on heat exchanger.

NMED Exhibit 53

Figure 3-1

NMED Exhibit 53

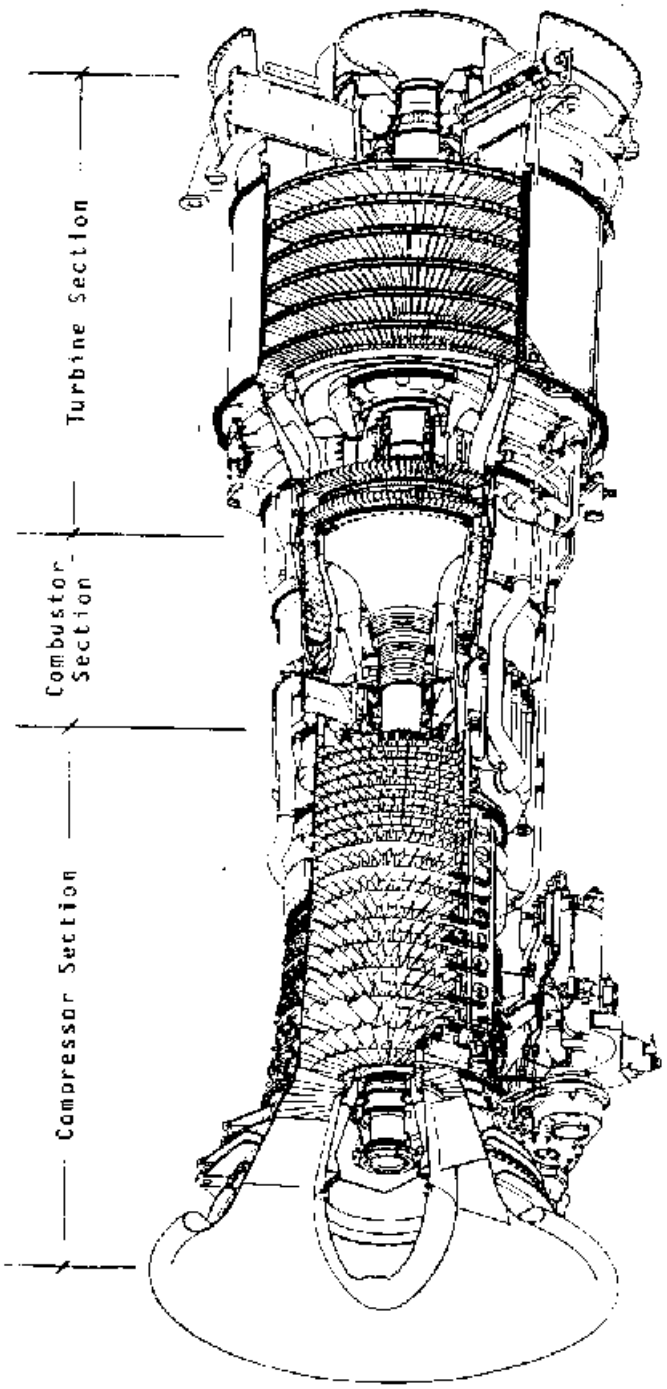

Figure 3-1. The three primary sections of a gas turbine.[1]

NMED Exhibit 53

presents a cutaway view showing the three primary sections of a gas turbine: the compressor, the combustor, and the turbine.[1] The compressor draws in ambient air and compresses it by a pressure ratio of up to 30 times ambient pressure.[2] The compressed air is then directed to the combustor section, where fuel is introduced, ignited, and burned. There are three types of combustors: annular, can-annular, and silo. An annular combustor is a single continuous chamber roughly the shape of a doughnut that rings the turbine in a plane perpendicular to the air flow. The can-annular type uses a similar configuration but is a series of can-shaped chambers rather than a single continuous chamber. The silo combustor type is one or more chambers mounted external to the gas turbine body. These three combustor types are shown in Figure 3-2

NMED Exhibit 53

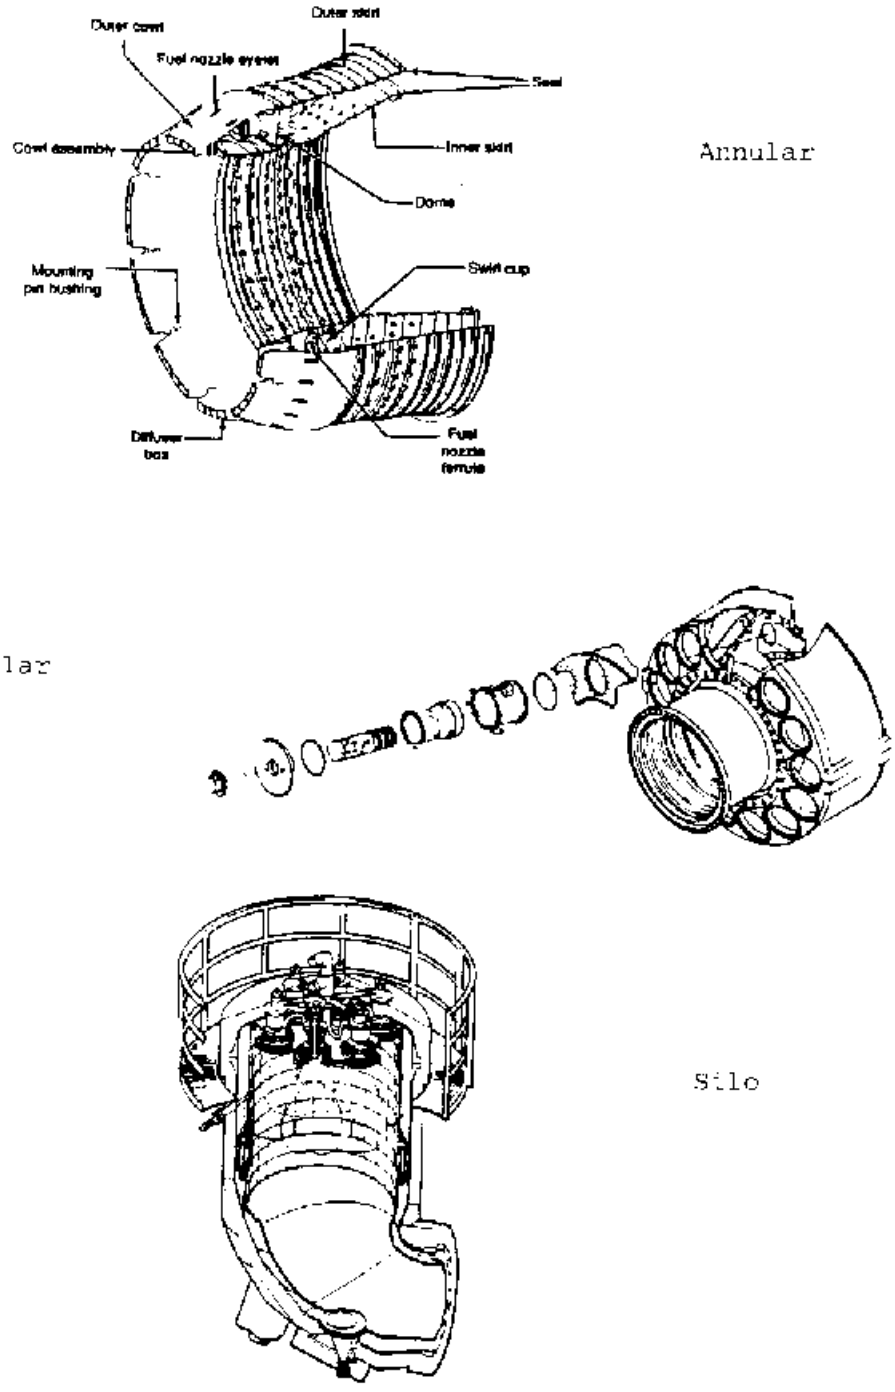

Figure 3-2. Types of gas turbine combustors.[3-5]

NMED Exhibit 53

; further discussion of combustors is found in Chapter 5.[3-5] Flame temperatures in the combustor can reach 2000°C (3600°F).[6] The hot combustion gases

NMED Exhibit 53

are then diluted with additional cool air from the compressor section and directed to the turbine section at temperatures up to 1285°C (2350°F).[6] Energy is recovered in the turbine section in the form of shaft horsepower, of which typically greater than 50 percent is required to drive the internal compressor section.[7] The balance of the recovered shaft energy is available to drive the external load unit.

The compressor and turbine sections can each be a single fan-like wheel assembly, or stage, but are usually made up of a series of stages. In a single-shaft gas turbine, shown in Figure 3-3

NMED Exhibit 53

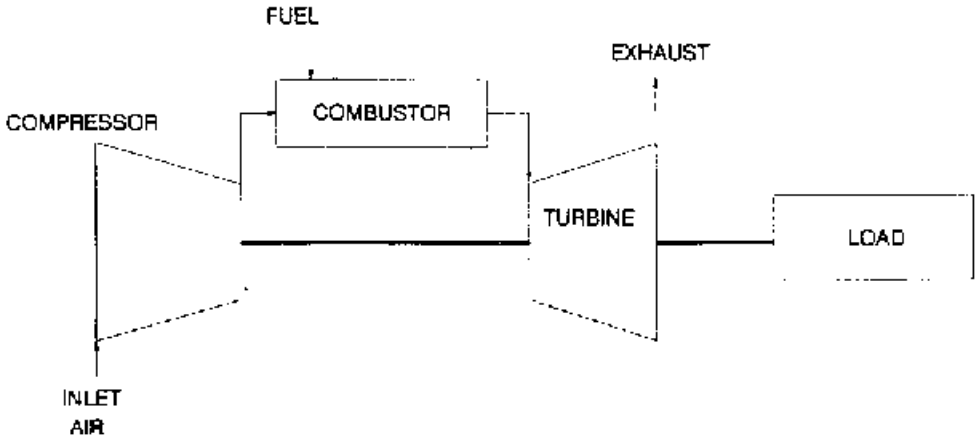

Figure 3-3. Single-shaft gas turbine.

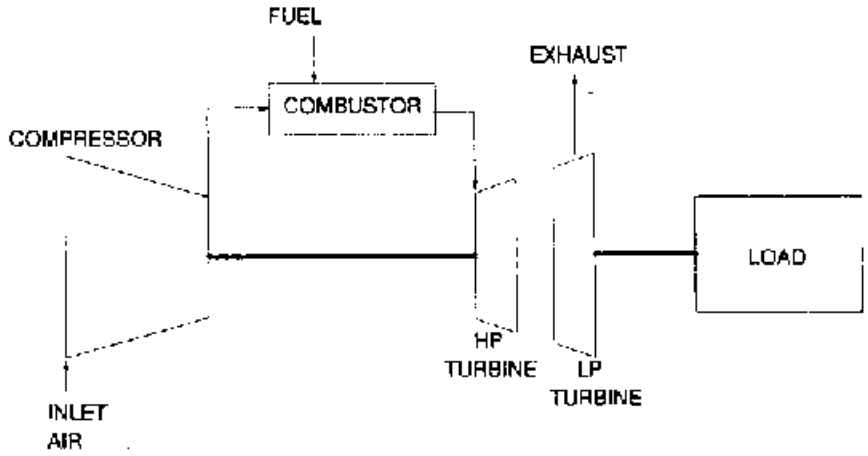

Figure 3-4. Two-shaft gas turbine.

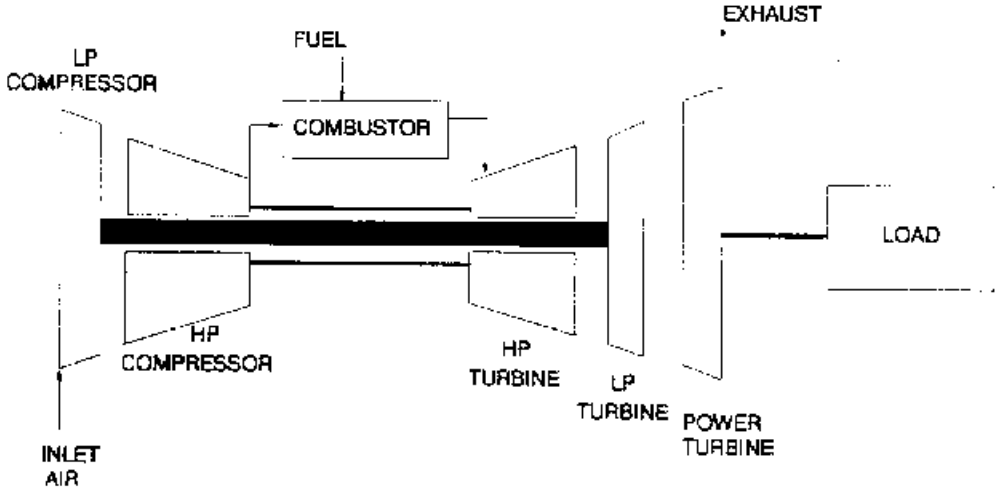

Figure 3-5. Three-shaft gas turbine.

NMED Exhibit 53

, all compressor and turbine stages are fixed to a single, continuous shaft and operate at the same speed. A single-shaft gas turbine is typically used to drive electric generators where there is little speed variation.

A two-shaft gas turbine is shown in Figure 3-4. In this design, the turbine section is divided into a high-pressure and low-pressure arrangement, where the high-pressure turbine is mechanically tied to the compressor section by one shaft, while the low-pressure turbine, or power turbine, has its own shaft and is connected to the external load unit. This configuration allows the high-pressure turbine/compressor shaft assembly, or rotor, to operate at or near optimum design speeds, while the power turbine rotor speed can vary over as wide a range as is required by most external-load units in mechanical drive applications (i.e., compressors and pumps).

A third configuration is a three-shaft gas turbine. As shown in Figure 3-5, the compressor section is divided into a low-pressure and high-pressure configuration. The low-pressure compressor stages are mechanically tied to the low-pressure turbine stages, and the high-pressure compressor stages are similarly connected to the high-pressure turbine stages in a concentric shaft arrangement. These low-pressure and high-pressure rotors operate at optimum design speeds independent of each other. The power turbine stages are mounted on a third independent shaft and form the power turbine rotor, the speed of

NMED Exhibit 53

which can vary over as wide a range as is necessary for mechanical drive applications.

Gas turbines can burn a variety of fuels. Most burn natural gas, waste process gases, or liquid fuels such as distillate oils (primarily No. 2 fuel oil). Some gas turbines are capable of burning lower-grade residual or even crude oil with minimal processing. Coal-derived gases can be burned in some turbines.

The capacity of individual gas turbines ranges from approximately 0.08 to over 200 megawatts (MW) (107 to 268,000 horsepower [hp]).[2] Manufacturers continue to increase the horsepower of individual gas turbines, and frequently they are "ganged," or installed in groups so that the total horsepower output from one location can meet virtually any installation's power requirements.

Several characteristics of gas turbines make them attractive power sources. These characteristics include a high horsepower-to-size ratio, which allows for efficient space utilization, and a short time from order placement to on-line operation. Many suppliers offer the gas turbine, load unit, and all accessories as a fully assembled package that can be performance tested at the supplier's facility. This packaging is cost effective and saves substantial installation time. Other advantages of gas turbines are:

1. Low vibration;
2. High reliability;
3. No requirement for cooling water;
4. Suitability for remote operation;
5. Lower capital costs than reciprocating engines; and
6. Lower capital costs than boiler/steam turbine-based electric power generating plants.[8]

3.2 OPERATING CYCLES

The four basic operating cycles for gas turbines are simple, regenerative, cogeneration, and combined cycles. Each of these cycles is described separately below.

NMED Exhibit 53

3.2.1 Simple Cycle

The simple cycle is the most basic operating cycle of a gas turbine. In a simple cycle application, a gas turbine functions with only the three primary sections described in Section 3.1, as depicted in Figure 3-6.

NMED Exhibit 53

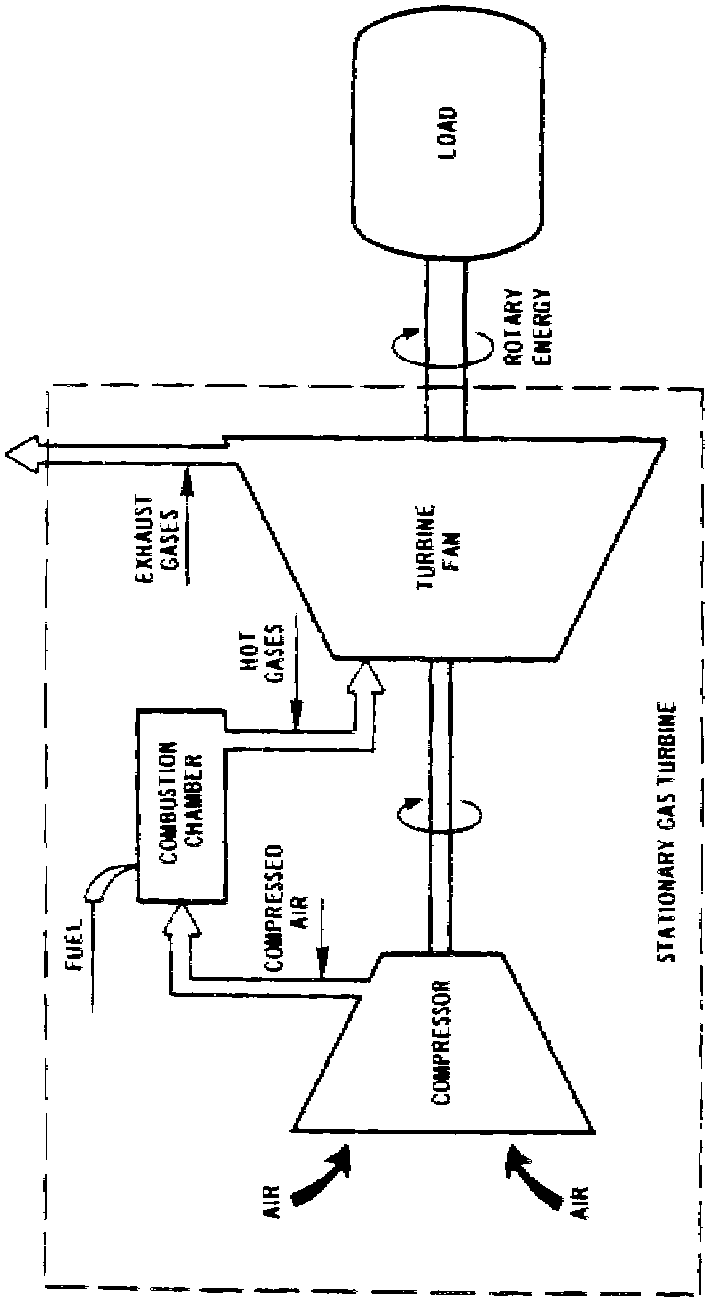

Figure 3-6. Simple cycle gas turbine appplication.[10]

NMED Exhibit 53

[10] Cycle efficiency, defined as a percentage of useful shaft energy output to fuel energy input, is typically in the 30 to 35 percent range, although one manufacturer states an efficiency of 40 percent for an engine recently introduced to the market.[9] In addition to shaft energy output, 1 to 2 percent of the fuel input energy can be attributed to mechanical losses; the balance is exhausted from the turbine in the form of heat.[7] Simple cycle operation is typically used when there is a requirement for shaft horsepower without recovery of the exhaust heat. This cycle offers the lowest installed capital cost but also provides the least efficient use of fuel and therefore the highest operating cost.

3.2.2 Regenerative Cycle

The regenerative cycle gas turbine is essentially a simple cycle gas turbine with an added heat exchanger, called a regenerator or recuperator, to preheat the combustion air. In the regenerative cycle, thermal energy from the exhaust gases is transferred to the compressor discharge air prior to being introduced into the combustor. A diagram of this cycle is depicted in Figure 3-7

NMED Exhibit 53

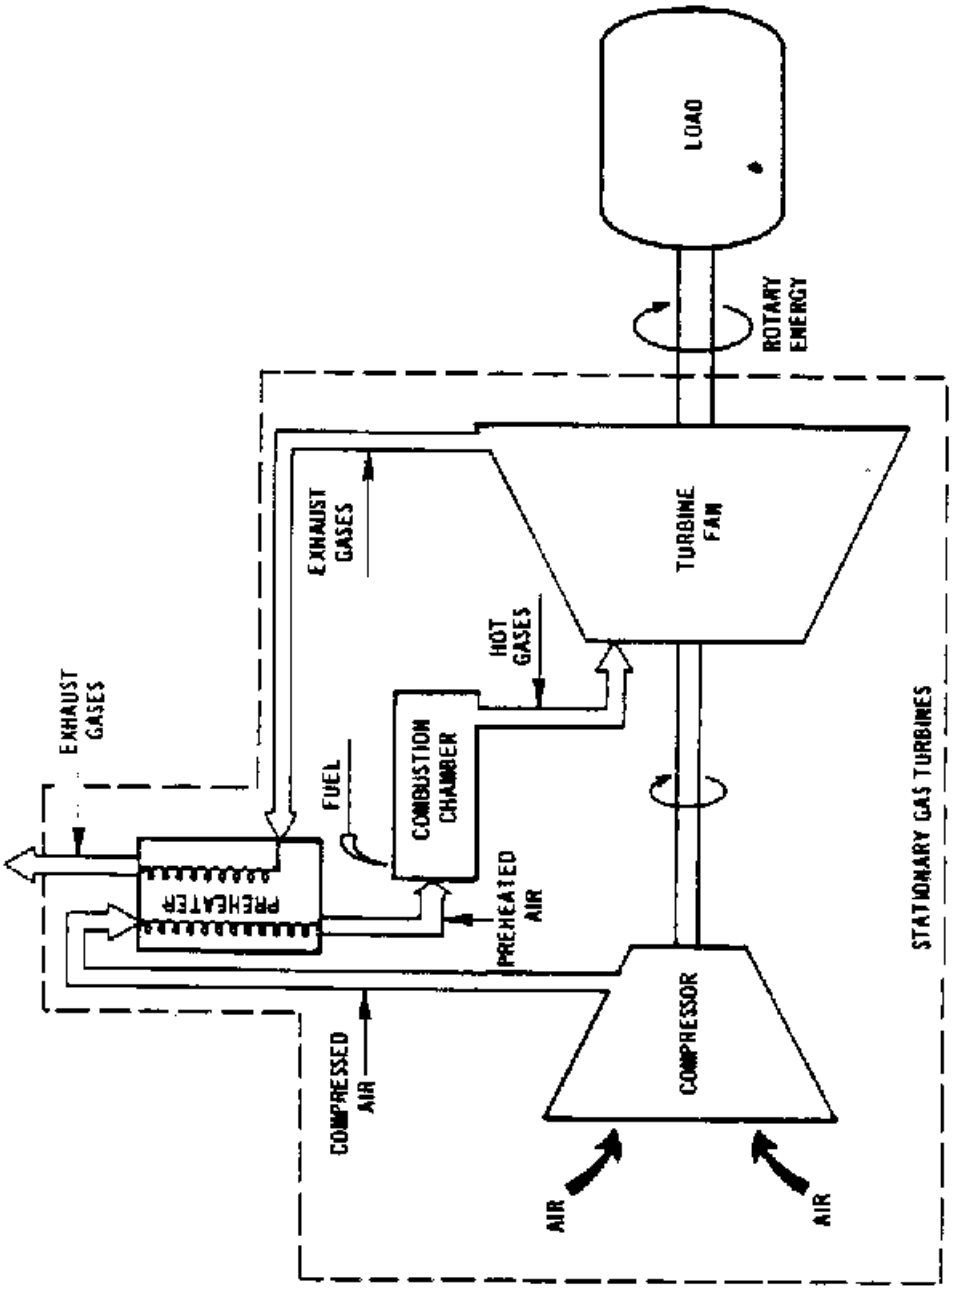

Figure 3-7. Regenerative cycle gas turbine.[11]

NMED Exhibit 53

.[11] Preheating the combustion air reduces the amount of fuel required to reach design combustor temperatures and therefore improves the overall cycle efficiency over that of simple cycle operation. The efficiency gain is directly proportional to the differential temperature between the exhaust gases and compressor discharge air. Since the compressor discharge air temperature increases with an increase in pressure ratio, higher regenerative cycle efficiency gains are realized from lower compressor pressure ratios typically found in older gas turbine models.[7] Most new or updated gas turbine models with high compressor pressure ratios render regenerative cycle operation economically unattractive because the capital cost of the regenerator cannot be justified by the marginal fuel savings.

NMED Exhibit 53

NMED Exhibit 53

3.2.3 Cogeneration Cycle

A gas turbine used in a cogeneration cycle application is essentially a simple cycle gas turbine with an added exhaust heat exchanger, called a heat recovery steam generator (HRSG). This configuration is shown in Figure 3-8

NMED Exhibit 53

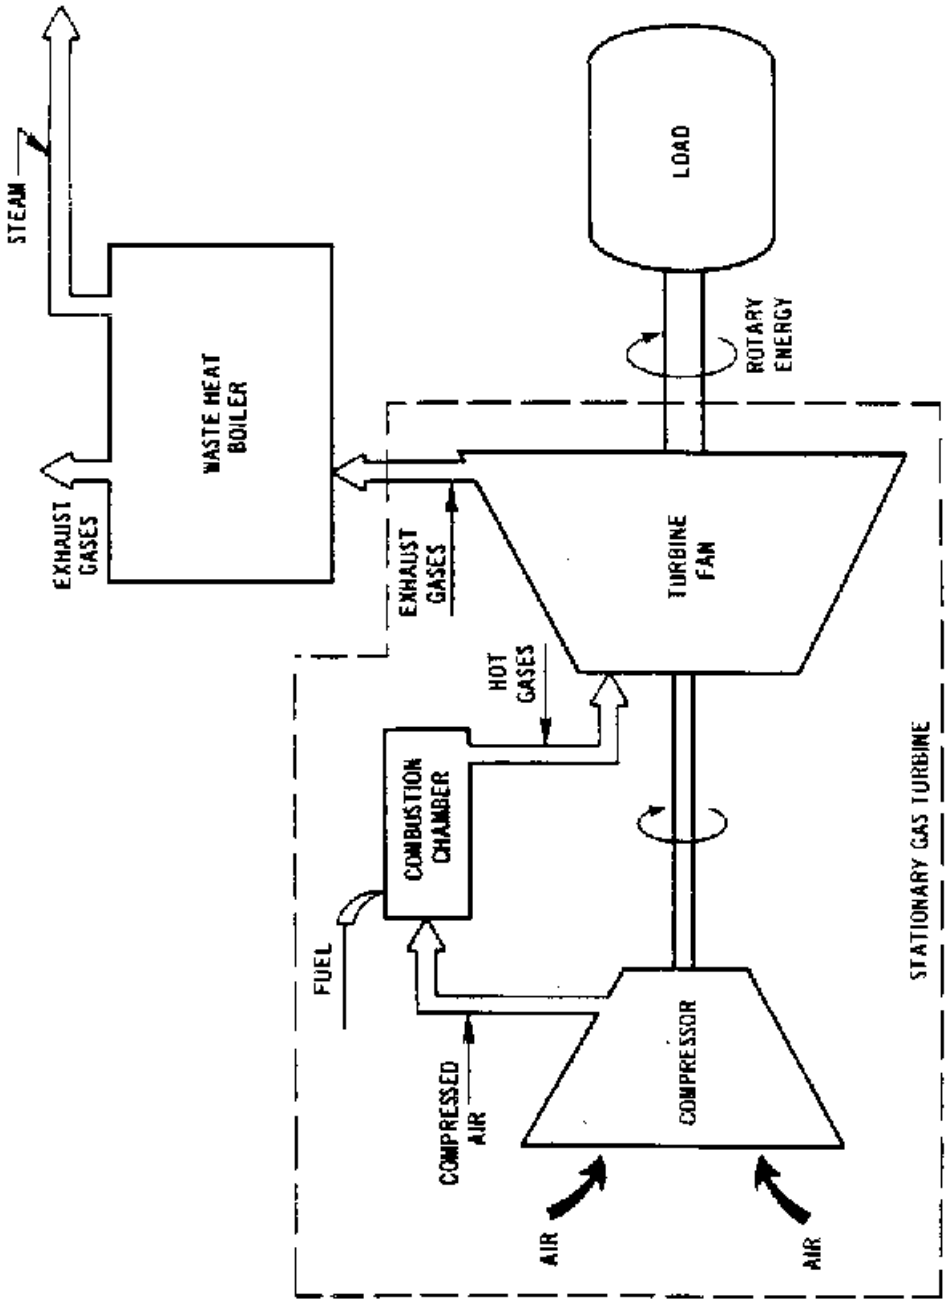

Figure 3-8. Cogeneration cycle gas turbine application.[12]

NMED Exhibit 53

.[12] The steam generated by the exhaust heat can be delivered at a variety of pressure and temperature conditions to meet site thermal process requirements. Where the exhaust heat is not sufficient to meet site requirements, a supplementary burner, or duct burner, can be placed in the exhaust duct upstream of the HRSG to increase the exhaust heat energy. Adding the HRSG equipment increases the capital cost, but recovering the exhaust heat increases the overall cycle efficiency to as high as 75 percent.[13]

3.2.4 Combined Cycle

A combined cycle is the terminology commonly used for a gas turbine/HRSG configuration as applied at an electric utility. This cycle, shown in Figure 3-9

NMED Exhibit 53

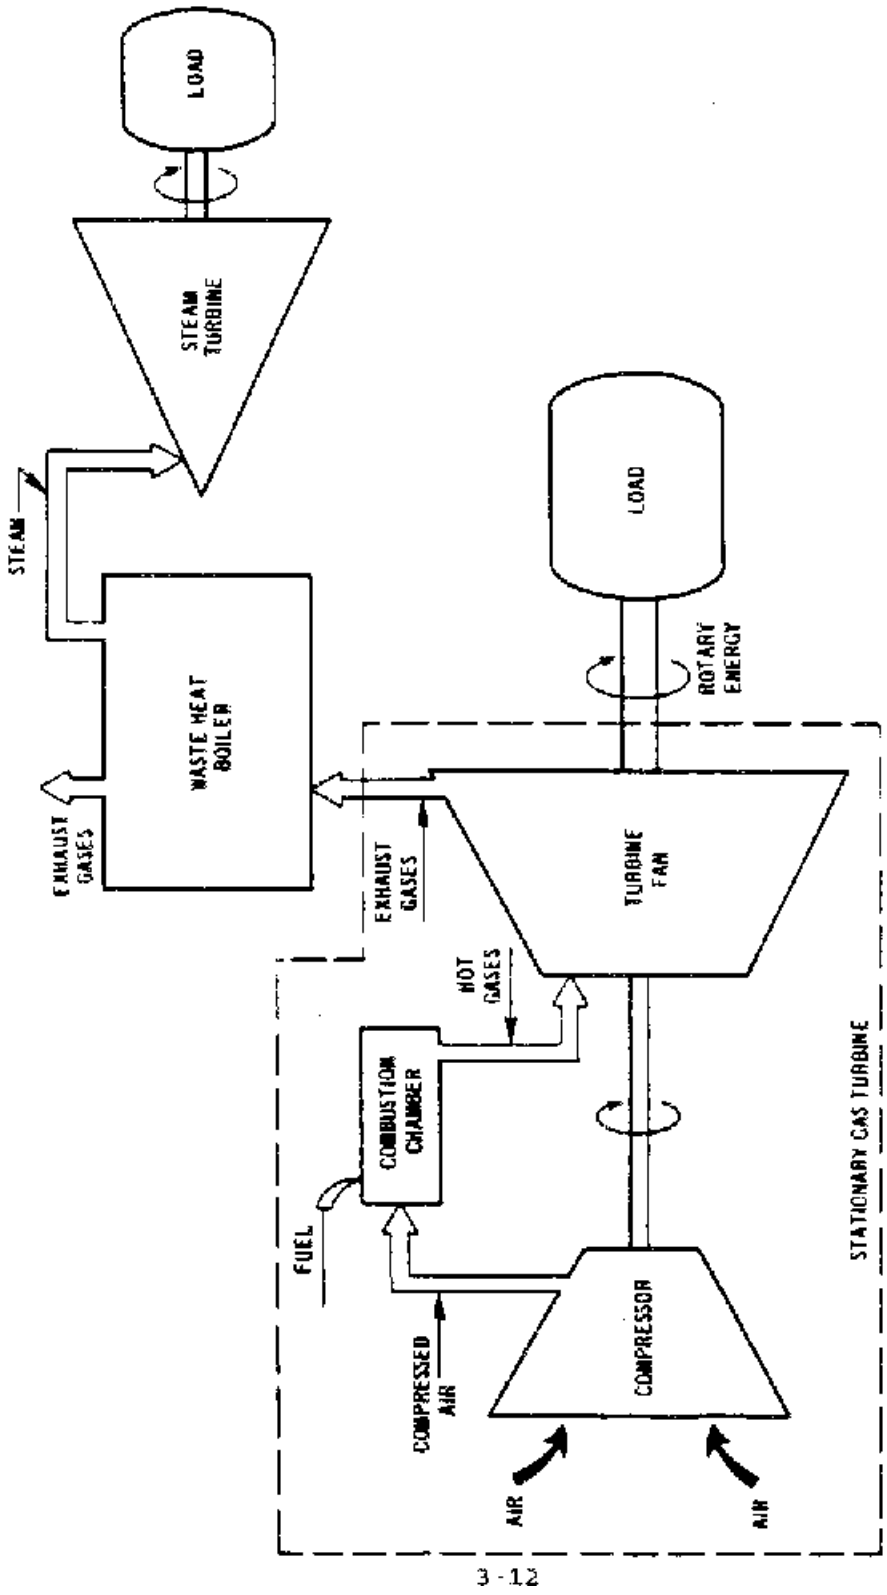

Figure 3-9. Combined cycle gas turbine application.[12]

NMED Exhibit 53

, is used to generate electric power.[12] The gas turbine drives an electric generator, and the steam produced in the HRSG is delivered to a steam turbine, which also drives an electric generator. The boiler may be supplementary-fired to increase the steam production where desired. Cycle efficiencies can exceed 50 percent.

3.3 INDUSTRY APPLICATIONS

Gas turbines are used by industry in both mechanical and electrical drive applications. Compressors and pumps are most often the driven load unit in mechanical drive applications, and electric generators are driven in electrical drive installations. Few sites have gas/air compression or fluid pumping requirements that exceed 15 MW (20,100 hp), and for this reason mechanical drive applications generally use gas turbines in the 0.08- to 15.0-MW (107- to 20,100-hp) range.[14] Electric power requirements range over the entire available range of gas turbines, however, and all sizes can be found in electrical drive applications, from 0.08 to greater than 200 MW (107 to 268,000 hp).[15]

The primary applications for gas turbines can be divided into five broad categories: the oil and gas industry,

NMED Exhibit 53

NMED Exhibit 53

stand-by/emergency electric power generation, independent electric power producers, electric utilities, and other industrial applications.[16] Where a facility has a requirement for mechanical shaft power only, the installation is typically simple or regenerative cycle. For facilities where either electric power or mechanical shaft power and steam generation are required, the installation is often cogeneration or combined cycle to capitalize on these cycles' higher efficiencies.

3.3.1 Oil and Gas Industry

The bulk of mechanical drive applications are in the oil and gas industry. Gas turbines in the oil and gas industry are used primarily to provide shaft horsepower for oil and gas extraction and transmission equipment, although they are also used in downstream refinery operations. Most gas turbines found in this industry are in the 0.08- to 15.0-MW (107- to 20,100-hp) range.

Gas turbines are particularly well suited to this industry, as they can be fueled by a wide range of gaseous and liquid fuels often available at the site. Natural gas and distillate oil are the most common fuels. Many turbines can burn waste process gases, and some turbines can burn residual oils and even crude oil. In addition, gas turbines are suitable for remote installation sites and unattended operation. Most turbines used in this industry operate continuously, 8,000+ hours per year, unless the installation is a pipeline transmission application with seasonal operation.

Competition from reciprocating engines in this industry is significant. Although gas turbines have a considerable capital cost advantage, reciprocating engines require less fuel to produce the same horsepower and consequently have a lower operating cost.[17] Selection of gas turbines vs. reciprocating engines is generally determined by site-specific criteria such as installed capital costs, costs for any required emissions control equipment, fuel costs and availability, annual operating hours, installation and structural considerations, compatibility with existing equipment, and operating experience.

NMED Exhibit 53

3.3.2 Stand-By/Emergency Electric Power Generation

Small electric generator sets make up a considerable number of all gas turbine sales under 3.7 MW (5,000 hp). The majority of these installations provide backup or emergency power to critical networks or equipment and use liquid fuel. Telephone companies are a principal user, and hospitals and small municipalities also are included in this market. These turbines operate on an as-needed basis, which typically is between 75 and 200 hours per year.

Gas turbines offer reliable starting, low weight, small size, low vibration, and relatively low maintenance, which are important criteria for this application. Gas turbines in this size range have a relatively high capital cost, however, and reciprocating engines dominate this market, especially for applications under 2,000 kW (2,700 hp).[18,19]

3.3.3 Independent Electrical Power Producers

Large industrial complexes and refining facilities consume considerable amounts of electricity, and many sites choose to generate their own power. Gas turbines can be used to drive electric generators in simple cycle operation, or an HRSG system may be added to yield a more efficient cogeneration cycle. The vast majority of cogeneration installations operate in a combined cycle capacity, using a steam turbine to provide additional electric power. The Public Utility Regulatory Policies Act (PURPA) of 1978 encourages independent cogenerators to generate electric power by requiring electric utilities to (1) purchase electricity from qualifying producers at a price equal to the cost the utility can avoid by not having to otherwise supply that power (avoided cost) and (2) provide backup power to the cogenerator at reasonable rates. Between 1980 and 1986, approximately 20,000 MW of gas turbine-produced electrical generating capacity was certified as qualifying for PURPA benefits. This installed capacity by private industry power generators is more than the sum of all utility gas turbine orders for all types of central power plants during this period.[20] The Department of Energy (DOE) expects an additional 27,000 MW

NMED Exhibit 53

capacity to be purchased by private industry in the next 10 years.[21]

Gas turbines installed in this market range in power from 1 to over 100 MW (1,340 to 134,000 hp) and operate typically between 4,000 and 8,000 hours per year. While reciprocating engines compete with the gas turbine at the lower end of this market (under approximately 7.5 MW [10,000 hp]), the advantages of lower installed costs, high reliability, and low maintenance requirements make gas turbines a strong competitor.

3.3.4 Electric Utilities

Electric utilities are the largest user of gas turbines on an installed horsepower basis. They have traditionally installed these turbines for use as peaking units to meet the electric power demand peaks typically imposed by large commercial and industrial users on a daily or seasonal basis; consequently, gas turbines in this application operate less than 2,000 hours per year.[22] The power range used by the utility market is 15 MW to over 150 MW (20,100 to 201,000 hp). Peaking units typically operate in simple cycle.

The demand for gas turbines from the utility market was flat through the late 1970's and 1980's as the cost of fuel increased and the supplies of gas and oil became unpredictable. There are signs, however, that the utility market is poised to again purchase considerable generating capacity. The capacity margin, which is the utility industry's measure of excess generation capacity, peaked at 30 percent in 1982. By 1990, the capacity margin had dropped to approximately 20 percent, and, based on current construction plans, will reach the industry rule-of-thumb minimum of 15 percent by 1995.[21] The utility industry is adding new capacity and repowering existing older plants, and gas turbines are expected to play a considerable role.

Many utilities are now installing gas turbine-based combined cycle installations with provisions for burning coal-derived gas fuel at some future date. This application is known as integrated coal gasification combined cycle (IGCC). At least five power plant projects have been announced, and several more

NMED Exhibit 53

are being negotiated. Capital costs for these plants are in many cases higher than comparable natural gas-fueled applications, but future price increases for natural gas could make IGCC an attractive option for the future.[23]

Utility orders for gas turbines have doubled in each of the last 2 years. The DOE says that electric utilities will need to add an additional 73,000 MW to capacity to meet demand by the year 2000, and as Figure 3-10

NMED Exhibit 53

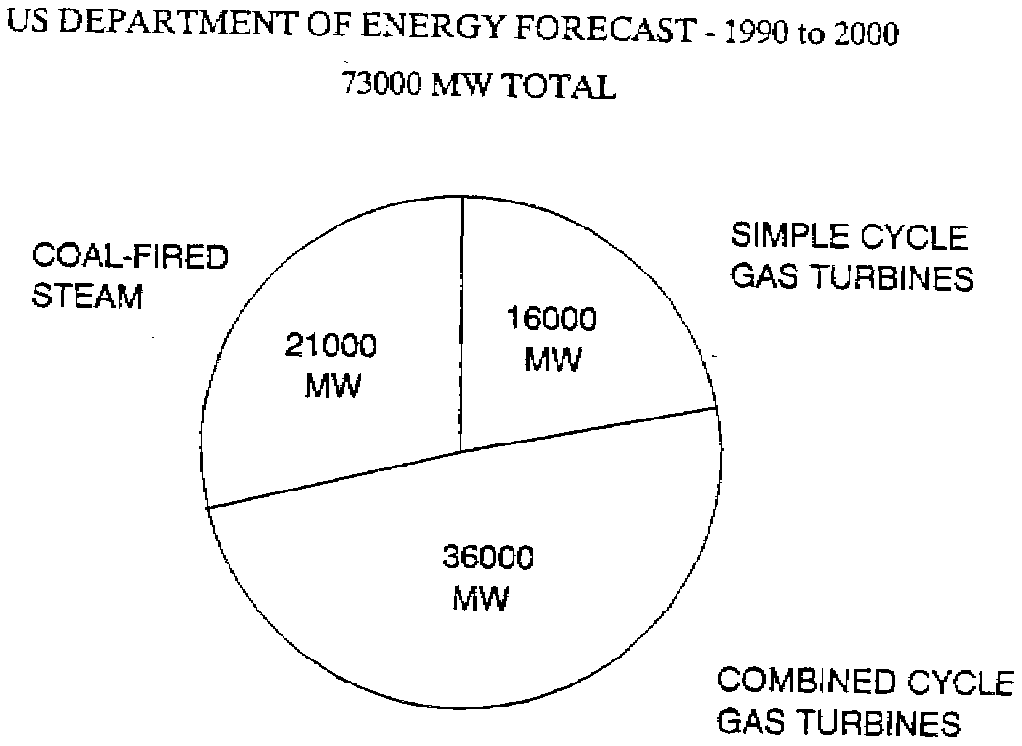

Figure 3-10. Total capacity to be purchased by the utility industry.[21]

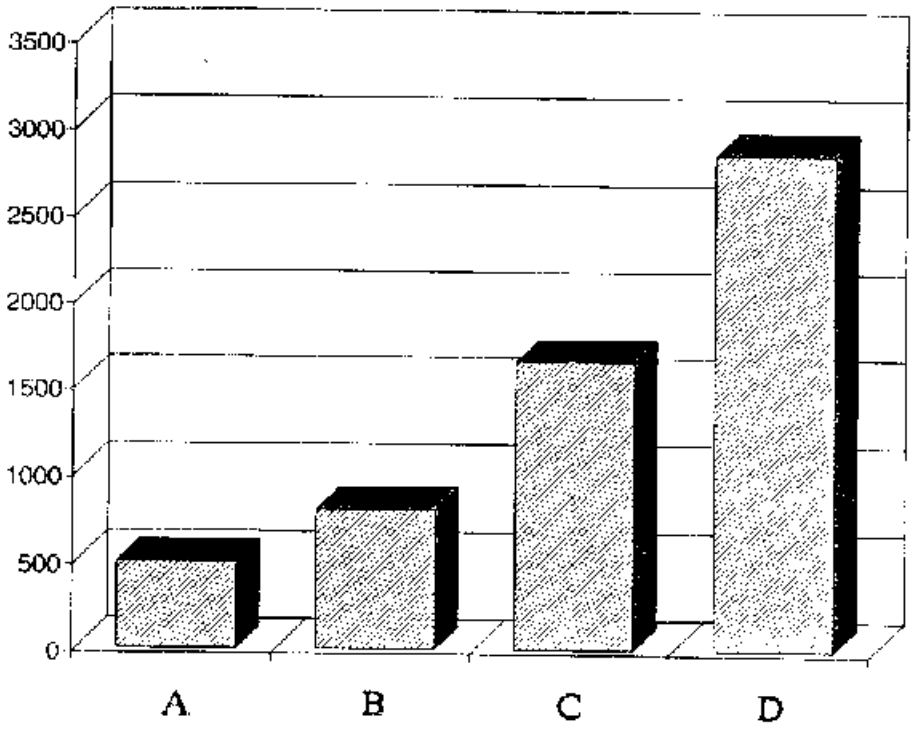
NMED Exhibit 53

shows, DOE expects 36,000 MW of combined cycle and 16,000 MW of simple cycle gas turbines to be purchased. This renewed interest in gas turbines is a result of:

1. The introduction of new, larger, more efficient gas turbines;

2. Lower natural gas prices and proven reserves to meet current demand levels for more than 100 years;



3. Shorter lead times than those of competing equipment; and

4. Lower capital costs for gas turbines.[21]

NMED Exhibit 53

B - New plant using combined cycle gas turbines
C - New plant using coal fired boilers
D - New plant using nuclear power

Figure 3-11. Capital costs for electric utility plants.[24]

NMED Exhibit 53

, are (1) $500 per KW for repowering existing plants with combined cycle gas turbines, (2) $800 per KW for new combined cycle plants, (3) $1,650 per KW for new coal-fired plants, and (4) $2,850 per KW for new nuclear-powered plants.[24]

Gas turbines are also an alternative to displace planned or existing nuclear facilities. A total of 1,020 MW of gas turbine-generated electric power was recently commissioned in Michigan at a plant where initial design and construction had begun for a nuclear plant. Four additional idle nuclear sites are considering switching to gas turbine-based power production due to the legal, regulatory, financial, and public obstacles facing nuclear facilities.[24]

3.3.5 Other Industrial Applications

Industrial applications for gas turbines include various types of mechanical drive and air compression equipment. These applications peaked in the late 1960's and declined through the 1970's.[25] With the promulgation of PURPA in 1978 (see Section 3.3.3), many industrial facilities have found it

NMED Exhibit 53

economically feasible to install a combined cycle gas turbine to meet power and steam requirements. Review of editions of Gas Turbine World over the last several years shows that a broad range of industries (e.g., pulp and paper, chemical, and food processing) have installed combined cycle gas turbines to meet their energy requirements.

4.0 CHARACTERIZATION OF NO_x EMISSIONS

This section presents the principles of NO_x formation, the types of NO_x emitted (i.e., thermal NO_x, prompt NO_x, and fuel NO_x), and how they are generated in a gas turbine combustion process. Estimated NO_x emission factors for gas turbines and the bases for the estimates are also presented.

4.1 THE FORMATION OF NO_x

Nitrogen oxides form in the gas turbine combustion process as a result of the dissociation of nitrogen (N_2) and oxygen (O_2) into N and O, respectively. Reactions following this dissociation result in seven known oxides of nitrogen: NO, NO_2, NO_3, N_2O, N_2O_3, N_2O_4, and N_2O_5. Of these, nitric oxide (NO) and nitrogen dioxide (NO_2) are formed in sufficient quantities to be significant in atmospheric pollution.[1] In this document, "NO_x" refers to either or both of these gaseous oxides of nitrogen.

Virtually all NO_x emissions originate as NO. This NO is further oxidized in the exhaust system or later in the atmosphere to form the more stable NO_2 molecule.[2] There are two mechanisms by which NO_x is formed in turbine combustors: (1) the oxidation of atmospheric nitrogen found in the combustion air (thermal NO_x and prompt NO_x) and (2) the conversion of nitrogen chemically bound in the fuel (fuel NO_x). These mechanisms are discussed below.

4.1.1 Formation of Thermal and Prompt NO_x

Thermal NO_x is formed by a series of chemical reactions in which oxygen and nitrogen present in the combustion air dissociate and subsequently react to form oxides of nitrogen.

NMED Exhibit 53

The major contributing chemical reactions are known as the Zeldovich mechanism and take place in the high temperature area of the gas turbine combustor.[3] Simply stated, the Zeldovich mechanism postulates that thermal NO_x formation increases exponentially with increases in temperature and linearly with increases in residence time.[4]

Flame temperature is dependent upon the equivalence ratio, which is the ratio of fuel burned in a flame to the amount of fuel that consumes all of the available oxygen.[5] An equivalence ratio of 1.0 corresponds to the stoichiometric ratio and is the point at which a flame burns at its highest theoretical temperature.[5] Figure 4-1

NMED Exhibit 53

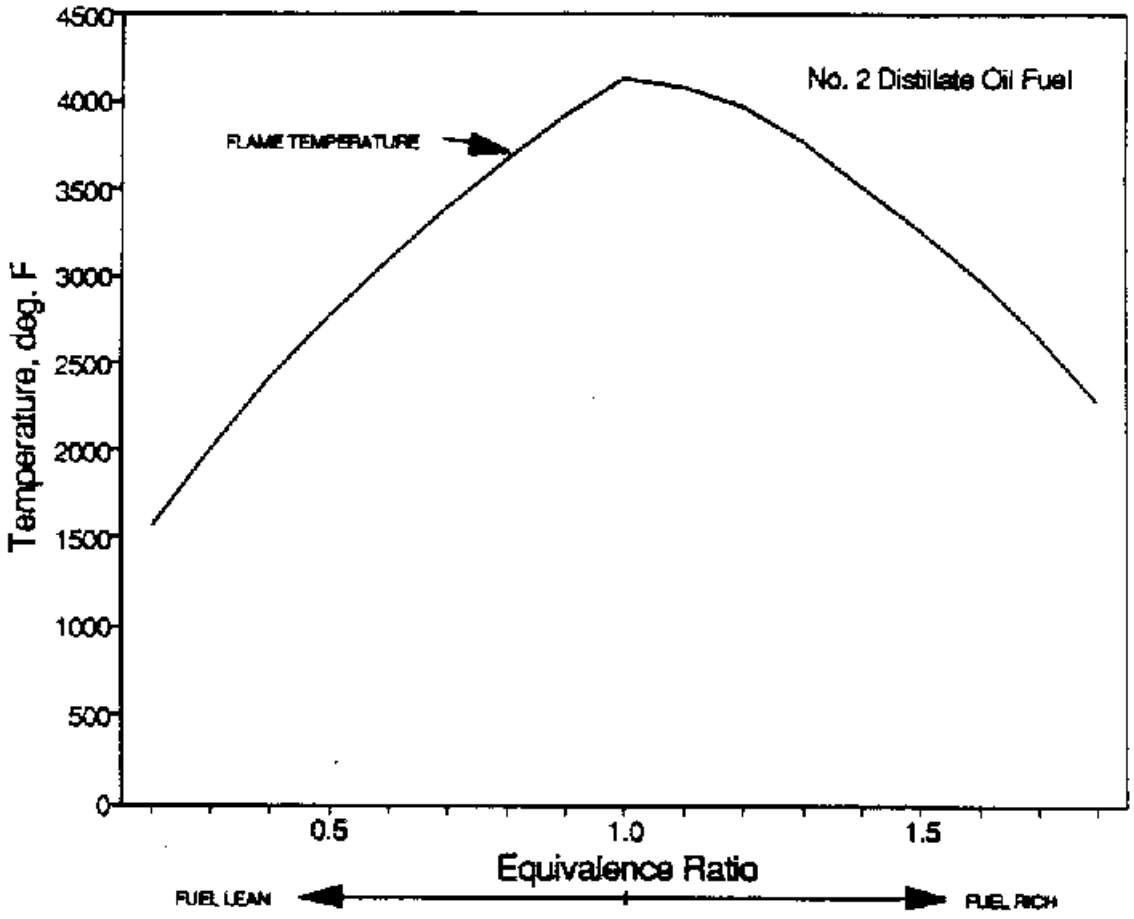

Figure 4-1. Influence of equivalence ratio on flame temperature.[4]

NMED Exhibit 53

shows the flame temperature and equivalence ratio relationship for combustion using No. 2 distillate fuel oil (DF-2).[4]

The series of chemical reactions that form thermal NO_x according to the Zeldovich mechanism are presented below.[3]

1. $O_2 \rightleftharpoons 2O$;

2. $N_2 \rightleftharpoons 2N$;

3. $N + O \rightleftharpoons NO$;

4. $N + O_2 \rightleftharpoons NO + O$; and

5. $O + N_2 \rightleftharpoons NO + N$.

This series of equations applies to a fuel-lean combustion process. Combustion is said to be fuel-lean when there is excess oxygen available (equivalence ratio <1.0). Conversely, combustion is fuel-rich if insufficient oxygen is present to burn all of the available fuel (equivalence ratio >1.0). Additional equations have been developed that apply to fuel-rich combustion. These equations are an expansion of the above series to add an intermediate hydroxide molecule (OH):[3]

NMED Exhibit 53

NMED Exhibit 53

6. $N + OH \rightleftharpoons NO + H$,

and further to include an intermediate product, hydrogen cyanide (HCN), in the formation process:[3]

7. $N_2 + CH \rightleftharpoons HCN + N$ and

8. $N + OH \rightleftharpoons H + NO$.

The overall equivalence ratio for gases exiting the gas turbine combustor is less than 1.0.[4] Fuel-rich areas do exist in the overall fuel-lean environment, however, due to less-than-ideal fuel/air mixing prior to combustion. This being the case, the above equations for both fuel-lean and fuel-rich combustion apply for thermal NO_x formation in gas turbines.

Prompt NO_x is formed in the proximity of the flame front as intermediate combustion products such as HCN, N, and NH are oxidized to form NO_x as shown in the following equations:

1. $CH + N_2 \rightleftharpoons HCN + N$;

2. $CH_2 + N_2 \rightleftharpoons HCN + NH$; and

3. $HCN, N, NH + O_x \rightleftharpoons NO + ...$[6]

Prompt NO_x is formed in both fuel-rich flame zones and fuel-lean premixed combustion zones. The contribution of prompt NO_x to overall NO_x emissions is relatively small in conventional near-stoichiometric combustors, but this contribution increases with decreases in the equivalence ratio (fuel-lean mixtures). For this reason, prompt NO_x becomes an important consideration for the low-NO_x combustor designs described in Chapter 5 and establishes a minimum NO_x level attainable in lean mixtures.[7]

4.1.2 Formation of Fuel NO_x

Fuel NO_x (also known as organic NO_x) is formed when fuels containing nitrogen are burned. Molecular nitrogen, present as

NMED Exhibit 53

N_2 in some natural gas, does not contribute significantly to fuel NO_x formation.[8] However, nitrogen compounds are present in coal and petroleum fuels as pyridine-like (C_5H_5N) structures that tend to concentrate in the heavy resin and asphalt fractions upon distillation. Some low-British thermal unit (Btu) synthetic fuels contain nitrogen in the form of ammonia (NH_3), and other low-Btu fuels such as sewage and process waste-stream gases also contain nitrogen. When these fuels are burned, the nitrogen bonds break and some of the resulting free nitrogen oxidizes to form NO_x.[9] With excess air, the degree of fuel NO_x formation is primarily a function of the nitrogen content in the fuel. The fraction of fuel-bound nitrogen (FBN) converted to fuel NO_x decreases with increasing nitrogen content, although the absolute magnitude of fuel NO_x increases. For example, a fuel with 0.01 percent nitrogen may have 100 percent of its FBN converted to fuel NO_x, whereas a fuel with a 1.0 percent FBN may have only a 40 percent fuel NO_x conversion rate. The low-percentage FBN fuel has a 100 percent conversion rate, but its overall NO_x emission level would be lower than that of the high-percentage FBN fuel with a 40 percent conversion rate.[10]

Nitrogen content varies from 0.1 to 0.5 percent in most residual oils and from 0.5 to 2 percent for most U.S. coals.[11] Traditionally, most light distillate oils have had less than 0.015 percent nitrogen content by weight. However, today many distillate oils are produced from poorer-quality crudes, especially in the northeastern United States, and these distillate oils may contain percentages of nitrogen exceeding the 0.015 threshold; this higher nitrogen content can increase fuel NO_x formation.[4] At least one gas turbine installation burning coal-derived fuel is in commercial operation in the United States.[12]

Most gas turbines that operate in a continuous duty cycle are fueled by natural gas that typically contains little or no FBN. As a result, when compared to thermal NO_x, fuel NO_x is not

NMED Exhibit 53

currently a major contributor to overall NO_x emissions from stationary gas turbines.

4.2 UNCONTROLLED NO_x EMISSIONS

The NO_x emissions from gas turbines are generated entirely in the combustor section and are released into the atmosphere via the stack. In the case of simple and regenerative cycle operation, the combustor is the only source of NO_x emissions. In cogeneration and combined cycle applications, a duct burner may be placed in the exhaust ducting between the gas turbine and the heat recovery steam generator (HRSG); this burner also generates NO_x emissions. (Gas turbine operating cycles are discussed in Section 3.2.) The amount of NO_x formed in the combustion zone is "frozen" at this level regardless of any temperature reductions that occur at the downstream end of the combustor and is released to the atmosphere at this level.[1]

4.2.1 Parameters Influencing Uncontrolled NO_x Emissions

The level of NO_x formation in a gas turbine, and hence the NO_x emissions, is unique (by design factors) to each gas turbine model and operating mode. The primary factors that determine the amount of NO_x generated are the combustor design, the types of fuel being burned, ambient conditions, operating cycles, and the power output level as a percentage of the rated full power output of the turbine. These factors are discussed below.

4.2.1.1 Combustor Design. The design of the combustor is the most important factor influencing the formation of NO_x. Design considerations are presented here and discussed further in Chapter 5.

Thermal NO_x formation, as discussed in Section 4.1.1, is influenced primarily by flame temperature and residence time. Design parameters controlling equivalence ratios and the introduction of cooling air into the combustor strongly influence thermal NO_x formation. The extent of fuel/air mixing prior to combustion also affects NO_x formation. Simultaneous mixing and combustion results in localized fuel-rich zones that yield high flame temperatures in which substantial thermal NO_x production

NMED Exhibit 53

takes place.[13] The dependence of thermal NO_x formation on flame temperature and equivalence ratio is shown in Figure 4-2

NMED Exhibit 53

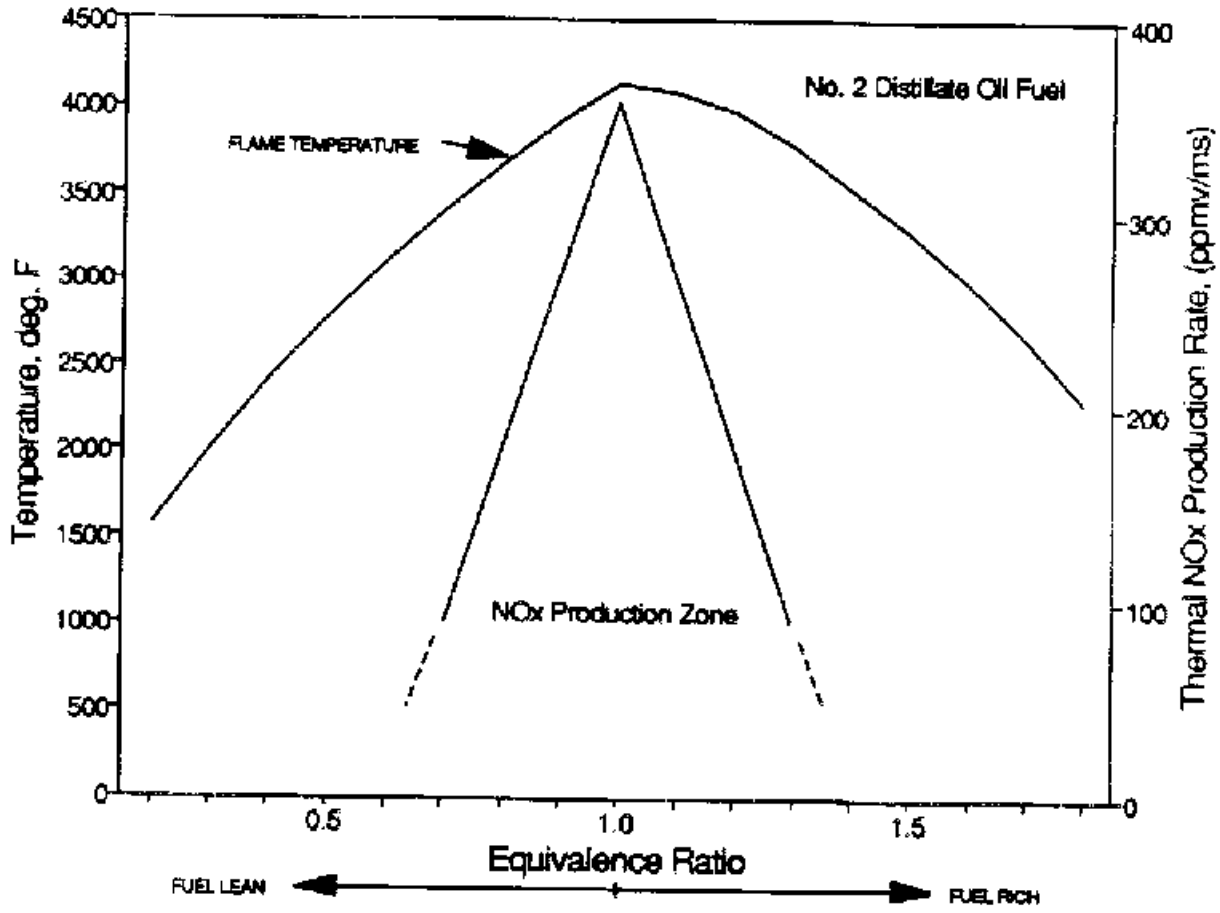

Figure 4-2. Thermal NO_x production as a function of flame temperature and equivalence ratio.[4]

NMED Exhibit 53

for DF-2.[4] Conversely, prompt NO_x is largely insensitive to changes in temperature and pressure.[7]

Fuel NO_x formation, as discussed in Section 4.1.2, is formed when FBN is released during combustion and oxidizes to form NO_x. Design parameters that control equivalence ratio and residence time influence fuel NO_x formation.[14]

4.2.1.2 Type of Fuel. The level of NO_x emissions varies for different fuels. In the case of thermal NO_x, this level increases with flame temperature. For gaseous fuels, the constituents in the gas can significantly affect NO_x emissions levels. Gaseous fuel mixtures containing hydrocarbons with molecular weights higher than that of methane (e.g., ethane, propane, and butane) burn at higher flame temperatures and as a result can increase NO_x emissions greater than 50 percent over NO_x levels for methane gas fuel. Refinery gases and some unprocessed field gases contain significant levels of these higher molecular weight hydrocarbons. Conversely, gas fuels that contain significant inert gases, such as CO_2, generally produce lower NO_x emissions. These inert gases serve to absorb heat during combustion, thereby lowering flame temperatures and reducing NO_x emissions. Examples of this type of gas fuel are air-blown gasifier fuels and some field gases.[15] Combustion of hydrogen also results in high flame temperatures, and gases with significant hydrogen content produce relatively high NO_x emissions. Refinery gases can have hydrogen contents exceeding 50 percent.[16]

NMED Exhibit 53

As is shown in Figure 4-3

NMED Exhibit 53

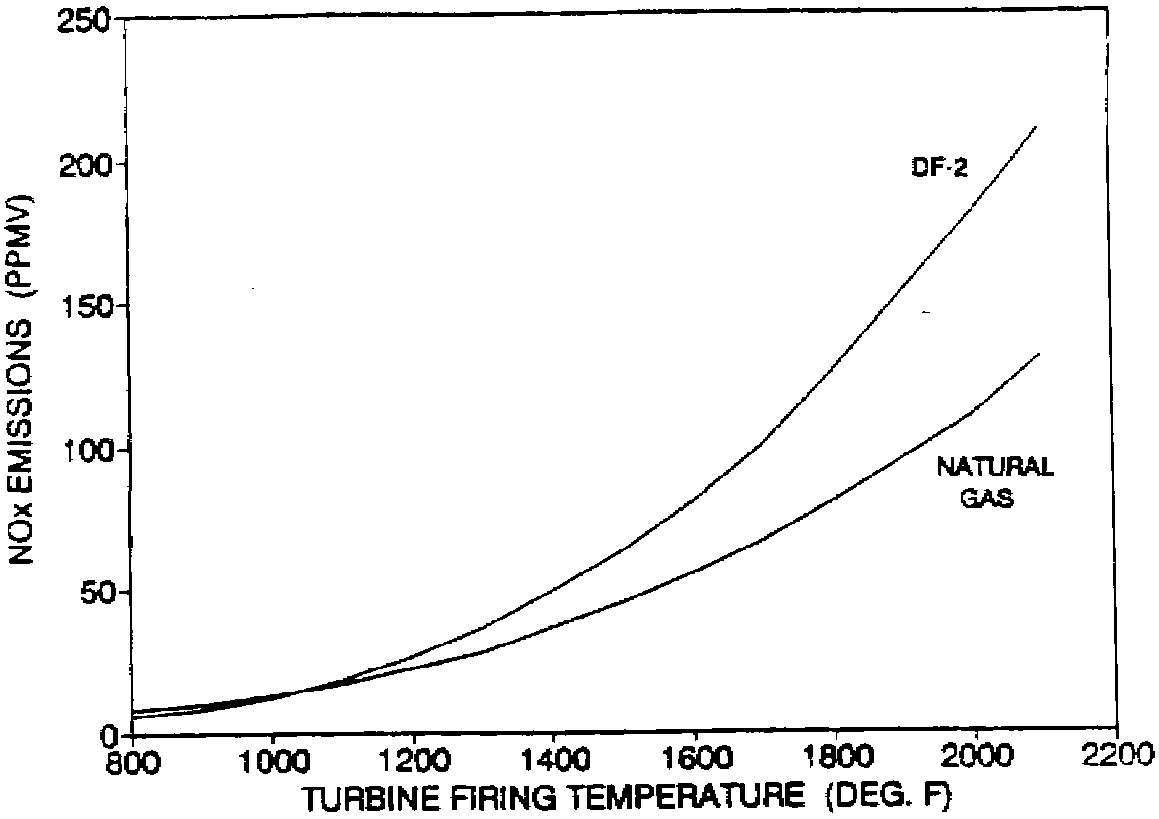

Figure 4-3. Influence of firing temperature on thermal NO_x formation.[17]

NMED Exhibit 53

, DF-2 burns at a flame temperature that is approximately 75°C (100°F) higher than that of natural gas, and as a result, NO_x emissions are higher when burning DF-2 than they are when burning natural gas.[17] Low-Btu fuels such as coal gas burn with lower flame temperatures, which result in

NMED Exhibit 53

NMED Exhibit 53

substantially lower thermal NO_x emissions than natural gas or DF-2.[18] For fuels containing FBN, the fuel NO_x production increases with increasing levels of FBN.

4.2.1.3 Ambient Conditions. Ambient conditions that affect NO_x formation are humidity, temperature, and pressure. Of these ambient conditions, humidity has the greatest effect on NO_x formation.[19] The energy required to heat the airborne water vapor has a quenching effect on combustion temperatures, which reduces thermal NO_x formation. At low humidity levels, NO_x emissions increase with increases in ambient temperature. At high humidity levels, the effect of changes in ambient temperature on NO_x formation varies. At high humidity levels and low ambient temperatures, NO_x emissions increase with increasing temperature. Conversely, at high humidity levels and ambient temperatures above 10°C (50°F), NO_x emissions decrease with increasing temperature.

NMED Exhibit 53

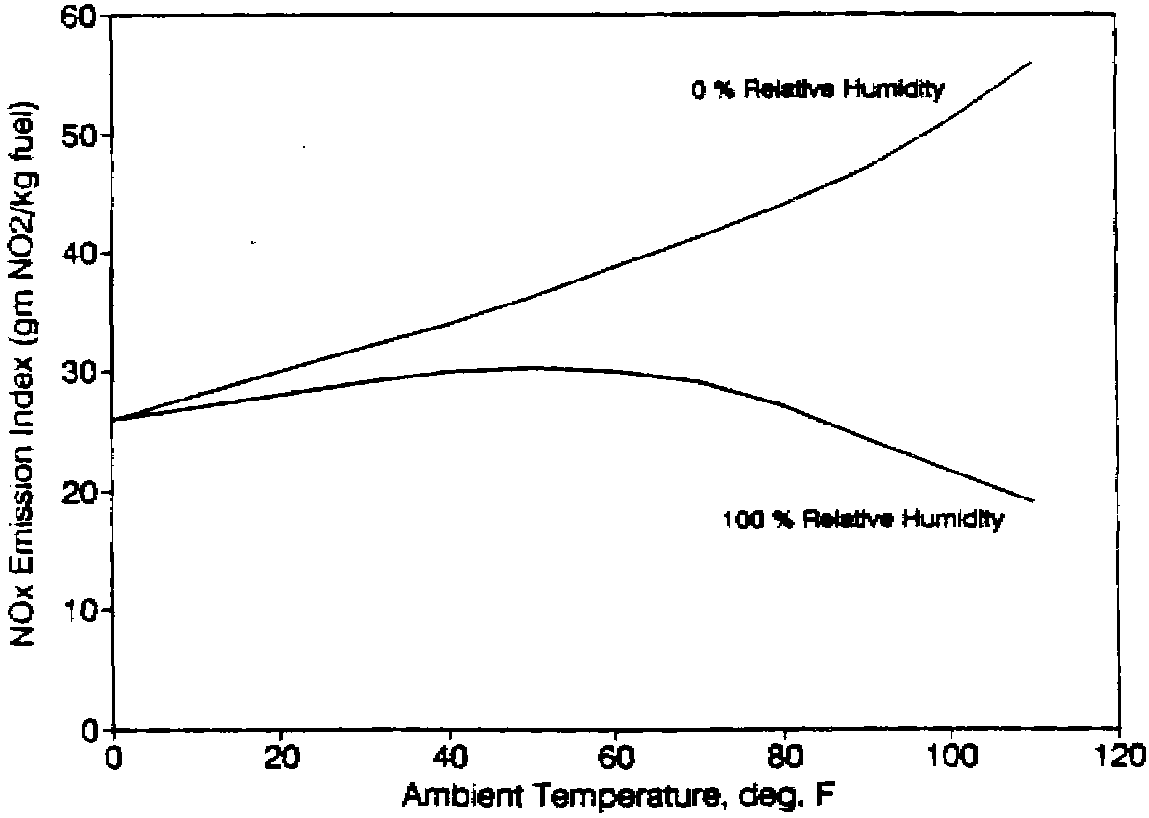

Figure 4-4. Influence of relative humidity and ambient temperature on NO_x formation.[19]

NMED Exhibit 53

This effect of humidity and temperature on NO_x formation is shown in Figure 4-4. A rise in ambient pressure results in higher pressure and temperature levels entering the combustor and so No_x production levels increase with increases in ambient pressure.[19]

The influence of ambient conditions on measured NO_x emission levels can be corrected using the following equation:[20]

$$NO_x = (NO_{xo})(P_r/P_o)^{0.5} e^{19(Ho-0.00633)} (288°K/T_a)^{1.53}$$

where:

NO_x = emission rate of NO_x at 15 percent O_2 and International Standards Organization (ISO) ambient conditions, volume percent;

NO_{xo} = observed NO_x concentration, parts per million by volume (ppmv) referenced to 15 percent O_2;

P_r = reference compressor inlet absolute pressure at 101.3 kilopascals ambient pressure, millimeters mercury (mm Hg);

P_o = observed compressor inlet absolute pressure at test, mm Hg;

NMED Exhibit 53

NMED Exhibit 53

H_o = observed humidity of ambient air, g H_2O/g air;

e = transcendental constant, 2.718; and

T_a = ambient temperature, K.

At least two manufacturers state that this equation does not accurately correct NO_x emissions for their turbine models.[8,12] It is expected that these turbine manufacturers could provide corrections to this equation that would more accurately correct NO_x emissions for the effects of ambient conditions based on test data for their turbine models.

4.2.1.4 Operating Cycles. Emissions from identical turbines used in simple and cogeneration cycles have similar NO_x emissions levels, provided no duct burner is used in heat recovery applications. The NO_x emissions are similar because, as stated in Section 4.2, NO_x is formed only in the turbine combustor and remains at this level regardless of downstream temperature reductions. A turbine operated in a regenerative cycle produces higher NO_x levels, however, due to increased combustor inlet temperatures present in regenerative cycle applications.[21]

4.2.1.5 Power Output Level. The power output level of a gas turbine is directly related to the firing temperature, which is directly related to flame temperature. Each gas turbine has a base-rated power level and corresponding NO_x level. At power outputs below this base-rated level, the flame temperature is lower, so NO_x emissions are lower. Conversely, at peak power outputs above the base rating, NO_x emissions are higher due to higher flame temperature. The NO_x emissions for a range of firing temperatures are shown in Figure 4-3 for one manufacturer's gas turbine.[17]

4.2.2 NO_x Emissions From Duct Burners

In some cogeneration and combined cycle applications, the exhaust heat from the gas turbine is not sufficient to produce the desired quantity of steam from the HRSG, and a supplemental burner, or duct burner, is placed in the exhaust duct between the gas turbine and HRSG to increase temperatures to sufficient

NMED Exhibit 53

levels. In addition to providing additional steam capacity, this burner also increases the overall system efficiency since essentially all energy added by the duct burner can be recovered in the HRSG.[22]

The level of NO_x produced by a duct burner is approximately 0.1 pound per million Btu (lb/MMBtu) of fuel burned. The ppmv level depends upon the flowrate of gas turbine exhaust gases in which the duct burner is operating and thus varies with the size of the turbine.[23]

Typical NO_x production levels added by a duct burner operating on natural gas fuel are:[23]

Gas turbine output, megawatts (MW)	Duct burner NO_x, ppmv, referenced to 15 percent O_2
3 to 50	10 to 30
50+	5 to 10

NMED Exhibit 53

Uncontrolled emission factors are presented in Table 4-1. These factors are based on uncontrolled emission levels provided by manufacturers in ppmv, dry, and corrected to 15 percent O_2, corresponding to 100 percent output load and International Standards Organization (ISO) conditions of 15°C (59°F) and 1 atmosphere (14.7 psia). Sample calculations are given in Appendix A. The uncontrolled emissions factors range from 0.397 to 1.72 lb/MMBtu (99 to 430 ppmv) for natural gas and 0.551 to 2.50 lb/MMBtu (150 to 680 ppmv) for DF-2.

NMED Exhibit 53

5.0 NO_x CONTROL TECHNIQUES

Nationwide NO_x emission limits have been established for stationary gas turbines in the new source performance standards (NSPS) promulgated in 1979.[1] This standard, summarized in Table 5-1

NMED Exhibit 53

TABLE 5-1. NO_x EMISSION LIMITS AS ESTABLISHED BY THE NEW SOURCE PERFORMANCE STANDARDS FOR GAS TURBINES[1]

Fuel input MMBtu/hr	Size, MW	Application(s)	NO_x limit, ppmv at 15% O_2, dry[a] [b]
<10	1[c]	All	None
10-100	1-10[c]	All	150
>100	10+[c] <30[c] >30[c]	Utility[d] Nonutility Nonutility	75 150 None
<100	10[c]	Regenerative cycle	None
All	All	e	None

[a]Based on thermal efficiency of 25 percent. This limit may be increased for higher efficiencies by multiplying the limit in the table by 14.4/actual heat rate, in kJ/watt-hr.

[b]A fuel-bound nitrogen allowance may be added to the limits listed in the table according to the table listed below:

Fuel-bound nitrogen (N), percent by weight	Allowable increase, ppmv
$N \leq 0.015$	0
$0.015 < N \leq 0.1$	400 x N
$0.1 < N \leq 0.25$	40 + [6.7 x (N - 0.1)]
$N > 0.25$	50

[c]Based on gas turbine heat rate of 10,000 Btu/kW-hr.

[d]An installation is considered a utility if more than 1/3 of its potential electrical output is sold.

[e]Emergency/stand-by, military (except garrison facilities), military training, research and development, firefighting, and emergency fuel operation applications are exempt from NO_x emission limits.

, effectively sets a limit for new, modified, or reconstructed gas turbines greater than 10.7 gigajoules per hour (approximately 3,800 horsepower [hp]) of 75 or 150 parts per million by volume (ppmv), corrected to 15 percent oxygen (O_2) on a dry basis, depending upon the size and application of the turbine. State and regional regulatory agencies may set more restrictive limits, and two organizations have established limits as low as 9 ppmv: the South Coast Air Quality Management District (SCAQMD) has defined limits as listed in Table 5-2

NMED Exhibit 53

TABLE 5-2. NO_x COMPLIANCE LIMITS AS ESTABLISHED BY THE SOUTH COAST AIR QUALITY MANAGEMENT DISTRICT (SCAQMD) FOR EXISTING TURBINES. RULE 1134. ADOPTED AUGUST 1989.[a,2]

Unit size, megawatt rating (MW)	NO_x limit, ppmv, 15% O_2 dry[b]
0.3 to <2.9 MW	25
2.9 to <10.0 MW	9
2.9 to <10.0 MW No SCR	15
10.0 MW and over	9
10.0 MW and over No SCR	12
60 MW and over Combined cycle No SCR	15
60 MW and over Combined cycle	9
Compliance limit = Reference limit X EFF/25 percent	
where: $EFF = \frac{3,413 \times 100\%}{\text{Actual heat rate at HHV of fuel (Btu/kW-hr)}}$ or EFF^c = (Manufacturer's rated efficiency at LHV) x $\frac{LHV}{HHV}$	

[a]The NO_x reference limits to be effective by December 31, 1995.
[b]Averaged over 15 consecutive minutes.
[c]EFF = the demonstrated percent efficiency of the gas turbine only as calculated without consideration of any down-stream energy recovery from the actual heat rate (Btu/kW-hr), or 1.34 (Btu/hp-hr); corrected to the higher heating value (HHV) of the fuel and ISO conditions, as measured at peak load for that facility; or the manufacturer's continuous rated percent efficiency (manufacturer's rated efficiency) of the gas turbine after correction from lower heating value (LHV) to the HHV of the fuel, whichever efficiency is higher. The value of EFF shall not be less than 25 percent. Gas turbines with lower efficiencies will be assigned a 25 percent efficiency for this calculation.

NMED Exhibit 53

; and the Northeast States for Coordinated Air Use Management (NESCAUM) has recommended limits as listed in Table 5-3.

NMED Exhibit 53

TABLE 5-3. NO_x EMISSION LIMITS RECOMMENDED BY THE NORTHEAST STATES FOR COORDINATED AIR USE MANAGEMENT (NESCAUM)

NEW TURBINES[3]

Fuel input, MMBtu/hr	Size, MW[a]	Fuel type	NO_x limit, ppmv[b]
1-100	1-10	Gas Oil	42 65
>100	10+	Gas Oil Gas/oil back-up	9[c] 9[c] 9[c]/18[c d]

[a]Based on gas turbine heat rate of 10,000 Btu/kW-hr.
[b]Dry basis, corrected to 15 percent oxygen.
[c]Based on use of selective catalytic reduction (SCR). Limits for operation without SCR, where permitted, should be the turbine manufacturer's lowest guaranteed NO_x limit.
[d]Based on the use of SCR and a fuel-bound nitrogen content of 600 ppm or less.

EXISTING TURBINES[4]

Operating cycle	Fuel	NO_x emission limit, ppmv, 15 percent O_2
Simple	Gas, no oil back-up	55
	Oil	75
	Gas, with oil back-up	55 (Gas fuel) 75 (Oil fuel)
Combined	Gas, no oil back-up	42
	Oil	65
	Gas, with oil back-up	42 (Gas fuel) 65 (Oil fuel)

Note: Applies to existing turbines rated at 25 MMBtu/hr or above (maximum heat input rate).

NMED Exhibit 53

This chapter discusses the control techniques that are available to reduce NO_x emissions for stationary turbines, the use of duct burners, the use of alternate fuels to lower NO_x emissions, and the applicability of NO_x control techniques to offshore applications. Each control technique is structured into categories to discuss the process description, applicability, factors that affect performance, and achievable controlled NO_x emission levels. Where information for a technique is limited, one or more categories may be combined. Section 5.1 describes wet controls, including water and steam injection. Section 5.2 describes combustion controls, including lean and staged combustion. Selective catalytic reduction (SCR), a postcombustion technique, is described in Section 5.3, and the combination of SCR with other control techniques is described in

NMED Exhibit 53

NMED Exhibit 53

NMED Exhibit 53

Section 5.4. Emissions from duct burners and their impact on total NO_x emissions are described in Section 5.5. Section 5.6 describes NO_x emission impacts when using alternate fuels. Two control techniques that show potential for future use, selective noncatalytic reduction (SNCR) and catalytic combustion, are described in Sections 5.7 and 5.8, respectively. Control technologies for offshore oil platforms are described in Section 5.9. Finally, references for Chapter 5 are found in Section 5.10.

5.1 WET CONTROLS

The injection of either water or steam directly into the combustor lowers the flame temperature and thereby reduces thermal NO_x formation. This control technique is available from all gas turbine manufacturers contacted for this study.[5-11]

The process description, applicability, factors affecting performance, emissions data and manufacturers' guarantees, impacts on other emissions, and gas turbine performance and maintenance impacts are discussed in this section.

5.1.1 Process Description

Injecting water into the flame area of a turbine combustor provides a heat sink that lowers the flame temperature and thereby reduces thermal NO_x formation. Injection rates for both water and steam are usually described by a water-to-fuel ratio (WFR) and are usually given on a weight basis (e.g., lb water to lb fuel).

A water injection system consists of a water treatment system, pump(s), water metering valves and instrumentation, turbine-mounted injection nozzles, and the necessary interconnecting piping. Water purity is essential to prevent or mitigate erosion and/or the formation of deposits in the hot section of the turbine; Table 5-4

NMED Exhibit 53

TABLE 5-4. WATER QUALITY SPECIFICATIONS OF SELECTED GAS TURBINE MANUFACTURERS FOR WATER INJECTION SYSTEMS[11-18]

	Turbine Manufacturer							
Element	A	B	C	D	E	F	G	H

[c]Including vanadium and lead.
[d]AD - aeroderivative turbine.
[e]90 percent of 0.1 gram particles shall be less than 5 microns.

NMED Exhibit 53

summarizes the water quality specifications for eight gas turbine manufacturers.

In a steam injection system, steam replaces water as the injected fluid. The injection system is similar to that for water injection, but the pump is replaced by a steam-producing boiler. This boiler is usually a heat recovery steam generator

NMED Exhibit 53

(HRSG) that recovers the gas turbine exhaust heat and generates steam. The balance of the steam system is similar to the water injection system. The water treatment required for boiler feed water to the HRSG yields a steam quality that is suitable for injection into the turbine. The additional steam requirement for NO_x control, however, may require that additional capacity be added to the boiler feed water treatment system.

Another technique that is commercially available for oil-fired aeroderivative and industrial turbines uses a water-in-oil emulsion to reduce NO_x emissions. This technique introduces water into the combustion process by emulsifying water in the fuel oil prior to injection. This emulsion has a water content of 20 to 50 percent by volume and is finely dispersed and chemically stabilized in the oil phase. The principle of NO_x control is similar to conventional water injection, but the uniform dispersion of the water in the oil provides greater NO_x reduction than conventional water injection at similar WFR's.[19]

A water-in-oil emulsion injection system consists of mechanical emulsification equipment, chemical stabilizer injection equipment, water metering valves, chemical storage and metering valves, and instrumentation. In most cases the emulsifying system can be retrofitted to the existing fuel delivery system, which eliminates the requirement for a separate delivery system for water injection. At multiunit installations, one emulsion system can be used to supply emulsified fuel to several turbines. For dual fuel turbines, the emulsion can be injected through the oil fuel system to control NO_x emissions.[19]

Data provided by the vendor for this technique indicates that testing has been performed on oil-fired turbines operating in peaking duty. Long-term testing has not been completed at this point to quantify the long-term effects of the emulsifier on the operation and maintenance of the turbine.

NMED Exhibit 53

5.1.2 Applicability of Wet Controls

Wet controls have been applied effectively to both aeroderivative and heavy-duty gas turbines and to all configurations except regenerative cycle applications.[20] It is expected that wet controls can be used with regenerative cycle turbines, but no such installations were identified. All manufacturers contacted have water injection control systems available for their gas turbine models; many also offer steam injection control systems. Where both systems are available, the decision of which control to use depends upon steam availability and economic factors specific to each site.

Wet controls can be added as a retrofit to most gas turbine installations. In the case of water injection, one limitation is the possible unavailability of injection nozzles for turbines operating in dual fuel applications. In this application, the injection nozzle as designed by the manufacturer may not physically accommodate a third injection port for water injection. This limitation also applies to steam injection. In addition, steam injection is not an available control option from some gas turbine manufacturers.

5.1.3 Factors Affecting the Performance of Wet Controls

The WFR is the most important factor affecting the performance of wet controls. Other factors affecting performance are the combustor geometry and injection nozzle(s) design and the fuel-bound nitrogen (FBN) content. These factors are discussed below.

The WFR has a significant impact on NO_x emissions. Tables 5-5 and 5-6 provide NO_x reduction and WFRs for natural gas and

NMED Exhibit 53

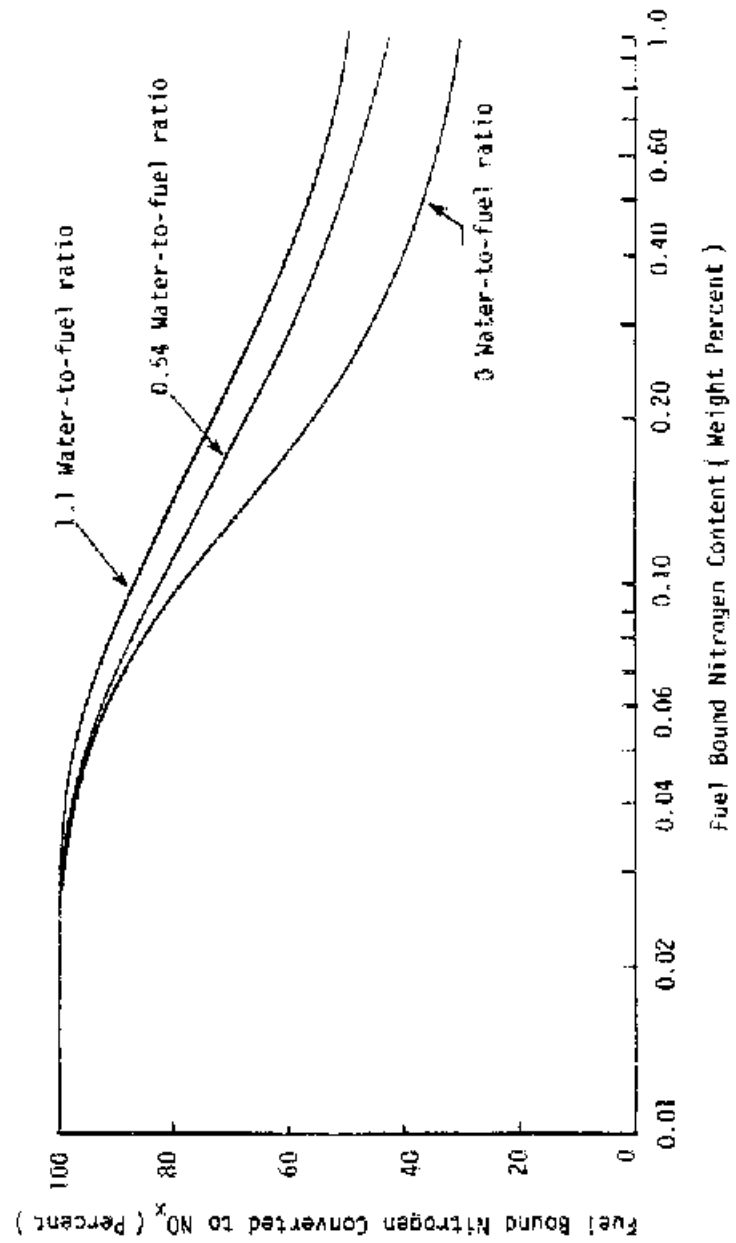
distillate oil fuels, respectively, based on information provided by gas turbine manufacturers. For natural gas fuel, WFR's for water or steam injection range from 0.33 to 2.48 to achieve controlled NO_x emission levels ranging from 25 to 75 ppmv, corrected to 15 percent oxygen. For oil fuel, WFR's range from 0.46 to 2.28 to achieve controlled NO_x emission levels ranging from 42 to 110 ppmv, corrected to 15 percent oxygen. Nitrogen oxide reduction efficiency increases as the WFR

NMED Exhibit 53

NMED Exhibit 53



increases. As shown in Tables 5-5 and 5-6, reduction efficiencies of 70 to 90 percent are common. Note that, in general, the WFR's for steam are higher than for water injection because water acts as a better heat sink than steam due to the heat absorbed by vaporization; therefore, higher levels of steam than water must be injected for a given reduction level.

The combustor geometry and injection nozzle design and location also affect the performance of wet controls. For maximum NO_x reduction efficiency, the water must be atomized and injected in a spray pattern that provides a homogeneous mixture of water droplets and fuel in the combustor. Failure to achieve this mixing yields localized hot spots in the combustor that produce increased NO_x emissions.

The type of fuel affects the performance of wet controls. In general, lower controlled NO_x emission levels can be achieved with gaseous fuels than with oil fuels. The FBN content also affects the performance of wet controls. Those fuels with relatively high nitrogen content, such as coal-derived liquids, shale oil, and residual oils, result in significant fuel NO_x formation. Natural gas and most distillate oils are low-nitrogen fuels. Consequently, fuel NO_x formation is minimal when these fuels are burned.

Wet controls serve only to lower the flame temperature and therefore are an effective control only for thermal NO_x formation; water injection may in fact increase the rate of fuel NO_x formation, as shown in Figure 5-1.[25] The mechanisms responsible for this potential increase were not identified.

NMED Exhibit 53

NMED Exhibit 53

5.1.4 Achievable NO_x Emissions Levels Using Wet Controls

This section presents the achievable controlled NO_x emission levels for wet injection, as guaranteed by gas turbine manufacturers. Emission test data, obtained using EPA Test Method 20 or equivalent, are also presented.

Guaranteed NO_x emission levels as provided by gas turbine manufacturers for wet controls are shown in Figures 5-2 and

NMED Exhibit 53

5-3. These figures show manufacturers' guaranteed NO_x emission levels of 42 ppmv for most natural gas-fired turbines, and from 42 to

NMED Exhibit 53

75 ppmv for most oil-fired turbines. The percent reduction in NO_x emissions varies for each turbine, ranging from 60 to 94 percent depending upon each model's uncontrolled emission level and whether water or steam is injected.

Emissions data for water and steam injection are presented to show the effects of wet injection on NO_x emissions. These data show:

1. That NO_x emissions decrease with increasing WFR's; and
2. That NO_x emissions are higher for oil fuel than for natural gas.

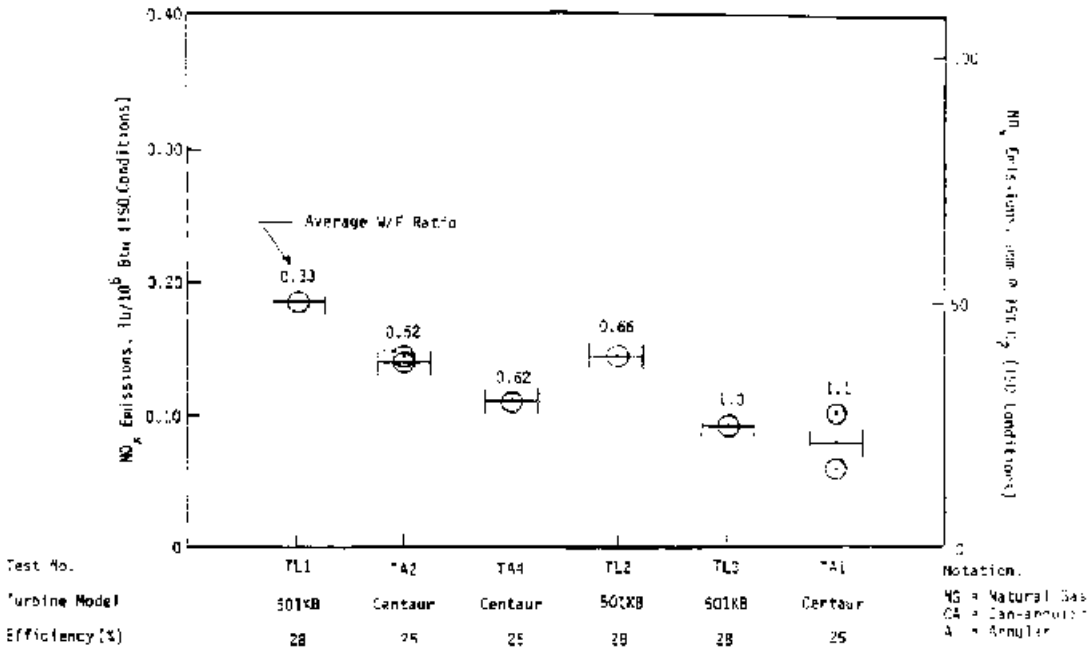
From the available data, reduction efficiencies of 70 to over 85 percent were achieved. The emission data and WFRs shown for specific turbine models may not reflect the emission levels of current production models, since manufacturers periodically update or otherwise modify their turbines, thereby altering specific emissions levels.

Each emission test in the following figures consists of one or more data points. Where data points were obtained under similar conditions, they are grouped together and presented as a single test. For these cases, each data point, along with the arithmetic average of all of the data points, is shown.

The nomenclature used to identify the tests consists of two letters followed by a number. The first letter of the two-letter designator specifies the turbine type. These types are as follows:

Letter	Turbine type
A	Aircraft-derivative turbine
H	Heavy-duty turbine
T	Small and low-efficiency turbine (less than 7.5 MW output, less than 30 percent simple-cycle efficiency)

The second letter identifies the facility. The number identifies the number of tests performed at the facility. Tests performed at the same facility on different turbines or at different times have the same two-letter designator but are followed by different test numbers. The short horizontal lines represent the average of the test data.



NMED Exhibit 53

Also presented are the available data on the turbine, wet controls, uncontrolled NO_x emissions, percent NO_x reduction, and fuel type. All of the data shown are representative of the performance of wet controls when the turbine is operated at base load or peak load. These loads represent the worst-case conditions for NO_x emission reduction. Information on the WFR, turbine model, efficiency, control type, and fuel are included with the emission test data.

NMED Exhibit 53

NMED Exhibit 53

for water injection on turbines fired with natural gas. These turbines have NO_x emissions ranging from approximately 20 to 105 ppm with WFR's ranging from 0.16 to 1.32. Turbine sizes range from 2.8 to 97 MW. Based on these data, water injection is effective on all types of gas turbines and NO_x emission levels decrease as the WFR increases. However, some turbines require a higher WFR to meet a specific emission level. For example, the gas turbines at sites HH and HC (Figure 5-6) require much higher WFR's to achieve NO_x emission levels similar to the other gas turbine models shown. This particular gas turbine also has the highest uncontrolled NO_x emission levels. Conversely, the gas turbine at site AH, shown in Figure 5-5, has the lowest uncontrolled NO_x emission level and requires the least amount of water to achieve a given emission level. Uncontrolled NO_x emission levels vary for different turbine models depending upon design factors such as efficiency, firing temperature, and the extent of combustion controls incorporated in the combustor design (see Section 4.2.1.1). In general, aircraft-derivative and heavy-duty gas turbines require similar WFR's to achieve a specific emission level. Small, low-efficiency gas turbines require less water to achieve a specific emission level.

The NO_x emissions for turbines firing distillate oil are shown in Figures 5-7, 5-8, and 5-9. The data range from

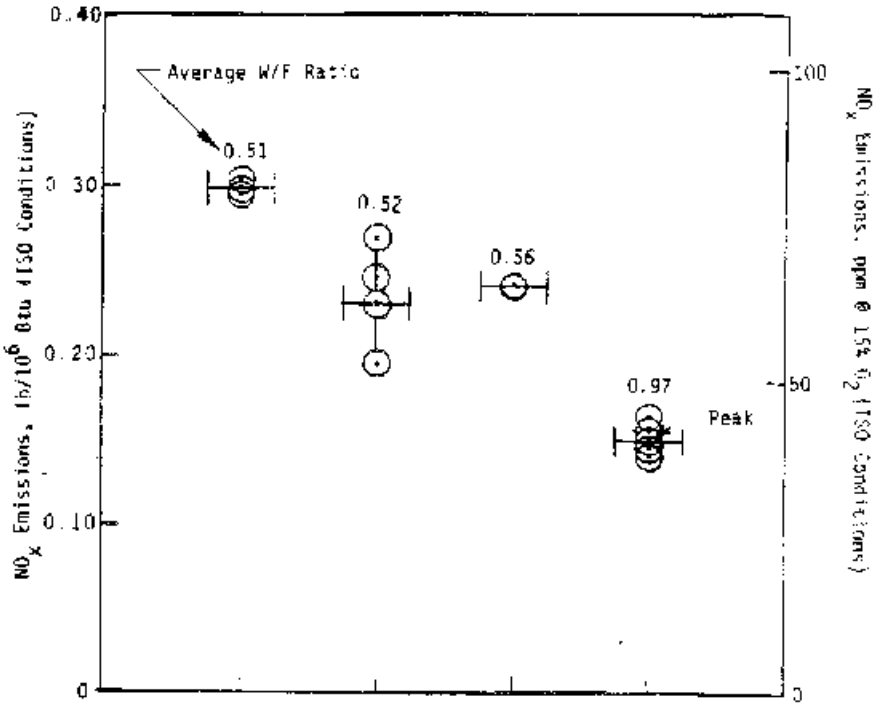
approximately 30 to 135 ppm, with WFR's ranging from 0.24 to 1.31. The gas turbine sizes range from 19 to 95 MW. The data for distillate oil-fired turbines show the same general trends as the data for natural gas-fired turbines. Site HH (Figure 5-9)

NMED Exhibit 53

NMED Exhibit 53



NMED Exhibit 53

NMED Exhibit 53

again shows that higher WFR's are required due to the high uncontrolled NO_x emissions from this gas turbine. Also, by comparing the emission data for the distillate oil-fired turbines and natural gas-fired turbines, the data show that burning distillate oil requires higher WFR's than does burning natural gas for a given level of NO_x emissions. Higher WFR's are required because distillate oil produces higher uncontrolled NO_x levels than does natural gas (see Section 4.2.1.2).

The NO_x emission test data for steam injection are presented in Figures 5-10

NMED Exhibit 53

and 5-11 for natural gas-fired turbines and distillate oil-fired turbines, respectively. The turbines firing natural gas have NO_x emissions ranging from approximately 40 to 80 ppm, with WFR's ranging from 0.50 to 1.02. The gas turbine sizes range from 30 to 70 MW.

The NO_x emissions for turbines firing distillate oil range from approximately 65 to 95 ppm, with WFR's ranging from 0.65 to 1.01, and the gas turbine sizes tested were 36 and 70 MW. Fewer data points are available for steam injection than for water injection. However, the available data for both distillate oil-fired and natural gas-fired turbines show that NO_x emissions decrease as the steam-to-fuel ratio increases.

Reductions in NO_x emissions similar to water injection with oil-fired turbines have been achieved using water-in-oil emulsions. Results of emission tests for four turbines are shown in Table 5-7

NMED Exhibit 53

. The controlled NO_x emissions range from 29 to 60 ppmv, corresponding to NO_x reductions of 54 to 77 percent.[19] The controlled NO_x emission levels and percent reduction are consistent with those achieved using conventional water injection. Limited testing has shown that the emulsion achieves a given NO_x reduction level with a lower WFR than does a separate water injection arrangement. Test data for one oil-fired turbine showing a comparison of the WFR's for a water-in-oil emulsion versus a separate water injection system are shown in Figure 5-12

NMED Exhibit 53

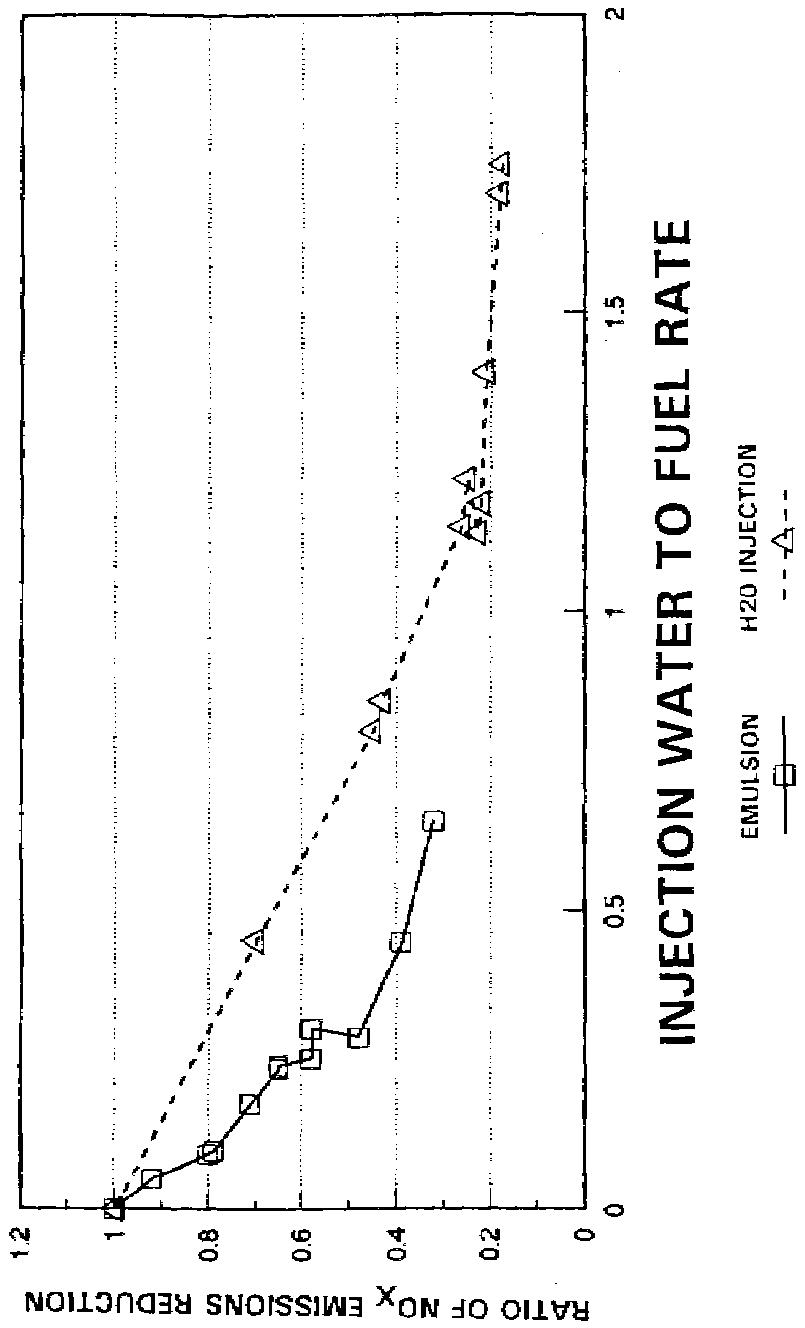

Figure 5-12. Comparison of the WFR requirement for water-in-oil emulsion versus separate water injection for an oil-fired turbine.[28]

NMED Exhibit 53

. As shown here, NO_x reductions achieved by a water injection system at a WFR of 1.0 can be achieved by a water-in-oil emulsion at a WFR of 0.6.

NMED Exhibit 53

NMED Exhibit 53

NMED Exhibit 53

On a mass basis, the reduction in NO_x emissions using water injection is shown in Table 5-8

NMED Exhibit 53

As an example, a 21.8 MW turbine burning natural gas fuel can reduce NO_x emissions by 452 tons/yr (8,000 hours operation) using water injection and 511 tons/yr using steam injection. This same turbine burning oil fuel will reduce annual NO_x emissions by 1,040 tons using water injection and by 925 tons using steam injection.

5.1.5 Impacts of Wet Controls on CO and HC Emissions

While carbon monoxide (CO) and hydrocarbon (HC) emissions are relatively low for most gas turbines, water injection may increase these emissions. Figure 5-13

NMED Exhibit 53

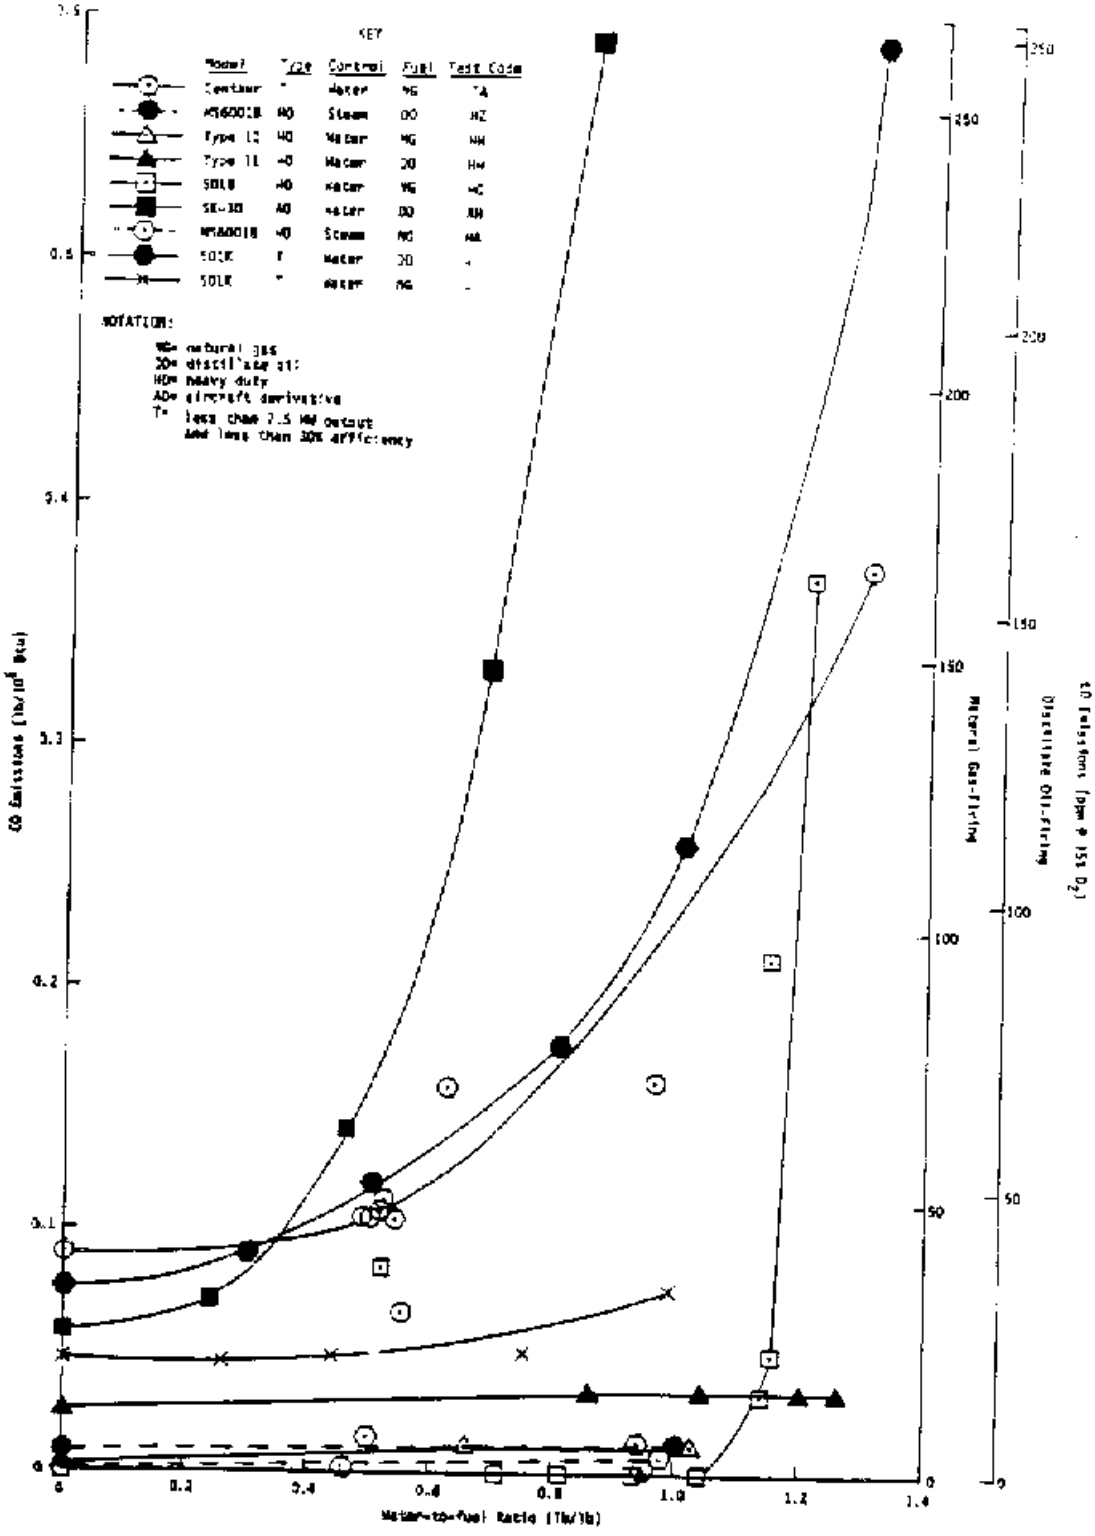

Figure 5-13. Effect of wet injection on CO emissions.[29]

NMED Exhibit 53

shows the impact of water injection on CO emissions for several production gas turbines. In many turbines, CO emissions increase as the WFR increases, especially at WFR's above 0.8. Steam injection also increases CO emissions at relatively high WFR's, but the impact is less than that of water injection.[29,30]

Water and steam injection also increase HC emissions, but to a lesser extent than CO emissions.[29,30] The effect of water injection on HC emissions for one turbine is shown in

NMED Exhibit 53

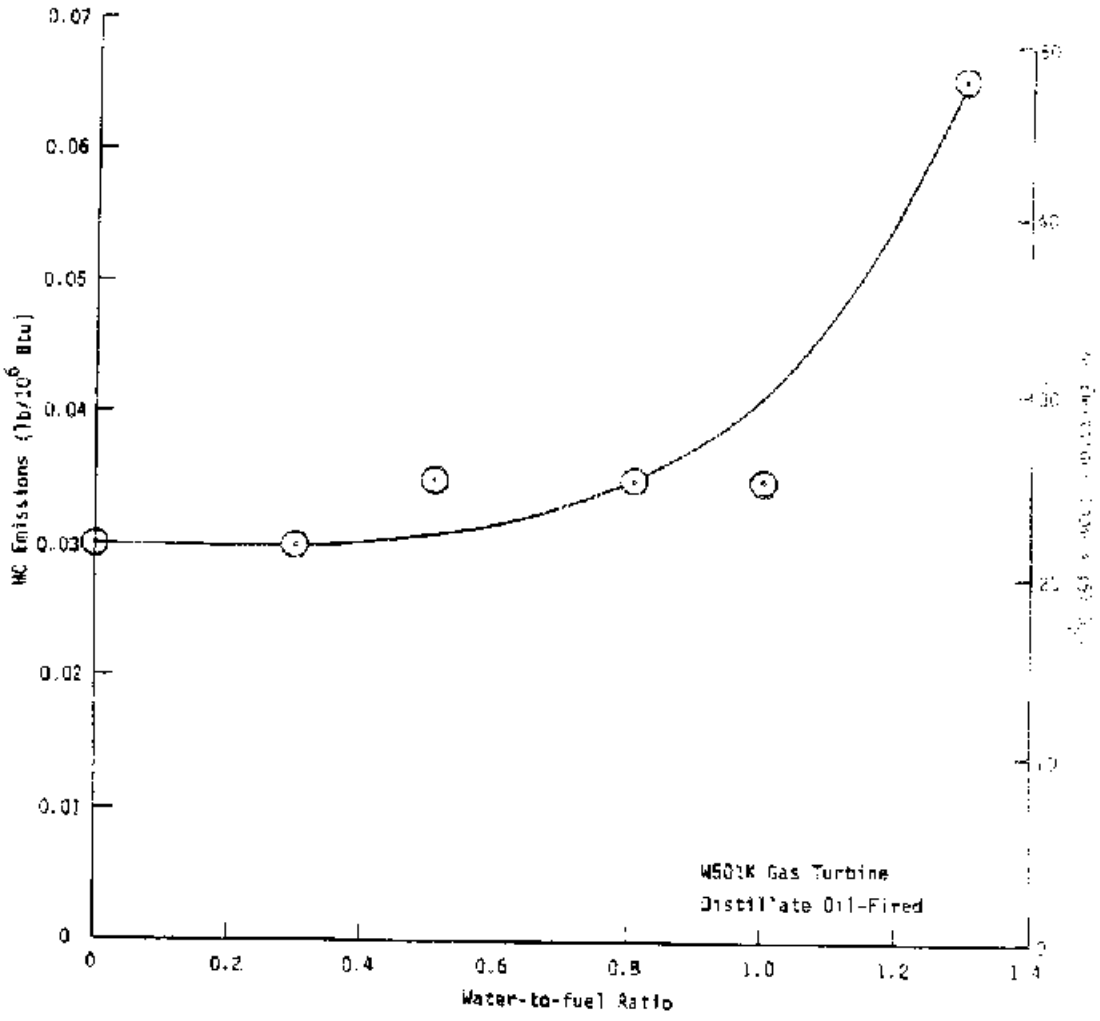

Figure 5-14. Effect of water injection on HC emissions for one turbine model.[29]

NMED Exhibit 53

Figure 5-14. Like CO emissions, hydrocarbon emissions increase at WFR's above 0.8.

For applications where the water or steam injection rates required for NO_x emission reductions result in excess CO and/or HC emissions, it may be possible to select an alternative turbine and/or fuel with a relatively flat CO curve, as indicated in Figure 5-13. Another alternative is an oxidation catalyst to reduce these emissions. This oxidation catalyst is an add-on control device that is placed in the turbine exhaust duct or HRSG and serves to oxidize CO and HC to H_2O and CO_2. The catalyst material is usually a precious metal (platinum, palladium, or rhodium), and oxidation efficiencies of 90 percent or higher can be achieved. The oxidation process takes place spontaneously, without the requirement for introducing reactants (such as ammonia) into the flue gas stream.[31]

NMED Exhibit 53

NMED Exhibit 53

NMED Exhibit 53

NMED Exhibit 53

5.1.6 Impacts of Wet Controls on Gas Turbine Performance

Wet controls affect gas turbine performance in two ways: power output increases and efficiency decreases. The energy from the added mass flow and heat capacity of the injected water or steam can be recovered in the turbine, which results in an increase in power output. For water injection, the fuel energy required to vaporize the water in the turbine combustor, however, results in a net penalty to the overall efficiency of the turbine. For steam injection, there is an energy penalty associated with generating the steam, which results in a net penalty to the overall cycle efficiency. Where the steam source is exhaust heat, which would otherwise be exhausted to the atmosphere, the heat recovery results in a net gain in gas turbine efficiency.[32] The actual efficiency reduction associated with wet controls is specific to each turbine and the actual WFR required to meet a specific NO_x reduction. The overall efficiency penalty increases with increasing WFR and is usually higher for water injection than for steam injection due to the heat of vaporization associated with water. The impacts on output and efficiency for one manufacturer's gas turbines are shown in Table 5-10.

5.1.7 Impacts of Wet Controls on Gas Turbine Maintenance

Water injection increases dynamic pressure oscillation activity in the turbine combustor.[33] This activity can, in some turbine models, increase erosion and wear in the hot section of the turbine, thereby increasing maintenance requirements. As a result, the turbine must be removed from service more frequently for inspection and repairs to the hot section components. A summary of the maintenance impacts as provided by manufacturers is shown in Table 5-11.

[a]Applies only to 25 ppmv level. No impact for 42 ppmv.
[b]This interval applies to time between overhaul (TBO).
[c]Steam injection is not available for this model.
[d]Data not available.

NMED Exhibit 53

As this table shows, the maintenance impact, if any, varies from manufacturer to manufacturer and model to model. Some manufacturers stated that there is no impact on maintenance intervals associated with water or steam injection for their turbine models. Data were provided only for operation with natural gas.

NMED Exhibit 53

5.2 COMBUSTION CONTROLS

The formation of both thermal NO_x and fuel NO_x depends upon combustion conditions, so modification of these conditions affects NO_x formation. The following combustion modifications are used to control NO_x emission levels:

1. Lean combustion;
2. Reduced combustor residence time;
3. Lean premixed combustion; and
4. Two-stage rich/lean combustion.

These combustion modifications can be applied singly or in combination to control NO_x emissions.

The mechanisms by which each of these techniques reduce NO_x formation, their applicability to new gas turbines, and the design or operating factors that influence NO_x reduction performance are discussed below by control technique.

5.2.1 Lean Combustion and Reduced Combustor Residence Time

5.2.1.1 Process Description. Gas turbine combustors were originally designed to operate with a primary zone equivalence ratio of approximately 1.0. (An equivalence ratio of 1.0 indicates a stoichiometric ratio of fuel and air. Equivalence ratios below 1.0 indicate fuel-lean conditions, and ratios above 1.0 indicate fuel-rich conditions.) With lean combustion, the additional excess air cools the flame, which reduces the peak flame temperature and reduces the rate of thermal NO_x formation.[34]

In all gas turbine combustor designs, the high-temperature combustion gases are cooled with dilution air to an acceptable temperature prior to entering the turbine. This dilution air rapidly cools the hot gases to temperatures below those required for thermal NO_x formation. With reduced residence time combustors, dilution air is added sooner than with standard combustors. Because the combustion gases are at a high temperature for a shorter time, the amount of thermal NO_x formed decreases.[34]

Shortening the residence time of the combustion products at high temperatures may result in increased CO and HC emissions if

NMED Exhibit 53

no other changes are made in the combustor. In order to avoid increases in CO and HC emissions, combustors with reduced residence time also incorporate design changes in the air distribution ports to promote turbulence, which improves fuel/air mixing and reduces the time required for the combustion process to be completed. These designs may also incorporate fuel/air premixing chambers. Therefore, the differences between reduced residence time combustors and standard combustors are the placement of the air ports, the design of the circulation flow patterns in the combustor, and a shorter combustor length.[34]

5.2.1.2 Applicability. Lean primary zone combustion and reduced residence time combustion have been applied to annular, can-annular, and silo combustor designs.[35-37] Almost all gas turbines presently being manufactured incorporate lean combustion and/or reduced residence time to some extent in their combustor designs, incorporating these features into production models since 1975.[38,39] However, the varying uncontrolled NO_x emission levels of gas turbines shown in Figures 5-2 and 5-3 indicate that these controls are not incorporated to the same degree in every gas turbine and may be limited in some turbines by the quantity of dilution air available for lean combustion.

Lean primary zone and reduced residence time are most applicable to low-nitrogen fuels, such as natural gas and distillate oil fuels. These modifications are not effective in reducing fuel NO_x.[40]

5.2.1.3 Factors Affecting Performance. For a given combustor, the performance of lean combustion is directly affected by the primary zone equivalence ratio. As shown in Figure 4-2, the further the equivalence ratio is reduced below 1.0, the greater the reduction in NO_x emissions. However, if the equivalence ratio is reduced too far, CO emissions increase and flame stability problems occur.[41] This emissions tradeoff effectively limits the amount of NO_x reduction that can be achieved by lean combustion alone.

NMED Exhibit 53

For combustors with reduced residence time, the amount of NO_x emission reduction achieved is directly related to the decrease in residence time in the high-temperature flame zone.

5.2.1.4 Achievable NO_x Emission Levels Using Lean Combustion and Reduced Residence Time Combustors. Lean combustion reduces NO_x emissions, and when used in combination with reduced residence time, NO_x emissions are further reduced. Figure 5-1

NMED Exhibit 53

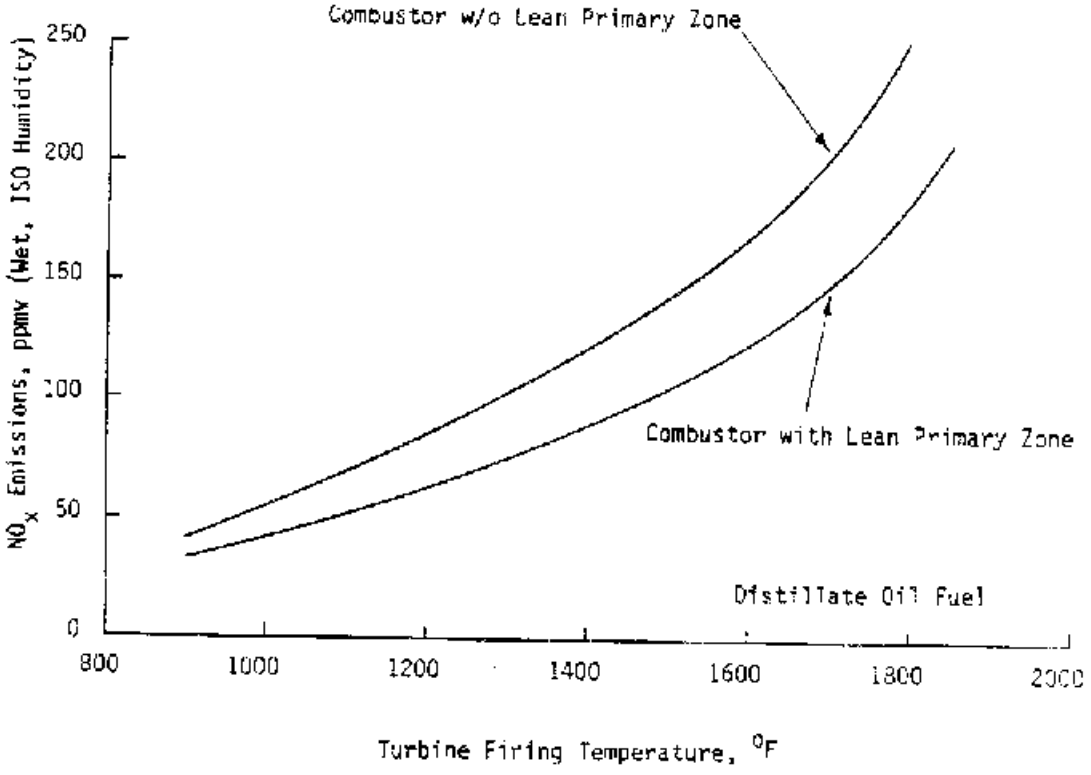

Figure 5-15. Nitrogen oxide emissions versus turbine firing temperature for combustors with and without a lean primary zone.[42]

NMED Exhibit 53

5 shows a comparison of NO_x emissions from a combustor with a lean primary zone and NO_x emissions from the same combustor without a lean primary zone. At the same firing temperature, NO_x emissions reductions of up to 30 percent are achieved using lean primary zone combustion without increasing CO emissions. Reducing the residence time at elevated temperatures reduces NO_x emissions. One test at 1065°C (1950°F) yielded a reduction in NO_x emissions of 40 percent by reducing the residence time. Carbon monoxide emissions increased from less than 10 to approximately 30 ppm.[42-45]

5.2.2 Lean Premixed Combustors

5.2.2.1 Process Description. In a conventional combustor, the fuel and air are introduced directly into the combustion zone and fuel/air mixing and combustion take place simultaneously. Wide variations in the air-to-fuel ratio (A/F) exist, and combustion of localized fuel-rich pockets produces significant levels of NO_x emissions. In a lean premixed combustor design, the air and fuel is premixed at very lean A/F's prior to introduction into the combustion zone. The excess air in the lean mixture acts as a heat sink, which lowers combustion temperatures. Premixing results in a homogeneous mixture, which minimizes localized fuel-rich zones. The resultant uniform, fuel-lean mixture results in greatly reduced NO_x formation rates.[17]

To achieve NO_x levels below 50 ppmv, referenced to 15 percent O_2, the design A/F approaches the lean flammability limit. To stabilize the flame, ensure complete combustion, and minimize CO emissions, a pilot flame is incorporated into the combustor or burner design. In most designs, the relatively

NMED Exhibit 53

small amount of air and fuel supplied to this pilot flame is not premixed and the A/F is nearly stoichiometric, so the pilot flame temperature is relatively high. As a result, NO_x emissions from the pilot flame are higher than from the lean premixed combustion.[46]

Virtually all gas turbine manufacturers have implemented lean premixed combustion development programs. Three manufacturers' designs that are available in production turbines are described below.

