STATE OF NEW MEXICO
ENVIRONMENTAL IMPROVEMENT BOARD

IN THE MATTER OF PROPOSED NEW REGULATION,
20.2.50 NMAC – *Oil and Gas Sector – Ozone Precursor Pollutants* **No. EIB 21-27 (R)**

DIRECT TESTIMONY OF MICHAEL BACA

My name is Michael Baca, and I am the Control Strategies Manager for the Air Quality Bureau ("Bureau") of the New Mexico Environment Department ("NMED" or "Department"). I am presenting this written testimony on behalf of the Department in this proceeding on proposed new air quality regulations at 20.2.50 NMAC ("Part 50"). My testimony will address the following topics: the federal and state statutory authorities and regulatory frameworks for ozone, NMED's Ozone Attainment Initiative, and the EPA Ozone Advance program.

I. QUALIFICATIONS

I have been an employee of the Department for 16 years, 13 of which have been with the Bureau. In my current position as the staff manager for the Bureau's Control Strategies Unit, I oversee a staff of six that are responsible for the development of air quality plans and regulations, including the State Implementation Plan ("SIP") for New Mexico. I hold a B.A. degree in Chemistry from Carleton College.

My full background and qualifications are set forth in my resume, which is marked as NMED Exhibit 2.

II. THE CLEAN AIR ACT REGULATORY FRAMEWORK FOR OZONE

The federal Clean Air Act ("CAA") requires the U.S. Environmental Protection Agency ("EPA") to set National Ambient Air Quality Standards ("NAAQS") for pollutants that EPA determines are harmful to public health and the environment. *See* 42 U.S.C. § 7408. These standards are in the form of maximum allowable concentrations in the ambient air during a

specified time period and are designed to protect the most sensitive individuals from harm from airborne pollutants. The CAA identifies two sets of NAAQS to accomplish this: Primary standards provide public health protection, including protecting the health of vulnerable populations such as asthmatics, children, and the elderly; Secondary standards provide public welfare protection, including protection against decreased visibility and damage to animals, crops, vegetation, and buildings. *Id* at § 7408(b).

The EPA has set NAAQS for six principal pollutants, known as "criteria" air pollutants: ozone, nitrogen dioxide, sulfur dioxide, carbon monoxide, particulate matter 10 microns or less, particulate matter 2.5 microns or less, and lead. *See* 40 C.F.R. Part 50. The CAA requires EPA to review the standards on a periodic basis, which may result in the standards being revised based on health and environmental criteria that apply to the concentration of a pollutant in outdoor air to limit harmful exposures and detrimental effects. 42 U.S.C. § 7409(d). The primary ozone NAAQS are set to protect people most at risk from breathing ozone in the ambient air, including asthmatics, children, older adults and people who are active outdoors, such as workers. Children are at greatest risk from ozone exposure because their lungs are still developing and they are more likely to be active outdoors when ozone levels are high, which increases their exposure. Some of the health problems caused by ozone include coughing, sore throat, difficulty breathing, inflammation and damage to airways, increased frequency of asthma attacks, and aggravation of lung diseases such as asthma, emphysema and chronic bronchitis. *See* NMED Exhibit 3 – EPA Integrated Science Assessment ("ISA") for Ozone and Related Photochemical Oxidants, Executive Summary (April 2020);[1] *see also* 85 Fed. Reg. 87256, 87268-87275.

[1] Full ISA available at https://cfpub.epa.gov/ncea/isa/recordisplay.cfm?deid=348522

Air quality management agencies use data from monitors to calculate a "design value" to determine an area's compliance status with the NAAQS. The design value represents the metric used to compare monitoring data to the level specified by the standard. Ozone monitoring and the federal requirements for monitoring equipment are addressed in the testimony of NMED witness Brent Ellington. Calculation of design values, quality assurance of data, and submission of data to EPA are addressed in the testimony of NMED witness Andrew Ahr.

Following promulgation of a new or revised NAAQS, EPA undertakes a process of designating all areas within each state as in attainment, nonattainment, or unclassifiable for the standard. *See* 42 U.S.C. § 7407(d). This process entails collaborating with states and tribes and considering their recommendations, including proposed nonattainment boundaries based on data and information from air quality monitors or modeling. If the concentrations of a criteria pollutant in a geographic area meets or fall below the NAAQS, the area is designated as in "attainment" of the standard. Areas that exceed the NAAQS are designated as "nonattainment" areas. Areas that do not have monitoring data available are designated as "attainment/unclassifiable" or "unclassifiable". EPA is required to designate areas of the States within two years of promulgating a new or revised NAAQS. *Id.*

In October 2015, following a periodic review, EPA revised the ozone NAAQS downward from 0.075 parts per million (ppm) to 0.070 ppm. *See* 80 Fed. Reg. 65291. For the 2015 ozone NAAQS, all states were required to submit their designation recommendations to EPA by October 1, 2016. Ozone data collected by NMED from 2014 through 2016 showed that a monitor located in the Sunland Park area in southern New Mexico was violating the revised ozone standard. NMED submitted a nonattainment area recommendation for the Sunland Park area and recommended attainment or attainment/unclassifiable designations for the remainder of

New Mexico. EPA concurred with the recommendations and finalized the area designations for New Mexico on August 3, 2018. *See* 83 Fed. Reg. 25776.

On December 23, 2020, EPA retained the existing 2015 ozone NAAQS. *See* 85 Fed. Reg. 87256. The CAA does not require EPA to promulgate area designations when an existing NAAQS is retained following the periodic review process. In line with this and historical practice, EPA did not designate new nonattainment areas following this periodic NAAQS review. However, the current EPA administration has indicated that it intends to revisit the review process, including the available scientific evidence and exposure/risk information, to assess the adequacy of public health and welfare protection provided under the current NAAQS.

Ozone monitoring data for 2018-2020 indicate that other areas of the state are approaching or violating the 2015 ozone NAAQS. In particular, Eddy County and sites in southern Doña Ana County are monitoring ozone levels in violation of the NAAQS, while San Juan, Lea, Santa Fe, Sandoval and Valencia Counties are within 95% of the standard. Additionally, oil and gas sources located in Rio Arriba and Chaves Counties contribute to elevated ozone concentrations in the San Juan and Permian Basins, respectively.

The New Mexico Air Quality Control Act ("AQCA"), NMSA 1978, Sections 74-2-1 to -17, requires the State to plan for ozone mitigation in areas where sources cause or contribute to ozone levels greater than or equal to 95% of the ozone standard. NMED is addressing these areas through the Ozone Attainment Initiative and EPA's Ozone Advance program, as discussed below.

III. OZONE REGULATION UNDER THE NEW MEXICO AIR QUALITY CONTROL ACT AND REGULATIONS

The Environmental Improvement Board ("Board") is authorized to adopt Part 50 pursuant to the AQCA. Section 74-2-5(A) of the AQCA provides that the Board "shall prevent or

abate air pollution." Section 74-2-5(B)(1) states that the Board shall "adopt, promulgate, publish, amend, and repeal rules and standards consistent with the Air Quality Control Act to attain and maintain national ambient air quality standards and prevent or abate air pollution . . ." The AQCA defines "air pollution" as

> the emission, except emission that occurs in nature, into the outdoor atmosphere of one or more air contaminants in quantities and of a duration that may with reasonable probability injure human health or animal or plant life or as may unreasonably interfere with the public welfare, visibility or the reasonable use of property.

NMSA 1978, § 74-2-2(B). "Air contaminant" is defined as "a substance, including any particulate matter, fly ash, dust, fumes, gas, mist, smoke, vapor, micro-organisms, radioactive material, any combination thereof or any decay or reaction product thereof." NMSA 1978, § 74-2-2(A).

The AQCA also contains provisions that specifically authorize the Board to adopt regulations to ensure attainment and maintenance of the ozone NAAQS. Section 74-2-5(C) of the AQCA mandates that the Board take action to control VOC and NOx emissions when the Board determines that emissions from sources within its jurisdiction cause or contribute to ozone concentrations in excess of ninety-five percent of the ozone NAAQS. Under this statutory provision, the Board is required to "adopt a plan, including rules, to control emissions of oxides of nitrogen, or NO_X, and volatile organic compounds, or VOCs, to provide for the attainment and maintenance of the standard."

IV. THE DEPARTMENT'S OZONE ATTAINMENT INITIATIVE

Currently, nine counties under the Board's jurisdiction are registering or contributing to ozone design values exceeding 95% of the NAAQS: San Juan, Rio Arriba, Santa Fe, Sandoval, Valencia, Eddy, Lea, Chaves and Doña Ana.

To address the statutory requirement in Section 74-2-5(C) of the AQCA, the Bureau has embarked upon the Ozone Attainment Initiative ("OAI") to develop a plan that consists of a series of mandatory rules and voluntary measures to mitigate emissions of NO_X and VOCs in the aforementioned counties. This rulemaking is the first of the mandatory rules being brought before the Board under the OAI. The Department intends to propose addition rules targeting other sectors. For instance, Section 177 of the Clean Air Act allows other states to adopt California's motor vehicle emission standards, and the Department intends to bring before the Board regulations setting standards for low emission vehicles ("LEV"), and zero emission vehicles ("ZEV") for adoption in 2022 that will provide further mitigation of ozone precursors.

The Department has also submitted a letter of participation to EPA for the Ozone Advance Program. The Advance Program is a means to promote local actions in areas designated as in attainment to reduce ozone levels for the continued maintenance of the NAAQS. The Bureau will coordinate efforts with local governments, industry, academia, and the public to take proactive steps towards the protection of air quality. In addition to positioning areas to avoid a nonattainment designation, the Advance Program can allow communities to choose control measures that are cost effective and that make the most sense for their area, potentially resulting in multi-pollutant benefits.

The Department has developed a path forward for Ozone Advance that outlines all the activities, programs, and control measures to be included as part of our program. A copy of the "Ozone Advance Path Forward for New Mexico" is included as NMED Exhibit 4. The Department requests that the Board adopt this document as the "Plan" required by Section 74-5-3(C) of the AQCA.

Because the ozone design value in Bernalillo County also exceeds 95% of the ozone NAAQS, the Bureau is coordinating its efforts for ozone mitigation with the City of Albuquerque's Environmental Health Department, which has jurisdiction over air quality in Bernalillo County. In addition to the OAI, Ozone Advance and vehicle emissions standards, the Department is also working with the City of Albuquerque on preparing revised Regional Haze SIPs for submittal to EPA in July of 2021. The goal of the Regional Haze provisions of the CAA is to improve visibility in protected national parks and wilderness areas (referred to as "Class I" areas), and states are required to make reasonable progress over time towards the long-term goal of attaining natural visibility conditions by 2064. The Regional Haze program requires states to submit Regional Haze SIPs approximately once every ten years. Based on data collected at monitors operated by federal land managers, visibility impairment at the Class I areas in New Mexico is driven by sulfates and nitrates, so the Department is evaluating potential additional controls for sulfur dioxide (SO_2) and NO_X emissions from twenty-three major sources within our jurisdiction. Three of these sources are electric generating units, and the remainder are in the oil and gas sector, specifically, natural gas compressor stations and processing plants. Any additional NO_X controls for these sources adopted as part of this Regional Haze SIP revision will also serve to reduce the formation of ozone.

MICHAEL G. BACA

EDUCATION

September 1999-June 2004 Carleton College Northfield, MN
Bachelors Degree in Chemistry

PROFESSIONAL EXPERIENCE

January 2019-Present
New Mexico Environment Department, Air Quality Bureau
Staff Manager

- Manage the Control Strategies Section to insure proper implementation of the federal Clean Air Act in New Mexico through the development and revision of the State Implementation Plan and other air quality management plans and rules for the state.
- Oversee, lead and assist with rulemaking and section projects including the preparation of testimony and exhibits to present before the Environmental Improvement Board for adoption of rules and management plans.
- Manage air quality programs and research projects to ensure proper procurement procedures, awarding of contracts and grants, timely submission of deliverables and appropriate financial expenditures to meet contractual obligations and compliance with state rules.
- Ensure that the Bureau's Performance Measures are achieved through high technical and professional standards while maintaining the section as a desirable place to work.
- Assign, prioritize and oversee completion of tasks and projects by reviewing work products and providing timely, substantive feedback including guidance to staff on programs, policies, rules, regulations, and resources.
- Conduct meaningful and constructive employee evaluations by providing appropriate recognition of strengths, weaknesses and recommendations for improvement.
- Fill vacancies by completing efficient and effective personnel hiring actions.

July 2008-December 2018
New Mexico Environment Department, Air Quality Bureau
Environmental Analyst-Advanced

- Represent the State of New Mexico as the air quality liaison with border air quality agencies and stakeholders, participating in the Joint Advisory Committee and the USEPA Border 2020 Program.
- Develop and prepare technical testimony and exhibits for public hearings in front of the Environmental Improvement Board to present and defend air quality plans and rules for adoption in New Mexico, including state implementation plans required by the USEPA.
- Analyze ambient air quality monitoring data and prepare technical support documents for submission to the USEPA for high wind blowing dust events that cause air pollution episodes.

- Conduct public education and outreach meetings and develop educational material regarding air quality, rule requirements, and rule development.
- Review and comment on Title V and PSD permits, Environmental Impact Statements and Environmental Assessments in the border region for compliance with federal and state rules and standards.
- Manage air quality research projects and contracts in the border area to ensure timely submission of deliverables and appropriate financial expenditures.

February 2005 -July 2008
New Mexico Environment Department, Field Operations
Environmental Scientist and Specialist-Advanced

- Review engineering plans and approve permits for construction of swimming pool and bath facilities.
- Oversee district operations to ensure adequate permitting and inspection of public swimming pool facilities.
- Conduct training for swimming pool department staff and operators.
- Permit and inspect restaurants and food processors, swimming pool facilities, and liquid waste disposal system installations for compliance with applicable regulations.
- Conduct public education and outreach to help the regulated and general public comply with administrative requirements and state regulations.

Integrated Science Assessment for Ozone and Related Photochemical Oxidants

April 2020

Center for Public Health and Environmental Assessment
Office of Research and Development
U.S. Environmental Protection Agency
Research Triangle Park, NC

NMED Exhibit 3 - 0001

EXECUTIVE SUMMARY

ES.1 Purpose and Scope of the Integrated Science Assessment

This Integrated Science Assessment (ISA)[1] is a comprehensive evaluation and synthesis of the policy-relevant science aimed at characterizing the health and welfare[2] effects caused by ozone. It communicates critical science judgments of the health-based and welfare-based criteria for ozone and related photochemical oxidants in ambient air. In 2015, the U.S. EPA lowered the health- and welfare-based National Ambient Air Quality Standards (NAAQS) for ozone to 0.070 ppm (annual fourth-highest daily max 8-hour concentration averaged over 3 years[3]). The health-based ozone NAAQS is meant to protect public health, including at-risk populations such as children and people with asthma, with an adequate margin of safety. The welfare-based ozone standard is intended to protect the public welfare from known or anticipated adverse effects associated with the presence of ozone in ambient air.

The ISA identifies and critically evaluates the most policy-relevant scientific literature across scientific disciplines, including epidemiology, controlled human exposure studies, animal toxicology, atmospheric science, exposure science, vegetation studies, agricultural science, ecology, and climate-related science. Key scientific conclusions (e.g., causality determinations; Section ES.4) are presented and explained. These conclusions provide the scientific basis for developing risk and exposure analyses, policy evaluations, and policy decisions for the review. This ISA draws conclusions about the causal nature of the relationships between ozone exposure and health and welfare effects by integrating recent evidence across scientific disciplines with the evidence base evaluated in previous reviews. U.S. EPA engages the Clean Air Scientific Advisory Committee (CASAC) as an independent federal advisory committee to conduct peer reviews of draft ISA and other materials. Peer review comments provided by the CASAC and public comments about the external review draft were considered in the development of this ISA (Section 10.4). The ISA thus provides the policy-relevant scientific information necessary to conduct a review of the NAAQS.

This Executive Summary provides an overview of the important conclusions drawn in the ISA across scientific disciplines, beginning with information on sources, concentrations, estimated background concentrations of ozone and ozone exposure, followed by health and welfare effects. A more detailed summary of the evidence is presented in the Integrated Synthesis, and individual Appendices for

[1] The general process for developing an ISA, including the framework for evaluating weight of evidence and drawing scientific conclusions and causality determinations, is described in a companion document, Preamble to the Integrated Science Assessments (U.S. EPA, 2015), www.epa.gov/isa.

[2] Under Clean Air Act section 302(h), effects on welfare include, but are not limited to, "effects on soils, water, crops, vegetation, manmade materials, animals, wildlife, weather, visibility, and climate, damage to and deterioration of property, and hazards to transportation, as well as effects on economic values and on personal comfort and well-being."

[3] Final rule signed October 1, 2015, and effective December 28, 2015 (80 FR 65291).

NMED Exhibit 3 - 0002

each topic area include study-level information and an in-depth characterization of the weight-of-evidence conclusions.

ES.2 Ozone in Ambient Air

The general photochemistry of tropospheric ozone is well-established. Ozone is produced in urban areas and downwind of sources mainly by the reaction of volatile organic compounds (VOCs) with oxides of nitrogen (NO_X) in the presence of sunlight, and outside of polluted areas mainly by reactions of carbon monoxide (CO) and methane (CH_4) with NO_X (Section 1.4). Recent developments in understanding ozone chemistry include observations of higher ozone concentrations during the winter in some western U.S. mountain basins (Section 1.4.1) and new research on the role of marine halogen chemistry in suppressing coastal ozone concentrations (Section 1.4.2). Air monitoring data for the period 2015−2017 show that U.S. daily max 8-hour avg concentrations of ozone (MDA8) are higher in spring and summer (median = 46 ppb) than in autumn (median = 38 ppb) and winter (median = 34 ppb). Figure ES-1 shows the highest values of the 3-year avg of annual fourth-highest MDA8 ozone concentrations (design values above 70 ppb) occur in central and southern California, Arizona, Colorado, Utah, Texas, along the shore of Lake Michigan, and in the Northeast Corridor, typically during the ozone season between May and September (Section 1.2.1.1).

NMED Exhibit 3 - 0003

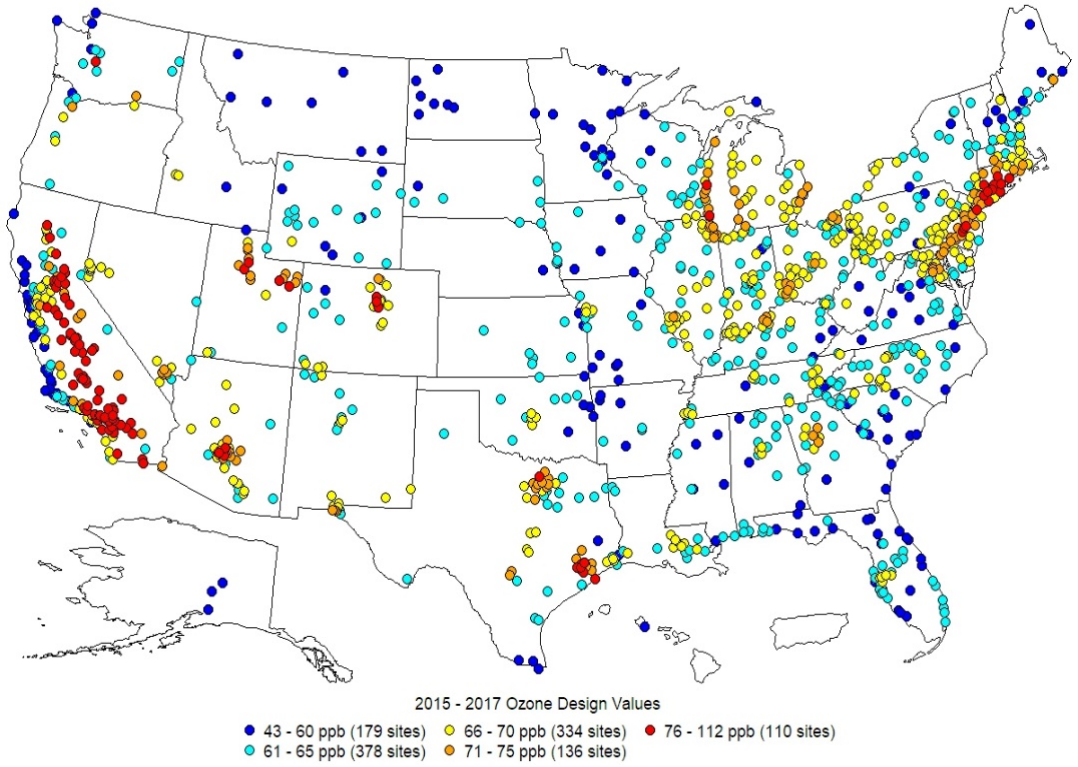

Figure ES-1 Individual monitor ozone concentrations in terms of design values (i.e., 3-year avg of annual fourth-highest max daily 8-hour avg ozone concentration) for 2015−2017.

A better understanding of the origins of ground-level U.S. background (USB) ozone and its concentration trends has emerged since the 2013 Ozone ISA. USB ozone concentration is defined as the ozone concentration that would occur if all U.S. anthropogenic ozone precursor emissions were removed (Section IS.2.2). Major contributors to USB ozone concentrations are stratospheric exchange, international transport, wildfires, lightning, global methane emissions, and natural biogenic and geogenic precursor emissions. Ozone monitors cannot discern the portion of ambient ozone concentrations that come from USB. Instead, USB concentrations are estimated using photochemistry and transport models. The estimates of USB ozone concentrations include uncertainties of about 10 ppb for seasonal average concentrations, with higher uncertainty for MDA8 concentrations. Models consistently estimate higher USB ozone concentrations at higher elevations of the western U.S. than in the eastern U.S. or along the Pacific coast. The estimated seasonal pattern in USB ozone concentrations tends to indicate lower USB in the summer than during the rest of the year. Several modeling studies using different approaches indicate that for MDA8 concentrations above 50−60 ppb, USB concentration estimates generally do not increase with increasing total ozone concentration (i.e., USB ozone concentrations are no higher on high ozone days than on low or moderate ozone days). The temporal trend in estimated USB ozone concentrations indicates increasing concentrations at high elevation western U.S. sites through approximately 2010.

NMED Exhibit 3 - 0004

Recently, however, this trend has shown signs of slowing or even reversing, possibly due to decreasing East Asian precursor emissions.

ES.3 Exposure to Ozone

Ambient air ozone concentrations, either measured at fixed-site monitors or estimated by models, are often used as surrogates for personal exposure in epidemiologic studies. Exposure measurement error can lead to reduced precision and an underestimation of the association between short-term ambient ozone exposure and a health effect (Section 2.6.1). For studies of long-term exposure, the true effect of exposure to ambient ozone may be underestimated or overestimated when the exposure model respectively overestimates or underestimates ozone exposure. It is much more common for the effect to be underestimated, and bias in the effect estimate is typically small in magnitude (Section 2.6.2). The availability and sophistication of models to predict ambient ozone concentrations to estimate exposure have increased substantially in recent years (Section 2.3.2). For effects elicited by ozone, the use of exposure estimates that do not account for population behavior and mobility (e.g., via use of time-activity data) may result in underestimation of the true effect and reduced precision (Section 2.4.1).

Tropospheric ozone can cause plant damage, which can then have negative impacts on terrestrial ecosystems as shown in observational and controlled exposure studies and in models using experimental data to extrapolate to effects at the community and ecosystem scale. Robust exposure indices that quantify exposure as it relates to measured plant response (e.g., growth) have been in use for decades and are derived from hourly ozone concentrations. Exposure duration influences the degree of plant response, and ozone effects on plants are cumulative. Cumulative indices summarize ozone concentrations over time and provide a consistent metric for reviewing and comparing exposure-response effects obtained from various studies. Cumulative indices of exposure that differentially weight hourly concentrations have been found to be best suited to characterize vegetation exposure to ozone with regard to reductions in vegetation growth and yield (Section 8.1.2.1).

ES.4 Health and Welfare Effects of Ozone Exposure

Broad health and welfare effect categories are evaluated independently in the Appendices of this ISA. Determinations are made about causation by evaluating evidence across scientific disciplines and are based on judgments of consistency, coherence, and biological plausibility of observed effects, as well as related uncertainties. The ISA uses a formal causality framework to classify the weight of evidence using a five-level hierarchy described in Table II of the Preamble (U.S. EPA, 2015). The subsequent sections characterize the evidence that forms the basis of causality determinations for health and welfare effect categories of a "causal relationship" or a "likely to be causal relationship," or describe instances where a causality determination has changed (i.e., "likely to be causal" changed to "suggestive of, but not sufficient to infer, a causal relationship"). Other relationships between ozone and health effects are *"suggestive of, but not sufficient to infer*" and "*inadequate to infer*" a causal relationship. These causality

NMED Exhibit 3 - 0005

determinations appear in Table ES-1, and are more fully discussed in the respective health effects Appendices.

ES.4.1 Health Effects of Ozone Exposure

Ozone-induced effects can occur through a variety of complex pathways within the body. After inhalation, ozone reacts with lipids, proteins, and antioxidants in the epithelial lining fluid of the respiratory tract, creating secondary oxidation products (Section 5.2.3). Initial ozone exposure leads to physiological reactions that may induce a host of autonomic, endocrine, immune, and inflammatory responses throughout the body at the cellular, tissue, and organ level. Recent evidence continues to support ozone-induced effects on the respiratory system. In addition, recent evidence indicates that short-term exposure to ozone is likely to induce metabolic effects, as shown in Figure ES-2. There is also some evidence that ozone exposure can affect the cardiovascular and nervous systems, reproduction and development, and mortality, although there are more uncertainties associated with interpretation of the evidence for these effects.

NMED Exhibit 3 - 0006

Table ES-1 Summary of causality determinations by exposure duration and health outcome.

Health Outcome[a]	Conclusions from 2013 Ozone ISA	Conclusions in the 2020 ISA
Short-term exposure to ozone		
Respiratory effects	Causal relationship	Causal relationship
Cardiovascular effects	Likely to be causal relationship	Suggestive of, but not sufficient to infer, a causal relationship[c]
Metabolic effects	No determination made	Likely to be causal relationship[b]
Total mortality	Likely to be causal relationship	Suggestive of, but not sufficient to infer, a causal relationship[c]
Central nervous system effects	Suggestive of a causal relationship[d]	Suggestive of, but not sufficient to infer, a causal relationship
Long-term exposure to ozone		
Respiratory effects	Likely to be causal relationship	Likely to be causal relationship
Cardiovascular effects	Suggestive of a causal relationship[d]	Suggestive of, but not sufficient to infer, a causal relationship
Metabolic effects	No determination made	Suggestive of, but not sufficient to infer, a causal relationship[b]
Total mortality	Suggestive of a causal relationship[d]	Suggestive of, but not sufficient to infer, a causal relationship
Reproductive effects	Suggestive of a causal relationship[d]	Effects on fertility and reproduction: suggestive of, but not sufficient to infer, a causal relationship[b]
		Effects on pregnancy and birth outcomes: suggestive of, but not sufficient to infer, a causal relationship[b]
Central nervous system effects	Suggestive of a causal relationship[d]	Suggestive of, but not sufficient to infer, a causal relationship
Cancer	Inadequate to infer a causal relationship	Inadequate to infer the presence or absence of a causal relationship[e]

[a]Health effects (e.g., respiratory effects, cardiovascular effects) include the spectrum of outcomes, from measurable subclinical effects (e.g., decrements in lung function, blood pressure) to observable effects (e.g., medication use, hospital admissions) and cause-specific mortality. Total mortality includes all-cause (nonaccidental) mortality, as well as cause-specific mortality.

[b]Denotes new causality determination.

[c]Denotes change in causality determination from 2013 Ozone ISA.

[d]Since the 2013 Ozone ISA, the causality determination language has been updated and this category is now stated as suggestive of, but not sufficient to infer, a causal relationship.

[e]Since the 2013 Ozone ISA, the causality determination language has been updated and this category is now stated as inadequate to infer the presence or absence of a causal relationship.

NMED Exhibit 3 - 0007

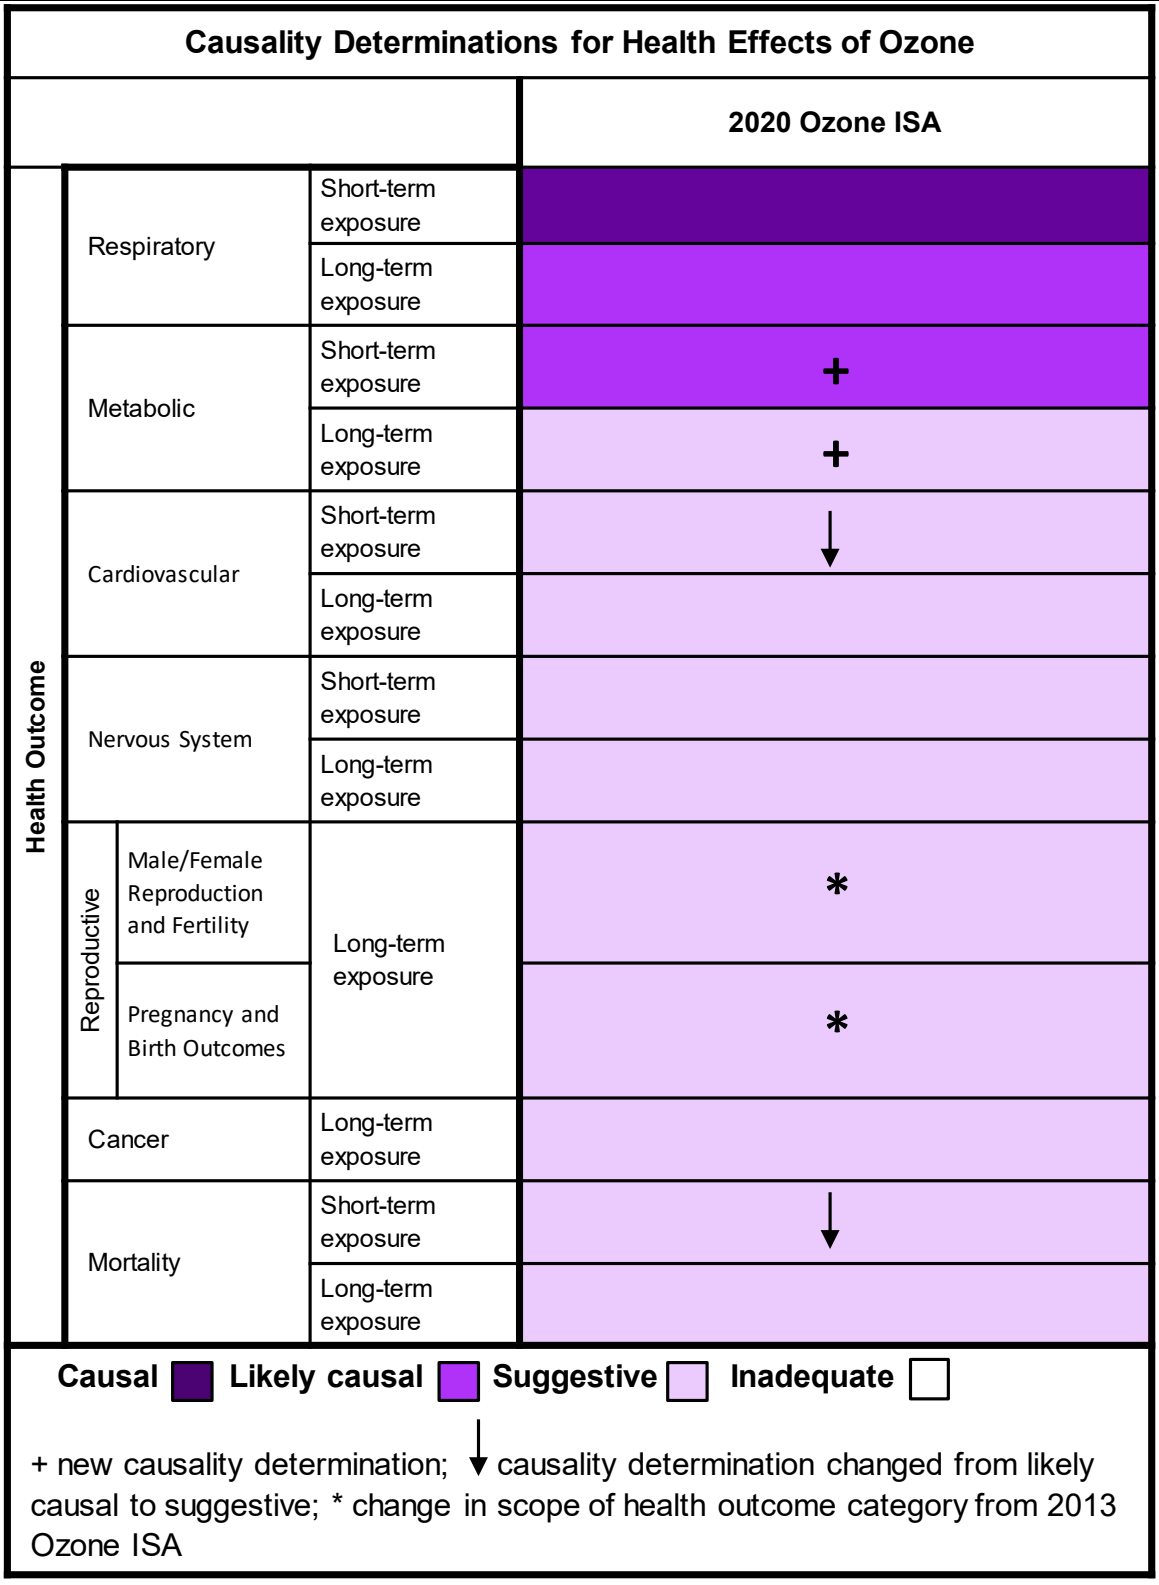

Figure ES-2 Causality determinations for health effects of short- and long-term exposure to ozone.

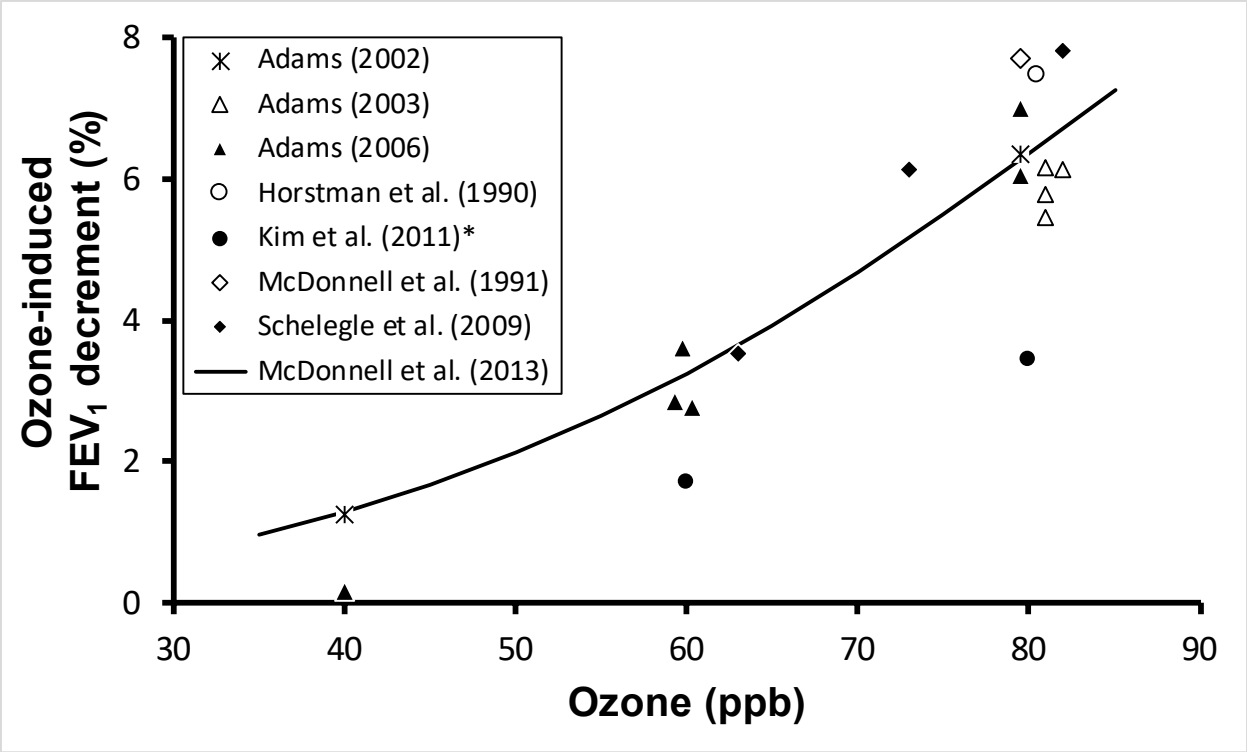
NMED Exhibit 3 - 0008

The strongest evidence for health effects due to ozone exposure continues to come from studies of short- and long-term ozone exposure and respiratory health, and this evidence is detailed in Appendix 3. Consistent with conclusions from the 2013 Ozone ISA (Table ES-1), **there is a "causal relationship" between short-term ozone exposure and respiratory effects** (Section 3.1.11), and **there is a "likely to be causal relationship" between long-term ozone exposure and respiratory effects** (Section 3.2.6).



For short-term ozone exposure, controlled human exposure studies conducted over many decades provide experimental evidence for ozone-induced lung function decrements (Figure ES-3), airway responsiveness, respiratory symptoms, and respiratory tract inflammation. Epidemiologic studies continue to provide evidence that ozone concentrations in ambient air are associated with a range of respiratory effects, including asthma exacerbation, chronic obstructive pulmonary disease (COPD) exacerbation, respiratory infection, and hospital admissions and emergency department (ED) visits for combined respiratory diseases.

A large body of animal toxicological studies demonstrate ozone-induced alterations in lung function, inflammation, increased airway responsiveness, and impaired lung host defense. These animal toxicological studies also aid in our understanding of potential mechanisms underlying respiratory effects at the population level and the biological plausibility of epidemiologic associations between short-term ozone exposure and respiratory-related ED visits and hospital admissions.

With respect to long-term ozone exposure, there is strong coherence between animal toxicological studies of changes in lung morphology and epidemiologic studies reporting positive associations between long-term ozone exposure and new-onset asthma, respiratory symptoms in children with asthma, and respiratory mortality. Furthermore, the experimental evidence provides biologically plausible pathways through which long-term ozone exposure could lead to respiratory effects reported in epidemiologic studies.

Metabolic effects related to ozone exposure are evaluated as a separate health endpoint category for the first time in this ISA (Appendix 5). Recent evidence from animal toxicological, controlled human exposure, and epidemiologic studies indicate that **there is a "likely to be causal relationship" between short-term ozone exposure and metabolic effects** (Section 5.1.8). The strongest evidence for this determination is provided by animal toxicological studies that demonstrate impaired glucose tolerance, increased serum triglycerides, fasting hyperglycemia, and increased hepatic gluconeogenesis in various stocks/strains of animals across multiple laboratories. Biological plausibility is provided by results from controlled human exposure and animal toxicological studies that demonstrate activation of sensory nerve pathways following ozone exposure triggers the central neuroendocrine stress response, which includes increased corticosterone, cortisol, and epinephrine production. These findings are coherent with epidemiologic studies that report associations between ozone exposure and perturbations in glucose and insulin homeostasis. In addition, these pathophysiological changes are often accompanied by increased inflammatory markers in peripheral tissues and by activation of the neuroendocrine system.

NMED Exhibit 3 - 0009

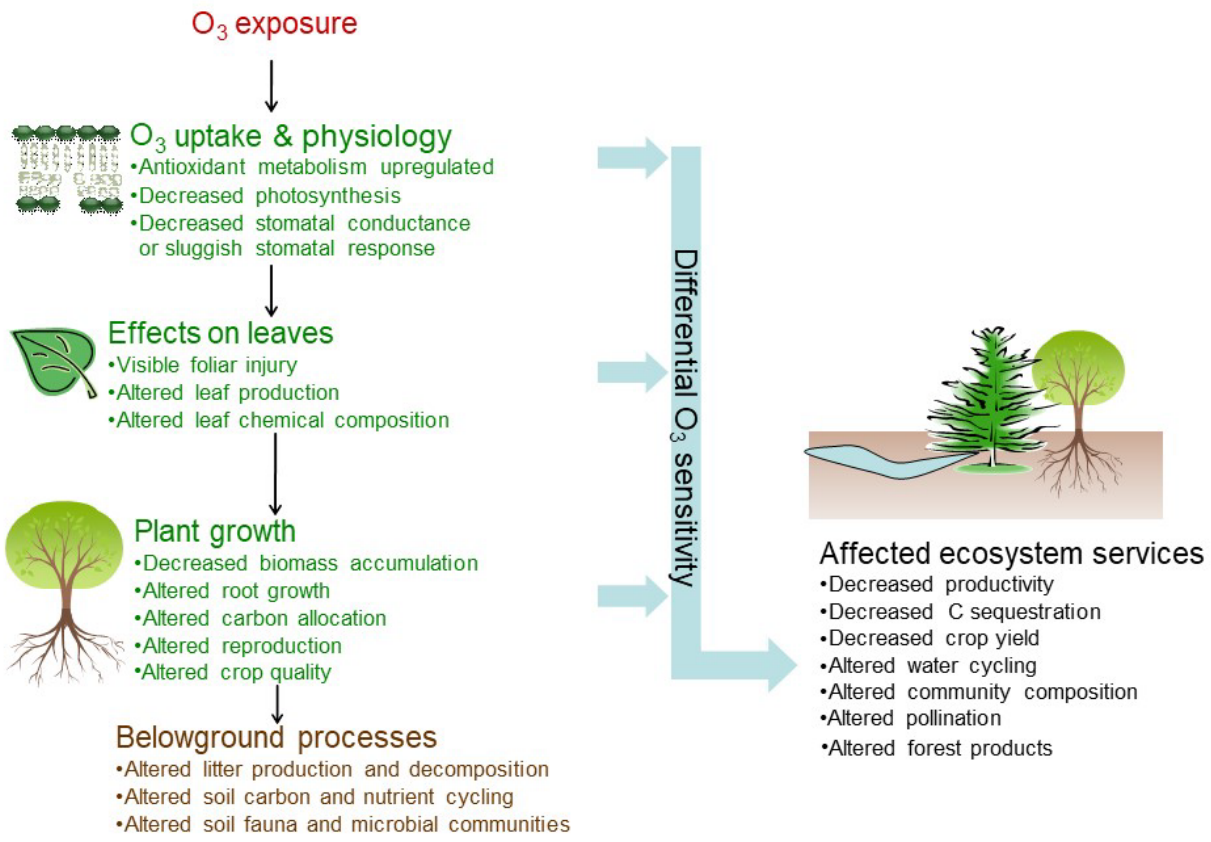
All responses at and above 70 ppb (targeted concentration) were statistically significant ($p < 0.05$). Adams (2006) found statistically significant responses to square-wave chamber exposures at 60 ppb based on the analysis of Brown et al. (2008) and Kim et al. (2011). During each hour of the exposures, subjects were engaged in moderate quasi-continuous exercise (20 L/minute per m^2 BSA) for 50 minutes and rest for 10 minutes. Following the 3rd hour, subjects had an additional 35-minute rest period for lunch. The data at 60 and 80 ppb have been offset on the *x* axis for illustrative purposes. The solid line illustrates the predicted FEV_1 decrements using Model 3 coefficients at 6.6 hours as a function of ozone concentration for a 23.8-year-old with a BMI of 23.1 kg/m^2 from McDonnell et al. (2013).

*80 ppb data for 30 health subjects were collected as part of the Kim et al. (2011) study, but only published in Figure 5 of McDonnell et al. (2012).

Adapted from Figure 6-1 of 2013 Ozone ISA (U.S. EPA, 2013). Studies appearing in the figure legend are: Adams (2006), Adams (2003), Adams (2002), Horstman et al. (1990), Kim et al. (2011), McDonnell et al. (2013), McDonnell et al. (1991), and Schelegle et al. (2009).

Figure ES-3 Cross-study comparisons of mean decrements in ozone-induced forced expiratory volume in 1 second (FEV_1) in young, healthy adults following 6.6 hours of exposure to ozone.

Notably, there are changes in the causality determinations for short-term ozone exposure and cardiovascular effects (Appendix 4), as well as for total mortality (Appendix 6). In both instances, the evidence synthesized in the 2013 Ozone ISA was sufficient to conclude a "likely to be causal relationship," but after integrating the previous evidence with recent data, **the collective evidence is "suggestive of, but not sufficient to infer, a causal relationship" between short-term ozone exposure and cardiovascular effects (Section 4.1.17) or total mortality (Section 6.1.8)** in this ISA. The evidence that supports this change in the causality determinations includes: (1) a growing body of controlled human exposure studies providing less consistent evidence for an effect of short-term ozone exposure on



NMED Exhibit 3 - 0010

cardiovascular health endpoints; (2) a paucity of positive evidence from epidemiologic studies for more severe cardiovascular morbidity endpoints (i.e., heart failure, ischemic heart disease and myocardial infarction, arrhythmia and cardiac arrest, and stroke); and (3) uncertainties due to a lack of control for potential confounding by copollutants in epidemiologic studies. Although there is generally consistent evidence for a limited number of ozone-induced cardiovascular endpoints in animal toxicological studies and for cardiovascular mortality in epidemiologic studies, these results are not coherent with results from controlled human exposure and epidemiologic studies examining cardiovascular morbidity endpoints. There remains evidence for ozone-induced cardiovascular mortality from epidemiologic studies. However, inconsistent results from a larger number of recent controlled human exposure studies that do not provide evidence of cardiovascular effects in response to short-term ozone exposure introduce additional uncertainties.

ES.4.2 Ozone Exposure and Welfare Effects

The scientific evidence for welfare effects of ozone consists mainly of effects on vegetation and ecosystems (Appendix 8) and effects on climate (Appendix 9). For ecological effects, damage to terrestrial ecosystems as evaluated through controlled exposure studies, observational studies and modeling based on experimental data, is largely a function of uptake of ozone into the leaf via stomata (gas exchange openings on leaves). Subsequent reactions with plant tissues alter whole-plant responses that cascade up to effects at higher levels of biological organization (i.e., from the cellular and subcellular level to the individual organism up to ecosystem level processes and services; Figure ES-4). At the leaf level, ozone uptake produces reactive oxygen species that affect cellular function (Section 8.1.3 and Figure 8-2). Reduced photosynthesis, altered carbon allocation, and impaired stomatal function lead to observable responses in plants. Observed vegetation responses to ozone include visible foliar injury (Section IS.5.1.1), and whole-plant level responses (Section IS.5.1.2), which encompass reduction in aboveground and belowground growth, reproduction and yield. Plant-fauna linkages affected by ozone include herbivores that feed on ozone-damaged vegetation and interactions of ozone with compounds emitted by plants that can alter attraction of pollinators to plants (Section IS.5.1.3). A combination of observational and experimental data, and modeling output provides evidence for broad changes in ecosystems such as decreased productivity and carbon sequestration (Section IS.5.1.4), altered belowground processes (Section IS.5.1.5), terrestrial community composition (Section IS.5.1.6), and water cycling (Section IS.5.1.7).

Source: Adapted from U.S. EPA (2013).

Figure ES-4 Illustrative diagram of ozone effects cascading from the cellular level to plants and ecosystems.

There are 12 causality determinations for ecological effects of ozone generally organized from the individual-organism scale to the ecosystem scale in Figure ES-5. Like the findings of the 2013 Ozone ISA (Table ES-2), five are causal relationships (i.e., visible foliar injury, reduced vegetation growth, reduced crop yield, reduced productivity, and altered belowground biogeochemical cycles) and two are likely to be causal relationships (i.e., reduced carbon sequestration, altered ecosystem water cycling). One of the endpoints, alteration of terrestrial community composition, is now concluded to be a causal relationship whereas in the 2013 Ozone ISA this endpoint was classified as a likely to be causal relationship. Three new endpoint categories (i.e., increased tree mortality, alteration of herbivore growth and reproduction, alteration of plant-insect signaling) not evaluated in the 2013 Ozone ISA, are all determined to have a likely to be causal relationship with ozone. Plant reproduction, previously considered as part of the evidence for growth effects, is now a stand-alone causal relationship.

Figure ES-5 Causality determinations for ozone across biological scales of organization and taxonomic groups.

NMED Exhibit 3 - 0013

Table ES-2 Summary of causality determinations for ecological effects.

Endpoint	Conclusions from 2013 Ozone ISA	Conclusions in the 2020 ISA
Visible foliar injury	Causal relationship	Causal relationship
Reduced vegetation growth	Causal relationship	Causal relationship
Reduced plant reproduction	No separate causality determination; included with plant growth	Causal relationship[a]
Increased tree mortality	Causality not assessed	Likely to be causal relationship[a]
Reduced yield and quality of agricultural crops	Causal relationship	Causal relationship
Alteration of herbivore growth and reproduction	Causality not assessed	Likely to be causal relationship[a]
Alteration of plant-insect signaling	Causality not assessed	Likely to be causal relationship[a]
Reduced productivity in terrestrial ecosystems	Causal relationship	Causal relationship
Reduced carbon sequestration in terrestrial ecosystems	Likely to be causal relationship	Likely to be causal relationship
Alteration of belowground biogeochemical cycles	Causal relationship	Causal relationship
Alteration of terrestrial community composition	Likely to be causal relationship	Causal relationship[b]
Alteration of ecosystem water cycling	Likely to be causal relationship	Likely to be causal relationship

[a]Denotes new causality determination.

[b]Denotes change in causality determination from 2013 Ozone ISA.

Visible foliar injury resulting from exposure to ozone has been well characterized and documented in over six decades of controlled experimental research involving many tree, shrub, herbaceous, and crop species and using both long-term field studies and laboratory approaches. Recent experimental evidence (Section 8.2) continues to show a consistent association between visible injury and ozone exposure supporting the conclusion of the 2013 Ozone ISA that, **there is a "causal relationship" between ozone and visible foliar injury.** Measured changes in photosynthesis and carbon allocation in ozone-exposed plants scale up to reduced growth documented in natural and managed (e.g., agriculture, forestry, landscaping) species (Section 8.3), as well as impaired reproduction in individual plants (Section 8.4.1). Consistent with the conclusions in the 2013 Ozone ISA, there is **a "causal relationship"**

NMED Exhibit 3 - 0014

between ozone and reduced plant growth and **a "causal relationship" between ozone and reduced crop yield and quality**. In the 2013 Ozone ISA, reproduction was considered in the same category with plant growth. Increased information on metrics of plant reproduction (e.g., observed flower number, fruit number, fruit weight, seed number, rate of seed germination) and evidence for direct negative effects on reproductive tissues as well as for indirect negative effects (resulting from decreased photosynthesis and other whole-plant physiological changes) warrants a separate causality determination of **a "causal relationship" between ozone exposure and reduced plant reproduction**. Since the 2013 Ozone ISA, a large-scale multivariate analysis of factors contributing to tree mortality (1971−2005) concluded that county-level ozone concentrations averaged over the study period significantly increased tree mortality in 7 out of 10 plant functional types in the eastern and central U.S. (Section 8.4.3). This evidence, combined with observations of long-term declines of conifer forests in several high ozone regions and new experimental evidence that sensitive genotypes of aspen have increased mortality with ozone exposure, supports **a "likely to be causal relationship" between ozone exposure and tree mortality.**

In addition to effects on plants, ozone can alter ecological interactions between plants and other species including herbivores consuming ozone-exposed vegetation. Studies of insect herbivores in previous ozone assessments and newer experimental studies covering a range of species at varying levels of ozone exposure frequently show statistically significant effects; however, effects on growth and reproduction are highly context- and species-specific, and not all species tested show a response (Section 8.6). **The collective evidence supports "a likely to be causal relationship" between ozone exposure and altered herbivore growth and reproduction.** Many plant-insect interactions are mediated through volatile plant signaling compounds which plants use to signal other community members. In the 2013 Ozone ISA, a few experimental and modeling studies reported altered insect-plant interactions that are mediated through chemical signaling. New evidence from multiple studies show altered/degraded emissions of chemical signals from plants and reduced detection of volatile plant signaling compounds by insects, including pollinators, in the presence of ozone (Section 8.7). **The collective evidence supports "a likely to be causal relationship" between ozone exposure and alteration of plant-insect signaling.**

At the ecosystem scale, ozone-caused decreases in plant photosynthesis can lead to reduced ecosystem carbon content. Changes in patterns of aboveground and belowground carbon allocation associated with ozone effects on plants can alter ecosystem properties of storage (e.g., productivity, carbon sequestration) and cycling (e.g., biogeochemistry) through both experimental and modeling studies. Consistent with the conclusions of the 2013 Ozone ISA, there is **a "causal relationship" between ozone exposure and reduced productivity and a "likely to be causal relationship" between ozone and reduced carbon sequestration** (Section 8.8). As described in the 2013 Ozone ISA and new experimental studies, processes such as carbon and nitrogen cycling and decomposition in soils are indirectly affected via ozone effects on the quality and quantity of carbon supply from plants and leaf litter (Section 8.9). **Recent evidence continues to support a "causal relationship" between ozone exposure and the alteration of belowground biogeochemical cycles**. Ozone can affect water use in plants through several mechanisms including damage to stomatal functioning, loss of leaf area, and

NMED Exhibit 3 - 0015

changes in wood anatomy (e.g., vessel size and density) that can affect plant and stand evapotranspiration and may lead, in turn, to possible effects on hydrological cycling as shown through a combination of experimental data and modeling (Section 8.11). Evidence continues to support the conclusion of the 2013 Ozone ISA that, **there is a "likely to be causal relationship" between ozone and alteration of ecosystem water cycling.** In terrestrial ecosystems, ozone may alter community composition by uneven effects on co-occurring species, decreasing the abundance of sensitive species, and giving tolerant species a competitive advantage. Alteration of community composition of some ecosystems including conifer forests, broadleaf forests, and grasslands and altered fungal and bacterial communities in soils reported in the 2013 Ozone ISA is augmented by additional experimental and modeling evidence for effects in forest and grassland communities (Section 8.10); collective evidence indicates a change in the causality determination to **a "causal relationship" between ozone exposure and altered terrestrial community composition of some ecosystems.**

For effects on climate, changes in the abundance of tropospheric ozone perturb the radiative balance of the atmosphere by interacting with incoming solar radiation and outgoing longwave radiation. This effect is quantified by radiative forcing.[1] Through this effect on the Earth's radiation balance, tropospheric ozone plays a major role in the climate system and increases in tropospheric ozone abundance contribute to climate change. **Recent evidence continues to support a "causal relationship" between tropospheric ozone and radiative forcing and a "likely to be causal relationship," via radiative forcing, between tropospheric ozone and temperature, precipitation, and related climate variables** (referred to as "climate change" in the 2013 Ozone ISA; the revised title for this causality determination provides a more accurate reflection of the available evidence; Table ES-3). The new evidence comes from the Intergovernmental Panel on Climate Change (IPCC) Fifth Assessment Report (AR5) and its supporting references, as well as a limited number of more recent studies, and builds on evidence presented in the 2013 Ozone ISA. The new studies further support the causality determinations included in the 2013 Ozone ISA.

Table ES-3 Summary of causality determinations for tropospheric ozone effects on climate.

	Conclusions in 2013 Ozone ISA	Conclusions in the 2020 ISA
Radiative forcing	Causal relationship	Causal relationship
Temperature, precipitation, and related climate variables	Likely to be causal relationship	Likely to be causal relationship

[1] Radiative forcing is the perturbation in net radiative flux at the tropopause (or top of the atmosphere) caused by a change in radiatively active forcing agent(s) after stratospheric temperatures have readjusted to radiative equilibrium [stratospherically adjusted radiative forcing; Myhre et al. (2013)].

NMED Exhibit 3 - 0016

ES.5 Key Aspects of Health and Welfare Effects Evidence

There is extensive scientific evidence that demonstrates health and welfare effects from exposure to ozone. As documented by the evaluation of evidence throughout the subsequent Appendices to this ISA, the U.S. EPA carefully considers uncertainties in the evidence, the extent to which recent studies have addressed or reduced uncertainties from previous assessments, and the strengths of the evidence. Uncertainties do not necessarily change the fundamental conclusions of the literature base. In fact, some conclusions are robust to such uncertainties. Where there is clear evidence linking ozone with health and welfare effects—with or despite remaining uncertainties—the U.S. EPA makes a determination of a causal or likely to be causal relationship. The identification of the strengths and limitations in the evidence will help in the prioritization of research efforts to support future ozone NAAQS reviews.

ES.5.1 Health Effects Evidence: Key Findings

A large body of scientific evidence spanning many decades clearly demonstrates there are health effects related to both short- and long-term exposure to ozone. The strongest evidence supports a relationship between ozone exposure and respiratory health effects. The collective body of evidence for each health outcome category evaluated in this ISA is considered systematically and assessed; this assessment includes evaluation of the inherent strengths, limitations, and uncertainties in the overall body of evidence for the health outcome, resulting in the causality determinations detailed in Table ES-1.

An inherent strength of the evidence integration in this ISA is the extensive amount (in both breadth and depth) of available evidence resulting from decades of scientific research that describes the relationship between both short- and long-term ozone exposure and health effects. The breadth of the enormous database is illustrated by the different scientific disciplines that provide evidence (e.g., controlled human exposure, epidemiologic, animal toxicological studies), the range of health outcomes examined (e.g., respiratory, cardiovascular, metabolic, reproductive, and nervous system effects, cancer and mortality), and the large number of studies within several of these outcome categories. The depth of the literature base is exemplified by the examination of effects that range from biomarkers of exposure, to subclinical effects, to overt clinical effects, and even mortality.

There is strong and consistent experimental evidence linking short- and long-term ozone exposure with respiratory effects and short-term ozone exposure with metabolic health effects. However, several uncertainties should be considered when evaluating and synthesizing evidence from these studies. Experimental animal studies are often conducted at ozone concentrations higher than those observed in ambient air (i.e., 250 to >1,000 ppb) to evoke a response within a short time period. These studies are informative and the conduct of studies at these concentrations is commonly used for identifying potential human hazards. There are also substantial differences in exposure concentrations and exposure durations between animal toxicological and controlled human exposure studies. Additionally, a number of animal toxicological studies are performed in rodent models of disease states, while controlled human exposure studies generally are conducted in healthy individuals. Controlled human exposure studies do not

NMED Exhibit 3 - 0017

typically include unhealthy or diseased individuals for ethical reasons; therefore, this exclusion represents an important uncertainty to consider in interpreting the results of these studies (i.e., that other individuals may be more sensitive and at risk to ozone than those in the study groups). Additional factors that differ between human and experimental animal exposures include: exposure concentration and disease status; differences in physiology (e.g., rodents are obligate nose breathers); differences in the duration and timing of exposure (e.g., rodents are exposed typically during the day, during their resting cycle, while humans are exposed during the day when they are normally active); and differences in the temperature at which the exposure was conducted. These factors may contribute to any lack of coherence between results of experimental animal and human studies. Despite these factors, there is consistent and coherent evidence that spans scientific disciplines for respiratory and metabolic health effects.

Epidemiologic studies contribute important evidence supporting the relationship between short- and long-term ozone exposure with respiratory effects. Although susceptible to chance, bias, and other potential confounding due to their observational nature, epidemiologic studies have the benefit of evaluating real-world exposure scenarios and can include sensitive populations that cannot typically be included in controlled human exposure studies. Innovations in epidemiologic study designs and methods have substantially reduced the role of chance, bias, and other potential confounders in well-designed, well-conducted epidemiologic studies. The most common source of uncertainty in epidemiologic studies of ozone is exposure measurement error. The exposure assignment methods used in short- and long-term ozone exposure epidemiologic studies have inherent strengths and limitations, and exposure measurement errors associated with those methods contribute bias and uncertainty to health effect estimates. For short-term exposure studies, exposure measurement error generally leads to underestimation and reduced precision of the association, whereas in long-term exposure studies exposure measurement error has the potential to bias effect estimates in either direction, although it is more common that they are underestimated. Furthermore, disentangling the effects of short-term ozone exposure from those of long-term ozone exposure (and vice versa) is an inherent uncertainty in the evidence base. When combined with coherent evidence from animal toxicological and controlled human exposure studies, the epidemiologic evidence can support and strengthen determinations of the causal nature of the relationship between health effects and exposure to ozone at relevant ambient air concentrations.

ES.5.2 Welfare Effects Evidence: Key Findings

The collective body of evidence for each welfare endpoint evaluated in this ISA was carefully considered and assessed, including the inherent strengths, limitations, and uncertainties in the overall body of evidence, resulting in the causality determinations for ecological effects detailed in Table ES-2 and effects on climate in Table ES-3. A large body of scientific evidence spanning more than 60 years clearly shows effects on vegetation due to ozone exposure. Decades of research on many plant species confirm effects on visible foliar injury, plant growth, reproduction and yield. The use of visible foliar injury to identify phytotoxic levels of ozone is an established and widely used methodology. There are robust exposure-response functions for reduced growth and yield (i.e., from carefully controlled

NMED Exhibit 3 - 0018

experimental conditions, involving multiple concentrations and based on multiple studies) for about a dozen important tree species and a dozen major commodity crop species. Newer evidence supports a role for ozone in tree mortality and shifts in community composition of forest tree and grassland species. While the effect of ozone on vegetation is well established in general, there are some knowledge gaps regarding precisely which species are sensitive, what exposures elicit adverse responses for many species and how plant response changes with age and size.

There is high certainty in ozone effects on impairment to leaf physiology as mechanisms for effects at higher levels of biological organization (i.e., from the cellular level through individual organisms to the level of communities and ecosystems) and how those can ultimately affect aboveground and belowground processes such as productivity, carbon sequestration, biogeochemical cycling, and hydrology. However, ecosystems are inherently complex, and it is difficult to partition observed responses within a suite of multiple stressors. Scaling ozone effects to the ecosystem level remains a challenge, but there is a large body of knowledge of how ecosystems work through ecological observations and models. Interactive effects in natural ecosystems with multiple stressors (e.g., drought, disease) are difficult to study, but some have been investigated using different statistical methods. Although models and methods for characterizing ecosystem-level responses to ozone are accompanied by inherent uncertainties, more research will strengthen understanding of scaling across different levels of biological organization.

There are multiple pathways in which ozone can affect plant-insect interactions. Studies that characterize volatile plant signaling compounds in ozone-enriched environments and assess insect response to altered chemical signals suggest that ozone alters scent-mediated interactions in ecological communities. A relatively small number of insect species and plant-insect associations have been assessed, and there are knowledge gaps in the mechanisms and consequences of modulation of signaling by ozone. There are multiple studies demonstrating ozone effects on fecundity and growth in insects that feed on ozone-exposed vegetation. However, no consistent directionality of response is observed across studies and uncertainties remain in regard to different plant consumption methods across species and the exposure conditions associated with particular severities of effects.

Changes in the abundance of tropospheric ozone affect radiative forcing, and thus tropospheric ozone is considered an important greenhouse gas. The recent IPCC AR5 estimates global tropospheric ozone radiative forcing to be 0.40 (0.20 to 0.60) W/m^2 and recent studies reinforce the AR5 estimates. Consistent with previous estimates, the effect of global, total tropospheric ozone increases on global mean surface temperature, through its impact on radiative forcing, continues to be estimated at roughly 0.1 to 0.3°C since preindustrial times with larger effects regionally. Some new research has explored certain additional aspects of the climate response to ozone radiative forcing beyond global and regional temperature change. Specifically, ozone changes are understood to have impacts on other climate metrics such as precipitation and atmospheric circulation patterns, and new evidence has continued to support and further quantify this understanding.

NMED Exhibit 3 - 0019

While the warming effect of tropospheric ozone in the climate system is well established in general, precisely quantifying changes in surface temperature due to tropospheric ozone changes, along with related climate effects, requires complex climate simulations that include all relevant feedbacks and interactions. For example, trends in free tropospheric ozone and upper tropospheric ozone (where radiative forcing is particularly sensitive to changes in ozone concentrations) are not captured well by models. In addition, substantial variation exists across models. Such modeling uncertainties make it especially difficult to provide precise quantitative estimates of the climate effects of regional-scale ozone changes. Uncertainties in estimates of preindustrial ozone concentrations represent another important source of uncertainty in climate effects resulting from long-term ozone concentration changes.

Introduction

Ozone Basics

Ozone (O_3) is a highly reactive gas composed of three oxygen atoms. It is both a natural and a man-made product that occurs in the Earth's upper (stratosphere) and lower (troposphere) atmosphere. Ground level ozone, the ozone EPA sets national standards for, is both harmful to human health and damaging to the environment

Both short- and long-term exposure to ozone can lead to adverse health impacts. Short-term exposures to ozone can make it more difficult to take a full, deep breath by inflaming the airways and causing symptoms such as chest pain, coughing, wheezing and shortness of breath. These short-term exposures can also aggravate asthma and other respiratory diseases and can make people more susceptible to infections.

Long-term exposure to ozone is linked to the development and aggravation of asthma and a variety of other impacts to the respiratory system. Through continued research, scientists are finding that long-term exposure (i.e., for periods longer than eight hours) may increase the risk of early death. Anyone who spends time where ozone concentrations are high may be at risk of experiencing adverse health effects.[1]

According to the Environmental Protection Agency (EPA), ozone affects sensitive vegetation and ecosystems, including forests, parks, wildlife refuges and wilderness areas. Ozone can especially cause damage during the growing season. When enough ozone enters the leaves of a sensitive plant, it can reduce photosynthesis; slow the plant's growth; and increase sensitive plants' risk of disease, damage from insects, effects of other pollutants, and harm from severe weather. [2]

EPA Advance Program

The EPA Advance Program began in April 2012 as a collaborative effort to encourage ozone and particulate matter (PM) emission reductions in attainment areas. Participants determine goals and measures they want to implement and achieve. Although participation in the program does not guarantee an attainment designation in the future, actions taken as part of the Ozone Advance Program could better position future non-attainment areas to develop an effective State Implementation Plan (SIP).

Ozone Advance provides emissions reductions that could result in a lower nonattainment classification or be credited in a future SIP. A key benefit to participating in the program is the flexibility to voluntarily reduce air pollution through control measures chosen to suit an area's social and economic demographics. Once designated nonattainment, the Clean Air Act affords less flexibility to select control measures.

Geographic Scope

---

[1] From *Health effects of ozone pollution*, Environmental Protection Agency, https://www.epa.gov/ground-level-ozone-pollution/health-effects-ozone-pollution

[2] From *Ecosystem effects of ozone pollution*, Environmental Protection Agency, https://www.epa.gov/ground-level-ozone-pollution/ecosystem-effects-ozone-pollution

The New Mexico Environment Department (NMED) is participating in the Ozone Advance Program with respect to three full counties and one partial county in New Mexico to preserve or improve the air quality in these areas. These counties are San Juan (northwest NM), Lea (southeast NM), Eddy (southeast NM) and Doña Ana, excluding the Sunland Park nonattainment area (south central NM). Since our acceptance into the Ozone Advance Program in April 2019, ozone levels in Rio Arriba, Sandoval, Santa Fe, and Valencia counties either currently or recently have exceeded 95% of the 2015 8-hour Ozone NAAQS (67 ppb) and could soon violate this standard. In total, the Ozone Advance Path Forward and outreach efforts will include the following nine counties (figure 1): Chaves, Doña Ana, Eddy, Lea, Rio Arriba, San Juan, Santa Fe, Sandoval, and Valencia.

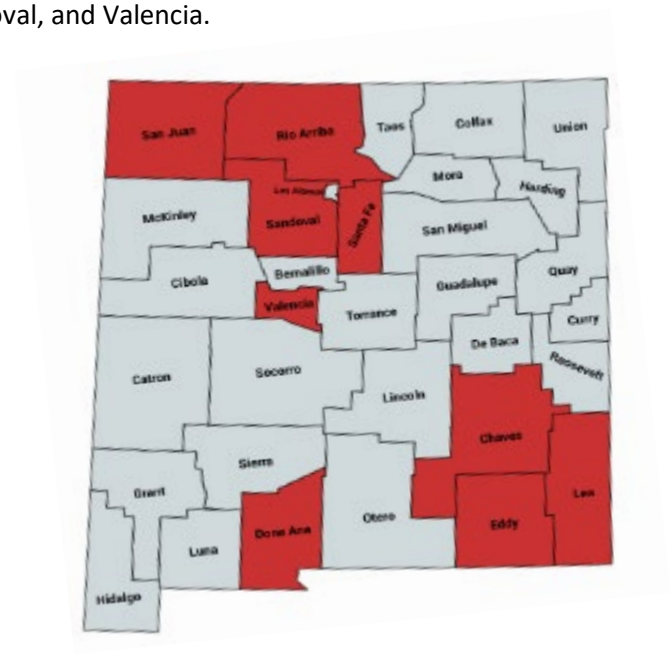

Figure 1: Map of New Mexico Counties to be included in Ozone Advance Path Forward

Although Chaves County does not have ozone monitors, the Bureau will include it in the Ozone Advance planning effort as it is part of the Permian Basin with Oil and Gas emissions that contribute to high ozone levels in Lea and Eddy counties. NMED understands our efforts under Ozone Advance may benefit these areas by potentially (1) reducing air pollution in terms of ozone as well as other air pollutants, (2) ensuring continued healthy ozone levels, (3) maintaining the ozone NAAQS and helping the Sunland Park Nonattainment Area attain the 2015 Ozone NAAQS, (4) helping avoid violations of the NAAQS that could lead to a future nonattainment designation, (5) increasing public awareness about ozone as an indirect air pollutant, and (6) targeting limited resources toward actions to address ozone problems quickly. NMED's goal is to implement measures and programs to reduce ozone in the near term, and ultimately to effect changes that will protect community well-being into the future. NMED agrees it is in our best interest to work together and in coordination with stakeholders and the public to proactively pursue this goal.

This path forward plan outlines several relevant strategies to realize this vision. It recommends measures that we, as a state, can and are implementing to protect air quality across New Mexico.

Background

Ground-level ozone is created by chemical reactions between nitrogen oxides (NO_X) and volatile organic compounds (VOCs), with sunlight as the driver. VOC and NO_X come in two forms: biogenic (natural), which is produced by vegetation: and anthropogenic, which is created by humans, primarily in industrial processes, and by modern transportation modes, particularly diesel and gas-driven motor vehicles. Hot, sunny days may produce unhealthy levels of ozone, especially in urban environments. Smoke from wildfires can also contribute pollutants that increase the formation of ozone.

High ozone levels in New Mexico are driven by different sources in different parts of the state. For example, NO_X and VOC emissions from the oil and gas industry in Eddy, Lea, Rio Arriba and San Juan counties combined with abundant desert sunshine create some of the highest ozone levels in New Mexico. Likewise, plentiful sunshine mixed with concentrated vehicle emissions in the Albuquerque metro area contribute to high ozone in the Sandoval and Valencia counties. By and large, Doña Ana County's high ozone levels are influenced by emissions from the large metropolitan area of El Paso, Texas and Juárez, Mexico.

Ozone Monitoring & Trends

The Air Quality Bureau (AQB) operates and maintains fourteen (14) continuous ozone monitors across the state. Except for a small portion of Doña Ana County near the City of Sunland Park, all of New Mexico is currently classified as "attainment" for the 2015 8-hour ozone NAAQS. The Sunland Park area's ozone levels are largely influenced by sources and emissions from outside of New Mexico.

Although the health-based ozone standard is set at .070 ppm, New Mexico law [74-2-5.3 NMSA 1978] requires that NMED develop plans to reduce ozone once monitored design values (DVs) in an area that exceed 95% of the standard (i.e., 0.067 ppm). In Table 1, 2018-2020 Design Value data indicate ozone levels at or above 95% of the ozone NAAQS at several New Mexico air quality monitors in eight counties.

County	Monitoring Location	2018-2020 Design Value
Doña Ana	La Union	70 ppb
	Chaparral	72 ppb
	Desert View	78 ppb
	Santa Teresa	74 ppb
	Solano	70 ppb
Eddy	Carlsbad	78 ppb
Lea	Hobbs	68 ppb
Rio Arriba	Coyote Ranger Station	65 ppb
Sandoval	Bernalillo	70 ppb
San Juan	Bloomfield	66 ppb
	Navajo Lake	68 ppb
	Substation	69 ppb
Santa Fe	Santa Fe	68 ppb
Valencia	Los Lunas	69 ppb

Table 1: 2018-2020 Design Values for Monitoring Locations in New Mexico

As shown in Figure 2, DVs for Doña Ana County have consistently exceeded the 2015 NAAQS standards, and have been continuing to rise since 2016-2018.

Eddy and San Juan counties' DVs remained constant from 2010-2012 through 2012-2014, dropped from 2013-2015 through 2014-2016, rose modestly from 2015-2017, then increased sharply from 2016-2018 through 2017-2019. San Juan has managed to remain just under the 2015 NAAQS standards in 2018-2020, but Eddy has shown a dramatic increase in ozone levels with a peak of 79 ppb in 2017-2019.

Sandoval County and Lea County have shown steady increases in ozone DVs between 2010-2012 and 2018-2020, rising from 61 to 70 ppb and 61 to 68 ppb, respectively. Valencia county has been steadily rising since 2014-2016.

The monitoring site at Rio Arriba first reported in 2014-2016 with an ozone DV of 64 ppb and rose to reach a peak of 70 ppb in 2017-2019, then decreased to 65 ppb for 2018-2020.

Between 2013-2015 and 2015-2017, all counties except Dona Ana showed a decrease in ozone DVs beginning to rise. Rio Arriba, Eddy, and Lea all had decreases in DV in 2018-2020, with the rest of the counties still rising.

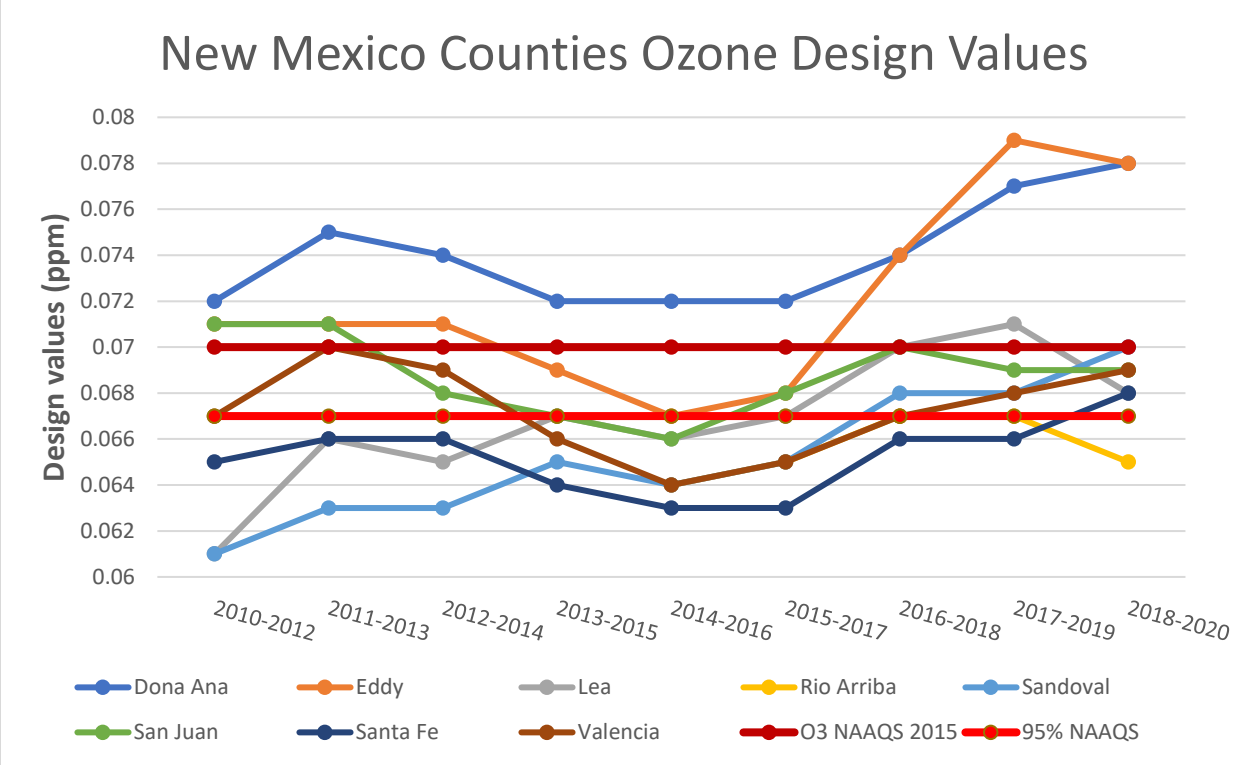

Figure 2: Design values for New Mexico counties included in the Advance Program, 10-year trends

Key Sources of Ozone and Precursor Pollutants

In addition to historical design value trends from 2010 through 2020, the 2017 NEI data was used to identify the major source categories. The National Emissions Inventory (NEI) is a comprehensive and detailed estimate of air criteria pollutant emissions, precursors, and hazardous air pollutants from air emissions sources.[3] Air pollution sources are separated into main source categories – point, nonpoint, on-road, and nonroad.

The point source category contains larger sources that are located at fixed, stationary locations. It includes large and certain smaller industrial facilities, (e.g., electric power plants, airports, non-industrial, and

[3] From *National Emissions Inventory*, Environmental Protection Agency, https://www.epa.gov/air-emissions-inventories/national-emissions-inventory-nei

commercial facilities). This category also includes a small number of portable sources, such as some asphalt or rock crushing operations, aircraft engine emissions (occurring during landing and takeoff operations), airport ground support and power unit equipment, and locomotive emissions at rail yards.[4]

Nonpoint sources include sources that individually are too small in magnitude to report as point sources. Examples include residential heating, commercial combustion, asphalt paving, and commercial and consumer solvent use. Non-railyard locomotive emissions, commercial marine vessel emissions (both underway and port emissions), dry cleaners, gas stations, and livestock facilities are also included as nonpoint sources.[5]

On-road sources are vehicles that use gasoline, diesel, and other fuels. These sources include light-duty and heavy-duty vehicles from operation on roads, highway ramps, and during idling.[6] Nonroad sources consist of off-road mobile sources that use gasoline, diesel, and other fuels. Source types in this category include construction equipment, lawn and garden equipment, locomotives, and commercial marine vessels.[7]

General NO_X and VOC Emission Trends

The National Emissions Inventory provides data on criteria pollutants to better understand current emissions in different areas. Several monitors are placed throughout New Mexico which collect and report data spanning multiple years. Table 2 shows total emissions in tons of NO_X and VOCs reported in the 2017 NEI in the counties that are included in the Ozone Advance Program. Both NO_X and VOCs are precursors of ozone, meaning they interact with other compounds in the atmosphere to create ozone.

	Dona Ana	Chaves	Eddy	Lea	Rio Arriba	Santa Fe	San Juan	Sandoval	Valencia
NOx	6,503	X,xxx	4,418	7,493	1,512	3,999	23,135	2,556	1,656
VOC	3,508	X,xxx	6,380	1,779	1,744	2,047	5,599	1,475	6,289

Table 2: 2017 NEI NOx and VOC Emissions in tons for New Mexico Ozone Advance Counties

NOx Emissions

Overall, San Juan County has the highest levels of estimated NO_X emissions at 23,135 tons. Doña Ana and Lea counties' NO_X emission estimates are 6,503 tons and 7,493 tons, respectively. NO_X emissions for Eddy, Rio Arriba, Santa Fe, Sandoval, and Valencia counties are estimated below 5,000 tons for each county.

Eddy, Valencia, and San Juan counties have the highest and nearly equal estimated levels of VOC emissions at 6,380; 6,289; and 5,600 tons; respectively. Likewise, Lea, Rio Arriba and Sandoval counties had nearly equal but much lower estimated levels of VOC emissions at 1,779; 1,745; and 1,475 tons, respectively. Doña Ana County's estimated VOC emissions were 3,508 tons, with Santa Fe County at approximately 2,047 tons.

[4] Ibid.
[5] Ibid.
[6] Ibid.
[7] Ibid.

NMED Exhibit 4 - 0007

According to 2017 NEI data shown in Figure 3, the on-road sector accounts for 61% (Rio Arriba) to as much as 96% (Santa Fe) of estimated NO_X emissions in Doña Ana, Rio Arriba, Santa Fe, Sandoval, and Valencia counties. The percentage of on-road NO_X emissions in Eddy, Lea, and San Juan County are considerably lower at 28%, 20%, and 9%, respectively.

Point sources in San Juan account for 90% estimated NO_X emissions in the county, this is 32% of all NO_X emissions in the counties that are a part of the Ozone Advance plan. Lea County point source emissions account for 76% of NO_x emissions in the county. Percentages for point source estimated NO_X emissions for Eddy and Rio Arriba counties are significantly lower at 26% and 21%, respectively. Doña Ana and Valencia have low estimated NO_X emissions at 15% and 11%, respectively, of the total NO_X emissions for those counties. Santa Fe County point source emissions only account for 1.5% of NO_x and Sandoval County's point source emissions are negligible at <1%.

Of all nine counties, Eddy County's Nonpoint sources are the greatest at 45% of estimated NO_X emissions. Rio Arriba County's nonpoint source emissions account for 13% of NO_X emissions. Santa Fe, Sandoval, Valencia, Doña Ana, Lea, and San Juan counties have 5% or less of nonpoint NO_X emissions.

Non-road sources account for less than 10% of total estimated NO_X emissions for Doña Ana, Eddy, Lea, Rio Ariba, San Juan, Santa Fe, and Valencia counties. Sandoval is the only county with non-road estimated NO_X emissions slightly higher at 14%.

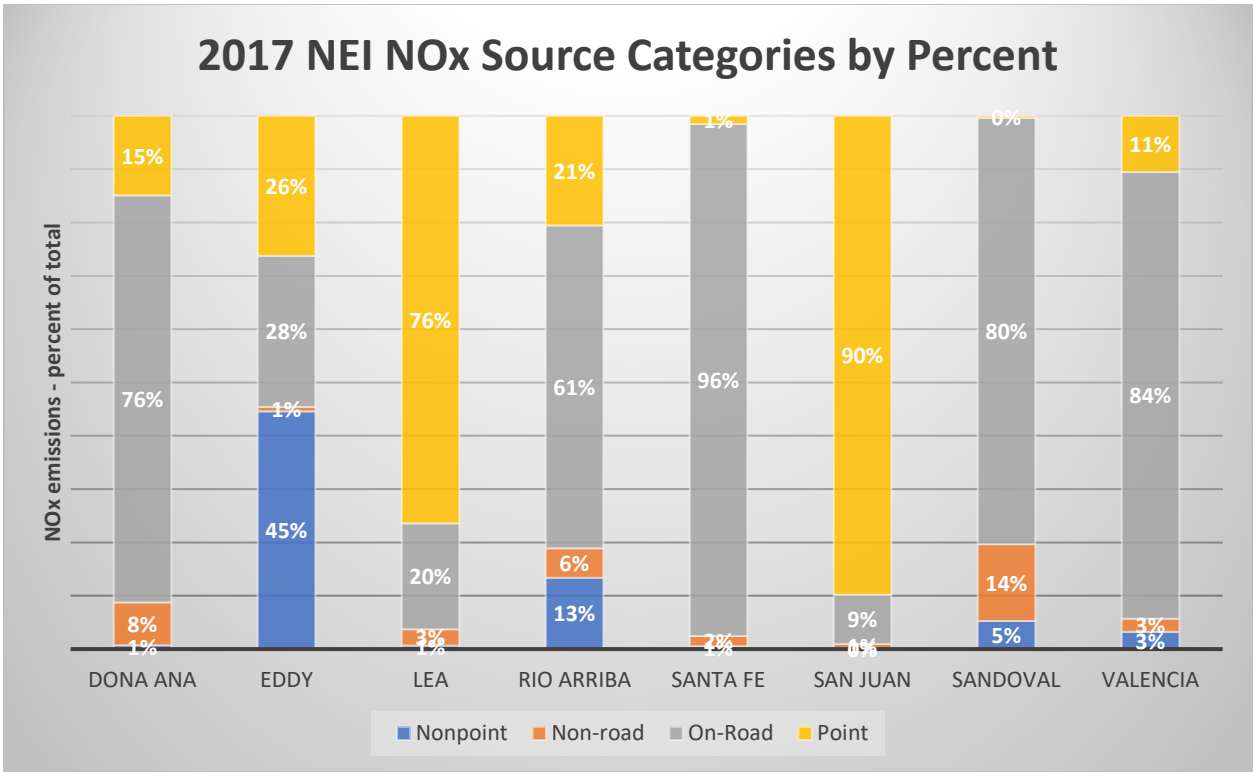

Figure 3: 2017NEI NOx Source Categories for Counties within 95% of the Ozone Standard.

VOC Emissions

According to 2017 NEI data (Figure 4), on-road source emissions in Santa Fe, Sandoval, and Doña Ana counties are 88%, 83%, and 64%, respectively, of the total estimated VOC emissions for these counties. Lea, Rio Arriba, & San Juan counties have moderate percentages of VOC emissions, between 21% and 38% from the on-road source sector. Eddy and Valencia counties have relatively low on-road VOC emissions at 9% and 12%, respectively.

Valencia and Eddy counties have the highest percentage of nonpoint VOC emissions at 87% and 78%, respectively. San Juan County has a moderately high percentage of nonpoint VOC emissions at 44%. Lea, Rio Arriba, and Doña Ana counties have relatively low percentages of nonpoint VOC emissions between 18% and 29%. Santa Fe and Sandoval Counties have a low percentage of nonpoint VOC emissions at 5% and 8% respectively.

Rio Arriba, Lea, and San Juan counties have moderately high percentages of point source VOC emissions at 43%, 42% and 33%, respectively. Eddy, Doña Ana, & Sandoval counties have point source VOC emissions percentages of 10% and less. Santa Fe County has the second lowest point source VOC emissions with just 1% and Valencia County's point source emissions are negligible at <1%. All seven counties have relatively low percentages of non-road VOC emissions of 11% or less.

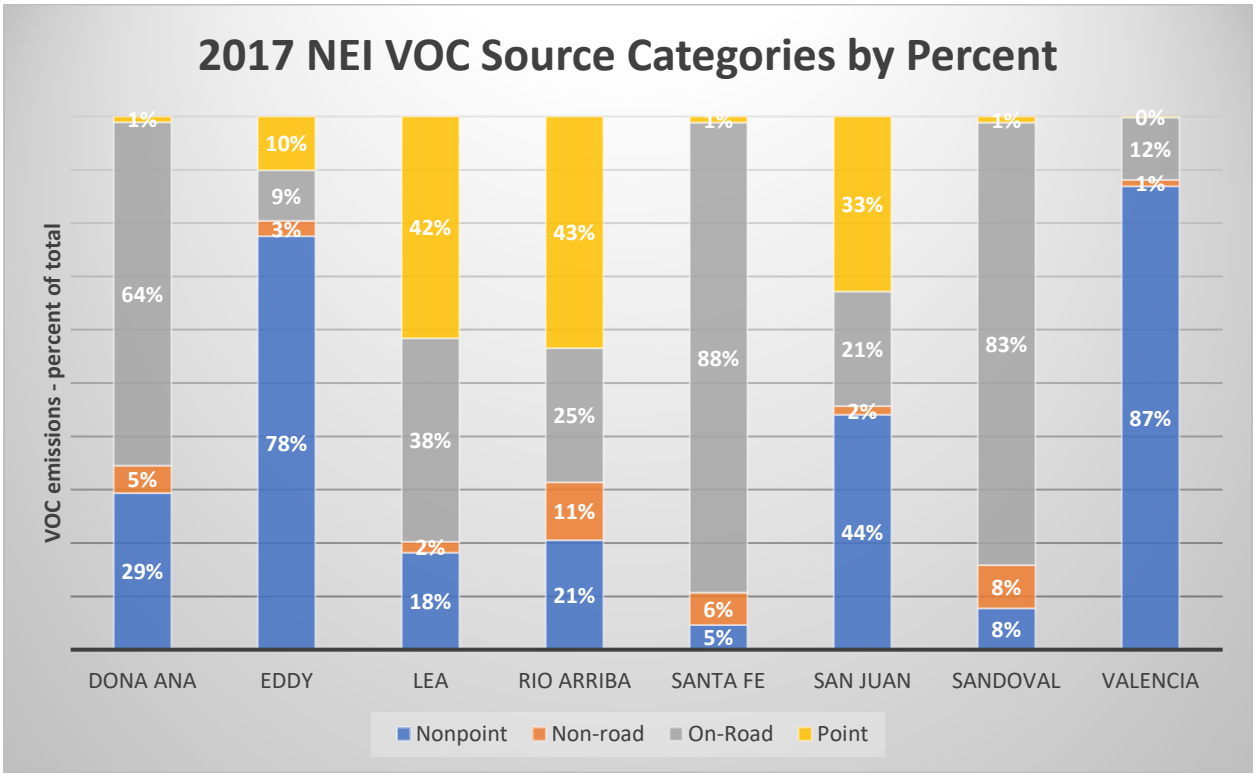

Figure 4: 2017 NEI VOC Source Categories for Ozone Advance Counties

Technical Analyses and Modeling

There are four interrelated but distinct conceptual models of ozone formation within New Mexico's airsheds: Albuquerque and surrounding areas, southcentral New Mexico, southeastern New Mexico, and northwestern New Mexico. They share the attribute that ozone transport from outside of New Mexico and/or the continental U.S. dominates ozone concentrations on all days. Days with the highest local ozone

formation are typically hot summer days with slow winds and without an excessive amount of precipitation (summer monsoon).[8] To study how ozone forms in the state, NMED has participated in photochemical modeling studies over the past twenty years. Most recently, photochemical modeling was completed in May of 2021 for New Mexico's draft ozone rule with a focus on the counties included in this path forward.

Photochemical Modeling for New Mexico

The modeling study for the draft ozone rule leverages the 2014 Photochemical Grid Model (PGM) modeling platform developed by the Western Regional Air Partnership (WRAP) in the Western Air Quality Study (WAQS). It enhances the PMG by adding a 4-km grid resolution modeling domain over New Mexico and surrounding areas, especially the oil and gas production regions in the Permian and San Juan Basins. The PGM modeling consists of 2014 base year modeling and model performance evaluation as well as 2028 future year modeling. The results of the 2028 future year modeling, source apportionment and control measure evaluation will assist the NMED in ozone air quality planning and rule development for the state.[9]

Preliminary conclusions indicate the draft ozone rule would reduce projected 2028 ozone DVs across New Mexico when compared to 2012-2016 DVs (Table 3). While the DVs from 2012-2016 show most sites to be within attainment of the NAAQS standards and the 95% threshold set for Ozone Advance, it should be noted that all sites have shown increases in Ozone levels in recent years (Table 1). The largest DV reductions by site are projected to be at the La Union monitoring site in Dona Ana County (6.3 ppb) and the Bernalillo site in Sandoval County (5.6 ppb).

The photochemical modeling shows a total of 60.3 ppb of ozone reduced in the Ozone Advance counties as a result of the Proposed Ozone Rule. Tables 3-5 show the predicted changes in DVs at 15 monitoring sites in the Ozone Advance counties in New Mexico.

	Site	2012-2016 DVC (ppb)	2028 DVF (ppb)	Difference
Rio Arriba	Coyote Ranger District	64	60.8	-3.2
Sandoval	Bernalillo	64	58.4	-5.6
San Juan	Bloomfield	64.3	61	-3.3
	Navajo Lake	67	64.8	-2.2
	Substation	63.7	60.8	-2.9
Santa Fe	Santa Fe Airport	64.3	60.6	-3.7
Dona Ana	La Union	66.3	60	-6.3
	Sunland Park City Yard	67	61.9	-5.1
	Chaparral	67	62.3	-4.7
	Desert View	72	67	-5.0
	Santa Teresa	71.3	66.1	-5.2
	Solano	65	60.3	-4.7
Eddy	Carlsbad	69	66.7	-2.3
Lea	Hobbs Jefferson	66	64	-2.0
Valencia	Los Lunas	66.3	62.2	-4.1

Path Forward – Planning Measures and Emission Reduction Strategies

Ozone Attainment Initiative and Ozone Precursor Rulemaking

To address the high observed ozone concentrations in New Mexico, the NMED has embarked on an Ozone Attainment Initiative ("OAI")[10] to protect the ozone attainment status of the state and ensure health and welfare of the residents of the state for future generations.[11] In total, the Initiative's planning and outreach efforts will include the following nine counties: Chavez, Doña Ana, Eddy, Lea, Rio Arriba, San Juan, Santa Fe, Sandoval and Valencia. This Initiative is undertaken pursuant to the Air Quality Control Act at NMSA 1978, Section 74-2-5(C), which states:

> If the environmental improvement board ... determines that emissions from sources within [its] jurisdiction cause or contribute to ozone concentrations in excess of ninety-five percent of a national ambient air quality standard for ozone…[the] board shall adopt a plan, including rules, to control emissions of oxides of nitrogen and volatile organic compounds to provide for attainment and maintenance of the standard.

The OAI is a multi-year planning effort, beginning in the summer of 2018 and continuing indefinitely, as necessary. Three phases of implementation include: (1) an effort to educate the public and gather initial information and ideas; (2) development of appropriate rules and other programs based on scientific analysis and public input; and (3) development and implementation of the OAI plan, including rules to control sources contributing significantly to high ozone levels. NMED intends to use this Ozone Advance Path Forward document as the OAI plan required by New Mexico's Air Quality Control Act.

Ozone Precursor Rule – 20.2.50 NMAC, Oil and Gas Sector

[10] From *Ozone Attainment Initiative*, NMED, https://www.env.nm.gov/air-quality/o3-initiative/

[11] New Mexico Ozone Attainment Initiative Photochemical Modeling Study – Draft Modeling Protocol, May 2020,Ramboll, https://www.wrapair2.org/pdf/NM_OAI_Modeling_Protocol_v5.pdf

Beyond the statutory authority provided to NMED by the Air Quality Control Act, Governor Michelle Lujan Grisham issued Executive Order ("E.O.") 2019-003, which directs NMED and the New Mexico Energy, Minerals, and Natural Resources Department ("EMNRD") to "jointly develop a statewide, enforceable regulatory framework to secure reductions in oil and gas sector methane emissions and to prevent waste from new and existing sources". EMNRD adopted rules effective at the beginning of 2021 that prohibits venting and limits flaring at oil and gas well sites to minimize methane emissions.

Under the statutory authority of the OAI and E.O. 2019-003, the Department has developed its first rule to reduce emissions of ozone precursors. Regulations developed under the OAI to reduce emissions of ozone precursor pollutants will have the co-benefit of reducing methane emissions because methane is released along with volatile organic compounds in oil and gas operations. Thus, the Department worked in close coordination with EMNRD in developing 20.2.50 NMAC, and the agencies endeavored to align their respective regulatory regimes as much as possible to avoid duplicative or conflicting requirements.

Beginning in the summer of 2019, the Department began an extensive stakeholder and public outreach process for its OAI and the NMED/EMNRD joint Methane Strategy. In June through August of 2019, NMED and EMNRD held numerous meetings throughout the State to provide information regarding the need for the regulatory initiatives and the relevant authorities for the regulatory actions; to hear input from stakeholders and members of the public; and to answer questions regarding the rulemaking process.

The agencies also convened a Methane Advisory Panel ("MAP"), consisting of technical stakeholders focusing on processes and equipment associated with oil and gas exploration, production, gathering, and processing. The MAP was comprised of 27 members with expertise in various parts of the oil and gas industry and included local and national environmental nongovernmental organizations as well as major and independent industry representatives from the upstream and midstream sectors. Additional expertise was provided by representatives from Los Alamos National Laboratory, Colorado State University, and the New Mexico Institute of Mining and Technology. The MAP met every other week over a four-month period and covered technical topics related to controlling VOC and methane emissions from equipment and operations employed in the oil and natural gas sector. Draft topic reports and all meeting presentations from the MAP meetings were posted online on both agencies' websites. In December of 2019, the MAP released a technical report for public review and input, and the agencies accepted comments on the report through February 20, 2020.

On July 20, 2020, NMED released an early stakeholder engagement draft of its ozone precursor regulation for the purpose of soliciting public and stakeholder input. In August of 2020, the Department met with stakeholder groups and held a public listening session during which participants were encouraged to provide both verbal and written feedback. The Department accepted written comments on the preliminary draft through September 20, 2020. A total of 524 written comments were received during the two-month comment period. From September 2020 through May 2021, the Department reviewed the input received from stakeholders and the public and made substantial revisions to the regulation based on that input.

The proposed draft regulation is the result of this two-year process of extensive public and stakeholder outreach and engagement, all of which is in addition to the public hearing process provided for by the Board's rulemaking procedures at 20.1.1 NMAC. the Department will continue to work diligently beyond the requirements of those procedures to communicate and work with stakeholders and the public regarding the proposed regulation and the hearing process to ensure that everyone who has an interest in the rules can participate in the rulemaking process to the fullest extent possible. NMED's proposed rule

will be brought before the Environmental Improvement Board ("Board") for adoption at a public hearing scheduled to begin on September 20, 2021.

Low Emission/Zero Emission Vehicle Standard

In 2019, Gov. Lujan Grisham announced New Mexico will adopt clean car standards that are more stringent than the federal standards. Pollution from transportation accounts for a large portion of New Mexico's greenhouse gas emissions and contributes heavily to the area's growing ozone problem. New Mexico's rule will adopt California's Low-Emission Vehicle criteria pollutant and greenhouse gas emission regulations and Zero-Emission Vehicle regulations under Section 177 of the Clean Air Act (42 U.S.C. §7507). The timeline for New Mexico to adopt the CA standards is in development, but the standards are likely to have an impact in areas with high levels of on-road emission sources.

DERA Program

In 2005, the U.S. Congress passed the Diesel Emission Reduction Act (DERA) as an amendment to the Energy Policy Act. DERA was designed to reduce diesel emissions from existing diesel fleets that did not meet the recently adopted federal emission standards. The goal of the New Mexico Clean Diesel Program is to reduce the amount of air pollution created by diesel-fueled heavy-duty trucks and buses to which the residents of New Mexico are exposed.[12] Diesel-powered vehicles and equipment account for nearly half of all NO_x and more than two-thirds of all PM emissions from US transportation sources.[13] Since 2008, NMED has administered grant funds for the qualifying diesel emissions reduction projects in San Juan, McKinley, Luna, Santa Fe, Taos, and Bernalillo counties:

- School bus retrofits in Bloomfield, Central Consolidated, Farmington, and Gallup/McKinley County School District;
- Replacement of diesel vehicles with natural gas vehicles for the cities of Deming and Santa Fe, Taos County, and Albuquerque Public Schools; and
- Dock outlets for trailer refrigeration units, aerodynamic fairings, and low rolling resistance tires for New Mexico Association Food Banks.

VW Settlement

In 2015, Volkswagen admitted to purposely employing defeat devices on emissions controls for NOx on some of their Volkswagen, Audi, and Porsche diesel-fueled vehicles. In 2017, the U.S. District Court for the Northern District of California finalized Consent Decrees between Volkswagen, the United States, and the State of California, adopting revisions made by the Trustee. New Mexico was eligible to receive over $17,900,000 to be used for NO_x emission reduction projects.[14]

[12] From *Diesel Emissions Reduction Act*, NMED, https://www.env.nm.gov/air-quality/diesel/

[13] From *Smog, Soot, and Other Air Pollution from Transportation*, Environmental Protection Agency, https://www.epa.gov/transportation-air-pollution-and-climate-change/smog-soot-and-local-air-pollution

[14] From *Volkswagen Settlement Information Fact Sheet*, NMED, https://www.env.nm.gov/wp-content/uploads/sites/26/2017/03/VW_Settlement_InBrief_November2017-1.pdf

The NMED has had two rounds of funding for the Volkswagen Settlement Allocation. NMED approved funding for seven projects in the first funding cycle and 43 projects in the second funding cycle of New Mexico's Volkswagen Settlement Allocation.

First funding cycle projects include new school buses in the Gallup-McKinley and Albuquerque School Districts; a new Public Works Vehicle for San Juan County; electric ground support equipment and associated infrastructure for Southwest Airlines and the Albuquerque International Sunport; as well as compressed natural gas-powered refuse vehicles; and replacing diesel delivery trucks for Sysco Leasing. In total, 123 vehicles in New Mexico were replaced or repowered, reducing NO_x emissions from both on-road and off-road diesel-fueled vehicles and equipment by roughly 160 tons in urban, rural, and Native communities in New Mexico.

In 2019, the Beneficiary Mitigation Plan (BMP) was revised and directed the remaining unallocated funds for future funding cycles to be used for the replacement of diesel-fueled vehicles with electric vehicles (EV), alternate-fueled vehicles, and light-duty zero emission vehicle (LDZEV) supply equipment. These projects will reduce emissions of NO_X by more than 40 tons in areas of New Mexico where residents bear a disproportionate share of NO_X pollution and in areas that are nearing the 2015 National Ambient Air Quality Standard for ground-level ozone.

The State remains committed to allocating the remaining 15% of the total funding (approximately $2.7 million) towards LDZEV infrastructure and has added a goal to focus efforts on a complete statewide electric vehicle charging network.[15]

Provisions for Public and Stakeholder Involvement

The AQB will conduct presentations for the industry, local governments, environmental groups, and school districts to garner support and participation in Ozone Advance. Also, the AQB will hold outreach and education events for businesses and private citizens to involve them in developing a "path forward" program for implementation. This will be done through a variety of projects including the existing partnerships and air quality improvement groups that NMED participates in and the creation of the Permian Basin Air Quality Task Force. NMED will provide additional opportunities to gather stakeholder input, hold ozone community workshops and develop voluntary ozone alert programs. Periodic update meetings will be held to keep stakeholders informed of progress and study results (e.g. rulemaking and modeling results) for all ozone advance path forward initiatives. This will allow for continuous feedback and participation as voluntary control measures, rules and programs are developed.

Joint Advisory Committee

On May 7, 1996, the United States and Mexico included Appendix 1 to Annex V to the "La Paz Agreement" that defined the bi-national Paso del Norte Air Basin and created the committee The Joint Advisory Committee (JAC) is a bi-national group charged with the development and recommendation of air quality improvement initiatives under the La Paz Agreement and EPA's Border Program (i.e., Border 2025). It is comprised of a mixture of federal, state, and local government officials along with private citizens, university officials, and non-governmental organizations from the United States and Mexico. The JAC is governed by operating procedures contained in their by-laws and meets triennially at a rotating location in southern Dona Ana County, New Mexico, El Paso, Texas and Cd. Juárez, Mexico. The JAC's priorities are

[15] From *Volkswagen Settlement*, NMED, https://www.env.nm.gov/vw-settlement/

NMED Exhibit 4 - 0014

developed from the ground up, building upon local stakeholder input and concerns. All JAC meetings are open to the public and time is set aside at the beginning and end of each meeting for public comments.

Four Corners Air Quality Group

The original purpose of the 4CAQTF was to bring together a diverse group of interested parties to learn about and discuss air quality issues in the Four Corners area. Increased development in the Four Corners area including power plants, oil and gas production, and population growth were contributing to air quality concerns. Ozone levels in the region were close to exceeding the health-based national air quality standards for outdoor air. Task Force members developed a broad list of options for improving air quality in the area to aid the regulatory agencies in managing air quality impacts. These options were included in a report that was finalized in November 2007.[16]

Initial work of the 4CAQTF resulted in the implementation of one "interim" recommendation: the Bureau of Land Management required new and replacement internal combustion gas field engines to comply with more stringent emission standards in New Mexico and Colorado. These requirements apply to oil and gas development within the Bureau of Land Management's jurisdiction.[17] As a result of this work, the 4CAQTF continues to operate as the Four Corners Air Quality Group.

The Four Corners Air Quality Group (4CAQG) is a forum for individuals interested in air quality to meet, learn about current conditions, review progress on mitigation of air quality impacts, and generally contribute to clean air in the Four Corners Area. The 4CAQG includes NMED, Colorado Department of Public Health and Environment, US EPA, US Department of the Interior's National Park Service and Bureau of Land Management, US Department of Agriculture's Forest Service, the Southern Ute Indian Tribe, and the Navajo Nation. The Group meets at least once per year and more often if circumstances warrant it.

Permian Basin Air Quality Task Force

The NMED plans to create the Permian Basin Air Quality Task Force to bring together a diverse group of interested parties to learn about and discuss air quality issues in the Permian Basin. Increased oil and gas well development and population growth in the Permian Basin are contributing to air quality concerns. Ozone levels in the region are close to exceeding the health-based national air quality standards.

The first step will be to engage the Texas Commission on Environmental Quality (TCEQ) and the U.S. EPA to join NMED as a founding task force partner. Once this trilateral commitment is established, we can engage and invite other stakeholders in the basin to become task force partners. Potential stakeholders include the oil and gas industry, local governments, environmental groups, and concerned citizens.

The Group will meet annually, biannually, and more often when necessary to discuss rule planning and initiatives. The Task Force members will be encouraged to develop a broad list of options that will aid the regulatory agencies in managing air quality impacts and improving air quality in the basin. These options will be included in a final report.

[16] From *Four Corners Air Quality Group*, NMED, https://www.env.nm.gov/air-quality/fcaqg/
[17] Four Corners Air Quality Task Force Report of Mitigation Options, November 2007, https://www.env.nm.gov/wp-content/uploads/sites/2/2016/11/4CAQTF_Report_FINAL.pdf

Gather Stakeholder Input

Understanding the concerns of impacted communities and stakeholders is an important part of creating an effective plan. As part of this initiative and in addition to the air quality groups listed above, NMED will hold meetings with various groups of stakeholders including environmental groups, tribes, the public, the regulated community, and local governments. The goal of these meetings will be to gather information about stakeholder concerns regarding ozone in their respective region and identify popular strategies that stakeholders are willing to participate in. NMED may also utilize focus groups comprised of various stakeholders to gather feedback on possible emission reduction activities. All these concerns will be taken into consideration as we assess our Ozone Advance plan in the future.

NMED understands that some people may not have the time or means to attend these meetings. To this end, NMED will also provide an opportunity for these groups and individuals to submit concerns and comments electronically, over the phone, or by mail. NMED may also provide surveys and other useful materials for stakeholders to complete.

Ozone Community Workshops and Voluntary Ozone Alert Programs

Community involvement in the Ozone Advance program will include workshops and voluntary ozone alert programs. The workshops will bring together community members and various stakeholders to learn about ozone and its impacts to their health, community, and the environment. This will also include training on how to minimize these impacts, particularly health impacts, during high ozone events and what voluntary actions individuals can do to minimize their ozone contribution.

If communities choose to, they can opt to creating a Voluntary Ozone Alert Program, crafted to the needs of their community. This program can include a variety of activities and projects such as, community-based air monitoring, flag programs, alert programs, and air quality training. These programs will also raise awareness for issues surrounding ozone in these communities.

STATE OF NEW MEXICO
ENVIRONMENTAL IMPROVEMENT BOARD

IN THE MATTER OF PROPOSED NEW REGULATION,
20.2.50 NMAC – *Oil and Gas Sector – Ozone Precursor Pollutants* **No. EIB 21-27 (R)**

DIRECT TESTIMONY OF ELIZABETH BISBEY-KUEHN

My name is Elizabeth Bisbey-Kuehn and I am the Bureau Chief of the Air Quality Bureau ("Bureau") of the New Mexico Environment Department ("NMED" or "Department"). I am presenting this written testimony on behalf of the Department in this proceeding on the Department's proposed new air quality regulation at 20.2.50 NMAC ("Part 50"). This part of my direct testimony will address public and stakeholder engagement in development of Part 50. I will also be presenting testimony on other topics in this rulemaking in separate pieces of pre-filed testimony.

I. QUALIFICATIONS

I have been an employee of the Bureau for over seventeen years, working as a staff member for seven years, staff manager for seven years, and in my current position as Bureau Chief for over three years. As a staff member and staff manager, I oversaw several complex, high-profile projects for the Department, including serving as the Department's technical expert for the Best Available Retrofit Technology analysis for the San Juan Generation Station. I developed multiple general construction permits for the oil and gas industry, led bi-monthly technical meetings for the State's Associated Contractors, drafted technical guidance and policy documents, and represented the Department in multiple public meetings and public hearings.

As the Air Quality Bureau Chief, I am charged with overseeing the air program and ensuring that the program is administered in accordance with the Department's enabling statutes

and the Board's regulations, and with the requirements of the federal Clean Air Act ("CAA") and regulations promulgated by the U.S. Environmental Protection Agency ("EPA") pursuant to the CAA. I manage the four Section Chiefs who oversee the four Sections of the Bureau. I direct the overall management of the Bureau, including the Bureau's resources; staff who enforce the state and federal air quality standards; air quality related planning and policy, operational, permitting, and compliance and enforcement services; financial oversight of the bureau's federal grant and state matching funds; and support services for the Bureau.

My full background and qualifications are set forth in my resume, which is marked as NMED Exhibit 6.

II. THE NMED AND EMNRD METHANE STRATEGY

In Executive Order 2019-03 ("EO 2019-03), Governor Michelle Lujan Grisham directed the New Mexico Environment Department ("NMED") and the Energy, Minerals and Natural Resources Department ("EMNRD") to "jointly develop a statewide, enforceable regulatory framework to secure reductions in oil and gas sector methane emissions and to prevent waste from new and existing sources and enact such rules as soon as practicable." *See* NMED Exhibit 7. At the time EO 2019-03 was issued, the Board did not have authority under the AQCA to pass regulations for methane that were more stringent than federal regulations, but it did have authority to pass more stringent regulations for VOCs for purposes of reducing ambient ozone concentrations. Because the ozone precursor VOC is emitted along with methane in oil and gas operations, requirements that reduce VOC emissions necessarily reduce methane emissions. Thus, the Boards regulatory authority for ozone precursors formed the basis for NMED's regulatory strategy under to the Governor's directive in EO 2019-03.

Methane Strategy Public Outreach

NMED held public engagement sessions to provide an initial opportunity for the public to be heard and ask questions answered early in the rulemaking process. Figure 1 shows NMED's Methane Strategy public participation schedule.

January 2019	Gov. Lujan Grisham signs Executive Order 2019-03 committing New Mexico to essential climate change action	
NMED Public Participation		
August 6, 2020	Listening session on NMED/EMNRD draft rules	Presentation (NMED Exhibit 8)

Figure 1. NMED's Methane Strategy public participation schedule

The Methane Advisory Panel

To move forward on the Governor's directives in a manner grounded in science, innovation, collaboration and compliance, NMED and EMNRD sought nominations for, and then convened, a technical Methane Advisory Panel ("MAP"). The purpose of the MAP was to bring together technical stakeholders to: (1) identify processes and equipment used in oil and gas production, gathering, and processing operations that are associated with release of methane gas; (2) to develop emission and waste-based standards for those processes and equipment; and (3) propose monitoring, recordkeeping and reporting structures. The MAP process yielded a technical background document identifying specific oil and natural gas equipment and processes for consideration in moving forward with an enforceable regulatory strategy.

The MAP was comprised of 27 individual members representing environmental organizations, the Nations, tribes and pueblos in New Mexico, and the oil and gas industry including small and large independent operators as well as the major, vertically-integrated companies. Industry representatives included companies with interests in the Permian and San Juan Basins that drill, develop, complete, and operate oil and natural gas wells and infrastructure. Additional technical expertise was provided by professionals from Los Alamos National Laboratory, Colorado State University and the New Mexico Institute of Mining and Technology.

The MAP met in series of four-hour meetings held every other week over a twelve-week period from August through November 2019. During these meetings, there were facilitated discussions focused on reducing methane waste and VOC emissions by equipment type and processes. There were ten topics covered during the MAP meetings:

- Section 1 - Pneumatic Controller/Pump
- Section 2 – Leak Detection and Repair

- Section 3 – Dehydration Units
- Section 4 – Compressors and Engines
- Section 5 – Infrastructure and Planning
- Section 6 – Venting and Flaring
- Section 7 – Workovers/Liquids Unloading
- Section 8 – Separators/Heaters/Storage Vessels
- Section 9 – Completions/Recompletions and Stimulations
- Section 10 – Cross-Cutting Path Forward Report

All technical documents were posted online throughout the process, along with the final draft technical report.

The MAP process culminated with a draft technical report, attached as NMED Exhibit 10, which provides an informational foundation on the technical side of the ways in which the oil and gas industry emits methane (and therefore VOCs), and what methods can curb methane emissions and prevent waste of this resource. The Draft MAP technical report was released for public comment December 19, 2019 through February 20, 2020, and approximately 42 comments were received.[1]

III. THE OZONE ATTAINMENT INITIATIVE

The Ozone Attainment Initiative ("OAI") is a state program developed by NMED for the purpose of reducing emissions of ozone precursor chemicals NOx and VOCs in areas of the State where ozone levels are within 95% of the 2015 8-hour ozone NAAQS. Through the OAI, NMED

[1] Comments for the Draft MAP technical report can be found at: https://www.env.nm.gov/new-mexico-methane-strategy/methane-advisory-panel.

has developed a plan, including voluntary measures and mandatory regulations, to reduce ozone precursors in areas with high ozone levels.[2]

In conjunction with NMED's Methane Strategy Public Participation, the Bureau hosted four public outreach events that focused on the development of the Ozone Attainment Initiative and associated rulemakings. These meetings were held at key locations throughout the state, including the Permian and San Juan Basins. The September 2019 Initial Public Outreach meeting presentation, attached as NMED Exhibit 11, provides a brief summary of ozone and its health effects, the OAI, and stakeholder involvement. Figure 2 provides an outline of the AQB's public outreach.

	the NM Sunshine Portal, Tribal contacts. A listserv announcement was also released.

Figure 2. OAI Public Outreach

IV PRE-PETITION DRAFT OF PART 50 AND PUBLIC COMMENT PERIOD

Proposed Part 50 is the first rulemaking under the OAI. The Department conducted extensive pre-petition outreach on the proposed rules, including a pre-petition draft rule, attached as NMED Exhibit 12, issued for stakeholder and public input. The pre-petition draft of Part 50 was released on July 20, 2020 for a 30-day informal comment period, which was extended to September 16, 2020. *See* Figure 2. The stakeholder and public comments received on the July 20, 2020 pre-petition draft are available on the Department's website.[3] During this comment period, NMED received comments from the general public, environmental organizations, industry, elected officials, local governments, tribal officials, and EPA. Based on the comments received on the July 20, 2020 draft, the Department made substantial revisions to the proposed rule that are reflected in the version included as part of the Department's Petition for Regulatory Change filed with the Board on May 6, 2021.

Liz Bisbey-Kuehn
Bureau Chief
Air Quality Bureau
525 Camino de los Marquez, Suite 1
Santa Fe, NM 87507
505-476-4305

Education

Attended M.Sc. Program in Soil Science, 08/2003-12/2004
University of Kentucky, Lexington, KY

B.S. in Environmental Studies
University of Iowa, Iowa City, IA., conferred May 2002.

Employment Experience

08/2013 to 03/2018 - Bureau Chief, Air Quality Bureau, NMED
My responsibilities include providing leadership and supervision of the administrative, financial, compliance, permitting, operations, and planning sections of the Air Quality Bureau. I direct the overall management of resources, including staff who enforce the state and federal air quality standards; provide air quality related planning and policy, operational, permitting, and compliance and enforcement services to New Mexico employers; financial oversight of the Bureau's federal grant and state matching funds, and support services for the Bureau.

08/2013 to 03/2018 - Minor Source Section Manager, Air Quality Bureau, NMED
My responsibilities included management of the Minor Source Permitting Section and direct management of six (6) full time Environmental Scientists and Specialists. The Section reviews complex air quality permit applications for the most technically complex and diverse industrial facilities, including oil and gas, construction, manufacturing, agricultural, power generation, and chemical processing plants.

01/2013 to 08/2013 - Acting Technical Services Manager, Air Quality Bureau, NMED

05/2012 – 10/2012 - Acting Minor Source Section Manager, Air Quality Bureau, NMED

02/28/2005 to 08/2013 - Permit Specialist, Minor and Major Source Permit Section, Air Quality Bureau, NMED
My primary responsibilities involve performing technical analyses of air quality permit applications; drafting permits in accordance with federal and state regulations; accomplishing special projects in support of the section, mentoring new staff, and assisting the regulated community and concerned citizens.

08/2002-05/2003 and 08/2003-12/2004
Teaching and Research Assistant, University of Kentucky, Lexington, KY
Introduction to Soil Science, Agronomy Department

Teaching Assistant, University of Iowa, Iowa City, IA
Introduction to Earth Systems Science, Geography Department
Introduction to Environmental Science, Geoscience Department

Professional Development and Training Courses

Effective Permit Writing
Sources and Control of PM Emissions
Introduction to Hazardous Air Pollutants
Control of Gaseous Emissions
Advance PSD Permitting
Permit Practices and Procedures I and II
NSR Reform and Advanced PSD
Basic NSR/PSD
Environmental Negotiations

EXECUTIVE ORDER 2019-003

EXECUTIVE ORDER ON ADDRESSING CLIMATE CHANGE AND ENERGY WASTE PREVENTION

I. Background and Purpose

To further New Mexico's responsibility and opportunity to build a clean energy future for our people, limit adverse climate change impacts that harm our natural and cultural heritage, prevent the waste of New Mexico energy resources and reduce pollution that threatens human health, I hereby issue this Executive Order.

II. Climate Change

WHEREAS, climate change creates new risks and exacerbates existing vulnerabilities in communities across New Mexico and presents growing challenges for human health and safety, quality of life, and the rate of economic growth.

WHEREAS, in a special report authored by the United Nations and World Meteorological Organization Intergovernmental Panel on Climate Change ("IPCC"), it was found that the planet has as little as 12 years to take meaningful climate action in order to limit the increase in global average temperature to 1.5°C – the level necessary to forestall dramatic climatic changes that will further imperil our water supplies.

WHEREAS, carbon dioxide, methane, nitrous oxide, hydrofluorocarbons (HFCs), perfluorocarbons, and sulfur hexafluoride are recognized as the six greenhouse gases contributing to climate change.

WHEREAS, in 2009, the U.S. Environmental Protection Agency ("EPA") found that these "six greenhouse gases taken in combination endanger both the public health and the public welfare of current and future generations."

WHEREAS, in May 2010, the National Research Council, the operating arm of the National Academy of Sciences, published an assessment which concluded that "climate change is occurring, is caused largely by human activities, and poses significant risks for - and in many cases is already affecting - a broad range of human and natural systems."

WHEREAS, carbon dioxide is emitted through the combustion of fossil fuels for electricity generation and for combustion-engine vehicles.

WHEREAS, the U.S. Energy Information Administration finds that the transportation sector is the largest anthropogenic source of carbon dioxide emissions in the United States.

WHEREAS, methane is a powerful greenhouse gas, 84 times more effective at trapping heat than carbon dioxide over a 20-year timeframe.

WHEREAS, the oil and gas industry is the largest industrial source of methane emissions.

WHEREAS, HFCs are potent greenhouse gases used in the refrigeration, air conditioning, and foam industries, for which alternatives are readily available and approved for use by the EPA.

WHEREAS, governments and global industries have expressed widespread support for a global transition to alternatives to HFCs, as agreed to in the 2016 Kigali Amendment to the Montreal Protocol.

WHEREAS, New Energy Conservation Code templates are developed by the International Code Council every three years. New Mexico adopted and is using the 2009 International Energy Conservation Code (IECC), which puts the state three full code cycles behind. As newer, safer, and more durable building materials, technologies, and techniques become more commonplace, they are voted on and incorporated into the model energy code.

WHEREAS, energy codes create safe, resilient, and habitable structures based on building science and physics principals for heat, air, and moisture transfer—all of which have real and significant impacts on human lives and health; they also can cut utility bills in buildings.

WHEREAS, low- and zero-emission vehicles can provide long-term public health, environmental, and climate benefits.

WHEREAS, federal rollbacks of climate protections, waste prevention, and clean air rules have made it imperative for New Mexico to act to protect our citizens and our economy from the damages of climate change impacts.

WHEREAS, emissions, venting, flaring, and leaks of natural gas by New Mexico's oil and gas industry results in the waste of an important source of domestic energy to the tune of an estimated $244 million per year.

WHEREAS, oil and gas production growth in the New Mexico Permian Basin resulted in an 18% increase in venting and flaring volumes during the first seven months of 2018 compared to 2017 according to official state statistics.

WHEREAS, efforts to reduce methane emissions throughout New Mexico will have a significant climate benefit as well as prevent the waste of energy resources.

WHEREAS, science, innovation, collaboration and compliance efforts can prevent waste, methane emissions and improve air quality while creating jobs for New Mexicans.

III. Directives

NOW, THEREFORE, by the authority vested in me as Governor by the Constitution and laws of the State of New Mexico, IT IS ORDERED:

1. The State of New Mexico will support the 2015 Paris Agreement Goals by joining the U.S. Climate Alliance. New Mexico's objective is to achieve a statewide reduction in greenhouse gas emissions of at least 45% by 2030 as compared to 2005 levels.

2. The Secretary (or designee) of each state agency shall serve on an interagency Climate Change Task Force which is hereby established. The Secretary (or designee) of the Energy, Minerals and Natural Resources Department ("EMNRD") and the Environment Department ("NMED") shall serve as the Co-Chairs, convening meetings, facilitating stakeholder participation, and providing strategic direction for achieving the above goals in developing a New Mexico Climate Strategy document.

3. All State Agencies shall evaluate the impacts of climate change on their programs and operations and integrate climate change mitigation and adaptation practices into their programs and operations. The agencies shall share these actions with the Climate Change Task Force for inclusion into the New Mexico Climate Strategy document.

4. EMNRD and NMED shall work with stakeholders on legislation to increase the New Mexico renewable portfolio standard ("RPS") and increase New Mexico's energy efficiency standards for electric utilities.

5. The Climate Change Task Force shall evaluate policies and regulatory strategies to achieve reductions in greenhouse gas pollution, consistent with the targets set out above, across all categories of emission sources. Such policies and regulatory strategies shall include, but not be limited to, the following:

    a. Adoption of a comprehensive market-based program that sets emission limits to reduce carbon dioxide, and other greenhouse gas pollution across New Mexico;
    b. Adoption of approaches to reduce greenhouse gas and criteria pollutant emissions from light-duty vehicles sold in state, including Low Emission Vehicle (LEV) emission standards and Zero Emission Vehicle (ZEV) performance standards;
    c. Adoption of building codes; and
    d. Collaboration with the Renewable Energy Transmission Authority (RETA) to identify transmission corridors needed to transport the state's renewable electricity to market.

6. EMNRD and NMED shall jointly develop a statewide, enforceable regulatory framework to secure reductions in oil and gas sector methane emissions and to prevent waste from new and existing sources and enact such rules as soon as practicable.

7. EMNRD and NMED shall coordinate as much as possible with the New Mexico State Land Office and federal bureaus and agencies that manage land and natural resources in New Mexico to help advance the priorities identified in this Executive Order.

8. The Climate Change Task Force will develop a *New Mexico Climate Strategy* document with initial recommendations and a status update, where applicable, to the Governor by September 15, 2019.

IV. Disclaimer

Nothing in this Executive Order is intended to create a private right of action to enforce any provision of this Order or to mandate the undertaking of any particular action pursuant to this Order; nor is this Order intended to diminish or expand any existing legal rights or remedies.

THIS ORDER supersedes any other previous orders, proclamations, or directives in conflict. This Executive Order shall take effect immediately and shall remain in effect until such time as it is rescinded by the Governor.

Developing New Mexico's Methane Strategy

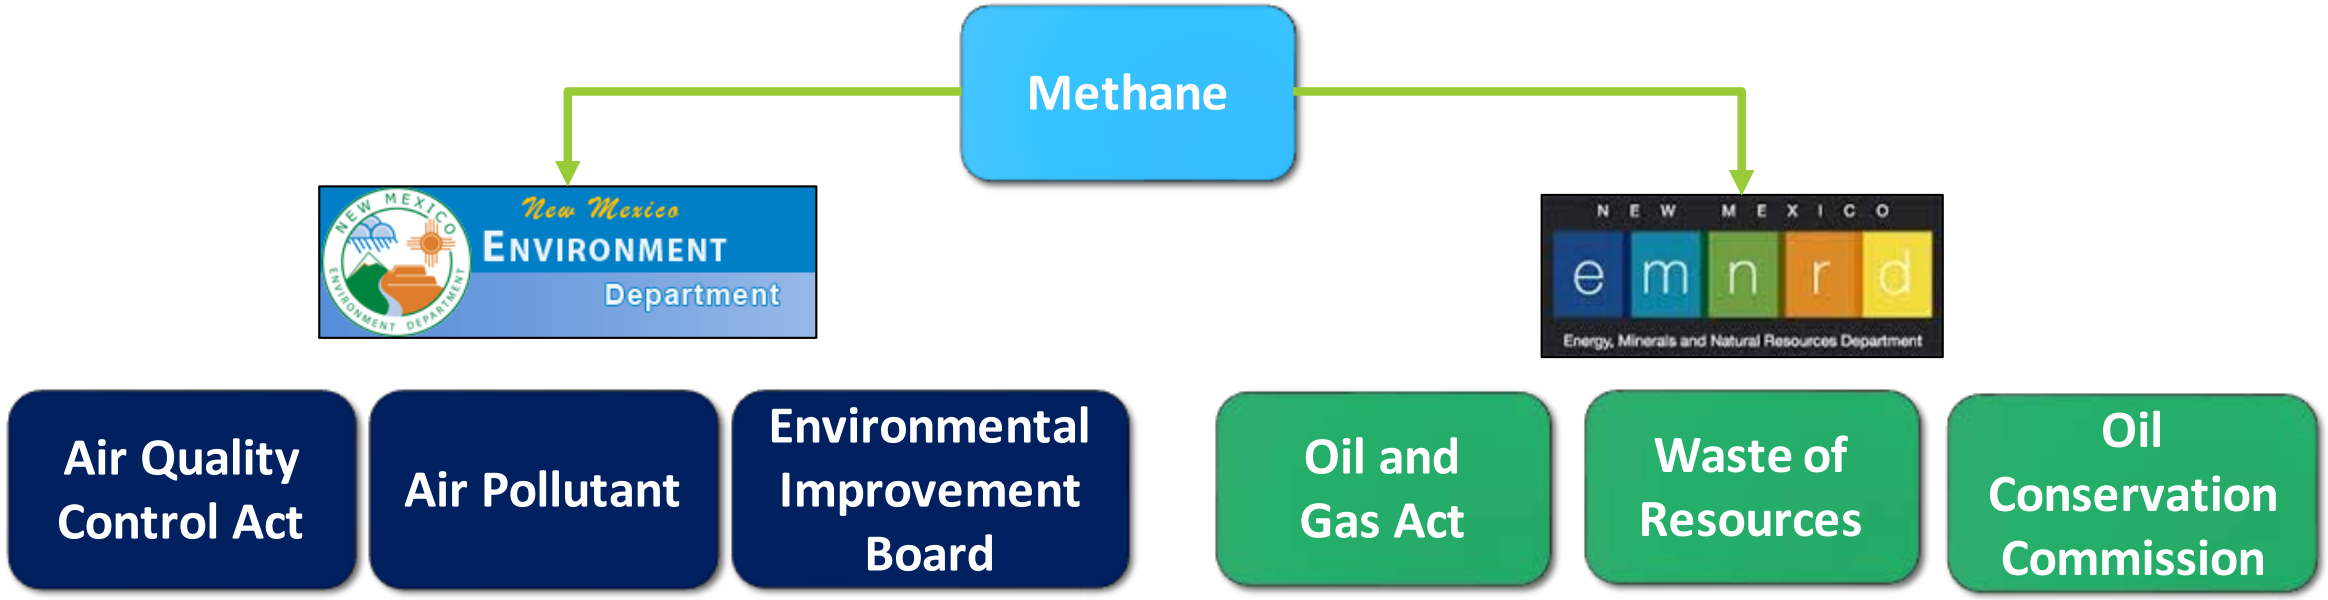
*"**EMNRD and NMED shall jointly develop a statewide, enforceable regulatory framework to secure reductions in oil and gas sector methane emissions and to prevent waste from new and existing sources and enact such rules as soon as practicable."***

- Governor Michelle Lujan Grisham

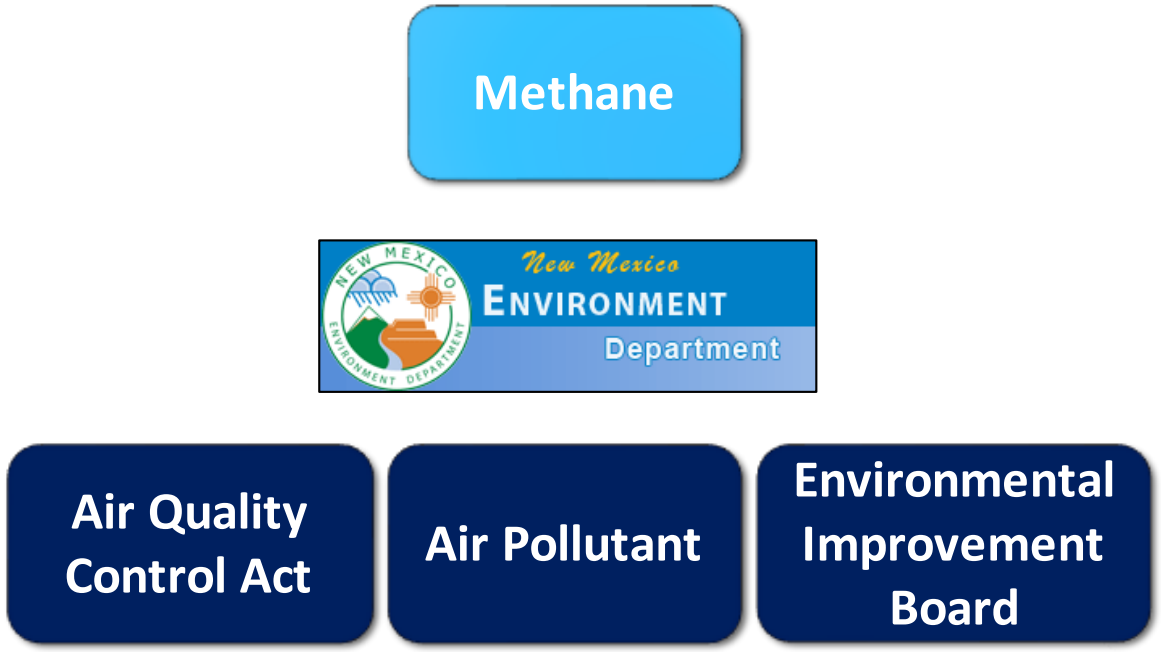
Developing the Rule

Science: Using the best available science to inform our decision-making in protecting public health, the environment and minimizing waste.

Innovation: Employing creative engineering and technological solutions to address the public health, environmental and waste challenges.



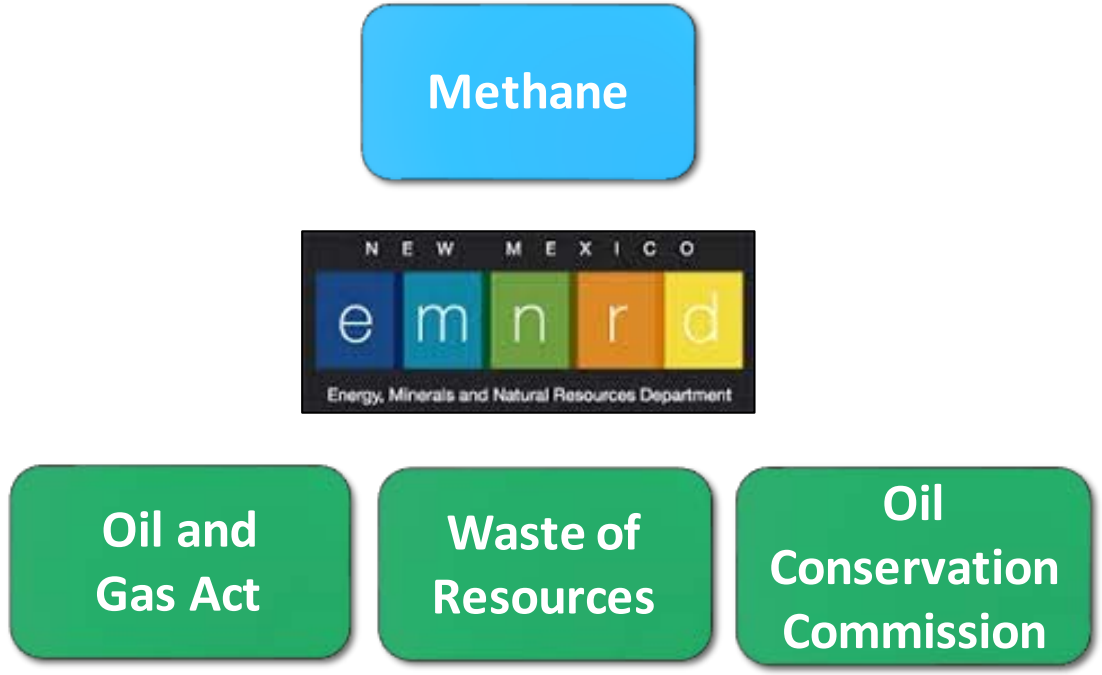
Collaboration: Engaging communities and interested stakeholders in our methane strategy decision-making.



Compliance: Ensuring meaningful compliance with state regulations and permits.

NMED Exhibit 8 - 0007

Developing New Mexico's Methane Strategy



Developing New Mexico's Methane Strategy

- The New Mexico Environment Department will regulate methane emissions from oil and natural gas operations.
- The Air Quality Control Act provides the legal authority.
- Proposed rules are reviewed and adopted through the Environmental Improvement Board.

Developing New Mexico's Methane Strategy

- The New Mexico Energy, Minerals and Natural Resources Department will regulate to prevent the waste of methane from oil and natural operations.
- The Oil and Gas Act provides the legal authority.
- Proposed rules are reviewed and adopted through the Oil Conservation Commission.

NMED Draft Rule Summary

NEW MEXICO ENERGY, MINERALS AND NATURAL RESOURCES DEPARTMENT

NEW MEXICO ENVIRONMENTAL DEPARTMENT

NMED Draft Ozone Precursor Rules

- NMED's enabling statute prohibits the state from directly regulating methane
- Statute requires the EIB to adopt regulations to control emissions of ozone precursors in areas of the state that exceed 95% of the ozone NAAQS (70 ppb)
- Currently seven counties exceed 95% of the standard. At least five of those counties are located in the San Juan and Permian Basins
- A preliminary draft was released for public input in advance of the formal rulemaking petition with the EIB
- We invite the public and stakeholders to provide us with feedback during this initial public input period, including feedback on the proposed language.
- Specifically seeking feedback on Alternative Monitoring Strategies (AMS) for to-be developed technology to have an onramp into the rule
- Need feedback on how to ensure AMS are enforceable, effective, and equivalent

NMED Draft Ozone Precursor Rules

NMED's draft rules target oil and gas industry equipment that emits VOCs and NOx. The draft rules establish requirements to reduce VOCs and NOx emissions from several types of equipment and processes:

- Hydrocarbon liquid loading/unloading: Requires control of VOC emissions from new and existing sources. Current requirements are zero control; rule requires 95% control
- Pig launching/receiving: Requires reductions of VOC emissions from new and existing sources. Current requirements are zero control; rule requires 95% control
- Glycol dehydrators: Requires control of VOC emissions from new and existing sources; more stringent than current state or federal standards
- Engines: Requires reduction in NOx and VOC from new and existing sources
- Equipment leaks: Requires control of VOC emissions from new and existing sources
- Heaters: Requires reduction of NOx emissions from existing sources.

NMED Draft Ozone Precursor Rules

NMED's draft rules target oil and gas industry equipment that emits VOCs and NOx. The draft rules establish requirements to reduce VOCs and NOx emissions from several types of equipment and processes:

- Storage tanks: Requires control of VOC emissions from new and existing sources with a potential to emit greater than 2 tons per year
- Well workovers: Requires methods to reduce VOC emissions from new and existing sources and notification to nearby residents
- Gas well liquids unloading: Requires methods to reduce VOC emissions from new and existing sources
- Compressor seals: Requires control of VOC emissions from new and existing sources
- Pneumatic controllers: Requires control of VOC emissions from new and existing sources with incentives to use low- to no-emission equipment through monitoring, recordkeeping and reporting
- Evaporative ponds: Requires control of VOC emissions from new and existing sources
- Standards for stripper wells and low emitting facilities: Requires monitoring of actual oil and gas throughput, emissions tracking for new and existing individual facilities and affirmative requirements to maintain equipment to prevent emissions

EMNRD Draft Rule Summary

NEW MEXICO ENERGY, MINERALS AND NATURAL RESOURCES DEPARTMENT

NEW MEXICO ENVIRONMENTAL DEPARTMENT

NMED Exhibit 8 - 0015

EMNRD Draft Waste Rule – Phase 1 Data and Reporting

- Having accurate data is critical to establishing meaningful baselines and enforceable goals to reduce natural gas waste.

- Data currently being reported is often inconsistent

- What does Phase 1 include?
  - Defines waste to include gas that is vented and flared;
  - Requires operators to measure and report all venting and flaring during operations;
  - Requires operators to disclose venting and flaring to mineral interest owners who own a share of the natural gas being wasted;
  - Exempts venting and flaring during emergencies;
  - Provides flexibility for stripper wells, which operate on the economic margin; and
  - Establishes an enforceable target for Phase 2, which requires operators to reduce natural gas waste

NMED Exhibit 8 - 0016

EMNRD Draft Waste Rule- Phase 2 Gas Capture Plan

- Starting from the current level of natural gas waste identified in Phase 1, each operator must reduce their waste by a fixed amount each year to achieve a gas capture rate of 98% by December 31, 2026.

- What does Phase 2 include?
  - Applies to operators in upstream (production) and midstream (gas gathering and boosting) sectors;
  - Includes design standards for gathering pipelines;
  - Allows each operator to decide how it will meet the statewide target, providing flexibility and opportunity for innovation in the industry;
  - Increases the statewide target each year to reduce natural gas waste over time
  - Incentivizes methane detection flyovers
  - Authorizes enforcement action if operators do not meet the gas capture targets:
    - Operators may be forced to cut back on production or shut in wells
    - Establishes new drilling permit approval criteria based off meeting gas capture targets, operators must demonstrate compliance or be at risk of not receiving new permit approval

Methane is a **potent greenhouse gas** with a global warming potential 25 times greater than that of carbon dioxide.

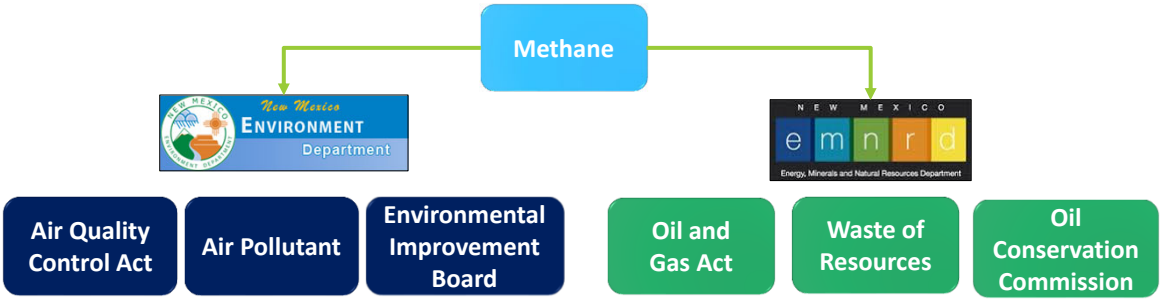
New Mexico Greenhouse Gas Emissions

New Mexico Methane Emissions

7

Developing New Mexico's Methane Strategy

In 2018, oil and natural gas companies reported over **36 billion cubic feet of vented or flared natural gas**. This information was collected using the New Mexico Oil Conservation Division's required production reports (known as C115 reports).



This equated to approximately **$10 million in lost revenues** to New Mexico in 2018.

8

8

Developing New Mexico's Methane Strategy

9

9

Developing New Mexico's Methane Strategy

New Mexico Environment Department

Methane from the oil and natural gas industry is **packaged with other pollutants:** volatile organic compounds (VOCs), which are a key ingredient in ground-level ozone (smog); and a number of other pollutants known as "air toxics" – in particular, benzene, toluene, ethylbenzene and xylene.

N E W M E X I C O e m n r d Energy, Minerals and Natural Resources Department

Methane can be a **waste product** from the oil and natural gas industry. This occurs through the venting and flaring of methane at various points across the oil and gas value chain. When a resource is wasted, the state of New Mexico is no longer able to collect royalties on the waste, and the resource is not available for future beneficial use.

10

Developing New Mexico's Methane Strategy

Waste Reported to EMNRD

Year	Venting	Flaring	Total
2016	3,376,009	21,799,677	25,175,686
2017	2,123,452	14,886,332	17,009,784
2018	3,462,237	32,749,804	36,212,041

*Values in Mscf
**Values reported in C115 form

11

11

Developing New Mexico's Methane Strategy

- The Air Quality Control Act requires the State to develop a plan, including the adoption of regulations, to reduce ozone precursors (VOC and NOx) in areas where monitored ozone levels are greater than 95% of the ozone standard.
- NMED is developing rules targeting VOC and NOx reductions in seven counties. **Such reductions in VOC will collaterally reduce methane.**
- Multiple stages of stakeholder and public engagement are planned.
- Outreach to the general public, industry, local and tribal governments will be followed by draft rules.

Seven Counties:

Bernalillo

Chavez

Doña Ana

Eddy

Lea

Rio Arriba

San Juan

New Mexico Environment Department

12

12

Developing New Mexico's Methane Strategy

- NMED is currently gathering or developing information related to ozone formation science in the seven counties; ozone-related health effects; monitoring data and source-specific emission information.
- In adopting regulations, state law requires the EIB to consider:

1. Public interest, including the social and economic value of the sources of emissions;
2. Energy, environmental, and economic impacts;
3. Efforts by sources to reduce emissions prior to the effective date of the rule; and the remaining useful life of existing sources.

New Mexico Environment Department

13

13

Developing New Mexico's Methane Strategy

- New Mexico Oil and Gas Act:
  - Written in 1935 and amended to prevent waste, protect correlative rights, and protect public health and the environment (70-2-12 NMSA)
  - The Oil and Gas Act prohibits "waste" from oil and gas production.
- To prevent waste of gas resources, the OCD has a "no vent or flare" rule.
  - Rule 19.15.18.12(A) NMAC, titled "Casinghead Gas" states: An operator shall not flare or vent casinghead gas produced from a well after 60 days following the well's completion

NEW MEXICO emnrd Energy, Minerals and Natural Resources Department

14

14

Developing New Mexico's Methane Strategy

- EMNRD will review the current rules governing the prevention of waste to determine what changes in rules and procedures are necessary.
- EMNRD will seek feedback from stakeholders on various options to address waste issues.
- EMNRD will develop draft rule proposals based on feedback during initial outreach.
- Draft rule changes will be made available for comment as part of the public outreach.

Developing New Mexico's Methane Strategy

- Methane Advisory Panel (MAP) formed, consisting of technical stakeholders focusing on processes and equipment associated with exploration, production, gathering and processing.
- Members included local and national eNGOs, major and independent upstream/midstream industry.
- Technical guests included academia and technology companies
- Charge to the MAP:
  - Develop emission- and waste-based standards for equipment and operations
  - Propose monitoring, recordkeeping and reporting structures

18

18

Developing New Mexico's Methane Strategy

- MAP Meeting Structure-
  - Two, four hour meetings every other week
  - Held over a twelve week period (mid August thru November)
  - Facilitated discussion focused on reducing waste and VOC emissions by equipment type and processes
  - Draft topic reports, documents and presentations posted online as developed
- Draft MAP report posted for a 60 comment period ending 2/20/2020

19

19

Developing New Mexico's Methane Strategy

Report Topics:

- Completions and Simulations
- Workovers
- Heater Treaters
- Venting and Flaring
- Infrastructure Planning
- Pneumatic Controllers and Pumps
- Leak Detection
- Compressors and Engines
- Workovers Liquids Unloading
- Separators/Heaters/ Storage Vessels
- Completions/Recompletions and Stimulations
- Dehydration Units

20

20

Developing New Mexico's Methane Strategy

How to engage in the process:

- **Phase 1 (2019):** Follow the MAP, attend public meetings, and provide input.
- **Phase 2 (2020):** Follow and provide public input during rulemaking development for OCC and EIB: https://www.env.nm.gov/new-mexico-methane-strategy/

Health Effects Institute-Energy

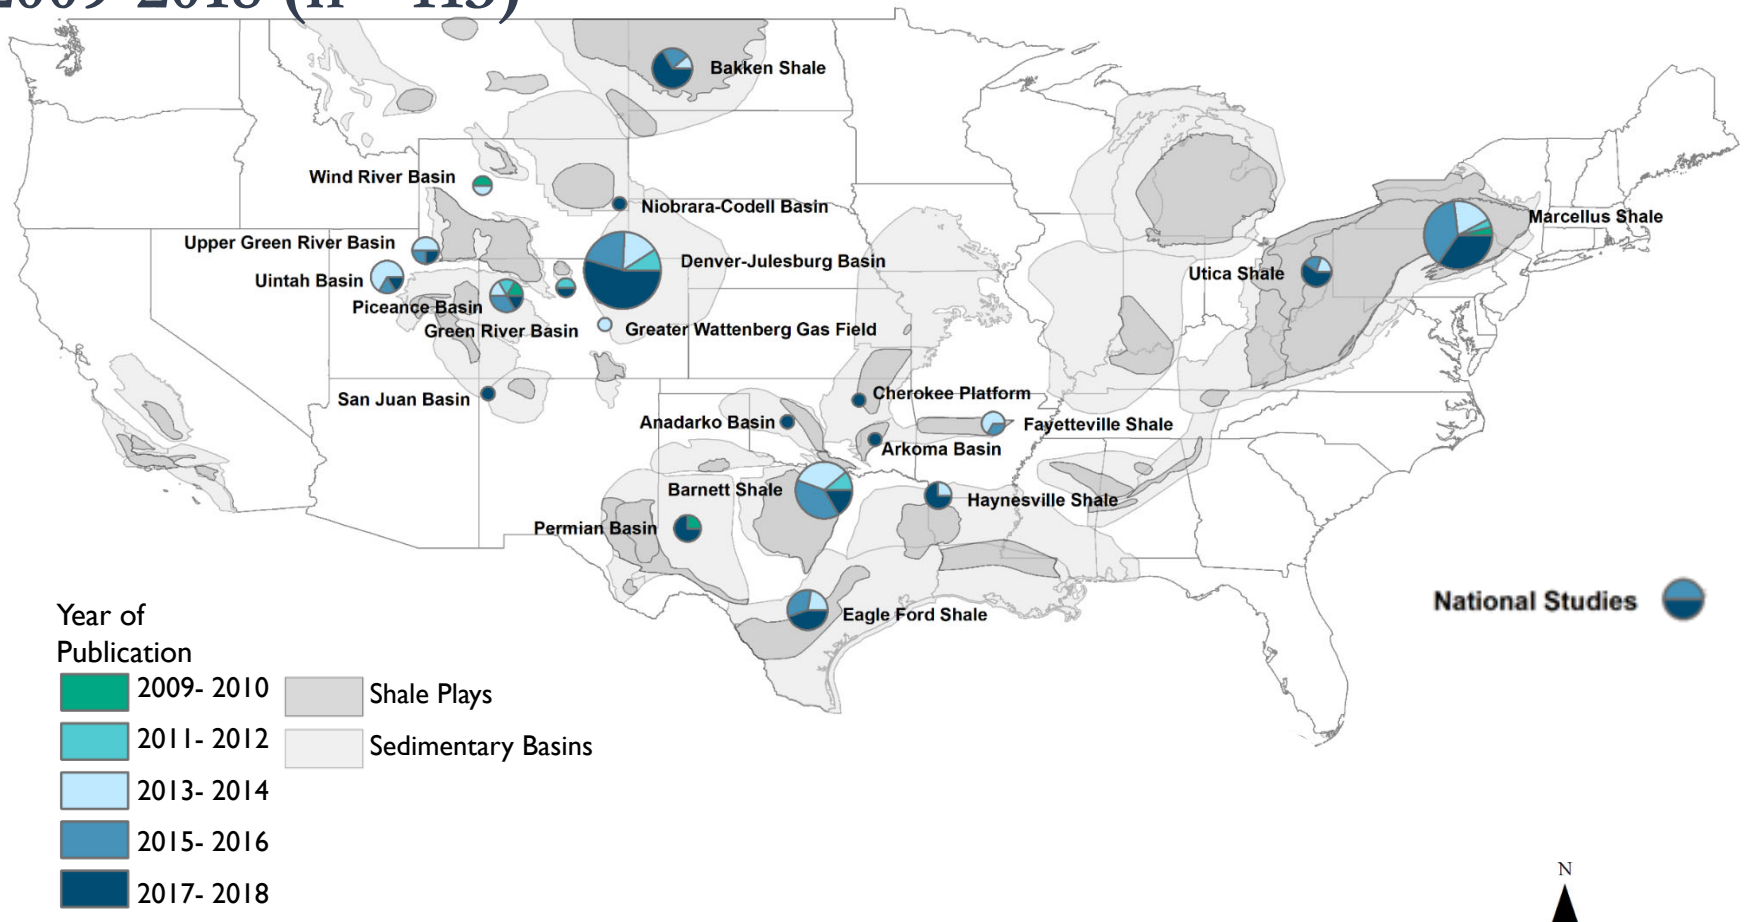
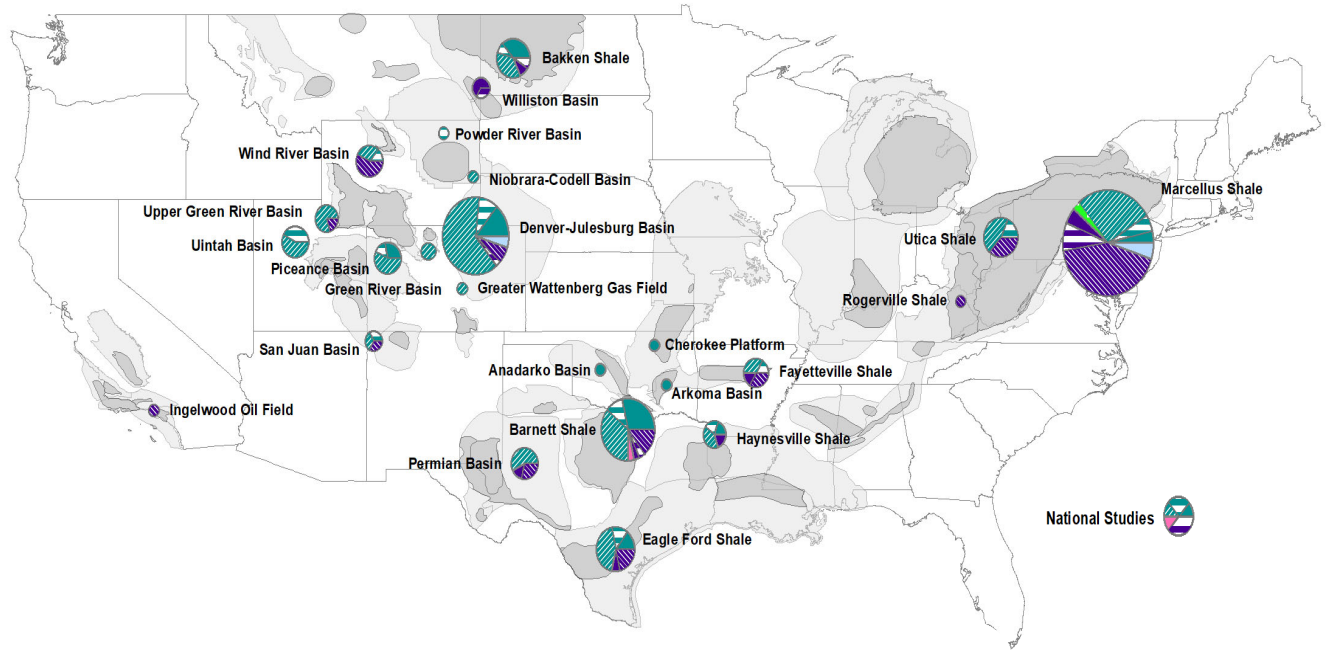
A ***new national research program***



- Research on human exposures associated with onshore development of oil and natural gas from shale and other unconventional resources across the United States
- As feasible and appropriate based on findings from the exposure studies, targeted efforts to assess the potential health effects that might result from exposures

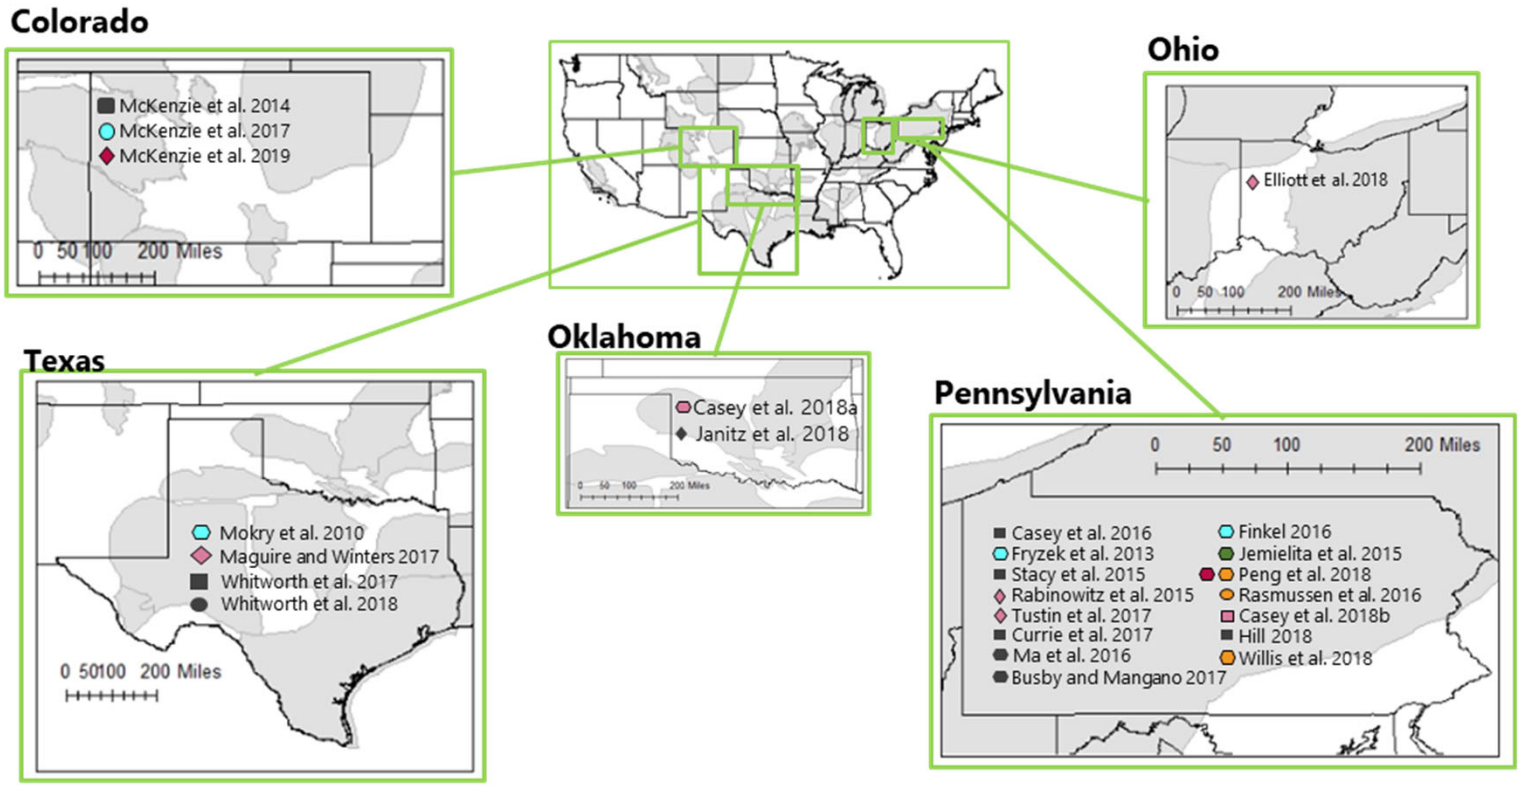
- Independent, nonprofit corporation chartered to provide policy-relevant, high-quality, and impartial science
- Funded jointly by government and the oil and natural gas industry
- Funds research that is selected, conducted, overseen, and reviewed independently of our sponsors

What we would like to know to assess health risk



Air Studies by Location and Year of Publication for 2009-2018 (n= 113)

*Largest chart represents 37 studies. Smallest represents 1 study.



Studies Monitoring or Modeling Levels of Chemical and Non-Chemical Agents (n=187)

Largest chart represents 80 studies. Smallest represents 1 study

HEI-Energy 2019 review of epidemiology literature

Studies displayed by location, study design, and assessed outcomes

Studies published since review:
Apergis et al. 2019; Brown et al. 2019; Casey et al. 2019; Denham et al. 2019; McKenzie et al. 2019.

Concluding Remarks

- Ongoing research about potential exposures and health effects associated with unconventional oil and gas development
- Next steps for the *Health Effects Institute-Energy*: funding community exposure research in multiple regions of the United States

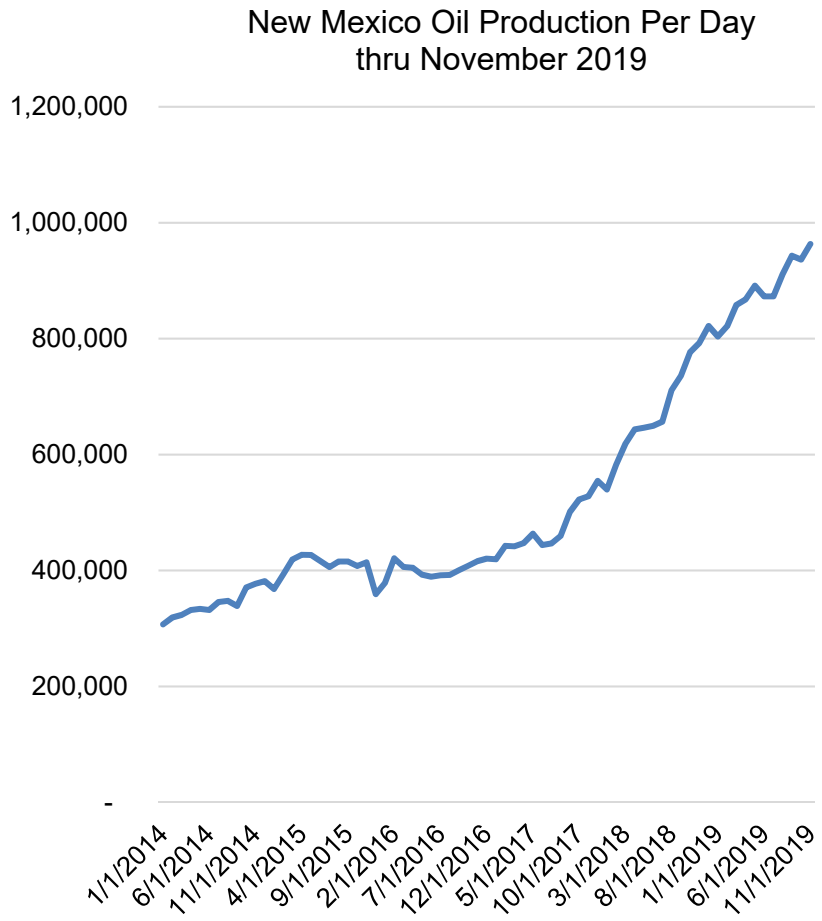
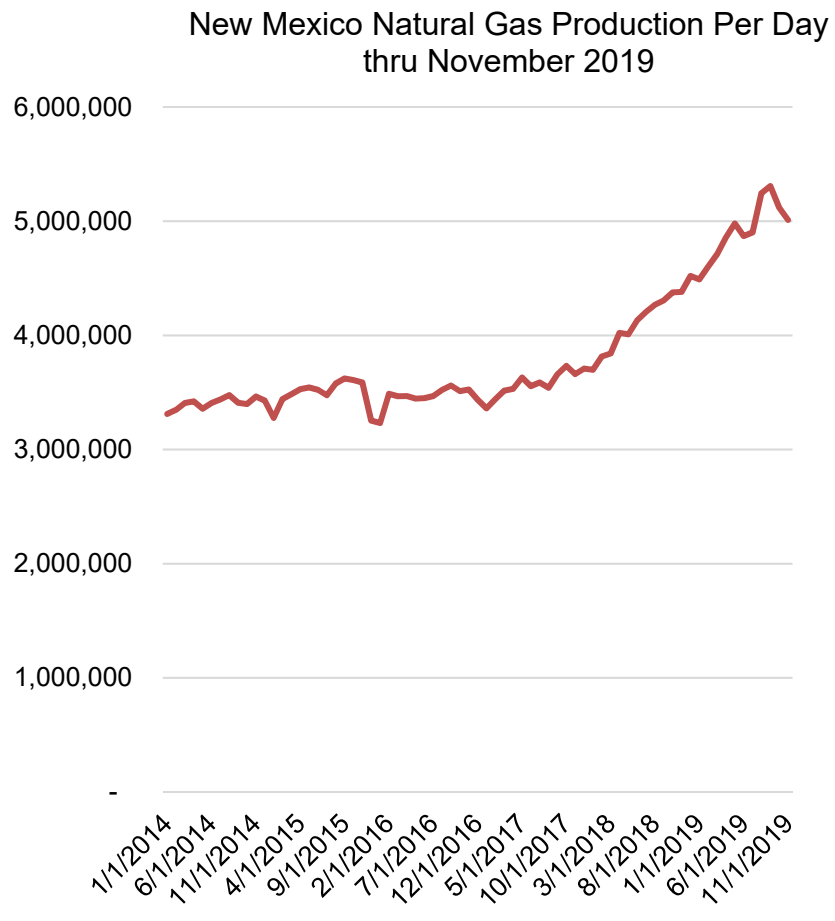
NEW MEXICO LEGISLATIVE FINANCE COMMITTEE

Overview of Economic and Fiscal Impacts of the Oil and Gas Industry in New Mexico



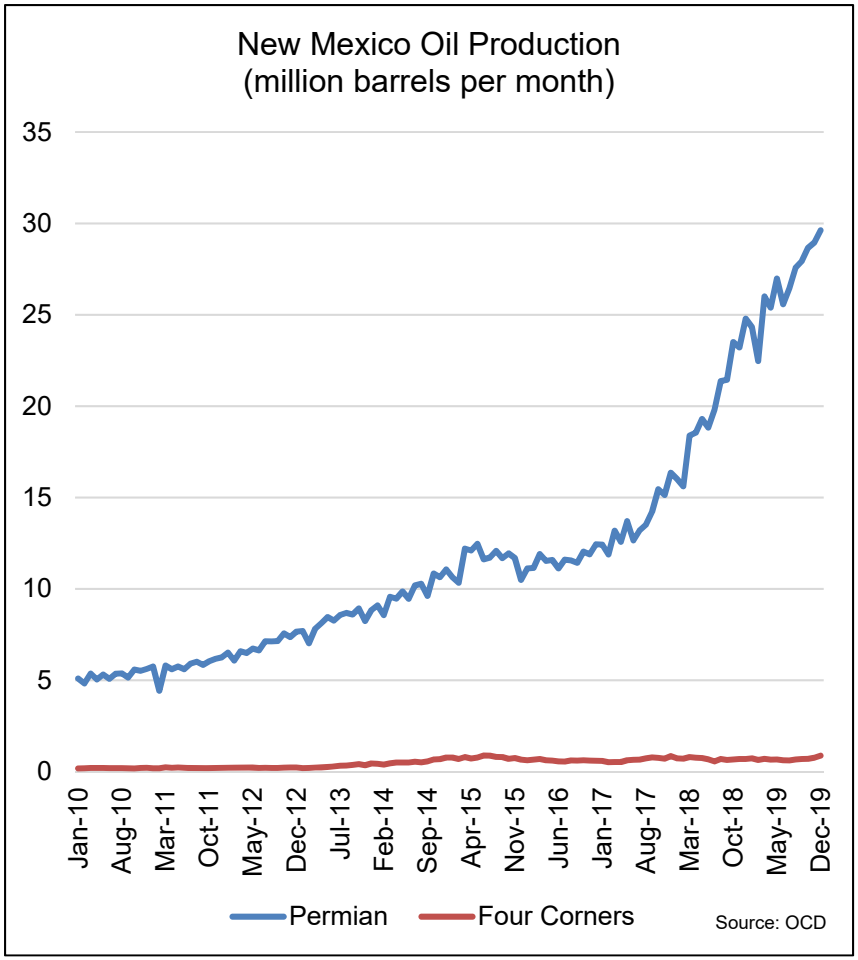
Presented to the Energy, Minerals, and Natural Resource Department's Community Input Meeting
March 19, 2020



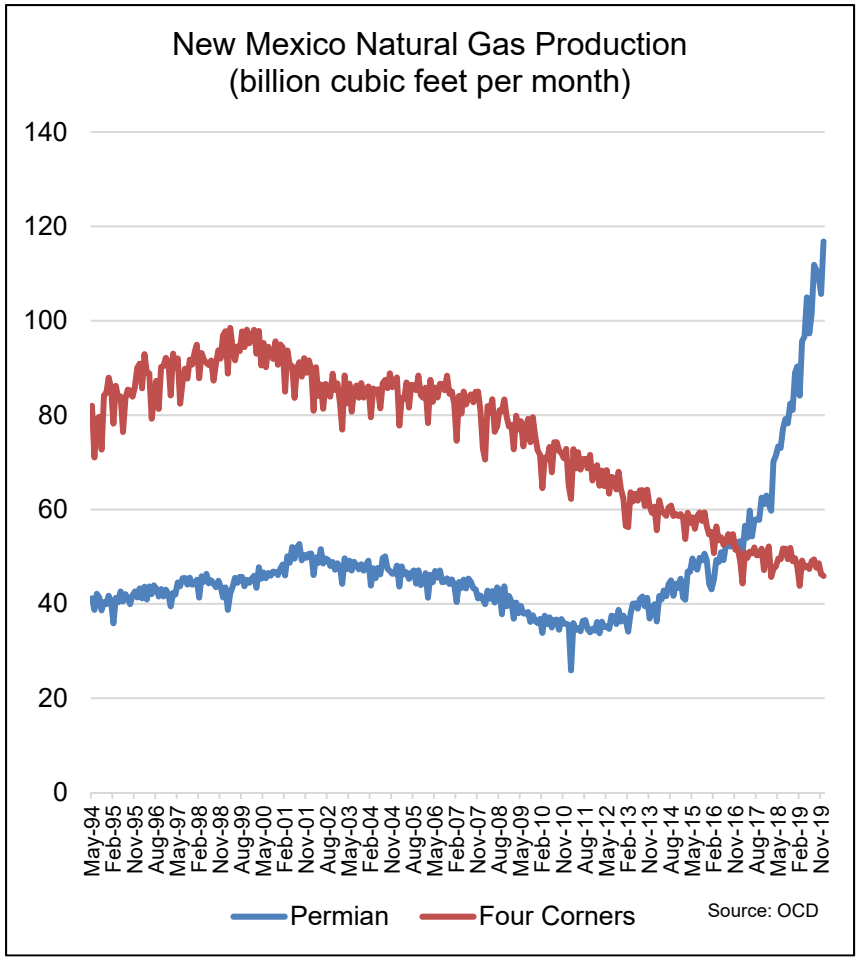
Dawn Iglesias, Chief Economist, LFC

Summary

- Oil producing regions enjoy significant economic growth during boom time, boosting state an local investment, employment, and household income.
  - Growth comes with its own challenges – strains on local housing, school, and infrastructure, as well as environmental considerations.
- Energy markets are volatile, adding uncertainty for state and local governments and residents over when, and to what extent, prices and production could fall.
- When prices drop, local and state economies face sharp declines, and decisions or investments made during the boom may become obsolete.
  - Create challenges for planning in both public and private sectors, with substantial risks for residents of oil producing regions



Unprecedented growth in oil and gas production in New Mexico…



Source: OCD

… with production growing in the Permian basin while San Juan basin continues gradual decline.

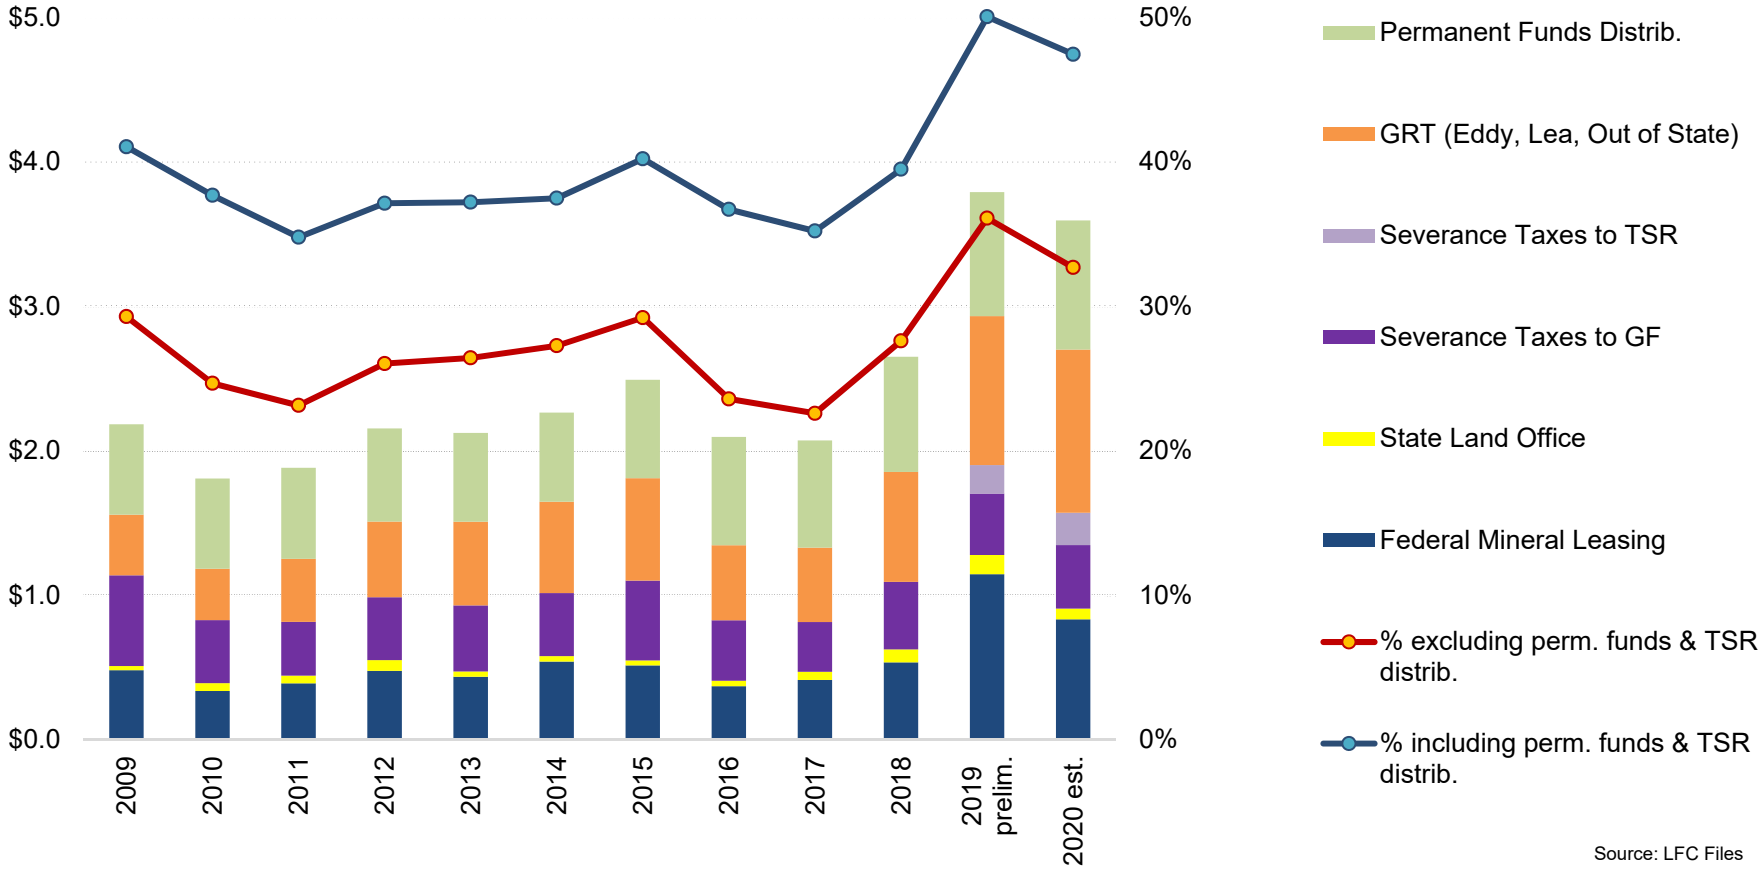
Distribution of New Mexico Oil and Gas Production Revenue: Production Taxes, Property Taxes, and Land Income (in billions)

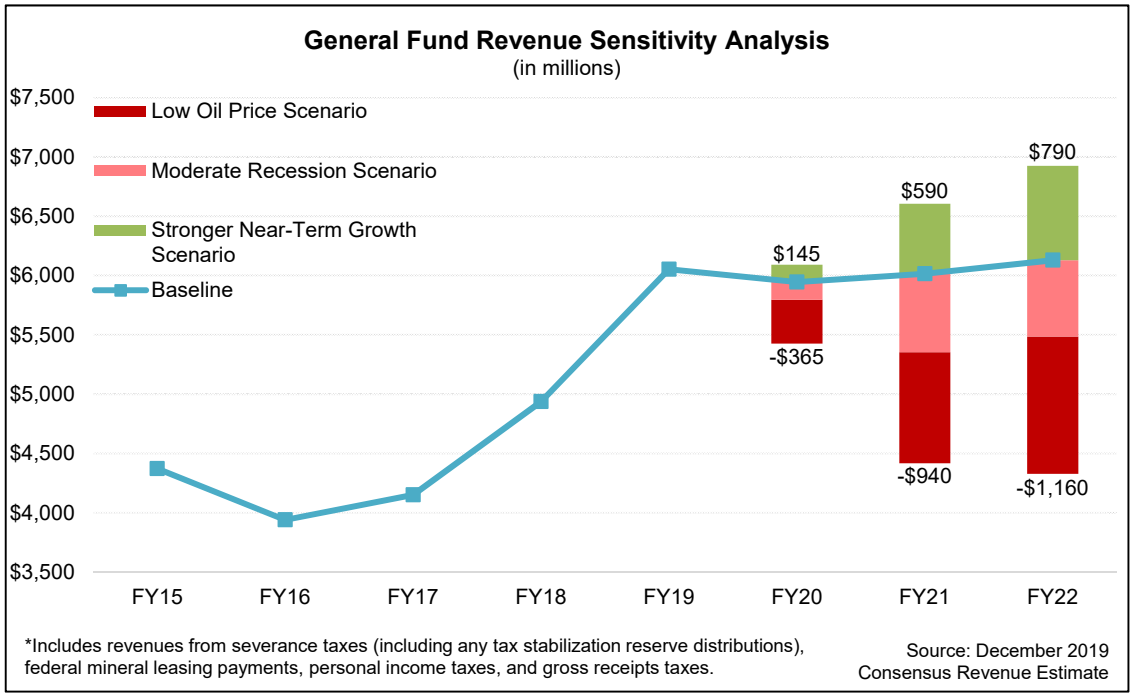


Note: Excludes federal distributions of royalty payments

Source: US Department of Interior, SLO, TRD, LFC Files

Growing dependence on general fund revenues from the oil and gas industry.

General Fund Revenues Dependent on Oil & Gas Industry ($ billions)



Source: LFC Files

What do changes in production and prices mean for the state general fund?

- Reliance on oil and gas related revenues increases general fund volatility and makes revenues forecasts particularly sensitive to changes in commodity prices and production.
- Based on projected FY20 direct oil and gas revenues (production taxes and federal royalties),
  - A $1 change in the annual average NM price of oil has about a $22 million impact on the general fund
  - A $0.10 change in the annual average NM price of natural gas has about a $17 million impact on the general fund
  - Each additional million barrels of oil generates about $3 million for the general fund
  - Each additional 10 billion cubic feet of natural gas generates about $2 million for the general fund

Stress tests show an energy downturn could impact general fund revenues greater than a moderate recession.

*Includes revenues from severance taxes (including any tax stabilization reserve distributions), federal mineral leasing payments, personal income taxes, and gross receipts taxes.

NMED Exhibit 10 - 0004

INTRODUCTION

In Executive Order 2019-03, Governor Michelle Lujan Grisham directed the New Mexico Environment Department (NMED) and Energy, Minerals and Natural Resources Department (EMNRD) to:

"…jointly develop a statewide, enforceable regulatory framework to secure reductions in oil and gas sector methane emissions and to prevent waste from new and existing sources and enact such rules as soon as practicable."

To move forward in a manner grounded in science, innovation, collaboration and compliance, NMED and EMNRD sought nominations for a technical Methane Advisory Panel (MAP). The 27 individual MAP members represented environmental organizations, the interests of the Nations, tribes and pueblos in New Mexico and the oil and gas industry – including small and large independent operators as well as the major, vertically-integrated companies. Industry representatives included companies with interests in the Permian and San Juan Basins that drill, develop, complete and operate oil and natural gas wells and infrastructure. Additional technical expertise was provided by professionals from Los Alamos National Laboratory, Colorado State University and the New Mexico Institute of Mining and Technology. The MAP developed the following draft report, which provides an informational foundation on the technical side of how the oil and gas industry emits methane and what methods can curb methane emissions and prevent waste of this resource. A list of MAP members, presentations and draft technical documents were posted online throughout the process, along with this full draft technical report.

The MAP's draft technical report is a New Mexico-specific treatise on methane emissions and potential reduction mechanisms. Once final, the Departments will use this report as a resource as they move into formal rulemaking next year. The MAP was tasked with considering a wide range of perspectives, so there is robust discussion of methane issues representing a diversity of technical opinions. The group was not asked to provide recommendations or to reach consensus. Rather, they were asked to provide a full description of processes that could result in methane emissions and waste and to identify multiple methane reduction strategies for NMED and EMNRD to investigate further. Through the lens of their varied individual experiences, the MAP members considered new and innovative technologies, as well as existing and proposed solutions found in other states.

NMED/EMNRD METHANE ADVISORY PANEL

SECTION 1, PNEUMATIC CONTROLLERS/PUMPS

Discussion for MAP members on September 27, 2019

NOTE: The focus of this report is processes, and the associated equipment, directly related to the release or capture of methane gas. We are not requesting information on processes/equipment that are not related to the release or capture of methane gas.

1. DESCRIPTION OF PROCESS AND EQUIPMENT

Provide a description of the processes and/or equipment used in oil and/or gas extraction for this topic. Note that this report template will be used for all topics of the MAP review and, thus, not all questions or information may be relevant for each topic. If information is not relevant, indicate N/A. Note any differences expected for differing well types, industry sector, or basin location.

Technical description of the process or equipment:

Pneumatic controllers are process control devices used throughout the oil and natural gas industry as part of the instrumentation to control the position of valves and may be actuated using pressurized natural gas. Natural gas- powered pneumatic controllers use natural gas as motive force operate valves that regulate safety shut-down, position, fluid level, pressure, temperature and flow rate. Methane emissions occur from natural-gas powered pneumatic controllers when the pressurized gas is directed to atmosphere after the control action is performed.

Pneumatic pumps are used to inject chemicals into the wellbore, to circulate glycol in cold climates/weather and to move liquids from one place to another (sump pumps). From US EPA's Control Technique Guidelines (2016):

https://www.epa.gov/sites/production/files/2016-10/documents/2016-ctg-oil-and-gas.pdf

"Chemical injection pumps are positive displacement, reciprocating units designed to inject precise amounts of chemical into a process stream. Positive displacement pumps work by allowing a fluid to

NMED Exhibit 10 - 0007

flow into an enclosed cavity from a low-pressure source, trapping the fluid, and then forcing it out into a high-pressure receiver by decreasing the volume of the cavity. A complete reciprocating stroke includes two movements, referred to as an upward motion or suction stroke, and a downward motion or power stroke. During the suction stroke, the chemical is lifted through the suction check valve into the fluid cylinder. The suction check valve is forced open by the suction lift produced by the plunger and the head of the liquid being pumped. Simultaneously, the discharge check valve remains closed, thus allowing the chemical to remain in the fluid chamber. During the power stroke, the plunger assembly is forced downwards, immediately shutting off the suction check valve. Simultaneously, the chemical is displaced, forcing open the discharge check valve and allowing the fluid to be discharged.

Typical chemicals injected in an oil or natural gas field are biocides, demulsifiers, clarifiers, corrosion inhibitors, scale inhibitors, hydrate inhibitors, paraffin dewaxers, surfactants, oxygen scavengers, and H2S scavengers. These chemicals are normally injected at the wellhead and into gathering lines or at production separation facilities. Because the injection rates are typically small, the pumps are also small. They are often attached to barrels containing the chemical being injected.

Diaphragm pumps are positive displacement pumps, meaning they use contracting and expanding cavities to move fluids. Diaphragm pumps work by flexing the diaphragm out of the displacement chamber. When the diaphragm moves out, the volume of the pump chamber increases and causes the pressure within the chamber to decrease and draw in fluid. The inward stroke has the opposite effect, decreasing the volume and increasing the pressure of the chamber to move out fluid."

Methane emissions occur from pneumatic pumps when the pressurized natural gas that is used to drive the pumping action is released to atmosphere after being used for the pumping action. The amount of methane emitted will depend on the type of pump utilized and the concentration of methane in the associated gas stream.

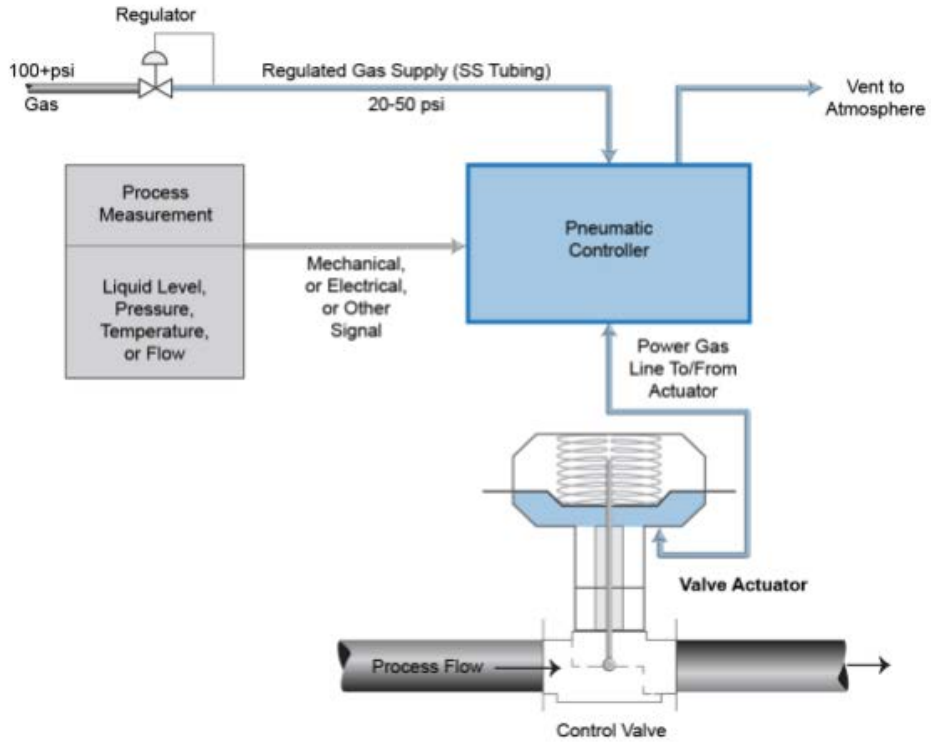
Gas-assisted glycol pumps, are a specific type of pneumatic pump used to circulate the glycol fluid used in glycol dehydrators. The MAP process discussed this type of pump during the dehydrator session and they will not be discussed in this document.

Provide the segment(s) of the industry that the equipment or process is found:

The equipment is found throughout the production, midstream, gas plants and transmission sectors.

Describe how the equipment or process is used:

Pneumatic controllers are used to control multiple processes based on a sensed process parameter. Pneumatic controllers can be used as emergency shut off devices, to regulate flow or liquid levels, as temperature and pressure regulators, etc. An example of the function of a pneumatic controller would be to control liquid level in a separator. When the liquid level in a separator reaches a high set-point in the separator based on the setting of a level gauge, the associated pneumatic controller sends a signal



NMED Exhibit 10 - 0008

to open the control valve between the separator and the tank. For an emitting pneumatic controller, this signal would consist of pressurized pneumatic gas to turn the valve from the "closed" to the "open" position. When the level in the separator reaches a low level, the pneumatic controller sends a signal to the control valve to close and to stop flow from the separator to the tank.

Pneumatic pumps range from chemical injection pumps which may inject a few tablespoons of corrosion inhibitor to a wellbore to large diaphragm pumps which move thousands of gallons of product an hour from one tank to another, to pump water out of containment areas after wet weather, or for heat trace to protect pipes from freezing in cold weather.

Provide the common process configurations that use this equipment or process:

Pneumatic controllers can be installed in many types of service. The controller is placed at or near the valve to actuate it. The placement of the valve depends on the type of service. The diagram below from the University of Texas demonstrates where a typical controller is placed in a generic process: http://dept.ceer.utexas.edu/methane2/study/docs/UT%20Study%20Pneumatics%20FAQ%20to%20SC.pdf

Pneumatic Piston Pump

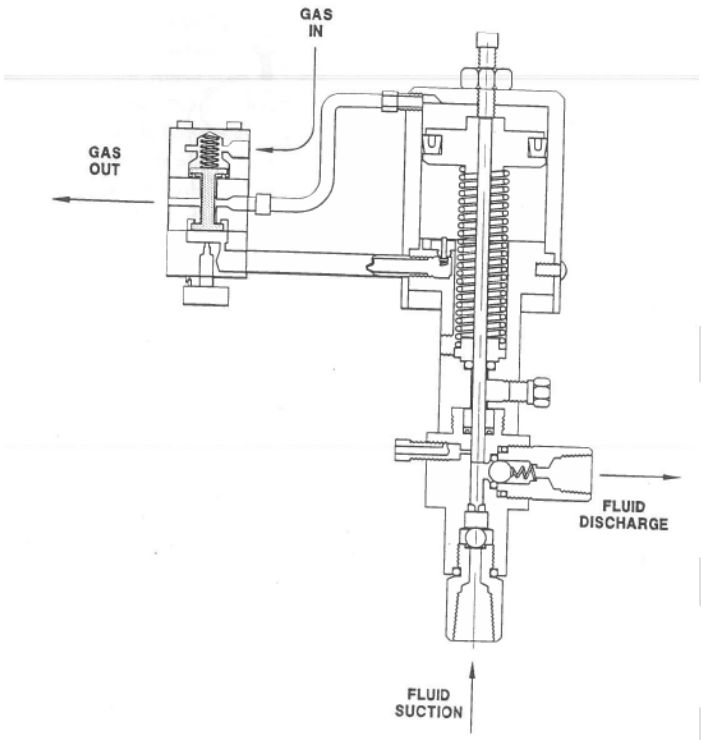


Figure 3-2. Piston Pump Cut-away Schematic

Pneumatic Diaphragm Pump

DRAFT

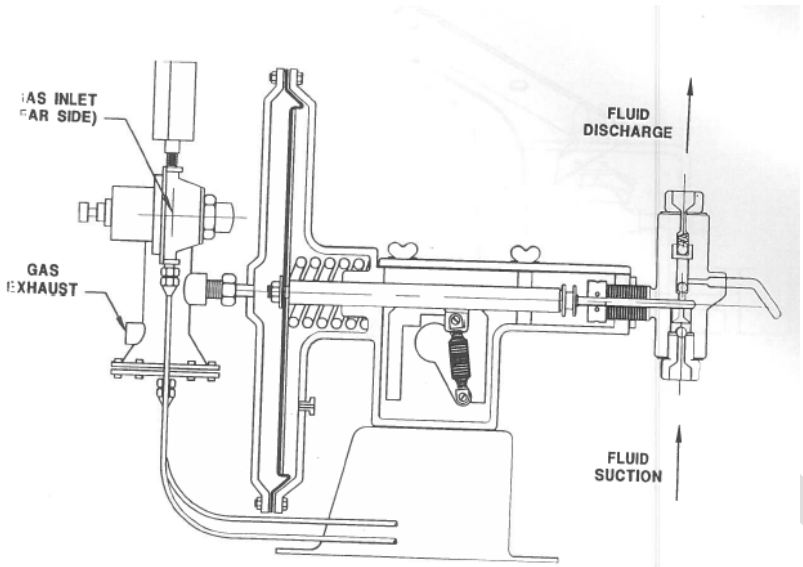

Figure 3-6. Diaphragm Pump Cut-away Schematic

What is the distribution of the equipment or process across business segments?

This equipment is found in upstream, midstream and transmission segments.

How has this equipment or process evolved over time?

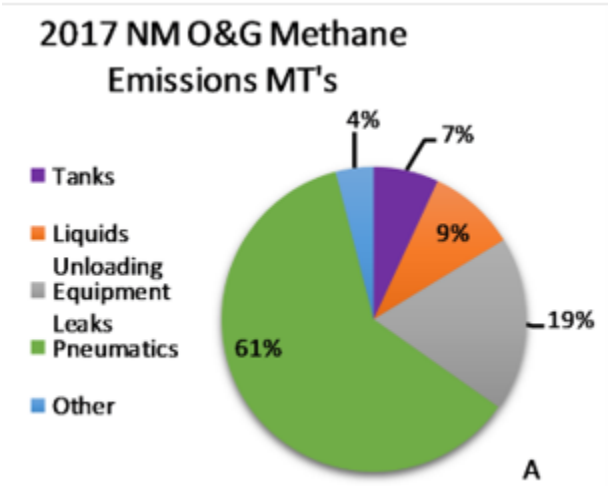
The technology remains similar, though there may be greater application of compressed air in new oil well locations where there is electricity. Manufacturers have focused on developing lower bleed devices which industry has been adopting for new facilities.

In recent years, low-powered electric controllers have become available for some pneumatic controller applications, including controllers that can be powered with air-powered systems with battery storage.

Solar-powered electric injection pumps have become options in recent years.

2. INFORMATION ON EQUIPMENT OR PROCESS COSTS, SOURCES OF METHANE EMISSIONS, AND REDUCTION OR CONTROL OPTIONS

Identify the capital and operating costs for the equipment or the process. Identify how methane is emitted or could be leaked into the air. Please **prioritize** the list to identify first the largest source of methane from the process or equipment and where there is **potential** for the greatest reduction of methane emissions. Note any differences expected for differing well types, industry sector, or basin location.



NMED Exhibit 10 - 0011

Sources of Methane:

Provide an overview of the sources of methane from this equipment or process:

Natural gas driven pneumatic controllers are a direct source of methane emissions (see diagram in section one). Continuous bleed controllers emit natural gas all the time, while intermittent vent controllers emit natural gas only when actuating if operating properly. In the Control Technique Guidelines, EPA found that continuous low bleed controllers emit between 0.2 scfhr up to 5 scfhr, while high bleeds vent from 7 scfhr to 100 scfhr. (US EPA Control Technique Guidelines 6.2.2.2 https://www.epa.gov/sites/production/files/2016-10/documents/2016-ctg-oil-and-gas.pdf)

Analysis of GHGRP data found in the New Mexico Oil and Gas Association's Methane Mitigation Roadmap below: https://www.nmoga.org/methaneroadmap

New Wells:

Pneumatic controllers and pumps are used in both new and existing facilities.

Existing Wells:

Pneumatic controllers and pumps are used in both new and existing facilities.

How are the emissions calculated for this equipment or process?

US EPA defines pneumatic controllers in three different categories, each with its own emissions factor in the production and gathering and boosting segments (link):

- Continuous high bleed: these controllers vent continuously at a rate of over 6 scf/hour per manufacturer specifications. EPA Emissions Factor: 37.3 scf/hr/device

- Continuous low bleed: these controllers vent continuously at a rate of less than 6 scf/hour per manufacturer specifications. EPA Emissions Factor: 1.39 scf/hr/device
- Intermittent: These controllers vent only when actuating. Depending on the type of service or operation the controller is in, it can actuate only a few times a year or multiple times per hour. Current regulatory emission factors do not account for the frequency of actuation or other parameters than may influence emissions and are intended to be an average emission rate over a large population of devices. EPA Emissions Factor: 13.5 scf/hr/device. It is important to note that intermittent vent controllers make up a large majority of the inventory in most basins. Also, some studies conclude that emission factors for intermittent vent controllers are too high. The variability in these factors are dependent on geographical area. Should an alternate emission factor be used to estimate emissions from these devices, the total emissions would be vastly lower than what is reflected in GHGRP.

The latest multi-region emission factor study for pneumatic controllers in the United States (Allen 2014) does not include sufficient information to develop a basin-specific emission factor for the Permian or San Juan as emission factors were developed based on regions used in EPA GHG Inventory estimation at that time. The study found a national-average emission of 5.5 scf/hr/device. The study-average emission rate in the Midcontinent region, which geographically includes the Permian Basin, was 5.8 scf/hr/device. The study-average emission rate in the Rocky Mountain region, which geographically includes the San Juan Basin, was 0.8 scf/hr/device. It is not possible to discern if any of the regional measurements occurred in the Permian or San Juan basins.

For pneumatic controller emission reporting, US EPA requires that operators provide an actual count of devices that emit natural gas to atmosphere by each of the three categories at the basin (i.e. Permian or San Juan) and segment (i.e. production or gathering and boosting) level in each year. The count of devices, the emission factor, and a gas composition (i.e. percent of methane in the gas) drive the emission calculation for this source. There is no requirement to report or count of other types of pneumatic controllers that do not have associated emissions to atmosphere.

Equation from GHGRP Subpart W: https://www.ecfr.gov/cgi-bin/text-idx?SID=3393fe39418e975c59618f6249f55516&mc=true&node=se40.23.98_1233&rgn=div8

$$E_{s,i} = \sum_{t=1}^{3} Count_t * EF_t * GHG_i * T_t \qquad \text{(Eq. W-1)}$$

Where:

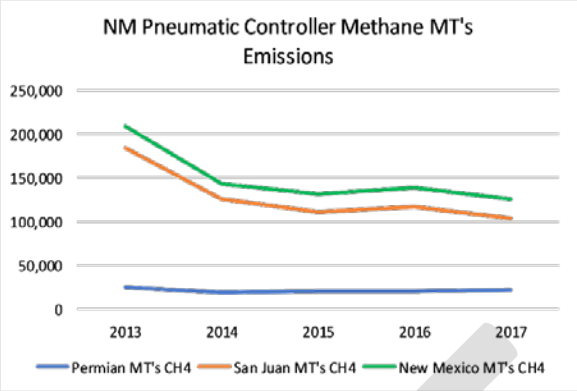
$E_{s,i}$ = Annual total volumetric GHG emissions at standard conditions in standard cubic feet per year from natural gas pneumatic device vents, of types "t" (continuous high bleed, continuous low bleed, intermittent bleed), for GHG_i.

NMED Exhibit 10 - 0013

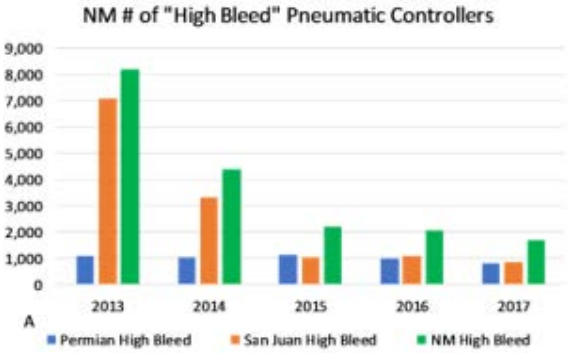
$Count_t$ = Total number of natural gas pneumatic devices of type "t" (continuous high bleed, continuous low bleed, intermittent bleed) as determined in paragraph (a)(1) or (a)(2) of this section.

EF_t = Population emission factors for natural gas pneumatic device vents (in standard cubic feet per hour per device) of each type "t" listed in Tables W-1A, W-3B, and W-4B to this subpart for onshore petroleum and natural gas production, onshore natural gas transmission compression, and underground natural gas storage facilities, respectively. Onshore petroleum and natural gas gathering and boosting facilities must use the population emission factors listed in Table W-1A to this subpart.

GHG_i = For onshore petroleum and natural gas production facilities, onshore petroleum and natural gas gathering and boosting facilities, onshore natural gas transmission compression facilities, and underground natural gas storage facilities, concentration of GHG_i, CH_4 or CO_2, in produced natural gas or processed natural gas for each facility as specified in paragraphs (u)(2)(i), (iii), and (iv) of this section.



T_t = Average estimated number of hours in the operating year the devices, of each type "t", were operational using engineering estimates based on best available data. Default is 8,760 hours.



US EPA has a single emission factor for all pneumatic pumps (link) that is 13.3 scf/hr/pump and are defined as any natural gas-driven pneumatic pump that is not part of a dehydration system since those types of pumps are reported with emissions from dehydrators. As with pneumatic controllers, operators provide a count of pneumatic pumps in operation at the basin-level for each segment. Emissions are then estimated based on the emission factor, the count of pneumatic pumps, and the gas composition.

What data is available to quantify emissions/waste for this equipment or process?

The US EPA publishes most of the emission information and activity data that it receives as part of the US GHG Reporting Program annually (https://ghgdata.epa.gov/ghgp/main.do?site_preference=normal#). By March 31st of each year, operators upload their emission information to the EPA website for the previous year (i.e. 2018 emission information was reported in March 2019), EPA undertakes a quality assurance process, and uploads the information in October to a publicly accessible website. Care should be taken in estimating emissions from this inventory for New Mexico since both the Permian and San Juan Basins span multiple states and are challenging to separate emissions between states for all source categories. In the analysis below, NM data was separated from surrounding state data. Also, operators with less than 25,000 MT CO_2e emissions are exempt from reporting emissions to the GHGRP. Therefore, the production segment, all emissions were scaled up to the total well count reported by the New Mexico Oil Conservation Division (NMOCD) (EIA for national). For the G&B segment, there is no information to enable scaling-up GHGRP reported emissions and raw GHGRP reported emission quantities are shown.

NMED Exhibit 10 - 0014

Analysis of GHGRP data found in the New Mexico Oil and Gas Association's Methane Mitigation Roadmap: https://www.nmoga.org/methaneroadmap

The large discrepancy in emissions from Permian vs San Juan Basin reflects distinguishing characteristics of the two basins. In gas plays, the per site controller counts are much lower than oil plays, thus, creating a disincentive for the use of more expensive compressed air applications as those installations are uneconomic unless there is a significant number of controllers needed for the process. Also, Permian basin gas also contains less methane by composition in the stream than San Juan Basin gas, therefore, the resulting methane concentration as a variable to calculating emissions result in lower per-controller emissions in the Permian.

What are the data gaps in quantifying emissions/waste for this equipment?

Current US EPA emission factors are based on a relatively small sample of pneumatic controller measurements that were conducted in the early 1990's. More recently, several direct measurement studies have been undertaken to try to update the US EPA emission factor by directly measuring emissions from a population of devices as they were encountered in the field. On average, these studies, which are outlined in the table below, have found that aggregate emissions per pneumatic controller measured are lower than those used in the GHGRP. It is recognized that each study

conducted has certain limitations such as equipment reliability and calibration, measurement techniques, duration of sample collection, sample size and representativeness, etc.

There have been a number of studies, some of which find that the EPA emission factors are overestimated in some cases:

Study Name	# PC Samples	Application	Duration of Measurement	Whole gas (avg ER) (scf/hr)
EDF/UTexas 2014	377	Well pads natural gas production, several U.S. basins	15 minutes	5.5
EPA – Thoma Utah Study 2016	80	Unitah Basin well pads, oil and gas production	1 hour or more	0.36
Oklahoma Independent Producers Association	680	Oil and gas production in Oklahoma	NA	1.05 (calc)
Prasino 2013	601	British Columbia oil and gas sites, measured high bleeds only	30 minutes	8.7 – 9.2
Luck et al 2019 (Gathering facilities) (data quality affected by meter problem)	72	US gathering facilities Due to potential biases associated with flow meter errors, updates to EPA emission factors based on these data are not proposed	76 hours (avg) Authors found that many of the problems observed would not have been observed using typical measurement durations	Low-bleed: 7.6 High-bleed: 19.3 Intermittent-bleed: 11.1 Overall: 10.9
Cap-On Energy BC Oil and Gas Methane Emissions Field Study (Data tables here)		British Columbia wellpads	Direct equip. cts. from 266 pads, with EFs calculated based on counts of specific models and recent measured EFs for each model	Emissions reported by controller function (irrespective of continuous-bleed / intermittent-bleed distinction. See figure below.

From Cap-On BC study. Cap-On Energy BC Oil and Gas Methane Emissions Field Study. Page 53.

Challenges persist in the national extrapolation of emission factors from any single measurement study as different studies have noted regional, company, and service-level emission differences in emissions of pneumatic controllers. Most notably, studies such as EDF/UTexas have found large variation in emission rates for intermittent vent controllers with a small subset of devices (~19%) being responsible for the majority of the device emissions (~95%) and more than 50% of the sampled devices had no recorded emissions over the sample period. Based on analysis of time series data from the study measurements, the team was able to identify that most of the devices with elevated emissions were emitting in a manner that was inconsistent with manufacturer design.

A significant contribution to the uncertainty in emissions from pneumatic controllers is the high incidence of improper operations for pneumatic controllers. These problems have been identified in a number of studies, including the Ft. Worth AQ Study, the Prasino study linked above, and EDF/UTexas 2014. A recent study from Colorado State and U Texas (Luck et al. 2019) found that 42% of the 72 controllers successfully measured at US gas gathering sites were operating abnormally, with much higher emissions than from devices operating normally. 25 of the 40 (62.5%) intermittent-bleed controllers the researchers examined were operating abnormally, with high average emissions for the devices operating abnormally (about 16

scfh). The researchers also noted that in many cases the high emissions and abnormal operations were only observed because of the long observation time (average was over three days). Note that the precision and accuracy of the emission factors produced by this study was degraded by an instrumental problem described in the paper, but the authors concluded that the qualitative results of the study are robust despite the instrumental problem.

Baker Hughes, a GE Company, (BHGE) has released a report for Environmental and Climate Change Canada (ECCC) and Petroleum Technology Alliance Canada (PTAC) on 7-site (54 component) case study on the performance of a new component-level continuous monitoring technology (LUMEN). Briefly, the LUMEN technology is placed 12-16 inches from a known methane vent point to collect real-time part per million (ppm) methane readings. The methane reading is combined with on-site meteorological data into a model to infer associated emission rates. BHGE does not provide references or supporting information in the report to show the expected accuracy of the method relative to controlled releases. Experience in US-based testing of ambient methane detection technologies has shown that new technologies are often better at detection than emission rate quantification due to the inherent uncertainties in generating near-field dispersion characteristics directly. Components selected for the study were found to have emissions from an on-site screening, and 34 pneumatic controllers (3 dump valves, 18 level controllers, and 13 pressure controllers) were selected for long-term LUMEN deployment. In particular, several high bleeds were selected to show the difference between pre and post retrofits with lower emission technologies. Care should be taken in drawing conclusion between the long-term LUMEN measurements, and other methods of reporting emissions since the comparison to High Flow measurements is based on spot samples (versus time series, as is best practice in emission studies) and to emission factors as the comparison is being made in the report to emission factors from components (like valves) rather than pneumatic devices.

Economic Description of the Process or Equipment:

What is the per unit cost of the equipment or the costs associated with the process?

Costs vary widely based upon type of unit and type of service.

Table 1 of the "Cost-Effectiveness of Comprehensive Oil and Gas Emissions Reduction Rules in New Mexico" lists per unit costs for low-bleed pneumatic controller abatement technology as $49.30 per mcf of reduced methane ($2,563.40 per tonne).[1]

[1] "Cost-Effectiveness of Comprehensive Oil and Gas Emissions Reduction Rules in New Mexico," Erin Camp, PhD, Nate Garner, Asa Hopkins, PhD, Synapse Energy Economics, Inc., September 13, 2019, page 9, Table 1, http://blogs.edf.org/energyexchange/files/2019/09/Synapse-Methane-Cost-Benefit-Report.pdf.

What are the annualized operating costs for the equipment or costs associated with the process?

Costs vary widely based upon type of service.

If the equipment or process is powered, what are the costs?

If electricity is available, some process controls and/or very small pumps may be able to be electrically powered. Air compression may be required. Solar-powered systems to power electric controllers have been demonstrated at production sites. Costs for solar-powered systems vary by facility size / configuration. Tools are available to estimate costs of solar-powered systems for a given site configuration.

Carbon Limits' produced a report with cost information for electric controllers (including solar power) and air-driven systems. https://www.carbonlimits.no/project/zero-emission-technologies-pneumatic-controllers-in-usa/

Additionally, Carbon Limits produced an Excel Tool which can be used to calculate costs and emission reductions, using data from their report, for a site with a given configuration (power already available or not, various numbers of controllers and pumps, etc.). This Excel file is provided.

There is not a "one size fits all" tool (such as the Carbon Limits tool) that works on every oil and gas site with pneumatic controllers and pumps. For example, many tools apply tax break scenarios or credits that are assumed to be in the future or credits available today but are scheduled to not be available in the next few years. Oil and gas operators have internal tools to access feasibility, application, emission reductions and cost scenarios that can provide site specific applications.

Much of California has access to electricity in the oil and gas fields which changes feasibility and costs associated with applications of electric or air driven pumps. Colorado regulations have specific scenarios where implementation of the regulations are dependent on electrical availability and/or existing control devices. It is important to consider various conditions of existing location infrastructure on a site by site basis when developing costs for existing sources

What are the maintenance and repair costs for existing or new equipment?

Costs vary widely based upon type of service and type of unit.

Existing Reduction Strategies:

How has industry reduced emissions/waste from this equipment or process historically?

There may be greater application of compressed air on new oil well locations with access to electricity. Manufacturers have focused on developing lower bleed devices which industry has been adopting for new facilities. EPA's New Source Performance Standard OOOO (2012) limited the installation of continuous high

NMED Exhibit 10 - 0019

bleed controllers in new construction, so over time, controllers are more likely to be low bleed, intermittent or compressed air. There are some services that require high bleed for safety or process purposes.

Existing LDAR quarterly reporting procedures may capture additional emissions reductions from malfunctioning pneumatic controllers with minimal extra cost to operators.[2]

New Wells:

N/A

Existing Wells:

N/A

How have the emission/waste reductions been measured?

Utilizing EPA emissions factors.

How have states and the federal government reduced emissions/waste from this equipment or process historically? In addition, please identify voluntary reductions achieved whether or not they were in response to a regulatory action/requirement.

Federal Regulations

EPA's New Source Performance Standard OOOO (2012) limited the installation of continuous high bleed controllers in new construction, so over time, controllers are more likely to be low bleed, intermittent or compressed air. https://www.ecfr.gov/cgi-bin/text-idx?node=sp40.7.60.oooo

NSPS OOOOa requires that natural gas driven diaphragm pump constructed or modified after September 18, 2015 and in use more than 90 days per year must reduce emissions by 95% unless there is not a control device; i.e., a flare or combustion device, or process available onsite. If a device is available but not capable of 95% reduction, operators must still route emissions to the device. If it is technically infeasible to capture and route the gas to a control device (for example if no low-pressure devices are available), operators are not required to meet the control standard. It is important to note that chemical injection pumps are exempt from these requirements.
https://ecfr.io/Title-40/sp40.8.60.oooo_0a

In 43 CFR 3178, BLM considers the use of produced gas as a motive force for actuating pneumatic controllers and pumps a beneficial use and, therefore, not waste. However, the original BLM methane

[2] "Cost-Effectiveness of Comprehensive Oil and Gas Emissions Reduction Rules in New Mexico," Erin Camp, PhD, Nate Garner, Asa Hopkins, PhD, Synapse Energy Economics, Inc., September 13, 2019, page 9, Table 1, http://blogs.edf.org/energyexchange/files/2019/09/Synapse-Methane-Cost-Benefit-Report.pdf.

waste prevention rule did consider such gas a source of waste if the controller emits in excess of 6 scf per hour and required the operator to replace such pneumatic controllers with a controller (including but not limited to a continuous or intermittent pneumatic controller) having a bleed rate of 6 scf per hour or less within established timeframes. It also required the operator to ensure pneumatic controllers are functioning within manufacturers' specifications. For pneumatic diaphragm pumps, the rule required operators to replace all existing pumps with zero emissions pumps, which may be an electric-powered pump; or route the pump exhaust gas to processing equipment for capture and sale. 43 CFR 3179 [link to be identified]

State Regulations

Colorado's Regulation 7 Section XVIII
https://drive.google.com/file/d/168v7vMsFJtS7D8BWlnMbaXWA6uZUlyj8/view

Requires continuous bleed controllers to be replaced or retrofitted to be low bleed unless a high bleed is required for safety or process purposes. New controllers installed after May 2, 2014 use no-bleed where there is on-site electrical grid power and is technically and economically feasible. Controllers at gas processing plants installed after 1/1/2018 must be zero bleed. This is a statewide requirement.

In the ozone nonattainment control area, beginning 1/1/2018, owners or operators of natural gas driven pneumatics must inspect controllers at a frequency aligned with existing leak detection requirements.

California no longer allows installation of continuous-bleed pneumatic controllers (high-bleed or low-bleed). Continuous bleed natural gas-powered pneumatic devices installed prior to January 1, 2016 may be used. Emissions from existing continuous-bleed pneumatic controllers must be measured annually to ensure that the device emits below 6 scfh; any device emitting above 6 scfh must be repaired. Furthermore, California requires operators to inspect each intermittent-bleed controller during each (quarterly) LDAR inspection to ensure that the device is not emitting gas between actuations. Finally, pneumatic pumps may not vent to atmosphere in California. Note LDAR inspection frequency is summarized above as quarterly but frequency could be annual depending on whether it was subject to an LDAR program at the district level prior to the state rule implementation.

See https://ww2.arb.ca.gov/sites/default/files/2018-06/2017%20Final%20Reg%20Orders%20GHG%20Emission%20Standards.pdf, § 95668(e) (pages 18-19)

British Columbia will not allow the installation of pneumatic controllers venting gas to atmosphere at new facilities built after 1/1/21, and will not allow existing pneumatic controllers to vent from large (>4000 HP) compressor stations after 1/1/22, in addition to limiting venting from all remaining controllers (including intermittent-bleed controllers) to 6 scfh (with exceptions for process/safety needs). BC will prohibit venting from new pneumatic pumps installed after 1/1/21 that operate more than 750 hours/year.

NMED Exhibit 10 - 0021

See http://www.bclaws.ca/civix/document/id/regulationbulletin/regulationbulletin/Reg286 2018, pp 6-7.

Alberta requires that 90% of new controllers (at all facilities, new and existing) installed after 1/1/22 not vent to atmosphere. Alberta will also limit emissions from all controllers (intermittent-bleed and continuous-bleed), with the exception of level controllers, to 6 scfh. Level controllers that actuate more than 4x per hour must either "use a relay that has been designed to reduce or minimize transient or dynamic venting or adjust the actuation frequency to ensure that the time between actuations is greater than 15 minutes." Alberta will prohibit venting from new pneumatic pumps installed after 1/1/22 that operate more than 750 hours/year.

See https://www.aer.ca/documents/directives/Directive060_2020.pdf, §8.6.1 (pp 77-79).

What are examples of process changes/modifications that reduce or eliminate emissions/waste from this equipment or process?

In some situations, you can route gas from a pump back to a process or control. Feasibility depends on access to low pressure process device in close proximity for the pumps.

As described above, Colorado and California require regular inspection of pneumatic controllers at all sites to ensure that they are not emitting excessively.

As described above, Alberta requires specific actions for level controllers which actuate more than 4x per hour – either reducing actuation frequency, or installing a "relay that has been designed to reduce or minimize transient or dynamic venting."

Technology Alternatives:

List of technology alternatives with link to information or contact information for the company/developers.

Name/Description of Technology	Link (and contact info for company if available)	Availability	Feasibility	Cost Range (choose one)
Replace or retrofit high bleed pneumatic controllers	https://theenvironmentalpartnership.org/what-were-doing/pneumatic-controllers-upgrades/	**In use**	High	**Low**
Replace natural gas with air to actuate	https://www.epa.gov/sites/production/files/2016-06/documents/ll_instrument_air.pdf	**In use**	Medium – need access to reliable	Medium

pneumatic devices air on newly constructed oil wells	(note older document, cost of controls and price of gas are no longer accurate) https://www.carbonlimits.no/project/zero-emission-technologies-pneumatic-controllers-in-usa/		grid power and only economic with a very large number of controllers on one site	
Route gas from a pump back to a process or control	https://www.epa.gov/sites/production/files/2016-10/documents/2016-ctg-oil-and-gas.pdf	**In use**	Low/Medium – need to have a low pressure process device in close proximity to the pump

Supplier has not verified feasible in NM, power demand may be greater than solar can supply.	**Varies with site size / amt of pneumatic equipment.**

What technology alternatives exist to reduce or detect emissions? Please list all alternatives identified along with contact information for further investigation of this technology or process.

Replace or retrofit continuous, gas powered high bleed pneumatic controllers.

What are the pros and cons of the alternatives?

DRAFT

Replacement or retrofit of high bleed devices is, in almost all cases, an effective emissions reduction.

For compressed air applications, economic drawbacks and challenges will create barriers for gas plays and smaller scale locations. In gas plays, the per-controller counts are much lower than oil plays, thus, creating a disincentive for the use of more expensive compressed air applications as those installations are uneconomic unless there is a significant number of controllers needed for the process. There are also application limitations as some services require rapid actuation response times; electric (including solar) may not be appropriate for pneumatic operations that require such rapid actuation response times.

With respect to controlling pumps, there are numerous potential safety and operational issues with connecting the discharge from a pneumatic pump to an existing control device and closed vent system. These issues can impact both the performance of the pump and result in back pressure on the other sources being controlled.

Whether considering a VRU, flare, enclosed combustion device, or any other control technique, control devices are designed for a specific set of conditions with a number of key assumptions. For example, a flare header might be designed to allow enough flow to permit two pressure safety valves (PSV) to open simultaneously without creating so much back pressure as to take either PSV out of critical flow. The design is sensitive to other flow streams in the pipe and putting a pump exhaust into that header could result in too much backpressure for the safety devices to function as intended. Conversely, but equally important, a pneumatic pump is chosen for a specific backpressure and the backpressure imposed by a PSV could stop the pump from functioning at a critical moment, exacerbating the already unstable situation that resulted in the opening of the PSVs.

Typically, pneumatics operate on a low-pressure gas stream. If the control device on a site is located a long distance from the pneumatic, the gas emitted from the controller make not make it to the control device, which can cause backpressure on the pneumatic and not allow for operation of the device. In particular, flares are often located at a safe setback distance from operational equipment. At times, control devices, such as flares, may operate at higher pressures than pneumatic devices, which would not allow for routing to the control device.

Additionally, enclosed combustion devices are designed for a maximum BTU load and may not be able to accommodate the exhaust gas from a pneumatic pump affected source without replacing the control device.

The design process for VRUs are even more sensitive to changes than other control devices. The VRU equipment is designed to recover vapors and raise their pressure enough to be useful, is expensive, and has a limited range of possible flow rates. Adding vapor loads to a VRU must be carefully evaluated on a case-by-case basis.

NMED Exhibit 10 - 0024

In some instances, an existing control device on a particular site may be owned and operated by a third party, such as a control device owned and operated by a gathering and collection system operator with a glycol dehydration unit on a well site. In these instances, the well site operator does not have the right to route a pneumatic pump affected source exhaust to the control device.

When evaluating use of compressed air on a location one important consideration is the system can introduce water into the pneumatic lines. Instrument air system have a tendency to introduce water into the pneumatic lines. Water can freeze in colder climates damaging the line or the device/pump. Water that makes it way to the device itself could cause the device to not operate or mis-operate. This could result in excess emissions on site.

What is needed and available for new wells?

NSPS OOOO already applies to new devices since October 2013. Pumps have been subject to NSPS OOOOa since late 2015.

Zero bleed solutions, including solar-powered, have been demonstrated at wellsites in Canada (noted above).

What is needed and available for existing wells?

Continuous high bleed pneumatic devices can be replaced in existing wells. NSPS OOOOa requirements are triggered for pumps that are replaced.

For larger existing wellpads (multiwell), retrofit with zero-bleed technology may be cost-effective.

What technology alternatives exist for this equipment or process itself?

In some cases, mechanical valves can be utilized without a pneumatic controller, but there are significant limitations including the control must be in close proximity to the process, can only be used for liquid level, and it may not be sufficient for some processes (like larger process flow or pressure). Retrofit is not feasible.

What are the pros and cons of the alternatives?

See above.

Costs of Methane Reductions:

What is the cost to achieve methane emission reductions?

The cost of switching from a continuous high bleed controller to a lower emitting option depends on the option chosen, which is dependent on the type of service, and can be dependent on access to electricity. US EPA's control technique guidelines cite an average capital cost per unit as $2,698. https://www.epa.gov/sites/production/files/2016-10/documents/2016-ctg-oil-and-gas.pdf

What would be the implementation cost?

For new wells?

See above

Costs for compressed air vary depending on the size of the location the presence of reliable grid power, etc. Bringing power to a location for the sole purpose of a compressed air system is not cost effective.

For zero-bleed solutions such as solar-powered electric systems, cost and cost-effectiveness are a function of site size (chiefly, the number of controllers and pumps on site). Larger multi-well pads are more cost-effective for solar systems because of common equipment required for any size site (batteries, control panels, etc.) so costs do not scale with the number of controllers at the low end.

For existing wells?

See above

Clean Air Task Force prepared cost estimates of zero-bleed systems for existing wellsites in Colorado, as part of participation in rulemaking hearings in Colorado. Cost estimates were based on data from Carbon Limits' report, linked above. CATF used a tool prepared by Carbon Limits to calculate cost-effectiveness of the use of zero-bleed controllers (electric with solar power, or air-driven) at wellpads with various numbers of wells/controllers. Costs are shown in exhibit A, attached, pages 14-20.

There is not a "one size fits all" tool (such as the Carbon Limits tool) that works on every oil and gas site with pneumatic controllers and pumps. For example, many tools apply tax break scenarios or credits that are assumed to be in the future or credits available today but are scheduled to not be available in the next few years. Oil and gas operators have internal tools to access feasibility, application, emission reductions and cost scenarios that can provide site specific applications.

Much of California has access to electricity in the oil and gas fields which changes feasibility and costs associated with applications of electric or air driven pumps. Colorado regulations have specific scenarios where implementation of the regulations are dependent on electrical availability and/or existing control devices. It is important to consider various conditions of existing location infrastructure on a site by site basis when developing costs for existing sources.

Are there low-cost solutions available?

See above

If a solution is high-cost, why is that the case?

Solutions requiring the addition of reliable electricity would be cost prohibitive in most applications. In addition to the cost of bringing power to the site, the cost of electric counterparts to pneumatic devices could be about double the price in some applications.

Solar powered systems add costs to electric systems. Note that operators have reported lower maintenance costs for electric systems compared to field gas-driven pneumatic systems. See https://www.carbonlimits.no/project/zero-emission-technologies-pneumatic-controllers-in-usa/ These lower costs offset higher equipment costs relative to venting gas-driven pneumatics.

Are there additional technical analyses needed to refine benefits/costs estimates?

N/A

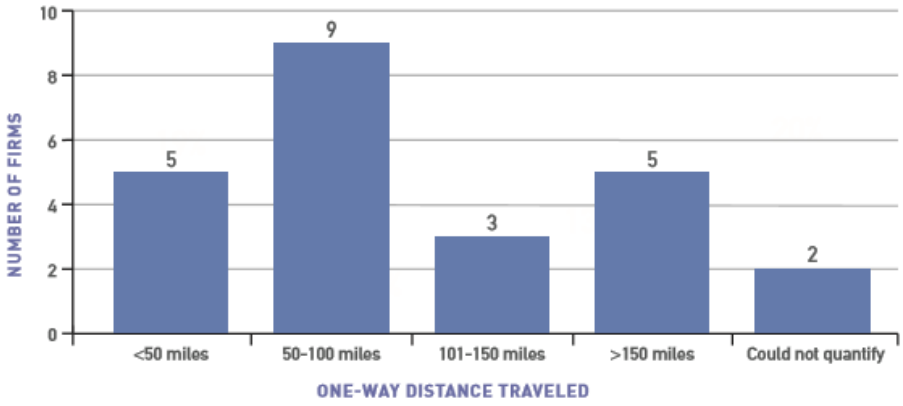
3. IMPLEMENTATION

For each piece of equipment or process, please consider the following questions and add other relevant information. If relevant, please identify if the answers are different for large company and small company requirements or are different for well type or basin.

Implementation Feasibility:

What is the feasibility of implementation (availability of required technology or contractors, potential permitting requirements, potential for innovation)?

With sufficient time for manufacturers to stock parts, it is feasible to replace or retrofit continuous high bleed controllers with a reasonable implementation period. For some replacements or retrofit activities, it is necessary to conduct such work during a turnaround.



For leak detection, intermittent bleed controllers which are part of an existing LDAR program can be surveyed by waiting for the device to be non-actuating before using an optical gas imager or sniffer to see if there are emissions. For continuous bleed controllers, it is very difficult and subjective, to determine if the device is operating as designed or not. Conducting LDAR on a site just to monitor a controller can be very expensive, the variability is primarily driven by the cost of bringing out an operator to a site for an inspection. In 2017, EDF published a study called “The Emerging Methane Detection Industry” which indicates that median one-way travel distance to a site for an LDAR contractor is 50-100 miles. The study notes that 21% of firms interviewed have a typical travel distance of 300-1,000 miles one way to a site.

California also subjects both continuous and intermittent bleed natural gas pneumatic devices to LDAR. 17 C.C.R. § 95668 (e). Colorado subjects natural gas driven pneumatics to LDAR requirements (with stricter requirements for non-attainment areas). 5 CO ADC 1001-9:XVIII.D.

See final MAP Leak Detection and Repair Report.

NMED Exhibit 10 - 0027

FIGURE 7. Typical One-Way Travel Distance Reported

SOURCE: Industry Interviews
NOTE: Based on a sub-sample of 24 LDAR firms

https://www.daturesearch.com/wp-content/uploads/Methane-Mitigation-Industry-Report_Final.pdf

What is the useful life of equipment?

N/A

What are the maintenance and repair requirements for equipment required for methane reduction?

There is no difference in maintenance and repair between a high and low bleed continuous emitting controller.

How would emissions be detected, reductions verified and reported?

Operators report the number of devices through the GHGRP if they meet the emissions threshold per basin to require reporting.

4. CHALLENGES AND OPPORTUNITIES TO ACHIEVE METHANE REDUCTION IN NEW MEXICO

For each piece of equipment or process, please consider the following questions and add other relevant information. If relevant, please identify if the answers are different for large company and small company requirements or are different for well type or basin.

What regulatory gaps exist for this equipment or process? Are there regulatory gaps filled by the proposed implementation?

Gaps filled by proposed continuous high bleed retrofit or replacement.

Where do conflicting priorities exist between NMED, EMNRD, and NMSLO? Are there opportunities for coordination between these agencies?

None

Are there existing regulations related to methane that do not address the intended purpose? Identify any unintended barriers to methane reductions/capture that may hinder proposed processes.

No

Other considerations or comments (e.g. particular design or technological challenges/opportunities, co-benefits, non-air environmental impacts, etc?):

None

	pump back to a process.				
	COMMENT A. This is only feasible if there is a low-pressure device in close proximity to the pump. Otherwise there is not enough pressure. [page 20] B. Limited applicability (b/c of number of diaphragm pump.) Requires low pressure process device to take the gas in close proximity to the pump. [page 22] C. Maybe used at a large site. [page 25]		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
1.6	LDAR on intermittent bleed pneumatics when not actuating	Quarterly LDAR for malfunctioning: 68% reduction (Source: https://www.edf.org/nm-oil-gas/scenarios)	1 2 3 4 5 HIGH If part of an existing LDAR program.		San Juan Permian **Both**
	COMMENT A. If there is an existing LDAR program. Would add an additional 15 minutes if already conducting LDAR inspection. [page 27] B. Not a binary decision – see citation for CO rule and how pneumatics are treated differently. [page 22]		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		

DRAFT

SECTION 2, LEAK DETECTION AND REPAIR

Discussion for MAP members on November 7 and 8, 2019

NOTE: The focus of this report is processes, and the associated equipment, directly related to the release or capture of methane gas. We are not requesting information on processes/equipment that are not related to the release or capture of methane gas.

1. DESCRIPTION OF PROCESS AND EQUIPMENT

Provide a description of the processes and/or equipment used in oil and/or gas extraction for this topic. Note that this report template will be used for all topics of the MAP review and, thus, not all questions or information may be relevant for each topic. If information is not relevant, indicate N/A. Note any differences expected for differing well types, industry sector, or basin location.

Technical description of the process or equipment:

Oil and gas production facilities contain numerous equipment components such as connectors, covers, closed vent systems (CVS's), flanges, instruments, meters, open ended lines (OEL's), pressure relief devices (PRD's), thief hatches, valves and others (see list from EPA 4/12/2018 Memo: Equivalency of State Fugitive Emissions Programs…). These components are manufactured and installed in ways intended to contain gases or liquids. Although these equipment components are designed to be gas tight, over time leaks can occur. The leaks (emissions) from these components are called fugitive emissions[4]. Fugitive emissions do not include equipment that is designed to vent or release emissions as part of normal operations or equipment that is already subject to monthly AVO inspections under NSPS 60.5411a or 60.5395a (see OOOOa definition of Fugitive Emission Component). Fugitive emissions result from changes in pressure, temperature or mechanical stresses or when seals and gaskets are not fitted or deteriorate over time.

The largest sources of fugitive emissions are generally detected quickly without advanced detection tools. These events are usually detected by observable changes by operators conducting routine inspections using sight, sound or smell (specifically in older facilities, and in operating parameters (i.e. Supervisory Control and Data Acquisition (SCADA) system detection when available, change in sales volume at the meter, compressor shut down).

Leak detection and repair (LDAR) programs employ specialized detection equipment to detect fugitive emissions, which also sometimes include audio, visual, and olfactory observations, generally target sources of fugitive emissions. The most commonly used leak detection equipment is an optical gas imager, but in some areas like parts of California, companies

[4] Where devices are designed to vent as part of normal operations, such as natural gas-driven pneumatic devices or uncontrolled storage vessels, the natural gas and associated VOC emissions are not considered a fugitive emission. These emissions are covered in other MAP papers.

also use handheld "sniffers" (portable hydrocarbon detectors) and Tunable Diode Laser Absorption Spectroscopy devices. The detection technology space has received significant investment over the past several years, including the U.S. Department of Energy's MONITOR program[5]. The results of this investment are just beginning deployment and are beginning to approach commercial scale for some technologies.

In 1990, the Clean Air Act was enacted to address several subject matters including volatile organic compounds (VOCs). This action included the implementation of a Leak Detection and Repair (LDAR) Program to use portable instrumentation and processes to locate emission leaks on process equipment that includes, but is not limited to, things such as compressors, flanges, and valves. If leaks are discovered, they are scheduled for repair.
Traditional technology leak detection technologies allowed by Method 21 include: gas sniffers such as Toxic Vapor Analyzers, organic vapor analyzers, and flame ionization detectors (FID). Moreover, the traditional Method 21 protocol also allows the use of soap bubbles for leak detection which can be very sensitive for small leaks but is not appropriate for hot surfaces. With the introduction of handheld optical gas imaging (OGI) in 2005, the EPA was urged to enact "smart LDAR." Thus, the EPA's Alternative Work Practice (AWP) was enacted to allow OGI in lieu of the "sniffer" method in December 2008. In June 2016, the EPA published an amendment to the NSPS regulations that recognized OGI as the Best System for Emissions Reduction (BSER). Traditional Method 21 is now an alternative to OGI with conditions.

Provide the segment(s) of the industry that the equipment or process is found:

Components that have potential to leak can be found throughout the production, midstream, gas plants, transmission and distribution sectors.

Describe how the equipment or process is used:

Components serve numerous purposes throughout the value chain. They are all intended to contain gas, but may develop leaks.

Provide the common process configurations that use this equipment or process

N/A

What is the distribution of the equipment or process across business segments?

This equipment is found in upstream, midstream, transmission and distribution segments.

How has this equipment or process evolved over time?

Over time, awareness of the potential for leaks has grown, so has the number of technology solutions available to detect leaks. Over time, operators minimize threaded connections, receive specific training, conduct preventive maintenance and utilize tools such as SCADA to monitor for changes in process parameters which may indicate a leak.

Federal regulations first specifically addressed oil and natural gas related emissions with the implementation of the Method 21 Alternative Work Practices (AWP) in 2008 and later with the NSPS 2012 OOOO and 2016 OOOOa regulations. Though traditional Method 21 sampling methodologies have been in existence for years, the LDAR components of these most recent regulations were aided by the introduction of OGI and various vent gas recovery infrastructure and procedures.

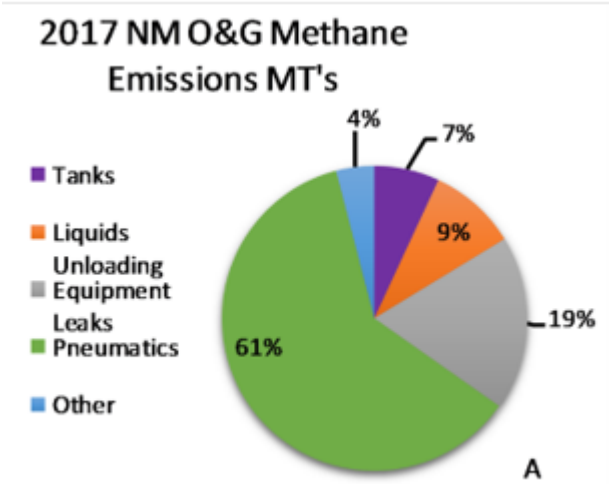
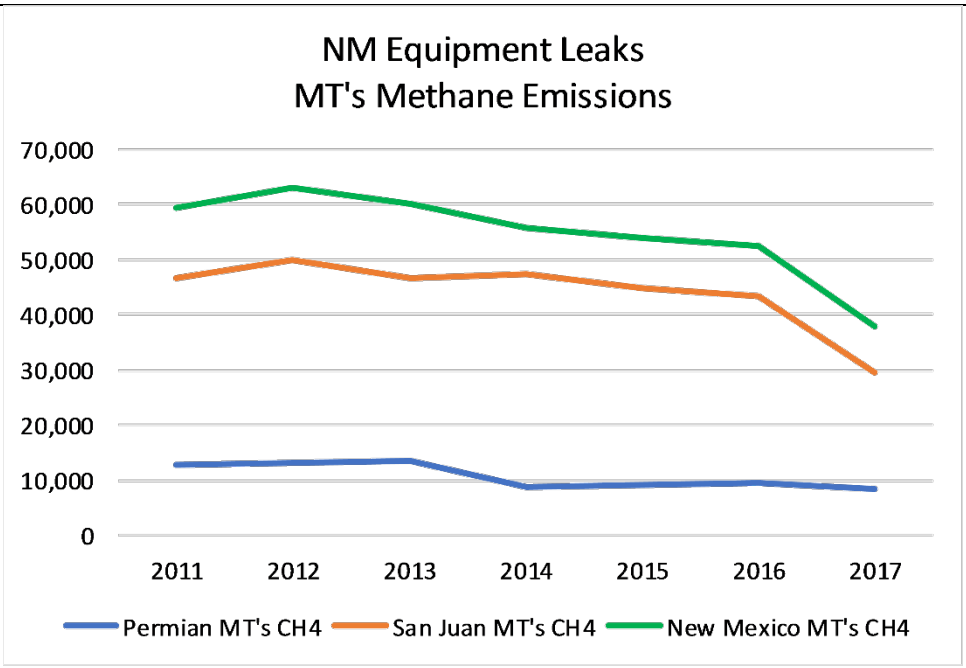
2. INFORMATION ON EQUIPMENT OR PROCESS COSTS, SOURCES OF METHANE EMISSIONS, AND REDUCTION OR CONTROL OPTIONS



Identify the capital and operating costs for the equipment or the process. Identify how methane is emitted or could be leaked into the air. Please **prioritize** the list to identify first the largest source of methane from the process or equipment and where there is **potential** for the greatest reduction of methane emissions. Note any differences expected for differing well types, industry sector, or basin location.



Sources of Methane:

Provide an overview of the sources of methane from this equipment or process:

Leaks, or fugitive emissions, can develop in a range of equipment that is widely deployed across the value chain. Connectors, valves, seals, tubing, open ended lines, and flanges, while designed to contain gas, can develop leaks over time.

Analysis of GHGRP data found in the New Mexico Oil and Gas Association's Methane Mitigation Roadmap below: https://www.nmoga.org/methaneroadmap

NM equipment leak methane emissions

Leaking components, and equipment as well as improperly operating or malfunctioning equipment, contribute leaks that can be addressed by frequent inspections. The following summarizes studies identifying leaks from a variety of oil and gas sources.

I. Field Studies Using Direct Measurement Demonstrate the Need for Frequent Instrument-Based Inspections: Significant Emissions May Emanate From Individual Components and Operations

The scientific consensus, based on numerous studies involving direct measurement of oil and gas leaks, demonstrates the heterogeneous, unpredictable, and ever-shifting nature of equipment leaks. These characteristics strongly point toward the need for frequent, *if not continuous*, inspections to identify and repair leaking components and equipment. Specifically:

- **Leaks are Heterogeneously Distributed.** There is considerable evidence that emissions from equipment leaks are heterogeneously distributed—with a small percentage of sources accounting for a large portion of emissions.[6] The concentration of emissions within a relatively small proportion of sources has been observed both among groups

[6] *See, e.g.*, Allen, D.T., *et al.*, "Measurements of methane emissions at natural gas production sites in the United States," *Proc. Natl. Acad.*, 110 (44) pp. 17768–17773 ("Allen (2013)"), *available at* http://www.pnas.org/content/110/44/17768.full; ERG and Sage Environmental Consulting, LP, "City of Fort Worth Natural Gas Air Quality Study, Final Report" ("Fort Worth Study") (July 13, 2011), *available at* http://fortworthtexas.gov/gaswells/default.aspx?id=87074 (finding that the highest 20 percent of emitting sites account for 60–80 percent of total emissions from all sites; the lowest 50 percent of sites account for only 3–10 percent of total emissions); Zavala-Araiza, *et al.*, (2015) "Toward a Functional Definition of Methane Super-Emitters: Application to Natural Gas Production Sites," *Environ. Sci. Technol.*, 49, at 8167−8174 ("Zavala-Araiza (2015)"), *available at* http://pubs.acs.org/doi/pdfplus/10.1021/acs.est.5b00133 (finding that "functional super-emitter" sites represented approximately 15% of sites within each of several different "cohorts" based on production, but accounted for approximately 58 to 80% of emissions within each production cohort); Zavala-Araiza et al., (2015) "Reconciling divergent estimates of oil and gas methane emissions," Proceedings of the National Academy of Sciences, vol. 112, no. 51, 15597 at 15600 (finding that "at any one time, 2% of facilities in the Barnett region are responsible for 90% of emissions, and 10% are responsible for 90% of emissions.") ("Barnett Synthesis").

of components within a site and among groups of entire facilities.[7] One study in particular found that a small number of sources are responsible for a disproportionate amount of emissions, noting specifically that "sites with high proportional loss rates have excess emissions resulting from abnormal or otherwise avoidable operating conditions, such as improperly functioning equipment."[8]

- **Super-Emitters Are Not Included in Inventories**. Existing inventories do not accurately reflect the presence of disproportionally high emissions or "super-emitters."[9] A recent series of studies in the Barnett Shale region in Texas (the "Barnett Coordinated Campaign")—incorporating both top-down and bottom-up measurement—found that emissions were 50 percent greater than estimates based on the GHGI.[10] This study confirms the findings of various prior studies.

  The first of these studies, conducted by an independent team of scientists at the University of Texas, found that emissions from equipment leaks, pneumatic controllers and chemical injection pumps were each 38%, 63% and 100% higher, respectively, than as estimated in national inventories.[11] This study also found that 5% of the facilities were responsible for 27% of the emissions.[12]

  Two follow-up studies focused specifically on emissions from pneumatic controllers and liquids unloading activities at wells found similar results.[13] Specifically, the studies found that 19 percent of the pneumatic devices accounted for 95 percent of the emissions from the devices tested, and about 20 percent of the wells with unloading emissions accounted for 65 to 83 percent of those emissions. The average methane emissions per pneumatic controller were 17 percent higher than the average emissions per pneumatic controller in EPA's national greenhouse gas inventory.[14]

  These findings were reiterated again in a series of direct measurement studies focusing on emissions from compressor stations in the gathering and processing segment and in the transmission and storage segment. The gathering and processing study found substantial venting from liquids storage tanks at approximately 20 percent of the sampled gathering facilities.[15] Emission rates at these facilities were on average four times higher than rates observed at other facilities and, at some of these sites with substantial emissions, the authors found that company representatives made adjustments resulting in immediate reductions in emissions. In the study on transmission and storage emissions, the two sites with very significant emissions were both due to leaks or venting at isolation

valves.[16] The study also found that leaks were a major source of emissions across sources, concluding that measured emissions are larger than would be estimated by the emission factors used in EPA's reporting program.

- **Equipment Leaks are Unpredictable**. Recent studies have assessed whether well characteristics and configurations can predict super-emitters, concluding that they are only weakly related,[17] and that these emissions are largely stochastic. A recent helicopter study of 8,220 well pads in seven basins confirms that leaks occur randomly and are not well correlated with characteristics of well pads, such as age, production type or well count.[18] That study focused only on very high emitting sources, given the helicopter survey detection limit which ranged from 35–105 metric tons per year of methane. The paper reported that emissions exceeding the high detection limits were found at 327 sites. 92 percent of the emission sources identified were associated with tanks, including some tanks with control devices that were not functioning properly and so could be expected to be addressed through a leak detection and repair program. While the study did not characterize the individually smaller but collectively significant leaks that fell below the detection limit, it nonetheless confirms that high-emitting leaks occur at a significant number of production sites and that total emissions from such leaks are very likely underestimated in official inventories.

- **Super-Emitters Shift in Time and Space**. Abnormal operating conditions, such as improperly functioning equipment, can occur at different points in time across facilities.[19] While it is true that at any one time roughly 90% of emissions come from 10% of sites, these sites shift over time and space—meaning that, at a future time, a different 10% of sources could be responsible for the majority of emissions.[20]

Other studies resulted in similar findings. In a 2013 study measuring emissions from 200 well pads in the Barnett Shale researchers found that approximately 20% of the well pads were responsible for 80% of the emissions detected.[21] Another study focusing on short-term and maintenance-related emissions at well pads in Texas, Wyoming and Colorado found "a weak correlation between emission and production rates."[22] This multi-state study suggests that maintenance-related stochastic variables and the ways in which facilities and control equipment are designed can be important factors affecting emissions. (NOTE: to be determined if this is a modeling or measurement study.)

[22] Brantley, supra note 12, at 48.

A recent synthesis of the U.S. studies conducted over the past six years concluded that U.S. production emissions are 60% higher than inventories suggest.[23] Data for this study included measurement of emissions from over 400 individual well pads in six different US basins, validated against "top-down" airborne measurements of emissions from nine oil and gas producing basins. The authors of this synthesis study, as well as the underlying studies analyzed in the synthesis paper, include academics from twenty-five different research institutions. These scientists have concluded that the substantial extra emissions observed in these studies, compared to official inventories, likely arise from improper and abnormal operating conditions at the site level that are best addressed by frequent, if not continuous, inspections.

The nature of these events, specifically that they are unforeseen and unpredictable, require that operators vigilantly inspect their equipment and operations for leaks. Frequent inspections using modern leak detection equipment is one of the most effective way to minimize the pollution associated with these stochastic events.

The table and summary below, taken from the 2018 Omara et al study (link also below) shows the kg/hr of various studies in various basins. When compared to the EDF report referenced above there appears to be some information that stands out. In the recent report EDF says the following about the kg/hr emissions rates, the weighted average is about 14. The Omara study had an average of 1.79 kg/hr.

	Basin-level activity					Basin-level CH4 emissions					CH4 distribution			
Major O&NG Basin (EIA sedimentary basin boundary)	Total # well pad sites	# Wells /Pad	CH4 fraction in NG	CH4 fraction in NG reference	Basin-level CH4 prod (kg/h)	Mean Basin-level CH4 (kg/h)	Basin-level CH4, Lower bound (kg/h)	Basin-level CH4, Upper bound (kg/h)	CH4 kg/h/ site	Basin-level mean prod-normalized CH4 emissions (%)	% of mean total CH4 contributed by <10 Mcfd sites	% of mean total CH4 contributed by 10 to 100 Mcfd sites	% of mean total CH4 contributed by 100 to 1,000 Mcfd sites	% of mean total CH4 contributed by >1,000 Mcfd sites

For the 42 complex sites, there was a good log-normal fit; bootstrapping from the log-normal function resulted in a mean and 95% confidence interval EF of 18.2 (5.2 - 79) kg CH_4 site^{-1} h^{-1}. Human classification of satellite imagery outsourced with Amazon Mechanical Turk estimated that 33% of Permian well pad sites were complex with a slight dependence of percentage of complex sites on gas production. The 15th percentile lower bound EF of 9.2 kg CH_4 h^{-1} was applied to ~8,600 complex sites; the 0.04 kg CH_4 h^{-1} detection limit was applied to the ~17,200 simple sites. (LINK: https://pubs.acs.org/doi/10.1021/acs.est.8b03535)

[23] Alvarez, et al., "Assessment of methane emissions from the U.S. oil and gas supply chain" Science, June 2018, http://science.sciencemag.org/content/early/2018/06/20/science.aar7204.full.

I also think this table is interesting. In 7 months, EDF went from saying GHGRP is 3.5 times too low to 5 times too low.

EDF Study or Report Title	Primary Study Author	Compared to GHGRP	Methane (metric tons)
EDF Report	EDF - April 11, 2019	5 times too low	1,000,000
Methane emissions from natural gas production sites in the United States: Data synthesis and national estimate	Omara – Sept 2018	3.5 times too low	570,000

Recent studies show a dynamic change in leak rate. It appears the Littlefield study and the Alvarez study used the same measurement data, but there is a significant increase in leak rate between the two.

EDF Study or Report Title	Primary Study Author	Methane Leak Rate
Methane emissions from natural gas production sites in the United States: Data synthesis and national estimate	Omara – Sept 2018	3.4%
Assessment of methane emissions from the US oil and gas supply chain	Alvarez – July 2018	2.3%
Synthesis of Recent Ground-level Methane Emission Measurements from the U.S. Natural Gas Supply Chain	Littlefield - January 2017	1.7%

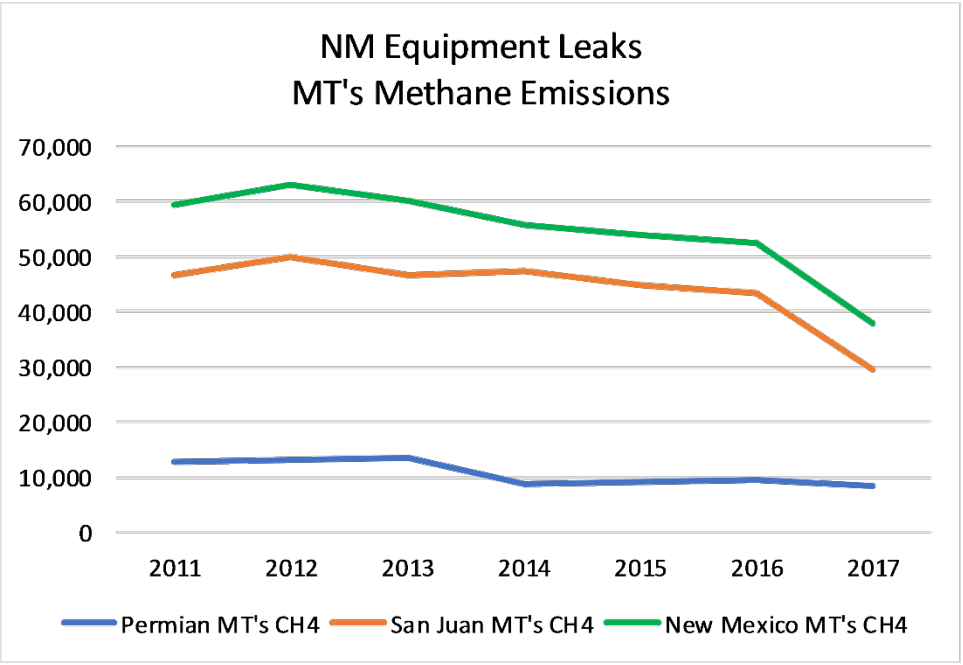
New Wells:

Leaks can be found at new and existing facilities. Data provided by the American Petroleum Institute (API) to EPA shows that the number of leaking components per site during initial instrument-based inspection is less than 2, and falls to less than 1 in subsequent surveys. (link) This dataset consisted of 6,000 total surveys across 3,482 sites and 13

operators across CO, LA, ND, NM, OH, OK, PA, TX, WY. The percent of sites where zero leaks were found is 58% and the average number of leaks found per site was 1.42 for the first survey and declines for subsequent surveys.

Existing Wells:

Leaks can be found at new and existing facilities.



How are the emissions calculated for this equipment or process?

US EPA provides multiple methods for estimating fugitive emissions which can be found at the link below. Traditionally, most operators use an approach that was based on site major equipment counts (i.e. number of separators, wellheads, etc.), default component counts (i.e. valves, flanges, etc.) per piece of major equipment, and default emission factor per component (i.e. average scf per hour per valve) that includes an assumed percentage of leaking components based on field work in the 1990s. Revisions to the EPA methods linked to OOOOa reporting, but voluntarily open to operators for use for sites not subject to OOOOa sites, use actual leak occurrence rate from instrumented surveys and a leak/no leak emissions factor. This method is just beginning to be required for OOOO sites but it does appear that when operators switch from the assumed leak occurrence rate to actual leak occurrence rate, emissions estimates are lower.

Equation from GHGRP Subpart W: https://www.ecfr.gov/cgi-bin/text-idx?SID=3393fe39418e975c59618f6249f55516&mc=true&node=se40.23.98_1233&rgn=div8

What data is available to quantify emissions/waste for this equipment or process?

The US EPA publishes most of the emission information and activity data that it receives as part of the US GHG Reporting Program annually (https://ghgdata.epa.gov/ghgp/main.do?site_preference=normal#). By March 31st of each year, operators upload their emission information based up on the annual national average and prescribed EPA methodologies to the EPA website for the previous year (i.e. 2018 emission information was reported in March 2019), EPA undertakes a quality assurance process, and uploads the information in October to a publicly accessible website. Care should be taken in estimating emissions from this inventory for New Mexico since both the Permian and San Juan Basins span multiple states and it's challenging to separate emissions between states for all source categories. In the analysis below, NM data was separated from surrounding state data utilizing DrillingInfo data (a database of state well permit information). Also, operators with less than 25,000 MT CO_2e emissions are exempt from reporting emissions to the GHGRP. Therefore, for the production segment, all emissions were scaled up to the total well count reported by the New Mexico Oil Conservation Division (NMOCD) (EIA for national). For the G&B segment, there is no information to enable scaling-up GHGRP reported emissions and raw GHGRP reported emission quantities are shown.

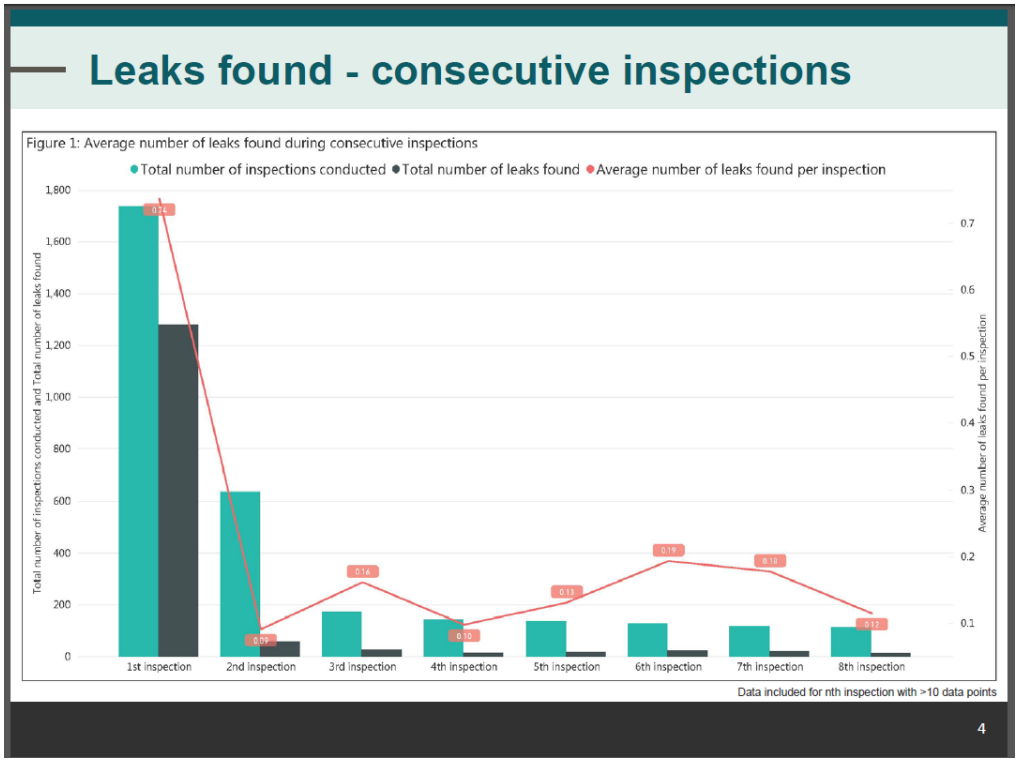
NM equipment leak methane emissions

Analysis of GHGRP data found in the New Mexico Oil and Gas Association's Methane Mitigation Roadmap: https://www.nmoga.org/methaneroadmap

What are the data gaps in quantifying emissions/waste for this equipment?

Numerous studies have measured emission rates from specific types of oil and gas sources, including equipment components that are the primary focus of LDAR programs. Other types of studies have conducted off-site measurements (such as ambient methane concentration data collected on roads near sites using OTM33a) or detection of emissions (such as from aerial helicopter surveys) and have inferred emission rates based on atmospheric modeling or other indirect methods. While different study approaches can provide different information on methane emissions, the most useful studies for assessing emission detection and mitigation from LDAR components focus on approaches that provide component-specific information and that utilize proven tools deployed in the upstream oil and gas industry.