The first design uses a can-annular combustor and is shown in Figure 5-16

NMED Exhibit 53

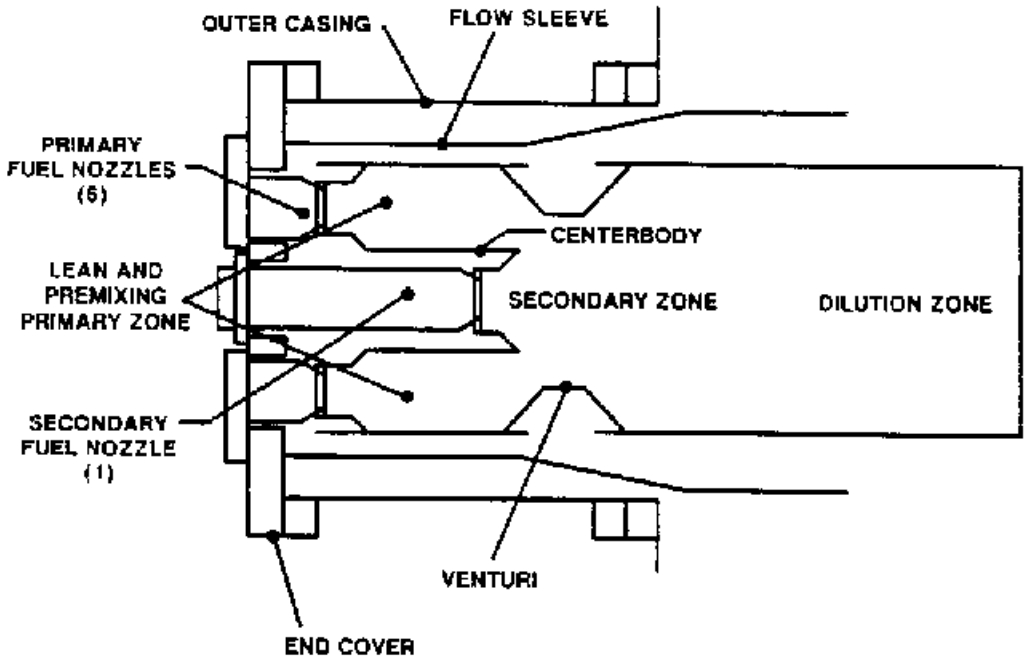

Figure 5-6. Cross-section of a lean premixed can-annular combustor.[47]

NMED Exhibit 53

. This is a two-stage premixed combustor: the first stage is the portion of the combustor upstream of the venturi section and includes the six primary fuel nozzles; the second stage is the balance of the combustor and includes the single secondary fuel nozzle.[33]

The operating modes for this combustor design are shown in Figure 5-17. For ignition, warmup, and acceleration to approximately 20 percent load, the first stage serves as the complete combustor.

NMED Exhibit 53

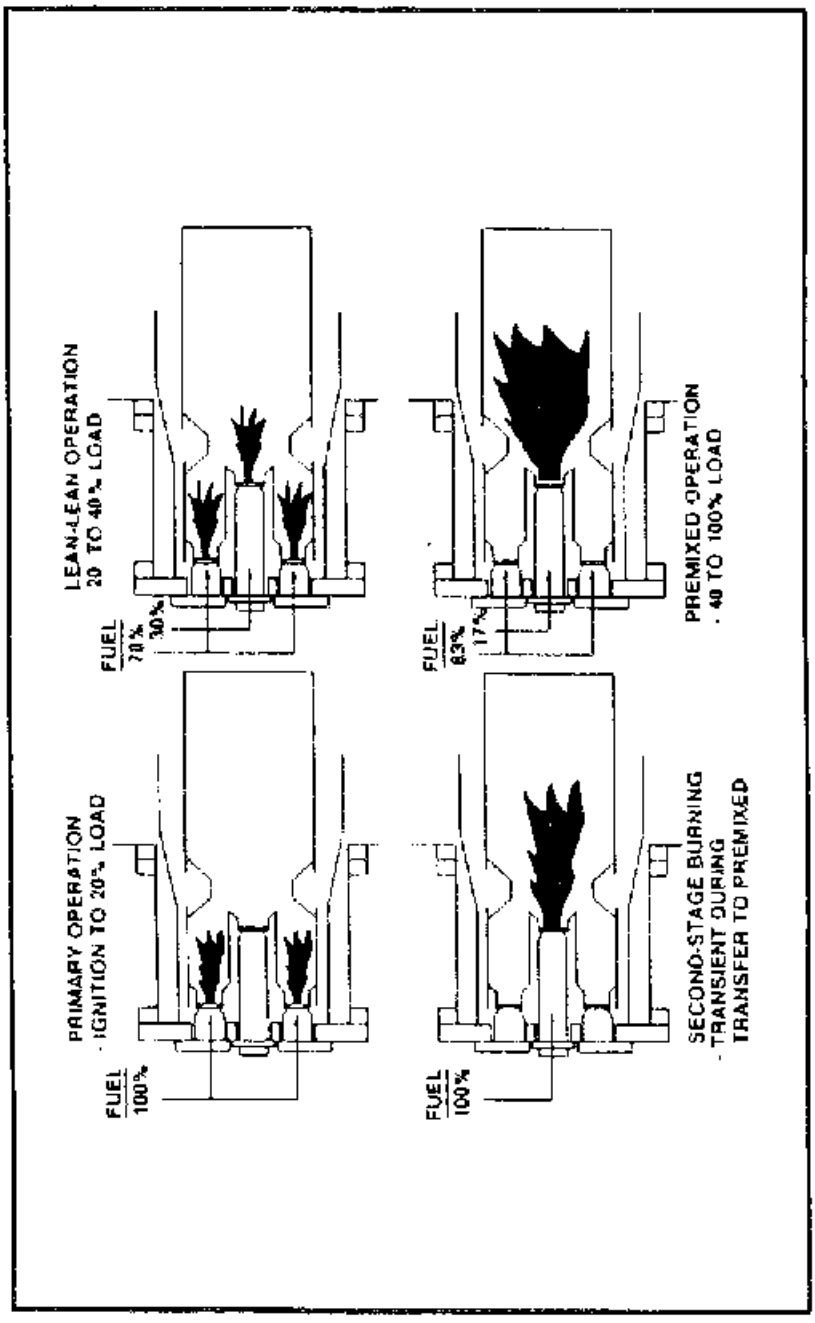

Figure 5-17. Operating modes for a lean premixed can-annular combustor.[33]

NMED Exhibit 53

Flame is present only in the first stage, and the equivalence ratio is kept as low as stable combustion will permit. With increasing load, fuel is introduced into the secondary stage, and combustion takes place in both stages. Again, the equivalence ratio is kept as low as possible in both stages to minimize NO_x emissions. When the load reaches approximately 40 percent, fuel is cut off to the first stage and the flame in this stage is extinguished. The venturi ensures the flame in the second stage cannot propagate upstream to the first stage. When the first-stage flame is extinguished (as verified by internal flame detectors), fuel is again introduced into the first stage, which becomes a premixing zone to deliver a lean, unburned, uniform mixture to the second stage. The second stage acts as the complete combustor in this configuration.[33]

For operation on distillate oil, fuel is introduced and burned only in the first stage for ignition and for loads up to approximately 50 percent. For loads greater than 50 percent, fuel is introduced and burned in both stages.[33]

NMED Exhibit 53

NMED Exhibit 53

Figure 5-18 shows a lean premixed combustor design used by another manufacturer for an annular combustor.

NMED Exhibit 53

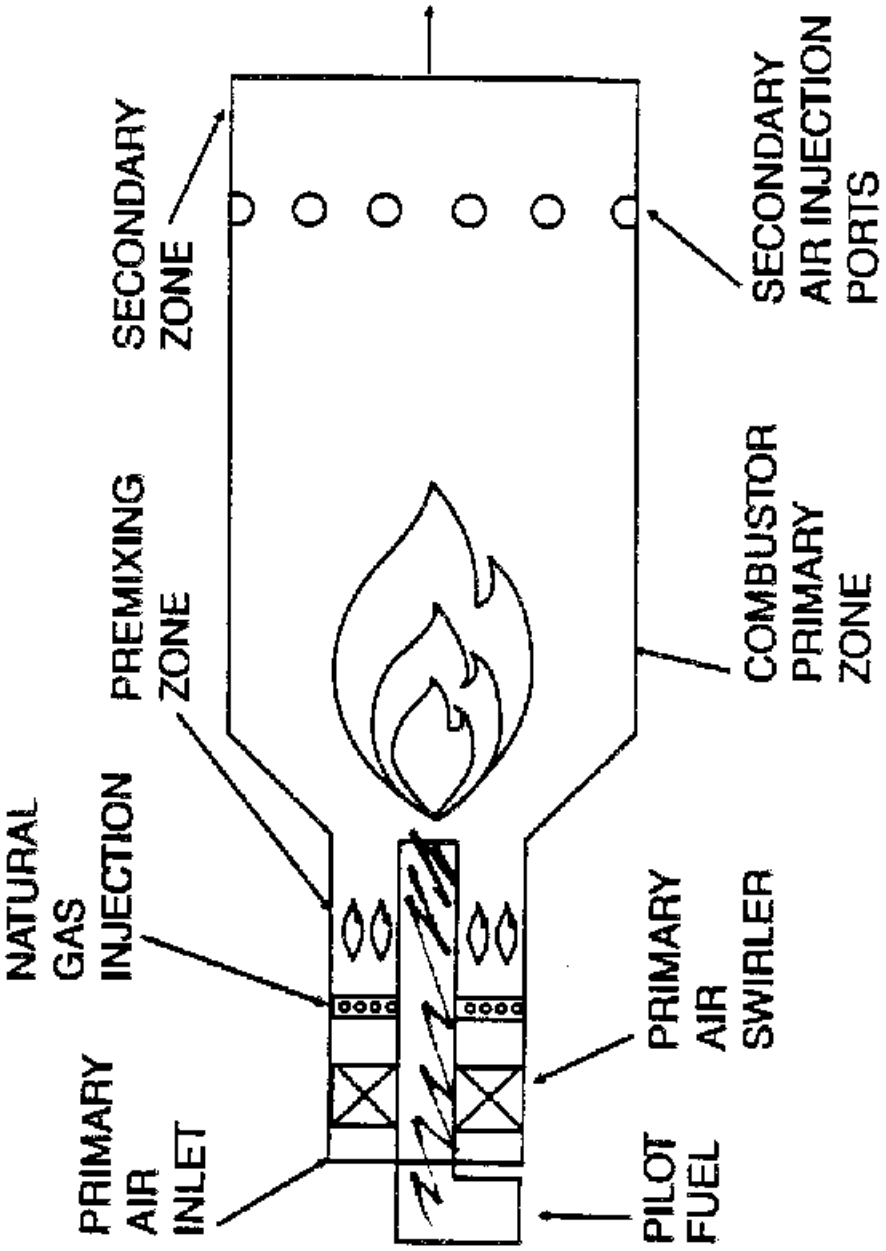

Figure 5-18. Cross-section of lean premixed annular combustion design.[47]

NMED Exhibit 53

The air and fuel are premixed using a very lean A/F, and the resultant uniform mixture is delivered to the primary combustion zone where combustion is stabilized using a pilot flame. Using one or more mechanical systems to regulate the airflow delivered to the combustor, the premix mode is operable for output loads between 50 and 100 percent. Below 50 percent load, only the pilot flame is operating, and NO_x emissions levels are similar to those for conventional combustors.[46]

Another manufacturer's production low-NO_x design uses a silo combustor. Unlike the can-annular and annular designs, the silo combustor is mounted externally to the turbine and can therefore be modified without significantly affecting the rest of the turbine design, provided the mounting flange to the turbine is unchanged. In addition, this large combustion chamber is fitted with a ceramic lining that shields the metal surfaces from peak flame temperatures. This lining reduces the requirement for cooling air, so more air is available for the combustion process.[17]

This silo low-NO_x combustor design uses six burners, as shown in Figure 5-19

NMED Exhibit 53

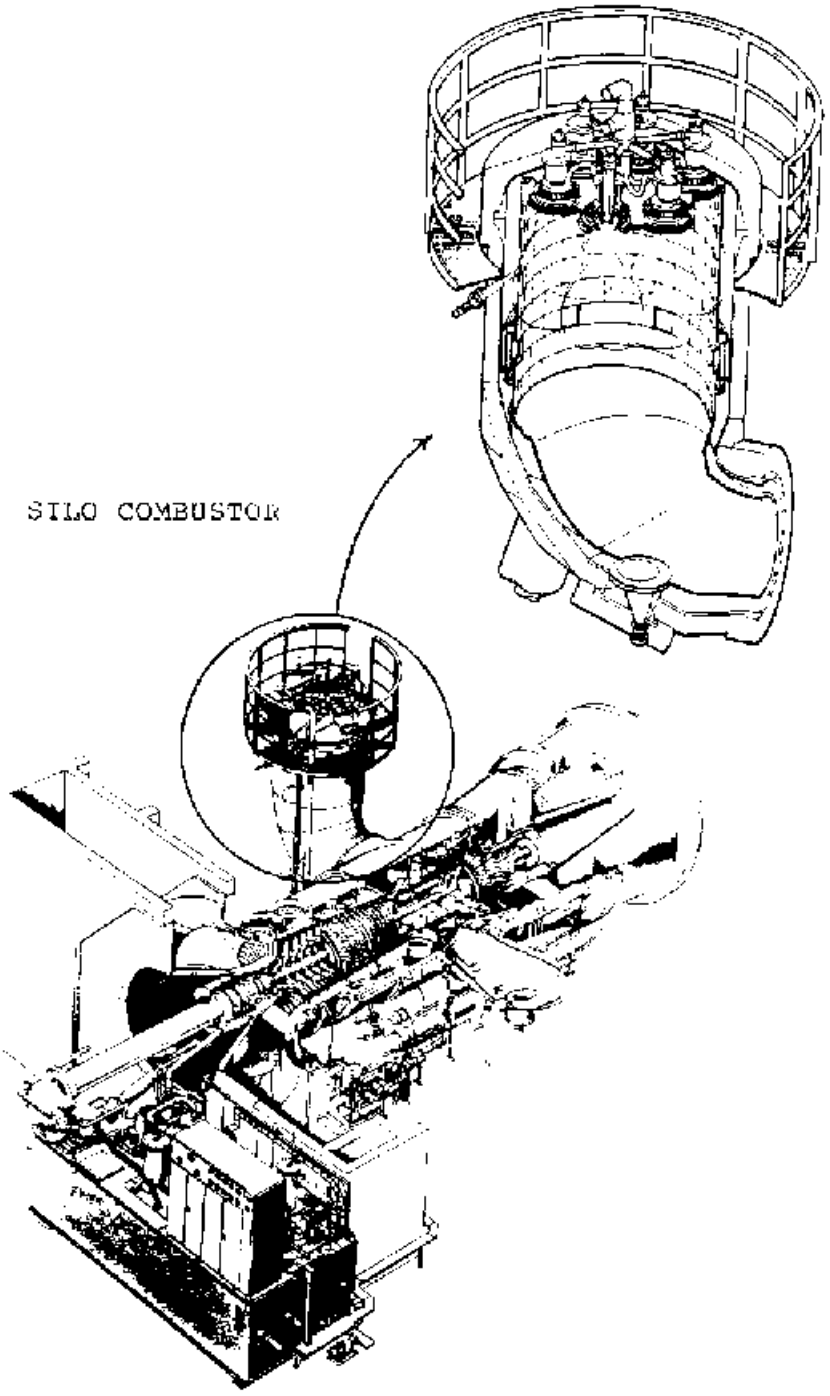

Figure 5-19. Cross-section of a low NO_x silo combustor.[35,48]

NMED Exhibit 53

. For operation on natural gas, each burner serves to premix the air and fuel to deliver a lean and uniform mixture to the combustion zone. To achieve the lowest possible NO_x emissions, the A/F of the premixed gases is kept very near the lean flammability limit and a pilot flame is used to stabilize the overall combustion process. This burner design is shown in Figure 5-20

NMED Exhibit 53

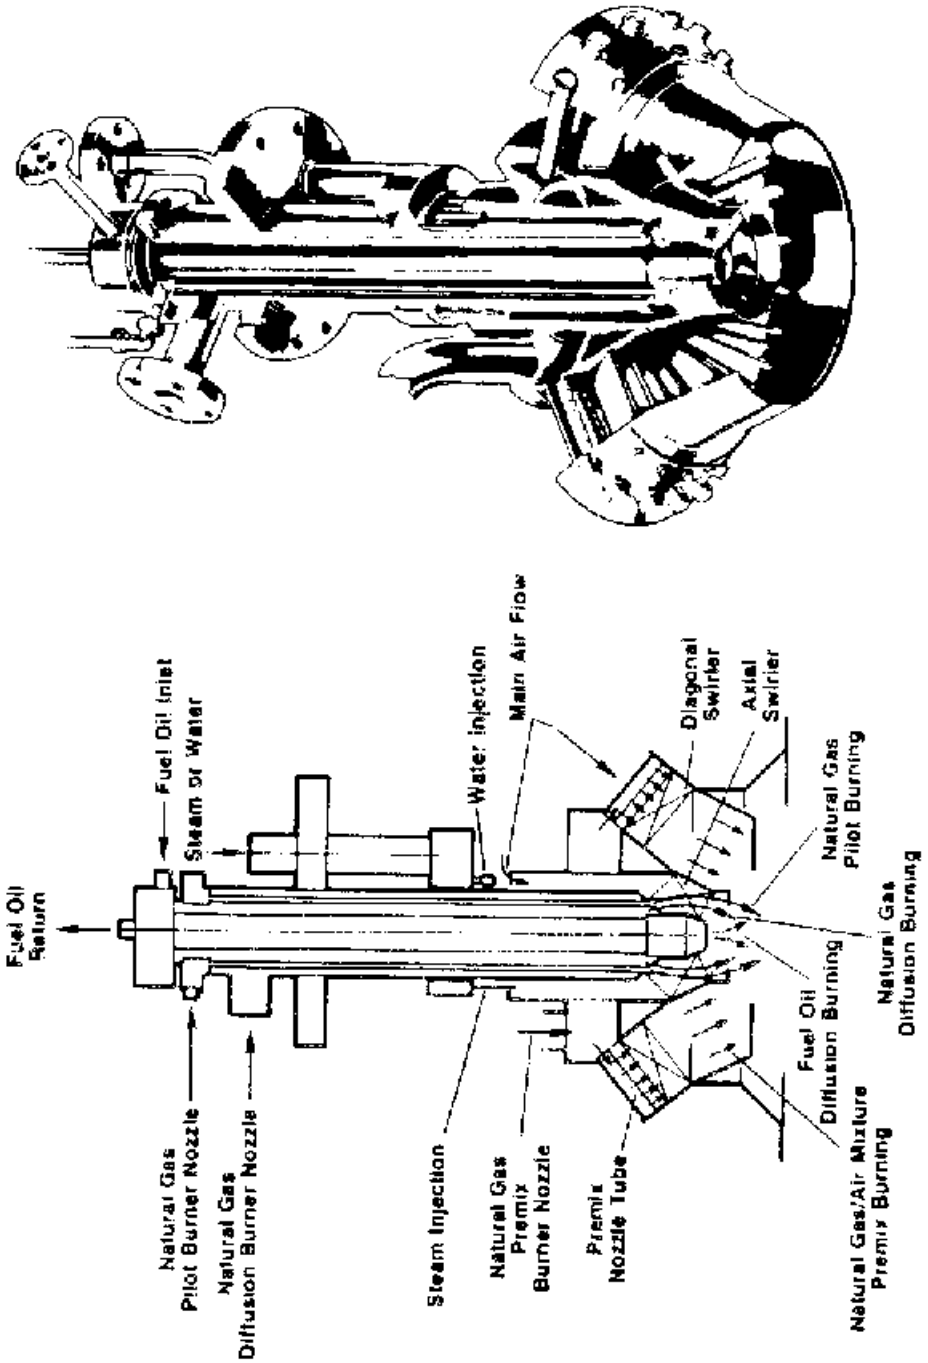

Figure 5-20. Low-NO_x burner for a silo combustor.[48]

NMED Exhibit 53

. Like the can-annular design, the burner in the silo combustor cannot operate over the full power range of the gas turbine in the premix mode due to inability of the premix mode to deliver suitable A/F's at low power output levels. For this reason, the burners are designed to operate in a conventional diffusion burning mode at startup and low power outputs and switch to a premix burning mode at higher power output levels.

NMED Exhibit 53

NMED Exhibit 53

NMED Exhibit 53

For operation on distillate oil with the current burner design, combustion occurs only in a diffusion mode and there is no premixing of air and fuel.

5.2.2.2 Applicability. As discussed in Section 5.2.2.1, lean premixed combustors apply to can-annular, annular, and silo combustors. This combustion modification is effective in reducing thermal NO_x emissions for both natural gas and distillate oil but is not effective on fuel NO_x. Therefore, lean premixed combustion is not as effective in reducing NO_x levels if high-nitrogen fuels are fired.[49]

The multiple operating modes associated with the percent operating load results in "stepped" NO_x emission levels. To date, low NO_x emission levels occur only at loads greater than 40 to 75 percent.

Lean premixed combustors currently are available for limited models from three manufacturers contacted for this study.[6,17,24] Two additional manufacturers project an availability date of 1993 or 1994 for lean premixed combustors for some turbine models.[11,50] All of these manufacturers state that these lean premixed combustors will be available for retrofit applications.

5.2.2.3 Factors Affecting Performance. The primary factors affecting the performance of lean, premixed combustors are A/F and the type of fuel. To achieve low NO_x emission levels, the A/F must be maintained in a narrow range near the lean flammability limit of the mixture. Lean premixed combustors are designed to maintain this A/F at rated load. At reduced load conditions, the fuel input requirement decreases. To avoid combustion instability and excessive CO emissions that would occur as the A/F reaches the lean flammability limit, all manufacturers' lean premixed combustors switch to a diffusion-type combustion mode at reduced load conditions, typically between 40 and 60 percent load. This switchover to a diffusion combustion mode results in higher NO_x emissions.

Natural gas produces lower NO_x levels than do oil fuels. The reasons for this are the lower flame temperature of natural gas and the ability to premix this fuel with air prior to

NMED Exhibit 53

delivery into the second combustion stage. For operation on liquid fuels, currently available lean premixed combustor designs require water injection to achieve appreciable NO_x reduction.

5.2.2.4 Achievable NO_x Emission Levels. The achievable controlled NO_x emission levels for lean premixed combustors vary depending upon the manufacturer. At least three manufacturers currently guarantee NO_x emission levels of 25 ppmv, corrected to 15 percent O_2 for most or all of their gas turbines for operation on natural gas fuel without wet injection.[6,17,24] Each of these three manufacturers has achieved controlled NO_x emission levels of less than 10 ppmv at one or more installations in the United States and/or Europe and guarantee this NO_x level for a limited number of their gas turbine models.[51] All three manufacturers offer gas turbines in the 10+ MW (13,400 hp+) range and anticipate that guaranteed NO_x emission levels of 10 ppmv or less will be available for all of their gas turbines for operation on natural gas fuel in the next few years. These low-NO_x combustor designs apply to new turbines and existing installation retrofits.

For gas turbines in the range of 10 MW (13,400 hp) and under, one gas turbine manufacturer offers a guarantee for its lean premixed combustor, without wet injection, of 42 ppmv using natural gas fuel for two of its turbine models for 1994 delivery. This manufacturer states that a controlled NO_x emission level of 25 ppmv has been achieved by in-house testing, and this 25 ppmv level firing natural gas fuel is the goal for all of its gas turbine models, for both new equipment and retrofit applications.[50]

These controlled NO_x emission levels of 9 to 42 ppmv correspond to full output load; at reduced loads, the NO_x levels increase, often in "stepped" fashion in accordance with changes in combustor operation from premixed mode to conventional or diffusion-mode operation (see Section 5.2.2.3). Figure 5-21

NMED Exhibit 53

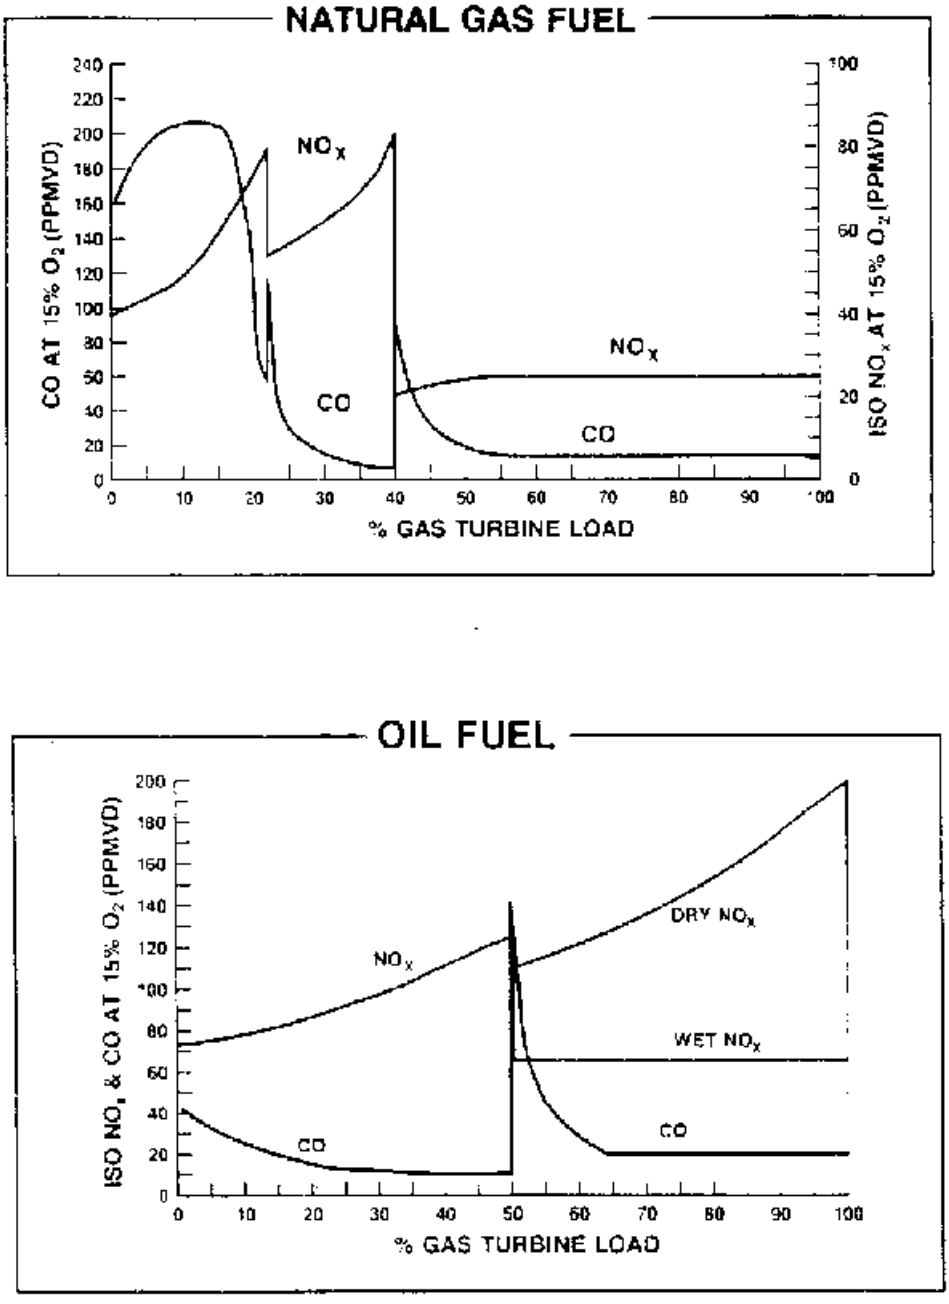

Figure 5-21. "Stepped" NO_x and CO emissions for a low-NO_x can-annular combustor burning natural gas and distillate oil fuels.[47]

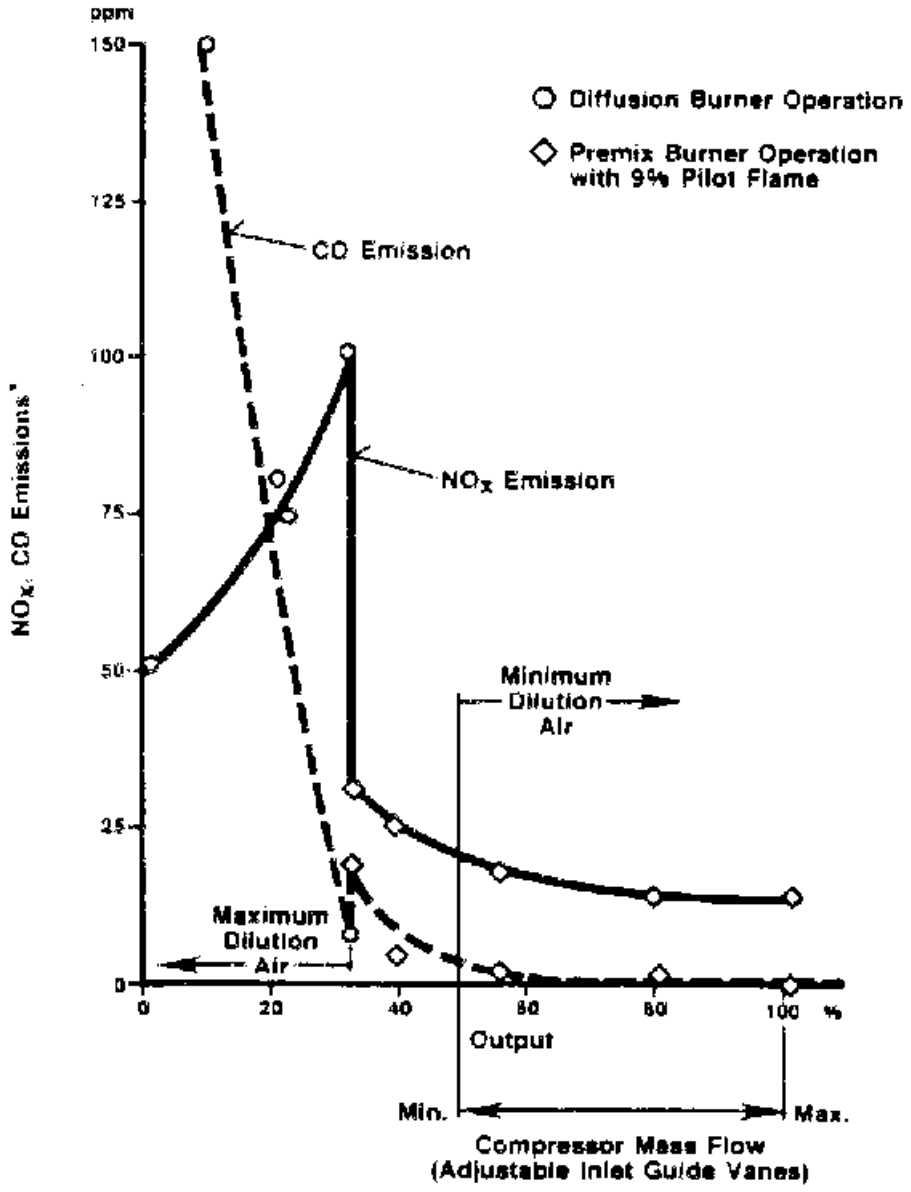

Figure 5-22. "Stepped" NO_x and CO emissions for a low-NO_x silo combustor burning natural gas.[35]

NMED Exhibit 53

shows these stepped NO_x emissions levels for a can-annular combustor for natural gas and oil fuel operation. Figure 5-22

NMED Exhibit 53

NMED Exhibit 53

shows the emissions for a silo combustor operating on natural gas only.

NMED Exhibit 53

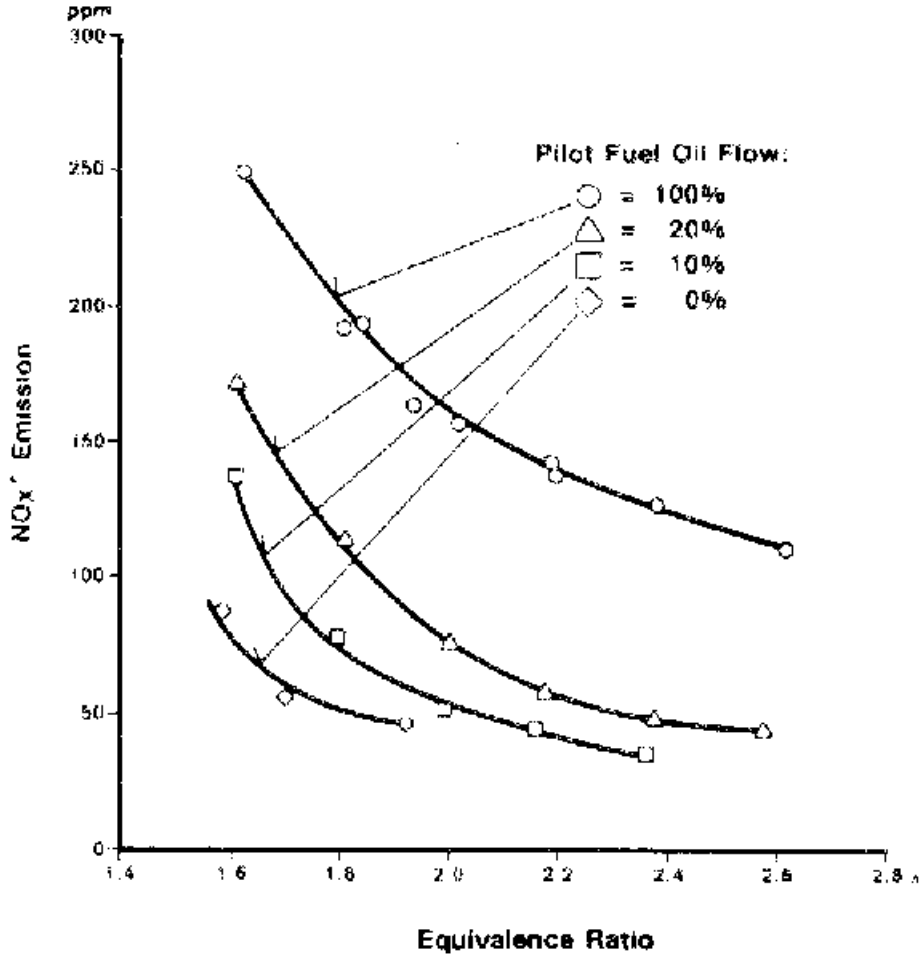

Figure 5-23. Nitrogen oxide emission text results from a lean premix silo combustor firing fuel oil without wet injection.[53]

NMED Exhibit 53

The emission levels shown in Figures 5-21 and 5-22 correspond to full-scale production turbines currently available from the manufacturers.

Reduced NO_x emissions when burning oil fuel in currently available lean premixed combustor designs have been achieved only with water or steam injection. With water or steam injection, a 65 ppmv NO_x level can be achieved in the turbine with a can-annular combustor design; a 65 ppmv level can also be met with water injection in the turbine with a silo combustor at a WFR of 1.4.[48,52] This 65 ppmv level for lean premixed combustors is higher than the controlled NO_x levels achieved with water injection in oil-fired turbines using a conventional combustor design.

Modification of the existing burner design used in the silo combustor to allow premixing of the oil fuel with air prior to combustion is under development. Tests performed using a 12 MW (16,200 hp) turbine achieved NO_x emission levels below 50 ppmv without wet injection, corrected to 15 percent O_2, compared to uncontrolled levels of 150 ppmv or higher. The NO_x levels, without wet injection, as a function of equivalence ratio are shown in Figure 5-23. The design equivalence ratio at rated load is approximately 2.1. As shown in this figure, NO_x emissions below 50 ppmv were achieved at rated power output at pilot fuel flow levels of 10 percent of the total fuel input.[52]

Site test data for two turbines using silo-type lean premixed combustors, as reported by the manufacturer, are shown in Table 5-12. As this table shows, NO_x emission levels as low as 16.5 ppmv were recorded for using natural gas fuel without

[b]Maximum design goal for CO emissions. Most in-house test configurations have achieved CO emission levels between 5 and 25 ppmv.

NMED Exhibit 53

For natural gas-fueled turbines with rated outputs of 10 MW (13,400 hp) or less, controlled NO_x emission levels of 25 to 42 ppmv result in a rise in CO emission levels from 25 ppmv or less to as high as 50 ppmv.[43] For turbines above 10 MW (13,400 hp), controlled NO_x emission levels of 9 ppmv result in a rise in CO emissions from 10 to 25 ppmv for natural gas fuel. Conversely, for controlled NO_x emission levels of 25 ppmv, the CO emissions drop from 25 to 15 ppmv.[51] For one manufacturer's lean premixed silo combustor design, CO emissions at rated load are less than 5 ppmv, as shown previously in Figure 5-21. This limited data suggest that the effect of lean premixed combustors on CO emissions depends upon the specific combustor design and the controlled NO_x emission level.

The emission levels shown in Table 5-15 correspond to rated power output. Like NO_x emission levels, CO emissions change with changes in combustor operating mode at reduced power output. The "stepped" effect on CO emissions is shown in Figures 5-21 and 5-22, shown previously.

Operation on oil fuel with wet injection, shown previously in Figure 5-21, shows CO emission levels of 20 ppmv. Additional CO emission data were not available for operation on oil fuel with water injection in lean premixed combustors. Developmental tests for operation on oil fuel without wet injection in a silo combustor are presented in Figure 5-24

NMED Exhibit 53

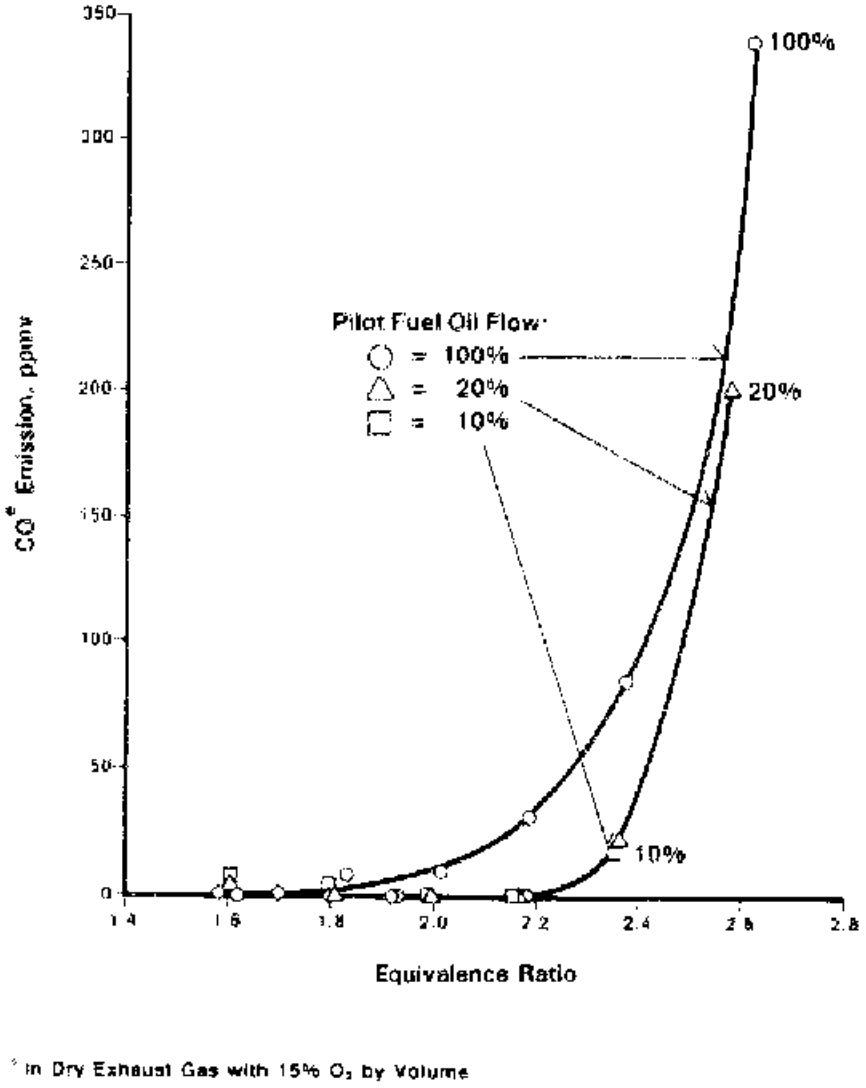

Figure 5-24. The CO emission test results from a lean premix silo combustor firing fuel oil without wet injection.

NMED Exhibit 53

. At rated load, shown in this figure at an equivalence ratio of approximately 2.1, CO emissions are less than 10 ppmv, corrected to 15 percent $O_{2,}$

NMED Exhibit 53

NMED Exhibit 53

and are in the range of 0 to 2 ppmv for a pilot oil fuel flow of 10 percent (representing 10 percent of the total fuel flow).[53] This 10 percent pilot fuel flow corresponds to controlled NO_x emission levels below 50 ppmv, as shown previously in Figure 5-22. No data for HC emissions were available for lean premixed burner designs.

5.2.3 Rich/Quench/Lean Combustion

5.2.3.1 Process Description. Rich/quench/lean (RQL) combustors burn fuel-rich in the primary zone and fuel-lean in the secondary zone. Incomplete combustion under fuel-rich conditions in the primary zone produces an atmosphere with a high concentration of CO and hydrogen (H_2). The CO and H_2 replace some of the oxygen normally available for NO_x formation and also act as reducing agents for any NO_x formed in the primary zone. Thus, fuel nitrogen is released with minimal conversion to NO_x. The lower peak flame temperatures due to partial combustion also reduce the formation of thermal NO_x.[55]

As the combustion products leave the primary zone, they pass through a low-residence-time quench zone where the combustion products are rapidly diluted with additional combustion air or water. This rapid dilution cools the combustion products and at the same time produces a lean A/F. Combustion is then completed under fuel-lean conditions. This secondary lean combustion step minimally contributes to the formation of fuel NO_x because most of the fuel nitrogen will have been converted to N_2 prior to the lean combustion phase. Thermal NO_x is minimized during lean combustion due to the low flame temperature.[55]

5.2.3.2 Applicability. The RQL combustion concept applies to all types of gas turbines. None of the manufacturers contacted for this study, however, currently have this design available for their production turbines. This may be due to lack of demand for this design due to the current limited use of high-nitrogen-content fuels in gas turbines.

5.2.3.3 Factors Affecting Performance. The NO_x emissions from RQL combustors are affected primarily by the equivalence ratio in the primary combustion zone and the quench airflow rate.

NMED Exhibit 53

Careful selection of equivalence ratios in the fuel-rich zone will minimize both thermal and fuel NO_x formation. Further NO_x reduction is achieved with increasing quench airflow rates, which serve to reduce the equivalence ratio in the secondary (lean) combustion stage.

5.2.3.4 Achievable NO_x Emissions Levels Using Rich/Quench/Lean Combustion. The RQL staged combustion has been demonstrated in rig tests to be effective in reducing both thermal NO_x and fuel NO_x. As shown in Figure 5-25, NO_x emissions are reduced by 40 to 50 percent in a test rig burning diesel fuel.

NMED Exhibit 53

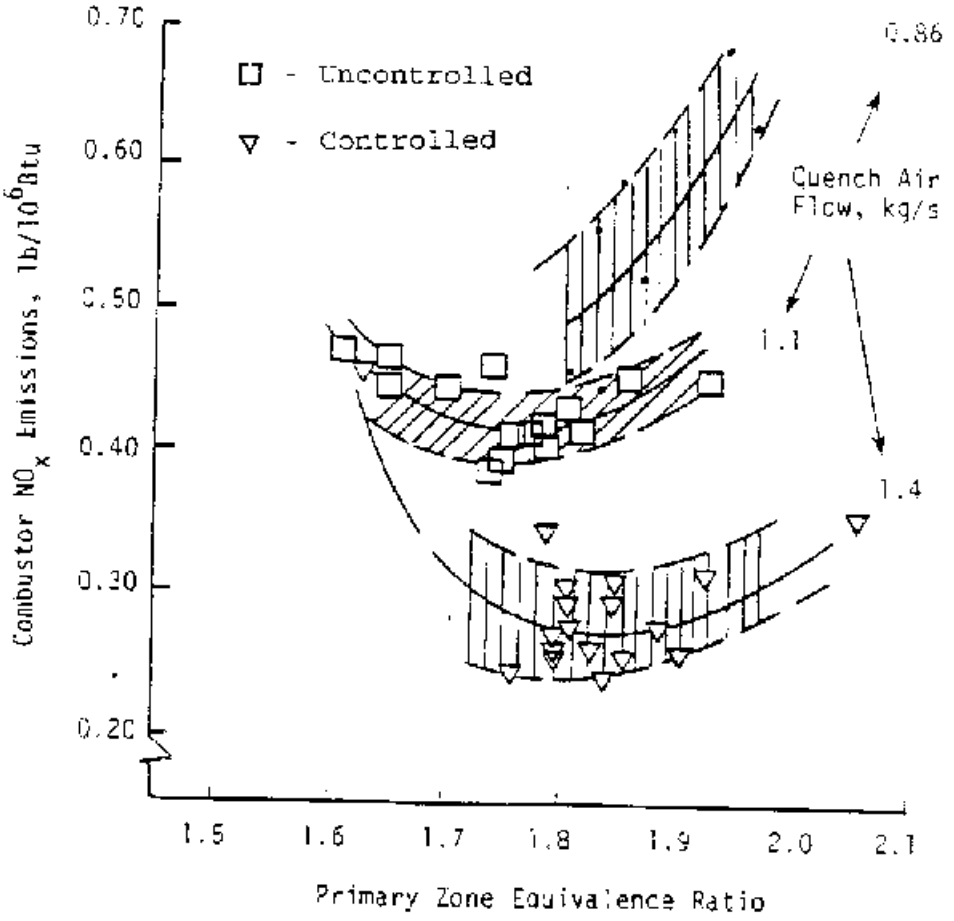

Figure 5-25. Nitrogen oxide emissions versus primary zone equivalence ratio for a rich/quench/lean combustor firing distillate oil.[56]

NMED Exhibit 53

At an equivalence ratio of 1.8, the NO_x emissions can be reduced from 0.50 to 0.27 lb/MMBtu by increasing the quench airflow from 0.86 to 1.4 kg/sec. Data were not available to convert the NO_x emissions figures to ppmv. The effectiveness of rich/lean staged combustion in reducing fuel NO_x when firing high-FBN fuels is shown in Figure 5-26.

NMED Exhibit 53

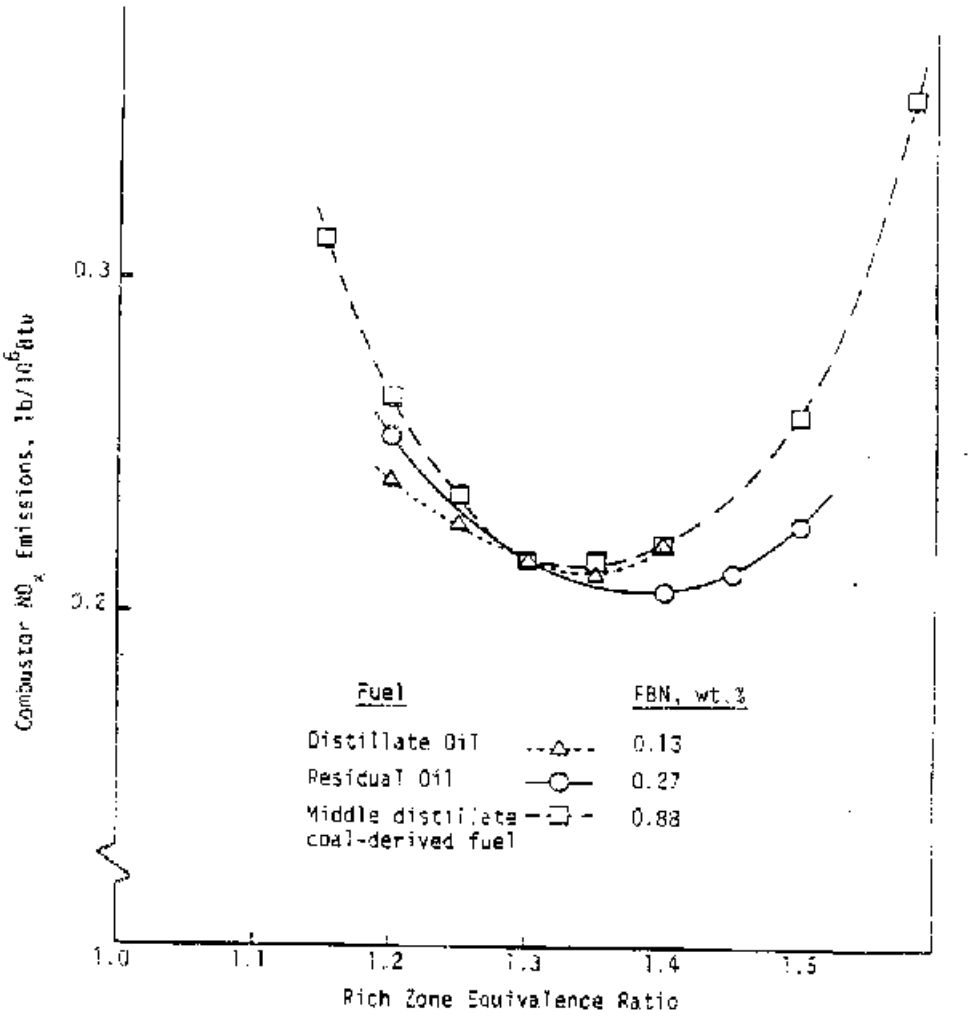

Figure 5-26. Effects of fuel bound nitrogen (FBN) content of NO_x emissions for a rich/quench/lean combustor.[57]

NMED Exhibit 53

Increasing the FBN content from 0.13 to 0.88 percent has little impact on the total NO_x formation at an operating equivalence ratio of 1.3 to 1.4. Tests on other rich/lean combustors indicate fuel nitrogen conversions to NO_x of about 7 to 20 percent.[58,59] These fuel nitrogen conversions represent a fuel NO_x emission reduction of approximately 50 to 80 percent.

One manufacturer has tested an RQL combustor design in a 4 MW (5,360 hp) gas turbine fueled with a finely ground coal and water mixture. The coal partially combusts in a fuel-rich zone at temperatures of 1650°C (3000°F), with low O_2 levels and an extremely short residence time. The partially combusted products are then rapidly quenched with water, cooling combustion temperatures to inhibit thermal NO_x formation. Additional combustion air is then introduced, and combustion is completed under fuel-lean conditions. In tests at the manufacturer's plant, cosponsored by the U. S. Department of Energy, a NO_x emission level of 25 ppmv at 15 percent O_2 was achieved. This combustor design can also be used with natural gas and oil fuels. Single-digit NO_x emission levels are reported for operation on

NMED Exhibit 53

NMED Exhibit 53

natural gas fuel. This combustor design is not yet available for production turbines.[60]

5.3 SELECTIVE CATALYTIC REDUCTION

Selective catalytic reduction (SCR) is an add-on NO_x control technique that is placed in the exhaust stream following the gas turbine. Over 100 gas turbine installations use SCR in the United States.[61] An SCR process description, the applicability of SCR for gas turbines, the factors affecting SCR performance, and the achievable NO_x reduction efficiencies are discussed in this section.

5.3.1 Process Description

The SCR process reduces NO_x emissions by injecting ammonia into the flue gas. The ammonia reacts with NO_x in the presence of a catalyst to form water and nitrogen. In the catalyst unit, the ammonia reacts with NO_x primarily by the following equations:[62]

$$NH_3 + NO + 1/4\ O_2 \rightarrow N_2 + 3/2\ H_2O;\ \text{and}$$

$$NH_3 + 1/2\ NO_2 + 1/4\ O_2 \rightarrow 3/2\ N_2 + 3/2\ H_2O.$$

The catalyst's active surface is usually either a noble metal, base metal (titanium or vanadium) oxide, or a zeolite-based material. Metal-based catalysts are usually applied as a coating over a metal or ceramic substrate. Zeolite catalysts are typically a homogenous material that forms both the active surface and the substrate. The geometric configuration of the catalyst body is designed for maximum surface area and minimum obstruction of the flue gas flow path to maximize conversion efficiency and minimize back-pressure on the gas turbine. The most common catalyst body configuration is a monolith, "honeycomb" design, as shown in Figure 5-27.

NMED Exhibit 53

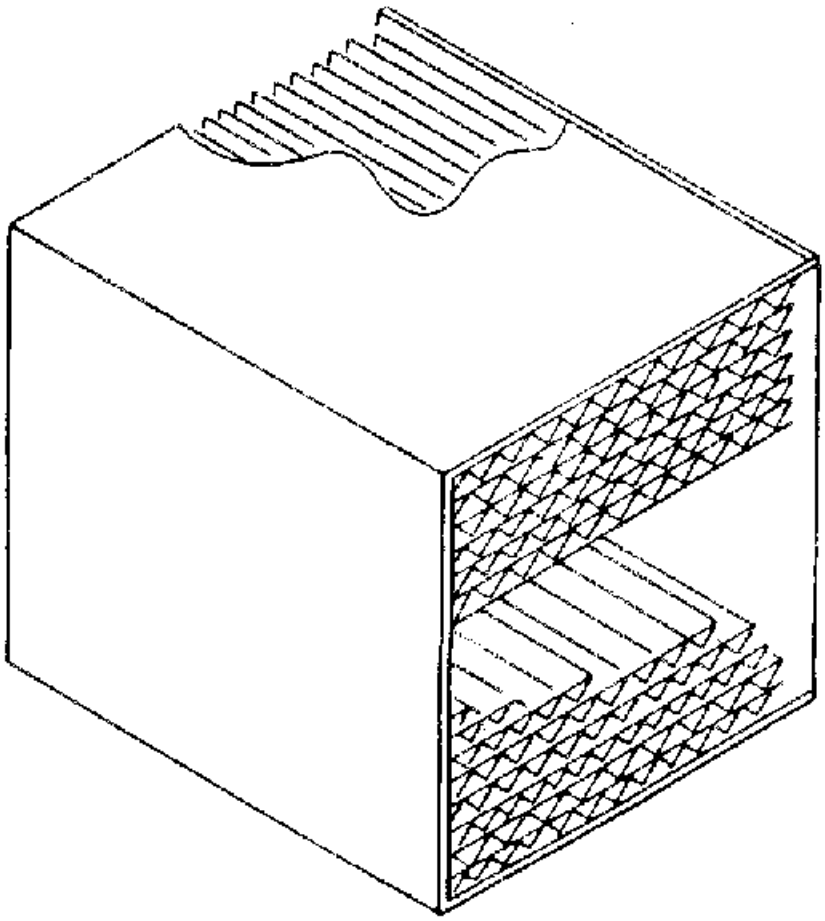

Figure 5-27. Cutaway view of a typical monolith catalyst body with honeycomb configuration.[62]

NMED Exhibit 53

An ammonia injection grid is located upstream of the catalyst body and is designed to disperse the ammonia uniformly throughout the exhaust flow before it enters the catalyst unit. In a typical ammonia injection system, anhydrous ammonia is drawn from a storage tank and evaporated using a steam- or electric-heated vaporizer. The vapor is mixed with a pressurized carrier gas to provide both sufficient momentum through the

NMED Exhibit 53

injection nozzles and effective mixing of the ammonia with the flue gases. The carrier gas is usually compressed air or steam, and the ammonia concentration in the carrier gas is about 5 percent.[62]

An alternative to using the anhydrous ammonia/carrier gas system is to inject an a aqueous ammonia solution. This system is currently not as common but removes the potential safety hazards associated with transporting and storing anhydrous ammonia and is often used in installations with close proximity to populated areas.[61,62]

The NH_3/NO_x ratio can be varied to achieve the desired level of NO_x reduction. As indicated by the chemical reaction equations listed above, it takes one mole of NH_3 to reduce one mole of NO, and two moles of NH_3 to reduce one mole of NO_2. The NO_x composition in the flue gas from a gas turbine is over 85 percent NO, and SCR systems generally operate with a molar NH_3/NO_x ratio of approximately 1.0.[63] Increasing this ratio will further reduce NO_x emissions but will also result in increased unreacted ammonia passing through the catalyst and into the atmosphere. This unreacted ammonia is known as ammonia slip.

5.3.2 Applicability of SCR for Gas Turbines

Selective catalytic reduction applies to all gas turbine types and is equally effective in reducing both thermal and fuel NO_x emissions. There are, however, factors that may limit the applicability of SCR.

An important factor that affects the performance of SCR is operating temperature. Gas turbines that operate in simple cycle have exhaust gas temperatures ranging from approximately 450° to 540°C (850° to 1000°F). Base-metal catalysts have an operating temperature window for clean fuel applications of approximately 260° to 400°C (400° to 800°F). For sulfur-bearing fuels that produce greater than 1 ppm SO_3 in the flue gas, the catalyst operating temperature range narrows to 315° to 400°C (600° to 800°F). The upper range of this temperature window can be

NMED Exhibit 53

increased using a zeolite catalyst to a maximum of 590°C (1100°F).[64]

Base metal catalysts are most commonly used in gas turbine SCR applications, accounting for approximately 80 percent of all U.S. installations, and operate in cogeneration or combined cycle applications. The catalyst is installed within the HRSG, where the heat recovery process reduces exhaust gas temperatures to the proper operating range for the catalyst. The specific location of the SCR within the HRSG is application-specific; Figure 5-28 shows two possible SCR locations.

NMED Exhibit 53

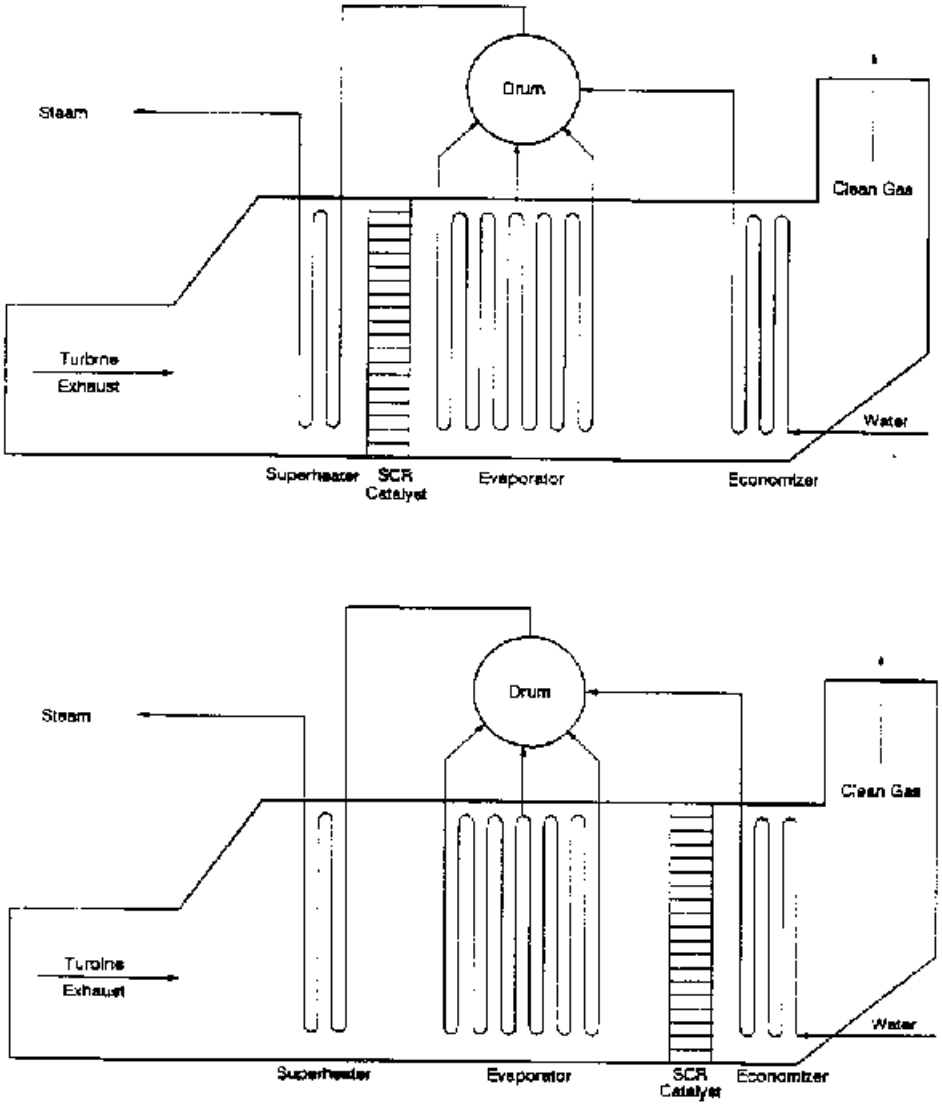

Figure 5-28. Possible locations for SCR unit in HRSG.[62]

NMED Exhibit 53

In addition to the locations shown, the catalyst may also be located within the evaporator section of the HRSG.

As noted above, zeolite catalysts have a maximum operating temperature range of up to 590°C (1100°F), which is compatible with simple cycle turbine exhaust temperatures. To date, however, there is only one SCR installation operating with a zeolite catalyst directly downstream of the turbine. This catalyst, commissioned in December 1989, has an operating range of 260° to 515°C (500° to 960°F) and operates approximately 90 percent of the time at temperatures above 500°C (930°F).[65]

Another consideration in determining the applicability of SCR is complications arising from sulfur-bearing fuels. The sulfur content in pipeline quality natural gas is negligible, but distillate and residual oils as well as some low-Btu fuel gases such as coal gas have sulfur contents that present problems when used with SCR systems. Combustion of sulfur-bearing fuels produces SO_2 and SO_3 emissions. A portion of the SO_2 oxidizes to SO_3 as it passes through the HRSG, and base metal catalysts have an SO_2-to-SO_3 oxidation rate of up to five percent.[64] In addition, oxidation catalysts, when used to reduce CO emissions, will also oxidize SO_2 to SO_3 at rates of up to 50 percent.[66]

Unreacted ammonia passing through the catalyst reacts with SO_3 to form ammonium bisulfate (NH_4HSO_4) and ammonium sulfate [$(NH_4)_2\ SO_4$] in the low-temperature section of the HRSG. The rate of ammonium salt formation increases with increasing levels of SO_3 and NH_3, and the formation rate increases with decreasing

NMED Exhibit 53

temperature. Below 200°C (400°F), ammonium salt formation occurs with single-digit ppmv levels of SO_3 and NH_3.[66]

The exhaust temperature exiting the HRSG is typically in the range of 150° to 175°C (300° to 350°F), so ammonium salt formation typically occurs in the low-temperature section of the HRSG.[66] Ammonium bisulfate is a sticky substance that over time corrodes the HRSG boiler tubes. Additionally, it deposits on both the boiler and catalyst bed surfaces, leading to fouling and plugging of these surfaces. These deposits result in increased back pressure on the turbine and reduced heat transfer efficiency in the HRSG. This requires that the HRSG be removed from service periodically to water-wash the affected surfaces. Ammonium sulfate is not corrosive, but like ammonium bisulfate, it deposits on the HRSG surfaces and contributes to plugging and fouling of the heat transfer system.[33]

Formation of ammonium salts can be avoided by limiting the sulfur content of the fuel and/or limiting the ammonia slip. Low SO_2-to-SO_3 oxidizing catalysts are also available. Base metal catalysts are available with oxidation rates of less than 1 percent, but these low oxidation formulas also have lower NO_x reduction activity per unit volume and therefore require a greater catalyst volume to achieve a given NO_x reduction level. Zeolite catalysts are reported to have intrinsic SO_2-to-SO_3 oxidation rates of less than 1 percent.[64,66] As stated above, pipeline-quality natural gas has negligible sulfur content, but some sources of natural gas contain H_2S, which may contribute to ammonium salt formation. For oil fuels, even the lowest-sulfur distillate oil or liquid aviation fuel contains sulfur levels that can produce ammonium salts. According to catalyst vendors, SCR systems can be designed for 90 percent NO_x reduction and 10 ppm or lower NH_3 slip for sulfur-bearing fuels up to 0.3 percent by weight.[64] Continuous emission monitoring equipment has been developed for NH_3, and may be instrumental in regulating ammonia injection to minimize slip.[67]

To date, there is limited operating experience using SCR with oil-fired gas turbine installations. One combined cycle

NMED Exhibit 53

installation using oil fuel, a United Airlines facility in San Francisco installed in 1985, experienced fuel-related catalyst problems and now uses only natural gas fuel.[33] In the past, sulfur was found to poison the catalyst material. Sulfur-resistant catalyst materials are now available, however, and catalyst formulation improvements have proven effective in resisting performance degradation with oil fuels in Europe and Japan, where catalyst life in excess of 4 to 6 years has been achieved, versus 8 to 10 years with natural gas fuel.[64] A zeolite catalyst installed on a 5 MW (6710 hp) dual fuel reciprocating engine in the northeastern United States has operated for over 3 years and burned approximately 600,000 gallons of diesel fuel while maintaining a NO_x reduction efficiency of greater than 90 percent.[3]

In its guidance to member states, NESCAUM recommends that SCR be considered for NO_x reduction in dual-fueled turbine applications. There are four combined cycle gas turbines installations operating with SCR in the northeast United States burning natural gas as the primary fuel with oil fuel as a back-up.[3] These installations, listed in Table 5-16,

NMED Exhibit 53

TABLE 5-16. GAS TURBINE INSTALLATIONS IN THE NORTHEASTERN UNITED STATES WITH SCR AND PERMITTED FOR BOTH NATURAL GAS AND OIL FUELS[3]

[d]This installation requires the SCR system to be operational when burning oil fuel.

[e]This installation operated 185 hours on oil fuel in 1991, burning approximately 354,000 gallons of oil fuel.

[f]Ammonia injection is shut down during operation on oil fuel.

NMED Exhibit 53

began operating recently and have limited hours of operation on oil fuel. As indicated in the table, two of these installations shut down the ammonia injection when operating on oil fuel to prevent potential operating problems arising from sulfur-bearing fuels. Permits issued more recently in this region for other dual-fuel installations, however, require that the SCR system be operational on either fuel.[3]

A final consideration for SCR is catalyst masking or poisoning agents. Natural gas is considered clean and free of contaminants, but other fuels may contain agents that can degrade catalyst performance. For refinery, field, or digester gas fuel applications, it is important to have an analysis of the fuel and properly design the catalyst for any identified contaminants. Arsenic, iron, and silica may be present in field gases, along with zinc and phosphorus. Catalyst life with these fuels depends upon the content of the gas and is a function of the initial

NMED Exhibit 53

design parameters. With oil fuels, in addition to the potential for ammonium salt formation, it is important to be aware of heavy metal content. Particulates in the flue gas can also mask the catalyst.[64]

Selective catalytic reduction may not be readily applicable to gas turbines firing fuels that produce high ash loadings or high levels of contaminants because these elements can lead to fouling and poisoning of the catalyst bed. However, because gas turbines are also subject to damage from these elements, fuels with high levels of ash or contaminants typically are not used.

Coal, while not currently a common fuel for turbines, has a number of potential catalyst deactivators. High dust concentrations, alkali, earth metals, alkaline heavy metals, calcium sulfate, and chlorides all can produce a masking or blinding effect on the catalyst. High dust can also erode the catalyst. Erosion commonly occurs only on the leading face of the catalyst. Airflow deflectors and dummy layers of catalyst can be used to straighten out the airflow and reduce erosion. There is currently no commercial U.S. experience with coal. In Japan, which burns low-sulfur coal with moderate dust levels, catalyst life has been 5 years or more without replacement. In Germany, with high dust loadings, the experience has also been 5 years or more.[64]

Masking agents deposit on the surface of the catalyst, forming a barrier between the active catalyst surface and the exhaust gas, inhibiting catalytic activity. Poisoning agents chemically react with the catalyst and render the affected area inactive. Masking agents can be removed by vacuuming or by using soot blowers or superheated steam. Catalysts cleaned in this manner can recover greater than 90 percent of the original reduction activity. The effects of poisoning agents, however, are permanent and the affected catalyst surface cannot be regenerated.[64]

Retrofit applications for SCR may require the addition of a heat exchanger for simple cycle installations, and replacement or extensive modification of the existing HRSG in cogeneration and

NMED Exhibit 53

combined cycle applications to accommodate the catalyst body. For these reasons, retrofit applications for SCR could involve high capital costs.

5.3.3 Factors Affecting SCR Performance

The NO_x reduction efficiency for an SCR system is influenced by catalyst material and condition, reactor temperature, space velocity, and the NH_3/NO_x ratio.[63] These design and operating variables are discussed below.

Several catalyst materials are available, and each has an optimum NO_x removal efficiency range corresponding to a specific temperature range. Proprietary formulations containing titanium dioxide, vanadium pentoxide, platinum, or zeolite are available to meet a wide spectrum of operating temperatures. The NO_x removal efficiencies for these catalysts are typically between 80 and 90 percent when new. The NO_x removal efficiency gradually decreases over the operating life of the catalyst due to deterioration from masking, poisoning, or sintering.[63] The rate of catalyst performance degradation depends upon operating conditions and is therefore site-specific.

The space velocity (volumetric flue gas flow divided by the catalyst volume) is an indicator of gas residence time in the catalyst unit. The lower the space velocity, the higher the residence time, and the higher the potential for increased NO_x reduction. Because the gas flow is a constant determined by the gas turbine, the space velocity depends upon the catalyst volume, or total active surface area. The distance across the opening between plates or cells in the catalyst, referred to as the pitch, affects the overall size of the catalyst body. The smaller the pitch, the greater the number of rows or cells that can be placed in a given volume. Therefore, for a given catalyst body size, the smaller the pitch, the larger the catalyst volume and the lower the space velocity. For natural gas applications the catalyst pitch is typically 2.5 millimeters (mm) (0.10 inch [in.]), increasing to 5 to 7 mm (0.20 to 0.28 in.) for coal-fuel applications.[64]

NMED Exhibit 53

As discussed in Section 5.3.1, the NH_3/NO_x ratio can be varied to achieve the desired level of NO_x reduction. Increasing this ratio increases the level of NO_x reduction but may also result in higher ammonia slip levels.

5.3.4 Achievable NO_x Emission Reduction Efficiency Using SCR

Most SCR systems operating in the United States have a space velocity of about 30,000/hr, a NH_3/NO_x ratio of about 1.0, and ammonia slip levels of approximately 10 ppm. The resulting NO_x reduction efficiency is about 90 percent.[41] Reduction efficiency is the level of NO_x removed as a percentage of the level of NO_x entering the SCR unit. Only one gas turbine installation in the United States was identified using only SCR to reduce NO_x emissions. This installation has two natural gas-fired 8.5 MW gas turbines, each with its own HRSG in which is installed an SCR system. A summary of emission testing at this site lists NO_x emissions at the inlet to the SCR catalyst at 130 ppmv. Controlled NO_x emissions downstream of the catalyst were 18 ppmv, indicating a NO_x reduction efficiency of 86 percent. Maximum ammonia slip levels were listed at 35 ppmv.[68]

All other gas turbine installations identified as using SCR in the United States use this control method in combination with wet injection and/or low-NO_x combustors. The emission levels that can be achieved by this combination of controls are found in Section 5.4.

5.3.5 Disposal Considerations for SCR

The SCR catalyst material has a finite life, and disposal can pose a problem. The guaranteed catalyst life offered by catalyst suppliers ranges from 2 to 3 years.[64] In Japan, where SCR systems have been in operation since 1980, experience shows that many catalysts in operation with natural gas-fired boilers have performed well for 7 years or longer.[63,64] In any case, at some point the catalyst must be replaced, and those units containing heavy metal oxides such as vanadium or titanium potentially could be considered hazardous wastes. While the amount of hazardous material in the catalyst is relatively small, the volume of the catalyst body can be quite large, and disposal

NMED Exhibit 53

of this waste could be costly. Some suppliers provide for the removal and disposal of spent catalyst. Precious metal and zeolite catalysts do not contain hazardous wastes.

5.4 CONTROLS USED IN COMBINATION WITH SCR

With but one exception, SCR units installed in the United States are used in combination with wet controls or combustion controls described in Sections 5.1 and 5.2. Wet controls yield NO_x emission levels of 25 to 42 ppmv for natural gas and 42 to 110 ppmv for distillate oil, based on the data provided by gas turbine manufacturers and shown in Figures 5-10 and 5-11. A carefully designed SCR system can achieve NO_x reduction efficiencies as high as 90 percent, with ammonia slip levels of 10 ppmv or less for natural gas and low-sulfur (<0.3 percent by weight) fuel applications.[64]

As discussed for wet injection in Sections 5.1.4 and 5.2.2.4, controlled NO_x emission levels for natural gas range from 25 to 42 ppmv for natural gas fuel and from 42 to 110 ppmv for oil fuel. Applying a 90 percent reduction efficiency for SCR, NO_x levels can be theoretically reduced to 2.5 to 4.2 and 4.2 to 11.0 ppmv for natural gas and oil fuels, respectively. For oil fuels and other sulfur-bearing fuels, a reduction efficiency of 90 percent requires special design considerations to address potential operational problems caused by the sulfur content in the fuel. This subject is discussed in Section 5.3.2. The final controlled NO_x emission level depends upon the NO_x level exiting the turbine and the achievable SCR reduction efficiency.

Test reports provided by SCAQMD include three gas turbine combined cycle installations fired with natural gas that have achieved NO_x emission levels of 3.4 to 7.2 ppmv, referenced to 15 percent oxygen. The NO_x and CO emissions reported for these tests are shown in Table 5-17

NMED Exhibit 53

[a]Calculated from ppmv entering the SCR and percent reduction figures.
[b]NH_3 permit limit. Test emission level not available.
[c]Test was run at less than permit NH_3/NO_x ratio of 1.1. SCR designed for exhaust from total of 5 turbines. Only one turbine operating during test.
[d]This site does not use wet injection for gas turbine NO_x reduction.
[e]NH_3 compliance test not required. NH_3 level from NH_3 monitor testing.

Ammonia slip levels were not reported. Ammonia slip levels

NMED Exhibit 53

were reported, however, in a summary of emission tests for 13 SCR installations and are presented in Table 5-18.[68] For these sites, operating on natural gas fuel, the NO_x reduction efficiency of the catalyst ranges

NMED Exhibit 53

NMED Exhibit 53

from 60 to 96 percent, with most reduction efficiencies between 80 and 90 percent. Ammonia slip levels range from 1 to 35 ppmv. The site with the 35 ppmv ammonia slip level is unique in that it is the only site identified in the United States that uses only SCR rather than a combination of SCR and wet injection to reduce NO_x emissions. With the exception of this site, all NH_3 slip levels in Table 5-18 that are based on test data are less than 10 ppmv. Based on information received from catalyst vendors, it is expected that an SCR system operating downstream of a gas turbine without wet injection could be designed to limit ammonia slip levels to 10 ppmv or less.[64] No test data are available for SCR operation on gas turbines fired with distillate oil fuels.

5.5 EFFECT OF ADDING A DUCT BURNER IN HRSG APPLICATIONS

A duct burner is often added in cogeneration and combined cycle applications to increase the steam capacity of the HRSG (see Section 4.2.2). Duct burners in gas turbine exhaust streams consist of pipes or small burners that are placed in the exhaust gas stream to allow firing of additional fuel, usually natural gas. Duct burners can raise gas turbine exhaust temperatures to 1000°C (2000°F), but a more common temperature is 760°C (1400°F). The gas turbine exhaust is the source of oxygen for the duct burner.

NMED Exhibit 53

Figure 5-29 shows a typical natural gas-fired duct burner

NMED Exhibit 53

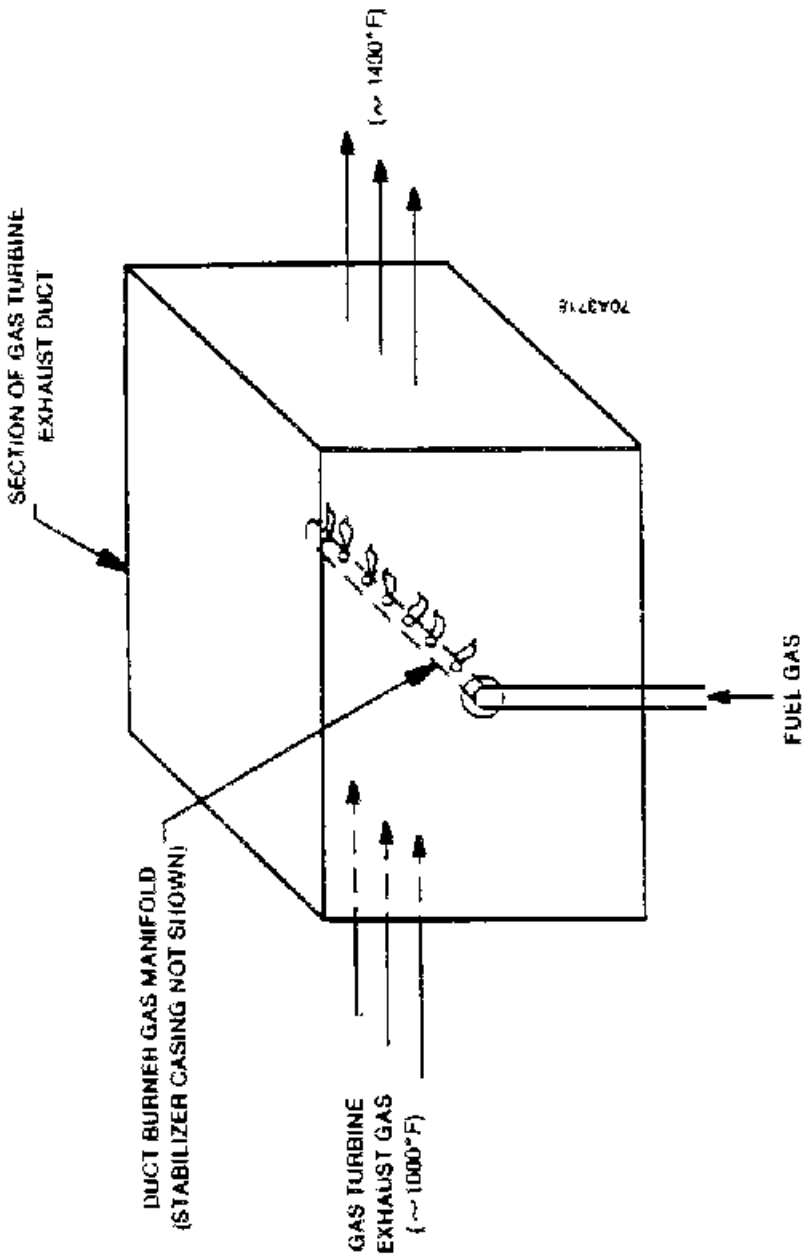

Figure 5-29. Typical duct burner for gas turbine exhaust application.[72]

NMED Exhibit 53

installation. Figure 5-30 is a cross-sectional view of one style

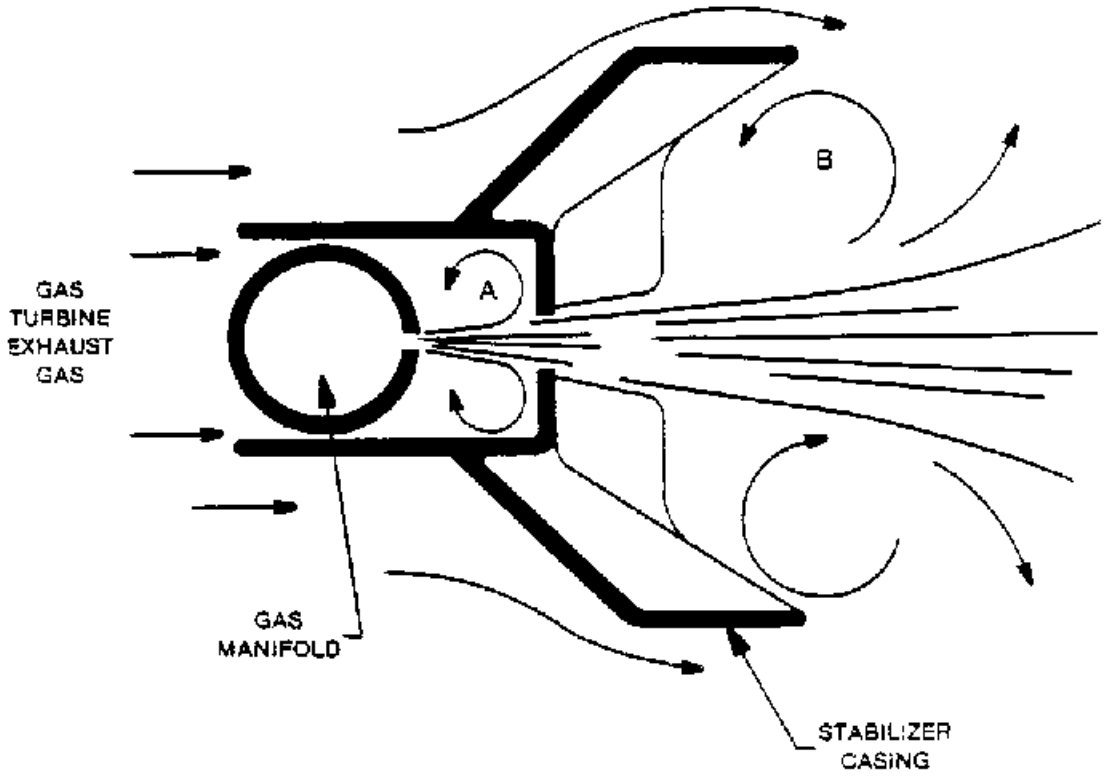

Figure 5-30. Cross-sectional view of a low-NO_x duct burner.[73,74]

NMED Exhibit 53

of duct burner that incorporates design features to reduce NO_x. In this low-NO_x design, natural gas exits the orifice in the manifold and mixes with the gas turbine exhaust entering through a small slot between the casing and the gas manifold. This mixture forms a jet diffusion flame that causes the recirculation shown in Zone "A." Due to the limited amount of turbine exhaust that can enter Zone A, combustion in this zone is fuel-rich. As the burning gas jet exits into Zone "B," it mixes with combustion products that are recirculated by the flow eddies behind the wings of the stabilizer casing. The flame then expands into the turbine exhaust gas stream, where combustion is completed.

NMED Exhibit 53

NMED Exhibit 53

For oil-fired burners, the design principles of the burner are the same. However, the physical layout is slightly different, as shown in

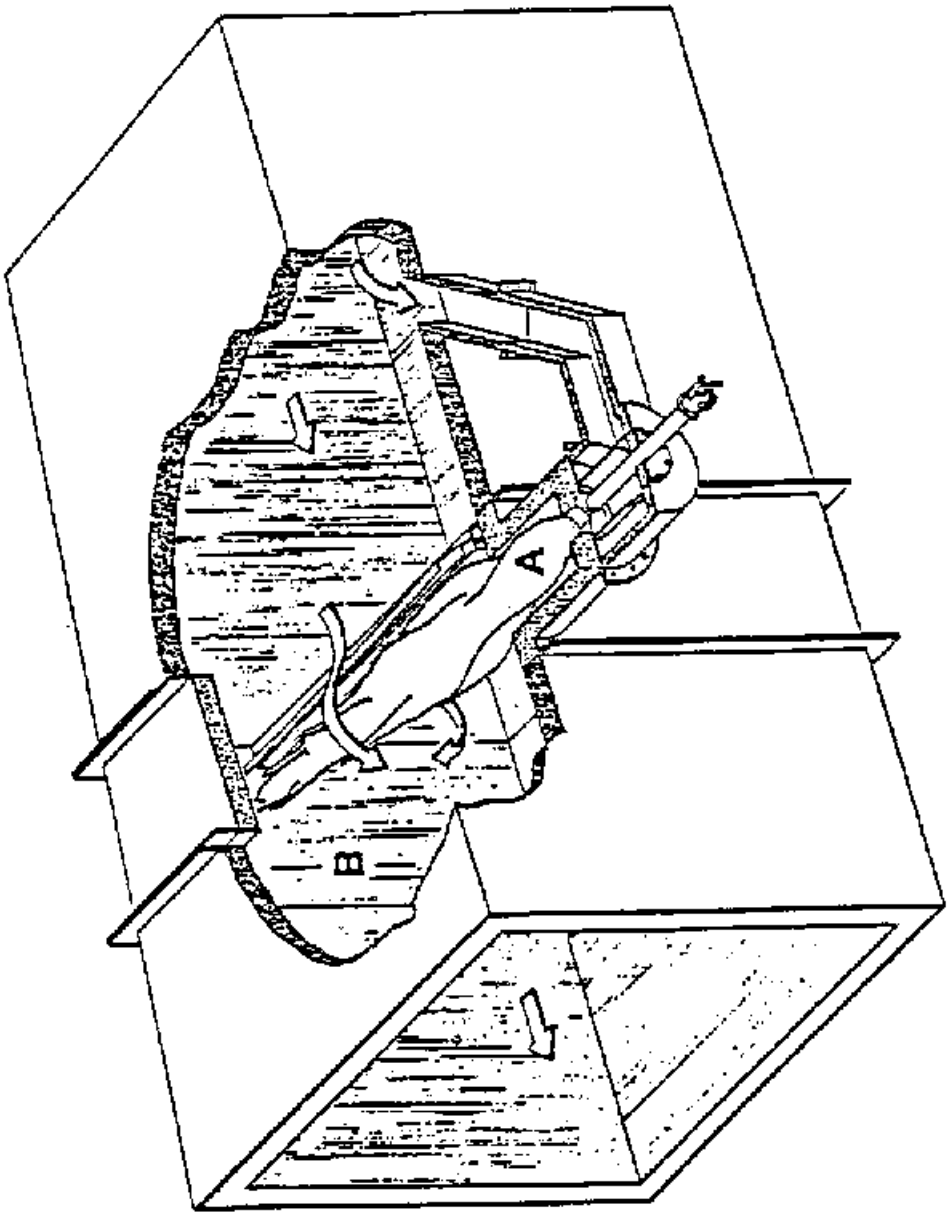

Figure 5-31. Low-NO_x duct burner designed for oil firing.[73,75]

NMED Exhibit 53

Figure 5-31. Turbine exhaust gas is supplied in substoichiometric quantities by a slip stream duct to the burner. This slip stream supplies the combustion air for the fuel-rich Zone A. The flame shield produces the flow eddies, which recirculate the combustion products into Zone B.[76]

Most duct burners now in service fire natural gas. In all cases, a duct burner will produce a relatively small level of NO_x emissions during operation (See Section 4.2.2), but the net impact on total exhaust emissions (i.e., the gas turbine plus the duct burner) varies with operating conditions, and in some cases may even reduce the overall NO_x emissions. Table 5-19 shows the NO_x emissions measured at one site upstream and downstream of a duct burner. This table shows that NO_x emissions are reduced across the duct burner in five of the eight test runs.

NMED Exhibit 53

TABLE 5-19. NO_x EMISSIONS MEASURED BEFORE AND AFTER A DUCT BURNER [77]

Gas turbine operation parameters			Duct burner operating parameters		Duct burner inlet		Duct burner outlet		Change across duct burner

NMED Exhibit 53

The reason for this net NO_x reduction is not known, but it is believed to be a result of the reburning process in which the intermediate combustion products from the duct burner interact with the NO_x already present in the gas turbine exhaust. The manufacturer of the burner whose emission test results are shown in Table 5-19 states that the following conditions are necessary for reburning to occur:

1. The burner flame must produce a high temperature in a fuel-rich zone;

2. A portion of the turbine exhaust containing NO_x must be introduced into the localized fuel-rich zone with a residence time sufficient for the reburning process to convert the turbine NO_x to N_2 and O_2; and

3. The burner fuel should contain no FBN.[78]

In general, sites using a high degree of supplementary firing have the highest potential for a significant amount of reburning. In practice, only a limited number of sites achieve these reburning conditions due to specific plant operating requirements.[78]

NMED Exhibit 53

NMED Exhibit 53

5.6 ALTERNATE FUELS

Because thermal NO_x production is an exponential function of flame temperature (see Section 4.1.1), it follows that using fuels with flame temperatures lower than those of natural gas or distillate oils results in lower thermal NO_x emissions. Coal-derived gas and methanol have demonstrated lower NO_x emissions than more conventional natural gas or oil fuels. For applications using fuels with high FBN contents, switching to a fuel with a lower FBN content will reduce thermal NO_x formation and thereby lower total NO_x emissions.

5.6.1 Coal-Derived Gas

Combustor rig tests have demonstrated that burning coal-derived gas (coal gas) that has been treated to remove FBN produces approximately 30 percent of the NO_x emission levels experienced when burning natural gas. This is because coal gas has a low heat energy level of around 300 Btu or less, which results in a flame temperature lower than that of natural gas.[79] The cost associated with producing coal gas suitable for combustion in a gas turbine has made this alternative economically unattractive, but recent advances in coal gasification technology have renewed interest in this fuel.

A coal gas-fueled power plant is currently operating in the United States at a Dow Chemical plant in Placquemine, Louisiana. This facility operates with a subsidy from the Federal Government, which compensates for the price difference between coal gas and conventional fuels. Several commercial projects have been recently announced using technology developed by Texaco, Shell, Dow Chemical, and the U.S. Department of Energy. Facilities have been permitted for construction in Massachusetts and Delaware.[80]

A demonstration facility, known as Cool Water, operated using coal gas for 5 years in Southern California in the early 1980's. The NO_x emissions were reported at 0.07 lb/MMBtu.[80] Fuel analysis data is not available to convert this NO_x emission level to a ppmv figure. No other emissions data are available.

NMED Exhibit 53

5.6.2 Methanol

Methanol has a flame temperature of 1925°C (3500°F) versus 2015°C (3660°F) for natural gas and greater than 2100°C (3800°F) for distillate oils. As a result, the NO_x emission levels when burning methanol are lower than those for either natural gas or distillate oils.

Table 5-20 presents NO_x emission data for a full-scale turbine firing methanol.

NMED Exhibit 53

TABLE 5-20. NO_x EMISSIONS TEST DATA FOR A GAS TURBINE FIRING METHANOL AT BASELOAD[a,81]

P	0.23	18	62.7
Q	0.24	18	62.7

[a]Baseload = 25 MW output
[b]Calculated using the average of the uncontrolled emissions.

NMED Exhibit 53

The NO_x emissions from firing methanol without water injection ranged from 41 to 60 ppmv and averaged 49 ppmv. This test also indicated that methanol increases turbine output due to the higher mass flows that result from methanol firing. Methanol firing increased CO and HC emissions slightly compared to the same turbine's firing distillate oil with water injection. All other aspects of turbine performance were as good when firing methanol as when the turbine fired natural gas or distillate oil.[82] Turbine maintenance requirements were estimated to be lower and turbine life was estimated to be longer on methanol fuel than on distillate oil fuel because methanol produced fewer deposits in the combustor and power turbine.

Table 5-20 also presents NO_x emission data for methanol firing with water injection. At water-to-fuel ratios from 0.11 to 0.24, NO_x emissions when firing methanol range from 17 to 28 ppmv, a reduction of 42 to 65 percent.

In a study conducted at an existing 3.2 MW gas turbine installation in 1984, a gas turbine was modified to burn methanol. This study was conducted at the University of California at Davis and was sponsored by the California Energy Commission. A new fuel delivery system for methanol was required, but the only major modifications required for the turbine used in this study were new fuel manifolds and nozzles. Tests conducted burning methanol showed no visible smoke emissions, and only minor increases in CO emissions. Figure 5-32 shows the NO_x emissions measured while burning

NMED Exhibit 53

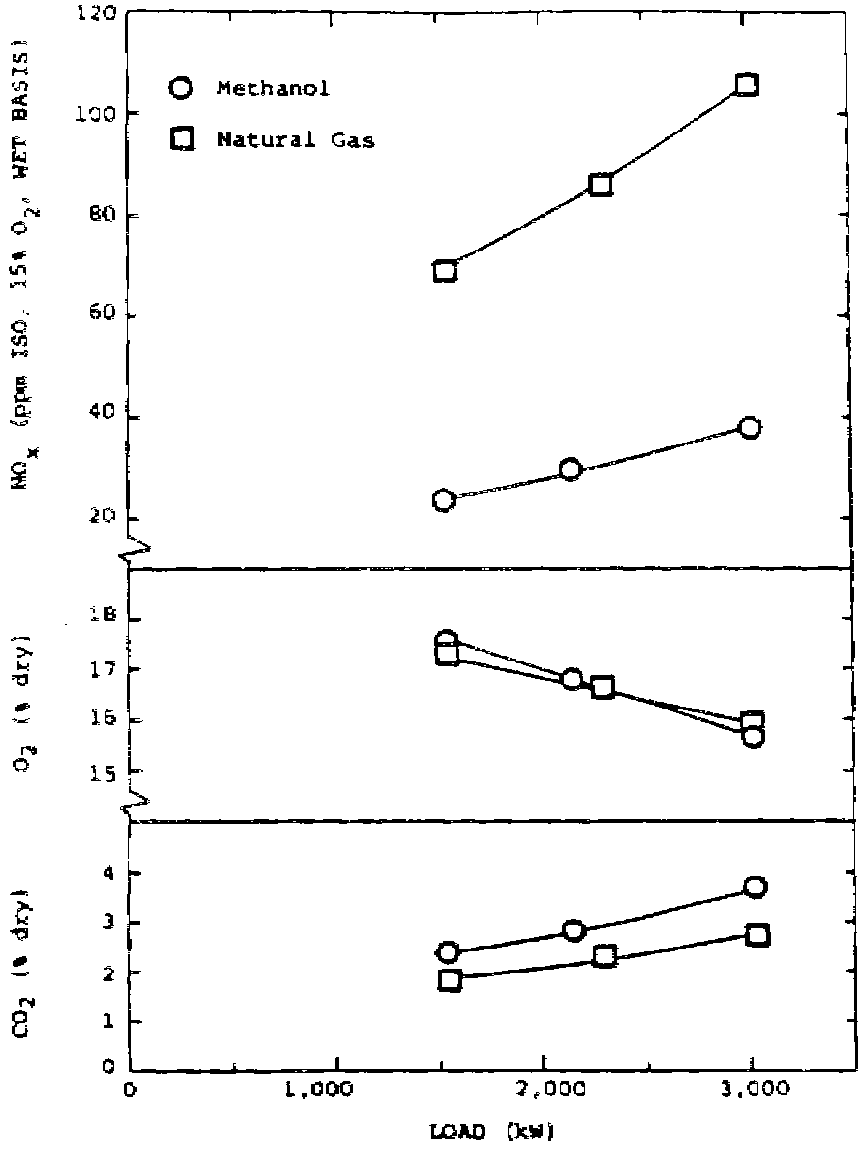

Figure 5-32. Influence of load on NO_x, and CO_2 emissions for methanol and natural gas.[83]

NMED Exhibit 53

methanol and natural gas. Reductions of up to 65 percent were achieved, as NO_x emissions were 22 to 38 ppm when burning methanol versus

NMED Exhibit 53

NMED Exhibit 53

62 to 100 ppm for natural gas. In addition to the intrinsically lower NO_x production, water can be readily mixed with methanol prior to delivery to the turbine to obtain the additional NO_x reduction levels achievable with wet injection. Gas turbine performance characteristics, including startup, acceleration, load changes, and full load power, were all deemed acceptable by the turbine manufacturer.[83]

The current economics of using methanol as a primary fuel are not attractive. There are no confirmed commercial methanol-fueled gas turbine installations in the United States.

5.7 SELECTIVE NONCATALYTIC REDUCTION

Selective noncatalytic reduction (SNCR) is an add-on technology that reduces NO_x using ammonia or urea injection similar to SCR but operates at a higher temperature. At this higher operating temperature of 870° to 1200°C (1600° to 2200°F), the following reaction occurs:[84]

$$NO_x + NH_3 + O_2 + H_2O + (H_2) \rightarrow N_2 + H_2O.$$

This reaction occurs without requiring a catalyst, effectively reducing NO_x to nitrogen and water. The operating temperature can be lowered from 870°C (1600°F) to 700°C (1300°F) by injecting hydrogen (H_2) with the ammonia, as is shown in the above equation.

Above the upper temperature limit, the following reaction occurs:[84]

$$NH_3 + O_2 \rightarrow NO_x + H_2O.$$

Levels of NO_x emissions increase when injecting ammonia or urea into the flue gas at temperatures above the upper temperature limits of 1200°C (2200°F).

Since SNCR does not require a catalyst, this process is more attractive than SCR from an economic standpoint. The operating temperature window, however, is not compatible with gas turbine exhaust temperatures, which do not exceed 600°C (1100°F). Additionally, the residence time required for the reaction is approximately 100 milliseconds, which is relatively slow for gas turbine operating flow velocities.[85]

NMED Exhibit 53

It may be feasible, however, to initiate this reaction in the gas turbine where operating temperatures fall within the reaction window, if suitable gas turbine modifications and injection systems can be developed.[85] This control technology has not been applied to gas turbines to date.

5.8 CATALYTIC COMBUSTION

5.8.1 Process Description

In a catalytic combustor, fuel and air are premixed into a fuel-lean mixture (fuel/air ratio of approximately 0.02) and then pass into a catalyst bed. In the bed, the mixture oxidizes without forming a high-temperature flame front. Peak combustion temperatures can be limited to below 1540°C (2800°F), which is below the temperature at which significant amounts of thermal NO_x begin to form.[86] An example of a lean catalytic combustor is shown in Figure 5-33.

NMED Exhibit 53

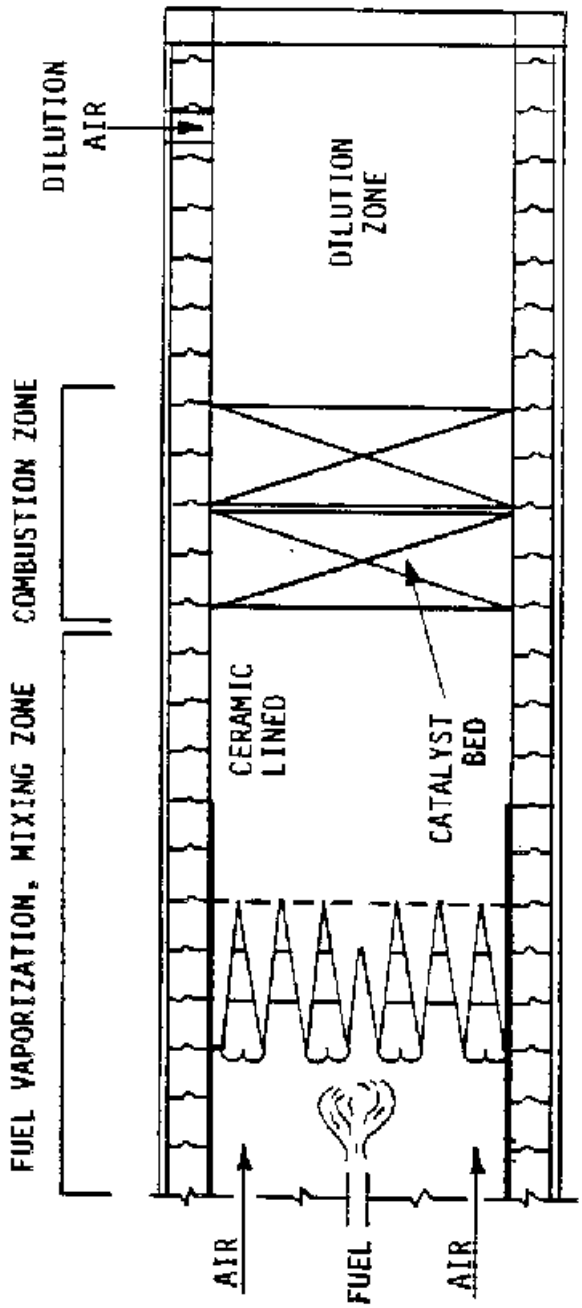

Figure 5-33. A lean catalytic combustor.87

NMED Exhibit 53

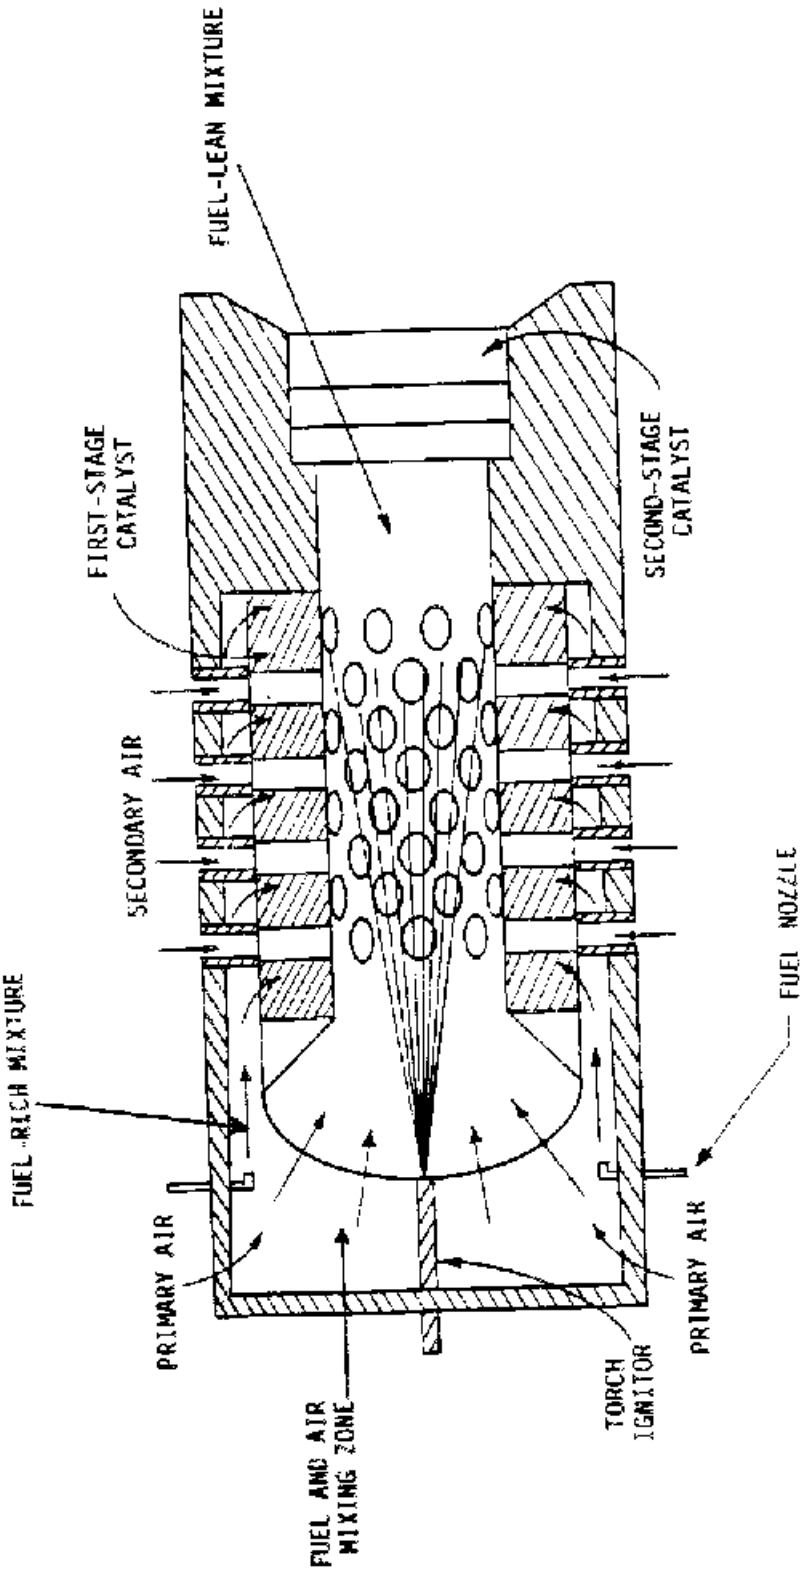

Figure 5-34. A rich/lean catalytic combustor.[89]

NMED Exhibit 53

Catalytic combustors can also be designed to operate in a rich/lean configuration, as shown in Figure 5-34. In this configuration, the air and fuel are premixed to form a fuel-rich mixture, which passes through a first stage catalyst where combustion begins. Secondary air is then added to produce a lean mixture, and combustion is completed in a second stage catalyst bed.[89]

5.8.2 Applicability

Catalytic combustion techniques apply to all combustor types and are effective on both distillate oil- and natural gas-fired turbines. Because of the limited operating temperature range, catalytic combustors may not be easily applied to gas turbines subject to rapid load changes (such as utility peaking turbines).[90] Gas turbines that operate continuously at base load (such as industrial cogeneration applications) would not be as adversely affected by any limits on load following capability.[91]

5.8.3 Development Status

Presently, the development of catalytic combustors has been limited to bench-scale tests of prototype combustors. The major problem is the development of a catalyst that will have an acceptable life in the high-temperature and -pressure environment

NMED Exhibit 53

of gas turbine combustors. Additional problems that must be solved are combustor ignition and how to design the catalyst to operate over the full gas turbine operating range (idle to full load).[92]

5.9 OFFSHORE OIL PLATFORM APPLICATIONS

Gas turbines are used on offshore platforms to meet compression and electrical power requirements. This application presents unique challenges for NO_x emissions control due to the duty cycle, lack of a potable water source for wet injection, and limited space and weight considerations. The duty cycle for electric power applications of offshore platforms is unique. This duty cycle is subject to frequent load changes that can instantaneously increase or decrease by as much as a factor of 10.[93] Fluctuating loads result in substantial swings in turbine exhaust gas temperatures and flow rates. This presents a problem for SCR applications because the NO_x reduction efficiency depends upon temperature and space velocity (see Section 5.3.3).

The lack of a potable water supply means that water must be shipped to the platform or sea water must be desalinated and treated. The limited space and weight requirements associated with an SCR system may also have an impact on capital costs of the platform.

A 4-year study is underway for the Santa Barbara County Air Pollution Control Board to evaluate suitable NO_x control techniques for offshore applications. The goals of the study are to reduce turbine NO_x emissions at full load to 9 ppmv, corrected to 15 percent O_2, firing platform gas fuel and to achieve part load reductions of 50 percent. The study consists of two phases. The first phase, an engineering evaluation of available and emerging emission control technologies, is completed. The second phase will select the final control technologies and develop these technologies for offshore platform applications. Phase I

NMED Exhibit 53

of this study concludes that the technologies with the highest estimated probability for success in offshore applications are:

- Water injection plus SCR (80 percent);
- Methanol fuel plus SCR (70 percent);
- Lean premixed combustion plus SCR (65 percent); and
- Steam dilution of fuel prior to combustion plus SCR (65 percent).

A key conclusion drawn from Phase I of this study is that none of the above technologies or combination of technologies in offshore platform applications currently has a high probability of successfully achieving the NO_x emission reduction goals of this study without substantial cost and impacts to platform and turbine operations, added safety considerations, and other environmental concerns. These issues will be further studied in Phase II for the above control technologies.

6.0 CONTROL COSTS

Capital and annual costs are presented in this chapter for the nitrogen oxide (NO_x) control techniques described in Chapter 5.0. These control techniques are water and steam injection, low-NO_x combustion, and selective catalytic reduction (SCR) used in combination with these controls. Model plants were developed to evaluate the control techniques for a range of gas turbine sizes, fuel types, and annual operating hours. The gas turbines chosen for these model plants range in size from 1.1 to 160 megawatts (MW) (1,500 to 215,000 horsepower [hp]) and include both aeroderivative and heavy-duty turbines. Model plants were developed for both natural gas and distillate oil fuels. For offshore oil production platforms, cost information was available only for one turbine model.

The life of the control equipment depends upon many factors, including application, operating environment, maintenance practices, and materials of construction. For this study, a 15-year life was chosen.

Both new and retrofit costs are presented in this chapter. For water and steam injection, these costs were assumed to be the same because most of the water treatment system installation can be completed while the plant is operating and because gas turbine nozzle replacement and piping connections to the treated water supply can be performed during a scheduled downtime for maintenance. Estimated costs are provided for both new and retrofit low-NO_x combustion applications. No SCR retrofit applications were identified, and costs for SCR retrofit applications were not available. The cost to retrofit an

NMED Exhibit 53

existing gas turbine installation with SCR would be considerably higher than the costs shown for a new installation, especially for combined cycle and cogeneration installations where the heat-recovery steam generator (HRSG) would have to be modified or replaced to accommodate the catalyst reactor.

This chapter is organized into five sections. Water and steam injection costs are described in Section 6.1. Low-NO_x combustor costs are summarized in Section 6.2. Costs for SCR used in combination with water or steam injection or low-NO_x combustion are described in Section 6.3. Water injection and SCR costs for offshore gas turbines are presented in Section 6.4, and references are listed in Section 6.5.

a. WATER AND STEAM INJECTION AND OIL-IN-WATER EMULSION

Ten gas turbines models were selected, and from these turbines 24 model plants were developed using water or steam injection or water-in-oil emulsion to control NO_x emissions. These 24 models, shown in Table 6-1

NMED Exhibit 53

TABLE 6-1. GAS TURBINE MODEL PLANTS FOR NO_x CONTROL TECHNIQUES

[a]Model plant legend:

First entry: annual operating hours
CON--continuous duty, 8,000 hours
PKR--peaking duty, 2,000 hours
STD--stand-by duty, 1,000 hours

Second entry: fuel type
G = natural gas fuel
O = oil fuel

Third entry: control type
W = water injection
S = steam injection
E = water-in-oil emulsion

Fourth entry: power output in MW

For example, CON-G-W-3.3 designates that the model plant is continuous-duty, uses natural gas fuel, has water injection, and has a power output of 3.3 MW.

NMED Exhibit 53

, characterize variations in existing units with respect to turbine size, type (i.e., aero-derivative vs. heavy duty), operating hours, and type of fuel. A total of 24 model plants were developed; 16 of these were continuous-duty (8,000 hours per year) and 8 were intermittent-duty (2,000 or 1,000 hours per year). Thirteen of the continuous-duty model plants burn natural gas fuel; 6 of the 13 use water injection, and 7 use steam injection to reduce NO_x emissions. The three remaining continuous-duty model plants burn distillate oil fuel and use water injection to reduce NO_x emissions. Of the eight intermittent-duty model plants, six operate 2,000 hours per year (three natural gas-fueled and three distillate oil-fueled), and two operate 1,000 hours per year (both distillate oil-fueled). All intermittent-duty model plants use water rather than steam for NO_x reduction because it was assumed that the additional capital costs associated with steam-generating equipment could not be justified for intermittent service.

Costs were available for applying water-in-oil emulsion technology to only one gas turbine, and insufficient data were available to develop costs for a similar water-injected model

NMED Exhibit 53

plant for this turbine. As a result, the costs and cost effectiveness for the water-in-oil emulsion model plant should not be compared to those of water-injected model plants.

Capital costs are described in Section 6.1.1, annual costs are described in Section 6.1.2, and emission reductions and the cost effectiveness of wet injection controls are discussed in Section 6.1.3. Additional discussion of the cost methodology and details about some of the cost estimating procedures are provided in Appendix B.

Fuel rates and water flow rates were calculated for each model plant using published design power output and efficiency, expressed as heat rate, in British thermal units per kilowatt-hour (Btu/kWh).[1] The values for these parameters are presented in Table 6-2

NMED Exhibit 53

TABLE 6-2. FUEL AND WATER FLOW RATES FOR WATER AND STEAM INJECTION (1990 $)

[a]Natural gas: lb/hr = HR x kW x (lb/20,610 Btu). Diesel oil: lb/hr = HR x kW x (lb/18,330 Btu).

[b]MMBtu/yr = HR x kW x (MM/10^6) x (operating hours/year).

[c]Water (or steam) flow, gal/min = Fuel flow (lb/hr) x (1 hr/60 min) x (1 gal/8.33, lb. H_2O) x WFR.

[d]A 30 percent design factor has been included per discussion with system supplier, and the waste stream from the water treatment system is calculated to be 29 percent. The design capacity is therefore Water Flow x 1.3 x 1.29.

NMED Exhibit 53

for each model plant. Fuel rates were estimated based on the heat rates, the design output, and the lower heating value (LHV) of the fuel. The LHV's used in this analysis for natural gas and diesel fuel are 20,610 Btu per pound (Btu/lb) and 18,330 Btu/lb, respectively, as shown in Table 6-3

NMED Exhibit 53

TABLE 6-3. FUEL PROPERTIES AND UTILITY AND LABOR RATES[a]

Fuel properties	Factor	Units	Reference
Natural gas	20,610	Btu/lb	Ref. 3
	930	Btu/scf[c] (LHV)	Ref. 3
Diesel fuel	18,330	Btu/lb (LHV)	Ref. 2
	7.21	lb/gal	Ref. 2
Utility rates			
Natural gas[b]	3.88	$/scf	Ref. 4
Diesel fuel	0.77	$/gal	Ref. 5
Electricity	0.06	$/kW-hr	Ref.'s 6 and 7

Maintenance	31.20	$/hr	Ref. 2, escalated @ 5% per year

[a]All costs are average costs in 1990 dollars.
[b]Natural gas and electricity costs from Reference 4 are the average of the costs for industrial and commercial customers.
[c]scf = standard cubic foot.

NMED Exhibit 53

.[2] Water (or steam) injection rates were calculated based on published fuel rates and water-to-fuel ratios (WFR) provided by manufacturers.[8-12] According to a water treatment system supplier, treatment facilities are designed with a capacity factor of 1.3.[13] An additional 29 percent of the treated water flow rate is discarded as wastewater.[2] Consequently, the water treatment facility design capacity is 68 percent (1.30 x 1.29) greater than the water (or steam) injection rate.

i. Capital Costs

The capital costs for each model plant are presented in Table 6-4

NMED Exhibit 53

[b]Injection nozzle costs provided by manufacturers. Balance of water injection system calculated at a cost of $4,200 x GPM.

[c]WTS = 43,900 x (design capacity, gal/min) $^{0.5}$

[d]Direct installation cost is estimated at $50,000 for model plants rated at 5 MW or less.

[e]Indirect installation cost factor of 33 percent is reduced to 20 percent for model plants rated at 5 MW or less.

[f]NA = cost calculations based on using a portable demineralizer systems during turbine operating periods. Cost for system usage is included in Table 6-5.

NMED Exhibit 53

. These costs were developed based on methodology in Reference 2, which is presented in this section. The capital costs include purchased equipment costs, direct and indirect installation costs, and contingency costs.

(1) Purchased Equipment Costs. Purchased equipment costs consist of the injection system, the water treatment system, taxes, and freight. All costs are presented in 1990 dollars.

NMED Exhibit 53

NMED Exhibit 53

NMED Exhibit 53

(a) Water injection system. The injection system delivers water from the treatment system to the combustor. This system includes the turbine-mounted injection nozzles, the flow metering controls, pumps, and hardware and interconnecting piping from the treatment system to the turbine. On-engine hardware (the injection nozzles) costs were provided by turbine manufacturers.[9,14-17] Flow metering controls and hardware, pumps, and interconnecting piping costs for all turbines were calculated using data provided by General Electric for four heavy-duty turbine models.[17] No relationship between costs and either turbine output or water flow was evident, so the sum of the four costs was divided by the sum of the water flow requirements for the four turbines. This process yielded a cost of $4,200 per gallon per minute (gal/min), and this cost, added to the on-engine hardware costs, was used for all model plants.

(b) Water treatment system. The water treatment process, and hence the treatment system components, varies according to the degree to which the water at a given site must be treated. For this cost analysis, the water treatment system includes a reverse osmosis and mixed-bed demineralizer system. The water treatment system capital cost for each model plant was estimated based on an equation developed in Reference 2:

$$WTS = 43{,}900 \times (G)^{0.50}$$

where

WTS = water treatment system capital cost, $; and

G = water treatment system design capacity, gal/min.

This equation yields costs that are generally consistent with the range of costs presented in Reference 18.

(c) Taxes and freight. This cost covers applicable sales taxes and shipment to the site for the injection and water treatment systems. A figure of 8 percent of the total system cost was used.[2,7]

(2) Direct Installation Costs. This cost includes the labor and material costs associated with installing the foundation and supports, erecting and handling equipment, electrical work, piping, insulation, and painting. For smaller

NMED Exhibit 53

turbines, the water treatment system is typically skid-mounted and is shipped to the site as a packaged unit, which minimizes field assembly and interconnections. The cost to install a skid-mounted water treatment skid is typically $50,000, and this cost is used for the direct installation cost for model plants less than 5 MW (6700 hp).[19] For larger turbines, it is expected that the water treatment system must be field-assembled and the direct installation costs were calculated as 45 percent of the injection and water treatment systems, including taxes and freight.[2]

(3) Indirect Installation Costs. This cost covers the indirect costs (engineering, supervisory personnel, office personnel, temporary offices, etc.) associated with installing the equipment. The cost was taken to be 33 percent of the systems' costs, taxes and freight, and direct costs, plus $5,000 for model plants above 5 MW (6,700 hp).[2] The indirect installation costs for skid-mounted water treatment systems are expected to be less than for field-assembled systems; therefore, for model plants with an output of less than 5 MW (6,700 hp), the cost percentage factor was reduced from 33 to 20 percent.

(4) Contingency Cost. This cost is a catch-all meant to cover unforeseen costs such as equipment redesign/ modification, cost escalations, and delays encountered in startup. This cost was estimated as 20 percent of the sum of the systems, taxes and freight, and direct and indirect costs.[2]

ii. Annual Costs

NMED Exhibit 53

The annual costs are summarized in Table 6-5

NMED Exhibit 53

[a]FP for water = 0.035 x WFR x (MMBtu/yr) x (ft ^{3}/940 Btu) x ($3.88/1,000 ft ^{3}) x (10^6/MM).
[b]E = Water flow rate (gal/min) x 0.161 x operating hours x ($0.06/kWH).
[c]Maintenance costs for the Centaur and Allison 501 turbines were obtained from the manufacturers. Costs for the MS5001 and MS7001 were estimated based on information about inspections and parts replacement presented in Appendix B. Maintenance for turbines that use diesel fuel are 30 percent higher than costs for comparable turbines using natural gas. No additional maintenance costs were assessed for steam injection.
[d]WT includes treatment chemicals, raw water, sewage disposal, and operating labor.
[e]Raw Water Cost = Water Flow (gal/min) x ($0.384/1,000 gal) x (60 min/hour) x operating hours x 1.29.
[f]Treatment Cost = Water Flow (gal/min) x ($1.97/1,000 gal) x (60 min/hour) x operating hours x 1.29.
[g]Labor Cost for water = Water Flow (gal/min) x ($.70/1,000 gal) x (60 min/hour) x operating hours x 1.29.
Labor Cost for steam = Water Flow (gal/min) x ($.70/1,000 gal) x (60 min/hour) x operating hours x 1.29 x 0.5.
[h]Disposal Cost = Water Flow (gal/min) x ($3.82/1,000 gal) x (60 min/hour) x operating hours x 0.29.
[i]GATI = 0.04 x TCC (TCC is shown in Table 6-4).
[j]CR = 0.1315 x TCC based on an equipment life of 15 years and a 10 percent interest rate.

NMED Exhibit 53

for each model plant. Annual costs include the fuel penalty; electricity; maintenance requirements; water treatment; overhead, general and administrative, taxes, and insurance; and capital recovery, as discussed in this section.

(1) Fuel Penalty. The reduction in efficiency associated with water injection varies for each turbine model. Based on data in Reference 2, it was estimated that a WFR of 1.0 corresponds to a fuel penalty of 3.5 percent for water injection and 1.0 percent for steam injection. This percentage was multiplied by the actual WFR and the annual fuel cost to

NMED Exhibit 53

determine the fuel penalty for each model plant. The fuel flow was multiplied by the unit fuel costs to determine the annual fuel costs. As shown in Table 6-3, the natural gas cost is $3.88/1,000 standard cubic feet (scf) and the diesel fuel cost is $0.77/gal.[4,5]

An increase in output from the turbine accompanies the decrease in efficiency. This increase was not considered, however, because not all sites have a demand for the available excess power. In applications such as electric power generation, where the excess power can be used at the site or added to utility power sales, this additional output would serve to decrease or offset the fuel penalty impact.

(2) Electricity Cost. The electricity costs shown in Table 6-5 apply to the feedwater pump(s) for water or steam injection. The pump power requirements are estimated from the pump head (ft) and the water flow rate as shown in the following equation:[2]

$$\text{power pump } (kW_e) = \frac{FR}{3{,}960} \times H \times (S.G.) \times \frac{1}{0.6} \times \frac{0.7457\ kW}{hp} \times \frac{1}{0.9}$$

where:

FR = feedwater flow rate, gal/min (from Table 6-2);
H = total pump head (ft);
S.G. = specific gravity of the feed water;
0.6 = pump efficiency of 60 percent;
0.9 = electric motor efficiency of 90 percent;
3,960 = factor to correct units in FR and H to hp; and
0.7457 = factor to convert hp to kW.

For water injection, the feedwater pump(s) supply treated water to the gas turbine injection system. For steam injection, the feedwater pump(s) supply treated water to the boiler for steam generation. This cost analysis uses a feedwater temperature of 55°C (130°F) with a density of 61.6 lb/ft^3 and a total pump head requirement of 200 pounds per square inch, gauge (psig)

NMED Exhibit 53

(468 ft).[2] Based on these values, the pump electrical demand for either water or steam injection is calculated as follows:

$$\text{pump power } (kW_e) = \frac{FR \times 468}{3{,}960} \times \frac{61.6}{62.4} \times \frac{1}{0.6} \times 0.7457 \times \frac{1}{0.9}$$

$$= 0.161 \times FR$$

The electrical cost for each model plant is the product of the pump electrical demand, the annual hours of operation, and the unit cost of electricity. The unit cost of electricity, shown in Table 6-3, is $0.06/kWH.[6,7]

Maintenance costs were developed based on information from manufacturers, and water treatment labor costs were estimated based on information from a water treatment vendor. Other costs were developed based on the methodology presented in Reference 2.

No backup steam or electricity costs were developed for water or steam injection because it was assumed that no additional downtime would be required for scheduled inspections and repairs. Maintenance intervals could be scheduled to coincide with the 760 hr/yr of downtime that are currently allocated for scheduled maintenance. If this were done, the annual utilization of the backup source would not increase.

(3) Added Maintenance Costs. Based on discussions with gas turbine manufacturers, additional maintenance is required for some gas turbines with water injection. The analysis procedures used to develop the incremental maintenance costs are presented in Appendix B.

The incremental maintenance cost associated with water injection for natural gas-fueled turbines was provided by the gas turbine manufacturers.[10,20-24] All gas turbine manufacturers contacted stated that there were no incremental maintenance costs for operation with steam injection. Two manufacturers provided maintenance costs for natural gas and oil fuel operation without water injection.[10,20] Using an average of these costs, incremental maintenance costs for water injection are 30 percent higher for

NMED Exhibit 53

plants that use diesel fuel instead of natural gas. Costs were prorated for model plants that operate less than 8,000 hr/yr.

(4) Water Treatment Costs. Water treatment operating costs include the cost of treatment (e.g., for chemicals and media filters), operating labor, raw water, and wastewater disposal. The raw water flow rate is equal to the treated water flow rate (the water or steam injection rate) plus the flow rate of the wastewater generated in the treatment plant. As noted in Section 6.1, the wastewater flow rate is equal to 29 percent of the injection flow rate. The annual raw water, treated water, and wastewater flow rates were multiplied by the appropriate unit costs in Table 6-3 to determine the annual costs. Water treatment labor costs were calculated at $0.70/1,000 gal for water injection.[25] This cost was multiplied by the total annual treated water flow rate to determine the annual water treatment labor cost for water injection. Labor costs for steam injection were assumed to be half as much as the costs for water injection because it was assumed that the facility already has a water treatment plant for the boiler feedwater. Therefore, the operator requirements would be only those associated with the increase in capacity of the existing treatment plant.

(5) Plant Overhead. This cost is the overhead associated with the additional maintenance effort required for water injection. The cost was calculated as 30 percent of the added maintenance cost from Section 6.1.2.3.[2]

(6) General and Administrative, Taxes, and Insurance Costs (GATI). This cost covers those expenses for administrative overhead, property taxes, and insurance and was calculated as 4 percent of the total capital cost.[2]

(7) Capital Recovery. A capital recovery factor (CRF) was multiplied by the total capital investment to estimate uniform end-of-year payments necessary to repay the investment. The CRF used in this analysis is 0.1315, which is based on an equipment life of 15 years and an interest rate of 10 percent.

(8) Total Annual Cost. This cost is the sum of the annual costs presented in Sections 6.1.2.1 through 6.1.2.7 and is the

NMED Exhibit 53

total cost that must be paid each year to install and operate water or steam injection NO_x emissions control for a gas turbine.

[a]Example NO_x emission calculations are given in Appendix A.
[b]Referenced to 15 percent oxygen.
[c]From Table 6-5.

NMED Exhibit 53

The uncontrolled and controlled NO_x emissions and the annual emission reductions for the model plants are shown in Table 6-6. The emissions, in tons per year (tons/yr), were calculated as shown in Appendix A.

The total annual cost was divided by the annual emission reductions to determine the cost effectiveness for each model plant. For continuous-duty natural gas-fired model plants, the cost-effectiveness figures range from approximately $600 to $2,100 per ton of NO_x removed for water injection, and decrease to approximately $400 to $1,850 per ton for steam injection. The lower range of cost-effectiveness figures for steam injection is primarily due to the greater NO_x reduction achieved with steam injection. For continuous-duty oil-fired model plants, the cost effectiveness ranges from approximately $675 to $1,750 per ton of NO_x removed, which is comparable to figures for gas-fired model plants. The cost-effectiveness figures are higher for gas turbines with lower power outputs because the fixed capital costs associated with wet injection system installation have the greatest impact on the smaller gas turbines.

Cost-effectiveness figures increase as annual operating hours decrease. For turbines operating 2,000 hr/yr, the cost-effectiveness figures are two to nearly three times higher than those for continuous-duty model plants, and increase further for model plants operating 1,000 hr/yr. For the oil-in-water emulsion model plant, the cost effectiveness corresponding to 1,000 annual operating hours is $1,840/ton of NO_x removed. No data were available to prepare a conventional water injection model plant for this turbine to compare the relative cost-effectiveness values.

NMED Exhibit 53

NMED Exhibit 53

b. LOW-NO_x COMBUSTORS

Incremental capital costs for low-NO_x combustors relative to standard designs for new applications were provided by three manufacturers for several turbines.[3,14,26] Based on information from the manufacturers, the performance and maintenance requirements for a low-NO_x combustor are expected to be the same as for a standard combustor, and so the only annual cost associated with low-NO_x combustors is the capital recovery. The capital recovery factor is 0.1315, assuming a life of 15 years and an interest rate of 10 percent.

NMED Exhibit 53

[a]Model plant legend: First entry: annual operating hours Second entry: control technique Third entry: power output, in MW Fourth entry: controlled NO_x level, ppmv at 15 percent O
CON - Continuous duty, 8,000 hours L - dry low-NO_x combustor
PKR - peaking/intermittent duty, 2,000 hours

For example, CON-L-3.3-42 designates that the model plant operates 8,000 hours per year, is fitted with a dry low-NO_x combustor, has a power output of 3.3 MW, and has a controlled NO_x level of 42 ppmv.

[b]Example NO_x emission calculations are shown in Appendix A.

[c]Referenced to 15 percent oxygen.

[d]Incremental capital costs were provided by the manufacturers.

NMED Exhibit 53

presents the uncontrolled and controlled emission levels, the annual emission reductions, incremental costs for a low-NO_x combustor over a conventional design, and the cost effectiveness of low-NO_x combustors for all gas turbine models for which sufficient data were available. Cost-effectiveness figures were calculated for 8,000 and 2,000 hours of operation annually, using controlled NO_x emission levels of 42, 25, and 9 parts per million, by volume (ppmv), referenced to 15 percent oxygen, which are the achievable levels stated by the turbine manufacturers. The cost effectiveness varies according to the uncontrolled NO_x emission level for the conventional combustor design and the achievable controlled emission level for the low-NO_x design. For continuous-duty applications, cost effectiveness for a controlled NO_x emission level of 42 ppmv ranges from $353 to $1,060 per ton of NO_x removed. The cost-effectiveness range decreases to $57 to $832 per ton of NO_x removed for a controlled NO_x emission level of 25 ppmv and decreases further to $55 to $137 per ton of NO_x removed for a 9 ppmv control level. In all cases, the cost effectiveness increases as the operating hours decrease. In general, the cost effectiveness is higher for smaller gas turbines than for larger turbines due to the relatively higher capital cost per kW for low-NO_x combustors for smaller turbines.

The cost-effectiveness range is lower for low-NO_x combustors than for water or steam injection because the total annual costs are lower and, in some cases, the controlled emission levels are

NMED Exhibit 53

also lower. According to two turbine manufacturers, retrofit costs are 40 to 60 percent greater than the incremental costs shown in Table 6-7 for new installations.[3,14]

c. SELECTIVE CATALYTIC REDUCTION

The costs for SCR for new installations were estimated for all model plants. Retrofit costs for SCR were not available but could be considerably higher than the costs shown for new installations, especially in applications where an existing heat recovery steam generator (HRSG) would have to be moved, modified, or replaced to accommodate the addition of a catalyst reactor.

To date, most gas turbine SCR applications use a base metal catalyst with an operating temperature range that requires cooling of the exhaust gas from the turbine. For this reason, SCR applications to date have been limited to combined cycle or cogeneration applications that include an HRSG, which serves to cool the exhaust gas to temperatures compatible with the catalyst. The introduction of high-temperature zeolite catalysts, however, makes it possible to install the catalyst directly downstream of the turbine, and therefore feasible to use SCR with simple-cycle applications as well as heat recovery applications. As discussed in Section 5.3.2, to date there is at least one gas turbine installation with a high-temperature zeolite catalyst installed downstream of the turbine and upstream of an HRSG. At present, no identified SCR systems are installed in simple-cycle gas turbine applications.

An overview of the procedures used to estimate capital and annual costs are described in Sections 6.3.1 and 6.3.2, respectively; a detailed cost algorithm is presented in Appendix B. The emission reduction and cost-effectiveness calculations are described in Section 6.3.3.

i. <u>Capital Costs</u>

Five documents in the technical literature contained SCR capital costs for 21 gas turbine facilities. Most of these documents presented costs that were obtained from vendors, but some may have also developed at least some costs based on their own experiences.[27-31] Most of the documents presented only the

NMED Exhibit 53

total capital costs, not costs for individual components, and they did not provide complete descriptions of what the costs included. These costs were plotted on a graph of total capital costs versus gas turbine size. To this graph were added estimates of total installed costs for a high-temperature catalyst SCR system for installation upstream of the HRSG for four turbine installations ranging in size from 4.5 to 83 MW (6,030 to 111,000 hp). These high-temperature SCR system estimates include the catalyst reactor, air injection system for exhaust temperature control, ammonia storage and injection system, instrumentation, and continuous emission monitoring equipment. These SCR costs were estimated by the California Air Resources Board (CARB) in 1991 dollars and are based on NO_x emission levels of 42 ppmv into and 9 ppmv out of the SCR.[35] These estimated costs, shown in Appendix B, fit well within the range of costs from the 21 installations discussed above, and the equation of a line determined by linear regression adequately fits the data ($R^2 = 0.76$) for all 25 points. Based on this graph, the total capital cost for either a base-metal SCR system installed within the HRSG or a high-temperature zeolite catalyst SCR system installed directly downstream of the turbine can be calculated using the equation determined by the linear

NMED Exhibit 53

TABLE 6-8. PROCEDURES FOR ESTIMATING CAPITAL AND ANNUAL COSTS FOR SCR CONTROL OF NO_X EMISSIONS FROM GAS TURBINES[a]

A. Total capital investment, $[b]	=	(49,700 x TMW) + 459,000
B. Direct annual costs, $/yr		
1. Operating labor[c]	=	(1.0 hr/8 hr-shift) x ($25.60/hr) x (H)
2. Supervisory labor	=	(0.15) x (operating labor)
3. Maintenance labor and materials	=	(1,250 x TMW) + 25,800
4. Catalyst replacement	=	(4,700 x TMW) + 37,200
5. Catalyst disposal[d]	=	(V) x ($15/ft^3) x (.2638)
6. Anhydrous ammonia[e]	=	(N) x ($360/ton)
7. Dilution steam[f]	=	(N) x (0.95/0.05) x (MW H_2O/MW NH_3) x ($6/1,000 lb steam) x (2,000 lb/ton)
8. Electricity[g]	=	N/A
9. Performance loss[h]	=	(0.005) x (TMW) x ($0.06/KWH) x (1,000 KW/MW) x (H)
10. Blower (if needed)	=	0.1 x (Performance Loss)
11. Production loss[i]	=	None
C. Indirect annual costs, $/yr		
1. Overhead	=	(0.6) x (all labor and maintenance material costs)
2. Property taxes, insurance, and administration	=	(0.04) x (total capital investment)
3. Capital recovery[j]	=	(0.13147) x [total capital investment - (catalyst replacement/0.2638)]

[a]All costs are in average 1990 dollars.

[b]TMW=turbine output in MW for each model plant.

[c]The annual operating hours are represented by the variable H. The labor rate of $25.60/hr is from Table 6-3.

[d]The catalyst volume in ft^3 is represented by the variable V. The catalyst volume for each model plant is estimated as V = (TMW) x (6,180 ft^3/83 MW).

[e]The ammonia requirement in tons is represented by the variable N and is calculated using a NH_3-to-NO_x molar ratio of 1.0.

The annual tonnage of NO_x is taken from the controlled levels shown in Tables 6-11 and 6-12.

[f]The ammonia is diluted with steam to 5 percent by volume before injection.

[g]The amount of electricity required for ammonia pumps and exhaust fans is not known, but is expected to be small. The electricity cost comprised less than 1 percent of the total annual cost estimated by the South Coast Air Quality Management District (SCAQMD) for SCR applied to a 1.1 MW turbine.

[h]Based on information from three sources, the backpressure from the SCR reduces turbine output by an average of about 0.9 percent.

[i]No production losses are estimated because it is assumed that all SCR maintenance, inspections, cleaning, etc. can be performed during the 760 hours of scheduled downtime per year.

[j]The capital recovery factor for the SCR is 0.13147, based on a 15-year equipment life and 10 percent interest rate. The catalyst is replaced every 5 years. The 0.2638 figure is the capital recovery factor for a 5-year equipment life and a 10 percent interest rate.

NMED Exhibit 53

regression. This equation is shown in Table 6-8 and was used to calculate the total capital investment for SCR for each model plant shown in Tables 6-9 and 6-10.

NMED Exhibit 53

[a] See Table 6-7 for model plant legend.

[b] Costs shown are for SCR systems used downstream of gas turbines with dry low-NO_x combustion to achieve controlled NO_x emission levels at the inlet to the SCR as shown in Table 6-7.

NMED Exhibit 53

ii. Annual Costs

Total annual costs for SCR control were developed following standard EPA procedures described in the OAQPS Control Cost Manual for other types of add-on air pollution control devices (APCD's). Information about annual costs was obtained from the same sources that provided capital costs.[27-31] Total annual costs consist of direct and indirect costs; parameters that make up these categories and the equations for estimating the costs are

NMED Exhibit 53

NMED Exhibit 53

presented in Table 6-8 and are discussed below. The annual costs are shown in Tables 6-9 and 6-10 for injection and dry low-NO_x combustion, respectively, for each of the model plants.

(1) Operating and Supervisory Labor. Information about operating labor requirements was unavailable. Most facilities have fully automated controls and monitoring/recording equipment, which minimizes operator attention. Therefore, it was assumed that 1 hr of operator attention would be required during an 8-hr shift, regardless of turbine size. This operating labor requirement is at the low end of the range recommended in the OAQPS Control Cost Manual for other types of APCD's.[7] Operator wage rates were estimated to be $25.60/hr in 1990, based on escalating the costs presented in Reference 2 by 5 percent per year to account for inflation. Supervisory labor costs were estimated to be 15 percent of the operating labor costs, consistent with the OAQPS Control Cost Manual.

(2) Maintenance Labor and Materials. Combined maintenance labor and materials costs for 14 facilities were obtained from four articles, but almost half of the data (6 facilities) were provided by one source.[27-30] The costs were escalated to 1990 dollars assuming an inflation rate of 5 percent per year. All of the data are for facilities that burn natural gas. Provided that ammonium salt formation is avoided by limiting ammonia slip and sulfur content, the cost for operation with natural gas should also apply for distillate oil fuel.[32] Therefore, it was assumed that the cost data also apply to SCR control for turbines that fire distillate oil fuel. The costs were plotted versus the turbine size, and least-squares linear regression was used to determine the equation of the line through the data (see Appendix B). This equation, shown in Table 6-8, was used to estimate the maintenance labor and materials costs shown in Table 6-9 for the model plants.

(3) Catalyst Replacement. Replacement costs were obtained for nine gas turbine facilities, and combined replacement and disposal costs were obtained for another six gas turbine facilities.[27-30] The disposal costs were estimated for the six

NMED Exhibit 53

facilities as described below and in Appendix B. The replacement costs for these six facilities were then estimated by subtracting the estimated disposal costs from the combined costs. A catalyst life of 5 years was used. All replacement costs were escalated to 1990 dollars assuming a 5 percent annual inflation rate.

The estimated 1990 replacement costs were plotted versus the turbine size, and least-squares linear regression was used to determine the equation of the line through the data (see Appendix B). This equation is shown in Table 6-8 and was used to estimate the catalyst replacement costs shown in Table 6-9 for the model plants.

(4) Catalyst Disposal. Catalyst disposal costs were estimated based on a unit disposal cost of $\$15/ft^3$, which was obtained from a zeolite catalyst vendor.[32] This cost was used for each model plant, but the disposal cost may in fact be higher for catalysts that contain heavy metals and are classified as hazardous wastes. The catalyst volume for each model plant was estimated based on information about the catalyst volume for one facility and the assumption that there is a direct relationship between the catalyst volume and the turbine output (i.e., the design space velocity is the same regardless of the SCR size). At one facility, 175 m^3 (6,180 ft^3) of catalyst is used in the SCR with an 83 MW (111,000 hp) turbine.[33] The disposal cost for this catalyst would be \$92,700, using a cost of $\$15/ft^3$.

(5) Ammonia. The annual ammonia (NH_3) requirement is calculated from the annual NO_x reduction achieved by the SCR system. Based on an NH_3/NO_x molar ratio of 1.0, the annual ammonia requirement, in tons, would equal the annual NO_x reduction, in tons, multiplied by the ratio of the molecular weights for NH_3 and NO_x. Anhydrous ammonia with a unit cost of \$360/ton was used.[34,35] The equation to calculate the annual cost for ammonia is shown in Table 6-8.

(6) Dilution Steam. As indicated in Section 5.3.1, steam is used to dilute the ammonia to about 5 percent by volume before injection into the HRSG. According to the OAQPS Control Cost

NMED Exhibit 53

Manual, the cost to produce steam, or to purchase it, is about $6/1,000 lb.

(7) Electricity. Electricity requirements to operate such equipment as ammonia pumps and ventilation fans is believed to be small. For one facility, the cost of electricity to operate these components was estimated to make up less than 1 percent of the total annual cost, but it is not clear that the number and size of the fans and pumps represent a typical installation.[27] This cost for electricity is expected to be minor, however, for all installations and was not included in this analysis.

For high-temperature catalysts installed upstream of the HRSG, a blower may be required to inject ambient air into the exhaust to regulate the temperature and avoid temperature excursions above the catalyst design temperature range. The cost to operate the blower is calculated to be 10 percent of the fuel penalty.[35]

(8) Performance Loss. The performance loss due to backpressure from the SCR is approximately 0.5 percent of the turbine's design output.[34-36] To make up for this lost output, it was assumed that electricity would have to be purchased at a cost of $0.06/kWH, as indicated in Table 6-3.

(9) Production Loss. No costs for production losses were included in this analysis. It was assumed that scheduled inspections, cleaning, and other maintenance will coincide with the 760 hr/yr of expected or scheduled downtime. It should be recognized that adding the SCR system increases the overall system complexity and the probability of unscheduled outages. This factor should be taken into account when considering the addition of an SCR system.

(10) Overhead. Standard EPA procedures for estimating annual control costs include overhead costs that are equal to 60 percent of all labor and maintenance material costs.

(11) Property Taxes, Insurance, and Administration. According to standard EPA procedures for estimating annual control costs, property taxes, insurance, and administration

NMED Exhibit 53

costs are equal to 4 percent of the total capital investment for the control system.

(12) Capital Recovery. The CRF for SCR was estimated to be 0.13147 based on the assumption that the equipment life is 15 years and the interest rate is 10 percent.

iii. Cost Effectiveness for SCR

As indicated in Section 5.4, virtually all gas turbine installations using SCR to reduce NO_x emissions also incorporate wet injection or low-NO_x combustors. The NO_x emission levels into the SCR, therefore, were in all cases taken to be equal to the controlled NO_x emission levels shown for these control techniques in Tables 6-6 and 6-7. The most common controlled NO_x emission limit for gas-fired SCR applications is 9 ppmv, referenced to 15 percent oxygen. The capital costs used in this analysis are expected to correspond to SCR systems sized to reduce controlled NO_x emissions ranging from 25 to 42 ppmv from gas-fired turbines to a controlled level of approximately 9 ppmv downstream of the SCR. Based on the controlled NO_x emission limits established by the Northeast States for Coordinated Air Use Management (NESCAUM), shown in Table 5-3, these SCR systems would reduce NO_x emissions to 18 ppmv for oil-fired applications. Cost-effectiveness figures for SCR in this analysis are therefore calculated based on controlled NO_x emission levels of 9 and 18 ppmv, corrected to 15 percent oxygen, for gas- and oil-fired SCR model plants, respectively.

Cost effectiveness for SCR used downstream of wet injection or dry low-NO_x combustion is shown in Tables 6-11

[c]Referenced to 15 percent oxygen.
[d]From Table 6-10.

NMED Exhibit 53

model plants using water or steam injection,the cost effectiveness for SCR ranges from approximately $3,500 to $10,800 per ton of NO_x removed.

The cost-effectiveness range for SCR installed downstream of continuous-duty, natural gas-fired turbines from 3 to 10 MW (4,000 to 13,400 hp) using dry low-NO_x combustion is $6,290 to $10,800 per ton of NO_x removed for an inlet NO_x emission level of 42 ppmv. The cost-effectiveness range for SCR increases for an

NMED Exhibit 53

NMED Exhibit 53

inlet NO_x emission level of 25 ppmv due to the lower NO_x reduction efficiency. For an inlet NO_x level of 25 ppmv, the cost effectiveness ranges from $12,800 to $22,100 per ton of NO_x removed for 3 to 10 MW (4,000 to 13,400 hp) turbines and decreases to $6,940 to $7,660 per ton of NO_x removed for larger turbines ranging from 39 to 85 MW (52,300 to 114,000 hp). As these ranges indicate, the cost effectiveness for SCR is affected by the inlet NO_x emission level and not the type of combustion control technique used for the turbine. The cost effectiveness for continuous-duty, oil-fired model plants ranges from approximately $2,450 to $8,350 per ton of NO_x removed. The SCR cost-effectiveness range for oil-fired applications is lower than that for gas-fired installations in this cost analysis because the same capital costs were used for both fuels (capital costs were not available for applications using only distillate oil fuel). The percent NO_x reduction for oil-fired applications is higher, so the resulting cost-effectiveness figures for oil-fired applications are lower. It should be noted that this higher NO_x reduction for oil-fired applications may require a larger catalyst reactor, at a higher capital cost. As a result, the cost-effectiveness figures may actually be higher than those shown in Table 6-11 for oil-fired applications.

The cost-effectiveness figures are higher for smaller gas turbines because the fixed capital costs associated with the installation of an SCR system have the greatest impact on smaller gas turbines. Cost-effectiveness figures increase as annual operating hours decrease. For turbines operating 2,000 hours per year, cost-effectiveness figures are more than double those for continuous-duty model plants, and they increase even further for model plants operating 1,000 hr/yr.

Because virtually all SCR systems are installed downstream of controlled gas turbines, combined cost-effectiveness figures for wet injection plus SCR and also dry low-NO_x combustion plus SCR have been calculated and are shown in Tables 6-13

[c]Total for both dry low-NO_x combustion plus SCR control techniques.

and 6-14, respectively. These combined cost-effectiveness

NMED Exhibit 53

figures are calculated by dividing the sum of the total annual costs by the

NMED Exhibit 53

NMED Exhibit 53

sum of the annual reduction of NO_x emissions for the combined emission control techniques. For continuous-duty, natural gas-fired model plants, the combined cost-effectiveness figures for wet injection plus SCR range from approximately $650 to $4,500 per ton of NO_x removed. For continuous-duty, oil-fired model plants, the combined cost effectiveness ranges from approximately $1,100 to $3,550 per ton of NO_x removed. The combined cost-effectiveness figures for dry low-NO_x combustion plus SCR for continuous-duty, natural gas-fired model plants range from approximately $350 to $3,550 per ton of NO_x removed.

The combined cost-effectiveness figures increase with decreasing turbine size and annual operating hours. Data were not available to quantify the wet injection requirements and controlled emissions levels for oil-fired turbines with low-NO_x combustors, so cost-effectiveness figures were not tabulated for this control scenario.

d. OFFSHORE TURBINES

The only available information about the cost of NO_x controls for offshore gas turbines was presented in a report prepared for the Santa Barbara County Air Pollution Control District (SBCAPCD) in California.[37] The performance and cost of about 20 NO_x control techniques for a 2.8 MW (3,750 hp) turbine were described in the report. Wet injection and SCR were included in the analysis; low-NO_x combustors were not. The costs from the report are presented in Table 6-15

NMED Exhibit 53

TABLE 6-15. PROJECTED WET INJECTION AND SCR COSTS FOR AN OFFSHORE GAS TURBINE[a]

	Wet injection costs	SCR costs
Capital cost, $	70,000	585,000
Annual costs, $/yr		
Ammonia	N/A[b]	3,050[c]
Catalyst replacement	N/A	28,000
Operating and maintenance[d]	24,600	18,000
Fuel penalty[e]	10,500	5,000
Capital recovery[f]	14,000	117,000
Total annual costs, $/yr	49,100	171,000

[a]Costs are for a 2.8 MW gas turbine and are obtained from Reference 37.
[b]N/A = Not applicable.
[c]Ammonia cost is based on $150/ton and 0.4 lb NH_3/lb NO_X.
[d]Operating and maintenance cost for SCR is estimated as 3 percent of the total capital investment.
[e]Fuel penalty is estimated as 2 percent of the annual fuel consumption for wet injection and 1 percent for SCR.
[f]Capital recovery is estimated based on an equipment life of 8 years and an interest rate of 13 percent.

NMED Exhibit 53

without adjustment because there is insufficient cost information to know what adjustments need to be made. Additionally, insufficient information is available to scale up these costs for larger turbines. The water and steam injection costs and SCR costs for offshore applications are discussed in Sections 6.4.1 and 6.4.2, respectively.

i. Wet Injection

The report prepared for SBCAPCD assumed water injection costs are the same as steam injection costs. The report did not describe the components in the capital cost analysis for these injection systems, but the results are much lower than those that

would be estimated by the procedures described in Section 6.1.1 of this report. The authors may have assumed that the engine-mounted injection equipment cost was included in the turbine capital cost and that a less rigorous water treatment process is installed. Annual costs are also much lower than those that would be estimated by the procedures described in Section 6.1.2 of this report. There are at least three reasons for the difference: (1) the low capital cost leads to a low CRF, even though the turbine life was assumed to be only 8 years; (2) overhead costs and taxes, insurance, and administration costs are not considered; and (3) the capacity factor is only 50 percent (i.e., about 4,400 hr/yr, vs. 8,000 hr/yr, as in Section 6.1.2). The turbine life was only 8 years, which may correspond to a typical service life of an offshore platform.

ii. Selective Catalytic Reduction

The total capital costs presented in the report for SBCAPCD are similar to those that would be estimated by the procedures in Section 6.2.1 of this report. However, it appears that $150,000 of the total in Reference 37 is for structural modifications to the platform and $75,000 is for retrofit installation. When the difference in the load factor is taken into account, some of the annual costs are similar to those that would be estimated by the procedures in Section 6.2.2 for a similarly sized turbine. The catalyst replacement cost, however, is much lower; neither the type of catalyst nor the replacement frequency were identified. Ammonia costs are lower because the uncontrolled NO_x emission level was assumed to be 110 ppmv instead of 150 ppmv and because a unit cost of $150/ton was used instead of $400/ton. The reference does not indicate whether or not catalyst disposal, overhead, taxes, freight, and administration costs were considered. Capital recovery costs are higher because the equipment life is assumed to be only 8 years on the offshore platform.

7..0 ENVIRONMENTAL AND ENERGY IMPACTS

This chapter presents environmental and energy impacts for the nitrogen oxide (NO_x) emissions control techniques described in Chapter 5.0. These control techniques are water or steam injection, dry low-NO_x combustors, and selective catalytic reduction (SCR). The impacts of the control techniques on air pollution, solid waste disposal, water pollution, and energy consumption are discussed.

The remainder of this chapter is organized in five sections. Section 7.1 presents the air pollution impacts; Section 7.2 presents the solid waste disposal impacts; Section 7.3 presents the water pollution impacts; and Section 7.4 presents the energy consumption impacts. References for the chapter are listed in Section 7.5.

a. AIR POLLUTION

i. Emission Reductions

Applying any of the control techniques discussed in Chapter 5 will reduce NO_x emissions from gas turbines. These emission reductions were estimated for the model plants presented in Table 6-1 and are shown in Table 7-1. For each model plant, the uncontrolled and controlled emissions, emission reductions, and percent reductions are presented. The following paragraphs discuss NO_x emission reductions for each control technique.

Nitrogen oxide emission reductions for water or steam injection are estimated as discussed in Section 6.1.3. The percent reduction in emissions from uncontrolled levels varies for each model plant ranging, from 60 to 96 percent. This reduction depends on each model's uncontrolled emissions, the

[a]Uncontrolled and controlled NO_x emissions are from cost-effectiveness tables in Chapter 6.

[b]Controlled NO_x emission level for wet injection plus SCR is 9 ppmv for natural gas fuel and 18 ppmv for distillate oil fuel.

[c]Ammonia emissions, in tons per year = (SLIP, ppmv) x (MM/1,000,000) x (GT exhaust,lb/sec) x (MW NH3 = 15/MW exhaust = 28.6) x (3,600 sec/hr) x (ton/2,000 lb) x (annual operating hrs).

[d]NA-control technology not available for this model plant.

[e]NC-data not available to calculate emissions for this control scenario.

NMED Exhibit 53

water-to-fuel ratio (WFR), and type of fuel and whether water or steam is injected.

Achievable emission levels from gas turbines using dry low-NO_x combustors were obtained from manufacturers. Controlled NO_x levels of 42, 25, and 9 parts per million, by volume (ppmv), referenced to 15 percent oxygen, were reported by the various turbine manufacturers, and each of these levels is shown in Table 7-1, where applicable, for each model plant. The percent reduction in NO_x emissions from uncontrolled levels for gas turbines using these combustors ranges from 68 to 98 percent. Virtually all SCR units installed in the United States are used in combination with either wet controls or combustion controls. For this analysis, emission reductions were calculated for SCR in combination with water or steam injection. Using the turbine manufacturers' guaranteed NO_x emissions figures for wet injection and a controlled NO_x emission level of 9 ppmv, referenced to 15 percent oxygen, exiting the SCR, the percent reduction in NO_x emissions for this combination of control techniques ranges from 93 to 99 percent.

Estimated ammonia (NH_3) emissions, in tons per year, corresponding to ammonia slip from the SCR system are also shown in Table 7-1. These estimates are based on an ammonia slip level of 10 ppmv, consistent with information and data presented in Section 5.4. For continuous-duty model plants, the annual NH_3 emissions range from approximately 3 tons for a 3.3 megawatt (MW) (4,425 horsepower [hp]) model plant to 72 tons for a 160 MW (215,000 hp) model plant.

ii. Emissions Trade-Offs

The formation of both thermal and fuel NO_x depends upon combustion conditions. Water/steam injection, lean combustion, and reduced residence time modify combustion conditions to reduce the amount of NO_x formed. These combustion modifications may increase carbon monoxide (CO) and unburned hydrocarbon (HC) emissions. Using SCR to control NO_x emissions produces ammonia emissions. The impacts of these NO_x controls on CO, HC, and ammonia emissions are discussed below.

NMED Exhibit 53

(1) Impacts of Wet Controls on CO and HC Emissions. As discussed in Section 5.1.5, wet injection may increase CO and HC emissions. Injecting water or steam into the flame area of a turbine combustor lowers the flame temperature and thereby reduces NO_x emissions. This reduction in temperature to some extent inhibits complete combustion, resulting in increased CO and HC emissions. Figure 5-12 shows the impact of water and steam injection on CO emissions for production gas turbines.[2] The impact of steam injection on CO emissions is less than that of water injection. As seen in Figure 5-12, CO emissions increase with increasing WFR's. Wet injection increases HC emissions to a lesser extent than it increases CO emissions. Figure 5-13 shows the impact of water injection on HC emissions for one turbine. In cases where water and steam injection result in excessive CO and HC emissions, an oxidation catalyst (add-on control) can be installed to reduce these emissions by converting the CO and HC to water (H_2O) and carbon dioxide (CO_2).

(2) Impacts of Combustion Controls on CO and HC Emissions. As discussed in Section 5.2.1, the performance of lean combustion in limiting NO_x emissions relies in part on reduced equivalence ratios. As the equivalence ratio is reduced below the stoichiometric level of 1.0, combustion flame temperatures drop, and as a result NO_x emissions are reduced. Shortening the residence time in the high-temperature flame zone also will reduce the amount of thermal NO_x formed. These lower equivalence ratios and/or reduced residence time, however, may result in incomplete combustion, which may increase CO and HC emissions. The extent of the increase in CO and HC emissions is specific to each turbine manufacturer's combustor designs and therefore varies for each turbine model. As with wet injection, if necessary, an oxidation catalyst can be installed to reduce excessive CO and HC emissions by converting the CO and HC to CO_2 and H_2O.

(3) Ammonia Emissions from SCR. The SCR process reduces NO_x emissions by injecting NH_3 into the flue gas. The NH_3 reacts with NO_x in the presence of a catalyst to form H_2O and nitrogen

NMED Exhibit 53

(N_2). The NO_x removal efficiency of this process is partially dependent on the NH_3/NO_x ratio. Increasing this ratio reduces NO_x emissions but increases the probability that unreacted ammonia will pass through the catalyst unit into the atmosphere (known as ammonia "slip"). Some ammonia slip is unavoidable because of ammonia injection control limitations and imperfect distribution of the reacting gases. A properly designed SCR system will limit ammonia slip to less than 10 ppmv (see Section 5.4).

b. SOLID WASTE DISPOSAL

Catalytic materials used in SCR units for gas turbines include precious metals (e.g., platinum), zeolites, and heavy metal oxides (e.g., vanadium, titanium). Vanadium pentoxide, the most commonly used SCR catalyst in the United States, is identified as an acute hazardous waste under RCRA Part 261, Subpart D - Lists of Hazardous Wastes. The Best Demonstrated Available Technology (BDAT) Treatment Standards for Vanadium P119 and P120 states that spent catalysts containing vanadium pentoxide are not classified as hazardous waste.[1] State and local regulatory agencies, however, are authorized to establish their own hazardous waste classification criteria, and spent catalysts containing vanadium pentoxide may be classified as a hazardous waste in some areas. Although the actual amount of vanadium pentoxide contained in the catalyst bed is small, the volume of the catalyst unit containing this material is quite large and disposal can be costly. Where classified by State or local agencies as a hazardous waste, this waste may be subject to the Land Disposal Restrictions in 40 CFR Part 268, which allows land disposal only if the hazardous waste is treated in accordance with Subpart D - Treatment Standards. Such disposal problems are not encountered with other catalyst materials, such as precious metals and zeolites, because these materials are not hazardous wastes.

c. WATER USAGE AND WASTE WATER DISPOSAL

Water availability and waste water disposal are environmental factors to be considered with wet injection. The impact of water usage on the water supply at some remote sites,

NMED Exhibit 53

in small communities, or in areas where water resources may be limited is an environmental factor that should be examined when considering wet injection. The volume of water required for wet injection is shown in Table 7-2

NMED Exhibit 53

for each model plant.

Water purity is essential for wet injection systems in order to prevent erosion and/or the formation of deposits in the hot sections of the gas turbine. Water treatment systems are used to achieve water quality specifications set by gas turbine manufacturers. Table 5-4 summarizes these specifications for six manufacturers.

Discharges from these water treatment systems have a potential impact on water quality. As indicated in Section 6.1, approximately 29 percent of the treated water flow rate (22.5 percent of the raw water flow rate) is considered to be discharged as wastewater. The wastewater flow rates for each of the model plants with a water or steam injection control system are estimated using this factor, and the results are presented in Table 7-2. The wastewater contains increased levels of those pollutants in the raw water (e.g., calcium, silica, sulfur, as listed in Table 5-4) that are removed by the water treatment system, along with any chemicals introduced by the treatment process. Based on a wastewater flowrate equal to 29 percent of the influent raw water, the concentration of pollutants discharged from the water treatment system is approximately three times higher than the pollutant concentrations in the raw water.

The impacts of these pollutants on water quality are site-specific and depend on the type of water supply and on the discharge restrictions. Influent water obtained from a municipality will not contain high concentrations of pollutants. However, surface water or well water used at a remote site might contain high pollutant concentrations and may require additional pretreatment to meet the water quality specifications set by

NMED Exhibit 53

manufacturers. This additional pretreatment will increase the pollutant concentrations of the wastewater discharge. Wastewater discharges to publicly-owned treatment works (POTW's) must meet the requirements of applicable Approved POTW Pretreatment Programs.

d. ENERGY CONSUMPTION

Additional fuel and electrical energy is required over baseline for wet injection controls, while additional electrical energy is required for SCR controls. The following paragraphs discuss these energy consumption impacts.

Injecting water or steam into the turbine combustor lowers the net cycle efficiency and increases the power output of the turbine. The thermodynamic efficiency of the combustion process is reduced because energy that could otherwise be available to perform work in the turbine must now be used to heat the water/steam. This lower efficiency is seen as an increase in fuel use. Table 5-10 shows the impacts of wet injection on gas turbine performance for one manufacturer. This table shows a 2 to 4 percent loss in efficiency associated with WFR's required to achieve NO_x emission levels of 25 to 42 ppmv in gas turbines burning natural gas. The actual efficiency loss is specific to each turbine model but generally increases with increasing WFR's and is higher for water injection than for steam injection (additional energy is required to heat and vaporize the water). One exception to this efficiency penalty occurs with steam injection, in which exhaust heat from the gas turbine is used to generate the steam for injection. If the heat recovered in generating the steam would otherwise be exhausted to atmosphere, the result is an increase in net cycle efficiency.

The energy from the increased mass flow and heat capacity of the injected water/steam can be recovered in the turbine, resulting in an increase in power output accompanying the reduced efficiency of the turbine (shown in Table 5-10 for one manufacturer). This increase in power output can be significant and could lessen the impact of the loss in efficiency if the facility has a demand for the available excess power.

NMED Exhibit 53

Water and steam injection controls also require additional electrical energy to operate the water injection feed water pumps. The annual electricity usage for each model is the product of the pump power demand, discussed in Section 6.1.2.2, and the annual hours of operation. Table 7-2 summarizes this electricity usage for each of the model plants.

For SCR units, additional electrical energy is required to operate ammonia pumps and ventilation fans. This energy requirement, however, is believed to be small and was not included in this analysis.

The increased back-pressure in the turbine exhaust system resulting from adding an SCR system reduces the power output from the turbine. As discussed in Section 6.3.2.9, the power output is typically reduced by approximately 0.5 percent. This power penalty has been calculated for each model plant and is shown in Table 7-2.

e. REFERENCE FOR CHAPTER 7

1.. 55 FR 22276, June 1, 1990.

NMED Exhibit 53

APPENDIX A

Exhaust NO_x emission levels were provided by gas turbine manufacturers in units of parts per million, by volume (ppmv), on a dry basis and corrected to 15 percent oxygen. A method of converting these exhaust concentration levels to a mass flow rate of pounds of NO_x per hour (lb NO_x/hr) was provided by one gas turbine manufacturer.[1] This method uses an emission index ($EINO_x$), in units of lb NO_x/1,000 lb fuel, which is proportional to the exhaust NO_x emission levels in ppmv by a constant, K. The relationship between $EINO_x$ and ppmv for NO_x emissions is stated in Equation 1 below and applies for complete combustion of a hydrocarbon fuel and combustion air having no CO_2 and an O_2 mole percent of 20.95:

$$\frac{NO_x \text{ Ref. } 15\% \ 0_2}{EINO_x} = K \qquad \text{Equation 1}$$

where: NO_x Ref. 15% 0_2 = NO_x, ppmvd @15% O_2 (provided by gas turbine manufacturers);

$EINO_x$ = NO_x emission index, lb NO_x/1,000 lb fuel; and

K = constant, based on the molar hydrocarbon

ratio of the fuel.

The derivation of Equation 1 was provided by the turbine manufacturer and is based on basic thermodynamic laws and supported by test data provided by the manufacturer. According to the manufacturer, this equation can be used to estimate NO_x emissions for operation with or without water/steam injection.

Equation 1 shows that NO_x emissions are dependent only upon the molar hydrocarbon ratio of the fuel and are independent of the air/fuel ratio (A/F). The equation therefore is valid for all gas turbine designs for a given fuel. The validity of this approach to calculate NO_x emissions was supported by a second

turbine manufacturer.[2] Values for K were provided for several fuels and are given below:[1,2]

Pipeline quality natural gas:

K = 12.1

Distillate fuel oil No. 1 (DF-1):

K = 13.1

Distillate fuel oil No. 2 (DF-2):

K = 13.2

Jet propellant No. 4 (JP-4):

K = 13.0

Jet propellant No. 5 (JP-5):

K = 13.1

Methane:

K = 11.6

The following examples are provided for calculating NO_x emissions on a mass basis, given the fuel type and NO_x emission level, in ppmv, dry (ppmvd), and corrected to 15 percent O_2.

Example 1. Natural gas fuel

Gas turbine:
Solar Centaur 'H'
Power output:
4,040 kW
Heat rate:
12,200 Btu/kW-hr
NO_x emissions:
105 ppmvd, corrected to 15 percent O_2
Fuel:

Natural gas

- lower heating value = 20,610 Btu/lb

- K = 12.1

Fuel flow:

$$4{,}040 \text{ kW} \times \frac{12{,}200 \text{ Btu}}{\text{kW-hr}} \times \frac{1 \text{ lb fuel}}{20{,}610 \text{ Btu}} = 2{,}391 \text{ lb/hr}$$

From Equation 1:

$$\frac{105}{EINO_x} = 12.1$$

NO_x emissions, lb/hr:

$$2{,}391 \frac{\text{lb fuel}}{\text{hr}} \times \frac{8.68 \text{ lb } NO_x}{1{,}000 \text{ lb fuel}} = 20.8 \frac{\text{lb } NO_x}{\text{hr}}$$

Example 2. Distillate oil fuel

Gas turbine:

General Electric LM2500

Power output:

22670 kW

Heat rate:

9296 Btu/kW-hr

No_x emissions: 345 ppmvd, corrected to 15 percent O_2

Fuel:

Distillate oil No. 2

-

lower heating value = 18,330 Btu/lb

- K = 13.2

Fuel flow:

$$22{,}670 \text{ kW} \times 9296 \frac{\text{Btu}}{\text{kW-hr}} \times \frac{1 \text{ lb fuel}}{18{,}330 \text{Btu}} = 11{,}500 \text{ lb/hr}$$

From Equation 1:

$$\frac{345}{EINO_x} = 13.2$$

NO_x emissions, lb/hr:

$$11{,}500 \frac{\text{lb fuel}}{\text{hr}} \times \frac{26.1 \text{ lb } NO_x}{1{,}000 \text{ lb fuel}} = 300 \frac{\text{lb } NO_x}{\text{hr}}$$

APPENDIX B. COST DATA AND METHODOLOGY USED TO PREPARE COST FIGURES PRESENTED IN CHAPTER 6

APPENDIX B. RAW COST DATA AND COST ALGORITHMS

The maintenance costs for water injection and several of the SCR costs presented in Chapter 5 are based on information from turbine manufacturers and other sources that required interpretation and analysis. Information about additional gas turbine maintenance costs associated with water injection is presented in Section B.1. Information on SCR capital costs, catalyst replacement and disposal costs, and maintenance costs is presented in Section B.2. References are listed in Section B.3.

B.1 WATER INJECTION MAINTENANCE COSTS

Information from each manufacturer and the applicable analysis procedures used to develop maintenance cost impacts for water injection are described in the following sections.

B.1.1 Solar

This manufacturer indicated that the annual maintenance cost for the Centaur is $16,000/year.[1] The cost for the Saturn was estimated to be $8,000.[2] This $8,000 cost was then prorated for operation at 1,000/hr/yr, and was multiplied by 1.3 to account for the additional maintenance required for oil fuel.

B.1.2 Allison

Maintenance costs for water injection were provided by a company that packages Allison gas turbines for stationary applications. This packager stated that for the 501 gas turbine model, a maintenance contract is available which covers all maintenance materials and labor costs associated with the turbine, including all scheduled and unscheduled activities. The cost of this contract for the 501 model is $0.0005 to $0.0010 per KW-hour (KWH) more for water injection than for a turbine not using water injection.[3] For an installation operating 8,000 hours per year at a base-rated output of 4,000 KW, and using an average cost of $0.00075 per KWH, the annual additional maintenance cost is $24,000. By the nature of the contract offered, this figure represents a worst case scenario and to some extent may exceed the actual incremental maintenance costs that would be expected for water injection for this turbine.

NMED Exhibit 53

B.1.3 General Electric

General Electric (GE) offers both aero-derivative type (LM-series models) and heavy-duty type (MS-series models) gas turbines. For the aero-derivative turbines, GE states that the incremental maintenance cost associated with water injection is $3.50 per fired hour. This cost is used to calculate the maintenance cost for water injection for GE aeroderivative turbines. No figures were provided for steam injection and no maintenance cost was used for steam injection with these turbines.[4]

Water injection also impacts the maintenance costs for the heavy-duty MS-series models. Costs associated with more frequent maintenance intervals required for models using water injection have been calculated and summarized below. A GE representative stated that the primary components which must be repaired at each maintenance interval are the combustor liner and transition pieces.[5] Approximate costs to repair these pieces were provided by GE.[5] For this analysis, the maximum cost estimates were used to calculate annual costs to accommodate repairs that may be required periodically for injection nozzles, cross-fire tubes, and other miscellaneous hardware. According to GE, a rule of thumb is that if the repair cost exceeds 60 percent of the cost of a new part, the part is replaced.[5] The cost of a replacement part is therefore considered to be 1.67 times the maximum repair cost. If water purity requirements are met, there are no significant adverse impacts on maintenance requirements on other turbine components, and hot gas path inspections and major inspection schedules are not impacted.[5] Combustion repair schedules, material costs, and labor hours are shown in Table B-1. Scheduled maintenance intervals for models with water injection were provided in Reference 6. Corresponding maintenance intervals for models with steam injection were assumed to be the same as models with no wet injection; these scheduled maintenance intervals were provided in Reference 7. Using the information in Table B-1, the total annual cost is

NMED Exhibit 53

calculated and shown in Table B-2 for three GE heavy-duty turbine models.

B.1.4 Asea Brown Boveri

This manufacturer states there are no maintenance impacts associated with water injection.[8]

B.2 SCR COSTS

The total capital investment, catalyst replacement, and maintenance costs are estimated based on information from the technical literature. The cost algorithms are described in the following sections.

B.2.1 Total Capital Investment

Total capital investment costs, which include purchased costs and installation costs, were available for SCR systems for combined cycle and cogeneration applications from five sources.[9-13] These costs were scaled to 1990 costs using the Chemical Engineering annual plant cost indexes and are applicable to SCR systems in which the catalyst was placed within the heat recovery steam generator (HRSG). In addition, estimated capital investment costs were available from one source for SCR systems in which a high temperature zeolite catalyst is installed upstream of the HRSG.[14] Both the original data and the scaled costs are presented in Table B-3. The scaled costs were plotted against the turbine size and this plot is shown in Figure B-1. A linear regression analysis was performed to determine the equation for the line that best fits the data. This equation was used to estimate the total capital investment for SCR for the model plants and was extrapolated to estimate the costs for model plants larger than 90 MW.

B.2.2 Maintenance Costs

Maintenance costs for SCR controls were obtained from four literature sources, although 6 of the 14 points were obtained from one article.[9,11-13] These costs were scaled to 1990 costs assuming an inflation rate of five percent per year. All of the data are for turbines that use natural gas fuel. Because there are no data to quantify differences in SCR maintenance costs for oil-fired applications, the available data for operation on

NMED Exhibit 53

natural gas were used for both fuels. Both the original data and the scaled costs are presented in Table B-4. The scaled costs were plotted versus the turbine size in Figure B-2. The equation for the line through the data was determined by linear regression, and it was used to estimate the maintenance costs for the model plants.

B.2.3 Catalyst Replacement Costs

Catalyst replacement costs were obtained from three articles for nine gas turbine installations.[9,11,13] Combined catalyst replacement and disposal costs were obtained for another six gas turbine installations from one article.[12] The disposal costs for these six gas turbine installations were estimated based on estimated catalyst volumes and a unit disposal cost of $\$15/ft^3$, given in Reference 15.

The catalyst volumes were estimated assuming there is a direct relationship between the volume and the turbine size; the catalyst volume stated in Reference 16 for one 83 MW turbine is 175 m^3. The resulting disposal costs for these six facilities were subtracted from the combined replacement and disposal costs to estimate the replacement-only costs. All of the replacement costs were scaled to 1990 costs assuming an inflation rate of 5 percent per year. The original data and the scaled costs are presented in Table B-5, and the scaled replacement costs were also plotted versus the turbine size in Figure B-3. Linear regression was used to determine the equation for the line through the data. This equation was used to estimate the catalyst replacement costs for the model plants.

NMED Exhibit 53

TABLE B-2. ANNUAL COST OF ADDITIONAL MAINTENANCE REQUIRED FOR WATER INJECTION

	Number of inspections over 15 years						Material costs		Labor, each inspection		Total added cost 15 years	Total added annual cost
	Dry		Wet		Added number for wet							
GT Model	Inspection	Replacement	Inspection	Replacement	Inspection	Replacement	Inspection	Replacement	Hours	Cost		
MS5001P [a]												
Combustor liners	8	2	15	5	7	3	15,000	25,000			18,000	
Transition pieces	8	2	15	5	7	3	20,000	42,000	160	4,998	315,980	
											495,980	33,065
MS7001E [e]												
Combustor liners	12	3	15	3.5	3	0.5	30,000	50,000			115,000	
Transition pieces	13	2	15.5	3	2.5	1	50,000	83,000	576	17,994	270,979	
											385,979	25,732
MS9001E [e]												
Combustor liners	12	3	15	3.5	3	0.5	62,000	103,000			237,500	
Transition pieces	13	2	15.5	3	2.5	1	124,000	206,000	624	19,494	584,229	
											821,729	54,782

[a]Based on $31.24/hr. Since parts are normally removed and a spare set is installed at each inspection, the labor cost would be the same for either repair or replacement interval.

[b]Schedule assumes liners and transition pieces are replaced every fourth inspection interval.

[c](7 x $15,000) + (3 x $25,000) = $180,000.

[d](7 x $20,000) + (3 x $42,000) + ($4,998 x 10) = $315,980.

[e]Schedule assumes liners are replaced every fifth interval and transition pieces every sixth interval.

83	5,360,000	1991	14	1.0	5,360,000

continued

TABLE B-3. (Continued)

[a]Total capital costs were provided by several sources, but it is not clear that they are on the same basis. For example, it is likely that the type of catalyst varies and the target NO_x reduction efficiency may also vary. In addition, some estimates may not include costs for emission monitors; auxiliary equipment like the ammonia storage, handling, and transfer system; taxes and freight; or installation.

[b]Reference 12 also provided costs for SCR used with 136 MW and 145 MW turbines. All of the costs for this reference are lower than the costs from other sources, and the differential increases as the turbine size increases. Because there are no costs from other sources for such large turbines, these two data points would exert undue influence on the analysis; therefore, they have been excluded. Costs for large model plants were estimated by extrapolating with the equation determined by linear regression through the data for turbines with capacities less than 90 MW (see Figure B-1).

[c]Costs for years prior to 1990 are adjusted to 1990 dollars based on the annual CE plant cost indexes. Costs estimated in 1991 dollars were not adjusted.

NMED Exhibit 53

TABLE B-4. MAINTENANCE COSTS FOR SCR

Gas turbine size, MW	SCR maintenance cost[a]			Scaling factor[b]	1990 SCR maintenance cost, $
	$/yr	Year	Ref		
1.1	52,200	1989	9	1.050	54,800
3.2	50,000	1989	11	1.050	52,500
3.7	43,000	1988	11	1.103	47,400
3.7	15,500	1988	12	1.103	17,100
8.4	22,000	1986	11	1.216	26,700
8.9	18,000	1988	11	1.103	19,800
9	25,000	1987	13	1.158	28,900
20	50,000	1987	13	1.158	57,900
21	37,900	1988	12	1.103	41,800
33	63,700	1988	12	1.103	70,200
80	124,000	1988	12	1.103	137,000
80	60,000	1987	13	1.158	69,500
136	184,000	1988	12	1.103	203,000
145	205,000	1988	12	1.103	226,000

[a]All of the maintenance costs are for turbines that are fired with natural gas. Although sulfur in diesel fuel can cause maintenance problems, there are no data to quantify the impact. Therefore, the maintenance costs presented in this table were used for both natural gas and diesel fuel applications.
[b]Scaling factors are based on an estimated inflation rate of 5 percent per year.

NMED Exhibit 53

TABLE B-5. CATALYST REPLACEMENT AND DISPOSAL COSTS

3.7		1988	12	1.103	215,000	56,600	7.80	4,130	1,090	57,700
3.7	100,000	1988	11	1.103	110,000	29,000	7.80	4,130	1,090	30,100
4.5	300,000	1988	11	1.103	331,000	87,300	9.49	5,030	1,330	89,000
8.4	200,000	1986	11	1.216	243,000	64,100	17.7	9,380	2,470	67,000
9	255,000	1987	13	1.158	295,000	77,800	19.0	10,100	2,660	80,000
20	434,000	1987	13	1.158	502,000	132,000	42.2	22,300	5,880	138,000
21		1988	12	1.103	512,000	135,000	44.3	23,500	6,200	141,000
22	400,000	1987	11	1.158	463,000	122,000	46.4	24,600	6,490	128,000
33		1988	12	1.103	864,000	228,000	69.6	36,900	9,700	238,000
80		1988	12	1.103	1,660,000	437,000	169	89,300	23,600	461,000
80	1,400,000	1987	13	1.158	1,620,000	427,000	169	89,300	23,600	451,000
136		1988	12	1.103	2,450,000	645,000	287	152,000	40,100	685,000
145		1988	12	1.103	2,740,000	723,000	306	162,000	42,700	766,000

[a]Reference 12 provided only combined catalyst replacement and disposal costs.

[b]Scaling factors are based on an inflation rate of 5 percent per year.

[c]Annual costs are based on the assumption that the catalyst will be replaced every 5 years. Therefore, the capital recovery factor is 0.2638, assuming an annual interest rate of 10 percent.

[d]In one SCR application, 175 m^3 of catalyst is used with an 83 MW turbine. If the space velocity is the same for any size SCR (assuming the same catalyst), then there is a direct relationship between the amount of catalyst and the exhaust gas flow rate. The exhaust gas flow rate was calculated as equal to the inlet air flow rate, and as Figure B-4 shows, there is nearly a direct relationship between the inlet airflow rate and turbine capacity. Therefore, the catalyst volume for the turbines in this table were estimated assuming there is a direct relationship between the catalyst volume and the turbine output.

[e]Disposal costs are estimated based on a unit cost of $15/$ft^3$.

NMED Exhibit 54

OTC Regulatory and Technical Guideline for Control of Nitrogen Oxides (NOx) Emissions from Natural Gas Pipeline Compressor Fuel-Fired Prime Movers

This Guideline was developed by the Ozone Transport Commission (OTC) as part of a regional effort to attain and maintain the eight-hour ozone standard, and reduce eight-hour ozone levels.

Notes:

1. *States opting to promulgate rules based on this Guideline must comply with State specific administrative requirements and procedures.*
2. *The term <OTC STATE AGENCY> is a placeholder for individual State Agency names.*
3. *If the owner or operator of a natural gas fueled prime mover subject to this Guideline is unable to comply with the NOx emissions rate limitations or % NOx reduction from uncontrolled shown in specified Section 4 of this Guideline, the owner or operator shall submit an alternative NOx RACT determination, in accordance with Section 5 of this Guideline, for review and approval by the appropriate State Agency which will prepare a revised SIP submittal to the U.S. EPA as required.*

1. Purpose

The purpose of this Guideline is to provide NOx emissions limitations for existing natural gas fueled prime movers powering compressors used for pipeline transportation of natural gas, and to also provide NOx emissions limitations for existing natural gas fueled prime movers powering compressors used for the storage (injection and extraction) of natural gas. Control of NOx emissions from subject sources will help reduce the adverse impact of those emissions on public health, safety, and welfare.

2. Definitions

Note: The definitions used in this section are provided as examples for OTC state agency adoption as needed.

The following words and terms, when used in this Guideline, shall have the following meanings:

2.1 Combustion turbine means a device in which expanding gases from the combustion chamber(s) drive the blades of a turbine to generate mechanical energy in the form of a rotating shaft.

2.2 Compressor means a mechanical device (including, but not limited to reciprocating, axial flow, centrifugal, etc.) designed to increase the pressure of the natural gas in order to facilitate the movement of the natural gas through a pipeline.

NMED Exhibit 54

2.3 Existing means the natural gas fueled compressor prime mover was in operation no later than MM-DD-YYYY in any location.

2.4 Field gathering means taking natural gas from the wellhead, and sometimes boosting the natural gas pressure from the wellhead pressure, and injecting the natural gas into field gathering pipelines to transport the natural gas to processing facilities and/or to inject the natural gas into the transport pipelines.

2.5 Four stroke (4S) means any type of engine which completes the power cycle in two crankshaft revolutions, with intake and compression strokes in the first revolution and power and exhaust strokes in the second revolution.

2.6 Lean burn (LB) means any two-stroke or four-stroke spark ignited reciprocating internal combustion engine that does not meet the definition of a rich burn engine.

2.7 Nameplate rating means: for reciprocating engine natural gas fueled compressor prime movers, the manufacturer's design maximum capacity in horsepower (hp) at the installation site conditions, and for combustion turbine natural gas fuel compressor prime movers, the manufacturer's design maximum capacity at International Organization for Standardization (ISO) 2533 conditions (59^{o} Fahrenheit or 288 Kelvin, 60% relative humidity, and 101.3 kilopascals of pressure). Starting from the completion of any physical change in the prime mover resulting in an increase in the maximum output (in hp) that the prime mover is capable of producing on a steady state basis and during continuous operation, such increased maximum output (at site location conditions for reciprocating prime movers and ISO conditions for combustion turbine prime movers) shall be as specified by the person conducting the physical change.

2.8 Natural gas means a naturally occurring mixture of hydrocarbon and non-hydrocarbon gases found in geologic formations beneath the Earth's surface, of which the principal constituent is methane. Natural gas may be field or pipeline quality.

2.9 Natural gas fueled means that ≥90% of the prime mover's heat input, excluding recirculated or recuperated exhaust heat, is derived from the combustion of natural gas.

2.10 Operator means any person who operates, controls, or supervises a natural gas fueled prime mover subject to this Guideline and shall include, but not be limited to, any holding company, utility system, or plant manager of such natural gas fueled prime mover.

2.11 Owner means any holder of any portion of the legal or equitable title in a natural gas fueled prime mover subject to this Guideline.

NMED Exhibit 54

2.12 Pipeline transportation of natural gas means the movement of natural gas through an interconnected network of compressors and pipeline components, from field gathering networks near wellheads to end users, including:

a. The compressor and pipeline network used for field gathering of natural gas from the wellheads for delivery to either processing facilities or connections to pipelines used for intrastate or interstate transportation of the natural gas.

b. The compressor and pipeline network used to transport the natural gas from field gathering networks or processing facilities over a distance (intrastate or interstate) to and from storage facilities, to large natural gas end-users, and to distribution organizations that provide the natural gas to end-users.

2.13 Prime mover means a spark-ignited reciprocating internal combustion engine or combustion turbine.

2.14 Reasonably available control technology (RACT) means the lowest emission limit for NOx that a particular source is capable of meeting by the application of NOx emissions control technology that is reasonably available considering technological and economic feasibility.

2.15 Reciprocating internal combustion engine means a reciprocating engine in which power, produced by heat and/or pressure that is developed in the engine combustion chambers by the burning of a mixture of air and fuel, is subsequently converted to mechanical work.

2.16 Rich burn (RB) means any four-stroke spark ignited reciprocating internal combustion engine where the manufacturer's recommended operating air/fuel ratio divided by the stoichiometric air/fuel ratio at full load conditions is less than or equal to 1.1. Internal combustion engines originally manufactured as rich burn engines, but modified with passive emission control technology for NO_X (such as pre-combustion chambers) will be considered lean burn engines. Also, existing internal combustion engines where there are no manufacturer's recommendations regarding air/fuel ratio will be considered a rich burn engine if the excess oxygen content of the exhaust at full load conditions is less than or equal to 2 percent.

2.17 Spark ignited means a reciprocating internal combustion engine utilizing a spark plug (or other sparking device) to ignite the air/fuel mixture and with operating characteristics significantly similar to the theoretical Otto combustion cycle.

2.18 Shutdown means the period of unit operation between when the compressor prime mover has been unloaded to the minimum load and when the combustion of fuel in the prime mover has ceased.

2.19 Startup means the period of unit operation between when fuel combustion commences in the prime mover and when the compressor prime mover has been loaded to its minimum load.

NMED Exhibit 54

2.20 Stoichiometric means the theoretical air-to-fuel ratio required for complete combustion.

2.21 Two stroke (2S) means a type of reciprocating internal combustion engine which completes the power cycle in a single crankshaft revolution by combining the intake and compression operations into one stroke (one-half revolution) and the power and exhaust operations into a second stroke. This system requires auxiliary exhaust scavenging of the combustion products and inherently runs lean (excess of air) of stoichiometry.

2.22 Uncontrolled means the full load (±25% of nameplate rating) NOx emissions rate of a natural gas fueled compressor prime mover prior to the installation of any NOx controls, including NOx controls installed during prior NOx reduction processes, as documented by Continuous Emission Monitoring Systems (CEMS), stack test, or other method or information approved by the <OTC STATE AGENCY>.

3. Applicability

This Guideline is applicable to existing natural gas fueled prime movers powering compressors used for pipeline transportation of natural gas and the underground storage of natural gas.

3.1 This Rule does not apply to:

3.1.1 Prime movers with nameplate horse-power ratings of <200 hp.

3.1.2 In accordance with the provisions of Section 7 of this Guideline, natural gas fueled compressor prime movers that operate less than 438 hours per year are exempt from the NOx emissions limitations and testing requirements of this Guideline provided they meet the applicable requirements of Section 7 of this Guideline.

4. Emissions Limitations

Except as provided for in Section 5 of this Guideline, no later than MM-DD-YYYY, natural gas compressor prime movers subject to this Guideline shall not exceed the following NOx emissions limits:

4.1 For two-stroke lean burn internal combustion engines, the following NOx emissions limitations are applicable:

4.1.1 Output rating of 200 HP ≤ nameplate rating < 500 HP:

4.1.1.1 2.0 g/BHP-hr, or an emissions rate equivalent to 80% reduction from uncontrolled, whichever emissions rate is greater; or

4.1.1.2 An hourly NOx mass emissions no greater than the mass emissions calculated by multiplying the applicable NOx emissions

NMED Exhibit 54

rate from Section 4.1.1.1 of this rule times the prime mover's nameplate rating.

4.1.2 Output rating of 500 HP ≤ nameplate rating < 2000 HP:

4.1.2.1 1.5 g/BHP-hr, or an emissions rate equivalent to 80% reduction from uncontrolled, whichever emissions rate is greater; or

4.1.2.2 An hourly NOx mass emissions no greater than the mass emissions calculated by multiplying the applicable NOx emissions rate from Section 4.1.2.1 of this rule times the prime mover's nameplate rating.

4.1.3 Nameplate rating of ≥2000 HP:

4.1.3.1 1.5 g/BHP-hr, or an emissions rate equivalent to 90% reduction from uncontrolled, whichever emissions rate is greater; or

4.1.3.2 An hourly NOx mass emissions no greater than the mass emissions calculated by multiplying the applicable NOx emissions rate from Section 4.1.3.1 of this rule times the prime mover's nameplate rating.

4.2 For four stroke lean burn internal combustion engines, the following NOx emissions limitations are applicable:

4.2.1 Output rating of 200 HP ≤ nameplate rating < 500 HP:

4.2.1.1 1.5 g/BHP-hr, or an emissions rate equivalent to 90% reduction from uncontrolled, whichever emissions rate is greater; or

4.2.1.2 An hourly NOx mass emissions no greater than the mass emissions calculated by multiplying the applicable NOx emissions rate from Section 4.2.1.1 of this rule times the prime mover's nameplate rating.

4.2.2 Output rating of 500 HP ≤ nameplate rating < 2000 HP:

4.2.2.1 1.5 g/BHP-hr, or an emissions rate equivalent to 90% reduction from uncontrolled, whichever emissions rate is greater; or

4.2.2.2 An hourly NOx mass emissions no greater than the mass emissions calculated by multiplying the applicable NOx emissions rate from Section 4.2.2.1 of this rule times the prime mover's nameplate rating.

4.2.3 Nameplate rating of 2000 HP or more:

4.2.3.1 1.5 g/BHP-hr, or an emissions rate equivalent to 90% reduction from uncontrolled, whichever emissions rate is greater; or

4.2.3.2 An hourly NOx mass emissions no greater than the mass emissions calculated by multiplying the applicable NOx emissions

NMED Exhibit 54

rate from Section 4.2.3.1 of this rule times the prime mover's nameplate rating.

4.3 For four stroke rich burn internal combustion engines, the following NOx emissions limitations are applicable:

4.3.1 Output rating of 200 HP $\leq$ nameplate rating < 500 HP:

4.3.1.1 1.5 g/BHP-hr, or an emissions rate equivalent to 90% reduction from uncontrolled, whichever emissions rate is greater; or

4.3.1.2 An hourly NOx mass emissions no greater than the mass emissions calculated by multiplying the applicable NOx emissions rate from Section 4.3.1.1 of this rule times the prime mover's nameplate rating.

4.3.2 Output rating of 500 HP $\leq$ nameplate rating < 2000 HP:

4.3.2.1 1.5 g/BHP-hr, or an emissions rate equivalent to 90% reduction from uncontrolled, whichever emissions rate is greater; or

4.3.2.2 An hourly NOx mass emissions no greater than the mass emissions calculated by multiplying the applicable NOx emissions rate from Section 4.3.2.1 of this rule times the prime mover's nameplate rating.

4.3.3 Nameplate rating of ≥2000 HP:

4.3.3.1 1.0 g/BHP-hr, or an emissions rate equivalent to 95% reduction from uncontrolled, whichever emissions rate is greater; or

4.3.3.2 An hourly NOx mass emissions no greater than the mass emissions calculated by multiplying the applicable NOx emissions rate from Section 4.3.3.1 of this rule times the prime mover's nameplate rating.

4.4 For combustion turbines, the following NOx emissions limitations are applicable:

4.4.1 Nameplate rating of less than 2000 HP:

4.4.1.1 150 ppmvd @ 15% O_2, or 80% reduction from uncontrolled, whichever emissions rate is greater; or

4.4.1.2 An hourly NOx mass emissions no greater than the mass emissions equivalent of the combustion turbine operating at its nameplate rating at the applicable NOx emissions rate from Section 4.4.1.1 of this rule.

4.4.2 Output rating of 2000 HP $\leq$ nameplate rating < 5000 HP:

4.4.2.1 50 ppmvd @ 15% O_2, or 80% reduction from uncontrolled, whichever emissions rate is greater; or

NMED Exhibit 54

4.4.2.2 An hourly NOx mass emissions no greater than the mass emissions equivalent of the combustion turbine operating at its nameplate rating at the applicable NOx emissions rate from Section 4.4.2.1 of this rule.

4.4.3 Nameplate rating of 5000 HP or more:

4.4.3.1 25 ppmvd @ 15% O_2, or 80% reduction from uncontrolled, whichever emissions rate is greater; or

4.4.3.2 An hourly NOx mass emissions no greater than the mass emissions equivalent of the combustion turbine operating at its nameplate rating at the applicable NOx emissions rate from Section 4.4.3.1 of this rule.

Table 1 NOx LIMITS*

Two-Stroke Lean Burn ICE

Nameplate Rating (HP)	NOx Rate (g/BHP-hr) or (% Reduction)
200 - 499	2.0 (80%)
500 - 1999	1.5 (80%)
≥2000	1.5 (90%)

Four-Stroke Lean Burn ICE

Nameplate Rating (HP)	NOx Rate (g/BHP-hr) or (% Reduction)
200 - 499	1.5 (90%)
500 - 1999	1.5 (90%)
≥2000	1.5 (90%)

Four-Stroke Rich Burn ICE

Nameplate Rating (HP)	NOx Rate (g/BHP-hr) or (% Reduction)
200 - 499	1.5 (90%)
500 - 1999	1.5 (90%)
≥2000	1.0 (95%)

Combustion Turbines**

Nameplate Rating (HP) (MW)	NOx Rate (ppmvd @ 15% O_2)
≤2000 (1.5)	150.0 (6.0 lb/MWhr)
2000 - 4999 (1.5-3.7)	50.0 (2.0 lb/MWhr)
≥5000 (3.7)	25.0 (1.0 lb/MWhr)

NMED Exhibit 54

Notes:

*If the owner or operator of a natural gas fueled prime mover subject to this Guideline is unable to comply with the NOx emissions rate limitations or % NOx reduction from uncontrolled shown in Table 1 above and specified Section 4 of this Guideline, the owner or operator shall submit an alternative NOx RACT determination, in accordance with Section 5 of this Guideline, for review and approval by the appropriate State Agency which will prepare a revised SIP submittal to the U.S. EPA as required.

**Combustion Turbine NOx rates are from 40 CFR 60 Subpart KKKK Table 1[1].

4.5 The emissions limitations of Sections 4.1 through 4.4 of this Guideline are applicable during all periods of natural gas fueled compressor prime mover operation, except:

4.5.1 Reserved.

4.5.2 Combustion turbine prime movers operating at ambient temperatures less than 0^{o} F.

4.5.3 Combustion turbine prime movers operating below the effective NOx control range of any installed low-NOx combustion controls.

4.5.4 Natural gas fueled compressor prime movers utilizing post-combustion NOx controls operating at loads below the effective NOx control range of the installed post-combustion controls.

4.4.5 During periods of operation covered by Sections 4.5.1 through 4.5.4 of this Guideline, hourly NOx mass emissions shall not exceed the hourly NOx mass emissions equivalent to the combustion turbine operating at its nameplate rating at the applicable NOx emissions rate from Sections 4.4.1.1, 4.4.2.1, or 4.4.3.1 of this rule.

5. Alternative RACT Emissions Limitation Determination

5.1 If the owner or operator of a natural gas fueled prime mover subject to this Guideline is unable to comply with the emissions rate limitations of Section 4 of this Guideline, the owner or operator shall submit an alternative NOx RACT determination, in accordance with Section 5 of this Guideline, for review and approval by the <OTC STATE AGENCY> and for the <OTC STATE AGENCY> to prepare a revised SIP submittal to the USEPA as required.

5.1.1 An alternative RACT proposal may address the NOx emissions from a specific, single natural gas fueled prime mover, or

5.1.2 An alternative RACT proposal may address NOx emissions averaging of multiple natural gas fueled prime movers under the control of a common

[1] 40 CFR Appendix Table 1 to Subpart KKKK of Part 60, Nitrogen Oxide Emission Limits for New Stationary Combustion Turbines. https://www.gpo.gov/fdsys/pkg/CFR-2014-title40-vol7/pdf/CFR-2014-title40-vol7-part60-subpartKKKK-app1.pdf

NMED Exhibit 54

owner or operator at a single facility to achieve the same level of NOx reductions that would be achieved if all of the natural gas fueled prime movers at the location met the applicable NOx emissions limitations of Section 4 of this rule.

5.2 Alternative RACT determinations made pursuant to Section 5.1 of this Guideline shall be submitted to <OTC STATE AGENCY> no later than MM-DD-YYYY for review and approval.

5.3 An alternative NOx RACT determination submitted in accordance with Section 5.1 of this Guideline shall include, as a minimum, the following information:

5.3.1 The name and address of the owner and operator

5.3.2 The address of the subject natural gas compressor prime mover

5.3.3 Latitude and longitude coordinates of the subject natural gas compressor prime mover

5.3.4 Prime mover technical information including

5.3.4.1 Prime mover manufacturer

5.3.4.2 Prime mover model

5.3.4.3 Prime mover serial number

5.3.4.4 Prime mover configuration (combustion turbine, two stroke lean burn, four stoke lean burn, four stroke rich burn)

5.3.4.5 Prime mover original installation/startup date

5.3.4.6 Prime mover nameplate power rating

5.3.4.7 NOx emissions controls

5.3.4.8 Actual, if available, or estimated NOx emissions rate

5.3.5 Identification of the available NO_x control technologies, the projected effectiveness of the technologies considered, and the estimated costs for installation and operation for each of the technologies

5.3.6 If applicable, description and discussion of any previous NOx reduction modifications, changes in operating practices, etc

5.3.7 Identification of equipment or process modifications that are proposed as RACT for implementation on the subject natural gas fueled prime mover, including a technical evaluation and an economic evaluation supporting the selection of the proposed RACT

5.3.8 Expected NOx emission rate(s) for the range of normal operation of the subject natural gas fueled prime mover.

5.3.9 Proposed testing, monitoring, and reporting procedures

5.3.10 The NOx emission rates for the subject existing natural gas fueled prime movers, prior to implementation of the alternative RACT, established with

NMED Exhibit 54

approved Continuous Emission Monitoring Systems (CEMS), stack test, or other method approved by the <OTC STATE AGENCY>.

5.3.11 Proposed implementation schedule.

5.3.12 Any other information requested by the <OTC STATE AGENCY>.

6. Testing Requirements

6.1 The owner or operator shall conduct an initial performance test to demonstrate compliance with the applicable NOx emissions limitations of Section 4 of this Guideline no later than MM-DD-YYYY.

6.1.1 The owner or operator shall submit a test protocol to the <OTC STATE AGENCY> at least 30 days prior to emissions testing.

6.2.2 The test methodology shall meet the applicable requirements of 40 CFR Part 60, Appendix A, and the guidance of 40 CFR Part 60 Subpart GG for combustion turbines and the guidance of 40 CFR Part 60 Subpart JJJJ for spark ignited internal combustion engines.

6.2.3 The owner or operator shall submit a compliance test report containing the results of the emissions test to the <OTC STATE AGENCY> no later than 60 days following completion of the emissions test.

6.2 The owner or operator of a natural gas compressor prime mover subject to an alternative RACT emissions limitation in accordance with the provisions of Section 5 of this Guideline shall conduct an initial performance test to demonstrate compliance with the provisions of the approved RACT determination.

6.2.1 The owner or operator shall submit a test protocol to the <OTC STATE AGENCY> at least 30 days prior to emissions testing.

6.2.2 The test methodology shall meet the applicable requirements of 40 CFR Part 60, Appendix A, and the guidance of 40 CFR Part 60 Subpart GG for combustion turbines and the guidance of 40 CFR Part 60 Subpart JJJJ for spark ignited internal combustion engines.

6.2.3 The owner or operator shall submit a compliance test report containing the results of the emissions test to the <OTC STATE AGENCY> no later than 60 days following completion of the emissions test.

6.3 Except as provided in Section 6.4, at least twice per year the owner or operator shall conduct periodic NOx emissions testing of subject natural gas fueled compressor prime movers to demonstrate compliance with the applicable NOx emissions limitations of Section 5 of this Guideline or the applicable alternative RACT NOx emission rate determined in accordance with Section 6 of this Guideline.

NMED Exhibit 54

6.3.1 The use of reference method equivalent portable analyzers is acceptable provided the portable analyzer is certified using appropriate reference method procedures in 40 CFR Part 60, Appendix A.

6.3.2 The owner or operator shall submit a test protocol to the <OTC STATE AGENCY> for review and approval prior to the first NOx emission test conducted in compliance with Section 6.3 as follows:

6.3.2.1 Test protocols utilizing reference test methods shall be submitted at least 30 days prior to the conduct of the emissions testing.

6.3.2.2 Test protocols utilizing reference method equivalent analyzers shall be submitted at least 30 days prior to the conduct of the first periodic emissions test under Section 6.3 using the reference method equivalent analyzer.

6.3.2.3 Test protocols utilizing reference method equivalent analyzers for testing subsequent to the first periodic emissions test conducted under Section 6.3 utilizing reference method equivalent analyzers are not required to be submitted to the <OTC STATE AGENCY> provided no changes to the protocol have been made subsequent to the initial <OTC STATE AGENCY> approval of such first period emissions test.

6.3.3 The owner or operator shall submit a test report containing the results of the emissions test to the <OTC STATE AGENCY> no later than 30 days following the completion of the emissions test.

6.3.4 Following the conduct of an initial periodic performance test conducted in accordance with Section 6.3, subsequent period performance rests conducted in accordance with Section 6.3 shall be conducted no less than 90 days following the conduct of the most recent NOx emissions performance test.

6.3.5 NOx emissions testing in compliance with the requirements of Section 6.3 of this Guideline may be conducted at any normal operating load from 40% to 100% of the subject natural gas fueled compressor prime mover's nameplate rating.

6.3.6 Each compliance test must include three test runs where each run lasts at least one hour. Compliance is demonstrated by the average of the three 1-hour or longer test runs.

6.4 If a natural gas fueled compressor prime mover demonstrates compliance with the applicable NOx emission limit of Section 5 or Section 6 of this Guideline for three consecutive tests, the testing frequency requirements of Section 6.3 of this Guideline may be reduced from at least twice per year to at least once per year.

NMED Exhibit 54

6.4.1 If a natural gas fueled compressor prime mover that has met the requirements to reduce testing in accordance with Section 6.4 of this Guideline fails to demonstrate compliance with applicable NOx emission limits in any subsequent emissions test, that natural gas compressor prime mover shall meet the testing frequency requirements of Section 6.3 of this Guideline.

6.4.1.1 If the compliance demonstration failure occurs during the first half of a calendar year, the testing frequency requirements of Section 6.3 become effective during that calendar year.

6.4.1.2 If the compliance demonstration failure occurs during the second half of a calendar year, the testing frequency requirements of Section 6.3 become effective during the subsequent calendar year.

6.4.2 All other testing requirements of Section 6.3 remain unchanged.

6.4.3 There are no limits on the number of time a natural gas fueled compressor prime mover may qualify for reduced testing frequency in accordance with Section 6.4 of this Guideline.

7. Exemptions

7.1 Natural gas fueled compressor prime movers that operate 438 or fewer hours per year are exempt from the emissions limitation requirements of Sections 4 and 5 of this Guideline and are exempt from the testing requirements of Section 6 of this Guideline.

7.2 The owner or operator of a natural gas fueled compressor prime mover seeking exemption in accordance with Section 7.1 of this Guideline shall install a non-resettable operating hour metering device on the prime mover. Annual operating hours for the natural gas fueled compressor prime mover shall be monitored, recorded, and reported to <OTC STATE AGENCY> no later than March 31 of each subsequent calendar year in accordance with the reporting requirements of Section 9.3 of this Guideline.

7.3 A natural gas fueled compressor prime mover that was previously exempt in accordance with Section 7.1 of this Guideline shall permanently lose that exemption if the natural gas fueled compressor prime mover exceeds 438 hours per year of operation in any calendar year.

7.3.1 The owner or operator shall submit a plan for the natural gas compressor prime mover's compliance with all applicable requirements of this Guideline no later than March 31 of the year following the calendar year in

NMED Exhibit 54

which the natural gas fueled compressor prime mover's exceeded 438 hours of annual operation.

7.3.2 Compliance with all applicable requirements of this Guideline shall be attained no later than December 31 of the year following the calendar year that the natural gas fueled compressor prime mover exceeded 438 hours of annual operation.

7.4 If a natural gas fueled compressor prime mover subject to this Guideline is required by state or federal regulation to monitor and report NOx emissions utilizing <OTC STATE AGENCY> approved CEMS, or the owner or operator of a natural gas fueled compressor prime mover subject to this Guideline elects to monitor and report NOx emissions utilizing <OTC STATE AGENCY> approved CEMS, the owner or operator of the subject natural gas fueled compressor prime mover may petition the <OTC STATE AGENCY> for exemption from the testing requirements of Section 6.3 of this Guideline.

8. Other Requirements

8.1 The owner or operator of a natural gas fueled compressor prime mover subject to this Guideline shall follow an inspection and maintenance plan, incorporating appropriate operating and maintenance experience and any applicable prime mover and emission control manufacturer recommendations, to ensure proper maintenance of the natural gas fueled compressor prime mover and related NOx emissions control equipment in a manner consistent with good air pollution control practices for minimizing emissions. Records and documentation supporting the inspection and maintenance plan shall be permanently maintained at the source facility. Records of inspections and maintenance performed shall be maintained as required by Section 9.1 of this Guideline.

8.2 The owner or operator shall follow operating practices and procedures for the natural gas fueled compressor prime mover and related emissions controls consistent with good air pollution control practices for minimizing NOx emissions across the entire load range of the natural gas fueled compressor prime mover, including, as much as practical, periods of startup, shutdown, and malfunction. Records and documentation supporting the subject operating practices and procedures shall be permanently maintained at the source facility.

8.3 If a natural gas fueled compressor prime mover requires major maintenance and natural gas system conditions require the temporary replacement of the natural gas fueled compressor prime mover, a temporary replacement prime mover may be installed as follows:

NMED Exhibit 54

8.3.1 The temporary replacement natural gas fueled compressor prime mover shall be similar to the prime mover being temporarily replaced, with similar NOx emissions controls and expected NOx emissions characteristics.

8.3.2 If the temporary replacement natural gas fueled compressor prime mover remains installed for a period exceeding 3 months

8.3.2.1 The temporary replacement natural gas fueled compressor prime mover shall meet the applicable NOx emissions limits specified in Section 4 of this Guideline

8.3.2.2 Compliance with the applicable NOx emissions limitations shall be demonstrated by NOx emissions testing in accordance with the requirements of Section 6.1 of this Guideline, except the testing shall take place within 30 days of exceeding the 3 months temporary replacement period

8.3.3 The owner or operator of a natural gas fueled compressor prime mover shall notify the <OTC STATE AGENCY> of a temporary prime mover replacement within 5 working days of performing the temporary replacement.

8.3.4 The owner or operator of a natural gas fueled compressor prime mover that is being returned to service after temporary replacement shall:

8.3.4.1 Notify the <OTC STATE AGENCY> within 5 working days of the prime movers return to service

8.3.4.2 Demonstrate compliance with the applicable NOx emissions limitations by NOx emissions testing conducted in accordance with Section 6.1 of this Guideline, except the performance test shall be conducted within 30 days of the return to service date.

8.4 If a natural gas fueled compressor prime mover is replaced as part of a routine maintenance prime mover exchange program, a replacement prime mover may be installed as follows:

8.3.1 The replacement natural gas fueled compressor prime mover shall be similar to the prime mover being temporarily replaced, with similar NOx emissions controls and expected NOx emissions characteristics.

8.3.1.1 The replacement natural gas fueled compressor prime mover shall meet the applicable NOx emissions limits specified in Section 4 of this Guideline or alternative NOx RACT plan approved in accordance with Section 5 of this Guideline.

8.3.1.2 Compliance with the applicable NOx emissions limitations shall be demonstrated by NOx emissions testing in accordance with the requirements of Section 6.2 of this Guideline, except the testing

NMED Exhibit 54

shall take place within 30 days of the replacement natural gas fueled compressor prime mover's initial startup after installation.

8.3.2 The owner or operator of a natural gas fueled compressor prime mover shall notify the <OTC STATE AGENCY> of a natural gas fueled compressor prime mover replacement within 5 working days of performing the replacement.

9. Recordkeeping and Reporting

9.1 The owner or operator of a natural gas fueled compressor prime mover subject to this Guideline shall maintain all records necessary for determining compliance with the provisions of this Guideline at the facility for a period of at least five years, unless otherwise specified in this Guideline.

9.2 No later than MM-DD-YYYY the owner or operator of a natural gas fueled compressor prime mover subject to this Guideline shall submit an initial compliance evaluation to the <OTC STATE AGENCY> for review and approval. The initial compliance evaluation shall include, as a minimum, the following information:

9.2.1 The name and address of the owner and operator

9.2.2 The address of the subject natural gas compressor prime mover

9.2.3 Longitude and latitude coordinates of the subject natural gas compressor prime mover

9.2.4 Prime mover technical information including

9.2.4.1 Prime mover manufacturer

9.2.4.2 Prime mover model

9.2.4.3 Prime mover serial number

9.2.4.4 Prime mover configuration (combustion turbine, two stroke lean burn, four stoke lean burn, four stroke rich burn)

9.2.4.5 Prime mover original installation/startup date

9.2.4.6 Prime mover nameplate power rating

9.2.4.7 NOx emissions controls

9.2.4.8 Actual, if available, or estimated NOx emissions rate

9.2.5 Plan for compliance with the requirements of this Guideline

9.2.5.1 Proposed compliance strategy or identification of proposed NOx controls

9.2.5.2 Estimated NOx emissions after installation of controls or strategy

9.2.5.3 Proposed compliance schedule

NMED Exhibit 54

9.2.6 Any other information requested by the <OTC STATE AGENCY>.

9.2.7 An alternative RACT emission limitation determination submitted in compliance with the requirements of Section 5 of this Guideline shall fulfill the initial compliance evaluation submittal requirements of Section 9.2 of this Guideline.

9.3 Beginning on MM-DD-YYYY, on March 31 of each calendar year the owner or operator of a natural gas fueled compressor prime mover subject to this Guideline shall submit an annual report to the <OTC STATE AGENCY> containing the following information:

9.3.1 The name and address of the owner and operator

9.3.2 The address of the subject natural gas fueled compressor prime mover

9.3.3 Longitude and latitude coordinates of the subject natural gas compressor prime mover

9.3.4 Identification of the subject natural gas fueled compressor prime mover

9.3.5 Statement of compliance with the applicable emission rate limitations of this Guideline

9.3.6 Statement of compliance regarding the conduct of maintenance and operations in a manner consistent with good air pollution control practices for minimizing emissions, as established in accordance with Section 8 of this Guideline.

9.3.7 For subject natural gas fueled compressor prime movers seeking exemption for prime movers operating less than 438 hours per year in accordance with the requirements of Section 8 of this Guideline, provide applicable hour-meter readings and the calculated prime mover operating hours for the previous calendar year.

9.3.8 If applicable, a statement documenting any change in the operating characteristics of the subject natural gas fueled compressor prime mover.

9.3.9 A statement certifying that the information included in the annual report is complete and accurate.

9.3.10 The annual reports for multiple subject natural gas fueled compressor prime movers at a single source may be combined into a single annual report.

NMED Exhibit 54

3.3 Gasoline And Diesel Industrial Engines

3.3.1 General

The engine category addressed by this section covers a wide variety of industrial applications of both gasoline and diesel internal combustion (IC) engines such as aerial lifts, fork lifts, mobile refrigeration units, generators, pumps, industrial sweepers/scrubbers, material handling equipment (such as conveyors), and portable well-drilling equipment. The three primary fuels for reciprocating IC engines are gasoline, diesel fuel oil (No.2), and natural gas. Gasoline is used primarily for mobile and portable engines. Diesel fuel oil is the most versatile fuel and is used in IC engines of all sizes. The rated power of these engines covers a rather substantial range, up to 250 horsepower (hp) for gasoline engines and up to 600 hp for diesel engines. (Diesel engines greater than 600 hp are covered in Section 3.4, "Large Stationary Diesel And All Stationary Dual-fuel Engines".) Understandably, substantial differences in engine duty cycles exist. It was necessary, therefore, to make reasonable assumptions concerning usage in order to formulate some of the emission factors.

3.3.2 Process Description

All reciprocating IC engines operate by the same basic process. A combustible mixture is first compressed in a small volume between the head of a piston and its surrounding cylinder. The mixture is then ignited, and the resulting high-pressure products of combustion push the piston through the cylinder. This movement is converted from linear to rotary motion by a crankshaft. The piston returns, pushing out exhaust gases, and the cycle is repeated.

There are 2 methods used for stationary reciprocating IC engines: compression ignition (CI) and spark ignition (SI). This section deals with both types of reciprocating IC engines. All diesel-fueled engines are compression ignited, and all gasoline-fueled engines are spark ignited.

In CI engines, combustion air is first compression heated in the cylinder, and diesel fuel oil is then injected into the hot air. Ignition is spontaneous because the air temperature is above the autoignition temperature of the fuel. SI engines initiate combustion by the spark of an electrical discharge. Usually the fuel is mixed with the air in a carburetor (for gasoline) or at the intake valve (for natural gas), but occasionally the fuel is injected into the compressed air in the cylinder.

CI engines usually operate at a higher compression ratio (ratio of cylinder volume when the piston is at the bottom of its stroke to the volume when it is at the top) than SI engines because fuel is not present during compression; hence there is no danger of premature autoignition. Since engine thermal efficiency rises with increasing pressure ratio (and pressure ratio varies directly with compression ratio), CI engines are more efficient than SI engines. This increased efficiency is gained at the expense of poorer response to load changes and a heavier structure to withstand the higher pressures.[1]

3.3.3 Emissions

Most of the pollutants from IC engines are emitted through the exhaust. However, some total organic compounds (TOC) escape from the crankcase as a result of blowby (gases that are vented from the oil pan after they have escaped from the cylinder past the piston rings) and from the fuel tank and carburetor because of evaporation. Nearly all of the TOCs from diesel CI engines enter the

NMED Exhibit 55 - 0001

atmosphere from the exhaust. Evaporative losses are insignificant in diesel engines due to the low volatility of diesel fuels.

The primary pollutants from internal combustion engines are oxides of nitrogen (NO_x), total organic compounds (TOC), carbon monoxide (CO), and particulates, which include both visible (smoke) and nonvisible emissions. Nitrogen oxide formation is directly related to high pressures and temperatures during the combustion process and to the nitrogen content, if any, of the fuel. The other pollutants, HC, CO, and smoke, are primarily the result of incomplete combustion. Ash and metallic additives in the fuel also contribute to the particulate content of the exhaust. Sulfur oxides (SO_x) also appear in the exhaust from IC engines. The sulfur compounds, mainly sulfur dioxide (SO_2), are directly related to the sulfur content of the fuel.[2]

3.3.3.1 Nitrogen Oxides -

Nitrogen oxide formation occurs by two fundamentally different mechanisms. The predominant mechanism with internal combustion engines is thermal NO_x which arises from the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules in the combustion air. Most thermal NO_x is formed in the high-temperature region of the flame from dissociated molecular nitrogen in the combustion air. Some NO_x, called prompt NO_x, is formed in the early part of the flame from reaction of nitrogen intermediary species, and HC radicals in the flame. The second mechanism, fuel NO_x, stems from the evolution and reaction of fuel-bound nitrogen compounds with oxygen. Gasoline, and most distillate oils have no chemically-bound fuel N_2 and essentially all NO_x formed is thermal NO_x.

3.3.3.2 Total Organic Compounds -

The pollutants commonly classified as hydrocarbons are composed of a wide variety of organic compounds and are discharged into the atmosphere when some of the fuel remains unburned or is only partially burned during the combustion process. Most unburned hydrocarbon emissions result from fuel droplets that were transported or injected into the quench layer during combustion. This is the region immediately adjacent to the combustion chamber surfaces, where heat transfer outward through the cylinder walls causes the mixture temperatures to be too low to support combustion.

Partially burned hydrocarbons can occur because of poor air and fuel homogeneity due to incomplete mixing, before or during combustion; incorrect air/fuel ratios in the cylinder during combustion due to maladjustment of the engine fuel system; excessively large fuel droplets (diesel engines); and low cylinder temperature due to excessive cooling (quenching) through the walls or early cooling of the gases by expansion of the combustion volume caused by piston motion before combustion is completed.[2]

3.3.3.3 Carbon Monoxide -

Carbon monoxide is a colorless, odorless, relatively inert gas formed as an intermediate combustion product that appears in the exhaust when the reaction of CO to CO_2 cannot proceed to completion. This situation occurs if there is a lack of available oxygen near the hydrocarbon (fuel) molecule during combustion, if the gas temperature is too low, or if the residence time in the cylinder is too short. The oxidation rate of CO is limited by reaction kinetics and, as a consequence, can be accelerated only to a certain extent by improvements in air and fuel mixing during the combustion process.[2-3]

NMED Exhibit 55 - 0002

3.3.3.4 Smoke and Particulate Matter -

White, blue, and black smoke may be emitted from IC engines. Liquid particulates appear as white smoke in the exhaust during an engine cold start, idling, or low load operation. These are formed in the quench layer adjacent to the cylinder walls, where the temperature is not high enough to ignite the fuel. Blue smoke is emitted when lubricating oil leaks, often past worn piston rings, into the combustion chamber and is partially burned. Proper maintenance is the most effective method of preventing blue smoke emissions from all types of IC engines. The primary constituent of black smoke is agglomerated carbon particles (soot) formed in regions of the combustion mixtures that are oxygen deficient.[2]

3.3.3.5 Sulfur Oxides -

Sulfur oxides emissions are a function of only the sulfur content in the fuel rather than any combustion variables. In fact, during the combustion process, essentially all the sulfur in the fuel is oxidized to SO_2. The oxidation of SO_2 gives sulfur trioxide (SO_3), which reacts with water to give sulfuric acid (H_2SO_4), a contributor to acid precipitation. Sulfuric acid reacts with basic substances to give sulfates, which are fine particulates that contribute to PM-10 and visibility reduction. Sulfur oxide emissions also contribute to corrosion of the engine parts.[2-3]

3.3.4 Control Technologies

Control measures to date are primarily directed at limiting NO_x and CO emissions since they are the primary pollutants from these engines. From a NO_x control viewpoint, the most important distinction between different engine models and types of reciprocating engines is whether they are rich-burn or lean-burn. Rich-burn engines have an air-to-fuel ratio operating range that is near stoichiometric or fuel-rich of stoichiometric and as a result the exhaust gas has little or no excess oxygen. A lean-burn engine has an air-to-fuel operating range that is fuel-lean of stoichiometric; therefore, the exhaust from these engines is characterized by medium to high levels of O_2. The most common NO_x control technique for diesel and dual-fuel engines focuses on modifying the combustion process. However, selective catalytic reduction (SCR) and nonselective catalytic reduction (NSCR) which are post-combustion techniques are becoming available. Controls for CO have been partly adapted from mobile sources.[4]

Combustion modifications include injection timing retard (ITR), preignition chamber combustion (PCC), air-to-fuel ratio adjustments, and derating. Injection of fuel into the cylinder of a CI engine initiates the combustion process. Retarding the timing of the diesel fuel injection causes the combustion process to occur later in the power stroke when the piston is in the downward motion and combustion chamber volume is increasing. By increasing the volume, the combustion temperature and pressure are lowered, thereby lowering NO_x formation. ITR reduces NO_x from all diesel engines; however, the effectiveness is specific to each engine model. The amount of NO_x reduction with ITR diminishes with increasing levels of retard.[4]

Improved swirl patterns promote thorough air and fuel mixing and may include a precombustion chamber (PCC). A PCC is an antechamber that ignites a fuel-rich mixture that propagates to the main combustion chamber. The high exit velocity from the PCC results in improved mixing and complete combustion of the lean air/fuel mixture which lowers combustion temperature, thereby reducing NO_x emissions.[4]

NMED Exhibit 55 - 0003

The air-to-fuel ratio for each cylinder can be adjusted by controlling the amount of fuel that enters each cylinder. At air-to-fuel ratios less than stoichiometric (fuel-rich), combustion occurs under conditions of insufficient oxygen which causes NO_x to decrease because of lower oxygen and lower temperatures. Derating involves restricting the engine operation to lower than normal levels of power production for the given application. Derating reduces cylinder pressures and temperatures, thereby lowering NO_x formation rates.[4]

SCR is an add-on NO_x control placed in the exhaust stream following the engine and involves injecting ammonia (NH_3) into the flue gas. The NH_3 reacts with NO_x in the presence of a catalyst to form water and nitrogen. The effectiveness of SCR depends on fuel quality and engine duty cycle (load fluctuations). Contaminants in the fuel may poison or mask the catalyst surface causing a reduction or termination in catalyst activity. Load fluctuations can cause variations in exhaust temperature and NO_x concentration which can create problems with the effectiveness of the SCR system.[4]

NSCR is often referred to as a three-way conversion catalyst system because the catalyst reactor simultaneously reduces NO_x, CO, and HC and involves placing a catalyst in the exhaust stream of the engine. The reaction requires that the O_2 levels be kept low and that the engine be operated at fuel-rich air-to-fuel ratios.[4]

The most accurate method for calculating such emissions is on the basis of "brake-specific" emission factors (pounds per horsepower-hour [lb/hp-hr]). Emissions are the product of the brake-specific emission factor, the usage in hours, the rated power available, and the load factor (the power actually used divided by the power available). However, for emission inventory purposes, it is often easier to assess this activity on the basis of fuel used.

Once reasonable usage and duty cycles for this category were ascertained, emission values were aggregated to arrive at the factors for criteria and organic pollutants presented. Factors in Table 3.3-1 are in pounds per million British thermal unit (lb/MMBtu). Emission data for a specific design type were weighted according to estimated material share for industrial engines. The emission factors in these tables, because of their aggregate nature, are most appropriately applied to a population of industrial engines rather than to an individual power plant. Table 3.3-2 shows unweighted speciated organic compound and air toxic emission factors based upon only 2 engines. Their inclusion in this section is intended for rough order-of-magnitude estimates only.

Table 3.3-3 summarizes whether the various diesel emission reduction technologies (some of which may be applicable to gasoline engines) will generally increase or decrease the selected parameter. These technologies are categorized into fuel modifications, engine modifications, and exhaust after-treatments. Current data are insufficient to quantify the results of the modifications. Table 3.3-3 provides general information on the trends of changes on selected parameters.

NMED Exhibit 55 - 0004

3.3.5 Updates Since the Fifth Edition

The Fifth Edition was released in January 1995. Revisions to this section since that date are summarized below. For further detail, consult the memoranda describing each supplement or the background report for this section.

Supplement A, February 1996

No changes.

Supplement B, October 1996

- Text was revised concerning emissions and controls.
- The CO_2 emission factor was adjusted to reflect 98.5 percent conversion efficiency.

NMED Exhibit 55 - 0005

Table 3.3-1. EMISSION FACTORS FOR UNCONTROLLED GASOLINE AND DIESEL INDUSTRIAL ENGINES[a]

Final Technical Support Document (TSD)
for the Cross-State Air Pollution Rule for the 2008 Ozone NAAQS
Docket ID No. EPA-HQ-OAR-2015-0500

Assessment of Non-EGU NOx Emission Controls, Cost of Controls, and Time for Compliance Final TSD

U.S. Environmental Protection Agency
Office of Air and Radiation
August 2016

NMED Exhibit 60 - 0001

1 Introduction/Purpose

The purpose of this Technical Support Document (TSD) is to discuss the currently available information on emissions and control measures for sources of NO_X other than electric generating units (EGUs). This information provides more detail about why EGUs are the focus of the final rulemaking, namely the uncertainty that exists regarding whether significant aggregate NO_X mitigation is achievable from non-EGU point sources by the 2017 ozone season, and the fact that the limited available information points to an apparent scarcity of non-EGU reductions that could be accomplished in this timeframe. Notwithstanding these conclusions as regards the 2017 ozone season, the EPA continues to assess the role of NO_X emissions from non-EGU sources to downwind nonattainment problems.

This TSD begins by briefly discussing the non-EGU emissions inventories used in the proposed and final Cross-State Air Pollution Rule (CSAPR) Update analyses, both for the 2011 base year and 2017 future baseline assessed for this rule. The TSD then presents an evaluation of whether non-EGU emissions can be reduced in a cost-effective manner for particular categories. Then, it assesses the available NO_X emission reductions from such categories and presents the category-by-category emissions reduction potential. This assessment considers and presents the annualized costs per ton of these reductions, with a focus on technologies that achieve cost-effective reductions within a range of costs similar to that evaluated for EGUs. The TSD then presents estimates of the time required to install and implement the control measures, both for comparison to the 2017 compliance timeframe, and for discussion of installation time should such measures be required in the future. It should be noted that no changes to these data or estimates have been made for this final TSD compared to the draft version of this TSD provided in the docket for the proposed rule. Finally, the TSD presents a summary of comments received on the proposed rule TSD, along with responses as appropriate.

For the reasons stated in the preamble, the data and discussion in this TSD are intended to focus on the eastern states that are included in the CSAPR Update rule. Information inclusive of western states[1] is presented where available and appropriate.

[1] For the purpose of this action, the western United States (or the West) consists of the 11 western contiguous states of Arizona, California, Colorado, Idaho, Montana, New Mexico, Nevada, Oregon, Utah, Washington, and Wyoming, and the eastern U.S. (or East) consists of the remaining states in the contiguous U.S.

NMED Exhibit 60 - 0002

2 Background

In this section we present annual and ozone-season NO_X emission inventory totals and the relative percentages for non-EGU source categories statewide and/or nationally. This information is summary in nature and is not meant to replace other, more detailed information available from the EPA, such as the EPA's 2011v6.2 Emissions Modeling Platform TSD[2] as well as the Notice of Data Availability[3] (NODA) and Regulatory Impact Analysis[4] (RIA) for the proposed and final rule.

Table 1 lists 2011 and 2017 projected NO_X emissions by sector, in summary form, for the 48 contiguous states of the United States (CONUS).

Table 1: 2011 Base Year and 2017 Projected NO_X Emissions by Sector (tons), for the 48 CONUS

Sector	2011 NO_X, annual	2017 NO_X, annual	2011 NO_X, ozone season	2017 NO_X, ozone season
EGU-point	2,000,000	1,500,000	942,000	689,000
NonEGU-point	1,200,000	1,200,000	515,000	502,000
Point oil and gas	500,000	410,000	213,000	172,000
Wild and prescribed fires	330,000	330,000	165,000	165,000
Nonpoint oil and gas	650,000	690,000	275,000	293,000
Residential wood combustion	34,000	35,000	3,000	3,000
Other nonpoint	760,000	730,000	204,000	211,000
Nonroad	1,600,000	1,100,000	825,000	582,000
Onroad	5,700,000	3,200,000	2,417,000	1,329,000
C3 commercial marine vessel (CMV)	130,000	130,000	58,000	58,000
Locomotive and C1/C2 CMV	1,100,000	910,000	451,000	384,000
Biogenics	1,000,000	1,000,000	630,000	630,000
TOTAL	**15,000,000**	**11,200,000**	**6,698,000**	**5,018,000**

It is clear from Table 1 that NOx emissions are projected to remain constant or decrease for most sectors in the 48 states between 2011 and 2017, and this is true whether examining annual or ozone season (OS) tons. Emissions from the non-EGU point source sector and the other nonpoint source sector are not projected to change significantly, while emissions

The official versions are available in the docket for this rulemaking.

NMED Exhibit 60 - 0003

from the nonpoint oil and gas source sector are projected to grow (approximately 6%)during this time period. Based on the values in Table 1, Figures 1 and 2 show the relative contributions of the various sectors to overall NOx emissions (left panel) in the CONUS and for the non-EGU sectors (right panel) for 2011 and 2017, respectively.

Figure 1: 2011 NOx emissions by sector, with further non-EGU breakout (48 states)

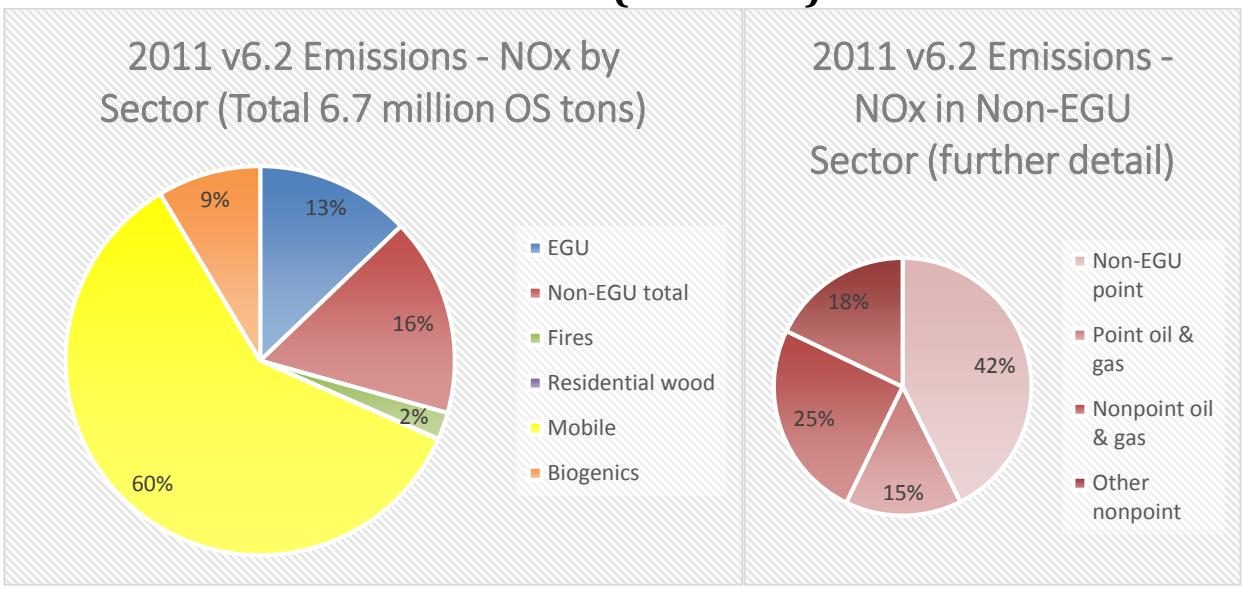

Figure 2: Projected 2017 NOx emissions by sector, with further non-EGU breakout (48 states)

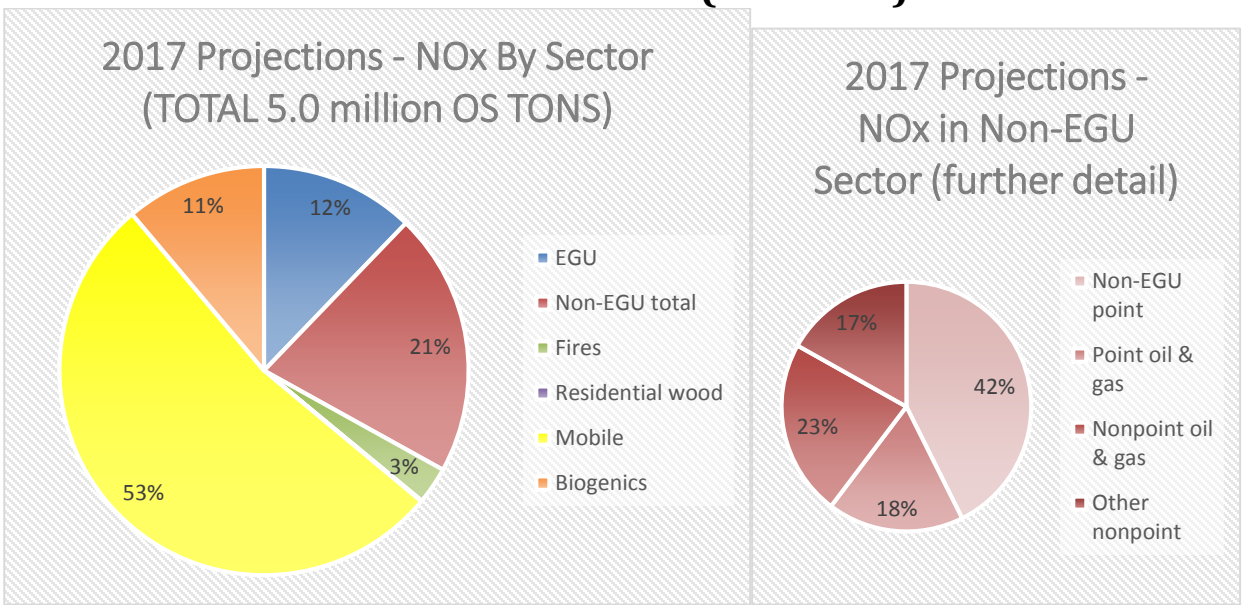

Figure 1 depicts the CONUS total ozone season NOx emissions of 6,698,000 tons in 2011 and Figure 2 depicts the CONUS total ozone season NOx emissions of 5,018,000 tons in 2017. In both 2011 and 2017, the mobile source sector has the largest NOx emissions.[5] Substantial reductions in mobile source NOx emissions are projected to occur by 2017. Mobile source emissions are projected to decrease because of sector-specific standards related to fuels, fuel economy, pollution controls, and repair and replacement of the existing fleet. Because these reductions are already expected to occur, mobile source emission reductions are not included in this analysis of non-EGU emission reductions achievable by the 2017 ozone season.

For the purposes of preliminary analysis in this TSD, "non-EGU total" refers to four separate categories of sources: non-EGU point, point oil and gas, nonpoint oil and gas, and other nonpoint (and does not include mobile sources). The oil and gas point and nonpoint sources are separated from the remaining non-EGU point and nonpoint sources due to the magnitude of their contribution to the inventory and other aspects related to the inventory development, emissions modeling, and future year projections for that industry. The point oil and gas sources are also separated out from the other non-EGU point sources according to the North American Industry Classification System (NAICS) code specified for the various sources. Note that point oil and gas sources include a variety of types of processes, and there is overlap with the processes included in the rest of the non-EGU point inventory. More information on the emissions sectors is available in the 2011v6.2 Emissions Modeling Platform TSD.

Comparing the proportions of the total inventory for non-EGUs (Figures 1 and 2), it becomes clear that, although they are decreasing in the absolute sense, non-EGU NOx emissions are becoming a larger share of overall ozone-season NOx emissions (16% in 2011 compared with 21% in 2017).

Table 2 compares statewide projected total anthropogenic NOx emissions (inclusive of all sectors listed in Table 1 with the exception of fires and biogenics) for the 2017 ozone season to non-EGU NOx emissions for the 2017 ozone season for each of the 48 contiguous United States . Totals are given for the 48 contiguous United States (the 37 eastern states plus the District of Columbia that are addressed in the rule are highlighted below in blue). Non-EGU sources in this table are broken down into two groups (non-EGU point sources, including point oil & gas sources, and other nonpoint and nonpoint oil & gas sources).

[5] The mobile source sector comprises multiple different types of sources (onroad cars & trucks, boats, ships, trains, construction equipment, mining equipment, tractors, etc.).

NMED Exhibit 60 - 0005

Table 2 indicates that, in the projected 2017 inventory, non-EGU sources comprising non-EGU point and point oil and gas sources are estimated to make up 16% of anthropogenic NOx emissions in the 48 contiguous United States. In individual states, the percentage of anthropogenic emissions contributed by these two non-EGUs categories range from 3% to 26% (eastern states) and from 7% to 38% (western states).

We also note that in the projected 2017 inventory, non-EGU sources comprising nonpoint oil & gas and other nonpoint sources are estimated to make up 12% of anthropogenic NOx emissions in the entire continental U.S. In individual states, the percentage of anthropogenic emissions contributed by these non-EGUs ranges from 2% to 25% (eastern states) and from 4% to 31% (western states).

The EPA's preliminary analysis indicates that NOx emissions from oil and gas sources (inclusive of emissions from the point oil and gas and nonpoint oil and gas sectors) comprise an average of 11% of the total ozone season NOx emissions inventory. For some states, this percentage increases up to 43%, with oil and gas emissions exceeding non-EGU point totals in a number of states. The key sources of NOx emissions in the oil and gas sector are from the combustion of fossil fuel (primarily drilling rigs, internal combustion (IC) engines and pipeline compressors) and flares. Please refer to the EPA's 2011v6.2 Emissions Modeling Platform TSD for more information on emissions from these sectors.

NMED Exhibit 60 - 0007

3 Preliminary Analysis

For the purposes of the proposed rule, the EPA performed a preliminary analysis to characterize whether there are non-EGU source groups with a substantial amount of available cost-effective NOx reductions achievable by the 2017 ozone season. The EPA received no comments that would substantively change this analysis, therefore there was no need to repeat this preliminary analysis for the final CSAPR Update rule.

3.1 Methodology

The EPA's preliminary analysis of potential non-EGU NOx emission reductions was performed using the Control Strategy Tool (CoST). CoST is the software tool the EPA uses to estimate the emission reductions and costs associated with future-year control strategies, and then to generate emission inventories that result from the control strategies applied. CoST tracks information about control measures, their costs, and the types of emissions sources to which they apply. The purpose of CoST is to support national- and regional-scale multi-pollutant analyses, primarily for Regulatory Impact Analyses (RIAs) of the National Ambient Air Quality Standards (NAAQS). CoST is also a component of the Emissions Modeling Framework (EMF) that was used to generate the 2017 non-EGU emissions presented above and in the Emissions Modeling Platform TSD for the proposed CSAPR Update rule. Further discussion and documentation of CoST is available on the EPA's website at http://www.epa.gov/ttnecas1/cost.htm.

Appendices to this TSD discuss recommendations for updates to CoST, including corrections for inapplicable controls, sources already controlled by state rules, sources with permit emissions limits or that have clearly identified controls in place, and sources subject to future NOx emission limits. Appendix A discusses contractor RTI International's work to review estimates for lean burn internal combustion (IC) engines, glass manufacturing, ammonia reformers, and gas turbines.[7] Appendix B discusses contractor SRA International's work on a variety of other categories including many of the others evaluated in this TSD.[8]

EPA has prepared a set of data called the Control Measure Data Base (CMDB) that is used as an important input to CoST. This data includes all control measures utilized by the tool for control strategy analysis. It should be noted that most of the NOx measures included in this report are currently in the Control Measure Data Base used by CoST, and generally do not reflect the updates suggested in these contractor reports. Obstacles to full incorporation of the recommended changes include availability of accurate costs for these measures, and to have cost equations rather than average cost/ton to estimate costs. Control efficiencies are readily available for measures, but costs, particularly those that can be estimated using equations that consider source size or capacity, often are not. In addition, the Pennsylvania

[7] "Update of NOx Control Measure Data in the CoST Control Measure Database for Four Industrial Source Categories: Ammonia Reformers, NonEGU Combustion Turbines, Glass Manufacturing, and Lean Burn Reciprocating Internal Combustion Engines," Revised Draft Report, RTI International, 2014.

NMED Exhibit 60 - 0008

Department of Environmental Protection's Additional RACT Requirements for Major Sources of NOx and VOCs rule,[9] which was recently finalized, is not included in these contractor reports. The EPA will consider whether or not to incorporate these recommendations for changes or additions to the NOx controls for non-EGUs to support NOx control efforts for future rules and other efforts. The EPA will also consider updates to reflect state emission control requirements (i.e., Pennsylvania's RACT rule). Nonetheless, the information from these reports helped inform our assessment in terms of uncertainty surrounding non-EGU emission reduction potential. Further details on the CMDB can be found on the CoST web site shown above.

For the purpose of identifying a list of non-EGU NOx source groups with controls available, the EPA ran CoST for non-EGU point sources for the 37 eastern U.S. with NOx emissions of greater than 25 tons/year in 2017. The analysis using CoST was a basis for the review of NOx control measures for non-EGUs undertaken by two different contractors for EPA. Through a contractual agreement with EPA, SRA International and RTI International provided reports within which CoST examined a number of source categories of non-EGUs with annualized control costs up to $10,000 per ton (in 2011 dollars). These reports are included in the Appendices of this TSD. CoST selected particular control technologies based on application of a least-cost criterion for control measures applied as part of the control strategy. Other NOx control measures are available for some of these categories, but on average, annualized costs for these measures were at higher cost.

3.2 Uncertainties and Limitations

The EPA acknowledges several important limitations of the non-EGU cost analysis included in this TSD, which include the following:

Boundary of the cost analysis: In this cost analysis we include only the impacts to the regulated industry, such as the costs for purchase, installation, operation, and maintenance of control equipment over the lifetime of the equipment. Recordkeeping, reporting, testing and monitoring costs are not included. Additional profit or income may be generated by industries supplying the regulated industry, especially for control equipment manufacturers, distributors, or service providers. These types of secondary impacts are not included in this cost analysis.

Cost and effectiveness of control measures: Our application of control measures reflect nationwide average retrofit factors and equipment life. We do not account for regional or local variation in capital and annual cost items such as energy, labor, materials, and others. Our estimates of control measure costs may over- or under-estimate the costs depending on how the difficulty of actual retrofitting and equipment life compares with our control assumptions. In addition, our estimates of control efficiencies for control measures included in our analysis assume that the control devices are properly installed and maintained. There is also variability in scale of application that is difficult to reflect for small area sources of emissions.

[9] Available at: http://www.pabulletin.com/secure/data/vol46/46-17/694.html

NMED Exhibit 60 - 0009

Discount (interest) rate: Because we obtain control cost data from many sources, we are not always able to obtain consistent data across original data sources. If disaggregated control cost data are not available (i.e., where capital, equipment life value, and operation and maintenance [O&M] costs are not shown separately), the EPA assumes that the estimated control costs are annualized using a 7 percent discount rate, which is the discount (interest) rate used in accordance with OMB guidance in Circular A-4. In general, we have some disaggregated data available for non-EGU point source controls. In addition, while these interest rates are consistent with OMB guidance, the actual interest rates may vary regionally or locally.

Accuracy of control costs: We estimate that there is an accuracy range of +/- 30 percent for non-EGU point source control costs. This level of accuracy is described in the EPA Air Pollution Control Cost Manual, which is a basis for the estimation of non-EGU control cost estimates included in this TSD. This level of accuracy is consistent with either the budget or bid/tender level of cost estimation as defined by the American Association for Cost Engineering (AACE) International. In addition, the accuracy of costs is also influenced by the availability of data underlying the cost estimates for individual control measures. For some control measures, we recognize that there is limited data available to generate robust cost estimates. This is reflected in the derivation of costs for some of the non-EGU NOx control measures discussed in Appendix A for this TSD.

3.3 CoST Results

The results of the CoST analysis are displayed in Table 3. In Table 3, we display the source groups selected by CoST, the Source Classification Codes (SCCs) included in those groups[10], the least-cost control technology for a given source group (selected by CoST), the current estimate (in dollars per ton, using 2011 dollars) of the annualized cost per ton NOx reduced of the control technology, the current estimate of the time necessary to install the selected control technology (not including permitting time), the estimated ozone season emissions in the East from the non-EGU source group in 2017 in the absence of the installation of the selected controls, and the estimated potential ozone season reductions in the East from the non-EGU source group in 2017 assuming the CoST selected controls could be fully installed and operational prior to the 2017 ozone season (which as discussed in more detail later, is not the case for many of the categories examined). Note that CoST does not account for installation time or time required for the permitting process. Instead it provides information on the control measures applicable to sources in the inventory, along with the cost of installation and operation and maintenance of the selected measures.

[10] The CoST results do not indicate applicability of the recommended control technology to all sources in the source group but only to the specific SCCs for which control technologies are applicable. For example, for the cement kilns source group, Biosolid Injection Technology (BSI) is applicable only for the types of cement kilns covered by the listed SCCs.

NMED Exhibit 60 - 0010

Table 3: CoST Results: Non-EGU Source Groups with NOx Reductions

Non-EGU Source Group	SCCs	Control Technology Recommended by CoST	Current estimate of NOx $/ton, CoST (2011 $)	Time to install[11] [12](excluding permitting, reporting preparation, programmatic and administrative considerations[13])	2017[14] NOx Emissions (37 States + DC), OS tons, CoST	2017 Potential Reductions [15] (37 States + DC), OS tons, CoST
Cement Kilns	30500622 (preheater kiln), 30500623 (preheater/precalciner); 39000201 (kiln/dryer); 39000288 (kiln in process coal)	Biosolid Injection Technology (BSI)	$410	Uncertain	24,760	4,207

[11] Time to install is not an output of CoST, but are rather estimates determined by the EPA based on research from a variety of sources. See, "Typical Installation Timelines for NOx Emissions Control Technologies on Industrial Sources," Institute of Clean Air Companies, December 2006 (all sources except Cement Kilns and RICE (Reciprocating Internal Combustion Engines)), "Cement Kilns Technical Support Document for the NOx FIP," EPA, January 2001 (cement kilns), and "Availability and Limitations of NOx Emission Control Resources for Natural Gas-Fired Reciprocating Engine Prime Movers Used in the Interstate Natural Gas Transmission Industry," Innovative Environmental Solutions Inc., July 2014 (prepared for the INGAA Foundation).

[12] In general, for control retrofits to non-EGU sectors, it appears that the full sector-wide compliance time is uncertain, but is longer than the installation time shown above for a typical unit. We have insufficient information on capacity and experience within the OEM suppliers and major engineering firms supply chain to offer conclusions on their availability to execute the project work for non-EGU sectors.

[13] Non-EGUs of any type – boiler or turbine – that are not currently required to monitor and report in accordance with 40 CFR Part 75 and/or not currently participating in the CSAPR program will require additional time relative to EGUs that are currently equipped with Part 75 monitoring and reporting and/or participating in the current CSAPR program. Installation of NOx monitors for the reporting of NOx mass requires the construction of platforms, CEM shelters, procurement of equipment, certification testing, and electronic data reporting programming of a data handling system. These added timing considerations for infrastructure on the non-EGU sources combined with the additional programmatic adoption measures necessary make installation of controls by the 2017 timeframe established in this rule less likely and more uncertain for industrial sources.

[14] Emissions and potential reductions for Gas Turbines ($163/ton grouping), Cement Kiln/Dryer (Bituminous Coal) ($942/ton grouping), Coal Cleaning – Thermal Dryer (2), Spreader Strokers, Petroleum Refinery Process Heaters, Incinerators, Boilers & Process Heaters, Gas-Fired Process Heaters, Coal Boilers, By-Product Coke Manufacturing, ICI Boilers – Residual Oil, Ammonia Production, Glass Manufacturing, ICI Boilers, Iron & Steel - In-Process Combustion - Bituminous Coal, Industrial Processes Miscellaneous, Catalytic Cracking, Process Heaters, & Coke Ovens, Petroleum Refinery Gas-Fired Process Heaters, Glass Manufacturing – Pressed, Glass Manufacturing – Container, Petroleum Refinery Gas-Fired Process Heaters, and RICE source groups were calculated for 2018, however they are likely to be virtually identical to projections for 2017. Non-EGU source groups with projected aggregate 2017 NOx emissions below 100 OS tons are excluded from this table.

[15] Potential reductions assume fully implemented controls by the start of the 2017 ozone season.

3.4 Discussion of Non-EGU Source Groups

The below discussion utilizes the information in Table 3 in order to assess whether significant aggregate NOx mitigation is achievable from non-EGU sources by the 2017 ozone season.

It is clear that a number of source categories have been identified by CoST using the least-cost procedure that have the potential for non-EGU stationary source emissions reductions. There are some notable source categories that have the potential for substantial non-EGU stationary source emissions reductions below $10,000 per ton.[16] However, for the purposes of this analysis, the EPA did not further examine control options above $3,400 per ton. This is consistent with the range we analyzed for EGUs in the proposed and final rules, and is also consistent with what the EPA has identified in previous transport rules as highly cost-effective, including the NOx SIP call.[17] Again, this was done because the objective of this analysis is to characterize whether significant aggregate NOx mitigation is achievable from non-EGU sources by the 2017 ozone season, so we focused the search on categories with highly cost-effective technologies. This focus excludes several source groups with high emissions reduction potential because reductions from those source groups are not available for $3,400 per ton or less, including: ICI boilers using SCR & LNB; Catalytic Cracking, Process Heaters, & Coke Ovens using LNB & FGR; and Pressed and Container Glass Manufacturing using OXY-Firing.

At a cost level of $3,400 per ton or less, there are a number of source groups with substantial reduction potential. However the table also identifies several source groups whose reduction potential is not significant, and which the EPA did not weigh heavily in assessing the aggregate non-EGU NOx emission reduction potential. This is because the aggregate potential reductions from these "insignificant" source groups is small. These "insignificant" source groups comprise those source groups with many small sources, as well those containing a limited number of larger sources; for either of these types of groups, potential aggregate emission reductions are small relative to reductions available from other source categories. The EPA does not believe that small sources have significant emission reduction potential in the aggregate because most small sources emit less than 100 tons of NOx per year. (It is worth noting that small sources account for a significant percentage of the total number of non-EGU point sources. See Appendix A/B for more information on the number of sources within certain states.) The EPA therefore excludes from the focus of this analysis these insignificant source groups, namely, those with aggregate potential reductions of 1,000 tons per year or less (which represents less than 0.1 percent of the anthropogenic ozone season inventory).

The EPA will now focus on the several source groups with significant cost-effective reductions identified in Table 3. These source groups include cement kilns, two types of cement manufacturing (dry and wet), gas turbines, four separate groups of natural gas reciprocating IC engines (RICE), incinerators, boilers & process heaters, by-product coke

[16] $10,000 per ton represents the cost/ton for Best Available Control Technology (BACT) determinations, which usually do not exceed $10,000/ton in the Eastern U.S.

[17] $3,400 per ton represents the $2,000 per ton value (in 1990 dollars) used in the NOx SIP call, adjusted to the 2011 dollars used throughout this proposal Adjustment of costs was made using the Chemical Engineering Plant Cost Index (CEPCI) annual values for 1990 and 2011.

NMED Exhibit 60 - 0018

manufacturing, ammonia production, and flat glass manufacturing. These source groups are listed below with their control technologies, estimated annualized control costs, and estimated installation time. These groups have been organized into 7 categories for clarity, based on either common control technologies (categories 1 through 6) or similarity of source groups (category 7).

Category 1	**Control Tech.**	**Est. Cost**	**Est. Inst. Time**
-Cement Mfg (dry)	SNCR	$1,255	42-51 weeks
-Incinerators	SNCR	$1,842	42-51 weeks
-By-Product Coke Manufacturing	SNCR	$2,673	42-51 weeks
Category 2			
-Cement Kilns	Biosolid Injection Technology (BSI)	$410	Uncertain
Category 3			
-Gas Turbines	Low NOx Burner (LNB)	$800	6-8 months
Category 4			
-Cement Mfg (wet)	Mid-Kiln Firing	$73	5-7 months
Category 5			
-Boilers & Process Heaters	SCR	$2,235	28-58 weeks
-Ammonia Production	SCR	$2,896	28-58 weeks
Category 6			
-Glass Manufacturing - Flat	OXY-Firing	$3,097	Uncertain
Category 7			
-Gas RICE Pipeline Compressors	Adjust AFR and Ignition Retard	$249	Uncertain
-Gas RICE Miscellaneous	Adjust AFR and Ignition Retard	$447	Uncertain
-Gas RICE Pipeline Compressors, Rich Burn	NSCR	$517	Uncertain
-Gas RICE Pipeline Compressors, Lean/Clean Burn	Low Emission Combustion (LEC)	$649	Uncertain

The EPA makes the following observations about the potential reductions from these significant cost-effective categories.

The source groups listed in Category 1 would utilize SNCR as the recommended control technology. The time necessary to install SNCR equipment is generally well known. A typical installation timeline of 42-51 weeks is generally needed to complete a SNCR project

NMED Exhibit 60 - 0019

going from the bid evaluation through startup, which installation timeline is specific to non-EGUs. Based on this fact alone (which does not consider additional time likely necessary for permitting or installation of monitoring equipment), the ability for SNCR technology to be installed and operational in time for the 2017 ozone season seems very unlikely.

The source group listed in Category 2 contains a specific source of uncertainty in regards to biosolid injection technology (BSI). Due in large part to the lack of widespread use of this control technology, research performed by the EPA has been unable to uncover any reliable information on the time required to install the necessary BSI equipment on cement kilns. Compliance timing with regard to biosolid injection technology should therefore be considered extremely uncertain. Based on this fact alone (and aside from additional time likely necessary for permitting or installation of monitoring equipment), the ability for this technology to be installed and operational at all facilities in this category in time for the 2017 ozone season is unknown.