Leak data on marginal wells is very limited and warrants further study through objective, transparent, repeatable, and reliable emissions measurements.



Different industry trade associations have collected information on the number and frequency of leaks detected under existing Federal and state-level programs. As with typical LDAR programs, the number of leaks detected and repaired are recorded but quantification of the detected leaks was not reported.

- A recent review of NSPS OOOOa leak survey data indicates that annual inspection frequency is appropriate for non-marginal well sites or facilities.[24] . (link) Data from various federal and state and inspection programs, including Colorado, demonstrates that the initial component leak rate from initial inspection surveys, show a significantly lower

[24] https://www.regulations.gov/document?D=EPA-HQ-OAR-2017-0483-0015

number of leaks than previously assumed. For example, an API analysis of initial NSPS OOOOa inspections showed that only 0.4% of components are found to be leaking during the initial inspection. (link)

- West Slope Colorado data represented in the figure below from 6 operators at 1,700 facilities showed a 0.74 component leaks per site with emissions less than 6 tons per year VOC. (link)

- Additionally, the number of leaks found in inspections at subject facilities in Colorado show a 52% decrease in the number of leaks from 2015 to 2017, while the number of facilities inspected increased by 9%.[25].

Several peer-reviewed studies have also assessed equipment leak emissions more directly by utilizing typical LDAR tools (FLIR cameras, sniffers, etc.) to detect leaks on sites and specialized tools like high volume samplers to quantify emissions from detected leaks. Due to the time requirements for quantification, the sample sizes of sites tend to be smaller than the data presented from industry LDAR programs like those mentioned in the bullets above. In total, these studies have typically found that emission estimates for equipment leaks (leaking valves, flanges, etc.) that are similar to or lower than emission estimates used in EPA reporting. These studies include:

- Researchers at the University of Texas at Austin led a field campaign (link) that measured methane emissions at 190 new onshore gas well sites in the United States, including from 278 identified equipment leaks. The study developed regional emission factors for estimated methane emissions from equipment leaks per well to compare with methods that EPA had utilized for estimating emissions for national emission inventories at the time of the study and found that emissions per well were similar to EPA emission factors at the time. EPA has since changed its approach for estimating equipment leaks nationally to reflect the equipment-specific information that is available through the GHGRP.
- A 2015 field campaign (link) that was funded by the American Petroleum Institute (API) included leak detection at 67 production and gathering and boosting sites throughout the Western United States with both a FLIR camera and

[25] https://www.colorado.gov/pacific/cdphe/2017-ldar-annual-reports-regulation-7-section-xvii

a sniffer as well as quantification of all leaks determined with either method. The study found a leak rate of 0.39% of components surveyed and that quantified emission rates from equipment leaks were 22%-36% less than would have been calculated from EPA emission factors based on site-level component counts. The study also notes that the study upon which current EPA emission factors were based from the early 1990's identified 1.77% of components as leaking with a sniffer versus 0.35% with the same technology (sniffer) and leak definition (500 ppm) in the 2015 field campaign.

- A study of 25 natural gas sites in California (link) found that component-level emission factors (i.e. methane emissions per valve) were lower than those used in EPA GHG reporting.

To our industry knowledge, no specific peer-reviewed studies have been undertaken to develop New Mexico-specific emission factors for equipment leaks. The API 2015 field campaign did include measurements in the San Juan and Permian Basins, but metadata to identify the location at the state-level was not provided with the study results. The table below compares the study results in the Permian and San Juan Basins to the other basins in the study (Anadarko and Eagle Ford). Note that the study sample sizes at the basin level are small and the statistical significance of such comparisons has not been verified. Sites measured in the Permian Basin tended to have a smaller fraction of leaking components and overall emissions than those in other geographic regions in the study.

Basin	Number Sites	Number of Components Screened	# Leaks Identified	Equipment Leak Emissions Measured (scfh)	Percent of Components Identified as Leaking	Emissions (scfh)/Site
San Juan	10	10012	45	241.3	0.45%	24.13
Permian	13	19027	43	65.7	0.23%	5.05
Other Basins	42	54921	238	1125.8	0.43%	26.81

Economic Description of the Process or Equipment:

What is the per unit cost of the equipment or the costs associated with the process?

Costs vary widely based upon type of component and type of service.

A good quality FID might cost approximately $10-$15,000, while a new OGI camera costs an estimated between $85,000 and $110,000 depending on whether it has one fixed lens or multiple lenses.
https://www.trinityconsultants.com/news/federal/the-tangled-web-of-ldar-requirements-for-the-oil-and-gas-industry
FLIR® and Opgal® are the two main players in the OGI market, with both companies supplying EPA-recognized cameras that can be used to demonstrate compliance with federal LDAR rules. If quantification of emissions is desired, the FLIR GF320 camera can be used with a Providence Photonics QL320 tablet to quantitate the emissions. This QL320 tablet has an

approximate $20,000 cost. The FLIR® GF77® is a new uncooled infrared camera on the market that can visually detect methane for a lower estimated price of $50,000.

Neither camera is capable of speciation.

What are the annualized operating costs for the equipment or costs associated with the process?

Costs vary widely based upon type of service.
Depending on financial constraints or business models, companies have two basic options to conduct LDAR inspections. First, a company can purchase its own equipment and hire employees to conduct its LDAR functions. However, a company can also hire a third-party contractor to use its equipment to perform LDAR services. Though pricing can fluctuate, a 2014 study determined that average cost of hiring an external service provider to conduct OGI LDAR surveys was estimated to be $2,300 for a compressor station, $5,000 for a gas plant, $1,200 for a multi-well battery, $600 for a single well battery, and $400 for a well site. https://ourenergypolicy.org/wp-content/uploads/2014/03/Carbon_Limits_LDAR.pdf

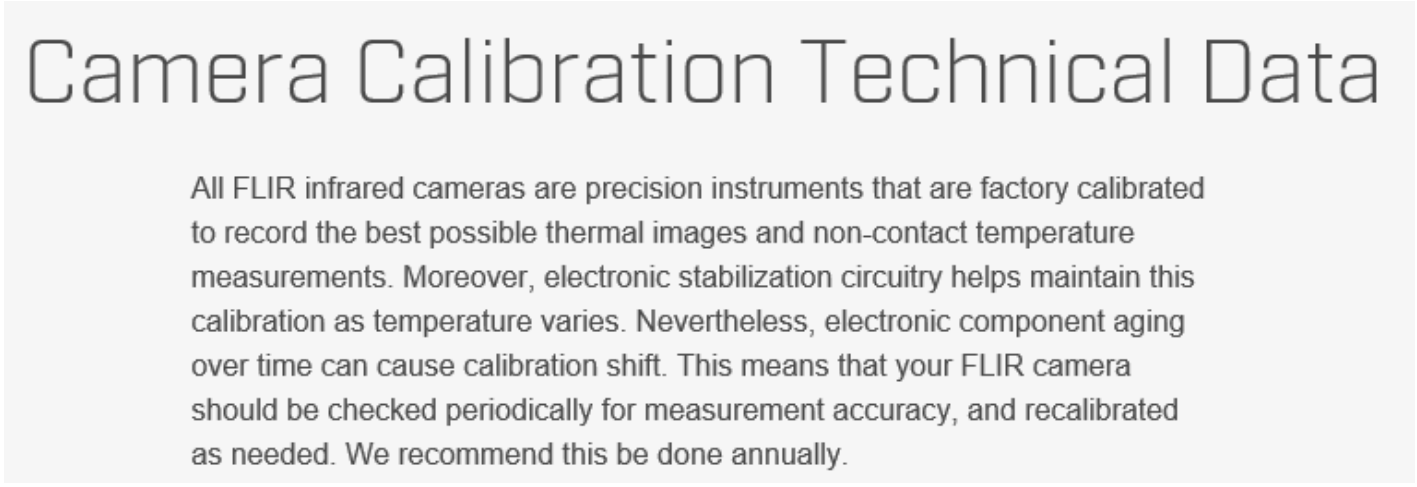
That being said, the state of Colorado estimates an estimated inspection cost of $450, Rebellion Photonics was quoted at $250 per site, and Jonah Energy estimated a cost of $99-$29 per inspection.
http://www.methanefacts.org/files/2016/05/LDAR-Fact-Sheet-FINAL.pdf

If a company chooses to hire its own employees for the LDAR function, the starting salary for such a technician is somewhere in the $15-$20 per hour range, though shortages in a hot market may affect that cost.

Glassdoor's "Gas Leak Survey Technician" job category shows the following average rates:– $47,831 annual/2080 hours (conservative, no vacation, no sick leave, no benefits) = $23/hour
https://www.glassdoor.com/Job/gas-leak-survey-technician-jobs-SRCH_KO0,26.htm?srs=TAB_OVER_SALARY_SEARCH

Permian salary: $1,100/week or $27.5 per hour per Dallas Federal Reserve.

Maintenance procedures are occasionally required on gas sniffers and are estimated to be $500 - $1,500 annually. This would not include the replacement of photo-ionization bulbs or calibration gases. Calibration gas costs are estimated to be $500 - $1,500 annually, while carrier gas costs may double that estimate if not readily available. If conducting soap bubble-based LDAR procedures, annualized equipment and supply costs are minimal.
Though not mandated, internal and third-party audits of a facility LDAR program are considered an LDAR best practice per the EPA's *Leak Detection and Repair – Best Practices Guide*. An audit checks that the correct equipment is being monitored and that Method 21 procedures are being followed, leaks are being fixed, and that the required records are being kept. Note: EPA's guide is intended for refineries and chemical plants.



Camera users require training. One course with publicly available information shows $2,000 and three days for the basic certification. https://courses.infraredtraining.com/index.cfm?action=registration.schedule&courseId=3

The below text is from FLIR, a manufacturer of optical gas imagers, noting their recommendation that cameras be calibrated annually.
https://www.flir.com/support-center/Instruments/service/calibration-technical-data/

Camera Calibration Technical Data

All FLIR infrared cameras are precision instruments that are factory calibrated to record the best possible thermal images and non-contact temperature measurements. Moreover, electronic stabilization circuitry helps maintain this calibration as temperature varies. Nevertheless, electronic component aging over time can cause calibration shift.

This means that your FLIR camera should be checked periodically for measurement accuracy and recalibrated as needed. We recommend this be done annually.

https://www.flir.com/discover/professional-tools/how-do-you-calibrate-a-thermal-imaging-camera/

How Do You Calibrate a Thermal Imaging Camera?

Calibrating a thermal camera is the process of correlating what the camera sees (infrared radiation) with known temperatures, so that the camera can accurately measure the radiation it detects. All FLIR cameras are calibrated to factory specifications, but over time, electronic component aging can cause calibration shift and produce inaccurate temperature measurements.

If this happens, can you recalibrate your thermal camera by yourself? Unfortunately, the answer is no: to maintain the accuracy of your thermal camera, you will need to send it in for regular calibration by the camera manufacturer. We recommend this be done annually.

End text from FLIR website.

Annual maintenance costs about $1500 - $2000.

If the equipment or process is powered, what are the costs?

Electricity need varies based upon the type of component. Most components in a leak program do not require electricity.

What are the maintenance and repair costs for existing or new equipment?

Costs vary widely based upon type of service and type of unit.

If measuring accurate temperatures are important, an annual calibration is required on FLIR GF320 cameras. This cost for this required factory calibration is estimated to be $2,000 per single lens. Annual calibrations are not recommended for FLIR gas finding cameras. Toxic vapor analyzers, flame ionization and photo-ionization detectors, and OGI's have a useful life of an estimated 10-15 years, if properly maintained.

Additional costs include mapping, tagging and recordkeeping

Existing Reduction Strategies:

How has industry reduced emissions/waste from this equipment or process historically?

There are two main strategies for reducing leak emissions:

1. Operator Routine Duties: Operators and contractors are given training and/or a checklist of activities to complete on each visit, including listening for leaks, looking for signs of potential leaks (i.e. frozen equipment), and examining operating parameters (drop in sales, SCADA indicators). Operators wear LEL (lower explosive limit) monitors for safety that detect emissions. These strategies are generally employed more frequently and are successful at catching larger leaks.
2. Instrument Based Leak Detection and Repair: Utilizing an instrument (generally optical gas imaging or a handheld gas detector "sniffer") at a prescribed frequency. Sniffer based programs have existed for decades, optical gas imaging is newer, but has been in use for a decade. In the past few years, there has been significant investment into new technologies, outlined below.

New Wells:

N/A

Existing Wells:

N/A

How have the emission/waste reductions been measured?

Utilizing EPA GHGRP emissions calculations.

How have states and the federal government reduced emissions/waste from this equipment or process historically? In addition, please identify voluntary reductions achieved whether or not they were in response to a regulatory action/requirement.

Federal Regulations

NSPS OOOOa requires semi-annual inspections at well sites and quarterly inspections at compressor stations. The definition of modification of a wellsite includes adding production to an existing battery, even if that battery remains below the original throughput levels. This means that many centralized facilities built before OOOOa was in effect are subject to the leak provisions. Similarly, the definition of a modification at a compressor station includes adding a compressor to an existing compressor station or replacing an existing compressor with one of greater horsepower. Modified compressor stations also become subject to leak provisions even if they were built before OOOOa went into effect.

OOOOa allows for surveys using optical gas imaging or handheld gas detectors. There is a process to request permission to utilize alternative technologies but the process is generally viewed as onerous and no technology has been approved. The approval process requires over one year, and is only applicable to one site if approval is received. At this point, we are aware of no operator who has requested approval of an alternative technology.
https://ecfr.io/Title-40/sp40.8.60.oooo_0a

State Regulations

The April 12, 2018 EPA Memo regarding the *Equivalency of State Fugitive Emission Programs for Well Sites and Compressor Stations to Proposed Standards at 40 CFR Part 60, Subpart OOOOa* summarizes the requirements of various state fugitive emissions programs. Summary tables for each state program are in the memo. https://www.epa.gov/sites/production/files/2018-09/documents/equivalency_of_state_fugitive_emissions_programs_for_well_sites_and_compressor_stations.pdf

Texas requires fugitive emission leak inspections at various frequencies, depending on the level of facility-wide potential emissions and the type of air permit issued to the facility. Under certain permitting mechanisms, the inspection frequency can be reduced to annual if the percentage of leaking components is consistently low. If the percentage of leaking components increases, then the inspection frequency also increases. The state allows optical gas imaging, handheld sniffers, and routine personnel duty AVO inspections under the various programs. Fugitive emission control credits are also allowed depending on the stringency of the Best Available Control Technology (BACT) program implemented.

https://www.tceq.texas.gov/permitting/air/guidance/newsourcereview/fugitives/nsr_fac_eqfug.html
https://www.tceq.texas.gov/assets/public/permitting/air/Guidance/NewSourceReview/fugitive-guidance.pdf

Colorado's Regulation 7 Section XVIII https://drive.google.com/file/d/168v7vMsFJtS7D8BWlnMbaXWA6uZUIyj8/view Requires inspections at a frequency determined by the sites potential to emit and by whether it is in an attainment or non-attainment area. The state allows optical gas imaging, handhelds, and has approved a small number of alternative technologies.

In Colorado, regulations require an initial survey within 30 days of commencing operation or rule application for existing sources. The inspection frequency is tiered depending on actual fugitive VOC tpy emissions as follows: Compressor stations: 0-12: Annual; 13-50: Quarterly; Over 50: Monthly. Well sites: 0-6: One-time; 7-12: Annual; 13-50: Quarterly; 50 and above: Monthly; Multi-well sites >20TPY without tanks: Monthly. Additionally, Colorado operators must use OGI, Method 21 or another approved technology. The rules also create incentives for using continuous emission monitors. If operators choose to use Method 21, there is a 500 ppm leak threshold (new compressor stations and new and existing well sites) and 2,000 ppm (existing compressor stations). Monitoring for LDAR applies to storage tanks and traditional components as well. Repairs must be made within 5 days, unless a delayed repair is warranted. If delayed, repairs must be made within 15 days after the delay ceases (e.g., receipt of part if part not in stock).[26] Colorado is also proposing new rules for LDAR which would increase the inspection frequency to semi-annual for compressor stations with VOC emissions greater than 0 and less than 12 tpy, on a rolling 12-month basis. The proposed rules would also require owners or operators of well production facilities with estimated uncontrolled actual VOC emissions greater than or equal to 2 but less than or equal to 12 tpy, based on a rolling twelve-month total, to inspect components for leaks using an approved instrument monitoring method at least semi-annually.[27]

In a review of the Colorado Air Pollution Control Division (APCD) analysis, it references "cost effectiveness" of various components of the LDAR program in units of cost($)/ton, but does not reference LDAR as highly cost effective implying positive net present values, particularly in the marginal well sector of the industry. In fact, the cited COST-BENEFIT ANALYSIS SUBMITTED PER 24-4-103(2.5), C.R.S. states that in addition to the direct costs of LDAR, implementation of the proposed strategies could potentially result in the shut-in of marginally producing wells, resulting in indirect costs in the form of lost revenues to oil and gas companies, loss of jobs associated with these facilities, lost royalty payments, and lost

[26] Colorado Air Quality Control Commission, 5 C.C.R. 1001-9, CO Reg. 7, § XVII.F. (Feb. 24, 2014), available at https://drive.google.com/file/d/168v7vMsFJtS7D8BWlnMbaXWA6uZUIyj8/view

[27] Colorado Air Quality Control Commission, proposed revisions to Regulation 7, available at https://drive.google.com/drive/folders/14fvt4C0Tzl79to4c2tVuLDKucksk5uaB

severance taxes. Based on available information the CAPCD found it could not reasonably calculate the amount of oil and gas that could be shut-in due to the proposed rule. All this at a natural gas price of $3.50 Mcf that the CAPCD used for calculation purposes in preparation for the 2014 hearing. After deducting lease bonus and New Mexico production tax deductions, $3.50/Mcf is a Henry Hub wellhead price that has not been seen on an annualized basis for the last 10 years, nor during the first 9 months of 2019 (EIA data). The average 9-month year-to-date Henry Hub wellhead price is $1.93/Mcf before basis, midstream or pipeline transportation, processing, dehydration, or compression costs are deducted. Furthermore, the CAPCD recognized that smaller companies cannot fully utilize an in-house inspection program and therefore would have to use a higher cost third party contractor for inspections. For well and well production facilities, the CAPCD assumed that any company with 500 or more inspections per year would conduct inspections in-house, and that companies with less than 500 inspections per year would use third party contractors. Using this assumption in New Mexico with the IHS statewide dataset of over 400 New Mexico operators reveals 4.8% operate 500 or more wells each, and 95.2% operate less than 500 wells each and would be using the more costly third-party services.

California requires LDAR at an annual or quarterly frequency depending on when the component came under an LDAR program. The state allows optical gas imaging or handhelds, though Air District programs may require handhelds. Heavy oil (API gravity 20 or less) bearing components are exempt from the program.
See https://ww2.arb.ca.gov/sites/default/files/2018-06/2017%20Final%20Reg%20Orders%20GHG%20Emission%20Standards.pdf

In California, owners or operators must conduct quarterly inspections using Method 21. After January 1, 2020, there will be a 1,000 ppm leak threshold for repairs. Leaks must be repaired within 2, 5 or 14 days, depending on the size of the leak. Components or component parts which incur 5 repair actions within a continuous 12-month period must be replaced and re-measured to determine that the component is below the minimum leak threshold.[28]

In Wyoming, New and Existing facilities must be inspected quarterly for leaks of 4 tpy or more of VOCs. Operators in Wyoming must record dates and results of LDAR inspections, including the date and type of corrective action taken as a result of the inspections. Components to be inspected include flanges, connectors, open-ended lines, pumps, valves, and "other" components listed in EPA Table 2-4. Operators must inspect using OGI, Method 21 or another approved technology.[29] Note this is for the non-attainment area.

Utah requires operators to develop an emissions monitoring plan that must include: (i) monitoring frequency; (ii) monitoring technique and equipment; (iii) procedures and timeframes for identifying and repairing leaks; (iv) recordkeeping practices; and (v) calibration and maintenance procedures for monitoring equipment. The plan must address monitoring for difficult-to-monitor & unsafe-to-monitor components. Operators must conduct monitoring surveys on site to observe each fugitive emissions component. The schedule for monitoring surveys is as follows: (i) No later than 180 days after 1/1/2018, or no later than 60 days after startup of production, whichever is later. (ii) Semiannually after the initial monitoring survey. Consecutive semiannual monitoring surveys conducted at least 4 months apart. (iii) Annually after the initial monitoring survey for "difficult-to-monitor" components. (iv) As required by the owner/operator's monitoring plan for "unsafe-to-monitor" components. Operators must use OGI or Method 21 or both. If fugitive emissions are detected, operators must repair the component as soon as possible but no later than 15 calendar days. If repair or replacement is technically infeasible, would require a vent blowdown, a well shutdown or well shut-in, or would be unsafe to repair during operation of the unit, repair or replacement shall be completed during the next well shutdown, well shut-in, after an unscheduled,

[28] 17 C.C.R. § 95669 (March 24, 2006), available at https://www.arb.ca.gov/cc/oil-gas/Oil%20and%20Gas%20Appx%20A%20Regulation%20Text.pdf
[29] WDEQ, Oil and Gas Production Facilities Ch. 6, Section 2 Permitting Guidance for the UGRB (2016), available at http://deq.wyoming.gov/media/attachments/Air%20Quality/New%20Source%20Review/Guidance%20Documents/5-12-2016%20Oil%20and%20Gas%20Guidance.pdf

planned or emergency vent blowdown or within 24 months, whichever is earlier. Operators must resurvey repaired or replaced fugitive emission component no later than 30 calendar days after fugitive emission component is repaired.[30]

Ohio and Pennsylvania both require LDAR for new sources. In Ohio, the Initial inspection must be within 90 days of startup and then quarterly for the next 4 quarters. Operators can step down to semi-annual after 4 consecutive quarters with no more than 2% of components leaking and down to annual after 2 consecutive semi-annual inspections if no more than 2% of components leaking. Operators must step up to the original quarterly inspections whenever 2% of more of components are leaking. Acceptable inspection methods include FLIR cameras or Method 21 compliant analyzers.[31] In Pennsylvania, GP 5 covers sources at natural gas compression stations, processing plants, and transmission Stations, and requires quarterly LDAR. GP 5A covers sources at unconventional natural gas well sites, and requires quarterly LDAR with step down to semi-annual based on 2% of components leaking after 2 consecutive inspections. Operators must step back up to quarterly inspections if more than 2% of components are found leaking at any time. Modified existing wells (those that are re-fracked) are also subject to this requirement.[32]

The field of leak detection technology is evolving rapidly. Emerging technologies and inspection methods, such as mobile mounted IR cameras and lasers, and continuous stationary monitors, have the potential to significantly cut down on inspection time while also increasing the speed at which leaks are detected. EPA, a handful of states including Colorado, Wyoming, and Pennsylvania, and the countries of Canada and Mexico have revised their rules and General Permits to include a provision that allows operators to request approval to use an alternative leak detection method or technology in order to provide a pathway for approval of these innovative approaches. Colorado's alternative compliance pathway provides a good example. Colorado requires that an alternative method must be able to demonstrate it is capable of achieving emission reductions that are at least as effective as the emissions reduction achieved using an IR camera or EPA Reference Method 21.[33] In addition, the proposed alternative must be commercially available.[34] Applicants must provide detailed information on the alternative technology or method, including but not limited to, its limitations, the process for recordkeeping, whether it has been approved for other applications or by other regulators, and any modeling results or test data.[35] Colorado allows manufacturers of alternative instrument monitoring methods (AIMM), as well as operators, to apply to use an alternative AIMM. Approved AIMM may be used by any operator in Colorado to comply with well production facility and compressor station LDAR inspections. In addition, approved AIMM may be used to conduct inspections of pneumatic controllers in the Denver nonattainment area.[36] In Colorado, the application and approval process are subject to public notice and comment if the request is for use in the Denver metropolitan ozone nonattainment area.

Internationally, Mexico requires quarterly LDAR and inspection frequency is tied to emission thresholds.[37] Canadian operators must have an LDAR program and inspections must occur three times a year. LDAR in Canada applies to all sources of unintentional venting and traditional components but is not applicable at standalone well heads.[38]

Note, no current state or federal rules allow for easy adopting of new technologies, nor do they allow the flexibility that would be required for companies to adopt new technologies.

What are examples of process changes/modifications that reduce or eliminate emissions/waste from this equipment or process?

Limiting the number of components where leaks can occur is one potential process modification, however, this is not often feasible due to operational needs for components. Lowering pressure could potentially reduce the volume of emissions from a leak. Other papers provide information on need for and opportunities to reduce components.

Per the EPA's *Leak Detection and Repair – Best Practices Guide*, "Facilities can control emissions for equipment leaks…by modifying/replacing leaking equipment with "leakless" components. Emissions from pumps and valves can also be reduced through the use of "leakless" valves and "sealless" pumps. Common leakless valves include bellows and diaphragm valves, while common sealless pumps include diaphragm pumps, canned motor pumps, and magnetic drive pumps. Leaks from pumps can also be reduced by using dual seals with or without barrier fluid.https://www.epa.gov/sites/production/files/2014-02/documents/ldarguide.pdf

(note this guidance document is for refineries and chemical plants)

Regarding potential emission leaks from tank hatches, gates, valves, and other mechanisms, the Unico UWS™ Hatch Sense wireless sensor is designed to monitor those devices. https://www.unicous.com/products/uws-hatch-sense-system It contains a magnetic proximity switch that detects if the latch on the hatch is open or closed by using Bluetooth Low Energy technology to communicate with a mobile device or a Unico UWS™ Gateway.https://www.unicous.com/sites/default/files/user_files/UWS%20Hatch%20Sense%204.25%20-%20Gateway%20UWS%20Hatch%20Sense.pdf

Moreover, the use of low bleed or no bleed pneumatic devices, including but not limited to controller boxes, would reduce existing and new methane emissions. Such emissions are relevant as they add to total airshed methane concentrations that would be readily detected by OGI's while conducting LDAR surveys.

Technology Alternatives:

List of technology alternatives with link to information or contact information for the company/developers.

What technology alternatives exist to reduce or detect emissions? Please list all alternatives identified along with contact information for further investigation of this technology or process.

Name/Description of Technology	Link (and contact info for company if available)	Availability	Feasibility	Cost Range (choose one)
Satellite Technologies	https://www.ghgsat.com/ https://www.edf.org/climate/space-technology-can-cut-climate-pollution-earth/satellite-ted-talk?gclid=Cj0KCQjwoqDtBRD-ARIsAL4pviCVquAnSTU-omgAqlYBASV79h5DJ	**In use, though not for site level leak detection**	Current detection threshold makes identifying specific sites with emissions a challenge	Not yet in common use

Aerial basin level surveys	http://kairosaerospace.com/ https://www.bridgerphotonics.com/ http://www.scientificaviation.com https://www.leaksurveysinc.com/ https://www.ball.com/aerospace/newsroom/features/light_the_way_with_methane_monitoring	**In some commercial use**	Range of detection thresholds, generally an order of magnitude or more greater than optical gas imaging. Therefore, the technologies generally serve as a screening method. If emissions are detected, a crew with a secondary device will need to visit the site to isolate the piece of equipment.	Medium
Site level surveys (aerial drone or truck)	https://www.seekops.com/ http://www.aerodyne.com/aerodyne-mobile-laboratory https://www.bhge.com/news/bhge-launches-lumen-ground-drone-based-advanced-methane-detection-reduction-system https://www.elementascience.org/articles/10.1525/elementa.373/	**In use.** For the drone, until there is beyond visual line of site, this is nearly as limited for many places in terms of personnel needing to visit each site, but now requires a much more specialized skilled operator to operate. The cost of the LDAR technician goes up for similar time, resulting in a solution with slightly less detection sensitivity but just as much resource.	Detection at the equipment level is still being piloted, so serves as a screening method. Also may detect non fugitive sources. If emissions are detected, a crew with a secondary device will need to visit the site to isolate the piece of equipment.	Medium -High depending on density and proximity. Currently not approved by regulators except for Optical Gas Imager on drone. Drones provide major equipment group level information that requires more detailed inspection to identify a specific leaking component. Trucks provide site-level information

				that will require more detailed inspection to locate component level information (directed LDAR).
Equipment level surveys	https://www.flir.com/browse/industrial/gas-detection-cameras/ https://www.raesystems.com https://heathus.com/products/rmld-cs/	**In use**	Medium – Instruments range from ~10-15K (handheld sniffer – see above) to ~100k (optical gas imaging – sited in various regulatory impact assessments), significant personnel time required for both technologies. Handheld sniffer may require significant tagging expense and generally require more time in the field.	**Varies with site size / amount of travel time**
Fixed/Continuous Monitoring	Troposphere Quanta3 Lumen IBM https://www.projectcanary.com/ https://rebellionphotonics.com/	Being piloted	Generally works as an alarm requiring follow-up. Does not quantify or identify the specific piece of equipment or component. May require meteorological data to corroborate source of readings. Has certain electricity and data management/network requirements.	Still in development with some pilot testing. Provides site-level information that will require more detailed inspection to locate component level information (directed LDAR).

Though not mandated, FLIR GF320 OGI's can be equipped with a QL 320 quantification tool developed by Providence Photonics. This QL320 can also be used in other FLIR GF series cameras by asking the factory to add the Q Mode for offline processing. By combining these two technologies, it is possible to quantitate emission losses. The QL320 calculates the leak quantity in multiple units (as desired) based on the image and response factors unique to each gas. With continued changes to the software and post-processing capabilities, accuracy of measurements has increased substantially since the first release of the technology. Under correct use, the QL320 can achieve field accuracy of +/- 10% of a one minute running average of emissions rates. Lab results using measured releases have achieved 2% accuracy.

In 2018 – 2019, Earthworks has used the QL 320 to quantify emissions from storage tanks, pipe fitting leaks, pneumatic controller exhaust, unlit flares, and other sources in several states, including 30 measurements in New Mexico from ten different sites in Eddy, Rio Arriba, Sandoval, and San Juan counties. Average leak rates for the New Mexico sites have ranged from 52.44 to 0.2 lbs/hr. The QL 320 quantification software is still in the development phase.

This link goes to the Broomfield monitoring site where the monitoring technology, parameters and data are all posted. A year's worth of data has been collected and posted.

TCEQ helicopter flyover program is internally funded by TCEQ's air quality division. There is some information about the TCEQ helicopter program in this presentation:
https://tipro.org/UserFiles/TCEQ_OG_Update_TIPRO_August_2018.pdf.

What are the pros and cons of the alternatives?

While new technologies have shown great promise in detecting emissions at a lower cost, there is generally a tradeoff in terms of detection limit and ability to pinpoint the location of a leak. There is some funding at Colorado State University, who has convened discussions, to continue to develop a next generation of FEAST model which will help inform this and an associated technical project.

What is needed and available for new wells?

NSPS OOOOa applies to facilities built after September 18, 2015 or taking new production after that same date. Due to the small number of components, EPA exempts wellhead only facilities.

What is needed and available for existing wells?

Marginal wells (< 15 barrels of oil equivalent per day) should be excluded from the LDAR program. Marginal wells, by their nature, are lower producing and generally requires less equipment with fewer components. In fact, data (see API study noted above) has indicated that leak detection is most effective on the initial inspection to ensure that all components and equipment are tightened from the outset and that the frequency of detection lowers over time. These factors mean that the cost of each marginal well LDAR survey often outweighs the benefits of the potential emission reductions and can threaten their financial viability. In the oil-and-gas Control Technique Guidelines, EPA expressly recognized that fugitive emissions at low-production sites are inherently low and thus included an exemption from the LDAR program for well sites with an average production of less than 15 barrels of oil equivalent per day. Unless and until additional comprehensive and conclusive data has been collected to suggest that marginal wells warrant inclusion in an LDAR program, these wells should be excluded. Leak data on marginal wells is very limited and warrants further study through objective, transparent, repeatable, and reliable emissions measurements. The sample size of the current data set is too small to provide conclusive results. Proper inspection methods and associate frequency must be informed by well-established data that can correlate production and emissions. Other factors that must be weighed are type and quantity of equipment, frequency of episodic emission events, equipment age/condition, and absolute contribution to total emissions. The Department of Energy is co-funding such a study titled "Quantification of Methane Emissions from Marginal (Small Producing) Oil and Gas Wells" being conducted by GSI Environmental Inc.

Wellhead only locations should not be included in the LDAR program due to very limited equipment, therefore limited potential to emit, on location, consistent with NSPS OOOOa. Facilities that do not require permits similarly have very limited equipment and should be exempt from a LDAR program. Facilities without controlled equipment would not benefit from an LDAR program as a low level of emissions will occur under allowable permit limits with or without an inspection program.

What technology alternatives exist for this equipment or process itself?

N/A

What are the pros and cons of the alternatives?

See above.

Costs of Methane Reductions:

What is the cost to achieve methane emission reductions?

It is very difficult to generalize costs due to the wide range of technology applications and other variables such as distance to survey, repair costs, etc. See API LDAR paper in the data section.

Information from various U.S. jurisdictions and independent consulting groups demonstrates that quarterly LDAR inspections are highly cost effective: [note – one member's opinion]

- **Colorado**. The final cost benefit analysis prepared by the Colorado Air Pollution Control Division (APCD) in support of its LDAR program demonstrates that quarterly inspections are cost effective. For mid-sized well sites, Colorado found the cost effectiveness of quarterly LDAR inspections to be $1,019 per ton of VOC reduced and $679 per ton of CH4/ethane reduced for facilities located in the Denver non-attainment area. For remote facilities located outside the Denver-Julesburg basin, Colorado determined quarterly inspections to be cost effective at $1,268 per ton of VOC reduced and $648 per ton of CH4/ethane reduced.[39] Colorado determined that requiring quarterly inspections for compressor stations is cost effective, estimating a control cost of $2,273 per ton of VOC reduced.[40] In a review of the APCD analysis, it references "cost effectiveness" of various components of the LDAR program in units of cost($)/ton, but does not reference LDAR as highly cost effective implying positive net present values, particularly in the marginal well sector of the industry. In fact, the cited COST-BENEFIT ANALYSIS SUBMITTED PER 24-4-103(2.5), C.R.S. states that in addition to the direct costs of LDAR, implementation of the proposed strategies could potentially result in the shut-in of marginally producing wells, resulting in indirect costs in the form of lost revenues to oil and gas companies, loss of jobs associated with these facilities, lost royalty payments, and lost severance taxes. Based on available information the CAPCD found it could not reasonably calculate the amount of oil and gas that could be shut-in due to the proposed rule. All this at a natural gas price of $3.50 Mcf that the CAPCD used for calculation purposes in preparation for the 2014 hearing. After deducting lease bonus and New Mexico production tax deductions, $3.50/Mcf is a Henry Hub wellhead price that has not been seen on an annualized basis for the last 10 years, nor during the first 9 months of 2019 (EIA data). The average 9 month year-to-date Henry Hub wellhead price is $1.93/Mcf before basis, midstream or

[39] Colorado Air Pollution Control Division, Cost-Benefit Analysis for Proposed Revisions to AQCC Regulations No. 3 and 7 (February 7, 2014) ("CAPCD Cost-Benefit"), at 28, Table 34, *available at* https://www.regulations.gov/document?D=EPA-HQ-OAR-2010-0505-7573.

[40] Colorado Air Pollution Control Division, Economic Impact Analysis (Final) for Regulation 7, Sections II., XII., XVII., XVIII. p.5 (October 4, 2017).

pipeline transportation, processing, dehydration, or compression costs are deducted. Furthermore, the CAPCD recognized that smaller companies cannot fully utilize an in-house inspection program and therefore would have to use a higher cost third party contractor for inspections. For well and well production facilities, the CAPCD assumed that any company with 500 or more inspections per year would conduct inspections in-house, and that companies with less than 500 inspections per year would use third party contractors. Using this assumption in New Mexico with the IHS statewide dataset of over 400 New Mexico operators reveals 4.8% operate 500 or more wells each, and 95.2% operate less than 500 wells each and would be using the more costly third party services.

- **California**. The California Air Resources Board (CARB) has found conducting quarterly inspections at production facilities to be highly cost effective. CARB estimates the costs are $23 per metric ton of CO_2e reduced (accounting for savings from recovered product) to $26 per metric ton of CO_2e reduced (not accounting for savings).[41] These estimates assume a 20-year global warming potential for methane. (Note: current carbon trading price in California is $15 per metric ton). Again, as in the Colorado citation above, CARB made cost effectiveness comparisons on a cost/ton basis, but made no claim in the citation that quarterly inspections are "highly cost effective" implying positive net present value. Also, as in the California study, an overly optimistic natural gas price of $3.44/Mcf was used as compared to current and historic Henry Hub wellhead pricing discussed above. The CARB citation was abbreviated as compared to the Colorado study and did not break out the LDAR abatement costs for the well and well facility sector. The LDAR abatement metrics found on page 3 not only included both onshore and offshore well and well facilities, but also facilities involving natural gas processing and natural gas storage. There is a comment about "idle wells" but marginal wells were not mentioned in the CARB study. The LDAR abatement costs in the CARB study are most likely skewed downward by the larger facilities and "super leaker" data and not representative of the well and marginal well sector alone.

- **Carbon Limits Study**. This study is based on actual leak data from over 4,000 LDAR inspections of oil and gas facilities, such as well sites, gas compressor stations, and gas processing plants. The inspectors used infrared cameras to identify over 58,000 individual components that were leaking or venting gas. The inspection firms provided facility inspection costs and, for every leak they found, data such as the size of the leak and how much it would cost to repair. LDAR surveys performed quarterly would abate methane at a net cost of less than $280 per metric ton ($11/ton CO_2e using a global warming potential of 25) for all types of facilities. Per this study, over 90% of the gas leaking from these facilities is from leaks that can be fixed with a payback period of less than one year (assuming gas prices of $3 per thousand cubic feet).[42]

- The study breaks down facilities into three categories, 1) compressor stations, 2) gas plants, and 3) well and well batteries that include anywhere from 1 to 15 wells per battery. This last category is beneficial to exam as it relates to marginal wells. There were 1,764 surveys of well and well batteries which represents 41% of all surveys. Although the well and well batteries are nearly half of the surveyed components, the study found that fully 36% (one third) of the well sites and batteries had no leaks. The remaining 64% of the well and well facilities were only 5.5% of the total leak rate attributed to all facilities combined. Fully 94.5% of the leak rate is attributed to compressor stations and gas plants. Within the study an economic assessment was run on the well and well batteries category in the form of three economic cases at varying gas prices. The three cases were run at a natural gas price of $3, $4, and $5 per Mcfg respectively with the average or base case being at $4/Mcfg. As discussed previously this $4/Mcf base case price is over 2 times higher than the average 9 month year-to-date Henry Hub wellhead price, and repeating, before any basis, transportation, processing, dehydration, or compression costs are deducted from the Henry Hub price. The study found that the LDAR program on the well and well battery category has the highest percentage of surveys with a negative NPV (positive or negative NPV being the difference between a project being economic versus uneconomic),

[41] CARB. Revised Emission and Cost Estimates for the Leak Detection and Repair Provision, (February, 2017). Available at: https://www.arb.ca.gov/regact/2016/oilandgas2016/oilgasatt2.pdf.

[42] Carbon Limits, Fact Sheet, Fixing the Leaks: What would it cost to clean up natural gas leaks?, available at http://www.catf.us/resources/factsheets/files/LDAR_Fact_Sheet.pdf. Full report available at http://www.catf.us/resources/publications/files/Carbon_Limits_LDAR.pdf.

concluding that over 80% of surveys are uneconomic even with the inflated natural gas pricing. Quoting the study, "This is because leak rates for well sites and batteries are generally smaller than that for gas plants or compressor stations". As far as a payback of less than one year for repair as stated above, it was found that the repair costs used in the study were seriously underestimated. As an example, an average valve repair is stated to cost $90. Adding transportation and roustabout crew time in Southeastern New Mexico for the repair puts the cost at $610 thus the realistic cost of a valve repair is nearly 7 times more than the study states, seriously calling into question the method of costing repairs in the study. The implication derived from this study is that all surveys on marginal wells would be uneconomic, particularly if economics were run at a more realistic natural gas wellhead price. Mandated quarterly surveys on marginal wells would create a situation of premature abandonment and underground waste of resource from the absolute lowest category of emitting facilities as identified by the Carbon Limits study.

- Concerning the exorbitant natural gas pricing used in economics within the older reports and studies cited heretofore, a more recent report prepared for the Environmental Defense Fund by Synapse Energy Economics, Inc. dated September of 2019 is available.[38A] This report utilizes Henry Hub natural gas index pricing and NYMEX forward pricing, less basis, to project the natural gas price for the next 10 years. Per the Synapse report "*Gas prices paid to producers in New Mexico are lower than the Henry Hub price (the most common national benchmark for natural gas prices) because of the cost to transport gas to the national market. This difference between Henry Hub and New Mexico gas prices is called the "basis.*"" Deducting lease burdens and New Mexico production taxes from the Synapse forward pricing yields an average 10 year forward projection of natural gas wellhead pricing in the Permian Basin of $1.60/MCF. This is a much more realistic natural gas price to utilize for average case economics. The Synapse study projected Permian gas price is 54% lower than the price used in Colorado economics, and 60% lower than the price used for base case economics in the Carbon Limits study.

- **Center for Methane Emissions Solutions**, **Colorado Case Study**. CMES interviewed 10 companies in Colorado operating after Colorado adopted its LDAR program in 2014. It found that 7 out of 10 companies interviewed reported that additional revenues from fixing leaks more than covers the costs of finding and fixing leaks.[43] An attempt to open the citation rendered a message "website expired".

- **ICF.** ICF developed a complex model to investigate the distribution of LDAR cost profiles at well sites (Attachment 1). This analysis seeks to develop facility models that replicate real world situations and capture variations in these characteristics by using a Monte Carlo simulation to analyze facility emissions, reductions and costs. These results further demonstrate that quarterly monitoring is cost-effective. ICF's estimate of the control costs for quarterly LDAR are equal to $262 per short ton of methane reduced, assuming $3 gas; $234 per short ton of methane reduced, assuming $4 gas; and $187 per short ton of methane reduced assuming $3 gas and the use of a contractor to perform the inspection.[44] The attached PowerPoint describes the modeling concepts and model inputs in greater detail. Page 8 of Attachment 1 indicates that the cost($)/Mcf-reduced metric is the "ratio of the total cost to conduct an LDAR survey to the difference in Mcf of emissions from the baseline each year where the baseline is assumed to be the uncontrolled emissions in the first year". This assumption is problematic for monitoring emissions on a depleting hydrocarbon flow rate as the emissions in the first year will diminish from year to year, even without emission controls, as the well producing rate declines. With many southeast New Mexico horizontal wells having an initial hyperbolic decline rate of 90% or more in the first year, this could be a large misrepresentation of the $/Mcf-reduced metric.

[43] Center for Methane Emissions Solutions, Colorado Case Study, available at https://static1.squarespace.com/static/558c5da5e4b0df58d72989de/t/57110da386db43c4be349dd8/1460735396217/Methane+Study.pdf.

[44] ICF's cost effectiveness estimates have been converted into dollars per short tons of methane.

- **Industry**. Jonah Energy—an operator in the Upper Green River Basin in Wyoming— has expressed its support of at least quarterly instrument-based inspections,[45] noting that it already complies with the proposal because "each month, Jonah Energy conducts infrared camera surveys using a forward-looking infrared camera ("FLIR") camera at each of our production facility locations."[46] According to Jonah, "[b]ased on a market value of natural gas of $4/MMBtu, the estimated gas savings from the repair of leaks identified exceeded the labor and material cost of repairing the identified leaks" while also significantly reducing pollution.[47] Jonah has reported that this highly cost-effective quarterly LDAR program has reduced fugitive VOC emissions from its facilities by over 75%, indicating that methane and other hydrocarbon losses have also been reduced by a similar proportion.[48] Jonah's experience that gas savings from repairs often exceed the cost of performing repairs to identified leaks is also borne out by the Carbon Limits report[49] and analysis carried out by Colorado.[50] There is mounting industry-supplied evidence that frequent LDAR is cost-effective.[51]

When Colorado and EPA initially drafted their rules, they had very little data to estimate the number of leaks and the baseline fugitive emissions, so based on aEPA's1995 Protocol for Equipment Leak Emission Estimates, EPA and Colorado relied upon VOC emission factors in Table 2-4 of the 1995 EPA Leak Protocol. (link) Figures 5-16 through 5-34 of the 1995 EPA Leak Protocol demonstrate that the VOC emission factors within Table 2-4 correspond to between 1.6% and 2.5% of components that are assumed to be leaking. The lower value represents an assumed 10,000 ppm Method 12 leak definition and the higher value assumes a 500 ppm leak definition. NSPS OOOOa's leak definition is 500 ppm, which would correlate to the 2.5% component leak rate. In contrast, API surveyed its members and found an average initial leak incidence for all well sites was 0.4% of the components surveyed. (link)The 1995 EPA Leak Protocol contains an alternate set of VOC emission factors in Table 2-8, which allows for the incorporation of an actual % component leak rate that is based upon more recent data such as the API dataset. Establishing a more realistic baseline emission total using Table 2-8 will more accurately reflect the emissions benefit for a cost benefit analysis. Another key component to establishing an accurate and basin specific baseline is to have an accurate and representative % VOC and an accurate and representative fugitive component count by basin.

What would be the implementation cost?
For new wells?

[45] Jonah Energy stated: "We support the [recent Wyoming rule for existing sources in the UGRB], as proposed, with some minor suggested changes [to the proposed tank requirements] outlined below." Comments submitted to Mr. Steven A. Dietrich from Jonah Energy LLC on Proposed Regulation WAQSR, Chapter 8, Nonattainment Area Regulations, Section 6, Upper Green River Basin Permit by Rule for Existing Sources (April 13, 2015).
[46] *Id*.
[47] Comments submitted to Mr. Steven A. Dietrich from Jonah Energy LLC on Proposed Regulation WAQSR, Chapter 8, Nonattainment Area Regulations, Section 6, Upper Green River Basin Existing Source Regulations (Dec. 10, 2014).
[48] Jonah Energy, Presentation at WCCA Spring Meeting at 16 (May 8, 2015).
[49] Carbon Limits, Quantifying Cost-effectiveness of Systematic Leak Detection and Repair Programs Using Infrared Cameras, 16 (Mar. 2014) ("Carbon Limits 2014"), available at http://www.catf.us/resources/publications/files/.
[50] Colorado Air Pollution Control Division used an entirely different method than Carbon Limits to predict that almost 80 percent of repair costs for well facilities will be covered by the value of conserved gas. *See* CAPCD Cost-Benefit, at Table 30. .Table 30 also identifies Total Annual Inspection and Repair Cost at $22,150,520 and the Total Annual Value of Recovered Natural Gas at $4,503,532 therefore the value of recovered gas will only cover 20% of the annual inspection and repair cost at the inflated natural gas price of $3.50/MCF used by CAPCD. At the average 10 year forward wellhead price of $1.60/MCF derived from the Synapse Report, the recovered gas will only cover 9% of the annual inspection and repair cost.
[51] Several companies that engaged in the development of Colorado's regulations provided evidence that frequent LDAR is cost-effective. In particular, Noble estimated the cost-effectiveness of Colorado's tiered program at "between approximately $50/ton and $380/ton VOC removed" at well production facilities. (Rebuttal Statement of Noble Energy, Inc. and Anadarko Petroleum Corporation in the Matter of Proposed Revisions to Regulation Number 3, Parts A, B, and C, Regulation Number 6, part A, and Regulation Number 7 Before the Colorado Air Quality Control Commission, at 7).

The cost is ongoing depending on the number and type of repairs, frequency, technology, personnel and distance to sites. There are initial costs linked to purchasing software to plan and track results of surveys, purchasing and insuring equipment and operator training.

For existing wells?

See above – costs are the same for new and existing wells. Marginal oil and gas wells (10 BOE/day or less per IOGCC definition) make up 66% of all wells in New Mexico. These wells average 2.5 BOPD for marginal oil wells and 23.3 Mcfd for marginal gas wells[1]. Under an LDAR program, marginal well operators would need third party LDAR inspection services which are currently $2,000 to $2,500 per day per day plus travel[2] for optical services. Inspection time per location would need to include prorated travel time for third party vendors from service point to operating basin, travel time from site to site, along with the time required for each site survey. Travel and survey times range from 2.7 to 6.4 hours per site per studies below (Colorado rulemaking)[3]. A quarterly LDAR program using the average time of 4.6 hrs per inspection would increase the average marginal oil well annual direct operating expense[4] by 24% and marginal gas wells would be a larger increase in direct operating expense. The indirect administrative and reporting costs are not included, but would further reduce marginal well profitability. This would have the effect of rendering some marginal wells uneconomic, and increasing the abandonment producing rate on all marginal wells creating a situation of premature abandonment and underground waste of resource.

Economic Analysis of Methane Emission Reduction Opportunities in the U.S. Onshore Oil and Natural Gas Industries (ICF Report):

This report created an array of cost effectiveness calculations in $/mcf based on a series of critical assumptions. The report touts its findings as demonstrating that methane emissions can be reduced with technologies that only cost cents per day. While aggregating all of the cost effective technologies with the cost ineffective technologies might produce such a result, individual technology options do not. Equally significant are the ICF report assumptions of the value of natural gas in calculating the benefits of regulations and the efficiency of the requirements. These are particularly important in the context of the fugitive emissions proposals.

The ICF Report concludes that a quarterly fugitive emissions program for natural gas wells would recover 264 mcf/y using a 60 percent recovery rate on emissions of 440 mcf/y and have a cost burden of $7.60/mcf without recovery benefits and $2.52/mcf with recovery.

Putting this evaluation in some context changes the perspective. First, looking at the emissions and recovery quantities on a daily basis shows them to be 0.72 mcfd and 1.2 mcfd, respectively. These are small volumes for even the average well. The ICF Report does not indicate the average production rate for the wells it assumes for the average emissions, but the average US natural gas well produces about 127 mcfd. Therefore, the approximate emissions rate would be about 1.0 percent. Nor does The ICF Report appear to distinguish sources of emissions in its fugitive discussion. For example, it does not discuss the share of emissions coming from equipment and those coming

from storage tanks that have permitted releases. Since an LDAR program would not apply to these allowable emissions, the efficiency/cost estimates must be questioned.

A second key point of the analysis relates to the value of natural gas where The ICF Report assumes a price of $4.00/mcf. Producers have not received such a price for a long time and do not foresee such a price for many years. Assuming a price for natural gas at $2.22/mcf of which the producer receives approximately $1.67/mcf, the value of the recovered natural gas would drop from $1360 to $440 annually. Correspondingly, the cost effectiveness would change in the net case from $2.52/mcf to $5.48/mcf.

A third point relates to the scope of fugitive leaks of the Leak Detection and Repair (LDAR) program. A study done by Carbon Limits (described below) concluded that fugitive leak emissions at well sites accounted for 17 percent of the total site emissions. Using this assessment of the 440 mcf/y of site emissions, only 75 mcf/y would be addressed by the LDAR program. And using the generous assumption of a 60 percent recovery, 45 mcf/y (0.12 mcfd) would be recovered. This would result in $75 in recovered value. The cost effectiveness would then become $44.58/mcf in the gross case and $42.91/mcf in the net case

More critically, the issue of larger significance here is the application of an LDAR program to low production wells. These wells average about 24 mcfd rather than 127 mcfd. Moreover, in some significant natural gas producing states the average low production natural gas well is much less; in Pennsylvania, for example, it is 6.1 mcfd. Using the same ratio of emissions to production for the average national well would yield low production emissions rates of 0.24 mcfd nationally and 0.06 mcfd for Pennsylvania. On this basis the potential recovery would be 9 mcf/y for the national average low production well and 2.2 mcf/y for the Pennsylvania well. The gross and net cost effectiveness values would be $222.89/mcf and $221.22/mcf for the national wells and $911.81/mcf and $910.15/mcf for the Pennsylvania wells, respectively. Setting aside that most of the likely emissions would be from permitted storage tank vents, these assessments argue that the Optical Gas Imaging OGI LDAR approach is not cost effective.

Are there low-cost solutions available?

Operators conducting routine inspections using sight, sound and smell. OOOOa allows the use of a soap solution to confirm leak repairs (60.5397a(h)(3)(iii)(A)). This method, listed under Alternative Screening Procedures from Method 21, Section 8.3.3, is a cost-effective, efficient and acceptable way to confirm leak repairs.
https://www.epa.gov/emc/method-21-volatile-organic-compound-leaks

If a solution is high-cost, why is that the case?

The cost of leak detection depends on many variables and is difficult to generalize. However, the primary driver of cost effectiveness is the baseline emissions estimates and the number of leaks detected. When Colorado and EPA initially drafted their rules, they had very little data to estimate the number of leaks and the baseline fugitive emissions, so based on aEPA's1995 Protocol for Equipment Leak Emission Estimates, EPA and Colorado relied upon VOC emission factors in Table 2-4 of the 1995 EPA Leak Protocol. (link) Figures 5-16 through 5-34 of the 1995 EPA Leak Protocol demonstrate that the VOC emission factors within Table 2-4 correspond to between 1.6% and 2.5% of components that are assumed to be leaking. The lower value represents an assumed 10,000 ppm Method 12 leak definition and the higher value assumes a 500 ppm leak definition. NSPS OOOOa's leak definition is 500 ppm, which would correlate to the 2.5% component leak rate. In contrast, API surveyed its members and found an average initial leak incidence for all well sites was 0.4% of the components surveyed. (link) The 1995 EPA Leak Protocol contains an alternate set of VOC emission factors in Table 2-8, which allows for the incorporation of an actual % component leak rate that is based upon more recent data such as the API dataset. Establishing a more realistic baseline emission total using Table 2-8 will more accurately reflect the emissions benefit for a cost benefit analysis. Another key component to establishing an accurate and basin specific

baseline is to have an accurate and representative % VOC and an accurate and representative fugitive component count by basin.

Capital costs, personnel time, training, travel time to sites all make instrument-based programs high.

Are there additional technical analyses needed to refine benefits/costs estimates?

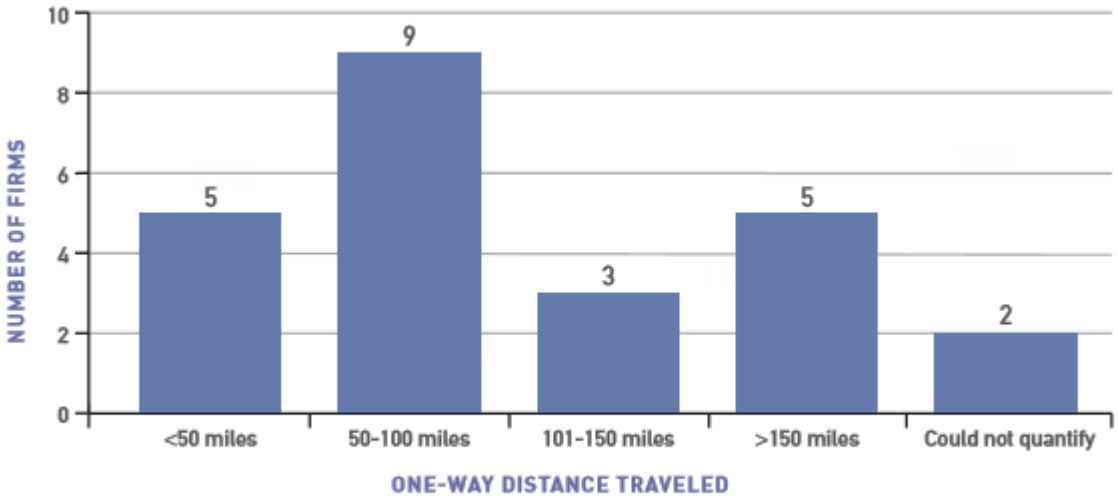
Continued piloting and testing of new technologies in field and controlled settings such as the studies conducted at Colorado State University. METEC[52] Colorado State University is a project in collaboration with US Department of Energy's ARPA-E and their methane initiatives. The goal of the METEC facility is to provide a location that models natural gas facilities, so that researchers can test methane sensing technologies and evaluate their performance. In order to evaluate the performance of each Methane Observation Networks with Innovative Technology to Obtain Reductions (MONITOR) technology to locate and quantify fugitive methane emissions, the MONITOR Field Test Site develops a representative test facility that simulates real-world natural gas operations—at the wellpad and further downstream. Specifically, the MONITOR Test Site supports the operation of a multi-user field test site for MONITOR performers to validate performance under realistic use-case scenarios–and meet the MONITOR program's required metrics related to localization, quantification, communications and cost. Data generated during the field tests demonstrates the performance capabilities of the technologies and could be used by the MONITOR performers to accelerate the commercialization and/or regulatory approval of their technologies.

The Stanford/EDF Mobile Monitoring Challenge also provides results from 10 vehicle, drone, and plane based leak detection technologies. In this test, 6 of the 10 technologies correctly detected 90% of the test scenarios. All technologies demonstrated site-level localization of leaks, while 6 of the 10 technologies could assign a leak to the specific piece of equipment in at least 50% of test scenarios. Even as this study provides the first independent verification of the performance of mobile technologies, it only represents the first step in the road to demonstrating that these technologies will provide emissions reductions that are equivalent to existing regulatory approaches. (link)

To better understand cost effectiveness, the emissions benefits from these various tests should be considered.

3. IMPLEMENTATION

For each piece of equipment or process, please consider the following questions and add other relevant information. If relevant, please identify if the answers are different for large company and small company requirements or are different for well type or basin.



Implementation Feasibility:

What is the feasibility of implementation (availability of required technology or contractors, potential permitting requirements, potential for innovation)?

Leak detection is feasible, and contractors are available, though may have to travel significant distances to visit sites.

[52] https://energy.colostate.edu/metec/

FIGURE 7. Typical One-Way Travel Distance Reported

SOURCE: Industry Interviews
NOTE: Based on a sub-sample of 24 LDAR firms

https://www.daturesearch.com/wp-content/uploads/Methane-Mitigation-Industry-Report_Final.pdf

What is the useful life of equipment?

N/A

What are the maintenance and repair requirements for equipment required for methane reduction?

Optical gas imagers generally need to be sent back to the manufacturer for calibration and testing on a regular basis. Sniffers need to be calibrated on a daily basis to ensure accurate ppm readings.

How would emissions be detected, reductions verified and reported?

Operators can report using EPA's leak/no leak emissions factors through existing reporting processes (GHGRP).

4. CHALLENGES AND OPPORTUNITIES TO ACHIEVE METHANE REDUCTION IN NEW MEXICO

For each piece of equipment or process, please consider the following questions and add other relevant information. If relevant, please identify if the answers are different for large company and small company requirements or are different for well type or basin.

What regulatory gaps exist for this equipment or process? Are there regulatory gaps filled by the proposed implementation?

Inspections are currently required for all gas plants (NSPS KKK) and for new and modified production facilities under OOOOa.

NM does not have its own LDAR requirements

Where do conflicting priorities exist between NMED, EMNRD, and NMSLO? Are there opportunities for coordination between these agencies?

None

Are there existing regulations related to methane that do not address the intended purpose? Identify any unintended barriers to methane reductions/capture that may hinder proposed processes.

In other states and with EPA, there is very limited ability to adopt new technologies. New Mexico has an opportunity to avoid the unintended consequence of requiring old technology by creating flexibility.

Other considerations or comments (e.g. particular design or technological challenges/opportunities, co-benefits, non-air environmental impacts, etc.?):

None

NMED Exhibit 10 - 0065

	controlled equipment would not benefit from an LDAR program as a low level of emissions will occur under allowable permit limits with or without an inspection program.				
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
2.2	Quarterly LDAR	Independent research across the United States has shown that emissions at oil and gas sites from leaks, broken or worn out equipment, and improper operations are substantial and greatly underestimated in inventories. Regular, quarterly LDAR is needed to mitigate these unnecessary and harmful emissions and can be implemented for a reasonable cost. A recent synthesis of the U.S. studies conducted over the past six years concluded that U.S. production emissions are 60% higher than inventories suggest.[54] California Air Resources Board, 17 C.C.R. § 95669 (March 24, 2006), available at https://www.arb.ca.gov/cc/oil-gas/Oil%20and%20Gas%20Appx%20A%20Regulation%20Text.pdf; Colorado Air Quality Control Commission, 5 C.C.R. 1001-9, CO Reg. 7, § XVII.F. [54] Alvarez, et al., "Assessment of methane emissions from the U.S. oil and gas supply chain" Science, June 2018, http://science.sciencemag.org/content/early/2018/06/20/science.aar7204.full. Data for this study included measurement of emissions from over 400 individual well pads in six different US basins, validated against "top-down" airborne measurements of emissions from nine oil and gas producing basins. The authors of this synthesis study, as well as the underlying studies analyzed in the synthesis paper, include academics from twenty-five different research institutions. These scientists have concluded that the substantial extra emissions observed in these studies, compared to official inventories, likely arise from improper and abnormal operating conditions at the site level that are best addressed by frequent, if not continuous, inspections.

SECTION 3, DEHYDRATION UNITS

Discussion for MAP members on September 13, 2019

NOTE: The focus of this report is processes, and the associated equipment, directly related to the release or capture of methane gas. We are not requesting information on processes/equipment that are not related to the release or capture of methane gas.

1. DESCRIPTION OF PROCESS AND EQUIPMENT

Provide a description of the processes and/or equipment used in oil and/or gas extraction for this topic. Note that this report template will be used for all topics of the MAP review and, thus, not all questions or information may be relevant for each topic. If information is not relevant, indicate N/A. Note any differences expected for differing well types, industry sector, or basin location.

Technical description of the process or equipment:

Operators are often required to dehydrate natural gas streams that are saturated with water vapor to meet pipeline specifications. Water in natural gas pipelines can result in hydrates (solids) formation that obstruct or plug the pipe. Also, water vapor in a pipeline can cause corrosion. Commonly, operators use liquid desiccant dehydrators to remove water from natural gas to meet pipeline water content requirements, where the liquid desiccant most often utilized is triethylene glycol (TEG or 'glycol'). Glycol also will absorb volatile organic compounds (VOCs), some Hazardous Air Pollutants (HAPs) and methane in this process.

In the dehydration unit process, wet gas enters near the bottom of the glycol contactor tower(absorber) and comes into contact with lean glycol (water poor) in the contactor tower. In the glycol contactor tower, water in the natural gas is absorbed by the glycol circulating in the tower. This reduces water in the natural gas and the gas dew point is reduced. It is in this process that the glycol also absorbs methane, HAPs and VOCs. The dehydrated gas, referred to as dry gas, exits through the top of the glycol contactor tower. The glycol that absorbed the water is called rich glycol. The rich glycol exits from the bottom of the glycol contactor and flows to the regeneration system. The regeneration system typically includes a glycol flash tank (gas-condensate-glycol separator) and a reboiler. If a glycol flash tank is not installed, the rich glycol is routed directly to the reboiler.

NMED Exhibit 10 - 0068

The glycol flash tank (gas-condensate-glycol separator) serves as a separator to recover entrained gas and condensate from the glycol. It also reduces the pressure of the rich glycol prior to entering the reboiler. After the flash tank, the glycol enters the reboiler. Here, the glycol is heated to boil off water from the glycol to produce lean glycol. The lean glycol is cooled using a heat exchanger and pumped back to the glycol contactor tower to repeat the cycle. It is within this process that methane, HAPs and VOCs are boiled off and separated from the glycol.

Typical dry gas pipeline requirements range from 4 to 7 lbs water per mmscf of natural gas.

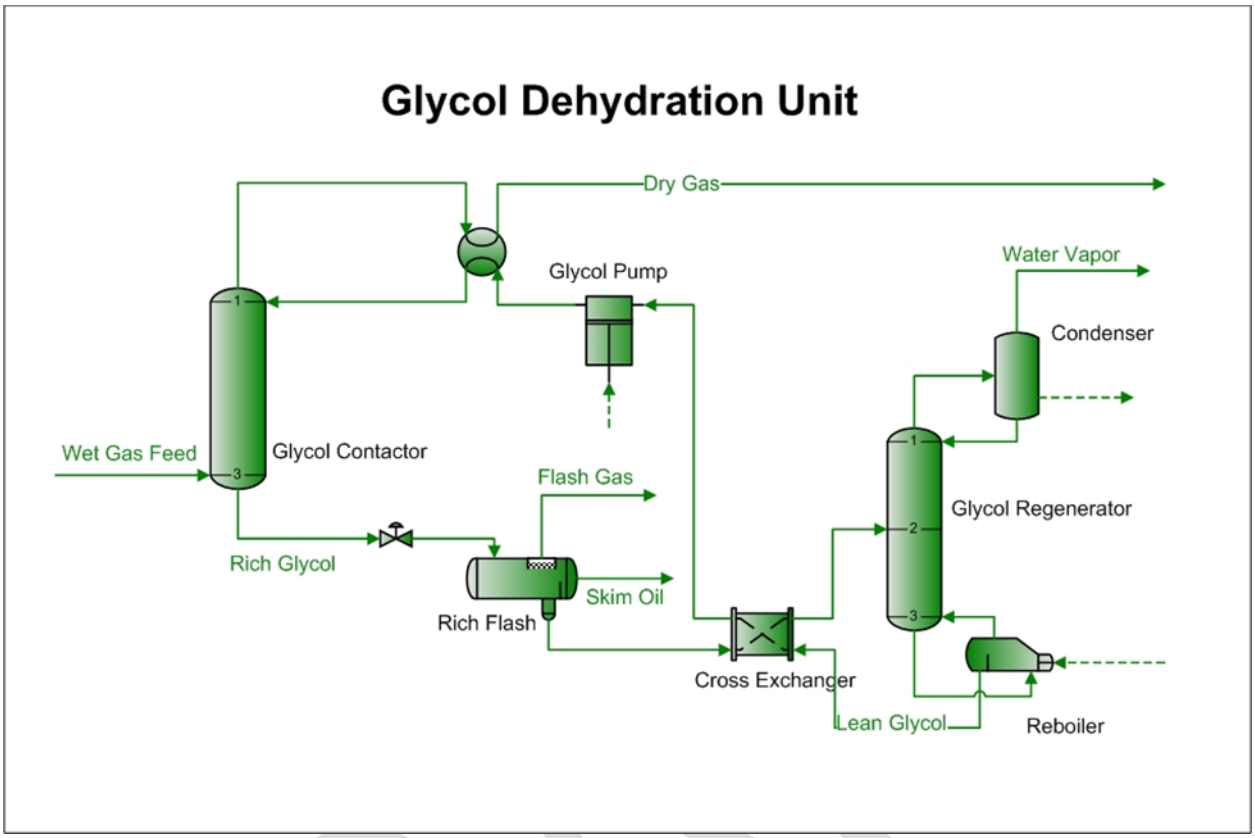
A glycol circulation pump is used to circulate glycol through the system. There are many varieties of pumps used including positive displacement (gas-injection) pumps, other pneumatic pumps and electric reciprocating and centrifugal pumps. Larger glycol dehydrators often use electric motor-driven pumps.

The reboiler uses a still column (reflux condenser coil) to separate water from the glycol. The still column's vent gas will contain water vapor and VOCs. The heat from the reboiler is generated by burning natural gas.

Although glycol dehydrators are most common, solid desiccant dehydration is another process which can be used. Solid desiccants use salt crystals with large surface areas to attract water molecules. Refrigeration is another method of dehydration. This involves cooling gas to a temperature below the condensation point of water.

Provide the segment(s) of the industry that the equipment or process is found:

The equipment/process is largely found in the oil and gas midstream gathering segment of industry. In addition, the equipment/process is commonly found in the upstream and natural gas processing sector.



Describe how the equipment or process is used:

Dehydration units are used to remove water from natural gas.

Provide the common process configurations that use this equipment or process:

Below is a schematic of the common process configuration of this process. There are slight variations of the configuration that are commonly utilized. For example, some configurations exclude the flash tank so that all flashing occurs in the regenerator. There are many variations regarding control of the two primary emission points (the regenerator vent and the flash tank vent) discussed below.

NMED Exhibit 10 - 0069

The emission streams from the flash tank (labeled flash gas on the schematic) and the condenser (labeled water vapor on the schematic) are typically controlled by one of several methods, including combustion in the reboiler firebox of by a flare and captured by a VRU, among others discussed in Section 2.

What is the distribution of the equipment or process across business segments?

This equipment is largely found in the oil and gas midstream gathering segment of industry. In addition, the equipment/process is commonly found in the upstream and natural gas processing segment.

How has this equipment or process evolved over time?

This equipment or process has not changed much over time. The development of the cryogenic gas plant (early '70s) necessitated the need to remove almost all water from the gas stream in order to prevent freezing in the cryogenic portion of the plant.

2. INFORMATION ON EQUIPMENT OR PROCESS COSTS, SOURCES OF METHANE EMISSIONS, AND REDUCTION OR CONTROL OPTIONS

Identify the capital and operating costs for the equipment or the process. Identify how methane is emitted or could be leaked into the air. Please **prioritize** the list to identify first the largest source of methane from the process or equipment and where there is **potential** for the greatest reduction of methane emissions. Note any differences expected for differing well types, industry sector, or basin location.

Sources of Methane:

Provide an overview of the sources of methane from this equipment or process:

Natural gas streams contain varying amounts of methane, VOCs and hazardous air pollutants (HAP). HAPs in natural gas include benzene, toluene, ethylbenzene, xylenes, (BTEX), n-hexane and 2,2,4-trimethylpentane. These HAPs are slightly soluble in the TEG used and as a result, HAPs are absorbed in the glycol contactor. Also, methane and VOCs (other than BTEX) will be entrained in the rich glycol due to the high operating pressure of the glycol contactor (600 to >1000 psig).

Flash gas liberated from the flash tank (located between glycol contactor and reboiler) will be natural gas that is mostly methane and some VOCs and small amounts of BTEX.

Regeneration of the rich glycol in the reboiler results in emissions of methane, VOCs and HAPs to be released with the water vapor exiting the still column vent.

The sources of and types of air pollution from a TEG glycol dehydrator include the following:

1. Still Column (Regenerator) Vent – water, methane, VOCs, HAPs
2. Flash Tank – primarily natural gas similar to fuel gas (primarily methane and some VOC and BTEX)
3. Reboiler – combustion emissions from the reboiler burning natural gas.

Methane is absorbed into the glycol in the absorber tower. The methane will flash off in the flash gas separator, if installed. Flash gas separators are typically controlled and not vented to the atmosphere. If a flash gas separator is not installed, the methane will be removed from the glycol in the regenerator and vented through the still vent stack

New Wells:

Dehydration units are typically located at gathering compressor stations but can be located at new well sites.

DRAFT

Existing Wells:

Dehydrations units are typically located at gathering compressor stations. However, there are instances in which a small dehydration unit may be placed at an existing well site.

How are the emissions calculated for this equipment or process?

Emission rate calculations involve using a process simulator to estimate emissions. Simulators typically used include GRI-GLYCalc, PROMAX and HYSYS. Manufacturer's data and state/federal guidance are utilized to determine the control efficiencies of the various types of controls.

What data is available to quantify emissions/waste for this equipment or process?

https://www.epa.gov/ghgreporting

Dehydration unit emissions range from less than 1% to 5% of a site's emissions. Specifically, within processing facilities, dehydration unit emissions represent less than 1% of processing facility emissions.

What are the data gaps in quantifying emissions/waste for this equipment?

There are no gaps identified for emissions of glycol dehydration units as emissions are quantified in air permits and reporting to NMED. The NMED AQB NSR and TV document on glycol dehydrators (May 23, 2011) notes that there is a 'lack of experience with field tests on glycol dehydrators'. As above reference provided in emissions calculations, NMED AQB requires proven process simulator modeling. Data gaps for this source category include lack of measurement data and the reporting threshold for Subpart W of the Greenhouse Gas Reporting Program.

Economic Description of the Process or Equipment:

What is the per unit cost of the equipment or the costs associated with the process?

Costs vary widely based upon size.

Table 1 of the "Cost-Effectiveness of Comprehensive Oil and Gas Emissions Reduction Rules in New Mexico" lists unit costs for VRU abatement technology as $4.18 per mcf of reduced methane ($217.36 per tonne).[55]

What are the annualized operating costs for the equipment or costs associated with the process?

Costs vary widely based upon size.

If the equipment or process is powered, what are the costs?

Costs vary widely based upon size.

[55] "Cost-Effectiveness of Comprehensive Oil and Gas Emissions Reduction Rules in New Mexico," Erin Camp, PhD, Nate Garner, Asa Hopkins, PhD, Synapse Energy Economics, Inc., September 13, 2019,page 9, Table 1, http://blogs.edf.org/energyexchange/files/2019/09/Synapse-Methane-Cost-Benefit-Report.pdf.

What are the maintenance and repair costs for existing or new equipment?

Costs vary widely based upon size.

Existing Reduction Strategies:

How has industry reduced emissions/waste from this equipment or process historically?

Glycol dehydration units are already regulated under 40 CFR 63, Subpart HH. While this regulation covers benzene emissions, the controls placed on dehydration units will also reduce methane emissions. The primary driver for emissions reductions has been to meet this requirement which, in turn, captures and controls methane.

The GCP asks to control the glycol circulation rate, and as control has options of

1. installing a BTEX condenser, which is a common control for the still column
2. route flash tank emissions to a combustion device
3. route flash tank emissions to a closed loop system
4. VRU for the still vent and/or flash tank
5. Other control devices such as flare or thermal oxidizer
6. Install electric or instrument-air recirculation pumps (using onsite electricity, solar, etc.).

NSPS Subpart HH

The control device used to reduce HAP emissions in accordance with the standards of this subpart shall be one of the control devices.

1. An enclosed combustion device (e.g., thermal vapor incinerator, catalytic vapor incinerator, boiler, or process heater) to control TOC or total HAP in the gases vented to the device by 95.0 percent by weight or greater
2. A vapor recovery device (e.g., carbon adsorption system or condenser)
3. A flare

In addition to the federal rules, the states of Colorado, Wyoming and Pennsylvania regulate emissions from dehydration units. Citations to rules are provided below.

Note: NSPS Subpart HH does not regulate for methane.

New Wells:

N/A

Existing Wells:

N/A

DRAFT

NMED Exhibit 10 - 0073

How have the emission/waste reductions been measured?

Dehydration emissions are included during the permitting process and simulated prior to the development of a facility to ensure emissions meeting required permitted limits. Additionally, dehydration methane and GHG emissions are reported under the GHG Reporting Rule.

How have states and the federal government reduced emissions/waste from this equipment or process historically? In addition, please identify voluntary reductions achieved whether or not they were in response to a regulatory action/requirement.

Glycol dehydration units have been regulated under 40 CFR 63, Subpart HH. While this regulation covers benzene emissions, the controls placed on dehydration units also reduce methane emissions. The primary driver for emissions reductions has been to meet this requirement which, in turn, captures and controls methane. The control device used to reduce HAP emissions in accordance with the standards of this subpart include enclosed combustion devices, vapor recovery devices and flares. This regulation was updated as recently as 2012 to include small dehydrators.

These regulations typically require the units to control still column vent and flash tank emissions and may require that the unit operate below a calculated glycol circulation rate. EPA regulations affecting glycol dehydration units include the hazardous air pollutant rules (HAPs) in 40 CFR 63, Subpart HH—National Emission Standards for Hazardous Air Pollutants from Oil and Natural Gas Production Facilities. This regulation impacts onshore oil and gas production facilities glycol dehydrators and some oil storage tanks. This rule regulates Major HAP sources as well as glycol units at small sources, called Area Sources. The requirements for area sources are less robust than those for major sources.

NESHAP Subpart HH for Oil and Natural Gas Production Facilities distinguishes between “Large” and “Small” glycol dehydration units. Large units are defined as units that process >85,000 standard cubic meters per day and emit greater than 1 tpy benzene. Both new and existing small glycol dehydrators at major sources must meet the unit-specific BTEX (benzene, toluene, ethylbenzene and xylene) limit for emissions that is based on the unit’s natural gas throughput and gas composition. Newly constructed “small” glycol dehydrators (dehy), built after August 23, 2011, must meet the exemption requirement to demonstrate the gas throughput is less than 85,000 standard cubic meters per day or emit less than 1 tpy benzene. To ensure compliance, this exemption demonstration should be reviewed and documented on an annual basis. If the small dehy does not meet the emission control exemption, the unit must meet the control standards upon startup. Existing small glycol dehydrators were required to be in compliance by October 15, 2015.

In Colorado, state-wide rules require that all existing glycol natural gas dehydrators with uncontrolled actual VOC emissions of 6 tpy or greater be controlled with air pollution control equipment achieving at least a 95%

NMED Exhibit 10 - 0074

reduction. The rules also require that all new glycol natural gas dehydrators with uncontrolled actual VOC emissions of 2 tpy or greater be controlled with air pollution control equipment achieving at least 95% reduction. If a combustion device is used, it must have a design destruction efficiency of at least 98%, with few exceptions.

(Colorado Air Quality Control Commission, 5 C.C.R. 1001-9, CO Reg. 7, XVII.D.3. (Feb. 24, 2014)). The Colorado Oil and Gas Conservation Commission also has a rule requiring all glycol dehydrators with uncontrolled actual emissions of VOC of 5 tpy or greater, located within 1,320 feet of a Building Unit, or a Designated Outside Activity Area use an emission control device capable of achieving 90% control efficiency of VOC. (COGCC Rule 805b(2)B). These rules apply to production facilities, compressor stations and gas processing plants.

At existing facilities in Wyoming, when a combustion unit is required for control of dehydration unit emissions, all non-condensable still vent vapors must be collected and routed to a combustion unit for at least 98% control of VOC and HAP emissions. All glycol flash separator vapors must be collected and routed to the combustion unit for at least 98% control of VOC and HAP emissions and/or used as fuel for process equipment burners. For new PAD facilities in Wyoming, upon first day of production, all dehydration unit VOC and HAP emissions must be controlled by at least 98%. After one year, combustion units used to achieve the 98% control may be removed if total potential VOC and HAP emissions from all units are less than 4 tpy and all units are equipped with still vent condensers. At new single-well facilities, within 60 days of the first day of production, if total potential uncontrolled VOC and HAP emissions from all units are greater than or equal to 6 tpy (4 tpy in the UGRB), emissions from all units must be controlled by at least 98%. After one year, combustion units used to achieve the 98% control may be removed if the total potential VOC and HAP emissions from all units are less than 4 tpy and all units are equipped with still vent condensers. Removal of controls is not allowed in the Jonah Pinedale Anticline Development Area. WDEQ, Air Quality Division Rules, Chapter 8, section 6(d)(i) (May 19, 2015), WDEQ, Oil and Gas Production Facilities Chapter 6, Section 2 Permitting Guidance (May 2016). These rules apply to production facilities.

In Pennsylvania, for new glycol dehydrators, whose uncontrolled emissions are greater than or equal to the methane de minimis level of 200 tpy, VOC de minimis level of 2.7 tpy, single HAP limit of 0.5 tpy, or combined HAP limit of 1 tpy, emission controls must be installed and emissions must be reduced by at least 98%. Existing glycol dehydrators installed prior to February 2, 2013, which have a total uncontrolled PTE of VOC in excess of 10 tpy, must be controlled by at least 85% with a condenser, enclosed flare, or other air cleaning device approved by the Department. Existing glycol dehydrators installed on or after February 2, 2013, but before August 8, 2018 at a natural gas compression station or processing plant, with total uncontrolled PTE of VOC in excess of 5 tpy, must be controlled by at least 95% with a condenser, enclosed flare or other air cleaning device approved by the Department. Existing glycol dehydrators installed on or after August 10, 2013, but before August 8, 2018 at an unconventional

NMED Exhibit 10 - 0075

natural gas well site or remote pigging station, with a total uncontrolled VOC emission rate greater than or equal to 2.7 tpy, an uncontrolled single HAP emission rate greater than or equal to 0.5 tpy, or a total HAP emission rate greater than or equal to 1.0 tpy, must be controlled by at least 95%. (PA DEP, Bureau of Air Quality, Technical Support Document, June 2018).

In Ohio, General Permits for Natural Gas Compressor Stations and Similar Facilities mandate a 0.42 ton per month of VOC limit for dehydrators with throughput less than 90 MMscf/day and a 0.70 limit for dehydrators with greater than 90 but less than 150 MM scf/d throughput. (Ohio General Permits, https://www.epa.ohio.gov/dapc/genpermit/ngcs).

The NMED General Construction Permit (GCP) requires controls reducing VOCs and HAPs, which also reduce methane. Moreover, the NMED permits require conditions to ensure that the controls remain effective. For example, the GCP Oil and Gas requires inspection of controls, periodic gas sampling of the gas routed to the glycol dehydration unit, monitoring of glycol pump rates and other requirements. The requirements (conditions) are intended to ensure the emissions from glycol dehydrators remain below permit allowances.

What are examples of process changes/modifications that reduce or eliminate emissions/waste from this equipment or process?

The addition of the controls and/or practices outlined above can reduce methane emissions from glycol dehydrators. These strategies are widely utilized and required by permit.

Technology Alternatives:

List of technology alternatives with link to information or contact information for the company/developers.

Name/Description of Technology	Link (and contact info for company if available)	Availability	Feasibility	Cost Range (choose one)
Use Zero Emissions Dehydrators These dehydrators combine flash tanks, electric pumps, and electric control valves to virtually eliminate emissions.	https://www.epa.gov/sites/production/files/2016-06/documents/zeroemissionsdehy.pdf	In use	No feasibility limitations. Combines a set of widespread technologies—flash tanks, electric pumps, and electric control valves.	Low – Medium **High**
Use solid desiccant dehydrators	https://www.epa.gov/sites/production/files/2016-06/documents/ll_desde.pdf	In use	Not viable when gas temperatures	Low **Medium** High

Use salt crystals with large surface areas to attract water molecules—are used in the oil and gas industry. These dehydrators do not require an external power supply, have no moving parts, and are capable of reducing emissions by 99 percent.			are high. Especially difficult in remote areas to properly maintain can lead to increased methane emissions.	
Optimize glycol circulation. The manner in which a glycol dehydrator is used can also impact emission rates. For example, both the efficiency and emission rate of a glycol dehydrator are directly proportional to the rate at which gas is circulated. In certain cases, operators may be able to reduce circulation rates to reduce emissions, while still removing enough water from the gas to meet sales specifications.	https://www.epa.gov/sites/production/files/2016-06/documents/ll_flashtanks3.pdf	In use	No feasibility limitations, however, many operators may already be operating at optimal circulation rates.	**Low** Medium High
Install flash tank separator. A flash tank separator brings the rich glycol to a lower pressure at which hydrocarbons will evaporate but water will remain in solution with the glycol. The flash tank captures approximately 90 percent of the methane	https://www.epa.gov/sites/production/files/2016-06/documents/ll_flashtanks3.pdf	In use	No feasibility limitations.	Low **Medium** High

DRAFT

and 10 to 40 percent of the VOCs entrained by the glycol. The captured gas is then routed to a fuel line, a compression suction, or a flare.				
Use Electric Pumps Instead of Pneumatic Pumps. A pneumatic pump must circulate significantly more gas, because gas pressure drives the circulation process. Pneumatic pumps may also leak rich (wet) glycol into the lean (dry) glycol, which decreases the efficiency of the system and requires greater circulation—leading to greater emissions.	https://www.epa.gov/sites/production/files/2016-06/documents/ll_glycol_pumps3.pdf	In use	Requires electricity	Low **Medium** High
Reroute Glycol Skimmer Gas. In the glycol dehydration process, rich glycol is circulated through a regenerator where the liquid is heated and water and hydrocarbons are vaporized and vented to the atmosphere. Some glycol dehydrators have glycol vent condensers and condensate separators to recover natural gas liquids and reduce VOC and HAP emissions. The condensate gas can be rerouted to the reboiler or other low-pressure	https://www.epa.gov/sites/production/files/2016-06/documents/rerouteglycolskimmer.pdf	In use		Low **Medium** High

DRAFT

fuel gas system for fuel use.				
Route Recovered Gas to Vapor Recovery Unit. *Rather than venting gas that evaporates from the rich glycol in the flash tank separator, some operators have piped this gas to a vapor recovery unit, where it can be put to beneficial use.*	*https://www.epa.gov/sites/production/files/2016-06/documents/pipeglycoldehydratortovru.pdf* *California includes the following language regarding low-NOx VRU:* *If the vapor control device is to be installed in a region classified as non-attainment with, or which has not been classified as in attainment of, all state and federal ambient air quality standards, the owner or operator must install one of the following devices that meets all applicable federal, state, and local air district requirements:* *(A) A non-destructive vapor control device that achieves at least 95 percent vapor control efficiency of total emissions and does not result in emissions of nitrogen oxides (NOx); or,* *(B) A vapor control device that achieves at least 95 percent vapor control efficiency of total emissions and does not generate more than 15 parts per million volume (ppmv) NOx when measured at 3 percent oxygen and does not require the use of supplemental fuel gas, other than gas required for a pilot burner, to operate.* Source: https://ww3.arb.ca.gov/regact/2016/oilandgas2016/ogfro.pdf Example: http://www.aereon.com/enclosed-combustion-systems/certified-ultra-low-emissions-burner-ceb	In use		Low **Medium** High

What technology alternatives exist to reduce or detect emissions? Please list all alternatives identified along with contact information for further investigation of this technology or process.

DRAFT

NMED Exhibit 10 - 0079

No new controls are necessary due to current control mechanisms and efficiency of process. The cost to achieve additional reductions would be high due to glycol dehydrators already being heavily regulated and there being little opportunity to make further reductions.

Various states identified above have determined that there is a need for state requirements in addition to the federal NESHAP requirements. The NESHAP MACT requirements apply only in certain circumstances, e.g., at major sources and the NESHAPs require less-protective requirements for dehydration units located at area sources. State requirements apply at minor sources and to dehydration units located at production facilities with emissions that may not trigger the application of the NESHAP requirements.

What are the pros and cons of the alternatives?

This is discussed above in the table. Many of them are already in use per best practice and regulation.

What is needed and available for new wells?

Discussed above in table.

See WY, CO, and PA requirements.

What is needed and available for existing wells?

Discussed above in table.

See WY and CO requirements

What technology alternatives exist for this equipment or process itself?

Discussed above in table

What are the pros and cons of the alternatives?

Discussed above in table.

Costs of Methane Reductions:

What is the cost to achieve methane emission reductions?

No new controls are necessary due to current control mechanisms and efficiency of process.

ICF found that replacing positive displacement pumps with electric pumps results in overall savings of $4.17/Mcf of methane reduced. (Source: ICF 2014, https://www.edf.org/sites/default/files/methane_cost_curve_report.pdf) Gas price at which this savings occurs is unknown.

What would be the implementation cost?

For new wells?

DRAFT

N/A

For existing wells?

N/A

Are there low-cost solutions available?

N/A

If a solution is high-cost, why is that the case?

N/A

Are there additional technical analyses needed to refine benefits/costs estimates?

N/A

3. IMPLEMENTATION

For each piece of equipment or process, please consider the following questions and add other relevant information. If relevant, please identify if the answers are different for large company and small company requirements or are different for well type or basin.

Implementation Feasibility:

What is the feasibility of implementation (availability of required technology or contractors, potential permitting requirements, potential for innovation)?

N/A

What is the useful life of equipment?

Standard life of control equipment

What are the maintenance and repair requirements for equipment required for methane reduction?

Discussed in table

How would emissions be detected, reductions verified and reported?

Most dehydration units are covered in the GHGRP.

4. CHALLENGES AND OPPORTUNITIES TO ACHIEVE METHANE REDUCTION IN NEW MEXICO

For each piece of equipment or process, please consider the following questions and add other relevant information. If relevant, please identify if the answers are different for large company and small company requirements or are different for well type or basin.

DRAFT

NMED Exhibit 10 - 0081

What regulatory gaps exist for this equipment or process? Are there regulatory gaps filled by the proposed implementation?

None.

As noted above, the NESHAPs have limited applicability to major sources and large dehydration units. There is a gap for the state to fill with respect to controlling minor source emissions and emissions from smaller dehydration units located at major sources.

Where do conflicting priorities exist between NMED, EMNRD, and NMSLO? Are there opportunities for coordination between these agencies?

None

Are there existing regulations related to methane that do not address the intended purpose? Identify any unintended barriers to methane reductions/capture that may hinder proposed processes.

No

Other considerations or comments (e.g. particular design or technological challenges/opportunities, co-benefits, non-air environmental impacts, etc?):

None

DRAFT

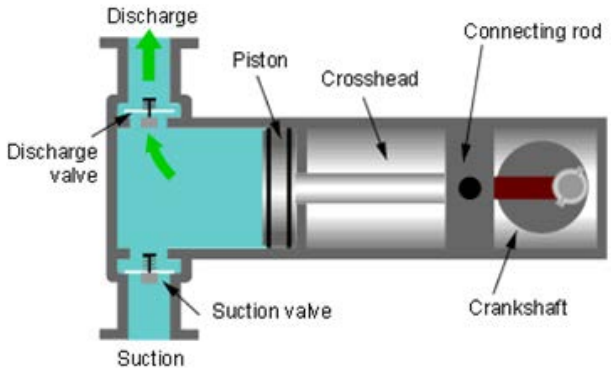
NMED Exhibit 10 - 0083

NMED/EMNRD METHANE ADVISORY PANEL

SECTION 4, COMPRESSORS AND ENGINES

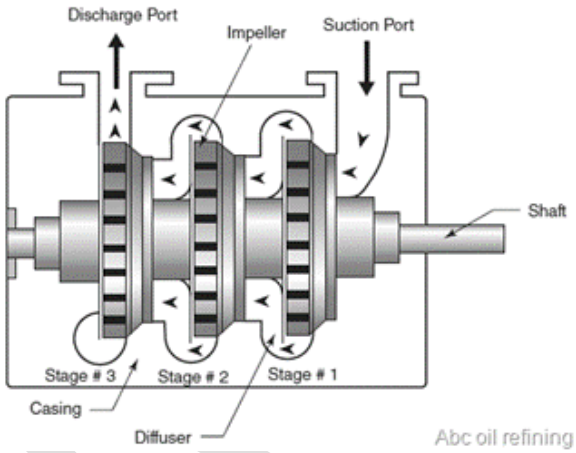
Discussion for MAP members on September 26, 2019

NOTE: The focus of this report is processes, and the associated equipment, directly related to the release or capture of methane gas. We are not requesting information on processes/equipment that are not related to the release or capture of methane gas.



1. DESCRIPTION OF PROCESS AND EQUIPMENT

Provide a description of the processes and/or equipment used in oil and/or gas extraction for this topic. Note that this report template will be used for all topics of the MAP review and, thus, not all questions or information may be relevant for each topic. If information is not relevant, indicate N/A. Note any differences expected for differing well types, industry sector, or basin location.

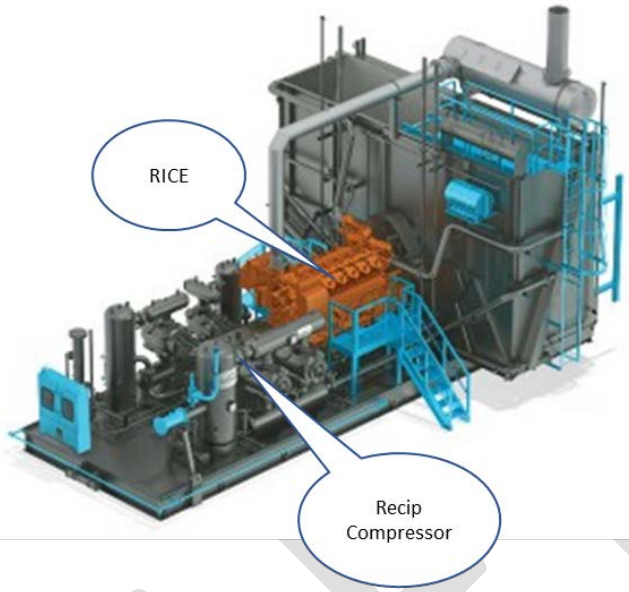


Technical description of the process or equipment:

One of the most common processes in the natural gas sector is compression. Compressors are mechanical devices that increase the pressure of natural gas to allow the natural gas to move through the natural gas value chain. Compressors are also used within processes at natural gas processing facilities and at oil and gas production facilities to enable production. In the oil and natural gas sector, the most prevalent types of compressors are reciprocating and centrifugal compressors. The choice between a reciprocating and centrifugal compressor is always a case-by-case determination and depends on a variety of operating conditions, such as required discharge pressure, gas volume and temperature, efficiency and cost.

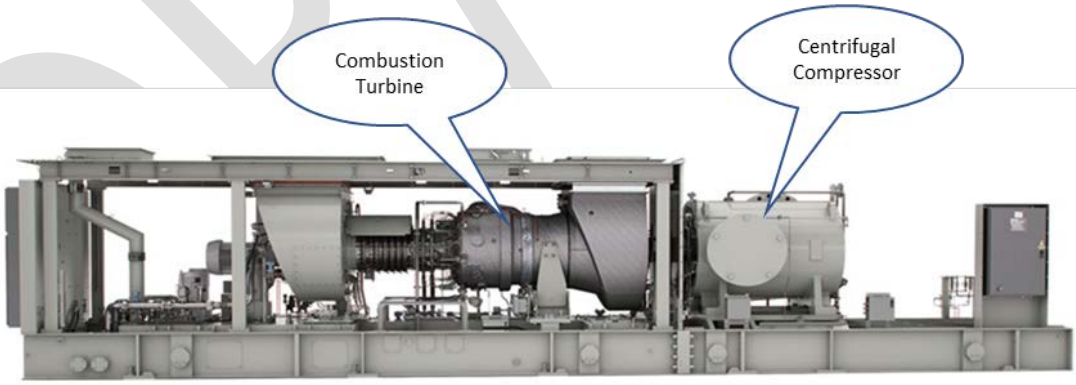
> **Reciprocating compressor** increase the pressure of a gas by positive displacement. Natural gas enters the compression cylinder through the suction manifold, where it is compressed by a piston driven in a reciprocating motion by the crankshaft. See diagram below.

Centrifugal compressor increases pressure of a gas by drawing in low pressure natural gas through the suction port and discharging significantly higher pressure natural gas by means of mechanical rotating vanes or impellers. See Diagram below.



Compressors are paired with a driver. In the oil and natural gas sector, compressors are commonly powered by gas fired reciprocating internal combustion engines (RICE) for reciprocating compressors and gas fired combustion turbines for centrifugal compressors. In some cases, compressors may be paired with electrical motors rather than gas fired RICE or turbines.

Gas fired reciprocating internal combustion engines use pistons that alternatively move back and forth to convert pressure into rotating motion, which drives the crankshaft of the compressor. These are similar to the engines in most cars, with the exception that vehicles typically use gasoline as fuel.



NMED Exhibit 10 - 0085

Reciprocating Compressor and RICE Engine

Gas fired combustion turbines heat a mixture of air and fuel at very high temperatures resulting in combustion of the gases, causing the turbine blades to spin at a very high speed, which drives the shaft of the centrifugal compressor. These are similar to the engines on a jet plane.

Centrifugal Compressor and Combustion Turbine

Provide the segment(s) of the industry that the equipment or process is found:

Production, gathering, processing, transmission, storage.

Describe how the equipment or process is used:

This link to the EPA GHG Reporting Program, includes a description of the oil and gas value chain and identifies some of the locations where compression occurs.

To produce oil and natural gas and keep natural gas pressures at the level required to move gas from the wellhead to the consumer, compressors and the associated driver are found at multiple locations in the natural gas value chain, including:

- Oil and gas production operations for enhanced oil recovery, maintaining reservoir pressures, gas lift, gas reinjection, wellhead compression of natural gas, and capturing tank vapors for recovery (vapor recovery unit).
- Gas gathering compressor stations to move raw natural gas from the wellhead to natural gas processing plants
- Moving gas into and out of natural gas processing plants and within the natural gas processing plant to pressurize process gasses, for example to increase the pressure of gasses used in the refrigeration or cryogenic processes at a natural gas processing facility
- Downstream of the natural gas processing plant in the gas transmission sector to move natural gas long distances in large diameter pipelines to
    - natural gas storage facilities
    - natural gas distribution systems for delivery to end users
    - directly to large industrial, commercial, or power generation customers
- Moving natural gas into and out of natural gas storage facilities

In addition to driving compressors, engines may also be used as the driver for power generators that provide electrical power to sites that are not connected to the commercial electrical grid or may be used as backup power supply in case of a power outage. Engines are also used to drive pumpjacks in the oil production sector. Pumpjacks are used to mechanically lift liquid out of the well if bottom hole pressure is not high enough to allow liquid to flow to the surface.

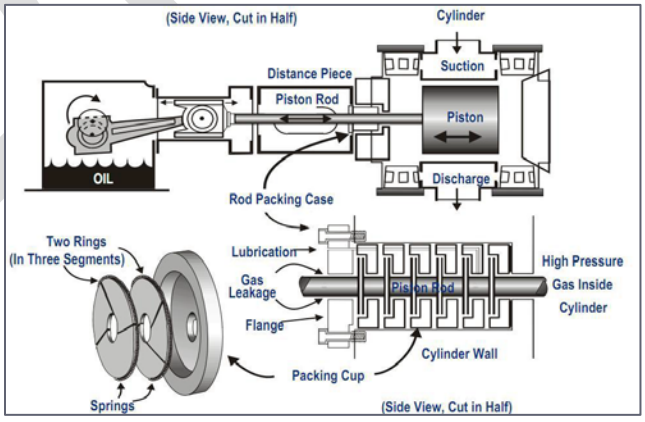
Provide the common process configurations that use this equipment or process:

A diagram of the configuration of a typical natural gas compressor station (from enbridge.com) is provided below. This configuration is similar for gas gathering and gas transmission compressor stations. The configuration of compressors at gas processing facilities is similar, but perhaps more complex. At gas processing plants, compression can take place at the front end of the plant (inlet gas compression), as the processed natural gas exits the plant (residue compression), or within the process to compress refrigeration gases.

NMED Exhibit 10 - 0087

2. INFORMATION ON EQUIPMENT OR PROCESS COSTS, SOURCES OF METHANE EMISSIONS, AND REDUCTION OR CONTROL OPTIONS

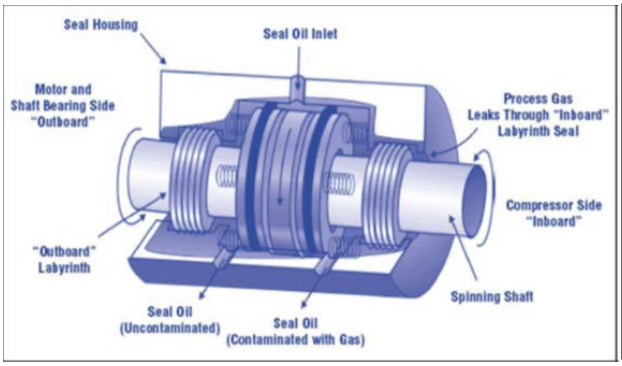
Identify the capital and operating costs for the equipment or the process. Identify how methane is emitted or could be leaked into the air. Please **prioritize** the list to identify first the largest source of methane from the process or equipment and where there is **potential** for the greatest reduction of methane emissions. Note any differences expected for differing well types, industry sector, or basin location.



Sources of Methane:

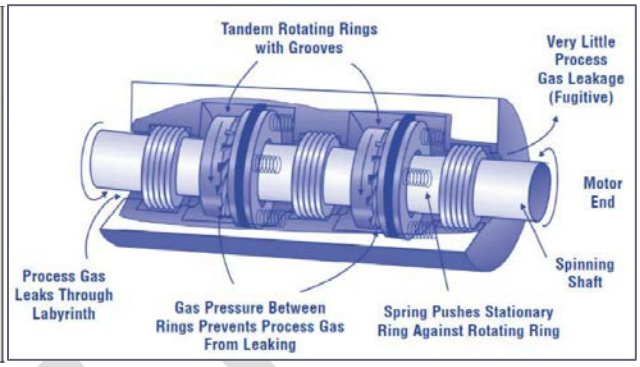
Provide an overview of the sources of methane from this equipment or process:

Compressors



The primary source of methane emissions from compressors are from seals around the piston rod of a reciprocating compressor and around the spinning shaft of a centrifugal compressor. There are two types of seals for centrifugal compressors, dry seals and wet seals. In all cases the seals prevent natural gas from exiting the compression chambers and entering the atmosphere. The following link to a paper published by USEPA Office of Air Quality Planning and Standards (OAQPS) titled "Oil and Natural Gas Sector Compressors, Report of oil and Natural Gas Sector Compressors Review Panel, April 2014", provides a good description of the seals systems in both reciprocating compressors (see top diagram below and section 2.1 of the EPA paper) and centrifugal compressors (see bottom diagrams below and section 2.2 of the EPA paper).

Rod Packing Seal System in Reciprocating Compressor



NMED Exhibit 10 - 0088

Wet Seal System in Centrifugal Compressor

Dry Seal System in Centrifugal Compressor

Another source of methane emissions from compressors are the fugitive emissions from piping components, such as valves, flanges, and connectors. These sources of fugitive emissions are not unique to compressors and will be considered in more detail during the LDAR discussion topic.

Engines

Emissions from engines are typically associated with engine exhaust from combustion of fuel, in this case natural gas. Combustion emissions include primarily NOx, CO, VOC and CO2. In addition, methane is emitted from the engine exhaust (often referred to as "methane slip" or "combustion slip") and is the result of unburned methane from the fuel that is emitted with the engine exhaust. Methane slip emissions are the result of the fundamental combustion design and type of combustion system for various engine types. The following link to a paper published by the International Council on Combustion Engines (CIMAC) titled "CIMAC Position Paper, Methane and Formaldehyde Emissions of Gas Engines, April 2014" provides details about methane in engine exhaust.

How are the emissions calculated for this equipment or process?

Emissions for individual compressors and engines can be calculated using emissions factors (for example EPA AP-42 emission factors for engines or GHGRP protocols) in combination with activity data, using engineering calculations, or by direct measurement of emissions.

What data is available to quantify emissions/waste for this equipment or process?

There have been many papers written by a variety of governmental agencies, non-governmental organizations, academia, and industry groups related to methane emissions from compressors and engines. In addition, there have been documents generated during rulemaking activities, primarily the EPA, that include data about emissions from these sources. While not exhaustive, below are links to some of these documents, each citing additional data sources, for example the U.S. EPA Greenhouse Gas

NMED Exhibit 10 - 0089

Inventory data. Some of the papers, or cited data sources, generated emission data by direct measurement of emissions.

1) EPA Office of Air Quality Planning and Standards (OAQPS), April 2014. From the introduction: "The purpose of this paper is to summarize the EPA's understanding of vented VOC and methane emissions from compressors, and the EPA's understanding of available mitigation techniques (practices and equipment) to reduce vented emissions from compressors. Included in the mitigation techniques discussion is our understanding of the efficacy and cost of these technologies and the prevalence of use of the technologies in the industry". "Oil and Natural Gas Sector Compressors, Report for Oil and Natural Gas Sector Compressors Review Panel"
2) EPA Air Emissions Factors and Quantification. This is a link to EPA background information on natural gas fired reciprocating internal combustion engines (RICE) and Chapter 3.2 of EPA's *Compilation of Air Pollutant Emissions Factors (AP-42)* for RICE. AP 42, Fifth Edition, Volume I, Chapter 3: Stationary Internal Combustion Sources.
3) EPA Greenhouse Gas Reporting Program.
    a. This link contains EPA basic information on sources of GHG emissions in the petroleum and natural gas industries (Subpart W), emissions data reported, and guidance for reporters. This subpart covers compressors venting and most fugitive and venting sources from oil and gas facilities, plus engines in the production and gathering and boosting segments. GHGRP for Petroleum and Natural Gas Systems (Subpart W).
    b. This link contains EPA information on sources of GHG emissions from stationary fuel combustion sources, including engines (Subpart C). This subpart covers engine exhaust emissions at gas processing plants and transmission compressor stations. GHGRP for General Stationary Fuel Combustion Sources (Subpart C).
4) Colorado State University, Energy Institute, 2019. From the introduction: "The study had two primary objectives: 1) Collect data on equipment counts and types (activity data) of gathering stations and 2) Perform component level leak measurements suitable for developing new emission factors". "Characterization of Methane Emissions from Gathering Stations: Final Report"
5) Colorado State University, Energy Institute, 2019. This paper presents the technical information related to the CSU Gathering Station study direct measurement of methane emissions in the exhaust of engines. "Methane Emissions from Gathering and Boosting Compressor Stations in the U.S. Supporting Volume 2: Compressor Engine Exhaust Measurements"
6) Climate & Clean Air Coalition, 2017. From the introduction: "This is a technical guidance document for Partners to the CCAC Oil and Gas Methane Partnership (OGMP). This document is one in a series that describes a core source of methane emissions. The document introduces suggested source-specific methodologies for quantifying methane emissions and describes established mitigation options that Partners should reference when determining if the source is

“mitigated””. This document is specific to centrifugal compressors with wet seals. "Technical Guidance Document Number 3: Centrifugal Compressors with "Wet" (Oil) Seals"

7) Climate & Clean Air Coalition, 2017. From the introduction: “This document provides technical guidance to Partners of the CCAC Oil and Gas Methane Partnership (OGMP). It is one in a series describing a core source of methane emissions from oil and natural gas production operations. The guidance documents introduce suggested methodologies for quantifying methane emissions from specific sources and describe established mitigation options that Partners should reference when determining if the source is “mitigated””. This document is specific to reciprocating compressors. "Technical Guidance Document Number 4: Reciprocating Compressors Rod Seal/Packing Vents”
8) Joint Institute for Strategic Energy Analysis, August 2015. From the Executive Summary: “Based on a review of recent research and analysis of the U.S. GHGI emission estimates, this report briefly summarizes the methods and results of the 2014 U.S. GHGI (EPA 2014a), discusses challenges to constructing the U.S. GHGI, and suggests some opportunities that could improve the accuracy of the methane emissions estimates”. "Estimating U.S. Methane Emissions from the Natural Gas Supply Chain: Approaches, Uncertainties, Current Estimates, and Future Studies"
9) INGAA, August 2018. From the introductory comments of the whitepaper: “This white paper supplements those commitments by explaining the sources of methane emissions for the interstate natural gas transmission and storage sector, which is comprised of a network of high-pressure pipelines, compressor stations, and storage assets (salt caverns and reservoirs), as well as the basis for the methane emissions commitments that INGAA members voluntarily adopted”. "Improving Methane Emissions from Natural Gas Transmission and Storage"
10) One Future/ICF International, May 2016. From the Executive Summary: “Our Nation’s Energy Future Coalition (ONE Future) 1 commissioned ICF to conduct this analysis of the marginal abatement cost (MAC) of various methane emission abatement technologies and work practices for the natural gas industry. The goal of this MAC analysis is threefold: (1) to identify the emission sources that provide the greatest opportunity for methane emission reduction from the natural gas system, (2) to develop a comprehensive listing of known emission abatement technologies for each of the identified emission sources, and (3) to calculate the cost of deploying each emission abatement technology and to develop a MAC curve for these emission reductions”. "Economic Analysis of Methane Emission Reduction Potential from Natural Gas Systems"
11) EPA & EC/R Inc., July 2011. From the forward: “This background technical support document (TSD) provides information relevant to the proposal of New Source Performance Standards (NSPS) for limiting VOC emissions from the Oil and Natural Gas Sector”. "Oil and Natural Gas

Sector: Standards of Performance for Crude Oil and Natural Gas Production, Transmission, and Distribution: Background Technical Support Document for Proposed Standards"

12) EPA & GRI, June 1996. From the introduction: "This report describes how the emissions from compressor driver exhaust were determined. Section 3 discusses the data used to make the emission estimates. Section 4 presents the development of the emission factors for engines and turbines. Section 5 describes the development of the activity factors for each industry segment (production, processing, and transmission, including storage and generators). The annual emissions for each segment and the overall national emissions estimate are provided in Section 6. Conclusions are given in Section 7". "Methane Emissions from the Natural Gas Industry, Volume II: Compressor Driver Exhaust, Final Report"

What are the data gaps in quantifying emissions/waste for this equipment?

Numerous studies have published estimates of methane emissions from compressors and engines, using either top-down or bottom-up methodologies. Each methodology has its associated pros and cons, which results in varying emission estimates and activity data for these sources. Some of the data quality issues or data gaps that impact emission estimates, and therefore the ability to assess effectiveness of reduction efforts, include:

- Variation in emissions between source sub-types, for example different engine designs and configurations.
- Variation in emissions for similar equipment due to specific operational conditions at facilities or across geographic areas.
- Consistency of and lack of activity data and data regarding the number of sources, by type and sub-type, as well as by industry sector.
- Due to changing regulations and application of best practices, data more than a few years old may no longer be representative of actual emissions.
- It has proven difficult to reconcile differences between emission estimates, for example there are some significant inconsistencies between the EPA GHG Inventory and the EPA GHG reporting program data.

Arbitrary categorizations that may obscure important information. For example, EPA GHGRP only uses a single emissions factor, appropriate for a small compressor, for vented gas from any reciprocating compressor located at a well pad. While many compressors at well pads are small, no data is collected on the prevalence of larger compressors at these facilities, which would be expected to have higher emissions.

Economic Description of the Process or Equipment:

What is the per unit cost of the equipment or the costs associated with the process?

Equipment costs for engines and compressors vary greatly across the natural gas value chain based on facility requirements, operational conditions, and location. As such, equipment costs must be determined on a case-by-case basis.

What are the annualized operating costs for the equipment or costs associated with the process?

Operating costs for engines and compressors vary greatly across the natural gas value chain based on equipment type, facility requirements, operational conditions, and location. As such, operating costs must be determined on a case-by-case basis.

If the equipment or process is powered, what are the costs?

The cost to power compressors is related to the fuel cost to operate a combustion engine or turbine, or the cost of electricity for compressors that are driven by electric motors. Fuel and electricity costs vary greatly across the natural gas value chain based on equipment type and location. As such, power costs must be determined on a case-by-case basis.

What are the maintenance and repair costs for existing or new equipment?

Maintenance costs for engines and compressors vary greatly across the natural gas value chain based on equipment type, facility requirements, operational conditions, and location. As such, maintenance costs must be determined on a case-by-case basis.

Existing Reduction Strategies:

How has industry reduced emissions/waste from this equipment or process historically?

Voluntary methane emission reduction best practices used in the oil and natural gas industry for compressors and engines are identified in the following link to the EPA Natural Gas STAR Program "Recommended Technologies to Reduce Methane Emissions".

It should be noted that the information presented by NG STAR partners related to costs to implement methane reduction opportunities may be specific to a location or an individual company. The decision to implement and the cost to implement a voluntary methane reduction technology is always a case-by-case determination based on facility requirements, operational conditions, and location. One example of variation in the feasibility analysis is related to the value of natural gas. Many of the NG STAR opportunities assess cost benefits based on natural gas values that are dated and may not reflect the lower values of natural gas in today's market.

For example, many of the NG STAR examples use a range of value for natural gas of $3-$7/Mcf. Gas values today, and for the past 5 years, are typically below $3/Mcf. It is notable that in some producing basins, including the Permian Basin of SENM, gas values are even more depressed due to local market conditions. Permian Basin spot natural gas prices (at Waha Hub) averaged less than $0.75/Mcf during

NMED Exhibit 10 - 0093

the first eight months of 2019, after touching a record low of negative $9.00 in April 2019, and compared with an average of $2.10 in 2018 and a 2014-18 average of $2.80.

The EIA notes that low Permian Basin spot prices are largely the result of constraints on pipeline capacity, and that prices rose in September in anticipation of the opening of the Gulf Coast Express Pipeline. EIA notes that "Limited natural gas pipeline takeaway capacity from the region has kept prices very low" and that seven additional natural gas pipelines are planned in the region. https://www.eia.gov/todayinenergy/detail.php?id=41213.

Primary reduction strategies include:

- Centrifugal Compressor Wet Seals - Replacing Wet Seals with Dry Seals
    - EPA NG STAR Partner Reported Opportunity
    - May not be technically feasible in some cases due to design of existing compressor or operational conditions, such as:
        - Sour gas service, i.e. gas with H2S, common in SENM
        - Certain pressure & temperature conditions
    - If feasible, potential to reduce methane emissions by 95%
    - High cost to implement reported by a NG STAR partner as $324,000 in 2006 dollars ($475,000 in today's dollars w/ 3% inflation)
    - May be offset over time by lower OPEX
- Centrifugal Compressor Wet Seals - Wet Seal Degassing Capture
    - EPA NG STAR Partner Reported Opportunity
    - Collect vapor from seal oil degassing and route for other uses or destruction, such as:
        - Compressor suction
        - High pressure turbine fuel gas
        - Low pressure fuel gas for heaters/burners
        - Flare purge gas
        - Flared, if no use is feasible
    - If feasible, potential to reduce methane emissions by 95%. Some of the above uses may not feasible, e.g. for sour gas.
    - Requires capital costs to install seal oil separator, oil demister/filter, piping, flow controls, and instrumentation
    - Cost to implement can be highly variable based on facility requirements. One NG STAR partner reported costs to be $33,000 in 2014 dollars.
- Reciprocating Compressor Rod Packing – Rod Packing Replacement
    - EPA NG STAR Partner Reported Opportunity
    - Rod packing emissions increase over time due to wear at the seal surfaces

NMED Exhibit 10 - 0094

    - Replacement of rod packing is routine maintenance task
    - Cost to replace compressor rod packings is highly variable
        - Dependent on size of the compressor, composition of the gas being compressed, operating pressures, operating temperatures, other operating conditions (such as demand and speed), technology selected, and materials selected.
    - One NG STAR partner reported costs to be $1,350 - $1,700 per compression cylinder. For a typical compressor with 4 cylinders this would equate to a range of $5,400 - $6,800 for parts & labor
- Reciprocating Compressor Rod Packing – Vapor Capture
    - Collect vapor from rod packing and route for engine fuel
    - May not be feasible for all application, for example sour gas

With regards to methane slip in engine exhaust, the paper published by the International Council on Combustion Engines (CIMAC) titled "CIMAC Position Paper, Methane and Formaldehyde Emissions of Gas Engines, April 2014" also provides a list of potential methods to reduce methane slip emissions. Many of the reduction methods are related to changing the fundamental design of the combustion chambers in engines to reduce methane slip and improve engine efficiency (Section 6 of the paper). There is also discussion regarding exhaust gas after-treatment using oxidation catalyst to lower methane slip (Section 7 of the paper). At this time, it appears there are unresolved technical issues related to methane conversion at low exhaust temperature and catalyst degradation. Using catalyst to reduce methane emissions appears to be unproven and further development is required to make this technology available. The paper published by One Future/ICF International (May 2016), "Economic Analysis of Methane Emission Reduction Potential from Natural Gas Systems", states in section 2.3, "Several of the sources identified in Table 2-1 do not have commercially available mitigation technologies (e.g., engine exhaust) …".

How have the emission/waste reductions been measured?

Voluntary methane emission reductions are reported by Natural Gas STAR Partners and summarized in EPA's annual program reports in this link to the "Natural Gas STAR Program Accomplishments"

How have states and the federal government reduced emissions/waste from this equipment or process historically? In addition, please identify voluntary reductions achieved whether or not they were in response to a regulatory action/requirement.

New compressors have been regulated since 2012 by the New Source Performance Standard at 40 CFR 60, subpart OOOO and New Source Performance Standard at 40 CFR 60, subpart OOOOa. Under these rules, new centrifugal compressors are required to reduce methane and VOC emissions from wet seal systems by at least 95%, which also provides a similar reduction in methane emissions. Reciprocating

NMED Exhibit 10 - 0095

compressors are required to change the rod packing at least every 26,000 operating hours or every 3 years. Modification to existing compressors triggers these NSPS requirements if the change results in an increase in horsepower. Compressors located at a well site, or an adjacent well site and servicing more than one well site, are not subject to these requirements. In leu of changing the rod packing, NSPS OOOO/OOOOa allows the operator to collect and route emissions from the compressor rod packing to a process through a closed vent system.

Some states have implemented regulations that are more stringent than the federal rules, to reduce VOC emissions in ozone non-attainment areas or as regulations to reduce methane emissions. In Colorado, for example, per CO Air Quality Control Commission, Regulation 7, the federal OOOO/OOOOa compressor requirements generally apply to compressors regardless of installation date (see Reg 7, Sections XII.J.1 & XVII.B.3.b for Centrifugal Compressors and Reg 7, Sections XII.J.2 & XVII.B.3.c for Reciprocating Compressors). In addition, centrifugal compressors with wet seal systems must complete annual inspections and leak monitoring of wet seal capture systems. Unless a compressor is already subject to OOOO/OOOOa, Reg 7, Section XVII.B.3.b & c do not include the same intensive recordkeeping and reporting requirement as provided for in Reg 7, Section XII.J. The recordkeeping and reporting in Section XII.J are a function of ensuring the related emissions reductions can be credited toward the attainment demonstration.

California, Canadian Federal rules, and two Canadian provinces have taken a somewhat different, more protective approach. Canadian jurisdictions require control (approx. 95%) of rod-packing emissions from any new reciprocating compressor.

Effective dates – after which new reciprocating compressors must be controlled

Canadian Federal 1/1/2023
Alberta 1/1/2022 (Only recips with 4 or more cylinders)
British Columbia 1/1/2021 (Only recips with 4 or more cylinders)

For existing reciprocating compressors, these jurisdictions require periodic measurement of rod packing vent volumes. Typically, the measurement must be performed annually. After the effective dates listed above (1/1/2019 for California), when an operator measures vent volume in excess of a threshold, the compressor must be repaired (e.g., rod-packing replacement or similar).

Vent Volume Repair Thresholds (per cylinder, scf/minute)

California 2.0
Canadian Federal 0.81
Alberta & British Columbia 0.49, *averaged across all compressors in an operator's provincial fleet.*

In Canadian jurisdictions, these rules are applied to all recips except those under 100 HP and (for the provincial rules) those operated less than 450 hours per year. California applies standards to all

NMED Exhibit 10 - 0096

compressors operated 200 or more hours per year. The standards described above are applied to all recips except those at wellpads. California subjects wellpad compressors that do not route rod-packing emissions to a process or control to LDAR requirements. If there is any significant amount of vent gas from rod-packing for these compressors, the LDAR program must treat the compressor as a leak source and it must be repaired.

New and existing engines have been regulated by the EPA and states for many years, dating to 2004, with a regulatory focus on criteria pollutants (NOx, CO, VOC) and hazardous air pollutants (formaldehyde). Federal engine regulations include the National Emission Standard for Hazardous Air Pollutants at 40 CFR 63, subpart ZZZZ, and the New Source Performance Standard at 40 CFR 60, subpart JJJJ. Requirements in NESHAP ZZZZ and NSPS JJJJ for engines vary depending on age, engine type, size, and location. While emission limits and control requirements of these two regulations target NOx, CO, VOC, and formaldehyde, methane is also reduced. For example, catalytic controls that reduce other pollutants, also reduce methane, although to a lesser degree. In addition, the maintenance, inspection and testing requirements in these regulations and state issued permits ensure that engines operated in an efficient manner that minimizes methane emissions along with criteria and hazardous air pollutants.

EPA requires annual reporting of GHG emissions from these sources at plants/basins with over 25,000 mtCO2e. Also, annual monitoring of vented wet seal and rod packing emissions at subject gas processing plants.

What are examples of process changes/modifications that reduce or eliminate emissions/waste from this equipment or process?

Voluntary emission reduction best practices used in the industry for compressors and engines are identified in the following link to the EPA Natural Gas STAR Program "Recommended Technologies to Reduce Methane Emissions"

NMED Exhibit 10 - 0097

Technology Alternatives:

List of technology alternatives with link to information or contact information for the company/developers.

Voluntary methane emission reduction best practices used in the industry for compressors and engines are listed the following link to the EPA Natural Gas STAR Program "Recommended Technologies to Reduce Methane Emissions"

Feasibility and cost of the NG STAR partner reported opportunities are always a case-by-case determination based on facility requirements, operational conditions, and location. One example of variation in the feasibility analysis is related to the value of natural gas. Many of the NG STAR opportunities assess cost benefits based on natural gas values that are dated and may not reflect the lower values of natural gas in today's market.

For example, many of the NG STAR examples use a range of value for natural gas of $3-$7/Mcf. Gas values today, and for the past 5 years, are typically below $3/Mcf. It is notable that in some producing basins, including the Permian Basin of SENM, gas values are even more depressed due to local market conditions. Permian Basin spot natural gas prices (at Waha Hub) averaged less than $0.75/Mcf during the first eight months of 2019, after touching a record low of negative $9.00 in April 2019, and compared with an average of $2.10 in 2018 and a 2014-18 average of $2.80.

What technology alternatives exist to reduce or detect emissions? Please list all alternatives identified along with contact information for further investigation of this technology or process.

See above link to EPA NG STAR reported opportunities for complete discussion on each reduction technology.

What are the pros and cons of the alternatives?

See above link to EPA NG STAR reported opportunities for complete discussion on each reduction technology.

What is needed and available for new wells?

These emissions are not specific to wells.

What is needed and available for existing wells?

These emissions are not specific to wells.

What technology alternatives exist for this equipment or process itself?

Compression is a basic, must run process for the natural gas industry. No alternatives exist to replace the use of compressors to move natural gas through the value chain.

As discussed in earlier sections, the driver for a compressor can be an internal combustion engine, a combustion turbine, or an electric motor. In some situations, oil and gas operators determine that electrified compression is a viable and preferred technology in place of natural gas fired engines or turbines.

What are the pros and cons of the alternatives?

With regards to electric driven compression:

Pros:

- Eliminates local engine/turbine related emissions of criteria pollutants and HAPs, along with methane emissions. There are still emissions, including GHG emissions, related to power generation.

Cons:

- Many locations do not have access to adequate and reliable third-party power
- Cost

Costs of Methane Reductions:

What is the cost to achieve methane emission reductions?

Cost of the NG STAR reported opportunities is discussed in the EPA Natural Gas STAR Program "Recommended Technologies to Reduce Methane Emissions".

Costs are always a case-by-case determination based on facility requirements, operational conditions, and location. Many of the NG STAR opportunities assess cost benefit based on natural gas values that are dated and may not reflect the lower values of natural gas in today's market.

For example, many of the NG STAR examples use a range of value for natural gas of $3-$7/Mcf. Gas values today, and for the past 5 years, are typically below $3/Mcf. It is notable that in some producing basins, including the Permian Basin of SENM, gas values are even more depressed due to local market conditions. Permian Basin spot natural gas prices (at Waha Hub) averaged less than $0.75/Mcf during the first eight months of 2019, after touching a record low of negative $9.00 in April 2019, and compared with an average of $2.10 in 2018 and a 2014-18 average of $2.80.

Table 1 of the "Cost-Effectiveness of Comprehensive Oil and Gas Emissions Reduction Rules in New Mexico" lists per unit costs for centrifugal compressor abatement technology as $0.82 per mcf of reduced methane ($42.64 per tonne).[57]

[57] "Cost-Effectiveness of Comprehensive Oil and Gas Emissions Reduction Rules in New Mexico," Erin Camp, PhD, Nate Garner, Asa Hopkins, PhD, Synapse Energy Economics, Inc., September 13,

NMED Exhibit 10 - 0099

What would be the implementation cost?

For new wells?

These emissions are not specific to wells.

For existing wells?

These emissions are not specific to wells.

Are there low-cost solutions available?

See EPA Natural Gas STAR opportunities linked above.

If a solution is high-cost, why is that the case?

See EPA Natural Gas STAR opportunities linked above.

Are there additional technical analyses needed to refine benefits/costs estimates?

Costs are always a case-by-case determination based on facility requirements, operational conditions, and location.

3. IMPLEMENTATION

For each piece of equipment or process, please consider the following questions and add other relevant information. If relevant, please identify if the answers are different for large company and small company requirements or are different for well type or basin.

Implementation Feasibility:

What is the feasibility of implementation (availability of required technology or contractors, potential permitting requirements, potential for innovation)?

See EPA Natural Gas STAR opportunities linked above.

What is the useful life of equipment?

See EPA Natural Gas STAR opportunities linked above.

What are the maintenance and repair requirements for equipment required for methane reduction?

See EPA Natural Gas STAR opportunities linked above.

How would emissions be detected, reductions verified and reported?

2019, page 9, Table 1, http://blogs.edf.org/energyexchange/files/2019/09/Synapse-Methane-Cost-Benefit-Report.pdf.

Emissions for individual compressors and engines can be calculated using emissions factors (for example EPA AP-42 emission factors for engines or GHGRP protocols) in combination with activity data, using engineering calculations, or by direct measurement of emissions.

4. CHALLENGES AND OPPORTUNITIES TO ACHIEVE METHANE REDUCTION IN NEW MEXICO

For each piece of equipment or process, please consider the following questions and add other relevant information. If relevant, please identify if the answers are different for large company and small company requirements or are different for well type or basin.

What regulatory gaps exist for this equipment or process? Are there regulatory gaps filled by the proposed implementation?

See Section 2 above regarding regulation of compressors and engines. Potential gaps are related to sources that are not covered by NSPS OOOO/OOOOa (grandfathered) or are located at wellsites.

Where do conflicting priorities exist between NMED, EMNRD, and NMSLO? Are there opportunities for coordination between these agencies?

Engines and compressors are stationary sources located at facilities subject to NMED air quality rules and permits.

Are there existing regulations related to methane that do not address the intended purpose? Identify any unintended barriers to methane reductions/capture that may hinder proposed processes.

NA

Other considerations or comments (e.g. particular design or technological challenges/opportunities, co-benefits, non-air environmental impacts, etc.?):

5. COMPRESSORS AND ENGINES- PATH FORWARD[58]

	OPTIONS	DESCRIPTION AND LINK TO INFORMATION IF AVAILABLE. 4.1	Centrifugal Compressor Wet Seals - Wet Seal Degassing Capture: retrofit wet seal installations with equipment that directs gas from seal oil degassing unit to other use, or flare for destruction.	https://www.epa.gov/sites/production/files/2016-06/documents/capturemethanefromcentrifugalcompressionsealoildegassing.pdf Capture for use may not be technically feasible in some cases due to design of existing compressor or operational conditions, such as: • Sour gas service, i.e. gas with H2S, common in SENM If feasible, potential to reduce methane emissions by 95%. Some of the above uses may not be feasible, e.g. for sour gas. Requires capital costs to install seal oil separator, oil demister/filter, piping, flow controls, and instrumentation. Cost to implement can be highly variable based on facility requirements. One NG STAR partner reported costs to be $33,000 in 2014 dollars.	1 2 3 4 5		San Juan Permian Both

[58] The format of the Path Forward table evolved over the course of the meetings as the group tried to identify the best method for capturing the most useful information. As a result, there is some variation in the table headers from topic to topic in the final consolidated report.

NMED Exhibit 10 - 0102

		While flaring is less preferred than capture for use due to waste & emissions of CO2 and other pollutants, it is certainly preferable to venting.			
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
4.2	Centrifugal Compressor Wet Seals - Replacing Wet Seals with Dry Seals	https://www.epa.gov/sites/production/files/2016-06/documents/capturemethanefromcentrifugalcompressionsealoildegassing.pdf May not be technically feasible in some cases due to design of existing compressor or operational conditions, such as: • Sour gas service, i.e. gas with H2S, common in SENM • Certain pressure & temperature conditions If feasible, potential to reduce methane emissions by 95%. High cost to implement reported by a NG STAR partner as $324,000 in 2006 dollars ($475,000 in today's dollars w/ 3% inflation). Costs may be offset by lower opex after retrofit.	1 2 3 4 5		San Juan Permian Both
	COMMENT A. Wet seals do not apply to reciprocating compressors. [page 88]		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
4.3	Reciprocating Compressor Rod Packing – Vapor Capture and route for engine fuel [page 95]	May not be feasible for all application, for example sour gas	1 2 3 4 5		San Juan Permian Both
	COMMENT A. The concerns raised by EPA are still valid. In the Federal Register notice dated August 23, 2011 regarding proposed NSPS Subpart OOOO regulation, EPA evaluated the possibility of reducing VOC emissions from a control device but did not propose it due to technical considerations at Page 53762: "Although it is possible to construct an enclosure around the rod packing area and vent the emissions outside for safety purposes, connection to a closed vent system would		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		

NMED Exhibit 10 - 0103

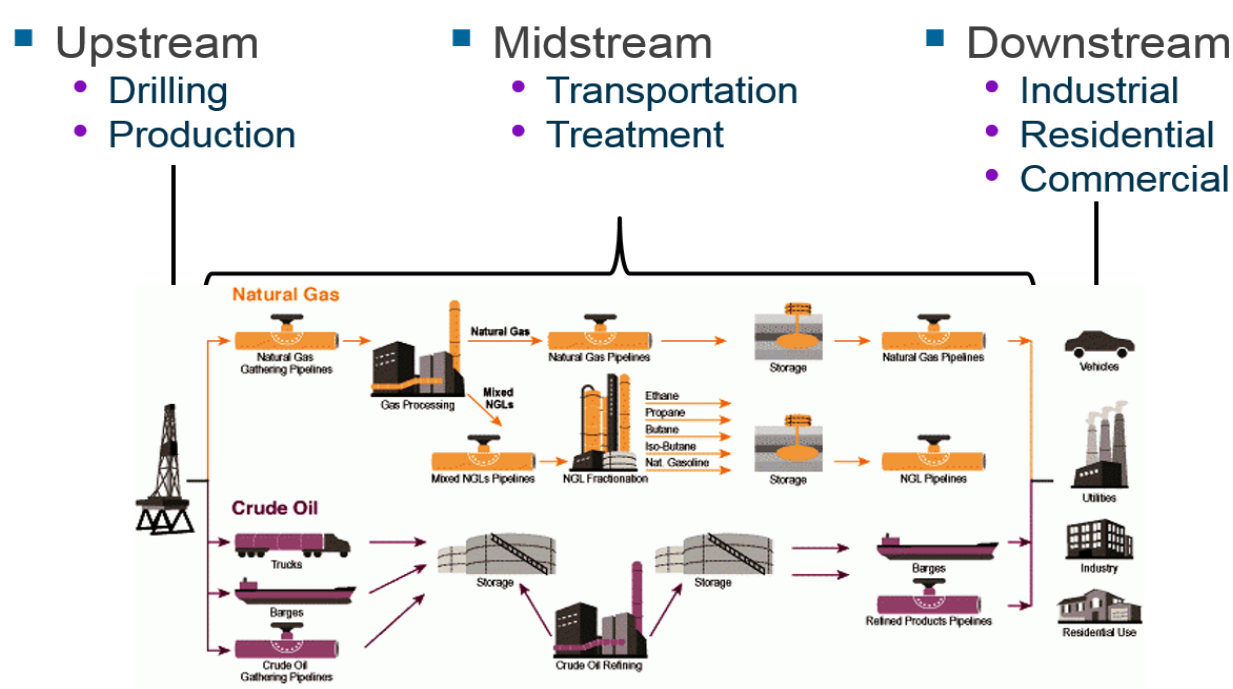
	create back pressure on the leaking gas. This back pressure would cause the leaked gas instead to be forced inside the crankcase of the engine, which would dilute lubricating oil, causing premature failure of engine bearings, pose an explosion hazard and eventually be vented from the crankcase breather, defeating the purpose of a control device." B. Allowed in other states [cite in paper]				
4.4	Reciprocating Compressor Rod Packing – Rod Packing Replacement [page 94]	https://www.epa.gov/sites/production/files/2016-06/documents/ll_rodpack.pdf	1 2 3 4 5		San Juan Permian Both
	COMMENT A. Cost to replace compressor rod packings is highly variable. Dependent on size of the compressor, composition of the gas being compressed, operating pressures, operating temperatures, other operating conditions (such as demand and speed), technology selected, and materials selected. [page 95] B. One NG STAR partner reported costs to be $1,350 - $1,700 per compression cylinder. For a typical compressor with 4 cylinders this would equate to a range of $5,400 - $6,800 for parts & labor [page 95] C. [Reference not in paper.] In the Federal Register notice dated August 23, 2011 regarding proposed NSPS Subpart OOOO regulation, EPA considered the cost-effectiveness of replacing rod packing replacement costs for reciprocating compressors at wellheads at Page 53762: "Reciprocating compressors at wellheads are small and operate at lower pressures, which limit VOC emissions from these sources. Due to the low VOC emissions from these compressors, about 0.044 tpy, combined with an annual cost of approximately $3,700, the cost per ton of VOC reduction is rather high. We estimated that the cost effectiveness of controlling wellhead compressors is over $84,000 per ton of VOC reduced which we believe to be too high, and therefore, not reasonable."		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		

	EPA estimated the cost effectiveness of VOC emissions by rod packing replacement would be $870 per ton of VOC at gathering and boosting stations. The cost effectiveness numbers would have to be evaluated for the new well site compressors which may be larger. However, for many of the older, existing well site compressors these numbers may still be valid.				
4.5	Reciprocating Compressors: Annual volumetric measurement of rod-packing venting; repair compressor when emissions exceed threshold level.	See California & Canadian rule material. California rules distinguish between compressors at production facilities and other facilities (including gathering and boosting, transmission etc.). At production facilities, the rules require leak detection measurement. Volumetric measurement is required at facilities other than production.	1 2 3 4 5		San Juan Permian Both
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		

DRAFT

SECTION 5, INFRASTRUCTURE PLANNING

Discussion for MAP members on October 10, 2019



NOTE: The focus of this report is processes, and the associated equipment, directly related to the release or capture of methane gas. We are not requesting information on processes/equipment that are not related to the release or capture of methane gas.

1. DESCRIPTION OF PROCESS AND EQUIPMENT

Provide a description of the processes and/or equipment used in oil and/or gas extraction for this topic. Note that this report template will be used for all topics of the MAP review and, thus, not all questions or information may be relevant for each topic. If information is not relevant, indicate N/A. Note any differences expected for differing well types, industry sector, or basin location.

Technical description of the process or equipment:

Infrastructure is a broad topic within the oil and gas space. This paper will mainly focus on pipelines and associated facilities, as well as the planning process for well development and gathering facility infrastructure. As a general matter, however, oil and gas infrastructure can include pipelines, gas compression, gas processing, NGL fractionation, gas storage, oil terminals, oil refining, trucks, barges and downstream operations such as residential, commercial, and industrial. Here is a graphic to demonstrate such infrastructure:

1. The Growth Project Planning Process (Business Development)
   a. Buildout of midstream (gathering and processing, intrastate pipelines) and downstream (interstate pipelines, storage, fractionation and refining) facilities is a complex commercial process that requires collaboration between operators in each industry segment. New capacity won't be constructed without some degree of certainty around future drilling activity and production, which are ultimately driven by market demand, pricing, producer financing/growth strategy, regulatory climate, etc.
      i. Midstream gas gathering and processing facilities. Natural gas may be produced from gas wells, which are drilled primarily to produce natural gas (together with some component of natural gas liquids (NGLs) and/or condensate), or as associated gas that is produced essentially as a byproduct of wells that are drilled primarily to produce crude oil. In either case, in order to facilitate and provide a market for growing natural gas production, midstream companies must make long-term capital investment decisions in advance to construct the infrastructure necessary to gather and process producers' gas volumes.

         Those midstream facilities are generally comprised of gathering pipeline systems that connect to individual wells, field compression or "booster" facilities, and natural gas processing plants (collectively, gathering and processing or "G&P" facilities). These G&P facilities are designed to operate over a long useful life (30+ years) in order to service production in a particular geographic area; they are permanently located facilities that require ongoing maintenance capital and have a much lengthier capital recovery horizon when contrasted to an upstream producer's investment in an individual well. While upstream producers can elect how and where to drill their acreage, reallocating their capital budgets from basin to basin, G&P assets remain in place once built.

         As a result, in order to construct new G&P capacity, midstream companies seek to secure substantial acreage commitments or minimum volume dedications from producers in advance of a final investment decision. Producers benefit from these arrangements by having a market for their production, often at preferable terms offered by the midstream operator in order to secure their advance commitment. Absent these types of commitments, a midstream company faces the risk that competitors might

undercut their growth strategy by obtaining similar dedications, or that drilling activity might shift to another basin or geographic region, leaving their own newly constructed G&P facilities behind as stranded investments.

ii. Downstream long-haul takeaway pipelines. Before pipeline developers break ground on the construction of a new pipeline, which can cost billions of dollars, the developers seek long-term commitments to ship oil, gas, or NGLs through the pipeline. Shippers may elect to sign long-term contracts during a period called an "open season." During the open season, a shipper can sign a Transportation Services Agreement, or TSA, agreeing to ship a certain quantity at a certain rate for a certain term if the pipeline is built, thereby securing "firm" or guaranteed pipeline access for the volume committed.

Before a pipeline company commits to building a pipeline, the company tries to obtain a minimum level of shipping commitments through TSAs. Shippers typically benefit from committing during the open season because the rates offered during an open season to shippers willing to make a long-term shipping commitment are usually lower than the rates charged to other shippers who do not commit yet seek access after the pipeline is constructed.

b. Over time, the necessary midstream and downstream infrastructure will ultimately be developed to accommodate long term production trends, but not without encountering periods marked either by bottlenecks or by excess capacity. Bottlenecks or capacity constraints are particularly relevant to and may result in periodic increases in flaring.

c. Notably, additional constraints may and in recent years have developed further downstream, in the form of limited NGL fractionation capacity. Long-haul NGL pipelines typically ship "Y-grade" NGL product, which is a blend of NGLs (ethane, propane, butane, isobutene, etc.) in their mixed, unfractionated form. Once the Y-grade product reaches downstream markets – which for Permian Basin production is generally centered on the Texas gulf coast in and around Mont Belvieu, Texas – downstream purchasers fractionate or separate the Y-grade into constituent purity products for further marketing and use.

d. As drilling activity fluctuates over time and initial production levels from new wells tapers off, G&P systems typically have capacity available to connect new wells from existing and/or new producer customers, whether from dedicated acreage or not.

2. Connecting Wells to Midstream Gathering Pipelines: Right-of-Way Acquisition

a. The process of connecting wells to gas gathering systems begins with right-of-way (ROW) acquisition. Once commercial negotiations are complete and an agreement is in place between the upstream producer and the midstream operator, midstream ROW professionals receive authorization to initiate the process beginning with a survey that is used to determine the planned route of the gathering pipeline and any associated compression facilities or other appurtenances. Depending upon land ownership patterns along the selected route, the process and permitting requirements vary as outlined below.

i. Federal Lands (primarily BLM, but also Tribal, USFS, BOR, etc.). The same general process and requirements apply to securing ROW for gathering pipelines, compressor stations, or gas processing plants. The midstream operator as applicant submits to the agency a route or location survey together with an environmental assessment, archaeological study, geologic survey (karsts) and all other materials required to be submitted with the ROW application in conformance with all applicable federal laws (separate authorization is required for the U.S. Army Corps of Engineers for regulated crossings of navigable waters). The application goes through multiple levels of review by Natural Resource Specialists, each of whom has a specific area of expertise in determining the completeness and adequacy of the application and considering any potential conditions to be placed on the ROW grant. The standard term for a BLM ROW grant is 30 years.

Each year BLM offices in New Mexico ask operators for any available planning information or forecast of anticipated ROW activity for the upcoming year, in an effort to budget their own offices and activities. While these can be difficult for midstream operators to forecast with accuracy, efforts are made in an effort to ensure adequate agency staffing levels, which is a persistent and historical source of project delay.

ii. State Lands. The New Mexico State Land Office (SLO) has jurisdiction over a vast amount of state trust lands located in the heart of the oil and gas producing areas of the state. While the process for obtaining ROW grant on state lands is very similar to that for federal lands, there are some differences. Gathering pipelines are laid under a ROW agreement, which is initiated by filing a completed application that includes a survey (conducted under the prior approval of the SLO) . The ROW application is reviewed by the appropriate SLO District Resource Manager, which can be a source of delay based solely on personnel limitations and workloads: currently, the SLO needs to staff more appropriately. After staff review, a grant agreement is sent back to the applicant for review and signature, after which it is submitted for final approval by the Land Commissioner and execution of the ROW grant agreement. The standard term for an SLO ROW grant is 35 years.

Natural gas compressor stations and processing plants can be located on state lands pursuant to a business lease, rather than a ROW grant. Application requirements are similar to those required for ROW, but at times delays are incurred if the surface area is already subject to a grazing lease. In these instances, the SLO leaves it to the midstream operator to obtain from the grazing lessee either (a) a relinquishment of acreage from the grazing lease, or (b) a right to lease leased lands, an arrangement that must thereafter be renewed every 5 years.

iii. Private Lands. ROW acquisition on private lands is a private negotiation and transaction between the midstream operator and the landowner. The midstream company determines the intended pipeline route and initiates contact with the affected landowner(s) that are identified. ROW agents typically obtain permission to conduct survey while negotiations are taking place, and once the parties reach agreement the ROW easement is conveyed and the landowner is compensated with the amount agreed to. If a landowner wishes not to engage in negotiations and grant an easement, the company seeks alternate routes and/or works with the upstream producer to potentially lay gathering lines pursuant to their rights of access under the oil and gas lease or landowner surface agreement.

iv. Tribal Nations
    1. Navajo Nation
    2. Jicarilla Apache Nation
    3. Pueblo
    4. Ute
    5. Indian Allottee

3. Permitting Requirements for Midstream Facilities (non-ROW)
    a. Upstream, midstream, and downstream operators each face their own unique suite of regulatory schemes that entail numerous but often varying federal and state permitting agencies, which operate pursuant to different organic statutes. Ultimately, project timing and execution can be impacted by agency funding and/or staffing issues, changes in laws, regulation, or political leadership, opposition by landowners, NGOs, and others, etc. For projects located in New Mexico, the relevant agencies and processes are summarized below.
        i. U.S. Federal Energy Regulatory Commission (FERC)
            1. Certificate of Public Convenience and Necessity (interstate pipelines)

2. Regulation of rates, terms and conditions of service (interstate pipelines)

ii. U.S. Environmental Protection Agency (EPA)
   1. NPDES discharge permits
   2. Spill Prevention, Control, and Countermeasure (SPCC) permits

iii. U.S. Army Corps of Engineers
   1. Nationwide permits (navigable water crossings)

iv. New Mexico Environment Department
   1. Air construction/operation permits (state and federal EPA requirements)
   2. Hazardous waste generation/transport/storage
   3. Underground storage tanks
   4. Drinking water systems

v. New Mexico EMNRD, Oil Conservation Division
   1. Pipeline hydrostatic test water discharge (pipeline construction)
   2. WQCC/discharge permits
   3. Below-grade tanks/pit permits
   4. AGI/disposal wells

4. Planned Maintenance Activities
   a. As with our own personal vehicles, in order to responsibly maintain the reliable and safe operation of midstream G&P systems, these assets are subject to regular and routine maintenance activities. Depending on production volumes flowing from upstream wells and space available on downstream takeaway pipelines, these planned activities can either be performed with little or no interruption in production flow or may result in upstream curtailment, which may at times lead to flaring.

      Gas processors make volume commitments or "nominations" for residue gas sales into downstream interstate pipelines one to two days ahead of actual delivery. If, on a Monday, a processor is making nominations for Wednesday deliveries and knows that planned maintenance activities are scheduled at either a compressions station or a processing plant on that date, the processor will lower the volume of gas nominated accordingly. In some circumstances, the processor will be able to reroute volumes upstream of the compressor or plant to another facility with available capacity, increasing nominations on an alternate pipeline and proceeding with little or no upstream disruption. If gas cannot be rerouted, the planned maintenance may require upstream production volumes to be shut in at the wellhead. G&P field personnel will inform producer customers usually a full day in advance, communicating the nature and expected duration of the maintenance activity.

      For extended maintenance activities that will keep G&P operations offline for an extended period of time, midstream companies will typically send written notice of curtailment or volume allocation to their customers. Different equipment and components have different maintenance schedules, with defined maintenance due at 30/60/90,000 operating hour intervals, or annual vs. 5-year shutdowns and repair. A "turnaround" is a scheduled maintenance activity that may keep a facility down for 5-10 days for engine overhauls, vessel inspection and repair, fixing of leaks identified by LDAR inspection, etc.

5. Infrastructure Challenges
   a. Not all assets are created equally. Gas processing facilities, for example, can vary greatly in how they are designed and operated, based in part on whether they are paired with a certain level of field treatment, and variables such as the quality characteristics of the raw product at the inlet (e.g., wet vs. dry gas, SO2 content, contaminants, etc.). Age of the system, variations in field pressures, and third-party incidents can also cause system-wide disruptions irrespective of any regulatory scheme that might be imposed. Often overlooked,

human resources can often be an overriding and sometimes persistent factor in achieving optimal operation of various assets, implicating regulatory compliance and emissions performance.

The age or "vintage" of a G&P system often dictates how new production is connected. Much of the recent production growth in SENM is being serviced by newly constructed facilities in which gathering systems, compression and processing are all designed to accommodate the high volumes and pressures associated with horizontal drilling. In many instances, older existing systems may have been designed for lower-pressure vertical (legacy) production and were not constructed to standards that allow for the safe gathering of gas at the volumes and pressures associated with most modern horizontal shale wells.

Fluctuations in any one or more of these variables may result in operational upsets of midstream facilities that lead to unplanned maintenance and repair events, whether that be in response to an issue or event or something else, such as the installation of system upgrades.

b. Availability of electrical infrastructure can create operational issues. The need for available and reliable power can create operational challenges for infrastructure. Onsite power generation may be needed to control or power a process. The ability, or the lack thereof, to have power can slow or impede infrastructure development.

Electricity reliability and voltage requirements-Oilfield equipment power requirements are quite varied ranging from instrumentation at a single well pad needing approximately 35W to operate up to approximately 2,000 kW (note unit change) to operate a single frac/stimulation pump. The power demand required to operate equipment determines if single phase power (household) is adequate or if three phase power (industrial) is necessary.

In the overall electrical grid, distribution substations connect to the transmission system and lower the transmission voltage to medium voltage (2kV and 35kV) using transformers. Primary distribution lines carry this medium voltage power to distribution transformers located closer to end users. Most customers are connected to the secondary distribution system through service drops. Customers demanding much larger amounts of power may be connected directly to the primary distribution level or the subtransmission level.

Much of the commonly seen distribution lines are secondary distribution systems for domestic and commercial needs that do not require high voltage transmission. The proximity of primary distribution level or subtransmission level to the required location is critical in determining 1) the economic feasibility of utilizing high voltage (3 phase) grid power to operate upstream and midstream higher HP equipment and 2) the timing around getting the local utility to run the necessary lines to the site. In many cases, higher HP equipment will need to be operated on generators due to both proximity of adequate transmission lines, lead times for connecting lines, and potential issues with grid instability resulting from high demand users on a system not originally designed for industry load.

In general, most of the compressors, engines and motors utilized in the oilfield require 3 phase power. This equipment is utilized for artificial lift, dehydration, gas compression, etc. Equipment that has the potential to operate on potentially more readily available single phase power, such as instrumentation and controllers, are critical to safe operation of the facilities. Due to the critical nature of this equipment, an unreliable or unstable grid, will result in unnecessary facility shutdowns when power is insufficient. The system upsets caused by potential outages from an unstable grid can result in equipment damage, well damage, and flaring. In addition, even secondary transmission lines may not be available in very rural areas. It can sometimes take

months of working with the local utilities to get even secondary transmission lines run to the facility, which is only adequate to operate a small amount of onsite equipment.

Due to the challenges around the development of adequate power supply to remote locations, many sites are supplied by onsite generation.

Infrastructure planning for oil and natural gas is the process by which producers, midstream operators, state and federal regulators, and state and federal land managers collectively, but not necessarily in coordination, determine the timing, extent, and location of new or re-fractured oil and gas wells, natural gas gathering and boosting systems (i.e., pipelines and compressors) and processing plants, as well as oil transport modes and facilities which are not addressed here.

Currently, infrastructure planning occurs primarily within individual segments of the oil and gas value chain or within individual firms, and it takes the form of multiple individual decisions by those entities, with some, but limited, information exchange and coordination. Producers make decisions to acquire new leases, drill new wells, re-complete existing wells, operate and maintain existing wells, and sometimes invest in flow lines and compressors. Midstream companies build or expand gathering, boosting, and processing infrastructure. Planning for a particular segment, for example production, may take place amongst several companies whose leaseholds are unitized.

As noted above, federal, tribal, state, and local agencies oversee and approve different aspects of such activities, including by determining, for federal public lands and state trust lands, where lands should be leased for development or where rights-of-way for infrastructure, such as pipelines, are appropriate. This oversight is also often fragmented, a function of "checkerboarded" land ownership prevalent in New Mexico and distinct, if sometimes overlapping, legal and regulatory authorities.

A critical outcome of infrastructure planning, or the lack thereof, is the alignment, or misalignment, between the volumes and locations of gas produced, particularly with respect to the associated natural gas produced at oil wells, and the capacity of natural gas gathering and processing systems to bring that gas to market.[59] Where there is insufficient available gathering, compression, and processing capacity for the amount of gas produced, operators must handle the gas through other means. Gas that is produced but not beneficially used by the producer at the well or fed into the gathering system is typically vented or flared. Both venting and flaring release pollution and constitute waste—the loss of the natural gas resource that could otherwise be sold into the market.

A substantial volume of gas is vented or flared in New Mexico, and the volume has been rising with the recent production boom, as discussed below in Section 2. However, there is tremendous variation among producers in the share of production that is reported as vented or flared, ranging from zero methane waste to 100% waste, with rates from 10% to almost 70% seen among major producers. Producers with associated gas and relatively little reported venting and flaring presumably have coordinated their planning with midstream companies to optimize the location and timing of anticipated production for takeaway. Associated gas producers with high reported rates of venting and flaring presumably have insufficient access to gathering and processing system infrastructure, which can indicate insufficient development planning and coordination with midstream companies.

[59] Associated gas is defined as natural gas that is produced from oil wells during unconventional oil production (also referred to as shale oil or tight oil). "Improving utilization of associated gas in U.S. tight oil fields", Carbon Limits, April 2015. https://www.catf.us/wp-content/uploads/2015/04/CATF_Pub_PuttingOuttheFire.pdf

While inadequate infrastructure planning is one explanation for infrastructure misalignment and waste, there are other plausible explanations as well. These include violation of the state's ban on venting from gas wells (NMAC 19.15.19.10 http://164.64.110.134/parts/title19/19.015.0019.pdf), violations of the state's time limit for venting and flaring from oil wells (NMAC 19.15.18.12 http://164.64.110.134/parts/title19/19.015.0018.html), and abuse of the No-Flare Rule Exception process; i.e., long-term flaring via serial approvals (Form C-129 Application for Exception to No-Flare Rule http://www.emnrd.state.nm.us/OCD/documents/C-12920110801.pdf). It is also possible that of the venting and flaring reported to OCD on the C-115s, venting is from oil wells only and venting and flaring is within the 60-day limit after completions or authorized through C-129 exceptions. In any case, industry, states, and the Federal government have recognized the strong connection between methane emissions and waste, and infrastructure planning, as discussed below in Section 2.

Provide the segment(s) of the industry that conduct infrastructure planning ~~the equipment or process is found~~:

Infrastructure can be found in upstream, midstream, and downstream business segments.

Upstream and midstream. As noted, the U.S. Bureau of Land Management (BLM) and State Land Office also influence infrastructure planning activity through the leasing of, respectively, federal public or state trust lands for oil and gas development and issuance of rights-of-way. To illustrate how this plays out for federal public lands, BLM manages oil and gas development through a three-stage process. First, BLM prepares "Resource Management Plans" that govern what lands are open to leasing and under what conditions. Second, BLM sells leases, which are specifically conditioned via the use of lease stipulations. Third, the BLM approves specific Applications for Permit to Drill or rights-of-way. In this third and site-specific stage, BLM may impose Conditions of Approval consistent with law and lease rights. BLM also plays a role in the unitization and communitization of leases with the goal of facilitating orderly and efficient development of federal leases.

Describe how the equipment or process is used:

Oil and gas infrastructure in New Mexico includes pipelines, natural gas compression facilities, natural gas processing, oil terminals, and oil refinery/fractionation.

Infrastructure planning by upstream producers can generate information for midstream companies about the timing and location of well development and projected production volumes with sufficient advance notice to enable midstream companies to respond with adequate gathering and processing capacity. While midstream companies may view the current process and level of information exchange as generally adequate for their own business purposes, the large volumes of venting and flaring indicate that additional large volumes of gas could be marketed if gathering capacity were sufficiently available where and when operators develop oil wells with associated gas. Midstream entities evaluate expected regional volumes for assessment in their hydraulic analyses and improved gas capture planning with better information about expected gas takeaway strategy and capacity at the future date of completion could improve the ability of midstream entities to conduct these analyses and support investment planning. Conversely, midstream companies could share existing and planned future capacity information with E&P operators during the commercial and business development process to better align E&P operators' drilling schedules and other investments.

Conversely, planning by midstream companies can inform producers of existing capacity, projected capacity additions, and capacity constraints, allowing producers to respond proactively, such as by locating and timing development to coincide with projected available gathering capacity, or by pausing or slowing production. For example, "Some companies have recently opted to scale back production in the gassier portions of the Permian. In April, Houston's

Apache Corp. said it dramatically cut back natural gas production in its Alpine High development in the Permian because of steep pricing discounts caused by pipeline shortages."
"Permian gas flaring hits new record highs for 'widespread waste,' pollution." The Houston Chronicle, June 4, 2019
https://www.houstonchronicle.com/business/energy/article/Permian-methane-emissions-back-on-the-rise-after-14412700.php
Also, midstream companies can inform producers of short-term capacity constraints from, e.g., planned maintenance activities, to allow producers to prepare to use other means to capture gas or temporarily pause production during such activities.

Provide the common process configurations that use this equipment or process:

n/a

What is the distribution of the equipment or process across business segments?

The process to build infrastructure is application, geographic, weather, and terrain specific.

How has this equipment or process evolved over time?

n/a

2. INFORMATION ON EQUIPMENT OR PROCESS COSTS, SOURCES OF METHANE EMISSIONS, AND REDUCTION OR CONTROL OPTIONS

Identify the capital and operating costs for the equipment or the process. Identify how methane is emitted or could be leaked into the air. Please **prioritize** the list to identify first the largest source of methane from the process or equipment and where there is **potential** for the greatest reduction of methane emissions. Note any differences expected for differing well types, industry sector, or basin location.

Sources of Methane:

Provide an overview of the sources of methane from this equipment or process:

Possible sources of methane can come from Natural Gas and Oil infrastructure.

The main source of methane emissions and waste linked to poor infrastructure planning is the venting and flaring of associated gas. According to production statistics reported by Operators to the OCD, Operators vented 3.1 MMcf or 0.2% of total production in 2018 and 1.4 MMcf or 0.2% of production in the first half of 2019. Operators flared 33.4 MMcf or 2.2% of total production in 2018 and 16.8 MMcf or 2% of total production for the first half of 2019. As discussed below, venting and flaring rates are considerably higher when only oil wells are considered.

Venting emits methane directly, as methane is the largest constituent of natural gas. Flaring also emits some methane due to incomplete combustion, and the amount of methane will be large if the flare is malfunctioning or unlit. Where air permits are required, compliant flares should achieve methane destruction rates of between 95-98%, with 2-5% of the gas emitted uncombusted.

https://www.env.nm.gov/wp-content/uploads/2018/04/GCP-Oil__Gas.pdf

It is important to note that while substituting flaring substantially reduces the climate impacts of venting methane, flaring still directly releases CO2 and smaller quantities of methane, as well as wasting the resource. At large volumes of flaring, the combined CO2 and methane emissions from flares can have climate impacts comparable to those of other large sources. For example, if venting and flaring from oil and gas production in NM continue at the current pace for the remainder of 2019, the resulting volume of GHG emissions will be equivalent to the GHG emissions from two units of the coal-fired San Juan Generating Station over the same period (see Exhibit 1 for calculations).

New Wells:

See venting and flaring topic paper.

Venting and flaring will occur at new wells if take-away capacity or field use does not accommodate all of the gas that is produced. New wells, by virtue of high initial production pressures, may also "bump off" older, lower-pressure wells from natural gas gathering systems, leading to operators deciding to vent or flare natural gas at those older sites.

Existing Wells:

See venting and flaring, pneumatics, compression topic papers.

Venting and flaring will occur at existing wells if take-away capacity or field use does not accommodate all of the gas that is produced. Again, existing wells may also get "bumped off" of gathering systems if they lack needed compression when new, higher-pressure wells come on-line, resulting in venting or flaring of natural gas that, before the new well came on-line, was able to flow through the natural gas gathering system.

How are the emissions calculated for this equipment or process?

NMED currently regulates midstream facilities, such as natural gas compression and oil terminals.

Vented and flared volumes are reported to OCD by operators on Form C-115 Operator's Monthly Report, which records the volumes of oil and gas production and disposition by well. For a description see http://www.emnrd.state.nm.us/OCD/documents/C115_Instructions2019.pdf

Any Vented/blowdown volumes greater than 50 MCF released from a pipeline are required to be reported to NMOCD via the C-141 report. NMAC 19.15.29.7

http://164.64.110.134/parts/title19/19.015.0029.html

What data is available to quantify emissions/waste for this equipment or process?

Depending on size, midstream facilities (e.g. most compressor stations, gas plants, or oil terminals) require NMED air permits and any excess emission during a routine or predictable startup, shutdown, or scheduled maintenance event (20.2.7.7 D. & 20.2.7.110 NMAC). The Air Quality Bureau has recently announced a new initiative to post excess emissions online on a monthly basis. See https://content.govdelivery.com/accounts/NMED/bulletins/2664784

"Excess emission" means the emission of an air contaminant, including a fugitive emission, in excess of the quantity, rate, opacity or concentration specified by an air quality regulation or permit condition.

http://164.64.110.134/parts/title20/20.002.0007.html

EPA Greenhouse Gas Reporting Rule also include pipelines and gathering systems under the gathering and boosting.

Onshore petroleum and natural gas gathering and boosting means gathering pipelines and other equipment used to collect petroleum and/or natural gas from onshore production wells and to compress and transport gas to a natural gas processing facility, transmission pipeline, or a distribution pipeline.

https://www.ecfr.gov/cgi-bin/text-idx?tpl=/ecfrbrowse/Title40/40cfr98_main_02.tpl
https://www.epa.gov/ghgreporting/ghgrp-and-oil-and-gas-industry

As shown in Table 1 below, overall reported venting and flaring from all oil and gas operations in New Mexico increased by 115% in 2018 and by 21% for the first half of 2019, far outpacing increased gas production in 2018 and keeping pace with the gas production increase thus far for this year, which is also up by 21%. Reported flaring increased by 125% in 2018 and by 28% in the first half of 2019. Reported venting increased by 47% in 2018 and, due to a dramatic decrease by one major operator, fell by 23% in the first half of 2019. Statewide, 2.1% of gas production was reported vented and flared in both 2018 and the first half of 2019. See also Venting/Flaring Report Tables 1 and 2 for additional information and analysis regarding total associated gas venting and flaring.

Recent reporting by the Houston Chronicle highlights these trends:

> Methane emissions and pollution in the booming Permian Basin likely hit a new record high in the second quarter after taking a small, but surprising, dip early this year, according to a new study. [This] is more than triple the amount of pollution and waste from just two years ago, according to the Norwegian research firm Rystad Energy. . . . The report estimates that the volumes of methane from natural gas burned off or vented into the atmosphere averaged of 663 million cubic feet per day in the second quarter ... For context, flaring in the Permian was less than 200 million cubic feet a day in mid-2017 and was less than 20 million cubic feet daily at the beginning of 2011 before the recent Permian boom took off.

"Permian gas flaring hits new record highs for 'widespread waste,' pollution." The Houston Chronicle, June 4, 2019
https://www.houstonchronicle.com/business/energy/article/Permian-methane-emissions-back-on-the-rise-after-14412700.php

Table 1: Total Reported Venting and Flaring: Change 2017-2019 (mcf) (Source: OCD C-155 data see http://www.emnrd.state.nm.us/OCD/statistics.html)

January – June (mcf)	**2017**	**2018**	**2019**	**17-18 % change**	**18-19 % change**
Flared	6,777,979	13,146,398	16,791,319	94%	28%
Vented	1,092,445	1,864,133	1,436,580	71%	-23%
Vented+Flared	7,870,424	15,010,531	18,227,899	91%	21%
Gas Production	630,088,033	705,510,340	855,313,871	12%	21%
% of gas production	1.2%	2.1%	2.1%		
Full Year (mcf)	2017	2018	17-18 % change		

Flared	14,886,176	33,421,502	125%
Vented	2,123,438	3,115,734	47%
Vented+Flared	17,009,614	36,537,236	115%
Gas Production	1,296,993,949	1,503,246,867	
% of gas production	1.3%	2.4%	

Table 2 shows that reported venting and flaring rates are consistently higher in the NM Permian than they are in the San Juan Basin. This is not surprising since the San Juan Basin has a far greater proportion of natural gas wells, and, presumably, Operators conduct extensive infrastructure planning to ensure that wells are connected to gathering systems and have adequate processing capacity to move produced gas to market. It is important to note that the C-115 data may not include venting and flaring during completion and production testing, possibly undercounting the amount of venting and flaring actually occurring in the San Juan Basin.

(See Exhibit 1 at the end of this paper for conversion into metric tons.)

Table 2: Reported venting and flaring as a percent of total gas production by basin: 2017-2019 (mcf) (Source: OCD C-155 data see http://www.emnrd.state.nm.us/OCD/statistics.html)

Operators vary widely in the amount of production they report vented and flared, as shown in Table 3, with some reporting 100% methane waste and others reporting zero waste. Among major producers, many report high rates of venting and flaring, ranging from 10% to 70%. Some of these differences, particularly reports of zero volumes of venting or flaring, may be due to reporting discrepancies rather than real differences between operators. Even so, there is clearly substantial variation in venting and flaring rates across operators. While location and well production are factors, it also appears likely that some operators are more successfully capturing more of their produced gas, and infrastructure planning is likely to be playing a role in this. See also Venting/Flaring Report Table 3 for additional information and analysis regarding variation in the amount of production operators report as vented or flared.

Table 3: 2019 reported V/F data by company ranked by percent V+F in descending order (mcf) Companies numbered in descending order of gas production (Source: OCD C-155 data see http://www.emnrd.state.nm.us/OCD/statistics.html)

In addition, the rates vary over time, with several major producers doubling or tripling the amount of gas flared so far in 2019.

Table 4: 2018 and 2019 reported venting and flaring change by operator (Jan-June) (Source: OCD C-155 data see http://www.emnrd.state.nm.us/OCD/statistics.html)

	Flared (January - June)		
Company	**2018**	**2019**	**Percent Change '18-'19**

51	2,357	3,118	32%
52		2,408	X

The data above represent the percentage of venting and flaring based on total gas production, including production from gas wells, which generally have little to no flaring. With respect to venting and flaring that might be avoided through improved infrastructure planning, it is more relevant to look at venting and flaring of associated gas from oil wells, which occur at significantly higher rates. As shown in Table 5, in the Permian, a reported 5.2% of associated gas was vented and flared in 2018, while 4.2% was vented and flared in the first half of 2019.

Table 5: Reported venting and flaring % of production, oil wells only (mcf) (Source: OCD C-155 data see http://www.emnrd.state.nm.us/OCD/statistics.html)

	total gas production	oil well gas production	total gas production	oil well gas production	total gas production	oil well gas production
	Permian		San Juan		State Wide

2017	2.3%	0.3%	0.2%	3.1%	1.3%	3.1%

What are the data gaps in quantifying emissions/waste for this equipment?

Emissions from smaller operators that emit less than 25,000 metric tons CO2e are not captured under the GHGRP.

There are also significant gaps in the volumes of gas reported as vented and flared through the C-115 forms. In a Notice to Operators in 2017, OCD "determined that not all Operators are following the requirement to report flared and vented volumes. Out of 603 well Operators active in the state, only 51 Operators are reporting volumes using the "V" and "F" code. It is very important that all Operators in New Mexico report flared and vented volumes since part of the evaluation will help determine any policy or requirements setting goals for reduction of flared gas. We urge all companies to work with their operations and production accounting groups to ensure proper production reporting."

Notice to Oil and Gas Operators, Vented & Flared Volumes Reporting Communication, March 8, 2017. Available at http://www.emnrd.state.nm.us/OCD/documents/20173-8NoticetoOperators.pdf

Another significant gap in the data is identification of the amount of flaring that is authorized under NMAC 19.15.18.12 (60 days following completion) or under the Form C-129s Exception to No-Flare Rule. For the latter, information is needed on the extent to which operators have obtained repeated exceptions to continue to flare for long period of time.

There is currently no information publicly available about the role that New Mexico's current gas capture planning requirement has played in facilitating the flow of information between producers and midstream companies and resulting effects on the volumes of vented and flared associated gas.

Economic Description of the Process or Equipment:

What is the per unit cost of the equipment or the costs associated with the process?

n/a

What are the annualized operating costs for the equipment or costs associated with the process?

n/a

Existing Reduction Strategies:

How has industry reduced emissions/waste from this equipment or process historically?

New Wells:

See state/federal discussion below

Existing Wells:

See state/federal discussion below

How have the emission/waste reductions been measured?

How have states and the federal government reduced emissions/waste from this equipment or process historically? In addition, please identify voluntary reductions achieved whether or not they were in response to a regulatory action/requirement.

In response to public concern about substantial increases in venting and flaring, i.e., waste, of associated gas accompanying the growth of drilling for oil in shale formations in the period 2014-2016, several states and the federal government adopted requirements for gas capture planning. The requirements were intended to strengthen the infrastructure planning process by ensuring that producers: (1) evaluate and acquire gathering and processing capacity prior to well development; and (2) communicate expected volumes, location and timing of production to midstream companies to facilitate timely investment in expanded capacity. Continued growth of venting and flaring in the New Mexico Permian and other shale-oil producing regions of the country suggest that additional improvements are needed for gas capture planning to reach its full potential.

North Dakota pioneered requirements for producers to prepare gas capture plans and coordinate with midstream companies to reduce wasteful venting and flaring. In 2014, the state adopted a proposal developed by the North Dakota Petroleum Council ("State moves to capture 90% of flared gas by 2020", Energy Wire, July 2, 2014 https://www.eenews.net/energywire/stories/1060002259). The North Dakota rule requires that gas capture plans accompany all Applications for Permit to Drill (Order 24665, available at https://www.dmr.nd.gov/oilgas/or24665.pdf). Detailed instructions for the contents of the plan were issued in a May 8, 2014 Letter to Operators from the North Dakota Oil and Gas Division (Available at https://www.dmr.nd.gov/oilgas/Gas%20Capture%20Plans%20Required%20on%20All%20APD's%20050814.pdf). Gas Capture Plans must include information about well location and anticipated production, the location and capacity of existing pipeline systems, current levels of flaring, and producers and midstream gas gathering companies must meet semi-annually. The North Dakota rule also requires operators to develop Gas Capture Plans for "increased density, temporary spacing, and proper spacing cases." (See Order 24665).

Wyoming adopted a gas capture plan requirement in April, 2016. The WY requirements are significantly less detailed that North Dakota's, requiring only information about gas gatherer(s) available to provide take-away capacity and available processing plant capacity. (Wyoming Administrative Code Chapter 3 Section 39.H https://docs.google.com/a/wyo.gov/viewer?a=v&pid=sites&srcid=d3lvLmdvdnxvaWwtYW5kLWdhc3Rlc3R8Z3g6NzE2ZjM3ODg3NmU5ZWQzYg

New Mexico adopted a requirement for producers to develop gas capture plans for all new drilling permits on April 8, 2016. Notice to Operators, October 19, 2015 (Notice to Operators, April 8, 2016. Available at http://www.emnrd.state.nm.us/OCD/documents/20164-25GasCapturePlan.pdf). The requirements were developed by a New Mexico Gas Capture Plan Committee established in late 2015 to review activities related to venting and flaring of natural gas and consisting of representatives from state and federal agencies and operators including Agave, Concho, Conoco-Phillips, Devon, Mack, Oxy, Synergy, and WPX. The stated goal for gas capture planning was "to reduce natural gas emission[s]." A plan template was adopted requiring Operators to "outline actions to be taken by the Operator to reduce well/production facility flaring/venting for new completion[s] (new drill, recomplete to new zone, re-frac) activity." Information required in a plan includes, for each well covered by the plan, expected production, planned volumes to be vented or flared (in conjunction with the No-Flare exemption), and identification of the Gas Transporter, gathering system to be connected to if one is in place, miles of pipeline required, and the processing plant where the gas will be processed. Operators are required to "provide (periodically) to Gas Transporter a drilling, completion, and estimated first production date for wells that are scheduled to be drilled in the foreseeable future," and "Operator and Gas Transporter [are to] have periodic conference calls to discuss changes to drilling and completion schedules." The plan template also includes the statement, presumably affirmed when submitted, that

"Based on current information, it is Operator's belief the system can take this gas upon completion of the well's." The Notice states that these requirements apply to State, Fee, Federal, & Tribal wells.

Pennsylvania requires the use of a pigging device with 95% control if emissions are 200 tpy of CH_4, or 2.7 TPY of VOC. If emissions are less than these thresholds, operators must use best management practices to minimize liquids and emissions.[1] In Ohio, operators must use an add-on pigging control which includes flare or vapor recovery to limit VOC emissions to 0.27 tpy, on average, over a rolling 12-month period.[2]

[1] Ohio GPs for compressor stations, available at http://epa.ohio.gov/dapc/genpermit/ngcs.aspx

The Bureau of Land Management adopted a waste minimization planning requirement in its 2016 methane waste prevention rule, *Waste Prevention, Production Subject to Royalties, and Resource Conservation; Final Rule*, 81 Fed. Reg. 83,008 (Nov. 18, 2016) (https://www.federalregister.gov/documents/2016/11/18/2016-27637/waste-prevention-production-subject-to-royalties-and-resource-conservation). Waste minimization plans were required to accompany Applications for Permit to Drill for federal oil wells to "explain how the operator plans to capture associated gas upon the start of oil production." Failure to submit a complete and adequate plan was grounds for denying or disapproving the APD. Information required in the plan included expected completion and production dates and production rates, identification of the intended destination gas pipeline or, alternatively, information about pipeline systems in the field where the well would be located, and identification of the intended destination or nearest processing plant. Operators were also required to include information about all venting and flaring in the field where the well would be located. The rule also required "certification that the operator has provided one or more midstream processing companies with information about the operator's production plans." These requirements were subsequently rescinded by BLM in *Waste Prevention, Production Subject to Royalties, and Resource Conservation; Rescission or Revision of Certain Requirements; Final Rule,* 83 Fed. Reg. 49,184 (Sept. 28, 2018).
https://www.federalregister.gov/documents/2018/09/28/2018-20689/waste-prevention-production-subject-to-royalties-and-resource-conservation-rescission-or-revision-of
BLM's 2018 rescission of the 2016 Methane Waste Rule is the subject of ongoing litigation. Of note, the preamble to the 2016 Methane Waste Rule also, in response to requests for integration of front-end planning requirements into the rule, stated the following:

> The BLM already has land use planning and NEPA tools and processes in place that can be used to help achieve the specific goals of this rulemaking—to reduce the wasteful and environmentally harmful loss of gas through venting, flaring, and leaks. The BLM conducts NEPA analyses for both regional planning decisions and project level decisions. These analyses take a hard look at the direct effects, indirect effects, and cumulative effects of the proposed federal action on various resources during the land use planning or project approval process, such as the effects on wildlife, air quality, or recreation opportunities. The BLM's NEPA analyses also quantify GHG emissions associated with the proposed planning decision alternatives under consideration. In particular, the land use planning and NEPA processes for new RMPs and MLPs provide important opportunities to consider the effects of oil and gas development over a larger area and to optimize planned development to minimize impacts from venting and flaring, among other activities. The planning process gives the BLM the opportunity to consider how a specific land management plan could address the timing and location of development of oil and gas and related infrastructure, such as pipelines, and the projected consequences of such decisions in terms of the quantities of vented and flared gas and the impacts associated with those emissions.

81 Fed. Reg. 83,008, 83040.

Both the North Dakota and 2016 BLM gas capture planning provisions also required information about volumes of venting and flaring from existing wells in the field where the proposed well would be located to provide a more holistic picture of methane waste, flag current capacity constraints, and help identify opportunities to aggregate production volumes to justify new gathering system infrastructure investment. Because midstream pipelines, compression and processing facilities are systems designed to serve many wells, a well-by-well approach to planning and approvals can provide an incomplete view of the costs to minimize waste. Colorado has adopted a rule providing for Comprehensive Drilling Plans wherein operators identify "all foreseeable oil and gas activities in a defined geographic area, facilitate discussions about potential impacts, and identify measures to minimize adverse impacts" including methane emissions. Information to be submitted in these plans include "all proposed oil and gas facilities to be installed within the area covered by the Comprehensive Drilling Plan over the time of the Plan and the anticipated timing of the installation." Colorado Rules and Regulations 216 Comprehensive Drilling Plans. See https://cogcc.state.co.us/documents/reg/Rules/LATEST/200Series.pdf

What are examples of process changes/modifications that reduce or eliminate emissions/waste from this equipment or process?

In addition to better gas capture planning, other potential modifications include:

1. Oil and gas lessees and operators, in their proposals for well spacing and density rules, and in applications seeking to intensify well density and spacing, could be required to estimate surface loss of natural gas as complement to estimates regarding underground recovery efficiency and to identify infrastructure investment and other actions they will take across the oil and gas pool to prevent surface waste. This would provide a basis for OCD to consider and impose conditions to minimize surface waste in association with spacing and density decisions.

2. Proposals for unitization or unit agreements, intended to ensure more orderly and efficient development of leases within a given field, could also include plans to better synchronize production from unitized fields with midstream oil and gas operations. Operators could elevate surface waste management and not defer consideration of need/opportunity to prevent waste to the drilling stage, where field-level opportunities to prevent waste may be lost.

3. Operators could package into a single application all planned/foreseeable drilling/infrastructure approval requests anticipated over a 6- to 12-month time period within a given field or unit and based on geographic proximity or potential use of shared infrastructure such as gathering systems, compressor stations, or processing facilities. This would facilitate more holistic decision-making across an entire field/unit (or, at least, an area larger than the footprint of an individual well pad), inclusive of existing oil and gas wells that may be operating at lower production pressures than new wells.

Technology Alternatives:

Costs of Methane Reductions:

What is the cost to achieve methane emission reductions?

Gas capture planning is already required. Costs from deploying onsite capture or use equipment, re-injecting gas, and/or delaying development of new wells to better align with gathering and/or processing infrastructure development would be associated with requirements to limit venting and flaring rates or volumes, rather than attributed to requirements to improve the infrastructure planning process. Other process changes, for example multi-well "Comprehensive Drilling Plans" or "Master Development Plans" and integration of methane waste capture and marketing provisions in unitization agreements make use of existing oil and gas development decision points. While they impose new requirements that presumably come with additional planning and analytical costs, a front-end investment in planning would presumably lead to additional natural gas capture and thus boost sales and profits. In addition, multi-well "Comprehensive Drilling Plans," "Master Development Plans," and unitization agreements are intrinsically designed to promote orderly and efficient development of resources—i.e., they are a wise investment that pays dividends through orderly and efficient resource development.

For reducing emissions from gathering station blowdowns, the Synapse report estimates installing technology for Transmission Station Venting -Redesign Blowdown Systems/ESD Practices to have a unit cost of $3.84 per mcf of reduced methane and $199.68 per tonne of reduced methane.[3] The Synapse report also estimates the cost of installing LDAR (weighted average) for gathering stations to be $7.35 per mcf of reduced methane and $382.20 per tonne of reduced methane.[4]

[1] Synapse, Cost-Effectiveness of Comprehensive Oil and Gas Emissions Reduction Rules in New Mexico (Sept. 2019), available at http://blogs.edf.org/energyexchange/files/2019/09/Synapse-Methane-Cost-Benefit-Report.pdf
[1] *Id*.

What would be the implementation cost?
For new wells?

n/a

For existing wells?

n/a

Are there low-cost solutions available?

Yes, improved infrastructure planning and coordination is very low cost.

If a solution is high-cost, why is that the case?

n/a

Are there additional technical analyses needed to refine benefits/costs estimates?

Given the very low cost of and fairly broad agreement on the value of improving infrastructure planning, as well as the difficulty in directly measuring results, it does not appear that this would be a high priority area of focus for refining benefit/cost estimates, relative to other technologies and processes under consideration.

3. IMPLEMENTATION

For each piece of equipment or process, please consider the following questions and add other relevant information. If relevant, please identify if the answers are different for large company and small company requirements or are different for well type or basin.

Implementation Feasibility:

What is the feasibility of implementation (availability of required technology or contractors, potential permitting requirements, potential for innovation)?

Implementation requires gathering information and developing a plan, both of which are straightforward activities. "In the past, Operators have objected to proposals for gas capture plans with detailed information regarding gathering system availability, asserting that Operators do not have access to some of the information that would be necessary to develop such plans. Specifically, Operators have objected to including the following information:
—the name and location of the nearest gas processing plant and the intended destination gas processing plant;
—maximum current daily capacity, current throughput, and anticipated daily capacity of the gas pipeline to which the operator plans to connect; and

—any plans known to the operator for expansion of pipeline capacity in the area of the well.

BLM believed that Operators would generally be able to obtain such information from midstream companies. *See* BLM, *BLM's Responses to Public Comments on Final Rule,* 171-172 (2016).

The commercial agreements between E&P and midstream operators typically dictate what information can and cannot be shared. E&P operators may be constrained to share or provide information during the APD process. Commercial contracts typically restrict the sharing of sensitive or proprietary information, with respect to midstream infrastructure. The constraints could include not knowing downstream details of midstream operator's pipeline or facilities, or details around pipeline or gas plant capacities could be proprietary and not shared with the E&P operators. These details could include information to E&P or midstream operator's competitors and makes it difficult, to share in a public process.

Midstream operators, by virtue of iterative communications with E&P sector operators and completion of hydraulic analysis of pipeline and compressor infrastructure, may be in an excellent position to complement E&P gas capture planning. This could involve an aggregation of reasonably foreseeable regional volumes of natural gas to provide regulators with information pertinent to infrastructure planning across the value chain that nonetheless complies with any legal restrictions on the sharing of sensitive or proprietary information. Also, commercial agreements are adopted by E&P and midstream operators for their mutual benefit and may, of course be modified. To the extent that such commercial agreements may constrain information sharing necessary to comply with any regulatory requirements established for gas capture plans and infrastructure planning, those provisions of the agreements are likely unenforceable and certainly may be changed. Furthermore,

What is the useful life of equipment?

n/a

What are the maintenance and repair requirements for equipment required for methane reduction?

n/a

How would emissions be detected, reductions verified and reported?

4. CHALLENGES AND OPPORTUNITIES TO ACHIEVE METHANE REDUCTION IN NEW MEXICO

For each piece of equipment or process, please consider the following questions and add other relevant information. If relevant, please identify if the answers are different for large company and small company requirements or are different for well type or basin.

What regulatory gaps exist for this equipment or process? Are there regulatory gaps filled by the proposed implementation?

Given continuing increases in venting and flaring in states with gas capture plan requirements, this measure has not yet reached its potential to reduce methane waste. See, for example,

"Flaring reaches record high amid pipeline, gas plant shutdowns," Bismarck Tribune, August 15, 2019
https://bismarcktribune.com/bakken/flaring-reaches-record-high-amid-pipeline-gas-plant-shutdowns/article_610d6c94-6b03-57df-b5b2-9a25a82d9271.html

Private	29	3	10%	26	90%

"Curbing Methane Pollution and Waste: New Mexico's Problem and Opportunity," presentation by EDF to the Water and Natural Resources Interim Committee, November 20, 2017 (see Exhibit 4).

A key regulatory gap in gas capture planning is that plans have not been adequate to provide certainty that, at least for development oil wells, takeaway capacity will be in place once the well has been completed and begins producing. Redesigning the gas capture plan template to require additional information and assurance of projected outcomes is needed to close this regulatory gap. For adequate planning, more detailed information is needed on when the proposed well is expected to be completed and the anticipated volume of production, as well as the anticipated capacity of the gathering system to which the operator intends to connect. To ensure results – i.e., that gathering capacity is consistently available when and where it is needed – requires more certainty up front that takeaway capacity will be available when new wells begin production, such as documentation of contracts or agreements indicating that the operator has obtained firm takeaway capacity from a midstream company. To enhance compliance, plans should be a mandatory element of the drilling permit approval process; i.e., APD approvals should be deferred or denied if plans are inadequate. To address changed circumstances, Operators should be required to update plans when material changes occur, such as if drilling is delayed or more information becomes available about well characteristics.

The current gas capture plan requirements also fail to require operators to consider alternatives to venting or flaring where gathering capacity is not available. See the MAP Report on Venting and Flaring for discussion of this issue.

In addition to gas capture planning by operators, planning requirements could also be developed for midstream companies to "plan backwards/upstream" when seeking state approvals, i.e., that they have reviewed gas capture plans for new wells in the locations to be served by their projects. For example, a gas capture planning requirement could be adopted by the State Land Office for ROW applications and by NMED for air permit applications. These plans could also be shared with operators to inform their planning.

A gap also exists in providing information about other wells in the vicinity of the proposed well, both existing wells that may be venting or flaring and new wells that are planned to be developed by the Operator, to provide midstream companies with a more complete picture of production that may be available to be aggregated to support takeaway capacity. This information is not available in piecemeal, well-by-well drilling applications. This gap could be addressed by requirements for Operators to package into a single application all planned/foreseeable drilling/infrastructure approval requests anticipated over a 6- to 12-month time period within a given field or unit based on geographic proximity or potential use of shared infrastructure such as gathering systems, compressor stations, or processing facilities. The U.S. Bureau of Land Management, in its Gold Book (*see* p. 8), provides for a "master development plan" type approach that illustrates the utility of moving from well-by-well permitting to multi-well permitting in a developing field. This approach is echoed in Bureau of Land Management Information Bulletin No. 2018-061 (June 26, 2018) which provides, in section III.A., for the consolidation of multiple drilling permit applications in a single Master Development Plan accompanied by a single environmental review process (promoting efficiencies and streamlining the process relative to APD-specific environmental reviews). In accord with this BLM guidance, the Master Development Plan can also encompass sundry notices and proposed oil & gas rights-of-way. If coupled with requirements that such plans account for infrastructure planning to reduce methane pollution and waste, this approach to drilling permits would create incentives for industry to conduct planning, investment, and permitting activities in a more efficient and comprehensive manner. Under this approach OCD would not approve multiple drilling requests in one fell swoop that would fail to address site-level considerations; on the contrary, OCD would still make its drilling approval decisions on an individual-well basis, if based on an omnibus, overarching infrastructure plan. The effectiveness of this state-level comprehensive drilling plan would be optimized by considering the full life-cycle of infrastructure development in a given field or drilling unit, providing information that can be used to synchronize infrastructure development to facilitate methane capture and marketing and to understand how to best reduce the loss of methane as the field declines and its wells are eventually plugged and abandoned. In addition, comprehensive drilling plans should be designed to facilitate multi-jurisdictional coordination between OCD, BLM, SLO, and NMED and to minimize redundancies.

A regulatory gap also exists in preventing methane waste in spacing and density rules. The Oil and Gas Act, N.M. Stat. § 70-2-3, expressly provides that "surface waste" can result from the "manner of spacing." 19.15.15 NMAC. Yet a gap currently exists in addressing surface waste management issues in OCC and OCD decision-making on well spacing and density rules. This gap could be addressed by placing "surface waste" management on an equal footing with "underground waste" management by requiring oil and gas lessees and operators to identify infrastructure investment and other actions they could take to prevent surface waste in their proposals for spacing and density, and in applications seeking to intensify well density and spacing. This would provide a basis for OCD to consider and impose conditions to minimize surface waste in association with spacing and density decisions. Well spacing and density rules set the spatial pattern of development across a particular oil and gas pool. As such, they provide an early and essential opportunity to consider ways to prevent methane waste across an entire pool.

Similarly, a gap in addressing methane waste exists in unitization or unit agreements. These agreements facilitate the orderly development and reduce the total costs of operating oil and gas fields owned by multiple lessees. They do this by consolidating and coordinating operations across all lessees under a single operator, sharing the risks and costs of development, improving the economics of production, and consolidating infrastructure. In so doing, unit

agreements set the stage for the development and approval of individual drilling permits in specific locations within an oil and gas field. Requirements to include consideration of methane waste in unitization agreements could drive better synchronization of production from unitized fields with midstream companies. Addressing waste in unitization would avoid deferring consideration of the need and opportunity to prevent waste to the drilling stage where unit-level opportunities to prevent waste may be lost. OCC and OCD could exercise authority to deny or condition unit agreements to ensure that they acknowledge and account for methane waste at the field level.

Where do conflicting priorities exist between NMED, EMNRD, and NMSLO? Are there opportunities for coordination between these agencies?

Opportunities exist for integrated data systems, information sharing/notifications, and coordinated approval processes to support achievement of each other's missions:

- SLO could provide information to OCD about planned lease sales, enabling OCD to anticipate APDs, unitization, and spacing applications
- OCD could provide information to SLO about areas with high venting or flaring rates to consider reorienting leasing to areas with more available takeaway capacity.
- OCD could provide Gas Capture Plan information to NMED about planned venting and flaring during well completion and production testing to monitor for AQ violations
- NMED could utilize C-115 venting and flaring data to monitor for AQ violations
- NMED could provide methane emissions data to support OCD verification of C-115 venting and flaring reporting

Are there existing regulations related to methane that do not address the intended purpose? Identify any unintended barriers to methane reductions/capture that may hinder proposed processes.

n/a

Other considerations or comments (e.g. particular design or technological challenges/opportunities, co-benefits, non-air environmental impacts, etc.?):

There may be a need to study the end-of-life of the well infrastructure plans for wells as improperly plugged or abandoned well are not done up to standard process that ensures methane is not released. ("Measuring methane emissions from abandoned and active oil and gas wells in West Virginia" https://www.princeton.edu/~mauzeral/papers/Measuring%20methane%20in%20West%20Virginia.pdf; "Measurement of methane emissions from abandoned oil and gas wells in Hillman State Park, Pennsylvania" https://www.tandfonline.com/doi/figure/10.1080/17583004.2018.1443642?scroll=top&needAccess=true)

The PHMSA Gas Transmission Integrity Management rule resulted in regulations (49 CFR Part 192, Subpart O) which specify how pipeline operators must identify, prioritize, assess, evaluate, repair and validate the integrity of gas transmission pipelines that could, in the event of a leak or failure, affect High Consequence Areas (HCAs) within the United States.

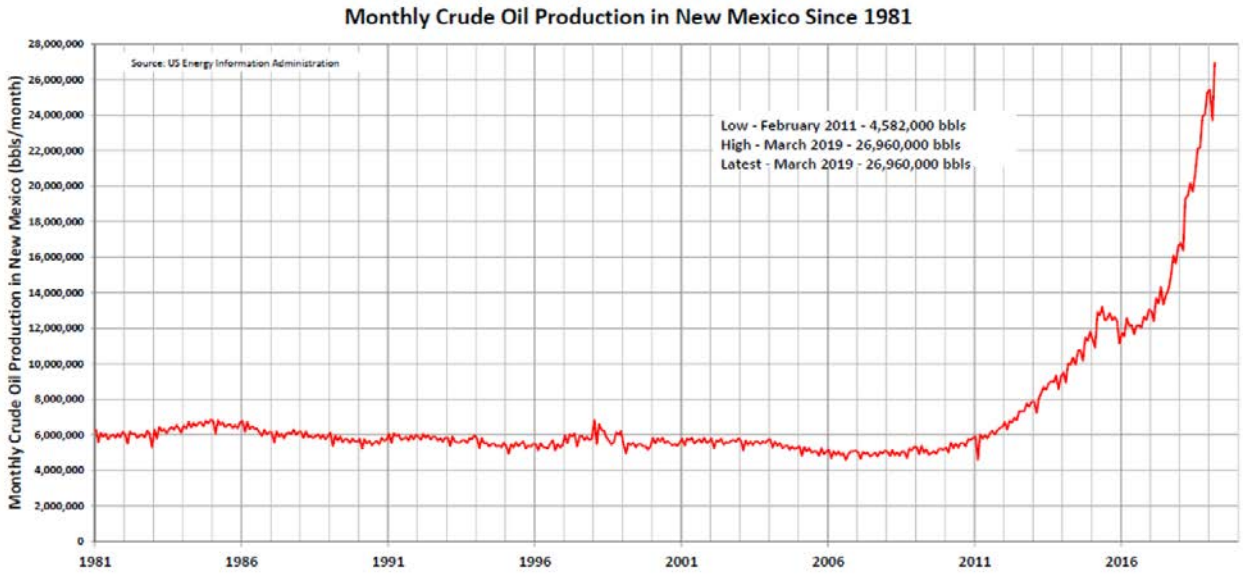
SECTION 6, VENTING/FLARING

Discussion for MAP members on October 11, 2019

NOTE: The focus of this report is processes, and the associated equipment, directly related to the release or capture of methane gas. We are not requesting information on processes/equipment that are not related to the release or capture of methane gas.

1. DESCRIPTION OF PROCESS AND EQUIPMENT

Provide a description of the processes and/or equipment used in oil and/or gas extraction for this topic. Note that this report template will be used for all topics of the MAP review and, thus, not all questions or information may be relevant for each topic. If information is not relevant, indicate N/A. Note any differences expected for differing well types, industry sector, or basin location.



Technical description of the process or equipment:

In the oil and natural gas industry, flaring is the controlled combustion of natural gas that can occur during drilling and completion activities, oil and natural gas field production, pipeline gas gathering, and facility processing of oil and natural gas. Flaring refers to routing natural gas from anywhere in the flow path to a device where the gas is combusted as it leaves the tip of the flare, typically elevated well above ground level.

As most sources of venting will be addressed in the other topic reports, this document focuses primarily on flaring. Also, tank vapor flaring will be discussed in other topic reports; therefore, the scope will be further limited to associated gas (casinghead gas) flaring, with some discussion of associated gas venting as well. Associated gas described in this report is raw, unprocessed gas from the separator and treater and is not marketable at the wellhead for industrial, power generation, and feedstock applications without the pipeline and gas processing infrastructure that is necessary to reduce the heating content and liquid content suitable to meet downstream pipeline specifications, although there may be other potentially un-economic ways to utilize gas at wellheads

The economics of these alternative means of gas utilization will vary.

Beginning in 2011, the Delaware Basin shale boom in southeast New Mexico resulted in a dramatic increase in oil production along with associated natural gas, which led to capacity constraints in the existing pipeline infrastructure. Since that time, oil and gas (upstream and midstream companies) have permitted significant pipeline and gas plant projects and upgrades to alleviate the constraints.

During 2015 Legislative Session, SM 29 was issued requesting EMNRD, NMED, the Indian Affairs Department, and the Department of Finance and Administration to convene a joint task force to study the economic and environmental impact of the increase in natural gas flaring and venting in New Mexico. While SM 29 requested a study to be conducted, the Senate did not allocate funding for such a study. Instead, EMNRD chose to use the committee's time to address the Oil Conservation Division's (OCD) current rules about venting and flaring.

A Gas Capture Plan Committee (GCPC) was formed in July 2015 consisting of NMOCD and Industry representatives. First meeting was held on August 19th, 2015. Below is timeline of events of the group:

- November 2015 - Implemented new "F" code for flared volumes to be reported on C-115s.
- November 2015 – The GCPC expanded to include representatives from New Mexico Environment Department (NMED), State Land Office (SLO), Bureau of Land Management (BLM), and Energy Conservation and Management Division (ECMD). The purpose is to inform and ensure that other State Departments/Agencies are working together to achieve same goal in the reduction of flaring without duplicating or conflicting each other.
- May 1, 2016 – Gas Capture Plan required to be submitted for new drill, recomplete to new zone, or re-frac applications.
- November 2017 – Sec. McQueen prepared report for House Energy Committee on GCPC efforts.
- November 2017-November 2018 – monitored vented and flared volumes being reported.

Subsequent to the GCPC activities, several other flaring related agency and administration actions have occurred:

- October 5, 2018 – General Construction Permit to allow temporary flares at NOI oil and gas production facilities was issued.
- January 29, 2019 – Executive Order on addressing Climate change and Energy Waste Prevention issued by Governor Lujan Grisham.
- June 2019 – NMED and EMNRD begin statewide public stakeholder engagement meetings.
- August 2019 – NMED and EMNRD convene Methane Advisory Panel as it begins the process of developing new methane emission and flaring reduction rules.

Provide the segment(s) of the industry that the equipment or process is found:

Flares can be found throughout the production and midstream segments.

NMED Exhibit 10 - 0143

Describe how the equipment or process is used:

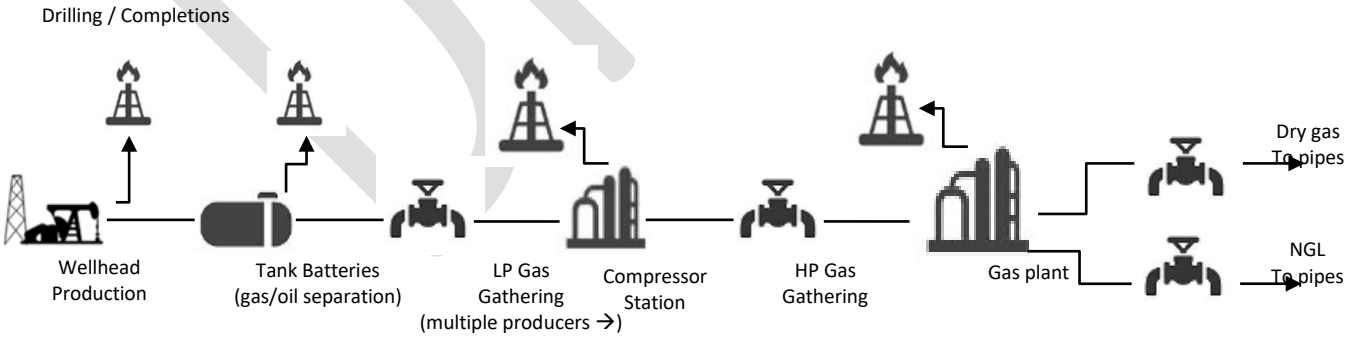
Equipment

Flaring refers to routing natural gas from anywhere in the flow path to a device where the gas is combusted as it leaves the tip of the flare.

The flare system will consist of a header, stack, tip, and ignition system. Gas is sent to the flare through a header system and is combusted as it exits the flare stack at the tip. The flare tip is designed to ensure the proper mix of gas and air to achieve the proper burn efficiency. Ignition of the gas stream is through the use of a continuously burning pilot or auto-ignition system.

Process

Flaring is an essential and necessary part of drilling and completion activities, oil and natural gas field production, pipeline gas gathering, and facility processing of oil and natural gas because of safety considerations (personnel and equipment) and its effectiveness in combusting harmful emissions (environmental). Even at the global level, an entity called the World Bank has identified certain categories where flaring is acceptable and necessary as well as acknowledged that some 'routine' flaring was to be anticipated under certain circumstances. http://documents.worldbank.org/curated/en/755071467695306362/pdf/106662-NEWS-PUBLIC-GFR-Gas-Flaring-Definitions-29-June-2016.pdf

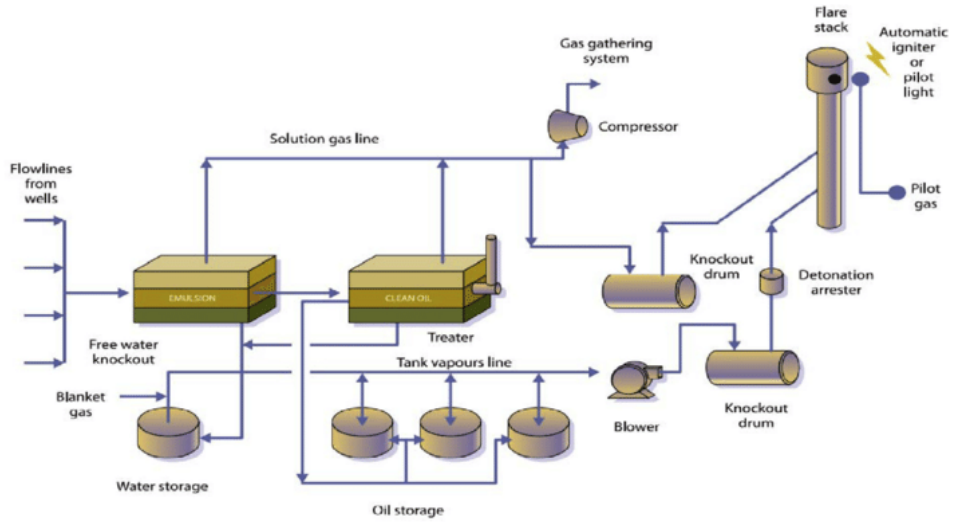


The Bank defines routine flaring "of gas at oil production facilities as flaring during normal oil production operations in the absence of sufficient facilities or amenable geology to re-inject the produced gas, utilize it on-site, or dispatch it to a market." It includes "flaring from oil/gas separators; flaring of gas production that exceeds existing gas infrastructure capacity; and flaring from process units such as oil storage tanks, tail gas treatment units, glycol dehydration facilities, produced water treatment facilities, except where required for safety reasons." The Bank is calling upon governments, development institutions, and oil companies to endorse the "Zero Routine Flaring by 2030 Initiative." https://www.worldbank.org/en/programs/zero-routine-flaring-by-2030.

There are several reasons why natural gas may be flared at any step during producing and processing of crude oil and natural gas. The following is a list of situations where flaring may be necessary. Data currently reported on C-115 does not provide enough detail to differentiate what would or would not constitute waste.

- Temporary flaring during drilling and completion activities or flowback/well testing.
- To protect personnel or the public from potentially unsafe conditions that would result in exceeding the maximum allowable operating pressure (MAOP) of vessels or components. For example, natural gas processing plants rely on safety flares in emergency situations in which piping becomes over-pressured to mitigate risks of fires and explosions.
- To combust gas that may have hydrogen sulfide or other contaminants that are unsafe to human health.
- Required maintenance outages. Maintenance on equipment at any step in the gas transportation process may result in flaring (e.g. transmission pipelines must be taken out of service for inspections causing a cascading effect on production all the way back to the wellhead). For producers this might be maintenance at a gathering/processing facility. For gathering/processing companies this might be maintenance by the downstream gas/NGL pipeline operators resulting in flaring at a gas plant, perhaps shutting down the gas plant, which can then cause producers to flare.
- Instances where the gas takeaway capacity is interrupted with little notice for a variety of reasons. Examples can include, but are not limited to, unplanned upsets or malfunctions at gas gathering or processing facilities. When the flow of gas through a facility is stopped due to an unplanned upset or malfunction, the flow of gas is shut off immediately resulting in quickly increasing upstream pressures, potentially all the way back to the

wellhead. Flaring the gas released by the pressure control valves or the pressure safety valves is the safest, most expedient way to handle that situation.



- Regulatory constraints, including permitting, may impact any step in the development and production of crude oil and natural gas. The long lead time to receive Right of Ways (ROWs) necessary to construct and install electrical infrastructure and natural gas pipelines and facilities cause delays that may lead to flaring if well development and completion moves forward without supporting infrastructure in place.
- Limited infrastructure capacity to move natural gas or natural gas liquid (NGL) volumes out of NM Basins, including gas gathering capacity, gas processing capacity and/or capacity on long haul transmission pipelines for natural gas or NGL. Takeaway restrictions may not be predictable. For example, gas processing plants may experience limits on takeaway volumes when the sales valve is suddenly closed by the pipeline operator, resulting in the gas plant flaring, perhaps shutting down, which can then cause producers to flare. Or, oil and gas producers may experience capacity limitations on common gathering pipelines when higher than expected volumes of gas enter the lines by other operators, resulting in insufficient take-away capacity for the natural gas produced.
- Valuable information is needed in order to make decisions regarding future well and infrastructure requirements in step out or wildcat areas; therefore, flaring may be prevalent until the field fills in and infrastructure is built out.
- During pigging operations, additional backpressure on the system may cause flaring. Pigging is a necessary maintenance procedure to manage liquids buildup in the gathering lines.
- Flaring may also occur during hydrate remediation on gathering lines.
- Gas quality or composition can vary such that the gas is not suitable for pipeline transportation, processing plants, or for sales (e.g., H2S from the reservoir, oxygen introduced into the line via vapor recovery unit and other processes, temperature), that leads to flaring.
- Gas pressure at the well or facility is insufficient and the gas cannot be routed to a sales line. This is an issue for both the producer and the midstream operators.
- Electrical infrastructure issues
    - Lightning strikes and localized weather events that knock out power to compression facilities and require the use of flares.
    - Power availability and reliability needed to transport, treat, and process the hydrocarbon vapors and natural gas.

Provide the common process configurations that use this equipment or process:

Flaring is a common process as it is the safer alternative to venting. The figure below shows a simplified oil and gas production operation with a number of wells connected to a central tank battery by flowlines. The wellhead fluids flow to the battery where separation can occur in one or more vessels. Each vessel will be designed for a maximum allowable operating pressure (MAOP) and the system will be equipped with a variety of safety relief devices to ensure

safe operation. Safety relief devices include pressure control valves that can either stop the flow of fluids through the vessel or route excess fluid to a safety system which typically results in vapor flowing to a flare and the liquids to a tank.

http://dx.doi.org/10.1016/j.jestch.2016.09.012

What is the distribution of the equipment or process across business segments?

Although flaring occurs in the production segment, flaring also occurs in the midstream segment. Midstream activities may include any or all of the following: compression; dehydration; treating to remove any contaminants; and processing the hydrocarbons to recover natural gas liquids (NGL's) and saleable residue natural gas. At any of those steps, if the flow of the gas through a facility is stopped due to an unplanned upset or malfunction, the flow of gas is shut off immediately resulting in quickly increasing upstream pressures, potentially all the way back to the wellhead. Flaring the gas released by the pressure control valves or the pressure safety valves is the safest, most expedient way to handle that situation.

Note: Natural gas flared in the midstream operations is downstream of the sales meter.

How has this equipment or process evolved over time?

Equipment

Over the past several years, there have been advancements in tip design in order to yield a broader range of smokeless burn, as well as advancements in the accessories associated with the flare that aid in their reliability. Auto-ignition pilots, thermocouples, pressure switches, feasible flow measurement, malfunction alarms, etc. are technical advances that have improved operation of flares, both on location and remotely.

Process

In November 2015, flared volumes began to be reported as a separate non-transported disposition (F code) on the NMOCD C-115 Form (Operators Monthly Report). Prior to November 2015, vented and flared volumes were reported as one non-transported disposition. NMOCD posts the vented and flared volumes on their website at this link: http://www.emnrd.state.nm.us/OCD/documents/C-115Non-TransportedProductDispositionFlared2016-2019.pdf

The current Gas Capture Plan was made part of the application process through "Notice to Operators" issued on April 8, 2016, with an effective date of May 1, 2016.

- Per the Notice to Operators - The Gas Capture Plan outlines actions to be taken by the Operator to reduce well/production facility flaring and venting, for new completion (new drill, recomplete to new zone, re-frac)

activity. The requirement applies to Federal, State, Fee, & Tribal Wells.

- A Gas Capture Plan's purpose is to ensure that operators are working with gatherers/processors to provide a way to get the gas to market for sales rather than flare.

2. INFORMATION ON EQUIPMENT OR PROCESS COSTS, SOURCES OF METHANE EMISSIONS, AND REDUCTION OR CONTROL OPTIONS

Identify the capital and operating costs for the equipment or the process. Identify how methane is emitted or could be leaked into the air. Please **prioritize** the list to identify first the largest source of methane from the process or equipment and where there is **potential** for the greatest reduction of methane emissions. Note any differences expected for differing well types, industry sector, or basin location.

Sources of Methane:

Provide an overview of the sources of methane from this equipment or process:

The flare is elevated well above ground level, and combusted. Modern, properly operated flares have a destruction efficiency of at least 98%, thus reducing the methane and volatile organic compounds (VOCs) that would otherwise be emitted to the atmosphere had the gas been vented (the destruction efficiency of older flares generally ranges from 95%-98%). The remaining 2-5% of uncombusted gas contains methane, and is reported to EPA under the GHGRP.

A recent study of flaring in the Bakken found that while the median destruction efficiency for methane and ethane was 98%, "the efficiency distribution is skewed, exhibiting log-normal behavior." The researchers concluded: "this suggests incomplete combustion from flares contributes almost 1/5 of the total field emissions of methane and ethane measured in the Bakken shale, more than double the expected value if 98% efficiency was representative."[61]

Also, some flares have one or more continuously burning pilot flames, while others automatically ignite pilot flames in preparation for use. Pilots can be blown out by wind and gas is occasionally released to an unlit flare. In addition to the volume of methane that is vented when the pilot is blown out, there are emissions from incomplete combustion of the fuel gas used for the pilot.

Venting of associated gas directly releases methane (and other pollutants) into the atmosphere. Flaring releases methane from the unburned portion of the gas, and whenever the flare sputters or is unlit, such as when the pilot light goes out. Flaring also results in the loss of large quantities of natural gas through intentional combustion for means of disposal, and flaring is a significant source of the GHG CO_2 and many other pollutants.

Venting and flaring of associated gas largely occurs in situations where oil development outpaces infrastructure to take the gas to market. In the Permian, while almost all of the producing wells are connected to gas-gathering infrastructure, gas production growth is nonetheless overwhelming the capacity of the gathering system.[62] This is

[61] Gvakharia et al, Methane, Black Carbon, and Ethane Emissions from Natural Gas Flares in the Bakken Shale, North Dakota, *Environ. Sci. Technol.* 2017, 51, 9, 5317-5325 (April 12, 2017) (https://pubs.acs.org/doi/10.1021/acs.est.6b05183#).

[62] See BLM, Waste Prevention, Production Subject to Royalties, and Resource Conservation; Proposed Rule, 81 Fed Reg. 6616, 6638 (Feb. 8, 2016) (https://www.federalregister.gov/documents/2016/02/08/2016-01865/waste-prevention-production-subject-to-royalties-and-resource-conservation) (hereinafter BLM Proposed Rule).

also true in North Dakota, where the North Dakota Industrial Commission noted that "the majority of the gas flared . . . is from wells already connected to a gas gathering system."[63]

Inadequate pipeline/gathering capacity is commonly identified as a reason for venting and flaring, and certainly, given the choice, operators would prefer to sell gas to market than flare it. But even as substantial additional gathering, processing, and pipeline capacity has come online in recent years, associated gas production has increased more rapidly and outpaced available capacity.[64] This mismatch between the volume of gas being produced and the available midstream or downstream capacity is occurring in part because the volume and timing of gas production in areas such as the Permian and Bakken is being driven not by the value of the gas, but the value of oil.[65] Because oil prices are relatively so much higher than gas prices, there is an incentive for operators in certain basins to pursue oil development and treat associated gas as a waste product. As noted by the Government Accountability Office, even though it may be profitable for operators to make investments to capture gas, it can be even more profitable for operators to invest in further oil development instead.[66] Absent a regulatory requirement or price incentive to capture associated gas (or significant changes in the relationship between oil and gas prices), operators are likely to continue to ramp up associated gas production faster than gas takeaway capacity is expanded in oil-producing basins, all else being equal.

The conclusions in the October 2010 GAO report mentioned above and throughout this document assumed the following gas prices. More recent data from the U.S. Energy Information Administration is included below:

	GAO	U.S. Energy Information Administration
Natural Gas	$4.01/MMBtu	$1.44/MMBtu[67] - Southwest

This is not the only factor driving flaring, however. There is frequently a time lag between initial production or expansion of associated gas production in a given area and the development of additional gathering system capacity, as various barriers may prevent midstream companies from acquiring adequate information about operators' production plans and midstream companies do not generally build infrastructure without some assurance of supply.

Also, even when there is sufficient capacity on a gathering system as a general matter, new hydraulically fractured wells initially produce at very high pressures and can bump older, lower-pressure wells off the system until pressures decline (or until operators boost compression at the older wells), effectively creating takeaway capacity shortfalls for a period of time.[68]

Finally, planned or unplanned maintenance or upsets on gathering lines, processing plants, and pipelines also temporarily reduce takeaway capacity and drive flaring.

[67] https://www.eia.gov/todayinenergy/prices.php
[68] See North Dakota Department of Mineral Resources, Oil & Gas Update (Oct. 25, 2018) (https://www.dmr.nd.gov/oilgas/policies.asp, link to Gas Capture Background Sheet) ("Seeing increased frequency of new high=producing wells and historically compliant wells in non-compliance du to their location on the same gathering system.").

New Wells:

Flares are used at both new and existing wells.

Venting and flaring occurs at new and existing wells. New wells may not be connected to gathering lines, or the capacity of those lines may not have been expanded to handle the additional gas being produced.

Existing Wells:

Flares are used at both new and existing wells.

Venting and flaring occurs at new and existing wells. Existing lower pressure wells that are connected to gathering systems may be bumped off the system by new wells operating at much higher pressures.

How are the emissions calculated for this equipment or process?

Flaring volumes may be included in any of these three categories; well testing venting and flaring, associated gas flaring, and/or flare stacks.

Equations from GHGRP Subpart W:

(l) *Well testing venting and flaring.* Calculate CH_4 and CO_2 annual emissions from well testing venting as specified in paragraphs (l)(1) through (5) of this section. If emissions from well testing venting are routed to a flare, you must calculate CH_4, CO_2, and N_2O annual emissions as specified in paragraph (l)(6) of this section.

(3) Estimate venting emissions using Equation W-17A (for oil wells) or Equation W-17B (for gas wells) of this section.

$$E_{a,n} = GOR * FR * D \qquad \text{(Eq. W-17A)}$$

$$E_{a,n} = PR * D \qquad \text{(Eq. W-17B)}$$

Where:

$E_{a,n}$ = Annual volumetric natural gas emissions from well(s) testing in cubic feet under actual conditions.

GOR = Gas to oil ratio in cubic feet of gas per barrel of oil; oil here refers to hydrocarbon liquids produced of all API gravities.

FR = Average annual flow rate in barrels of oil per day for the oil well(s) being tested.

PR = Average annual production rate in actual cubic feet per day for the gas well(s) being tested.

D = Number of days during the calendar year that the well(s) is tested.

(m) *Associated gas venting and flaring.* Calculate CH_4 and CO_2 annual emissions from associated gas venting not in conjunction with well testing (refer to paragraph (l): Well testing venting and flaring of this section) as specified in paragraphs (m)(1) through (4) of this section. If emissions from associated gas venting are routed to a flare, you must calculate CH_4, CO_2, and N_2O annual emissions as specified in paragraph (m)(5) of this section.

(3) Estimate venting emissions using Equation W-18 of this section.

$$E_{s,n} = \sum_{q=1}^{y} \sum_{p=1}^{x} [(GOR_{p,q} * V_{p,q}) - SG_{p,q}] \qquad \text{(Eq. W-18)}$$

Where:

$E_{s,n}$ = Annual volumetric natural gas emissions, at the facility level, from associated gas venting at standard conditions, in cubic feet.

$GOR_{p,q}$ = Gas to oil ratio, for well p in sub-basin q, in standard cubic feet of gas per barrel of oil; oil here refers to hydrocarbon liquids produced of all API gravities.

$V_{p,q}$ = Volume of oil produced, for well p in sub-basin q, in barrels in the calendar year during time periods in which associated gas was vented or flared.
$SG_{p,q}$ = Volume of associated gas sent to sales, for well p in sub-basin q, in standard cubic feet of gas in the calendar year during time periods in which associated gas was vented or flared.
x = Total number of wells in sub-basin that vent or flare associated gas.
y = Total number of sub-basins in a basin that contain wells that vent or flare associated gas.

(n) *Flare stack emissions.* Calculate CO_2, CH_4, and N_2O emissions from a flare stack as specified in paragraphs (n)(1) through (9) of this section.

(5) Calculate GHG volumetric emissions from flaring at standard conditions using Equations W-19 and W-20 of this section.

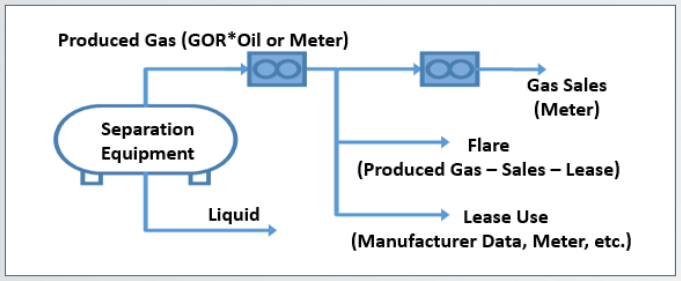
$$E_{s,CH_4} = V_s * X_{CH4} * \left[(1-\eta) * Z_L + Z_U\right] \quad \text{(Eq. W-19)}$$

$$E_{s,CO2} = V_s * X_{CO2} + \sum_{j=1}^{5}\left(\eta * V_s * Y_j * R_j * Z_L\right) \quad \text{(Eq. W-20)}$$

Where:
$E_{s,CH4}$ = Annual CH_4 emissions from flare stack in cubic feet, at standard conditions.
$E_{s,CO2}$ = Annual CO_2 emissions from flare stack in cubic feet, at standard conditions.
V_s = Volume of gas sent to flare in standard cubic feet, during the year as determined in paragraph (n)(1) of this section.
η = Flare combustion efficiency, expressed as fraction of gas combusted by a burning flare (default is 0.98).
X_{CH4} = Mole fraction of CH_4 in the feed gas to the flare as determined in paragraph (n)(2) of this section.
X_{CO2} = Mole fraction of CO_2 in the feed gas to the flare as determined in paragraph (n)(2) of this section.
Z_U = Fraction of the feed gas sent to an un-lit flare determined by engineering estimate and process knowledge based on best available data and operating records.
Z_L = Fraction of the feed gas sent to a burning flare (equal to $1 - Z_U$).
Y_j = Mole fraction of hydrocarbon constituents j (such as methane, ethane, propane, butane, and pentanes-plus) in the feed gas to the flare as determined in paragraph (n)(1) of this section.
R_j = Number of carbon atoms in the hydrocarbon constituent j in the feed gas to the flare: 1 for methane, 2 for ethane, 3 for propane, 4 for butane, and 5 for pentanes-plus).

Metering of gas sent to flares. In some cases, vented or flared amounts are calculated using gas/oil ratios (GORs) that are measured periodically, with gas then calculated from measured oil production. In cases where a portion of gas from a system is sold, this portion will be metered, and operators may calculate vented or flared volumes by subtracting the captured portion from the total volume. These approaches are generally less accurate than direct metering of flared or vented streams because of issues such as temporal variation in GOR, the accuracy of emissions factors for gas diverted to use for engines and such, and other problems.

In the final 2016 BLM Methane and Waste Prevention Rule, BLM allowed for "either metering or a GOR-based calculation of flare volumes in circumstances where a GOR-based approach would allow the BLM to independently verify the volume, rate, and heating value of the flared gas.[69]



[69] BLM, Waste Prevention, Production Subject to Royalties, and Resource Conservation; Final Rule, 81 Fed Reg. 83008, 83053 (Nov. 18, 2016) (https://www.federalregister.gov/documents/2016/11/18/2016-27637/waste-prevention-production-subject-to-royalties-and-resource-conservation).

During the 2016 BLM Waste Prevention, Production Subject to Royalties, and Resource Conservation rulemaking, BLM acknowledged that due to the performance limitations of many commonly used meters, a properly designed GOR based approach to estimating flare volumes could also produce adequately accurate results.[70] A GOR-based method for calculating volumes of flared gas uses known GOR and measured volumes of oil production and sold gas. The GOR itself is determined based on a test that directly measures in a controlled manner all of the oil and gas produced by the well over a given period of time. Calculating the volumes of flared gas based on GOR can be quite accurate, if the GOR value used is accurate and the well conditions are relatively stable. This is consistent with BLM's long standing (January 1, 1980) policy.[71]

BLM continued: "Since the GOR will vary as well conditions change, the accuracy of the GOR value for a well can be enhanced by more frequent GOR testing, either on a set frequency and/or in response to changes in the well's production. The BLM expects that to meet the standards of § 3179.9, GOR tests would need to be performed at least monthly for most wells."[72]

Both the state of North Dakota also considers calculation methods to be an acceptable method for compliance with NDIC Order #24665 as outlined in implementation Flaring Questions.[73]

Below is an example of the subtraction method:

What data is available to quantify emissions/waste for this equipment or process?

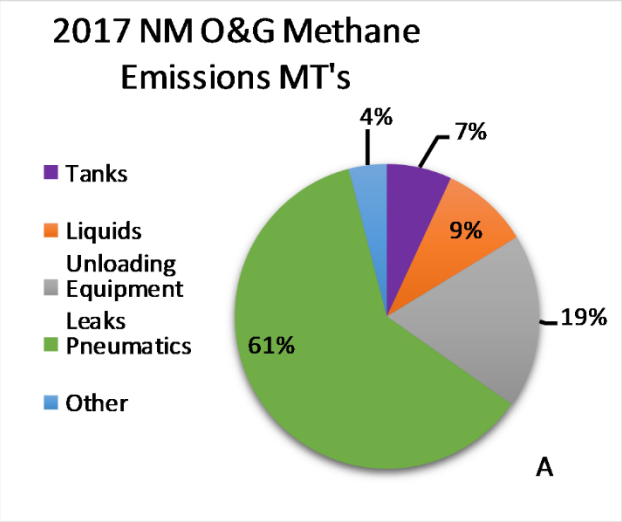
The US EPA publishes most of the emission information and activity data that it receives as part of the US GHG Reporting Program annually (https://ghgdata.epa.gov/ghgp/main.do?site_preference=normal#). By March 31st of each year, operators upload their emission information to the EPA website for the previous year (i.e. 2018 emission information was reported in March 2019), EPA undertakes a quality assurance process, and uploads the information in October to a publicly accessible website. Care should be taken in estimating emissions from this inventory for New Mexico since both the Permian and San Juan Basins span multiple states and it is challenging to separate emissions between states for all source categories.

Here, we present an analysis of methane emissions from the oil and gas production and gathering & boosting (G&B) segments as reported to the EPA's Greenhouse Gas Reporting Program (GHGRP). GHGRP reporting began in 2011 for the production segment and in 2016 for the G&B segment. Operators with less than 25,000 MT CO_2e emissions are exempt from reporting emissions to the GHGRP.

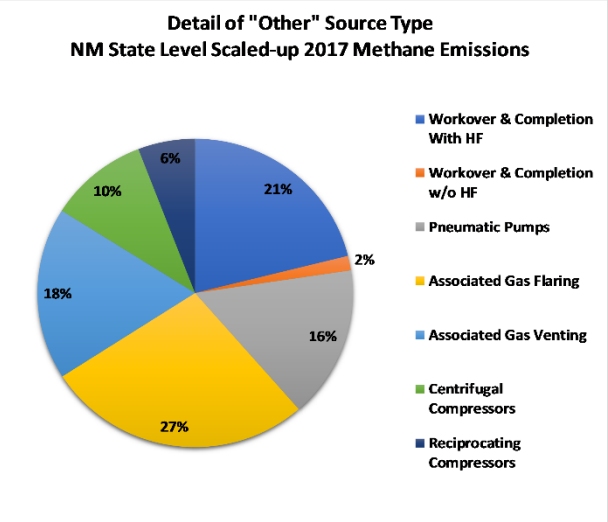
[70] BLM, Waste Prevention, Production Subject to Royalties, and Resource Conservation; Final Rule, 81 Fed Reg. 83053 (Nov. 18, 2016) (https://www.federalregister.gov/documents/2016/11/18/2016-27637/waste-prevention-production-subject-to-royalties-and-resource-conservation).

[71] Notice to Lessees and Operators of Onshore Federal and Indian Oil and Gas Leases, Royalty or Compensation for Oil and Gas Lost

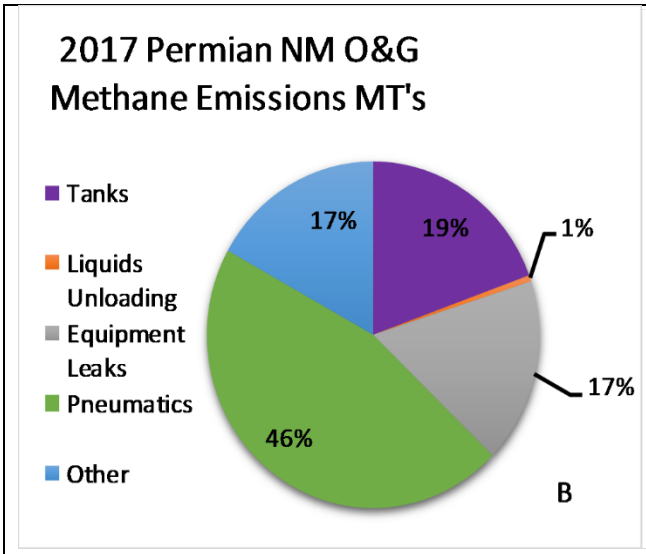
[72] BLM, Waste Prevention, Production Subject to Royalties, and Resource Conservation; Final Rule, 81 Fed Reg. at 83053 (Nov. 18, 2016) (https://www.federalregister.gov/documents/2016/11/18/2016-27637/waste-prevention-production-subject-to-royalties-and-resource-conservation).



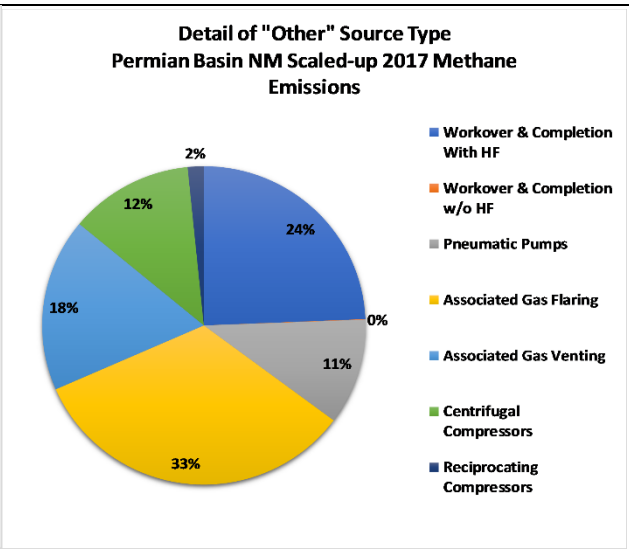
[73] Hicks, Bruce E. "NDPC Flaring Questions ICO#24665." Letter to Mr. Ron Ness. 4 July 2014.



However, it is important to note that in this analysis we have scaled emissions to account for exempt operators by basin.



In 2011, 50% of wells in the Permian basin were included in GHGRP reporting, and by 2017 coverage increased to 72%. In the San Juan Basin, over 85% of wells have been included in GHGRP reporting since 2011. For the production segment, we have scaled all emissions in each year up to the total well count reported by the New Mexico Oil Conservation Division (NMOCD) (EIA for national). For the G&B segment, no information to enable scaling-up GHGRP reported emissions is available and raw GHGRP reported emission quantities are shown.



In 2017, scaled-up New Mexico statewide GHGRP reported methane emissions totaled 205,470 metric tonnes (MT's). Of these, associated gas flaring accounted for approximately 3,536 metric tons. This amounts to 1.7% of the total New Mexico statewide methane emissions.

In 2017, scaled-up New Mexico Permian GHGRP reported methane emissions totaled 48,805 metric tonnes (MT's). Of these, associated gas flaring accounted for approximately 3,536 metric tons. This amounts to 7.2% of the total New Mexico Permian methane emissions.
*This data does not include CO2 emissions from flaring. CO2 equivalent data is of interest as well.

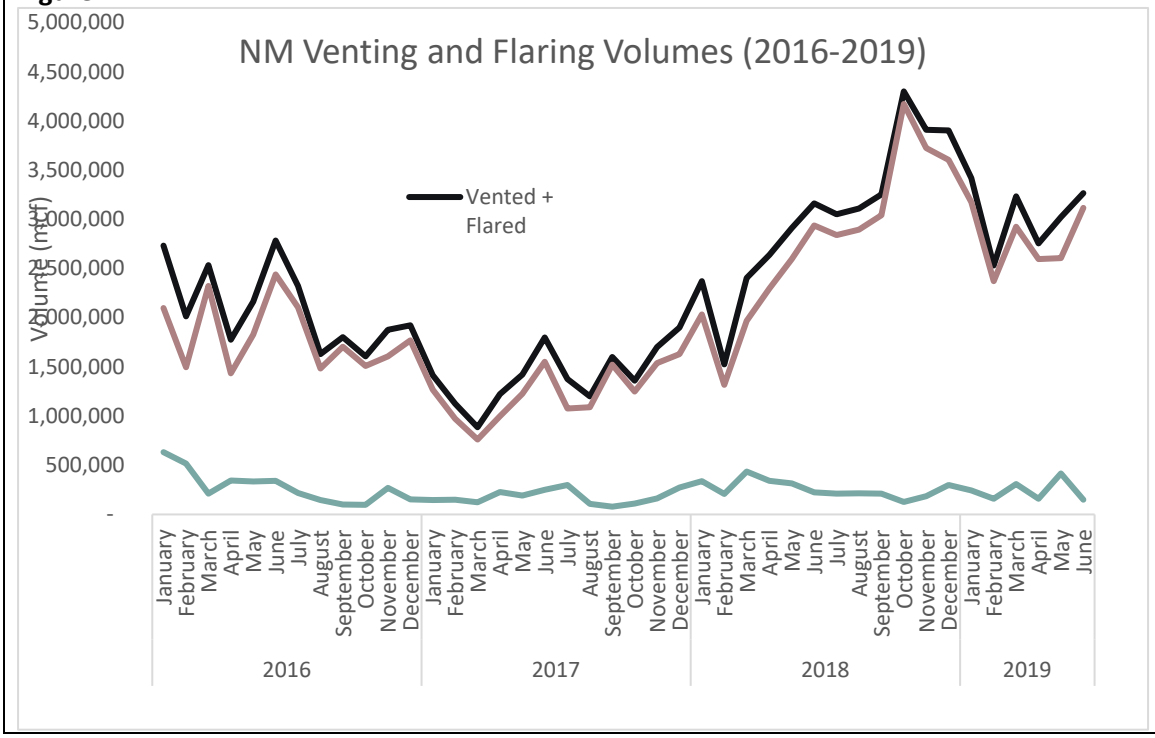
When both methane and carbon dioxide are considered, flaring contributes a larger portion of Oil and Gas greenhouse gas. For example, considering GHGRP data for 2018 for Permian wellpads, 29% of reported greenhouse gas emissions is from associated gas venting and flaring (considering the sum of CO_2-equivalent emissions, using a GWP of 25 to convert methane emissions to CO_2e):

Permian Wide-Emissions by Category, 2018	GHG, tCO2e	%
Combustion Equipment	7,449,180	32%
Associated Gas Venting and Flaring	**6,684,148**	**29%**
Natural Gas Pneumatic Devices	2,260,725	10%
Atmospheric Storage Tanks	2,237,552	10%
Flare Stacks [98.236(n)]	1,840,021	8.0%
Completions and Workovers with Hydraulic Fracturing	1,257,098	5.5%
Equipment Leaks Surveys and Population Counts	714,443	3.1%
Centrifugal Compressors	312,546	1.4%
Natural Gas Driven Pneumatic Pumps	112,017	0.5%
Well Venting for Liquids Unloading	41,775	0.2%
Other Equipment	82,542	0.4%
SUM	**22,992,045**	**100%**

Data downloaded from Envirofacts and summarized by CATF. GWP of 25 used to convert methane emissions to CO_2e.

While this data is Permian-wide and therefore not specific to NM, the large contribution from associated gas venting & flaring to basin-wide greenhouse gas indicates that this source is an important GHG source.

A primary source of data on the quantities of gas vented and flared are the producers' C-115 reports, which require reporting of the volumes of produced gas disposed of through flaring and, separately, through venting. In addition, the report template provides disposition codes for "gas lift," "lost," "repressurizing," "used on property," and "other." As discussed elsewhere in this section, US EPA Greenhouse Gas Reporting Program data is another source of data on methane emissions, although it does not include data from smaller entities.



As shown in Table 1 and Figure 1 below, reported venting and flaring increased significantly since 2016 (even with a small decline in the first half of 2019). Reported venting has declined significantly since early 2016, which indicates that operators have reduced the practice of simply venting gas. However, the increase in reported flaring has more

than made up for the decreased venting; as gas production from oil wells has increased, development has outpaced infrastructure to handle the increased gas production. However, in New Mexico, capacity constraints may not be the main or only cause of flaring (see section on "Describe how the equipment or process is used").

Table 1*	Total Reported Volume (mcf)		
	Vented	Flared	Vented + Flared
2019 Q2	724,641	8,319,266	9,043,907
2019 Q1	711,939	8,472,053	9,183,992
2018 Q4	613,390	11,499,805	12,113,195
2018 Q3	638,211	8,775,299	9,413,510
2018 Q2	880,210	7,828,529	8,708,739
2018 Q1	983,923	5,317,869	6,301,792
2017 Q4	544,849	4,418,534	4,963,383
2017 Q3	486,144	3,689,663	4,175,807
2017 Q2	669,194	3,774,982	4,444,176
2017 Q1	423,251	3,002,997	3,426,248

2016 Q1	1,361,619	5,919,156	7,280,775

*Data derived from C-115 reports.

Figure 1*

*Data derived from C-115 reports.

As shown in Table 2, the average rate of reported venting and flaring for the past four years is over 4% (as a percent of gas production at oil wells[74]). While the data shows some monthly and quarterly fluctuations, the overall story is clear -- venting and flaring rates are high, and the situation is not improving.

Table 2*	% of oil well gas production		
	Vented	Flared	Vented + Flared
2019 Q2	0.3%	3.6%	3.9%
2019 Q1	0.3%	4.1%	4.5%
2018 Q4	0.3%	5.9%	6.2%
2018 Q3	0.4%	4.9%	5.2%
2018 Q2	0.5%	4.6%	5.1%
2018 Q1	0.6%	3.5%	4.2%
2017 Q4	0.4%	3.0%	3.4%
2017 Q3	0.4%	2.7%	3.0%
2017 Q2	0.5%	2.8%	3.3%
2017 Q1	0.3%	2.3%	2.6%
2016 Q4	0.4%	3.8%	4.2%
2016 Q3	0.4%	4.0%	4.3%
2016 Q2	0.8%	4.3%	5.1%
2016 Q1	1.1%	4.9%	6.0%

*Data derived from C-115 reports.

Table 3 shows Operators vary widely in the amount of production they report as vented or flared as shown in Tables 3 and 4, with several major producers significantly increasing the amount of gas flared and vented so far in 2019.[75]

Top 10 Flaring Companies (January - June) *			
Anonymized Company	**2018**	**2019**	**Percent Change '18-'19**
1	2,207,775	2,250,606	2%
2	494,948	1,541,514	211%
3	1,302,579	1,470,907	13%
4	685,554	1,418,580	107%
5	816,429	1,401,131	72%

[74] Note: We calculate these rates as a percent of reported gas production at oil wells because the significant majority of the venting and flaring problem occurs at these oil wells and the discussion in this MAP report focuses on the associated gas problem. While there is a small amount of flaring occurring at gas wells, we assume that this is mainly driven by upsets and emergency situations rather than routine well operation. There is also non-trivial venting from gas wells, from activities such as liquids unloading and maintenance operations. This produces methane emissions, but is addressed in other MAP reports.

[75] Note: Company names have been removed and replaced with a number.

6	516,427	1,289,238	150%
7	300,128	1,064,029	255%
8	1,915,770	1,042,110	-46%
9	1,156,207	999,721	-14%
10	297,487	912,654	207%

*Data derived from C-115 reports.

Top 10 Venting Companies (January - June)*			
Anonymized Company	**2018**	**2019**	**Percent Change '18-'19**
42	806,124	621,981	-23%
10	791,003	166,101	-79%
46	26,367	132,888	404%
4	6,191	121,443	1862%
47	None reported	110,758	X
2	135,473	109,856	-19%
18	None reported	73,000	X
3	1,353	21,855	1515%
48	31,317	21,788	-30%
49	None reported	18,794	X

*Data derived from C-115 reports.

Note that as a generality, about half of the lifetime well production of associated gas occurs in the first two years of production, which has important implications for the timing of flaring reduction measures.[76] Gas-to-oil ratios and production decline vary greatly by well and basin.

Given the lack of consistency and standardization of reporting vented and flared volumes, it is difficult to make conclusions with the existing C-115 dataset. Industry supports a more detailed reporting program to establish consistency across the state.

What are the data gaps in quantifying emissions/waste for this equipment?

When reporting of flared volumes (F code) was rolled out, the only guidance given to operators was "The new code "F" is to be used to report the volume of gas that is flared on a well basis, or total volume if flared at a common battery or gathering system and reported under one point of disposition." There was no formal standard or protocol that detailed what types of flaring to report or how to measure or estimate flared volumes.

Also, C-115s are a requirement for operators of oil and gas wells. Midstream flaring is either permitted or reported to NMED.

[76] Carbon Limits, Improving utilization of associated gas in US tight oil fields, 8 (April 2015) (https://www.google.com/url?sa=t&rct=j&q=&esrc=s&source=web&cd=2&ved=2ahUKEwiEw6T9j_vkAhVyU98KHWW5DSkQFjABegQIABAC&url=http%3A%2F%2Fwww.catf.us%2Fresources%2Fpublications%2Ffiles%2FFlaring_Report.pdf&usg=AOvVaw3ishdgM_o2N8haqov8YIBf). Carbon Limits, a consultant to Clean Air Task Force, is headquartered in Oslo, Norway.

The quality of the data from C-115 reports is not robust, for several reasons. First, incomplete or inaccurate reporting results in incomplete data, which biases the emissions/waste estimates downwards. We do not know the extent of such reporting noncompliance, but in the past, it has been substantial, and there is no basis to conclude that the problem has been fully corrected.[77]

Second, there is a lack of guidance to operators from OCD on how to categorize the various losses of gas. Consequently, it is highly likely that there are inconsistencies across operators regarding whether all disposed gas is actually reported, and which disposition codes are used for which sources of gas. For example, it appears likely that most operators include as "vented" only the intentional direct venting of associated gas, but this excludes gas vented at temporarily unlit flares and the portion of gas that is emitted unburned from operating flares. It is also unclear whether all operators include in the flared or vented volumes gas that is flared or vented, for example, during completions or well-testing. It is also unclear, for example, whether operators are including in their C-115 reports flaring volumes that they reported on their C-129s (requests for approval to flare) or C-141s (release notification and corrective action), or whether operators are including in their C-115s only volumes that they have not otherwise reported.

Third, this data may depend to some extent on estimates of flared and vented volumes. For example, some operators may calculate flared/vented volume based on periodic GOR tests and ongoing measurement of quantities of oil production, not direct metering, as described above.

Fourth, according to OCD, it has had little capacity to audit or verify reported quantities, and operators do not generally use third party audits to spot check the accuracy of their venting and flaring reporting. As a result, there is little external incentive for operators to prioritize complete and accurate reporting of venting and flaring volumes.

Finally, it is worth noting that C-115s do not include data on venting and flaring that occurs during midstream operations. It is not clear what data is available on those volumes, although it may be possible to derive data on this from NMED permits, excess emissions reporting, and/or the GHGRP.

The likelihood that C-115 data captures only a subset of overall venting and flaring from oil and gas activities is reinforced by NOAA satellite flaring data for recent years, which indicates that that OCD flaring data is too low.[78]

NOAA Quantification of Flaring from NM

[77] For example, in a Notice to Operators in 2017, OCD "determined that not all Operators are following the requirement to report flared and vented volumes. Out of 603 well Operators active in the state, only 51 Operators are reporting volumes using the "V" and "F" code. It is very important that all Operators in New Mexico report flared and vented volumes since part of the evaluation will help determine any policy or requirements setting goals for reduction of flared gas. We urge all companies to work with their operations and production accounting groups to ensure proper production reporting." Notice to Oil and Gas Operators, Vented & Flared Volumes Reporting Communication, March 8, 2017. Available at http://www.emnrd.state.nm.us/OCD/documents/20173-8NoticetoOperators.pdf

Year	Bcf gas flared
2012	14.4
2013	24.3
2014	31.3
2015	41.2
2016	30.5
2017	22.4
2018	41.5

These NOAA estimates are derived from radiance measurements in the SWIR part of the spectrum (nonvisible light, falling roughly between 1400 and 3000 nanometers) measured by the VIIRS instrument (whiskbroom scanning radiometer that collects imagery and radiometric measurements) at night. There are several steps that are required to derive flaring emission estimates from radiance measurements from VIIRS:

1. First, a determination as to which bright pixels are flares or fires – this requires a certain set of assumptions that introduce uncertainty;
2. Once a determination of whether a bright pixel is a flare, flaring duration must be assessed. VIIRS provides data for one second of a day unless a cloud is blocking the bright pixel. Based upon that one second, a determination as to whether the observed flare is persistent or intermittent must be made. The easiest assumption is persistence, but may not always be valid and could lead to overestimates of flared gas.
3. The next step requires a conversion of flare radiance to an emission rate. This conversion is performed by a logarithmic fit between measured radiance-derived Fire Radiative Power and reported flared gas volumes from the Cedigaz database. Such a calibration neglects very real variability in flare combustion efficiency as well as variability in gas composition (gas heating values). Also, the Cedigaz database includes both flaring and venting, however, this study assumed venting was negligible in the Cedigaz numbers.

In summary the emissions estimates presented here are only as good as the aforementioned assumptions used to derive them. In the table below, it is important to note that there is no uncertainty of ranges included. Without a secondary verification through correlating direct measurement at these bright pixelated locations, it is impossible to determine the accuracy of these emissions estimates. Emissions estimates such as these may be more useful in understanding year-to-year trends in flared gas volume, rather than the absolute amount of gas flared.

Economic Description of the Process or Equipment:

What is the per unit cost of the equipment or the costs associated with the process?

Equipment costs for flares vary greatly and must be determined on a case-by-case basis.

What are the annualized operating costs for the equipment or costs associated with the process?

Equipment costs for flares vary greatly and must be determined on a case-by-case basis.

If the equipment or process is powered, what are the costs?

N/A

What are the maintenance and repair costs for existing or new equipment?

Maintenance costs for flares vary greatly and must be determined on a case-by-case basis.

Existing Reduction Strategies:

How has industry reduced emissions/waste from this equipment or process historically?

Engineering advancements of flare tip designs to improve combustion efficiency. Also, Gas Capture Plans ensure operators are working with gatherers/processors to develop solutions to get the gas to market for sales rather than flare. Operators are proactively working with midstream solution providers, internal and 3rd party, to construct and commission facilities and pipelines in advance of drilling. Leases and other oil and gas agreements often require operators to drill in given time frames, although these terms may be subject modification by regulations. When possible, operators are shifting drilling and production schedules to minimize the number of stranded wells and the need to flare gas due to a lack of take away pipelines or downstream facilities.

Operators are designing multiple well pads which provide additional time to install the required pipelines and facilities and reduce the number of stranded wells. Operators will occasionally shut in production to mitigate a flaring event. However, shutting in production results in the loss of royalties paid to all interest holders, including the public if the New Mexico State Land Office or Federal Bureau of Land Management receive revenue from that particular lease and may result in formation damage which could impact total recovered hydrocarbons.

Companies also utilize several technological advancements to increase the destruction and removal efficiency of flares and identify beneficial uses in oil and gas operations.

It is important to note that the best solution to flaring is always having a sales pipeline.

With respect to temporary shut in of production, royalties should be considered deferred, not lost, as the production from the well is delayed, not ended.

New Wells:

Existing Wells:

How have the emission/waste reductions been measured?

Emissions from a flare rely heavily upon flow to the flare which can be estimated or measured. Estimation in this instance involves the use of known well or reservoir information such as periodic well tests or a well's gas to oil ratio to estimate a well's gas production rate. For example, if a production flow test is conducted monthly on a well, the resulting rate could provide a reliable basis to calculate the well's gas production for the entire month. Similarly, if a well has a gas to oil ratio that is uniform over time, the operator could estimate the rate of gas production based on the measured rate of oil production and the gas to oil ratio. Gas volume estimation using these protocols is suitable for reporting flared gas volumes in many cases.

There are also various technologies for measuring flow to the flare. Measurement options are primarily limited to volumes sent to the high pressure flare. In these operating circumstances there is enough volume and energy in the

process stream to measure the flowrate. However, in low pressure conditions, such as storage tank vent headers, emissions/flare volumes are typically calculated from process conditions using EPA guidance due to technical feasibility issues with measurement of these low flow, low energy flows.

High pressure flare volumes fluctuate widely: from small volumes under normal conditions to full gas stream under upset or emergency conditions, even changing repeatedly throughout the day depending on sales line capacity. Any meter for a high pressure flare must accurately accommodate this broad production range.

Conversely, to improve accuracy at low volumes, a smaller orifice size is required but such a restriction in the flare piping introduces intolerable safety concerns when flow increases. Furthermore, an orifice meter will restrict the line to the flare such that when large volumes are flared for emergency purposes, it will result in an explosion. Other meter options such as ultrasonic or thermal mass can be more costly, and depending on technology, can be very sensitive to operating and ambient conditions at low flow conditions, e.g. thermal mass meter.

North Dakota Petroleum Council Summary			
Common Meter Types	**Accuracy**	**Limitations**	**Cost**
Differential Pressure (Orifice)	Poor	Adds pressure drop (safety), poor for high variability, calibration challenge	Low - High
Thermal Mass	Poor	Gas composition, moisture	Medium
Ultrasonic	<10%	Low velocity, moisture	High

API Manual of Petroleum Measurement Standards (MPMS) Chapter 14, Section 10, Measurement of Flow to Flares addresses measurement of flow to flares and includes:

- application considerations,
- selection criteria and other considerations for flare meters and related
- instrumentation,
- installation considerations,
- limitations of flare measurement technologies,
- calibration,
- operation,
- uncertainty and propagation of error, and
- calculations.

Technology	Sensitivity to Entrained Mist or Liquid	Sensitivity to Fouling	Ability to Detect Fouling
Differential Pressure	Low to Moderate (varies with liquid load)	Moderate	Physical Inspection
Thermal Flow	High	High	Physical Inspection
Optical	Moderate	High	Meter Diagnostics
Ultrasonic	Low (unless sensor is immersed in liquid, then very high)	High	Meter Diagnostics
Vortex	Low (if meter is installed in horizontal line and bluff body is horizontal)	Low to High (varies with meter design)	Physical Inspection

Waste reductions are measured as the change in the measured volumes and percentages of produced gas that are vented or flared per well/lease/operator/state over time.

How have states and the federal government reduced emissions/waste from this equipment or process historically? In addition, please identify voluntary reductions achieved whether or not they were in response to a regulatory action/requirement.

VOLUNTARY

Some oil and gas companies have committed to voluntary initiatives to reduce flaring. Companies also utilize several technological advancements to increase the destruction and removal efficiency of flares and identify beneficial uses in oil and gas operations. (See "Existing Reduction Strategy" section above).

FEDERAL - BLM

43 CFR Subpart 3179 Waste Prevention and Resource Conservation includes requirements and determinations of waste for oil well flaring.

- §3179.4(a) & (b) outline what is considered avoidable (royalty bearing) and unavoidable (non-royalty bearing) lost production.
- §3179.6(b). The operator must flare, rather than vent, any gas that is not captured, except under certain circumstances.
- §3179.101 – 104 outlines "Authorized Flaring and Venting of Gas." "Authorized" is described as being unavoidable royalty-free gas.
    - §3179.101 Initial production testing
    - §3179.102 Subsequent well tests
    - §3179.103 Emergencies
    - §3179.104 Downhole well maintenance and liquids unloading
- §3179.201(a) Oil-well gas
    - Except as provided in §§ 3179.101,3179.102, 3179.103, and 3179.104, vented or flared oil-well gas is royalty free if it is vented or flared pursuant to applicable rules, regulations, or orders of the appropriate State regulatory agency or tribe. Applicable State or tribal rules, regulations, or orders are appropriate if they place limitations on the venting and flaring of oil-well gas, including through general or qualified prohibitions, volume or time limitations, capture percentage requirements, or trading mechanisms.

BLM

Prior to 2016, BLM addressed venting and flaring of associated gas under NTL-4A, which prohibited operators from venting or flaring oil well gas unless approved in advance by BLM. Approval could be granted if justified by "(1) an evaluation report supported by engineering, geologic, and economic data which demonstrates to the satisfaction of [BLM] that the expenditures necessary to market or beneficially use such gas are not economically justified and that conservation of the gas, if required, would lead to the premature abandonment of recoverable oil reserves and ultimately to a greater loss of equivalent energy than would be recovered if the venting or flaring were permitted to continue or (2) an action plan that will eliminate venting or flaring of the gas within 1 year from the date of application."[79] NTL-4A further provided that "[w]hen evaluating the feasibility of requiring conservation of the gas, the total leasehold production, including both oil and gas, as well as the economics of a field wide plan shall be considered by [BLM] in determining whether the lease can be operated successfully if it is required that the gas be conserved."[80] Thus, the text of NTL-4A required an assessment of whether the operator could still successfully operate the entire leasehold, including the profits from both oil and gas production, while conserving gas (not merely a showing that it would cost the operator more to conserve the gas than to capture it, as has at times been asserted).

[79] NTL-4A, 3-4.

[80] NTL-4A, 4.

In practice, however, BLM appears to have accepted more minimal showings as a basis for routinely approving requests to allow venting and flaring.

Concerned about growing volumes of waste of gas, particularly from venting and flaring of associated gas, and with reforms urged by oversight entities such as the Government Accountability Office (GAO) and the IG Inspector General, BLM undertook a multi-year rulemaking to replace NTL-4A with far more effective requirements to control the waste of natural gas.[81] The final Methane and Waste Prevention Rule, issued in November 2016, established new controls on venting and flaring of associated gas.[82] With respect to venting and flaring, the rule: (1) required operators to file Waste Minimization Plans as a condition of receiving approval of an Application for Permit to Drill (43 CFR 3162.3-1); (2) prohibited flaring or venting of gas well gas, except where the gas was "unavoidably lost" as defined in the regulations (43 CFR 3179.6(a)); (3) required operators to flare rather than vent any gas that is not captured, except under specific circumstances detailed in the regulations (43 CFR 3179.6(b)); and (4) established gas capture requirements to ensure that operators must, over time, capture rather than flare an increasing volume of their gas (43 CFR 3179.7).

Specifically, the percentage of gas that operators were required to capture (which includes beneficial on-lease use) ratcheted up from 85% beginning in 2018, to 90% in 2020, to 95% in 2023, to 98% in 2026. These percentages applied to the "adjusted total volume of gas produced" by an operator each month. This "adjusted total volume of gas produced" was the operator's total volume of gas captured, plus the total volume of gas flared from high pressure flares from development oil wells, minus an allowable amount of flaring per well, all calculated on a monthly basis. The allowable amount of flaring per well ratcheted down over time (as the percentage capture requirement ratcheted up) from 3,600 Mcf/well beginning in 2019, to 1,800 Mcf/well in 2020, to 1,500 Mcf/well in 2021, to 1,200 Mcf/well in 2022, to 900 Mcf/well in 2024, to 750 Mcf/well from 2025 on.[83] Operators had the option of complying on a lease-by-lease, county-by-county, or state-wide basis, which gave operators the maximum flexibility to average capture volumes across all of an operator's wells within each state.

Note that because the BLM rule applied to then-current conditions across multiple states, it was calibrated to assure feasibility even in the most extreme venting and flaring circumstances, which were then (and still are) occurring in North Dakota. Absent those circumstances, BLM's flaring data analysis underlying the rule would likely have supported lower limits. The percentage and volume limitations considered appropriate for a national rule promulgated in 2016 would not necessarily be directly applicable for a single state-specific rule promulgated in 2020. The BLM 2016 percent gas capture rule dataset was limited to federal minerals and relied upon the broad application of uneconomic temporary capture technologies and unrealistic market assumptions. These percent capture provisions were stayed by a federal district court on April 4, 2018, therefore, were never observed for effectiveness in any real-world field-wide practice.

[81] See, e.g., GAO, Federal Oil and Gas Leases: Opportunities Exist to Capture Vented and Flared Natural Gas Which Would Increase Royalty Payments and Reduce Greenhouse Gases, GAO-11-34, 24 (Oct. 2010) (https://www.gao.gov/products/GAO-11-34). CITE GAO, IG reports.

[82] BLM, Waste Prevention, Production Subject to Royalties, and Resource Conservation; Final Rule, 81 Fed Reg. 83008 (Nov. 18, 2016) (https://www.federalregister.gov/documents/2016/11/18/2016-27637/waste-prevention-production-subject-to-royalties-and-resource-conservation).

[83] BLM selected these values based on its analysis of flaring rates of gas from oil wells in 15,530 records from data of the Office of Natural Resources Revenues, representing monthly flared volumes on a lease or unit basis from over 2,000 unique leases or units over a yearlong period from October 1, 2013 to September 30, 2014, as well as BLM data on the number of wells per lease. BLM Proposed Rule at 6639.

The rule also established measurement and reporting requirements for all volumes of gas vented or flared (43 CFR 3179.9).

In 2018, BLM largely rescinded the 2016 rule, although the constraints on venting remain in place (43 CFR 3179.6).[84] The 2018 rule provides that venting or flaring oil-well gas does not require approval from BLM and is royalty free, "if it is vented or flared pursuant to applicable rules, regulations, or orders of the appropriate State regulatory agency or tribe." (43 CFR 3179.201)

NEW MEXICO

Current NMOCD regulation:

The current regulatory framework in New Mexico requires approval from the NMOCD if an operator needs to flare beyond the first 60 days after completion (NMAC 19.15.18.12.A & B).

- 19.15.18.12.A. NMAC An operator shall not flare or vent casinghead gas produced from a well after 60 days following the well's completion.
- 19.15.18.12.B. NMAC An operator seeking an exception to Subsection A of 19.15.18.12 NMAC shall file an application for an exception on form C-129 with the appropriate division district office. The district supervisor may grant an exception when the flaring or venting casinghead gas appears reasonably necessary to protect correlative rights, prevent waste or prevent undue hardships on the applicant. The district supervisor shall either grant the exception within 10 days after the application's receipt or refer it to the director who shall advertise the matter for public hearing if the applicant desires a hearing.

In addition, current NMOCD regulation authorizes flaring and requires volumes to be reported on C-115 (NMAC 19.15.18.12.F.)

- 19.15.18.12.F. NMAC Pending connection of a well to a gas-gathering facility, or when a well has been excepted from the provisions of Subsection A of 19.15.18.12 NMAC, the operator shall burn all gas produced and not used, and report the estimated volume on form C-115.

From a midstream perspective, NMOCD requires notification of prolonged mechanical difficulties or plant shut downs (NMAC 19.15.18.12.E.)