The source group listed in Category 3 would utilize LNB as the recommended control technology, with a necessary installation time of approximately 6-8 months. Some of the LNB combustion control technology identified for non-EGU sources reflects a different technology that may have different timing considerations than that considered for EGU boilers. For instance, LNB at non-EGU combustion turbines in this assessment refers to "dry low-NOx burners" (DLNB) which, in addition to the usual diffusion burner, typically also include provisions to "premix" natural gas and combustion air prior to combustion. In spite of the similarity in naming, this is a different technology than the LNB technology examined and assumed for reductions at EGU boilers. Therefore, the same timing assumptions assumed and demonstrated on the EGU side are not necessarily applicable to combustion control technology for non-EGU sources. Moreover, non-EGUs of any type – boiler or turbine – that are not currently required to monitor and report in accordance with 40 CFR Part 75 will require additional time relative to EGUs that are currently equipped with Part 75 monitoring and reporting (such as those EGUs covered under federal transport rulemakings and this one). Installation of NOx monitors for the reporting of NOx mass requires the construction of platforms, Continuous Emissions Monitoring (CEM) shelters, procurement of equipment, certification testing, and electronic data reporting programming of a data handling system. These timing considerations on the non-EGU sources make installation of controls by the 2017 timeframe established in this rule less likely and more uncertain for industrial sources.

The source group listed in Category 4 would utilize mid-kiln firing as the recommended control technology. A fairly well-known aspect is the time necessary to install this equipment; typically, 5-7 months is needed to complete a mid-kiln firing project going from the bid evaluation through startup. However, the above-discussed issues regarding monitoring and reporting of NOx mass on non-EGU sources that currently lack such monitoring equipment make installation of controls by the 2017 timeframe of this rule less likely and more uncertain for industrial sources such as those in the cement manufacturing (wet) source group.

NMED Exhibit 60 - 0020

The source groups listed in Category 5 would utilize SCR as the recommended control technology, with an installation time of 28-58 weeks for SCR (dependent on exhaust gas flow rates; larger systems require longer installation times). Based on the installation time frame alone (which does not consider additional time likely necessary for permitting or installation of monitoring equipment), the ability for SCR technology to be installed and operational in time for the 2017 ozone season seems unlikely. In addition to this uncertainty, the above-discussed issues regarding monitoring and reporting of NOx mass on non-EGU sources that currently lack such monitoring equipment make installation of controls by the 2017 timeframe established in this rule less likely and more uncertain for industrial sources such as those in Category 5 source groups.

The source group listed in Category 6 would utilize OXY-Firing as the recommended control technology, with an uncertain necessary installation. A specific source of uncertainty with regard to the estimated installation time of this control technology is that OXY-Firing is generally installed only at the time of a furnace rebuild, which rebuilds may occur at infrequent intervals of a decade or more.[18] In addition to this uncertainty, the above-discussed issues regarding monitoring and reporting of NOx mass on non-EGU sources that currently lack such monitoring equipment make installation of controls by the 2017 timeframe established in this rule less likely and more uncertain for industrial sources such as those in Category 6 source group.

Finally, the source groups listed in Category 7 are all RICE. While some of the recommended control technologies may involve installation timelines that are relatively short on a per-engine basis, there is substantial uncertainty in large-scale installation over numerous sources. References indicate that implementation of NOx controls of any type on a large number of RICE will require significant lead time to train and develop resources to implement emission reduction projects; market demand could significantly exceed the available resource base of skilled professionals.[19] Additionally, in order not to disrupt pipeline capacity, engine outages must be staggered and scheduled during periods of low system demands for those engines involved in natural gas pipelines (as is the case with 3 of the 4 RICE source groups with significant cost-effective reductions). In addition to this uncertainty, the above-discussed issues regarding monitoring and reporting of NOx mass on non-EGU sources that currently lack such monitoring equipment make installation of controls by the 2017 timeframe established in this rule less likely and more uncertain for industrial sources such as RICE.

4 Summary of Comments Received on Proposed Rule TSD

The EPA received relatively few comments on the draft Assessment of Non-EGU NOx Emission Controls, Cost of Controls, and Time for Compliance TSD provided in the docket for this rule. None of these comments changed our conclusions reached in the draft TSD, as commenters generally agreed with the EPA's assessment with respect to the regulation of

[18] See Appendix B.

[19] "Availability and Limitations of NOx Emission Control Resources for Natural Gas-Fired Reciprocating Engine Prime Movers Used in the Interstate Natural Gas Transmission Industry," Innovative Environmental Solutions Inc., July 2014.

NMED Exhibit 60 - 0021

non-EGUs in this rule. Detailed responses to these comments can be found in the response to comments document available in the docket for this final rule. A brief discussion of one comment containing data on control information is presented below.

Commenter Fuel Tech, Inc. (FTI) provided information on the installation time required for SNCR equipment, stating that "FTI has provided SNCR systems in 8-12 months (from contract award to performance guarantee certification)…"[20] This timeframe is largely consistent with the 42-51 week (9.7-11.7 month) timeframe estimate presented by the EPA in the draft TSD.

In addition, FTI provided information on a range of SNCR cost per ton based on installations from 2010 to 2015 on non-EGU sources, stating that "these recent examples show NOx reduction cost effectiveness in the range of $2,200 to $2,900 per ton of NOx removed on an annual basis."[21] FTI's "Figure 1"[22] also provided a chart of cost effectiveness ($/ton) versus unit size (mmBTU/hr) for both annual and ozone season NOx. A log fit of the ozone season curve shows cost effectiveness in the range of approximately $2,000 to approximately $6,500 per ton of ozone season NOx removed, with installations tending to be more expensive for smaller unit sizes. Although FTI's estimates are based on different interest rates and capital investments than our estimates, they are worthwhile to note in comparison to our stated estimate of $1,300 to $2,700 per ton of NOx removed on an ozone season basis.

5 Conclusion

The above preliminary analysis performed by the EPA indicates that uncertainty exists regarding whether significant aggregate NOx mitigation is achievable from non-EGU point sources by the 2017 ozone season. Reducing this uncertainty requires further understanding of potentially available control measures that could have annualized costs of $3,400 per ton or less. In addition, further implementation of the recommendations in the Appendices to this TSD, the extent of which as determined by the EPA to be needed, may also reduce our uncertainty regarding the credibility of data for control measures included in future non-EGU NOx control strategy efforts. Please note that while the information in these Appendices supports our conclusion regarding whether significant aggregate NOx mitigation is achievable from non-EGU point sources by the 2017 ozone season, this final TSD is making no conclusions about the recommendations for further improvements.

While a number of source groups with control options were identified, the EPA did not further examine control options above $3,400 per ton, consistent with the range analyzed for EGUs in the proposed and final rules and with what the EPA has identified in previous transport rules as highly cost-effective. A number of source groups were identified at a cost level of $3,400 per ton or less, however the EPA believes several of these source groups may not be significant. Of the remaining source groups, a variety of factors indicated the ability for control technology to be installed and operational in time for the 2017 ozone

[20] EPA-HQ-OAR-2015-0500-0356, page 3.

[22] EPA-HQ-OAR-2015-0500-0356, page 6.

NMED Exhibit 60 - 0022

season seemed unlikely, with an overarching consideration being that non-EGUs of any type that are not currently required to monitor and report in accordance with 40 CFR Part 75 will require additional time for implementation relative to EGUs that are currently equipped with Part 75 monitoring and reporting. These added timing considerations on the non-EGU sources make installation of controls by the 2017 timeframe established in this rule less likely and more uncertain for industrial sources.

With all of these factors being considered, the limited available information points to an apparent scarcity of non-EGU reductions that could be accomplished by the beginning of the 2017 ozone season. As noted in the proposed and final rule, this conclusion has led the EPA to focus the final FIPs on EGU reductions. Both the proposal and the final rule acknowledge that this may not be the full remedy that is ultimately needed to eliminate an upwind state's significant contribution to nonattainment or interference with maintenance of the 2008 ozone NAAQS (or, for that matter, the 2015 ozone NAAQS) in other states. Emissions reductions from the non-EGU categories discussed above may be necessary, though on a longer timeframe than the 2017 compliance deadline being finalized in this rulemaking. The EPA intends to explore this question further in future ozone transport rulemakings.

SECTION 1
INTRODUCTION

The U.S. Environmental Protection Agency (EPA) Health and Environmental Impacts Division (HEID) has developed the Control Strategy Tool (CoST) to support national- and regional-scale multipollutant air quality modeling analyses. CoST allows users to estimate the emissions reductions and costs associated with future-year emission control strategies, and then to generate emission inventories that reflect the effects of applying the control strategies. The tool uses EPA HEID's Control Measures Database (CMDB) to develop control strategies and provides a user interface to that database. The CMDB is a relational database that contains information on an extensive set of control measures for point sources, nonpoint sources, and mobile sources. Information contained in the database includes descriptions of the measures, control efficiencies for the pollutants affected, costs of control, and the types of sources or processes to which the control measures can be applied. The database includes robust cost equations to determine engineering costs for some control measures that take into account how control costs vary with respect to variables for the source such as unit size or flow rate. The database also includes simple cost factors for all source types in terms of dollars per ton of pollutant reduced that can be used to calculate the cost of the control measure if the applicable source variable data are unavailable or no equation has been developed.

This report presents the results of an effort to review and enhance the CMDB with new and/or updated NOx control measure data for the following four industrial source categories: ammonia reformers, combustion turbines (nonEGU), glass manufacturing, and lean burn reciprocating internal combustion engines. Section 2 of this report describes the procedures used to locate more recent data than that currently in the CMDB for control measures applicable to ammonia reformers. Section 2 also identifies the source of the new data, describes any modifications to the assumptions or procedures in the referenced analyses needed to make the results consistent with results for other control measures in the database (such as operating hours for determination of total annual costs), and describes the specific recommended changes or additions to the database. Sections 3 through 5 of this report provide similar details for combustion turbines, glass manufacturing, and lean burn reciprocating internal combustion engines, respectively. Appendix A presents all of the records for ammonia reformer control measures in each of the CMDB tables showing their content after making the recommended revisions described in the report. Appendixes B through D provide comparable tables for the combustion turbine, glass manufacturing, and lean burn reciprocating internal combustion engine (RICE) source categories, respectively. Appendix E provides answers to questions on lean-burn RICE NOx

Appendix A

NMED Exhibit 60 - 0030

emissions and available control measures. It should be noted that these revisions and updates will improve the accuracy and quality of NOx non-EGU control strategy and cost analyses for EPA rulemakings.

Appendix A

NMED Exhibit 60 - 0031

SECTION 2
AMMONIA REFORMERS SECTOR

The control measures database includes the following NO_X emissions control measures for ammonia reformers:

- Oxygen trim and water injection,
- Low NO_X burners and flue gas recirculation,
- Selective non-catalytic reduction (SNCR),
- Selective catalytic reduction (SCR), and
- Low NO_X burners.

In order to update the existing control measures database, a literature search was conducted using the following terms:

- reformer
- cost
- "NO_X" or "nitrogen oxide"
- "Low NO_X burner" or "LNB"
- "Flue gas recirculation" or "FGR"
- oxygen trim
- water injection
- "Selective catalytic reduction" or "SCR"
- "Selective non catalytic reduction" or "SNCR"
- emission reduction
- control efficiency

Due to the use of SCR and SNCR to control NO_X emissions and the fact that ammonia is used in the operation of SCR and SNCR, the literature search resulted in NO_X reductions on processes other than ammonia production.

Appendix A

NMED Exhibit 60 - 0032

In order to focus on ammonia production, a focused internet search for operating permits, BACT analyses, and NO_X controls was conducted using the 22 ammonia production facilities in the United States.

As a result of the following facts, most of the internet search results included NO_X reductions from the production of nitric acid production instead of ammonia production:

- The NO_X emissions from nitric acid production are covered by a New Source Performance Standard (NSPS) codified as Subpart G and Subpart Ga of Part 60.
- Nitric acid facilities covered by the NSPS are required to install NO_X continuous emission monitoring systems (CEMS).
- Many nitric acid facilities use SCR to control NO_X emissions.
- Many ammonia production facilities are co-located with nitric acid production facilities.

The internet search resulted in one new NO_X reduction project, which was the result of a voluntary agreement between Terra Nitrogen and the Indian Nations Council of Governments to install "ultra-low NO_X burner technology to an existing ammonia reformer [and] reduce the unit's NO_X emissions by approximately 60% at a projected capital cost of two million dollars." The existing ammonia reformer is located at Terra Nitrogen, L.P., Verdigris Plant in Claremore, Oklahoma.

Based on information known to EPA and collected for this report, Low NO_X burner technologies are known and demonstrated control techniques for ammonia reformers.

The following sections outline the deletions, additions, changes, and other comments recommended for the CMDB in relation to NO_X emissions from ammonia reformers.

2.1 Recommended Deletions

No deletions are recommended.

2.2 Recommended Additions

The only addition to the CMDB is to add the following reference: *Tulsa Metropolitan Area 8-Hour Ozone Flex Plan: 2008 8-O_3 Flex Program*. Prepared by Indian Nations Council of Governments (INCOG), 201 W. 5th Street, Suite 600, Tulsa, OK 74103. March 6, 2008. http://www.epa.gov/ozoneadvance/pdfs/Flex-Tulsa.pdf.

This addition is shown in Appendix A as Table A-1.

Appendix A

NMED Exhibit 60 - 0033

2.3 Recommended Changes

Updates to costs and Efficiencies.

Changes to one record (LNB applied to large source types) are recommended to reflect the new reference dated March 6, 2008.

Using the new reference and a reference already contained in the CMDB, the following assumptions were made:

- NO_X reductions of 425 tons per year[1]
- Capital cost of $2 million[1]
- Maintenance costs are 2.75% of capital costs[2]
- Equipment life of 10 years
- Interest rate of 7%
- Capital recovery factor of 0.1424.

The resulting annual costs are $339,800 and the cost effectiveness is $800 per ton of NO_X reduction (both in 2008 dollars). The capital to annual cost ratio is 5.9.

The previous entry showed a cost effectiveness of $650 per ton of NO_X reduction (in 1990 dollars) and a capital to annual cost ratio is 5.5. The changes are included in Appendix A as Table A-2 and Table A-3. Changes are indicated by red, italic text.

Updates to Source Classification Codes.

The U.S. Environmental Protection Agency (USEPA) developed the Source Classification Code (SCC) system, which assigns an eight digit code to each emission unit based on the general criteria pollutant emission point type, the major industry group, specific industry group, and specific process unit/fuel combination. The system allows similar emission points to be grouped together for analyses.

For ammonia reformers, there are seven applicable SCCs, as shown in Table 2-1.

[2] U.S. Environmental Protection Agency. Alternative Control Techniques Document— NO_X Emissions from Process Heaters (Revised), document EPA-453/R-93-034, dated September 1993.

Appendix A

NMED Exhibit 60 - 0034

Table 2-1. Applicable SCCs for the Ammonia Production Industry

SCC	SCC 1	SCC3	SCC6	SCC8
30100305	Industrial Processes	Chemical Manufacturing	Ammonia Production	Feedstock Desulfurization
30100306	Industrial Processes	Chemical Manufacturing	Ammonia Production	Primary Reformer: Natural Gas Fired
30100307	Industrial Processes	Chemical Manufacturing	Ammonia Production	Primary Reformer: Oil Fired
30100308	Industrial Processes	Chemical Manufacturing	Ammonia Production	Carbon Dioxide Regenerator
30100309	Industrial Processes	Chemical Manufacturing	Ammonia Production	Condensate Stripper
30100310	Industrial Processes	Chemical Manufacturing	Ammonia Production	Storage and Loading Tanks
30100399	Industrial Processes	Chemical Manufacturing	Ammonia Production	Other Not Classified

In an analysis of NO_X emissions for the Ozone Transport Region in 2011, four of the SCCs in Table 2-1 were identified. These SCCs are 30100306, 30100307, 30100310, and 30100399. Only SCCs 30100306 and 30100307 are associated with ammonia reformer NO_X controls in the current CMDB.

The known control techniques for ammonia reformers are typically used for point emission sources, such as stacks. Emissions from SCC 30100310 are not typically vented, so capture and control of these emissions is likely not feasible. Therefore, no changes related to SCC 30100310 are recommended for the CMDB.

For the purposes of this analysis, SCC 30100399 is assumed to include combustion emissions from gaseous fuels other than natural gas. Therefore, all control techniques that are applicable to natural gas fired ammonia reformers are assumed to also apply to SCC 30100399. Also, the cost to control NO_X emissions from gaseous fuels is assumed to be comparable to the cost to control NO_X emissions from natural gas. Therefore, the costs related to those control techniques are assumed to apply to SCC 30100399.

The applicable SCC from Table 2-1 was added to the Description field for each control technique in Table A-2 of Appendix A. SCC 30100306 was already included in the table; SCCs 30100305, 30100307, and 30100399 were added, where appropriate. Changes are indicated by red text.

Appendix A

NMED Exhibit 60 - 0035

2.4 Other Comments

Control measures used by ICI boilers. Review of NO_X control measures used for boilers was not included in this analysis. However, many of the SCR costs in the CMDB for natural gas fired ammonia reformers are based on SCR costs for Industrial/Commercial/Institutional (ICI) Boilers using Process Gas. No SCR costs specific to ammonia reformers were noted in the CMDB.

At a later time, it may be pertinent to review recent final ICI Boilers regulations or other sources for potential updates to the cost of SCR on ammonia reformers. The final major source NESHAP for ICI Boilers was promulgated on January 31, 2013 and the final area source NESHAP for ICI Boilers was promulgated on February 1, 2013.

Potential NO_X limits for ammonia reformers based on boiler NO_X limits. According to NO_X Reasonably Acceptable Control Technology (RACT), the states of New Jersey and New York have established emission limits for ICI Natural Gas Boilers (greater than 100 million BTU per hour) that could be applicable to natural gas ammonia reformers. These RACT limits are shown in Table 2-2.

Table 2-2. RACT NO_X Limits for ICI Natural Gas Boilers

State	Boiler Size	Limit (lb NO_X/MMBTU)	Effective Date
New Jersey[a]	>100 MMBTU	0.10	Already in effect
New York	>100 MMBTU and ≤ 250 MMBTU	0.06	7/1/14
New York	> 250 MMBTU	0.08	7/1/14

[a] The limit also applies to other indirect heat exchangers.

Appendix A

NMED Exhibit 60 - 0036

SECTION 3
COMBUSTION TURBINES

The CMDB includes the following NO_X emissions control measures for Combustion Turbines:

- Water injection for natural gas-fired turbines (achieves 76 percent reduction)
- Steam injection for natural gas-fired turbines (achieves 80 percent reduction)
- Low NOx Burners for natural gas-fired turbines (achieves 84 percent reduction)
- SCR on natural gas-fired turbines that also have water injection (achieves 95 percent reduction)
- SCR on natural gas-fired turbines that also have steam injection (achieves 95 percent control)
- SCR on natural gas-fired turbines that also have low NOx burners (achieves 94 percent reduction)
- Water injection for oil-fired turbines (achieves 68 percent reduction)
- SCR on oil-fired turbines that also have water injection (achieves 90 percent reduction)
- Water injection for jet fuel-fired turbines (achieves 68 percent reduction)
- SCR on jet fuel-fired turbines that also have water injection (achieves 90 percent reduction)
- Water injection for aeroderivative turbines (achieves 40 percent reduction)

All of the cost data are in 1990 dollars, except the costs of water injection for aeroderivative turbines, which are in 2005 dollars. In addition, all of the costs are based on estimated operation for 8,000 hr/yr, except the costs of water injection for aeroderivative turbines, which are for intermittently operated units. The costs in 1990 dollars are based primarily on analyses in EPA's 1993 ACT document for NOx Emissions from Stationary Gas Turbines (EPA, 1993). Capital and annual cost equations are provided for all of the controls except those for jet fuel-fired turbines and water injection for aeroderivative turbines.

Literature search. In order to update the existing CMDB, a literature search was conducted for articles and papers published since 2008. In addition, an internet search was conducted for BACT analysis reports and control technology reports prepared for federal and

Appendix A

NMED Exhibit 60 - 0037

state agencies and RPOs. The literature search did not identify any documents with cost data, but the internet search identified the documents listed in Section 3.5 of this report.

Changes to CMDB. The following sections outline the deletions, additions, and other changes recommended for the CMDB in relation to NO_X emissions from Combustion Turbines. All cost data and calculations are in an Excel Worksheet (RTI, 2014). Copies of the CMDB tables with recommended revisions to the records for combustion turbine controls are provided in Appendix B.

The coefficient of determination (R^2) is 1.0 for many of the regression equations presented in sections 3.2 and 3.3. The R2 value is exactly 1.0 in cases where the analysis was based on only two data points; these cases are noted in the discussions for the particular control measure. In other cases, actual R2 values greater than 0.995 have been rounded to 1.0. These high values likely are due to the fact that available data for most control measures are from a single source, and those sources may have already developed a correlation and then picked specific data points from that correlation for presentation in their documentation.

3.1 Recommended Deletions

RTI recommends deleting the record for water injection for aeroderivative turbines because the estimated costs are for combustion turbines that operate on a limited and intermittent basis (i.e., peaking EGUs). In principle, data for small EGU combustion turbines would be acceptable for estimating costs of control measures for nonEGUs. However, the limited operation of peaking units is inconsistent with the assumed operating time of about 8,000 hr/yr for all of the other nonEGU combustion turbine control measures in the database. For several SCCs that are currently associated with this control measure in the CMDB we are recommending applying other existing control measures, as discussed in Section 3.3.11 of this report.

The CMDB also currently applies several gas turbine control measures to reciprocating internal combustion engine SCCs and to gas turbine SCCs for evaporative losses from fuel storage and delivery systems. We recommend deleting these applications of the gas turbine control measures, as discussed in Section 3.3.11 and Section 5.9 of this report.

3.2 Recommended Additions

There are 3 control technique additions for emerging technologies to be added to the CMDB; these additions include:

- Catalytic Combustion; Gas Turbines—Natural Gas;

Appendix A

NMED Exhibit 60 - 0038

- EMx and Water Injection; Gas Turbines—Natural Gas;
- EMx and Dry Low NOx Combustion; Gas Turbines—Natural Gas.

3.2.1 Catalytic Combustion; Gas Turbines—Natural Gas (NCATCGTNG)

Catalytic combustion is a flameless process that allows fuel oxidation to occur at temperatures approximately 1800°F lower than those of conventional combustors (OSEC, 1999). Lower temperatures are desirable because NOx emissions levels are strongly correlated with temperature. One design that has been commercialized is the Xonon™ combustor (now called K-Lean™). In the Xonon combustor, a small amount of fuel is burned in a low temperature pre-combustor. Additional fuel is then mixed with the air and combustion gases from the pre-combustor and passed through a catalyst module. The catalyst promotes a flameless reaction between some of the fuel and oxygen. The gases then enter a burnout zone in which the remaining fuel burns. The maximum temperature in the system is between 2300°F and 2700°F. In addition to low NOx emissions, the catalytic combustor generates very little CO emissions. (Peltier, 2003; CARB, 2004; Leposky, 2004; Kawasaki, 2010; Quackenbush, 2012)

Since 1999 at least six Xonon combustors have been installed; all are 1.4 MW units (CARB, 2004; Kawasaki, 2010; Quackenbush, 2012). Testing of four of the operating Xonon combustors has shown NOx emissions less than 3 parts per million by volume on a dry basis (ppmvd) at 15% oxygen, and permit limits range from 3 ppmvd to 20 ppmvd at 15% oxygen (CARB, 2004; Quackenbush, 2012). Several companies have conducted research into developing larger catalytic combustors and other types of designs, but no information was found indicating that such units have been commercialized (CARB, 2004; Leposky, 2004; Cybulski, 2006).

Although one type of catalytic combustor has been commercialized, we recommend considering catalytic combustion as an emerging technology in the CMDB because so few units are in operation, and they are all only one size. In addition, as of 1999, issues with catalytic combustors include the need for the air-fuel mixture to have completely uniform temperature, composition, and velocity profile to assure effective use of all the catalyst and to prevent damage to the substrate from high temperatures. Also the catalyst durability is uncertain (OSEC, 1999).

The recommended costs are based on costs presented in a report by Onsite Sycom Energy Corporation (OSEC, 1999). The only change we made to the OSEC costs was to calculate capital recovery using an interest rate of 7 percent instead of 10 percent; this change makes the capital recovery costs consistent with guidance in Circular A-4 from the Office of Management and Budget. Table 3-1 summarizes the recommended cost effectiveness and capital to annual cost ratios for implementing the catalytic combustion NOx control technology. With an outlet

Appendix A

NMED Exhibit 60 - 0039

concentration of 3 ppmvd, catalytic combustion achieves an average reduction of 98 percent relative to uncontrolled conventional diffusion combustion.

Table 3-1. Summary of Cost Effectiveness and Supporting Data for Catalytic Combustion

Turbine Output, MW	Cost Year	Uncontrolled NOx Emissions		Outlet Concentration, ppmvd	Cost Effectiveness, $/ton NOx	Capital to Annual Cost Ratio
		Avg. ppmvd	tpy			
Small (5.2)	1999	150	<365	3	920	1.7
Small (26.3)	1999	130	>365	3	670	1.2
Large (170)	1999	210	>365	3	370	0.7

Based on regression of the data in the analysis, the best fit trend lines are represented by the following equations for the uncontrolled scenario:

Total capital investment (1999 dollars) = 20668 x (MMBtu/hr) ^ 0.57 (R^2=1.0)

Total annual cost (1999 dollars) = 4254.2 x (MMBtu/hr) ^ 0.82 (R^2=1.0)

For all but the smallest turbines, the incremental cost of catalytic combustors relative to conventional combustors is less than the incremental cost of DLN combustion versus conventional combustors. Thus, there are no incremental capital costs for catalytic combustion relative to conventional combustion. However, there are incremental annual costs because the cost of catalyst replacement is high. A best fit equation for incremental catalytic combustion total annual costs relative to a RACT baseline of DLN combustion is:

Total annual cost (1999 dollars) = 743.22 x (MMBtu/hr) + 54105 (R^2=1.0)

3.2.2 EMx and Water Injection; Gas Turbines—Natural Gas (NEMXWGTNG)

Like SCR, EMx™ (formerly called SCONOX™) is a post-combustion catalytic NOx reduction technology. EMx uses a precious metal catalyst and a NOx absorption/regeneration process to convert CO and NOx to CO2, H2O, and N2. NOx reacts with the potassium carbonate absorbent coating the surface of the oxidation catalyst in the EMx reactor, forming potassium nitrites and nitrates that are deposited onto the catalyst surface. Each segment, or "can," within the reactor becomes saturated with potassium nitrites and nitrates over time and must be desorbed. Regeneration is accomplished by isolating the can via stainless steel lovers and

Appendix A

NMED Exhibit 60 - 0040

injecting hydrogen diluted with steam. Hydrogen is generated onsite with a small reformer that uses natural gas and steam as input streams. The hydrogen concentration of the reformed gas is typically 5 percent. Hydrogen and carbon dioxide react with the potassium nitrites and nitrates to form N2 and H2O and to regenerate the potassium carbonate for another absorption cycle. (OSEC, 1999; CARB, 2004)

At least 8 EMx systems at 6 facilities have been installed on combustion turbines with capacities up to 45 MW. Permit limits at most of these facilities have been set at 2.5 ppmvd for gas-fired operation. EPA has certified it as "demonstrated in practice" LAER-level technology that reduces NOx to less than 5 ppmvd. The operating range of the catalyst is 300 to 700°F, which means the technology is not applicable for simple cycle turbines. The vendor for the technology has indicated that these systems also reduce carbon monoxide emissions to undetectable levels (essentially 100 percent reduction), reduce volatile organic compound emissions by greater than 90 percent, and reduce fine particulate matter emissions by 30 percent (EmeraChem, 2004). Test data documenting these reductions are not available. For the purposes of the CMDB database, we recommend that this control measure be listed as an emerging technology (rather than known) because its use has been limited to only a few small turbines.

The recommended costs for EMx in the combined EMx/water injection control measure are based on costs presented in a 2008 cost estimate prepared by EmeraChem Power for the Bay Area Air Quality Management District (ECP, 2008). For the purposes of developing 2008 cost inputs for the CMDB, we made the following changes to the data and assumptions used in the ECP analysis:

- Increased the indirect cost for engineering from $200,000 to $255,000 for the 50 MW turbine. ECP's documentation indicated that this cost (as well as most of the other direct installation and indirect costs) would be the same as for an SCR system on the same turbine. The reported cost of $200,000 was inconsistent with this statement.

- Increased the contingencies cost for the 50 MW turbine from $76,486 to $244,101. This change makes the cost consistent with ECP's statement that the cost for contingencies is estimated to be equal to 5 percent of the total purchased equipment cost, excluding the cost of the precious metals in the catalyst, sales taxes, and freight.

- Added a cost for the performance loss due to back pressure from the EMx system for both turbines. ECP estimated the loss to be 0.5 percent, which is consistent with the estimate in the 1993 ACT for SCR and the estimate OSEC used in a cost analysis for SCONOx (EPA, 1993; OSEC, 1999). However, the ECP analysis did not include a corresponding dollar amount for this element.

Appendix A

NMED Exhibit 60 - 0041

- Changed the operating hours from 7,884 hr/yr to 8,000 hr/yr. This change also had a small effect on the annual costs for utilities.

- Added costs for natural gas to generate steam for the 50 MW turbine using the same procedures presented in the ECP analysis for the 180 MW turbine. ECP did not report the basis for the amount of steam needed for the 180 MW turbine. Therefore, we plotted the reported steam consumption versus turbine size for this unit and for two turbines identified in a CARB analysis (CARB, 2004). We calculated the quantity of steam needed for EMx on the 50 MW turbine using the regression equation from this plot. Note that the unit cost for natural gas is $9.75/1000 scf. This was a reasonable annual average cost in 2008, but it would be much too high for an analysis in 2014.

- Deleted the credit for recovery of precious metals in the spent catalyst because the cost for replacement catalyst considers only the difference between the total purchase price minus the value of the recovered material.

- Estimated the annualized cost of replacement catalyst (both the non-precious metal substrate and the precious metal coating) using the future worth factor, whereas the cost in the ECP analysis was the purchased cost divided by the 10-year replacement interval.

- Estimated the cost of annual catalyst cleaning based on the average if data reported by CARB (CARB, 2004) plus the amounts reported by ECP. Although ECP reported a slightly higher cleaning cost for the 180 MW turbine than for the 50 MW turbine, an analysis of all the cleaning data showed no correlation with turbine size. Thus, we used the average of all reported costs for both turbines.

- Revised the indirect annual cost for administrative charges. ECP estimated that these costs are the same as for an SCR system on the same turbines. We factored the cost as 2 percent of the TCI for the applicable EMx systems, which is consistent with the approach for all control devices in the EPA Control Cost Manual. This resulted in slightly higher costs.

- Increased the indirect costs for insurance, property tax, and capital recovery for both turbines because the ECP analysis excluded the precious metal costs from the TCI used in these calculations.

- Calculated capital recovery using an interest rate of 7 percent instead of 10 percent.

The capital costs for water injection in the combined EMx/water injection control measure were estimated in 1999 dollars using the regression equation for the water injection control measure (see Section 3.3.1) and then scaled to 2008 dollars using the Chemical Engineering Plant Cost Index (CEPCI). Total annual costs for water injection were first estimated in 1999 dollars using the regression equation for the water injection control option. On average, 25 percent of these costs were estimated to be for indirect costs that are factored from

Appendix A

NMED Exhibit 60 - 0042

the system capital cost, and the remaining 75 percent is for direct annual costs and overhead. To estimate the total annual costs for water injection in 2008, the indirect costs were scaled from the 1999 estimate using the CEPCI, and the direct annual costs and overhead were assumed to be the same as in 1999.

Table 3-2 summarizes the recommended cost effectiveness and capital to annual cost ratios for implementing the EMx plus water injection NOx control measure. With an outlet concentration of 2 ppmvd, this control measure achieves an average reduction of 99 percent relative to uncontrolled conventional diffusion combustion.

Table 3-2. Summary of Cost Effectiveness and Supporting Data for EMx Plus Water Injection

Turbine Output, MW	Cost Year	Uncontrolled NOx Emissions		EMx Outlet Concentration, ppmvd	Cost Effectiveness, $/ton NOx	Capital to Annual Cost Ratio	Incremental Cost Relative to RACT Baseline of WI, $/ton NOx
		Avg ppmvd	tpy				
Large (50-180)	2008	160[a]	>365	2.0	2,760	3.1	6,810

[a]Uncontrolled concentrations were not reported in the referenced analysis. Thus, the value used in this analysis is an assumed average that results in the estimated 84 percent reduction for DLN combustion, as described in Section 3.3.3 of this report.

Based on regression of the data in the analysis, the best fit trend lines are represented by the following power equations for the uncontrolled scenario (the R^2 =1.0 for both equations because there were only two data points in the analysis):

Total capital investment (2008 dollars) = 196928 x (MMBtu/hr) ^ 0.68

Total annual cost (2008 dollars) = 18747 x (MMBtu/hr) ^ 0.86

Best fit equations for incremental EMx costs relative to a RACT baseline of water injection are:

Total capital investment (2008 dollars) = 156349 x (MMBtu/hr) ^ 0.68

Total annual cost (2008 dollars) = 17252 x (MMBtu/hr) ^ 0.80

Appendix A

NMED Exhibit 60 - 0043

3.2.3 EMx and Dry Low NOx Combustion; Gas Turbines—Natural Gas (NEMXDGTNG)

Table 3-3 summarizes the recommended cost effectiveness and capital to annual cost ratios for implementing the EMx plus dry low NOx combustion control measure. With an outlet concentration of 2 ppmvd, this control measure achieves an average reduction of 99 percent relative to uncontrolled conventional diffusion combustion. For the same reasons noted in Section 3.2.2, we recommend that this control measure be listed as an emerging technology in the CMDB.

Table 3-3. Summary of Cost Effectiveness and Supporting Data for EMx Plus Dry Low NOx Combustion

Turbine Output, MW	Cost Year	Uncontrolled NOx Emissions		EMx Outlet Concentration, ppmvd	Cost Effectiveness, $/ton NOx	Capital to Annual Cost Ratio	Incremental Cost Relative to RACT Baseline of DLN, $/ton NOx
		Avg ppmvd	tpy				
Small (4.2)	1999	134	<365	2.0	2,860	3.9	14,940
Small (23)	1999	174	>365	2.0	1,720	4.1	10,270
Large (170)	1999	210	>365	2.0	840	3.9	6,600
Large (50-180)	2008	160[a]	>365	2.0	2,050	4.1	12,390

[a]Uncontrolled concentrations were not reported in the referenced analysis. Thus, the value used in this analysis is an assumed average that results in the estimated 84 percent reduction for DLN combustion, as described in Section 3.3.3 of this report.

The recommended costs for EMx in 2008 dollars for the combined EMx/dry low NOx combustion control measure are the same as in the estimate for the EMx/water injection control measure described in Section 3.2.2. The recommended costs for EMx in 1999 dollars are based on an analysis prepared by Onsite Sycom Energy Corporation (OSEC, 1999). For this analysis the only changes we made to OSEC's analysis were to reduce the operating hours from 8,400 hr/yr to 8,000 hr/yr, which slightly reduced the energy penalty and utilities costs, and we calculated the capital recovery factor using an interest rate of 7 percent instead of 10 percent. Note that the total annual costs for natural gas (or purchased steam) are considerably lower in this analysis than in the 2008 analysis because the unit cost of natural gas was considerably lower in 1999.

The recommended total capital investment and total annual cost for dry low NOx combustion in 1999 dollars for the combined EMx/dry low NOx combustion control measure are the same as in the estimate for the dry low NOx combustion control measure alone as described in Section 3.3.3. The recommended total capital investment for dry low NOx combustion in 2008

Appendix A

NMED Exhibit 60 - 0044

dollars was estimated in 1999 dollars using the regression equation for the water injection control measure (see Section 3.3.1) and then scaled to 2008 dollars using the CEPCI. The recommended total annual costs for dry low NOx combustion consist of capital recovery plus the cost for parts and repair; capital recovery costs in 2008 dollars were estimated by escalating the 1999 costs using the CEPCI, and annual parts and repairs costs were assumed to be the same in 2008 as in 1999.

Based on regression of the data in both the 1999 and 2008 cost analyses, the best fit trend lines are represented by the following power equations for the uncontrolled scenario (the R^2 =1.0 for the equations in 2008 dollars because there were only two data points in the analysis; R^2 for the equations in 1999 dollars round to 1.0 when only two significant figures are presented):

Total capital investment (1999 dollars) = 58237 x (MMBtu/hr) ^ 0.78

Total annual cost (1999 dollars) = 15004 x (MMBtu/hr) ^ 0.78

Total capital investment (2008 dollars) = 126892 x (MMBtu/hr) ^ 0.74

Total annual cost (2008 dollars) = 20041 x (MMBtu/hr) ^ 0.80

Best fit equations for incremental EMx costs relative to a RACT baseline of DLN combustion are:

Total capital investment (1999 dollars) = 65163 x (MMBtu/hr) ^ 0.72

Total annual cost (1999 dollars) = 13702 x (MMBtu/hr) ^ 0.76

Total capital investment (2008 dollars) = 156349 x (MMBtu/hr) ^ 0.68

Total annual cost (2008 dollars) = 17252 x (MMBtu/hr) ^ 0.80

3.3 Recommended Changes

This section presents updated cost estimates for combustion turbine control measures that are currently in the CMDB, and it describes the basis for such changes. These changes include both more recent costs for some control measures as well as minor revisions to existing estimates for other control measures. The changes affect both cost per ton values and equations.

Appendix A

NMED Exhibit 60 - 0045

This section also identifies applicable SCCs for the new control measures described in Section 3.2, and it identifies additional SCCs for which the control measures in this section are applicable.

3.3.1 Water Injection; Gas Turbines—Natural Gas (NWTINGTNG)

Recommended updates to the costs for water injection are based on analyses in a report prepared by OnSite Sycom Energy Corporation for the U.S. Department of Energy (OSEC, 1999). OSEC estimated costs for some of the same small turbine model sizes as in EPA's 1993 ACT document (4 MW and 23 MW). OSEC obtained water injection equipment costs in 1999 dollars. They then estimated total capital investment and total annual costs using the same procedures as in the 1993 ACT document, and they concluded that 1999 costs for water injection were essentially the same as the 1990 costs presented in the ACT document. Because the ACT analysis included a greater number of models over a wider range of sizes, RTI recommends continuing to use the cost data from the ACT analysis in the CMDB, except the cost year should be updated from 1990 to 1999. RTI also recommends the four additional changes noted below.

Our second recommendation is to split the record for small sources into two records—one for sources with uncontrolled emissions less than 365 tpy, and the other for emissions greater than 365 tpy. The 2006 AirControlNET Documentation Report indicates that small sources are turbines with design outputs up to 34.4 MW. Four model turbines in the ACT analysis have outputs below this threshold. The two turbines with uncontrolled emissions <365 tpy have an average cost effectiveness of $1,790/ton of NOx. The two turbines with uncontrolled emissions >365 tpy have an average cost effectiveness of $1,000/ton of NOx.

Our third recommendation is to revise the control efficiency for water injection from 76 percent to 72 percent. The 76 percent control level is the average reduction for all 6 model turbines in the 1993 ACT analysis. Five of those models were guaranteed to reduce NOx emissions to less than 42 ppmvd, while the sixth was guaranteed to meet 25 ppmvd. Although water injection may be more effective on some combustion turbines than others, 42 ppmvd is the generally accepted threshold. Thus, we think this threshold should be incorporated in the CMDB. The average reduction of the 5 models in the 1993 ACT analysis with an outlet concentration of 42 ppmvd was 72 percent.

Our fourth recommendation is to use a capital to annual cost ratio of 2.4 in the new record for small sources with uncontrolled emissions >365 tpy; this is the average value for the two turbines in the ACT analysis in this size range. (The capital to annual cost ratio for the small sources with uncontrolled emissions <365 tpy would remain at 3.1 because this is the average

Appendix A

NMED Exhibit 60 - 0046

value for the two turbines in this size range; it is not clear why this value was applied for all small sources in the current version of the CMDB.) The total annual costs in this calculation are based on using a 7 percent interest rate in the calculation of capital recovery, instead of the 10 percent value in the 1993 ACT. Even if capital recovery was estimated using the 10 percent interest rate, it is not clear how the 3.1 value was developed.

Our fifth recommendation is to revise the constants in the CMDB table of equations for estimating capital and annual costs. Based on regression of the data in the 1993 ACT, the best fit trend lines are represented by the following revised power equations for both uncontrolled and RACT baseline scenarios:

$$\text{Total capital investment (1999 dollars)} = 27665 \times (\text{MMBtu/hr})^{0.69} \quad (R^2 = 0.97)$$

$$\text{Total annual cost (1999 dollars)} = 3700.2 \times (\text{MMBtu/hr})^{0.95} \quad (R^2 = 0.95)$$

3.3.2 Steam Injection; Gas Turbines—Natural Gas (NSTINGTNG)

The only available information on the cost of steam injection was in the 1999 report from Onsite Sycom Energy Corporation (OSEC, 1999). OSEC discussed steam injection only in the context of large GE Frame 7F turbines (170 MW). They noted that only the first such model, operational in 1990 when the ACT analysis was being conducted, was equipped with steam injection. All subsequent units (at least through 1999) were equipped with DLN combustion technology.

Because the limited available information suggests that steam injection costs, like water injection costs, were essentially the same in 1999 as in 1990, we recommend continuing to base the steam injection costs on the results in the 1993 ACT, but update the cost year from 1990 to 1999. In addition, as for water injection, we recommend splitting the one record for small sources into two records—one for sources with uncontrolled NOx emissions <365 tpy, and the other for uncontrolled NOx emissions >365 tpy. This split results in average cost effectiveness values of $1,690/ton of NOx for the small sources with uncontrolled NOx emissions <365 tons/yr and $820/ton of NOx for the small sources with uncontrolled NOx emissions >365 tons/yr. The capital cost to annual cost ratios also are slightly less than the current values in the CMDB.

Based on regression of the data in the 1993 ACT, the best fit trend lines are represented by the following revised power equations for both uncontrolled and RACT baseline scenarios:

Appendix A

NMED Exhibit 60 - 0047

Total capital investment (1999 dollars) = 43092 x (MMBtu/hr) ^ 0.82 (R^2=0.95)

Total annual cost (1999 dollars) = 7282 x (MMBtu/hr) ^ 0.76 (R^2=0.96)

3.3.3 Dry Low NOx Combustion; Gas Turbines—Natural Gas (NDLNCGTNG)

Dry low NOx (DLN) combustion technology premixes air and a lean fuel mixture that significantly reduces peak flame temperature and thermal NOx formation. In some cases, this can be accomplished by using low NOx burners, but in other cases, the combustor design itself differs as well as the burner design. For example, the DLN combustor volume is typically twice that of a conventional combustor (OSEC, 1999). Therefore, we recommend revising the current control technology name in the CMDB from "Low NOx Burners" to "Dry Low NOx Combustion." In addition, the CM abbreviation should be changed from NLNBUGTNG to NDLNCGTNG.

Recommended updates to the costs for DLN Combustion are based on analyses in a report prepared by Onsite Sycom Energy Corporation for the U.S. Department of Energy (OSEC, 1999). OSEC estimated costs for some of the six turbines with design outputs ranging from 4 MW to 169 MW.

OSEC obtained installed equipment costs and annual repair costs in 1999 dollars from three turbine manufacturers, but there are some uncertainties in the data. Although the reported tabular summary indicates the equipment costs are incremental relative to the cost of a conventional combustor, the text of the report states that the costs for 169 MW turbines are the total cost to replace a conventional combustor (which may explain why the regression equation for the capital costs is linear rather than a power function). Annual costs for parts and repair for some of the turbines were proprietary for two of the small turbines and thus could not be reported. As a result, the annual costs for those turbines are biased low. In addition, because parts and repair costs were unavailable for the 169 MW turbine, OSEC assumed these costs could be represented by the costs for the 23 MW turbine.

The only change we made to the assumptions and data reported by OSEC was to calculate capital recovery using an interest rate of 7 percent instead of 10 percent.

Table 3-4 summarizes the recommended new cost effectiveness and capital to annual cost ratios for implementing the DLN combustion NOx control technology. In addition to changing these costs in the CMDB, we also recommend changing the control efficiency for DLN combustion applied to small sources from 68 percent to 84 percent. The 84 percent level is

Appendix A

NMED Exhibit 60 - 0048

currently used for large sources, and it is consistent with the efficiency for DLN combustion (or low NOx burners) in the 1993 ACT. It appears the 68 percent entry was a data transcription error because that is the control efficiency for water injection applied to oil-fired turbines.

Table 3-4. Summary of Cost Effectiveness and Supporting Data for DLN Combustion

Turbine Output, MW	Cost Year	Uncontrolled NOx Emissions		Outlet Concentration, ppmvd	Cost Effectiveness, $/ton NOx	Capital to Annual Cost Ratio
		Avg. ppmvd	tpy			
Small (4-23)	1999	152	<365	25	300	5.0
Large (170)	1999	210	>365	25	130	7.4

Based on regression of the data in both analyses, the best fit trend lines are represented by the following revised equations for both uncontrolled and RACT baseline scenarios:

Total capital investment (1999 dollars) = 2860.6 x (MMBtu/hr) + 25427 (R^2=1.0)

Total annual cost (1999 dollars) = 584.5 x (MMBtu/hr) ^ $^{0.96}$ (R^2=0.95)

3.3.4 SCR and Water Injection; Gas Turbines—Natural Gas (NSCRWGTNG)

Recommended updates to the costs for SCR combined with water injection are based on two sets of cost analyses. One set of costs is in 1999 dollars for three turbines ranging in size from 4.2 MW to 161 MW (OSEC, 1999). The second is in 2008 dollars for two larger turbines with design outputs of 50 MW and 180 MW (ECP, 2008). For SCR, the referenced analyses estimated direct installation costs and indirect costs based on scaling from the purchased equipment costs using standard factors as in the Control Cost Manual. Annual costs were estimated for the same cost elements that were used in the SCR analysis in the 1993 ACT. Water injection costs for the two smallest turbines in the 1999 analysis were estimated as described above for the water injection control option. Water injection costs for the large turbines were not estimated in the referenced analyses.

For the purposes of developing 1999 cost inputs for the CMDB, we made the following changes to the data and assumptions used in the OSEC analysis:

- Increased the engineering cost for SCR for the 161 MW turbine from $100,000 to $228,865. The revised value is equal to 10 percent of the purchased equipment cost, which is consistent with the approach used for the smaller turbines. The report did not explain why $100,000 was used instead of the factor.

Appendix A

NMED Exhibit 60 - 0049

- Estimated performance penalty costs and electricity costs for the blower and pumps in the ammonia injection system using operating hours of 8,000 hr/yr instead of 8,400 hr/yr.

- Calculated capital recovery for the SCR system using an interest rate of 7 percent instead of 10 percent.

- Calculated annual catalyst replacement and disposal costs using a future worth factor instead of a capital recovery factor.

- Estimated total capital investment and total annual costs for the 161 MW turbine using the regression equations for the water injection control option. (Maybe it would be better to drop the large model from this analysis and just present 1999 costs for small turbines and 2008 costs for large turbines.)

For the purposes of developing 2008 cost inputs for the CMDB, we started with the ECP analysis for SCR costs and then made the following changes to the data and assumptions:

- Calculated the performance penalty for SCR using an electricity cost of $0.06/kwh instead of $0.1/kwh and 8,000 hr/yr instead of 8,400 hr/yr. In addition, although it appears that the referenced analysis assumed a performance loss equal to 0.5 percent of the turbine's design output, the cited cost was significantly greater than it should be for that percentage loss, even if the cited electricity cost and operating hours were used in the calculation. We changed the cost to be consistent with the calculated amount.

- Calculated capital recovery for the SCR system using an interest rate of 7 percent instead of 10 percent.

- Estimated capital costs for water injection in 1999 dollars using the regression equation for the water injection control option, and then scaled the costs to 2008 dollars using the CEPCI.

- Estimated total annual costs for water injection following the same procedure described in Section 3.2.2 for the water injection portion of a combined water injection and EMx control measure. Thus, the total annual costs for water injection are the same in both control measures.

Table 3-5 summarizes the recommended new cost effectiveness and capital to annual cost ratios values for implementing SCR plus water injection on natural gas-fired combustion turbines. Table 3-5 also presents revised incremental costs of SCR relative to a RACT baseline of water injection for the different categories of turbines. Note that the SCR outlet NOx level was assumed to be 2.5 ppmvd in the ECP analysis, which results in an overall control efficiency of 98 percent versus the 94 percent for the OSEC and ACT analyses.

Appendix A

Table 3-5. Summary of Cost Effectiveness and Supporting Data for SCR Plus Water Injection

Turbine Output, MW	Cost Year	Uncontrolled NOx Emissions		SCR Outlet Concentration, ppmvd	Cost Effectiveness, $/ton NOx	Capital to Annual Cost Ratio	Incremental Cost Relative to RACT Baseline of WI, $/ton NOx
		Avg. ppmvd	tpy				
Small (4.2)	1999	134	<365	9	2,790	3.0	5,840
Small (22.7)	1999	174	>365	9	1,370	2.9	3,130
Large (161)	1999	210	>365	9	1,070	1.5	1,690
Large (50-180)	2008	160[a]	>365	2.5	1,830	2.7	3,170

[a]Uncontrolled concentrations were not reported in the referenced analysis. Thus, the value used in this analysis is an assumed average that results in the estimated 84 percent reduction for DLN combustion, as described in Section 3.3.3 of this report.

Based on regression of the data in both analyses, the revised best fit trend lines are represented by the following power equations for both uncontrolled scenarios (R^2=1 for the 2008 costs because the analysis was based on only two data points):

Total capital investment (1999 dollars) = 62962 x (MMBtu/hr) ^ 0.66 (R^2=1.0)

Total annual cost (1999 dollars) = 8590 x (MMBtu/hr) ^ 0.87 (R^2=0.99)

Total capital investment (2008 dollars) = 34533 x (MMBtu/hr) ^ 0.85 (R^2=1.0)

Total annual cost (2008 dollars) = 6794 x (MMBtu/hr) ^ 0.94 (R^2=1.0)

Revised best fit equations for incremental SCR costs relative to a RACT baseline of water injection are (R^2=1 for the 2008 costs because the analysis was based on only two data points):

Total capital investment (1999 dollars) = 37193 x (MMBtu/hr) ^ 0.63 (R^2=1.0)

Total annual cost (1999 dollars) = 12065 x (MMBtu/hr) ^ 0.64 (R^2=1.0)

Total capital investment (2008 dollars) = 10323 x (MMBtu/hr) ^ 0.96 (R^2=1.0)

Total annual cost (2008 dollars) = 3106.1 x (MMBtu/hr) ^ 0.94 (R^2=1.0)

Appendix A

NMED Exhibit 60 - 0051

3.3.5 SCR and Steam Injection; Gas Turbines—Natural Gas (NSCTSGTNG)

Combined costs for SCR and steam injection were not presented in any available references. Thus, costs for combined control systems were estimated in 1999 dollars for four model turbines ranging from 4 MW to 161 MW using the procedures described above for steam injection alone and for SCR as part of combined SCR and water injection control systems. Specifically, steam injection costs for each model turbine were assumed to be the same as in the 1993 ACT, consistent with the description above for steam injection control costs. Since OSEC did not estimate SCR costs for the specific turbines in this analysis, we estimated the SCR costs using the trendlines that we developed for incremental SCR costs relative to a RACT baseline of water injection. We then summed the separate SCR and steam injection costs to obtain the combined system costs.

We also estimated costs for a combined steam injection and SCR control measure in 2008 dollars. The SCR portion of the costs are the same as for SCR in the combined water injection plus SCR control measure, as described in Section 3.3.4. Total capital investment for the steam injection portion were estimated in 1999 dollars using the regression equation developed for steam injection alone, as described in Section 3.3.2. These costs were escalated to 2008 costs using the CEPCI. Total annual costs for steam injection were first estimated in 1999 dollars using the regression equation for the steam injection control option (see Section 3.3.2). On average, 40 percent of these costs were estimated to be for indirect costs that are factored from the system capital cost, and the remaining 60 percent is for direct annual costs and overhead. To estimate the total annual costs for steam injection in 2008, the indirect costs were scaled from the 1999 estimate using the CEPCI, and the direct annual costs and overhead were assumed to be the same as in 1999.

Table 3-6 summarizes the recommended new cost effectiveness and capital to annual cost ratios values for implementing SCR plus steam injection on natural gas-fired combustion turbines. Table 3-6 also presents revised incremental costs of SCR relative to a RACT baseline of steam injection for the different categories of turbines. Note that the incremental costs are slightly different from the costs in Table 3-5. The costs should be the same for a given turbine category. They differ because the two analyses examined a different number of turbines, and the sizes were not exactly the same. At a later date, the analysis could be improved by combining the SCR costs from both analyses and developing a single set of incremental SCR costs.

Appendix A

NMED Exhibit 60 - 0052

Table 3-6. Summary of Cost Effectiveness and Supporting Data for SCR Plus Steam Injection (SI)

Turbine Output, MW	Cost Year	Uncontrolled NOx Emissions		SCR Outlet Concentration, ppmvd	Cost Effectiveness, $/ton NOx	Capital to Annual Cost Ratio	Incremental Cost Relative to RACT Baseline of SI, $/ton NOx
		Avg. ppmvd	tpy				
Small (4.2)	1999	155	<365	9	2,570	3.3	5,550
Small (26.8)	1999	142	>365	9	1,380	3.1	2,870
Large (83–161)	1999	300	>365	9	570	2.7	1,810
Large (50–180)	2008	160[a]	>365	2.5	1,420	3.9	3,170

[a]Uncontrolled concentrations were not reported in the referenced analysis. Thus, the value used in this analysis is an assumed average that results in the estimated 84 percent reduction for DLN combustion, as described in Section 3.3.3 of this report.

Based on regression of the data in the analysis, the revised best fit trend lines are represented by the following power equations for the uncontrolled scenario (R^2=1 for the 2008 costs because the analysis was based on only two data points):

Total capital investment (1999 dollars) = 72169 x (MMBtu/hr) ^ 0.66 (R^2=0.99)

Total annual cost (1999 dollars) = 17551 x (MMBtu/hr) ^ 0.72 (R^2=0.98)

Total capital investment (2008 dollars) = 46492 x (MMBtu/hr) ^ 0.82 (R^2=1.0)

Total annual cost (2008 dollars) = 8704 x (MMBtu/hr) ^ 0.86 (R^2=1.0)

Revised best fit equations for incremental SCR costs relative to a RACT baseline of steam injection are assumed to be the same as noted above in the discussion of costs for SCR and water injection.

3.3.6 SCR and Dry Low NOx Combustion; Gas Turbines—Natural Gas (NSCRDGTNG)

Updated costs for combined SCR and DLN combustion control systems were estimated in 1999 dollars for all turbine sizes, 2007 dollars for small turbines, and 2008 dollars for large turbines. The 1999 costs were estimated by combining the separate costs for DLN combustion and SCR provided by Onsite Sycom Energy Systems (OSEC, 1999). The 2007 costs were estimated by combining SCR costs developed by Energy and Environmental Analysis in a report prepared for EPA with the OSEC costs for DLN combustion in 1999 dollars, escalated to 2007 dollars (EEA, 2008). Similarly, costs in 2008 dollars were estimated by combining SCR costs

Appendix A

NMED Exhibit 60 - 0053

developed by EmeraChem Power in an analysis for the Bay Area Air Quality Management District with escalated DLN combustion costs (ECP, 2008). The EEA analysis provided only capital costs; therefore, we estimated annual costs using the same factors provided in ECP's analysis of costs in 2008 dollars. For both the 2007 and 2008 cost estimates, DLN capital costs and capital recovery were escalated from 1999 dollars using the CEPCI, and annual parts and repairs costs were assumed to be the same in all three years.

Table 3-7 summarizes the recommended new cost effectiveness and capital to annual cost ratios values for implementing SCR plus dry low NOx combustion on natural gas-fired combustion turbines. Table 3-7 also presents revised incremental costs of SCR relative to a RACT baseline of steam injection for the different categories of turbines. Note that the SCR outlet NOx level was assumed to be 2.5 ppmvd in the ECP analysis, which results in an overall control efficiency of 98 percent versus the 94 percent for the OSEC analyses. We also used an outlet concentration of 2.5 ppmvd to estimate emissions to use with EEA's 2007 costs. The ECP and EEA analyses did not specify inlet NOx emissions concentrations to the SCR; therefore, we assumed 25 ppmvd, as in other DLN analyses. We also assumed an average uncontrolled emissions level of 160 ppmvd for all models so that the overall control efficiency of the DLN combustion plus the SCR was 98 percent. Note that the incremental costs in 1999 dollars are significantly higher than those for SCR following water injection and steam injection; this is due to the inlet concentration being 25 ppmvd for this analysis and 42 ppmvd for water injection and steam injection.

Table 3-7. Summary of Cost Effectiveness and Supporting Data for SCR Plus DLN Combustion

Turbine Output, MW	Cost Year	Uncontrolled NOx Emissions		SCR Outlet Concentration, ppmvd	Cost Effectiveness, $/ton NOx	Capital to Annual Cost Ratio	Incremental Cost Relative to RACT Baseline of DLN, $/ton NOx
		Avg. ppmvd	tpy				
Small (4.2)	1999	134	<365	9	1,800	2.9	11,900
Small (26.8)	1999	174	>365	9	990	3.6	6,320
Large (161)	1999	210	>365	9	390	4.2	3,340
Small (1–10.2)	2007	160[a]	<365	2.5	2,910	4.3	18,900
Small (25)	2007	160[a]	>365	2.5	1,460	3.8	7,510
Large (50–180)	2008	160[a]	>365	2.5	1,040	4.5	5,560

[a]Uncontrolled concentrations were not reported in the referenced analysis. Thus, the value used in this analysis is an assumed average that results in the estimated 84 percent reduction for DLN combustion, as described in Section 3.3.3 of this report.

Appendix A

NMED Exhibit 60 - 0054

Based on regression of the data in each analysis, the best fit trend lines are represented by the following power equations for uncontrolled scenarios (R^2=1 for the 2008 costs because the analysis was based on only two data points, and note that the R^2 for the 2007 equations is not meaningful because the DLN portion of the costs are based on a regression equation instead of independent, model-specific data):

Total capital investment (1999 dollars) = 24854 x (MMBtu/hr) ^ $^{0.79}$ (R^2=1.0)

Total annual cost (1999 dollars) = 12725 x (MMBtu/hr) ^ $^{0.69}$ (R^2=1.0)

Total capital investment (2007 dollars) = 187647 x (MMBtu/hr) ^ $^{0.54}$ (R^2=1.0)

Total annual cost (2007 dollars) = 2782 x (MMBtu/hr) + 167494 (R^2=1.0)

Total capital investment (2008 dollars) = 14790 x (MMBtu/hr) ^ $^{0.97}$ (R^2=1.0)

Total annual cost (2008 dollars) = 5263.5 x (MMBtu/hr) ^ $^{0.90}$ (R^2=1.0)

The equations to estimate incremental costs for SCR relative to a RACT baseline of dry low NOx combustion in 1999 dollars and 2008 dollars are assumed to be the same as noted in Section 3.3.4 for incremental costs relative to a RACT baseline of water injection. Incremental costs for SCR relative to a RACT baseline of water injection in 2007 dollars are estimated using the following equations:

Total capital investment (2007 dollars) = 210883 x (MMBtu/hr) ^ $^{0.46}$ (R^2=1.0)

Total annual cost (2007 dollars) = 1894 x (MMBtu/hr) + 185570 (R^2=0.99)

3.3.7 Water Injection; Gas Turbines—Oil (NWTINGTOL)

No new data are available on costs of water injection for oil-fired combustion turbines. However, because the water injection costs for natural gas-fired turbines were determined to be essentially the same in 1999 as in 1990, we assume the same would be true for water injection on oil-fired turbines; the costs for both types of turbines also were the same in the 1993 ACT analysis. Therefore, we recommend continuing to base costs on the results of the 1993 ACT analysis, but to update the cost year from 1990 to 1999. In addition, we changed the size of the large model in the ACT analysis from 83.3 MW to 84.7 MW because it appears the incorrect

Appendix A

NMED Exhibit 60 - 0055

model was used in the ACT analysis. As for the natural gas-fired turbines, we also recommend splitting the single record for small sources into two records—one for source with uncontrolled NOx emissions <365 tpy, and the other for sources with uncontrolled NOx emissions >365 tpy. The resulting cost effectiveness values for the turbines with uncontrolled NOx emissions <365 tpy and >365 tpy are $1,630/ton of NOx and $960/ton of NOx, respectively. The capital to annual cost ratios also change slightly.

As for other control technologies, the constants in the equations to estimate total capital costs and total annual costs differ from those in the regression analyses performed in Excel. In this case, the differences are small, but we recommend revising the constants so that all equations are developed based on the same approach. The revised equations for both the uncontrolled and RACT baseline scenarios are:

$$\text{Total capital investment (1999 dollars)} = 43255 \times (\text{MMBtu/hr})^{0.60} \quad (R^2=1.0)$$

$$\text{Total annual cost (1999 dollars)} = 6796.8 \times (\text{MMBtu/hr})^{0.80} \quad (R^2=1.0)$$

3.3.8 SCR and Water Injection; Gas Turbines—Oil (NSCRWGTNG)

SCR costs were developed in a BACT analysis for a 48 MW oil-fired combustion turbine (FMPA, 2004). Because water injection costs in 2004 dollars are not available, we calculated costs in 1999 dollars as described above for the water injection option, and then estimated costs in 2004 dollars by scaling up the 1999 capital costs (and capital recovery) using the CEPCI; other annual operating and maintenance costs were assumed to be unchanged. We used the SCR capital cost as presented in the FMPA analysis, but we made several changes to the annual costs. Although the original values may have been appropriate for the specific application evaluated by FMPA, the following changes were made to be consistent with the calculations for other controls in this analysis:

- Estimated O&M costs assuming operation for 8,000 hr/yr instead of 4,422 hr/yr.
- Excluded cost for one week of lost power generation while catalyst is being replaced, assuming that catalyst replacement can be performed during scheduled annual downtime.
- Reduced sales tax and freight cost for catalyst from 12.25 percent of the purchased cost to 8 percent of the purchased cost.
- Deleted capital recovery cost for catalyst because the catalyst is replaced annually.

Appendix A

NMED Exhibit 60 - 0056

- The reported annual cost for ammonia was based on a stoichiometric ratio of 1.4 (possibly because they assumed a significant generation of NO2 relative to NO). They also applied a factor of 1.05, apparently to account for ammonia slip, as in the Control Cost Manual procedures for SCR on boilers. However, both factors should not be needed. For this analysis, we used just the 1.05 factor (also used the reported unit cost of $750/ton of ammonia, which may have been high for 2004).

- Reduced the property tax factor from 2.75 percent of the TCI to 1 percent of the TCI.

Table 3-8 summarizes the recommended cost effectiveness and capital to annual cost ratios values for implementing SCR plus water injection on oil-fired combustion turbines. Table 3-8 also presents incremental costs of SCR relative to a RACT baseline of water injection. The 1990 costs are essentially the same as the costs currently in the CMDB, except that we recommend splitting the one record for small sources into two records.

Table 3-8. Summary of Cost Effectiveness and Supporting Data for SCR Plus Water Injection (WI) for Oil-Fired Turbines

Turbine Output, MW	Cost Year	Uncontrolled NOx Emissions		SCR Outlet Concentration, ppmvd	Cost Effectiveness, $/ton NOx	Capital to Annual Cost Ratio	Incremental Cost Relative to RACT Baseline of WI, $/ton NOx
		Avg. ppmvd	tpy				
Small (3.3)	1990	179	<365	18	3,200	2.9	7,620
Small (26.3)	1990	211	>365	18	1,320	2.3	2,450
Large (84)	1990	228	>365	18	1,000	2.4	2,210
Large (48)	2004	200[a]	>365	5	1,560	2.3	4,790

aThe referenced analysis did not report an uncontrolled emissions level. The value used in this analysis is the average of the uncontrolled emissions concentrations for oil-fired model turbines in the 1993 ACT.

Based on regression of the data in the 1993 ACT, the best fit trend lines are represented by the following revised power equations for the uncontrolled scenario:

$$\text{Total capital investment (1990 dollars)} = 95837 \times (\text{MMBtu/hr})^{0.62} \quad (R^2=0.99)$$

$$\text{Total annual cost (1990 dollars)} = 25990 \times (\text{MMBtu/hr})^{0.70} \quad (R^2=1.0)$$

Revised best fit equations for incremental SCR costs relative to a RACT baseline of water injection are:

$$\text{Total capital investment (1990 dollars)} = 4744 \times (\text{MMBtu/hr}) + 368162 \quad (R^2=1.0)$$

NMED Exhibit 60 - 0057

Appendix A

Total annual cost (1990 dollars) = 1522.5 x (MMBtu/hr) + 142643 (R^2=1.0)

We could not develop equations for this control system in 2004 dollars because 2004 data are available for only one turbine, and thus are insufficient for this purpose.

3.3.9 Water Injection; Gas Turbines—Jet Fuel (NWTINGTJF)

The current CMDB assumes costs for jet fuel-fired turbines are the same as for oil-fired turbines. Thus, we recommend the same changes for jet fuel fired turbines as noted above for oil-fired turbines.

3.3.10 SCR and Water Injection; Gas Turbines—Jet Fuel (NSCTWGTJF)

The current CMDB assumes costs for jet fuel-fired turbines are the same as for oil-fired turbines. Thus, we recommend the same changes for jet fuel fired turbines as noted above for oil-fired turbines.

3.3.11 Applicable Control Measures for Gas Turbine SCCs

The first column in Table 3-9 lists all of the gas turbine SCCs that are associated with one or more gas turbine control measures in the CMDB table called "Table 03_SCCs." In addition, the last seven SCCs in Table 3-9 are additional gas turbine SCCs that are not currently assigned any NOx control measures in the CMDB. These seven SCCs, as well as many of the others at the top of Table 3-9, were identified with NOx emissions in an EPA query of the NEI for facilities in the Ozone Transport Group Assessment Region (i.e., 37 states that are partially or completely to the east of 100^{o}W longitude). The first 11 control measures in column headings in Table 3-9 are the gas turbine control measures that are currently in the CMDB; the last three column headings are the new control measures identified in this review and described in Section 3.2 of this report.

Each control measure that was determined to be applicable for a specific SCC is identified by either an "E" or an "N" in the cell at the intersection of the applicable SCC row and the control measure column. An "E" means the control measure is already listed in the CMDB for the particular SCC, and we concur with that designation. An "N" means the control measure is not currently linked to a particular SCC, but we recommend adding this link in the database. In some cases, we recommend applying new links between existing control measures and existing SCCs. For example, some of the SCCs are for turbines that are fired with relatively uncommon fuels such as landfill gas or gasoline. We have not located any analyses that determined the applicable controls and related costs for gas turbines fired with such fuels. In order to conduct CoST modeling analyses for these turbines, the most representative available control measures

[a]SCCs in regular font are associated with one or more gas turbine control measures in the current CMDB. The SCCs in bold font represent gas turbine activities that were identified with NOx emissions in the Ozone Transport Assessment Group Region analysis but are not associated with gas turbine control measures in the current CMDB.

[b]ICE means "Internal Combustion Engines" and WD means "Waste Disposal."

[c]Ind means "Industrial," C/I means "Commercial/Institutional," ET means "Engine Testing," and SWD-G means "Solid Waste Disposal-Government."

[d]An "E" means the control measure is currently associated with the SCC in the CMDB, and no changes are recommended. A "D" means the control measure is currently associated with the SCC, but this control measure should be deleted because it is not appropriate for the SCC. An "N" means the control measure is not currently associated with the SCC in the CMDB, but adding it is recommended.

[e]The control measure is assumed to be representative for the SCC; control cost data are unavailable for the specific fuel type for the SCC.

[f]The fuel type is unknown. For the purposes of this analysis it is assumed to be a liquid because most of the emissions identified for the engine testing SCCs in the analysis done in the Ozone Transport Assessment Group Region were from liquid fuel-fired turbines.

Appendix A

should be assigned. For turbines that burn miscellaneous gaseous fuels, the most representative control measures are those for natural gas-fired turbines. Similarly, for turbines that burn miscellaneous liquid fuels, the most representative available control measures are those for oil-fired turbines. The description field in the CMDB table called "Table 02_Efficiencies" could be revised to indicate that the control measures for natural gas units are assumed to be applicable for all gaseous fuel fired units, and the control measures for oil-fired units are assumed to be applicable for all liquid fuel-fired units (note that the separate control measures already in the CMDB for jet fuel-fired turbines are also based on the data for oil-fired units).

Finally, gas turbine SCCs for evaporative losses from turbine fuel storage and delivery systems are associated with NOx control measures in the current CMDB. We recommend deleting these NOx control measure/SCC records from the CMDB table called "Table 03_SCCs" because there should be no NOx emissions from the sources represented by these SCCs. These control measure/SCC combinations are identified with a "D" in the applicable cells in Table 3-9.

3.4 Example Emission Limits for NonEGU Combustion Turbines

NonEGU combustion turbines are subject to several emission regulations, including NSPS in 40 CFR part 60 and various state regulations. Example emission limits in state regulations are presented in Table 3-10.

Table 3-10. NOx Emissions Limits for NonEGU Combustion Turbines in New York

State	Type of Service	Type of Combustion Turbine Operating Cycle	Emission Limit	Effective Date
New York[a]	Any—gaseous fuel	Combined cycle	42 ppmdv (at 15% O2)	Current
		Simple cycle or regenerative cycle	50 ppmdv (at 15% O2)	Current
	Any—oil-fired	Combined cycle	65 ppmdv (at 15% O2)	Current
		Simple cycle or regenerative cycle	100 ppmdv (at 15% O2)	Current

[a]The requirements apply to combustion turbines with a maximum heat input rate greater than or equal to 10 million Btu per hour at major sources of NOx emissions. The specified limits apply until July 1, 2014; beginning on July 1, 2014, owners/operators must submit a proposal for RACT (NYCRR, 2014).

SECTION 4
GLASS MANUFACTURING SECTOR

4.1 Introduction

The control cost database separates the glass manufacturing sector into four different types; flat glass, container glass, pressed glass, and general glass manufacturing. The CMDB listed six different control technologies for NOx emissions which were all reviewed in 2006 and included cullet preheat, oxy-firing, electric boost, low NOx burners, selective catalytic reduction (SCR) and selective non-catalytic reduction (SNCR). A literature and internet search was conducted to find any new control technologies for NOx or any updates to existing controls regarding cost and efficiencies. Operating permits for some glass manufacturing plants were reviewed and control system vendors were also contacted for information. A brief summary of data from each reference reviewed in included in the spreadsheet "CoST_Glass Mfg.xlsx."

4.2 Example NOx Regulatory Limits

4.2.1 Wisconsin

Glass manufacturing furnace with a maximum heat input capacity equal to or greater than 50 mmBtu per hour, 2.0 pounds per ton of produced glass.[1]

4.2.2 New Jersey

Commercial container glass, specialty container glass, borosilicate recipe glass, pressed glass, blown glass, and fiberglass manufacturing furnaces: 4.0 lbs/ton glass removed. Flat glass manufacturing furnaces: 9.2 lbs/ton glass removed.

4.2.3 New York

NOx emissions are covered under NY's case-by case RACT regulations.

4.3 Recommended Additions

The following NOx controls are recommended additions for the glass manufacturing industry that are not currently in the control cost database, and a tabular summary of the costs is presented in Table 4-1.

- Electric Boost—Three entries for electric boost controls were in the CMDB for container, flat, and pressed glass manufacturing. A cost estimate for electric boost was found for "general" glass manufacturing (DOE, 2002), since the CMDB did not have a "general" entry for electric boost controls, an entry for "Electric Boost; Glass Manufacturing—General" was added with a new abbreviation of NELBOGMGN. The

[1] http://dnr.wi.gov/About/NRB/2007/January/01-07-3A4.pdf

Appendix A

NMED Exhibit 60 - 0065

reference provided an annualized cost of $7,100 per ton of NOx removed based on a 250 ton of glass per day glass melting furnace operating with an emission rate of 8-lb NOx per ton glass produced and a NOx removal efficiency of 30 percent. Since the reference did not provide capital costs, the capital to annual cost ratio could not be determined, and the capital recovery factor was assumed to be the same as the electric boost entries for container, flat, and pressed glass (i.e., 0.1424, assuming equipment life of 10 years).

- Oxy-firing—Three entries for oxy-firing were in the CMDB for container, flat, and pressed glass manufacturing. Similar to electric boost controls, an updated cost estimate for oxy-firing was found for "general" glass manufacturing (DOE, 2002); since the CMDB did not have a "general" entry for oxy-firing, an entry for "OXY-Firing; Glass Manufacturing—General" was added to the CMDB with a new abbreviation of NOXYFGMGN. The reference provided an annualized cost of $2,352 per ton of NOx removed based on a 250 ton of glass per day glass melting furnace emitting 8-lb NOx per ton glass produced and a NOx removal efficiency of 85 percent.[1] Since the capital costs were not provided the capital to annual cost ratio and the capital recovery factor were assumed to be the same as the oxy-firing entries for container, flat, and pressed glass, which all had the same values.

- Catalytic Ceramic Filter—This new control technology for NOx reduction was not previously in the database and was added for flat glass manufacturing with a new abbreviation of CATCFGMFT. A vendor was contacted for information (2013 Vendor Quote). The minimum and maximum cost per ton estimates were based on regenerative gas-fired furnace with pull rates of 600 tons per day and 490 tons per day, respectively. The estimate provided by the vendor included capital cost, annualized capital costs, and annual operational cost in 2013 dollars; it also included NOx reductions based on a 95 percent NOx efficiency.

Table 4-1. Summary of Cost Effectiveness and Supporting Data for Recommended Additions

Technology	Furnace Production Rate (ton/day)	Cost Year	NOx Removal Efficiency (%)	Cost Effectiveness, $/ton NOx	Capital to Annual Cost Ratio
Electric Boost (general)	250	2002	30	7,100	N/A[a]
Oxy-firing General	250	2002	85	2,352	2.7
Catalytic Ceramic Filter	490	2013	95	1,045	4.6
	600	2013	95	997	4.6

[a]The ratio cannot be calculated because capital costs are not available.

Appendix A

NMED Exhibit 60 - 0066

4.4 Recommended Changes

Changes to the CMDB are recommended for the following three types of control measures, which are also summarized in Table 4-2.

- Low NOx Burner General—Three entries for Low NOX burners were in the cost database for container, flat, and pressed glass manufacturing. An updated cost estimate for low NOx burners for flat glass and container glass manufacturing (EC, 2013) was found and entries NLNBUGMCN and NLNBUGMFT were updated. The reference provided capital costs and an annualized cost in euros per kilogram of NOx removed which was converted to dollars per ton of NOx. For flat glass the minimum cost per ton estimate was based on a 900 ton per day gas fired furnace, and the maximum cost per ton estimate was based on a 500 ton per day gas fired furnace. For container glass the minimum cost per ton estimate was based on 450 ton per day gas fired furnace, and the maximum cost per ton estimate was based on a 200 ton per day gas fired furnace. The capital recovery factor and the capital to annual cost ratio were also updated. We also recommend changing the equipment life for low NOx burners on flat glass furnaces from 3 years to 10 years (EC, 2013).

  Additionally, equations for low NOx burners were added for entries NLNBUGMCN and NLNBUGMFT to "Table 04_Equations" of the CMDB based on the best fit trend lines of the total capital investment and total annual cost for the facilities with the production levels described above, the best fit trend line results were as follows:

  NLNBUGMCN (The correlation coefficients are high because the data are from a single source, and they may reflect data points from a correlation performed by that source)

  Total capital investment (2007 dollars) = 30,930 x (tons/day)$^{0.45}$ (R^2 = 0.99)

  Total annual cost (2007 dollars) = 9,377 x (tons/day) $^{0.40}$ (R^2 = 0.99)

  NLNBUGMFT (The correlation coefficients are a perfect 1.0 because only two data points are available)

  Total capital investment (2007 dollars) = 527 x (tons/day) + 664,557 (R^2 = 1.0)

  Total annual cost (2007 dollars) = 132x (tons/day) + 150,105 (R^2 = 1.0)

- Cullet Preheating—Two entries for cullet preheating controls were in the cost database for container and pressed glass manufacturing. An updated annualized cost per ton value and NOx efficiency for pressed and container glass entries (IT, 2002) were found and updated for entries NCLPTGMCN and NCUPHGMPD. The reference provided an annualized cost of $5,000 per ton of NOx removed based on a 250 ton of glass per day glass melting furnace emitting 8-lb NOx per ton glass produced and a NOx removal efficiency of 5 percent.[1] Since the reference did not

[1] Annualized cost includes capital and O&M costs and is based on 2002 dollars.

Appendix A

NMED Exhibit 60 - 0067

provide capital costs separately, the capital to annual cost ratio and the capital recovery factor were not updated. Additionally, based on information from EPA's OECA staff, class entries for cullet preheating should be changed from "known" to "emerging" in Table 01_Summary of the CMDB because this control measure is technically feasible but has rarely been implemented.[1]

- Selective Catalytic Reduction—Three entries for selective catalytic reduction were in the CMDB for container, flat, and pressed glass manufacturing. An updated cost estimate for SCR for flat glass and container glass manufacturing (EC, 2013) was found, and entries NSCRGMCN and NSCRGMFT were updated. The reference provided capital costs and an annualized cost in euros per kilogram of NOx removed which was converted to dollars per ton of NOx.[2] For flat glass the minimum and maximum cost per ton estimates were based on a 900 and 500 ton per day gas fired furnace, respectively. For container glass the minimum and maximum estimates were based on a 450 and 200 ton per day gas fired furnaces, respectively. The capital to annual cost ratio were also updated.

  Equations for SCR were added for entries NSCRGMCN and NSCRGMFT to Table 4 of the CMDB based on the best fit trend lines of the total capital investment and total annual cost for the facilities with the production levels described above, the best fit trend line results were as follows:

  NSCRGMCN (The correlation coefficients are high because the data are from a single source, and they may reflect data points from a correlation performed by that source)

  Total capital investment (2007 dollars) = 79,415 x (tons/day) $^{0.51}$ (R^2 = 0.99)

  Total annual cost (2007 dollars) = 643 x (tons/day) + 135,302 (R^2 = 1.0)

  NSCRGMFT (The correlation coefficients are a perfect 1.0 because only two data points are available)

  Total capital investment (2007 dollars) = 3681 x (tons/day) + 1.0E+06 (R^2 = 1.0)

  Total annual cost (2007 dollars) = 842 x (tons/day) + 424,930 (R^2 = 1.0)

4.5 Recommended Deletions

- Selective Non-Catalytic Reduction—Three entries for selective non-catalytic reduction were in the cost database for container, flat, and pressed glass manufacturing. Based on conversations between EPA and OECA staff, SNCR entries for glass manufacturing should be removed based on recent NSR settlements that indicate SNCR is not a technically feasible control technology for the removal of NOx.[1]

4.6 Updates to Source Classification Codes

- There are twenty applicable SCCs for glass manufacturing as shown in Table 4-3.

- In an analysis of NO_X emissions for the Ozone Transport Assessment Group Region in 2011, fourteen of the SCCs in Table 4-3 were identified. The six SCCs not included in the Ozone Transport Region are shown at the bottom of Table 4-3. Four of the SCCs, 30501401, 30501402, 30501403, and 30501404 are associated with glass manufacturing NO_X controls in the current CMDB.

- Furnaces are the primary source of NOx emissions in the glass manufacturing industry, therefore NOx emission control techniques are typically for point emission sources associated with furnace emissions. The four SCCs identified in the CMDB pertain to four types of melting furnaces; general, flat, container, and pressed. The

[1] Personal communication. Katie McClintock, US EPA/OCEA, with Larry Sorrels, US EPA/OAR/OAQPS, Feb. 13, 2014.

Appendix A

NMED Exhibit 60 - 0069

remaining sixteen SCCs in Table 4-3 are not associated with furnaces. Therefore, no changes related to SCCs are recommended for the CMDB.

- For new control techniques added to the CMDB for glass manufacturing, the applicable SCC from Table 4-3 was added to the Description field for each control technique in Table 01_Summary in the CMDB (Table C-1of Appendix C of this report). These related control measures and SCCs should also be added to "Table 03_SCCs" in the CMDB.

Appendix A

NMED Exhibit 60 - 0071

SECTION 5
LEAN BURN ENGINES

The CMDB includes the following NO_X emissions control measures for Lean Burn Engines:

- Air to fuel ratio (AFR) (achieves 20 percent reduction)
- Air to fuel ratio (AFR) and Ignition retard (IR) (achieves 30 percent reduction)
- Ignition retard (IR) (achieves 20 percent reduction)
- Low emission combustion (achieves 87 percent reduction)
- Low emissions combustion, low speed (achieves 87 percent reduction)
- Low emissions combustion, medium speed (achieves 87 percent reduction)
- Nonselective catalytic reduction (NSCR) (achieves 90 percent reduction)
- Selective catalytic reduction (SCR) (achieves 90 percent reduction)
- Selective noncatalytic reduction (SNCR) (achieves 90 percent reduction)

Based on the literature review and the new cost data identified for Lean Burn control technologies, several changes to the CMDB are recommended. No changes to existing records in CMDB are recommended. The following sections outline the additions and other comments recommended for the CMDB in relation to NO_X emissions from Lean Burn Engines.

5.1 Literature Search

In order to update the existing control measures database, a literature search was conducted for articles and papers published since 2008 (to include 2008 through August 2013) using the following terms:

- engine
- lean burn
- cost
- NOx or “nitrogen oxides”
- scr or “selective catalytic reduction”
- turbocharge

Appendix A

NMED Exhibit 60 - 0072

- air/fuel ratio
- layered combustion
- high energy ignition
- high pressure fuel injection
- "low emission control" or LEC
- electronic engine control
- combustion modification
- timing
- exhaust gas recirculation
- lean NOx catalyst
- lean NOx trap
- control efficiency
- emission reduction

The literature search identified a total of 19 references, and the abstracts for these references were reviewed. Three references of potential interest were identified and two of these were obtained for review in the lean burn engine control device study.

5.2 Document Review

A brief summary of data from each reference reviewed in included in the spreadsheet "CoST_leanburn.xlsx," in worksheet "Overall Sum—New Ref Review." The information and data available from each reference is provided in table format, along with indication of whether the data were used or not.

There are 6 control technique additions to be added to the CMDB from 5 references.

The recommended additions include:

- Low Emission Combustion, LEC (for natural gas engines);
- Layered Combustion, LC (for 2 stroke natural gas engines);
- Layered Combustion, LC (for 2 stroke Large Bore natural gas engines);

Appendix A

NMED Exhibit 60 - 0073

- Air to Fuel Ratio Controller, AFRC;
- Selective Catalytic Reduction, SCR (for 4 stroke natural gas engines); and
- SCR (for diesel engines).

Recent cost data for these control techniques were available from reports dated 2001 through 2012.

The references for the added control techniques are included on the "**Table 06 References**" worksheet and are as follows:

5.3 Low Emission Combustion (LEC) (NLECICENG)

The costs and cost effectiveness for applying LEC to natural gas Lean Burn engines are obtained from the document *Appendix B, Cost Effectiveness Analysis for Rule 4702 (Internal Combustion Engines—Phase 2)* (SJVAPCD 2003). Information was provided on Capital costs, Annual costs, uncontrolled emissions, and reduction efficiency. The assumptions for the original reference analysis are provided in Table 5-1 for LEC along with changes in assumptions for the current analysis.

LEC are described as retrofit kits that allow engines to operate on extremely lean fuel mixtures to minimize NOx emissions. The LEC retrofit may include: (1) redesign of cylinder head and pistons to improve mixing (on smaller engines), (2) Precombustion chamber (on larger engines), lower cost, simple versions, (3) Turbocharger, (4) High energy ignition system,

Appendix A

NMED Exhibit 60 - 0074

Table 5-1. LEC for Natural Gas Lean Burn Engines

Assumptions in Original Reference	Changes to Assumptions Made in Current Analysis
Capital costs	
Control efficiency: 80%	None.
Capital costs: provided for multiple models	None.
Annual Costs	
Equipment life: 10 yr	None.
Interest rate: 10%	Interest rate: 7%
Operating hours: 2000 hr/yr	None.
Emission rate, uncontrolled: 740 ppmv	Emission rate, uncontrolled: Assumed mid to upper end hp rating for each model.
Emission rate, controlled: 80% reduction	None.
Annualized equipment cost: provided for multiple model sizes	CRF: 0.1424
Annual O&M cost: assumed $0.	None.

(5) Aftercooler, and (6) Air to fuel ratio controller. (A discussion of individual technologies is provided in Appendix B of the original reference, pp. B-1 to B-28). No detail was provided on the exact combination of combustion modifications included in the example cost analysis; some references indicate that LEC on larger engines often includes a PCC (p.B-10) (CARB 2001). LEC are known or demonstrated control techniques for lean burn engines. An 80 percent NOx emission reduction can be achieved by LEC with little or no fuel penalty (in fact, LEC technologies are expected to decrease fuel consumption because they result in leaner burning engine, though the costs do not account for fuel consumption decrease). The original reference assumed an 80 percent reduction in the cost example.

Capital and annual costs were provided for multiple size ranges of engines. The capital costs ranged from $14,000 to $256,000. Costs for the 1000 to 3000 hp model were given as $40,000 to $256,000, and a mid-range cost of $148,000 was assumed in the current analysis. The total annual costs ranged from $2,000 to $21,000 (these costs are very similar to the costs calculated in the original reference analysis). The original reference assumed there are no annual operation and maintenance costs incurred from the combustion modification technologies, and the only annual cost provided is for annualized capital costs. No emission reductions are provided in the document (however the final cost effectiveness values are provided and the reduction assumed in the original analysis can be back-calculated). In the current analysis, a hp

Appendix A

NMED Exhibit 60 - 0075

rating based on the middle or upper end of each size range was assumed for estimating the uncontrolled NOx emissions. An estimate of emissions was made in the current analysis. Uncontrolled NOx emissions were estimated based on an uncontrolled NOx concentration of 740 ppmv (this equates to approximately 9 g/bhp-hr), the operating hours were provided as 2000 hr/yr in the original reference, and controlled emissions were estimated based on 80 percent reduction as stated in the reference. Uncontrolled NOx emissions ranged from 1.1 to 34 tpy for the models, and the NOx reductions ranged from 0.90 to 27 tpy for the models.

The current analysis shows a cost effectiveness of $2,200/ton of NOx reduction to $780/ton for 2000 hr/yr operation, and the average cost effectiveness across all the models is $1,000/ton of NOx reduction.

The cost year is not provided in the reference; assumed the cost year is the date of the cited reference, 2001$.

Based on the cost calculations for engines of varying hp, the following equations were developed for the capital cost and annual costs for LEC on natural gas Lean Burn engines:

$$\text{Capital cost} = 16019\ e^{0.0016 \times (hp)}$$

$$\text{Annual cost} = 2280.8\ e^{0.0016 \times (hp)}$$

The R^2 value for these equations is 0.96. These equations should be included in the CoST database file under a new equation type.

See the cost calculations in worksheet "LEC (CARB)-2001" of the Excel file.

5.4 Layered Combustion (LC), 2 Stroke (NLCICE2SNG)

The costs and cost effectiveness for applying LC to natural gas Lean Burn engines (2 stroke) are obtained from the document *Technical Information Oil and Gas Sector, Significant Stationary Sources of NOx Emissions* (OTC 2012). Information was provided on Capital costs; assumptions were made to determine Annual costs, uncontrolled emissions, and reduction efficiency. The assumptions for the original reference analysis are provided in Table 5-2 for LC for 2 stroke engines, along with changes in assumptions for the current analysis.

LC consists of multiple combustion modification technologies. The combustion modifications included in this example are related to (1) Air supply; (2) Fuel supply, (3) Ignition, (4) Electronic controls, and (5) Engine monitoring (a discussion of individual technologies is provided on pp. 17 to 19 for 2 stroke Lean Burn engines). No significant detail was provided on which specific combustion modification technologies were applied. In the example study, 3 of

Appendix A

NMED Exhibit 60 - 0076

the most representative manufacturer and models of 2 stroke Lean Burn engines used for integral compressors were selected for evaluation; these 3 engines were Cooper GMVH-10 2250 hp,

Table 5-2. LC for Natural Gas Lean Burn Engines, 2-stroke

Assumptions in Original Reference	Changes to Assumptions Made in Current Analysis
Capital costs	
Control efficiency: Not provided.	Control efficiency: derived value is 97% (this is high)
Capital costs: based on cited ERLE 2009 project (First unit upgrade costs)	Capital costs: used average based on the provided range for each make/model engine.
Annual Costs	
Equipment life: Not provided.	Equipment life: 10 yr
Interest rate: Not provided.	Interest rate: 7%
Operating hours: Not provided.	Operating hours: 2000 hr/yr
Emission rate, uncontrolled: Not provided	Emission rate, uncontrolled: 16.8 g/bhp-hr
Emission rate, controlled: 0.5 g/bhp-hr	None.
Annualized equipment cost: Not provided.	CRF: 0.1424
Annual O&M cost: Not provided.	Annual O&M cost: $0.

Clark TLA-6 2000 hp, and Cooper GMW-10 2500 hp (cited ERLE 2009 report "ERLE Cost Study of the Retrofit Legacy Pipeline Engines to Satisfy 0.5 g/bhp-hr NOx"). LC are known or demonstrated control techniques for lean burn, 2 stroke engines. A NOx emissions rate of 0.5 g/bhp-hr was achieved. The OTC 2012 document provided an estimate of the capital cost range for retrofitting technologies to achieve the outlet NOx limit for each engine. An average cost based on the range was estimated for each engine and used in the current analysis. Details on the buildup of these costs are not provided in the OTC 2012 document. No annual costs are provided in the document. No emission reductions are provided in the document.

Based on the review of other references in this analysis, it was assumed that there are no additional annual operating costs incurred from the combustion modification technologies, except for annualized capital costs (CARB 2001). Because no emission reduction data were provided, an estimate of emissions was made in the current analysis. Uncontrolled NOx emissions were assumed to be 16.8 g/bhp-hr (EPA 2003), controlled emissions were 0.5 g/bhp-hr as stated in the reference, and the operating hours were assumed to be 2000 hr/yr (this assumption is consistent with the LEC operating hours in the CARB 2001 document).

Appendix A

NMED Exhibit 60 - 0077

Uncontrolled NOx emissions for the 3 similar sized engines ranged from 74 to 93 tpy, and the NOx reductions ranged from 72 to 90 tpy.

Based on the 3 make and model engines, the average cost was estimated to be $2,800,000 for approximately 2250 hp engines (average hp of the 3 units), and the average total annual cost was estimated to be $390,000. The average cost effectiveness is $4,900/ton of NOx reduction for 2000 hr/yr operation.

The cost year is not provided in the reference; we assumed the cost year is the date of the cited Cameron 2010 retrofit project, 2010$.

See the cost calculations in worksheet "Overall Sum—New Ref Review" of the Excel file, rows 21 through 25.

5.5 Layered Combustion (LC), Large Bore, 2 Stroke, Low Speed (NLCICE2SLBNG)

The costs and cost effectiveness for applying LC to natural gas Lean Burn engines (2 stroke Large Bore) are obtained from the document *Technical Information Oil and Gas Sector, Significant Stationary Sources of NOx Emissions* (OTC 2012). Large Bore RICE are those with large piston diameters. The larger the bore (or piston diameter), the larger the volume available for engine combustion, and hence the greater the power delivered by the engine. Information was provided on Capital costs; assumptions were made to determine Annual costs, uncontrolled emissions, and reduction efficiency. The assumptions for the original reference analysis are provided in Table 5-3 for LC for large bore 2 Stroke engines, along with changes in assumptions for the current analysis.

LC consists of multiple combustion modification technologies. The combustion modifications included (1) High pressure fuel injection; (2) Turbocharging, (3) Precombustion chamber, and (4) Cylinder head modifications (a discussion of individual technologies is provided on pp. 18 to 19 for 2 stroke Lean Burn engines). LC are known or demonstrated control techniques for lean burn, large bore, 2 stroke engines. These modifications achieved a NOx emissions rate of 0.5 g/bhp-hr. The OTC 2012 document provided ranges of capital costs for retrofitting combustion modifications for large bore 2 stroke Lean Burn engines from 200 to 11,000 hp (cited Cameron 2011 presentation "Available Emission Reduction Technology for Existing Large Bore Slow Speed Two Stroke Engines." A copy of this presentation was not found.). Details on the buildup of these costs are not provided in the OTC 2012 document. No annual costs are provided in the document. No emission reductions are provided in the document.

Appendix A

NMED Exhibit 60 - 0078

Based on the review of other references in this analysis, it was assumed that there are no additional annual operating costs incurred from the combustion modification technologies, except for annualized capital costs (CARB 2001). Because no emission reduction data were provided, an estimate of emissions was made in the current analysis. Uncontrolled NOx

Table 5-3. LC for Natural Gas Lean Burn Engines, Large Bore 2-stroke

Assumptions in Original Reference	Changes to Assumptions Made in Current Analysis
Capital costs	
Control efficiency: Not provided.	Control efficiency: derived value is 97% (this is high)
Capital costs: based on cited Cameron 2010 project	None.
Annual Costs	
Equipment life: Not provided.	Equipment life: 10 yr
Interest rate: Not provided.	Interest rate: 7%
Operating hours: Not provided.	Operating hours: 2,000 hr/yr
Emission rate, uncontrolled: Not provided	Emission rate, uncontrolled: 16.8 g/bhp-hr
Emission rate, controlled: 0.5 g/bhp-hr	None.
Annualized equipment cost: Not provided.	CRF: 0.1424
Annual O&M cost: Not provided.	Annual O&M cost: $0.

emissions were assumed to be 16.8 g/bhp-hr (EPA 2003), controlled emissions were 0.5 g/bhp-hr as stated in the reference, and the operating hours were assumed to be 2000 hr/yr (this assumption is consistent with the LEC operating hours in the CARB 2001 document). Uncontrolled NOx emissions were estimated to be 410 tpy for the larger 11,000 hp engines and were estimated to be 7.4 tpy for the smaller 200 hp engines.

For the larger 11,000 hp engines, the current analysis shows a cost effectiveness of $1,500/ton of NOx reduction, and for the smaller 200 hp engines, the cost effectiveness is $38,000/ton of NOx reduction.

The cost year is not provided in the reference; assumed the cost year is the date of the cited Cameron 2010 retrofit project, 2010$.

See the cost calculations in worksheet “Overall Sum—New Ref Review” of the Excel file, rows 12 and 13.

Appendix A

NMED Exhibit 60 - 0079

5.6 Air to Fuel Ratio Controller (AFRC) (NAFRCICENG)

The costs and cost effectiveness for applying AFRC to natural gas Lean Burn engines are obtained from the document *Determination of Reasonably Available Control Technology and Best Available Retrofit Control Technology for Stationary Spark-Ignited Internal Combustion Engines* (CARB 2001). Information was provided on Capital costs; assumptions were made to determine Annual costs, uncontrolled emissions, and reduction efficiency. The assumptions for the original reference analysis are provided in Table 5-4 for AFRC, along with changes in assumptions for the current analysis.

Table 5-4. AFRC for Natural Gas Lean Burn Engines

Assumptions in Original Reference	Changes to Assumptions Made in Current Analysis
Capital costs	
Control efficiency: not provided	Control efficiency: assumed 20%
Capital costs: provided for multiple models	None.
Annual Costs	
Equipment life: 10 yr	None.
Interest rate: 10%	Interest rate: 7%
Operating hours: 2000 hr/yr	None.
Emission rate, uncontrolled: 740 ppmv	Emission rate, uncontrolled: Assumed mid to upper end hp rating for each model.
Emission rate, controlled: 80% reduction	None.
Annualized equipment cost: provided for multiple model sizes	CRF: 0.1424
Annual O&M cost: assumed $0.	None.

AFRC are electronic engine controls that typically monitor engine parameters and atmospheric conditions to determine the correct air/fuel mixture for the operating condition, such as varying engine load or speed conditions, varying ambient conditions, or startup/shutdown conditions. (OTC 2012) (A discussion of individual technologies is provided in Appendix B of the original reference, CARB 2001, pp. B-1 to B-28). AFRC are known or demonstrated control techniques for lean burn engines. An 80 percent NOx emission reduction can be achieved by AFRC in combination with other combustion modifications, however a fuel consumption penalty of up to 3 percent can occur due to AFRC.

Capital were provided for multiple size ranges of engines. The capital costs ranged from $4,200 to $6,500 per engine.

Appendix A

NMED Exhibit 60 - 0080

No annual costs were provided in the document. No emissions reductions were provided in the document. Based on the cost analysis for other combustion technology controls in this document, it was assumed that there are no additional annual operating costs incurred from the combustion modification technologies, except for annualized capital costs (this assumption ignores the fuel penalty issue). The total annual costs ranged from $600 to $930. Because no emission reductions were provided in the document, an estimate of emissions was made in the current analysis. In the current analysis, a hp rating based on the middle or upper end of each size range was assumed for estimating the uncontrolled NOx emissions. Uncontrolled NOx emissions were estimated based on an uncontrolled NOx concentration of 740 ppmv (this equates to approximately 9 g/bhp-hr), the operating hours were assumed to be 2000 hr/yr (similar to the operating hours for other control technology analyses provided in the document), and controlled emissions were estimated based on an assumption of 20 percent reduction. Uncontrolled NOx emissions ranged from 1.1 to 34 tpy for the models, and the NOx reductions ranged from 0.22 to 6.7 tpy for the models.

The current analysis shows a cost effectiveness of $2,700/ton of NOx reduction to $140/ton for 2000 hr/yr operation, and the average cost effectiveness across all the models is $810/ton of NOx reduction.

The cost year is not provided in the reference; assumed the cost year is the date of the cited reference, 2001$.

Based on the cost calculations for engines of varying hp, the following equations were developed for the capital cost and annual costs for AFRC on natural gas Lean Burn engines:

$$\text{Capital cost} = 1.3007 \times (\text{hp}) + 4354.5$$

$$\text{Annual cost} = 0.1852 \times (\text{hp}) + 619.99$$

The R^2 value for these equations is 0.87. These equations should be included in the CoST database file under a new equation type.

See the cost calculations in worksheet “AFRC (CARB)-2001” of the Excel file.

5.7 SCR (for 4 Stroke Natural Gas Engines) (NSCRICE4SNG)

The costs and cost effectiveness for applying SCR to natural gas engines are obtained from the document *Appendix B, Cost Effectiveness Analysis for Rule 4702 (Internal Combustion*

Appendix A

NMED Exhibit 60 - 0081

Engines—Phase 2) (SJVAPCD 2003). Information was provided on Capital costs, Annual costs, uncontrolled emissions, and reduction efficiency. The assumptions for the original reference analysis are provided in Table 5-5 for SCR for natural gas engines along with changes in assumptions for the current analysis. SCR is a known or demonstrated control technique for lean burn engines, although multiple references indicate that the feasibility of SCR application for lean burn engines is highly site-specific.

Table 5-5. SCR for Natural Gas Lean Burn Engines, 4-stroke.

Assumptions in Original Reference	Changes to Assumptions Made in Current Analysis
Capital costs	
Control efficiency: 90%	None.
Capital costs: based on RACT/BARCT Determination.	None.
Annual Costs	
Equipment life: 10 years	None.
Interest rate: 10%	Interest rate: 7%
Operating hours rate 1: 2190 hr/yr (equivalent to capacity factor of 0.25)	None.
Operating hours rate 2: 6570 hr/yr (equivalent to capacity factor of 0.75)	None.
Emission rate, uncontrolled: 740 ppmv NOx	None.
Emission rate, controlled: 65 ppmv NOx	None.
Annualized equipment cost: based on RACT/BARCT Determination.	None.
Annual O&M cost: based on RACT/BARCT Determination.	None.

The installed equipment capital cost ranged from $45,000 to $185,000 for 50 hp engines and 1500 hp engines, respectively. The total annual costs ranged from $27,000 for a 50 hp engine to $140,000 for a 1500 hp engine (these costs are very similar to the costs calculated in the original reference analysis; the only difference in annual costs is related to the CRF, i.e., changing the interest rate from 10 percent in the original reference analysis to 7 percent in the current analysis). NOx emissions are provided for two cases: a capacity factor of 0.25 (2190 hr/yr) and a capacity factor of 0.75 (6570 hr/yr). The uncontrolled NOx emissions ranged from 1.2 to 37 tpy for the lower capacity case, and the NOx reductions ranged from 1.1 to 33 tpy. For the higher capacity case, uncontrolled NOx emissions ranged from 3.7 to 110 tpy, and the NOx reductions achieved ranged from 3.3 to 100 tpy. The current analysis shows an average cost

Appendix A

NMED Exhibit 60 - 0082

effectiveness of $8,700/ton of NOx reduction for 2190 hr/yr of operation, and $2,900/ton of NOx reduction for 6570 hr/yr operation (these cost effectiveness values are very similar to the costs shown in the original reference analysis).

Based on the cost calculations for engines of varying hp and annual capacity operating, the following linear equations were developed for the capital cost and annual costs for SCR on natural gas 4-stroke lean burn engines:

$$\text{Capital cost} = 107.1 \times (\text{hp}) + 27186$$

$$\text{Annual cost} = 83.64 \times (\text{hp}) + 14718$$

The R^2 values for these equations are 0.95 for capital cost and 0.98 for annual cost. These equations should be included in the CoST database file under a new equation type for linear equations.

The cost year is not provided in the reference; assumed the cost year is the date of the cost-basis document, 2001$.

See the cost calculations in worksheet "SCR NG (SJVAPCD)-2003" of the Excel file. [Other cost effectiveness values for SCR are available from the PA DEP that are higher than the cost effectiveness values shown for the SJVAPCD SCR analysis, and other analyses. See the summary of SCR costs in worksheet "Other SCR Cost Info" of the Excel file.]

5.8 SCR (for Diesel Engines) (NSCRICEDS)

The costs and cost effectiveness for applying SCR to diesel lean burn engines is provided in *Alternative Control Techniques Document: Stationary Diesel Engines* (EPA 2010). The assumptions for the original reference analysis are provided in Table 5-6 for SCR for diesel engines, along with changes in assumptions for the current analysis. SCR is a known or demonstrated control technique for lean burn, diesel engines.

Approximately 76 percent of the population of stationary diesel engines is less than 300 hp and the remaining 24 percent is greater than 300 hp. Applications for stationary engines under 300 hp include standby power generation, agriculture, and industrial applications, and less than 5 percent are used for continuous power generation. Applications for stationary engines greater than 300 hp are primarily power generation and are almost evenly divided between continuous duty and standby applications.

Appendix A

NMED Exhibit 60 - 0083

The cost analysis provided in the original reference includes an assumption that stationary diesel lean burn engines operate approximately 1000 hr/yr. This assumption is likely appropriate for the majority of those units that are less than 300 hp and for half of the diesel engines greater than 300 hp, i.e., approximately 87 percent of diesel lean burn engines (this ignores the "fewer than 5 percent" used for continuous power generation). For the remaining 13 percent of engines that are greater than 300 hp and used in continuous power generation applications, an assumption for longer operating hours, such as 8000 hr/yr, may be needed to estimate the cost effectiveness.

Table 5-6. SCR for Diesel Lean Burn Engines—Assumptions

Assumptions in Original Reference	Changes to Assumptions Made in Current Analysis
Capital costs	
Control efficiency: 90 %	None.
Equipment life: 15 year	None.
Interest rate: 7%	None.
Capital costs: $98/hp	None.
Annual Costs	
Operating hours: 1000 hr/yr	None.
Annual costs: $40/hp (based on 1000 hr/yr operation; already includes Capital Recovery)	None.

The original reference analysis provided a capital cost of $98/hp, and based on the mid-range hp rating for four model engines, the capital costs ranged from $7,300 to $98,000 for SCR. The original reference analysis provided an annual cost of $40/hp, and the annual costs ranged from $3,000 to $40,000 per year. Uncontrolled NOx emissions factors in the original reference were based on Tier 0 to Tier 3 values[1] and an assumption of 1000 hr/yr operation. Uncontrolled NOx emissions range from 0.25 to 9.2 tpy across the four models, and the NOx reductions ranged from 0.22 to 8.3 tpy.

The current analysis shows an average cost effectiveness of $9,300/ton of NOx reduction for 1000 hr/yr of operation (no weighting to the average based on engine age was applied). The cost effectiveness over the engine size range varied from $4,800/ton to $16,000/ton for diesel engines (and are very similar to the costs shown in the original reference analysis). It is

[1] Federal Standards, from the *Exhaust and Crankcase Emission Factors for Nonroad Engine Modeling—Compression Ignition*. EPA Publication No. EPA420-P-04_009. April 2004.

Appendix A

NMED Exhibit 60 - 0084

important to note that the cost effectiveness is correlated to the manufacturing year of the diesel engine, i.e., the Tier limit for NOx emissions. Older engines manufactured prior to 1998 have the most lenient emissions limit while later model years have more stringent NOx emission limits (lower baseline emissions). The overall magnitude of emission reduction achieved by the SCR is lower for later model years as compared to earlier years, and therefore, the cost effectiveness values are higher for later model years.

[Note: This analysis shows emission reductions and cost effectiveness for existing and new diesel engines through approximately 2011, the last year for phase in of the Tiered emission values. The original reference provided information (circa 2005) on the age of the stationary engine population, with approximately 57 percent of engines at that time being manufactured prior to 1994 and approximately 42 percent manufactured after 1994 (note that the grouping of the age data does not align well with the Tier years, in that the age data shows breaks in 1994 and 2003 while the Tier ranges show breaks in 1996, 1998, 2002, 2003, etc.). As the diesel engine population continues to age and older engines are retired (i.e., those diesel engines subject to the Pre-1998 and the Tier 1 (1998 to 2003) or Tier 1 (1996 to 2001), etc. and are replaced with newer engines achieving lower NOx baseline emissions, the cost effectiveness for new engines would tend to be in the higher end shown for each model and would contribute to a somewhat higher average cost-effectiveness value. The average cost effectiveness will likely move toward the $13,000/ton to $16,000/ton of NOx reduction range.]

See the cost calculations in worksheet "SCR Diesel (EPA Dies ACT)-2010" of the Excel file.

5.9 Applicable SCCs for Lean Burn Engine Control Measures

Table 5-7 lists all of the ICE SCCs that are associated with one or more gas lean burn ICR control measures in the CMDB table called "Table 03_SCCs." These SCCs were identified with NOx emissions in an EPA query of the NEI for facilities in the Ozone Transport Group Assessment Region (i.e., 37 states that are partially or completely to the east of 100oW longitude). The control measures shown in the column headings in Table 5-7 are the ICE control measures that are currently in the CMDB. Each control measure that was determined to be applicable for a specific SCC is identified with an "N" in the cell, meaning the control measure is "new," i.e., not currently linked to this particular SCC, but we recommend adding this link in the database. In some cases, we recommend applying new links between existing control measures and existing SCCs. For example, some of the SCCs are for ICE that are fired with relatively uncommon fuels such as process gas, methanol, digester gas, or landfill gas. While we have not

[a]SCCs represent reciprocating engine activities that were identified with NOx emissions in the Ozone Transport Assessment Group Region analysis but are not associated with reciprocating engine control measures in the current CMDB.

[b]ICE means "Internal Combustion Engines."

[c]Ind means "Industrial," C/I means "Commercial/Institutional," and ET means "Engine Testing."

[d]The control measure is assumed to be representative for the SCC; control cost data are unavailable for the specific fuel type for the SCC.

Appendix A

NMED Exhibit 60 - 0086

located any analyses that determined the applicable controls and related costs for ICE fired with such fuels, similar control measures can be assigned to these SCCs. In order to conduct CoST modeling analyses for these ICE, the most representative available control measures could be assigned. For ICE that burn miscellaneous gaseous fuels, the most representative control measures are those for natural gas-fired ICE. Similarly, for ICE that burn miscellaneous liquid fuels such as methanol, gasoline, kerosene/diesel, and LPG, the most representative available control measures are those for gas- or diesel-fired ICE. Also, for ICE that burn liquid fuels such as diesel/kerosene, the most representative available control measures are those for gas-, diesel-, or oil-fired ICE.

Six new control measures have been added to the CMDB for lean burn engines under this review and these control measures are described in Sections 5.3 through 5.8 of this report. Table 5-8 lists those SCCs that should be associated with the newly added lean burn engine control measures. Each control measure that was determined to be applicable for a specific SCC is identified by a "Y," which means yes.

In Table 5-9, a number of recommendations were made to delete NOx control measure/SCC combinations from the CMDB. ICE SCCs for evaporative losses from fuel storage and delivery systems are incorrectly associated with NOx control measures in the current CMDB, and we recommend deleting these all NOx control measure/SCC records from the CMDB table called "Table 03_SCCs" because there should be no NOx emissions from the sources represented by these SCCs. In addition, multiple ICE control measures are misassigned to turbine SCCs and we recommend deleting these NOx control measure/SCC records. The reverse issue also exists where multiple turbine control measures are misassigned to ICE SCCs, and we recommend deleting these NOx control measure/SCC records, as well. These control measure/SCC combinations are identified in Table 5-9.

5.10 Pennsylvania General Permit 5 (GP-5) for Natural Gas Compression and/or Processing Facilities

Pennsylvania DEP recently released a general permit for Natural Gas Compression and/or Processing Facilities that includes limits on NOx emissions from ICE. NOx emission limits from this general permit, along with other NOx limits for Pennsylvania, are shown in Table 5-10. Typical emission rates and the cost-effectiveness values for applying certain control measures are shown for lean burn and rich burn engines in Table 5-11.

Low NOx Burner; Ammonia—NG-Fired Reformers	NLNBUFRNG	N0561	NOx	Low NOx Burner	Ammonia—NG-Fired Reformers	ptnonipm	Known	10	204|205	*2013*	*AR-1 |186*		Application: This control is the use of low NOx burner (LNB) technology to reduce NOx emissions. LNBs reduce the amount of NOx created from reaction between fuel nitrogen and oxygen by lowering the temperature of one combustion zone and reducing the amount of oxygen available in another. This control is applicable to small (<1 ton NOx per OSD) ammonia production operations with natural gas-fired reformers (SCC 30100306) and uncontrolled NOx emissions greater than 10 tons per year. Discussion: LNBs are designed to "stage" combustion so that two combustion zones are created, one fuel-rich combustion and one at a lower temperature. Staging techniques are usually used by LNB to supply excess air to cool the combustion process or to reduce available oxygen in the flame zone. Staged-air LNBs create a fuel-rich reducing primary combustion zone and a fuel-lean secondary combustion zone. Staged-fuel LNBs create a lean combustion zone that is relatively cool due to the presence of excess air, which acts as a heat sink to lower combustion temperatures (EPA, 2002).
Low NOx Burner and Flue Gas Recirculation; Ammonia—NG-Fired Reformers	NLNBFFRNG	N0562	NOx	Low NOx Burner and Flue Gas Recirculation	Ammonia—NG-Fired Reformers	ptnonipm	Known	10		2006	72|172|175|179|186		Application: This control is the use of low NOx burner (LNB) technology and flue gas recirculation (FGR) to reduce NOx emissions. LNBs reduce the amount of NOx created from reaction between fuel nitrogen and oxygen by lowering the temperature of one combustion zone and reducing the amount of oxygen available in another. This control is applicable to small (<1 ton NOx per OSD) ammonia production operations with natural gas-fired reformers (SCC 30100306) and uncontrolled NOx emissions greater than 10 tons per year. Discussion: LNBs are designed to "stage" combustion so that two combustion zones are created, one fuel-rich combustion and one at a lower temperature. Staging techniques are usually used by LNB to supply excess air to cool the combustion process or to reduce available oxygen in the flame zone. Staged-air LNBs create a fuel-rich reducing primary combustion zone and a fuel-lean secondary combustion zone. Staged-fuel LNBs create a lean combustion zone that is relatively cool due to the presence of excess air, which acts as a heat sink to lower combustion temperatures (EPA, 2002).
Low NOx Burner and Flue Gas Recirculation; Ammonia—Oil-Fired Reformers	NLNBFFROL	N0572	NOx	Low NOx Burner and Flue Gas Recirculation	Ammonia—Oil-Fired Reformers	ptnonipm	Known	10		2006	72		Application: This control is the use of low NOx burner (LNB) technology and flue gas recirculation (FGR) to reduce NOx emissions. LNBs reduce the amount of NOx created from reaction between fuel nitrogen and oxygen by lowering the temperature of one combustion zone and reducing the amount of oxygen available in another. This control is applicable to ammonia production operations with oil-fired reformers (SCC 30100307). Discussion: LNBs are designed to "stage" combustion so that two combustion zones are created, one fuel-rich combustion and one at a lower temperature. Staging techniques are usually used by LNB to supply excess air to cool the combustion process or to reduce available oxygen in the flame zone. Staged-air LNBs create a fuel-rich reducing primary combustion zone and a fuel-lean secondary combustion zone. Staged-fuel LNBs create a lean combustion zone that is relatively cool due to the presence of excess air, which acts as a heat sink to lower combustion temperatures (EPA, 2002).
Low NOx Burner and Flue Gas Recirculation; Ammonia Prod; Feedstock Desulfurization	NLNBFAPFD	N0622	NOx	Low NOx Burner and Flue Gas Recirculation	Ammonia Prod; Feedstock Desulfurization	ptnonipm	Known	10		2006	72|172|175|179|185		Application: This control is the use of low NOx burner (LNB) technology and flue gas recirculation (FGR) to reduce NOx emissions. LNBs reduce the amount of NOx created from reaction between fuel nitrogen and oxygen by lowering the temperature of one combustion zone and reducing the amount of oxygen available in another. This control is applicable to small (<1 ton per OSD) feedstock desulfurization processes in ammonia products operations (SCC 30100305) with uncontrolled NOx emissions greater than 10 tons per year. Discussion: It is assumed that the superheated steam needed to regenerate the activated carbon bed used in the desulfurization process is the NOx source. LNBs are designed to "stage" combustion so that two combustion zones are created, one fuel-rich combustion and one at a lower temperature. Staging techniques are usually used by LNB to supply excess air to cool the combustion process or to reduce available oxygen in the flame zone. Staged-air LNBs create a fuel-rich reducing primary combustion zone and a fuel-lean secondary combustion zone. Staged-fuel LNBs create a lean combustion zone that is relatively cool due to the presence of excess air, which acts as a heat sink to lower combustion temperatures (EPA, 2002).
Oxygen Trim and Water Injection; Ammonia—NG-Fired Reformers	NOTWIFRNG	N0563	NOx	Oxygen Trim and Water Injection	Ammonia—NG-Fired Reformers	ptnonipm	Known	10		2006	72|172|175|179|184|185		Application: This control is the use of OT + WI to reduce NOx emissions This control is applicable to small (<1 ton NOx per OSD) ammonia production operations with natural gas-fired reformers (SCC 30100306) and uncontrolled NOx emissions greater than 10 tons per year. This control is also applicable to miscellaneous combustion emissions from ammonia production operations (SCC 30100399). Discussion: Water is injected into the gas turbine, reducing the temperatures in the NOx-forming regions. The water can be injected into the fuel, the combustion air or directly into the combustion chamber (ERG, 2000).

Table A-2. CMDB Table 01 Summary (continued)

cmname	Cm Abbreviation	Pechan Meas Code	Major Poll	Control Technology	Source Group	Sector	Class	Equip Life	Nei Device Code	Date Reviewed	Data Source	Months	Description
Selective Catalytic Reduction; Ammonia—NG-Fired Reformers	NSCRFRNG	N0564	NOx	Selective Catalytic Reduction	Ammonia—NG-Fired Reformers	ptnonipm	Known	20	139	2006	72|167|175|179|224|225|226		Application: This control is the selective catalytic reduction of NOx through add-on controls. SCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). The SCR utilizes a catalyst to increase the NOx removal efficiency, which allows the process to occur at lower temperatures. Applies to natural-gas fired reformers involved in the production of ammonia (SCC 30100306) with uncontrolled NOx emissions greater than 10 tons per year. Discussion: Selective Catalytic Reduction (SCR) has been widely applied to stationary source, fossil fuel-fired, combustion units for emission control since the early 1970s. SCR is typically implemented on units requiring a higher level of NOx control than achievable by SNCR or other combustion controls (EPA, 2002). Like SNCR, SCR is based on the chemical reduction of the NOx molecule. The primary difference between SNCR and SCR is that SCR uses a metal-based catalyst to increase the rate of reaction (EPA, 2002). A nitrogen based reducing reagent, such as ammonia or urea, is injected into the flue gas. The reagent reacts selectively with the flue gas NOx within a specific temperature range and in the presence of the catalyst and oxygen to reduce the NOx. The use of a catalyst results in two advantages of the SCR process over SNCR, the higher NOx reduction efficiency and the lower and broader temperature ranges. However, the decrease in reaction temperature and increase in efficiency is accompanied by a significant increase in capital and operating costs (EPA, 2002). The cost increase is due to the large amount of catalyst required. The SCR system can utilize either aqueous or anhydrous ammonia as the reagent. Anhydrous ammonia is a gas at atmospheric pressure and normal temperatures. There are safety issues with the use of anhydrous ammonia, as it must be transported and stored under pressure (EPA, 2002). Aqueous ammonia is generally transported and stored at a concentration of 29.4% ammonia in water.
Selective Catalytic Reduction; Ammonia—Oil-Fired Reformers	NSCRFROL	N0573	NOx	Selective Catalytic Reduction	Ammonia—Oil-Fired Reformers	ptnonipm	Known	20	139	2006	72		Application: This control is the selective catalytic reduction of NOx through add-on controls. SCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). The SCR utilizes a catalyst to increase the NOx removal efficiency, which allows the process to occur at lower temperatures. Applies to natural-gas fired reformers involved in the production of ammonia (SCC 30100306) with uncontrolled NOx emissions greater than 10 tons per year. Discussion: Selective Catalytic Reduction (SCR) has been widely applied to stationary source, fossil fuel-fired, combustion units for emission control since the early 1970s. SCR is typically implemented on units requiring a higher level of NOx control than achievable by SNCR or other combustion controls (EPA, 2002). Like SNCR, SCR is based on the chemical reduction of the NOx molecule. The primary difference between SNCR and SCR is that SCR uses a metal-based catalyst to increase the rate of reaction (EPA, 2002). A nitrogen based reducing reagent, such as ammonia or urea, is injected into the flue gas. The reagent reacts selectively with the flue gas NOx within a specific temperature range and in the presence of the catalyst and oxygen to reduce the NOx. The use of a catalyst results in two advantages of the SCR process over SNCR, the higher NOx reduction efficiency and the lower and broader temperature ranges. However, the decrease in reaction temperature and increase in efficiency is accompanied by a significant increase in capital and operating costs (EPA, 2002). The cost increase is due to the large amount of catalyst required. The SCR system can utilize either aqueous or anhydrous ammonia as the reagent. Anhydrous ammonia is a gas at atmospheric pressure and normal temperatures. There are safety issues with the use of anhydrous ammonia, as it must be transported and stored under pressure (EPA, 2002). Aqueous ammonia is generally transported and stored at a concentration of 29.4% ammonia in water. Today, catalyst formulations include single component, multi-component, or active phase with a support structure. Most catalyst formulations contain additional compounds or sup-ports, providing thermal and structural stability or to increase surface area (EPA, 2002). The rate of reaction determines the amount of NOx removed from the flue gas. The important design and operational factors that affect the rate of reduction include: reaction temperature range; residence time available in the optimum temperature range; degree of mixing between the injected reagent and the combustion gases; uncontrolled NOx concentration level; molar ratio of injected reagent to uncontrolled NOx; ammonia slip; catalyst activity; catalyst selectivity; pressure drop across the catalyst; catalyst pitch; catalyst deactivation; and catalyst management (EPA, 2001).

Selective Non-Catalytic Reduction—Ammonia; NG-Fired Reformers	NSNCRFRNG	N0565	NOx	Selective Non-Catalytic Reduction	Ammonia—NG-Fired Reformers	ptnonipm	Known	20	107	2006	72|172|175|179|185		Application: This control is the reduction of NOx emission through selective non-catalytic reduction add-on controls. SNCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). This control applies to small (<1 ton NOx per OSD) ammonia production natural gas fired reformers (SCC 30100306) with uncontrolled NOx emissions greater than 10 tons per year. Discussion: SNCR is the reduction of NOx in flue gas to N2 and water vapor. This reduction is done with a nitrogen based reducing reagent, such as ammonia or urea. The reagent can react with a number of flue gas components. However, the NOx reduction reaction is favored for a specific temperature range and in the presence of oxygen (EPA, 2002). Both ammonia and urea are used as reagents. The cost of the reagent represents a large part of the annual costs of an SNCR system. Ammonia is generally less expensive than urea. However, the choice of reagent is also based on physical properties and operational considerations (EPA, 2002). Ammonia can be utilized in either aqueous or anhydrous form. Anhydrous ammonia is a gas at atmospheric pressure and normal temperatures. There are safety issues with the use of anhydrous ammonia, as it must be transported and stored under pressure (EPA, 2002). Aqueous ammonia is generally transported and stored at a concentration of 29.4% ammonia in water. Urea based systems have several advantages, including several safety aspects. Urea is a nontoxic, less volatile liquid that can be stored and handled more safely than ammonia. Urea solution droplets can penetrate farther into the flue gas when injected into the boiler, enhancing mixing (EPA, 2002). Because of these advantages, urea is more commonly used than ammonia in large boiler applications.
Low NOx Burner; Ammonia—Oil-Fired Reformers	NLNBUFROL	N0571	NOx	Low NOx Burner	Ammonia—Oil-Fired Reformers	ptnonipm	Known	10	204|205	2006	72		Application: This control is the use of low NOx burner (LNB) technology to reduce NOx emissions. LNBs reduce the amount of NOx created from reaction between fuel nitrogen and oxygen by lowering the temperature of one combustion zone and reducing the amount of oxygen available in another. This control is applicable to ammonia production operations with oil-fired reformers (SCC 30100307). Discussion: LNBs are designed to “stage” combustion so that two combustion zones are created, one fuel-rich combustion and one at a lower temperature. Staging techniques are usually used by LNB to supply excess air to cool the combustion process or to reduce available oxygen in the flame zone. Staged-air LNBs create a fuel-rich reducing primary combustion zone and a fuel-lean secondary combustion zone. Staged-fuel LNBs create a lean combustion zone that is relatively cool due to the presence of excess air, which acts as a heat sink to lower combustion temperatures (EPA, 2002).
Selective Non-Catalytic Reduction—Ammonia; Oil-Fired Reformers	NSNCRFROL	N0574	NOx	Selective Non-Catalytic Reduction	Ammonia—Oil-Fired Reformers	ptnonipm	Known	20	107	2006	72		Application: This control is the reduction of NOx emission through selective non-catalytic reduction add-on controls. Table B-1. CMDB Table 01_Summary (continued)

cmabbreviation	Description
NDLNCGTNG	Application: This control is the use of dry low NOx combustion (DLN) technology to reduce NOx emissions. DLN combustion reduces the amount of NOx created from reaction between fuel nitrogen and oxygen by lowering the temperature of one combustion zone and reducing the amount of oxygen available in another. This control applies to large (83.3 MW to 161 MW) natural gas fired turbines with uncontrolled NOx emissions greater than 10 tons per year. Discussion: LNBs are designed to "stage" combustion so that two combustion zones are created, one fuel-rich combustion and one at a lower temperature. Staging techniques are usually used by LNB to supply excess air to cool the combustion process or to reduce available oxygen in the flame zone. Staged-air LNBs create a fuel-rich reducing primary combustion zone and a fuel-lean secondary combustion zone. Staged-fuel LNBs create a lean combustion zone that is relatively cool due to the presence of excess air, which acts as a heat sink to lower combustion temperatures (EPA, 2002).
NSCRDGTNG	Application: This control is the selective catalytic reduction of NOx through add-on controls. SCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). The SCR utilizes a catalyst to increase the NOx removal efficiency, which allows the process to occur at lower temperatures. This control applies to natural gas fired turbines with NOx emissions greater than 10 tons per year. Discussion: Selective Catalytic Reduction (SCR) has been widely applied to stationary source, fossil fuel-fired, combustion units for emission control since the early 1970s. SCR is typically implemented on units requiring a higher level of NOx control than achievable by SNCR or other combustion controls (EPA, 2002). Like SNCR, SCR is based on the chemical reduction of the NOx molecule. The primary difference between SNCR and SCR is that SCR uses a metal-based catalyst to increase the rate of reaction (EPA, 2002). A nitrogen based reducing reagent, such as ammonia or urea, is injected into the flue gas. The reagent reacts selectively with the flue gas NOx within a specific temperature range and in the presence of the catalyst and oxygen to reduce the NOx. The use of a catalyst results in two advantages of the SCR process over SNCR, the higher NOx reduction efficiency and the lower and broader temperature ranges. However, the decrease in reaction temperature and increase in efficiency is accompanied by a significant increase in capital and operating costs (EPA, 2002). The cost increase is due to the large amount of catalyst required. The SCR system can utilize either aqueous or anhydrous ammonia as the reagent. Anhydrous ammonia is a gas at atmospheric pressure and normal temperatures. There are safety issues with the use of anhydrous ammonia, as it must be transported and stored under pressure (EPA, 2002). Aqueous ammonia is generally transported and stored at a concentration of 29.4% ammonia in water. Today, catalyst formulations include single component, multi-component, or active phase with a support structure. Most catalyst formulations contain additional compounds or supports, providing thermal and structural stability or to increase surface area (EPA, 2002). The rate of reaction determines the amount of NOx removed from the flue gas. The important design and operational factors that affect the rate of reduction include: reaction temperature range; residence time available in the optimum temperature range; degree of mixing between the injected reagent and the combustion gases; uncontrolled NOx concentration level; molar ratio of injected reagent to uncontrolled NOx; ammonia slip; catalyst activity; catalyst selectivity; pressure drop across the catalyst; catalyst pitch; catalyst deactivation; and catalyst management (EPA, 2001).
NSCRSGTNG	Application: This control is the selective catalytic reduction of NOx through add-on controls. SCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). The SCR utilizes a catalyst to increase the NOx removal efficiency, which allows the process to occur at lower temperatures. This control applies to natural gas fired turbines with NOx emissions greater than 10 tons per year.

NSCRSGTNG (cont.)	Discussion: Selective Catalytic Reduction (SCR) has been widely applied to stationary source, fossil fuel-fired, combustion units for emission control since the early 1970s. SCR is typically implemented on units requiring a higher level of NOx control than achievable by SNCR or other combustion controls (EPA, 2002). Like SNCR, SCR is based on the chemical reduction of the NOx molecule. The primary difference between SNCR and SCR is that SCR uses a metal-based catalyst to increase the rate of reaction (EPA, 2002). A nitrogen based reducing reagent, such as ammonia or urea, is injected into the flue gas. The reagent reacts selectively with the flue gas NOx within a specific temperature range and in the presence of the catalyst and oxygen to reduce the NOx. The use of a catalyst results in two advantages of the SCR process over SNCR, the higher NOx reduction efficiency and the lower and broader temperature ranges. However, the decrease in reaction temperature and increase in efficiency is accompanied by a significant increase in capital and operating costs (EPA, 2002). The cost increase is due to the large amount of catalyst required. The SCR system can utilize either aqueous or anhydrous ammonia as the reagent. Anhydrous ammonia is a gas at atmospheric pressure and normal temperatures. There are safety issues with the use of anhydrous ammonia, as it must be transported and stored under pressure (EPA, 2002). Aqueous ammonia is generally transported and stored at a concentration of 29.4% ammonia in water. Today, catalyst formulations include single component, multi-component, or active phase with a support structure. Most catalyst formulations contain additional compounds or supports, providing thermal and structural stability or to increase surface area (EPA, 2002). The rate of reaction determines the amount of NOx removed from the flue gas. The important design and operational factors that affect the rate of reduction include: reaction temperature range; residence time available in the optimum temperature range; degree of mixing between the injected reagent and the combustion gases; uncontrolled NOx concentration level; molar ratio of injected reagent to uncontrolled NOx; ammonia slip; catalyst activity; catalyst selectivity; pressure drop across the catalyst; catalyst pitch; catalyst deactivation; and catalyst management (EPA, 2001).
NSCRWGTJF	Application: This control is the selective catalytic reduction of NOx through add-on controls in combination with water injection. SCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). The SCR utilizes a catalyst to increase the NOx removal efficiency, which allows the process to occur at lower temperatures. This control applies to jet fuel-fired turbines with uncontrolled NOx emissions greater than 10 tons per year. Discussion: Selective Catalytic Reduction (SCR) has been widely applied to stationary source, fossil fuel-fired, combustion units for emission control since the early 1970s. SCR is typically implemented on units requiring a higher level of NOx control than achievable by SNCR or other combustion controls (EPA, 2002). Like SNCR, SCR is based on the chemical reduction of the NOx molecule. The primary difference between SNCR and SCR is that SCR uses a metal-based catalyst to increase the rate of reaction (EPA, 2002). A nitrogen based reducing reagent, such as ammonia or urea, is injected into the flue gas. The reagent reacts selectively with the flue gas NOx within a specific temperature range and in the presence of the catalyst and oxygen to reduce the NOx. The use of a catalyst results in two advantages of the SCR process over SNCR, the higher NOx reduction efficiency and the lower and broader temperature ranges. However, the decrease in reaction temperature and increase in efficiency is accompanied by a significant increase in capital and operating costs (EPA, 2002). The cost increase is due to the large amount of catalyst required. The SCR system can utilize either aqueous or anhydrous ammonia as the reagent. Anhydrous ammonia is a gas at atmospheric pressure and normal temperatures. There are safety issues with the use of anhydrous ammonia, as it must be transported and stored under pressure (EPA, 2002). Aqueous ammonia is generally transported and stored at a concentration of 29.4% ammonia in water.

Table B-1. CMDB Table 01_Summary (continued)

cmabbreviation	Description
NCATCGTNG	Application: This control is the use of catalytic combustion to reduce NOx emissions. Catalytic combustors reduce the amount of NOx created by oxidizing fuel at lower temperatures (and without a flame) than in conventional combustors. Catalytic combustion uses a catalytic bed to oxidize a lean air fuel mixture within a combustor instead of burning with a flame. The fuel and air mixture oxidizes at lower temperatures than in a conventional combustor, producing less NOx. Currently installed only on a few 1.4 MW combustion turbines, and commercially available for turbines rated up to 10 MW (CT-1).
NEMXDGTNG	Application: This control is the use of EMx in combination with dry low NOx combustion. EMx is a post-combustion catalytic oxidation and absorption technology that uses a two-stage catalyst/absorber system for the control of NOx as well as CO, VOC, and optionally SOx. A coated catalyst oxidizes NO to NO2, CO to CO2, and VOC to CO2 and water. The NO2 is then absorbed onto the catalyst surface where it is chemically converted to and stored as potassium nitrates and nitrites. A proprietary regeneration gas is periodically passed through the catalyst to desorb the NO2 from the catalyst and reduce it to elemental nitrogen (N2). EMx has been successfully demonstrated on several small combustion turbine projects up to 45 MW. The manufacturer has claimed that EMx can be effectively scaled up to larger turbines (CT-1). Cost estimates for DLN combustion in 2008 dollars are not available. Thus, the total system cost in this analysis in 2008 dollars was developed from 1999 cost estimates for DLN combustion that were escalated to 2008 dollars and added to the available 2008 estimate for the EMx system.
NEMXWGTNG	Application: This control is the use of EMx in combination with water injection. Cost estimates for water injection in 2008 dollars are not available. Thus, the total system cost in this analysis in 2008 dollars was developed from 1999 cost estimates for water injection that were escalated to 2008 dollars and added to the available 2008 estimate for the EMx system.

NSCRWGTOL	Type "L"	NOx	1999					4868.5	349694	1546.1	139203		

[a]Type "L" is a linear equation; variables are the slope and intercept. No incremental TCI for NCATCGTNG relative to DLN because the capital costs for catalytic combustion are lower than the capital costs for DLN for all but the smallest turbines. The underlying data for 2008 costs for SCR and EMx are for large turbines (50 MW to 180 MW). The underlying data for 2007 costs are for 1 MW to 40 MW turbines.

Table C-1. CMDB Table 01 Summary—Description Field

cmabbreviation	description
NCLPTGMCN	Application: This control is the use of cullet preheat technologies to reduce NOx emissions from glass manufacturing operations. This control is applicable to container glass manufacturing operations classified under 305010402.
NCUPHGMPD	Application: This control is the use of cullet preheat technologies to reduce NOx emissions from glass manufacturing operations. This control is applicable to pressed glass manufacturing operations classified under 305010404.
NDOXYFGMG	Application: This control is the use of OXY-firing in glass manufacturing furnaces to reduce NOx emissions. Oxygen enrichment refers to the substitution of oxygen for nitrogen in the combustion air used to burn the fuel in a glass furnace. Oxygen enrichment above 90 percent is sometimes called "oxy-firing." Discussion: The basic rationale for oxy-firing is improved efficiency, i.e., more of the theoretical heat of combustion is transferred to the glass melt and is not lost in the flue gas. Many other combustion modification techniques (e.g., flue gas recirculation, staged combustion, and low excess air combustion) reduce NOx formation but also reduce the combustion efficiency. Oxy-firing was originally developed to improve the combustion efficiency primarily by eliminating the sensible heat lost in heating the nitrogen present in air, which is then lost in the flue gas.
NELBOGMGN	Application: This control is the use of electric boost technologies to reduce NOx emissions from glass manufacturing operations. This control applies to general glass manufacturing operations classified under SCC 30501401.
NELBOGMCN	Application: This control is the use of electric boost technologies to reduce NOx emissions from glass manufacturing operations. This control applies to container glass manufacturing operations classified under SCC 30501402. Discussion: The 250 tons per day plant is assumed to be representative of container glass plants (Pechan, 1998).
NELBOGMFT	Application: This control is the use of electric boost technologies to reduce NOx emissions from glass manufacturing operations. This control applies to flat glass manufacturing operations classified under SCC 30501403. Discussion: The 500 tons per day plant is assumed to be representative of flat glass plants (Pechan, 1998).
NELBOGMPD	Application: This control is the use of electric boost technologies to reduce NOx emissions from glass manufacturing operations. This control applies to pressed glass manufacturing operations classified under SCC 30501403. Discussion: The 50 tons per day plant is assumed to be representative of pressed glass plants (Pechan, 1998).
NLNBUGMCN	Application: This control is the use of low NOx burner (LNB) technology to reduce NOx emissions. LNBs reduce the amount of NOx created from reaction between fuel nitrogen and oxygen by lowering the temperature of one combustion zone and reducing the amount of oxygen available in another. This control is applicable to container glass manufacturing operations classified under 305010402 with uncontrolled NOx emissions greater than 10 tons per year. Discussion: The 250 tons per day plant is assumed to be representative of container glass plants (Pechan, 1998). LNBs are designed to "stage" combustion so that two combustion zones are created, one fuel-rich combustion and one at a lower temperature. Staging techniques are usually used by LNB to supply excess air to cool the combustion process or to reduce available oxygen in the flame zone. Staged-air LNBs create a fuel-rich reducing primary combustion zone and a fuel-lean secondary combustion zone. Staged-fuel LNBs create a lean combustion zone that is relatively cool due to the presence of excess air, which acts as a heat sink to lower combustion temperatures (EPA, 2002).
NLNBUGMFT	Application: This control is the use of low NOx burner (LNB) technology to reduce NOx emissions. LNBs reduce the amount of NOx created from reaction between fuel nitrogen and oxygen by lowering the temperature of one combustion zone and reducing the amount of oxygen available in another. This control is applicable to flat glass manufacturing operations classified under 305010404 with uncontrolled NOx emissions greater than 10 tons per year. Discussion: The 500 tons per day plant is assumed to be representative of flat glass plants (Pechan, 1998). LNBs are designed to "stage" combustion so that two combustion zones are created, one fuel-rich combustion and one at a lower temperature. Staging techniques are usually used by LNB to supply excess air to cool the combustion process or to reduce available oxygen in the flame zone. Staged-air LNBs create a fuel-rich reducing primary combustion zone and a fuel-lean secondary combustion zone. Staged-fuel LNBs create a lean combustion zone that is relatively cool due to the presence of excess air, which acts as a heat sink to lower combustion temperatures (EPA, 2002).

Table C-1. CMDB Table 01 Summary—Description Field (continued)

cmabbreviation	description
NSCRGMCN	Application: This control is the selective catalytic reduction of NOx through add-on controls. SCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). The SCR utilizes a catalyst to increase the NOx removal efficiency, which allows the process to occur at lower temperatures. Applies to glass-container manufacturing processes, classified under SCC 30501402 and uncontrolled NOx emissions greater than 10 tons per year. Discussion: Selective Catalytic Reduction (SCR) has been widely applied to stationary source, fossil fuel-fired, combustion units for emission control since the early 1970s. SCR is typically implemented on units requiring a higher level of NOx control than achievable by SNCR or other combustion controls (EPA, 2002). Like SNCR, SCR is based on the chemical reduction of the NOx molecule. The primary difference between SNCR and SCR is that SCR uses a metal-based catalyst to increase the rate of reaction (EPA, 2002). A nitrogen based reducing reagent, such as ammonia or urea, is injected into the flue gas. The reagent reacts selectively with the flue gas NOx within a specific temperature range and in the presence of the catalyst and oxygen to reduce the NOx. The use of a catalyst results in two advantages of the SCR process over SNCR, the higher NOx reduction efficiency and the lower and broader temperature ranges. However, the decrease in reaction temperature and increase in efficiency is accompanied by a significant increase in capital and operating costs (EPA, 2002). The cost increase is due to the large amount of catalyst required. The SCR system can utilize either aqueous or anhydrous ammonia as the reagent. Anhydrous ammonia is a gas at atmospheric pressure and normal temperatures. There are safety issues with the use of anhydrous ammonia, as it must be transported and stored under pressure (EPA, 2002). Aqueous ammonia is generally transported and stored at a concentration of 29.4% ammonia in water. Today, catalyst formulations include single component, multi-component, or active phase with a support structure. Most catalyst formulations contain additional compounds or sup-ports, providing thermal and structural stability or to increase surface area (EPA, 2002). The rate of reaction determines the amount of NOx removed from the flue gas. The important design and operational factors that affect the rate of reduction include: reaction temperature range; residence time available in the optimum temperature range; degree of mixing between the injected reagent and the combustion gases; uncontrolled NOx concentration level; molar ratio of injected reagent to uncontrolled NOx; ammonia slip; catalyst activity; catalyst selectivity; pressure drop across the catalyst; catalyst pitch; catalyst deactivation; and catalyst management (EPA, 2001).
NSCRGMFT	Application: This control is the selective catalytic reduction of NOx through add-on controls. SCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). The SCR utilizes a catalyst to increase the NOx removal efficiency, which allows the process to occur at lower temperatures. Applies to large(>1 ton NOx per OSD) flat-glass manufacturing operations (SCC 30501403) with uncontrolled NOx emissions greater than 10 tons per year. Discussion: Selective Catalytic Reduction (SCR) has been widely applied to stationary source, fossil fuel-fired, combustion units for emission control since the early 1970s. SCR is typically implemented on units requiring a higher level of NOx control than achievable by SNCR or other combustion controls (EPA, 2002). Like SNCR, SCR is based on the chemical reduction of the NOx molecule. The primary difference between SNCR and SCR is that SCR uses a metal-based catalyst to increase the rate of reaction (EPA, 2002). A nitrogen based reducing reagent, such as ammonia or urea, is injected into the flue gas. NOTES PROVIDED HERE TO EPA QUESTIONS ON LEAN BURN RICE

Appendix A

NMED Exhibit 60 - 0128

EPA Question 1: What is the applicability of SCR to RICE, especially Lean Burn?

Notes for Question 1

In addition to the two documents cited in Section 5 of the report with costs for selective catalytic reduction (SCR) for Lean Burn (LB) engines, there are several other references that indicate SCR is feasible for LB engines and several that provide input on technical issues related to SCR use for LB engines. In summary, from the references reviewed, SCR seems to be technically feasible in most instances for LB engines, however, SCR application may not be feasible in all cases due to technical issues at individual sites and individual engines. In addition, SCR costs are higher relative to other NOx control techniques for LB engines. See more detailed discussion below.

SCR can be applied to LB engines, achieving greater than 90 percent NOx reductions (Table 4 on p. 6 provides a slightly different value, greater than 95 percent). The costs [assumed this referred to capital costs] ranged from $50/hp to $125/hp. No annual operating costs were provided. In discussions on p. 8 regarding "catalysts on IC engines" in general (including NSCR, SCR, oxidation, and Lean-NOx), it is noted that "Thousands of stationary IC engine catalyst applications have been effectively used for stationary IC engine gaseous emission control for five years or more. Some installations, however, do experience performance loss over time," however the text goes on to explain remedies for catalyst poisoning issues. Costs [capital] for SCR, LB ranged from $50 to $125/hp (no cost year provided). (MECA 1997)

The literature suggests that SCR is technically feasible for LB engines but there are problems that make SCR installation questionable. Two stroke (2S) LB engines are sensitive to changes in exhaust pressure, which could be problematic for retrofit of SCR on existing engines, but can be alleviated with proper design and sizing of airflow and exhaust components. This reference cited a presentation that indicated the following issues with SCR: applying SCR to pipeline engines is not feasible because the exhaust temperatures (T) are below the operating window for SCR or where SCR effectiveness is reduced; SCR installations are at unmanned facilities; and SCR has not been demonstrated for variable loads. However, the OTC 2012 reference responded to each of these issues, stating that there are several manufacturers and suppliers that offer SCR systems that indicate their catalysts are capable of effectively operating over a wide range of exhaust gas T; modern software based controls and SCADA communication technologies allow operation from a remote location; and SCR can function properly over a broad range of loads given catalysts that are effective over wide T ranges, modern controls regulate fuel and air flows to ensure combustion O_2 and T are at expected levels

Appendix A

NMED Exhibit 60 - 0129

and to regulate reagent flow. A study conducted for retrofitting existing pipeline engines indicates that SCR is a high cost alternative to combustion improvements, primarily due to the high cost of ongoing reagent consumption. (p. 25-26) (There is a similar discussion for SCR for four stroke (4S) LB on p. 39-40; cited presentation at Gas Machinery Conference in October 2011.) (OTC 2012)

Shell indicated they have installed SCR on diesel engines (LB) that they utilize in drilling rig operations. Shell indicated that have been able to achieve greater than 90 percent reduction in NOx emissions while encountering minimal operational issues (see p. 10). (OTC 2012)

The OTC 2012 document indicated that MECA has noted there have been limited examples to date of SCR retrofit on 2S LB engines as demonstration test programs, but the results of these programs have not been published (see p. 27). It appears that SCR for NOx does not appear to be technically infeasible generically but that individual 2S LB engine characteristics and installations may be greatly problematic or not cost effective, although this site-specific issue is not altogether different than other emission reduction technologies (see p.27, 40). (OTC 2012)

The OTC 2012 document indicated that MECA has stated the commercial use of SCR systems for LB stationary engines have been in place since the mid-1980's in Europe and since the early 1990s in the US. One MECA member company has installed over 400 SCR systems worldwide for stationary engines with varying fuel combinations, including dozens of NG compressor engines in the US. These 4S LB engines with urea-SCR achieve >90% NOx reduction (see p.40). (OTC 2012)

EF&EE announced in November 2010 that is received an order from Clean Air Power Inc. for 6 SCR systems, to be installed on large LB NG compressor engines at gas storage sites in TX and MS (see p.40). (OTC 2012)

Clean Air Power cited: 4 SCRs supplied at Pine Prairie Energy Center, Louisiana; 1 SCR supplied at EXTERRAN/TRESPALACIOS, Texas; and 4 SCRs supplied to EXTERRAN/LEAF River, Mississippi (see p.41). (OTC 2012)

A PowerPoint slide presentation from a MARAMA workshop discusses the use of SCR for RICE and LB. Johnson Mathey (JM) included SCR as a feasible control for LB engines in a presentation at a May 2011 MARAMA Workshop. (The SCR systems included Urea and Ethanol as reagents.) SCR operating temperatures range from 700 to 900°F for internal combustion (IC) engines and achieved 90 percent NOx reductions. The budgetary costs

Appendix A

[assumed this referred to capital costs] ranged from $150/ hp for a 500 hp unit (approximately $75,000) to $42/hp for a 3000 hp unit (approximately $126,000) (cost year not provided). No annual operating costs were provided. JM cited 4 LB engine installations of SCR on gas compressors at 2 locations, including Loudon Compressor Station in Clarksburg, WV and Lodi Compressor/Storage in Kirby Hills, CA. (Chu 2011) These engines are listed in the following table:

SCR for Lean Burn Engines—Johnson Mathey presentation at 2007 MARAMA Workshop

Engine Model	Engine hp	NOx, g/bhp-hr	NOx Reduction, %
CAT G3516	1,340	1.5	90%
CAT G3608	2,370	0.7	90%
CAT G3612	3,550	0.7	90%
CAT G3616	4,735	0.7	90%

NMED Exhibit 60 - 0131

EPA Question 2: What are credible estimates of the percentage of RICE NOx Emissions that are lean burn versus rich burn when RICE emissions are unspecified?

Notes for Question 2

There does not seem to be much information on NOx emission totals for LB and rich burn (RB) engines. A few references attempted to provide information on the numbers or populations of LB and RB engines. Several of the references highlighted surveys of engine populations and summary information from various engine databases. These data in general tend to point to a large LB engine population, however most of the references noted that RB engines are typically not captured or covered in surveys, databases, or by permits because the RB engines tend to be smaller in size. In general, larger engines tend to be LB and smaller engines tend to be RB. The ERLE 2009 study noted that approximately 73% of the 5,600 engines/horsepower capacity covered in their study of NG pipeline systems are LB, and approximately 6% are RB (the balance is not known). In the KSU 2011 database, approximately 66% of the 4,729 engines used in E&P at major sources are LB and 34% are RB. In addition, the EDF 2008 document cited a 2007 survey conducted for DFW NAA and AA that attempted to identify those engines that did not meet reporting requirement thresholds and were therefore not included in the TCEQ inventory. This reference, which included small engines, indicated that for smaller engines <500 hp, approximately 96% are RB and 4% are LB. The reference also indicated that for larger engines >500 hp, there is approximately a 50-50 split of LB and RB engines and of horsepower capacity. The ETCG 2013 reference also highlights engines in the Barnett Shale region. Data from the TCEQ Barnett Shale Special Inventory (Phase I) survey indicated that the majority of engines in the Barnett Shale are RB (84%). For those engines <240 hp, 95% are RB and 5% are LB, however, in looking at those engines >240 hp, 59% are LB and 41% are RB. More details for each of these references are provided in the discussion that follows.

Note also that the emissions rate in g/bhp-hr for LB engines tend to be higher, and the emissions rate for RB engines tends to be lower. (See the tables under Question 4 of this appendix for relative emission rate values for LB and RB engines in various states and local districts.)

A summary of the information available from various references is provided below.

The CARB 2001 reference indicated that LB engines tend to be larger in size, and smaller engines tend to be RB (p.B-4). (CARB 2001)

EPA received comments from the Interstate Natural Gas Association of America (INGAA) on the 2002 proposed rule, where EPA indicated that 156 of 168 large engines listed in

Appendix A

the NOx SIP Call Inventory that have SIC codes associated with the NG transmission industry are LB engines (with the exception that the other 12 engines are no longer in service, are owned by a company not included in the industry database, or are duplicates). INGAA recommended that EPA assume all large NG stationary engines in the inventory are LB. (EPA 2003).

One prominent use of large Reciprocating Internal Combustion Engines (RICE) is to drive NG pipeline compressor stations; almost all engines affected by the NOx SIP Call Phase 2 rule in IL (except for 3 engines) are used to compress NG at NG pipeline stations. (IEPA 2007)

A 2009 ERLE study cited in this reference indicated there are 5,600 engines on the NG pipeline systems with a collective rating of 9,150,000 hp. That study further indicated that approximately 80 percent of the rated output was low speed 2S, low speed 4S integral engines and diesel medium speed engines converted to spark ignition (SI). Of these 80 percent of engines, 78 percent were 2S LB, 14 percent were 4S LB, and 8 percent were 4S RB. (On a rated horsepower basis, 80 percent was 2S LB, 15 percent was 4S LB, and 5 percent 4S RB) (p. 16). [On an overall basis, compared to the full 9,150,000 hp collective rating, 2S LB would be roughly 62%, 4S LB would be roughly 11%, and 4S RB would be roughly 6% of the overall rating/engines. So 73% would be LB, 6% would be RB, and the balance is not known.] (OTC 2012)

Engine Type	No. Engines, %	Horsepower, %
2S LB	78	80
4S LB	14	15
4S RB	8	5

The DE 2012 document cited a 2003 Pipeline Research Council International (PRCI) document that identified 5,686 engines: 71% are LB and 29% are RB (based on dropping the turbine numbers in the table below) (p.19). (DE 2012) [These data may be repeated in OTC 2012, as it looks fairly similar to the 2009 ERLE study data cited above from OTC 2012.]

2003 Pipeline Research Council International Data (PRCI)

Unit Type	U.S. Total Units (%)	Avg hp
2S LB	2,955 (44%)	2,113
4S LB	1,059 (16%)	1,844
RB	1,672 (25%)	589
Turbine	1,016 (15%)	6,121

Appendix A

Energy Information Agency (EIA) data cited in the OTC 2012 reference indicated there were 1201 NG mainline compressor stations in the U.S. in 2006, with combined rating of 16,800,000 hp. Between 2007 and 2010, the Federal Energy Regulation Commission (FERC) approved new compressor stations or upgrades to existing compressor facilities that were expected to add 2,600,000 hp (p. 16). (OTC 2012)

The Kansas State University (KSU) 2011 document included a database on 4,729 engines used in Exploration and Production (E&P) at major sources. LB engines accounted for 66 percent of engines (17 percent are 2S and 49 percent are 4S), and RB engines accounted for 34 percent. LB outnumbers RB among engines included in the database; because many engines rating less than 100 hp are not included, and because the majority of the smaller units are 4S RB, RB are actually underrepresented in the database. A listing of the engines (manufacturer and model), air to fuel (A/F) ratio type, cycle, and horsepower are included in Appendix I of the KSU 2011 document. The database was not meant to collect every single engine in use but rather to provide a frequency distribution of engines. The data was pulled from multiple sources, including the State of Wyoming Engine Inventory Database, EPA ICCR Database, GTI/PRCI Engine and Turbine Database, and Database of Colorado and New Mexico Engines (from Universal Compression). The engine database likely includes only permitted engines, and lower-hp engines are underrepresented in the database. (pp. 5-7) (KSU 2011)

The EDF 2008 reference indicated most engines in Barnett Shale area of Texas are 100 to 500 hp but some large engines of 1000+ hp are also used. (EDF 2008)

The EDF 2008 reference indicated that the TCEQ Point Source Emissions Inventory (PSEI) does not include a substantial fraction of compressor engine emissions. Most of the missing engines in the DFW NAA were units with emissions below the reporting thresholds, but the combined emissions from large numbers of these engines can be substantial (pp. 13-14). The 2007 DFW Engine survey indicated there were approximately 680,000 hp of installed engine capacity in DFW NAA not previously reported to the TCEQ PSEI (p. 14). The report also estimated that there is approximately 132,000 hp of engines in Attainment Area (AA) counties within the Barnett Shale that don't report to PSEI (non-PSEI) (p. 14). The LB and RB engine data from the 2007 DFW Engine Survey for the DFW NAA is provided in the table below. In this survey, there seem to be fairly even numbers of LB (51%) and RB (49%) engines in the >500 hp category, and there seems to be fairly even horsepower capacity for the LB and RB engines. For smaller engines that are <500 hp, there are significantly more RB engines (736

Appendix A

engines, or 96%) than LB engines (27 engines, or 4%). In addition, for the smaller engines <500 hp, the horsepower capacity for RB represents 15% and for LB is <1%. (EDF 2008)

Installed Engine Capacity in 2007 DFW Engine Survey by Engine Type and Size, in DFW NAA (EDF 2008)

Engine Type	Engine Size, hp	Number of Engines	Percent of Engines, %	Typical Size, hp	Installed Capacity, hp	Percent of Installed Capacity, %
RB	<50	12	1.03%	50	585	0.086%
RB	50–500	724	62%	140	101,000	15%
RB	>500	200	17%	1,400	280,000	41%
LB	<500	27	2.3%	185	4,940	0.72%
LB	>500	206	18%	1,425	294,000	44%

The EDF 2008 reference looked at all of the compressor engines in the Barnett Shale region, including both the engines located within the DFW NAA and the engines in the DFW AA (including those larger engines that report to the PSEI and those non-PSEI engines). New TCEQ rules became effective in 2009 to reduce NOx from the subset of engines located in the DFW NAA that typically are not reported to the PSEI (due to their small size) for major sources (p. 25). Engines that are located outside the DFW NAA are not subject to the 2009 rule. As shown in the table below, a 50% reduction of emissions from 2007 to 2009 was estimated in DFW NAA, taking into account the growth, regulation affect, and NSCR installations. For AA engines, emissions will increase from 2007 to 2009 due to growth and the fact that no regulation applies (these engines not subject to 2009 engine regulation) (p. 19). (EDF 2008)

NOx Emissions from Compressor Engines in Barnett Shale of Texas (EDF 2008)

Area	2007 NOx Emissions, tpd	2009 NOx Emissions, tpd
DFW NAA engines	32	16
AA engines	20	31
Barnett Shale engines, total	52	47

The reference then looked at emission reductions for extending the 2009 rule to all engines in the Barnett Shale (including those in the AA). By extending the 2009 engine rule,

Appendix A

NMED Exhibit 60 - 0135

NOx emissions from AA engines would drop by approximately 6.5 tpd (p.25) (this approach reduces emissions from a large number of engines, in particular RB engines between 50 to 500 hp). (EDF 2008)

The ETCG 2013 reference indicated that analysis of test reports at the TCEQ Tyler office showed 68 compressor engines: 9 engines (13%) <240 hp and 59 engines (87%) ≥240 hp (and 69% of all engines ≥500 hp) (p.11). (A graph showing the distribution of the hp for all 68 engines is shown on p.12 of the reference document.) (ETCG 2013)

The ETCG 2013 reference discussed TCEQ Barnett Shale Special Inventory (Phase I) survey data. The table below is a summary of the engine horsepower distribution. (A graph showing the distribution of NG engines in the Barnett Shale region is shown in Figure 5-1 on p. 21 of the reference document.) The majority of engines in the Barnett Shale are RB and are <240 hp, see the two tables below. This data set shows that smaller hp engines are predominantly RB, with 2,089 engines <240 hp are RB (95%) and 104 engines (5%) are LB. For engines >240 hp, 327 engines (59%) are LB and 230 engines (41%) are RB.

2009 Equipment Inventory of Stationary NG Engines by Horsepower for Barnett Shale Region. (ETCG 2013)

Engine Size	Total Engines	Percent of Total Engines	Engine Type, RB or LB	Number of Engines	Percent of Each Size Category
0 to 50 hp	317	12%	RB	302	95%
			LB	15	4.7%
50 to 240 hp	1,876	68%	RB	1,787	95%
			LB	89	4.7%
>240 hp	557	20%	RB	230	41%
			LB	327	59%

Appendix A

Barnett Shale Special Inventory Phase I Equipment Survey Data on Stationary Gas-Fired Engines for 2009. (ETCG 2013)

Engine counts		
<240 hp	**≥240 hp**	**Total**
RB and LB		
2,193	557	2,750
RB only		
2,089	230	2,319
LB only		
104	327	431

The CO DPHE reference indicates that large NG RICE represent 16% of the statewide point source NOx emissions (16,199 tpy of 101,818 tpy) and 73% of the ICE NOx emissions (16,199 tpy of 22,210 tpy) (p. 1). (CO DPHE)

Example Emissions Estimates: It is difficult to draw conclusions for the emissions from LB versus RB from the data provided. However, some assumptions could be made to help draw conclusions for the defined scenario. If assume that the total capacity between LB and RB in the ERLE study is more representative of the total reporting population than the 50–50 split in the EDF study; assume that operating hours are similarly distributed for both LB and RB; and if the EFs tend to be higher for LB than for RB engines, then it is likely that 90% plus of the total emissions are from LB.

EPA Question 3: What is the effect of NOx SIP call controls on RICE in NOx SIP call states? That is, what percent reduction and types of controls have gone into place in states affected by the NOx SIP call?

Notes for Question 3

The applicability, reduction achieved, and cost for RICE NOx controls are often engine specific and highly variable. (DE 2012) (OTC 2012)

Common NOx control techniques are provided in the table below, along with NOx emission reductions achievable. (References from other areas outside of the NOx SIP call states also provided details on controls and emissions reductions achieved by these controls and are included in the table.)

Effectiveness of Combustion Control Technologies and Add-On Controls

Control Technique	(OTC 2012)	(KSU 2011)	(CARB 2001)	(CO DPHE)
2 Stroke, LB				
Improved combustion air flow, Turbocharger	(p. 18, 31): up to 75%	Up to 90%; 0.5 to 2 g/bhp-hr (increases fuel economy; may increase CO) (p. 9)	—	—
Retard ignition timing	(p. 54): diesel, 10% (reduces engine efficiency; increases PM)	Up to 10% (increase fuel economy; may increase CO) (p. 9)	(p. B-7,8): 15 to 30% (increases fuel consumption; increases VOC, HAP)	20% (pp. 5-7); $310 to $2,000/ton (p. 8)
Improved air fuel mixing, High Pressure Fuel Injection	(p. 18, 31): up to 90%	—	—	—
Advanced In-cylinder mixing	—	30 to 70% (p. 11)	—	—
Precombustion chamber (PCC) ignition system	(p. 19, 31-32): up to 90%	1 g/bhp-hr (p. 10)	—	—
Micro Precombustion chamber (MPCC), hybrid of High energy Ignition system and PCC	—	2 to 4 g/bhp-hr (p. 10)	—	—
Screw-in PCC	—	1 g/bhp-hr (p. 10)	—	—
Autobalance cylinders	(p. 23): not provided	—	—	—

(continued)

Appendix A

Effectiveness of Combustion Control Technologies and Add-On Controls (continued)

Control Technique	(OTC 2012)	(KSU 2011)	(CARB 2001)	(CO DPHE)
2 Stroke, LB (cont.)				
Air to Fuel Ratio Controller (AFRC)	(p. 19, 32): not provided	Not provided; use in combo with Increased air flow, or postcombustion Catalyst; a few thousand $ for small engine to $30K for larger engines (p. 12).	(p. B-8): not provided (fuel consumption penalty of 3%; may increase CO, VOC)	5 to 30% (pp. 5-7); $320 to $8,300/ton (p. 7)
Combustion modifications, Layered Combustion controls	(p. 25): 60 to 90%; range of 0.5 to 3 g/bhp-hr	—	—	—
4 stroke, LB				
EGR and NSCR	(p. 32): (emissions lower than SCR)[a]	—	—	—
Combustion modifications, Layered Combustion controls	(p. 38): 90%; range of 0.5 to 2 g/bhp-hr	—	—	—
Engines (general) or LB				
High energy ignition system (HEIS)	(p. 18, 31, 44): 10%	2.5 to 3 g/bhp-hr (pp. 9-10)	(p. B-12): 200 ppm NOx	—
Low emission combustion (LEC)/precombustion chamber retrofit (PCC) [also applicable to RB]	—	—	(p. B-10): 80% (may increase VOC, CO)	—
Turbocharging/ supercharging, and Aftercooling	(p. 18): Up to 75%	—	(p. B-13): 3 to 35% for Aftercooling (may reduce VOC, CO; increases engine efficiency, power rating)	—
EGR	(p. 55): diesel, >40% (loss of fuel efficiency; loss of engine output)	Still under development for NG engines; not cost effective at this time (p. 11).	(p. B-14): 30% (reduces engine peak power; reduces fuel efficiency by 2 to 12%)	—
Ignition system improvement	—	—	(p. B-11-2): not provided (may increase VOC, CO)	—

Appendix A

Effectiveness of Combustion Control Technologies and Add-On Controls (continued)

Control Technique	(OTC 2012)	(KSU 2011)	(CARB 2001)	(CO DPHE)
Engines (general) or LB (cont.)				
Fuel switching, methanol	—	—	(p. B-16): 30% for conversion from NG to methanol (can generate formaldehyde emissions)	—
Hybrid system, modification of dual bed NSCR system	—	—	(p. B-22): 3 to 4 ppm NOx	—
Use of electric motors in place of combustion engines	—	—	(p. B-27): >60%	60 to 100% (pp. 5-7); $100 to $4,700/ton [not include full costs] (p. 9)
RB				
Nonselective catalytic reduction (NSCR) plus AFRC	(p. 45, 49-51): 90 to 99% (reduces CO, VOC)	>90%, < 1 g/bhp-hr (reduces CO, HC) (p. 13)	(p. B-19-20): >90% (reduces CO >80%; reduces CO>50%; increases fuel consumption)	80 to 90% (pp. 5-7); Capital cost is $35,000; O&M is $6,000; Annualized capital is $4,851; TAC is $10,851; $571/ton (p. 8)
Convert RB to LB	(p. 45): not provided	—	—	—
EGR	(p. 49): up to 80% (increase power output by 10%; decrease fuel consumption by 7%)	—	—	—
Pre-stratified charge (converts RB to LB)	—	For 4S, RB, 2 g/bhp-hr (may de-rate engine power by 20%; costs significant) (p. 11)	(p. B-15): >80% (improved fuel efficiency)	—

Appendix A

[a]Some industry literature suggests that some particular 4S RB SI reciprocating engines can be converted to LB configurations with the accompanying LB engine NOx reduction capabilities. One vendor indicates that conversion to a LB configuration and the use of exhaust gas recirculation (EGR) delivers the advantages of a LB engine's efficiency and the RB engine's capability of utilizing NSCR for NOx control. The ability to convert a RB engine to a LB configuration is highly unit specific and does appear to have had widespread application in industry (p. 45). (OTC 2012)

Illinois: IEPA projected 2007 NOx emissions from 28 engines subject to the NOx SIP call to be 6,618 ton/season. NOx emission reductions from these sources were estimated to be 5,422 ton/season, and controlled NOx emissions levels were estimated to be 1,196 ton/season. (So baseline emissions were estimated to be 6,618 ton/season and controlled emissions were estimated to be 1,196 ton/season.) (IEPA 2007)

IEPA 2002 base year emissions inventory was 23,347 tpy NOx emitted from RICE and turbines, or approximately 8.4 percent of total point source NOx emissions (277,899 tpy NOx emissions from all point sources in Illinois) (p. 12). (IEPA 2007)

In addition to the NOx SIP Call requirements, IEPA also included additional units in its NOx regulation. NOx SIP Call units were to comply by May 2007, and additional units in NAA and AA were to comply in 2009, 2011, and 2012 (p. 51). The IL regulation will potentially affect 202 RICE engines and 36 turbines and reduce NOx emissions by 5,422 ton/season in 2007 ozone control season (p. 10). (IEPA 2007) [Full implementation of the IL regulation in 2012, to include additional units in NAA and AA counties down to the 500 hp size [28 NOx SIP Call units plus an additional 246 engines], was projected to reduce NOx emissions statewide by 17,082 tpy and 7,206 ton/season, which is 65 percent reduction on an annual basis and 55 percent reduction in O_3 season emissions (pp. 11 and 56). Uncontrolled NOx emissions in 2012 were projected to be 21,532 tpy and 9,134 ton/season, for those units included under the full implementation of the rule (p. 56). (IEPA 2007)]

Other Available Information

Additional RB control technologies and data are available in the OTC 2012.

Additional Diesel control technologies and data are available in OTC 2012.

EPA Question 4: What are typical or realistic baseline and controlled NOx emissions factors (grams/hp-hr) for RICE in the OTC states?

Notes for Question 4

NOx control requirements for several of the Ozone Transport Commission (OTC) states were provided for Connecticut, New Jersey, New York, and Rhode Island, based on a 1994 STAPPA/ALAPCO document (p. 45). (IEPA 2007) These could potentially be used as maximum EF for RICE units. NOx control requirements are listed in the following table.

NOx Control Requirements for RICE in Some OTC States and Other States

State	Covered	NOx Control Level	Reference
Connecticut	≥3 MMBtu/hr (1175 hp)	Liquid-fired, CI: 8 g/bhp-hr (584 ppm)	IEPA 2007
New York	RACT for Major Facilities of NOx, Severe O_3 NAA ≥200 hp and Rest of state ≥400 hp	▪ Thru March 31, 2005, NG, RICE, LB: 3 g/bhp-hr (220 ppm) ▪ After April 1, 2005, LB: 1.5 g/bhp-hr (110 ppm) ▪ Thru March 31, 2005, Liquid-fired, CI: 9 g/bhp-hr (657 ppm) ▪ After April 1, 2005: 2.3 g/bhp-hr (168 ppm)	OTC 2012, DE 2012, IEPA 2007
New York (RACT)	Major facilities >25 tpy, NYC and Lower Orange Co: ≥200 kW Rest of state, major facilities >100 tpy: ≥400 kW	▪ NG: 1.5 g/bhp-hr ▪ Landfill or digester gas: 2.0 g/bhp-hr	
New Jersey		▪ NG, LB, ≥500 hp: 2.5 g/bhp-hr (182 ppm) ▪ Liquid-fired, CI, ≥500 hp: 8 g/bhp-hr (584 ppm)	IEPA 2007
New Jersey (RACT)	≥148 kW Group of 2 or more engines, each at ≥37 to <148 kW, but total combined power ≥148 kW	▪ Gas, LB: 1.5 g/bhp-hr, or 80% reduction ▪ Gas, RB: 1.5 g/bhp-hr	
New Jersey (RACT)	≥37 kW	▪ Commenced on or after March 7, 2007: 0.9 g/bhp-hr ▪ Modified on or after March 7, 2007: 0.9 g/bhp-hr, or 90% reduction	
Maryland	NG pipeline engines with >15% capacity factor	NA	IEPA 2007
Other States and Areas			
Illinois	NA	▪ 3 g/bhp-hr (210 ppm)	NA

(continued)

Appendix A

NOx Control Requirements for RICE in Local Areas.

State or Area	Criteria	NOx control level	Reference
SCAQMD (July 2010)	Rule 1110.2 Emissions from Gaseous and Liquid Fueled Engines	▪ ≥500 hp: 0.5 g/bhp-hr (36 ppmvd) ▪ <500 hp: 0.6 g/bhp-hr (45 ppmvd) ▪ After July 1, 2010, ≥500 hp: 0.15 g/bhp-hr (11 ppmvd) ▪ After July 1, 2010, <500 hp: 0.6 g/bhp-hr (45 ppmvd) ▪ After July 1, 2011, All: 0.15 g/bhp-hr (11 ppmvd)	OTC 2012

For engines with unknown pre-rule emissions, NOx emissions were assumed to be 16.4 g/bhp-hr for 2S and 18.9 g/bhp-hr for 4S. (DE 2012)

A list of Stack test results for engines in PA that are >500 hp are given in Appendix A, Table 3 of the PA DEP 2013 reference (p. 53). (PA DEP 2013) [Capital] costs for NSCR, RB ranged from $10 to $12/bhp. (p. 9) NSCR, RB ranged from $10 to $15/bhp (slightly different value given here). (p. 16) (MECA 1997)

IC Engine Typical Emissions Levels (MECA 1997)

Engine Type	Lambda (Actual A/F ratio to Stoichiometric A/F ratio)	Mode	NOx, g/bhp-hr
NG	0.98	Rich	8.3
	0.99	Rich	11.0
	1.06	Lean	18.0
	1.74	Lean	0.7
Diesel	1.6–3.2	Lean	11.6
Dual Fuel	1.6–1.9	Lean	4.1

For RB, CARB 2001 document has Costs for NSCR w/o AFRC achieving 96% reduction. Capital costs ranged from $11,000 to $44,000; Annual costs ranged from $8,200 to $18,000; and cost effectiveness ranged from $2,100/ton to $300/ton NOx reduction (p. V-2 to V-3). (CARB 2001)

For RB, CARB 2001 document has Costs for Pre-stratified Charge, achieving 80% reduction. Capital costs ranged from $10,000 to $47,000; Annual costs ranged from $2,700 to

Appendix A

$11,000; and cost effectiveness ranged from $800/ton to $200/ton NOx reduction (pp. V-2 to V-3). (CARB 2001)

CARB 2001 document has costs for Ignition Timing Retard (ITR), although the description of the combustion technology indicates it is less popular on Stationary engines than mobile source engines (pp. V-2, B-7 to B-8). (CARB 2001)

The EDF 2008 reference provided NOx EF for engines in the Bartlett Shale region. The document notes that extending the 2009 engine rules in Barnett Shale to counties outside the DFW NAA would likely result in many engine operators installing NSCR on RB engines. NSCR costs were cited as follows: $330/ton (IEPA 2007); $92 to $105/ton (EPA 2006); and $112 to $183/ton (northeast Texas 2005 report). Another control technique reviewed in this report included replacement of compressor engines with electric motors. There are multiple compressors driven by electric motors throughout Texas (p. 26). Use of electric motors instead of gas-fired engines eliminates combustion emissions (p. 27). The costs are time and site specific, based on the cost of electricity, cost of NG, hours of operation per year, number of compressors, size of compressor, etc. (EDF 2008)

NOx Emission Factors for Engines Identified in DFW 2007 Engine Survey (EDF 2008)

NMED Exhibit 60 - 0150

EPA Question 5: Using FERC data or other data sources, what is the relationship between RICE model and age, and emissions (both for baseline and with controls)? In particular, what is the relationship for RICE built before the imposition of the SI (spark ignition, natural gas-fired) RICE NSPS in 2007?

Notes for Question 5

The DE 2012 reference stated that many of the installed mainline NG compressors are of the age (in excess of 40 years old) to have pre-dated modern original equipment manufacturer (OEM) installed NOx emission controls and otherwise applicable new source performance standards (NSPS). There is little information on the number of units that may have undergone NOx modifications as a result of federal or State rules and regulations. The reference cited a 2003 Pipeline Research Council International (PRCI) document that identified 5,686 engines: 71% are LB and 29% are RB (based on dropping the turbine numbers in the table below). The average age for each unit type is shown in the following table. [These data are repeated in OTC 2012.] [Based on these data, it is estimated that the LB and RB engines are 37 years old on average (based on dropping the turbine numbers in the table below).] (p. 19) (DE 2012)

2003 Pipeline Research Council International Data (PRCI)

Unit Type	U.S Total Units (%)	Average Age (as of 2003)	Avg hp
2S LB	2,955 (44%)	42	2,113
4S LB	1,059 (16%)	33	1,844
RB	1,672 (25%)	32	589
Turbine	1,016 (15%)	24	6,121

The OTC 2012 reference indicated that many of the reciprocating engines driving mainline NG compressors are in excess of 40 years old, pre-dating any applicable modern OEM installed NOx emission control and any otherwise applicable NSPS NOx controls (p. 16). (OTC 2012)

The DE 2012 reference discussed a 2005 study conducted for NG field gathering engines in Eastern Texas; the study was able to determine the age only for a very small portion of the engines, and the engine age ranged from 2 to 25 years. The output ratings of engines in the study ranged from 26 to 1478 hp, with the majority rated between 50 and 200 hp (p. 12). (DE 2012)

The DE 2012 reference indicated they reviewed MARAMA's 2007 Point Source Inventory and 2007 FERC data. The 2007 FERC data are provided as Attachment III to the

Appendix A

reference. The two sets of data did not match: 2007 MARAMA data indicated 107 compressor facilities, and 2007 FERC data indicated 150 compressor facilities. The reviewed databases did not provide any information regarding NOx emission rates (g/bhp-hr, ppmvd). NOx emission rates were obtained for a small number of prime movers, through operating permits: 2SLB range from 1 to 13.3 g/bhp-hr; 4SLB range from 0.5 to 6 g/bhp-hr; and 4SRB were 3 g/bhp-hr. The data are not sufficient to estimate actual NOx emission rates and NOx reductions. Note that the FERC data addresses large entities, and smaller companies may not be required to report data to FERC. The 2007 OTC compressors from FERC are provided in the following table. (DE 2012)

State	No. Compressors	Total Rated hp
CT	10	35,300
MA	15	25,702
MD	17	52,250
ME	4	33,244
NJ	36	129,130
NY	120	359,487
PA	467	1,331,164
RI	6	29,170
VA (OTR area only)	22	49,390

The KSU 2011 reference discussed control technologies testing performed in the laboratory on a 1966 Ajax DP-115 (Lean Burn) that has none of the low emissions controls that are currently OEM standard. The published emission factor (EF) for this engine is 4.4 g/bhp-hr, and the emissions from actual testing were 4.69±0.18 g/bhp-hr (the Lab testing results are discussed on pp. 19-27). There is additional discussion of Field testing conducted on multiple LB engines with NOx emission control techniques, including (1) Increased air flow, and precombustion chamber (PCC) screw-in type, (2) PCC screw-in type and Upgraded turbocharger, (3) Integral PCC and high-output turbocharger (pp. 27-29). Discussion of Field testing conducted on two RB engines with NOx emission control techniques (p. 29). Integrated nonselective catalytic reduction (NSCR) with modeling and enhanced controller is also discussed. (KSU 2011).

EPA Question 6: What is the variability in NOx emissions from RICE within each State, both for baseline and with controls?

Notes for Question 6

No data were found. [Likely a review of RICE SCCs in the NEI across states would be a useful exercise to see the relative levels of baseline and/or controlled NOx emissions, however this exercise was not part of this task.]

NMED Exhibit 60 - 0154

To: US EPA OAQPS

From: SRA International, Inc.

Subject: Review of CoST Model Emission Reduction Estimates

Date: September 30, 2014

EPA uses the Control Strategy Tool (CoST) to estimate the emission reductions and engineering costs associated with control strategies applied to point, area, and mobile sources of air pollutant emissions to support the analyses of air pollution policies and regulations. CoST accomplishes this by matching control measures to emission sources using algorithms such as "maximum emissions reduction", "least cost", and "apply measures in series". There was a concern that the baseline inventory used by CoST did not completely account for emission control requirements already in place, and that the emission reductions were perhaps overestimated.

SRA reviewed the CoST results and made recommendations for changing the CoST control measure assignment and the estimated reductions for oxides of nitrogen (NOx). The recommendations were based on a review of source permits, state regulations, enforcement actions, and other available information. The analysis was conducted for a 24-state area in the eastern two-thirds of the U.S. The focus was on stationary point sources other than electric generating units (non-EGUs). The purpose of this memo is to document the data used and assumptions made in recommending changes to the CoST results, and to summarize the differences between the CoST results and the recommended changes.

The findings in this memo are based on review of CoST results for a 2018 emissions inventory projected from the 2011 National Emission Inventory (NEI). This work was in support of EPA's current Transport Rule efforts for implementing the 75 ppb ozone standard. If EPA considers establishing a tighter ozone standard in the future, it is likely that a more distant future year will be used and that some of the conclusions reached in this memo could change.

CoST DATA PROVIDED BY EPA

EPA provided SRA with the outputs from a CoST scenario that identified sources for which NOx controls were available at a cost-effectiveness level of less than $10,000 per ton. The CoST outputs included source identifiers, control technology, baseline emissions and estimates of NOx emission reductions. The CoST results were divided into two groups. The first group included sources where CoST estimated NOx emission reductions of more than 100 tons per year. There were 547 sources in this group where CoST controls were initially applied. The second group included sources where CoST estimated emission reductions for sources whose 2018 projected emissions were greater than 25 tons/year, excluding those

Appendix B

NMED Exhibit 60 - 0155

with reductions greater than 100 tons/year. There were 1,280 sources in this group where CoST controls were initially applied.

Another contractor reviewed the CoST results for additional source categories, and their recommendations were merged with SRA's recommendations in the summary tables and maps that follow. The data used, assumptions made and results for IC engines are documented elsewhere[1].

REVIEW OF CoST RESULTS FOR THE GREATER THAN 100 TPY GROUP

Table 1 summarizes the source categories included in our analysis, the CoST recommendation for NOx control, and the recommendation for changing the CoST control measure assignment and associated emission reduction estimates. Following Table 1, there is a discussion for each source group to provide more detail on the rationale for the recommended changes for each source group. Attachments 1 to 4 are tabular comparisons of the initial CoST emission reduction estimates and the recommended changes. All Attachments present the results in terms of tons per ozone season, simply estimated by assuming that ozone season emissions were equal to 5/12 of the annual emissions. Maps 1A and 1B graphically show the location of sources and the magnitude of the recommended emission reductions.

Table 1 – CoST Controls and Recommended Changes for Greater than 100 TPY Sources

Source Group	CoST Control Recommendation	Summary of Recommended Changes to CoST Controls and Reductions
Ammonia – NG-fired Reformers	Selective Catalytic Reduction	Agreed with CoST recommendation of SCR except for those sources where a permit or state regulation already required the source to be controlled.
By-Product Coke Mfg; Oven Underfiring	Selective Non-Catalytic Reduction	Review of a source-specific NOx RACT permit indicated that NOx controls were technically or economically infeasible.
Cement Kilns	Biosolid Injection Technology	Disagreed with CoST recommendation based on concerns about biosolids availability and information from EPA's ISIS (Industrial Sector Integrated Solutions) Model; recommended SNCR for all sources, except those that already have SNCR due to NOx SIP Call, NSR requirement, Consent Decree, or other state regulation.

[1] Update of NOx Control Measure Data in the CoST Control Measures Database for Four Industrial Source Categories: Ammonia Reformers, NonEGU Combustion Turbines,Glass Manufacturing, and Lean Burn Reciprocating Internal Combustion Engines," prepared by Research Triangle Institute, July 2014.

Appendix B

Source Group	CoST Control Recommendation	Summary of Recommended Changes to CoST Controls and Reductions
Cement Manufacturing - Dry	Selective Non-Catalytic Reduction	Agreed with CoST recommendation except when already controlled due to NOx SIP Call, NSR requirement, Consent Decree, or other state regulation.
Cement Manufacturing – Wet	Mid-kiln Firing	Disagreed with CoST recommendation based on information from EPA's ISIS Model; recommended SNCR for all sources, except those that already controlled
Coal Cleaning – Thermal Dryer	Low NOx Burner	Agreed with CoST recommendation
Comm/Inst Incinerators	Selective Non-Catalytic Reduction	Both sources are already controlled with SNCR
External Combustion Boilers, Elec Gen, Solid Waste	Selective Non-Catalytic Reduction	All 6 sources are already controlled with SNCR
Fluid Catalytic Cracking Units	Low NOx Burner and Flue Gas Recirculation	Nearly all FCCUs are already controlled due to the OECA global refinery consent decrees. There is one small refinery in West Texas that does not appear to be covered by a consent decree, so the CoST recommendation was accepted.
Glass Manufacturing – Container, Flat, Pressed	OXY-Firing	Disagreed with CoST recommendation. OXY-firing is not generally required under recent OECA consent decrees. More common control is oxygen-enriched air staging (OEAS). OXY-firing can only be implemented at the time of furnace rebuild, which is generally done every 10-15 years. Changed recommended control to OEAS with a 50% NOx reduction instead of OXY-firing at 85% NOx reduction, except for sources that already had NOx controls in place due to a consent decree, NSR requirement, or state regulation. Assumed that a furnace with a NOx emission limit of less than 4 lbs/ton of glass pulled was already reasonably controlled.
ICI Boilers – Coal/Cyclone	Selective Catalytic Reduction	Agreed with CoST recommendation of SCR except for those sources where a permit or state regulation already required the source to be controlled. LADCO/OTC also recommends SCR
ICI Boilers – Coal/Stoker	Selective Catalytic Reduction	Disagreed with CoST recommendation of SCR. CoST has $2200/ton, which appears

Appendix B

Source Group	CoST Control Recommendation	Summary of Recommended Changes to CoST Controls and Reductions
		very low for ICI boilers. Used LADCO/OTC recommendation of SNCR for Coal-Stokers with a 50% reduction, except for those sources where a permit or state regulation already required the source to be controlled.
ICI Boilers – Coal/Wall	Low NOx Burner and Selective Catalytic Reduction	Agreed with CoST recommendation of SCR except for those sources where a permit or state regulation already required the source to be controlled. LADCO/OTC also recommends LNB/SCR
ICI Boilers – Gas, Natural Gas, Process Gas	Selective Catalytic Reduction	Disagreed with CoST recommendation of SCR. CoST has $3456/ton, which appears very low for ICI boilers. Used LADCO/OTC recommendation of Low NOx Burners plus Flue Gas Recirculation for Gas-fire ICI boilers with a 60% reduction, except for those sources where a permit or state regulation already required the source to be controlled
Industrial Incinerators	Selective Non-Catalytic Reduction	Agreed with CoST recommendation of SNCR except for those sources where a permit or state regulation already required the source to be controlled.
Iron & Steel Mills – Reheating	Low NOx Burner and Flue Gas Recirculation	Agreed with CoST recommendation except for those sources where a permit or state regulation already required the source to be controlled.
Municipal Waste Combustors	Selective Non-Catalytic Reduction	Agreed with CoST recommendation of SNCR except for those sources where a permit or state regulation already required the source to be controlled.
Nitric Acid Manufacturing	Nonselective Catalytic Reduction	Agreed with CoST recommendation of NSCR except for those sources where a permit or state regulation already required the source to be controlled.
Petroleum Refinery Process Heaters	SCR-95%	Nearly all refineries are already controlled due to the OECA global refinery consent decrees, which generally require 40-60% reductions across all boilers/heaters that each company operates. Not possible at present to identify the individual boilers/heaters that actually have been controlled or are scheduled to be controlled due to confidentiality agreements between EPA and companies.

Appendix B

Source Group	CoST Control Recommendation	Summary of Recommended Changes to CoST Controls and Reductions
Taconite Ore Processing – Induration – Coal or Gas	Selective Catalytic Reduction	Disagree with CoST recommendation of SCR. EPA Region V considers SCR/SNCR to be infeasible. Used Low NOx Burners at 70% reduction instead as reasonable control, except for those sources where a permit or state regulation already required the source to be controlled. .
Utility Boilers* – Coal/Wall	Selective Catalytic Reduction	Agreed with CoST recommendation of SCR except for those sources where a permit or state regulation already required the source to be controlled.
Utility Boilers* – Oil/Gas	Selective Catalytic Reduction	Agreed with CoST recommendation of SCR except for those sources where a permit or state regulation already required the source to be controlled.

The utility boilers included in the context of this report are non-IPM utility boilers. In the NEI, these units have an SCC of 1-01—xxx-xx (the SCC series generally used for electric generating units. However, the sources included in this analysis do not sell electricity to the grid.

Ammonia – NG-fired Reformers

There are 15 sources in this category. The CoST control technology was selective catalytic reduction (SCR) with a 90% reduction in NOx emissions. We determined that four of these sources were already controlled by either SCR or ultra-NOx burners and recommended no further control/reductions. For all other sources, we agreed with the CoST control and emission reduction estimate.

By-Product Coke Mfg; Oven Underfiring

There are 14 sources in this category. The CoST control technology was selective non-catalytic reduction (SNCR) with a 60% reduction in NOx emissions. We reviewed a detailed RACT analysis for a facility in Pennsylvania that determined that no controls were feasible. For all sources in this category, we recommended that no controls were feasible and thus no reductions were appropriate.

Cement Preheater/Precalciner Kilns

There are 36 sources in this category. The CoST control technology was biosolid injection technology with a 23% reduction in NOx emissions. We reviewed permits and consent decrees to identify those kilns that are already controlled. Several kilns are already controlled based on NOx SIP Call requirements that typically required low NOx burners, mid-kiln firing, or an approved alternative that resulted in a 30% reduction. Other kilns already had SNCR installed due to a consent decree, new source review requirement, or other state-level requirement.

Appendix B

EPA expressed a concern whether there was sufficient biosolids availability for use by the uncontrolled kilns. Also, EPA has done considerable research on cement kiln NOx controls as part of its Industrial Sector Integrated Solutions (ISIS) project. EPA uses the ISIS-cement model help analyze policy options for various rulemakings. Based on the ISIS work, we recommended that low-NOx burners and SNCR as the appropriate control for all types of kilns.

For uncontrolled kilns, we applied a 65% reduction in NOx emissions. For kilns already controlled with low-NOx burners or mid-kiln firing, we applied a 35% incremental reduction to account for the additional reductions from SNCR. For kilns already controlled with SNCR, we applied no additional emission reductions.

Cement Manufacturing - Dry Process

There are 20 sources in this category. The CoST control technology was SNCR with a 50% reduction in NOx emissions. We reviewed permits and consent decrees to identify those kilns that are already controlled. Several kilns are already controlled based on NOx SIP Call requirements that typically required low NOx burners, mid-kiln firing, or an approved alternative that resulted in a 30% reduction. Other kilns already had SNCR installed due to a consent decree, new source review requirement, or other state-level requirement.

As discussed earlier, we recommended that low-NOx burners and SNCR as the appropriate control for all types of kilns based on the ISIS work. For uncontrolled kilns, we applied a 65% reduction in NOx emissions. For kilns already controlled with low-NOx burners or mid-kiln firing, we applied a 35% incremental reduction to account for the additional reductions from SNCR. For kilns already controlled with SNCR, we applied no additional emission reductions.

Cement Manufacturing – Wet Process

There are seven sources in this category. The CoST control technology was mid-kiln firing with a 30% reduction in NOx emissions. We determined that two of these kilns were installing a pilot SCR system as part of a consent decree. One kiln recently went through NSR review and has state-of-the-art control. Another kiln is required to install SNCR as part of a consent decree. No additional reductions were applied for these kilns. For the remaining kilns, we applied low-NOx burners and SNCR as described in the previous sections.

Coal Cleaning – Thermal Dryer

There was one source in this category. The CoST control technology was a low-NOx burner with a 50% reduction in NOx emissions. We could not find any information on this source and accepted the CoST controls.

Appendix B

Comm/Inst Incinerators

There are two sources in this category. The CoST control technology was SNCR with a 45% reduction in NOx emissions. Both of these sources are already controlled by SNCR and we applied no additional emission reductions.

External Combustion Boilers, Elec Gen, Solid Waste

There are six sources in this category. The CoST control technology was SNCR with a 50% reduction in NOx emissions. All six of these sources are already controlled by SNCR and we applied no additional emission reductions.

Fluid Catalytic Cracking Units

There are six sources in this category. The CoST control technology was low-NOx burners and flue gas recirculation with a 55% reduction in NOx emissions. Nearly all sources are already controlled or required to install controls as a result of the EPA's global refinery consent decrees. There is one small refinery in West Texas that does not appear to be covered by a consent decree, so the CoST recommendation was accepted.

Glass Manufacturing – Container, Flat, Pressed

There are 65 sources in this category. The CoST control technology was oxy-firing with an 85% reduction in NOx emissions. There were several concerns about using oxy-firing for this analysis. First, there is a concern about the timing of installing oxy-firing technology. Oxy-firing is typically installed at the time of a furnace rebuild, which is typically done every 10 to 15 years. Second, oxy-firing is not generally required under recent EPA consent decrees. More common control is oxygen-enriched air staging (OEAS). We recommended that OEAS with a 50% NOx reduction instead of OXY-firing at 85% NOx reduction, except for sources that already had NOx controls in place due to a consent decree, NSR requirement, or state regulation. We assumed that a furnace with a NOx emission limit of less than 4 lbs/ton of glass pulled was already reasonably controlled.

ICI Boilers – Coal/Cyclone

There are eight sources in this category. The CoST control technology was SCR with an 80% reduction in NOx emissions. We reviewed the *Evaluation of Control Options for Industrial, Commercial and Institutional (ICI) Boilers Technical Support Document (TSD), March, 2011* prepared by the Lake Michigan Air Directors Consortium (LADCO) and the Ozone Transport Commission (OTC). LADCO/OTC also recommended SCR for coal-cyclone boilers. Since the LADCO/OTC recommendation was consistent with the CoST control, we agreed with the CoST control technology for five sources which we determined were uncontrolled. Two sources were determined to be already controlled. One source appears to have shut down their coal-fired boilers. No reductions were applied for these three sources since they are already controlled.

Appendix B

ICI Boilers – Coal/Stoker

There are 45 sources in this category. The CoST control technology was SCR with an 80% reduction in NOx emissions. The LADCO/OTC recommendation was for combustion tuning and SNCR. We agreed with the LADCO/OTC recommendation and assumed a 50% control efficiency. We determined that most of these sources are currently uncontrolled. Two coal-fired boilers are scheduled to be replaced with gas-fired boilers. Two other boilers recently installed SNCR.

ICI Boilers – Coal/Wall

There are 54 sources in this category. The CoST control technology was low-NOx burners and SCR with a 91% reduction in NOx emissions. The LADCO/OTC recommendation was also for low-NOx burners and SCR. Since the LADCO/OTC recommendation was consistent with the CoST control, we agreed with the CoST control technology and emission reductions.

ICI Boilers – Gas, Natural Gas, Process Gas

There are 130 sources in this category. The CoST control technology was SCR with an 80% reduction in NOx emissions. The LADCO/OTC recommendation was for low-NOx burners, flue gas recirculation, or low-NOx burners combined with flue gas recirculation. We agreed with the LADCO/OTC recommendation of low-NOx burners combined with flue gas recirculation and assumed a 60% control efficiency.

Several of these sources are located in the OTR or ozone nonattainment areas, and as a result already have a RACT control requirement or emission limitation that is consistent with the LADCO/OTC recommendations. A few of these sources are located at petroleum refineries and were assumed to be already controlled due to EPA's refinery enforcement initiative.

Municipal Waste Combustors

There are 55 sources in this category. The CoST control technology was SNCR with a 45% reduction in NOx emissions. We determined that 35 of these sources are already controlled with SNCR and no additional reductions were applied. For the remaining uncontrolled sources, we agreed with the CoST controls and emission reductions.

Nitric Acid Manufacturing

There are seven sources in this category. The CoST control technology was non-selective catalytic reduction (NSCR) with a 98% reduction in NOx emissions. All but one of these sources is already controlled by NSCR or SCR.

Petroleum Refinery Process Heaters

There are 28 sources in this category. The CoST control technology was SCR with a 95% reduction in NOx emissions. All of the sources in this category are covered sources under EPA's global refinery enforcement initiative. The settlements generally require 40-60% reductions across all boilers/heaters that

Appendix B

each company operates. Companies have submitted NOx compliance plans to OECA that identify the specific sources that have been controlled or are planned to be controlled, along with the technology used. But it is not possible at present to identify the individual boilers/heaters that actually have been controlled or are scheduled to be controlled due to confidentiality agreements between EPA and companies. No additional reductions were included for this category.

Taconite Ore Processing – Induration – Coal or Gas

There are 10 sources in this category. The CoST control technology was SCR with a 90% reduction in NOx emissions. All of the sources in this category are already subject to Best Available Retrofit Technology (BART) requirements under the Regional Haze program. EPA Region V determined that BART is low-NOx burners and agreed that SCR controls are infeasible for indurating furnaces. No additional reductions were included for this category.

Utility Boilers – Coal/Wall, Oil, Gas

There are 11 sources in this category. The CoST control technology was SCR with a 80 to 90% reduction in NOx emissions depending on fuel type. All of the sources in this category appear to be uncontrolled and we agreed with the CoST control and emission reduction estimate.

REVIEW OF CoST RESULTS FOR THE 25 TO 100 TPY GROUP

Due to the large number of sources in this group, we were not able to review individual permits to determine whether the individual source was already controlled. Instead, our recommendations were based on of state regulations, enforcement actions, engineering judgment, and other available information. We generally assumed that sources located in areas with stringent NOx rules are already well controlled and we assumed that no additional reductions were likely from these sources. This assumption was generally applied in New Jersey, New York and sources located in the Houston nonattainment area. Given more time, we would like to have also applied this assumption in other areas with stringent existing regulations, such as Chicago, Milwaukee, and Baton Rouge. In any future analysis, it would be useful to examine the stringency of rules that apply strictly to nonattainment areas.

Table 2 summarizes the source categories included in our analysis, the CoST recommendation for NOx control, and the recommendation for changing the CoST control measure assignment and associated emission reduction estimates. Following Table 2, there is a discussion for each source group to provide more detail on the rationale for the recommended changes for each source group. Attachments 5 to 8 are tabular comparisons of the initial CoST emission reduction estimates and the recommended changes. All Attachments present the results in terms of tons per ozone season, simply estimated by assuming that

Appendix B

NMED Exhibit 60 - 0163

ozone season emissions were equal to 5/12 of the annual emissions. Maps 3A and 3B graphically show the location of sources and the magnitude of the recommended emission reductions.

Table 2 – CoST Controls and Recommended Changes for 25 to 100 TPY Sources

Source Group	CoST Control Recommendation	Summary of Recommended Changes to CoST Controls and Reductions
Ammonia – NG-fired Reformers	Selective Catalytic Reduction	Agreed with CoST recommendation of SCR except for those sources where a permit or state regulation already required the source to be controlled.
Cement Kilns	Biosolid Injection Technology	Because of low emissions, assume that the kiln is already controlled or have very low usage which would result in a unreasonably high cost-effectiveness
Cement Manufacturing – Wet	Mid-kiln Firing	Because of low emissions, assume that the kiln is already controlled or have very low usage which would result in a unreasonably high cost-effectiveness
Ceramic Clay Mfg; Drying	Low NOx Burner	Questions about technical feasibility for these category, assume zero reductions
Coal Cleaning – Thermal Dryer	Low NOx Burner	Agree with CoST recommendation
Comm/Inst Incinerators	Selective Non-Catalytic Reduction	Agree with CoST recommendation
External Combustion Boilers, Elec Gen, Sub/Bit Coal	Selective Non-Catalytic Reduction	Agree with CoST recommendation, although questions as to whether the source is already controlled or very low usage which would result in a unreasonably high cost-effectiveness
Fluid Catalytic Cracking Units	Low NOx Burner and Flue Gas Recirculation	Nearly all FCCUs are already controlled due to the OECA global refinery consent decrees.
Gas Turbines	Low NOx Burners	Agreed with CoST recommendation except for those sources where a state regulation already required the source to be controlled.
Glass Manufacturing – Container, Flat, Pressed	OXY-Firing	Because of low emissions, assume that the furnace is already controlled or have very low usage which would result in a unreasonably high cost-effectiveness
ICI Boilers – Coal/Stoker	Selective Catalytic Reduction	Disagreed with CoST recommendation of SCR. CoST has $2200/ton, which appears very low for ICI boilers. Used LADCO/OTC recommendation of SNCR for Coal-Stokers with a 50% reduction, except for those sources where a state regulation already required the source to be controlled.
ICI Boilers – Coal/Wall	Low NOx Burner and Selective Catalytic Reduction	Agreed with CoST recommendation of SCR except for those sources where a state regulation already required the source to be

Appendix B

Source Group	CoST Control Recommendation	Summary of Recommended Changes to CoST Controls and Reductions
		controlled. LADCO/OTC also recommends LNB/SCR
ICI Boilers – Distillate Oil or Process Gas	Selective Catalytic Reduction	Because of low emissions, assume that the boiler is already controlled or have very low usage which would result in a unreasonably high cost-effectiveness
ICI Boilers – Natural Gas	Low NOx Burner and Selective Catalytic Reduction	Disagreed with CoST recommendation of SCR. Used LADCO/OTC recommendation of Low NOx Burners plus Flue Gas Recirculation for Gas-fire ICI boilers with a 60% reduction, except for those sources where a permit or state regulation already required the source to be controlled
ICI Boilers – Residual Oil	Low NOx Burner and Selective Non-Catalytic Reduction	Agreed with CoST recommendation of SCR except for those sources where a state regulation already required the source to be controlled.
Industrial Incinerators	Selective Non-Catalytic Reduction	Agreed with CoST recommendation of SNCR except for those sources where a state regulation already required the source to be controlled.
Iron & Steel Mills – Reheating	Low NOx Burner and Flue Gas Recirculation	Agreed with CoST recommendation except for those sources where a state regulation already required the source to be controlled.
Municipal Waste Combustors	Selective Non-Catalytic Reduction	Agreed with CoST recommendation of SNCR except for those sources where a state regulation already required the source to be controlled.
Nitric Acid Manufacturing	Nonselective Catalytic Reduction	Agreed with CoST recommendation of NSCR except for those sources where a state regulation already required the source to be controlled.
Petroleum Refinery Process Heaters	SCR or Ultra-Low NOx Burner	Nearly all refineries are already controlled due to the OECA global refinery consent decrees, which generally require 40-60% reductions across all boilers/heaters that each company operates. Not possible at present to identify the individual boilers/heaters that actually have been controlled or are scheduled to be control due to confidentiality agreements between EPA and companies.
Utility Boilers – Coal/Wall	Selective Catalytic Reduction	Agreed with CoST recommendation of SCR except for those sources where a state regulation already required the source to be controlled
Utility Boilers – Oil/Gas	Selective Catalytic Reduction	Because of low emissions, assume unreasonably high cost-effectiveness for SCR; use LNB/FGR as reasonable control.

Appendix B

Ammonia – NG-fired Reformers

There are seven sources in this category. The CoST control technology was SCR with a 90% reduction in NOx emissions. For all other sources, we agreed with the CoST control and emission reduction estimate.

Cement Kilns

There are six sources in this category. The CoST control technology was either biosolid injection technology with a 23% reduction in NOx emissions or mid-kiln firing with a 30% reduction. Because of the low baseline emissions for these kilns, we assumed that the kilns were already controlled or have low usage which would result in a very high cost-effectiveness. We determined that no reductions be applied for these sources.

Coal Cleaning – Thermal Dryer

There are 10 sources in this category. The CoST control technology was a low-NOx burner with a 50% reduction in NOx emissions. We agreed with the CoST control and emission reduction estimate.

Commercial/Institutional Incinerators

There are four sources in this category. The CoST control technology was SNCR with a 45% reduction in NOx emissions. We agreed with the CoST control and emission reduction estimate.

External Combustion Boilers, Electric Generation, Coal

There are 14 sources in this category. The CoST control technology was SNCR with a 40% reduction in NOx emissions. It appears that the sources in this category are low usage spreader stokers. Although there may be a concern about the cost-effectiveness for these sources, we agreed with the CoST control and emission reduction estimate.

Fluid Catalytic Cracking Units

There are 21 sources in this category. The CoST control technology was low-NOx burners and flue gas recirculation with a 55% reduction in NOx emissions. All sources in this category are assumed subject to existing control requirements resulting from the OECA global refinery enforcement initiative. Additionally, eight of the sources are located in the Houston nonattainment area and are likely subject to stringent controls. For these reasons, we assumed no further control or emission reductions for the FCCUs.

Gas Turbines

There are 438 sources in this category. The CoST control technology was for low-NOx burners with a 68% reduction in NOx emissions. We agreed with the CoST control and emission reduction estimate, except for those sources located in the OTR and Houston ozone nonattainment area, where we assumed that these sources already had RACT controls.

Glass Manufacturing – Container, Flat, Pressed

Appendix B

NMED Exhibit 60 - 0166

There are eight sources in this category. The CoST control technology was SCR with a 90% reduction in NOx emissions. Because of the low baseline emissions for these furnaces, we assumed that the furnaces were already controlled and determined that no reductions be applied for these sources.

ICI Boilers – Coal/Stoker

There are 133 sources in this category. The CoST control technology was SCR with a 90% reduction in NOx emissions. The LADCO/OTC recommendation was for combustion tuning and SNCR. We agreed with the LADCO/OTC recommendation and assumed a 50% control efficiency.

ICI Boilers – Coal/Wall

There are 11 sources in this category. The CoST control technology was SCR with a 90% reduction in NOx emissions. The CoST control technology was low-NOx burners and SCR with a 91% reduction in NOx emissions. The LADCO/OTC recommendation was also for low-NOx burners and SCR. Since the LADCO/OTC recommendation was consistent with the CoST control, we agreed with the CoST control technology and emission reductions.

ICI Boilers – Natural Gas

There are 376 sources in this category. The CoST control technology was low-NOx burners and SCR with a 91% reduction in NOx emissions. The LADCO/OTC recommendation was for low-NOx burners, flue gas recirculation, or low-NOx burners combined with flue gas recirculation. We agreed with the LADCO/OTC recommendation of low-NOx burners combined with flue gas recirculation and assumed a 50% control efficiency, except for those sources located in the OTR and Houston ozone nonattainment area, where we assumed that these sources already had RACT controls.

ICI Boilers – Process Gas

There are 57 sources in this category. The CoST control technology was SCR with a 90% reduction in NOx emissions. Most of these sources are located at petroleum refineries and are assumed subject to existing control requirements resulting from the OECA global refinery enforcement initiative, or are located in the Houston nonattainment area and are likely subject to stringent controls. For these reasons, we assumed no further control or emission reductions.

ICI Boilers – Residual Oil

There are 28 sources in this category. The CoST control technology was low-NOx burner and SNCR with a 69.5% reduction in NOx emissions. We agreed with the CoST control and emission reduction estimate, except for those sources located in the OTR and Houston ozone nonattainment area, where we assumed that these sources already had RACT controls.

Industrial Incinerators

There are 21 sources in this category. The CoST control technology was SNCR with a 45% reduction in NOx emissions. We agreed with the CoST control and emission reduction estimate, except for those

Appendix D

sources located in the OTR and Houston ozone nonattainment area, where we assumed that these sources already had RACT controls.

Iron & Steel Mills – Reheating

There are 32 sources in this category. The CoST control technology was low-NOx burners and flue gas recirculation with a 77% reduction in NOx emissions. We agreed with the CoST control and emission reduction estimate.

Municipal Waste Combustors

There are 25 sources in this category. The CoST control technology was SCR with a 90% reduction in NOx emissions. RTI identified the sources are already controlled and no additional reductions were applied for these sources. For the remaining sources, we agreed with the CoST controls and emission reductions.

Nitric Acid Manufacturing

There are 14 sources in this category. The CoST control technology was NSCR with a 98% reduction in NOx emissions. We agreed with the CoST control and emission reduction estimate.

Petroleum Refinery Process Heaters

There are 30 sources in this category. The CoST control technology was SCR with a 90-98% reduction or ultra-low NOx burners with a 30-50% reductions in NOx emissions. Most of these sources are located at petroleum refineries and are assumed subject to existing control requirements resulting from the OECA global refinery enforcement initiative, or are located in the Houston nonattainment area and are likely subject to stringent controls. For these reasons, we assumed no further control or emission reductions.

Utility Boilers – Coal/Wall

There are three sources in this category. The CoST control technology was SCR with a 90% reduction in NOx emissions. We agreed with the CoST control and emission reduction estimate.

Utility Boilers – Oil/Gas

There are 27 sources in this category. The CoST control technology was SCR with a 80% reduction in NOx emissions. The LADCO/OTC recommendation was for low-NOx burners or flue gas recirculation. We agreed with the LADCO/OTC recommendation of low-NOx burners combined with flue gas recirculation and assumed a 60% control efficiency.

To: US EPA OAQPS

From: SRA International, Inc.

Subject: Summary of State NOx Regulations for Selected Stationary Sources

Date: September 30, 2014

SRA compiled a summary of state/local NOx emission control regulations pertaining six categories of nonEGUs:

- Cement kilns
- Industrial/Commercial/Institutional (ICI) Boilers – Coal-fired
- ICI Boilers – Gas-fired
- ICI Boilers – Oil-fired
- Gas Turbines
- Internal Combustion (IC) Engines

The analysis included 27 states in the eastern two-thirds of the U.S. For each of these states and source categories, we identified state-specific sub-categories (e.g. fuel type or size threshold), the NOx emission limit or control requirement, averaging time for the emission limit, geographic applicability within the state, testing/monitoring requirements, and rule citation. This information is contained in the attached spreadsheet (Draft State NOx RACT Limits 2014_04_01.xlsx).

Attachment 1 is an overall summary of the relative stringency of the NOx requirements by geographic area and source category. We also prepared a 2-page summary for each of the six categories to concisely compare state NOx emission limits or control requirements. These are shown in Attachments 2 to 7, along with notes highlighting the major differences between the state regulations.

Please let us know should you have questions or comments about any of the data presented in this memorandum.

Appendix B

NMED Exhibit 60 - 0180

Attachment 1 – Relative Stringency of NOx Requirements

Source Category	States/Areas with Most Stringent Regulations	States/Areas with Less Stringent Regulations	States with No Regulations or Sources
Cement Kilns[1]	*States*: IL, MD, NY, PA, TX *Areas*: Ellis County, TX	*States*: AL (NOx SIP area), IN, KY, MO, MI, OH, SC, TN, VA, WV	*States*: AR, FL, GA, MS, OK *States with no cement kilns*: CT, DE, LA, MA, NC, NJ, WI
Coal-fired ICI Boilers[2]	*States*: NY *Areas*: Chicago, St. Louis (IL portion), Baton Rouge, Houston-Galveston (coke-fired), Milwaukee,	*States*: FL, GA, IN, MA, MD, MI, PA, TN, VA *Areas*: Chicago, St. Louis (MO portion), Baton Rouge, Charlotte, Cleveland	*States*: AL, AR, KY, MS, OK, SC, TX (except Houston-Galveston) WV *NE States with no coal-fired ICI boilers*: CT, DE, NJ
Gas-fired ICI Boilers	*States*: NJ, NY, PA *Areas*: Chicago, St. Louis (IL portion), Baton Rouge, Beaumont-Port Arthur, Cleveland, Dallas, Houston, Milwaukee	*States*: CT, DE, FL,GA, MA, MD, MI, MO, TN, VA *Areas*: Clark/Floyd Counties, St. Louis (MO portion), Charlotte	*States*: AL, AR, KY, MS, OK, SC, WV
Oil-fired ICI Boilers	*States*: NJ, NY, PA *Areas*: Chicago, St. Louis (IL portion), Baton Rouge, Cleveland, Dallas, Houston, Milwaukee	*States*: CT, DE, FL, GA, MA, MD, MI, TN, VA *Areas*: Clark/Floyd Counties, St. Louis (MO portion), Charlotte	*States*: AL, AR, KY, MS, OK, SC, WV
Gas Turbines	*States*: NJ *Areas*: GA 45-county area, Dallas, Houston, Milwaukee	*States*: CT, DE, FL, LA, MA, MD, NY, PA, TN, VA *Areas*: Chicago, St. Louis (IL portion), St. Louis (MO portion), Charlotte, Cleveland,	*States*: AL, AR, IN, KY, MI, MS, OK, SC, WV
IC Engines > about 500 hp	*States*: MD, NJ, NY *Areas*: Chicago, St. Louis (IL portion), Dallas, Houston	*States*: CT, DE, MA, MI, PA, TN, VA *Areas*: Baton Rouge, St. Louis (MO portion), Charlotte, Cleveland, Milwaukee	*States*: AL, AR, IN, KY, MS, OK, SC, WV

1) Cement kiln emission limits imposed by recent EPA enforcement settlements tend to be more stringent than the emission control requirements in state rules.

2) CT, DE and NJ have no active coal-fired boilers, so the stringency of their regulations for coal-fired ICI boilers is difficult to evaluate

WI	No Cement Kilns in State			
WV	Ozone season: low-NOx burners, mid-kiln system firing, or approved ACT			

ACT = Alternative Control Technology

* Pennsylvania has proposed “RACT 2” presumptive RACT limits

APPENDIX B

Observations Regarding State NOx Rules for Cement Kilns:

- ❖ Geographic Applicability
  - All NOx SIP Call states with cement kilns have NOx rules in place
  - Since only portions of Alabama, Michigan, and Missouri were affected by NOx SIP Call, the NOx rules only apply in the affected counties.
  - States not included in the NOx SIP Call do not have NOx RACT for cement kilns, except for Texas. The Texas NOx requirements only apply in in Bexar, Comal, Ellis, Hays, and McLennan Counties.
- ❖ Form of NOx Limitation or Control Requirement
  - A few states express the requirement as "at least one of the following: low-NOx burners, mid-kiln system firing, alternative control techniques or reasonably available control technology approved by the Director and the EPA as achieving at least the same emissions decreases as with low-NOX burners or mid-kiln system firing."
  - A few states specify presumptive emission limits in terms of pounds of NOx per ton of clinker.
  - Three states do not set presumptive emission limits but rather require facilities to submit a case-by-case RACT determination. Pennsylvania has a proposed regulation that will specify presumptive RACT limits; current rules require sources to hold 1 trading allowance per ton of NOx calculated by multiplying tons clinker by the presumptive NOx limit.
- ❖ Stringency of NOx Limitation or Control Requirement
  - For states requiring "low-NOX burners, mid-kiln system firing, or ACT", it is generally assumed that this will result in a 30% reduction from uncontrolled levels.
  - For states with numerical emission limits, the limits generally represent a 20 – 40 % reduction from uncontrolled levels, depending on the type of kiln.
  - Texas has very stringent limits for kilns in Ellis County.
  - Pennsylvania has proposed presumptive RACT emission limitations in April 2014 that are more stringent than existing presumptive RACT limits in other states.

WV	Statewide	No limits	No limits	No limits

Appendix B

Observations Regarding State NOx Rules for Coal-fired Boilers:

- ❖ Geographic Applicability
  - States in the OTR (CT, DE, MA, MD, NJ, NY, and PA) have NOx emission requirements that apply statewide, not just in ozone nonattainment areas.
  - Six states (AL, AR, KY, MS, OK, and WV) do not have regulations limiting NOx emissions.
  - For the remaining states (FL, GA, IL, IN, KY, LA, MI, MO, NC, OH, TN, VA, WI), the NOx emission control requirements only apply in ozone nonattainment areas.
  - Texas only has emission limitations for coke-fired boilers in the Houston-Galveston nonattainment area.
- ❖ Size Applicability
  - Most of the states do not have NOx emission requirements for boilers less than 100 mmBtu/hour.
  - 10 states do regulation boilers in the 50-100 mmBtu size range.
- ❖ Form of NOx Limitation or Control Requirement
  - Nearly all states express the NOx emission limits in terms of lbs/mmBtu.
  - A few states require either a case-by-case RACT determination or specify specific types of control equipment (e.g., low-NOx burners, flue gas recirculation).
- ❖ Stringency of NOx Limitation or Control Requirement
  - Most states specify different emission limits for different types of boilers and firing types (e.g., dry bottom tangential-fired) vs. dry bottom wall-fired)
  - A few states in the Northeast have very few or no coal-fired ICI boilers, so the stringency of the regulations in those states is difficult to evaluate. These states are CT, DE, NJ and MA.
  - For boilers greater than 100 mmBtu/hour, the LADCO/OTC[1] Phase I recommended limits are in the 0.2-0.3 lbs/mmBtu range (depending on boiler/firing configuration). The LADCO/OTC Phase II recommended limits are in the 0.1-0.2 lbs/mmBtu range. Four areas have limits that generally meet the LADCO/OTC recommendations (Chicago, Baton Rouge, New York State, and Milwaukee.
  - Texas has a very stringent limit (0.057 lbs/mmBtu) for coke-fired boilers in the Houston-Galveston area.

[1] *Evaluation of Control Options for Industrial, Commercial and Institutional (ICI) Boilers Technical Support Document (TSD), March, 2011* prepared by the Lake Michigan Air Directors Consortium (LADCO) and the Ozone Transport Commission (OTC).

Appendix B

Observations Regarding State NOx Rules for Gas-fired Boilers:

- ❖ Geographic Applicability
  - States in the OTR (CT, DE, MA, MD, NJ, NY, and PA) have NOx emission requirements that apply statewide, not just in ozone nonattainment areas.
  - Six states (AL, AR, KY, MS, OK, and WV) do not have regulations limiting NOx emissions.
  - For the remaining states (FL, GA, IL, IN, KY, LA, MI, MO, NC, OH, TN, TX,VA, WI), the NOx emission control requirements only apply in ozone nonattainment areas.
- ❖ Size Applicability
  - About half of the states have NOx emission requirements for boilers less than 100 mmBtu/hour, ranging from combustion tuning to emission limits as low as 0.05 lbs/mmBtu.
- ❖ Form of NOx Limitation or Control Requirement
  - Nearly all states express the NOx emission limits in terms of lbs/mmBtu.
  - A few states require either a case-by-case RACT determination or specify specific types of control equipment (e.g., low-NOx burners, flue gas recirculation).
- ❖ Stringency of NOx Limitation or Control Requirement
  - The LADCO/OTC Phase I recommendations are combustion tuning for boilers less than 100 mmBtu/hour, and either 0.1 lbs/mmBtu or 50% reduction for boilers greater than 100 mmBtu/hr.
  - The LADCO/OTC Phase II recommendations are either 0.05-0.1 lbs/mmBtu or 60% reduction.
  - New Jersey and New York have state-wide limits that are consistent with the OTC/LADCO Phase II recommendations. Pennsylvania has proposed state-wide limits that are consistent with the OTC/LADCO Phase II recommendations.
  - Five areas (Chicago, Baton Rouge, Beaumont-Port Arthur, Cleveland, and Milwaukee) have limits that are consistent with the OTC/LADCO Phase II recommendations.
  - Dallas and Houston have the most stringent emission limitations – 0.02 lbs/mmBtu for greater that 100 mmBtu/hr units.

Appendix B

Attachment 5 – Oil-fired Boilers

		NOx Limit (lbs/mmBtu)

Appendix B

Observations Regarding State NOx Rules for Oil-fired Boilers:

- ❖ Geographic Applicability
  - States in the OTR (CT, DE, MA, MD, NJ, NY, and PA) have NOx emission requirements that apply statewide, not just in ozone nonattainment areas.
  - Six states (AL, AR, MS, OK, SC, and WV) do not have regulations limiting NOx emissions.
  - For the remaining states (FL, GA, IL, IN, KY, LA, MI, MO, NC, OH, TN, TX, VA, WI), the NOx emission control requirements only apply in ozone nonattainment areas.
- ❖ Size Applicability
  - About half of the states have NOx emission requirements for boilers less than 100 mmBtu/hour, ranging from combustion tuning to emission limits as low as 0.08 lbs/mmBtu.
- ❖ Form of NOx Limitation or Control Requirement
  - Nearly all states express the NOx emission limits in terms of lbs/mmBtu.
  - A few states require either a case-by-case RACT determination or specify specific types of control equipment (e.g., low-NOx burners, flue gas recirculation).
- ❖ Stringency of NOx Limitation or Control Requirement
  - The LADCO/OTC Phase I recommendations for distillate oil are combustion tuning for boilers less than 100 mmBtu/hour, and either 0.1 lbs/mmBtu or 50% reduction for boilers greater than 100 mmBtu/hr. The LADCO/OTC Phase II recommendations for distillate oil are either 0.08-0.1 lbs/mmBtu or 60% reduction.
  - Only New Jersey has state-wide limits that are consistent with the OTC/LADCO Phase II recommendations for distillate oil.
  - Three areas (Chicago, Baton Rouge, and Milwaukee) have limits that are consistent with the OTC/LADCO Phase II recommendations for distillate oil.
  - The LADCO/OTC Phase I recommendations for residual oil are combustion tuning for boilers less than 100 mmBtu/hour, and either 0.2 lbs/mmBtu or 60% reduction for boilers greater than 100 mmBtu/hr. The LADCO/OTC Phase II recommendations for residual oil are either 0.2 lbs/mmBtu or 50-70% reduction.
  - New Jersey and New York have state-wide limits that are consistent with the OTC/LADCO Phase II recommendations for residual oil. Pennsylvania has proposed state-wide limits that are consistent with the OTC/LADCO Phase II recommendations for residual oil.
  - Four areas (Chicago, Baton Rouge, Charlotte, and Milwaukee) have limits that are consistent with the OTC/LADCO Phase II recommendations for residual oil
  - Dallas and Houston have the most stringent emission limitations – 0.01 lbs/mmBtu for greater that 100 mmBtu/hr units.

Appendix B

Appendix B

Observations Regarding State NOx Rules for Gas Turbines:

- ❖ Geographic Applicability
  - States in the OTR (CT, DE, MA, MD, NJ, NY, and PA) have NOx emission requirements that apply statewide, not just in ozone nonattainment areas.
  - Nine states (AL, AR, IN, KY, MI, MS, OK, SC, and WV) do not have regulations limiting NOx emissions.
  - For the remaining states (GA, IL, LA, MO, NC, OH, TN, TX, VA, WI), the NOx emission control requirements only apply in ozone nonattainment areas.
- ❖ Other Applicability Criteria
  - States use a variety size thresholds. For example, Ohio's rules differentiate between units < 3.5 MW and > 3.5 MW. Wisconsin has requirements for three size ranges: 10-25 MW, 25-50 MW, and >50 MW.
  - State limits generally differ by type of fuel – gas or oil. Wisconsin also includes limits for biologically derived fuel.
  - Some states have different limits for simple-cycle and combined-cycle units. Other states have a single limit that applies to both types of units.
- ❖ Form of NOx Limitation or Control Requirement
  - States do not specify specific types of control techniques, but rather set a numerical emission limit.
  - Most states express limits in terms of "ppmv at 15% oxygen". Some states use lbs/mmBtu, and the equivalent limits shown in the table above were calculated using based on Part 75 Eq-F5 and F-factors. New Jersey's limits are in terms of lbs/MHr.
- ❖ Stringency of NOx Limitation or Control Requirement
  - Three areas have very low limits compared to other states/areas: the 45 county area in Georgia, Dallas and Houston-Galveston

Appendix D

Observations Regarding State NOx Rules for IC Engines:

- ❖ Geographic Applicability
  - States in the OTR (CT, DE, MA, MD, NJ, NY, and PA) have NOx emission requirements that apply statewide, not just in ozone nonattainment areas.
  - Eight states (AL, AR, IN, KY, MS, OK, SC, and WV) do not have regulations limiting NOx emissions.
  - For the remaining states (GA, IL, LA, MI, MO, NC, OH, TN, TX, VA, WI), the NOx emission control requirements only apply in ozone nonattainment areas.
- ❖ Other Applicability Criteria
  - States use a variety size thresholds. For example, Louisiana's rules have separate limits for IC engines that are 150-300 hp, >300 hp, and >1500 hp. New York uses > 200 hp and > 400 hp. Delaware uses > 450 hp, while North Carolina uses > 650 hp.
  - State limits generally differ by type of fuel – gas, oil, dual-fuel or landfill/digester gas.
  - A few states have different limits lean-burn and rich-burn engines. Other states have a single limit that applies to both types of units.
- ❖ Form of NOx Limitation or Control Requirement
  - Most states express limits in terms of "gram per brake horsepower hour".
  - Some states use "ppmvd @ 15% O2", and the equivalent limits shown in the table above were calculated using conversion factors from ppmv @ 15% O2 to g/hp-hr from EPA ACT, July 1993 EPA453-R-93-032.
  - Delaware specifies control technology standards rather than numerical emission limits.
- ❖ Stringency of NOx Limitation or Control Requirement
  - Maryland, New Jersey, New York and the Dallas/Houston areas of Texas have limits that are more stringent than other states/areas.

NMED Exhibit 61 -

Executive Summary

New and proposed changes in air emission regulations are likely to impact the interstate natural gas transportation industry. Regulations that are expected to impact the industry include the ozone National Ambient Air Quality Standards (NAAQS) and the nitrogen dioxide (NO_2) one hour NAAQS. Since nitrogen oxides (NOx) react in the atmosphere to form ozone, it is regulated as a precursor to ozone. As emission control rules are developed and permitting actions implemented in response to these federal standards, there will be ongoing pressure to reduce emissions of NOx from existing equipment that has not yet been impacted by NOx control rules, or has been minimally impacted. For example, EPA and states have not yet implemented permitting requirements related to a recent revision to the NO_2 NAAQS. In addition, due to lawsuits and evolving EPA policy, states have been passive in recent years regarding the next set of rules to reduce NOx to address ozone NAAQS concerns. In response to a new ozone NAAQS planned for 2015, there is a potential for broad NOx controls in the eastern half of the U.S. to address NOx transport. Along with the revised ozone NAAQS and implementation of the NO_2 NAAQS, upcoming court decisions, including a Supreme Court decision on EPA authority to institute regional NOx rules, will likely break the regulatory logjam.

Based on these expected air regulation changes that result in new requirements to reduce NOx from existing equipment, a significant number of stationary engines that drive natural gas compressors in interstate natural gas transmission service will likely require modification to meet new federal or state NOx rules or permitting requirements. **Based on current technical resources, the projected time to implement retrofit NOx control (or replacement) is far in excess of typical regulatory schedules.**

The focus of the research for this report was to evaluate the resources required of the operating companies, emission reduction suppliers, engineering service providers, and contractors to implement NOx control regulations for low speed reciprocating engines used in the interstate natural gas transportation industry. The information gathered in developing this report included input solicited from both operating companies and vendors who provide emission reduction retrofit equipment. The assessment included an evaluation of an industry database to estimate the number and type of engines that would be impacted by changes to the emission regulations. Resource and schedule requirements assessed in this report are based on the actual fleet (i.e., make, model, NOx control status) from that database. This study found:

- The special technical expertise to design, construct, and commission emission reduction projects is not widely available to the industry for the slow speed integral engines prevalent in natural gas transmission. Regulations that require installation of NOx control on a large number of reciprocating engines will require a significant lead time to train and develop employees and service provider resources to implement emission reduction projects on a timely basis.
  - Availability of this special technical expertise and building this capability is the primary resource constraint that will affect the ability to meet regulatory obligations, if those regulations affect a large percentage of the existing fleet. Based on current capabilities and a scenario where NOx regulations broadly affect the existing fleet of uncontrolled reciprocating engines, the estimated time to complete upgrades to over 2600 engines is

NMED Exhibit 61 -

nearly forty years. Although strategies to comply may result in many engines (e.g., lower horsepower, lower use engines) being retired or replaced, scheduling implications due to the lack of available expertise would still extend far beyond the expected regulatory timelines. In addition, even if a smaller percentage of the fleet requires control, the required time (e.g., 15 years for 1000 engines) would likely exceed any expected regulatory schedule. Building this technical expertise to address regulatory implementation timelines are significant concerns.

- Engine NOx control projects are generally much less costly than engine replacement. If the anticipated regulations are implemented, capital costs to modify currently uncontrolled reciprocating engines used in the interstate natural gas transmission industry are estimated at approximately $4 billion to achieve NOx emission rates of 3 grams per horsepower hour (g/hp-hr) and over $6 billion to achieve 1 g/hp-hr.
- The age of the impacted equipment (most of the engines are over 40 years old) requires additional time to engineer and construct reliable emission reduction modifications due to inaccurate or missing engineering records that reflect the current equipment configuration.
- Some engines with low specific power output will require extra time to properly design and construct emission reduction modifications and maintain the same power operating range.
- Based on previous experience, the timeline of obtaining air permits is a key parameter defining the overall schedule for completing a specific emission reduction project – i.e., permitting can slow the project timeline.
- Equipment outages that last several weeks to over a month to implement emission reduction modifications may have significant impact on available pipeline capacity and could cause significant capacity disruption, especially if the schedule overlaps with implementation of other regulations such as pipeline integrity testing.

1.0 Introduction

As shown below, air emissions from a natural gas compressor station are regulated by a complex web of federal and state regulation. This report focuses on the potential availability of resources – equipment, people, and expenditures – needed to modify these compressor stations to meet possible NOx emission requirements.

Air emissions continue to be a major regulatory issue, and air quality regulations pose a risk to normal operations of existing natural gas transmission infrastructure. NOx emissions are the primary air pollutant of interest from natural gas-fired combustion sources. NOx can react in the atmosphere to form ozone, so NOx is regulated as a precursor to ozone. NOx can also react to form nitrates, and ammonium nitrate is an aerosol that comprises a portion of atmospheric fine particulate ($PM_{2.5}$). The U.S. Environmental Protection Agency (EPA) establishes NAAQS for six criteria pollutants, including ozone, NO_2, and $PM_{2.5}$. NOx emissions are comprised of NO and NO_2, but all NOx emissions are generally considered NO_2 under the NO_2 NAAQS.

Based on ambient air monitoring, if the air quality in a particular location does not meet (i.e., "attain") the NAAQS, that geographical area will be designated as a "nonattainment" area. Then, state or local agencies are required to develop regulations that decrease emissions from *existing sources* to reduce ambient pollutant levels and attain the NAAQS. In addition, NOx emissions may be evaluated by regulatory agencies using a model that simulates the behavior of the exhaust plume (i.e., a "dispersion model") to assess whether NO_2 impacts beyond the compressor station fence line exceed the NO_2 NAAQS. If so, mitigation would likely be required.

For example, NOx Reasonably Achievable Control Technology (RACT) regulations may be adopted by a state to address ozone nonattainment within the state. These rules may apply to limited in-state areas (e.g., urban nonattainment areas) or statewide. In addition, many urban and eastern U.S. areas have already reduced NOx emissions, but NOx transported from upwind states contributes to nonattainment. This phenomenon is referred to as "NOx transport," and EPA may adopt multi-state regional rules to reduce NOx across the eastern U.S. and mitigate NOx transport. For natural gas-fired combustion sources, NOx is the primary pollutant that may be regulated by these rules. Emissions of other pollutants such as formaldehyde, which is regulated as a hazardous air pollutant (HAP), may also trigger emission controls. However, it is generally expected that existing catalyst control providers can meet demands to address new regulatory requirements.

Thus, this report focuses on potential resource constraints associated with regulations that require retrofit installation of NOx emission control technologies. More specifically, the report focuses on combustion-based technologies – i.e., low emissions combustion (LEC) – for lean burn reciprocating engines commonly used in interstate transmission and most likely subject to retrofit NOx control in the future (i.e., this older equipment is typically "grandfathered" and many units have not been subject to NOx regulations to date). The reciprocating engines of interest are low speed "integral" engines uniquely used for gas compression, where the compressor and its driver – i.e., the reciprocating engine used to power the compressor – are integrated into a single piece of equipment with a common crankshaft. These legacy integral engines comprise a large portion of the horsepower capacity in interstate natural gas compression and can also be found in gas processing and, to a lesser extent, in gathering compression. Although these engines have been

NMED Exhibit 61 -

in service for many years, because they were designed specifically to compress natural gas, natural gas-fired integral engines remain the most efficient option for gas compression.

LEC is the preferred approach to reduce lean burn engine NOx emissions, but EPA or states may consider additional controls such as selective catalytic reduction (SCR). Rich burn reciprocating engines may require non-selective catalytic reduction (NSCR) to reduce NOx and formaldehyde, but rich burn engines are a smaller percentage of interstate transmission prime movers and many rich burns already use NSCR emissions control in response to the federal HAP standard or state requirements.

The focus of this report is to assess the availability of resources to implement air emission modifications on the reciprocating engines used to transport natural gas on the interstate pipeline system. For example, there are currently a handful (or less) of service providers that provide LEC control for reciprocating engines. Thus, depending upon the breadth and timing of emission control requirements, there is a concern that resource constraints may impact timely compliance or the reliability of gas delivery.

This report will identify potential constraints, including potential bottlenecks in the supply chain, regarding availability of capital equipment and technology service providers to address retrofit NOx control of the existing fleet of equipment. Scheduling issues will be discussed, including constraints that may point to the need for phasing regulatory compliance.

The regulatory context is based on an expectation that existing reciprocating engines that do not include NOx control technology will eventually be required to retrofit NOx control technology in response to recent or upcoming revisions to the federal ozone or NO_2 NAAQS. NOx control resource availability for reciprocating engines is the most probable resource constraint due to the limited service providers and trained labor in this field, so this report focuses on potential resource limitations and the time required to control these engines, especially lean burn engines.

In addition to this Introduction, the report includes:

- An Executive Summary.
- Section 2 discusses the study approach.
- Section 3 provides an overview of reciprocating engine NOx control technologies,
- Section 4 discusses engine demographics (population and type) for interstate transmission prime movers.
- Section 5 presents NOx related air quality regulatory concerns and analysis assumptions and methodology.
- Section 6 presents methodology and results related to costs and schedule.
- Section 7 presents the analysis and discussion of limitation by project phase, and Section 8 provides conclusions.
- Appendices provide a list of acronyms and the survey questions used for discussions with operators, equipment manufacturers, and service providers.

NMED Exhibit 61 -

2.0 Study Approach

The information in this report was gathered confidentially by Innovative Environmental Solutions (IES) and Optimized Technical Solutions (OTS) and the information has been consolidated in a manner that the individual responses cannot be broken out by the vendor or operator supplying the information. This is done to prevent business strategies or other competitive information from reaching competitors. All efforts were made to prevent the communication of information that could result in anticompetitive practices.

Interviews were performed with multiple emission reduction vendors and operating companies. In addition, a literature review was performed, and relevant information is cited. There is significant uncertainty regarding the requirements (e.g., required emission levels), geographical breadth, and timing of NOx regulations. Since there are many possible regulatory outcomes, specific dates and regulations are not a focus, but a general discussion of the NOx control regulatory threat is provided in Section 5. Instead of considering a specific regulation, the analysis in this report focuses on identifying potential resource constraints based on an assumption that many legacy prime movers without NOx control will eventually require upgrade (or replacement). To consider technology needs, costs, and scheduling, the analysis considers the engine types (i.e., model) based on an available database. Two NOx targets are considered (i.e., 3 g/bhp-hr or 1 g/bhp-hr) based on previous experience for likely regulatory endpoints and guidance from advisors, and a general ranking of regulatory risk for three geographical areas is used when assessing implications. States were categorized as high risk/stringency (where regulations may already be in place in some cases – e.g., northeast state where much of the fleet is already controlled), moderate risk (e.g., midwest and eastern states where compressor stations may be implicated as contributors to eastern U.S. NOx transport), and lower risk states, where regulation is less likely (e.g., northern plains states, where control is less likely unless EPA initiates broad national requirements for existing equipment). In addition, costs were considered under the premise that NOx control would be widely required for uncontrolled units either due to NOx regulations (e.g., in response to ozone nonattainment) or permitting actions to address conformance with the NO_2 NAAQS.

This effort began with interviews of multiple interstate gas pipeline operating companies that had previous experience with NOx reduction projects. In addition, independent interviews were conducted with six different suppliers of equipment and services that modify reciprocating engines used in the interstate natural gas transportation industry. Interviews covered all aspects of the execution of NOx reduction projects from start to finish. Specific topics in project execution included:

- **Permitting** – Permitting is the process of obtaining air emission permits from the regulating agency – typically a state agency. This phase requires an initial engineering analysis to determine the modifications required and the expected air emissions for each emission source at a facility for the permit application. Defined technologies must be settled upon prior to completing the permit.
- **Initial design** – This portion of the project assesses: (1) which emission reduction technologies are suitable for a facility and the associated suppliers for the emission reduction equipment, (2) the reduction in air emissions that can be expected with the applicable emission reduction equipment, and (3) the initial design for the equipment changes. Input from the suppliers of

NMED Exhibit 61 -

emission reduction equipment is usually required during this portion of the project. Initial design information is also necessary to provide information for the permitting process, but other, more detailed design considerations are also addressed under this topic.

- **Cost estimating and scheduling** – This part of the project establishes the expected timeframe and financial costs expected to modify the equipment for emissions control. Personnel resource availability and allocations are also typically performed in this portion of the project execution.
- **Contracting and procurement** – In this portion of the project, detailed cost and schedule information to implement an emission control project is solicited from suppliers and contractors. This requires the creation of design specifications, evaluation criteria, and contractual terms and conditions.
- **Detailed design** – This phase involves developing detailed designs based on specific emission control equipment selected. Detailed design includes but is not limited to the development of material lists, drawings, engine control system modifications, and commission plans.
- **Construction** – This portion of the emission control project is where physical modifications are made to the engine and ancillary equipment.
- **Commissioning** – This is the phase of the emission control project where calibration, configuration, and tuning of the engine is performed to ready the engine for continuous operation. Training of the operating and maintenance personnel is also often performed during this phase.
- **Operation and maintenance** – This is the post-conversion and commissioning portion of the project. Proper operation and maintenance of the engine and emission control equipment is required to ensure compliance with the emission limits.

This report discusses resource constraints for each of these phases for reciprocating engine NOx control projects, as described by the operators and suppliers of emission reduction equipment. For NSCR application to rich burn engines, a higher level review was conducted because it is likely that there are an adequate number of vendors to address market demand and fewer engines are likely to be affected.

Cost and schedule estimates are based on the number and size of engines to be converted, information provided by pipeline operators and suppliers of emission reduction equipment, and reference publications. Factors that influence technology requirements and costs for reciprocating engines include:

- Combustion cycle (two-stroke, four-stroke),
- The engine make and model,
- Brake mean effective pressure (BMEP) of the engine,
- Engine aspiration type (natural, turbocharged), and
- The number of power cylinders.

Based on engines identified in an industry database, this information was used to determine the most probable type of modifications needed to achieve the target NOx emission level.

3.0 Reciprocating Engine NOx Emission Reduction Technology Overview

NOx control technologies for reciprocating engines are discussed below. LEC technologies for lean burn engines are discussed in Section 3.1, and NSCR for rich burn engines is discussed in section 3.2. Section 3.3 discusses SCR. Although SCR has not been applied to existing integral engines, it could be considered by regulatory agencies, especially for lean burn engines where LEC is not available or cannot achieve the target NOx level.

3.1 Reciprocating Internal Combustion Engines – LEC for Lean Burn Engines

An overview of LEC NOx control technologies for lean burn reciprocating engines is described in this section. [1] [2] [3]

NOx emissions from natural gas combustion are formed from nitrogen and oxygen in the combustion air, and NOx emissions increase significantly at higher combustion temperatures. LEC achieves lower NOx by providing sufficient excess air to reduce the maximum combustion temperature and minimize NOx formation. The use of LEC to control NOx is possible on fuel-injected two-stroke cycle engines and many four-stroke cycle engines. Since the excess air may hinder combustion or light-off of the air-fuel charge in the cylinder, LEC-equipped engines generally require a high energy ignition source. This is most commonly implemented by the use of pre-chamber combustion systems that ignite a smaller charge that then ignites the in-cylinder air-fuel mixture. The power operating range may decrease on two-stroke cycle engines when converted to LEC.

Since peak combustion temperatures are influenced by the amount of excess air and air-fuel mixing, there are several methods that can be used to minimize peak temperatures and NOx formation during lean combustion. Regulatory agencies use the term "LEC" broadly and a number of technology approaches can be used depending on the engine and NOx emission limit. In many cases, multiple LEC related technologies may be required – e.g., additional air through new or upgraded turbocharging, higher energy ignition /precombustion chambers, and enhanced mixing. Several primary technologies are described below. For the engine types in the fleet, the analysis considered the proper technology approach to achieve target NOx emissions of 3 g/hp-hr or 1 g/hp-hr.

3.1.1 Enhanced Mixing

Pockets of rich fuel can exist in engines equipped with direct fuel injection. The resulting locally rich fuel mixtures result in localized higher combustion temperatures with an associated increase in NOx formation. Engine modifications to produce enhanced air/fuel mixing can counteract this effect. For example, "high pressure" fuel injection systems have been developed that take advantage of the higher pressure gas available from the pipeline to greatly improve air-fuel mixing. On some engines, enhanced mixing modifications may also require high energy ignition modifications to prevent engine misfires.

3.1.2 Mechanical Modifications

Modifications that can be used to reduce NOx emissions include upgrading or conversion to turbocharging, adding additional turbocharger after-cooling, installing different cam shafts, installing different (e.g., electronic) fuel injection valves, etc. These are not discussed in detail

NMED Exhibit 61 -

here as they usually result in minor reductions as an independent action, but are typical technologies that may be included as part of the emissions reduction project. Since dispersion modeling may be required to ensure that modeled offsite impacts do not exceed the NO_2 NAAQS, stack height extensions are a modification that can reduce modeled ground level concentrations. In general, a stack height that is at least 1.5 times the height of the compressor building peak height is desired to avoid building-induced "downwash" that brings the plume to ground level sooner and results in higher modeled impacts.

3.1.3 Operational Control – Ignition Timing

The peak combustion pressure (and thereby the peak combustion temperature) can be lowered by retarding (or delaying) the ignition timing of the engine. The lower combustion temperature results in lower NOx emissions. Only nominal NOx reductions are achieved when used in isolation and fuel consumption increases. This may also reduce the maximum power the engine can produce, and typically increases carbon monoxide (CO), volatile organic compounds (VOCs), and total unburned hydrocarbons (THC) emissions. VOCs are regulated as an ozone precursor and are a subset of THC (the methane and ethane components of THC are excluded from VOCs because these two hydrocarbons are minimally reactive in ozone producing atmospheric reactions).

3.1.4 Operational Control – Air/Fuel Ratio

Altering engine control methods can reduce the formation of NOx and improve the reliability of maintaining emissions at the prescribed level. On engines that utilize air/fuel controls, some NOx reductions may be possible by changing the control curve to operate the engine leaner without other engine modifications. This control change is limited by the amount of air available from the turbocharger and the ability of the ignition system to ignite the leaner mixture without misfires.

3.1.5 Other (non-LEC) Technologies

The technologies described above are not intended to be a comprehensive list. There are other control methods such as exhaust gas recirculation that are not covered here due to their limited effectiveness and limited use on the types of engines typically utilized in interstate natural gas transmission.

3.2 Rich Burn Reciprocating Internal Combustion Engines – Nonselective Catalytic Reduction

Rich burn engines are designed to operate with minimal excess air – i.e., with combustion air approximately equal to the amount required to completely combust the fuel with minimal excess air. The "stoichiometric" amount of air is the exact amount required to burn the fuel with no excess. For reciprocating engines that operate near stoichiometric conditions (excess oxygen in the exhaust <0.5%), NSCR is the accepted emissions control option. This type of exhaust control technology is commonly used on automobiles and also referred to as a 3-way catalyst because emissions of NOx, CO, and VOCs can be reduced. For this control technology to work effectively for all three pollutants, an air to fuel ratio controller (AFRC) is required that maintains the AFR over a very narrow operating band. With too little air, NOx will be low, but CO and VOCs may significantly increase. With too much air (and thus too much oxygen available), CO and VOCs will be reduced (i.e., NSCR operates as an oxidation catalyst), but

NMED Exhibit 61 -

NOx reduction across the catalyst will be impacted and post-catalyst NOx will significantly increase.

Catalytic elements used in NSCR can be contaminated by engine oil carryover and other operating factors. Cleaning and replacement is required on a periodic basis. Unburned hydrocarbons in the exhaust stream reduce the life of the catalyst. This is the common technology of choice for rich burn four-stroke cycle engines.

3.3 Selective Catalytic Reduction for Lean Burn Engines

For NOx control from lean burn engines, this report focuses on LEC. SCR is discussed here because it is often considered by regulators when assessing NOx controls for combustion equipment and future control rules may require SCR in some cases (e.g., if LEC is not effective on a particular engine model). SCR is an exhaust control for lean combustion (i.e., excess air is available) that reduces NOx by reaction with ammonia or urea over a catalyst. [4] [5] Ammonia or urea injection is required with precise reagent feedrate control based on the NOx concentration and the NO/NO_2 ratio of the NOx. The reagent and NOx "selectively" react on the catalyst to (ideally) form water and molecular nitrogen (N_2). To date, SCR application to U.S. gas transmission sources has been very limited, and SCR has not been applied to an existing integral engine. Technical concerns about the SCR performance for gas transmission engines include exhaust temperature requirements, reagent control (and sophistication of current systems), and treatment of potential variations in the reciprocating engine exhaust NO/NO_2 ratio.

SCR has been more commonly applied to larger utility scale turbines and boilers, with very limited gas transmission applications to date. Recently, some new 4-stroke cycle lean burn engines have been sited with SCR, but retrofit application to lean burn prime movers has not occurred. While NSCR for rich burn engines exploits the chemical processes available at stoichiometric combustion to reduce multiple pollutants, SCR "selectively" reduces NOx. The use of SCR is most effective when operating in the exhaust temperature range of 480 to 800 °F. The minimum operating temperature of the catalyst is dependent on the composition of the exhaust gases and the type of catalyst materials used, and the typical exhaust temperature range for some lean burn engines may present challenges. Engines that have variable power loads require more sophisticated controls to inject the proper amount of reagent, and it is not evident that robust control schemes have been developed for transmission applications. The installation of a continuous emissions monitor could be required to effectively control the amount of reagent necessary to achieve the desired NOx emission rate.

SCR catalytic elements can be contaminated by byproducts of combustion (such as oil ash) and engine oil carryover. Cleaning and replacement is required on a periodic basis, and extra management is required to ensure adequate inventories of reagent are maintained.

Due to the issues described above and the desire to prevent NOx formation rather than controlling NOx in the exhaust, LEC is preferred over SCR for existing lean burn engines.

NMED Exhibit 61 -

4.0 Reciprocating Engine Demographics (Population and Type)

An INGAA engine database (originally developed by PRCI and GRI over 10 years ago) includes 3665 *low speed* reciprocating engines used in the interstate natural gas industry. It should be noted that the number of engines in the tables below reflect large bore, low speed reciprocating engines. There are other engines used in the natural gas transportation industry. Most of the other engines are newer high-speed four-stroke cycle engines that are already equipped with low NOx emissions (typically LEC or NSCR) technology, such as best achievable control technology (BACT) required during permitting of new units or technology to meet New Source Performance Standards (NSPS) and National Emission Standard for Hazardous Air Pollutants (NESHAP) regulations.

Although this database is not complete (e.g., it was estimated to include over 80% of interstate transmission facilities when it was compiled), and changes in the fleet have occurred since the database was last updated, the information from this source still provides a reasonable basis to assess counts of existing engines and technology requirements for NOx control. Of the 3665 low speed engines, 35 are known to have been abandoned or replaced leaving a net of 3630 engines. These engines were categorized by engine type and geographical region as described in Section 5, where regulatory risk (i.e., likelihood and level of control) was used to categorize states into three regulatory risk categories depending on the state where the engine is located. Table 4-1 shows engine counts for each category for the three primary engine types. (The states in each risk category are identified in section 5.)

Table 4-1. Engine Type by Geographical Regulatory Risk Category.

Engine type	Category 1	Category 2	Category 3	Total
2-stroke cycle	321	1975	344	2640
4-stroke cycle lean	82	320	51	453
4-stroke cycle (rich)	50	405	82	537
Total	453	2700	477	3630

The average engine size is 2145 brake horsepower with an average of 12 power cylinders per engine. To assess technology requirements and potential resource issues, these engines have been grouped or classified based on different engine types/subtypes and current emission control capabilities. Each group type requires a different approach to NOx reduction with an associated impact on costs and schedules. The two-stroke cycle and four-stroke cycle lean engines are candidates for LEC and the four-stroke cycle rich burn engines are candidates for NSCR NOx control technologies. For the purposes of this discussion, the "rich burn" engines include older, horizontal engines that do not include air to fuel ratio control and may operate near stoichiometric conditions (i.e., "rich") or leaner (i.e., with excess air). The term "stoichiometric" refers to the condition where the amount of oxygen available from the combustion air is equivalent to the amount required to completely combust all of the fuel without any excess oxygen. Rich burn engines operate near stoichiometric conditions, while lean burn engines have excess air. Regulatory definitions, such as the federal NSPS and NESHAP standards, typically

NMED Exhibit 61 -

use ten percent excess air (which is equivalent to two percent excess oxygen in the exhaust) as the threshold between rich and lean operation.

To estimate the number of engines that would require NOx emissions control, and assess associated capital costs and timeline, the INGAA database of engines was analyzed by current emission levels as shown in Table 4-2. Note that this table excludes 417 low BMEP four-stroke rich burn engines that are assumed to have NSCR catalysts as described in Section 4-2.

Table 4-2. Engine Counts by NOx Emission Levels.

Emission capability	Category 1	Category 2	Category 3	Total
NOx $\leq$ 1 g/hp-hr	64	0	0	64
1 < NOx $\leq$ 3 g/hp-hr	339	162	36	537
NOx > 3 g/hp-hr	0	2238	374	2612
Total	403	2400	410	3213

The majority of reciprocating engines used in the interstate natural gas transportation industry were installed before 1960. Most have been exempt from clean air regulations issued after they were installed since existing units are "grandfathered" – i.e., exempt from regulations that affect new sources. A common exception is engines that have been controlled in response to NOx RACT or similar rules adopted to decrease the NOx inventory from existing sources as a strategy to address ozone nonattainment. A discussion follows on each of the primary engine categories, related engine counts, and NOx control technology available.

4.1 Horizontal engines

Horizontal engines are four-stroke cycle naturally aspirated engines with four double acting power pistons. These engines were manufactured by Cooper-Bessemer (Type 22 through Type 26) and Worthington (24X36 and 26X36). These engines are the first type of reciprocating engines widely used to compress natural gas for transportation. They are a derivative of horizontal steam engines. The double acting power cylinders (combustion occurs on both sides of the piston) have very large cylinder bores (22" to 26") and strokes (typically 36"). It is difficult to control the air/fuel mixture for these units – e.g., for use with post-combustion catalytic control. Likewise, they are not suited to LEC conversion. Per the INGAA database, there are 120 engines in this group, where a retrofit NOx control technology is not available, with an average power rating of 1530 hp.

NMED Exhibit 61 -

Figure 4-1. Horizontal Engine

Because these engines have higher operating and maintenance costs, they are generally operated on a last on, first off basis in response to demand. Therefore, their annual operating hours tend to be lower than newer engines operating at the same facility.

Since technology upgrades are not available, the assumed "NOx control" option for these engines is replacement. For cost estimating purposes, the assumed replacement equipment is 3000-4000 hp gas turbines equipped with dry low NOx (lean premixed) combustors. Although larger gas turbines would reduce the capital replacement costs, smaller gas turbines are a better match (although still larger) to the engines being replaced. Larger engines do not have the necessary turndown capability to match the horizontal engines. Gas turbines were selected over other engine types due to the lower capital costs. Where minimizing fuel is a major consideration, high speed four-stroke cycle reciprocating engines would be selected as the replacement engine. All of these engines are located in geographical regulatory risk Categories 2 and 3 as shown in Table 4-3. These engines are a subset of the four-stroke rich burn engines found in Table 4-1. All horizontal engines are assumed to have NOx emission rates greater than 3 g/hp-hr.

Table 4-3. Number of horizontal engines.

Engine Type	Category 1	Category 2	Category 3	Total
4-stroke – horizontal	0	105	15	120

4.2 Low BMEP four-stroke cycle naturally aspirated engines

Like the horizontal engines, the low BMEP four-stroke cycle engines (see Figure 4-2) used in natural gas transmission sometimes operate near stoichiometric conditions and other times operate lean. These engines differ from horizontal engines in that they can generally be fitted

NMED Exhibit 61 -

with air-fuel controls to enable operation with NSCR. However, depending on the units, operation with NSCR sometimes requires higher exhaust temperatures than the unit was initially designed. Alternatives technologies include converting to LEC (with the addition of a turbocharger) [6] or installing SCR. SCR has had very limited application to existing reciprocating engines, and installation of SCR may limit the ability of the engine to operate at rated power.

Figure 4-2. Ingersoll-Rand KVG

The analysis in this report assumes that NOx reductions would be achieved with installation of NSCR, with engine modifications completed as necessary to accommodate higher exhaust temperatures. However, existing rich burn engines at "major sources" (i.e., larger facilities such as compressor stations with multiple reciprocating engines) were required to install NSCR to comply with an EPA regulation, with compliance required by 2007 for the 2004 RICE NESHAP rule. Therefore, resource limitation were not assessed and costs to modify these engines are not estimated here because any incremental costs (e.g., to better tune the air to fuel ratio controller (AFRC) for NOx reduction) should be minimal. It is likely that some of these engines will require control or additional modifications to achieve required NOx reductions. The number of these engines in each geographical regulatory risk category can be found in Table 4-4. This is a subset of the four-stroke cycle rich burn engines in Table 4-1.

Table 4-4. Number of low BMEP four-stroke cycle engines.

Engine Type	Category 1	Category 2	Category 3	Total
4-stroke cycle low BMEP	50	300	67	417

NMED Exhibit 61 -

4.3 Opposed piston two-stroke cycle engines

The gas pipeline transportation industry employs about 14 two-stroke cycle opposed piston engines such as the Fairbanks-Morse engine shown in Figure 4-3. These engines typically use superchargers to provide scavenging air.

The engines utilize two power pistons per power cylinder with intake and exhaust ports at opposite ends of the cylinder liner. The two pistons are connected to separate crankshafts which are synchronized through a vertical driveshaft and bevel gears. Because of the higher number of moving parts on these engines, they tend to have higher maintenance costs than other engines used in this industry.