- 19.15.18.12.E. NMAC In the event of a more prolonged mechanical difficulty or in the event of plant shut-downs or curtailment because of scheduled or non-scheduled maintenance or testing operations or other reasons, or in the event a plant is unable to accept, process and market all of the casinghead gas produced by wells connected to its system, the plant operator shall notify the division as soon as possible of the full details of the shut-down or curtailment, following which the division shall take such action as is necessary to reduce the total flow of gas to the plant.

Current NMAC 19.15.7.24. Operators Monthly Report (Form C-115) requires complete information and data indicated, which includes Non-transported volumes (disposition codes F-flared and V-vented), on the forms to be submitted. Also, NMOCD has authority to cancel the operator's authority to transport from or inject into all wells it operates for failure to file an acceptable and complete form C-115 (19.15.7.24.C. NMAC).

- 19.15.7.24.A. NMAC An operator shall file a form C-115 for each non-plugged well completion for which the division has approved a form C-104 and for each secondary or other enhanced recovery project or pressure maintenance project injection well or other injection well within the state, setting forth complete information and data indicated on the forms in the order, format and style the director prescribes. The operator shall

[84] BLM, Waste Prevention, Production Subject to Royalties, and Resource Conservation; Rescission or Revision of Certain Requirements; Final Rule, 83 Fed Reg. 83008 (Sept. 28, 2018) (https://www.federalregister.gov/documents/2018/09/28/2018-20689/waste-prevention-production-subject-to-royalties-and-resource-conservation-rescission-or-revision-of).

estimate oil production from wells producing into common storage as accurately as possible on the basis of periodic tests.

- 19.15.7.24.C. NMAC If an operator fails to file a form C-115 that the division accepts, the division shall, within 30 days of the appropriate filing date, notify the operator by electronic mail or letter of its intent to cancel the operator's authorization to transport or inject if the operator does not file an acceptable and complete form C-115. The notice shall inform the operator of the right to request a hearing pursuant to 19.15.4.8 NMAC. If the operator does not either file an acceptable and complete form C-115 or request a hearing on the proposed cancellation within 60 days of the original due date of the form C-115, the division may cancel the operator's authority to transport from or inject into all wells it operates.

The current Gas Capture Plan was made part of the application process through "Notice to Operators" issued on April 8, 2016, with an effective date of May 1, 2016.

- Per the Notice to Operators - The Gas Capture Plan outlines actions to be taken by the Operator to reduce well/production facility flaring and venting for new completion (new drill, recomplete to new zone, re-frac) activity. The requirement applies to Federal, State, Fee, & Tribal Wells.
- A Gas Capture Plan purpose is to ensure operators are working with gatherers/processors to provide a way to get the gas to market for sales rather than flare.

Current NMED regulations:
Emissions from venting and flaring is authorized by NMED:

- 20.2.72.200. Permits must be obtained from the department by: (1) Any person constructing a stationary source which has the potential emission rate greater than 10 pounds per hour or 25 tons per year of any regulated air contaminant for which there is a National or New Mexico Ambient Air Quality Standard.
- Combustion emissions resulting from routine flaring is authorized through one or more air permits.
  - The GCP-Temporary Control Major and Minor permits authorize the flaring or combustion of stranded gas for a period not to exceed 12 consecutive months.
  - The GCP-Oil & Gas may also be used to authorize routine process flaring.
  - The GCP-6 permit authorizes flares and other methods to reduce emissions from oil and gas storage tanks.
  - Per 20.2.70, an NSR/Title V Operating Permit is required for stationary sources that have actual or potential emissions equal to or greater than 100 tons per year of any regulated air pollutant.
- The flaring emissions to be authorized will be dependent on specific facility configuration, operating conditions, gas composition, and volume of gas sent to the flare.
- Per 20.2.7, flaring in excess of an authorization is required to be reported to NMED as an excess emission event.

<u>New Mexico</u>
The applicable NM law defines "surface waste" to include "the unnecessary or excessive surface loss of destruction without beneficial use . . . of natural gas of any type or in any form . . . including the loss or destruction, without beneficial use, resulting from evaporation, seepage, leakage or fire, especially such loss or destruction incident or resulting from the manner of spacing, equipping, operating or producing, well or wells, or incident to or resulting from . . . the production of . . . natural gas in excess of the reasonable market demand."[85] The NM regulations clearly prohibit "the production or handling" of gas "in a manner, under conditions or in an amount as to constitute or result

[85] New Mexico Statutes Annotated, section 70-2-3 B.

in waste."[86] The regulations further provide that operators "shall conduct their operations in or related to the drilling, equipping, operating, producing . . . of oil, gas . . . wells or other facilities . . . in a manner that prevents waste of oil and gas . . . " and bar operators from "wastefully utiliz[ing] oil or gas or allowing either to leak or escape" from reservoirs, wells and other operating equipment.[87]

In general, the New Mexico Oil and Gas Act requires the New Mexico Oil Conservation Commission (NMOCC) and New Mexico Oil Conservation Division (NMOCD) to prohibit production and oil and gas handling practices which constitute or result in waste. NMSA 1978, § 70-2-2. The concept of "waste" has been statutorily defined by the New Mexico Legislature to include both underground waste and surface waste. NMSA 1978, § 70-2-3. Underground waste can consist of any practice that reduces or tends to reduce the total quantity of crude oil or natural gas ultimately recovered from a reservoir, e.g. shutting in a well; whereas surface waste consists of unnecessary or excessive surface loss or destruction of oil or gas, without beneficial use. Thus, NMOCC and NMOCD are required by statute to encourage the optimum recovery of oil and gas resources. The federal government and other oil and gas producing states similarly prohibit the creation of waste. *See e.g.,* 30 U.S.C. § 187; 30 U.S.C. § 225; WYO. STAT. ANN. § 30-5-101.

For the purpose of limiting venting and flaring, "waste" has historically been defined by the federal government and other oil and gas producing jurisdictions as a "preventable loss of [oil or gas] the value of which exceeds the cost of avoidance." Stephen L. McDonald, Petroleum Conservation in the United States, and Economic Analysis, Johns Hopkins Press, 1971 (Reprinted in 2011 by Resources for the Future) ("Petroleum Conservation Economics"), at 129. NMOCD regulations have likewise allowed flaring in situations where "the flaring or venting casinghead gas appears reasonably necessary to protect correlative rights, prevent waste or prevent undue hardships" on the operator. 19.15.18.12.B NMAC. Indeed, flare may provide environmental benefits in certain situations. The New Mexico Environment Department (NMED) has approved flaring in a variety of situations, and the federal government requires specifically requires flaring in certain situations. *See* NMED, Air Quality Bureau General Construction Permits; 43 C.F.R. § 3179.6(b).

The current NM regulations on casinghead gas also generally bar flaring or venting of casinghead gas, beginning 60 days after the well's completion.[88] In addition to the exemption for the first 60 days of production, these provisions allow for an exception wherever flaring or venting "appears reasonably necessary" to "prevent undue hardships on the applicant."[89] If the application for an exception is not granted in 10 days, it must be referred to the director, who must hold a hearing the matter if the applicant wishes.[90] In effect, this means that to maintain the general prohibition on flaring, the director would have to hold a hearing on and make the decision to reject each individual flaring application. This is simply untenable from an agency workload perspective, and it is no surprise that OCD routinely grants most or almost all flaring exception applications.

Thus, current OCD regulations have not been effective in limiting venting and flaring of associated gas.

WYOMING

Wyoming Oil and Gas Conservation Commission rules (055-3 WYO. CODE R. § 39) impose restrictions on venting and flaring. The Wyoming rules authorize venting and flaring under the following circumstances: (1) emergencies, (2) well purging and evaluation tests, and (3) production tests (for 15 days, unless a longer period is authorized). In addition, the rules authorize the flaring of up to 60 Mcf of gas per day from individual oil wells. (Associated gas may be vented where the rate does not exceed 20 Mcf per day.) An operator may also apply for authorization to flare in other circumstances. An operator's application for authorization to flare must include, among other information, a gas

[86] NMAC 19.15.2.8.
[87] *Id.*
[88] NMAC 19.15.18.12.
[89] *Id.*
[90] *Id.*

capture plan identifying gas gathering and transportation facilities in the area, the name of gas gatherers providing "gas take-away capacity," and information on the gas gathering line to which the operator proposes to connect.

COLORADO

Colorado Oil and Gas Conservation Commission regulations restrict the venting or flaring of natural gas. 2 COLO. CODE REGS. § 404-1-912. Under those regulations, "[t]he unnecessary or excessive venting or flaring of natural gas from a well is prohibited." An operator must obtain prior approval from the Commission for venting or flaring, "[e]xcept for gas flared or vented during an upset condition, well maintenance, well stimulation flowback, purging operations, or a productivity test." Gas flared, vented, or used on the lease must be estimated using a gas-to-oil ratio test or other approved method and reported on a monthly basis.

NORTH DAKOTA

North Dakota's statutory restrictions on the flaring of associated gas are found in North Dakota Century Code section 38-08-06.4.

- Under this statute, operators are allowed to flare associated gas for a period of one year from the date of first production of the well. After that period, the well must be: (1) capped, (2) connected to a gathering line, (3) equipped with an electrical generator that consumes 75% the gas, (4) equipped with an approved process that reduces the volume or intensity of the flare by 60%, or (5) equipped with a system that captures 75% of the gas for consumption by means of use as fuel, transport to processing, production of chemicals/fertilizer, or separating and collecting over 50% of the propane and heavier hydrocarbons. Operators who violate section 38-08-06.4 must pay royalties and taxes on the flared gas.
- An operator may obtain an exemption from section 38-08-06.4 from the North Dakota Industrial Commission by showing "that connection of the well to a natural gas gathering line is economically infeasible at the time of the application or in the foreseeable future or that a market for the gas is not available and that equipping the well with an electrical generator to produce electricity from gas or employing a collection system . . . is economically infeasible."

The North Dakota Industrial Commission has established a special policy for wells in the Bakken, Bakken/Three Forks, and Three Forks Pools. See NDIC Order 24665.

- In those fields, wells are allowed to produce at the maximum efficient rate for the first 90 days, after which the wells may continue to produce at the maximum efficient rate only if the well or operator meets or exceeds Commission approved gas capture goals. (This restriction does not apply to (1) the first horizontal well completed in a non-overlapping spacing unit, or (2) wells that have received an exemption from North Dakota Century Code section 38-08-06.4.) The NDIC has established the following gas capture goals:

  74% October 1, 2014 through December 31, 2014
  77% January 1, 2015 through March 31, 2016
  80% April 1, 2016 through October 31, 2016
  85% November 1, 2016 through October 31, 2018
  88% November 1, 2018 through October 31, 2020
  91 % beginning November 1, 2020

North Dakota Industrial Commission Order 24665 Policy/Guidance Version 102215 (Oct. 22, 2015).

- North Dakota requires that Applications for a Permit to Drill (APD) be accompanied by a Gas Capture Plan containing the following: (1) affidavit indicating coordination with a mid-stream company, (2) a detailed gas gathering pipeline system location map, (3) information on the gathering line to which the operator proposes to connect, (4) the anticipated date of first production and the anticipated production rates, (5) the amount of gas the applicant is flaring, and (6) explanation of alternatives to flaring.

North Dakota

In response to very high flaring rates of associated gas, the North Dakota Industrial Commission adopted in July 2014, Order 24665 to limit flaring.[91] The Commission supplemented this order with guidance and several letters to operators, which the Commission has modified over time. As supplemented, the order provides that operators in the Bakken/Three Forks areas must capture 74% of gas by Oct. 1, 2014; 77% by Jan. 1, 2015; 80% by April 1, 2016; 85% by Nov. 1, 2016; 88% by Nov. 1, 2018, and 91% by Oct. 1, 2020, with potential for 95% capture as attainable.[92]

The guidance requires:
--gas capture plans for increased density and spacing cased and a sworn affidavit that the operator has provided gas production forecast data to midstream gas gathering companies;
--gas capture plans "for all applications for a permit to drill filed by an operator who has failed to meet gas capture goals in any of the most recent three months;"
--meeting the gas capture goals on a monthly basis, statewide, by county, by field, or by well for each operator.[93]

In calculating compliance with the capture goals, operators were initially allowed to remove: the initial 14 days of flowback; flaring due to a force majeure event on the gas gathering system; and the flared remainder after application of a "value-added" process (such as stripping out the NGLs) that reduces flare volume or intensity by over 60%.[94]

If an operator fails to meet the gas capture goals, the guidance states that "well(s) will be restricted to 200 barrels of oil per day if at least 60%" of the gas is captured, or 100 barrels per day otherwise.[95] In practice, however, production restrictions have been applied to very small quantities of production for limited time frames. In part this is because the guidance allows operators to exempt substantial quantities of flared gas from their compliance calculations, and in part this is because even when operators are not in compliance, the Commission appears to have applied production restrictions only rarely.[96]

Initially, it appeared that the new requirements were having some effect – the percentage of produced gas that was flared fell from roughly a third in 2013 to a low of slightly less than 10% in one month in 2015. Since then, however, the percentage of produced gas flared has risen again, rather than continuing to improve, and it has been falling further short of the percentage capture goals.[97] Analysis conducted by Clean Air Task Force on production and flaring in 2017 showed that a number of operators producing oil and gas from the Bakken/Three Forks formations consistently failed to meet the Commission's Gas Capture standard (even considering the provisions allowing operators to exclude certain flared gas volumes when calculating their gas capture percentage), yet they did not suffer any sanction from NDIC.[98] Note that no information is publicly available on why NDIC chose not to sanction operators that fail to meet the Gas Capture standard or on related matters such as declared force majeure events.

Given the virtual absence of sanctions for exceedances, it is not surprising that ND's approach has failed to solve the problem.

At the same time, the Commission has softened the requirements, making companies substantially less likely to be in violation, even as the problem has worsened. The current applicable goal is for operators to capture 88% of produced gas. In March 2019, however, operators flared about 20% of the produced gas, and at that time, operators had exceeded the target for the past 13 months in a row.[99]

For the first four years, the guidance stated that the policy goals were to reduce the flaring volume, duration, and number of wells.[100] In November 2018, however, the Commission changed the goals to "increase the volume of captured gas and reduce the percentage of flared gas," and to "incentivize investment in gas capture infrastructure," dropping the goals of reducing the volume and duration of flaring.[101] In addition, in April 2018 and November 2018, the Commission substantially expanded the quantities of flared gas that operators could remove from their compliance calculations.[102] In addition to the exemptions detailed above, operators may now remove: 60 days of flaring during initial production (versus 14 days); flaring where "gas gathering and processing capacity curtailment" is documented; flaring from existing wells bumped off the gathering system by new wells; and flaring under the following documented circumstances:
--landowner, tribal or federal right-of-way delays;
--midstream down-time for upgrades/maintenance;
--federal regulatory restrictions/delays
--safety issues;
--delayed access to electrical power; or
--possible reservoir damage.[103]
Also, outside of the "Bakken core area" or in a previously undrilled township, an operator may apply to designate gas from up to 6 horizontal wells as "stranded gas," which allows the operator to exclude the first year of production from those wells from compliance calculations and bars curtailment of those wells. It is difficult to conceive of situations in which an operator could not plausibly assert that one or more of the broad range exemptions apply.

UTAH
Utah's regulatory restrictions on the flaring of associated gas are found in section R649-3-20 of the Utah Administrative Code. That regulation allows for up to 1,800 Mcf of associated gas to be flared from an individual well on a monthly basis without approval. The regulation also allows for necessary flaring during production tests and for the "unavoidable or short-term" venting or flaring of gas without approval. "Unavoidable or short-term" venting or flaring includes (1) venting from storage tanks (unless the division determines that the recovery of such gas is warranted), and (2) venting or flaring during line failures, equipment failures, blowouts, or other emergencies if shutting in the well would cause waste or an adverse impact on the reservoir. Venting or flaring is allowed during well purging or evaluation tests for a period not to exceed 24 hours or a maximum of 144 hours in a month. If an operator wishes to vent or flare associated gas in circumstances not expressly provided for in the regulation (e.g., where the operator finds conservation of the gas to be not economically viable), then the operator may request approval for such venting or flaring from the state regulatory agency.

CALIFORNIA

The California Public Resources Code prohibits the "unreasonable waste of natural gas." CAL. PUB. RES. CODE § 3300. The "blowing, release or escape of gas into the air" is considered prima facie evidence of "unreasonable waste." Upon complaint or petition to the state regulatory agency showing probable cause that the unreasonable waste of gas is occurring or is threatened, the state regulatory agency will order a public hearing to determine whether such waste is in fact occurring or threatened. *Id.* §§ 3302, 3306. If the waste of gas is found to be unreasonable, the state regulatory agency will issue an order directing the waste to be discontinued or curtailed. *Id.* § 3308.

Even in the absence of the hearing process described above, the director of the state regulatory agency may institute an action to enjoin the unreasonable waste of gas when he or she determines that such waste is occurring. *Id.* § 3312.

MONTANA

Montana regulations limit the flaring of associated gas from a well to 100 Mcf per day (after a 60-day well test period). MONT. ADMIN. R. 36.22.1220. However, if the operator finds it necessary to flare more than 100 Mcf a day, it may seek approval for such additional flaring from the state regulatory agency. In order to obtain approval, the operator must submit an application "justifying" the need to flare more than 100 Mcf per day. The regulations identify certain information that must be included in the application (e.g., estimated gas reserves, proximity of the well to market, reinjection potential) and also ask for "any other information pertinent to a determination of whether marketing or not marketing or otherwise conserving the associated gas is economically feasible."

Montana regulations require gas to be flared rather than vented when the volume of gas exceeds 20 Mcf per day for a period in excess of 72 hours. MONT. ADMIN. R. 36.22.1221. An operator may apply for a variance from this requirement. The application for a variance must include information on the potential for human exposure, the relative isolation of the location, restriction of access to the location, low gas volume, and low BTU content.

TEXAS

The Railroad Commission of Texas – the state regulatory agency for oil and gas production in Texas – regulates the venting and flaring of gas pursuant to "Statewide Rule 32" (16 TEX. ADMIN. CODE § 3.32).

In general, Rule 32 requires operators to flare (rather than vent) all gas releases greater than 24 hours in duration. Released gas must be measured (or estimated) and reported to the Commission. Leaks and gas releases associated with storage tanks, well drilling, well completions, and blowdowns are exempted from the requirements of Rule 32. 16 TEX. ADMIN. CODE § 3.32(d). However, Rule 32 provides that the commission may require such releases to be flared for safety reasons.

Rule 32 authorizes the release of gas under the following circumstances: (1) gas may be flared for up to 10 producing days following initial completion, recompletion, or workover; (2) gas may be vented during unloading/clean-up for a period not to exceed 24 hours in a single event or 72 hours in one month; (3) gas may be released for up to 24 hours in the event of a full or partial shutdown of a gas gathering system, compression facility, or gas plant servicing the well (the operator may request an extension of the 24-hour period); and, (4) low pressure separator gas may be released up to 15 Mcf/day/well or 50 Mcf/day/lease. 16 TEX. ADMIN. CODE § 3.32(f)(1).

The Commission may authorize additional venting or flaring when the operator makes a showing of the "necessity of the release." 16 TEX. ADMIN. CODE § 3.32(f)(2). Situations where additional venting or flaring is a "necessity" include: (1) cleaning of well solids or fluids; (2) unloading excess formation fluid buildup; releases of low-pressure gas that cannot be captured due to "mechanical, physical, or economic impracticality"; and (3) (for casinghead gas only) the unavailability of a gas pipeline or other marketing facility.

ALASKA

Alaska regulations place significant restrictions on venting and flaring. 20 ALASKA ADMIN. CODE § 25.235. Under those regulations, gas that is vented or flared constitutes waste, except that: (1) flaring or venting for up to one hour as the result of an emergency or operational upset is authorized for safety purposes; (2) flaring or venting for up to one hour as the result of a planned lease operation is authorized for safety purposes; (3) flaring pilot or purge gas to

test or fuel the safety flare system is authorized for safety, and (4) de minimis venting of gas incidental to normal oil field operations is authorized.

Alaska

In response to high rates of flaring, Alaska adopted regulations in the 1970s that largely prohibit venting or flaring. All flaring or venting is waste except:

(1) flaring or venting for no more than 1 hour needed for safety due to either "an emergency or operational upset," or "a planned lease operation;"
(2) "flaring pilot or purge gas to test or fuel the safety flare system;"
(3) "de minimis venting . . . incidental to normal oil field operations;" and
(4) flaring or venting with approval from the commission for well testing before regular production.

The commission may also authorize flaring or venting for a period of more than 1 hour based on a report describing why the gas was flared or vented, the beginning and ending time, the volume, and actions taken to minimize the volume, if the flaring or venting is:

(1) "necessary for facility operations, repairs, upgrades or testing procedures; "
(2) required by "an emergency that threatens life or property," unless failure to operate in a safe and skillful manner causes the emergency; or
(3) "necessary to prevent loss of ultimate recovery."

In addition, operators are required to act "in accordance with good oil field engineering practices and conservation purposes to minimize the volume of gas released, burned, or permitted to escape in the air."

According to the Alaska Oil and Gas Conservation Commission, the effect of the prohibition on venting and flaring has been widespread reinjection of associated gas for conservation and oil recovery, and Alaska estimates that roughly 0.4 percent of gas production is flared.[104]

It should be noted that the vast majority of gas produced on the north slope of Alaska is stranded because there is no pipeline to take the gas to market, and north slope production exceeds local demand for power generation and petroleum industry needs. Nevertheless, Alaska has effectively banned routing flaring as a means to dispose of gas. Most north slope gas is re-injected (and therefore has some value for maintaining reservoir pressure).

OKLAHOMA

Oklahoma regulations allow an operator to vent or flare up to 50 Mcf/day without a permit where it is not economically feasible to market the gas. OKLA. ADMIN. CODE § 165:10-3-15(b). Operators are allowed to "blow down" a well for up to 72 hours, and operators may vent or flare during initial flowback following completion or recompletion for a 14-day period (which may be extended by up to 30 days) if it is not economically feasible to market the gas. OKLA. ADMIN. CODE § 165:10-3-15(a), (d), (e).

An operator may apply for a permit to vent or flare in excess of 50 Mcf/day where "it is not economically feasible to capture the gas." OKLA. ADMIN. CODE § 165:10-3-15(c). The operator's application for the permit to flare must list the maximum daily volume of gas to be vented or flared.

What are examples of process changes/modifications that reduce or eliminate emissions/waste from this equipment or process?

It is important to note that the best solution to flaring is always having a sales pipeline. However, as an industry we continue to investigate new techniques and technologies that reduce flaring. An example is the onsite generation of

[104] BLM, Waste Prevention Rule; proposed rule at 6633 (citing telephone communication with Alaska Oil and Gas Conservation Commission, April 30, 2015); see also, Hoffman et al., The Benefits of Reinjecting Instead of Flaring Produced Gas in Unconventional Oil Reservoirs, Unconventional Resources Technology Conference,1640, 1642 (Aug. 25-27, 2014).

power production using produced hydrocarbon vapors as fuel. NM electric power provider's willingness to accept distributed generation from oil and gas sites with stranded gas or limited takeaway capacity could allow the gas to be utilized to support the electrical demands of the state, thus offsetting flaring. Distributed generation could allow for on-site equipment to utilize electricity reducing demand on diesel generators or the grid and supplement the grid with power generated in excess of site demand.

Some operators have pilot programs planned to inject gas for Enhanced Oil Recovery projects. Re-injecting the gas versus putting in the pipeline, could help alleviate some of the pipeline capacity constraints.

Planning the location and timing of the development of new/recompleted wells based on the projected or confirmed present and future availability of takeaway capacity allows operators of such wells to largely avoid routine flaring of associated gas. In making decisions about where to develop the next new wells or set of wells, or in making decisions on whether and when to pursue and sign agreements with midstream companies, the degree to which operators explicitly weigh takeaway capacity availability is unclear. If, however, operators were to optimize their development planning and processes around maximizing capture of associated gas, along with return on capital etc., it appears highly likely that operators would be very successful in increasing gas capture.

For existing wells, operators can add compression to counter the effect of higher pressure new wells pushing lower pressure older wells off the gathering system. While, as noted below, there are limits to the overall pressures and throughputs allowed on gathering systems, adding compression to boost the pressure of gas from lower pressure wells is a reasonable low cost strategy that operators already use at times and might use more frequently if flaring were not an extremely low cost alternative.

Operators providing information on planned development and expected volumes and timing to midstream operators can facilitate midstream investment aligned with future production and minimize any time lag between increased volumes of associated gas production and expansion of takeaway capacity.

When wells are first completed, the pressure into the gas sales line may exceed the gas sales pressure of neighboring well locations. It is not possible to create a system to manipulate well pressures to ensure that all leases connected to a given gas pipeline have access to it. Also, because leases may consist of federal and non-federal leases, where the lateral section of the horizontal well may pass through and drain more than one mineral estate, all royalty owners in that lateral would have an interest in the production. Therefore, it would be an inaccurate assumption that a gas system can be pressure balanced in the form of curtailment of production as a means of preventing loss associated with lack of access to pipeline capacity. Also, the MAOP of gathering lines limits the amount of compression that can be introduced to ensure gas is being produced into the gathering system.

Entering into contractual arrangements with midstream operators that guarantee access to the gathering system and processing facilities would provide far greater certainty regarding available takeaway capacity for both new and existing wells. Alternatively, or in addition, larger operators could directly invest in additional takeaway capacity.

Operators can coordinate with midstream companies regarding planned maintenance and arrange for reduced production or temporary alternative on-site capture technologies, such as CNG trucking, during those periods.

Technology Alternatives:

List of technology alternatives with link to information or contact information for the company/developers.

Name/Description of Technology	Link (and contact info for company if available)	Availability	Feasibility	Cost Range (choose one)
		In use or in development		Low Medium High

Auto igniters for new flares	Link	In use	Feasible	Low
Auto Igniters (including requirements to retrofit older existing flares)	Link	In use in some flare designs, but not all	Feasible for some flare designs, but not all	Medium to high
NGL recovery		In use – e.g., in ND	Scaleable; effective; best for rich gas; reduces only a portion of the associated gas. Well pads designed for hydraulic fracturing equipment will have additional available space when that equipment is removed. Residue gas contains methane, ethane and small amounts of propane; too "rich" for natural gas vehicles. Equipment footprint and spacing requirements often	Low to negative High

			present challenges, especially after interim reclamation Increases product storage and truck traffic at production site.	
Compressed natural gas (CNG) transported to processing plant or other input point on gathering system by truck.		In use Operating at 5 or more well sites in 2015.	Scalable; works for all gas compositions; best for wells within 20-25 miles of gathering system/processing plant access; can address all of the associated gas. CNG marketed for vehicle engines is challenged as infrastructure is lacking and fuel standards require high-purity methane. CNG viability vs. diesel is dependent upon CNG transportation costs.	Low to negative High
Gas to power generation for on-site use		In use	saleable; effective; best with lean gas; can pair with NGL recovery; uses only a portion of the associated gas. Reliability of generation system is critical to ensuring power for production equipment. On well by well basis cannot capture all gas to generate power.	Low to negative High
Gas to power generation for grid		In use	Requires multiple wells for viable scale and location near grid Low price for power makes economics of grid-interconnect challenging at the wellsite. NM electric power provider's	Low to negative High

			willingness to accept distributed generation is not widespread.	
Reinjection of associated gas for EOR		In use At least 5 producers in TX;[105] long-term use in Alaska	Long-established technology for conventional wells. Requires available depleted oil fields or other reservoirs, capital investment, compressors, possibly additional flow lines; effectiveness depends on particular formation.[106]	Low to negative Profitable where effective in boosting oil recovery (e.g., potential for "significant" additional recovery; "30-70% gain in oil output from older wells")[107]
Reinjection of associated gas for storage		Long-term use in AK	Long-established technology. Requires available depleted oil fields or other reservoirs, capital investment, compressors. If reinjected into a different reservoir (salt cavern, aquifer) would require new well.	??
Reinjection solutions that have been presented to NMOCD. These may require development of appropriate permitting procedures.				

What technology alternatives exist to reduce or detect emissions? Please list all alternatives identified along with contact information for further investigation of this technology or process.

It is important to note that the best solution to flaring is always having a sales pipeline. Industry proactively employs science, innovation, technology, and collaboration to prevent waste and reduce environmental impacts. Some oil and

[107] Hoffman et al., The Benefits of Reinjecting Instead of Flaring Produced Gas in Unconventional Oil Reservoirs, Unconventional Resources Technology Conference, 1640 (Aug. 25-27, 2014); Energywire, Texas' gas glut is so bad, drillers pump it down wells (June 10, 2019); Carbon Limits, Improving utilization of associated gas in US tight oil fields, Appendix 2, 10 (April 2015).

gas companies have committed to voluntary initiatives to reduce flaring without regulatory requirements. Companies also utilize some of these technology alternatives in the EERC and HARC databases to increase the destruction and removal efficiency of flares and identify beneficial or lease uses of gas in oil and gas operations.

There are a number of technologies in use today that can assist companies with gathering associated gas that might otherwise be flared in the absence of adequate infrastructure. These technologies utilize mobile conditioning and processing equipment to produce a marketable product transportable by truck:

- Natural Gas Liquids (NGL) Skids – liquids (e.g. C3+) are extracted from the gas phase (typically through mechanical refrigeration or JT (Joule-Thompson) effect) and hauled by truck off location, leaving a leaner residue gas phase on site; liquids are delivered to a plant or pipeline for sales.
- Compressed Natural Gas (CNG) – gas is compressed to reduce shipping volume and transported in special trailers where it can be delivered to a plant or used for power generation for production operations or hydraulic fracturing or other gas use.
- Liquefied Natural Gas (LNG) – lean gas is cooled to approximately -260°F to convert to a liquid state so it can be transported in special trailers to a gas plant for sales or to a remote location for power generation or other gas use; the liquid will be re-gasified at these destinations.

Another example is the onsite generation of power production using produced hydrocarbon vapors as fuel mentioned above. See section above for more details.

Auto igniters can also assist in maintaining the pilot. This technology replaces the intermittently or continuously burning flare pilots with electrical sparking pilots similar to a modern gas stove. These sparking pilots require low electrical power that can be supplied from a battery with solar recharge in remote sites. In addition to using electronic flare ignition devices for pilots, facilities may also install sensors to detect the pilot flame and shut off fuel gas if the pilot is extinguished.

What are the pros and cons of the alternatives?

Each technology alternative has its own pros and cons. Featured below are the pros and cons of two specific alternatives.

Natural Gas Liquids Skids

It is only possible to install temporary capture equipment (such as a natural gas liquids (NGL) extraction skid) on locations that are large enough to accommodate the NGL skid, ancillary equipment, and tanks and still meet spacing and safety requirements.

NGL Skids will not operate at very low flows (there is a minimum turndown rate), meaning that these units cannot reasonably be used to process the sometimes small flare volumes occurring when sales lines are at maximum capacity. Gas production may quickly decline to rates much lower than the temporary capture equipment's minimum turndown rate necessary for operation. When the production rate declines, the unit must be moved to a new location, which incurs relocation costs and requires an active drilling program to provide new pads with adequate volumes to justify equipment deployment and operation based on sufficient gas production. Otherwise the equipment would need to be on standby, and operators would be required to pay significant costs to guarantee immediate deployment when the equipment is necessary.

Furthermore, as referenced in the North Dakota's Energy and Environment Research Center study, it has been shown that NGL operations in the Bakken have poor runtime under some operational scenarios.
https://undeerc.org/flaring_solutions/pdf/CW_Tech_Study_April-2013.pdf

Due to high temporary capture equipment cost, economics may be poor, especially during periods of low gas and NGL commodity pricing. Third party companies offering turnkey temporary capture solutions often charge high premiums to cover capital and operating costs that will not be offset by liquids revenue in today's market. Furthermore, pairing two or more technologies such as NGL and CNG for liquids recovery and sales of the gas may compound the economic infeasibility of temporary capture technology. This is a case-by-case assessment for individual operators.

Liquid recovery equipment, including compression and refrigeration hardware for NGL, CNG, or LNG, is not designed to operate as an interruptible service. When employed as a backup to a primary gas gathering pipeline, all inlet gas supply to the temporary capture equipment is interruptible. The equipment will not function properly with an interruptible gas supply and will shut down when the gas supply is interrupted. Most liquid recovery equipment requires an operator onsite to manually restart the equipment following a shutdown of the gas supply, meaning that widespread usage of liquid recovery units as a backup to the primary gas gathering pipeline would require an unreasonable number of operators, which is another factor potentially impacting economics.

In addition to requiring a constant gas supply, liquid recovery equipment also requires a consistent rate of gas supply. Due to fluctuating sales capacity on the gathering pipelines, the gas stream to the liquid recovery equipment is highly variable and would not allow for proper equipment function when temporary capture equipment is used for capturing any excess gas not sold via permanent gas gathering lines. Liquid recovery equipment relies on trucking to remove liquids offsite, which can be unreliable during wintertime. In addition, trucking is an expensive mode of transportation, particularly relative to low liquids prices.

NGL, CNG, or LNG produced would still need to find an end market to absorb the product. For example, NGLs will still have to be fractionated. Gas plants are not normally designed to handle large and frequent truck volumes of NGLs. CNG and LNG will have to find a use or available reinjection point (which then requires further equipment).

Onsite Electrical Power Generation

Onsite electrical power generation, in excess of that required onsite, can only be used where there is acceptance by electrical power providers of electrical power generated by burning hydrocarbon vapors on-site at production facilities. The power produced would help alleviate electrical power supply constraints in areas where crude oil and natural gas production activities place the highest demands on the grid.

NM electric power provider's willingness to accept distributed generation from oil and gas sites with stranded gas or limited takeaway capacity could allow the gas to be utilized to support the electrical demands of the state, thus offsetting flaring. Distributed generation could allow for on-site equipment to utilize electricity, reducing demand on diesel generators or the grid and supplement the grid with power generated in excess of site demand.

<u>Reinjection and on-site capture technologies</u>

Reinjecting associated gas for storage and/or EOR avoids the waste of such gas, except for the small portion that may be released during production using EOR, and EOR can significantly boost oil production.[108] Reinjection for EOR has long been used in conventional oil production, and is currently being used by at least five producers of tight oil in Texas.[109] It requires availability of appropriate oil reservoirs or other reservoirs. Operators would have to incur the capital costs of developing an injection well (or adapting older wells to be used as injection wells), as well as operating costs of

[108] Hoffman et al., The Benefits of Reinjecting Instead of Flaring Produced Gas in Unconventional Oil Reservoirs, Unconventional Resources Technology Conference,1640 (Aug. 25-27, 2014); Energywire, Texas' gas glut is so bad, drillers pump it down wells (June 10, 2019).

[109] Texas' gas glut is so bad, drillers pump it down wells (June 10, 2019).

compressors.[110] For EOR, some make up gas and additional flow lines might also be needed at single well sites.[111] The effectiveness for EOR depends upon the particular formation targeted to enhance oil production.[112] Reinjection for EOR could be profitable where effective in boosting oil recovery. One study found the potential for "significant" additional recovery, a payback period of 7 years, and a 17% rate of return at $55/barrel oil.[113] Recent use in the Eagle Ford has shown a "30-70% gain in oil output from older wells," and that it "can potentially extend crude production volumes in older wells by 18 to 24 months."[114]

Operators can also use alternative on-site capture technologies to beneficially use the gas on-site or reduce the flared volumes. Proven technologies already in use include:
--NGL recovery, which reduces the volume/intensity of the flare, while recovering higher value product for sale;[115]
--Compressed natural gas (CNG) trucking;[116] and
--Gas to power generation, at a local or grid level.[117]
These technologies would not replace traditional gas gathering, but give operators flexibility in finding ways to utilize gas from a pad. For example, if build-out of a gathering system is delayed, these portable approaches could be used to utilize gas in the gap period.

NGL recovery is portable, scalable and low or negative cost. It works best with rich gas. It is only a partial solution, as it eliminates only a portion of the flare (from 5% to 21% depending on the type of NGL system and whether it is a single or multiple wells), but it also works well in combination with other alternative technologies, such as power generation for local load, because the remaining gas is more suitable for engines and compressors. NGL recovery can use a simpler or more complex system. A simpler system is smaller and requires less capital, but also eliminates less of the flaring volume.[118] If allowed, the use of NGL recovery on wells selling gas into gathering systems could also increase the throughput of the gathering system by reducing liquids drop-out in gathering pipelines.

With respect to potential space constraints noted above, the well sites at issue are designed to accommodate fracking equipment at the time of completion/recompletion, which means additional space is available on most sites. However, safety setbacks do impact space constraints for the various equipment types. It is unclear how many sites would be precluded from deploying this option due to space constraints.

With respect to concerns noted above regarding decline rates, NGL skids are designed to be mobile and moved from site-to-site to address that reality, and many or most operators in the Permian do have "active drilling programs," which means that equipment could be moved to new sites if the operator continues to need to reduce flaring volumes.

Note that cost of transport can create a significant discount to benchmark prices and negatively impact an already uneconomic technology.[119]

Note that the study cited as support for the previous sentence concludes: "NGL removal will not single-handedly reduce the number of flares, but it will reduce the overall quantity of flared gas and will create a viable secondary revenue stream for wells for which gathering pipelines have not yet been installed. In fact, several companies are now pursuing this business opportunity within the Bakken region."[120]

CNG trucking is portable, scalable and low or negative cost. It works with all gas compositions, and is most feasible at wells that are within 20-25 miles of a processing plant or other point that the gas can be put into the gathering system. It can reduce the flared volume by 91% to 98%, depending on the composition of the gas and whether it is deployed for a single or multiple wells.[121] This option would be most effective not as an intermittent backup for temporary upsets in the gathering system, but rather as a longer term (but not long-term) alternative if a planned capacity increase is delayed for a period.

Gas to power generation for on-site loads is portable, scalable and low or negative cost, with significant cost savings from substitution for diesel. It works best with lean gas, and thus can be coupled with NGL recovery. It can reduce the flare volume by an estimated 18% to 22%, depending on the electricity load of the site, and can use either a reciprocating engine or gas turbine.[122] Generation for use on-site can also support other methane emission reduction efforts such as using electric power rather than pneumatic power to run equipment such as pumps and controllers. In addition, generation for local use might potentially help provide electricity used in gathering systems as well.

Gas to power generation for the grid is low or negative cost (due to electricity generation revenues) where deployable, but requires a larger quantity of gas from multiple wells and proximity to the grid.[123]

Additional alternatives that are less well-proven but have potential include: ammonia production; mini gas-to-liquids – methanol; mini gas-to-liquids – Fischer Tropsch; and mini-liquefied natural gas.[124]

Better development planning, communication with midstream companies, and focus on optimizing the timing of new production with the availability of takeaway capacity offers the potential for substantial reductions in flaring, at potentially low or negative costs. To the extent that this is implemented through better communication with midstream operators and realignment of how the operator prioritizes the next project for development, it could require managerial resources. Where aligning new production with takeaway capacity availability may involve some delays and/or additional investment in gathering systems, there is potential cost to operators. Similarly, entering into contractual arrangements to ensure access to the gathering system would impose some costs. Some of these costs would be recouped by selling rather than flaring the gas.

As discussed above, all of the technological alternatives discussed in detail here use proven technologies that are in use or have been used by some operators. Some technological alternatives work best for rich or lean gas, while others work with all gas compositions. All of the alternatives discussed above (except power generation for the grid) can be deployed at single well sites or scaled up to multiple well sites. Analyses indicate that each of these alternatives have low to negative costs. Some, such as NGL recovery or local power generation are only partial

solutions, but if low cost, that would still be worthwhile, and they would be more effective in combination. Some alternatives are relatively technologically straightforward, such as NGL recovery, CNG trucking, and power generation, while the effectiveness of gas reinjection for EOR in tight oil formations appears to depend upon the specific formation in which it is used and may well improve with additional testing and refinement.

Below is a summary of the 2015 market prices assumed in the Carbon Limits report as compared to current market prices:

	Carbon Limits[125]	U.S. Energy Information Administration
Natural Gas	$4.00/MMBtu	$1.44/MMBtu[126] - Southwest
Natural Gas Liquids	$13/MMBtu	$4.62/MMBtu[127] - July 2019

Costs of Methane Reductions:

What is the cost to achieve methane emission reductions?

As of August 2019, the EERC's Flaring Solutions database contained 33 companies with technologies in the following categories. Approximately 50% of these companies have had units deployed at some point in time.

- NGL recovery
- Power production
- CNG or LNG production
- Gas conversion to chemicals or fuels

Below is a summary of the EERC NGL Liquid Recovery Economics for the Bakken from August 2019. The Key Challenge: Low NGL and ethane value, and large distance from Bakken formation to market (transportation cost)

	August 2019
Total gas treated[1]	1000 mcfd

[125] Carbon Limits, Improving utilization of associated gas in US tight oil fields at 57 (April 2015).
[126] https://www.eia.gov/todayinenergy/prices.php
[127] https://www.eia.gov/dnav/ng/hist/ngm_epg0_plc_nus_dmmbtum.htm

NGL Recovery[2]	3 gal/mcf
NGL Value[3] (net back)	<$0.20/gal
Annual costs[4] (lease, mobilization, royalty)	$569,520
Annual NGL Revenue[5]	$196,800
Net Profit[6] (Loss)	($372,720)

Assumptions:
[1] Larger systems have few locations where 100% capacity is achievable. Smaller systems suffer from economy of scale.
[2] Higher recovery efficiency typically results in higher ethane content and value deduction.
[3] NGL over supply and cost of transport can create a significant discount to benchmark prices.
[4] Annual costs ranging from $0.75-2.00/mcfd capacity ($22,500/mo. - $60,000/mo); three mobilizations/yr at $60k each; and royalty of 15% on NGLs sold.
[5] Annual NGL revenue assumes 90% capacity factor
[6] NGL recovery systems provide challenged economics under the best conditions.
https://undeerc.org/flaring_solutions/pdf/CW_Tech_Study_April-2013.pdf

Note that the scenario presented above (recovery of 3000 gallons of NGL per day for a year, with an annual cost of $373,000, rather than combusting those NGLs if left in the gas sent to the flare) would prevent significant amounts of pollution. Assuming a density of NGLs of ~0.6 (relative to water) and that the NGL is 83% carbon by weight (based on the elemental ratio of butane), flaring 3000 gallons of NGLs a day for one year would emit 7,500 tons of carbon dioxide, assuming perfect combustion. (To the degree combustion is not perfect, the flare is emitting other pollutants aside from CO_2.)

As discussed above, more and better coordination with midstream companies and engaging in development planning to better align the location and timing of new associated gas production with available takeaway capacity are approaches to reducing venting and flaring that operators can use at negative cost. If operators delay production at wells where, for example, projected takeaway capacity has not yet become available, that will impose costs, with the magnitude depending on multiple economic factors regarding the financing of the well, as well as the length of delay. If, however, as a technical matter, operators can deploy other alternative technologies such as NGL recovery, CNG trucking, gas to power generation, or reinjection at a lower cost than the cost imposed by delaying production, those alternative costs, rather than the cost of delay, should be considered the applicable cost of ensuring capture in such situations.

As noted above, for reinjection for EOR, one study found the potential for "significant" additional recovery, a payback period of 7 years, and a 17% rate of return at $55/barrel oil.[128] Recent use in the Eagle Ford has shown a "30-70% gain in oil output from older wells," and that it "can potentially extend crude production volumes in older wells by 18 to 24 months."[129]

Carbon Limits' report on alternatives to flaring for tight oil formations[130] provides extensive cost information for CNG trucking, NGL removal, and on-site electrical generation, where the cost of the measure depends upon many factors such as the amount of gas available at the site, composition of the gas, location and configuration of the sites, etc.

[129] Energywire, Texas' gas glut is so bad, drillers pump it down wells (June 10, 2019);
[130] http://www.catf.us/wp-content/uploads/2015/04/CATF_Pub_PuttingOuttheFire.pdf

Using data from the Carbon Limits study, MJ Bradley and Associates (MJB&A) calculated the costs of the flaring rule that BLM proposed in early 2016. They concluded that CNG trucking would be an appropriate way for operators to comply with the rule, and calculated that costs of the rule assuming that all capture of gas (relative to current flaring levels at BLM leases) would occur via CNG trucking. This is a conservative assumption, since many operators will get pipelines hooked up to wells under a gas capture standard, and pipeline transport will be more efficient than CNG trucking in many cases. MJB&A also used conservative (high) cost assumptions for CNG trucking. They found that the standards, as BLM proposed them, would have low or negative cost for operators (maximum *nationwide* cost to operators of the BLM gas capture requirement would have been $1.5 million, according to MJB&A). However, we note that MJB&A was using a discounted projection of Henry Hub prices for gas, which are higher than current Waha hub prices. Finally, MJB&A found that when avoided damages from climate pollution were included (i.e., using the social cost of CO_2, the flaring standard BLM proposed would have an overall benefit to society of about $100 million per year.

When BLM finalized the 2016 flaring standard, the agency modeled the costs and benefits of the finalized standard (which was slightly modified from the proposed standard that MJB&A analyzed).[131] BLM's analysis assumed that the predominant response by operators to the flaring standard would be CNG trucking (but unlike MJB&A's analysis, BLM did not assume that 100% of operator response would be CNG trucking). BLM also used costs from the Carbon Limits report for the CNG trucking portion of operator response. Depending on discount rate, and neglecting the societal benefit from reduced pollution, BLM estimated that over a ten year period, the rule would have had a low benefit to operators if CNG trucking costs are low, and would have had a net nationwide cost to operators of ~$250 million over ten years if CNG trucking costs are high.

What would be the implementation cost?
For new wells?
See Technology Alternatives Above

For existing wells?

Are there additional technical analyses needed to refine benefits/costs estimates?

[131] See pages 45-50 of BLM's Regulatory Impact Analysis for 2016 Final Venting and Flaring Rule (available here: https://www.regulations.gov/document?D=BLM-2016-0001-9127).

3. IMPLEMENTATION

For each piece of equipment or process, please consider the following questions and add other relevant information. If relevant, please identify if the answers are different for large company and small company requirements or are different for well type or basin.

Implementation Feasibility:

What is the feasibility of implementation (availability of required technology or contractors, potential permitting requirements, potential for innovation)?

It should be noted that the various technologies are engineered solutions and are site specific with respect to current facility design, economics and technical feasibility.

See Technology Alternatives Above

See discussion of better planning and alternative technologies above, as well as the discussion of the pros and cons of alternatives.

What is the useful life of equipment?

See Technology Alternatives Above

What are the maintenance and repair requirements for equipment required for methane reduction?

See Technology Alternatives Above

How would emissions be detected, reductions verified and reported?

Avoided venting and flaring would reduce reported venting and flaring volumes. There would not be a need to separately report the volumes avoided by specific activities.

4. CHALLENGES AND OPPORTUNITIES TO ACHIEVE METHANE REDUCTION IN NEW MEXICO

For each piece of equipment or process, please consider the following questions and add other relevant information. If relevant, please identify if the answers are different for large company and small company requirements or are different for well type or basin.

What regulatory gaps exist for this equipment or process? Are there regulatory gaps filled by the proposed implementation?

When reporting of flared volumes (F code) was rolled out, the only guidance given to operators was “The new code “F” is to be used to report the volume of gas that is flared on a well basis, or total volume if flared at a common battery or gathering system and reported under one point of disposition.” There was no formal standard or protocol that detailed what types of flaring to report or how to measure or estimate flared volumes.

Also, C-115s are a requirement for operators of oil and gas wells. Midstream flaring is either permitted or reported to NMED.

Because the aforementioned technology alternatives may not be cost effective in all instances, regulatory incentives should be considered to assist in promoting their use. For example, North Dakota recognizes the following as surplus gas being utilized in a beneficial manner that may be considered as captured gas:

- Equipping the well(s) with an electrical generator that consumes surplus gas
- Equipping the well(s) with a system that intakes the surplus gas and natural gas liquids volume from the well for beneficial consumption by means of compression to liquid for use as fuel, transport to a processing facility, production of petrochemicals or fertilizer, conversion to liquid fuels, separating and collecting the propane and heavier hydrocarbons.
- Equipping the well(s) with other value-added processes as approved by the Director which reduce the volume or intensity of the flare by more than 60%.

Where do conflicting priorities exist between NMED, EMNRD, and NMSLO? Are there opportunities for coordination between these agencies?

The oil and natural gas industry (industry) and royalty interest owners, including the State of New Mexico have an aligned and vested interest in capturing the natural gas produced. The industry has invested billions of dollars, and continues to invest in infrastructure to capture the gas, gather it from thousands of well sites, and transport it through pipelines to sales. When gas cannot be gathered and transported to market for sales, industry has made further substantial investments in flare and combustion devices and gas capture technology to minimize its impact to the environment.

Since some of the flaring is temporary, if there are air permitting requirements for some of these alternative technologies (NGL Skids, etc.), the timing for NMED air permitting approval may not accommodate timely placement of the equipment.

NM contains approximately 27 million acres of Federal Land. The Bureau of Land Management (BLM) manages all permitting of ROWs on federal land. The NEPA process is triggered when a federal agency develops and/or is presented with a proposal for a federal action (e.g., ROW application). There are different levels and scope of a NEPA Review: Environmental Impact Statement (EIS) is the most rigorous; Environmental Assessment (EA) is the most common, and Categorical Exclusions (CEs). The level of NEPA review required will determine the timeframe for approval, which can vary greatly. Consequently, the timing of ROW approval hinders the construction of infrastructure that is needed to reduce flaring.

NMSLO is proposing a rule for cultural properties on trust land which includes an element of landscape planning at the same time it has implemented a policy related to species surveys.

While the NM statute and regulations prohibit waste of gas, as discussed above, the current regulations allow for almost unlimited exceptions and have failed to adequately control venting and flaring.

In addition, the current regulations do not clearly require operators to flare in lieu of venting in all situations in which flaring is possible (exceptions should be limited to situations such as emergencies, where quantities are too small to route to a flare, or where flaring is prohibited (such as due to wildfire risk)). 19.15.18.12.F. NMAC states that "Pending connection of a well to a gas-gathering facility, or when a well has been excepted from the provisions of Subsection A of 19.15.18.12 NMAC, the operator shall burn all gas produced and not used, and report the estimated volume on form C-115." Additionally, BLM's 2018 rule in §3179.6(b). "The operator must flare, rather than vent, any gas that is not captured, except under certain circumstances."

The current regulations require operators to submit a gas capture plan, but the form provided has failed to generate meaningful or effective plans.[132] It requires a simple statement that the gas will be connected to a gas transporter (who is supposed to be identified) and that the operator believes the system can take the gas, but there is nothing that would require an operator to make a real inquiry or analysis of whether the system is expected to have available capacity at the time the well is to come on line, much less provide any such assurance. There is also a section titled "Alternatives to Reduce Flaring" which lists "alternatives considered from a conceptual standpoint to reduce the amount of gas flared." The form itself lists the alternatives *along with reasons to reject them* (e.g., for NGL Removal the form states "Plants are expensive, residue gas is still flared, and uneconomical to operate when gas volume declines"). Since the operator has to provide no information for that section and the form itself rejects the alternatives, it appears highly unlikely that the requirement to file a Gas Capture Plan has incentivized any operator to consider, let alone seriously evaluate the feasibility and economic implications of, implementing any of the listed alternatives.

Reducing venting and flaring reduces resource waste and air pollution, and where the gas is captured, increases the production of gas resources and the resulting revenues without additional land disturbance. Thus, policies to reduce venting and flaring should be regarded as win-win-win, and there should be no conflicting priorities among these agencies.

Are there existing regulations related to methane that do not address the intended purpose? Identify any unintended barriers to methane reductions/capture that may hinder proposed processes.

Other considerations or comments (e.g. particular design or technological challenges/opportunities, co-benefits, non-air environmental impacts, etc.?):

All policies to reduce venting and flaring reduce not only methane, but also VOCs, NOx and toxic air pollutants, producing improved air quality and health benefits for nearby residents.

SHUTTING IN A WELL OR CURTAILING PRODUCTION

In general, the New Mexico Oil and Gas Act requires the New Mexico Oil Conservation Commission (NMOCC) and New Mexico Oil Conservation Division (NMOCD) to prohibit production voluntarily to address various conditions including poor price environments and downstream upset conditions. and oil and gas handling practices which constitute or result in waste. NMSA 1978, § 70-2-2. The concept of "waste" has been statutorily defined by the New Mexico Legislature to include both underground waste and surface waste. NMSA 1978, § 70-2-3. Underground waste can consist of any practice that reduces or tends to reduce the total quantity of crude oil or natural gas ultimately recovered from a reservoir, e.g. shutting in a well; whereas surface waste consists of unnecessary or excessive surface loss or destruction of oil or gas, without beneficial use. Thus, NMOCC and NMOCD are required by statute to encourage the optimum recovery of oil and gas resources. The federal government and other oil and gas producing states similarly prohibit the creation of waste. *See e.g.,* 30 U.S.C. § 187; 30 U.S.C. § 225; WYO. STAT. ANN. § 30-5-101.

For the purpose of limiting venting and flaring, "waste" has historically been defined by the federal government and other oil and gas producing jurisdictions as a "preventable loss of [oil or gas] the value of which exceeds the cost of avoidance." Stephen L. McDonald, Petroleum Conservation in the United States, and Economic Analysis, Johns Hopkins Press, 1971 (Reprinted in 2011 by Resources for the Future) ("Petroleum Conservation Economics"), at 129. NMOCD regulations have likewise allowed flaring in situations where "the flaring or venting casinghead gas appears reasonably necessary to protect correlative rights, prevent waste or prevent undue hardships" on the operator. 19.15.18.12.B NMAC. Indeed, flare may provide environmental benefits in certain situations. The New Mexico Environment Department (NMED) has approved

[132] See Gas Capture Plan (ADD LINK TO FORM).

flaring in a variety of situations, and the federal government requires specifically requires flaring in certain situations. *See* NMED, Air Quality Bureau General Construction Permits; 43 C.F.R. § 3179.6(b).

Shutting-in production to avoid flaring would lead to unmanageable gathering system swings. If all operators in the area were to shut-in wells throughout the day to avoid flaring, there would be unmanageable swings on the wells and the pipeline system, with high frequency starts/stops, as all operators shut-in at high pressures, resume production when pressure drops, and immediately back up the pipeline system again when flowing, which again causes all wells in the area to shut-in. This can also lead to frequent trips at the compressor station and additional delays as equipment must be restarted, often manually.

Shutting-in production would affect necessary and routine maintenance operations like pigging. Pigging is the process of launching a malleable or hard plug (called a pig) from an upstream location and allowing pressure to carry the pig to a receiver. The pig sweeps liquid forward and thus reduces liquid in the line. As the pig and liquid front sweep through the system, pressure increases upstream and can thus reduce sales volumes. In areas with rich produced gas (high liquid content), the gas gatherers must frequently pig their lines to manage liquid buildup. Shutting in wells can cause the pig to become stuck because the pressure is too low to drive the pig. Once a pig is stuck, flaring is exacerbated as it is infeasible to override the shut-in valve when pigging occurs with high frequency.

Shutting-in production can also lead to lease default and/or lease maintenance issues. This could ultimately lead to suspended production and the royalties on that production, and wells being shut in (or otherwise cease producing) beyond the term of the lease or leases in question.

Frequent shut-ins can kill a flowing well and lead to premature installation of artificial lift at a significant cost. When a new well is still naturally flowing, artificial lift is unnecessary. Any shutdown poses a risk of liquid loading up in the wellbore and liquid head is greater than available pressure. This is known as "killing" the well. To resume production, a swabbing rig is brought on site to unload the liquids or some means of artificial lift (temporary or permanent) is utilized. If the well has been naturally flowing for a few months, an extended shut-in may require the well be prematurely put on a continuous artificial lift at a cost (gas lift, electric submersible pump, rod pump, etc.). Frequent swabbing increases venting of methane or premature installation of artificial lift again adversely affect well economics. Given lead times and rig schedules, it may take several months to install artificial lift, during which time the well is not producing and may be shut-in or otherwise cease producing.

Shut-in events have the potential to impact the productivity of low permeability hydraulically fractured reservoirs due to various reservoir and mechanical causes. These effects, either individually or combined, have often resulted in a negative effect on productivity of the well and/or an increase in operating costs. It has been well documented in the technical literature that several mechanistic effects associated with shut-in of hydraulically fractured wells can impact productivity and ultimate oil recovery[133]. The damage from repeat shut ins is irreversible and permanent, and is likely to lead to lower ultimate recovery and increased waste. Examples of mechanistic effects include:

[133]S. A. Holditch and D. M. Blakeley, "Flow Characteristics of Hydraulic Fracture Proppants Subjected to Repeated Production Cycles," SPE 19091, 1992.

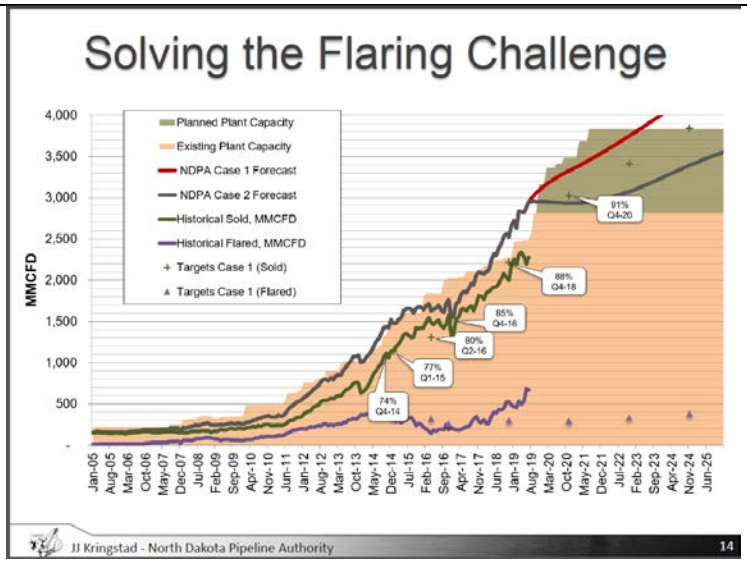
J. Terracina, "Effects of Proppant Selection on Shale Fracture Treatments," JPT Update, May 2011.

- Mechanical stress cycling on the proppant
- Generation of fines
- Potential damage due to fracture fluids
- Need to restore the productivity of the shut-in well through intervention.

PERCENT GAS CAPTURE REQUIREMENTS

Without a robust dataset and a long term coordinated effort including producers, midstream companies and state agency leadership, percent gas capture goals would have no basis in NM. This is why these data improvement changes, as well as better gas capture planning, are noted below as Paths Forward. Informing an appropriate and achievable percent capture goal requires a robust toolkit in a manner that considers anti-trust laws.



- Comprehensive, accurate, consistent and reason based flare volume reports
- Detailed information on current market, pipeline, compression & plant capacity constraints
- Comprehensive overlay of forecasted infrastructure and production data
- Detailed understanding of compression and electrical grid reliability
- Streamlined right-of-way permitting and execution process
- Comprehensive understanding of gas-to-oil ratios (SE NM has 10+ producing zones)
- Incentives for alternative technologies
- Comprehensive gas capture plans that enable best case scenario gas contracts to prevent as much flaring as possible and a hydraulic analysis by my midstream entity, along with the impact of expected volumes from other operators

It is important to note that BLM and North Dakota are the only entities to have attempted to implement a percent capture goal. The BLM's scheme was stayed by a federal district court, thus, the effectiveness and viability was never tested. As explained below and in the case of North Dakota, there are market, rights-of-way, political and other conditions that have impacted the ability for North Dakota to achieve the established goals.

In the fall of 2013, the North Dakota Petroleum Council formed the Flaring Task Force. Members of the task force sought to pool the knowledge and experience of producers and midstream companies operating in the Bakken to identify solutions to better optimize the resource at the wellhead and increase and improve existing infrastructure to transport gas for processing elsewhere. The Task Force's goals were to offer balanced, effective solutions for policy makers and regulators. The Flaring Task Force addressed the North Dakota Industry Commission on January 29, 2014, which resulted in the first of its kind percent gas capture requirements.

In North Dakota, the Pipeline Authority provides monthly updates to the public. The updates provide an overlay of associated gas forecasts and infrastructure buildout as well as month to month maps of where flaring is occurring. NDPA's purpose is to diversify and expand the North Dakota economy by facilitating development of pipeline facilities to support the production, transportation, and utilization of North Dakota energy-related commodities. NDPA is a non-policy, non-regulatory entity.
https://northdakotapipelines.com/directors-cut/

S. Agrawal and M. Sharma, "Impact of liquid Loading in Hydraulic Fracture on Well Productivity," SPE 163837, 2013.
J. W. Crafton, and S. L. Noe, "Impact of Delays and Shut-Ins on Well Productivity," SPE 165705, 2013.

Despite efforts described above, ND is still struggling with meeting gas capture limits. In addition, the depressed market inhibited investment in gas processing and transmission assets. Also exacerbating the issue were 2 rights-of-way issues that amounted to a total of 6% of the total gas flared in ND. Industry reactivated the Task Force with 6 separate committees to assess infrastructure buildout, right-of-way and tribal regulatory challenges, H2S contamination, remote capture technologies, new operator engagement, and reworking of the gas capture plan requirements. In the fall of 2015, the Flaring Taskforce provided the updated information to the North Dakota Industrial Commission in the fall of 2015, which resulted in the adjustment of the gas capture goals.

Note that the near-absence of any sanctions or penalties for companies that fail to meet the targets, as discussed above, means that the regulation as implemented provides little incentive for companies to expend resources on compliance. Given that compliance is likely to involve some cost, while noncompliance involves little to no cost, a profit-maximizing entity will be acting rationally in failing to comply. NDIC guidance updates indicate their enforcement mechanism is production curtailment but it has only issued an enforcement action a handful of times despite clear violations. Data for voluntary curtailment is not available.

5. VENTING AND FLARING - PATH FORWARD[134]

	OPTIONS	DESCRIPTION AND LINK TO INFORMATION IF AVAILABLE. PLEASE LIST THE BENEFIT THAT COULD BE ACHIEVED THROUGH THIS OPTION AND ANY DRAWBACKS OR CHALLENGES TO IMPLEMENTATION	EFFECTIVENESS OF COST NOW (choose one)	REPORTING, MONITORING AND RECORDING OPTIONS, INCLUDING REMOTE DATA COLLECTION	IS THIS OPTION HELPFUL IN THE SAN JUAN BASIN, PERMIAN BASIN OR BOTH
6.1	More detailed reporting on C-115 form (production report)	Developing more consistency across the state in how flared gas volumes are reported (i.e., measurement v. estimation, source of gas reported, requirement to report) will benefit the state as it establishes future rules, requirements, and reduction targets.	HIGHLY COST EFFECTIVE	The reporting requirement should include a protocol that establishes consistent reporting, specifies types of flaring that should be reported and an approved standard for measuring flared gas (or accepted methodology for estimating and verifying flared gas volumes).	
	COMMENT: A. Clarify scope of C-115 – This is currently a production report and it would be helpful to keep that scope rather than adding additional scope (tank vapors, etc.) to this specific report. A separate report for NMED would be appropriate for an emissions inventory.		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
6.2	Establishing requirement to submit Gas Capture Plan with APD through rulemaking	Making it a requirement to submit a Gas Capture Plan through rulemaking makes the submittal of the Gas Capture plan enforceable	HIGHLY COST EFFECTIVE	Submittal of Gas Capture Plan	
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		

[134] The format of the Path Forward table evolved over the course of the meetings as the group tried to identify the best method for capturing the most useful information. As a result, there is some variation in the table headers from topic to topic in the final consolidated report.

6.3	Operators do not vent when gas can be flared instead.	See BLM rules. Substantial methane reductions. Consistent with best safety practices, which already strongly discourage venting methane.	Operators do not vent when gas can be flared instead.	See BLM rules. Substantial methane reductions. Consistent with best safety practices, which already strongly discourage venting methane.	
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
6.4	Operators engage with midstream in more active development planning [Addressed in MAP infrastructure planning report]				
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
6.5	Current regulation (19.15.18.12A NMAC) prohibits an operator from flaring or venting casinghead gas produced from a well after 60 days of the well's completion. Provided the exception process is better defined and includes a notice provision, a reduction to 30 days from the 60 days currently authorized is proposed.	Prevention/reduction of waste Consistent with BLM requirement	HIGHLY COST EFFECTIVE	To be reported as a non-transported volume on C-115	
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
6.6	Auto igniters for new flares	Ensures pilots are lit, minimizing venting from unlit flares	HIGHLY COST EFFECTIVE		
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
6.7	Ensure that all venting and flaring from oil and gas production and gathering upstream of the processing plant is reported on a monthly basis, consistent with clear standards, and made publicly available online. Clarify that C-115 (or another appropriate form) should include venting and flaring that occurs:	Developing more consistency across the state in how flared gas volumes are reported (i.e., measurement v. estimation, source of gas reported, requirement to report) will reduce ambiguity and confusion for industry on what they are required to report, enhance data quality, help the state to develop the most efficient and effective future rules, requirements, and reduction targets, and benefit the public in better understanding how NM's natural resources are	HIGHLY COST EFFECTIVE	The reporting requirement should include a protocol that establishes consistent reporting, specifies types of flaring that should be reported and an approved standard for measuring flared gas (or accepted

	(e.g., monthly) measurements of gas-to-oil ratio.				
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
6.9	Require use of reliable tools for measuring or estimating flared volumes; require regulatory oversight of purchase and calibration of measurement tools (It is important to note that OCD has no authority over purchasing of equipment and BLM requires use of approved equipment under the new measurement rules.)	Norway requires that a regulator is present from the moment the operator places an order to buy instruments (design phase) to calibration of the instruments and tools to decommissioning.	HIGH COST EFFECTIVENESS	Robust recordkeeping and reporting of flared volumes necessary to ensure compliance.	
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
6.10	Establish electronic reporting system for all sources of venting and flaring (e.g., including C-129s and C-141s) upstream of processing plants and make results publicly available online. Note that C-129s are submitted by operators as a "just in case" and volumes are estimated. C-141s are after-the-fact and volumes reported as a non-transported disposition code "L" for lost. Therefore, any actual volumes are reported on C-115s. See "enhanced reporting and measurement protocols."	Reporting all venting and flaring information electronically would reduce administrative burdens for industry and the state, greatly facilitate data analysis, and make results accessible to the public	HIGHLY COST EFFECTIVE		
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
6.11	Condition grant of APD on submission of adequate Gas Capture Plan with APD.	Conditioning grant of APD on submission of an adequate Gas Capture Plan provides operators a strong incentive to submit adequate gas capture plans and makes the submittal of the Gas Capture plan readily enforceable with minimal state effort.	HIGHLY COST EFFECTIVE	Submittal of Gas Capture Plan	
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		

DRAFT

6.12	Specify gas capture plan elements to include (items highlighted below are already part of the NM Gas Capture Plan): --well location; expected drilling, completion, and first production date; expected volumes and pressures; --from multiple wells for the above if operator is planning multiple wells in same area within relevant timeframe; --information about the operator's other current production, and venting and flaring, in the vicinity of the proposed well; --identification of intended gathering system and processing facility for gas production, including pipeline size, pressure, and available capacity now and for the period over which the well is projected to produce, and plan for additional compression if needed; --showing/certification that the operator has communicated projected gas volumes and timing for all operations in the vicinity of the destination pipeline to the midstream company, including current venting and flaring; --showing/certification that midstream company projects there will be available capacity to accept the projected gas production from the specified well; --if pipeline capacity not projected to be available, specific plan for alternative gas use/disposal, with demonstration that the operator has	Compliance with comprehensive GCP requirements would greatly improve information available to midstream operators to plan their systems to align with expected gas production in a timely fashion. It would also document for OCD that the producer has obtained transportation and processing capacity for wells that are drilled at the time they go into production. However, the data supplied during this phase of planning is a snapshot in time and may or may not be drilled. See ND, BLM 2016 rules. Expanding the elements required for an adequate GCP would ensure that the operator produces a plan that results in capturing (or disposing through a means other than venting / flaring) the projected volumes of gas over the projected lifetime of the well. For operators seeking APDs for wells without a drilling schedule or sufficient information to forecast production, OCD should consider establishing a process for conditional APD approvals with requirements to update the GCP when required information is available before final drilling approval is granted.	HIGHLY COST EFFECTIVE

	the ability to implement such plan (e.g., if plan to reinject gas, show permit applications submitted; if plan to generate for grid, show communications with grid operator, etc.) -measures to prevent waste over the life of the well, including additional compression and operator elected proper plugging and abandonment to avoid the rare instance of orphan well venting scenarios.				
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
6.13	Define "undue hardships" (e.g. maintenance, emergencies) as per 19.15.18.12.B NMAC while maintaining the ability to apply for an exception.	Provides regulatory certainty on flaring events that establishes a basis for NMOCD to make an inform decision to grant or deny an exception. See: "Describe how the equipment or process is used:" section starting on page 3 that describes "When Flaring is Necessary". Consistent with some NMED exceptions. Note that other recommendations below would move the state away from case-by-case exemptions to reduce administrative burden on the state and industry and boost overall effectiveness of limits on venting and flaring.	HIGHLY COST EFFECTIVE	Documentation and notification of events, record keeping limits	
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		

DRAFT

6.14	Prohibit operators from venting whenever gas can be flared instead; i.e., only allow venting when flaring is not possible as a technical matter or where flaring is prohibited due, e.g., to wildfire risk. Note that both the BLM and OCD have rules requiring flaring rather than venting. See page 162 for BLM rule §3179.6(b) and page 163 for NMOCD rule 19.15.18.12.F.	See BLM rules. Substantial methane reductions. Consistent with best safety practices, which already strongly discourage venting methane.	HIGH COST EFFECTIVENESS	Report all venting events, volumes and circumstances allowing (e.g., liquids recovery operation). Continue remote sensing/satellites to track area-wide decreases in methane emissions.	
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
6.15	Adopt performance standard for new and existing flares to ensure high destruction removal efficiency (minimum 98%) and continuous burning pilots.	Minimizes excess emissions due to incomplete combustion and improperly operating flares. See CO, WY, ND.	HIGH COST EFFECTIVENESS	Require operators provide manufacturer specification for flares demonstrating compliance with DRE and require operators inspect flares routinely to ensure proper operation	
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
6.16	Set overall limit (with no exceptions for specific activities/circumstances) on the gas flared by each operator. Limit could take the form of a minimum percentage and/or volume of total gas production from the operator in the State that must be captured. If apply sufficiently stringent overall percentage limits, could potentially allow for a limited volume of flaring/well on average over all of an operator's wells (note that C-115s are required to be	See ND and 2016 BLM rules, and specifically 2016 BLM rule set volume of allowed flaring rather than case-by-case exemptions. Allows market to optimize approach rather than requiring the state to select or mandate use of particular technologies or practices. For example, had operators been limited to flaring no more than 1% of their reported associated gas in 2018, this measure would have avoided the waste of 77% or 28 bcf of gas in that year, as well as the associated volumes of CO2, NOx and other pollutants.[135] This approach still recognizes that avoiding flaring in some circumstances, such as emergencies, may	HIGH COST EFFECTIVENESS	Report all flaring volumes, without exceptions. Robust recordkeeping and reporting of flared volumes necessary to ensure compliance.	

[135] Calculation by Clean Air Task Force based on C-115 data.

NMED Exhibit 10 - 0194

	submitted the 15th day of the second month following the month of production, therefore, an average will not be based on most current volumes) that may be deducted from the capture percentage compliance calculation (in lieu of requiring burdensome case-by-case requests and approvals for emergencies, maintenance, and force-majeure events etc.), and ratchet that deductible volume down over time, giving operators an incentive and opportunity to fine-tune operations to reduce such events.	not be cost-effective or even possible, but it does so without requiring industry and OCD to engage in the burdensome process of case-by-case requests for exemptions, reviews, and determinations.			
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
6.17	Establish automatic consequences for failure to meet capture percentage standards. E.g., set a meaningful fee per mcf gas flared/vented in contravention of applicable capture standard, due upon notice of exceedance; and/or require operator to be in compliance with capture percentage standard as a pre-condition for issuance of any new APD for such operator. Ensure flaring policy is enforceable and penalties sufficient to outweigh financial incentives to flare rather than capture.	Effectiveness of ND rules has been severely undermined by lack of enforcement or even consequences for operators that consistently fail to achieve capture standards. OCD has very limited enforcement resources. Establishing automatic penalties would provide a clear, consistent incentive for operators and minimize implementation burden on OCD. Limiting production as a penalty for failing to meet capture standards may be less effective than (meaningful) financial penalties, as both the state and the industry aim to increase, not reduce, production.	HIGH COST EFFECTIVENESS	Robust recordkeeping and reporting of flared volumes necessary to ensure compliance.	
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
6.18	Assess severance tax and royalties on all gas produced rather than only on gas produced or sold	May require legislative fix to change tax and royalty policy.	HIGH COST EFFECTIVENESS	Calculate additional revenues from alternative tax and royalty levels.	

DRAFT

	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
6.19	Prohibit flaring unless permitted by OCD. Only permit flaring required for specific delineated circumstances (e.g., safety emergencies, unplanned infrastructure maintenance, upset conditions, etc.). Permit would specify volume and/or time limit. Consider exempting defined de minimis amount of flaring from permit requirement. Monitor to avoid repeat exemptions and long-term flaring.	See Alaska (clear prohibition on flaring other than in narrow circumstances); Norway (extends capture requirements to all phases of production) Ensures any allowable flaring, in particular during emergencies or for safety, is kept to a minimum.	HIGH COST EFFECTIVENESS	Robust recordkeeping and reporting of flared volumes necessary to ensure compliance. System to flag repeat applications to flare.	
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
6.20	Create permitting options for some of the more recent reinjection solutions that have been presented to NMOCD.	New EOR projects by injecting produced gas may reduce flaring by not crowding pipeline capacity.		UIC permit application type and requirements.	
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
6.21	Approve alternative technology by more streamlined NMED permitting process.	Once alternative technology is proven, permitting process should be expedited to accommodate temporary flaring events.	HIGH COST EFFECTIVENESS	Document proven alternative technologies and make available via NMED website.	
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
6.22	Clarify the definition of waste in venting/flaring regardless of whether or not it is an authorized exemption.	Identify/define “waste” for the purposes of royalty reporting.	HIGHLY COST EFFECTIVE	Line by line C-115 reporting	
	COMMENT A. Evaluate compatibility with existing statutes/regulations.		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
6.23	Ability to amend C-115 by line to ensure accurate reporting/ability to amend reports vs. requiring a company’s statewide C-115 production to be re-submitted.	The benefit would be that agencies could more readily assess line by line modifications and would also minimize production inaccuracies for both the company and the agencies.			
	COMMENT:		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:

NMED/EMNRD METHANE ADVISORY PANEL

SECTION 7, WORKOVERS/LIQUIDS UNLOADING

Discussion for MAP members on September 12, 2019

NOTE: The focus of this report is processes, and the associated equipment, directly related to the release or capture of methane gas. We are not requesting information on processes/equipment that are not related to the release or capture of methane gas.

1. DESCRIPTION OF PROCESS AND EQUIPMENT

Provide a description of the processes and/or equipment used in oil and/or gas extraction for this topic. Note that this report template will be used for all topics of the MAP review and, thus, not all questions or information may be relevant for each topic. If information is not relevant, indicate N/A. Note any differences expected for differing well types, industry sector, or basin location.

Technical description of the process or equipment:

Manual Liquid Unloading:

Managing wellbore liquid build-up in gas wells is fundamental to maintaining production, avoiding early abandonment of wells and maximizing resource recovery. Wells and reservoirs follow a continuum of flow regimes in their economic life as the reservoir depletes, production declines, wellbore (tubing) velocity goes down, and liquid loading begins to occur in the wellbore. Liquid loading begins when the velocity up the production string is not sufficient to lift liquids up to the surface at a pressure that will allow production to overcome the surface equipment and out of the wellbore. While pressure is a factor, it is generally a lack of velocity, which causes liquids to accumulate in the wellbore (i.e., "to load/load up"). Gas well unloading is a complex field of science and engineering where a large number of different technologies, tools and practices must be matched to an individual well's characteristics at each stage of its lifecycle to most efficiently manage liquids and maintain economic viability of the well. No single technique will be adequate or appropriate across the full lifecycle of a well.

DRAFT

As a well moves through its lifecycle, the appropriate approach to managing liquids changes. New wells typically have sufficient production rates and flowing velocity so that liquids loading is not an issue. As the portion of the reservoir accessed by a well depletes, the production rate and velocity declines and eventually a point is reached where liquids loading begins to be an issue. The time at which liquids loading occurs is dependent on the reservoir characteristics and varies from well to well. At the onset of liquids unloading, techniques that rely on the reservoir energy are typically used. These include:

- **Intermitting:** Shutting in a well for a period of time to allow the reservoir to "refill" the pressure and volume "void" in the near-wellbore reservoir so that when the well is restarted the production rate and velocity are higher and the well can "unload" liquids through the normal production route to sales;
- **Velocity strings:** Installing a smaller diameter tubing string in the well that increases the flow velocity at a given production rate sufficiently to drag liquids up the wellbore and prevent liquid loading;
- **Surfactants and foaming agents**: Introducing surfactants and foaming agents to the bottom of a well (various techniques are used) creating foam with lower specific gravity which enables liquids to be carried up the wellbore at lower velocities.

These techniques can be used individually or in combination to manage wellbore liquids and maintain production.

Eventually a well will reach a point where the reservoir energy is not sufficient to remove the liquids from the well and adding energy to the well is necessary to continue production. Common approaches are to install artificial lift. Two common methods are:

- Installing a plunger lift system that changes the dynamic for removing liquids from velocity to differential pressure between the bottom-hole and the surface/gas collection line; or
- Installing wellhead compression that lowers the surface back-pressure on a well, increases production rate and flowing velocity, and increases the differential pressure between the reservoir and the collection/sales line.

There are a number of different pump types and gas lift systems, each more effective in some respects than others. Installation of a system to add energy to a well is an economic decision based on whether the continuing production will be sufficient to support the costs of installing and operating a pump or gas lift system.

There are some cases where the need to create additional differential pressure is necessary to manually unload accumulated liquids. These cases include onsite or downstream equipment downtime in the gas gathering system.

DRAFT

NMED Exhibit 10 - 0199

One item of clarification is that deliquification, liquid unloading and venting are not synonymous terms. Liquids can and are routinely removed from gas wells without venting.

Workovers:

Some wells may need to be re-stimulated in a previously completed formation or in a new reservoir in the same wellbore. These operations are called recompletions. Additionally, some wells will require supplementary maintenance to maintain production or minimize the decline in production and are referred to as workovers. Typical workovers include rod, tubing and casing repairs, siphon string or artificial lift installation, paraffin removal, and pump repairs.

Both recompletions and workovers differ from completions in that they are performed on wells that that have previously been completed and have produced some reservoir fluids (water, oil, and/or natural gas). These wells will have to be prepared before recompletion or workover operations can begin. If the well is still producing and/or has pressure, the well will need to be blown down before it is safe to remove the tubing head and install the blowout preventers (BOP's). The well pressure can be decreased by opening the casing to the sales line or the suction of a wellsite compressor. In many cases the fluids in the wellbore will build up to the point the well dies, this is referring to the instance where the hydrostatic pressure of the accumulated fluids is equal to the reservoir pressure. In some cases, it will be necessary to pump water or other fluids in the wellbore to kill the well. As a safety precaution, after the BOP's are installed the well is usually vented to atmosphere via a tank.

In the case of a recompletion, after the well is prepared (well blown down, BOP's installed, and the tubing removed) the stimulation and flow back will be the same as the issues that were presented in the COMPLETIONS/STIMULATIONS Report. A recompletion would be a stimulation of an existing well, in a different horizon, that has already been completed. The preparation of the well for a recompletion is the source covered in this Workovers/Liquids Unloading Report. The preparation of the well, as mentioned above is the process in which the pressure on the wellbore is reduced to atmospheric pressure by venting the well through an atmospheric storage tank. The pressure is relieved to atmosphere to ensure the well can safely be worked on (workover) or recompleted.

Workovers are usually short duration projects that only last a few days or weeks at the most. After the well is prepared (well blown down and the BOP's installed) the workover operations can begin. For the safety of the rig crew, the well is usually allowed to vent to atmosphere via a tank for the duration of the workover. Since these operations are usually performed during daylight hours, the well is shut in or returned to the sales line at the end of the day.

Provide the segment(s) of the industry that the equipment or process is found:

This process is found in the oil and gas production segment of the industry.

NMED Exhibit 10 - 0200

Describe how the equipment or process is used:

The production from the wellbore (tubing and/or casing) is routed to an atmospheric tank to create the differential pressure necessary to manually unload the liquids accumulated in the wellbore or to make the wellbore safe to perform downhole maintenance.

Provide the common process configurations that use this equipment or process:

The liquids unloading process applies primarily to gas wells. The workover operations apply both to oil and gas wells.

What is the distribution of the equipment or process across business segments?

This process primarily relates to the onshore oil and gas production sector.

How has this equipment or process evolved over time?

The technology for gas well deliquification has advanced over time and operators have adopted many wellbore best management practices that have minimized the amount of manual liquids unloading events necessary to keep well production optimized. Advanced planning to reduce the wells pressure prior to blowing the well down have resulted in reduced emissions.

2. INFORMATION ON EQUIPMENT OR PROCESS COSTS, SOURCES OF METHANE EMISSIONS, AND REDUCTION OR CONTROL OPTIONS

Identify the capital and operating costs for the equipment or the process. Identify how methane is emitted or could be leaked into the air. Please **prioritize** the list to identify first the largest source of methane from the process or equipment and where there is **potential** for the greatest reduction of methane emissions. Note any differences expected for differing well types, industry sector, or basin location.

Sources of Methane:

Provide an overview of the sources of methane from this equipment or process:

The source of methane emissions for liquids unloading and workover operations is the venting of a well to an atmospheric tank.[136]

[136] Leaks, upsets and other fugitive emissions are addressed in the leak detection and repair report.

NMED Exhibit 10 - 0201

New Wells:

New wells typically have sufficient production rates and flowing velocity so that liquids loading is not an issue. New wells normally do not require downhole maintenance but if a workover is necessary the process is the same for new and existing wells.

Existing Wells:

The methane emissions for workovers/liquids unloading operations comes from the venting of the well through atmospheric tanks to unload liquids or make the wellbore safe to preform downhole maintenance.

How are the emissions calculated for this equipment or process?

The formulas included below reflect the calculation methodology for estimating emissions from manual liquids unloading events under the EPA Greenhouse Gas Reporting Program (GHGRP). Note that emissions from workovers are combined with completions in the GHGRP program. This calculation methodology contains 3 layers of conservatism in estimating emissions that result in a gross overestimation of emissions. First, the first term of the calculation methodology assumes the full wellbore contains gas only, which does not account for the space occupied by liquid. This asumption over estimates the volume of gas in the column and, therefore, the amount of gas vented. Also, if the tubing or casing were occupied by gas only, a manual liquids unload would not be required. Second, the GHGRP calculation methodology also assumes these activities are no more than 1 hour and 0.5 hour, respectively. After this timeframe, the method assumes the well is venting at the production rate, which leads to another layer of overestimation of emissions. Third, during a manual liquids unloading activity, the valve that allows for flow to the tank may be open for period of time with no liquid/gas movement, therefore, the method assumes flow when there may not be.

Blowdown volumes for wells without plungers (assumes casing)

$$\left(\left\{\begin{matrix}Physical\ Volume\ of\ Casing\\ Being\ Blown\ Down\\ [ft^3]\end{matrix}\right\}\times\left\{\begin{matrix}Convert\ to\ Atmospheric\\ Pressure\end{matrix}\right\}\right)+\left(\left\{\begin{matrix}Avg\ Gas\\ Flowrate\\ \left[\frac{scf}{hr}\right]\end{matrix}\right\}\times\left(\begin{matrix}Blowdown\\ Duration\\ [hrs]\end{matrix}-1\right)\times\left(\begin{matrix}1\ [if\ duration\ longer\ than\ 1\ hr]\\ or\\ 0\ [if\ duration\ shorter\ than\ 1\ hr]\end{matrix}\right)\right)$$

DRAFT

GHGRP:

(f)**Well venting for liquids unloadings**. Calculate annual volumetric natural gas emissions from well venting for liquids unloading using one of the calculation methods described in paragraphs (f)(1), (2), or (3) of this section. Calculate annual CH4 and CO2 volumetric and mass emissions using the method described in paragraph (f)(4) of this section.

(1)*Calculation Method 1.* Calculate emissions from wells with plunger lifts and wells without plunger lifts separately. For at least one well of each unique well tubing diameter group and pressure group combination in each sub-basin category (see § 98.238 for the definitions of tubing diameter group, pressure group, and sub-basin category), where gas wells are vented to the atmosphere to expel liquids accumulated in the tubing, install a recording flow meter on the vent line used to vent gas from the well (*e.g.,* on the vent line off the wellhead separator or atmospheric storage tank) according to methods set forth in § 98.234(b). Calculate the total emissions from well venting to the atmosphere for liquids unloading using Equation W-7A of this section. For any tubing diameter group and pressure group combination in a sub-basin where liquids unloading occurs both with and without plunger lifts, Equation W-7A will be used twice, once for wells with plunger lifts and once for wells without plunger lifts.

Ea=FR∑hp=1Tp(Eq. W-7A)Ea=FR∑p=1hTp(Eq. W-7A)

Where:

Ea = Annual natural gas emissions for all wells of the same tubing diameter group and pressure group combination in a sub-basin at actual conditions, a, in cubic feet. Calculate emission from wells with plunger lifts and wells without plunger lifts separately.

h = Total number of wells of the same tubing diameter group and pressure group combination in a sub-basin either with or without plunger lifts.

p = Wells 1 through h of the same tubing diameter group and pressure group combination in a sub-basin.

Tp = Cumulative amount of time in hours of venting for each well, p, of the same tubing diameter group and pressure group combination in a sub-basin during the year. If the available venting data do not contain a record of the date of the venting events and data are not available to provide the venting hours for the specific time period of January 1 to December 31, you may calculate an annualized vent time, Tp, using Equation W-7B of this section.

FR = Average flow rate in cubic feet per hour for all measured wells of the same tubing diameter group and pressure group combination in a sub-basin, over the duration of the liquids unloading, under actual conditions as determined in paragraph (f)(1)(i) of this section.

Tp=HRpMPp×Dp(Eq. W-7B)Tp=HRpMPp×Dp(Eq. W-7B)

NMED Exhibit 10 - 0203

Where:

HRp = Cumulative amount of time in hours of venting for each well, p, during the monitoring period.

MPp = Time period, in days, of the monitoring period for each well, p. A minimum of 300 days in a calendar year are required. The next period of data collection must start immediately following the end of data collection for the previous reporting year.

Dp = Time period, in days during which the well, p, was in production (365 if the well was in production for the entire year).

(i) Determine the well vent average flow rate ("FR" in Equation W-7A of this section) as specified in paragraphs (f)(1)(i)(A) through (C) of this section for at least one well in a unique well tubing diameter group and pressure group combination in each sub-basin category. Calculate emissions from wells with plunger lifts and wells without plunger lifts separately.

(A) Calculate the average flow rate per hour of venting for each unique tubing diameter group and pressure group combination in each sub-basin category by dividing the recorded total annual flow by the recorded time (in hours) for all measured liquid unloading events with venting to the atmosphere.

(B) Apply the average hourly flow rate calculated under paragraph (f)(1)(i)(A) of this section to all wells in the same pressure group that have the same tubing diameter group, for the number of hours of venting these wells.

(C) Calculate a new average flow rate every other calendar year starting with the first calendar year of data collection. For a new producing sub-basin category, calculate an average flow rate beginning in the first year of production.

(ii) Calculate natural gas volumetric emissions at standard conditions using calculations in paragraph (t) of this section.

(2)*Calculation Method 2.* Calculate the total emissions for each sub-basin from well venting to the atmosphere for liquids unloading without plunger lift assist using Equation W-8 of this section.

$$E_s = \sum_{p=1}^{W}\left[V_p \times \left(\left(0.37\times10^{-3}\right)\times CD_p^2 \times WD_p \times SP_p\right) + \sum_{q=1}^{V_p}\left(SFR_p \times \left(HR_{p,q} - 1.0\right)\times Z_{p,q}\right)\right] \qquad \text{(Eq. W-8)}$$

Where:

Es = Annual natural gas emissions for each sub-basin at standard conditions, s, in cubic feet per year.

W = Total number of wells with well venting for liquids unloading for each sub-basin.

p = Wells 1 through W with well venting for liquids unloading for each sub-basin.

Vp = Total number of unloading events in the monitoring period per well, p.

0.37 × 10−3 = {3.14 (pi)/4}/{14.7*144} (psia converted to pounds per square feet).

NMED Exhibit 10 - 0204

CDp = Casing internal diameter for each well, p, in inches.

WDp = Well depth from either the top of the well or the lowest packer to the bottom of the well, for each well, p, in feet.

SPp = For each well, p, shut-in pressure or surface pressure for wells with tubing production, or casing pressure for each well with no packers, in pounds per square inch absolute (psia). If casing pressure is not available for each well, you may determine the casing pressure by multiplying the tubing pressure of each well with a ratio of casing pressure to tubing pressure from a well in the same sub-basin for which the casing pressure is known. The tubing pressure must be measured during gas flow to a flow-line. The shut-in pressure, surface pressure, or casing pressure must be determined just prior to liquids unloading when the well production is impeded by liquids loading or closed to the flow-line by surface valves.

SFRp = Average flow-line rate of gas for well, p, at standard conditions in cubic feet per hour. Use Equation W-33 of this section to calculate the average flow-line rate at standard conditions.

HRp,q = Hours that each well, p, was left open to the atmosphere during each unloading event, q.

1.0 = Hours for average well to blowdown casing volume at shut-in pressure.

q = Unloading event.

Zp,q = If HRp,q is less than 1.0 then Zp,q is equal to 0. If HRp,q is greater than or equal to 1.0 then Zp,q is equal to 1.

(3)*Calculation Method 3.* Calculate the total emissions for each sub-basin from well venting to the atmosphere for liquids unloading with plunger lift assist using Equation W-9 of this section.

$$E_s = \sum_{p=1}^{W}\left[V_p \times \left((0.37\times10^{-3})\times TD_p^2 \times WD_p \times SP_p\right) + \sum_{q=1}^{V_p}\left(SFR_p \times \left(HR_{p,q} - 0.5\right)\times Z_{p,q}\right)\right] \qquad \text{(Eq. W-9)}$$

Where:

Es = Annual natural gas emissions for each sub-basin at standard conditions, s, in cubic feet per year.

W = Total number of wells with plunger lift assist and well venting for liquids unloading for each sub-basin.

p = Wells 1 through W with well venting for liquids unloading for each sub-basin.

Vp = Total number of unloading events in the monitoring period for each well, p.

0.37 × 10−3 = {3.14 (pi)/4}/{14.7*144} (psia converted to pounds per square feet).

TDp = Tubing internal diameter for each well, p, in inches.

WDp = Tubing depth to plunger bumper for each well, p, in feet.

SPp = Flow-line pressure for each well, p, in pounds per square inch absolute (psia), using engineering estimate based on best available data.

SFRp = Average flow-line rate of gas for well, p, at standard conditions in cubic feet per hour. Use Equation W-33 of this section to calculate the average flow-line rate at standard conditions.

HRp,q = Hours that each well, p, was left open to the atmosphere during each unloading event, q.

0.5 = Hours for average well to blowdown tubing volume at flow-line pressure.

q = Unloading event.

Zp,q = If HRp,q is less than 0.5 then Zp,q is equal to 0. If HRp,q is greater than or equal to 0.5 then Zp,q is equal to 1.

(4) Calculate CH4 and CO2 volumetric and mass emissions from volumetric gas emissions using calculations in paragraphs (u) and (v) of this section.

EDF Synthesis:

We did not incorporate liquids unloading data from Allen et al 2014b (*) because the GHGRP provided more detailed data on event counts and emission rates; the Allen et al estimate of 2012 national emissions from liquids unloading was within a few percent of the GHGRP estimate.

The data suggest that the central estimate of national emissions from unloadings (270 Gg/yr, 95% confidence range of 190–400 Gg) are within a few percent of the emissions estimated in the EPA 2012 Greenhouse Gas National Emission Inventory (released in 2014), with emissions dominated by wells with high frequencies of unloadings. (*)

(*) *D. T. Allen, D. W. Sullivan, D. Zavala-Araiza, A. P. Pacsi, M. Harrison, K. Keen, M. P. Fraser, A. Daniel Hill, B. K. Lamb, R. F. Sawyer, J. H. Seinfeld, Methane emissions from process equipment at natural gas production sites in the United States: Liquid unloadings. Environ. Sci. Technol. 49, 641–648 (2015). doi:10.1021/es504016r Medline*

What data is available to quantify emissions/waste for this equipment or process?

https://www.epa.gov/ghgreporting

About 85% of the gas wells in the U.S. have production rates low enough to have liquids loading issues, and only about 13% have liquids unloading venting to assist liquid removal in 2012 (gross up of GHGRP data).

NMED Exhibit 10 - 0206

- The frequency and amount of venting to assist liquids unloading is highly skewed, with 10 of the 1991 non-zero datasets reported at the "sub-basin" level (less than 0.5%) datasets accounting for more than 50% of the emissions reported;
- At the facility (basin) and reporter level (251 non-zero data sets) the top 1 (0.4%) accounted for about 37% of the total reported emissions; and
- The top 3 (1.2%) accounted for over 50% of the total methane reported and the top 11 accounted for over 75% of the reported methane emissions.

Methane emissions attributed to LU venting are a fairly small portion of the industry emissions in the GHGI and are trending down

GHGI - 2016 (2018 release) LU Venting
6.1% of Natural Gas Systems E&P CH4
2.0%of Natural Gas Systems CH4
1.6% of Natural Gas + Petroleum Systems CH4

GHGRP, Allen et al 2014b, operator data, etc.

According to the Synthesis* study, EDF estimates about 21,700 metric tons CH4 from unloading in NM in 2017. Better records of unloading process information would provide better estimates of total emissions. Not surprisingly, the majority of these emissions occur in the San Juan Basin.

According to the EDF Synthesis study* data, 8.5% of production CH4 emissions are attributable to LU in NM (excluding abnormal process emissions, for consistency with GHGI) vs. 4.9% nationally (or 6.1% per GHGI for the US). This demonstrates a disproportionately high percentage of LU emissions in NM versus the national rate. On tribal lands in NM, Synthesis* data indicates liquids unloading emissions account for 9.9% of production emissions, even higher than the New Mexico total rate.

*EDF Synthesis study:
https://science.sciencemag.org/content/361/6398/186.full?ijkey=42lcrJ/vdyyZA&keytype=ref&siteid=sci

What are the data gaps in quantifying emissions/waste for this equipment?

Unloading emissions are more often estimated than measured. It is important that operators record process information for better estimates of unloading emissions, such as **number of unloading events and duration of each event**. Operators should also indicate if/how an artificial or plunger lift was utilized.

NMED Exhibit 10 - 0207

Further, the Subpart W Greenhouse Gas Reporting Program (GHGRP) requirements only apply to facilities above the emissions threshold. Therefore, not all unloading events are reported under the program.

Economic Description of the Process or Equipment:

What is the per unit cost of the equipment or the costs associated with the process?

The cost for supervision of manual liquid unloading events is dependent upon each unique situation. Additional labor cost of having a lease operator onsite is variable, which make it very difficult to establish a fixed value or even a range.

What are the annualized operating costs for the equipment or costs associated with the process?

N/A

If the equipment or process is powered, what are the costs?

N/A

What are the maintenance and repair costs for existing or new equipment?

N/A

Existing Reduction Strategies:

How has industry reduced emissions/waste from this equipment or process historically?

Operators have developed and employed several wellbore best management practices over the life of the well to avoid the need to perform manual liquids unloads. These best management practices include revisiting the application of refined technology in terms of artificial lift. In order to increase gas sales and reduce emissions/waste during these manual liquids unloading activities, operators should monitor manual liquids unloading events onsite, within close proximity or via remote telemetry to return the wells to normal production operation as soon as possible. Advanced planning to reduce pressure prior to blowing the well down has resulted in reduced emissions.

1. Create differential pressure to minimize the need for venting during unloading activities (artificial lift engine/pump jack, electric submersible pump, etc.)
2. Plunger lifts including automated plunger lifts
3. BMPs - Operators onsite to close vents and monitor the unloading events

Between artificial lift engines, plunger lifts, and supervised manual unloading, one option will result in the lowest emissions relative to the others. This lowest emitting option will serve to mitigate emissions

DRAFT

relative to the others, and should therefore be selected and employed by the operator for liquids unloading at a site.[137]

New Wells:

New wells typically have sufficient production rates and flowing velocity so that manual liquids loading is not required. New wells do not require workovers. Workovers are the downhole maintenance activities performed on existing wells that have previously been capable of producing hydrocarbons.

Existing Wells:

In order to increase gas sales and reduce emissions/waste during manual liquids unloading activities, operators should monitor manual liquids unloading events onsite, within a close proximity or via remote telemetry to return the wells to normal production operation as soon as possible.

How have the emission/waste reductions been measured?

New Mexico Oil and Gas Association report on methane sources and mitigation.

GHGRP 2011-2016 https://www.nmoga.org/methaneroadmap

GHGRP emissions trends data is the most reliable source to establish emission reductions, as described in Section 3 below.

Various studies have measured or modeled emissions from manual liquids unloading events.

Temporal Variations in Methane Emissions from an Unconventional Well Site

https://pubs.acs.org/doi/pdf/10.1021/acsomega.8b03246

Temporal Variability Largely Explains Difference in Top-down and Bottom-up Estimates of Methane Emissions from a Natural Gas Production Region

https://www.pnas.org/content/115/46/11712

Comparison of methane emission estimates from multiple measurement techniques at natural gas production pads

[137] The application of artificial lift is very dependent on the specific characteristics of each well. The operating parameters of the wells will dictate the appropriate artificial lift application. The misapplication of artificial lift could result in an increase in methane emissions in the case of plunger lift installations.

DRAFT

NMED Exhibit 10 - 0209

https://www.elementascience.org/article/10.1525/elementa.266/

Improved Mechanistic Understanding of Natural Gas Methane Emissions from Spatially-Resolved Aircraft Measurements

Measurements Of Methane Emissions At Natural Gas Production Sites In The United States

https://www.pnas.org/content/110/44/17768

If the artificial lift engine operates properly, the only emissions will be combustion. Depending on conditions, plunger lifts can reduce emissions 90% compared to unmitigated venting. (Source: ICF MACC Report, 2014, available at , https://www.edf.org/sites/default/files/methane_cost_curve_report.pdf)

How have other jurisdictions, including state, federal, and tribal, reduced emissions/waste from this equipment or process historically? In addition, please identify voluntary reductions achieved whether or not they were in response to a regulatory action/requirement.

Outside of the initial well preparation the number of activities that can be accomplished under the heading of Recompletions/Workovers is so varied with multiple variables that are well specific, regulating venting and emissions associated with these activities is not feasible. Use of best management practice to manage wellbore pressure makes the most sense because it allows operators to determine the best way to reduce venting on a case by case basis specifically from each well as the situation dictates.

The complexity of liquids unloading is why EPA concluded for NSPS OOOOa that imposing specific regulatory requirements for venting and emissions associated with managing wellbore liquids is not feasible. Requirements for monitoring the activity to manage venting makes the most sense because it allows operators to determine the best way to manage manual unloading on a case by case basis specifically from each well as it changes over time.

BLM's final waste prevention rule requires operators to minimize venting and the need for venting and operators must consider alternatives to manual venting and determine if they are infeasible; if manual venting, operators must remain onsite. BLM, 81 Fed. Reg, 83008 (Nov. 18, 2016)

4. 2016 rule: The final rule requires an operator to: (1) Minimize gas vented to unload liquids, consistent with safe operations; (2) optimize the operation of the plunger lift or automated well

NMED Exhibit 10 - 0210

control system, at wells equipped with such a system, to minimize gas losses from the system to the extent possible; (3) consider other methods for liquids unloading and determine that they are technically infeasible or unduly costly, prior to manually purging a well for the first time; and (4) comply with specified procedures and document venting events when unloading liquids by manual well purging… The operator must notify the BLM by Sundry Notice within 30 days after the first liquids unloading by manual or automated well purging after the effective date of the rule. Additionally, operators must notify the BLM by Sundry Notice within 30 days after the following conditions are met: (1) The cumulative duration of manual well purging events for a well exceeds 24 hours during any production month; or (2) the estimated volume of gas vented in the process of conducting liquids unloading by manual well purging for a well exceeds 75 Mcf during any production month.

5. The requirements to minimize wasted gas remain essentially the same between the two rules. The main difference between the 2016 and 2018 Rules are that the 2016 Rule required recordkeeping and reporting of liquids unloading events, and the 2018 Rule removed those requirements.

Colorado State Regulation to minimize methane emissions in the oil and gas industry:

Colorado, Reg.7, Section XVIII.H.,
https://drive.google.com/file/d/168v7vMsFJtS7D8BWlnMbaXWA6uZUIyj8/view

requires operators to use best management practices to reduce emissions and operators must remain onsite during manual unloading. Colorado is proposing new recordkeeping and reporting requirements to gather better data on emissions and BMPs to reduce emissions.

Wyoming requires operators use BMPs to minimize emissions and operators must remain onsite during manual unloading (see "blowdown and venting" requirements).
http://deq.wyoming.gov/media/attachments/Air%20Quality/New%20Source%20Review/Guidance%20Documents/FINAL_2018_Oil%20and%20Gas%20Guidance.pdf (pps. 13, 19, 24)

Pennsylvania requires operators use BMPs to minimize emissions. GP-5A, Section L,
http://www.depgreenport.state.pa.us/elibrary/GetFolder?FolderID=36120

What are examples of process changes/modifications that reduce or eliminate emissions/waste from this equipment or process?

Liquids Unloading:

- Create differential pressure to eliminate the need to vent a well to unload liquids.
    - Equalize the well
    - Allow the well to build pressure
- Reduce wellbore pressure as much as possible prior to opening to atmosphere via storage tank.

NMED Exhibit 10 - 0211

        - If possible route the initial volume of gas into the sales line prior to venting. Monitor the pressure and the flowrate to determine the optimal time to vent the well to create the differential pressure to unload the well.
- Monitoring manual liquid unloading events onsite, within a close proximity or via remote telemetry to return the wells to normal production operation as soon as possible.

Recompletions/Workovers:

- Open casing to the sales line or the wellhead compressor to reduce the wellbore pressure prior to venting.
    - Equalize with line pressure or compressor suction pressure prior to blow down operations
    - Route gas flow to sales overnight if possible

DRAFT

Technology Alternatives:

List of technology alternatives with link to information or contact information for the company/developers.

Name/Description of Technology	Link (and contact info for company if available)	Availability	Feasibility	Cost Range (choose one)
BMP – operator onsite monitoring	Operator	In use	High	Low
Artificial lift engine (rod pump)	https://ediplungerlift.com/products/engine-packages/	In use	Medium-High.[138]	Medium
Plunger Lifts	https://ediplungerlift.com/products/plungers/	In use (common)	High	Low-Medium

It is important to note that artificial lift deployment is a process that operators carry out to maximize production and production value currently. A well may start off with sufficient production rates to lift liquids out of the wellbore but as the wells production declines below the critical rate, artificial lift must be implemented to optimize production. The operator will select the best artificial lift method based on the well parameters and current conditions. The manual liquid unloading events being discussed in this report are primarily related to the action that must be taken due to an abnormal operating condition, such as an increase in the gas sales line pressure. The increased line pressure causes the well to load up with liquid and production to decrease. This applies to both free flowing wells and wells with plunger lift installations. The act of venting the well through an atmospheric storage tank creates the differential pressure necessary to unload the liquids from the well and return the well back to normal operation.

What technology alternatives exist to reduce or detect emissions? Please list all alternatives identified along with contact information for further investigation of this technology or process.

Artificial lift engines

[138] The feasibility of installing a rod pumping system on a well depends on a number of variables such as the depth, casing size and production rates.

NMED Exhibit 10 - 0213

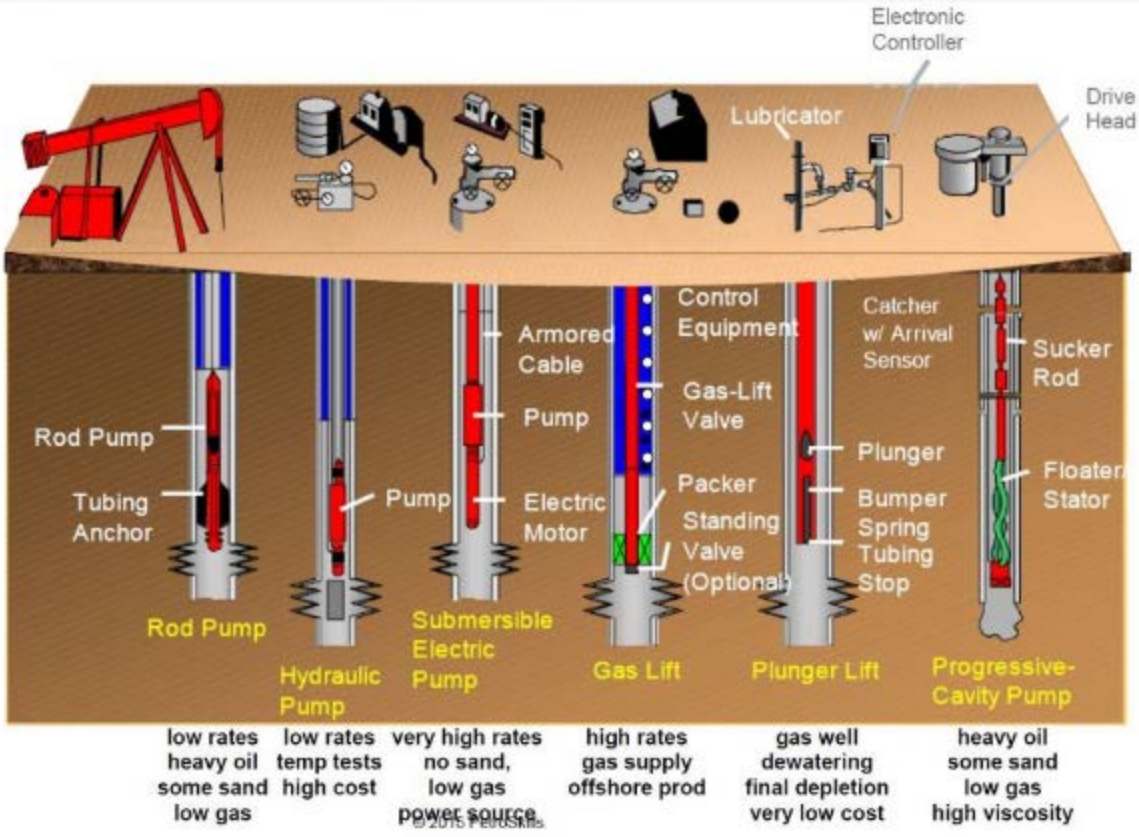

Figure 1-1 *Examples of the primary methods of artificial lift.*

Source: https://www.petroskills.com/blog/entry/00_totm/sept17-sub-totm-artificial-lift?page=5#.XZO2dm9KjIU

As shown above the various artificial lift methods have limitations and drawbacks. It is critically important to consider the application of artificial lift on an individual well basis.

What are the pros and cons of the alternatives?

Pro: The act of liquids unloading increases production. Mitigating unloading emissions increases production and minimizes emissions. Artificial lift engines can prolong the life of a well and operate at lower pressures than plunger lifts (i.e., wider operating range). (*source*: https://www.ourenergypolicy.org/wp-content/uploads/2014/04/epa-liquids-unloading.pdf)

Con: external power source required, higher cost

What is needed and available for new wells?

See above

What is needed and available for existing wells?

See above

What technology alternatives exist for this equipment or process itself?

Plunger lifts (See above schematic)

There are many artificial lift options available and must be selected based on the well parameters and wellsite conditions.

What are the pros and cons of the alternatives?

See above

Pro: The act of liquids unloading increases production. Mitigating unloading emissions using plunger lifts increases production and minimizes emissions. Estimates indicate production increase of 3 to 300,000 scf/day.

Con: Plunger lifts can operate at low-pressure wells but they do have pressure limits.

Costs of Methane Reductions:

What is the cost to achieve methane emission reductions?

The cost to achieve methane emission reductions by monitoring the manual venting of a well is tied to the incremental labor cost associated with monitoring each event. The cost to monitor each event is unique in terms of the well configuration, associated pressures (tubing, casing and line).

The cost to reduce the wellbore pressure prior to a workover operation is minimal and is usually offset by the sales proceeds of the gas being sold.

Depends on reduction technology, effectiveness and gas price. Increased productivity in addition to cost benefits of the saved gas can lead to overall savings for artificial lift engines or plunger lift systems.

Table 1 of the "Cost-Effectiveness of Comprehensive Oil and Gas Emissions Reduction Rules in New Mexico" lists per unit costs for installing a plunger lift system in gas wells as $5.03 per mcf of reduced methane ($261.56 per tonne).[139]

[139] "Cost-Effectiveness of Comprehensive Oil and Gas Emissions Reduction Rules in New Mexico," Erin Camp, PhD, Nate Garner, Asa Hopkins, PhD, Synapse Energy Economics, Inc., September 13,

NMED Exhibit 10 - 0215

What would be the implementation cost?

For new wells?

N/A

Based on results reported by Natural Gas STAR Partners, the cost of implementing artificial lift systems range from $41,000 - $62,000. This is an old report and estimates have likely decreased.[140]

Gas STAR estimates for plunger lift installation range from $2,500 to $10,000 (*Installing Plunger Lift Systems In Gas Wells* http://epa.gov/gasstar/documents/ll_plungerlift.pdf). Some operators estimate $15,000 (ICF 2014).

For existing wells?

The cost of monitoring the manual liquids unloading events depends on how long it takes to unload the well.

Are there low-cost solutions available?

Some BMPs, like having an operator onsite to monitor unloading events, are very low cost.

Other methods (like plunger lifts or lift engines) have higher implementation costs, but are often paid for by the additive benefits of increased productivity and saved gas. In fact, ICF estimates an overall benefit of $0.05/Mcf of methane reduced by installing plunger lifts.

(Source: https://www.edf.org/sites/default/files/methane_cost_curve_report.pdf)

If a solution is high-cost, why is that the case?

Artificial lift engines and plunger lifts require technology implementation.

Are there additional technical analyses needed to refine benefits/costs estimates?

N/A

Can develop cost-benefit estimates with industry input.

2019, page 9, Table 1, http://blogs.edf.org/energyexchange/files/2019/09/Synapse-Methane-Cost-Benefit-Report.pdf.

[140] The cost of artificial lift installation is highly variable depending on the application. The range provide from the Gas STAR Partners does not reflect the cost of all artificial lift cost. The cost of a rod pump installation could exceed $500,000.00 depending on well depth and production desired pump capacity.

NMED Exhibit 10 - 0216

3. IMPLEMENTATION

For each piece of equipment or process, please consider the following questions and add other relevant information. If relevant, please identify if the answers are different for large company and small company requirements or are different for well type or basin.

Implementation Feasibility:

What is the feasibility of implementation (availability of required technology or contractors, potential permitting requirements, potential for innovation)?

Manual Liquids Unloading:

The lease operators are already deployed in the field to monitor manual liquids unloading events; it is a matter of prioritizing the efforts for monitoring manual liquids unloading events. Recompletion and Workover rig supervisors are experienced and trained in the best ways to minimize venting during the initial well blowdown.

Plunger Lifts and Artificial lift engines:

Many operators already utilize plunger or artificial engine lifts for liquids unloading (deliquification) activities. Indeed, one of these technologies is likely to result in less unloading emissions than manual unloading. In the event that either plunger lifts or artificial lift engines would lead to less methane emissions relative to manual unloading, an operator should verify that the lift option is technically feasible and implement that technology mitigation option for unloading at the facility.[141]

What is the useful life of equipment?

N/A

What are the maintenance and repair requirements for equipment required for methane reduction?

N/A

[141] The application of artificial lift is very dependent on the specific characteristics of each well. The operating parameters of the wells will dictate the appropriate artificial lift application. The misapplication of artificial lift could result in an increase in emissions in the case of plunger lift installations.

How would emissions be detected, reductions verified and reported?

Each venting event is timed and the emission volume calculated and reported to EPA under the GHGRP program and can be trended over time as illustrated below.

As EDF has noted, due to the reporting threshold and fluctuations in well counts, production, location, and age, the GHGRP data does not reflect all facilities or unloading events or trends thereof. Therefore, GHGRP trends should be considered in that context and not relied upon to accurately represent true liquids unloading emissions trends over time.

In addition to current estimation and reporting methods (see section 2), operators can also directly measure unloading event emissions.[142]

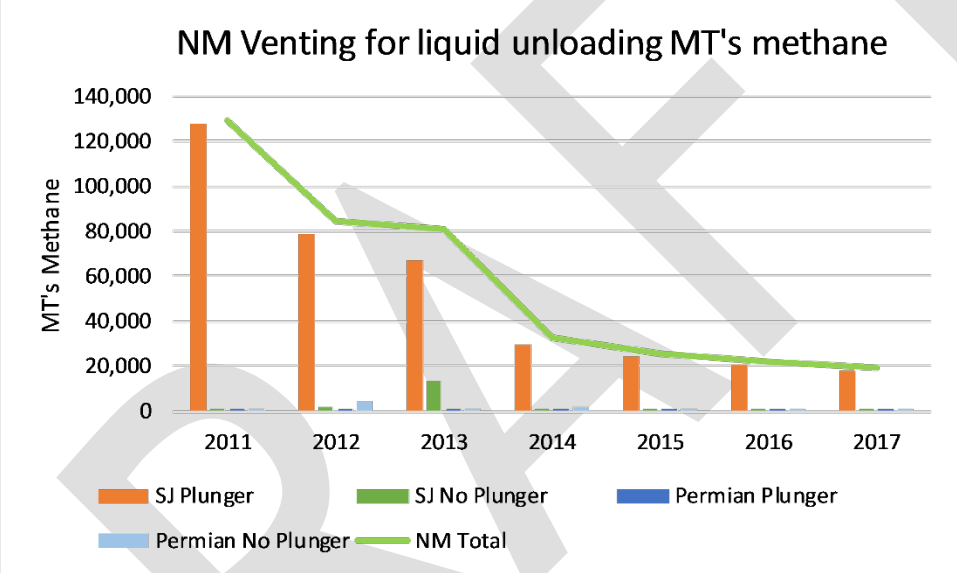

Figure 1: NM LU venting trends

4. CHALLENGES AND OPPORTUNITIES TO ACHIEVE METHANE REDUCTION IN NEW MEXICO

For each piece of equipment or process, please consider the following questions and add other relevant information. If relevant, please identify if the answers are different for large company and small company requirements or are different for well type or basin.

What regulatory gaps exist for this equipment or process? Are there regulatory gaps filled by the proposed implementation?

[142] Accurate direct measurement is difficult and can result in backpressure that will impede the process of unloading or blowing down a well.

DRAFT

EPA does not regulate liquids unloading.

Where do conflicting priorities exist between NMED, EMNRD, and NMSLO? Are there opportunities for coordination between these agencies?

N/A

Are there existing regulations related to methane that do not address the intended purpose? Identify any unintended barriers to methane reductions/capture that may hinder proposed processes.

N/A

Other considerations or comments (e.g. particular design or technological challenges/opportunities, co-benefits, non-air environmental impacts, etc.?):

Safety is a core value for the industry. Being able to safely and effectively unload or blow down a well is a key point to keep in mind with methane reduction efforts during these activities.

DRAFT

5. WORKOVERS AND LIQUID UNLOADING - PATH FORWARD[143]

	OPTIONS	DESCRIPTION AND LINK TO INFORMATION IF AVAILABLE. PLEASE LIST THE BENEFIT THAT COULD BE ACHIEVED THROUGH THIS OPTION AND ANY DRAWBACKS OR CHALLENGES TO IMPLEMENTATION	EMISSIONS REDUCTIONS ARE EASY TO ACHIEVE AND ARE COST EFFECTIVE 1 = EASY 5 = HARD	REPORTING, MONITORING AND RECORDING OPTIONS, INCLUDING REMOTE DATA COLLECTION	IS THIS OPTION HELPFUL IN THE SAN JUAN BASIN, PERMIAN BASIN OR BOTH
7.1	Create differential pressure to eliminate the need to vent a well to unload liquids.	▪ Equalize the well ▪ Allow the well to build pressure Colorado rule [page 211]	1 2 3 4 5		San Juan Permian Both
	COMMENT A. Explanation of differential pressure [page 201]: The well pressure has to be greater than the pipeline pressure for the well to flow. If the well is also unloading liquids then the well pressure will have to be greater than the pipeline pressure plus the hydrostatic pressure of the liquid plus the friction of the liquids to flow. This differential pressure can be maximized by several methods depending on the wells characteristics. For example, shutting in the well for longer periods, or minimizing the after flow after the liquid slug or plunger arrives at the surface, or tripping the plunger more often are methods of creating the required differential pressure for the well to flow.		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
7.2	As a best management practice, minimize volume vented for manual liquid	Route the initial volume of gas to the sales line prior to venting, monitor flow rate and pressures and vent once	1 2 3 4 5		San Juan Permian

[143] The format of the Path Forward table evolved over the course of the meetings as the group tried to identify the best method for capturing the most useful information. As a result, there is some variation in the table headers from topic to topic in the final consolidated report.

NMED Exhibit 10 - 0220

	unloading events by lowering the wellhead pressure	the rate or pressure indicate additional differential pressure is necessary to unload.			Both
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
7.3	As a best management practice, monitor manual venting onsite, in close proximity or via remote telemetry.	Reduce the venting time and emission volume by returning well to normal operation as soon as possible			
	COMMENT A. Place performance standards on monitoring systems to ensure a minimum level of accuracy. [page 208]		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
7.4	As a best management practice, minimize venting for workovers by lowering the wellhead pressure as much as possible prior to blow down.	Open casing to the sales line or the wellhead compressor to reduce the wellbore pressure prior to venting. ▪ Equalize with line pressure or suction pressure prior to blow down operations.			
	COMMENT A. Reduce wellbore pressure as much as possible prior to opening to atmosphere via storage tank. [BMP] [page 211] B. There are not rules that address workovers in other states. [page 202] C. BMPs need to be flexible and not dictated. D. Maybe guidance documents not regulations for BMPs.		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
7.5	As a best management practice, consider the lowest-emitting liquids unloading	Select the lowest-emitting, technically feasible option if economically viable.			

DRAFT

	option between (1) artificial lift, including plunger lifts, and (2) supervised manual unloading. Verify the option is technically feasible and implement that option for liquids unloading at the facility.	The different options available for artificial lift are considered to optimize well production. Well conditions as well as other considerations such as availability of adequate, reliable electricity and well economics are considered prior to installation.			
	COMMENT A. We're focused on liquids unloading and not artificial lift.		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
7.6	Establish a liquids unloading emissions limit (e.g., emissions per event, emissions per facility, or some combination thereof)	Operator may choose any of the three unloading options (or others that become/are available) as long as they can demonstrably meet the established emissions limit.			
	COMMENT A. It would be very hard to set a predetermined limit on emissions given all of the different circumstances in the field. [page 210] B. What would be the recourse if a well could not meet a predetermined limit? Premature plugging? C. Given the differences in individual well and reservoir characteristics it would be difficult to have a single emissions limit per event. [page 210] D. Path forward 6.6 is not a control method that operators can take to reduce methane emissions but the goal of our whole process. There are too many variables involved at each wellsite to predetermine what an allowable emission limit should be.		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		

NMED Exhibit 10 - 0222

SECTION 8, SEPARATORS / HEATERS / STORAGE VESSELS

Discussion for MAP members on October 24, 2019

NOTE: The focus of this report is processes, and the associated equipment, directly related to the release or capture of methane gas. We are not requesting information on processes/equipment that are not related to the release or capture of methane gas.

1. DESCRIPTION OF PROCESS AND EQUIPMENT

Provide a description of the processes and/or equipment used in oil and/or gas extraction for this topic. Note that this report template will be used for all topics of the MAP review and, thus, not all questions or information may be relevant for each topic. If information is not relevant, indicate N/A. Note any differences expected for differing well types, industry sector, or basin location.

Technical description of the process or equipment:

There are two primary basins in New Mexico. The San Juan Basin produces primarily natural gas with the possibility of some crude/condensate. The Permian Basin produces primarily oil with associated natural gas. Production facility operators process (separation and treating) the production (oil, gas and water) from the wells to meet pipeline/truck specifications for sales (oil and gas) or disposal/recycling (produced water). Process equipment in use can date back to pre-1940's.

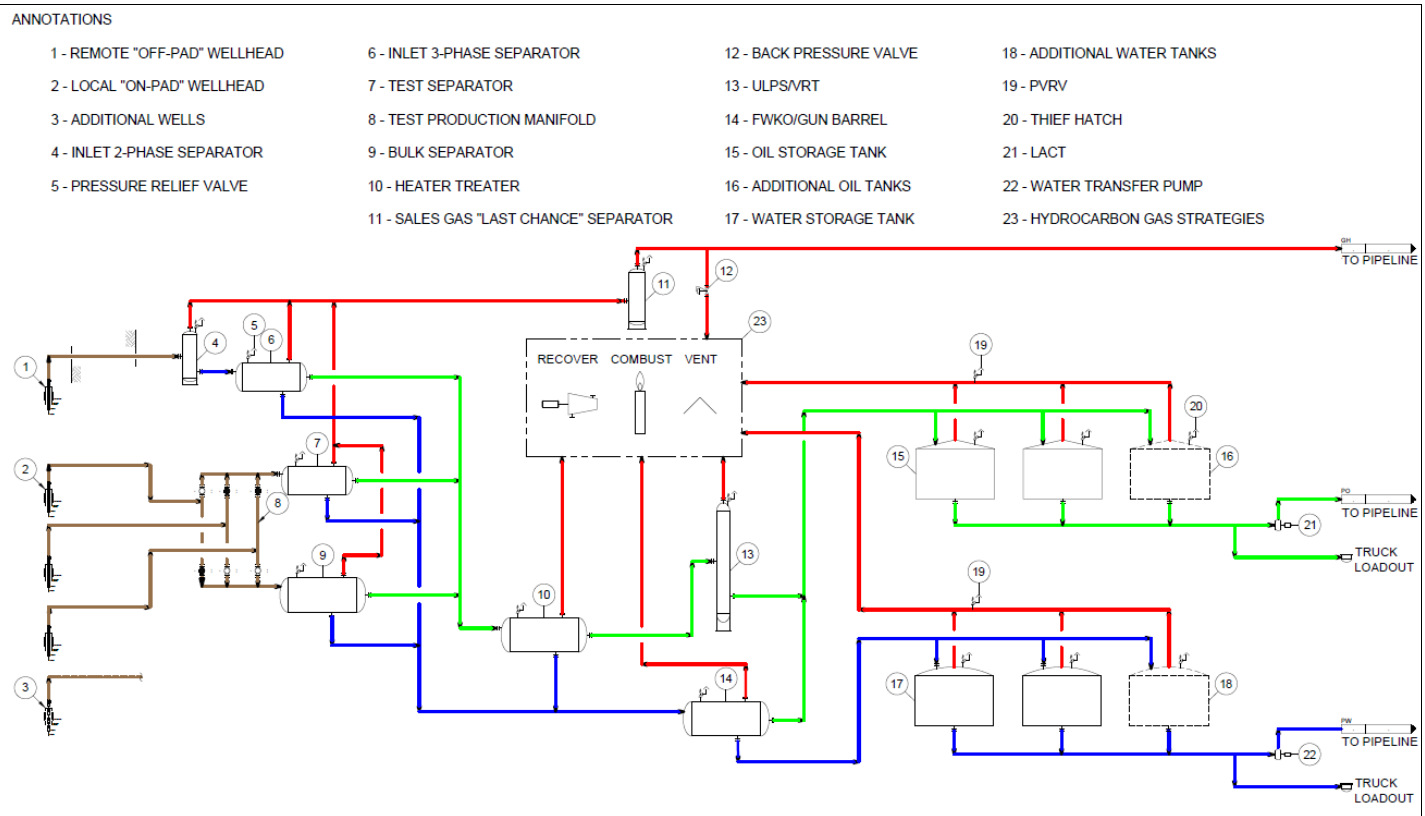
Production facilities can vary based on many factors. Design considerations include, but are not limited to:

1) Rates – Oil, gas, water, gas-to-oil ratio (GOR), decline, etc.
2) Composition – dry gas, heavy oil, light condensate, sweet (low H2S), sour (high H2S), etc.
3) Product Takeaway Specifications – natural gas water content, Reid Vapor Pressure, API gravity, etc.
4) Secondary, Tertiary, etc. Recovery Strategies – Gas Lift, Electric Submersible Pump (ESP), Beam Pumping, etc.
5) Location – Equipment size/count/spacing constraints, automation strategy, storage strategy, etc.
6) Regulatory/Permitting Requirements – recovery, combustion, venting strategies

Common equipment used in production facilities includes:

1) Pressure Vessels ("Separators") – Vertical, horizontal, 2-Phase (vapor/liquid), 3-Phase (vapor/light-liquid/heavy-liquid), heated ("heater treaters" or "production units"), un-heated, etc.
2) Storage Tanks
3) Pumps
4) Compressors
5) Combustion Equipment – flares, enclosed combustors, etc.

6) Fluid loading points



NOTE: Production facilities often contain additional equipment including compressors, pneumatic devices, flares, and vents, which are discussed in separate MAP topic papers. Leak detection and repair (LDAR) for pressure vessels and storage tanks is also discussed in a separate MAP topic paper. Unless otherwise stated, the process descriptions and operational discussions throughout this paper assume a production facility that is properly authorized and operating under normal (non-upset) conditions.

A general process description for production facilities is below. It should be used in conjunction with the below process flow diagram with accompanying annotations. Note: the center box shows the 3 potential ways of managing vent gas: recovery (typically compression to sales or site use), combustion (typically flaring), or venting. See page 22 for further description about the drivers and challenges when determining a particular vent gas management strategy.

From the wellhead, the combined production stream (oil, gas and water) flows to inlet separation processes (i.e. some configuration of 2-Phase and 3-Phase separation) where it is mechanically separated into independent streams. After initial separation, and if necessary, secondary stages of separation are typically applied to

1) oil (e.g. “Heater Treaters”) for further conditioning to meet sales specifications
2) gas (e.g. “Sales Separators”) to prevent inadvertent flow of oil to gas takeaway due to upset conditions (e.g. dump valve malfunction)
3) water (e.g. “Free Water Knockouts” and “Gun Barrels”) to prevent inadvertent flow of oil to water takeaway due to upset conditions (e.g. dump valve malfunction)

Beyond secondary stages of separation, it is common to flow oil to vapor recovery tower (“VRT”) to safely recover as much flash gas as possible prior to storage. Oil will ultimately flow to storage tanks and be sold (typically via Lease Automatic Custody Transfer (LACT) Unit) to pipeline or truck. Water will ultimately flow to storage tanks and be sent to disposal/recycle via pipeline or truck. Under normal operating conditions, associated gas (from inlet separation) is sold via pipeline. Under upset conditions, associated gas must be recovered, combusted or vented. Vapor from all other stages of separation and storage is recovered, combusted or vented.

In its most basic form, a production facility is used to process raw production (oil, gas and water) to meet sales specifications. The goal is to maximize recovery while minimizing cost. The challenge is to do it effectively, safely and within compliance. Our tools are pressure, temperature, gravity, time, chemistry, surface area and agitation.

1 - REMOTE "OFF-PAD" WELLHEAD
Wellheads may be located remotely away from the production facility. This distance can be anywhere from 50’ to 2 miles or longer. Production is delivered to the facility via a “flowline”.
2 - LOCAL "ON-PAD" WELLHEAD
Wellheads and production facilities may even share the same pad. It is also not uncommon for a production facility to have both remote and local wellheads.
3 - ADDITIONAL WELLS
Production facilities are not limited by well count. They can be designed to accommodate ranges from single well applications to an entire section or more.
4 - INLET 2-PHASE SEPARATOR (PRESSURE VESSEL)
Typically used to separator gas from bulk liquids (oil & water). Note that vertical separators are more common in higher GOR applications. It is also important to note that all vessels may be heated or unheated.
5 - PRESSURE RELIEF VALVE
Safety device designed to prevent critical failure during upset conditions. PRV’s used on pressure vessels typically use simple spring-loaded actuators.
6 - INLET 3-PHASE SEPARATOR (PRESSURE VESSEL)
Typically used to separate all three production streams (gas, oil & water). Note that horizontal separators are more common in lower GOR applications.
7 - TEST SEPARATOR (PRESSURE VESSEL)
It is common for operators to employ either a “single well separation” or a “test well separation” strategy. Single well separation strategies utilize an inlet separator for every well (typically for measurement purposes). Test well

separation strategies employ a test separator that cycles wells for a certain period (remaining wells flow to bulk separator when not in testing).
8 - TEST PRODUCTION MANIFOLD
Used in test separation strategies to direct flow of wells to either test separator or bulk separator.
9 - BULK SEPARATOR (PRESSURE VESSEL)
Used in test separation strategies for wells not in their testing cycle.
10 - HEATER TREATER (PRESSURE VESSEL)
Typically employed as a second stage of separation. Its purpose is to further “treat” the oil with heat and additional residence time to ensure it meets sales specifications.
11 - SALES GAS "LAST CHANCE" SEPARATOR (PRESSURE VESSEL)
Used to recover any additional entrained hydrocarbon liquid within the gas stream that may have slipped previous stages of separation.
12 - BACK PRESSURE VALVE
A “BPV” hold processes to a desired pressure for a facility to operate as designed. The illustrated BPV in the diagram is specifically used as a common response to upset (high) sales line pressure conditions.
13 - ULPS/VRT (PRESSURE VESSEL)
A VRT/ULPS is a special type of 2-Phase separator designed to operate at as low of a pressure as possible to minimize flash gas in storage vessels. It is typically used in conjunction with a VRU to deliver flash gas to sales. It was designed out of the need to avoid risks associated with vapor recovery from near atmospheric storage vessels.
14 - FWKO (PRESSURE VESSEL)/GUN BARREL
Used to prevent oil from flowing to water storage due to imperfect separation or upset conditions (e.g. dump valve FAIL-OPEN malfunction).
15 - OIL STORAGE TANK
Oil tanks store product prior to being delivered to sales via truck or pipeline. Their height is used as a driving force (i.e. head pressure) to make delivery easier. They are typically constructed with steel and have a pressure rating between 0-1 PSIG (0-16 OSIG). It is critical to note that this small pressure range yields drastically different operational strategies.
16 - ADDITIONAL OIL TANKS
The quantity of tanks is determined by rate and is a risk-based decision from the operator.
17 - WATER STORAGE TANK
Water tanks store byproduct prior to being delivered to sales via truck or pipeline. They are typically constructed with fiberglass or steel and have a pressure rating between 0-1 PSIG.
18 - ADDITIONAL WATER TANKS
The quantity of tanks is determined by rate and is a risk-based decision from the operator.
19 – PVRV
A Pressure-Vacuum Relief Valve is a safety device designed to prevent critical failure during upset conditions. The illustrated PVRV in the diagram is specifically used on storage vessels. Due to the small design pressure range of storage vessels, small differences in set pressure can yield significantly different operating strategies.
20 - THIEF HATCH (Maintenance hatch)
An opening in the top of a storage tank. Typically used by operators for a variety of reasons, these are sized similar to the storage tank PVRV. The thief hatch allows tank access for a thief or other level measuring device. Opening and closing of a thief hatch is a manual operation by an operator.
21 – LACT
Used to deliver oil to sales via pipeline or truck at required pressures typically higher than atmospheric.
22 - WATER TRANSFER PUMP
Used to deliver water to disposal/recycle via pipeline or truck at required pressures typically higher than atmospheric.
23 - HYDROCARBON GAS STRATEGIES

Gas streams operating below pipeline pressure must either be recovered, destroyed or vented. Each strategy comes with its own benefits and challenges. Examples of engineering considerations can be found in the chart below. Utilization ranges from a single strategy to a combination of all three. As noted in the chart, the design complexity and costs increase as one progresses from venting to recovery of storage tank vents. In general, the more complex combust/recovery installations are at larger surface facilities where there is adequate gas volume for capture, appropriate available infrastructure, such as grid power, and sufficient production to support the installation and operational costs.

	RECOVER	**COMBUST**	**VENT**
STRENGTHS	• Gas to Sales • >95% Efficient • Centralized Production Opportunities • OOOOa Enforceable if Applicable	• Not as complex as recovery - No 3rd Party Maintenance • More reliable than recovery • >95% Efficient • OOOOa Enforceable is Applicable	• Negligible Complexity • Negligible Cost

24 - Vent pipeline-Generally denotes pipelines that allow for pressure equalization for the head space of vessels. Use of the word "vent" does not necessarily imply that the vessel is vented to atmosphere-rather than the vessel utilizes a vent system to manage vapors produced in vessels.

https://library.e.abb.com/public/34d5b70e18f7d6c8c1257be500438ac3/Oil%20and%20gas%20production%20handbook%20ed3x0_web.pdf

Mid-stream tank configuration description:

On the midstream side, storage tanks are used in a variety of ways. At compressor stations, liquids from inlet scrubbers, compressors and glycol dehydrators can be temporally stored in tanks. Midstream storage tanks can also contain liquids that may accumulate in gathering system lines over time. These liquids from lines can be removed/recovered by "pigging" the line. Pigging is a process involving a plug that is forced through the line, pushing accumulated liquids ahead of it to a pig catching station where it is recovered to tankage. The process of pigging only happens periodically as needed and results in short term emission events, not continuous. These emission events are typically covered by the operating permit for the site where the tank is located. Volume of liquids in the lines removed by pigging varies greatly on the type of product moving through the line and the size of the pipe.

Below are additional technical details.

Pressure Vessels:
The American Society of Mechanical Engineers (ASME) defines pressure vessels as "containers for the containment of pressure, either internal or external." Two common exemptions from this definition are

1) "Vessels having an internal or external pressure not exceeding 15 psi"
2) "Vessels having an inside diameter, width, height, or cross sectional diagonal not exceeding 6 in., with no limitation on length of vessel or pressure"

Based on this definition, it is reasonable to assume that all separators (e.g. Inlet 2Phase, Heater Treaters, Sales Separators, etc.) are pressure vessels. There could be some exception applied to VRT's based on individual design considerations. One glaring clarification to make, however, is that storage tanks are not pressure vessels.

The primary function of pressure vessels in the oil & gas industry is phase separation. The three basic separation principles applied are:

1) Mechanical separation of immiscible fluids using gravity
2) Partial vaporization of a homogenous, single-phase solution using heat transfer
3) Flash vaporization of a homogenous, single-phase solution using pressure reduction

Pressure vessels may be

1) Oriented vertically or horizontally
2) Heated or unheated
3) Configured for 2-Phase (V/L) or 3-Phase (V/L/L) separation
4) Outfitted with internals (plates, weirs, etc.)

5) Etc.

It is common practice to operate pressure vessels at as low of a pressure as possible. The two primary constraints are

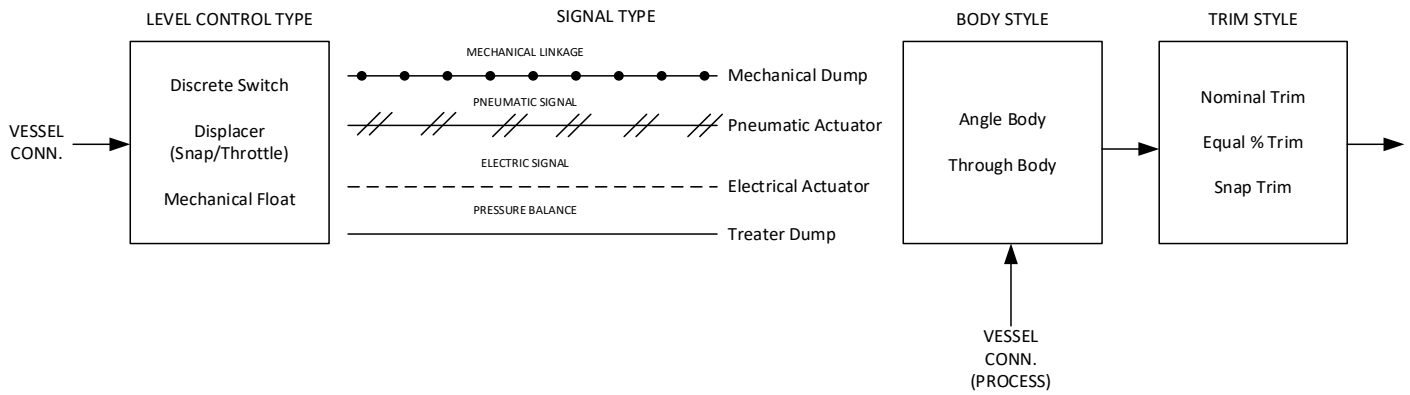
1) Having enough pressure to get into the gas sales line (Inlet separation only) and
2) Having enough pressure to dump liquid(s) to the next stage of the process.

Higher pressures yield more flash vaporization downstream in the process. Pressure is typically maintained on the vessel by use of a valve. There are a variety of valves for a variety of applications.

LINK: https://blog.kimray.com/what-does-back-pressure-mean-and-why-is-it-important/

Liquids flow out of the vessel using a liquid level controller in conjunction with a level control ("dump") valve. Once liquid in the vessel reaches a determined set point, the level controller will send a signal to an actuator that will open or close the valve accordingly. Three common types of liquid level controllers are

1) Discrete (1/0) Switch – Sends a command to either open or close. Does not have a range. Can have either a pneumatic or electric signal to a respectively pneumatic or electric actuator. Typically used on scrubber (pressure vessels in low liquid dropout service (e.g. fuel scrubbers)) dumps.
2) Displacer – Sends a ranged command to either open or close. The more the displacer travels, the more the actuator/valve responds. Can have either a pneumatic or electric signal to a respectively pneumatic or electric actuator. It is common for displacers to be configured as either "snap" or "throttle". A snap controller yields a more aggressive actuator response to displacer travel and is useful in applications with lower liquid rates. A throttle controller yields less aggressive actuator response and is useful in applications where it is important to maintain a certain liquid level within a process.
3) Mechanical – Sends a ranged command to either open or close. The more the float travels, the most the valve responds. Mechanical floats are mechanically attached to the valve.

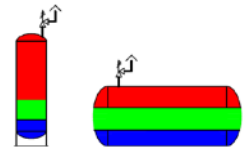


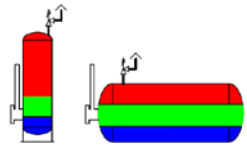
LINK: https://blog.kimray.com/valve-actuator/
LINK: https://blog.kimray.com/how-does-the-kimray-dump-valve-work/
LINK: https://blog.kimray.com/how-to-operate-the-kimray-high-pressure-control-valve/
LINK: https://blog.kimray.com/valve-sizing-3-most-important-factors-selecting-control-valve/

Pneumatic actuators are used to manage the fluids in the separator, heater treater, and storage vessels, and require the use of a gas. Pneumatic operations are discussed in a separate MAP Topic paper.

Trim style is also important to consider and is selected based on how a valve needs to operate as a function of stem travel.

LINK: https://blog.kimray.com/3-types-control-valve-trim/

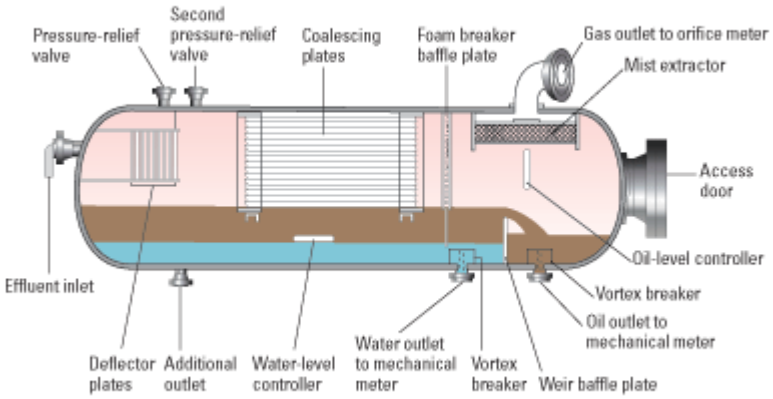




The below flowchart depicts common configurations. Configuration selection considers cost, availability of power/instrument air/instrument gas, reliability, required dump rates, etc. The impact of selection is the instantaneous dump rate yielded. It is important to consider instantaneous rates when designing a facility.

Dump valve failures do occur and typically result in the valves inability to fully close. This can be caused by a stuck debris (plug pieces, sand, etc.) or worn seats, stems and balls. Critical failure (100% Cv) of a dump valve is rare and is considered an upset condition that requires engineered safety controls (i.e. pressure relief valves). Regardless of the extent of the failure, if it is left unattended it will eventually empty the vessel of all liquids, allowing gas to leak or "blow by" to the next stage of the process. If communications are available on site, it is possible to install a level switch that will trip in a low liquid event.

For simplicity, pressure vessels used at production facilities are organized into one of three categories



1) Normal Pressure Vessels
2) Heater Treaters
3) VRT's

Category		Pressure	Temperature	Separation Principle(s)	Comment
Normal Pressure Vessels		15-1440 PSIG	Variable	Mechanical Flash Vaporization	Inlet separators, 2Phase, 3Phase, Sales Separators, FWKO, etc.
Heater Treaters		< First Stage	80-140 °F	Mechanical Flash Vaporization Heat Transfer	Uses fuel gas for combustion
VRT's		0-5 PSIG	Variable	Mechanical Flash Vaporization	Gravity feeds to tanks; no dump valve

It is critical to note that the purpose of the VRT is to be used in conjunction with a VRU (where the gas can be sold) to minimize flash vaporization in the tanks. While using a VRU to pull vapors directly from the tanks is theoretically feasible, the potential risk of introducing oxygen into a hydrocarbon rich vapor space adds complexity to the design. If there is inadequate gas produced by flash vaporization in the tanks, the compressor will pull the pressure of the tank below zero (vacuum). The result would be the activation of a PVRD which would allow air to be drawn into the head space of a tank and commingled with the flash gas sent to sales. Introducing oxygen into a hydrocarbon rich vapor space also creates the possibility of an explosive atmosphere. Failure of the PVRD to draw in adequate air to relieve the vacuum may result in tank collapse/failure. In addition, introduction of air/oxygen into the gas stream may result in rejection of the gas due to

composition specification. The result could be flaring of additional gas at the site due to the quality issues. Blanket gas systems can be installed to mitigate the vacuum/introduction of air issue. However, there is disagreement on the use of blanket gas as a viable solution to this challenge. For sites with low production of flash gas and/or limited access to appropriate electrical power other methods may produce more emissions than the alternative. Regardless, the use of a VRT can reduce phase separation VOC's in the tanks by 90+%.

Storage Vessels (Tanks):

Tanks are designed to operate at "near atmospheric" pressure. It is common practice to refer to their design rating in ounces of pressure instead of pounds. One (1) pound per square inch gauge (psig) = 16 ounces per square inch gauge (osig).

In the most recent version of API 12F (January 2019), tanks built to the standard have a design pressure of 16 (ounces per square inch gage) osig (with provisions for 24 osig during emergency upset conditions). However, existing tanks throughout New Mexico can have a design pressure ranging from 0-16 osig and be constructed with either carbon steel of fiberglass (only used in water service). 8 osig for carbon steel tanks and 4 osig for fiberglass tanks are likely the most common at existing sites.

Tanks in the production sector of the oil and natural gas industry are used to temporarily store segregated oil and water. Storage vessels can be installed as a single unit or in a grouping of similar or identical vessels, commonly referred to as a "tank battery." The reason for temporary storage is for feasibility of takeaway via pipeline or truck. In cases of pipeline (and pumps in general), it is important to minimize the number of times fluid drivers cycle on and off. There are also net positive suction head requirements to consider when pumping oil. In cases of trucking, it is important to have an appreciable load for takeaway. At sites where multiple tanks are located, tanks are often connected by a manifold. The method of tank operation varies depending on site-specific conditions.

Pipeline is the preferred method of takeaway but requires both a pipeline and available power. Trucking is the other option and has emissions associated with it that are quantified using EPA's AP-42 Emissions Factors (Section 5.2). Vapor balance return lines allow operators to take credit for reduced emission factors and are relatively easy to install. However, the challenge is in finding trucks that are certified in the practice of vapor balance. It is also difficult for operators to enforce the use of vapor balance. There is a perception that truck loading is the primary cause for left open thief hatches, but there is lack of industry data to corroborate.

The industry considers three separation mechanisms from storage tanks:

1) Flash vaporization of a homogenous, single-phase solution using pressure reduction
2) "Working" Losses due to changes in tank levels from filling/emptying
3) "Breathing" Losses due to changes in ambient conditions throughout any given day

Vapors created from this separation must either be recovered, destroyed or vented. For recovery and destruction strategies, it is paramount to adequately maintain pressure on storage tanks by use of thief hatches, pressure/vacuum relief valves and emergency relief valves. Vapor will flow to the path of least resistance. If a storage tank relief device is not properly specified or correctly installed, it can become the path of least resistance. If a storage tank relief device is not properly maintained (i.e. seal failures, worn springs, etc.), it can become the path of least resistance. If a thief hatch is left open after gauging, truck loading, maintenance, etc., it will definitely become the path of least resistance. This is a challenge for storage tanks because the range of control is relatively small and very sensitive to any errors or malfunction. It is especially challenging for existing locations that have even less of a design operating pressure. This plays a pivotal role in NSPS OOOOa compliance determination for closed vent systems if applicable.

Vapor Recovery Units (VRUs) work by using a small compressor to capture and compress the vapor emissions from the oil at low to near atmospheric pressures, reducing the amount of gas that is sent to the vapor combustion device from the storage tanks. They may be operated in conjunction with VRTs, where they compress the flashed gas for sales upstream of the tanks. VRU's can also be tied directly to the tank vent header system or CVS as long as there is an adequate gas blanket system installed to capture emissions directly from the tank and routed to a sales point instead of a combustion device. The VRU compressor is driven by a small natural gas or electric engine. The size is determined by site-specific conditions and production rates. At sites where there is not an adequate and/or reliable electric power source, natural gas engines must be used. VRU's, like all compressors, are rate limited; meaning, available compressors will be too large to run efficiently to control the vapors when emissions are very low. In some cases, VRT/VRU installations may be temporary. Installations would normally occur during the early phase of a well's life when production is highest. This equipment may be removed later when production falls below an economic or operational feasibility threshold. Installation of VRU's on tank headers is generally not recommended due to the safety and gas quality concerns this may introduce to the process (see page 7). In general, for sites authorized under NOI the NMED does not consider different operating strategies. Sites are evaluated for the maximum emissions expected from a site and do not consider the emission reductions/gas capture associated with the use of VRT's/VRU's.

Provide the segment(s) of the industry that the equipment or process is found:

The equipment/process is found in the upstream, midstream, and transmission segments.

Describe how the equipment or process is used:

Addressed in previous section.

Provide the common process configurations that use this equipment or process:

Addressed in previous section.

What is the distribution of the equipment or process across business segments?

Addressed in previous section.

How has this equipment or process evolved over time?

Tank standards changed to move from 8 oz to 16 oz pressure set points due to a change in API Standard 12F in January 2019 (available by subscription at https://www.monogramwebstore.org/publications/item.cgi?fce92c8f-40c7-4108-90d2-ba38757d174c). An increase in the pressure rating allows operators to set pressure relief devices at a higher setpoint, decreasing the likelihood of triggering relief devices that could vent to atmosphere. However, not all tanks are operated at these higher pressure ranges under normal operating conditions. It is important to note that retrofitting/replacing tanks is a significant economic challenge. Replacing tanks requires existing tanks to be cleaned, tested/treated for naturally occurring radioactive material (NORM), have piping removed, transported, and sold at a price that hardly recovers any value. Installing a new tank is roughly twice the cost of the tank. Retrofitting tanks really only applies when an operator decides to switch a tank from oil service to water service due to hazards associated with fiberglass tanks. The challenge in this is adequately protecting the retrofitted tank from corrosion. Newly constructed tanks are typically internally coated with a protective barrier in between the fluid and the carbon steel wall. This is performed in a controlled environment. Internally coating a tank in the field is much more difficult and commonly results in imperfections that accelerate corrosion. An alternative option is placing sacrificial anodes in the tanks, but this requires constant maintenance. Production decline rarely makes replacing/retrofitting tanks a viable option.

Thief hatch design changes have improved resulting in better seals to prevent tank emissions to atmosphere and better relieving control (closer to tank rating).

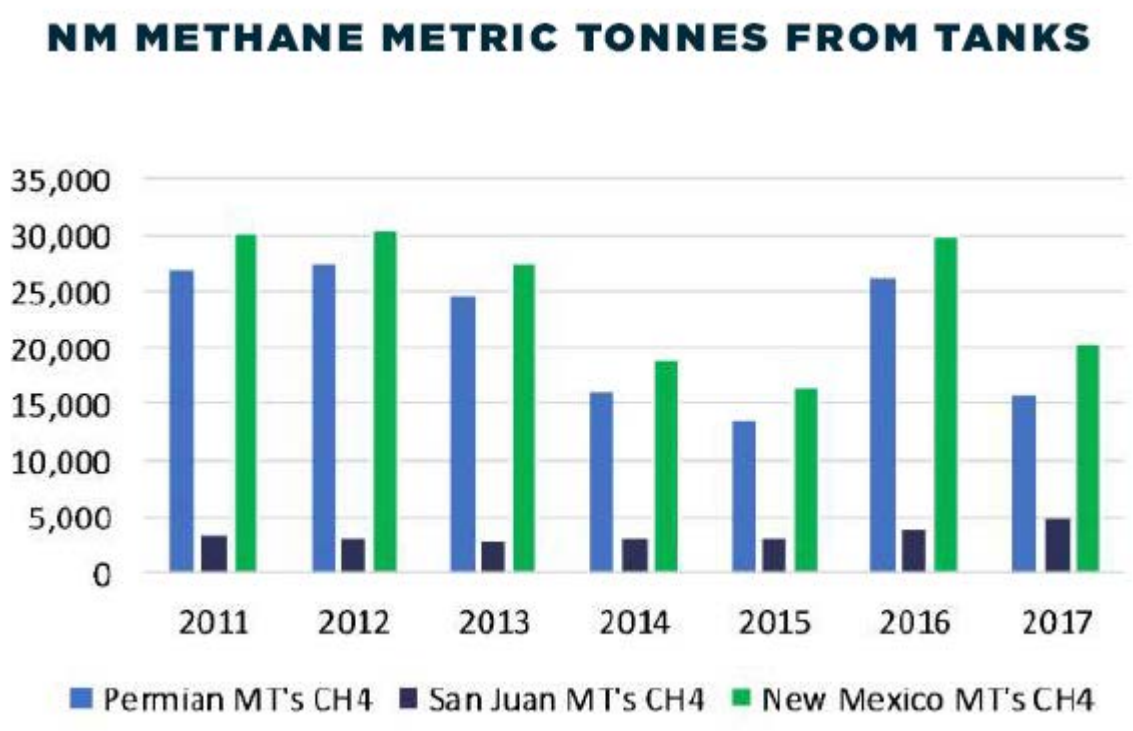
There is some recent technology that allows for operators to monitor the open/close status of thief hatches using magnetic switches. However, at this point in its development, reliability is unproven. There is also an economic burden given that it would require installation on every thief hatch. It would also require communications for remote monitoring.

Operators may consider the type of dump valve and the use and its intended service. Snap acting valves and throttling valves can be more appropriate in different settings, and an evaluation of the most appropriate device for the setting can improve dump valve performance. Advancements in communication technology (i.e. internet, email, etc.) have made it easier to right-size valves.

The most significant evolution in upstream has been in the ability to remotely monitor and control processes. Programmable Logic Control (PLC), Supervisory Control and Data Acquisition (SCADA) systems, etc. allow operators to monitor, trend, and control different aspects of their process that are enabled through the use of instrumentation (e.g. Pressure Transmitters, Flow Transmitters, Level Switches, Level Transmitters, etc.). While SCADA is installed for operational purposes, analysis of that data and integration of more SCADA over time can result in lower emissions as facilities are run more efficiently. PLC and SCADA systems require both instrumentation and communication equipment. This poses an economic burden and may not be scalable to smaller operators or many existing locations.

2. INFORMATION ON EQUIPMENT OR PROCESS COSTS, SOURCES OF METHANE EMISSIONS, AND REDUCTION OR CONTROL OPTIONS

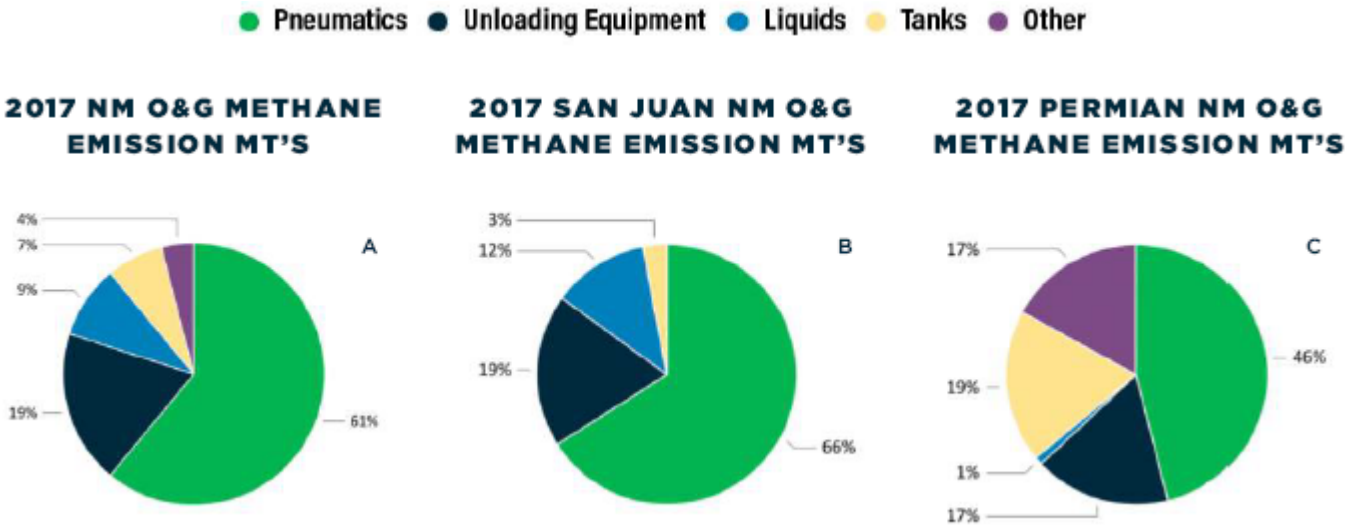
Identify the capital and operating costs for the equipment or the process. Identify how methane is emitted or could be leaked into the air. Please **prioritize** the list to identify first the largest source of methane from the process or equipment and where there is **potential** for the greatest reduction of methane emissions. Note any differences expected for differing well types, industry sector, or basin location.



Sources of Methane:

Provide an overview of the sources of methane from this equipment or process:

Separator and tank/process flash gas are primarily composed of methane, VOCs, and small amounts of BTEX. In addition to flash emissions previously discussed, storage tanks also have the potential to create working and breathing (or standing) emissions depending upon how tank vents are handled. Working emissions are generated when liquid is added to or removed from the tanks. Turbulence in the liquid may cause vapor to be released from the oil. Breathing or standing emissions occur during the normal expansion and contraction of the tank vapor and is dependent on changes in the ambient temperature.



The potential methane emission sources for processing and storage vessels are thief hatches (opening in the top of a tank, which provide access for a thief or level measuring device and also often functions as a pressure/vacuum relief device), pressure vacuum relief valves (PVRV), other safety relief devices (PRV), combustion equipment associated with heater treaters, malfunctioning control equipment such as level controllers/dump valves (fugitive emissions which will be covered in the leak detection paper) and vents. If operating pressures in separators or storage tanks exceed the pressure relief device set point, the device will vent to prevent vessel over-pressure. For thief hatches, worn or dirty gaskets may also prevent a tight seal from forming. Any methane emissions from combustion equipment (e.g. heater treaters, line heaters, and vapor combustion devices/flares) would be very small as combustion efficiency greater than 98% is expected.

In general, emissions in this category come from #2 and #19 in the flow chart on page 2.

https://d3n8a8pro7vhmx.cloudfront.net/nmoga/pages/1008/attachments/original/1563831145/NMOGA_MethaneMitigationRoadmap.pdf

The emissions reported to subpart W include flashing, breathing and working losses, but do not include emissions from tank thief hatches or other system/VRU malfunctions.

Per Synthesis data[144], as reported in the April 11th, 2019 EDF report[145] and associated data platform[146], EDF estimates about 23,000 metric tons of methane from tank vents in New Mexico in 2017 (55% from produced water tanks and 45% from oil/condensate tanks). Additionally, EDF estimates about 650,000 metric tons of methane from all sources that result from abnormal process conditions in NM, https://www.edf.org/energy/explore-new-mexicos-oil-and-gas-pollution There are many observations by researchers and authors of measurement studies which suggest that storage tanks are the likely release point of most large emissions and many of these may be due to abnormal conditions such as tank control system failures and upstream malfunctions such as stuck separator dump valves. "Anecdotal data" is based on or consisting of reports or observations of usually unscientific observers. (https://www.merriam-webster.com/dictionary/anecdotal)

Control System Failures

Tank control system failures can also lead to methane emissions. Common causes of system failure include the following:

- Design Flaws
  - VRUs undersized
  - Separators undersized / dumping very frequently
  - Separator dump valve leakage
  - Liquid pooling
- Mechanical Failures
  - Thief hatch mechanical failure (gasket failure, weak or defective sealing mechanisms, etc.)
  - Pilot flame fuel supply and igniter failures
  - Incomplete combustion
- Operational Failures / Errors
  - Thief hatches open
  - Other issues – intentional bypass, flares unlit
- Leaks in the system

Truck Loading

Truck loading is another source of methane emissions. As discussed in a previous section, pipeline is the preferred method of takeaway, but is only feasible if 1) a pipeline is available, 2) power is available for pumps, and 3) it is economically justifiable. If a pipeline is not available, truck hauling is the only viable option. Loading occurs at atmospheric pressure (after fluid pressure reduction), and losses occur as vapors in empty tank trucks are displaced to the atmosphere by the liquid being loaded into the tanks. These vapors are a composite of 1) vapors formed in the empty tank by evaporation of residual product from previous loads, 2) vapors transferred to the tank in vapor balance systems as product is being unloaded, and 3) vapors generated in the tank as new product is being loaded. Utilizing a vapor balance system can reduce emissions, however, by returning these vapors to the storage vessels.

There are three state jurisdictions currently regulating truck loading, including Wyoming, Utah, and Pennsylvania. Specifically, in Wyoming, loading emissions containing greater than or equal to 6 tpy VOC and HAP emissions must be controlled. Operators of new facilities must utilize a vapor collection system or equivalent device for the truck loading operation that captures a minimum of 70% of the truck loading vapors, and to route the vapors to device with a destruction efficiency of 98%.[147] In Utah, tanker trucks used for intermediate hydrocarbon liquid or produced water must be loaded using bottom filling or a submerged fill pipe. Operators must control VOC emissions during truck

[144] Alvarez et al., Assessment of Methane Emissions from the U.S. Oil and Gas Supply Chain, 361 SCIENCE, 186–188 (2018) http://science.sciencemag.org/content/361/6398/186

[145] https://www.edf.org/energy/explore-new-mexicos-oil-and-gas-pollution

[146] https://www.edf.org/nm-oil-gas/

[147] WDEQ Permitting Guidance, at 11.

loading operations at all times using a vapor capture line. The vapor capture line must be connected from the tanker truck to a control device or process, resulting in a minimum 95% VOC destruction efficiency.[148] In Pennsylvania, since August 10, 2013, in accordance with Category 38 of the Air Quality Permit Exemptions document tanker truck load out operations are required to be equipped with controls achieving VOC, and HAP emissions reductions of 95% or greater unless their uncontrolled VOC, single HAP, and total HAP emissions are below the control thresholds of 2.7 tpy, 0.5 tpy, and 1.0 tpy, respectively. Per GP-5 and GP-5A, tanker truck loadout operations that take liquids from storage vessels with emissions above the control thresholds are required to use a vapor balancing system and ensure each truck used to unload liquids has passed an annual leak test.[149] As shown by the initial EIA, these measures will be cost effective.[150]

New Wells:

Surface facility processing and storage vessels are used in both new and existing facilities. On site storage capacity is determined based on expected production of oil and water. NSPS OOOOa requires that new, modified, or reconstructed storage tanks which emit greater than 6 tons per year of VOC reduce emissions by 95% or greater within 60 days after startup. NSPS OOOOa allows storage tanks whose emissions decrease below 4 tpy of VOC for at least 12 consecutive months to operate uncontrolled. EPA provides for removal of controls at 4 tpy as it is no longer cost effective.

Existing Wells:

Surface facility processing and storage vessels are used in both new and existing facilities. On site storage vessels capacity is determined based on expected production of oil and water. As well production rates decline, storage needs may decrease allowing for isolation or removal of some tanks.

Older existing storage tanks may not be equipped with a vapor collection and combustion device to control tank emissions depending on actual production and permitting thresholds. In some situations, it may be technically infeasible to install a control device as there may not be enough gas (volume and pressure) to safely operate a control device.

How are the emissions calculated for this equipment or process?

Emissions from storage vessels are calculated as part of an NMED air permit application, NMED emissions inventories, and EPA GHG reporting. Flash emissions are dependent on a multitude of factors, including oil throughput, oil composition, API gravity, and separator/heater treater temperature and pressure. Due to the complex nature of flash emissions, they are typically estimated using a process simulator such as ProMax and HYSIS using equations of state or by using transient programs such as OLGA, HYSIS DYNAMIC, Ledaflow. Storage tank working and breathing losses may be calculated using AP-42 equations or software built using AP-42 equations (e.g. EPA TANKS, E&P Tanks). Manufacturer's data and state/federal guidance are utilized to determine the control efficiencies of the various types of controls (e.g. VRUs, combustion devices). Typically, multiple storage vessels are connected to a single combustion device through a common header system.

For EPA GHGRP, Basins (Permian and SJ) are broken out into Production and Gathering & Boosting segments. For emission calculation purposes, the total number of oil storage tanks and associated vent management systems (VRT, VCU, uncontrolled) per location are considered along with the volume of oil produced annually utilizing storage at the

[148] EDF_PHS_EX-080, Utah Ann. Code § 307-504-4
[149] Pennsylvania BAQ-GPA/GP-5, § F(1)(a); Pennsylvania BAQ-GPA/GP-5A, § F(1)(a).
[150] Initial EIA, at 29-30.

corresponding site to calculate a methane emission estimate for each facility. Estimated emissions are reported for each segment per county. For pressure relief devices, leaks found during LDAR surveys are reported and quantified/estimated in GHGRP as well using EPA approved emission factors for the type of equipment (e.g. valve) and the type of service the equipment is in (e.g. light oil).

Note that not all storage tank emissions are reported under the Subpart W GHGRP due to the reporting threshold. Additionally, calculated tank emissions figures do not include abnormal process conditions, such as stuck dump valves or open thief hatches, which are responsible for large amounts of methane and VOC emissions.

GHGRP – Calculation tool link:
https://ccdsupport.com/confluence/display/help/Optional+Calculation+Spreadsheet+Instructions

NMED Air Emission Calculation Tool (AECT) link: https://www.env.nm.gov/air-quality/air-emissions-calculation-tool-aect/

What data is available to quantify emissions/waste for this equipment or process?

The US EPA publishes most of the emission information and activity data that it receives as part of the US GHG Reporting Program annually (https://ghgdata.epa.gov/ghgp/main.do?site_preference=normal#). By March 31st of each year, operators upload their emission information to the EPA website for the previous year (i.e. 2018 emission information was reported in March 2019), EPA undertakes a quality assurance process, and uploads the information in October to a publicly accessible website. Care should be taken in estimating emissions from this inventory for New Mexico since both the Permian and San Juan Basins span multiple states and are challenging to separate emissions between states for all source categories.

https://www.epa.gov/ghgreporting

NMED currently conducts annual emission inventories for permitted major sources. NMED will also be conducting an emission inventory for calendar year 2020 which will include emissions from all sources with an air quality construction permit (including general construction permits such as the GCP-O&G) or notice of intent (NOI). The emissions inventory will be reported to NMED by April 1, 2021.

In addition to the above-mentioned inventories, companies are required to report emissions in excess of the quantity, rate, opacity, or concentration specified by an air quality regulation or permit condition. Therefore, emissions in excess of a limit or rate established by an air permit (including the GCP-O&G, NSR, or other air permit) are reported to NMED through excess emission reports per 20.2.7 NMAC.

Various studies and information indicate tank emissions are higher than estimated and likely account for many of the largest emissions releases. Relevant studies include the following:

EDF Synthesis study: Alvarez et al., Assessment of Methane Emissions from the U.S. Oil and Gas Supply Chain, 361 SCIENCE, 186–188 (2018) http://science.sciencemag.org/content/361/6398/186

Clean Air Task Force (CATF) analysis of emissions from controlled tank systems in the helicopter study is available here: https://www.epa.gov/sites/production/files/2017-11/documents/5._catf_tank_presentation_for_inventory_workshop_final.pdf

What are the data gaps in quantifying emissions/waste for this equipment?

There are gaps in quantifying emissions at sites that do not have remote monitoring or control, and it may not be reasonable to retrofit these existing facilities.

There are also gaps in direct measurement of emissions from storage tanks regardless of whether they are destroyed or vented. In low-pressure conditions, such as storage tank vent headers, technical feasibility issues exist with measurement of these low flow, low energy flows. To improve accuracy at low volumes sent to a flare, a smaller orifice size is required but such a restriction in the flare piping introduces intolerable safety concerns when flow increases. Furthermore, an orifice meter will restrict the line to the flare such that when large volumes are flared for emergency purposes, it will result in an explosion. Other meter options such as ultrasonic or thermal mass can be more costly, and depending on technology, can be very sensitive to operating and ambient conditions at low flow conditions (e.g., thermal mass meter). In most situations, the only economically feasible form of measurement is using a thermal mass meter, which is too dependent on calibration to be considered reliably accurate. In lieu of direct measurement, process modeling or metering downstream of the compressors is a more viable option to quantify emissions.

Economic Description of the Process or Equipment:

What is the per unit cost of the equipment or the costs associated with the process?

Costs vary widely based upon design, materials of construction, and capacity. Because the operation of VRUs is not always economical or feasible, VRUs are often leased rather than purchased by an operator.

What are the annualized operating costs for the equipment or costs associated with the process?

Costs vary widely based capacity and service conditions. VRUs are often leased and operators will be charged as long as the VRU is on site. There typically comes a point at which the operation of the VRU is no longer economic due to low volumes of gas being recovered or low gas prices.

Note that a VRU can be used to capture emissions streams in addition to tank emissions, such as dehydrators and pneumatics. This makes the economics of the VRU more attractive to an operator.

If the equipment or process is powered, what are the costs?

Generally, the processing vessels and tanks are not powered. The control equipment (controllers, actuators, process indicators) for the vessels consume power. The exception is heater treaters, which are generally use field gas to generate heat through combustion. VRUs require a powered driver for the compressor (electric or natural gas engine).

The availability of reliable and adequate voltage electrical grid power is a determining factor on control strategy. In addition to cost of power, reliability is an important consideration for control devices as interruption will result in controllers going to a fail-safe condition. If an electric VRU is on site and power fails, gas will go to flare or potentially be vented from tank pressure relief devices.

What are the maintenance and repair costs for existing or new equipment?

Costs vary widely based upon size, age, and configuration.

Existing Reduction Strategies:

How has industry reduced emissions/waste from this equipment or process historically?

Pursuant to 20.2.72 NMAC and 20.2.74 NMAC. oil and gas companies that wish to build or modify facilities must obtain an air quality permit from NMED prior to construction based on the potential air emission rate or potential to emit (PER or PTE) of the entire facility. Air permits are required for any facility with potential emissions greater than 10 pounds per hour or 25 tons per year of pollutants with a national or state ambient air quality standard. The NMED has issued several General Construction Permits (GCP) specifically for the oil and gas industry. GCP-Oil & Gas (issued 4/27/2018) may be obtained for a variety of oil and gas facilities, and GCP-6 (issued 1/14/2014) authorizes voluntary controls for storage vessels. Both permits are relevant to current emissions concerns and aim to reduce emissions.

Smaller well pad facilities may quality to operate under a Notice of Intent (NOI) registration if potential emissions are more than 10 tons per year of any regulated pollutant, but less than the threshold required to obtain a minor construction permit such as the GCP-Oil & Gas.

The rapid growth in crude oil production in southeast New Mexico began in 2011, which corresponds with the initial NSPS OOOO applicability date. As such, many existing storage vessels are currently subject to controls under NSPS OOOO/OOOOa. In New Mexico, the enforceable state program (GCP-Oil & Gas) allows operators to account for emissions reductions processes when calculating potential emission rate (PER) to determine NSPS OOOO/OOOOa applicability for new and modified storage vessels. EPA expressly allows for operators to account for enforceable limitations under state programs to prevent operators from being subject to duplicative requirements under state and federal law. To avoid duplication, storage vessels should only be required to comply with either NSPS OOOO/OOOOa or the state program, not both. It is estimated that more than 59% of oil production in New Mexico is either subject to the control requirements of NSPS OOOO/OOOOa, subject to the control requirements of the enforceable state program, or utilizes process equipment which results in emission rates that allow for registration under the NOI.

According to DrillingInfo[151] data, EDF estimates that **only 15% of well sites** in New Mexico are new/modified after August 23, 2011 and are therefore subject to the NSPS standards. As such, the remaining 85% of existing sources (the large majority of facilities) are not currently subject to OOOOa tank standards unless there have been modifications to the tanks

151 https://www.enverus.com/?utm_source=google&utm_medium=cpc&utm_term=drillinginfo&utm_campaign=DrillingInfo_Brand&utm_adgroup=DI_Generic_Brand_Match&_bt=341635638623&_bm=e&_bn=g&_bk=drillinginfo&gclid=CjwKCAiA_MPuBRB5EiwAHTTvMUwsPpq8U3RAVQxq9gYqyMw74CrIsimx5htzAbI_jZ_kJBVUT4Jh7BoCUF8QAvD_BwE?utm_source=google&utm_medium=cpc&utm_term=drillinginfo&utm_campaign=DrillingInfo_Brand&utm_adgroup=DI_Generic_Brand_Match&_bt=341635638623&_bm=e&_bn=g&_bk=drillinginfo&gclid=CjwKCAiA_MPuBRB5EiwAHTTvMUwsPpq8U3RAVQxq9gYqyMw74CrIsimx5htzAbI_jZ_kJBVUT4Jh7BoCUF8QAvD_BwE

at the site. Using the same DrillingInfo data, EDF calculates that the existing facilities are responsible for 87% of total cumulative production since August 2011 in New Mexico, illustrating that the majority of wells and production are not subject to the NSPS.

Tank modifications, such as adding a new oil and gas well's production to the tank battery, tank modifications, etc. result in the tank becoming subject to OOOOa regulations. These newer wells (15%) added 129 million barrels of annual oil production (180% increase) over the time period, bringing total current annual oil production to 200 million barrels. The remaining 85% of well sites account for 71 million barrels, or 1/3, of current annual oil production. (http://www.emnrd.state.nm.us/ADMIN/publications.html)

Tank replacement or retrofits of old storage tanks ~~have~~ can been employed to allow tank emissions to be routed to a control device when needed on a case-by-case. Replacement or retrofits of old tanks are usually required because many existing storage vessels at older facilities were not designed to employ vent control devices and are subject to new emission reduction needs. The additional back pressure on the tank from an improperly designed controlled vent header may pose a safety risk by compromising tank integrity from over-pressurization. However, the economics and technical feasibility of this option is predicated on various factors. Costs, estimated useful equipment life, product value, production type and volume (well life), and geographic issues and logistical constraints are all factors in the determination. Additionally, in the San Juan Basin, tank retrofit is not a technically feasible option for the open-top tanks that are commonly used.

Storage tank equipment control requirements for existing facilities, not already subject to NSPS OOOO/OOOOa, should be based on appropriate thresholds (e.g., low production facilities that cannot support new technology controls). Existing source engineered retrofits are more costly than controls on a new source. The throughput impacts the ability of the control equipment to function effectively, so for existing storage tanks, the control threshold should be even higher due to the additional cost to retrofit the equipment.
Retrofit engineering analysis requires collection of facility and production data, an engineering review of the entire system (including retrofit or tank replacement), and economic considerations.

Facility Data/Information Collection (inlet to outlet) needs:

1. Vessel/tank(s)/piping/valves/connections inspection (integrity), maintenance, and operational condition
    a. Tanks
        i. Roof and sides (shell)
        ii. Foundation
        iii. As-builts including controls/automation
        iv. Internal inspection
        v. Specification sheet
    b. Vessels (separator) /Piping
        i. Pressurized fluids analysis
        ii. Shell vessel inspection (welds, thickness, penetrations, mechanical function)
        iii. As-built (piping size, connections, valves), metallurgy, and automation
        iv. Specification sheet
    c. Mechanical Integrity (MI)
        i. Non-destructive examination (NDE)
        ii. Metal thickness
        iii. Brittle fracture
        iv. Joints (welds)
        v. Penetrations
    d. Maintenance
        i. Inspections records
        ii. Equipment maintenance records (vessels, tanks, piping, PRVs, Thief Hatches)

iii. Releases (spills, LDAR, etc.)

e. Operations
   i. Placement of equipment (spacing)
   ii. Suitability for Service
   iii. Automation
   iv. Air permit/Regulatory requirements
   v. Marginal production facility / GIS-remote location
   vi. Operational changes over time

2. Oil/Gas throughput, pressure, temperature, liquids analysis, and extended gas analysis (VOCs, methane)
3. Power source (electricity, generator, solar)
4. Oil and gas pipeline/infrastructure (e.g., collection system, LACT, meter, etc.) in place

Engineering Review (retrofit verses remove/replace separators/storage vessels):

1. Process model/simulations e.g., Promax, Hysys, Pipesim
2. Process results … system flowrate, pressure, equipment specs
3. Compare process results to existing equipment/facility data
4. Process optimization
   a. Vessels – (e.g., pressure, corrosion (internal), wall thickness)
   b. Tanks – (e.g., pressure, corrosion (internal, top), wall thickness, compatible materials)
   c. Piping/Valves/Connections (e.g., size, corrosion, wall thickness, compatible materials)
5. Tanks/vessels out of service to complete the retrofit (PVRV/thief hatch condition).

Economic Considerations -- Technical Feasibility / Costs / Remaining Useful Life of Equipment:

Based on the above engineering analysis, operators can then decide the most feasible methane control based on technical feasibility, costs (e.g., rate-of-return/return of capital/or payback standpoint), and remaining useful life of equipment (e.g., mechanical integrity and replacement costs). In many cases, the production rate of older stripper[1] oil and gas wells will not support facility retrofits. In addition, due to the low well production rates the emissions from these tanks may be low resulting in a high cost/benefit ratio.

There are 57,868 oil and gas wells in the state of New Mexico of which 11,670 oil wells produce 10 BOPD or less, and average 2.5 BOPD per well. There are 26,282 natural gas wells that average 23 mcfd per well. Combined, these oil and natural gas stripper wells make up 66% of all wells in New Mexico and produce 12.4 million barrels of oil and 225 billion cubic feet of natural gas annually. (https://www.eia.gov/petroleum/wells/pdf/full_report.pdf)

By their very nature of marginal producing rates this class of well is cost sensitive. Frequently, these wells and facilities may be shut in or plugged and abandoned rather than retrofitted resulting in underground waste from unrecovered hydrocarbons. The reservoirs that stripper wells access are not necessarily depleted, in many cases they still hold two thirds of its potential value, however due to the low operating margin of a stripper well they are at risk of premature abandonment, leaving large quantities of oil and gas reserves behind.
(http://iogcc.ok.gov/Websites/iogcc/images/MarginalWell/MarginalWell-2015.pdf)

Any storage vessels not currently subject to OOOO/OOOOa, which are replaced due to state regulations or due to reaching the end of useful life, will be subject to OOOO/OOOOa, which would provide additional emission reductions. At very low levels of gas, in order to run a combustion device, operators would need to bring out supplemental fuel.

[1]Stripper Well: An oil well that produces 10 BOPD or less, and a gas well that produces 60 Mcfd or less as defined by the Interstate Oil & Gas Compact Commission.

Remaining useful like of equipment include wells and tank settings. For discussion purposes:

- Technical Feasibility: For retrofitting a tank setting, the operator must have adequate Q (including production decline), P, and tank integrity to address delta P operations with a control device to be technically feasible. If the tank integrity is in question, then tank modifications or replacement (along with tank cleanout) is required.

- Costs: Cost comes in several different ways, one being monthly lease operating expense (LOE), and others coming as deductions from product income streams such as lease burdens (State & Federal royalty, ORRI, production payments, etc.), production taxes, and product price deductions for items such as gathering and transportation, dehydration, processing, and compression.

- Cash flow: Revenue minus lease burden (expenses, taxes, etc.).

- Cash Flow Deferral – Time when well and facility operates at a loss.

- Useful life of a well/facility: Generally, if the cash flow deferral is greater than 3 years, the well/facility may be considered no more useful resulting in waste of resources in the oil and gas reservoir.

STRIPPER OR MARGINAL WELL CASE:

- Avg stripper (also referred to as marginal) oil well 2.5 BOPD, average stripper gas well 23 MCFD
- Monthly Revenue at $50/BO and $2/MCF is $3,800 and $1,400 respectively.
- Monthly Income (deducting lease burden and taxes) $2,800 and $1,030 respectively.
- Monthly Cash Flow (deducting LOE) $1,200 and $530 respectively.
- This case for a stripper well operating near the current product pricing level above illustrates the annual cash flow to be $14,400 for oil and $6,360 for gas. From these cash flow numbers, it can be easily seen that stripper (marginal) wells are extremely cost sensitive and any one time expense of $14,400 for a stripper oil well or $6,360 for a stripper gas well would render the well uneconomic for an entire year. An annually reoccurring expense of the same magnitude would render the well permanently uneconomic to operate, production would cease, and the well would be plugged and abandoned (P&A). This case also illustrates even fractional increases in operating expense have a significant impact on profitability and subsequently a significant impact on the companies that operate stripper or marginal wells.

As noted previously on page 7, connection of a tank vent header to a VRU requires a more complex design/installation to manage the potential failure consequences. The potential to draw tank pressure down below 0 osig in the condition of 1) inadequate flash gas from the influent, 2) no/inadequate blanket gas system, 3) inadequate/malfunctioning PVRV can result in tank failure/collapse. Blanket gas systems, if present, are normally installed on newer and/or larger facilities due to cost and complexity. Without blanket gas systems, air/oxygen can be drawn into the tanks through the PVRV producing a potentially combustible mixture and/or gas that does not meet midstream specifications. The mixture imposes a safety risk and also may result in curtailment of the gas sales line which leads to flaring.

New Wells:

In newer high producing wells, there are more opportunities to control emissions via vapor recovery. Newer sources are also covered by NSPS OOOO/OOOOa.

Existing Wells:

N/A

How have the emission/waste reductions been measured?

NMED emissions calculations for the permitting process and process simulation prior to the development of a facility to ensure emissions are in compliance with required permitted limits. Additionally, tank methane and GHG emissions are reported under the GHG Reporting Rule.

How have states and the federal government reduced emissions/waste from this equipment or process historically? In addition, please identify voluntary reductions achieved whether or not they were in response to a regulatory action/requirement.

The NMED General Construction Permit (GCP) requires controls reducing VOCs and HAPs, which also reduce methane. Moreover, the NMED permits require conditions to ensure that the controls remain effective. For example, the GCP Oil and Gas requires inspection of controls, periodic gas sampling of the gas routed to the separator/tanks, and other requirements. The requirements (conditions) are intended to ensure the emissions from the tanks remain below permit allowances.

CO: https://www.colorado.gov/pacific/cdphe/air-oilandgas-storagetankguidelines

EPA: https://www.epa.gov/sites/production/files/2015-09/documents/oilgascompliancealert.pdf

In Colorado, state rules require 95% control efficiency of hydrocarbons from individual new storage tanks with the PTE 6 tpy of VOCs.[152] Colorado is also proposing new rules for storage tanks which would lower the threshold at which an owner or operator must control storage tank emissions on a state-wide basis from 6 tpy to 2 tpy.[153] In addition, Colorado is proposing operators install automatic tank gauging on storage tanks to monitor the liquid level.[154] Finally, Colorado is proposing operators of storage tanks with uncontrolled actual VOC emissions greater than or equal to 2 tpy must control emissions from the loadout of hydrocarbon liquids from storage tanks to transport vehicles by using submerged fill and a vapor collection and return system and/or air pollution control equipment.[155]

Colorado's proposed 2-tpy threshold for installing storage tank controls is not supported by the cost data and will not result in cost-effective emission reductions. Of perhaps most importance, Colorado's economic analysis utilizes a 15 year period over which to annualize the costs associated with hydrocarbon liquid and produced water tanks. With respect to at least a subset of these storage tanks, historic evidence and current plans demonstrate that those tanks will not be in existence within 15 years and thus annualizing the cost out over the life of the equipment – as opposed to over the remaining life of the well is inappropriate. Colorado also incorrectly assumes that the emissions reductions remain steady year over year. The reality is that a number of wells operating today within the 2 to 4 tpy framework, will not be operational within five years. Even for those low-emitting storage tanks that are not expected to be plugged and abandoned in the next several years, the production is continuing to decline and thus, so are the emissions – limiting the value of emission reduced each year. Of significance as well, cost-effectiveness is not the only metric that is of importance – and frankly is not the metric utilized by operators. Rather, operators evaluate the production from the well, the operating costs of the wells, the continued life of the well, and the taxes and other expenses of the wells in determining its path

[152] Colorado Air Quality Control Commission, 5 C.C.R. 1001-9, CO Reg. 7 §XVII.C.1.b. (Feb. 24, 2014). Available at https://drive.google.com/file/d/168v7vMsFJtS7D8BWlnMbaXWA6uZUIyj8/view

[154] *Id*.

[155] *Id*.

forward with respect to any given well. Expenses such as those proposed in in Colorado will come at the outset and at considerable cost. As a result, operators may be forced to evaluate if they can continue operating wells and whether there remains sufficient value in a particular well to justify the costs of compliance (and for how long). Ignoring these considerations is not appropriate.

Colorado has proposed to require operators of storage tanks with 2 tpy of VOCs to use submerged fill and either a vapor collection and return system, air pollution control equipment, or both to reduce tank loadout emissions.[156]

https://doc-0o-68-docs.googleusercontent.com/docs/securesc/ha0ro937gcuc7l7deffksulhg5h7mbp1/v7vu3oupcqapualargdbcm4uedb202ac/1573596000000/09887998073533830170/*/1ot2dCFpgp18S8cqQWMHlZGQ_uz0VYKHy?e=download

Wyoming regulations specific to the Upper Green River Basin require new and existing tanks control flash emissions by at least 98%. Removal of flashing emissions control devices is allowed after 1 year if VOC flashing emissions have declined to less than, and are reasonably expected to remain below, 4 tpy. Statewide, Wyoming requires 98% control for tanks with 6 tpy of VOCs.[157] The Wyoming threshold is applied to the cumulative emissions from all tanks located at a well production facility. Accordingly, if there is more than one manifolded storage vessel onsite, operators must apply controls if the sum of all emissions from both manifolded vessels are 4 tons per year or greater.

Utah similarly requires 95% control of storage tank emissions if emissions are at least 4 tpy of VOCs.[158] Utah, similarly, requires operators to aggregate tanks and glycol dehydrators emissions, in order to calculate emissions for purposes of determining whether controls are required.[159]

In California, tanks with 10 metric tons of CH_4 or more must route emissions to a vapor collection system. Combustion using a low-NOx flare is only allowed if capture is demonstrated to be infeasible.[160] Pennsylvania general permit and exemption requirements mandate 95% control if emissions are 200 tpy of CH_4, or 2.7 tpy of VOC.[161]

Mexico adopted the same 10 metric tons of CH_4 threshold as CARB, recently, in its adoption of country-wide methane rules.[162] Mexico also requires operators capture emissions and route to vapor recovery unless it is infeasible to do so.[163]

[163] Id., Article 50.

Pennsylvania has required new storage tanks located at unconventional well sites to limit VOC emissions to 2.7 tons per year since 2013.[164] Recently the state retained this requirement in its general permits, GP-5 and GP-5A. GP-5 applies to midstream compression, gas processing, and gas transmission facilities. GP-5A applies to new or modified unconventional natural gas well site operations and remote pigging stations.[165] The Pennsylvania Department of Environmental Protection has proposed to require existing storage tanks installed at unconventional well sites on or after August 10, 2013, with potential to emit 2.7 tpy of VOCs to control emissions by 95% as part of its implementation of the EPA Control Techniques Guidelines.[166]

Canadian operators are subject to a facility venting limit of 15,000 standard cubic meters per year. Rules also require operators to reduce venting by 95% if produced and received gas amounts to 60,000 cubic meters per year (PTE threshold).[167] In British Columbia, new tanks which begin operations after Jan. 1, 2022, are subject to an emissions limit of 1,250 m3 per month. Existing tanks that begin operations before Jan. 1, 2022, are subject to an emissions limit of 9,000 m3 per month. Operators must retain records of emissions from uncontrolled storage tanks on a monthly basis.[168]

Various jurisdictions require operators control vapors when unloading liquids from storage tanks. Specifically, in Wyoming, loading emissions containing greater than or equal to 6 tpy VOC and HAP emissions must be controlled. Operators of new facilities must utilize a vapor collection system or equivalent device for the truck loading operation that captures a minimum of 70% of the truck loading vapors, and to route the vapors to device with a destruction efficiency of 98%.[169] In Utah, tanker trucks used for intermediate hydrocarbon liquid or produced water must be loaded using bottom filling or a submerged fill pipe. Operators must control VOC emissions during truck loading operations at all times using a vapor capture line. The vapor capture line must be connected from the tanker truck to a control device or process, resulting in a minimum 95% VOC destruction efficiency.[170] In Pennsylvania, since August 10, 2013, in accordance with Category 38 of the Air Quality Permit Exemptions document tanker truck load out operations are required to be equipped with controls achieving VOC, and HAP emissions reductions of 95% or greater unless their uncontrolled VOC, single HAP, and total HAP emissions are below the control thresholds of 2.7 tpy, 0.5 tpy, and 1.0 tpy, respectively. Per GP-5 and GP-5A, tanker truck load-out operations that take liquids from storage vessels with emissions above the control thresholds are required to use a vapor balancing system and ensure each truck used to unload liquids has passed an annual leak test.[171]

What are examples of process changes/modifications that reduce or eliminate emissions/waste from this equipment or process?

The addition of the controls and/or practices outlined above can reduce methane emissions from tanks. These strategies are widely utilized and required by permit.

Technology Alternatives:

List of technology alternatives with link to information or contact information for the company/developers.

Name/Description of Technology	Link (and contact info for company if available)	Availability	Feasibility	Cost Range (choose one)
Low production threshold / Vent	Need emissions inventory and remaining useful equipment analysis.	In use or in development		**Low** Medium High
VCU / Flare		In use or in development		Low **Medium** High
VRU / Gas Sales	https://hy-bon.com/blog/faq-about-vapor-recovery-units/	In use or in development		Low Medium High
Equipment (VRT) / Separator operating Practices	https://greasebook.com/blog/separators-heater-treaters-pressure/	In use or in development		Low Medium High
Heater Treater operating practices		In use or in development	Region specific	Low Medium High
Relief devices and thief hatches operating practices		In use or in development		Low Medium High
Solar Heating for Site Located Oil Storage or Separation	Utilizes solar power to supplement fired combustors in heating oil to improve separation. Patent No: US 9,394,780 B2	In use or in development		Low Medium High
SCADA		In use	Typically used to monitor/control larger facilities due to high installation costs	
Secondary Vapor Capture				

What technology alternatives exist to reduce or detect emissions? Please list all alternatives identified along with contact information for further investigation of this technology or process.

Radiant heat transmitted to stored hydrocarbons can affect product vaporization and increase vent flows from storage. In hot climates, lighter colors were chosen to reduce evaporative product losses in tanks which would route to vent or flare depending on the configuration of the tank battery. As noted in the Khark island study (citation below) the impact of paint color (dark versus light) can impact the amount of product lost due to evaporation by

250%. Currently, storage tank paint color may be dictated through BLM, landowner agreement, etc. with the intent to minimize the aesthetic impact of facilities on the landscape. Flexibility in the choice of storage tank paint colors on new installations could reduce venting in cases where tank vents are not controlled and low pressure flaring on controlled installations.

		Solar Absorptance (α) (dimensionless) Surface Condition

What are the pros and cons of the alternatives?

This is discussed above in the table. Many of them are already in use per best practice and regulation.

What is needed and available for new wells?

Discussed above in table.

What is needed and available for existing wells?

Discussed above in table.

What technology alternatives exist for this equipment or process itself?

Discussed above in table

What are the pros and cons of the alternatives?

Discussed above in table.

Costs of Methane Reductions:

What is the cost to achieve methane emission reductions?

No new controls are necessary due to current control mechanisms and efficiency of process.

A 2014 ICF International Report analyzed the cost of vapor recovery units (VRUs), which collect and compress gas, which can then be re-directed to a sales line, used on-site for fuel, or flared. The report states, "[B]ased on Gas STAR and industry data, the capital cost of this measure is assumed to be $100,000 with an operating cost (electricity) of $7,500 per year and a reduction of 13,410 Mcf per year. This yields a reduction cost of -$0.51/Mcf if the gas is recovered for sale or $4.57/Mcf if it is flared."[172] The recently released Synapse report estimates the unit cost ($/mcf of reduced methane) of adding VRUs to oil and condensate tanks to be $4.18 and the unit cost ($/tonne of reduced methane) to be $217.36.[173]

In connection with Colorado's proposed rule for lowering the control threshold for tanks from 6 tpy to 2 tpy, the Colorado AQCC estimated the annualized cumulative cost of installing 65 flare control devices in the Denver Metro Front Range North (DMFRN) area to be about $421,700 dollars, with an average cost effectiveness of about $2,232 per ton of VOC reduced. For the smallest category of tanks (2-3 tpy) the incremental cost of controls on 36 tanks is estimated at $2,843 per ton of VOC reduced.[174] For crude oil and water tanks in the remainder of the state, the AQCC estimates the annualized cost of installing 202 flare control devices at about $1.31 million dollars with an average cost effectiveness of about $1,512 per ton of VOC reduced. For the smallest category of tanks (2-3 tons/year) the incremental cost of controls on 80 tanks is estimated at $2,688 per ton of VOC reduced.[175] For condensate tanks outside the DMFRN, the estimated annualized cost of installing 444 flare control devices is about $2.88 million dollars with an average cost effectiveness of about $1,679 per ton of VOC reduced. For the smallest category of tanks (2-3 tons/year) the incremental cost of controls on 175 tanks is estimated at $2,817 per ton of VOC reduced.[176] Colorado estimates the cost of a vapor collection and return system to control tank loadout emissions to be $12,000-$15,0000 for initial set-up. Per the Colorado Initial Economic Impact, "Emission reductions will depend on how frequently the storage tank is unloaded. EPA estimates the cost purchasing additional connections to route a transport vehicle vent to a useful outlet at $1,000 (estimated implementation cost) and additional operating costs to connect the lines at $200 (incremental operating cost). EPA also estimates that recovering these vapors can payback in two years depending on the frequency of loading, load volumes, and the value of the gas.27 In most cases, the storage tank will already be controlled as required by the Regulation Number 7 storage tank control programs; therefore, the additional costs to control the transport vehicle emissions are related only to the installation of

[175] *Id*.
[176] *Id*.

vapor return lines to the storage tank such that transport vehicle emissions are then routed to the existing control device."[177]

The California Air Resources Board estimates the cost of installing VRUs for tanks at $4,700,000 annually, with annual savings of $500,000. CARB estimates reductions from the installation of VRUs of 540,000 MT CO2e, with a cost per ton of $9 per MT CO2e reduced (using the 20 year GWP). The Cost per Ton is estimated at $25 per MT CO2e reduced using the 100 year GWP.[178]

What would be the implementation cost?
For new wells?

N/A

For existing wells?

N/A

Are there low-cost solutions available?

N/A

If a solution is high-cost, why is that the case?

N/A

Are there additional technical analyses needed to refine benefits/costs estimates?

3. IMPLEMENTATION

For each piece of equipment or process, please consider the following questions and add other relevant information. If relevant, please identify if the answers are different for large company and small company requirements or are different for well type or basin.

Implementation Feasibility:

What is the feasibility of implementation (availability of required technology or contractors, potential permitting requirements, potential for innovation)?

See above section on economic and technical analysis of replacements/retrofits.

What is the useful life of equipment?

[177] CO APCD, Economic Impact Analysis (Initial Analysis), Sept. 19, 2019, p. 29, available at https://drive.google.com/drive/folders/14fvt4C0Tzl79to4c2tVuLDKucksk5uaB

[178] 17 C.C.R. §§95665 et seq., Subarticle 13: Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities, Attachment 2: Summary of Cost, Emissions, and Cost per Ton using the 20 year and 100 year GWP, respectively, available at https://ww3.arb.ca.gov/regact/2016/oilandgas2016/oilgasatt2.pdf

Standard life of control equipment. Processing and storage vessels generally have long useful lives, 20 to 30 years is common.

What are the maintenance and repair requirements for equipment required for methane reduction?

Discussed in table

How would emissions be detected, reductions verified and reported?

Emissions from storage vessels are calculated as part of an NMED air permit application and reported to NMED as part of any required emission inventories. This includes emissions that result from the volume of tank vapors routed at low pressure to an enclosed combustor or flare used as a control device.

No direct measurement; calculate pre and post-actual/PER for the control technology.

Remote monitoring of control equipment.

4. CHALLENGES AND OPPORTUNITIES TO ACHIEVE METHANE REDUCTION IN NEW MEXICO

For each piece of equipment or process, please consider the following questions and add other relevant information. If relevant, please identify if the answers are different for large company and small company requirements or are different for well type or basin.

What regulatory gaps exist for this equipment or process? Are there regulatory gaps filled by the proposed implementation?

None.

Where do conflicting priorities exist between NMED, EMNRD, and NMSLO? Are there opportunities for coordination between these agencies?

None

Are there existing regulations related to methane that do not address the intended purpose? Identify any unintended barriers to methane reductions/capture that may hinder proposed processes.

No

Other considerations or comments (e.g. particular design or technological challenges/opportunities, co-benefits, non-air environmental impacts, etc.?):

None

5. SEPARATORS - PATH FORWARD[179]

	OPTIONS	DESCRIPTION AND LINK TO INFORMATION IF AVAILABLE. PLEASE LIST THE BENEFIT THAT COULD BE ACHIEVED THROUGH THIS OPTION AND ANY DRAWBACKS OR CHALLENGES TO IMPLEMENTATION	EFFECTIVENESS OF COST NOW (choose one)	REPORTING, MONITORING AND RECORDING OPTIONS, INCLUDING REMOTE DATA COLLECTION	IS THIS OPTION HELPFUL IN THE SAN JUAN BASIN, PERMIAN BASIN OR BOTH
8.1	Applicability threshold	Storage tank equipment control requirements for existing facilities, not already subject to NSPS OOOO/OOOOa, should be based on appropriate thresholds. American Petroleum Institute's December 4, 2015 comments to EPA on the draft Control Techniques Guidelines suggests that a 15 tons per year VOC threshold is appropriate as existing source retrofits are more costly than controls on a new source. The throughput impacts the ability of the control equipment to function effectively. As noted in EPA's OOOO/OOOOa, requiring controls for new storage tanks below a certain VOC threshold may not be effective. For existing storage tanks, the control threshold will be even higher due to the additional cost to retrofit the equipment.	**LOW** MODERATE HIGH	Covered in NMED permit conditions	San Juan Permian Both
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
8.2	Controls – VCUs and VRUs: Consider incorporating VCUs and VRUs into facility design to capture additional "flash		LOW **MODERATE** HIGH	Covered in NMED permit conditions	San Juan Permian

	gas" not captured by separator, especially early in the well life when production is highest.				Both
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
8.3	Separators / VRTs: Optimize separator design/operating parameters to maximize gas separation. Consider use of VRT after the separator as a second opportunity to minimize "flashing" in the storage tanks.	The facility should be designed and operated to safely recover as much flash gas as possible prior to storage.	**LOW** MODERATE HIGH	Covered in NMED permit conditions	San Juan Permian Both
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
8.4	Inclusion of controlled tanks and relief devices in site specific LDAR	Minimize leaks from controlled tanks and relief devices through their inclusion in the existing site specific LDAR program (at the same frequency as the existing program).			San Juan Permian Both
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
8.5	Control storage tanks with emissions above specified threshold (e.g., 10 tpy of CH4 or 2 tpy of VOCs) by 98%	See discussion above of CARB and Colorado proposed requirements in section discussing existing reduction strategies.	**Cost effective**	Robust recordkeeping and reporting requirements essential for compliance monitoring	San Juan Permian Both
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		

8.6	Require operators route tank emissions to VRU unless technically infeasible.	See discussion above of CARB requirements in section discussing existing reduction strategies.	**Cost effective**	Robust recordkeeping and reporting requirements essential for compliance monitoring	San Juan Permian Both
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
8.7	Require operators use automated tank gauges to reduce fugitive emissions from thief hatches	See discussion above of Colorado proposed requirements in section discussing existing reduction strategies.	**Cost effective**	Robust recordkeeping and reporting requirements essential for compliance monitoring	San Juan Permian Both
	COMMENT A. Require operators to install vapor balance return lines. Delay effective date of regulations (by 1 year) to allow truck drivers to receive training and certification in operation. Require monitoring and reporting.		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
8.8	Require operators control emissions during unloading of emissions from tanks into trucks	See discussion above of Colorado proposed requirements in section discussing existing reduction strategies.	**Cost effective**	Robust recordkeeping and reporting requirements essential for compliance monitoring	San Juan Permian Both
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
8.9	Convert Water Tank Blanket from Natural Gas to Produced CO2 Gas	https://www.epa.gov/sites/production/files/2016-06/documents/convertwatertank.pdf Natural Gas STAR Partner has switched water tank blanket from natural gas to CO2-rich produced gas, saving 32,600 Mcf per year of methane.	$1,000-$10,000		San Juan Permian Both

	COMMENT A. There is an applicability restraint for this option: "This practice can be implemented where there is a source of CO2-rich produced gas or a nearby gas processing plant with acid gas removal."		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
8.10	Recover Gas During Condensate Loading	https://www.epa.gov/sites/production/files/2016-06/documents/recyclelinerecovers.pdf Natural Gas STAR: "Lease condensate production, when transferred from storage into tank trucks, can generate significant volumes of methane vapor due to pressure and temperature changes and evaporation. This methane is typically vented to the atmosphere to prevent the internal tank pressure from rising. One [Natural Gas STAR] Partner reported capturing methane that would otherwise be vented by connecting the tank truck vent to the condensate storage tank, or to a vapor recovery line… Partners have reported reducing methane emissions by 6,500 Mcf to 39,000 Mcf per year, which includes flashing loses.	< $1,000		San Juan Permian Both
	COMMENT Applicability "This technology applies to all condensate production operations using tank trucks or railroad tanks."		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
8.11	Install Pressurized Storage of Condensate	https://www.epa.gov/sites/production/files/2016-06/documents/installpressurized.pdf Natural Gas STAR: "When transferred to atmospheric storage tanks, a pressure drop occurs causing the methane to flash out. Operators often vent this gas to the atmosphere. Interstage knockout in multi-stage compressors with interstage cooling also contains raw natural gas liquids (NGL) saturated in methane. If transferred to atmospheric storage, nearly all the methane will flash and vent to the atmosphere	$10,000-$50,000		San Juan Permian Both

		One [Natural Gas STAR] partner reported installing pressurized storage, requiring pressurized transport of condensate to a gas plant for economic recovery of gas liquids and associated methane, volatile organic compounds (VOCs), and hazardous air pollutants (HAPs) emissions reductions…Total partner reported methane emissions savings were 27,992 Mcf per year for 4 installations of pressurized storage tanks."			
	COMMENT A. Applicability: This technology is applicable on all gas well and gathering/booster compressors.		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
8.12	Apply control threshold to tank emissions from all tanks located at a facility, rather than individual tanks or individual tanks manifolded together.	See discussion above about Wyoming and Utah approaches.			
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
8.13	Consider installation of remote monitoring to notify/control critical controllers or components, such as malfunctioning dump valves or open thief hatches	Programmable Logic Control (PLC), Supervisory Control and Data Acquisition (SCADA) systems, etc. allow operators to monitor, trend, and control different aspects of their process that are enabled through the use of instrumentation (e.g. Pressure Transmitters, Flow Transmitters, Level Switches, Level Transmitters, etc.). While SCADA is installed for operational purposes, analysis of that data and integration of more SCADA over time can result in lower emissions as facilities are run more efficiently. PLC and SCADA systems require both instrumentation and communication equipment. This poses an economic burden and may not be scalable to smaller operators or many existing locations.			
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		

8.14	Consideration of a control credit similar to TCEQ program	See page 12 of Enhanced Vapor Recovery presentation. The addition of additional control equipment can result in an increased percent emission reduction credit.			
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
8.15	Install enhanced vapor recovery in addition to a VRU system.	See Enhanced Vapor Recovery presentation. This (or similar) enhanced gas recovery technology allows operators to capture up to 100% of flash gas for sale. https://www.ecovaporrs.com/	Cost-effective (often economically beneficial)		
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:

NMED/EMNRD METHANE ADVISORY PANEL

SECTION 9, COMPLETIONS/ RECOMPLETIONS AND STIMULATIONS

Discussion for MAP members on August 30, 2019

NOTE: The focus of this report is processes, and the associated equipment, directly related to the release or capture of methane gas. We are not requesting information on processes/equipment that are not related to the release or capture of methane gas.

1. DESCRIPTION OF PROCESS AND EQUIPMENT

Provide a description of the processes and/or equipment used in oil and/or gas extraction for this topic. Note that this report template will be used for all topics of the MAP review and, thus, not all questions or information may be relevant for each topic. If information is not relevant, indicate N/A. Note any differences expected for differing well types, industry sector, or basin location.

Technical description of the process or equipment:

A typical oil or gas well goes through several phases during its life. The first phase is the actual drilling of well. Drilling is followed by completions. After a well is completed the well can produce hydrocarbons for several years or decades. For an existing well, it may be necessary to complete a well stimulation to increase production in case of production decline. In any case, the emissions during completions/stimulations are associated with a relatively short period in a decades-long well life cycle.

All oil and natural gas wells must be “completed” after initial drilling in preparation for production. Oil and natural gas completion activities not only will vary across formations but can vary between wells in the same formation. Well completion activities include multiple steps after the well bore hole has reached the target depth. These steps include inserting and cementing-in well casing, perforating the casing at one or more producing horizons, and potentially hydraulically fracturing one or more zones in the reservoir to stimulate production.

Well stimulation is a well intervention performed on an oil or gas well to increase production by improving the flow of hydrocarbons from the reservoir into the well bore. Unconventional gas reservoirs are more dispersed and found in lower concentrations and may require stimulation (such as hydraulic fracturing) to extract hydrocarbons.

In the process of hydraulic fracturing, high-pressure fluid typically water emulsion, or inert gas, with a proppant (sand) is injected into the formation resulting in fractures of the formation rock. Typically, truck mounted pumps are used to inject the high-pressure fluid into the formation. The fracturing process is often carried out in stages on sections of the well tubing or casing. After each section of the well and formation is hydraulically fractured, plugs are inserted in the well prior to fracturing the next section. This process is repeated many times over the length of the wellbore.

Once the fracturing is completed, a workover/completion rig or coil tubing unit is used to drill through the plugs and begin the well cleaning process.

After a new or existing well has been hydraulically fractured and the plugs have been cleaned out, the well begins its flowback process which is primarily water (with additives) or inert gas and proppants. This material has to be evacuated to prepare the well for production. When flowback is initiated, various forces act on the fluid in the well tubing. These include the weight of frac fluid column itself, formation pressure, back pressure from the gas gathering line of the flowback gas and the surface equipment connected to the well. These forces have to be overcome in order for the fluids in the wellbore to come to the surface.

During the flowback, the fracturing fluid or a mix of hydrocarbons and fracturing fluid from the formation come to the surface. As the fracturing fluid flows to the surface, reservoir hydrocarbons and produced water replace the fracturing fluid in the well tubing. Thus, initially the amount of hydrocarbons coming to the surface is very limited. Initial flowback is discussed in the preamble to NSPS Subpart OOOOa regulations and can be found on Page 56630 of the following document:

https://www.govinfo.gov/content/pkg/FR-2015-09-18/pdf/2015-21023.pdf. As the fracturing fluid reach the surface, they are processed per New Source Performance Standards (NSPS) regulations, 40 CFR Part 60, Subpart OOOOa which govern the managing of fluids during flowback. In most cases, NSPS OOOOa requires Reduced Emission Completions (RECs) as discussed later. The regulations are available at https://ecfr.io/Title-40/sp40.8.60.oooo_0a .The regulations related to well completions are at 40 CFR §60.5375a.

Useful information on RECs can be found at http://www.ipieca.org/resources/energy-efficiency-solutions/units-and-plants-practices/green-completions/ .

Provide the segment(s) of the industry that the equipment or process is found:

NMED Exhibit 10 - 0261

This process is found in the oil and gas production segment of the industry.

Describe how the equipment or process is used:

Reduced emission completions are mandated by NSPS Subpart OOOOa regulations for both gas and oil wells with some exceptions for certain well types. In many cases, the flowback is first routed to a solids separator (often called a sand trap). This is necessary since some of the sand that is injected in the hydraulic fracturing process comes back to the surface along with the injected water. Removal of solids is needed to prevent damage to downstream equipment. From the solids separator the fluid can be routed to additional separators where gas, oil, and water can be separated. Once gas quality is such that it can meet specifications for gas sales, it is typically routed to a sales line unless it is technically infeasible to do so. In that case, gas must be combusted until there is a fire hazard or a negative impact to tundra, permafrost or waterways.

Provide the common process configurations that use this equipment or process:

Typical equipment used in flowback can include sand separator, two or three phase separators, frac tanks, tanks, completion combustion device, or permanent production-phase equipment. Depending upon the amount of flowback expected and the availability of equipment to be used during production, flowback can be routed to temporary equipment or the permanent equipment. The flowback period typically lasts for days or a few weeks following which the well transitions to a production phase. The flowback period ends when either the well is shut in and permanently disconnected from the flowback equipment or at the startup of production. NSPS Subpart OOOOa has different gas capture requirements for initial flowback and separator flowback. During initial flowback, gas may be vented if it is technically infeasible for a separator to function (i.e., any gas present in the initial flowback stage is not subject to control under NSPS OOOOa). During separator flowback all gas must be recovered and sold or rescued if technically feasible to do so. If not technically feasible, it must be routed for combustion. NSPS Subpart OOOOa hydraulic fracturing requirements are now in place for all hydraulic fracturing operations onshore in the U.S.

What is the distribution of the equipment or process across business segments?

This process primarily relates to the onshore oil and gas production sector.

How has this equipment or process evolved over time?

Hydraulic fracturing itself has used since the 1940's in the industry.

There are many reported instances where industry started voluntarily using reduced emission completions (REC). EPA's Natural Gas STAR program has reports of RECs since the 2004. These

NMED Exhibit 10 - 0262

voluntary activities resulted in reduced emissions as reported by various operators. Additional information about the Natural Gas STAR program and reduced emission completions can be found at https://www.epa.gov/sites/production/files/2016-06/documents/reduced_emissions_completions.pdf https://www.epa.gov/sites/production/files/2017-09/documents/greencompletions.pdf

Federal regulations first addressed emission associated with completions in the 2012 NSPS regulations at 40 C.F.R. Part 60 Subpart OOOO: https://www.ecfr.gov/cgi-bin/text-idx?node=sp40.7.60.oooo . These regulations require the use of RECs to completions at gas wells following hydraulic fracturing. NSPS Subpart OOOOa, finalized in 2016, requires RECs for oil wells as well.

2. INFORMATION ON EQUIPMENT OR PROCESS COSTS, SOURCES OF METHANE EMISSIONS, AND REDUCTION OR CONTROL OPTIONS

Identify the capital and operating costs for the equipment or the process. Identify how methane is emitted or could be leaked into the air. Please **prioritize** the list to identify first the largest source of methane from the process or equipment and where there is **potential** for the greatest reduction of methane emissions. Note any differences expected for differing well types, industry sector, or basin location.

Sources of Methane:

Provide an overview of the sources of methane from this equipment or process:

During the hydraulic fracturing process itself, injection of water, or inert gas, and proppant is handled by pumps powered by engines. This process itself lasts only a few days per well depending upon the well stimulation design. The emissions during the actual hydraulic fracturing are combustion emissions associated with diesel usage.

The flowback period involves the return to surface of the fracking fluids, or inert gas, as well as some formation hydrocarbons. This is the primary source of methane emissions for completions activity. NSPS Subpart OOOOa requires that, when feasible, hydrocarbons are captured and sent to sales or combusted if sales are not technically feasible.

New Wells:

New wells that fall into the category of wildcat or delineation, wells or low-pressure wells are allowed to route the recovered gases during flowback to a completion combustion device. In this case, the emissions of methane are due to uncombusted methane from the combustion device.

NMED Exhibit 10 - 0263

Low pressure wells may also be exempted from sending entrained gas to sales instead sending the full stream of production to a well completion vessel or frac tank.

New wells that do not fall into the wildcat or delineation, category are required to route gas emissions of saleable gas to a gas sales line unless it is technically infeasible to do so, in which case the gas must be sent to a completion combustion device.

Existing Wells:

The same requirements apply to refracturing at existing wells as for new wells. It is however, less likely that existing wells will meet the definitions of a wildcat well. Note there may be technical infeasibility due to reservoir low pressure to operate control equipment on the surface.

The Grant Schreiber study (below), based on Gas Capture Plans submitted by operators in San Juan and Rio Arriba Counties in November 2018, found that 100% of Gas Capture Plans provided for either venting or flaring of recompletions—with 68.5% of recompletions vented and 31.5% of recompletions flared.

*68.5% of recompletions (37 wells) are vented

**31.5% of recompletions (17 wells) are flared

Note on the study [from non-participants]: During the Methane Advisory Panel's discussion about data located in OCD Gas Capture Plans, it was suggested that Gas Capture Plan data should not be used to characterize emissions that may occur after recompletions. Data entered into the Gas Capture Plans reflect estimates made prior to the project taking place and are merely estimated volumes of what could happen to produced gas. Accordingly, vented and flared volumes represented in Gas Capture Plans are estimates of what could be potentially vented or flared if there isn't a gathering or sales pipeline in place for the pipeline quality gas and are not accurate. It was instead suggested that information on production accounting reports from the OCD be used when discussing green completion emissions. The data from the production accounting reports reflects actual data points following completion and are far more accurate. In addition, the data from the Grant Schreiber study as described contains no context or other explanation regarding controls, volumes, timing or whether the venting or flaring was conducted pursuant to regulation.

How are the emissions calculated for this equipment or process?

Emissions from this source can be calculated using the EPA GHG reporting rule (Subpart W) or at https://ecfr.io/Title-40/sp40.23.98.w. These are reported to EPA in accordance with the GHG reporting rule. Equations for estimating emissions from well venting during completions and workovers with hydraulic fracturing are given at 40 CFR 98.233(g), Equations W-10A and W-10B.

What data is available to quantify emissions/waste for this equipment?

EPA has discussed emissions from this source in Section 1 of the Technical Support Document for the NSPS OOOO regulation found here: https://www.regulations.gov/document?D=EPA-HQ-OAR-2010-0505-4550 .

In 2017, the total methane emissions reported from Petroleum and Natural Gas Systems for the entire country were 88 million metric tons CO2e. The onshore production sector reported approximately half or 44 million metric tons CO2e. Of these, well completion and workovers with hydraulic fracturing reported approximately 1 million metric tons CO2e. This number is an approximation from the sector summary. Thus, the methane emissions from the well completions sector are approximately 2% of total methane emissions from the onshore production sector or approximately 1% of total methane emissions from the Petroleum and Natural Gas Systems sector.

https://www.epa.gov/sites/production/files/2018-10/documents/subpart_w_2017_industrial_profile.pdf

Allen et al (2013), University of Texas and Environmental Defense Fund (EDF) study did actual measurements from 27 completions in various areas of the country. The study can be found here: https://www.pnas.org/content/110/44/17768

The duration of the flowbacks in their study ranged from 5 hours to 2 weeks. Measured emissions of methane over an entire completion averaged to be about 1.7 metric tons methane with a range of 0.01 to 17 metric tons. They extrapolated these values to come up with estimates of national methane emissions from completions ranging from 0.125 million metric tons of CO2e to 0.675 million metric tons of CO2e with an average of 0.45 million metric tons of CO2e. These are less than the EPA GHG reported number of approximately 1 million metric tons CO2e for 2017.

What are the data gaps in quantifying emissions/waste for this equipment?

These emissions are estimated and reported in accordance with the GHG reporting rule.

Economic Description of the Process or Equipment:

What is the per unit cost of the equipment or the costs associated with the process?

The total cost of completion events including hydraulic fracturing greatly varies depending upon the well, hydraulic fracturing setup, length of flowback, availability of permanent equipment, sales line availability and quality of gas.

The cost of RECs with and without combustion has been discussed in detail in the Technical Support Documents to the EPA NSPS Subparts OOOO and OOOOa regulations. The costs are with and without any anticipated savings from sale of recovered gas. Note that the Technical Support Documents provide economic date that is generalized across the Onshore industry for both gas (2012) and oil (2015) wells, and that this data is not specific to New Mexico.

The Technical Support Document for NSPS OOOO regulations discusses emissions and control options in Sections 1 through 4 of

DRAFT

https://www.regulations.gov/document?D=EPA-HQ-OAR-2010-0505-4550

The Technical Support Document for NSPS OOOOa regulations discusses emissions and control options in Section 3 of https://www.regulations.gov/contentStreamer?documentId=EPA-HQ-OAR-2010-0505-7646&attachmentNumber=6&contentType=pdf

Detail spreadsheet about the costs associated with the controls is found in this attachment to the Technical Support Document: https://www.regulations.gov/contentStreamer?documentId=EPA-HQ-OAR-2010-0505-7646&attachmentNumber=14&contentType=excel12book

Note that in certain circumstances that the Technical Support Documents are no longer representative in that the economic data is not always reflective of current design, but they do have the best data we have thus far. The oil and gas completions and stimulation industry is regularly evolving. While traditional stimulation activities and equipment exist, the data does not take into account permanent facility utilization.

What are the annualized operating costs for the equipment or costs associated with the process?

See above

If the equipment or process is powered, what are the costs?

See above

What is the useful life of the equipment?

The REC and rig/stimulation equipment is used for several hours or weeks during the completion, stimulation and flowback operations. Well servicing, coil tubing and stimulation equipment have a useful life primarily based upon the power unit, but is also limited based upon technological advances requiring a different tool for the job.

What are the maintenance and repair requirements for existing or new equipment?

Maintenance costs are included in the cost of the equipment above.

Existing Reduction Strategies:

How has industry reduced emissions/waste from this equipment or process historically?

NSPS requirements have been applicable to completions following hydraulic fracturing for gas wells since 2012 and for oil wells since 2016. Prior to 2012, while many operators practiced voluntary RECs,

DRAFT

various configurations were prevalent including allowing the flowback to flow into frac tanks with the gas being vented or combusted.

Voluntary reductions from completions with hydraulic fracturing are also discussed in Section 5.0 of the NSPS OOOO Technical Support Document at: https://www.regulations.gov/document?D=EPA-HQ-OAR-2010-0505-4550

There are many reported instances where industry started voluntarily using reduced emission completions. EPA's Natural Gas STAR program has reports of RECs since the 2004. These voluntary activities resulted in reduced emissions as reported by various operators. Additional information about the Natural Gas STAR program and reduced emission completions can be found at https://www.epa.gov/sites/production/files/2016-06/documents/reduced_emissions_completions.pdf https://www.epa.gov/sites/production/files/2017-09/documents/greencompletions.pdf

New Wells:

Existing Wells:

How have the emission/waste reductions been measured?

Emissions from completions are reported annually to EPA's GHG reporting program. Based on industry sector summaries of Petroleum and Natural Gas systems, the methane emissions from completions have decreased from approximately 7 million metric tons CO2e in 2012 to approximately 1 million metric ton CO2e in 2017. References for the above estimates are found on Pages 7 and 9 respectively of the following documents:
https://www.epa.gov/sites/production/files/2015-07/documents/petroleumandnaturalgassystemsector2012.pdf

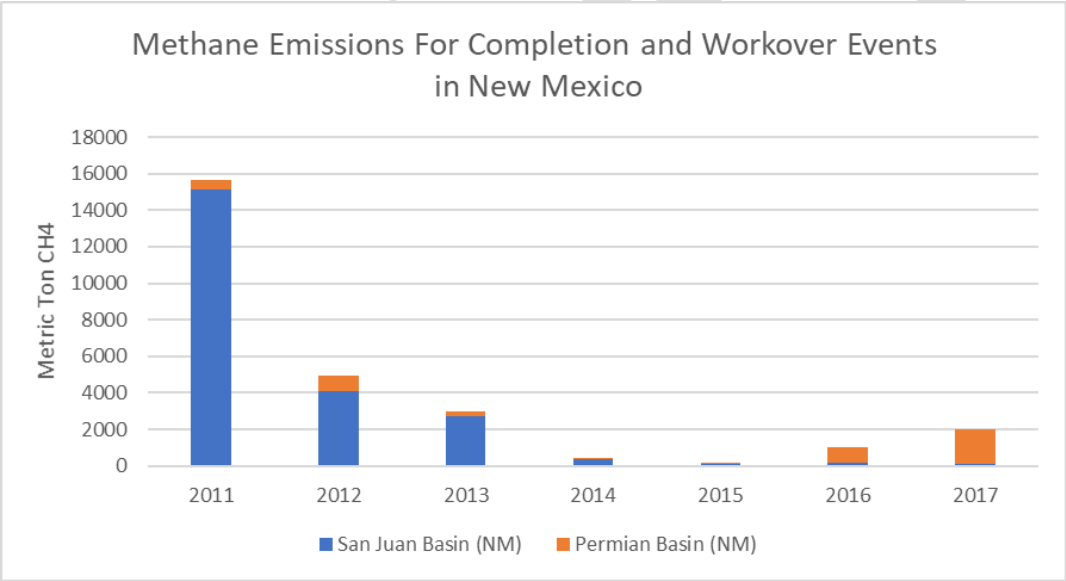
https://www.epa.gov/sites/production/files/2018-10/documents/subpart_w_2017_industrial_profile.pdf

EPA's GHG Emissions database EnviroFacts allows for download and additional analysis of reported GHG emissions. The database can be accessed here:
https://www.epa.gov/enviro/greenhouse-gas-customized-search

While nationally emissions have decreased, in the Permian Basin, total GHG emissions (including both CO2 and methane) from completions have increased from approximately 82,481 million metric tons CO2e in 2015 to approximately 615,096 million metric tons CO2e in 2016 and 974,877 million metric tonnes in 2017. Further, the CO2e figures are converted from raw methane at a GWP of 25 rather than the current 100-year GWP recognized by the IPCC of 36 suggesting that, along with the 25,000 metric ton GHGRP reporting threshold, the EPA figures represent a potentially significant underestimation of completion emissions.

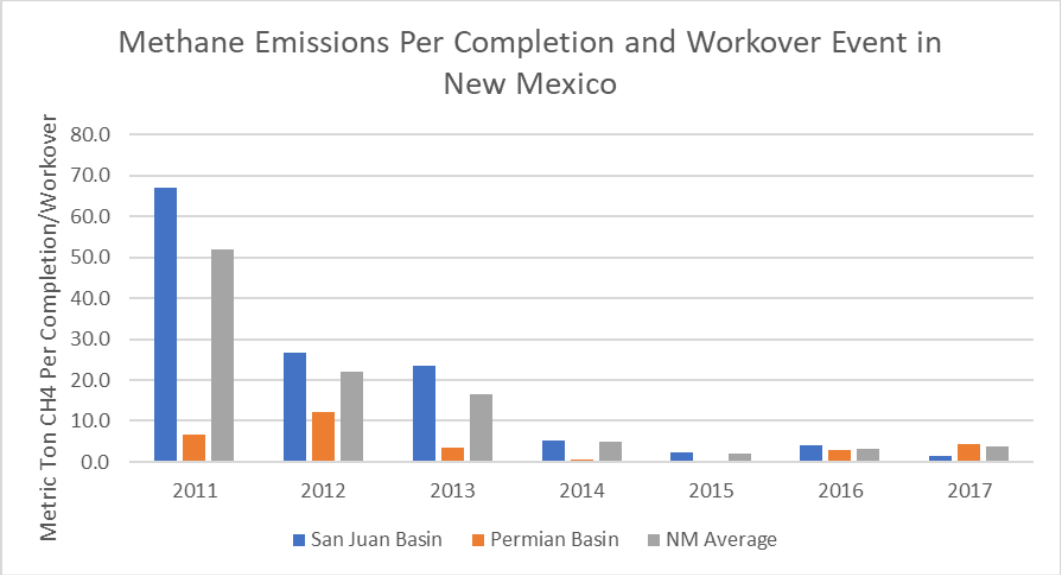
DRAFT

In 2017, as reported to EPA and downloaded from EPA's EnviroFacts database, emissions associated with completions and workovers in the Permian basin are 7,773 metric tons of methane relative to 184,941 metric tons of methane from all sources in the onshore petroleum and natural gas production sector for Permian basin. Thus, the emissions are approximately 4% of the total onshore production sector emissions.



Completion and workover emissions with hydraulic fracturing for New Mexico for 2017 were downloaded from the EnviroFacts Database and are as follows.

San Juan Basin (NM only)– 124 metric tons methane



Permian Basin (NM only) - 1867 metric tons methane

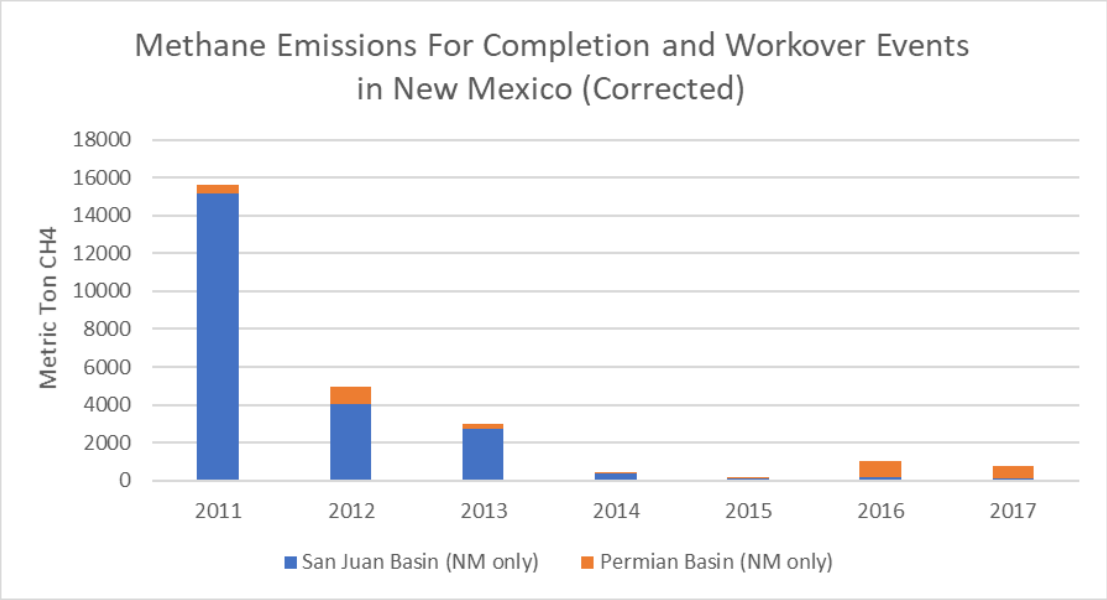
NM emissions for both basins – 1994 metric tons methane

The trend from methane emissions associated with completions and workover emissions with hydraulic fracturing is shown in the chart

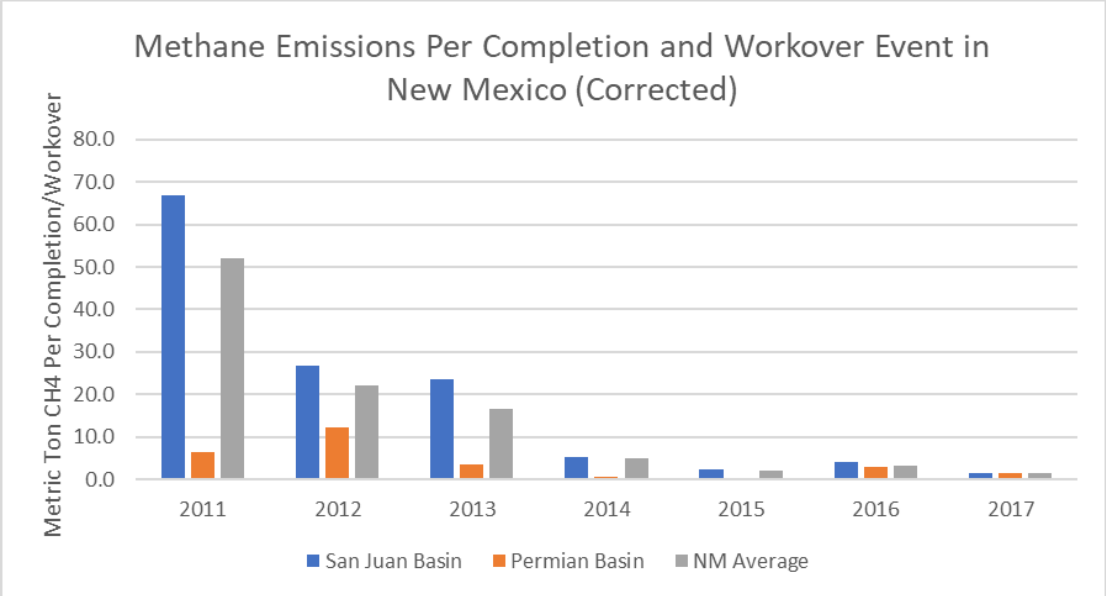
On a per-completion basis, methane emissions are as follows:

Further analysis of the data indicated an operator had relatively elevated emissions compared to the number of completions. When contacted, the operator revealed that some of the reported emissions were in error and that corrected data has been submitted to EPA. However, the EPA database has not been updated with the corrected data as of September 2017.

Using the corrected data, the emissions are as follows:



San Juan Basin (NM only)– 124 metric tons methane



Permian Basin (NM only) - 645 metric tons methane (instead of 1867 metric tons methane)

Total NM for both basins – 769 metric tons methane (instead of 1994 metric tons methane)

The revised charts are presented below:

DRAFT

How have states and the federal government reduced emissions/waste from this equipment or process historically? In addition, please identify voluntary reductions achieved whether or not they were in response to a regulatory action/requirement.

Voluntary reductions were achieved by operators as reported to EPA's Natural Gas Star program and have been discussed earlier in this document.

Completions following hydraulic fracturing have to meet the emission standards outlined in federal NSPS regulations. NSPS OOOO regulations (2012) addressed emissions from gas wells. NSPS OOOOa regulations (2015) added oil well requirements for completions beginning November 2016.

The requirements for completions in the NSPS OOOOa regulations can be found at https://ecfr.io/Title-40/sp40.8.60.oooo_0a.

The regulations related to well completions are at 40 CFR §60.5375a. In addition, the federal register notice contains information about the requirements for completions. https://www.govinfo.gov/content/pkg/FR-2015-09-18/pdf/2015-21023.pdf

In general, the regulations classify completions at four categories of wells:

1. Nonwildcat and non-delineation wells
2. Wildcat and delineation wells
3. Low pressure wells
4. Low gas-oil ratio (GOR) wells

Non-wildcat and non-delineation wells

For these wells, the flowback period of a well completion has been defined as consisting of two distinct stages, the ‘‘initial flowback stage’’ and the ‘‘separation flowback stage.’’ The initial flowback stage begins with the onset of flowback and ends when the flowback is routed to a separator. Routing of the flowback to a separator is required as soon as a separator is able to function (i.e., the operator must route the flowback to a separator unless it is technically infeasible for a separator to function). Any gas in the flowback prior to the point at which a separator begins functioning is not subject to control. The point at which the separator can function marks the beginning of the separation flowback stage. During this stage, the operator must do the following, unless technically infeasible to do so as discussed below: (1) Route all salable quality gas from the separator to a gas flow line or collection system; (2) re-inject the gas into the well or another well; (3) use the gas as an onsite fuel source; or (4) use the gas for another useful purpose that a purchased fuel or raw material would serve. If the operator assesses all four options for use of recovered gas, and still finds it technically infeasible to route the gas as described, the operator must route the gas to a completion combustion device with a continuous pilot flame and document the technical infeasibility assessment. No direct venting of gas is allowed during the separation flowback stage unless combustion creates a fire or safety hazard or can damage tundra, permafrost or waterways.

Wildcat and Delineation wells

DRAFT

A wildcat well, also referred to as an exploratory well, is a well drilled outside known fields or is the first well drilled in an oil or gas field where no other oil and gas production exists. A delineation well is a well drilled to determine the boundary of a field or producing reservoir.

For these wells regulations require either (1) routing all flowback directly to a completion combustion device with a continuous pilot flame (which can include a pit flare) or, at the option of the operator, (2) routing the flowback to a well completion vessel and sending the flowback to a separator as soon as a separator will function and then directing the separated gas to a completion combustion device with a continuous pilot flame. For option 2, any gas in the flowback prior to the point when the separator will function is not subject to control. In either case, combustion is not required if combustion creates a fire or safety hazard or can damage tundra, permafrost or waterways.

Low Pressure wells

Low pressure well means a well that satisfies at least one of the following conditions: (1) The static pressure at the wellhead following fracturing but prior to the onset of flowback is less than the flow line pressure at the sales meter; (2) The pressure of flowback fluid immediately before it enters the flow line, is less than the flow line pressure at the sales meter; or (3) Flowback of the fracture fluids will not occur without the use of artificial lift equipment.

Regulatory standards for low pressure wells are the same as that for a wildcat well.

Low GOR wells

While subject to the rule, wells with a GOR of less than 300 scf of gas per stock tank barrel of oil produced have no well completion requirements. The reason for the proposed threshold GOR of 300 is that based on industry experience separators typically do not operate at a GOR less than 300. Though in theory any amount of free gas could be separated from the liquid, in reality this is not practical given the design and operating parameters of separation units operating in the field.

A majority of the wells in New Mexico that are undergoing completions at this time fall into the non-wildcat and non-delineation wells and the full requirements of the NSPS regulations, i.e., REC and combustion devices apply to these wells.

Use of combustion devices

On Pages 56628 and 56629 of the Federal Register notice (see reference below) EPA has discussed the infeasibility of traditional combustion devices such as flares or enclosed combustion devices because the flowback following hydraulic fracturing consists of liquids, gases and sand in a high-volume, multiphase slug flow.
https://www.govinfo.gov/content/pkg/FR-2015-09-18/pdf/2015-21023.pdf

NMED Exhibit 10 - 0274

What are examples of process changes/modifications that reduce or eliminate emissions/waste from this equipment or process?

Some operators have been voluntarily practicing reduced-emission completions for this source over the past several years. These reductions have been reported to the EPA Natural Gas Star program:
https://www.epa.gov/sites/production/files/2016-06/documents/reduced_emissions_completions.pdf
https://www.epa.gov/sites/production/files/2017-09/documents/greencompletions.pdf

Furthermore, federal requirements apply to all new completions. While there are exemptions from the full REC requirements for some types of completions it would be technically infeasible to extend the full REC requirements to exploratory, low-pressure, or low GOR wells.

Technology Alternatives:

List of technology alternatives with link to information or contact information for the company/developers.

Name/Description of Technology	Link (and contact info for company if available)	Availability	Feasibility	Cost Range (choose one)
		In use or in development		Low Medium High

Would new technology or equipment be needed to reduce methane emissions?

As discussed earlier most well completions are subject to the NSPS REC requirements. Additional control requirement for non-wildcat and non-exploratory wells are not easily identifiable. In addition, at this stage, it is not evident that there are technology options available to extend the full REC requirements to exploratory, low-pressure, or low-GOR wells.

What technology alternatives exist to reduce or detect emissions?

At this stage, it is not clear what additional technology alternatives exist to reduce emissions further from these wells.

What are the pros and cons of the alternatives?

3. IMPLEMENTATION

For each piece of equipment or process, please consider the following questions and add other relevant information. If relevant, please identify if the answers are different for large company and small company requirements or are different for well type or basin.

Implementation Feasibility:

What is the feasibility of implementation (availability of required technology or contractors, potential permitting requirements, potential for innovation)?

DRAFT

Reduced emission completion technology has been required for all gas completions since 2012 and for all completions since 2016 with limited exceptions outlined in the regulations. This is an accepted process and is readily available for most completions across the country.

What is the useful life of equipment?

Completion activities typically last from several days to several weeks. Depending upon the specific circumstances, operators have the option of using either (permanent) equipment installed for production purposes or rental equipment. If rental, operators source this equipment for the expected duration of completion activities.

What are the maintenance and repair requirements for equipment required for methane reduction?

The separators and any temporary equipment including frac tanks is sourced by the operator prior to the commencement of flowback following completion activities. Perhaps the most critical aspect of the flowback period is the necessity to remove sand using an effective sand separator to prevent damage to downstream equipment.

How would emissions be detected, reductions verified and reported?

Operators continue to report emissions from flowback activities in accordance with EPA GHG reporting program.

4. CHALLENGES AND OPPORTUNITIES TO ACHIEVE METHANE REDUCTION IN NEW MEXICO

For each piece of equipment or process, please consider the following questions and add other relevant information. If relevant, please identify if the answers are different for large company and small company requirements or are different for well type or basin.

What regulatory gaps exist for this equipment or process? Are there regulatory gaps filled by the proposed implementation?

As discussed earlier, NSPS standards apply to essentially all completions across the country. Due to technical considerations, wildcat, low-pressure, and low-GOR wells are not required to meet the same standards as non-wildcat and non-delineation wells. For technical feasibility reasons, it is important to have these different standards for completions at these special categories of wells. EPA considered and ultimately did not require prior approval for the technical feasibility exemptions for reasons discussed in the previously referenced preamble to the NSPS OOOOa regulations.

EPA requires operators to record the basis for a claim of technical infeasibility to comply with the reduced emission completion requirement, and to provide the recorded information to EPA in an annual

DRAFT

compliance report. 40 C.F.R. Section 60.5420a(c). There is no requirement that operators notify EPA, or the delegated state agency, prior to claiming an exception. One potential improvement to the federal requirements would be for the state to require operators to notify the state prior to claiming an exception from the reduced emission completion requirement. The notice could require the same information EPA currently requires operators record as the basis for the exception claim. The state could require approval of an exception claim prior to completions commencing. This would provide more information to the state as to how many operators are claiming exceptions, and the reasons for such claims. Additional oversight as to the grounds for exception requests could lead to additional emission reductions were the state to find that some exception requests are not warranted (e.g., increased coordination between upstream and midstream operators prior to drilling may lead to the availability of gas pipeline infrastructure being in place prior to completions, thereby making reduced emission completions technically feasible).

Other considerations or comments (e.g. particular design or technological challenges/opportunities, non-air environmental impacts, etc.?):

NA

DRAFT

5. COMPLETIONS, RECOMPLETIONS AND STIMULATIONS - PATH FORWARD[180]

	OPTIONS	DESCRIPTION AND LINK TO INFORMATION IF AVAILABLE. PLEASE LIST THE BENEFIT THAT COULD BE ACHIEVED THROUGH THIS OPTION AND ANY DRAWBACKS OR CHALLENGES TO IMPLEMENTATION	EMISSIONS REDUCTIONS ARE EASY TO ACHIEVE AND ARE COST EFFECTIVE 1 = EASY 5 = HARD	REPORTING, MONITORING AND RECORDING OPTIONS, INCLUDING REMOTE DATA COLLECTION	IS THIS OPTION HELPFUL IN THE SAN JUAN BASIN, PERMIAN BASIN OR BOTH
9.1	Existing federal NSPS requirements adequately address the completion activities in NM.	Federal regulations create a set of common standards that are applicable for completion activities in New Mexico where both producing basins (Permian and San Juan) each straddle two states.	1 2 3 4 5	Continue with the requirement to report emissions in accordance with EPA's GHG reporting program.	San Juan Permian Both
	COMMENT A. As indicated in the Completions document, emissions from this activity are a small percent of total methane emissions. In order to get the necessary reduction, it would be more practical to focus on sources contributing more to the methane emissions. [page 267] B. Continue to allow flaring when technically infeasible to conduct a Reduced Emission Completion. [page 262] C. Data from operator's failure to capture methane emissions [page 263] in completions/recompletions are unknown—therefore comment A. above is unfounded [page 267]. Every effort is being made to capture emissions from		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		

[180] The format of the Path Forward table evolved over the course of the meetings as the group tried to identify the best method for capturing the most useful information. As a result, there is some variation in the table headers from topic to topic in the final consolidated report.

	smaller sources of methane emissions through the LDAR process. However, completions/recompletions may very well be in excess of volumes we are actively seeking to stop with LDAR; and we should pursue completions/recompletions as a significant source of methane pollution. More complete methane emission data regarding completions/recompletions must be collected before reaching the conclusion that the current NSPS regulations are adequate. In fact, Expert Presentation by Dr. Robert Balch suggests that methane emission data reported by operators is underestimated and incomplete https://www.env.nm.gov/wp-content/uploads/sites/15/2019/08/Flaring-and-Venting-Stats-by-District-9-27-19.pdf.				
9.2	Codify existing federal regulations to protect against possible roll-back.	NMED should not rely on any existing federal regulations, given uncertainty as to what might be repealed. We should codify existing federal regulations and take steps that go beyond OOOOa to further cut emissions.	1 2 3 4 5		San Juan Permian Both
	COMMENT A. There is no indication that OOOOa regulations are being rolled back for oil and gas production sources in general and for completions in particular. B. Federal environmental protections including those for methane emission reductions are actively being rolled back at this time—continuing a federal record since 2017 of dismantling both EPA and BLM regulations. There is no indication that current federal policies to eliminate methane regulations will cease.		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
9.3	Eliminate "Technical Infeasibility" Exemption where infeasibility could have been recognized in advance.	NSPS Subpart OOOOa allows operators to obtain an exemption from green completion requirements on technical infeasibility grounds even when the grounds for the exemption (e.g., lack of gathering lines) are known in advance. See 81 FR 35852. In adopting this rule, EPA considered but rejected comments urging the agency to disallow technical infeasibility exemptions in these cases. Id. The agency also considered but rejected comments suggesting that the agency require advanced	1 2 3 4 5		San Juan Permian Both

		notification of an operator's decision to invoke the technical infeasibility. Id. As EPA's discussion indicates, in many cases operators know in advance that it is not feasible to comply with EPA's green completion requirements due to lack of gathering lines, right of way issues, or similar factors. In these cases, there is a technically feasible alternative to wasting the gas: delay drilling until it is technically feasible to perform a green completion.			
	COMMENT A. Wells may be connected to pipeline but may still need to flare due to capacity or pressure issues. There are technical infeasibilities that arise even when capture options have been planned, making the need to flare difficult to predict ahead of time. Abrupt shut-ins or restricted well flow can cause formation damage to wells and result in underground waste. [page 274] B. Sometimes technical infeasibility issues can come up very late in the process despite operator plans (GCP submittal for example) to connect to a gathering line and to route the gas to sales. For example, pipeline may have operational issues on the day of the completion activity. Or there may be a right of way issue that prevents a connection at the last minute. Or the gas quality may prevent routing the gas into the gas pipeline. [page 262] There can be unforeseen circumstances which cannot be predicted in "advance". The option needs to make provisions for unforeseen and unpredictable circumstances despite advanced planning. C. The comment B. (above) misinterprets the scope of 8.3 PATH FORWARD. To discredit the PATH FORWARD, the Comment cites instances of flaring that are "difficult to predict ahead of time" while this PATH FORWARD specifically refers to instances where infeasibility could have been recognized "in *advance*."		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		

NMED Exhibit 10 - 0281

	D. Comment B. (above) fails to consider that flaring events will be easier to predict with increase of data research and multiple options to flaring exist as outlined in detail in Expert Presentations. E. Comment B. (above) assumes that state agency resources will not increase in the future. This assumption is contrary to recent political climate justice trends in New Mexico, and also to consistent historical evidence of technological and process solutions to existing problems after regulations have been put in place, i.e., D.D.T. 1950's https://www.epa.gov/ingredients-used-pesticide-products/ddt-brief-history-and-status and lead in gasoline 1975 https://archive.epa.gov/epa/aboutepa/epa-takes-final-step-phaseout-leaded-gasoline.html				
9.4	NM state rule that contains the following components for all completions, re-completions, and stimulations: Provide notice prior to completion/re-completion/stimulation (required)	*If operator <u>has</u> monitoring equipment with data recording on site*, notice must be made **two (2) days** prior to completion/re-completion/stimulation. Data must be submitted within 48 hours. OR *If operator <u>does not</u> have monitoring equipment with data recording on site*, notice must be provided **fifteen (15) days** prior to completion/re-completion/stimulation	**2**	Monitoring required using portable combined FID/PID toxic vapor analyzer with data logging technologies or another technology capable of measurement within acceptable parameters such as FTIR/laser or other innovative and	Both

[a]Some technologies were limited in their speed due to speed-limits at the METEC test-site (10 mph).

181 https://doi.org/10.1525/elementa.373.t1

182 This price quote is from one commercial vendor, LDAR Solutions. Most distributors of this technology only offer quotes directly to a purchasing company, which generally results in a lower per-unit price.

	A. It is not clear how this would actually reduce emissions. It will be helpful to have emission reductions quantified to warrant changing the existing notification requirements. [page 275] B. At this time, actual methane emissions from completions/recompletion amounts have not been quantified or made public. The Colorado notification requirement encourages operators to have methane detection equipment in place as shown in Table 1 (DOI link).for the purpose of determining pollution volumes. Until such time that volumes have been established, emission reductions will be impossible to quantify. (See 8.1 above). Nonetheless, this PATH FORWARD encourages a methane-reducing practice. A lack of complete data does not justify the failure to promote gas-capture practices. Expert Presentation by Dr. Robert Balch suggests that methane emission data reported by operators is underestimated and incomplete https://www.env.nm.gov/wp-content/uploads/sites/15/2019/08/Flaring-and-Venting-Stats-by-District-9-27-19.pdf.		consistency in regulations, familiarity for both operating and OCD field personnel, and reduced paperwork. Requirements are verbal notice to the appropriate OCD District Office prior to spud, then prior to cementing operations with minimum time frames. Same could be done for verbal notice prior to moving in on completion operations and prior verbal notice before stimulation work. Verbal notice dates and times are referenced on appropriate C-103 forms. [page 278]		
9.5	NM state rule that contains the following components for all completions, re-completions, and stimulations: No venting exceptions during completion/re-completion/stimulation	Multiple additional options are available to operators during completions/re-completions/stimulation of a well that make any venting unnecessary: CNG in a box; Capture and conversion to NGL (mobile refrigeration skid); reduced emissions completions.	**3 - 4**	*See* innovative and emerging technologies	Both
	COMMENT A. Generally, there is not a large amount of gas production during the completions phase. [page 267] Conversion to sales options (CNG, NGL) require both an adequate supply of gas and sales quality gas which may not be present during completions. [page 262] Capture of the gas as CNG/NGL would be prohibitively expensive given the short deployment and small amount of captured gas. Equipment availability is also very limited. B. The comment A. above incorrectly asserts that completions are not a significant source of methane emissions (See comments in 8.1 and 8.4). Conversion of		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		

	flowback to sales have an established record of success. Many options exist (Natural Gas STAR program studies: (1) https://www.epa.gov/sites/production/files/2016-06/documents/reduced_emissions_completions.pdf (2) https://www.epa.gov/sites/production/files/2017-09/documents/greencompletions.pdf (3) http://www.ipieca.org/resources/energy-efficiency-solutions/units-and-plants-practices/green-completions/ Existing affordable capture technology exists and will be brought to market when regulations require it. [page 267] Equipment was once available, can be again, and at presumed improved function, cost, and availability.				
9.6	NM state rule that contains the following components for all completions, re-completions, and stimulations: Limit technical feasibility exceptions for flaring within volumetric limitation	Requests for flaring within volumetric limitations must provide detailed data and costs to be considered. This cost information must include actual equipment costs and estimated operational costs of both capture and flaring for comparison, as well as percentage of expected net yield lost to these costs.	**2**	Requests could be submitted electronically under a confidential procedure managed by the regulating agency.	Permian
	COMMENT A. Wells may be connected to pipeline but may still need to flare due to capacity or pressure issues. There are technical infeasibilities that arise even when capture options have been planned, making the need to flare difficult to predict ahead of time. Agency resources may be too limited to process requests in a timely manner. Abrupt shut-ins or restricted well flow can cause formation damage to wells and result in underground waste. [page 274] B. NSPS OOOOa requires operators to comply with REC requirements with exemptions for certain wells such as wild cat wells. [page 275] This suggestion would be feasible in those cases where the operator knows "in advance" that it is technically infeasible to route the gas to a pipeline. It is not practical for unforeseen circumstances.		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		

	C. Comments A. and B. [above] do not address the fact that increasing the amount of data that industry provides to state agencies is beneficial for the purpose of reducing methane emissions. [page 278] D. Comments A. and B. [above] unwarrantedly rely heavily on a minority of cases (i.e. "capacity or pressure", instances that are "difficult to predict ahead of time") that do not represent the majority of flaring requests that the agency processes. E. Comment A. [above] fails to distinguish between a flaring event being "difficult" to predict from a flaring event being impossible to predict; and, additionally, fails to justify why "difficulty" of a methane-reducing measure grants operators a pass on taking precautionary measures. F. Comments A. and B. [above] fail to consider that flaring events will be easier to predict with increase of data research and that multiple options to flaring exist as outlined in detail in Expert Presentations. G. Comment A. [above] assumes that state agency resources will not increase in the future. This assumption is contrary to recent political climate justice trends in New Mexico, and also to consistent historical evidence of technological and process solutions to existing problems after regulations have been put in place, i.e., D.D.T. 1950's https://www.epa.gov/ingredients-used-pesticide-products/ddt-brief-history-and-status and lead in gasoline 1975 https://archive.epa.gov/epa/aboutepa/epa-takes-final-step-phaseout-leaded-gasoline.html H. We have ample evidence that not only [are operators] failing to capture methane and avoid emitting it during completions/recompletions, they are also venting it (see: Grant-Schreiber study [page 264] "2. Sources of Methane Emissions"—"Existing wells"). NSPS OOOOa says that green completions/R.E.C. will not be vented or flared (40 C.F.R §60.5375a https://www.govinfo.gov/content/pkg/FR-2016-06-03/pdf/2016-11971.pdf). Extensive evidence of methane emission capture and successful sales line access is listed in comment 8.4 above.	

SECTION 10, CROSS-CUTTING PATH FORWARD REPORT

Discussion for MAP members on October 11, 2019

DRAFT

1. NARRATIVE INTRODUCING THE CROSS- CUTTING PATH FORWARD

The MAP members determined that several Path Forward concepts would apply to more than one piece of equipment or were more over-arching ideas. This report collects those over-arching ideas.