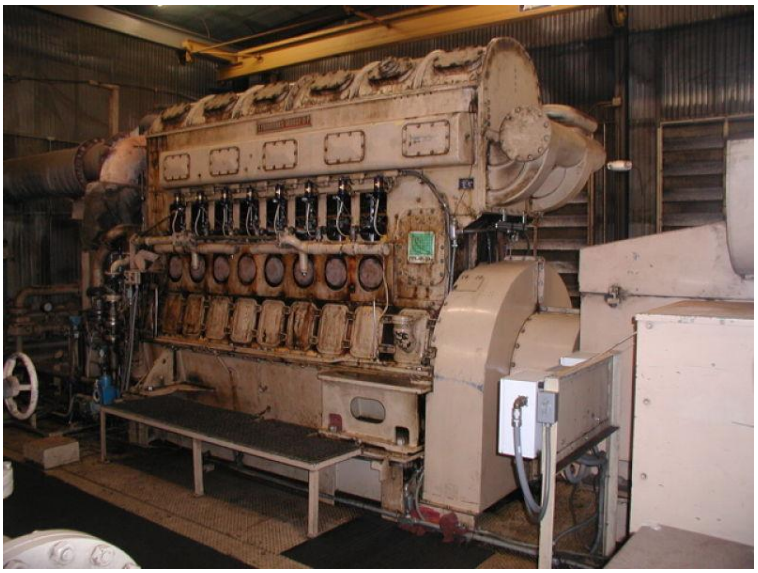

Figure 4-3. Fairbanks-Morse MEP-8

The engines can be converted to lean burn combustion or controlled using post-combustion catalytic reduction. NOx emission rates below 3 g/hp-hr are difficult to achieve at full load and speed on these engines through lean combustion alone. Based on the operating cost of these engines and emission characteristics, the analysis in this report assumes emission reduction is achieved with lean burn conversion and an emission rate of 3 g/hp-hr. Replacement is assumed if lower emission rates are required. The location of these engines by geographical regulatory risk category is in Table 4-5. This is a subset of the two-stroke cycle engines in Table 4-1.

Table 4-5. Number of opposed piston two-stroke cycle engines.

Engine type	Category 1	Category 2	Category 3	Total
2-stroke cycle opposed piston	1	13	0	14

4.4 Medium and higher BMEP four-stroke cycle turbocharged engines

Medium and higher BMEP four-stroke cycle turbocharged engines (see example in Figure 4-4) operate too lean to utilize NSCR for NOx reduction, and these engines are generally suited to

NMED Exhibit 61 -

NOx control through lean burn combustion and enhanced mixing methods – i.e., LEC technologies.

Figure 4-4. Ingersoll-Rand 616KVT

For cost estimating and resource availability assessment purposes in this study, reducing emissions to 3 g/hp-hr is assumed to be achieved through lean combustion. To lower NOx emissions to 1 g/hp-hr requires the addition of enhanced fuel mixing. The assumed emissions and location of these engines by geographical regulatory risk category can be found in Table 4-6. This table is a subset of four-stroke cycle rich and four-stroke cycle lean engines in Table 4-1.

Table 4-6. Number of medium and higher BMEP four-stroke cycle turbocharged engines.

Emission type	Category 1	Category 2	Category 3	Total
NOx $\leq$ 1 g/hp-hr	36	0	0	36
1 < NOx $\leq$ 3 g/hp-hr	46	26	5	77
NOx > 3 g/hp-hr	0	308	46	354
Total	82	334	51	467

4.5 Low BMEP two-stroke cycle engines

Low BMEP two-stroke cycle engines are generally older engines (i.e., the "first generation" of pipeline integral 2-stroke engines) that utilize low volume pumps or blowers to provide engine scavenging (Figure 4-5). To reduce NOx emissions, LEC is applied through the removal of the mechanically driven scavenging and installation of turbochargers with after-cooling and precombustion chambers. Because of the low BMEP of these engines, there is typically less exhaust energy to support turbocharger operation. As a result, the power turndown range of converted units is limited. The addition of enhanced fuel mixing technologies would extend the power operating range for these engines.

NMED Exhibit 61 -

Figure 4-5. Clark HBA Low BMEP Engine

Therefore, conversion to 3 g/hp-hr of NOx is assumed to require both conversion to leaner combustion and the installation of enhanced fuel mixing. With these modifications, the engines are capable of achieving 1 g/hp-hr of NOx in a narrower range near rated speed and power.

Adding a turbocharger sometimes allow these engines to operate at a higher rated power. This can increase the available turndown range of these engines as more heat energy is available to drive the turbocharger. Power increases of 5-40% are possible. The ability to increase the rated power of the engines is dependent on the design of the mechanical, structural, and auxiliary components (crankshaft, connecting rods, pistons, foundation, jacket water cooling, etc.) to handle the higher loads on the engine. The gas compressor cylinders may also require modifications to be able to utilize the additional power. This is usually achieved by installing larger compressor pistons and additional unloaders.

An increase of the engine power rating usually requires modifications to the air permit and filing with the Federal Energy Regulatory Commission. In some cases, the update of several engines could allow the abandonment of another engine thereby eliminating the need (and associated costs) to control emissions for that engine.

On a per horsepower basis, the costs of NOx control conversion for these units are generally more than the costs for higher BMEP two-stroke cycle engines (discussed below). This is due to additional intake/exhaust manifold modifications and the installation (versus an upgrade) of a turbocharger/after-cooler system. The assumed emission limits and location of these engines by geographical regulatory risk category is shown in Table 4-7. This is a subset of the two-stroke cycle engines in Table 4-1.

NMED Exhibit 61 -

Table 4-7. Number of low BMEP two-stroke cycle engines.

Emission type	Category 1	Category 2	Category 3	Total
NOx $\leq$ 1 g/hp-hr	5	0	0	5
1 < NOx $\leq$ 3 g/hp-hr	72	0	0	72
NOx > 3 g/hp-hr	0	461	44	505
Total	77	461	44	582

4.6 Medium and higher BMEP two-stroke cycle engines

Medium and high BMEP two-stroke cycle engines are engines that utilize centrifugal blowers and/or turbochargers to provide engine scavenging (Figure 6). These engines are generally larger than the first generation low BMEP 2-cycle engines discussed above. They are well suited to lean burn combustion to reduce NOx formation. A reduction in the power operating range can be expected on some of these engines in order to maintain very low NOx emissions. The addition of enhanced fuel mixing technologies extends the operating range of these engines and/or further reduces NOx emissions.

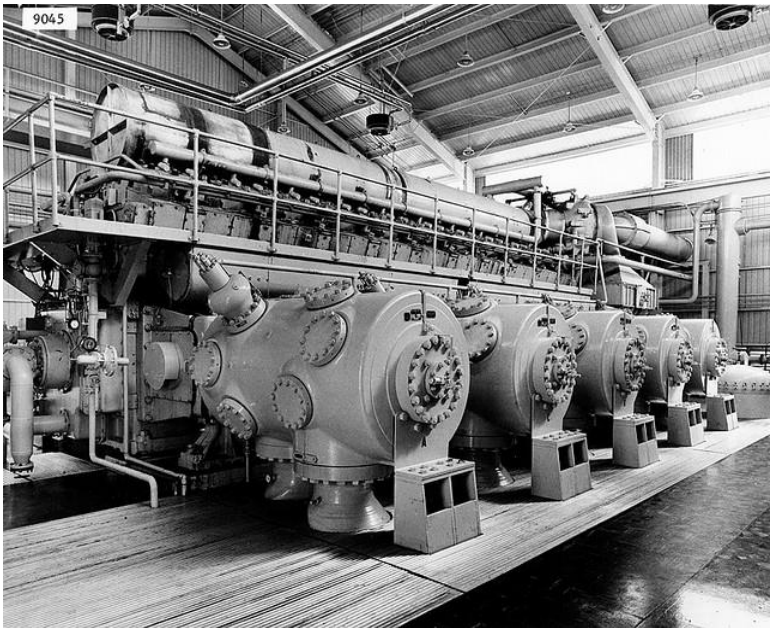

Figure 4-6. Cooper-Bessemer Z330

For the cost estimating purposes of this study, reducing emissions to 3 g/hp-hr is assumed to be achieved through lean combustion. This emission level is consistent with NOx limits for retrofit control of lean burn engines in federal and status rules, and is an expected upper bound target in upcoming rules. However, it is possible that lower NOx emission levels, such as 1 g/hp-hr limits, will be pursued in some jurisdictions. Lower emission limits also require the addition of enhanced fuel mixing. The assumed emission limits and location of these engines by geographical regulatory risk category is shown in Table 4-8. This is a subset of the two-stroke cycle engines in Table 4-1. Note that this group includes many engines, and often these engines are more highly utilized than smaller, older low BMEP engines discussed in the previous section.

NMED Exhibit 61 -

Thus, the medium to high BMEP two-stroke cycle engines are a prime candidate for regulation when states or EPA consider NOx control regulations.

Table 4-8. Number of medium and high BMEP two-stroke cycle engines.

Emission type	Category 1	Category 2	Category 3	Total
NOx $\leq$ 1 g/hp-hr	23	0	0	23
1 < NOx $\leq$ 3 g/hp-hr	221	134	31	386
NOx > 3 g/hp-hr	0	1372	269	1641
Total	244	1506	300	2050

5.0 Regulatory Background and Analysis Assumptions and Methodology

NOx emission regulations continue to evolve and are not fully defined at this time. However, as EPA and the states implement regulations in response to ozone NAAQS nonattainment and the NO_2 NAAQS, it is expected that new regulations and permitting actions over the next 5 to 15 years will impact the status of many engines that are currently uncontrolled. The following section provides an overview of NOx regulations and regulatory risk, and section 5.2 discusses assumptions used to assess implications.

5.1 NOx Regulations – Background and Regulatory Risk

For existing equipment, NOx regulations are generally in response to concerns with ozone NAAQS nonattainment because NOx is an ozone precursor – i.e., it reacts in the atmosphere to form ozone. In addition, 2010 revisions to the NO_2 NAAQS increased the stringency of that rule. If offsite impacts (i.e., beyond the facility fence line) of NO_2 determined using a dispersion model exceed the NAAQS, then mitigation may be required. At this time, the most likely triggers for retrofit NOx control for natural gas transmission prime movers are:

- NOx RACT Rules: Revisions to the ozone NAAQS planned for 2014 – 2015 will likely increase the number of nonattainment areas, and result in new state-level NOx RACT rules later this decade. Such rules are highly likely to occur unless EPA provides a different regional solution, and state rules could result in different requirements and applicability (e.g., statewide or county-specific rule) from state to state. States tend to rely on rules developed by other states, so states that are early actors in the next few years could provide "model rules" that would be broadly implemented.
- Regional Rule: EPA may implement a broad (e.g., eastern half of U.S.) regional rule similar to the 2004 NOx SIP Call Phase 2 Rule that required NOx reductions from large sources. Over 200 natural gas-fired prime movers were controlled in response to the 2004 SIP Call Rule. A similar new regional rule could supplant or supplement state NOx RACT Rules (see previous bullet), could quicken the schedule, and would likely affect many eastern U.S. engines. EPA may be hesitant to pursue this (and instead defer to the states) due to legal issues that remain to be resolved with a regional rule for electric utilities.
- NO_2 NAAQS mitigation: To date, there have been minimal regulatory actions in response to the 2010 NO_2 NAAQS revision. However, example modeling has shown that the relatively short stacks common for reciprocating engines and conservatism in AERMOD (the regulatory

NMED Exhibit 61 -

dispersion model) may result in offsite impacts that exceed the 100 ppbv 1-hour NO_2 NAAQS for uncontrolled reciprocating engines. Although there has been limited action to date, this could result in state or federal requirements to mitigate these impacts, and agency actions could be prompted by litigation or pressure from third parties. For existing facilities, EPA or the state could require modeling at any time, such as when the operating permit undergoes its five year renewal. Third party challenges could also force states or EPA to act regardless of the permit renewal schedule. This issue has the potential to impact many existing, uncontrolled reciprocating engine prime movers. Mitigation may require multiple measures, including NOx control, increasing stack height, and/or increasing the property buffer (e.g., land purchase, moving the fence to the property line).

Regarding the ozone NAAQS, EPA planned to revise the NAAQS in 2011 in response to legal challenges. This was delayed and it was decided to complete the next revision under the schedule that requires NAAQS review every 5 years. That schedule currently plans for a proposed rule in the spring of 2014 and a final rule by mid-2015. That rulemaking will likely result in more nonattainment areas than under the current 75 ppbv NAAQS. This is illustrated in Figure 5-1 and Figure 5-2.

Nonattainment is determined by assessing whether the 3-year average value (from ozone monitoring) exceeds the NAAQS. Projected nonattainment areas from EPA maps in 2010 for an ozone NAAQS of 60, 65 or 70 ppbv are shown in the left map in Figure 5-1. Those ozone levels were being considered for the 2011 rule that was deferred. The right map shows actual ozone nonattainment areas determined in 2012 for the current 75 ppbv standard. The projections for 60 to 70 ppbv were based on 2006 – 2008 data. The nonattainment areas defined in 2012 are based on a 3-year average from 2008 – 2010 or 2009 – 2011. The eastern U.S. had a cool and wet summer in 2009, and hot, sunny weather is more conducive to ozone formation. Thus, states and third parties are challenging EPA and would like to plan for broader nonattainment and address NOx transport from upwind states. Figure 5-2 shows an analysis completed by the Ozone Transport Commission, a group of 12 northeastern states that collaboratively assess air quality in that area. If 2009 data is excluded and the 3-year average is based on 2010 – 2012 data, the figure shows significantly more areas above 75 ppbv and also shows areas that would not achieve a lower, 70 ppbv standard.

Thus, if upcoming summers are not cool (like 2009), and EPA fulfills expectations to lower the ozone NAAQQS to a level between 60 and 70 ppbv in 2015, nonattainment areas will more likely resemble the 60 – 70 ppbv map on the left in Figure 5-1; or, for the northeast, the map in Figure 5-2. This would result in either a broad regional NOx control rule or requirements for many states to develop or update NOx RACT regulations for existing sources.

NMED Exhibit 61 -

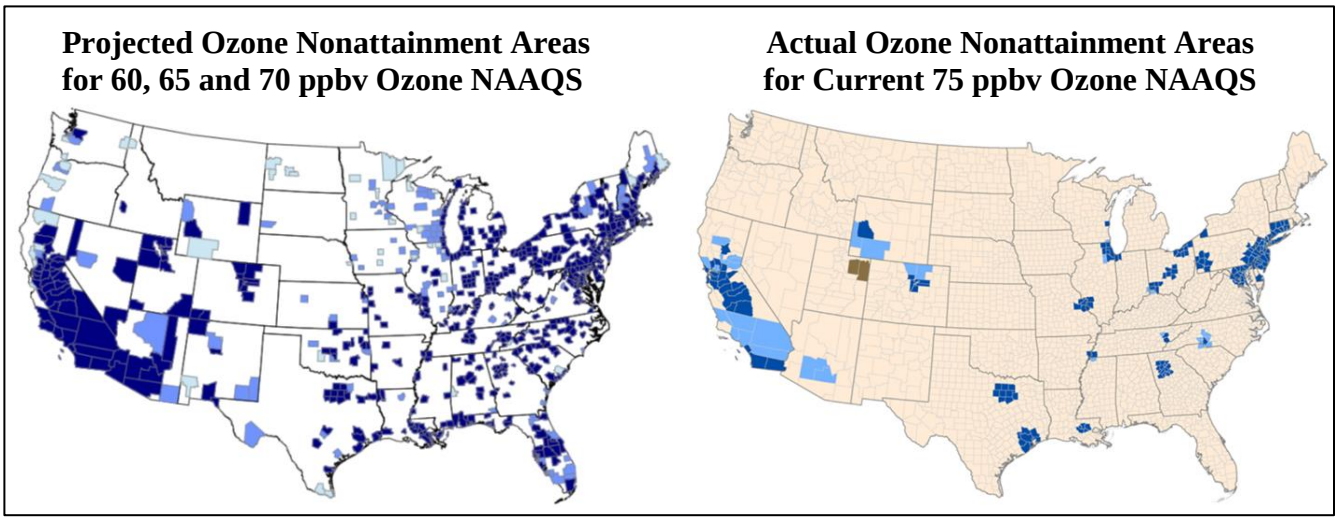

Figure 5-1. Projected ozone nonattainment areas (left map) for ozone NAAQS of 60 ppbv (light blue), 65 ppbv (blue) or 70 ppbv (dark blue) and actual ozone nonattainment areas (right map) for the 75 ppbv ozone NAAQS (dark blue – whole county; light blue – partial county; green – unclassifiable).

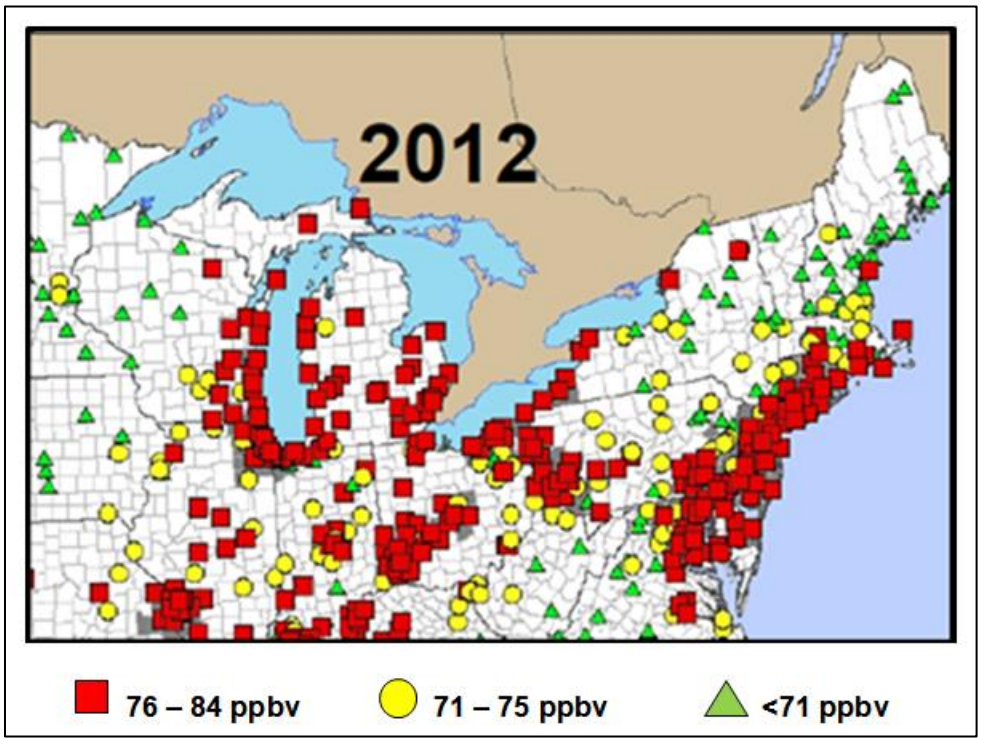

Figure 5-2. Updated northeast U.S. ozone air quality projections from the Ozone Transport Commission based on 2010 – 2012 ozone data (3-year average).

Regarding the NO_2 NAAQS, a committee of state and federal modelers has published example modeling results that show "typical" compression facilities with offsite impacts well above the NAAQS. [7] In Pennsylvania, a third party has requested that the state require modeling for all

compressor facilities based on an independent report presenting modeling results with impacts above the NAAQS. [8] To date, the state has provided analysis and data to justify not requiring such modeling, but additional third party challenges are likely. Thus, although requirements in response to the 2010 NO_2 NAAQS have not yet been common, the 2010 NO_2 NAAQS provides a platform for requirements that could broadly affect reciprocating engines that are not equipped with low NOx technology.

Thus, although schedules and mandates are highly uncertain, implementation of current and pending regulations will likely require retrofit NOx control (or replacement) for many existing natural gas-fired reciprocating engines. For this report, the specific timing and count of affected units was not defined. The analysis conducted, based on the actual engines in the fleet discussed in Section 4, focused on available resources and the cost and schedule to install controls based on NOx endpoints of 3 g/bhp-hr or 1 g/hp-hr. These emission levels are based on anticipated emission limits for typical NOx rules, with the lower limit based on potential requirements in more aggressive states.

In judging the likelihood of control and target NOx level (i.e., 3 or 1 g/bhp-hr), states were divided into three categories based on a judgment of the risk of NOx control and stringency over the next 5 to 15 years. This assessment was based on experiences with different states, proximity to areas that have previously failed to attain the ozone NAAQS or are expected to not attain if the ozone NAAQS is lowered in 2015, or within an area that has been targeted by eastern U.S. nonattainment areas as a "NOx transport" area. When considering the time required to install NOx controls, engine location and this ranking were considered (e.g., likelihood that a NOx level of 1 g/hp-hr NOx would be required). For assessing the likelihood of control and the NOx endpoint (3 g/hp-hr or 1 g/hp-hr), states were placed into one of three regulatory risk categories:

- Category 1 (high risk and stringency) – geographical region (i.e., states) where stringent NOx emissions limits are already in place (e.g., northeast states, California, Colorado); if NOx control is not in place, there is a high probability engine modifications will be required;
- Category 2 – geographical region where there is a moderate probability that lower NOx emission limits will be required (e.g., Midwest and southeast states implicated as contributors to NOx transport); and,
- Category 3 – geographical region with a lower probability that lower NOx emission limits will be required.

The INGAA database includes engines in forty-one states, and the list of states and their ranking is shown in Table 5-1.

NMED Exhibit 61 -

5.2 Assumptions and Methodology for Reciprocating Internal Combustion Engines (NOx)

The following assumptions and methods were used when assessing technology and resource requirements, schedules, and costs.

- Many rich burn engines employed in interstate natural gas transmission have been modified to reduce HAP emissions under the 2004 RICE NESHAP. Typically these four-stroke cycle rich burn engines added NSCR technology, including the associated engine air-to-fuel ratio control (AFRC). This technology also reduces NOx emissions. As such, four-stroke cycle rich burn engines were excluded from this analysis. It is believed that this is a reasonable assumption with the following caveats:
  - Some of the smaller four-stroke cycle rich burn engines or engines at small facilities may not have installed NSCR.
  - Some engines may require additional modifications or more attention to AFRC to meet NOx limits. This may be achieved by installing a larger catalyst or an upgraded AFRC.
- Some engines (i.e., horizontals) do not have suitable control technologies to reduce NOx emissions as they sometimes operate near stoichiometric conditions (rich) at full load and lean conditions at reduced load. These engines lack the ability to control the air to fuel ratio across the load range. In addition, the engines are of older designs that have limited parts availability and higher operating costs. For the purposes of this study, it is assumed these engines are replaced with new engines and the associated compressor and ancillary equipment. Specific engine types include:
  - Cooper-Bessemer four-stroke cycle horizontal engines, and
  - Worthington four-stroke cycle horizontal engines.
- Some of the engines in the INGAA database have been removed from service since the database was last updated. Those units were removed from the analysis where information was provided by the operator or the author had personal knowledge regarding those units.
- For cost estimating purposes, the following scope of work was assumed for NOx control:
  - 3 g/hp-hr NOx emission rate limit:
    - NOx control through low emissions combustion,
    - High energy ignition system is assumed to be precombustion chamber, either:
      - Screw-in, or
      - Head replacement;
    - Turbocharger modifications are required for lean combustion,
    - Turbocharger after-cooling enhancements are required, and
    - May or may not require (depending on engine model):
      - Fin fan after-cooler upgrades,
      - Coolant surge tank modifications,
      - Auxiliary generator upgrades,
      - Air inlet piping and filter modifications, and/or
      - Exhaust manifold, silencer, and exhaust stack modifications.

NMED Exhibit 61 -

        - Alternate or additive approaches (depending on the engine and emission target) include:
            - Enhanced mixing with or without high energy ignition system modifications, and
            - Post-combustion treatment utilizing SCR in select cases.
    - 1.0 g/hp-hr NOx emission rate limit:
        - Modifications for 3 g/hp-hr NOx as outlined above plus enhanced mixing and/or post-combustion treatment utilizing SCR.
- To identify those engines already controlled, existing emission capabilities were assumed based on descriptions and attributes in the INGAA engine database. Specifically, engines were assumed to be controlled to:
    - 3 g/hp-hr NOx or lower if:
        - The engine was identified as having low NOx emission controls,
        - The engine was identified as having post-combustion catalytic treatment (i.e., this implies that permitting closely scrutinized emissions),
        - The engine make and model number is known to be a low NOx emissions unit,
        - The engine is located in a state where control is already required for reasonably available control technology (RACT), or
        - The operating company and/or emission reduction vendor identified specific engines that have been modified to achieve low NOx emissions.
    - 1 g/hp-hr NOx or lower if the operating company and/or emission reduction vendor identified specific engines that were modified to be capable of this emission level.
- As discussed in Section 5-1 and shown in Table 5-1, U.S. locations were divided into three areas based on a judgment of the risk of NOx control requirements and stringency over the next 5 to 15 years.
- New air emission regulations or permitting requirements are expected to eliminate the grandfather provision in many cases and institute NOx control requirements for existing engines that currently are not controlled. The timing that the States (or other agencies) will implement NOx reduction rules and the level of NOx reduction cannot be defined at this time. For assessing the likelihood (and stringency) of control, States were categorized into three geographical regulatory risk categories as discussed above and shown in Table 5-1.
- To understand worst case scenarios in regards to the number of affected engines and a conservative cost projection, it was generally assumed that some level of control would be required for uncontrolled units. For example, engines in northern plains states that may not be affected by a regulation to address nonattainment could still require control to address NO_2 modeled impacts. In general, with the exception of the rich burn engines in Table 4-4, engine counts without controls (e.g., horizontal engines; engines >3 g/hp-hr) from Section 4 tables were included in the cost estimate and scheduling assessment, and additional engines (i.e., units currently controlled but with emissions between 1 and 3 g/hp-hr) are considered for the 1 g/hp-hr NOx limit, depending on location. These total over 2600 uncontrolled engines and over 500 engines that may require additional control if NOx requirements are reduced to 1 g/hp-hr. At this time, it is not expected that the lower NOx level would be

NMED Exhibit 61 -

broadly required. So, while costs are estimated for the 1 g/hp-hr endpoint to provide that estimate in the report, the schedule to complete all retrofits judges the engine location when assessing the likelihood of a 1 g/hp-hr NOx requirement.

6.0 Cost and Schedule Estimates

The primary purpose of this report is to assess resource constraints associated with retrofit NOx control. In assessing technology requirements and resource constraints, costs were also determined. Cost and schedules are discussed in this section, and Section 7 discusses resource availability (i.e., skill sets and staffing) for each project phase. Information is tabulated for:

- Capital cost for NOx control to achieve NOx emissions of either 3 or 1 g/hp-hr (see Tables 6-1 and 6-2). Separate costs are shows for each emission level, and these costs are not incremental.
- Annual engine retrofits (or replacements) that can be completed based on *current* staffing levels for key technology and engineering service providers (see Table 6-3).
- Time required to complete retrofits (or replacements) for the projected engine counts, based on an emission level of 3 or 1 g/hp-hr and current staffing levels.
  - Table 6-2 shows the number of years required to control engines to 3 g/hp-hr.
  - Marginally longer time is required to achieve 1 g/hp-hr for some engine types. Table 6-5 shows the *incremental time required* to achieve the lower NOx limit.
- The regulatory risk "categories" shown in the tables are based geographical assignment of regulatory risk by state as discussed in Section 5.1 and shown in Table 5-1.

6.1 Capital costs

The costs to modify or replace engines to reduce NOx emissions were gathered through interviews with operating companies, other published sources, and the author's experience.

As described above, unit (engine and compressor) replacement was assumed for horizontal and in some cases opposed piston two-stroke cycle engines. Replacement units were assumed to be dry low NOx gas turbines. Replacement costs were estimated at a fixed cost per unit ($1,800,000) plus a variable cost proportional to engine size ($895/hp). In the case of horizontal and opposed piston two-stroke cycle units, one new turbine unit was assumed for every two units that were replaced.

In select cases where SCR was considered, costs were estimated at a fixed cost per unit ($250,000) plus a variable cost proportional to engine size ($375/hp). Lean burn combustion modifications were estimated at a fixed cost per unit ($152,000) plus a variable cost proportional to engine size ($725/hp). Because of additional turbocharger and after-cooling requirements for two-stroke cycle engines, multipliers for the variable costs (for lean combustion conversion only) are 1.22 and 1.08 for low BMEP and medium/high BMEP two-stroke cycle engines respectively.

Enhanced mixing modifications were estimated at a fixed cost per unit ($235,000) plus a variable cost proportional to engine size ($85/hp). When both lean combustion and enhanced mixing modifications are implemented at the same time (e.g., converting from > 3 g/hp-hr to <1 g/hp-hr)

NMED Exhibit 61 -

costs were estimated at a fixed cost per unit ($427,000) plus a variable cost proportional to engine size ($785/hp).

Costs were assessed for affected engines to reduce emissions to 3 g/hp-hr. For reducing to less than 1 g/hp-hr, the additional costs were determined for further reducing emissions from these engines. In addition, costs were determined for additional engines that are already controlled to 3g/hp-hr that require additional reductions to achieve 1 g/hp-hr. Note that the costs to modify engines for NOx control are significantly lower than the replacement costs. This is due in large part to the fact that both the engine and the gas compressor must be replaced if the engine is replaced. As a general rule, the replacement equipment has a lower overall unit efficiency[1] and therefore uses more fuel (and by correlation has higher CO_2 emissions) than the units they are replacing.

The total estimated NOx control capital costs to modify reciprocating engines used in the natural gas transportation industry are summarized below. Table 6-1 represents the costs to reduce emission rates to less than 3 g/hp-hr, and Table 6-2 represents the costs to reduce emission rates to less than 1 g/hp-hr. For 3 g/hp-hr, total costs are nearly $4 billion and "average" costs per unit for the different engine types were about $1 to $1.5 million for 2-stroke engines and $2 million for 4-stroke engines. Replacement costs exceeded $2 million per unit.

Note that these two tables are exclusive, i.e., the tables present costs to achieve either 3 or 1 g/hp-hr and are not to be added together. In addition, while many units may need to achieve NOx limits on the order of 3 g/hp-hr, it is currently not expected that a large percentage of the fleet will need to achieve 1 g/hp-hr. For example, engines in higher risk areas (Category 1) are more likely to face the more stringent emission limit, while engines in lower risk Category 3 would be far less likely to require a 1g/hp-hr emission limit. Thus, costs to achieve 1 g/hp-hr NOx are a conservative upper bound (i.e., broad NOx regulations are more stringent than expected) for the engine fleet in the INGAA database.

Table 6-1. Costs to achieve 3 g/hp-hr ($ in thousands).

Emission type	Category 1	Category 2	Category 3	Total
Horizontal engines	$0	$236,308	$36,054	$272,362
Opposed piston	$756	$14,311	$0	$15,067
Med & high BMEP 4-stroke	$0	$660,355	$89,798	$750,153
Low BMEP 2-stroke	$0	$685,751	$65,811	$751,562
Med & high BMEP 2-stroke	$0	$1,770,389	$330,588	$2,100,977
Total	$ 756	$3,367,114	$522,251	$3,890,121

[1] Generally reciprocating engines drive reciprocating compressors while gas turbine engines drive centrifugal compressors. As a general rule, reciprocating engines are more fuel efficient than gas turbines. Likewise, reciprocating compressors are generally more efficient than the centrifugal compressors. There are exceptions where the gas turbine unit is the more efficient option. An example would be a high speed, low BMEP reciprocating engine driving a reciprocating compressor with small valve flow area replaced with a gas turbine/centrifugal compressor.

NMED Exhibit 61 -

Table 6-2. Costs to achieve 1 g/hp-hr ($ in thousands).

Emission type	Category 1	Category 2	Category 3	Total
Horizontal engines	$0	$236,308	$36,054	$272,362
Opposed piston	$2,108	$38,100	$0	$40,208
Med & high BMEP 4-stroke	$18,235	$807,287	$111,779	$937,301
Low BMEP 2-stroke	$24,290	$629,647	$60,415	$714,352
Med & high BMEP 2-stroke	$94,840	$3,645,435	$680,204	$4,420,479
Total	$ 139,473	$5,356,777	$888,452	$6,384,702

6.2 Schedule

Starting in 1999 as part of the NOx State Implementation Plan (SIP) Call (an eastern U.S. regional NOx rule for large existing sources), approximately 200 natural gas transmission engines were converted to LEC. From interviews with the operators and the emission reduction equipment suppliers, the conversion process took six years in total to fully implement. Additional engines were controlled in the late-1990's through about 2009 in response to state RACT rules.

Based on interviews with pipeline operations and emission reduction equipment suppliers having experience with previous conversion projects, NOx control for each engine requires between 1 and 2 ½ years to complete (from inception to completion of commissioning). The longer duration projects are those that require more infrastructure modifications (such as cooling equipment and auxiliary generators), on-engine modifications (after-coolers, turbochargers, lubrication systems, cooling systems, fuel systems, pre-chambers, intake/exhaust systems, and controls), and engine overhaul. Generally, older engines require more time to design the conversion. This is due to inaccurate or missing engineering records on the current configuration of and ancillary equipment used on the engine.

Taking into account both the lead time and conversion time and based on *currently available resources* (i.e., trained personnel), the average number of units that can be modified to lean combustion on a sustained basis is ***approximately 75 engines per year***. This is the key resource constraint that will affect NOx control requirements that affect these engines, even if only a subset of engines (e.g., a quarter of the current total capacity) is affected by new NOx control rules. Note that this projection is somewhat higher than the approximately 50 units per year converted under the NOx SIP Call even though additional technical resources are not in place at this time. The higher number of units converted per year assumes some efficiency of scale will be achieved based on processes and standards developed from previous efforts. A relatively optimistic projection for the annual number of conversions was selected so that the analysis reflects an "optimistic" scenario without considering how staffing and training will respond to market demand.

The estimated number of engines that can be retrofit per year is based on *current* resource availability. While a dramatic increase in market demand would likely result in hiring and training of additional resources, the special skills associated with this niche market would require time to build that resource. In addition, until new regulations are adopted the market and timing is not clear, thus this resource base will not grow until the market is clear.

NMED Exhibit 61 -

Based on the engine counts in Section 4 and the regional location of the engines, an estimate of the number of engines that can be modified per year is shown in Table 6-3, and the resulting number of years necessary to address NOx controls for the reciprocating engines used in natural gas transmission is presented in Tables 6-4 and 6-5.

The number of engines that can be modified per year depends on differences in scope related to the engine type (e.g., some engines are configured for lean combustion while others are not). The estimated number of engines that can be modified per year by engine type and emission level is shown in Table 6-3. The count varies for different engine types and emission level due to the complexity of the retrofit (e.g., need for additional equipment such as turbochargers, need to upgrade ancillary support such as cooling, etc.). It is not anticipated that the number of annual engine conversions can be significantly improved upon within a short timeframe (e.g., if demand for NOx control significantly and quickly increases) because specific skills and specialized training are necessary to serve this market.

Table 6-3. Estimated number of engines that can be modified/replaced per year.

	Modified to achieve NOx emission levels of:	
Engine type & initial emissions	**≤ 3 g/hp-hr**	**≤ 1g/hp-hr**
Horizontal engines	40	40
Opposed piston	40	40
Med & high BMEP 4-stroke > 3 g/hp-hr	75	64
Med & high BMEP 4-stroke ≤ 3 g/hp-hr	N/A	82
Low BMEP 2-stroke > 3 g/hp-hr	60	50
Low BMEP 2-stroke ≤ 3 g/hp-hr	N/A	75
Med & high BMEP 2-stroke > 3 g/hp-hr	75	64
Med & high BMEP 2-stroke ≤ 3 g/hp-hr	N/A	80

Based on the number of engines to be controlled (engine counts from the INGAA database as shown in Section 4) and the estimated number of engines that can be modified per year, the estimated time required to implement modifications to achieve 3 g/hp-hr is shown in Table 6-4.[2]

For NOx levels of 1 g/hp-hr, far fewer engines will be affected. To provide an upper bound on capital costs for control, , costs in Table 6-2 were estimated assuming that all of the affected units would need to achieve the low NOx level. The schedule to achieve the lower NOx level and timing presented in Table 6-5 considers a much smaller subset of engines, such as engines in a high risk location such as the northeast (Category 1). While Table 6-2 shows the costs to control all engines to 1 g/hp-hr, Table 6-5 shows the nominal *incremental time* required for this smaller subset of "high regulatory risk" engines to achieve 1 g/hp-hr.

[2] While the elapsed time for an engine retrofit or replacement from inception to completion may take 1-2 calendar years, the work can be performed by multiple engineering firms and construction companies resulting in an average resource time of less than one year per project.

NMED Exhibit 61 -

Based on current technical resources, the projected time to implement retrofit NOx control (or replacement) is far in excess of typical regulatory schedules. Primarily due to the large number of engines in Category 2 (units primarily in southeast and midwest states), *Table 6-4 shows that it would take **decades** to address NOx controls for a large number of engines*, even if the annual rate of retrofit conversions is doubled. Since the retrofit market is currently very limited (i.e., rules are not currently requiring installation of retrofit NOx controls), *there is no incentive to increase capacity* at this time. So, this limitation will not be addressed until indicated by market demand and confirmed regulations. Section 7 includes additional discussion of manpower and other resource constraints on a project level basis.

Table 6-4. Time required to modify engines to achieve 3 g/hp-hr (in years) [3]

Emission type	Category 1	Category 2	Category 3	Total
Horizontal engines	0.00	2.6	0.4	3.0
Opposed piston	0.03	0.3	0.00	0.3
Med & high BMEP 4-stroke	0.00	4.1	0.6	4.7
Low BMEP 2-stroke	0.00	7.7	0.7	8.4
Med & high BMEP 2-stroke	0.00	18.2	3.6	21.8
Total	0.03	32.9	5.3	38.2

A small number of engines (e.g., in Category 1) may require control to the more stringent 1 g/hp-hr NOx level. Table 6-5 shows the *incremental* time required to address that more stringent mandate and shows minimal impact on schedule to achieve the lower NOx level. However, considering capital costs in Tables 6-1 and 6-2, a lower NOx limit will have a significant cost impact, with engine-specific costs on average about 65% higher to achieve 1 g/hp-hr.

Table 6-5. Incremental time required to modify a subset of high risk engines to 1 g/hp-hr rather than 3 g/hp-hr (in years).

Emission type	Category 1	Category 2	Category 3	Total
Horizontal engines	0.00	0.07	0.01	0.08
Opposed piston	0.00	0.01	0.00	0.01
Med & high BMEP 4-stroke	0.00	0.06	0.01	0.07
Low BMEP 2-stroke	0.00	0.15	0.01	0.16
Med & high BMEP 2-stroke	0.00	0.28	0.06	0.34
Total	0.00	0.57	0.09	0.66

[3] Unless resource constraints are addressed via staffing and training, the overall timeline cannot be shortened by executing the projects for multiple regions/engine types simultaneously. For example, replacing all of the horizontal engines in Categories 2 and 3 will take about 3 years even if the work for both categories is performed at the same time. This is because executing projects in Category 3 states concurrently with projects in Category 2 states will require the reallocation of resources away from Category 2 states.

NMED Exhibit 61 -

7.0 Resource Analysis and Limitations by Project Phase

This section discusses resource requirements and constraints chronologically by project phase. The resource considered in this section is available manpower – i.e., staffing and expertise by topical area. All phases of project planning and execution are discussed even though several have minimal impact on schedule or cost. The information gathered identified several constraints and concerns associated with the available resources to implement NOx emission reduction projects. Constraints are due to the availability of skilled or expert staff necessary to complete key project tasks, and the requirements and limitations are discussed qualitatively by project task.

Interview subjects included multiple operating companies and six different suppliers of equipment and services to modify natural gas transmission reciprocating engines.

7.1 Permitting

The permitting portion of the project typically involves evaluating many different cases. Design iterations are made to determine technology requirements to reduce emissions to required levels within the required timeframe. Secondary factors include the impact the proposed retrofit NOx control technology has on equipment efficiency and operational turndown. Due to the workload of the permitting agencies, the permitting process typically takes a long time to complete (months to years in some cases). Because of the long lead time involved, air quality permit applications are often filed before design optimization for the NOx control equipment can be completed.

Complicating factors may include other regulatory limits. For example, implementing significant modifications to a piece of equipment to reduce air emissions may require modifications to reduce noise emissions to conform to local noise regulations. In addition, special care must be made to ensure retrofitting NOx control technology does not adversely impact emissions of other pollutants such as THC and CO, or additional controls (i.e., oxidation catalyst for CO or hydrocarbons) are considered to address this situation.

The operators expressed concern that regulations to reduce NOx emissions will result in constraints at the state regulating agencies (e.g., timing to process permits and potential backlog due to state budget and staffing issues). The result could include:

- Slow response time in issuing air permits. This can result in delays to the project execution schedule, and can make it difficult to comply with new regulations with a hard deadline for implementation.
- Limited flexibility in approving new emission reduction technologies (i.e., time constraints due to agency staffing).
- Limited ability to modify the design for optimization after the permit application has been submitted without causing further delays.

These concerns could be mitigated somewhat if longer or phased implementation schedules are allowed. States generally propose a short compliance schedule (e.g., 18 months to two years from the rule date). It is incumbent upon the affected industry to try to convince the state during rule development to allow longer schedules, including phased schedules. Thus, operators need to

NMED Exhibit 61 -

be proactive in working with states (or EPA) to achieve "reasonable" schedules. However, it is highly unlikely that a decades long implementation scenario indicated by Table 6-4 will be achievable.

7.2 Initial design

Based on the expected number of engines to be modified, pipeline operating companies will require additional engineering staff to perform initial design of NOx reduction modifications. Some of this will be achieved through the hiring of additional staff. However, based on the current trends and practices, most of this resource will be provided by firms that provide contract engineering services or turnkey solutions from LEC technology providers. Examples include: Black & Veatch, E-N Engineering, Mustang Engineering, Cameron, Dresser Rand, Hoerbiger, GE Oil and Gas, and many others. The experience and knowledge of these engineering firms for retrofit NOx control projects is varied and in most cases is limited. This is due in part to high turnover that occurs in these firms and the wide variability of equipment to be modified. The use of engineering staff additions and/or engineering services will require a significant learning curve and training. This will require more time to execute initial engine modification designs. As experience improves over time, the project execution duration should be reduced.

During this phase of project execution, providers of emission reduction equipment such as Cameron, Dresser Rand, and Hoerbiger will receive numerous requests for potential options for emission reduction technologies. This is especially likely where:

- Very low emission rates are required,
- Few engines of the make/model have previously been modified for low NOx technology,
- The engine has a unique design and configuration that requires specialized engineering analysis, and/or
- The engine is required to operate in special modes (e.g., requires a wide power range).

This demand for quotes is a potential resource constraint for the emission reduction equipment providers, especially when demand initially increases. In general, the unique attributes associated with legacy integral reciprocating engines provide a common theme regarding personnel / expertise based constraints. If regulatory timelines can be extended for projects that are unique in design or configuration, this can be mitigated.

Some emission reduction equipment providers will provide turnkey services (design, procure, construct, commission). However, there are currently only a handful of companies that provide this service for NOx control of legacy integral units. The number of engines modified using turnkey services will be limited to what emission reduction equipment providers can provide with moderate increases in qualified technical staff through using contract employees, part time staff, subcontractors, and retirees.

7.3 Procurement

Provided adequate personnel resources and experience exist in the initial design phase to produce procurement specifications, the actual procurement process should have minimal resource constraints. Qualified procurement personnel are available on a contract basis. In many cases,

NMED Exhibit 61 -

the pipeline operating company will use the same contract engineering services to perform the procurement process.

Discussions with NOx emission control equipment suppliers indicated that manufacturing production can be increased to provide the equipment within a reasonable time period (assumed to be *at least 3 years*). As such, the procurement of the hardware required for NOx emission reduction projects is not expected to be a constraint as long as reasonable regulatory schedules are negotiated, trends for increased demand are understood, and production responds accordingly.

7.4 Cost estimating and scheduling

The cost estimating and scheduling phase typically use the same resources used in the initial design. This phase is not expected to have a significant resource constraint.

7.5 Detailed design

Detailed design for emission reduction projects will encounter much of the same resource constraints as described under initial design. The difference in this phase is more resources will be required to produce engineering drawings and project specification documents. Like the initial design phase, this will be achieved through a mix of additional employees for the pipeline operating company, contract services, and turnkey providers, with turnkey LEC technology companies the predominant resource – unless rapid growth in market demand prompts an alternative in the future.

At this phase of the project, the pipeline operating company will require additional resources to provide detailed project management oversight for the life of the project. Again, this will likely be achieved through the use of a mix of new employees and contract services with an associated training and learning curve period.

7.6 Construction

Pipeline operating companies and turnkey emission reduction vendors typically use contract construction services to implement the physical modifications to engines. These resources are generally available and should not be a constraint unless there are a number of major pipeline construction projects that would overlap with the timing of the engine emission reduction projects. Review of the potential for competing infrastructure projects is beyond the scope of this report, but other studies are available, such as the INGAA Foundation Report on midstream infrastructure projections through 2035. [9]

There is one exception; there is currently a shortage of welders qualified for natural gas piping. Modifying a large number of engines to reduce NOx emissions (e.g., 25%, 50%, or possibly the vast majority of over 2600 engines identified in Section 4) would further constrain this resource. Increasing the timeline available to implement engine modifications and avoiding an overlap in the execution of those projects with major pipeline expansion projects would help mitigate this constraint.

During the construction period, the equipment is not available for the transportation of natural gas. To minimize the impact on pipeline capacity and associated disruption for shippers, outages are optimized by:

NMED Exhibit 61 -

- Scheduling the construction during periods of low system demands (such as during the summer for pipeline systems that have peak demands during the winter heating season),[4]
- Scheduling outages such that only one or two engines are out of service at any one station during any period of time, and
- Scheduling outages such that outages at compressor stations are staggered (e.g., start with outages at Stations A, C, E, & G, and when the modifications at those stations are completed, then Stations B, D, F, & H)

Future PHMSA regulations [10] may require pipeline operators to complete hydrostatic testing of pipelines (e.g., those installed prior to 1970). If the schedule to install NOx controls overlaps with other pipeline regulations, a reduction in available pipeline capacity may occur. This is exasperated by the overlapping vintage of the pipe that may be affected by PHMSA rules and the compressor engines likely to require NOx control. The result could result in shortages of natural gas in some areas of the country. To mitigate this possibility, it is important to understand not only air quality (or safety) regulatory schedules, but possible implications from different compliance activities across all regulations that occur in the same timeframe. Possible implications from overlapping requirements need to be communicated to regulators to try to avoid impacts on pipeline capacity and natural gas delivery.

7.7 Commissioning and Start-up

Proper commissioning of NOx reduction equipment is critical to assure the modified engine reliably meets air emission limits. The process of commissioning and safely placing into service an engine with new NOx control technology requires many different skills and specialized equipment, including:

- Engine mechanical specialist to tune the operation of the engine and equipment to measure the developed engine power,
- Control technicians to calibrate additional measurement points, verify pump rotations, etc.,
- Control system specialists to modify control software (to accommodate additional measurement points and control algorithms) and tune control loops,
- Qualified operating personnel to safely introduce fluids and energize systems,
- Subsystem specialists with specific expertise in control valves, gas measurement, and communications,
- Air emissions testing equipment and analysts, and
- Specialists to train the equipment operators on the operation and maintenance of the new equipment.

Due to the specialized skills required during this phase and expectations that demand will exceed the currently available resources, *these are personnel resources that are likely to be constrained*

[4] With the increase in the number of natural gas fueled power plants installed over the last decade, many interstate pipelines that historically had peak loads during the winter heating season now also have peak demand periods in the summer. Off peak periods for these pipelines are now during the spring and fall.

NMED Exhibit 61 -

for NOx control projects. Mitigation measures include utilizing available temporary resources (such as qualified contractors and retired employees), hiring and training new staff, and extending the timeline for modifications.

7.8 Operation and Maintenance

Within the first year after commissioning an engine, additional adjustments are commonly required after break-in and to address changes to seasonal ambient conditions. This typically requires the same technical personnel and equipment used to commission the engine as discussed above. The same mitigation measures described above would apply to operation and maintenance of the equipment.

If adequate operating spares for the newly installed equipment are purchased as part of the project, material resources should not be a constraint.

8.0 Conclusions

There is a great deal of uncertainty about the breadth (i.e., how geographically broad), depth (i.e., stringency of the rule), and schedule for new NOx regulations that will affect existing natural gas-fired reciprocating engines. Litigation and scheduling delays have slowed the regulatory process. Although the timing and breadth of new NOx control regulations remains uncertain, it is likely that many of the natural gas-fired reciprocating engines in the existing prime mover fleet will require NOx control by 2025. There are several thousand legacy natural gas-fired reciprocating engines driving compressors in interstate transmission, and their location (i.e., in rural areas where emission rules are more rare) and history (i.e., operating prior to rulemakings that affect new equipment) make these engines candidates for future regulation.

Based on previous projects and interviews with industry experts, modifying these engines will require significant time and capital. The capital required to address the fleet of engines without low NOx technology is significant. In addition, the lack of available expertise is likely to be a primary constraint in addressing broad, new regulations on a timely basis.

Based on interviews with operators, equipment vendors, and service providers, the primary conclusions from this study include:

- The special technical expertise to design, construct, and commission emission reduction projects for the low speed integral engines prevalent in natural gas transmission is available from a handful of companies, and with few NOx rules being adopted in recent years, this expertise may be migrating to other markets. Regulations that require installation of NOx control on a large number of reciprocating engines will require a significant lead time to train and develop resources to implement emission reduction projects. For example, if upcoming NOx regulations impact 25% of the current fleet of legacy reciprocating engines, the number of units requiring NOx control (over 600) would exceed the total number of units that have been controlled over the last 20 years. A higher percentage could be impacted (e.g., 50% of units affected is over 1300 units; even high impacts are possible), and market demand could significantly exceed the available resource base of skilled professionals.
- **Availability of this special technical expertise and building this resource is the primary resource constraint that will affect the ability to meet regulatory obligations that affect**

a large percentage of the fleet. Based on current capabilities and a scenario where NOx regulations broadly affect the existing fleet of uncontrolled reciprocating engines, *the estimated time to complete upgrades to over 2600 engines is nearly forty years.*

  - Although regulations may affect a smaller subset of engines or compliance strategies may result in many engines (e.g., lower horsepower, lower use engines) being retired or replaced, schedule implications due to the lack of available expertise will likely extend far beyond the required regulatory timeline (e.g., 1000 engines would require 15 years).
  - There is no incentive to begin to build this resource base until it is clear that a market will exist – i.e., the regulations and associated schedule are in place. Since lawsuits and EPA priorities have slowed the next cycle of NOx regulations, it is not possible to project the timing, stringency, number of affected units, or schedule for implementing new NOx rules.
  - In addition to regulatory risk associated with NOx rules in response to nonattainment with the ozone NAAQS, revisions that increased the stringency of the NO_2 NAAQS in 2010 could trigger new NOx control requirements for existing facilities through the permitting process – e.g., during permit renewal. This issue has the potential to trigger NOx control requirements *sooner* than the current ozone NAAQS timeline.

- Due to this resource constraint, it is imperative that companies engage state and federal regulators when NOx rulemakings commence. Emission regulations typically allow only one to two years to implement controls, and additional time and phased implementation will be needed to provide a more reasonable schedule. However, once the next round of NOx rules are initiated, it is unlikely that a decade(s) long schedule will be allowed. The schedule conflicts associated with regulatory timelines, market demand, current supply (i.e., available resources), and service provider growth will likely present a significant challenge over the next 5 to 10 years.
- Engine NOx control projects are generally much less costly than engine replacement. Capital costs to modify the fleet of currently uncontrolled reciprocating engines used in the interstate natural gas transmission industry are estimated at $3,890 million and $6,385 million to achieve NOx emission rates of 3 g/hp-hr and 1 g/hp-hr respectively.
- The age of the impacted equipment (most of the engines are over 40 years old) requires additional time to engineer and construct reliable emission reduction modifications due to inaccurate or missing engineering records that reflect the current equipment configuration.
- Some engines with low specific power output will require extra time to properly design and construct emission reduction modifications and maintain the same power operating range.
- Based on previous experience, the timeline to obtain air permits is a key parameter defining the overall schedule for completing a specific emission reduction project – i.e., permitting can slow the project timeline.
- Equipment outages to implement emission reduction modifications may have a significant impact on available pipeline capacity, especially if the timeline overlaps with implementation of other regulations, such as pipeline integrity assessments that may be required by PHMSA.

Appendix A: Acronyms

AFRC	Air to Fuel Ratio Controller
BACT	Best available control technology
BHP	Brake horsepower
BMEP	Brake mean effective pressure
CO	Carbon monoxide
EPA	Environmental Protection Agency
g	Grams
hp	Horsepower
Hr	Hour
INGAA	Interstate Natural Gas Association of America
LEC	Low emission combustion
MACT	Maximum achievable control technology
NAAQS	National Ambient Air Quality Standards
NESHAP	National Emission Standard for Hazardous Air Pollutants
NO_2	Nitrogen dioxide
NOx	Nitrogen oxides
NSCR	Nonselective catalytic reduction
NSPS	New Source Performance Standard
O_2	Oxygen
PHMSA	U.S. Dept. of Transportation Pipeline and Hazardous Materials Safety Administration
RACT	Reasonably available control technology
RICE	Reciprocating internal combustion engine
SCR	Selective catalytic reduction
SIP	State implementation plan (Dresser-Rand and others also use "SIP" for screw-in pre-chamber.)
THC	Total unburned hydrocarbons
VOC	Volatile organic compounds (For gas-fired combustion, VOCs are THC excluding methane and ethane, which are the two most prevalent exhaust hydrocarbons). Formaldehyde is also a VOC but is excluded from some regulations (e.g., it is more difficult to measure than THC and may not be included in data used to establish a VOC standard or emission limit).

NMED Exhibit 61 -

Appendix B: Survey Questions for Operator and Service Provider Interviews

1. Over the last three years, approximately how many engines has your company modified (as prime contractor) to meet emission levels of 3 g/hp-hr or less?

2. How many of those modifications were achieved through lean emission reduction?

3. Over the last three years, approximately how many engines has your company supplied parts, equipment, material, start-up support, or training to operating companies so they could modify their engines to meet emission levels of 3 g/hp-hr or less?

4. Over the last three years, approximately how many engines has your company supplied parts, equipment, material, start-up support, or training to other vendors or contractors so they could modify their engines to meet emission levels of 3 g/hp-hr or less (acting as a subcontractor)?

5. Over the last three years, approximately how many engines has your company modified (as prime contractor) to meet emission levels of 1 g/hp-hr or less (this should be a subset of (1) above)?

6. How many of those modifications were achieved through lean emission reduction (this should be a subset of (2) above)?

7. Over the last three years, approximately how many engines has your company supplied parts, equipment, material, start-up support, or training to operating companies so they could modify their engines to meet emission levels of 1 g/hp-hr or less (this should be a subset of (3) above)?

8. Over the last three years, approximately how many engines has your company supplied parts, equipment, material, start-up support, or training to other vendors or contractors so they could modify their engines to meet emission levels of 1 g/hp-hr or less (acting as a subcontractor) (this should be a subset of (4) above)?

9. Estimate average number of employees and subcontract staff (i.e. full time equivalent positions) utilized to support the emissions reduction projects over the last three years.

10. Over the last three years, the qualified staffing to support emission reduction projects has:
    a. Increased significantly
    b. Increased some
    c. Stayed about the same
    d. Decreased some
    e. Decreased significantly

NMED Exhibit 61 -

11. Based on current staffing, estimate the number of projects per year your company can support acting as the prime contractor.

12. Based on current staffing, estimate the number of projects per year your company can support acting as a subcontractor/parts provider.

13. Based on the technical skills required, estimate the time required to hire and fully train new staff to support emission reductions projects:
    a. Up to six months
    b. Six months to one year
    c. One to two years
    d. More than two years

14. Please describe any issues or concerns associated with implementing a large number of emission reduction modifications over a three year time span.

ALPHA-GAMMA TECHNOLOGIES, INC.

MEMORANDUM

DATE: April 28, 2006

SUBJECT: Control Costs for Reciprocating Internal Combustion Engines at Major and Area Sources

FROM: Bradley Nelson, Alpha-Gamma Technologies, Inc.

TO: Jaime Pagán, EPA Energy Strategies Group

The purpose of this memorandum is to present information on the costs of control technology options for reducing hazardous air pollutants (HAP) emissions from stationary reciprocating internal combustion engines (RICE).

Introduction

The EPA has determined that oxidation catalysts, catalyzed diesel particulate filters (CDPF), and non-selective catalytic reduction (NSCR) are applicable controls for HAP reduction from stationary RICE. Equipment cost information from a vendor was obtained and used to calculate cost equations for oxidation catalysts and NSCR. The cost equations were used to estimate the national impacts of controlling emissions from existing and new engines. Cost information developed by the California Air Resources Board (ARB) for the Airborne Toxic Control Measure for stationary compression ignition (CI) engines and costs developed for the proposed new source performance standards (NSPS) for stationary CI engines were used to estimate costs for installation of CDPF on existing and new engines, respectively.

NMED Exhibit 62 - 0001

Methodology for Determining Cost Equations

The EPA determined that CDPF, oxidation catalysts, and NSCR are applicable controls for the reduction of HAP emissions from RICE. This is based on the theory that HAP reduction will only occur if an oxidation process occurs. At the time of this memorandum, these are the only known add-on control technologies that utilize oxidation. The following sections describe how the capital and annual costs for these control technologies were derived.

The capital and annual costs were determined using the Office of Air Quality Planning and Standards (OAQPS) Control Cost Methodology described below:

Determine:

1 - Total Capital Costs
2 - Total Annual Costs

1 - Total Capital Cost Components and Factors:

Total Capital Cost (TCC) = Direct Costs (DC) + Indirect Costs (IC)

1.1 - Direct Costs (DC): DC = PEC + DIC

1.1.1 - Purchased Equipment Costs (PEC):

- Control Device and Auxiliary Equipment (EC)
- Instrumentation (10% of EC)
- Sales Tax (3% of EC)
- Freight (5% of EC)

PEC = 118% EC

1.1.2 - Direct Installation Costs (DIC)

- Foundations and Supports (8% of PEC)
- Handling and Erection (14% of PEC)
- Electrical (4% of PEC)
- Piping (2% of PEC)
- Insulation for Ductwork (1% of PEC)
- Painting (1% of PEC)

DIC = 30% PEC

DC = PEC + 0.3 PEC = 1.3 PEC

1.2 - Indirect Costs (IC): IC = ICC + C

1.2.1 - Indirect Installation Costs (IIC)

- Engineering (10% of PEC)
- Construction and Field Expenses (5% of PEC)
- Contractor Fees (10% of PEC)
- Startup (2% of PEC)
- Performance Test (1% of PEC)

IIC = 28% PEC = 0.28 PEC

1.2.2 - Contingencies (C) (3% of PEC)

- Equipment Redesign and Modifications
- Cost Escalations
- Delays in Startup

C = 3% PEC = 0.03 PEC

IC = 0.28 PEC + 0.03 PEC = 0.31 PEC

TCC = 1.3 PEC + 0.31 PEC = 1.61 PEC = 1.61 (1.18 EC) = 1.9 EC

2 - Total Annual Cost Elements and Factors

Total Annual Cost (TAC) = Direct Annual Costs (DC) + Indirect Annual Costs (IC)

2.1 - Direct Annual Costs (DC):

- Utilities
- Operating Labor
- Maintenance
- Annual Compliance Test
- Catalyst Cleaning
- Catalyst Replacement
- Catalyst Disposal

2.2 - Indirect Annual Costs (IC)

- Overhead (60% of operating labor and maintenance costs)

- Fuel Penalty
- Property Tax (1% of TCC)
- Insurance (1% of TCC)
- Administrative Charges (2% of TCC)
- Capital Recovery = $[I*(1+I)^n/((1+I)^n-1)*TCC]$ where I is the interest rate, and n is the equipment life.

Oxidation Catalysts

The cost of adding an oxidation catalyst to a new or existing lean burn spark ignition (SI) engine was estimated based on information obtained from a manufacturer of oxidation catalysts for RICE[1]. The vendor provided equipment cost estimates for six generic sized engines ranging from 500 to 8,000 horsepower (HP). The data obtained from the vendor were used to calculate capital and annual cost equations for oxidation catalyst control for RICE at major and area sources. Based on vendor information, EPA assumed there would be no difference between installing oxidation catalyst control on an existing source versus on a new source.

The equipment cost from the oxidation catalyst manufacturer and the OAQPS control cost methodology were used to calculate capital and annualized costs. The capital cost includes the direct, indirect, and contingency costs of installation of the oxidation catalyst. The total annual cost includes the direct and indirect annual costs of operating and maintaining the oxidation catalyst. Maintenance costs were estimated based on maintenance information for CDPF presented in Table 6.2-30 of the nonroad diesel engine regulatory impact analysis (RIA)[2]. The nonroad diesel RIA did not provide any maintenance costs for oxidation catalysts. The EPA would expect that similar maintenance costs would be associated with CDPF and oxidation catalysts, and therefore felt it was appropriate to use the maintenance cost information from the nonroad diesel RIA. Table 6.2-30 of the nonroad diesel RIA indicated that a maintenance interval of 3,000 hours for engines below 175 HP and 4,500 hours for engines above 175 HP was appropriate. Table 6.2-30 estimates the cost for maintenance is $65 for engines up to 600 HP and $260 per event for engines above 600 HP. The EPA has used the assumption that SI engines operate 2,800 hours per year. To provide a conservative estimate of annual maintenance costs for an oxidation catalyst, it was assumed that maintenance is required for all oxidation catalysts every year and the cost for maintenance would be $260. An equipment life of 20 years and an interest rate of 7 percent were used to estimate the indirect annual costs. The fuel penalty associated with operating an oxidation catalyst was assumed to be negligible.

A summary of the costs and linear regression statistical results is provided in Appendix A. The annualized cost equation for oxidation catalyst on lean burn SI engines was estimated at:

Oxidation Catalyst Annual Cost = 1.52 * HP + 393

where;

HP = engine size in HP.

The capital cost equation for installing an oxidation catalyst on a lean burn SI engine was calculated to be:

Oxidation Catalyst Capital Cost = 11.3 * HP - 170

where;

HP = engine size in HP.

The linear equations have a correlation coefficient of 0.9907, which shows the data fit the equations very closely. Therefore, the equations were used to estimate annualized and capital cost for oxidation catalysts for stationary RICE. A summary of the cost calculations, regression analyses, and graphical representations of the annual and capital cost data are presented in Appendix A.

Non-Selective Catalytic Reduction

Non-selective catalytic reduction, also referred to as a "three way catalyst," is the only available control technology for rich burn RICE that can effectively reduce the emissions of HAP. This is because rich burn engines operate at stoichiometric air-to-fuel ratios and therefore do not have sufficient oxygen available for oxidation catalysts. The catalyst is formulated to enhance both reduction and oxidation reactions, which reduces the emissions of nitrogen oxides (NO_x), carbon monoxide (CO), and volatile organic compounds (VOC). Cost data were obtained from a manufacturer of NSCR[3,4]. The cost data contained information for three Caterpillar engine models and five generic sized rich burn engines. Again, based on vendor information, EPA assumed there would be no difference between installing NSCR on an existing source versus a on new source.

The capital cost includes the direct, indirect, and contingency costs of installation of NSCR. The total annual cost includes the direct and indirect annual costs of operating and maintaining the catalyst. Maintenance costs were estimated using the maintenance cost information for CDPF presented in Table 6.2-30 of the nonroad diesel RIA, referenced earlier. The catalyst manufacturer that provided the NSCR cost information recommends a maintenance interval of 3,000 hours. The EPA would expect that similar maintenance costs would be associated with CDPF and NSCR, and therefore felt it was appropriate to use the maintenance cost information from the

nonroad diesel RIA. Table 6.2-30 of the nonroad diesel RIA estimates the cost for maintenance was $65 for engines up to 600 HP and $260 per event for engines above 600 HP. The EPA has used the assumption that SI engines operate 2,800 hours per year. To provide a conservative estimate of annual maintenance costs for the NSCR, it was assumed that maintenance is required every year at a cost of $260. An equipment life of 20 years and an interest rate of 7 percent were used to estimate the indirect annual costs. The fuel penalty associated with operating the NSCR was assumed to be negligible.

A linear regression analysis was done on the data set for NSCR on rich burn engines and the linear equation for annualized cost was;

NSCR Annual Cost = 2.65 * HP + 657

where;

HP = engine size in HP.

The capital cost equation for installing a NSCR on a rich burn SI engine was calculated to be:

NSCR Capital Cost = 19.7 * HP + 1799

where;

HP = engine size in HP.

The linear equations have a correlation coefficient of 0.9887, which shows the equations are a good estimation of the cost data. Therefore, this equation was used to estimate annualized and capital cost for NSCR for stationary RICE. A summary of the costs, linear regression statistics, and a graph of the data are presented in Appendix A.

Catalyzed Diesel Particulate Filters

Catalyzed diesel particulate filters is a control technology that reduces the emissions of HAP from diesel CI engines. It is primarily installed on engines for the reduction of particulate matter (PM) from diesel exhaust. The catalyst element in the CDPF is also effective in reducing the emissions of CO, VOC, and HAP. Costs for CI engines will be calculated for existing and for new engines. This is because installation costs and compliance costs will be different for new and existing CI engines and therefore will be estimated separately in this analysis. Using equipment cost data and the OAQPS cost methodology, a cost equation was developed for prime and emergency CI RICE.

Existing CI Engines

Cost data for retrofitting CDPF on existing engines were obtained from the California ARB presentation entitled "Methods and Key Assumptions for Estimating the Costs for In-Use Stationary Engines[5]." The data set included annualized cost data for 11 engines. The cost data available for CDPF include a passive or active catalyst element. The passive CDPF use a catalyzed coating to reduce emissions of CO, VOC, and HAP emissions, and reduce the ignition temperature necessary for oxidation of PM. The active filters use heat from the engine or from a secondary source to regenerate the catalyst media.

A linear regression analysis was done on the data set and the linear equation for annualized cost was;

$$\text{CDPF Annual Cost} = 6.27 * HP + 1094$$

where;

HP = engine size in HP.

The capital cost equation for installing a CDPF on a CI engine was calculated to be:

$$\text{CDPF Capital Cost} = 7.48 * HP + 1304$$

where;

HP = engine size in HP.

The linear equations have a correlation coefficient of 0.8038, which shows the equation is a good approximation of the data. Therefore, this equation was used to estimate annualized cost and capital cost for retrofitting CDPF for stationary CI prime and emergency engines. A graphical representation of the cost data is shown in Appendix A.

New CI Engines

For the cost of installing CDPF on new engines, EPA used the cost information that was developed for the proposed NSPS for stationary CI engines[6]. These costs were presented in the memorandum entitled "Control Costs for NO_x Adsorbers and CDPF for CI engines," which can be found in the rulemaking docket for the CI NSPS (Docket ID Number EPA-HQ-OAR-2005-0029). The costs for CDPF in that memorandum were based on information obtained from the nonroad diesel RIA. For the stationary CI NSPS, EPA estimated that annualized costs for installing CDPF on new stationary CI engines varied from $130 to $3,100 depending on engine size. Based on these costs, EPA estimated the average annualized cost to be $1/HP for both prime and emergency stationary CI engines. The average cost per HP was used to

estimate annualized cost for CDPF for new CI prime and emergency engines at major and area sources. The capital cost was estimated using the same data points and was calculated to be $1.5/HP.

Summary

The following table presents a summary of the costs for control devices to reduce HAP emissions from engines located at area and major sources. The equations can be used to estimate regulatory costs for existing and new engines, as applicable.

Table 1. Summary of Control Costs for HAP Controls

Engine Type	HAP Control Device	Annualized Costs	Capital Costs
2SLB SI	Oxidation Catalyst	1.52 * HP + 393	11.3 * HP - 170
4SLB SI	Oxidation Catalyst	1.52 * HP + 393	11.3 * HP - 170
4SRB SI	NSCR	2.65 * HP + 657	19.7 * HP + 1799
CI – retrofit	CDPF	6.27 * HP + 1094	7.48 * HP + 1304
CI – new	CDPF	$1/HP	$1.5/HP

MEMORANDUM

DATE: June 29, 2010

SUBJECT: Control Costs for Existing Stationary SI RICE

FROM: Bradley Nelson, EC/R, Inc.

TO: Melanie King, EPA OAQPS/SPPD/ESG

1.0 PURPOSE

The purpose of this memorandum is to present information on the costs of control technology options for reducing hazardous air pollutants (HAP) emissions from existing stationary spark ignition (SI) reciprocating internal combustion engines (RICE). The memorandum will look at the cost of retrofitting control technology on existing engines. This information will be used to determine national impacts associated with the final rule.

2.0 INTRODUCTION

EPA has determined that oxidation catalysts for two-stroke lean burn (2SLB) and four-stroke lean burn (4SLB) engines, and non-selective catalytic reduction (NSCR) for four-stroke rich burn (4SRB) engines are applicable controls for HAP reduction from existing stationary SI RICE. To determine the capital and annual costs for these control technologies, equipment cost information was obtained from industry groups[1] and vendors and manufacturers of SI engine control technology. In some cases, the industry groups provided a breakdown of the capital and annual cost components for each of the retrofit options. Using this cost data, annualized cost and capital cost equations for oxidation catalysts and NSCR were developed.

[1] Reciprocating Internal Combustion Engine National Emission Standards for Hazardous Air Pollutants (RICE NESHAP) Proposed Revisions – Emission Control Costs Analysis Background for "Above the Floor" Emission Controls for Natural Gas-Fired RICE, Innovative Environmental Solutions Inc., October 2009. (EPA-HQ-OAR-2008-0708-0279) .

3.0 CONTROL COST METHODOLOGY

The following sections describe the methodology used to derive the total capital and total annual costs for each of the control technology options. These methodologies were used to calculate total capital and total annual costs when only purchased equipment costs were available (e.g., vendor equipment costs). The methodologies were not used for cost data provided by industry groups because they included a breakdown of the actual total capital and total annual costs. A summary of the methodologies, equations, and assumptions used to estimate the total capital and total annual costs for some of the costs data are described in the following sections.

3.1 Total Capital Costs

The total capital cost includes the direct and indirect costs of purchasing and installing the control equipment. The direct cost includes the cost of purchasing the equipment and instrumentation, cost of shipping, and the cost of installing the control equipment. The indirect cost includes the costs for engineering, contractor fees, testing costs, and also includes costs for contingencies, such as additional modifications, or delays in startup. The total capital cost equation can be summarized as follows:

Total Capital Cost (TCC) = Direct Costs (DC) + Indirect Costs (IC)

The direct costs include the costs of purchasing and installing the control equipment and can be summarized using the following equation;

DC = Purchased Equipment Cost (PEC) + Direct Installation Costs (DIC).

A summary of the cost assumptions for PEC includes the following:

- Control Device and Auxiliary Equipment (EC);
- Instrumentation (10% of EC);
- Sales Tax (3% of EC);
- Freight (5% of EC);

and can be summarized as:

PEC = 118% EC.

A summary of the cost assumptions for DIC includes the following:

- Foundations and Supports (8% of PEC);
- Handling and Erection (14% of PEC);
- Electrical (4% of PEC);
- Piping (2% of PEC);
- Insulation for Ductwork (1% of PEC);

NMED Exhibit 63 - 0002

- Painting (1% of PEC);

and can be summarized as:

DIC = 30% PEC = 0.3 PEC.

Therefore, the direct costs can be simplified using the following equation:

DC = PEC + 0.3 PEC = 1.3 PEC.

The indirect costs include the costs of engineering and contractor fees and contingencies and can be summarized using the following equation:

IC = Indirect Installation Costs (ICC) + Contingencies (C).

A summary of the cost assumptions for ICC includes the following:

- Engineering (10% of PEC);
- Construction and Field Expenses (5% of PEC);
- Contractor Fees (10% of PEC);
- Startup (2% of PEC);
- Performance Test (1% of PEC);

and can be summarized as:

IIC = 28% PEC = 0.28 PEC.

A summary of the cost assumptions for C includes the following:

- Equipment Redesign and Modifications;
- Cost Escalations;
- Delays in Startup;

and is assumed to be:

C = 3% PEC = 0.03 PEC.

Therefore, the IC can be summarized using the following equation:

IC = 0.28 PEC + 0.03 PEC = 0.31 PEC,

and the simplified TCC equation can be expressed as:

TCC = 1.3 PEC + 0.31 PEC = 1.61 PEC = 1.61 (1.18 EC) = 1.9 EC

NMED Exhibit 63 - 0003

3.2 Total Annual Costs

The total annual cost includes the direct and indirect annual costs of operating and maintaining the control equipment. The direct annual cost includes the cost of the utilities, operating labor, and control device cleaning and maintenance. The indirect annual cost includes the overhead costs such as spare parts for the control equipment, administrative charges, and the capital recovery of the control technology. The total annual cost equation can be summarized as follows:

Total Annual Cost (TAC) = Direct Annual Costs (DAC) + Indirect Annual Costs (IAC).

The DAC includes the following parameters:

- Utilities;
- Operating Labor;
- Maintenance;
- Annual Compliance Test;
- Catalyst Cleaning;
- Catalyst Replacement;
- Catalyst Disposal.

The IAC includes the following parameters:

- Overhead;
- Fuel Penalty;
- Property Tax;
- Insurance;
- Administrative Charges;
- Capital Recovery = $\{I(1+I)^n/((1+I)^n-1)*TCC\}$ where I is the interest rate, and n is the equipment life.

To calculate DAC, the costs were broken up into three separate costs: operation and maintenance materials cost, operation and maintenance labor cost, and the cost for annual performance testing or downtime or allowance for catalyst washing. Actual annual cost data from the industry groups were used to estimate the DAC for each of the control technologies. The IAC was broken up into three separate costs: administrative, fuel penalty, and capital recovery. Again, cost data from the industry groups was used to estimate these costs for each of the control technologies. No fuel penalty was estimated for the oxidation catalyst control technologies, because this control technology does not increase the fuel usage of the SI engine.

NMED Exhibit 63 - 0004

4.0 CONTROL COST EQUATIONS

Control cost equations were developed for 2SLB oxidation catalyst, 4SLB oxidation catalyst, and a NSCR for 4SRB engines using the total capital cost and total annual cost data for each control technology. Control cost equations for 2SLB and 4SLB oxidation catalysts were developed separately because the 2SLB oxidation catalyst requires a premium catalyst to reduce the HAP compounds because of the low exhaust temperature of 2SLB engines.

4.1 2SLB Oxidation Catalyst

The 2SLB oxidation catalyst is an effective control technology that reduces HAP emissions from a 2SLB SI engine by oxidizing organic compounds using a catalyst. The oxidation catalyst unit contains a honeycomb-like structure or substrate with a large surface area that is coated with a premium active catalyst layer, such as, platinum or palladium. The oxidation catalyst works by oxidizing carbon monoxide (CO) and gaseous hydrocarbons (HAP) in the exhaust gas to carbon dioxide (CO_2) and water. The reduction of CO and HAP varies depending on the type of catalyst used and the exhaust temperature of the pollutant stream.

The cost of retrofitting an oxidation catalyst to an existing 2SLB engine was estimated using cost data obtained from vendors and industry groups covering engines ranging from 58 horsepower (HP) to 4,670 HP. An equipment life of 10 years and an interest rate of 7 percent were used to estimate the capital recovery of the control technology and the fuel penalty was assumed to be negligible. The cost equations are presented in 2009 dollars.

The total annualized cost equation for retrofitting an oxidation catalyst on a 2SLB engine was estimated to be:

$$\text{2SLB Oxidation Catalyst Total Annual Cost} = \$11.4 \times HP + \$13{,}928$$

where;

HP = engine size in HP.

The linear equation has a correlation coefficient of 0.8046, which shows the data fits the equation closely. Therefore, this equation was used to estimate annualized cost for an oxidation catalyst on a 2SLB engine.

The total capital cost equation for retrofitting an oxidation catalyst on a 2SLB engine was estimated to be:

$$\text{2SLB Oxidation Catalyst Total Capital Cost} = \$47.1 \times HP + \$41{,}603$$

where;

HP = engine size in HP.

NMED Exhibit 63 - 0005

A summary of the cost calculations, regression analyses, and graphical representations of the annual and capital cost data are presented in Appendix A.

4.2 4SLB Oxidation Catalyst

The 4SLB oxidation catalyst is an effective control technology that reduces HAP emissions from a 4SLB SI engine by oxidizing organic compounds using a catalyst. The oxidation catalyst unit contains a honeycomb-like structure or substrate with a large surface area that is coated with a premium active catalyst layer, such as, platinum or palladium. The oxidation catalyst works by oxidizing CO and gaseous hydrocarbons (HAP) in the exhaust gas to CO_2 and water. The reductions of CO and HAP vary depending on the type of catalyst used and the exhaust temperature of the pollutant stream.

The cost of retrofitting an oxidation catalyst to an existing 4SLB engine was estimated using cost data obtained from vendors and industry groups covering engines ranging from 400 HP to 8,000 HP. Again, an equipment life of 10 years and an interest rate of 7 percent were used to estimate the capital recovery of the control technology and the fuel penalty was assumed to be negligible. The cost equations are presented in 2009 dollars.

The total annualized cost equation for retrofitting an oxidation catalyst on a 4SLB engine was estimated to be:

4SLB Oxidation Catalyst Total Annual Cost = $1.81 x HP + $3,442

where;

HP = engine size in HP.

The linear equation has a correlation coefficient of 0.9779, which shows the data fits the equation very closely. Therefore, this equation was used to estimate annualized cost for an oxidation catalyst on a 4SLB engine.

The total capital cost equation for retrofitting an oxidation catalyst on a 4SLB SI engine was estimated to be:

4SLB Oxidation Catalyst Total Capital Cost = $12.8 x HP + $3,069

where;

HP = engine size in HP.

A summary of the cost calculations, regression analyses, and graphical representations of the annual and capital cost data are presented in Appendix A.

NMED Exhibit 63 - 0006

4.3 Non-Selective Catalytic Reduction

The NSCR or three-way catalyst is used to control HAP emissions from 4SRB engines. In addition to HAP reductions, NSCR also reduces the emissions of nitrogen oxides (NO_x), CO, and other hydrocarbons (HC). The reduction of HAP and CO takes place through an oxidation reaction that converts HAP to CO_2 and water and converts CO to CO_2. The conversion of NO_x takes place through a reduction of the NO_x to nitrogen gas and oxygen.

The cost of retrofitting an NSCR on an existing 4SRB engine was estimated based on cost data received from vendors and industry groups. A linear regression analysis was done on the data set and the linear equation for annualized cost was;

$$\text{NSCR Annual Cost} = \$4.77 \times HP + \$5{,}679$$

where;

HP = engine size in HP.

The linear equation has a correlation coefficient of 0.7987, which shows an acceptable representation of the cost data. Therefore, this equation was used to estimate annualized cost for retrofitting the NSCR control technology on 4SRB engines.

The capital cost equation for retrofitting an air-to-fuel ratio (AFR) controller and NSCR on a 4SRB engine was estimated to be:

$$\text{NSCR Capital Cost} = \$24.9 \times HP + \$13{,}118$$

where;

HP = engine size in HP.

A summary of the cost calculations, regression analyses, and graphical representations of the annual and capital cost data are presented in Appendix A.

NMED Exhibit 63 - 0007

5.0 SUMMARY

The following table presents a summary of the annual and capital control costs as a function of engine size for the control technologies applicable to existing stationary SI engines, as discussed in this memorandum.

Table 1. Summary of Annual and Capital Costs Equations for Existing Stationary SI Engines

HAP Control Device	Annual Cost ($2009)	Capital Cost ($2009)
2SLB Oxidation Catalyst	$11.4 x HP + $13,928	$47.1 x HP + $41,603
4SLB Oxidation Catalyst	$1.81 x HP + $3,442	$12.8 x HP + $3,069
NSCR	$4.77 x HP + $5,679	$24.9 x HP + $13,118

Wet Seal Degassing Recovery System for Centrifugal Compressors

Technology/Practice Overview

Description

Centrifugal compressors are used throughout the natural gas industry to compress gas for processing, movement through pipelines, and other needs. These compressors require seals around the rotating shaft to prevent high pressure gases from escaping where the shaft exits the compressor casing. Seals may be either wet seals using oil as a barrier or dry seals that use a mechanical barrier with most new compressors equipped with dry seal. However, there are a large number of centrifugal compressors with wet seals in operation. Wet seals use specialty oil which is circulated under higher pressure than the gas in the adjacent compressor case, between rings around the compressor shaft, forming a barrier against the compressed gas leakage. In the wet seal design shown in Exhibit 1, the center ring is attached to the rotating shaft, while the two rings on each side are stationary in the seal housing, pressed against a thin film of oil flowing between the rings to both lubricate and act as a leak barrier. "O-ring" rubber seals prevent leakage around the stationary rings. Very little gas escapes through the oil barrier; considerably more gas is entrained in the oil that comes in direct contact with the high pressures gas at the "inboard" (compressor side) interface, thus contaminating the seal oil. Prior to recirculation, seal oil must be purged of natural gas (which is primarily methane) in a process called seal oil "degassing." Methane released during degassing is commonly vented to the atmosphere with vent outlets usually located in elevated areas that are not easily accessible to operators for inspection or maintenance (e.g., roof vent stacks). As a result, the majority of methane emissions from a centrifugal compressor often go undetected by operators.

[1] *At each gas price, the costs and savings are for one and four compressors at a station.*

Wet Seal Degassing Recovery System for Centrifugal Compressors

Exhibit 1: A typical wet seal setup, the seal oil enters through the inlet (top) and provides a barrier to gas attempting to escape by forming two thin films under higher pressure between the center rotating ring and the two stationary rings (seen with surrounding o-rings).

One Partner has reduced methane emissions from centrifugal compressor seal oil degassing by separating gas from seal oil in a small separator/disengagement vessel and routing it back into the compressor suction, to high pressure turbine fuel gas, or to low pressure fuel gas for heaters/burners. A diagram illustrating this partner's approach is shown in Exhibit 2. Seal oil with entrained gas is typically routed directly to an atmospheric pressure degassing tank from which disengaged gas is vented to the atmosphere. In the capture system, the contaminated seal oil is instead separated from entrained gas in a separator operating at seal oil pressure with gas flow control by a critical orifice. The entrained gas captured from the seal oil is

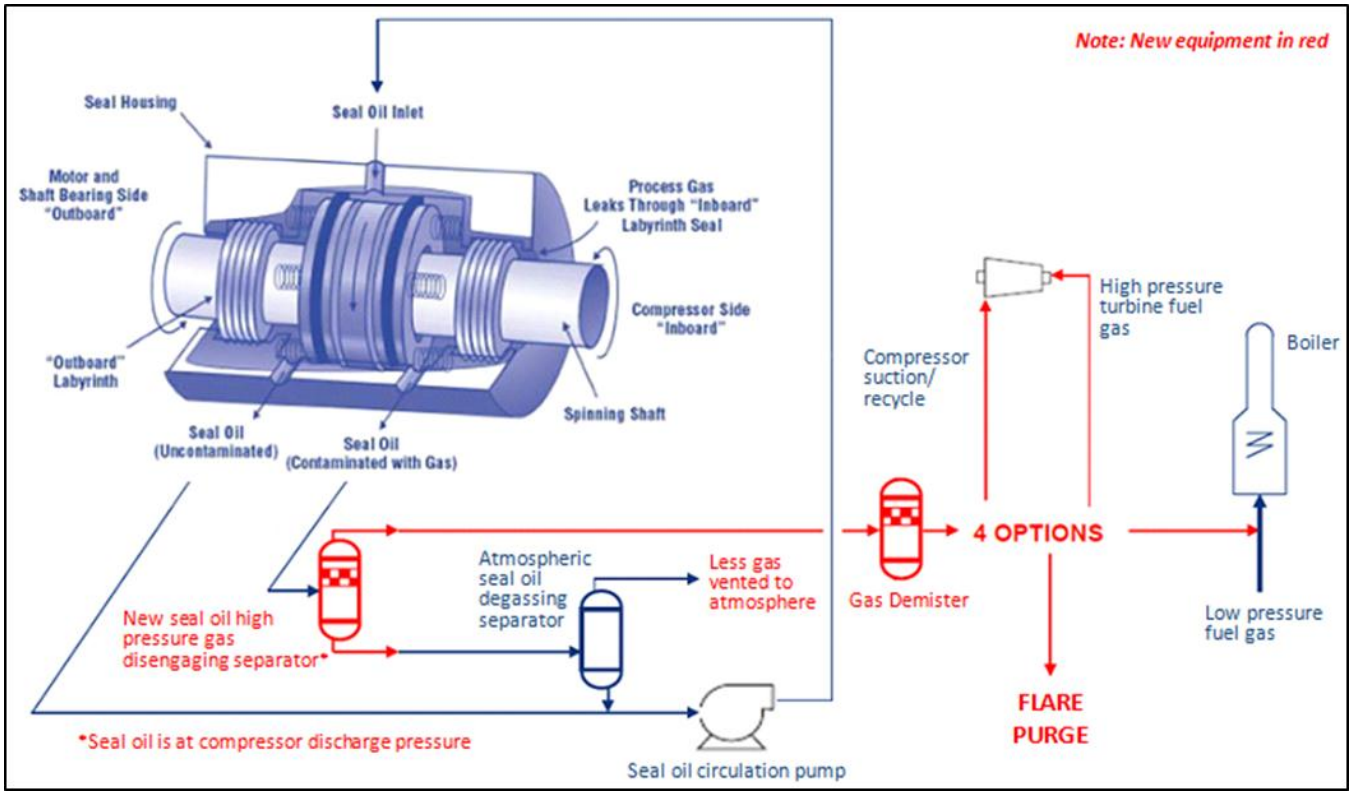

Exhibit 2: General process flow of wet seal degassing recovery system. Existing equipment is shown in blue or black and new equipment for seal oil degassing recovery is shown in red.

NMED Exhibit 65 - 0002

routed to a seal oil demister to remove entrained seal oil before routing to beneficial use. The seal oil then flows from the bottom of the seal oil degassing separator to the atmospheric degassing separator where the remaining minimal volume of entrained/dissolved gas is removed and vented to the atmosphere. The regenerated seal oil is then recirculated back to the compressor seal oil system.

Operating Requirements

In order to implement this recovery and use of gas separated from seal oil there must be a use for the recovered gas. Operators may configure the wet seal degassing recovery system to route the recovered gas as low pressure heater/boiler fuel (approximately 50 pounds per square inch gauge [psig]), high pressure turbine fuel (approximately 250 psig), to compressor suction, flare sweep gas, or any combination of the four options. One Partner has configured their wet seal degassing recovery systems to route recovered gas from multiple centrifugal compressors to all four of these choices. If routed to fuel gas use, the small amount of entrained seal oil mist in the gas stream from the new seal oil high pressure gas disengagement separator (shown in red in Exhibit 2 above) requires a demister/filter knock-out vessel (s) be installed to remove residual oil.

Applicability

Wet seal degassing recovery systems could be installed at most locations with wet seal centrifugal compressors, particularly in lieu of retrofitting compressors with dry seals. Retrofitting wet seal centrifugal compressors with dry seals is not always feasible due to operating conditions/requirements, substantial costs, and compressor downtime. Wet seal degassing recovery systems offer an economic alternative to installing dry seals to mitigate methane emissions from wet seal degassing with very little downtime.

Methane Emissions

According to previous measurements of seal oil degassing reported in Bylin, et al. (2009), emissions from degassing centrifugal compressor seal oil can be as high as 185 standard cubic feet per minute (scfm) (5.2 cubic meters (m3) per minute) of gas per compressor, with an average value of 63 scfm (1.8 m3 per minute) of gas per compressor. Gas volume from degassing centrifugal compressor seal oil varies primarily due to: the number of seals per centrifugal compressor, the rate of seal oil circulation, the size of the compressor, and the compressor discharge pressure. One Partner currently operates wet seal degassing recovery systems that recover 99 percent of the degassing emissions from fifteen centrifugal compressors – four low pressure compressors, nine high pressure compressors, and two tandem compressors at one facility. Based on a study conducted at this particular facility, the wet seal gas recovery system captures 3,300 scfm of gas; that equates to 1.6 billion cubic feet (Bcf) of gas per year (8,500 hours of operation per year as indicated by the Partner). This Partner reports another approximately 85 wet seal centrifugal compressors with the same or similar seal oil gas recovery systems in this particular operation.

Economic Analysis

The analysis for installing a wet seal degassing recovery system should consider the capital and operational costs along with the revenue generated by recovered gas. As shown in the overview table (Economic and Environmental Benefits) above, the economics for recovering wet seal degassing losses are compelling at even low gas prices. The detailed economic analysis in Exhibit 3 below presents two scenarios. The first scenario depicts the wet seal degassing recovery system installed for one centrifugal compressor, and the second scenario illustrates a wet seal degassing recovery system installed at a centrifugal compressor station with four centrifugal compressors. These examples are based on one Partner's emissions measurements, savings, and installed equipment costs which have high pressure gas disengagement separators on each seal of 15 compressors, with one recovered gas two stage filter/demister system.

Capital Costs

The investment per compressor to recover seal oil degassing emissions using this technology includes the cost of a high pressure seal oil gas disengagement separator for each compressor seal or pair of seals operating at the same seal oil pressure, new piping, the appropriate pressure and flow controls, and the labor to design and install the equipment. Operating and maintenance (O&M) costs are expected to be minimal. The investment per station to condition the recovered degassing emissions for injection into a low pressure fuel system would include the cost of a gas demister to remove residual seal oil from the recovered gas. If the recovered gas is routed to a higher pressure turbine fuel system, a second seal oil high efficiency filter/separator

NMED Exhibit 65 - 0003

is likely required to ensure all remaining seal oil mist is removed.

The capital cost (estimated) for each separator includes the purchase cost of the process vessel, piping, instrumentation, structural support, electrical, painting, shipping, insurance, and installation. Exhibit 3 summarizes the estimated capital costs for each piece of equipment installed in a wet seal degassing recovery system.

design pressure of 720 psig. The cost for a seal oil single-stage demister/filter system designed for a single centrifugal compressor or a compressor station with four centrifugal compressors is $9,000.

If any of the recovered gas is being used as high pressure turbine fuel, the recovery system may include a second seal oil gas high-efficiency filter to ensure trace amounts of seal oil do not foul the turbine fuel injectors. This economic analysis assumes the seal oil gas filter

Exhibit 3: Wet Seal Degassing Recovery System Installation and Equipment Costs

Equipment	One Centrifugal Compressor Capital Cost ($2011)	Centrifugal Compressor Station Capital Cost ($2011)
Seal-Oil/Gas Separator [1]	$19,000	$76,000
Seal Oil Gas Demister – Low Quality Gas	$9,000	$9,000
Seal Oil Gas Demister – High Quality Gas	$5,000	$5,000
Total	**$33,000**	**$90,000**

[1] *Assuming two seals per centrifugal compressor and four centrifugal compressors at the station. An individual high pressure seal oil gas separator costs $9,500 per seal.*

High Pressure Seal Oil Gas Disengagement Separators

For each centrifugal compressor connected to the wet seal degassing recovery system, a seal oil gas separator will be installed for each seal or pair of seals if operating at the same seal oil pressure. The seal oil gas separators can be designed to operate at the same pressure as the seal oil exiting the seal housing. Based on a Partner's installation, the size of these separators assumes 1-foot diameter, 3-foot height seal oil gas separators with a 1,125 psig design pressure and made of carbon steel. The total cost of each seal oil gas separator is $9,500; assuming two seal-oil/gas separators per compressor, the total cost per compressor is $19,000.

Seal Oil Recovered Gas Demister/Filter

Before the recovered gas can be sent to a fuel line it must pass through at least one high-efficiency demister to remove entrained seal oil that may foul burners and potentially clog fuel injectors. The seal oil gas demister can be designed to receive recovered gas from multiple centrifugal compressors with wet seals. Therefore, the design characteristics of this vessel will vary depending on the number of centrifugal compressors connected to the vessel. Based on a Partner's installation, this economic analysis assumes, for a single centrifugal compressor, the seal oil gas demister will be vertical and have a 1-foot diameter and 4-foot height with a

for turbine fuel quality gas will be vertical and have a 1-foot diameter and 3-foot height with a design pressure of 300 psig and be made of carbon steel. The cost for the second seal oil high-efficiency filter for a single centrifugal compressor or a compressor station is $5,000.

Piping and Instrumentation

Operators will need to route seal oil exiting the compressor seal to the new seal-oil/gas separator and then to the degassing tank which will require piping modifications. Additionally, pipes and valves to transport the recovered gas from the seal oil gas disengagement separators to the seal oil gas demister/filters and further to the fuel gas, compressor suction or flare line(s) will be required. Pressure and flow controls will also need to be installed to regulate the pressure and flow of the recovered gas from each high pressure seal oil degassing separator. In this Partner's installations this is accomplished with a critical orifice (1/16 inch/1.59 mm) on the gas outlet from each seal-oil/gas separator which restricts gas flow using choke flow effects. For example, this Partner has set up the wet seal degassing recovery system to route captured gas to a high pressure turbine fuel line, low pressure process heater fuel line, and flare purge which requires additional instrumentation and flow control. The majority of the gas is routed to the high pressure

NMED Exhibit 65 - 0004

turbine fuel line with excess gas routed to the low pressure process heater fuel line or flare, depending on fuel requirements. The piping and instrumentation costs are included in the installation and capital costs for each individual piece of equipment listed in Exhibit 3.

Estimated Savings

The savings for capturing seal oil degassing emissions are realized by generating additional gas sales and revenue through using recovered gas for site fuel gas or recycling directly to suction and sales or processing. Based on the measurement studies discussed in Bylin, et al. (2009), the average methane emissions from centrifugal compressor wet seal degassing is 63 scfm (1.8 m3 per minute) of gas per compressor. Assuming 8,000 hours of operation per year, the total gas emissions per year is 30 million cubic feet (MMcf) per compressor. Based on one Partner's experience, over 99 percent of the entrained gas in the seal oil was captured and used as fuel – proving this technology performs as well as dry seal systems from an emission perspective. This analysis assumes 99 percent of the potential degassing emissions are captured and 1 percent is vented. Therefore, 30 MMcf of gas is recovered per centrifugal compressor and displaces the same volume in fuel gas or is routed to compressor suction and sales. At $3.00 per thousand cubic feet (Mcf), savings from reduced fuel gas consumption is estimated to be $90,000 per year per centrifugal compressor connected to a wet seal degassing recovery system. A station with four centrifugal compressors connected to a wet seal degassing recovery system could potentially generate $360,000 per year of additional revenue.

Comparing Costs to Savings

The economics of implementing a wet seal degassing recovery system is shown below using a five-year cash flow table. This analysis presented in Exhibit 4 and Exhibit 5 considers capital costs and methane emissions savings. The capital and installation costs in this economic analysis assume the operator installs both the seal oil gas demister/filter separator for low pressure fuel gas and seal oil gas high efficiency filter for high pressure turbine fuel gas, which will allow the operator to route to a flare, low pressure burner, or turbine fuel line. Exhibit 3 shows the detailed breakdown of the equipment and capital cost used in this economic analysis. It is important to note that all analyses will be highly site-specific, but the economics of installing a wet

Exhibit 4: Wet Seal Degassing Recovery System Costs and Savings for One Compressor

Costs and Savings ($)	Year 0	Year 1	Year 2	Year 3	Year 4	Year 5
Wet seal recovery system capital & installation costs	($33,000)					
Annual natural gas savings ($3.00/Mcf of Methane)		$90,000	$90,000	$90,000	$90,000	$90,000
						NPV (Net Present Value) = $280,000
						IRR (Internal Rate of Return) = 270%
						Payback Period = 5 months

Exhibit 5: Wet Seal Degassing Recovery System Costs and Savings for Four Compressors at a Station

Costs and Savings ($)	Year 0	Year 1	Year 2	Year 3	Year 4	Year 5
Wet seal recovery system capital & installation costs	($90,000)					
Annual natural gas savings ($3.00/Mcf of Methane)		$360,000	$360,000	$360,000	$360,000	$360,000
						NPV (Net Present Value) = $1,200,000
						IRR (Internal Rate of Return) = 400%
						Payback Period = 3 months

seal gas recovery system are so attractive that companies should consider implementing this technology at any and all facilities with at least one centrifugal compressor with wet seals.

Exhibit 4 presents the economics of installing a wet seal degassing recovery system for a single centrifugal compressor. Exhibit 5 presents the economics of installing a wet seal degassing recovery system at a station with four centrifugal compressors. The net present value and payback period are calculated using a 10 percent discount rate.

Operational Reliability

The Partner reporting the seal oil degassing systems reports them being in place with constant use since 1977 and no failures due to the degassing systems. With about 100 such systems installed and operating from very low pressures to very high pressures across a range of gas compositions, the operational reliability of seal oil degassing systems has been clearly demonstrated.

Discussion

A wet seal oil degassing recovery system is likely to provide the lowest cost for retrofit with the quickest payback for compressor stations, offshore production platforms or gas processing plants with single or multiple wet seal centrifugal compressors. All options pay back in less than a year. The economics are compelling, but the installation may require a brief shut-down of each compressor to tie the seal oil circulation piping into the new gas disengagement vessels. New facilities requiring the installation of wet seal centrifugal compressors can also integrate wet seal degassing recovery systems into their process design at the same costs. As demonstrated by a Partner facility, wet seal degassing recovery systems are highly effective at capturing degassing emissions from wet seal centrifugal compressors and subsequently reducing fuel gas purchases and/or increasing gas sales with a high rate of return.

METHOD 22—VISUAL DETERMINATION OF FUGITIVE EMISSIONS FROM MATERIAL SOURCES AND SMOKE EMISSIONS FROM FLARES

NOTE: This method is not inclusive with respect to observer certification. Some material is incorporated by reference from Method 9.

1.0 Scope and Application

This method is applicable for the determination of the frequency of fugitive emissions from stationary sources, only as specified in an applicable subpart of the regulations. This method also is applicable for the determination of the frequency of visible smoke emissions from flares.

2.0 Summary of Method

2.1 Fugitive emissions produced during material processing, handling, and transfer operations or smoke emissions from flares are visually determined by an observer without the aid of instruments.

2.2 This method is used also to determine visible smoke emissions from flares used for combustion of waste process materials.

2.3 This method determines the amount of time that visible emissions occur during the observation period (*i.e.*, the accumulated emission time). This method does not require that the opacity of emissions be determined. Since this procedure requires only the determination of whether visible emissions occur and does not require the determination of opacity levels, observer certification according to the procedures of Method 9 is not required. However, it is necessary that the observer is knowledgeable with respect to the general procedures for determining the presence of visible emissions. At a minimum, the observer must be trained and knowledgeable regarding the effects of background contrast, ambient lighting, observer position relative to lighting, wind, and the presence of uncombined water (condensing water vapor) on the visibility of emissions. This training is to be obtained from written materials found in References 1 and 2 or from the lecture portion of the Method 9 certification course.

3.0 Definitions

3.1 *Emission frequency* means the percentage of time that emissions are visible during the observation period.

3.2 *Emission time* means the accumulated amount of time that emissions are visible during the observation period.

3.3 *Fugitive emissions* means emissions generated by an affected facility which is not collected by a capture system and is released to the atmosphere. This includes emissions that (1) escape capture by process equipment exhaust hoods; (2) are emitted during material transfer; (3) are emitted from buildings housing material processing or handling equipment; or (4) are emitted directly from process equipment.

3.4 *Observation period* means the accumulated time period during which observations are conducted, not to be less than the period specified in the applicable regulation.

3.5 *Smoke emissions* means a pollutant generated by combustion in a flare and occurring immediately downstream of the flame. Smoke occurring within the flame, but not downstream of the flame, is not considered a smoke emission.

4.0 Interferences

4.1 Occasionally, fugitive emissions from sources other than the affected facility (*e.g.*, road dust) may prevent a clear view of the affected facility. This may particularly be a problem during periods of high wind. If the view of the potential emission points is obscured to such a degree that the observer questions the validity of continuing observations, then the observations shall be terminated, and the observer shall clearly note this fact on the data form.

5.0 Safety

5.1 Disclaimer. This method may involve hazardous materials, operations, and equipment. This test method may not address all of the safety problems associated with its use. It is the responsibility of the user of this test method to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to performing this test method.

6.0 Equipment

6.1 Stopwatches (two). Accumulative type with unit divisions of at least 0.5 seconds.

6.2 Light Meter. Light meter capable of measuring illuminance in the 50 to 200 lux range, required for indoor observations only.

7.0 Reagents and Supplies [Reserved]

8.0 Sample Collection, Preservation, Storage, and Transfer [Reserved]

9.0 Quality Control [Reserved]

10.0 Calibration and Standardization [Reserved]

11.0 Analytical Procedure

11.1 Selection of Observation Location. Survey the affected facility, or the building or structure housing the process to be observed, and determine the locations of potential emissions. If the

affected facility is located inside a building, determine an observation location that is consistent with the requirements of the applicable regulation (*i.e.,* outside observation of emissions escaping the building/structure or inside observation of emissions directly emitted from the affected facility process unit). Then select a position that enables a clear view of the potential emission point(s) of the affected facility or of the building or structure housing the affected facility, as appropriate for the applicable subpart. A position at least 4.6 m (15 feet), but not more than 400 m (0.25 miles), from the emission source is recommended. For outdoor locations, select a position where the sunlight is not shining directly in the observer's eyes.

11.2 Field Records.

11.2.1 Outdoor Location. Record the following information on the field data sheet (Figure 22-1): Company name, industry, process unit, observer's name, observer's affiliation, and date. Record also the estimated wind speed, wind direction, and sky condition. Sketch the process unit being observed, and note the observer location relative to the source and the sun. Indicate the potential and actual emission points on the sketch. Alternatively, digital photography as described in section 11.2.3 may be used for a subset of the recordkeeping requirements of this section.

11.2.2 Indoor Location. Record the following information on the field data sheet (Figure 22-2): Company name, industry, process unit, observer's name, observer's affiliation, and date. Record as appropriate the type, location, and intensity of lighting on the data sheet. Sketch the process unit being observed, and note the observer location relative to the source. Indicate the potential and actual fugitive emission points on the sketch. Alternatively, digital photography as described in section 11.2.3 may be used for a subset of the recordkeeping requirements of this section.

11.2.3 Digital Photographic Records. Digital photographs, annotated or unaltered, may be used to record and report sky conditions, observer's location relative to the source, observer's location relative to the sun, process unit being observed, potential emission points and actual emission points for the requirements in sections 11.2.1 and 11.2.2. The image must have the proper lighting, field of view and depth of field to properly distinguish the sky condition (if applicable), process unit, potential emission point and actual emission point. At least one digital photograph must be from the point of the view of the observer. The photograph(s) representing the environmental conditions including the sky conditions and the position of the sun relative to the observer and the emission point must be taken within a reasonable time of the observation (*i.e.,* 15 minutes). When observations are taken from exactly the same observation point on a routine basis (*i.e.,* daily) and as long as there are no modifications to the units depicted, only a single photograph each is necessary to document the observer's location relative to the emissions source, the process unit being observed, and the location of potential and actual emission points. Any photographs altered or annotated must be retained in an unaltered format for recordkeeping purposes.

11.3 Indoor Lighting Requirements. For indoor locations, use a light meter to measure the level of illumination at a location as close to the emission source(s) as is feasible. An illumination of greater than 100 lux (10 foot candles) is considered necessary for proper application of this method.

11.4 Observations.

11.4.1 Procedure. Record the clock time when observations begin. Use one stopwatch to monitor the duration of the observation period. Start this stopwatch when the observation period begins. If the observation period is divided into two or more segments by process shutdowns or observer rest breaks (see section 11.4.3), stop the stopwatch when a break begins and restart the stopwatch without resetting it when the break ends. Stop the stopwatch at the end of the observation period. The accumulated time indicated by this stopwatch is the duration of observation period. When the observation period is completed, record the clock time. During the observation period, continuously watch the emission source. Upon observing an emission (condensed water vapor is not considered an emission), start the second accumulative stopwatch; stop the watch when the emission stops. Continue this procedure for the entire observation period. The accumulated elapsed time on this stopwatch is the total time emissions were visible during the observation period (*i.e.*, the emission time.)

11.4.2 Observation Period. Choose an observation period of sufficient length to meet the requirements for determining compliance with the emission standard in the applicable subpart of the regulations. When the length of the observation period is specifically stated in the applicable subpart, it may not be necessary to observe the source for this entire period if the emission time required to indicate noncompliance (based on the specified observation period) is observed in a shorter time period. In other words, if the regulation prohibits emissions for more than 6 minutes in any hour, then observations may (optional) be stopped after an emission time of 6 minutes is exceeded. Similarly, when the regulation is expressed as an emission frequency and the regulation prohibits emissions for greater than 10 percent of the time in any hour, then observations may (optional) be terminated after 6 minutes of emission are observed since 6 minutes is 10 percent of an hour. In any case, the observation period shall not be less than 6 minutes in duration. In some cases, the process operation may be intermittent or cyclic. In such cases, it may be convenient for the observation period to coincide with the length of the process cycle.

11.4.3 Observer Rest Breaks. Do not observe emissions continuously for a period of more than 15 to 20 minutes without taking a rest break. For sources requiring observation periods of greater than 20 minutes, the observer shall take a break of not less than 5 minutes and not more than 10 minutes after every 15 to 20 minutes of observation. If continuous observations are desired for extended time periods, two observers can alternate between making observations and taking breaks.

11.5 Recording Observations. Record the accumulated time of the observation period on the data sheet as the observation period duration. Record the accumulated time emissions were observed on the data sheet as the emission time. Record the clock time the observation period began and ended, as well as the clock time any observer breaks began and ended.

12.0 Data Analysis and Calculations

If the applicable subpart requires that the emission rate be expressed as an emission frequency (in percent), determine this value as follows: Divide the accumulated emission time (in seconds)

by the duration of the observation period (in seconds) or by any minimum observation period required in the applicable subpart, if the actual observation period is less than the required period, and multiply this quotient by 100.

EXECUTIVE SUMMARY

This study provides estimates of criteria air pollutant and greenhouse gas emissions for oil and gas (O&G) exploration and production operations in the Western States Air Resources Council-Western Regional Air Partnership (WESTAR-WRAP) region for a 2014-2016 baseline period. This analysis was sponsored by the Western Regional Air Partnership Oil and Gas Working Group (WRAP OGWG).

The WESTAR-WRAP region consists of 15 states in the Western US, several of which have substantial O&G exploration and production activities. Accurate O&G emission inventories are critical for air quality, including regional haze planning. In 2014, O&G activity in the WESTAR-WRAP Region included close to 12,000 spuds, over 225,000 active O&G wells, over 9 trillion cubic feet of natural gas production, and over 1 billion barrels of oil production. Over 70% of active wells in the WESTAR-WRAP region in 2014 were vertical wells and over 75% of spuds were horizontal or directional wells, indicating a shift from development of vertical to horizontal and directional wells.

To develop the baseline 2014-2016 WESTAR-WRAP region emission inventory base year 2014 emissions were compiled from existing emission inventory sources (described in Section 2.1). Subsequent to compilation of the base year 2014 emission inventory, outreach was conducted to gather additional data from regulatory agencies and upstream O&G operators to enhance the emissions inventory and, to the extent that data was provided, make the inventory applicable to the 2014-2016 baseline period (described in Section 2.2). A survey data collection effort was used to collect new information to enhance emission inventory accuracy as part of the outreach effort. Survey data collection targeted specific equipment types, production areas, and operators that could substantially enhance the WESTAR-WRAP O&G emission inventory. The survey was first distributed to state agencies so that in-house agency data could be leveraged prior to asking O&G operators to provide survey data. After state agencies filled out the survey, it was distributed to O&G operators to fill remaining data gaps. O&G emissions from California are excluded from this analysis since California Air Resources Board is developing O&G emissions independently and results were not available for inclusion in this report.

Integrating the data collected as part of survey outreach into the 2014-2016 baseline emission inventory resulted in NOx emissions increases of 8% over the WESTAR-WRAP region compared the base year 2014 WRAP emission inventory. Hydraulic fracturing engine emissions accounted for 47% of nitrogen oxides (NOx) emission increases and emissions from artificial lift engines accounted for 38% of NOx emissions increases. Volatile organic compound (VOC) emissions decreased by 22% over the WESTAR-WRAP region based on integration of operator survey data into the inventory, primarily as a result of increases to oil tank control prevalence.

State-level WESTAR-WRAP region O&G emissions by state are presented in Table ES-1.

Table ES-1. WESTAR-WRAP region O&G emissions by state.

Pollutant	Criteria Air Pollutant Emissions (tons/yr) and Greenhouse Gas Emissions (1000 tons/yr)												
	AK	AZ	CO	ID	MT	ND	NM	NV	OR	SD	UT	WA	WY

The contents of the report by Chapter are summarized as follows:

- Chapter 1.0 provides introductory information on study methodology, scope, and O&G activity in the WESTAR-WRAP region;
- Chapter 2.0 describes the steps taken to compile the emission inventory based on reference inventories, agency submitted data, and survey responses;
- Chapter 3.0 presents summaries of baseline 2014-2016 emissions.

NMED Exhibit 68

1.0 INTRODUCTION

The WRAP OGWG is sponsoring the development of O&G emission inventories as part of efforts to support regional haze planning in the Western States Air Resources Council-Western Regional Air Partnership (WESTAR-WRAP) region. The O&G emission inventories developed under WRAP OGWG sponsorship will also facilitate other types of air quality planning (e.g., photochemical ozone modeling). More information about WRAP OGWG emission inventory development efforts may be found at the project webpage: https://www.wrapair2.org/ogwg.aspx.

This report describes the development of a criteria air pollutant and greenhouse gas (GHG) emissions inventory for O&G field operations in the WESTAR-WRAP region for a baseline 2014-2016 period, including point (midstream) and nonpoint (wellsite) sources. The baseline emissions inventory was compiled based on existing emission inventory sources and improvements based on collected survey data.

1.1 Scope

1.1.1 Sources

The emission inventory documented herein includes emissions from upstream and midstream O&G sources, consistent with the OGWG Road Map Scope of Work[1] and the OGWG Roadmap Phase I Report (Grant et al., 2018b). Downstream O&G emissions are not included. The baseline O&G emission inventory includes wellsite, gathering, and processing subsectors (items 1, 5, and 6 in Figure 1-1). Item 1) On-shore Petroleum and Natural Gas Production is referred to as "wellsite" sources; emissions from wellsite sources are typically classified as nonpoint sources[2]. Items 5) Gathering and Boosting and 6) Gas Processing Plant are collectively referred to as "midstream" sources; emissions from midstream sources are typically classified as point sources. The classification of well-site emissions as nonpoint and midstream emissions as point sources is consistent with O&G emission inventory classifications used in the WRAP Phase III study[3], West-wide Jumpstart Air Quality Modeling Study (WestJUMP AQMS)[4], 2011 Western Air Quality Study[5], and 2014 NEI methodology[6].

[1] https://www.wrapair2.org/pdf/11162017_WRAPO&GWorkgroup_RoadMapSOW.pdf

[2] There are exceptions; for example, several wellsite sources in the Uinta Basin are available by facility and will be included in emission inventories as point source emissions.

NMED Exhibit 68

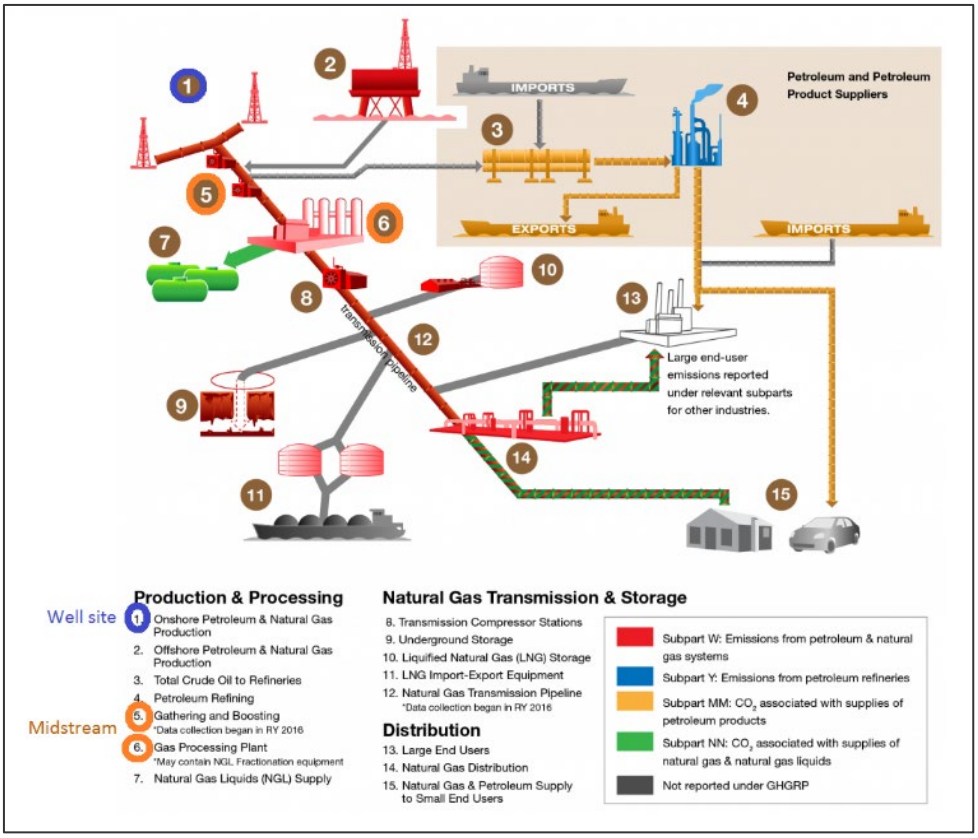

Figure 1-1. Example Petroleum and Natural Gas Industry schematic[7,8].

1.1.2 Geographical Scope

The WESTAR-WRAP region includes 15 states, several of which have substantial O&G production and generate substantial O&G emissions. Figure 1-2 shows major basins in the WESTAR-WRAP region. California O&G emissions are estimated by the California Air Resources Board and are not included herein. Several states have limited or zero O&G production and O&G sector emissions: Arizona, Hawaii, Idaho, Nevada, Oregon, South Dakota, and Washington. Emissions were estimated by county, distinguishing between tribal and non-tribal sources.

[7] Source: https://www.epa.gov/ghgreporting/ghgrp-and-oil-and-gas-industry

[8] This figure shows O&G subsectors for which emissions have been developed in this study. It is important to consider that Petroleum and Natural Gas Industry equipment is typically tailored to meet field, basin, and/or region-specific infrastructure requirements.

NMED Exhibit 68

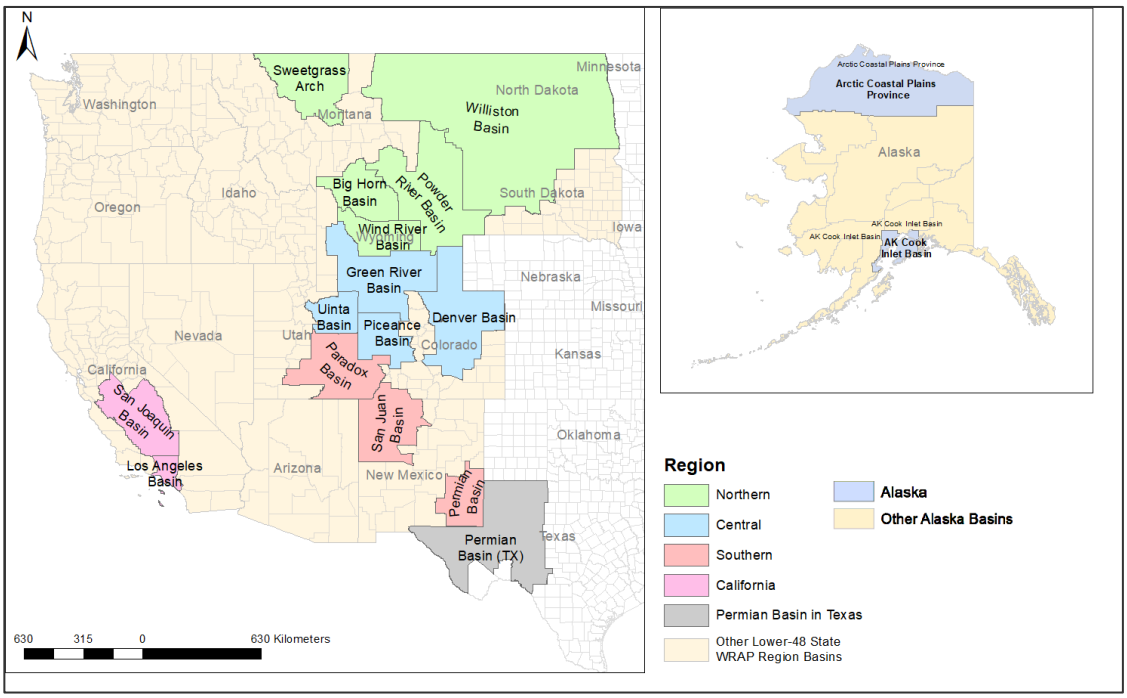

Figure 1-2. WESTAR-WRAP region, including major O&G basins.

1.1.3 Temporal Scope

The baseline emission inventory was developed with annual emissions for the baseline period 2014-2016. Base year 2014 emission inventories that were the basis of the emission inventory compilation were updated, to the extent that data was made available, to include updated 2014-2016 emission inventory inputs provided by regulatory agencies and O&G operators. In general, midstream facility emissions are derived from state and federal agency data for calendar year 2014. Wellsite input factors were developed for activities in calendar year 2014, with updates to input factors as described in Section 2.2. All well count and production data used to develop the emission inventory were obtained from the IHS Enerdeq database for calendar year 2014.

1.1.4 Pollutants

Emissions were estimated for the following pollutants;

- Nitrogen oxide (NOx)
- Volatile organic compounds (VOC)
- Carbon monoxide (CO)
- Particular matter less than 10 microns (PM_{10})
- Particulate matter less than 2.5 microns ($PM_{2.5}$)
- Sulfur oxides (SOx)
- Carbon dioxide (CO_2)
- Methane (CH_4)
- Nitrous oxide (N_2O)

1.2 Well Count and Production Data

Oil and gas related activity data were obtained from the IHS Enerdeq database[9] queried via online interface. The IHS Enerdeq database uses data from each state's Oil and Gas Conservation Commission (OGCC or equivalent) as sources of information for oil and gas activity. This data is also available directly through database querying tools maintained by the respective agencies. It was determined that the IHS database is more accurate and complete than the state databases. The IHS database was also used to develop emission inventories in the WRAP Phase III, WestJump AQMS, and IWDW studies. Therefore, the IHS database was chosen as the basis for O&G activity statistics for this analysis. Two types of data were queried from the Enerdeq database: production data and well data. Production data includes information relevant to producing wells while well data includes information relevant to drilling activity ("spuds") and completions.

Production data were obtained for all counties in the WRAP region as IHS "298" format data files. The "298" well data contain information regarding historical O&G production. The "298"well data were processed with a PERL script to develop a database by American Petroleum Institute (API)-number, well type (oil, gas, or coalbed methane; CBM), spud type (directional, horizontal, or vertical), annual gas production, oil production, and water production with latitude and longitude information.

The API number in the IHS database consists of 14 digits as follows:

- Digits 1 to 2: state identifier
- Digits 3 to 5: county identifier
- Digits 6 to 10: borehole identifier
- Digits 11 to 12: sidetracks
- Digits 13 to 14: event sequence code (recompletions)

Based on the expectation that the first 10 digits, which include geographic and borehole identifiers, would predict unique sets of well head equipment, the unique wells were identified by the first 10 digits of the API number.

Well data were also obtained from the IHS Enerdeq database for all WRAP region states as IHS "297" well data. The "297" well data contain information on spuds and completions. The "297" well data were processed with a PERL script to arrive at a database of by-API-number and spud type, spud and completion dates with latitude and longitude information. Drilling events in 2014 were identified by indication that the spud occurred within 2014. If the well API number indicated the well was a recompletion, it was not counted as a drilling event, but if the API number indicated the well was a sidetrack, it was counted as a drilling event.

O&G activity for the WRAP Region states is summarized in Table 1-1; details by basin, spud type and well types are available in the 2014 O&G activity spreadsheet[10].

[9] All data queried from IHS Enerdeq is subject to copyright protections

NMED Exhibit 68

2.0 METHODOLOGY

To develop the baseline 2014-2016 WESTAR-WRAP region emission inventory, first, base year 2014 emissions were compiled from existing emission inventory sources (described in Section 2.1). Subsequent to compilation of the base year 2014 emission inventory, outreach was conducted to gather additional data from regulatory agencies and upstream O&G operators to enhance the emissions inventory and, to the extent that data was provided, make the inventory applicable to the 2014-2016 baseline period (described in Section 2.2).

2.1 2014 WRAP OGWG Baseline O&G Emission Inventory version 1

Ramboll compiled a WESTAR-WRAP region 2014 base year O&G emission inventory version 1 (also referred to herein as the WRAP OGWG v1 emission inventory)[11] from the following emission inventories:

- 2014 Greater San Juan and Permian Basin Emission Inventory (Grant et al., 2018a)
- 2014 Intermountain West O&G Basin Emission Inventory (Parikh et al., 2017)
- Uinta Basin 2014 Air Agencies Oil and Gas Emissions Inventory (Utah Division of Air Quality [UDAQ], 2017)
- Colorado Department of Health and Environment (CDPHE) Denver Basin Emission Inventory (CDPHE, 2018)
- US Environmental Protection Agency (EPA) 2014 NEI O&G Inventory, version 2 (EPA, 2018)[12]

O&G emissions on tribal land in the above studies included nonpoint emissions which were based on tribe specific emissions only if they were provided directly by a tribe (e.g., Southern Ute Indian Tribe in Grant et al. [2018a]); otherwise, tribal nonpoint emissions were typically estimated by apportioning county-level emissions to tribal and non-tribal land based on O&G activity. For inventories that did not fully distinguish tribal from non-tribal sources, tribal and non-tribal splits were added by allocating emissions according to the fraction of O&G activity surrogates on and off tribal land in each county. Point source emissions on tribal lands consist of Part 71 sources and other minor sources (e.g., sources reported under the Tribal Minor New Source Rule) to the extent that each inventory included those emission sources.

Table 2-1 shows data sources by basin used to compile the version 1 emission inventory.

Table 2-1. Inventory data source by basin.

Basin	State	Reference
Greater San Juan	CO and NM	Grant et al. (2018a)
Permian	NM	Grant et al. (2018a)
Denver	CO	Parikh et al. (2017) and CDPHE (2018)
Uinta	UT	Parikh et al. (2017) and UDAQ (2017)
Piceance	CO	Parikh et al. (2017)
Paradox	CO	

[11] https://www.wrapair2.org/pdf/WESTAR_OGWG_Emissions_Inventory_2014_Webdistribution_081018.xlsx

[12] To extract emissions from the NEI, nonpoint emissions were extracted for all source classification (SCC) codes beginning with "2310". For point sources, O&G emissions were extracted for North American Industry Classification System (NAICS) codes: 2111, 4862, 21111, 48611, 48621, 211111,211112, 213111,213112, 486110, 486210.

NMED Exhibit 68

Basin	State	Reference
Raton	CO	
Big Horn	WY and MT	
Powder River	WY and MT	
Green River	WY	
Central Western Overthrust	WY	
Wind River	WY	
Williston	MT, ND and SD	
Sweetgrass Arch	MT	
Central Montana Uplift	MT	
Other Basins	All	EPA (2018)

Emission inventory data gaps were filled to ensure completeness, to the extent feasible according to the following:

- $PM_{2.5}$ emissions were not included in Grant et al. (2018a) and Parikh et al. (2017). $PM_{2.5}$ emissions were assumed equivalent to PM_{10} emissions taken from these reference sources.
- GHG emissions were not available in Parikh et al. (2017). GHG emissions were estimated by multiplying criteria air pollutant emissions for a given source category by a source category specific GHG to criteria air pollutant emissions mass ratio. For venting, fugitive, and tank sources, basin and well type specific GHG to VOC mass ratios available from the EPA O&G Tool were used. AP-42 process specific emission factors from the Greater San Juan and Permian Basin Inventory Study were used to estimate GHG to NOx emission ratios for combustion sources.

2.2 Survey Updates for 2014-2016 baseline inventory

As part of technical improvements to the WESTAR-WRAP O&G emission inventory, a survey data collection effort was used to collect new information to enhance emission inventory accuracy. Survey data collection targeted specific equipment types, production areas, and operators that could substantially enhance the WESTAR-WRAP O&G emission inventory. First, the survey was distributed to state agencies so that in-house agency data could be leveraged prior to asking O&G operators to provide survey data. After state agencies filled out the survey, it was distributed to O&G operators to fill remaining data gaps.

In this section survey results are applicable to baseline emission inventory updates are reported and integration into the baseline year inventory (also referred to herein as the WRAP OGWG v2 emission inventory) is described.

2.2.1 Survey Content

Survey content was decided upon in collaboration with the WRAP OGWG and focused on gathering information on several key O&G emissions source categories. Two surveys were developed, one survey requesting a complete set of inputs for each source category, and a second survey focused only on emission controls practices and technology related inputs. Each

NMED Exhibit 68

agency decided whether to distribute the survey to operators and if the operators would fill out the complete or controls-focused survey.

Table 2-2 shows the source categories and associated data requested in the survey. Several tabs in the survey request *representative* O&G equipment configuration and operation data. Survey respondents were instructed to provide *representative* data that, as accurately as feasible, reflects configuration(s) that represent a vast majority of activity in a given basin. The request for representative inputs is consistent with the estimation of upstream O&G emissions as nonpoint sources. Surveyed agencies and operators were also given the option to provide data files with individual configurations, in addition to, or in place of representative data. The O&G survey is available online: complete survey[13] and controls-focused survey[14].

Table 2-2. Survey Content

Source Category	Survey Data Fields
Upstream Exploration	
Drill Rigs	Spud type, well type, representative engine configuration (number, hours per spud, horsepower), engine age distribution, fleet turnover frequency
Hydraulic Fracturing Engines	Spud type, well type, representative engine configuration (number, hours per spud, horsepower), engine age distribution, fleet turnover frequency
Upstream Production	
Condensate Tanks	Spud type, VOC flashing emission rate, control type and prevalence, capture efficiency and basis, inspection type and frequency
Oil Tanks	Spud type, VOC flashing emission rate, control type and prevalence, capture efficiency and basis, inspection type and frequency
Wellhead Engines	Spud type, well type, number of engines per well by function (compressor, artificial lift, etc.), representative engine configuration (number, hours per spud, horsepower), engine age distribution
Gas Composition	
Produced Gas	Extended gas composition by spud type and/or well type.
Flash Gas Composition	Extended gas composition by spud type and/or well type

2.2.2 Survey Distribution and Collection

The survey was first provided to WRAP OGWG member state agencies. State agencies reviewed the survey and, if available, provided in-house agency data responses. State agencies determined whether they would distribute the survey to operators, and if so, whether to distribute the complete or controls-focused survey. Subsequently, the survey was distributed by agencies to select operators. Operators were responsible for contacting their drilling, hydraulic fracturing, etc. contractors to obtain relevant survey data.

[13] https://www.wrapair2.org/pdf/WRAP_OGWG_Survey_SelectSrc_08Jan2019.xlsx

[14] https://www.wrapair2.org/pdf/WRAP_OGWG_Survey_ControlsOnly_08Jan2019.xlsx

NMED Exhibit 68

Survey distribution to operators, including supplemental outreach and operator activity data is described below.

1. Ramboll distributed the following materials to each WRAP OGWG state agency member:
    a. Survey form
    b. High priority operator list ranked by oil and gas (O&G) activity/ownership for each basin
    c. Recommendations for survey collection and distribution
    d. Survey cover letter template for agency survey distribution
2. Member state agency gathered survey data. Ramboll staff answered technical questions about the survey.
    a. Each agency gathered survey data from internal agency sources and/or external sources such as O&G exploration and production companies.
    b. If the agency chose to distribute the survey to O&G companies, the survey was distributed to the high priority operators chosen by the agency.
    c. Each agency performed follow-up with operators the agency designated to fill out the survey to ensure that surveys were completed and submitted prior to the survey due date.

The type of survey distributed and the basins for which surveys were distributed is shown in Table 2-3.

Table 2-3. Operator survey distribution

State	Distributing Agency	Basin	Survey Type
Montana	MTDEQ	Big Horn	Complete
		Central Montana Uplift	Complete
		Powder River	Complete
		Sweetgrass Arch	Complete
		Williston	Complete
New Mexico	NMED	Permian	Complete
		San Juan	Complete
North Dakota	NDDOH	Williston	Complete
Wyoming	WYDEQ	Denver	Controls-focused
		Green River	Controls-focused
		Powder River	Controls-focused

2.2.3 Survey Collection

Several agencies provided data for specific O&G basins in response to the survey as indicated below.

- **Alaska** (Arctic Coastal Plains Province and Cook Inlet Basin): Baseline emission inventory updates.
- **Colorado** (Denver Basin): 2017 emission inventory. A*pplicable to future year emission inventory controls.*

NMED Exhibit 68

- **Montana** (Central Montana Uplift, Sweetgrass Arch, and Williston Basin): Gas compositions.
- **Wyoming** (Denver Basin, Green River Basin, and Powder River Basin): 2014 and 2017 detailed operator submissions to be used in the estimation of future year control factors. A*pplicable to future year emission inventory controls.*
- **Utah** (Uinta Basin): Engine age distributions to be used in the estimation of future year control factors. A*pplicable to future year emission inventory controls*

A total of 42 operators surveys were collected, with the largest number of surveys (17) collected in the Williston Basin in North Dakota (see Table 2-4). Operator survey results are documented below.

Table 2-4. Returned operator surveys.

State	Basin	No. of Returned Surveys	Percent of 2014 Basin-wide Activity Represented by Returned Surveys		
			Well Count	Oil Production	Gas Production
Montana	Big Horn	1	5%	0%	6%
	Central Montana Uplift	2	62%	5%	85%
	Powder River	1	23%	91%	90%
	Sweetgrass Arch	2	23%	19%	53%
	Williston	6	25%	64%	31%
New Mexico	Permian	4	66%	80%	86%
	San Juan	0	-	-	-
North Dakota	Williston	17	11%	25%	26%
Wyoming [a]	Denver	1	18%	46%	52%
	Green River	4	46%	51%	53%
	Powder River	4	4%	34%	13%

[a] Control-focused survey, not applicable to baseline emission inventory improvements.

2.2.4 Operator Survey-Based Emission Inventory Updates

In this section operator survey results applicable to baseline emission inventory updates are reported and integration into the baseline year inventory is described. Table 2-5 shows, by basin, the categories for which operators submitted survey data. Emission inventory updates based on operator survey data are limited to the basins and source categories listed in Table 2-5.

NMED Exhibit 68

Table 2-5. Categories for which survey data applicable to baseline inventory updates was submitted.

Source Category	Big Horn Basin	Central Montana Uplift	Sweetgrass Arch	Powder River Basin	Permian Basin	Williston Basin	
	MT	MT	MT	MT	NM	MT	ND
Drilling	-	-	-	-	×	×	×
Hydraulic Fracturing	-	-	-	-	×	×	×
Tanks	×	×	×	×	×	×	×
Wellhead Engines	×	×	×	×	×	×	×
Gas Compositions	×	×	×	×	×	×	×

For basins in which survey-based operator data was available for only one operator, if the operator represented greater than 10% of the O&G activity metric associated with a given source category, representative input factors were developed by assuming that the remaining O&G activity in the basin would have input factors equivalent to those used in the development of the WRAP OGWG v1 emission inventory. If the operator represented less than 10% of the O&G activity metric, a representative factor was not developed to preserve the confidentiality of a single operator's data.

2.2.4.1 Drill Rigs

Updated drill rig inputs were developed for the Permian Basin, Williston Basin in Montana, and Williston Basin in North Dakota (see Table A1). Rig activity per spud, estimated as total horsepower-hours (i.e., the product of number of engines, rated horsepower per engine, and hours per spud) decreased for each basin by 20%-53% relative to current inventory estimates. Permian Basin drill rigs were comprised of a substantial fraction of Tier 4 engines and Williston Basin drill rigs were comprised almost exclusively of Tier 2 engines. For operators that indicated use of Tier 4 engines, those engines were described as "generators". Therefore, Tier 4 drill rig engines were assumed to meet stringent generator-set emission standards. The baseline emission inventory was updated to be based on the drill rig configuration inputs in Table A1 for the indicated basins.

Table 2-6 shows the basis of drill rig emissions for basins in which survey-based input factors were developed. Survey-based emission rates per spud were developed based on survey-based factors in Table A1 and multiplied by the number of horizontal spuds in each county in applicable basins to estimate emissions. These emissions replaced estimates of drill rig emissions from horizontal spuds in the WRAP OGWG v1 emission inventory. County-level emissions were apportioned to non-tribal and tribal land according the fraction of spuds in each county on non-tribal and tribal land.

NMED Exhibit 68

Table 2-6. Emission inventory basis for basins with drill rig survey data.

Basin	Horizontal [b]		Vertical	
	Non-tribal	Tribal	Non-tribal	Tribal
Permian	Survey-based factors	[a]	OGWG v1	[a]
Williston (MT)	Survey-based factors		OGWG v1	
Williston (ND)	Survey-based factors		OGWG v1	

[a] not applicable, no tribal activity

[b] horizontal input factors were applied to directional wells

2.2.4.2 Hydraulic Fracturing Engines

Updated hydraulic fracturing engine inputs were developed for the Permian Basin and Williston Basin in North Dakota (see Table A2). Fracturing engine activity per spud, estimated as total horsepower-hours (i.e., the product of number of engines, rated horsepower per engine, and hours per spud) increased substantially compared to current inventory estimates; Permian Basin total horsepower-hours increased by approximately 8 times and Williston Basin increased by approximately 27 times. Horsepower-hour increases are being driven by more intensive hydraulic fracturing activities at horizontal wells than assumed for previous inventories. Emission rates also changed substantially from previous estimates, with substantial use of Tier 4 engines in both the Williston and Basin Permian Basin and use of both natural gas turbine and electrified engine configurations in addition to diesel engine configurations in the Permian Basin. Based on input from several operators, hydraulic fracturing pump arrays that use Tier 4 diesel engines are configured to use generator-sets. Therefore, Tier 4 engines in hydraulic fracturing pump arrays were assumed to meet stringent Tier 4 generator-set standards. Other, less prevalent engines with smaller rated-power per engine such as light plants or blenders were assumed to meet Tier 4 interim standards.

Table 2-7 shows the basis of hydraulic fracturing engine emissions for basins in which survey-based input factors were developed. Survey-based emission rates per fracturing event were developed based on survey-based factors in Table A2 and multiplied by the number of horizontal spuds in each county in applicable basins to estimate emissions; one hydraulic fracturing event was assumed per spud. These emissions replaced estimates of hydraulic fracturing engine emissions from horizontal wells in the WRAP OGWG v1 emission inventory. County-level emissions were apportioned to non-tribal and tribal land according the fraction of spuds in each county on non-tribal and tribal land.

Table 2-7. Emission inventory basis for basins with hydraulic fracturing engine survey data.

Basin	Horizontal [b]		Vertical	
	Non-tribal	Tribal	Non-tribal	Tribal
Permian	Survey-based factors	[a]	OGWG v1	[a]
Williston (ND & MT)	Survey-based factors		OGWG v1	

[a] not applicable, no tribal activity

[b] horizontal input factors were applied to directional wells

NMED Exhibit 68

2.2.4.3 Tanks

Oil Tanks

Updated oil tank inputs were developed for several O&G basins (see Table A3). There are substantial differences in oil tank input factors compared to input factors in the current inventory. For example, the fraction of uncontrolled tanks changed from 73% to 19% for the Permian Basin, from 14% to 1% for the Powder River Basin, from 17% to < 1% for horizontal and vertical wells in the Williston Basin. Decreases in the prevalence of uncontrolled tanks indicates that a higher fraction of tanks are being controlled to comply with regulations such as EPA New Source Performance Standard (NSPS) Subpart OOOO. Uncontrolled VOC flash emission factors decreased for several basins. For example, uncontrolled VOC flash emission factors decreased by 16% and 61% for oil tanks in the Williston Basin, in Montana and North Dakota, respectively. Flash emission factor decreases may result from factors such as better sampling and/or the use of more site specific information in E&P Tank model runs and/or process simulation software in the submitted surveys compared to previously compiled emission inventory inputs.

Table 2-8 shows the basis of oil tank emissions for basins in which survey-based input factors were developed. Survey-based emission rates per barrel of oil produced were developed based on survey-based factors in Table A3 and multiplied by the amount oil production from horizontal or vertical wells in each county in applicable basins to estimate emissions. These emissions replaced estimates of oil tank emissions from horizontal wells and vertical wells in the WRAP OGWG v1 emission inventory. County-level emissions were apportioned to non-tribal and tribal land according the fraction of oil production in each county from wells on non-tribal and tribal land.

Table 2-8. Emission inventory basis for basins with oil tank survey data.

Basin	Horizontal [b]		Vertical	
	Non-tribal	Tribal	Non-tribal	Tribal
Central Montana Uplift	OGWG v1		Survey-based factors	
Permian	Survey-based factors	[a]	OGWG v1	[a]
Powder River (MT)	OGWG v1		Survey-based factors	
Sweetgrass Arch	OGWG v1		Survey-based factors	
Williston (MT)	Survey-based factors			
Williston (ND)	Survey-based factors			

[a] not applicable, no tribal activity

[b] horizontal input factors were applied to directional wells

Condensate Tanks

Updated condensate tank inputs were developed for the Sweetgrass Arch and Williston Basin in North Dakota and Montana (see Table A4). The fraction of uncontrolled tanks increased from 31% to 100% in the Sweetgrass Arch Basin and decreased from 8% to 4% and 8% to 1% in the Williston Basin, in Montana and North Dakota, respectively.

NMED Exhibit 68

Table 2-9 shows the basis of condensate tank emissions for basins in which survey-based input factors were developed. Survey-based emission rates per barrel of condensate produced were developed based on survey-based factors in Table A4 and multiplied by the amount oil production from horizontal or vertical wells in each county in applicable basins to estimate emissions. These emissions replaced estimates of condensate tank emissions from horizontal wells and vertical wells in the WRAP OGWG v1 emission inventory. County-level emissions were apportioned to non-tribal and tribal land according the fraction of condensate production in each county from wells on non-tribal and tribal land.

Table 2-9. Emission inventory basis for basins with condensate tank survey data.

Basin	Horizontal [b]		Vertical	
	Non-tribal	Tribal	Non-tribal	Tribal
Sweetgrass Arch	OGWG v1		Survey-based factors	
Williston (MT)	Survey-based factors		OGWG v1	
Williston (ND)	Survey-based factors		OGWG v1	

[a] not applicable, no tribal activity

[b] horizontal input factors were applied to directional wells

Capture Efficiency

For tanks with emission controls, capture efficiency represents the percent of uncontrolled emissions that are controlled by the control device. Open thief hatches result in uncontrolled fugitive tank emissions. Across all returned operator surveys, 20 condensate tank configurations and 51 oil tank configurations were submitted. 75% of condensate tank configuration and 57% of oil tank configuration responses included a response to the thief hatch status (summarized in Table 2-10). The overall average percent of thief hatches open was 2.8% for condensate tanks and 3.0% for oil tanks.

Table 2-10. Open thief hatch survey response summary.

Operator Response	Survey Field: Percentage of Tanks Observed with Thief Hatches Open	Average Percentage of Tanks Observed with Thief Hatches Open
	Number of Responses	
Condensate Tanks		
No Response / Not available	5	2.8%
Zero	7	
Minimal	3	
Non-zero Value	5	
Oil Tanks		
No Response / Not tracked	29	3.0%
Zero	9	
Minimal	1	
Non-zero Value	12	

NMED Exhibit 68

Assuming that a tank with an open thief hatch emits VOCs at the uncontrolled tank VOC emission rate, a capture efficiency of 97% (i.e., 3% of tank emissions are not routed to the flare) would result in emissions that are 2.5 times higher for a 98% efficient control device and 1.6 times higher for 95% efficient control device (see Figure 2-1).

More study is needed to (1) develop robust capture efficiency estimates and (2) estimate VOC emission magnitude when a thief hatch is open; the increases in emissions estimated in Figure 2-1 are screening level estimates.

At this time, sufficient information is not available to extrapolate the average capture efficiency shown in Table 2-10 across the WESTAR-WRAP region. Variation in capture efficiency by production type and geography is not available. Therefore, capture efficiency is assumed to be 100%, consistent with previous inventories.

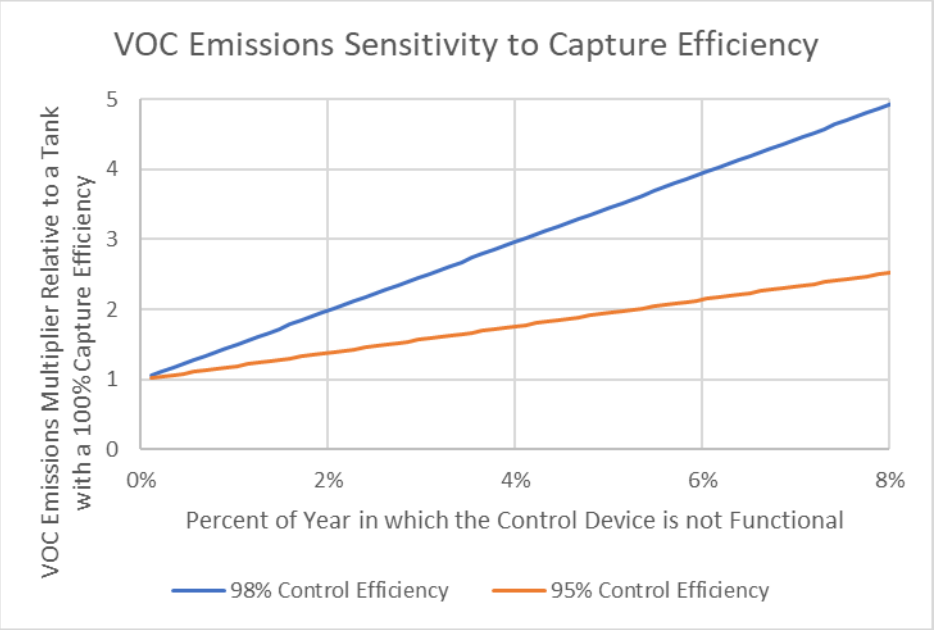

Figure 2-1. Tank VOC emissions sensitivity to capture efficiency.

2.2.4.4 Wellhead Engines

Updated wellhead configurations were developed for the basin and engine types listed below and are included in Table A5.

- **Sweetgrass Arch Wellhead Compressors Engines:** WRAP OGWG v1 input factors indicated zero activity from this source category. Operator submitted survey data indicated substantial use of wellhead compressors in this basin.
- **Bighorn Basin Lateral Compressor Engines:** Survey-based input factors are similar to WRAP OGWG v1 input factors.
- **Central Montana Uplift Lateral Compressor Engines:** Survey-based input factors include lower annual activity and higher prevalence compared to WRAP OGWG v1 input factors.

- **Williston Basin Artificial Lift Engines:** Survey-based input factors were developed by horizontal and vertical spud types for Montana and North Dakota. For each spud type and state, the survey-based input factors showed substantially higher electrification compared to the WRAP OGWG v1 input factors.
- **Permian Basin Artificial Lift Engines:** Survey-based input factors were developed by horizontal spud type for New Mexico. Survey-based input factors showed lower prevalence and electrification and higher average engine rated-power compared to the WRAP OGWG v1 input factors.
- **Williston Basin Generators**: Survey-based input factors were developed for generators operating at horizontal oil wells. Wellhead generators were not included in the WRAP OGWG v1 emission inventory. 11% of horizontal oil wells are estimated to have a generator.

Table 2-11 shows the basis of wellhead engine emissions for basins in which survey-based input factors were developed. Survey-based emission rates per active well were developed based on survey-based factors in Table A5 and multiplied by the number of active horizontal oil, horizontal gas, vertical oil, or vertical gas wells in each county in applicable basins to estimate emissions. These emissions replaced estimates of wellhead engine emissions in the WRAP OGWG v1 emission inventory. County-level emissions were apportioned to non-tribal and tribal land according the fraction of active wells in each county from wells on non-tribal and tribal land.

Table 2-11. Emission inventory basis for basins with wellhead engine survey data.

Basin	Engine Type	Well Type	Horizontal [b]		Vertical	
			Non-tribal	Tribal	Non-tribal	Tribal
Sweetgrass Arch	Wellhead Compressors	Gas	OGWG v1		Survey-based factors	
Bighorn Basin	Lateral Compressor	Gas	OGWG v1		Survey-based factors	
Central Montana Uplift	Lateral Compressor	Gas	OGWG v1		Survey-based factors	
Williston Basin (ND & MT)	Artificial Lift	Oil	Survey-based factors			
Permian Basin	Artificial Lift	Oil	Survey-based factors		OGWG v1	
Williston Basin (ND & MT)	Generators	Oil	Survey-based factors		[c]	

[a] not applicable, no tribal activity

[b] horizontal input factors were applied to directional wells

[c] not applicable, generator engine inputs are not available for vertical wells in the survey or WRAP OGWG v1. No emissions are estimated for this engine type at vertical wells.

NMED Exhibit 68

2.2.4.5 Emission Changes Resulting from Integration of Operator Survey Data

NOx emissions increased by 8% over the WESTAR-WRAP region based on integration of operator survey data into the inventory (see Table 2-12). Hydraulic fracturing engine emissions accounted for 47% of NOx emission increases. Operator surveys indicated the use of pump engine arrays with more engines and more operational hours than previous inventories. Emissions from artificial lift engines accounted for 38% of NOx emissions increases. Operator surveys indicated the use of artificial life engines with higher rated power than assumed in previous inventories. Emissions from drill rig emissions accounted for close to 100% of NOx emission decreases as a result of lower overall combined activity in horsepower-hours relative to previous inventories.

Table 2-12. NOx Emission Changes Resulting from Integration of Operator Survey Data.

Basin	Source Category	NOx (tpy)
Williston , ND	Hydraulic Fracturing Engines	18,369
Williston , ND	Artificial Lift Engines	11,894
Williston , ND	Generator Engines	2,848

Percent Change		**8%**

VOC emissions decreased by 22% over the WESTAR-WRAP region based on integration of operator survey data into the inventory (see Table 2-13). VOC emission increases were small compared to VOC emission decreases. Emissions from oil tanks accounted for close to 100% of VOC emission decreases as a results of higher emission control prevalence.

2.2.5 Agency Survey-Based Emission Inventory Updates

The 2014 NEI v2 was the sole basis of Alaska O&G emissions in the WRAP OGWG v1 emission inventory. Alaska Department of Environmental Conservation (ADEC) noted that emissions from several facilities emitting below Title V thresholds were not included in the 2014 NEI v2. ADEC provided emissions for these sources (see Table 2-14) were added to the WRAP OGWG v2 emission inventory.

Table 2-14. Alaska O&G emissions from small nonpoint sources.

Facility	Emissions (tons/year)					
	NOx	VOC	CO	SO_2	PM_{10}	$PM_{2.5}$

NMED Exhibit 68

3.0 SUMMARY RESULTS

O&G emissions results for the baseline 2014-2016 WRAP OGWG v2 emission inventory for the WESTAR-WRAP region are presented below as a series of tables and charts. Additional summaries and fully detailed emission inventory data are available in spreadsheets that accompany this report which are posted on the WRAP OGWG website (https://www.wrapair2.org/OGWG.aspx).

3.1 2014-2016 WRAP OGWG v2 emission inventory

2014-2016 WRAP OGWG v2 NOx and VOC emissions for all WRAP region basins are summarized in Table 3-1 and Table 3-2 respectively. Across the WESTAR-WRAP region, most nonpoint O&G emissions are emitted from wellsite sources and point O&G emission are emitted from midstream sources. Approximately 58% of 2014 NOx emissions and over 85% of 2014 VOC emissions were from nonpoint sources. Basin specific nonpoint and point source contributions result from basin specific equipment and operational characteristics and infrastructure, and in some cases basin specific accounting. For example, the Uinta Basin includes several wellsite source categories in the point source emission inventory. The top-seven emitting bases account for approximately 75% of NOx emissions and the top-five basin and state combinations account for over 80% of VOC emissions.

Table 3-1. Summary of nonpoint and point NOx emissions (tons/yr) by basin.

Basin and State	NOx Emissions (tons/yr)		
	Nonpoint	Point	Total
Williston, ND	55,003	2,703	57,706

Total	**867,318**	**148,791**	**1,016,110**

Figure 3-1 and Figure 3-2 show NOx and VOC nonpoint emissions contributions, respectively, for basin and state combinations with the largest nonpoint emission contributions.

The largest source of nonpoint NOx emissions are hydraulic fracturing engines, wellhead engines, process heaters, and drill rigs. Wellhead engines (including artificial lift engines, wellhead and lateral compressor engines, generators and other miscellaneous engines) are the largest contributor to nonpoint NOx emissions in the San Juan Basin (NM; 90%), San Juan Basin (CO; 95%), and Permian Basin (NM; 52%). Hydraulic fracturing engines are the largest contributor to NOx emissions for the Williston Basin (ND; 43%) and Powder River Basin (WY; 81%). Drill rigs are the largest contributor to NOx emissions for the Denver Basin (CO; 32%) and Piceance Basin (CO; 40%).

The largest nonpoint VOC emissions sources vary by basin. In the Williston Basin (ND), casinghead gas accounts for 50% of VOC emissions. In the Powder River Basin (WY), hydraulic fracturing and completion activities account for 91% of VOC emissions. In the Denver Basin (CO), condensate tanks account for 76% of VOC emissions. In the Permian Basin (NM), oil tanks account for 45% of VOC emissions. In the San Juan Basin (NM), pneumatic devices account for 32% of VOC emissions.

NMED Exhibit 68

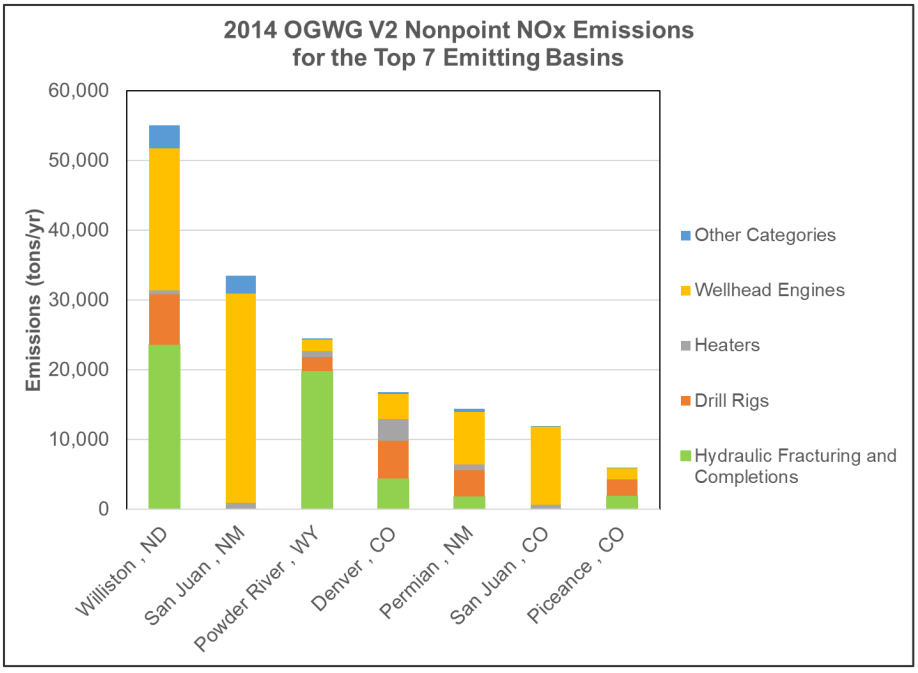

Figure 3-1. 2014 OGWG V2 nonpoint NOx emissions (tons/yr) contribution by source category for top 7 highest emitting basins.

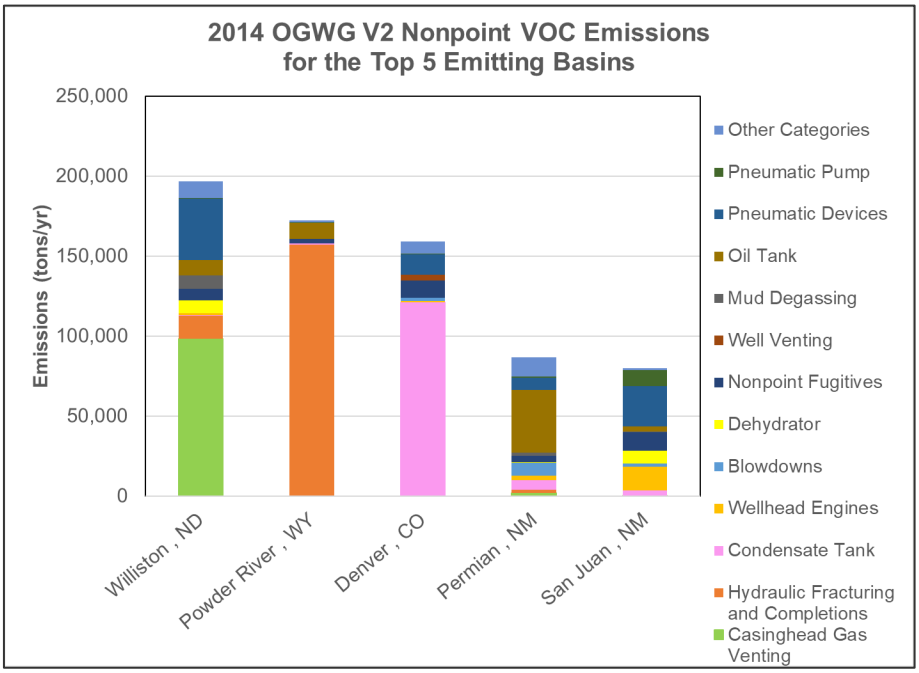

Figure 3-2. 2014 OGWG V2 nonpoint VOC emissions (tons/yr) contribution by source category for top 5 highest emitting basins.

3.1.1 2014-2016 Baseline Comparison to 2014 Emission Inventories

Changes from the 2014 NEI v2 to the 2014 base year WRAP OGWG v1 to the 2014-2016 baseline WRAP OGWG v2 are shown below for NOx (Figure 3-3) and VOC (Figure 3-4).

Changes from 2014 NEI v2 to the WRAP OGWG v1 inventory are based on state supplied emission inventory updates (e.g., Colorado condensate tanks and Uinta Basin 2014 Air Agencies Oil and Gas Emissions Inventory); differences between NEI v2 emissions and the 2014 IWDW emission inventory that was the basis of WRAP OGWG v1 emission inventory for several states (e.g., Wyoming, Colorado); and for the Greater San Juan (Colorado and New Mexico) and Permian Basin (New Mexico), differences between Grant et al. (2018a) and the EPA NEI v2. WESTAR-WRAP region-wide emission increased by 16% for NOx and 14% for VOC from 2014 NEI v2 to 2014 base year WRAP OGWG v2.

Changes from the WRAP OGWG v1 to the WRAP OGWG v2 emission inventory are based on updates per agency and operator survey responses. WESTAR-WRAP region-wide NOx emissions increased by 9% and VOC decreased by 22%. NOx emission increases for North Dakota, Montana, and New Mexico resulting from survey-based updates were the primary cause of WESTAR-WRAP region-wide NOx emission increases. VOC emission decreases for North Dakota, Montana, and New Mexico resulting from survey-based updates were the primary cause of WESTAR-WRAP region-wide VOC emission decreases.

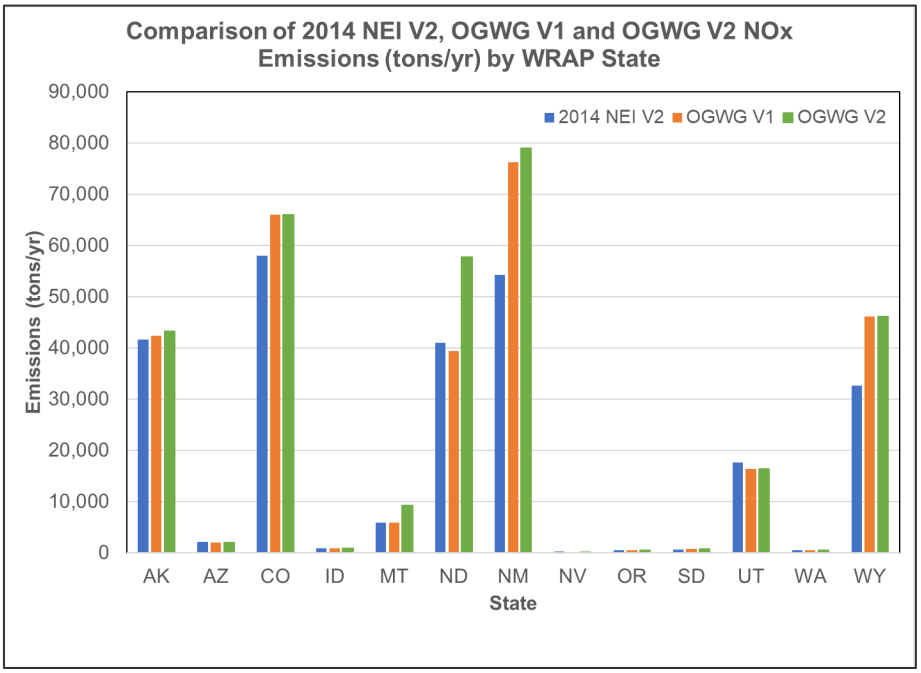

Figure 3-3. Comparison of 2014 NEI, OGWG V1 and OGWG V2 NOx emissions by WRAP region State.

NMED Exhibit 68

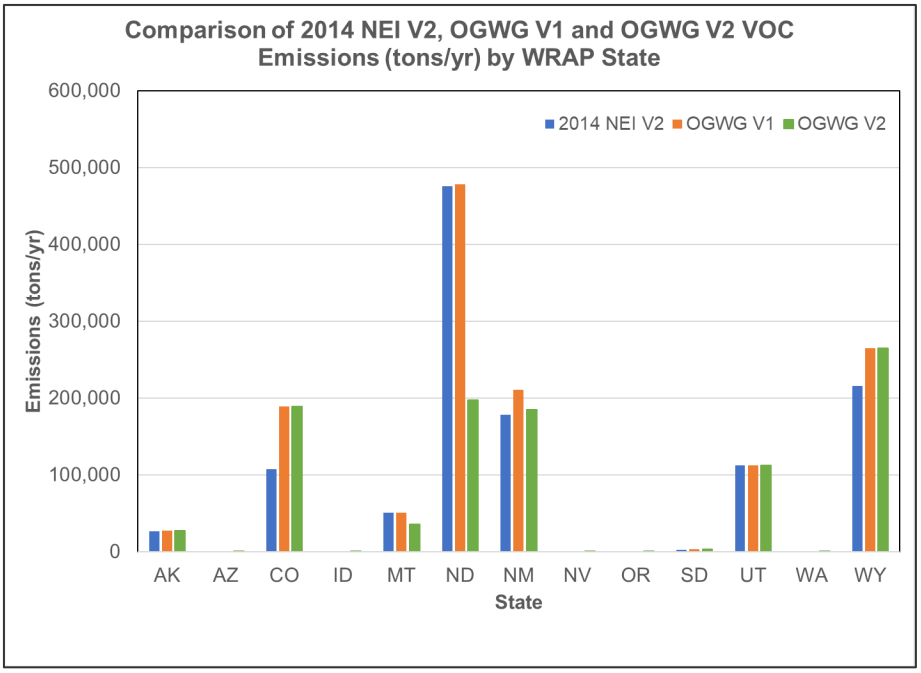

Figure 3-4. Comparison of 2014 NEI, OGWG V1 and OGWG V2 VOC emissions by WRAP region State.

3.1.2 2008, 2011, 2014-2016 baseline summaries

Figure 3-5 and Figure 3-6 show emission trends for WESTAR-WRAP basins which were included in the WestJUMP AQMS [15] and/or WAQS [16]. The geographical extent of each basin is not always the same across these inventories, however, core O&G activity counties in each basin generally did not change across inventories.

Substantial NOx emission increases from the 2008 to 2014-2016 inventory are noted for several basins, although emission increases appear to be moderated for several basins by lower emissions per unit of production based on regulatory controls and/or infrastructure configurations. Denver Basin NOx emission increases of 20% and VOC increases of 66% from 2008 to 2014-2016 are substantially less than the Colorado-wide 287% oil production increase from 2008 to 2016. Permian Basin NOx emission increases of 34% and VOC decreases of 24% from 2008 to 2014-2016 are substantially less than the New Mexico-wide 143% oil production increase from 2008 to 2016. Williston Basin NOx emission increases of 117% and VOC decreases of 23% from 2011 to 2014-2016 are less than the North Dakota-wide oil production increases of 148% from 2011 to 2016. Increases in San Juan Basin NOx (25%) and VOC (60%) emissions from 2011 to 2014-2016 are due primarily to updated emission inventory inputs and methodology in the 2014 Greater San Juan Basin emission inventory study (Grant et al. [2018a]). Changes in Uinta Basin emissions are expected to result from both oil and gas production changes and changes to emission inventory compilation methodology in the most recent Utah Agencies Uinta Basin emission inventory.

Powder River Basin (MT)		
Survey response was limited to one operator, comprising a very small fraction of activity, therefore, no input factors were developed.		
Williston Basin (MT)		
Survey response was limited to two operators comprising 2% of exploration activity. Recommend assuming that Willison Basin, Montana hydraulic fracturing inputs are equivalent to Williston Basin, North Dakota.

1.0 INTRODUCTION

This background technical support document (TSD) provides information relevant to the development of the final rule Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources. The final rule establishes GHG standards, in the form of limitations on methane, for certain sources that are currently regulated for VOC but not GHG. It also establishes both VOC and GHG standards certain sources that are currently unregulated for either emissions.

Chapter 2 presents an overview of the oil and natural gas sector and source category. This chapter is intended to provide introductory material on the oil and natural gas source category, as listed under section 111(b)(1)(A).

The remainder of the TSD is presented in two volumes; Volume 1 provides the unit-level analysis supporting the determination of the best system of emission reduction (BSER); and Volume 2 presents the national impacts of the regulatory decisions for the final rule.

1.1 Volume 1 - Unit-Level BSER Analysis

Chapters 3 through Chapter 7 present detailed information and analyses pertaining to each emissions source that was considered in this regulatory action. They include emission data and discussions of available control options and their costs that are considered in the development of standards reflecting the BSER for these emission sources.

1.2 Volume 2 - National Level Impacts

Chapters 8 through Chapter 15 present the estimates of national level impacts needed to inform the Preamble of the final rule and the Regulatory Impact Analysis (RIA) for the rule, as required under Executive Order 12866. Specifically, each chapter summarizes the national baseline, nationwide emission reductions and cost impacts for use in the Preamble and RIA. It is important to note that that national impacts estimates incorporate in to the baseline the fact that some states already have requirements of emissions sources addressed by this final rule. Further, this analysis is separate and apart from the analyses required to identify the BSER based on which standards are to be established under section 111(b) of the CAA. Chapter 13 summarizes the natural gas savings from the application of emissions controls.

Finally, the Appendix to the TSD provides technical information on the background and development of the low pressure well equation.

NMED Exhibit 70

1.3 Supporting Documentation

This action follows the development of several prior oil and gas NSPS related actions. This review references several documents that were published as a consequence of these prior actions. For ease of presentation, the following documents are consistently cited in the following sections:

- The TSD for the 2011 NSPS proposal, published in July, 2011, will be referred to in this document as "2011 NSPS TSD".[1]
- The supplemental TSD for the 2012 final NSPS standards, published April, 2012, will be referred to in this document as "2012 NSPS STSD".[2]
- The gas composition memo that was developed during the NSPS process which characterizes and analysis of data to determine the gas composition and develop ratios for natural gas composition to be used for the various segments in the development of regulations for the oil and natural gas sector. This document will be referred to as "2011 Gas Composition Memorandum".[3]
- Emissions information and counts for various emission sources were developed from facility-level data submitted to the Greenhouse Gas Reporting Program (GHGRP) and data used to calculate national emissions in the Inventory of U.S. Greenhouse Gas Emissions and Sinks. The most recent available data from the GHG Inventory at the time of the development of this analysis was for 2013, and was used for various portions of the analysis. For the purposes of this document these data sources are referred to as "GHGRP" and “GHG Inventory”. Currently available GHGRP reported data cover 2011 through 2014 and the most recent available GHG Inventory covers data from 1990-2014.[4] These new activity data have been reviewed for the final rule and incorporated into this analysis appropriate
- The TSD for the 2015 NSPS proposal, published in August, 2015, will be referred to in this document as "2015 NSPS Proposal TSD". Note that this TSD includes all information from the proposal TSD that did not change and that continues to support the decisions of final rule, as well

NMED Exhibit 70

2.0 OIL AND NATURAL GAS SOURCE CATEGORY OVERVIEW

The final rule covers emission sources within the oil and natural gas source category, which includes onshore crude oil production and natural gas production, processing, transmission and storage.

Production operations include the wells and all related processes used in the extraction, production, recovery, lifting, stabilization, separation or treatment of oil and/or natural gas (including condensate). Production components may include, but are not limited to, wells and related casing head, tubing head and "Christmas tree" piping, as well as pumps, compressors, heater treaters, separators, storage vessels, pneumatic devices and dehydrators. Production operations also include well drilling, completion and recompletion processes; which includes all the portable non-self-propelled apparatus associated with those operations. Production sites include not only the "pads" where the wells are located, but also include stand-alone sites where oil, condensate, produced water and gas from several wells may be separated, stored and treated. The production segment also includes the low pressure, small diameter, gathering pipelines and related components that collect and transport the oil, gas and other materials and wastes from the wells to the refineries or natural gas processing plants.

There are two basic types of wells: oil wells and gas wells. Oil wells can have "associated" natural gas that is separated and processed or the crude oil can be the only product processed. Crude oil production includes the well and extends to the point of custody transfer to the crude oil transmission pipeline. Once the crude oil is separated from water and other impurities, it is essentially ready to be transported to the refinery via truck, railcar or pipeline. The oil refinery sector is considered separately from the oil and natural gas sector. Therefore, at the point of custody transfer at the refinery, the oil leaves the oil and natural gas sector and enters the petroleum refining sector.

Natural gas is primarily made up of methane. It commonly exists in mixtures with other hydrocarbons. They are sold separately and have a variety of different uses. The raw natural gas often contains water vapor, hydrogen sulfide (H_2S), carbon dioxide (CO_2), helium, nitrogen and other compounds. Natural gas processing consists of separating certain hydrocarbons and fluids from the natural gas to produced "pipeline quality" dry natural gas. While some of the processing can be accomplished in the production segment, the complete processing of natural gas takes place in the natural gas processing segment. Natural gas processing operations separate and recover NGL or other non-methane gases and liquids from a stream of produced natural gas through components performing one or more of the following processes: Oil and condensate separation, water removal, separation of natural gas liquids,

NMED Exhibit 70

sulfur and CO_2 removal, fractionation of natural gas liquid and other processes, such as the capture of CO_2 separated from natural gas streams for delivery outside the facility.

The pipeline quality natural gas leaves the processing segment and enters the transmission and storage segment. Pipelines in the natural gas transmission and storage segment can be interstate pipelines that carry natural gas across state boundaries or intrastate pipelines, which transport the gas within a single state. While interstate pipelines may be of a larger diameter and operated at a higher pressure than intrastate pipelines, the basic components are the same. To ensure that the natural gas flowing through any pipeline remains pressurized, compression of the gas is required periodically along the pipeline. This is accomplished by compressor stations usually placed between 40 and 100 mile intervals along the pipeline. At a compressor station, the natural gas enters the station, where it is compressed by reciprocating or centrifugal compressors.

In addition to the pipelines and compressor stations, the natural gas transmission and storage segment includes aboveground and underground storage facilities. Underground natural gas storage includes subsurface storage, which typically consists of depleted gas or oil reservoirs and salt dome caverns used for storing natural gas. One purpose of this storage is for load balancing (equalizing the receipt and delivery of natural gas). At an underground storage site, there are typically other processes, including compression, dehydration and flow measurement.

Emissions can occur from a variety of processes and points throughout the oil and natural gas source category. Primarily, these emissions are organic compounds such as methane, ethane, VOC and organic HAP. The most common organic HAP are n-hexane and BTEX compounds (benzene, toluene, ethylbenzene and xylenes). Hydrogen sulfide and SO_2 are emitted from production and processing operations that handle and treat sour gas.[6]

The analysis in this document addresses only emission sources in the oil and natural gas source category. Unless otherwise noted, use of the term "gas" refers to natural gas.

[6] Sour gas is defined as natural gas with a maximum H_2S content of 0.25 gr/100 scf (4 parts per million by volume (ppmv)) along with the presence of CO_2.

NMED Exhibit 70

VOLUME 1: UNIT LEVEL BSER ANALYSIS

3.0 HYDRAULICALLY FRACTURED OIL WELL COMPLETIONS AND RECOMPLETIONS

During development of the 2012 NSPS amendments, methane and VOC emissions from hydraulically fractured oil and natural gas well completions and recompletions were estimated and included in the cost and impact analysis. See the 2011 NSPS TSD. The 2012 NSPS promulgated requirements for control of emissions from hydraulically fractured natural gas well completions and recompletions.

The EPA has reevaluated hydraulically fractured oil well completion emissions based on more recent data and information as discussed below. As was determined with respect to gas wells, oil well completions and recompletions use multi-phase processes with various sources of emissions where the highest emissions result from the venting of natural gas to the atmosphere during flowback. The flowback emissions are short-term in nature and occur as a specific event during completion of a new well or during recompletion activities that involve re-drilling or re-fracturing an existing well. This chapter describes hydraulically fractured oil well completions and recompletions, and provides estimates for representative oil wells and nationwide emissions. With respect to control technology, the same control technology can be employed to control emissions from oil well completions as were found to be appropriate for gas well completions. In this chapter, the EPA evaluated costs, emission reductions, and secondary impacts for oil well completions and recompletions based on the revised emissions profile.

Because oil well completions and recompletions were included in the proposed NSPS amendments in 2011 (76 FR 52738), for the sake of convenience the EPA repeat below the process description and control technology discussions from the 2012 NSPS TSD with minimal edits.

3.1 Process Description

3.1.1 Oil Well Completions

All oil wells must be “completed” after initial drilling in preparation for production.

Well completion activities include multiple steps after the well bore hole has reached the target depth. These steps include inserting and cementing-in well casing, perforating the casing at one or more producing horizons, and often hydraulically fracturing one or more zones in the reservoir to stimulate production. Surface components, including wellheads, pumps, dehydrators, separators, tanks, and

NMED Exhibit 70

gathering lines are installed as necessary for production to begin.[7]

Developmental wells are drilled within known boundaries of a proven oil or gas field, and are located near existing well sites where well parameters are already recorded and necessary surface equipment is in place. When drilling occurs in areas of new or unknown potential, well parameters such as gas composition, flow rates of various phases (oil, gas, and water), oil API gravity, and pressure and temperature from the formation need to be ascertained before surface facilities required for production can be adequately sized and brought on site. In this instance, exploratory (also referred to as "wildcat") wells and field boundary delineation wells typically either vent or combust the flowback gas.

One completion step for improving oil production is to fracture the reservoir rock with very high pressure fluid, typically a water emulsion with a proppant (generally sand) that "props open" the fractures after fluid pressure is reduced. Natural gas emissions are a result of the flowback of the fracture fluids and reservoir gas at high pressure and velocity necessary to clean and lift excess proppant to the surface. Natural gas from the completion flowback escapes to the atmosphere during the reclamation of water, sand, and hydrocarbon liquids during the collection of the multi-phase mixture directed to a surface impoundment. As the fracture fluids are depleted, the flowback eventually contains a higher volume of natural gas from the formation. Due to the specific additional equipment and resources involved and the nature of the flowback of the fracture fluids, completions involving hydraulic fracturing have higher costs and vent substantially more natural gas than completions not involving hydraulic fracturing.

3.1.2 Oil Well Recompletions Recompletions are remedial operations conducted to maintain production or minimize the decline in production. Examples of the variety of recompletion activities include completion of a new producing zone, re-fracture of a previously fractured zone, removal of paraffin buildup, replacing rod breaks or tubing tears in the wellbore, and addressing a malfunctioning downhole pump. During a recompletion, portable equipment is conveyed back to the well site temporarily and some recompletions require the use of a service rig. As with well completions, recompletions are highly specialized activities, requiring special equipment, and are usually performed by well service contractors specializing in well maintenance. Any flowback event during a recompletion, such as after a hydraulic fracture, will result in emissions to the atmosphere

[7] U.S. EPA. Lessons Learned: Reduced Emissions Completions. Office of Air and Radiation (OAR): Natural Gas Star Program, Washington, DC, 2011.

NMED Exhibit 70

unless the flowback gas is captured.

When hydraulic re-fracturing (recompletions) is performed, the emissions are essentially the same as new well completions involving hydraulic fracture, except that surface gas collection equipment will already be present at the wellhead after the initial fracture. The flowback velocity during re-fracturing will typically be too high for the normal wellhead equipment (separator, dehydrator, lease meter), while the production separator is not typically designed for separating sand.

Flowback emissions are a result of free gas being produced by the well following hydraulic fracturing during a well completion and recompletion activity. The high rate flowback, with intermittent slugs of water and sand along with free gas, is directed to an impoundment or vessels until the well is fully cleaned up, where the free gas vents to the atmosphere while the water and sand remain in the impoundment or vessels. Therefore, nearly all of the flowback emissions originate from the recompletion process but may be vented as the flowback enters the impoundment or vessels.

3.2 Emission Data and Emission Factors

3.2.1 Summary of Major Studies and Emission Factors

Together with the sources of information and data reviewed during the development of the 2012 NSPS, the EPA reviewed recent data and information as was discussed in the white paper titled “Oil and Natural Gas Sector Hydraulically Fractured Oil Well Completions and Associated Gas during Ongoing Production" published by the EPA in April, 2014.[8] Table 3-1 presents a list of the studies and information sources consulted for development of the NSPS and the 2014 white paper. The list below includes sources with information on hydraulically fractured gas and oil well completions and workovers.

3.2.2 Representative Completion and Recompletion Emissions

As previously mentioned, one specific emission source during completion and recompletion activities is the venting of natural gas to the atmosphere during flowback. Flowback emissions are short-term in nature and occur as a specific event during the completion of a new well or during recompletion activities that involve re-drilling or re-fracturing of an existing well. For this analysis, well completion

NMED Exhibit 70

and recompletion emissions are estimated as the venting of emissions from the well following hydraulic fracturing during a well completion or recompletion activity.

This analysis assumes wells completed/recompleted with hydraulic fracturing are found in tight sand, shale, or coal bed methane formations. The basic approach for this analysis was to use natural gas production data to approximate natural gas emissions from representative oil well completions and recompletions and then estimate methane and VOC emissions using the representative gas composition values developed in the 2011 Gas Composition Memorandum for the 2012 NSPS.[9]

Based on the comments received during the development of the NSPS, the EPA recognized that there are instances where gas produced by a well is incidental to oil production and that the gas flow would not support operation of a separator if low levels of gas produced. Though, in theory, any amount of free gas could be separated from the liquid, the reality is that this is not practical given the design and operating parameters of separation units operating in the field. EIA data show that the number of "oil only" wells drilled from 2007-2012 was less than 20 percent.[10] Therefore, the EPA evaluated available information to determine a minimum threshold of gas produced.

Non-volatile "black oils" (oil likely to not have gases or light hydrocarbons associated with it) are generally defined as having GOR values in the range of 200 to 900.[11] Therefore, oil wells with GORs less than 300 are at the lower end of this range, and likely will not have enough associated gas that can be separated.[12] Based on this consideration, the EPA concludes that a separator will not function at a well with a of GOR of less than 300 scf/barrel and, therefore, well completion of such well would not be reasonably capable of capturing and controlling emissions. Consequently, removed these oil wells from our analysis conducted to determine emissions from hydraulically fractured oil wells.

The following methodology was used to estimate the potential methane and VOC emissions from hydraulically fractured oil well completions.

---

[9] See U.S. EPA Docket ID Number EPA-HQ-OAR-2010-0505-0084.
[10] http://www.eia.gov/todayinenergy/detail.cfm?id=13571#
[11] http://petrowiki.org/Oil_fluid_characteristics
[12] The reason for the proposed threshold GOR of 300 was that separators typically do not operate at a GOR less than 300, which is based on industry experience rather than a vetted technical specification for separator performance. Though in theory any amount of free gas could be separated from the liquid, in reality this is not practical given the design and operating parameters of separation units operating in the field. On February 24, 2015, API submitted a comment to EPA stating that oil wells with GOR values less than 300 do not have sufficient gas to operate a separator. http://www.regulations.gov/#!documentDetail;D=EPA-HQ-OAR-2014-0831-0137.

NMED Exhibit 70

1. The EPA obtained well production data from the DrillingInfo database dated February, 2014.[13] The DrillingInfo database consists of oil and natural gas well information maintained by a private organization that provides parameters describing the location, operator, and production characteristics. DrillingInfo collects information on a well basis such as the operator, state, basin, field, annual gas production, annual oil production, well depth, and shut-in pressure, all of which is aggregated from operator reports to state governments. The data extract from the DrillingInfo database included the population of all wells with gas or hydrocarbon liquid production during 2010 to 2012 and with a recorded completion year of 2010 to the date of the extract (February, 2014).
2. The data was then processed to identify oil wells that were hydraulically fractured using a methodology based on a crosswalk of formation types and other information. See the ERG memorandum titled "*2013 GHGRP Subpart W and NSPS/NESHAP DrillingInfo Processing Methodology*" available in the docket, for a detailed description of the process to identify hydraulically fractured oil wells from the total oil well population.
3. From the dataset of hydraulically fractured oil wells, the EPA identified the wells completed in 2012 using the "completion year" record or the year of the "first month of production". Wells with a completion year of 2012 could have been completed for the first time in 2012 or could have been re-completed (i.e., re-fractured in 2012). The EPA also removed from the dataset all wells not characterized in the DrillingInfo database as “oil,” “gas” or “oil and gas”.
4. For the above identified hydraulically fractured oil well population, the EPA calculated the gas to oil ratio (GOR) by dividing the standard cubic feet (scf) of gas produced during the first month of production by the barrels (bbl) of petroleum liquid produced during the first month. The EPA then used the GOR to categorize the wells into oil and gas wells. Oil wells were defined to be those wells with a GOR of less than 100,000 scf/bbl. This threshold was chosen because it is consistent with the threshold used in the EPA National Emissions Inventory Oil and Gas Emission Estimation Tool and the threshold used in several states, including Texas[14] and New Mexico[15].
5. Based on the calculated GOR for the wells identified above, the EPA eliminated from the

[13] DrillingInfo is a private organization specializing in compiling primarily publically available oil and gas data, conducting statistical analysis, and providing analysis platforms for customers. The DrillingInfo database is particularly focused on historical oil and gas production data and drilling permit data.

[15] Available at http://164.64.110.239/nmac/parts/title19/19.015.0002.htm.

NMED Exhibit 70

evaluation wells with a GOR of less than 300 scf of gas per barrel produced.

6. The EPA then calculated the following average daily gas production values for each oil well;
    - Average daily gas production over the first month of operation by dividing the total gas production in the first month of operation by the average number of days in a month (30.42);
    - Average daily gas production over the first 6 months of operation by dividing the total gas production in the first six months of operation by the average number of days in 6 months (182.5); and
    - Average daily gas production over the first year of operation by dividing the total gas production in the first year of operation by the total days in one year (365).
7. The EPA assumed that the average daily gas production during the first month was representative of the daily potential emissions during a hydraulically fractured oil well completion. Therefore, the estimated gas production from a representative oil well completion was determined by taking the average of the average daily natural gas production during the first month of operation for each of the above identified oil wells (i.e., hydraulically fractured, and completed in 2012).
8. To determine the potential methane and VOC emissions for a representative oil well completion or recompletion, the EPA converted the average natural gas potential emissions per day to short tons of potential methane and VOC emissions. The conversion factors used are those developed for the NSPS and outlined in the memorandum titled "*Composition of Natural Gas for use in the Oil and Natural Gas Sector Rulemaking"*, available in the docket.[16] Specifically, the EPA assumes natural gas is 46.71% methane by volume, the density of methane is 0.0208 tons per Mcf, and that there is 0.8374 lbs of VOC per pound of methane.

The EPA then calculated the potential VOC and methane emissions during a hydraulically fractured oil well flowback by multiplying potential methane and VOC emissions per day by the number of days in the average flowback event. The data sources referenced in the white papers noted a range of flowback duration from 1-10 days. Some of the values in the ranges were based on study observation and some based on assumptions. Comments on the oil well completion white paper supported a flowback duration on the low end of the range. Our analysis assumes an oil well flowback duration is toward the low end of that range, 3 days.

[16] *See footnote* 3.

NMED Exhibit 70

Table 3-2 presents the estimated potential (i.e., uncontrolled) emissions from a representative oil well completion or recompletion. The data sources in the white papers and comments received on the white papers showed a broad range of potential emission estimates (8 to around 200 tons methane per completion or workover) for hydraulically fractured oil well completions. Some of the values were developed using data on gas production and assumptions about flowback; others used measurement data. As described above, the estimates presented in the table below were developed using flowback characteristics and gas production data and include the effect of a GOR threshold of 300 that excludes oil wells with very little gas production. The estimates in the table below represent emissions from that population of wells, in the absence of controls. To calculate emissions to the atmosphere using these values, additional information on gas that is not emitted (e.g., through use of RECs or flaring) is needed.

Table 3-2. Uncontrolled Emission Estimates from Representative Oil Well Completion or Recompletion

	Average Daily Production Natural Gas (Mcf/event)	Potential Emissions Methane [a] (tons/event)	Potential Emissions VOC [b] (tons/event)
3-Day Completion or Recompletion Event	999	9.72	8.14

a. It is assumed methane comprises 46.732 percent by volume of natural gas. The factor used to convert methane from volume to weight is 0.0208 tons methane per thousand cubic feet (Mcf) of methane.[17]
b. Assumes 0.8374 lb. VOC/lb. methane.

3.3 Control Techniques

3.3.1 Potential Control Techniques

The techniques that have been proven to reduce emissions from oil well completions and recompletions are the same as those that were evaluated for development of the 2012 NSPS for gas well completions and recompletions; specifically RECs and completion combustion. As with natural gas wells, the use of a REC not only reduces emissions but delivers natural gas product to the sales meter that would typically be vented. Completion combustion destroys the organic compounds. Based on our research as published in the oil completions white paper, these technologies have been found to be technically feasible for oil well completions and recompletions, and are in use in the industry to control emissions from oil wells. The EPA identified no other potential control options for oil well completions. For the sake of convenience, the description sections included below are from the 2012 NSPS TSD with limited edits. The

[17] U.S EPA. Methodology for Estimating CH_4 and CO_2 Emissions from Petroleum Systems. Greenhouse Gas Inventory: Emission and Sinks 1990-2008. Washington, DC. 2010. Appendix B, Pgs. 87-89.

NMED Exhibit 70

following sections describe the cost impact of these technologies with respect to oil well completions based on our current analysis of emissions.

3.3.2 Reduce Emission Completions and Recompletions

3.3.2.1 Description

Reduced emission completions, also referred to as "green" completions, use specially designed equipment at the well site to capture and treat gas during well completion activities. This process prevents some natural gas from venting and results in additional revenues for producers from the sale or use of captured gas and, if present, gas condensate. Additional equipment required to conduct a REC may include additional tankage, special gas-liquid-sand separator traps, and a gas dehydrator.[18]

In many cases, portable equipment used for RECs operate in tandem with the permanent equipment that will remain after well drilling is completed. In other instances, permanent equipment is designed (e.g. oversized) to specifically accommodate initial flowback. Some limitations exist for performing RECs since technical barriers fluctuate from well to well. Three main limitations include the following for RECs:

- Proximity of pipelines. For exploratory wells, no nearby sales line may exist. The lack of a nearby sales line incurs higher capital outlay risk for exploration and production companies and/or pipeline companies constructing lines in exploratory fields. The State of Wyoming has set a precedent by stating proximity to gathering lines for wells is not a sufficient excuse to avoid RECs unless they are deemed exploratory, or the first well drilled in an area that has never had oil and gas well production prior to that drilling instance (i.e., a wildcat well).[19] In instances where formations are stacked vertically and horizontal drilling could take place, it may be possible that existing surface REC equipment may be located near an exploratory well, which would allow for a REC.
- Pressure of produced gas. During the completion/recompletion process, the pressure of flowback fluids may not be sufficient to overcome the gathering line backpressure. In this case, combustion of flowback gas is one option, either for the duration of the flowback or until a point during flowback when the pressure increases to flow to the sales line. Another potential

[18] U.S. EPA Fact Sheet No. 703: Green Completions. OAR: Natural Gas Star Program. Washington, DC. September 2004.
[19] Memorandum to Bruce Moore, U.S. EPA from Denise Grubert, EC/R. API Meeting Minutes. July 2010.

NMED Exhibit 70

compressor application is to boost pressure of the flowback gas after it exits the separator. This technique is experimental because of the difficulty operating a compressor on widely fluctuating flowback rate.

- Inert gas concentration. If the concentration of inert gas, such as nitrogen or CO_2, in the flowback gas exceeds sales line concentration limits, venting or combustion of the flowback may be necessary for the duration of flowback or until the gas energy content increases to allow flow to the sales line. Further, since the energy content of the flowback gas may not be high enough to sustain a flame due to the presence of the inert gases, combustion of the flowback stream would require a continuous ignition source with its own separate fuel supply.

3.3.2.1 Emission Reduction Potential

RECs are an effective emission reductions method for oil well completions and recompletions performed with hydraulic fracturing based on the estimated flowback emissions described in Section 2.2. The emission reductions vary according to reservoir characteristics and other parameters including length of completion, number of fractured zones, pressure, gas composition, and fracturing technology/technique. Based on information presented in the white papers, this analysis assumes 90 percent of flowback gas can be recovered during a REC.[20] Any amount of gas that cannot be recovered can be directed to a combustion device in order to achieve a minimum 95 percent reduction in emissions.

3.3.2.2 Cost Impacts

All completions incur some costs to a company. Performing a REC will add to these costs. Equipment costs associated with RECs vary from well to well. High production rates may require larger equipment to perform the REC and will increase costs. If permanent equipment, such as a glycol dehydrator, is already installed or is planned to be in place at the well site as normal operations, costs may be reduced as this equipment can be used or resized rather than installing a portable dehydrator for temporary use during the completion. Some operators normally install equipment used in RECs, such as sand traps and three-phase separators, further reducing incremental REC costs. The EPA received information and comment from multiple technical experts that the equipment necessary to perform a REC for an oil well completion is the same as that for a gas well completion.

Therefore, as was determined in the 2011 NSPS TSD[21], the annual cost of performing a REC

[20] Memorandum to Bruce Moore, U.S. EPA from ICF Consulting. Percent of Emissions Recovered by Reduced Emission Completions. May 2011.
[21] *See footnote 1*.

NMED Exhibit 70

was estimated to be $12,735 for a representative well completion lasting 3 days[22]. For our analysis, the cost is adjusted to 2012 dollars using the Gross Domestic Product: Implicit Price Deflator.[23] The resulting cost for performing a REC for a well completion or recompletion lasting 3 days is estimated to be $13,459.

Monetary savings associated with additional gas captured to the sales line is estimated based on a natural gas price of $4.00 per Mcf.[24] It was assumed that all gas captured would be included as sales gas. Therefore, assuming that 90 percent of the gas is captured and sold, this equates to a total recovery of 899 Mcf of natural gas per completion or recompletion. The estimated value of the recovered natural gas for a representative natural gas well with hydraulic fracturing is approximately $3,597. When considering these savings from REC, for a completion or recompletion with hydraulic fracturing, there is a net cost on the order of $9,862 per completion.

RECs are considered one-time events per well; therefore annual costs were conservatively assumed to be the same as capital costs. The cost per ton of emissions reduced was then calculated in two ways, both of which reflect that REC is a multi-pollutant control measure (VOC and GHG (in the form of limitations on methane)). The first method, the single-pollutant method, allocates all of the costs to one pollutant and zero to the other. The second method, the multi-pollutant method, allocates costs among the pollutants that a given technology reduced. This proration was based on estimates of the percentage reduction expected for each pollutant.

Based on expected emission reductions from the use of a REC, the cost of control for methane is $1,539 per ton and $1,837 per ton of VOC when 100 percent of the cost is attributed to one pollutant and zero cost to the other. The cost is $769 per ton of methane and $919 per ton of VOC when the total cost is allocated equally between methane and VOC (i.e., 50 percent to methane and 50 percent to VOC). Table 2-3 provides a summary of REC cost per ton of emission reduction.

Because a REC accomplishes gas savings, the cost of control for methane is $1,127 per ton and $1,346 per ton of VOC when 100 percent of the cost is attributed to one pollutant and zero cost to the

[22] This cost was based on state of the industry in 2006 and adjusted to 2008 US Dollars. For the 2012 NSPS the EPA determined a cost per day value, however, the 2012 NSPS applied this per day cost to a 7-day event duration. Here the EPA use the same cost per day and a 3-day event duration.
[23] Available at http://research.stlouisfed.org/fred2/series/GDPDEF/.
[24] When including the additional natural gas recovery in the cost analysis, the EPA assume that producers are paid $4 per thousand cubic feet (Mcf) for the recovered gas at the wellhead. The Energy Information Administration's 2014 Annual Energy Outlook forecasted wellhead prices paid to lower 48 state producers to be $4.46/Mcf in 2020 and $5.06/Mcf in 2025. The $4/Mcf price assumed in this RIA is intended to reflect the AEO estimate but simultaneously be conservatively low.

other, and the monetary gas savings is considered. Likewise, the cost is $564 per ton of methane and $673 per ton of VOC when the total cost is reduced by the gas savings and is allocated equally between methane and VOC (i.e., 50 percent to methane and 50 percent to VOC). Table 2-3 provides a summary of REC cost per ton of emission reduction.

As mentioned earlier, during a well completion, gas that cannot be recovered with REC can be combusted. For the purposes of this analysis, the EPA also analyzed costs for the a REC combined with the cost of a combustion device as described below in section 2.3.3.1. For the combined REC and combustion scenario, the cost of control for methane is $1,861 per ton and $2,222 per ton of VOC when 100 percent of the cost is attributed to one pollutant and zero to the other. The cost is $930 per ton of methane and $1,111 per ton of VOC when the total cost is allocated equally between methane and VOC (i.e., 50 percent to methane and 50 percent to VOC).

When gas savings is considered, for the combined REC and combustion, the cost of control for methane is $1,471 per ton and $1,757 per ton of VOC when 100 percent of the cost is attributed to one pollutant and zero cost to the other, and the monetary gas savings is considered. Likewise, the cost is $736 per ton of methane and $879 per ton of VOC when the total cost is reduced by the gas savings and is allocated equally between methane and VOC (i.e., 50 percent to methane and 50 percent to VOC). Table 2-3 provides a summary of REC cost per ton of emission reduction.

3.3.2.3 Secondary Impacts

A REC is a pollution prevention technique that is used to recover natural gas that would otherwise be emitted. No secondary emissions (e.g., NO_x, PM, etc.) would be generated, no wastes should be created, no wastewater generated, and no electricity needed. Therefore, there are no secondary impacts expected due to REC.

3.3.3 Combustion Devices

3.3.3.1 Description

As mentioned earlier, during a well completion, gas that cannot be recovered with REC can be combusted. Combustion is a high-temperature oxidation process used to burn combustible components, mostly hydrocarbons, found in waste streams.[25] Combustion devices are used to control VOC in many industrial settings, since these devices can normally handle fluctuations in concentration, flow rate,

[25] U.S. EPA. AP-42, Fifth Edition, Volume I, Chapter 13.5 Industrial Flares. OAQPS. 1991.

NMED Exhibit 70

heating value, and inert species content.[26] Combustion devices commonly found on drilling sites are rather crude and portable, often installed horizontally due to the liquids that accompany the flowback gas. These devices can be as simple as a pipe with a basic ignition mechanism and discharge over a pit near the wellhead (i.e., a pit flare). The flow directed to a combustion device during a well completion may or may not be combustible depending on the inert gas composition of flowback gas, which would require a continuous ignition source. On the other end of the spectrum is the enclosed combustor that is specifically designed for completions that is an integral part of a completion equipment package. For the purpose of this analysis, the term combustion device represents any types of combustion devices used in the industry for control of hydrocarbon emissions.

3.3.3.2 Emission Reduction Potential

It is difficult to measure precisely the destruction efficiency of a combustion device during a well completion activity. The actual destruction efficiency achieved in practice can be expected to vary with the amount of noncombustible gas and liquids in the gas flow. For the purposes of this analysis, a destruction efficiency of 95 percent, consistent with the expected destruction efficiency of a properly designed and operated flare, was assumed for completion combustion devices over the duration of the completion or recompletion. If the energy content of natural gas is low, then the combustion mechanism can be extinguished by the flowback gas. Therefore, it is more reliable to install an igniter fueled by a consistent and continuous ignition source. This scenario would be especially true for energized fractures where the initial flowback concentration will be extremely high in inert gases. This analysis assumes the use of a continuous ignition source with an independent external fuel supply to achieve an average of 95 percent control over the entire flowback period. Additionally, because of the nature of the flowback (i.e., with periods of water, condensate, and gas in slug flow), conveying the entire portion of this stream to a completion combustion device or other control device is not always feasible. Because of the exposed flame, open pit flaring can present a fire hazard or other undesirable impacts in some situations (e.g., dry, windy conditions, proximity to residences). As a result, the design and nature of combustion devices used for completions must handle multiphase flow and stream compositions well site conditions that vary during the flowback period and not all unrecoverable gas can be safely combusted in every case.

[26] U.S. EPA. Air Pollution Control Technology Fact Sheet: FLARES. Clean Air Technology Center.

NMED Exhibit 70

3.3.3.3 Cost Potential

An analysis estimating the cost for wells including combustion devices was conducted for the 2012 NSPS, resulting in an estimated average completion combustion device cost of approximately $3,523 (2008 dollars).[27] For our analysis, this cost was adjusted to 2012 dollars using the Gross Domestic Product: Implicit Price Deflator [28] resulting in an estimated annual cost of $3,723 per well completion. As with the REC, because completion combustion devices are purchased for these one-time events, annual costs were conservatively assumed to be equal to the capital costs.

It is assumed that the cost of a continuous ignition source is included in the combustion completion device cost estimate. It is understood that multiple completions and recompletions can be controlled with the same completion combustion device, not only for the lifetime of the combustion device but within the same yearly time period. However, to be conservative, costs were estimated as the total cost of the completion combustion device itself, which corresponds to the assumption that only one device will control one completion per year. The cost per ton of emissions reduced was then calculated in two ways. The first method (the single-pollutant approach) allocated all of the costs to one pollutant and zero cost to the other. The second method (the multi-pollutant approach) allocated costs among the pollutants that a given technology reduced (i.e., in this case GHG in the form of limitations on methane, and VOC). This allocation was based on estimates of the percentage reduction expected for each pollutant. Completion combustion devices have a cost of control of $403 per ton of methane or $481 per ton of VOC for oil well completions and recompletions when 100 percent of the cost is attributed to one pollutant and zero to the other. Under the multipollutant approach where the cost is prorated to both pollutants equally (i.e., a 50 percent to methane and 50 percent to VOC), the cost of control is $202 per ton of methane and $241 per ton of VOC. The cost impacts of using a completion combustion device to reduce emissions from representative completions/recompletions are provided in Table 3-3.

3.3.3.4 Secondary Impacts

Noise and heat are the two primary undesirable outcomes of completion combustion device operation. In addition, combustion and partial combustion of many pollutants also create secondary pollutants including NO_x, CO, sulfur oxides (SO_x), CO_2, and smoke/particulates. The degree of combustion depends on the rate and extent of fuel mixing with air and the temperature maintained by the

[27] The Chemical Engineering Cost Index was used to convert dollar years. For the combustion device the 2009 value equals the 2009 average value for the combustion device is $3,195.
[28] Available at http://research.stlouisfed.org/fred2/series/GDPDEF/.

NMED Exhibit 70

flame. Most hydrocarbons with carbon-to-hydrogen ratios greater than 0.33 are likely to smoke.[29] The high methane content of the gas stream routed to the completion combustion device suggests that there should not be smoke except in specific circumstances (e.g., energized fractures). The stream to be combusted may also contain liquids and solids that will also affect the potential for smoke. Soot can typically be eliminated by adding steam. Based on current industry trends in the design of completion combustion devices and in the decentralized nature of completions, virtually no completion combustion devices include steam assistance.[30]

Reliable data for emission factors from flare operations during natural gas well completions are limited. Guidelines published in AP-42 for flare operations are based on tests from a mixture containing 80 percent propylene and 20 percent propane.[31] These emissions factors, however, are the best indication for secondary pollutants from flare operations currently available. These secondary emission factors are provided in Table 3-5.

a. Based on combustion efficiency of 98 percent.
b. Measured as methane-equivalent.
c. Soot in concentration values: nonsmoking flares, 0 micrograms per liter (µg/L); lightly smoking flares, 40 µg/L; average smoking flares, 177 µg/L; and heavily smoking flares, 274 µg/L.
d. Carbon dioxide factor is derived from the CO_2 emission factor obtained from 40 CFR Part 98, subpart Y, Equation Y-2.

3.4 Regulatory Options

The REC pollution prevention approach would not result in emissions of CO, NO_x, and particulate matter (PM) from the combustion of the completion gases in the completion combustion device. Taking this into consideration, the following regulatory alternatives were evaluated:

- Regulatory Option 1. Require combustion for all hydraulically fractured oil well completions and recompletions;
- Regulatory Option 2. Require REC for all hydraulically fractured oil well completions and recompletions;
- Regulatory Option 3. Require REC and combustion for hydraulically fractured oil well completions and recompletions where gas can be recovered with REC; and
- Regulatory Option 4. Require combustion where gas cannot be recovered with REC.

The following sections discuss these regulatory options.

3.4.1 Evaluation of Regulatory Options

Under Regulatory Option 1, nearly all of the natural gas emitted from the well during flowback would be destroyed by sending flowback gas through a combustion unit. Not only would this regulatory option result in the destruction of a natural resource with no recovery of salable gas, it also would result in an increase in emissions of secondary pollutants (e.g., NO_x, CO). Therefore, EPA rejected Regulatory

NMED Exhibit 70

Option 1.

The second regulatory option would require RECs for all completions and recompletions of hydraulically fractured oil wells. As stated previously, RECs are not technically feasible for all well completions, such as exploratory wells due to their distance from sales lines. Further, RECs are also not always technically feasible for each well at all times during completion and recompletion activities due to the variability of the pressure of produced gas or inert gas concentrations.

The third regulatory option consists of a combination of REC and combustion for hydraulically fractured oil well completions. As discussed for Regulatory Option 2, RECs are not feasible for every well at all times during completion or recompletion activities due to variability of produced gas pressure or inert gas concentrations. In order to allow for owners and operators to continue to reduce emissions when RECs are not feasible due to well characteristics (e.g., wellhead pressure or inert gas concentrations), or infrastructure issues (e.g., absence of pipelines or processes on-site which can be used to route captured gas) Regulatory Option 3 also allows for the use of a completion combustion device in combination with RECs.

Under this option, some venting must be allowed in lieu of combustion for situations in which combustion would present safety hazards, other concerns.

Regulatory Option 4 reduces emissions through combustion in situation where gas cannot re recovered through REC (for exploratory and delineation wells due to their distance from sales lines, low pressure wells).

NMED Exhibit 70

4.0 FUGITIVE EMISSIONS STANDARDS

In the TSD for the proposed rule, monitoring options for reducing fugitive emissions from well sites and compressor stations were analyzed. The monitoring options that were analyzed included optical gas imaging (OGI) and Method 21 at monitoring frequencies of annual, semiannual and quarterly. For Method 21 repair thresholds of 10,000 ppm, 2,500 ppm and 500 ppm were also analyzed for each of the monitoring frequencies. Based on the analysis in the proposed rule TSD, the semiannual OGI monitoring option was selected as BSER for well sites and compressor stations. Comments on the proposed BSER analysis were received during the proposed rule comment period, and the BSER analysis for the OGI option was re-evaluated to take into account these comments. In response to comments, Method 21 was also re-evaluated as an alternative option for fugitive emission monitoring.

4.1 Fugitive Emissions Description

There are several potential sources of fugitive emissions throughout the oil and natural gas source category. Fugitive emissions occur when connection points are not fitted properly or when seals and gaskets start to deteriorate. Changes in pressure and mechanical stresses can also cause components or equipment to emit fugitive emissions. Poor maintenance or operating practices, such as improperly reseated PRVs or thief hatches on controlled storage vessels that are left open after sampling, are also potential sources of fugitive emissions. Potential sources of fugitive emissions include agitator seals, connectors, pump diaphragms, flanges, instruments, meters, open-ended lines (OELs), pressure relief devices such as pressure release valves (PRVs), pump seals, valves or improperly controlled liquid storage tanks. These fugitive emissions do not include devices that vent as part of normal operations, such as gas driven pneumatic controllers or gas driven pneumatic pumps, insofar as the natural gas discharged from the device's vent is not considered a fugitive emission.

For the purposes of the analysis and regulatory evaluation of fugitive emissions from components and equipment, the EPA differentiated between the current definition of "equipment" in the rule[32] and the intended definition for the purposes of addressing fugitive emissions. Therefore in the final rule, the EPA have defined a new term, "fugitive emissions component" as the focus of the

[32] The Oil and Natural Gas Sector NSPS (40 CFR 60, subpart OOOO) specifically defines "equipment" relative to standards for equipment leaks of VOC from onshore natural gas processing plants. As used in this chapter, the term "equipment" is used in a broader context and is not meant to be limited by the manner in which the term is currently used in subpart OOOO.

NMED Exhibit 70

requirements for fugitive emissions. The proposed definition for fugitive emissions component is as follows:

> Fugitive emissions component means any component that has the potential to emit fugitive emissions of methane or VOC, including but not limited to valves, connectors, pressure relief devices, open-ended lines, access doors, flanges, closed vent systems, thief hatches or other openings on a storage vessels, agitator seals, distance pieces, crankcase vents, blowdown vents, pump seals or diaphragms, compressors, separators, pressure vessels, dehydrators, heaters, instruments, and meters. Devices that vent as part of normal operations, such as a gas-driven pneumatic controller or a gas-driven pump, are not fugitive emissions components, insofar as the gas discharged from the device's vent is not considered a fugitive emission. Emissions originating from sites other than the vent, such as the seals around the bellows of a diaphragm pump, would be considered fugitive emissions.

The EPA received comment that this proposed fugitive emissions component definition was too broad and vague and may include equipment such as separators, pressure vessels, and dehydrators instead of the components (i.e., valves, connectors) on the equipment. The commenters also asserted that the "included but not limited to" description adds uncertainty to what should be included in the collection of fugitive emissions components. Based on these comments, the EPA has revised the definition of fugitive emissions component in the final rule to read:

> *Fugitive emissions component means any component that has the potential to emit fugitive emissions of methane or VOC at a well site or compressor station, including but not limited to valves, connectors, pressure relief devices, open-ended lines, flanges, covers and closed vent systems not subject to §60.5411a, thief hatches or other openings on a controlled storage vesselnot subject to §60.5395a, compressors, instruments, and meters. Devices that vent as part of normal operations, such as natural gas-driven pneumatic controllers or natural gas-driven pumps, are not fugitive emissions components, insofar as the natural gas discharged from the device's vent is not considered a fugitive emission. Emissions originating from other than the vent, such as the thief hatch on a controlled storage vessel, would be considered fugitive emissions.*

NMED Exhibit 70

In April of 2014, the EPA published a white paper[33] which summarized the EPA's current understanding of methane and VOC fugitive emissions at onshore oil and natural gas production, processing and transmission and storage facilities. The white paper also outlined the EPA's understanding of the available mitigation techniques (practices and equipment) available to reduce these emissions along with the cost and emission reduction potential of these practices and technologies.

4.2 Fugitive Emissions Data and Emissions Factors

4.2.1 Model Plants

For the proposed rule, model plants were developed to estimate fugitive emissions from well sites and compressor stations. Data from the 2016 draft GHG Inventory[34], developed with the most recently published GHGRP reported data, were used to determine the equipment counts for well sites and compressor stations. Component counts per piece of equipment were those used in the GHG Inventory and GHGRP, which were derived the EPA/GRI study and 40 CFR, part 98, subpart W tables, were then used to determine the total number of fugitive components (valves, connectors, OELs, and PRVs) at each of these sites. A description of the data and methodology for determining fugitive emissions for these model plants are discussed in the following sections.

4.2.2 Oil and Gas Production Well Sites

Oil and natural gas production practices and equipment vary from site-to-site. Some production sites may include only a single wellhead that is extracting oil or natural gas from the ground, while other sites may include multiple wellheads attached to a well pad. A well site is a site where the production, extraction, recovery, lifting, stabilization, separation and/or treating of petroleum and/or natural gas (including condensate) occurs. These sites include all equipment (including piping and associated components, compressors, generators, separators, storage vessels, and other equipment) that have associated components that may be sources of fugitive emissions associated with these operations. A well site can serve one well on a pad or multiple wells on a pad. Therefore, the number of components with potential for fugitive emissions can vary depending on the number of wells at the site.

Baseline model plant emissions for the natural gas and oil production well sites were calculated using the fugitive emissions equipment counts from GHG Inventory, derived from GHGRP, EPA/GRI,

[33] U.S. EPA. *Oil and Natural Gas Sector Leaks*, OAQPS. Research Triangle Park, NC. April 2014. Available at http://www.epa.gov/airquality/oilandgas/2014papers/20140415leaks.pdf.

[34] The draft 2016 GHG Inventory was the most recent data available at the time of this analysis. The 2016 GHG Inventory was finalized April 15, 2016 with the same data that was used in the public review draft. Therefore, this analysis is consistent with the most recent final GHG Inventory.

NMED Exhibit 70

and 40 CFR part 98, subpart W tables as described above, and the component oil and natural gas production emission factors from AP-42[35]. Annual emissions were calculated assuming 8,760 hours of operation each year. The emissions factors are provided for total organic compounds (TOC) and include non-VOCs such as methane and ethane. The emission factors used to estimate the emissions from the production segment (e.g., oil production well sites and natural gas production well sites) are presented in Table 4-1. The emission factors in Table 4-1 are also used to calculate fugitive emissions from gathering and boosting stations.

PRV	Gas	8.8E-03

a. Data Source: EPA, Protocol for Equipment Leak Emission Estimates, Table 2-4, November 1995. (EPA-453/R-95-017)

4.2.2.1 Proposed Rule Well Site Model Plant

A model plant for natural gas and oil well sites was developed using the average number of wells associated with a well site using data from the DrillingInfo HPDI® database[36]. The analysis, described in the TSD for the proposed rule, determined that the national average of wells per well site was 1.81, and was rounded to 2.0 wells per well site for the model plant fugitive analysis for both natural gas production and oil production well sites.

For the proposed rule, average equipment count per well data from the EPA/GRI document for natural gas production well sites and GHG Inventory for oil production well sites were used to determine the number of production equipment located at a well site. The average equipment count per well for each of the equipment types were multiplied by the average number of wells at a well site (2) and then rounded up to the nearest integer.

The types of production equipment located at a natural gas well site includes: gas wellheads, separators, meters/piping, in-line heaters, and dehydrators. The types of components that are associated

[35] U.S. EPA, Protocol for Equipment Leak Emission Estimates, Table 2-4, November 1995. (EPA-453/R-95-017)
[36] Drilling Information, Inc. 2011. *DI Desktop.* 2011 Production Information Database.

NMED Exhibit 70

with this production equipment include: valves, connectors, OELs, and PRVs. Component counts for each of the production equipment items were calculated using the average component counts for onshore production equipment in the Eastern U.S and the Western U.S. from the EPA/GRI report. Fractions of components were rounded up to the nearest integer.

Baseline fugitive emissions for the proposed rule were calculated using the estimated component counts for the natural gas well site and the total organic compound (TOC) emission factors from AP-42. Annual emissions were calculated assuming 8,760 hours of operation each year. The TOC emissions were converted to methane and VOC using methane/TOC and VOC/TOC weight ratios as described in the 2011 Gas Composition Memorandum developed for the 2012 NSPS[37]. For the proposed rule, the fugitive emissions for the natural gas production well site model plant were determined to be 4.54 tons per year of methane and 1.26 tons per year of VOC.

For oil well sites, data from the GHG Inventory, derived from GHGRP reported data, were used to estimate equipment counts for these sources. The types of oil well site equipment include: oil well heads, separators, headers and heater/treaters. Fugitive emissions components counts for these equipment types were estimated using component count data from Table W-1C of 40 CFR part 98, subpart W.

The estimated baseline fugitive emissions from oil well sites were calculated using the estimated component counts and the total organic compound (TOC) emission factors from AP-42. Annual emissions were calculated assuming 8,760 hours of operation each year. The TOC emissions were converted to methane and VOC using methane/TOC and VOC/TOC weight ratios in the gas composition memorandum. For the proposed rule, the fugitive emissions for the oil well site model plant were determined to be 1.09 tons per year of methane and 0.30 tons per year of VOC.

4.2.2.2 Final Rule Natural Gas Well Site Model Plant

During the comment period for the proposed rule, updated data on equipment counts per well (derived from GHGRP reported data) became available for 2013 (the most recent year of data available in the public review draft) from the draft 2016[38] GHG Inventory, and was used to revise the equipment

[37] Memorandum to Bruce Moore. U.S. EPA from Heather Brown, EC/R. "Composition of Natural Gas for Use in the Oil and Natural Gas Sector Rulemaking". July 28, 2011.
[38] In the final 2016 GHG Inventory, the equipment counts per well are the same as those in the draft GHG inventory used in this analysis.

NMED Exhibit 70

counts for the natural gas well sites. The average equipment count per well was multiplied by the average number of wells per well site (2) and rounded to the next highest integer. The updated equipment counts per natural gas well site were 2 separators, 3 meters/piping, 1 in-line heaters, and 1 dehydrators per well. In comparison to the model plant in the proposed rule TSD, the only change in equipment counts was for meters/piping which increased from 1 to 3. Average component counts for each piece of equipment were calculated using the average component counts for onshore production equipment in the Eastern U.S and the Western U.S. from the EPA/GRI study. The total number of fugitive emissions components was calculated by multiplying the rounded equipment counts by the component count per piece of equipment and rounding to the nearest integer. A summary of the fugitive emissions component counts for natural gas production well sites is presented in Table 4-2.

The baseline fugitive emissions for the natural gas well site model plant were calculated using the revised component counts for the natural gas well site model plant and the oil and natural gas production AP-42 TOC emission factors. Annual emissions were calculated assuming 8,760 hours of operation each year. The TOC emissions were converted to methane and VOC using methane/TOC and VOC/TOC weight ratios in the gas composition memorandum. The fugitive emissions for the natural gas well site model plant were determined to be 5.50 tons per year of methane and 1.53 tons per year of VOC and are provided in Table 4-3.

4.2.2.3 Final Rule Oil Well Site Model Plant

Comments on the proposed rules stated that methane emissions from oil well site model plants were underestimated. While some oil wells produce very little natural gas (oil wells with a gas-to-oil-ratio less than 300 standard cubic feet of gas per stock barrel of oil), other oil wells produce significant volumes of natural gas (oil wells with a gas-to-oil-ratio greater than 300 standard cubic feet of gas per stock barrel of oil). To address these types of oil wells, two model plants were developed to estimate fugitive emissions from oil well sites. The oil well site model plant developed for the proposed rule was used to define the oils wells with a gas-to-oil ratio less than 300 standard cubic feet of gas per stock barrel of oil (< 300 GOR). During the comment period for the proposed rule, updated data on equipment counts per well (derived from GHGRP reported data) became available for 2013 (the most recent year of data available in the public review draft) from the draft 2016[39] GHG Inventory, and was used to revise

[39] In the final 2016 GHG Inventory, the equipment counts per well are the same as those in the draft GHG inventory used in this analysis.

NMED Exhibit 70

the equipment counts for the oil well sites. The equipment count for this model plant consists of 2 oil wellheads, 1 separator, 1 header, and 1 heater/treater. To develop the model plant for oil well sites with a gas-to-oil ratio greater than 300 standard cubic feet of gas per stock barrel of oil (> 300 GOR), three meters/piping were added to the equipment counts included for the < 300 GOR model plant to account for the handling of the natural gas from the well. Component counts for the oil well equipment (wellhead, separator, header, heater/treater) were obtained from Table W-1C of subpart W The component counts for meters/piping were obtained from the average component counts for onshore production equipment in the Eastern U.S and the Western U.S. from the EPA/GRI study. The total number of fugitive emissions components was calculated by multiplying the rounded equipment counts by the component count per production equipment and rounding to the nearest integer. A summary of the fugitive emissions component counts for oil well site model plants are presented in Table 4-4.

Baseline model plant emissions for the oil well site model plants were calculated using the fugitive emissions component counts and the component oil and natural gas production emission factors from AP-42. Annual emissions were calculated assuming 8,760 hours of operation each year. The TOC emissions were converted to methane and VOC using methane/TOC and VOC/TOC weight ratios in the gas composition memorandum. The fugitive emissions for the < 300 GOR model plant were determined to be 1.23 tons per year of methane and 0.33 tons per year of VOC. The fugitive emissions for the > 300 GOR model plant were determined to be 2.75 tons per year of methane and 0.75 tons per year of VOC. A summary of the emissions are provided in Table 4-5.

4.2.3 Compressor Stations

The proposed rule TSD evaluated fugitive monitoring at three types of compressor stations; gathering and boosting stations, transmission stations and storage stations. The equipment associated with these compressor stations vary depending on the volume of natural gas that is transported and whether any treatment of the gas, such as the removal of water or hydrocarbons occurs. These sites include all equipment (including piping and associated components, compressors, generators, separators, storage vessels, and other equipment) that have associated components (e.g., valves, connectors) that may be sources of fugitive emissions associated with these operations.

NMED Exhibit 70

4.2.3.1 Proposed Rule Compressor Station Model Plant

For the proposed rule TSD, baseline model plant emissions for compressor stations were calculated using the fugitive emissions component counts from the EPA/GRI document and the component oil and natural gas production emission factors from AP-42 for gathering and boosting stations and EPA/GRI emission factors for transmission and storage stations. Annual emissions were calculated assuming 8,760 hours of operation each year. The AP-42 emission factors are provided for total organic compounds (TOC) and include non-VOCs such as methane and ethane. The emission factors used to estimate the new source emissions from the gathering and boosting stations are presented in Table 4-1. In the proposed rule TSD, the fugitive emissions from gathering and boosting stations were estimated to be 35.1 tons per year of methane and 9.77 tons per year of VOC. The model plant fugitive emissions for transmission stations were estimated to be 62.4 tons per year of methane and 1.73 tons per year of VOC, and 164.4 tons per year of methane and 4.55 tons per year of VOC for storage stations.

4.2.3.2 Final Rule Compressor Station Model Plant

Gathering and boosting stations are sites that collect oil and natural gas from well sites and direct them to the natural gas processing plants. These stations have similar production equipment (including separators, meters, piping, compressors, in-line heaters, dehydrators and other equipment) to well sites; however, they are not directly connected to the wellheads. The EPA/GRI document does not have specific equipment counts for the gathering and boosting segment, but does include equipment counts for gathering compressors within the oil and natural gas production data. To estimate the equipment at a gathering and boosting model plant, the weighted averages of equipment counts for the Eastern and Western U.S. data sets for onshore production equipment were calculated. The weighted averages of the data sets were determined to be 11 separators, 7 meters/piping, 5 gathering compressors, 7 in-line heaters, and 5 dehydrators. These average equipment counts were used to create the model plant for gathering and boosting stations. The components for gathering compressors were included in the model plant total counts, but the compressor seals were excluded. Compressors seals are addressed in Chapter 8 of this document. A summary of the fugitive emissions component counts for oil and gas gathering and boosting stations are presented in Table 4-6.

NMED Exhibit 70

The proposed gathering and boosting model plant did not change from proposal. Therefore, the baseline emissions that are discussed in Section 4.2.3.1 remain the same for the final TSD and are summarized in Table 4-7. The emissions were used to estimate the potential emission reductions and cost of control of a fugitive emissions reduction program.

4.2.3.3 Final Rule Natural Gas Transmission and Storage Model Plant

Natural gas transmission and storage stations are facilities that use compressors to move natural gas at elevated pressure from production fields or natural gas processing facilities, in transmission pipelines, to natural gas distribution pipelines, or into storage. In addition, transmission stations may include production equipment for liquids separation, natural gas dehydration, and tanks for the storage of water and hydrocarbon liquids. Residue (sales) gas compressors operated by natural gas processing facilities are included in the onshore natural gas processing segment and are excluded from this segment. The segments include fugitive emissions from components related to inlet and outlet pipelines, meter runs, dehydrators, and other piping located at the compressor building for transmission and storage stations, and injection/withdrawal components associated with the injection/withdrawal well piping at storage stations. This industry segment also includes emissions from compressor related components, but does not include emissions from compressor seals or site blowdown open-ended lines. The blowdown open-ended lines were included in the proposed rule TSD, but were determined, based on comments, to be a vent rather than a fugitive emission source. Therefore in this analysis, emissions from blowdown open-ended lines were removed from the component list and the associated emissions were not included in the total fugitive emissions from transmission and storage stations. For the other components at these facilities, fugitive emissions component counts and methane emission factors were obtained from the EPA/GRI study. A summary of the fugitive emissions component counts, component emission factors and baseline methane and VOC emissions for transmission and storage model plants are presented in Table 4-8. The average fugitive emissions for transmission stations were determined to be 40.4 tons per year of methane and 1.12 tons per year of VOC and 142.4 tons per year of methane and 3.94 tons per year of VOC for storage facilities. These emissions were used to estimate the potential emission reductions and cost of control of a fugitive emissions reduction program.

a. Component counts and methane emission factors for non-compressor related components obtained from EPA/GRI, Methane Emissions from the Natural Gas Industry, Volume 8: Equipment Leaks, Table 4-17 and 4-24, June 1996. (EPA-600/R-96-080h)
b. Methane emissions calculated by multiplying the model plant component count by the component methane emission factor and converting to tons using the conversion factor 0.02082 tons methane/Mscf methane.
c. VOC emissions calculated using 0.0277 weight ratio for VOC/methane obtained from Gas Composition memorandum.

4.3 Control Techniques

4.3.1 Potential Control Techniques

The use of OGI and Method 21 to monitor and reduce fugitive emissions from well sites and compressor stations was evaluated in the TSD for the proposed rule. Based on this analysis, it was determined that semiannual monitoring using OGI was BSER for both well sites and compressor stations. The EPA received numerous comments on this BSER determination and re-evaluated the OGI option using updated information received during the comment period. The re-evaluation for the final rule is provided in the following sections.

NMED Exhibit 70

4.3.2 Fugitive Emissions Detection and Repair with OGI

4.3.2.1 Description

The reduction of fugitive emissions from well sites and compressor stations (i.e., gathering and boosting stations, transmission stations, and storage facilities) involves the development of a fugitive emissions monitoring plan. Under this option, the final rule states that monitoring is conducted using OGI, and the company develops and implements a monitoring plan that covers the collection of fugitive emissions components at well sites or compressor stations within a company defined area. The monitoring plan would include inspection of the collection of all fugitive emissions components, such as connectors, open-ended lines/valves, pressure relief devices, closed vent systems, compressors, and thief hatches on controlled storage vessels. The plan would include provisions to repair or replace fugitive emissions components if evidence of fugitive emissions is discovered during the OGI survey (e.g., any visible emissions from a fugitive emissions component observed using OGI).

In order to estimate the cost of implementation of a monitoring and repair plan, the EPA needed to estimate the cost of repair, which is based on the number of components found to have fugitive emissions. Since OGI visualizes gaseous emissions using active or passive infrared imaging, the OGI the operator would not be able to determine the exact concentration or emission rate of the fugitive emissions; however, all visualized fugitive emissions would be required to be repaired. If a fugitive emissions component cannot be immediately repaired during the monitoring survey, the operator must repair or replace the component as soon as practicable, but no later than 30 days after detection of the fugitive emissions. For this resurvey, the operator may use OGI, Method 21 or the alternative screening procedures specified in section 8.3.3 of Method 21 to confirm that the component is no longer emitting fugitive emissions. When OGI is used for the resurvey, no visible emissions indicate that the fugitive emissions component has been repaired. When Method 21 is used for the resurvey, no detectable emissions (e.g., a concentration of less than 500 ppm above background) indicate that the fugitive emissions component has been repaired.

4.3.2.2 Emission Reduction Potential

Information in the white paper related to the potential emission reductions from OGI monitoring and repair varied from 40 to 99 percent. The data from these studies are based on the gathering of individual OGI surveys at various oil and natural gas segment sites. The variation in the percent reductions from these OGI surveys generally depended on whether large fugitive emission sources were found during the OGI survey and assumptions made by the authors. However, these studies in the white paper did not

NMED Exhibit 70

provide information on the potential emission reductions from the implementation of an annual, semiannual, quarterly or monthly OGI monitoring and repair program. A report was found after the publication of the white paper from the Colorado Air Quality Control Commission[40] which estimated 40 percent reduction for annual OGI monitoring for well production tank batteries with an uncontrolled VOC emissions of greater than 6 tpy or less than or equal to 12 tpy (≥ 6 to ≤ 12 tpy), 60 percent reduction for quarterly OGI monitoring for well production tank batteries with an uncontrolled VOC emissions of greater than 12 tpy and less than or equal to 50 tpy (> 12 to ≤ 50 tpy), and 80 percent reduction for monthly OGI monitoring at well production tank batteries with an uncontrolled VOC emission greater than 50 tpy (> 50 tpy).

From the review of the studies in the white paper and the Colorado Economic Impact Analysis, the EPA expects the emission reductions from the implementation of an OGI monitoring and repair program to vary depending on the frequency of monitoring. As noted above, Colorado estimated that monthly monitoring would achieve 80 percent at well production tank batteries with an uncontrolled VOC emission rate of greater than 50 tpy. We believe, based on our review of the studies, monthly monitoring should achieve much higher emission reductions. Based on the information in the studies and EPA's engineering judgement, the potential emission reduction percentages for the proposed rule were estimated to be 40 percent for annual monitoring, 60 percent for semiannual monitoring, and 80 percent for quarterly monitoring.

Data from the EPA Protocol document estimates monthly Method 21 monitoring to achieve 87 percent reductions at a leak definition of 10,000 ppm and 92 percent reductions at a leak definition of 500 ppm. Potential emissions reductions for annual, semiannual, and quarterly monitoring frequencies[41] were calculated using the data from the EPA Protocol document. For quarterly monitoring, the Method 21 data from the EPA Protocol document estimates a 67 percent reduction at a leak definition of 10,000 ppm and an 83 percent reduction at a leak definition of 500 ppm. Using Method 21 data from the EPA Protocol document, we estimated the percent reductions from semiannual monitoring to be 55 percent at a leak definition of 10,000 ppm and 75 percent reduction at a leak definition of 500 ppm. The potential emission reduction percentages for annual monitoring were calculated to be 42 percent at a leak definition of 10,000 ppm and 68 percent at a leak definition of 500 ppm. The OGI camera is capable of viewing leaks at a 500

[41] Memorandum from Bradley Nelson, EC/R to Jodi Howard, EPA/OAQPS/SPPD, Estimation of Potential Emission Reductions with the Implementation of a Method 21 Monitoring Program, April 25, 2016.

NMED Exhibit 70

ppm level, and achieve similar reductions as a Method 21 monitoring program. Based on this information, we believe the expected emission reductions from an OGI monitoring and repair program falls somewhere in the 500 and 10,000 ppm range found in the Method 21 monitoring programs, but closer to the 500 ppm level.

A study performed by ICF[42] using data from Subpart W, EPA/ GRI, City of Fort Worth Natural Gas Air Quality Study, UT Study - Methane Emissions in the Natural Gas Supply Chain: Production, UT Study - Methane Emissions from Process Equipment at Natural Gas Production Sites in the United States Pneumatic Controllers and Jonah Energy LLC WCCA Spring Meeting Presentation determined that the Year 3 fugitive emissions reductions from a quarterly LDAR program to be 78 percent. The data provided in the study supports 40, 60, 80 percent emission reductions for annual, semi-annual and quarterly monitoring, respectively.

On the basis of the analysis and the data described here, it was concluded that an OGI monitoring program in combination with a repair program can reduce fugitive methane and VOC emissions from these segments by 40 percent on an annual frequency, 60 percent on a semiannual frequency and 80 percent on a quarterly frequency as well as minimize the loss of salable gas.

To be conservative, we performed a sensitivity analysis using the midpoint between the potential emissions reductions that were calculated for each of the Method 21 monitoring frequencies at leak definitions of 10,000 ppm and 500 ppm, which were determined to be 55, 65, and 75 percent for annual, semiannual and quarterly monitoring, respectively. We then compared the potential emissions reductions from 40, 60, 80 percent reductions with the Method 21 midpoint reduction percentages of 55, 65 and 75 and found that the annual methane and VOC emission reductions at each of the monitoring frequency intervals were comparable.[43]

4.3.2.3 Cost Impacts

Costs for preparing an OGI fugitive emission monitoring and repair plan for a company defined area (i.e., field or district) were estimated using hourly estimates for each of the monitoring and repair plan elements. The costs are based on the following assumptions:

[42] ICF International, Leak Detection and Repair Cost-Effectiveness Analysis, Prepared for Environmental Defense Fund, December 4, 2015, Revised May 2, 2016.
[43] See Emission Reduction Comparison - Well Sites.xls and Emission Reduction Comparison – Compressor Stations.xls in the docket for more information.

NMED Exhibit 70

- Labor cost for each of the monitoring plan elements, such as reading the rule, was estimated to be $57.80 per hour.
- Reading of the rule and instructions would take 1 person 4 hours to complete at a cost of $231.
- Development of a fugitive emission monitoring plan would take 2.5 people a total of 60 hours to complete at a cost of $3,468.
- Initial activities planning are estimated to take 2 people a total of 8 hours per person for each monitoring event. Cost for annual monitoring was estimated to be $925 semiannual monitoring was estimated to be $1,850 and quarterly monitoring $3,699.
- Notification of compliance status was estimated to take 1 person 1 hour to complete at a cost of $58 for compressor stations (i.e., gathering and boosting stations, transmission stations, and storage facilities). For companies that own and operate well sites, the cost notification of compliance status was estimated to be $58 per well site for each company defined area, which is estimated to operate 22 well sites within the defined area for a total of $1,272.
- Cost of a Method 21 Monitoring Device of $10,800.
- Costs for implementing a fugitive emission monitoring plan for a company defined area (i.e., field or district) were estimated for each of the monitoring and repair elements. The costs are based on the following assumptions:
- Subsequent activities planning are estimated to take 2 people a total of 8 hours per person to complete at a cost of $925 per monitoring event. For oil and natural gas production well sites, this cost was divided among the total number of well sites owned in a company defined area, which was assumed to be 22. The cost per well site was estimated to be $42 per monitoring event.
- The cost for OGI monitoring using an outside contractor was assumed to be $600 for a well site and $2,300 for a compressor station.[44]
- Annual repair costs were estimated to be $299 per monitoring event for well sites, $3,436 per monitoring event for gathering and boosting stations, $3,361 per monitoring event for transmission stations, and $6,946 per monitoring event for storage facilities. These costs were estimated assuming that 1.18 percent of the components are found to leak[45] during monitoring and 75 percent are repaired online and 25 percent are repaired offline.

[44] Costs for contractor based OGI monitoring obtained from the Carbon Limits report.

[45] The assumption of 1.18% leak rate for OGI monitoring was obtained from Table 5 of the Uniform Standards memorandum. The 1.18% value is the baseline leak frequency for valves in gas/vapor service. None of the other baseline frequencies in this table were used because the equipment are in liquid service (e.g., pumps LL, valve LL, agitators LL). There is no information

NMED Exhibit 70

- Costs to resurvey the repaired components that could not be fixed during the initial survey using a Method 21 device was estimated using a resurvey time of 5 minutes per leak at a cost of $58 per hour. This assumes the company is able to perform the resurvey without retaining contractors. The capital costs include the cost of Method 21 instrumentation (estimated to be $10,800[46]). For compressor stations, the cost to resurvey repaired components was estimated to be $2.00 per component.
- Preparation of annual reports was estimated to take 1 person a total of 4 hours to complete at a cost of $231.

The initial setup cost or capital cost for oil and natural gas well sites was calculated by summing up the costs for reading the rule, development of fugitive emissions monitoring plan, initial activities planning, notification of initial compliance status, and purchase of a Method 21 instrumentation. The total capital cost of these activities was calculated to be $17,620 per company defined areas for semiannual monitoring and $19,470 per company define areas for quarterly monitoring. Assuming that each company owns and operates 22 well sites within a company defined area[47], the capital cost per well site was estimated to be $759 for annual monitoring, $801 for semiannual monitoring and $885 for quarterly monitoring. For compressor stations (gathering and boosting stations, transmission stations and storage facilities) the capital cost for reading the rule, development of fugitive emissions monitoring plan, initial activities planning notification of initial compliance status, and purchase of a Method 21 instrumentation was calculated to be $16,407 per facility. For gathering and boosting stations, this capital cost was assumed to be shared with other gathering and boosting stations within the company defined area. These stations are estimated to be approximately 70 miles apart. Therefore, within a 210 mile radius of a central location, there would be an estimated 7 gathering and boosting stations, and the capital cost of each of these stations was estimated to be $2,393.

For all oil and natural gas segments, the annual cost includes; subsequent activities planning, OGI survey, cost of repair of fugitive emissions found, resurvey of repaired components, preparation and

---

on the number of leaks located at uncontrolled facilities, only average percentages of the total number of components at a facility. Therefore, our methodology was to use the 1.18% leak frequency value from the Uniform Standards memorandum and apply that value to the total number of components at the oil and natural gas model plant. (Uniform Standards Memorandum to Jodi Howard, EPA/OAQPS from Cindy Hancy, RTI International, Analysis of Emission Reduction Techniques for Equipment Leaks, December 21, 2011. EPA-HQ-OAR-2002-0037-0180).

[46] Average of subsequent monitoring costs in Table 13 from the Memorandum to Jodi Howard, EPA/OAQPS from Cindy Hancy, RTI International, Analysis of Emission Reduction Techniques for Equipment Leaks, December 21, 2011. EPA-HQ-OAR-2002-0037-0180

[47] The number of well sites owned and operated by companies was calculated using data from the Fort Worth study.

NMED Exhibit 70

submittal of an annual report, and the amortized capital cost over 8 years at 7 percent interest. For our analysis the EPA calculated the annual cost for annual, semiannual and quarterly OGI surveys. The OGI monitoring cost memorandum[48] present the analyses for other costing methodologies, including a company-based OGI monitoring program and an OGI program using cost methodologies developed for the Colorado fugitive leak program to estimate the annual cost of implementing an OGI monitoring and repair program for oil and natural gas well sites, gathering and boosting, transmission and storage compressor stations for the respective OGI monitoring frequencies.

The cost per ton of emissions reduced was calculated using two separate methods. The first method allocated all of the costs to one pollutant and zero to the other (single-pollutant approach) using representative unit costs for each control option. The second method allocates the annual cost among the pollutants (multi-pollutant approach) that a given technology reduced (i.e., GHG (in the form of limiting methane emissions) and VOC). This proration was based on estimates of the percentage reduction expected for each pollutant. In the case of fugitives, the percent reductions for methane and VOC emissions are equal; and therefore the proration of the annual cost was divided equally and applied to the methane and VOC reductions.

Based on estimated emissions reductions and the estimated cost for implementing an OGI fugitive emissions monitoring and repair program at the affected facilities, the EPA calculated a cost of control for methane and VOC for the various options for oil and natural gas production well sites, gathering and boosting, and transmission and storage compressor stations. The EPA then calculated the cost of control of well sites and compressor stations using the weighted average cost of control for all well sites and all compressor stations (i.e., gathering and boosting, transmission and storage). Table 4-9, 4-10 and 4-11 presents a summary of the cost of control for methane and VOC for the three OGI monitoring frequency options (i.e., annual, semiannual and quarterly, respectively) based on the single-pollutant method. Tables 4-12, 4-13 and 4-14 present a summary of the capital and annual costs, and the cost of control for methane and VOC using the multi-pollutant method (i.e., 50 percent of the cost attributed to methane and 50 percent of the cost attributed to VOC).

[48] Memorandum from Bradley Nelson, EC/R to Jodi Howard, EPA, Evaluation of Cost methodologies for OGI Monitoring, April 6, 2016.

NMED Exhibit 70

4.3.2.4 Secondary Impacts

No secondary gaseous pollutant emissions or wastewater are generated during the monitoring and repair of fugitive emissions components. There are some emissions that would be generated by the OGI camera monitoring contractors with respect to driving to and from the site for the fugitive emissions survey. Using AP-42 mobile emission factors[49] and assuming a distance of 70 miles to the well site or compressor station, the emissions generated from semiannual monitoring at a well site (140 miles to and from the well site twice a year) is estimated to be 0.35 pounds per year (lb/yr) of hydrocarbons, 6.0 lb/yr of carbon monoxide (CO) and 0.40 lb/yr of nitrogen dioxides (NO_X). The emissions generated from quarterly monitoring at a compressor station (140 miles to and from the compressor station four times a year) is estimated to be 0.70 lb/yr of hydrocarbons, 12.0 lb/yr of CO and 0.80 lb/yr of NO_X.

NMED Exhibit 70

Table 4-9. Summary of the Model Plant Cost of Control for Annual OGI Monitoring Option – Single Pollutant[50]

Model Plant	Annual Emission Reductions[a] (tpy)		Capital Cost[b] ($)	Annual Cost ($/year)		Cost of Control (without savings) ($/ton)		Cost of Control (with saving)[c] ($/ton)	
	CH_4	VOC		without savings	with savings	CH_4	VOC	CH_4	VOC
Natural Gas Well Site[d]	2.20	0.61	$759	$1,318	$809	$600	$2,158	$368	$1,324
Oil Well Site (GOR < 300)[d]	0.49	0.13	$759	$1,318	$1,204	$2,670	$9,953	$2,438	$9,089
Oil Well Site (GOR > 300 GOR)[d]	1.10	0.30	$759	$1,318	$1,063	$1,198	$4,380	$967	$3,533
Well Site Program Weighted Average[h]						**$1,224**	**$4,464**	**$993**	**$3,619**
Gathering & Boosting Station[e]	14.1	3.91	$2,393	$7,777	$7,777	$553	$1,990	$553	$1,990
Transmission Station[f]	16.2	0.45	$16,407	$10,117	$10,117	$626	$22,626	$626	$22,626
Storage Facility[g]	57.0	1.58	$16,407	$13,798	$13,798	$242	$8,751	$242	$8,751
Compressor Stations Program Weighted Average[h]						**$541**	**$3,098**	**$541**	**$3,098**

a. Assumes 40% reduction with the implementation of annual IR camera monitoring.
b. The capital cost for oil and natural gas production well sites includes the cost of implementing the monitoring program divided between an average of 22 well sites per company district. The capital cost for implementing the monitoring program at gathering and boosting stations was divided between 7 stations within a company defined area. The capital cost for transmission and storage segments includes the cost of implementing the monitoring program.
c. Recovery credits for oil and natural gas production well sites and gathering and boosting stations were calculated assuming natural gas reductions based methane reductions, methane as 82.9% of natural gas composition, and the value of the natural gas recovered as $4 Mcf.
d. Annual cost for well sites includes annual monitoring and repair cost and amortization of the capital cost over 8 years at 7% interest.
e. Annual cost for gathering and boosting stations includes annual monitoring and repair cost and amortization of the capital cost over 8 years at 7% interest.
f. Annual cost for transmission station includes annual monitoring and repair cost and amortization of the capital cost over 8 years at 7% interest.
g. Annual cost for storage facilities includes annual monitoring and repair cost and amortization of the capital cost over 8 years at 7% interest.
h. The weighted average for the segments were calculated using the 2012 activity counts of 3,346 gas well sites, 6,812 oil well sites (GOR<300), 9,330 oil well sites (GOR>300), 96 G&B stations, 4 transmission stations and 5 storage facilities.
Note: Gathering and boosting, transmission and storage facilities do not own the natural gas; therefore revenues from reducing the amount of natural gas as the result of equipment leaks was not estimated for these segments.

[50] As explained earlier, this control option simultaneously reduces both methane (which is being evaluated for controlling the pollutant GHG) and VOC. Under the single pollutant approach, all costs are attributed to one pollutant and zero to the other. For simplicity, the table presents the cost per ton of the assigned pollutant; the table does not present the cost per ton of the one that is assigned zero cost because it is always zero.

NMED Exhibit 70

Table 4-10. Summary of the Model Plant Cost of Control for the Semiannual OGI Monitoring Option – Single Pollutant[51]

Model Plant	Annual Emission Reductions[a] (tpy)		Capital Cost[b] ($)	Annual Cost ($/year)		Cost of Control (without savings) ($/ton)		Cost of Control (with saving)[c] ($/ton)	
	CH_4	VOC		without savings	with savings	CH_4	VOC	CH_4	VOC
Natural Gas Production Well Site[d]	3.3	0.917	$801	$2,285	$1,521	$693	$2,494	$461	$1,660
Oil Well Sites (GOR < 300) [d]	0.74	0.199	$801	$2,285	$2,114	$3,085	$11,503	$2,854	$10,639
Oil Well Site (GOR > 300 GOR)[d]	1.65	0.451	$801	$2,285	$1,903	$1,385	$5,062	$1,153	$4,215
Well Site Program Weighted Average[h]						**$1,415**	**$5,160**	**$1,183**	**$4,314**
Gathering & Boosting Station[e]	21.1	5.86	$2,393	$13,534	$13,534	$642	$2,309	$642	$2,309

a. Assumes 40% reduction with the implementation of annual IR camera monitoring.
b. The capital cost for oil and natural gas production well sites includes the cost of implementing the monitoring program of $16,696 divided between an average of 22 well sites per company. The capital cost for implementing the monitoring program at gathering and boosting stations was estimated to be $16,753 divided between 7 stations within a company defined area. The capital cost for the transmission and storage segments includes the cost of implementing the monitoring program of $16,407.
c. Recovery credits for oil and natural gas production well sites and gathering and boosting stations were calculated assuming natural gas reductions based methane reductions, methane as 82.9% of natural gas composition, and the value of the natural gas recovered as $4 Mcf.
d. Annual cost for well sites includes annual monitoring and repair cost of $1,191 and amortization of the capital cost over 8 years at 7% interest.
e. Annual cost for gathering and boosting stations includes annual monitoring and repair cost of $7,376 and amortization of the capital cost over 8 years at 7% interest.
f. Annual cost for transmission station includes annual monitoring and repair cost of $7,369 and amortization of the capital cost over 8 years at 7% interest.
g. Annual cost for storage facilities includes annual monitoring and repair cost of $11,050 and amortization of the capital cost over 8 years at 7% interest.
h. The weighted average for the segments were calculated using the 2012 activity counts of 3,346 gas well sites, 6,812 oil well sites (GOR<300), 9,330 oil well sites (GOR>300), 96 G&B stations, 4 transmission stations and 5 storage facilities.
Note: Gathering and boosting, transmission and storage facilities do not own the natural gas; therefore revenues from reducing the amount of natural gas as the result of equipment leaks was not estimated for these segments.

a. Assumes 80% reduction with the implementation of quarterly IR camera monitoring.
b The capital cost for oil and natural gas production well sites includes the cost of implementing the monitoring program of $19,470 divided between an average of 22 well sites per company. The capital cost for implementing the monitoring program at gathering and boosting stations was estimated to be $16,753 divided between 7 stations within a company defined area. The capital cost for the transmission and storage segments includes the cost of implementing the monitoring program of $16,407.
c. Recovery credits for oil and natural gas production well sites and gathering and boosting stations were calculated assuming natural gas reductions based methane reductions, methane as 82.9% of natural gas composition, and the value of the natural gas recovered as $4 Mcf.
d. Annual cost for well sites includes annual monitoring and repair cost of $4,071 and amortization of the capital cost over 8 years at 7% interest.
e. Annual cost for gathering and boosting stations includes annual monitoring and repair cost of $24,649 and amortization of the capital cost over 8 years at 7% interest.
f. Annual cost for transmission station includes annual monitoring and repair cost of $24,622 and amortization of the capital cost over 8 years at 7% interest.
g. Annual cost for storage facilities includes annual monitoring and repair cost of $39,345 and amortization of the capital cost over 8 years at 7% interest.
h. The weighted average for the segments were calculated using the 2012 activity counts of 3,346 gas well sites, 6,812 oil well sites (GOR<300), 9,330 oil well sites (GOR>300), 96 G&B stations, 4 transmission stations and 5 storage facilities.
Note: Gathering and boosting, transmission and storage facilities do not own the natural gas; therefore revenues from reducing the amount of natural gas as the result of equipment leaks was not estimated for these segments.

NMED Exhibit 70

4.4 Regulatory Options

Monitoring of fugitive emissions was evaluated using OGI and Method 21 in the TSD for the proposed rule. For OGI, monitoring frequencies of annual, semiannual and quarterly were evaluated for well sites and compressor stations. Annual, semiannual and quartering monitoring was also evaluated for Method 21 at three different leak definitions; 500 ppm, 2,500 ppm and 10,000 ppm. Based on the results of these evaluations, semiannual monitoring using OGI was selected as BSER for well sites and compressor stations.

For this analysis, the OGI monitoring options were updated for the final rule using information received since proposal for the proposed rule. The OGI monitoring options include;

- Regulatory Option 1 – The implementation of an annual OGI fugitive emissions monitoring and repair program.
- Regulatory Option 2 - The implementation of a semiannual OGI fugitive emissions monitoring and repair program.
- Regulatory Option 3 - The implementation of a quarterly OGI fugitive emissions monitoring and repair program.

4.4.1 OGI Monitoring Options

As noted above, the EPA calculated a weighted average cost of control for well sites (which includes oil wells, oil wells with associated gas, and natural gas production well sites) and compressor stations (which includes gathering and boosting stations, transmission stations and storage facilities). For ease of review the EPA has summarized the cost of control for the options for well sites and compressor stations in Table 4-15.

NMED Exhibit 70

Table 4-15. Summary of the Cost of Control for the OGI Monitoring Options[53]

Option	Cost of Control (without gas savings)				Cost of Control (with gas savings)			
	Single-Pollutant ($/ton)		Multi-Pollutant ($/ton)		Single-Pollutant ($/ton)		Multi-Pollutant ($/ton)	
	Methane	VOC	Methane	VOC	Methane	VOC	Methane	VOC
Well Sites								
1 - Annual	$1,224	$4,464	$612	$2,232	$993	$3,619	$496	$1,810
2 - Semiannual	$1,415	$5,160	$708	$2,580	$1,183	$4,314	$592	$2,157
3 - Quarterly	$1,960	$7,145	$980	$3,572	$1,728	$6,299	$864	$3,150
Compressor Stations								
1 - Annual	$504	$2,225	$252	$1,112	$272	$1,201	$136	$601
2 - Semiannual	$580	$2,562	$290	$1,281	$396	$1,749	$198	$875
3 - Quarterly	$802	$3,540	$401	$1,770	$618	$2,728	$309	$1,364

4.4.2 EPA Method 21 as an Alternative to OGI Monitoring

4.4.2.1 Description

As an alternative to OGI monitoring, the EPA evaluated allowing the use of Method 21 to detect fugitive emissions from the collection of the fugitive emissions components at well sites and compressor stations to determine if the emissions reductions were equal to or greater than the emissions reductions achieved using OGI monitoring. As with OGI monitoring, emissions reductions vary based on the frequency of the monitoring of the components as well as the repair threshold. Based on comments received on the proposed rule, the EPA evaluated repair thresholds of 500 ppm and 10,000 for Method 21fugitive emissions monitoring.

4.4.2.2 Emission Reduction Potential

The EPA based the emission reduction analysis on the method for estimating leak detection and repair (LDAR) control effectiveness from Chapter 5.3.1 of the Protocol for Equipment Leak Emission Estimates (EPA-453/R-95-017). Under this method, the control effectiveness is calculated using a stepwise approach that starts from the initial leak frequency and adds monitoring cycles until the leak frequency after monitoring reaches steady state. The difference between the initial leak rate and the final leak rate provides the control effectiveness for the fugitive emissions monitoring program. Other parameters included in the monitoring cycle calculations are the percentage of successfully repair

[53] *Ibid.*

NMED Exhibit 70

components, the percentage of new leaks and the percentage of leaks that were repaired but have reoccurred. The EPA Protocol does not provide these data for oil and natural gas production; only for the Synthetic Organic Chemical Manufacturing Industry (SOCMI) and refineries. The refinery emissions data are provided in non-methane organic compound (NMOC) units, which would require assumed TOC and methane weight fractions to determine the TOC emission factors, whereas the SOCMI emissions data is already based on TOC. The assumed TOC and methane weight fractions would add another level of uncertainty to the emission reduction percentage calculations if the refinery data were used. Therefore, we determined that using the SOCMI data would provide the best estimate of potential fugitive emission reduction percentages for a typical Method 21 monitoring program, and would be comparable to the potential fugitive emission reductions for oil and gas production, if the other parameters were available for this segment. The potential emission reduction from the implementation of a Method 21 program was calculated using this SOCMI data. Table 4-16 provides a summary of the parameters used to calculate the monitoring cycles. An example of the methodology is provided in Chapter 5.3.2 of the EPA Protocol document. The SOCMI data in the EPA Protocol document only included occurrence rates for monthly and quarterly monitoring. To calculate annual and semiannual occurrence rates, a logarithmic equation was derived from the data points. Initial leak frequencies were calculated using the EPA Protocol average leak rate equations for 500 and 10,000 ppm gas valves (see Table 5-4) and the average SOCMI emission factor for gas valves of 0.00597 kilograms per hour per source (see Table 2-1) and solving for leak fraction. The initial leak frequencies can also extrapolated using the lines in Figure 5-1 in the EPA Protocol document. The average leak fraction equation and calculated initial leak frequency are provided in Table 4-16.

Using the parameters in Table 4-16, the estimated emission reductions were calculated using the monitoring cycle approach in the EPA Protocol document. The leak frequency after monitoring reached steady state on the sixth monitoring cycle and the percent reduction was calculated. The results of the emission reductions are presented in Table 4-17.

NMED Exhibit 70

Table 4-16. Parameters and Assumptions Used to Calculate Monitoring Cycles

Parameter	Parameter Value (500 ppm)	Parameter Value (10,000 ppm)
Occurrence Rate	5.46% Annual, 4.21% Semiannual, 2.97% Quarterly	5.46% Annual, 4.21% Semiannual, 2.97% Quarterly
Recurrence Rate	14%	14%
Unsuccessful Repair Rate	10%	10%
Initial Leak Frequency	13.53%	7.49%
Average Leak Rate Equation	ALR = 0.044*LF + 0.000017	ALR = 0.078*LF + 0.00013

Table 4-17. Percent Reduction in Emissions for EPA Method 21 Monitoring and Repair

Monitoring Frequency	Fugitive Percent Reduction		
	Method 21 Repair Threshold		OGI
	10,000 ppm	500 ppm	
Annual	42	68	40
Semiannual	55	75	60
Quarterly	67	83	80

As noted in Table 4-17 above, in all cases the percent reduction for the 500 parts per million Method 21 alternative is equal to or greater than the estimated OGI monitoring and repair percent reduction. The percent reduction for the 10,000 parts per million leak threshold was only greater than the OGI option for annual monitoring. Based on the estimated OGI monitoring model plant emission reductions (see Tables 4-9 through 4-14), Table 4-18 summarizes the estimated model plant emission reductions for the alternative Method 21 monitoring and repair option for 500 and 10,000 parts per million leak thresholds. For annual monitoring, both the Method 21 leak thresholds had higher emission reductions then the OGI monitoring option. Only the 500 parts per million leak threshold had emission reductions that were equal to or greater than the OGI monitoring option for semiannual and quarterly monitoring.

a. Assumes baseline emissions shown in Tables 4-5 and 4-8 and percent reduction shown in Table 4-21.

NMED Exhibit 70

5.0 PNEUMATIC CONTROLLERS

The natural gas industry uses a variety of process control devices to operate valves that regulate pressure, flow, temperature, and liquid levels. Most instrumentation and control equipment falls into one of three categories: (1) pneumatic; (2) electrical; or (3) mechanical. Of these, only pneumatic devices are direct sources of air emissions. Pneumatic controllers are used throughout the oil and natural gas sector as part of the instrumentation to control the position of valves.

The 2012 NSPS promulgated requirements for control of emissions from pneumatic controllers in the production and processing segments. During development of the 2012 NSPS amendments, methane and VOC emissions for these sources were estimated and included in the cost and impact analysis. See the 2011 NSPS TSD.

This chapter describes pneumatic controllers in the transmission and storage segment, including their function and associated emissions. Options available to reduce emissions from pneumatic controllers in the transmission and storage segment are presented, along with costs, emission reductions, and secondary impacts. Finally, this chapter discusses considerations in developing regulatory alternatives for pneumatic controllers.