2. CROSS-CUTTING - PATH FORWARD[183]

	OPTIONS	DESCRIPTION AND LINK TO INFORMATION IF AVAILABLE. PLEASE LIST THE BENEFIT THAT COULD BE ACHIEVED THROUGH THIS OPTION AND ANY DRAWBACKS OR CHALLENGES TO IMPLEMENTATION	EMISSIONS REDUCTIONS ARE EASY TO ACHIEVE AND ARE COST EFFECTIVE 1 = EASY 5 = HARD	REPORTING, MONITORING AND RECORDING OPTIONS, INCLUDING REMOTE DATA COLLECTION	IS THIS OPTION HELPFUL IN THE SAN JUAN BASIN, PERMIAN BASIN OR BOTH
10.1	Comprehensively Improve Methane Emissions Reporting	Use multiple reporting and monitoring tools to create a comprehensive structure for reporting of methane emissions in the state, tracking emissions reductions, and supporting compliance and enforcement. This system could include: • Clearer guidance for OCD C115 reporting on venting and flaring, including venting during completions and recompletions, and data from those forms; • Improvements to OCD Form 129 and Gas Capture Plan data requirements; • Data from NMED's 2020 Minor Source Emission Inventory (and future year inventories); • U.S. GHGRP data; • Satellite Data from Descartes' Labs Data Refinery https://www.currentargus.com/story/news/local/2019/09/30/new-mexico-works-data-firm-track-oil-and-gas-methane-emissions/3819579002/); and • Data from third parties, such as the newly announced EDF/ Pennsylvania State University/ University of Wyoming/ and Scientific Aviation Permian Basin	2		BOTH

[183] The format of the Path Forward table evolved over the course of the meetings as the group tried to identify the best method for capturing the most useful information. As a result, there is some variation in the table headers from topic to topic in the final consolidated report.

		methane emissions mapping and monitoring initiative. https://www.edf.org/media/new-initiative-will-map-and-measure-methane-emissions-across-permian-basin The system should incorporate mechanisms for using data from satellite, tower, or mobile monitoring sources to identify potential gaps or shortfalls in bottom-up reporting through OCD, NMED, or US GHGRP.			
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
10.2	Consider co-benefits in evaluating methane control mechanisms and work processes	Many control mechanisms and work processes for reducing methane emissions in oil and gas development provide co-benefits, or can be implemented in ways that provide co-benefits. When considering the methane reduction potential of these control strategies and work processes, agencies should also consider co-benefits. These co-benefits can include: • Reducing emissions of Volatile Organic Compounds and Hazardous Air Pollutants, which cause adverse health impacts for nearby communities. *See* OOOOa Rulemaking: https://www.govinfo.gov/content/pkg/FR-2016-06-03/pdf/2016-11971.pdf; John L. Adgate et al., *Potential Public Health Hazards, Exposures and Health Effects from Unconventional Natural Gas Development,* 48 Environ. Sci. Technol. 8307–8320 (2014), https://pubs.acs.org/doi/10.1021/es404621d; Clean Air Task Force, Fossil Fumes: A Public Health Analysis of Toxic Air Pollution from the Oil and Gas Industry, https://www.catf.us/resource/fossil-fumes-public-health-analysis. Using a multi-pollutant approach to regulation has also been widely supported in public policy literature. *See e.g.,*	3		BOTH

		National Research Council, *Air Quality Management in the United States* (2004) https://doi.org/10.17226/10728. Using setback requirements can also prevent localized health harms; an October 2019 Colorado Health Impacts Assessment found that "there is a possibility of negative health impacts at distances from 300 feet out to 2000 feet" near oil and gas facilities. (CPDHE Press Release, https://www.colorado.gov/pacific/cdphe/news/oil-and-gas-health-risk-study; Chris Holder et al., *Evaluating potential human health risks from modeled inhalation exposures to volatile organic compounds emitted from oil and gas operations*, J. AIR & WASTE MANAGEMENT ASSOC., DOI: 10.1080/10962247.2019.1680459 (2019). • Reducing noise pollution, for example by using electric power instead of a combustion engine. • Potential reduced surface impacts such as dust, noise, water contamination, and truck traffic, as well as impact to Tribal Cultural Properties, for example where infrastructure planning processes that require pipelines can be used to reduce surface impacts from truck traffic. *See* Mark Squillace, Managing Unconventional Oil and Gas Development as if Communities Mattered, 40 VT. L.REV. 525 (2016), https://scholar.law.colorado.edu/articles/22. • Creation of local jobs, for example through leak detection and repair requirements. Marie Veyrier, Datu Research, Find and Fix: Job Creation in the Emerging Leak Detection and Repair Industry (2017), https://www.edf.org/how-reducing-methane-emissions-creates-jobs Effective methane mitigation, in particular relative to infrastructure planning, can, if done right, induce these			

		positive co-benefits to environmental, cultural, and community resources (or, if done wrong, cause negative impacts to these resources).			
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
10.3	Consider history of technology innovation and deployment to meet regulatory requirements	Historically, innovation and technology deployment has outpaced predictions to meet regulatory requirements. For example, the Clean Air Act's implementing regulations required electric utilities to control SO2 from power plant smokestacks. Despite industry predictions that the new regulatory requirements would induce high costs, innovation yielded inexpensive scrubbers to satisfy the CAA requirements. Margaret R. Taylor et al., *Control of SO2 emissions from power plants: A case of induced technological innovation in the U.S.*, 72 TECH. FORECASTING & SOC'L CHANGE 697 (2005), https://doi.org/10.1016/j.techfore.2004.11.001. In another case, a study found that performance-based, technology forcing car standards induced substantial innovation in vehicle pollution control technologies. Jaegul Lee et al, *Linking Induced Technological Change, and Environmental Regulation: Evidence from Patenting in the U.S. Auto Industry*, 40 Research Policy 1240 (2011), https://www.sciencedirect.com/science/article/pii/S0048733311001193. At least one study documents how methane control requirements create jobs. "Companies have already experienced 5–30% business growth in states with methane regulations." Marie Veyrier, Datu Research, Find and Fix: Job Creation in the Emerging Leak Detection and Repair Industry (2017), https://www.edf.org/how-reducing-methane-emissions-creates-jobs.	2		BOTH
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		

10.4	Well Site Electrification: Incentives for Utility Co-ops	Providing a well site with electricity allows operators to implement methane-reducing technologies such as zero-emission dehydrators, electric pumps, and heater treaters. This would require the expansion of service territories for Utility Co-ops surrounding the Permian Basin and San Juan. Expanding utility service territories requires substantial infrastructure investment. But with the right market conditions (i.e. State regulations, financial incentives), this expansion could be economically and environmentally beneficial--especially considering the potential for methane reduction with well site electrification. In the case that the agency would decide to contact utilities regarding this topic, the following is a link with contact information for electric companies relevant to San Juan or Permian Basin: [184]			
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
10.5	Require Large Operators to Submit Biennial Progress Reports Detailing Steps Taken to Achieve Net Zero Emission Target	In order to prevent warming in excess of 1.5°C, global net anthropogenic CO2 emissions must fall to zero by around 2050. Intergovernmental Panel on Climate Change, Global Warming of 1.5 ºC, Summary for Policymakers at 12. Methane emissions must also be reduced dramatically during the same time-frame. *Id.* In order to be viable in a carbon constrained world, the oil-and-gas industry must eliminate net GHG emissions within a matter of decades. Large oil and gas operators could be required to submit to NMED a comprehensive status report every 2 years, updating the agency on their progress towards this zero emission target.			
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		

[184] https://docs.google.com/spreadsheets/d/10_IOLsuWtE6hEzFe5Tfgcfa8BdcZ3qckMLbr224_WT4/edit?usp=sharing

10.6	Utilize Flexible Policy Instruments (Including Market-Based Policies) to Incentivize Continuous Emission Reduction	There are a variety of policy instruments that have been developed to address situations where significant emission reductions from an industry are possible, but it is difficult to mandate the use of specific techniques to achieve these reductions. Examples include company-wide emission reduction targets, fleet-wide averages for particular equipment, cap-and-trade, and emission fees. These instruments can operate in conjunction with equipment, design, and operational standards that are more prescriptive. The agencies should consider combining flexible policy instruments that drive continuous emissions reductions with more prescriptive measures that establish a baseline level of performance for the entire industry.			
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
10.7	Exempt stripper wells	Exempt all identified emissions reduction options (column 1) and be specific to stripper well production. As defined by the Interstate Oil & Gas Compact Commission (IOGCC), a stripper oil well produces 10 BOPD or less, or 60 Mcf/day or less if a gas well. This is an important segment of the oil and gas industry in New Mexico that should not be overlooked, as 66% of the total 57,868 wells (EIA) in this state fall under the IOGCC definition. The majority of wells in New Mexico are marginal wells yet will have the lowest emissions profile and stand to generate the largest increase in emissions generated by mandating quarterly LDAR.			
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
10.8	MOU between state agencies to 1) speed the development of electrical infrastructure to the oilfield	*Electricity reliability and voltage requirements-Oilfield equipment power requirements are quite varied ranging from instrumentation at a single well pad needing approximately 35W to operate up to approximately 2,000 kW (note unit change) to operate a single frac/stimulation pump. The power demand required to operate equipment determines if*		Metering of gas used for generation (would royalties be due since the gas utilized would alternately be flared).	BOTH

NMED Exhibit 10 - 0293

	2) willingness of electrical utilities to accept and manage distributed generation put onto the grid from oilfield sites Impacts suggestions: Conversion of pneumatic controllers, compressors, etc. to electrical power. Use of available associated gas for onsite generation	*single phase power (household) is adequate or if three phase power (industrial) is necessary. See Infrastructure planning paper for a further detailed description of the status of electrification in the field and needs of the oilfield.* *Due to the challenges around the development of adequate power supply to remote locations and the temporary nature of some areas of oilfield demand, many sites are supplied by onsite generation.* *Solar or wind installations typically require a back-up power source for reliability purposes. This necessary back-up significantly impacts the economic feasibility of the solutions and may also result in emissions dampening some of the benefit of alternate installation.* *Management of distributed oilfield generated power on the grid would offset the load on the existing system, reduce generation from existing power plants, and convert a source of stranded energy.* *Management and stability of the grid are critical considerations when considering adding distributed sources of power.* *Collection of produced gas in "mini" gathering systems may be necessary to provide a stable source of gas to generators.* *Determination of gas royalties and/or payment for power generated would need to be sorted out to maximize economic options.* *Expedited right of way for electrical lines would be necessary to maximize generation capability and minimize associated gas flaring.*		Metering of electrical production.	However, the lack of supporting electrical infrastructure is more predominant in the Permian due to growth in remote locations.
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
10.9	Consider where methane reduction strategies and	Native communities experience unique and disproportionate harms from Oil and Gas production. For example, Oil and Gas Production has impacted Diné society, it structures			

NMED Exhibit 10 - 0294

	processes have the potential to reduce negative impacts to native communities, native lifeways, or tribal cultural properties, including through consultation with the NM Department of Indian Affairs	relationships with family, community and ecosystems, and that fracking caused a significant perturbation of practice and reverence of Hozhoo. The NM Health Impact Assessment Report, *A Cultural, Spiritual, and Health Impact Assessment of Oil Drilling Operations in the Navajo Nation Areas of Counselor, Torreon, and Ojo Encino Chapters*. 2019. Herbert Benally, PhD, and Moroni Benally, MPP, MSPPA. *Spatial Justice and Indigenous People' Protection of Sacred Places: Adding Indigenous Dimensions to the Conversation*. March, 2017. June L. Lorenzo, PhD, NM Attorney. Moreover, as sovereign nations, Tribal communities are owed government-to-government consultation under federal and state laws and policies. See New Mexico State-Tribal Collaboration Act, NMSA 11-18-1 et seq; Consultation and Coordination with Indian Tribal Governments, Exec. Order 13175 (Nov. 6, 2000). Tribal communities, lifeways, and cultural properties are also protected by numerous federal and state laws. See e.g., New Mexico Cultural Properties Act, NMSA 18-6-1 et seq.; National Historic Preservation Act, 54 U.S.C. § 302706. A number of promising methane reduction technologies and work processes can either harm or benefit Tribal communities, lifeways, and cultural properties. In the process of rulemaking, agencies should consider how regulatory options could harm or benefit Tribal communities, lifeways, and cultural processes, and where possible should require options to be implemented in ways that will reduce harmful effects or secure co-benefits for Tribal Communities, lifeways, and cultural properties. Agencies should consult with Tribes and with the NM Indian Affairs Department to identify potential co-benefits and harms.			

NMED Exhibit 10 - 0295

	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
10.10	Federal Regulations that may affect some path forwards. Section 106 Tribal consultation. Regional Haze.	https://www.npi.org/nepa-and-section-106-national-historic-preservation-act This may affect infrastructure. https://www.epa.gov/visibility/regional-haze-program			
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
10.11	Navajo Nation Regulations need to be considered regarding paths forward	Proposed Navajo Nation Environmental Protection Agency proposed minor new source regulations. These rules will be a unitary permit. This follows 76. FED. Reg. 38784 (July 1, 2011), 40 CFR sections 49.151-161 Navajo EPA will have proposed rule out for comment in the near future.			
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
10.12	Navajo Nation Aquifer Protection Act affect multiple path forward sections	This regulation needs consideration on Checkerboarded lands. http://www.navajopublicwater.org/26_NPDWR-2600_Aquifer_Protection-Regulations_Rev.pdf			
	COMMENT A. Adjustable regulations: Do not pass the point of regulatory diminishing returns. Energy expended and greenhouse gases emitted chasing down small leaks are greater than the environmental impact of the leaks themselves. Repetitive monitoring makes little sense as the percentage of leaking components decreases. This calls for a fresh look at regulatory regimens in light of current sealing and monitoring technologies.		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE		
10.13	Consider incentives / recognition of companies that are meeting / exceeding expectations – differentiate through public recognition	Adjusting behavior in any organization requires application of both positive recognition for those reflecting the behaviors expected as well as negative influence with others who aren't moving quickly enough to meet the new behavioral expectations. Studies show that positive recognition has a greater influence on behavior than negative.	**1**	It is recommended that a report or portal be created to allow a company that is striving to meet or exceed NM expectations can answer voluntary questions regarding their	BOTH

				proactive work (i.e. more frequent FLIR studies, complete changeout to Viton gaskets, etc.) which is auditable. If those companies achieve a score of X or higher against proactive and voluntary reporting, they would be incentivized through Governor or other governmental recognition of their company in order to promote great behavior and motivate others to strive for this recognition. It would also be good to incentivize this verified good behavior to reduce reporting or other regulatory burdens.	
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
10.14	Add more detail to the New Mexico Civil Penalty Policy – Appendix D (https://www.env.nm.gov/air-quality/civil-penalty-policy/)	The Texas EHS Audit Privilege Act (https://crgtexas.com/2018/03/05/texas-environmental-health-safety-audit-privilege-act/) is extremely detailed in its design and would allow NMED, OCD and the company to enter an agreement in a much more protected manner. Highly recommend emulating this structure in NM. It is important to note that the Texas RRC has adopted this EHS	**1**	The Texas Audit Privilege Act has strong guidance which would help NM in objective communication of expectations and also provide clear gates through which a	BOTH

DRAFT

	using the Texas Environmental, Health and Safety Audit Privilege Act (both TCEQ and RRC have adopted this program) as a foundation.	Audit Privilege program in recent years – it was founded within TCEQ.		company must follow to meet its expectations. This would lead to more use of the system.	
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
10.15	Temporary (< 1 year on site) gen set power allowed to be placed on site in the event line power is not available without forcing NMED permitting staff to write permit for this temporary requirement and requires company to wait up to 120 for this permit modification – with this timing sometimes forcing flaring while waiting on gen set power.	Many states allow the placement of temporary gen set power on a site in the event there are delays in getting line power to a site. This minimizes flaring in the event line power is delayed. Most states allow this and it would have an immediate impact on improving methane capture in New Mexico.	1	Company would be obligated to remove temporary power by end of year. Companies would always prefer to use line power versus gen set power so the financial benefits of getting line power ASAP is the primary driver to get away from gen sets.	BOTH
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
10.16	Adjustable regulations	Do not pass the point of regulatory diminishing returns. Energy expended and greenhouse gases emitted chasing down small leaks are greater than the environmental impact of the leaks themselves. Repetitive monitoring makes little sense as the percentage of leaking components decreases. The majority of wells in New Mexico are marginal wells yet will have the lowest emissions profile and stand to generate			

NMED Exhibit 10 - 0298

		the largest increase in emissions generated by mandating quarterly LDAR. This calls for a fresh look at regulatory regimens in light of current sealing and monitoring technologies.			
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
10.17	Incorporating the Social Cost of Methane	When state agencies are considering cost-benefit analyses to determine the "economic feasibility" of a certain methane reducing technology, the social cost of methane (SCM) should be taken into account. Methane emissions have externality costs (i.e. perpetuating the climate crisis, damaging public health, harming agriculture yields) that industry does not internalize. Scholarship on this issue suggests that "quantifying these damages to the planetary commons by calculating the social cost of methane (SCM) facilitates more comprehensive cost-benefit analyses of methane emissions control measures and is the first step to potentially incorporating them into the marketplace." Interagency Working Group on Social Cost of Carbon, United States Government, *Technical Support Document: Social Cost of Carbon for Regulatory Impact Analysis Under Executive Order 12866* (February 2010) (IWG (2010)). Interagency Working Group on Social Cost of Carbon, United States Government, *Addendum to Technical Support Document on Social Cost of Carbon for Regulatory Impact Analysis under Executive Order 12866: Application of the Methodology to Estimate the Social Cost of Methane and the Social Cost of Nitrous Oxide (August 2016)* (IWG (2016))	2		

		Interagency Working Group on Social Cost of Carbon, United States Government, *Technical Support Document: Technical Update of the Social Cost of Carbon for Regulatory Impact Analysis Under Executive Order 12866* (August 2016) (IWG (2016)). Hindell, D. T., Fuglestvedt, J. S. and Collins, W. J. (2017) The social cost of methane: theory and applications. Faraday Discussions, 200. pp. 429-451. ISSN 1364-5498 (http://centaur.reading.ac.uk/72181/)			
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
10.18	Require consideration of ambient constant noise level dBA regulation/policy for mechanical, hydraulic, pneumatic, compressors or other devices in sites that are close to residential areas.				
	COMMENT		SUGGESTION TO MAKE THIS OPTION MORE WORKABLE:		
10.19	Increase FTE count and funding at OCD and NMED AQB in order to more effectively implement and enforce methane reduction regulations.	As underlined by the consensus industry, environmental organizations, and state regulators in the 2019 State Review of Oil and Natural Gas Environmental Regulations (STRONGER) New Mexico State Review Report key recommendations 10.2.6 (AQB) and 10.2.6a (OCD), both agencies require increases in full time employee (FTE) counts and funding from the Governor and State Legislature in order to accomplish their statutory duties including the implementation and enforcement of methane waste and pollution reduction regulations. Therefore, effectuating these	3		BOTH

	"Community Ombudsman"	increases will be key to realizing these methane reductions going forward. There is a body of existing knowledge on the effect of oil and gas development/production on rural and indigenous communities. An opportunity exists to create additional reference for people who are either impacted by oil and gas development initially or are otherwise challenged by oil and gas production to get advice and references that will help give access to pertinent agencies, speed up response times and help orient them to the challenges ahead. For example, organizations like Earthworks' Oil & Gas Accountability Project and San Juan Citizens Alliance have been providing support to individuals and communities throughout New Mexico living with oil and gas development for over 30 years. These organizations and groups like them could help inform a neutral "community ombudsman" office established by the state to work with those directly affected by oil and gas development to better understand their rights and best practices available to prevent and reduce the impacts caused by development.

New Mexico Environment Department

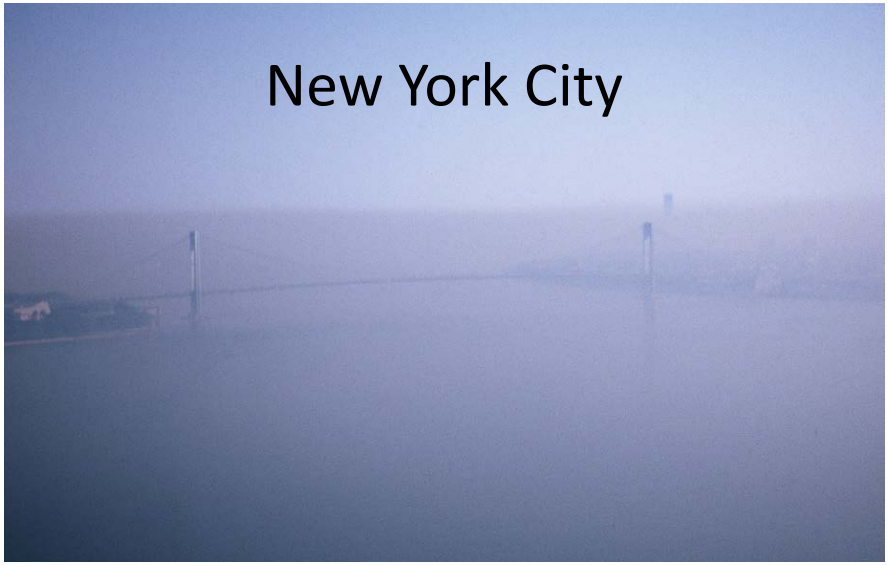
Ozone Attainment Initiative
Air Quality Bureau, Control Strategies
September 26, 2019

New Mexico Ozone Attainment Initiative Development

Our mission is to protect the inhabitants and natural beauty of New Mexico by preventing the deterioration of air quality.

The NMED will use the following during the development of the Ozone Attainment Initiative (OAI):

- Science: We will use the best available science to inform our decision-making.
- Innovation: We will employ creative engineering and technological solutions.
- Collaboration: We will engage with communities and interested stakeholders in our OAI development strategy.
- Compliance: We will ensure compliance with National Ambient Air Quality Standards and state regulations.

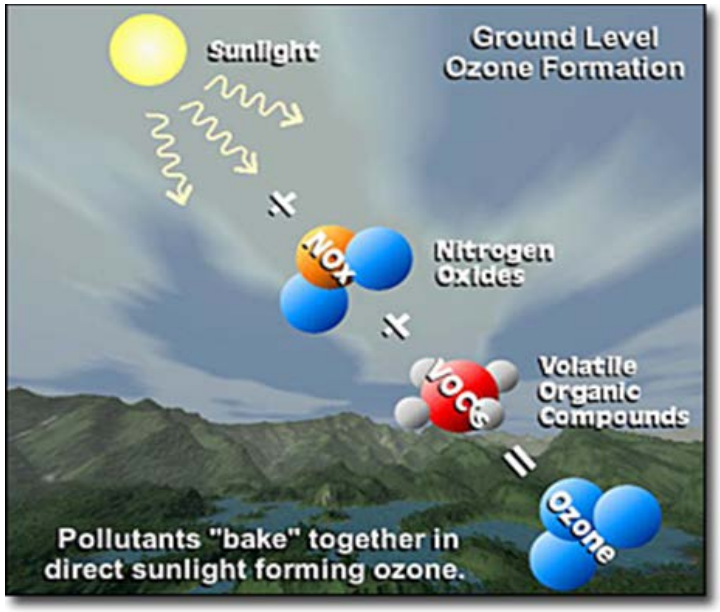


Outline

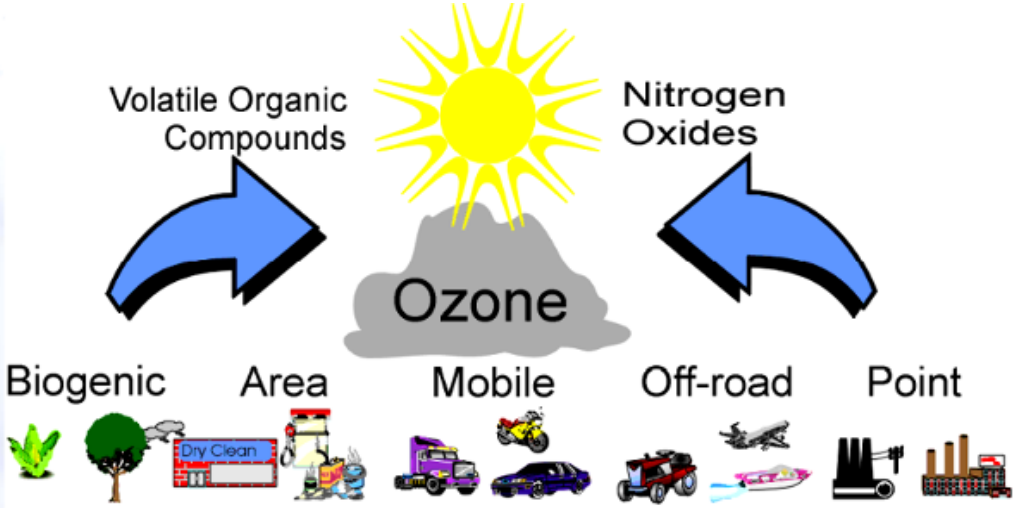
- What is Ozone?
- What are the health effects of ground level ozone?
- What is the Ozone Attainment Initiative?
- Why do we need the OAI?
- How will NMED implement the OAI?
- Where are the focus areas?
- What is the projected timeline?
- How can stakeholders get involved?

Smog

Denver Colorado



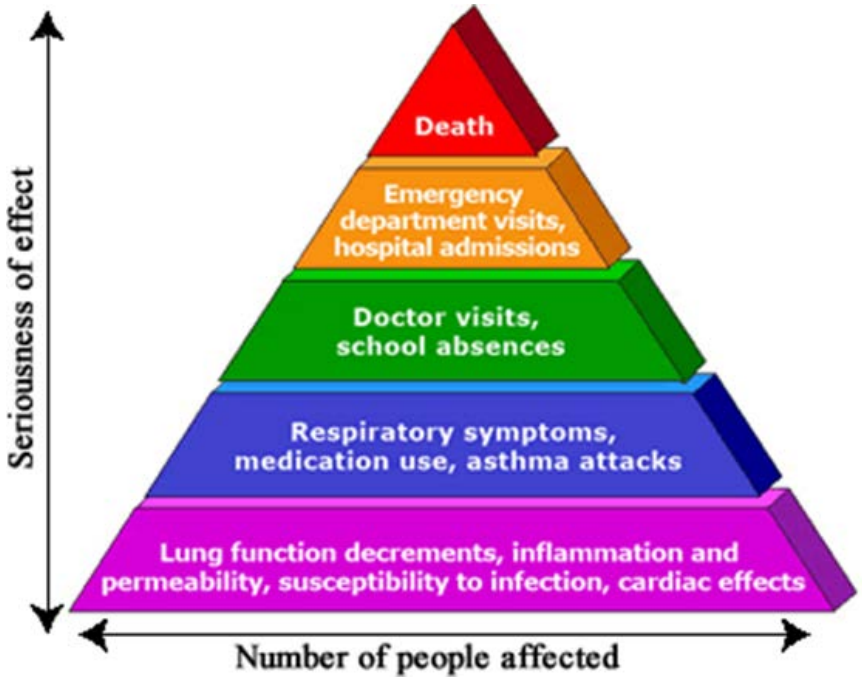
A layer of smog hovers over Los Angeles



New York City

Ground-level Ozone Formation

The main pollutants that form ozone are oxides of nitrogen (NOx) and volatile organic compounds (VOC).



Ground level ozone, is not emitted directly into the air, but is created by chemical reactions between the "precursor" pollutants of nitrogen oxides (NOx) and volatile organic compounds (VOC) in the presence of sunlight.

Ozone Pollution Health Effects

- Effects seen across a wide range of health outcomes
- Sensitive groups include:
  - Asthmatic children and other people with lung disease
  - All children and older adults, especially people active outdoors
  - Outdoor workers

https://www.epa.gov/ozone-pollution-and-your-patients-health/health-effects-ozone-patients-asthma-and-other-chronic

NAAQS and Nonattainment

National Ambient Air Quality Standards (NAAQS)

- Standards for criteria pollutants
- Established by the U.S. Environmental Protection Agency (EPA)
- Nonattainment Area= Can be an area that violates/exceeds one of the NAAQS

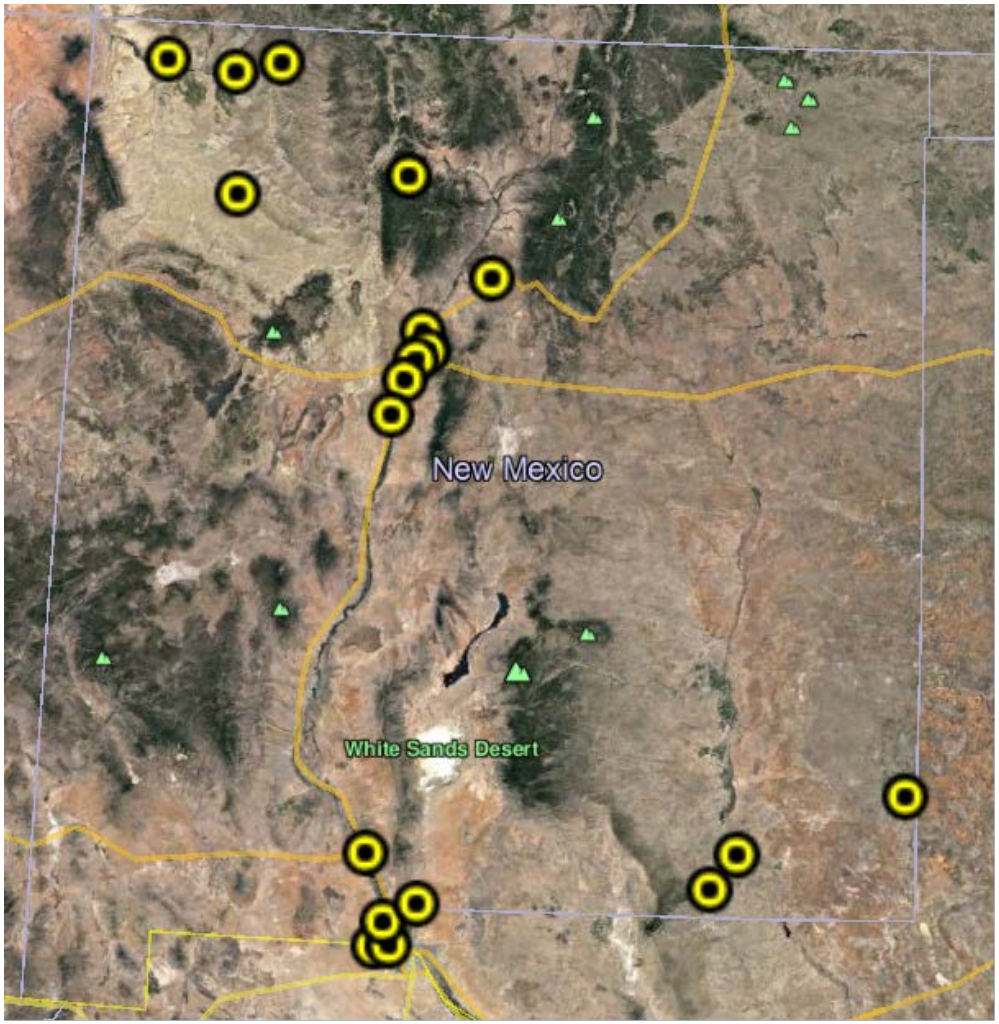
Pollutant	Type	Standard	Averaging	Form
Ozone (O_3)	Primary and Secondary	0.070 ppm (70 ppb)	8-hour	Annual 4th high daily maximum 8-hr. avg., averaged over 3 yrs.*

*EPA's calculation methodology can be found at:
https://www.epa.gov/air-trends/air-quality-design-values

What is the Ozone Attainment Initiative (OAI)?

Monitoring data show several areas in the State approaching the level of the National Ambient Air Quality Standard (NAAQS) for Ozone

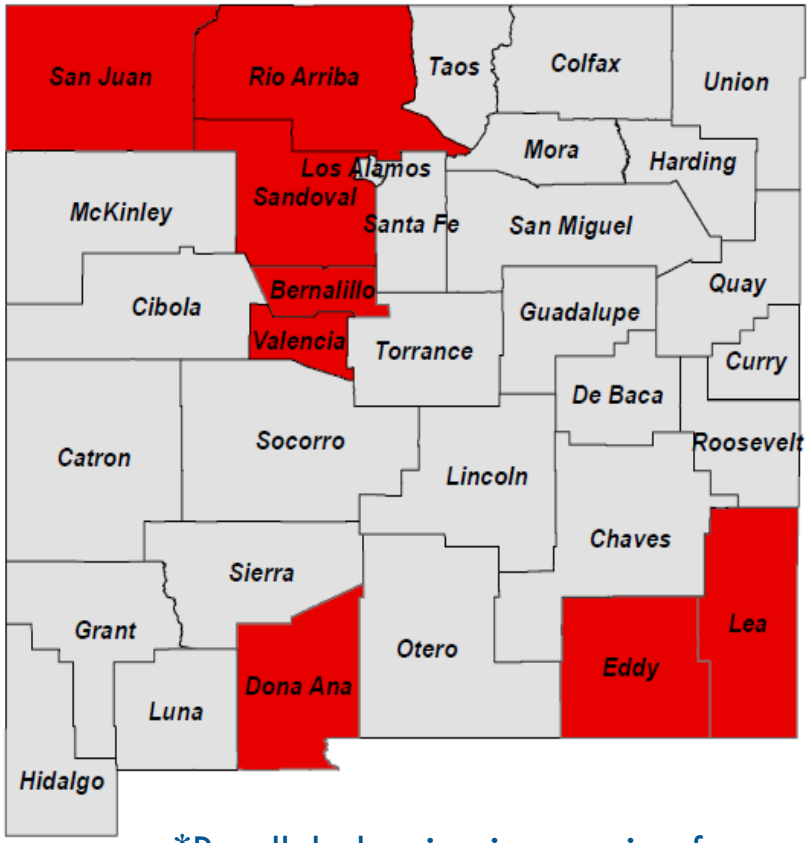
The OAI aims to:



- Protect the attainment/unclassifiable status of all areas in the state
- Ensure the health and welfare of the residents of the state for future generations

Why do we need the OAI?

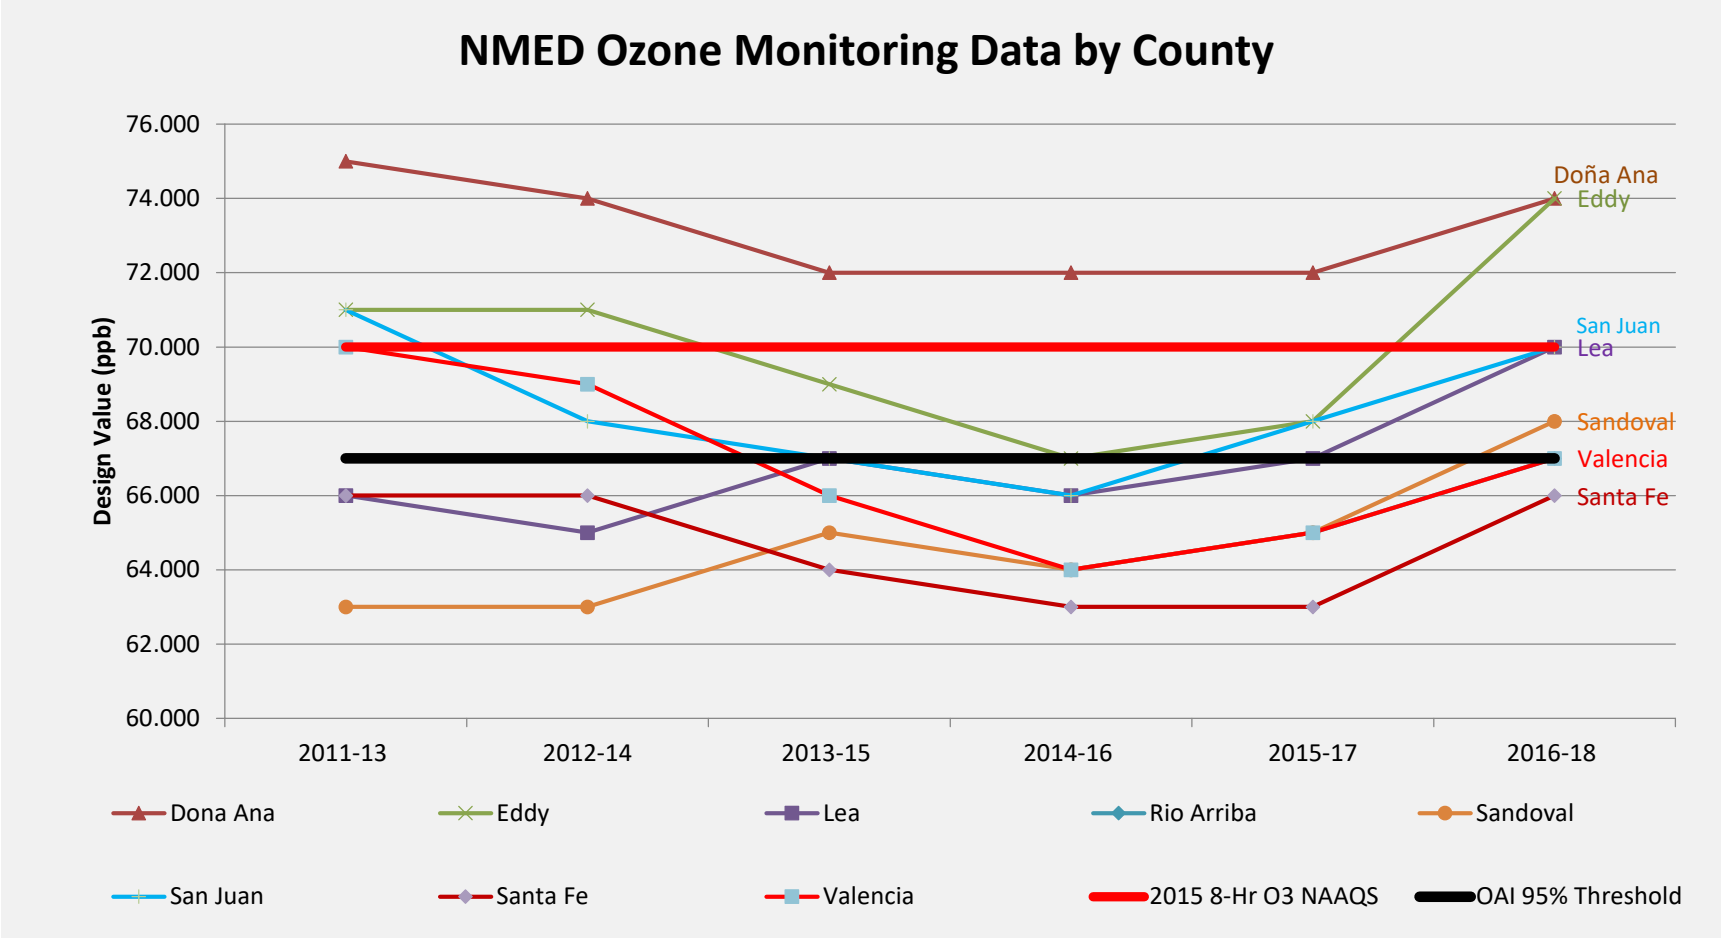
74-2-5.3 NMSA 1978



- If the EIB finds that sources cause or contribute to ozone concentrations in excess of ninety-five percent of a national ambient air quality standard for ozone, then
- NMED shall adopt a plan to control oxides of nitrogen and volatile organic compounds.

Affected Monitoring Stations*

- Includes CABQ/EHD O_3 monitoring sites. Each monitoring station includes several air monitors that each monitor a different pollutant.

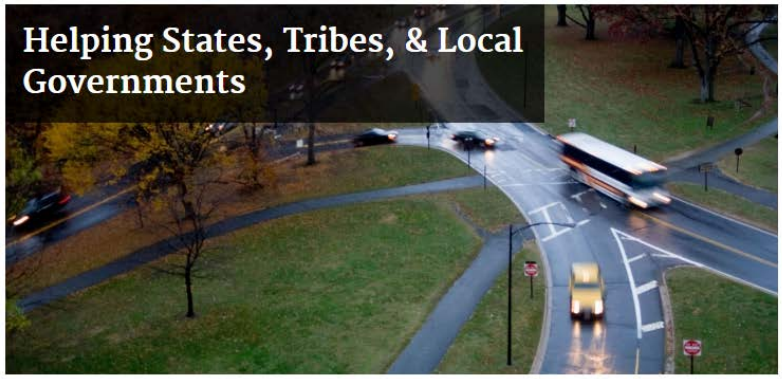


Focus Areas

*Parallel planning is occurring for Bernalillo County through the Albuquerque/Bernalillo County Department of Environmental Health

- Counties within 95% of the standard:
  - San Juan (Navajo Lake, 70 ppb)
  - Doña Ana (several monitors, 74 ppb)
  - Eddy (Carlsbad, 74 ppb)
  - Lea (Hobbs, 70 ppb)
  - Rio Arriba (Coyote, 67 ppb)
  - Sandoval (Bernalillo, 68 ppb)
  - Valencia (Los Lunas, 67 ppb)

NMED Ozone Monitoring Data by County



95% of the 70 ppb standard ≥ 67 ppb

How Will NMED Implement the OAI?

- Data Gathering
  - Emissions Inventories, Modeling and Continued Monitoring
    - O_3 and NOx Concentrations
    - Source sector contributions
    - Ozone formation and its transport
- Mandatory and/or Voluntary Measures
  - Normal NMED rulemaking process
  - EPA's Ozone Advance Program
- Robust stakeholder involvement
  - Stay informed through the OAI Listserv!

Ozone Advance

Currently, 38 areas are actively participating in Advance. These areas are located in 21 states and 9 of the 10 EPA Regions. They include 21 Ozone Advance areas, 7 PM Advance areas, and 10 areas that are participating in both Ozone and PM Advance.

- Is a collaborative effort by EPA, states, tribes and local governments to encourage emission reductions to help them continue to meet the NAAQS
- Take near-term steps to improve local air quality and ensure continued health protection
- Flexibility, participant determine their own goals and the measures
- Actions taken could better position an area to handle nonattainment requirements.

https://www.epa.gov/advance

Why are Early Efforts Important

- Local steps to reduce air pollution voluntarily, before becomes a requirement
- Improving air quality to ensure continued health protection
- Proactive efforts could better position areas to stay in attainment.
- Areas working voluntarily to reduce air pollution have more flexibility to choose measures that make sense to them
  - Once a nonattainment designation has occurred, less flexibility is available

Projected Timeline*

- **2018**
  - **Spring**
    - Kick off OAI planning meeting; and
    - Development of outreach and educational materials.
- **2019**
  - **Summer**
    - Initial public outreach including education and initial input request.
  - **Fall/Winter**
    - Conduct modeling;
    - Research and review mandatory or voluntary control measures; and
    - Additional public outreach.
- **2020**
  - **Winter/Spring**
    - Gather input; and
    - More public comment opportunities.
  - **Summer**
    - Analyze input;
    - Develop rules; and
    - Other measures for inclusion in programs.
  - **Fall/Winter**
    - OAI Plan drafted and released with formal comment period; and
    - EIB hearing to adopt proposed plan/rules.

*Note that NMED is in the initial stages of planning, which only includes the educational component and planning for public outreach. No rules/programs have yet been discussed.

Path Forward and Next Steps

Path Forward

- Modeling and Data Analyses
  - Identify source categories causing elevated ozone
  - Predict effectiveness of a proposed strategy or control measure
- Control and pollution reduction measures
  - Once sources and types are identified, a list of potential air quality improvements and/or emission reduction options can be developed

How can stakeholders get involved?

- NMED is committed to a robust, transparent process where feedback and suggestions are encouraged.
- Provide input!
  - Attend public meetings
  - Share comments and suggestions
- Stay current
  - OAI Listserv: public.govdelivery.com/accounts/NMED/subscriber/new
  - OAI webpage: www.env.nm.gov/air-quality/o3-initiative/
  - Air Monitoring Network: https://www.env.nm.gov/air-quality/air-monitoring-network-2/

Questions or comments?

Thank you. We look forward to working with our stakeholders.

Rule Preamble: The New Mexico Environment Department has developed the following draft regulation pursuant to the directives of Section 74-2-5.3 of the New Mexico Air Quality Control Act. The objective of the proposed rule is to establish emissions standards for volatile organic compounds (VOC) and nitrogen oxides (NOx) for oil and gas production and processing sources located in areas of the State within the Environmental Improvement Board's jurisdiction where ozone concentrations are exceeding 95% of the national ambient air quality standard.

This is a preliminary draft being released for public input in advance of the Department filing a formal rulemaking petition with the Board and requesting a public hearing. The purpose of this initial, pre-petition comment period is to foster transparency and facilitate continued engagement from stakeholders, members of the public, and other interested parties. Specifically, the Department is seeking public input on the proposed rule language to assist in identifying potential regulatory and technical issues, and areas that require additional clarification or modification. Additional opportunities for public input and changes to the draft rule will occur through the formal rule-making process following the filing of the rulemaking petition. This initial, pre-petition process will help ensure that major issues or problematic areas are identified and can be addressed prior to the initiation of the formal process.

NMED is soliciting specific review and public input on a number of proposed provisions and concepts in the draft rule. In particular, for the equipment standards section, NMED requests feedback on the following:

1. The proposed definitions of stripper wells and marginal wells under the draft rule and the regulatory requirements that would apply to those wells under Section 20.2.50.25 NMAC;
2. Examples of technologies or regulatory programs utilizing non-combustion emission control technologies, like fuel cells, as a means of reducing or eliminating emissions for inclusion in Section 20.2.50.15 NMAC;
3. Specific regulatory language regarding criteria necessary to demonstrate equivalency of alternative equipment leak monitoring plans in Section 20.2.50.16(C) NMAC;
4. Specific regulatory language to establish a pre-approved equipment leak monitoring plan in 20.2.50.16(C) NMAC;
5. For leak detection and repair requirements under Section 20.2.50.16 NMAC, specific standards to be used by NMED to determine if certain new or existing technologies (real-time remote fence line and aerial surveillance, for example) or proposals are enforceable, effective, and equivalent. Specific feedback on data capture requirements, quality assurance, error rates, calibration requirements, training and certification, interference issues, quantification methods, and pollutant identification will assist the Department in exploring this option further;
6. Regulatory requirements for oil and gas evaporative ponds in Section 20.2.50.26 NMAC, including whether to establish emission standards based on the pond's potential to emit or throughput; and
7. Opportunities for greater transparency.

Comments or input on the draft rules may be submitted electronically to nm.methanestrategy@state.nm.us or via hardcopy to Liz Bisbey-Kuehn, NMED Air Quality Bureau, 525 Camino de los Marquez, Santa Fe, NM 87505 by 5 p.m. Aug. 20, 2020.

TITLE 20 ENVIRONMENTAL PROTECTION
CHAPTER 2 AIR QUALITY (STATEWIDE)
PART 50 OIL AND NATURAL GAS REGULATION FOR OZONE PRECURSORS

20.2.50.1 ISSUING AGENCY:
New Mexico Environmental Improvement Board.

20.2.50.2 SCOPE:
This rule applies to sources located within counties that have areas with ambient ozone concentrations in excess of ninety-five percent of the national ambient air quality standard for ozone, including but not limited to Chaves, Eddy, Lea, Rio Arriba, Sandoval, and San Juan. Sources located in Bernalillo County, on Tribal Lands, and in other areas that are not within the Board's jurisdiction are excluded.

20.2.50.3 STATUTORY AUTHORITY: NMSA 1978, § 74-2-5.3

20.2.50.4 DURATION: Permanent.

20.2.50.5 EFFECTIVE DATE:
[To be determined], except where a later date is cited in a section or paragraph.

20.2.50.6 APPLICABILITY:
A. Except as provided in paragraph (B), Part 50 applies to crude oil production and natural gas production equipment and operations that extract, collect, store, transport, or handle hydrocarbon liquids or produced water in the areas specified in 20.2.50.2 NMAC. Crude oil production includes the well and extends to the point of custody transfer to the crude oil transmission pipeline or any other form of transportation. Natural gas production, processing, transmission, and storage includes the well and extends to, but does not include, the local distribution company custody transfer station.
B. Oil refineries are not subject to this Part.
C. Equipment located at stripper wells, as defined in 20.2.50.8 NMAC, is exempt from the requirements of this Part 50, except as specified in 20.2.50.25 NMAC.
D. Individual facilities with a site-wide total annual potential to emit less than 15 tons per year (tpy) of volatile organic compounds (VOC) are exempt from the requirements of this Part, except as specified in 20.2.50.25 NMAC.

20.2.50.7 OBJECTIVE:
The objective of this Part is to establish emission standards for volatile organic compounds (VOC) and nitrogen oxides (NO_x) for oil and gas production and processing sources.

20.2.50.8 DEFINITIONS:
In addition to the terms defined in 20.2.2 NMAC (Definitions), as used in this Part:
A. "Air Pollution Control Equipment" means open flares, enclosed combustion devices, thermal oxidizers, vapor recovery units, fuel cells, condensers, other combustion devices, air fuel ratio controllers, oxidative catalytic converters, selective and non-selective catalytic converters, or emission reduction equipment or technologies used to

DRAFT

comply with emission standards and emission reduction requirements in 20.2.50 NMAC that are approved by the Department.

B. "Approved Instrument Monitoring Method" means an infra-red camera, U.S. EPA Method 21, or other instrument-based monitoring method or program approved by the Department in advance and in accordance with 20.2.50 NMAC.

C. "Auto-Igniter" means a device which will automatically attempt to relight the pilot flame in the combustion chamber of a control device in order to combust volatile organic compound emissions.

D. "Bleed rate" means the rate in standard cubic feet per hour at which natural gas and VOC is continuously vented (bleeds) from a pneumatic controller.

E. "Calendar Year" means a year beginning January 1 and ending December 31.

F. "Centrifugal Compressor" means any machine used for raising the pressure of natural gas by drawing in low pressure natural gas and discharging significantly higher-pressure natural gas by means of mechanical rotating vanes or impellers. Screw, sliding vane, and liquid ring compressors are not centrifugal compressors.

G. "Commencement of operation" means for oil and natural gas wellheads, the date any permanent production equipment is in use and product is flowing to sales lines, gathering lines, or storage tanks from the first producing well at the stationary source, but no later than the end of well completion operations.

H. "Compressor station" means any permanent combination of one or more compressors that move natural gas at increased pressure through gathering or transmission pipelines, or into or out of storage. This includes, but is not limited to, gathering and boosting stations and transmission compressor stations.

I. "Component" means each pump seal, flange, pressure relief device (including thief hatches or other openings on a controlled storage tank), connector, and valve that contains or contacts a process stream with hydrocarbons, except for components in process streams consisting of glycol, amine, produced water, or methanol.

J. "Connector" means flanged, screwed, or other joined fittings used to connect two pipes or a pipe and a piece of process equipment or that close an opening in a pipe that could be connected to another pipe. Joined fittings welded completely around the circumference of the interface are not considered connectors.

K. "Custody Transfer" means the transfer of oil or natural gas after processing and/or treatment in the producing operations or from storage vessels or automatic transfer facilities or other such equipment, including product loading racks, to pipelines or any other forms of transportation.

L. "Department" means the New Mexico Environment Department.

M. "Downtime" means the period of time when equipment is not operational or a well is producing and the air pollution control equipment is not in operation.

N. "Enclosed Combustion Device" means any combustion device where gaseous fuel is combusted in an enclosed chamber. This may include, but is not limited to enclosed flares, boilers, re-boilers, and heaters.

O. "Existing" means any piece of equipment regulated by this Part that began operation prior to the effective date of the rule and has not since been modified or reconstructed.

P. "Gas processing plant" means equipment assembled for the extraction of natural gas liquids from natural gas, the fractionation of the liquids into natural gas products, or other operations associated with the processing of natural gas products. A process unit

DRAFT

can operate independently if supplied with sufficient feed or raw materials and sufficient storage facilities for the products.

Q. "Gathering and boosting site" means any permanent combination of equipment that collect or move natural gas, crude oil, condensate, or produced water between the wellhead site and midstream oil and natural gas collection or distribution facilities such as tank batteries or compressor stations, or into or out of storage.

R. "Glycol Dehydrator" means any device in which a liquid glycol absorbent (including, ethylene glycol, diethylene glycol, or triethylene glycol) directly contacts a natural gas stream and absorbs water.

S. "Hydrocarbon liquids" means any naturally occurring, unrefined petroleum liquid and can include oil, condensate, produced water, and intermediate hydrocarbons.

T. "Infra-red Camera" means an optical gas imaging instrument designed for and capable of detecting hydrocarbons.

U. "Liquids Unloading" means the removal of accumulated liquids from the wellbore that reduce or stop natural gas production.

V. "Liquid Transfers" means the loading and unloading of hydrocarbon liquids or produced water between storage tanks and tanker trucks or tanker rail cars for transport.

W. "Modification" means any physical change in, or change in the method of operation of, a stationary source which results in an increase in the potential emission rate of any regulated air contaminant emitted by the source or which results in the emission of any regulated air contaminant not previously emitted, but does not include:

- **(1)** a change in ownership of the source;
- **(2)** routine maintenance, repair or replacement;
- **(3)** installation of air pollution control equipment, and all related process equipment and materials necessary for its operation, undertaken for the purpose of complying with regulations adopted by the board or pursuant to the federal act; or
- **(4)** unless previously limited by enforceable permit conditions:
  - **(a)** an increase in the production rate, if such increase does not exceed the operating design capacity of the source;
  - **(b)** an increase in the hours of operation; or
  - **(c)** use of an alternative fuel or raw material if, prior to January 6, l975, the source was capable of accommodating such fuel or raw material, or if use of an alternate fuel or raw material is caused by any natural gas curtailment or emergency allocation or any other lack of supply of natural gas.

X. "Natural Gas Compressor Station" means one or more compressors designed to compress natural gas from well pressure to gathering system pressure prior to the inlet of a natural gas processing plant, or to move compressed natural gas through a transmission pipeline.

Y. "Natural Gas-Fired Heater" means an enclosed device using controlled flame and with a primary purpose to transfer heat directly to a process material or to a heat transfer material for use in a process.

Z. "Natural Gas Processing Plant" means any processing equipment engaged in the extraction of natural gas liquids from natural gas, fractionation of mixed natural gas liquids to natural gas products, or both. A Joule-Thompson valve, a dew point

DRAFT

depression valve, or an isolated or standalone Joule-Thompson skid is not a natural gas processing plant.

AA. "New" means any piece of equipment regulated by this Part that began operation on or after the effective date.

BB. "Optical gas imaging" means an imaging technology that utilizes high-sensitivity infra-red cameras designed for and capable of detecting hydrocarbons.

CC. "Pneumatic Controller" means an automated instrument used for maintaining a process condition such as liquid level, pressure, flow volume, delta-pressure and temperature.

DD. "Pneumatic Pump" means a positive displacement pump powered by pressurized natural gas that uses the reciprocating action of flexible diaphragms in conjunction with check valves to pump a fluid. A pump in which a fluid is displaced by a piston driven by a diaphragm is not considered a diaphragm pump. A lean glycol circulation pump that relies on energy exchange with the rich glycol from the contactor is not considered a diaphragm pump.

EE. "Potential to Emit" means the maximum capacity of a stationary source to emit any air pollutant under its physical and operational design. Any physical or operational limitation on the capacity of a source to emit an air pollutant, including air pollution control equipment and restrictions on hours of operation or on the type or amount of material combusted, stored, or processed, shall be treated as part of its design if the limitation is federally enforceable. The potential to emit for nitrogen dioxide shall be based on total oxides of nitrogen.

FF. "Produced Water" means water that is extracted from the earth from an oil or natural gas production well, or that is separated from crude oil, condensate, or natural gas after extraction.

GG. "Reciprocating Compressor" means a piece of equipment that increases the pressure of process gas by positive displacement, employing linear movement of the piston rod.

HH. "Responsible Official" means one of the following:

(1) For a corporation: a president, secretary, treasurer, or vice-president of the corporation in charge of a principal business function, or any other person who performs similar policy or decision-making functions for the corporation, or a duly authorized representative of such person if the representative is responsible for the overall operation of one or more manufacturing, production, or operating.

(2) For a partnership or sole proprietorship: a general partner or the proprietor, respectively.

(3) For a municipality, state, federal or other public agency: either a principal executive officer or ranking elected official. For the purposes of this part, a principal executive officer of a federal agency includes the chief executive officer having responsibility for the overall operations of a principal geographic unit of the agency (e.g., a regional administrator of US EPA).

II. "Startup" means the setting into operation of any air pollution control equipment or process equipment.

JJ. "Storage tank" means any process vessel, or fixed roof storage vessel or series of storage vessels that are connected together via a liquid line.

KK. "Storage vessel" means a single tank or other vessel that is designed to contain an accumulation of hydrocarbon liquids or produced water and is constructed primarily of non-earthen materials (such as wood, concrete, steel, fiberglass, or plastic) which

DRAFT

provide structural support, or a process vessel such as surge control vessels, bottom receivers, or knockout vessels. A well completion vessel that receives recovered liquids from a well after commencement of operation for a period which exceeds 60 days is considered a storage vessel. A storage vessel does not include: vessels that are skid-mounted or permanently attached to something that is mobile (such as trucks, railcars, barges, or ships); are located at the site for less than 180 consecutive days; or pressure vessels designed to operate in excess of 204.9 kilopascals and without emissions to the atmosphere.

LL. "Stripper well" means an oil well with a maximum daily average oil production not exceeding 10 barrels of oil per day, or a natural gas well with a maximum daily average natural gas production not exceeding 60,000 standard cubic feet per day, or a well with a maximum daily average combined oil and natural gas production not exceeding 10 barrels of oil equivalent per day during any 12-month consecutive time period.

MM. "Wellhead site" means all equipment at a single stationary source directly associated with one or more oil wells or natural gas wells upstream of the natural gas processing plant. This equipment includes, but is not limited to, equipment used for extraction, collection, routing, storage, separation, treating, dehydration, artificial lift, combustion, compression, pumping, metering, monitoring, and flowline.

20.2.50.9 AMENDMENT AND SUPERSESSION OF PRIOR REGULATIONS [PLACEHOLDER]

20.2.50.10 DOCUMENTS:

Documents incorporated and cited in this Part may be viewed at the New Mexico Environment Department, Air Quality Bureau, Harold Runnels Building, 1190 St. Francis Dr., or 2048 Galisteo St., Santa Fe, NM 87502 [87505].

20.2.50.11 PLACEHOLDER

20.2.50.12 GENERAL PROVISIONS

A. General Requirements

(1) All equipment subject to requirements under 20.2.50 NMAC shall be operated and maintained consistent with manufacturer specifications and good engineering and maintenance practices. The owner or operator shall keep manufacturer specifications and maintenance practices on file and make them available upon request by the Department.

(2) Owners and operators of equipment subject to requirements under 20.2.50 NMAC shall establish and implement a plan to minimize emissions during routine or predictable startup, shutdown, and scheduled maintenance through work practice standards and good air pollution control practices. [20.2.7.14 NMAC]

(3) The emission of an air contaminant in excess of the quantity, rate, opacity, or concentration specified in 20.2.50 NMAC that results in an excess emission is a violation of 20.2.50 NMAC.

DRAFT

(4) The owner or operator of equipment having an excess emission shall comply with 20.2.7 NMAC and, to the extent practicable, operate the equipment, including associated air pollution control equipment, in a manner consistent with good air pollution control practices for minimizing emissions.
(5) The owner or operator of equipment that has an excess emission may claim an affirmative defense for the excess emission pursuant to 20.2.7.111, 20.2.7.112, and 20.2.7.113 NMAC.
(6) Within one year of the effective date of this rule, owners and operators of equipment requiring an Equipment Monitoring Information and Tracking Tag (EMITT) shall physically tag the unit with an EMITT that is scannable with a hand held scanner (RFID or QR) that uniquely identifies the unit to which it is assigned and the EMITT shall be maintained by the owner or operator. Data in the EMITT shall be scannable by state inspectors to provide at a minimum, the following information:
    (a) Unique unit identification number;
    (b) UTM coordinates of the facility;
    (c) Type of unit (tank, VRU, dehydrator, pneumatic controller, etc.);
    (d) For equipment, the VOC (and NOx, if applicable) potential to emit in pounds per hour and tons per year; and
    (e) For control equipment, the controlled VOC (and NOx, if applicable) potential to emit in pounds per hour and tons per year and the design control efficiency in percent.
(7) The EMITT shall be linked to an EMITT Database accessible to state inspectors that at a minimum supplies the data required by Section 20.2.50.12 NMAC and any other data required for that equipment under this Part.

B. Monitoring Requirements
(1) All equipment subject to control or monitoring requirements under this Part shall be inspected monthly to ensure proper maintenance and operation, unless a different inspection schedule is specified in the section below applicable to that particular type equipment. If the emission unit is shutdown at the time when periodic monitoring or inspections are due to be accomplished, the owner or operator is not required to restart the unit for the sole purpose of performing the monitoring or inspection but shall so note in the equipment or controller's records.
(2) All periodic monitoring events shall be conducted at 90% or greater of the unit's capacity. If the 90% capacity cannot be achieved, the monitoring will be conducted at the maximum achievable load under prevailing operating conditions.
(3) In order to allow for equivalent new and alternate monitoring technologies that satisfy the requirements of this regulation, prior to implementing, owners and operators may request an equally effective, enforceable, and equivalent alternative monitoring strategy to the Department for approval.
    (a) Each request shall be made on application forms provided by the Department. Upon approval of a request, the Department will issue an Alternative Monitoring Approval Letter. All Alternative Monitoring Approval Letters will

NMED Exhibit 12

be published on a link on the Department's webpage to provide authorization for the use of the approved alternative monitoring method.

(b) Each owner or operator will need to request and receive approval from the Department in order to operate under an approved Alternative Monitoring Strategy.

(4) Each EMITT shall be initially scanned and the required monitoring data shall be electronically captured during the monitoring event. The captured data shall be uploaded (either live or subsequently) into the database. At a minimum, the uploaded data shall include:

(a) Date and time of the monitoring event;
(b) The name of the monitoring personnel;
(c) Unique unit identification number;
(d) Type of unit;
(e) A description of any maintenance or repair activities conducted; and
(f) Required results of any monitoring required by 20.2.50 NMAC.

C. Recordkeeping Requirements

(1) Owners and operators shall keep records of any inspections and/or maintenance required under this Part. Records shall include:

(a) Date and time of the monitoring event;
(b) The name of the monitoring personnel;
(c) Unique unit identification number;
(d) Type of unit;
(e) Required results of any monitoring required by 20.2.50 NMAC;
(f) Equipment make, model and serial number;
(g) A copy of the equipment manufacturer's maintenance or repair recommendations;
(h) A description of any maintenance or repair activities conducted; and
(i) All results of any required parameter readings.

(2) Owners and operators shall keep records required this Part for a period of five years. The records shall be retained electronically. The Department may treat any loss of data or failure to maintain records (including failure to transfer records upon sale or transfer or ownership or operating authority) as a failure to collect the data.

(3) Owners and operators shall keep records of emissions from equipment malfunctions and routine or predictable emissions during startup, shutdown, and scheduled maintenance.

(4) Owners and operators of equipment having an excess emission shall record the following information no later than ten (10) days after the end of the excess emission event:

(a) The equipment type and identification number;
(b) The location, date, and time;
(c) The emission limit or air quality regulation that was exceeded;
(d) The air contaminant and the magnitude of the excess emission expressed in the units of the limit or air quality regulation;

DRAFT

(e) The cause of the excess emission and any steps taken to limit the magnitude and duration of the excess emissions;
(f) The corrective action(s) taken to eliminate the cause of the excess emission and prevent a recurrence, if required; and
(g) Whether the owner or operator attributes the excess emission to malfunction, startup, or shutdown.

(5) Records of each EMITT monitoring event required by 20.2.50.12.B NMAC shall be electronically uploaded (either in real time or subsequently) into the EMITT database. At a minimum, the uploaded data shall include the data required in 20.2.50.12.B(4) and 20.2.50.12.C(4) NMAC.

(6) Prior to the transfer of ownership of any equipment subject to this Part, the current owner or operator shall conduct and document a full compliance evaluation of all equipment subject to the rule. The documentation shall indicate whether or not each piece of equipment subject to requirements under this Part is currently complying with those requirements. The compliance determination shall be conducted no earlier than one year prior to the transfer.

D. Reporting Requirements

(1) Owners and operators shall submit reports upon the request of the Department. Any reports requested by the Department shall be submitted electronically via the Department's Secure Extranet Portal (SEP) at https://sep.net.env.nm.gov/sep/login-form.

(2) Owner and operators of a source having an excess emission shall submit a Root Cause and Corrective Action Analysis, as directed in 20.2.7.114 NMAC, upon the request of the department.

20.2.50.13 STANDARDS FOR ENGINES AND TURBINES

A. Applicability

(1) New and existing portable and stationary natural gas-fired spark ignition engines, compression ignition engines, and natural gas-fired combustion turbines located at wellheads, tank batteries, gathering and boosting sites, natural gas processing plants, and transmission compressor stations are subject to the requirements of 20.2.50.13 NMAC.

(2) Existing sources that were subject to federal standards of performance under 40 CFR Part 60 and Part 63 between March 25, 2004 and January 1, 2009 are exempt from the requirements of 20.2.50.13 NMAC.

B. Emission Standards

(1) Owners and operators of each portable or stationary natural gas-fired spark ignition engine, compression ignition engine, and natural gas-fired combustion turbine shall ensure compliance with the emission standards in 20.2.50.13.B NMAC by the dates specified in 20.2.50.13.B NMAC.

(2) Each natural gas-fired spark ignition engine shall comply with the applicable emission standards in Table 1 of 20.2.50.13 NMAC.

DRAFT

(3) By January 1, 2022, owners and operators of existing engines shall complete an inventory of all existing engines and shall prepare a schedule for each existing engine to ensure that all existing engines comply with these requirements and meet or exceed the emission standards in Table 1 by January 1, 2028. The schedule shall meet the following requirements:

(a) By January 1, 2024, owners and operators shall ensure 30% of the company's fleet of existing engines meet the requirements of Table 1.

(b) By January 1, 2026, owners and operators shall ensure an additional 35% of the company's fleet of existing engines meet the requirements of Table 1.

(c) By January 1, 2028, owners and operators shall ensure that the remaining 35% of the company's fleet of existing engines meet the requirements of Table 1.

Table 1 - Emission Standards for Natural Gas-Fired Spark-Ignition Engines

For each natural gas-fired spark-ignition engine constructed or reconstructed and installed before the effective date of 20.2.50 NMAC, the owner or operator shall ensure the existing engine(s) does not exceed the following emission standards as determined by the compliance schedule required in 20.2.50.13.B(3) NMAC:				
Engine Type	Rated bhp	NOx	CO	NMNEHC (as propane)
Lean-burn	≤100	2.0 g/bhp-h	2.0 g/bhp-h	-
Lean-burn	>100 - ≤500	1.0 g/bhp-h	2.0 g/bhp-h	0.70 g/bhp-h
Lean-burn	>500	0.50 g/bhp-h	47 ppmvd @ 15% O2 or 93% reduction	0.30 g/bhp-h
Rich-burn	≤100	2.0 g/bhp-h	2.0 g/bhp-h	-
Rich-burn	>100 - ≤500	0.25 g/bhp-h	0.30 g/bhp-h	0.20 g/bhp-h
Rich-burn	>500	0.20 g/bhp-h	0.30 g/bhp-h	0.20 g/bhp-h
For each natural gas-fired spark-ignition engine constructed or reconstructed and installed on or after the effective date of 20.2.50 NMAC, the owner or operator shall ensure the engine does not exceed the following emission standards upon startup:				
Engine Type	Rated bhp	NOx	CO	NMNEHC (as propane)
Lean-burn	≤100	1.0 g/bhp-h	2.0 g/bhp-h	0.70 g/bhp-h
Lean-burn	>100 - ≤500	1.0 g/bhp-h	0.70 g/bhp-h	0.30 g/bhp-h
Lean-burn	>500 - <2,370	0.50 g/bhp-h	0.25 g/bhp-h	0.30 g/bhp-h
Lean-burn	≥2,370	0.30 g/bhp-h Uncontrolled or 0.05 g/bhp-h with Control	0.25 g/bhp-h	0.30 g/bhp-h
Rich-burn	≤100	1.0 g/bhp-h	2.0 g/bhp-h	0.70 g/bhp-h
Rich-burn	>100 - ≤500	0.25 g/bhp-h	0.30 g/bhp-h	0.20 g/bhp-h
Rich-burn	>500	0.20 g/bhp-h	0.30 g/bhp-h	0.20 g/bhp-h

(4) Owners and operators of natural gas-fired spark ignition engines that control NOx emissions with a control technology that uses ammonia or urea as a reagent shall ensure that the exhaust ammonia slip is limited to 10 ppmvd or less, corrected to

DRAFT

15 percent oxygen.

(5) Owners and operators of each compression ignition engine shall ensure compliance with the applicable emission standards in 20.2.50.13.B(5)(a) NMAC and 20.2.50.13.B(5)(b) NMAC.

(a) Stationary compression ignition engines that are subject to and complying with standards in 40 CFR Part 60, subpart IIII, Standards of Performance for Stationary Compression Ignition Internal Combustion Engines, are exempt from the requirements of this paragraph.

(b) Portable and stationary compression ignition engines with a maximum design power output equal to or greater than 500 horsepower that are not subject to the emission standards under 20.2.50.13.B(5)(a) NMAC shall limit NOx emissions to no more than 9 g/bhp-h. For each compression-ignition engine constructed or reconstructed and installed before the effective date of this Part, the owner or operator shall ensure compliance no later than one year from the effective date. For each compression-ignition engine constructed or reconstructed and installed on or after the effective date of this Part, the owner or operator shall ensure compliance upon startup.

(6) Owners and operators of portable or stationary compression ignition engines that control NOx emissions with a control technology that uses ammonia or urea as a reagent shall ensure that the exhaust ammonia slip is limited to 10 ppmvd or less corrected to 15 percent oxygen.

(7) Owners and operators of stationary natural gas-fired combustion turbines with a maximum design rating equal to or greater than 1,000 bhp (or a maximum heat input capacity equal to or greater than 2.54 MMBtu/hr) shall comply with the applicable emission standards for existing, new, or reconstructed turbines listed in Table 2 of 20.2.50.13 NMAC.

Table 2 - Emission Standards for Stationary Combustion Turbines

For each natural gas-fired combustion turbine constructed or reconstructed and installed before the effective date of 20.2.50 NMAC, the owner or operator shall ensure the turbine does not exceed the following emission standards no later than one year from the effective date:				
Turbine Rating (bhp)	Turbine Rating (MMBtu/hr)	NOx (ppmvd @15% O2)	CO (ppmvd @ 15% O2)	NMNEHC (as propane, ppmvd @15% O2)
≥1,000 and <5,000	≥2.54 and <12.7	25	25	9
≥5,000 and <15,000	≥12.7 and <38.2	15	25	9
≥15,000	≥38.2	15	10 or 93% reduction	5 or 50% reduction
For each natural gas-fired combustion turbine constructed or reconstructed and installed on or after the effective date of 20.2.50 NMAC, the owner or operator shall ensure the turbine does not exceed the following emission standards upon startup:				
Turbine Rating (bhp)	Turbine Rating (MMBtu/hr)	NOx (ppmvd @15% O2)	CO (ppmvd @ 15% O2)	NMNEHC (as propane, ppmvd @15% O2)

DRAFT

≥1,000 and <5,000	≥2.54 and <12.7	25	25	9
≥5,000 and <15,900	≥12.7 and <40.4	15	10	9
≥15,900	≥40.4	9.0 Uncontrolled or 2.0 with Control	10 Uncontrolled or 1.8 with Control	5

(8) Owners and operators of stationary natural gas-fired combustion turbines that control NOx emissions with a control technology that uses ammonia or urea as a reagent shall ensure that the exhaust ammonia slip is limited to 10 ppmvd or less, corrected to 15% oxygen.

(9) Owners and operators of new or existing engines or turbines shall install an Equipment Monitoring and Information Tracking Tag (EMITT) on each engine or turbine in accordance with 20.2.50.12 NMAC.

C. Monitoring Requirements

(1) Maintenance and repair for all spark ignition engines, compression ignition engines, and stationary combustion turbines shall meet the minimum engine or turbine manufacturer's recommended maintenance schedule. Activities that involve engine or turbine maintenance, adjustment, replacement, or repair of functional components with the potential to affect the operation of an emission unit shall be documented as they occur for the following events:

(a) Routine maintenance that takes a unit out of service for more than two hours during any 24-hour period.

(b) Unscheduled repairs that require a unit to be taken out of service for more than two hours in any 24-hour period.

(2) Oxidation catalytic converters, selective and non-selective catalytic converters, and air-fuel ratio (AFR) controllers shall be maintained according to manufacturer's or supplier's recommended maintenance, including replacement of oxygen sensors as necessary for oxygen-based controllers. During periods of catalyst or AFR controller maintenance, the owner or operator shall shut down the engine(s) or turbine(s) until the catalyst or AFR controller can be replaced with a functionally equivalent spare to allow the engine or turbine to remain in operation.

(3) Compliance with the emission standards in 20.2.50.13.B NMAC shall be demonstrated by performing an initial and annual test for NOx, CO, and non-methane non-ethane hydrocarbons (NMNEHC) using a portable analyzer or EPA Reference Methods. For units with g/hp-hr emission standards, the engine load shall be calculated by using the following equations:

$$\text{Load (Hp)} = \frac{\text{Fuel consumption (scfh) x Measured fuel heating value (LHV btu/scf)}}{\text{Manufacturer's rated BSFC (btu/bhp-hr) at 100\% load or best efficiency}}$$

$$\text{Load (Hp)} = \frac{\text{Fuel consumption (gal/hr) x Measured fuel heating value (LHV btu/gal)}}{\text{Manufacturer's rated BSFC (btu/bhp-hr) at 100\% load or best efficiency}}$$

DRAFT

Where:
LVH = lower heating value, btu/scf, or btu/gal, as appropriate
BSCF = brake specific fuel consumption

(a) Periodic monitoring utilizing a portable analyzer shall be conducted in accordance with the requirements of the current version of ASTM D 6522. However, if a facility has met a previously approved Department criterion for portable analyzers, the analyzer may be operated in accordance with that criterion until it is replaced.
(b) The default time period for each test run shall be at least 20 minutes.
(c) Each performance test shall consist of three separate runs. The arithmetic mean of results of the three runs shall be used to determine compliance with the applicable emission standard.
(d) For all periodic monitoring events, three test runs shall be conducted at 90% or greater of the unit's capacity. If the 90% capacity cannot be achieved, the monitoring will be conducted at the maximum achievable load under prevailing operating conditions. The load and the parameters used to calculate it shall be recorded to document operating conditions and shall be included with the monitoring test report.
(e) During emissions tests, pollutant and diluent concentration shall be monitored and recorded. Fuel flow rate shall be monitored and recorded if stack gas flow rate is determined utilizing EPA Reference Method 19. This information shall be included with the monitoring test report.
(f) Stack gas flow rate shall be calculated in accordance with EPA Reference Method 19 utilizing fuel flow rate (scf) determined by a dedicated fuel flow meter and fuel heating value (Btu/scf). The owner or operator shall provide a contemporaneous fuel gas analysis (preferably on the day of the test, but no earlier than three months prior to the test date) and a recent fuel flow meter calibration certificate (within the most recent quarter) with the final test report. Alternatively, stack gas flow rate may be determined by using EPA Reference Methods 1 through 4.
(g) The owner or operator shall submit a notification and protocol for periodic emissions tests upon the request of the Department.

(4) Testing shall be conducted once per calendar year. Performance testing required by 40 CFR 60, Subparts GG, IIII, JJJJ, or KKKK, or 40 CFR 63, Subpart ZZZZ may be used to satisfy these periodic testing requirements if they meet the requirements of this section and are completed once per calendar year.
(5) Each monitoring, testing, inspection, or tune-up of an engine or turbine shall include the initial scanning of the EMITT, and the monitoring data entry shall be made in accordance with the requirements of 20.2.50.12 NMAC.

D. Recordkeeping Requirements
(1) The owner or operator of spark ignition engines, compression ignition engines, or stationary combustion turbines shall maintain records in accordance with 20.2.50.12 NMAC for each engine or turbine of:

DRAFT

(a) The make, model, serial number, and equipment identification number for each engine, turbine, and any control equipment,
(b) A copy of the engine or turbine manufacturer's or control equipment manufacturer's recommended maintenance and repair schedule,
(c) Inspections, maintenance and repairs activities on all engines, turbines, and control equipment, including:
(i) Date(s) and time(s) of inspection, maintenance, and/or repair;
(ii) Date(s) any subsequent analyses were performed (if applicable);
(iii) Name of the person or qualified entity conducting the inspection, maintenance, and/or repair;
(iv) A description of the physical condition of the equipment as found during any required inspection;
(v) Description of maintenance or repair activities conducted; and
(vi) Results of required equipment inspections including a description of any condition which required adjustment to bring the equipment back into compliance and a description of the required adjustments.
(d) Results of any required parameter readings.

(2) The owner or operator of spark ignition engines, compression ignition engines, or stationary combustion turbines shall maintain records of initial and annual performance testing in accordance with 20.2.50.12 NMAC for each engine or turbine, including:
(a) The make, model, serial number, and equipment identification number for all tested engines, turbines, and emission control equipment);
(b) Date(s) and time(s) of sampling or measurements;
(c) Date(s) analyses were performed;
(d) The qualified entity that performed the analyses;
(e) Analytical or test methods used;
(f) Results of analyses or tests; and
(g) Operating conditions existing at the time of sampling or measurement.

(3) Owners and operators shall comply with the recordkeeping requirements in 20.2.50.12 NMAC.

E. Reporting Requirements.

Owners and operators shall comply with the reporting requirements in 20.2.50.12 NMAC.

20.2.50.14 STANDARDS FOR COMPRESSOR SEALS

A. Applicability

(1) All new and existing centrifugal compressors using wet seals located at tank batteries, gathering and boosting sites, natural gas processing plants, and transmission compressor stations are subject to the requirements of 20.2.50.14 NMAC. Any new or existing centrifugal compressor located at a wellhead is not subject to the requirements of 20.2.50.14 NMAC.

(2) All new and existing reciprocating compressors located at tank batteries,

DRAFT

gathering and boosting sites, natural gas processing plants, and transmission compressor stations are subject to the requirements of 20.2.50.14 NMAC. Any new or existing reciprocating compressor located at a wellhead is not subject to the requirements of 20.2.50.14 NMAC.

B. Emission Standards

(1) Owners and operators of existing centrifugal compressors shall control VOC emissions from each centrifugal compressor wet seal fluid degassing system by 95%, beginning on the effective date of this Part. Emissions shall be captured and routed via a closed vent system to a control system, a recovery system, fuel cell, or a process stream.

(2) Owners and operators of existing reciprocating compressors shall, either:

(a) Replace the reciprocating compressor rod packing after every 26,000 hours of compressor operation or every 36 months, whichever is reached later. The owner or operator shall begin counting the hours and months of compressor operation toward the first replacement of the rod packing beginning no later than one year from the effective date; OR

(b) Beginning no later than one year from the effective date, collect emissions from the rod packing under negative pressure and route via a closed vent system to a control system, a recovery system, fuel cell, or a process stream.

(3) Owners and operators of new centrifugal compressors shall control VOC emissions from each centrifugal compressor wet seal fluid degassing system by 98% upon startup. Emissions shall be captured and routed via a closed vent system to a control system, a recovery system, fuel cell, or a process stream.

(4) Owners and operators of new reciprocating compressors shall, upon startup, either:

(a) Replace the reciprocating compressor rod packing after every 26,000 hours of compressor operation, or every 36 months, whichever is reached later; OR

(b) Collect emissions from the rod packing under negative pressure and route via a closed vent system to a control system, a recovery system, fuel cell, or a process stream.

(5) Owners and operators of new and existing centrifugal and reciprocating compressors shall install an Equipment Monitoring Information Tracking Tag (EMITT) on each compressor in accordance with 20.2.50.12 NMAC.

(6) Owners and operators complying with the control requirements in 20.2.50.14.B NMAC through use of a control device shall comply with the control device requirements in 20.2.50.15 NMAC.

(7) Owners and operators with an air permit shall incorporate these requirements in their permit during their next scheduled or requested permit or permit revision.

C. Monitoring Requirements

(1) The owner or operator of a centrifugal compressor complying with 20.2.50.14.B(1) NMAC or 20.2.50.14.B(3) NMAC shall maintain a closed vent system encompassing the wet seal fluid degassing system that complies with the monitoring requirements in 20.2.50.15 NMAC.

(2) The owner or operator of a reciprocating compressor complying with

DRAFT

20.2.50.14.B(2)(a) NMAC or 20.2.50.14.B(4)(a) NMAC shall continuously monitor the number of hours of operation with a non-resettable hour meter and track the number of months since initial startup or since the previous reciprocating compressor rod packing replacement.

(3) The owner or operator of a reciprocating compressor complying with 20.2.50.14.B(2)(b) NMAC or 20.2.50.14.B(4)(b) NMAC shall monitor the rod packing emissions collection system semiannually to ensure that it operates under negative pressure and routes emissions through a closed vent system to a control device.

(4) Owners and operators complying with the requirements in 20.2.50.14.B NMAC through use of a control device shall comply with the monitoring requirements in 20.2.50.15 NMAC.

(5) Owners and operators of new and existing centrifugal and reciprocating compressors, during each required monitoring activity, shall scan the compressor EMITT and perform monitoring data entry in accordance with the requirements of 20.2.50.12 NMAC.

(6) Owners and operators shall comply with the monitoring requirements in 20.2.50.12 NMAC.

D. Recordkeeping Requirements

(1) The owner or operator of a centrifugal compressor shall maintain records of:

(a) The identification number and location of each centrifugal compressor using a wet seal system,

(b) The date of construction, reconstruction, or modification of each centrifugal compressor,

(c) The records of the monitoring and inspections required in 20.2.50.14.C NMAC. The records shall include the time and date of the inspection, the person conducting the inspection, a notation of which checks required in 20.2.50.12.C NMAC were completed, a description of any problems observed during the inspection, and a description and date of any corrective actions taken, and

(d) The location, type, make, model and unique identification number of any control equipment, recovery system, fuel cell, or process used to comply with the control requirements in 20.2.50.14.B NMAC.

(2) The owner or operator of a reciprocating compressor shall maintain records of the following:

(a) The identification number and location of each reciprocating compressor;

(b) The date of construction, reconstruction, or modification of each reciprocating compressor; and

(c) The records of the monitoring and inspections required in 20.2.50.14.C NMAC. The records shall meet the requirements of 20.2.50.14.C NMAC and shall include:

(i) The number of hours of operation and the number of months of operation since initial startup or the last rod packing replacement;

(ii) The records of pressure in the rod packing emissions collection system; and

NMED Exhibit 12

(iii) The time and date of the inspection, the person conducting the inspection, a notation of which checks required in 20.2.50.14.C NMAC were completed, a description of any problems observed during the inspection, and a description and date of any corrective actions taken.

(3) Owners and operators complying with the requirements in 20.2.50.14.B NMAC through use of a control device shall comply with the recordkeeping requirements in 20.2.50.15 NMAC.

(4) Owners and operators shall comply with the recordkeeping requirements in 20.2.50.12 NMAC.

E. Reporting Requirements

(1) Owners and operators shall comply with the reporting requirements in 20.2.50.12 NMAC.

20.2.50.15 STANDARDS FOR CONTROL DEVICES

A. Applicability

(1) These requirements apply to open flares, enclosed combustors, thermal oxidizers, vapor recovery units, condensers, closed vent collection systems, other combustion devices, or emissions reduction equipment or technologies used to comply with the emission standards and emission reduction requirements in this Part.

B. General Requirements

(1) All air pollution control equipment used to demonstrate compliance with this Part shall be installed, operated, and maintained consistent with manufacturer specifications and good engineering and maintenance practices.

(2) All air pollution control equipment shall be adequately designed and sized to achieve the control efficiency rates required by this Part and to handle fluctuations in emissions of VOC or NOx.

(3) Owners and operators of a flare, combustion device, vapor recovery equipment, or other emission reduction technology or control device used to comply with the emission standards in this Part shall install an Equipment Monitoring and Information Tracking Tag (EMITT) on each flare, combustion device, vapor recovery equipment, or other emission reduction technology or control device in accordance with 20.2.50.12 NMAC.

(4) Owners and operators shall inspect all air pollution control equipment used to control emissions from equipment subject to emission standards under this Part at least monthly to ensure proper maintenance and operation. Each EMITT inspection or monitoring event shall be initially scanned and the required monitoring data shall be electronically captured during the monitoring event.

(5) Owners and operators shall ensure that any flare, combustion device, vapor recovery equipment, or other emission reduction technology or control device used to comply with emission standards in this Part shall at all times operate as a closed vent system that captures and routes all VOC emissions from equipment

DRAFT

subject to regulation under this Part to the control or vapor recovery device and that un-combusted gas is not vented to the atmosphere.

(6) Owners and operators shall keep manufacturer specifications for all control or vapor recovery equipment on file. The information shall include:
   (a) Manufacturer's name, control device name and model;
   (b) Maximum heating value for open flares, enclosed combustors, and thermal oxidizers;
   (c) Fuel gas flow range for open flares, enclosed combustors, and thermal oxidizers; and
   (d) Designed destruction or vapor recovery efficiency.

(7) Owners and operators shall keep records of any stack testing or control or vapor recovery efficiency testing for all control equipment. The records shall be kept in accordance with 20.2.50.12 NMAC for each flare, combustion device, vapor recovery equipment, or other emission reduction technology or control device and shall include:
   (a) Control device type, name and model;
   (b) Location;
   (c) Date of the stack test; and
   (d) A summary of the stack test results.

C. Requirements for Open Flares

(1) Emission Standards
   (a) The flare shall combust all gas sent to the flare. Owners and operators shall not send gas to the flare in excess of the flare's maximum rated capacity.
   (b) Owners and operators shall equip all flares with a continuous pilot flame, an auto-igniter, or require manual ignition.
      (i) Flares with a continuous pilot flame or an auto-igniter shall be equipped with a system to ensure the flare is operated with a flame present at all times that gas is being sent to the flare.
      (ii) Owners and operators of flares with manual ignition shall inspect and ensure a flame is present upon initiating each flaring event.
      (iii) Any new flare constructed or re-constructed after the effective date of this Part shall be equipped with an auto-igniter. The auto-igniter shall be installed and operational upon startup.
      (iv) Any existing flare constructed prior to the effective date of this Part shall be equipped with an auto-igniter no later than one year after the effective date.
   (c) Owners and operators shall operate any flare used for controlling VOC emissions to comply with this Part with no visible emissions, except for periods not to exceed a total of sixty (60) seconds during any fifteen (15) consecutive minutes. The flare shall be designed so that an observer can, by means of visual observation from the outside of the flare, or by other means such as a continuous monitoring device, determine whether it is operating properly.

(2) Monitoring Requirements

DRAFT

(a) Owners and operators of flares with a continuous pilot or an auto igniter shall continuously monitor the presence of a pilot flame using a thermocouple equipped with a continuous recorder and alarm to detect the presence of a flame. Owners and operators may use any other equivalent device that fulfills the same purpose.
(b) Owners and operators of manually ignited flares shall monitor the presence of a flame using continual visual observation during each flaring event.
(c) Owners and operators, at least quarterly, and upon observing any visible emissions, shall perform a U.S. EPA Method 22 observation while the flare pilot flame is present to certify compliance with visible emission requirements. The observation period shall be a minimum of fifteen (15) consecutive minutes.
(d) Each EMITT inspection or monitoring event shall be initially scanned and the required monitoring data shall be electronically captured during the monitoring event in accordance with the monitoring requirements of 20.2.50.12 NMAC.

(3) Recordkeeping Requirements

(a) The owner or operator of open flares subject to regulation under 20.2.50.15.A NMAC shall keep records for each flare in accordance with 20.2.50.12 NMAC of the following:
(i) All instances of alarm activation, including the date and cause of alarm activation, actions taken to bring the flare into a normal operating condition, the name of the personnel conducting the inspection, and any maintenance activities performed;
(ii) The results of the U.S. EPA Method 22 observations and flame inspection for manual flares and
(iii) The results of any gas analysis for the gas being flared, including VOC content and heating value.

(4) Reporting Requirements

Owners and operators shall comply with the reporting requirements in 20.2.50.12 NMAC.

D. Requirements for Enclosed Combustion Devices (ECD) and Thermal Oxidizers (TO)

(1) Emission Standards

(a) The ECD/TO shall combust all gas sent to the ECD/TO. Owners and operators shall not send gas to the ECD/TO in excess of the ECD/TO's maximum rated capacity.
(b) Owners and operators shall equip all ECDs/TOs with a continuous pilot flame or an operational auto-igniter. ECDs/TOs constructed or re-constructed prior to the effective date of this Part shall be equipped with a continuous pilot flame or an auto-igniter no later than one year after the effective date. ECDs/TOs constructed or re-constructed on or after the effective date shall be equipped with a continuous pilot flame or an operational auto-igniter upon startup.
(c) ECDs/TOs with a continuous pilot flame or an auto-igniter shall be equipped with a system to ensure that the ECD/TO is operated with a flame present at

DRAFT

all times that gas is being sent the ECD/TO. Combustion shall be maintained for the duration of time that gas is being sent to the ECD/TO.

(d) Owners and operators shall operate ECDs/TOs used to control VOC emissions to comply with the emission standards in this Part with no visible emissions, except for periods not to exceed a total of sixty (60) seconds during any fifteen (15) consecutive minutes. The combustion device shall be designed so that an observer can, by means of visual observation from the outside of the combustion device, or by other means, such as a continuous monitoring device, determine whether it is operating properly.

(2) Monitoring Requirements

(a) Owners and operators of ECDs/TOs with a continuous pilot or an auto igniter shall continuously monitor the presence of a pilot flame using a thermocouple equipped with a continuous recorder and alarm to detect the presence of a flame. Owners and operators may use any other equivalent device that fulfills the same purpose.

(b) Owners and operators, at least quarterly, and upon observing any visible emissions, shall perform a Method 22 observation while the ECD/TO pilot flame is present to certify compliance with the visible emission requirements. The observation shall be a minimum of fifteen minutes.

(c) Each EMITT inspection or monitoring event shall be initially scanned and the required monitoring data shall be electronically captured during the monitoring event in accordance with the monitoring requirements of 20.2.50.12 NMAC.

(3) Recordkeeping Requirements

(a) The owner or operator of an ECD/TO subject to regulation under 20.2.50.15.A NMAC shall keep records in accordance with 20.2.50.12 NMAC for each ECD/TO of:

(i) All instances of alarm activation, including the date and cause of alarm activation, actions taken to bring the ECD/TO into normal operating conditions, the name of the personnel conducting the inspection, and any maintenance activities performed;

(ii) The results of the Method 22 observations; and

(iii)The results of any gas analysis for the gas being combusted, including VOC content and heating value.

(4) Reporting Requirements

(a) Owners and operators shall comply with the reporting requirements in 20.2.50.12 NMAC.

E. Requirements for Vapor Recovery Units (VRU)

(1) Emission Standards

(a) Owners and operators shall operate the VRU as a closed vent system that captures and routes all VOC emissions from units back to the process stream or to a sales pipeline and does not vent to the atmosphere.

(b) Owners and operators shall control emissions during startup, shutdown, and maintenance (SSM) or other VRU downtime with a backup control device (flare/ECD/TO) or redundant VRU.

DRAFT

(2) Monitoring Requirements
  (a) Owners and operators shall comply with the standards for equipment leaks in 20.2.50.16 NMAC, or, alternatively, shall implement a program that meets the requirements of NSPS Subpart OOOOa (40 CFR 60.5416a).
  (b) Each VRU EMITT inspection or monitoring event shall be initially scanned and the required monitoring data shall be electronically captured during the monitoring event requirements of 20.2.50.12 NMAC.
(3) Recordkeeping Requirements
  (a) For each VRU inspection or monitoring event, the owner or operator shall record the results of the VRU inspections in accordance with 20.2.50.12 NMAC, including the name of the personnel conducting the inspection, and noting any maintenance or repairs that are required.
(4) Reporting Requirements
  Owners and operators shall comply with the reporting requirements in 20.2.50.12 NMAC.

20.2.50.16 STANDARDS FOR EQUIPMENT LEAKS

A. Applicability
  All new and existing wellheads, tank batteries, gathering and boosting sites, gas processing plants, transmission compressor stations and associated piping are subject to the requirements of 20.2.50.16 NMAC.

B. Emission Standards
  Each owner and operator of oil and gas production and processing equipment located at a site identified in 20.2.50.16.A NMAC shall demonstrate compliance with 20.2.50.16 NMAC by performing the monitoring, recordkeeping, and reporting requirements specified in this Section.

C. Monitoring Requirements
  (1) Owners or operators shall comply with the monitoring requirements in 20.2.50.12 NMAC.
  (2) Default Equipment Leak Monitoring Requirements:
    (a) Owners or operators shall conduct an audible, visual, and olfactory (AVO) inspection of each thief hatch, closed vent system, pump, compressor, pressure relief device, open-ended valve or line, valve, flange, connector, piping, and any associated equipment to identify defects and leaking components at least weekly as follows:
      (i) Visually inspect for cracks, holes or gaps in piping or covers; loose connections; liquid leaks; broken or missing caps; broken, cracked or otherwise damaged seals or gaskets; broken or missing hatches; or broken or open access covers or other closure devices;
      (ii) Listen for pressure leaks or liquid leaks.
      (iii) Smell for unusual or strong odors.

DRAFT

(iv) Any positive audible, visual, or odorous indication shall be considered a leak. All AVO leaks shall be tagged with a visible tag and reported to management or designee within three calendar days.

(b) Owners or operators shall conduct an inspection using EPA Reference Method 21 (40 CFR 60, Appendix B) (RM 21) or optical gas imaging (OGI) with infrared cameras of each thief hatch, closed vent system, pump, compressor, pressure relief device, open-ended valve or line, valve, flange, connector, piping, and any associated equipment to identify leaking components at a frequency determined according to the following schedule:

(i) For well production and tank battery facilities:

(A) Annually at facilities with a potential to emit less than 2 tpy VOC.

(B) Semi-annually at facilities with a potential to emit equal to or greater than 2 tpy and less than 5 tpy VOC.

(C) Quarterly at facilities with a potential to emit equal to or greater than 5 tpy VOC.

(ii) For gathering and boosting sites, gas processing plants, and transmission compressor stations:

(A) Quarterly at facilities with a potential to emit less than 25 tpy VOC.

(B) Monthly at facilities with a potential to emit equal to or greater than 25 tpy VOC.

(c) The inspections required under 20.2.50.16.C(2)(b) NMAC shall be conducted using RM 21 or OGI with infrared cameras.

(i) For leaks determined using RM 21:

(A) The instrument shall be calibrated before each day of its use by the procedures specified in RM 21.

(B) The instrument shall be calibrated with zero air (less than 10 ppm of hydrocarbon in air); and a mixture of methane or n-hexane and air at a concentration of about, but less than, 10,000 ppm methane or n-hexane.

(C) A leak is detected if an instrument reading of 500 ppm or greater of hydrocarbon is measured that is not associated with normal equipment operation, such as pneumatic device actuation and crank case ventilation.

(ii) For leaks determined using OGI:

(A) The instrument must comply with the specifications, the daily instrument checks, and the leak survey requirements at 40 CFR 60.18(i)(1) through (3).

(B) A leak is detected if any emissions are imaged by the OGI instrument that are not associated with normal equipment operation, such as pneumatic device actuation and crank case ventilation.

(d) If a component is unsafe, difficult, or inaccessible to monitor, the owner or operator is not required to inspect the component until it becomes feasible to do so.

(i) Difficult to monitor components are those that cannot be monitored without elevating the monitoring personnel more than two (2) meters

NMED Exhibit 12

above a supported surface or are unable to be reached via a wheeled scissor-lift or hydraulic type scaffold that allows access to components up to 7.6 meters (25 feet) above the ground.

(ii) Unsafe to monitor components are those that cannot be monitored without exposing monitoring personnel to an immediate danger as a consequence of completing the monitoring.

(iii) Inaccessible to monitor components are those that are buried, insulated, or obstructed by equipment or piping that prevents access to the components by monitoring personnel.

(3) Alternative Equipment Leak Monitoring Plans

(a) As an equivalent means of compliance with 20.2.50.16 NMAC, owners or operators may comply with the equipment leak requirements through an individual alternative monitoring plan approved by the Department, subject to the following requirements:

(i) Upon the Department's approval of an alternative monitoring plan, the owner or operator shall comply with the terms and conditions of the approved alternative monitoring plan.

(ii) A responsible official shall certify compliance with the approved alternative monitoring plan on behalf of the owner or operator on an annual basis.

(iii) The Department may terminate an approved alternative monitoring plan if the Department finds that the owner or operator failed to comply with any provision of the plan and failed to correct and disclose the violation(s) to the Department within 15 calendar days of identifying the violation.

(iv) Upon the Department's denial or termination of an approved alternative monitoring plan, the owner or operator shall comply with the default monitoring requirements under 20.2.50.16.C(2) NMAC within 30 days.

(b) As an equivalent means of compliance with 20.2.50.16 NMAC, owners or operators may comply with equipment leak requirements through one of the pre-approved monitoring plans maintained by the Department, subject to the following requirements:

(i) The owner or operator shall notify the Department of the pre-approved monitoring plan that the owner or operator will follow and shall comply with the terms and conditions of the pre-approved monitoring plan.

(ii) A responsible official shall certify compliance with the pre-approved monitoring plan on behalf of the owner or operator on an annual basis.

(iii) The Department may terminate the use of a pre-approved monitoring plan by the owner or operator if the Department finds that the owner or operator failed to comply with any provision of the plan and failed to correct and disclose the violation(s) to the Department within 15 calendar days of identifying the violation.

(iv) Upon the Department terminating the use of an approved monitoring plan by an owner or operator, the owner or operator shall comply with the

DRAFT

default monitoring requirements under 20.2.50.16.C(2) NMAC within 30 days.

D. Repair Requirements
   (1) For any leaks detected in 20.2.50.16(C) NMAC:
      (a) The owner or operator shall place a visible tag on the leaking component until the component has been repaired;
      (b) All leaks detected using optical gas imaging shall be repaired within 7 days of discovery, all other leaks shall be repaired within 15 days of discovery;
      (c) The equipment must be re-monitored no later than 15 days after discovery of the leak to demonstrate that it has been repaired; and
      (d) If the leak cannot be repaired within 7 days for leaks detected using optical gas imaging and within 14 days for all other leaks without a process unit shutdown, it may be designated "Repair delayed," and must be repaired before the end of the next process unit shutdown.

E. Recordkeeping Requirements
   (1) Owners or operators shall keep records of all monitoring under 20.2.50.16.C NMAC and provide such records to the Department upon request.
   (2) Owners or operators subject to 20.2.50.16.C NMAC shall keep records of the following for all AVO, RM21, and OGI inspections conducted as required under 20.2.50.16.C NMAC:
      (a) The facility location and unique inventory control number or name;
      (b) The date of inspection;
      (c) The monitoring method (AVO, RM 21, or OGI);
      (d) The name of the operator(s) performing the inspection;
      (e) A list of the leaks requiring repair or a statement that no leaks were found; and
      (f) Whether a visible flag was placed on the leak or not;
   (3) Owners or operators shall keep the following records for any leak detected:
      (a) Date the leak is detected;
      (b) Dates of attempts to repair;
      (c) For leaks with a designation of "repair delayed" keep the following:
         (i) The reason for delay if the leak is not repaired within 30 days of leak discovery;
         (ii) The signature of the authorized representative whose decision it was that the repair could not be implemented without a process shutdown;
      (d) The date of successful leak repair;
      (e) The date the leak was monitored after the repair and the results of the monitoring; and
      (f) A list of components that are designated as unsafe, difficult, or inaccessible to monitor, an explanation stating why the component is so designated, and the schedule for monitoring such component(s).
   (4) For leaks determined using optical gas imaging with infrared cameras, owners or operators shall keep the records of the specifications, the daily instrument checks and the leak survey requirements specified at 40 CFR §60.18(i)(1) – (3).
   (5) Owners or operators shall comply with the recordkeeping requirements in

DRAFT

20.2.50.12 NMAC.

F. Reporting Requirements
   (1) Owners and operators shall report the certifications required under 20.2.50.16.C(3)(a)(ii) and (b)(ii) NMAC to the Department annually.
   (2) Owners or operators shall comply with the reporting requirements in 20.2.50.12 NMAC.

20.2.50.17 STANDARDS FOR NATURAL GAS WELL LIQUIDS UNLOADING

A. Applicability
   (1) All manual liquids unloading, including those associated with down-hole well maintenance events, performed at natural gas wells are subject to the requirements of 20.2.50.17 NMAC.
   (2) Owners and operators shall comply with these requirements for any manual liquids unloading performed after the effective date of this Part.

B. Emission Standards
   (1) Owners and operators of natural gas wells shall use best management practices during the life of the well to avoid the need for manual liquids unloading.
   (2) Owners and operators of natural gas wells shall use the following best management practices during manual liquids unloading to minimize emissions, consistent with well site conditions and good engineering practices:
      (a) Reduce wellhead pressure prior to blowdown;
      (b) Monitor manual liquids unloading in close proximity to the well or via remote telemetry; and
      (c) Close all well head vents to the atmosphere and return the well to normal production operation as soon as practicable.
   (3) Owners and operators of a natural gas well shall install an Equipment Monitoring and Information Tracking Tag (EMITT) on each natural gas well in accordance with 20.2.50.12 NMAC.

C. Monitoring Requirements
   (1) Owners and operators subject to 20.2.50.17 NMAC shall monitor the following parameters during manual liquids unloading:
      (a) Wellhead pressure;
      (b) Flow rate of the vented natural gas (to the extent feasible); and
      (c) Duration of venting to the storage tank/atmosphere.
   (2) Owners and operators shall calculate the volume and mass of VOC vented during each manual liquids unloading event.
   (3) Each manual liquids unloading event shall include the scanning of the EMITT and monitoring data entry in accordance with the requirements of 20.2.50.12 NMAC.
   (4) Owners and operators shall comply with the monitoring requirements in 20.2.50.12 NMAC.

D. Recordkeeping Requirements

DRAFT

(1) Owners and operators subject to 20.2.50.17 NMAC shall keep the following records for each manual liquids unloading:
  (a) The identification number and location of the well;
  (b) The date(s) the manual liquids unloading was performed;
  (c) Wellhead pressure;
  (d) Flow rate of the vented natural gas (to the extent feasible. If not feasible, the owner or operator shall use the maximum potential flow rate in the emission calculation);
  (e) Duration of venting to the storage tank/atmosphere;
  (f) A description of the management practices used to minimize release of VOC prior to and during the manual liquids unloading; and
  (g) A calculation of the VOC emissions vented during the manual liquids unloading based on the duration, volume, and mass of VOC.
(2) Owners and operators shall comply with the recordkeeping requirements in 20.2.50.12 NMAC.

E. Reporting Requirements

Owners and operators shall comply with the reporting requirements in 20.2.50.12 NMAC.

20.2.50.18 STANDARDS FOR GLYCOL DEHYDRATORS

A. Applicability

(1) All new and existing glycol dehydrators with a potential to emit equal to or greater than 2 tpy of VOC and located at wellhead sites, tank batteries, gathering and boosting sites, natural gas processing plants, and transmission compressor stations are subject to the requirements of 20.2.50.18 NMAC.

B. Emission Standards

(1) Owners and operators of an existing glycol dehydrator constructed on or before the effective date of this Part with a potential to emit equal to or greater than 2 tpy of VOC shall have a minimum combined capture and control efficiency of 95 percent of VOC emissions from the still vent and flash tank, no later than one year after the effective date. If a combustion control device is used, the combustion control device shall have a minimum design combustion efficiency of 98 percent.
(2) Owners and operators of a new glycol dehydrator constructed after the effective date of this Part with a potential to emit equal to or greater than 2 tpy of VOC shall have a combined capture and control efficiency of 95 percent of VOC emissions from the still vent and flash tank upon startup. If a combustion control device is used, the combustion control device shall have a minimum design combustion efficiency of 98 percent.
(3) Owners and operators of a new or existing glycol dehydrator subject to control requirements under 20.2.50.18 NMAC shall comply with the following equipment requirements:
  (a) The still vent and flash tank emissions shall be routed at all times to the

DRAFT

reboiler firebox, condenser, combustion control device, fuel cell, to a process point that either recycles or recompresses the emissions or uses the emissions as fuel, or to a vapor recovery unit (VRU) that reinjects the VRU VOC emissions back into the process stream or natural gas gathering pipeline.

(b) If a VRU is used, it shall consist of a closed loop system of seals, ducts, and a compressor that will reinject the natural gas into the process stream or the natural gas gathering pipeline. The VRU shall be operational at least 95 percent of the time the facility is in operation, resulting in a minimum combined capture and control efficiency of 95 percent. The VRU shall be installed, operated, and maintained according to the manufacturer's specifications.

(c) The still vent and flash tank emissions shall not be vented to the atmosphere.

(d) Owners and operators of a glycol dehydrator shall install an Equipment Monitoring and Information Tracking Tag (EMITT) on each glycol dehydrator in accordance with 20.2.50.12 NMAC.

(4) Any new or existing glycol dehydrator subject to control requirements under 20.2.50.18 NMAC will become exempt from these requirements when its uncontrolled actual annual VOC emissions decreases to an amount less than 2 tpy.

(5) Owners and operators complying with the control requirements in 20.2.50.18.B(1) NMAC or 20.2.50.18.B(2) NMAC through use of a control device shall comply with the control device operational requirements in 20.2.50.15 NMAC.

C. Monitoring Requirements

(1) The owner or operator of a glycol dehydrator subject to control requirements in 20.2.50.18 NMAC shall conduct an annual extended gas analysis on the dehydrator inlet gas and calculate the uncontrolled VOC emissions (tpy) and controlled VOC emissions (tpy).

(2) The owner or operator of any glycol dehydrator subject to control requirements shall inspect the glycol dehydrator, including the reboiler and regenerator, and the control equipment semi-annually to ensure it is operating as initially designed and in accordance with the manufacturer's recommended procedures.

(3) Owners and operators complying with the requirements in 20.2.50.18.B(1) NMAC or 20.2.50.18.B(2) NMAC through use of a control device shall comply with the monitoring requirements in 20.2.50.15 NMAC.

(4) Owners and operators shall comply with the monitoring requirements in 20.2.50.12 NMAC.

D. Recordkeeping Requirements

(1) Owners and operators subject to control requirements in 20.2.50.18 NMAC shall maintain records of the following for each glycol dehydrator, in accordance with 20.2.50.12 NMAC:

(a) The dehydrator's location and unique inventory control number or name;

(b) Glycol circulation rate, monthly natural gas throughput, and the date of the most recent throughput measurement;

(c) The data and methodology used to estimate the potential to emit of VOC (the method must be a Department approved calculation methodology);

DRAFT

(d) The controlled and uncontrolled VOC emissions (tpy);
(e) The location, type, make, model and unique identification number of any control equipment;
(f) The date and the results of all equipment inspections, including any maintenance or repairs needed to bring the glycol dehydrator into compliance; and
(g) Copies of the glycol dehydrator manufacturer's operation and maintenance recommendations.

(2) Owners and operators complying with the requirements in 20.2.50.18.B(1) NMAC or 20.2.50.18.B(2) NMAC through use of a control device shall comply with the recordkeeping requirements in 20.2.50.15 NMAC.

(3) Owners and operators shall comply with the recordkeeping requirements in 20.2.50.12 NMAC.

E. Reporting Requirements.

(1) Owners and operators complying with the requirements in 20.2.50.18.B(1) NMAC or 20.2.50.18.B(2) NMAC through use of a control device shall comply with the reporting requirements in 20.2.50.15 NMAC.

(2) Owners and operators shall comply with the reporting requirements in 20.2.50.12 NMAC.

20.2.50.19 STANDARDS FOR HEATERS

A. Applicability

(1) All new and existing natural gas-fired heater units with a rated heat input equal to or greater than 10 MMBtu/hr including, but not limited to, heater treaters, heated flash separator units, evaporator units, fractionation column heaters, and glycol dehydrator reboilers in use at wellhead sites, tank batteries, gathering and boosting sites, natural gas processing plants, and transmission compressor stations are subject to the requirements of 20.2.50.19 NMAC.

B. Emission Standards

(1) In order to ensure compliance with good combustion engineering practices, the owner or operator of a natural gas-fired heater units shall ensure compliance with the emission limits in Table 1 of 20.2.50.19 NMAC.

Table 1 - Emission Standards for NO_x and CO

Date of Construction:	NO_x (ppmvd @ 3% O_2)	CO (ppmvd @ 3% O_2)
Constructed or reconstructed before the effective date of 20.2.50 NMAC	30	300
Constructed or reconstructed on or after the effective date of 20.2.50 NMAC	30	130

DRAFT

(2) Natural gas-fired heater units constructed or reconstructed prior to the effective date of this Part shall come into compliance with the requirements of 20.2.50.19 NMAC beginning no later than one year after the effective date.
(3) Natural gas-fired heater units that are constructed or reconstructed on or after the effective date of this Part shall be in compliance with the requirements of this section upon startup.
(4) Owners and operators of a natural gas-fired heater unit shall install an Equipment Monitoring and Information Tracking Tag (EMITT) on each combustion unit in accordance with 20.2.50.12 NMAC.

C. Monitoring Requirements
(1) Owners and operators of natural gas-fired heater units with a rated heat input of greater than or equal to 10 MMBtu/hr shall:
(a) Conduct the monitoring for NOx and CO specified in paragraph C(2) of this section within 180 days of the compliance date specified in the relevant paragraph B(2) or B(3) of this section and every 2 years thereafter.
(b) inspect, maintain, and repair each combustion unit consistent with the manufacturers specifications at least once every 2 years following the compliance date specified in the relevant paragraph B(2) or B(3) of this section. The inspection, maintenance, and repair shall include, at a minimum:
(i) Inspecting the burner and cleaning or replacing any components of the burner as necessary;
(ii) Inspecting the flame pattern and adjusting the burner as necessary to optimize the flame pattern consistent with the manufacturer's specifications or good combustion engineering practices;
(iii) Inspecting the system air-to-fuel ratio controller and ensuring it is calibrated and functioning properly;
(iv) Optimizing total emissions of CO consistent with the NO_x requirement and the manufacturer's specifications or good combustion engineering practices; and
(v) Measuring the concentrations in the effluent stream of CO in ppmvd and O_2 in volume percent before and after adjustments are made in accordance with paragraph C(2)(a) of this section.
(2) Owners and operators of combustion units shall comply with the following combustion unit periodic monitoring requirements:
(a) Conduct three test runs of at least 20-minutes duration within 10% of 100% peak (or the highest achievable) load;
(b) Determine NO_X and CO emissions and O_2 concentrations in the exhaust with either an electro-chemical cell portable gas analyzer used and maintained in accordance with the manufacturer's specifications and following the procedures specified in the current version of ASTM D6522;
(c) If the measured NO_X or CO emissions concentrations are exceeding the emissions limits of Table 1 of this section, the owner or operator shall repeat the inspection and tune-up in paragraph C(1)(b) of this section within 180 days of the periodic monitoring; and

DRAFT

(d) If at any time the owner or operator operates the combustion unit in excess of the highest achievable load plus 10%, the owner or operator shall perform the monitoring specified in paragraph C(2)(a) within 180 days from the anomalous operation.

(3) When conducting periodic monitoring on a combustion unit, the owner or operator shall follow the procedures in paragraph C(2) of this section. If the owner or operator decides to deviate from those procedures, they must submit a request to use an alternative procedure, in writing, at least 60 days prior to performing the periodic monitoring. In the alternative procedure request, the owner or operator must demonstrate the alternative procedure's equivalence to the standard procedure to the satisfaction of the Department.

(4) The owner or operator of any combustion unit subject to periodic monitoring, inspections, and/or tune-up shall monitor, inspect, maintain, and repair as required under 20.2.50.19.C NMAC. Each monitoring, inspection, maintenance or repair event shall include the scanning of the EMITT and the simultaneous monitoring data entry in accordance with the requirements of 20.2.50.12 NMAC.

D. Recordkeeping Requirements

(1) For each combustion unit with a rated heat input of greater than or equal to 10 MMBtu/h, the owner or operator shall maintain the following records in accordance with 20.2.50.12 NMAC:

(a) The location of the combustion unit;

(b) Either the summary for each complete test report described in paragraph C(2) of this section, or the results of each periodic monitoring described in paragraph C(3) this section;

(c) The records of the inspection/maintenance/repair described in paragraph C(1)(c) of this section, which shall include at a minimum:

(i) The date the inspection/maintenance/repair was conducted;

(ii) The concentrations in the effluent stream of CO in ppmv and O_2 in volume percent as determined in paragraph C(2)(a) of this section; and

(iii) A description of any corrective actions taken as part of the inspection/maintenance/repair.

E. Reporting Requirements

Owners or operators shall comply with the reporting requirements in 20.2.50.12 NMAC.

20.2.50.20 STANDARDS FOR HYDROCARBON LIQUID TRANSFERS

A. Applicability

(1) All new and existing hydrocarbon liquid transfer operations located at wellheads, tank batteries, gathering and boosting sites, natural gas processing plants, and transmission compressor stations are subject to the requirements of 20.2.50.20 NMAC, beginning on the effective date of this Part.

DRAFT

B. Emission Standards

(1) Owners and operators of all existing and new liquid transfer operations subject to 20.2.50.20 NMAC shall use vapor balance, vapor recovery, or control VOC emissions by 98% or greater using vapor combustion when transferring liquids from storage tanks to transfer vessels, or when transferring liquids from transfer vessels to storage tanks.

(2) Owners and operators using vapor balance during liquid transfer operations shall:
(i) Transfer the vapors displaced from the vessel being loaded back to the vessel being emptied via pipes and/or hoses connected prior to the start of transfer operations;
(ii) Ensure that the transfer does not begin until the vapor collection and return system is connected;
(iii) Maintain connector pipes, hoses, couplers, valves, and pressure relief devices in a condition that prevents leaks;
(iv) Check all liquid and vapor line connections for proper connection prior to commencing transfer operations; and
(v) Operate all transfer equipment at a pressure that is less than the pressure relief valve setting of the receiving transport vehicle or storage tank.

(3) Bottom loading or submerged filling shall be used for all liquids transfers.

(4) Connector pipes and couplers shall be maintained in a condition that prevents leaks.

(5) All connections of hoses or piping used during liquid transfer operations shall be supported on a drip tray that collects any leaks, and any material collected shall be returned to the process or disposed of in a manner compliant with the state law.

(6) Any liquid leaks that occur shall be cleaned and disposed of in a manner that prevents emissions to the atmosphere, and any material collected shall be returned to the process or disposed of in a manner compliant with the state law.

(7) All owners and operators complying with the control requirements in 20.2.50.20.B(1) NMAC through use of a control device shall comply with the control device operational requirements in 20.2.50.15 NMAC.

C. Monitoring Requirements

(1) All transfer equipment must be visually inspected during transfer operations to ensure that liquid transfer lines, hoses, couplings, valves, and pipes are not dripping or leaking. All leaking components shall be repaired to prevent dripping or leaking before the next transfer operation.

(2) The owner or operator of any liquid transfer operations controlled by air pollution control equipment must follow manufacturer's recommended operation and maintenance procedures.

(3) All tanker trucks or tanker rail cars used in liquid transfer service shall be tested annually for vapor tightness in accordance with the following test methods and vapor tightness standards:

(i) Method 27, appendix A, 40 CFR Part 60. Conduct the test using a time period (t) for the pressure and vacuum tests of 5 minutes. The initial pressure (Pi) for the pressure test shall be 460 mm H_2O (18 in. H_2O), gauge. The initial vacuum (Vi) for the vacuum test shall be 150 mm H_2O

DRAFT

(6 in. H_2O), gauge. The maximum allowable pressure and vacuum changes (Δ p, Δ v) are as shown in Table 1 of this section.

Table 1 - Allowable Cargo Tank Test Pressure or Vacuum Change

Cargo tank or compartment capacity, liters (gal)	Allowable vacuum change (Δv) in 5 minutes, mm H_2O (in. H_2O)	Allowable pressure change (Δp) in 5 minutes, mm H_2O (in. H_2O)
less than 3,785 (less than 1,000)	64 (2.5)	102 (4.0)
3,785 to less than 5,678 (1,000 to less than 1,500)	51 (2.0)	89 (3.5)
5,678 less than 9,464 (1,500 to less than 2,500)	38 (1.5)	76 (3.0)
9,464 or more (2,500 or more)	25 (1.0)	64 (2.5)

(ii) Pressure test of the cargo tank's internal vapor valve as follows:
(*A*) After completing the tests under 20.2.50.20.C(3)(i) NMAC, use the procedures in Method 27 to repressurize the tank to 460 mm H_2O (18 in. H_2O), gauge. Close the tank's internal vapor valve(s), thereby isolating the vapor return line and manifold from the tank.
(*B*) Relieve the pressure in the vapor return line to atmospheric pressure, then reseal the line. After 5 minutes, record the gauge pressure in the vapor return line and manifold. The maximum allowable 5-minute pressure increase is 130 mm H_2O (5 in. H_2O).

(4) Owners or operators complying with the requirements in 20.2.50.20.B(1) NMAC through use of a control device shall comply with the monitoring requirements in 20.2.50.15 NMAC.
(5) Owners or operators shall comply with the monitoring requirements in 20.2.50.12 NMAC.

D. Recordkeeping Requirements
(1) For each liquid transfer operation, the owner or operator shall maintain records of:
(a) The tank's location and the tank's unique inventory control number or name and,
(b) The location, type, make, and model of any control equipment.
(2) Each owner or operator shall maintain records of the inspections required in 20.2.50.20.C NMAC. These records shall include the following:
(i) the time and date of the inspection;
(ii) the person conducting the inspection;
(iii) a notation that each of the checks required under 20.2.50.20.C NMAC were completed;
(iv) a description of any problems observed during the inspection; and
(v) a description and date of any repairs and corrective actions taken.
(3) Owners and operators shall create and maintain a calendar year record for each site summarizing, calculating, recording, and totaling the liquid loading operation

NMED Exhibit 12

liquids and associated VOC emissions. Each calendar year, the owners and operators shall create a company-wide record summarizing the liquid transfer total calculated emissions for the company.

(4) Owners and operators complying with the requirements in 20.2.50.20.B(1) NMAC through use of a control device shall comply with the recordkeeping requirements in 20.2.50.15 NMAC.

(5) Owners and operators shall comply with the recordkeeping requirements in 20.2.50.12 NMAC.

E. Reporting Requirements

(1) Owners and operators complying with the requirements in 20.2.50.20.B(1) NMAC through use of a control device shall comply with the reporting requirements in 20.2.50.15 NMAC.

(2) Owners and operators shall comply with the reporting requirements in 20.2.50.12 NMAC.

20.2.50.21 STANDARDS FOR PIG LAUNCHING AND RECEIVING

A. Applicability

(1) All new and existing pipeline pig launching and receiving operations located within the property boundary at wellhead sites, tank batteries, gathering and boosting sites, natural gas processing plants, and transmission compressor stations are subject to the requirements of 20.2.50.21 NMAC.

B. Emission Standards

(1) The owner or operator of new and existing pipeline pig launching and receiving operations with a potential to emit equal to or greater than 1.0 tpy of VOC shall capture and reduce VOC emissions by at least 98%, beginning on the effective date of this Part.

(2) The owner or operator conducting the pig launching and receiving operations shall:

(a) Employ best management practices to minimize the liquids present in the pig receiver chamber and to prevent emissions from the pig receiver chamber to the atmosphere after receiving the pig in the receiving chamber and prior to opening the receiving chamber to the atmosphere;

(b) Employ methods to prevent emissions including, but not limited to, installing liquids ramps, installing liquid drains, routing high-pressure chambers to a low-pressure line or vessel, using ball valve type chambers, or using multiple pig chambers;

(c) Recover and dispose of all receiver liquids in a manner that prevents emissions to the atmosphere; and

(d) Ensure that any material collected is returned to the process or disposed of in a manner compliant with the state law.

(3) Owners and operators of a pig launching and receiving operation shall install an Equipment Monitoring and Information Tracking Tag (EMITT) on each pig launcher and each pig receiver in accordance with 20.2.50.12 NMAC.

DRAFT

(4) Any existing pipeline pig launching and receiving operation subject to control requirements may become exempt from those requirements when its actual annual emissions of VOC decreases to an amount less than 0.5 tpy of VOC.
(5) Owners and operators complying with the control requirements in 20.2.50.21.B(2) NMAC through use of a control device shall comply with the control device operational requirements in 20.2.50.15 NMAC.

C. Monitoring Requirements
(1) The owner or operator of any pig launching and receiving equipment shall monitor the type and volume of liquids cleared.
(2) The owner or operator of any pig launching and receiving equipment subject to control requirements shall inspect the equipment for leaks using RM 21 or OGI with infrared cameras immediately prior to the commencement and immediately after the conclusion of each pig launching or receiving operation, and according to the requirements in 20.2.50.16 NMAC.
(3) Owners and operators complying with the requirements in 20.2.50.21.B(1) NMAC through use of a control device shall comply with the monitoring requirements in 20.2.50.15 NMAC.
(4) Owners and operators shall comply with the monitoring requirements in 20.2.50.12 NMAC.

D. Recordkeeping Requirements
(1) Owners and operators shall maintain the following records in accordance with 20.2.50.12.C NMAC for each pig launching and receiving operation or event:
(a) Records of each pigging operation including the date and time of the pigging operation, and the type and volume of liquids cleared;
(b) The data and methodology used to estimate the actual emissions to the atmosphere;
(c) The data and methodology used to estimate the potential to emit; and
(d) The type of control(s), location, make, model and, if applicable, the unique identification number of the control equipment.
(2) Owners and operators complying with the requirements in 20.2.50.21.B(1) NMAC through use of a control device shall comply with the recordkeeping requirements in 20.2.50.15 NMAC.
(3) Owners and operators shall comply with the recordkeeping requirements in 20.2.50.12 NMAC.

E. Reporting Requirements
(1) Owners and operators complying with the requirements in 20.2.50.21.B(1) NMAC through use of a control device shall comply with the reporting requirements in 20.2.50.15 NMAC.
(2) Owners and operators shall comply with the reporting requirements in 20.2.50.12 NMAC.

DRAFT

NMED Exhibit 12

20.2.50.22 STANDARDS FOR PNEUMATIC CONTROLLERS AND PUMPS

A. Applicability

(1) All new and existing natural gas-driven pneumatic controllers and pumps located at wellhead sites, tank batteries, gathering and boosting sites, natural gas processing plants, and transmission compressor stations are subject to the requirements of 20.2.50.22 NMAC.

B. Emission Standards

(1) Natural gas-driven pneumatic controllers and natural gas-driven pneumatic pumps constructed on or after the effective date of this Part shall comply with the requirements of 20.2.50.22 NMAC upon startup.

(2) Natural gas-driven pneumatic controllers and natural gas-driven pneumatic pumps constructed before the effective date of this Part shall comply with the requirements of 20.2.50.22 NMAC within one year of the effective date of this Part.

(3) Standards for natural gas-driven pneumatic controllers.

(a) Owners and operators of each pneumatic controller located at a natural gas processing plant shall ensure the pneumatic controller has a VOC emission rate of zero.

(b) Owners and operators of each pneumatic controller located at a wellhead site, tank battery, gathering and boosting site, or transmission compressor station with access to electrical power shall ensure the pneumatic controller has a VOC emission rate of zero.

(c) Owners and operators of each pneumatic controller located at a wellhead site, tank battery, gathering and boosting site, or transmission compressor station without access to electrical power shall ensure the pneumatic controller has a bleed rate of less than or equal to 6 standard cubic feet per hour.

(d) Pneumatic controllers with a bleed rate greater than 6 standard cubic feet per hour are permitted where the owner or operator has demonstrated that a higher bleed rate is required based on functional needs, including but not limited to response time, safety, and positive actuation.

(4) Standards for natural gas-driven pneumatic pumps.

(a) Owners and operators of each pneumatic pump located at a natural gas processing plant shall ensure the pneumatic pump has a VOC emission rate of zero.

(b) Owners and operators of each pneumatic pump located at a wellhead site, tank battery, gathering and boosting site, or transmission compressor station with access to electrical power shall ensure the pump has a VOC emission rate of zero.

(c) Owners and operators of each pneumatic pump located at a wellhead site, tank battery, gathering and boosting site, or transmission compressor station without access to electrical power shall reduce VOC emissions from the pneumatic pump by 95% if it is technically feasible to route emissions to a control device, fuel cell, or process.

(d) If there is a control device available onsite, but it is unable to achieve a 95%

DRAFT

emission reduction, and it is not technically feasible to route the pneumatic pump emissions to a fuel cell or process this section, the owner or operator shall route the pneumatic pump emissions to this control device.

C. Monitoring Requirements

(1) Owners and operators of pneumatic controllers or pumps with a natural gas bleed rate equal to zero are not subject to the requirements of this section.

(2) Owners and operators of pneumatic controllers with a natural gas bleed rate greater than zero shall on a monthly basis scan each controller and, considering the EMITT specified design continuous or intermittent bleed rate, conduct an audible, visual, and olfactory (AVO) inspection and shall also inspect each pneumatic controller, perform necessary maintenance (such as cleaning, tuning, and repairing leaking gaskets, tubing fittings, and seals; tuning to operate over a broader range of proportional band; eliminating unnecessary valve positioners), and maintain the pneumatic controller according to manufacturer specifications to ensure that the controller's natural gas emissions are minimized.

(3) Each EMITT shall be linked to a database allowing the state inspectors to, at a minimum, identify:

(a) unique pneumatic controller and pneumatic pump identification number;
(b) type of controller (continuous or intermittent);
(c) if continuous, design continuous bleed rate in standard cubic feet per hour;
(d) if intermittent, bleed volume per intermittent bleed in standard cubic feet; and
(e) design annual bleed in standard cubic feet per year.

(4) Owners and operators of natural gas-driven a pneumatic pump with a natural gas bleed rate greater than zero shall on a monthly basis scan each pump or actuator and, considering the EMITT specified design pump rate or actuation volume, conduct an audible, visual, and olfactory (AVO) inspection and shall also inspect the pneumatic pump and perform necessary maintenance, and maintain the pneumatic pump according to manufacturer specifications to ensure that the pump's natural gas emissions are minimized.

(5) Owners and operators shall comply with the monitoring requirements in 20.2.50.12 NMAC.

D. Recordkeeping Requirements

(1) Owners and operators of pneumatic controllers, pumps with a natural gas bleed rate equal to zero are not subject to the requirements of this section.

(2) Owners and operators shall maintain an electronic pneumatic controller inspection log for each pneumatic controller with a natural gas bleed rate greater than zero at each facility, including for each inspection:

(a) Unique pneumatic controller ID number;
(b) EMITT scanned inspection dates;
(c) Name of the inspector;
(d) AVO inspection results;
(e) Any AVO level discrepancy in continuous or intermittent bleed rate;
(f) Maintenance dates; and
(g) Maintenance activities.

DRAFT

(3) Owners and operators who determine that the use of a natural gas-driven pneumatic controller with a bleed rate greater than 6 standard cubic feet per hour is required shall maintain a record in the EMITT database of each such pneumatic controller documenting why a bleed rate greater than 6 standard cubic feet per hour is required per the requirements in 20.2.50.22.B NMAC.

(4) Owners and operators shall maintain records in the EMITT database of natural gas-driven pneumatic pumps with an emission rate greater than zero and their associated pump numbers at each facility, including:

(a) For natural gas-driven pneumatic pumps in operation less than 90 days per calendar year, records of the days of operation each calendar year.

(b) Records of control devices designed to achieve less than 95% emission reduction, including an evaluation or manufacturer specifications indicating the percentage reduction the control device is designed to achieve.

(c) Records of the engineering assessment and certification by a qualified professional engineer that routing pneumatic pump emissions to a control device, fuel cell, or process is technically infeasible.

(5) Owners and operators shall comply with the recordkeeping requirements in 20.2.50.12 NMAC.

E. Reporting Requirements.

Owners and operators shall comply with the reporting requirements in 20.2.50.12 NMAC.

20.2.50.23 STANDARDS FOR STORAGE TANKS

A. Applicability

(1) All new and existing hydrocarbon storage tanks with an uncontrolled potential to emit equal to or greater than 2 tpy of VOC and located at wellhead sites, tank batteries, gathering and boosting sites, natural gas processing plants, and transmission compressor stations are subject to regulation under 20.2.50.23 NMAC.

B. Emission Standards

(1) All existing storage tanks with a potential to emit equal to or greater than 2 tpy and less than 10 tpy of VOC shall have a combined capture and control of VOC emissions by at least 95 percent no later than one year after the effective date of this Part.

(2) All existing storage tanks with a potential to emit equal to or greater than 10 tpy of VOC shall have a combined capture and control of VOC emissions by at least 98 percent, no later than one year after the effective date of this Part.

(3) All new storage tanks constructed after the effective date of this part with a potential to emit equal to or greater than 2 tpy and less than 10 tpy of VOC shall have a combined capture and control of VOC emissions by at least 95 percent upon startup.

(4) All new storage tanks constructed after the effective date of this Part with a

DRAFT

potential to emit equal to or greater than 10 tpy of VOC shall have a combined capture and control and control of VOC emissions by at least 98 percent upon startup.

(5) Any new or existing storage tank subject to control requirements under 20.2.50.23 NMAC becomes exempt from those requirements when its uncontrolled actual annual VOC emissions decreases to less than 2 tpy.

(6) If air pollution control equipment is not installed by the applicable date specified in 20.2.50.23.B(1) through 20.2.50.23.B(4) NMAC, compliance with 20.2.50.23.B(1) through 20.2.50.23.B(4) NMAC may be demonstrated by shutting in all wells producing into that storage tank by that applicable date and so long as production does not resume from any such well until the air pollution control equipment is installed and operational.

(7) Owners and operators of an existing or new tank with a thief hatch shall install a control device on the thief hatch which allows the thief hatch to open sufficiently to relieve overpressure in the tank and to automatically close once the tank overpressure is relieved. The thief hatch shall be equipped with a manual lock-open safety device to ensure positive hatch opening during times of human ingress. The lock-open safety device will only be engaged during in the presence of owner or operator staff and during active ingress activities.

(8) Owners and operators of a new or existing hydrocarbon storage tank(s) shall install an Equipment Monitoring and Information Tracking Tag (EMITT) on each storage tank in accordance with 20.2.50.12 NMAC.

(9) Owners and operators complying with the control requirements in 20.2.50.23.B(1) NMAC through 20.2.50.23.B(4) NMAC through use of a control device shall comply with the control device operational requirements in 20.2.50.15 NMAC.

(10) After the compliance deadlines established in the rule, it is a violation to operate any tank not complying with the requirements of this section.

C. Monitoring Requirements

(1) The owner or operator of any storage tank subject to control requirements shall monitor the total monthly liquid throughput (barrels) and the upstream separator pressure (psig) on a monthly basis. Any time the storage tank is unloaded less frequently than monthly, the throughput and separator pressure monitoring shall be conducted prior to the storage tank being unloaded.

(2) The owner or operator of any storage tank subject to control requirements shall conduct an auditory, visual, and olfactory (AVO) inspection on a weekly basis. Any time the storage tank is unloaded less frequently than weekly, the AVO inspections shall be conducted prior to the storage tank being unloaded.

(3) The owner or operator of any storage tank subject to control requirements shall inspect the tanks monthly to ensure compliance with the requirements of 20.2.50.23 NMAC. Inspections shall include a check to ensure the tanks have no leaks, that all hatches are closed, the pressure relief valves are properly seated, and all vent lines are closed.

(4) Each monitoring or inspection shall include the scanning of the EMITT and the simultaneous entry of the required monitoring data in accordance with the requirements of 20.2.50.12 NMAC.

DRAFT

(5) Owners and operators complying with the requirements in 20.2.50.23.B(1) NMAC through 20.2.50.23.B(4) NMAC through use of a control device shall comply with the monitoring requirements in 20.2.50.15 NMAC.
(6) Owners and operators shall comply with the monitoring requirements in 20.2.50.12 NMAC.

D. Recordkeeping Requirements
(1) Owners and operators subject to control requirements under 20.2.50.23 NMAC shall, on a monthly basis, maintain records in accordance with 20.2.50.12 NMAC for each storage tank of:
(a) The tank's location and unique inventory control number or name;
(b) Monthly liquid throughput and the most recent date of measurement;
(c) The average monthly upstream separator pressure;
(d) The data and methodology used to calculate the potential to emit of VOC (the calculation methodology must be a Department approved methodology);
(e) The controlled and uncontrolled VOC emissions (tpy); and
(f) The location, type, make, model and unique identification number of any control equipment.
(2) Records of liquid throughput required in 20.2.50.23.D(1) NMAC shall be verified by dated delivery receipts from the purchaser of the hydrocarbon liquids, or metered volumes of hydrocarbon liquids sent downstream, or other proof of transfer.
(3) Records of the inspections required in 20.2.50.23.C NMAC shall include the time and date of the inspection, the person conducting the inspection, a notation that each check required under 20.2.50.23.C NMAC was completed, a description of any problems observed during the inspection, and a description and date of any corrective actions taken in accordance with 20.2.50.12 NMAC.
(4) Owners and operators complying with the requirements in 20.2.50.23.B(1) NMAC through 20.2.50.23.B(4) NMAC through use of a control device shall comply with the recordkeeping requirements in 20.2.50.15 NMAC.
(5) Owners and operators shall comply with the recordkeeping requirements in 20.2.50.12 NMAC.

E. Reporting Requirements.
(1) Owners and operators complying with the requirements in 20.2.50.23.B(1) NMAC through 20.2.50.23.B(4) NMAC through use of a control device shall comply with the reporting requirements in 20.2.50.15 NMAC.
(2) Owners and operators shall comply with the reporting requirements in 20.2.50.12 NMAC.

20.2.50.24 STANDARDS FOR WORKOVERS

A. Applicability
(1) All workovers performed at oil and natural gas wells are subject to the requirements of 20.2.50.24 NMAC for any workovers performed after the effective date of this Part.

DRAFT

B. Emission Standards
   (1) Owners and operators of oil or natural gas wells shall use the following best management practices during workovers to minimize emissions, consistent with well site conditions and good engineering practices:
      (a) Reduce wellhead pressure prior to blowdown to minimize the volume of natural gas vented;
      (b) Monitor manual venting in close proximity to the well or via remote telemetry; and
      (c) Route natural gas flow to the sales line, if possible.

C. Monitoring Requirements
   (1) Owners and operators subject to 20.2.50.24 NMAC shall monitor the following parameters during workovers:
      (a) Wellhead pressure;
      (b) Flow rate of the vented natural gas (to the extent feasible); and
      (c) Duration of venting to the atmosphere.
   (2) Owners and operators shall calculate the volume and mass of VOC vented during each workover.
   (3) Owners and operators shall comply with the monitoring requirements in 20.2.50.12 NMAC.

D. Recordkeeping Requirements
   (1) Owners and operators subject to 20.2.50.24 NMAC shall keep the following records for each workover:
      (a) The identification number and location of the well;
      (b) The date(s) the workover was performed;
      (c) Wellhead pressure;
      (d) Flow rate of the vented natural gas (to the extent feasible. If measurement of the flow rate is not feasible, the owner or operator shall use the maximum potential flow rate in the emission calculation);
      (e) Duration of venting to the atmosphere;
      (f) A description of the management practices used to minimize release of VOC prior to and during the workover; and
      (g) A calculation of the VOC emissions vented during the workover based on the duration, volume, and mass of VOC.
   (2) Owners and operators shall comply with the recordkeeping requirements in 20.2.50.12 NMAC.

E. Reporting Requirements
   (1) Owners and operators shall comply with the reporting requirements in 20.2.50.12 NMAC.
   (2) If it is not feasible to prevent VOC emissions from being emitted to the atmosphere from any workover event, the owner or operator shall notify all residents by certified mail located within 0.25 miles of the well of the planned workover at least three (3) calendar days prior to the workover event.

DRAFT

20.2.50.25 STANDARDS FOR OIL AND NATURAL GAS STRIPPER WELLS AND FACILITIES WITH SITE-WIDE VOC POTENTIAL TO EMIT LESS THAN 15 TPY

A. Applicability
   (1) Stripper wells, defined as any oil and natural gas well producing less than 10 barrels of oil per day or less than 60 thousand standard cubic feet of natural gas per day, are subject to the requirements of 20.2.50.25 NMAC.
   (2) Owners or operators of stripper wells shall comply with these requirements no later than one year after the effective date of this Part.
   (3) Facilities with a site-wide annual PTE of less than 15 tons per year of VOC are subject to the requirements of 20.2.50.25 NMAC.
   (4) Owners or operators of facilities with a site-wide annual PTE of less than 15 tons per year of VOC shall comply with these requirements no later than one year after the effective date of this Part.
   (5) If at any time a facility identified in 20.2.50.25.A(1) or (3) NMAC exceeds the daily production limit or PTE threshold of 15 tpy of VOC, the owner or operator shall conduct semi-annual LDAR monitoring as required by 20.2.50.16.C(2)(b) NMAC for a period of two years.

B. Emission Standards
   (1) Owners or operators shall ensure that all equipment located at a stripper well or low-PTE facility shall be operated and maintained consistent with manufacturer specifications and good engineering and maintenance practices. The owner or operator shall keep manufacturer specifications and maintenance practices on file and make them available upon request by the Department.
   (2) Owners or operators of an oil or natural gas stripper well or individual facility with a site-wide PTE less than 15 tpy of VOC shall, within the first calendar quarter of the year, use actual production volumes to calculate the VOC and NOx emissions from the stripper well site.
   (3) Owners or operators of an oil or natural gas stripper well(s) or facility(s) with a site-wide PTE less than 15 tpy of VOC shall maintain a database of company-wide calculated VOC and NOx emissions estimates for each site and must update the database annually.

C. Monitoring Requirements
   (1) Owners or operators complying with 20.2.50.25 NMAC shall monitor the following for each stripper well or facility with a site-wide PTE of VOC less than 15 tpy:
      (a) the unique identifier of the stripper well or facility (number and name, as applicable);
      (b) the UTM coordinates of the stripper well or facility and its county of location;
      (c) the annual total well production rate in barrels of oil per year and natural gas production in thousand standard cubic feet per year; and
      (d) Dates, duration, and VOC emission estimates of any venting or flaring event longer than eight (8) hours.

DRAFT

(2) Owners or operators shall comply with the monitoring requirements in 20.2.50.12 NMAC.

D. Recordkeeping Requirements

(1) Owners or operators complying with 20.2.50.25 NMAC shall:

(a) maintain electronic records of the following for each stripper well and low-PTE facility:

(i) the unique identifier of the stripper well and low-PTE facility (number and name, as applicable);

(ii) the UTM coordinates of the stripper well and low-PTE facility and its county of location;

(iii) the total annual well production in barrels of oil per year and natural gas production in thousand standard cubic feet; and

(iv) Dates, duration, and VOC emission calculation of any venting or flaring event lasting longer than eight (8) hours, and the cause of the event.

(2) Within the first calendar quarter of the year, record the calculated total annual emissions of VOC and NOx from each stripper well site and low-PTE facility in tons, and the company-wide total VOC and NOx emissions from stripper wells and low-PTE facilities in tons. All venting and flaring emissions shall be included in the calculated total annual emissions.

(3) Within the first calendar quarter of the year, provide a description of the management practices used to minimize and prevent the release of VOC and NOx at each stripper well and low-PTE facility.

(4) Owners or operators shall comply with the recordkeeping requirements in 20.2.50.12 NMAC.

E. Reporting Requirements

Owners or operators shall comply with the reporting requirements in 20.2.50.12 NMAC.

20.2.50.26 STANDARDS FOR EVAPORATION PONDS

A. Applicability

(1) All new and existing oil and natural gas evaporation ponds with pond capacity equal to or greater than [TBD barrels] or a potential to emit greater than [10 lbs/day VOC] and located at wellhead sites, tank batteries, gathering and boosting sites, natural gas processing plants, transmission compressor stations, or not associated with a facility but located in San Juan, Lea, Eddy, Rio Arriba, Sandoval counties are subject to the requirements of 20.2.50.26 NMAC.

(2) Owners or operators of oil and natural gas evaporation ponds shall comply with these requirements no later than 180 days after the effective date of this Part.

B. Emission Standards

(1) Owners or operators of an oil or natural gas evaporation pond shall use best management practices to minimize emissions of VOC, consistent with good engineering practices.

DRAFT

(2) Prior to unloading into a pond(s), all liquids shall be first loaded into a 20.2.50.23 NMAC compliant liquid storage tank designed to minimize subsequent VOC emissions from the pond.
(3) Owners or operators shall install an impermeable continuous barrier or cover over the entire surface area of the liquid, which prevents VOC emissions from being emitted to the atmosphere. Owners and operators shall ensure that VOC emissions are collected and routed to a control device for destruction.

C. Monitoring Requirements
(1) For each oil or natural gas evaporation pond, the owners or operators subject to 20.2.50.26 NMAC shall:
(a) on a monthly basis, perform an inspection to ensure that the barrier is an impermeable continuous barrier or cover that covers the entire surface area of liquid;
(b) on a monthly basis, ensure that all VOC emissions are being captured and routed to a control device; and
(c) monitor the monthly total and annual total oil and natural gas evaporation pond throughput in thousands of gallons of liquids.
(2) Owners or operators shall comply with the monitoring requirements in 20.2.50.12 NMAC.

D. Recordkeeping Requirements
(1) Owners or operators subject to 20.2.50.26 NMAC shall maintain electronic records of the following for each evaporation pond:
(a) the unique identifier of the evaporation pond (number and name, as applicable);
(b) the UTM coordinates of the evaporation pond site and its county of location;
(c) the results of the barrier or cover inspection, including the date, time, and name of the personnel performing the inspection;
(d) the results of the VOC capture and control device inspection, including the date, time, and name of the personnel performing the inspection; and
(e) the total calculated VOC emissions in tons per year.
(2) Owners or operators of an oil or natural gas evaporation pond shall, within the first calendar quarter of the year, record the calculated emission estimates of VOC from the evaporation pond in tons per year.
(3) Owners or operators of an oil or natural gas evaporation pond shall record a description of the management practices used to minimize release of VOC at the evaporation pond, and the company-wide total VOC emissions from evaporation ponds in tons per year.
(4) Owners or operators of an oil or natural gas evaporation pond shall, within the first calendar quarter of the year, use actual volumes of liquid loaded into each site's pond(s) to calculate total site-wide VOC emissions from all evaporation ponds.
(5) Owners or operators of an oil or natural gas evaporation pond(s) shall maintain a database of company-wide calculated annual total VOC emissions estimates in tons per year from each pond.

DRAFT

(6) Owners or operators shall comply with the recordkeeping requirements in 20.2.50.12 NMAC.

E. Reporting Requirements

Owners or operators shall comply with the reporting requirements in 20.2.50.12 NMAC.

20.2.50.27 PROHIBITED ACTIVITIES AND CREDIBLE INFORMATION PRESUMPTIONS

A. Failure to comply with any of the emissions standards, recordkeeping, reporting, or other requirements of this Part within the timeframes specified shall constitute a violation of this Part subject to enforcement action under Section 74-2-12 of the Act.

B. If credible information obtained by the Department indicates that a source is not in compliance with any provision of this Part, the source shall be presumed to be in violation of this Part unless and until the owner or operator provides credible evidence or information demonstrating otherwise.

C. If credible information provided to the Department by a member of the public indicates that a source is not in compliance with any provision of this Part, the source shall be presumed to be in violation of this Part unless and until the owner or operator provides credible evidence or information demonstrating otherwise.

DRAFT

STATE OF NEW MEXICO
ENVIRONMENTAL IMPROVEMENT BOARD

IN THE MATTER OF PROPOSED NEW REGULATION,
20.2.50 NMAC – *Oil and Gas Sector – Ozone Precursor Pollutants* **No. EIB 21-27 (R)**

DIRECT TESTIMONY OF ANGELA RASO

My name is Angel Raso, and I am a dispersion modeler for the New Mexico Environment Department's ("Department" or "NMED") Air Quality Bureau ("Bureau"). I am presenting this written testimony on behalf of the Department in this proceeding on proposed new air quality regulations at 20.2.50 NMAC ("Part 50"). My testimony will address the chemistry of ozone in the atmosphere, and NMED's review of the photochemical modeling performed by Ramboll for this rulemaking.

I. QUALIFICATIONS

I have been a dispersion modeler for the Bureau for 3 years. As a dispersion modeler, I routinely evaluate the air quality impacts of complex facilities. I hold a PhD in chemistry from Purdue University, and a BA in chemistry from Whitman College. My PhD research focused on the chemistry and interactions of ozone in the atmospheric boundary layer.

My full background and qualifications are set forth in my resume, which is marked as NMED Exhibit 14.

II. TROPOSPHERIC OZONE FORMATION

Dry air in the atmosphere is composed of 78.08% molecular nitrogen (N_2), 20.95% molecular oxygen (O_2), 0.93% Argon, and 0.04% other trace gases by volume. In many respects the most important trace gas in the atmosphere is ozone. The impacts of ozone depend on where in the atmosphere it exists. In the upper atmosphere, stratospheric ozone absorbs biologically

harmful solar ultraviolet light, protecting living organisms. At the surface, high ozone concentrations can be detrimental to human and plant health.

Rather than being directly emitted by sources ozone is produced by a set of chemical reactions between Nitrous Oxides (NO_x) and Volatile Organic Compounds (VOCs). Therefore, reductions in ozone concentration must be achieved through regulation of these precursor pollutants. Nitric Oxide (NO) is formed when N_2 and O_2 combine under high heat. This occurs both naturally (such as during lightning strikes), and due to human (anthropogenic) activities, such as fossil fuel combustion. More than 90% of the NO released to the atmosphere is anthropogenic [EPA 456/F-99-006R, 1999]. In the presence of ozone (O_3) and sunlight, NO and NO_2 are rapidly interconverted. The sum of NO and NO_2 are referred to as NO_x. VOCs are a subset of hydrocarbons that are volatile enough to evaporate and enter the atmosphere to undergo photochemical (light dependent) chemical reactions. Most VOCs in the atmosphere are emitted by plant life. In some areas with large anthropogenic emissions, such as densely populated cities, VOC emissions from anthropogenic activities can be nearly equal to emissions from plants.

In the presence of sunlight, NOx and VOCs react to form ozone. This cycle of radical photochemical (involving light) reactions begins with ozone separating (undergoing photolysis) to form a hydroxyl radical (OH). Hydroxyl radicals rapidly oxidize VOCs (shown in the reactions below as hydrocarbons, RH). Oxidation of VOCs in the atmosphere causes them to become more water soluble, and ultimately facilitates the removal of VOCs from the atmosphere. However, in the presence of NO, each oxidized VOC produces two O_3 molecules without the net removal of NO_x from the atmosphere.

$$OH^{\cdot} + RH + O_2 \rightarrow H_2O + RO_2^{\cdot}$$

$$RO_2^{\cdot} + NO^{\cdot} \rightarrow NO_2^{\cdot} + RO^{\cdot}$$

$$RO^{\cdot} + O_2 \rightarrow HO_2^{\cdot} + carbonyl\ compound$$

$$HO_2^{\cdot} + NO^{\cdot} \rightarrow NO_2^{\cdot} + OH^{\cdot}$$

$$2NO_2^{\cdot} + 2O_2 + light \rightarrow 2NO^{\cdot} + 2O_3$$

$$NET: RH + 4O_2 + light \rightarrow H_2O + carbonyl\ compound + 2O_3$$

The formation of OH and subsequent oxidation reactions to form O_3 are highly dependent on light and temperature. The dependence of these reactions on light and heat leads to the largest O_3 concentrations occurring on warm, sunny days during the summer.

Ozone has been regulated in the U.S. as a pollutant since the establishment of the National Ambient Air Quality Standards ("NAAQS") under the Clean Air Act in 1971. Since 1979, the U.S. Environmental Protection Agency ("EPA") has been incrementally decreasing the ozone NAAQS as more evidence emerges on the public health and environmental consequences of ozone. Most recently, EPA decreased the ozone NAAQS from 0.75 ppm (parts per million) to 0.70 ppm in 2015. Regulation has successfully reduced mean ozone concentrations in the U.S. by 33% since 1980, as shown in Figure 1.

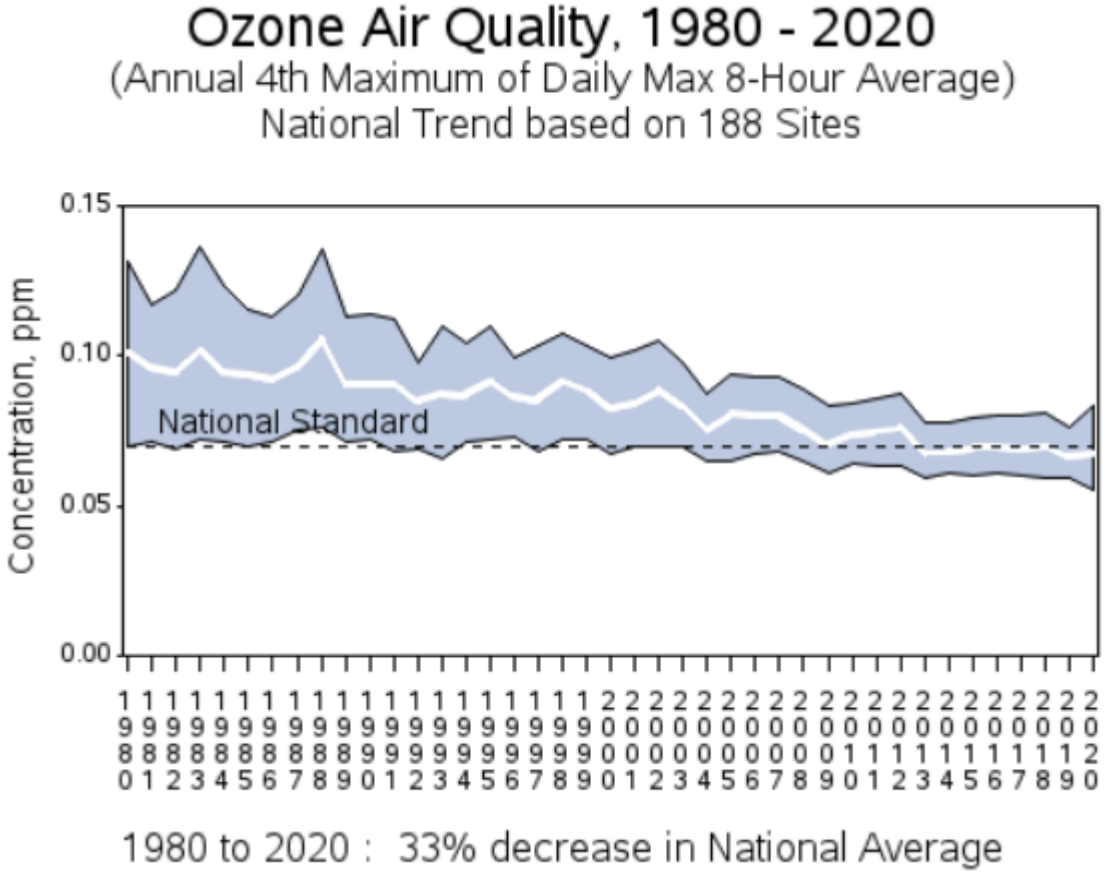

Figure 1: Mean (white line) and 10%-90% ozone daily values nationally for the U.S. from 1980-2020.[1]

The photochemical cycle that leads to the formation of ozone is comprised of a complex series of emissions, chemical reactions, and physical processes and is dependent on the time of day, sunlight, temperature, and other meteorological conditions. Understanding the potential reductions in ozone concentrations from reductions in emissions of anthropogenic precursors requires an integrated assessment of these factors. In order to conduct this assessment, a photochemical model is utilized. Testimony on the photochemical modeling performed for this rulemaking will be presented by Ralph Morris of Ramboll.

IV. NMED REVIEW OF RAMBOLL PHOTOCHEMICAL MODELING

On behalf of the Bureau, I reviewed the photochemical work products that were produced by Ramboll. A table of photochemical modeling products produced by Ramboll and reviewed by the Bureau is included below.

Product	Topics
NMED Exhibit 15 - Photochemical Modeling Protocol	Planning and Communication Document Describing Proposed Modeling Strategy
NMED Exhibit 16 - 2014 Modeling Platform Development and Model Evaluation	Work Product Document Describing Development of the Base Case Modeling and Evaluation of Modeling Performance
NMED Exhibit 17 - Air Quality Technical Support Document	Work Product Document Containing Technical Specifications of Modeling Performed
NMED Exhibit 18 - New Mexico OAI Study Photochemical First Monthly Webinar May 2020	• Existing Meteorological Modeling • Evaluation of Boundary Conditions • Modeling Protocol Overview • 2014 and Future Year Emissions
NMED Exhibit 19 - New Mexico OAI Study Photochemical Monthly Webinar June 2020	• 2014 and Future Year Emissions • Meteorological Modeling
NMED Exhibit 20 - 2014 and 2023 Emissions, CAMx WRF Sensitivity Tests and Final Model Configuration	• 2014 and Future Year Emissions, Quality Assurance and Processing • Photochemical Modeling, Sensitivity Tests, and Base Case Configuration
NMED Exhibit 21 - Emissions, CAMx, Base and Model Performance, 2023 CAMx Model Status	• 2014 and Future Year Emissions, Natural Sources and Processing • Photochemical Modeling, Base Case Configuration and Model Performance Evaluation
NMED Exhibit 22 - 2014 and 2028 Emissions Development	• Development of 2014 and Future Year Emissions Sources • Processing of Emissions for Modeling
NMED Exhibit 23 - Revised 2014v2 Base Case, 2028 Base Case	• 2014 Modeling • Future Year (2028) Base Case Modeling • Future Year (2028) Control Strategy Modeling

Modeling and 2028 NM O&G Control Strategy (Feb 2021)	• Design of Source Apportionment Modeling
NMED Exhibit 24 - Sensitivity of 2028 Ozone Projections to Current Year Ozone, Draft TSD	• Summary of Future Year (2028) modeling Design Value Projections • Sensitivity of Future Year Design Values to Current Year Design Values • Status of Ozone Source Apportionment Modeling
NMED Exhibit 25 - 2028 Source Sector APCA Ozone Source Apportionment Modeling, Revised Draft TSD (April 2021)	• Summary of Future Year Design Value Projections and Sensitivity • Future Year Source Sector Apportionment Modeling Results (APCA Modeling) • Status of Source Apportionment Results for VOC/NOx Sensitivity (OSAT Modeling)
NMED Exhibit 26 - 2028 VOC and NOx Sensitivity OSAT Ozone Source Apportionment Modeling and Draft Final TSD (April 2021)	• Overview of OSAT Modeling for VOC/NOx Sensitivity • Summary of Source Sector Apportionment Modeling (APCA modeling) • Future Year (2028) VOC/NOx Sensitivity OSAT Ozone Source Apportionment Modeling Results

A full discussion of the modeling and the deliverables produced by Ramboll is provided in the testimony of NMED witness Ralph Morris.

Santa Fe, New Mexico

Angela R. W. Raso

(505)476-4345
Angela.Raso@state.nm.us

Education

Purdue University, West Lafayette, IN **December 2018**
Doctor of Philosophy, Analytical chemistry
Dissertation: "Halogen Photochemistry and Emissions from the Arctic Snowpack"
Advisor Dr. Paul B. Shepson, Dr. Kerri A. Pratt (University of Michigan)

Whitman College, Walla Walla, WA **May 2012**
Bachelor of Arts, Chemistry. Mathematics minor.
Undergraduate Thesis: "Determining the Presence of Dense Non-Aqueous Phase Liquid (DNAPL) Pollutants in River Sediments"
Advisor Dr. Frank M. Dunnivant

Professional Experience

Dispersion Modeler, New Mexico Environment Department, Air Quality Bureau September 2018 - Present

- Evaluate facilities emissions for compliance with Ambient Air Quality Standards using dispersion models
- Assist with data analysis and evaluation related to emissions inventories
- Assist with special projects involving modeling and emissions inventories including; preparation for photochemical modeling, modeling for state implementation plans

Research Experience

Research Assistant, Purdue University **Fall 2012 – August 2018**

- Lead field work based research on gas phase oxidation processes in the Arctic to understand a complex environmental system
- Collaboratively design and perform atmospheric chemistry experiments in the Arctic including eddy covariance flux measurements
- Full process responsibility for analytical measurements in a remote Arctic environment
- Coordinate logistical needs to ensure successful Arctic fieldwork in Barrow, Alaska
- Manage instrumentation including a homebuilt chemical ionization mass spectrometer, and an ion chromatography / liquid chromatography system
- Mentor and train students to safely and effectively use instrumentation
- Conduct zero- and one- dimensional photochemical modeling to understand and contextualize the importance of measurements

Visiting Research Assistant, University of Michigan **Fall & Winter 2015**

- Collaboratively planned for a spring 2016 field study in Barrow, Alaska

User, Environmental Molecular Sciences Laboratory, **October 2015**
Pacific Northwest National Laboratory

- Acquired first ever measurements of iodide in Arctic snow using ion chromatography coupled with inductively coupled plasma mass spectrometry (IC-ICPMS)

Undergraduate Research Assistant, Whitman College **Fall 2010 –Spring 2012**

- Conducted research on dense non-aqueous phase liquids in mixed stream-bed media for detection at highly polluted sites using gas chromatography – electron capture detection

Teaching Experience

General Chemistry Adjunct, Santa Fe Community College **Spring & Fall 2019**

- Instructed General Chemistry Laboratories

Analytical Chemistry TA, Purdue Chemistry Department **Fall 2013**

- Instructed laboratory sessions for upper division chemistry students in a major required course

- Wrote and graded exam questions and graded written lab reports, giving important feedback to students

Fundamental General Chemistry TA, Purdue Chemistry Department **Spring 2013**

- Instructed laboratory and recitation for students with no previous chemistry courses to give a gentle introduction to important laboratory and scientific skills

General Chemistry for Engineers TA, Purdue Chemistry Department **Fall 2012**

- Instructed laboratory and recitation sessions to introduce freshman engineers and scientists to college level science courses.

Chemistry Tutor, Whitman Chemistry Department **2010 -2012**

- Demonstrated concepts and problem solving techniques for students from general, organic and analytical chemistry classes in an open "drop in" environment using a variety of teaching methods

Organic Chemistry Laboratory Assistant, Whitman Chemistry Department **Fall 2011**

- Supported students in an organic chemistry laboratory to ensure safe, time effective, and comprehensive completion of experiments

Quantitative Analysis Lab. Assistant, Whitman Chemistry Department **Fall 2011**

- Supported students in a data rich laboratory to introduce analytical methods to chemistry majors
- Corrected spreadsheet style lab reports to give important feedback to students

Tutor, Whitman College Academic Resource Center **2010-2012**

- Tutored general chemistry, organic chemistry, calculus I, calculus II and differential equations to support student understanding and grades

1. INTRODUCTION

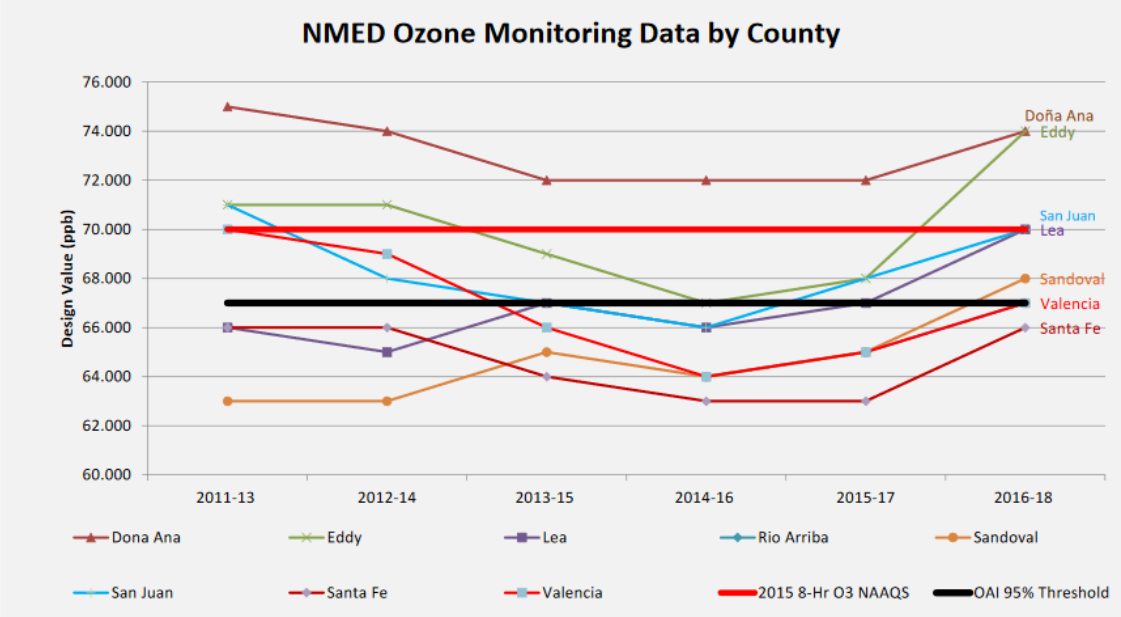
This document is a Modeling Protocol and an informal Quality Assurance Project Plan (QAPP) for the New Mexico (NM) Ozone Attainment Initiative (OAI) Photochemical Modeling Study ("NM OAI Study"). The New Mexico Environmental Division (NMED) has contracted with a team consisting of Western States Air Resources Council (WESTAR) and Ramboll US Corporation to conduct the NM OAI Study. The NM OAI Study leverages the 2014 photochemical grid model (PGM) modeling platform developed by the Western Regional Air Partnership (WRAP) in the Western Air Quality Study (WAQS) and enhances it by adding a 4-km grid resolution modeling domain over New Mexico. 2023 future year modeling, source apportionment and control measure evaluation will be performed to assist the NMED in ozone air quality planning for the state.

1.1 NM OAI Project Genesis

The NMED Air Quality Bureau has authority over air quality management activities throughout the state of New Mexico, with the exception Bernalillo County and Tribal Lands. The City of Albuquerque/Air Quality Division has authority in Bernalillo County and, except for where Tribal Implementation Plans have been approved, EPA oversees air quality issues in Tribal Lands. The New Mexico Air Quality Control Act (NMAQCA) requires the NMED to develop a plan to address elevated ozone levels when air quality is within 95% of the ozone NAAQS (74-3-5.3, NMSA 1978[1]). The ozone NAAQS was revised in 2015 with a threshold of 0.070 ppm (70 ppb) with the relevant metric being the ozone Design Value (DV) that is expressed as the three-year average of the fourth highest Daily Maximum Average 8-hour (DMAX8) ozone concentrations. Figure 1-1 displays the trends in observed ozone DVs at 8 New Mexico monitoring sites from 2013 to 2018 and compares them with the 70 ppb 2015 ozone NAAQS (red line) and 95% of the 70 ppb NAAQS (i.e., ≥ 67 ppb; black line). This results in 7[2] counties in New Mexico under NMED jurisdiction with measured 2016-2018 ozone DVs at or exceeding 95% of the 70 ppb ozone NAAQS, as shown in Figure 1-1.

[1] https://law.justia.com/codes/new-mexico/2017/chapter-74/article-2/section-74-2-5.3/

[2] 8 total counties in New Mexico if you also include Bernalillo County whose air quality is under the jurisdiction of the City of Albuquerque.



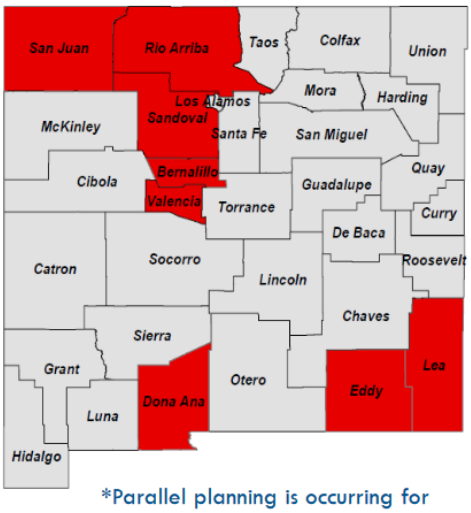


Figure 1-1. Trends in observed ozone DVs between 2013 and 2018 at 7 monitoring sites in New Mexico (Source: https://www.env.nm.gov/air-quality/wp-content/uploads/sites/2/2019/10/OAI_Presentation_09262019.pdf).

- Counties within 95% of the standard:
  - San Juan (Navajo Lake, 70 ppb)
  - Doña Ana (several monitors, 74 ppb)
  - Eddy (Carlsbad, 74 ppb)
  - Lea (Hobbs, 70 ppb)
  - Rio Arriba (Coyote, 67 ppb)
  - Sandoval (Bernalillo, 68 ppb)
  - Valencia (Los Lunas, 67 ppb)

Figure 1-2. 7 counties in New Mexico under the jurisdiction of the NMED whose observed 2016-2018 ozone DVs are at or exceed 95% of the 2015 ozone NAAQS (70 ppb) (Source: https://www.env.nm.gov/air-quality/wp-content/uploads/sites/2/2019/10/OAI_Presentation_09262019.pdf).

To address the high observed ozone concentrations in New Mexico, the NMED has embarked on an Ozone Attainment Initiative (OAI[3]) to protect the ozone attainment status of the state and ensure health and welfare of the residents of the state for future generations. The OAI was initiated in Spring 2018. As part of the OAI, NMED released a Request for Proposal (RFP#20 667 4040 0001) the NM OAI Study. The NM OAI Study PGM modeling was awarded to a contracting team of WESTAR and Ramboll. This Modeling Protocol is the first major deliverable under that contract.

1.2 Overview of NM OAI Study Modeling Approach

This Modeling Protocol describes the modeling activities to be performed under the NM OAI Study. The NM OAI Study will conduct PGM modeling by enhancing the WRAP/WAQS 2014 modeling platform[4] to use a 4-km grid resolution domain covering New Mexico and surrounding areas, especially the oil and gas (O&G) production regions in the Permian and San Juan Basins. The NM OAI Study PGM modeling will conduct 2014 base year modeling and model performance evaluation as well as 2023 future year modeling. The 2023 future year modeling will include ozone source apportionment and control measure sensitivity modeling. The NM OAI Study PGM modeling will be conducted in accordance with EPA's guidance for ozone State Implementation Plan (SIP) attainment demonstration modeling.

1.2.1 EPA Guidance for Ozone Attainment Demonstration Modeling Protocols

A comprehensive Modeling Protocol for an 8-hour ozone SIP attainment demonstration study consists of many elements. Its main function is to serve as a roadmap for planning and communicating how a modeled attainment demonstration will be performed before it occurs. The protocol guides the technical details of a modeling study and provides a formal framework within which the scientific assumptions, operational details, commitments and expectations of the various participants can be set forth explicitly.

On November 28, 2018 EPA released a final 8-hour ozone modeling guidance (EPA, 2018d) that replaces the previous final guidance (EPA, 2007) and draft guidance (EPA, 2014d). The EPA 2018 ozone modeling guidance is similar to the draft 2014 guidance with updates (e.g., slight modification to the recommended ozone DV projection approach). As stated in EPA's latest modeling guidance (EPA, 2018d, pp. 15):

> "The most important function of the modeling protocol is to serve as a blueprint for planning how the modeled demonstration will be performed. The protocol should be a valuable communication device by which air agencies, EPA, and other stakeholders can assess the applicability of default recommendations and develop area-specific alternatives, where needed, prior to conducting the work to build the modeling system. A suitable protocol should lead to extensive participation by stakeholders in developing the demonstration. It should also reduce the risk of spending time and resources on efforts that are unproductive or inconsistent with EPA rules, policy, and guidance. While the modeling protocol

[3] https://www.env.nm.gov/air-quality/o3-initiative/

[4] http://views.cira.colostate.edu/wiki#WAQS-2014-Modeling-Platform

is initially developed at the beginning of a modeling exercise to foster communication, it is advisable to modify the document as needed throughout the modeling process when alterations from the original modeling plan are necessary. Again, any changes to the protocol should be fully communicated between affected air agencies, stakeholders, and the EPA."

1.2.1.1 Contents of the Modeling Protocol

EPA's 8-hour ozone SIP modeling guidance identifies specific "core elements" that should be part of any ozone SIP Modeling Protocol. These "core elements" are repeated below along with where they are addressed in this NM OAI Study Modeling Protocol (EPA, 2018d, pp. 15-16):

- Overview of the air quality issue being considered including historical background: Chapter 1 provides an overview of ozone issues in New Mexico including past and related ozone modeling studies for the region.
- List of the planned participants in the analysis and their expected roles: The principal participants in the NM OAI Study are listed in Table 1-1 at the end of Chapter 1.
- Schedule for completion of key steps in the analysis and final documentation: The current schedule is presented in Tables 1-2 and 1-3 at the end of Chapter 1.
- Description of the conceptual model for the area: The Conceptual Model of ozone formation in the NM OAI Study is provided in Section 1.4.
- Description of periods to be modeled, how they comport with the conceptual model, and why they are sufficient: Chapter 3 presents the Episode Selection and justifies the selection of the summer of 2014 modeling period for the NM OAI Study.
- Models to be used in the demonstration and why they are appropriate: Model selection and justification is presented in Chapter 2.
- Description of model inputs and their expected sources (e.g., emissions, meteorology, etc.): The source of data and description of the model inputs are given in Chapters 4, 5 and 6.
- Description and justification of the domain to be modeled (expanse and resolution): Domain selection and justification is provided in Chapter 4.
- Process for evaluating base year model performance (meteorology, emissions, and air quality) and demonstrating that the model is an appropriate tool for the intended use: The procedures for conducting the 2014 base case photochemical modeling and model performance evaluation is given in Chapter 7. Procedures for conducting the meteorological modeling and evaluation are provided in Chapter 5. Emission inputs are discussed in Chapter 6.
- Description of the future years to be modeled and how projection inputs will be prepared: Future year modeling procedures are provided in Chapter 8.
- Description of the NAAQS attainment test procedures and (if known) planned weight of evidence, and/or description of the procedures for calculating RPGs from the modeling outputs, as applicable: The ozone attainment demonstration procedures for the 2023 future years are described in Chapter 9 along with

potential additional weight of evidence (WOE) analysis to support the modeled attainment demonstration.

- Expected diagnostic or supplemental analyses needed to develop weight of evidence analyses: Potential WOE analysis are described in Chapter 9.
- Commitment to specific deliverables fully documenting the completed analysis: Deliverables to support the modeling component of the NM OAI Study are listed at the end of Chapter 9 with schedule for the deliverables listed in Tables 1-2 and 1-3.
- Quality Assurance Project Plan (QAPP): Although not part of EPA's guidance Modeling Protocol. Elements of a QAPP are contained throughout the Modeling Protocol and in each process of the PGM database development. Chapter 10 discusses the contents of a QAPP and where they can be found in this Modeling Protocol.

1.3 Related Studies

There are numerous other studies related to the NM OAI Study whose results may provide insight or provide data useful to the study that are summarized below.

1.3.1 Historic EPA and More Recent EPA-MJO-States Modeling Platforms

EPA routinely develops national PGM modeling platforms that are used to evaluate the air quality impacts of national rules, make transport assessments, such as the Cross-State Air Pollution Rule (CSAPR[5]), or other regional air quality analysis, such as the recent 2028 national regional haze modeling.[6] The national PGM modeling platforms typically coincide with the triennial National Emission Inventory (NEI[7]) years (e.g., 2008, 2011, 2014). Below we discuss the current (May 2020) status of EPA's more recent national PGM modeling platforms.

2011v6.3 Modeling Platform: The EPA 2011v6.3[8] PGM modeling platform is the result of many years of development and refinements (e.g., v6.0, v6.1 and v6.2[9]). It consists of a base year 2011 meteorological conditions and emissions and three future year emission scenarios: 2017, 2023 and 2028. It has been used in numerous EPA rulemakings (e.g., CSAPR Update). As with the other recent EPA modeling platforms, the 2011v6.3 modeling platform uses a 12-km grid resolution continental U.S. (12US2) modeling domain that is the red domain shown in Figure 1-3.

2014v7.1 Modeling Platform: The EPA 2014v7.1[10] PGM modeling platform was used in the 2014 National Air Toxics Assessment (NATA[11]) modeling. It also uses the 12-km 12US2 modeling (Figure 1-3, red domain). 2014 was a relatively low ozone year in the eastern U.S. so EPA did not pursue using the 2014 platform for national rulemakings

[5] https://www.epa.gov/csapr
[6] https://www.epa.gov/visibility/technical-support-document-epas-updated-2028-regional-haze-modeling
[7] https://www.epa.gov/air-emissions-inventories/national-emissions-inventory-nei
[8] https://www.epa.gov/air-emissions-modeling/2011-version-63-platform
[9] https://www.epa.gov/air-emissions-modeling/2011-version-6-air-emissions-modeling-platforms
[10] https://www.epa.gov/air-emissions-modeling/2014-version-71-platform
[11] https://www.epa.gov/national-air-toxics-assessment

(except for the NATA) developed a 2016 modeling platform for ozone, $PM_{2.5}$ and regional haze modeling.

2015 Alpha Modeling Platform: EPA has made data available to model 2015 using data based on the 2014v7.1 platform. However, a full 2015 PGM modeling platform was never developed.

2016 Modeling Platform: The EPA, Multi-Jurisdictional Organizations (MJOs), and states conducted a collaborative national emissions modeling platform[12] (2016 EMP) to develop a 2016 emissions inventory of comparable or better quality than the NEI, with projections to 2023 and 2028. Separately, EPA developed a 2016 PGM modeling platform that used the same 12-km grid resolution continental U.S. domain used in previous EPA PGM platforms (e.g., 2011) but added an expanded 36-km grid resolution 36US3 domain as shown in Figure 1-3. EPA has released several versions of their 2016 36/12-km PGM modeling platforms as follows:

- 2016v7.1 Alpha[13] PGM platform was available in June 2019 and uses the 2016 EMP Alpha version emissions, which were based mainly on the 2014 NEIv7.1 emissions (called the 2016fd emissions scenario by EPA).
- The 2016v7.2 Beta (called 2016ff by EPA) PGM platform uses the 2016 EMP Beta version emissions[14] from the EPA/MJO/states emissions collaborative study. The original 2016v7.2 Beta PGM platform was released in March 2019 through the Intermountain West Data Warehouse (IWDW[15]). EPA made some updates to the 2016v7.2 PGM platform and used the 2016v7.2 Beta Prime (called 2016fg by EPA) modeling platform for their preliminary 2028 regional haze modeling. Details on EPA's 2016v7.2 modeling platform are contained in a Technical Support Document (TSD; EPA, 2019).
- The final EPA 2016v1[16] (called 2016fh by EPA) PGM modeling platform uses the 2016 EMP version 1 emissions[17] from the EPA/MJO/states emissions collaborative study. It was released in November 2019 with updates to Commercial Marine Vessels (CMV) occurring in February 2020 and WRAP region O&G data, and is also available on the IWDW. The 2016v1 inventory included emission projections for 2023 and 2028.

1.3.2 Denver Ozone SIP Modeling and Analysis

The Denver Metropolitan (DM) and North Front Range (NFR) ozone nonattainment area (NAA) has undergone several rounds of ozone SIPs to address attainment of a series of ozone NAAQSs.

Denver 2003 EAC SIP: The 2003 Denver Early Action Compact (EAC) SIP modeling performed 36/12/4/1.33 km photochemical modeling of the DM/NFR NAA for a summer 2002 period using the meteorological based on the MM5 model (McNally, Tesche and Morris, 2003), EPS3 emissions and CAMx photochemical grid models. The 1.33-km fine grid was ultimately not used because of little improvement in model performance over using a 4-km resolution grid at the expense of high additional computational requirements. The Denver EAC SIP developed an Ozone Action Plan[18] and

[18] http://www.colorado.gov/airquality/tech_doc_repository.aspx?action=open&file=EAC_SIP_031104-aqcc_DRAFT.pdf

demonstrated that the region would attain the 1997 ozone NAAQS by 2007 (Morris et al., 2004a,b,c,d).

Denver 2008 Ozone SIP: The 2008 Denver ozone SIP[19] modeling used the MM5 meteorological, SMOKE/CONCEPT emissions and CAMx photochemical grid models (Morris et al., 2007). The CONCEPT model was interfaced with link-based Vehicle Miles Traveled (VMT) and other mobile source activity data (e.g., speeds, fleet mix, temporal variations, etc.) from a Traffic Demand Model (TDM) operated by DRCOG, on-road emission factors from the MOBILE6 model and hourly meteorological data from MM5 to generate detailed on-road mobile source emissions for the DMA. Other emission inputs were generated using SMOKE. The MM5/SMOKE/CONCEPT/CAMx modeling system was applied to the June-July 2006 period and used to demonstrate that the DMA/NFR region would attain the 1997 8-hour ozone NAAQS by 2010 (Morris et al., 2008a,b,c; 2009a,b).

The 2008 ozone SIP 2006 modeling platform was also used to investigate improvements to the modeling system (Morris et al., 2011) and evaluate the VOC/NOx emissions inventory that suggested 2006 oil and gas emissions in Weld County were understated (Morris, Tai and Sturtz, 2011).

Denver 2016 Ozone SIP: The 2016 Denver ozone SIP[20] modeling addressed the 2017 attainment of the DM/NFR Moderate NAA under the 2008 ozone NAAQS (RAQC and CDPHE, 2016). The 2016 ozone SIP used a 2011 36/12/4-km modeling platform based on the WRAP/WAQS modeling platform available on the IWDW and adding a 4-km domain focused on Colorado (Ramboll and Alpine, 2015; 2016a,b; 2017).

The 2016 Denver ozone SIP 2011 36/12/4-km modeling platform was used to conduct additional future-year sensitivity modeling and other analysis in anticipation of the requirements needed to attain the 2015 ozone NAAQS. These results were presented at a November 2, 2017 Modeling Forum[21] and included the following:

- 2017 local source contributions to ozone concentrations in the DM/NFR NAA;
- Contributions of international anthropogenic emissions to 2011 ozone concentrations in the DM/NFR NAA; and
- Preliminary 2023 ozone projections and sensitivity to VOC/NOx anthropogenic emissions reductions.

Current Denver Ozone SIP 2020 and 2023 Attainment Demonstration Modeling: Current Denver ozone SIP efforts are using a 2016 36/12/4-km CAMx modeling platform based in part on EPA's 2016v1 modeling platform with new WRF meteorological modeling and a 4-km domain covering Colorado added. The new Denver 2016 36/12/4-km CAMx platform will be used to demonstrated attainment in 2020 to address the area as a

[19] https://www.colorado.gov/airquality/documents/deno308/

[20] https://raqc.org/sip/moderate-area-2008-8-hour-ozone-standard-state-implementation-plan/

[21] https://raqc.org/reports/?titlePost=Modeling+Forum

Serious NAA under the 2008 ozone NAAQS and in 2023 to address the area as a Moderate NAA under the 2015 ozone NAAQS.

1.3.3 West-wide Jumpstart Air Quality Modeling Study

The Western Regional Air Partnership (WRAP) initiated a new round of regional ozone, particulate matter, visibility and deposition modeling for the western U.S. starting with the West-wide Jumpstart Air Quality Modeling Study (WestJumpAQMS[22]; ENVIRON, 2013). WestJumpAQMS performed 36/12/4-km modeling for the 2008 calendar year with the 12-km domain focused on the western U.S., and the 4-km domain focused on the states of CO, NM, UT and WY (ENVIRON and Alpine, 2012). The WestJumpAQMS was completed in September 2013 and calculated, among other things, the contributions of transport to ozone in the Denver area and contributions of emissions from Colorado (including Denver) to downwind ozone and $PM_{2.5}$ concentrations (ENVIRON, Alpine and UNC, 2013). The 2008 base year from the WestJumpAQMS platform was used in the development of the 3-State Data Warehouse and Air Quality Study, the predecessor to the Intermountain West Data Warehouse and Western Air Quality Study, described next.

1.3.4 Intermountain West Data Warehouse and Western Air Quality Study

The WRAP Intermountain West Data Warehouse (IWDW[23]) was developed to be a repository and source of ambient air quality and modeling data that can be used by the western states. The Western Air Quality Study (WAQS) developed 2011 PGM modeling platforms to assess air quality, visibility and deposition in the western states and was used to populate the IWDW. The WAQS started by enhancing the WestJumpAQMS 2008 WRF/SMOKE/CAMx/CMAQ 36/12 km database and making it available through the IWDW. WAQS then developed new 2011 WRF/SMOKE/CAMx/CMAQ modeling platforms (Adelman, Shankar, Yang and Morris, 2014; 2016; Adelman and Baek, 2015) that was also made available through the IWDW. IWDW is not only a source of modeling data, but also includes data analysis and visualization tools and is a repository of data from other modeling studies.

1.3.5 Southern New Mexico Ozone Study (SNMOS)

The Southern New Mexico Ozone Study (SNMOS[24]) conducted WRF meteorological, SMOKE emissions and CAMx ozone modeling for a 2011 base and 2025 future year using a 12/4-km modeling domain, as shown in the right panel of Figure 1-4. SNMOS found that a vast majority of ozone in Southwestern New Mexico is due to ozone transport from outside of New Mexico. For example, Figure 1-4 (left panel) displays the 2011 and 2025 ozone contributions to the ozone Design Value (DV) at the Desert View monitoring site in Dona Ana County by geographic regions within the 12/4-km PGM modeling domain also shown in Figure 1-4. Only 3 percent of the 2011 ozone DV at Desert View is due to anthropogenic emissions from New Mexico, and New Mexico

[22] http://www.wrapair2.org/pdf/WestJumpAQMS_FinRpt_Finalv2.pdf

[23] http://views.cira.colostate.edu/iwdw/

[24] https://www.wrapair2.org/SNMOS.aspx

emissions contribute less than 2 percent of the projected 2025 ozone DV at Desert View.

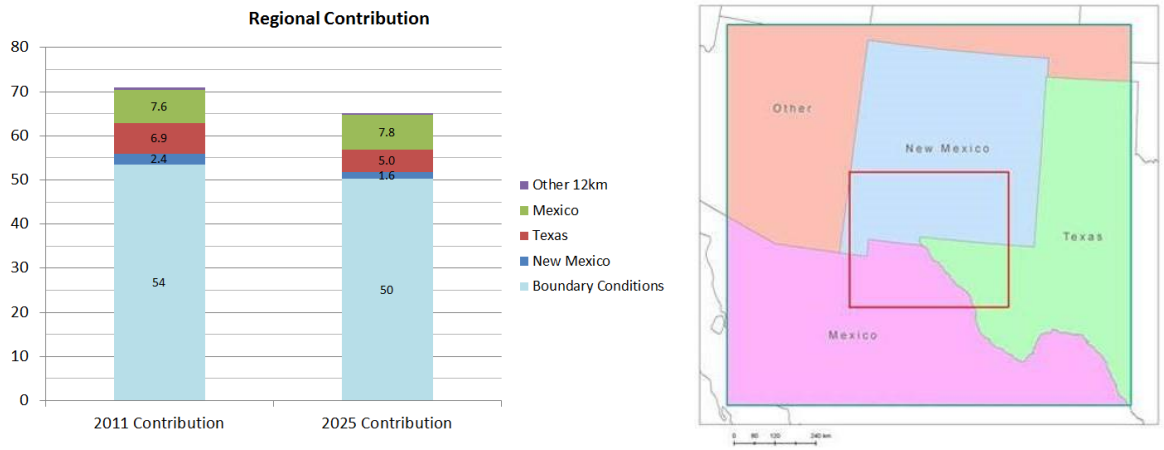

Figure 1-4. Contributions of geographic regions (including Boundary Conditions) to the 2011 and 2025 ozone Design Values at Desert View monitoring site in Dona Ana County in Southwestern New Mexico.

The SNMOS 2011 and 2025 ozone source apportionment modeling also obtained contributions by Source Sector in addition to the four Source Regions depicted in the left panel of Figure 1-4. Figure 1-5 displays the Source Sector contributions to the 2011 and 2025 ozone DV at Desert View monitor as well as the 10 highest Source Groups (i.e., Source Sector emissions from Source Regions) contributions. On-road mobile sources has the highest contribution to ozone DVs in both 2011 and 2025 (Figure 1-5, top panel), but that is mainly due to on-road mobile source emissions in Texas and Mexico that are the two highest contributing Source Groups (Figure 1-5, bottom panel).

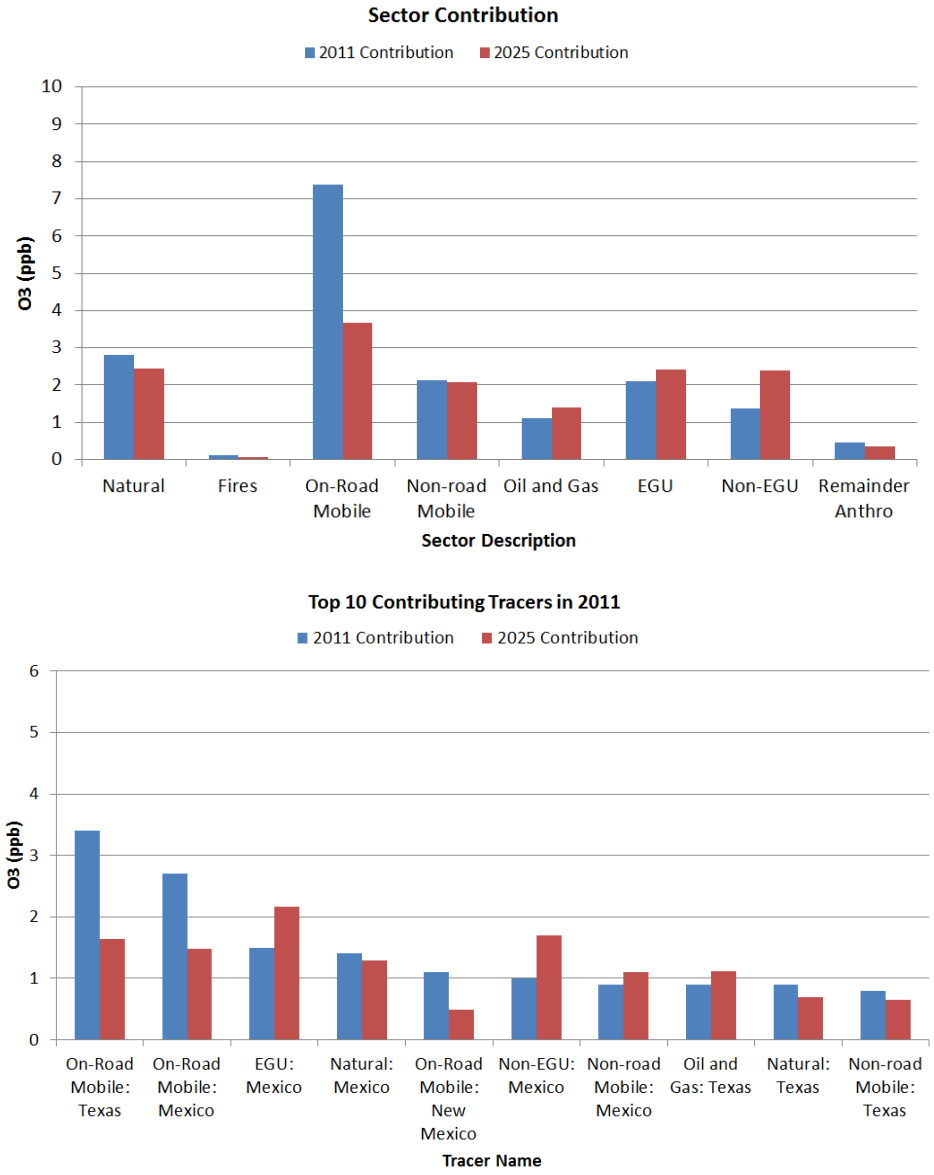

Figure 1-5. Contributions of Source Sector emissions within the 12/4-km modeling domain to the 2011 and 2025 ozone Design Value at Desert View monitoring site (top) and top ten Source Group contributions (bottom).

Figure 1-6 examines the contributions of emissions from New Mexico to 2011 and 2025 ozone DVs at nine monitoring sites in Southeast New Mexico. With one exception, on-road mobile source emissions are the largest contributing Source Sector in New Mexico to 2011 ozone DVs in southeastern New Mexico with the contribution at the Solano monitoring site being higher than the others. The one exception is the Carlsbad monitoring site in Eddy County where O&G emissions is the largest contributing Source Sector in New Mexico due to its close proximity to the Permian Basin. Although on-road mobile source emissions are the largest contributor in 2011, it is also the Source

Sector whose New Mexico ozone contribution is reduced the most in 2025, by over a factor of two. This is in contrast to O&G whose contribution at the Carlsbad monitoring site is projected to increase between 2011 and 2025, although future year projections of O&G emissions are highly uncertain. In any event, by 2025 the SNMOS estimate that on-road mobile, non-road mobile and O&G Source Sectors in New Mexico will contribute the most, with New Mexico EGU and non-EGU point sources and other anthropogenic emission Source Sectors having relatively lower ozone contributions.

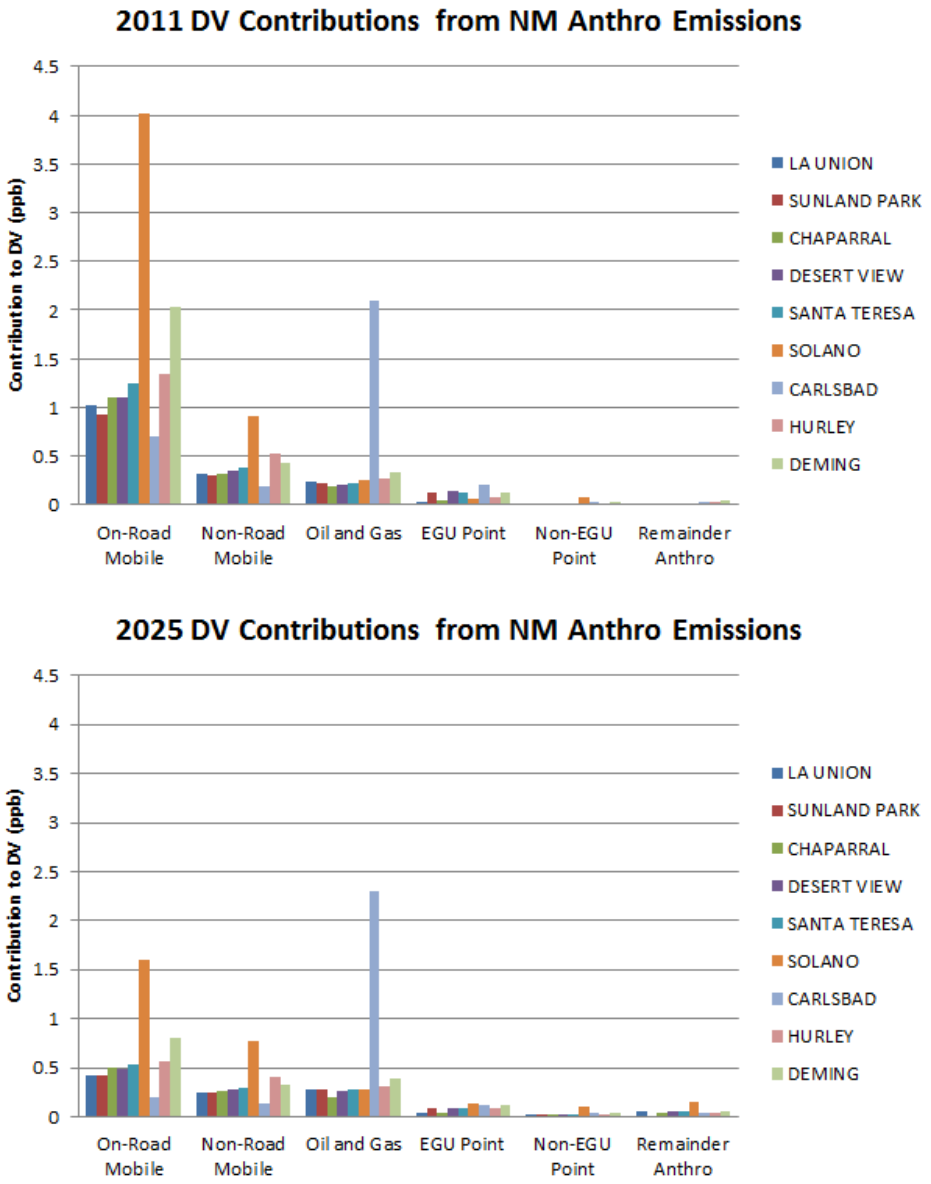

Figure 1-6. Contributions of major Source Sectors in New Mexico to 2011 (top) and 2025 (bottom) ozone DVs at nine monitoring sites in Southwestern New Mexico.

1.3.6 City of Albuquerque Ozone Modeling Study

The City of Albuquerque conducted an ozone modeling study[25] for two episodes in 2017: June 12-16, 2017 and July 3-14, 2017. The purpose of the study was to better understand the source of high ozone concentrations in Bernalillo County and what types of control strategies, if needed, would be most effective at reducing ozone concentrations in the County.

Figure 1-7 displays the maximum ozone DVs in Albuquerque from 2013 to 2018 and their relationship with the 80, 75 and 70 ppb ozone NAAQS. 2016 is a low point in the ozone DV trend (~65 ppb) followed by increases so by 2018 the maximum Bernalillo County ozone DV is at the 2015 ozone NAAQS.

The City of Albuquerque Ozone Modeling Study conducted WRF meteorological and SMOKE emissions modeling using a 12/4-km CAMx ozone modeling database, with the 4-km domain covering New Mexico and the 12-km domain covering the western states (Figure 1-7, right panel).

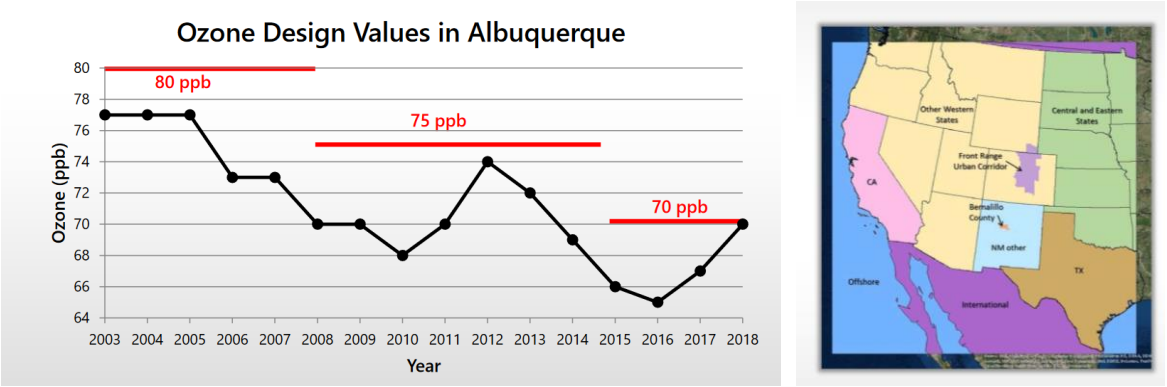

Figure 1-7. Trends in maximum ozone Design Values in Albuquerque from 2013 to 2018 (left) and 12-km modeling domain and source apportionment geographic regions (right).

Ozone source apportionment was performed to determine the geographic regions (Figure 1-7, right) that contributed to elevated ozone concentrations in Albuquerque. Figure 1-8 displays the contributions to ozone concentrations in Albuquerque for the June and July episodes. Anthropogenic emissions from New Mexico contributed 14% and 24% to ozone in Albuquerque during the, respectively, June and July 2017 episodes. And anthropogenic emissions from Bernalillo County accounted for up to 75% of the New Mexico contribution.

[25] https://www.cabq.gov/airquality/documents/06-ken-craig-sonoma-technology-inc-ozone-modeling-presentation-10-17-2018-aqcb-meeting.pdf

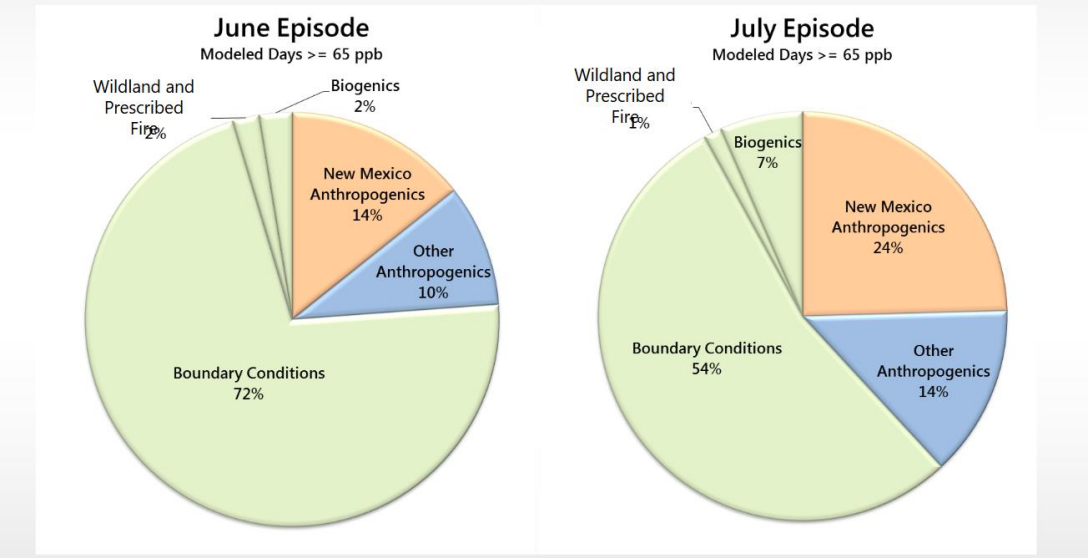

Figure 1-8. Contributions to ozone in Albuquerque during the June and July 2017 modeling episodes.

Although only two short episodes were modeled, so any conclusions are limited to those conditions, the City of Albuquerque Ozone Modeling Study concluded as follows:

- Transport from outside of New Mexico is always important and accounts for over half of the ozone in Albuquerque.
- Local emissions in Albuquerque and Bernalillo County are also important with half of the locally generated ozone due to on-road mobile sources in 2017.
- On high ozone days for the two modeled episodes, contributions from major power plants in northern New Mexico were small at sites in Albuquerque.
- Impacts from man-made emissions in western states, including California, are non-negligible.
- Ozone contributions from wildfire smoke were important for both episodes.
- As on-road mobile source emissions are reduced, emissions from non-road and non-mobile sources are becoming increasingly important. NOx emission controls are more effective at reducing high ozone concentrations in Albuquerque than VOC controls.
- Ozone in Albuquerque is sensitive to emissions from O&G sources throughout New Mexico.

1.3.7 Relationship Between Meteorology and Ozone in the Intermountain West Region

Reddy and Pfister (2016) and CDPHE and RAQC (2016c) analyzed meteorological factors that contributed to the interannual variability in midsummer ozone concentrations focusing mainly on Utah and Colorado. They analyzed ozone and

meteorology for July during 1995-2013 and found several meteorological variables that were able to explain the years with higher ozone formation conditions. The most powerful meteorological variable for describing high ozone formation potential conditions (i.e. ozone conducive conditions) was the height of the 500 hPa[26] pressure level. The current Denver ozone SIP modeling study extended the analysis of meteorology conducive to ozone formation and observed ozone trends analysis of Reddy and Pfister (2016) and CDPHE and RAQC (2016c) to include the most recent years (through 2018) and for summer-average conditions. Figure 1-9 shows the relationship between summer-average 500 hPa heights and summer-average ozone at the Rocky Flats North (RFNO) monitoring site northwest of downtown Denver and the years 1995-2018, results for the other sites are similar.

Figure 1-10 displays the correlation between elevated ozone concentrations and 500 hPa heights in the western U.S. and some of the sites in New Mexico are also weakly to moderately correlated to the 500 hPa heights like the sites in Denver and Utah. Elevated ozone at sites in northwestern New Mexico show less correlation with 500 hPa heights as it is believed that the large point source NOx and oil and gas NOx and VOC emissions in the region swamp the signal.

[26] hPa is100 Pa where Pa is short for Pascal that is a unit of pressure where 500 hPa = 500 mb.

NMED Exhibit 15

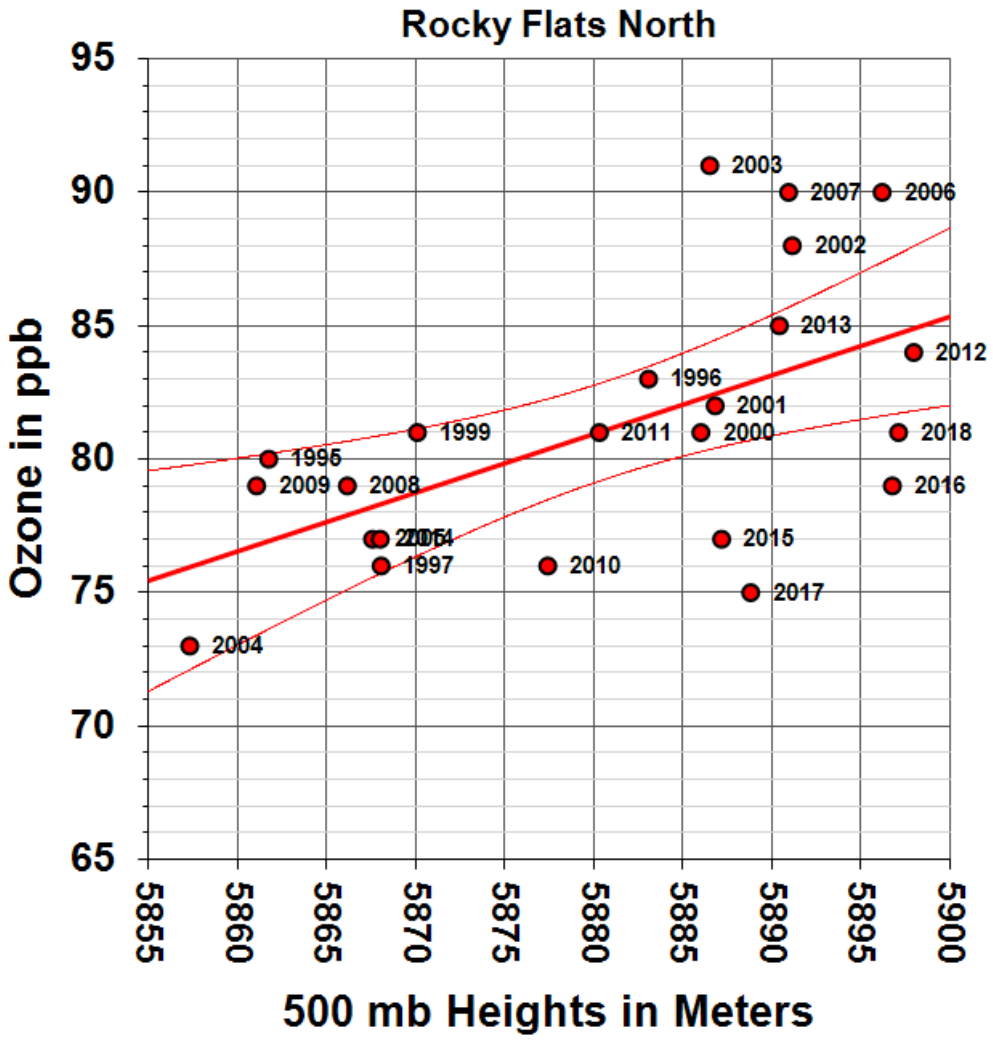

Figure 1-9. Linear regression of the annual 4th highest MDA8 ozone concentrations and mean July through August NCEP/NCAR Reanalysis 500 hPa (or 500 mb) heights for the DM/NFR NAA region at the Rocky Flats North (RFNO) monitoring site for the years 1995 to 2018.

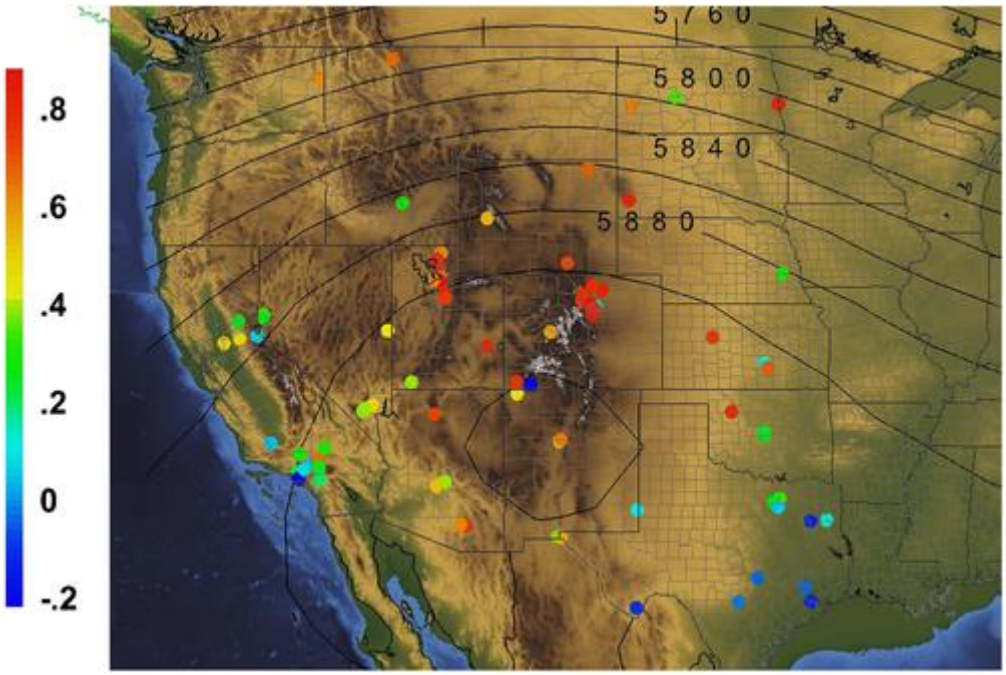

Figure 1-10. Correlation between 500 hPa heights and elevated ozone concentrations for monitoring sites in the western U.S.[27]

1.3.8 The Four Corners Air Quality Task Force

The Four Corners Air Quality Task Force (FCAQTF) was convened by the states of New Mexico and Colorado in 2005 and comprised of over 100 members and over 150 of interested parties. Its goals were to address air quality issues in the Four Corners region and consider mitigation options to reduce air pollution and acid deposition and improve visibility in the region. They found that transport from outside of the region was the largest contributor to ozone concentrations. Several large power plants and O&G production in the San Juan Basin, as well as mobile sources, also contributed to ozone in the region. The FCAQTF was completed in November 2007 with the release of a report[28] that contained over 100 potential mitigation measures for reducing emissions in the Four Corners region. The FCAQTF has been replaced by the Four Corners Air Quality Group (FCAQG[29]).

1.3.9 Other Studies

There are numerous other studies that may also be relevant to the NM OAI Study.

- Summary of State Regulations Applicable to Oil and Gas Sources in the WESTAR-WRAP Region (PDF) and companion spreadsheet (XLS)
- Final Work Products - Low and High Emissions Scenarios

San Juan & Permian Basins' O&G 2014 Emission Inventory Project

The National Park Service (NPS) has conducted studies of visibility impairment and nitrogen/sulfur deposition at National Parks throughout the U.S. For example, the Rocky Mountain Atmospheric Nitrogen and Sulfur Study (ROMANS) studied nitrogen deposition and potential mitigation scenarios at Rocky Mountains National Park (RMNP). RMNP studies have included data collection, data analysis, modeling and the development of a nitrogen deposition reduction plan. Details on these activities can be found at:

https://www.colorado.gov/pacific/cdphe/rocky-mountain-national-park-initiative

http://www.nature.nps.gov/air/studies/romans.cfm

The Bureau of Land Management (BLM) has conducted several iterations of the Colorado Air Resource Management Modeling Study (CARMMS) using a CAMx 4-km modeling database with a 4-km grid resolution domain covering Colorado and northwest New Mexico. Future year source apportionment modeling was conducted to assess the ozone, $PM_{2.5}$, visibility and sulfur and nitrogen deposition impacts at Class I

and sensitive Class II Area due to oil and gas and mining development on Federal lands in Colorado and northern New Mexico.

1.4 New Mexico Conceptual Models for High Ozone Concentrations

There are three interrelated but distinct Conceptual Models of ozone formation within New Mexico: southeastern New Mexico, Albuquerque and surrounding areas, and northwestern New Mexico. They share the attribute that ozone transport dominates ozone concentrations on all days. Days with the highest local ozone formation are typically hot summer days with slow winds and without an excessive amount of precipitation (summer monsoon).

1.4.1 Southeastern New Mexico

Ozone at monitoring sites in southeastern New Mexico, including Dona Ana, Eddy and Lea Counties, is dominated by ozone transport from outside of New Mexico. This transport includes long-range transport from the remainder of U.S. and global sources (e.g., Asia) as well as medium-range transport from Texas and Mexico. Current year on-road mobile source emissions tend to be the largest contributing Source Sector within southwestern New Mexico and nearby areas, with non-road mobile and O&G sources also contributing. With the exception of emissions from Mexico, the contributions of Electrical Generating Units (EGU) and other large industrial point sources tends to be smaller than the other Source Sectors.

The SNMOS discussed in Section 1.3.5 provides more details on the sources that contribute to elevated ozone concentrations in southeastern New Mexico. It found only 3% of the 2011 ozone Design Value was due to emissions from New Mexico. Emissions from nearby areas in Mexico and Texas contribute the most after long-range transport of ozone.

1.4.2 City of Albuquerque

Ozone transport also dominates elevated ozone concentrations in and near the City of Albuquerque. The Albuquerque modeling study discussed in Section 1.3.6 provides details on source contributions, but sources within New Mexico contributed a large fraction (e.g., 14% and 24%) to elevated ozone in Albuquerque with emissions from Albuquerque contributing up to 75% of the New Mexico contribution. Emissions from on-road and non-road mobile and state-wide O&G also have substantial contributions.

1.4.3 Northwest New Mexico

Although ozone transport dominates ozone in the New Mexico Four Corners region, there are significant contributions due to local power plants and O&G production in the San Juan Basin. The FCAQTF identified numerous local control measures that could mitigate elevated ozone concentrations in the region (see Section 1.3.7).

1.5 Overview of the Modeling Approach

The NM OAI Study will conduct photochemical modeling for a 2014 base and 2023 future year and perform 2023 ozone source apportionment and control strategy sensitivity modeling.

1.5.1 Episode Selection

The May-August 2014 modeling period was selected as it has a high quality emissions inventory with western state updates and has a PGM platform already developed from the WRAP/WAQS regional haze modeling (see Chapter 3 for more details).

1.5.2 Model Selection

Details on the rationale for model selection are provided in Chapter 2. The Weather Research Forecast (WRF) prognostic meteorological model was selected with the 4-km grid covering New Mexico. Emissions modeling will be performed using the Sparse Matric Operator Kernel Emissions (SMOKE) model for most source categories. The Model of Emissions of Gases and Aerosols from Nature (MEGAN) will be used for biogenic emissions and there are special processors for fires, windblown dust (WBD), lightning NOx (LNOx) and oceanic sea salt (NaCl) and Dimethyl Sulfide (DMS) emissions. The 2014 version of the MOtor Vehicle Emissions Simulator (MOVES2014b) on-road mobile source emissions model will be used with SMOKE-MOVES and WRF meteorological data to generate on-road mobile source emissions for the 4-km New Mexico and 12-km western U.S. modeling domains.

The Comprehensive Air-quality Model (CAMx) photochemical grid model (PGM) will be used because it supports two-way grid nesting, includes a subgrid-scale Plume-in-Grid module, contains a well-vetted ozone source apportionment tool and has a rich and successful history of application to the region.

1.5.3 Domain Selection

The same 36-km 36US and 12-km 12WUS2 modeling domains as used in the WRAP/WAQS 2014 modeling will be used in the NM OAI Study modeling. A higher resolution 4-km domain will be added covering New Mexico and adjacent areas. New 2014 36/12/4-km WRF meteorological modeling will be conducted to provide the higher resolution meteorological fields needed for the 4-km New Mexico domain. Details on the domain definition are presented in Chapter 4.

1.5.4 Base and Future Year Emissions Data

The 2014 base year emissions data will be based on the WRAP/WAQS 2014v2 emissions that was in turn based on the 2014NEIv2 with updates from western states. New emissions will be generated for natural emission sources (e.g., biogenic and LNOx) as needed. 2023 future year emissions will be mostly based on the EPA 2016v1 emissions (2023fh inventories). 2023 mobile source emissions will be created using SMOKE-MOVES modeling with 2023 MOVES emission factor look-up table and 2014 WRF meteorology. 2023 O&G emissions for the WRAP states will be based on the WRAP 2023 O&G emissions. The 2014 and 2023 emissions for New Mexico will be reviewed by NMED and updated as needed.

1.5.5 Emissions Input Preparation and QA/QC

Quality assurance (QA) and quality control (QC) of the emissions datasets are some of the most critical steps in performing air quality modeling studies. Because emissions processing is tedious, time consuming and involves complex manipulation of many different types of large databases, rigorous QA measures are a necessity to prevent errors in emissions processing from occurring. The NM OAI Study modeling study will perform a multistep emissions QA/QC approach as developed for the WRAP 2002 modeling (Adelman, 2004) and following the procedures in EPA's latest ozone modeling guidance (EPA, 2018a, pp. 60) and Section 2.20 of the SMOKE User's Manuel (UNC, 2018, pp. 94). This includes the initial emissions QA/QC by the NMED of their emissions for New Mexico as well as QA/QC by the WESTAR/Ramboll team.

1.5.6 Meteorology Input Preparation and QA/QC

The CAMx 2014 36/12/4-km meteorological inputs will be based on a new 2014 WRF meteorological modeling conducted by the Ramboll. The new WRF 2014 36/12/4-km modeling will be evaluated against measured meteorological parameters in a model performance evaluation. The 2014 36/12/4-km WRF output will be processed by WRFCAMx processors to generate meteorological inputs for CAMx. Details on the NM OAI Study 2014 36/12/4-km WRF modeling are provided in Chapter 5.

1.5.7 Initial and Boundary Conditions Development

Initial concentrations (IC) and Boundary Conditions (BCs) are important inputs to PGMs. We intend to run approximately the first two-weeks of May on the 36/12/4-km domains to spin-up the model before the first high ozone day in New Mexico (68 ppb on May 17). This will "wash out" the influence of the ICs before elevated ozone concentrations occur in New Mexico.

BCs for the 36-km 36US domain will be based on a 2014 simulation of the GEOS-Chem global chemistry model conducted by WRAP processed by the GC2CAMx converter. The result is day-specific diurnally varying BCs for the lateral boundaries around the 36-km 36US modeling domain (i.e., GCBC). The top BC (TopCon) will be based on a zero-gradient assumption where concentrations above the top of the model (at 50 mb, or ~19-km above sea level) are assumed to be the same as in the top vertical layer of the model.

1.5.8 Air Quality Modeling Input Preparation and QA/QC

Each step of the air quality modeling will be subjected to QA/QC procedures. These procedures include verification of model configurations, confirmation that the correct data were used and were processed correctly and other procedures. Visualization of model inputs are a critical component of the QA/QC process.

1.5.9 Model Performance Evaluation

The Model Performance Evaluation (MPE) will follow EPA's MPE recommendations in their ozone modeling guidance (EPA, 2007; 2014d; 2018a) and other sources (e.g., Simon, Baker and Phillips, 2012; Emery et al., 2016) and use many elements in EPA Region 8's MPE checklist (EPA, 2015a). The CAMx 2014 36/12/4-km base case

simulation will focus on ozone and precursor model performance within the 4-km New Mexico domain. Details on the MPE are provided in Chapter 7.

1.5.10 Diagnostic Sensitivity Analyses

Depending on the results of the CAMx 2014 base case modeling and MPE, diagnostic sensitivity tests may be conducted to try and improve model performance. The definition of these diagnostic sensitivity tests will depend on the results of the initial MPE. The WRAP/WAQS development of the CAMx 2014 36/12-km modeling database conducted numerous sensitivity tests[30] leading to the final 2014v2 base case.

Under the NM OAI Study we expect most of the sensitivity tests to be conducted for the 2023 future-year where both emissions control strategy sensitivity and ozone source apportionment modeling is planned.

1.5.11 Future Year Control Strategy Modeling

Future year modeling for ozone will be performed for the 2023 future year. A CAMx 2023 36/12/4-km base case simulation will be conducted and projected 2023 ozone DVs calculated. The procedures to calculate projected 2023 ozone DVs will follow EPA's latest guidance (EPA, 2018d). These procedures use the modeling results in a relative fashion to scale the current year observed 8-hour ozone Design Values (DVCs) to project future year ozone Design Values (DVFs). The scaling factors are called Relative Response Factors (RRFs) and are the ratio of the future-year to current-year modeling results for the 10 highest base year modeled MDA8 ozone days near the monitoring site. EPA has developed the Speciated Modeled Attainment Test (SMAT[31]) tool that includes the recommended procedures in the latest EPA guidance for projecting ozone DVFs.

2023 future year control strategy sensitivity modeling will be performed. The future year controls will be defined by the NMED.

1.5.12 Future Year Source Apportionment Modeling

2023 future year ozone source apportionment modeling will be conducted using the CAMx Anthropogenic Precursor Culpability Assessment (APCA) ozone source apportionment tool. The WRAP 2014 GEOS-Chem global chemistry base case, ZROW and NAT simulation will be processed to isolate the contributions of U.S. anthropogenic, International anthropogenic and natural sources to the BCs. Within New Mexico, contributions will be obtained for the major Source Sectors. A NM OAI Study 2023 ozone source apportionment plan will be developed and discussed with NMED.

1.6 Project Participants and Contacts

The NMED is leading the NM OAI Study that is being carried out by the contracting team of WESTAR and Ramboll. Key participants in the NM OAI Study and their contact information are provided in Table 1-1.

1.7 Communication

Frequent communication between the NMED and the WESTAR and Ramboll modeling team and other potentially participants is anticipated. These communications will include e-mails, conference calls and potentially face-to-face meetings.

1.8 Schedule

The task structure and schedule for the NM OAI Study key deliverables are shown in Table 1-2. The study will be continuously documented with PowerPoint presentations and other documents that will be presented to the NMED each month in a webinar whose current schedule and topics are shown in Table 1-3. After each webinar, and with approval of the NMED, the presentations will be posted to a NM OAI Study webpage that will be hosted on the WRAP website. There are two formal reports for the study: (1) a 2014 base case modeling and model performance evaluation report prepared under Task 5, with a draft report currently scheduled for delivery in September 2020; and (2) an Air Quality Technical Support Document (AQTSD) that documents the entire study including the 2023 modeling prepared under Task 7, with a draft report currently scheduled for delivery in November 2020..

Table 1-2. Current schedule for NM OAI Study.

Task	Deliverable	Date
1. Formal Modeling Protocol/QAPP and Work Plan		
	Kick-Off Conference Call	Apr 2020
	Draft Modeling Protocol/QAPP and Work Plan	May 2020
	Webinar PPT on final approach and project plan	May 2020
	Final Modeling Protocol/QAPP and Work Plan	May2020
	Response-to-Comments (RTC) Document	May 2020
2. Base Year Meteorological Modeling (Met)		
2.1 Evaluate Met Modeling	*Webinar PPT on WAQS 12-km WRF MPE and WAQS 12-km PGM ozone performance in New Mexico*	May 2020
2.2 Additional Met Modeling	*Webinar PPT on WRF 4-km MPE in New Mexico and Comparison with WAQS 12-km WRF*	Jun 2020
2.3 Process Met Data	PGM summer 2014 36/12/4-km meteorological inputs	Jun 2020
3. Boundary Conditions (BC)		
3.1 Evaluate BC Data	*Webinar PPT on WRAP/WAQS 2014 GEOS-Chem BCs and latest updates to GEOS-Chem*	Jun 2020
4. Base Year (2014) and Future Year (2023) Emissions		
4.1 & 4.3. 2014 and 2023 Emissions for 4-km New Mexico Domain	*Webinar PPT on recommended sources for 2014 and 2023 emissions in the 4-km New Mexico domain*	May 2020

Task	Deliverable	Date
	Webinar PPT and tile plots/excel spreadsheets for selected 2014 and 2023 emissions for sources in the 4-km NM domain	Jun 2020
4.2 Mobile Sources		
4.2.1 Evaluate Mobile Emissions	*Webinar PPT on options for 2014 & 2023 mobile source emission inputs and advantages/disadvantages*	Jun 2020
	Webinar PPT on final 2014 & 2023 selected mobile source emissions options	Jun 2020
4.2.3 Prepare Mobile Source Emission Inputs	*Webinar PPT on SMOKE-MOVES modeling to generate 2014 and 2023 mobile source emission inputs for 4-km NM domain*	Aug 2020
	Model-ready 2014/2023 mobile source emissions inputs	Aug 2020
4.4 Biogenic/Natural Emissions	*Webinar PPT on biogenic and natural emission modeling*	Jul 2020
	Model-ready 2014 natural emissions inputs (Bio, LNOx, Fires)	Jul 2020
4.5 SMOKE Modeling	*Webinar PPT on SMOKE modeling 2014/2023 anthropogenic emissions*	Aug 2020
	Model-ready 2014/2023 anthropogenic emissions inputs	Aug 2020
4.6 FY Emissions Strategies	*Webinar PPT on FY 2023 SMOKE control/strategies*	Aug 2020
	Summary tables and tile plots of emissions for 2023 scenarios	Aug 2020
5. 2014 Base Year (2014) Air Quality Modeling		
	Webinar PPT on final 2014 base case and MPE	Sep 2020
	Draft report on 2014 base case, MPE and Tasks 2-5	Sep 2020
	Final Report on 2014 base case, MPE & Tasks 2-5	Oct 2020
	RtC on 2014 base case and MPE report	Oct 2020
6. Future Year (2023) Air Quality Modeling		
6.1 FY PGM Modeling	*Webinar PPT on FY 2023 PGM Modeling*	Oct 2020
	Difference plots of FY-BY Ozone Concentrations	Oct 2020
6.2 Modeled Attainment Test	*Webinar PPT on FY ozone DV projections*	Oct 2020

Task	Deliverable	Date
6.4 FY Source Apportionment	*Webinar PPT on FY Source Apportionment Modeling*	Nov 2020
	Interactive Excel spreadsheets with Source Apportionment modeling Results	Nov 2020
6.3 FY Controls Modeling	*Webinar PPT on FT control strategy/sensitivity*	Nov 2020
	Excel Spreadsheet of 2023 ozone DV projections	Nov 2020
7. Air Quality Technical Support Document and Data Transfer		
	Draft Air Quality Technical Support Document (AQTSD)	Nov 2020
	Final Air Quality Technical Support Document (AQTSD)	Dec 2020
	RtC document on AQTSD comments	Dec 2020
	Data Transfer of BY and FY modeling databases and results	Dec 2020

Table 1-3. Current schedule for monthly webinars for the NM OAI Study.

Webinar No.	Webinar Topics by Task	Date
1.	1. Modeling Protocol and Work Plan 2.1 Evaluate Existing Met 4.1 Recommend 2014 and 2023 Emissions 4.2.1 Recommend 2014 & 2023 Mobile Source Emissions	May 2020
2.	2.2 Additional Met Modeling 3.1 Evaluate BC Data 4.1 Summary of 2014 and 2023 Emissions	Jun 2020
3.	4.2.1 Summary of 2014 and 2023 Mobile Source Emissions 4.4 2014 Natural Emissions Results (e.g., Biogenic and LNOx)	Jul 2020
4.	4.2.3 2014 & 2023 SMOKE-MOVES Results for 4-km NM Domain 4.5 2014 & 2023 SMOKE Emissions Modeling Results	Aug 2020
5.	4.6 FY Emissions Strategy Results 5. 2014 CAMx Base Case Modeling and MPE	Sep 2020
6.	6.1 2023 CAMx Modeling Results 6.2 2023 Ozone Design Value Projections	Oct 2020
7.	6.3 2023 Control Strategy Results 6.4 2023 Source Apportionment Modeling Results	Nov 2020

2. MODEL SELECTION

This section introduces the models to be used in the NM OAI Study. The selection methodology presented follows EPA's guidance for regulatory modeling in support of ozone attainment demonstrations (EPA, 2007; 2014d; 2018d). Unlike some of EPA's previous ozone modeling guidance that specified a particular ozone model to be used (e.g., EPA's 1991 ozone modeling guidance that specified the Urban Airshed Model [UAM; Morris and Myers, 1990]), the EPA now recommends that models be selected for ozone, $PM_{2.5}$ and regional haze SIP modeling on a case-by-case basis (EPA, 2018d). The latest EPA ozone guidance (EPA, 2018d) explicitly mentions the CMAQ and CAMx PGMs as the most commonly used PGMs that would satisfy EPA's selection criteria but notes that this is not an exhaustive list and does not imply that they are "preferred" over other PGMs that could also be considered and used with appropriate justification. EPA's ozone modeling guidance lists several criteria for model selection that are paraphrased as follows (EPA, 2018d, pp. 24-27):

- It should not be proprietary;
- It should have received a scientific peer review;
- It should be demonstrated to be applicable to the problem on a theoretical basis;
- It should be used with data bases which are available and adequate to support its application;
- It should be shown to have performed well in past modeling applications;
- It should be applied consistently with an established protocol on methods and procedures;
- It should have a user's guide and technical description;
- The availability of advanced features (e.g., probing tools or science algorithms) is desirable; and
- When other criteria are satisfied, resource considerations may be important and are a legitimate concern.

For the NM OAI Study, we will use the same WRF/SMOKE/MOVES2014/MEGAN/CAMx modeling system as used in many recent studies and satisfies all the selection criteria above. The CAMx modeling system was used in the Western Regional Air Partnership (WRAP) West-wide Jump Start Air Quality Modeling Study (WestJumpAQMS; ENVIRON, 2011; ENVIRON and Alpine, 2012; ENVIRON, Alpine and UNC, 2013), Western Air Quality Study (WAQS; Adelman, Shankar, Yang and Morris, 2014; 2016), EPA's September 2019 Regional Haze modeling (EPA, 2019) and transport (CSAPR) modeling, and for a series of Denver ozone SIP modeling [e.g., 2003 EAC SIP (Morris et al., 2004c,b,c,d), 2008 SIP (Morris et al., 2007; 2008a,b,c) and 2016 SIP (Ramboll and Alpine, 2016a,b; 2017a; RAQC and CDPHE, 2017)] so has a long history of demonstrated success for simulating ozone concentrations in the western U.S.

2.1 Meteorological Model

The Weather Research and Forecasting (WRF) Model is a mesoscale numerical weather prediction system designed to serve both operational forecasting and atmospheric research needs (Skamarock, 2004; 2006; Skamarock et al., 2005; 2008; 2019). The Advanced Research WRF (ARW) version of WRF will be used in the NM OAI Study. It features multiple dynamical cores, sophisticated data assimilation system, and a software architecture allowing for computational parallelism and system extensibility. WRF is suitable for a broad spectrum of applications across scales ranging from meters to thousands of kilometers. The effort to develop WRF has been a collaborative partnership, principally among the National Center for Atmospheric Research (NCAR), the National Oceanic and Atmospheric Administration (NOAA), the National Centers for Environmental Prediction (NCEP) and the Forecast Systems Laboratory (FSL), the Air Force Weather Agency (AFWA), the Naval Research Laboratory, the University of Oklahoma, and the Federal Aviation Administration (FAA). WRF allows researchers the ability to conduct simulations reflecting either real data or idealized configurations. WRF provides operational forecasting a model that is flexible and efficient computationally, while offering the advances in physics, numerics, and data assimilation contributed by the research community.

WRF is publicly available, has full documentation and has demonstrated success in simulating meteorological conditions in New Mexico and Intermountain West (IMW) to support PGM modeling efforts in numerous studies (e.g., SNOMS, WRAP WestJumpAQMS and WAQS, EPA national studies and more recent Denver ozone SIPs).

2.2 Emissions Models

2.2.1 Sparse Matrix Operator Kernel Emissions (SMOKE)

The Sparse Matrix Operator Kernel Emissions (SMOKE) is an emissions modeling system that generates hourly gridded speciated emission inputs of mobile, non-road, area, point, fire and biogenic emission sources for PGMs (Coats, 1995; Houyoux and Vukovich, 1999; UNC, 2019). As with most "emissions models," SMOKE is principally an emission processing system and not a true emissions modeling system in which emissions estimates are simulated from "first principles." This means that, except for mobile sources, its purpose is to provide an efficient, modern tool for converting an existing base emissions inventory data that is typically at the county or point source level into the hourly gridded speciated formatted emission files required by a PGM. SMOKE will be used to prepare emission inputs for non-road mobile, non-point (area) and point sources. SMOKE performs three main functions to convert emissions to the hourly gridded emission inputs for a PGM: (1) spatial allocation, spatial allocates county-level emissions to the PGM model grid cells typically using a surrogate distribution (e.g., population); (2) temporal allocation, allocates annual emissions to time of year (e.g., monthly or seasonally) and day-of-week (typically weekday, Saturday and Sunday); and (3) chemical speciation, maps the emissions to the species in the chemical mechanism used by the PGM, most important for VOC and $PM_{2.5}$ emissions.

NMED Exhibit 15

2.2.2 MOtor Vehicle Emissions Simulator (MOVES)

The MOtor Vehicle Emissions Simulator (MOVES2014b) is EPA's latest on-road mobile source emissions model that was first released in July 2014 (EPA, 2014a,b,c). MOVES2014 includes the latest on-road mobile source emissions factor information. The NM OAI Study will use a version 2014b of MOVES (MOVES2014b[32]) with CB6 species that was released in August 2018.

2.2.3 SMOKE-MOVES

SMOKE-MOVES uses an Emissions Factor (EF) Look-Up Table from MOVES, vehicle miles travelled (VMT) and other activity data and hourly gridded meteorological data (typically from WRF) for the base modeling year and generates hourly gridded speciated on-road mobile source emissions inputs. SMOKE-MOVES will be used to generate on-road mobile source emissions for the 4-km New Mexico domain using the 4-km WRF data developed in this study. It will also be used to generate mobile source emissions inputs for the 12-km western U.S. domain.

2.2.4 Model of Emissions of Gases and Aerosols from Nature (MEGAN)

Biogenic emissions will be generated using version 3.1 of the Model of Emissions of Gases and Aerosols from Nature (MEGAN). MEGAN is the latest biogenic emissions model that was originally developed by researchers from the National Center for Atmospheric Research (NCAR) and is currently supported by the University of California at Irvine. MEGAN includes the full range of ozone and PM precursor species from biogenic sources (Guenther and Wiedinmyer, 2004; Wiedinmyer, Sakulyanontvittaya and Guenther, 2007). The NM OAI Study will use the latest version of MEGAN v3.1 that includes more western states plant emissions data that were implemented by WRAP (Sakulyanontvittaya, Yarwood and Guenther, 2012).

2.3 Photochemical Grid Model

2.3.1 Comprehensive Air-quality Model with extensions (CAMx)

The Comprehensive Air-quality Model with Extensions (CAMx; Ramboll, 2018a) is a state-of-science "One-Atmosphere" multi-scale photochemical grid model capable of addressing ozone, particulate matter (PM), visibility and acid deposition at regional, urban and local scale typically for periods of a year. CAMx is a publicly available open-source computer modeling system for the integrated assessment of gaseous and particulate air pollution. Built on today's understanding that air quality issues are complex, interrelated, and reach beyond the urban scale, CAMx is designed to (a) simulate air quality over many geographic scales, (b) treat a wide variety of inert and chemically active pollutants including ozone, inorganic and organic $PM_{2.5}$ and PM_{10} and mercury and toxics, (c) provide source-receptor, sensitivity, and process analyses and (d) be computationally efficient and easy to use.

The U.S. EPA has approved the use of CAMx for numerous ozone and PM State Implementation Plans throughout the U.S. (including the Denver 2003, 2008 and 2016 ozone SIPs) and has used this model to evaluate regional mitigation strategies

[32] https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P100V7H1.pdf

including those for most recent national transport rules, such as the Cross-State Air Pollution Rule (CSAPR) and CSAPR Update. The most recent version of CAMx is Version 7.0 that was used in the WRAP/WAQS 2014v2 modeling and EPA's recent national Regional Haze modeling (EPA, 2019). The latest EPA ozone guidance (EPA, 2018d, pp. 24) explicitly mentions the CMAQ and CAMx PGMs as the most commonly used PGMs that would satisfy EPA's selection criteria but notes that this is not an exhaustive list and does not imply that they are "preferred" over other PGMs that could also be considered and used with appropriate justification. EPA has conducted an analysis of the appropriateness for using CAMx and CMAQ for single-source ozone and secondary $PM_{2.5}$ modeling justifying their use (EPA, 2017c).

2.4 Final Justification for Model Selection

At the beginning of this Chapter we presented EPA's criteria for model selection (EPA, 2018d). The proposed WRF/SMOKE/MOVES/CAMx modeling system satisfies all of these criteria as follows:

- It should not be proprietary: The WRF[33], SMOKE[34], MOVES[35], MEGAN[36] and CAMx[37] models are all publicly available at no cost and can be downloaded from their websites.
- It should have received a scientific peer review: All the models considered have been published in 100s of peer-review journal articles. The CAMx model has been subject to their own peer-review reports[38] and an assessment by EPA that they are suitable for ozone SIP modeling (EPA, 2018d).
- It should be appropriate for the specific application on a theoretical basis: The WRF model was designed to simulate time varying three-dimensional meteorological fields and provide all the meteorological information necessary for ozone modeling. The SMOKE, MOVES and MEGAN models provide the hourly gridded speciated emissions information required for ozone modeling. And the CAMx model was designed to have all the processes necessary to simulate ozone formation in the troposphere.
- It should be used with data bases which are available and adequate to support its application: The procedures outlined for the development of the 2014 modeling platform to support ozone modeling of New Mexico use databases that are adequate to support the meteorological, emission and photochemical model applications.
- It should be shown to have performed well in past modeling applications: The WRF/SMOKE/CAMx modeling system has a demonstrated history in simulating ozone formation in the western U.S. in general and New Mexico in particular. CAMx was used in the New Mexico EAC SIP, FCAQTF, CARMMS, WRAP WAQS[39]

NMED Exhibit 15

and WestJumpAQMS[40], and Denver ozone SIP modeling, including the 2008[41] and 2016[42] Denver ozone SIPs.

- It should be applied consistently with an established protocol on methods and procedures: The NM OAI Study WRF/SMOKE/CAMx application methodology follows the established procedures used in the past (e.g., see studies discussed above) with enhancements (i.e., 4-km New Mexico domain and use of latest model versions).
- It should have a user's guide and technical description: Each of the models cited has a technical description and procedures for application (see websites in footnotes). The CAMx model has an up-to-date and comprehensive user's guide (Ramboll, 2018a) that has a detailed technical description and procedures for application.
- The availability of advanced features (e.g., probing tools or science algorithms) is desirable: One of the reasons for selecting CAMx is due to the availability of advanced features such as the Plume-in-Grid module and Ozone Source Apportionment Technology (OSAT/APCA) in addition to latest science updates (e.g., CB6 chemistry and Decoupled Direct Method).
- When other criteria are satisfied, resource considerations may be important and are a legitimate concern: CAMx is computationally efficient and supports both MPI and OpenMP multi-processing approaches and allows for layer collapsing. CMAQ does not support OpenMP or allow for layer collapsing so runs over 1.5 times slower than CAMx.

3. EPISODE SELECTION

EPA's current and past 8-hour ozone modeling guidance (EPA, 2007; 2014d; 2018d) contains recommended procedures for selecting modeling episodes for demonstrating attainment of the ozone NAAQS. The NM OAI Study modeling will use the summer of 2014 as the base year modeling period because it is representative of high ozone conditions and has available modeling databases to leverage for the analysis.

3.1 Candidate Year for Modeling Episodes

Given the need to leverage an existing photochemical grid model (PGM) modeling platform for the NM OAI Study, there are only two candidate years for episode selection, 2014 and 2016. The WRAP/WAQS has developed a PGM modeling platform for the 2014 year and the EPA/MJO collaborative emissions study and EPA have built a PGM modeling platform for 2016. EPA's previous PGM modeling platform was for 2011, which is too old. And EPA is working on a new PGM modeling platform for 2017 that is not yet available.

3.2 EPA Episode Selection Criteria

EPA's 8-hour ozone SIP modeling guidance (EPA, 2018d) identifies specific criteria to consider when selecting one or more episodes for use in demonstrating attainment of the 8-hour ozone NAAQS. This guidance builds off the 1-hour ozone modeling guidance (EPA, 1991) and the original (EPA, 2007) and revised draft (EPA, 2014d) 8-hour ozone modeling guidance that recommends selecting multiple episodes representing diverse meteorological conditions that lead to exceedances of the ozone NAAQS in the region under study. For the NM OAI Study, an entire summer ozone season will be modeled to capture a wide range of different types of meteorological and emission conditions that lead to observed ozone high ozone concentrations at monitoring sites in New Mexico.

Below we address each of EPA's episode selection criteria (EPA, 2018a, pp. 19) and the justification for using the summer 2014 modeling period for the NM OAI Study.

3.2.1 Model a Time Period that Corresponds to a Year with an Available National Emissions Inventory (NEI) and has Air Quality and Meteorological Data Available

NEI's are prepared every three years. The most recent currently available NEIs are for the 2011 and 2014 years. The 2017 NEI is in preparation and a usable version is not yet available. Thus, the 2014NEI is the latest NEI available.

3.2.2 Model Time Periods in which Observed Ozone Concentrations are Close to the Appropriate Base Year Ozone Design Values*.*

Appendix A presents the observed MDA8 ozone concentrations at monitoring sites within the proposed 4-km New Mexico domain including those in New Mexico (FIP State Code = 35). Observed DMAX8 ozone concentrations that exceed the 2015 ozone NAAQS are colored red. And ozone values that are above approximately 95% of the 2015 ozone NAAQS but below the ozone NAAQS (i.e., 67 ppb ≤ ozone < 70 ppb) are

colored yellow. The number of 2015 ozone NAAQS exceedances (i/e/., 71 ppb or higher) and between 67 and 71 ppb in the three main geographic regions in New Mexico are shown in Table 3-1.

For southeast New Mexico (e.g., Dona Ana County), the peak ozone in 2016 (79 ppb) is higher than in 2014 (76 ppb), but there are many more ozone exceedances days in 2014 (8) than 2016 (3). Both potential candidate modeling years have comparable levels to the observed highest 2014-2016 ozone DV in southeast New Mexico (74 ppb).The highest 2014-2016 ozone DV in northwest New Mexico is 70 ppb in San Juan County. Both candidate modeling years have a highest observed MDA8 ozone in 2014 and 2016 of 69 ppb and two days per year with ozone between 67 and 71 ppb.

Finally, for Bernalillo and Valencia Counties 2016 has a higher peak ozone than 2014 (70 vs. 68 ppb) and more days per year between 67 and 71 ppb (5 vs. 3 days per year).

Table 3-1. Maximum observed DMAX8 ozone concentrations and number of days ozone is above the 2015 ozone NAAQS or between 67 and 71 ppb in the three geographic regions of New Mexico and the 2014 and 2016 candidate modeling years.

NM Region	Max Ozone		Days ≥ 71 ppb		Days ≥ 67 ppb	
	2014	2016	2014	2016	2014	2016
NM All Sites	76	79	8	3	24	27
Albuquerque[a]	68	70	0	0	3	5
Southeast NM	76	79	8	3	21	22
Northwest NM	69	69	0	0	2	2

[a] The Albuquerque geographic region in this table included Bernalillo and Valencia Counties.

3.3 Episode Selection Conclusions

Based on the above analysis, the May-August summer season of 2014 was selected for modeling, because:

- 2014 has a PGM modeling database developed by the WRAP/WAQS.
- It corresponds with a NEI emissions year.
- The 2014 emissions have been reviewed and updated by the western states.
- The ozone air quality is comparable to current ozone DVs.
- It has more ozone exceedance days (8) than the other candidate year (3).

NMED Exhibit 15

4. MODELING DOMAIN SELECTION AND DATA AVAILABILITY

This Chapter summarizes the definition of the horizontal modeling domains for the NM OAI Study PGM modeling. This includes the map projection, domain coverage, grid resolution and grid nesting. As the vertical structure of the PGM model will be defined based on the vertical structure of the WRF meteorological model, it is discussed in Chapter 5. This Chapter also discusses emissions, aerometric and other data available for use in model input preparation and performance testing.

4.1 Horizontal Domain

The NM OAI Study modeling will use the same 36-km 36US and 12-km 12WUS2 domains as used in the WRAP/WAQS 2014 modeling platform. A 4-km New Mexico domain will be added to the 36/12-km domain structure. Figure 4-1 displays the 36/12/4-km domain structure with Figure 4-2 showing the 4-km New Mexico domain. New WRF 2014 36/12/4-km meteorological modeling will be conducted to generate finer scale 4-km meteorological conditions for the New Mexico domain and consistent meteorology among the 36/12/4-km domains.

CAMx will be run using the 36/12/4-km domain structure shown in Figure 4-1 using two-way interactive grid nesting.

NMED Exhibit 15

Grid	Origin (SW) (km)	Extent (NE) (km)	NX	NY
36-km	(-2736, -2088)	(2592, 1944)	148	112
12-km*	(-2388, -1236)	(336, 1344)	227	215
4-km*	(-1192, -1120)	(-212, -212)	245	227

*Definition includes outer row/column of buffer cells required by CAMx for nested domains

4.2 Data Availability

The CAMx modeling system requires emissions, meteorology, surface characteristics, initial and boundary conditions (IC/BC), and ozone column data for defining the inputs.

4.2.1 Emissions Data

Except for on-road mobile source emissions for the 4-km domain, the 2014 base year anthropogenic emissions inventory for New Mexico will be based on the WAQS 2014v2 emissions. The NMED will review the WAQS 2014v2 emissions for New Mexico and provide updates as needed. The sources of the 2014 emissions data are as follows.

- Major point source SO_2 and NO_x emissions will be based off measured Continuous Emissions Monitor (CEM) data that are available online from the EPA Clean Air Markets Division (CAMD[43]) website. These data are hour-specific for SO_2, NO_x, and heat input. The temporal variability of other pollutant emissions (e.g., PM) from the CEM sources will be simulated using the hourly CEM heat input data using the annual emissions from the WAQS 2014v2 emissions inventory.
- WRAP developed new 2014 oil and gas emissions for WRAP states that includes New Mexico that will be used. Outside of the WRAP states the EPA 2014NEI will be used.
- On-road mobile sources will be based on the EPA's MOVES2014 on-road emissions model (EPA, 2014a,b,c). The WAQS 36/12-km 2014v2 emissions will be used as is. Within the New Mexico 4-km domain, SMOKE-MOVES will be used

[43] http://www.epa.gov/AIRMARKETS/

with EPA's MOVES2014 2014 emission factor (EF) table and county-level vehicle activity data and 2014 hourly 4-km WRF meteorology developed in this study.

- The 2014 fire emissions developed for the 2014NEI and then updated by the WRAP Fire and Smoke Work Group will be used.
- 2014 biogenic emissions will be generated for the 36/12/4-km domains using version 3.1 of the Model of Emissions of Gases and Aerosols in Nature (MEGAN[44]) that was updated by WRAP[45] to include western U.S. plant types.
- Mexico and Canada emissions will be based on the EPA 2014 modeling platform.

4.2.2 Air Quality Data

Data from ambient air quality monitoring networks for gaseous species are used in the model performance evaluation. Table 4-3 summarizes routine ambient gaseous and PM monitoring networks available in the U.S. For this project only the routine ozone monitoring sites within the New Mexico 4-km modeling domain operating during 2014 (Figure 4-2) will be used to perform an operational evaluation of the CAMx 2014 4-km base case simulation.

NMED Exhibit 15

4.2.3 Ozone Column Data

Additional data used in the air quality modeling include ozone column data from the Ozone Monitoring Instrument (OMI) which continues the Total Ozone Mapping Spectrometer (TOMS) record for total ozone and other atmospheric parameters related to ozone chemistry (OMI officially replaced the TOMS ozone column satellite data on January 1, 2006). OMI data are available every 24-hours and are obtained from the TOMS ftp site.[46] The CAMx o3map program reads the OMI ozone column txt file data and interpolates to fill gaps and generated gridded daily ozone column input data. The OMI data are used in the CAMx (TUV) radiation models to calculate photolysis rates. The CAMx o3map processor also allows for the use of episode and monthly average data, although in this study daily data are used. Note that a new ozone column satellite product is available (OMPS) that may be used if appropriate.

4.2.4 Meteorological Data

Meteorological data for PGM modeling will be obtained from the WRF meteorological model as described in Chapter 5.

4.2.5 Initial and Boundary Conditions Data

Boundary conditions (BCs) for the 36-km 36US domain for both the base and future years will be derived from the output from a 2014 simulation of the GEOS-Chem global chemistry model conducted by WRAP.

[46] ftp://toms.gsfc.nasa.gov/pub/omi/data/

NMED Exhibit 15

5. WRF METEOROLOGICAL MODELING

This chapter describes how the Weather Research Forecasting (WRF) meteorological model will be used to generate 2014 36/12/4-km meteorological inputs for CAMx photochemical grid modeling. The WRF model contains separate modules to compute different physical processes, such as surface energy budgets and soil interactions, turbulence, cloud microphysics, and atmospheric radiation. Within WRF, the user has many options for selecting the different schemes for each type of physical process. The WRF Pre-processing System (WPS) generates the initial conditions (ICs) and boundary conditions (BCs) and analysis fields used by WRF, based on topographic datasets, land use information, and larger-scale atmospheric and oceanic models.

5.1 Description of WRF

WRF's research and operational application ensures state-of-the-science physics and adaptability to a wide range of environments, through a broad selection of physics options, allowing us to develop the best-performing configuration for simulating meteorology in the region.

The non-hydrostatic version of the Advanced Research version of the Weather Research and Forecast (WRF-ARW) model (Skamarock et al., 2005; 2008; 2019) is a three-dimensional, limited-area, primitive equation, prognostic model that has been used widely in regional air quality model applications. WRF is a next-generation mesoscale prognostic meteorological model routinely used in urban- and regional-scale photochemical, fine particulate and regional haze regulatory modeling studies. Developed jointly by the National Center for Atmospheric Research (NCAR) and NCEP, WRF is maintained and supported as a community model by researchers and practitioners around the globe. It is suitable for use in a broad spectrum of applications across scales ranging from hundreds of meters to thousands of kilometers.

5.2 WRF Model Domain

The PGM (CAMx) 2014 36/12/4-km modeling domains were shown in Figure 4-1 in the previous Chapter. The WRF 2014 36/12/4-km modeling domains are defined slightly larger than the PGM 36/12/4-km domains so that any modeling artifacts that occur near the WRF boundaries as the BCs come into dynamic balance with the WRF numerical algorithms are not present in the PGM meteorological inputs.

5.3 WRF Model Configuration

Below we summarized the proposed WRF configuration and input to be used to generate 2014 36/12/4-km meteorological inputs for the PGM 2014 photochemical modeling. WPS and WRF version 4.2 are used for this modeling analysis. Previous studies utilizing WRF at high resolution over New Mexico, such as the WRAP WestJumpAQMS, WAQS, Southern New Mexico Ozone Study (SNMOS) and EPA modeling platform development, have evaluated different configurations of WRF. Table 5-1 below summarizes the WRF configurations used in the WAQS 2014 and EPA 2014/2015/2016 WRF modeling. Preliminary analysis of WAQS 12 km model performance in New Mexico shows superior summertime precipitation performance

compared to EPA 2014 WRF modeling. Therefore, we propose that the NM OAI Study match the WRF physics configuration options used by 2014 WAQS modeling, except where noted below.

We propose to match the NM OAI 36/12-km WRF/PGM grid configuration (e.g., horizontal domains and vertical layer structure) with the WAQS 2014 WRF/PGM grid configuration in order the facilitate the use of data between the two studies. The following paragraphs describe the proposed WRF configuration for the NM OAI 2014 photochemical modeling.

5.3.1 Model Vertical Resolution

The WAQS 2011/2014 WRF modeling used 36 vertical levels (35 vertical layers) from the surface to a 50 mb (hPa) height (approximately 19-km above sea level). The EPA 2014 and 2015 WRF modeling used 35 vertical layers also up to a 50 mb height. Table 5-1 displays the 36-vertical layer structure used in the WAQS 2011/2014 WRF modeling that will be the layer structure proposed for our WRF 2014 NM OAI 36/12/4-km modeling.

NMED Exhibit 15

Table 5-1. WRF 36 level vertical layer structure for the NM OAI study. This is the same WRF layer structure as used in WAQS 2011/2014 WRF modeling.

WRF Layer	Sigma	Pressure (mb)	Height (m)	Thickness (m)
36	0.0000	50.00	19260	2055
35	0.0270	75.65	17205	1850
34	0.0600	107.00	15355	1725
33	0.1000	145.00	13630	1701
32	0.1500	192.50	11930	1389
31	0.2000	240.00	10541	1181
30	0.2500	287.50	9360	1032

2	0.9970	997.15	24	12
1	0.9985	998.58	12	12
0	1.0000	1000.00	0	

5.3.2 Vertical Coordinate

Since its inception, WRF has used the eta (sometimes called sigma or "terrain-following") vertical coordinate system. One weakness of the eta coordinate is that

variations in terrain (especially steep topography) can increase numerical errors in the model. To reduce these errors, Park et al., (2018) developed a hybrid sigma–pressure coordinate that is now included as the default vertical coordinate system for the WRF model (Skamarock et al., 2019).

In Figure 5-1, we present vertical cross sections of layer interface heights over the Rocky Mountains during a strong near-surface wind event (Park et al., 2018). The left panel shows the results using the eta or terrain-following vertical coordinate and the right panel shows the same results but using the hybrid vertical coordinate. The eta coordinate cross-sections show the influence of terrain extending high into the stratosphere. This is a representation of numerical noise and results in erroneous vertical motion in the model. Park et al., (2018) found that the simulation using the eta vertical coordinate produced high turbulence forecasts aloft which were not observed by pilots or soundings. In CAMx, erroneous vertical motion can help transport stratospheric ozone toward the surface. In contrast, the same simulation using the hybrid vertical coordinate produced lower turbulence forecasts that agreed more closely with observations. The hybrid vertical coordinate cross-sections show a gradual damping of terrain effects with increasing altitude until the layer interfaces are flat aloft. The purpose of using the hybrid vertical coordinate in the CAMx is to better represent ozone in the upper troposphere and lower stratosphere. Eliminating this source of numerical noise reduces spurious downward transport of stratospheric ozone.

We will use a new version of the WRFCAMx processor that has been updated to use WRF's hybrid vertical coordinate.

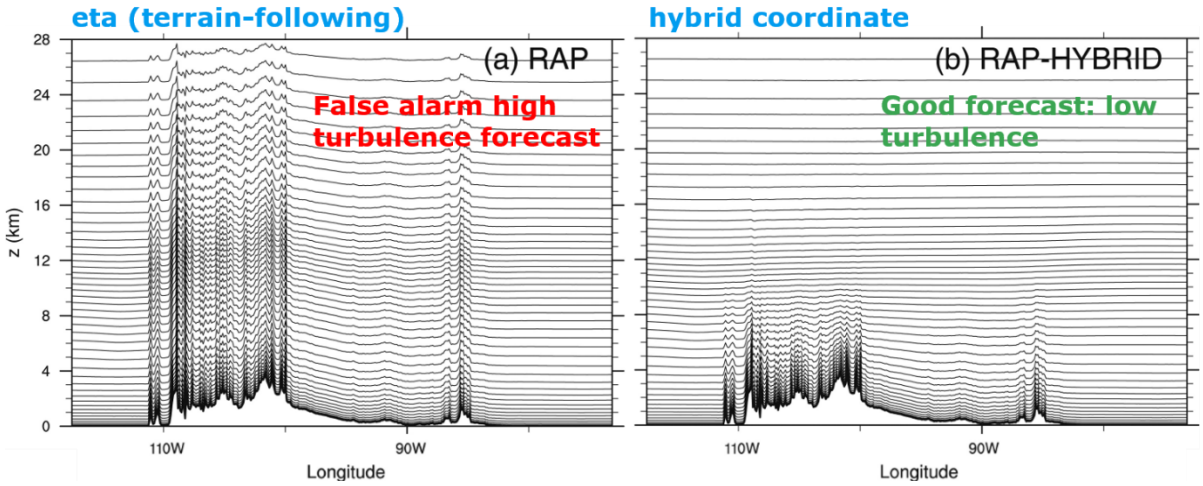

Figure 5-1. Cross-sections of layer interface heights over the Rocky Mountains for the eta (left panel) and hybrid (right panel) vertical coordinates for the WRF-Based Rapid Refresh (RAP) model. Adapted from Park et al., (2018).

5.3.3 Topographic Inputs

Topographic information for WRF will be based on a combination of the standard WRF terrain databases and high-resolution terrain. The 36-km 36US domain will use the 10-minute global data, the 12-km 12WUS2 domain will use the 2-minute data, and the 4-km New Mexico domain will use the 30 second data.

5.3.4 Vegetation Type and Land Use Inputs

Vegetation type and land use information will use the United States Geological Survey (USGS) land use databases from the most recently released WRF databases provided with the WRF distribution. Standard WRF surface characteristics corresponding to each land use category will be employed.

5.3.5 Atmospheric Data Inputs

WRF relies on other model or re-analysis output meteorological fields to provide initial and boundary conditions (IC/BC) and fields for the four-dimensional data assimilation (FDDA). FDDA refers to the nudging of the WRF meteorological fields to observed analysis fields so that the WRF meteorological fields better represent what was observed and prevent the model from drifting away from the observed meteorology. As seen in Table 5-2, both the WAQS 2014 and EPA 2014/2015/2016 12-km WRF modeling used the 12-km resolution North American (NAM) analysis fields for IC/BC and analysis nudging.

We propose to use both NAM and the ~30 km European Center for Medium-Range Weather Forecasting (ECMWF) Re-Analysis (ERA5[47]) dataset analysis fields for IC/BC and FDDA. We have found from previous work that the ERA-Interim (lower resolution predecessor to ERA5) dataset has lower humidity near the surface and higher humidity aloft, leading to lower convective available potential energy (CAPE), which lowers overall precipitation rates, especially during the summer Monsoon season. Many WRF simulations of the southwest U.S. summer Monsoon have featured an over-prediction of summertime (convective) precipitation when the NAM analysis fields are used. The Southern New Mexico Ozone Study (SNMOS) conducted PGM ozone sensitivity modeling using meteorological fields based on WRF simulations using the NAM and ERA analysis fields and found that the PGM ozone performance using the WRF/ERA meteorological inputs produced superior ozone performance than when WRF/NAM inputs were used.[48]

The ERA5 is a fairly new analysis fields product that has not been used in WRF modeling as extensively as the ERA fields. We will conduct WRF and PGM sensitivity modeling using the NAM and ERA5 analysis fields to determine which configuration provides the best meteorological inputs and potentially resultant ozone model performance. The ERA5 fields will be objectively re-analyzed using meteorological observational data to the higher resolution for the 36-km and 12-km grid domains using the OBSGRID program. These fields are used both to initialize the model and used with analysis nudging (on selected domains) to guide the model to best match the observations. The initialization dataset with the best WRF performance will be chosen for the final PGM configuration.

[48] https://www.wrapair2.org/SNMOS.aspx

NMED Exhibit 15

5.3.6 Time Integration

Third-order Runge-Kutta integration will be used (rk_ord = 3). The maximum time step, defined for the outer-most domain (36 km) only, should be set by evaluating the following equation:

$$dt = \frac{6dx}{F_{map}}$$

Where dx is the grid cell size in km, Fmap is the maximum map factor (which can be found in the output from REAL.EXE), and dt is the resulting time-step in seconds. For the case of the 36 km RPO domain, dx = 36 and Fmap = 1.08, so *dt* should be taken to be less than 200 seconds. Longer time steps risk CFL errors, associated with large values of vertical velocity, which tend to occur in areas of steep terrain (especially during stable conditions typical of winter). For this WRF run, adaptive time-stepping will be used with a maximum timestep of 180s.

5.3.7 Diffusion Options

Horizontal Smagorinsky first-order closure (km_opt=4) with sixth-order numerical diffusion and suppressed up-gradient diffusion (diff_6th_opt=2) will be used.

5.3.8 Lateral Boundary Conditions

Lateral boundary conditions will be specified from the initialization dataset on the 36-km WRF domain with continuous updates nested from each "parent" domain to its "child" domain, using one-way nesting (feedback=0).

5.3.9 Top and Bottom Boundary Conditions

The implicit Rayleigh dampening for the vertical velocity will be used for the top boundary conditions. Consistent with the model application for non-idealized cases, the bottom boundary condition was selected as physical, not free-slip.

5.3.10 Sea Surface Temperature Inputs

The water temperature data for the refined WRF configurations will be taken from the Fleet Numerical Meteorology and Oceanography Center (FNMOC)[49]. The FNMOC product has horizontal resolution of about 9-km in the mid-latitudes but is produced *four* times per day using AVHRR satellite sensors and in-situ observations.

5.3.11 Four Dimensional Data Assimilation (FDDA)

Analysis nudging will be used for winds, temperature, and humidity on the 36-km and 12-km domains. Both surface and aloft nudging will be used but nudging for temperature and mixing ratio will not be not performed within the boundary layer. Observation nudging will not be performed even on the 4-km domain.

[49] http://www.usgodae.org/cgi-bin/datalist.pl?summary=Go&dset=fnmoc_ghrsst

NMED Exhibit 15

5.3.12 New Lightning Data Assimilation

More recently, the assimilation of lightning data in WRF simulations has been shown to improve the locations and amounts of convective precipitation. The use of lighting detection networks, such as the National Lightning Detection Network (NLDN), have been used in WRF simulations and used to force deep convection (thunderstorms) when lightning is observed and only allow shallow convection when lightning is not present. The use of the new lightning assimilation approach has been demonstrated to improve both WRF convective precipitation as well as PGM concentration and deposition performance (Heath et al., 2016). The new lightning data assimilation algorithms will not be used in the 2014 WRF modeling for the NM OAI Study for the following reasons: (1) it would have to be tested and evaluated and there is insufficient time in the schedule to conduct such diagnostic testing; (2) the NLDN data used to date with the WRF lightning assimilation is a commercial product that is expensive and not in the budget; and (3) the implementation of the lightning detection data assimilation in WRF has a flaw that it doesn't distinguish between no lightning detects and missing data and suppresses convection in areas with missing data (e.g., over the Gulf of Mexico).

5.3.13 PBL and LSM Physics Options

The YSU Planetary Boundary Layer (PBL) and Noah Land Surface Model (LSM) physics options will be used in the NM OAI Study 2014 36/12/4-km modeling. Previous WRF sensitivity modeling for the IMW region found the YSU/Noah PBL/LSM schemes produces the most realistic meteorological fields. Note that EPA's 2014/2015/2016 WRF modeling uses the ACM2 PBL and Pleim-Xiu (PX) LSM schemes (Table 5-2). The WAQS tried to evaluate WRF using the ACM2/PX PBL/LSM and found it more difficult to implement and didn't always run so that annual fields could not be generated. Furthermore, the PX LSM scheme requires each run segment of a WRF run soil moisture inputs to be initialized using the previous WRF run segment PX output so that an annual WRF simulations must be run in series. This contrasts with the Noah LSM scheme that initializes soil moisture based on observations with some spin-up time (typically 12-hours) that allows annual WRF runs to be performed using parallel run segments (e.g., 5.5 day run segments). Thus, annual WRF simulations using the YSU/NOAH PBL/LSM physics options can be completed much faster than when ACM2/PX is used.

5.3.14 Remaining WRF Physics Options

Table 5-2 lists the remaining WRF physics options for the NM OAI Study 2014 36/12/4-km WRF application. These are standard WRF physics options and consistent with the WRF options used in the WAQS 2014 and EPA 2014/2015/2016 WRF modeling. Our preliminary comparison of 2014 WAQS and 2014 EPA WRF modeling for summertime precipitation performance in New Mexico finds that WAQS WRF outperformed EPA WRF modeling. Therefore, we propose to use the same microphysics and cumulus schemes for the NM OAI Study as used in 2014 WAQS (Thompson and Multi-Scale Kain-Fritsch, respectively).

NMED Exhibit 15

Table 5-2. Proposed NM OAI 2014 WRF model configuration and comparison with the WRF configuration used in the WAQS 2014 and EPA 2014/2015 WRF modeling.

WRF Option	Proposed NM OAI	2014 WAQS	2014/2015 EPA
Domains run	36/12/4-km	36/12/4-km	12-km
Microphysics	Thompson	Thompson	Morrison 2

Sea Sfc Temp	FNMOC	FNMOC	FNMOC

5.3.15 Application Methodology

The WRF model will be executed in 5.5-day blocks initialized at 12Z every five days. Model results will be output every 60 minutes, split at twelve (12) hour intervals. Twelve (12) hours of spin-up is included in each 5-day block before the data is used in the subsequent evaluation and PGM meteorological inputs.

5.4 WRF Model Evaluation

Quantitative and qualitative evaluations of the NM OAI Study 2014 WRF 36/12/4-km simulation will be conducted. The quantitative evaluations compare integrated surface hourly meteorological observations with WRF predictions matched by time and location. The qualitative evaluations compared time series plots of modeled wind speed and wind direction to the observations at specific sites. The evaluation is conducted for meteorological observation sites across the western U.S., with particular focus on sites within the 4-km New Mexico domain.

5.4.1 Quantitative Evaluation Using METSTAT

A quantitative model performance evaluation of the NM OAI Study 2014 WRF modeling will be performed using the publicly-available METSTAT software (Ramboll Environ, 2015) evaluation tool. Output from the WRF meteorological model will be compared

against meteorological observations from the various networks operating in the study area. This is carried out both graphically and statistically to evaluate model performance for surface winds, temperatures, humidity, and the placement, intensity, and evolution of key weather phenomena. The purpose of these evaluations is to establish a first-order acceptance/rejection of the simulation in adequately replicating the weather phenomena in the study area. Thus, this approach screens for obvious model flaws and errors.

5.4.1.1 Quantitative Statistics

The quantitative analysis will be conducted using METSTAT. Statistical measures calculated by METSTAT include observation and prediction means, prediction bias, and prediction error that are given as follows.

Mean Observation (M_o) is calculated using values from all sites for a given time period by Eq. **(5-1)**:

$$M_o = \frac{1}{IJ}\sum_{j=1}^{J}\sum_{i=1}^{I} O_j^i \qquad (5\text{-}1)$$

where O^i_j is the individual observed quantity at site i and time j, and the summations are over all sites (I) and over time periods (J).

Mean Prediction (M_p) is calculated from simulation results that are interpolated to each observation used to calculate the mean observation for a given time period by Eq. **(5-2)**:

$$M_p = \frac{1}{IJ}\sum_{j=1}^{J}\sum_{i=1}^{I} P_j^i \qquad (5\text{-}2)$$

where P^i_j is the individual predicted quantity at site i and time j. Note the predicted mean wind speed and mean resultant direction are derived from the vector-average (for east-west component u and north-south component v), from which the

Bias (B) is calculated as the mean difference in prediction-observation pairings with valid data within a given analysis region and for a given time period by Eq. **(5-3)**:

$$B = \frac{1}{IJ}\sum_{j=1}^{J}\sum_{i=1}^{I}\left(P_j^i - O_j^i\right) \qquad (5\text{-}3)$$

Gross Error (E) is calculated as the mean *absolute* difference in prediction-observation pairings with valid data within a given analysis region and for a given time period by Eq. **(5-4)**:

$$E = \frac{1}{IJ}\sum_{j=1}^{J}\sum_{i=1}^{I}\left|P_j^i - O_j^i\right| \qquad (5\text{-}4)$$

NMED Exhibit 15

Note that the bias and gross error for winds are calculated from the predicted-observed residuals in speed and direction (not from vector components *u* and *v*). The direction error for a given prediction-observation pairing is limited to range from 0 to ±180°.

Root Mean Square Error (RMSE) is calculated as the square root of the mean squared difference in prediction-observation pairings with valid data within a given analysis region and for a given time period by Eq **(5-5)**:

$$RMSE = \left[\frac{1}{IJ}\sum_{j=1}^{J}\sum_{i=1}^{I}\left(P_j^i - O_j^i\right)^2\right]^{\frac{1}{2}} \quad (5\text{-}5)$$

The RMSE, as with the gross error, is a good overall measure of model performance. However, since large errors are weighted heavily (due to squaring), large errors in a small sub-region may produce a large RMSE even though the errors may be small and quite acceptable elsewhere.

5.4.1.2 METSTAT Processing

METSTAT was developed to calculate and graphically present statistics associated with temporally paired meteorological model predictions and observations. The horizontal analysis range can be given for an entire output grid, by a coordinate box, or as a list of specific site identifiers (such as WBAN or AIRS numbers), as labeled on the observational file. This allows for an evaluation at a single site, a subset of specific sites (e.g., within a state) or over an entire regional domain. The program then proceeds to calculate statistics for each hour and for each day of the time window.

The process involves statistical comparisons of model data from the WRF grid cells to observational measurements located with each grid cell. METSTAT evaluates wind speed and direction, air temperature, and air humidity using both bias and error statistics. METSTAT has been widely applied to WRF runs for many years, across many modeling domains. Using a consistent definition of the statistical quantities to be calculated and a consistent methodology for pairing observations in time, METSTAT allows for more straightforward comparisons between model applications in widely different regions and time periods.

5.4.2 Statistical Benchmarks

METSTAT calculates statistical performance metrics for bias, error and correlation for surface winds, temperature, and mixing ratio (i.e., water vapor or humidity). To evaluate the performance of a meteorological model simulation for air quality model applications, a number of performance benchmarks for comparison are typically used. Table 5-3 lists the meteorological model performance benchmarks for simple (Emery et al., 2001) and complex (Kemball-Cook et al., 2005) situations. The simple benchmarks were developed by analyzing well-performing meteorological model evaluation results for simple, mostly flat terrain conditions and simple meteorological conditions (e.g., stationary high pressure) that were mostly conducted to support air quality modeling studies (e.g., ozone SIP modeling). The complex benchmarks were developed during the Western Regional Air Partnership (WRAP) regional haze modeling and are

performance benchmarks for more complex conditions, such as the complex terrain of the Rocky Mountains and Alaska (Kemball-Cook et al., 2005). McNally (2009) analyzed multiple annual runs that included complex terrain conditions and suggested an alternative set of benchmarks for temperature under more complex conditions. The purpose of the benchmarks is to understand how good or poor the results are relative to other model applications run for the U.S.

The NM OAI Study 2014 WRF application will compare the WRF meteorological variables to the benchmarks as an indication of WRF model performance. These benchmarks include bias and error in temperature, wind direction and mixing ratio as well as the wind speed bias and Root Mean Squared Error (RMSE) between the models and databases.

Table 5-3. Meteorological model performance benchmarks for simple and complex conditions.

Parameter	Emery et al. (2001)	Kemball-Cook et al. (2005)	McNally (2009)	Resulting Criteria
Conditions	Simple	Complex	Complex	Complex
Temperature Bias	≤ ±0.5 K	≤ ±2.0 K	≤ ±1.0 K	≤ ±1.0 K
Temperature Error	≤ 2.0 K	≤ 3.5 K	≤ 3.0 K	≤ 3.0 K
Temperature IOA	≥ 0.8	(not addressed)	(not addressed)	≥ 0.8
Humidity Bias	≤ ±1.0 g/kg	≤ ±0.8 g/kg	≤ ±1.0 g/kg	≤ ±1.0 g/kg
Humidity Error	≤ 2.0 g/kg	≤ 2.0 g/kg	≤ 2.0 g/kg	≤ 2.0 g/kg
Humidity IOA	≥ 0.6	(not addressed)	(not addressed)	≥ 0.6
Wind Speed Bias	≤ ±0.5 m/s	≤ ±1.5 m/s	(not addressed)	≤ ±1.5 m/s
Wind Speed RMSE	≤ 2.0 m/s	≤ 2.5 m/s	(not addressed)	≤ 2.5 m/s
Wind Speed IOA	≥ 0.6	(not addressed)	(not addressed)	≥ 0.6
Wind Dir. Bias	≤ ±10 degrees	(not addressed)	(not addressed)	≤ ±10 degrees
Wind Dir. Error	≤ 30 degrees	≤ 55 degrees	(not addressed)	≤ 55 degrees

The output from the 2014 36/12/4-km WRF simulations will be compared against meteorological data obtained from the National Climate Data Center's (NCDC) global-scale, quality-controlled DS3505 integrated surface hourly observational (ISHO) data (NOAA-NCDC, 2015) as verification data. Global hourly and synoptic observations are compiled from numerous sources into a single common ASCII format and common data model. The DS3505 database contains records of most official surface meteorological stations from airports, military bases, reservoirs/dams, agricultural sites, and other sources dating from 1901 to the present.

A standard set of statistical metrics from the METSTAT package will be used. These metrics will be calculated on hourly, daily and monthly time frames for wind speed, wind direction, temperature, and humidity at the surface, using all available observational weather data. The WRF surface meteorological model performance metrics will be compared against the simple and complex model performance goals using "soccer plots." Soccer plots use two WRF performance metrics as X-axis and Y-axis values (e.g., temperature bias as X, and temperature error as Y) along with the

performance benchmarks. The closer the symbols are to the zero origin, the better the model performance. It is also easy to see when the two WRF performance metrics fall within the benchmark lines. Figure 5-2 displays an example WRF monthly temperature soccer plot from the 2011 WRF simulations used in the 2017 Denver ozone SIP modeling. We will present WRF 2014 monthly-averaged surface meteorological model performance from the 4-km New Mexico domain with additional performance products produced for the 12-km 12WUS2 and 36-km 36US domains.

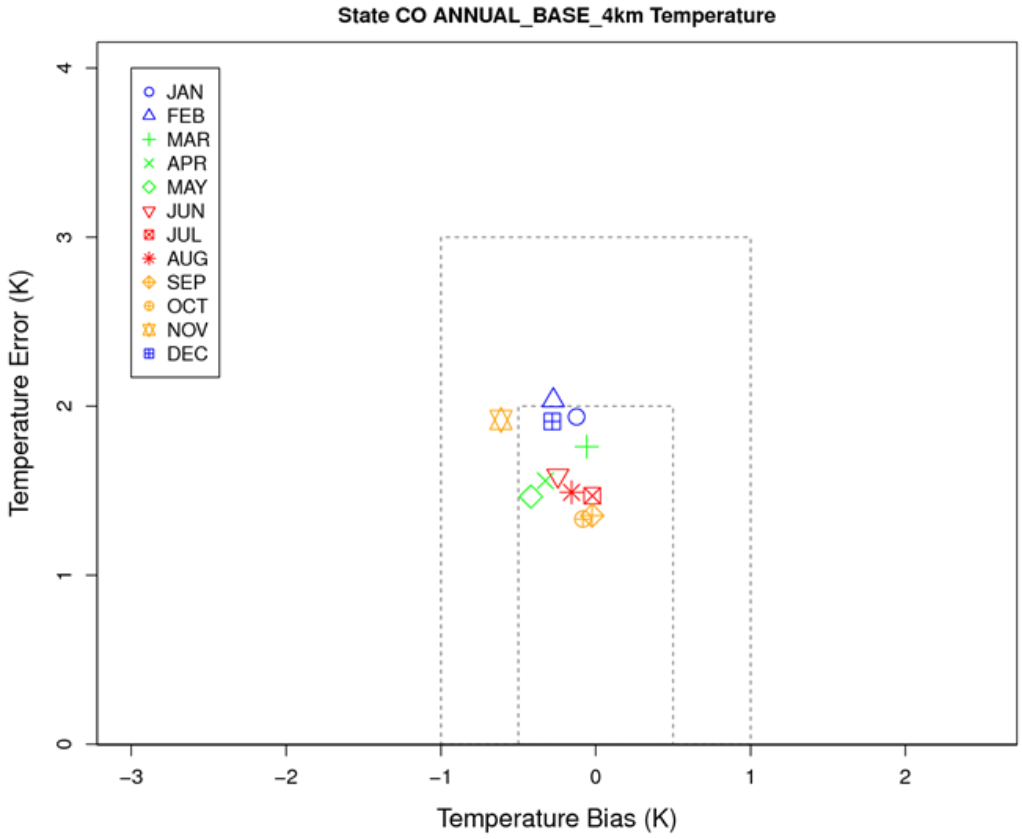

Figure 5-2. Example Soccer plot of monthly temperature error and bias (K) for 4-km domain.

5.4.3 Qualitative Evaluations Using PRISM Data

Oregon State University (OSU) publishes precipitation analysis fields based on observations that can be used to qualitatively evaluate the WRF precipitation fields. The Parameter-elevation Relationships on Independent Slopes Model (PRISM[50]) is used to generate the precipitation analysis fields (Daly et al., 2008). The PRISM interpolation method was used to develop data sets that reflected, as closely as possible, the current state of knowledge of spatial climate patterns in the United States. PRISM calculates a climate – elevation regression for each digital elevation model

[50] http://prism.oregonstate.edu/

(DEM) grid cell, and stations entering the regression are assigned weights based primarily on the physiographic similarity of the station to the grid cell. Factors considered are location, elevation, coastal proximity, topographic facet orientation, vertical atmospheric layer, topographic position, and orographic effectiveness of the terrain.

Spatial plots of the WRF monthly precipitation fields will be compared with the PRISM spatial maps for the 12-km 12WUS2 and 4-km New Mexico modeling domains in a qualitative model evaluation (note that PRISM does not include any analysis fields outside of the U.S.). Daily PRISM precipitation fields will be compared against the WRF daily spatial maps within the 12WUS2 domain and the New Mexico 4-km domain. The WRF performance for daily convective precipitations will be analyzed in particular as overstated summer convective precipitation can suppress ozone formation and its correct simulation is critically important for ozone modeling in New Mexico during the summer monsoon season. In the past WRF has had difficulty in accurately predicting the spatial extent and magnitude of the summer convective precipitation in the IMW region. Note that the PRISM precipitation interpolation scheme works better for synoptic weather systems than for convective showers that can be spotty and intermittent. So even though quantitative statistics can be calculated using the PRISM and WRF precipitation data, the evaluation will still be qualitative in nature as the PRISM interpolation scheme has greater uncertainties for convective precipitation.

NMED Exhibit 15

6. PGM BASE YEAR INPUT PREPARATION PROCEDURES

This section summarizes the procedures to be used for developing the base case meteorological, emissions, and air quality inputs for the CAMx photochemical grid model and the summer 2014 modeling period. The modeling procedures used in the NM OAI Study modeling are consistent with almost 30 years of EPA ozone modeling guidance documents (e.g., EPA, 1991; 1999; 2005a; 2007; 2014d; 2018d), past modeling studies of the western U.S. conducted by WRAP and others (see, for example, Morris et al., 2004a,b, 2005a,b; 2007; 2008a,b,c; Tesche et al., 2005a,b; Stoeckenius et al., 2009; ENVIRON, Alpine and UNC, 2013; Adelman, Shankar, Yang and Morris, 2014; 2016), Denver 8-hour ozone SIP modeling (Morris and Mansell, 2003a; Morris et al., 2004d; Morris et al., 2008a,b; Ramboll and Alpine, 2016a,b; 2017a; RAQC and CDPHE, 2017) as well as the methods used by EPA in support of their recent Transport analysis (EPA, 2010; 2015b, EPA, 2016c) and national regional haze modeling (EPA, 2019).

6.1 Meteorological Inputs

Procedures for WRF meteorological modeling for the NM OAI Study 2014 36/12/4-km applications were described in Chapter 5. The WRF meteorological model output data will be processed to provide inputs for the CAMx photochemical grid model.

6.1.1 WRFCAMx Processing of 2014 WRF Output

The WRFCAMx processor maps WRF meteorological fields to the format required by CAMx. It also calculates turbulent vertical exchange coefficients (Kz) that define the rate and depth of vertical mixing in CAMx. Steps in the WRFCAMx processing include:

- Reading in meteorological model output files;
- Extracting meteorological data for PGM domain;
- Collapsing meteorological data if coarser vertical resolution data is requested in the PGMs than used in WRF;
- Computing vertical diffusivities (Kz); and
- Output the meteorological fields in the formats used by CAMx.

Several options are available to derive vertical turbulent exchange coefficient (also known as: Kv, Kz or vertical diffusivity) fields from WRF output in WRFCAMx. When TKE (turbulent kinetic energy) is not available from the WRF output (as is the case with the YSU PBL selected WRF physics options), Kv fields are diagnosed from wind, temperature, and Planetary Boundary Layer (PBL) parameters in WRFCAMx. For this application the CMAQ-like Kv profile option was selected in WRFCAMx, although the YSU Kv profile options will also be investigated.

6.1.2 Treatment of Minimum Kv

The CAMx Kv_patch pre-processor program sets the minimum Kv value to 0.1 to 1.0 m^2/s depending on the amount urban land use category in grid cell in the lowest 100 m

NMED Exhibit 15

of the atmosphere. This is done to account for the urban heat island effect that enhances vertical mixing through-out the day.

6.2 Emission Inputs

6.2.1 Available Emissions Inventory Datasets

The emissions inventories developed for the CAMx 2014 36/2/4-km base case modeling will be based on the WRAP/WAQS 2014v2 emissions inventory. Within the 36-km 36US North American and 12-km 12WUS2 western U.S. domains, the 2014v2 base case emissions developed by WRAP/WAQS will be used as is.

For the 4-km New Mexico domain, the WRAP/WAQS 2014v2 emissions will be reviewed by the NMED, who will provide updates as needed. For on-road mobile sources, the 4-km domain emissions will be based on MOVES2014 model, 2014 activity data and day-specific hourly gridded 2014 WRF meteorology run through SMOKE-MOVES.

6.2.2 Development of CAMx Emission Inputs

CAMx emission inputs will be generated mainly by the SMOKE and MEGAN emissions models. CAMx requires two emission input files for each day: (1) low level gridded emissions that are emitted directly into the first layer of the model from sources whose emissions are released at the surface with little or no plume rise; and (2) elevated point sources (stacks) with plume rise calculated from stack parameters and meteorological conditions. CAMx will be operated using version 6 revision 4 of the Carbon Bond chemical mechanism (CB6r4) (Yarwood et al., 2010).

A 2014 base case 4-km New Mexico domain emission inputs for CAMx and the May to August 2014 modeling period will be based on the WRAP/WAQS 2014v2 emissions that were based on the 2014NEIv2 with updates provide by the western states. The New Mexico emissions from the 2014v2 database will be reviewed by the NMED who will provide updates as needed. The 2014v2 emissions for New Mexico and portions of surrounding states within the 4-km New Mexico domain will be processed by the Sparse Matrix Operator Kernel Emissions (SMOKE) modeling system (UNC, 2015). SMOKE version 4.7 is the current version of SMOKE that was released in October 2019.[51]

6.2.2.1 Day-Specific On-Road Mobile Source Emissions

The 2014 on-road mobile source emission inputs for the 4-km New Mexico domain will be generated using the SMOKE-MOVES emissions model. SMOKE-MOVES will use a 2014 mobile source emission factor (EF) lookup table generated by the Motor Vehicle Emission Simulator (MOVES2014[52]) model (EPA, 2014a,b,c). The SMOKE-MOVES default county-level 2014 vehicle activity data for New Mexico will be reviewed by NMED and updated as needed. SMOKE-MOVES uses the 2014 MOVES EF lookup table, hourly gridded 4-km meteorological data from the 2014 WRF simulation conducted in this study and 2014 county-level activity data (e.g., vehicle miles travelled [VMT],

[51] https://www.cmascenter.org/smoke/

[52] http://www.epa.gov/oms/models/moves/#user

speed, etc.) to generate 2014 day-specific hourly gridded on-road mobile source emission inputs for CAMx and the 4-km New Mexico domain.

6.2.2.2 Point Source Emissions

2014 point source emissions will be based on the WRAP/WAQS 2014v2 emissions inventory. The 2014v2 New Mexico point source emissions will be reviewed by NMED and updated a needed. Point sources will be processed in two streams: (1) major point sources with Continuous Emissions Monitoring (CEM) devices, which are primarily fossil-fueled Electrical Generating Units (EGU) with capacity of 25 MW or greater; and (2) point sources without CEMs. For point sources with CEM data, day-specific hourly NO_X and SO_2 emissions will be used for the 2014 base case emissions scenario. The VOC, CO and PM emissions for point sources with CEM data will be based on the annual data in the 2014v2 inventory temporally allocated to each hour of the year using the CEM hourly heat input. The hourly CEM data available in the Acid Rain database on the EPA Clean Air Market Division (CAMD) website fills hours with missing CEM data with maximum potential to emit (PTE) emission rates and flags the data. This is because the purpose of the Acid Rain database is to assure that the source is not emitting higher emissions than its cap. Using PTE emissions rates is inappropriate for PGM modeling since the goal is to be accurate. Thus, a data filling program is used that uses the missing data flags to identify hours when the data filled PTE emissions occur, and they are replaced with typical emission rates.

For all point sources the locations of the point sources will be converted to the LCC coordinate system used in the modeling. Non-CEM point sources will be processed by SMOKE to generate the temporally varying (i.e., seasonal, day-of-week and hour-of-day) speciated emissions needed by CAMx. The 2014 point source emissions without CEM data will be processed using SMOKE using the default temporal (e.g., monthly, day-of-week and hourly) and speciation profiles.

6.2.2.3 Area and Non-Road Source Emissions

The 2014v2 area and non-road sources will be spatially allocated to the 4-km New Mexico grid using an appropriate surrogate distribution (e.g., population for home heating, etc.). The area sources will be temporally allocated by month and by hour of day using the SMOKE source-specific temporal allocation factors. The SMOKE source-specific CB6r4 speciation allocation profiles will also be used.

6.2.2.4 Episodic Biogenic Emissions

Biogenic emissions will be generated using Version 3.1 of the MEGAN biogenic emissions model. MEGAN uses high resolution GIS data on plant types and biomass loadings and the 2014 WRF surface temperature fields, and solar radiation to develop hourly emissions for biogenic species on the 36/12/4-km grids. MEGAN generates gridded, speciated, temporally allocated emission files. The MEGAN biogenic emissions will be used for the 36-km 36US, 12-km 12WUS2 and 4-km New Mexico modeling domains. Note that the BEIS biogenic emissions were used in the WRAP/WAQS 2014v2 modeling platform. WRAP/WAQS conducted sensitivity tests using MEGAN v3.0 and BEIS biogenic emissions and found they produced comparable ozone estimates (because the isoprene emissions were similar), but CAMx with BEIS has better Organic

Aerosol (OA) performance[53] than CAMx with MEGAN v3.0 biogenic emissions so WAQS selected BEIS. Since then MEGAN has been updated to version 3.1 and the CAMx OA performance is now similar using MEGAN v3.1 and BEIS.

6.2.2.5 Wildfires, Prescribed Burns, Agricultural Burns

2014 emissions from open-land burning including wildfires, prescribed burns and agricultural burning will be based on the WRAP/WAQS 2014v2 emissions inventory. The WRAP Fire and Smoke Work Group (FSWG[54]) processed the 2014NEIv2 Bluesky/SMARTFIRE fire emissions for the U.S. and classified them as either wildfires (WF), prescribed burns (Rx) or agricultural burning (Ag) and made other updates for the 2014v2 inventory. The 2014NEIv2 fire emissions for Mexico and Canada will be used as is.

6.2.2.6 Other Natural Emissions

Lightning NO_x (LNOx), oceanic sea salt (SSA) and dimethyl sulphide (DMS) and windblown dust (WBD) emissions will be generated using special CAMx processors and WRF 2014 meteorological data.

6.2.2.7 QA/QC and Emissions Merging

The emissions for the 4-km New Mexico domain will be processed by major source category in several different "streams", including area sources, on-road mobile sources, non-road mobile sources, biogenic sources, non-CEM point sources, CEM point sources using day-specific hourly emissions, and emissions from fires. Separate Quality Assurance (QA) and Quality Control (QC) will be performed for each stream of emissions processing and in each step following the procedures developed by WRAP (Adelman, 2004). SMOKE includes advanced quality assurance features that include error logs when emissions are dropped or added. In addition, we will generate visual displays that include:

- Spatial plots of the hourly emissions for each major species (e.g., NO_X, VOC, and CO).
- Summary tables of emissions for major species for each grid and by major source category.
- This QA information will be examined against the original point and area source data and summarized in an overall QA/QC assessment.

Scripts to perform the emissions merging of the appropriate biogenic, on-road, non-road, area and low-level point sources (i.e., point sources with little or no plume rise so they are released into the first layer of the PGM) emission files will be written to generate the CAMx-ready two-dimensional day and domain-specific hourly speciated gridded emission inputs. The point source and fire, emissions would be processed into the day-specific hourly speciated emissions in the CAMx-ready point source format.

[53] http://views.cira.colostate.edu/iwdw/docs/waqs_2014v1_shakeout_study.aspx

[54] https://www.wrapair2.org/FSWG.aspx

NMED Exhibit 15

For the 36/12-km domains we plan on using the model-ready emissions from the WRAP/WAQS 2014v2 modeling platform, with the exception of biogenic emissions where we would replace the BEIS biogenic emissions with those from MEGAN.

The resultant CAMx model-ready emissions will be subjected to a final QA using spatial maps to: (1) assure that the emissions were merged properly and CAMx inputs contain the same total emissions; and (2) provide additional QA/QC information.

6.2.2.8 Use of the Plume-in-Grid (PiG) Subgrid-Scale Plume Treatment

CAMx includes a Plume-in-Grid (PiG) sub-model treats the early plume chemistry and dynamics of emissions from point sources and then releases the emissions into the grid model farther downwind at such time that the plume is adequately resolved by the grid. Large NO_X emissions point sources within the 4-km New Mexico domain will be selected for treatment by the subgrid-scale PiG module. The selection of which sources to be treated by the PiG module will be made after a review of the inventory.

6.2.2.9 QA/QC of Model-Ready Emissions

In addition to the CAMx-ready emission input files generated for each hour of all days modeled in the May-August 2014 modeling period, a number of quality assurance (QA) files will be prepared and used to check for gross errors in the emissions inputs. Importing the model-ready emissions into PAVE or VERDI and examine both the spatial and temporal distribution of the emission to investigate the quality and accuracy of the emissions inputs.

- Visualizing the model-ready emissions with the scale of the plots set to a very low value, we can determine whether there are areas omitted from the raw inventory or if emissions sources are erroneously located in water cells;
- Spot-checking the holiday emissions files to confirm that they are temporally allocated like Sundays;
- Producing pie charts emission summaries that highlight the contribution of each emissions source component (e.g. non-road mobile);
- Normalizing the emissions by population for each state will illustrate where the inventories may be deficient and provide a reality check of the inventories.

State inventory summaries prepared prior to the emissions processing will be used to compare against SMOKE output report totals generated after each major step of the emissions generation process. To check the chemical speciation of the emissions to CB6 species, we will compare reports generated with SMOKE to target these specific areas of the processing. For speciation, the inventory state import totals will be compared against the same state totals with the speciation matrix applied.

The quantitative QA analyses often reveal significant deficiencies in the input data or the model setup. It may become necessary to tailor these procedures to track down the source of each major problem. As such, one can only outline the basic quantitative QA steps that we will perform in an attempt to reveal the underlying problems with the inventories or processing.

NMED Exhibit 15

6.3 Photochemical Model Inputs

6.3.1 PGM Science Configuration and Input Configuration

This section describes the CAMx configuration and science options to be used in the NM OAI Study ozone modeling. Table 6-1 summarizes the CAMx configuration to be used, with more details provided below.

6.3.1.1 PGM Model Versions

The latest version 7.0 (v7.0) of CAMx will be used in the NM OAI Study. This is the same version as used in the WRAP/WAQS 2014v2, Representative Baseline and 2028 On-the-Books (OTB) modeling as well as EPA in their national Regional Haze modeling (EPA, 2019). The model will be configured to predict both ozone and PM species.

6.3.1.2 PGM Grid Nesting Strategy

CAMx will be operated using the 36/12/4-km nested grid structure using two-way grid nesting for all simulations.

6.3.1.3 Initial and Boundary Conditions

Boundary Conditions for the CAMx most outer 36-km 36US modeling domain will be based on output from a 2014 simulation of the GEOS-Chem global chemistry conducted by WRAP for their 2014v2 modeling platform. For their 2014v1 modeling platform WRAP used BCs based on EPA's 2014 GEOS-Chem simulation. EPA's 2014 modeling platform was used in the 2014 National Air Toxics Assessment (NATA[55]). However, EPA's 2014 BCs produced a large sulfate overestimation bias in June and July and a year-round ozone overestimation bias. So, WRAP conducted their own 2014 GEOS-Chem modeling to generate new BCs that did not have those problems.

CAMx will be started on May 1, 2016 using the 36/12/4-km domains that will give it over two-weeks to initialize the model before the first high ozone day on May 17, 2014.

6.3.1.4 Other PGM Model Options

The CAMx model options and setup are defined in Table 6-1. The PPM advection solver (Colella and Woodward, 1984) will be used for horizontal transport along with the spatially varying (Smagorinsky) horizontal diffusion approach. K-theory will be used for vertical diffusion. The CB6r4 gas-phase chemical mechanism is selected because it includes the very latest chemical kinetic rates with halogen chemistry that affects ozone levels over the ocean. The latest aerosol mechanism will be used in CAMx along with the standard wet and dry deposition schemes. The Plume-in-Grid module will be used to treat the near-source chemistry and dispersion of major NO_X emissions sources in the New Mexico 4-km domain. For the future year modeling the same point sources will be selected for the plume-in-grid treatment, if they are still operating.

NMED Exhibit 15

Table 6-1. CAMx model configuration for the NM OAI Study.

Science Options	CAMx	Comment
Model Codes	CAMx v7.0	Latest version of CAMx used in WRAP/WAQS 2014v2 and EPA Regional Haze modeling
Horizontal Grid Mesh	36/12/4-km	
36-km grid	148 x 112 cells	36US domain
12-km grid	227 x 215 cells	12WUS2 domain. Includes buffer cells
4-km grid	245 x 227 cells	New Mexico 4-km domain. Includes buffer cells
Vertical Grid Mesh	25 vertical layers, defined by WRF	Layer 1 thickness ~20 m. Model top at 50 mb (~19 km)
Grid Interaction	36/12/4 km two-way nesting	
Initial Conditions	Start on May 1, 2014	First high ozone day is May 17, 2014
Boundary Conditions	WRAP 2014 GEOS-Chem	For 36US domain
Emissions		
Baseline Emissions Processing	SMOKE, SMOKE-MOVES2014, MEGAN	WRAP/WAQS 2014v2 emissions and EPA 2023fh for future year
Sub-grid-scale Plumes	Plume-in-Grid for major NO_X sources in New Mexico	Keep same PiG sources in 2014 and 2023 emission years
Chemistry		
Gas Phase Chemistry	CB6r4	Latest chemical reactions and kinetic rates with halogen chemistry (Yarwood et al., 2010)
Meteorological Processor	WRFCAMx	Compatible with CAMx v7.0
Horizontal Diffusion	Spatially varying	K-theory with Kh grid size dependence
Vertical Diffusion	CMAQ-like Kv	Evaluate YSU Kv scheme
Diffusivity Lower Limit	Kv-min = 0.1 to 1.0 m^2/s in lowest 100 m	Depends on urban land use fraction
Deposition Schemes		
Dry Deposition	Zhang dry deposition scheme	(Zhang et. al, 2001; 2003)
Wet Deposition	CAMx -specific formulation	rain/snow/graupel
Numerics		
Gas Phase Chemistry Solver	Euler Backward Iterative(EBI)	EBI fast and accurate solver
Vertical Advection Scheme	Implicit scheme w/ vertical velocity update	Emery et al., (2009a,b; 2011)
Horizontal Advection Scheme	Piecewise Parabolic Method (PPM) scheme	Colella and Woodward (1984)
Integration Time Step	Wind speed dependent	~0.5-1 min (4-km), 1-5 min (12-km), 5-15 min (36-km)

7. 2014 BASE CASE MODELING AND MODEL PERFORMANCE EVALUATION

This Chapter describes the CAMx 2014 base case simulations and procedures for model performance evaluation (MPE). The primary purposes of the MPE is to establish the reliability of the CAMx 2014 base case modeling for predicting maximum daily average 8-hour (MDA8) ozone and related concentrations in New Mexico to have confidence that the modeled ozone responses to changes in emissions within New Mexico are accurate enough for air quality planning. The CAMx 2014 base case model estimates are compared against the observed ambient ozone and other concentrations to establish that the model is able to reproduce the current year observed concentrations, so it is likely a reliable tool for estimating future year ozone levels. The model performance evaluation will include many types of graphical and statistical comparisons of the predicted and observed ozone concentrations including spatial plots, scatter plots and time series analysis.

7.1 2014 Base Case Modeling

A CAMx 2014 May-August 36/12/4-km base case simulation will be performed following the procedures outlined in the previous Chapters. The CAMx 2014 base case simulations will then be subjected to a model performance evaluation following the procedures outlined in this Chapter.

7.2 EPA Model Performance Evaluation Recommendations

7.2.1 Overview of EPA Model Performance Evaluation Recommendations

EPA's ozone modeling guidance (EPA, 2018d) describes a MPE framework that has four components:

- Operation Evaluation: The Operation Evaluation compares the modeled concentration estimates against concurrent observations using statistical and graphical analysis aimed at determining how well the model simulates the base year observed concentrations (i.e., does the model get the right answer).
- Diagnostic Evaluation: The Diagnostic Evaluation evaluates various components of the modeling system. It focuses on process-oriented evaluation and whether the model simulates the important processes for the air quality problem being studied (i.e., does the model get the right answer for the right reason).
- Dynamic Evaluation: The ability of the model's air quality predictions to correctly respond to changes in emissions and meteorology is part of the Dynamic Evaluation. This can include running the model for historical years to see whether the model's predictions match the changes in observations; comparison of model performance on weekdays versus weekend days can also help elucidate whether the model response to changes in emissions correctly.
- Probabilistic Evaluation: The Probabilistic Evaluation assess the level of confidence in the model predictions and estimates model uncertainty through techniques such as ensemble model simulations.

NMED Exhibit 15

EPA's guidance recommends that "At a minimum, a model used for air quality planning should include a complete operational MPE using all available ambient monitoring data for the base case model simulations period" (EPA, 2018d, pg. 68). And goes on to say, "Where practical, the MPE should also include some level of diagnostic evaluation." EPA notes that there is no single definite test for evaluating model performance, but instead there are a series of statistical and graphical MPE elements to examine model performance in as many ways as possible while building a "weight of evidence" (WOE) that the model is performing sufficiently well for the air quality problem being studied.

7.2.2 WRAP/WAQS Companion Model Performance Evaluation

The WRAP/WAQS has conducted CAMx 2014v2 36/12-km base case modeling and MPE. The MPE of the WRAP/WAQS 2014v2 platform results will be used to help interpret the NM OAI Study MPE and put it into context.

7.3 Overview of Evaluation of CAMx 2014 Base Case Procedures

This section describes the procedures for evaluating the performance of the CAMx model focusing on ozone and related species in New Mexico.

7.3.1 Photochemical Model Evaluation Methodology

The CAMx performance evaluations will follow the procedures recommended in the EPA photochemical modeling guidance documents (EPA, 1991; 1999; 2005a; 2007; 2014d; 2018d), EPA MPE Checklist (EPA, 2015a,b), procedures discussed by Boylan and Russell (2006), Simon, Baker and Phillips (2012) and Emery and co-workers (2016). The NM OAI Study CAMx 2014 MPE will be conducted in a series of levels with each level diving more deeply into the MPE. An initial performance would focus on ozone performance at key monitors in New Mexico in 2014 to identify systematic problems that would require immediate corrective action. The MPE would then be expanded to ozone and ozone precursors across New Mexico and nearby states, especially those portions within the 4-km New Mexico domain. Finally, a broad-brush evaluation would be conducted across the western U.S. for ozone and where available its precursors.

7.3.2 Model Performance Goals and Benchmarks

EPA first proposed the use of ozone model performance goals in their 1991 ozone modeling guidance (EPA, 1991) with goals for bias (≤±15%) and error (≤35%). Since then, EPA has de-emphasized the use model performance goals as some users were focusing on achieving the model performance goals not on whether the model was accurately simulating atmospheric processes that led to the high ozone concentrations. However, model performance goals are still useful for interpreting model performance and putting the model performance into context. Since the EPA 1991 ozone guidance performance goals, Boylan and Russell (2006) extended the performance goals to PM species and visibility. Simon, Baker and Phillips (2012) summarized the model performance statistics from 69 PGM applications from 2006 to 2012 and found lots of variability but were able to isolate model performance statistical levels for the best performing models.

Emery et al., (2016) built off the work of Simon, Baker and Phillips (2012) adding additional PGM model applications and coming up with a set of PGM model performance

goals and criteria based on the variability in the past PGM model performance. "Goals" indicate statistical values that about a third of the top performance past PGM applications have met and should be viewed as the best a model can be expected to achieve. "Criteria" indicates statistics values that about two thirds of past PGM applications have met and should be viewed as what a majority of the models have achieved. We will compare the CAMx 2014 base case simulations model performance statistics for normalized mean bias (NMB), normalized mean error (NME) and correlation coefficient (r) against the model performance goals and criteria summarized by Emery et al., (2016) that are given in Table 7-1.

Table 7-1. Recommended benchmarks for photochemical model statistics (Source: Emery et al., 2016).

Species	NMB		NME		r	
	Goal	Criteria	Goal	Criteria	Goal	Criteria
1-hr & MDA8 Ozone	<±5%	<±15%	<15%	<25%	>0.75	>0.50
24-hr $PM_{2.5}$, SO_4, NH_4	<±10%	<±30%	<35%	<50%	>0.70	>0.40
24-hr NO_3	<±15%	<±65%	<65%	<115%	NA	NA
24-hr OC	<±15%	<±50%	<45%	<65%	NA	NA
24-hr EC	<±20%	<±40%	<55%	<75%	NA	NA

7.3.3 Available Aerometric Data for the Evaluations

The following monitoring networks were operating in 2014 so these data that can be used in the MPE.

EPA AQS Surface Air Quality Data: Data files containing hourly-averaged concentration measurements at a wide variety of state and EPA monitoring networks are available in the Air Quality System (AQS[56]) database throughout the U.S. Typical surface measurements at the ground level routine AIRS monitoring stations include ozone, NO_2, NO_X and CO.

IMPROVE Monitoring Network: The Interagency Monitoring of Protected Visual Environments (IMPROVE[57]) network collects 24-hour average $PM_{2.5}$ and PM_{10} mass and speciated $PM_{2.5}$ concentrations at many sites across the U.S. on a 1:3 day sampling frequency, including most Class I areas.

CSN Monitoring Network: The Chemical Speciation Network (CSN[58]) collects 24-hour average speciated $PM_{2.5}$ components on a 1:3 or 1:6-day sampling frequency. CSN monitoring sites tend to be urban oriented as compared to IMPROVE sites that are typically rural.

[56] http://www.epa.gov/ttn/airs/airsaqs/aqsweb/
[57] http://vista.cira.colostate.edu/IMPROVE/
[58] http://www.epa.gov/ttnamti1/speciepg.html

FRM Monitoring Network: 24-hour total $PM_{2.5}$ mass is collected using the federal Reference Method (FRM[59]) on a 1:3-day sampling schedule.

CASTNet Monitoring Network: The Clean Air Status and Trends Network (CASTNet[60]) operates approximately 80 monitoring sites in mainly rural areas across the U.S. CASTNet sites typically collect hourly ozone and weekly speciated $PM_{2.5}$, including HNO3. There is one CASTNet site located in the northwest corner of New Mexico (Chaco Culture NHP), although there are several more within the 4-km New Mexico modeling domain in neighboring states (i.e., Colorado and Arizona).

NADP Network: The National Acid Deposition Program (NADP[61]) collects weekly samples of SO_4, NO_3 and NH_4 in precipitation (wet deposition). There are also some sites that collect daily samples as well as mercury.

7.4 Operational Evaluation

As noted above, the Operational Evaluation compares the modeled concentrations with concurrent observations. Various tools and graphical displays and statistical methods are used as part of the Operational Evaluation as discussed below.

7.4.1 Atmospheric Model Evaluation Tool (AMET)

The Atmospheric Model Evaluation Tool (AMET[62]) (Appel et al., 2011) is a suite of software designed to facilitate the analysis and evaluation of predictions from meteorological and air quality models. AMET matches the model output for grid cells with observations from monitoring site locations from one or more networks of monitors. AMET also does species mappings to map the modeled species to the corresponding observations. These pairings of values (model and observation) are then used to statistically and graphically analyze the model's performance using a variety of techniques, many of which will be used in the CAMx 2014 base case MPE. The latest version of AMET is version 1.4, but AMET website doesn't have any information on its release date or documentation so we assume the documentation for AMET v1.3[63] is pertinent for AMET v1.4.

7.4.2 Example Operational Model Performance Evaluation Products

Below we use the results from the 2016 Denver ozone SIP (RAQC and CDPHE, 2016) modeling MPE (Ramboll and Alpine, 2017) for the 2011 CAMx ozone modeling platform to illustrate the type of MPE products that will be produced in the NM OAI Study. Summary tables of ozone statistical model performance metrics across sites in New Mexico will be produced. Such ozone performance statistics can be calculated with and without observed cut-off concentrations as illustrated in the next section. AMET comes pre-loaded with observation data from multiple networks that were described previously:

[59] http://www.epa.gov/ttn/airs/airsaqs/detaildata/downloadaqsdata.htm
[60] http://java.epa.gov/castnet/
[61] http://nadp.sws.uiuc.edu/NADP/
[62] https://www.cmascenter.org/amet/
[63] https://www.cmascenter.org/help/documentation.cfm

- Air Quality System (AQS) network
- Clean Air Status and Trends Network (CASTNET)
- Interagency Monitoring of PROtected Visual Environments (IMPROVE)
- Mercury Deposition Network (MDN)
- National Atmospheric Deposition Program (NADP)
- South-Eastern Aerosol Research and Characterization Study (SEARCH)
- Chemical Speciation Network (CSN; formerly STN)

AMET will be the primary MPE tool used in the CAMx 2014 base case simulations augmented by other MPE tools as necessary. Some example MPE displays are described in the following sections.

7.4.2.1 Soccer Plots for Comparing Performance Statistics with Goals and Criteria

Soccer Plots display ozone (or other species) model performance statistics against model performance goals and/or criteria using a scatter plot, such as bias on the x-axis and error on the y-axis. When the statistics achieves the goal, it falls within the box outlined by the goals. For example, Figure 7-1 shows ozone monthly fractional bias and error (FB and FE) performance statistics against a 15% and 35% performance goal, respectively, for the 2011 CAMx base case from the 2016 Denver ozone SIP. The Soccer Plots are for hourly (right) and MDA8 (left) ozone using no (top) and a 60 ppb (bottom) cut-off concentration. Using Soccer Plots, it is easy to determine when the performance statistics are achieving the goals and as the symbols approach the (0,0) origin that indicates better model performance. Although the example in Figure 7-1 is for monthly performance, the different symbols could be for different monitoring sites, specific modeling days with ozone exceedance days, stratified by observed ozone concentrations or stratified by any other variable that provides insight into the MPE.

NMED Exhibit 15

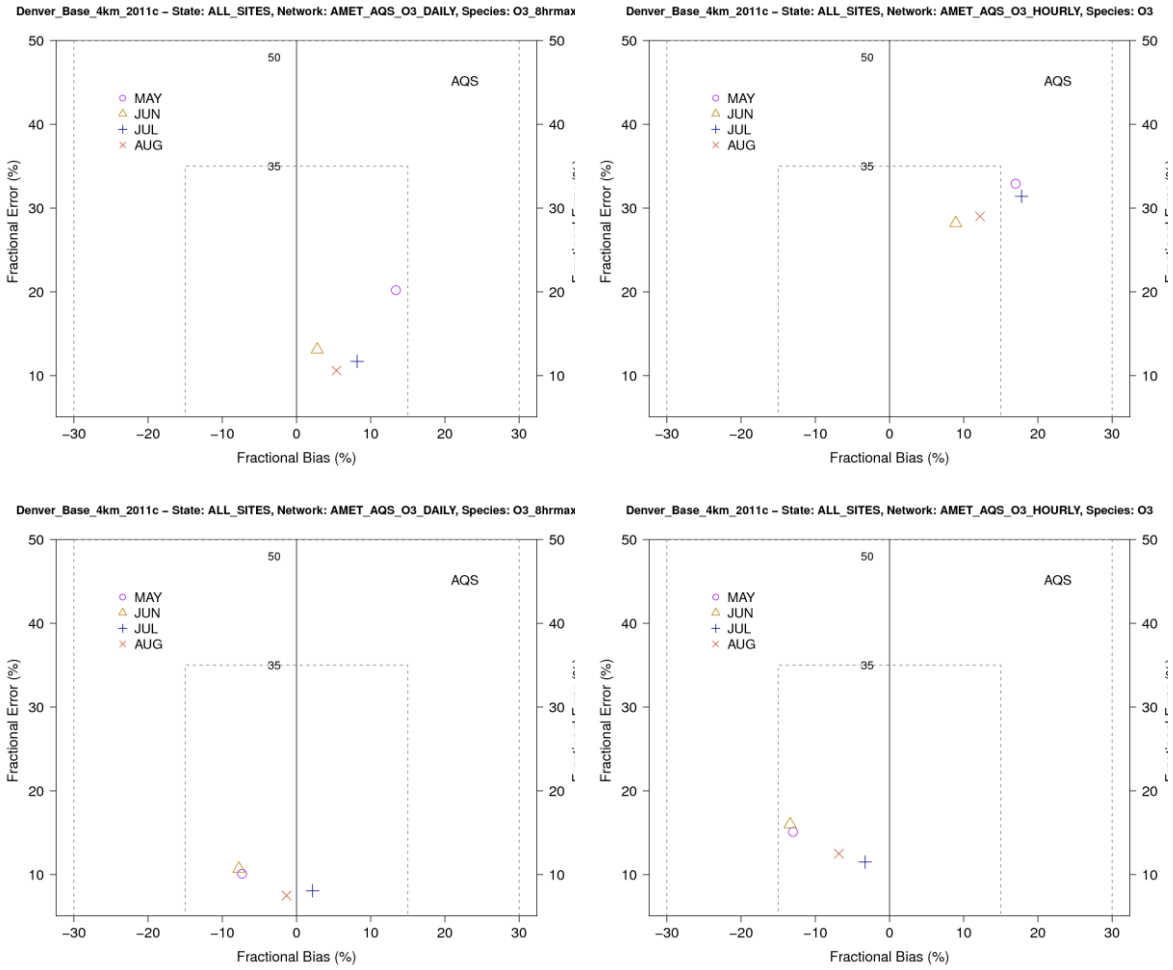

Figure 7-1. Example Soccer Plots of MDA8 (left) and hourly (right) ozone bias (FB) and error (FE) performance using no (top) and 60 ppb (bottom) observed ozone cut-off concentration (Source: Ramboll and Alpine, 2017).

7.4.2.2 Spatial Maps of Statistical Model Performance

AMET can generate spatial maps of different statistical performance metrics where the different colored symbols at the locations of monitoring sites allows an assessment of performance by geographic location. For example, Figure 7-2 displays the MDA8 ozone monthly bias (NMB) spatial plot from the CAMx 2011 base case simulation and shows an overestimation bias in May at many sites (yellow) with most of the sites achieving the <±15% performance goal for the other three months. The exception is the DMAS site in downtown Denver and the FTCO site in Fort Collins that are located close to mobile NOx emissions that titrate the ozone that is not reproduced by the model due to dilution of the local NOx emissions across a 4-km grid cell.

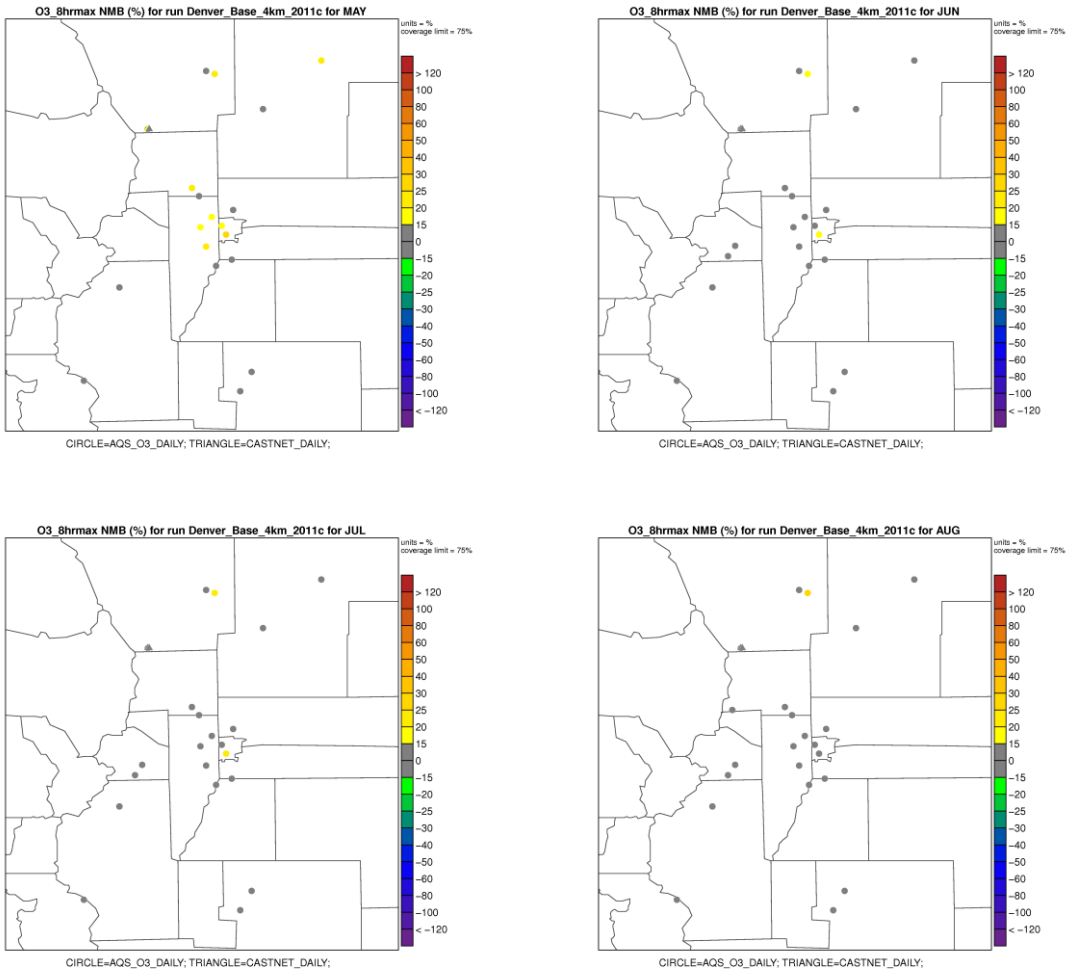

Figure 7-2. Spatial statistics plot of MDA8 monthly ozone model performance for Normalized Mean Bias (NMB), AQS sites in the Denver Metro/NFR NAA using no observed ozone cut-off concentration and May (top left), June (top right), July (bottom left) and August (bottom right) (Source: Ramboll and Alpine, 2017).

7.4.3 Scatter Plots of Model Performance

Scatter Plots are a main stay of MPE as they allow you to directly see the point-by-point comparison of predicted and observed concentrations. Figure 7-3 shows example MDA8 (left) and hourly (right) ozone scatter plots for July without (top) and with a 60 ppb observed ozone cut-off concentration from the CAMx 2011 base case simulations. In this case ozone performance for two different CAMX base cases are shown (red and blue symbols) and summary performance statistics are also displayed. The model has difficulty in predicting the lowest observed hourly ozone concentrations (see comment above on DMAS and FTCO ozone over-prediction bias), which appears to have little effect on MDA8 ozone MPE or hourly ozone performance when a 60 ppb observed ozone cut-off is used.

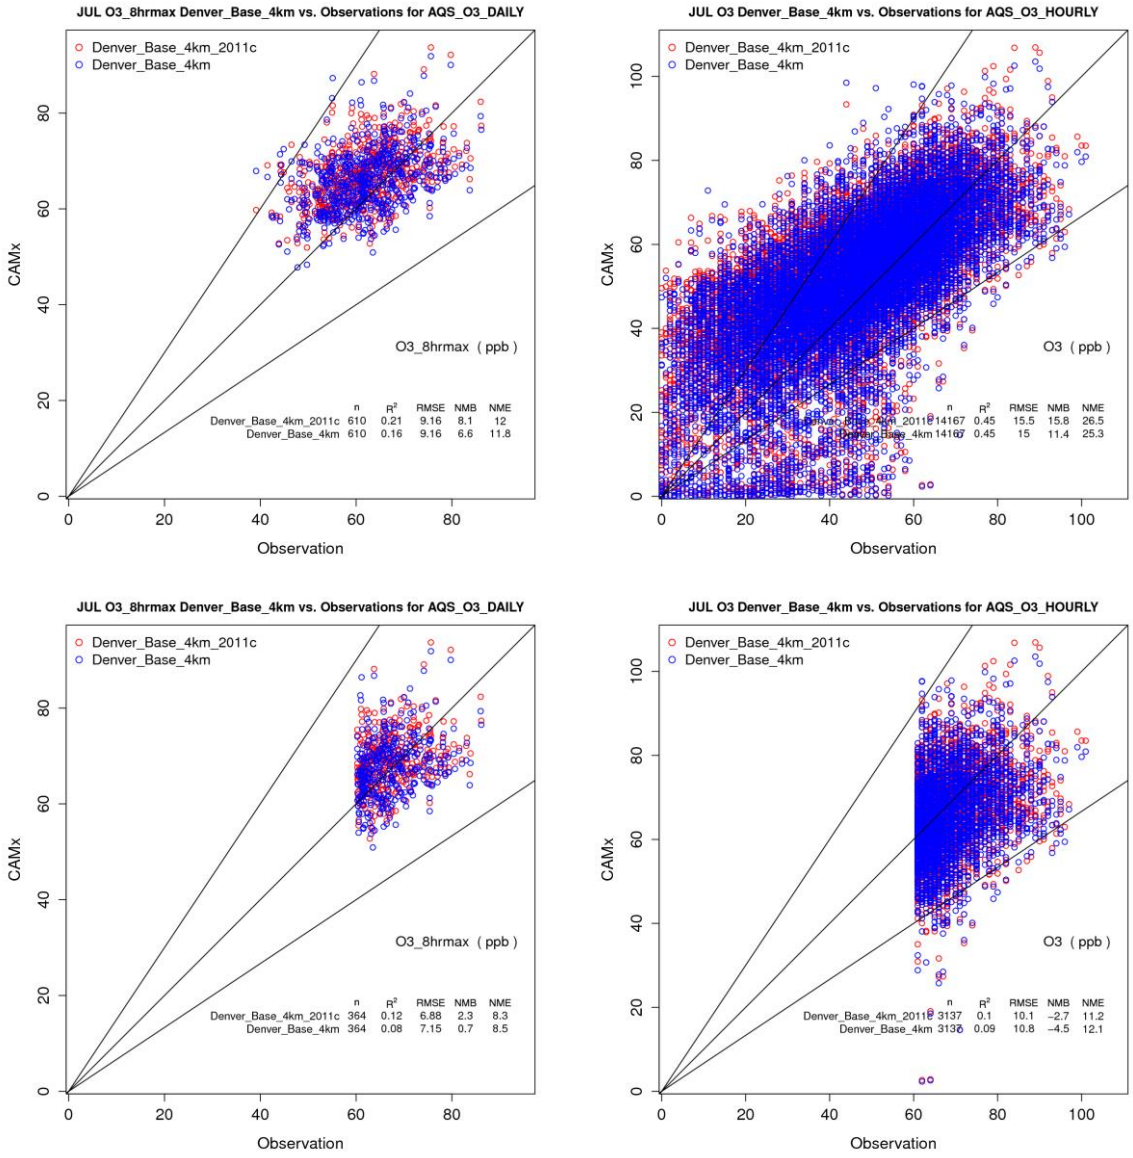

Figure 7-3. Scatter plots and model performance statistics for MDA8 (left) and hourly (right) ozone concentrations using no (top) and 60 ppb (bottom) observed ozone cut-off concentrations during the month of July (Source: Ramboll and Alpine, 2017).

7.4.4 Time Series of Predicted and Observed Concentrations

Time series of predicted and observed concentrations is another main stay of a MPE and focuses of the temporal evaluation of model performance at particular sites. For example, Figure 7-4 displays time series of predicted and observed July and August MDA8 ozone concentrations at the RFNO monitoring site for two CAMx 2011 base case simulations from 2016 Denver ozone SIP. These displays not only include the MDA8 ozone concentrations levels but the daily bias (i.e., different in the predicted and observed MDA8 ozone.

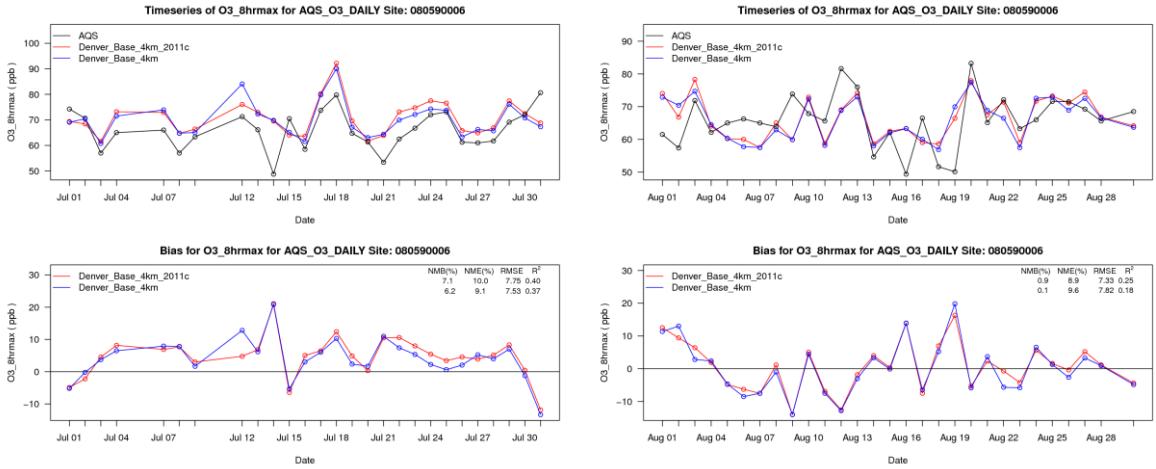

Figure 7-4. Time series of predicted and observed (black) MDA8 ozone concentrations (top panel) and bias (bottom panel) at Rocky Flats North (RFNO) for the preliminary 2011b1 (blue) and final 2011c (red) CAMx 4 km base case simulations and the months of July (left) and August (right) (Source: Ramboll and Alpine, 2017).

7.4.5 Evaluation for the Modeled MDA8 Ozone Concentrations

An important component of a PGM MPE is to evaluate the model for how well it predicts the modeled 10 highest MDA8 ozone concentrations because of the way the base and future year modeling results are used to project future year ozone DVs. The relative change in the base and future modeling results are used to project the current year observed ozone DVs to the future year. EPA's modeling guidance (EPA, 2018d) describes how to use the PGM modeling results to make the future year ozone DV projections with details presented in Chapter 8. The 10 highest base year modeled MDA8 ozone concentrations near a monitoring site are used to make the future year DV projections. It is desirable for the modeled MDA8 ozone concentrations on these 10 highest modeled base year ozone concentrations to match the observed MDA8 ozone concentrations on the same day sufficiently well. Thus, the model performance for the days used in the future year ozone DV projections are evaluated. As discussed in more detai8l in Chapter 8, alternative ozone DV projection techniques use the 10 highest modeled MDA8 ozone concentrations near a monitor just on those days in which the

modeled MDA8 ozone reproduces the observed MDA8 ozone with some performance criteria (e.g., < 10%. < 15%, < 20%).

7.5 Diagnostic Evaluation

The goal of the diagnostic evaluation is to assure that the model is simulating the correct physical and chemical processes that control the formation of ozone from the precursor emissions. Such processes include transport, dispersion, deposition and chemical transformation. The diagnostic evaluation investigates the processes that determine the ambient concentrations of ozone and related pollutants to develop confidence that the model's ozone response to changes in emissions will be accurate.

7.5.1 Base Year Base Case Diagnostic Sensitivity Tests

When developing a PGM base year base case model configuration, diagnostic sensitivity tests are frequently used to evaluate the sensitivity of the model to alternative inputs or model options in an effort to obtain a better performing base year base case simulation. For example, if two WRF base year simulations are available, the PGM could be run with both sets of WRF meteorological inputs to determine which one produces better performing PGM simulations. However, care must be taken that compensatory errors are not introduced.[64] For the NM OAI Study that is leveraging the WRAP/WAQS 2014v2 modeling platform, many diagnostic tests have already been performed so additional diagnostic sensitivity tests are likely not needed unless performance issues arise. The WRAP/WAQS modeling conducted the following diagnostic sensitivity tests that led to the 2014v2 base case CAMx configuration.

- Boundary Conditions (BC) Sensitivity: WRAP/WAQS initially used BCs based on EPA's 2014 GEOS-Chem simulation and found them inadequate so WRAP conducted their own 2014 GEOS-Chem simulation and generated BCs that greatly improved model performance.
- Vertical Mixing Sensitivity: This is a frequent sensitivity test to analyze alternative formulation of vertical mixing (Kz) formulations and the treatment of the minimum Kz near the surface that is especially important for cities where the urban heat island affects vertical mixing.
- Other Meteorological Sensitivity: The WRAP/WAQS evaluated the EPA's 2014 WRF meteorological simulations as input to CAMx and selected the WAQS 12-km data due to better precipitation model performance.
- Emissions Sensitivity: Increases or decreases in emissions (e.g., VOC and/or NO_x) from specific source categories or other emissions perturbation:
  - Top down studies have suggested oil and gas emissions may be under- or over-estimated.
  - Some studies have suggested MOVES mobile source NOx emissions may be overestimated, particularly in urban areas.
  - NO_x emissions are almost always produced by combustion so typically are hotter than ambient air so have some buoyancy and plume rise even if

[64] Compensatory errors can occur when two incorrect inputs compensate for each other so the PGM achieves seemingly good model performance, but for the wrong reason. For example, PGM modeling of Los Angeles in the late 1970s and early 1980s had a deficient VOC emissions inventory that was compensated for by overstated the Boundary Conditions.

NMED Exhibit 15

emitted at the surface (e.g., mobile sources). By trapping them in the lowest layer (20-m in this case) it may overstate surface NO_x emissions. Emitting some of the NO_x in layer 2 may alleviate this condition, alternative the surface minimum Kz mixing parameter may also address this issue.

- Biogenic and lightning NO_x emissions are uncertain and the sensitivity to their estimates could be investigated.

- Other Sensitivity: In the development of the CAMx 2014 base case modeling platform we may find inputs or parameterizations that are uncertain how to define so warrant further investigation.

When the initial results of the CAMx 2014 base year base case MPE are obtained, they will be shared with NMED to determine a path forward and if additional sensitivity tests may be needed and as time and resource constraints allow.

7.5.2 Additional Diagnostic Evaluation Approaches

Diagnostic Evaluation of a PGM can use several different techniques to diagnose features regarding model performance, such as evaluation of how the model responds to changes in inputs or simulates specific processes important for simulating the air quality issue being studied. The CAMx is instrumented with "probing tools" that can explore attributes of the model during a simulation, including ozone and particulate source apportionment (OSAT/PSAT), Decoupled Direct Method (DDM) sensitivity and Process Analysis. The most common type of diagnostic evaluation involves using the Brute Force (BF) approach where a model base case and model perturbation case is performed, and the sensitivity of the model estimates are the differences in the output concentrations between the two BF runs.

The comparison of modeling results with observations for key indicator species can also be a useful diagnostic evaluation technique. Section 3.4.2 of EPA's PGM modeling guidance list several species indicator ratios that suggest whether the atmosphere and/or model ozone formation is more VOC-limited or NO_x-limited (EPA, 2018a, pp. 92-95). However, many of these indicator ratios involve species not routinely measured and may require more precision than typically obtained.

Although a comprehensive diagnostic sensitivity analysis may not be possible given resource and time constraints, some elements of a Diagnostic Evaluation is expected to occur.

7.6 Dynamic Evaluation

The Dynamic Evaluation evaluates a PGM for the way it is primary used in an ozone SIP as it evaluates how well the modeled ozone response to emissions changes with observed responses. The most comprehensive dynamic evaluation is to compare model responses to observed historical changes in ozone concentrations in a retrospective analysis. Because differences in meteorology between years can have as much or even more effect on observed ozone concentrations, such dynamic evaluation could include not only running with different historical years of emissions, but also running with different historical years of meteorology. Thus, this kind of retrospective analysis dynamic evaluation can be quite resource and time intensive. The WRAP/WAQS is

conducting a Dynamic Evaluation of their 2014v2/RepBase modeling platform by back casting 2014v2 emissions to 2002 and comparing the changes in observed and modeled concentrations form a past year (2002), to a current year (2014 and RepBase) that can be potentially used as a Dynamic Evaluation in the NM OAI Study.

Another dynamic evaluation approach that is not as resource intensive as a retrospective modeling analysis is to stratify the operational model performance under varying conditions, such as day-of-week (e.g., weekday vs. weekend day), by season or by region. When the model shows the same ozone response as observed across these different chemical regimes, it supports the assertion that the modeled ozone concentrations would respond correctly to changes in emissions over time.

7.6.1 Probabilistic Evaluation

The probabilistic evaluation attempts to assess the level of confidence in the model predictions through techniques such as ensemble of model simulations. At this time, there are no plans to incorporate the probabilistic evaluation as part of the NM OAI Study.

NMED Exhibit 15

8. FUTURE YEAR MODELING

This Chapter describes the 2023 future year modeling to evaluate source contributions to ozone concentrations in New Mexico and potential control strategies designed to reduce ozone.

8.1 Future Year to be Modeled

There is no Federal regulation guiding the NM OAI Study future year modeling. Thus, we selected the 2023 future year due to the available of EPA's 2023fh emissions inventories developed as part of the EPA 2016v1 modeling platform. EPA also developed a 2028fh emissions that is too far out in the future and portions of a 2020 emissions inventory that is too current. Thus, the 2023 future year seemed an ideal choice for the NM OAI Study.

8.2 Future Year Emissions

2023 future year anthropogenic emissions will be used in the future year modeling. The following natural emission sources will be assumed to remain unchanged from 2014 base year base case levels:

- Biogenic emissions.
- Lighting NOx emissions.
- Ocean Sea Salt and DMS emissions.
- Windblown Dust.
- Open Land Fires (Wildfires, Prescribed Burns and Agricultural Burning).

8.2.1 2023 Future Year Anthropogenic Emissions

The primary source of the 2023 future year anthropogenic emissions is the 2023fh emission projections from the joint EPA/MJO 2016 emissions inventory collaborative development study. EPA's 2016v1 modeling platform included model-ready 2023 emissions for the 36/12-km domains that can be used "as is" for the NM OAI Study except for on-road mobile source emissions that were developed using SMOKE-MOVES and the 2016 meteorological conditions. For the 12-km 12WUS2 domain we will run SMOKE-MOVES using the 2023 MOVES EF Look-Up table, 2023 vehicle activity and the 2014 WRF meteorological conditions.

For the 4-km New Mexico domain, the EPA 2023fh New Mexico emissions will be reviewed and updated by NMED as needed and processed with SMOKE to generate 4-km resolution emission inputs for the 4-km New Mexico domain. The 2023 MOVES inputs and 2023 vehicle activity data will also be reviewed and updated by NMED as needed and SMOKE-MOVES run using the 2023 MOVES EF Look-Up table, 2023 vehicle activity and 4-km hourly gridded WRF data to generate 2023 on-road mobile emission inputs.

NMED Exhibit 15

8.2.2 Future Year Emissions Quality Assurance

Similar QA/QC procedures (e.g., as described in Adelman, 2004; UNC, 2018; EPA, 2018a) will be performed on the future year model-ready emissions inventories as were utilized in checking the base year datasets described previously. Standard inventory assessment methods will be employed to generate the future year emissions data including, but not limited to: (a) visualizing the model-ready emissions graphically, (b) spot-checking the holiday emissions files to confirm that they are temporally allocated like Sundays, (c) producing pie charts emission summaries for each source category, and (d) normalizing the emissions by population for each state to reveal where the future year inventories may be suspect. Of particular importance will be the comparison of the 2014 base year and 2023 future year emissions by source category and region to make sure the expected changes occurred in the modeling inventories.

8.3 Future Year CAMx Modeling

The 2023 future year CAMx base case modeling will be performed the same way that the 2024 base year base case modeling was performed only using the 2023 future year anthropogenic emissions. The CAMx PGM will be applied on the 36/12/4-km nested grid domain structure using two-way grid nesting. Due to uncertainties in global emissions, the BCs based on the WRAP 2014 GEOS-Chem simulation will also be used for 2023.

Future year ozone DV projections will be made using the 2014 base case and 2023 future year CAMx simulation outputs following the procedures given in Chapter 9 that use EPA's latest 8-hour ozone modeling guidance (EPA, 2018d).

8.3.1 Future Year Ozone Source Apportionment Modeling

The CAMx Anthropogenic Precursor Culpability Assessment (APCA) version of the Ozone Source Apportionment Technology (OSAT) will be used to estimate 2023 future year contributions of emissions from U.S. and international anthropogenic emissions and natural emissions from different geographic regions on ozone concentrations in New Mexico. A 2023 future year CAMx 36/12/4-km nested grid simulations will be conducted using geographic source regions defined by New Mexico and other nearby state boundaries and separating anthropogenic sources from natural sources. Fires would also be treated as a separate source category. The CAMx 2023 future year ozone source apportionment modeling will also provide separate contributions by Source sector for emissions in New Mexico and outside New Mexico as follows:

- Upstream Oil and Gas.
- Midstream Oil and Gas.
- EGU Point.
- Non-EGU Point.
- On-Road Mobile.
- Non-Road Mobile.
- Other Anthropogenic.

NMED Exhibit 15

- Fires (WF, Rx and Ag).
- Natural
- BC from International Anthropogenic Emissions.
- BC from US Anthropogenic Emissions.
- BC from Natural Sources.
- Initial Concentrations.

The exact definition of the 2023 ozone source apportionment modeling will be documented and provided to NMED for review and refinements later in the NM OAI Study.

8.3.2 Future Year Sensitivity and Control Strategy Simulations

2023 future year control strategy sensitivity simulations will be conducted. The definitions for the 2023 control strategy sensitivity scenarios will be provided by NMED at a later date,

NMED Exhibit 15

9. FUTURE YEAR OZONE PROJECTIONS

EPA's latest ozone State Implementation Plan (SIP) modeling guidance (EPA, 2018d) contains detailed procedures for how to use base year and future year photochemical grid model (PGM) modeling results to make future year ozone Design Value (DV) projections. The EPA-recommended ozone attainment demonstration includes a model attainment test for projecting base year ozone DVs to the future year and a weight of evidence (WOE) analysis used to confirm and corroborate the modeled attainment demonstration test. EPA has developed the Speciated Modeled Attainment Test (SMAT[65]) tool that includes the EPA (2018d) recommended procedures for projecting ozone DVFs.

9.1 EPA Recommended Future Year Ozone DV Projection Procedures

The procedures for making future year ozone DV projections are outlined in Chapter 4 of EPA's latest ozone modeling guidance (EPA, 2018d, pp. 99-110). EPA recommends using PGM modeling results in a relative fashion the scale base year ozone DV (DVB) to estimate the future year ozone DV (DVF). The model derived scaling factors are called Relative Response Factors (RRF) and are the ratio of future to base year ozone modeling results.

$$DVF = DVB \times RRF$$

Below we highlight the key elements in EPA's recommended ozone DV projection approach, more details and justification for the approach are provided in EPA's modeling guidance (EPA, 2018d).

9.1.1 Base Year Ozone Design Value (DVB)

The DVB is defined as the average of three-years of ozone DVs centered on the base modeling year. As an ozone DV is defined as the three-year average of the 4th highest MDA8 ozone concentrations at a monitor, the DVB is based on 5 years of 4th highest MDA8 ozone concentrations centered on the base year so the highest weight (3x) is on the 4th highest MDA8 ozone for the base year with less weights in the 2 years before and after the base year (i.e., weighting factors of 1, 2, 3, 2, 1).

For the NM OAI Study modeling, the base year is 2014 so that the DVB at each site will be defined from three years of ozone DVs as follows:

$$DVB_{2014} = (DV_{2012\text{-}2014} + DV_{2013\text{-}2015} + DV_{2014\text{-}2016}) / 3$$

9.1.2 Calculation of Relative Response Factors (RRFs)

The RRF is defined as the ratio of the average of the PGM future year (FY) to base year (BY) MDA8 ozone concentrations near the monitor for the 10 days with the -highest base year modeled MDA8 ozone concentrations near the monitoring site.

[65] https://www.epa.gov/scram/photochemical-modeling-tools

$$RRF = \sum MDA8\ Ozone_{FY} / \sum MDA8\ Ozone_{BY}$$

Near the Monitor: By near the monitor, the highest modeled base year MDA8 ozone is selected in a 3x3 array of grid cells centered on the monitor is used. For the future year, the future year MDA8 ozone is selected from the same grid cell in the 3x3 array centered on the monitor as used in the base year.

10 Highest Base Year MDA8 Ozone Days: The RRF is based on the 10 days with the highest base year modeled MDA8 ozone concentrations near the monitor, provided the base year MDA8 ozone is greater or equal to 60 ppb. If there are less than 10 days with base year MDA8 ≥ 60 ppb, then just the days ≥ 60 ppb are used provided there are at least 5 days. If there are less than 5 days with base year MDA8 ozone ≥ 60 ppb EPA recommends that RRFs not be calculated for that site.

9.1.3 Flexibility in RRF Calculations

EPA's modeling guidance includes the flexibility to modify the recommended ozone DV projection procedure. For example, there may be a reason that grid cells in the 3x3 array centered on the monitor may not be representative of conditions at the monitor. For example, if a grid cell is dominated by water so has different mixing characteristics or the monitor is in an area with sharp terrain gradients.

There may be also reasons that one of the highest 10 base year MDA8 ozone days should not be used in the RRF. For example, if the modeled base year MDA8 ozone is highly influenced by emissions from wildfires it could be excluded and then the next highest modeled MDA8 ozone included so that 10 modeled days are still used in the RRF.

The PGM model performance on the 10 highest modeled MDA8 ozone days may also be considered in selected the top 10 modeled MDA8 ozone days to use in the RRFs.

9.2 Unmonitored Area Analysis (UAA)

An unmonitored area analysis (UAA) will be conducted using the SMAT tool. The UAA first interpolates the ozone DVB to each 4-km grid cell in the New Mexico 4-km domain. The interpolation will be done with and without accounting for modeled concentration gradients. Once a gridded field of ozone DVB is obtained, the ozone DVB are projected to the future using the same procedures as used in the modeled attainment test only the modeling results at the grid cell containing the monitor is used and there is typically some relaxation of the requirement for MDA8 ozone to be above 60 ppb since the UAA is making projections in fairly clean ozone concentrations regions. The gridded future year ozone DVFs are then analyzed to determine locations with grid cells that exceed the ozone NAAQS. Note that estimate locations of ozone DVFs above the ozone NAAQS in the UAA does not necessarily imply a failure to demonstrate attainment. For example, when modeled concentration fields are used in the UAA ozone DVB interpolation frequently at locations of wildfires the ozone DVB and DVF are above the NAAQS. But any UAA ozone DVF exceedances of the NAAQS should be identified and explained in the analysis.

NMED Exhibit 15

9.3 Weight of Evidence (WOE) Attainment Demonstration

The Weight of Evidence (WOE) is a necessary and critically important component of the ozone attainment demonstration. As stated in EPA's modeling guidance, "By definition, models are simplistic approximations of complex phenomena" (EPA, 2018a, pp. 169). EPA guidance recommends three types of supplemental analysis to support a modeled attainment demonstration:

1. Additional modeling analysis.
2. Analysis of trends in ambient concentrations and emissions.
3. Additional emission controls.

As the NM OAI Study is not a formal regulatory SIP ozone attainment demonstration study, then a formal WOE is not needed. However, the concept of a WOE should be integrated into the NM OAI Study.

9.4 Documentation of the PGM Modeling

Results of the NM OAI Study will be documented in PowerPoint (PPT) presentations and other documents that will be presented to the NMED in monthly webinars following the schedule in Tables 1-2 and 1-3. After each webinar presentations and with approval from NMED, the documents will be posted to a webpage on the WRAP website, like we did for the Southern New Mexico Ozone Study (SNMOS[66]). Two formal reports will be generated, one on the developed of the NM OAI Study 2014 36/12/4-km CAMx modeling platform and model performance evaluation and an Air Quality Technical Support Document (AQTSD) that documents the entire study including the 2023 future year modeling, ozone design Value projections, source apportionment modeling and control strategy sensitivity modeling.

NMED Exhibit 15

10. QUALITY ASSURANCE PROJECT PLAN (QAPP)

This Modeling Protocol also serves as an informal Quality Assurance Project Plan (QAPP) for the NM OAI Study. A formal QAPP is a stand-alone document that discusses the Quality Assurance (QA) and Quality Control (QC) aspects of a study. QAPPs are typically required for Federal studies and are designed to assure that data are collected in the most rigorous ways possible, subjected to detailed QA/QC and have a chain of custodia review of data to preserve the quality. QAPPs are particularly important for measurement studies where the study must assure that the data collected meet a level of QA/QC as, unlike a modeling study where one can go back and rerun the model, if data collected at a certain time and place is ruled invalid there is no way to collect the measurement data under the same circumstances. This is not to say QA/QC is not important for modeling studies and, as shown below, this Modeling Protocol is full of QA/QC processes in each step of the modeling.

EPA has developed a template for developing a formal QAPP.[67] EPA has also developed a document that describes the elements of a QAPP.[68] Below we go through each of the seven elements EPA recommends be part of a QAPP and discuss where they can be found in this Modeling Protocol.

10.1 Title Page And Approval Page

As this is not a formal QAPP , there is no Approval Page. However, we have a list of Project Participants in Table 1-1 that are responsible for reviewing and accepting the Modeling Protocol/QAPP.

10.2 Quality System Components

This section of a QAPP describes the study's quality assurance program and procedures and who has responsibility for the QA/QC. Below we point to sections in this Modeling Protocol where rigorous QA/QC procedures are put in place for the NM OAI Study.

10.2.1 Roles of Personal for QA/QC of the NM OAI Study

The two Co-Principal Investigators, Tom Moore of WESTAR and Ralph Morris of Ramboll, have overall responsibility for the QA/QC of the NM OAI Study. Together they have over 50 years' experience in managing large air quality studies including instituting comprehensive QA/QC procedures. In Table 1-1 we also list the leads for each major component of the modeling study (emissions, meteorological and photochemical modeling) who will oversee the QA/QC of each component of the database development. Also listed in Table 1-1 is the NM OAI Study Project Manager and staff at NMED who will review and comment on each phase of the study. Each month during the NM OAI Study we will have a Webinar and present elements of the study to the NMED for their review and comment following the schedule in Table 1-3.

[68] https://www.epa.gov/sites/production/files/2015-05/documents/assess4.pdf

NMED Exhibit 15

10.2.2 QA/QC of the 2014 Base Year and 2023 Future Year Emissions Data

The QA/QC of the base and future year emissions data is described in Section 1.5.4. The 2014 base year emissions were based on the 2014NEIv2 that have gone through several rounds of review and updates by EPA and the states. The WRAP states then conducted further review and updates of the 2014NEIv2 emissions in two phases to develop the WRAP/WAQ 2014v1 and final 2014v2 emissions used in the WRAP/WAQS 2014v2 modeling platform. Finally, under the NM OAI Study, the NMED will make further review of the New Mexico emissions in the 2014v2 inventory and make updates as needed.

The 2023 future year emissions used in the study are part of EPA's 2016v1 modeling platform (2023fh inventory). They are the result of several iterations of EPA making future year emission projections and represent their current best estimate of future year emissions. The NMED will also review the 2023 emissions for New Mexico and make updates as needed.

10.2.3 QA/QC of 2014 and 2023 Emissions Processing

Section 1.5.5 describes the process that will be used in processing the 2014 and 2023 emissions into the gridded, hourly and speciated emissions inputs needed for the CAMx PGM. The NM OAI Study modeling study will perform a multistep emissions QA/QC approach as developed for the WRAP 2002 modeling (Adelman, 2004) and following the procedures in EPA's latest ozone modeling guidance (EPA, 2018a, pp. 60) and Section 2.20 of the SMOKE User's Manuel (UNC, 2018, pp. 94). These steps include making sure that the mass input to the emissions models is consistent with the output and generation numerous QA/QC visualization graphics, including spatial maps and time series plots. Sections 6.2.2.7 and 6.2.2.9 provide more details on the QA/QC process for the emissions modeling. The QA/QC of the 2023 emissions processing is discussed in Section 8.2.2.

10.2.4 QA/QC of the Meteorological Modeling

The QA/QC of the meteorological modeling is briefly discussed in Section 1.5.6 with a more detailed discussions contained in Chapter 5. The NM OAI Study has separate work elements to evaluate the performance of the current WRAP/WAQS 2014 WRF simulation in New Mexico as well as a more detailed evaluation of the 36/12/4-km WRF simulation being conducted under the NM OAI Study that is described in Section 5.4.

10.2.5 QA/QC of the Boundary Conditions

The WRAP/WAQS study did a detailed QA/QC of EPA's 2014 GEOS-Chem modeling that was used in the initial BCs in the 2014v1 platform and found the ozone BCs to be inadequate, so WRAP ended up doing their own 2014 GEOS-Chem modeling that improved the 2014 BCs. The NM OAI Study will conduct a QA/QC of the WRAP 2014 GEOS-Chem BCs for sites in New Mexico

10.2.6 QA/QC of the Air Quality Modeling

The QA/QC of the CAMx air quality modeling will included independent review of the run scripts against the Modeling Protocol to make sure that the model configuration is

correct, as discussed in Section1.5.7. The NM OAI Study CAMx 36/12/4-km base case simulation will be subjected to a model performance evaluation (MPE) to assure that the model is replicating 2014 observed ozone concentrations sufficiently well that it can be used for making future year ozone projections (Section 1.5.9). Chapter 7 goes into details on how the CAMx Operational MPE will be conducted that includes statistical performance measures that are compared against Goals and Criteria and graphical MPE products. Elements of Diagnostic MPE being conducted are discussed in Section 1.5.10 with details of the diagnostic model performance evaluation provided in Section 7.5.

10.3 Project Definition and Background

Section 1-1 provides the impetus for the NM OAI Study with an overview of the study provided in Section 1-2. The background on related studies in provided in Section 1.3.

10.4 Data Quality Objectives

The data quality objectives for the meteorological, emissions and photochemical modeling are contained in Chapters 5, 6 and 7 respectively. Of particular note are meteorological model performance benchmarks listed in Table 5-3 that the NM OAI Study WRF 22014 36/12/4-km simulation will be compared against as part of the assessment of the meteorological data quality. Similarly, Table 7-1 contains model Performance Goals and Criteria that the CAMx 2014 base case simulation model performance will be compared against as part of the assessment of the data quality of the photochemical model simulation.

10.5 Project Organization and Responsibilities of the Researchers

Table 1-2 lists the organization of the NM OAI Study by task with schedule. The responsibilities of the NM OAI Study project participants are given in Table 1-1.

10.6 Project Description, Documentation and Reporting

This Modeling Protocol has a complete description of how the NM OAI Study will be carried. A description of the documentation and how the study will be reported is given in Section 1.8. And a summary of the documentation is also provided at the end of Chapter 9.

10.7 Reconcile with Data Quality Objectives

This Modeling Protocol provides a roadmap for how the NM OAI Study will be conducted. However, it is a living document that can be modified as issues or new information comes up. During the course of the study, WESTAR/Ramboll will have regular webinars that are scheduled monthly to go over progress and results for the previous month. If issues come up or problems are encountered, the WESTAR/Ramboll team will discuss them with the NMED and develop corrective action to reconcile any issues/difficulties.

NMED Exhibit 15

APPENDIX A

Observed MDA8 Ozone Concentrations during 2014. Red indicates ozone ≥71 ppb and yellow indicates ozone between 67 and 71 ppb.

NMED Exhibit 15

Observed MDA8 Ozone Concentrations during 2014. Red indicates ozone ≥71 ppb and yellow indicates ozone between 67 and 71 ppb.

APPENDIX B

Observed MDA8 Ozone Concentrations during 2016. Red indicates ozone ≥71 ppb and yellow indicates ozone between 67 and 71 ppb.

NMED Exhibit 15

Observed MDA8 Ozone Concentrations during 2016. Red indicates ozone ≥71 ppb and yellow indicates ozone between 67 and 71 ppb.

NEW MEXICO OZONE ATTAINMENT INITIATIVE PHOTOCHEMICAL MODELING STUDY – 2014 MODELING PLATFORM DEVELOPMENT AND MODEL EVALUATION

Project name	**New Mexico Ozone Attainment Initiative Photochemical Modeling Study**
Project no.	**1690017454**
Recipient	**New Mexico Environmental Division**
Document type	**Technical Report**
Version	**V3.0**
Date	**September 2020**
Prepared by	**Ralph Morris, Marco Rodriguez, Tejas Shah, Jeremiah Johnson, Jung Chien, Pradeepa Vennam and Fiona Jiang, Ramboll Environment and Health** **Tom Moore and Mary Uhl, Western States Air Resources Council**

CONTENTS

ACRONYMS and ABBREVIATIONS		**viii**
1.	**INTRODUCTION**	**1**
1.1	NM OAI Project Genesis	1
1.2	Conceptual Model for High Ozone Concentrations in New Mexico	3
1.2.1	Southern New Mexico	3
1.2.2	Bernalillo County and Vicinity	7
1.2.3	Northern New Mexico	8
1.3	Overview of NM OAI Study Modeling Approach	10
1.3.1	WRAP-WAQS 2014 PGM Platform Development Study	11
1.3.2	EPA 2016v1 Modeling Platform	12
1.3.3	Episode Selection	13
1.3.4	Model Selection	13
1.3.5	Domain Selection	14
1.3.6	Base and Future Year Emissions Data	16
1.3.7	Initial and Boundary Conditions Development	16
1.3.8	Diagnostic Sensitivity Analyses	16
1.3.9	Model Performance Evaluation	16
1.3.10	Future Year Base and Control Strategy Modeling	17
1.3.11	Future Year Source Apportionment Modeling	17
2.	**2014 WRF METEOROLOGICAL MODELING**	**18**
2.1	WRF Meteorological Model	18
2.2	WRF Horizontal Modeling Domain	18
2.3	WRF Model Configuration	19
2.3.1	Model Vertical Resolution	20
2.3.2	Vertical Coordinate	20
2.3.3	Topographic Inputs	22
2.3.4	Vegetation Type and Land Use Inputs	22
2.3.5	Atmospheric Data Inputs	22
2.3.6	Time Integration	23
2.3.7	Diffusion Options	23
2.3.8	Lateral Boundary Conditions	24
2.3.9	Top and Bottom Boundary Conditions	24
2.3.10	Sea Surface Temperature Inputs	24
2.3.11	Four Dimensional Data Assimilation (FDDA)	24
2.3.12	New Lightning Data Assimilation	24
2.3.13	PBL and LSM Physics Options	24
2.3.14	Remaining WRF Physics Options	25
2.3.15	Application Methodology	26
2.4	WRF Model Evaluation	26
2.4.1	Quantitative Evaluation Using METSTAT	26
2.4.2	Qualitative Evaluations Using PRISM Data	37
2.4.3	Conclusions of 2014 WRF Model Performance	40

NMED Exhibit 16

3.	**BOUNDARY CONDITION INPUTS**	**41**
3.1	WRAP 2014 GEOS-Chem Modeling	41
3.2	2014 GEOS-Chem Model Evaluation	43
4.	**2014 EMISSION INPUTS**	**44**
4.1	Available Emissions Inventory Datasets	44
4.2	Development of CAMx Emission Inputs	44
4.2.1	Day-Specific On-Road Mobile Source Emissions	44
4.2.2	Point Source Emissions	45
4.2.3	Area and Non-Road Source Emissions	45
4.2.4	Episodic Biogenic Emissions	45
4.2.5	Wildfires, Prescribed Burns, Agricultural Burns	46
4.2.6	Other Natural Emissions	46
4.2.7	QA/QC of Emissions Processing and Emissions Merging	46
4.2.8	Use of the Plume-in-Grid (PiG) Subgrid-Scale Plume Treatment	47
4.2.9	QA/QC of Model-Ready Emissions	47
4.2.10	Summary of Emissions for 4-km New Mexico Domain	48
5.	**DIAGNOSTIC SENSITIVITY TESTS**	**54**
5.1	WRFCAMx Processing of 2014 WRF Output	54
5.1.1	Treatment of Minimum Kv	54
5.1.2	Layer Collapsing Strategy	54
5.2	CAMx Meteorological Diagnostic Sensitivity Tests	56
5.3	Summary CAMx Diagnostic Sensitivity Tests	63
6.	**FINAL MODEL BASE CASE CONFIGURATION**	**64**
6.1	Meteorological Inputs	64
6.2	Emission Inputs	64
6.3	Photochemical Model Inputs	64
6.3.1	PGM Science Configuration and Input Configuration	64
7.	**2014 BASE CASE MODELING AND MODEL PERFORMANCE EVALUATION**	**67**
7.1	2014 Base Case Modeling	67
7.2	EPA Model Performance Evaluation Recommendations	67
7.2.1	Overview of EPA Model Performance Evaluation Recommendations	67
7.3	Overview of Evaluation of CAMx 2014 Base Case Procedures	68
7.3.1	Photochemical Model Evaluation Methodology	68
7.3.2	Model Performance Goals and Benchmarks	68
7.3.3	Available Aerometric Data for the Evaluations	69
7.3.4	Atmospheric Model Evaluation Tool (AMET)	69
7.4	Ozone Evaluation Across the 4-km New Mexico Domain	70
7.5	Ozone Evaluation Across New Mexico	71
7.6	Ozone Evaluation in New Mexico Subregions	74
7.7	Ozone Evaluation at Individual New Mexico Monitoring Sites	76
7.8	Ozone Performance Related to Future Year Ozone Projections	83
7.8.1	Bloomfield Top 10 Ozone Performance	84

NMED Exhibit 16

7.8.2 Desert View Top 10 Ozone Performance 86
7.8.3 Carlsbad Top 10 Ozone Performance 87

8. SUMMARY AND CONCLUSIONS 88

9. REFERENCES 90

APPENDIX

Appendix A Time Series of Predicted and Observed MDA8 Ozone Concentrations at Sites in New Mexico

TABLE OF TABLES

Table 1-1. Lambert Conformal Conic (LCC) projection parameters for the NM OAI Study 36/12/4 modeling domains. 15

Table 1-2. Grid definitions for CAMx NM OAI Study 2014 36/12/4-km modeling domains. 15

Table 2-1. WRF 36 level vertical layer structure for the NM OAI study. This is the same WRF layer structure as used in WAQS 2011/2014/2016 and EPA 2016 WRF modeling. 21

Table 2-2. NM OAI Study 2014 WRF model configuration and comparison with the WRF configuration used in the WRAP-WAQS 2014 and EPA 2014/2015/2016 WRF modeling. 25

Table 2-3. Meteorological model performance benchmarks for simple and complex conditions. 29

Table 3-1. 2014 GEOS-Chem simulation model configuration used by WRAP whose output is used to define the 2014 day-specific diurnally varying BC inputs for the NM OAI Study photochemical modeling. 41

Table 4-1. 2014 base case biogenic emissions summary by month (in short tons per day) for the 4-km New Mexico domain.46

Table 4-2. New Mexico 4-km domain emissions processing categories. 49

Table 4-3. 2014 base case anthropogenic emissions summary (episode average short tons per day) by source category for the 4-km New Mexico domain. 50

Table 5-1. WRF to CAMx vertical layer collapsing strategy used in the NM OAI Study. 55

Table 6-1. Final CAMx model configuration for the NM OAI Study. 66

Table 7-1. Recommended benchmarks for photochemical model statistics (Source: Emery et al., 2016). 69

NMED Exhibit 16

Table 7-2. AQS monitoring sites categorized into subregions of southern New Mexico (orange), Bernalillo County (yellow) and southern New Mexico (blue). 75

Table 7-3. Region specific NMB and NME values for MDA8 Ozone and MDA8 Ozone when Observed Value is above 60 ppb. 75

Table 7-4. CAMx 2014 base case model performance statistics for MDA8 Ozone concentrations by monitoring site for summer (May15-Aug) modeling period. 77

Table 7-5. 2014 Base Case model performance statistics of MDA8 Ozone with an observed ozone 60 ppb cut-off by monitoring site for summer (May 15-Aug) modeling period. 78

Table 7-6. Predicted and observed MDA8 ozone concentrations (ppb) at Bloomfield for CAMx 2014 base case for modeled ranked 36 highest MDA8 ozone concentrations. 85

Table 7-7. Predicted and observed MDA8 ozone concentrations (ppb) at Desert View for CAMx 2014 base case for modeled ranked 36 highest MDA8 ozone concentrations. 86

Table 7-8. Predicted and observed MDA8 ozone concentrations (ppb) at Carlsbad for CAMx 2014 base case for modeled ranked 36 highest MDA8 ozone concentrations. 87

TABLE OF FIGURES

Figure 1-1. Trends in observed ozone DVs between 2013 and 2018 at 7 monitoring sites in New Mexico (Source: https://www.env.nm.gov/air-quality/wp-content/uploads/sites/2/2019/10/OAI_Presentation_09262019.pdf). 2

Figure 1-2. 7 counties in New Mexico under the jurisdiction of the NMED whose observed 2016-2018 ozone DVs are at or exceed 95% of the 2015 ozone NAAQS (70 ppb) (Source: https://www.env.nm.gov/air-quality/wp-content/uploads/sites/2/2019/10/OAI_Presentation_09262019.pdf). 2

Figure 1-3. Contributions of geographic regions (including Boundary Conditions) to the 2011 and 2025 ozone Design Values at Desert View monitoring site in Dona Ana County in southern New Mexico (left) and 12/4-km modeling domain and definition of source regions (right). 4

Figure 1-4. Contributions of Source Sector emissions within the 12/4-km modeling domain to the 2011 and 2025 ozone Design

NMED Exhibit 16

Value at Desert View monitoring site (top) and top ten Source Group contributions (bottom). 5

Figure 1-5. Contributions of major Source Sectors in New Mexico to 2011 (top) and 2025 (bottom) ozone DVs at nine monitoring sites in Southwestern New Mexico. 6

Figure 1-6. Contributions to ozone in Albuquerque during the June and July 2017 modeling episodes. 7

Figure 1-7. Linear regression of the annual 4th highest MDA8 ozone concentrations and mean July through August NCEP/NCAR Reanalysis 500 hPa (or 500 mb) heights for the DM/NFR NAA region at the Rocky Flats North (RFNO) monitoring site for the years 1995 to 2018. 9

Figure 1-8. Correlation between 500 hPa heights and elevated ozone concentrations for monitoring sites in the western U.S. 10

Figure 1-9. 36-km continental U.S. (36US1) and 12-km western U.S. (12WUS2) modeling domains used in the WRAP-WAQS CAMx 2014v2 modeling platform. 12

Figure 1-10. NM OAI Study 2014 36/12/4-km PGM and emissions modeling domains. 14

Figure 1-11. 4-km New Mexico modeling domain for PGM and emissions modeling, with locations of New Mexico ozone monitors that were operating during some portion of 2014. 15

Figure 2-1. WRF 36-km (outer extent), 12-km (d02) and 4-km (d03) modeling domains used in the NM OAI Study. 19

Figure 2-2. Cross-sections of layer interface heights over the Rocky Mountains for the eta (left panel) and hybrid (right panel) vertical coordinates for the WRF-Based Rapid Refresh (RAP) model. Adapted from Park et al., (2018). 22

Figure 2-3. Soccer plot comparing WRF/NAM (top) and WRF/ERA5 (bottom) surface wind speed (m/s) model performance against the Simple and Complex Benchmarks for monthly RMSE (y-axis) and Mean Bias (x-axis). 31

Figure 2-4. Soccer plot comparing WRF/NAM (top) and WRF/ERA5 (bottom) surface wind direction (degrees) model performance against the Simple and Complex Benchmarks for monthly RMSE (y-axis) and Mean Bias (x-axis). 32

Figure 2-5. Soccer plot comparing WRF/NAM (top) and WRF/ERA5 (bottom) surface temperature (K) model performance against the Simple and Complex Benchmarks for monthly RMSE (y-axis) and Mean Bias (x-axis). 33

NMED Exhibit 16

Figure 2-6. Soccer plot comparing WRF/NAM (top) and WRF/ERA5 (bottom) surface humidity (g/kg) model performance against the Simple and Complex Benchmarks for monthly RMSE (y-axis) and Mean Bias (x-axis). 34

Figure 2-7. Time series plot of predicted and observed (black) daily humidity (g/kg) at Las Cruces International Airport for the WRF/ERA5 (red) and WRF/NAM (blue) simulations. 35

Figure 2-8. Soccer plot comparing WRF/NAM (top) and WRF/ERA5 (bottom) surface humidity (g/kg) model performance at Las Cruces International Airport against the Simple and Complex Benchmarks for monthly RMSE (y-axis) and Mean Bias (x-axis). 36

Figure 2-9. May monthly precipitation amounts from PRISM based on observations (left) and predicted by WRF/NAM (middle) and WRF/ERA5 (right). 38

Figure 2-10. June monthly precipitation amounts from PRISM based on observations (left) and predicted by WRF/NAM (middle) and WRF/ERA5 (right). 38

Figure 2-11. July monthly precipitation amounts from PRISM based on observations (left) and predicted by WRF/NAM (middle) and WRF/ERA5 (right). 39

Figure 2-12. June monthly precipitation amounts from PRISM based on observations (left) and predicted by WRF/NAM (middle) and WRF/ERA5 (right). 39

Figure 4-1. New Mexico 2014 base case anthropogenic NOx and VOC emissions by source category. 51

Figure 4-2. Spatial distribution of the non-point (top) and point (bottom) source oil and gas NOx (left) and VOC (right) emissions (episode avg tons per day) for New Mexico 4-km domain. 52

Figure 4-3. Spatial distribution of on-road (top), rail (middle) and non-point/non-road equipment (bottom) NOx (left) and VOC (right) emissions (episode avg tons per day) for New Mexico 4-km domain. 53

Figure 5-1. Comparison of sensitivity tests NMB with 60 ppb cutoff spatial plots over NM. 57

Figure 7-1. Scatter plot of predicted and observed MDA8 ozone across the AQS and CASTNET monitoring sites within the 4-km New Mexico domain during the modeling period (May 15-Aug 31, 2014) for the CAMx 2014 base case simulations. 70

NMED Exhibit 16

Figure 7-2. Spatial distribution of CAMx 2014 base case simulation period (May15-Aug 31) site-specific Normalized Mean Bias within the 4-km domain for MDA8 O3 (left) and MDA8 O3 above 60ppb cut-off (right). 71

Figure 7-3. Scatter plots of predicted and observed MDA8 ozone (left) and MDA8 ozone when observed value is above 60 ppb cut-off (right) across the AQS monitoring sites in New Mexico during modeling period (May15-Aug 31) for the CAMx 2014 base case simulations. 72

Figure 7-4. Soccer plots of MDA8 ozone (left) and MDA8 ozone when observed value is above a 60 ppb cut-off (right) with monthly average NMB and NME values across sites in New Mexico. The dashed lines represents the performance goals and criteria. 73

Figure 7-5. Spatial distribution of site-specific Normalized Mean Bias for sites in New Mexico and the CAMx 2014 May-August base case simulation for all MDA8 ozone data (left) and MDA8 ozone with observed value above a 60 ppb cut-off (right). 73

Figure 7-6. Time series of predicted and observed MDA8 ozone concentrations (ppb; top)and daily bias (ppb; bottom) at Bloomfield monitoring site (Site ID: 350450009). 79

Figure 7-7. Time series of predicted and observed MDA8 ozone concentrations (ppb; top) and daily bias (ppb; bottom) at Coyote Ranger monitoring site (Site ID: 350390026). 80

Figure 7-8. Time series of predicted and observed MDA8 ozone concentrations (ppb; top) and daily bias (ppb; bottom) at South Valley monitoring site (Site ID: 350010029). 81

Figure 7-9. Time series of predicted and observed MDA8 ozone concentrations (ppb; top) and daily bias (ppb; bottom) at Desert View monitoring site (Site ID: 350130021). 82

Figure 7-10. Time series of predicted and observed MDA8 ozone concentrations (ppb; top) and daily bias (ppb; bottom) at Carlsbad monitoring site (Site ID: 350151005). 83

NMED Exhibit 16

1. INTRODUCTION

This document presents the development and evaluation of a photochemical grid model (PGM) modeling platform for the New Mexico (NM) Ozone Attainment Initiative (OAI) Photochemical Modeling Study ("NM OAI Study"). The New Mexico Environmental Division (NMED) has contracted with a team consisting of Western States Air Resources Council (WESTAR) and Ramboll US Corporation to conduct the NM OAI Study. The NM OAI Study leverages the 2014 PGM modeling platform developed by the Western Regional Air Partnership (WRAP) in the Western Air Quality Study (WAQS) and enhances it by adding a 4-km grid resolution modeling domain covering New Mexico and adjacent regions. Future year modeling, source apportionment and control measure evaluation are planned to assist the NMED in ozone air quality planning for the state.

1.1 NM OAI Project Genesis

The NMED Air Quality Bureau has authority over air quality management activities throughout the state of New Mexico, with the exception Bernalillo County and Tribal Lands. The City of Albuquerque/Air Quality Division has authority in Bernalillo County and, except for where Tribal Implementation Plans have been approved, EPA oversees air quality issues in Tribal Lands. The New Mexico Air Quality Control Act (NMAQCA) requires the NMED to develop a plan to address elevated ozone levels when air quality is within 95% of the ozone NAAQS (74-3-5.3, NMSA 1978[1]). The ozone NAAQS was revised in 2015 with a threshold of 0.070 ppm (70 ppb) with the relevant metric being the ozone Design Value (DV) that is expressed as the three-year average of the fourth highest Maximum Daily Average 8-hour (MDA8) ozone concentrations. Figure 1-1 displays the trends in observed ozone DVs at 8 New Mexico monitoring sites from 2013 to 2018 and compares them with the 70 ppb 2015 ozone NAAQS (red line) and 95% of the 70 ppb NAAQS (i.e., ≥ 67 ppb; black line). This results in 7[2] counties in New Mexico under NMED jurisdiction with measured 2016-2018 ozone DVs at or exceeding 95% of the 70 ppb ozone NAAQS, as shown in Figure 1-1.

[1] https://law.justia.com/codes/new-mexico/2017/chapter-74/article-2/section-74-2-5.3/

[2] 8 total counties in New Mexico if you also include Bernalillo County whose air quality is under the jurisdiction of the City of Albuquerque.

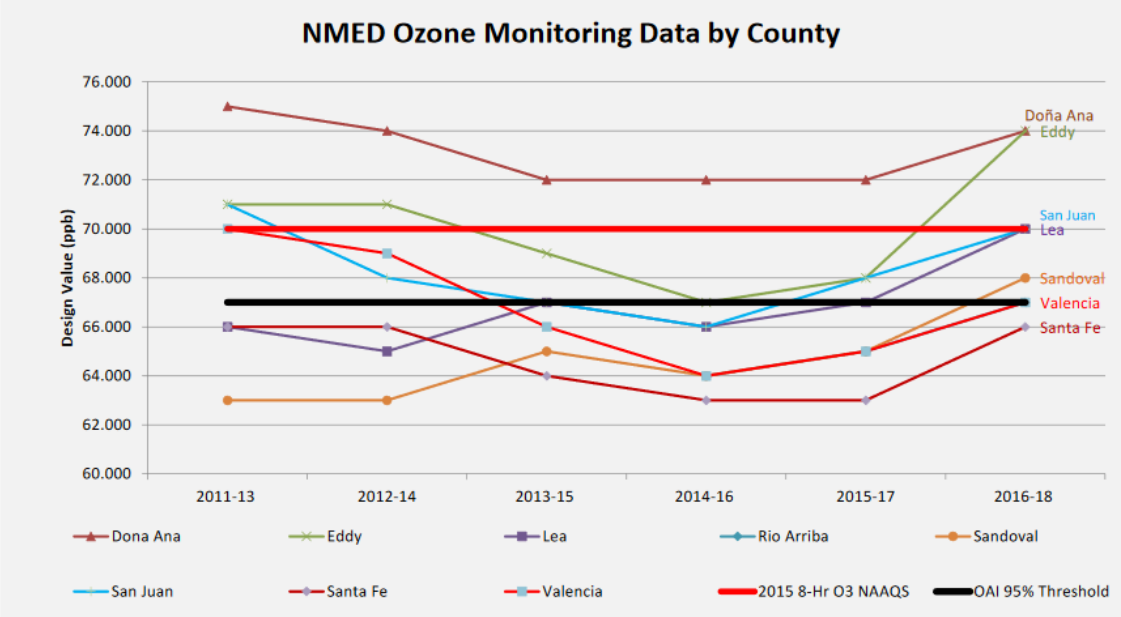

Figure 1-1. Trends in observed ozone DVs between 2013 and 2018 at 7 monitoring sites in New Mexico (Source: https://www.env.nm.gov/air-quality/wp-content/uploads/sites/2/2019/10/OAI_Presentation_09262019.pdf).

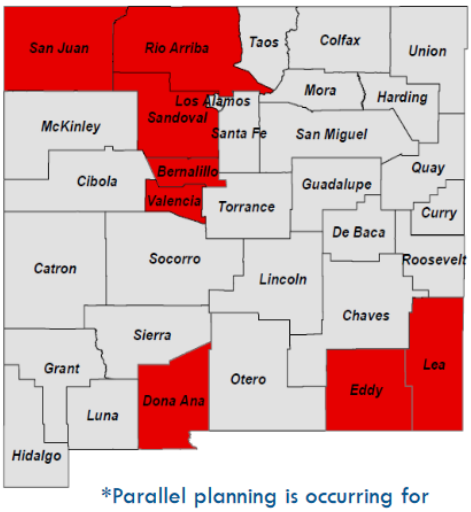

Figure 1-2. 7 counties in New Mexico under the jurisdiction of the NMED whose observed 2016-2018 ozone DVs are at or exceed 95% of the 2015 ozone NAAQS (70 ppb) (Source: https://www.env.nm.gov/air-quality/wp-content/uploads/sites/2/2019/10/OAI_Presentation_09262019.pdf).

To address the high observed ozone concentrations in New Mexico, the NMED has embarked on an Ozone Attainment Initiative (OAI[3]) to protect the ozone attainment status of the state and ensure health and welfare of the residents of the state for future generations. The OAI was initiated in Spring 2018. As part of the OAI, NMED released a Request for Proposal (RFP#20 667 4040 0001) for the NM OAI Study and the NM OAI Study PGM modeling was awarded to a contracting team of WESTAR and Ramboll. .

1.2 Conceptual Model for High Ozone Concentrations in New Mexico

There are three interrelated but distinct Conceptual Models of ozone formation within New Mexico: southern New Mexico, Bernalillo County and surrounding areas, and northern New Mexico. All three regions share the attribute that ozone transport dominates ozone concentrations on all days. Days with the highest local ozone formation are typically hot summer days with slow winds and without an excessive amount of precipitation (summer monsoon).

1.2.1 Southern New Mexico

Ozone at monitoring sites in southern New Mexico, including Dona Ana, Eddy and Lea Counties, is dominated by ozone transport from outside of New Mexico. This transport includes long-range transport from the remainder of U.S. and global sources (e.g., Central America and Asia) as well as medium-range transport from Texas and Mexico. Current year on-road mobile source emissions tend to be the largest contributing Source Sector within southern New Mexico and nearby areas, with non-road mobile and O&G sources also contributing. With the exception of emissions from Mexico, the contributions of Electrical Generating Units (EGU) and other large industrial point sources tends to be smaller than the other Source Sectors.

The Southern New Mexico Ozone Study (SNMOS[4]) conducted CAMx ozone modeling for a 2011 base and 2025 future year using a 12/4-km modeling domain, as shown in the right panel of Figure 1-3. SNMOS found that a vast majority of ozone in southern New Mexico is due to ozone transport from outside of New Mexico. For example, the left panel in Figure 1-3 displays the 2011 and 2025 ozone contributions to the ozone Design Value (DV) at the Desert View monitoring site in Dona Ana County by geographic regions within the 12/4-km PGM modeling domain shown in the right panel in Figure 1-3. Only 3 percent of the 2011 ozone DV at the Desert View monitor in Dona Ana County is due to anthropogenic emissions from New Mexico, and New Mexico emissions contribute less than 2 percent of the projected 2025 ozone DV at Desert View (not shown).

[3] https://www.env.nm.gov/air-quality/o3-initiative/

[4] https://www.wrapair2.org/SNMOS.aspx

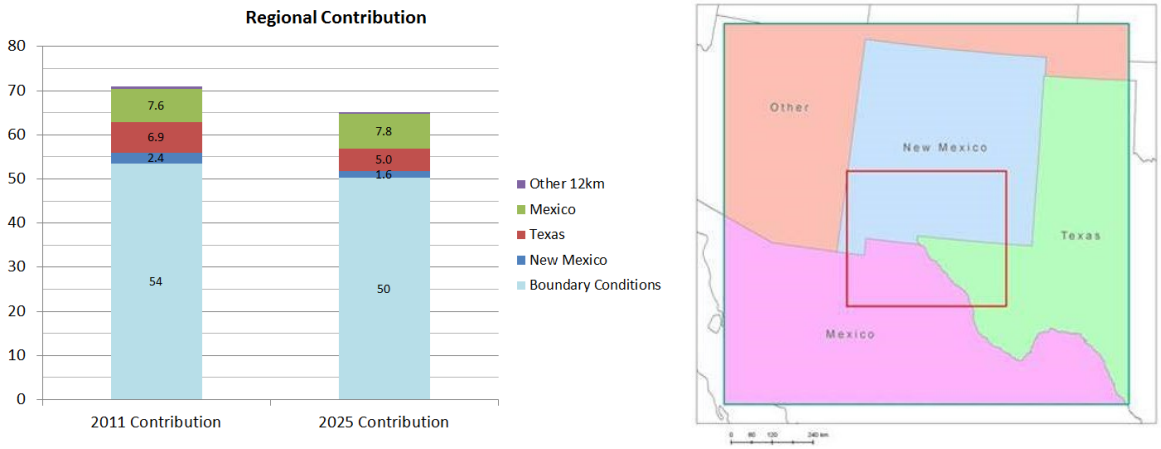

Figure 1-3. Contributions of geographic regions (including Boundary Conditions) to the 2011 and 2025 ozone Design Values at Desert View monitoring site in Dona Ana County in southern New Mexico (left) and 12/4-km modeling domain and definition of source regions (right).

The SNMOS 2011 and 2025 ozone source apportionment modeling also obtained contributions by Source Sector in addition to the four Source Regions depicted in the right panel of Figure 1-3. Figure 1-4 displays the Source Sector contributions to the 2011 and 2025 ozone DV at the Desert View monitor as well as the 10 highest Source Groups (i.e., Source Sector emissions from Source Regions) contributions. On-road mobile sources has the highest contribution to ozone DVs in both 2011 and 2025 (Figure 1-4, top panel), but that is mainly due to on-road mobile source emissions in Texas and Mexico that are the two highest contributing Source Groups (Figure 1-4, bottom panel).

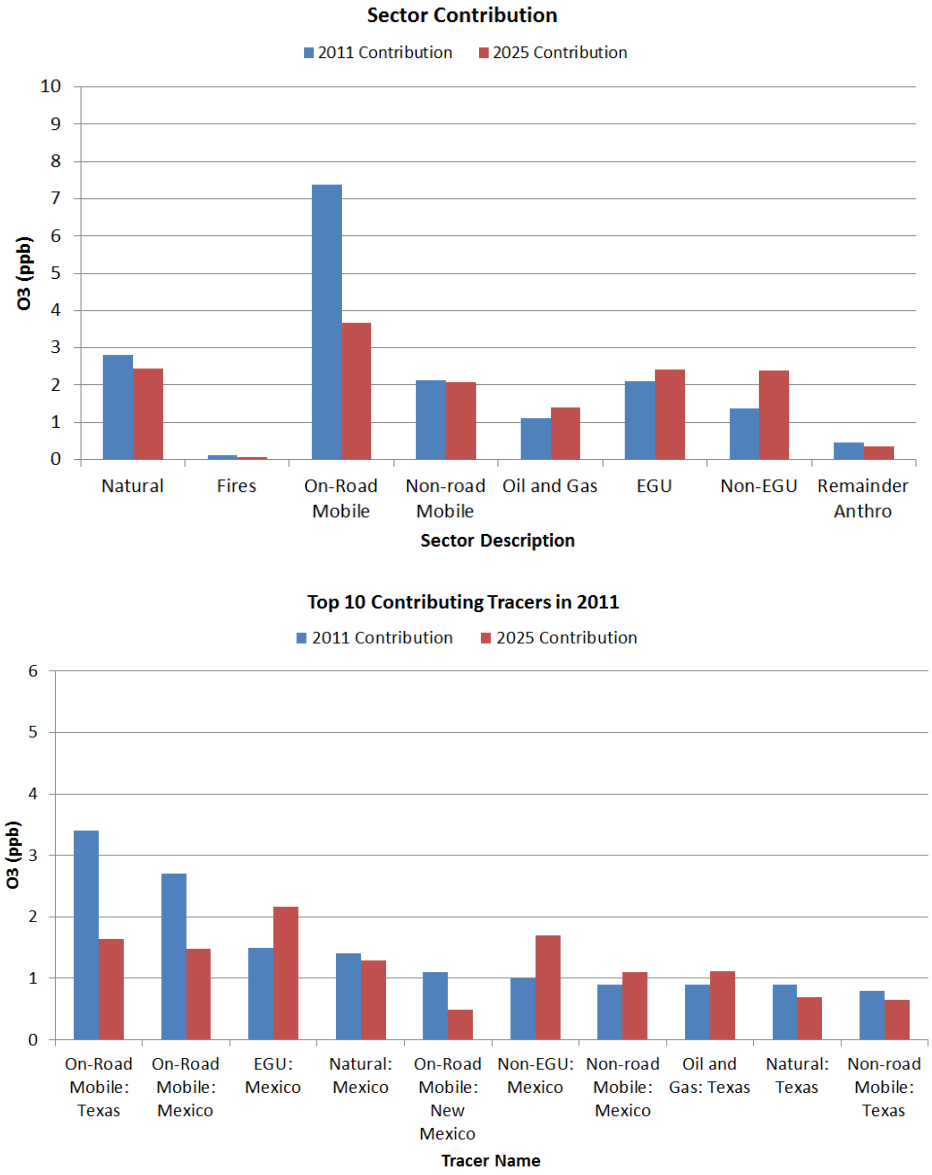

Figure 1-4. Contributions of Source Sector emissions within the 12/4-km modeling domain to the 2011 and 2025 ozone Design Value at Desert View monitoring site (top) and top ten Source Group contributions (bottom).

Figure 1-5 examines the contributions of emissions from New Mexico to 2011 and 2025 ozone DVs at nine monitoring sites in southern New Mexico. With one exception, on-road mobile source emissions are the largest contributing Source Sector in New Mexico to 2011 ozone DVs in southern New Mexico with the on-road mobile contribution at the Solano monitoring site being higher than the others. The one exception is the furthest east Carlsbad monitoring site in Eddy County where O&G emissions are the largest contributing Source Sector in New Mexico due to being within the Permian Basin O&G development region. Although on-road mobile source emissions are the largest

contributor in 2011, it is also the Source Sector whose New Mexico ozone contribution is reduced the most in 2025, by over a factor of two. This is in contrast to O&G whose contribution at the Carlsbad monitoring site is projected to increase between 2011 and 2025, although future year projections of O&G emissions are highly uncertain. In any event, by 2025 the SNMOS estimate that on-road mobile, non-road mobile and O&G Source Sectors in New Mexico will contribute the most, with New Mexico EGU and non-EGU point sources and other anthropogenic emission Source Sectors having relatively lower ozone contributions.

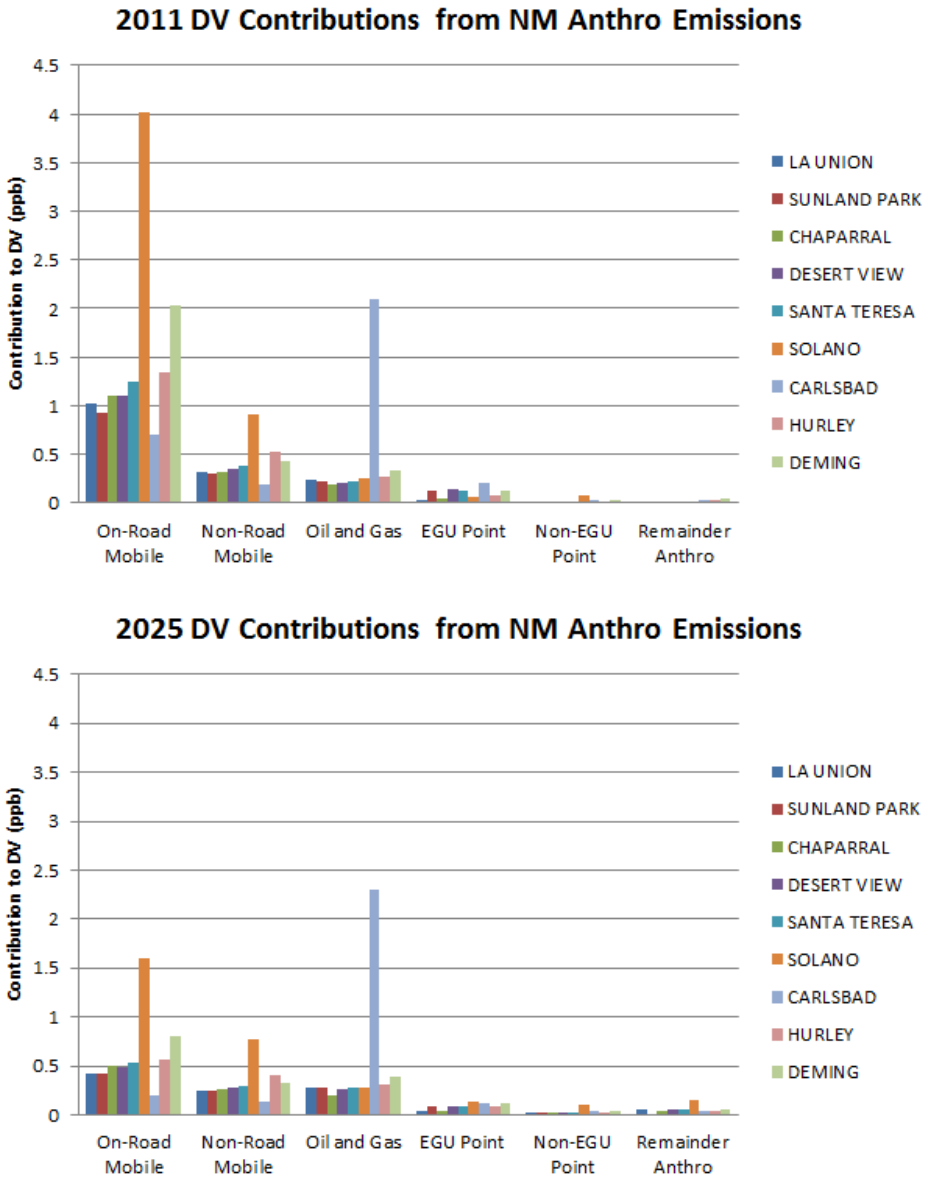

Figure 1-5. Contributions of major Source Sectors in New Mexico to 2011 (top) and 2025 (bottom) ozone DVs at nine monitoring sites in Southwestern New Mexico.

1.2.2 Bernalillo County and Vicinity

High ozone in Bernalillo County and nearby areas is dominated by ozone transport and shares some of same ozone Conceptual Model attributes as northern New Mexico, with the addition of local contributions from a major city (Albuquerque). The City of Albuquerque conducted an ozone modeling study[5] for two episodes in 2017: June 12-16, 2017 and July 3-14, 2017. The purpose of the study was to better understand the source of high ozone concentrations in Bernalillo County and what types of control strategies, if needed, would be most effective at reducing ozone concentrations in the County. Ozone source apportionment was performed to determine the geographic regions that contributed to elevated ozone concentrations in Albuquerque. Figure 1-6 displays the contributions to ozone concentrations in Albuquerque for the June and July episodes. Anthropogenic emissions from New Mexico contributed 14% and 24% to ozone in Albuquerque during the, respectively, June and July 2017 episodes. And anthropogenic emissions from Bernalillo County accounted for up to 75% of the New Mexico contribution. But sources other than New Mexico anthropogenic emissions (e.g., natural sources and sources outside of New Mexico) were the largest contributor accounting for 86% and 76% of the ozone during the, respectively, June and July episodes.

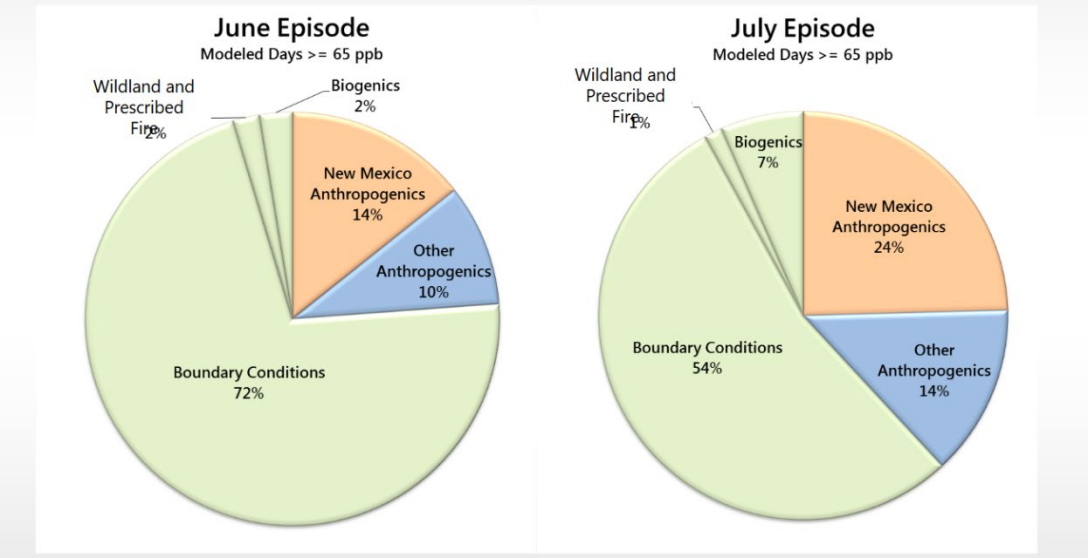

Figure 1-6. Contributions to ozone in Albuquerque during the June and July 2017 modeling episodes.

Although only two short episodes were modeled so any conclusions are limited to those conditions, the City of Albuquerque Ozone Modeling Study concluded as follows:

- Transport from outside of New Mexico is always important and accounts for over half of the ozone in Albuquerque.

[5] https://www.cabq.gov/airquality/documents/06-ken-craig-sonoma-technology-inc-ozone-modeling-presentation-10-17-2018-aqcb-meeting.pdf

- Local emissions in Albuquerque and Bernalillo County are also important with half of the locally generated ozone due to on-road mobile sources in 2017.
- On high ozone days for the two modeled episodes, contributions from major power plants in northern New Mexico were small at sites in Albuquerque.
- Impacts from man-made emissions in western states, including California, are non-negligible.
- Ozone contributions from wildfire smoke were important for both episodes.
- As on-road mobile source emissions are reduced, emissions from non-road and non-mobile sources are becoming increasingly more important.
- NOx emission controls are more effective at reducing high ozone concentrations in Albuquerque than VOC controls.
- Ozone in Albuquerque is sensitive to emissions from O&G sources throughout New Mexico.

1.2.3 Northern New Mexico

The Four Corners Air Quality Task Force (FCAQTF) conducted a comprehensive modeling study of the region and found, although there are significant contributions due to local power plants and O&G production in the San Juan Basin, ozone transport was by far the largest contributor. The FCAQTF identified numerous local control measures that could help mitigate elevated ozone concentrations in the region.

Reddy and Pfister (2016) and CDPHE and RAQC (2016c) analyzed meteorological factors that contributed to the interannual variability in midsummer ozone concentrations focusing mainly on Utah and Colorado that is also relevant to northern New Mexico. Reddy and Pfister analyzed ozone and meteorology for July during 1995-2013 and found several meteorological variables that were able to explain the years with higher ozone formation conditions. The most powerful meteorological variable for describing high ozone formation potential conditions (i.e. ozone conducive conditions) was the height of the 500 hPa[6] pressure level. The Denver 2017 ozone SIP modeling study (CDPHE and RAQC, 2016c) extended the analysis to include more recent years and for summer-average conditions. Figure 1-7 shows the relationship between summer-average 500 hPa heights and summer-average ozone at the Rocky Flats North (RFNO) monitoring site northwest of downtown Denver and the years 1995-2018 that shows years with higher 500 hPa heights tend to have higher ozone, and vice versa.

Figure 1-8 displays the correlation between elevated ozone concentrations and 500 hPa heights in the western U.S. Some of the sites in New Mexico are also weakly to moderately correlated to the 500 hPa heights, like the sites in Denver and Utah. Elevated ozone at sites in northern New Mexico show less correlation with 500 hPa heights as it is believed that the large point source NOx and oil and gas NOx and VOC emissions in the region swamp the signal. But the presence of a large high pressure over the region, which results in slow winds and hot temperatures, is corelated with high ozone concentrations in northern New Mexico.

[6] hPa is100 Pa where Pa is short for Pascal that is a unit of pressure where 500 hPa = 500 mb.

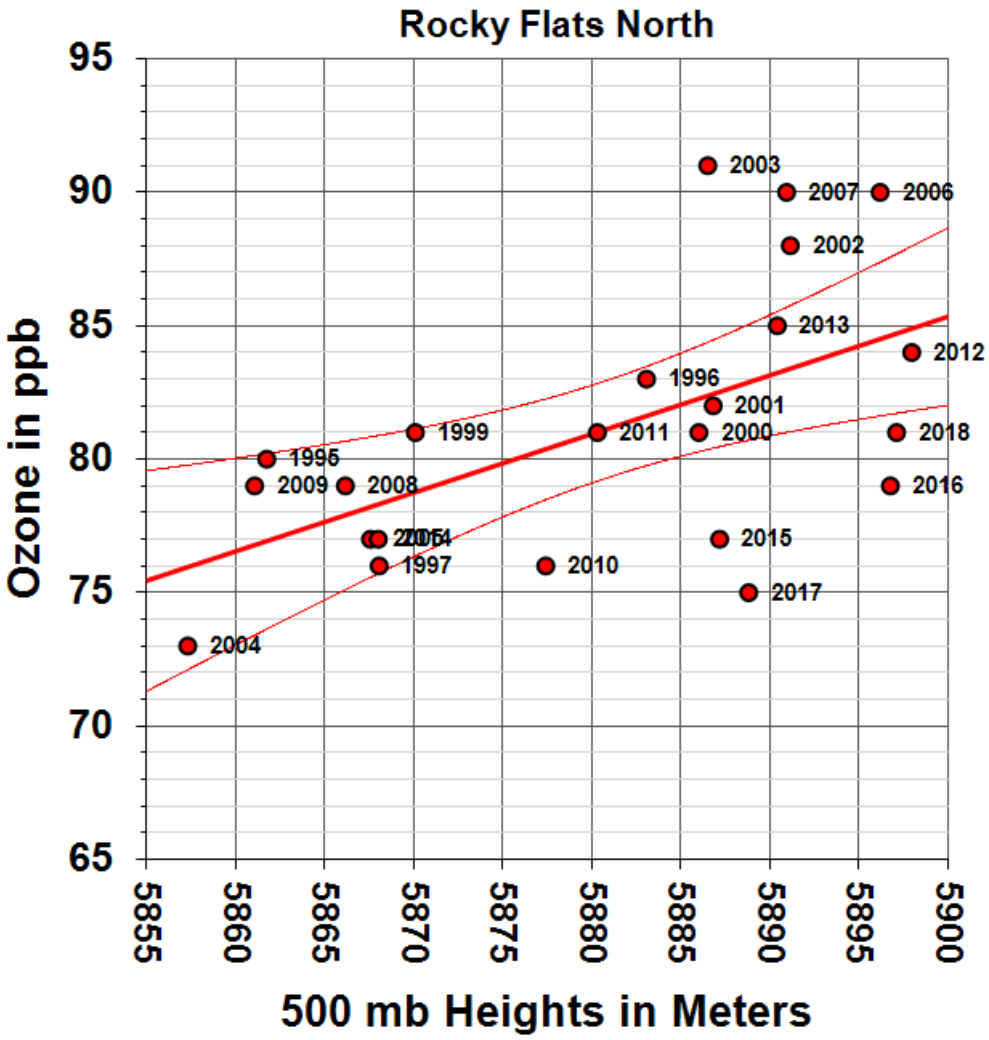

Figure 1-7. Linear regression of the annual 4th highest MDA8 ozone concentrations and mean July through August NCEP/NCAR Reanalysis 500 hPa (or 500 mb) heights for the DM/NFR NAA region at the Rocky Flats North (RFNO) monitoring site for the years 1995 to 2018.

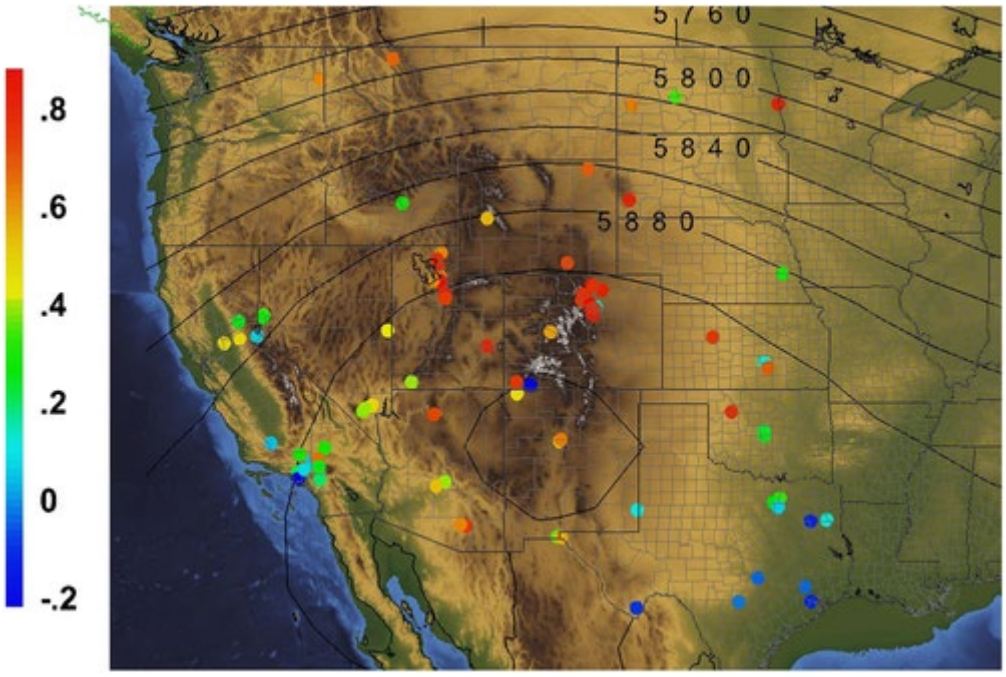

Figure 1-8. Correlation between 500 hPa heights and elevated ozone concentrations for monitoring sites in the western U.S.[7]

1.3 Overview of NM OAI Study Modeling Approach

The procedures used for the NM OAI Study photochemical modeling were described in a detailed Modeling Protocol dated May 19, 2020 (Ramboll and WESTAR, 2020a[8]). A description of the tasks and schedule for completing the NM OAI Study is contained in a Work Plan (Ramboll and WESTAR, 2020b[9]) with presentations, results and reports posted to the NM OAI Study webpage[10] as they are produced.

The NM OAI Study is conducting PGM modeling by enhancing the WRAP-WAQS 2014v2 36/12-km PGM modeling platform[11] with the addition of a new 4-km grid resolution domain covering New Mexico and surrounding areas, especially the oil and gas (O&G) production regions in the Permian and San Juan Basins. The NM OAI Study PGM modeling is performing 2014 base year modeling and model performance evaluation. Future year modeling will also be conducted. The NM OAI Study PGM modeling is being conducted in accordance with EPA's guidance for ozone State Implementation Plan (SIP) attainment demonstration modeling (EPA, 2018d).

[10] https://www.wrapair2.org/NMOAI.aspx
[11] http://views.cira.colostate.edu/wiki#WAQS-2014-Modeling-Platform

The two main studies that the NM OAI Study modeling is leveraging off of to cost-effectively develop a PGM modeling platform for analyzing ozone issues in New Mexico are discussed below.

1.3.1 WRAP-WAQS 2014 PGM Platform Development Study

The WRAP-WAQS developed an annual 2014 PGM modeling platform to address air quality issues in the western states. The initial use of the WRAP-WAQS 2014 PGM modeling platform is to address the western state technical needs for their Regional Haze SIPs that are scheduled to be submitted to EPA by July 2021. But the platform is designed so it can be used to address visibility, ozone, particulate matter, deposition and other air quality and air quality related values issues in the western states.

An initial WRAP-WAQS 2014v1 PGM modeling platform was developed in 2019 for the CAMx and CMAQ PGMs that is documented in a webpage[12] on the Intermountain West Data Warehouse (IWDW). Additional diagnostic sensitivity tests were conducted to address several model performance issues culminating in the WRAP-WAQS 2014v2 36/12-km CAMx modeling database that was used as the starting point for the NM OAI Study CAMx summer of 2014 36/12/4-km modeling database. The develop of the WRAP-WAQS 2014v2 PGM database and model performance evaluation is available in a webpage[13] on the IWDW.

The WRAP-WAQS 2014v2 CAMx platform used a 36/12-km grid resolution domains structure as shown in Figure 1-9. Meteorological inputs were based on the WAQS 2014 36/12/4-km WRF meteorological model simulation (Bowden, Talgo and Adelman, 2016[14]). The 2014 emissions were based on the 2014 National Emissions Inventory (2014NEI[15]) with updates from western states[16]. Boundary Condition (BC) inputs were based on a WRAP 2014 GEOS-Chem model simulation.

Because the NM OAI Study requires a 4-km modeling domain for New Mexico, new summer of 2014 36/12/4-km WRF meteorological modeling was conducted that was used to develop 36/12/4-km meteorological inputs for CAMx. The NM OAI Study defined their 36/12-km domains to match WRAP-WAQS 2014v2 36/12-km domains so the WRAP-WAQS 2014v2 36/12-km emission and some other inputs (e.g., BCs) can be directly used in the NM OAI Study PGM modeling.

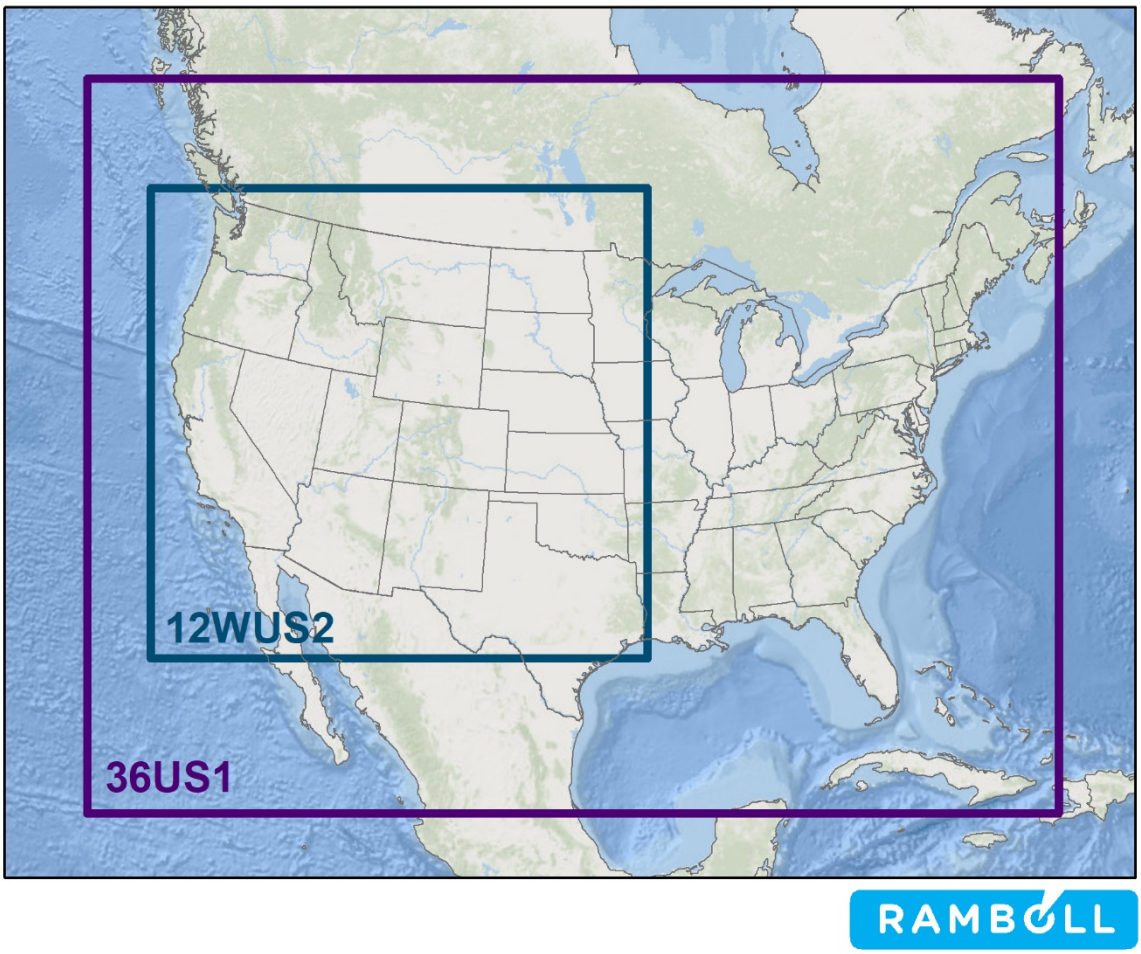

Figure 1-9. 36-km continental U.S. (36US1) and 12-km western U.S. (12WUS2) modeling domains used in the WRAP-WAQS CAMx 2014v2 modeling platform.

1.3.2 EPA 2016v1 Modeling Platform

The EPA, Multi-Jurisdictional Organizations (MJOs), and states conducted a collaborative national 2016 emissions modeling platform[17] (2016 EMP) study to develop a 2016 emissions inventory of comparable quality to the NEI. Separately, EPA developed a 2016 PGM modeling platform that used a 12-km grid resolution continental U.S. domain and an expanded 36-km grid resolution 36US3 domain. EPA has released several versions of their 2016 36/12-km PGM modeling platform with version 1 being the latest version (2016v1).

EPA's 2016v1[18] PGM modeling platform uses the 2016 EMP version 1 emissions[19] from the EPA/MJO/states emissions collaborative study (called 2016fh). It was released in

[17] http://views.cira.colostate.edu/wiki/wiki/9169

[18] https://www.epa.gov/air-emissions-modeling/2016v1-platform

[19] http://views.cira.colostate.edu/wiki/wiki/10202

October 2019 with future year emissions for 2023 and 2028 (2023fh and 2028fh inventories). Since the release of the EPA 2016v1 modeling platform in October 2019, there have been several updates to the emissions, as follows:

1. Updates to 2023 and 2028 EGU emissions to address the accidental dropping of NOx and SO2 emissions for a few EGU sources (January 2020). EPA found that source/hour where the heat input, steam load, and gross load are all zero in the hourly CEMs data, SMOKE will set all emissions to zero for that source/hour, even if the CEMs NO_X or SO2 for that source/hour is not zero.[20]
2. The 2023 and 2028 Commercial Marine Vessel (CMV) emissions were updated to address hoteling and to match the 2016 days-of-week (February 2020).[21]
3. The WRAP 2016 and 2023 O&G emissions were added as an option to EPA's 2016 and 2023 O&G estimates (April 2020). This resulted in double counting as EPA incorrectly had O&G emissions in files that were not supposed to include O&G emissions (i.e., non-EGU point) so corrections have to be made if the WRAP 2023 O&G emissions are used.
4. New 2016, 2023 and 2028 airport emissions for all airports to correct an error that resulted in airport emissions that are a little more than half of the airport emissions in the initial release of the 2016v1 inventories.
5. The SMOKE processing of the 2016 EGU emissions dropped some EGUs as duplicates when they were not. This appears to be a minor issues for EGUs in the western states (August 2020).

The NM OAI Study plans to use the EPA 2016v1 emission projections in their future year modeling.

1.3.3 Episode Selection

The May-August 2014 modeling period was selected as it has a high quality emissions inventory with western state updates and has a PGM platform already developed from the WRAP-WAQS regional haze modeling that can be leveraged for the NM OAI Study. Details on the episode selection are contained in Chapter 3 of the NM OAI Study Modeling Protocol (Ramboll and WESTAR, 2020a).

1.3.4 Model Selection

Details on the rationale for model selection are provided in Chapter 2 of the NM OAI Study Modeling Protocol (Ramboll and WESTAR, 2020a). The Weather Research Forecast (WRF) prognostic meteorological model was selected. Emissions modeling will be performed using the Sparse Matric Operator Kernel Emissions (SMOKE) model for most source categories. The Model of Emissions of Gases and Aerosols from Nature (MEGAN v3.1) will be used for biogenic emissions. There are special processors for fires, windblown dust (WBD), lightning NOx (LNOx) and oceanic sea salt (NaCl) and Dimethyl Sulfide (DMS) emissions that were used. The 2014 version of the MOtor Vehicle Emissions Simulator (MOVES2014b) on-road mobile source emissions model

[20] ftp://newftp.epa.gov/Air/emismod/2016/v1/2023fh1_2028fh1_addendum/README_2023fh1_2028fh1_ptegu_addendum.txt

[21] http://views.cira.colostate.edu/wiki/wiki/11205

will be used with SMOKE-MOVES and WRF meteorological data to generate on-road mobile source emissions for the 4-km New Mexico modeling domain.

The Comprehensive Air-quality Model with extensions (CAMx) photochemical grid model (PGM) was used because it supports two-way grid nesting, was used in the WRAP-WAQS regional haze modeling, contains a well-vetted ozone source apportionment tool and has a rich and successful history of application to the region.

1.3.5 Domain Selection

The NM OAI Study modeling is using the same 36-km 36US and 12-km 12WUS2 domains as used in the WRAP-WAQS 2014 modeling platform (Figure 1-9). A new 4-km New Mexico domain was added to the 36/12-km domain structure. Figure 1-10 displays the 36/12/4-km domain structure with Figure 1-11 showing the 4-km New Mexico domain. New WRF 2014 36/12/4-km meteorological modeling was conducted to generate finer scale 4-km meteorological conditions for the New Mexico domain and consistent meteorology among the 36/12/4-km domains. The domains use a Lambert Conformal Conic (LCC) projection using the parameters given in Table 1-1 with the definitions of the extent of the 36/12/4-km domains given in Table 1-2. CAMx will be run using the 36/12/4-km domain structure shown in Figure 1-10 using two-way interactive grid nesting.

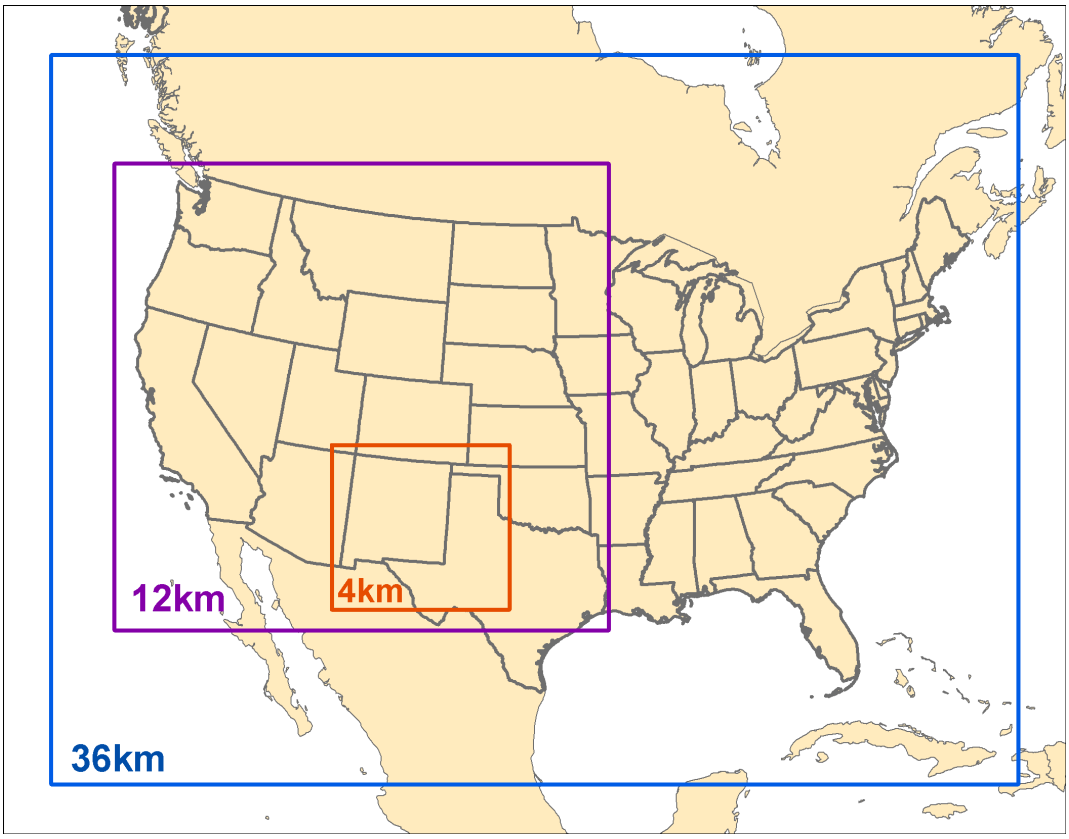

Figure 1-10. NM OAI Study 2014 36/12/4-km PGM and emissions modeling domains.

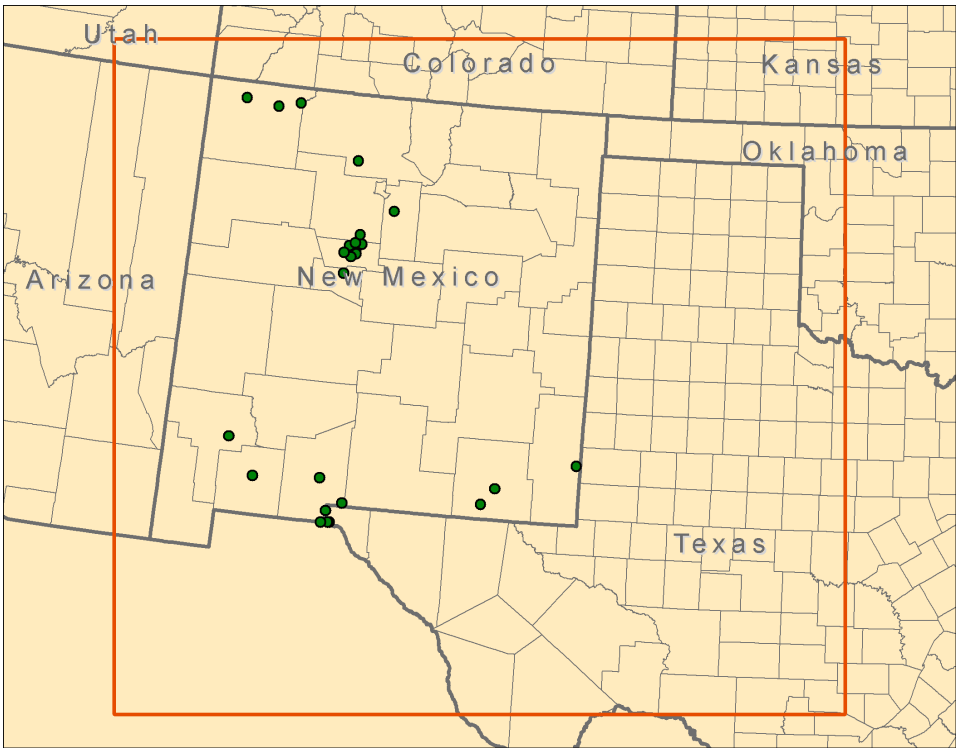

Figure 1-11. 4-km New Mexico modeling domain for PGM and emissions modeling, with locations of New Mexico ozone monitors that were operating during some portion of 2014.

Table 1-1. Lambert Conformal Conic (LCC) projection parameters for the NM OAI Study 36/12/4 modeling domains.

Parameter	Value
Projection	Lambert-Conformal
1st True Latitude	33 degrees N
2nd True Latitude	45 degrees N
Central Longitude	-97 degrees W
Central Latitude	40 degrees N

Table 1-2. Grid definitions for CAMx NM OAI Study 2014 36/12/4-km modeling domains.

Grid	Origin (SW) (km)	Extent (NE) (km)	NX	NY
36-km	(-2736, -2088)	(2592, 1944)	148	112
12-km*	(-2388, -1236)	(336, 1344)	227	215
4-km*	(-1192, -1120)	(-212, -212)	245	227

*Definition includes outer row/column of buffer cells required by CAMx for nested domains

1.3.6 Base and Future Year Emissions Data

The 2014 base year emissions data were based on the WRAP-WAQS 2014v2 emissions that were in turn based on the 2014NEIv2 with updates from western states. New emissions were generated for natural emission sources (e.g., biogenic and LNOx). Future year emissions are based on the EPA 2016v1 modeling platform. The 2014, 2023 and 2028 emissions for New Mexico were reviewed by NMED and updated to address their comments.

1.3.7 Initial and Boundary Conditions Development

The first two-weeks of May were run on the 36/12/4-km domains to spin-up the model before the first high ozone day in New Mexico (68 ppb on May 17). This washes out the influence of the initial concentrations (IC) before elevated ozone concentrations occur in New Mexico.

Boundary conditions (BC) for the outer 36-km 36US domain were based on a 2014 simulation of the GEOS-Chem global chemistry model conducted by WRAP processed by the GC2CAMx converter. The result is day-specific diurnally varying BCs for the lateral boundaries around the 36-km 36US modeling domain. The top BC (TopCon) was based on a zero-gradient assumption where concentrations above the top of the model (above 50 mb, or ~19-km above sea level) are assumed to be the same as in the top vertical layer of CAMx.

Chapter 3 has more details on the development of the 2014 CAMx BC inputs. Because of uncertainties in international emissions and their projections, the 2014 BCs will be held constant for the future year modeling.

1.3.8 Diagnostic Sensitivity Analyses

The NM OAI Study conducted four diagnostic sensitivity tests for the CAMx 2014 36/12/4-km base case that compared the CAMx ozone performance for four alternative meteorological inputs. The NM OAI Study conducted two WRF 2014 36/12/4-km WRF simulations that used different analysis fields as input. The two 2014 36/12/4-km WRF outputs were processed with WRFCAMx using two different options for vertical turbulent exchange (i.e., vertical mixing) coefficients (Kv or Kz). This resulted in four different CAMx meteorological inputs that were evaluated using CAMx diagnostic sensitivity tests that are described in Chapter 5.

1.3.9 Model Performance Evaluation

The NM OAI Study CAMx 2014 36/12/4-km base case simulation Model Performance Evaluation (MPE) followed EPA's MPE recommendations in their ozone modeling guidance (EPA, 2018a) and other sources (e.g., Simon, Baker and Phillips, 2012; Emery et al., 2016). The CAMx 2014 36/12/4-km base case simulation MPE focuses on ozone model performance within the 4-km New Mexico domain, and especially within New Mexico. The CAMx 2014 MPE is presented in Chapter 7.

1.3.10 Future Year Base and Control Strategy Modeling

Future year modeling for ozone will be performed using the EPA 2016v1 platform 2028 emission projections. A CAMx future year 36/12/4-km base case simulation will be conducted and used to project future year ozone design values (DVs). The procedures to calculate projected ozone DVs will follow EPA's latest guidance (EPA, 2018d). These procedures use the modeling results in a relative fashion to scale the current year observed 8-hour ozone Design Values (DVCs) to project future year ozone Design Values (DVFs). The scaling factors are called Relative Response Factors (RRFs) and are the ratio of the future-year to current-year modeling results for the 10 highest base year modeled MDA8 ozone days near the monitoring site. EPA has developed the Speciated Modeled Attainment Test (SMAT[22]) tool that includes the recommended procedures in the latest EPA guidance for projecting ozone DVFs.

The current NM OAI Study also plans to conduct future year emission reduction control strategy sensitivity modeling. The future year modeling will be discussed in a separate report at a later date.

1.3.11 Future Year Source Apportionment Modeling

The current NM OAI Study has plans to conduct future year ozone source apportionment modeling using the CAMx Anthropogenic Precursor Culpability Assessment (APCA) ozone source apportionment tool. The WRAP 2014 GEOS-Chem global chemistry base case, ZROW and NAT simulation will be processed to isolate the contributions of U.S. anthropogenic, International anthropogenic and natural sources to the BCs. Within New Mexico, contributions will be obtained for the major Source Sectors. A NM OAI Study future year ozone source apportionment plan will be developed and discussed with NMED prior to conducting the source apportionment modeling.

2. 2014 WRF METEOROLOGICAL MODELING

The NM OAI Study conducted 2014 36/12/4-km WRF meteorological modeling to generate CAMx meteorological inputs for the summer of 2014 and the 36/12/4-km domain structure shown in Figure 1-10.

2.1 WRF Meteorological Model

The Weather Research and Forecasting (WRF) Model is a mesoscale numerical weather prediction system designed to serve both operational forecasting and atmospheric research needs (Skamarock, 2004; 2006; Skamarock et al., 2005; 2008; 2019). The Advanced Research WRF (ARW) version of WRF was used in the NM OAI Study.

This chapter describes the application and evaluation of the WRF meteorological model to generate 2014 36/12/4-km meteorological inputs for CAMx photochemical grid modeling. The WRF model contains separate modules to compute different physical processes, such as surface energy budgets and soil interactions, turbulence, cloud microphysics, and atmospheric radiation. Within WRF, the user has many options for selecting the different schemes for each type of physical process. The WRF Pre-processing System (WPS) generates the initial conditions (ICs) and boundary conditions (BCs) and analysis fields used by WRF, based on topographic datasets, land use information, and larger-scale atmospheric and oceanic models.

2.2 WRF Horizontal Modeling Domain

The PGM (CAMx) 2014 36/12/4-km modeling domains were shown in Figure 1-10 in the previous Chapter. The WRF 2014 36/12/4-km modeling domains are shown in Figure 2-1 and were defined slightly larger than the PGM 36/12/4-km domains so that any modeling artifacts that occur near the WRF boundaries as the BCs come into dynamic balance with the WRF numerical algorithms are not present in the PGM meteorological inputs.

NMED Exhibit 16

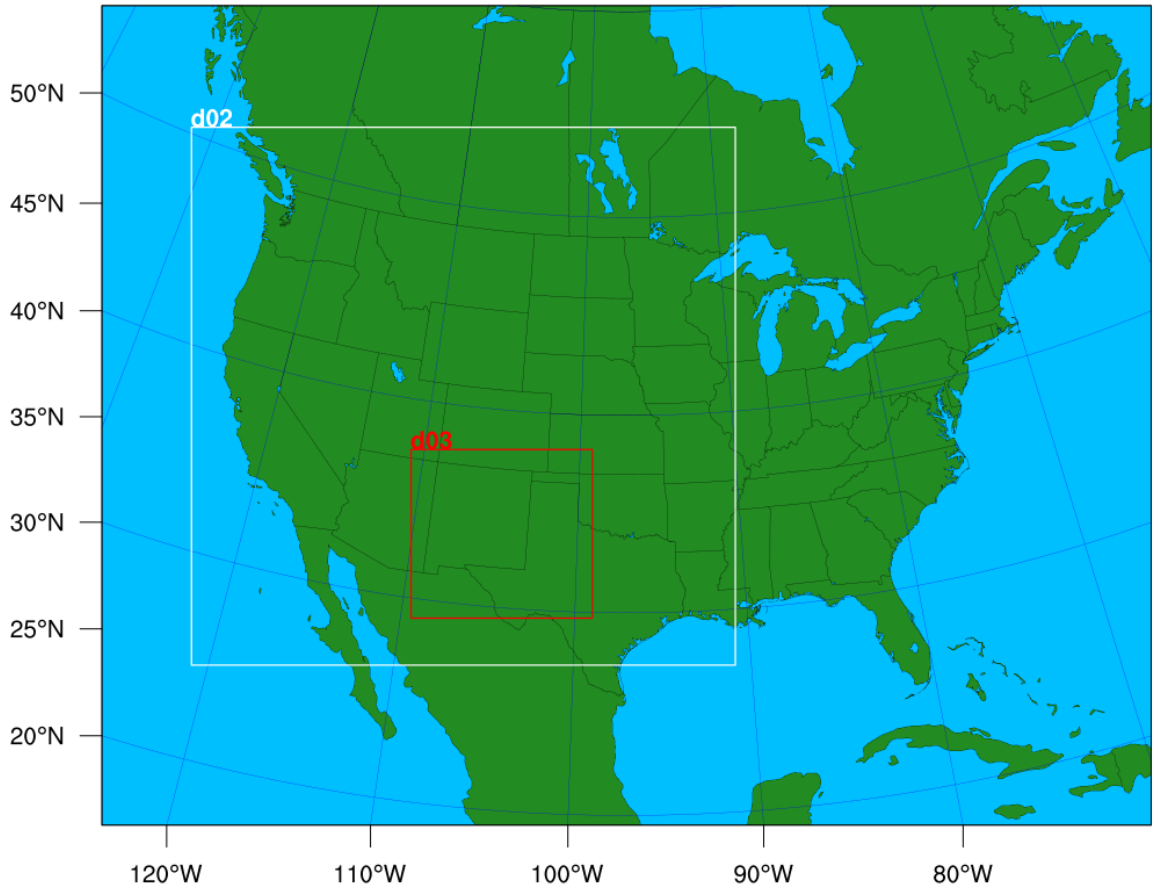

Figure 2-1. WRF 36-km (outer extent), 12-km (d02) and 4-km (d03) modeling domains used in the NM OAI Study.

2.3 WRF Model Configuration

WPS and WRF version 4.2 were used for this modeling analysis. Previous studies utilizing WRF at high resolution over New Mexico, such as the WRAP WestJumpAQMS, WAQS, SNMOS and EPA modeling platform development, have evaluated different configurations of WRF. Table 2-2 presented later in this section summarizes the WRF configurations used in the NM OAI Study and compares it to the WRF configuration used in the WRAP-WAQS 2014 and EPA 2014/2015/2016 WRF modeling. Preliminary analysis of WRAP-WAQS 2014 WRF 12 km model performance in New Mexico showed superior summertime precipitation performance compared to EPA's 2014 WRF modeling.[23] Therefore, the NM OAI Study WRF application was set to match the WRF physics configuration options used by WRAP-WAQS 2014 WRF modeling, except where noted below.

The NM OAI Study 36/12-km WRF/PGM grid configuration (e.g., horizontal domains and vertical layer structure) was designed to be identical to the WRAP-WAQS 2014

[23] https://www.wrapair2.org/pdf/NM_OAI_Study_Webinar1_2020-05-28.pdf

WRF/PGM grid configuration in order the facilitate the use of data between the two studies.

2.3.1 Model Vertical Resolution

The WAQS 2011/2014 WRF modeling used 36 vertical levels (35 vertical layers) from the surface to a 50 mb (hPa) height (approximately 19-km above sea level). The EPA 2014, 2015 and 2016 WRF modeling also used 35 vertical layers up to a 50 mb height. Table 2-1 displays the 36-vertical layer structure used in the WRAP-WAQS 2011/2014 WRF modeling that was also adopted for the NM OAI Study WRF 2014 36/12/4-km modeling.

2.3.2 Vertical Coordinate

Since its inception, WRF has used the eta (sometimes called sigma or "terrain-following") vertical coordinate system. One weakness of the eta coordinate is that variations in terrain (especially steep topography) can increase numerical errors in the model. To reduce these errors, Park et al., (2018) developed a hybrid sigma–pressure coordinate that is now included as the default vertical coordinate system for the WRF model (Skamarock et al., 2019).

Figure 2-2 shows vertical cross sections of layer interface heights over the Rocky Mountains during a strong near-surface wind event (Park et al., 2018). The left panel shows the results using the eta or terrain-following vertical coordinate and the right panel shows the same results but using the new hybrid vertical coordinate. The eta coordinate cross-sections show the influence of terrain extending high into the stratosphere. This is a representation of numerical noise and results in erroneous vertical motion in the model. Park et al., (2018) found that the simulation using the eta vertical coordinate produced high turbulence forecasts aloft which were not observed by pilots or soundings. In CAMx, erroneous vertical motion can help transport stratospheric ozone toward the surface. In contrast, the same simulation using the hybrid vertical coordinate produced lower turbulence forecasts that agreed more closely with observations. The hybrid vertical coordinate cross-sections show a gradual damping of terrain effects with increasing altitude until the layer interfaces are flat aloft. The purpose of using the hybrid vertical coordinate in the CAMx is to better represent ozone in the upper troposphere and lower stratosphere. Eliminating this source of numerical noise reduces spurious downward transport of stratospheric ozone.

For the NM OAI Study 2014 36/12/4-km WRF modeling, we used the new hybrid vertical coordinate system and a new version of the WRFCAMx processor that has been updated to use WRF's hybrid vertical coordinate. The hybrid vertical coordinate system and use of 4-km New Mexico domain are the two biggest differences between the NM OAI Study and WRAP-WAQS 2014 WRF modeling. The WRAP-WAQS 2014 WRF/CAMx modeling did not use the hybrid vertical coordinate system in WRF because at the time it was not supported in the WRFCAMx processor.

NMED Exhibit 16

Table 2-1. WRF 36 level vertical layer structure for the NM OAI study. This is the same WRF layer structure as used in WAQS 2011/2014/2016 and EPA 2016 WRF modeling.

WRF Layer	Sigma	Pressure (mb)	Height (m)	Thickness (m)
36	0.0000	50.00	19260	2055

NMED Exhibit 16

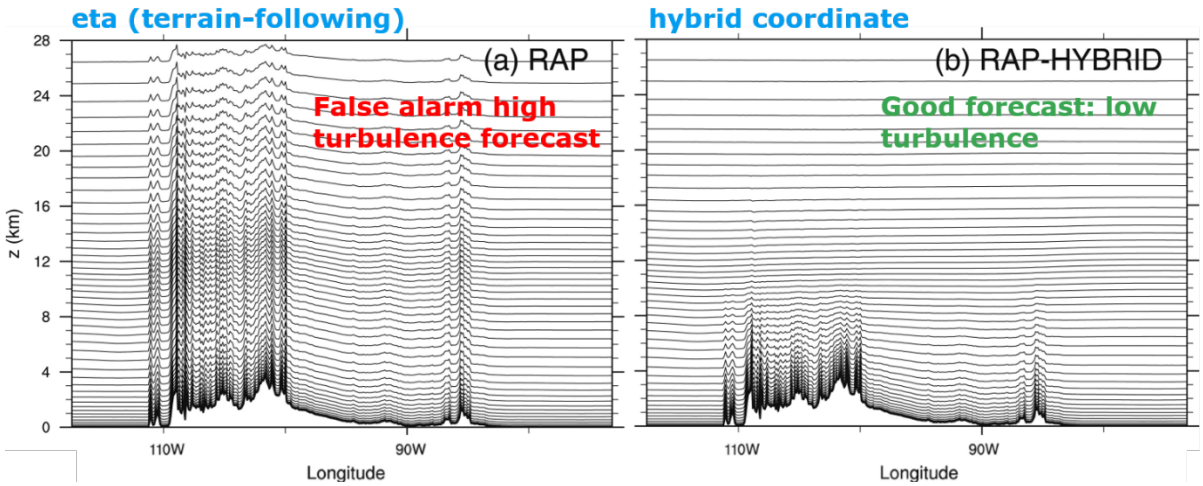

Figure 2-2. Cross-sections of layer interface heights over the Rocky Mountains for the eta (left panel) and hybrid (right panel) vertical coordinates for the WRF-Based Rapid Refresh (RAP) model. Adapted from Park et al., (2018).

2.3.3 Topographic Inputs

Topographic information for WRF was based on a combination of the standard WRF terrain databases and high-resolution terrain. The 36-km 36US domain used the 10-minute global data, the 12-km 12WUS2 domain used the 2-minute data, and the 4-km New Mexico domain used the 30 second data.

2.3.4 Vegetation Type and Land Use Inputs

Vegetation type and land use information used the United States Geological Survey (USGS) land use databases from the most recently released WRF databases provided with the WRF distribution. Standard WRF surface characteristics corresponding to each land use category was employed.

2.3.5 Atmospheric Data Inputs

WRF relies on other model or re-analysis output meteorological fields to provide initial and boundary conditions (IC/BC) and fields for the four-dimensional data assimilation (FDDA). FDDA refers to the nudging of the WRF meteorological fields to observed analysis fields so that the WRF meteorological fields better represent what was observed and prevent the model from drifting away from the observed meteorology. As seen in Table 2-2, both the WRAP-WAQS 2014 and EPA 2014/2015/2016 12-km WRF modeling used the 12-km resolution North American Mesoscale Forecast System (NAM[24]) analysis fields for IC/BC and analysis nudging (i.e., FDDA).

The NM OAI Study applied WRF with two different analysis fields that were evaluated for their performance against meteorological variables as well as their effect on CAMx ozone model performance. Both the NAM and the ~30-km resolution European Center for Medium-Range Weather Forecasting (ECMWF) Re-Analysis (ERA5[25]) dataset analysis

[24] https://www.ncdc.noaa.gov/data-access/model-data/model-datasets/north-american-mesoscale-forecast-system-nam

[25] https://www.ecmwf.int/en/forecasts/datasets/archive-datasets/reanalysis-datasets/era5

fields were used for IC/BC and FDDA in the two NM OAI Study WRF sensitivity simulations. We have found from previous work that the ERA-Interim (lower resolution predecessor to ERA5) dataset has lower humidity near the surface and higher humidity aloft leading to lower convective available potential energy (CAPE), which lowers overall precipitation rates, especially during the summer Monsoon season that is important for ozone modeling in New Mexico. Many WRF simulations of the southwest U.S. summer Monsoon have featured an over-prediction of summertime (convective) precipitation when the NAM analysis fields are used. The Southern New Mexico Ozone Study (SNMOS) conducted PGM ozone sensitivity modeling using meteorological fields based on WRF simulations using the NAM and ERA analysis fields and found that the PGM results using the WRF/ERA meteorological inputs produced superior ozone performance than when WRF/NAM inputs were used so the SNOMS ended up using the WRF/ERA meteorological inputs.[26]

The ERA5 is a fairly new analysis fields product that has not been used in WRF modeling as extensively as the ERA fields. We conducted WRF and PGM sensitivity modeling using the NAM and ERA5 analysis fields to determine which configuration provides the best meteorological inputs and best ozone model performance. The ERA5 fields were objectively re-analyzed using meteorological observational data to the higher resolution for the 36-km and 12-km grid domains using the OBSGRID program. These fields are used both to initialize the model and used with analysis nudging FDDA (on the 36/12-km domains) to guide the model to better match the observations.

2.3.6 Time Integration

Third-order Runge-Kutta integration was used (rk_ord = 3). The maximum time step, defined for the outer-most domain (36 km) only, is set by evaluating the following equation:

$$dt = \frac{6dx}{F_{map}}$$

Where dx is the grid cell size in km, Fmap is the maximum map factor (which can be found in the output from REAL.EXE), and dt is the resulting time-step in seconds. For the case of the 36 km RPO domain, dx = 36 and Fmap = 1.08, so *dt* should be taken to be less than 200 seconds. Longer time steps risk CFL errors, associated with large values of vertical velocity, which tend to occur in areas of steep terrain (especially during stable conditions typical of winter). For this WRF run, adaptive time-stepping was used with a maximum timestep of 180s.

2.3.7 Diffusion Options

Horizontal Smagorinsky first-order closure (km_opt=4) with sixth-order numerical diffusion and suppressed up-gradient diffusion (diff_6th_opt=2) was used.

[26] https://www.wrapair2.org/SNMOS.aspx

NMED Exhibit 16

2.3.8 Lateral Boundary Conditions

Lateral boundary conditions was specified from the initialization dataset (i.e., either NAM or ERA5) on the 36-km WRF domain with continuous updates nested from each "parent" domain to its "child" domain, using one-way nesting (feedback=0).

2.3.9 Top and Bottom Boundary Conditions

The implicit Rayleigh dampening for the vertical velocity was used for the top boundary conditions. Consistent with the model application for non-idealized cases, the bottom boundary condition was selected as physical, not free-slip.

2.3.10 Sea Surface Temperature Inputs

The water temperature data for the WRF application was taken from the Fleet Numerical Meteorology and Oceanography Center (FNMOC)[27]. The FNMOC product has horizontal resolution of about 9-km in the mid-latitudes but is produced *four* times per day using AVHRR satellite sensors and in-situ observations.

2.3.11 Four Dimensional Data Assimilation (FDDA)

Analysis nudging was used for winds, temperature, and humidity on the 36-km and 12-km domains. Both surface and aloft nudging was used but nudging for temperature and mixing ratio was not performed within the boundary layer. Observation nudging was not used, even on the 4-km domain.

2.3.12 New Lightning Data Assimilation

More recently, the assimilation of lightning data in WRF simulations has shown to improve the locations and amounts of convective precipitation. The use of lighting detection networks, such as the National Lightning Detection Network (NLDN), have been used in WRF simulations and used to force deep convection (thunderstorms) when lightning is observed and only allow shallow convection when lightning is not present. The use of the new lightning assimilation approach has been demonstrated to improve both WRF convective precipitation as well as PGM concentration and deposition performance (Heath et al., 2016). The new lightning data assimilation algorithms was not used in the NM OAI Study 2014 WRF modeling for several reasons: (1) it would have to be tested and evaluated and there is insufficient time in the schedule to conduct such diagnostic testing; (2) the NLDN data used to date with the WRF lightning assimilation is a commercial product that is expensive and not within the budget; (3) the implementation of the lightning detection data assimilation in WRF has a flaw that it doesn't distinguish between no lightning detects and missing data and suppresses convection in areas with missing data (e.g., over the Gulf of Mexico); and (4) the lightning detection data assimilation algorithm has not been implemented in the latest versions of WRF so its use would limit the use of other model options.

2.3.13 PBL and LSM Physics Options

As used in the WRAP-WAQS 2014 WRF modeling, the YSU Planetary Boundary Layer (PBL) and Noah Land Surface Model (LSM) physics options were used in the NM OAI

[27] https://www.usno.navy.mil/FNMOC

Study 2014 36/12/4-km WRF modeling. Previous WRF sensitivity modeling for the intermountain west region found the YSU/Noah PBL/LSM schemes produces the most realistic meteorological fields. Note that EPA's 2014/2015/2016 WRF modeling uses the ACM2 PBL and Pleim-Xiu (PX) LSM schemes (Table 2-2). The WRAP-WAQS tried to evaluate WRF using the ACM2/PX PBL/LSM and found it more difficult to implement and didn't always run so that annual fields could not be generated. Furthermore, the PX LSM scheme requires each run segment of a WRF run soil moisture inputs to be initialized using the previous WRF run segment PX output so that an annual WRF simulations must be run in series. This contrasts with the Noah LSM scheme that initializes soil moisture based on observations with some spin-up time (typically 12-hours) that allows annual WRF runs to be performed using parallel run segments (e.g., 5.5 day run segments). Thus, annual WRF simulations using the YSU/NOAH PBL/LSM physics options can be completed much faster than when ACM2/PX is used.

2.3.14 Remaining WRF Physics Options

Table 2-2 lists the remaining WRF physics options for the NM OAI Study 2014 36/12/4-km WRF application. These are standard WRF physics options and consistent with the WRF options used in the WRAP-WAQS 2014 and EPA 2014/2015/2016 WRF modeling. Our comparison of 2014 WRAP-WAQS and 2014 EPA WRF modeling for summertime precipitation performance in New Mexico found that the WRAP-WAQS WRF meteorological model performance was better than EPA WRF for most variables. Therefore, we used the same microphysics and cumulus schemes for the NM OAI Study as used in 2014 WRAP-WAQS (Thompson and Multi-Scale Kain-Fritsch, respectively) and most of the same other physics options (Table 2-2).

Table 2-2. NM OAI Study 2014 WRF model configuration and comparison with the WRF configuration used in the WRAP-WAQS 2014 and EPA 2014/2015/2016 WRF modeling.

WRF Option	NM OAI Study	2014 WRAP-WAQS	2014 EPA
Horizontal Domains	36/12/4-km	36/12/4-km	12-km
Vertical Coordinate	Hybrid Sigma	Sigma	Sigma

Obs Nudging	None	4-km	None
Sea Sfc Temp	FNMOC	FNMOC	FNMOC

NMED Exhibit 16

2.3.15 Application Methodology

The WRF model was executed in 5.5-day blocks initialized at 12Z every five days. Model results were output every 60 minutes, split at twelve (12) hour intervals. Twelve (12) hours of spin-up is included in each 5-day block before the data is used in the subsequent evaluation and PGM meteorological inputs.

2.4 WRF Model Evaluation

Quantitative and qualitative evaluations of the NM OAI Study 2014 WRF 36/12/4-km simulation meteorological performance was conducted for both the WRF/NAM and WRF/ERA5 applications. The quantitative evaluations compare integrated surface hourly meteorological observations with WRF predictions matched by time and location and included the calculation of model performance statistical metrics that were compared against performance benchmarks. The qualitative evaluations compared time series plots of modeled wind speed and wind direction to the observations at specific sites. The qualitative evaluation also compared spatial plots of WRF precipitation estimates against spatial maps of precipitation analysis fields based on observations The evaluation focuses on the meteorological model performance within the 4-km New Mexico domain.

2.4.1 Quantitative Evaluation Using METSTAT

A quantitative model performance evaluation of the NM OAI Study 2014 WRF modeling was conducted using the publicly available METSTAT software (Ramboll Environ, 2015) evaluation tool. Output from the WRF meteorological model was compared against meteorological observations for sites located in New Mexico. This was carried out both graphically and statistically to evaluate model performance for surface winds, temperatures and humidity. The purpose of these evaluations is to establish a first-order acceptance/rejection of the simulation in adequately replicating the weather phenomena in the study area. Thus, this approach screens for obvious model flaws and errors.

2.4.1.1 Quantitative Statistics

The quantitative analysis was conducted using METSTAT. Statistical measures calculated by METSTAT include observation and prediction means, prediction bias, and prediction error that are given as follows.

Mean Observation (M_o) is calculated using values from all sites for a given time period by Eq. **(5-1)**:

$$M_o = \frac{1}{IJ}\sum_{j=1}^{J}\sum_{i=1}^{I} O_j^i \qquad (5\text{-}1)$$

where O^i_j is the individual observed quantity at site i and time j, and the summations are over all sites (I) and over time periods (J).

Mean Prediction (M_p) is calculated from simulation results that are interpolated to each observation used to calculate the mean observation for a given time period by Eq. **(5-2)**:

$$M_p = \frac{1}{IJ}\sum_{j=1}^{J}\sum_{i=1}^{I} P_j^i \quad (5\text{-}2)$$

where P^i_j is the individual predicted quantity at site *i* and time *j*. Note the predicted mean wind speed and mean resultant direction are derived from the vector-average (for east-west component *u* and north-south component *v*), from which the

Bias (B) is calculated as the mean difference in prediction-observation pairings with valid data within a given analysis region and for a given time period by Eq. **(5-3)**:

$$B = \frac{1}{IJ}\sum_{j=1}^{J}\sum_{i=1}^{I}\left(P_j^i - O_j^i\right) \quad (5\text{-}3)$$

Gross Error (E) is calculated as the mean *absolute* difference in prediction-observation pairings with valid data within a given analysis region and for a given time period by Eq. **(5-4)**:

$$E = \frac{1}{IJ}\sum_{j=1}^{J}\sum_{i=1}^{I}\left|P_j^i - O_j^i\right| \quad (5\text{-}4)$$

Note that the bias and gross error for winds are calculated from the predicted-observed residuals in speed and direction (not from vector components *u* and *v*). The direction error for a given prediction-observation pairing is limited to range from 0 to ±180°.

Root Mean Square Error (RMSE) is calculated as the square root of the mean squared difference in prediction-observation pairings with valid data within a given analysis region and for a given time period by Eq **(5-5)**:

$$RMSE = \left[\frac{1}{IJ}\sum_{j=1}^{J}\sum_{i=1}^{I}\left(P_j^i - O_j^i\right)^2\right]^{\frac{1}{2}} \quad (5\text{-}5)$$

The RMSE, as with the gross error, is a good overall measure of model performance. However, since large errors are weighted heavily (due to squaring), large errors in a small sub-region may produce a large RMSE even though the errors may be small and quite acceptable elsewhere.

2.4.1.2 METSTAT Processing

METSTAT was developed to calculate and graphically present statistics associated with temporally paired meteorological model predictions and observations. The horizontal analysis range can be given for an entire output grid, by a coordinate box, or as a list of specific site identifiers (such as WBAN or AIRS numbers), as labeled on the observational file. This allows for an evaluation at a single site, a subset of specific sites (e.g., within a state) or over an entire regional domain. The program then proceeds to calculate statistics for each hour and for each day of the time window.

NMED Exhibit 16

The process involves statistical comparisons of model data from the WRF grid cells to observational measurements located with each grid cell. METSTAT evaluates wind speed and direction, air temperature, and air humidity using both bias and error statistics. METSTAT has been widely applied to WRF runs for many years, across many modeling domains. Using a consistent definition of the statistical quantities to be calculated and a consistent methodology for pairing observations in time, METSTAT allows for more straightforward comparisons between model applications in widely different regions and time periods.

2.4.1.3 Statistical Benchmarks

METSTAT calculates statistical performance metrics for bias, error and correlation for surface winds, temperature, and mixing ratio (i.e., water vapor or humidity). To evaluate the performance of a meteorological model simulation for air quality model applications, a number of performance benchmarks for comparison are typically used. Table 2-3 lists the meteorological model performance benchmarks for simple (Emery et al., 2001) and complex (Kemball-Cook et al., 2005) situations. The simple benchmarks were developed by analyzing well-performing meteorological model evaluation results for simple, mostly flat terrain conditions and simple meteorological conditions (e.g., stationary high pressure) that were mostly conducted to support air quality modeling studies (e.g., ozone SIP modeling). The complex benchmarks were developed during the Western Regional Air Partnership (WRAP) regional haze modeling and are performance benchmarks for more complex conditions, such as the complex terrain of the Rocky Mountains and Alaska (Kemball-Cook et al., 2005). McNally (2009) analyzed multiple annual runs that included complex terrain conditions and suggested an alternative set of benchmarks for temperature under more complex conditions. The purpose of the benchmarks is to understand how good or poor the results are relative to other model applications run for the U.S.

The NM OAI Study 2014 WRF application compared the WRF meteorological variables to the benchmarks as an indication of WRF model performance. These benchmarks include bias and error in temperature, wind direction and mixing ratio as well as the wind speed bias and Root Mean Squared Error (RMSE) between the models and databases.

NMED Exhibit 16

Table 2-3. Meteorological model performance benchmarks for simple and complex conditions.

Parameter	Emery et al. (2001)	Kemball-Cook et al. (2005)	McNally (2009)	Resulting Criteria
Conditions	Simple	Complex	Complex	Complex
Temperature Bias	≤ ±0.5 K	≤ ±2.0 K	≤ ±1.0 K	≤ ±1.0 K
Temperature Error	≤ 2.0 K	≤ 3.5 K	≤ 3.0 K	≤ 3.0 K
Temperature IOA	≥ 0.8	(not addressed)	(not addressed)	≥ 0.8
Humidity Bias	≤ ±1.0 g/kg	≤ ±0.8 g/kg	≤ ±1.0 g/kg	≤ ±1.0 g/kg
Humidity Error	≤ 2.0 g/kg	≤ 2.0 g/kg	≤ 2.0 g/kg	≤ 2.0 g/kg
Humidity IOA	≥ 0.6	(not addressed)	(not addressed)	≥ 0.6
Wind Speed Bias	≤ ±0.5 m/s	≤ ±1.5 m/s	(not addressed)	≤ ±1.5 m/s
Wind Speed RMSE	≤ 2.0 m/s	≤ 2.5 m/s	(not addressed)	≤ 2.5 m/s
Wind Speed IOA	≥ 0.6	(not addressed)	(not addressed)	≥ 0.6

Wind Dir. Error	≤ 30 degrees	≤ 55 degrees	(not addressed)	≤ 55 degrees

The output from the 2014 WRF 4-km domain was compared against meteorological data obtained from the National Climate Data Center's (NCDC) global-scale, quality-controlled DS3505 integrated surface hourly observational (ISHO) data (NOAA-NCDC, 2015) as verification data. Global hourly and synoptic observations are compiled from numerous sources into a single common ASCII format and common data model. The DS3505 database contains records of most official surface meteorological stations from airports, military bases, reservoirs/dams, agricultural sites, and other sources dating from 1901 to the present.

A standard set of statistical metrics from the METSTAT package was used. These metrics were calculated on hourly, daily and monthly time frames for wind speed, wind direction, temperature, and humidity at the surface, using all available observational weather data. The WRF surface meteorological model performance metrics were compared against the simple and complex model performance goals using "soccer plots." Soccer plots use two WRF performance metrics as X-axis and Y-axis values (e.g., temperature bias as X, and temperature error as Y) along with the performance benchmarks. The closer the symbols are to the zero origin, the better the model performance. It is also easy to see when the two WRF performance metrics fall within the benchmark lines.

2.4.1.4 Surface Wind Speed Performance

Figure 2-3 displays the WRF/NAM and WRF/ERA5 wind speed soccer plot that compares monthly measures of wind speed bias and error across surface monitoring sites in New Mexico with the simple and complex benchmarks. The monthly wind speed performance of the two WRF simulations are remarkably similar with both having near zero bias that achieves the simple benchmark (≤±0.5 m/s). The error (RMSE) for the two WRF simulations falls between the simple and complex benchmarks (i.e., between 2.0 and 2.5 m/s) for all four months (May through August).

2.4.1.5 Surface Wind Direction Performance

The monthly wind direction bias and error statistics for the two WRF simulations are also nearly identical with bias values of ~5 degrees that achieves the ≤±5 degree simple benchmark and error statistics that falls between the 30 degree simple and 50 degree complex benchmarks (Figure 2-4).

2.4.1.6 Surface Temperature Performance

There are differences in the two WRF simulations temperature performance and more differences in the monthly values than seen for winds (Figure 2-5). The WRF/ERA5 simulations has a near zero temperature bias in May and June with the bias and error achieving the simple benchmark for both months. The WRF/NAM has a warm bias for May and June that straddle the simple benchmark upper bound (+0.5 K). The two WRF simulations have similar Jul and August performance that have a warm bias of ~1.0 K that fails to achieve the simple benchmark. For both WRF simulations, the temperature bias is right at but mostly within the 2.0 K simple benchmark.

2.4.1.7 Surface Humidity Performance

The WRF/ERA5 clearly has better surface humidity performance than WRF/NAM (Figure 2-6). For July and August, the WRF/NAM has a wet bias in July and August of ~1.5 g/kg so fails to achieve the simple (≤±0.8 g/kg) and complex (≤±1.0 g/kg) bias benchmarks. The WRF/ERA5 also has a wet bias for July and August that is not as large as WRF/NAM as it is right at the simple benchmark (~ 1.0 g/kg) but achieving the complex benchmark. The WRF/ERA5 also has better humidity error performance in July and August, although both simulations achieve the error performance benchmarks.

The two WRF simulations have better humidity performance in May and June that achieves the simple benchmark, albeit with a moist bias. May is the best performing month with nearly identical humidity model performance with a bias of ~0.6 g/kg and error of ~0.9 g/kg. In June, the WRF/ERA5 humidity performance is slightly better than WRF/NAM.

NMED Exhibit 16

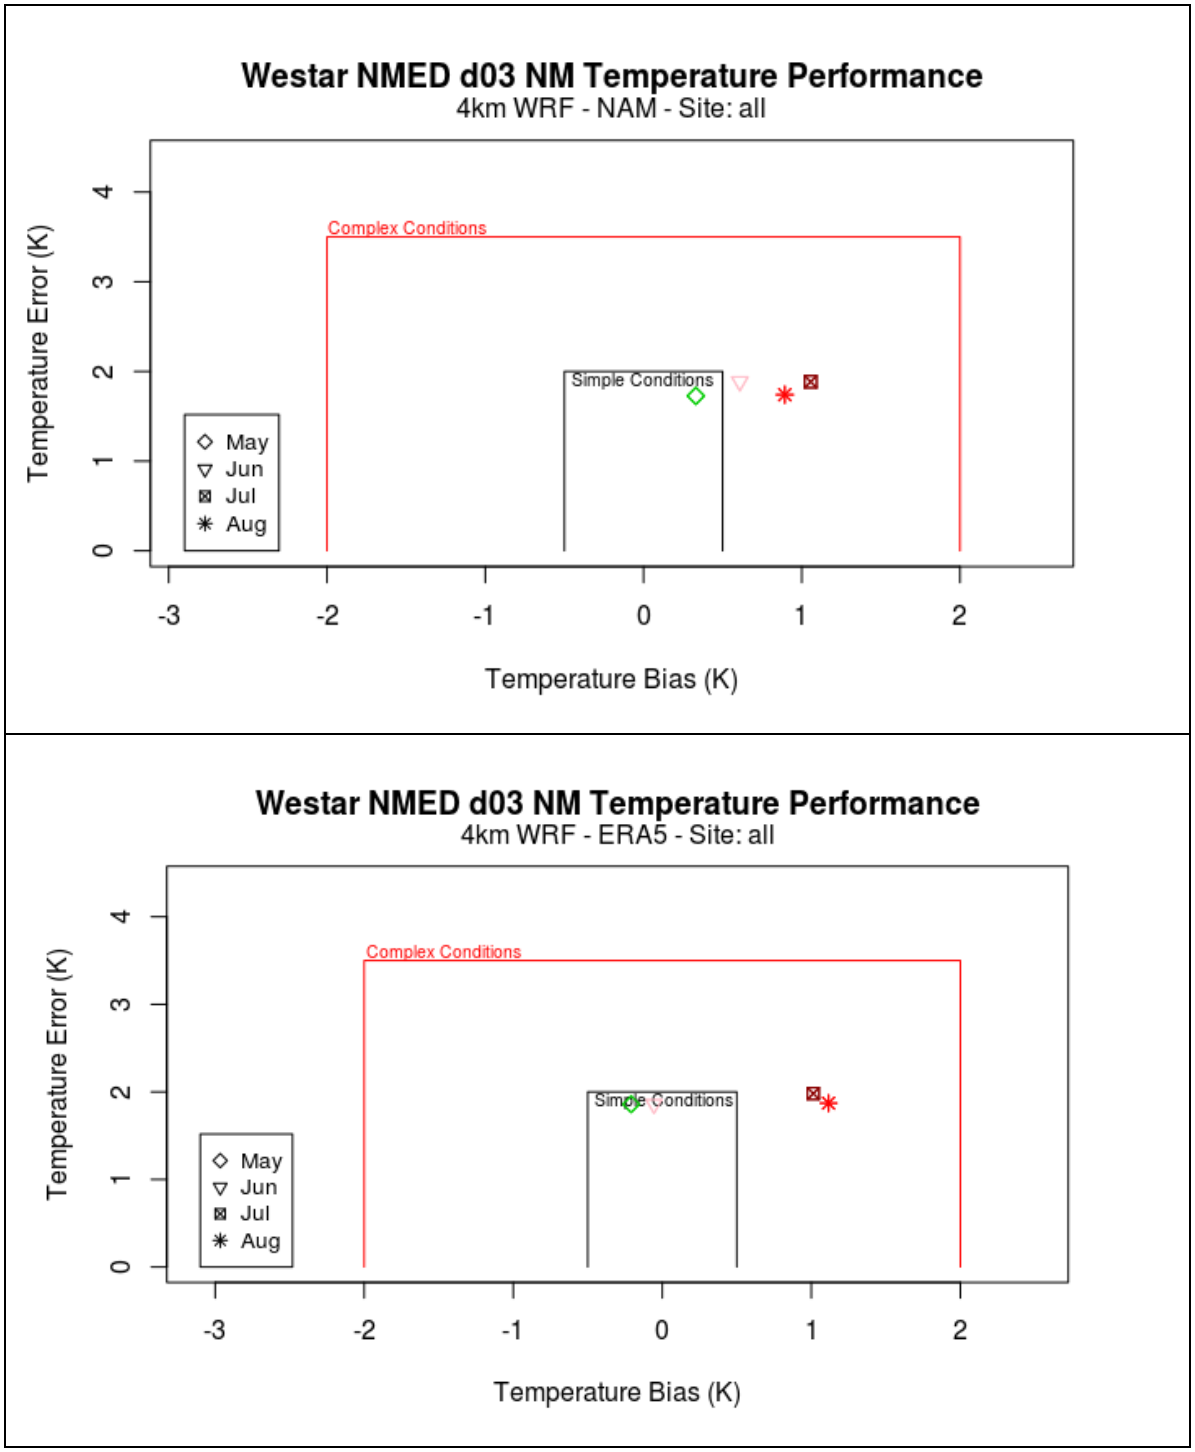

Figure 2-5. Soccer plot comparing WRF/NAM (top) and WRF/ERA5 (bottom) surface temperature (K) model performance against the Simple and Complex Benchmarks for monthly RMSE (y-axis) and Mean Bias (x-axis).

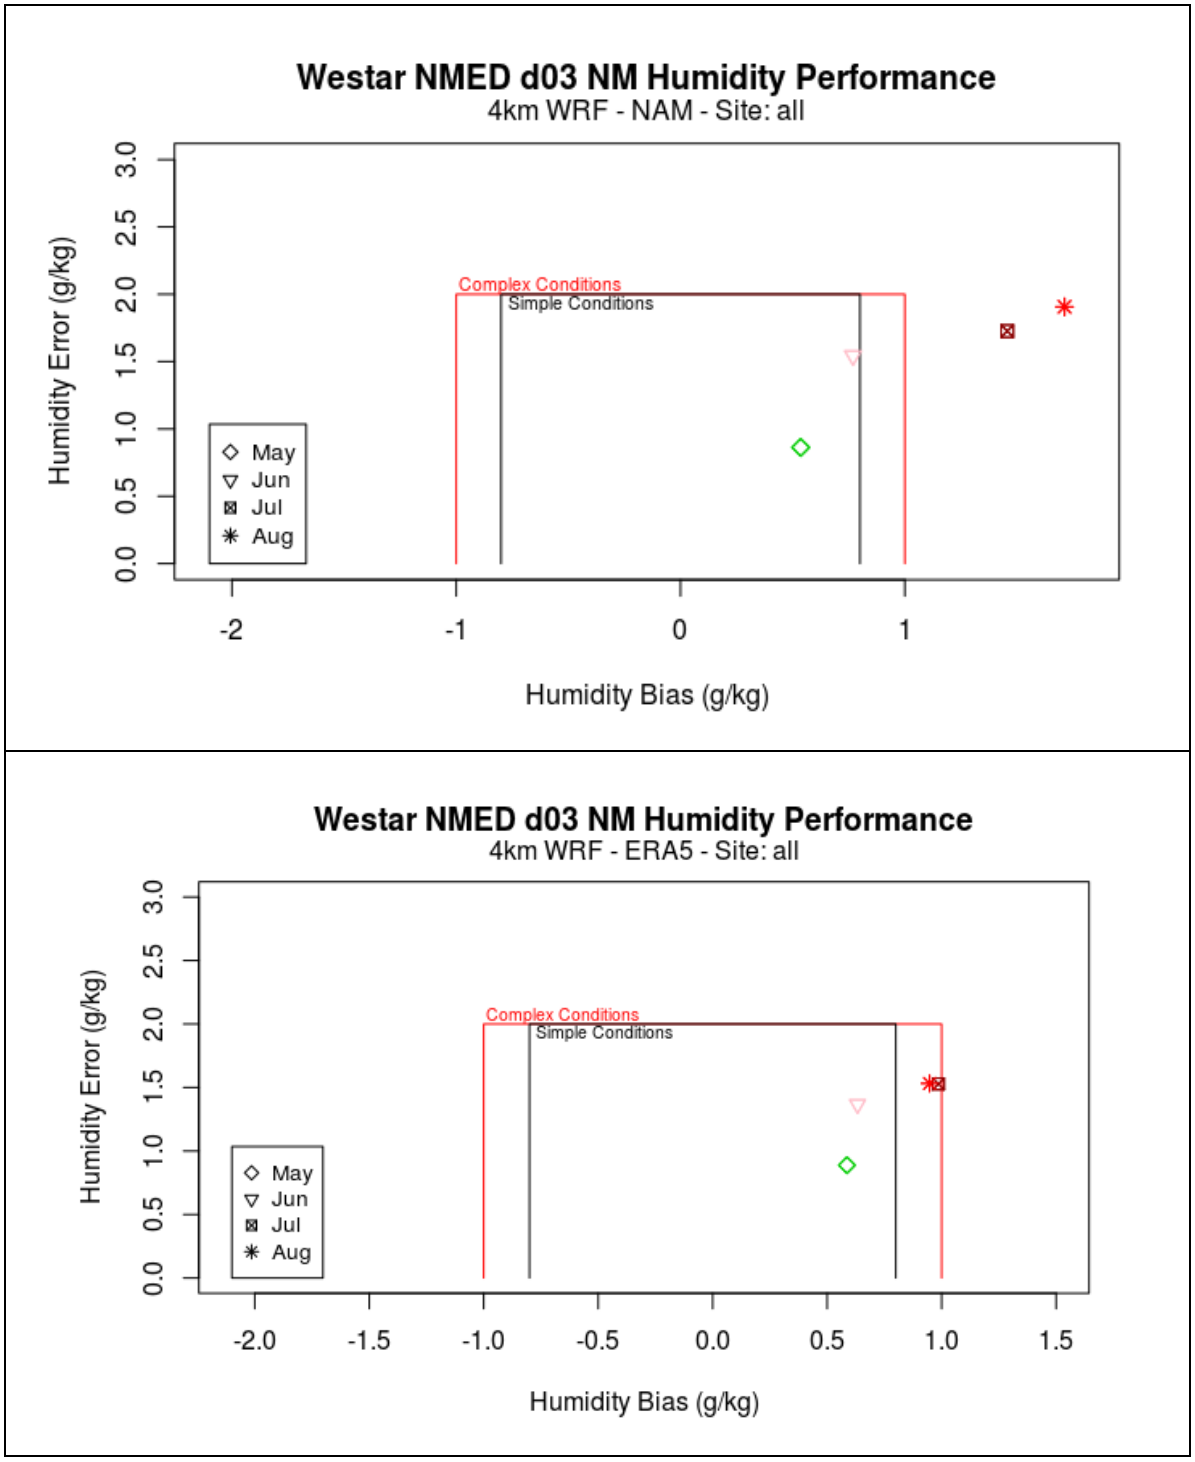

Figure 2-6. Soccer plot comparing WRF/NAM (top) and WRF/ERA5 (bottom) surface humidity (g/kg) model performance against the Simple and Complex Benchmarks for monthly RMSE (y-axis) and Mean Bias (x-axis).

2.4.1.8 Example Site-Specific Humidity Performance

METSTAT was used to evaluate the two WRF simulations for surface meteorological performance for each site in New Mexico. Figures 2-7 and 2-8 show example humidity model performance time series and soccer plots at the Las Cruces International Airport that is 8 miles west of the City of Las Cruces in Dona Ana County. In May, the two WRF simulations have nearly identical daily humidity performance at Las Cruces with a slight overestimation bias that is approximately 0.5 g/kg (Figure 2-7). In June, the humidity performance of the two WRF simulations at Las Cruces start to deviate from each other so by mid-June the WRF/NAM starts to have a large humidity overestimation bias that is as high as 4 g/kg; both simulations have large swings in variations in humidity bias. During the second half of June through July and August the WRF/NAM humidity bias tends to range from 0 to 3 g/kg, while the WRF/ERA5 bias ranges from -1 to +1.5 g/kg. These variations are likely due to the occurrence of monsoonal convective activity that can be very spotty and are also very difficult phenomena for a meteorological model to accurately reproduce.

The soccer plot of monthly humidity model performance at Las Cruces (Figure 2-8) shows that the WRF/ERA5 is clearly performing better with all months achieving the simple benchmark with a slight moist bias of from 0.2 to 0.6 g/kg. The WRF/NAM May humidity performance also achieves the simple benchmark and is nearly identical to WRF/ERA5, but for June, July and August the WRF/NAM monthly humidity performance at Las Cruces has a moist bias of from 1.5 to 2.1 g/kg that fails to achieve the benchmarks (≤±1.0 g/kg).

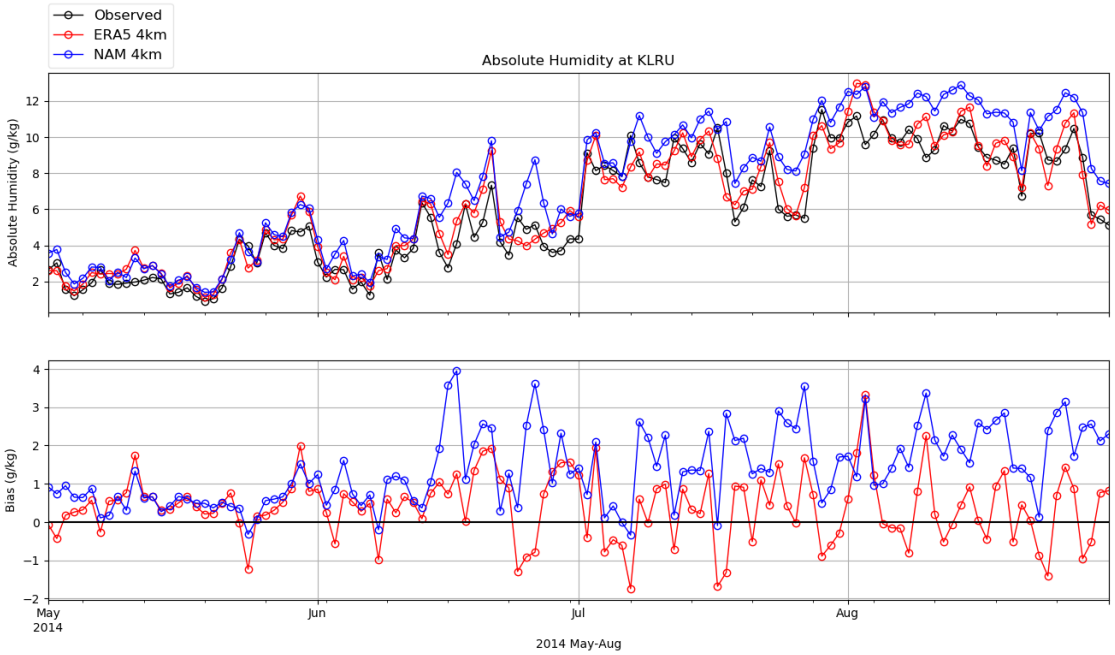

Figure 2-7. Time series plot of predicted and observed (black) daily humidity (g/kg) at Las Cruces International Airport for the WRF/ERA5 (red) and WRF/NAM (blue) simulations.

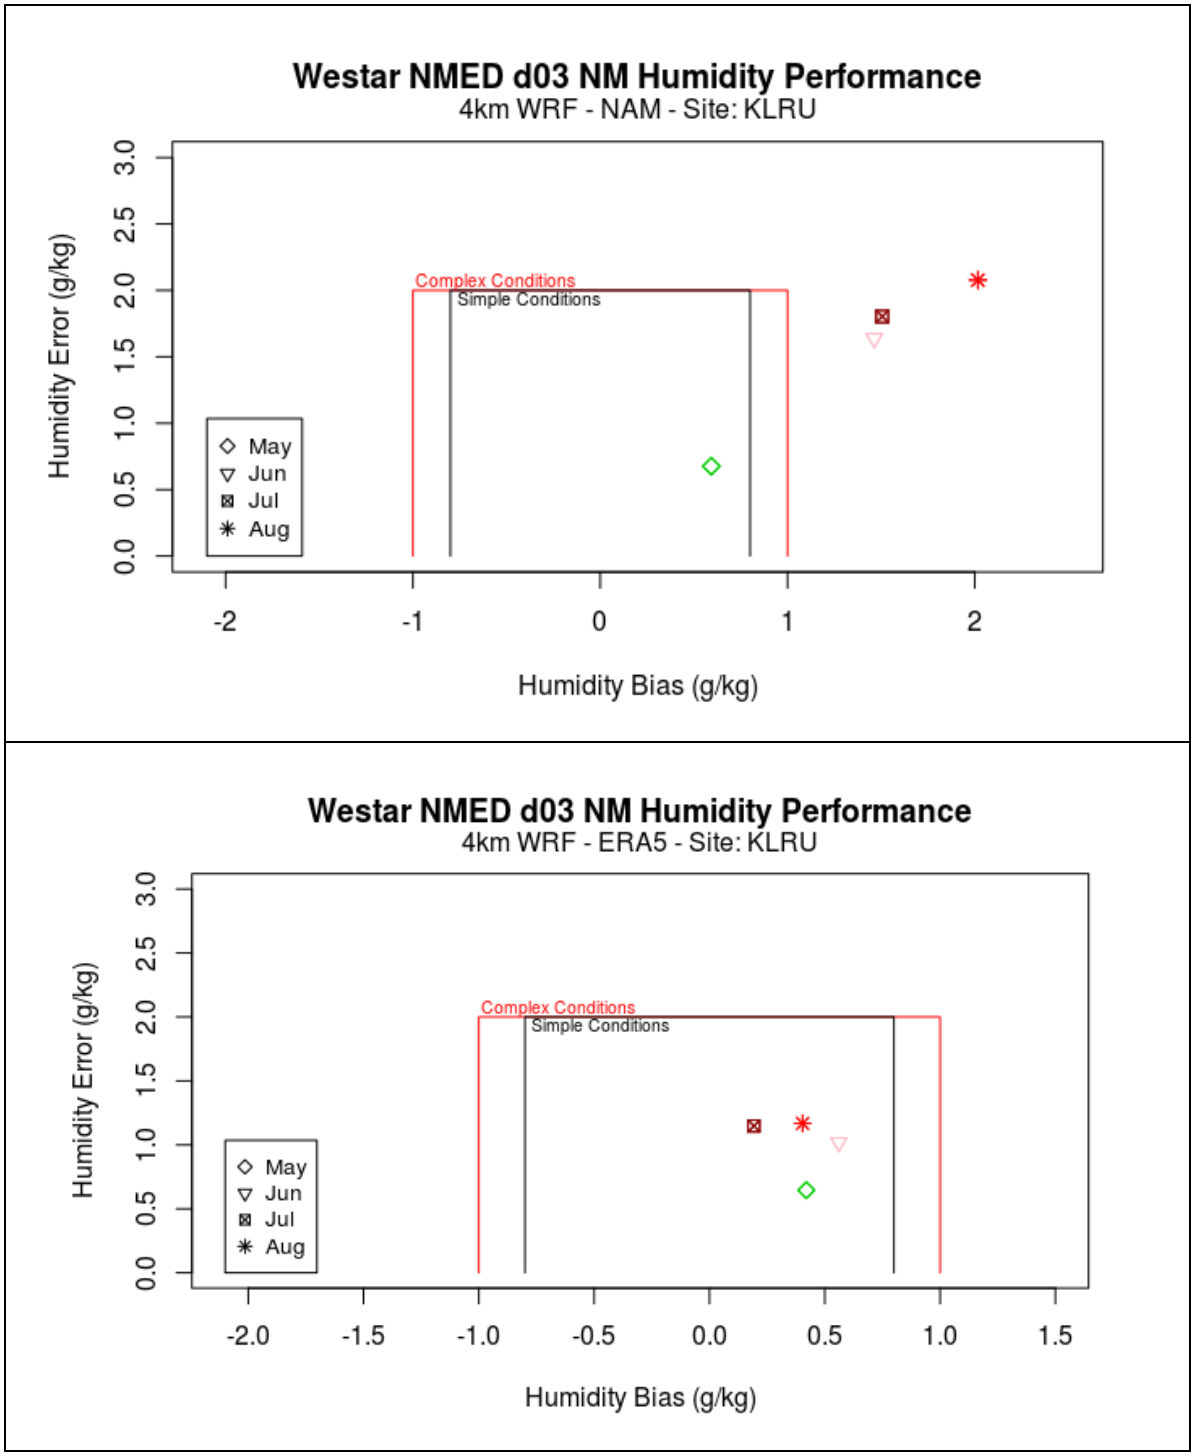

Figure 2-8. Soccer plot comparing WRF/NAM (top) and WRF/ERA5 (bottom) surface humidity (g/kg) model performance at Las Cruces International Airport against the Simple and Complex Benchmarks for monthly RMSE (y-axis) and Mean Bias (x-axis).

2.4.2 Qualitative Evaluations Using PRISM Data

Oregon State University (OSU) publishes precipitation analysis fields based on observations that can be used to qualitatively evaluate the WRF precipitation fields. The Parameter-elevation Relationships on Independent Slopes Model (PRISM[28]) is used to generate the precipitation analysis fields (Daly et al., 2008). The PRISM interpolation method of observed precipitation reflect, as closely as possible, the current state of knowledge of spatial climate patterns in the United States. PRISM calculates a climate – elevation regression for each digital elevation model (DEM) grid cell, and stations entering the regression are assigned weights based primarily on the physiographic similarity of the station to the grid cell. Factors considered are location, elevation, coastal proximity, topographic facet orientation, vertical atmospheric layer, topographic position, and orographic effectives of the terrain.

Figure 2-9 compares the PRISM May monthly total precipitation across the 4-km New Mexico domain with the WRF/NAM and WRF/ERA5 model estimates. The PRISM and WRF estimate May precipitation amounts over New Mexico are similar with all three estimating little precipitation in the west and small amounts in the central eastern portion of New Mexico. However, neither WRF simulation reproduces the PRISM precipitation in the southeast corner of the 4-km domain in West Texas near Midland. And the WRF/NAM greatly overstates the PRISM precipitation over the Texas panhandle, with WRF/ERA5 just having a slight overstatement in this region.

The June monthly precipitation comparisons are provided in Figure 2-10. Both models have reasonable June monthly precipitation over New Mexico that is very light. And PRISM and the two WRF simulations agree with the much higher precipitation over the Texas panhandle, with WRF/ERA5 performing better than WRF/NAM that has an overestimation bias.

There is much more observed and estimated precipitation over New Mexico in July 2014 (Figure 2-11). WRF/NAM overestimates the July monthly precipitation over northeast New Mexico in July, with WRF/ERA5 having an overestimation bias in most northerly Texas. But both WRF simulations have a dry bias for monthly precipitation over the remainder of New Mexico.

WRF/ERA5 does a better job at reproducing the locations and magnitudes of the August monthly PRISM precipitation than WRF/NAM (Figure 2-12). WRF/NAM overstates the August precipitation in central-south New Mexico.

NMED Exhibit 16

2.4.3 Conclusions of 2014 WRF Model Performance

The model performance of both WRF simulations is reasonable and very similar for most meteorological variables (e.g., winds and temperature). This is in contrast to the WRAP-WAQS and EPA WRF 2014 simulations that had very different performance characteristics over New Mexico.[29] The biggest difference in the performance of the two WRF simulations was for humidity and precipitation. The WRF/NAM simulation had a moist bias for June-August that is likely partly associated with overactive convective precipitation that was greater in WRF/NAM than WRF/ERA5. It is unclear whether the WRF/NAM overstated precipitation is due to overactive convective events when they occur, or having events occur when they are not observed.

From the meteorological model performance evaluation, it is not possible to determine which set of WRF meteorological inputs will produce better ozone model performance when used as meteorological inputs for CAMx. There are variations in spatial and temporal model performance that are difficult to estimate what effects they will have on ozone concentrations. Furthermore, there may be meteorological inputs (e.g., level of mixing) that are more important for ozone modeling than the parameters we have data to evaluate the meteorological model for (i.e., winds, temperature, humidity and precipitation). Although it appears that WRF/NAM overstates the monthly precipitation, if that does not occur on high ozone days it may not matter to the ozone model performance.

CAMx was run for a portion of the summer of 2014 episode with meteorological inputs based on both the WRF/NAM and WRF/ERA5 simulations and the ozone estimates compared to determine which meteorological inputs performed best so were selected for use in the final CAMX 2014 36/12/4-km base case simulation. The meteorological diagnostic sensitivity tests using the CAMx photochemical model are described in Chapter 5.

NMED Exhibit 16

3. BOUNDARY CONDITION INPUTS

The Boundary Conditions (BCs) for the CAMx most outer 36-km 36US modeling domain lateral boundaries were based on output from a 2014 simulation of the GEOS-Chem global chemistry conducted by WRAP for their 2014v2 modeling platform.

3.1 WRAP 2014 GEOS-Chem Modeling

The WRAP-WAQS 20914v1 36/12-km CAMx and CMAQ base case simulations used BCs based on EPA's 2014 GEOS-Chem simulation that was used in EPA's 2014 modeling platform used in the 2014 National Air Toxics Assessment (NATA[30]). The CAMx and CMAQ 2014v1 base case simulation and sensitivity modeling found that the BCs based on EPA's 2014 GEOS-Chem caused year-long ozone overestimation bias throughout the western U.S.[31] Thus, WRAP conducted their own 2014 GEOS-Chem simulation using newer version of the model with updated emissions that resulted in much better CAMx ozone model performance without the systematic ozone over-prediction bias.[32] Table 3-1 presents the WRAP 2014 GEOS-Chem model configuration.

Table 3-1. 2014 GEOS-Chem simulation model configuration used by WRAP whose output is used to define the 2014 day-specific diurnally varying BC inputs for the NM OAI Study photochemical modeling.

Science Options	WRAP 2014 GEOS-Chem Base Case
Version	Version 12.2.0 (release date: 2019-02-19)
Vertical Grid Mesh	72 Layers
Chemistry mechanism	GEOS-Chem standard chemistry with complex SOA option[33].
Horizontal Grids	2x2.5 degree (Nx, Ny = 144, 91)
Initial Conditions	6-month spin-up; starting from provided initial conditions for standard chemistry
Meteorology	2014 GEOS-FP meteorology
Photolysis mechanism	Default (FAST-J)
Advection Scheme	Default (TPCORE)
Cloud convection scheme	On / Relaxed Arakawa-Schubert
Planetary Boundary Layer mixing	On / non-local scheme implemented by Lin and McElroy
Dry deposition scheme	Default (Wesely)
Chemistry Solver	Default (FLEXCHEM)
Parallelization	Open Multi-Processing (OMP)

[33] We recommend turning off semivolatile primary organic aerosol (POA) chemistry and isoprene SOA reactions via the volatility-based scheme (VBS) [Pye et al., 2010] to avoid risk of double-counting in the complex SOA chemistry scheme. For more information, see http://maraisresearchgroup.co.uk/Publications/GC-v11-02-SOA-options.pdf

NMED Exhibit 16

NMED Exhibit 16

3.2 2014 GEOS-Chem Model Evaluation

The results of the WRAP 2014 GEOS-Chem simulation and CAMx sensitivity modeling using the new BCs can be found on the WAQS-WRAP2014v2 model evaluation webpage[34]. Relevant for the NM OAI Study is the fact that this updated 2014 GEOS-Chem BCs do lead to better CAMx model performance for ozone concentrations and corrects a persistent year-long ozone overestimation bias observed with the previous 2014 GEOS-Chem simulation conducted by EPA and used in the EPA 2014 modeling platform. The NM OAI Study evaluated the use of the WRAP 2014 GEOS-Chem BCs for CAMx modeling at several sites in New Mexico and found good ozone performance that achieved ozone model performance goals.[35] Thus, the WAQS-WRAP 2014v2 BC inputs based on the WRAP 2014 GEOS-Chem simulation were used as is for the NM OAI Study.

NMED Exhibit 16

4. 2014 EMISSION INPUTS

4.1 Available Emissions Inventory Datasets

The emissions inventories for the CAMx 2014 36/2/4-km base case modeling were based on the WRAP-WAQS 2014v2 emissions inventory. Within the 36-km 36US North American and 12-km 12WUS2 western U.S. domains, the WRAP-WAQS CAMx 2014v2 base case emission inputs were used without any changes.

For the 4-km New Mexico domain, the WRAP-WAQS 2014v2 emissions have been reviewed and updated as needed by the NMED. For on-road mobile sources, the 4-km domain emissions were based on MOVES2014 model, 2014 activity data and day-specific hourly gridded 2014 WRF 4-km meteorology run through SMOKE-MOVES.

4.2 Development of CAMx Emission Inputs

CAMx emission inputs were generated mainly by the SMOKE and MEGAN emissions models. CAMx requires two emission input files for each day: (1) low level gridded emissions that are emitted directly into the first layer of the model from sources whose emissions are released at the surface with little or no plume rise; and (2) elevated point sources (stacks) with plume rise calculated from stack parameters and meteorological conditions. CAMx was operated using version 6 revision 4 of the Carbon Bond chemical mechanism (CB6r4) (Yarwood et al., 2010).

The 2014 base case (May to August) 4-km New Mexico domain CAMx emission inputs were based on the WRAP-WAQS 2014v2 emissions that rely on the 2014NEIv2 with updates provide by the western states. The New Mexico emissions from the 2014v2 database were reviewed and updated by the NMED. The 2014v2 emissions for New Mexico and portions of surrounding states within the 4-km New Mexico domain were processed by the Sparse Matrix Operator Kernel Emissions (SMOKE) modeling system (UNC, 2015). SMOKE version 4.7 was used, which is the current version of SMOKE that was released in October 2019.[36]

4.2.1 Day-Specific On-Road Mobile Source Emissions

The 2014 on-road mobile source emission inputs for the 4-km New Mexico domain were generated using the SMOKE-MOVES emissions model. SMOKE-MOVES used a 2014 mobile source emission factor (EF) lookup table generated by the Motor Vehicle Emission Simulator (MOVES2014[37]) model (EPA, 2014a,b,c). The SMOKE-MOVES default county-level 2014 vehicle activity data for New Mexico was reviewed by NMED and updated as needed. SMOKE-MOVES uses the 2014 MOVES EF lookup table, hourly gridded 4-km meteorological data from the 2014 WRF simulation conducted in this study and 2014 county-level activity data (e.g., vehicle miles travelled [VMT], speed, etc.) to generate 2014 day-specific hourly gridded on-road mobile source emission inputs for CAMx and the 4-km New Mexico domain.

[36] https://www.cmascenter.org/smoke/

[37] http://www.epa.gov/oms/models/moves/#user

4.2.2 Point Source Emissions

2014 point source emissions were based on the WRAP-WAQS 2014v2 emissions inventory. The 2014v2 New Mexico point source emissions were reviewed and updated by NMED. Point sources were processed in two streams: (1) major point sources with Continuous Emissions Monitoring (CEM) devices, which are primarily fossil-fueled Electrical Generating Units (EGU) with capacity of 25 MW or greater; and (2) point sources without CEMs. For point sources with CEM data, day-specific hourly NO_X and SO_2 emissions were used for the 2014 base case emissions scenario. The VOC, CO and PM emissions for point sources with CEM data were based on the annual emissions data in the 2014v2 inventory temporally allocated to each hour of the year using the CEM hourly heat input. The hourly CEM data available in the Acid Rain database on the EPA Clean Air Market Division (CAMD) website fills hours with missing CEM data with maximum potential to emit (PTE) emission rates and flags the data. This is because the purpose of the Acid Rain database is to assure that the source is not emitting higher emissions than its cap. Using PTE emissions rates for hours with missing CEM data is inappropriate for PGM modeling since the goal is to obtain an accurate estimate of emissions. Thus, a data filling program is used that uses the missing data flags to identify hours when the data filled PTE emissions occur, and they are replaced with typical emission rates.

For all point sources, the locations of the point sources were converted to the LCC coordinate system used in the modeling. Non-CEM point sources were processed by SMOKE to generate the temporally varying (i.e., seasonal, day-of-week and hour-of-day) speciated emissions needed by CAMx. The 2014 point source emissions without CEM data were processed using SMOKE using the default temporal (e.g., monthly, day-of-week and hourly) and speciation profiles.

4.2.3 Area and Non-Road Source Emissions

The 2014v2 area and non-road sources were spatially allocated to the 4-km New Mexico grid using an appropriate surrogate distribution (e.g., population for home heating, etc.). The area sources were temporally allocated by month and by hour of day using the SMOKE source-specific temporal allocation factors, while chemical speciation used the SMOKE source-specific CB6r4 speciation allocation profiles.

4.2.4 Episodic Biogenic Emissions

Biogenic emissions were generated using Version 3.1 of the MEGAN biogenic emissions model. MEGAN uses high resolution GIS data on plant types and biomass loadings and the 2014 WRF surface temperature fields, and solar radiation to develop hourly emissions for biogenic species on the 36/12/4-km grids. MEGAN generates gridded, speciated, temporally allocated emission files. The MEGAN biogenic emissions were used for the 36-km 36US, and 4-km New Mexico modeling domains. Note that the BEIS biogenic emissions were used in the 12-km WRAP-WAQS 2014v2 modeling platform. WRAP/WAQS conducted sensitivity tests using MEGAN v3.0 and BEIS biogenic emissions and found they produced comparable ozone estimates (because the isoprene emissions were similar) but CAMx with BEIS had better Organic Aerosol (OA)

NMED Exhibit 16

performance[38] than CAMx with MEGAN v3.0 biogenic emissions so WAQS selected BEIS. Since then, MEGAN has been updated to version 3.1 and the CAMx OA performance is now similar using MEGAN v3.1 and BEIS.

Table 4-1 summarizes MEGAN v3.1 biogenic VOC (BVOC) and soil NOx emissions by month for the 4-km New Mexico domain. Biogenic emissions are controlled by ambient environmental variables, most notably temperature and light. Increases in temperature normally lead to increased BVOC emissions because of higher biological activity as evident in the Table 4-1.

Table 4-1. 2014 base case biogenic emissions summary by month (in short tons per day) for the 4-km New Mexico domain.

Month	NOx (in tons/day)	BVOC (in tons/day)
May	1,131	4,139
Jun	1,415	8,902
Jul	1,666	10,248
Aug	1,323	11,438

4.2.5 *Wildfires, Prescribed Burns, Agricultural Burns*

2014 emissions from open-land burning including wildfires, prescribed burns and agricultural burning were based on the WRAP-WAQS 2014v2 emissions inventory. The WRAP Fire and Smoke Work Group (FSWG[39]) processed the 2014NEIv2 Bluesky/SMARTFIRE fire emissions for the U.S. and classified them as either wildfires (WF), prescribed burns (Rx) or agricultural burning (Ag) and made other updates for the 2014v2 inventory. The 2014NEIv2 fire emissions for Mexico and Canada was used without any changes.

4.2.6 *Other Natural Emissions*

Lightning NO_x (LNOx), and windblown dust (WBD) emissions were generated for the 4-km domain using special CAMx processors and WRF 2014 meteorological data. Oceanic emissions such as sea salt spray aerosol (SSA) and dimethyl sulphide (DMS) were not generated for the 4-km New Mexico domain since this domain does not include any ocean within it. However, the LNOX, WBD and oceanic emissions for the 36-km and 12km were based on the WRAP-WAQS 2014v2 emissions and were included in the modeling.

4.2.7 *QA/QC of Emissions Processing and Emissions Merging*

The emissions for the 4-km New Mexico domain were processed by major source category in several different processing "streams", including area sources, on-road mobile sources, non-road mobile sources, biogenic sources, non-CEM point sources, CEM point sources using day-specific hourly emissions, and emissions from fires. Separate Quality Assurance (QA) and Quality Control (QC) were performed for each stream of emissions processing and in each step following the procedures developed by

[38] http://views.cira.colostate.edu/iwdw/docs/waqs_2014v1_shakeout_study.aspx

[39] https://www.wrapair2.org/FSWG.aspx

WRAP (Adelman, 2004). SMOKE includes advanced quality assurance features that include error logs when emissions are dropped or added. In addition, the following visual displays were generated:

- Spatial plots of the hourly emissions for each major species (e.g., NO_X, VOC, and CO).
- Summary tables of emissions for major species for each grid and by major source category.
- QA information examined against the original point and area source data and summarized in an overall QA/QC assessment.

Scripts to perform the emissions merging of the appropriate biogenic, on-road, non-road, area and low-level point sources (i.e., point sources with little or no plume rise so they are released into the first layer of the PGM) emission files were written to generate the CAMx-ready two-dimensional day and domain-specific hourly speciated gridded emission inputs. The point source and fire, emissions were then processed into the day-specific hourly speciated emissions in the CAMx-ready point source format.

For the 36/12-km domains the model-ready emissions from the WRAP/WAQS 2014v2 modeling platform were used in this study.

The resultant CAMx model-ready emissions were subjected to a final QA using spatial maps to: (1) assure that the emissions were merged properly and CAMx inputs contain the same total emissions; and (2) provide additional QA/QC information.

4.2.8 Use of the Plume-in-Grid (PiG) Subgrid-Scale Plume Treatment

CAMx includes a Plume-in-Grid (PiG) sub-model that treats the early plume chemistry and dynamics of emissions from point sources and then releases the emissions into the grid model farther downwind at such time that the plume is adequately resolved by the grid. Large NO_X emissions point sources within the 4-km New Mexico domain were selected for treatment by the subgrid-scale PiG module when their emissions rate were 5 tons per day or larger.

4.2.9 QA/QC of Model-Ready Emissions

In addition to the CAMx-ready emission input files generated for each hour of all days modeled in the May-August 2014 modeling period, a number of quality assurance (QA) files were prepared and used to check for gross errors in the emissions inputs. Importing the model-ready emissions into PAVE or VERDI and examine both the spatial and temporal distribution of the emission to investigate the quality and accuracy of the emissions inputs.

- Visualizing the model-ready emissions with the scale of the plots set to a very low value, we can determine whether there are areas omitted from the raw inventory or if emissions sources are erroneously located in water cells;
- Spot-checking the holiday emissions files to confirm that they are temporally allocated like Sundays;

NMED Exhibit 16

- Producing pie charts emission summaries that highlight the contribution of each emissions source component (e.g. non-road mobile);
- Normalizing the emissions by population for each state illustrates where the inventories may be deficient and provide a reality check of the inventories.

State inventory summaries prepared prior to the emissions processing were used to compare against SMOKE output report totals generated after each major step of the emissions generation process. To check the chemical speciation of the emissions to CB6 species, we compared reports generated with SMOKE to target these specific areas of the processing. For speciation, the inventory state import totals were compared against the same state totals with the speciation matrix applied.

4.2.10 Summary of Emissions for 4-km New Mexico Domain

This section presents 2014 base case anthropogenic emissions summary for the 4-km New Mexico domain. The emissions were processed by major source category in several different "streams" of emissions modeling. Each stream of emissions modeling generates a pre-merged CAMx-ready emissions model input with all pre-merged emissions inputs merged together to generate the final CAMx-ready two-dimensional gridded low-level (layer 1) and point source emission inputs. Table 4-2 lists an example of separate streams of emissions modeling by source category that are used.

NMED Exhibit 16

Table 4-2. New Mexico 4-km domain emissions processing categories.

Country/Region	Sector	Description
US Anthro	afdust_adj	Area fugitive dust
	ag	Agricultural ammonia sources
	nonpt	Other nonpoint sources
	np_oilgas_wrap	Non-point Oil and Gas for 7 WRAP States (CO, MT, NM, ND, SD, UT, WY)
	np_oilgas	Non-point Oil and Gas
	nonroad	Non-road mobile
	rail	Locomotive
	onroad	On-road mobile
	ptegu	EGU point sources
	ptnonipm	Non-EGU point sources
	pt_oilgas_wrap	Point Oil and Gas for 7 WRAP States (CO, MT, NM, ND, SD, UT, WY)
	pt_oilgas_wrap	Point Oil and Gas
	rwc	Residential Wood Combustion
Mexico Anthro	onroad_mex	Mexico onroad mobile
	othar	Mexico area
	othpt	Mexico point sources
Natural	MEGAN	Biogenic
	LtNOx	Lightning Nox
	AG fire	Ag Fire
	RX fire	Prescribed Fire
	WF fire	Wild Fire
	Ptfire_othna	Mexico fire
	WBD	Windblown Dust

Table 4-3 summarizes criteria air pollutant emissions in episode average short tons per day by source category for the 4-km New Mexico domain. These data represent the model-ready emissions input to the CAMx air quality model for the 2014 base case. Generally, emissions are summarized from the SMOKE reports generated by the SMKMRG program. There are a couple of exceptions to this general approach, fugitive dust and EGU sources. The fugitive dust emissions were adjusted after SMOKE processing to account for fugitive dust correction factors that are derived from the Biogenic Emission Landuse Database version 4 (BELD4). The correction factors are necessary to account for dust removal due to local vegetation scavenging so are not

transported downwind. Model-ready emissions for EGU and Mexico point sources were obtained from WRAP/WAQS 2014 platform so were summarized for the 4-km domain outside of SMOKE.

Table 4-3. 2014 base case anthropogenic emissions summary (episode average short tons per day) by source category for the 4-km New Mexico domain.

Country/ Category	Source Category	CO	NH_3	NOx	$PM_{2.5}$	PM_{10}	SO_2	VOC
US Anthro	Area fugitive dust	0.0	0.0	0.0	253.3	1,788.2	0.0	0.0
	Agricultural ammonia sources	0.0	764.7	0.0	0.0	0.0	0.0	43.4
	Non-point Oil and Gas for 7 WRAP States (CO, MT, NM, ND, SD, UT, WY)	237.7	0.0	157.8	4.4	4.4	11.3	567.3
	Remaining Non-point Oil and Gas	286.8	0.0	311.7	6.9	6.9	30.0	1,642.5
	Residential Wood Combustion	7.0	0.1	0.1	0.5	0.5	0.0	1.2
	Other nonpoint sources	141.3	1.5	28.5	9.3	13.4	4.5	213.2

	Mexico point sources	28.4	0.7	20.2	4.8	5.7	16.4	8.3

Figure 4-1 presents pie charts showing the two main ozone precursor (VOCs and NOx) emissions from anthropogenic sources by source category for New Mexico and portion of surrounding states within the 4-km domain. Point and nonpoint oil and gas sectors account for majority of NOx emissions followed by on-road mobile and EGU sources. In New Mexico, oil and gas sources are the largest anthropogenic VOC emitters and accounts for nearly 80% of 4-km domain VOC emissions.

NMED Exhibit 16

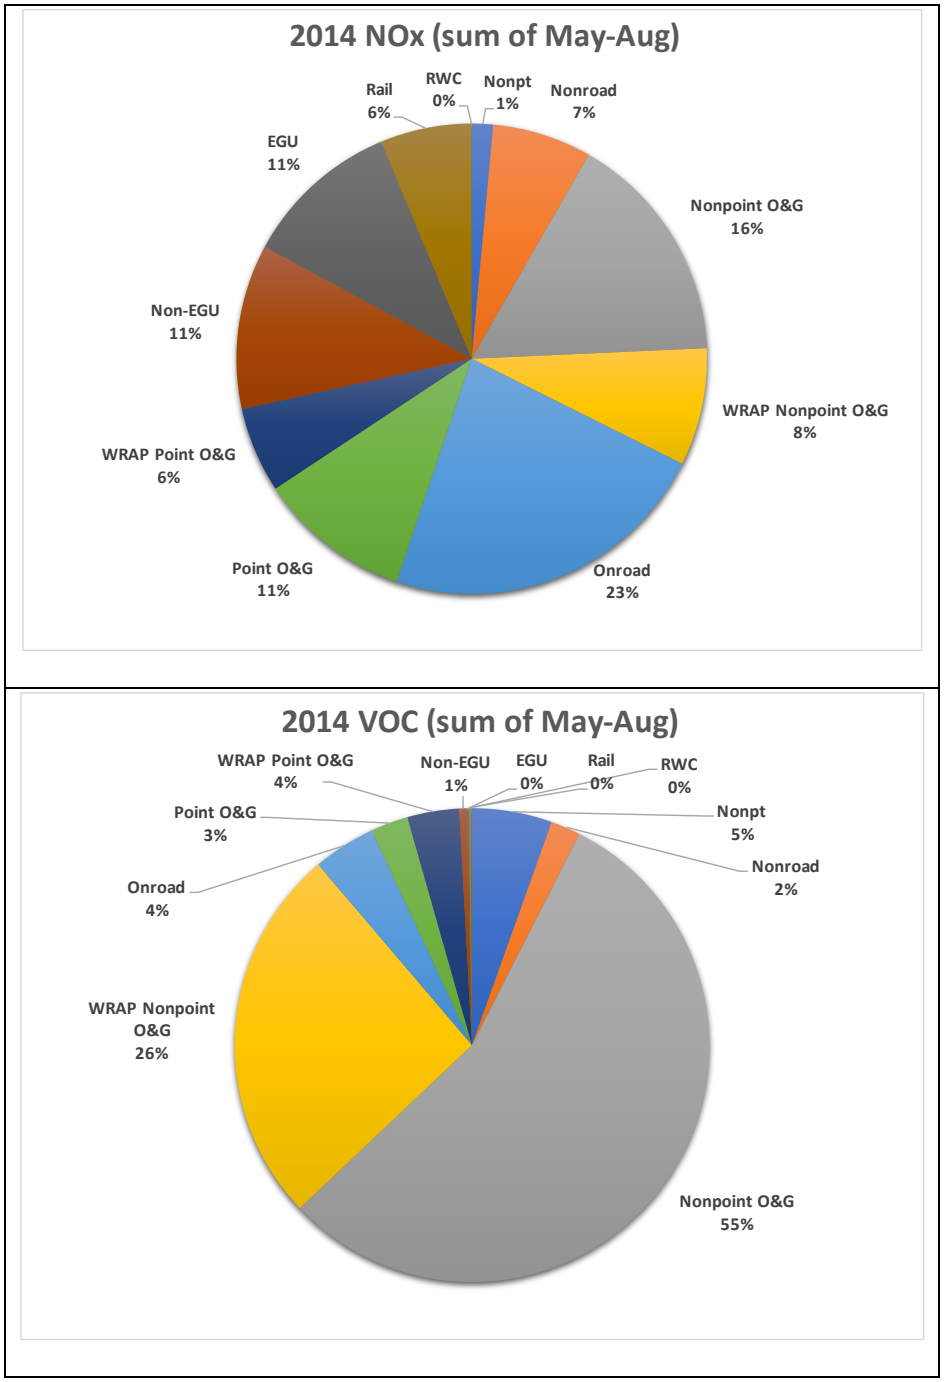

Figure 4-1. New Mexico 2014 base case anthropogenic NOx and VOC emissions by source category.

Figure 4-2 displays spatial maps of NOx and VOC anthropogenic emissions from the oil and gas sector across the 4-km New Mexico domain. Top panel shows emission maps for non-point O&G sources while bottom panel shows point O&G sources. The San Juan and Permian basins are clearly visible on the emissions map and confirm correct spatial allocation of oil and gas emissions. Figure 4-3 shows emission maps for on-road mobile (top panel), rail (middle panel) and non-point sources including non-road equipment (bottom panel).

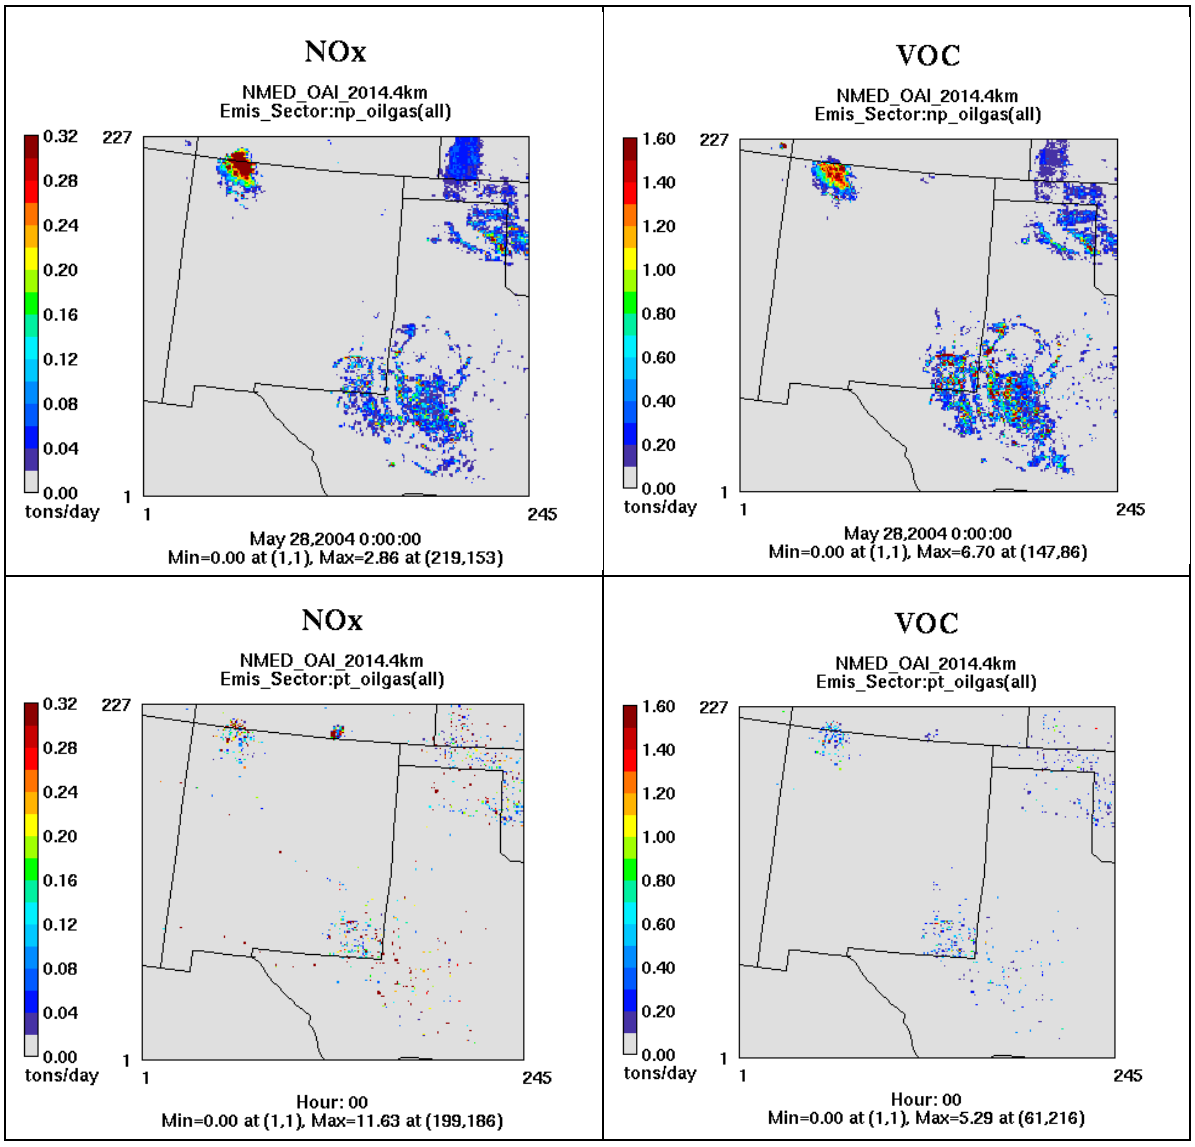

Figure 4-2. Spatial distribution of the non-point (top) and point (bottom) source oil and gas NOx (left) and VOC (right) emissions (episode avg tons per day) for New Mexico 4-km domain.

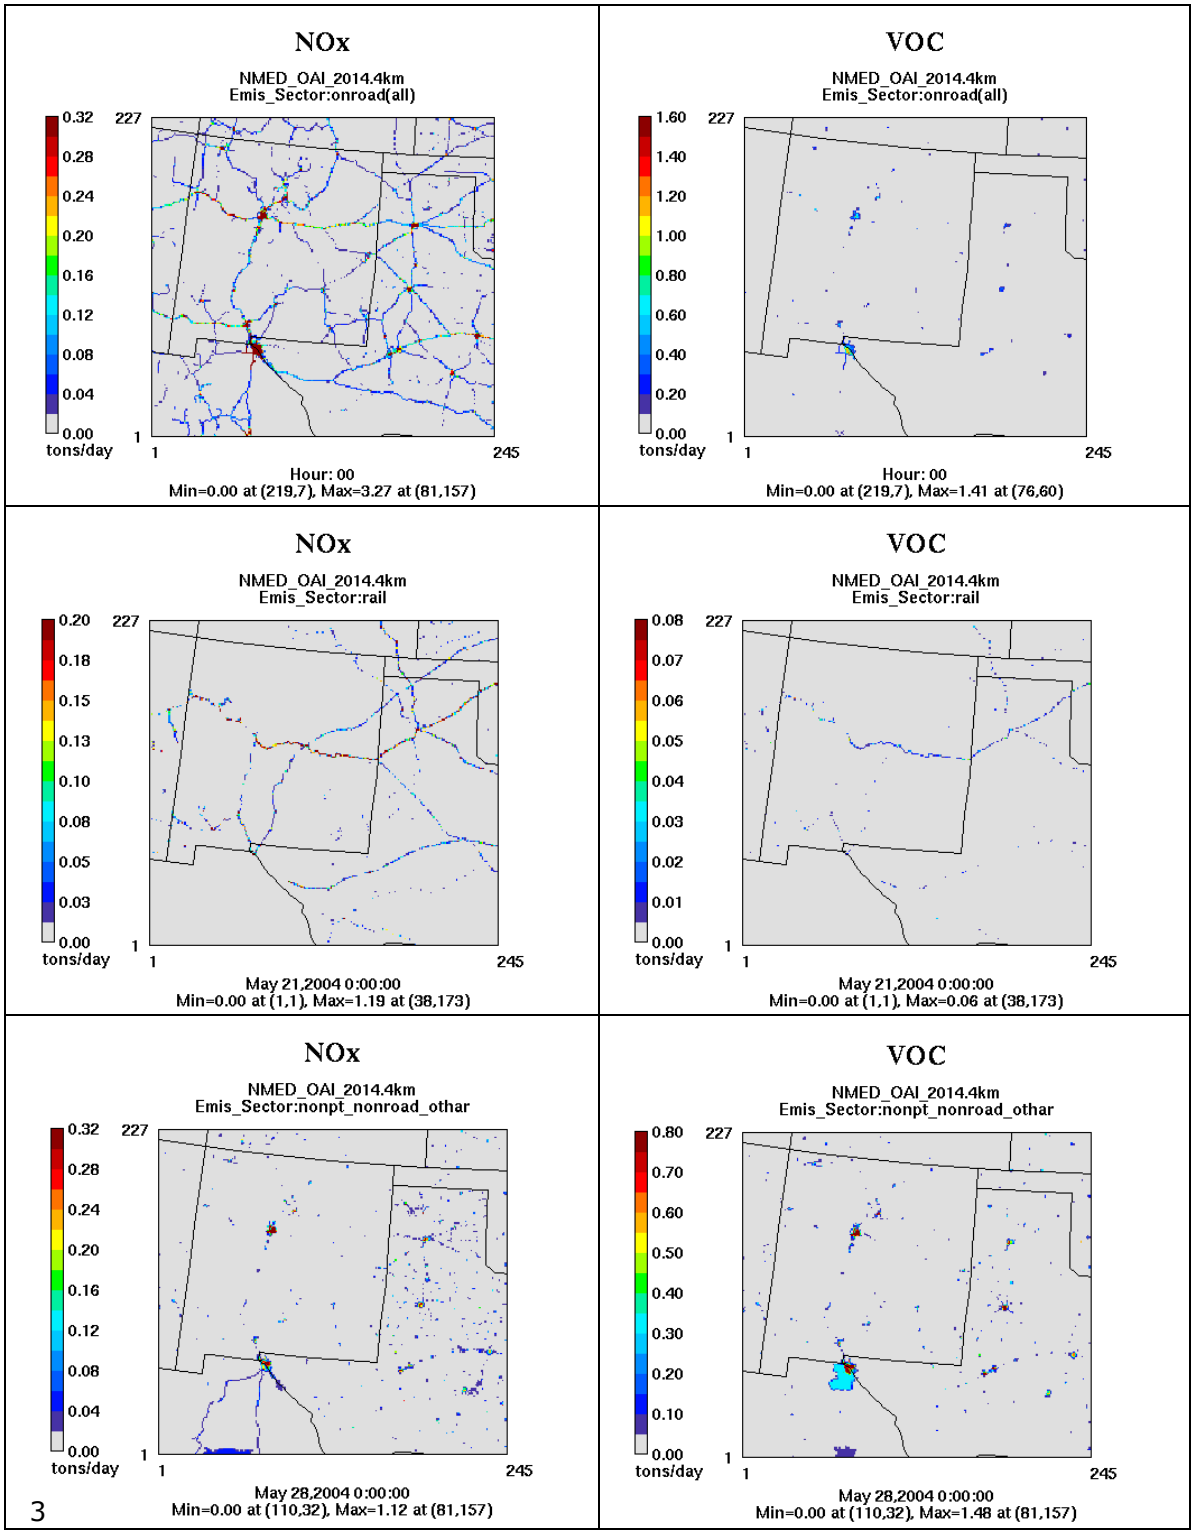

Figure 4-3. Spatial distribution of on-road (top), rail (middle) and non-point/non-road equipment (bottom) NOx (left) and VOC (right) emissions (episode avg tons per day) for New Mexico 4-km domain.

5. DIAGNOSTIC SENSITIVITY TESTS

Several CAMx diagnostic sensitivity tests were conducted to evaluate alternative meteorological inputs based on the 2014 36/12/4-km WRF meteorological model simulations discussed in Chapter 2. To develop the CAMx meteorological inputs, the WRF model output data must first be processed by the WRFCAMx processor.

5.1 WRFCAMx Processing of 2014 WRF Output

The WRFCAMx processor maps WRF meteorological fields to the format required by CAMx. It also calculates turbulent vertical exchange coefficients (Kv) that define the rate and depth of vertical mixing in CAMx. Steps in the WRFCAMx processing are as follows:

- Reading in WRF meteorological model output data;
- Extracting meteorological data for CAMx domain(s);
- Collapsing meteorological data if coarser vertical resolution data is requested in CAMx than used in WRF;
- Computing vertical diffusivities (Kv); and
- Output the meteorological fields in the formats used by CAMx.

Several options are available in WRFCAMx to derive vertical turbulent exchange coefficient (also known as: Kv, Kz or vertical diffusivity) fields from WRF output. When TKE (turbulent kinetic energy) is not available from the WRF output (as is the case with the YSU PBL selected WRF physics options), Kv fields are diagnosed from wind, temperature, and Planetary Boundary Layer (PBL) parameters in WRFCAMx. For this application, the WRFCAMx processing was performed to generate two sets of Kv profiles using two different Kv options in WRFCAMx, the CMAQ-like and YSU Kv profile options.

5.1.1 Treatment of Minimum Kv

The CAMx Kv_patch pre-processor program sets the minimum Kv value to 0.1 to 1.0 m^2/s in the lowest 100 m of the atmosphere depending on the amount urban land use category in a grid cell. This is done to account for the urban heat island effect that enhances vertical mixing through-out the day and night.