5.1 Process Description

5.1.1 Pneumatic Controllers

For the purpose of this document, a pneumatic controller is a device that uses natural gas to transmit a process signal or condition pneumatically and that may also adjust a valve position based on that signal, with the same bleed gas and/or a supplemental supply of power gas. In the vast majority of applications, the natural gas industry uses pneumatic controllers that make use of readily available high-pressure natural gas to provide the required energy and control signals. In the transmission and storage segment, an estimated 84,000 pneumatic controllers actuate isolation valves and regulate gas flow and pressure at compressor stations, pipelines, and storage facilities.[54]

Pneumatic controllers are automated instruments used for maintaining a process condition such as liquid level, pressure, pressure differential, and temperature. In many situations across all segments of the oil and natural gas industry, pneumatic controllers make use of the available high-pressure natural gas to

[54] U.S. EPA. Lessons Learned: Options for Reducing Methane Emissions From Pneumatic Devices in the Natural Gas Industry. OAR: Natural Gas Star. Washington, DC. February 2004.

NMED Exhibit 70

operate or control a valve. In these "gas-driven" pneumatic controllers, natural gas may be released with every valve movement and/or continuously from the valve control pilot. The rate at which the continuous release occurs is referred to as the bleed rate. Bleed rates are dependent on the design and operating characteristics of the device. Similar designs will have similar steady-state rates when operated under similar conditions. There are three basic designs: (1) continuous bleed devices are used to modulate flow, liquid level, or pressure, and gas is vented continuously at a rate that may vary over time; (2) intermittent controllers release gas only when they open or close a valve or as they throttle the gas flow; and (3) self-contained devices release gas to a downstream pipeline instead of to the atmosphere. This analysis assumes self-contained devices that release natural gas to a downstream pipeline instead of to the atmosphere have no emissions. Furthermore, it is recognized that "closed loop" systems are applicable only in instances with very low pressure[55] and may not be suitable to replace many applications of bleeding pneumatic devices. Therefore, these devices are not further discussed in this analysis.

Intermittent controllers are devices that only emit gas during actuation and do not have a continuous bleed rate. The actual amount of emissions from an intermittent controller is dependent on the amount of natural gas vented per actuation and how often it is actuated. Bleed devices also vent an additional volume of gas during actuation, in addition to the controller's bleed stream. Since actuation emissions serve the controller's functional purpose and can be highly variable, the emissions characterized for high-bleed and low-bleed devices in this analysis (as described in section 5.2.2) account for only the continuous flow of emissions (i.e., the bleed rate) and do not include emissions directly resulting from actuation. Intermittent controllers are assumed to have zero bleed emissions.[56] For most applications (but not all), intermittent controllers serve functionally different purposes than bleed devices. Therefore, because intermittent controllers are inherently low emitting sources and the total emissions are dependent on the applications in which they are used, the EPA did not include intermittent controllers in this analysis. This is consistent with the treatment of these controllers under the 2012 NSPS.

In addition, not all pneumatic controllers are gas driven. At sites with electrical service sufficient

[55] Memorandum to Bruce Moore, U.S. EPA from Denise Grubert, EC/R. Meeting Minutes from EPA Meeting with the API. October 2011.

[56] The EPA received comments indicating that in some cases intermittent controllers had continuous emissions, and low-bleed pneumatic controllers were observed to have emission rates that were 270 percent higher than the EPA's emission factor for these devices, in some cases approaching the emission rate of high-bleed controllers. The EPA believes this is the result of malfunctioning controllers. The data the EPA have does not indicate that emissions from intermittent controllers are significant under normal operating conditions. The EPA are continuing to research this issue; however, the EPA do not believe additional requirements are warranted for such controllers based on the incidental, non-standard operation observed during these studies.

NMED Exhibit 70

to power an instrument air compressor electrically powered pneumatic devices can be used. In addition, it may be possible to use electrically powered pneumatic devices at sites with electrical service. These "non-gas driven" pneumatic controllers can be mechanically operated or use sources of power other than pressurized natural gas, such as compressed "instrument air." Because these devices are not gas driven, they do not directly release natural gas. However, electrically powered systems have energy impacts, with associated secondary impacts related to generation of the electrical power required to drive the instrument air compressor system. Instrument air systems are feasible only at oil and natural gas locations where the devices can be driven by compressed instrument air systems and have electrical service sufficient to power an air compressor. This analysis assumes that natural gas processing plants are the only facilities in the oil and natural gas source category likely to have electrical service sufficient to power an instrument air system, and that most existing gas processing plants use instrument air instead of gas-driven devices.[57]

5.2 Emissions Data and Information

5.2.1 Summary of Major Studies and Emission

In the evaluation of the emissions from pneumatic controllers in the transmission and storage segment and the potential options available to reduce the emissions, the EPA consulted numerous studies and sources of information. Table 5-1 presents these studies and sources of information with an indication of the type of relevant information contained in each resource.

5.2.2 Representative Pneumatic Device Emissions

Continuous bleed pneumatic controllers can be classified into two types based on their emission rates: (1) high-bleed controllers and (2) low-bleed controllers. A controller is considered to be high-bleed when the continuous bleed emissions are in excess of 6 standard cubic feet per hour (scfh), while low-bleed devices bleed at a rate less than or equal to 6 scfh.[58]

For this analysis, the EPA consulted information in the appendices of the Natural Gas STAR Lessons Learned document on pneumatic devices, Subpart W of the GHG Reporting rule[59], the Inventory of GHG Emissions and Sinks, new studies, as well as pneumatic controller vendor information obtained during the development of the NSPS rulemaking. The data obtained from vendors included emission rates, costs, and any other pertinent information for each pneumatic device model (or model family). All pneumatic devices that a vendor offered were itemized and inquiries were made into the specifications of each device and whether it was applicable to oil and natural gas operations. High-bleed and low-bleed devices were differentiated using the 6 scfh threshold. Since publication of the white paper, additional data have become available on emissions from pneumatic controllers, including reporting year 2014 data from GHGRP, and new measurement data from Subramanian et al. 2015, and Allen et al. 2014. GHGRP reported methane emissions for 2014 are 197,387 tons CO_2 Eq.in transmission, and 111,354 tons CO_2 Eq.in storage. The 2016 GHG Inventory, with emissions data for 1990-2014, calculates that national methane emissions for pneumatic controllers are 694,801 tons CO_2Eq. in transmission and 734,112 tons CO_2Eq. in storage. In the Subramanian et al. 2015 data set, the average emission rate for pneumatic controllers in the transmission segment was 12.9 scfh, and the average emission rate for pneumatic controllers in the storage segment was 21.2 scfh. Information was not available on the fraction of high bleed versus low and intermittent bleed controllers in each population.

Although by definition, a low-bleed device can emit up to 6 scfh, through this vendor research, it was determined that the typical low-bleed device available currently on the market emits lower than the maximum rate allocated for the device type. Specifically, low-bleed devices on the market today have

[58] The classification of high-bleed and low-bleed devices originated from a report by Pacific Gas & Electric (PG&E) and the GRI in 1990 titled "Unaccounted for Gas Project Summary Volume." This classification was adopted for the October 1993 Report to Congress titled "Opportunities to Reduce Anthropogenic Methane Emissions in the United States". As described on page 2-16 of the report, "devices with emissions or 'bleed' rates of 0.1 to 0.5 cubic feet per minute are considered to be "high-bleed" types (PG&E 1990)." This range of bleed rates is equivalent to 6 to 30 cubic feet per hour.

[59] Available at http://www.epa.gov/ghgreporting/reporters/subpart/w.html.

NMED Exhibit 70

emissions from 0.2 scfh up to 5 scfh. Similarly, the available bleed rates for a high bleed device vary significantly from venting as low as 7 scfh to as high as 100 scfh.[60,61] While the vendor data provides useful information on specific makes and models, it did not yield sufficient information about the prevalence of each model type in the population of devices; which is an important factor in developing a representative emission factor. For this analysis, the EPA determined that best available emissions rate estimates for pneumatic controllers are presented in Table W-3 of the GHG Mandatory Reporting Rule for the Oil and Natural Gas Industry (Subpart W).

The basic approach used for this analysis of emissions from pneumatic controllers was to first approximate the natural gas emissions from the average pneumatic controller type in the transmission and storage segment then estimate methane and VOC using a representative gas composition.[62]

The specific ratios from the representative gas composition were 0.908 lbs of methane per pound of natural gas and 0.0277 lbs VOC per pound methane. Table 5-2 summarizes the estimated bleed emissions for a representative pneumatic controller by industry segment and device type.

Table 5-2. Average Bleed Emission Estimates per Pneumatic Controller in the Natural Gas Transmission and Storage Segment[a, b]

High-Bleed (tpy)		Low-Bleed (tpy)	
Methane	**VOC**	**Methane**	**VOC**
3.013	0.083	0.227	0.00628

a. The conversion factor used in this analysis is 1,000 cubic feet (Mcf) of methane is equal to 0.0208 tons methane.
b. Natural gas transmission and storage emission factors for continuous bleed controllers were derived from Table W-1A of Subpart W.

5.3 Control Techniques

Several options to reduce emissions from pneumatic controllers were identified. Table 5-3 provides a summary of these options for reducing emissions from pneumatic controllers including: instrument air, non-gas driven controls, and enhanced maintenance. The use of instrument air systems, as discussed in the 2012 NSPS TSD[63], requires a constant source of electric power. Because electric power is not necessarily available at all transmission and storage affected facilities, the use of instrument air systems would not be practically feasible as a control for emissions from pneumatic controllers in this

[60] U.S. EPA. GHG Emissions Reporting From the Petroleum and Natural Gas Industry: Background TSD. Climate Change Division. Washington, DC. November 2010.
[61] All rates are listed at an assumed supply gas pressure of 20 psig.
[62] *See footnote* 3.
[63] *See footnote 2*.

NMED Exhibit 70

industry segment. Likewise, because the mechanical systems identified for use in this industry would require, at minimum, a backup source of electric power, this option is also not considered to be practically feasible for use in controlling these pneumatic controller emissions. The enhanced maintenance option is considered to be too variable and costly as a viable option for control pneumatic controller emissions. Based on these concerns, further analyses of these options were not conducted.

Given the various applicability, cost of emission reductions and cost issues with the control options, the replacement of a high-bleed with a low-bleed device is the most likely scenario for reducing emissions from pneumatic controllers. This conclusion is consistent with and supported by requirements of States such as Colorado and Wyoming that require the use of low-bleed controllers in place of high-bleed controllers. Therefore, low-bleed controllers are further described in the following section, along with estimates of the impacts of their application for a representative device and nationwide basis.

As noted above, intermittent controllers are assumed to have zero bleed emissions. In addition, these controllers are assumed to not always be used in the same functional application as continuous bleed controllers. Therefore, intermittent controllers are not an appropriate option for control for all continuous bleed controllers. It is assumed intermittent, or no-bleed, controllers meet the definition of a low-bleed.

NMED Exhibit 70

Table 5-3. Alternative Control Options for Pneumatic Controllers

Option	Description	Applicability/Effectiveness	Estimated Cost Range
Install Low Bleed Device in Place of High Bleed Device	Low-bleed devices provide the same functional control as a high-bleed device, while emitting less continuous bleed emissions.	Applicability may depend on the function of instrumentation for an individual device on whether the device is a level, pressure, or temperature controller.	Low-bleed devices are, on average, around $165 more than high bleed versions.
Convert to Instrument Air[a]	Compressed air may be substituted for natural gas in pneumatic systems without altering any of the parts of the pneumatic control. In this type of system, atmospheric air is compressed, stored in a tank, filtered and then dried for instrument use. For utility purposes such as small pneumatic pumps, gas compressor motor starters, pneumatic tools and sand blasting, air would not need to be dried. Instrument air conversion requires additional equipment to properly compress and control the pressured air. This equipment includes a compressor, power source, air dehydrator and air storage vessel.	Replacing natural gas with instrument air in pneumatic controls eliminates VOC emissions from bleeding pneumatics. These systems can achieve 100 percent reduction in emissions. It is most effective at facilities where there are a high concentration of pneumatic control valves and an operator present. Since the systems are powered by electric compressors, they require a constant source of electrical power or a back- up natural gas pneumatic device.	A complete cost analysis is provided in Section 5.4.2. System costs are dependent on size of compressor, power supply needs, labor and other equipment.
Mechanical and Solar Powered Systems in place of Bleed Device[b]	Mechanical controls operate using a simple design comprised of levers, hand wheels, springs and flow channels. The most common mechanical control device is the liquid-level float to the drain valve position with mechanical linkages. Electricity or small electrical motors (including solar powered) have been used to operate valves. Solar control systems are driven by solar power cells that actuate mechanical devices using electric power. As such, solar cells require some type of back-up power or storage to ensure reliability.	Application of mechanical controls is limited because the control must be located in close proximity to the process measurement. Mechanical systems are also incapable of handling larger flow fluctuations. Electric powered valves are only reliable with a constant supply of electricity. Overall, these options are applicable in niche areas but can achieve 100 percent reduction in emissions where applicable.	Depending on supply of power, costs can range from below $1,000 to $10,000 for entire systems.

NMED Exhibit 70

Option	Description	Applicability/Effectiveness	Estimated Cost Range
Enhanced Maintenance[c]	Instrumentation in poor condition typically bleeds 5 to 10 scf per hour more than representative conditions due to worn seals, gaskets, diaphragms; nozzle corrosion or wear, or lose control tube fittings. This may not impact the operations but does increase emissions.	Enhanced maintenance to repair and maintain pneumatic devices periodically can reduce emissions. Proper methods of maintaining a device are highly variable and could incur significant costs.	Variable based on labor, time, and fuel required to travel to many remote locations.

5.3.1 Low-Bleed Controller Emission Reduction Potential

As discussed in the above sections, low-bleed controllers provide the same operational function as high-bleed controllers, but have lower continuous bleed emissions. As summarized in Table 5-4, the average achievable reduction in emissions per controller is estimated to be approximately 2.79 tons of methane and 0.077 tons of VOC. As noted in section 5.2, a low-bleed controller can emit up to 6 scfh, which is higher than the expected emissions from the typical low-bleed device currently available on the market.

Table 5-4. Estimated Annual Bleed Emission Reductions from Replacing a Representative High-Bleed Pneumatic Controller with a Representative Low-Bleed Pneumatic Controller in the Natural Gas Transmission and Storage Segment

Baseline Emission reductions - High-Bleed Replaced with Low-Bleed[a] (tpy)	
Methane	**VOC**
2.79	0.077

a. Average emission reductions based on the typical emission rate from high-bleed and low-bleed controllers as listed in Table 5-2.

5.3.2 Emission Reduction Potential

There are certain situations in which replacing and retrofitting are not feasible, such as instances where a minimal response time is needed, cases where large valves require a high bleed rate to actuate, or a safety isolation valve is involved. Based on criteria provided by the Natural Gas STAR Program, it is assumed about 80 percent of high-bleed devices can be replaced with low-bleed devices throughout the transmission and storage segment.[64] This corresponds to 96 new high-bleed devices in the production segment (out of 120) that can be replaced with a new low-bleed alternative.

Applicability may depend on the function of instrumentation for an individual device such as whether the device is a level, pressure, or temperature controller. High-bleed pneumatic devices may not be applicable for replacement with low-bleed devices because a process condition may require a fast or precise control response so that it does not stray too far from the desired set point. A slower-acting controller could potentially result in damage to equipment and/or become a safety issue. An example of this is on a compressor where pneumatic devices may monitor the suction and discharge pressure and actuate a re-cycle when one or the other is out of the specified target range. Other scenarios for fast and

[64] *See footnote* 54 .

NMED Exhibit 70

precise control include transient (non-steady) situations where a gas flow rate may fluctuate widely or unpredictably. This situation requires a responsive high-bleed device to ensure that the gas flow can be controlled in all situations. Temperature and level controllers are typically present in control situations that are not prone to fluctuate as widely or where the fluctuation can be readily and safely accommodated by the equipment. Therefore, such processes can accommodate control from a low-bleed device, which is slower-acting and less precise.

5.3.3 Cost Impacts

As described in Section 5.2.2, costs were based on the vendor research as a result of updating and expanding upon the information given in the appendices of the Natural Gas STAR Lessons Learned document on pneumatic devices.[65] As Table 5-5 indicates, the average cost for a low bleed pneumatic is $2,471, while the average cost for a high bleed is $2,698.[66] Thus, the incremental cost of installing a low-bleed device instead of a high-bleed device is on the order of $227 per device. In order to analyze cost impacts, the incremental cost to install a low-bleed instead of a high-bleed was annualized for a 15-year period using a 7 percent interest rate. This equated to an annualized cost of around $25 per low-bleed controller.

Table 5-5. Cost Projections for Representative Pneumatic Controllers[a]

Controller Type	Minimum Cost ($)	Maximum Cost ($)	Average Cost ($)	Low-Bleed Incremental Cost ($)
High-Bleed Controller	$387	$7,398	$2,471	$227
Low-Bleed Controller	$554	$9,356	$2,698	

a. Cost data from the 2012 NSPS was converted to 2012 dollars using the Federal Reserve Economic Data GDP Price Deflator. During the development of the 2012 NSPS major pneumatic controller vendors were surveyed for costs, emission rates, and any other pertinent information that would give an accurate picture of the present industry.

Although monetary savings associated with additional gas captured exist, these savings were not estimated for the transmission and storage segment because it is assumed the owner of the pneumatic controller generally is not the owner of the natural gas. The cost per ton of emissions reduced was then calculated in two ways. The first method, the single pollutant approach, allocated all of the costs to one pollutant and zero to the other(s). The second method, the multipollutant approach, prorated costs among the pollutants that a given technology reduced (in this case GHG in the form or limiting methane emissions, and VOC). This proration was based on estimates of the percentage reduction expected for

[65] Ibid.
[66] Costs are estimated in 2012 U.S. Dollars.

NMED Exhibit 70

each pollutant. Table 5-6 provides a summary of low-bleed pneumatic cost of control.

Table 5-6. Cost-of Control for Low-Bleed Pneumatic Controllers versus High Bleed Pneumatics for the Transmission and Storage Segment[67]

Method	Incremental Capital Cost Per Unit[a] ($)	Total Annual Cost Per Unit[b] ($/year)	Emission reductions (tpy)		Cost of Control ($/ton)	
			Methane	VOC	Methane	VOC
Single Pollutant Approach 100%	$227	$25	2.79	0.077	$9	$323
Multipollutant Approach 50/50	$227	$25	2.79	0.077	$4	$162

a. Incremental cost of a low bleed controller versus a high bleed controller as summarized in Table 6-7.
b. Annualized cost assumes a 7 percent interest rate over a 15-year equipment lifetime.

5.3.4 Secondary Impacts

Low-bleed pneumatic controllers are a replacement option for high-bleed devices that simply bleed less natural gas that would otherwise be emitted in the actuation of pneumatic valves. No wastes would be created, no wastewater generated, and no electricity required. Therefore, there are no secondary impacts expected from the use of low-bleed pneumatic devices.

5.4 Regulatory Options

EPA evaluated the following Regulatory alternatives for pneumatic controllers:

- Regulatory Option 1. Establish an emissions limit equal to 0 scfh.
- Regulatory Option 2. Establish an emissions limit equal to 6 scfh.

5.4.1 Evaluation of Regulatory Options

By establishing an emission limit of 0 scfh, facilities would most likely need to install instrument air systems to meet the threshold limit. Because facilities located in the transmission and storage segment might not always have sufficient electrical service to install an instrument air systems, this option would not be practically feasible in all situations. In addition, the cost of supplying electric power (which is highly variable) would need to be considered, which would likely render the cost of this control option unreasonable. Therefore, EPA rejected Regulatory Option 1 for facilities in the transmission and storage segment.

[67] As explained earlier, this control option simultaneously reduces both methane (which is being evaluated for controlling the pollutant GHG) and VOC. Under the single pollutant approach, all costs are attributed to one pollutant and zero to the other. For simplicity, the columns for the single pollutant approach present the cost per ton of the assigned pollutant; the table does not present the cost per ton of the one that is assigned zero cost because it is always zero.

Regulatory Option 2 would establish an emission limit equal to the maximum emissions allowed for a low-bleed device in the transmission and storage segment. This would most likely be met by the use of low-bleed controllers in place of a high-bleed controller, but allows flexibility in the chosen method of meeting the requirement. In the key instances related to pressure control that would disallow the use of a low-bleed device, specific monitoring and recordkeeping criteria would be required to ensure the device function dictates the precision of a high bleed device. Therefore, EPA is utilizing Regulatory Option 2 for facilities in the transmission and storage segment.

NMED Exhibit 70

6.0 PNEUMATIC PUMPS

The natural gas industry uses a variety of pneumatic gas-powered pumps where there is no reliable electrical power to "control processing problems and protect equipment".[68] Pneumatic pumps are "small positive displacement, reciprocating units used throughout the oil and natural gas production sector to inject precise amounts of chemicals into process streams [or for freeze protection glycol circulation]."[69] Most chemical injection pumps (CIPs) fall into two main types: diaphragm, generally for heat tracing or plunger/piston, generally for chemical and methanol injection. This chapter describes pneumatic pumps including their function and associated emissions. Options available to reduce emissions from pneumatic pumps are presented, along with costs, emission reductions, and secondary impacts. Finally, this chapter discusses considerations in developing regulatory alternatives for pneumatic pumps.

6.1 Process Description

In many situations across all segments of the oil and gas industry, pneumatic pumps make "use of gas pressure where electricity is not readily available."[70] In the production segment, the supply gas is mostly produced natural gas, whereas in processing, the supply gas may be compressed air. In these gas-driven pneumatic pumps, characteristics that affect methane emissions include "the frequency of operation, the size of the unit, the supply gas pressure, and the inlet methane composition."[71]

Pneumatic pumps are generally used for one of three purposes: glycol circulation in dehydrators, hot oil circulation for heat tracing/freeze protection, or chemical injection. Glycol dehydrator pumps "recover energy from the high-pressure rich glycol/gas mixture leaving the absorber and use that energy to pump the low-pressure lean glycol back into the absorber."[72] Diaphragm pumps are commonly used to circulate hot glycol or other heat-transfer fluids in tubing covered with insulation to prevent freezing in pipelines, vessels and tanks. CIPs, i.e. piston/plunger pumps or small diaphragm pumps, inject small desired amounts of chemicals such as methanol to prevent hydrate formation or corrosion inhibitors into process streams to regulate operations of a plant and protect the equipment.

[68] Radian International LLC. Methane Emissions from the Natural Gas Industry, Vol. 13: Chemical Injection Pumps. Prepared for the GRI and EPA. EPA-600/R-96-080b. June 1996.

[70] Ibid.
[71] Ibid.
[72] U.S. EPA OAQPS. Oil and Natural Gas Sector Pneumatic Devices. April 2014.

NMED Exhibit 70

The piston and diaphragm pumps have two major components, a driver side and a motive side, which operate in the same manner but with different reciprocating mechanisms. Pressurized gas provides energy to the driver side of the pump, which operates a piston or flexible diaphragm to draw fluid into the pump. The motive side of the pump delivers the energy to the fluid being moved in order to discharge the fluid from the pump. The natural gas leaving the exhaust port of the pump is either directly discharged into the atmosphere or is recovered and used as a fuel gas or stripping gas."[73]

Chemical injection pumps work by allowing a fluid to flow into an enclosed cavity from a low-pressure source, trapping the fluid, and then forcing it out into a high-pressure receiver by decreasing the volume of the cavity. A complete reciprocating stroke includes two movements, referred to as an upward motion or suction stroke, and a downward motion or power stroke. During the suction stroke, the chemical is lifted through the suction check valve into the fluid cylinder. The suction check valve is forced open by the suction lift produced by the plunger and the head of the liquid being pumped. Simultaneously, the discharge check valve remains closed, thus allowing the chemical to remain in the fluid chamber. During the power stroke, the plunger assembly is forced downwards, immediately shutting off the suction check valve. Simultaneously, the chemical is displaced, forcing open the discharge check valve and allowing the fluid to be discharged. This complete movement represents one full stroke.[74]

Typical chemicals injected in an oil or gas field are biocides, demulsifiers, clarifiers, corrosion inhibitors, scale inhibitors, hydrate inhibitors, paraffin dewaxers, surfactants, oxygen scavengers, and H_2S scavengers. These chemicals are normally injected at the wellhead and into gathering lines or at production separation facilities. Since the injection rates are typically small, the pumps are also small. They are often attached to barrels containing the chemical being injected.[75]

Diaphragm pumps work by flexing the diaphragm out of the displacement chamber. When the diaphragm moves out, the volume of the pump chamber increases and causes the pressure within the chamber to decrease and draw in fluid. The inward stroke has the opposite effect, decreasing the volume and increasing the pressure of the chamber to move out fluid.[76]

NMED Exhibit 70

In addition, not all pneumatic pumps are gas-driven. These "non-natural-gas driven" pneumatic pumps can be mechanically operated or use sources of power other than pressurized natural gas, such as compressed "instrument air." Because these devices are not natural gas-driven, they do not directly release natural gas or VOC emissions. However, these systems have other energy impacts, with associated secondary impacts related to generation of the electrical power required to drive the instrument air compressor system. Instrument air systems are feasible only at oil and natural gas locations where the devices can be driven by compressed instrument air systems and have electrical service sufficient and reliable enough to power an air control system. This analysis assumed that natural gas processing plants and natural gas transmission stations are the only facilities in the oil and natural gas source category highly likely to have electrical service sufficient to power an instrument air system, and that most existing gas processing plants use instrument air instead of gas-driven devices.[77] The application of electrical controls is further elaborated in Section 6.2.

6.1.1 Emissions Data and Information

In the evaluation of the emissions from pneumatic pumps and the potential options available to reduce these emissions, numerous studies were consulted. Table 6-1 lists these references with an indication of the type of relevant information contained in each study.

Table 6-1. Major Studies Reviewed for Consideration of Emissions and Activity Data

Report Name	Affiliation	Year of Report	Number of Devices	Emissions Information	Control Information

NMED Exhibit 70

6.1.1.1 Representative Pneumatic Pump Emissions

For this analysis, the EPA consulted information in the appendices of the Natural Gas STAR Lessons Learned document on pneumatic pumps[78,79], Subpart W of the GHG Reporting rule[80], U.S. GHG Natural Gas and Petroleum Inventories (GHG Inventory)[81], and U.S. EPA GRI Report[82]. Subpart W and GHG Inventory use the emission factors form the U.S. EPA GRI Report. Similarly, EPA determined that the best available emission factors for pneumatic pumps are presented in the U.S. EPA GRI Report. For the activity factor, EPA determined the best available data is the GHG Inventory. Since publication of the white paper, additional data have become available on emissions from pumps, including GHGRP 2014 reporting year data. In 2014, reported methane emissions from chemical injection pumps in the production segment were 3,037,798 tons of CO_2 Eq. In the Inventory of Greenhouse Gas Emissions and Sinks: 1990-2014, national methane emissions from chemical injection pumps for 2014 are around 8,034,400 tons of CO_2Eq.

The basic approach used for this analysis was to first approximate methane emissions from the average pneumatic pump in each industry segment and then estimate VOC and HAP using the gas composition as was determined for the NSPS.[83] The specific ratios from the gas composition used for this analysis were 0.278 lbs VOC per pound methane in the production and processing segments. Table 6-2 summarizes the estimated bleed emission factors for a representative pneumatic pump by industry segment.

In the development of the emission factor, the GRI study incorporated a usage factor of 44% for diaphragm pumps and 40% for piston pumps.
b. Assumes 8760 hrs/yr and volumetric fraction of methane is 82.9% of natural gas in natural gas production and processing.
c. Assumes density of methane is 19.26 g/scf.
d. Assumes 0.27797 VOC content per pound of methane in natural gas production and processing.

6.2 Control Techniques

Gas-driven chemical pumps emit methane during normal operations. Depending on the type of pump, and the constraints of the location, companies can utilize a variety of technologies to reduce emissions. Table 6-3 provides a summary of these options for reducing emissions from gas-driven chemical pumps including: instrument air, solar, electricity, or routing emissions to a gas capture system or flare.

In situations where the replacement of gas-driven pumps with electric, solar and instrument air pumps is not possible, emissions can be captured via a vapor recovery unit (VRU), or sent to a combustion device. Emission control options for gas-driven pumps are described in the following section.

NMED Exhibit 70

Table 6-3. Alternative Control Options for Gas-Driven Pumps

Option	Description	Applicability/Effectiveness	Estimated Cost Range
Convert to Solar Pumps	Solar power cells can generate electricity to power the pump. Solar cells can utilize a back-up power system to ensure reliability.	Solar powered pumps are only reliable in areas where the sun can power the pump reliably. These devices can result in 100 percent reduction in emissions where applicable.	Capital costs for converting to solar pumps is approximately $2,300 per device
Convert to Electric Pumps	Electric pumps can be used where a reliable source of electricity is available at the facility.	Electric powered pumps are only reliable with a constant supply of electricity. Overall, this option is applicable in niche areas but can achieve 100 percent reduction in emissions where applicable.	Capital costs range between $1,807 to $5,352 plus electricity costs and an average annual maintenance cost of $263 per device.
Convert to Instrument Air**Error! Bookmark not efined.**	Instrument air systems can be used by replacing compressed air for the gas in pumps. These systems include a compressor, electrical power source, air dehydrator (depending on the type of pump), and volume tank.	Instrument air systems reduce emissions by 100 percent by replacing natural gas with instrument air. This technology offers economies of scale, where it is more economical at facilities with more pneumatic pumps. The system requires a reliable source of electrical power.	A complete cost analysis is provided in Section 6.3.3 System costs are dependent on size of compressor, power supply needs, labor and other equipment.
Route Natural Gas to an Existing Control Device	Routing natural gas from a gas-driven pump entails piping to a control device inlet stream.	Routing natural gas pumps to a combustion device reduces VOC and methane emissions by 95 percent. Routing natural gas to a control device is an option when a control device with available capacity is present on site.	Capital costs will vary depending on the distance of pipeline necessary, but are approximately $5,433 per device.
Route Natural Gas to Newly Installed Control Device	Routing natural gas from a gas-driven pump to a control device requires installation of a control device and piping between the pump and the control device.	Routing natural gas-driven pumps to a combustion control device typically reduces VOC and methane emissions by 95 percent. Routing natural gas to a control device is an option when utilities (i.e., electricity, water) needed to run the device are readily available.	Capital costs will be approximately $48,500 with annual costs around $104,000.
Route Natural Gas to Existing Gas Capture System	Routing natural gas from a gas-driven pump entails piping to a VRU.	Routing natural gas-driven pumps to a VRU reduces VOC and methane emissions through gas capture where emission reduction efficiencies are typically 95 percent. Routing natural gas	Capital costs will vary depending on the distance of pipeline necessary, but are estimated to be approximately $5, 433 per device.

NMED Exhibit 70

Option	Description	Applicability/Effectiveness	Estimated Cost Range
		to a VRU is applicable when an existing VRU with available capacity is present on site.	
Route Natural Gas to Newly Installed Gas Capture System	Routing natural gas from a gas-driven pump to a gas capture system requires the installation of a gas capture system such as a VRU and piping between the pump and the capture system. There must also be an onsite use for the captured gas such as a combustion engine; otherwise, a control device would be required.	Installing a VRU and sending natural gas from pumps results in emission reductions of approximately 95percent. This option is most effective at facilities with a large number of pumps, and other emission sources that can also be sent to the VRU.	Capital costs will be approximately $36,000 with annual costs around $7,500.

NMED Exhibit 70

6.2.1 Solar Pumps

6.*2.1.1 Emissions Reduction Potential*

Solar pumps provide the same functionality as gas-driven pumps, and can be utilized at remote sites where a reliable source of electricity is not available. Solar-charged direct current (DC) pumps can handle a range of throughputs up to 100 gallons per day with maximum injection pressure around 3,000 pounds per square inch gage (psig) and have zero natural gas emissions. Replacing a natural gas-driven pump with a solar pump can result in 100 percent reduction in methane and VOC emissions. Therefore, based on the emissions from Table 6-2 above, the EPA estimates converting natural gas-driven chemical pumps to solar-powered pumps can reduce methane emissions by 3.46 tons per year per diaphragm pump and 0.38 tons per year per piston pump for all segments. Based on the gas composition for natural gas in the production segment, the EPA estimates that replacement of a natural gas-driven pump with a solar-powered pump will reduce VOC emissions by 0.96 tons per year per diaphragm pump and 0.11 tons per year per piston pump. Likewise, for the transmission and storage segment, the EPA estimates that replacement of a natural gas-driven pump with a solar-powered pump will reduce methane emissions by 3.46 tons per year per diaphragm pump and 0.38 tons per year per piston pump VOC emissions by 0.1 tons per year per diaphragm pump and 0.01 tons per year for a piston pump.

6.2.1.2 Effectiveness

Replacing a natural gas-driven pump with a solar pump can result in 100 percent reduction in methane and VOC emissions and is feasible in regions where there is sufficient sunlight to power the pump, and backup power is not required. Solar-powered pumps are typically low volume pumps that inject methanol or corrosion inhibitors into a well with typical volumes ranging from 6 to 8 gallons per day. In addition to low volume pumps, large volume pumps used to replace natural gas-assisted circulation pumps for glycol dehydrators can also be converted to solar.

6.2.1.3 Cost Impacts

The primary costs associated with conversion to solar pumps are the initial capital expenditures and annual maintenance costs which are typically lower than gas-driven pump maintenance costs. The cost being attributed to the replacement of pneumatic pumps with solar powered pumps includes the capital cost of replacing the pump with a solar powered pump and operating cost. The operating costs are estimated to be 10 percent of the capital costs. Based on Natural Gas STAR document, “PRO Fact Sheet:

NMED Exhibit 70

Convert Natural Gas-Driven Chemical Pumps"[84], the cost for solar-powered electric pumps are approximately $2,000 with solar panels having a lifespan of 15 years and electric motors lasting 5 years. The total capital cost, including installation and labor are $2,227 (2012 dollars). The EPA estimates there would be no additional annual operating cost for solar pumps above and beyond that of ordinary field personnel duties. Annualized over the life of the pump at a 7 percent discount rate, the annualized cost of replacing a natural gas-driven pump with a solar pump is $317. In addition, the use of electric pumps will have savings realized from the gas not released. The EPA estimates that each diaphragm pump replaced will save 197 Mcf per year of natural gas from being emitted and each piston pump will have a natural gas savings of 22 Mcf per year. The value of the natural gas saved based on $4.00 per Mcf would be $786 per year for diaphragm pumps and $87 per year per piston pump.

6.2.1.4 Secondary Impacts

No secondary impacts from conversion to solar powered pumps are expected.

6.2.2 Electric Pumps

6.2.2.1 Emission Reduction Potential

Electric pumps also provide the same functionality as gas-driven pumps, and are only restricted by availability of a reliable source of electricity. Electric pumps have zero natural gas emissions, as summarized in Table 6-4, and converting gas-driven chemical pumps to an electric pump can reduce methane emissions by an estimated 3.46 tons per year per diaphragm pump and 0.38 tons per year per piston pump. Based on the gas composition for natural gas in the production segment, the EPA estimates that replacement of a pneumatic pump with an electric pump will reduce VOC emissions by 0.96 tons per year per diaphragm pump and 0.11 tons per year for a piston pump. Likewise, for the transmission and storage segment, the EPA estimates that replacement of a pneumatic pump with an electric pump will reduce methane emissions by an estimated 3.46 tons per year per diaphragm pump and 0.38 tons per year per piston pump and VOC emissions by 0.1 tons per year per diaphragm pump and 0.01 tons per year for a piston pump.

[84] U.S. EPA. PRO Fact Sheet No. 202. Convert Natural Gas-Driven Chemical Pumps. Available at http://www.epa.gov/gasstar/documents/convertgasdrivenchemicalpumpstoinstrumentair.pdf.

NMED Exhibit 70

6.2.2.2 Effectiveness

Replacing a natural gas-driven pump with an electric pump can result in 100 percent reduction in emissions. However, use of electric pumps requires a sufficient and reliable source of electricity. These pumps are, therefore, more common at processing plants or large dehydration facilities that have access to reliable power.

6.2.2.3 Cost Impacts

The primary costs associated with converting natural gas-driven pumps to electric pumps are the initial capital expenditures, installation and ongoing operation and maintenance. Based on the Natural Gas STAR document, "PRO Fact Sheet: Convert Natural Gas-Driven Chemical Pumps,"[85] the cost of electric pumps to replace diaphragm pumps is $4,647 and to replace a piston pump is $1,819 in 2012 dollars depending on the horsepower of the unit.[86] The annual operating costs for the electric pumps is estimated to be $293. Annualizing the capital cost over the life expectancy of the pump at a 7 percent discount rate, the annual cost for replacing a natural gas-driven pump with an electric pump is $954 for diaphragm pump, and $552 for a piston. In addition, the use of electric pumps will have savings realized from the gas not released. The EPA estimates that each diaphragm pump replaced will save 197 Mcf per year of natural gas from being emitted and each piston pump will save of 22 Mcf per year. The value of the natural gas saved based on $4.00 per Mcf would be $786 per year for diaphragm pumps and $87 per year per piston pump.

6.2.2.4 Secondary Impacts

The secondary impacts from electric pumps are indirect, variable and dependent on the electrical supply used to power the compressor. No other secondary impacts are expected.

6.2.3 Instrument Air System

6.2.3.1 Process Description

Instrument air systems require a compressor, power source, dehydrator, and volume tank. The same natural gas-driven pumps can be used for natural gas and compressed air, without altering any of the parts of the pump, but instrument air eliminates the emissions of natural gas. All facilities that have access to a reliable source of electricity can install an instrument air system. A description of each of the

[85] Ibid.

[86] U.S. EPA. Lessons Learned. Replacing Gas-Assisted Glycol Pumps with Electric Pumps. Available online - http://www.epa.gov/gasstar/documents/ll_glycol_pumps3.pdf.

NMED Exhibit 70

components as described in the Natural Gas STAR document, "PRO Fact Sheet: Convert Gas Pneumatic Controls to Instrument Air":[87]

- Compressors used for instrument air delivery are available in various types and sizes, from rotary screw (centrifugal) compressors to positive displacement (reciprocating piston) types. The size of the compressor depends on the size of the facility, the number of control devices operated by the system, and the typical bleed rates of these devices. The compressor is usually driven by an electric motor that turns on and off, depending on the pressure in the volume tank. For reliability, a full spare compressor is normally installed.
- A critical component of the instrument air control system is the power source required to operate the compressor. Because high-pressure natural gas is abundant and readily available, gas pneumatic systems can run uninterrupted on a 24-hour, 7-day per week schedule. The reliability of an instrument air system, however, depends on the reliability of the compressor and electric power supply. Most large natural gas plants have either an existing electric power supply or have their own power generation system. For smaller facilities and remote locations, however, a reliable source of electric power can be difficult to assure. In some instances, solar-powered battery-operated air compressors can be cost effective for remote locations, which reduce both methane emissions and energy consumption. Small natural gas powered fuel cells are also being developed.
- Dehydrators, or air dryers, are an integral part of the instrument air compressor system. Water vapor present in atmospheric air condenses when the air is pressurized and cooled, and can cause a number of problems to these systems, including corrosion of the instrument parts and blockage of instrument air piping and controller orifices.
- The volume tank holds enough air to allow the pneumatic control system to have an uninterrupted supply of high pressure air without having to run the air compressor continuously. The volume tank allows a large withdrawal of compressed air for a short time, without affecting the process control functions.

6.2.3.2 Emission Reduction Potential and Effectiveness

Instrument air eliminates all emissions from natural gas-driven pumps, but can only be used in locations with sufficient and reliable electrical power. Furthermore, instrument air systems are more

[87] *See footnote 78.*

NMED Exhibit 70

economical and therefore more common at facilities with a high concentration of pneumatic devices and where an operator can ensure the system is properly functioning.[88] Because all emissions can be avoided by converting natural gas-driven chemical pumps to instrument air, methane emissions can be reduced by an estimated 3.46 tons per year per diaphragm pump and 0.38 tons per year per piston pump. Based on the gas composition for natural gas in the production segment, the EPA estimates that replacement of a pneumatic pump converted to instrument air will reduce VOC emissions by 0.96 tons per year per diaphragm pump and 0.11 tons per year for a piston pump. Likewise, for the transmission and storage segment, the EPA estimates that replacement of a pneumatic pump converted to instrument air will reduce methane emissions by an estimated 3.46 tons per year per diaphragm pump and 0.38 tons per year per piston pump and VOC emissions by 0.1 tons per year per diaphragm pump and 0.01 tons per year for a piston pump.

6.2.3.3 Cost Impacts

As stated earlier, instrument air conversions require a compressor with a capacity based on the number of control loops at the location. The compressor size is equivalent to the volume of natural gas used by the control loops after adjusting for gas losses during drying, plus any utility air necessary at the facility. This volume can either be calculated via a meter or utilizing a rule of thumb of one cubic foot per minute (cfm) of instrument air per control loop.[89]

For natural gas processing, the cost of emission reductions of the three representative instrument air system sizes was evaluated based on the emissions mitigated from the number of control loops the system can provide and not on a per device basis. This approach was chosen because the EPA assumes new processing plants will need to provide instrumentation for multiple control loops and size the instrument air system accordingly. As was discussed in the 2011 NSPS TSD, the EPA assumes that existing processing plants have an instrument air system in place, including backup systems, and that the cost of adding additional air load to the system would be confined to the incremental cost of upgrading or replacing the compressor and connecting the natural gas-driven pumps to the system. Therefore, for this analysis, the cost being attributed to the replacement of natural gas-driven pumps with air-driven pumps includes the annualized cost of replacing or adding a compressor and installation of the associated piping to connect the pumps to the existing system, and the associated energy costs for operating the new

NMED Exhibit 70

compressor. The size of the compressor required would depend on the additional air load required for the instrument air system to handle the pneumatic pumps.

Because the EPA has no data to characterize the number and types of gas-driven pumps at natural gas processing plants, the EPA developed several model plant scenarios that would likely cover a reasonable range of the numbers and types of pumps that might be found at natural gas processing plants. The model plants represented processing plants with 4, 10, 20, 50 and 100 total pumps. Because there is a significant variation in emission profiles between natural gas-driven diaphragm and piston pumps, the EPA also evaluated, within each model plant, three distribution scenarios for the pumps (i.e., 50 percent diaphragm and 50 percent piston, 25 percent diaphragm and 75 percent piston, and 75 percent diaphragm and 25 percent piston.). In our analysis, the EPA determined the total additional air capacity needed based on the estimated natural gas emission rate for the two types of natural gas-driven pumps, and based on the model plant scenarios, determined the volume of additional air capacity that would need to be addressed by the compressor. The EPA then based the analysis on the use of 90 percent of available capacity of the system. The EPA determined that there were basically three sizes (small, medium and large) compressors that would address the range of model plants. Table 6-4 summarizes the model plant analysis of required system capacity and potential emission reductions. The compressor costs used in our analysis were drawn from the costing analysis conducted for the 2011 NSPS proposal for instrument air systems for pneumatic controllers (See Section 5 of the 2011 TSD). The EPA estimated costs, including operating costs, at three size levels; small, medium and large. Table 6-5 summarizes the cost replacement of the various size compressors into an existing instrument air system.

Because gas emissions are avoided, the use of an instrument air system to control natural gas-driven pumps will have natural gas savings realized from the gas not released. The EPA estimates that each diaphragm pump replaced will save 197 Mcf per year of natural gas from being emitted and each piston pump will save of 22 Mcf per year. The value of the natural gas saved based on $4.00 per Mcf would be $786 per year per diaphragm pumps and $87 per year per piston pump.

6.2.3.4 Secondary Impacts

The secondary impacts from instrument air systems are indirect, variable and dependent on the electrical supply used to power the compressor. No other secondary impacts are expected.

d. The total O&M includes both the annual labor cost and the annual power cost.
e. The total annual cost includes the annualized capital cost and the total O&M.

NMED Exhibit 70

6.2.4 Install or Route Gas to Combustion Device

6.2.4.1 Emission Reduction Potential

Routing emissions from a natural gas-driven pump to an existing combustion device, or a newly installed combustion device does not reduce the volume of natural gas emitted, but rather combusts the gas volume. Costs for routing the natural gas to a combustion device are further described in Table 6-3. The EPA estimates capture and combustion device efficiency to be 95 percent reduction. Therefore, methane reductions are estimated to be 3.29 tons per year for a diaphragm pump and 0.36 tons per year for a piston pump. Based on the gas composition for natural gas in the production segment, the EPA estimates that routing emissions to a combustion device will reduce VOC emissions by 0.91 tons per year per diaphragm pump and 0.1 tons per year for a piston pump.

6.2.4.2 Effectiveness

Capture systems combined with combustion devices are considered a reliable mechanism to reduce approximately 95 percent of emissions. Each combustion device requires a reliable ignition source where the average gas consumption per pilot burner is 70 scf per hour.[90] Most processing plants or large dehydration facilities already have at least one existing combustion device.

6.2.4.3 Cost Impacts

Routing natural gas to an existing combustion device or installing a new combustion device have associated capital costs and operating costs. Based on the analysis conducted for the 2012 NSPS for a combustion device to control emissions from storage vessels,[91] the capital cost for installing a new combustion device is $32,301 in 2008 dollars. The EPA estimates that the capital cost for installing a new combustion device is $34,250 and the annual operating costs are $17,001 in 2012 dollars. Based on the life expectancy for a combustion device, the EPA estimate the annualized cost of installing a new combustion device to be $21,877 using a 7 percent discount rate. For the proposal, the estimated annualized cost of routing emissions to an existing combustion device was $285 using a 7 percent discount rate. Because the gas captured is combusted there is no gas savings associated with use of a combustion device.

Based on comments received from the proposal, the EPA revised our estimated cost for routing emissions to an existing control device. EPA received cost estimates from two commenters that claimed

[90] Ibid.
[91] U.S. EPA docket ID: EPA-HQ-OAR-2010-0505-0045.

NMED Exhibit 70

that the proposed cost estimate for routing emissions to an existing control device or process was too low. One commenter[92] claimed that there were engineering costs in addition to the cost to pipe emissions in a closed vent system (CVS) to a control device and that the total capital cost would be $5,800. Another commenter[93] provided detailed cost with respect to installing a CVS that considers that there could be a significant distance between the pump location and the control device on a site. This commenter suggested that the cost would be $8,500 to route emissions through a CVS to an existing control device.

The cost estimates the EPA received from the commenters were not directly comparable to each other, nor were they directly comparable to the proposal cost estimate. Therefore, in order to consider the additional costs provided by the commenters in our analysis, the EPA treated the costs as individual, all-inclusive cost estimates for routing emissions to an existing control device. The EPA calculated the average of the capital cost from proposal and the two commenter estimates and found the estimated capital cost to be $5,433. Using the 7 percent discount rate, the EPA calculated the annualized cost for each of the commenter estimates to be $826 (from the $5,800 estimate) and $1,210 (from the $8,500 estimate). The EPA averaged these annualized costs with the proposed annualized cost of $285 which resulted in a revised annualized cost of $774.

6.2.4.4 Secondary Impacts

There are secondary impacts from combustion of emissions routed from natural gas-driven pumps. The combustion of the recovered natural gas creates secondary emissions of hydrocarbons, NO_X, CO_2, and CO. A summary of the estimated secondary emission are presented in Table 6-6. No other wastes should be created or wastewater generated.

e. Based on combustion of natural gas stream and AP-42 Particulate Matter emission factors for industrial flares. Assumes a "lightly smoking" flare.

6.2.5 Install or Route Gas to VRU

6.2.5.1 Emission Reduction Potential

Use of a vapor recovery technology has the potential to reduce the emissions from natural gas-drive pumps by 100 percent if all vapor is recovered. However, the effectiveness of the gas capture system and downtime for maintenance would reduce capture efficiency and therefore, the EPA estimates that routing emissions from a natural gas-driven pump to an existing VRU, or a newly installed VRU can reduce the gas emitted by approximately 95 percent, while at the same time, capturing the gas for beneficial use. The EPA estimates that methane emission reductions for routing gas to a VRU to be 3.29 tons per year for a diaphragm pump and 0.36 tons per year for a piston pump. Based on the gas composition for natural gas in the production segment, the EPA estimates that routing emissions to a VRU will reduce VOC emissions by 0.91 tons per year per diaphragm pump and 0.1 tons per year for a piston pump.

6.2.5.2 Effectiveness

VRUs are reliable, typically with a backup compressor system to allow for shutdowns and repairs. VRUs are more economical for facilities with multiple gas emission sources that can be routed to the VRU. Some of these other emission sources can include tanks, dehydrators, and compressors and as a result, VRUs are more common at natural gas processing plants and large dehydration facilities.

6.2.5.3 Cost Impacts

Routing natural gas to an existing VRU or installing a new VRU, have both capital costs and maintenance costs. Based on the analysis conducted for the 2012 NSPS for control of emissions from

NMED Exhibit 70

storage vessels[94], the capital cost and installation costs for a VRU is estimated to be $98,186 in 2008 dollars. The EPA estimates the capital cost of installation of a VRU to be $104,111 and the annual operation and maintenance cost to be $9,932 in 2012 dollars. If a VRU is already on site, then the additional costs for routing emissions from a pump are small, as the majority of costs are piping. The total annualized cost of a new VRU is estimated to be $24,755 based on a 7 percent discount rate.

As discussed above, for the proposal the EPA estimated the cost of routing emissions to an existing VRU to be $2,000 in 2012 dollars. The annualized cost of routing gas to an existing VRU is estimated to be $285 based on a 7 percent discount rate. In addition, because there is potential for beneficial use of gas recovered through the VRU, the EPA estimates an annual gas recovered as 187 Mcf per year per diaphragm pump and 21 Mcf per year per piston pump. The gas savings realized is estimated to be $749 per diaphragm pump and $84 per piston pump, per year based on $4.00 value per Mcf of gas recovered.

As discussed above in section 6.2.4.3 with respect to routing emissions to an existing combustion control device, the EPA considered additional cost estimates submitted during the proposed rule public comment period and have revised the estimated cost for routing emissions to an existing VRU to be the same as the cost of routing to an existing combustion device, or $774 annualized cost.

6.2.5.4 Secondary Impacts

The secondary impacts from use of a VRU are indirect, variable and dependent on the electrical supply used to power the VRU. No other secondary impacts are expected.

6.3 Regulatory Options

The control technologies evaluated for natural gas-driven pumps included options that provided 100 percent emission reductions. These options included replacing the pumps with solar-powered pumps or electric pumps or use of instrument air systems to eliminate natural gas emissions. The EPA also evaluated gas recovery and gas combustion technologies that would result in 95 percent emission reductions.

The use of instrument air systems and electric pumps requires a consistent supply of electric power and the use of solar-powered pumps and routing emissions to a VRU requires a reliable supply of backup electric power. Because reliable electric power is not universally available for production, gathering and boosting and transmission and storage locations these control technologies were

[94] Ibid.

NMED Exhibit 70

determined to not be technically viable options for those segments. Because electric power is typically available at natural gas processing plants, those technologies are considered technically viable for the processing segment.

For the final rule, we have revaluated our best available emissions and usage data for piston pumps. Based on our emissions data these pumps have inherently low emissions primarily due to size. In addition, available information indicates that these pumps are typically used intermittently which further limits their emission potential. Therefore, we determined that based on their low emissions, control of piston pumps is not warranted at this time and we have excluded piston pumps from further evaluation.

Based on the costs and estimated emission reductions for each of the viable emission control alternatives, the EPA further evaluated the cost per ton of emissions reduced for methane and VOC. The cost per ton of emissions reduced was calculated in two ways. The first method, or single-pollutant approach, allocated all of the costs to one pollutant and zero cost to the other. The second method, or the multipollutant approach, allocated costs among the pollutants that a given technology reduced (i.e., methane and VOC). This multipollutant approach is based on estimates of the percentage reduction expected for each pollutant.

Based on the above considerations, for the proposal the EPA evaluated the following regulatory alternatives:

- Regulatory Option 1. Require a zero emission standard for diaphragm pumps at natural gas processing plants.
- Regulatory Option 2. Require a 95 percent emissions reduction standard for diaphragm pumps production facilities.
- Regulatory Option 3. Require a 95 percent emissions reduction standard for diaphragm pumps production facilities only where an existing control device or process is available.

6.3.1 Evaluation of Regulatory Options

Regulatory Option 1 would require zero emissions of methane and VOC from gas-driven, diaphragm pumps at natural gas processing plants. To attain this emission reduction, the facility would need to either replace the natural gas-driven diaphragm pumps with solar-powered or electric pumps or use instrument air systems to replace natural gas-driven function with air-driven function. The EPA evaluated the cost of control for each of these options based on the estimated emission reductions as detailed above.

NMED Exhibit 70

Using the single-pollutant (allocate all of the costs to one pollutant and zero to the other) for calculating cost of control, for the use of an instrument air system at natural gas processing plants the EPA estimates the cost per ton of methane reduced to be between $374 and $2,185 and the cost per ton of VOC reduced to be between $1,344 and $7,861 without considering gas savings. With gas savings, for the use of an instrument air system at natural gas processing plants, the cost per ton of methane reduced was $146 and $1,957, and the cost per ton of VOC reduced was between $527 and $7,042. Using the multi-pollutant method of allocating cost between methane and VOC, the EPA estimates the cost of control, without considering gas savings, ranged from $187 to 1,093 per ton of methane reduced and $672 and $3,930 per ton of VOC reduced. When considering gas savings, the EPA found the cost of control to range from $73 to $979 per ton of methane reduced and $263 to $3,521 per ton of VOC reduced. The range of cost per ton is dependent on the size of the system/compressor needed for the facility.

Under the single pollutant approach, the EPA estimates the cost of control for installation of either an electric pump or solar-powered pumps to be between ($136) and $1,223 per ton of methane reduced or between ($489) and $4,235 per ton of VOC reduced, considering gas savings.[95] Under the multi-pollutant approach and considering savings, the EPA estimates the cost of control for installation of either an electric pump or solar-powered pump to be between ($68) and $1,337 per ton of methane reduced and between ($244) and $2,112 per ton of VOC reduced, considering gas savings. The EPA considers these costs to be reasonable. Based on these cost of control values for methane and VOC, EPA determined that Regulatory Option 1 is appropriate for the natural gas processing segment. Tables 6-7 through 6-10 summarize the cost of control for each of these options for the natural gas processing segment. For the final rule, the EPA had no changes to this analysis for natural gas processing plants.

The control technologies that produce zero emissions (or 100 percent reduction in emissions) (i.e., solar-powered and electric pumps and instrument air systems) are not technically viable alternatives for the production and transmission and storage segments where reliable electric power is not universally available. Instead, the available control technologies for those segments produce a 95 percent emission reduction. Therefore, the second regulatory option would require a 95 percent reduction in emissions at production sites, transmission stations and storage facilities. To attain this emission reduction, the facility could route emissions to a VRU or a combustion device.

[95] Negative cost reflects a net savings considering gas saved.

NMED Exhibit 70

For the proposal, the EPA calculated the cost of control for this option for each control technology by the single-pollutant and multi-pollutant methods described above. For the installation of a new VRU or combustion device, the cost of control for methane and VOC emission reductions ranged from $3,652 to over $1 million per ton. The cost of control for a new combustion device ranged between $3,328 to over $1 million per ton. Based on these cost of control values for methane and VOC, Regulatory Option 2 was rejected for all segments. For the final rule, the EPA had no changes to this analysis. Tables 6-11 through 6-14 summarize the cost of control for Option 2 for all segments.

For the proposal, EPA evaluated Regulatory Option 3 to require 95 percent control of emissions in all segments only where an existing control device or process was available. The sole cost associated with this option that would be attributed to the emission reduction would be the cost of routing the diaphragm pump emissions to the control device. As discussed above, for the final rule, the EPA has revised the estimated cost to route emissions to either an existing VRU or an existing combustion device based on commenter provided cost estimates. Under the new analysis the capital cost is approximately $5,433, which when annualized at a 7 percent discount rate, resulted in an annualized cost of $774. Based on this annualized cost, using the single-pollutant approach of calculating cost of control, the cost of control for methane emission reductions with an existing VRU or an existing combustion device is $235 per ton for all segments. The cost of control for VOC reductions is $847 per ton for the production and processing segments and $8,496 per ton for the transmission and storage segment. Considering natural gas savings when an existing VRU is used, the cost of control for methane emission reductions is $8 per ton for all segments. The cost of control for VOC emission reductions is $27 per ton for the production and processing segments and $274 per ton for the transmission and storage segment.

Using the multi-pollutant approach of calculating cost of control, the cost of control for methane emission reductions with an existing VRU or an existing combustion device is $118 per ton for all segments. The cost of control for VOC reductions is $423 per ton for the production and processing segments and $4,248 per ton for the transmission and storage segment. Considering natural gas savings when an existing VRU is used, the cost of control for methane emission reductions is $4 per ton for all segments. The cost of control for VOC emission reductions is $14 per ton for the production and processing segments and $137 per ton for the transmission and storage segment... EPA found these methane costs to be reasonable and selected Option 3 for control of natural gas-driven diaphragm pump emissions for all segments. Tables 6-15 through 6-16 summarize results of our cost of control analyses.

NMED Exhibit 70

Table 6-7. Cost of Control for Use of Instrument Air Systems at Natural Gas Processing Plants - Single-Pollutant[96]

Plant Size	Compressor Cost[a]	Scenario[b]	Total Number of Pumps	Total Gas Saved[c] (Mcf)	Emission reductions[d] (tpy)		Cost of control (without savings) ($/ton)		Cost of control (with savings)[c] ($/ton)	
					Methane	VOC	Methane	VOC	Methane	VOC
Small	$10,051	50/50	4	49.8	7.7	2.1	$1,309	$4,708	$1,081	$3,890
		75/25	4	69.8	10.8	3.0	$934	$3,360	$707	$2,543
		25/75	4	29.9	4.6	1.3	$2,185	$7,861	$1,957	$7,042

Medium	$32,271	50/50	20	249.2	38.4	10.7	$840	$3,023	$613	$2,205
		75/25	20	349.1	53.8	15.0	$600	$2,158	$373	$1,340
		25/75	20	149.4	23.0	6.4	$1,403	$5,048	$1,175	$4,229
Medium Large	$72,394	50/50	50	623.1	96.0	26.7	$837	$3,011	$527	$1,895
		75/25	50	872.7	134.5	37.4	$558	$2,007	$311	$1,119
		25/75	50	373.5	57.5	16.0	$1,674	$6,022	$1,031	$3,711
Large	$72,394	50/50	100	1246.2	192.0	53.4	$418	$1,505	$150	$539
		75/25	100	1745.4	269.0	74.8	NA - Beyond Capacity			
		25/75	100	747.0	115.0	32.0	$837	$3,011	$402	$1,446

a. See Table 6-5 for compressor cost analysis.
b. Allocation of type of pumps (i.e., 50/50 is half the pumps are diaphragm and half are piston, 75/25 is 75% of the pumps are diaphragm and 25% are piston, etc.).
c. Based on raw gas emissions of 22.45 scf/hr for a diaphragm pump and 2.48 scf/hr for a piston pump, resulting in $786 savings per diaphragm pump and $87 savings per piston pump.
d. Based on 3.36 tons per year of methane and 0.96 tons per year of VOC per diaphragm pump and 0.36 tons per year of methane and 0.11 tons per year of VOC per piston pump.

[96] As explained earlier, this control option simultaneously reduces both methane (which is being evaluated for controlling the pollutant GHG) and VOC. Under the single pollutant approach, all costs are attributed to one pollutant and zero to the other. For simplicity, the table presents the cost per ton of the assigned pollutant; the table does not present the cost per ton of the one that is assigned zero cost because it is always zero.

NMED Exhibit 70

7.0 COMPRESSORS

Compressors are mechanical devices that increase the pressure of natural gas and allow the natural gas to be transported from the production site, through the supply chain, and to the consumer. The types of compressors that are used by the oil and natural gas industry as prime movers are reciprocating and centrifugal compressors.

The 2012 NSPS promulgated requirements for control of emissions from wet seal centrifugal compressors and reciprocating compressors in the production and processing segments. During development of the 2012 NSPS amendments, methane and VOC emissions for these sources were estimated and included in the cost and impact analysis. See the 2011 NSPS TSD for information on the production and processing segments.

This chapter discusses the emissions from these compressors in the transmission and storage segment and provides emission estimates for reducing emission from these types of compressors. In addition, nationwide emissions estimates from new sources are estimated. Options for controlling emissions from these compressors are presented, along with costs, emission reductions, and secondary impacts. Finally, this chapter discusses considerations in developing regulatory alternatives for both reciprocating and centrifugal compressors.

7.1 Process Description

7.1.1 Reciprocating Compressors

In a reciprocating compressor, natural gas enters the suction manifold, and then flows into a compression cylinder where it is compressed by a piston driven in a reciprocating motion by the crankshaft powered by an internal combustion engine. Emissions occur when natural gas leaks around the piston rod when pressurized natural gas is in the cylinder. The compressor rod packing system consists of a series of flexible rings that create a seal around the piston rod to prevent gas from escaping between the rod and the inboard cylinder head. However, over time, during operation of the compressor, the rings become worn and the packing system will need to be replaced to prevent excessive leaking from the compression cylinder.

7.1.2 Centrifugal Compressors

Centrifugal compressors use a rotating disk or impeller to increase the velocity of the gas where it is directed to a divergent duct section that converts the velocity energy to pressure energy.

NMED Exhibit 70

These compressors are primarily used for continuous, stationary transport of natural gas in the processing and transmission systems. Many centrifugal compressors use wet (meaning oil) seals around the rotating shaft to prevent natural gas from escaping where the compressor shaft exits the compressor casing. The wet seals use oil which is circulated at high pressure to form a barrier against compressed natural gas leakage. The circulated oil entrains and absorbs some compressed natural gas which is released to the atmosphere during the seal oil recirculation process. Alternatively, dry seals can be used in place of wet seals in centrifugal compressors. Dry seals prevent leakage by using the opposing force created by hydrodynamic groves and springs. The opposing forces create a thin gap of high pressure gas between the rings through which little gas can leak. The rings do not wear or need lubrication because they are not in contact with each other. Therefore, operation and maintenance costs are typically lower for dry seals in comparison to wet seals.

7.2 Emissions Data and Emissions Factors

7.2.1 Summary of Major Studies and Emissions Factors

There are a few studies that have been conducted that provide emission estimates from reciprocating and centrifugal compressors. These studies are provided in Table 7-1, along with the type of information contained in the study.

7.2.2 Representative Reciprocating and Centrifugal Compressor Emissions

The methodology for estimating emission from reciprocating compressor rod packing was to use the methane emission factors referenced in the EPA/GRI study[98] and the methane-to-VOC ratio developed in the gas composition memorandum.[99] The emission factors in the EPA/GRI document were expressed in thousand standard cubic feet per cylinder (Mscf/cyl), and were multiplied by the average number of cylinder per reciprocating compressor at each oil and gas industry segment. The volumetric methane emission rate was converted to a mass emission rate using a density of 41.63 lbs of methane per Mcf. This conversion factor was developed assuming that methane is an ideal gas and using the ideal gas law to calculate the density. A summary of the methane emission factors is presented in Table 7-2. Once the methane emissions were calculated, the ratio of VOC-to-methane

[98] National Risk Management Research Laboratory. GRI/EPA Research and Development, Methane Emissions from the Natural Gas Industry, Volume 8: Equipment Leaks. Prepared for the U.S. Department of Energy, Energy Information Administration. EPA-600/R-96-080h. June 1996.
[99] See footnote *3*.

NMED Exhibit 70

was used to estimate VOC emissions. The specific VOC-to-methane ratios used for this analysis were 0.278 lbs VOC per pound of methane for the production and processing segments, and 0.0277 lbs VOC per pound of methane for the transmission and storage segment. A summary of the reciprocating compressor emissions are presented in Table 7-3.

The centrifugal compressor emission factors for wet seals and dry seals are based on data used in the GHG Inventory[100]. The wet seals methane emission factor was calculated based on a sampling of 48 wet seal centrifugal compressors. The dry seal methane emission factor was based on data collected by the Natural Gas STAR Program. The methane emissions were converted to VOC and HAP emissions using the same gas composition ratios that were used for reciprocating engines.[101]

Since publication of the white paper, additional data have become available on compressor emissions in transmission and storage, including reporting year 2014 data from GHGRP, and new measurement data from Subramanian et al. 2015. These data confirm the significant emissions from these sources, but indicate that emissions levels differ from those assumed in this analysis. In the 2013 GHGRP transmission and storage data set, reported emissions from reciprocating compressors are 2,100,647 tons CO_2 Eq. of methane, and reported emissions from centrifugal compressors are 697,643 tons CO_2 Eq. of methane. The Subramanian study, compared total average methane emissions per compressor in transmission and storage for both reciprocating and centrifugal compressors to those in the 2015 GHG Inventory, and found that the 2015 GHG Inventory had higher average emissions. The 2016 GHGI inventory includes updated estimates for reciprocating and centrifugal compressors, based on data from the Subramanian study and GHGRP.

7.3 Control Techniques

7.3.1 Potential Control Techniques

The potential control options reviewed for reducing emissions from reciprocating compressors include control techniques that limit the leaking of natural gas across the piston rod packing. This includes replacement of the compressor rod packing or replacement of the piston rod.

The replacement of the rod packing is a maintenance task performed on reciprocating compressors to reduce the leakage of natural gas across the piston rod. Over time the packing rings wear and allow more natural gas to escape around the piston rod. Regular replacement of these rings

NMED Exhibit 70

reduces methane and VOC emissions. Therefore, this control technique was determined to be an appropriate option for reciprocating compressors.

Like the packing rings, piston rods on reciprocating compressors also deteriorate. Piston rods, however, wear more slowly than packing rings, having a life of about 10 years.[102] Rods wear "out-of-round" or taper when poorly aligned, which affects the fit of packing rings against the shaft (and therefore the tightness of the seal) and the rate of ring wear. An out-of-round shaft not only seals poorly, allowing more leakage, but also causes uneven wear on the seals, thereby shortening the life of the piston rod and the packing seal. Replacing or upgrading the rod can reduce reciprocating compressor rod packing emissions. A summary of these techniques are presented in the following sections.

Potential control options to reduce emissions from centrifugal compressors include control techniques that limit the leaking of natural gas across the rotating shaft, or capture and destruction of the emissions using a combustion device. A summary of these techniques are presented in the following sections.

One control technique for limiting or reducing the emission from the rotating shaft of a centrifugal compressor is a mechanical dry seal system. This control technique uses rings to prevent the escape of natural gas across the rotating shaft. This control technique was determined to be a viable option for reducing emission from centrifugal compressors.

For centrifugal compressors equipped with wet seals, a combustion device was considered to be a viable option for reducing emissions from centrifugal compressors. Centrifugal compressors require seals around the rotating shaft to prevent natural gas from escaping where the shaft exits the compressor casing. "Beam" type compressors have two seals, one on each end of the compressor, while "over-hung" compressors have a seal on only the "inboard" (motor end) side. These seals use oil, which is circulated under high pressure between three rings around the compressor shaft, forming a barrier against the compressed gas leakage. The center ring is attached to the rotating shaft, while the two rings on each side are stationary in the seal housing, pressed against a thin film of oil flowing between the rings to both lubricate and act as a leak barrier. The seal also includes "O-

[102] U.S. EPA. Lessons Learned: Reducing Methane Emissions from Compressor Rod Packing Systems. Natural Gas STAR. Washington DC. 2006.

NMED Exhibit 70

ring" rubber seals, which prevent leakage around the stationary rings. The oil barrier allows some gas to escape from the seal, but considerably more gas is entrained and absorbed in the oil under the high pressures at the "inboard" (compressor side) seal oil/gas interface, thus contaminating the seal oil. Seal oil is purged of the absorbed gas (using heaters, flash tanks, and degassing techniques) and recirculated back to the seal. As a control measure, the recovered gas would then be sent to a combustion device.

7.3.2 Reciprocating Compressor Rod Packing Replacement

7.3.2.1 Description

Reciprocating compressor rod packing consists of a series of flexible rings that fit around a shaft to create a seal against leakage. As the rings wear, they allow more compressed gas to escape, increasing rod packing emissions. Rod packing emissions typically occur around the rings from slight movement of the rings in the cups as the rod moves, but can also occur through the "nose gasket" around the packing case, between the packing cups, and between the rings and shaft. If the fit between the rod packing rings and rod is too loose, more compressed gas will escape. Periodically replacing the rod packing ensures the correct fit is maintained between packing rings and the rod.

7.3.2.2 Emissions Reduction Potential

As discussed above, regular replacement of the reciprocating compressor rod packing can reduce the leaking of natural gas across the piston rod. The emission reductions for the transmission and storage segments were calculated by multiplying the number of new reciprocating compressors in each segment by the difference between the average rod packing emission factors (as presented in Table 6-2) and the average emission factor for newly installed rod packing. This calculation, shown in the Equation 1 below, was performed for the transmission and storage segment.

Equation 1

$$R_{PTS} = \frac{Comp_{New}^{PTS}\left(E_{G\&B} - E_{New}\right) \times C \times O \times 8760}{10^6}$$

where:

R_{PTS} = Potential methane emission reductions from transmission or storage compressors replacing rod packing, in million cubic feet per year (MMcf/year).

$Comp_{New}^{PTS}$ = Number of new transmission or storage compressors.

$E_{G\&B}$ = Methane emission factor for transmission or storage compressors in Table 7-2, in cubic feet per hour per cylinder.

NMED Exhibit 70

E_{New}=Average emissions from a newly installed rod packing, assumed to be 11.5 cubic feet per hour per cylinder[103] for this analysis.
C = Average number of cylinders for transmission or storage compressors in Table 7-2.
O = Percent of time during the calendar year the average transmission or storage compressor is in the operating and standby pressurized modes, 79.1%, 67.5% respectively.
8760 = Number of days in a year.
10^6 = Number of cubic feet in a million cubic feet.

A summary of the potential emission reductions for reciprocating compressor rod packing replacement in the transmission and storage segment is presented in Table 7-4. The emissions of VOC were estimated using the methane emissions calculated above and the methane-to-VOC- ratio developed for each of the segments in the gas composition analysis conducted for the NSPS.[104]

Table 7-4. Estimated Annual Reciprocating Compressor Emission Reductions from Replacing Rod Packing for a Typical Year

Compressor Location	Number of New Sources Per Year	Individual Compressor Emission Reductions (tons/compressor-year)		Nationwide Emission Reductions (tpy)	
		Methane	VOC	Methane	VOC
Typical Year					
Transmission	15	21.7	0.601	325	9
Storage	17	21.8	0.605	109	10

7.3.2.3 Cost Impacts

Costs for the replacement of reciprocating compressor rod packing were obtained from a Natural Gas STAR Lessons Learned document[105] which estimated the cost to replace the rod packing rings to be $1,712 per cylinder. It was assumed that rod packing replacement would occur during planned shutdowns and maintenance and therefore, no travel costs will be incurred for implementing the rod packing replacement program. In addition, no costs were included for monitoring because the rod packing placement is based on number of hours that the compressor operates, or the time since the last replacement. The replacement of rod packing for reciprocating compressors occurs on average every four years based on industry information from the Natural Gas STAR Program.[106] The

[103] Ibid.
[104] *See footnote* 3.
[105] *See footnote 102*.
[106] Ibid.

NMED Exhibit 70

cost impacts are based on the replacement of the rod packing every 26,000 hours that the reciprocating compressor operates in the pressurized mode.

For the 2012 NSPS, the number of hours used for the cost impacts was determined using a weighted average of the annual percentage that the reciprocating compressors are pressurized for all of the new sources. This percentage of hours is, on average, the number of hours per year a reciprocating compressor is pressurized and was used as the basis for the cost evaluation as it was determined to be the best available industry-wide percent pressurized value. The weighted average percentage was calculated to be 98.9 percent. This percentage was multiplied by the total number of hours in 3 years to obtain a value of 26,000 hours. This calculates to an average of 3.8 years for transmission compressors and 4.4 years for storage compressors using the operating factors in Table 7-2. The calculated years were assumed to be the equipment life of the compressor rod packing and were used to calculate the capital recovery factor for each of the segments. Assuming an interest rate of 7 percent, the capital recovery factors were calculated to be 0.3122 for transmission compressors and 0.2720 for storage compressors. The capital costs were calculated using the average rod packing cost of $1,712 and the average number of cylinders per segment as presented in Table 7-2. The annual costs were calculated using the capital cost and the capital recovery factors.

The cost per ton of emissions reduced was then calculated in two ways. The first method, or single-pollutant approach, allocated all of the costs to each pollutant separately. The second method, or multi-pollutant approach, allocated costs among the pollutants that a given technology reduced (i.e., methane and VOC). The multi-pollutant approach was based on estimates of the percentage reduction expected for each pollutant. A summary of the capital and annual costs for the transmission and storage segment is shown in Table 7-5.

There are monetary savings associated with the amount of gas saved with reciprocating compressor rod packing replacement, however, these savings were not included in the cost estimates for the transmission and storage segment because it is assumed that the owner/operator of the compressor generally is not the owner of the natural gas that is compressed at their compressor stations.

NMED Exhibit 70

Table 7-5. Cost of Control for Reciprocating Compressor Rod Packing Replacement ($2012)

Compressor Location	Capital Cost ($)	Annual Cost ($/yr)	Cost of Control Single-Pollutant Approach ($/ton)		Cost of Control Multi-Pollutant Approach ($/ton)	
			Methane	VOC	Methane	VOC
Transmission	$5,650	$1,748	$81	$2,910	$40	$1,455
Storage	$7,705	$2,077	$95	$3,434	$48	$1,717

7.3.2.4 Secondary Impacts

The reciprocating compressor rod packing replacement is an option that prevents the escape of natural gas from the piston rod. No wastes should be created, no wastewater generated, and no maintenance of electrical systems and therefore, no travel costs will be incurred for implementing the rod packing replacement program. In addition, no costs were included for monitoring because the rod packing is replaced based on operating hours or time since the last replacement.

7.3.3 Centrifugal Compressor Dry Seals

7.3.3.1 Description

Centrifugal compressor dry seals operate mechanically under the opposing force created by hydrodynamic grooves and springs. The hydrodynamic grooves are etched into the surface of the rotating ring affixed to the compressor shaft. When the compressor is not rotating, the stationary ring in the seal housing is pressed against the rotating ring by springs. When the compressor shaft rotates at high speed, compressed gas has only one pathway to leak down the shaft, and that is between the rotating and stationary rings. This gas is pumped between the rings by grooves in the rotating ring. The opposing force of high-pressure gas pumped between the rings and springs trying to push the rings together creates a very thin gap between the rings through which little gas can leak. While the compressor is operating, the rings are not in contact with each other, and therefore, do not wear or need lubrication. O-rings seal the stationary rings in the seal case.

Dry seals substantially reduce gas emissions compared to wet seals. At the same time, they significantly reduce operating costs and enhance compressor efficiency compared to wet seals. Economic and environmental advantages of using dry seals include:

NMED Exhibit 70

- Gas Leak Rates. During normal operation, dry seals leak at a rate of less than 6 scfm methane per compressor.[107] While this is equivalent to a wet seal's leakage rate at the seal face, wet seals generate additional emissions during degassing of the circulating oil. Gas separated from the seal oil before the oil is re-circulated is usually vented to the atmosphere bringing the total leakage rate for tandem wet seals to 47.7 scfm methane per compressor.[108, 109]
- Mechanically Simpler. Dry seal systems do not require additional oil circulation components and treatment facilities.
- Reduced Power Consumption. Because dry seals have no accessory oil circulation pumps and systems, they avoid "parasitic" equipment power losses. Wet seal systems require 50 to 100 kilowatt (kW) per hour, while dry seal systems need about 5 kW of power per hour.
- Improved Reliability. The highest percentage of downtime for a compressor using wet seals is due to seal system problems. Dry seals have fewer ancillary components, which translates into higher overall reliability and less compressor downtime.
- Lower Maintenance. Dry seal systems have lower maintenance costs than wet seals because they do not have moving parts associated with oil circulation (e.g., pumps, control valves, relief valves, and the seal oil cost itself).
- Elimination of Oil Leakage from Wet Seals. Substituting dry seals for wet seals eliminates seal oil leakage into the pipeline, thus avoiding contamination of the gas and degradation of the pipeline.

6.3.3.2 Emissions Reduction Potential

The emission reduction of the dry seal compressor was calculated by subtracting the dry seal emissions from the emissions from a centrifugal compressor equipped with wet seals. The centrifugal compressor emission factors in Table 7-2 were used in combination with an operating factor of 30 percent for transmission centrifugal compressors and 22.4 percent for storage centrifugal

NMED Exhibit 70

compressors. The operating factors are used to account for the percent of time in a year that a compressor is in the operating mode. The operating factors are based on data from the GHG Inventory.[110] The wet seals emission factor is an average of 48 different wet seal centrifugal compressors. The dry seal emission factor is based on information from the Natural Gas STAR Program.[111] A summary of the emission reduction from the replacement of wet seals with dry seals is shown in Table 7-6.

Table 7-6. Estimated Annual Centrifugal Compressor Emission Reductions from Replacing Wet Seals with Dry Seals

Compressor Location	Number of New Sources Per Year	Individual Compressor Emission Reductions (ton/compressor-year)		Nationwide Emission Reductions (tpy)	
		Methane	VOC	Methane	VOC
Transmission	0	137	3.79	0	0
Storage	1	102	2.83	102	2.83

7.3.3.3 Cost Impacts

The price difference between a brand new dry seal and brand new wet seal centrifugal compressor is insignificant relative to the cost for the entire compressor. From the Natural Gas STAR Program, General Electric (GE) stated that a natural gas transmission pipeline centrifugal compressor with dry seals cost between $50,000 and $100,000 more than the same centrifugal compressor with wet seals. However, this price difference is only about 1 to 3 percent of the total cost of the compressor. The price of a brand new natural gas transmission pipeline centrifugal compressor between 3,000 and 5,000 horsepower runs between $2 million to $5 million depending on the number of stages, desired pressure ratio, and gas throughput. The larger the compressor, the less significant the price difference is between dry seals and wet seals. This analysis assumes the additional capital cost for a dry seal compressor is $75,000 ($79,268 in 2012 dollars). The annual cost was calculated as the capital recovery of this capital cost assuming a 20-year equipment life and 7 percent interest which came to $7,482 per compressor. The Natural Gas STAR Program estimated that the annual operation and maintenance savings from the installation of dry seal compressor is $88,300 in comparison to wet seal compressor. The cost per ton of emissions reduced was then

[110] *See footnote* 4.
[111] U.S. EPA. Lessons Learned: Replacing Wet Seals with Dry Seals in Centrifugal Compressors. Natural Gas STAR. 2006.

NMED Exhibit 70

calculated in two ways. The single-pollutant method allocated all of the costs to each pollutant separately. The multi-pollutant method prorated costs among the pollutants that a given technology reduced (i.e., methane and VOC). The multi-pollutant method was based on estimates of the percentage reduction expected for each pollutant. A summary of the capital and annual costs for dry seals is presented in Table 7-7 along with the methane and VOC cost of control for the dry seal compressor option. We do not consider revenues from gas savings for transmission and storage facilities because it is assumed the owners of the compressor station do not own the natural gas that is compressed at the station.

Table 7-7. Cost of Reductions for Centrifugal Compressor Using Dry Seal Compressors ($2012)

Compressor Location	Capital Cost ($)	Annual Cost Per Compressor ($/compressor-year)		Methane Cost of Control ($/ton)		VOC Cost of Control ($/ton)	
		without savings	with O&M savings	without savings	with O&M savings	without savings	with O&M savings
Single-Pollutant

Storage	$79,268	$7,482	-$85,843	$73	-$840	$2,643	-$30,324
Multi-Pollutant Method							
Transmission	$79,268	$7,482	-$85,843	$27	-$314	$987	-$11,321
Storage	$79,268	$7,482	-$85,843	$37	-$420	$1,322	-$15,162

7.3.3.4 Secondary Impacts

Dry seals for centrifugal compressors are an option that prevents the escape of natural gas across the rotating compressor shaft. No wastes should be created, no wastewater generated, and no electricity needed. Therefore, there are no secondary impacts expected due to the installation of dry seals on centrifugal compressors.

7.3.4 Centrifugal Compressor Wet Seals Routed to a Combustion Device

7.3.4.1 Description

Another control option used to reduce emissions from centrifugal compressors equipped with wet seals is to route the emissions to a combustion device or capture the emissions and route them to a process (e.g., a fuel system). A wet seal system uses oil that is circulated under high pressure between three rings around the compressor shaft, forming a barrier against the compressed gas. The

NMED Exhibit 70

center ring is attached to the rotating shaft, while the two rings on each side are stationary in the seal housing, pressed against a thin film of oil flowing between the rings to both lubricate and act as a leak barrier. Compressed gas becomes absorbed and entrained in the fluid barrier and is removed using a heater, flash tank, or other degassing technique so that the oil can be recirculated back to the wet seal. The removed gas is either combusted or released to the atmosphere. The control technique investigated in this section is the use of wet seals with the removed gas sent to a combustion device or to a process.

7.3.4.2 Emissions Reduction Potential

Combustion devices have been used in the oil and natural gas industry to combust gas streams that have VOC and organic HAP. A combustion device typically achieves 95 percent reduction of these compounds when operated according to the manufacturer instructions. For this analysis, it was assumed that the entrained gas from the seal oil that is removed in the degassing process would be directed to a combustion device that achieves 95 percent reduction of methane, VOC, and organic HAP. The wet seal emissions in Table 7-2 were used along with the control efficiency to calculate the emission reductions from this option. A summary of the emission reductions is presented in Table 7-8.

Table 7-8. Estimated Annual Centrifugal Compressor Emission Reductions from Wet Seals Routed to a Combustion Device

Compressor Station	Number of New Sources Per Year	Individual Compressor Emission Reductions (tons/compressor-year)		Nationwide Emission Reductions (tpy)	
		Methane	VOC	Methane	VOC
Transmission	0	149	4.12	0	0
Storage	1	111	3.08	111	3.08

7.3.4.3 Cost Impacts

The capital and annual cost of the combustion device (an enclosed flare for the analysis) was calculated using the methodology in the EPA Control Cost Manual.[112] The heat content of the gas stream was calculated using information from the gas composition memorandum.[113] A summary of

[112] EPA Air Pollution Control Cost Manual - Sixth Edition, (EPA 452/B-02-001).
[113] See footnote 3.

NMED Exhibit 70

the capital and annual costs for wet seals routed to a flare is presented in Table 7-9. The cost per ton of emissions reduced was then calculated in two ways. The single-pollutant approach allocated all of the costs to each pollutant separately. The multi-pollutant approach allocated costs among the pollutants that a given technology reduced (i.e., methane and VOC). This allocation was based on estimates of the percentage reduction expected for each pollutant. The methane and VOC cost of control for the wet seals routed to a combustion device option is also shown in Table 7-9. There is no cost savings estimated for this option because the recovered gas is combusted.

Table 7-9. Cost of Control for Centrifugal Compressor Wet Seal Emission Routed to a Combustion Device

Compressor Location	Capital Cost ($)		Annual Cost per Compressor ($/compressor-year)		Cost of Control New CD ($/ton)		Cost of Control Existing CD ($/ton)	
	New CD	Existing CD	New CD	Existing CD	Methane	VOC	Methane	VOC
Single-Pollutant

CD = Control Device

7.3.4.4 Secondary Impacts

There are secondary impacts with the option to use wet seals with a combustion device. The combustion of the recovered gas creates secondary emissions of hydrocarbons (NO_X, CO_2, and CO emissions). A summary of the estimated secondary emission are presented in Table 7-10. No other wastes should be created or wastewater generated.

NMED Exhibit 70

Table 7-10. Secondary Impacts from Wet Seal Emissions Routed to a Combustion Device

e. Based on combustion of natural gas stream and AP-42 Particulate Matter emission factors for industrial flares. Assumes a "lightly smoking" flare.

7.4 Regulatory Options

EPA evaluated the following regulatory options:

- Regulatory Option 1. Require replacement of the reciprocating compressor rod packing based on 26,000 hours of operation while the compressor is pressurized.
- Regulatory Option 2. Require all centrifugal compressors to be equipped with dry seals.
- Regulatory Option 3. Require centrifugal compressors equipped with a wet seal to route the recovered gas emissions to a combustion device.

7.4.1 Evaluation of Regulatory Options

The first regulatory option for replacement of the reciprocating compressor rod packing based on the number of hours that the compressor operates in the pressurized mode was described in Section 7.3.1. The methane and VOC cost of control for reciprocating compressors at transmission stations is $81 and $2,910 per ton, respectively. The methane and VOC cost of control for reciprocating compressors at storage facilities is $95 and $3,434 per ton, respectively. Based on these cost of control values for methane, EPA selected Regulatory Option 1 for the transmission and storage segment.

The second regulatory option would require all centrifugal compressors to be equipped with dry seals. As presented in Section 7.3.2, dry seals are effective at reducing emissions from the rotating shaft of a centrifugal compressor. Dry seals also reduce operation and maintenance costs in

NMED Exhibit 70

comparison to wet seals. Under the single pollutant approach, the methane and VOC cost of emission reductions for dry seals compressors was calculated to be $55 per ton and $1,974 per ton respectively for centrifugal compressors located at transmission facilities, not including the savings from operation and maintenance costs. When those savings were considered the methane and VOC cost of control was calculated to be ($627) per ton and ($22,642) per ton. Also under the single pollutant approach, the methane and VOC cost of control for dry seal compressors was calculated to be $73 per ton and $2,643 per ton respectively for centrifugal compressors located at storage facilities, not including the savings from operation and maintenance costs.[114] When those savings were considered, the methane and VOC cost of control was calculated to be ($840) per ton and ($30,324) per ton. However, commenters on the 2011 Oil and Natural Gas NSPS noted that are certain situations where installing a dry seal system is not feasible, such as where gas composition is inadequate and in retrofits of some existing compressors due to housing design or operational requirements. Therefore, EPA rejected Regulatory Option 2 as a regulatory option for centrifugal compressors located at transmission or storage facilities.

The third regulatory option would allow the use of wet seals if the recovered gas emissions were routed to a combustion device or process. Under the single pollutant approach, the methane and VOC cost of control for routing emissions from a wet seal system to a combustion device was calculated to be $767 per ton and $27,705 per ton respectively for centrifugal compressors located at transmission facilities. Also under the single pollutant approach, the methane and VOC cost of control for routing emissions from a wet seal system to a combustion device was calculated to be $1,028 per ton and $37,105 per ton respectively for centrifugal compressors located at transmission facilities. However, facilities may already have a combustion device operating at the facility or would route the captured gas back to a useful process rather than flaring it. Those facilities would not incur the additional capital cost and operation and maintenance costs of the flare. Under the single pollutant approach for those facilities the methane and VOC cost of control were calculated to be $22 per ton and $804 per ton respectively for transmission facilities and $30 per ton and $1,076 per ton respectively for storage facilities. Based on these cost of control values, EPA is selecting Regulatory Option 3 for the transmission and storage segment.

[114] Negative cost is the result of operation and maintenance savings for dry seals.

NMED Exhibit 70

VOLUME 2: NATIONAL LEVEL IMPACTS

8.0 NATIONWIDE IMPACTS FOR HYDRAULICALLY FRACTURED OIL WELL COMPLETIONS AND RECOMPLETIONS

8.1 Nationwide Emissions

8.1.1 Determination of Number of Completions and Recompletions

The first step in this analysis is to estimate nationwide baseline emissions in 2012, the year selected as the baseline year. In order to develop the baseline emissions, the EPA estimate the average number of wells that would be affected using the number of completions and recompletions performed in a typical year derived from the DrillingInfo database extract as described above. This value was then multiplied by the potential uncontrolled emissions per well completion listed in Table 3-2.

The DrillingInfo database includes the most recent completion date for all reported wells in the US. Therefore, the methodology described above for calculating the number of hydraulically fractured oil well completions from the HPDI® database in 2012 identifies wells initially fractured in 2012 and wells that were refractured (recompletions) in 2012. Because these recompletions are included in the database and resulting extracted dataset, it is not necessary to calculate a refracture frequency.

To more accurately estimate baseline emissions for this analysis, and to ensure no emission reductions were calculated for sources already being controlled, it was necessary to evaluate the number of completions and recompletions already subject to regulation. The number of completions and recompletions already being controlled in the absence of federal regulation was estimated based on the existing state regulations that require control measures for completions and recompletions. Although there may be regulations issued by other local ordinances for cities and counties throughout the U.S., the number of wells impacted by local (as opposed to state level) regulations could not be determined because data for wells subject to county or local ordinance level regulations are not available. Therefore, the calculated percentage of wells subject to state regulation based on the identified state regulations should be considered a conservative estimate.

In order to determine the number of completions and recompletions that are already controlled under state regulations, the DrillingInfo database extract well count data (described

NMED Exhibit 70

above) was analyzed to determine the percentage of new wells currently undergoing completion and recompletion in the states identified as having existing controls. In our proposal, the EPA identified Colorado, and Wyoming as the only states requiring controls on completions comparable to the NSPS requirements prior to NSPS review. The State of Wyoming's Air Quality Division (WAQD) requires operators to complete wells without flaring or venting where the following criteria are met: (1) the flowback gas meets sales line specifications and (2) the pressure of the reservoir is high enough to enable REC. If the above criteria are not met, then the produced gas is to be flared.[115] The WAQD requires that, "emissions of VOC and HAP associated with the flaring and venting of hydrocarbon fluids (liquids and gas) associated with well completion and recompletion activities shall be eliminated to the extent practicable by routing the recovered liquids into storage tanks and routing the recovered gas into a gas sales line or collection system." Similar to Wyoming, the Colorado Oil and Gas Conservation Commission (COOGCC) requires a renewable energy certificate (REC) for both oil and natural gas wells.[116] It was assumed for proposal that the ratio of wells in Colorado and Wyoming to the total number of wells in the U.S. represents the percentage of controlled wells for well completions. The ratio of wells in Wyoming to the number of total nationwide wells was assumed to represent the percentage of controlled well recompletions as it was the only state identified as having regulations directly related to recompletions. The EPA used the referenced GOR of less than (<) 100,000 scf/bbl for oil wells to identify the oil wells located in Wyoming and Colorado. From this review it was estimated that 8.81 percent of oil well completions are controlled in absence of federal regulation.

The EPA received significant comment that the proposal did not consider the existing control requirements for a then-proposed, now-final requirements in North Dakota that requires flaring of all emissions during the flowback stage of completions. In particular, the North Dakota Air Pollution Control Rules require that all organic gases and vapors be burned by flares and the North Dakota Industrial Commission requires that all vented casinghead gas be burned, pending arrangements for disposition for some useful purpose.[117] Considering the comments, for the final

[115] Wyoming BACT permitting guidance. Available at http://deq.state.wy.us/aqd/Oil%20and%20Gas/September%202013%20FINAL_Oil%20and%20Gas%20Revision_UGRB.pdf.
[116] COGCC 805 Series Rules (805.b.(3)A). Available at http://cogcc.state.co.us/ and the Colorado Code of Regulations at: http://www.sos.state.co.us/CCR/Welcome.do.
[117] N.D. Admin. Code§ 33-15-07-02(1) and§ 43-02-03-45

NMED Exhibit 70

rule, the EPA determined that the percentage of completions and recompletions conducted in North Dakota for oil wells greater than or equal to 300 GOR was 9.4 percent.

Finally, the EPA determined the number of exploratory oil well completions based on the percentage breakdown between exploratory and development wells in the National Energy Modeling System (NEMS). NEMS is a model of the U.S. energy economy developed and maintained by the EIA. NEMS is used to produce the Annual Energy Outlook (AEO), a reference publication that provides detailed forecasts of the energy economy from the current year to 2040. The NEMS source code is publicly available and fully documented. The source code and accompanying documentation is released annually when a new AEO is produced. Because of the availability of NEMS, numerous agencies, national laboratories, research institutes, and academic and private-sector researchers have used NEMS to analyze a variety of issues. NEMS models the dynamics of energy markets and their interactions with the broader U.S. economy. Based on the NEMS AEO 2014 Reference Case, 3.8 percent of oil wells are exploratory and 96.2 percent are development wells.

In addition, as for the development of the 2012 NSPS for gas well completions, the EPA is aware that some oil well completions and workovers are controlled voluntarily using RECs or combustion devices. However, the EPA could not identify a national level data source on this practice from which the EPA could estimate the numbers of voluntarily controlled oil well completions. Therefore, due to lack of data and a reliable benchmark for estimating the number of voluntarily controlled completions, the EPA assumed zero for our analysis of baseline emissions.

In order to determine nationwide impacts of the number of new oil well completions and recompletions, the EPA used the base year of 2012 activity data (see the 2015 Proposal TSD for details on the 2012 base year projection) as described above and projected activity numbers for the years 2020 and 2025 based on predictions from the NEMS Oil and Gas Supply Model. The EPA calculated the compound annual growth rate (CAGR) between 2012 and 2015 for development and exploratory oil wells based on the AEO 2015 Reference Case. The CAGR for development wells was found to be -0.1 percent and the CAGR for exploratory wells was found to be 6.2 percent. These factors were used to calculate the number of exploratory and development oil well completion for the years 2020 and 2025.

Table 8-1 summarizes the estimated number of hydraulically fractured oil well completions derived from our analysis detailed above.

NMED Exhibit 70

Table 8-1. Estimated Number of Hydraulically Fractured Oil Well Completions and Recompletions - 2020 and 2025

Hydraulically Fractured Oil Well Completions	**2020**	**2025**
Total Oil Well Completions and Recompletions	19,703	20,988
Total with < 300 GOR		
Development	4,481	4,774
Exploratory/Delineation	177	188
Total with ≥ 300 GOR		
Development	13,862	14,730
Exploratory/Delineation	1,183	1,296
Total with ≥ 300 GOR and Regulated by States (CO and WY) (Comparable to NSPS)		
Development	1,100	1,168
Exploratory/Delineation	92	101
Total with ≥ 300 GOR and Regulated by States (ND) (Flaring only)		
Development	1,200	1,275
Exploratory/Delineation	103	112
Total with ≥ 300 GOR, Not Regulated by States (CO and WY)		
Development	12,762	13,562
Exploratory/Delineation	1,091	1,195

Because the proposed and final rule requirements affect oil well completions and recompletions differently, particularly where activities are currently controlled under a state regulation, the EPA estimated the number of projected well completions and recompletions which would be affected under different control scenarios under the NSPS. Specifically, the EPA calculated activity numbers for the following control scenarios:

- Development oil wells that are greater than or equal to 300 GOR which are currently venting and are capable of conducting a REC combined with combustion. This number is the number of new development oil well completions and recompletions that are not covered by a state regulation in CO or WY (i.e., 12,762 in 2020 and 13,562 in 2015) and not located in ND and that are capable of conducting a REC. The EPA estimate that 50 percent of these oil wells are capable of conducting a REC.
- Development oil wells that are greater than or equal to 300 GOR and are currently venting, however, it is technically infeasible for them to conduct a REC, therefore combust emissions. This number is the number of new development oil well completions and recompletions that are not covered by state regulation in CO or WY (i.e., 12,762 in 2020 and

NMED Exhibit 70

13,562 in 2025) and are not located in ND and that are not capable of conducting a REC due to technical infeasibility reasons (other than low pressure). See the discussion in 3.3.2.1 with respect to technical infeasibility as being reasons for not being required to conduct a REC. The EPA estimates that 10 percent of these oil wells are not capable of conducting a REC.

- Development oil wells that are greater than or equal to 300 GOR and are currently venting, however, due to low pressure cannot conduct a REC, and therefore combust emissions. This number is the number of new development oil well completions and recompletions that are not covered by state regulation in CO or WY (i.e., 12,762 in 2020 and 13,562 in 2025) and are not located in ND and that are not capable of conducting a REC due to low pressure. As discussed in section 8.2.1 below, the EPA estimate that 40 percent of these oil wells are not capable of conducting a REC.
- Development oil wells that are greater than or equal to 300 GOR and are currently flaring based on state requirements that are capable of conducting a REC combined with combustion. This number is the number of new development oil well completions and recompletions that are not covered by state regulation in CO or WY (i.e., 12,762 in 2020 and 13,562 in 2025) and are located in ND and that are capable of conducting a REC. As discussed in section 8.2.1 below the EPA estimate that 50 percent of these oil wells are capable of conducting a REC.
- All other development oil wells. This number is the development oil wells that are less than 300 GOR plus the greater than or equal to 300 GOR oil wells that are located in ND that are currently flaring and incapable of conducting a REC, plus the greater than or equal to 300 GOR oil wells that are controlled based on state regulation. This scenario results in no change in control status based on the NSPS.
- Exploratory and delineation oil wells that are greater than or equal to 300 GOR and are currently venting which would now be required to combust emissions. This is the number of exploratory and delineation oil wells that are not covered by state regulation in CO or WY and that are not located in ND. The EPA assumes that 100 percent of these wells are venting.
- All other exploratory and delineation oil wells. This number is the exploratory/delineation oil wells that are less than 300 GOR plus the greater than or equal to 300 GOR oil wells that are located in ND that are currently flaring and incapable of conducting a REC plus the

NMED Exhibit 70

greater than or equal to 300 GOR oil wells that are controlled based on state regulation. This scenario results in no change in control status based on the NSPS.

Table 8-2 summarizes the estimates of the numbers of oil well completions and recompletions based on these control scenarios above.

Table 8-2. Estimated Number of Total Oil Well Completions and Recompletions by Control Scenario under the NSPS for 2020 and 2025

Estimated Control Scenario Under NSPS	2020	2025
Development Oil Wells (Venting/REC with Combustion)	5,781	6,144
Development Oil Wells (Venting/TI for REC, Combustion)	1,156	1,229
Development Oil Wells (Venting, LP/Combustion)	4,625	4,915
Development Oil Wells (Flaring/REC)	600	637
Development Oil Wells (No change)	6,181	6,580
Exploratory/Delineation Oil Wells (Venting/Combustion)	988	1,083
Exploratory/Delineation Oil Wells (No change)	372	401

REC = Reduced Emissions Completion, TI for REC, Combustion = Technical infeasibility for a REC, combustion required, LP = Low pressure well

8.1.2 Nationwide Emission Estimates

Using the estimated emissions per source as shown in Table 3-2, number of uncontrolled and controlled wells at baseline, described above, nationwide emission estimates for oil well completions and recompletions in the base year 2012 and projected completions and recompletions for the projected years 2020 and 2025 were calculated and are summarized in Table 8-3. All values have been rounded to the nearest ton for estimation purposes.

NMED Exhibit 70

Table 8-3. Nationwide Baseline Emissions for 2020 and 2025 from Hydraulically Fractured Oil Well Completions and Recompletions

Well Source Subcategory	Emissions Per Event (tpy)		Number of Uncontrolled Wells[a]	Baseline Nationwide Emissions (tpy)	
	Methane	VOC		Methane[b]	VOC[b]
Projected Year 2020					
All Oil Wells	9.72	8.14	13,853	122,279	102,396
1. Developmental Oil Wells	9.72	8.14	12,162	112,672	94,351
2. Exploratory/Delineation Oil Wells	9.72	8.14	988	9,607	8,045
Projected Year 2025					
All Oil Wells	9.72	8.14	14,007	130,257	109,078
1. Developmental Oil Wells	9.72	8.14	12,925	119,734	100,266
2. Exploratory/Delineation Oil Wells	9.72	8.14	1,083	10,523	8,812

a. The number of controlled wells is equal to all wells less wells controlled based on state regulations in ND, CO and WY.
b. Based on the assumption that VOC content is 0.8374 lbs VOC per pound methane. This estimate accounts for 5 percent of emissions assumed as vented even when controlled. These values do not account for secondary emissions from portion of gas that is directed to a combustion device.

8.2 Nationwide Impacts of the Final Rule (for purposes of Regulatory Impact Analysis)

This section provides an analysis of the primary environmental impacts (i.e., emission reductions), cost impacts and secondary environmental impacts related to final standards for oil well completions and recompletions. See the rule package for details of the final standards.

8.2.1 Primary Environmental Impacts of Regulatory Options

The selected standards for oil well completions and recompletions are as follows:

- Subcategory 1 - Development (i.e., wells which do not meet the definition of exploratory or delineation wells) Oil Well Completions and Recompletions: Operational standard for completions and recompletions with hydraulic fracturing which requires a combination of REC with combustion, but allows for combustion alone or venting during specified situations.
- Subcategory 2 - Exploratory and Delineation Oil Well Completions and Recompletions: An operational standard for completions and recompletions with hydraulic fracturing which requires completion combustion devices with an allowance for venting during specified situations.

NMED Exhibit 70

As noted in section 3.3.1 above, there are several control scenarios under which an oil well might be affected under the NSPS. The number of completions and recompletions that would be subject to the various regulatory requirements under the NSPS is listed in Table 8-3.

Table 8-4 summarizes the nationwide emission reduction estimates for each of the estimated control scenarios for the projected years 2020 and 2025. It was estimated that RECs in combination with the combustion of gas unsuitable for entering the gathering line, can achieve an overall 95 percent VOC reduction over the duration of the completion or recompletion operation. The 95 percent recovery was estimated based on 90 percent of flowback being captured to the sales line and assuming an additional 5 percent of the remaining flowback would be sent to the combustion device. Additionally, were it is technically infeasible to conduct a REC, the EPA estimated a 95 percent emission reduction as the result of combustion where required. As discussed in section 3.3.2.1 above, there are several instances where conducting a REC is not feasible. The EPA estimate, for the purposes of estimating impacts that 50 percent of oil wells will be capable of conducting a REC and that 40 percent of the oil wells will not be able to conduct a REC due to low pressure in the well. Another 10 percent of the oil wells are estimated to not be able to conduct a REC due to other technical infeasibility such as access to gas lines, inert gas concentration, safety or other hazards where the separator cannot be operated. Nationwide emission reductions were estimated by applying this 95 percent reduction to the uncontrolled baseline emissions presented in Table 3-2.

8.2.2 Nationwide Cost Impacts

The operational standards for development wells that can conduct a REC include both REC and a completion combustion device, therefore the total incremental cost of the operational standard for developmental oil well completions and for recompletions is estimated at around $17,183, which includes the costs in Table 3-3 for the REC equipment and transportation in addition to the cost for the completion combustion device. The cost for a completion combustion device alone is estimated to be $3,723. The cost for addition of REC equipment to a site that is already combusting emissions is estimated to be $13,459.

For the projected year 2020, applying the cost for the combined REC with completion combustion device to the estimated 5,781 oil wells that are estimated to be capable of conducting a REC, the total nationwide cost was estimated to be approximately $78.5 million, which includes an estimated annual savings of approximately $20.8 million when natural gas savings are considered. Likewise, for projected year 2025, the cost for RECs with combustion device applied to 6,144

NMED Exhibit 70

development oil well completions and recompletions, the total nationwide cost was estimated to be approximately $83.5 million, including annual savings estimated at around $22.1 million when natural gas savings are considered.

For development oil wells not capable of conducting a REC due to technical infeasibility, the cost of a REC and combustion control device applied to the 1,156 completions in 2020 and the 1,229 completions in 2025, the nationwide cost was estimated to be approximately $19.9 million and $21 million respectively. These completions have no gas savings because the separator is estimated to not able to function and therefore no gas will be able to be recovered. Finally, for wells that are currently flaring emissions, the EPA estimate 600 wells in 2020 and 637 wells in 2025. The nationwide costs for addition of REC to these completions are approximately $5.9 million in 2020 and $6.3 million in 2025 which includes gas savings of approximately $2.2 million and $2.3 million, respectively.

For development oil wells that meet the definition of low pressure wells, the standard requires combustion of emissions and a separator is not required to be onsite.[118] Therefore, the EPA apply the cost of a combustion control device to the estimated 4,625 low pressure oils wells estimated for the year 2020 and the estimated 4,915 for the year 2025, the nationwide cost was estimated to be approximately $17.2 million and $18.3 million respectively. The total nationwide cost estimated for development oil well completions is approximately $121.7 million for the year 2020 (including $23 million in gas savings) and $129.2 million for the year 2025 (including $24.4 million in gas savings).

For exploratory and delineation oil well completions, the EPA apply the cost of a combustion control device to the 988 oil well completions estimated for the year 2020 and the 1,083 oil wells estimated for the year 2025, and the nationwide costs associated with exploratory and delineation oil well completions is approximately $3.7 million for 2020 and $4 million for 2025. Table 8-4 summarizes the estimated nationwide emission reductions and costs for each of these control scenarios.

[118] Note that for the final rule the low pressure well definition has been revised. See Appendix A for a full discussion of the revised low pressure well definition.

REC = Reduced Emissions Completion, TI for REC, Combustion = Technically infeasible to conduct REC, combustion required, LP = Low pressure wells

a. As presented in Table 4-43.

b. From Table 4-6.

c. Assumes no emission reductions for wells controlled by state regulation in CO, WY, and ND.

d. Assumes 0.90718474 metric tonnes per short ton and global warming potential of methane = 25.

e. Assumes savings only for scenarios where REC is performed.

NMED Exhibit 70

8.3 Nationwide Secondary Impacts

Regulatory Options 3 and 4 require some amount of combustion; therefore the estimated nationwide secondary impacts are a direct result of combusting all or partial flowback emissions. Although it is understood that the volume of gas captured, combusted and vented may vary significantly depending on well characteristics and flowback composition, for the purpose of estimating secondary impacts for Regulatory Options 3 and 4, it was assumed that 90 percent of flowback is captured and an additional 5 percent of the remaining gas is combusted. For Subcategory 1 oil well completions and recompletions with hydraulic fracturing, it is assumed around 50 Mcf (5 percent of 999 Mcf) of natural gas is combusted on a per well basis when a REC is performed. For Regulatory Option 3 for Subcategory 1 oil wells where combustion is used for control and for Regulatory Option 4 for Subcategory 2 oil well completions and recompletions with hydraulic fracturing, it is assumed that 949 Mcf (95 percent of 999 Mcf) of flowback emissions are combusted by the combustion device. The impacts of pollutant emissions per completion event was estimated assuming 1,089.3 Btu/scf saturated gross heating value of the "raw" natural gas and applying the AP-42 emissions factors listed in Table 3-5.

For the projected year 2020, for Subcategory 1 well completions and recompletions controlled by a REC combined with a combustion device, it is estimated 0.002 tons of NO_x are produced per event. This is based on assumptions that 5 percent of the flowback gas is combusted by the combustion device. For subcategory 1 and subcategory 2 well completions controlled with a combustion device alone, it is estimated 0.37 tons of NO_x are produced in secondary emissions per event. This is based on the assumption 95 percent of flowback gas is combusted by the combustion device. Based on the estimated number of completions and recompletions for projected year 2020, the proposed regulatory options are estimated to produce around 300 tons of NO_x in secondary emissions nationwide from controlling all or partial flowback by combustion. Table 8-5 summarizes the estimated secondary emissions of the selected regulatory options for projected year 2020 and Table 8-6 summarizes the estimated secondary emissions of the selected regulatory options for projected year 2025.

NMED Exhibit 70

Table 8-5. Nationwide Secondary Impacts of Selected Regulatory Options for Projected Year 2020[a]

Pollutant	Regulatory Option 3[b,c]				Regulatory Option 4[d]		Combined Options
	1. Developmental Oil Well - REC		1. Developmental Oil Well - Combustion		2. Exploratory/Delineation Oil Well		
	Emissions per Completion Event (tons)	Nationwide Secondary Emissions (tpy)	Emissions per Completion Event (tons)	Nationwide Secondary Emissions (tpy)	Emissions per Completion Event (tons)	Nationwide Secondary Emissions (tpy)	Nationwide Secondary Emissions (tpy)
THC	0.004	24	0.076	440	0.076	75	540
CO	0.008	54	0.169	975	0.169	167	1,196
NO_x	0.002	12	0.037	214	0.037	37	262
PM	0.000	0	0.001	7	0.001	1	9
CO_2	3.599	22,967	71.987	416,155	71.987	71,123	510,246

a. Nationwide impacts are based on AP-42 Emission Guidelines for Industrial Flares as outlined in Table 4-7. As such, these emissions should be considered the minimum level of secondary emissions expected.

b. The REC operational standard (Regulatory Option 3 – REC) combines REC and combustion is assumed to capture 90 percent of flowback gas. 5 percent of the flowback is assumed to be combusted by the combustion device. Therefore, it is estimated 50 Mcf is combusted per completion event. This analysis assumes there are 6,381 developmental oil well completions and recompletions using this control scenario.

c. The REC operational standard (Regulatory Option 3 – Combustion) Assumes 949 Mcf of natural gas is combusted per completion. This analysis assumes 5,781development oil well completions and recompletions exploratory wells fall into this category.

d. Assumes 949 Mcf of natural gas is combusted per completion. This analysis assumes 988 exploratory wells fall into this category.

NMED Exhibit 70

Table 8-6. Nationwide Secondary Impacts of Selected Regulatory Options for Projected Year 2025[a]

Pollutant	Regulatory Option 3[b,c]				Regulatory Option 4[d]		Combined Options
	1. Developmental Oil Well - REC		1. Developmental Oil Well - Combustion		2. Exploratory/Delineation Oil Well		
	Emissions per Completion Event (tons)	Nationwide Secondary Emissions (tpy)	Emissions per Completion Event (tons)	Nationwide Secondary Emissions (tpy)	Emissions per Completion Event (tons)	Nationwide Secondary Emissions (tpy)	Nationwide Secondary Emissions (tpy)
THC	0.004	26	0.076	468	0.076	83	576
CO	0.008	57	0.169	1,037	0.169	183	1,2763
NO_x	0.002	13	0.037	227	0.037	40	280
PM	0.000	0	0.001	8	0.001	1	9
CO_2	3.599	24,407	71.987	442,287	71.987	77,962	544,655

a. Nationwide impacts are based on AP-42 Emission Guidelines for Industrial Flares as outlined in Table 4-7. As such, these emissions should be considered the minimum level of secondary emissions expected.

b. The REC operational standard (Regulatory Options 3 REC) combines REC and combustion is assumed to capture 90 percent of flowback gas. 95 percent of the remaining flowback is assumed to be combusted by the combustion device. Therefore, it is estimated 50 Mcf is combusted per completion event. This analysis assumes there are 6,781 developmental oil well completions and recompletions using this control scenario.

c. Assumes 949 Mcf of natural gas is combusted per completion. This analysis assumes 6,144 development oil well completions and recompletions exploratory wells fall into this category.

d. Assumes 949 Mcf of natural gas is combusted per completion. This analysis assumes 1,083 exploratory wells fall into this category.

NMED Exhibit 70

9.0 NATIONWIDE IMPACTS FOR FUGITIVE EMISSIONS STANDARDS

9.1 Nationwide Emissions from New Sources

9.1.1 Overview of Approach

Similar to the approach used to calculate emissions from well site and compressor station model plants, nationwide emissions were calculated by using the model plant emissions that were calculated for the oil and natural well sites and compressor stations. These model plant emissions were used for estimating the baseline emissions and emission reductions for the new sources.

9.1.2 Activity Data

Data from oil and natural gas technical documents and inventories were used to estimate the number of new sources for each of the oil and natural gas segments. Information from the DrillingInfo HPDI® database and GHG Inventory were used to estimate the number of new well sites, gathering and boosting stations, and transmission and storage facilities in 2012. A summary of the steps used to estimate the new sources for each of the oil and gas segments is presented in the following sections.

9.1.2.1 Well Sites

The DrillingInfo database provided the information on the number of oil and natural gas wells completed or recompleted in the 2012 in the U.S. The total number of new natural gas well completions, both conventional and fractured was determined to be 8,456. From this number of wells, the EPA subtracted wells that were assumed to be covered by state leak regulations as of the effective date of the revised NSPS. Based on our research, four states have recently enacted leak regulations; Colorado, Ohio, Wyoming and Utah. Below is a brief discussion of these state regulations:

- Colorado: Effective on April 14, 2014, requires well production facilities and natural gas compression station owners/operators to inspect components for leaks using an approved instrument monitoring method (AIMM). This LDAR program began as early as January 1, 2015 with inspection frequency varying based on the amount of fugitive VOC emissions identified (i.e., 0-6 tpy - one-time, 6-12 tpy -annually, 12-50 tpy -quarterly, or >50 tpy -monthly). Monitoring inspections of well production facility and compressor station components must be conducted using Method 21, an infra-red camera, or other Division approved instrument based monitoring devices or methods. In addition, monthly audio, visual, and olfactory inspections must be

NMED Exhibit 70

conducted to identify leaks. When OGI is used for leak detection, a leak is defined as any detectable emissions that are not associated with normal equipment operation (e.g. pneumatic device actuation)[119]. For compressor station facilities constructed prior to May 1, 2014, a leak is defined as any concentration of hydrocarbon above 2,000 ppm when Method 21 is used to conduct monitoring inspections. For well sites and compressor stations that were constructed on or after May 1, 2014, a leaks is defined as any concentration of hydrocarbon above 500 ppm when Method 21 is used.

- Ohio: On May 19, 2014 Ohio EPA approved two types of oil and gas well-site production operations (small flares and large flares) and high volume horizontal hydraulic fracturing general permits for facilities that emit less than 1 ton per year of any toxic air contaminant (not including HAP emitting sources that are subject to MACT HH). Operators are required to develop and implement a site-specific LDAR program for ancillary equipment (e.g., vent, compressor, PRD, flange, etc.) that requires monitoring using a FLIR camera or Method 21. Quarterly monitoring is required for the first year and varies after that depending on performance.[120] Ohio has also proposed a package of general permits that have been designed around a natural gas compressor station that has the potential to leak greater than 10 tons per year of VOC. The general permit requirements include quarterly monitoring of ancillary equipment, including each pump, compressor, pressure relief device, connector, valve, flange, vent, cover, any bypass in the closed vent system, and each storage vessel using either an OGI or an analyzer meeting U.S. EPA Method 21 of 40 CFR Part 60, Appendix A.

- Utah: On June 5, 2014, Utah Department of Environmental Quality approved a "General Approval Order for a Crude Oil and Natural Gas Well Site and/or Tank Battery" on June 5, 2014. This GAO requires LDAR for equipment (e.g., valves, pumps, etc.) at least annually, and initial quarterly surveying of sources with projected annual throughput of crude oil and condensate combined that is greater than 25,000 barrels. The monitoring can be performed using Method 21 (leak definition of 500 ppm), a tunable diode laser absorption spectroscopy or an IR camera.[121]

NMED Exhibit 70

- Wyoming: On June 30, 2015, Wyoming Department of environmental Quality issued regulations for existing (as of January 1, 2014) PAD and single-well oil and gas production facilities that are located in the Upper Green River Basin. The rule regulates fugitive emissions from PAD and single-well facilities or sources, and compressor stations with fugitive emissions greater than or equal to 4 tons per year of VOC and requires owner/operators to develop and implement an LDAR protocol by January 1, 2017. Fugitive emissions monitoring can be conducted using a combination of Method 21, OGI, other instrument based technologies, or AVO inspections. However, an LDAR protocol consisting of only AVO inspections does not meet the requirements of the rule - at least one quarterly evaluation must be done using Method 21, OGI, or other instrument based technology. The rule requires quarterly monitoring of control equipment, systems, and devices (e.g. reboiler overhead condensers, storage tanks, vent lines, valves, connectors, etc.).[122]

9.1.3 Emission Estimates

The nationwide emissions were calculated using the model plant data and the estimated number of new and modified sources for each of the segments. The nationwide emission estimates for the total number of oil and natural gas production well sites, gathering and boosting stations, and transmission and storage facilities incrementally affected by the fugitive emission requirements in the NSPS for are summarized in Table 9-1. The summary includes baseline emissions for each of these segments for projected years 2020 and 2025.

Table 9-1. Nationwide Baseline Emissions for Sources Subject to NSPS Monitoring and Repair Plans in 2020 and 2025

Oil and Gas Segment	Number of Sources Subject to NSPS[a]	Methane Emissions (tpy)	VOC Emissions (tpy)
Projected Year 2020			
Natural Gas Well Sites	16,819	92,425	25,692
Oil Well Sites (GOR < 300)	32,392	39,989	10,726
Oil Well Sites (GOR > 300)	44,367	122,013	33,382
Gathering & Boosting Stations	480	16,868	4,689
Transmission Stations	20	808	22
Storage Stations	25	3,561	99

[122] Wyoming regulations are available at http://soswy.state.wy.us/Rules/RULES/9868.pdf.

NMED Exhibit 70

Oil and Gas Segment	Number of Sources Subject to NSPS[a]	Methane Emissions (tpy)	VOC Emissions (tpy)
Projected Year 2025			
Natural Gas Well Sites	34,487	189,515	52,680
Oil Well Sites (GOR < 300)	66,173	81,693	21,912
Oil Well Sites (GOR > 300)	90,636	249,256	68,196
Gathering & Boosting Stations	960	33,737	9,378
Transmission Stations	40	1,616	45
Storage Stations	50	7,122	197

a. Affected facilities in 2020 include new facilities in 2016 through 2020 which are assumed to still be operating in 2020. Affected facilities in 2025 includes new affected facilities in 2016 through 2025 which are assumed to still be operating in 2025.

According to our analysis, 20.87 percent of the total number of new natural gas well completions, both conventional and fractured, were covered by leak regulations in these four states. Therefore the number of new natural gas wells covered by federal regulations was estimated to be 6,691. Assuming an average of two natural gas wells per well site, the number of new well sites in 2012 was estimated to be 3,346. Projections from the NEMS data were used to estimate the total number of new natural gas completions, both conventional and hydraulically fractured in the years 2020 and 2025. The percentage of wells covered by state leak regulations, and the 2 natural gas wells per well site assumptions were applied to these totals to estimate the number of new natural gas production well sites. Our projected activity for year 2020 was developed to reflect the total number of affected facilities in 2020 which is the accumulation of newly affected facilities from 2016 through and including 2020. Likewise, our projected year 2025 reflects total accumulated newly affected facilities from 2016 through and including 2025. These activity estimates assume all newly affected facilities continue to be operating in the projected years. The number of natural gas well sites was estimated to be 16,819 well sites in 2020 and 34,487 in 2025. These estimated well site values were used to calculate the national fugitive emissions from natural gas well sites in 2012, 2020 and 2025. Low production wells were assumed to be 30 percent of the total natural gas well sites based on a sensitivity analysis of the well site data.

For oil wells, the same approach used for natural gas wells was used to estimate the number of new oil wells in the U.S. The number of new oil well completions in 2012, both conventional and hydraulically fractured, was determined to be 35,404. It was assumed that 8.81 percent of these oil wells are covered by state regulations in 2012 based on information in the HPDI database, which includes: Colorado, Ohio, Wyoming and Utah. Therefore 32,285 new oil wells were not covered by state leak regulations in 2012. Assuming an average of two oil production wells per well site, the number of new oil production well sites

NMED Exhibit 70

was determined to be 16,142 in 2012. Projections from the NEMS data were used to estimate the total number of new oil well completions in the years 2020 and 2025. The percentage of wells covered by State leak regulations, and the two oil wells per well site assumptions was applied to these totals to estimate the number of new oil well production sites. Because the requirements have impacts annually, our projected activity for years 2020 and 2025 were developed to reflect the facilities newly affected by the rule from 2016 through 2020 and 2016 through 2025, respectively, and assumed to still be in operation in the analysis years. The number of oil well sites were estimated to be 76,759 well sites in 2020 and 156,809 in 2025. These estimated well site values were used to calculate the national fugitive emissions from natural gas well sites in 2012, 2020 and 2025. Low production wells were assumed to be 43 percent of the total oil well sites based on a sensitivity analysis of the well site data. Oil well sites with a gas-to-oil ratio of greater than 300 were assumed to account for 57.8 percent of the total oil well sites based on data from the HPDI database as summarized in Table 9-1.

9.1.3.1 Gathering and Boosting Stations

The number of new gathering and boosting stations was estimated using the current number of gathering compressors estimated in the GHG Inventory. The total number of small and large gathering compressors was listed as 36,066 in the inventory. The EPA/GRI document does not include a separate list of individual compressors for gathering and boosting stations, but it does list the average number of compressors in the gas production section. It was assumed that this average of 4.5 compressors for gas production facilities is applicable to gathering and boosting stations. Therefore, using the total number of compressors in the GHG Inventory, the number of gathering and boosting stations was estimated to be 8,015. To estimate the number of new gathering and boosting stations, the EPA used an annual growth rate of 1.2 percent, which is based on the gas well CAGR for new gas wells divided by the average wells per well site. This provided an estimate of 96 new gathering and boosting stations each year that would be affected sources under the proposed NSPS in each of the years 2012 through 2025. Because the requirements have impacts annually, our projected activity for year 2025 was developed to reflect the impacts of the rule from 2020 through 2025 as summarized in Table 9-1. This approach was used to support the regulatory impacts assessment process to reflect rule impacts from the effective date through 2025.

9.1.3.2 Transmission and Storage Facilities

The number of new transmission and storage facilities was estimated by reviewing the annual number of facilities from the year 1990 to 2013 estimated in the GHG Inventory published in 2015 and determining

NMED Exhibit 70

the rate of change in the number of these facilities over this period. The average change for the last 10 years was reviewed and the annual number of new transmission stations was determined to be 4 and the annual number of storage facilities was determined to be 5. The values were used to estimate the number of affected sources under the NSPS in each of the years 2012 through 2025. Because the requirements have impacts annually, our projected activity for year 2025 was developed to reflect the impacts of the rule from 2020 through 2025 as summarized in Table 9-1. This approach was used to support the regulatory impacts assessment process to reflect rule impacts from the effective date through 2025.

9.1.4 Nationwide Impacts of Regulatory Options

This section provides an analysis of the primary environmental impacts (i.e., emission reductions), cost impacts and secondary environmental impacts related to the regulatory options which were selected as a viable options for reducing fugitive emissions from fugitive emissions components located at production well sites and compressor stations.

9.1.4.1 Primary Environmental Impacts of Regulatory Options

Based on the discussion above, the EPA reconsidered Regulatory Options 1 and 2 for well sites and Regulatory Options 1, 2 and 3 for compressor stations. A summary of the options are provided below;

- Regulatory Option 1. Require the implementation of a fugitive emissions monitoring and repair program which includes annual monitoring of fugitive emissions components using OGI.
- Regulatory Option 2. Require the implementation of a fugitive emissions monitoring and repair program which includes semiannual monitoring of fugitive emissions and components using OGI.
- Regulatory Option 3. Require the implementation of a fugitive emissions monitoring and repair program which includes quarterly monitoring of fugitive emissions components using OGI.

The number of oil and natural gas well sites, gathering and boosting stations, transmission stations, and storage facilities that would be subject to the regulatory options listed above were estimated using data from the HPDI database. In 2020, which include all new and modified sources since 2016, it was estimated that there would be 76,759 oil well sites, 16,819 gas well sites, 480 gathering and boosting stations, 20 transmission stations, and 25 storage facilities subject to these options. In 2025, which include all new and modified sources since 2016, it was estimated that there would be 156,809 oil well sites, 34,487 gas well sites, 960 gathering and boosting stations, 40 transmission stations, and 50 storage facilities subject to these options.

NMED Exhibit 70

It was estimated that OGI monitoring and repair can achieve an overall 40 percent VOC and methane reduction for annual monitoring, 60 percent VOC and methane reduction for semiannual monitoring, and 80 percent VOC and methane reduction for quarterly monitoring over the life span of the facility. These percent reduction values were estimated based on information from the EPA white paper and an analysis by the Colorado Air Quality Control Commission as described previously. Nationwide emission reductions were estimated by applying this 40, 60 and 80 percent VOC and methane reduction to the uncontrolled baseline emissions for well sites and compressor stations. In considering the three frequency options, the EPA considered the implementation issues with respect to the monitoring and repair plan and the EPA determined that, based on input from industry and regulatory agencies, that the program frequency should be consistent across the segments in the oil and natural gas source category. Therefore, nationwide impacts were estimated for these options as presented in Tables 9-2, 9-3 and 9-4.

9.1.4.2 Cost Impacts

OGI Monitoring and Repair Plans (Options 1, 2 and 3)

Regulatory Option 1 include annual monitoring of fugitive emissions components using OGI and repair of fugitive emissions components that are found to be leaking during the survey. The annual costs for these surveys (as summarized in Table 9-2) include the costs for having a contractor perform the annual OGI survey, activities planning, repair costs, resurvey of repaired components using a Method 21 device, preparation and submittal of an annual report and the amortization of the capital costs over 8 years at 7 percent interest. The potential natural gas saved from the implementation of an annual OGI monitoring and repair program at well sites was calculated to be 127 thousand standard cubic feet per year (Mscf/yr) for a natural gas production well site, 64 Mscf/yr for an oil well site with a GOR > 300, and 29 Mscf/yr for an oil production well site with a GOR < 300. For the compressor stations, the potential natural gas saved was calculated to be 815 Mscf/yr for gathering and boosting stations, 836 Mscf/yr for transmission stations, and 2,950 Mscf/yr for storage facilities.[123]