5.1.2 Layer Collapsing Strategy

WRF was run with 36 vertical levels (35 vertical layers) as shown in Table 2-1. For the NM OAI Study, a layer collapsing strategy was employed that reduced the 35 WRF vertical layers to 25 layers in CAMx, which reduces the CAMx run time by about a third. Table 5-1 displays the WRF to CAMx layer collapsing strategy. This is the same layer collapsing study employed by WRAP-WAQS.

NMED Exhibit 16

Table 5-1. WRF to CAMx vertical layer collapsing strategy used in the NM OAI Study.

CAMx Layers	WRF Layers	WRF hybrid eta	WRF Pressure (mb)	Height (m)
	0	1.0000	1000.0	0
	1	0.9985	998.6	12
1	2	0.9970	997.2	24

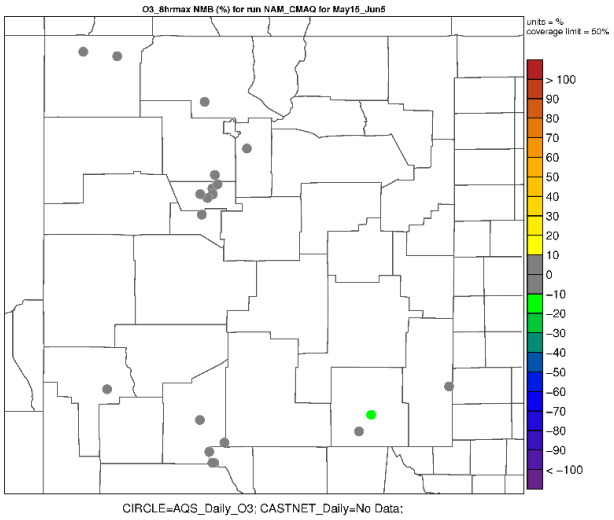
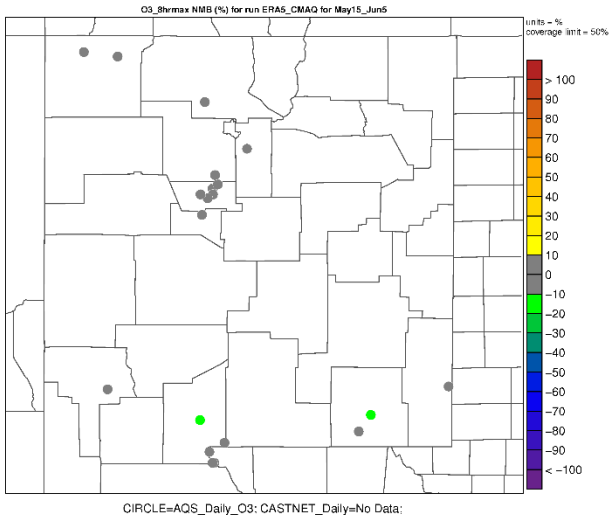
NMED Exhibit 16

5.2 CAMx Meteorological Diagnostic Sensitivity Tests



Four separate CAMx 2014 36/12/4-km diagnostic sensitivity tests were conducted for the first portion of the summer 2014 modeling episode that spanned May 15 to June 4, 2014. The purpose of the four meteorological inputs CAMx sensitivity tests was to identify the optimal meteorological inputs for the final CAMx 2014 base case simulation. The four sets of CAMx simulations were based on the WRF/NAM and WRF/ERA5 2014 36/12/4-km simulations described in Chapter 2 processed by WRFCAMx to generate two sets of vertical mixing coefficient (Kv) as described above:

1. WRF/NAM with CMAQ Kv
2. WRF/NAM with YSU Kv
3. WRF/ERA5 with CMAQ Kv
4. WRF/ERA5 with YSU Kv



Ozone model predictions from each sensitivity test were compared with observed ozone concentrations in New Mexico. Figures 5-1 and 5-2 summarize the normalized mean bias (NMB) and error (NME) for each site in New Mexico during the modeling period. The statistics presented in these figures were calculated using a 60 ppb cutoff value relative to observed MDA8 ozone concentrations to understand the performance of each sensitivity test when ozone concentrations are most relevant to the NAAQS. Figure 5-1 shows that the NMB is generally within ±10% (colored grey) at almost all sites (note that the NMB performance goal is ±5% and criteria is ±15%). All of the sensitivity simulations have an under-prediction bias for observed ozone greater than 60 ppb at sites in the southern portion of the domain such that for one or two sites have a bias even lower than -10% (i.e., colored bright green). The WRF/NAM with CMAQ Kv sensitivity test has slightly better performance than the others with less underestimation bias (e.g., all sites but one are within ±10% compared to two sites for the other tests). Figure 5-2 shows that the NME is also generally within the performance goal (less than 15%) in all cases, with the southern portions of NM showing the largest errors but still within the performance criteria (less than 25%). The figure shows that CAMx using the WRF/NAM inputs tends to have slightly lower error and better ozone performance than when the WRF/ERA5 meteorological inputs are used.

NAM CMAQ

ERA5 CMAQ

NAM YSU

ERA5 YSU

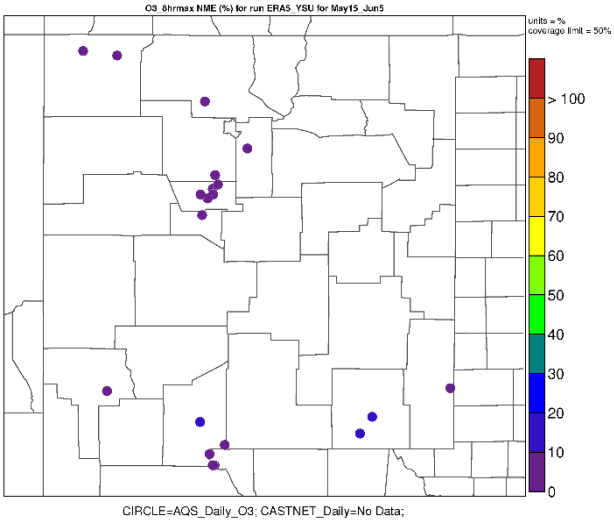

Figure 5-2. Comparison of sensitivity tests NME with 60 ppb cutoff spatial plots over NM.

Figure 5-3 presents soccer plots of bias and error for observed ozone above 60 ppb and all four CAMx sensitivity tests. This figure plots site-specific bias versus error with performance lines in the shape of a soccer goal, when the site-specific bias and error symbol falls within the soccer goal area (i.e., the red box) it is easy to see when the ozone performance goals are achieved. The figure shows that all sites have NMB and NME that fall within the performance criteria for bias (≤±15%) and error (≤25%), with most sites having an underestimation bias of the high (> 60 ppb) observed ozone concentrations. The CAMx simulations with the WRF/NAM meteorological inputs has slightly better performance than when the WRF/ERA5 inputs are used as more sites fall within the performance soccer goal area. Comparison between the NAM cases indicate that the test with CMAQ Kv has slightly smaller errors relative to the test with YSU Kv.

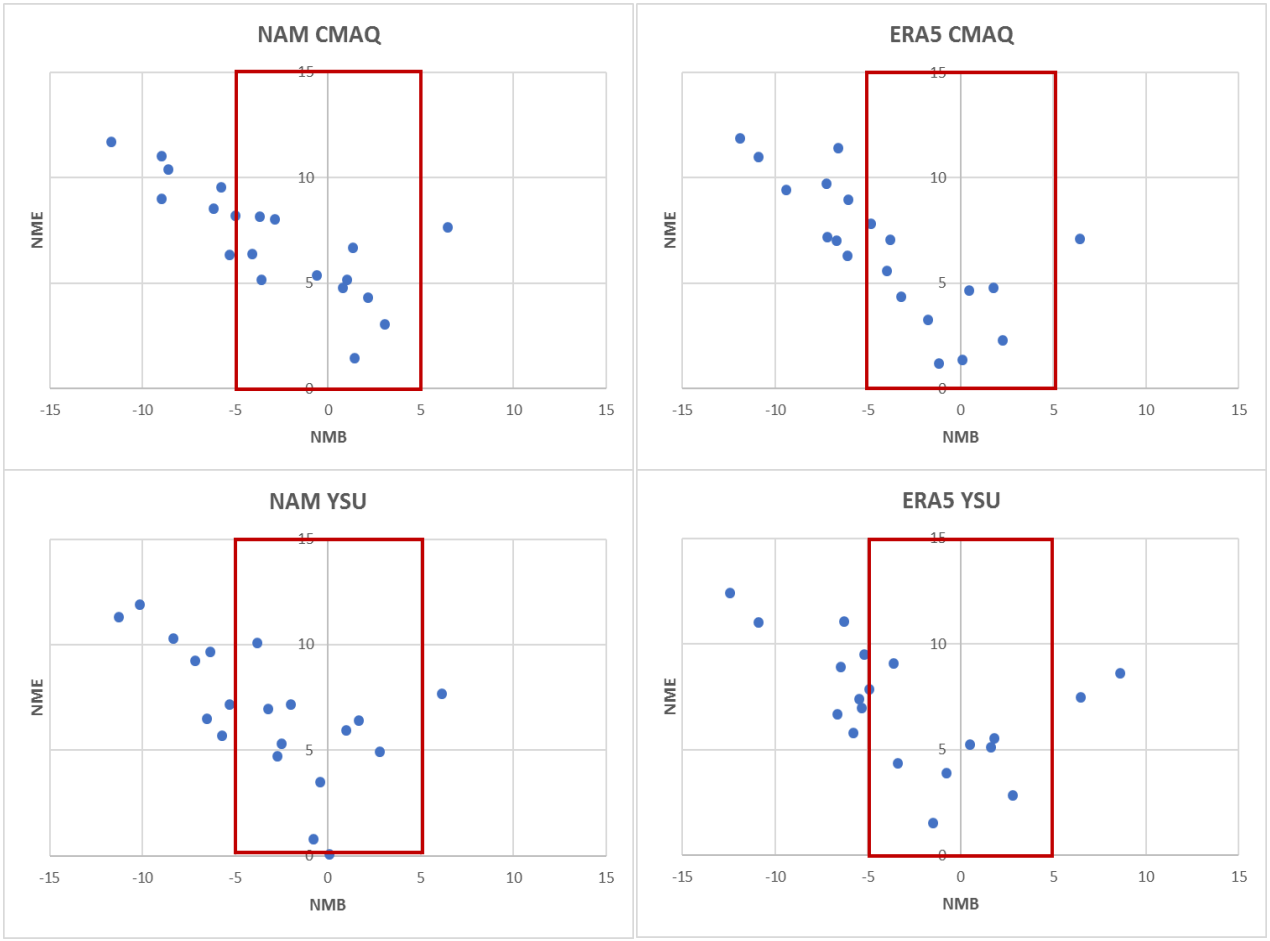

Figure 5-3. Comparison of sensitivity tests soccer plots with 60 ppb cutoff. Red rectangle indicates the performance goal soccer area.

Figures 5-4 to 5-7 present time series of predicted and observed MDA8 ozone concentrations for selected sites in Dona Ana, Eddy and Sandoval counties. At the Solano Road site in Dona Ana County the time series shows that the observed peak ozone concentration on May 29 is matched very well by the CAMx WRF/NAM sensitivity tests, while the CAMx WRF/ERA5 sensitivity test under-predicts by approximately 10 ppb (Figure 5-4). At the Desert View site, which is also in Dona Ana County, all four CAMx sensitivity tests underestimate the high observed ozone on May 28-29, but the CAMx WRF/NAM tests perform slightly better than the CAMx WRF/ERA5 test (Figure 5-5). At the Carlsbad site in Eddy County all test cases under-predict the high ozone concentration from May 27 to May 31 (Figure 5-6). For the site in Sandoval county (Figure 5-7) all four CAMx sensitivity tests track the daily variations of the observed MDA8 ozone including getting the timing and values of the observed ozone peak on May29, but the CAMx WRF/NAM with CMAQ Kv test exhibits the lowest biases.

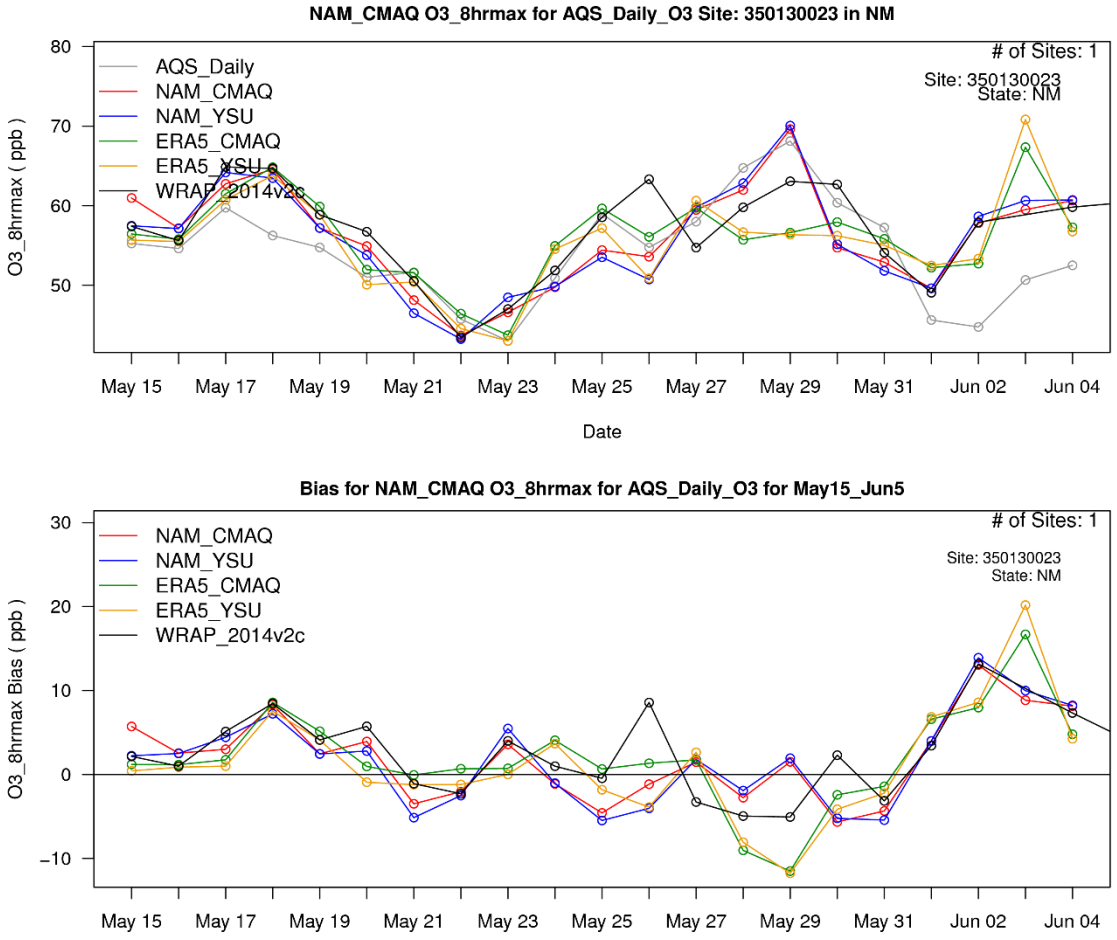

Figure 5-4. Timeseries comparison of sensitivity tests with observations (top) and bias (bottom) at Solano Road site, Dona Ana County

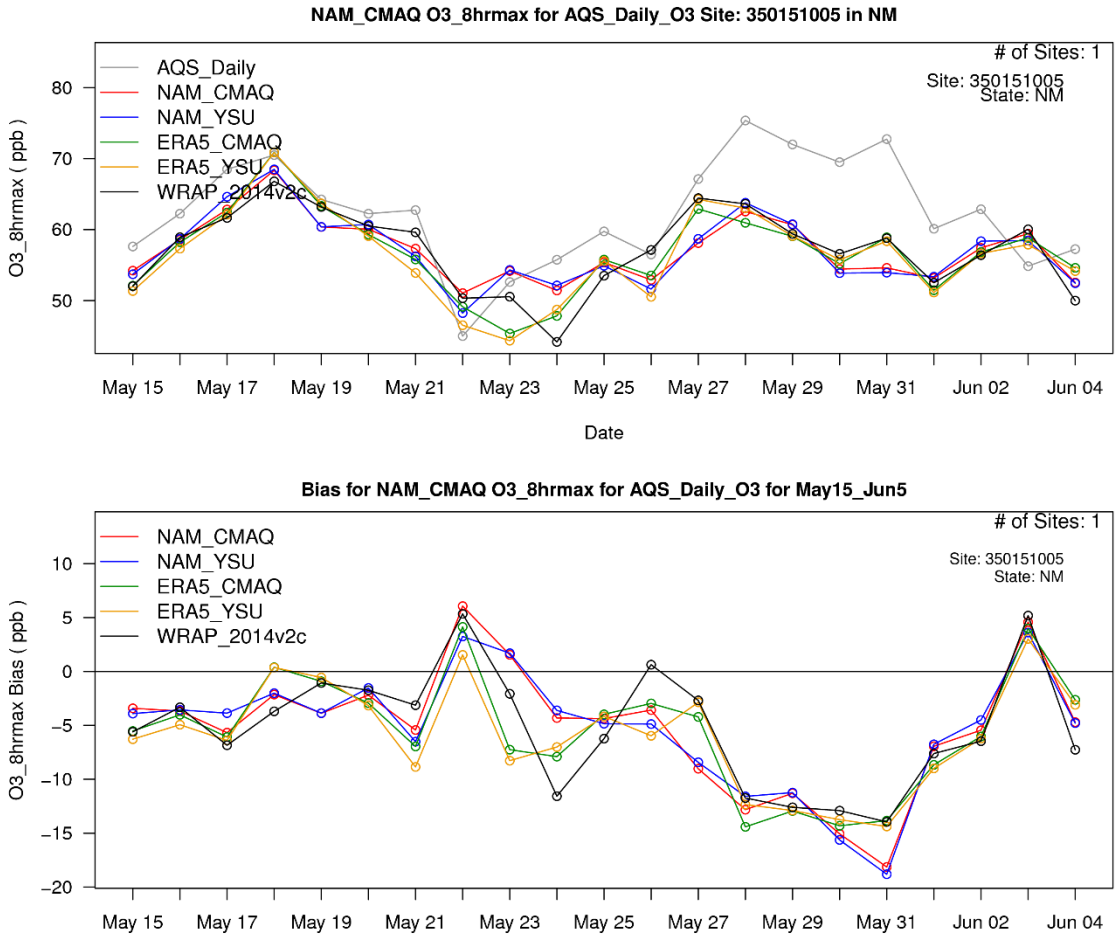

Figure 5-6. Timeseries comparison of sensitivity tests with observations (top) and bias (bottom) at Carlsbad site, Eddy County

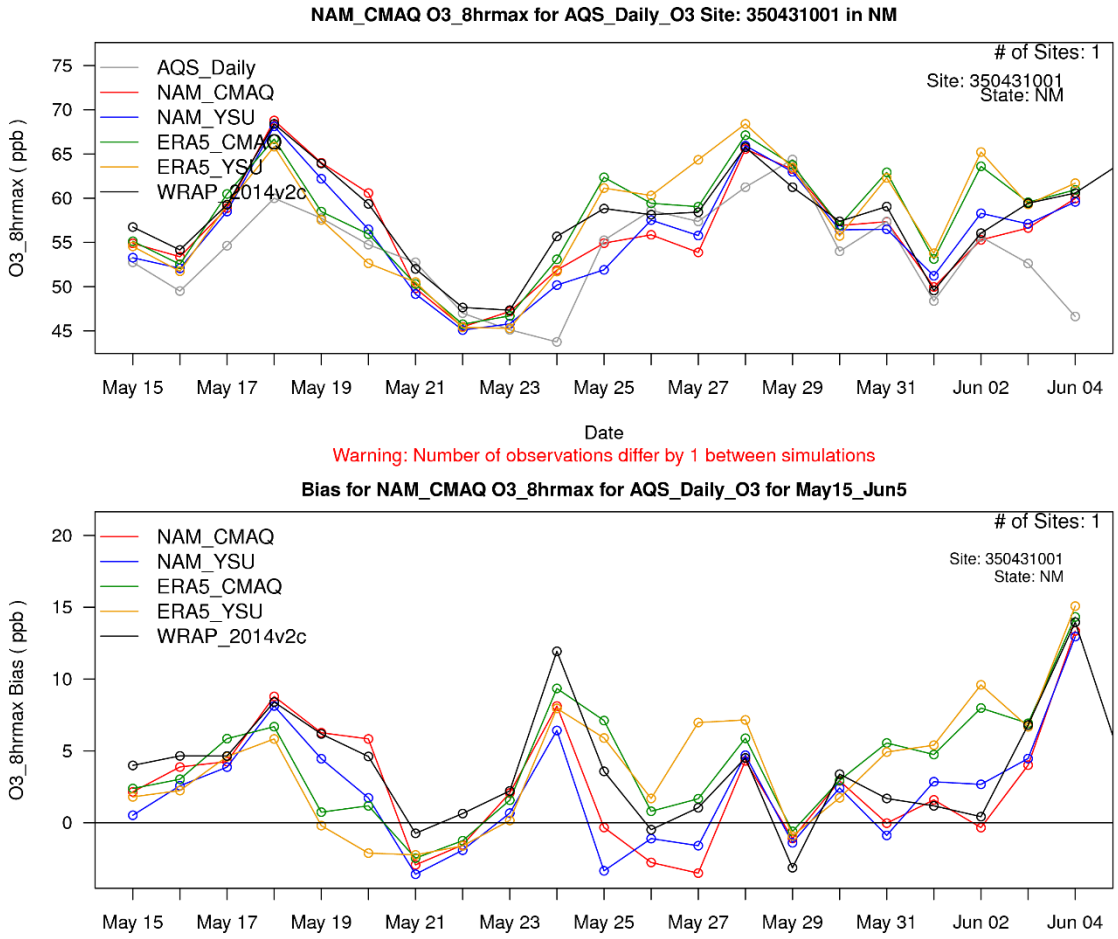

Figure 5-7. Timeseries comparison of sensitivity tests with observations (top) and bias (bottom) at Albuquerque site, Sandoval County

5.3 Summary CAMx Diagnostic Sensitivity Tests

All four of the CAMx meteorological sensitivity cases have biases and errors well within the performance criteria and in most cases even within the more stringent performance goals. For the modeled episode, the differences in performance among all the cases considered are relatively minor. On some sites and days, CAMx using the WRF/NAM meteorology tends to capture peak ozone concentrations better than when the WRF/ERA5 meteorology is used. Note that the sensitivity tests were performed on a period in late spring (May to June) when ozone concentrations exceed the NAAQS, however they may not reflect the observed precipitation biased observed in the WRF MPE for the period of June to August. Also, the WRF performance showed that precipitation biases could occur over northeast NM where there are no ozone monitors so CAMx model performance is unknown in that region. Based on the results presented here, the final CAMx 2014 base case model configuration will use the WRF/NAM with CMAQ Kv treatment meteorological inputs.

6. FINAL MODEL BASE CASE CONFIGURATION

This section summarizes the final CAMx base case model configuration for the summer of 2014 modeling of New Mexico that includes the meteorological, emissions, and air quality inputs as well as CAMx option and configuration. The modeling procedures used in the NM OAI Study modeling are consistent with EPA's latest ozone modeling guidance documents (EPA, 2018d) and past modeling studies of the western U.S. and followed the procedures laid out in the NM OAI Study modeling protocol (WESTAR and Ramboll, 2020a).

6.1 Meteorological Inputs

Procedures for WRF meteorological modeling for the NM OAI Study 2014 36/12/4-km applications are described in Chapter 2. Chapter 5 describes the CAMx diagnostic sensitivity tests using four different meteorological inputs that were based on two 2014 WRF simulations (WRF/NAM and WRF/ERA5) that were processed to generate CAMx inputs using two different two vertical mixing (Kv) options in the WRFCAMx processor (CMAQ-like and YSU). Although the ozone model performance for the four CAMx meteorological sensitivity tests were similar, the CAMx simulation using the WRF/NAM with CMAQ-like vertical mixing coefficients inputs was selected based on the best ozone model performance.

6.2 Emission Inputs

The 36-km and 12-km emissions used in the NM OAI Study CAMx 2014 base case simulation were based on the WRAP-WAQS 2014v2 emissions. Chapter 4 describes the updates to the WRAP-WAQS 2014v2 emissions for New Mexico and the development of the emission inputs for the New Mexico 4-km domain.

6.3 Photochemical Model Inputs

6.3.1 PGM Science Configuration and Input Configuration

This section describes the final CAMx 2014 base case configuration and science options used in the NM OAI Study ozone modeling. Table 6-1 summarizes the CAMx configuration and option used, with more details provided below.

6.3.1.1 PGM Model Versions

The latest version 7.0 (v7.0) of CAMx was used in the NM OAI Study. This is the same version used in the WRAP-WAQS 2014v2 modeling and as well as EPA in their national Regional Haze modeling (EPA, 2019). The model was configured to predict both ozone and PM species.

6.3.1.2 PGM Grid Nesting Strategy

CAMx was operated using the 36/12/4-km nested grid structure shown in Figure 1-10 using two-way grid nesting for all simulations.

NMED Exhibit 16

6.3.1.3 Initial and Boundary Conditions

Boundary Conditions (BCs) for the CAMx most outer 36-km 36US modeling domain lateral boundaries were based on output from a 2014 simulation of the GEOS-Chem global chemistry conducted by WRAP for their 2014v2 modeling platform. A zero-gradient top BC was specified where the concentrations above the top of CAMx are assumed to be the same as in the top layer of CAMx.

CAMx was started on May 1, 2016 using the 36/12/4-km domains that allowed the model over two-weeks to initialize the model and wash out the initial concentrations before the first high ozone day on May 17, 2014.

6.3.1.4 Other PGM Model Options

The CAMx model options and setup are defined in Table 6-1. The PPM advection solver (Colella and Woodward, 1984) was used for horizontal transport along with the spatially varying (Smagorinsky) horizontal diffusion approach. K-theory was used for vertical diffusion using the CMAQ-like Kv profiles from the WRFCAMx processing of the WRF/NAM output. The CB6r4 gas-phase chemical mechanism was selected because it includes the very latest chemical kinetic rates with halogen chemistry that affects ozone levels over the ocean. The latest aerosol mechanism was used in CAMx along with the standard wet and dry deposition schemes. The Plume-in-Grid module was used to treat the near-source chemistry and dispersion of major NO_X emissions sources in the New Mexico 4-km domain for sources with greater than 5 tons per day NOx emissions.

NMED Exhibit 16

Table 6-1. Final CAMx model configuration for the NM OAI Study.

Science Options	CAMx	Comment
Model Codes	CAMx v7.0	Latest version of CAMx made publicly available May 2020 (www.camx.com)
Horizontal Grid Mesh	36/12/4-km	
36-km grid	148 x 112 cells	36US domain
12-km grid	227 x 215 cells	12WUS2 domain. Includes buffer cells
4-km grid	245 x 227 cells	New Mexico 4-km domain. Includes buffer cells
Vertical Grid Mesh	25 vertical layers, defined by WRF	Layer 1 thickness ~20 m. Model top at 50 mb (~19 km). Layer collapsing from 35 vertical layers in WRF
Grid Interaction	36/12/4 km two-way nesting	
Initial Conditions	Start on May 1, 2014	First high ozone day is May 17, 2014
Boundary Conditions	WRAP 2014 GEOS-Chem	For 36US domain lateral boundaries
Emissions		
Baseline Emissions Processing	SMOKE, SMOKE-MOVES2014, MEGAN	WRAP/WAQS 2014v2 emissions and EPA 2023fh for future year
Sub-grid-scale Plumes	Plume-in-Grid for major NO_X sources in New Mexico	Point sources with NOx emission s greater than 5 tons per day
Chemistry		
Gas Phase Chemistry	CB6r4	Latest chemical reactions and kinetic rates with halogen chemistry (Yarwood et al., 2010)
Meteorological Processor	WRFCAMx	Compatible with CAMx v7.0
Horizontal Diffusion	Spatially varying	K-theory with Kh grid size dependence
Vertical Diffusion	CMAQ-like Kv	Evaluated YSU Kv scheme
Diffusivity Lower Limit	Kv-min = 0.1 to 1.0 m^2/s in lowest 100 m	Depends on urban land use fraction
Deposition Schemes		
Dry Deposition	Zhang dry deposition scheme	(Zhang et. al, 2001; 2003)
Wet Deposition	CAMx -specific formulation	rain/snow/graupel
Numerics		
Gas Phase Chemistry Solver	Euler Backward Iterative(EBI)	EBI fast and accurate solver
Vertical Advection Scheme	Implicit scheme w/ vertical velocity update	Emery et al., (2009a,b; 2011)
Horizontal Advection Scheme	Piecewise Parabolic Method (PPM) scheme	Colella and Woodward (1984)
Integration Time Step	Wind speed dependent	~0.5-1 min (4-km), 1-5 min (12-km), 5-15 min (36-km)

7. 2014 BASE CASE MODELING AND MODEL PERFORMANCE EVALUATION

This Chapter describes the CAMx 2014 base case simulations and model performance evaluation (MPE). The primary purposes of the MPE is to establish the reliability of the CAMx 2014 base case modeling for predicting maximum daily average 8-hour (MDA8) ozone and related concentrations in New Mexico to have confidence that the modeled ozone responses to changes in emissions are accurate enough for air quality planning in New Mexico. The CAMx 2014 base case model estimates are compared against the observed ambient ozone and other concentrations to establish that the model is able to reproduce the current year observed concentrations, so it is likely a reliable tool for estimating future year ozone levels. The model performance evaluation includes many types of graphical and statistical comparisons of the predicted and observed ozone concentrations, including spatial plots, scatter plots and time series analysis.

7.1 2014 Base Case Modeling

A CAMx 2014 May-August 36/12/4-km base case simulation was performed following the procedures outlined in the previous Chapters.

7.2 EPA Model Performance Evaluation Recommendations

7.2.1 Overview of EPA Model Performance Evaluation Recommendations

EPA's ozone modeling guidance (EPA, 2018d) describes a MPE framework that has four components:

- Operation Evaluation: The Operation Evaluation compares the modeled concentration estimates against concurrent observations using statistical and graphical analysis aimed at determining how well the model simulates the base year observed concentrations (i.e., does the model get the right answer).
- Diagnostic Evaluation: The Diagnostic Evaluation evaluates various components of the modeling system. It focuses on process-oriented evaluation and whether the model simulates the important processes for the air quality problem being studied (i.e., does the model get the right answer for the right reason).
- Dynamic Evaluation: The ability of the model's air quality predictions to correctly respond to changes in emissions and meteorology is part of the Dynamic Evaluation. This can include running the model for historical years to see whether the model's predictions match the changes in observations; comparison of model performance on weekdays versus weekend days can also help elucidate whether the model response to changes in emissions correctly.
- Probabilistic Evaluation: The Probabilistic Evaluation assess the level of confidence in the model predictions and estimates model uncertainty through techniques such as ensemble model simulations.

EPA's guidance recommends that "At a minimum, a model used for air quality planning should include a complete operational MPE using all available ambient monitoring data for the base case model simulations period" (EPA, 2018d, pg. 68). And goes on to say,

"Where practical, the MPE should also include some level of diagnostic evaluation." EPA notes that there is no single definite test for evaluating model performance, but instead there are a series of statistical and graphical MPE elements to examine model performance in as many ways as possible while building a "weight of evidence" (WOE) that the model is performing sufficiently well for the air quality problem being studied.

For the NM OAI Study we conducted an operational MPE for MDA8 ozone focusing on ozone model performance within the state of New Mexico. We also conducted some elements of a diagnostic evaluation as described in Chapter 5.

7.3 Overview of Evaluation of CAMx 2014 Base Case Procedures

This section provides an overview of the approach, procedures and tools used the procedures for evaluating the performance of the CAMx model focusing on ozone in New Mexico.

7.3.1 Photochemical Model Evaluation Methodology

The CAMx model performance evaluations will follow the procedures recommended in the EPA's latest photochemical modeling guidance (EPA, 2018d), some elements of EPA MPE Checklist (EPA, 2015a,b), and procedures discussed by Boylan and Russell (2006), Simon, Baker and Phillips (2012) and Emery and co-workers (2016).

7.3.2 Model Performance Goals and Benchmarks

EPA first proposed the use of ozone model performance goals in their 1991 ozone modeling guidance (EPA, 1991) with goals for bias (≤±15%) and error (≤35%). Since then, EPA has de-emphasized the use model performance goals as some users were focusing on achieving the model performance goals not on whether the model was accurately simulating atmospheric processes that led to the high ozone concentrations. However, model performance goals are still useful for helping interpret model performance and putting the model performance into context. Since the EPA 1991 ozone guidance performance goals, Boylan and Russell (2006) extended the performance goals to PM species and visibility. Simon, Baker and Phillips (2012) summarized the model performance statistics from 69 PGM applications from 2006 to 2012 and found lots of variability but were able to isolate model performance statistical levels for the best performing models.

Emery et al., (2016) built off the work of Simon, Baker and Phillips (2012) adding additional PGM model applications and coming up with a set of PGM model performance goals and criteria based on the variability in the past PGM model performance. "Goals" indicate statistical values that about a third of the top performance past PGM applications have met and should be viewed as the best a model can be expected to achieve. "Criteria" indicates statistics values that about two thirds of past PGM applications have met and should be viewed as what a majority of the models have achieved. In this Chapter we compare the CAMx 2014 base case simulations model performance statistics for normalized mean bias (NMB), normalized mean error (NME) and correlation coefficient (r) against the model performance goals and criteria summarized by Emery et al., (2016) that are given in Table 7-1.

NMED Exhibit 16

Table 7-1. Recommended benchmarks for photochemical model statistics (Source: Emery et al., 2016).

Species	NMB		NME		r	
	Goal	Criteria	Goal	Criteria	Goal	Criteria
1-hr & MDA8 Ozone	<±5%	<±15%	<15%	<25%	>0.75	>0.50
24-hr $PM_{2.5}$, SO_4, NH_4	<±10%	<±30%	<35%	<50%	>0.70	>0.40
24-hr NO_3	<±15%	<±65%	<65%	<115%	NA	NA
24-hr OC	<±15%	<±50%	<45%	<65%	NA	NA
24-hr EC	<±20%	<±40%	<55%	<75%	NA	NA

7.3.3 Available Aerometric Data for the Evaluations

There are two main ozone monitoring networks operating in New Mexico in 2014:

EPA AQS Surface Air Quality Data: Data files containing hourly-averaged concentration measurements at a wide variety of state and EPA monitoring networks are available in the Air Quality System (AQS[40]) database throughout the U.S. Typical surface measurements at the ground level routine AIRS monitoring stations include ozone, NO_2, NO_X and CO.

CASTNet Monitoring Network: The Clean Air Status and Trends Network (CASTNet[41]) operates approximately 80 monitoring sites in mainly rural areas across the U.S. CASTNet sites typically collect hourly ozone and weekly speciated $PM_{2.5}$, including HNO3. There is one CASTNet site located in the northwest corner of New Mexico (Chaco Culture NHP), although there are three more CASTNet sites in the 4-km New Mexico modeling domain: Mesa Verde in Colorado, Petrified Forest in Arizona and Palo Duro in Texas.

7.3.4 Atmospheric Model Evaluation Tool (AMET)

The Atmospheric Model Evaluation Tool (AMET[42]) (Appel et al., 2011) is a suite of software designed to facilitate the analysis and evaluation of predictions from meteorological and air quality models. AMET matches the model output for grid cells with observations from monitoring site locations from one or more networks of monitors. AMET also does species mappings to map the modeled species to the corresponding observations. These pairings of values (model and observation) are then used to statistically and graphically analyze the model's performance using a variety of techniques, many of which were used in the CAMx 2014 base case MPE. The latest version of AMET is version 1.4, but AMET website doesn't have any information on its release date or documentation so we assume the documentation for AMET v1.3[43] is pertinent for AMET v1.4.

[43] https://www.cmascenter.org/help/documentation.cfm

7.4 Ozone Evaluation Across the 4-km New Mexico Domain

Figure 7-1 shows the scatter plots of predicted and observed MDA8 ozone concentrations across AQS and CASTNet sites. The AQS sites (Figure 7-1, left) represent mainly the urban locations and whereas CASTNET (Figure 7-1, right) represent monitoring sites that are more rural. Most of the observation-model pair dots in the scatter plots appear to lie along the 1:1 line with very few outliers. The center of the AQS MDA8 ozone scatter plot lies slightly above the 1:1 line of perfect agreement indicating a slight overestimation bias. These scatter plots also displays the Normalized Mean Bias (NMB) and Error (NME) metrics. The average NMB for all MDA8 ozone concentrations and across all AQS sites shows an average overestimation bias of 6.2%, which is slightly higher than the bias performance goal (≤±5%) but within the bias performance criteria (≤±15%). The NME for MDA8 ozone across all AQS sites in the 4-km domain is 10.9%, which is well within the error performance goal (≤15%).

The average MDA8 ozone NMB at all CASTNet sites is 0.1% which is very low and quite good ozone performance well within the bias performance goal. The MDA8 ozone NME across the CASTNet sites is also very good at 7.9%.

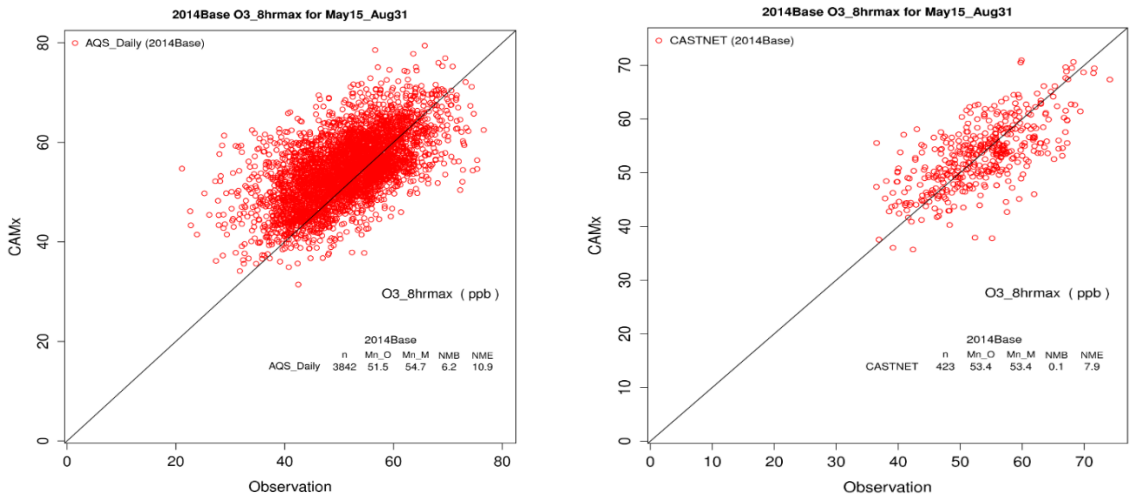

Figure 7-1. Scatter plot of predicted and observed MDA8 ozone across the AQS and CASTNET monitoring sites within the 4-km New Mexico domain during the modeling period (May 15-Aug 31, 2014) for the CAMx 2014 base case simulations.

Figure 7-2 displays the spatial distribution of the AQS and CASTNet site-specific NMB for the modeling period and for all MDA8 ozone (left) and MDA8 ozone when the observed ozone is above a 60 ppb cut-off (here after referred as MDA8_above60). Throughout the domain, the model NMB for all MDA8 ozone achieved the ozone bias performance goal (≤±5%) at majority of the sites (i.e., symbols colored grey). At few sites, the model showed an overprediction (yellow color) in predicting all MDA8 ozone concentrations. With one exception for a site colored orange in El Paso, the sites with the overestimation bias are colored bright yellow that indicates bias in the +5% to +15% range so achieve the ozone bias performance criteria.

For MDA8_above60 (Figure 7-2, right panel) for most sites in the 4-km domain the NMB symbols are colored grey indicting that they achieve the ozone bias performance goal. Several sites are colored bright green that indicates an underestimation bias that are unable to achieve bias performance goal (≤±5%) but is within the ozone bias performance criteria (≤±15%) so the bias is between -5% and -15%.

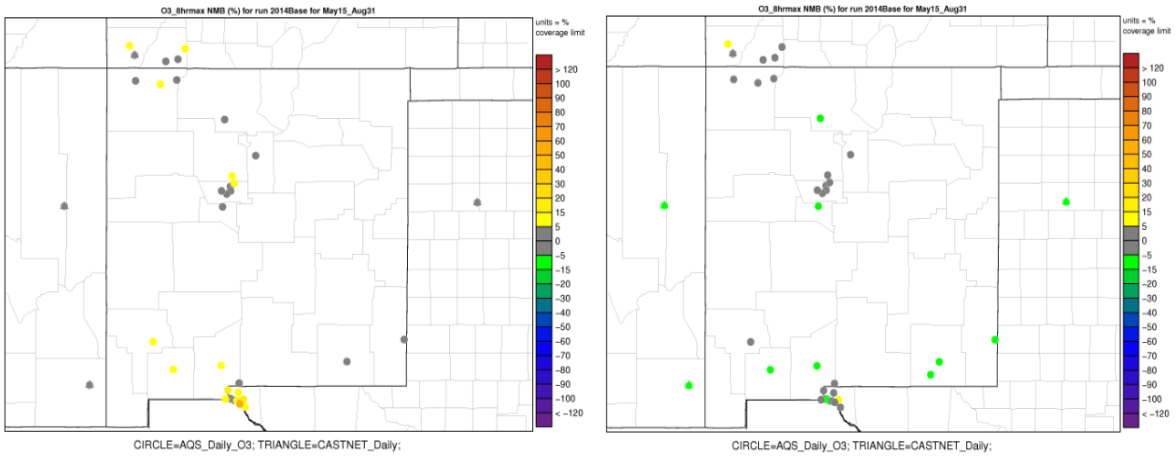

Figure 7-2. Spatial distribution of CAMx 2014 base case simulation period (May15-Aug 31) site-specific Normalized Mean Bias within the 4-km domain for MDA8 O3 (left) and MDA8 O3 above 60ppb cut-off (right).

7.5 Ozone Evaluation Across New Mexico

In this section we evaluated the modeled MDA8 ozone and MDA8_above60 ozone in the state of New Mexico at all AQS monitoring sites using scatter, soccer and spatial overlay plots. Figure 7-3 presents scatter plots of MDA8 and MDA8_above60 ozone modeled and observation paired concentrations, it indicate that the modeled values are close to the observations as majority of them lie along and in the vicinity of 1:1 line. The domain wide all AQS sites MPE statistics of MDA8 and MDA8_above60 ozone NMB (5.0%, -4.3%) and NME (9.8%, 8.0%) metrics are within the ozone performance goals (i.e., NMB<±5% and NME<15%).

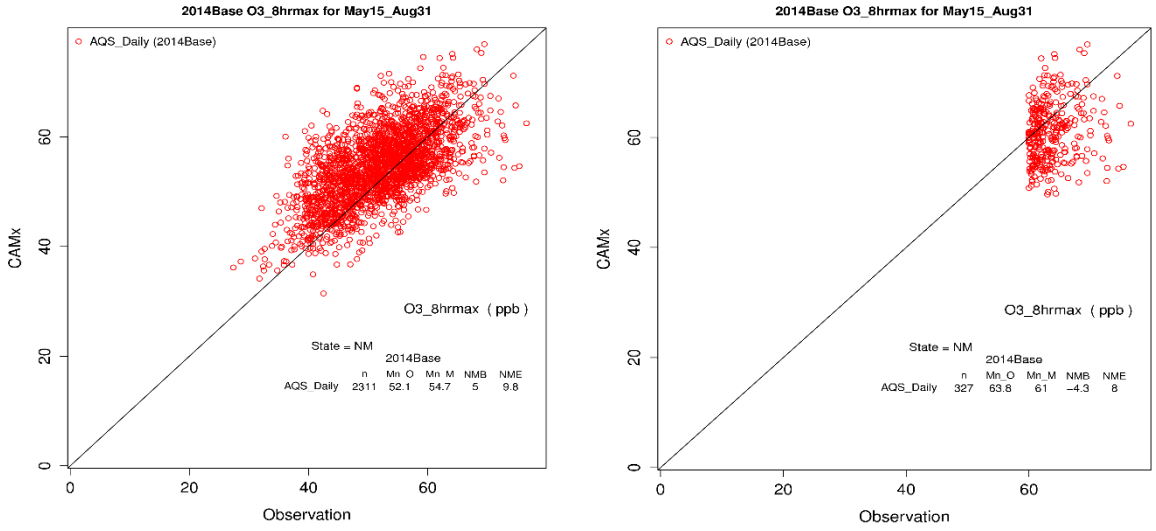

Figure 7-3. Scatter plots of predicted and observed MDA8 ozone (left) and MDA8 ozone when observed value is above 60 ppb cut-off (right) across the AQS monitoring sites in New Mexico during modeling period (May15-Aug 31) for the CAMx 2014 base case simulations.

Figure 7-4 displays the monthly soccer plot for sites in New Mexico and for MDA8 (left) and MDA8_above60 (right) ozone concentrations with the inner rectangle being the performance goal (NMB<±5% and NME<15%) and the outer rectangle being the performance criteria (NMB<±15% and NME<25%). Considering all MDA8 ozone data with no cut-off (i.e., Figure 7-4 left panel), the model is overestimating in the months of July and August achieving the performance criteria but not the performance goals. The months of May and June achieve the performance goals.

Considering the ozone data with 60 ppb cut-off (i.e., Figure 7-4 right panel), the model achieves the ozone performance goals in June, July and August months with an underestimation bias. In May, the underestimation bias for MDA8_above60 is lower than -5% so fails to achieve the bias performance goal, but does achieve the performance criteria. Overall, the soccer plots indicate that the model captures the observed MDA8 and MDA8-above60ppb ozone concentrations well during each month of the summer of 2014

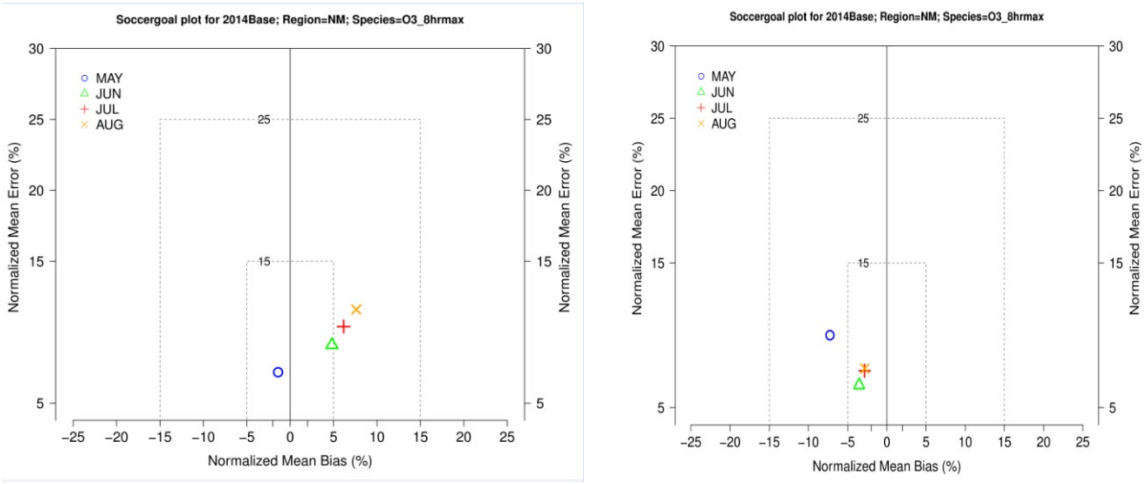

Figure 7-4. Soccer plots of MDA8 ozone (left) and MDA8 ozone when observed value is above a 60 ppb cut-off (right) with monthly average NMB and NME values across sites in New Mexico. The dashed lines represents the performance goals and criteria.

As shown in site-specific spatial NMB plot for New Mexico sites in Figure 7-5, the overestimation of MDA8 ozone (considering all values) that fails to achieve the bias performance goal occurs mainly at southern sites along with three other northerly sites (Bloomfield, North Valley and Foothills). The underestimation of MDA8_above60 that fails to achieve the bias performance goal occurs primarily at southern sites along with two more northerly sites (Coyote Ranger and Los Lunas).

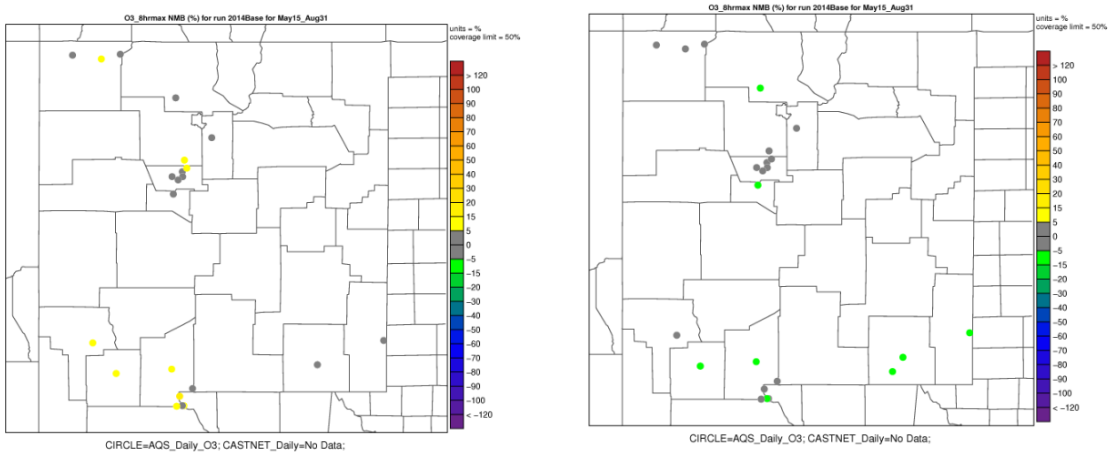

Figure 7-5. Spatial distribution of site-specific Normalized Mean Bias for sites in New Mexico and the CAMx 2014 May-August base case simulation for all MDA8 ozone data (left) and MDA8 ozone with observed value above a 60 ppb cut-off (right).

7.6 Ozone Evaluation in New Mexico Subregions

As shown in the New Mexico ozone performance above, and discussed in the conceptual model in Chapter 1, there are three distinct large regions of ozone formation conditions in New Mexico, each with their own subregional variations: northern New Mexico that shares ozone attributes of other sites in other states in the Four Corners region, Bernalillo County that has many of the attributes of the northern New Mexico sites only also including the presence of a major city; and sites in southern New Mexico. The ozone MPE is conducted separately for each of these major subregions in New Mexico. Table 7-2 shows the AQS sites available in the New Mexico with ozone data during 2014 that are categorized into northern New Mexico (blue), Bernalillo County (yellow) and south New Mexico (orange) subregions. The NMB and NME values shown in Table 7-3 are averaged across all sites in these regions and color coded based on the performance benchmarks for both MDA8 ozone and MDA8above60: green if achieve the performance goal; yellow if falling between the performance goal and criteria; and red if fails to achieve the performance criteria. Both northern and Bernalillo County regions achieve the ozone bias and error performance goal for both MDA8 ozone concentrations without and with an observed MDA8 ozone 60 ppb cut-off threshold. The southern region has NMB that fall between the ozone bias performance goal and criteria due to either a too high overestimation bias (all MDA8 data) or too low underestimation bias (MDA8_above60ppb). Although the bias just barely falls outside of the performance goal.

NMED Exhibit 16

7.7 Ozone Evaluation at Individual New Mexico Monitoring Sites

Table 7-4 contain individual AQS site MDA8 ozone model performance statistics for the CAMx 2014 base case simulation from May 15 to Aug 31, 2014. Among the 22 sites in the state, 13 sites (59%) achieve the bias performance goal (green color, NMB ≤±5%) and 8 sites (36%) exceeded the bias performance goal but achieve the bias performance criteria (orange color, NMB ≤±15%) leaving only one site (La Union in Dona Ana County) whose NMB fails to achieve the bias performance goal. With the exception of the Carlsbad monitor whose MDA8 ozone has a slight underestimation bias (NMB of -1.1%), all sites have a positive NMB when compared to all ozone observations indicating an overestimation bias, with just La Union having an NMB so large (17.4%) that it fails to achieve the ozone bias performance criteria. Also shown in Table 7-4 is the Fractional Bias (FB) whose results are similar to the NMB with just the La Union having a FB (16.4%) that fails to achieve the bias performance criteria.

In terms of NME, all sites achieve the error performance criteria and all sites except for two sites (La Union and Foot Hills) achieve the error performance goal (NME ≤15%). The results for the Fractional Error (FE) are similar to NME. Overall based on the average NMB and NME values at each site the model appeared to perform well during the modeling period.

Although not color-coded, the correlation (r) performance criteria (> 0.50) for MDA8 ozone is achieved at all monitoring sites. However, the correlation performance goal (>0.75) is only achieved at one site.

Similar to Table 7-4, Table 7-5 contain the individual AQS site performance statistics for MDA8 ozone with predicted and observed pairs when the observed value is above a 60 ppb cut-off threshold. Out of the 22 sites, 16 sites (73%) achieve the bias performance goal and the remainder 6 sites (27%) fall between the bias performance goal and criteria. Overall, all the sites showed a consistent slight under-prediction indicating that the model was unable to predict all of the observed ozone peak concentrations. The NME for all sites achieved the ozone error performance goal. The results for FB and FE are consistent with NMB and NME. Almost all of the correlation coefficients fail to achieve the performance criteria for MDA8_above60ppb, although the

sample size for the site-specific MDA8_above60ppb statistics is very small for some sites so the statistics are less meaningful.

Table 7-5. 2014 Base Case model performance statistics of MDA8 Ozone with an observed ozone 60 ppb cut-off by monitoring site for summer (May 15-Aug) modeling period.

Time series of predicted and observed MDA8 ozone concentrations at five representative sites (Bloomfield, Coyote Ranger, South Valley, Desert View and Carlsbad) are shown in Figure 7-6 to Figure 7-10. Time series sites for all sites are contained in Appendix A. Each time series plot consists of two panels: an upper panel that shows the predicted (blue) and observed (red) daily MDA8 ozone concentrations

NMED Exhibit 16

from May 15 to August 31, 2014; and a bottom panel that shows the difference (i.e., daily bias) in the daily predicted and observed MDA8 ozone concentrations. At the Bloomfield monitor in San Juan County in northern New Mexico, the predicted and observed MDA8 ozone concentrations match each other remarkably well in May and June and into the first part of July. However, by mid-July the model estimates a series of three mini ozone episodes at the end of July, beginning of August and mid-August that are not reflected in the observations.

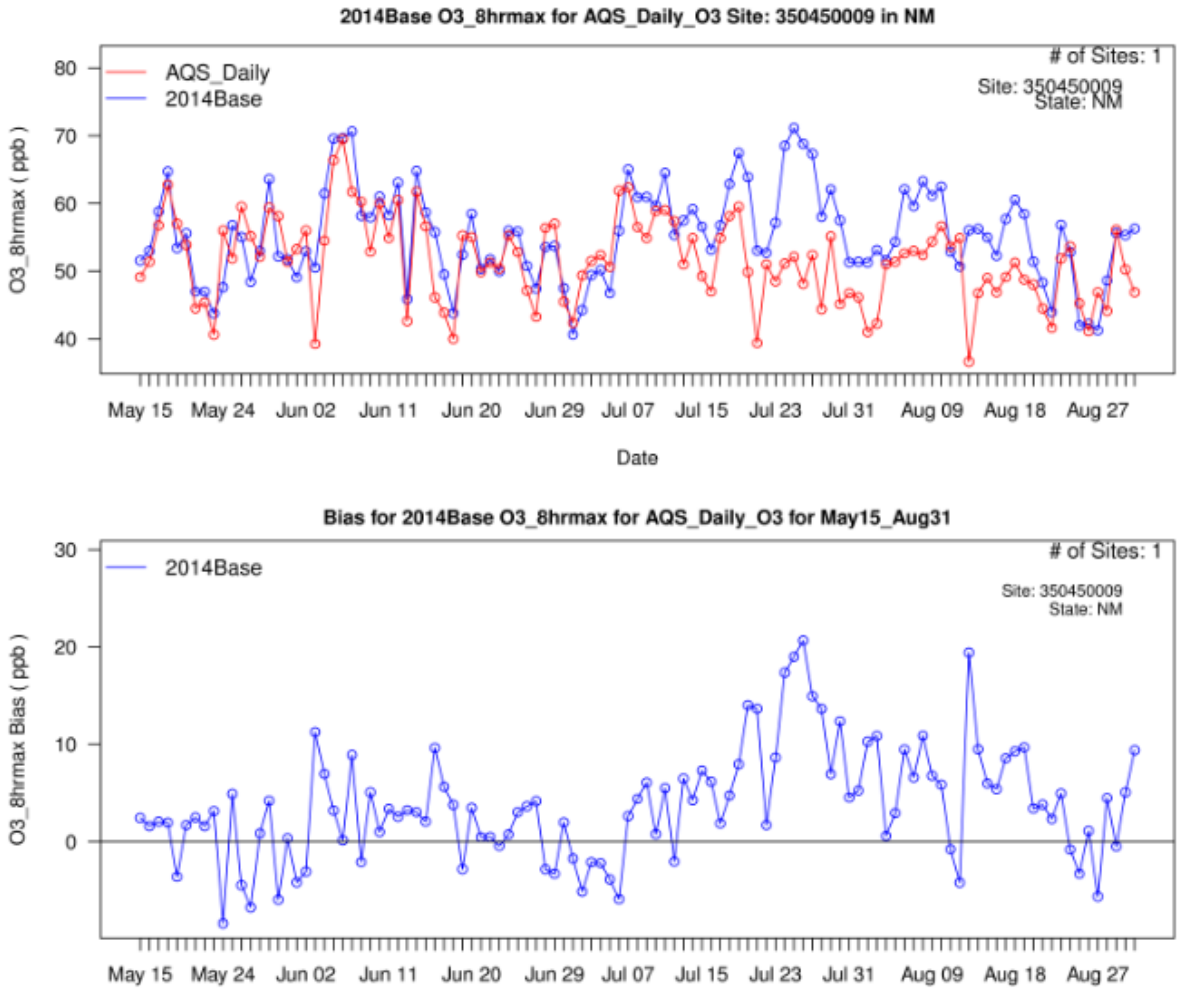

Figure 7-6. Time series of predicted and observed MDA8 ozone concentrations (ppb; top)and daily bias (ppb; bottom) at Bloomfield monitoring site (Site ID: 350450009).

The MDA8 ozone times series Coyote Ranger District site in Rio Arriba County shown in Figure 7-7 shares many of the same characteristics seen at Bloomfield. Extremely good daily MDA8 ozone performance is seen in May and June and the beginning of July. A third of the way into July, however, the model starts to exhibit an ozone overestimation bias with ozone peaks that are 10-20 ppb greater than observed, although better daily ozone performance is seen at Coyote Ranger District the end of August.

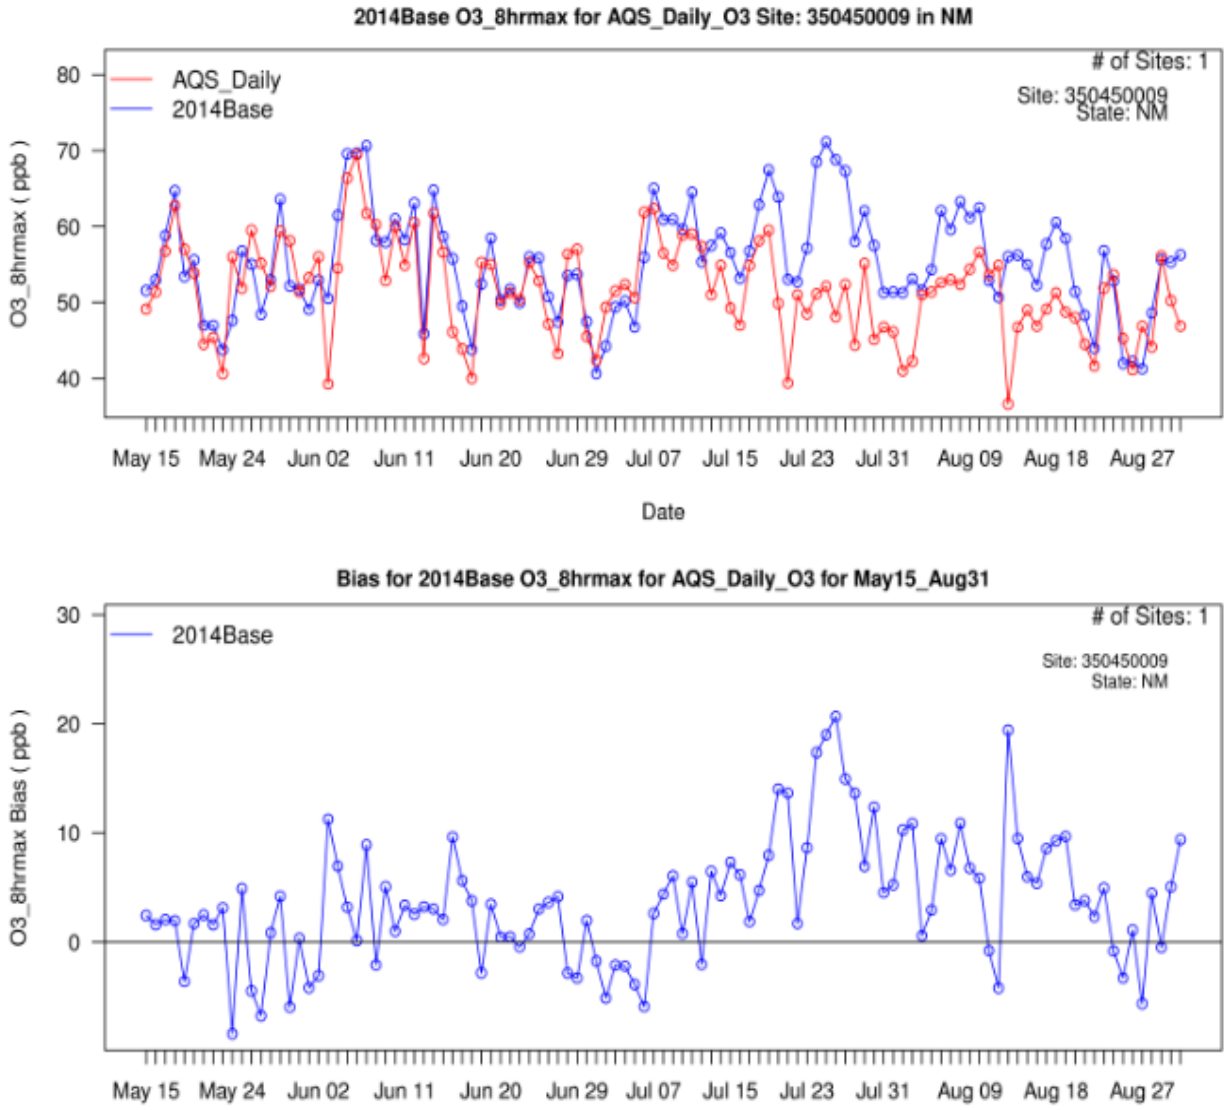

Figure 7-7. Time series of predicted and observed MDA8 ozone concentrations (ppb; top) and daily bias (ppb; bottom) at Coyote Ranger monitoring site (Site ID: 350390026).

The ozone time series at the South Valley site in Bernalillo County is fairly good throughout the May to August episode (Figure 7-8). The daily bias is almost always within ±10% and usually lower than that. The July-August systematic ozone estimation seen at the two northern New Mexico sites is not present, although there is a hint of that phenomena in mid-August.

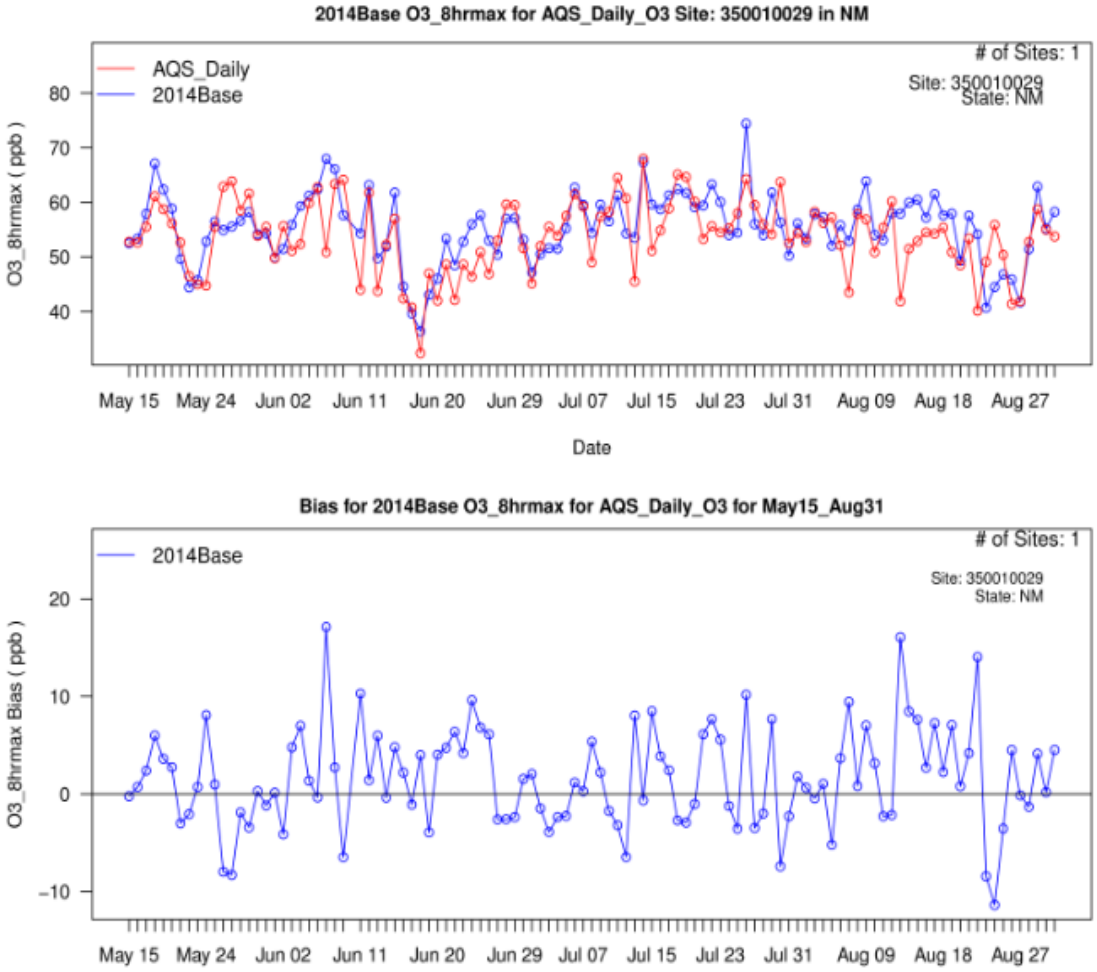

Figure 7-8. Time series of predicted and observed MDA8 ozone concentrations (ppb; top) and daily bias (ppb; bottom) at South Valley monitoring site (Site ID: 350010029).

The observed high MDA8 ozone concentrations at the Desert View monitoring site in Dona Ana County occur as ozone spikes that are a day or two in duration (Figure 7-9). In general, the model follows the observed daily variation on the observed MDA8 ozone concentrations well except for not capturing the observed ozone spikes during May, June and the first part of July. However, for the second half of July and in August the model does a good job in reproducing the observed ozone spikes at Desert View.

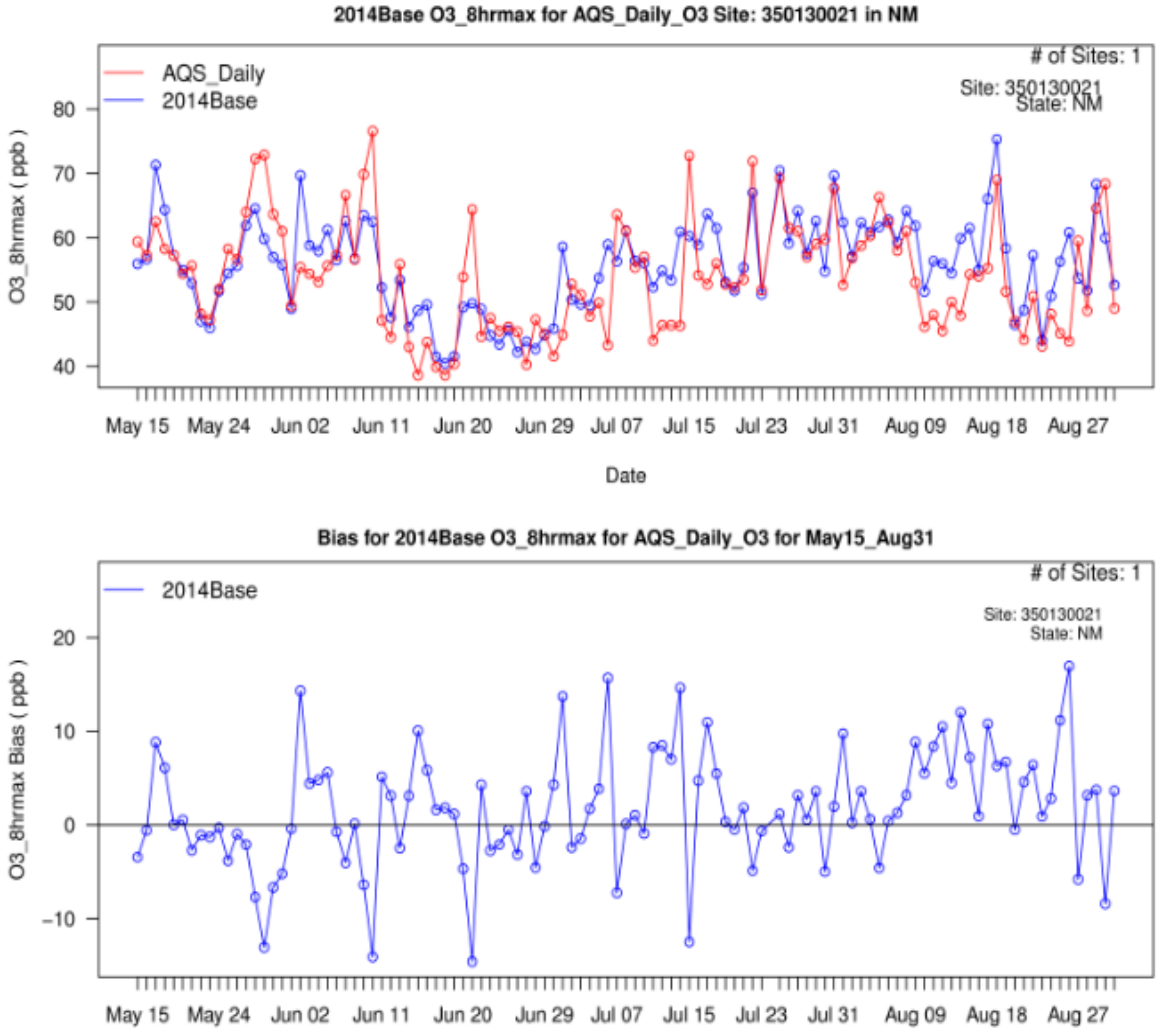

Figure 7-9. Time series of predicted and observed MDA8 ozone concentrations (ppb; top) and daily bias (ppb; bottom) at Desert View monitoring site (Site ID: 350130021).

The observed MDA8 ozone episode during May 29 to June 1 at the Carlsbad site in Eddy County in southeast New Mexico is completely missed by the model (Figure 7-10). Better performance is seen the remainder of the modeling period, although the model misses high ozone periods the end of July and early August. There is also a lot of missing observed data in August, which is unfortunate given the potential presence of high observed ozone during this period based on the data at Desert View.

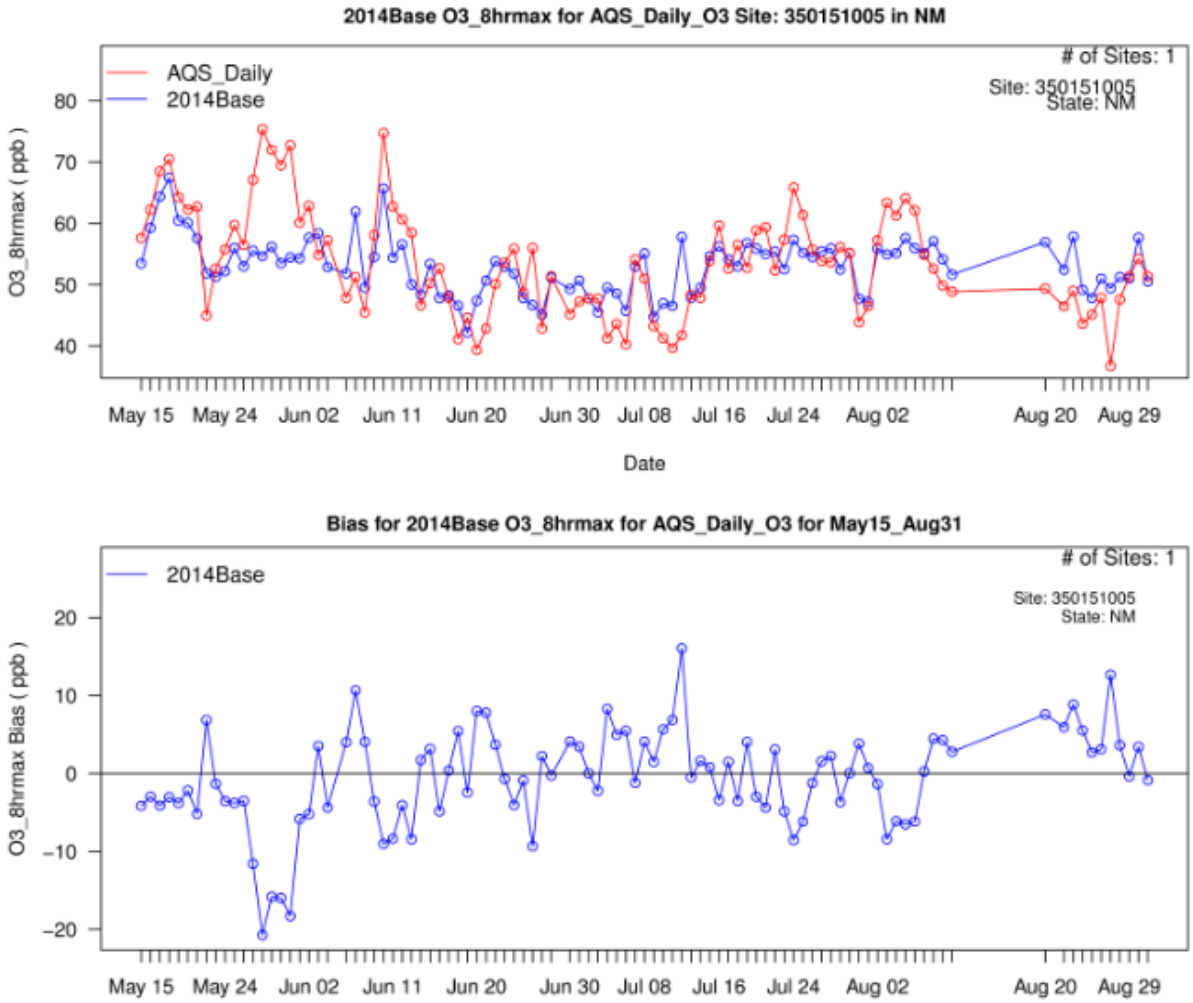

Figure 7-10. Time series of predicted and observed MDA8 ozone concentrations (ppb; top) and daily bias (ppb; bottom) at Carlsbad monitoring site (Site ID: 350151005).

7.8 Ozone Performance Related to Future Year Ozone Projections

EPA's ozone modeling guidance (EPA, 2018d) recommends making future year ozone design value projections using the relative changes in the future year to base year modeled MDA8 ozone concentrations for the 10 highest base year modeled MDA8 ozone concentrations. Thus, the model performance of the CAMx 2014 base case simulation for the 10 highest modeled ozone concentrations is of particular importance. In this

section we examine this issue for three sites: Bloomfield in San Juan County; Desert View in Dona Ana County; and Carlsbad in Eddy County.

7.8.1 Bloomfield Top 10 Ozone Performance

Table 7-2 displays the CAMx 2014 base case 36 highest modeled MDA8 ozone days at Bloomfield with concurrent observed MDA8 ozone, and the bias presented as concentration and percent. The observed top 20 highest MDA8 ozone concentrations are colored yellow, with the darker yellow indicating an observed top 10 MDA8 ozone concentration day. The 10 highest modeled MDA8 ozone concentrations at Bloomfield are also top 20 observed MDA8 ozone days for 6 of the 10 days; the top 10 observed MDA8 ozone concentration days occurring on 5 of the top 10 modeled ozone days. So, there is a good overlap of the top 10 modeled and top 20 observed highest MDA8 ozone days at Bloomfield.

The red shading on the bias percent in Table 7-2 indicates days in the top 10 modeled ozone days whose daily bias exceeds ±10%. An alternative future year ozone design value projection approach to the EPA-recommended modeled top 10 MDA8 ozone days is to use the top 10 modeled ozone days that meet a model performance requirement, such as within ±10% of the observed value. With a 10% MPE criteria projection approach, the additional days used to replace those whose bias exceeds ±10% (i.e., shaded red) are colored blue in Table 7-2. Under the 10% MPE criteria projection approach, the 10 modeled days used in the projection all overlap with the top 20 observed ozone days and 7 of the days are a top 10 observed MDA8 ozone day.

This analysis indicates that the model performance on the modeled top 10 days used for making ozone projections at Bloomfield is quite reasonable and has good overlap with the observed highest ozone days.

NMED Exhibit 16

Table 7-6. Predicted and observed MDA8 ozone concentrations (ppb) at Bloomfield for CAMx 2014 base case for modeled ranked 36 highest MDA8 ozone concentrations.

Bloomfield	Obs	Prd	Bias	%

7.8.2 Desert View Top 10 Ozone Performance

The evaluation of the CAMx 2014 base case for the top 10 modeled MDA8 ozone concentrations at Desert View is shown in Table 7-3. 7 of the top 10 modeled MDA8 ozone concentrations are also top 20 observed ozone days, with 5 of those days also being in the top 10 observed ozone days. Thus, there is good overlap between the highest modeled and observed ozone days at Desert View. 5 of the top 10 modeled ozone days have daily bias that does not meet a within ±10% performance criteria. Imposing a within ±10% performance criteria for selecting the top 10 modeled ozone days results in all 10 days overlapping with observed days in the top 20 of the observed distribution with 7 of those days being top 10 observed ozone days.

Table 7-7. Predicted and observed MDA8 ozone concentrations (ppb) at Desert View for CAMx 2014 base case for modeled ranked 36 highest MDA8 ozone concentrations.

Desert View	Obs	Prd	Bias	%

7.8.3 Carlsbad Top 10 Ozone Performance

6 of the top 10 modeled ozone days at Carlsbad occur during observed top 20 ozone days, 4 of those days within the top 10 of the observed ozone distribution (Table 7-4). Five of the modeled top 10 ozone days have bias that does not achieve the within ±10% criteria. When imposing the within ±10% performance criteria for the top 10 modeled ozone days, 7 of those days overlap with observed top 20 days.

Table 7-8. Predicted and observed MDA8 ozone concentrations (ppb) at Carlsbad for CAMx 2014 base case for modeled ranked 36 highest MDA8 ozone concentrations.

Carlsbad	Obs	Prd	Bias	%
5/18/2014	70.5	67.5	-3.0	-4.3%
6/10/2014	74.8	65.7	-9.0	-12.1%

NMED Exhibit 16

8. SUMMARY AND CONCLUSIONS

The evaluation of the NM OAI Study CAMx 2014 base case simulation focused on Maximum Daily 8-hour Average (MDA8) ozone model performance across all sites in the 4-km New Mexico domain, across all sites within New Mexico, within three subregions in New Mexico (northern, Bernalillo County, and southern) and at individual sites in New Mexico. When examining MDA8 ozone performance across groups of sites, the CAMx 2014 base case always achieves the ozone performance criteria and usually achieves the ozone performance goals. When examining MDA8 ozone performance across all observations, the model tended to have an ozone overestimation tendency but still always achieved the bias performance criteria (≤±15%) and usually achieved the bias performance goal (≤±5%). When comparing the model's ability to reproduce the highest observed ozone concentrations greater than 60 ppb, the model still always achieved the bias performance criteria and usually achieved the bias performance goal, albeit with an underestimation tendency. The MDA8 ozone error essentially always achieves the performance goal whether examining all ozone observations or just those observations greater than 60 ppb. More specifically:

- Across the 4-km New Mexico domain for all ozone observations, the Normalized Mean Bias (NMB) for the AQS network was 6.2% that achieves the bias performance criteria but not the bias performance goal. However, across the more rural CASTNet network the NMB (0.1%) is near zero achieving the performance goal.
- With New Mexico, the NMB achieves the performance goal whether using all ozone data (5.0%) or just ozone data when the observed ozone is greater than 60 ppb (-4.3%).
- Similar performance attributes are seen in the New Mexico subregional evaluation whether using all data or the 60 ppb ozone cut-off with the NMB in the northern New Mexico (4.3% and 0.0%) and Bernalillo County (4.3% and -2.8%) subregions achieving the bias performance goal. However, the NMB in the southern New Mexico region (5.8% and -6.1%) just barely falls outside of the performance goal region, but achieves the performance criteria.
- At individual monitoring sites using all ozone data the NMB achieves the bias performance criteria at all sites but one (La Union) with a majority of the sites (13 of 22 or 59%) also achieving the bias performance goal.
- The time series of predicted and observed MDA8 ozone concentrations shows that the model has very good agreement and tracks the day-to-day variations of the observed ozone in the northern New Mexico and Bernalillo County sites for the first half of the May-August 2014 modeling period. The second half of the modeling period the model generally has an ozone overestimation tendency at the northern New Mexico sites.
- Time series at the southern New Mexico show that the model has difficulty in reproducing the observed daily ozone spikes in the first half of the modeling period, but does a better job in reproducing the daily observed high ozone concentrations in the second half of the episode.

NMED Exhibit 16

An evaluation of the model performance for the top 10 modeled ozone days that are used for making future year ozone projections revels that they are also high observed ozone days over half of the time.

In conclusion, the NM OAI Study CAMx 2014 base case ozone model performance within New Mexico is as good or better than most recent PGM applications (e.g., WRAP-WAQS, EPA 2016v1 and Denver ozone SIP) and appears to be a reliable PGM modeling platform for evaluating emission reduction strategies for reducing ozone concentrations in New Mexico.

NEW MEXICO OZONE ATTAINMENT INITIATIVE PHOTOCHEMICAL MODELING STUDY – DRAFT FINAL AIR QUALITY TECHNICAL SUPPORT DOCUMENT

Project name	**New Mexico Ozone Attainment Initiative Photochemical Modeling Study**
Project no.	**1690017454**
Recipient	**New Mexico Environmental Division**
Document type	**Draft Final Technical Report**
Version	**V8.0**
Date	**May 2021**
Prepared by	**Ralph Morris, Marco Rodriguez, Tejas Shah, Jeremiah Johnson, Jung Chien, Pradeepa Vennam and Fiona Jiang, Ramboll US Consulting, Inc.** **Tom Moore and Mary Uhl, Western States Air Resources Council**

CONTENTS

ACRONYMS and ABBREVIATIONS		**xiv**
1.	**INTRODUCTION**	**1**
1.1	NM OAI Photochemical Modeling Study Genesis	1
1.2	Overview of NM OAI Study Modeling Approach	4
1.2.1	WRAP-WAQS 2014 PGM Platform Development	4
1.2.2	Episode Selection	5
1.2.3	Model Selection	5
1.2.4	Domain Selection	5
1.2.5	Base and Future Year Emissions Data	8
1.2.6	Initial and Boundary Conditions Development	8
1.2.7	Diagnostic Sensitivity Analyses	8
1.2.8	Model Performance Evaluation	8
1.2.9	2028 Future Year Base and Control Strategy Modeling	9
1.2.10	Future Year Source Apportionment Modeling	9
2.	**2014 WRF METEOROLOGICAL MODELING**	**10**
2.1	WRF Meteorological Model	10
2.2	WRF Horizontal Modeling Domain	10
2.3	WRF Model Configuration	10
2.3.1	Vertical Coordinate	12
2.3.2	Topographic Inputs	12
2.3.3	Vegetation Type and Land Use Inputs	12
2.3.4	Atmospheric Data Inputs	12
2.3.5	New Lightning Data Assimilation	13
2.3.6	PBL and LSM Physics Options	13
2.3.7	Remaining WRF Physics Options	13
2.3.8	Application Methodology	14
2.4	WRF Model Evaluation	14
2.4.1	Quantitative Evaluation Using METSTAT	14
2.4.2	Qualitative Evaluations for Precipitation Using PRISM Data	20
2.4.3	Conclusions of 2014 WRF Model Performance	22
3.	**BOUNDARY CONDITION INPUTS**	**23**
3.1	WRAP 2014 GEOS-Chem Modeling	23
3.2	2014 GEOS-Chem Model Evaluation	24
4.	**2014 AND 2028 EMISSION INPUTS**	**25**
4.1	Summary of Emissions Used in 2014 and 2028 Modeling	25
4.2	Development of CAMx 2014 Base Case Emission Inputs	25
4.2.1	Day-Specific On-Road Mobile Source Emissions	25
4.2.2	Point Source Emissions	26
4.2.3	Area and Non-Road Source Emissions	26
4.2.4	Episodic Biogenic Emissions	26
4.2.5	Wildfires, Prescribed Burns, Agricultural Burns	28
4.2.6	Other Natural Emissions	30
4.2.7	2014 Emission Results	30
4.3	Development of CAMx 2028 Emission Scenarios	35

NMED Exhibit 17

4.3.1	2028 Base Case New Mexico Oil and Gas Emissions	36
4.4	Summary of 2014 and 2028 Base Case Emissions	40
4.5	2028 New Mexico Oil and Gas Control Strategy	45
5.	**DIAGNOSTIC SENSITIVITY TESTS**	**49**
5.1	WRFCAMx Processing of 2014 WRF Output	49
5.2	CAMx Meteorological Diagnostic Sensitivity Tests	49
5.3	Summary of CAMx Diagnostic Sensitivity Tests	59
6.	**2014 BASE CASE MODELING AND MODEL PERFORMANCE EVALUATION**	**60**
6.1	Final CAMx 2014v2 Base Case Configuration	60
6.2	Ozone Model Performance Goals and Criteria	62
6.3	Spatial Ozone Model Performance	62
6.4	Scatter Plots of MDA8 Ozone	66
6.5	MDA8 Ozone Time Series	68
6.6	Summary Ozone Model Performance Statistics in New Mexico	71
6.7	Conclusions of 2014 Base Case Modeling and Model Performance Evaluation	74
7.	**2028 BASE CASE MODELING AND OZONE DESIGN VALUE PROJECTIONS**	**76**
7.1	EPA Recommended Ozone Design Value Projection Procedure	76
7.1.1	Ozone DV Unmonitored Area Analysis (UAA)	77
7.2	2028 Base Case Ozone DVF Projections at Monitoring Sites	77
7.3	2028 Base Case Ozone DVF Unmonitored Area Analysis	79
7.4	2014v2 and 2028 MDA8 Ozone Concentrations	84
7.4.1	Daily 2014v2 and 2028 Base Case MDA8 Ozone Concentrations	84
7.4.2	Comparison of Episode Maximum MDA8 and SMAT UAA Ozone DVF Differences	89
8.	**2028 OIL AND GAS CONTROL STRATEGY MODELING AND OZONE DESIGN VALUE PROJECTIONS**	**90**
8.1	2028 Ozone Design Value Comparisons	90
8.1.1	Ozone Design Values at the Monitoring Sites	90
8.1.2	2028 O&G Control Strategy Ozone DVF Unmonitored Area Analysis	93
8.2	2028 Base Case and 2028 O&G Control Strategy MDA8 Ozone Concentrations	96
8.2.1	Daily 2014v2 and 2028 Base Case MDA8 Ozone Concentrations	96
8.3	Conclusions of the 2028 Base and 2028 O&G Control Strategy Modeling	101
9.	**SENSITIVITY OF PROJECTED 2028 OZONE DESIGN VALUES TO CURRENT YEAR OZONE DESIGN VALUES**	**102**
9.1	2028 Ozone Design Value Sensitivity Analysis using $DVC_{2015\text{-}2019}$	102
9.2	2028 Ozone Design Value Sensitivity Analysis using $DVC_{2017\text{-}2019}$	103
10.	**2028 SOURCE SECTOR APCA OZONE SOURCE APPORTIONMENT MODELING**	**105**
10.1	Versions of Ozone Source Apportionment	105
10.2	2028 Source Sector APCA Ozone Source Apportionment Specifications	106
10.2.1	2028 O&G Control Strategy Emissions Scenario	106

10.2.2	Definition of Source Groups	106
10.3	2028 Source Sector APCA Ozone Source Apportionment Modeling Results	109
10.3.1	Source Sector Contributions to Projected 2028 Ozone DVFs	109
10.3.2	Source Sector Contributions to Modeled MDA8 Ozone Concentrations	134
10.3.3	International Anthropogenic Emissions Contributions to Projected 2028 ozone DVFs	152
11.	**2028 VOC AND NOX SENSITIVITY OSAT OZONE SOURCE APPORTIONMENT MODELING**	**158**
11.1	2028 OSAT Ozone Source Apportionment Design	158
11.2	Spatial Distribution of VOC/NO_x Ozone Formation Sensitivity	159
11.2.1	Percent NO_x Sensitive Ozone on May 17, 2014	160
11.2.2	Percent NO_x Sensitive Ozone on May 26, 2014	162
11.2.3	Percent NO_x Sensitive Ozone on May 28, 2014	162
11.2.4	Percent NO_x Sensitive Ozone on June 5, 2014	165
11.2.5	Percent NO_x Sensitive Ozone on July 12, 2014	165
11.2.6	Percent NO_x Sensitive Ozone on July 24, 2014	165
11.2.7	Percent NO_x Sensitive Ozone on July 26, 2014	169
11.2.8	Percent NO_x Sensitive Ozone on August 14, 2014	169
11.2.9	Percent NO_x Sensitive Ozone due to New Mexico Anthropogenic Emissions	169
11.3	Analysis of VOC/NOx Ozone Formation Sensitivity at Monitoring Sites in New Mexico	174
11.3.1	VOC/NO_x Sensitivity at Substation in San Juan County	174
11.3.2	VOC/NO_x Sensitivity at South East Heights in Bernalillo County	177
11.3.3	VOC/NO_x Sensitivity at Desert View in Doña Ana County	177
11.3.4	VOC/NO_x Sensitivity at Carlsbad in Eddy County	182
12.	**SUMMARY AND CONCLUSIONS**	**185**
12.1	Summary of CAMx 2014 36/12/4-km Photochemical Model Platform Development	185
12.2	Summary of 2028 Ozone Modeling Results and Ozone Design Value Projections	185
12.3	Sensitivity of 2028 Ozone Design Value Projections to Current Year Ozone Design Value	186
12.4	2028 Source Sector APCA Ozone Source Apportionment Modeling	187
12.5	2028 VOC/NO_x Sensitivity OSAT Ozone Source Apportionment Modeling	187
13.	**REFERENCES**	**188**

TABLE OF TABLES

Table 1-1.	Ozone design values (ppm) at sites in New Mexico from 2010 to 2019. Red above the 75 ppb 2008 NAAQS, yellow above 2015 70 ppb NAAQS and green within 95% of the 2015 NAAQS.	3
Table 1-2.	Lambert Conformal Conic (LCC) projection parameters for the NM OAI Study 36/12/4 modeling domains.	7

NMED Exhibit 17

Table 1-3.	Grid definitions for CAMx NM OAI Study 2014 36/12/4-km modeling domains.	7
Table 2-1.	WRF 36 level vertical layer structure for the NM OAI study. This is the same WRF layer structure as used in WAQS 2011/2014/2016 and EPA 2016 WRF modeling.	11
Table 2-2.	NM OAI Study 2014 WRF model configuration and comparison with the WRF configuration used in the WRAP-WAQS 2014 and EPA 2014/2015/2016 WRF modeling.	14
Table 3-1.	2014 GEOS-Chem simulation model configuration used by WRAP whose output is used to define the 2014 day-specific diurnally varying BC inputs for the NM OAI Study photochemical modeling.	23
Table 4-1.	2014 biogenic emissions (tons/month) in the 4-km NM domain estimated by MEGAN3.1 and BEIS3.7.	26
Table 4-2.	2014 fire emissions summary (tons/month) by fire type for the 4-km NM domain	29
Table 4-3.	2014 base case anthropogenic emissions summary (episode average short tons per day) by source category for the 4-km New Mexico domain.	31
Table 4-4.	Comparison of WRAP OGWG 2014 and 2023 New Mexico O&G emissions used in the 2014v2 and 2028OTBa2 scenarios with the NM OAI study 2028 base case New Mexico O&G emissions based on BLM forecast.	38
Table 4-5.	Comparison of WRAP OGWG 2014 and 2023 NO_x and VOC New Mexico O&G emissions with the NM OAI Study 2028 base case.	39
Table 4-6.	Summary of total emissions (tons/year) in New Mexico for the 2014 base case emissions scenario.	40
Table 4-7.	Summary of total emissions (tons/year) in New Mexico for the 2028 base case emissions scenario.	41
Table 4-8.	Percent differences in total New Mexico emissions between the 2014 and 2028 emission scenarios.	41
Table 4-9.	New Mexico NO_x and VOC O&G emissions (tons per year) for the 2028 Base Case and 2028 NM O&G control strategy.	45
Table 5-1.	WRF to CAMx vertical layer collapsing strategy used in the NM OAI Study.	50
Table 6-1.	Final CAMx model configuration for the 2014v2 base case simulation in NM OAI Study.	61
Table 6-2.	Recommended ozone benchmarks for photochemical model statistics (Source: Emery et al., 2016).	62
Table 6-3.	Bias and error MDA8 ozone performance statistics for the original CAMx 2014 base case and the three subregions of New Mexico calculated with and without using an observed MDA8 ozone 60 ppb cutoff.	71

Table 6-4. Bias and error MDA8 ozone performance statistics for the revised CAMx 2014v2 base case and the three subregions of New Mexico calculated with and without using an observed MDA8 ozone 60 ppb cutoff. 72

Table 6-5. Bias MDA8 ozone performance statistics with and without an observed ozone cutoff for each site in New Mexico and the original CAMx 2014 base case simulation. 73

Table 6-6. Bias MDA8 ozone performance statistics with and without an observed ozone cutoff for each site in New Mexico and the revised CAMx 2014v2 base case simulation. 74

Table 7-1. Current year $DVC_{2012\text{-}2016}$ and projected 2028 Base Case ozone DVFs at New Mexico monitoring sites within the 4-km NM domain. 78

Table 7-2. Current year $DVC_{2012\text{-}2016}$ and projected 2028 Base Case ozone DVFs at monitoring sites within the 4-km NM domain but outside of New Mexico. 79

Table 8-1. Observed ozone $DVC_{2012\text{-}2016}$ and projected 2028 ozone DVFs for the 2028 Base Case and 2028 O&G Control strategy and differences in the 2028 ozone DVFs ($DVF_{Cntl} - DVF_{Base}$). 91

Table 8-2. Observed ozone $DVC_{2012\text{-}2016}$ and projected 2028 ozone DVFs for the 2028 Base Case and 2028 O&G Control strategy and differences in the 2028 ozone DVFs ($DVF_{Cntl} - DVF_{Base}$). 92

TABLE OF FIGURES

Figure 1-1. NM OAI Study 2014 36/12/4-km PGM and emissions modeling domains. 6

Figure 1-2. 4-km New Mexico modeling domain for PGM and emissions modeling, with locations of New Mexico ozone monitors that were operating during some portion of 2014. 7

Figure 2-1. Soccer plot comparing WRF/NAM (top) and WRF/ERA5 (bottom) surface wind speed (m/s) model performance against the Simple and Complex Benchmarks for monthly RMSE (y-axis) and Mean Bias (x-axis). 16

Figure 2-2. Soccer plot comparing WRF/NAM (top) and WRF/ERA5 (bottom) surface wind direction (degrees) model performance against the Simple and Complex Benchmarks for monthly RMSE (y-axis) and Mean Bias (x-axis). 17

Figure 2-3. Soccer plot comparing WRF/NAM (top) and WRF/ERA5 (bottom) surface temperature (K) model performance against the Simple and Complex Benchmarks for monthly RMSE (y-axis) and Mean Bias (x-axis). 18

Figure 2-4. Soccer plot comparing WRF/NAM (top) and WRF/ERA5 (bottom) surface humidity (g/kg) model performance against the Simple and Complex Benchmarks for monthly RMSE (y-axis) and Mean Bias (x-axis). 19

Figure 2-5. July monthly precipitation amounts from PRISM based on observations (left) and predicted by WRF/NAM (middle) and WRF/ERA5 (right). 21

Figure 2-6. August monthly precipitation amounts from PRISM based on observations (left) and predicted by WRF/NAM (middle) and WRF/ERA5 (right). 21

Figure 4-1. Spatial distribution of NO_x (top panel) and VOC (bottom panel) biogenic emissions (episode average tons per day) in the 4-km NM domain estimated by MEGAN3.1 (left) and BEIS3.7 (right). 28

Figure 4-2. Spatial distribution of agricultural fires, prescribed fires, wildfires and Mexico fires (clockwise starting from top left) NO_x emissions (episode avg tons per day) for New Mexico 4-km domain. 30

Figure 4-3. New Mexico 2014 base case anthropogenic NO_x and VOC emissions by source category. 32

Figure 4-4. Spatial distribution of the non-point (top) and point (bottom) source oil and gas NO_x (left) and VOC (right) emissions (episode avg tons per day) for New Mexico 4-km domain. 33

Figure 4-5. Spatial distribution of on-road (top), rail (middle) and non-point/non-road equipment (bottom) NO_x (left) and VOC (right) emissions (episode avg tons per day) for New Mexico 4-km domain. 34

Figure 4-6. Example Petroleum and Natural Gas Industry schematic. 37

NMED Exhibit 17

Figure 4-7. Comparison of 2014 and 2028 New Mexico NO_X emissions by source sector. 42

Figure 4-8. Comparison of 2014 and 2028 New Mexico NO_X emissions by source sector. 42

Figure 4-9. Distribution of New Mexico NO_x emissions across source sectors for the 2014 (top) and 2028 (bottom) base cases. 43

Figure 4-10. Distribution of New Mexico VOC emissions across source sectors for the 2014 (top) and 2028 (bottom) base cases. 44

Figure 4-11. Comparison of 2028 Base Case and 2028 NM O&G control strategy NO_x emissions for the Non-Point (top) and Point (bottom) source sectors and the Permian (left) and San Juan (right) basins. 46

Figure 4-12. Comparison of 2028 Base Case and 2028 NM O&G control strategy VOC emissions for the Non-Point (top) and Point (bottom) source sectors and the Permian (left) and San Juan (right) basins. 47

Figure 4-13. Differences in 2028 O&G Control Strategy and 2028 Base Case oil and gas NO_x (top) and VOC (bottom) emissions for the Non-Point (left) and Point (right) source sectors. 48

Figure 5-1. Comparison of sensitivity tests NMB with 60 ppb cutoff spatial plots over NM. 53

Figure 6-1. Normalized Mean Bias (NMB) for MDA8 ozone concentrations for the revised 2014v2 (top) and original 2014 (bottom) CAMx base case simulations with no ozone cutoff. 64

Figure 6-2. Normalized Mean Bias (NMB) for MDA8 ozone concentrations for the revised 2014v2 (top) and original 2014 (bottom) CAMx base case simulations with an observed 60 ppb ozone cutoff. 65

Figure 6-3. Scatter plots of predicted and observed MDA8 ozone concentrations for AQS (top) and CASTNet (bottom) monitoring sites within the 4-km New Mexico domain and the revised 2014v2 (left) and original 2014 (right) CAMx base case simulations. 67

Figure 6-4. Time series of predicted and observed (red) MDA8 ozone at Desert View in Doña Ana County for the CAMx revised 2014v2 (blue) and original 2014 (green) CAMx base case simulations. 68

Figure 6-5. Time series of predicted and observed (red) MDA8 ozone at South East Heights in Bernalillo County for the CAMx revised 2014v2 (blue) and original 2014 (green) CAMx base case simulations. 69

Figure 6-6. Time series of predicted and observed (red) MDA8 ozone at Sub Station in San Juan County for the CAMx revised 2014v2 (blue) and original 2014 (green) CAMx base case simulations. 70

Figure 7-1. SMAT UAA current year ozone $DVC_{2012\text{-}2016}$ and projected 2028 future year ozone DVF for the 2028 Base Case using spatial interpolation with concentration gradients. 81

NMED Exhibit 17

Figure 7-2. SMAT UAA current year ozone $DVC_{2012\text{-}2016}$ (top) and projected 2028 future year ozone DVF for the 2028 Base Case using spatial interpolation without concentration gradients. 82

Figure 7-3. Differences between SMAT UAA current year ozone $DVC_{2012\text{-}2016}$ and projected 2028 future year ozone DVF for the 2028 Base Case using spatial interpolation with (top) and without (bottom) concentration gradients. 83

Figure 7-4. CAMx estimated MDA8 ozone concentrations (ppb) on May 17, 2014 for the 2014v2 Base Case (left), 2028 Base Case (middle) and their difference (right). 86

Figure 7-5. CAMx estimated MDA8 ozone concentrations (ppb) on June 5, 2014 for the 2014v2 Base Case (left), 2028 Base Case (middle) and their difference (right). 86

Figure 7-6. CAMx estimated MDA8 ozone concentrations (ppb) on July 12, 2014 for the 2014v2 Base Case (left), 2028 Base Case (middle) and their difference (right). 87

Figure 7-7. CAMx estimated MDA8 ozone concentrations (ppb) on July 24, 2014 for the 2014v2 Base Case (left), 2028 Base Case (middle) and their difference (right). 87

Figure 7-8. CAMx estimated MDA8 ozone concentrations (ppb) on July 26, 2014 for the 2014v2 Base Case (left), 2028 Base Case (middle) and their difference (right). 88

Figure 7-9. CAMx estimated MDA8 ozone concentrations (ppb) on August 14, 2014 for the 2014v2 Base Case (left), 2028 Base Case (middle) and their difference (right). 88

Figure 7-10. Differences in episode maximum MDA8 ozone concentrations (top) and SMAT UAA ozone DVs (bottom) between the 2014v2 and 2028 CAMx Base Case simulations. 89

Figure 8-1. SMAT UAA spatial distribution of projected 2028 ozone DVF_{Base} (top) and DVF_{Cntl} (bottom). 94

Figure 8-2. Differences in SMAT UAA projected 2028 ozone DVFs (ppb) for the 2028 Base Case and 2028 O&G Control Strategy (DVF_{Cntl} – DVF_{Base}) running SMAT without (top) and with (bottom) using modeled concentration gradients in the $DVC_{2012\text{-}2016}$ spatial interpolation. 95

1. INTRODUCTION

This is a draft final Air Quality Technical Support Document (AQTSD) for the New Mexico (NM) Ozone Attainment Initiative (OAI) Photochemical Modeling Study ("NM OAI Study"). The NM OAI Study has developed a 2014 base year photochemical grid model (PGM) modeling platform and conducted 2028 future year modeling for a Base Case and an Oil and Gas (O&G) Control Strategy scenario that implemented proposed controls on 2028 New Mexico O&G sources. The New Mexico Environmental Department (NMED) has contracted with a team consisting of Western States Air Resources Council (WESTAR) and Ramboll US Corporation (Ramboll) to conduct the NM OAI Study.

The NM OAI Study leverages the 2014 PGM modeling platform developed by the Western Regional Air Partnership (WRAP) in the Western Air Quality Study (WAQS) and enhances it by adding a 4-km grid resolution modeling domain covering New Mexico and adjacent regions. The NM OAI Study AQTSD documents the 2014 base case, 2028 future year base case and 2028 NM O&G control strategy modeling and includes a summary of the development of the 2014 PGM modeling platform with more details found on the NM OAI Study Website[1] and reports:

- New Mexico Ozone Attainment Initiative Photochemical Modeling Study – Draft Modeling Protocol (Ramboll and WESTAR, 2020a).[2]
- New Mexico Ozone Attainment Initiative Photochemical Modeling Study – Draft Work Plan (Ramboll and WESTAR, 2020b).[3]
- New Mexico Ozone Attainment Initiative Photochemical Modeling Study – 2014 Modeling Platform Development and Model Evaluation (Ramboll and WESTAR2020c).[4]
- New Mexico Ozone Attainment Initiative Photochemical Modeling Study – Revised 2014v2 Base Case and Model Performance Evaluation (Ramboll and WESTAR, 2021).[5]

Although the WESTAR/Ramboll team conducted the 2014 base year and 2028 base and O&G Control Strategy future year modeling, the implementation of the proposed NMED O&G ozone precursor control strategy in the 2028 O&G emissions was conducted by Eastern Research Group (ERG) under separate contract with NMED so is not documented in this report.

1.1 NM OAI Photochemical Modeling Study Genesis

The NMED Air Quality Bureau has authority over air quality management activities throughout the state of New Mexico, with the exception Bernalillo County and Tribal Lands. The City of Albuquerque/Air Quality Division has authority in Bernalillo County and, except for where Tribal Implementation Plans have been approved, EPA oversees air quality issues in Tribal Lands. The New Mexico Air Quality Control Act (NMAQCA) requires the NMED to develop a plan to address elevated ozone levels when air quality

[5] https://www.wrapair2.org/NMOAI.aspx

is within 95% of the ozone NAAQS (74-3-5.3, NMSA 1978[6]). The ozone NAAQS was revised in 2015 with a threshold of 0.070 ppm (70 ppb) with the relevant metric being the ozone Design Value (DV) that is expressed as the three-year average of the fourth highest Maximum Daily Average 8-hour (MDA8) ozone concentrations. Table 1-1 lists the observed ozone DVs at New Mexico monitoring sites from 2010 to 2019. The DVs are color-coded when they exceed the 75 ppb 2008 ozone NAAQS (red), 70 ppb 2015 ozone NAAQS (yellow) and within 95% of the 70 ppb ozone NAAQS (green, i.e., ≥ 67 ppb). In more recent years, the ozone DVs have exceeded the 70 ppb 2015 ozone NAAQS at several sites in southern New Mexico (e.g., in Doña Ana and Eddy Counties). In particular, the 2017-2019 ozone DVs are particularly high and even exceeded the 75 ppb 2008 ozone NAAQS at three sites in southern New Mexico (colored red in Table 1-1).

[6] https://law.justia.com/codes/new-mexico/2017/chapter-74/article-2/section-74-2-5.3/

Table 1-1. Ozone design values (ppm) at sites in New Mexico from 2010 to 2019. Red above the 75 ppb 2008 NAAQS, yellow above 2015 70 ppb NAAQS and green within 95% of the 2015 NAAQS.

To address the high observed ozone concentrations in New Mexico, the NMED has embarked on an Ozone Attainment Initiative (OAI[7]) to protect the ozone attainment status of the state and ensure health and welfare of the residents of the state for future generations. The OAI was initiated in Spring 2018. As part of the OAI, NMED released a Request for Proposal (RFP#20 667 4040 0001) for the NM OAI Study and the NM OAI Study PGM modeling was awarded to a contracting team of WESTAR and Ramboll.

[7] https://www.env.nm.gov/air-quality/o3-initiative/

1.2 Overview of NM OAI Study Modeling Approach

The procedures used for the NM OAI Study photochemical modeling were described in a detailed Modeling Protocol dated May 19, 2020 (Ramboll and WESTAR, 2020a). A description of the tasks and schedule for completing the NM OAI Study is contained in a Work Plan (Ramboll and WESTAR, 2020b) with presentations, results and reports posted to the NM OAI Study webpage[8] as they are produced. One objective of the study was to evaluate a proposed regulation to control ozone precursor emissions from oil and gas (O&G) development sources in New Mexico. The original future year emissions scenario in the NM OAI Study was 2023, when the proposed O&G rule would not be fully implemented. Thus, the future year to be modeled was changed to 2028 in a December 2020 Contract Amendment from NMED to the WESTAR/Ramboll team.

The NM OAI Study is conducting PGM modeling by enhancing the WRAP-WAQS 2014v2 36/12-km PGM modeling platform[9] with the addition of a new 4-km grid resolution domain covering New Mexico and surrounding areas, especially the O&G production regions in the Permian and San Juan Basins. The NM OAI Study PGM modeling is performing 2014 base year modeling and model performance evaluation. 2028 future year modeling was also conducted. The NM OAI Study PGM modeling is being conducted in accordance with EPA's guidance for ozone State Implementation Plan (SIP) ozone attainment demonstration modeling (EPA, 2018).

1.2.1 WRAP-WAQS 2014 PGM Platform Development

The WRAP-WAQS developed an annual 2014 PGM modeling platform to address air quality issues in the western states. An initial WRAP-WAQS 2014v1 PGM modeling platform was developed in 2019 for the CAMx and CMAQ PGMs that is documented in a webpage[10] on the Intermountain West Data Warehouse (IWDW). Additional diagnostic sensitivity tests were conducted to address several model performance issues culminating in the WRAP-WAQS 2014v2 36/12-km CAMx modeling database that was used as the starting point for the NM OAI Study CAMx summer of 2014 36/12/4-km modeling database. The development of the WRAP-WAQS 2014v2 PGM database and model performance evaluation is available in a webpage[11] on the IWDW.

The WRAP-WAQS 2014v2 CAMx platform used a 36/12-km grid resolution domain structure with meteorological inputs based on the WAQS 2014 36/12-km WRF meteorological model simulation (Bowden, Talgo and Adelman, 2016[12]). The 2014 emissions were based on the 2014 National Emissions Inventory (2014NEI[13]) with updates from western states[14]. Boundary Condition (BC) inputs were based on a WRAP 2014 GEOS-Chem model simulation.

Because the NM OAI Study requires a 4-km modeling domain for New Mexico, new summer of 2014 36/12/4-km WRF meteorological modeling was conducted, as

[14] https://www.wrapair2.org/pdf/WRAP%20Regional%20Haze%20SIP%20Emissions%20Inventory%20Review%20Documentation_for_Docket%20Feb2019.pdf

described in Chapter 2, that was used to develop 36/12/4-km meteorological inputs for CAMx. The NM OAI Study defined their 36/12-km domains to match WRAP-WAQS 2014v2 36/12-km domains so the WRAP-WAQS 2014v2 36/12-km emission and some other inputs (e.g., BCs) can be used directly in the NM OAI Study PGM modeling. Figure 1-1 shows the 36/12/4-km modeling domains used for the NM OAI Study PGM modeling with the 4-km grid resolution New Mexico domain shown in Figure 1-2.

1.2.2 Episode Selection

The May-August 2014 modeling period was selected as it has a high quality emissions inventory with western state updates and has a PGM platform already developed from the WRAP-WAQS regional haze modeling that can be leveraged for the NM OAI Study. Details on the episode selection are contained in Chapter 3 of the NM OAI Study Modeling Protocol (Ramboll and WESTAR, 2020a).

1.2.3 Model Selection

Details on the rationale for model selection are provided in Chapter 2 of the NM OAI Study Modeling Protocol (Ramboll and WESTAR, 2020a). The Weather Research Forecast (WRF) prognostic meteorological model was selected. Emissions modeling was conducted using the Sparse Matric Operator Kernel Emissions (SMOKE) model for most source categories. The Model of Emissions of Gases and Aerosols from Nature (MEGAN v3.1) was used initially for biogenic emissions in the 4-km domain for the original CAMx 2014 Base Case, but was ultimately replaced by biogenic emission based on the BEIS v3.7 model in the final CAMx 2014v2 base case. There are special processors for fires, windblown dust (WBD), lightning NO_x (LNO_x) and oceanic sea salt (NaCl) and Dimethyl Sulfide (DMS) emissions that were used. The 2014 version of the Motor Vehicle Emissions Simulator (MOVES2014b) on-road mobile source emissions model was used with SMOKE-MOVES and WRF meteorological data to generate on-road mobile source emissions for the 4-km New Mexico modeling domain.

The Comprehensive Air-quality Model with extensions (CAMx) photochemical grid model (PGM) was used because it supports two-way grid nesting, was used in the WRAP-WAQS regional haze modeling, contains a well-vetted ozone source apportionment tool and has a rich and successful history of successful application to the region.

1.2.4 Domain Selection

The NM OAI Study modeling is using the same 36-km 36US and 12-km 12WUS2 domains as used in the WRAP-WAQS 2014 modeling platform. A new 4-km New Mexico domain was added to the 36/12-km domain structure. Figure 1-1 displays the 36/12/4-km domain structure with Figure 1-1 showing the 4-km New Mexico domain. New WRF 2014 36/12/4-km meteorological modeling was conducted to generate finer scale 4-km meteorological conditions for the New Mexico domain and consistent meteorology among the 36/12/4-km domains. The domains use a Lambert Conformal Conic (LCC) projection using the parameters given in Table 1-2 with the definitions of the extent of the 36/12/4-km domains given in Table 1-3. CAMx was run using the 36/12/4-km domain structure shown in Figure 1-1 using two-way interactive grid nesting.

Grid	Origin (SW) (km)	Extent (NE) (km)	NX	NY
36-km	(-2736, -2088)	(2592, 1944)	148	112
12-km*	(-2388, -1236)	(336, 1344)	227	215
4-km*	(-1192, -1120)	(-212, -212)	245	227

*Definition includes outer row/column of buffer cells required by CAMx for nested domains

1.2.5 Base and Future Year Emissions Data

The 2014 base year emissions data were based on the WRAP-WAQS 2014v2 emissions that were in turn based on the 2014NEIv2 with updates from western states. New emissions were generated for natural emission sources (e.g., biogenic and LNO_x). 2028 emissions were based on the WRAP 2028 On-the-Books (2028OTBa2) emissions scenario with updated 2028 O&G emissions for New Mexico and using actual 2014 fires instead of Representative Baseline fires as used in the WRAP 2028OTBa2 scenario. The development of the 2014 and 2028 emission scenarios are discussed in Chapter 4.

1.2.6 Initial and Boundary Conditions Development

The first two-weeks of May were run on the 36/12/4-km domains to spin-up the model before the first high ozone day in New Mexico (68 ppb on May 17). This washed out the influence of the initial concentrations (IC) before elevated ozone concentrations occur in New Mexico.

Boundary conditions (BC) for the outer 36-km 36US domain were based on a 2014 simulation of the GEOS-Chem global chemistry model conducted by WRAP processed by the GC2CAMx converter. The result is day-specific diurnally varying BCs for the lateral boundaries around the 36-km 36US modeling domain. The top BC was based on a zero-gradient assumption where concentrations above the top of the model (above 50 mb, or ~19-km above sea level) are assumed to be the same as in the top vertical layer of CAMx.

Due to uncertainties in projecting future year international emissions, the CAMx BCs based on the 2014 GEOS-Chem global model simulation were held constant for the 2028 modeling. This is likely a conservative estimate of 2028 BCs.

Chapter 3 provides a summary of the development of the 2014 CAMx BC inputs with more details in Ramboll and WESTAR (2020c) and on the WRAP-WAQS 2014v2 modeling website.

1.2.7 Diagnostic Sensitivity Analyses

The NM OAI Study conducted four diagnostic sensitivity tests for the CAMx 2014 36/12/4-km base case that compared the CAMx ozone performance for four alternative meteorological inputs. The NM OAI Study conducted two WRF 2014 36/12/4-km WRF simulations that used different analysis fields as input. The two 2014 36/12/4-km WRF outputs were processed with WRFCAMx using two different options for vertical turbulent exchange (i.e., vertical mixing) coefficients (Kv). This resulted in four different CAMx meteorological inputs that were evaluated using CAMx diagnostic sensitivity tests that are summarized in Chapter 5 with details provided in Ramboll and WESTAR (2020c).

1.2.8 Model Performance Evaluation

The NM OAI Study CAMx 2014 36/12/4-km base case simulation Model Performance Evaluation (MPE) followed EPA's MPE recommendations in their ozone modeling guidance (EPA, 2018) and other sources (e.g., Simon, Baker and Phillips, 2012; Emery et al., 2016). The CAMx 2014 36/12/4-km base case simulation MPE focused on ozone model performance within the 4-km New Mexico domain, and especially within New Mexico. Two CAMx 2014 base case simulations were performed and subjected to an MPE. An original CAMx 2014 base case simulation used CAMx v7.0 and biogenic

emissions in the 4-km NM domain based on the MEGAN v3.1 model whose evaluation is documented in NM OAI Study 2014 platform development and 2014 base case modeling report (Ramboll and WESTAR, 2020c). A revised 2014v2 base case was conducted using CAMx v7.1 and biogenic emissions based on the BEIS v3.7, whose results are documented in an Addendum to the 2014 base case modeling report (Ramboll and WESTAR, 2021).

1.2.9 2028 Future Year Base and Control Strategy Modeling

2028 future year ozone modeling was conducted using the WRAP 2028OTBa2 emissions scenario with updated 2028 O&G emissions in New Mexico and using 2014 actual fires instead of the Representative Baseline fires used in the 2028OTBa2 scenario. These fire inventories were prepared for the WRAP Fire and Smoke Work Group and are documented in a report (Air Sciences, 2020) and presentation.[15] A CAMx 2028 future year 36/12/4-km base case simulation was conducted using CAMx v7.1 and used to project 2028 future year ozone design values (DVs). The procedures to calculate projected ozone DVs followed EPA's latest guidance (EPA, 2018). These procedures use the modeling results in a relative fashion to scale the current year observed 2012-2016 8-hour ozone design values (i.e., $DVC_{2012\text{-}2016}$) to project 2028 future year ozone Design Values (DVFs). The scaling factors are called Relative Response Factors (RRFs) and are the ratio of the future-year to current-year modeling results for the 10 highest base year modeled MDA8 ozone days near the monitoring site. EPA has developed the Speciated Modeled Attainment Test (SMAT[16]) tool that includes the recommended procedures in the latest EPA guidance for projecting ozone DVFs.

The NM OAI Study also conducted future year modeling for a 2028 O&G Control Strategy that implemented controls on ozone precursors from O&G sources within the San Juan and Permian Basins. The WESTAR/Ramboll team provided the 2028 NM O&G emissions to ERG who, under separate contract to NMED, implemented the proposed NM O&G ozone precursor control strategy in the 2028 NM O&G emissions and provided them to WESTAR/Ramboll for ozone modeling. This report does not document the implementation of the NM O&G ozone precursor control strategy as that was not performed by WESTAR/Ramboll.

1.2.10 Future Year Source Apportionment Modeling

The NM OAI Study also is conducting future year ozone source apportionment modeling for the 2028 O&G Control Strategy scenario using the CAMx ozone source apportionment tool. The CAMx 2028 Source Sector APCA ozone source apportionment modeling examined the ozone contributions of several major anthropogenic emission source sectors in New Mexico and other states as well as contributions of International anthropogenic emissions on ozone concentrations in New Mexico and is discussed in Chapter 9. CAMx 2028 VOC/NO_x Sensitivity OSAT ozone source apportionment modeling was also conducted to examine the level of VOC sensitive versus NO_x sensitive ozone formation in New Mexico and is discussed in Chapter 10.

2. 2014 WRF METEOROLOGICAL MODELING

The NM OAI Study conducted WRF meteorological modeling for the summer of 2014 to generate CAMx meteorological inputs for the 36/12/4-km horizontal domain structure shown in Figure 1-1.

2.1 WRF Meteorological Model

The Weather Research and Forecasting (WRF) Model is a mesoscale numerical weather prediction system designed to serve both operational forecasting and atmospheric research needs (Skamarock, 2004; 2006; Skamarock et al., 2005; 2008; 2019). The Advanced Research WRF (ARW) version of WRF was used in the NM OAI Study.

This chapter summarizes the application and evaluation of the WRF meteorological model to generate 2014 36/12/4-km meteorological inputs for CAMx photochemical grid modeling with more details provided in Chapter 2 of Ramboll and WESTAR (2020c).

2.2 WRF Horizontal Modeling Domain

The WRF 2014 36/12/4-km modeling domains were defined slightly larger than the PGM 36/12/4-km domains (Figure 1-1) so that any modeling artifacts that occur near the WRF boundaries as the boundary conditions (BCs) come into dynamic balance with the WRF numerical algorithms are not present in the PGM meteorological inputs.

2.3 WRF Model Configuration

WRF version 4.2 was used for this modeling analysis. The NM OAI Study 36/12-km WRF/PGM grid configuration (e.g., horizontal domains and vertical layer structure) was designed to be identical to the WRAP-WAQS 2014 WRF/PGM grid configuration in order to facilitate the use of data between the two studies. A 4-km domain was added covering New Mexico and adjacent regions.

The WAQS 2011/2014 WRF modeling used 36 vertical levels (35 vertical layers) from the surface to a 50 mb (hPa) height (approximately 19-km above sea level). The EPA 2014, 2015 and 2016 WRF modeling also used 35 vertical layers up to a 50 mb height.

Table 2-1 displays the 36-vertical layer structure used in the WRAP-WAQS 2011/2014 WRF modeling that was also adopted for the NM OAI Study WRF 2014 36/12/4-km modeling.

NMED Exhibit 17

Table 2-1. WRF 36 level vertical layer structure for the NM OAI study. This is the same WRF layer structure as used in WAQS 2011/2014/2016 and EPA 2016 WRF modeling.

WRF Layer	Sigma	Pressure (mb)	Height (m)	Thickness (m)
36	0.0000	50.00	19260	2055
35	0.0270	75.65	17205	1850

0	1.0000	1000.00	0	

NMED Exhibit 17

2.3.1 Vertical Coordinate

Since its inception, WRF has used the eta (sometimes called sigma or "terrain-following") vertical coordinate system. One weakness of the eta coordinate is that variations in terrain (especially steep topography) can increase numerical errors in the model. To reduce these errors, Park et al., (2018) developed a hybrid sigma–pressure coordinate that is now included as the default vertical coordinate system for the WRF model (Skamarock et al., 2019).

For the NM OAI Study 2014 36/12/4-km WRF modeling, we used the new hybrid vertical coordinate system and a new version of the WRFCAMx processor that has been updated to use WRF's hybrid vertical coordinate. The hybrid vertical coordinate system and use of 4-km New Mexico domain are the two biggest differences between the NM OAI Study and WRAP-WAQS 2014 WRF modeling. The WRAP-WAQS 2014 WRF/CAMx modeling did not use the hybrid vertical coordinate system in WRF because at the time it was not supported in the WRFCAMx processor.

2.3.2 Topographic Inputs

Topographic information for WRF was based on a combination of the standard WRF terrain databases and high-resolution terrain. The 36-km 36US domain used the 10-minute global data, the 12-km 12WUS2 domain used the 2-minute data, and the 4-km New Mexico domain used the 30 second data.

2.3.3 Vegetation Type and Land Use Inputs

Vegetation type and land use information used the United States Geological Survey (USGS) land use databases from the most recently released WRF databases provided with the WRF distribution. Standard WRF surface characteristics corresponding to each land use category was employed.

2.3.4 Atmospheric Data Inputs

WRF relies on other model or re-analysis output meteorological fields to provide initial and boundary conditions (IC/BC) and fields for the four-dimensional data assimilation (FDDA). FDDA refers to the nudging of the WRF meteorological fields to observed analysis fields so that the WRF meteorological fields better represent what was observed and prevent the model from drifting away from the observed meteorology. The NM OAI Study conducted two WRF simulations that used two different analysis fields that were evaluated for their performance against meteorological variables as well as their effect on CAMx ozone model performance. Both the 12-km resolution North American Model (NAM) and the ~30-km resolution European Center for Medium-Range Weather Forecasting (ECMWF) Re-Analysis (ERA5[17]) dataset analysis fields were used for IC/BC and FDDA in the two WRF 2014 36/12/4-km sensitivity simulations.

Analysis nudging (i.e., FDDA) was used for winds, temperature, and humidity on the 36-km and 12-km domains. Both surface and aloft nudging was used but nudging for temperature and mixing ratio was not performed within the boundary layer. Observation nudging was not used, even on the 4-km domain.

[17] https://www.ecmwf.int/en/forecasts/datasets/archive-datasets/reanalysis-datasets/era5

The effects of the two 2014 WRF simulations on CAMx ozone performance was evaluated in diagnostic sensitivity simulations and the best performing configuration selected as the final CAMx meteorological inputs, as described in Chapter 5.

2.3.5 New Lightning Data Assimilation

More recently, the assimilation of lightning data in WRF simulations has shown to improve the locations and amounts of convective precipitation. The use of lighting detection networks, such as the National Lightning Detection Network (NLDN), have been used in WRF simulations and used to force deep convection (thunderstorms) when lightning is observed and only allow shallow convection when lightning is not present. The use of the new lightning assimilation approach has been demonstrated to improve both WRF convective precipitation as well as PGM concentration and deposition performance (Heath et al., 2016). The new lightning data assimilation algorithms was not used in the NM OAI Study 2014 WRF modeling for the following reasons: (1) it would have to be tested and evaluated and there is insufficient time in the schedule to conduct such diagnostic testing; (2) the NLDN data used to date with the WRF lightning assimilation is a commercial product that is expensive and not within the budget; (3) the implementation of the lightning detection data assimilation in WRF has a flaw that it doesn't distinguish between no lightning detects and missing data and suppresses convection in areas with missing data (e.g., over the Gulf of Mexico); and (4) most importantly, the lightning detection data assimilation algorithm has not been implemented in the latest versions of WRF so its use would limit the use of other model new options, such as the hybrid vertical coordinate system.

2.3.6 PBL and LSM Physics Options

As used in the WRAP-WAQS 2014 WRF modeling, the YSU Planetary Boundary Layer (PBL) and Noah Land Surface Model (LSM) physics options were used in the NM OAI Study 2014 36/12/4-km WRF modeling. Previous WRF sensitivity modeling for the intermountain west region found the YSU/Noah PBL/LSM schemes produces the most realistic meteorological fields. Note that EPA's 2014/2015/2016 WRF modeling uses the ACM2 PBL and Pleim-Xiu (PX) LSM schemes (EPA, 2019).

2.3.7 Remaining WRF Physics Options

Table 2-2 lists the remaining WRF physics options for the NM OAI Study 2014 36/12/4-km WRF application. These are standard WRF physics options and consistent with the WRF options used in the WRAP-WAQS 2014 and EPA 2014/2015/2016 WRF modeling. Our comparison of 2014 WRAP-WAQS and 2014 EPA WRF modeling for summertime precipitation performance in New Mexico found that the WRAP-WAQS WRF meteorological model performance was better than EPA WRF for most variables. Therefore, we used the same microphysics and cumulus schemes for the NM OAI Study as used in 2014 WRAP-WAQS (Thompson and Multi-Scale Kain-Fritsch, respectively) and most of the same other physics options (see Table 2-2).

NMED Exhibit 17

Table 2-2. NM OAI Study 2014 WRF model configuration and comparison with the WRF configuration used in the WRAP-WAQS 2014 and EPA 2014/2015/2016 WRF modeling.

WRF Option	NM OAI Study	2014 WRAP-WAQS	2014 EPA
Horizontal Domains	36/12/4-km	36/12/4-km	12-km
Vertical Coordinate	Hybrid Sigma	Sigma	Sigma
Microphysics	Thompson	Thompson	Morrison 2
LW Radiation	RRTMG	RRTMG	RRTMG
SW Radiation	RRTMG	RRTMG	RRTMG
Sfc Layer Physics	MM5 similarity	MM5 similarity	MM5 similarity
LSM	Noah	Noah	Pleim-Xiu
PBL scheme	Yonsei University (YSU)	YSU	ACM2
Cumulus	36/12/4-km Multi-scale Kain Fritsch	36/12-km Multi-scale_Kain Fritsch; 4-km None	Kain-Fritsch
BC, IC Analysis Nudging Source	36/12-km NAM & ERA5	36/12-km NAM	12-km NAM
Analysis Nudging Grids	36/12-km	36/12-km	12-km
Obs Nudging	None	4-km	None
Sea Sfc Temp	FNMOC	FNMOC	FNMOC

2.3.8 Application Methodology

The WRF model was executed in 5.5-day blocks initialized at 12Z every five days. Model results were output every 60 minutes, split at twelve (12) hour intervals. Twelve (12) hours of spin-up is included in each 5-day block before the data is used in the subsequent evaluation and PGM meteorological inputs.

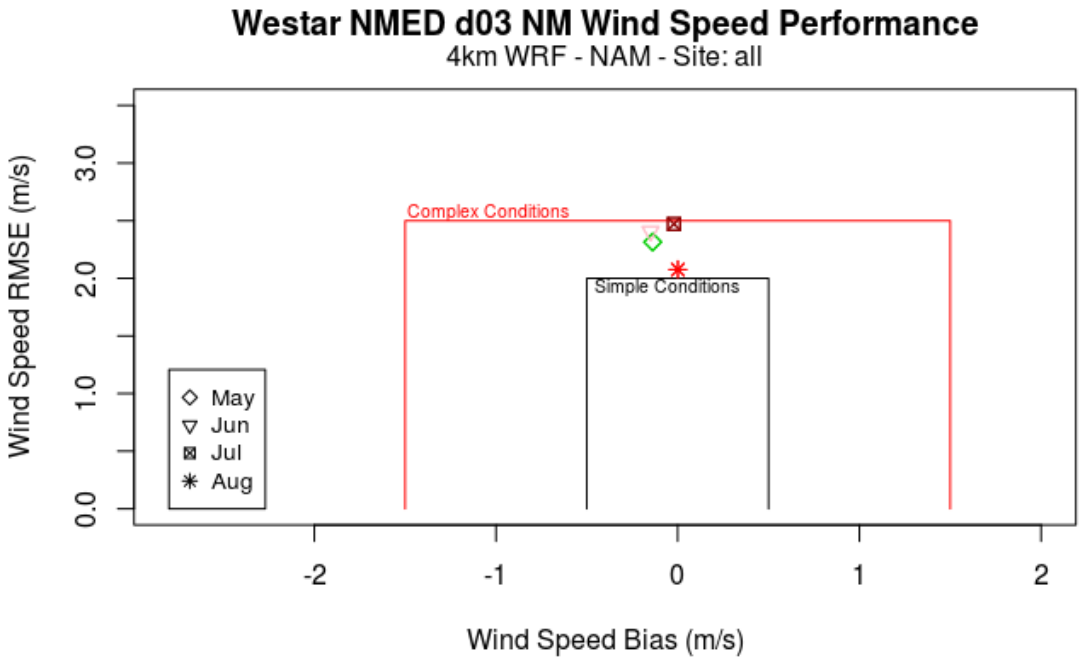
2.4 WRF Model Evaluation

Quantitative and qualitative evaluations of the NM OAI Study 2014 WRF 36/12/4-km simulation meteorological performance was conducted for both the WRF/NAM and WRF/ERA5 applications. The quantitative evaluations compare integrated surface hourly meteorological observations with WRF predictions matched by time and location and included the calculation of model performance statistical metrics that were compared against performance benchmarks. The qualitative evaluations compared time series plots of modeled wind speed and wind direction to the observations at specific sites. The qualitative evaluation also compared spatial plots of WRF precipitation estimates against spatial maps of precipitation analysis fields based on observations

2.4.1 Quantitative Evaluation Using METSTAT

METSTAT was used to evaluate the WRF/NAM and WRF/ERA model performance against observed surface meteorological observations of wind speed and direction, temperature and mixing ratio (humidity). Figure 2-1 displays the WRF/NAM and WRF/ERA5 wind speed soccer plot that compares monthly measures of wind speed bias and error across surface monitoring sites in New Mexico with the simple and complex performance benchmarks. The monthly wind speed performance of the two WRF simulations are remarkably similar with both having near zero bias that achieves the simple benchmark (≤±0.5 m/s). The error (RMSE) for the two WRF simulations falls between the simple

and complex benchmarks (i.e., between 2.0 and 2.5 m/s) for all four months (May through August).



The monthly wind direction bias and error statistics for the two WRF simulations are also nearly identical with bias values of ~5 degrees that achieves the ≤±5 degree simple benchmark and error statistics that falls between the 30 degree simple and 50 degree complex benchmarks (Figure 2-2).

There are differences in the two WRF simulations temperature performance and more differences in the monthly values than seen for winds (Figure 2-3). The WRF/ERA5 simulations has a near zero temperature bias in May and June with the bias and error achieving the simple benchmark for both months. The WRF/NAM has a warm bias for May and June that straddle the simple benchmark upper bound (+0.5 K). The two WRF simulations have similar July and August performance that have a warm bias of ~1.0 K that fails to achieve the simple benchmark. For both WRF simulations, the temperature bias is right at, but mostly within, the 2.0 K simple benchmark.

The WRF/ERA5 clearly has better surface humidity performance than WRF/NAM (Figure 2-4). For July and August, the WRF/NAM has a wet bias in July and August of ~1.5 g/kg so fails to achieve the simple (≤±0.8 g/kg) and complex (≤±1.0 g/kg) bias benchmarks. The WRF/ERA5 also has a wet bias for July and August that is not as large as WRF/NAM as it is right at the simple benchmark (~ 1.0 g/kg) but achieving the complex benchmark. The WRF/ERA5 also has better humidity error performance in July and August, although both simulations achieve the error performance benchmarks.

The two WRF simulations have better humidity performance in May and June that achieves the simple benchmark, albeit with a moist bias. May is the best performing month with nearly identical humidity model performance with a bias of ~0.6 g/kg and error of ~0.9 g/kg. In June, the WRF/ERA5 humidity performance is slightly better than WRF/NAM.

NMED Exhibit 17

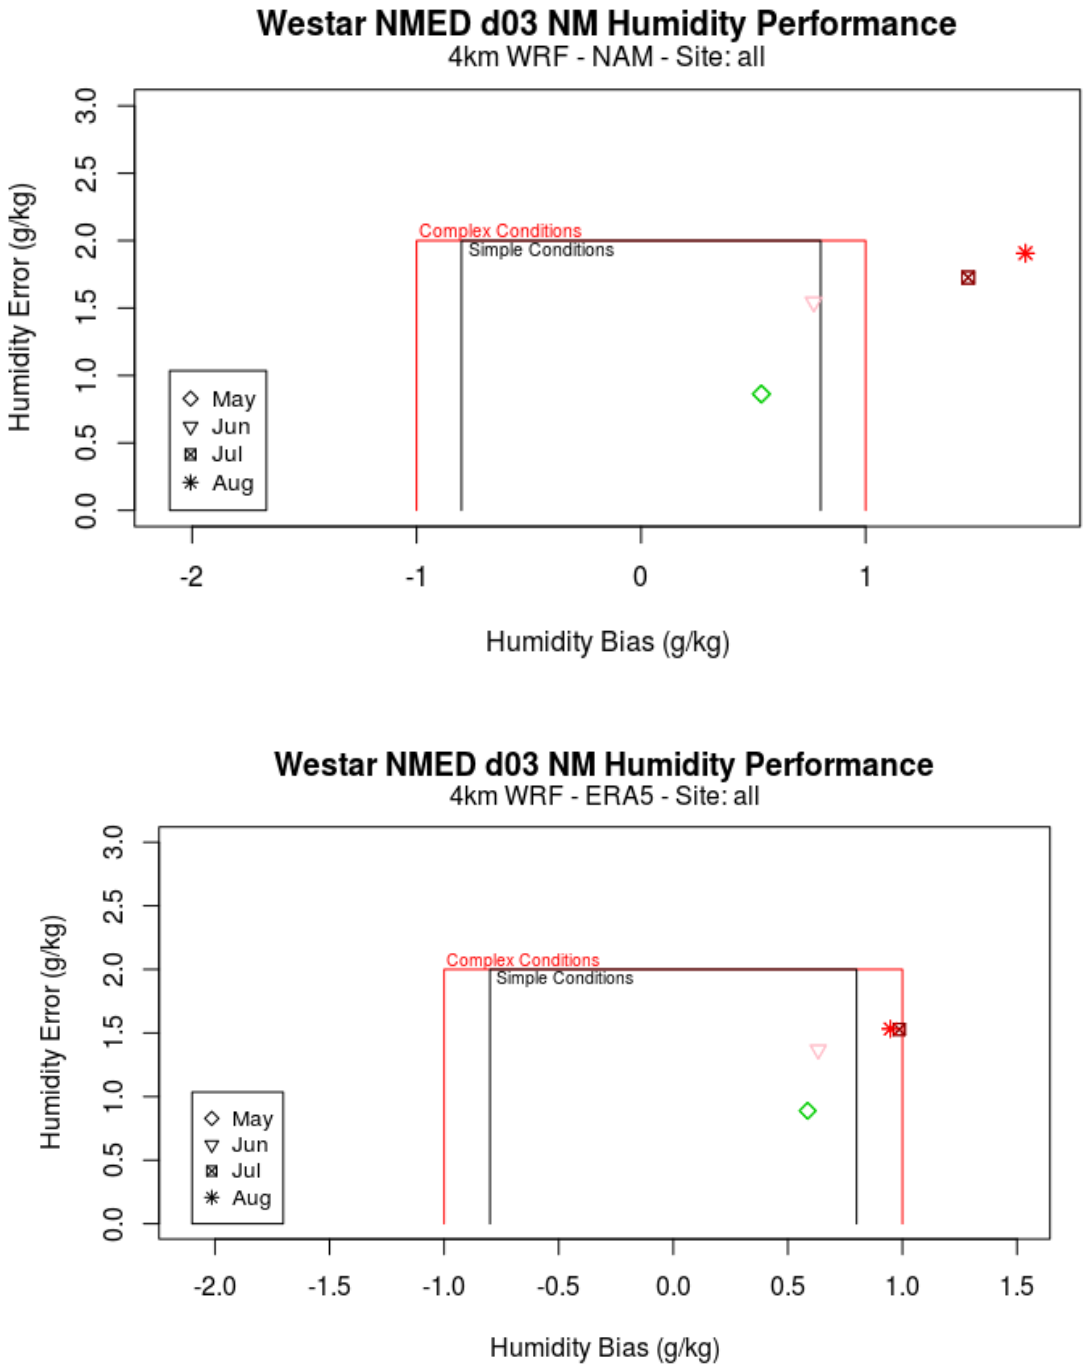

Figure 2-4. Soccer plot comparing WRF/NAM (top) and WRF/ERA5 (bottom) surface humidity (g/kg) model performance against the Simple and Complex Benchmarks for monthly RMSE (y-axis) and Mean Bias (x-axis).

2.4.2 Qualitative Evaluations for Precipitation Using PRISM Data

Oregon State University (OSU) publishes precipitation analysis fields based on observations that can be used to qualitatively evaluate the WRF precipitation fields. The Parameter-elevation Relationships on Independent Slopes Model (PRISM[18]) is used to generate the precipitation analysis fields (Daly et al., 2008). The PRISM interpolation method of observed precipitation reflects, as closely as possible, the current state of knowledge of spatial climate patterns in the United States. PRISM calculates a climate – elevation regression for each digital elevation model (DEM) grid cell, and stations entering the regression are assigned weights based primarily on the physiographic similarity of the station to the grid cell.

Figures 2-5 and 2-6 compares the PRISM monthly total precipitation across the 4-km New Mexico domain with the WRF/NAM and WRF/ERA5 model estimates for, respectively, July and August. Results for other months can be found in Ramboll and WESTAR (2020c). WRF/NAM overestimates the July monthly precipitation over northeast New Mexico, with WRF/ERA5 having an overestimation bias in most northerly Texas. But both WRF simulations have a dry bias for monthly precipitation over the remainder of New Mexico.

WRF/ERA5 does a better job at reproducing the locations and magnitudes of the August monthly PRISM precipitation than WRF/NAM (Figure 2-6). WRF/NAM overstates the August precipitation in central-south New Mexico.

[18] http://prism.oregonstate.edu/

NMED Exhibit 17

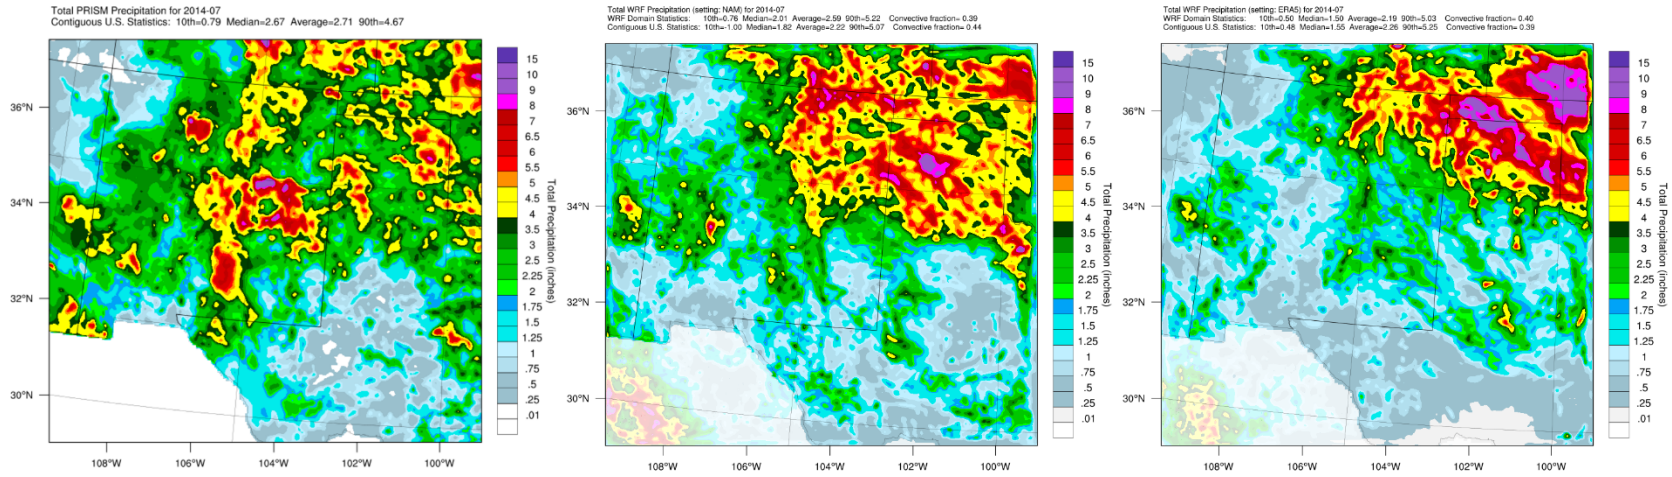

Figure 2-5. July monthly precipitation amounts from PRISM based on observations (left) and predicted by WRF/NAM (middle) and WRF/ERA5 (right).

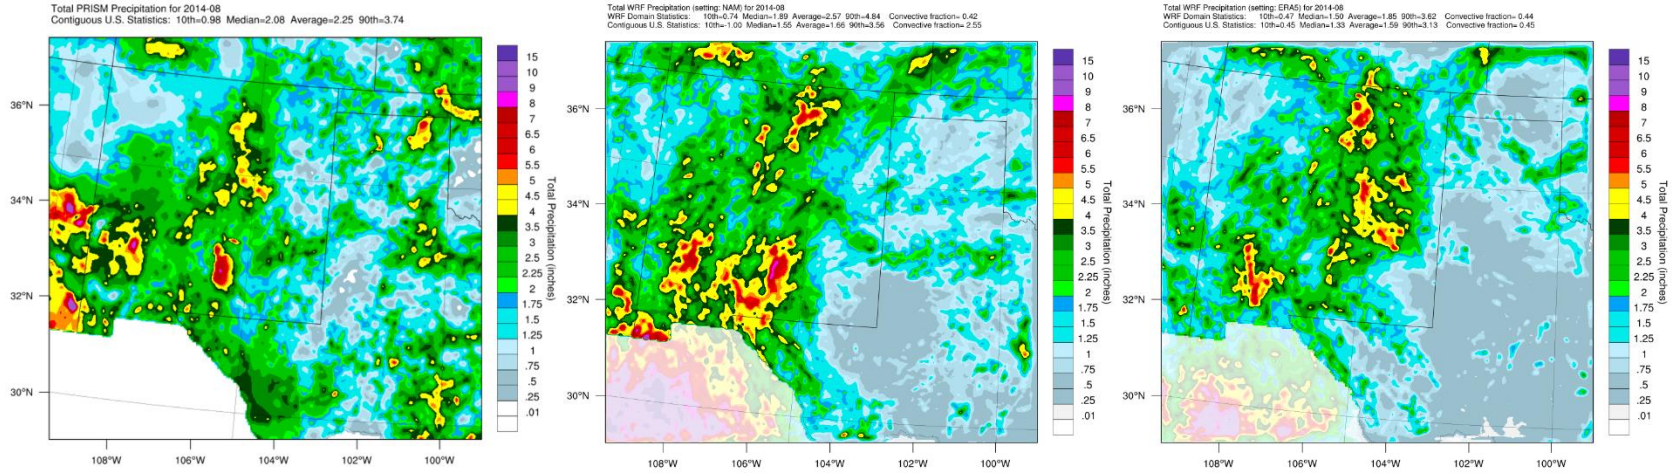

Figure 2-6. August monthly precipitation amounts from PRISM based on observations (left) and predicted by WRF/NAM (middle) and WRF/ERA5 (right).

2.4.3 Conclusions of 2014 WRF Model Performance

The model performance of the WRF/NAM and WRF/ERA5 simulations are reasonable and very similar for most meteorological variables (e.g., winds and temperature). This is in contrast to the WRAP-WAQS and EPA WRF 2014 simulations that had very different performance characteristics over New Mexico.[19] The biggest difference in the performance of the two WRF simulations was for humidity and precipitation. The WRF/NAM simulation had a moist bias for June-August that is likely partly associated with overactive convective precipitation that was greater in WRF/NAM than WRF/ERA5. It is unclear whether the WRF/NAM overstated precipitation is due to overactive convective events when they occur, or having events occur when they are not observed.

From the meteorological model performance evaluation, it is not possible to determine which set of WRF meteorological inputs will produce better ozone model performance when used as meteorological inputs for CAMx. There are variations in spatial and temporal model performance that are difficult to estimate what effects they will have on ozone concentrations. Furthermore, there may be meteorological inputs (e.g., level of mixing) that are more important for ozone modeling than the parameters we have observed data to evaluate the meteorological model for (i.e., winds, temperature, humidity and precipitation). Although it appears that WRF/NAM overstates the monthly precipitation if that does not occur on high ozone days it may not matter to the ozone model performance.

CAMx was run for a portion of the summer of 2014 episode with meteorological inputs based on both the WRF/NAM and WRF/ERA5 simulations and the ozone estimates compared to determine which meteorological inputs performed best so were selected for use in the final CAMX 2014 36/12/4-km base case simulation. The meteorological diagnostic sensitivity tests using the CAMx photochemical model are described in Chapter 5.

3. BOUNDARY CONDITION INPUTS

The Boundary Conditions (BCs) for the CAMx most outer 36-km 36US modeling domain lateral boundaries were based on output from a 2014 simulation of the GEOS-Chem global chemistry conducted by WRAP for their 2014v2 modeling platform.

3.1 WRAP 2014 GEOS-Chem Modeling

The WRAP-WAQS 2014v1 36/12-km CAMx and CMAQ base case simulations used BCs based on EPA's 2014 GEOS-Chem simulation that was used in EPA's 2014 modeling platform used in the 2014 National Air Toxics Assessment (NATA[20]). The CAMx and CMAQ 2014v1 base case simulation and sensitivity modeling found that the BCs based on EPA's 2014 GEOS-Chem caused year-long ozone overestimation bias throughout the western U.S.[21] Thus, WRAP conducted their own 2014 GEOS-Chem simulation using a newer version of the model and with updated emissions that resulted in much better CAMx ozone model performance without the systematic ozone over-prediction bias.[22] Table 3-1 presents the WRAP 2014 GEOS-Chem model configuration.

Table 3-1. 2014 GEOS-Chem simulation model configuration used by WRAP whose output is used to define the 2014 day-specific diurnally varying BC inputs for the NM OAI Study photochemical modeling.

Science Options	WRAP 2014 GEOS-Chem Base Case
Version	Version 12.2.0 (release date: 2019-02-19)
Vertical Grid Mesh	72 Layers
Chemistry mechanism	GEOS-Chem standard chemistry with complex SOA option[23].
Horizontal Grids	2x2.5 degree (Nx, Ny = 144, 91)
Initial Conditions	6-month spin-up; starting from provided initial conditions for standard chemistry
Meteorology	2014 GEOS-FP meteorology
Photolysis mechanism	Default (FAST-J)
Advection Scheme	Default (TPCORE)
Cloud convection scheme	On / Relaxed Arakawa-Schubert
Planetary Boundary Layer mixing	On / non-local scheme implemented by Lin and McElroy
Dry deposition scheme	Default (Wesely)
Chemistry Solver	Default (FLEXCHEM)
Parallelization	Open Multi-Processing (OMP)

[21] http://views.cira.colostate.edu/iwdw/docs/waqs_2014v1_shakeout_study.aspx
[22] https://www.wrapair2.org/pdf/WRAP_Shake-Out_Phase-III_Update_RTOWG_2019-09-10v3a.pptx
[23] We recommend turning off semivolatile primary organic aerosol (POA) chemistry and isoprene SOA reactions via the volatility-based scheme (VBS) [Pye et al., 2010] to avoid risk of double-counting in the complex SOA chemistry scheme. For more information, see http://maraisresearchgroup.co.uk/Publications/GC-v11-02-SOA-options.pdf

3.2 2014 GEOS-Chem Model Evaluation

The results of the WRAP 2014 GEOS-Chem simulation and CAMx sensitivity modeling using the new BCs can be found on the WAQS-WRAP2014v2 model evaluation webpage[24]. Relevant for the NM OAI Study is the fact that this updated 2014 GEOS-Chem BCs do lead to better CAMx model performance for ozone concentrations and corrects a persistent year-long ozone overestimation bias that occurred using the previous 2014 GEOS-Chem simulation conducted by EPA and used in the EPA 2014 modeling platform. The NM OAI Study evaluated the use of the WRAP 2014 GEOS-Chem BCs for CAMx modeling at several sites in New Mexico and found good ozone performance that achieved ozone model performance goals.[25] Thus, the WAQS-WRAP 2014v2 BC inputs based on the WRAP 2014 GEOS-Chem simulation were used "as is" for the NM OAI Study.

4. 2014 AND 2028 EMISSION INPUTS

4.1 Summary of Emissions Used in 2014 and 2028 Modeling

The emissions inventories for the CAMx 2014 36/2/4-km base case modeling were based on the WRAP-WAQS 2014v2 emissions inventory. Within the 36-km 36US North American and 12-km 12WUS2 western U.S. domains, the WRAP-WAQS CAMx 2014v2 base case emission inputs were used without any changes.

For the 4-km New Mexico domain, the WRAP-WAQS 2014v2 emissions have been reviewed and updated as needed by the NMED. For on-road mobile sources, the 4-km domain emissions were based on MOVES2014 model, 2014 activity data and day-specific hourly gridded 2014 WRF 4-km meteorology run through SMOKE-MOVES.

For the NM OAI Study future year 2028 Base Case and 2028 New Mexico O&G Control Strategy, the emissions were based on the WRAP 2028OTBa2 emissions inventory with updated New Mexico O&G emissions and use of 2014 actual fires instead of the Representative Baseline fires. The 2028OTBa2 CAMx-ready emission inputs for the 36/12-km domains were used "as is", substituting the 2014v2 actual 20014 fires for the Representative Baseline fires. For the 4-km NM domain, the 2028OTBa2 emissions were processed using SMOKE, with the new 2028 New Mexico (NM) oil and gas (O&G) emissions substituted for the NM O&G emissions used in the 2028OTBa2 emissions scenario.

The NM OAI Study 2028 O&G Control Strategy scenario used the exact same emissions as the NM OAI Study 2028 Base Case, only the controlled 2028 O&G emissions were used in New Mexico. The 2028 NM O&G Control Strategy oil and gas emissions were provided by ERG under separate contract to NMED.

4.2 Development of CAMx 2014 Base Case Emission Inputs

The CAMx 2014 base case emission inputs for the 36/12-km domains were based on the WRAP 2014v2 CAMx model-ready emission inputs and were used "as is." For the 4-km NM domain, the New Mexico emissions from the 2014v2 database were reviewed and updated by the NMED. The 2014v2 emissions for New Mexico and portions of surrounding states within the 4-km New Mexico domain were then processed by the Sparse Matrix Operator Kernel Emissions (SMOKE) modeling system (UNC, 2015). SMOKE version 4.7 was used, which was released in October 2019.[26]

4.2.1 Day-Specific On-Road Mobile Source Emissions

The 2014 on-road mobile source emission inputs for the 4-km New Mexico domain were generated using the SMOKE-MOVES emissions model. SMOKE-MOVES used a 2014 mobile source emission factor (EF) lookup table generated by the Motor Vehicle Emission Simulator (MOVES2014[27]) model (EPA, 2014a,b,c). The SMOKE-MOVES default county-level 2014 vehicle activity data for New Mexico was reviewed by NMED and updated as needed. SMOKE-MOVES uses the 2014 MOVES EF lookup table, hourly gridded 4-km meteorological data from the 2014 WRF simulation conducted in this study (see Chapter 2) and 2014 county-level activity data (e.g., vehicle miles travelled

[26] https://www.cmascenter.org/smoke/
[27] https://www.epa.gov/moves/moves-onroad-technical-reports#moves2014

[VMT], speed, etc.) to generate 2014 day-specific hourly gridded on-road mobile source emission inputs for CAMx and the 4-km New Mexico domain.

4.2.2 Point Source Emissions

2014 point source emissions were based on the WRAP-WAQS 2014v2 emissions inventory. The 2014v2 New Mexico point source emissions were reviewed and updated by NMED. Point sources were processed in two streams: (1) major point sources with Continuous Emissions Monitoring (CEM) devices, which are primarily fossil-fueled Electrical Generating Units (EGU) with capacity of 25 MW or greater; and (2) point sources without CEMs. For point sources with CEM data, day-specific hourly NO_X and SO_2 emissions were used for the 2014 base case emissions scenario. The VOC, CO, and PM emissions for point sources with CEM data were based on the annual emissions data in the 2014v2 inventory temporally allocated to each hour of the year using the CEM hourly heat input.

4.2.3 Area and Non-Road Source Emissions

The 2014 area and non-road sources were spatially allocated to the 4-km New Mexico grid using an appropriate surrogate distribution (e.g., population for home heating, etc.). The area sources were temporally allocated by month and by hour of day using the SMOKE source-specific temporal allocation factors, while chemical speciation used the SMOKE source-specific CB6r4 speciation allocation profiles.

4.2.4 Episodic Biogenic Emissions

Two different CAMx 2014 base case simulations were conducted using two different biogenic emission inputs within the 4-km NM domain. The first CAMx 2014 base case 4-km domain biogenic emissions were generated using Version 3.1 of the MEGAN biogenic emissions model. MEGAN v3.1 is a new version of MEGAN and comes with a Leaf Area Index (LAI) database that defines the vegetative biomass and type that when combined with temperature and light dependent emission factors produces biogenic VOC emissions using the day-specific hourly gridded WRF meteorology. However, the new LAI data in MEGAN v3.1 were missing for urban areas producing "holes" in the biogenic VOC emission inputs. Thus, revised CAMx 2014v2 base case 4-km NM biogenic emission inputs used the BEIS v3.7 biogenic emissions model. BEIS3.7 is the most recent version of BEIS released by EPA in October 2020. BEIS3.7 uses updated biomass and emissions factors, and the Biogenic Emissions Landcover Database version 5 (BELD5). Table 4-1 compares the biogenic NO_x and VOC emissions by month (in tons/month) for the 4-km NM domain and the two biogenic models. The BEIS NO_x emissions are substantially lower than MEGAN, and VOC emissions are mostly lower except early summer month showing slightly higher emissions with BEIS. Figure 4-1 displays the spatial distributions of emissions in the 4-km NM domain expressed as episode average tons per day. The BEIS NO_x and VOC emissions are mostly lower than MEGAN throughout the domain. The missing biogenic VOC emissions in urban areas (e.g., El Paso/Juarez) using MEGAN v3.1 is also evident in the spatial maps.

Table 4-1. 2014 biogenic emissions (tons/month) in the 4-km NM domain estimated by MEGAN3.1 and BEIS3.7.

Tons/month		MEGAN	BEIS	% Diff (BEIS-MEGAN)
NO_x	May	35,050	10,602	-69.8%
	Jun	42,445	13,134	-69.1%
	Jul	51,639	12,838	-75.1%
	Aug	41,002	11,923	-70.9%
VOC	May	128,323	159,809	24.5%
	Jun	267,055	256,379	-4.0%
	Jul	317,697	251,562	-20.8%
	Aug	354,570	216,032	-39.1%

NMED Exhibit 17

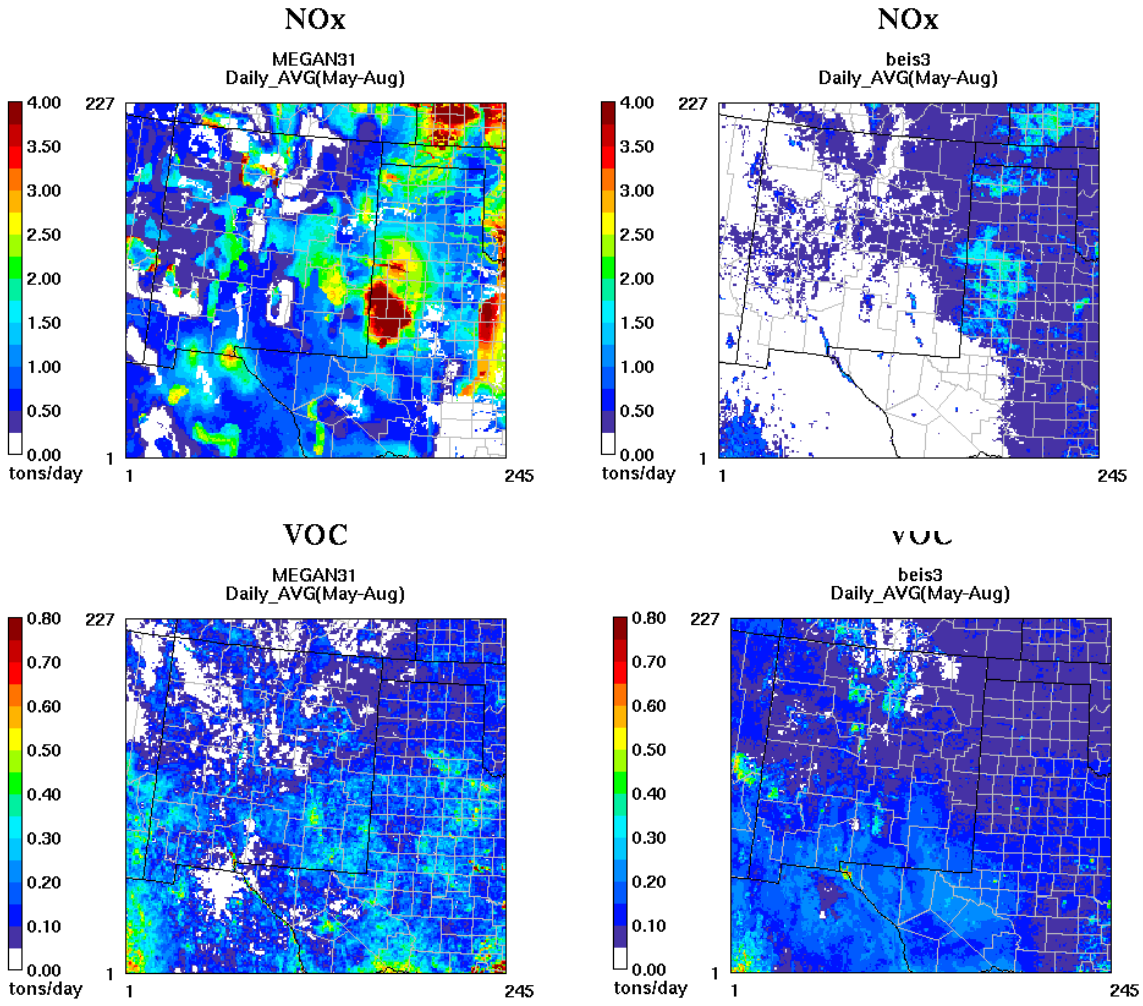

Figure 4-1. Spatial distribution of NO_x (top panel) and VOC (bottom panel) biogenic emissions (episode average tons per day) in the 4-km NM domain estimated by MEGAN3.1 (left) and BEIS3.7 (right).

4.2.5 Wildfires, Prescribed Burns, Agricultural Burns

2014 emissions from open-land burning including wildfires, wildland prescribed burns and agricultural burning were based on the WRAP-WAQS 2014v2 emissions inventory. The WRAP Fire and Smoke Work Group (FSWG[28]) processed the 2014NEIv2 Bluesky/SMARTFIRE fire emissions for the U.S. and classified them as either wildfires (WF), wildland prescribed burns (Rx) or agricultural burning (Ag) and made other updates for the 2014v2 inventory. The 2014NEIv2 fire emissions for Mexico and Canada were used without any changes. Table 4-2 displays NO_x and VOC emissions by month and fire type within the 4-km NM domain. Figure 4-2 displays spatial maps of NO_x emissions from 2014 summer fires for the 4-km NM domain. Emissions are expressed as episode average tons per day per grid cell. We see some hotspots on the wildfires plot in New Mexico and Arizona near the western boundary of the 4-km domain.

[28] https://www.wrapair2.org/FSWG.aspx

Table 4-2. 2014 fire emissions summary (tons/month) by fire type for the 4-km NM domain

Tons/month	Pollutant	Ag fires	Prescribed fires	Wildfires	Mexico fires
NO_x	May	36	90	597	49
	Jun	11	81	1,056	32
	Jul	18	13	332	8
	Aug	18	69	39	2
VOC	May	60	617	6,663	92
	Jun	18	736	17,641	187
	Jul	29	82	4,985	40
	Aug	28	1,376	371	13

NMED Exhibit 17

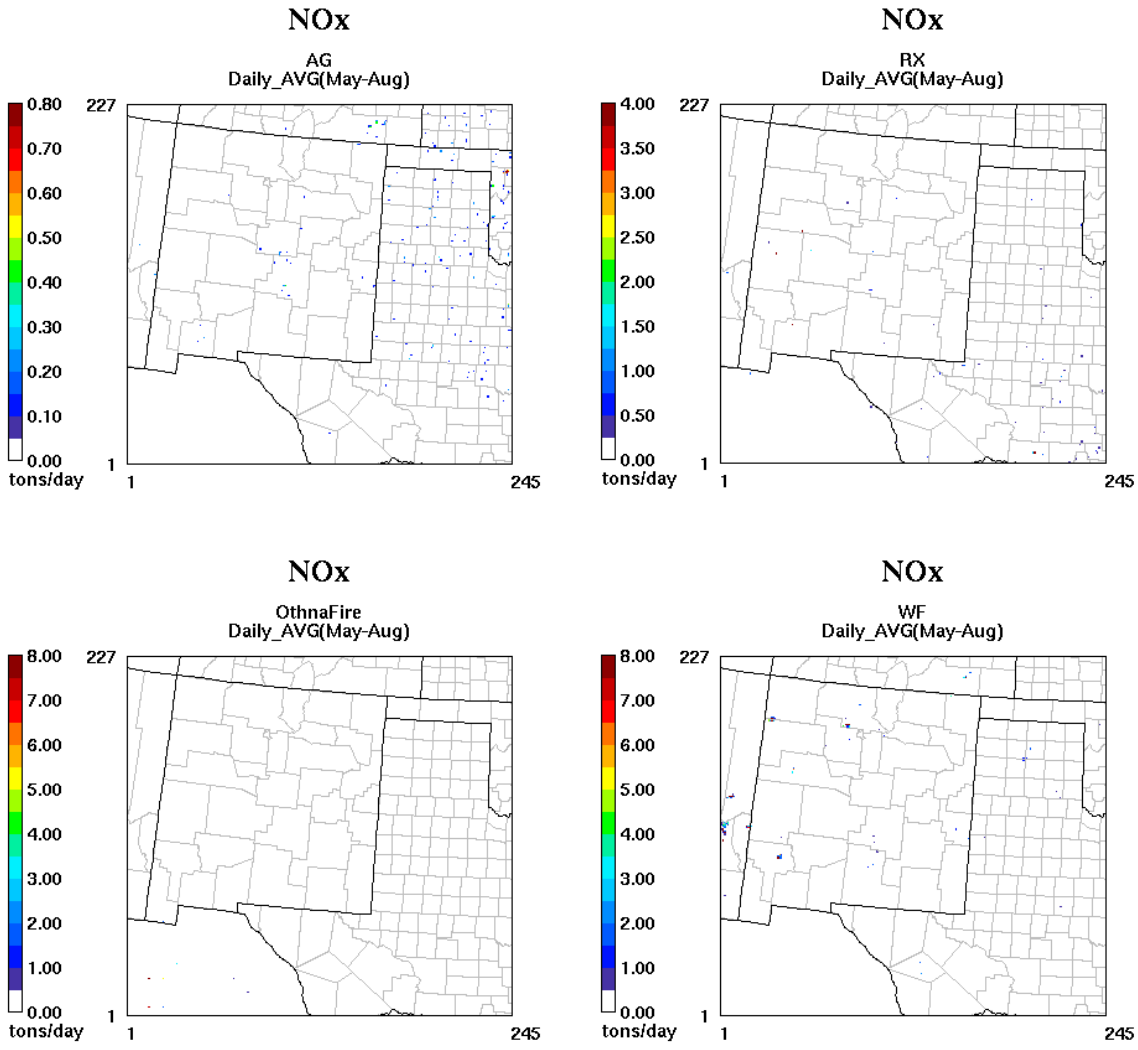

Figure 4-2. Spatial distribution of agricultural fires, prescribed fires, wildfires and Mexico fires (clockwise starting from top left) NO_x emissions (episode avg tons per day) for New Mexico 4-km domain.

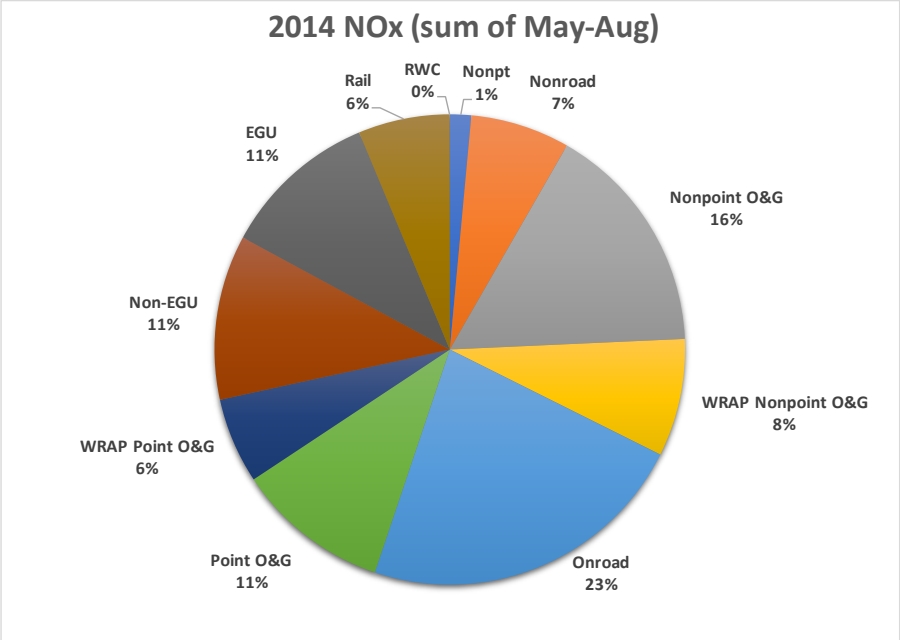
4.2.6 Other Natural Emissions

Lightning NO_x (LNO_X), and windblown dust (WBD) emissions were generated for the 4-km domain using special CAMx processors and WRF 2014 meteorological data. Oceanic emissions such as sea salt spray aerosol (SSA) and dimethyl sulphide (DMS) were not generated for the 4-km New Mexico domain since this domain does not include any ocean within it. However, the LNO_X, WBD and oceanic emissions for the 36-km and 12km were based on the WRAP-WAQS 2014v2 emissions and were included in the modeling.

4.2.7 2014 Emission Results

Table 4-3 summarizes the 2014 criteria air pollutant emissions in episode average short tons per day by source category for the 4-km New Mexico domain. These data represent the model-ready emissions input to the CAMx air quality model for the 2014



base case. Mostly, emissions are summarized from the SMOKE reports generated by the SMKMRG program. There are a couple of exceptions to this general approach, fugitive dust and EGU sources. The fugitive dust emissions were adjusted after SMOKE processing to account for fugitive dust correction factors that are derived from the Biogenic Emission Landuse Database version 4 (BELD4). The correction factors are necessary to account for dust removal due to local vegetation scavenging so are not transported downwind. Model-ready emissions for EGU and Mexico point sources were obtained from WRAP/WAQS 2014 platform so were summarized for the 4-km domain outside of SMOKE.

Table 4-3. 2014 base case anthropogenic emissions summary (episode average short tons per day) by source category for the 4-km New Mexico domain.

Country/ Category	Source Category	CO	NH_3	NO_x	$PM_{2.5}$	PM_{10}	SO_2	VOC
US Anthro	Area fugitive dust	0.0	0.0	0.0	253.3	1,788.2	0.0	0.0
	Agricultural ammonia sources	0.0	764.7	0.0	0.0	0.0	0.0	43.4
	Non-point Oil and Gas for 7 WRAP States (CO, MT, NM, ND, SD, UT, WY)	237.7	0.0	157.8	4.4	4.4	11.3	567.3
	Remaining Non-point Oil and Gas	286.8	0.0	311.7	6.9	6.9	30.0	1,642.5
	Residential Wood Combustion	7.0	0.1	0.1	0.5	0.5	0.0	1.2
	Other nonpoint sources	141.3	1.5	28.5	9.3	13.4	4.5	213.2
	On-road mobile	1,476.2	6.0	444.5	13.2	20.1	1.7	150.6
	Locomotive	22.9	0.1	122.7	2.9	3.1	0.1	6.2
	Non-road mobile	570.3	0.2	133.4	9.0	9.4	0.3	73.2
	EGU point sources	89.2	3.4	210.6	12.9	17.8	160.0	5.0
	Point Oil and Gas for 7 WRAP States (CO, MT, NM, ND, SD, UT, WY)	89.9	0.0	114.7	1.4	1.4	23.8	56.1
	Remaining Point Oil and Gas	113.8	0.1	205.2	3.2	3.3	27.1	48.4
	Non-EGU point sources	74.4	4.9	47.5	11.4	32.5	49.3	24.4
Mexico Anthro	Mexico area	19.9	33.2	42.2	5.8	15.7	1.7	103.3
	Mexico on-road mobile	356.3	0.6	98.4	1.5	2.6	1.4	34.4
	Mexico point sources	28.4	0.7	20.2	4.8	5.7	16.4	8.3

Figure 4-3 presents pie charts showing VOCs and NO_x emissions from anthropogenic sources by source category for New Mexico and portion of surrounding states within the 4-km domain. Point and non-point oil and gas sectors account for majority of NO_x emissions followed by on-road mobile and EGU sources. In New Mexico, oil and gas sources are the largest anthropogenic VOC emitters and accounts for nearly 80% of 4-km domain VOC emissions.

NMED Exhibit 17

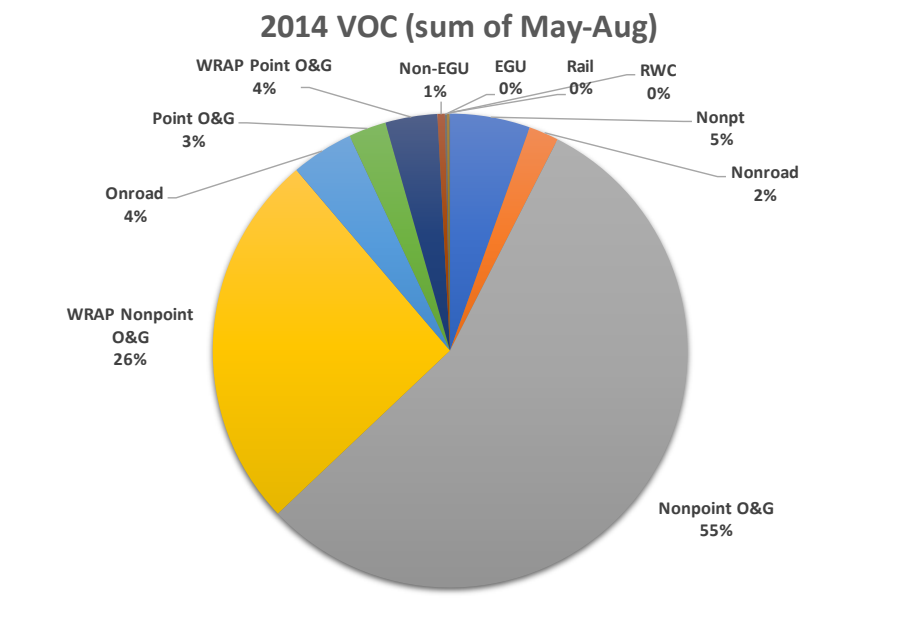


Figure 4-3. New Mexico 2014 base case anthropogenic NO_x and VOC emissions by source category.

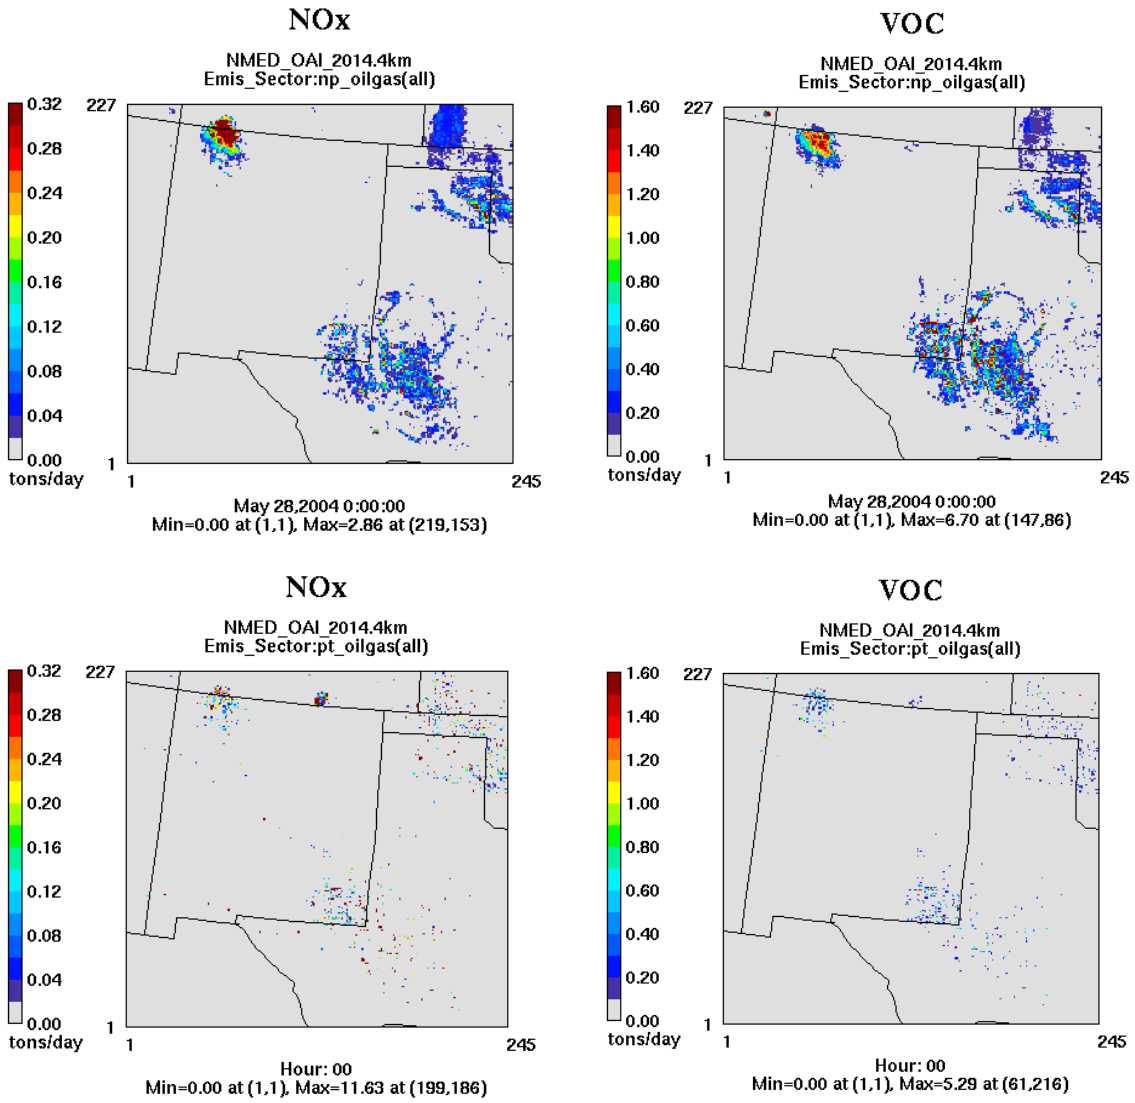
Figure 4-4 displays spatial maps of NO_x and VOC anthropogenic emissions from the oil and gas sector across the 4-km New Mexico domain. Top panel shows emission maps for non-point O&G sources while bottom panel shows point O&G sources. The San Juan and Permian basins are clearly visible on the emissions map and confirm correct spatial allocation of oil and gas emissions. Figure 4-5 shows emission maps for on-road mobile (top panel), rail (middle panel) and non-point sources including non-road equipment (bottom panel).



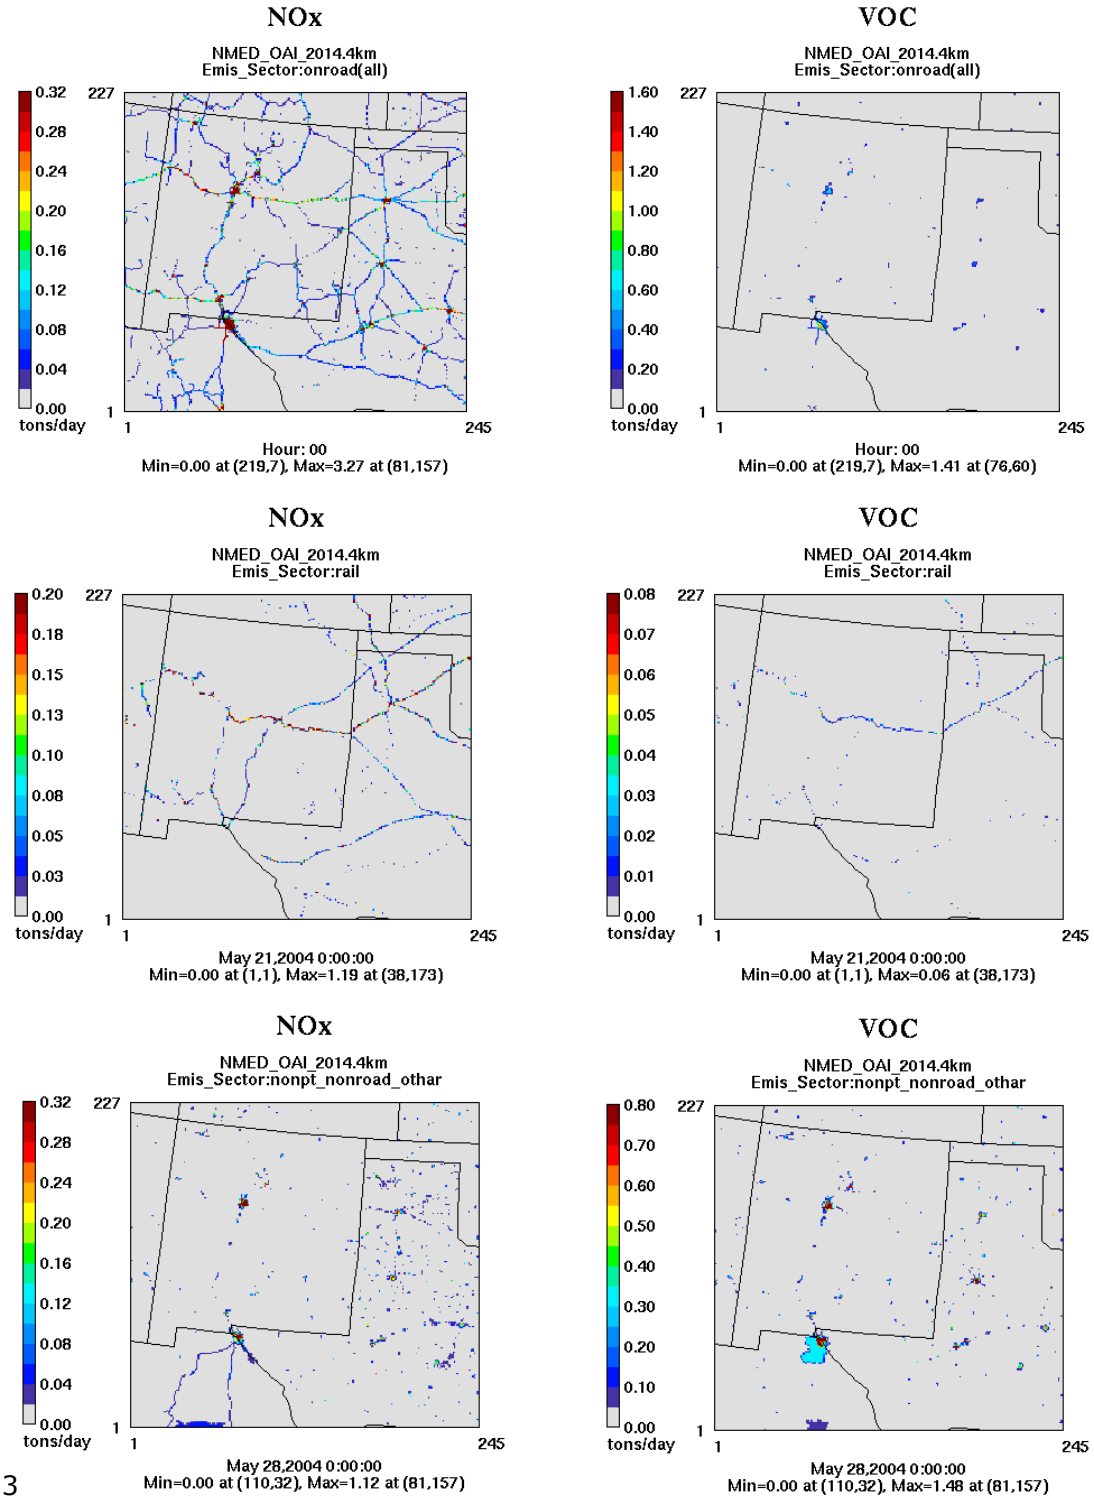


Figure 4-4. Spatial distribution of the non-point (top) and point (bottom) source oil and gas NO_x (left) and VOC (right) emissions (episode avg tons per day) for New Mexico 4-km domain.

3

Figure 4-5. Spatial distribution of on-road (top), rail (middle) and non-point/non-road equipment (bottom) NO_x (left) and VOC (right) emissions (episode avg tons per day) for New Mexico 4-km domain.

4.3 Development of CAMx 2028 Emission Scenarios

The NM OAI Study 2028 base case and 2028 O&G Control Strategy emissions were based on the WRAP 2028OTBa2 emissions inventory with updates to NM O&G emissions and using 2014 actual fires. Details on the 2028OTBa2 emission assumptions are contained in the WRAP Representative Baseline (RepBase2) and 2028 On-the-Books (2028OTBa2) CAMx Simulation Run Specification Sheet.[29] The original WRAP 2028OTBa emissions scenario used EPA's 2028 emission projections from their 2016v1 modeling platform[30] for several source sectors (e.g., non-EGU Point Sources). However, some of EPA's 2028 emission projections were inconsistent with the WRAP 2014v2 emission updates for the western states and there were double counted sources in EPA's 2016v1 platform 2028 emission projections. Thus, WRAP elected to use more source sector emissions from the EPA 2016v1 and WRAP 2014v2 emissions inventories that were vetted by many states resulting in the following source sectors used in the 2028OTBa2 emissions inventory with deviations from the WRAP 2028OTBa2 from the NM OAI Study 2028 base case discussed below (see details in Run Specification Sheet cited in footnote):

- The California Air Resources Board provided 2028 emissions for California and all source sectors.
- 2028 emissions for Electrical Generating Units (EGU) for fossil-fueled EGUs in WRAP states were reviewed in detail by the individual states starting from the results of the WRAP EGU Analysis Project.[31] 2028 emissions for Non-fossil-fueled EGU in the WRAP region and all EGUs outside of the WRAP region were based on EPA's 2016v1 modeling platform 2028 projections.
- 2028 O&G emissions for New Mexico were based on new estimates developed in the NM OAI Study as described later in this chapter. 2028 O&G emissions for other non-New Mexico WRAP region O&G basins are based on the WRAP projections out to 2023 (Ramboll, 2020a). The EPA 2016v1 platform 2016 O&G emissions were used for non-WRAP states. The 2028OTBa2 O&G emissions were reviewed in detail by WRAP region states to eliminate duplications and update sources as needed.
- Non-EGU Point Source emissions for the WRAP states were reviewed in detail by the individual states starting from the WRAP 2014v2 emissions, while the EPA 2016v1 platform emissions for 2016 were used for non-WRAP states.
- The SMOKE-MOVES model with 2014 meteorology, 2028 vehicle activity and 2028 MOVES2014 Emissions Factor Look-Up tables were used to generate 2028 on-road mobile source emissions by either WRAP[32] for the 12-km domain or the NM OAI Study for the 4-km domain.
- 2028 Non-road emissions were based on 2028 estimates by WRAP in the Mobile Source Emissions Inventory Projection Project for the WRAP region and EPA's 2028 estimates for the non-WRAP states.

[29] https://views.cira.colostate.edu/docs/iwdw/platformdocs/WRAP_2014/EmissionsSpecifications_WRAP_RepBase2_and_2028OTBa2_RegionalHazeModelingScenarios_Sept30_2020.pdf

[30] https://www.epa.gov/air-emissions-modeling/2016v1-platform

[31] https://www.wrapair2.org/EGU.aspx

[32] WRAP Mobile Source Emissions Inventory Projections Project

- WRAP region 2014v2 and EPA 2016v1 emissions were used for the Non-Point source sector in the 2028OTBa2 emissions scenario.
- The NM OAI Study 2028 fires were based on the WRAP region 2014v2 actual fire estimates.
- Natural emissions (biogenic, lighting NO_x, windblown dust and oceanic) were the same as used in the WRAP 2014v2, RepBase2 and 2028OTBa2 emission scenarios

4.3.1 2028 Base Case New Mexico Oil and Gas Emissions

A circa 2028 forecast oil and gas (O&G) emission inventory was developed for New Mexico for use in the NM OAI Study 2028 Base Case emission scenario. The basis of the forecast O&G emission inventory is circa 2028 O&G activity estimates provided by BLM[33] and emissions and emission per unit of O&G activity from the future year WRAP Oil and Gas Working Group (OGWG) emission inventory (Ramboll, 2020a). The WRAP OGWG developed 2023 future year O&G emissions for 7 of the WRAP states.

The 2028 New Mexico O&G emission inventory includes wellsite, gathering, and processing subsectors, which are items 1, 5, and 6 in Figure 4-6. Item 1 are On-Shore Petroleum and Natural Gas Production is referred to as "wellsite" sources; emissions from wellsite sources are classified as nonpoint sources. Item 2 are Gathering and Boosting sources. Item 6 consists of Gas Processing Plants are collectively referred to as "midstream" sources; emissions from midstream sources are classified as point sources. The classification of well-site emissions as nonpoint and midstream emissions as point sources is consistent with other O&G emission inventory classifications used in prior studies, such as the BLM Colorado Air Resource Management Modeling Study (CARMMS)[34].

[33] Email communication from BLM Staff (Forrest Cook) to Ramboll (John Grant). September 15, 2020.

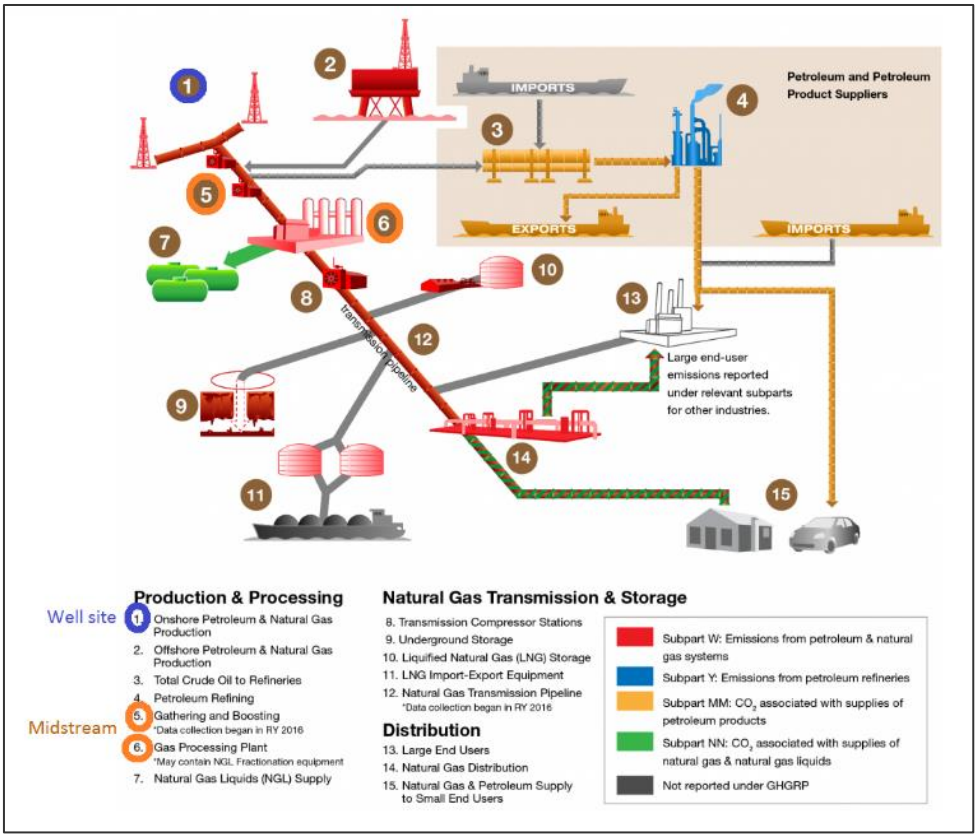

Figure 4-6. Example Petroleum and Natural Gas Industry schematic[35].

The BLM O&G forecast factors were used to project New Mexico O&G emissions to 2028. Table 4-4 compares the New Mexico O&G VOC and NO_x activity for the WRAP 2014 and 2023 scenarios with the NM OAI Study 2028 base case activity based on BLM forecasts. With the exception of spud count, the 2028 NM O&G activity is greater than 2014.

A comparison of the WRAP OGWG 2014 and 2023 New Mexico O&G emissions with the 2028 values from the NM OAI Study are given in Table 4-5. Across New Mexico, 2028 O&G NO_x and VOC emissions are, respectively, 29% and 15% higher than in 2014. In the Permian Basin, New Mexico 2028 O&G NO_x emissions are 64% higher than 2014, with VOC emissions 19% higher. The 2028 and 2014 New Mexico O&G emissions in the San Juan Basin are more comparable, with 2028 NO_x and VOC emissions, respectively, 1% and 10% higher than 2014.

4.4 Summary of 2014 and 2028 Base Case Emissions

Tables 4-6 through 4-8 summarizes the total emissions in New Mexico for the 2014 and 2028 base case emission scenarios and their differences. Graphical comparisons of the changes in NO_x and VOC emissions between 2014 and 2028 base cases are shown in, respectively, Figures 4-7 and 4-8. And the distribution of NO_x and VOC emissions across source sectors are shown in Figures 4-9 and 4-10, respectively. Total NO_x emissions in New Mexico are estimated to be reduced by -28% between 2014 and 2028 with the largest reductions coming from on-road mobile (-72%), EGU point (-69%) and non-road mobile (-51%) source sectors (Table 4-6 and Figure 4-7). These NO_x emission reductions were offset somewhat by increases in O&G point (+40%) and non-point (+36%) source sectors. Although there are large reductions in on-road (-61%) and non-road (-49%) mobile source VOC emissions between 2014 and 2028 base cases, the total reduction in New Mexico VOC emissions between 2014 and 2028 is only -6% because non-point O&G dominates (~75%; Figure 4-10) anthropogenic VOC emissions in New Mexico and they are only reduced by -5%.

Table 4-6. Summary of total emissions (tons/year) in New Mexico for the 2014 base case emissions scenario.

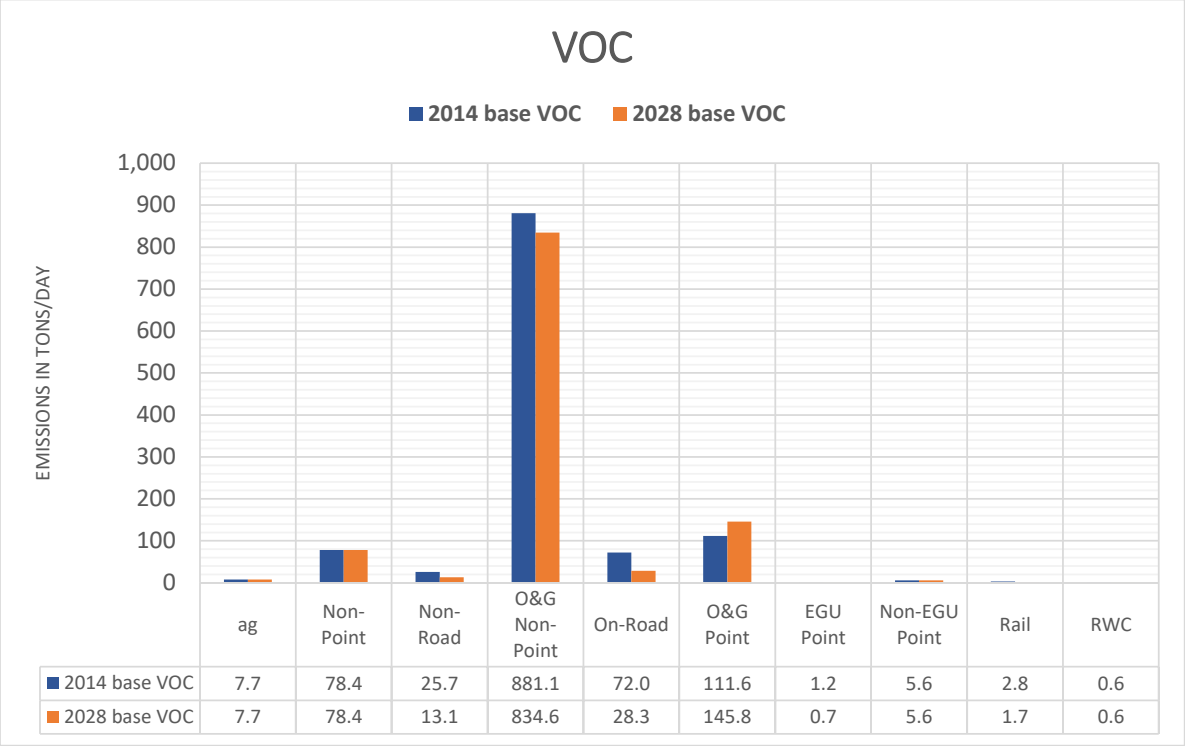

Figure 4-8. Comparison of 2014 and 2028 New Mexico NO_X emissions by source sector.

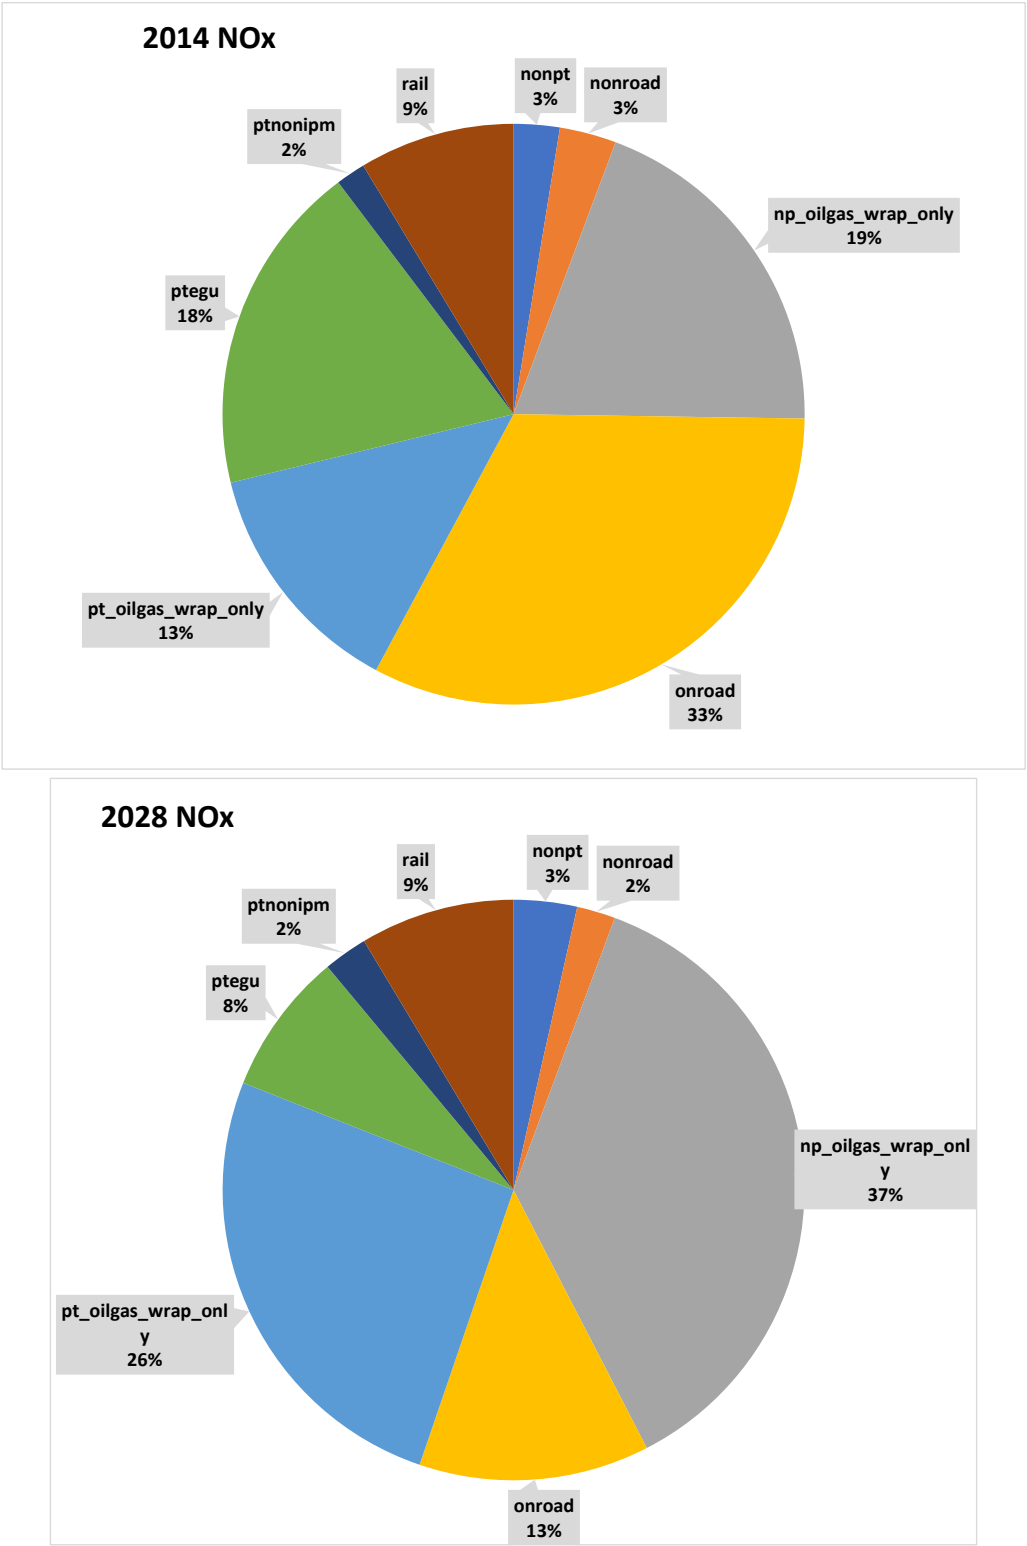

Figure 4-9. Distribution of New Mexico NO_x emissions across source sectors for the 2014 (top) and 2028 (bottom) base cases.

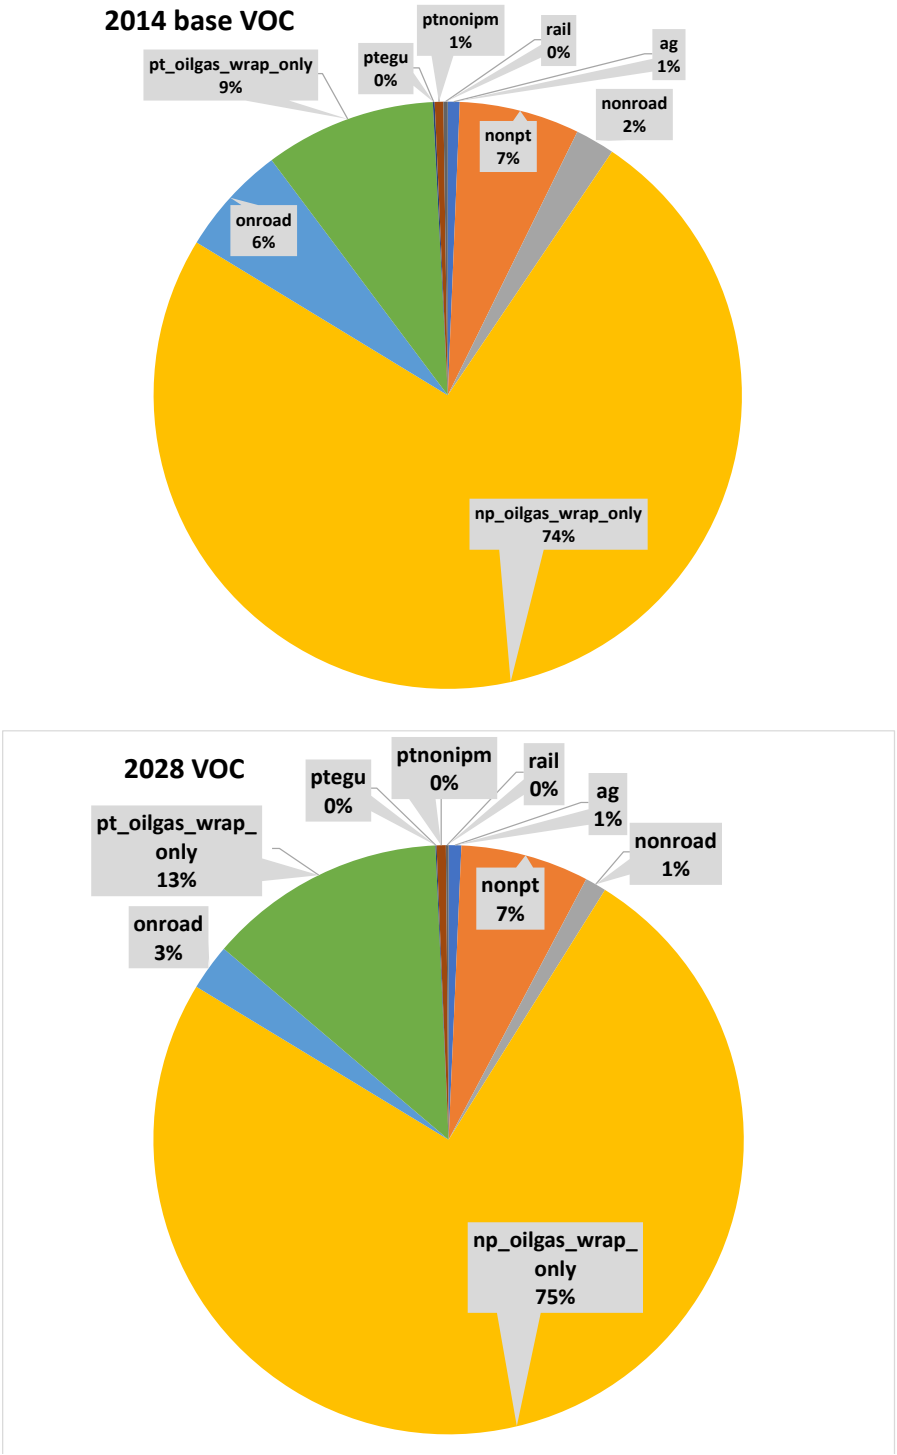

Figure 4-10. Distribution of New Mexico VOC emissions across source sectors for the 2014 (top) and 2028 (bottom) base cases.

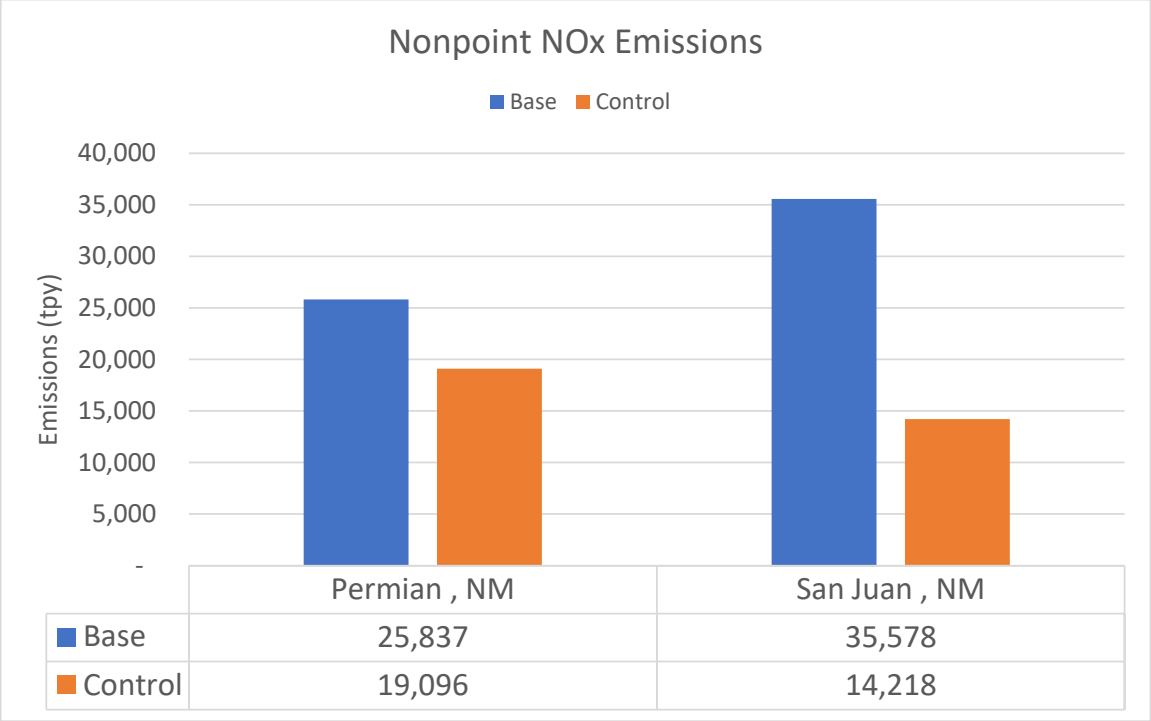
4.5 2028 New Mexico Oil and Gas Control Strategy

The WESTAR/Ramboll Team provided the New Mexico 2028 O&G base case emissions to the NMED. The Eastern Research Group (ERG) under separate contract with NMED implemented the emission controls in the 2028 NM O&G emissions based on their interpretation of the proposed New Mexico "Ozone Precursor Rule for Oil and Natural Gas Sector."[36] The 2028 O&G Control Strategy reduced O&G emissions in 7 counties in New Mexico.

The 2028 NM O&G controlled emissions were processed by SMOKE and substituted for the 2028 NM O&G Base Case emissions to create the 2028 O&G Control Strategy emissions scenario. The only difference between the NM OAI Study 2028 Base Case and 2028 O&G Control Strategy were the controls on O&G emissions in New Mexico as implemented by ERG.

Table 4-9 displays the New Mexico state-wide O&G emissions for the 2028 Base Case and 2028 O&G Control Strategy. State-wide O&G NO_x emissions are reduced approximately -45% with similar reductions from both the Point and Non-Point source sectors. State-wide O&G VOC emission reductions are reduced approximately -50% with more reductions coming from the Non-Point (-53%) than Point (-35%) source sectors.

Table 4-9. New Mexico NO_x and VOC O&G emissions (tons per year) for the 2028 Base Case and 2028 NM O&G control strategy.



Source Sector	NO_x Emissions (TPY)			VOC Emissions (TPY)		
	Base	Control	Diff	Base	Control	Diff
Non-Point	61,245	33,144	-46%	181,252	85,564	-53%
Point	41,066	22,872	-44%	30,340	19,608	-35%
Total	102,311	56,016	-45%	211,592	105,172	-50%

Figures 4-11 and 4-12 display the changes in, respectively, NO_x and VOC emissions in the Permian and San Juan Basins between the 2028 base and 2028 control cases. In the Permian Basin, O&G NO_x emissions are estimated to be reduced by approximately 21,000 TPY (64%). In the San Juan Basin, O&G NO_x emissions are estimated to be reduced by approximately 25,000 TPY (44%). 2028 VOC O&G emissions in the Permian and San Juan Basins are estimated to be reduced by approximately 53,000 TPY each (-46% and -55% reduction, respectively).

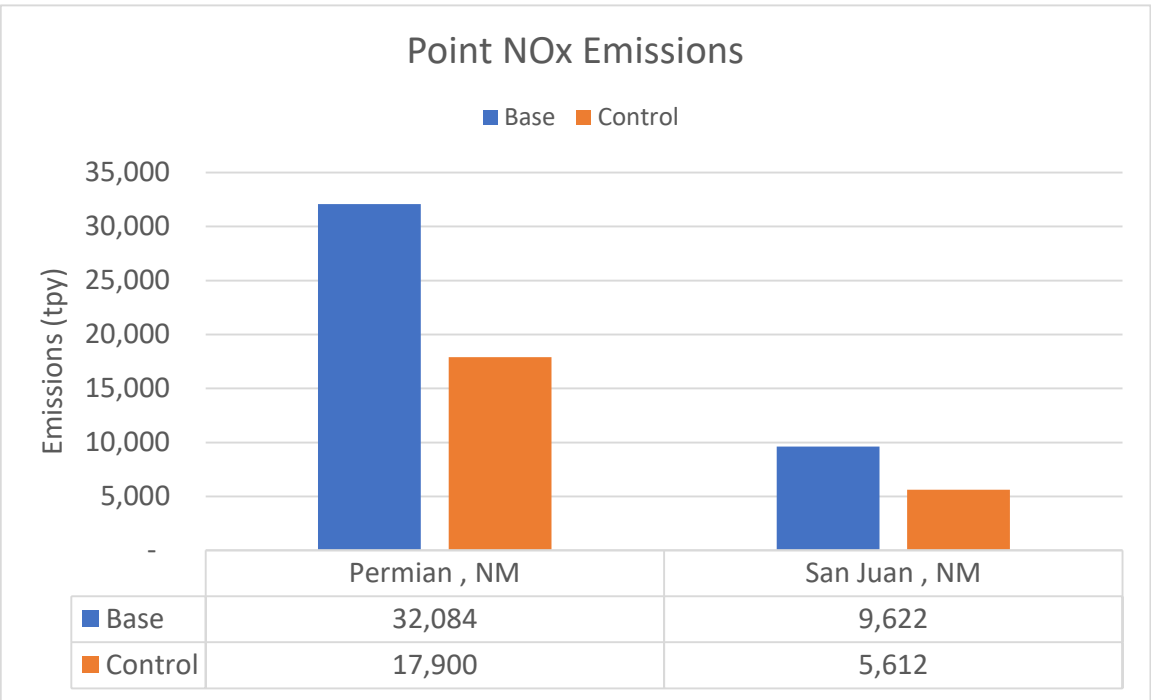


Figure 4-13 shows the spatial distribution of the differences Non-Point and Point O&G NO_x and VOC emissions between the 2028 Base Case and 2028 O&G Control Strategy scenario. The O&G emission reductions are restricted to the New Mexico portions of the San Juan and Permian Basins.

5. DIAGNOSTIC SENSITIVITY TESTS

Several CAMx diagnostic sensitivity tests were conducted to evaluate the effects that alternative meteorological inputs have on ozone concentrations.

5.1 WRFCAMx Processing of 2014 WRF Output

The WRFCAMx processor maps WRF meteorological fields to the format required by CAMx. It also calculates turbulent vertical exchange coefficients that define the rate and depth of vertical mixing in CAMx. Several options are available in WRFCAMx to derive vertical turbulent exchange coefficient (also known as Kv or vertical diffusivity) fields from WRF output. The Kv fields are diagnosed from wind, temperature, and Planetary Boundary Layer (PBL) parameters in WRFCAMx. For this application, the WRFCAMx processing was performed to generate two sets of Kv profiles using two different Kv options in WRFCAMx, the CMAQ-like and YSU Kv profile options.

The CAMx Kv_patch pre-processor program was used to set the minimum Kv value to 0.1 to 1.0 m^2/s in the lowest 100 m of the atmosphere depending on the amount urban land use category in a grid cell. This is done to account for the urban heat island effect that enhances vertical mixing through-out the day and night.

WRF was run with 36 vertical levels (35 vertical layers) as shown in Table 2-1. For the NM OAI Study, a layer collapsing strategy was employed that reduced the 35 WRF vertical layers to 25 layers in CAMx, which reduces the CAMx run time by about a third. Table 5-1 displays the WRF to CAMx layer collapsing strategy. This is the same layer collapsing study employed by WRAP-WAQS 2014 modeling platform.

5.2 CAMx Meteorological Diagnostic Sensitivity Tests

Four separate CAMx 2014 36/12/4-km diagnostic sensitivity tests were conducted for the first portion of the summer 2014 modeling episode that spanned May 15 to June 4, 2014. The purpose of the four meteorological inputs CAMx sensitivity tests was to identify the optimal meteorological inputs for the final CAMx 2014 base case simulation. The four sets of CAMx simulations were based on the WRF/NAM and WRF/ERA5 2014 36/12/4-km simulations described in Chapter 2 processed by WRFCAMx to generate two sets of vertical mixing coefficient (Kv) as described above:

1. WRF/NAM with CMAQ Kv
2. WRF/NAM with YSU Kv
3. WRF/ERA5 with CMAQ Kv
4. WRF/ERA5 with YSU Kv

NMED Exhibit 17

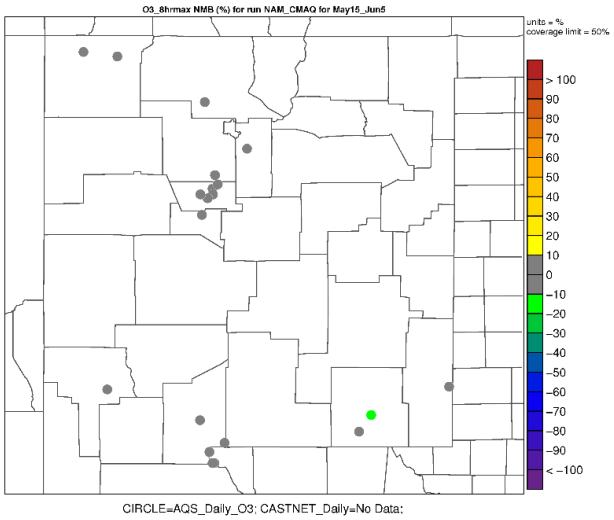
NMED Exhibit 17



NMED Exhibit 17

Figures 5-1 and 5-2 summarize the CAMx MDA8 ozone normalized mean bias (NMB) and error (NME) statistical performance metrics for each site in New Mexico and the four WRF meteorological inputs sensitivity tests. The statistics presented in these figures were calculated using a 60 ppb cutoff value relative to observed MDA8 ozone concentrations to understand the performance of each sensitivity test when ozone concentrations are most relevant to the NAAQS. Figure 5-1 shows that the NMB is generally within ±10% (colored grey) at almost all sites (note that the NMB performance goal is within ±5% and performance criteria is within ±15%). All of the sensitivity simulations have an under-prediction bias for observed ozone greater than 60 ppb at sites in the southern portion of the domain such that for one or two sites have a bias even lower than -10% (i.e., colored bright green). The WRF/NAM with CMAQ Kv sensitivity test has slightly better performance than the others with less underestimation bias (e.g., all sites but one are within ±10% compared to two sites for the other tests). Figure 5-2 shows that the NME is also generally within the performance goal (less than 15%) in all cases, with the southern portions of NM showing the largest errors but still within the performance criteria (less than 25%). The figure shows that CAMx using the WRF/NAM inputs tends to have slightly lower error and better ozone performance than when the WRF/ERA5 meteorological inputs are used.

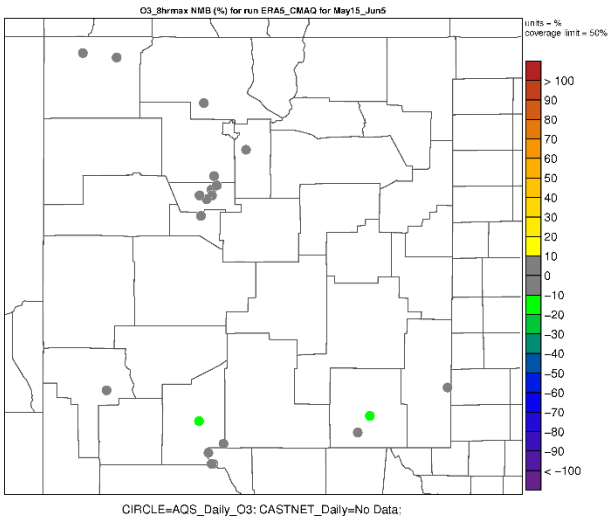


Figure 5-3 presents soccer plots of bias and error for observed ozone above 60 ppb and all four CAMx sensitivity tests. This figure plots site-specific bias versus error with performance lines in the shape of a soccer goal, when the site-specific bias and error symbol falls within the soccer goal area (i.e., the red box) it is easy to see when the ozone performance goals are achieved. The figure shows that all sites have NMB and NME that fall within the performance criteria for bias (≤±15%) and error (≤25%), with most sites having an underestimation bias of the high (> 60 ppb) observed ozone concentrations. The CAMx simulations with the WRF/NAM meteorological inputs has slightly better performance than when the WRF/ERA5 inputs are used as more sites fall within the performance goal area. Comparison between the NAM cases indicate that the CAMx sensitivity test with CMAQ Kv has slightly smaller errors relative to the test with YSU Kv.

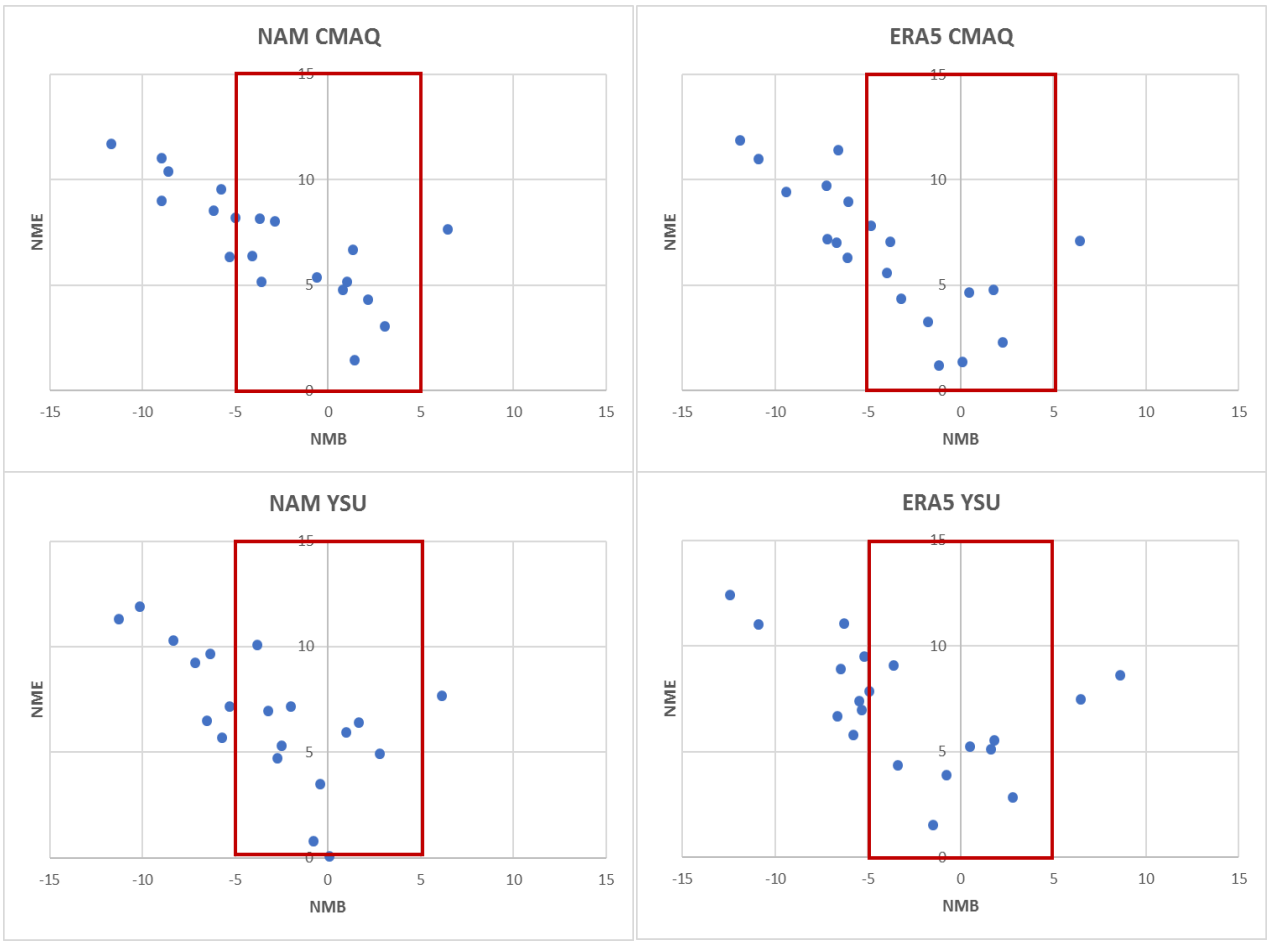

Figure 5-3. Comparison of sensitivity tests soccer plots with 60 ppb cutoff. Red rectangle indicates the performance goal soccer area.

Figures 5-4 to 5-7 present time series of predicted and observed MDA8 ozone concentrations for selected sites in Doña Ana, Eddy and Sandoval counties. At the Solano Road site in Doña Ana County the time series shows that the observed peak ozone concentration on May 29 is matched very well by the CAMx WRF/NAM sensitivity tests, while the CAMx WRF/ERA5 sensitivity test under-predicts by approximately 10 ppb (Figure 5-4). At the Desert View site, which is also in Doña Ana County, all four CAMx sensitivity tests underestimate the high observed ozone on May 28-29, but the CAMx WRF/NAM tests perform slightly better than the CAMx WRF/ERA5 test (Figure 5-5). At the Carlsbad site in Eddy County all test cases under-predict the high ozone concentration from May 27 to May 31 (Figure 5-6). For the site in Sandoval county (Figure 5-7) all four CAMx sensitivity tests track the daily variations of the observed MDA8 ozone including getting the timing and values of the observed ozone peak on May29, but the CAMx WRF/NAM with CMAQ Kv test exhibits the lowest biases.

5.3 Summary of CAMx Diagnostic Sensitivity Tests

All four of the CAMx meteorological sensitivity cases have biases and errors well within the performance criteria and in most cases even within the more stringent performance goals. For the modeled episode, the differences in performance among all the cases considered are relatively minor. On some sites and days, CAMx using the WRF/NAM meteorology tends to capture peak ozone concentrations better than when the WRF/ERA5 meteorology is used. Based on the results presented here, the final CAMx 2014 base case model configuration used the WRF/NAM with CMAQ Kv treatment meteorological inputs.

6. 2014 BASE CASE MODELING AND MODEL PERFORMANCE EVALUATION

The NM OAI Study conducted two CAMx 2014 36/12/4-km base case simulations. The original 2014 base case simulation used CAMx v7.0 and biogenic emissions in the 4-km based on the MEGAN v3.1 model and is documented in Ramboll and WESTAR (2020c). There were errors in the CAMx v7.0 source apportionment algorithms that did not significantly affect the CAMx v7.0 2014 base case ozone estimates but would affect planned future year ozone source apportionment modeling. So, a second CAMx 2014v2 base case simulation was performed using CAMx v7.1 that had corrections to the ozone source apportionment algorithms. The revised CAMx v7.1 2014v2 base case simulation also updated the biogenic emissions in the 4-km domain using the BEIS v3.7 biogenic emissions model. The MEGAN v3.1 biogenic model used in the first CAMx v7.0 2014 base case was missing leaf area index (LAI) data for urban areas so produced zero biogenic VOC emissions for the urban land use type. The development of New Mexico-specific urban LAI inputs was beyond the resource and time constraints of the study, so BEIS biogenic emissions were used for the revised 2014v2 CAMX base case simulation. Details on the CAMx 2014v2 final base case simulation and model performance are provided in Ramboll and WESTAR (2021) with a summary provided below.

6.1 Final CAMx 2014v2 Base Case Configuration

The final CAMx meteorological inputs were based on the WRF/NAM simulations using the CMAQ-like Kv profiles as described in Chapters 2 and 5.

The 2014 emissions used in the 36-km and 12-km domains were the same as the WRAP-WAQS 2014v2 emissions. For the 4-km New Mexico domain, the WRAP 2014v2 emissions were processed by the SMOKE emissions model to generate the gridded hourly speciated emissions for CAMx. Chapter 4 describes the updates to the WRAP-WAQS 2014v2 emissions for New Mexico and the development of the emission inputs for the New Mexico 4-km domain.

Table 6-1 summarizes the CAMx configuration and options used for the CAMx 20114v2 base case simulation. Version 7.1 (v7.1) of CAMx released in January 2021 was used in the final 2014v2 base case simulation. CAMx was operated using the 36/12/4-km nested grid structure shown in Figure 1-1 using two-way grid nesting for all simulations. Boundary Conditions (BCs) for the CAMx most outer 36-km 36US modeling domain lateral boundaries were based on output from a 2014 simulation of the GEOS-Chem global chemistry conducted by WRAP for their 2014v2 modeling platform. CAMx was started on May 1, 2016 using the 36/12/4-km domains that allowed the model over two-weeks to initialize the model and wash out the initial concentrations before the first high ozone day on May 17, 2014.

Other CAMx model options and setup are defined in Table 6-1. The PPM advection solver (Colella and Woodward, 1984) was used for horizontal transport along with the spatially varying (Smagorinsky) horizontal diffusion approach. K-theory was used for vertical diffusion using the CMAQ-like Kv profiles from the WRFCAMx processing of the WRF/NAM output. The CB6r4 gas-phase chemical mechanism was selected because it includes the very latest chemical kinetic rates with halogen chemistry that affects ozone levels over the ocean. The latest aerosol mechanism was used in CAMx along with the

standard wet and dry deposition schemes. The Plume-in-Grid module was used to treat the near-source chemistry and dispersion of major NO_X emissions sources in the New Mexico 4-km domain for sources with greater than 5 tons per day NO_x emissions.

Table 6-1. Final CAMx model configuration for the 2014v2 base case simulation in NM OAI Study.

Science Options	CAMx	Comment
Model Codes	CAMx v7.1	Latest version of CAMx at time of study released in January 2020 (www.camx.com)
Horizontal Grid Mesh	36/12/4-km	
36-km grid	148 x 112 cells	36US domain
12-km grid	227 x 215 cells	12WUS2 domain. Includes buffer cells
4-km grid	245 x 227 cells	New Mexico 4-km domain. Includes buffer cells
Vertical Grid Mesh	25 vertical layers, defined by WRF	Layer 1 thickness ~20 m. Model top at 50 mb (~19 km). Layer collapsing from 35 vertical layers in WRF
Grid Interaction	36/12/4 km two-way nesting	
Initial Conditions	Start on May 1, 2014	First high ozone day is May 17, 2014
Boundary Conditions	WRAP 2014 GEOS-Chem	For 36US domain lateral boundaries
Emissions		
Baseline Emissions Processing	SMOKE, SMOKE-MOVES2014, BEIS v3.7	WRAP/WAQS 2014v2 emissions
Sub-grid-scale Plumes	Plume-in-Grid for major NO_X sources in New Mexico	Point sources with NO_x emission s greater than 5 tons per day
Chemistry		
Gas Phase Chemistry	CB6r4	Latest chemical reactions and kinetic rates with halogen chemistry (Yarwood et al., 2010)
Meteorological Processor	WRFCAMx	Compatible with CAMx v7.0
Horizontal Diffusion	Spatially varying	K-theory with Kh grid size dependence
Vertical Diffusion	CMAQ-like Kv	Evaluated YSU Kv scheme
Diffusivity Lower Limit	Kv-min = 0.1 to 1.0 m^2/s in lowest 100 m	Depends on urban land use fraction
Deposition Schemes		
Dry Deposition	Zhang dry deposition scheme	(Zhang et. al, 2001; 2003)
Wet Deposition	CAMx -specific formulation	rain/snow/graupel
Numerics		
Gas Phase Chemistry Solver	Euler Backward Iterative(EBI)	EBI fast and accurate solver
Vertical Advection Scheme	Implicit scheme w/ vertical velocity update	Emery et al., (2009a,b; 2011)
Horizontal Advection Scheme	Piecewise Parabolic Method (PPM) scheme	Colella and Woodward (1984)
Integration Time Step	Wind speed dependent	~0.5-1 min (4-km), 1-5 min (12-km), 5-15 min (36-km)

6.2 Ozone Model Performance Goals and Criteria

Emery and co-workers (2016) analyzed almost 100 PGM model applications and developed a set of PGM model performance goals and criteria based on the variability in the past PGM model performance. "Goals" indicate statistical values that approximately a third of the top performance past PGM applications have met and should be viewed as the best a model can be expected to achieve. "Criteria" indicates statistics values that about two thirds of past PGM applications have met and should be viewed as what a majority of the models have achieved. The CAMx revised 2014v2 and original 2014 base case simulations ozone model performance statistics for normalized mean bias (NMB) and normalized mean error (NME) are compared against the ozone model performance goals and criteria developed by Emery et al., (2016) that are given in Table 6-2.

Table 6-2. Recommended ozone benchmarks for photochemical model statistics (Source: Emery et al., 2016).

Species	NMB		NME		r	
	Goal	Criteria	Goal	Criteria	Goal	Criteria
1-hr & MDA8 Ozone	<±5%	<±15%	<15%	<25%	>0.75	>0.50

6.3 Spatial Ozone Model Performance

Figures 6-1 and 6-2 display the spatial distribution of bias (NMB) performance at monitoring sites in the 4-km NM domain for the revised 2014v2 and original 2014 CAMx base case simulation with and without using a 60 ppb observed ozone cutoff concentrations (i.e., only include predicted and observed MDA8 ozone pairs in the statistics when the observed MDA8 ozone is greater than 60 ppb). When the symbols are grey, they achieve the within ±5% ozone bias Performance Goal and when the symbols are the brightest green or yellow colors they are within the ozone bias Performance Criteria (i.e., between ±5% and ±15%).

With the exception of one monitoring site in El Paso, the NMB at all of the ozone sites in the 4-km domain achieve the ozone Performance Criteria using no cutoff in both CAMx base case simulations, although some sites have an overestimation bias greater than 5% Performance Goal (Figure 6-1). The CAMx 2014v2 and 2014 base case ozone bias performance looks nearly identical with the only noticeable differences being two sites (one in Doña Ana County and one in Luna County) that achieve the ozone bias Performance Goal in the revised 2014v2 CAMx base case (i.e., are colored grey in Figure 6-1, top) but have bias between the 5% and 15% in the original CAMx base case (Figure 6-1, bottom) so fall between the Performance Goal and Criteria (i.e., are colored bright yellow).

Whereas the CAMx base cases tend to have a small ozone overestimation bias when no observed ozone 60 ppb cutoff is used, when using a 60 ppb observed ozone cutoff both base cases tend to have a small underestimation bias (Figure 6-2). With one exception, when using the cutoff all sites achieve the ozone Performance Criteria and many sites achieve the ozone bias Performance Goal. The bias performance of the two base case simulations are nearly identical. The one exception is the Carlsbad site in Eddy County that is between the Performance Goal and Criteria (i.e., between -5% and -15%) in the

original 2014 base case (Figure 3-2, bottom), but has a NMB between -15% and -20% in the revised 2014v2 base case so fails to achieve the ozone bias Performance Criteria (Figure 3-2, top).

We also compared the spatial model performance of the two base cases for error (NME) and correlation (r), but the spatial maps were identical so did not provide any relevant information on the relative performance of the two base case simulations.

NMED Exhibit 17

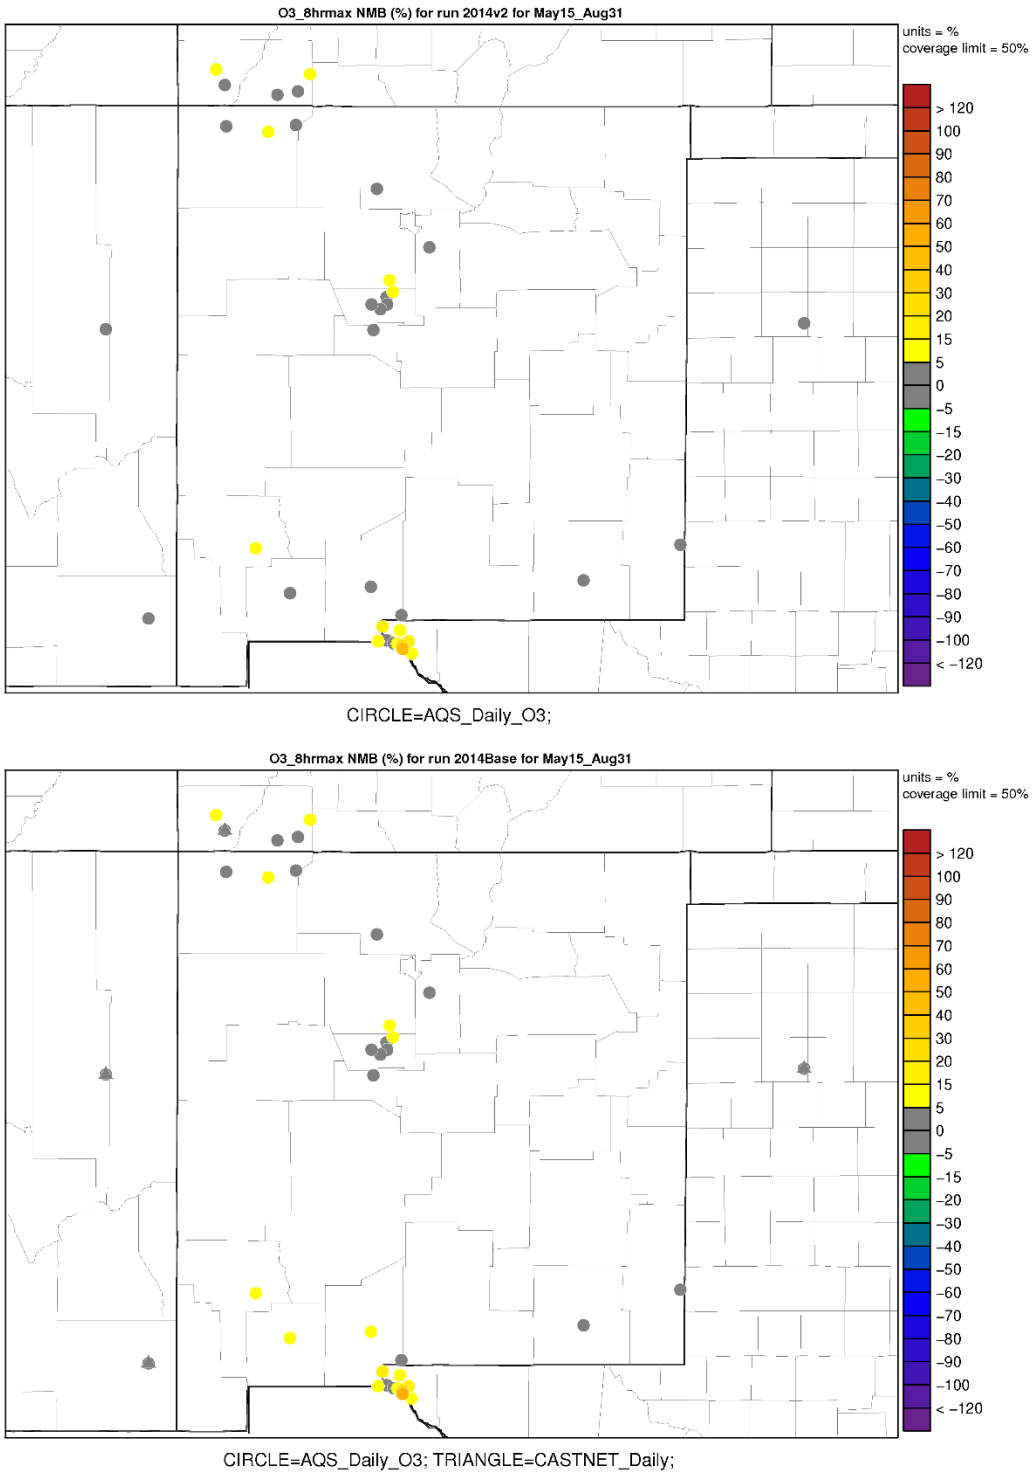

Figure 6-1. Normalized Mean Bias (NMB) for MDA8 ozone concentrations for the revised 2014v2 (top) and original 2014 (bottom) CAMx base case simulations with no ozone cutoff.

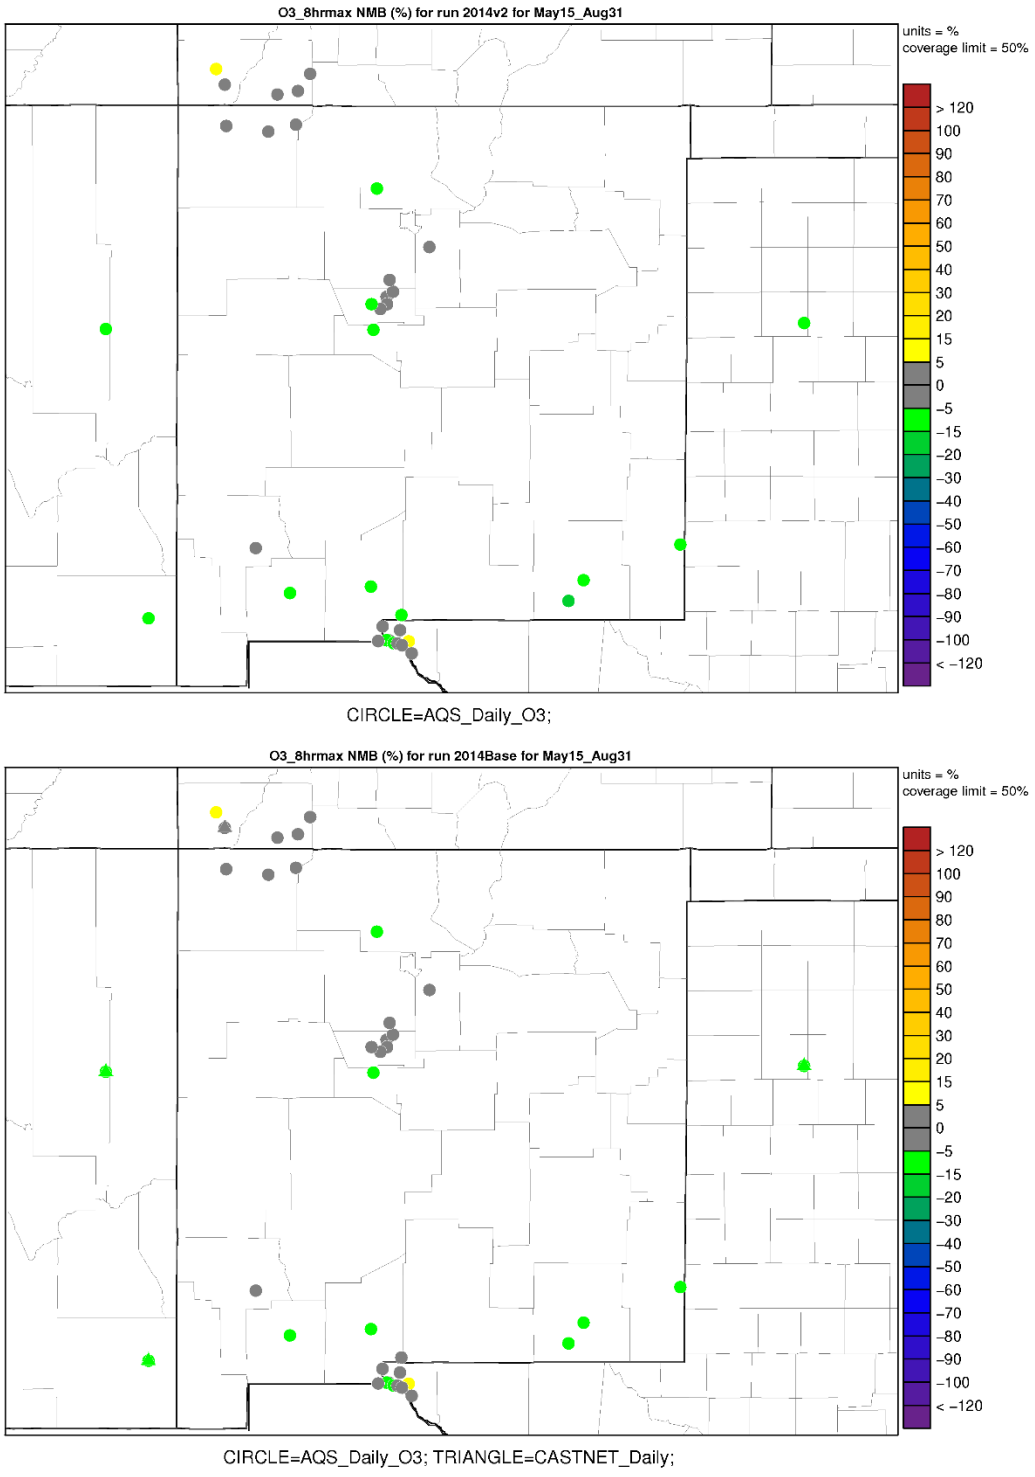

Figure 6-2. Normalized Mean Bias (NMB) for MDA8 ozone concentrations for the revised 2014v2 (top) and original 2014 (bottom) CAMx base case simulations with an observed 60 ppb ozone cutoff.

6.4 Scatter Plots of MDA8 Ozone

Figure 6-3 display scatter plots and summary statistics of MDA8 ozone across AQS or CASTNet sites in the 4-km domain for the revised 2014v2 and original 2014 CAMx base case simulations. The 2014v2 and 2014 MDA8 scatter plots look identical with the MDA8 performance at the AQS sites exhibiting a slight MDA8 ozone overestimation bias as indicated by the center density of the scatterplot being slightly above the 1:1 line of perfect agreement. This is in contrast to the CASTNet MDA8 scatterplots that are centered on the 1:1 line of perfect agreement so the two base case simulations are less biased.

The AQS performance statistics across the 4-km domain for the May-August 2014 modeling period show that the 2014v2 and 2014 MDA8 ozone performance is not exactly identical with the revised 2014v2 base case having a NMB of 4.4% that achieves the ozone bias Performance Goal, whereas the original 2014 base case has a NMB of 6.2% that falls between the ozone bias Performance Goal and Criteria. The 2014v2 NME (10.6%) is also slightly better than the original 2014 base case (10.9%).

Both CAMx base case simulations exhibit extremely good MDA8 ozone model performance across the CASTNet sites in the 4-km domain with near zero bias (-1.4% and +0.1%) and errors (8.1% and 7.9%) that are almost half the ozone error Performance Goal (<15%).

NMED Exhibit 17

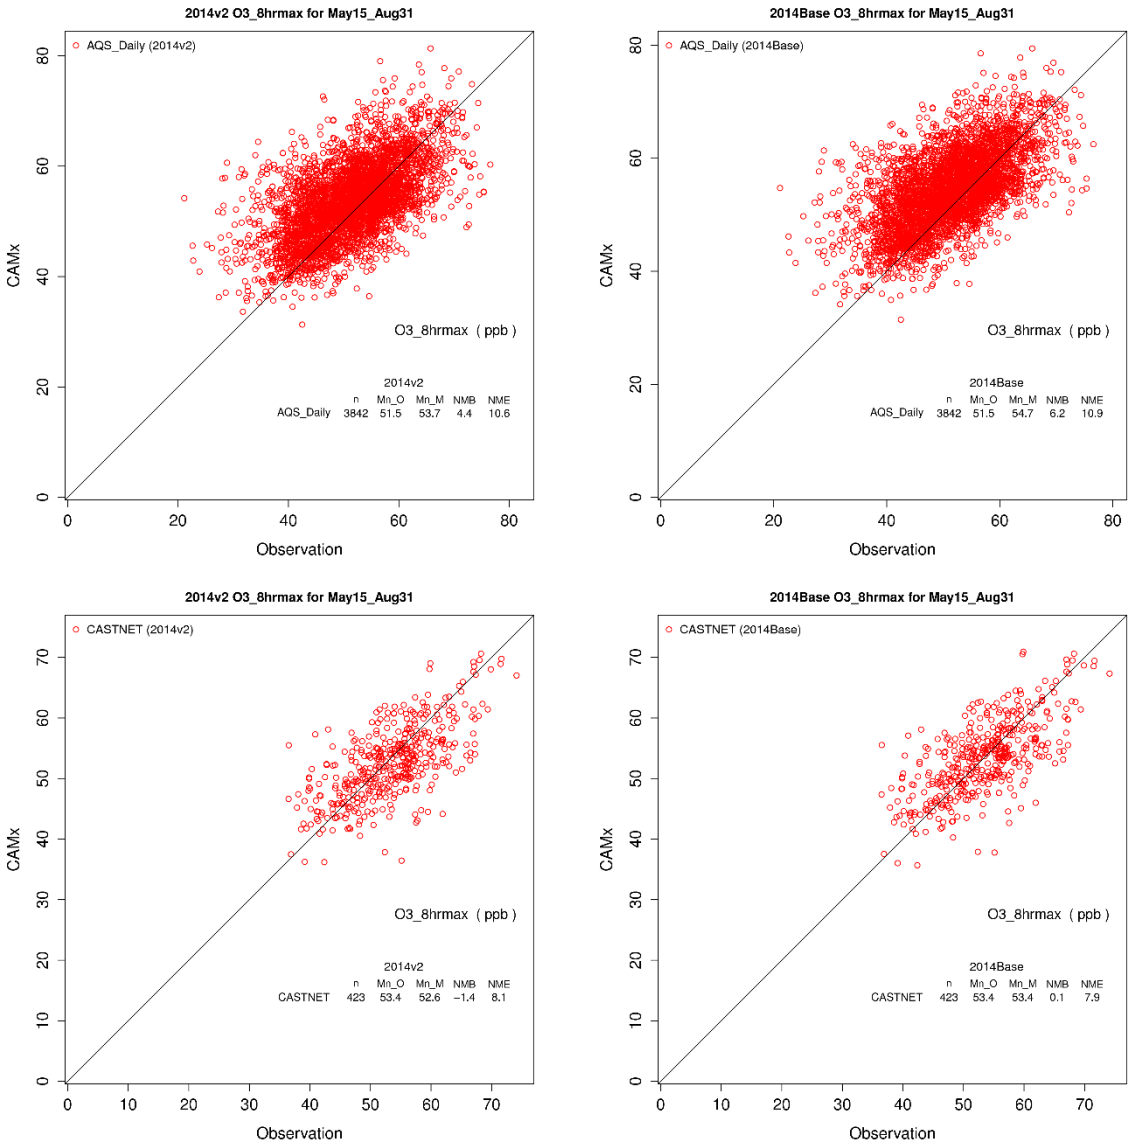

Figure 6-3. Scatter plots of predicted and observed MDA8 ozone concentrations for AQS (top) and CASTNet (bottom) monitoring sites within the 4-km New Mexico domain and the revised 2014v2 (left) and original 2014 (right) CAMx base case simulations.

6.5 MDA8 Ozone Time Series

Example predicted and observed MDA8 ozone time series at selected sites are presented below, with time series at all sites contained in the Appendix in Ramboll and WESTAR (2021). Figure 6-4 displays MDA8 ozone time series at the Desert View monitoring site in Doña Ana County in southern New Mexico. The CAMx MDA8 ozone predictions for the revised 2014v2 (blue) and original 2014 (green) base case simulations are almost on top of each other. In general, when they are a little different the revised 2014v2 MDA8 ozone is slightly lower, although that is not always the case as seen in the MDA8 ozone peaks in early June, mid-July, and end of August.

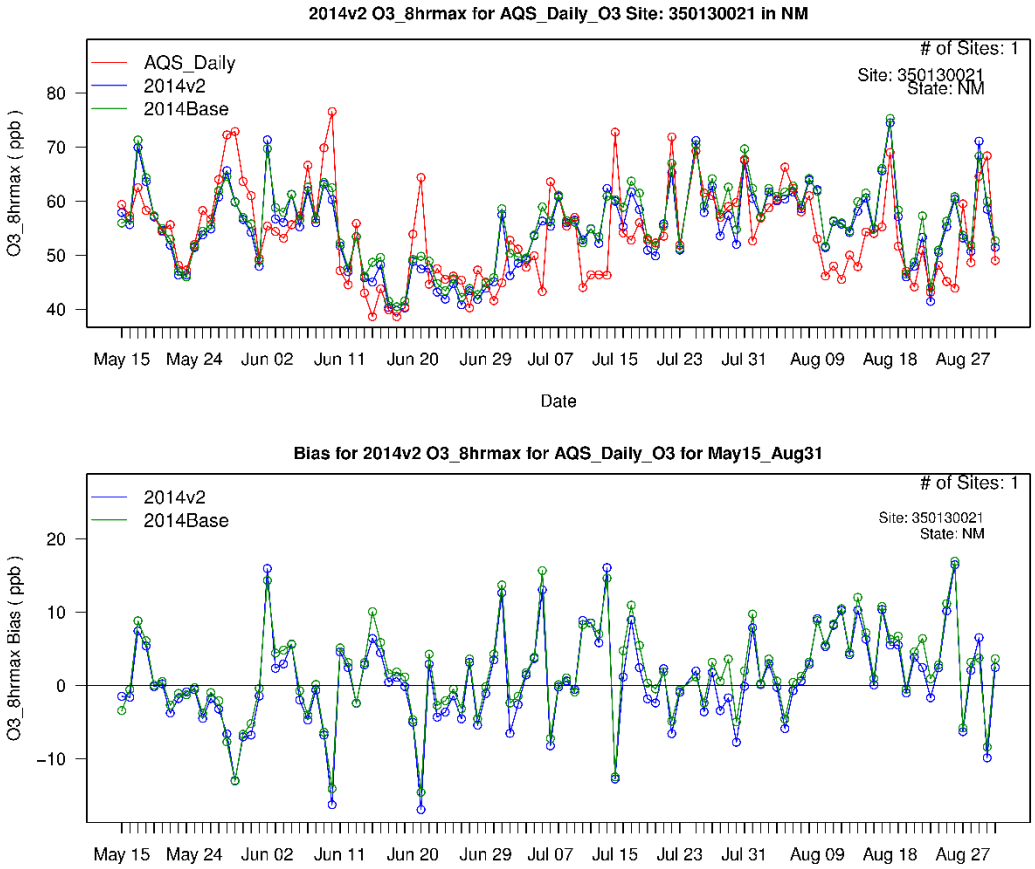

Figure 6-4. Time series of predicted and observed (red) MDA8 ozone at Desert View in Doña Ana County for the CAMx revised 2014v2 (blue) and original 2014 (green) CAMx base case simulations.

The MDA8 ozone time series comparison for the South East Heights monitoring site in Bernalillo County is shown in Figure 6-5. With the exception of a period in early July where the revised 2014v2 base case has a larger underestimation bias compared to the original 2014 base case, the two CAMx base case simulations are predicting nearly identical MDA8 ozone concentrations at this site.

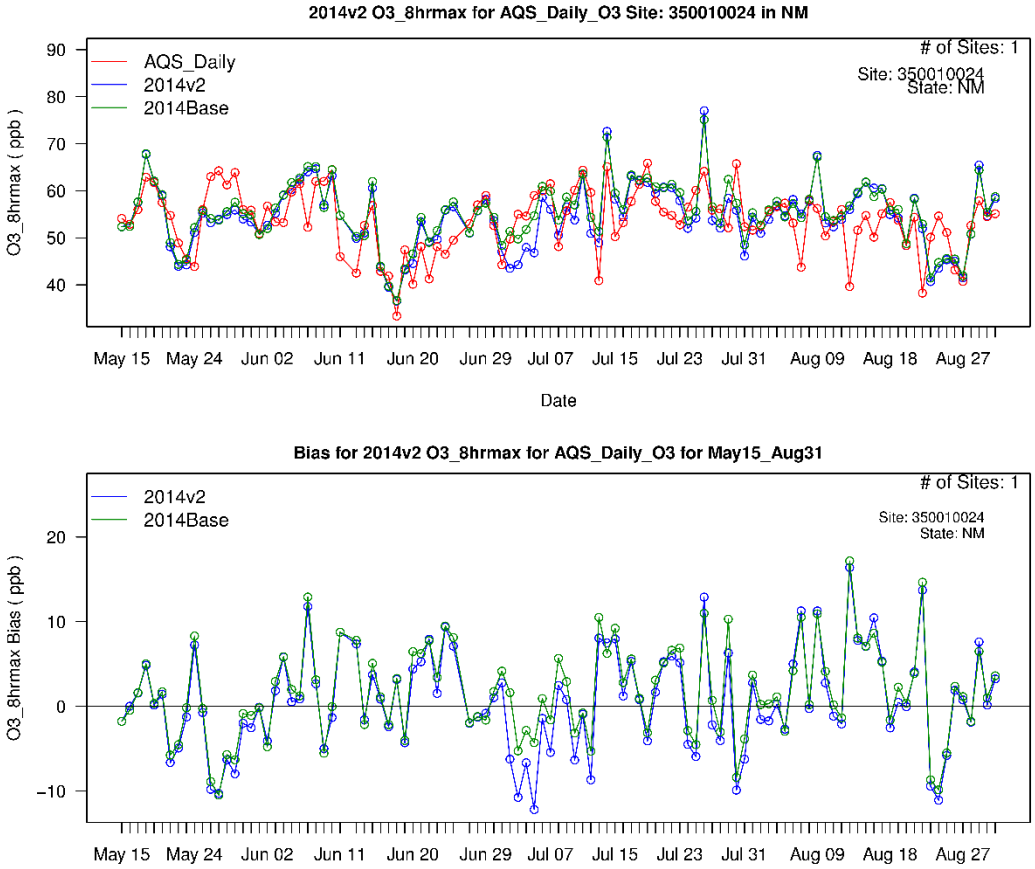

Figure 6-5. Time series of predicted and observed (red) MDA8 ozone at South East Heights in Bernalillo County for the CAMx revised 2014v2 (blue) and original 2014 (green) CAMx base case simulations.

The ozone time series at the Substation monitoring site in San Juan County is shown in Figure 6-6. Both CAMx base cases track the observed MDA8 ozone concentrations very well at the Substation monitoring site. Most of the time, the predicted MDA8 ozone are on top or nearly on top of each other and when different the revised 2014v2 MDA8 ozone is a little lower than the original CAMx 2014 base case.

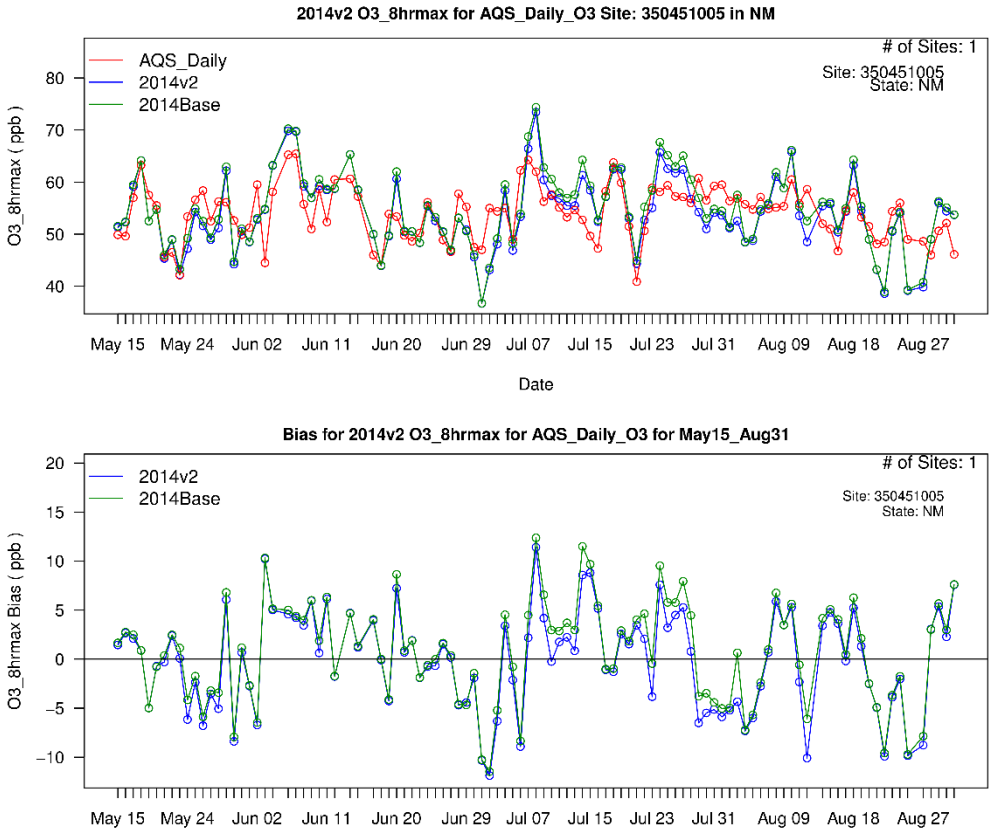

Figure 6-6. Time series of predicted and observed (red) MDA8 ozone at Sub Station in San Juan County for the CAMx revised 2014v2 (blue) and original 2014 (green) CAMx base case simulations.

6.6 Summary Ozone Model Performance Statistics in New Mexico

Ozone model performance statistics were calculated for three geographic regions in New Mexico. The central region was defined as all monitoring sites within Bernalillo County with the southern and northern regions defined as sites, respectively, south and north of Bernalillo County.

Tables 6-3 and 6-4 display the bias and error MDA8 ozone performance statistics with and without the observed MDA8 ozone 60 ppb cutoff for the three New Mexico subregions and the, respectively, original 2014 and revised 2014v2 CAMx base case simulations. The bias and error MDA8 ozone performance statistics are colored green when they achieve the Performance Goal, yellow when they lie between the Performance Goal and Criteria and red when they fail to achieve the Performance Criteria. The CAMx 2014 and 2014v2 base case performance statistics within the three New Mexico subregions are very good and very similar with the bias for the revised 2014v2 base case being 1-2 percentage points lower than the original 2014 CAMx base case simulation. Using no cutoff, when CAMx has a slight ozone overestimation tendency, the revised 2014v2 exhibits better performance statistics than the original 2014 base case. For example, the bias in the southern New Mexico region in original 2014 base case (5.8%) fails to achieve the ozone bias Performance Goal due to too high ozone overestimation, but achieves the ozone bias Performance Goal in the revised 2014v2 base case (3.5%). On the other hand, when an observed ozone 60 ppb cutoff is used the model tends to underestimate ozone a little so the revised 2014v2 base case ozone model performance is degraded a little compared to the original 2014 base case. For example, for the southern New Mexico subregion the original CAMx 2014 base case has a -6.1% NMB that is -7.8% for the revised CAMx 2014v2 base case, both of these NMB ozone performance statistics fall between the ozone bias Performance Goal and Criteria.

Table 6-3. Bias and error MDA8 ozone performance statistics for the original CAMx 2014 base case and the three subregions of New Mexico calculated with and without using an observed MDA8 ozone 60 ppb cutoff.

	Nocutoff		Withcutoff	
Region	NMB(%)	NME(%)	NMB(%)	NME(%)
North NM	4.3	9.1	0	6.4
Bernalillo	4.3	9.4	-2.8	7.1
South NM	5.8	10.5	-6.1	8.5

Table 6-4. Bias and error MDA8 ozone performance statistics for the revised CAMx 2014v2 base case and the three subregions of New Mexico calculated with and without using an observed MDA8 ozone 60 ppb cutoff.

	Nocutoff		Withcutoff	
Region	NMB(%)	NME(%)	NMB(%)	NME(%)
North NM	2.6	8.6	-1.0	6.6
Bernalillo	2.6	9.6	-4.3	8.5
South NM	3.5	10.2	-7.8	9.9

Tables 6-5 and 6-6 contain the bias performance statistics with and without a cutoff for each monitoring site in New Mexico and the, respectively, original CAMx 2014 and revised CAMx 2014v2 base case simulations. When not using the observed ozone cutoff, the original 2014 base case has 59% of the sites achieving the ozone bias Performance Goal with 36% of the sites falling between the Performance Goal and Criteria and one site failing to achieve the ozone bias Performance Criteria due to a 17.4% overestimation bias. The revised 2014v2 base case bias with no cutoff has 68% of the sites achieving the Performance Goal, 27% falling between the Performance Goal and Criteria and one site right at (15.0%) the Performance Criteria.

When an observed ozone cutoff is used, the number of sites achieving the ozone bias Performance Goal is flipped between the two base cases with 68% of the sites achieving the Performance Goal for the original 2014 base case and 59% of the sites achieving the Performance Goal for the revised 2014v2 base case with the remainder of the sites falling between the ozone bias Performance Goal and Criteria.

6.7 Conclusions of 2014 Base Case Modeling and Model Performance Evaluation

The evaluation of the NM OAI Study CAMx original 2014 and revised 2014v2 base case simulations focused on MDA8 ozone model performance across all sites within New Mexico, within three subregions in New Mexico (northern, Bernalillo County, and southern) and at individual sites in New Mexico. When examining MDA8 ozone performance across groups of sites, both CAMx 2014 base cases always achieves the ozone Performance Criteria and usually achieves the ozone Performance Goals. Except for one site (La Union in Doña Ana County) both CAMx base cases also achieve the ozone Performance Criteria at all monitoring sites and achieve the ozone Performance Goals as a majority of the sites in New Mexico. When examining MDA8 ozone performance across all observations, the model tended to have an ozone overestimation tendency but still always achieved the bias performance criteria (≤±15%) and usually achieved the bias performance goal (≤±5%). When comparing the model's ability to reproduce the highest observed ozone concentrations greater than 60 ppb, the model still always achieved the bias performance criteria and usually achieved the bias performance goal, albeit with an underestimation tendency. The

MDA8 ozone error essentially always achieves the performance goal whether examining all ozone observations or just those observations greater than 60 ppb.

In conclusion, the NM OAI Study original CAMx 2014 and revised CAMx 2014v2 base case simulations ozone model performance within New Mexico is as good or better than most recent PGM applications (e.g., WRAP-WAQS, EPA 2016v1 and Denver ozone SIP) and appears to be a reliable PGM modeling platform for evaluating emission reduction strategies for reducing ozone concentrations in New Mexico.

NMED Exhibit 17

7. 2028 BASE CASE MODELING AND OZONE DESIGN VALUE PROJECTIONS

A CAMx v7.1 2028 36/12/4-km Base Case model simulation was conducted using the WRF/NAM meteorological, 2014 Boundary Conditions (BCs) and 2028 base case emission inputs described in, respectively, Chapters 2, 3 and 4. The CAMx 2028 base case simulation used the same model configuration as used in the CAMx v7.1 2014v2 revised base case simulations presented in Chapter 6 only with the 2028 Base Case anthropogenic emissions.

The CAMx 2014v2 and 2028 Base Case simulations were used to make 2028 future-year ozone design value (DVF) projections.

7.1 EPA Recommended Ozone Design Value Projection Procedure

EPA recommends using photochemical grid model (PGM) modeling results in a relative fashion to scale the observed current year ozone design value (DVC) to estimate the future year ozone design value (DVF). The model derived scaling factors are called Relative Response Factors (RRF) and are the ratio of future (2028) to base (2014v2) year ozone modeling results averaged over the 10 highest base year base case modeled Maximum Daily 8-hour Average (MDA8) ozone concentrations near the monitor:

$$RRF = \sum Model_{2028} / \sum Model_{2014}$$

$$DVF = DVC \times RRF$$

EPA guidance recommends that the DVC is calculated as the average of three-years of ozone design values (DV) centered on the base modeling year, which is 2014 in this case:

$$DVC_{2012\text{-}2016} = (DV_{2012\text{-}2014} + DV_{2013\text{-}2015} + DV_{2014\text{-}2016}) / 3$$

By near the monitor, EPA guidance recommends that the highest modeled base year MDA8 ozone is selected within a 3x3 array of grid cells centered on the monitor. For the future year, the future year MDA8 ozone is selected from the same grid cell in the 3x3 array centered on the monitor as used in the base year.

EPA guidance recommends using the 10 highest modeled base year MDA8 ozone concentrations days with MDA8 ozone greater than 60 ppb in the RRFs. If there are less than 10 modeled days with base year MDA8 ozone greater than 60 ppb, EPA guidance states that RRFs can still be calculated as long as there are at least 5 days with ozone greater than 60 ppb.

EPA has codified their recommended ozone DVF projection approach in the Software for the Modeled Attainment Test (SMAT[37]). The SMAT tool was used to make 2028 ozone DVF projections in the NM OAI Study. The default SMAT specification were used except

[37] https://www.epa.gov/scram/photochemical-modeling-tools

that the minimum number of days needed to calculated an RRF was lowered from 5 to 4 in order to obtain 2028 ozone DV projections at all sites in New Mexico.

7.1.1 Ozone DV Unmonitored Area Analysis (UAA)

SMAT includes an unmonitored area analysis (UAA) that examines projected future year ozone DVFs away from the monitoring sites. The first step in the UAA is the spatial interpolation of the monitor-based ozone DVCs ($DVC_{2012\text{-}2016}$) across the domain being analyzed, which is the 4-km New Mexico domain in this case. The SMAT spatial interpolation of the monitoring site ozone DVC can be performed with and without using the modeled ozone concentration gradients. As shown below, the SMAT UAA analysis was run for the NM OAI Study 2028 base case ozone DVC projections with and without using the modeled concentration gradients. We recommend using the interpolation without the modeled concentration gradients because of the influence of fires on UAA interpolated ozone DVCs that are uncertain, unverifiable, and not regulatory relevant.

The SMAT UAA procedure for projecting the spatially interpolated ozone DVCs is the same as used at the monitor described above, only instead of using the modeling results in the in a 3x3 array of grid cells with the highest 2014 modeled MDA8 ozone to define near the monitor, the value at the grid cell is used (i.e., 1x1 array).

7.2 2028 Base Case Ozone DVF Projections at Monitoring Sites

Table 7-1 displays the current year $DVC_{2012\text{-}2016}$ and projected 2028 ozone DVFs at monitoring sites in New Mexico for the 2028 Base Case simulation and their differences. There are two sites in Doña Ana County with current year $DVC_{2012\text{-}2016}$ above the 70 ppb 2015 ozone NAAQS, Desert View (72.0 ppb) and Santa Teresa (71.3 ppb). However, it should be noted that measured ozone concentrations in Southern New Mexico have been higher in more recent years, as shown in Table 1-1. This issue is examined in a DVC sensitivity analysis presented in Chapter 9.

The 2028 Base Case ozone DVFs at monitoring sites in northern New Mexico are projected to be -2.2 ppb to -5.6 ppb lower than the observed $DVC_{2012\text{-}2016}$. For the northern New Mexico sites, Navajo Lake has the highest ozone $DVC_{2012\text{-}2016}$ (67.0 ppb) and 2028 Base Case projected DVF (64.8) and is the site with the lowest reduction between the DVC and DVF (-2.2 ppb).

The current observed $DVC_{2012\text{-}2016}$ in Bernalillo County range from 65.0 to 68.0 ppb and are projected to be reduced by -4.4 ppb to -5.9 ppb by 2028 with all 2028 Base Case projected ozone DVFs in Bernalillo County below 63 ppb.

The current ozone $DVC_{2012\text{-}2016}$ at the southern New Mexico sites range from 62.0 to 72.0 ppb and are reduced by -2.0 ppb to -6.3 ppb in the 2028 Base Case. The sites in Doña Ana County have the largest ozone DV reductions between 2014 and 2028 (-4.7 to -6.3 ppb). While those monitoring sites in southeast New Mexico have the lowest ozone DVF reduction between 2014 and 2028 Base Cases, -2.3 ppb at Carlsbad and -2.0 ppb at Hobbs in, respectively, Eddy and Lea Counties. The lower reductions in 2028 Base Case ozone DVFs at the two southeastern New Mexico sites are due to increased oil and gas emissions in the Permian Basin between 2014 and 2028 that offset the effects due to emission reductions from other source sectors, such as mobile sources (see Chapter 4).

NMED Exhibit 17

The current year $DVC_{2012\text{-}2016}$ and projected 2028 Base Case ozone DVFs at monitoring sites within the 4-km NM domain but outside of New Mexico are shown in Table 7-2. The El Paso UTEP site is the only site in Table 7-2 that has a $DVC_{2012\text{-}2016}$ that exceeds (71.0 ppb) the 2015 ozone NAAQS. Design values at monitoring sites in El Paso are projected to go down between -3.2 ppb to -5.2 ppb with projected 2028 Base Case ozone DVFs ranging from 62.5 ppb to 66.2 ppb.

The sites in Arizona and Colorado have current year $DVC_{2012\text{-}2016}$ that are 68 ppb or lower and are reduced from -1.6 ppb to -5.2 ppb with the smallest reductions occurring in La Plata County, Colorado and the largest reductions occurring in El Paso.

Table 7-2. Current year $DVC_{2012\text{-}2016}$ and projected 2028 Base Case ozone DVFs at monitoring sites within the 4-km NM domain but outside of New Mexico.

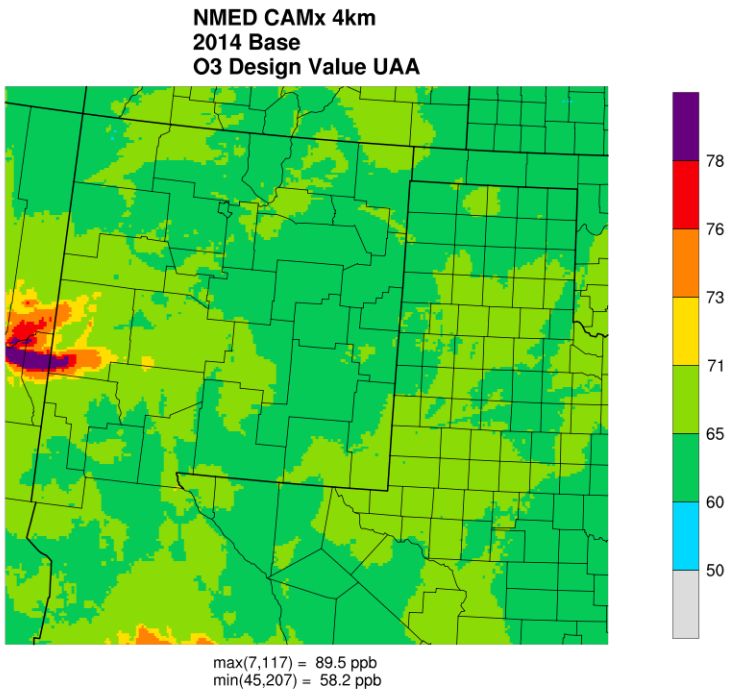
7.3 2028 Base Case Ozone DVF Unmonitored Area Analysis

SMAT was run using output the 2014v2 and 2028 Base Case CAMx simulations to obtain the spatial distribution of interpolated current year ozone $DVC_{2012\text{-}2016}$ and projected 2028 ozone DVF throughout the 4-km NM domain using the Unmonitored Area Analysis (UAA) feature. SMAT UAA was run with and without using modeled concentration gradients in the spatial interpolation of the observed ozone $DVC_{2012\text{-}2016}$ at the monitoring sites to each grid cell in the 4-km NM domain.

Figure 7-1 displays the spatial distribution of the SMAT UAA ozone $DVC_{2012\text{-}2016}$ and DVF across the 4-km NM domain calculated using CAMx modeled ozone concentrations gradients in the spatial interpolation of the $DVC_{2012\text{-}2016}$. Although the highest $DVC_{2012\text{-}2016}$ at a monitoring site is 72.0 ppb at Desert View, using modeled concentration



gradients produces an interpolated $DVC_{2012\text{-}2016}$ as high as 89.5 ppb that occurs in Arizona on the border with New Mexico that is reduced to 84.0 ppb for the maximum 2028 Base Case UAA DVF. These high MDA8 ozone concentrations in eastern Arizona and southwestern New Mexico are due to elevated ozone concentrations from wildfire emissions that are used in the SMAT UAA $DVC_{2012\text{-}2016}$ spatial interpolation when the option to use modeled concentration gradients is selected. Because they occur away from any monitoring sites, whether actual elevated ozone occurred in these wildfire ozone plumes is not known. Away from these wildfire ozone plumes, the SMAT UAA $DVC_{2012\text{-}2016}$ range from 60 to 71 ppb that are reduced to the 50 to 65 ppb range in for the SMAT UAA 2028 ozone DVF with small patches in the 65-71 ppb range scattered across New Mexico.

The SMAT UAA ozone $DVC_{2012\text{-}2016}$ and 2028 Base Case projections obtained without using the modeled concentrations gradients are shown in Figure 7-2. When doing the SMAT UAA spatial interpolation of the $DVC_{2012\text{-}2016}$ without including the concentrations gradients the ozone $DVC_{2012\text{-}2016}$ across the 4-km NM modeling domain are constrained by the $DVC_{2012\text{-}2016}$ values at the monitoring sites (i.e., Tables 7-1 and 7-2), which range from 61.4 to 71.0 ppb (10 ppb range; Figure 7-2). This is in contrast when the modeled concentrations gradients are used in the SMAT UAA interpolation and the $DVC_{2012\text{-}2016}$ range from 58.2 to 89.5 ppb across the domain (31 ppb range; Figure 7-1).

Figure 7-3 displays a spatial map of the differences in ozone $DVC_{2012\text{-}2016}$ and 2028 base case DVF (DVF – DVC) from the SMAT UAA with the top panel shown the differences with and the bottom panel showing the differences without using the modeled spatial gradients in the interpolation. Using the modeled concentration gradients in the interpolation has a significant effect on the DVC/DVFs, but has little effect on the differences in the SMAT UAA DVF and DVC. In fact, the only perceptible change in the ozone DVF and DVC differences is near the location of the modeled wildfire ozone plume in eastern Arizona.

The largest differences in current year ozone DVC and the 2028 Base Case DVF occurs in the eastern part of the domain with reductions of -4 to-11 ppb that are coming in from east Texas where there are larger emission reductions due to larger population centers. Over most of New Mexico, there are small reductions in the -1 to -4 ppb range with reductions in the -4 to -6 ppb range near Albuquerque. However, within the Permian and San Juan Basins there are small areas of ozone DVF increases with the largest increase of +3 ppb.

NMED Exhibit 17

7.4 2014v2 and 2028 MDA8 Ozone Concentrations

In this section we present spatial maps of daily MDA8 ozone and the differences in MDA8 ozone for the 2014v2 and 2028 Base Case CAMx simulations for six example days. MDA8 ozone concentration and difference plots were generated for all ~100 days of the modeling episode, most of which were fairly low ozone concentration days so are of less interest.

7.4.1 Daily 2014v2 and 2028 Base Case MDA8 Ozone Concentrations

Figures 7-4 through 7-9 display example spatial maps of MDA8 ozone concentrations for the CAMx 2014v2 and 2028 Base Case simulations and their differences for six example days.

The most prominent features in the estimated MDA8 ozone concentrations on May 17, 2014 are locations of very high (> 80 ppb) ozone concentrations in eastern Arizona and southwest New Mexico (Figure 7-4). These high ozone concentrations have a signature of ozone from wildfires with the largest being an ozone plume being transported into western New Mexico from a wildfire in eastern Arizona. Although there are no ozone monitors located in the center of these model-estimated highly elevated ozone plumes, the Chino Copper Smelter site in Grant County is within the edge of the plume where the model estimates MDA8 ozone concentrations in the 65-71 ppb range that match the observed concentrations at this site extremely well for the May-June 2014 portion of the episode (see Appendix A in Ramboll and WESTAR, 2020c; 2021). Over most of New Mexico, the 2028 Base Case has lower MDA8 ozone concentrations with reductions as high as -11 ppb in southwest Torrance County. However, the 2028 Base Case has MDA8 ozone increases in the San Juan and Permian Basins with a maximum MDA8 ozone increase of +5 ppb in Eddy County.

On June 5, 2014, the 2014v2 Base Case has CAMx-estimated MDA8 ozone concentrations in the 65-71 ppb range in northwest New Mexico and in Doña Ana County with even a small location of MDA8 ozone exceeding the 2015 ozone NAAQS in the northeast corner of San Juan County and a modeled peak MDA8 ozone concentration of 72.9 ppb occurring in El Paso just over the border from Doña Ana County (Figure 7-5). Although the emission changes from 2014v2 to 2028 reduce the intrusion of elevated ozone entering Doña Ana County from El Paso, the elevated ozone in northwest New Mexico is increased. The area of estimated MDA8 ozone in San Juan County that is above the 2015 ozone NAAQS is larger in the 2028 Base Case than the 2014v2 Base Case and stretches into Rio Arriba County with a peak ozone value of 74 ppb in Colorado at the border with New Mexico. As shown in the MDA8 ozone difference plot in Figure 7-5, increases in MDA8 ozone concentrations in the 2028 Base Case are due to increased O&G emissions within the Permian and San Juan Basins.

Although the 2014v2 and 2028 Base Case estimated MDA8 ozone on July 12, 2014 is well below the NAAQS (mostly < 60 ppb with small pockets in the 60-65 ppb range), the 2028 Base Case has increases MDA8 ozone in the San Juan and Permian Basins with a maximum increase of +11.4 ppb (Figure 7-6). The maximum decrease in MDA8 ozone is -7.6 ppb near Albuquerque.

On July 24, 2014, the CAMx 2014v2 Base Case estimates elevated MDA8 ozone concentrations in northwest New Mexico with values even exceeding the 2015 ozone

NMED Exhibit 17

NAAQS in San Juan County and a peak value of 74.7 ppb in Colorado at the border with New Mexico (Figure 7-7). The 2028 Base Case has lower ozone than the 2014v2 Base Case across New Mexico with only small areas of ozone increases. The area of MDA8 ozone in San Juan County that was above the 2015 ozone NAAQS in the 2014v2 Base Case is reduced to below the NAAQS in the 2028 Base Case, although the peak MDA8 ozone in Colorado at the border of New Mexico still exceeds the NAAQS (71.3 ppb).

The CAMx 2014v2 Base Case estimates a high peak MDA8 ozone concentration of 78.4 ppb in Albuquerque with several additional areas of high ozone above the NAAQS occurring in other northern New Mexico Counties on July 26, 2014 (Figure 7-8). Although the 2028 Base Case has reduced almost all of the areas with 2014v2 MDA8 ozone above the NAAQS, there is still an estimate ozone peak above the NAAQS (72.3 ppb) just west of Albuquerque in northeast Cibola County. Ozone increases are seen in the Permian and San Juan Basins on July 26 with the highest increase of +5.7 ppb occurring in the San Juan Basin.

An ozone peak of 74.1 ppb occurs on August 14 on the border of Doña Ana County and El Paso with ozone in excess of the NAAQS stretching into Doña County (Figure 7-9). The emission reductions in the 2028 Base Case appear reduce the estimated ozone in Doña County to below the NAAQS, although the peak ozone (71.2 ppb) just over the border in El Paso still exceeds the NAAQS. Ozone increases in the Permian and San Juan Basins are mostly less than +1 ppb and fairly isolated on this day.

7.4.2 Comparison of Episode Maximum MDA8 and SMAT UAA Ozone DVF Differences

Figure 7-10 compare the differences in episode maximum MDA8 ozone concentrations and SMAT UAA ozone DVs between the 2014v2 and 2028 Base Case simulations (the SMAT UAA ozone DV differences are without using concentration gradients and was shown previously in the bottom panel of Figure 7-3). Not surprisingly, since the SMAT UAA DVs represents an average across several modeling days, the episode maximum MDA8 ozone differences have higher changes than the SMAT UAA ozone differences with a maximum increase of +5 ppb vs. +3 ppb and maximum decrease of -12 ppb vs. -11 ppb for the, respectively, episode maximum MDA8 ozone and UAA DVs. The largest decreases occur in Albuquerque and in southern Doña Ana County on the border with El Paso. The largest increases in ozone occur in the San Juan and Permian Basin.

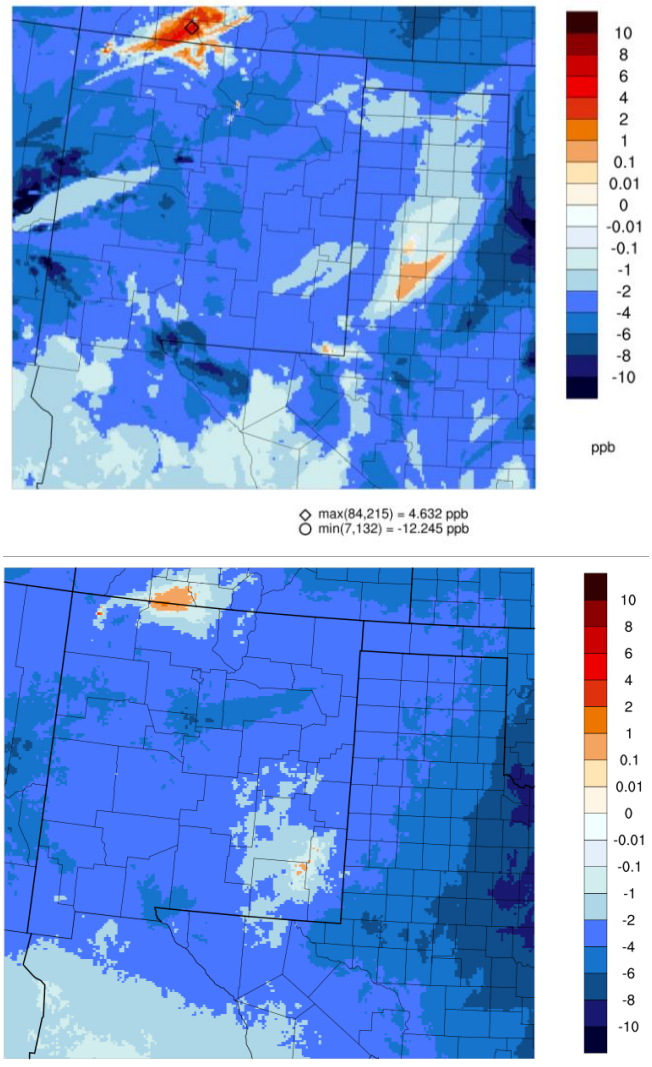

Figure 7-10. Differences in episode maximum MDA8 ozone concentrations (top) and SMAT UAA ozone DVs (bottom) between the 2014v2 and 2028 CAMx Base Case simulations.

8. 2028 OIL AND GAS CONTROL STRATEGY MODELING AND OZONE DESIGN VALUE PROJECTIONS

The implementation of the proposed New Mexico oil and gas (O&G) ozone precursor control strategy reduces VOC and NO_x emissions in the New Mexico portions of the San Juan and Permian Basins, as discussed in Section 4.5. Most of the O&G emission reduction in the San Juan Basin occur in northeastern San Juan and northwestern Rio Arriba Counties. While most of the emission reductions in the Permian Basin occur in Eddy and Lea Counties.

8.1 2028 Ozone Design Value Comparisons

The same procedures as used to project 2028 ozone DVFs for the CAMx 2028 Base Case (DVF_{Base}) were used to project the 2028 ozone DVFs for the 2028 O&G Control Strategy scenario (DVF_{Cntl}). These procedures start with an observed current year design value that is an average of 3 design values over 5-years ($DVC_{2012\text{-}2016}$) that is scaled by Relative Response Factors (RRFs) based on the ratio of the 2028 O&G Control Strategy over the 2014v2 Base Case CAMx ozone results to obtained a projected 2028 ozone DVF_{Cntl} for the 2028 O&G Control Strategy.

8.1.1 Ozone Design Values at the Monitoring Sites

Table 8-1 list the current year ozone $DVC_{2012\text{-}2016}$ and the projected 2028 ozone DVFs for the 2028 Base Case and 2028 O&G Control Strategy and the differences in the two 2028 ozone DVFs (DVF_{Cntl} – DVF_{Base}).

At monitoring sites in northern New Mexico, the 2028 ozone DVF_{Base} values are estimated to be reduced by -0.2 to -1.5 ppb due to the 2028 O&G Control Strategy with the largest reductions occurring at the Navajo Lake (-1.5 ppb) and Substation (-1.2 ppb) monitoring sites in San Juan County. After implementation of the 2028 O&G Control Strategy, the projected 2028 ozone DVF_{Cntl} in northern New Mexico range from 58.1 to 63.3 ppb.

Although not as close to the 2028 O&G emission reductions, the 2028 projected ozone DVF_{Cntl} in Bernalillo County see benefits of the 2028 O&G Control Strategy with ozone DVF reductions of -0.2 to -0.5 ppb. After implementation of the 2028 O&G Control Strategy, the projected 2028 ozone DVF_{Cntl} range from 58.8 to 62.1 ppb in Bernalillo County.

The 2028 ozone DVF reductions due to the 2028 O&G Control Strategy at the southern New Mexico monitoring sites range from -0.2 to -0.7 ppb with the largest reductions occurring at the Hobbs (-0.7 ppb) and Carlsbad (-0.3 ppb) monitoring sites in, respectively, Eddy and Lea Counties that lie within the Permian Basin. The other monitoring sites in southern New Mexico are farther away from the Permian Basin so have much more modest reductions in ozone DVFs (-0.1 to -0.2 ppb) due to the controls on oil and gas sources. After implementation of the 2028 O&G Control Strategies, the projected 2028 ozone DVF_{Cntl} at southern New Mexico sites range from 58.9 ppb to 66.8 ppb.

Table 8-2 list the observed ozone $DVC_{2012\text{-}2016}$ and projected 2028 ozone DVFs for monitoring sites outside of New Mexico but within the 4-km NM modeling domain. There are small reductions in projected ozone DVFs in Arizona (0.0 and -0.1 ppb) and El Paso, Texas (0.0 to -0.2 ppb) due to the New Mexico 2028 O&G Control Strategy. However, there are more substantial reductions in projected 2028 ozone DVFs at sites in La Plata (-0.7 and -0.9 ppb) and Montezuma (-0.5 ppb) counties in southwestern Colorado that are adjacent to the New Mexico portion of the San Juan Basin where some of the 2028 O&G Control Strategy emission reductions occur.

Table 8-2. Observed ozone $DVC_{2012\text{-}2016}$ and projected 2028 ozone DVFs for the 2028 Base Case and 2028 O&G Control strategy and differences in the 2028 ozone DVFs ($DVF_{Cntl} - DVF_{Base}$).

8.1.2 2028 O&G Control Strategy Ozone DVF Unmonitored Area Analysis

The SMAT Unmonitored Area Analysis (UAA) was applied to estimate the spatial distribution of projected 2028 ozone DVF_{Cntl} throughout the 4-km NM modeling domain. Figure 8-1 displays the spatial distribution of the SMAT UAA ozone DVFs for the 2028 Base Case and 2028 O&G Control Strategy where the SMAT UAA was applied without using concentration gradients in the spatial interpolation of the $DVC_{2012\text{-}2016}$. Within New Mexico, the projected 2028 DVF_{Base} tends to be mostly in the 60-71 ppb range, with a few small locations with the values dropping below 60 ppb. The highest ozone concentrations (65-71 ppb) in New Mexico for the 2028 ozone DVF_{Base} occur in the San Juan and Permian Basin as indicated by the lighter green shading (Figure 8-1, top panel). When the O&G Control Strategy is applied, the ozone DVF_{Cntl} in the San Juan Basin is lower (i.e., in the 60-65 ppb with the light green shading completely gone) and the area of ozone DVF_{Base} in the 65-71 ppb range is greatly reduced for the ozone DVF_{Cntl} case.

Figure 8-2 shows a spatial map of the differences in SMAT UAA projected 2028 ozone DVFs between the 2028 Base Case and 2028 O&G Control Strategy (DVF_{Cntl} – DVF_{Base}) where the top and bottom panels represent ozone DVF differences without and with using the modeled concentration gradients in the SMAT UAA spatial interpolation. As shown in Chapter 7, use of concentration gradients has a large effect on the projected 2028 ozone DVFs, but it has no material effect on the differences in the ozone DVFs for the two 2028 emission scenarios as the plots appear almost identical.

Within the Permian Basin, the 2028 O&G Control Strategy reduces the ozone DVF by -0.5 to -1.5 ppb with most of the largest reductions (-1.0 to -1.5 ppb) occurring in Lea County. The 2028 O&G Control Strategy has a larger effect on the 2028 ozone DVF in the San Jun Basin with reductions of -1.0 to -3.0 ppb with the largest reductions (-2.0 to -3.0 ppb) straddling the New Mexico/Colorado state line at Rio Arriba/Archuleta Counties.

There are also isolated grid cells of SMAT UAA ozone DVF increases in the Permian and San Juan Basins due to the 2028 O&G Control Strategy. These ozone DVF increases appear to be several isolated 4-km grid cells and are likely due to highly localized ozone increases at the locations of O&G point source NO_x emission reductions due to the O&G Control Strategy. Most (e.g., 90-95%) fresh emissions of oxides of nitrogen (NO_x) are in the form of nitric oxide (NO) that is converted fairly quickly to nitrogen dioxide (NO_2). The NO-O_3 titration reaction ($NO + O_3 \rightarrow NO_2 + O_2$) occurs very quickly and can locally deplete ozone concentrations due to the fresh NO emissions while forming NO_2 that can form ozone further downwind during photochemistry. This can result in localized ozone increases when NO_x emissions are reduced in high NO_x emission areas, such as large urban areas or within NO_x point source plumes. The so called "NO_x Disbenefits" effects (i.e., local ozone increases due to NO_x emission reductions) has been verified in numerous measurement and modeling studies and has been one reason that in the past Los Angeles was more likely to have higher ozone on weekend days than weekdays because of the lower morning NO_x emissions on weekend days (the "weekend effect"). Over the years as NO_x emissions have been controlled, the effects of "NO_x Disbenefits" has been lessening but can still occur in major urban areas and in NO_x point source plumes.

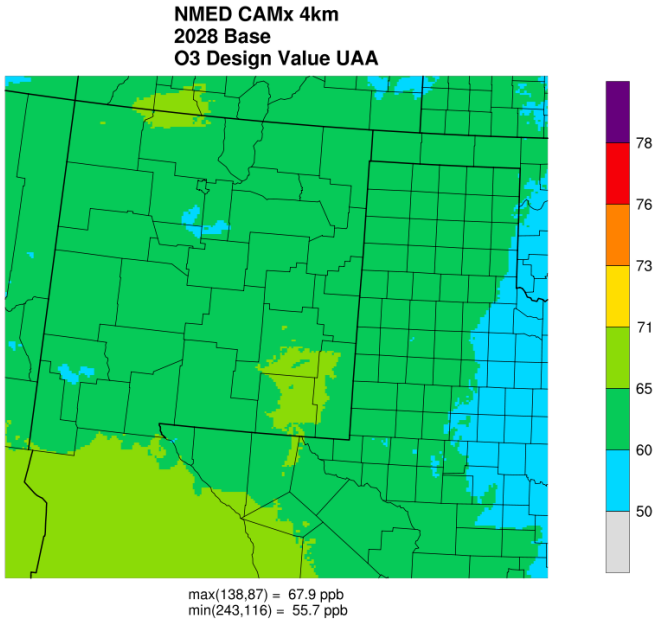

Figure 8-1. SMAT UAA spatial distribution of projected 2028 ozone DVF_{Base} (top) and DVF_{Cntl} (bottom).

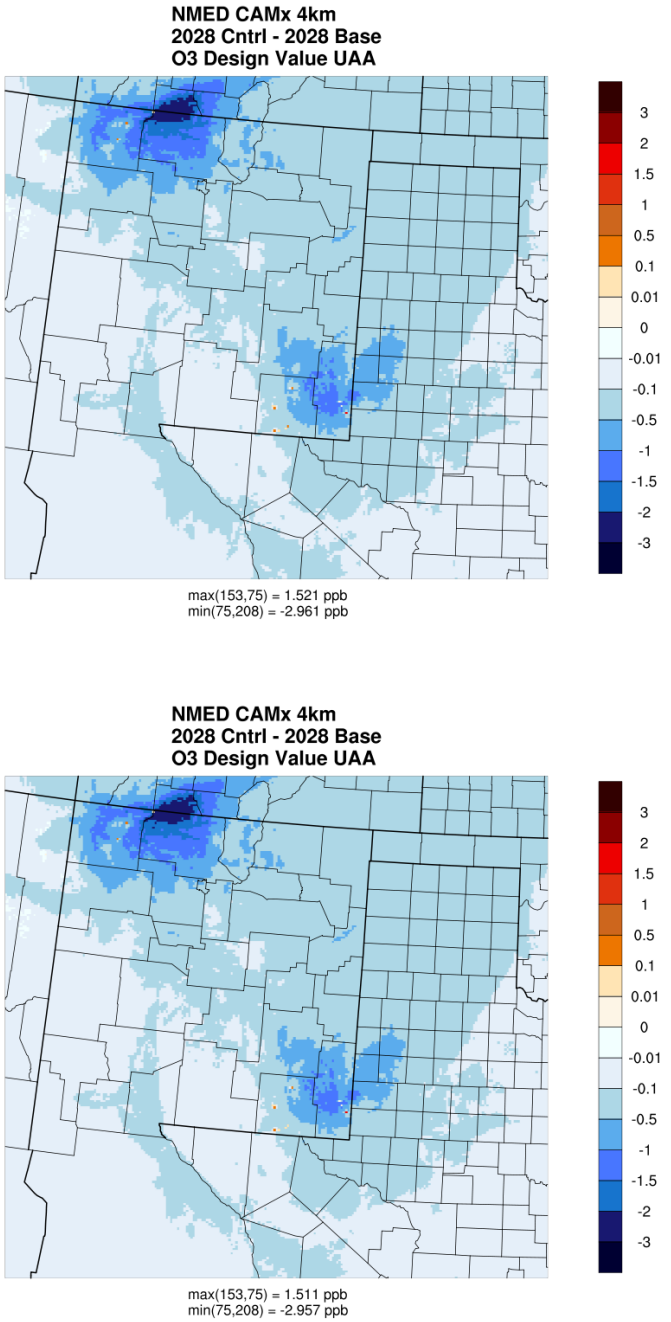

Figure 8-2. Differences in SMAT UAA projected 2028 ozone DVFs (ppb) for the 2028 Base Case and 2028 O&G Control Strategy (DVF_{Cntl} – DVF_{Base}) running SMAT without (top) and with (bottom) using modeled concentration gradients in the $DVC_{2012\text{-}2016}$ spatial interpolation.

8.2 2028 Base Case and 2028 O&G Control Strategy MDA8 Ozone Concentrations

In this section we present spatial maps of modeled MDA8 ozone and the differences in MDA8 ozone for the 2028 Base Case and O&G Control Strategy emission scenarios for several example days.

8.2.1 Daily 2014v2 and 2028 Base Case MDA8 Ozone Concentrations

Figures 8-3 through 8-8 display example spatial maps of MDA8 ozone concentrations and their differences for the two CAMx 2028 emission scenarios for the same six days that were used to compare the 2014v2 and 2028 Base Case results that were presented in Figures 7- through 7-9. However, in the MDA8 difference plots for the two 2028 emission scenarios, a finer scale is used to better illustrate the 2028 MDA8 ozone differences due to the implementation of the O&G Control Strategy in 2028.

As discussed in Chapter 7, CAMx estimates very high MDA8 ozone concentrations on May 17, 2014 that are due to emissions from wildfires (Figure 8-3). The 2028 O&G Control Strategy scenario reduces the MDA8 ozone within the San Juan and Permian Basins by from -1 to -3 ppb on May 17th, with ozone reductions of -0.1 to -0.5 ppb spanning the area between the two Basins. There are areas of MDA8 ozone increases around the western edges of the O&G control area in the San Juan Basin with ozone increases as high as +1.4 ppb.

On June 5, 2014, the 2028 Base Case has CAMx-estimated MDA8 ozone concentrations in excess of the 70 ppb 2015 ozone NAAQS in northeast San Juan and northwest Rio Arriba Counties with a peak MDA8 ozone of 74 ppb on the border with and just inside of Colorado (Figure 8-4). The 2028 O&G Control Strategy is very effectively reducing these high MDA8 ozone exceedances in the San Juan Basin with ozone reductions of up to -4.6 ppb that reduce the MDA8 ozone to below the 2015 ozone NAAQS in San Juan and Rio Arriba Counties. MDA8 ozone is also reduced in the Permian Basin, although not nearly as great as in the San Juan Basin on this day. There are very small areas of ozone increases due to the 2028 O&G Control Strategy within New Mexico that are less than 0.1 ppb, although they are as high as 0.4 ppb near the Four Corners location.

The 2028 Base Case MDA8 ozone on July 12, 2014 in New Mexico is mostly below 60 ppb (blue) with some isolated areas slightly above that (green; Figure 8-5). The 2028 O&G Control Strategy results in MDA8 ozone reductions of more than -0.5 ppb over large areas expanding out of the two O&G Basins with reductions as high as -4.6 ppb in the San Juan Basin and as high as -1.0 to -1.5 ppb reduction in the Permian Basin. In the Permian Basin in the southeast corner of New Mexico, there are ozone increases due to the 2028 O&G Control Strategy that appear to be mostly in the +0.1 to +0.5 ppb range, with a peak increase of +1.6 ppb.

Elevated MDA8 ozone concentrations approaching, but below, the 2015 ozone NAAQS are estimated to occur in San Juan County on July 24, 2014 with a peak value of 71.3 ppb that is above the NAAQS occurring right across the border in Colorado (Figure 8-6). Although the 2028 O&G Control Strategy reduces the MDA8 ozone on this day across wide areas of New Mexico, with ozone reductions as high as -2.8 ppb in the Permian Basin, there are estimated increases in MDA8 ozone in San Juan County. These MDA8 ozone increases in San Juan County due to the 2028 O&G Control Strategy and are as high as +6.4 ppb. These increased in MDA8 ozone concentrations in San Juan County

due to the 2028 O&G Control Strategy are sufficient to increase the MDA8 ozone concentration in one grid cell to 71.0 ppb, which exceeds the 2015 ozone NAAQS.

On July 26th there are patches of elevated MDA8 ozone in the 2028 Base Case in the 65-71 ppb range in northern New Mexico with a peak MDA8 ozone concentration of 72.3 ppb in the northeast corner of Cibola County that exceeds the ozone NAAQS (Figure 8-7). The 2028 O&G Control Strategy reduces the MDA8 ozone Peak in Cibola County by -0.4 ppb to 71.9 ppb, which still exceeds the NAAQS. The 2028 O&G Control Strategy results in reductions in MDA8 ozone concentrations in excess of -3.0 ppb in the San Juan and Permian Basins with a maximum reduction 0f -5.4 ppb. The ozone reductions in the San Juan Basin are sufficient to reduce MDA8 ozone concentrations that were in the 65-71 ppb range in the 2028 Base Case to below 65 ppb.

On August 14, 2014, there are small areas of MDA8 ozone concentrations in the 65-71 ppb range in New Mexico on the northern border with Colorado and in southern border in Doña Ana County with the domain-wide peak ozone of 71.2 ppb just over the border from Doña Ana County in El Paso (Figure 8-8). The 2028 O&G Control Strategy has little effects on the MDA8 ozone peak in El Paso that remains at 71.2 ppb. The 2028 O&G Control Strategy reduces MDA8 ozone in the San Juan and Permian Basins by as much as -1.8 ppb; the ozone reductions in San Juan County reduce the size of the elevated ozone in the 65-71 ppb range. There are also areas of ozone increases to the west and northeast of the San Juan Basin due to the 2028 O&G Control Strategy that are as much as +1.6 ppb.

8.3 Conclusions of the 2028 Base and 2028 O&G Control Strategy Modeling

The O&G Control Strategy results in wide areas of reductions in 2028 Base Case MDA8 ozone concentrations and SMAT UAA projected 2028 ozone DVFs across large portions of New Mexico, with the largest ozone reductions occurring in the San Juan and Permian Basins. There are also areas of increases in MDA8 ozone and SMAT UAA projected 2028 ozone DVFs due to the O&G Control Strategy that usually occur in isolated locations within and near the San Juan and Permian Basin. The ozone increases in the SMAT UAA projected DFVs across New Mexico due to the O&G Control Strategy occur in a few isolated grid cells in the San Juan and Permian Basins; the projected 2028 ozone DVFs at all the monitoring sites saw only ozone reductions with no ozone increases due to the O&G Control Strategy. The size of the areas and magnitudes of the ozone reductions due to the 2028 O&G Control Strategy scenario were much greater than the ozone increases.

Using the current year ozone design value from 2012-2016 ($DVC_{2012\text{-}2016}$), the projected 2028 ozone DVFs for both the 2028 Base Case and 2028 O&G Control Strategy are below the 70 ppb 2015 ozone NAAQS with the highest values for the 2028 Base and O&G Control Cases occurring at the Desert View (67.0 and 66.8 ppb) monitoring site in Doña Ana County and the Carlsbad (66.7 and 66.4 ppb) monitoring site in Eddy County. However, as noted in Chapter 1 (Table 1-1), more recent observed DVs at Desert View and Carlsbad are much higher than the observed current year $DVC_{2012\text{-}2016}$ used in the 2028 ozone DVF projections presented in Chapters 7 and 8. The sensitivity of the choice of current year DVC on the projected 2028 ozone DVFs is analyzed in Chapter 9.

NMED Exhibit 17

9. SENSITIVITY OF PROJECTED 2028 OZONE DESIGN VALUES TO CURRENT YEAR OZONE DESIGN VALUES

Following EPA photochemical grid modeling guidance ozone projection procedures, the projected 2028 future year ozone design values (DVFs) were below the 70 ppb 2015 ozone NAAQS at all monitoring sites in New Mexico. EPA's guidance uses as a starting point for the future year ozone projections an average of three current year design values centered on the base modeling year (i.e., $DVC_{2012\text{-}2016}$). However, at many sites in New Mexico, the current year $DVC_{2012\text{-}2016}$ is lower than the most recent 2017-2019 ozone design values ($DV_{2017\text{-}2019}$). For example, at the Desert View site in Doña Ana County the most recent $DV_{2017\text{-}2019}$ is 77 ppb that is 5 ppb higher than the $DVC_{2012\text{-}2016}$ (72.0 ppb). And the most recent $DV_{2017\text{-}2019}$ at the Carlsbad site in Eddy County (79 ppb) is 7.7 ppb higher than the $DVC_{2012\text{-}2016}$ (71.3 ppb) used in the 2028 ozone DVF projections presented in Chapters 7 and 8.

In this Chapter we examine the sensitivity of the 2028 ozone DVF projections to the observed current year ozone design value (DVC) used as the starting point for the 2028 ozone DVF projections. Instead of using the $DVC_{2012\text{-}2016}$ as the starting point for the 2028 ozone DVF projections, we use the average of three ozone design values from 2015-2019 5-year period (i.e., $DVC_{2015\text{-}2019}$) and also conduct 2028 ozone DVF projections using the latest ozone $DV_{2017\text{-}2019}$ as the DVC. Note that we are still using the CAMx 2014v2 Base Case modeling results for the denominator of the RRFs used to make the 2028 ozone DVF projections that will not account for the changes in emissions between 2014 and the more current years that affect the magnitude of the ozone $DVC_{2015\text{-}2019}$ and $DV_{2017\text{-}2019}$. This includes emission reductions from mobile sources as well as emission increases from O&G sources. Thus, the 2028 ozone DVF projection sensitivity analysis to base year ozone DVC has uncertainties and will likely overstate 2028 ozone DVFs in and near the Permian Basin where the more current year O&G emissions are higher than they were in 2014 and understate the DVFs in areas not affected by O&G emissions from the Permian Basin.

9.1 2028 Ozone Design Value Sensitivity Analysis using $DVC_{2015\text{-}2019}$

Table 9-1 presents the current year ozone design value from 2015-2019 ($DVC_{2015\text{-}2019}$) and the projected 2028 ozone DVFs using the $DVC_{2015\text{-}2019}$ as the ozone projection DVC starting point. The $DVC_{2015\text{-}2019}$ are higher than the EPA-recommended (EPA, 2018) $DVC_{2012\text{-}2016}$ used as the ozone DVF projection starting point in Chapters 7 and 8. For example, there are four monitoring sites with $DVC_{2015\text{-}2019}$ above the NAAQS with Desert View (74.3 ppb), Santa Teresa (74.0 ppb), and Carlsbad (73.7 ppb) having $DVC_{2015\text{-}2019}$ of, respectively, 2.3, 2.7 and 4.7 ppb higher than the corresponding $DVC_{2012\text{-}2016}$. Note that the $DVC_{2015\text{-}2019}$ at Carlsbad Caverns NP (71.0 ppb) also exceeds the NAAQS, however it was not in operation for the $DVC_{2012\text{-}2016}$ period and the $DVC_{2015\text{-}2019}$ is based on just 3-years of data (2016-2018), so is actually based on just one design value, $DV_{2016\text{-}2018}$.

NMED Exhibit 17

The 2028 projected ozone DVFs for the 2028 Base Case using the current year $DVC_{2015\text{-}2019}$ has one monitoring site that exceeds the 2015 ozone NAAQS, 71.2 ppb at Carlsbad. The next highest 2028 ozone DVFs for the 2028 Base Case are 69.3 ppb at Carlsbad Caverns NP and 69.1 ppb at Desert View.

The emissions controls in the 2028 O&G Control Strategy are sufficient to reduce the 2028 Base Case ozone DVF at Carlsbad (71.2 ppb) to below the ozone NAAQS (70.9 ppb) when $DVC_{2015\text{-}2019}$ current year design value is used in the 2028 ozone DVF projections.

Table 9-1. Projected 2028 ozone DVFs for the 2015-2019 current year design value $DVC_{2015\text{-}2019}$ sensitivity analysis.

9.2 2028 Ozone Design Value Sensitivity Analysis using $DVC_{2017\text{-}2019}$

Table 9-2 shows the results of the 2028 ozone DVF projection current year ozone design value sensitivity analysis using the latest 2017-2019 ozone design value as the starting point for the 2028 ozone projections. There are three monitors in New Mexico with $DV_{2015\text{-}2019}$ above the NAAQS: Desert View (77.0 ppb), Santa Teresa (76.0 ppb) and Carlsbad (79 ppb). These $DV_{2017\text{-}2019}$ values are, respectively, 5.0, 4.7 and 10.0 ppb higher than the $DVC_{2012\text{-}2016}$ used as the

ozone projection starting point in the 2028 ozone DVF projections presented in Chapters 7 and 8.

For the 2028 Base Case, there are two sites with projected 2028 ozone DVFs in the $DV_{2017\text{-}2019}$ current year design value sensitivity test that have DVF values above the 2015 ozone NAAQS: 71.6 ppb at Desert View and 76.4 ppb at Carlsbad. The 76.0 ppb $DV_{2017\text{-}2019}$ at Santa Teresa is reduced to 70.5 ppb under the 2028 Base Case so attains the ozone NAAQS.

The projected 2028 ozone DVF using the $DV_{2017\text{-}2019}$ as the current year DVC under the O&G Control Strategy are 71.4 ppb at Desert View and 76.0 at Carlsbad so still exceed the 2015 ozone NAAQS. In fact, the Carlsbad 76.0 ppb ozone DVF even exceeds the 2008 ozone NAAQS.

Table 9-2. Projected 2028 ozone DVFs for the 2017-2019 current year design value $DV_{2017\text{-}2019}$ sensitivity analysis.

NMED Exhibit 17

10. 2028 SOURCE SECTOR APCA OZONE SOURCE APPORTIONMENT MODELING

Ozone source apportionment modeling was conducted to determine the contributions of Source Sectors within New Mexico to 2028 ozone concentrations and projected future year ozone design values (DVF) under the 2028 New Mexico oil and gas (O&G) control strategy emissions scenario. The Anthropogenic Precursor Culpability Assessment (APCA) version of the CAMx ozone source apportionment tool was used and the modeling also obtained contributions from Colorado, Texas and the remainder of U.S. states as well as international anthropogenic emissions.

10.1 Versions of Ozone Source Apportionment

CAMx includes two ozone source apportionment tools: the Ozone Source Apportionment Technology (OSAT) and the Anthropogenic Precursor Culpability Assessment (APCA). Both use tagged tracer species that track ozone formation from VOC (V_i) and NO_x (NIT_i + RGN_i) emissions from each user-specified Source Group (i). A Source Group can consist of a Source Region and/or Source Category. A typical OSAT/APCA application will use a Source Region map that divides the modeling domain into geographic regions and separate emission files of different Source Categories are provided as input to CAMx; ozone source apportionment is obtained for Source Groups that are defined as the intersection of the Source Regions with the Source Categories (e.g., on-road mobile sources from New Mexico). The ozone source apportionment tool runs in parallel to the CAMx host model and extracts information on ozone formation and assigns it to the user-defined Source Groups.

There are 10 reactive tracers used to track ozone formation for each user-defined Source Group as follows:

V_i	VOC emissions
NIT_i	Nitric oxide (NO) and nitrous acid (HONO) emissions
RGN_i	Nitrogen dioxide (NO_2), nitrate radical (NO_3) and dinitrogen pentoxide (N_2O_5)
TPN_i	Peroxyl acetyl nitrate (PAN), analogues of PAN and peroxy nitric acid (PNA)
NTR_i	Organic nitrates (RNO_3)
$HN3_i$	Gaseous nitric acid (HNO_3)
$O3N_i$	Ozone formed under NOx sensitive conditions
$O3V_i$	Ozone formed under VOC sensitive conditions
OON_i	Odd-oxygen in NO_2 formed from O3Ni
OOV_i	Odd-oxygen in NO_2 formed from O3Vi

NMED Exhibit 17

For each time step and grid cell, when ozone is formed in the host model OSAT determines whether the ozone formation was more VOC sensitive or NO_x sensitive and apportions the ozone formed to Source Groups based on the relative contribution of the limiting precursor to the total precursor (e.g., under VOC sensitive conditions $V_i / \sum V_i$). APCA differs from OSAT in that it will only allocate ozone formed to natural (e.g., biogenic) emissions Source Groups when the ozone formed is due to natural VOC interacting with natural NO_x. So when ozone is formed due to biogenic VOC emissions interacting with anthropogenic NO_x emissions under VOC sensitive ozone formation conditions, a case OSAT would assign to the natural Source Group $O3V_i$ tracer, APCA redirects the ozone formed to the anthropogenic Source Group $O3N_i$ tracer. APCA was designed to provide more control strategy relevant information than OSAT and is used in identifying ozone contributions in emissions culpability assessments (e.g., CSAPR[38]). However, OSAT has to be used to obtain information on whether ozone formation is more VOC or NO_x sensitive. Details on the CAMx OSAT and APCA source apportionment tools are provided in Chapter 7 of the CAMx user's guide.[39] Since we are running CAMx v7.1, it uses the third version of OSAT3 and corresponding version of APCA.

As the main focus of the 2028 Source Sector ozone source apportionment modeling is to identify the contributions of anthropogenic emission source sectors and regions to elevated MDA8 ozone concentrations in New Mexico, the APCA version of ozone source apportionment tool was used.

10.2 2028 Source Sector APCA Ozone Source Apportionment Specifications

Details on the design and specifications of the 2028 Source Sector APCA ozone source apportionment simulate are provide below.

10.2.1 2028 O&G Control Strategy Emissions Scenario

The 2028 Source Sector APCA ozone source apportionment was conducted using the 2028 New Mexico O&G Control Strategy emissions scenario.

10.2.2 Definition of Source Groups

The 2028 Source Sector APCA ozone source apportionment simulation used a Source Region map to define geographic regions of emission areas to be tracked. Separate source contributions were also obtained for 9 emission Source Categories as well as contributions due to Boundary Conditions (BCs) around the lateral edges of the 36-km grid resolution domain.

10.2.2.1 Boundary Conditions

The CAMx v7 source apportionment tool has a new capability to provide separate contributions due to stratified BCs. Typically, these stratifications will be different source sectors from outside of the CAMx modeling domain. WRAP conducted 2014 GEOS-Chem modeling for a base case (BASE), a 2014 GEOS-Chem no

[38] https://www.epa.gov/csapr
[39] http://www.camx.com/files/camxusersguide_v7-10.pdf

international anthropogenic emissions case (i.e., Zero-out Rest of World or ZROW) and a no global anthropogenic emissions case (i.e., just natural emissions). Output from the three 2014 GEOS-Chem runs were processed to generate lateral BCs for the CAMx 36-km 36US1 North America modeling domain that contained: (1) the contributions of international anthropogenic emissions (BC_{Intl}); (2) the contributions of U.S. anthropogenic emissions (BC_{US}); and (3) the contributions of natural sources ($BC_{Natural}$). Details on the WRAP 2014 GEOS-Chem base, ZROW and Natural modeling are contained in a Run Specification Sheet[40] and the WRAP/WAQS 2014v2 model performance evaluation webpage.[41]

This results in the 2028 Source Sector APCA ozone source apportionment simulation tracking ozone contributions from three Source Groups for the lateral boundaries ($BC_{Natural}$, BC_{Intl} and BC_{US}). Contributions due to the top BC concentration as well as Initial Concentrations (IC) were also separately tracked resulting in 5 Source Groups used to track the contributions of BC and IC.

10.2.2.2 Source Regions

Five source regions were used in the 2028 Source Sector APCA ozone source apportionment simulation as shown in Figure 10-1:

1. New Mexico;
2. Texas;
3. Colorado;
4. Remainder U.S. states plus coastal water out to 200 nautical miles (nmi) from the U.S. coast; and
5. International, which included Mexico, Canada and waters off their coasts plus waters more than 200 nmi off the U.S. coast.

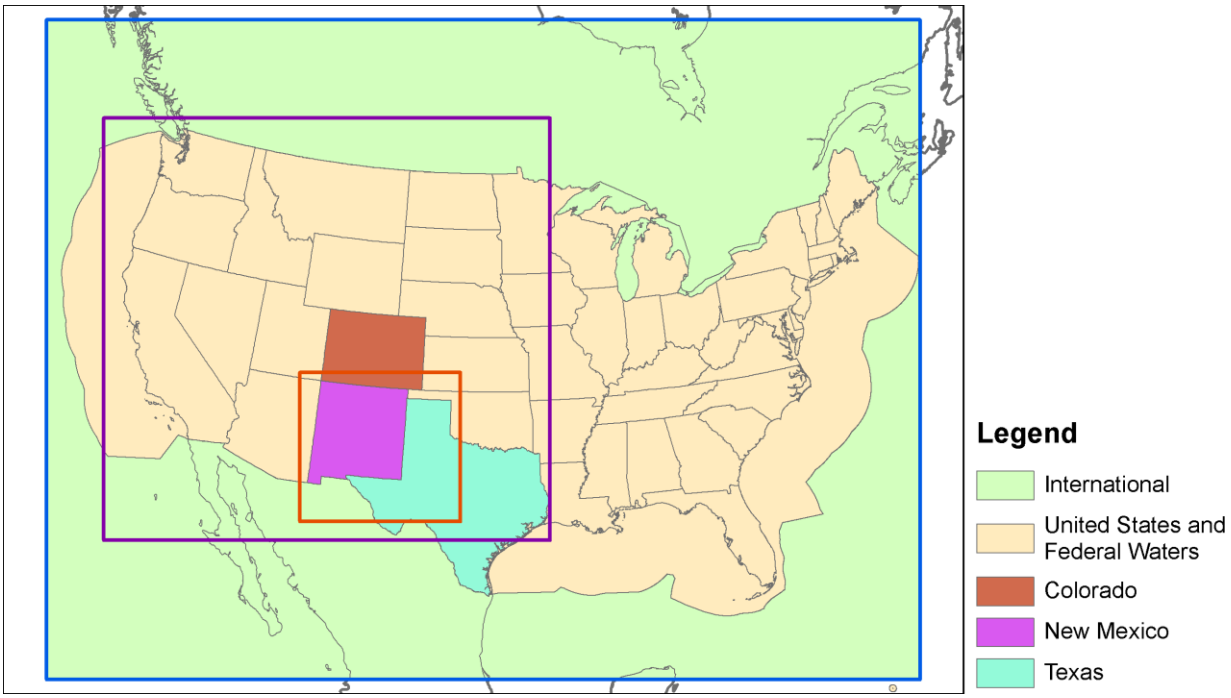

Figure 10-1. Source regions used in the 2028 Source Sector APCA ozone source apportionment simulation.

10.2.2.3 Source Categories

The emissions inventory was divided up into 9 Source Categories in the 2028 Source Sector APCA ozone source apportionment modeling as follows:

1. Natural (biogenic, lightning NO_x, windblown dust and oceanic [sea salt and dimethyl sulfide]);
2. Fires (U.S. wildfires, wildland prescribed burns and agricultural burning and other [Mexico/Canada] fires);
3. Oil and gas point sources (surrogate for midstream O&G);
4. Oil and gas non-point sources (surrogate for upstream O&G);
5. EGU point;
6. Non-EGU point;
7. On-road mobile;
8. Non-road mobile; and
9. Remainder anthropogenic.

Since the APCA version of the CAMx ozone source apportionment tool is being utilized, Natural emissions has to be the first Source Category so APCA knows which Source Category is uncontrollable.

10.2.2.4 Source Groups

With 5 Source Regions and 9 Source Categories, plus 5 Source Groups for IC/BC, there is a total of 50 Source Groups that separate ozone source contributions are obtained (50 = 5 x 9 + 5).

10.3 2028 Source Sector APCA Ozone Source Apportionment Modeling Results

The 2028 Source Sector APCA ozone source apportionment modeling results were analyzed to obtain the contributions of the different Source Sectors within New Mexico to projected future year 2028 ozone design values (DVFs) as well as contributions to Maximum Daily Average 8-hour (MDA8) ozone concentrations. The 2028 ozone DVF and modeled MDA8 ozone concentrations were analyzed at the monitoring sites as well as across the 4-km New Mexico domain. Figure 10-2 shows the locations of the monitoring sites within the 4-km New Mexico domain.

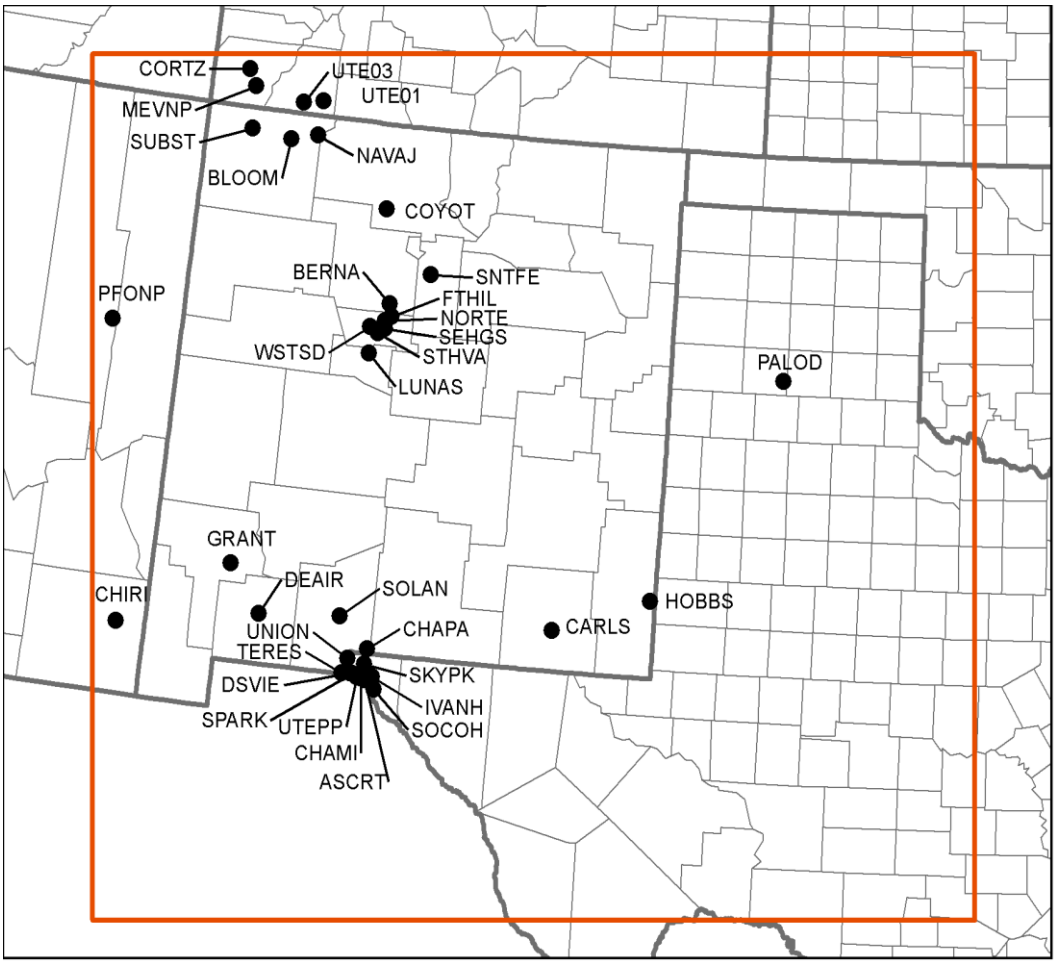

Figure 10-2. Locations of ozone monitoring sites within the 4-km New Mexico modeling domain.

10.3.1 Source Sector Contributions to Projected 2028 Ozone DVFs

In this section, the contributions of Source Sector emissions within New Mexico and the entire United States to future year projected 2028 ozone design values (DVF) at New Mexico monitoring sites and across the 4-km New Mexico domain are analyzed.

10.3.1.1 New Mexico Source Sector 2028 Ozone DVF Contributions

Table 10-1 displays the current year 2012-2016 DVC, the projected 2028 ozone DVF for the 2028 O&G Control Scenario and the reductions in the 2028 ozone DVF due to the removal of anthropogenic emissions in New Mexico for each of the 7 anthropogenic emissions Source Sectors at all monitoring sites in New Mexico. The incremental ozone contributions in the 2028 ozone DVF due to New Mexico emissions from the 7 Source Sectors are shown for several New Mexico monitoring sites in Figures 10-3 through 10-18.

At the three monitoring sites in San Juan County, New Mexico emissions from EGU and O&G Source Sectors contribute the most to the 2028 ozone DVF (Table 10-1). The largest ozone contribution is 3.1 ppb for the New Mexico EGU Source Sector at the SUBST site (Figure 10-5) due to its close proximity to the Four Corners Power Plant (FCPP) that is assumed to have Units 4 and 5 operating in 2028. The EGU ozone contributions fall off with distance from the FCPP as seen at the BLOOM (1.9 ppb; Figure 10-4), NAVAJ (1.7 ppb; Figure 10-3) and COYOT (0.5 ppb; Figure 10-6) monitoring sites. New Mexico O&G Point contributes 0.2 to 0.9 ppb and O&G Non-Point contributes 0.5 to 2.1 ppb to 2028 ozone DVFs at the four northern New Mexico monitoring sites in San Juan and Rio Arriba Counties. All other Source Sectors have contributions of 0.5 ppb or less at the northern New Mexico sites.

Sites in Central New Mexico include those in Bernalillo County (Figures 10-7 through 10-10) as well as two sites in neighboring counties (Figures 10-11 and 10-12). Ozone concentrations in Bernalillo County are highly influenced by emissions from Albuquerque, which is by far the largest city in New Mexico. So, Source Sectors associated with population centers (e.g., on-road, non-road and other anthropogenic) tend to have the highest contributions to the 2028 ozone DVFs at these sites. Although they have different magnitudes of ozone contributions, the rankings of the Source Sector contributions are very similar at the Bernalillo County sites with Other Anthropogenic being highest followed by On-Road and Non-Road mobile with the other four Source Sectors being half or less of the top three Source Sectors. On-Road mobile is the highest followed by Other Anthropogenic and Non-Road at the Santa Fe (Figure 10-11) and Sandoval County (Figure 10-12) sites, with all other Source Sector contributions being much lower.

Sites in the southern New Mexico (Figures 10-13 through 10-18) include those in southern Doña Ana County on the border with Texas that tend to have mostly small contributions from New Mexico Source Sectors with the exception of EGU (0.7 to 0.9 ppb), due to the close proximity of the Rio Grande Power Plant to some of the sites, and On-Road mobile (0.4-0.5 ppb) due to population centers along I-25 (e.g., Sunland Park, Santa Teresa, etc.). The Solano monitor (Figure 10-16) has higher ozone contributions due to On-Road (1.2 ppb) and Non-Road (0.7 ppb) mobile sources because of the higher mobile emissions from the City of Las Cruces, which is the second largest city in New Mexico.

NMED Exhibit 17

New Mexico emissions from the O&G Point and Non-Point Sources sectors have the highest ozone contribution at the Carlsbad (0.5 and 0.5 ppb) and Hobbs (0.9 and 1.1 ppb) monitoring sites in southeastern New Mexico (Figures 10-17 and 10-18). These two southeastern New Mexico monitors are essentially within the Permian Basin. The contribution of On-Road to the 2028 ozone DVF at Carlsbad and Hobbs sites is 0.3 ppb, with all other Source Sector contributions being lower.

Table 10-1. Reduction in 2028 ozone DVF due to the elimination of emissions from 7 Source Sectors in New Mexico.

NMED Exhibit 17

The SMAT Unmonitored Area Analysis (UAA) feature was used to estimate the spatial distribution 2028 ozone DVFs across the 4-km New Mexico domain for the 2028 O&G Control Scenario without New Mexico emissions from each of the 7 anthropogenic emission Source Sectors. Figures 10-19 and 10-20 display the reduction in 2028 ozone DVFs across the New Mexico 4-km domain due to the removal of New Mexico emissions for the 7 Source Sectors. Removing New Mexico EGU emissions reduces the 2028 ozone DVF by as much as 3.1 ppb in San Juan County with ozone reductions of 0.1 to 1.0 ppb in the upper half of New Mexico and from Doña Ana to Lea Counties in southern New Mexico (Figure 10-19a). The removal of New Mexico Non-EGU Point emissions results in a reduction of 1.3 ppb in eastern Bernalillo County and reductions of 0.1 to 1.0 in adjacent counties, with little effect over the rest of New Mexico away from Bernalillo County (Figure 10-19b).

New Mexico On-Road mobile contributes as much as 2.6 ppb to the 2028 ozone DVF with reductions of 1-2 ppb stretching from Albuquerque to Santa Fe and in Las Cruces (Figure 10-19c). New Mexico Non-Road mobile contributes as much as 2.1 ppb in Bernalillo County (Figure 10-19d).

New Mexico Non-Point O&G has large (> 2 ppb) contributions to the 2028 ozone DVF in the San Juan and Permian Basins (Figure 10-20a). Whereas, New Mexico Point O&G contributes as much as 1-2 ppb in the Permian Basin but less than 1 ppb in the San Juan Basin (Figure 10-20b). The Other Anthropogenic Source Sector contributions has a similar distribution as the two mobile Source Sectors with the highest ozone contributions centered on Bernalillo County (Figure 10-20c).

NMED Exhibit 17

10.3.1.2 United States Source Sector 2028 Ozone DVF Contributions

Table 10-2 displays the reductions in 2028 ozone DVFs due to the elimination of Source Sector emissions throughout the United States. Table 10-3 shows the percent of the all U.S. Source Sector ozone reduction that was due to just the Source Sector emissions in New Mexico (i.e., the percent the ozone reductions in Table 10-1 are of the ozone reductions in Table 10-2). At the three San Juan County sites, O&G non-point contributes the most (2-3 ppb) with approximately 60-78% coming from O&G non-point sources in New Mexico. Oil and gas point contributes 1.1 to 1.3 ppb at the three San Juan County sites with 55-69% coming from sources in New Mexico. The U.S. EGU Source Sector contributes 2.0 to 3.6 ppb to the 2028 ozone DVF at the three San Juan County sites with a vast majority (~85%) coming from New Mexico. On the other hand, the U.S. On-Road (1.7 ppb) and Non-Road (1.2 ppb) contribution at the three San Juan County sites comes mostly from outside of New Mexico (10-30%).

For sites in Bernalillo County in central New Mexico, 40% to 86% of the U.S. Source Sector contributions come from sources within New Mexico. The largest U.S. Source Sector contributions are for On-Road (3-4 ppb) and Non-Road (2-3 ppb) for which 60-70% of the contribution is due to sources from New Mexico.

At the Doña Ana County monitoring sites, approximately 25% (13-38%) of the U.S. O&G and 22-50% of the U.S. EGU Source Sector is from New Mexico. However, only 9-17% of the U.S. On-Road ozone contribution is from New Mexico sources with the exception of Solano that has 44% of the U.S. on-road mobile ozone contribution due to New Mexico on-road emissions. .

The Carlsbad and Hobbs monitors in southeast New Mexico have approximately half of their U.S. O&G ozone contributions from New Mexico sources, with only ~20% of U.S. mobile contribution coming from New Mexico.

The Grant monitor in southwest New Mexico has almost no ozone contributions from sources in New Mexico.

10.3.2 Source Sector Contributions to Modeled MDA8 Ozone Concentrations

The contributions of the Source Sector emissions to the absolute CAMx modeling results 2028 daily MDA8 ozone concentrations are analyzed in this section. We first present spatial maps of the episode maximum MDA8 ozone contributions across the 4-km New Mexico domain for each Source Region. The contributions of all and New Mexico Source Sectors to MDA8 ozone concentrations are then presented at four example New Mexico monitoring sites for the 10 days used to make the 2028 ozone DVF projections (i.e., the 10 SMAT days). Finally, the spatial maps of New Mexico and all United States Source sector contributions to daily MDA8 ozone concentrations are presented for six example days during the May-August 2014 modeling episode.

10.3.2.1 Episode Maximum Source Sector MDA8 Ozone Contributions by Source Region

Figures 10-21 and 10-22 display the episode maximum MDA8 ozone contributions due to Source Sector emissions from New Mexico. The maximum New Mexico EGU MDA8 ozone contribution is 10.9 ppb and occurs at the location of the Four Corners Power Plan in San Juan County (Figure 10-21a). Elevated ozone due to emissions from New Mexico EGUs is also seen in Lea County at the location of the Hobbs, Cunningham and Maddox EGUs and in southern Doña Ana County at the location of the Rio Grande EGU (Figure 10-21a). The highest New Mexico Non-EGU Point source contribution is 3.1 ppb in eastern Bernalillo County with the Non-EGU Point contribution mostly less than 1 ppb away from Bernalillo County (Figure 10-21b). The maximum New Mexico On-Road (4.7 ppb) and Non-Road (4.0 ppb) ozone contributions both occur in Albuquerque, with a secondary ozone maximum occurring in Las Cruces (Figure 10-21c and d). The On-Road ozone spatial patterns follow the major freeways, including east-west I-40 and north-south I-25, with even I-10 evident in Luna County in southwest New Mexico (Figure 10-21c).

The highest New Mexico O&G Non-Point (7.6 ppb) and O&G Point (5.4 ppb) both occur at the same location in the Permian Basin (Figure 10-22a and b). The O&G Non-Point ozone contributions exceed 5 ppb over large portions of the Permian and San Juan Basins (Figure 10-22a). The O&G Point source ozone contributions are lower, exceeding 3 ppb over large portions of the Permian Basin with much lower ozone contributions in the San Juan Basin (Figure 10-22b). The Other Anthropogenic ozone contribution has a bull’s eye centered on Albuquerque with a maximum of 6.2 ppb (Figure 10-22c). Fires are highly episodic with four distinct fire ozone plumes present in New Mexico with episode maximum exceeding 20 ppb (Figure 10-22d).

NMED Exhibit 17

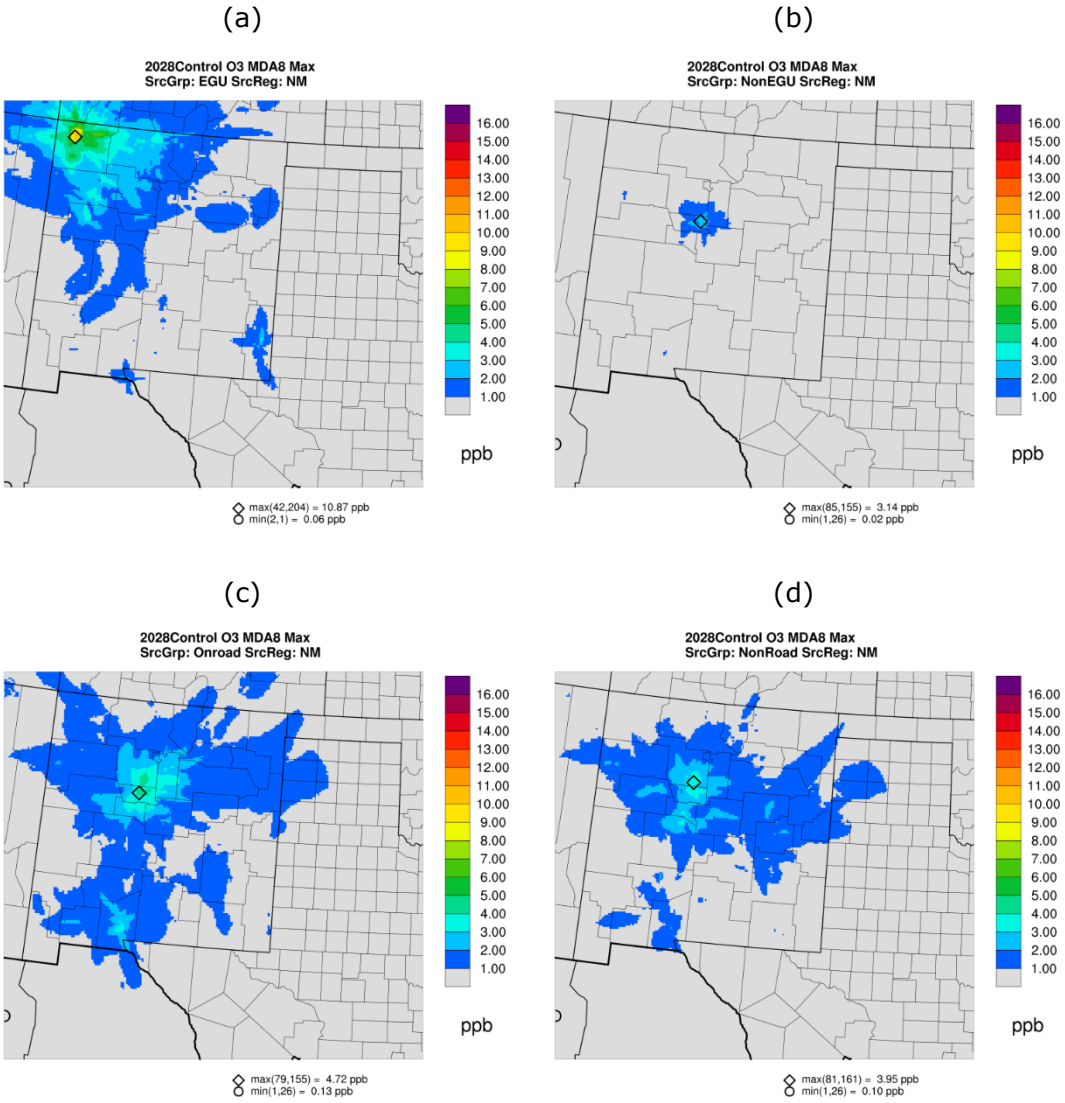

Figure 10-21. Episode maximum daily MDA8 ozone contributions from Source Sectors in New Mexico for: (a) EGU Point; (b) Non-EGU Point; (c) On-Road Mobile; and (d) Non-Road Mobile.

NMED Exhibit 17

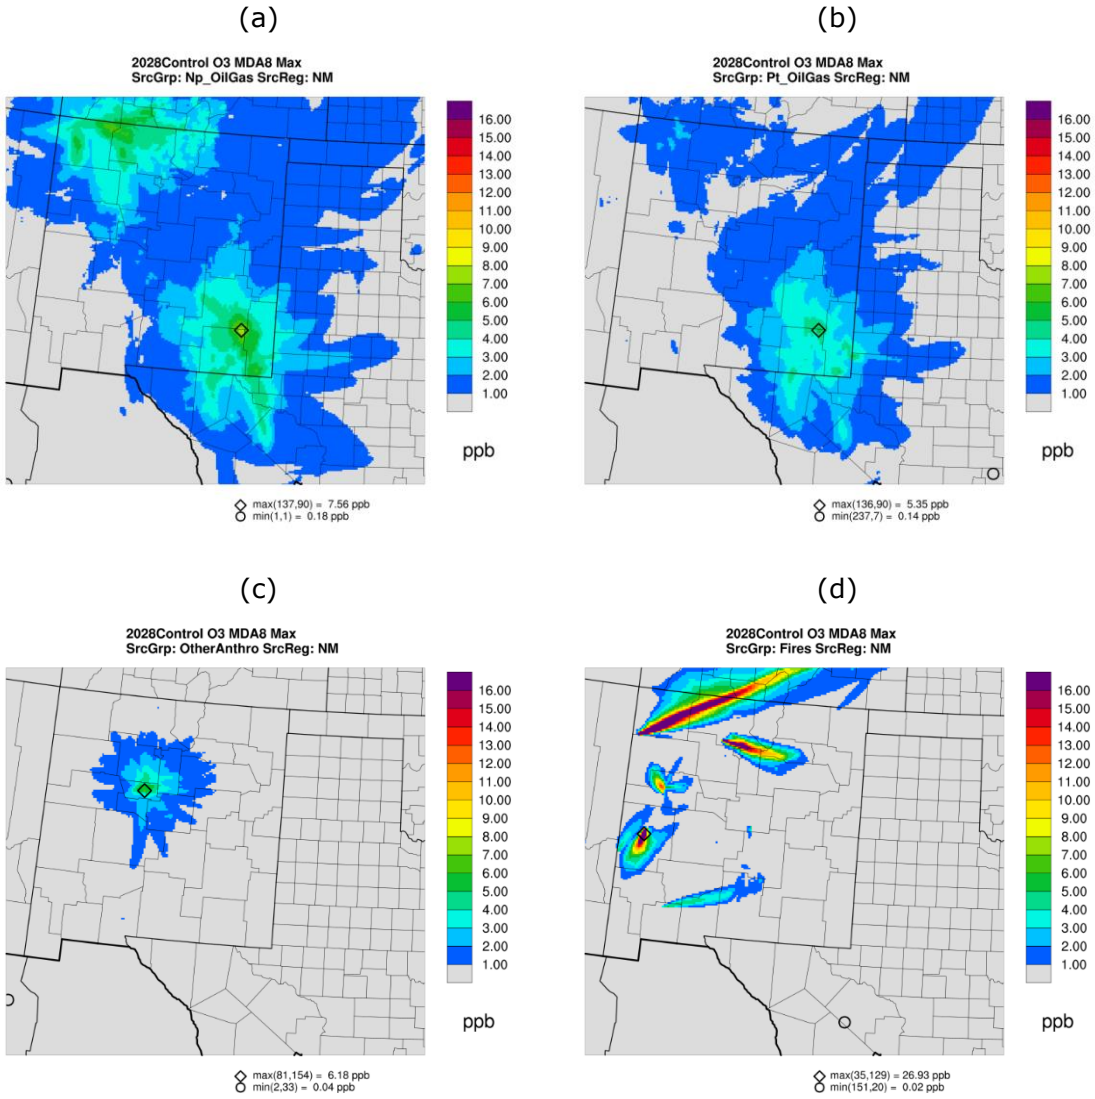

Figure 10-22. Episode maximum daily MDA8 ozone contributions from Source Sectors in New Mexico for: (a) Non-Point O&G; (b) Point O&G; (c) Other Anthropogenic; and (d) Fires.

NMED Exhibit 17

Figure 10-23 displays the episode maximum MDA8 ozone contributions due to emissions from Texas for 9 Source Sectors (7 anthropogenic Source Sectors plus fires and natural). The presence of EGUs in the Texas Panhandle is clearly evident (e.g., 1,100 MW Tolk coal EGU) that produce ozone in excess of 2 ppb entering eastern New Mexico (Figure 10-23, top left). Elevated ozone due to Texas Non-EGU Point, On-Road, Non-Road, and Other Anthropogenic is seen in El Paso with elevated ozone concentrations entering Doña Ana County. The Texas anthropogenic Source Sector that contributes the most to ozone in New Mexico is O&G. Texas O&G Non-Point (Figure 10-23, middle right) produces ozone above 4 ppb in Lea County and ozone in excess of 2 ppb as far north as Santa Fe and San Miguel Counties. Within the New Mexico portion of the Permian Basin, the maximum Texas O&G Non-Point ozone contribution exceeds 3 ppb and the maximum Texas O&G Point contribution exceeds 2 ppb.

The Colorado Source Sector with the largest contribution to New Mexico ozone concentrations is O&G Non-Point that has a peak ozone contribution in the 4-km domain of 7 ppb that occurs in Colorado just north of the border of San Juan and Rio Arriba Counties (Figure 10-24, middle right). Colorado O&G Non-Point contributes ozone in excess of 4 ppb in the northern portion of the two northwest New Mexico counties and ozone in excess of 1.5-2.0 ppb stretching south to Bernalillo County. Other Colorado anthropogenic emissions Source Sectors contribute ozone in excess of 0.5 ppb across large portions of New Mexico with O&G Point contributing ozone in excess of 1 ppb in San Juan County.

The highest Source Sector ozone contributions in the 4-km New Mexico domain due to all emissions in the U.S. are shown in Figure 10-25. The peak U.S. EGU ozone contribution is 11.5 ppb at the same locations as the New Mexico EGU peak ozone contribution with most of the U.S. EGU contribution at this location due to the FCPP in New Mexico (10.9 ppb, see Figure 10-21a). In addition to the EGU ozone hotspots in the Texas panhandle discussed above (Figure 10-23), there are also all U.S. EGU ozone hotspots in eastern Arizona at the locations of the Springerville and Coronado Generating Stations (Figure 10-25, top left). The U.S. On-Road, Non-Road and Other Anthropogenic ozone contributions (Figure 10-25) look similar to the New Mexico alone ozone contributions (Figures 10-21 and 10-22) with the addition of an incremental ozone concentrations across the 4-km domain due to the U.S. Source Sector emissions from outside New Mexico.

The peak U.S. O&G Non-Point ozone contribution is 10.5 ppb (Figure 10-25, middle right) and occurs at the same location in Colorado on the border with New Mexico as where the Colorado O&G Non-Point peak ozone (7.0 ppb) occurred (Figure 10-24, middle right). The additional 4.5 ppb ozone comes mainly from New Mexico O&G Non-Point emissions (Figure 10-22a). Ozone due to U.S. O&G Non-Point exceeds 8 ppb in the New Mexico portions of the San Juan and Permian Basins. Ozone due to U.S. O&G Point sources exceeds 4 ppb over a wide area in the Permian Basin, whereas U.S. O&G Point rarely exceeds 4 ppb in the San Juan Basin.

NMED Exhibit 17

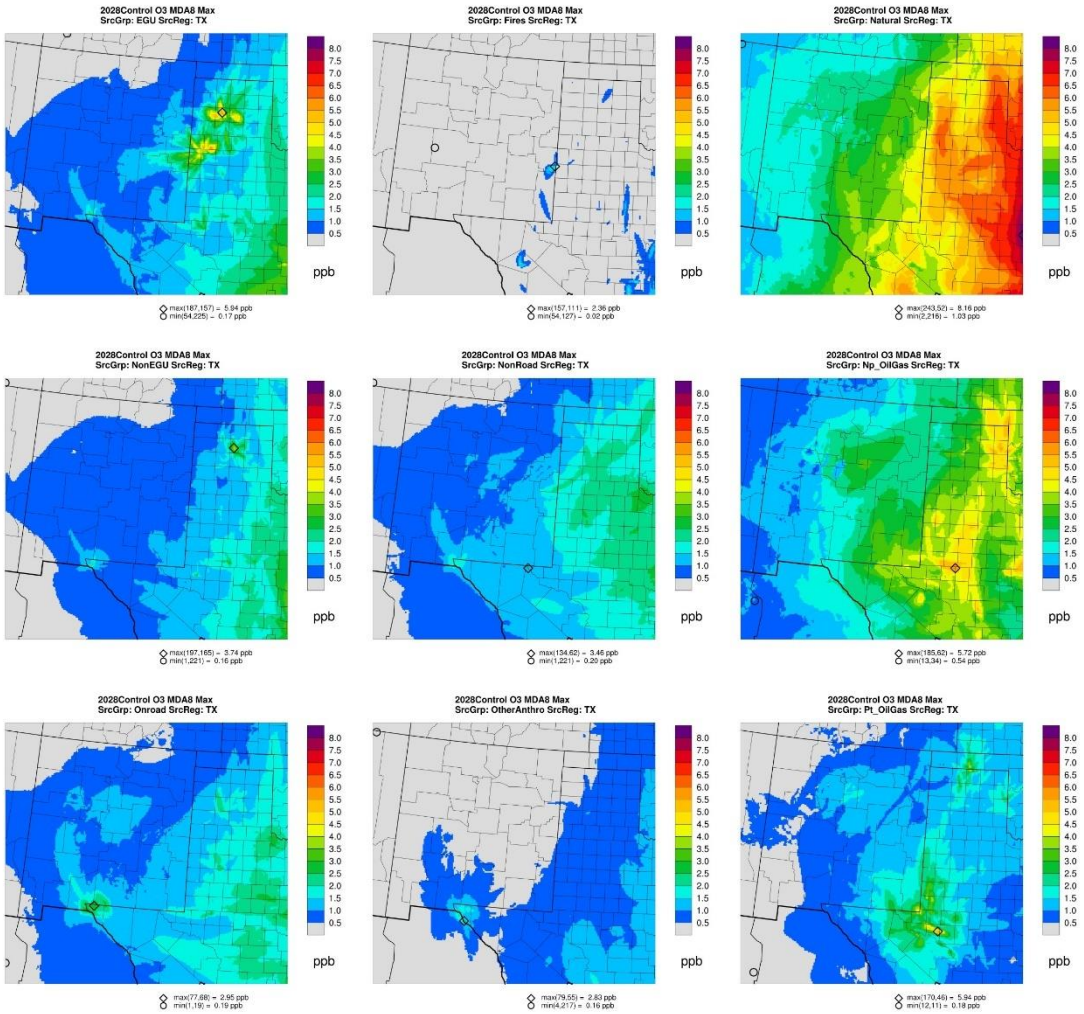

Figure 10-23. Episode maximum MDA8 ozone contributions from Source Sectors in Texas for EGU Point (top left), Fires (top middle), Natural (top right), Non-EGU Point (middle left), Non-Road (middle middle), O&G Non-Point (middle right), On-Road (bottom left), Other Anthropogenic (bottom middle) and O&G Point (bottom right) from the 2028 O&G Control Strategy emissions scenario.

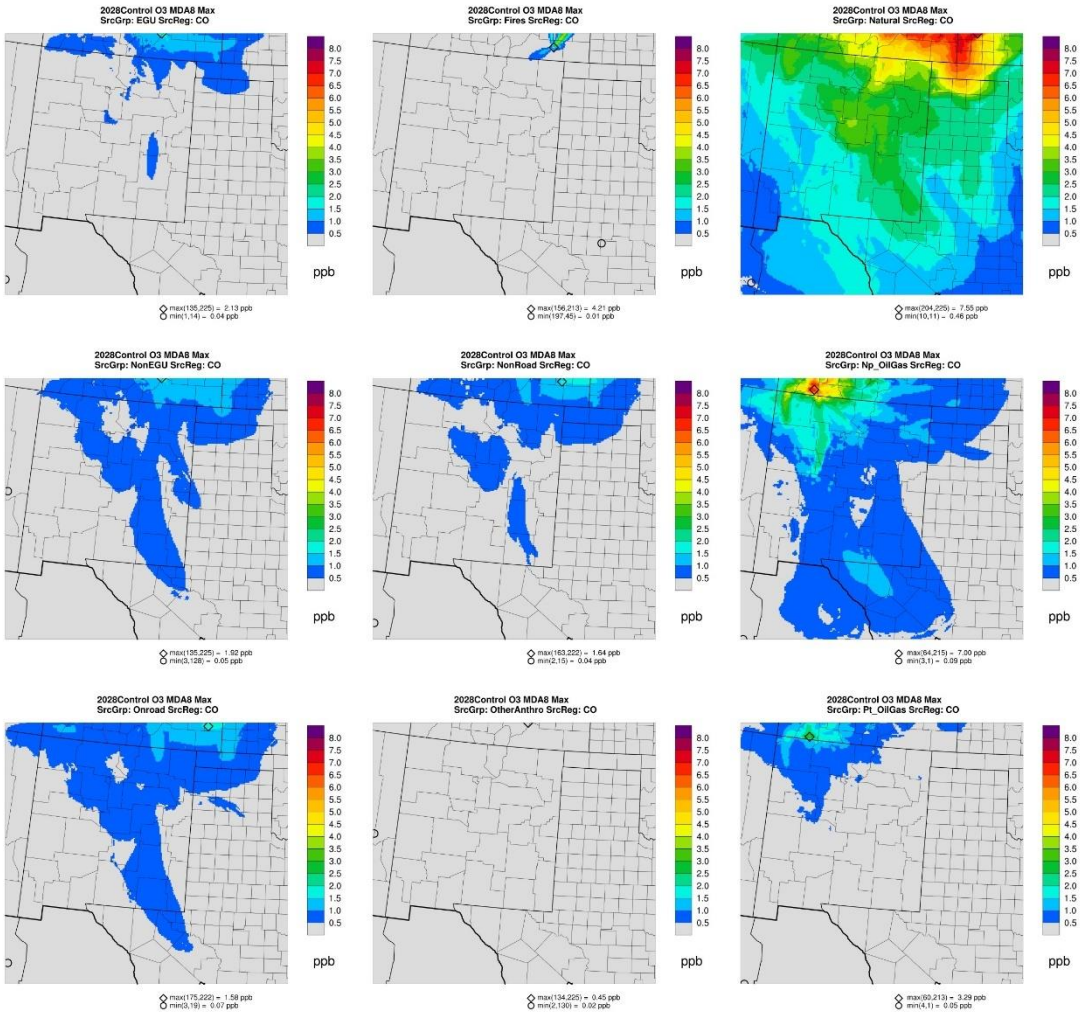

Figure 10-24. Episode maximum MDA8 ozone contributions from Source Sectors in Colorado for EGU Point (top left), Fires (top middle), Natural (top right), Non-EGU Point (middle left), Non-Road (middle middle), O&G Non-Point (middle right), On-Road (bottom left), Other Anthropogenic (bottom middle) and O&G Point (bottom right) from the 2028 O&G Control Strategy emissions scenario.

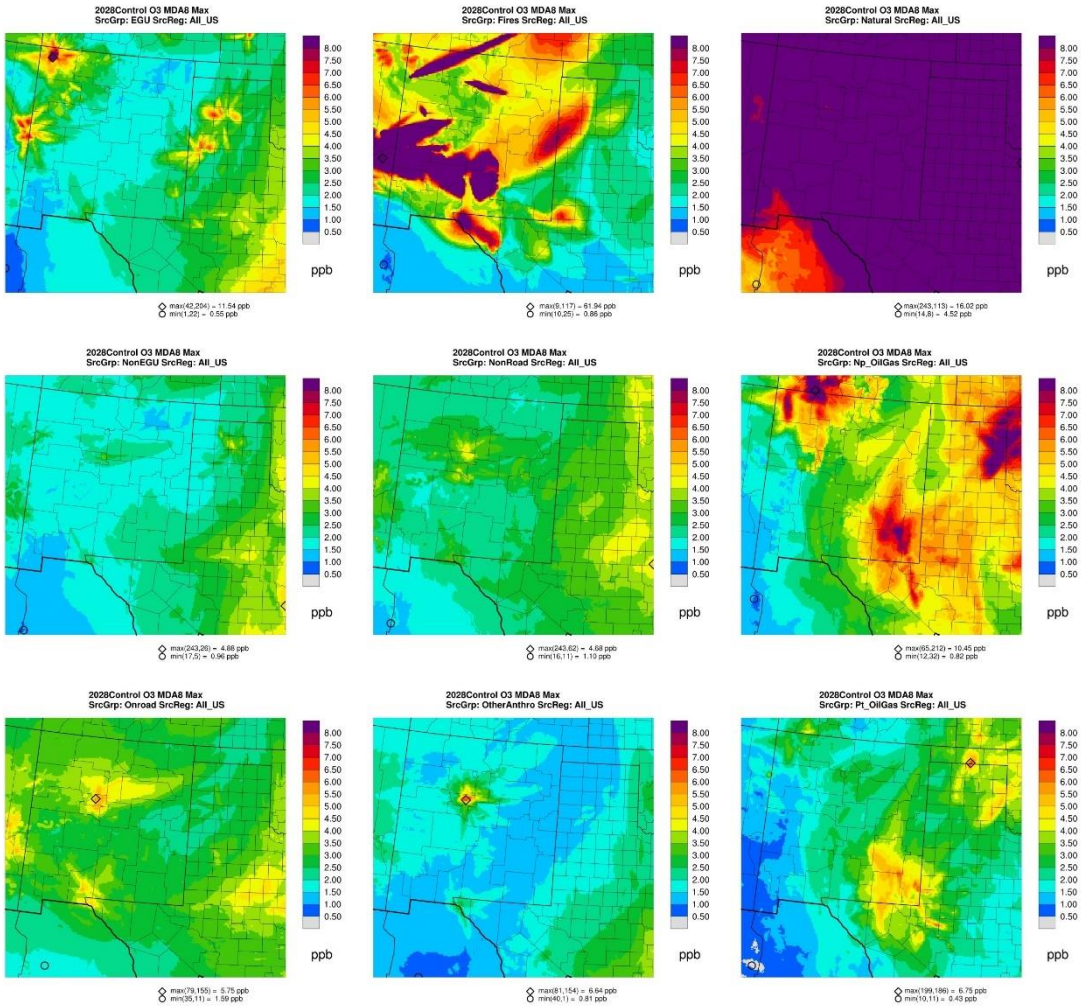

Figure 10-25. Episode maximum MDA8 ozone contributions from Source Sectors in United States for EGU Point (top left), Fires (top middle), Natural (top right), Non-EGU Point (middle left), Non-Road (middle middle), O&G Non-Point (middle right), On-Road (bottom left), Other Anthropogenic (bottom middle) and O&G Point (bottom right) from the 2028 O&G Control Strategy emissions scenario.

The top two panels in Figure 10-26 display the episode maximum MDA8 ozone contributions due to international anthropogenic emissions that are either within the CAMx 36/12/4-km modeling domain (i.e., mainly from in-domain Mexico emissions) or coming through the BCs (BC_{Intl}) from international emissions from outside of the CAMx modeling domains that were generated from 2014 GEOS-Chem simulations. The in-domain international anthropogenic emissions contribute high ozone concentrations in southern New Mexico with values exceeding 16 ppb stretching into Doña Ana, Luna and Otero Counties. The southeastern half of New Mexico has ozone contributions in excess of 8 ppb due to in-domain international emissions. Although the ozone peaks are not as high as the in-domain international anthropogenic emissions, the BC_{Intl} ozone contributions exceed 10 ppb across all of New Mexico and are as high as 13 ppb

(Figure 10-26b). The $BC_{Natural}$ ozone contributions is as high as 49 ppb in San Juan County (Figure 10-26c), while the BC_{US} ozone contributions ranges from 3-4 ppb across New Mexico (Figure 10-26d).

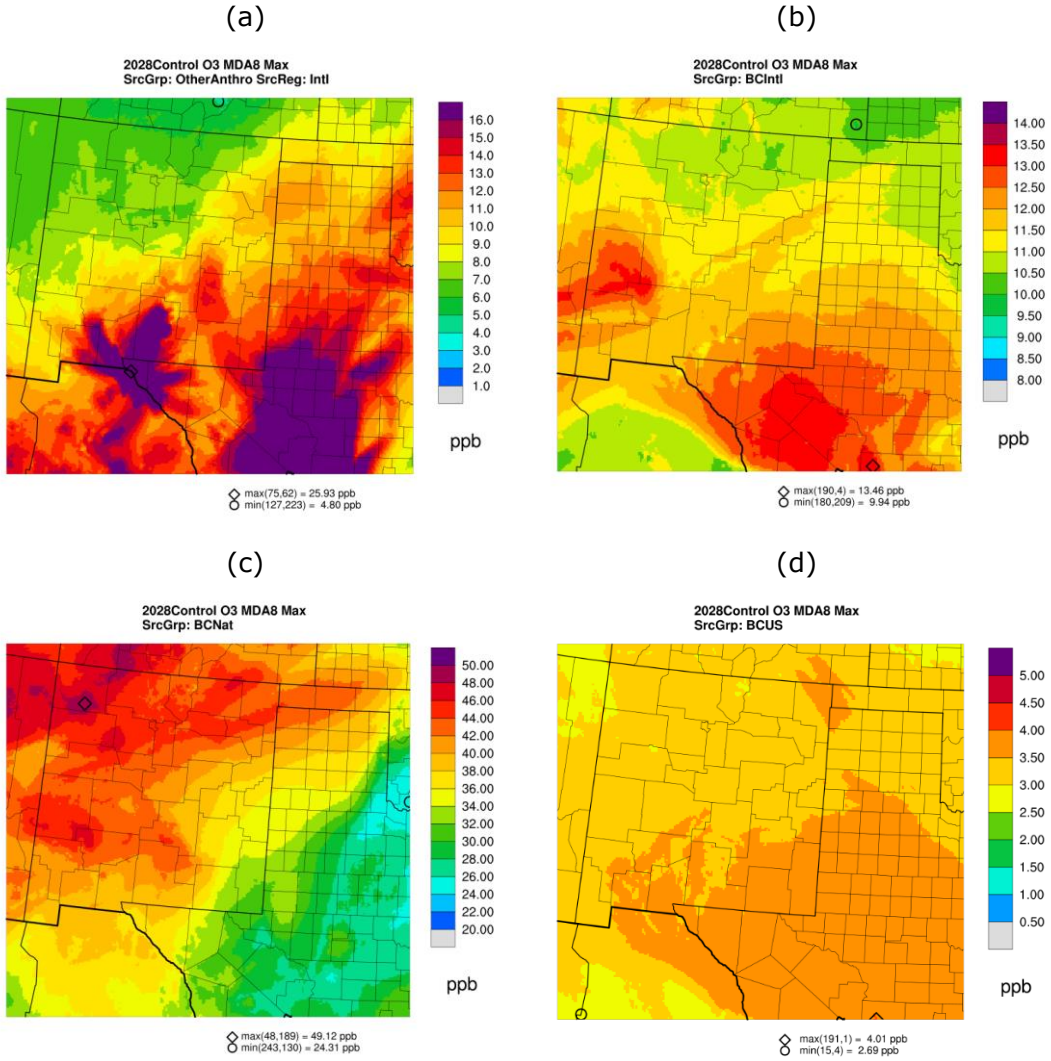

Figure 10-26. Episode maximum MDA8 ozone contributions from: (a) International Anthropogenic Emissions within CAMx 36/12/4-km domains; (b) BCs due to International Anthropogenic Emissions (BC_{Intl}); (c) BCs due to Natural sources ($BC_{Natural}$); and (d) BCs due to U.S. Anthropogenic Emissions (BC_{US}).

10.3.2.2 Source Sector Ozone Contributions to MDA8 Ozone Concentrations on Modeled High Ozone Days

The daily CAMx 2028 Source Sector APCA ozone source apportionment modeling results were extracted at the locations of the New Mexico ozone monitoring sites and loaded into an Excel Dashboard to visualize the source contributions using stacked bar, pie and tree charts. The Dashboard displays modeled 2028 MDA8 ozone concentrations at a user-selected monitoring site in groups of 10 high ozone days, and the average across the 10 days. These 10 days include the 10 days used in the SMAT 2028 ozone DVF projections, as well as the modeled 2028 first and second highest group of 10 days.

Figures 10-27 through 10-34 display results from the Dashboard for 5 monitoring sites representing different locations in New Mexico. Figures 10-27 and 10-28 display the modeled 2028 ozone results at the Navajo Lake monitor in northwest New Mexico for the 10 SMAT days. The top panel in Figure 10-27 shows stacked bar charts of daily MDA8 ozone contributions by Source Region and BCs for the 10 SMAT days at Navajo Lake. The total MDA8 ozone concentrations are 60-70 ppb and the BCs (grey bar) contribute by far the most with contributions ranging from 26 to 60 ppb. The New Mexico contribution ranges from near zero to 10.9 ppb. The bottom panel in Figure 10-27 shows a Tree Chart and breaks down each Source Region's contribution by Source Category averaged across the 10 SMAT days at Navajo Lake. The Natural category dominates the BC contribution followed by the BC International Anthropogenic Emissions category.

Figure 10-28 focuses on contributions due to emissions from New Mexico Source Categories to MDA8 ozone on the 10 SMAT days at Navajo Lake showing day by day results in the top panel and a pie chart of New Mexico contributions averaged across the 10 days in the bottom panel. For the Navajo Lake site, New Mexico O&G Non-Point is always the largest contributor (38% on average) followed by EGU (29% on average) and then O&G Point (16% on average). Next most important is either On-Road or Natural, depending on the day (6-7% on average). The other two San Juan County sites have higher EGU contributions, with EGU being the highest New Mexico Source Category accounting for 50% and 32% of the New Mexico ozone contribution at, respectively, Substation and Bloomfield.

Figures 10-29 and 10-30 show ozone contribution results for the 10 SMAT days at the Foothills monitoring site and represents typical contributions for sites in Bernalillo County. There is a wide-range of variation in the New Mexico ozone contribution to the 10 SMAT days at Foothills, from near zero to 15 ppb. BCs contribute the most, 27 to 47 ppb. The remaining U.S. and in-domain international emissions also contribute a fair amount. The three most important New Mexico Source Categories contributing to modeled MDA8 ozone at Foothills averaged across the 10 SMAT days are Other Anthropogenic (27%), On-Road (35%) and Non-Road (20%) (Figure 10-30).

NMED Exhibit 17

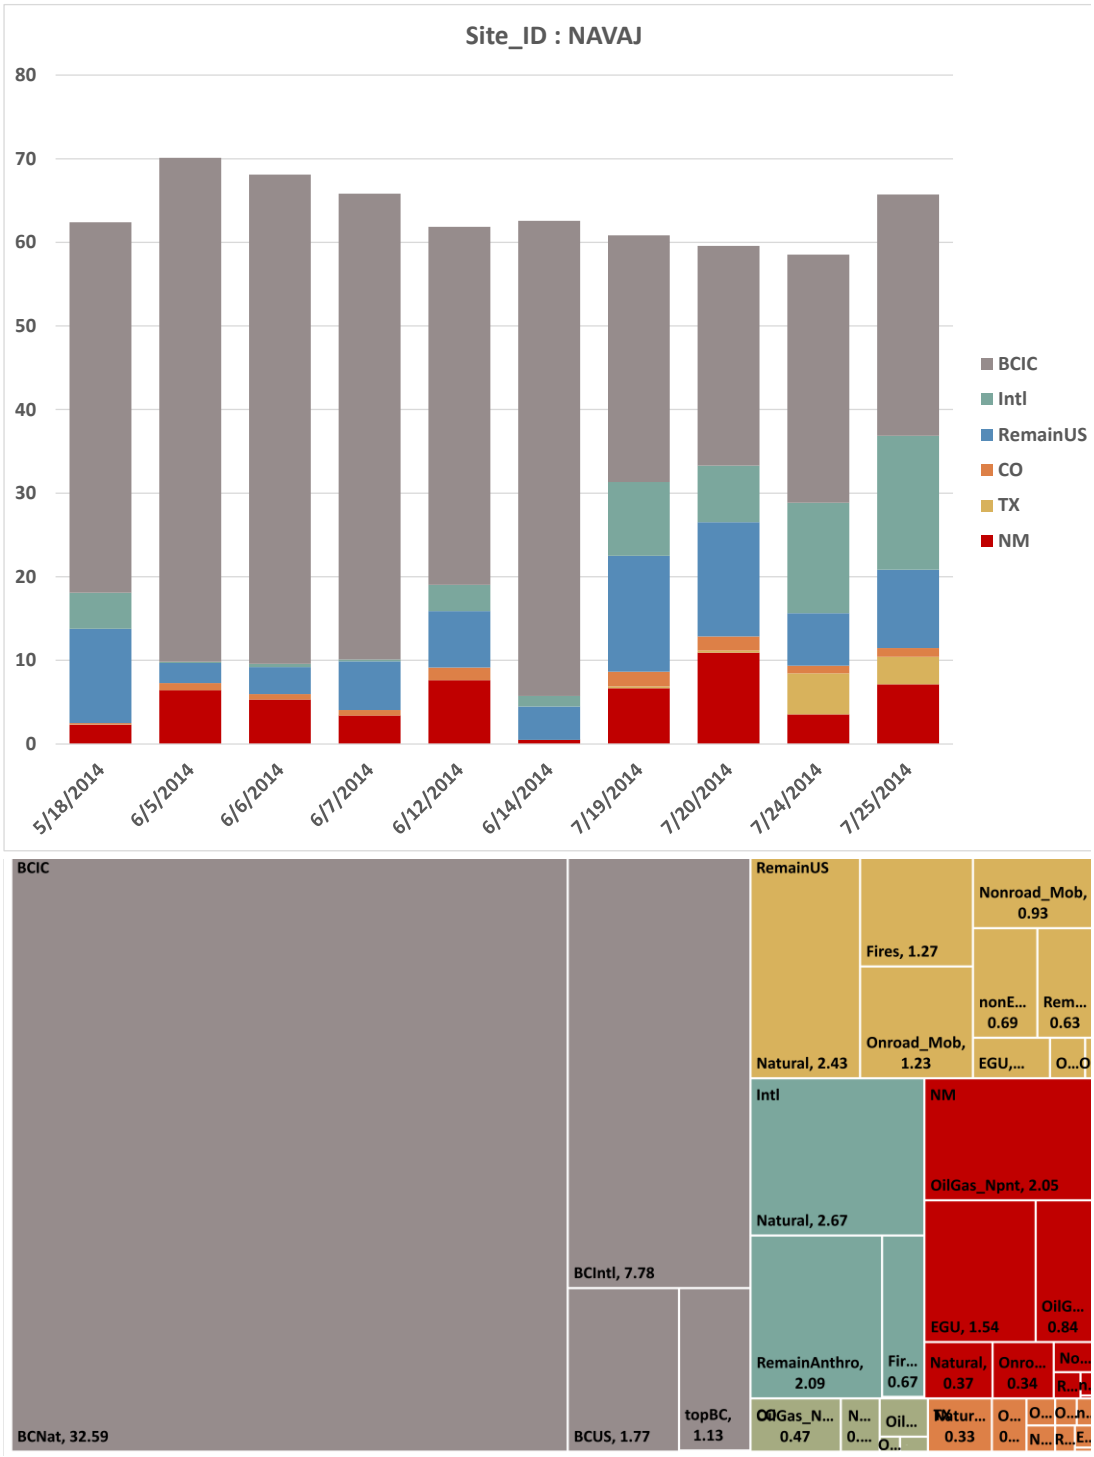

Figure 10-27. Contributions of all Source Groups to total MDA8 ozone concentrations at Navajo Lake for the 10 high SMAT ozone days (top) and average across the 10 SMAT days (bottom).

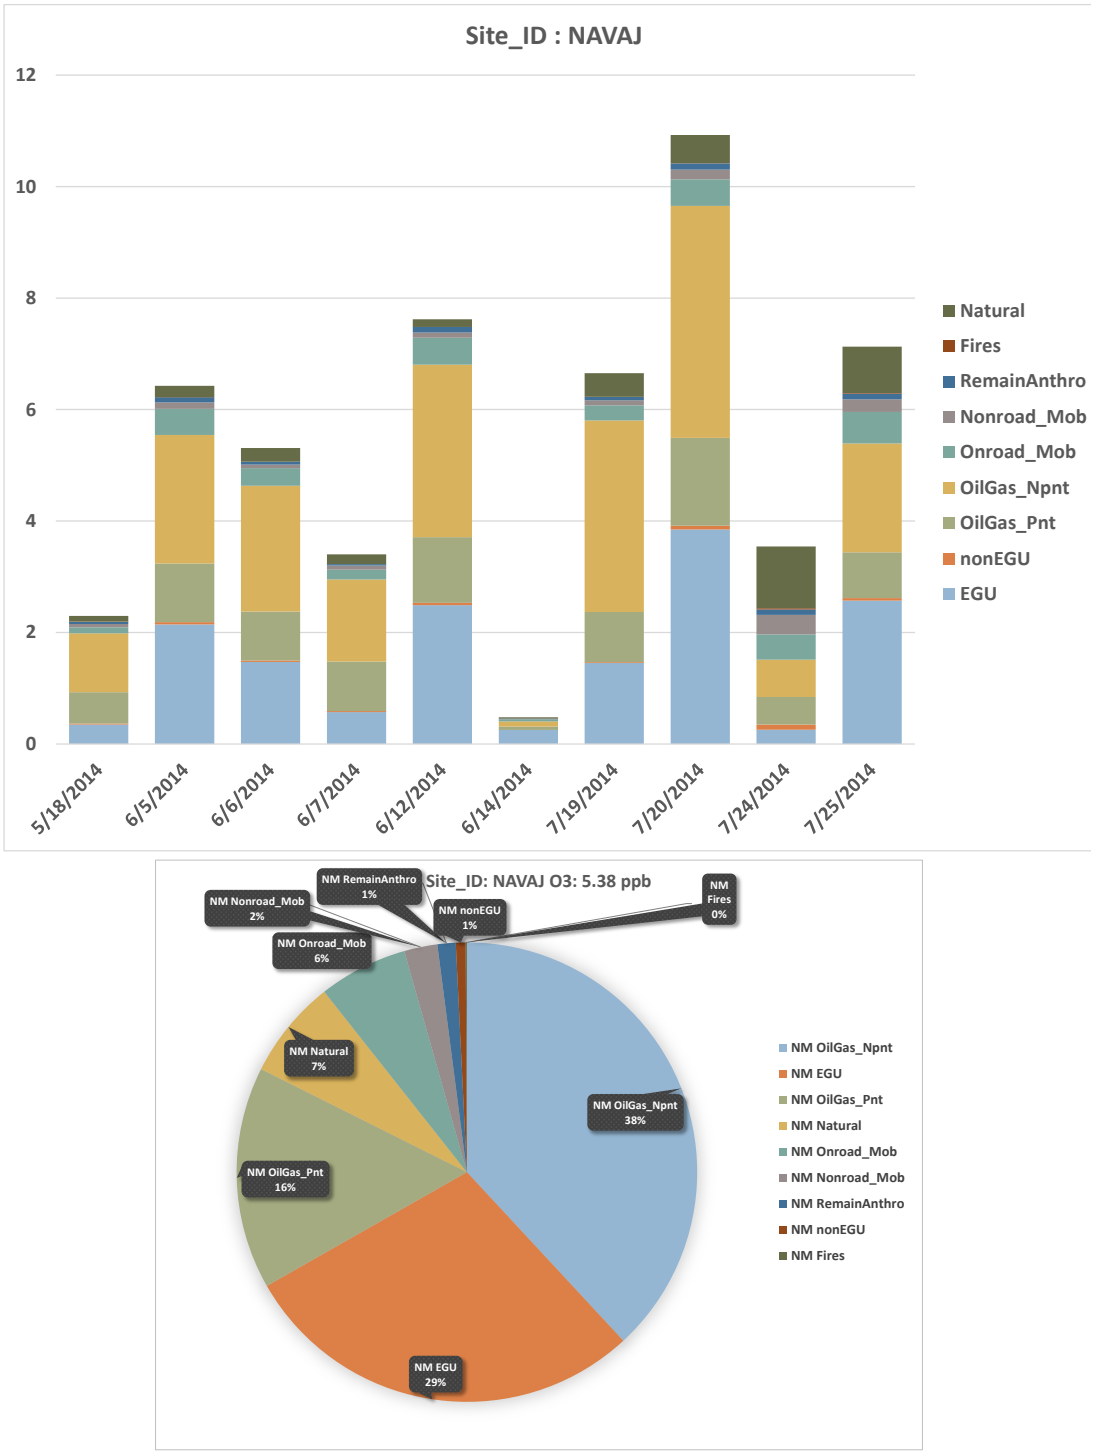

Figure 10-28. Contributions of New Mexico Source Groups to MDA8 ozone concentrations from New Mexico at Navajo Lake for the 10 high SMAT ozone days (top) and average across the 10 SMAT days (bottom).

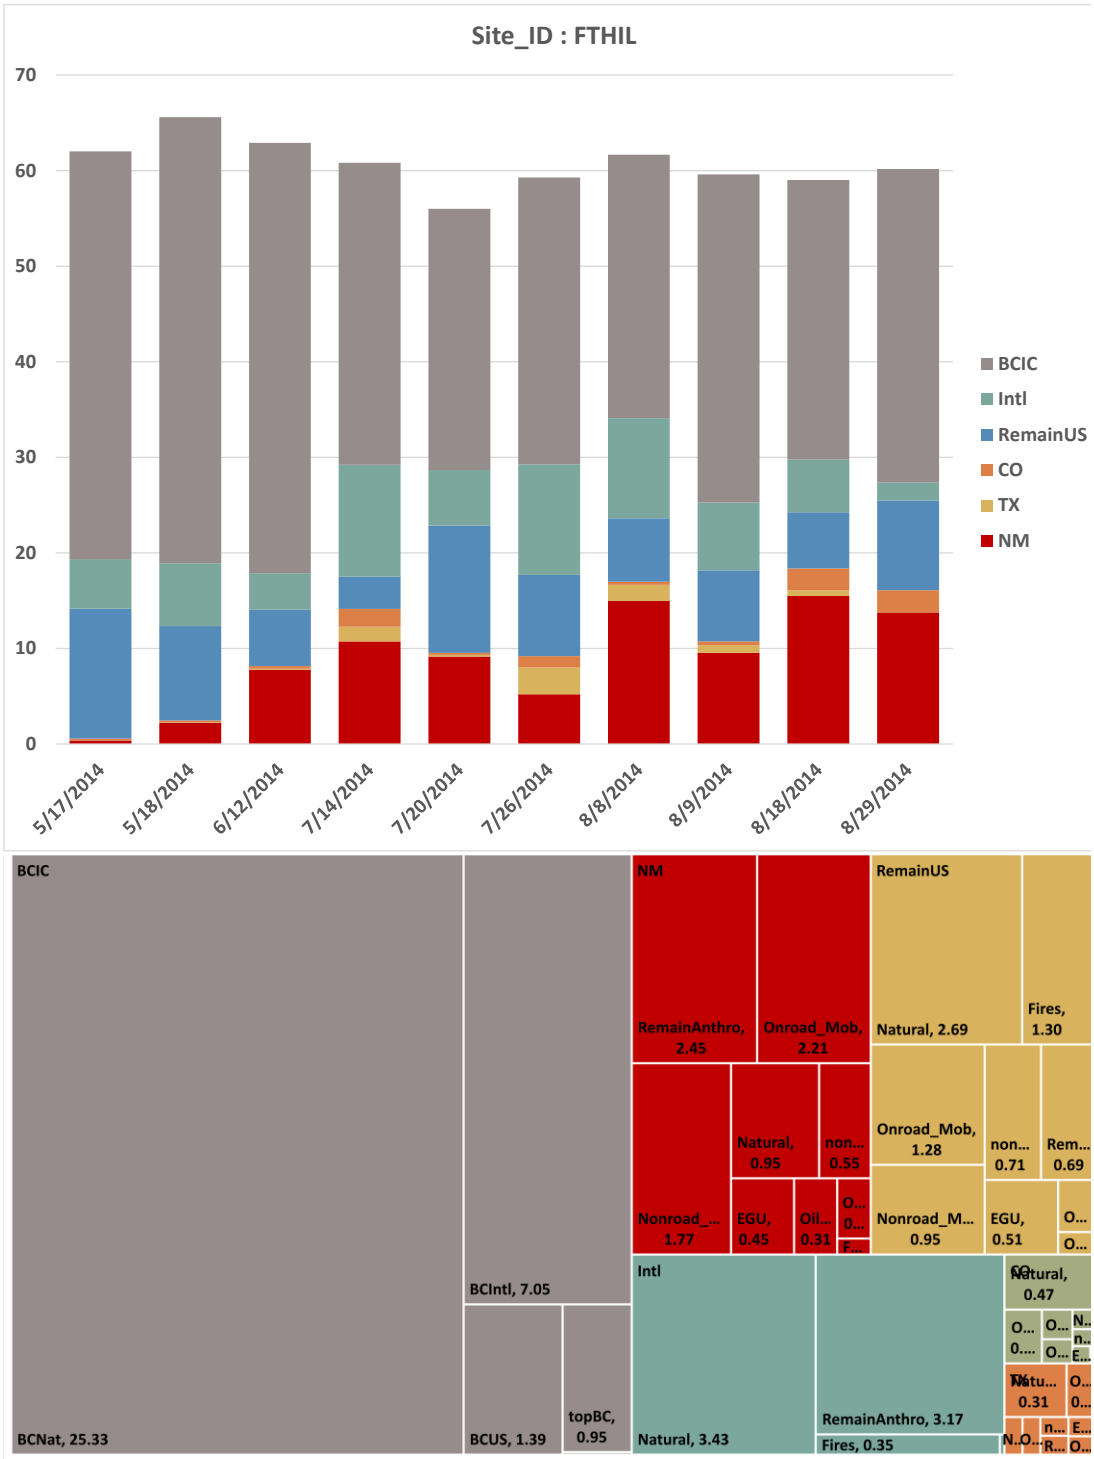

Figure 10-29. Contributions of all Source Groups to total MDA8 ozone concentrations at Foothills for the 10 high SMAT ozone days (top) and average across the 10 SMAT days (bottom).

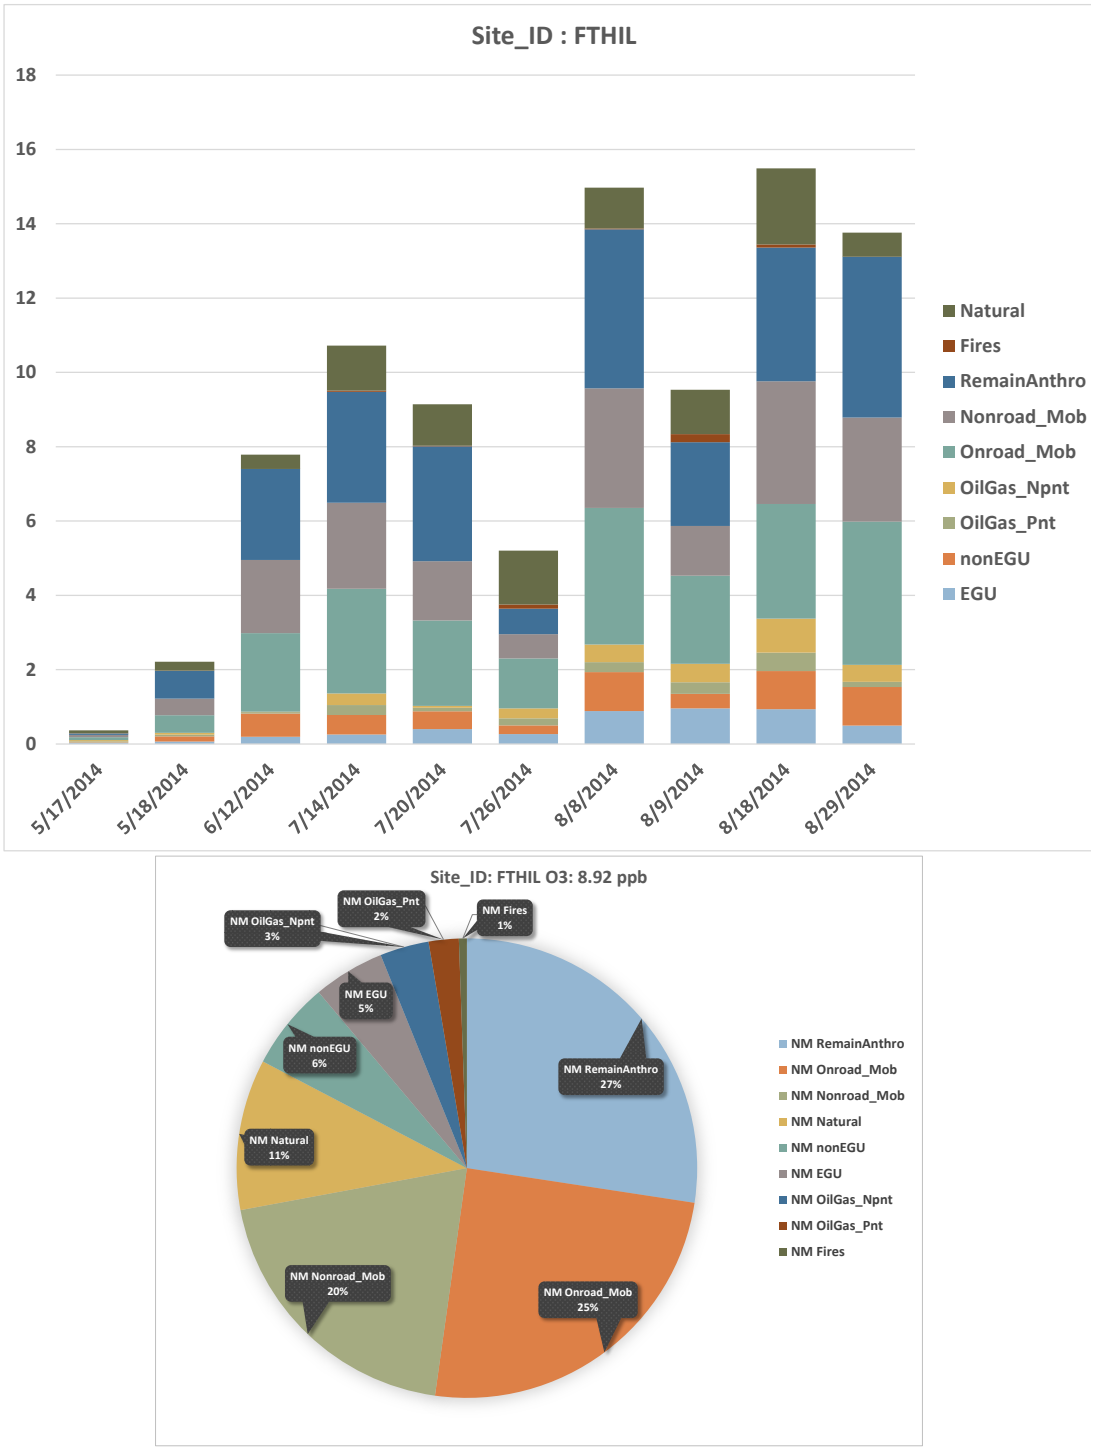

Figure 10-30. Contributions of New Mexico Source Groups to MDA8 ozone concentrations from New Mexico at Foothills for the 10 high SMAT ozone days (top) and average across the 10 SMAT days (bottom).

Ozone contributions for the 10 SMAT days at the Desert View monitor in Doña Ana County are shown in Figures 10-31 and 10-32. BCs from outside the 36-km North American domain is the largest contributor (45% on average), followed by in-domain international emissions (27%), Remainder US (14%) and Texas (8%). Emissions from New Mexico only contribute 4% of the total ozone averaged across the 10 SMAT days at Desert View. International anthropogenic emissions from BCs (5.8 ppb) and in-domain (i.e., Mexico) sources (13.0 ppb) contribute a combined 18.8 ppb (30%) of the average ozone across the 10 SMAT days at Desert View (Figure 10-31, bottom). As shown in Figure 10-32, the contributions from sources in New Mexico contributes from 1.3 to 4.4 ppb to the total MDA8 ozone on the 10 SMAT days, with an average contribution of 2.8 ppb. The largest New Mexico contributing Source Sector is EGU (29%), followed by Natural (18%), On-Road (15%) with 10% contribution coming from Non-Road and Remaining Anthropogenic (Figure 10-32, bottom).

Figures 10-33 and 10-34 displays the 10 SMAT day ozone contributions at the Carlsbad monitoring site. BC and in-domain international emissions contribute the most to ozone at Carlsbad. There is a lot of variation in the day-to-day contributions from New Mexico (0.2 to 5 ppb) with an average contribution of 2.0 ppb. Similar results are seen for Texas (0.5 to 9 ppb with an average of 2.5 ppb). Non-Point O&G and then Point O&G are the two largest anthropogenic Source Sector contributors from both New Mexico and Texas.

10.3.3 International Anthropogenic Emissions Contributions to Projected 2028 ozone DVFs

The SMAT ozone DVF projection tool was run using the CAMx 2028 O&G Control Strategy output with the contributions of international anthropogenic emissions removed. The ozone concentrations due to the BC_{Intl} and in-domain international emissions (i.e., Mexico, Canada and CMV_{Intl}) were removed from the CAMx 2028 O&G Control Strategy output and SMAT was run to obtain projected 2028 ozone DVFs without any contributions of international anthropogenic emissions. SMAT was run using three different current year ozone design values: $DVC_{2012\text{-}2016}$, $DVC_{2015\text{-}2019}$ and $DVC_{2017\text{-}2019}$ using the same procedures as used in the 2028 ozone DVF projection DVC sensitivity analysis discussed in Chapter 9. Tables 10-4 through 10-6 display the projected 2028 ozone DVFs for the 2028 O&G Control Strategy and 2028 no international anthropogenic emissions scenarios using the three sets of DVCs.

The elimination of the international anthropogenic emissions reduces the projected 2028 ozone DVFs by 13 to 25 ppb with the smallest reductions at the northern and largest reductions at the southern sites in New Mexico. For all DVC scenarios, the projected 2028 ozone DVFs at all monitoring sites in New Mexico are below the 2015 70 ppb ozone NAAQS when ozone contributions due to international anthropogenic emissions are removed. The highest projected 2028 ozone DVF under the no international anthropogenic emissions scenario is 52.8 ppb at the Carlsbad monitoring site when the $DVC_{2017\text{-}2019}$ current year design value is used in the 2028 ozone DVF projection.

Figure 10-35 displays the spatial distribution of the current year ozone DVC and the projected 2028 ozone DVF for the 2028 O&G Control Strategy using the SMAT UAA tool and the three definitions of DVCs. Using the $DVC_{2012\text{-}2016}$ and $DVC_{2015\text{-}2019}$, the SMAT projected 2028 ozone DVFs are all below the 2015 ozone NAAQS under the 2028 O&G Control Strategy emissions scenario. However, when the $DVC_{2017\text{-}2019}$ is used, the SMAT UAA estimates projected 2028 ozone DVFs in excess of the 2015 ozone NAAQS across all of Eddy County in southeast New Mexico.

The spatial distribution of the projected 2028 ozone DVF with no international anthropogenic emissions and its differences with the 2028 O&G Control Strategy 2028 ozone DVF using the three DVC definitions are shown in Figure 10-36. The removal of the international anthropogenic emission contributions reduces the 2028 ozone DVFs in New Mexico by 10-30 ppb. The highest 2028 ozone DVF in the 4-km New Mexico domain are 52.5, 55.2 and 56.4 ppb for the, respectively, $DVC_{2012\text{-}2016}$, $DVC_{2015\text{-}2019}$ and $DVC_{2017\text{-}2019}$ current year design value sensitivity scenarios, which are well below the 2015 70 ppb ozone NAAQS.

11. 2028 VOC AND NOX SENSITIVITY OSAT OZONE SOURCE APPORTIONMENT MODELING

A second CAMx 2028 ozone source apportionment model simulation was performed to estimate whether ozone formation that leads to elevated ozone concentrations in New Mexico occurs under conditions that are more sensitive to VOC or NO_x emissions. The VOC/NO_x emissions sensitivity ozone source apportionment simulation used the Ozone Source Apportionment Technology (OSAT) version of the CAMx ozone source apportionment tools. As discussed in Section 10.1, when using OSAT, the relative amounts of the O3V and O3N ozone source apportionment tracers provide an indication of whether ozone formation is more sensitive to VOC or NO_x emissions.

11.1 2028 OSAT Ozone Source Apportionment Design

The CAMx 2028 OSAT VOC/ NO_x sensitivity ozone source apportionment simulation used the 36/12/4-km nested domain structure, summer of 2014 meteorology and the 2028 O&G Control Strategy emissions scenario. The same five Source Regions as used in the 2028 Source Sector APCA ozone source apportionment simulation were used (See Figure 10-1):

1. New Mexico;
2. Texas;
3. Colorado;
4. Remainder U.S. states plus coastal water out to 200 nautical miles (nmi) of the U.S. coast; and
5. International, which include Mexico, Canada and waters off their coasts, plus waters more than 200 nmi off the U.S. coast.

Three Source Categories were specified in the 2028 OSAT ozone source apportionment modeling:

1. Anthropogenic emissions;
2. Fires; and
3. Natural emissions.

Fires include U.S. wildfires (WF), wildland prescribed burns (Rx) and agricultural burning (Ag), and other fires from Mexico and Canada. Natural emissions include biogenic, lightning NO_x (LNO_x), windblown dust (WBD) and oceanic (sea salt and DMS) sources.

With 5 Source Regions and 3 Source Categories, plus separate Source Groups for Initial Concentrations (IC) and Boundary Conditions (BC), that results in a total of 17 Source Groups for which separate ozone source contributions will be obtained in the 2028 OSAT ozone source apportionment modeling (17 = 5 x 3 + 2).

NMED Exhibit 17

11.2 Spatial Distribution of VOC/NO_x Ozone Formation Sensitivity

The sensitivity of ozone formation to VOC and NO_x emissions is obtained for each of the 15 emission Source Groups that consist of emissions from 3 source categories (i.e., anthropogenic, fires and natural) emitting from 5 Source Regions. The percent contribution of NO_x sensitive ozone formation metric is used to display the ozone formation sensitivity that is defined as follows:

$$\text{Percent } NO_x \text{ Sensitive Ozone (\%NOxSens)} = 100 \times \sum O3N_i \,/\, \sum (O3V_i + O3N_i)$$

Where the sum is performed over the 15 different emissions Source Groups (i) that consist of the three emission Source Categories emitting from the 5 Source Regions. The Percent VOC Sensitive Ozone will be 100 minus the Percent NO_x Sensitive Ozone metric.

Note that the O3V and O3N tracers for the IC and BC Source Groups are not used in the Percent NO_x Sensitive Ozone metric since they were defined from the 2014 simulation of the 2014 GEOS-Chem global chemistry model and the CAMx GEOS2CAMx processor arbitrarily assigns half of the GEOS-Chem total ozone to the O3V and O3N tracers each so do they not have accurate information on whether such IC/BC ozone concentrations are more VOC or NO_x sensitive.

Spatial displays of the Percent NO_x Sensitive Ozone metric were generated for Maximum Daily Average 8-hour (MDA8) ozone concentrations and several combinations of Source Groups for each day of the May-August 2014 modeling episode. When presenting the Percent NO_x Sensitive Ozone metric for a combination of Source Groups, it is also important to know the total MDA8 ozone due to the same combination of Source Groups in order to interpret the significance of the %NOxSens metric; if the MDA8 ozone concentrations due to the combination of Source Groups is very small (e.g., < 0.01 ppb), whether the ozone formed was more sensitive to VOC or NO_x emissions is inconsequential. Spatial maps across the New Mexico 4-km modeling domains were generated for total MDA8 ozone and Percent NO_x Sensitive Ozone for the following combinations of Source Groups:

- All emissions based Source Groups (i.e., anthropogenic, fires and natural emissions emitted from the 5 Source Regions in the CAMx modeling domain).
- All anthropogenic emissions based Source Groups across the CAMx modeling domain.
- The New Mexico anthropogenic emissions Source Group.

The Percent NO_x Sensitive Ozone for the New Mexico anthropogenic emissions Source Group provides information on whether New Mexico VOC or NO_x emissions may be more important to ozone formation.

Figures 11-1 through 11-8 display the total MDA8 ozone and Percent NO_x Sensitive ozone metric for eight example days during the episode that tended to have relatively higher ozone concentrations and included the six example days displayed in previous Chapters.

NMED Exhibit 17

11.2.1 Percent NO_x Sensitive Ozone on May 17, 2014

Figure 11-1 displays the 2028 OSAT source apportionment results for the May 17, 2014 day that was dominated by ozone concentrations from a fire in eastern Arizona that caused modeled elevated ozone concentrations in southwestern New Mexico. Figure 11-1a displays the MDA8 ozone concentrations from all Source Groups, including IC/BC, and is the modeled total MDA8 ozone on this day. The modeled peak MDA8 ozone on May 17th is 129 ppb and occurs within the fire ozone plume in eastern Arizona. The Percent NO_x Sensitive Ozone due to all emissions based source groups indicates ozone formation across the 4-km NM domain is more NO_x sensitive than VOC sensitive with the color scale going from green (%NOxSens > 65%) to red/orange (%NOxSens > 85%) (Figure 11-1b). Although, it is interesting to note that at the locations of the higher total MDA8 ozone concentrations, the amount of %NOxSens ozone is less, with the lowest value (%NOxSens = 64%) occurring at the same location as the peak modeled MDA8 ozone concentration in eastern Arizona.

Figure 11-1c and d show the MDA8 ozone and %NOxSens metric for all anthropogenic emissions on May 17th, with the anthropogenic emissions %NOxSens metric being mostly orange and red (%NOxSens > 90%), indicating mostly NO_x sensitive ozone formation. There are areas of high MDA8 ozone due to anthropogenic emissions in west Texas (peak of 23 ppb) where %NOxSens ozone is a little lower (80-90%), as well as a small area on the Colorado side of the San Juan Basin with lower %NOxSens metric. Figure 11-1e and f show the MDA8 ozone and %NOxSens metric for New Mexico anthropogenic emissions on May 17th. The highest contribution of New Mexico anthropogenic emissions to MDA8 ozone is 9 ppb and occurs in the Permian Basin with ozone formation being very NO_x sensitive (%NOxSens > 85%). The lowest New Mexico NO_x sensitive ozone is in the San Juan Basin with a minimum value of 32%, indicating a VOC sensitive ozone formation value of 68% (Figure 11-1f). The New Mexico anthropogenic emissions ozone contribution in the San Juan Basin is less than 3 ppb (Figure 11-1e).

NMED Exhibit 17

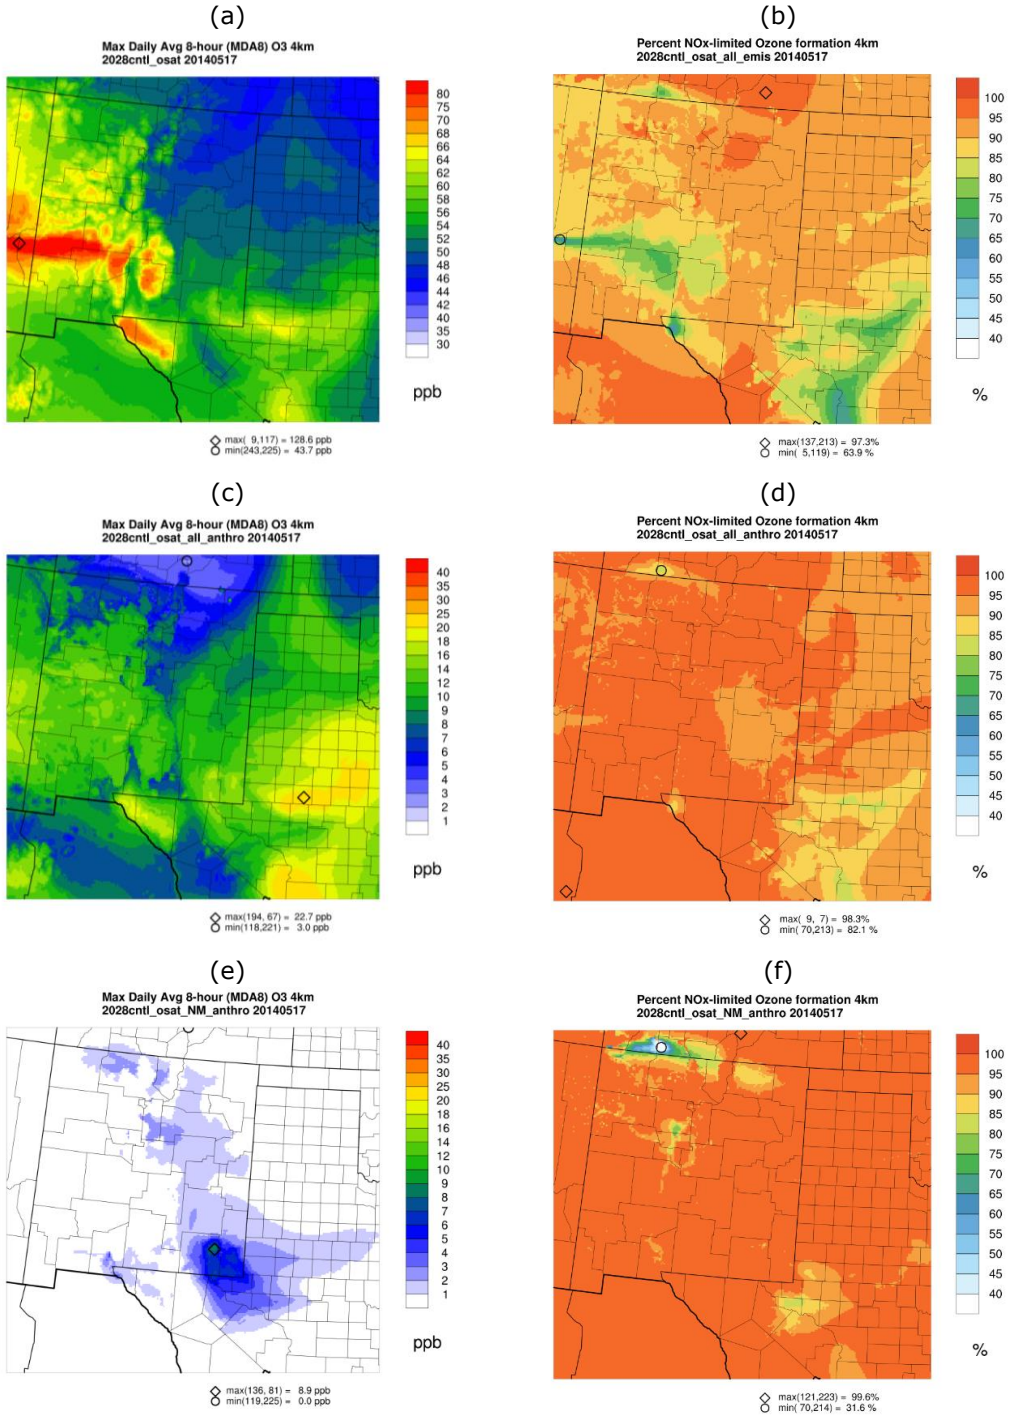

Figure 11-1. 2028 MDA8 ozone (left) and Percent NO_X Sensitive Ozone (right) on May 17, 2014 for: (a) total MDA8 ozone; (c) ozone due to anthropogenic emissions; (e) ozone due to New Mexico anthropogenic emissions; (b) %NOxSens for all emissions; (d) %NOxSens for all anthropogenic emissions; and (f) %NOxSens for New Mexico anthropogenic emissions.

11.2.2 Percent NO_x Sensitive Ozone on May 26, 2014

On May 26th, the peak modeled MDA8 ozone concentrations is 58 ppb and occurs in San Juan County (Figure 11-2a). Ozone formation from all emissions is mostly NO_x sensitive across New Mexico (Figure 11-2b). Although the lowest %NOxSens due to all emissions on May 26 (68%) occurs at the location of the peak MDA8 ozone in San Juan County. When looking at just anthropogenic emissions, the %NOxSens ozone is mostly greater than 90% across most of New Mexico on May 26th with the exception of San Juan County and stretching south into McKinley County with a %NOxSens minimum of 69% (Figure 11-2d) occurring at the same location as the modeled 58 ppb peak. The maximum MDA8 ozone due to New Mexico anthropogenic emissions on May 26th is 7 ppb and occurs at the same location as the 58 ppb total MDA8 ozone peak in San Juan County. Ozone formation due to New Mexico emissions at the location of this MDA8 ozone peak in San Juan County is split approximately equally between VOC and NO_x sensitive ozone formation (%NOxSens = 45%; Figure 11-2f).

11.2.3 Percent NO_x Sensitive Ozone on May 28, 2014

May 28th has elevated ozone concentrations in southern New Mexico, including southern Doña Ana County and the Permian Basin, as well as within the Albuquerque urban plume (Figure 11-3a). Ozone formation across New Mexico due to anthropogenic emission tends to be mostly NO_x sensitive on May 28th with the lowest NO_x sensitive ozone of 73% occurring at almost the exact same location in southern Doña Ana County as the ozone peak (Figure 11-3b). When just looking at the sensitivity of anthropogenic emissions, the %NOxSens value at the location of the peak in southern Doña Ana County increases from 73% to 81% (Figure 11-3d). Finally, the contributions of New Mexico anthropogenic emissions to the ozone peak in southern Doña Ana County is 2-4 ppb and is very NO_x sensitive (%NOxSens > 90%) (Figure 11-3e and f). The highest MDA8 ozone due to New Mexico anthropogenic emissions on May 28th is 9 ppb in the Albuquerque urban plume where %NOxSens is slightly lower than the surrounding areas (85-90%), with the lowest New Mexico anthropogenic emissions %NOxSens being 75% in a high ozone area in the Permian Basin.

11.2.4 Percent NO_x Sensitive Ozone on June 5, 2014

CAMx estimates 2028 high MDA8 ozone concentrations in excess of the 70 ppb ozone NAAQS on June 5, 2014 in the San Juan Basin and El Paso (Figure 11-4a). In these high ozone locations, ozone formation is split approximately 50%/50% between VOC and NO_x sensitive ozone formation conditions (Figure 11-4b). When looking at just anthropogenic emissions, ozone formation tends to be more NO_x sensitive with %NOxSens ranging from 60-85% in El Paso and 70-85% in San Juan Basin (Figure 11-4d). Ozone from New Mexico anthropogenic emissions is mainly NO_x sensitive in El Paso on June 5th, but in the San Juan Basin there is more VOC sensitive ozone formation with New Mexico anthropogenic emissions ozone contribution ranging from 1 to 4 ppb (Figure 11-4e and f). In particular, there are large areas of blue shaded %NOxSens ozone in San Juan County due to New Mexico anthropogenic emissions that indicates that New Mexico VOC and NO_x anthropogenic emissions are equally important to ozone formation in San Juan County on this day. On the other hand, ozone formation within the Permian Basin appears to be more NO_x sensitive on June 5th.

11.2.5 Percent NO_x Sensitive Ozone on July 12, 2014

The total MDA8 ozone on July 12th has elevated ozone concentrations entering New Mexico from the south that appears to have originated in Mexico (Figure 11-5a). Ozone formation from anthropogenic emissions on this day is estimated to occur primarily under NO_x sensitive conditions (%NOxSens of 86% to 100%; Figure 11-5d). Ozone formation from New Mexico anthropogenic emissions is primarily NO_x sensitive on July 12th with a relative larger amount of VOC sensitive ozone in the south where elevated ozone concentrations occur, but New Mexico's anthropogenic emissions ozone contribution is less than 1 ppb (Figure 11-5e and f).

11.2.6 Percent NO_x Sensitive Ozone on July 24, 2014

On July 24th, the peak MDA8 ozone in the 4-km domain is above the NAAQS (71.1 ppb) and occurs in San Juan County (Figure 11-6a). Although ozone formation is primarily NO_x sensitive across the 4-km NM domain, the largest VOC sensitive ozone due to all emissions (23% or %NOxSens = 77%) occurs at the location of the peak ozone in San Juan County (Figure 11-6b). However, the amount of VOC sensitive ozone at this location due to anthropogenic emissions is 13% (Figure 11-6d), and less than that (~10%) for anthropogenic emission from New Mexico (Figure 11-6f).

NMED Exhibit 17

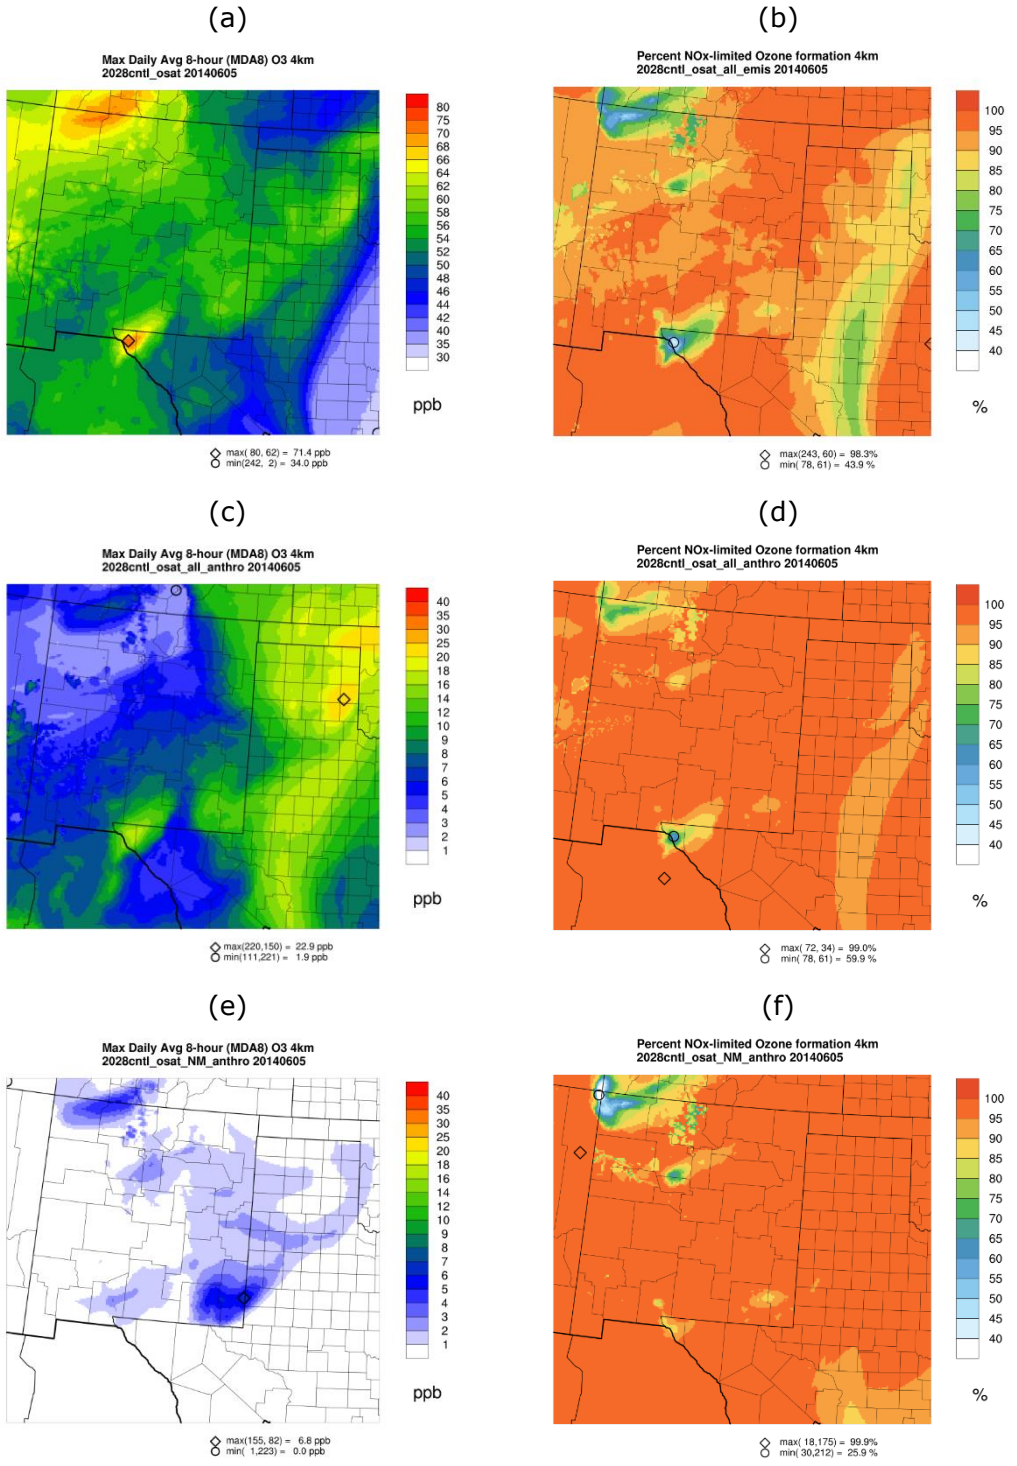

Figure 11-4. 2028 MDA8 ozone (left) and Percent NO_X Sensitive Ozone (right) on June 5, 2014 for: (a) total MDA8 ozone; (c) ozone due to anthropogenic emissions; (e) ozone due to New Mexico anthropogenic emissions; (b) %NOxSens for all emissions; (d) %NOxSens for all anthropogenic emissions; and (f) %NOxSens for New Mexico anthropogenic emissions .

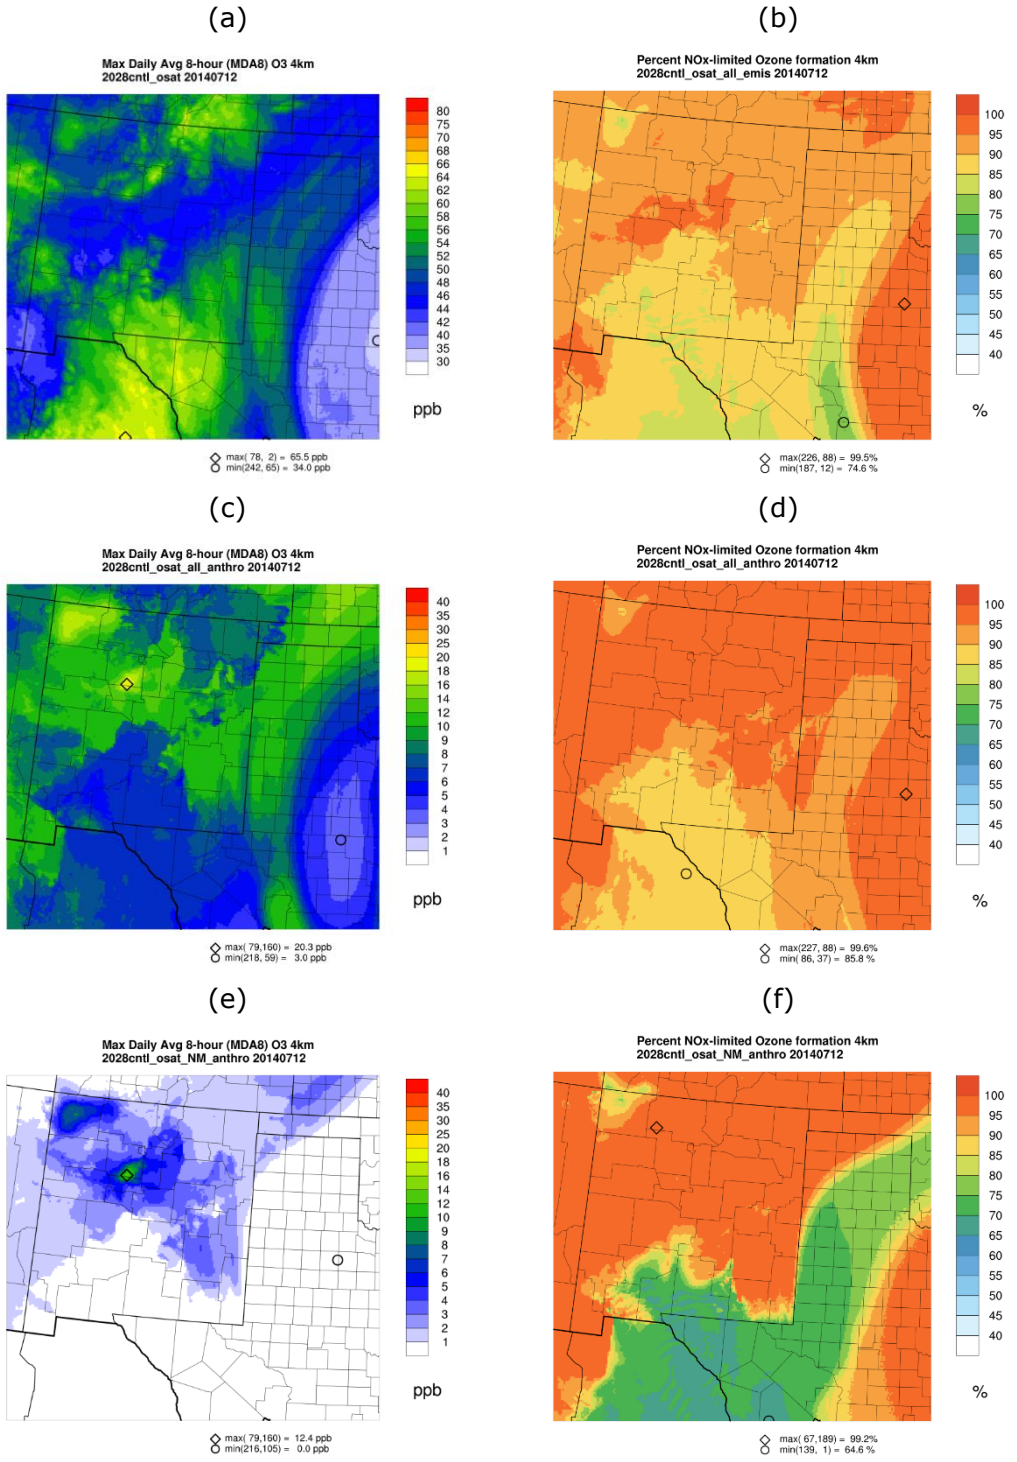

Figure 11-5. 2028 MDA8 ozone (left) and Percent NO_X Sensitive Ozone (right) on July 12, 2014 for: (a) total MDA8 ozone; (c) ozone due to anthropogenic emissions; (e) ozone due to New Mexico anthropogenic emissions; (b) %NOxSens for all emissions; (d) %NOxSens for all anthropogenic emissions; and (f) %NOxSens for New Mexico anthropogenic emissions.

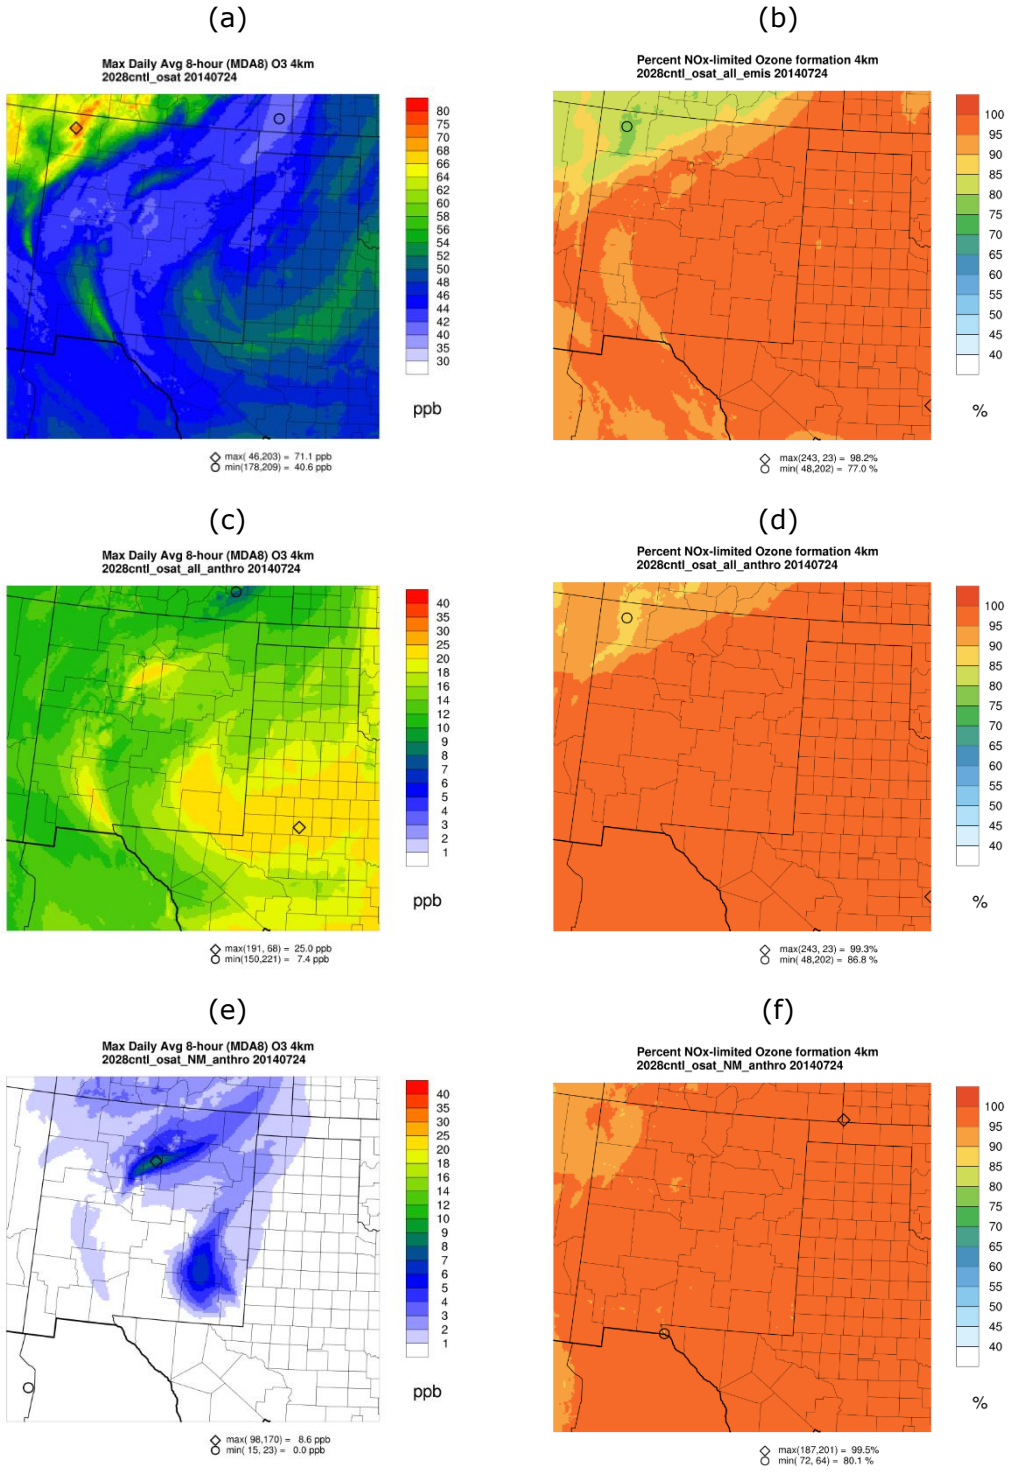

Figure 11-6. 2028 MDA8 ozone (left) and Percent NO_X Sensitive Ozone (right) on July 24, 2014 for: (a) total MDA8 ozone; (c) ozone due to anthropogenic emissions; (e) ozone due to New Mexico anthropogenic emissions; (b) %NOxSens for all emissions; (d) %NOxSens for all anthropogenic emissions; and (f) %NOxSens for New Mexico anthropogenic emissions.

11.2.7 Percent NO_x Sensitive Ozone on July 26, 2014

Modeled elevated MDA8 ozone concentrations occur in northern New Mexico on July 26th with a maximum value above the NAAQS (72 ppb) in northeast Cibola County, west of Albuquerque (Figure 11-7a). Ozone formation is primarily NO_x sensitive across northern New Mexico on this day (%NOxSens > 85%) with the lowest NO_x sensitivity occurring at the location of the 72 ppb ozone peak in Cibola County (78%; Figure 11-7b). However, the NO_x sensitive ozone formation due to anthropogenic emissions at this location is 88% (Figure 11-7d) with a similar value estimated for anthropogenic emission from New Mexico (Figure 11-7f). New Mexico anthropogenic emissions contribute a significant amount (14 ppb) of the 72 ppb ozone peak in northeast Cibola County (Figure 11-7e). Ozone formation due to New Mexico anthropogenic emissions in the San Juan Basin is more VOC sensitive than the rest of New Mexico on July 26th.

11.2.8 Percent NO_x Sensitive Ozone on August 14, 2014

On August 14th there is modeled elevated MDA8 ozone concentrations in northern Rio Arriba County in the San Juan Basin as well as in southern New Mexico with a peak MDA8 ozone in the 4-km domain of 71.2 ppb in El Paso (Figure 11-8a). Although ozone formation is primarily (85-95%) NO_x sensitive across New Mexico on this day, at the locations of the highest MDA8 ozone concentrations, there is relatively more VOC sensitive ozone formation (Figure 11-8b). At the location of the 71.2 ppb ozone peak in El Paso, the CAMx OSAT simulation estimates that ozone formation due to anthropogenic emissions is ~75% NO_x sensitive and ~25% VOC sensitive. Anthropogenic emissions from New Mexico contribute approximately 1 ppb to the ozone peak in El Paso that is primarily formed under NO_x sensitive conditions (Figure 11-8e and f).

11.2.9 Percent NO_x Sensitive Ozone due to New Mexico Anthropogenic Emissions

Figure 11-9 displays the spatial distribution of the Percent NO_x Sensitive Ozone metric due to New Mexico anthropogenic emissions for 15 example days from the May-August 2014 modeling episode, including the 8 days discussed above. As expected, given its mostly rural nature, the CAMx OSAT simulations estimates that ozone formation due to New Mexico anthropogenic emissions is primarily NO_x sensitive. However, there are several locations where ozone formation is estimated to have relatively higher VOC sensitive ozone formation conditions. The San Juan Basin consistently has higher VOC sensitive ozone formation conditions due to New Mexico anthropogenic emissions. Albuquerque also has higher VOC sensitive ozone formation conditions due to New Mexico anthropogenic emissions, and occasionally, ozone formation in the Permian Basin also has relatively higher VOC sensitive ozone formation. As discussed above, the highest MDA8 ozone conditions also have relatively higher VOC sensitive ozone formation conditions. For example, at the location of the relatively high (58 ppb) MDA8 ozone in San Juan County on May 26th the fraction of VOC sensitive ozone is 32% for all emissions, 31% for all anthropogenic emissions and 55% for New Mexico anthropogenic emissions (Figure 11-2). On May 28th the high ozone (64 ppb) in southern Dona Ana County on the border with Texas has a Percent VOC Sensitive Ozone of 27% for all emissions and 19% for all anthropogenic emissions with New Mexico anthropogenic emissions having Percent VOC

Sensitive Ozone for a secondary peak in the Permian Basin of 25% (Figure 11-3). June 5th is a day where there is high MDA8 ozone in the San Juan and Rio Arriba Counties that is approaching the NAAQS that is split approximately equally between VOC and NO_X sensitive ozone (Figure 11-4). On August 14th the modeled ozone peak exceeds the ozone NAAQS in El Paso and ~30% of the ozone was formed under VOC sensitive conditions (Figure 11-8).

NMED Exhibit 17

11.3 Analysis of VOC/NOx Ozone Formation Sensitivity at Monitoring Sites in New Mexico

The CAMx 2028 OSAT ozone source apportionment results were extracted at the locations of the New Mexico monitoring sites and loaded into an Excel Dashboard where the source apportionment contributions to daily MDA8 ozone concentrations can be visualized. The Dashboard displays the OSAT source apportionment O3V and O3N results for groups of 10 days and the average across the 10 days for different combinations of the 3 Source Categories and 5 Source regions within the CAMx modeling domain, with examples for several monitoring sites discussed below.

11.3.1 VOC/NO_x Sensitivity at Substation in San Juan County

Figure 11-10 displays the CAMx OSAT results at the Substation site in San Juan County using daily stacked bar charts of O3V and O3N for the 10 days used by SMAT to make the 2028 ozone DVF projections, along with a pie chart of the O3V and O3N results averaged across the 10 SMAT days. The Dashboard can also display results for the highest and second highest 10 modeled MDA8 ozone concentration days from the CAMx 2028 O&G Control Strategy simulation. As discussed in Chapter 7, the 10 SMAT days are selected as the 10 days with the highest modeled MDA8 ozone near the monitor in the CAMx 2014v2 Base Case, so there is a lot of overlap in days between the 10 SMAT days and the 10 highest modeled 2028 MDA8 ozone days.

The displays in Figure 11-10 use warmer colors (e.g., red) for the NO_x sensitive ozone O3N and cooler colors (e.g., blue) for the VOC sensitive ozone O3V. Emissions within the CAMx domain contribute from 6 to 36 ppb to the total MDA8 ozone across the 10 SMAT days at Substation, with a vast majority of the ozone formed being NO_x sensitive, whose daily variation ranges from approximately 70% to 90% of the SMAT 10 days daily MDA8 ozone concentrations due to emissions (Figure 11-10, top). Averaged across the 10 SMAT days, the total MDA8 ozone at Substation is 63.7 ppb with 67% of that due to BCs and the rest (21.1 ppb) due to in-domain emissions, of which 81% is NO_x sensitive and 19% is VOC sensitive (Figure 11-10, bottom). Since Figure 11-10 is for all emissions sources, the region-specific stacked bars and pie slices display the contributions of anthropogenic, fire and natural emissions from all of the Source Regions.

The Dashboard can be used to isolate the amount of VOC and NO_x sensitive ozone from the different Source Categories and Regions used in the CAMx OSAT simulation with two example pie charts averaged across the 10 SMAT days at Substation shown in Figure 11-11. The top pie chart in Figure 11-11 shows ozone contributions averaged across the 10 SMAT days for all anthropogenic emissions and all Source Regions. All emissions in the domain contributed 21.1 ppb to the average of the 10 SMAT days at Substation of which 11.4 is due to the anthropogenic emissions (Figure 11-11, top) so the remainder (9.7 ppb) is due to natural and fire emissions. Of the 11.4 ppb all anthropogenic emissions ozone contribution, 91% was formed under NOx sensitive and 9% was formed under VOC sensitive conditions. The bottom pie chart in Figure 11-11 shows the contributions to the average of the 10 SMAT days at Substation due to anthropogenic emissions from New Mexico and shows that New Mexico is

NMED Exhibit 17

contributing 42% of the anthropogenic emissions contribution (4.7 of 11.4 ppb) at Substation with most of that (87%) being NO_x sensitive ozone.

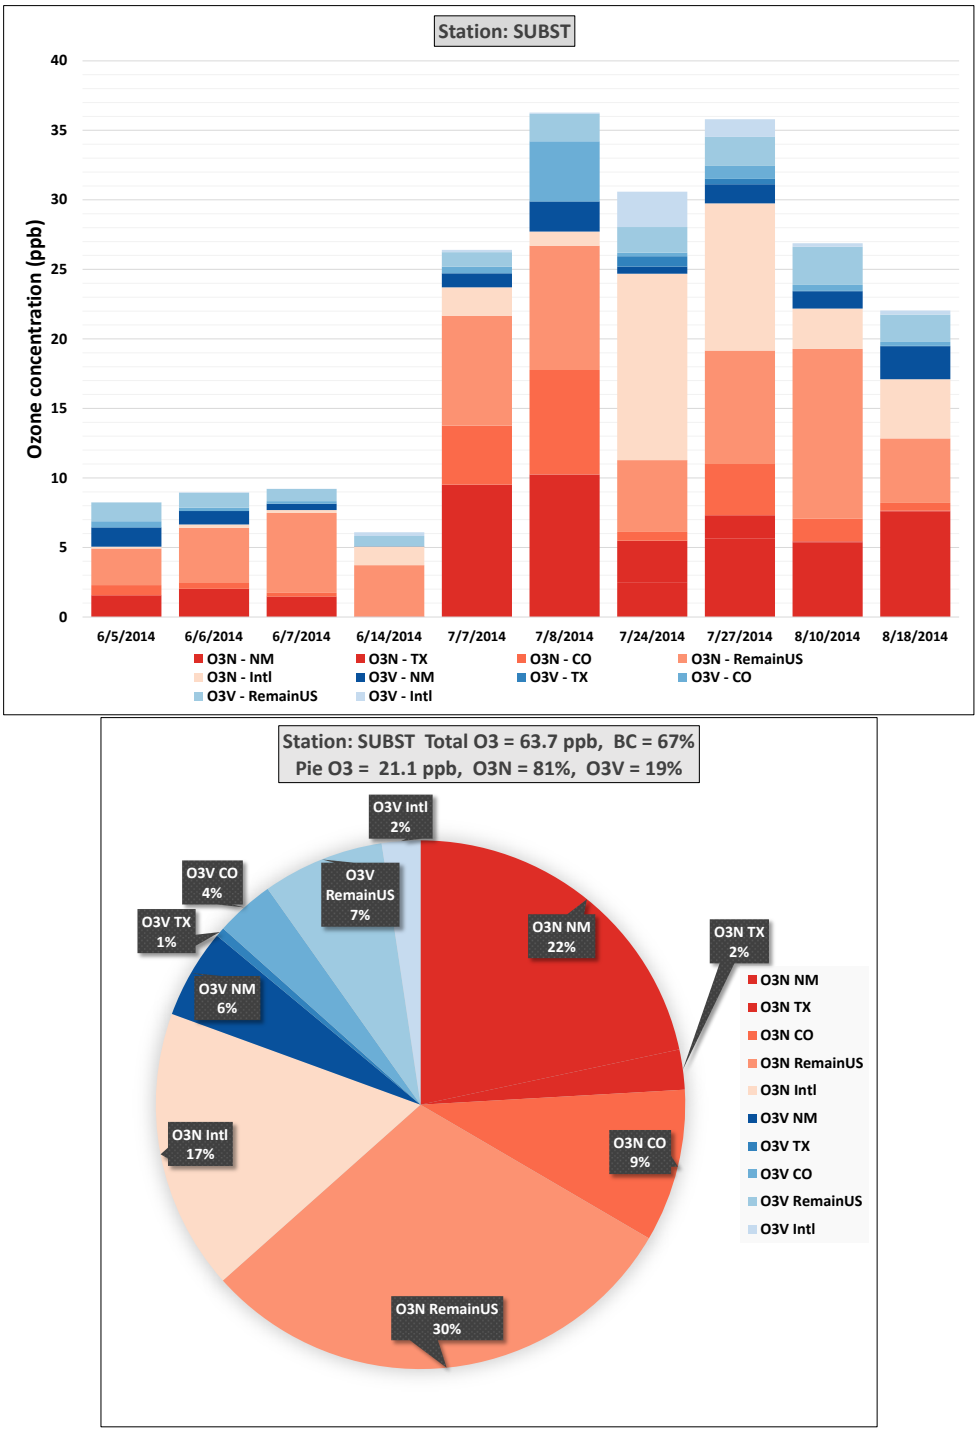

Figure 11-10. Bar Chart of daily O3V (blue) and O3N (red) contributions across the 10 days used by SMAT and pie chart of ozone contributions averaged across the 10 SMAT days for all Source Categories and Source Regions and the Substation monitor in San Juan County.

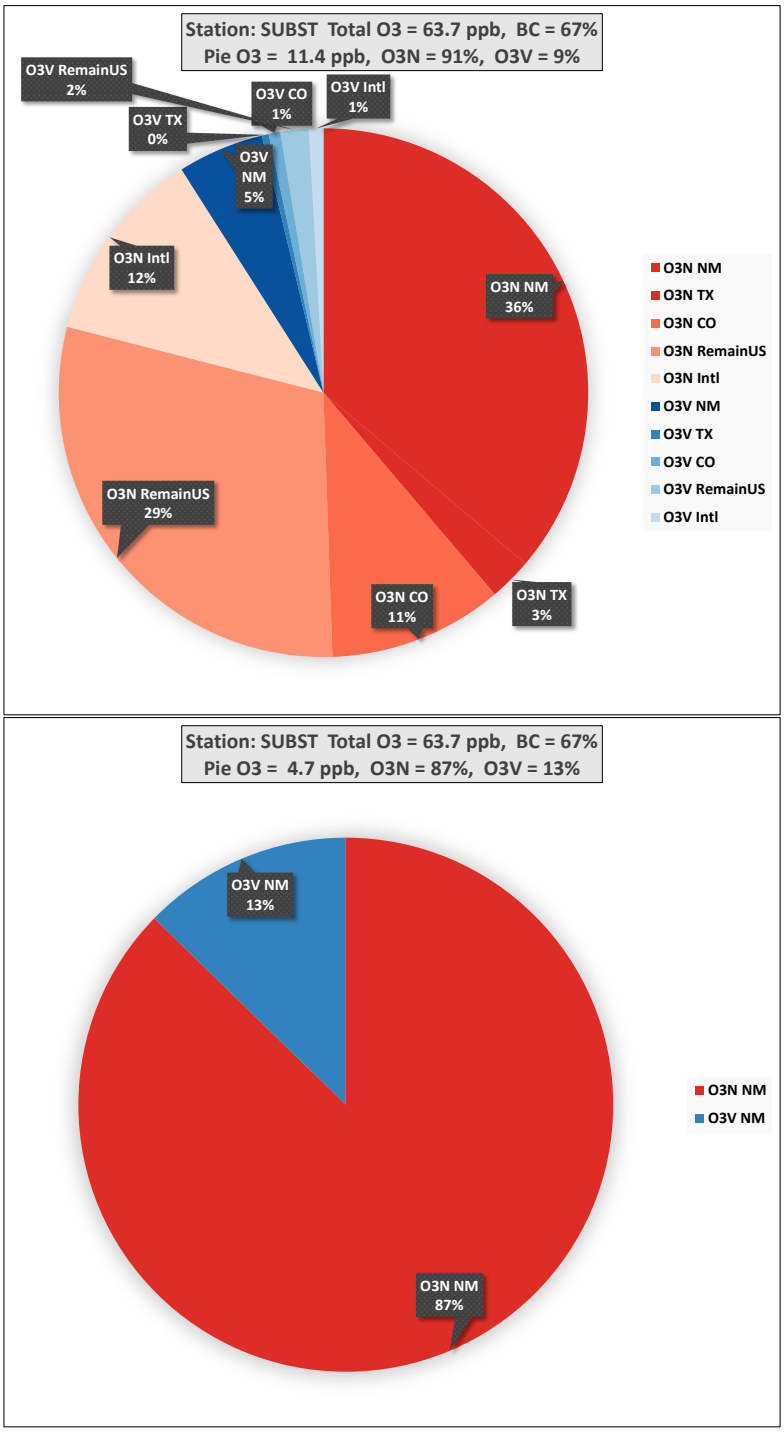

Figure 11-11. O3V and O3N contributions averaged across the 10 SMAT days at Substation for all anthropogenic emissions (top) and New Mexico anthropogenic emissions (bottom).

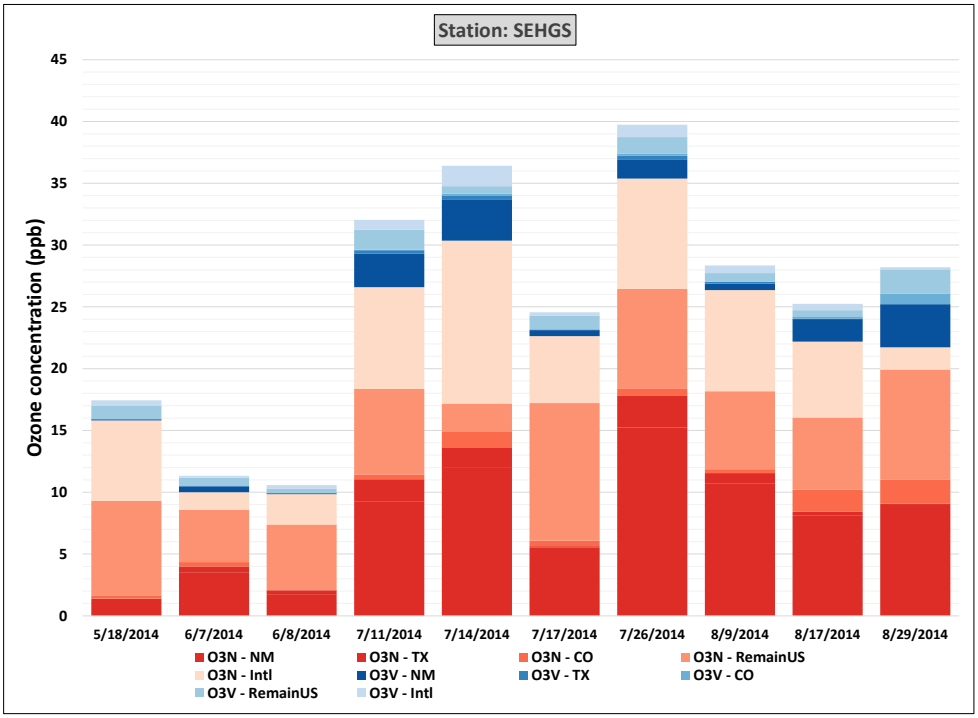
11.3.2 VOC/NO_x Sensitivity at South East Heights in Bernalillo County



The CAMx OSAT source apportionment results for the 10 SMAT days and all sources at the South East Heights monitoring in Bernalillo County are shown in Figure 11-12. There is a lot of day-to-day variability across the 10 SMAT days with in-domain emissions estimated to contribute from 10 to 40 ppb, with the remainder of the ozone coming from the BCs. On the two lowest in-domain emissions ozone days (June 7 and 8 with 10 and 11 ppb ozone from in-domain emissions), the ozone is almost completely (> 90%) NO_x sensitive, whereas on other days the VOC sensitive ozone can exceed 20% (e.g., August 29). This daily variation in VOC and NO_x sensitivity in Bernalillo County was also seen in the spatial maps (e.g., Figure 11-9). Averaged across the 10 SMAT days at South East Heights, in-domain emission sources contribute 25.4 ppb, of which 87% is NO_x sensitive ozone with the O3N from New Mexico (30%), remainder U.S. (26%) and international (25%) being the highest contributors.

A vast majority (93%) of the 14.5 ppb anthropogenic emissions ozone contribution at South East Heights was formed under NO_x sensitive conditions (Figure 11-12, top) with over half of that coming from New Mexico (7.4 ppb) that was also primarily (92%) NO_x sensitive ozone (Figure 11-13, bottom).

11.3.3 VOC/NO_x Sensitivity at Desert View in Doña Ana County

The CAMx OSAT results for the Desert View monitoring site in Doña Ana County are shown in Figures 11-14 and 11-15. Ozone from Texas and Mexico contributes greatly to ozone levels at Desert View. This includes ozone from El Paso that can have a higher fraction of VOC sensitive ozone (e.g., see Figure 11-4) that is seen on some days in the daily bar charts in Figure 11-14 (e.g., July 24, 2014). Emissions within the CAMx domain contribute 24 to 46 ppb of the daily MDA8 ozone on the 10 SMAT days at Desert View with 14 to 28 ppb of that being anthropogenic in origin. Across all emissions, the average of the 10 SMAT days is 81% NO_x sensitive, with the anthropogenic component of ozone being much more NO_x sensitive (90%) than the natural/fire component (69%). New Mexico anthropogenic emissions contribute 2 ppb (10%; Figure 11-15, bottom) of the 20.9 ppb anthropogenic ozone (Figure 11-15, top) at Desert View with emissions from Mexico contributing approximately half (10.6 ppb) and Texas (3.9 ppb), almost 20%.

NMED Exhibit 17

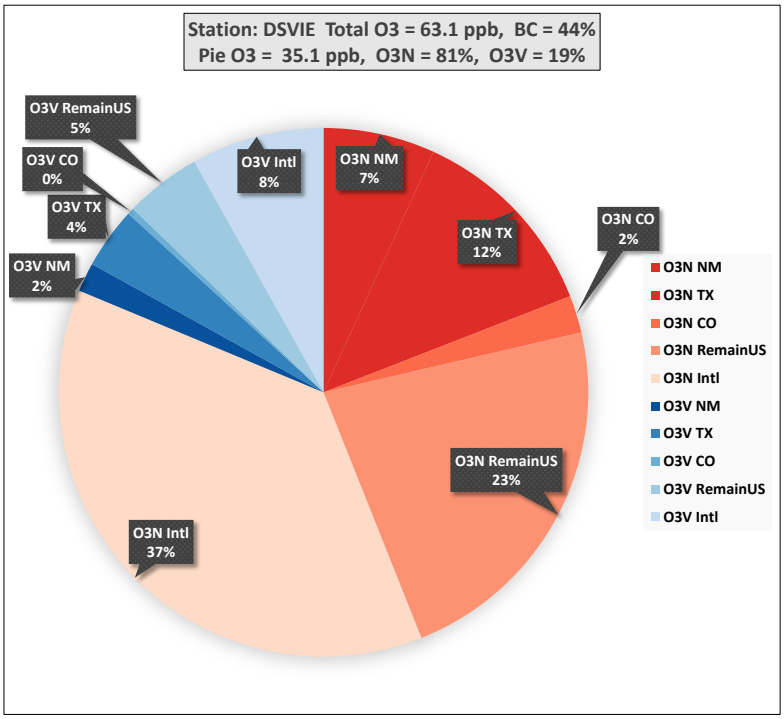

Figure 11-14. Bar Chart of daily O3V (blue) and O3N (red) contributions across the 10 days used by SMAT and pie chart of ozone contributions averaged across the 10 SMAT days for all Source Categories and Source Regions and the Desert View monitor in Doña Ana County.

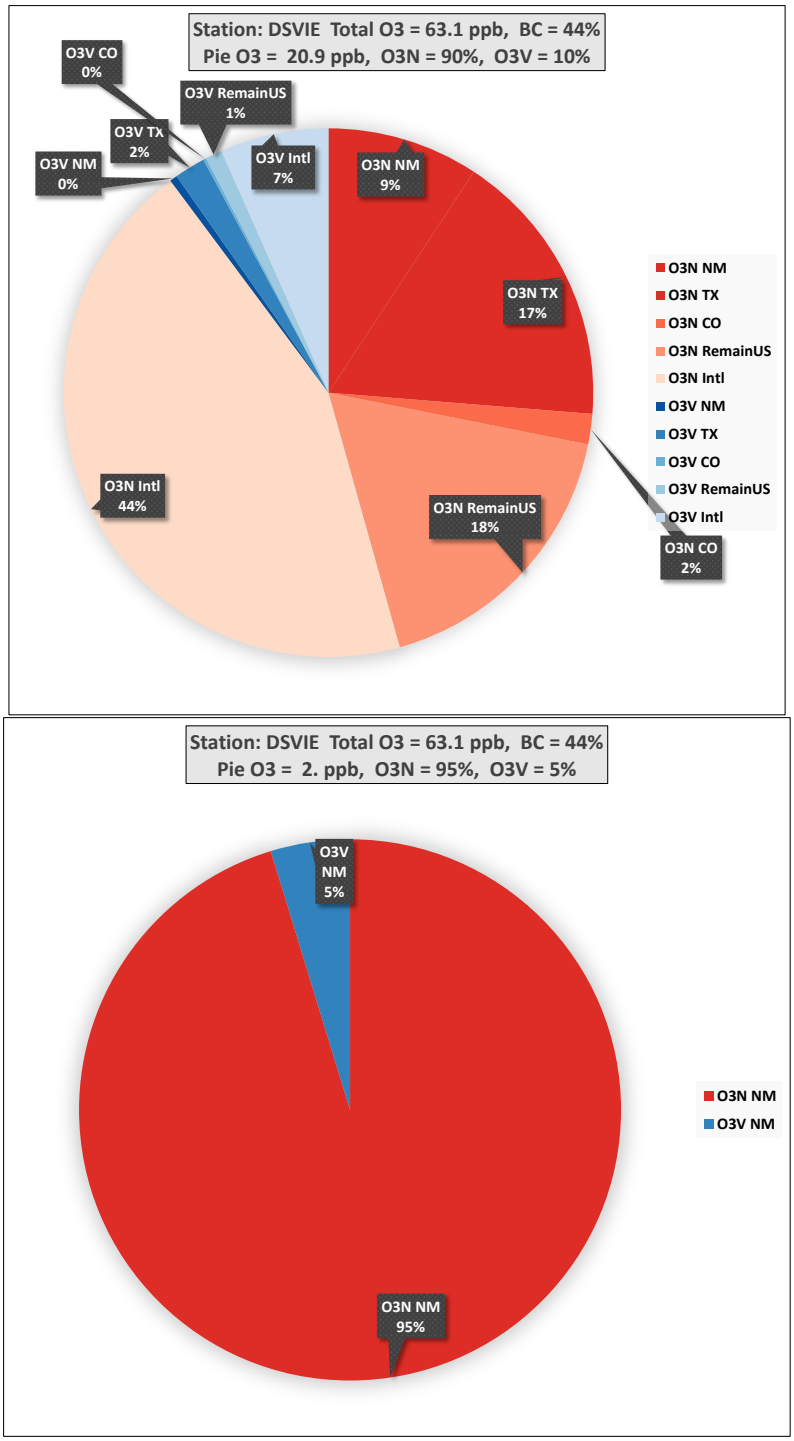

Figure 11-15. O3V and O3N contributions averaged across the 10 SMAT days at Desert View monitoring site for all anthropogenic emissions (top) and New Mexico anthropogenic emissions (bottom).

11.3.4 VOC/NO_x Sensitivity at Carlsbad in Eddy County

Figures 11-16 and 11-17 display the CAMx 2028 OSAT results at the Carlsbad monitor in Eddy County. Across the 10 SMAT days, emissions within the CAMx domain account for 11 to 27 ppb of the daily ozone at Carlsbad (Figure 11-16, top). The model estimates more NO_x sensitive ozone at Carlsbad (91% on average) than Desert View (81% on average). The ozone due to emissions averaged across the 10 SMAT days at Carlsbad is 19.1 ppb that is approximately equally split between anthropogenic (10.0 ppb) and natural/fire (9.1 ppb) sources, with the ozone from the anthropogenic emissions (94%) being more NO_x sensitive than the ozone from the natural/fire emissions (87%). Of the 10 ppb from anthropogenic emissions, almost half (4.7 ppb) is from international emissions with anthropogenic emissions from New Mexico and Texas both contributing 16% (1.6 ppb) each (Figure 11-17).

NMED Exhibit 17

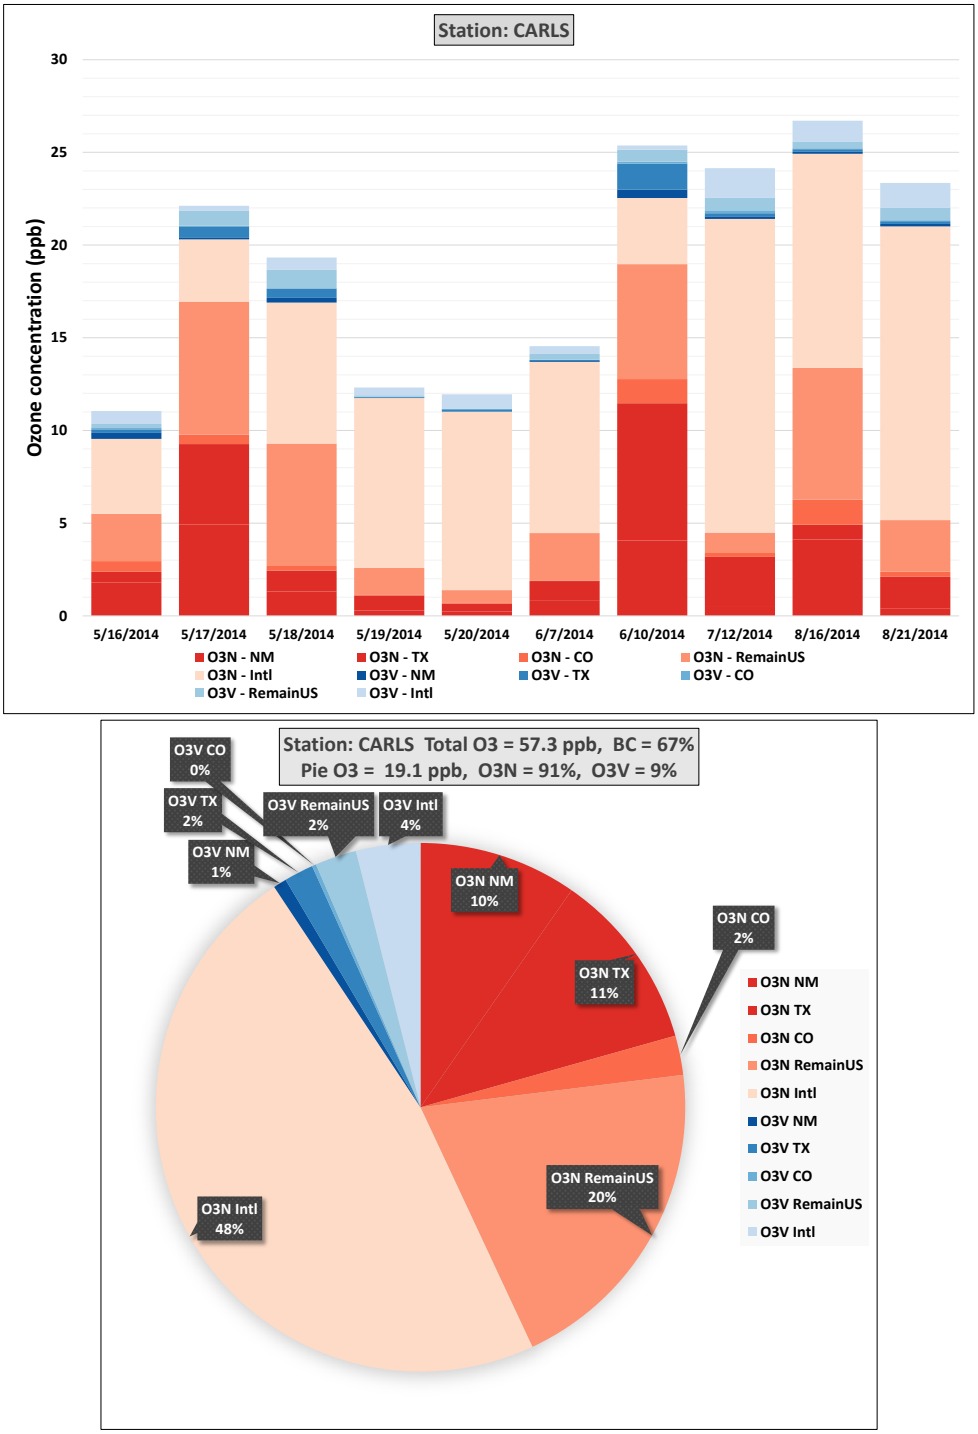

Figure 11-16. Bar Chart of daily O3V (blue) and O3N (red) contributions across the 10 days used by SMAT and pie chart of ozone contributions averaged across the 10 SMAT days for all Source Categories and Source Regions and the Carlsbad monitor in Eddy County.

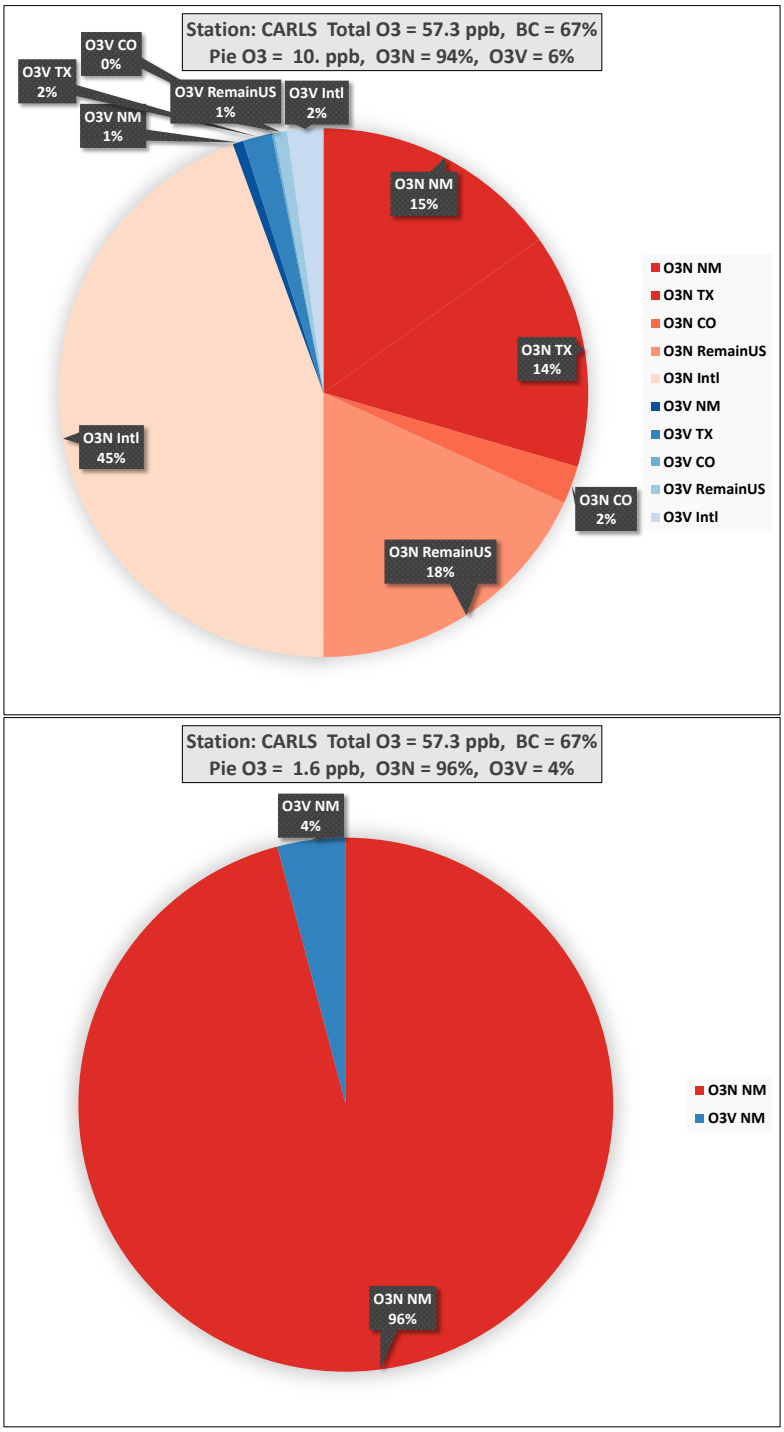

Figure 11-17. O3V and O3N contributions averaged across the 10 SMAT days at Carlsbad monitoring site for all anthropogenic emissions (top) and New Mexico anthropogenic emissions (bottom).

12. SUMMARY AND CONCLUSIONS

12.1 Summary of CAMx 2014 36/12/4-km Photochemical Model Platform Development

A CAMx 2014 36/12/4-km ozone modeling platform was developed with the 4-km domain focused on New Mexico and adjacent states. The CAMx 2014 36/12/4-km modeling platform was based on the Western Regional Air Partnership (WRAP), Western Air Quality Study (WAQS) CAMx 2014 36/12-km modeling platform. WRF meteorological modeling was conducted to generate CAMx meteorological inputs for the 36/12/4-km domains and summer of 2014. A model performance evaluation was conducted that compared CAMx 2014 estimated ozone concentrations with concurrent ozone observations that produced good ozone model performance. A revised CAMx 2014v2 base case was conducted with a newer version of the CAMx model and updated biogenic emissions that also produced very good ozone model performance.

SMOKE emission and CAMx ozone modeling was conducted for a 2014v2 Base Case, a 2028 Base Case and a 2028 O&G Control Strategy that implemented O&G controls on O&G sources in the New Mexico portions of the San Juan and Permian Basins. The proposed New Mexico O&G ozone precursor rule controls were implemented in the 2028 Base Case NM O&G emissions by Eastern Research Group (ERG) under separate contract with NMED.

12.2 Summary of 2028 Ozone Modeling Results and Ozone Design Value Projections

2028 projected future year ozone design values (DVF) were made using the CAMx 2014v2, 2028 Base Case and 2028 O&G Control Strategy modeling results following EPA's latest photochemical modeling guidance (EPA, 2018). EPA's modeling guidance recommends scaling the current year design value (DVC) using a Relative Response Factor (RRF) based on the ratio of the future to current year modeling results (i.e., RRF = CAMx $Ozone_{2028}$/CAMx $Ozone_{2014}$). The guidance recommends using a DVC based on an average of three ozone design values centered on the base modeling year, which in this case is 2014, so design values from 2012-2016 are used (i.e., $DVC_{2012\text{-}2016}$). Following EPA's ozone projection approach guidance, all 2028 projected ozone DVFs were below the 2015 ozone NAAQS at all monitoring sites in New Mexico using the $DVC_{2012\text{-}2016}$ observed ozone starting point for the projections.

A comparison of the CAMx absolute modeled daily MDA8 ozone concentrations for the 2028 Base Case and 2028 O&G Control Strategy found that the strategy resulted in MDA8 ozone reductions over large areas of New Mexico, with the largest ozone reductions occurring in the San Juan and Permian Basins. However, there were also isolated areas of ozone increases due to the 2028 O&G Control Strategy that usually occurred in or near the San Juan and Permian Basins that are likely due to "NO_x Disbenefits" where NO_x emission reductions can cause localized ozone increases. For at least one day (June 5, 2014) that CAMx 2028 Base Case had a large area with MDA8 ozone concentrations that exceeded the 70 ppb ozone NAAQS in San Juan County, the 2028 O&G Control Strategy was sufficient to reduce the MDA8 ozone concentrations to below the NAAQS. On

another day (July 24, 2014), the "NO_x Disbenefits" of the 2028 O&G Control Strategy was sufficient to increase the MDA8 ozone concentrations in one 4-km grid cell in San Juan County that was below the NAAQS in the 2028 Base Case to right at the threshold for exceeding the NAAQS (71.0 ppb) in the 2028 O&G Control Strategy.

12.3 Sensitivity of 2028 Ozone Design Value Projections to Current Year Ozone Design Value

Given the upward trend in ozone design values in southern New Mexico in recent years (see Table 1-1), the sensitivity of the 2028 future year ozone DVF projections to the current year ozone design value (DVC) was investigated by making 2028 ozone DVF projections using current year design values based on observations from 2015-2019 (i.e., $DVC_{2015\text{-}2019}$) and 2017-2019 (i.e., $DV_{2017\text{-}2019}$) instead of the $DVC_{2012\text{-}2016}$ current year design value recommended in EPA's ozone modeling guidance (EPA, 2018).

There were four monitoring sites with $DVC_{2015\text{-}2019}$ exceeding the 70 ppb ozone NAAQS, compared to two using the $DVC_{2012\text{-}2016}$. The Carlsbad site projected 2028 ozone DVF (71.2 ppb) still exceeded the ozone NAAQS for the 2028 Base Case when the $DVC_{2015\text{-}2019}$ current year design value was used in the projection. However, the emission reductions in the 2028 O&G Control Strategy were sufficient to bring the projected 2028 ozone DVF at the Carlsbad site (70.9 ppb) to below the ozone NAAQS in the $DVC_{2015\text{-}2019}$ current year design value sensitivity analysis.

Three monitors exceeded the 70 ppb ozone NAAQS using the most recent ozone design value ($DV_{2017\text{-}2019}$), but one of the sites that had their $DVC_{2015\text{-}2019}$ exceeding the NAAQS was no longer in operation in 2017-2019 (i.e., Carlsbad Caverns NP). Two of the sites were still estimated to have projected 2028 ozone DVFs that exceeded the ozone NAAQS for both the 2028 Base Case and 2028 O&G Control Strategy in the $DV_{2017\text{-}2019}$ current year DVC sensitivity analysis. Under the 2028 O&G Control Strategy, the projected 2028 ozone DVFs at Carlsbad and Desert View were, respectively, 76.0 and 71.4 ppb using the $DV_{2017\text{-}2019}$ as the current year DVC in the ozone projections.

There were significant increases in O&G emissions within the Permian Basin since 2014 that are not accounted for in the CAMx ozone modeling results in the $DVC_{2015\text{-}2019}$ and $DV_{2017\text{-}2019}$ current year design value sensitivity tests. If those additional O&G emissions were included in the CAMx base year base case simulations, the projected 2028 ozone DVFs would be lower in the vicinity of the Permian Basin because of the higher denominator in the RRF projections factors due to higher O&G emissions than occurred in 2014.

EPA recommends using the average of three years of design values for the DVC as it is more stable and has less year-to-year variability than a single design value period (EPA, 2018, pp. 101[42]). So, the 2028 ozone DVFs projection sensitivity test using the $DV_{2017\text{-}2019}$ has an additional caveat as it is less stable and more influenced by year-to-year variability in ozone concentrations.

NMED Exhibit 17

12.4 2028 Source Sector APCA Ozone Source Apportionment Modeling

The 2028 O&G Control Strategy Source Sector APCA ozone source apportionment modeling found that approximately half to two-thirds of the ozone on high MDA8 ozone days in New Mexico is due to Boundary Conditions (BCs) that are mainly from international and natural emissions from outside of the CAMx 36-km North America modeling domain. The highest contributing New Mexico Source Sector varied by location. For sites in San Juan County in northwestern New Mexico, EGU and O&G Non-Point sources were the two highest contributing Source Sectors followed by O&G Point sources. For sites in Bernalillo County in the central part of New Mexico, Other Anthropogenic, On-Road and Non-Road were the highest contributing Source Sectors. In Doña Ana County in southern New Mexico, New Mexico EGU and On-Road were the highest contribution Source Sectors. O&G Non-Point and Point sources were the highest contributing New Mexico Source Sectors at the Carlsbad and Hobbs sites in southeastern New Mexico. Texas and Mexico had large contributions to ozone in southern New Mexico, whereas Colorado had large contributions in northwestern New Mexico.

International anthropogenic emissions contributed 13 to 26 ppb to the projected 2028 ozone DVFs at New Mexico sites, with larger international contributions at the southern New Mexico sites. The elimination of the contributions of international anthropogenic emissions reduced the projected 2028 ozone DVFs to below 60 ppb under all scenarios, even when the $DVC_{2017\text{-}2019}$ was used that produced a projected 2028 ozone DVF at Carlsbad that exceeded both the 2008 and 2015 ozone NAAQS.

12.5 2028 VOC/NO_x Sensitivity OSAT Ozone Source Apportionment Modeling

The 2028 VOC/NO_x Sensitivity OSAT ozone source apportionment simulation found that ozone formation across New Mexico was primarily NO_x sensitive. There were some areas that had relatively higher VOC sensitive ozone formation conditions on some days, including the San Juan Basin, Albuquerque, the Texas part of El Paso, and to a lesser extent, the Permian Basin. There are even days (e.g., June 5th) where elevated MDA8 ozone concentrations in San Juan Basin that approached the ozone NAAQS and ozone formation was approximately evenly split between NO_x and VOC sensitive ozone formation conditions. But overall, ozone formation was more NO_x sensitive than VOC sensitive. The highest modeled ozone concentrations tend to have relatively higher VOC sensitive ozone concentrations. Thus, although ozone formation appears to be mainly NO_x sensitive, VOC controls will also have benefits in reducing some of the highest ozone concentrations in New Mexico.

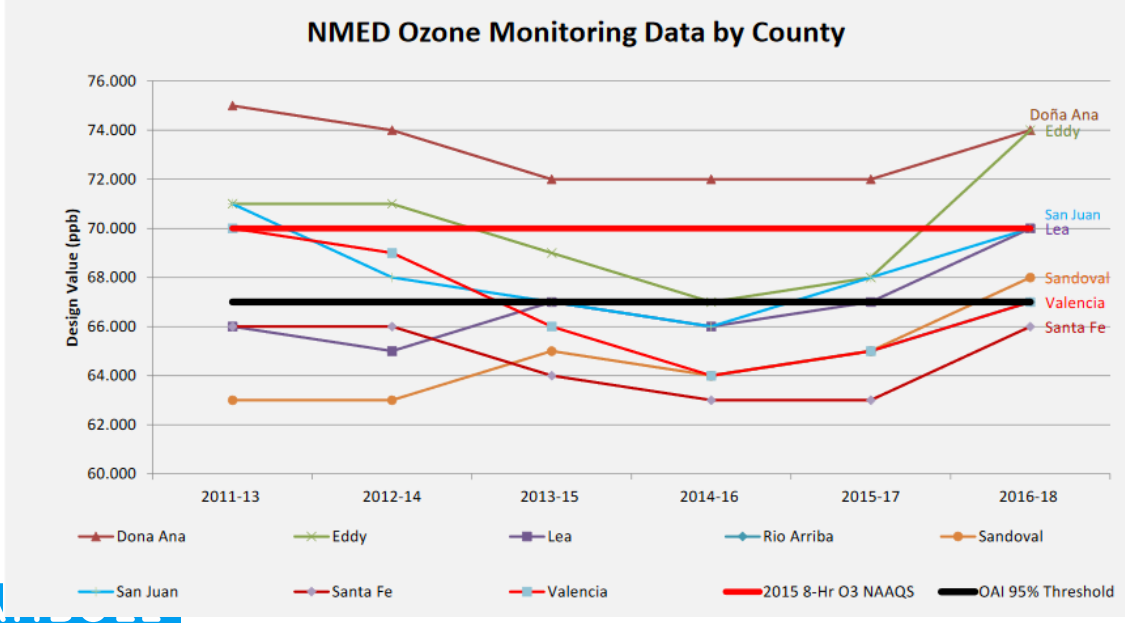
New Mexico OAI Study Photochemical Modeling – 1st Monthly Webinar May 2020

WESTAR and Ramboll

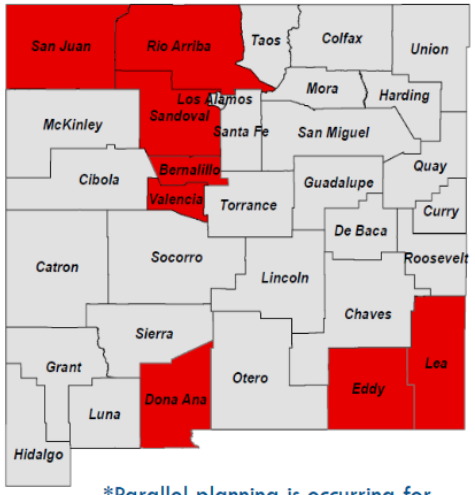
May 28, 2020

RAMBOLL

Bright ideas. Sustainable change.



Content

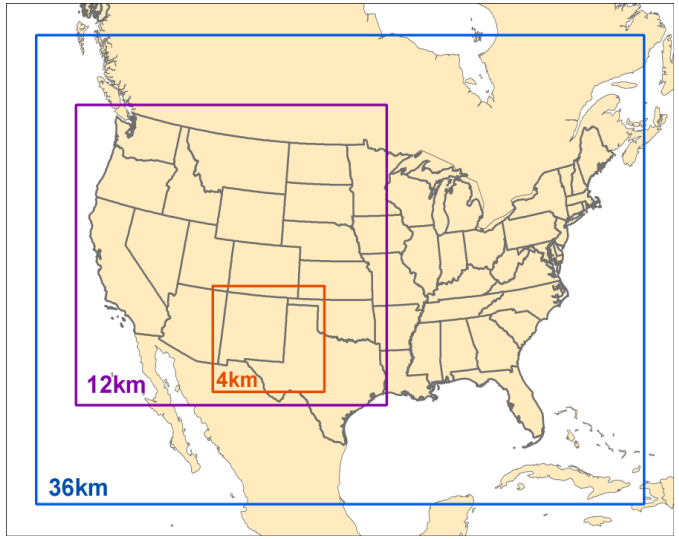


- Introduction
- Work Plan
- Evaluation of Existing 2014 WRF and Proposed NM OAI Study WRF Configuration
- Evaluation of 2014 Boundary Conditions (BCs) from WRAP 2014 GEOS-Chem
- Modeling Protocol Overview
- 2014 and 2023 Emissions for New Mexico
- 2014 and 2023 Mobile Source Assumptions and Activity Data for New Mexico
- Next Steps

RAMBOLL

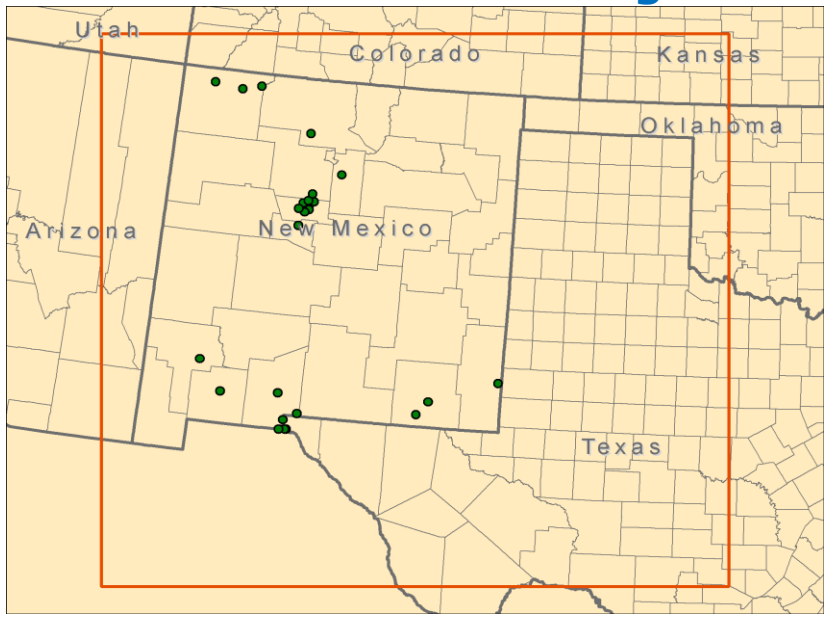
Introduction

- New Mexico Air Quality Control Act (NMAQCA) requires the NMED to develop a plan to address elevated ozone levels when air quality is within 95% of the ozone NAAQS (74-3-5.3, NMSA 1978)
- There are 8 counties in New Mexico with measured ozone concentrations within 95% of the 70 ppb 2015 ozone NAAQS
- NMED contracted with WESTAR/Ramboll to conduct 2014 and 2023 photochemical modeling to assess the contributions of sources to and effects of control measures on ozone concentrations



*Parallel planning is occurring for Bernalillo County through the Albuquerque/Bernalillo County Department of Environmental Health

- Counties within 95% of the standard:
  - San Juan (Navajo Lake, 70 ppb)
  - Doña Ana (several monitors, 74 ppb)
  - Eddy (Carlsbad, 74 ppb)
  - Lea (Hobbs, 70 ppb)
  - Rio Arriba (Coyote, 67 ppb)
  - Sandoval (Bernalillo, 68 ppb)
  - Valencia (Los Lunas, 67 ppb)



Work Plan (1 of 2)

- Task 1: Development Modeling Protocol/QAPP and Work Plan
  - Modeling Plan provides a roadmap on how the study will be carried, including episode, domain and model selection and current and future year modeling approaches

36/12/4-km Domain Structure

New Mexico 4-km Modeling Domain

- Task 2: WRF Meteorological Modeling
  - Develop CAMx meteorological inputs for May-Aug 2014 and 36/12/4-km domains
- Task 3: Evaluate Boundary Condition Inputs
  - Based on WRAP 2014 GEOS-Chem global chemistry model

RAMBOLL

Work Plan (2 of 2)

- Task 4: 2014 and 2023 Emissions Development
  - Sources of 2014 and 2023 Emissions
  - Mobile Source Emissions
  - Natural Emissions
  - SMOKE Emissions Modeling
  - 2023 Emission Control Measures
- Task 5: CAMx 2014 Base Case Modeling
  - Model Performance Evaluation
  - Formal 2016 Base Case Modeling and MPE Report on Tasks 2-5
- Task 6: 2023 Future Year CAMx Modeling
  - 2023 Base Case and Future Year Ozone Design Value Projections
  - 2023 Ozone Source Apportionment Modeling
  - 2023 Control Measure Evaluation
- Task 7: Air Quality Technical Support Document (AQTSD)
  - Prepare formal AQTSD documenting the study
  - Transfer Modeling Databases and Results to Intermountain West Data Warehouse (IWDW)
  - Maintain NM OAI Study Webpage on WRAP website throughout the study

RAMBOLL

Current Schedule

Task	Deliverable	Date
1. Formal Modeling Protocol/QAPP and Work Plan		
	Kick-Off Conference Call	Apr 2020
	Draft Modeling Protocol/QAPP and Work Plan	May 2020
	PPT on final approach and project plan	May 2020
	Final Modeling Protocol/QAPP and Work Plan	May2020
	Response-to-Comments (RTC) Document	May 2020
2. Base Year Meteorological Modeling (Met)		
2.1 Evaluate Met Model	*PPT on 2014 WAQS and EPA WRF*	May 2020
2.2 Additional Met Model	*PPT on New WRF 4-km MPE in New Mexico*	Jun 2020
2.3 Process Met Data	PGM summer 2014 36/12/4-km met inputs	Jun 2020
3. Boundary Conditions (BC)		
3.1 Evaluate BC Data	*PPT on WRAP 2014 GEOS-Chem BCs*	Jun 2020
4. Base Year (2014) and Future Year (2023) Emissions		
4.1 2014 and 2023 Emissions for 4-km New Mexico Domain	*PPT on sources of 2014 and 2023 New Mexico EI*	May 2020
	PPT and tile plots/excel spreadsheets for 2014 and 2023 emissions in the 4-km NM domain	Jun 2020
4.2 Mobile Sources		
4.2.1 Evaluate Mobile EI	*PPT on options for 2014/2023 mobile sources*	Jun 2020
	PPT on final 2014/2023 mobile source EI	Jun 2020
4.2.3 Prepare Mobile Source Emission Inputs	*PPT on 2014/2023 SMOKE-MOVES*	Aug 2020
	Model-ready 2014/2023 mobile source inputs	Aug 2020
4.3 Biogenic/Natural Emissions	*PPT on biogenic and natural emission modeling*	Jul 2020
	Model-ready 2014 natural emissions inputs	Jul 2020
4.4 SMOKE Modeling	*PPT on 2014/2023 SMOKE modeling*	Aug 2020
	Model-ready 2014/2023 anthropogenic EI inputs	Aug 2020
4.5 FY Emissions Strategies	*PPT on FY 2023 SMOKE control/strategies*	Aug 2020
	Summary tables/plots for 2023 scenarios	Aug 2020
5. 2014 Base Year (2014) Air Quality Modeling		
	Webinar PPT on final 2014 base case and MPE	Sep 2020
	Draft report on Tasks 2-5, 2014 Base and MPE	Sep 2020
	Final report on Tasks 2-5, 2014 Base and MPE	Oct 2020
	RtC on 2014 base case and MPE report	Oct 2020
6. Future Year (2023) Air Quality Modeling		
6.1 FY PGM Modeling	*PPT on 2023 PGM Modeling*	Oct 2020
	Difference plots of FY-BY Ozone Concentrations	Oct 2020
6.2 Attainment Test	*PPT on 2023 ozone DV projections*	Oct 2020
	PPT on FY Source Apportionment Modeling	Nov 2020

4.1 2014 and 2023 Emissions for 4-km New Mexico Domain	*PPT on sources of 2014 and 2023 New Mexico EI*	May 2020
	PPT and tile plots/excel spreadsheets for 2014 and 2023 emissions in the 4-km NM domain	Jun 2020
4.2 Mobile Sources		
4.2.1 Evaluate Mobile EI	*PPT on options for 2014/2023 mobile sources*	Jun 2020
	PPT on final 2014/2023 mobile source EI	Jun 2020
4.2.3 Prepare Mobile Source Emission Inputs	*PPT on 2014/2023 SMOKE-MOVES*	Aug 2020
	Model-ready 2014/2023 mobile source inputs	Aug 2020
4.3 Biogenic/Natural Emissions	*PPT on biogenic and natural emission modeling*	Jul 2020
	Model-ready 2014 natural emissions inputs	Jul 2020
4.4 SMOKE Modeling	*PPT on 2014/2023 SMOKE modeling*	Aug 2020
	Model-ready 2014/2023 anthropogenic EI inputs	Aug 2020
4.5 FY Emissions Strategies	*PPT on FY 2023 SMOKE control/strategies*	Aug 2020
	Summary tables/plots for 2023 scenarios	Aug 2020
5. 2014 Base Year (2014) Air Quality Modeling		
	Webinar PPT on final 2014 base case and MPE	Sep 2020
	Draft report on Tasks 2-5, 2014 Base and MPE	Sep 2020
	Final report on Tasks 2-5, 2014 Base and MPE	Oct 2020
	RtC on 2014 base case and MPE report	Oct 2020
6. Future Year (2023) Air Quality Modeling		
6.1 FY PGM Modeling	*PPT on 2023 PGM Modeling*	Oct 2020
	Difference plots of FY-BY Ozone Concentrations	Oct 2020
6.2 Attainment Test	*PPT on 2023 ozone DV projections*	Oct 2020
	PPT on FY Source Apportionment Modeling	Nov 2020

RAMBOLL

NMED Exhibit 18 - 0009

NM OAI vs WAQS vs EPA WRF Domains

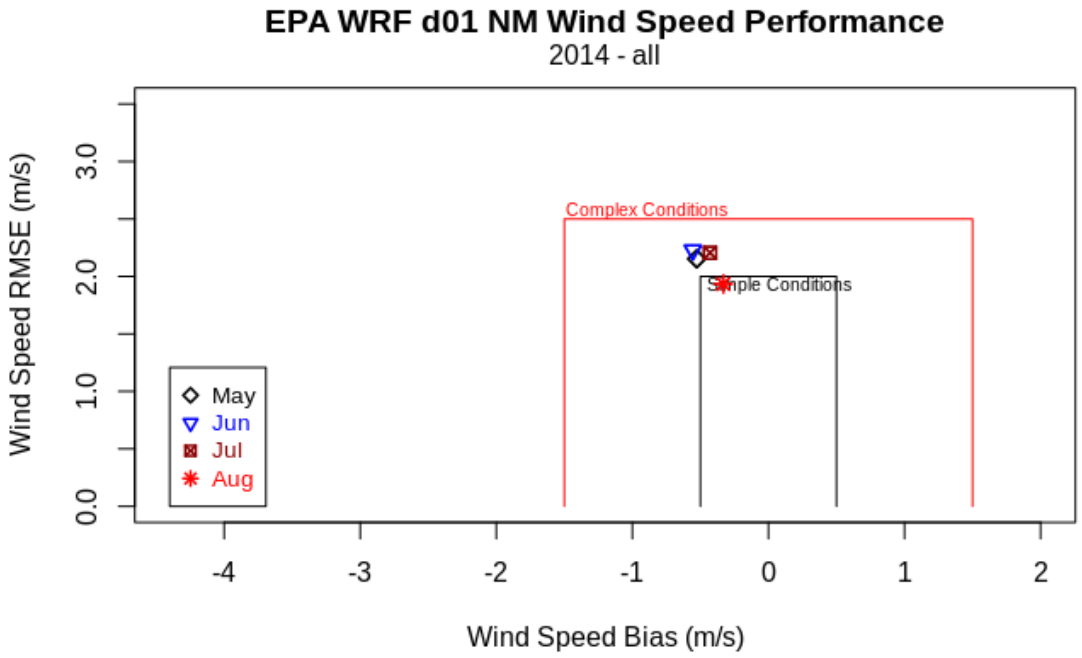
WAQS 36/12/4 km

NM OAI 36/12/4 km

NMED Exhibit 18 - 0010

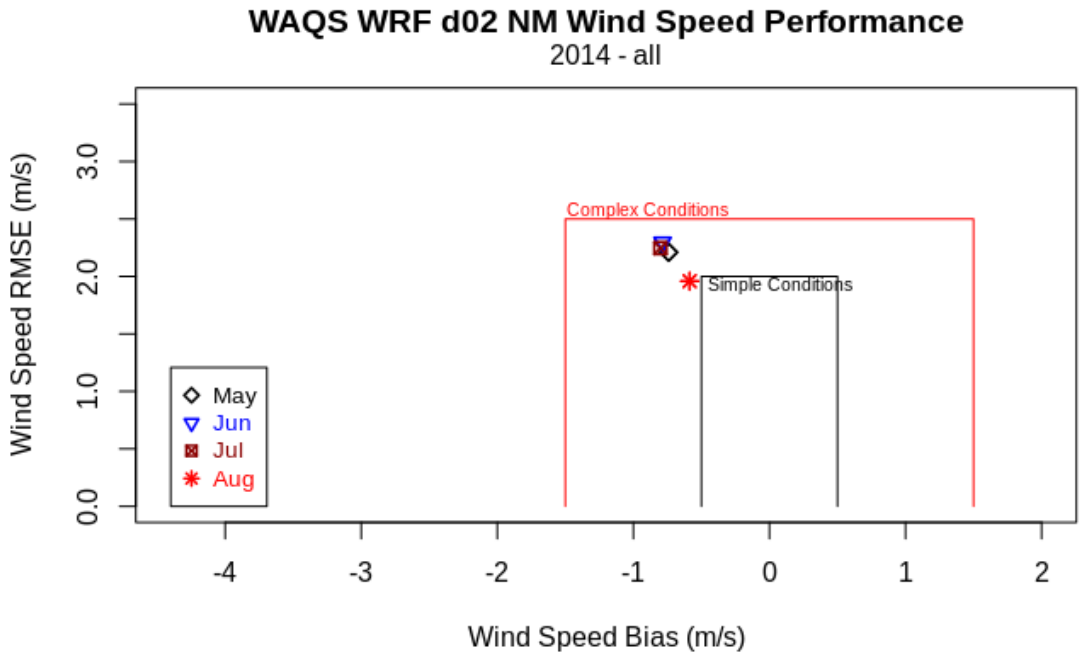
EPA vs WAQS WRF MPE Approach

- Evaluate EPA 12US1 and WAQS 12WUS2 for April-August 2014
  - For both EPA and WAQS, include observation sites within New Mexico only
- Quantitative Evaluation
  - METSTAT – model/obs pairing, bias/error statistics against NCAR ds3505 observations
    - Soccer plots – monthly stats
    - Time series – hourly and daily
    - Plots for all sites in NM, and each individual site within NM
- Qualitative Evaluation
  - PRISM precipitation spatial maps
    - Monthly and daily



WRF Statistical Benchmarks

Meteorological Variable	Simple Conditions		Complex Conditions	
	Bias	Error	Bias	Error
Temperature	< ±0.5 °C	< 2.0 °C	< ±2.0 °C	< 2.5 °C
Wind Speed	< ±0.5 m/s	< 2.0 m/s (RMSE)	< ±1.5 m/s	< 2.5 m/s (RMSE)
Wind Direction	< ±10 degrees	< 30 degrees	< ±10 degrees	< 50 degrees
Humidity	< ±0.8 g/kg	< 2.0 g/kg	< ±1.0 g/kg	< 2.0 g/kg

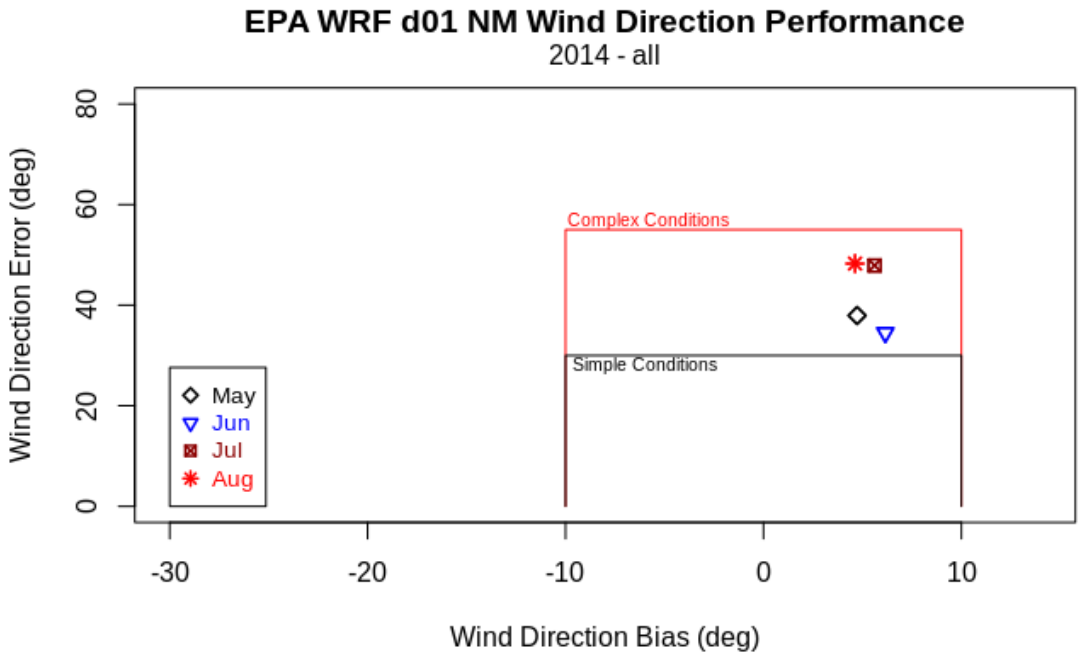


NMED Exhibit 18 - 0012

Soccer Plots – Wind Speed for all NM sites

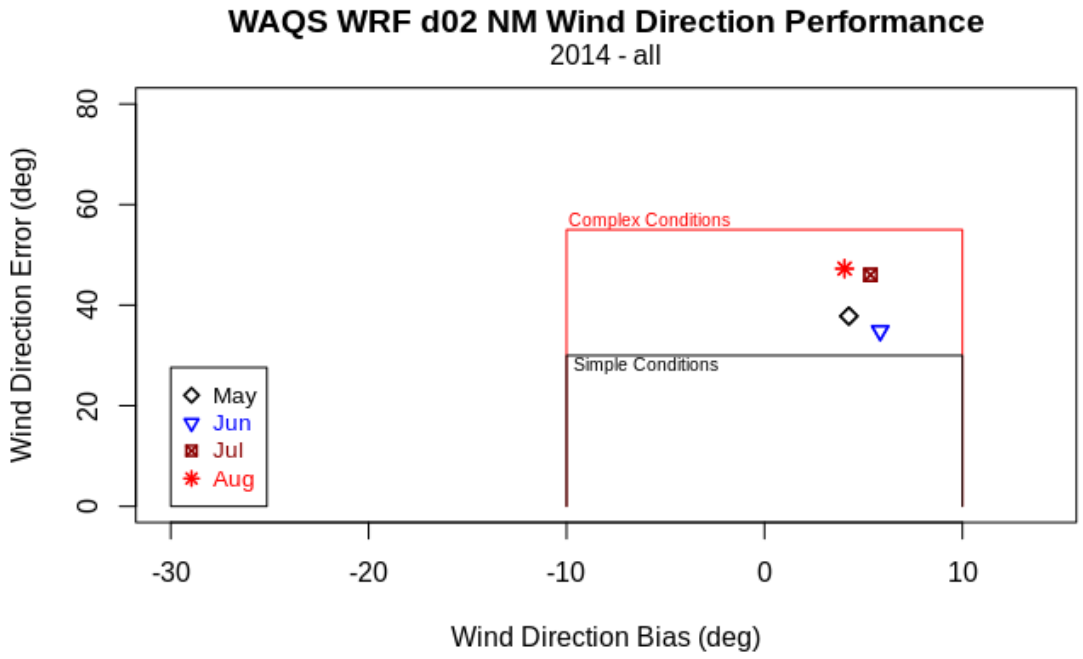
EPA 12 km

WAQS 12 km



All months within complex conditions goal for both runs

Both runs have underprediction bias for all months; EPA slightly better

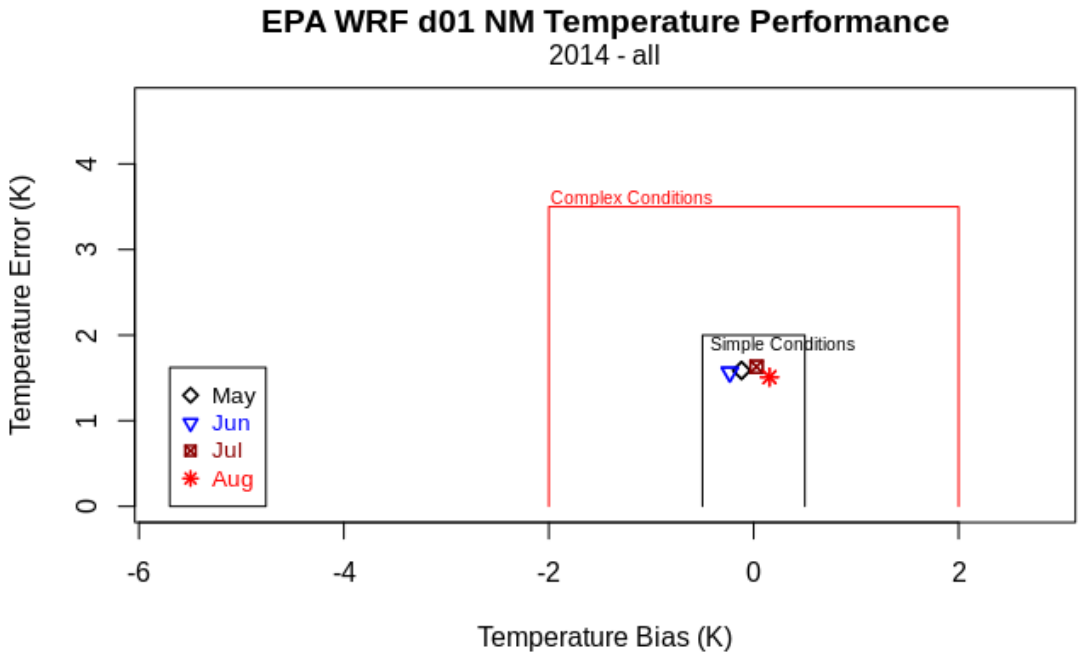


NMED Exhibit 18 - 0013

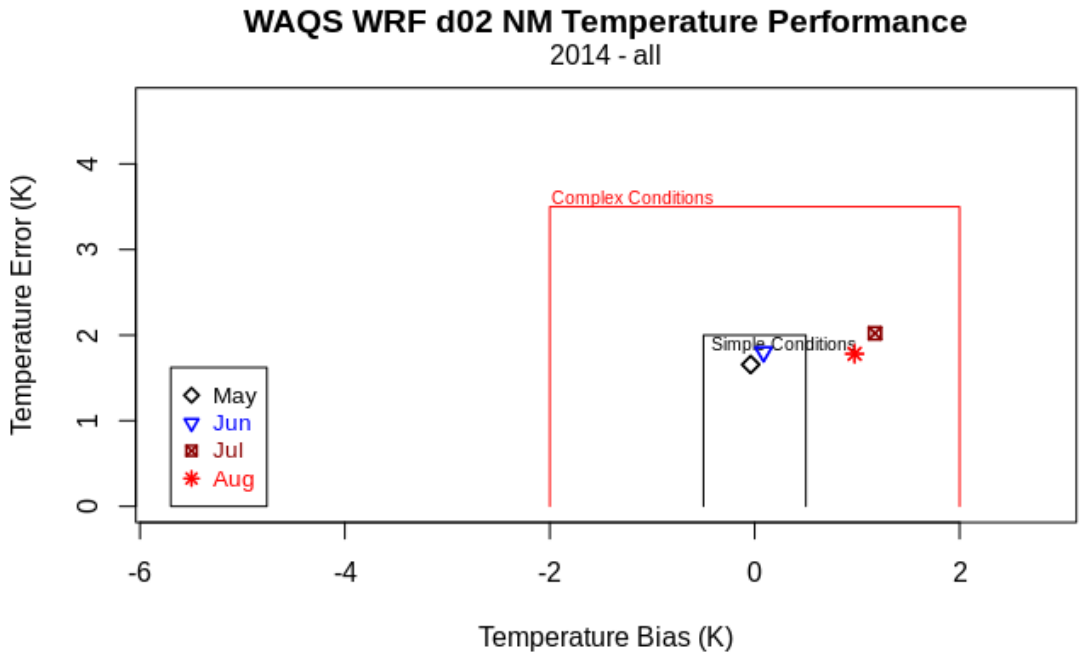
Soccer Plots – Wind Direction for all NM sites

EPA 12 km

WAQS 12 km



WAQS and EPA performance nearly identical



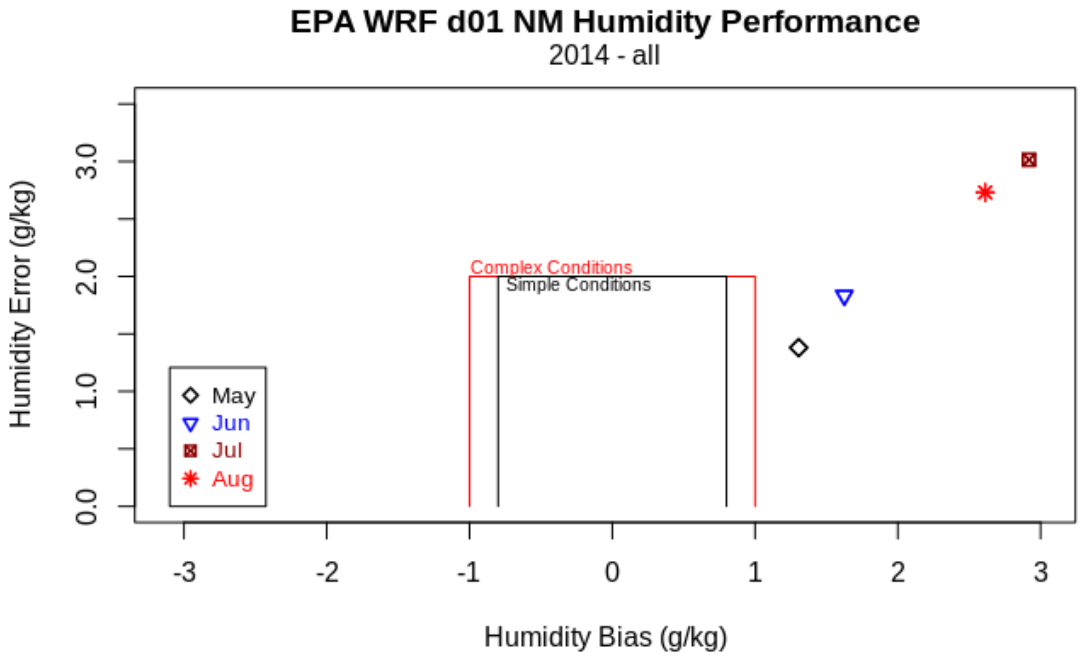
NMED Exhibit 18 - 0014

Soccer Plots – Temperature for all NM sites

EPA 12 km

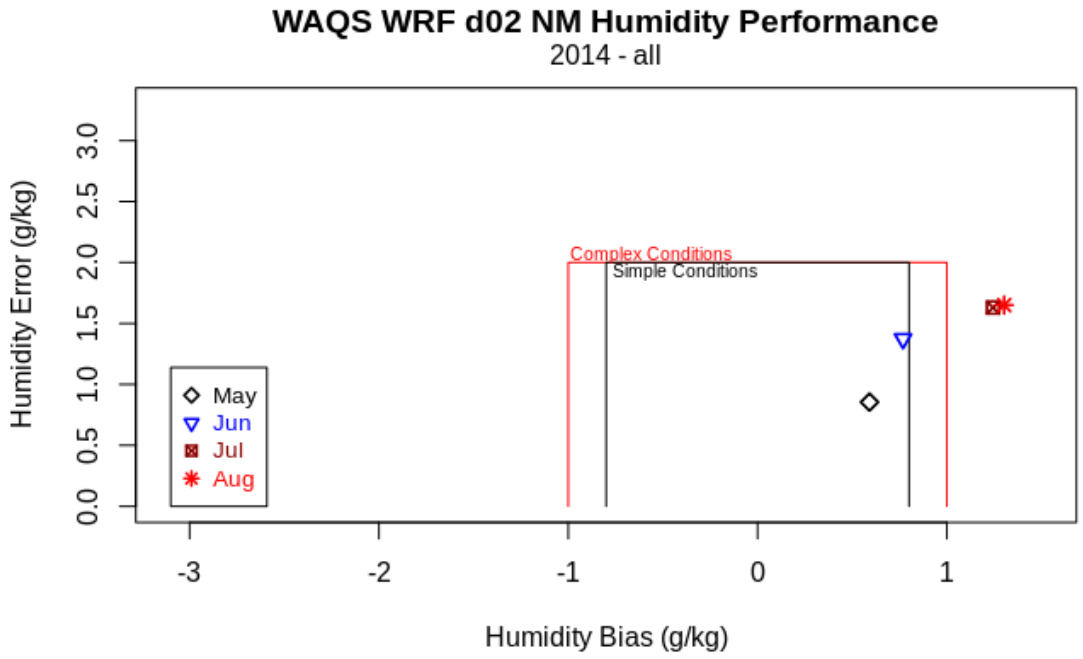
WAQS 12 km

EPA run outperforms WAQS



WAQS temperature poorest for Jul-Aug with warm bias

RAMBOLL

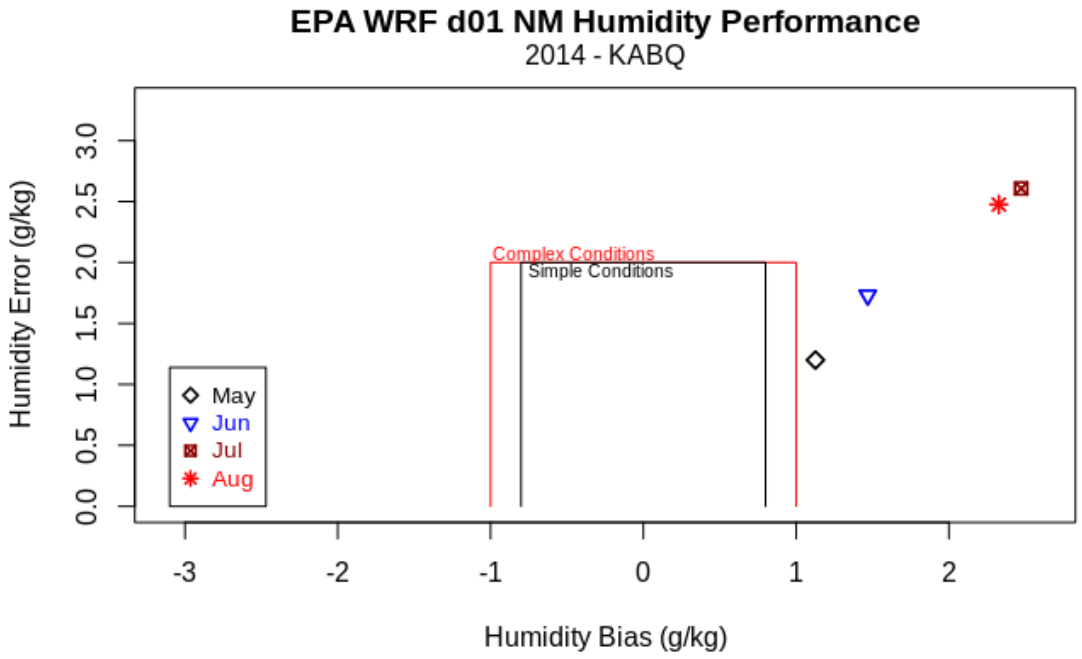


NMED Exhibit 18 - 0015

Soccer Plots – Humidity for all NM sites

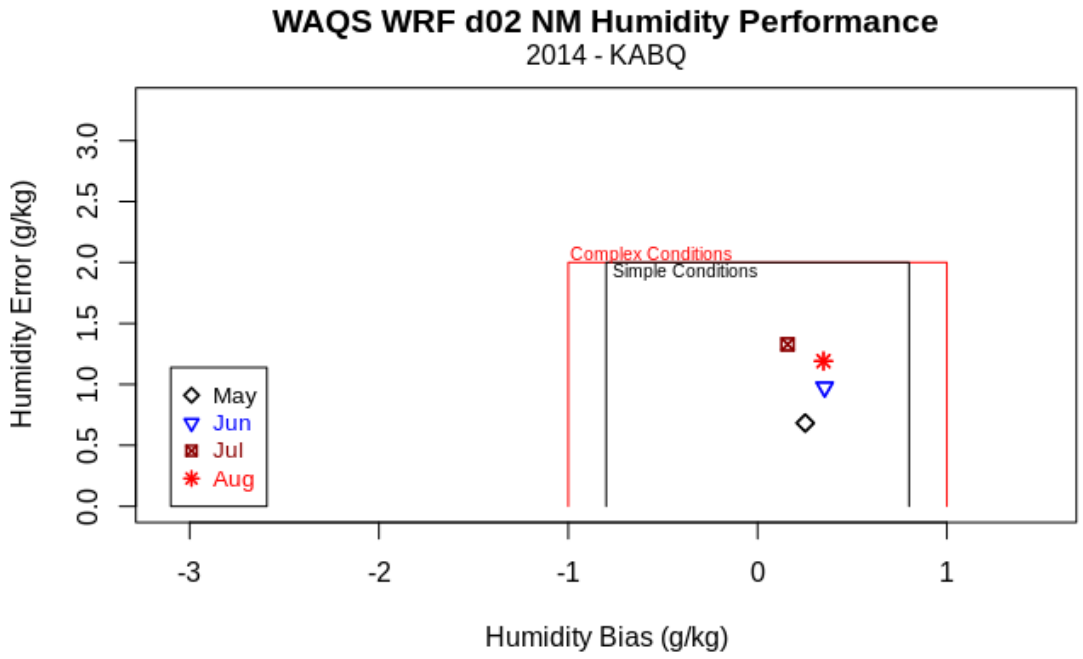
EPA 12 km

WAQS 12 km



WAQS run outperforms EPA; both runs have positive (wet) bias for all months

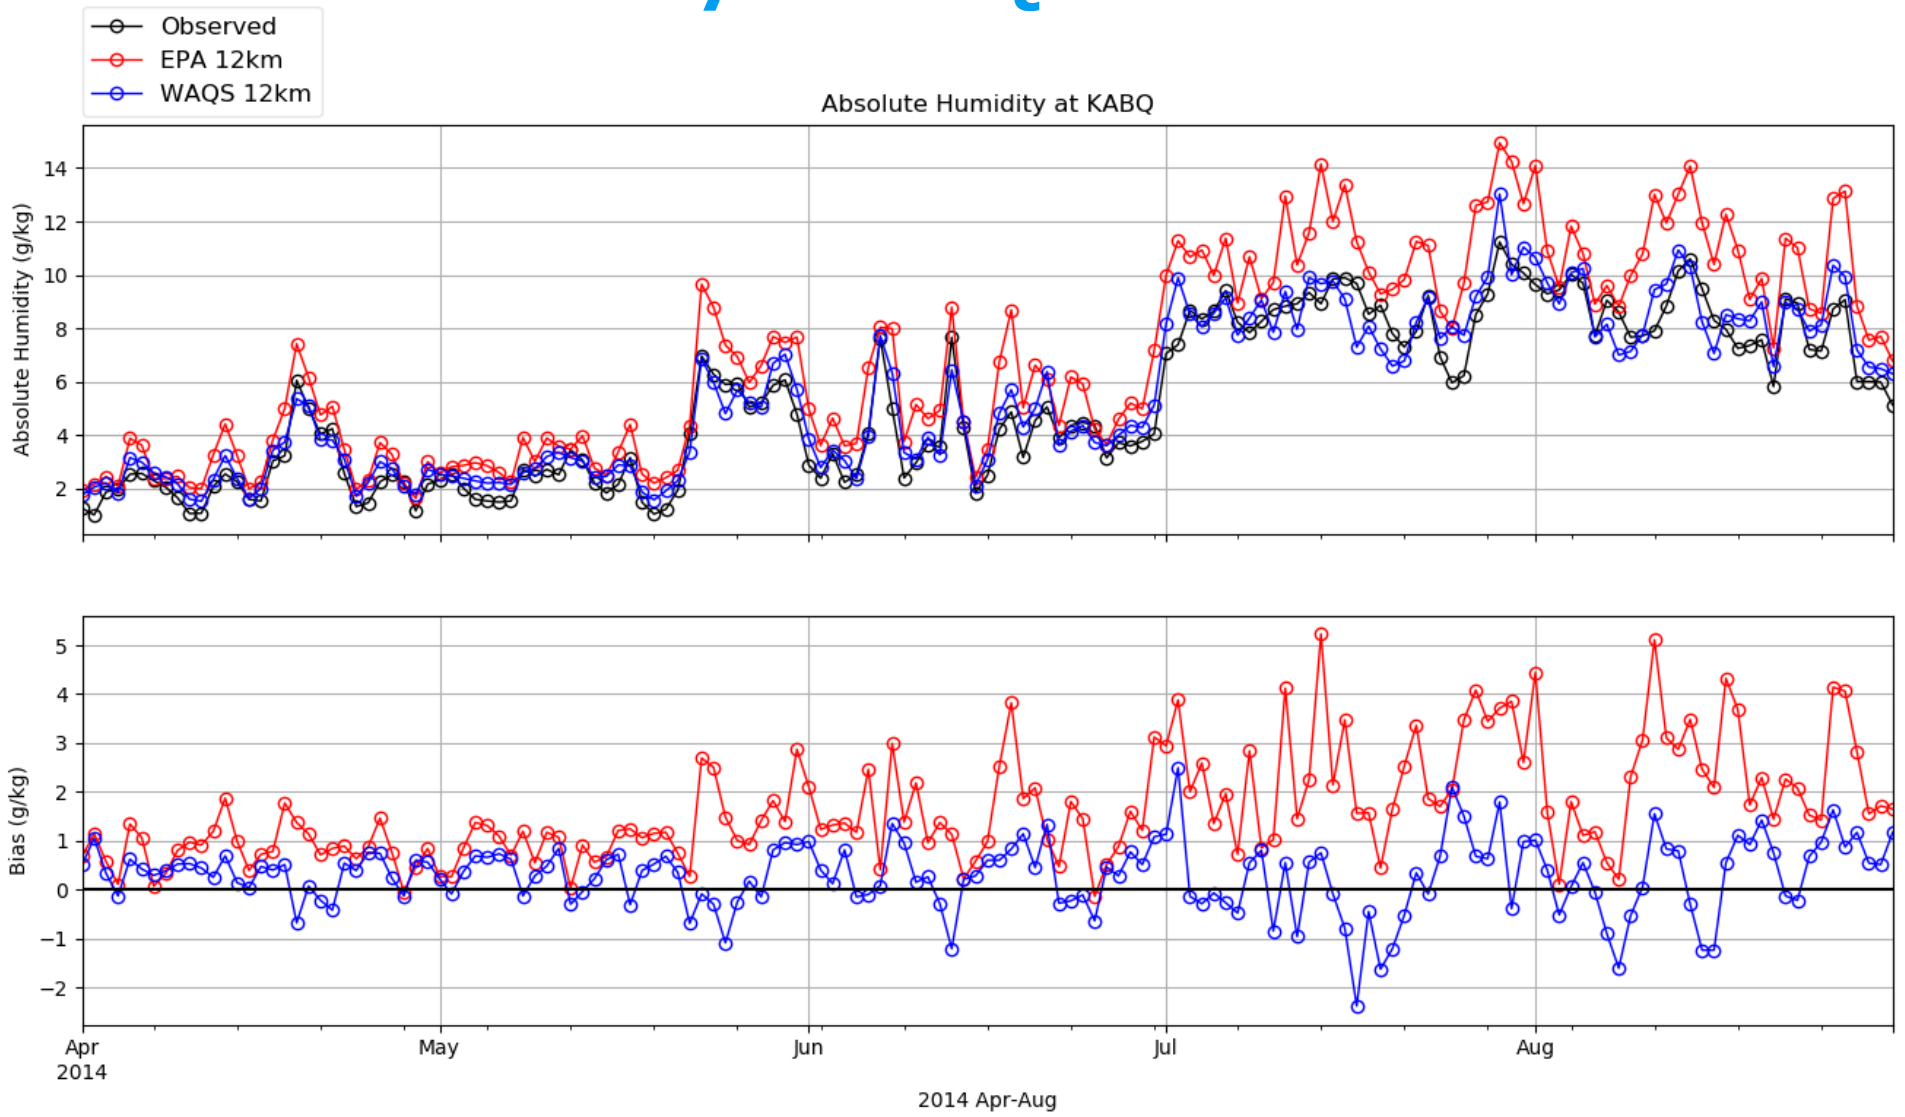
EPA performance poorest for Jul-Aug: overactive convection?



NMED Exhibit 18 - 0016

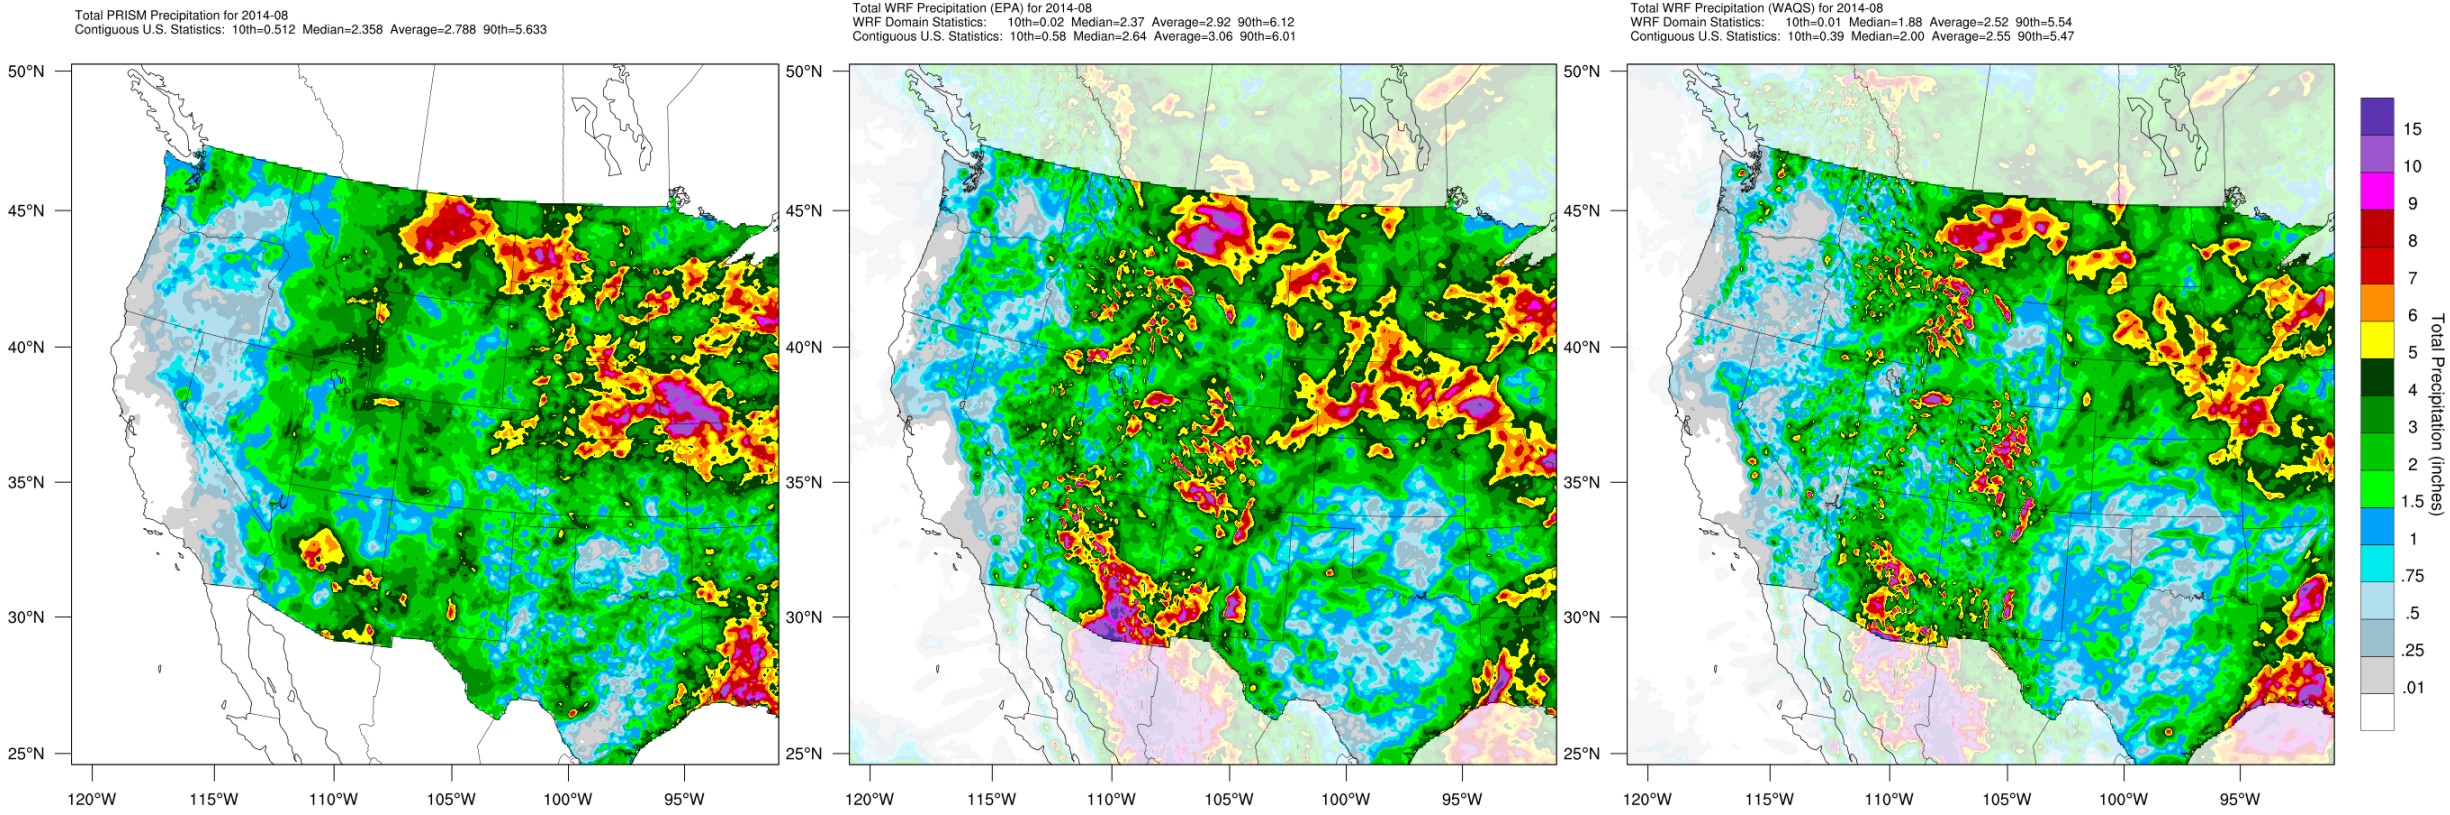
Soccer Plots – Humidity for KABQ

EPA 12 km



WAQS 12 km

WAQS run outperforms EPA; much smaller wet bias for all months



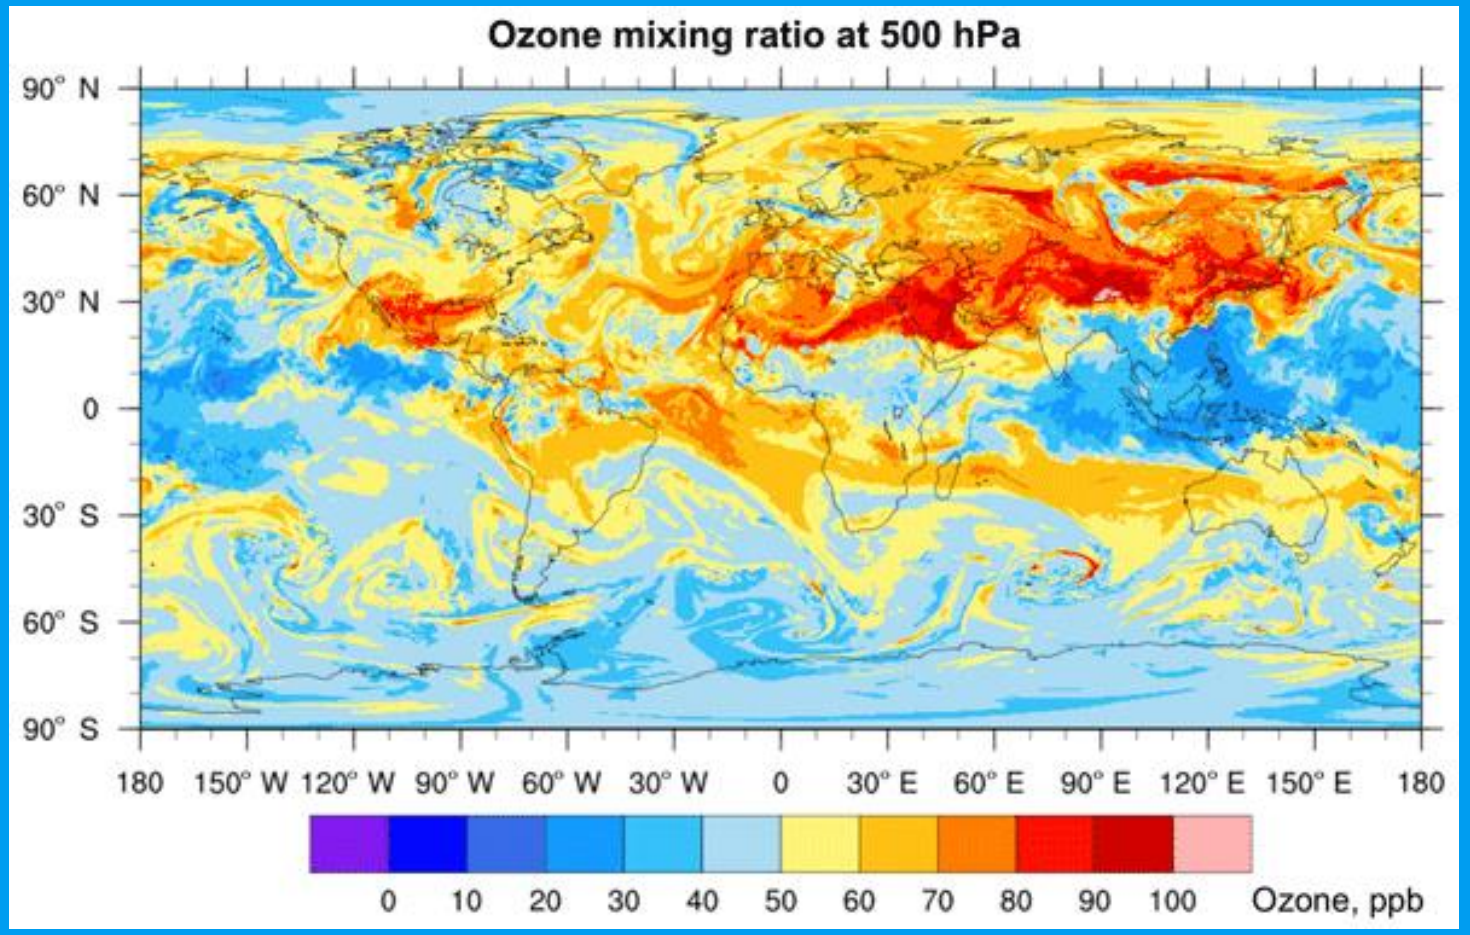
NMED Exhibit 18 - 0017

Time Series – Humidity at KABQ

Monthly Precipitation Plots – Aug 2014

PRISM Obs

EPA 12 km



WAQS 12 km

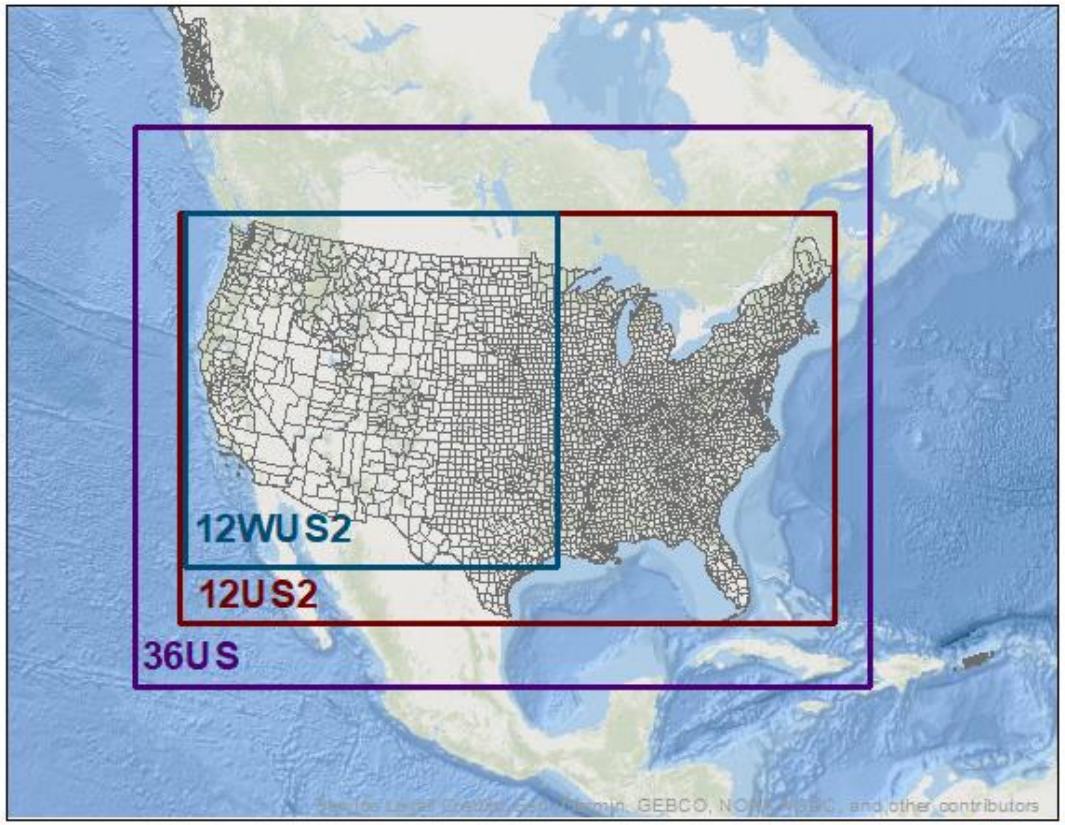
NMED Exhibit 18 - 0019

Existing 2014 WRF MPE Summary and Conclusions

- WRF performance reasonable for both simulations outside of humidity/precipitation
- EPA wet bias in summer months associated with overactive summer convection
- WAQS smaller wet bias
- NM OAI proposed WRF configuration aligns closely with WAQS to avoid overactive summer convection in New Mexico, with these differences
  - Reposition 4 km domain to encompass all of New Mexico
  - Use hybrid vertical coordinate to improve representation of upper troposphere/lower stratosphere
  - Add second simulation driven by ERA5 analysis
  - No observation nudging
- Two NM OAI WRF simulations (WRF/NAM12 and WRF/ERA5) currently running
- Present evaluation of these two simulations in June webinar

Task 3: Evaluate 2014 Boundary Conditions Based on WRAP 2014 GEOS-Chem

RAMBOLL

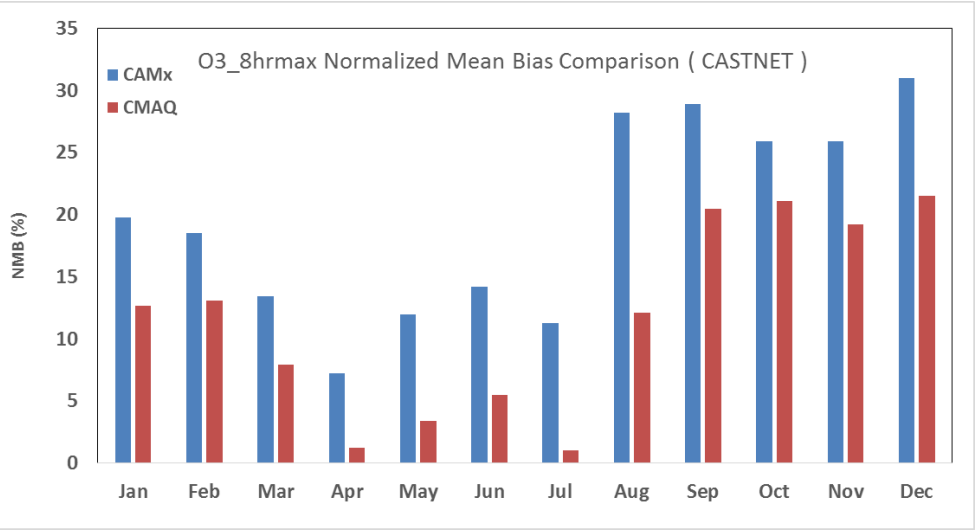


Overview of 2014 BC Evaluation

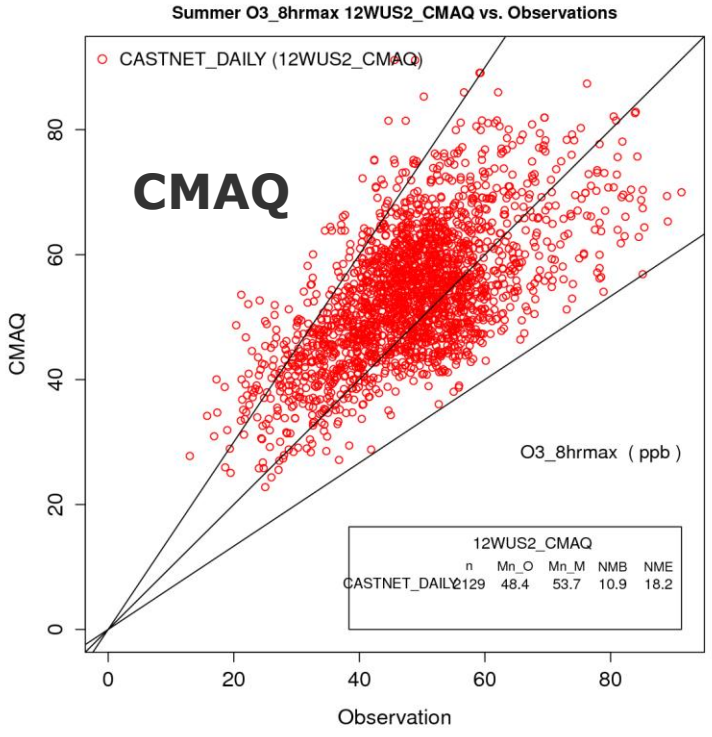
- Overview of WAQS-WRAP 2014 GEOS-Chem modeling
- Overview of WAQS 2014 Representative Base case Scenario
- Analysis of WAQS 2014 modeling results and BC contributions

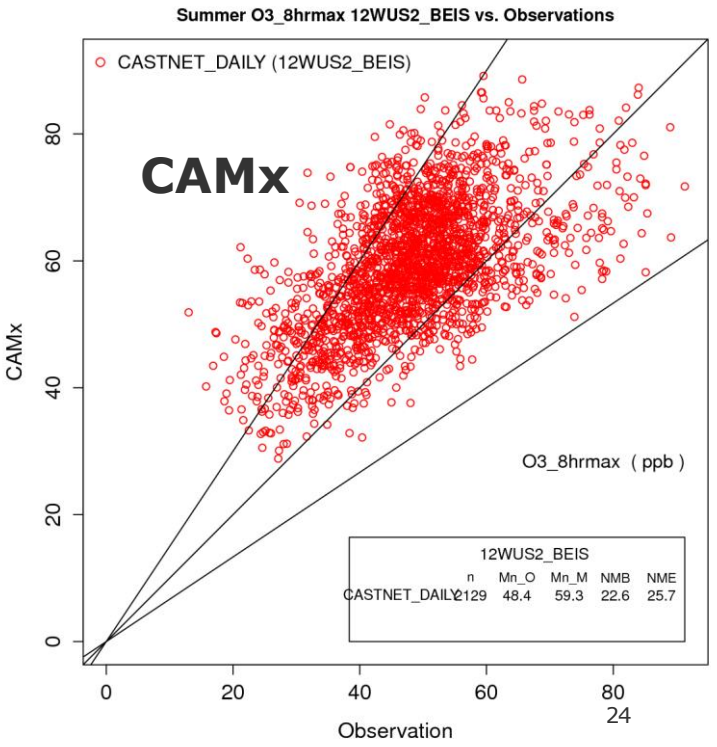
NMED Exhibit 18 - 0022

Background



- Phase I and II of WRAP 2014 Shake-Out study developed a 2014v1 PGM modeling platform:
  - 36-km 36US and 12-km 12WUS2 domains
  - CMAQ and CAMx PGMs
  - **EPA 2014 GEOS-Chem BCs**
  - 2014v1 Emissions
    - 2014NEIv2 with western state updates
  - BEIS Biogenic Emissions





RAMBOLL

BCs Based on EPA 2014 GEOS-Chem had issues

- Year-round ozone overestimation bias
  - In both CMAQ and CAMx, but more pronounced in CAMx
- Maybe some SO4 overestimation, even after eliminating volcano eruptions and DMS emissions

RAMBOLL

NMED Exhibit 18 - 0024

Revised 2014 GEOS-Chem simulation

- WRAP elected to conduct a revised 2014 GEOS-Chem simulation
  - Use updated emissions, newer GEOS-Chem version and other updates as used by EPA and Ramboll in their 2016 GEOS-Chem runs that produced BCs without the large ozone overestimation bias in the CMAQ and CAMx simulations.

Science Options	WRAP 2014 Basecase	EPA 2014 Basecase	EPRI 2016 Basecase

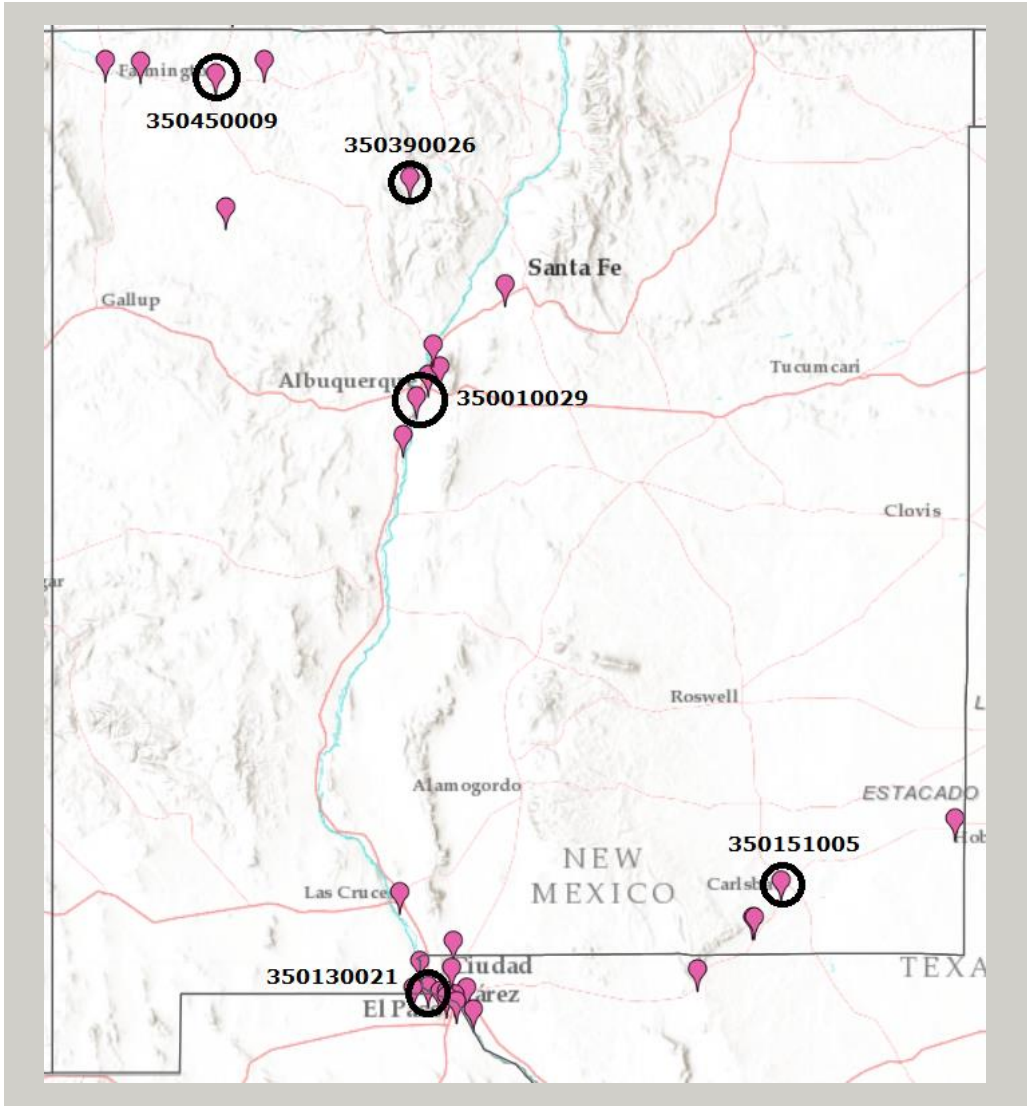
NMED Exhibit 18 - 0025



Representative Base Case Simulation Description

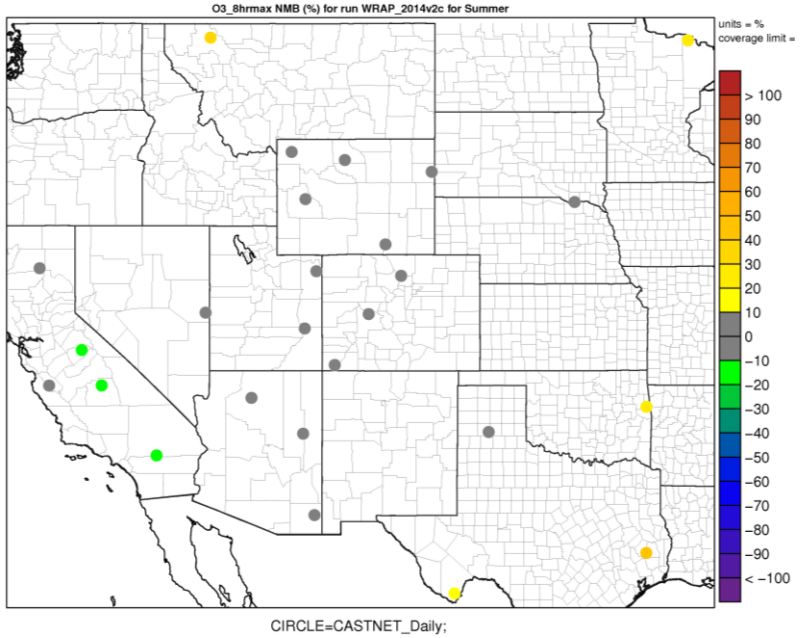
- WRAP 2014 GEOS-Chem used to derive Boundary conditions for 2014v2 and Representative Baseline (RepBase)
- Two additional GEOS-Chem simulations were performed to separate the Natural, Anthropogenic International and US contributions in the boundary conditions themselves:
  - Natural (NAT) and Zero-Rest-Of-the-World (ZROW)
- RepBase was instrumented in CAMx with source apportionment technology to track the ozone and PM contributions from the following 14 categories including boundary conditions:

Source Group Number	Brief Description
1	Natural Emissions
2	U.S. Wildfires (WF)
3	U.S. Prescribed Burns (Rx)
4	U.S. Agricultural Burning (Ag)
5	U.S. Anthropogenic Emissions (USAnthro)
6	Mexico Anthropogenic Emissions
7	Canada Anthropogenic Emissions
8	Off-Shore Commercial Marine Vessel (CMV) C3 Ocean Going Vessels (OGV) within 200 nautical miles of the coast (i.e., within the Emissions Control Area, ECA)
9	Remainder off-shore anthropogenic emissions that includes CMV C3 OGV outside of the ECA and non-U.S. O&G
10	Boundary Conditions: International contributions (BC_Intl)
11	Boundary Conditions: Natural contributions (BC_Nat)
12	Boundary Conditions: US contributions (BC_US)
13	Initial Conditions contributions
14	Top Boundary Concentrations contributions (top of the model)

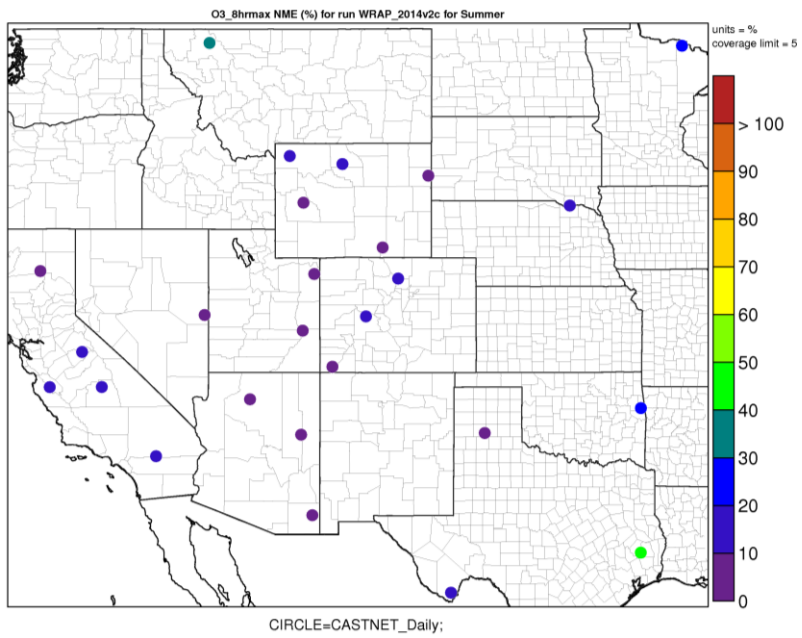
RAMBOLL

Boundary Conditions Analysis Sites

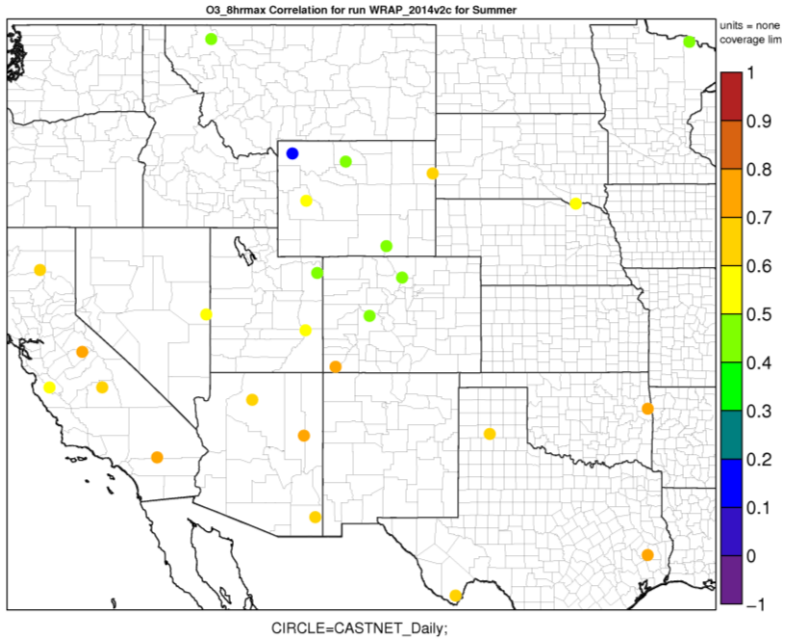
- Compared MDA8 ozone from WRAP Representative Base scenario (RepBase) source apportionment with a few selected and representative AQS sites in NM



Site ID	County	Latitude	Longitude
350450009	San_Juan	36.74	-107.98
350390026	Rio_Arriba	36.19	-106.70
350010029	Bernalillo	35.02	-106.66
350130021	Dona_Ana	31.80	-106.58
350151005	Eddy	32.38	-104.26

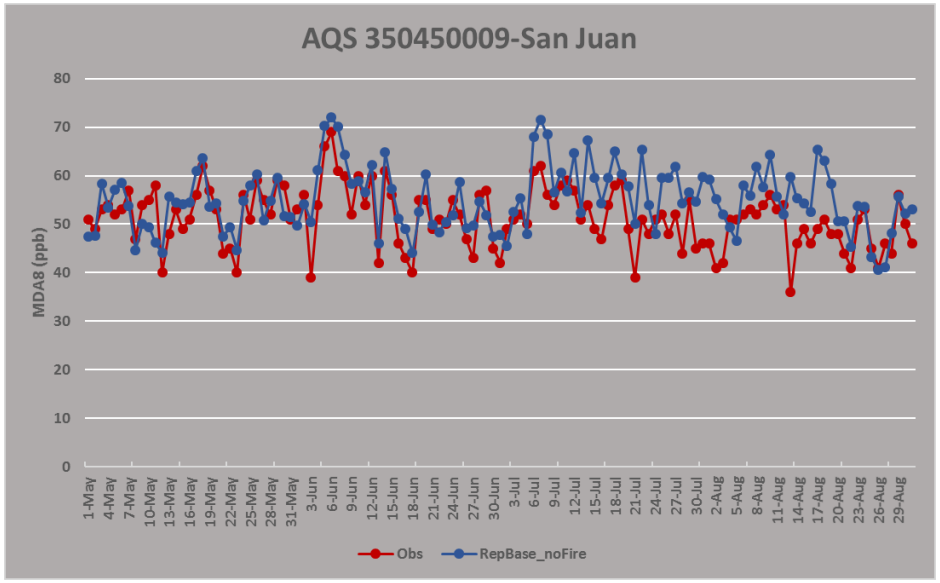


RAMBOLL

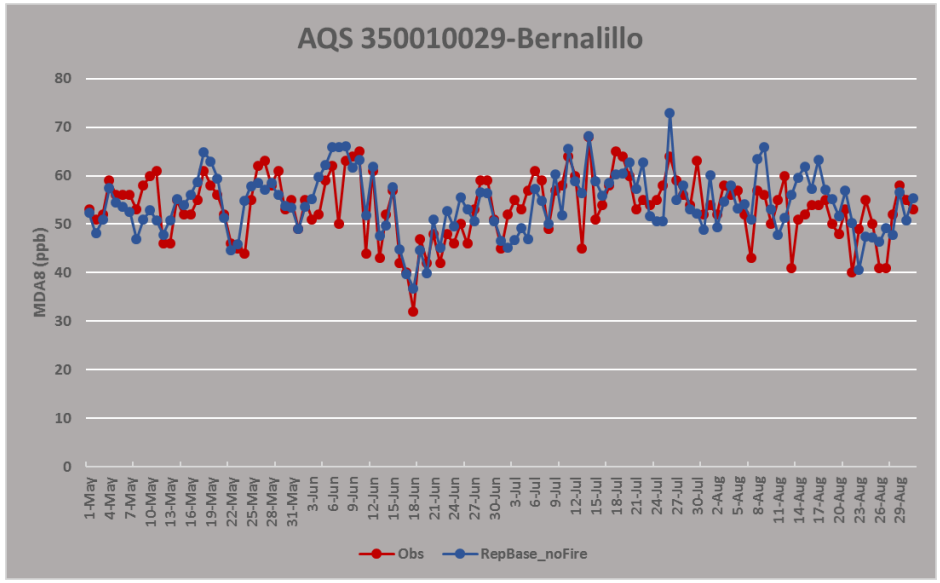


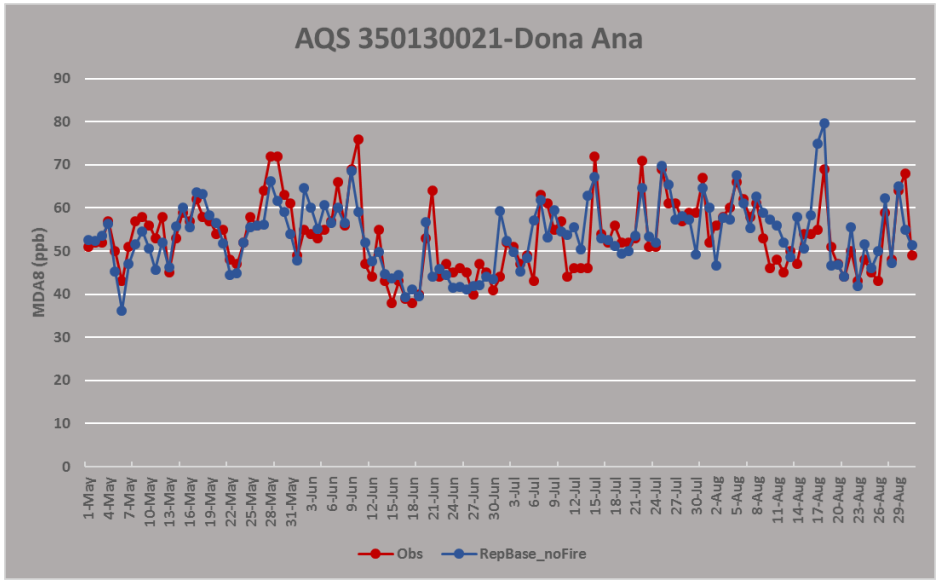
Selected Sites Ozone Model Performance

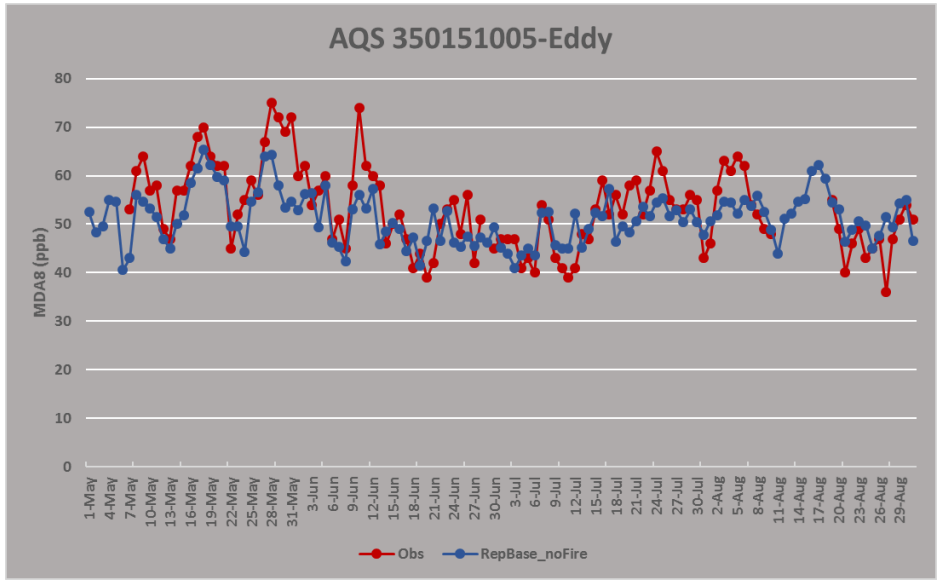
- RepBase does not have year specific emissions and is not meant to represent 2014. Fires contributions have been removed from this analysis
- RepBase statistics indicate performance for scenario in these sites are almost all within the goals for NMB and NME, within criteria for r
- Consistent with 2014v2 AZ, UT, CO ozone **NMB**, **NME** and **r** in the Summer (no CASTNET sites in NM)



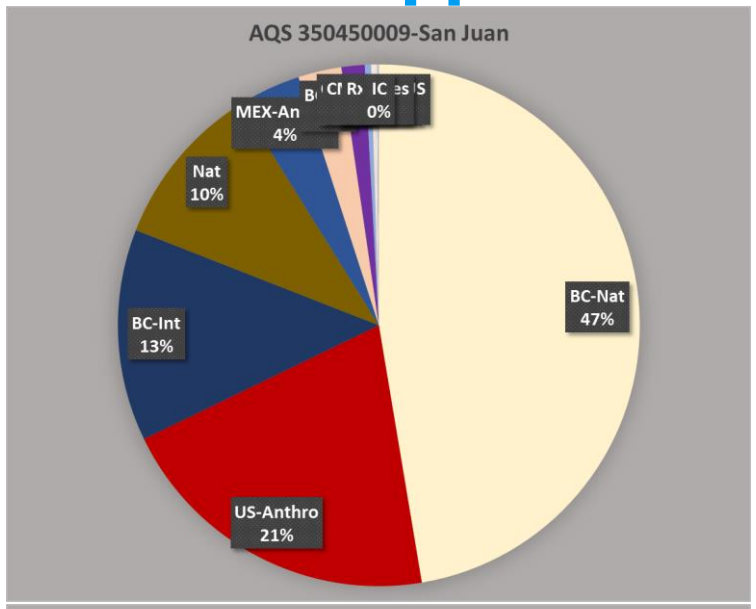
Site ID	County	NMB (%)	NME (%)	r
350450009	San_Juan	7.36	10.36	0.63
350390026	Rio_Arriba	3.24	8.62	0.57
350010029	Bernalillo	1.34	8.10	0.66
350130021	Dona_Ana	0.26	8.03	0.72
350151005	Eddy	-4.33	9.45	0.72

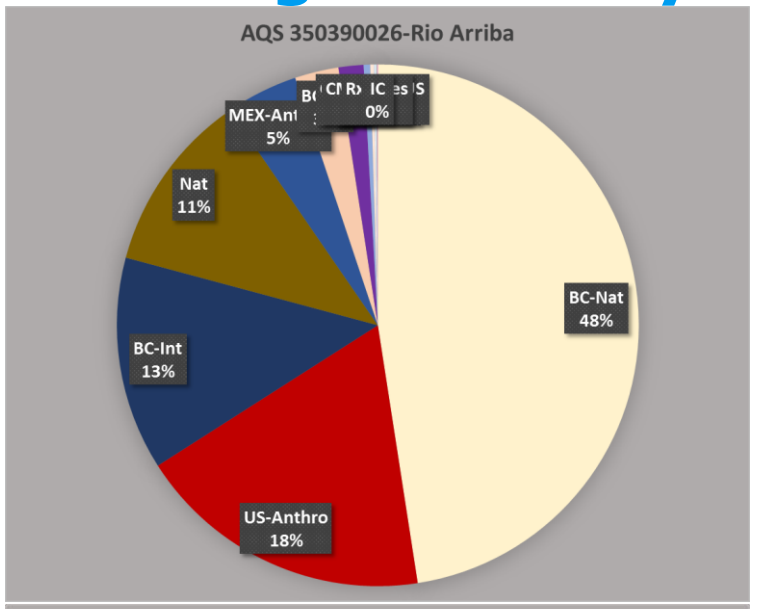


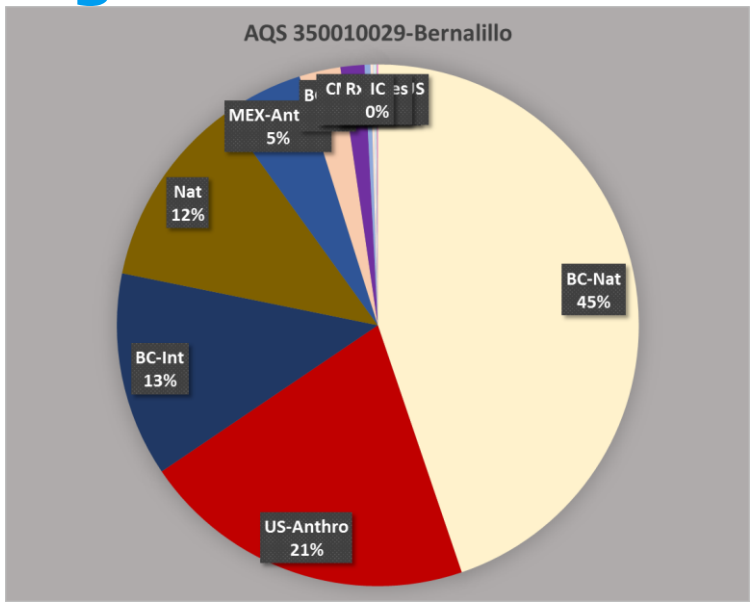


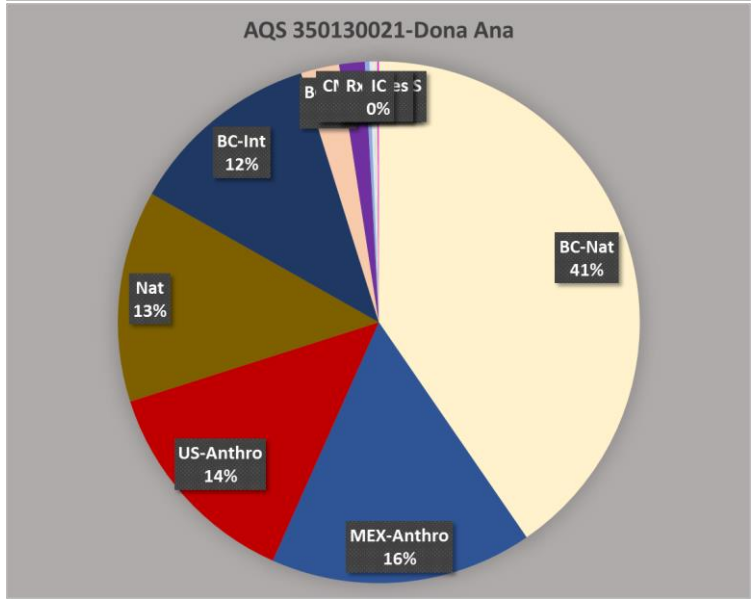


Selected Sites Time Series

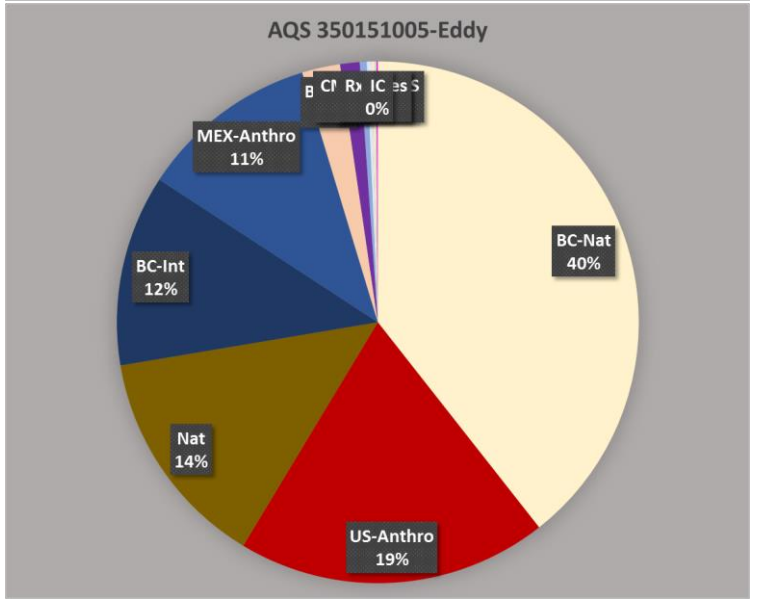




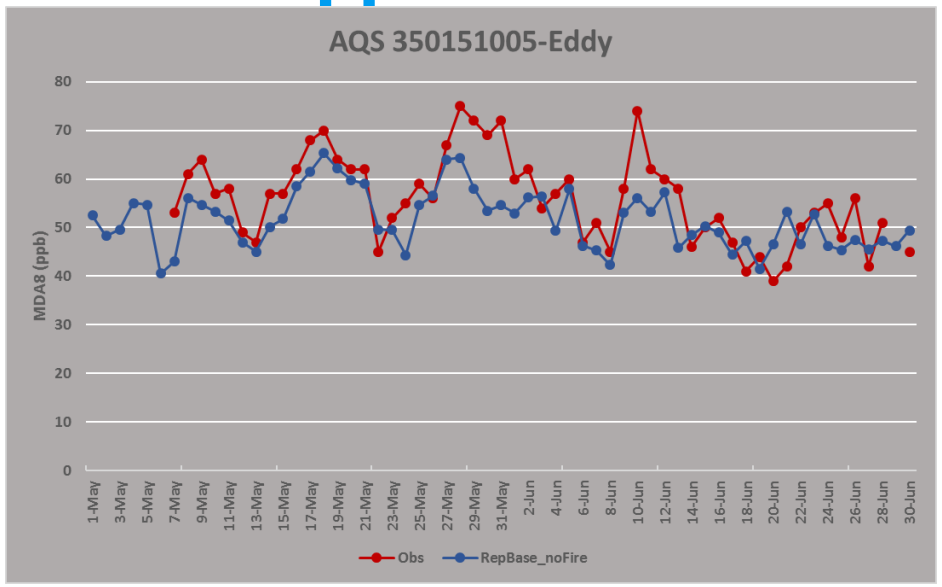


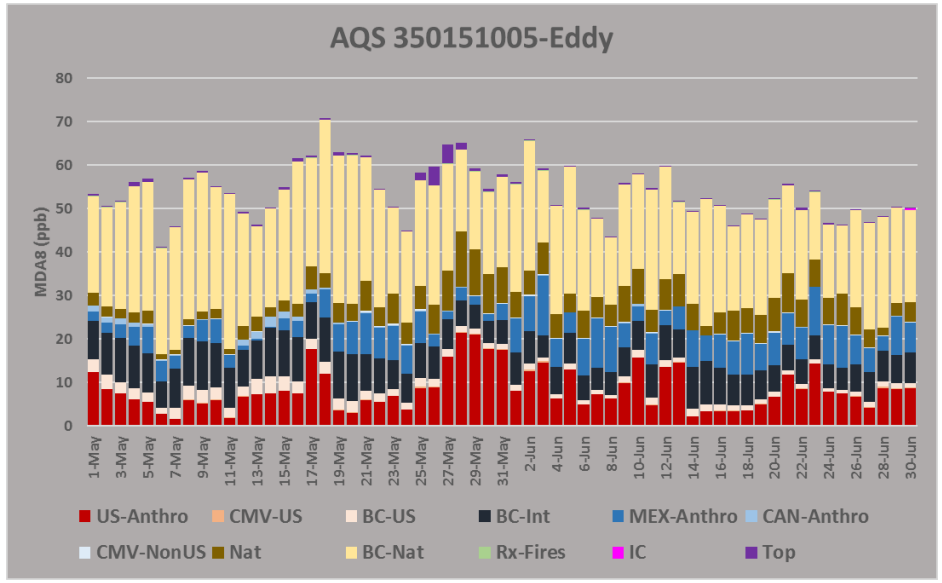


- RepBase statistics and time series suggest that is reasonable to use Source Apportionment results to understand sources of ozone at these sites

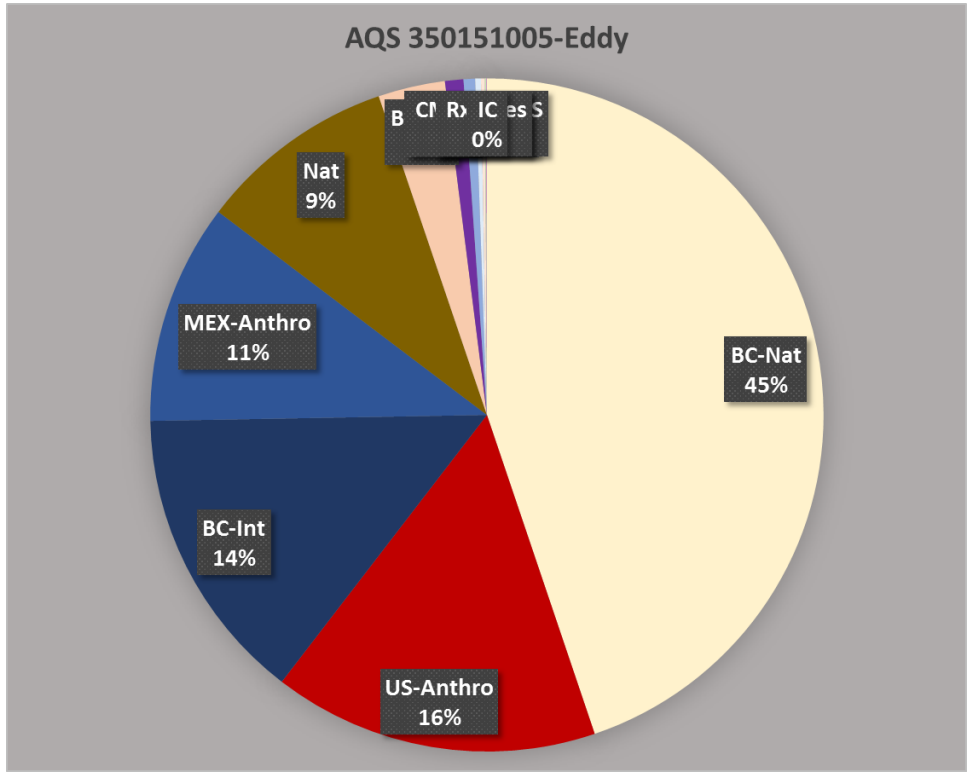


Source Apportionment Average over May to August



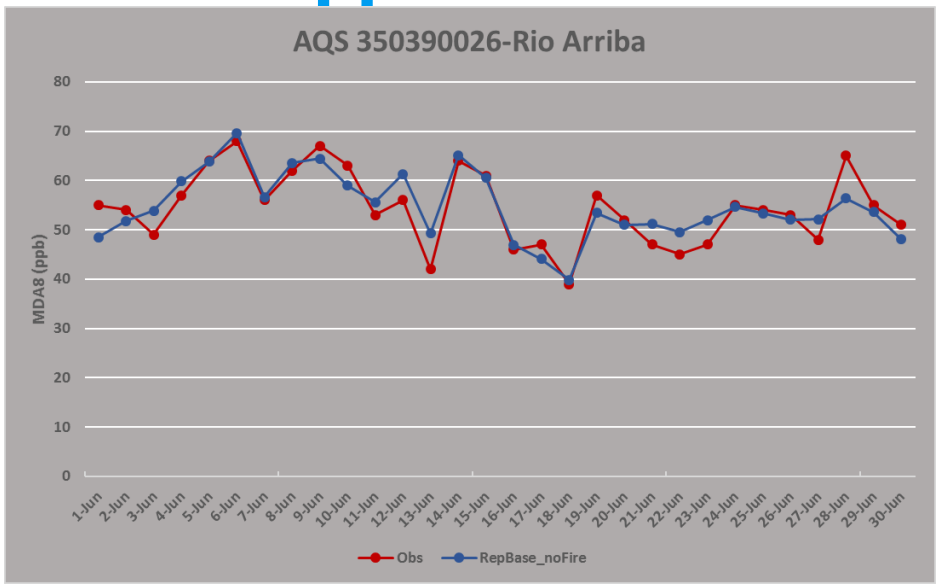


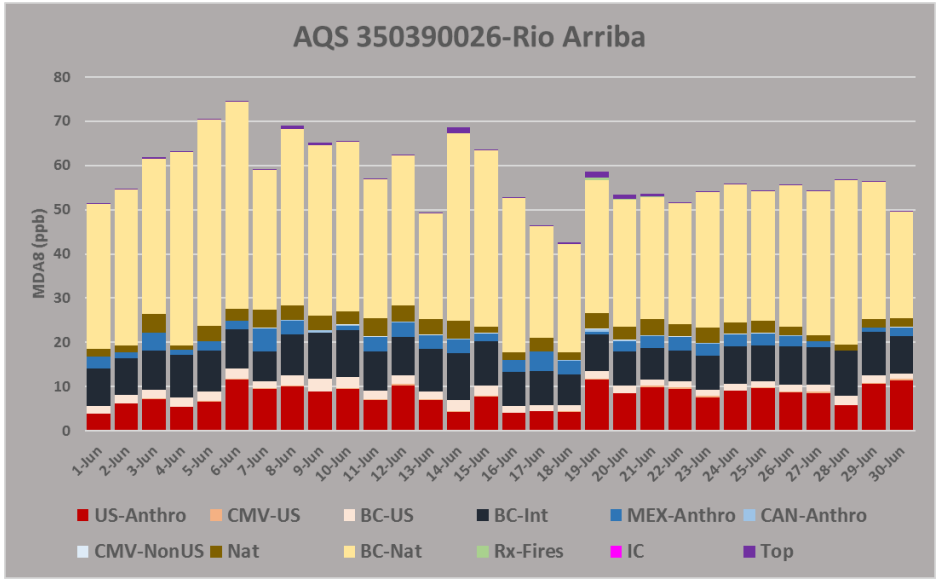
- Natural contribution from the GEOS-Chem Boundary Conditions ~ 40% to 48% of the ozone
- US Anthro ~ 14% to 21%
- International BC ~13%
- Mexican Anthro ~5%. Largest at Dona Ana county at 16%



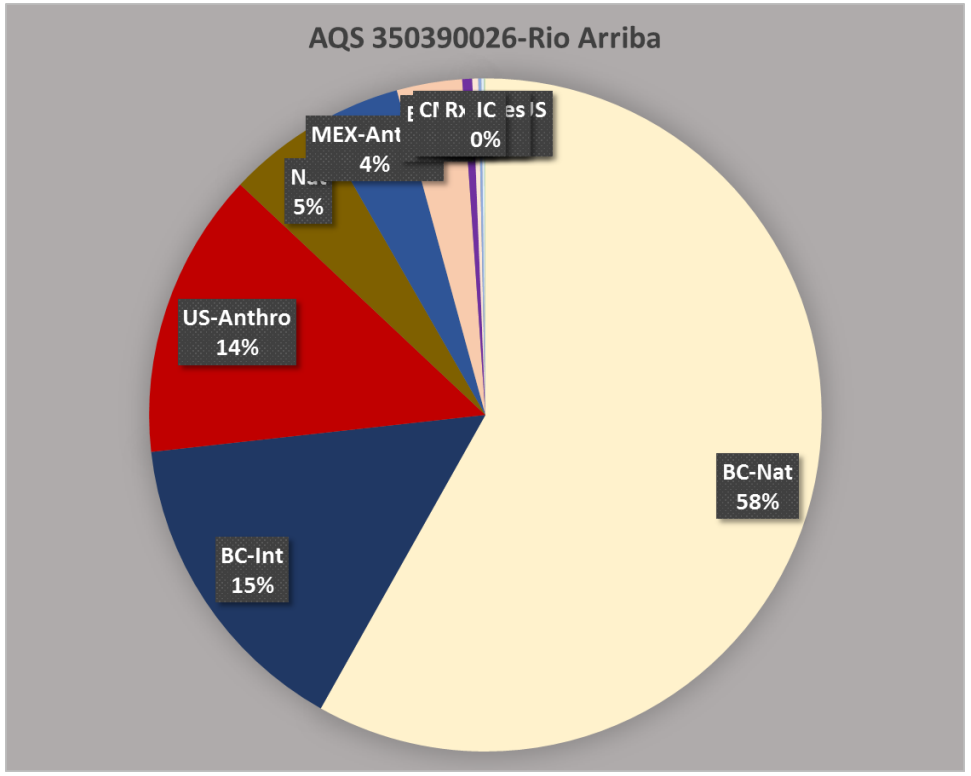
RAMBOLL

Source Apportionment: Eddy County



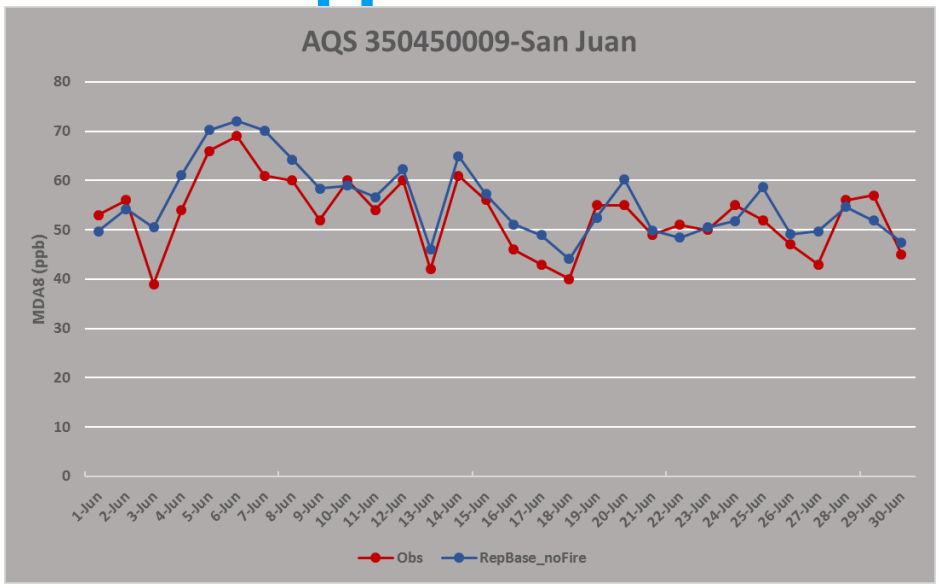


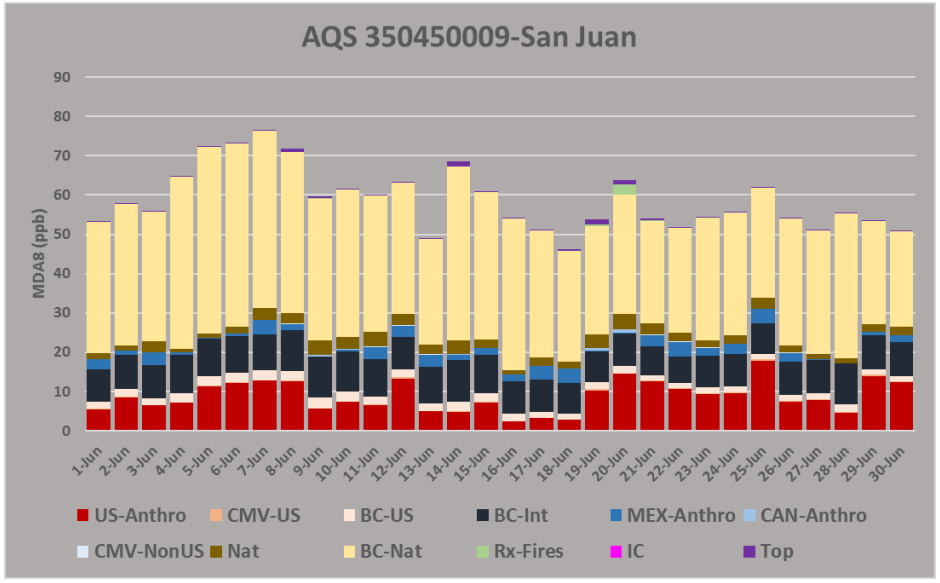
- Obs in Eddy County Site in May-Jun show multiple days with MDA8>70 ppb
- US Anthro and International BC contributions show equivalent contributions (16 and 14%)
- Peak on May 25 to 27 has some influence from the top of the model



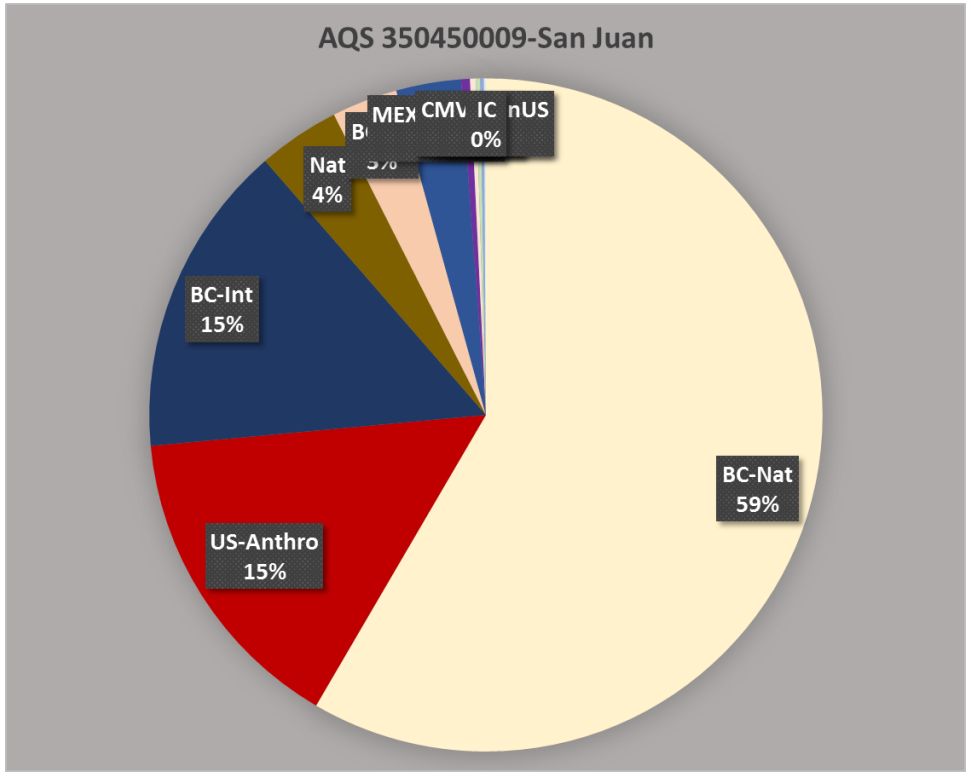
RAMBOLL

Source Apportionment: Rio Arriba county



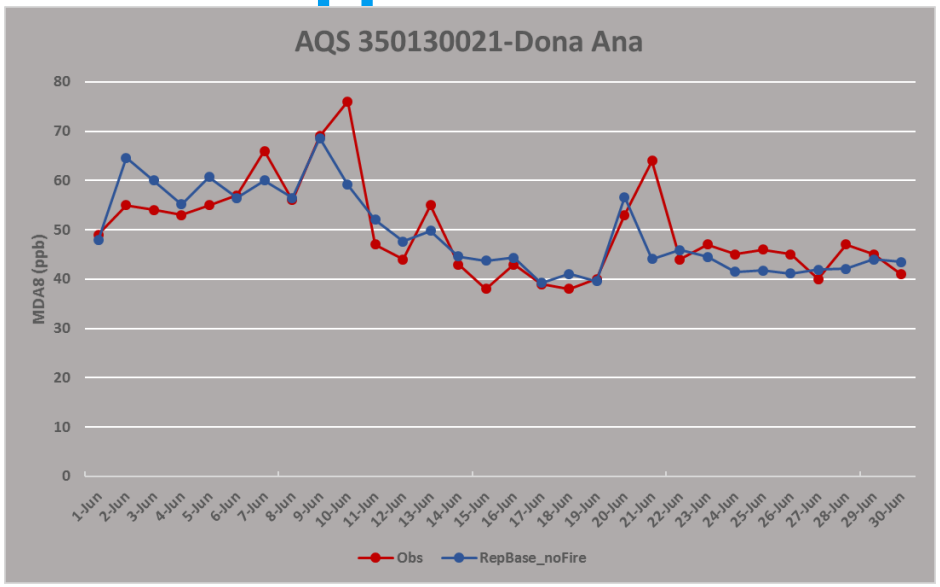


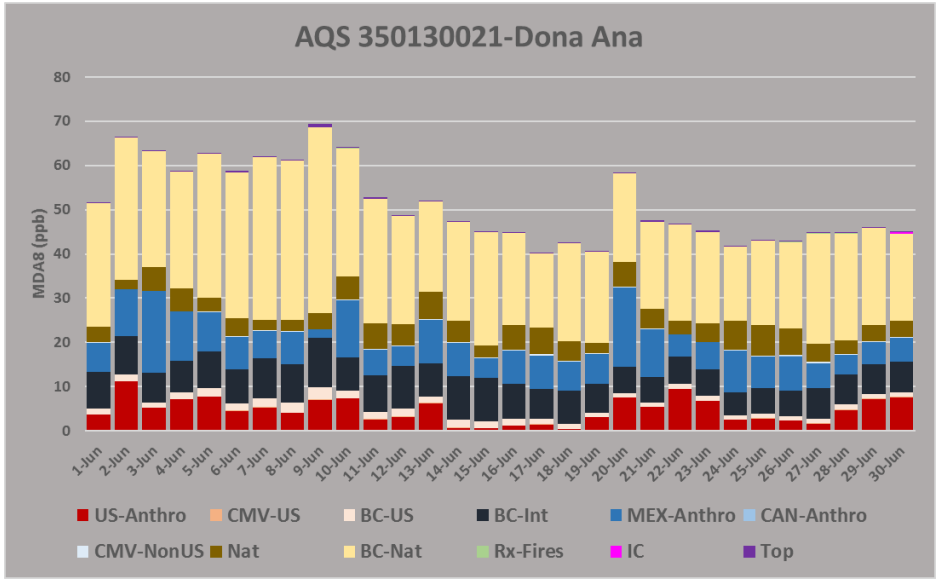
- International BC and US Anthro contributions show equivalent contributions (15 and 14%)
- Peak on June 6 dominated by Natural contributions from the Boundary



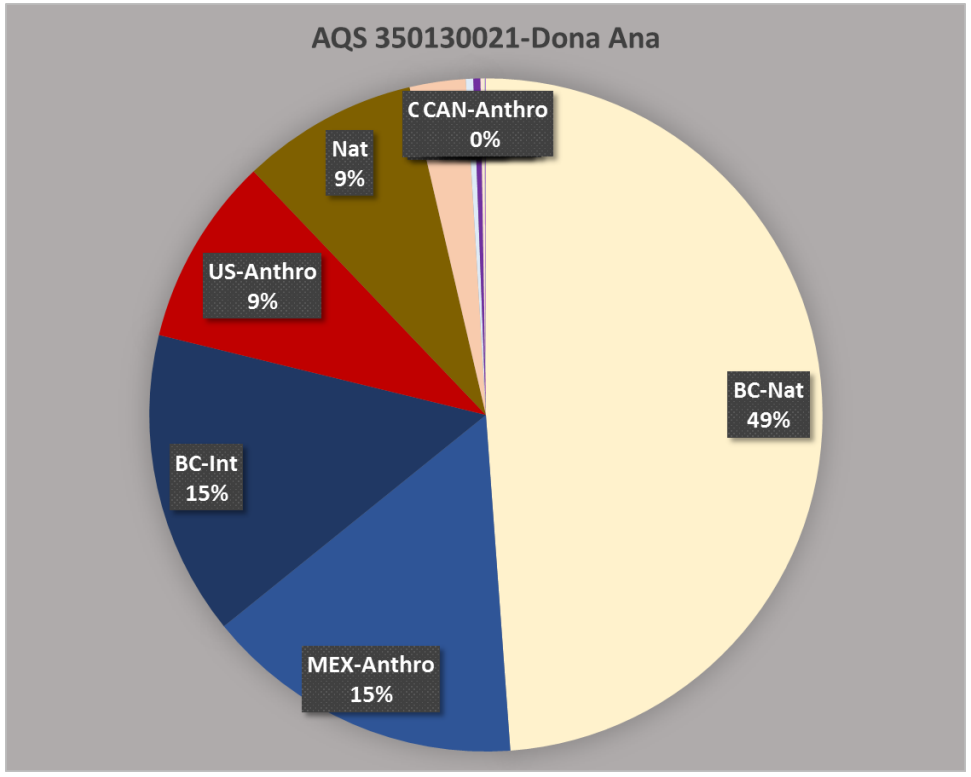
RAMBOLL

Source Apportionment: San Juan county



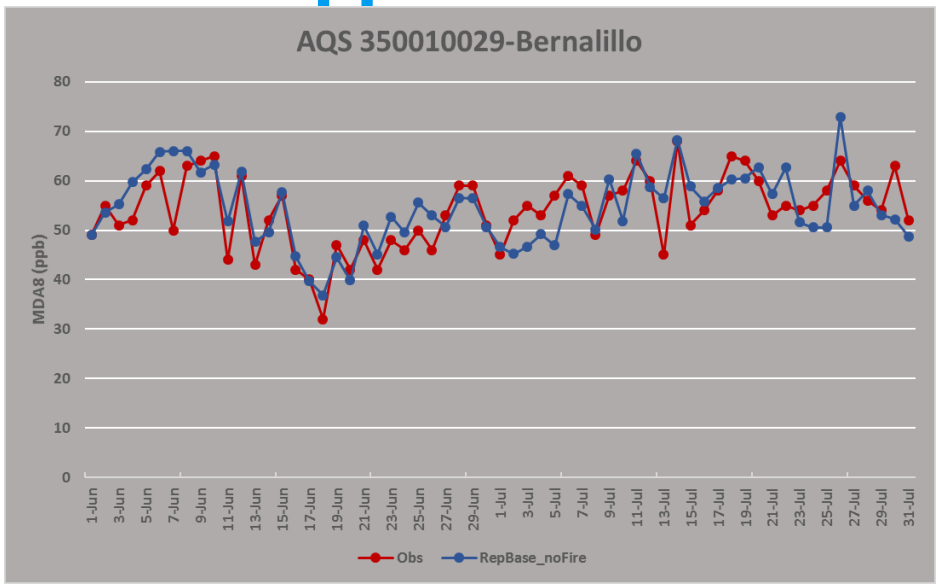


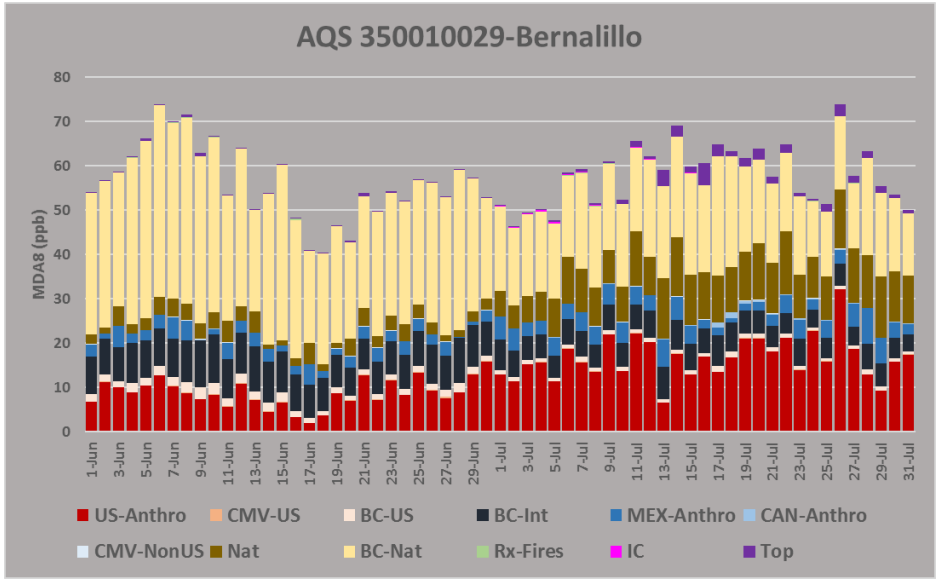
- International BC and US Anthro contributions show equivalent contributions (15%)
- Peak on June 7 dominated by Natural contributions from the Boundary



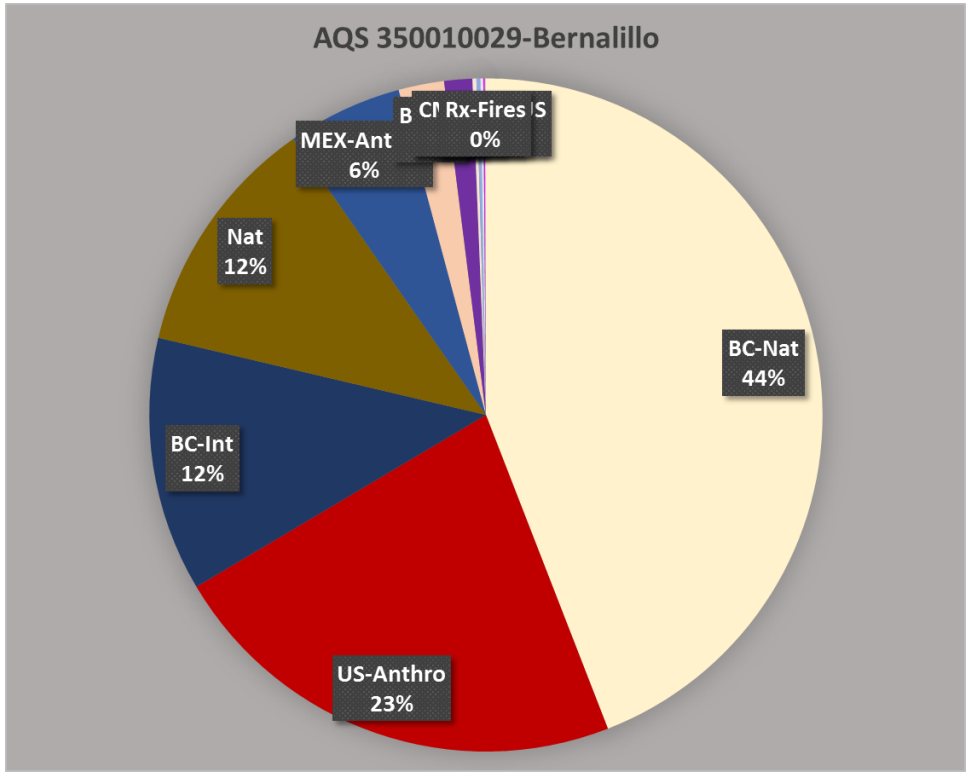
RAMBOLL

Source Apportionment: Dona Ana county





- International BC and Mexican Anthro contributions show equivalent contributions (15%)
- Peak on June 9 dominated by Natural contributions from the Boundary



RAMBOLL

Source Apportionment: Bernalillo county

- US Anthro is almost twice as large as International BC contributions
- First peak in June has large US and International contributions, second peak in July more dominated by US natural sources

RAMBOLL

GEOS-Chem Summary of Recent Updates

- WRAP 2014 Base Case used GEOS-Chem version 12.2.0 released 2019-02-19
- Current GC stable version is 12.8.2 released 2020-05-27
- Cumulative updates relevant for ozone :

Feature	Type	Version
Grid independent lighting NOx, biogenic and soil NOx emissions	Science	12.4.0
Updated offline biogenic emissions generated with GC 12.3.0	Science	12.5.0
Small alkyl nitrate chemistry	Science	12.7.0
Ozone deposition to the ocean	Science	12.8.0

http://wiki.seas.harvard.edu/geos-chem/index.php/GEOS-Chem_12#12.8.1

RAMBOLL

NMED Exhibit 18 - 0036

Conclusions: BCs from WRAP 2014 GEOS-Chem

- Initial WRAP 2014v1 CAMx and CMAQ simulations using EPA 2014 GEOS-Chem BCs exhibited large ozone overestimation bias year-round
  - Made it difficult to evaluate other model options (e.g., biogenic emissions)
- WRAP elected to conduct their own 2014 GEOS-Chem using new versions of the model and emission inventories in CAMx 2014v2 and RepBase simulation
  - Much better ozone model performance across the western states
- We more closely examined WRAP CAMx 2014v2 ozone model performance in New Mexico
  - CAMx 2014v2 ozone performance in New Mexico good mostly achieving ozone performance goals
- We examined WRAP CAMx RepBase ozone source apportionment at sites in New Mexico
  - Found approximately 60%-75% of ozone was due to BCs, BCs from natural sources higher (40-50%)
  - Higher BC ozone contribution in northwest than southeast Counties in New Mexico
- Few recent updates to GEOS-Chem could affect ozone but would likely not significantly affect ozone BCs and would affect costs and schedule

RAMBOLL

Task 1: Overview of Modeling Protocol

RAMBOLL

Modeling Protocol – 1. Introduction

1.1 New Mexico OAI Project Genesis

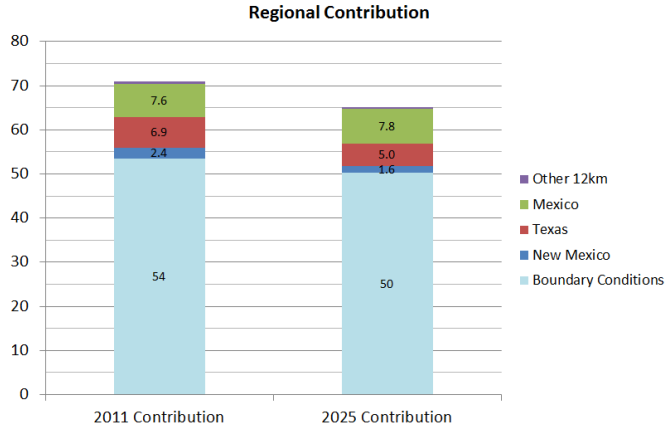
1.2 Overview of NM OAI Study Modeling Approach

1.3 Related Studies

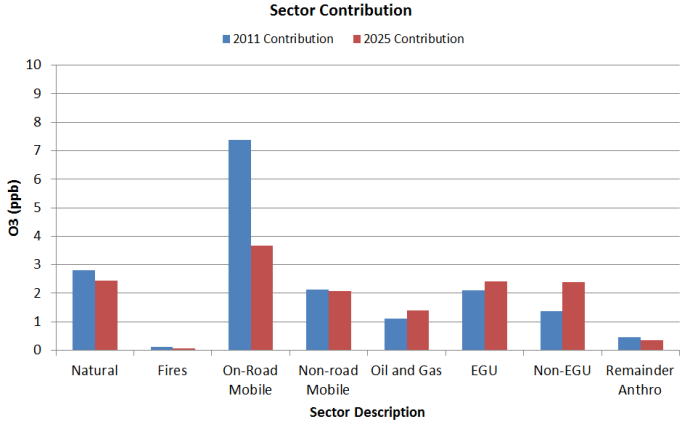
1.4 Conceptual Models for High Ozone in New Mexico

1.5 Overview of the Modeling Approach

1.6 Project Participants and Contacts

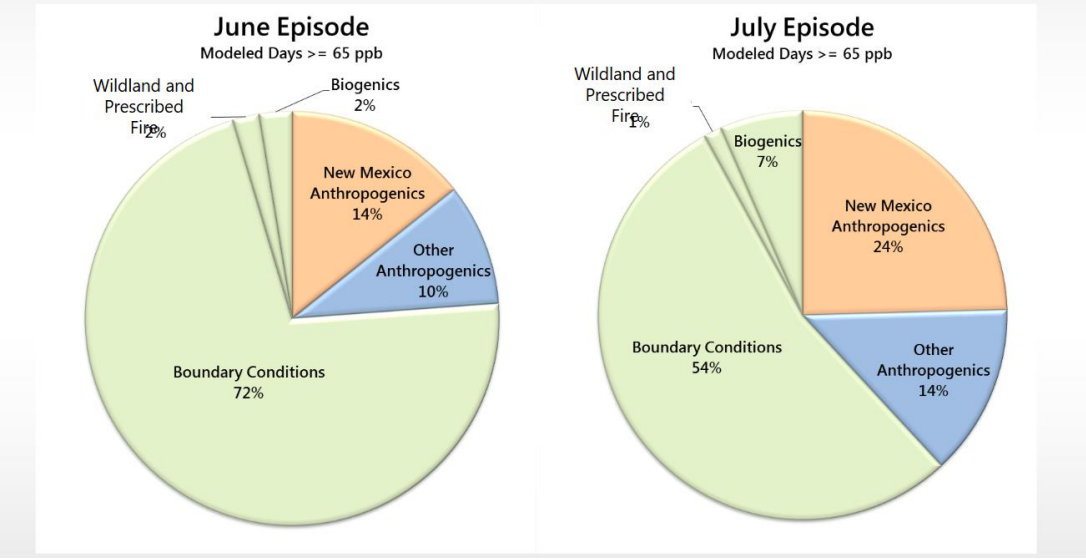


1.7 Communication



1.8 Schedule

RAMBOLL



Modeling Protocol – 1. Introduction – 1.3 Related Studies

- Southern New Mexico Ozone Study (SNMOS)
  - Contributions to 2011 and 2025 Ozone Design Values at Desert View (2-3% due to NM)

- City of Albuquerque Ozone Study – Contributions to Ozone in Albuquerque

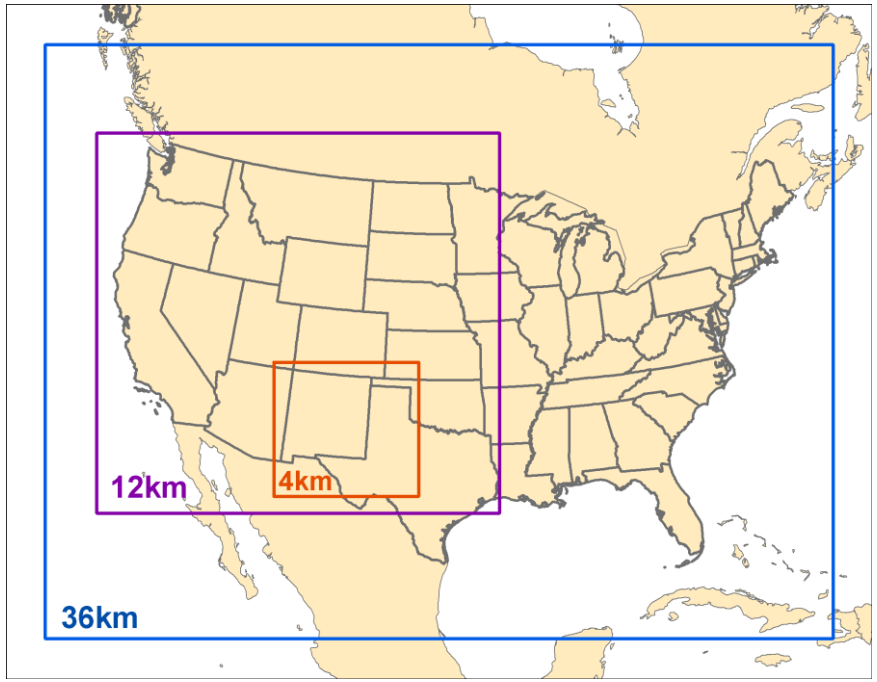
RAMBOLL

Modeling Protocol – Model and Episode Selection

2. Model Selection

- Mainly Consistent with WRAP/WAQS 2014v2 and EPA 2016v1 modeling platforms
- CAMx – Photochemical
  - Used in WRAP, SNMOS, EPA, Denver SIP, etc.
- WRF – Meteorological
  - Current state-of-science
- SMOKE – Emissions Processor
  - Most widely used Emissions Model
- MEGAN – Biogenic Emissions
  - Selected over BEIS used in WRAP 2014v2
- GEOS-Chem – Global
  - For 36-km domain Boundary Conditions (BCs)

3. Episode Selection – May-Aug 2014



- Need to leverage existing photochemical modeling database so choose between 2014 or 2016
- Select 2014 because:
  - Coincides with an NEI Year
  - Higher quality emissions with updates from western states (WRAP 2014v2)
  - Observed ozone close to ozone DVs
  - 2014 has more ozone exceedance days (8) than 2016 (3)

RAMBOLL

Modeling Protocol – Domain Selection and WRF Modeling

4. Domain Selection

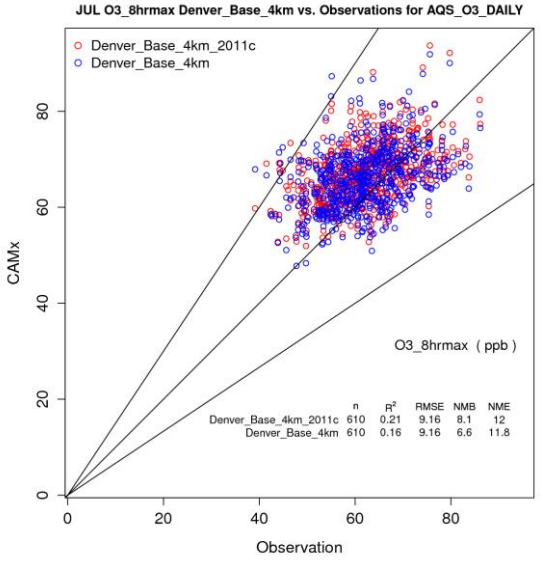
- 36/12/4-km domains
- 4-km domain include New Mexico and O&G production areas in San Juan and Permian Basin

5. WRF Modeling

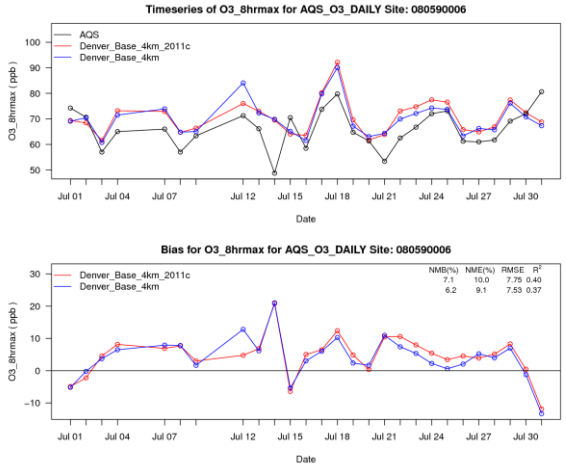
WRF Option	NM OAI Study	2014 WAQS	2014/2015 EPA
Vertical Coordinate	Hybrid	eta	eta
Domains run	36/12/4-km	36/12/4-km	12-km
Microphysics	Thompson	Thompson	Morrison 2
LW Radiation	RRTMG	RRTMG	RRTMG
SW Radiation	RRTMG	RRTMG	RRTMG
LSM	Noah	Noah	Pleim-Xiu
PBL scheme	YSU	YSU	ACM2
Sfc Layer Physics	MM5 similarity	MM5 similarity	MM5 similarity
Cumulus	36/12/4-km Multi-scale Kain Fritsch	36/12-km Multi-scale Kain Fritsch	Kain-Fritsch
BC, IC Analysis Nudging Source	12-km NAM/ERA5	12-km NAM	12-km NAM
Analysis Nudging Grids	36/12-km	36/12-km	12-km
Obs Nudging	None	4-km	None
Sea Sfc Temp	FNMOC	FNMOC	FNMOC

RAMBOLL

Modeling Protocol – 2014 Base Case & Model Performance Evaluation



6. CAMx 2014 Inputs Preparation



- CAMx Configuration and Options

Science Options	CAMx	Comment
Model Codes	CAMx v7.0	Latest version of CAMx used in WRAP/WAQS 2014v2 and EPA Regional Haze modeling
Horizontal Grid Mesh	36/12/4-km	
36-km grid	148 x 112 cells	36US domain
12-km grid	227 x 215 cells	12WUS2 domain. Includes buffer cells
4-km grid	245 x 227 cells	New Mexico 4-km domain. Includes buffer cells
Vertical Grid Mesh	25 vertical layers, defined by WRF	Layer 1 thickness ~20 m. Model top at 50 mb (~19 km)
Grid Interaction	36/12/4 km two-way nesting	
Initial Conditions	Start on May 1, 2014	First high ozone day is May 17, 2014
Boundary Conditions	WRAP 2014 GEOS-Chem	For 36US domain
Emissions		
Baseline Emissions Processing	SMOKE, SMOKE-MOVES2014, MEGAN	WRAP/WAQS 2014v2 emissions and EPA 2023fh for future year
Sub-grid-scale Plumes	Plume-in-Grid for major NO_X sources in New Mexico	Keep same PiG sources in 2014 and 2023 emission years
Chemistry		
Gas Phase Chemistry	CB6r4	Latest chemical reactions and kinetic rates with halogen chemistry (Yarwood et al., 2010)
Meteorological Processor	WRFCAMx	Compatible with CAMx v7.0
Horizontal Diffusion	Spatially varying	K-theory with Kh grid size dependence
Vertical Diffusion	CMAQ-like Kv	Evaluate YSU Kv scheme
Diffusivity Lower Limit	Kv-min = 0.1 to 1.0 m^2/s in lowest 100 m	Depends on urban land use fraction
Deposition Schemes		
Dry Deposition	Zhang dry deposition scheme	(Zhang et. al, 2001; 2003)
Wet Deposition	CAMx -specific formulation	rain/snow/graupel
Numerics		
Gas Phase Chemistry Solver	Euler Backward Iterative(EBI)	EBI fast and accurate solver
Vertical Advection Scheme	Implicit scheme w/ vertical velocity update	Emery et al., (2009a,b; 2011)
Horizontal Advection Scheme	Piecewise Parabolic Method (PPM) scheme	Colella and Woodward (1984)
Integration Time Step	Wind speed dependent	~0.5-1 min (4-km), 1-5 min (12-km), 5-15 min (36-km)

7. 2014 Base/Model Performance Evaluation

- Focus on ozone performance in NM 4-km Domain
- Ozone Performance Goals and Criteria
  - NMB < 5% & NMB < 15%
- AMET evaluation tool
- Diagnostic Sensitivity Tests:
  - WRF/NAM vs. WRF/ERA5
  - YSU vs. CMAQ-like Kv
- MPE Graphical Displays

Modeling Protocol – Future Year Modeling

8. 2023 CAMx Modeling

- EPA 2023fh Emission Projections
- Natural Emissions at 2016 Levels
- 2023 Control Measure Sensitivity Modeling
  - Control assumptions to be provided by NMED
- 2023 Ozone Source Apportionment
  - Design Document to be reviewed by NMED
  - Geographic Regions
    - NM, TX, OK, CO, AZ, CA, Mex, Can
  - Source Sectors
    - Upstream Oil and Gas, Midstream Oil and Gas, EGU Point, Non-EGU Point, On-Road Mobile, Non-Road Mobile, Other Anthropogenic, Fires (WF, Rx and Ag), Natural, BC from International Anthropogenic Emissions, BC from US Anthropogenic Emissions, BC from Natural Sources, Initial Concentrations

9. Ozone Design Value (DV) Projections

- EPA recommended ozone DV projection approach uses the model in a relative sense to scale the observed ozone DVB

$$DVF_{2023} = DVB_{2014} \times RRF$$

$$RRF = \sum MDA8\ Ozone_{2023} / \sum MDA8\ Ozone_{2014}$$

$$DVB_{2014} = (DV_{2012\text{-}2014} + DV_{2013\text{-}2015} + DV_{2014\text{-}2016}) / 3$$

10. Quality Assurance Project Plan (QAPP)

- Elements of QAPP built into sections of Modeling Protocol
- QA/QC critical component of all aspects of PGM modeling

11. References

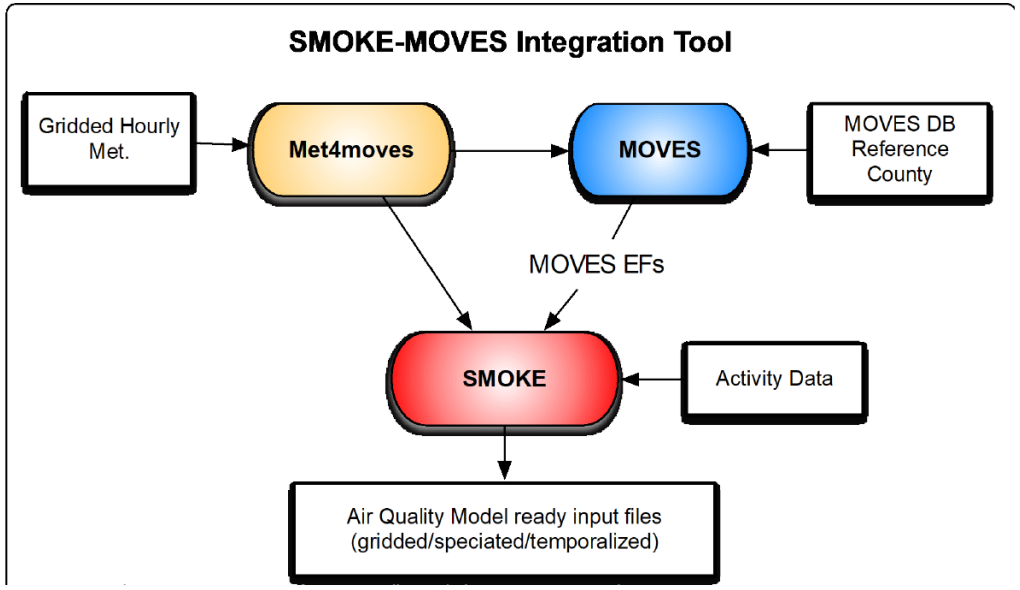
Overview of SMOKE-MOVES Processing

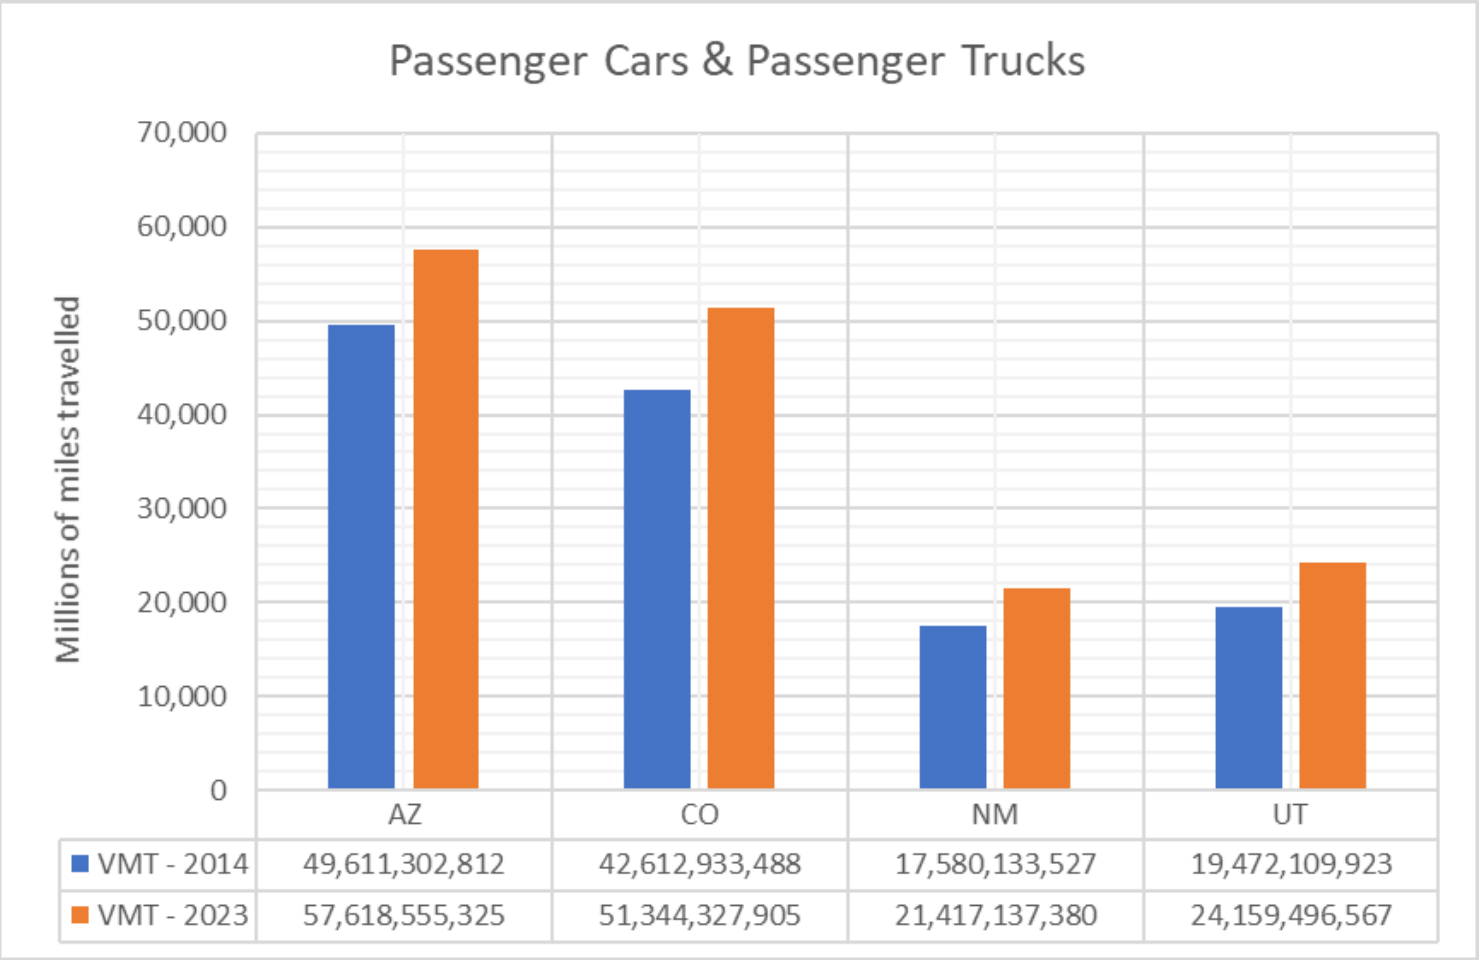


- Requires emission rate "lookup" tables generated by MOVES
  - EPA generated 2014 and 2023 MOVES "lookup" tables for modeling platform
- Uses gridded, hourly, day-specific temperatures
- Emission factors by temperature bin and speed for a series of "representative counties", to which every other county is mapped

NMED Exhibit 18 - 0052

Creating Onroad Emissions using SMOKE-MOVES

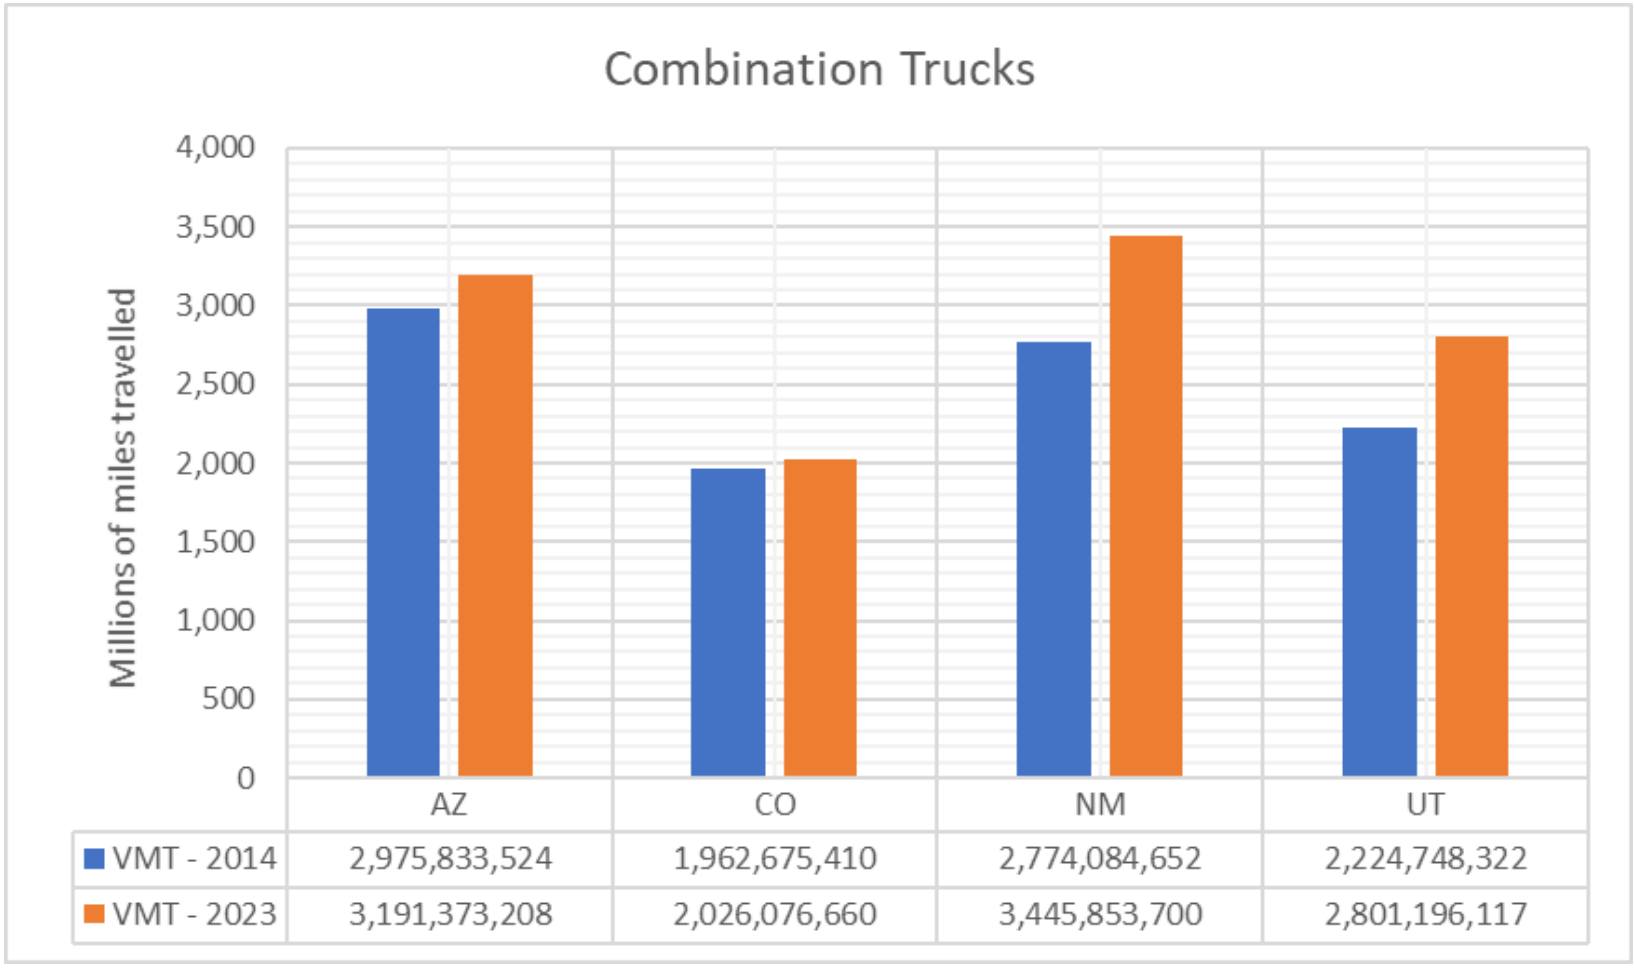
- Met4MOVES: Meteorological data preprocessor
- SMOKE processing applies the emission factors to the activity data to compute grid-cell emissions
- Activity Data
  - Vehicle Miles Travelled (VMT)
  - Vehicle Population
  - Extended Idling Hours



NMED Exhibit 18 - 0053

Review of On-Road Mobile Source Activity Data

- Activity data from EPA emission modeling platform
- Developed a spreadsheet tool to assist NMED to review activity data for 13 WRAP states
  - Show 2014 and 2023 population and activity of on-road vehicles
- The tab "Dashboard" shows comparisons of vehicle population and VMT by state, vehicle type, fuel type and road type.
- The tab "Scaling_factor" provides ratio of future year/base year activities by state, vehicle type and fuel type.



Gasoline Vehicles VMT for NM and Neighboring States

- Gasoline passenger vehicles
- Overall EPA projected 21% VMT increase in 2023 from 2014 for New Mexico

Heavy-Duty Diesel Trucks VMT for NM and Neighboring States

- Heavy-duty diesel truck VMT
- Overall EPA estimated 24% VMT increase in 2023 from 2014

	AZ	CO	NM	UT
VMT - 2014	2,975,833,524	1,962,675,410	2,774,084,652	2,224,748,322
VMT - 2023	3,191,373,208	2,026,076,660	3,445,853,700	2,801,196,117

RAMBOLL

2014 AND 2023 EMISSIONS

RAMBOLL

New Mexico Emissions Data

- 2014 anthropogenic emissions are based on the WAQS 2014v2
  - NMED provided information on a piece of equipment missing from the inventory (NOx 94 TPY and VOC 1 TPY)
  - Consistent emissions between Regional Haze and OAI studies
- 2023 anthropogenic emissions are based on the EPA 2016v1 platform
  - NMED updates: some Title V facilities are duplicates in the pt_oilgas and ptnonipm sectors
  - Added Lordsburg Generating Station missing from the 2023 inventory
- On-Road emissions based on SMOKE-MOVES processing with 2014/2023 activity data and day-specific hourly gridded 2014 WRF meteorology
- O&G emissions based on state-of-the-science O&G emissions estimates from the IWDW-WAQS platform

RAMBOLL

RECAP OF EPA/WAQS WRF EVALUATION

- Evaluated EPA 12US1 and WAQS 12WUS2 for May-August 2014
- EPA wet bias in summer months associated with overactive summer convection
- WAQS smaller wet bias

EPA 12 km

WAQS 12 km

RAMBOLL

NMED Exhibit 19 - 0017

RECAP OF NM OAI WRF SETUP AND PROCEDURE

- NM OAI proposed WRF configuration aligns closely with WAQS to reduce overactive summertime convection in New Mexico, with these differences
  - Reposition 4 km domain to encompass all of New Mexico
  - Use hybrid vertical coordinate to improve representation of upper troposphere/lower stratosphere
  - Add second simulation driven by ERA5 analysis
  - No observation nudging
- Two NM OAI WRF simulations (NAM12/ERA5) completed and evaluated
- Present evaluation of these two simulations for this webinar

RAMBOLL

NMED Exhibit 19 - 0018

RAMBOLL

ERA5 VS NAM WRF MPE APPROACH

- Evaluate ERA5 and NAM WRF simulations for May-August 2014
  - ERA5 and NAM analysis field inputs are critical inputs to a WRF simulation as they define initial and boundary conditions (IC and BC) and are used in the Four Dimensional Data Assimilation (FDDA) to continuously nudge the WRF predictions to the analysis fields
  - Evaluation include observation sites within New Mexico only
- Quantitative Evaluation
  - METSTAT – model/obs pairing, bias/error statistics against NCAR ds3505 observations
    - Soccer plots – monthly stats
    - Time series – hourly and daily
    - Plots for all sites in NM, and each individual site within NM
- Qualitative Evaluation
  - PRISM precipitation spatial maps
    - Monthly and daily

RAMBOLL

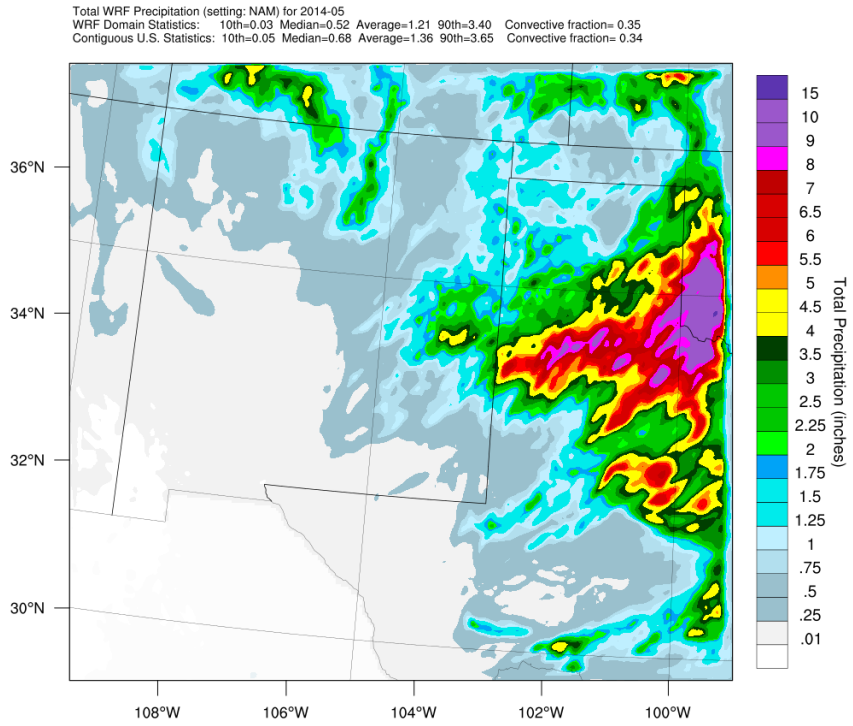
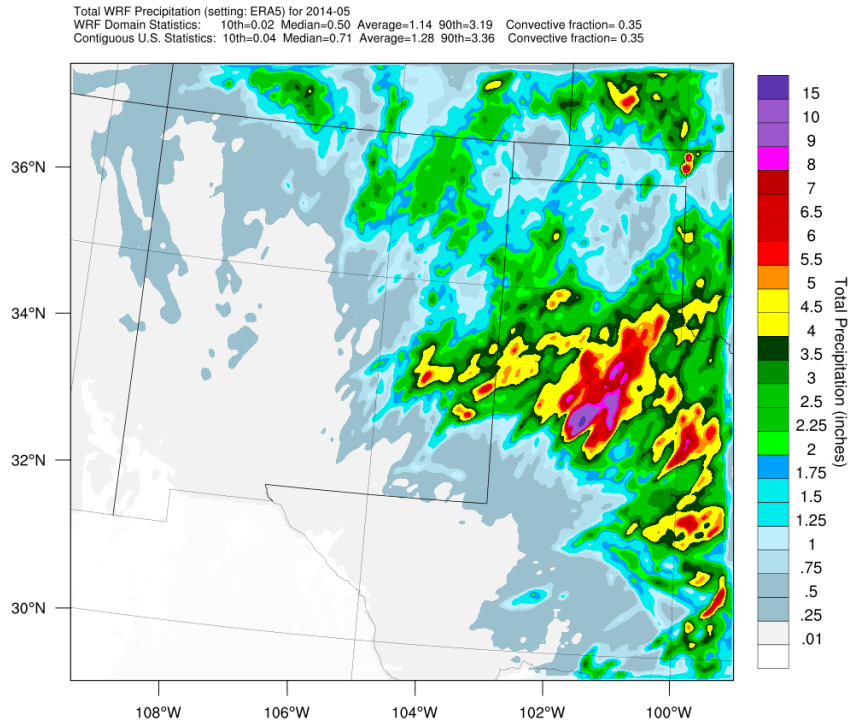
TIME SERIES – HUMIDITY AT KLRU (LAS CRUCES)



NMED Exhibit 19 - 0028

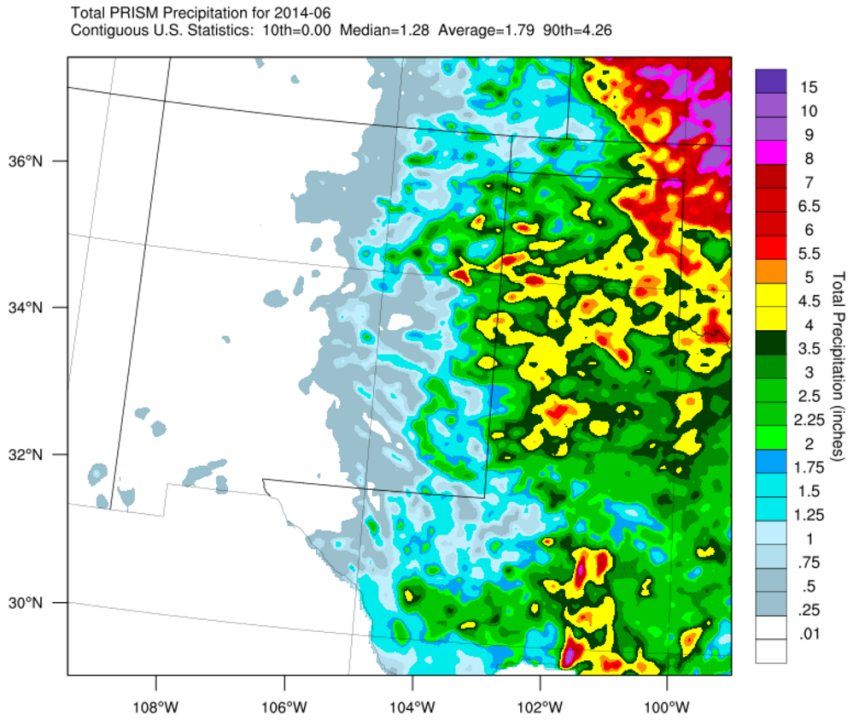
MONTHLY PRECIPITATION PLOTS – MAY 2014



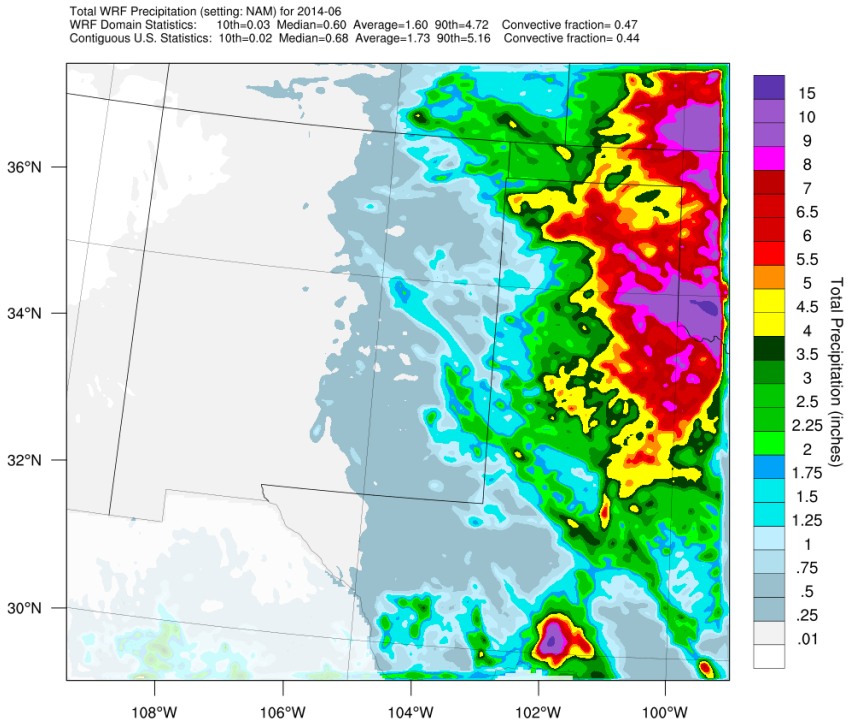
PRISM Obs

NAM

ERA5

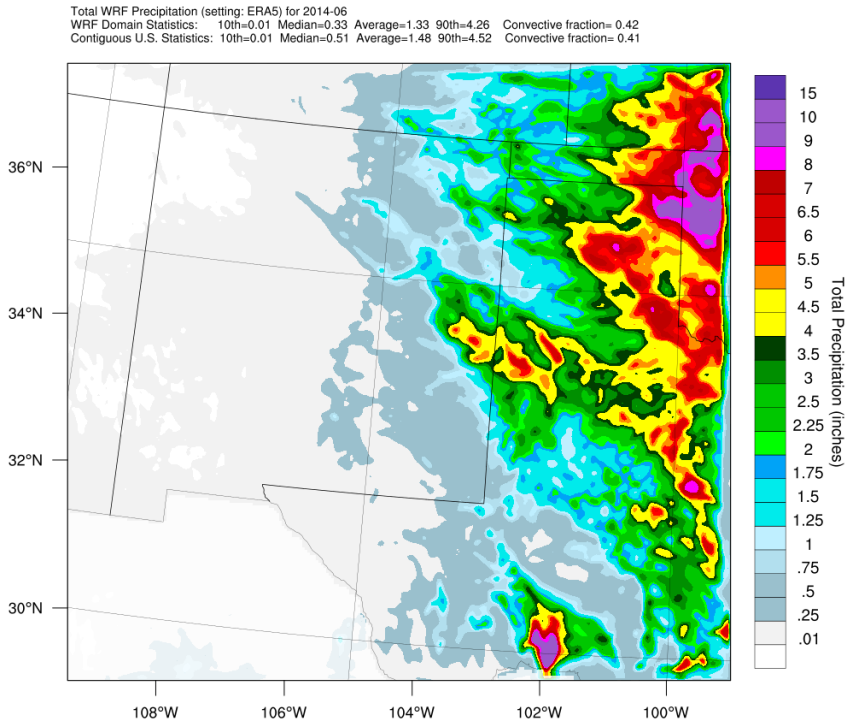


NAM and ERA5 are similar over New Mexico



RAMBOLL

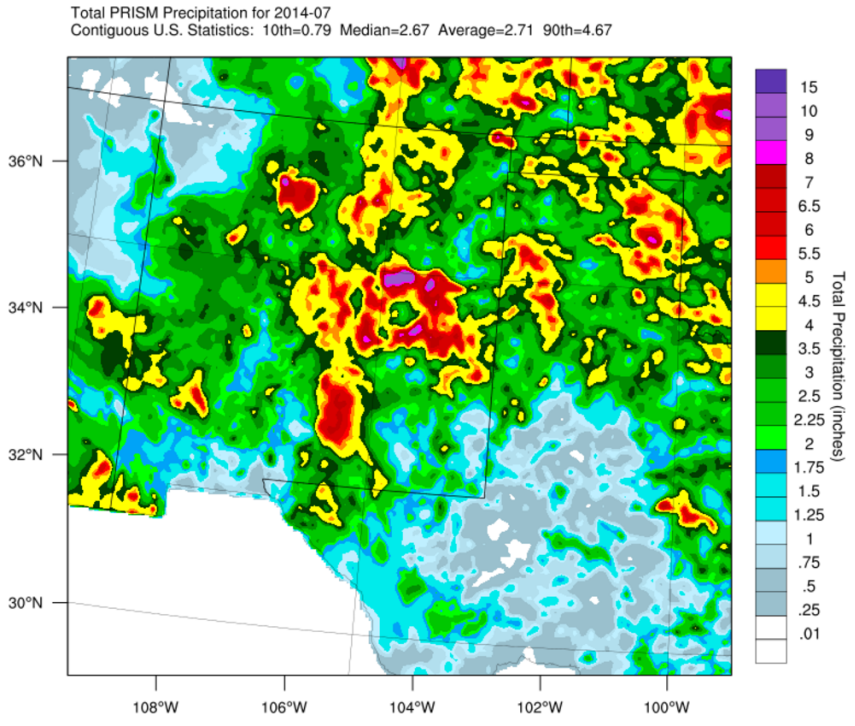
MONTHLY PRECIPITATION PLOTS – JUNE 2014



PRISM Obs

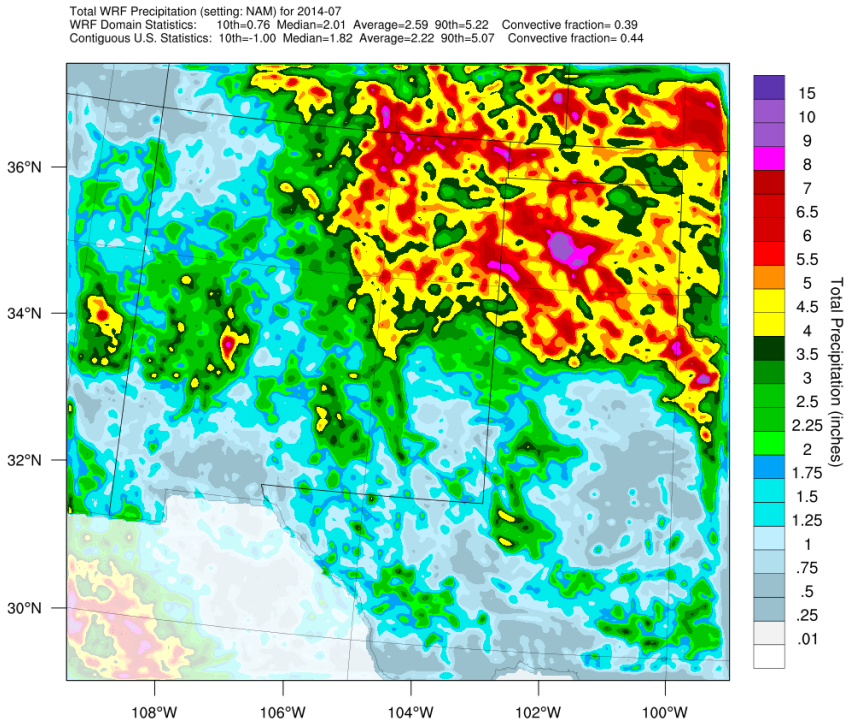
NAM

ERA5



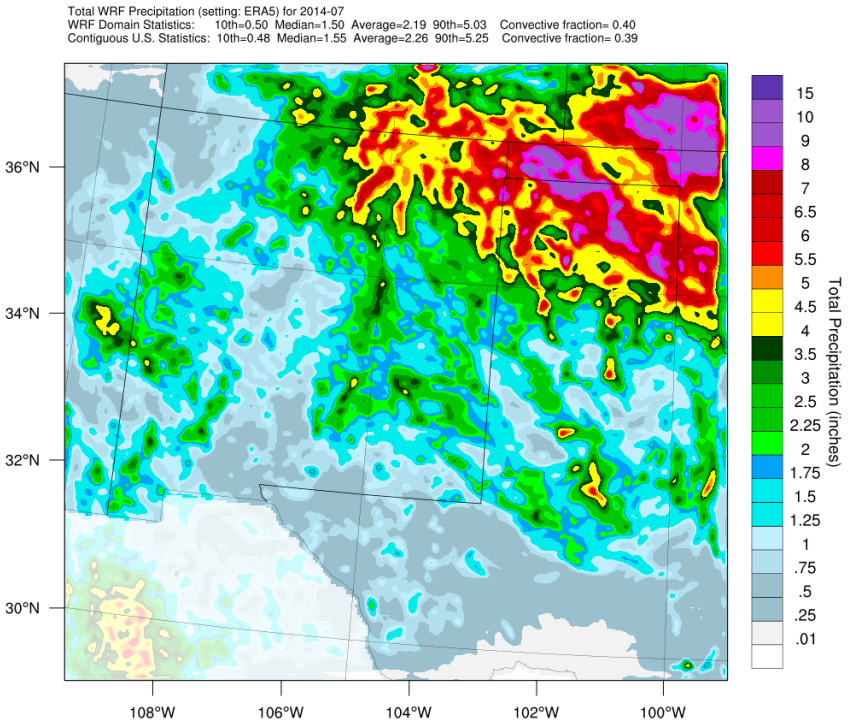
Both NAM and ERA5 are reasonable over NM; NAM overpredicts over North Texas

ERA5 slightly better



RAMBOLL

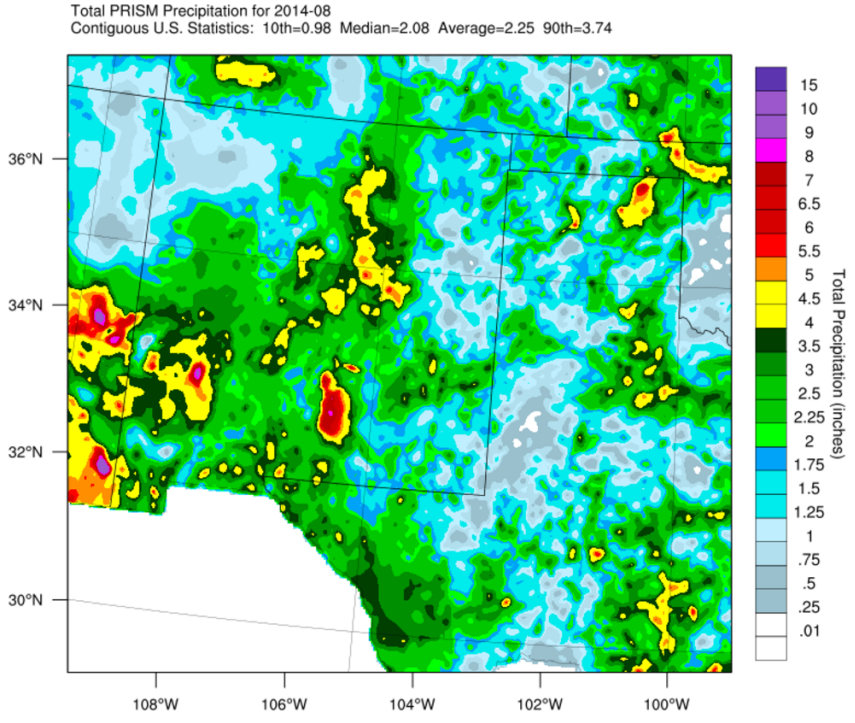
MONTHLY PRECIPITATION PLOTS – JULY 2014



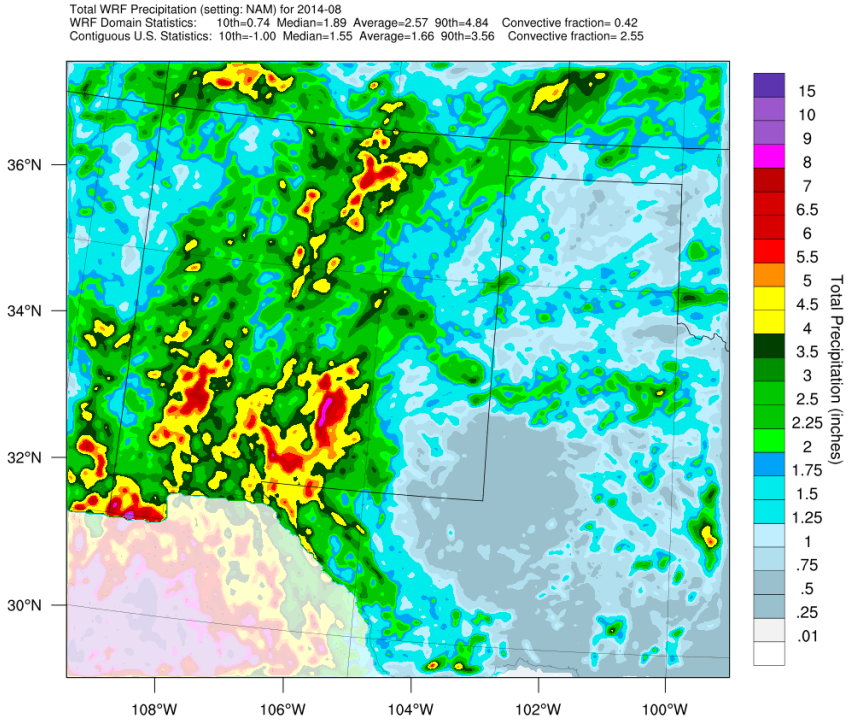
PRISM Obs

NAM

ERA5

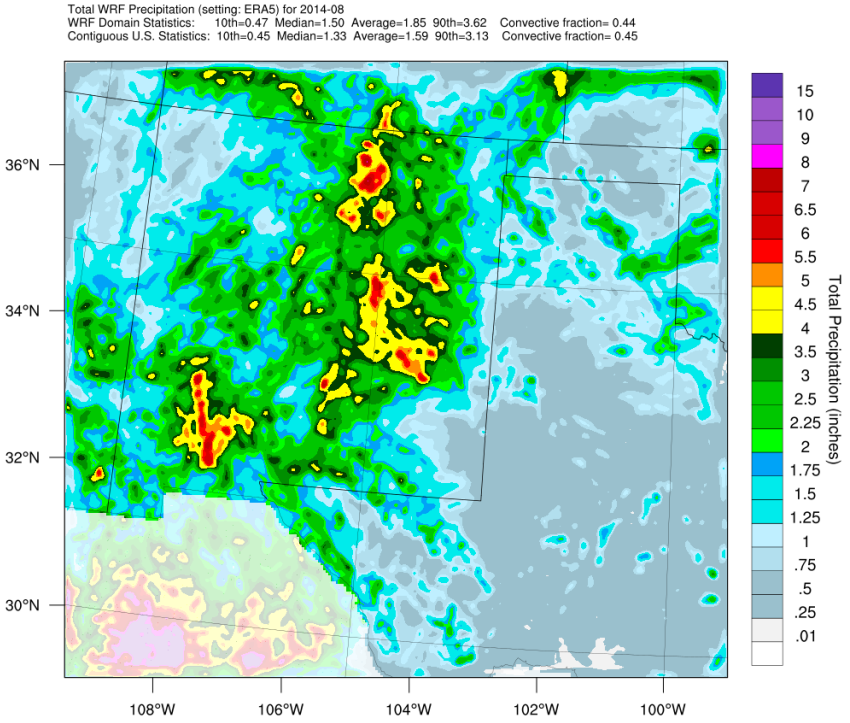


NAM overpredicts over NE New Mexico; both NAM and ERA5 show dry bias elsewhere in NM



RAMBOLL

MONTHLY PRECIPITATION PLOTS – AUG 2014



PRISM Obs

NAM

ERA5

ERA5 slightly better than NAM in matching location and magnitude of PRISM observations

RAMBOLL

2014 WRF SUMMARY AND CONCLUSIONS

- WRF performance reasonable for both NAM and ERA5 simulations
- Differences between NAM and ERA5 are smaller in comparison to EPA/WAQS
- NAM wet bias in June-August may be partly associated with overactive summer convection
- ERA5 has smaller wet bias
- Not possible to know which WRF simulation will result in better in CAMx ozone performance
  - Relative performance varies across parameters/seasons/locations
  - Best (or worst) performing WRF days may have small (or large) influence on AQ concentrations
  - Other meteorological variables (vertical diffusion, PBL heights, etc.) may be more important than the ones we can easily evaluate (T, Q, winds, precip)
- Proceed with both WRF simulations through CAMx and select best ozone performance for final CAMx configuration

RAMBOLL

NM OAI Study Next Steps

RAMBOLL

Next Up in July 2020

- July 2020: Task 4 -- 2014 and 2023 Emissions
  - 2014 SMOKE-MOVES and SMOKE for 4-km New Mexico Domain
  - 2014 36/12/4-km MEGAN biogenic and LNOx emissions modeling
  - Start 2023 SMOKE modeling
- July 2020: Task 5 – CAMx 2014 36/12/4-km Base Case Modeling
  - CAMx meteorological input sensitivity modeling
    - May 1 – June 16, 2014; 4 configurations: WRF/NAM and WRF/ERA5 using CMAQ/YSU vertical diffusivities (Kv)
  - Start CAMx 2014 36/12/4-km final base case May - August
- July 2020: NMED OAI Webinar
  - 2014 SMOKE Results for 4-km New Mexico domain (Anthro & Natural)
  - CAMx WRF meteorology sensitivity modeling
  - CAMx 2014 36/12/4-km final base case configuration
- Expected progress in August 2020
  - 2014 CAMx base case and MPE Report
  - 2023 Base and Control Strategy SMOKE Modeling and 2023 CAMx base case

NM OAI Study Webinar#3

July 27, 2020

RAMBOLL Bright ideas. Sustainable change.

AGENDA – NMED OAI STUDY WEBINAR#3 – JULY 27, 2020

- Welcome and agenda review – Tom and all
- 2014 and 2023 emissions QA, updates and processing – Ramboll
  - 2014 and 2023 Emissions QA and identification of duplicate sources
  - 2014 SMOKE emissions processing and results
  - 2014 natural emissions
- CAMx meteorological sensitivity tests and CAMx final 2014 base case configuration – Ramboll
  - WRF NAM and ERA simulations
  - Ozone evaluation of CAMx four meteorological input sensitivity tests
  - Final CAMx 2014 36/12/4-km base case configuration
- Upcoming schedule, milestones when NMED needs support for EIB process - all

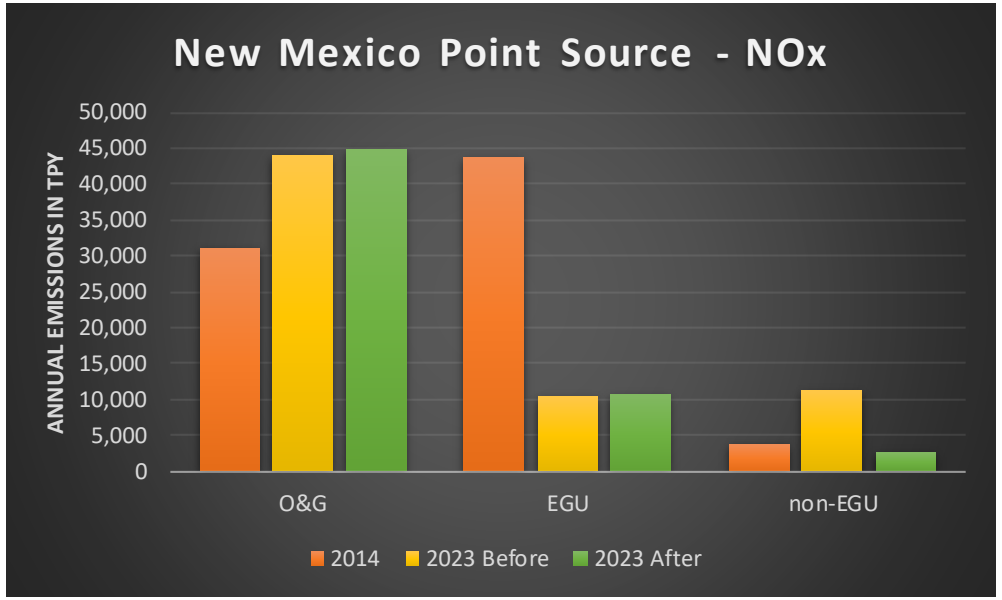
RAMBOLL

2014 AND 2023 EMISSIONS

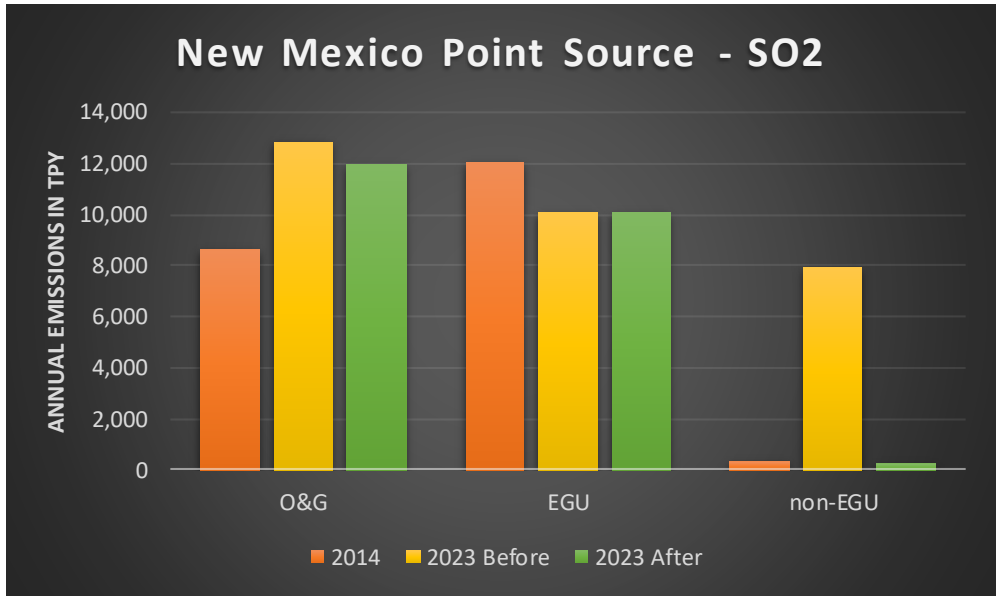
RAMBOLL

NEW MEXICO EMISSIONS DATA

- 2014 anthropogenic emissions are based on the WAQS 2014v2
  - NMED found a generator engine missing in 2014v2 inventory (94 tpy NOx)
  - No double counting of sources in 2014v2 inventory
  - Consistent emissions data between the Regional Haze and OAI studies



- 2023 anthropogenic emissions are based on the EPA 2016v1 platform
  - NMED found some point sources exist in both 2023 point O&G and non-EGU sectors
  - Found double counting of sources in WRAP O&G inventory: Title V and minor point sources
  - Found Lordsburg Generating Station is missing
  - Add two O&G sources: Chaco Gas Plant (NOx 2,053 tpy) and Mountainair CS (NOx 645 tpy)



RAMBOLL

NMED Exhibit 20 - 0004

DUPLICATE POINT SOURCES IN 2023

- NMED identified 21 facilities double counted in 2023 non-EGU and WRAP point O&G inventory
  - Double counted emissions: NOx 8,669 TPY and SO2 7,662 TPY
  - Represents approximately 9% (NOx) and 24% (SO2) of the New Mexico 2023 O&G emissions
- Duplicates in the WRAP O&G inventory: Some sources were present in Title V and minor point O&G sources datasets in the OGWG inventory.
  - Double counted emissions NOx: 1,927 TPY and SO2: 942 TPY

RAMBOLL

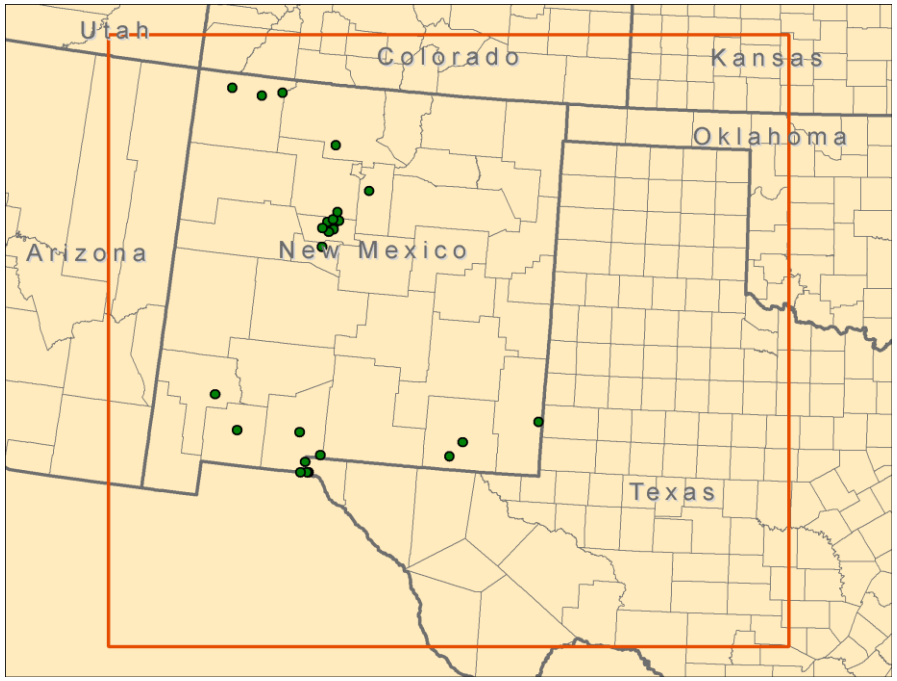
OVERVIEW OF SMOKE-MOVES PROCESSING



- Requires emission rate "lookup" tables generated by MOVES
- Uses gridded, hourly, day-specific temperatures
- SMOKE processing applies the emission factors to the activity data to compute grid-cell emissions

RAMBOLL

SMOKE PROCESSING OF 2014 EMISSIONS

- SMOKE version 4.7
- Process emissions for 4-km domain
- Spatial surrogates**:** O&G spatial surrogates are based on 2014 O&G activity data and other 4-km surrogates obtained from EPA's Emission Modeling Platform (EMP).
- Speciation for CB6r4 chemical mechanism in CAMx

RAMBOLL

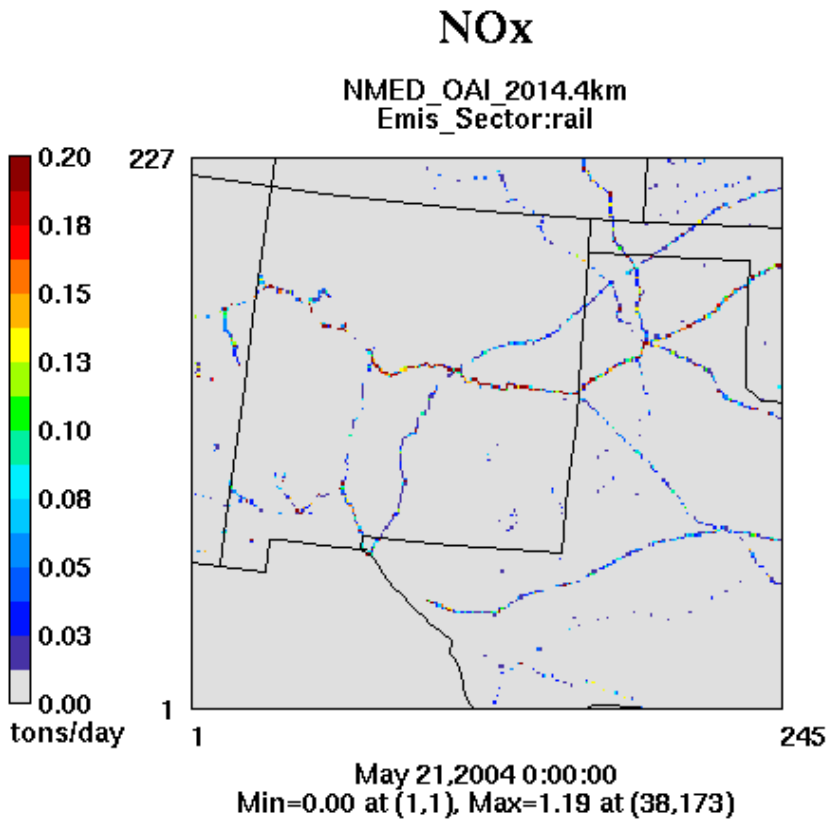
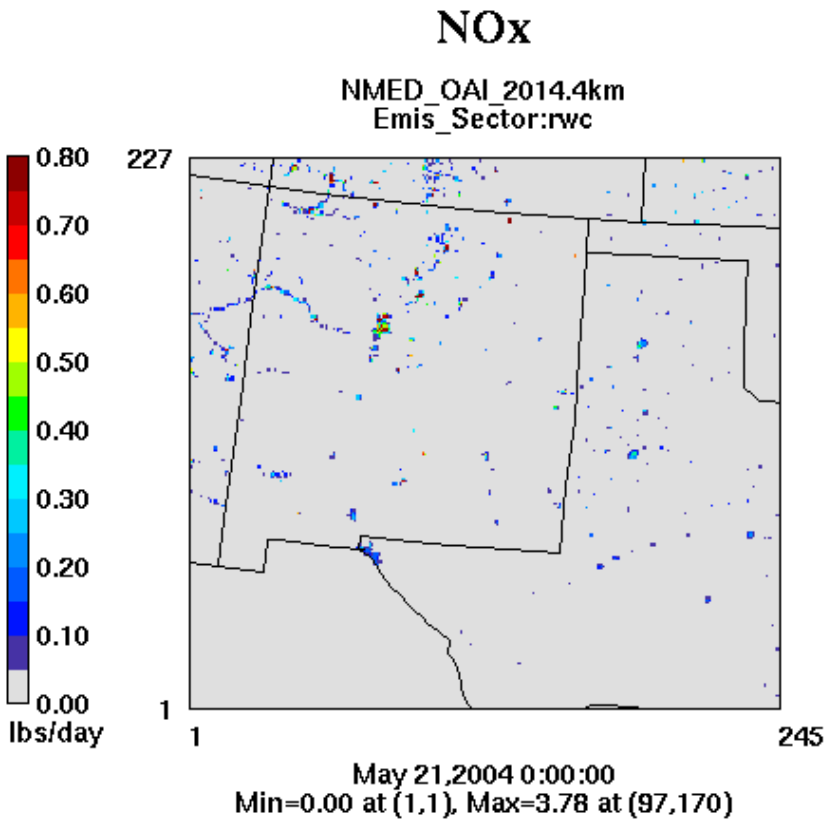
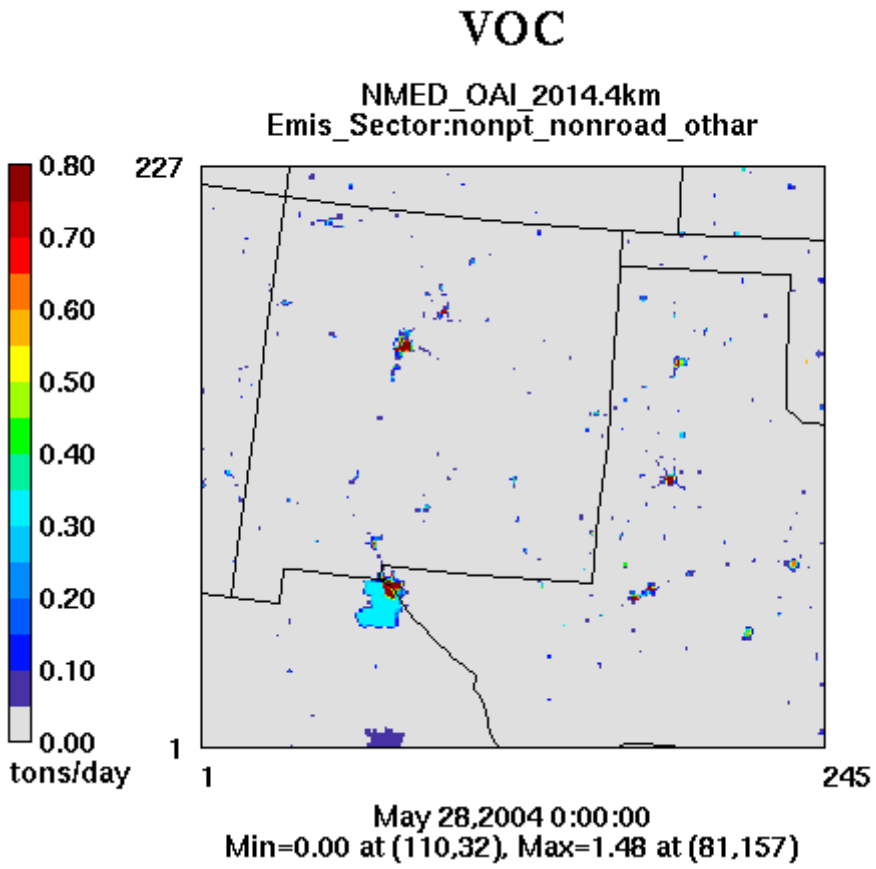
POINT SOURCE EMISSIONS

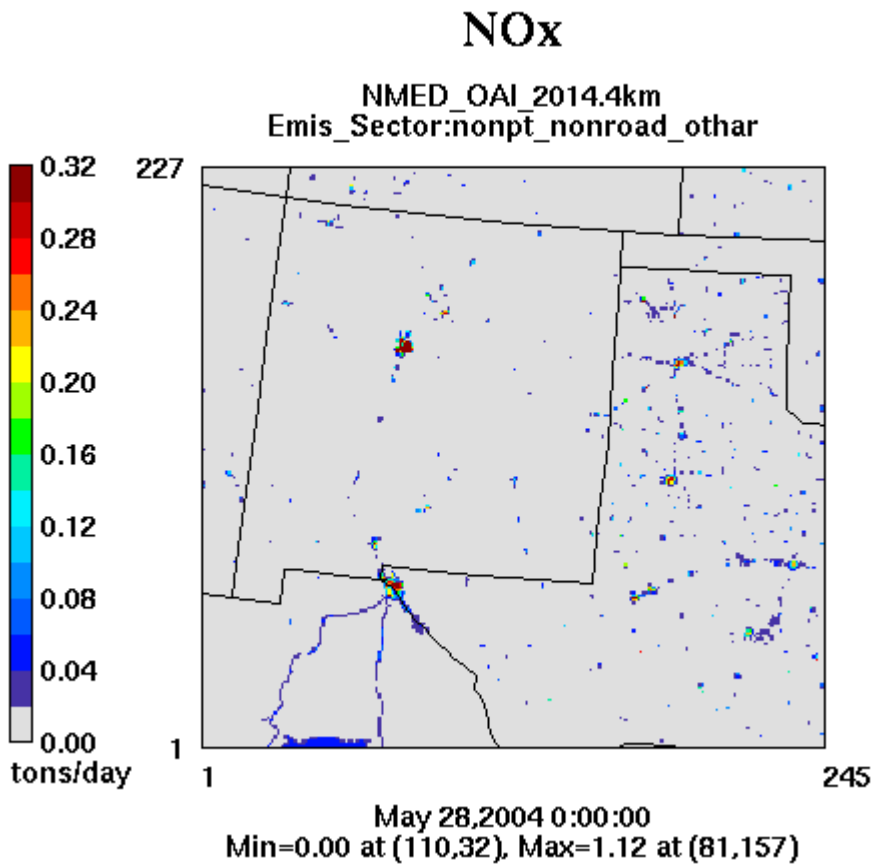


Point source processing generates elevated and low-level gridded files. Elevated files contain x/y coordinates for each point source so they are not domain dependent.





RAIL AND RWC EMISSIONS

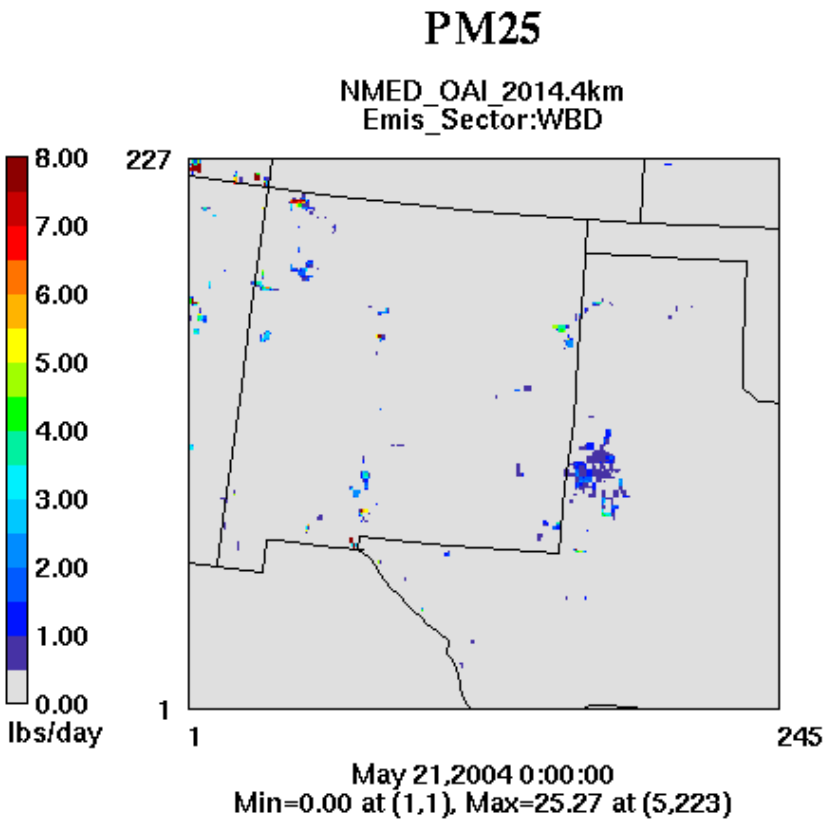


RAMBOLL

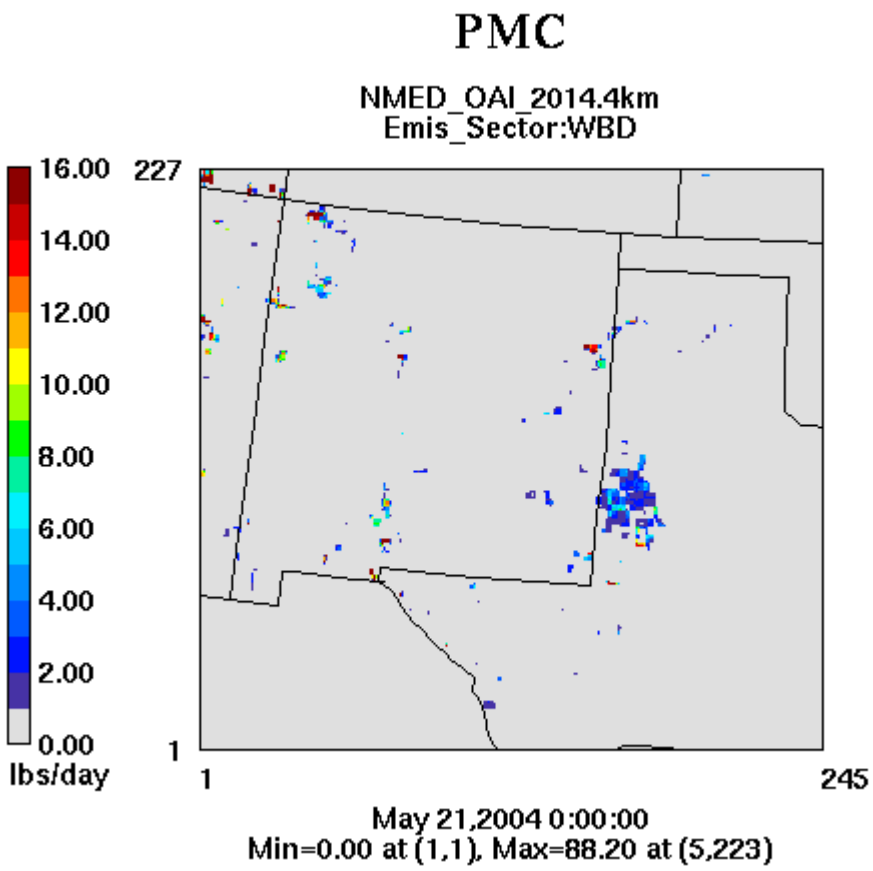
NONPOINT AND NONROAD EMISSIONS

RAMBOLL

NATURAL EMISSIONS



- Lightening NOx: Lightning NOx (LNOx) emissions processor with 2014 WRF meteorological data to generate CAMx-ready emissions
- Oceanic Emissions: OCEANIC emissions processor was used to generate sea salt and dimethyl sulfide (DMS) emissions
- Fire Emissions: Agricultural, prescribed burn and wildfire emissions from WRAP 2014v2 modeling developed by WRAP Smoke and Fire Workgroup
- Windblown dust: CAMx windblown dust (WBD) processor
- Biogenic Emissions: MEGAN or BEIS biogenic emissions model

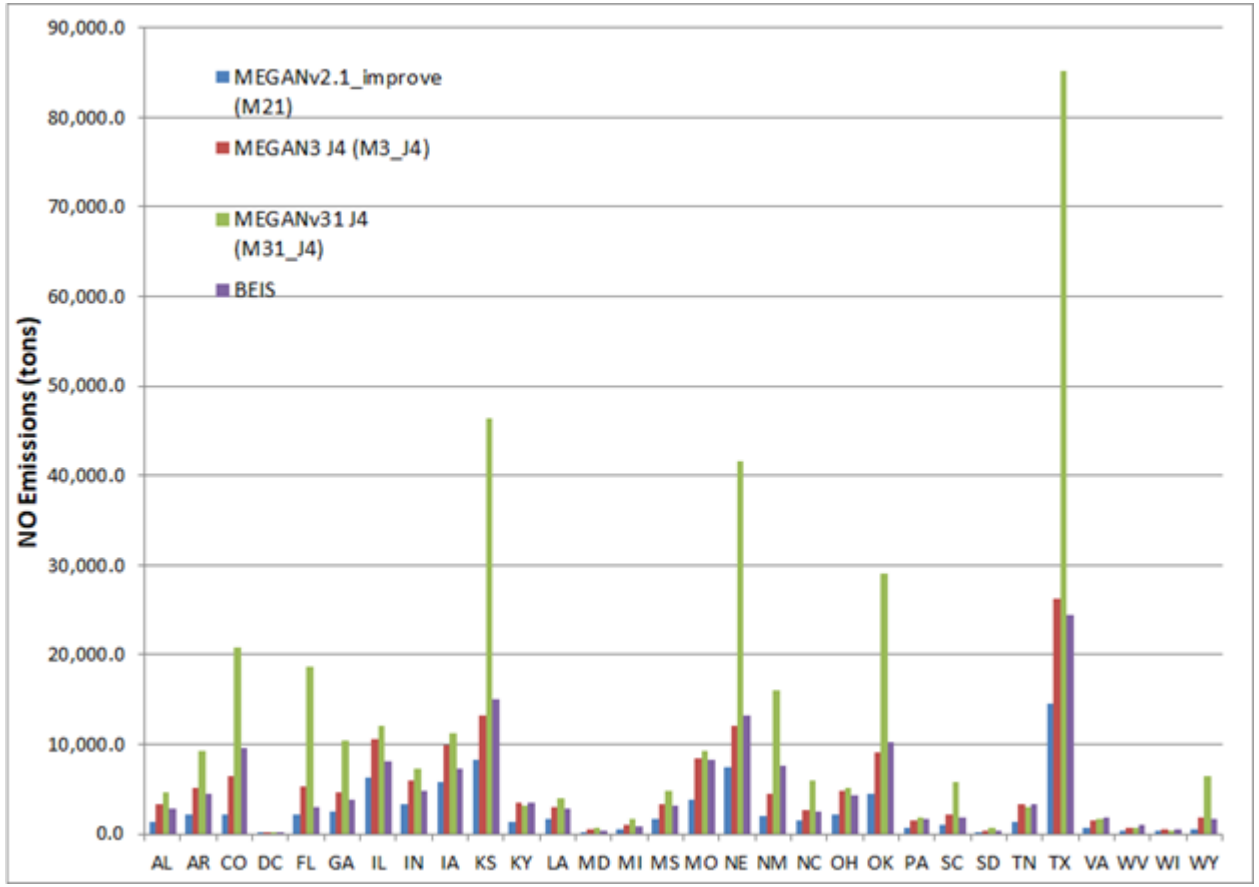


RAMBOLL

NMED Exhibit 20 - 0018

WINDBLOWN DUST EMISSIONS

	Emissions (tons/day)	
Year	PM2_5	CPRM
2014	20.9	80.2



RAMBOLL

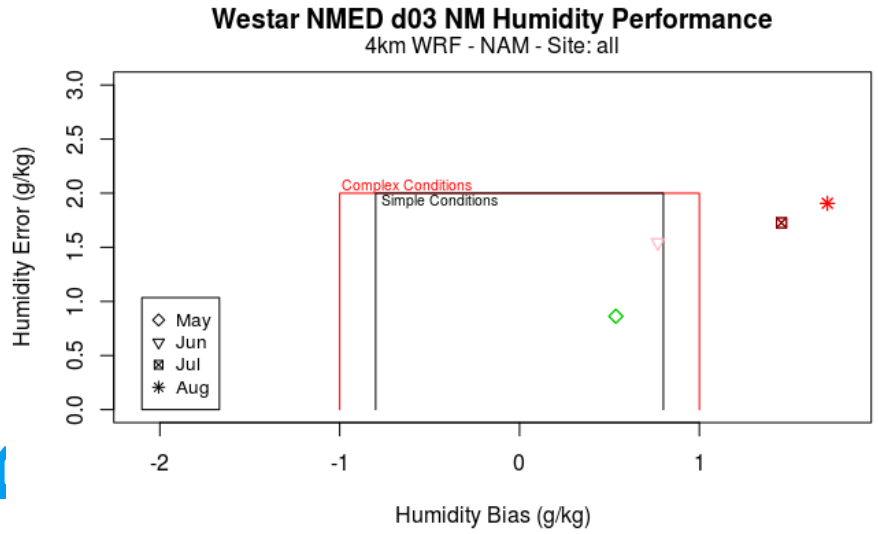
BIOGENIC EMISSIONS

- MEGAN3.1 improvement: Replaced soil NO code (Yienger and Levy approach) used by MEGAN3.0 (and BEIS) with state-of-the-art BDSNP approach. This model was already available to the community in GEOS-chem and WRF-CMAQ but required on-line AQ model.
- Summer soil NOx (June 1-July 15, 2013 period) for New Mexico estimated using different biogenic models.
- Agricultural regions with high fertilizer application rates have large NO emissions
- Will use MEGAN v3.1 emissions as latest data

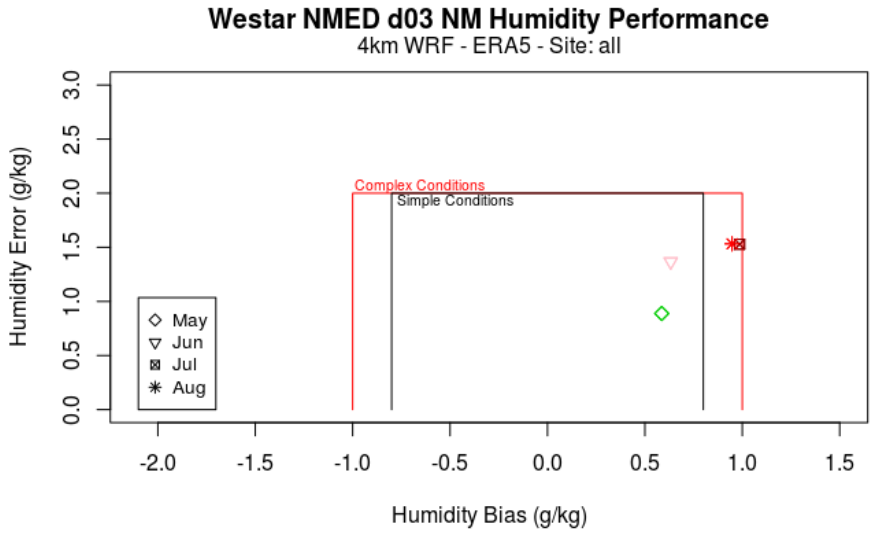
Reference: Guenther, A. et al (2018). Final Report For Project 18-005: Next steps for improving Texas biogenic VOC and NO emission estimates. Prepared for Air Quality Research Program (AQRP).

RAMBOLL

CAMX METEOROLOGICAL SENSITIVITY TESTS AND FINAL CONFIGURATION



RAMBOLL

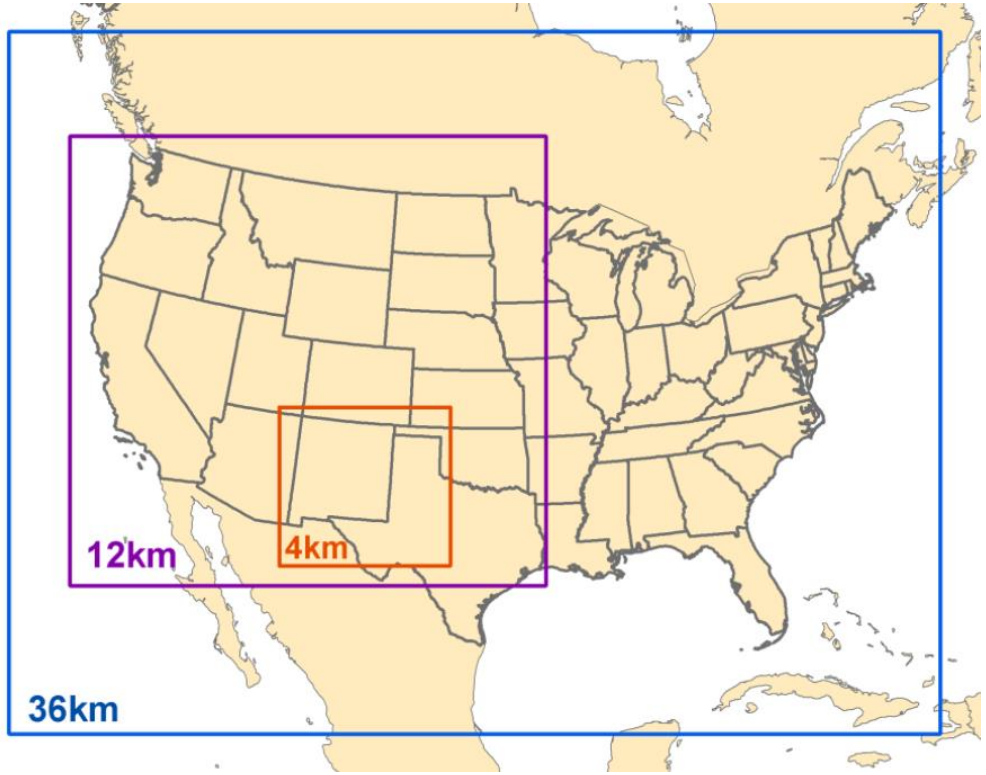


OVERVIEW

- Explore CAMx model performance using various WRF simulations presented on June 26, 2020 webinar (WRF sensitivities)
- CAMx model configurations used for WRF sensitivities
- Determine the WRF input and model configuration that best performs on selected period to use for 2014 CAMx base case

2014 WRF PERFORMANCE SUMMARY (JUNE 26 WEBINAR)

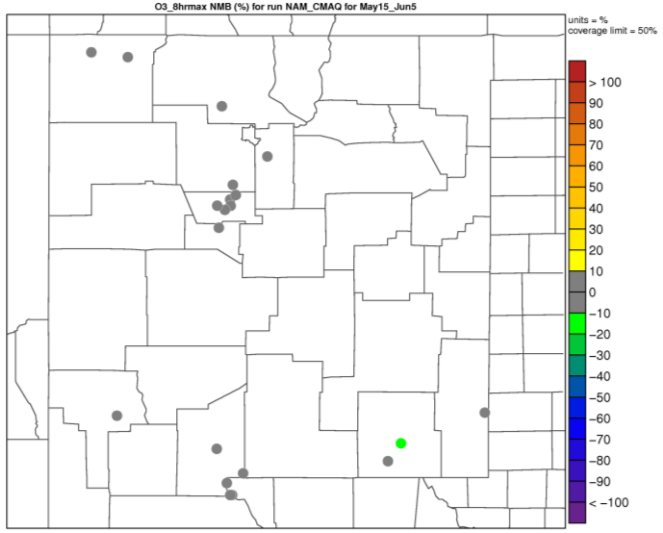
- WRF summer 2014 simulations using NAM and ERA5 analysis fields
  - Analysis fields used for initialization and boundary conditions (BCs) and for 36/12-km four-dimensional data assimilation (FDDA/nudging)
- WRF model performance reasonable for both NAM and ERA5 simulations
  - Surface meteorology (WS, WD, T, Q) and precipitation (PRISM)
- Differences between NAM and ERA5 are smaller in comparison to EPA/WAQS
- NAM wet bias in Jun-Aug may be partly associated with overactive summer convection
  - ERA5 has smaller wet bias



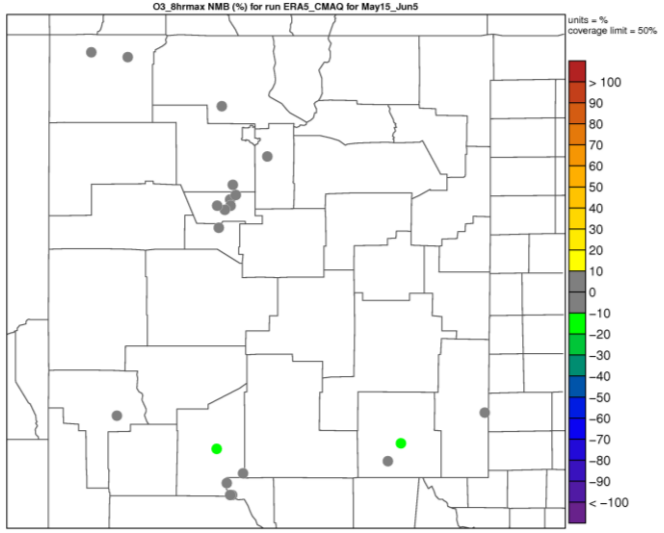
RAMBOLL

MODELING DOMAIN AND CONFIGURATION

- Performed CAMx simulations using 36/12/4-km nested domains with available WRF met (NAM and ERA5) for selected period: May 15 to Jun 5
- Emissions and other inputs identical on all sensitivities.
- CAMx flexi-nesting used for 4 km domain emissions
- Tested two types of vertical diffusivities (Kv): CMAQ and YSU
- Total of four CAMx sensitivities:
  1. **NAM CMAQ**
  2. **NAM YSU**
  3. **ERA5 CMAQ**
  4. **ERA5 YSU**

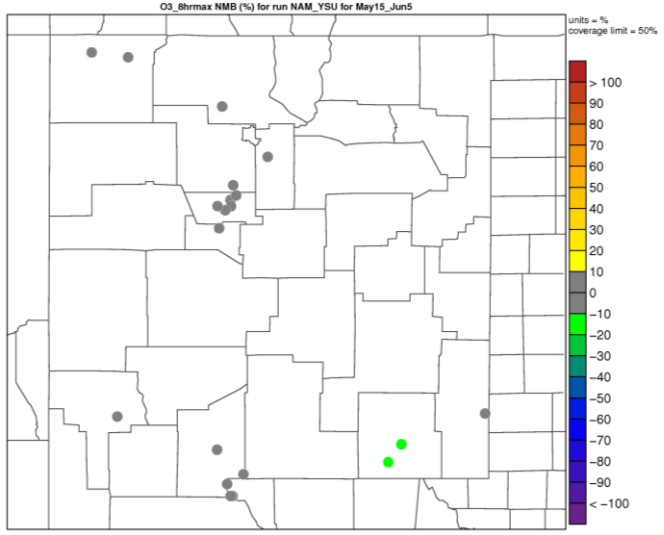


RAMBOLL

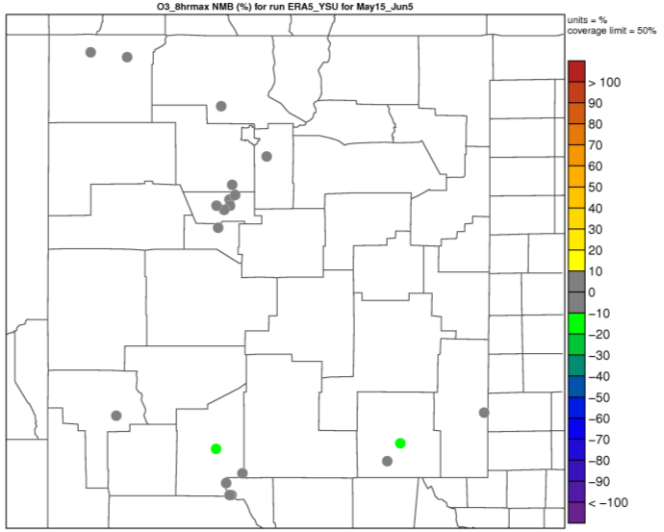


NMED Exhibit 20 - 0024

OZONE BIAS COMPARISON: NMB WITH 60 PPB CUT-OFF

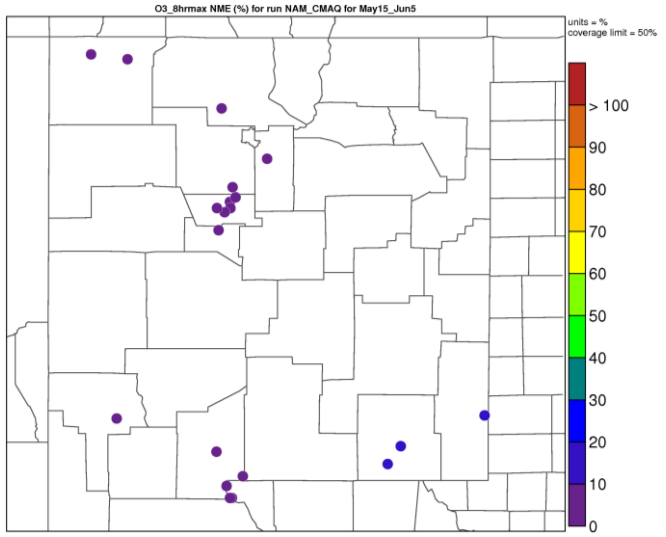


NAM CMAQ

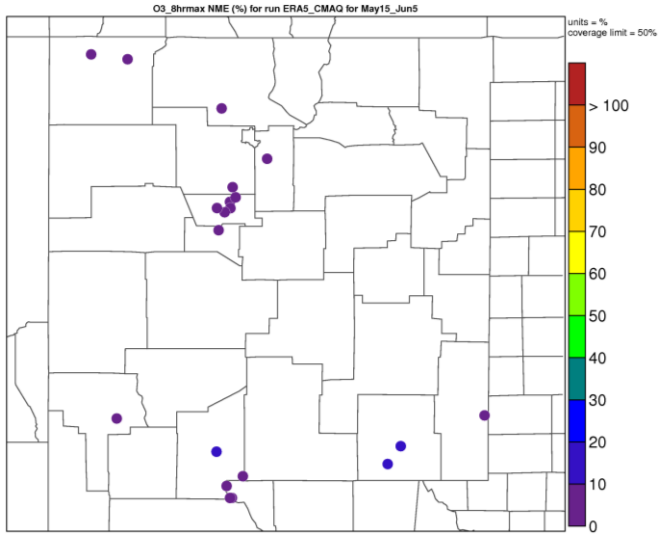


ERA5 CMAQ

NAM YSU

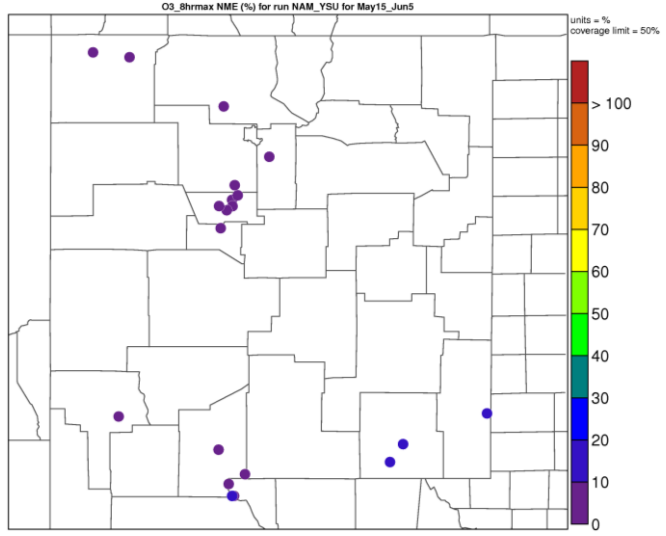


ERA5 YSU

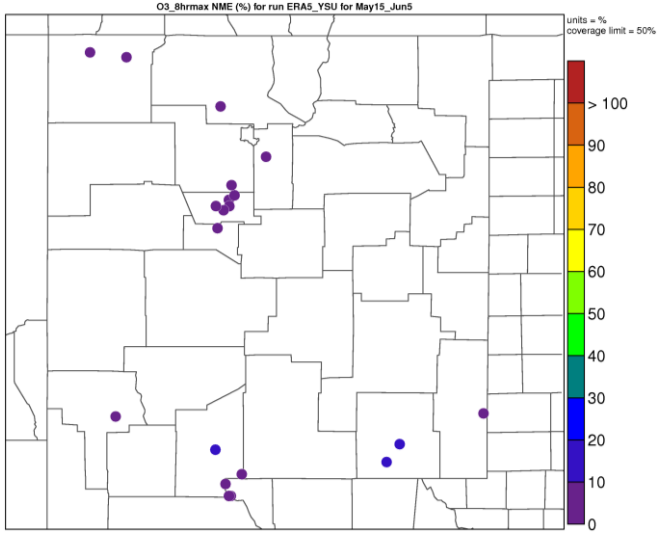


- NMB for all sensitivities generally within Performance Goal
  - Goal: NMB < ±5%
  - Criteria: NMB < ±15%
- Worst performance occurs in Southern portion of NM
- Based on NMB, NAM CMAQ is the configuration with best performance

OZONE ERROR COMPARISON: NME WITH 60 PPB CUT-OFF

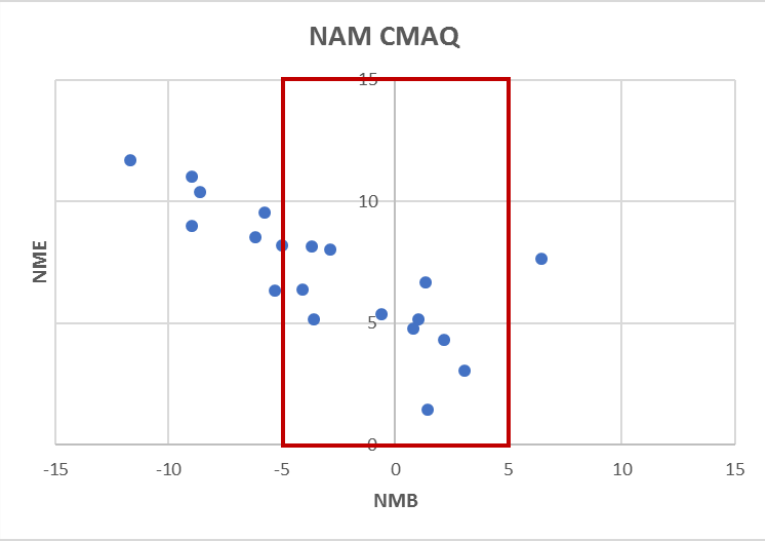


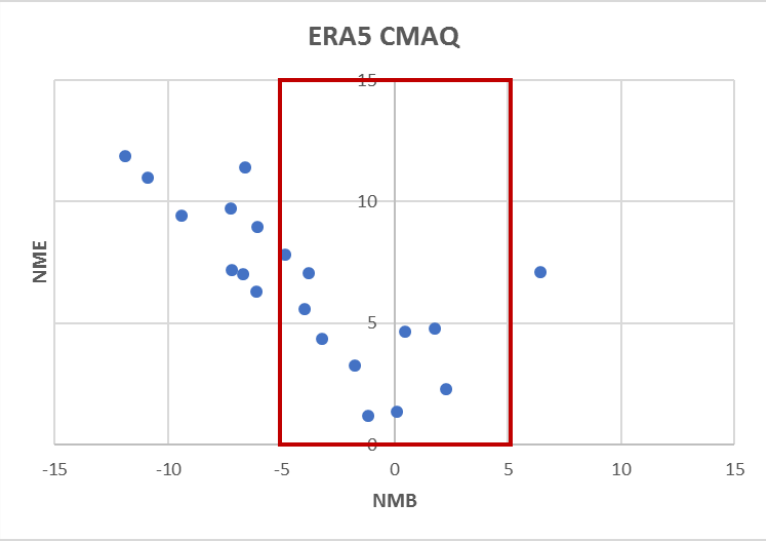
NAM CMAQ



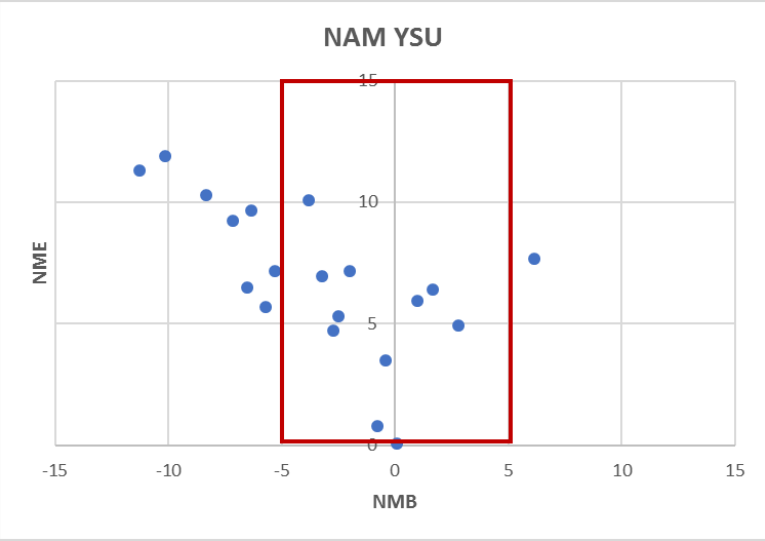
ERA5 CMAQ

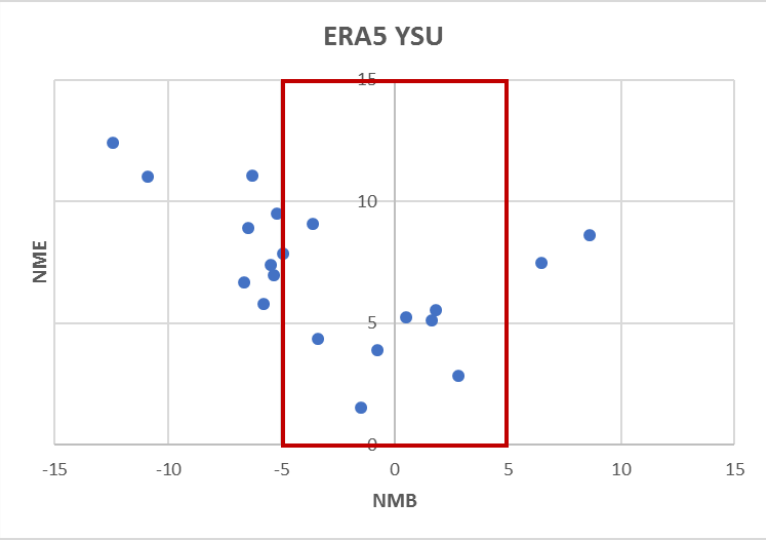
NAM YSU





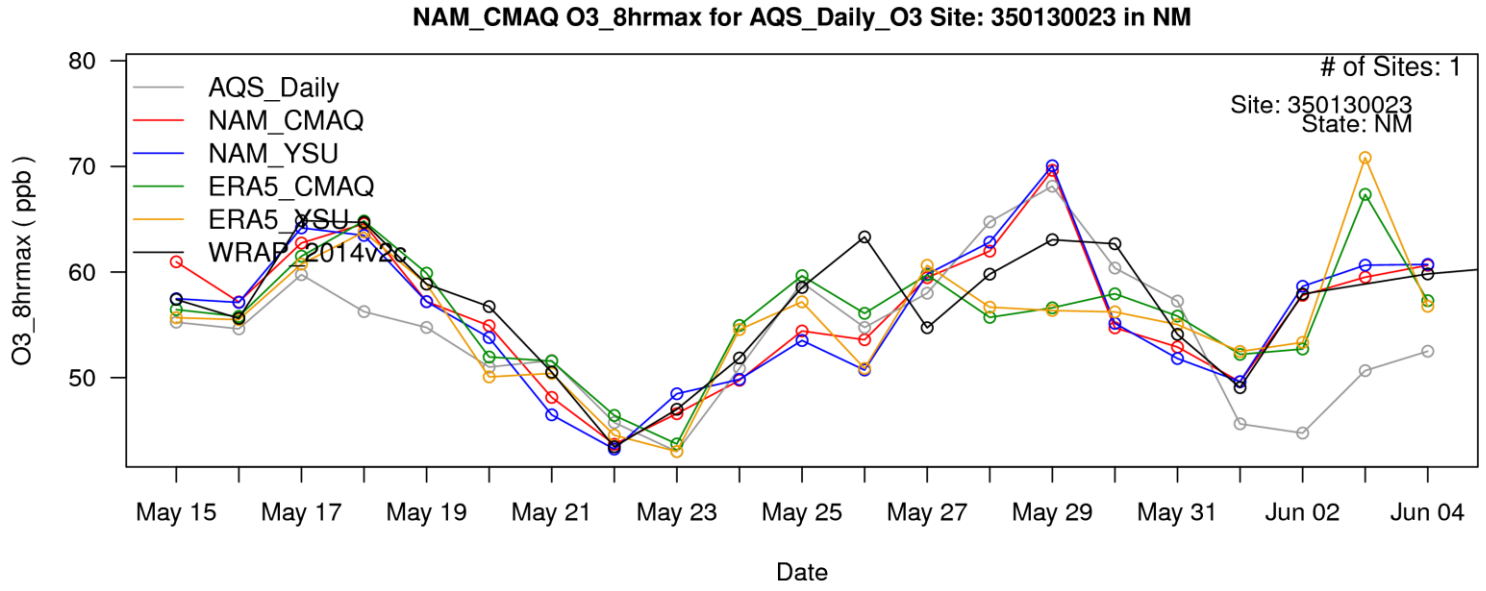
ERA5 YSU

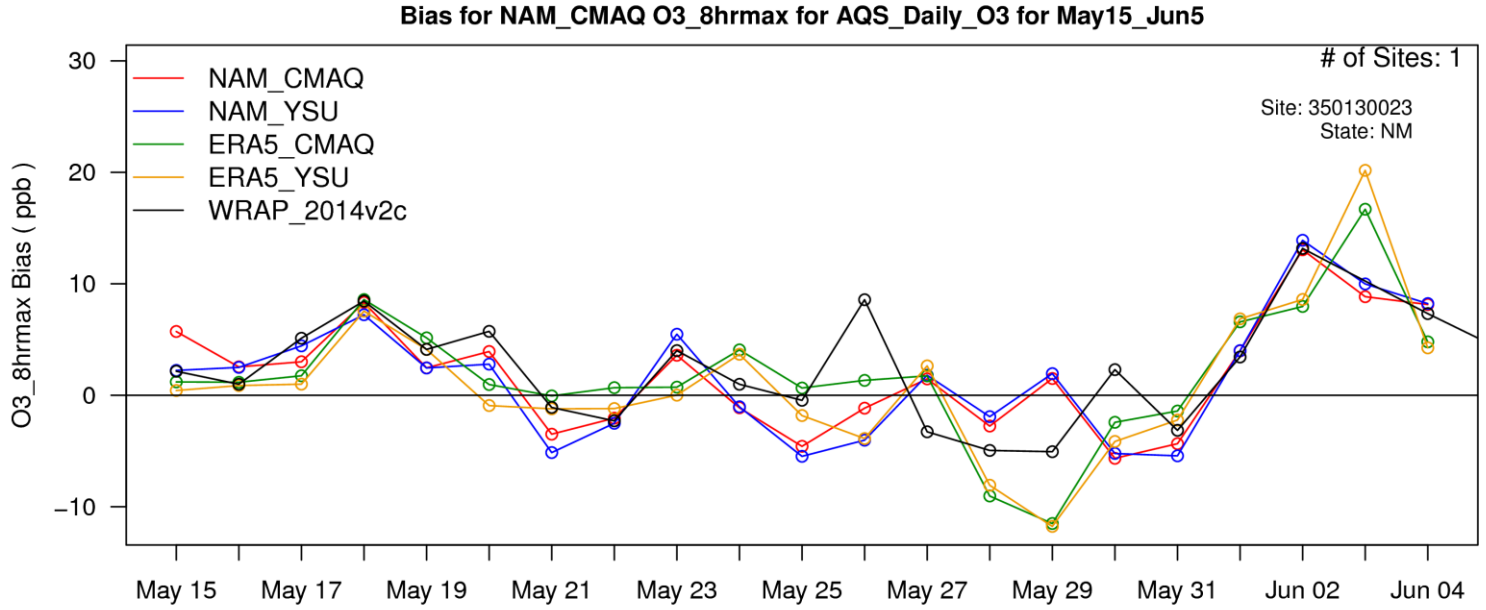




- NME for all sensitivities generally within Performance Goal
  - Goal: NME < 15%
  - Criteria: NMB < 25%
- Worst performance occurs in Southern portion of NM
- Based on NME, NAM meteorology is the best performing

SITE-SPECIFIC COMPARISON: SOCCER PLOTS 60 PPB CUT-OFF

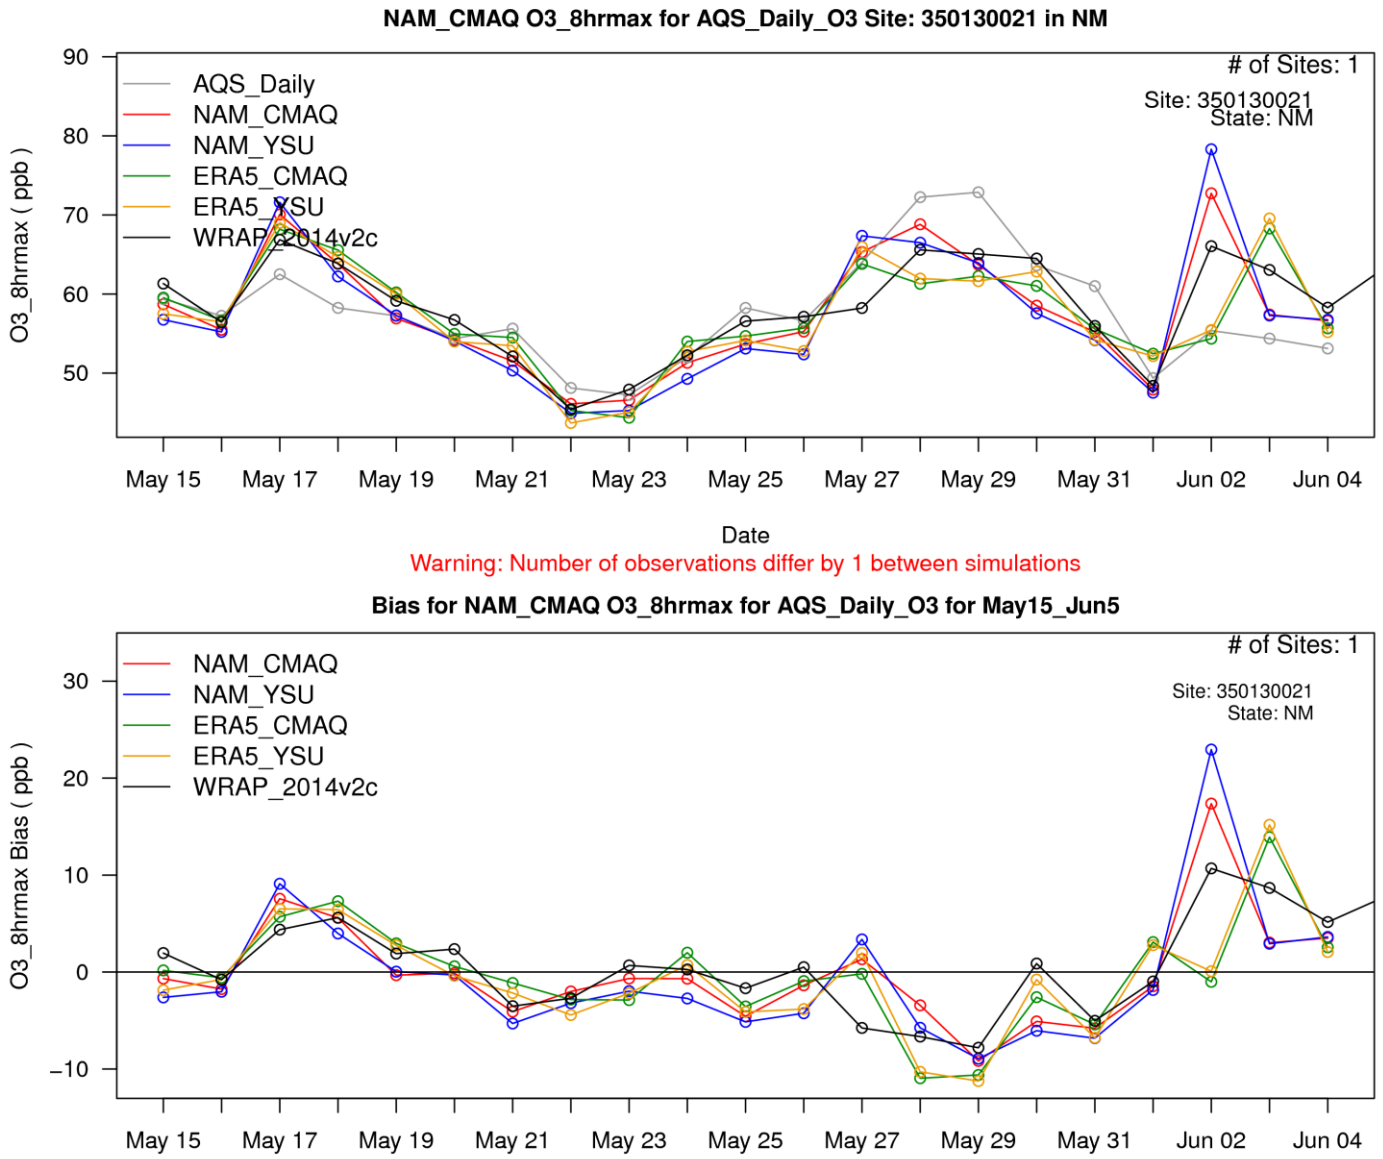




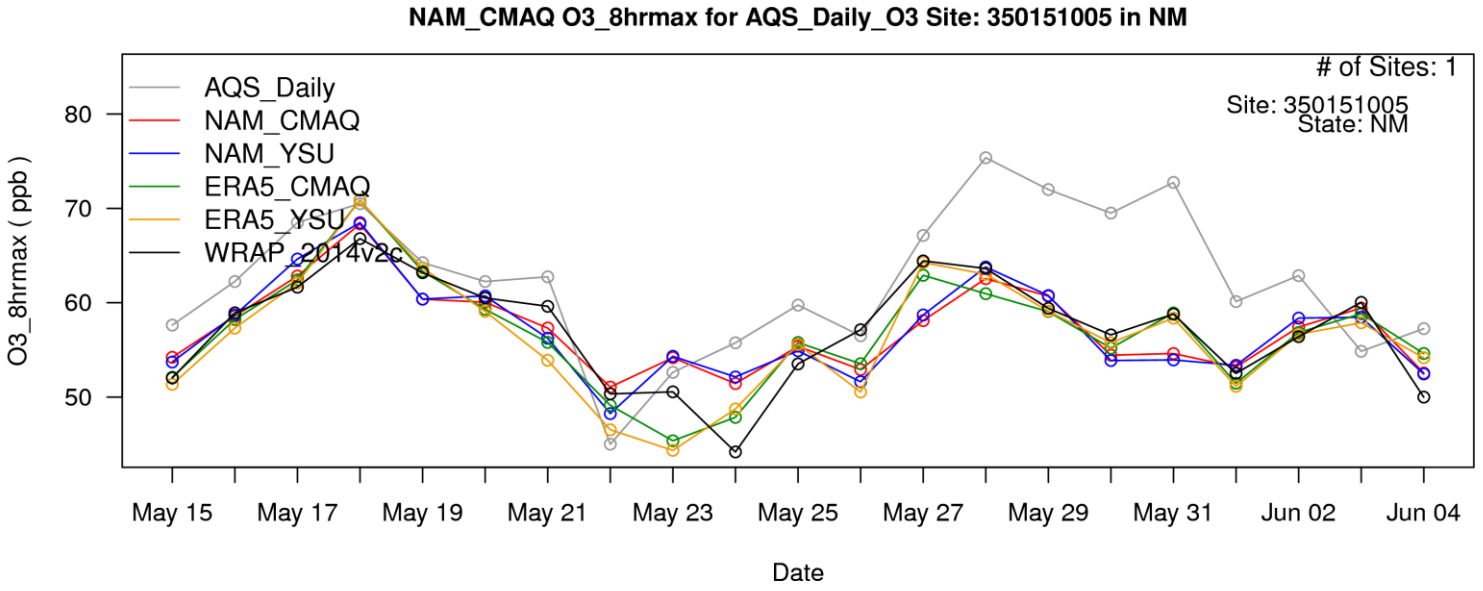
- With a 60 ppb cut-off all sensitivities show CAMx tends to underpredict ozone peaks
- Still all sensitivities within Performance Criteria
- NAM shows slightly better performance than ERA5
  - More sites achieve Performance Goals
- NAM CMAQ shows sites with smaller NME compared to NAM YSU

RAMBOLL

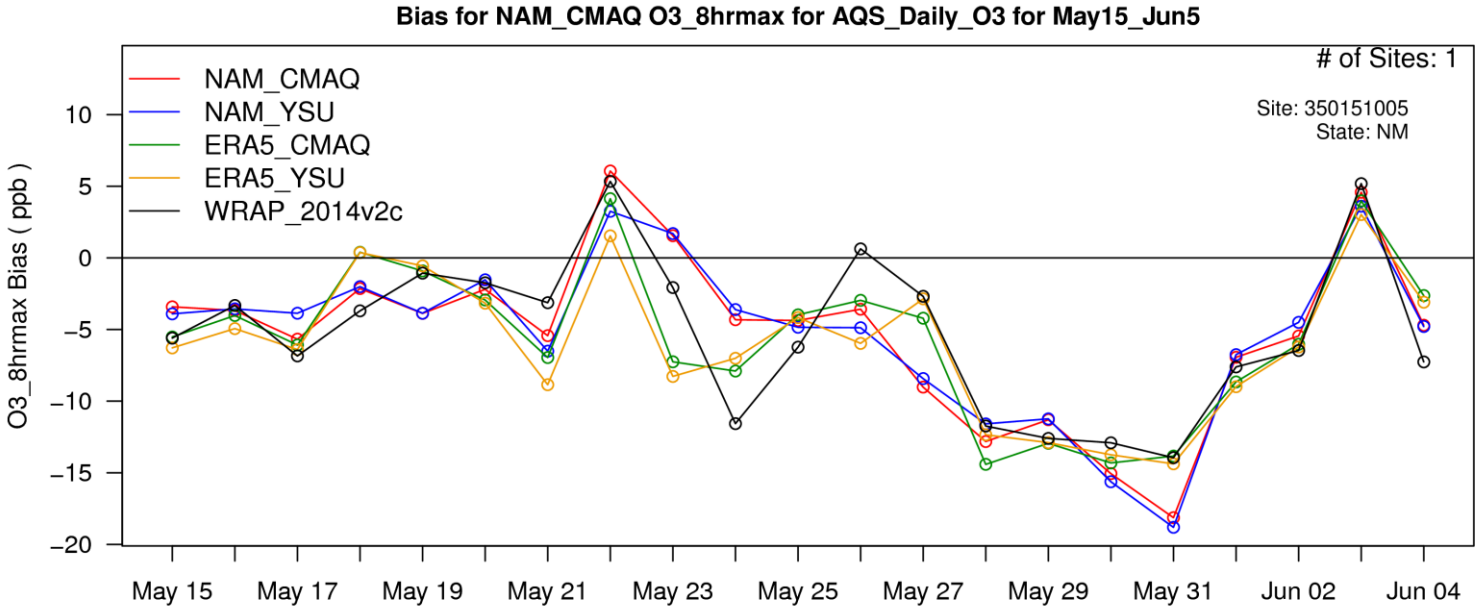
NMED Exhibit 20 - 0027



SELECTED SITES TIMESERIES: SOLANO RD (DONA ANA COUNTY)

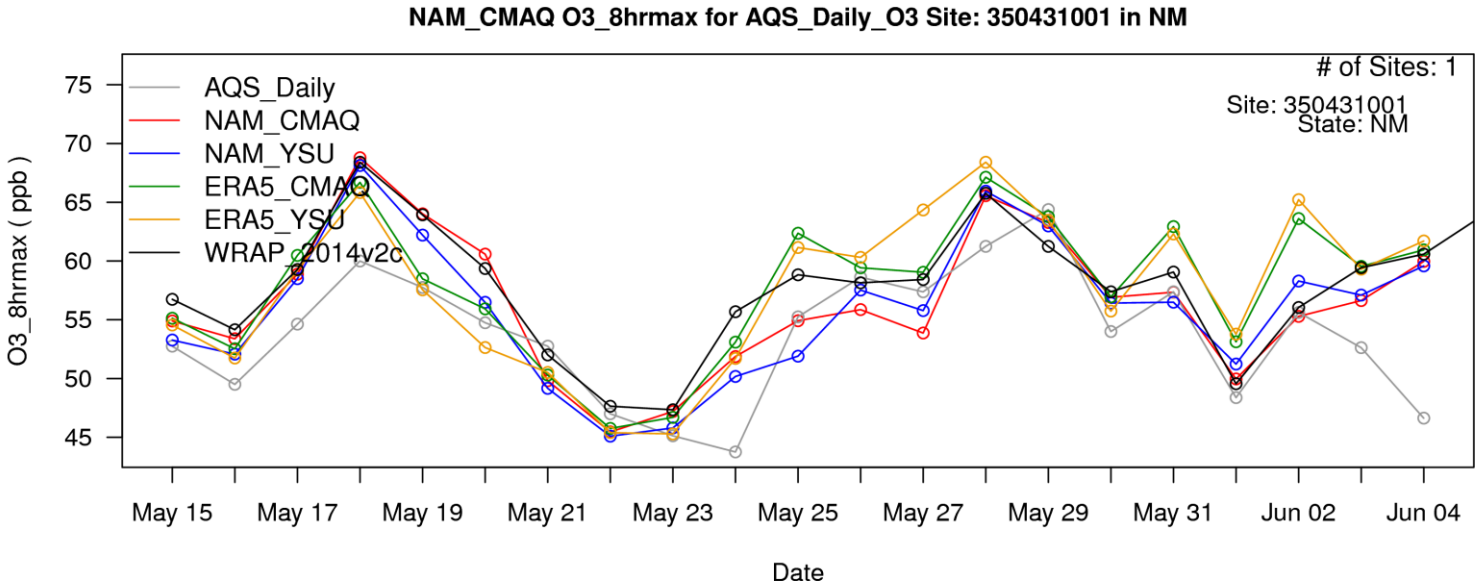


- NAM sensitivities better capture peak on May 29

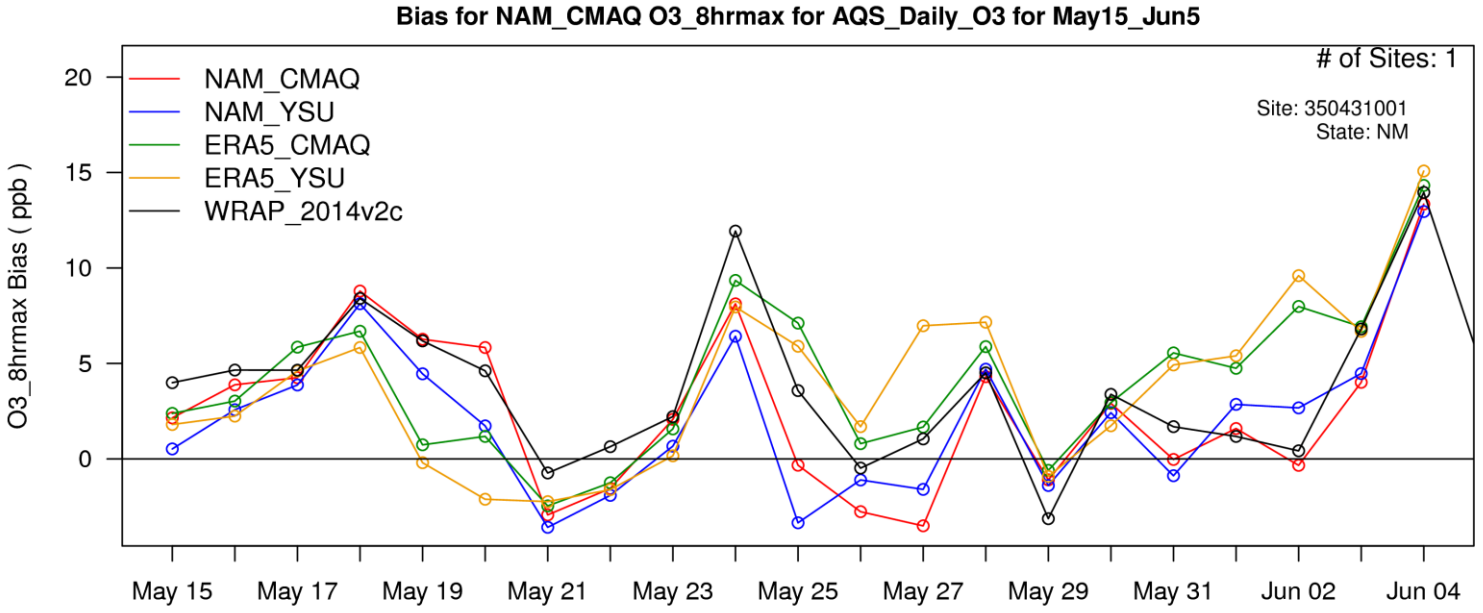


SELECTED SITES TIMESERIES: DESERT VIEW (DONA ANA COUNTY)

- Underestimate observed peaks May 28-29
- WRF/NAM better than other WRF



SELECTED SITES TIMESERIES: CARLSBAD (EDDY COUNTY)



- All sensitivities miss high ozone on May 27 to May 31

SELECTED SITES TIMESERIES: SANDOVAL COUNTY

- All sensitivities get high ozone on May 29. NAM CMAQ has lower bias

CAMX SENSITIVITIES SUMMARY

- All sensitivities have NMB and NME values that are within Performance Criteria, most sites within Performance Goals
- Differences between all sensitivities are relatively small among each other
- NAM meteorology captures peak ozone concentrations better than ERA5
- Caveats:
  - WRF sensitivities run for May-Jun so they may not reflect the observed precipitations biases in WRF for Jun-Aug
  - WRF performance showed that precipitation biases could occur over NE NM where there are no ozone monitors, so performance is unknown there
- NAM with CMAQ Kv treatment selected to simulate 2014 base case based on slightly better performance on NMB

RAMBOLL

NMED Exhibit 20 - 0032

FINAL CAMX 2014 BASE CASE CONFIGURATION

- CAMx summer 2014 36/12/4-km meteorological inputs based on WRF simulation using NAM analysis fields processed with WRFCAMx with CMAQ Kv option
  - Same WRF/NAM configuration as used by WRAP-WAQS CAMx 2014 base case

NM OAI Study Webinar#4

August 31, 2020

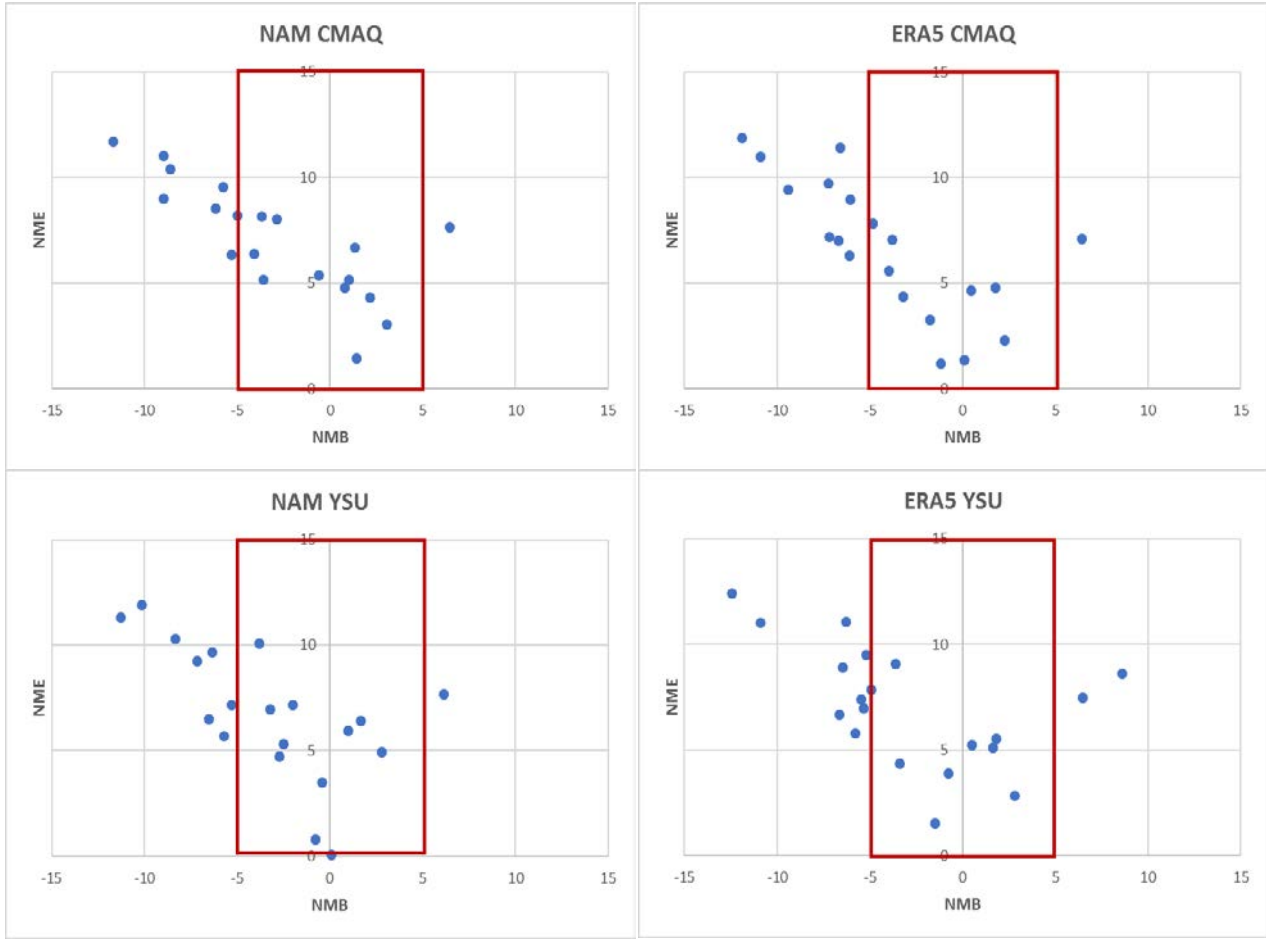
RAMBOLL Bright ideas. Sustainable change.

AGENDA – NMED OAI STUDY WEBINAR#4 – AUGUST 31, 2020

- 2014 and 2023 Emissions
  - Natural Emissions for 2014
  - Updates to 2023 Emissions to Remove Duplicates and Other Updates
  - SMOKE Emissions Modeling for 2014 and 2023
  - Summary of 2014 and 2023 Emissions
- CAMx 2014 36/12/4-km Base Case Modeling
  - Final CAMx Configuration for 2014 Base Case
  - CAMx 2014 Base Case Ozone Model Performance Evaluation
  - Status of Task 5 2014 Base Case and Model Evaluation Report
- Next Steps

RAMBOLL

OVERVIEW OF NM OAI PHOTOCHEMICAL MODELING STUDY



- *Task 1: Modeling Protocol, QAPP and Work Plan – Completed May 2020*
- *Task 2: Meteorological Modeling – Completed June 2020*
- *Task 3: Boundary Conditions – Completed June 2020*
- *Task 4: 2014 and 2023 Emissions – 2014 Completed June 2020*
  - *2023 Almost Completed August 2020 –* **only 2023 SMOKE-MOVES for 12-km 12WUS2 left**
- *Task 5: CAMx 2014 Base Case and Model Performance Evaluation – Work done August 2020*
  - **Working on Task 5 2014 Base Case and MPE report done in early September**
- **Task 6: Future Year (2023) Modeling**
  - **6.1: CAMx 2023 Base Case Modeling – Set-up ready to start (need 2023 12-km mobile)**
  - **6.2: Model Attainment Test – Not Started**
  - **6.3: Source Apportionment Modeling – Not Started**
  - **6.4: Emissions Sensitivity/Control Modeling – Not Started**
- **Task 7: Technical Support Document and Technology Transfer – Not Started**

PREVIOUS WEBINAR HIGHLIGHTS (JULY 27, 2020)

- 2014 and 2023 Emissions
  - Summary of SMOKE processing
  - Identification & elimination of duplicate sources
  - Preliminary results
- CAMx 2014 Meteorological Sensitivity Runs
  - WRF/NAM and WRF/ERA5 simulations
  - Kv = CMAQ-like and Kv = YSU
  - Four CAMx WRF sensitivity simulations
  - WRF/NAM w/ Kv=CMAQ selected
    - Ozone performance for all four runs close
    - WRF/NAM w/ Kv=CMAQ had slightly lower bias and better performance on some observed ozone peaks

Site-Specific Bias/Error Soccer Plots for Four CAMx WRF Sensitivity Tests

RAMBOLL

2014 AND 2023 EMISSIONS

RAMBOLL

NEW MEXICO EMISSIONS DATA

- 2014 anthropogenic emissions are based on the WRAP/WAQS 2014v2
  - Onroad emissions based on SMOKE-MOVES processing with 2014 activity and WRF meteorology
  - O&G emissions based on state-of-the-science WRAP OGWG emission estimates
  - NMED found a generator engine missing in 2014v2 inventory (94 tpy NOx)
  - Consistent emissions data between the Regional Haze and OAI studies
- 2023 anthropogenic emissions are based on the EPA 2016v1 platform
  - Like 2014, onroad emissions created using SMOKE-MOVES and O&G emissions based on WRAP OGWG
  - NMED found duplicate sources between WRAP O&G and EPA non-EGU sectors
  - Found double counting of NM sources in WRAP O&G inventory: Title V and minor point sources
  - Updated San Juan Generating Station (NOx 7,059 TPY) and added Lordsburg Generating Station
  - Updated three O&G sources: Chaco Gas Plant (NOx 2,053 tpy), Carlsbad CS, and Mountainair CS (NOx 645 tpy)

RAMBOLL

NMED Exhibit 21 - 0006

NATURAL EMISSIONS

Remained the same between 2014 and 2023

- Lightening NOx: Lightning NOx (LNOx) emissions processor with 2014 WRF meteorological data to generate CAMx-ready emissions
- Oceanic Emissions: OCEANIC emissions processor was used to generate sea salt and dimethyl sulfide (DMS) emissions
- Fire Emissions: Agricultural, prescribed burn and wildfire emissions from WRAP 2014v2 modeling developed by WRAP Smoke and Fire Workgroup
- Windblown dust: CAMx windblown dust (WBD) processor
- Biogenic Emissions: MEGAN v3.1 biogenic emissions model

RAMBOLL

RAMBOLL

DUPLICATE POINT SOURCES IN 2023

- NMED identified 21 facilities double counted in 2023 non-EGU and WRAP point O&G inventory
  - Double counted emissions: NOx 8,669 TPY and SO2 7,662 TPY
  - Represents approximately 9% (NOx) and 24% (SO2) of the New Mexico 2023 O&G emissions
- Duplicates in the WRAP O&G inventory: Some sources were present in Title V and minor point O&G sources datasets in the OGWG inventory.
  - Double counted emissions NOx: 1,927 TPY and SO2: 942 TPY

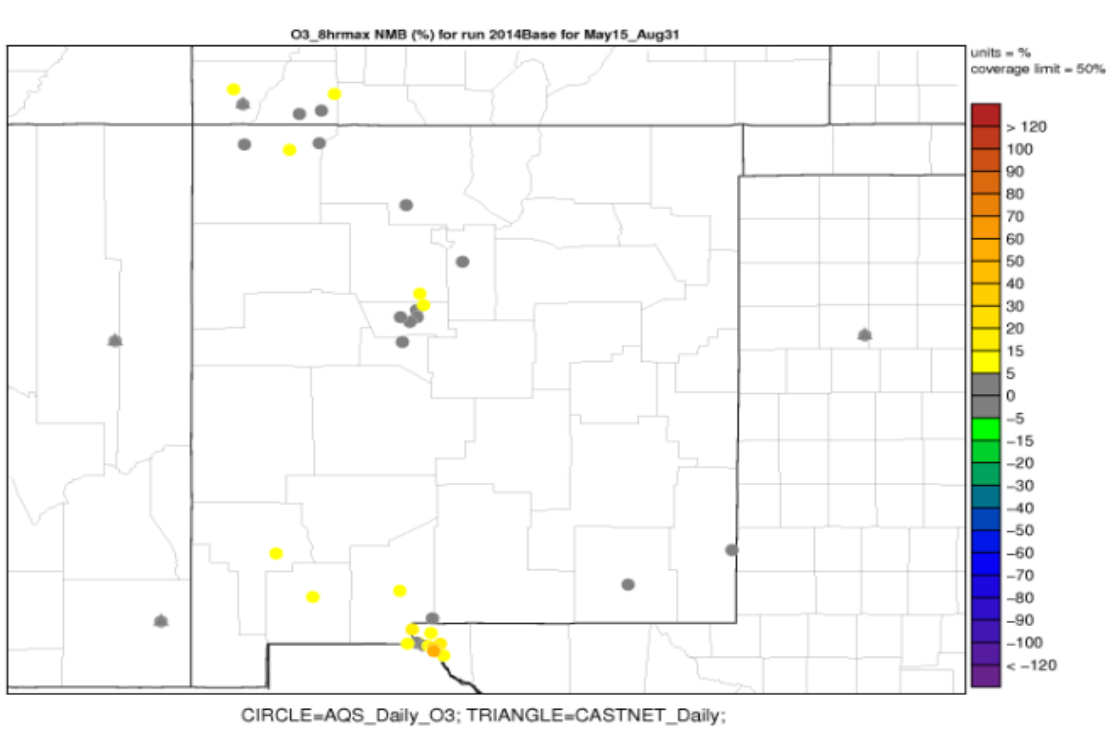
NMED Exhibit 21 - 0026

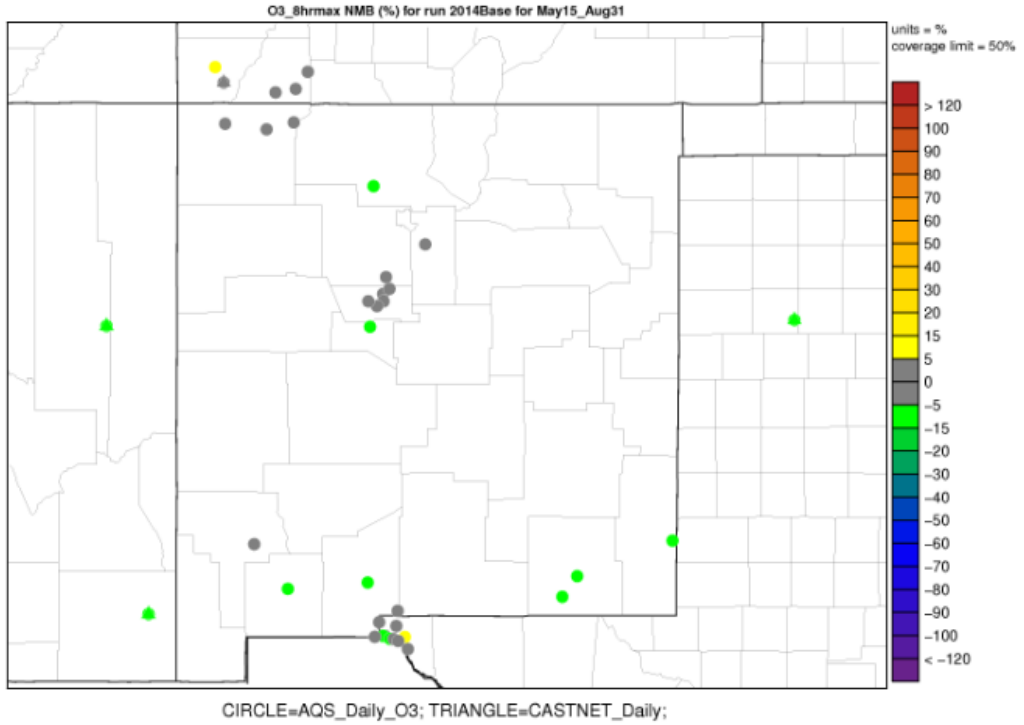
2014 BASE CASE MPE

- Used AMETv1.4 MPE tool
- Model evaluated against EPA AQS Surface Air Quality Data for 2014
- Model performance compared with standard PGM goals and criteria values (Emery et al., 2016)
- “Goals” : statistical value that the best model can be expected to achieve
- “Criteria” : statistical value that majority of models have achieved



Species	NMB		NME	
	Goal	Criteria	Goal	Criteria
1-hr & MDA8 Ozone	<±5%	<±15%	<15%	<25%

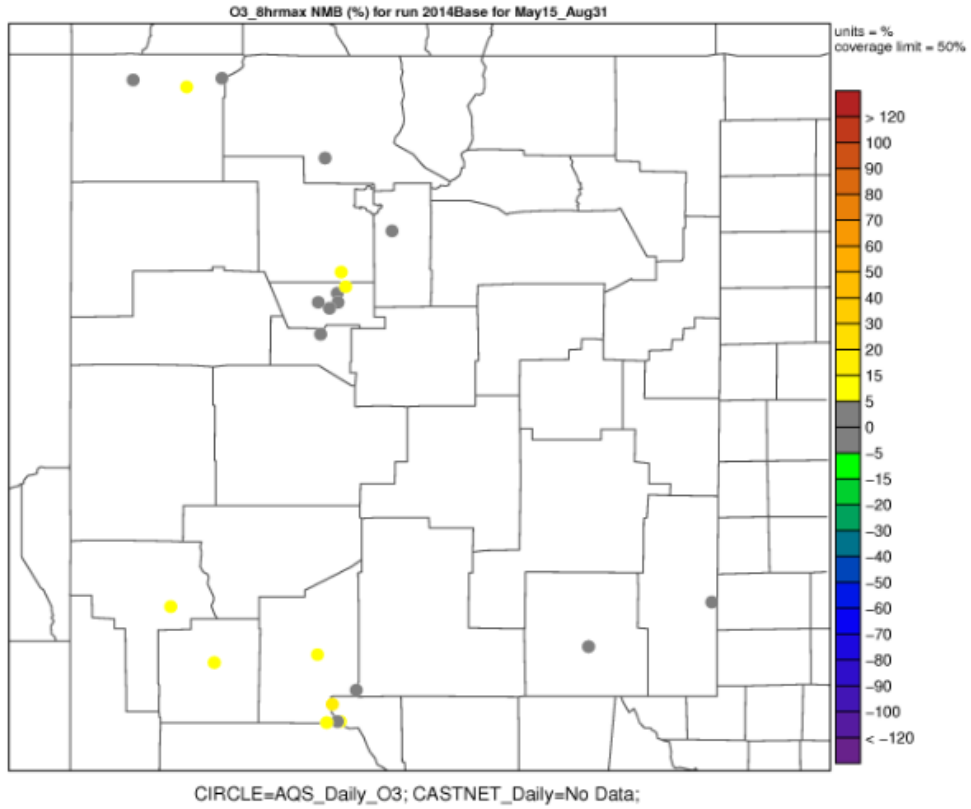
RAMBOLL



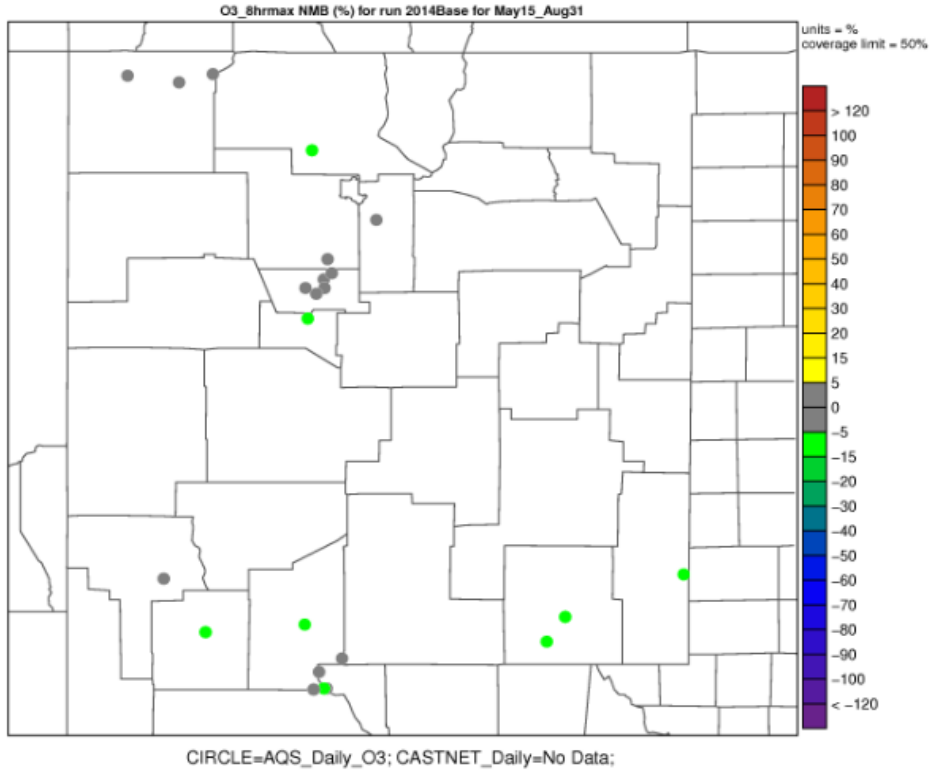
OZONE EVALUATION ACROSS 4KM DOMAIN

- Throughout the domain at most of the sites model is achieving performance goal with NMB <±5%.
- Few remaining sites are within the performance criteria with NMB <±15%, where model is overpredicting lower concentrations and underpredicting higher concentrations.

MDA8 O3 no cut-off



MDA8 O3 with 60 ppb cut-off

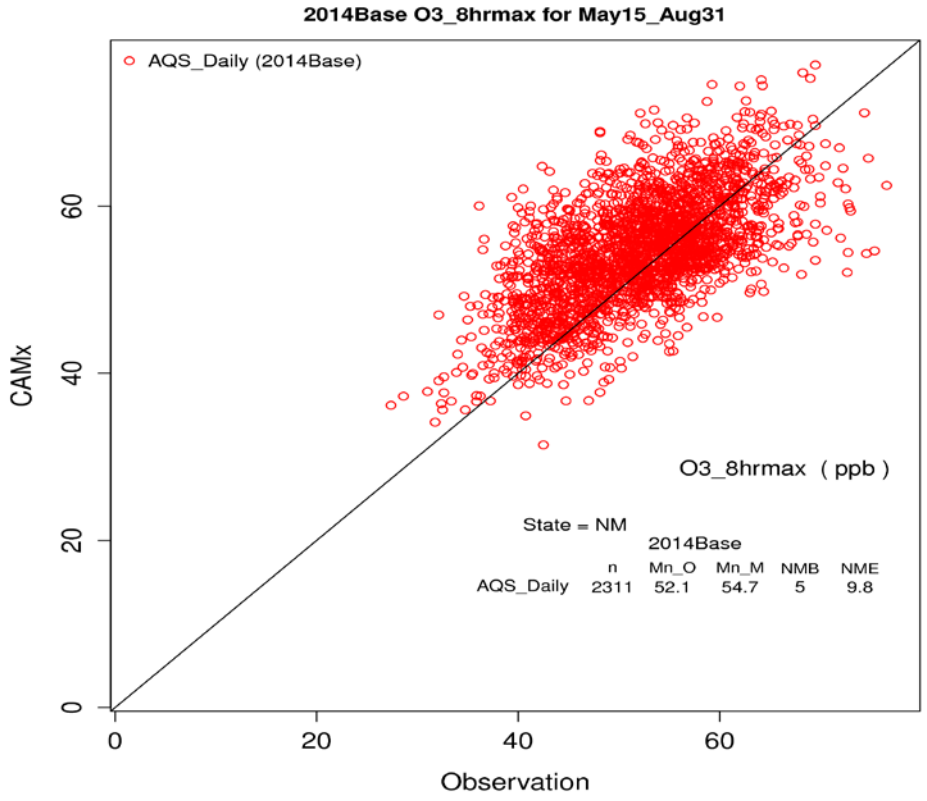


OZONE EVALUATION ACROSS NM DOMAIN

- Overall majority of sites in New Mexico are achieving performance goal (< ±5%) and criteria (< ±15%)
- Most of the southern New Mexico sites are underpredicting MDA8 concentrations higher than 60 ppb

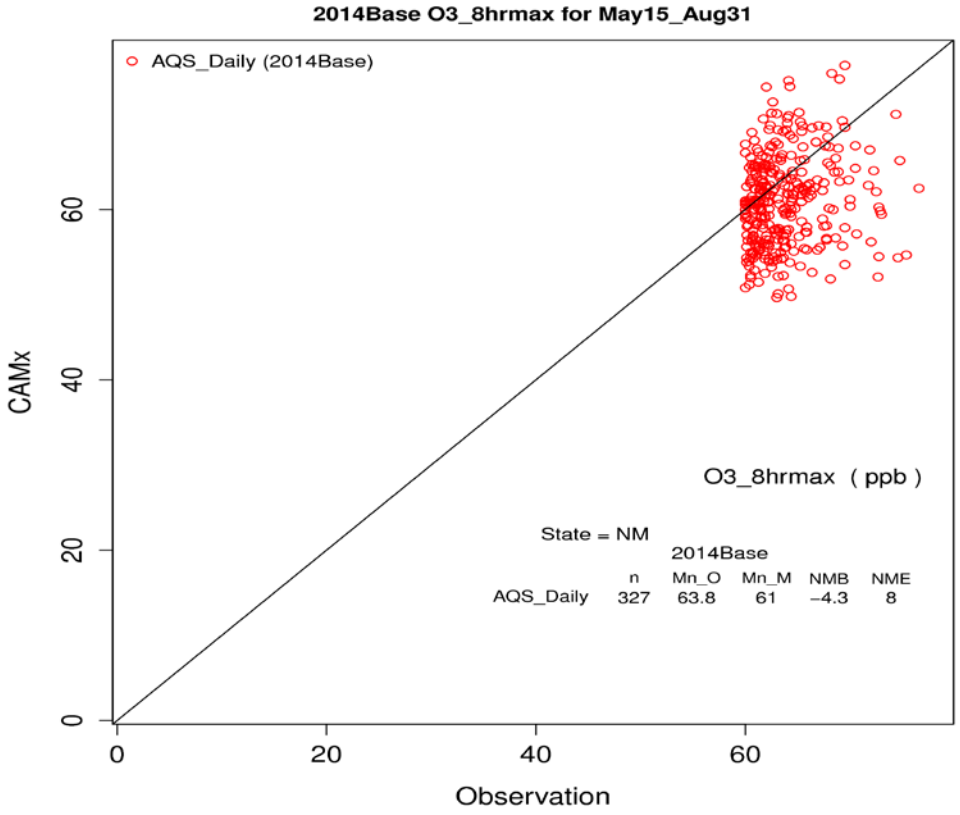
MDA8 O3 no cut-off

MDA8 O3 with 60 ppb cut-off



RAM

NMED Exhibit
21 - 0029

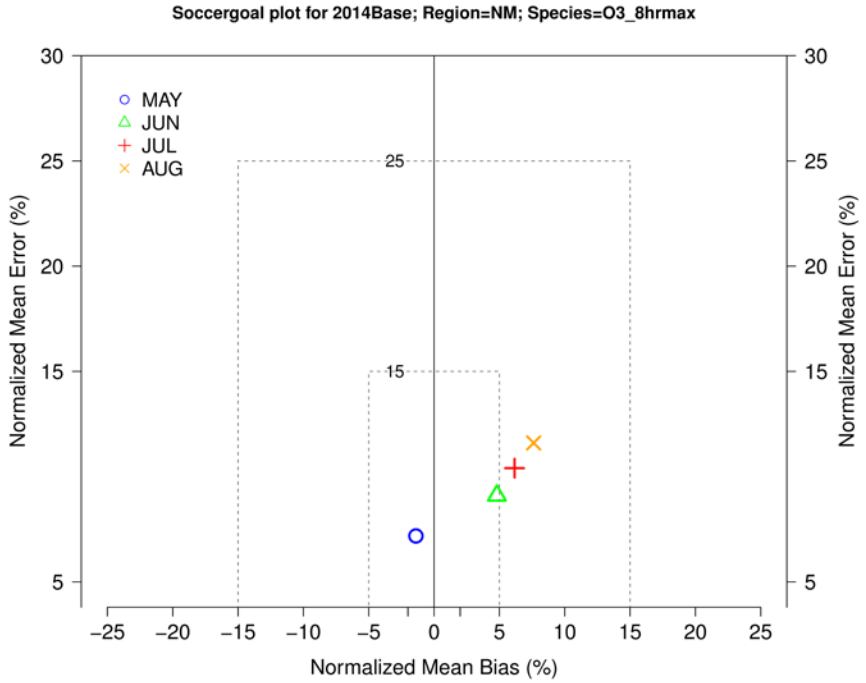


SCATTER PLOTS ACROSS AQS SITES IN NM

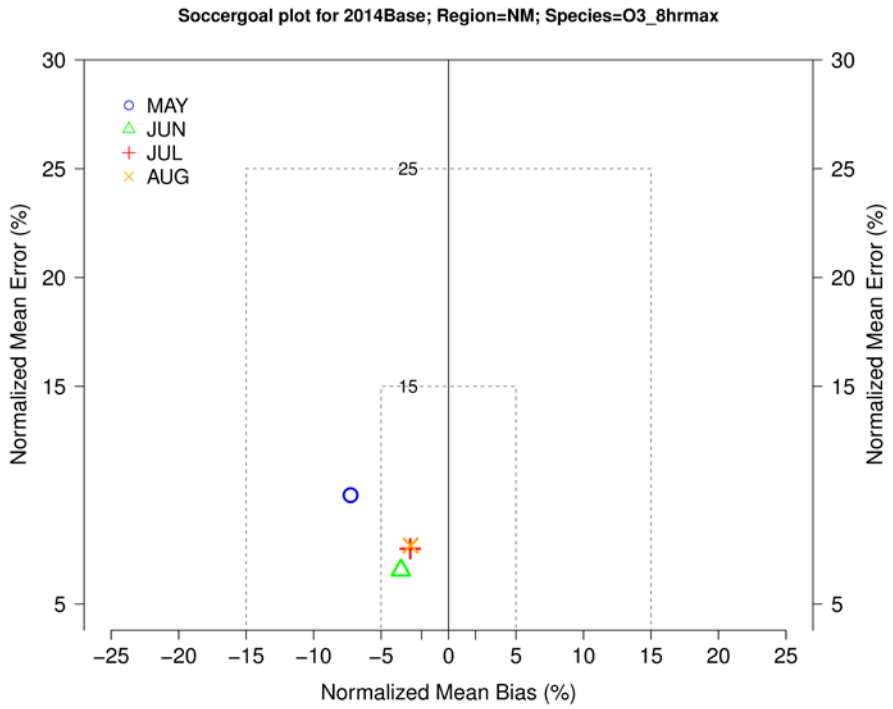
Domain wide all AQS sites MPE statistics w/ and w/o 60 ppb cut-off NMB (5.0%, -4.3%) and NME (9.8%, 8.0%) metrics are within performance goals (NMB<±5% and NME<15%).

MDA8 O3 without cut-off

MDA8 O3 with 60 ppb cut-off



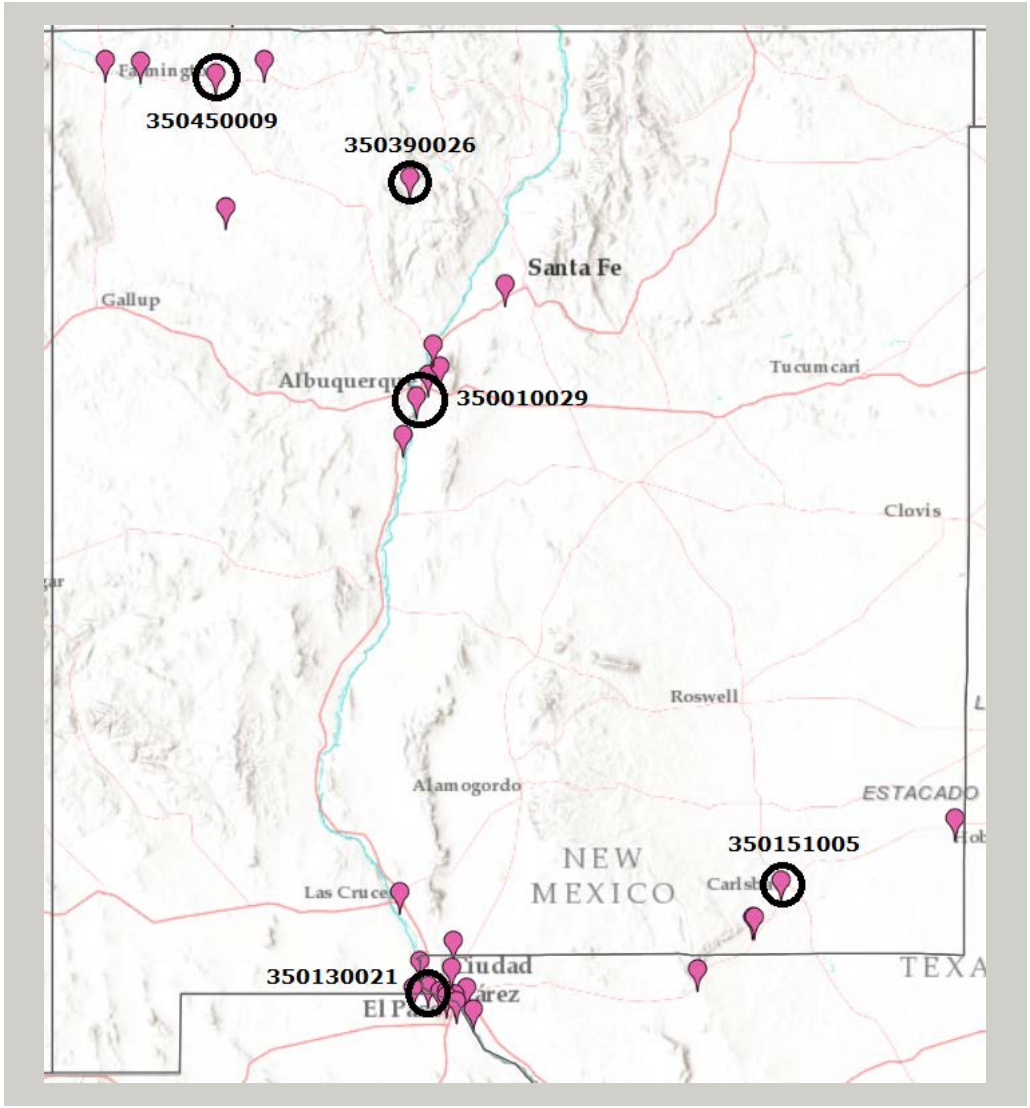
NMED Exhibit
21 - 0030



MONTHLY SOCCER PLOT FOR ALL NM AQS SITES

- May only includes only 15 days (i.e., May 15 -30) and has higher underestimation
- Using all ozone data slight overestimation with Jul and Aug bias falling between goal and criteria
- With 60 ppb observed MDA8 ozone cut-off slight underestimation bias that achieved goal in Jun-Jul-Aug
- All monthly average error metrics are within performance goal.

MDA8 O3 without cut-off



MDA8 O3 with 60 ppb cut-off

MPE FOR OZONE DESIGN VALUE PROJECTION

- EPA-recommended approach for making future year ozone Design Value (DV) projections uses the PGM base year top 10 highest MDA8 ozone concentrations to develop Relative Response Factors (RRF)
- The RRF is applied to the measured base year (BY) ozone design value (DVb) to projected a future year (FY) ozone design value (DVf)

$$RRF = \sum Model_{FY} / \sum Model_{BY}$$

$$DVf = DVb \times RRF$$

- The ozone model performance for the 10 highest modeled base year MDA8 ozone is therefore important
  - An alternative projection approach to the EPA-default is to use the top 10 highest modeled base year MDA8 ozone that meet a MPE requirement (e.g., within ±10%)

Red = bias greater than ±10%
Blue = Added model days using ±10% MPE criteria

RAMBOLL

CONCLUSIONS CAMX 2015 36/12/4-KM BASE CASE MPE

- Across all sites in New Mexico ozone performance meets the bias and error Performance Goals
  - Across all observations there is a slight overestimation but still meet bias goal (≤±5%)
  - Using just observed ozone above a 60 ppb cut-off, the goal is still met with an underestimation bias
- The northern NM and Bernalillo County subregions meet the ozone goals , but southern NM subregion bias falls between the performance goal and criterion
- Example evaluation for 10 highest modeled MDA8 ozone used to make ozone projections using EPA default approach found good overlap with observed highest MDA8 ozone:
  - At Desert View (Dona Ana County) 7 of top 10 modeled days were top 20 observed, 5 top 10 observed
  - At Carlsbad (Eddy County) 6 of top 10 modeled days were top 20 observed; 4 top 10 observed
  - At Bloomfield (San Juan County) 6 of top 10 modeled days were top 20 observed; 5 top 10 observed
- Although there were some periods of questionable model performance (e.g., late July in San Juan County and late May at Carlsbad), overall the model performance was quite reasonable and mostly achieved the performance goals and always achieved the performance criteria

NEXT STEPS

- NMED issues a stop work on 2023 modeling; redirect effort to 2028 modeling
- NMED requests WESTAR/Ramboll provide scope-of-work, cost estimate and schedule for three new tasks:
  - Develop 2028 base case O&G emissions for New Mexico
  - Develop CAMx 36/12/4-km 2028 emissions using WRAP 2028OTBa2 database with updated 2028 O&G emissions for New Mexico and run CAMx 2028 36/12/4-km base case simulation
  - Receive 2028 New Mexico O&G control strategy emissions from NMED and conduct CAMx 2028 36/12/4-km NM O&G control strategy simulation and provide ozone results to NMED
